We now want conditions ensuring that  $\pi_u$  is a closed immersion. We therefore preserve the hypotheses preceding 7.9 but no longer assume  $\pi_u$  surjective (only  $\pi_u$  an isomorphism on the generic fibers). We already know that  $\pi_u : G \rightarrow H$  is an open immersion, hence also  $\pi_{\{0\}} : G_{\{0\}} \rightarrow H_{\{0\}}$ , whose image therefore contains the connected component of the identity element  $(H_{\{0\}})^0$ . Note that, since  $G_0$  is smooth over  $k$  and "without additive component" over the algebraic closure of  $k$ , the same holds for  $H_0$ . Now we have:

**Lemma 7.11.** \*Let  $H$  be a commutative algebraic group over a field  $k$ , such that  $H \otimes_k \bar{k}$  contains no subgroup isomorphic to  $G_a$ . Let  $n = \deg H/H^0$ ; then the homomorphism

<!-- label: III.VIII.7.11 -->

$$\pi_{\{nH\}} : G \rightarrow H/H^0$$

is surjective.

One may indeed assume  $k$  algebraically closed, and then this follows from the well-known fact that  $H^0(k)$  is a

divisible group.

Suppose now (returning to our situation  $\mathcal{U} : G \rightarrow H$ ) that the  $\mathcal{U}_n$  ( $n > 0$ ) are proper over  $S$ , and the  $\mathcal{U}_n$  are separated over  $S$ . Note on the other hand that the  $\mathcal{U}_n$  are flat over  $S$ . Indeed, it suffices to see this at the points above  $s$ ; one is then reduced to proving that  $\mathcal{U}_n \cdot \text{id}_H$  is flat at the points above  $s$ , and for this one is reduced to verifying that  $\mathcal{U}_n$  is flat, which is equivalent (as we have already noted) to the fact that  $(H_0)^{\wedge 0}$  is smooth [N.D.E-VIII-40] over  $k$  and has no  $G_a$ -component over the algebraic closure of  $k$ . As  $(H_0)^{\wedge 0} = (G_0)^{\wedge 0}$ , this follows from the analogous hypothesis made on  $G_0$ . On the other hand, the  $\mathcal{U}_n$  are separated over  $S$  since  $H$  is, hence the morphism  $\mathcal{U}_n \rightarrow \mathcal{U}_0$  is proper, hence its image is closed. As this image contains the generic fiber of  $\mathcal{U}_n$  (since  $\mathcal{U}_{s_0} : G_{s_0} \rightarrow H_{s_0}$  is an isomorphism) and  $\mathcal{U}_0$  is flat over  $S$ , hence identical to the closure of its generic fiber, it follows that  $\mathcal{U}_n \rightarrow \mathcal{U}_0$  is surjective, hence  $G_0 \rightarrow H_0$  is surjective. Recalling that  $G_0 \supset (H_0)^{\wedge 0}$  and applying 7.11, one finds that  $G_0 \rightarrow H_0$  is surjective, hence  $\mathcal{U}$  is surjective. One thus obtains:

**Proposition 7.12.** With the notation of 7.9, suppose conditions (a) and (b) hold, as well as condition (c') (stronger than (c)), obtained by requiring that for every integer  $n > 0$  (not only of the form  $p^{\nu}$ ),  $\mathcal{U}_n$  be finite over  $S$  and  $\mathcal{U}_n$  separated over  $S$ . Under these conditions,  $\mathcal{U}$  is a closed immersion.\*

<!-- label: III.VIII.7.12 -->

<!-- original page 36 -->

**Remark 7.13.** a) One easily verifies that the separation hypothesis made on the  $\mathcal{U}_n$  implies in fact that  $H$  is separated over  $S$ . This is moreover formally contained in 7.12 by taking for  $G$  the unit  $S$ -group. Note also that when  $S$  is locally Noetherian, one may in 7.9 restrict to assuming  $H$  locally of finite type over  $S$  (in\*

<!-- label: III.VIII.7.13 -->

<!-- original page 30 -->

\*place of: of finite type over  $S$ ), the proof given applying as it stands; for 7.12 one will moreover assume that the fibers of  $H$  are of finite type.\*

b) Using 7.12, it is not difficult to prove that if  $\mathcal{U} : G \rightarrow H$  is a monomorphism of  $S$ -preschemes in groups of finite presentation, with  $G$  diagonalizable (or more generally, "of multiplicative type") and  $H$  separated over  $S$ , then  $\mathcal{U}$  is a closed immersion – which constitutes a satisfactory generalization of the first conclusion stated in 5.7. When  $G$  is smooth over  $S$ , it suffices to apply 7.12, and the general case reduces easily to that one. When one no longer assumes  $H$  separated over  $S$ , one can still show that  $\mathcal{U}$  is an immersion; in the case where  $G$  is a torus, this fact moreover follows also from what follows.\*

c) When in 7.9 one assumes  $G$  has connected fibers, one can in condition 7.9 (c) drop the hypothesis that the  $\mathcal{U}_{p^{\nu}}H$  be separated over  $S$ . Indeed, with the reductions made in the proof, one may assume  $H$  flat over  $S$  and  $\mathcal{U}$  bijective, hence  $H$  with connected fibers, hence  $H$  separated over  $S$  by virtue of Raynaud's theorem (VI\_B 5.5).\* [N.D.E-VIII-41]

[^VIII-0-0]: Version notice of the 2009 re-edition.

[^N.D.E-VIII-1]: N.D.E.: The original has been expanded in what follows.

[^N.D.E-VIII-2]: N.D.E.: We have added the numbering 1.0, 1.0.1, ... in order to highlight the definitions and statements that occur there.

[^N.D.E-VIII-3]: N.D.E.: We have added the sentence that follows.

[^N.D.E-VIII-4]: N.D.E.: We have expanded what follows.

[^N.D.E-VIII-5]: N.D.E.: Indeed, if one denotes by  $F(M)$  (resp.  $G(M)$ ) the left-hand (resp. right-hand) side of (2), and if  $M = M_{\{1\}} \oplus M_{\{2\}}$ , one has a canonical isomorphism  $F(M) = F(M_{\{1\}}) \oplus F(M_{\{2\}})$ , and likewise for  $G$ . This reduces us to verifying that  $\theta$  is an isomorphism when  $M = \mathbb{Z}/r\mathbb{Z}$ , for an integer  $r \geqslant 0$ . In this case,  $F(M) = (\mathbb{Z}/r\mathbb{Z})_S$ , where  $\mathbb{Z}/r\mathbb{Z}$  is the kernel of  $r \cdot \text{id}_{\mathbb{Z}}$ , and, for every  $T \rightarrow S$ , the homomorphism

$$F(M)(T) = \Gamma(\pi_N^* T/T) \rightarrow G(M)(T) = \pi_N^* \Gamma(N_T/T)$$

is bijective, whence the desired result.

[^N.D.E-VIII-6]: N.D.E.: The original stated after 1.5: "One concludes more generally that if  $G$ ,  $H$  are locally diagonalizable, with  $H$  of finite type, then  $\text{Hom}_{S\text{-gr.}}(G, H)$  is representable." We have included this assertion in the statement of 1.5, and have made its proof explicit in 1.7.

[^N.D.E-VIII-7]: N.D.E.: One should add a statement 1.5.1 treating the functor  $\text{Isom}_{S\text{-gr.}}(G, H)$ , considered in X 5.10 and 5.11...

[^N.D.E-VIII-8]: N.D.E.: We have added this paragraph, to make explicit the "local on  $S$ " character of the representability of certain sheaves on  $S$ , used many times in the sequel (and implicitly in the original).

[^N.D.E-VIII-9]: N.D.E.: See also Remark XI 3.4.

[^N.D.E-VIII-10]: N.D.E.: For another effectivity criterion, see later X 5.4–5.6.

[^N.D.E-VIII-11]: N.D.E.: (since  $G$  is flat over  $S$ , by (a)).

[^N.D.E-VIII-12]: N.D.E.: We have added what follows, and have detailed the proof accordingly.

[^N.D.E-VIII-13]: N.D.E.: The original has been expanded in what follows.

[^N.D.E-VIII-14]: N.D.E.: We have added what follows.

[^N.D.E-VIII-15]: N.D.E.: We have corrected 4.1 to 4.2.

[^N.D.E-VIII-16]: N.D.E.: We have expanded the passage that follows.

[^N.D.E-VIII-17]: N.D.E.: We have added the sentence that follows.

[^N.D.E-VIII-18]: N.D.E.: Indeed, for every  $b \in A$ ,  $a_m \in A_m$ , one has  $\theta(b \otimes a_m) = b a_m \otimes e_m$ , hence the surjectivity of  $\theta$  is equivalent to  $(*)$ .

[^N.D.E-VIII-19]: N.D.E.: We have denoted by  $K$  the ideal denoted  $J$  in the original, in order to distinguish it from the ideals  $J_p$  of  $A_0$  appearing in  $(**)$ . We have also made explicit later that the relations  $(**)$  are equivalent to the equality  $K = K'$  (see what follows).

[^N.D.E-VIII-20]: N.D.E.: It follows from 5.2 that  $\sum_{p \neq 0} J_p = A_0$ , hence  $\pi^*$  is written as a finite sum  $\sum_i x_i$ , with  $x_i \in J_{p_i}$ .

[^N.D.E-VIII-21]: N.D.E.: cf. EGA II, 2.7.1 (vi).

[^VIII-6-star]: The present § is independent of the theory of diagonalizable groups; its natural place would be in VI\_B.

[^N.D.E-VIII-22]: N.D.E.: One can replace "free" by "projective", cf. 6.8 below. On the other hand, this notion is to be compared with that of  $S$ -prescheme flat and pure, introduced and developed in [RG71]; see in particular \*loc.

cit.\*, Part I, 3.3.12 and Part II, 3.1.4.1.

[^N.D.E-VIII-23]: N.D.E.: Indeed, let  $(A, m)$  be an Artinian local ring,  $k$  its residue field,  $M$  an arbitrary  $A$ -module,  $(x_i)_{i \in I}$  elements of  $M$  whose images form a basis of  $M/mM$  over  $k$ . Let  $F$  be the free  $A$ -module with basis  $(e_i)_{i \in I}$ , and  $\phi : F \rightarrow M$  the  $A$ -morphism defined by  $\phi(e_i) = x_i$ . Then  $Q = \text{Coker } \phi$  satisfies  $Q = mQ$ , whence, since  $m$  is nilpotent,  $Q = 0$ . Suppose moreover  $M$  flat over  $A$ ; then  $K = \text{Ker } \phi$  satisfies  $K \otimes_A k = 0$ , i.e.  $K = mK$ , whence  $K = 0$ .

[^N.D.E-VIII-24]: N.D.E.: cf. II.1, where this functor is denoted  $\prod_{Z/S} Y$ .

[^N.D.E-VIII-25]: N.D.E.: We have corrected "Z" to "S".

[^N.D.E-VIII-26]: N.D.E.: We have expanded the original in what follows; see also 1.7.3.

[^N.D.E-VIII-27]: N.D.E.: We have corrected "S" to "S".

[^N.D.E-VIII-28]: N.D.E.: denoted  $\text{Transp}^{\text{str}}_G(Y, Z)$ .

[^N.D.E-VIII-29]: N.D.E.: We have kept the numbering of the original: there is no 6.6.

[^N.D.E-VIII-30]: N.D.E.: Indeed, over a field  $k$ , every subscheme in groups of  $G$  is closed, cf. VI\_A, 0.6.1.

[^N.D.E-VIII-31]: N.D.E.: We have expanded the original in what follows; in particular we have added Lemma 6.8.1.

[^N.D.E-VIII-32]: N.D.E.: cf. Exp. VI\_A, Theorems 3.2 and 3.3.2.

[^N.D.E-VIII-33]: N.D.E.: take into account the additions made in VI\_B...

[^VIII-7-star]: In fact, M. Raynaud has constructed a counter-example, with  $G$  smooth with connected fibers, cf. XVI 1.1 (c). If one does not assume  $G$  has connected fibers, one may take  $S = \operatorname{Spec}(\mathbb{Z}_{(2)})$ ,  $G = (\mathbb{Z}/2\mathbb{Z})_S$  deprived of the non-neutral closed point,  $H = (\mu_2)_S$ .

[^N.D.E-VIII-34]: N.D.E.: cf. EGA IV<sub>3</sub>, § 8, and Exp. VI\_B, § 10.

[^N.D.E-VIII-35]: N.D.E.: cf. EGA IV<sub>3</sub>, 8.11.5 and 15.7.1.

[^VIII-7-starstar]: Cf. EGA IV<sub>3</sub>, 15.7.

[^VIII-7-starstarstar]: Cf. EGA IV<sub>2</sub>, 2.8.

[^N.D.E-VIII-36]: N.D.E.: We have suppressed the word "closed".

[^N.D.E-VIII-37]: N.D.E.: Make this explicit in Exp. V and VI\_A...

[^N.D.E-VIII-38]: N.D.E.: We have suppressed here the hypothesis that  $Q$  be commutative, and have modified 7.3.1 accordingly. Note that if  $Q$  is not commutative, the  $n$ -th power morphism is not in general a group homomorphism.

[^N.D.E-VIII-39]: N.D.E.: Add this in VII\_A – On the other hand, the statement is true for every  $S$  if  $Q$  is commutative, cf. Deligne's theorem in [T070], p. 4.

[^N.D.E-VIII-40]: N.D.E.: We have updated the terminology, replacing "simple" by "smooth" (see, for example, footnote (1) of A. Grothendieck in SGA 1, Exp. II).

[^N.D.E-VIII-41]: N.D.E.: specify in VI\_B § 5 this attribution, which appeared in SGAD 1965, indicating the modifications between SGAD and Lect. Notes 151.

[^N.D.E-VIII-42]: N.D.E.: additional references cited in this Exposé.

# Exposé IX. Groups of multiplicative type: homomorphisms into a group scheme

<!-- label: III.IX -->

\*by A. Grothendieck\*

> Version 1.0 of 8 November 2009: additions in proof of 3.6 bis, 4.4–7, 5.0–6, 6.1, 7.1, 8.2. 8.1 and 4.5 to be  
> revised.[^IX-0-0]

## 1. Definitions

<!-- original page 37 -->

**Definition 1.1.** \*Let  $S$  be a prescheme and  $G$  an  $S$ -prescheme in groups. One says that  $G$  is a group of multiplicative type \*if  $G$  is locally diagonalizable in the sense of the faithfully flat quasi-compact topology (cf. IV 6.3), i.e. if for every  $s$  in  $S$ , there exist an open neighborhood  $U$  of  $s$  and a faithfully flat quasi-compact morphism  $S' \rightarrow U$  such that  $G' = G \times_S S'$  is a diagonalizable  $S'$ -group (I 4.4 and VIII 1.1).\*

<!-- label: III.IX.1.1 -->

– \*One says that  $G$  is\* of quasi-isotrivial multiplicative type \*if it is even locally diagonalizable in the sense of the étale topology (IV 6.3), i.e. if in the preceding definition one can even take  $S' \rightarrow U$  étale surjective, or again (which amounts to the same, as one sees by taking the disjoint-sum scheme of the various  $S'$  attached to the various  $s$  in  $S$ ) if there exists  $S' \rightarrow S$  étale and surjective such that  $G' = G \times_S S'$  is a locally diagonalizable  $S'$ -group.\*

– \*If one can even choose  $S' \rightarrow S$  étale surjective and finite, one says that  $G$  is\* of isotrivial multiplicative type.

– \*Finally, one says that  $G$  is a group of locally trivial \*(resp. locally isotrivial\\*) multiplicative type if every  $s$  in  $S$  admits an open neighborhood  $U$  such that  $G \times_S U$  is a diagonalizable  $U$ -group (resp. a group of isotrivial multiplicative type, i.e. there exists an étale surjective finite morphism  $S' \rightarrow U$  such that  $G \times_S S'$  is a diagonalizable  $S'$ -group).\*

**Comments 1.2.** One will note that the five preceding notions all derive from the notion of diagonalizable group by the process of localization, in the sense of five different "topologies" associated with  $(Sch)$ .

<!-- label: III.IX.1.2 -->

We agree, generally, that when the word "locally" is not made explicit <!-- original page 38 --> by specifying the topology envisaged, the Zariski topology is meant, in accordance with received terminology. In the terminology introduced here, "of locally trivial multiplicative type" is equivalent to "locally diagonalizable" of VIII 1.1, and likewise "trivial" translates as "diagonalizable". Among the five notions introduced, one has the following diagram of implications, which results from the corresponding relations between the topologies in play:

```
``text
 multiplicative type (general)
 ↑
 quasi-isotrivial
 ↑
locally isotrivial ← isotrivial
 ↑ ↑
locally trivial ← trivial
...

```

<!-- TRANSLATOR NOTE: original diagram is degraded by OCR; the implications are reconstructed from the surrounding text and from the standard implications between the five notions. -->

From the practical point of view, let us point out at once that all the groups of multiplicative type we shall encounter will be quasi-isotrivial; thus, we shall see in the following Exposé (X 4.5) that when  $G$  is of finite type over  $S$ , then  $G$  is automatically quasi-isotrivial, but we shall give examples where it is not locally isotrivial. We shall likewise see there that  $G$  may be locally trivial without being isotrivial nor, a fortiori, trivial (which easily implies that the inclusions of the preceding diagram are strict).

On the other hand, we shall also see there (X 5.16) that when  $S$  is locally noetherian and normal (more generally geometrically unibranch), every group of multiplicative type of finite type over  $S$  is necessarily isotrivial, and moreover trivial as soon as it is locally trivial (or even merely trivial on a dense open). This explains that most groups of multiplicative type one will encounter in practice will doubtless be isotrivial, all the more so since we shall see later that the maximal tori of semisimple group schemes are automatically isotrivial.

**\*\*Definition 1.3.\*\*** \*Let  $S$ ,  $G$  be as in 1.1. One says that  $G$  is a\* torus \*if it is locally isomorphic, in the sense of the faithfully flat quasi-compact topology, to a group of the form  $G^{\{r\}}_{\{m\}}$  (where  $r$  is an integer  $\geq 0$ ).

<!-- original page 39 -->

<!-- label: III.IX.1.3 -->

With the notation of 1.1, this means therefore that one can choose  $S'$  such that  $G'$  be isomorphic to a group of the form  $(G_{\{m, S'\}})^{\{r\}}$ . One will note that the integer  $r$  depends on  $s$  in  $S$ : it is the dimension of the fiber  $G_{\{s\}} = G \otimes_S \kappa(s)$ . It is a locally constant function of  $s$ , as one verifies at once. There is occasion to generalize this remark:

**\*\*Definition 1.4.\*\*** \*Let  $G$  be a diagonalizable group scheme over a field  $k$ , so that  $G$  is isomorphic to a group  $D_{\{k\}}(M)$ , where  $M$  is an ordinary commutative group, defined up to isomorphism by this condition – more precisely  $M \simeq \operatorname{Hom}_{\{k\}}(G, G_{\{m, k\}})$  (VIII 1.3). The isomorphism class of  $M$  is called the\* type \*of the diagonalizable group  $G$ ; it is evidently invariant under extension of the base field.\*

<!-- label: III.IX.1.4 -->

\*If now  $G$  is a group scheme of multiplicative type over an arbitrary prescheme  $S$ , then for every  $s$  in  $S$ , there exists an extension  $k$  of  $\kappa(s)$  such that  $G \otimes_S \operatorname{Spec}(k)$  is a diagonalizable  $k$ -group; \*its type is then independent of the chosen extension by the preceding remark, and will be called the\* type of  $G$  at  $s$ , \*or\* type of  $G_{\{s\}}$ . \*In particular, if  $G$  itself is diagonalizable, hence isomorphic to a group of the form  $D_{\{S\}}(M)$ , then for every  $s$  in  $S$ , the type of  $G$  at  $s$  equals the class of the group  $M$ .\*

\*In general, if  $G$  is a group of multiplicative type over  $S$  and  $M$  an ordinary commutative group, one will say that  $G$  is\* of type  $M$  \*if it is of type  $M$  at every point  $s$  in  $S$ , in other words if  $G$  is locally isomorphic to  $D_{\{S\}}(M)$  in the sense of the faithfully flat quasi-compact topology.\*

**\*\*Remark 1.4.1.\*\*** \*a) One sees immediately that for a given group of multiplicative type  $G$  over  $S$ , the function  $s \mapsto$  type of  $G_{\{s\}}$  is locally constant on  $S$ : indeed, with the notation of 1.1, if  $G$  is of type  $M$ , then  $G$  is of type  $M$  on the neighborhood  $U$  of  $s$ . It follows that one has a canonical partition of  $S$  into a disjoint sum of preschemes  $S_{\{i\}}$ , \*such that for every  $i$ ,  $G_{\{S_{\{i\}}\}}$  is of type  $M_{\{i\}}$ , where the  $M_{\{i\}}$  are pairwise non-isomorphic commutative groups.\*

<!-- label: III.IX.1.4.1 -->

\*b) In particular, if  $S$  is connected, the type of the fibers of  $G$  is constant, i.e. there exists a commutative group  $M$  such that  $G$  is of type  $M$ . Finally, if  $G$  is a torus, the type of  $G$  at  $s$  is characterized by the integer  $\dim G_{\{s\}}$  (indeed,  $G_{\{s\}}$  is of type  $\mathbb{Z}^{\{n\}}$ , where  $n = \dim G_{\{s\}}$ ).

**\*\*Remark 1.5.\*\*** \*a) It is trivial on definitions 1.1 and 1.3 that these are "compatible with base extension". Thus, if  $G$  is a prescheme in groups over  $S$ , and  $S' \rightarrow S$  is a base-change morphism, then if  $G$  is of multiplicative type (resp. of isotrivial multiplicative type, etc.), the same holds for  $G'$ .\*

<!-- label: III.IX.1.5 -->

\*b) When moreover  $S' \rightarrow S$  is faithfully flat and quasi-compact, then if  $G$  is of multiplicative type, resp. a torus, the same holds for  $G$ . If moreover  $S' \rightarrow S$  is étale (resp. finite étale), and  $G$  quasi-isotrivial (resp. isotrivial), the same holds for  $G$ .\*

\*c) Finally, returning to an arbitrary base-change morphism  $f : S' \rightarrow S$ , if  $s' \in S'$  and  $s = f(s')$ , then the type of  $G'$  at  $s'$  is equal to that of  $G$  at  $s$ , since  $G'_{\{s'\}} = G_{\{s\}} \otimes_{\kappa(s)} \kappa(s')$ .\*

## ## 2. Extension of certain properties of diagonalizable groups to groups of multiplicative type

The extensions in question are essentially trivial consequences of the results of the preceding Exposé, given Definitions 1.1 and the "local" nature (in the sense of the faithfully flat quasi-compact topology) of the results concerned.

**\*\*Definition 2.0.\*\*** \*We denote by  $M$  the set of faithfully flat quasi-compact morphisms.\*

<!-- label: III.IX.2.0 -->

**\*\*Proposition 2.1.\*\*** \*Let  $G_S$  be a group of multiplicative type over a prescheme  $S$ . One has the following:\*

<!-- label: III.IX.2.1 -->

\*a)  $G_S$  is faithfully flat over  $S$ , and affine over  $S$  (a fortiori quasi-compact over  $S$ ).\*

<!-- original page 41 -->

\*b)  $G_S$  of finite type over  $S \xrightarrow{\quad} G_S$  of finite presentation over  $S \xrightarrow{\quad}$  for every  $s \in S$ , the type of  $G_S$  at  $s$  is given by a commutative group of finite type.\*

\*c)  $G_S$  finite over  $S \xrightarrow{\quad}$  for every  $s \in S$ , the type of  $G_S$  at  $s$  is given by a finite commutative group  $\xrightarrow{\quad}$  (if  $S$  quasi-compact)  $G_S$  is of finite type over  $S$  and is annihilated by an integer  $n > 0$ .\*

\*c')  $G_S$  integral over  $S \xrightarrow{\quad}$  for every  $s \in S$ , the type of  $G_S$  at  $s$  is given by a torsion commutative group.\*

\*d)  $G_S$  is the unit group  $\xrightarrow{\quad}$  for every  $s \in S$ , the type of  $G_S$  at  $s$  is given by the zero commutative group.\*

\*e)  $G_S$  is smooth over  $S \xrightarrow{\quad}$  for every  $s \in S$ , the type of  $G_S$  at  $s$  is given by a commutative group of finite type whose torsion subgroup is of order prime to the characteristic of  $k(s)$ .\*

These statements follow from VIII 2.1, taking into account that the properties in question descend along faithfully flat quasi-compact morphisms (cf. SGA 1, VIII or EGA IV<sub>2</sub>, § 2).

Using VIII 3.5, one obtains likewise:

**\*\*Proposition 2.2.\*\*** \*Let  $G_S$  be a group of multiplicative type and of finite type over  $S$ ; then for every integer  $n \neq 0$ , the kernel  $\ker n \cdot \text{id}_G$  of  $n \cdot \text{id}_G$  is a group of multiplicative type, finite over  $S$ .\*

<!-- label: III.IX.2.2 -->

**\*\*Proposition 2.3.\*\*** \*Let  $G_S$  be a group of multiplicative type over the prescheme  $S$ , operating freely on the right on the  $S$ -prescheme  $X$  affine over  $S$ . Then:\*

<!-- label: III.IX.2.3 -->

\*a) The equivalence relation defined by  $G_S$  in  $X$  is  $M$ -effective (IV 3.4), and  $Y = X/G_S$  is affine over  $S$ .\*

\*b) If moreover  $X$  is of finite presentation (resp. of finite type) over  $S$ , the same holds for  $Y$ .\*

The first assertion follows from VIII 5.1, which treats the case where  $G_S$  is diagonalizable, <!-- original page 42 --> and from IV 3.5.2, which allows one to reduce to that case, given that faithfully flat quasi-compact morphisms  $S' \rightarrow S$  are morphisms of effective descent for the fibered category of affine schemes over others, i.e. for every  $Y'$  affine over  $S'$  endowed with a descent datum relative to  $S' \rightarrow S$ , this descent datum is effective, i.e.  $Y'$  comes from a  $Y$  affine over  $S$  (cf. SGA 1, VIII 2.1).

For the second assertion one is likewise reduced to the diagonalizable case VIII 5.8, since the finiteness conditions envisaged descend along faithfully flat quasi-compact morphisms (SGA 1, VIII 3.3 and 3.6[<sup>N.D.E</sup>-IX-4]). Proceeding as in VIII, Corollaries 5.5 to 5.7, one deduces from 2.3:

**\*\*Corollary 2.4.\*\*** \*Under the conditions of 2.3, the graph morphism\*

<!-- label: III.IX.2.4 -->

$$\begin{array}{c} \text{``text} \\ X \times_S G \rightarrow X \times_S X \\ \text{``} \end{array}$$

\*is a closed immersion. For every section  $\sigma$  of  $X$  over  $S$ , the corresponding morphism  $G \rightarrow X$ ,  $g \mapsto \sigma \cdot g$  is a closed immersion.\*

In particular:

**\*\*Corollary 2.5.\*\*** \*Let  $\varphi : G \rightarrow H$  be a monomorphism of  $S$ -preschemes in groups, with  $G$  of multiplicative type and  $H$  affine over  $S$ . Then  $\varphi$  is a closed immersion,  $H/G = Y$  exists and is affine over  $S$ , and finally  $H$  is a principal homogeneous bundle over  $Y$  with group  $G_Y$ .\*

<!-- label: III.IX.2.5 -->

**\*\*Remark 2.6.\*\*** \*Let  $\varphi : G \rightarrow H$  be a monomorphism of  $S$ -preschemes in groups, with  $G$  of multiplicative type and of finite type over  $S$ ,  $H$  of finite presentation over  $S$  and separated over  $S$ . Then one can show that  $\varphi$  is a closed immersion, using VIII 7.12 (see remark VIII 7.13 b)).\*

<!-- label: III.IX.2.6 -->

**\*\*Proposition 2.7.\*\*** \*Let  $\varphi : G \rightarrow H$  be a homomorphism of  $S$ -groups of multiplicative type, with  $H$  of finite type over  $S$ .\* <!-- original page 43 --> \*Then:\*

<!-- label: III.IX.2.7 -->

(i)  $G_0 = \text{Ker } \varphi$  is an  $S$ -group of multiplicative type, the equivalence relation defined by  $G_0$  in  $G$  is  $M$ -effective, hence (IV 3.4)  $\varphi$  factors as\*

```
```text
G → G/G_0 = I → H,
```
```

\*where  $I \rightarrow H$  is a monomorphism\* [N.D.E-IX-5] \*of  $S$ -groups;  $I$  is of multiplicative type, the equivalence relation in  $H$  defined by  $I$  is  $M$ -effective, consequently  $H_0 = H/I$  exists, and moreover  $H_0$  is of multiplicative type.\*

(ii)  $H_0$  and  $I$  are of finite type, and the same holds for  $G_0$  if  $G$  is.\*

**\*Proof.\*** Proceeding as for 2.3, one is reduced to the case where  $G$  and  $H$  are diagonalizable, and then 2.7 reduces to VIII 3.4.

Let us note the following corollaries:

**\*\*Corollary 2.8.\*\*** \*a) Let  $S$  be a prescheme. Then the category of  $S$ -groups of multiplicative type and of finite type is an abelian category.\*

<!-- label: III.IX.2.8 -->

\*b) Let  $\varphi : G \rightarrow H$  be a homomorphism in this category; for it to be a monomorphism (resp. an epimorphism, resp. an isomorphism) in this category, it is necessary and sufficient that  $\varphi$  be a monomorphism of preschemes (resp. that  $\varphi$  be faithfully flat, resp. that  $\varphi$  be an isomorphism of preschemes).\*

It suffices to note that the product of two  $S$ -groups of multiplicative type is again of multiplicative type (which is immediate), and evidently of finite type over  $S$  if both factors are. The rest of 2.8 follows immediately from 2.7; the detail is left to the reader.

**\*\*Corollary 2.9.\*\*** \*Let  $\varphi : G \rightarrow H$  be a homomorphism of  $S$ -groups of multiplicative type and of finite type. Let  $U$  be the set of points  $s \in S$  such that  $\varphi_s : G_s \rightarrow H_s$  is a monomorphism (resp. faithfully flat, resp. an isomorphism). Then  $U$  is both open and closed,\* <!-- original page 44 --> \*and the induced homomorphism  $\varphi_U : G_U \rightarrow H_U$  is a monomorphism (resp. faithfully flat, resp. an isomorphism).\*

<!-- label: III.IX.2.9 -->

Let  $P$  (resp.  $Q$ ) be the kernel (resp. cokernel) of  $\varphi$ . By 2.7,  $Q$  exists and  $P$  and  $Q$  are of multiplicative type; moreover the formation of  $P$  and of  $Q$  commutes with every base change  $S' \rightarrow S$ , in particular with the formation of fibers. On the other hand,  $\varphi$  is a monomorphism (resp. faithfully flat, resp. an isomorphism) if and only if  $P = 0$  (resp.  $Q = 0$ , resp.  $P = Q = 0$ ). Thanks to these remarks, one is therefore reduced to verifying the following: if  $R$  is an  $S$ -group of multiplicative type, then the set  $U$  of  $s \in S$  such that  $R_s = 0$  is open and closed, and  $R_U = 0$ . But this is contained in Remark 1.4.1 a).

**\*\*Corollary 2.10.\*\*** \*Let  $G$  be an  $S$ -group of multiplicative type and of finite type, and  $H, H'$  two subgroups of multiplicative type.\*

<!-- label: III.IX.2.10 -->

\*a)  $H' = H \cap H'$  is a subgroup of multiplicative type of  $G$ .

\*b) Let  $U$  be the set of  $s$  in  $S$  such that  $H_s \subseteq H'_s$  (resp.  $H_s = H'_s$ ). Then  $U$  is open and closed, and  $H_U \subseteq H'_U$  (resp.  $H_U = H'_U$ ).

Of course the intersection sign in  $H \cap H'$  denotes the intersection in the functorial sense, i.e.  $H \times_G H'$ , which is evidently an  $S$ -subgroup of  $G$ ; likewise the inclusion sign (resp. equality sign) denotes the order relation (resp. the equality) between subfunctors of  $H$  (and not inclusion (resp. equality) of underlying sets).

Applying first 2.7 to the inclusion morphism  $H \rightarrow G$ , one finds that  $H$  is of finite type; likewise  $H'$  is of finite type. It then follows from 2.8 that  $H \cap H'$  is of multiplicative type and of finite type (one will note that the canonical functor from the category envisaged in 2.8 to the category  $(\text{Sch})/S$  commutes with finite projective limits).

The formation of  $H \cap H'$  commutes with base extension, in particular with the formation of fibers. On the other hand,  $H \subseteq H'$  (resp.  $H = H'$ ) is equivalent to  $H' = H$  (resp.  $H' = H$  and  $H' = H$ ). Consider then the canonical homomorphisms  $H' \rightarrow H$  and  $H' \rightarrow H'$ ; then  $U$  is the set of  $s$  in  $S$  such that the induced homomorphism  $H'_s \rightarrow H_s$  is an isomorphism (resp. such that  $H'_s \rightarrow H_s$  and  $H'_s \rightarrow H'_s$  are isomorphisms). <!-- original page 45 --> By 2.9, it follows that  $U$  is open and closed, and that  $H'_U \rightarrow H_U$  (resp.  $H'_U \rightarrow H'_U$ ) are isomorphisms. Hence the desired conclusion.

**Proposition 2.11.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group of multiplicative type and of finite type over  $S$ ,  $H$  a subgroup of multiplicative type of  $G$ , and  $K = G/H$  (which is a group of multiplicative type, quotient of  $G$ ).

<!-- label: III.IX.2.11 -->

(i) Suppose  $G$  is trivial, i.e. diagonalizable. Then there exists a partition of  $S$  into open-and-closed parts  $S_i$ , such that for every  $i$ ,  $H_{S_i}$  and  $K_{S_i}$  are diagonalizable. In particular, if  $S$  is connected,  $H$  and  $K$  are diagonalizable.

(ii) Same statement as in (i), replacing "diagonalizable" by "isotrivial", provided that  $S$  is connected, or locally connected, or quasi-compact.

(iii) Suppose  $G$  is locally trivial (resp. locally isotrivial, resp. quasi-isotrivial); then the same holds for  $K$  and  $H$ .

**Proof.** (i) By hypothesis  $G = D_S(M)$ , where  $M$  is a commutative group of finite type. For every quotient group  $M_i$  of  $M$ , let  $H_i = D_S(M_i)$  be the corresponding diagonalizable subgroup of  $G$  (VIII 3.1). Let  $S_i$  be the set of  $s$  in  $S$  such that  $H_s = (H_i)_s$ ; by 2.10,  $S_i$  is open and closed, and one has  $H_{S_i} = (H_i)_{S_i}$ , hence  $H_{S_i}$  is diagonalizable, hence so is  $K_{S_i}$  (VIII 3.1). Evidently the  $S_i$  are pairwise disjoint; we claim that they cover  $S$ . This follows from the fact that for every  $s$ ,  $H_s$  is diagonalizable, as a subgroup of the diagonalizable group  $G_s$  (cf. 8.1 below [N.D.E-IX-6]); hence  $H_s$  is of the form  $D_{\kappa(s)}(M_i)_s$ , by VIII, 1.5 and 3.2 b). Restricting to the family of non-empty  $S_i$ , the conclusion (i) appears.

(ii) By hypothesis, there exists  $S' \rightarrow S$  étale finite surjective such that  $G_{S'}$  is diagonalizable. Hence every point of  $S'$  has an open-and-closed neighborhood  $U'$  such that  $H_{U'}$  and  $K_{U'}$  are diagonalizable. Then the image  $U$  of  $U'$  in  $S$  is open and closed, and  $S' \rightarrow S$  still induces an étale finite surjective morphism  $U' \rightarrow U$ ; hence one sees that every <!-- original page 46 --> point  $s$  of  $S$  has an open-and-closed neighborhood  $U$  such that  $H_U$  and  $K_U$  are isotrivial. The conclusion (ii) follows at once.

(iii) Follows at once from (i) and (ii) and the definitions. Note moreover that the "quasi-isotrivial" case will also follow from the more general fact that "finite type  $\Rightarrow$  quasi-isotrivial", announced in 1.2 (cf. X 4.5).

### ## 3. Infinitesimal properties: lifting and conjugation theorems

The fundamental infinitesimal properties of groups of multiplicative type follow from the following theorem:

**Theorem 3.1.** \*Let  $S$  be an affine scheme,  $H$  an  $S$ -group of multiplicative type,  $\mathcal{F}$  a quasi-coherent sheaf on  $S$  on which  $H$  operates (I 4.7). Then one has\*

<!-- label: III.IX.3.1 -->

```

```text
H^i(H, F) = 0      for      i > 0,
```

```

\*where  $H^i$  is the Hochschild cohomology studied in Exp. I, § 5.\*

Indeed, by loc. cit., 5.3, the Hochschild cohomology is described, in terms of the affine rings  $A$  of  $S$  and  $B$  of  $G$ , and the module  $M$  over  $A$  defining  $F$ , as the cohomology of a complex of  $A$ -modules  $C^\bullet(H, M)$ , the formation of which commutes with every base change  $A \rightarrow A'$ . Consequently, for a base change  $A \rightarrow A'$  with  $A'$  flat over  $A$ , one has

```

```text
H^i(H', F') = H^i(H, F) \otimes_{A'} A',
```

```

and consequently, if one supposes even  $A'$  faithfully flat over  $A$ , in order to prove that  $H^i(H, F)$  is zero, it suffices to prove that the same holds for  $H^i(H', F')$ . This remark reduces us to verifying 3.1 in the case where  $G$  is diagonalizable; in that case this was proved in I 5.3.3.

<!-- original page 47 -->

Using the results of Exposé III, we shall deduce from 3.1 various consequences of geometric nature:

**Theorem 3.2.** \*Let  $S$  be an affine scheme,  $S_0$  an affine subscheme defined by an ideal  $J$ ,  $H$  a group of multiplicative type over  $S$ ,  $G$  an arbitrary prescheme in groups over  $S$ ,  $u, v : H \rightarrow G$  two homomorphisms of groups,  $u_0, v_0 : H_0 \rightarrow G_0$  the homomorphisms deduced from  $u, v$  by the base change  $S_0 \rightarrow S$ . If  $J^2 = 0$  and  $u_0 = v_0$ , then there exists a  $g \in G(S)$  such that  $gv = \text{int}(g) \circ u$  and  $g_0 = e$ .\*

<!-- label: III.IX.3.2 -->

This follows from III 2.1 (ii), and from 3.1 (vanishing of  $H^1$ ).

**Corollary 3.3.** \*Under the preliminary conditions of 3.2, suppose moreover  $G$  smooth over  $S$ , but assume only  $J$  nilpotent (not necessarily of square zero). If there exists  $g_0 \in G_0(S_0)$  such that  $gv_0 = \text{int}(g_0) \circ u_0$ , then  $g_0$  lifts to a  $g \in G(S)$  such that  $gv = \text{int}(g) \circ u$ .\*

<!-- label: III.IX.3.3 -->

By induction on the integer  $n$  such that  $J^n = 0$ , one is reduced to the case where  $J$  is of square zero. Moreover,  $G$  being smooth over  $S$ , one can lift  $g_0$  to an element  $g'$  of  $G(S)$ . Replacing  $v$  by  $v' = \text{int}(g') \circ u$ , one is then reduced to the situation of 3.2.

**Corollary 3.4.** \*Under the preliminary conditions of 3.2, with  $J$  nilpotent, suppose moreover  $u$  is central (for example  $G$  commutative). Then  $u_0 = v_0$  implies  $u = v$ .\*

<!-- label: III.IX.3.4 -->

Indeed, the reduction to the case where  $J$  has square zero is again immediate, and then it suffices to apply 3.2. In particular:

**Corollary 3.5.** \*Let  $S$ ,  $S_0$ ,  $H$ ,  $G$  be as in 3.2, with  $J$  nilpotent. Let  $u : H \rightarrow G$  be a homomorphism of  $S$ -groups such that  $u_0 : H_0 \rightarrow G_0$  is the unit homomorphism. Then  $u$  is the unit homomorphism.\*

<!-- label: III.IX.3.5 -->

<!-- original page 48 -->

**Theorem 3.6.** \*Let  $S$  be an affine scheme,  $S_0$  a subscheme defined by a nilpotent ideal  $J$ ,  $H$  a group of multiplicative type over  $S$ ,  $G$  a prescheme in groups smooth over  $S$ ,  $u_0 : H_0 \rightarrow G_0$  a homomorphism of the  $S_0$ -groups deduced by the base change  $S_0 \rightarrow S$ .\*

<!-- label: III.IX.3.6 -->

\*Then there exists a homomorphism  $u : H \rightarrow G$  of  $S$ -groups which lifts  $u_0$  (and by 3.3 any two such liftings  $u, u'$  are conjugate by an element of  $G(S)$  reducing along the unit element of  $G(S_0)$ ).\*

This follows from III 2.1 and 2.3, and from 3.1 (vanishing of  $H^2$  for the existence of the lift of  $u_0$ , vanishing of  $H^1$  for the uniqueness up to conjugation).

One can prove in the same way the following variants of 3.2 to 3.6 (which in fact entail the preceding statements, by applying them to the graph subgroups of the homomorphisms envisaged in 3.2 to 3.6):

**Theorem 3.2 bis.** \*Let  $S$  be an affine scheme,  $S_0$  a subscheme defined by an ideal  $J$ ,  $G$  an  $S$ -prescheme in groups,  $H, H'$  subpreschemes in groups, of multiplicative type,  $G_0, H_0, H'_0$  the groups over  $S_0$  deduced by the base change  $S_0 \rightarrow S$ . If  $J^2 = 0$  and  $H_0 = H'_0$ , then there exists  $g \in G(S)$  such that  $H' = \text{int}(g)(H)$  and  $g_0 = e$ .\*

<!-- label: III.IX.3.2bis -->

**Corollary 3.3 bis.** \*Under the preliminary conditions of 3.2 bis, suppose moreover  $G$  smooth over  $S$ , and  $J$  nilpotent (not necessarily of square zero). Let  $g_0 \in G_0(S_0)$  be such that  $H'_0 = \text{int}(g_0)(H_0)$ ; then  $g_0$  lifts to  $g \in G(S)$  such that  $H' = \text{int}(g)(H)$ .\*

<!-- label: III.IX.3.3bis -->

**Corollary 3.4 bis.** \*Under the preliminary conditions of 3.2 bis, suppose  $J$  nilpotent,  $H$  central (for example  $G$  commutative). Then  $H_0 = H'_0$  implies  $H = H'$ .\*

<!-- label: III.IX.3.4bis -->

**Theorem 3.6 bis.** \*Let  $S$  be an affine scheme,  $S_0$  a subscheme defined by a nilpotent ideal  $J$ ,\* <!-- original page 49 --> \* $G$  an  $S$ -prescheme in groups smooth over  $S$ ,  $H_0$  a subprescheme in groups of  $G_0 = G \times_S S_0$ , of multiplicative type. Then:\*

<!-- label: III.IX.3.6bis -->

(a) There exists a subprescheme in groups  $H$  of  $G$ , flat over  $S$ , such that  $H \times_S S_0 = H_0$ .\*

(b) Such an  $H$  is necessarily of multiplicative type.\*

(c) Finally, by 3.2 bis, any two such liftings  $H, H'$  of  $H_0$  are conjugate by an element  $g \in G(S)$  reducing along the unit element of  $G(S_0)$ .\*

Let us show how one may prove 3.2 bis (of which 3.3 bis and 3.4 bis are an immediate consequence) and assertion (a) of 3.6 bis. The latter follows from 3.1 (vanishing of  $H^2$ ) and from III 4.37 (ii). Similarly 3.2 bis follows from 3.1 (vanishing of  $H^1$ ) and from III 4.37 (i), at least when  $G$  and  $H$  are smooth over  $S$ .

But using the results of the following Exposé, one can very simply deduce 3.2 bis and 3.6 bis, in the general form stated here, from 3.2 resp. 3.6. For 3.2 bis, it suffices indeed to note that by X 2.1,  $H$  and  $H'$  are isomorphic, which reduces us to 3.2.

For 3.6 bis, one notes that  $H_0$  is necessarily of finite type over  $S_0$ : [N.D.E-IX-7] indeed, as a subprescheme of  $G_0$ , which is smooth over  $S_0$ ,  $H_0$  is locally of finite type over  $S_0$ ; but, by 2.1 a),  $H_0$  is affine over  $S_0$ , hence is of finite type over  $S_0$ . Then, by X 4.5,  $H_0$  is quasi-isotrivial, hence comes, by X 2.1, from a group of multiplicative type  $H_0$  over  $S_0$ . [N.D.E-IX-8] Then, by 3.6, there exists a homomorphism of  $S$ -groups  $u : H \rightarrow G$  which lifts the immersion  $H_0 \hookrightarrow G_0$ ; since  $H$  and  $H_0$  (resp.  $G$  and  $G_0$ ) have the same underlying topological space, and since, for every  $h \in H$ , the morphism <!-- original page 50 -->  $u(G, u(h)) \rightarrow u_0(H, h)$  is surjective (since it is so after reduction modulo  $J$ , which is nilpotent),  $u$  is also an immersion (cf. EGA I, 4.2.2).

Finally, for every lifting  $H$  of  $H_0$  to a flat subgroup of  $G$ ,  $H$  is necessarily of multiplicative type by X 2.3, [N.D.E-IX-9] which also proves assertion (b) of 3.6 bis. (The reader will verify that the results 3.2 bis to 3.6 bis are not used in Exposé X, hence that there is no vicious circle!)

**Proposition 3.8.** [N.D.E-IX-10] \*Let  $S$  be a prescheme,  $S_0$  a closed subprescheme defined by a locally nilpotent ideal  $J$ ,  $G$  an  $S$ -group of multiplicative type,  $X$  an  $S$ -prescheme locally of finite presentation. Suppose that  $G$  operates on  $X$ , in such a way that  $G_0 = G \times_S S_0$  operates trivially on  $X_0 = X \times_S S_0$ . Under these conditions,  $G$  operates trivially on  $X$ .\*

<!-- label: III.IX.3.8 -->

The proof is that of III 2.4 b); one can also reduce to loc. cit. by noting that 3.8 reduces at once to the case where  $G_S$  is diagonalizable, which is the case envisaged in loc. cit.

**Corollary 3.9.** Let  $S, S_{\{0\}}$  be as above, and  $u : G \rightarrow H$  a homomorphism of  $S$ -groups, with  $G_S$  of multiplicative type and  $H_S$  locally of finite presentation over  $S$ . Suppose that the homomorphism  $u_{\{0\}} : G_{\{0\}} \rightarrow H_{\{0\}}$  deduced by base change  $S_{\{0\}} \rightarrow S$  is central. Then  $u_S$  is central.

<!-- label: III.IX.3.9 -->

Indeed, it suffices to apply 3.8 by taking  $X = H$  and making  $G_S$  operate on  $H_S$  by  $(g, h) \mapsto \text{int}(u(g)) \cdot h = u(g) \cdot h \cdot u(g)^{-1}$ .

#### ## 4. The density theorem

This theorem (cf. 4.7 below) [IX-4-1], together with the theorem [N.D.E-IX-11] of N° 7, will be the essential tool in the present Exposé and the two following, for passing from the infinitesimal properties of groups of multiplicative type, which have just been developed, to the "finite" properties.

**Definition 4.1.** Let  $X$  be a prescheme. A family  $(Z_i)_{i \in I}$  of subpreschemes of  $X$  is said to be schematically dense if for every open  $U$  of  $X$ , and every closed subprescheme  $U_0$  of  $U$  which majorizes the  $Z_i \cap U$ , one has  $U_0 = U$ .

<!-- label: III.IX.4.1 -->

One says that a subprescheme  $Z$  of  $X$  is schematically dense in  $X$  if such is the case of the family reduced to  $Z$ .

One sees immediately (cf. EGA IV<sub>3</sub>, 11.10.1) that the definition is equivalent to saying that for every open  $U$  of  $X$ , every section  $f$  of  $\mathcal{O}_U$  which is zero on the  $Z_i \cap U$  is zero, which also means that the intersection of the kernels of the canonical homomorphisms

$$u_i : \mathcal{O}_X \rightarrow (v_i)_*(\mathcal{O}_{Z_i})$$

is zero, where  $v_i : Z_i \rightarrow X$  is the canonical immersion. [N.D.E-IX-12] When  $X$  lies over a prescheme  $S$ , this is again equivalent to saying that for every open  $U$  of  $X$  and every pair  $(u, v)$  of morphisms from  $U$  into an  $S$ -prescheme  $Y$  separated over  $S$  that coincide on the  $Z_i \cap U$ , one has  $u = v$ . (Indeed, the relation  $u = v$  is equivalent to  $u_{\{0\}} = v_{\{0\}}$ , where  $U_0$  is the inverse image of the diagonal of  $Y \times_S Y$  by the  $S$ -morphism  $X \rightarrow Y \times_S Y$  defined by  $(u, v)$ ; <!-- original page 51 --> this diagonal is a closed subprescheme of  $Y \times_S Y$ , hence  $U_0$  is a closed subprescheme of  $U$ , majorizing the  $Z_i \cap U$  by the hypothesis on  $(u, v)$ ; hence if the family  $(Z_i)$  is schematically dense, one will have  $u_{\{0\}} = v_{\{0\}}$ , hence  $u = v$ ; the converse implication is seen by simply taking  $Y = \text{Spec } \mathcal{O}_S[T]$ .)

With the terminology introduced in EGA I, end of N° 9.5, to say that the subprescheme  $Z$  of  $X$  is schematically dense also means that  $X$  is identical to the adherence subprescheme of  $Z$  in  $X$ .

**Lemma 4.2.** Let  $X$  be a flat  $S$ -prescheme,  $(Z_i)_{i \in I}$  a family of subpreschemes of  $X$  flat over  $S$ . Let  $S_0$  be a subprescheme of  $S$ , defined by a nilpotent ideal  $J$ ; suppose the modules  $J^n/J^{n+1}$  locally free over  $S_0$ .

<!-- label: III.IX.4.2 -->

Let  $X_{\{0\}}, Z'_{\{i\}}$  be deduced from  $X, Z_i$  by the base change  $S_{\{0\}} \rightarrow S$ . Then, if the family  $(Z'_{\{i\}})_{i \in I}$  is schematically dense in  $X_{\{0\}}$ , the family  $(Z_{\{i\}})_{i \in I}$  is so in  $X$ .

Suppose  $J^{n+1} = 0$  (where  $n \geq 0$ ); let us argue by induction on  $n$ , the assertion being trivial for  $n = 0$ . Defining  $S_m, X_m, Z'_{\{i\}_m}$  by reduction modulo  $J^{m+1}$  as is customary, the induction hypothesis already implies that  $(Z'_{\{i\}_{n-1}})_{i \in I}$  is schematically dense in  $X_{\{0\}_{n-1}}$ . Replacing  $X$  by an induced open if necessary, we are reduced to proving that every section  $f$  of  $\mathcal{O}_X$  which vanishes on the  $Z_{\{i\}}$  is zero.

Now the section  $f_{n-1}$  of  $\mathcal{O}_{X_{n-1}} = \mathcal{O}_X/J^{n-1}$  defined by  $f$  vanishes on the  $Z'_{\{i\}_{n-1}}$ , hence is zero, hence  $f$  is a section of  $J^n \mathcal{O}_X$ . Since  $X$  is flat over  $S$ , one has

```

```text

$$J^n O_X \otimes E \otimes_{O_{S_0}} O_{X_0}, \quad \text{where } E = J^n = J^n/J^{n+1}.$$

```

```

Likewise, since each  $Z_i$  is flat over  $S$ , the restriction  $f_i$  of  $f$  to  $Z_i$  may be regarded as a section of:

```

```text

$$J^n O_{Z_i} \otimes E \otimes_{O_{S_0}} O_{Z'_i}.$$

```

```

By hypothesis, the  $f_i$  are zero. Now  $E$  is locally free by hypothesis, hence so is  $F = E \otimes_{O_{S_0}} O_{X_0}$ .

*original page 52 -->* Hence  $f$  is a section of the locally free module  $F$  over  $X_0$ , such that for every  $i$  its restriction to  $Z'_i$  is zero. Since  $(Z'_i)_i \in I$  is schematically dense in  $X_0$ , it follows at once that  $f$  is zero. QED.

**Corollary 4.3.** Let  $X$  be a locally noetherian  $S$ -prescheme flat over  $S$ ,  $(Z_i)_i \in I$  a family of subpreschemes of  $X$  flat over  $S$ . Suppose that for every  $s \in S$ , the family  $(Z_{i,s})_i \in I$  of fibers at  $s$  is schematically dense in  $X_s$ . Then the family  $(Z_i)_i \in I$  is schematically dense in  $X$ .

*label: III.IX.4.3 -->*

Replacing  $X$  by an induced open if necessary, one is reduced to proving that every section  $f$  of  $O_X$  whose restrictions to the  $Z_i$  are zero is itself zero. [N.D.E-IX-13] For this, it suffices to prove that for every  $x \in X$ , the image of  $f$  in  $O_{X,x}$  is zero. Denote by  $\mathfrak{m}_x$  the maximal ideal of  $O_{X,x}$ , and by  $\mathfrak{m}_s$  that of  $O_{S,s}$ , where  $s$  is the image of  $x$  in  $S$ . Since  $O_{X,x}$  is noetherian, one has  $\bigcap_{n \in \mathbb{N}} \mathfrak{m}_x^n = 0$ , hence a fortiori  $\bigcap_{n \in \mathbb{N}} \mathfrak{m}_x^n \cap O_{X,x} = 0$ .

So it suffices to show that, for every integer  $n$ , the section induced by  $f$  on  $X \times_S \operatorname{Spec}(O_{S,s}/\mathfrak{m}_s^{n+1})$  is zero. By hypothesis, the family of fibers  $Z_{i,s} = Z_i \otimes_{O_S} O_{S,s} \otimes_{O_{S,s}} \kappa(s)$  is schematically dense in the fiber  $X_s = X \otimes_{O_S} O_{S,s} \otimes_{O_{S,s}} \kappa(s)$ . This reduces us to the case where  $S$  is the spectrum of a local ring whose maximal ideal  $\mathfrak{J}$  is nilpotent,  $S_0 = \operatorname{Spec} \kappa(s)$ , and the hypotheses of 4.2 are satisfied; hence the conclusion.

**Lemma 4.4.** Let  $S$  be a locally noetherian prescheme,  $X$  a locally noetherian  $S$ -prescheme flat over  $S$ ,  $(Z_i)_i \in I$  a family of subpreschemes of  $X$  flat over  $S$ . Suppose that for every  $s \in S$ , the family  $(Z_{i,s})_i \in I$  of fibers at  $s$  is schematically dense in  $X_s$ .

*label: III.IX.4.4 -->*

Then, for every base change  $S' \rightarrow S$  ( $S'$  not necessarily locally noetherian), the family  $(Z'_i)_i \in I$  is schematically dense in  $X'$  (i.e. the family  $(Z_i)_i \in I$  is universally schematically dense in  $X$  relative to  $S$ , cf. EGA IV<sub>3</sub>, Def. 11.10.8).

**Proof.** [N.D.E-IX-14] Let  $f$  be a section of  $O_X$  over an open  $U$  of  $X$ , vanishing on the  $Z'_i$ ; we must show that  $f$  is zero. Let  $s' \in S'$ ; it suffices to prove that  $f$  is zero at every point of  $U$  above  $s'$ . Let  $s$  be the image of  $s'$  in  $S$ ; replacing  $S$ ,  $S'$  by the spectra of the local rings at  $s$ ,  $s'$  if necessary, one may suppose  $S$ ,  $S'$  *original page 53 -->* local with  $s$ ,  $s'$  as closed points. One may moreover suppose  $X$  affine, hence

```

```text

$$S = \operatorname{Spec}(A), \quad S' = \operatorname{Spec}(A'), \quad X = \operatorname{Spec}(B), \quad X' = \operatorname{Spec}(B'), \quad B' = B \otimes_A A'$$

```

```

where  $A$ ,  $A'$  are local,  $A \rightarrow A'$  is a local homomorphism, and  $A$ ,  $B$  are noetherian. One may also suppose  $U$  affine, of the form  $X'_{g'}$ , with  $g' \in B'$ .

For every sub- $A$ -algebra  $A''$  of  $A$ , consider  $S'' = \operatorname{Spec}(A'')$  and  $X''$ ,  $Z''_i$  deduced from  $X$ ,  $Z_i$  by the base change  $S'' \rightarrow S$ , giving the diagram:

$\square$

$$\begin{array}{ccccc}
Z_i & \leftarrow & Z_{i,n} & \leftarrow & Z'_i \\
\downarrow & & \downarrow & & \downarrow \\
X & \leftarrow & X' & \leftarrow & X' \\
\downarrow & & \downarrow & & \downarrow \\
S & \leftarrow & S' & \leftarrow & S'.
\end{array}$$

\$\$

We restrict in what follows to those  $A''$  which are localizations of finite-type sub- $A$ -algebras  $A''_{\{1\}}$  of  $A$  at  $\mathfrak{m} \cap A''_{\{1\}}$  (where  $\mathfrak{m}$  is the maximal ideal of  $A$ ), so that the homomorphisms  $A \rightarrow A'' \rightarrow A'$  are local. Note that these  $A''$  form an increasing filtered family of subalgebras whose union is  $A$ , hence their direct limit is also  $A$ . One has therefore likewise  $B' = \varinjlim_{A''} B \otimes_{A'} A''$ . Hence there exist an  $A''$  and an element  $g' \in B' = B \otimes_{A'} A''$  whose image in  $B'$  is  $g'$ .

[^N.D.E-IX-15] By Lemma 4.5 below, the property that the family of fibers  $(Z_{i,s})_{i \in I}$  be schematically dense in  $X_s$  is preserved by every base change  $S' \rightarrow S$ ; consequently, since each  $S'$  is locally noetherian, if one replaces  $S$  by an appropriate  $S'$ , and  $X, Z_i$  by  $X', Z'_i$ , the hypotheses of 4.4 will be preserved.

Hence, replacing  $S$  by  $S'$  (and  $X, Z_i$  by  $X', Z'_i$ ) if necessary, one may suppose that  $g'$  comes from  $g \in B$ . Replacing  $X$  by the open  $X_g = U$  if necessary, one may therefore suppose  $U' = X'$ . One sees likewise that one may suppose that  $f'$  comes from a section  $f$  of  $\pi_X$  over  $X$ .

Let  $Y = V(f)$  be the subscheme of  $X$  defined by  $f$ , and  $Y_i = Z_i \times_X Y$  its intersection with  $Z_i$ , which is a closed subscheme of  $Z_i$ , equal to  $V(f_i)$ , where  $f_i$  is the section of  $\pi_{Z_i}$  induced by  $f$ . Denoting by  $Y', Y'_i$  the  $S'$ -schemes deduced from the preceding by base change, one will again have

```text  
 $Y' = V(f'), \quad Y'_i = Z'_i \times_{X'} Y' = V(f'_i),$
 ```

and one has the analogous relations for  $Y'', Y''_i$ . The hypothesis that  $f'$  vanishes on the  $Z'_i$  is expressed by the relations  $Y'_i = Z'_i$  for every  $i$ . [^N.D.E-IX-16]

Let  $\mathfrak{m}$  be the maximal ideal of  $A$ . For every integer  $n \geq 0$ , introduce the subscheme  $S_n = \operatorname{Spec}(A/\mathfrak{m}^{n+1})$  of  $S$ , and the schemes  $X_n, Y_n, Z_n, Y_n, Y_n$  deduced from  $X, Y, Z_i, Y_i$  by the base change  $S_n \rightarrow S$ . In general, for every  $S$ -prescheme  $P$ , we shall set  $P_n = P \times_S S_n$ .

<!-- original page 54 -->

For every  $n$ , and  $i \in I$ , consider the functor

```text  
 $F^n_i = \square_{\{Z^n_i/S_n\}} Y^n_i/Z^n_i : (\operatorname{Sch})^o/S_n \rightarrow (\operatorname{Ens})$
 ```

defined by (cf. VIII, 6.4): for every  $P$  over  $S_n$ ,

```text  
 $F^n_i(P) = \Gamma((Y^n_i)_P / (Z^n_i)_P) = \begin{cases} \emptyset & \text{if } (Y^n_i)_P \neq (Z^n_i)_P; \\ \{id\} & \text{if } (Y^n_i)_P = (Z^n_i)_P. \end{cases}$
 ```

Since  $S_n$  is local artinian, and  $Z^n_i$  flat hence essentially free over  $S_n$ , then, by VIII, 6.4, each  $F^n_i$  is representable by a closed subscheme  $T^n_i$  of  $S_n$ .

[^N.D.E-IX-17] The completion  $\hat{A}$  of the local ring  $A$  is noetherian since  $A$  is, and it is the projective limit of the  $A_n$ . Denote by  $K^n_i$  the ideal of  $A_n$  defining  $T^n_i$  and  $K^i$  the projective limit of the  $K^n_i$ ; it is an ideal of  $\hat{A}$ .

For  $i$  fixed,  $m \geq n$  and every  $S_n$ -prescheme  $P$ , one has

```text  
 $(Y^n_i)_P = Y_i \times_S S_n \times_{S_n} P = Y_i \times_S P = (Y^m_i)_P,$
 ```

$$\begin{array}{c} \text{\$\$} \\ \theta \rightarrow K^{\{i\}_m} \rightarrow A_m \rightarrow O(T^{\{i\}_m}) \rightarrow \theta \\ \qquad \qquad \qquad \searrow \qquad \qquad \qquad \searrow \qquad \qquad \qquad \searrow \\ \theta \rightarrow K^{\{i\}_n} \rightarrow A_n \rightarrow O(T^{\{i\}_n}) \rightarrow \theta \\ \text{\$\$} \end{array}$$

In other words,  $\{T^i_{\{i\}_{-n}}\}_{-n}$  is an inductive system of affine artinian schemes, and the inductive limit  $T^{\wedge}_{\{i\}_{-}} = \varprojlim_{\{i\}_{-n}} T^i_{\{i\}_{-n}}$  is a closed formal subscheme of the formal scheme  $\hat{S} = \mathrm{Spf}(\hat{A})$  (cf. EGA I, § 10), whose reduction modulo  $\mathfrak{m}^{n+1}$  is  $T^i_{\{i\}_{-n}}$ .

Recall that  $f_{\{i\}}$  denotes the image of  $f \in B = O(X)$  in  $O(Z_{\{i\}})$ , and  $f'_{\{i\}}$  its image in  $O(Z'_{\{i\}}) = O(Z_{\{i\}}) \otimes_{\mathcal{O}_A} A'$ ; the hypothesis  $Y'_{\{i\}} = Z'_{\{i\}}$  is equivalent to the vanishing of  $f'_{\{i\}}$ . Since  $O(Z_{\{i\}}) \otimes_{\mathcal{O}_A} A'$  is the inductive limit of the subalgebras  $O(Z_{\{i\}}) \otimes_{\mathcal{O}_A} A''$  (where  $A''$  satisfies the conditions made explicit above), there exists therefore an  $A''$  such that  $Y'_{\{i\}} = Z'_{\{i\}}$ . A priori,  $A''$  depends on  $i$ , but one can find an  $A''$  that works for all  $i \in J$ , since  $J$  is finite. Set  $S'' = \operatorname{operatorname{Spec}}(A'')$  and  $S''_{\{n\}} = S'' \times_{\mathcal{O}_A} S_{\{n\}}$ . [N.D.E-IX-18]

Since the morphisms  $S_A \rightarrow A' \rightarrow A'$  are local, the image  $s_{s''}$  of  $s_{s'}$  in  $S''$  is the closed point of  $S''$ , corresponding to the maximal ideal  $m''$  of  $B''$ , and the image of  $s_{s'}$  in  $S$  is  $s_s$ . Fix  $n$  and denote now by  $S''_{\{n\}}$  the  $n$ -th infinitesimal neighborhood of  $s_{s'}$  in  $S''$ , that is,  $\operatorname{Spec}(A'/m'^{n+1})$ . Set  $B''_{\{n\}} = B''/m''^{n+1}$  and  $Z''_{\{n,i\}} = Z_{\{i\}} \times_{S'} S''_{\{n\}} = \operatorname{Spec}(B''_{\{n\}})$ . Then the image  $f''_{\{n\}}$  of  $f''_{\{n\}}$  in  $B''_{\{n\}}$  vanishes on  $Z''_{\{n,i\}}$ , for every  $i$ . Now, by Lemma 4.5 below, the family of fibers

$$\underline{Z}_{i'''} = \underline{Z}''_{[n,i]} \times_{\{S''_{[n]}} \kappa(s'') = \underline{Z}_{[i,s]} \times_{\{\kappa(s)\}} \kappa(s'')$$

Since  $B_S$  is noetherian and  $B'_S = B \otimes_{A_S} A'_S$  is a localization of a finite-type  $B_S$ -algebra,  $B'_S$  is noetherian, hence its local rings are separated for their usual topology. It follows that  $f'_S$  is zero at the points  $x'_S$  of  $X'_S$  such that  $\mathfrak{m}'_S(B'_S)$  is contained in the maximal ideal of  $0_{\{X'_S, x'_S\}}$ , i.e. at the points of  $X'_S$  above  $s'_S$ . A fortiori,  $f'_S$  is zero at the points  $x'_S$  of  $X'_S$  above  $s'_S$ . QED.

<!-- label: III.IX.4.5.0 -->

This follows from EGA IV<sub>3</sub>, 11.10.5 (i) and 11.9.10 (i). It remains to give the proof of:

**\*\*Lemma 4.5.\*\*** \*Let  $X$  be a locally noetherian prescheme\*<sup>[^N.D.E-IX-20]</sup> \*over a field  $k$ ,  $\{Z_i\}_{i \in I}$  a family of subpreschemes of  $X$ ,  $k'$  an extension of  $k$ ,  $X'$  and  $Z'_i$  the preschemes deduced from  $X$  and  $Z_i$  by the base change  $k'/k$ . For  $\{Z_i\}_{i \in I}$  to be schematically dense in  $X$ , it is necessary and sufficient that  $\{Z'_i\}_{i \in I}$  be so in  $X'$ .\*

<!-- label: III.IX.4.5 -->

The "if" follows from 4.5.0; let us prove the "only if".<sup>[^N.D.E-IX-21]</sup> First, one may suppose  $X = \operatorname{Spec}(B)$  affine. For every  $i$ , let  $\{Z_{ij}\}_{j \in J_i}$  be a covering of  $Z_i$  by affine opens; replacing  $\{Z_i\}_{i \in I}$  by the family  $\{Z_{ij}\}_{(i,j) \in J}$ , where  $J = \coprod_{i \in I} J_i$ , one may also suppose the  $Z_i$  affine.

Let  $g \in B' = B \otimes_k k'$  and  $t' \in B'_g$  be a section of  $\mathcal{O}_{X'}$  on the affine open  $U' = X'_g$ , vanishing on the  $Z'_i \cap U'$ , i.e. whose image in each  $(\mathcal{O}_{Z_i} \otimes_k k')_g$  is zero. There exists a finite-type sub- $k$ -algebra  $A$  of  $k'$  such that  $g \in B_A = B \otimes_k A$  <!-- original page 55 --> and  $t' \in (B_A)_g$ . The map  $\mathcal{O}_{Z_i} \otimes_k A \rightarrow \mathcal{O}_{Z_i} \otimes_k k'$  being injective, so is the map

```
``text
(0(Z_i) \otimes_k A)_g \rightarrow (0(Z_i) \otimes_k k')_g;
```

given the hypothesis, this implies that the image of  $t'$  in each  $(\mathcal{O}_{Z_i} \otimes_k A)_g$  is zero. This reduces us to showing that the family  $\{Z_i \cap U\}_{i \in I}$  is schematically dense in  $X_A$ ,<sup>[^N.D.E-IX-22]</sup> which follows from EGA IV<sub>3</sub>, 11.9.10 b).

Let us note in passing the following result, which will serve in a later Exposé:<sup>[^N.D.E-IX-23]</sup>

**\*\*Corollary 4.6.\*\*** \*Let  $X$  be a flat  $S$ -prescheme,  $U$  an open subset of  $X$ . Suppose that for every  $s \in S$ ,  $U_s$  is schematically dense in  $X_s$ , and that  $X$  is locally noetherian, or locally of finite presentation over  $S$ . Then  $U$  is schematically dense in  $X$ .\*

<!-- label: III.IX.4.6 -->

<!-- original page 56 -->

Suppose for simplicity  $U$  retrocompact in  $X$  (cf. EGA IV<sub>3</sub>, 11.10.10 and 11.9.17 for the general case). The case  $X$  locally noetherian is included only for memory; it is contained in 4.3.

In the second case envisaged, one may evidently suppose  $S$  and  $X$  affine; then  $X$  and  $U$  are of finite presentation over  $S = \operatorname{Spec}(A)$ . The ring  $A$  is the inductive limit of its finite-type sub- $\mathbb{Z}$ -algebras  $A_i$ . The "patented procedure" already used (cf. EGA IV<sub>3</sub>, 8.8.2 and 8.10.5 (iii)) shows that there exist an  $i$ , an affine scheme  $X_i$  over  $S_i = \operatorname{Spec}(A_i)$  and an open  $U_i$  in  $X_i$ , from which  $X, U$  are deduced by base change  $S \rightarrow S_i$ . Let  $E_i$  be the part of  $S_i$  consisting of  $s \in S_i$  such that  $(U_i)_s$  is schematically dense in  $(X_i)_s$ .

<sup>[^N.D.E-IX-24]</sup> By EGA IV<sub>2</sub>, 5.9.9 and 5.10.2,  $E_i$  is the set of  $s \in S_i$  such that  $(U_i)_s$  contains the set  $\operatorname{Ass} \mathcal{O}_{(X_i)_s}$  of points "associated" with the structure sheaf of  $(X_i)_s$ , and by EGA IV<sub>3</sub>, 11.9.17.1 this condition is of constructible nature, i.e.  $E_i$  is a constructible part of  $S_i$ .

<sup>[^N.D.E-IX-24]</sup> By 4.5, the inverse image of  $E_i$  by  $S_j \rightarrow S_i$  (resp. by  $S \rightarrow S_i$ ) is  $E_j$  (resp. the set  $E$  of  $s \in S$  such that  $U_s$  is schematically dense in  $X_s$ ). Moreover, by hypothesis,  $E = S$ , which is also the inverse image by each  $S \rightarrow S_i$  of  $E_i$ . By EGA IV<sub>3</sub>, 8.3.11, this implies that there exists  $j \geq i$  such that  $E_j = S_j$ , i.e. such that for every  $s \in S_j$ ,  $(U_j)_s$  is schematically dense in  $(X_j)_s$ .

Then, by 4.4 applied to  $(S_j, X_j, U_j)$  and to the base change  $S \rightarrow S_j$ , it follows that  $U$  is schematically dense in  $X$ . One will note moreover that we use 4.4 here only in the case of a family with finite index set (in fact, reduced to one element), in which case the proof of 4.4 simplifies considerably, as the reader will check.

**\*\*Theorem 4.7.\*\*** \*Let  $S$  be a prescheme,  $G$  a group of multiplicative type and of finite type over  $S$ . For every integer  $n > 0$ , let  $\{nG\}$  be the kernel of  $n \cdot \operatorname{id}_G$ . Then the family of subpreschemes  $\{(\{nG\})_{n > 0}\}$

of  $G$  is schematically dense (Def. 4.1).\*

<!-- label: III.IX.4.7 -->

We distinguish two cases.

a) Case  $S$  locally noetherian. Then by 4.3 one is reduced to the case where  $S$  is the spectrum of a field  $k$ . By 4.5.0, one may suppose  $k$  algebraically closed and  $G$  diagonalizable, i.e. of the form  $D_{\{k\}}(M)$ , where  $M$  is a commutative group of finite type. Then  $M$  is of the form  $\Gamma \times \mathbb{Z}^r$ , with  $\Gamma$  finite, hence  $G$  is of the form  $G_1 \times \mathbb{Z}^r$ , <!-- original page 57 --> with  $G_1 = D(\Gamma)$  and  $G_2 = G^r_{\{r\}}(m)$ ; and for  $n$  large multiplicatively (namely  $n$  a multiple of the order of  $\Gamma$ ) one will have  $_nG = G_1 \times _nG_2$  since one will have  $_nG_1 = G_1$ .

Applying again 4.3 to the projection  $G \rightarrow G_1$ , one is reduced to the case of  $G_2$ , i.e. to the case where  $G = G^r_{\{r\}}(m)$ . Since  $G$  is then reduced, it amounts to the same to say that  $(\{_{nG}\}_{n > 0})$  is schematically dense in  $G$ , or that the union of the  $\{_{nG}$  is dense in  $G$  for the ordinary topology. Since  $_nG = (_nG_m)^r$ , one is reduced to the case of  $G = G_m$ , hence  $G$  irreducible of dimension 1. Then this follows from the fact that the union of the  $\{_{nG}$  (equal to the set of roots of unity in  $k$ ) is infinite.

b) General case. For every point  $s$  of  $S$ , there exist an open neighborhood  $U$  of  $s$  and a faithfully flat quasi-compact morphism  $S' \rightarrow U$  such that  $G' = G_{\{S'\}}$  is diagonalizable, i.e. of the form  $D_{\{S'\}}(M)$ . By 4.5.0 again, one may reduce to the case of  $G'$ , so one may suppose  $G$  diagonalizable; hence it comes from the absolute group  $H = D_{\{\mathbb{Z}\}}(M)$  over  $\operatorname{Spec}(\mathbb{Z})$  by base change  $S \rightarrow \operatorname{Spec}(\mathbb{Z})$ . By the proof of a), for every  $s \in \operatorname{Spec}(\mathbb{Z})$ , the family  $(_nH_s)_{n > 0}$  is schematically dense in  $H_s$ ; it now suffices to apply 4.4.[^N.D.E-IX-25]

**Corollary 4.8.** \*a) Let  $u, v : H \rightarrow G$  be two homomorphisms of  $S$ -preschemes in groups, with  $H$  of multiplicative type and of finite type, and suppose that for every integer  $n > 0$ , the restrictions of  $u$  and  $v$  to  $\{_{nH}$  are identical. Then  $u = v$ .\*

<!-- label: III.IX.4.8 -->

\*b) Let  $H_1, H_2$  be two subgroups of multiplicative type and of finite type of a prescheme in groups  $G$ , and suppose that for every integer  $n > 0$ , one has  $_nH_1 = _nH_2$ ; then  $H_1 = H_2$ .\*

The first assertion follows from the second, by consideration of the subgroups  $H_1$  and  $H_2$  of  $H \times G$ , graphs of  $u$  and  $v$ . To prove b), let  $H = H_1 \cap H_2$ ; this is a subscheme in groups of  $H_i$  ( $i = 1, 2$ ); one must show that it is identical to  $H_i$ . Now the hypothesis means that it majorizes the  $_nH_i$ . One is therefore reduced to proving the:

**Corollary 4.9.** \*Let  $G$  be an  $S$ -group of multiplicative type and of finite type, and  $H$  a subscheme in groups which majorizes the  $\{_{nG}$ ,  $n > 0$ . Then  $H = G$ .\*

<!-- label: III.IX.4.9 -->

By 4.7, one is reduced to proving that the subscheme  $H$  is closed, or again that it equals  $G$  set-theoretically. This reduces us to the case where  $S$  is the spectrum <!-- original page 58 --> of a field; but then every subscheme in groups of  $G$  is closed (VI\_B 1.4.2), whence the conclusion.

**Remark 4.10.** \*Under the conditions of 4.7, let  $m$  be an integer  $> 0$  having the following properties: for every  $s \in S$ ,  $m$  is not a power of the characteristic of  $\kappa(s)$ , and if  $G_{\{s\}}$  is of type  $M$ , the prime divisors of the torsion of  $M$  divide  $m$ . (N.B. This second condition is always satisfied if  $G$  is a torus.) Then the proof given shows that in the statement of 4.7 and the Corollaries 4.8 and 4.9, one may restrict attention to subgroups of the form  $\{_{(m^r)}G$ , with  $r > 0$ .\*

<!-- label: III.IX.4.10 -->

Moreover, one sees at once that when  $G$  is smooth over  $S$ , then for every point  $s \in S$ , there exist an open neighborhood  $U$  of  $s$  and an integer  $m > 0$ , prime to all the residual characteristics of  $U$ , satisfying the preceding conditions for  $G_U$ . (Take for example for  $m$  the order of the torsion of the type of  $G$  at  $s$ , cf. 1.4.1 a) and 2.1 e).) Under these conditions, one finds  $\{_{(m^r)}G$  that are finite and étale over  $S$ , and whose family is schematically dense, provided one restricts to over  $S$ . This remark allows, in certain cases (notably those involving the theorems 3.2 and 3.2 bis, cf. XI 6, but not those involving the theorems 3.6 and 3.6 bis), to dispense with the theorem 3.1, which involves Hochschild cohomology.

## ## 5. Central homomorphisms of groups of multiplicative type

**\*\*Lemma 5.0.\*\*** <sup>[^N.D.E-IX-27]</sup> \*Let  $(A, \mathfrak{m})$  be a noetherian local ring,  $S = \operatorname{Spec}(A)$ , and  $H$  a finite scheme over  $S$ , so  $H = \operatorname{Spec}(B)$ , where  $B$  is finite over  $A$ . Let  $K$  be a subscheme of  $H$ , such that by reduction modulo  $\mathfrak{m}^{n+1}$  one has  $K_n = H_n$  for every  $n$ . Then  $K = H$ .\*

<!-- label: III.IX.5.0 -->

Let  $s$  be the closed point of  $S$ . Note first that  $K$  is a closed subscheme of  $H$ . Indeed, it is a priori a closed subscheme of an open  $U$  of  $H$ . But  $K$ , hence  $U$ , contains the fiber  $K_s = H_s$ ; since the morphism  $H \rightarrow S$  is finite, hence closed, it follows that the complement of  $U$  is empty, i.e.  $U = H$ . Hence  $K$  is defined by an ideal  $I$  of  $B$ . The hypothesis entails that  $I$  is contained in  $\mathfrak{m}^n B$  for every  $n$ ; since  $B$  is a finite  $A$ -module, it is separated for the  $\mathfrak{m}$ -adic topology, whence  $I = 0$ .

**\*\*Theorem 5.1.\*\*** \*Let  $u, v : H \rightarrow G$  be two homomorphisms of  $S$ -preschemes in groups, with  $H$  of multiplicative type and of finite type, and  $S$  locally noetherian or  $G$  of finite presentation over  $S$ . Let  $s \in S$  be such that  $u_s = v_s$ , and suppose  $u_s$  central. Then there exists an open neighborhood  $U$  of  $s$  such that  $u_U = v_U$ .\*

<!-- label: III.IX.5.1 -->

<!-- original page 59 -->

We distinguish the two cases:

a)  $S$  locally noetherian. <sup>[^N.D.E-IX-28]</sup> Let  $K = \ker(u, v)$  be the inverse image of the diagonal of  $G \times_S G$  by the morphism  $(u, v)$ ; this is a subscheme in groups of  $H$ . We wish to find  $U$  such that  $K_U = H_U$ . Note that, since  $S$  is locally noetherian and  $H$  of finite type over  $S$ ,  $H$  is locally noetherian, hence the immersion  $K \hookrightarrow H$  is of finite type (cf. EGA I, 6.3.5). Hence  $K$  is of finite type over  $S$ , hence of finite presentation over  $S$ , since  $S$  is locally noetherian. Consequently, by EGA IV<sub>3</sub>, 8.8.2.4, to show that there exists an open neighborhood  $U$  of  $s$  such that  $K_U = H_U$ , it suffices to show that  $K_{S_0} = H_{S_0}$ , where  $S_0$  is the spectrum of  $A = 0_{\{S, s\}}$ . One may therefore suppose  $S$  local with closed point  $s$ . Replacing the noetherian local ring  $A$  by its completion  $\hat{A}$  if necessary, which introduces a base change  $\hat{S} \rightarrow S$  faithfully flat and quasi-compact, one may even, if one wishes, suppose <sup>[^N.D.E-IX-29]</sup>  $A$  complete.

By 3.4 one has  $u_n = v_n$  for every  $n$ , where as usual the index  $n$  indicates reduction modulo  $\mathfrak{m}^{n+1}$  ( $\mathfrak{m}$  being the maximal ideal of  $A$ ). For every integer  $m > 0$ , denoting by  $\{\}_{\mu}$ ,  $\{\}_{\nu}$  the homomorphisms  $\{\}_{\mu H} \rightarrow G$  induced by  $u, v$ , one therefore also has  $\{\}_{\mu}_n = \{\}_{\nu}_n$ . This being true for every  $n$ , and  $\{\}_{\mu H}$  being finite over  $S$  by 2.2, it follows that  $\{\}_{\mu} = \{\}_{\nu}$  by 5.0. This being true for every  $m$ , one has therefore  $u = v$  by 4.7.

b)  $G$  of finite presentation. <sup>[^N.D.E-IX-30]</sup> Since  $H$  is also of finite presentation over  $S$ , then, by EGA IV<sub>3</sub>, 8.8.2, we may again suppose  $S$  local with closed point  $s$  and prove that then  $u = v$ . If  $f : S' \rightarrow S$  is a faithfully flat quasi-compact morphism, and if one denotes by  $f_H$  the morphism  $H' \rightarrow H$  and  $u', v' : H' \rightarrow G$  the morphisms deduced from  $u, v$ , then the equality  $u' = v'$  entails  $u' \circ f_H = v' \circ f_H$ , hence  $u = v$ , since  $f_H$  is an epimorphism. Hence, by making a faithfully flat quasi-compact extension of the base, one may suppose moreover  $H$  diagonalizable, hence of the form  $D_S(M)$ , with  $M$  a commutative group of finite type.

Introduce, as in the proof of 4.6, the increasing filtered family of finite-type sub- $\mathbb{Z}$ -algebras  $A_i$  of  $A = 0_{\{S, s\}}$ , and  $S_i = \operatorname{Spec}(A_i)$ . <sup>[^N.D.E-IX-30]</sup> Note that  $H = D_S(M)$  comes, for every  $i$ , from the diagonalizable group  $H_i = D_{S_i}(M)$ . Since  $G$  is of finite presentation over  $S$ , then, by EGA IV<sub>3</sub>, 8.8.2 (see also VI<sub>B</sub>, 10.2 and 10.3), there exist an index  $i$ , a prescheme in groups  $G_i$  of finite presentation over  $S_i$ , and morphisms of  $S_i$ -groups  $u_i, v_i : H_i \rightarrow G_i$  from which  $u, v$  come by base change. Let  $s_i$  be the image of  $s$  in  $S_i$  and let  $\rho_i : H_i \times_{S_i} G_i \rightarrow G_i$  be the morphism of  $S_i$ -preschemes defined by  $\rho_i(h, g) = u_i(h) g u_i(h)^{-1}$ . Then, since  $u_s$  is central,  $\rho_s = \rho_i \times_{\kappa(s_i)} \kappa(s)$  equals the second projection; so the same holds for  $\rho_i$  (since  $\kappa(s_i) \rightarrow \kappa(s)$  is faithfully flat and quasi-compact), i.e.  $(u_i)_s$  is central. Similarly, since  $u_s = v_s$  one has  $(u_i)_s = (v_i)_s$ . One can then apply a) to the situation over  $S_i$ , whence the announced conclusion.

**\*\*Corollary 5.2.\*\*** \*Let  $u : H \rightarrow G$  be a homomorphism of  $S$ -preschemes in groups, with  $H$  of multiplicative type and of finite type, and  $S$  locally noetherian or  $G$  of finite presentation over  $S$ . Let  $s \in S$  and suppose that  $u_s$  is the unit homomorphism. Then there exists an open neighborhood  $U$  of  $s$  such that  $u_U$  is the unit homomorphism.\*

<!-- label: III.IX.5.2 -->

**\*\*Corollary 5.3.\*\*** \*Let  $u, H, G$  be as in 5.2, suppose moreover  $G$  separated over  $S$ .\* <!-- original page 60 --> \*Let  $U$  be the set of  $s$  in  $S$  such that  $u_{\{s\}}$  is the unit homomorphism. Then  $U$  is an open-and-closed part of  $S$ , and  $u_{\{U\}} : H_{\{U\}} \rightarrow G_{\{U\}}$  is the unit homomorphism.\*

<!-- label: III.IX.5.3 -->

It remains only to prove that  $U$  is closed. Now let  $K = \text{Ker}(u)$ ; since  $G$  is separated over  $S$ ,  $K$  is a closed subscheme of  $H$ , and  $U$  is the set of  $s$  in  $S$  such that  $K_{\{s\}} = H_{\{s\}}$ . One then sees easily that  $U$  is closed, for example as an application of VIII 6.4 ( $H$  being essentially free over  $S$  by VIII 6.3), or by noting that one may suppose  $S$  reduced and  $U$  dense in  $S$ , hence schematically dense in  $S$ , which implies  $H_U$  schematically dense in  $H$  since  $H$  is flat over  $S$ , [^N.D.E-IX-31] and since  $u$  and the unit homomorphism coincide on  $H_U$ , they coincide on  $H$ .

**\*\*Corollary 5.4.\*\*** \*Let  $S$  be a prescheme,  $H$  and  $G$  two  $S$ -groups, with  $H$  of multiplicative type and of finite type and  $G$  separated and of finite presentation over  $S$ ,  $\pi : S' \rightarrow S$  a [^N.D.E-IX-32] \*universal effective epimorphism (for example, a faithfully flat quasi-compact morphism, or a morphism admitting a section, cf. IV 1.12) with geometrically connected fibers.\* [^N.D.E-IX-33]

<!-- label: III.IX.5.4 -->

\*Let  $u' : H' \rightarrow G'$  be a central homomorphism of the  $S'$ -groups deduced from  $H, G$  by the base change  $S' \rightarrow S$ . Then there exists a unique homomorphism  $u : H \rightarrow G$  of  $S$ -groups such that  $u_{\{S'\}} S' = u'$ . When  $S'/S$  admits a section  $g$ , then  $u$  is the morphism deduced from  $u'$  by the base change  $g : S \rightarrow S'$ .\*

Since  $\pi$  is a universal effective epimorphism, so is  $H' \rightarrow H$ , whence the uniqueness of  $u$ , cf. the beginning of the proof of 5.1 b). If  $\pi$  admits a section  $g$ , then  $u' = \pi^*(u)$  entails  $u = g^* \pi^*(u) = g^*(u')$ .

For the existence of  $u$ , one is reduced, by IV 2.3, to showing that the two homomorphisms  $u'_{\{1\}}, u'_{\{2\}} : H' \rightarrow G'$  of  $S'$ -groups deduced from  $u'$  by the two base changes  $\text{pr}_{\{1\}}, \text{pr}_{\{2\}} : S' = S \times_{S'} S' \rightarrow S'$ , are identical. Now they coincide on the diagonal of  $S'$ ; more precisely the inverse images of  $u'_{\{1\}}$  and  $u'_{\{2\}}$  by the diagonal morphism  $S' \rightarrow S'$  are identical (since both equal  $u'$ ). [^N.D.E-IX-34] Since  $u'_{\{1\}}$  and  $u'_{\{2\}}$  are central, one may apply 5.3 to the morphism  $u'_{\{1\}} (u'_{\{2\}})^{-1}$ . There exists therefore an open-and-closed part  $U$  of  $S'$ , <!-- original page 61 --> containing the diagonal of  $S'$ , such that  $u'_{\{1\}}$  and  $u'_{\{2\}}$  coincide above  $U$ .

Now the fibers of  $S'/S$  being geometrically connected, the same holds for those of  $S'/S$ , which are therefore a fortiori connected; whence it follows that  $U$  (containing the diagonals of the said fibers) contains the said fibers, hence is equal to  $S'$ , which completes the proof.

**\*\*Corollary 5.5.\*\*** \*Let  $S$  be a prescheme,  $K$  an  $S$ -prescheme in groups locally of finite type\* [^N.D.E-IX-35] \*and with connected fibers,  $H$  a subgroup of multiplicative type and of finite type, invariant in  $K$ . Then  $H$  is a central subgroup of  $K$ .\*

<!-- label: III.IX.5.5 -->

[^N.D.E-IX-36] Note first that  $\pi : K \rightarrow S$  has geometrically connected fibers, since for a group scheme locally of finite type over a field, connected implies geometrically connected (cf. VI\_A 2.4). One can then apply 5.4 by taking  $G = H$  and  $S' = K$ , to the homomorphism of  $K$ -groups  $u' : H_{\{K\}} \rightarrow H_{\{K\}}$  defined set-theoretically by  $(h, k) \mapsto (k h k^{-1}, k)$ , which is central since  $H$  is commutative. The inverse image of  $u'$  by the unit section  $\epsilon : S \rightarrow K$  is the identity homomorphism of  $K$ , hence by 5.4 the same holds for  $H_{\{K\}} \rightarrow H_{\{K\}}$ ; hence  $H$  is central in  $K$ .

Let us state the variants of the preceding results for central subgroups of multiplicative type. One obtains, by proceeding as for the preceding results (and using 3.2 bis):

**\*\*Theorem 5.1 bis.\*\*** \*Let  $G$  be an  $S$ -prescheme in groups,  $H_1$  and  $H_2$  two subschemes in groups of multiplicative type and of finite type, with  $(H_{\{1\}})_{\{s\}}$  central. Suppose  $S$  locally noetherian or  $G$  of finite presentation over  $S$ . Then for every  $s$  in  $S$  such that  $(H_{\{1\}})_{\{s\}} = (H_{\{2\}})_{\{s\}}$ , there exists an open neighborhood  $U$  of  $s$  such that  $H_{\{1\}}|_U = H_{\{2\}}|_U$ .\*

<!-- label: III.IX.5.1bis -->

**\*\*Corollary 5.3 bis.\*\*** \*Under the preceding conditions, suppose moreover  $G$  separated over  $S$ . Let  $U$  be the set of

$\$s \in S$  such that  $(H_{\{1\}})_s = (H_{\{2\}})_s$ . Then  $U$  is an open-and-closed part of  $S$ , and  $H_{\{1\}}|_U = H_{\{2\}}|_U$ .

<!-- label: III.IX.5.3bis -->

**Corollary 5.4 bis.** Let  $S$  be a prescheme,  $G$  a prescheme in groups separated and of finite presentation over  $S$ ,  $\pi : S' \rightarrow S$  a covering morphism for the faithfully flat quasi-compact topology, with geometrically connected fibers,  $H$  a subgroup of multiplicative type and of finite type of  $G' = G \times_S S'$ .

<!-- label: III.IX.5.4bis -->

Then there exists a unique subgroup  $H_S$  of  $G$  such that  $H' = H \times_S S'$ , and  $H_S$  is of multiplicative type and of finite type over  $S$ , by 1.1 and 2.1 b). If  $\pi : S' \rightarrow S$  admits a section  $g$ , then  $H_S$  is the inverse image of the subgroup  $H'$  of  $G'$  by  $g : S \rightarrow S'$ .

**Theorem 5.6.** Let  $S$  be a prescheme,  $u : H \rightarrow G$  a homomorphism of  $S$ -preschemes in groups, with  $H$  of multiplicative type and of finite type,  $G$  of finite presentation over  $S$ .

<!-- label: III.IX.5.6 -->

a) Suppose  $G$  has connected fibers, and let  $s \in S$  be such that  $u_s : H_s \rightarrow G_s$  is a central homomorphism. Then there exists an open neighborhood  $U$  of  $s$  such that the homomorphism  $H|_U \rightarrow G|_U$  induced by  $u$  is central.

b) Suppose that for every  $s \in S$ ,  $u_s : H_s \rightarrow G_s$  is central. Then  $u$  is central.

[N.D.E-IX-37] Let us prove (a). Proceeding exactly as in the proof of 5.1 (b), one may suppose  $S$  local with closed point  $s$ , then  $H = D_{\{S\}}(M)$  diagonalizable, then that there exist a finite-type sub- $\mathbb{Z}$ -algebra  $A_i$  of  $A = O_{\{S,s\}}$  and a morphism  $u_i : D_{\{S_i\}}(M) \rightarrow G_i$  such that  $u_{\{s_i\}}$  is central (where  $s_i$  is the image of  $s$  in  $S_i$ ) and from which  $u$  comes by base change. This reduces us to the case where  $S$  is local noetherian with closed point  $s$ , and one must then prove that  $u$  is central.

Let  $K$  be the subprescheme  $\text{Ker}(v, w)$ , where  $v, w : H \times_S G \rightarrow G$  are defined by

```
```text
v(h, g) = g,      w(h, g) = int(u(h)) · g = u(h) g u(h)-1.
```

Then K is a sub- G -group of the G -group $H_{\{G\}} = H \times_S G$; we wish to show that it is equal to H_G itself. By 4.9, one is reduced to proving that it majorizes the $\{ \}_{m}(H_{\{G\}}) = (\{ \}_{mH}) \times_S G$ for every integer $m > 0$, which reduces us to the case where $H = \{ \}_{mH}$, hence H finite over S .

Let e be the unit element of the fiber G_s ; then $S^{\{0\}} = \text{operatorname{Spec}}(O_{\{G,e\}})$ is a local noetherian scheme (G being of finite presentation over S noetherian); set $S^{\{0\}}_{\{n\}} = S^{\{0\}} \times_S S_{\{n\}}$, where $S_{\{n\}} = \text{operatorname{Spec}}(A/m^{n+1})$. Then $K_{\{S^{\{0\}}\}} = K \times_S S^{\{0\}}$ is a subprescheme of $H_{\{S^{\{0\}}\}} = H \times_S S^{\{0\}}$, and, <!-- original page 63 --> by 3.9, one has $K_{\{S^{\{0\}}\}_{\{n\}}} = H_{\{S^{\{0\}}\}_{\{n\}}}$ for every n . [N.D.E-IX-38] Since $H_{\{S^{\{0\}}\}}$ is finite over $S^{\{0\}}$, one concludes from 5.0 (applied to the noetherian local ring B) that $K_{\{S^{\{0\}}\}} = H_{\{S^{\{0\}}\}}$.

On the other hand, since $H \times_S G$ is noetherian (being of finite presentation over S noetherian), the immersion $K \hookrightarrow H \times_S G$ is of finite type (cf. EGA I, 6.3.5), so that K is of finite type, hence of finite presentation over G . Then the equality $K_{\{S^{\{0\}}\}} = H_{\{G\}} \times_S S^{\{0\}}$ entails, by EGA IV₃, 8.8.2.4, that there exists an open neighborhood W of e in G such that $K_{\{G\}} \times_S W = H_{\{G\}} \times_S W = H \times_S W$. Hence K majorizes the open neighborhood $V = H \times_S W$ of the unit section of H_G over H_S .

For every $t \in H$, the fiber G_t (being a $\kappa(t)$ -algebraic group) is Cohen-Macaulay (VI_A, 1.1.1), hence without embedded components; as it is moreover connected, hence irreducible (VI_A, 2.4), it has its generic point as unique associated point. Hence, by EGA IV₂, 3.1.8, the open V_t is schematically dense in G_t . By 4.3, V is therefore schematically dense in H_G . Moreover, since K is a sub- H -group of H_G , it induces on each fiber G_h a subgroup K_h , and since the latter majorizes an open neighborhood of the unit element and G_h is connected, it follows that $K_h = G_h$, hence $K = G_H$ set-theoretically. Thus K is a closed subprescheme of H_G which majorizes the schematically dense subprescheme V , hence $K = G_H$, which proves a).

Finally, b) is a direct consequence of 3.9, given that to verify that a subprescheme K of $P = G \times_S H$ is identical to P , it suffices to verify that for every base change $\pi : S' \rightarrow S$, where S' is an artinian quotient of S

local ring of S_s , one has $K' = P'$.

6. Monomorphisms of groups of multiplicative type, and canonical factorization of a homomorphism of such a group

Lemma 6.1. *Let S be a quasi-compact prescheme, G an S -prescheme in commutative groups, of finite presentation and quasi-finite over S . Then there exists an integer $n > 0$ such that $n \cdot \text{id}_G = 0$, i.e. $G = \{1\}$.*

<!-- label: III.IX.6.1 -->

<!-- original page 64 -->

If S is the spectrum of a field k , then G is finite over k , and by VII_A 8.5, it suffices to take $n = \deg(G/k)$. Suppose now $S = \text{Spec}(A)$ local artinian; let k be the residue field of A , $G_0 = G \otimes_A k$, and $n_0 = \deg(G_0/k)$. Distinguish two cases.

a) k is of characteristic zero. Then G_0 is separable over k , hence G is unramified over S . Then the unit section of G is an open immersion, hence $\{1\} = \text{Ker}(n \cdot \text{id}_G)$ is an open subscheme of G ; therefore in order that it be equal to G , it suffices that it be so set-theoretically; one may then take $n = n_0$.

b) k is of characteristic $p > 0$. Denote by $\mathfrak{m}$ the maximal ideal of A and $S_r = \text{Spec}(A/\mathfrak{m}^{r+1})$ for every r . Let m be an integer such that $\mathfrak{m}^{m+1} = 0$; we claim that one may take $n = p^m n_0$. Indeed, proceeding by induction on m , and setting $n' = p^{m-1} n_0$, one may suppose that $n' \cdot \text{id}_G$ induces the zero endomorphism in $G_{m-1} = G \otimes_S S_{m-1}$.

[^N.D.E-IX-39] Denote by E the set of endomorphisms u of G having this property and K the kernel of the morphism of functors in groups $G \mapsto \prod_{S_{m-1}/S} G$ (cf. III 0.1.2). Then E identifies with $\text{Hom}_{\{S\text{-gr.}\}}(G, K)$; in particular the abelian group law on E is induced by that of K . Now, by III 0.9, K is the S -functor in groups which to every $g : T \rightarrow S$ associates the k -vector space

$$\text{Hom}_{\{0 \rightarrow T \rightarrow 0\}}(g^* \otimes (\Omega^1_{G_0/S})), \quad m^m \cdot 0_T;$$

one has therefore $pu = 0$ for every $u \in E$. Hence one has $p \cdot n' \cdot \text{id}_G = 0$, i.e. $p^m n_0 \cdot \text{id}_G = 0$.

Suppose now S noetherian (one reduces to this in 6.1 by the customary reduction to the noetherian case[^N.D.E-IX-40]). It then suffices to combine the foregoing with the

Lemma 6.2. *Let X be a quasi-finite prescheme over S noetherian, and consider an increasing filtered family of subpreschemes $(X_i)_{i \in I}$ having the following property:*

<!-- label: III.IX.6.2 -->

``text
for every $s \in S$ and $n \geq 0$, setting $S_{\{s,n\}} = \text{Spec}(0_{\{S,s\}}/\mathfrak{m}^{n+1})$, there exists an $i \in I$ such that $X_i \times_S S_{\{s,n\}} = X \times_S S_{\{s,n\}}$.
``

Under these conditions, there exists an $i \in I$ such that $X_i = X$.

Since S is noetherian, there exists a maximal open U such that one has $X|_U = X_i|_U$ <!-- original page 65 --> for i large; we shall show that $U = S$. In other words, we shall show that if $U \neq S$, one can find a U_1 strictly larger than U , and an i such that $X|_{U_1} = X_i|_{U_1}$. Localizing at a maximal point s of $S - U$, one is reduced to the case where S is local with closed point s , and $U = S - \{s\}$. (Indeed, if one writes $S^0 = \text{Spec}(0_{\{S,s\}})$ and if there exists i such that $X \times_S S^0 = X_i \times_S S^0$ then, [^N.D.E-IX-41] there exists an open neighborhood V of s such that $X|_V = X_i|_V$; hence taking i large enough so that $X_i|_U = X|_U$, one will have $X|_W = X_i|_W$, where $W = U \cup V$.)

Then, for i large, since $X|_U = X_i|_U$, one sees that X_i is a closed subprescheme of X defined by an ideal $I^{\{i\}}$ of support contained in $X_{\{s\}} = X_0 = X \times_S S_0$ (where $S_n = \text{Spec}(A/\mathfrak{m}^{n+1})$, $S = \text{Spec}(A)$). Since X_0 is quasi-finite over S_0 , X_0 is a finite closed part of X noetherian, hence $I^{\{i\}}$ is a module of finite length. It follows that there exists an integer $n \geq 0$ such that $I^{\{i\}} \cap \mathfrak{m}^{n+1} \cdot 0_X = 0$. On the other hand, by the hypothesis in 6.2, one may suppose (by enlarging i if necessary) that the image of $I^{\{i\}}$ in $0_{X_n} = 0_X/\mathfrak{m}^{n+1} \cdot 0_X$ is zero. This implies $I^{\{i\}} = 0$, hence

$\$X_{\{i\}} = X\$$. QED.

****Lemma 6.3.**** *Let $\$S\$$ be a prescheme, $\$K\$$ a prescheme in groups over $\$S\$$, locally of finite presentation, $\$s \in S\$$ such that $\$K_{\{s\}}\$$ is quasi-finite (resp. unramified) over $\$\kappa(s)\$$ at the unit element. Then there exists an open neighborhood $\$U\$$ of $\$s\$$ such that $\$K|_U\$$ is locally quasi-finite (resp. unramified) over $\$U\$$.*^[IX-6-1]

<!-- label: III.IX.6.3 -->

Let $\$V\$$ be the set of points $\$x\$$ of $\$K\$$ such that, denoting by $\$t\$$ the image of $\$x\$$ in $\$S\$$, the fiber $\$K_{\{t\}}\$$ is quasi-finite (resp. unramified) over $\$\kappa(t)\$$ at $\$x\$$, i.e. such that $\$x\$$ is isolated in $\$K_{\{t\}}\$$ (resp. and its local ring in $\$K_{\{t\}}\$$ is a separable extension of $\$\kappa(t)\$$). One knows that $\$V\$$ is open since $\$K\$$ is locally of finite presentation over $\$S\$$,^[N.D.E-IX-42] hence if $\$\epsilon\$$ denotes the unit section of $\$K\$$, $\$\epsilon^{-1}(V)\$$ is open. By hypothesis it contains $\$s\$$, hence is an open neighborhood $\$U\$$ of $\$s\$$. The latter does the trick; in other words, $\$t \in U\$$ implies that $\$K_{\{t\}}\$$ is locally quasi-finite (resp. unramified) over $\$\kappa(t)\$$: indeed, <!-- original page 66 --> since $\$K_{\{t\}}\$$ is a group locally of finite type over $\$\kappa(t)\$$, this follows from the fact that it is quasi-finite (resp. unramified) over $\$\kappa(t)\$$ at the point $\$\epsilon(t)\$$, cf. VI_B 1.3.

Combining 6.1 and 6.3, one finds the

****Theorem 6.4.**** *Let $\$S\$$ be a prescheme, $\$H\$$ an $\$S\$$ -group of multiplicative type and of finite type, $\$K\$$ a closed subprescheme in groups, of finite presentation over $\$S\$$. Let $\$s \in S\$$ be such that $\$K_{\{s\}}\$$ is finite.*

<!-- label: III.IX.6.4 -->

Then there exists an open neighborhood $\$U\$$ of $\$s\$$ such that $\$K|_U\$$ is contained in $\$\{ \}_{nH}|_U\$$ for some $\$n\$$, and a fortiori $\$(\{ \}_{nH})\$$ being finite over $\$S\$$) such that $\$K|_U\$$ is finite over $\$U\$$.

Using Nakayama's lemma, one deduces:

****Corollary 6.5.**** *With the preceding notation, suppose that $\$K_{\{s\}}\$$ is the unit group. Then there exists an open neighborhood $\$U\$$ of $\$s\$$ such that $\$K|_U\$$ is the unit group.*

<!-- label: III.IX.6.5 -->

****Corollary 6.6.**** *Let $\$u : H \rightarrow G\$$ be a homomorphism of $\$S\$$ -preschemes in groups, with $\$H\$$ of multiplicative type and of finite type, and $\$G\$$ separated over $\$S\$$. Suppose moreover $\$S\$$ locally noetherian, or $\$G\$$ locally of finite presentation^[N.D.E-IX-43] over $\$S\$$.*

<!-- label: III.IX.6.6 -->

Let $\$s \in S\$$ be such that $\$u_{\{s\}} : H_{\{s\}} \rightarrow G_{\{s\}}\$$ is a monomorphism; then there exists an open neighborhood $\$U\$$ of $\$s\$$ such that $\$u\$$ induces a monomorphism $\$H|_U \rightarrow G|_U\$$.

Indeed, let $\$K = \text{Ker}(u)\$$; the hypothesis on $\$u_{\{s\}}\$$ means that $\$K_{\{s\}}\$$ is the unit group, the conclusion that $\$K|_U\$$ is the unit group, for a suitable $\$U\$$. Now $\$G\$$ being separated over $\$S\$$, $\$K\$$ is a closed subgroup of $\$H\$$; and in the case where one does not suppose $\$S\$$ locally noetherian but rather $\$G\$$ locally of finite presentation over $\$S\$$, $\$K\$$ is locally of finite presentation over $\$S\$$,^[N.D.E-IX-43] hence of finite presentation over $\$S\$$ since it is separated over $\$S\$$ ($\$H\$$ being so) and quasi-compact over $\$S\$$ (being closed in $\$H\$$ which is quasi-compact over $\$S\$$). One may therefore apply 6.5, whence 6.6.

****Remark 6.6.1.****^[N.D.E-IX-44] *Under the hypotheses of 6.6, one will note that when moreover $\$G\$$ is affine over $\$S\$$ (resp. of finite presentation over $\$S\$$), $\$H|_U \rightarrow G|_U\$$ is even a closed immersion, as was pointed out in 2.5 (resp. 2.6).*

<!-- label: III.IX.6.6.1 -->

****Corollary 6.7.**** *Let $\$u : H \rightarrow G\$$ be a homomorphism of $\$S\$$ -preschemes in groups,* <!-- original page 67 --> *with $\$H\$$ of multiplicative type and of finite type; suppose $\$S\$$ locally noetherian or $\$G\$$ locally of finite presentation over $\$S\$$.*

<!-- label: III.IX.6.7 -->

If all the homomorphisms induced on the fibers $\$u_{\{s\}} : H_{\{s\}} \rightarrow G_{\{s\}}\$$ are monomorphisms, then $\$u\$$ is a monomorphism.

The reasoning is the same as in 6.6; the hypothesis that G be separated over S is here unnecessary to ensure that K is closed in H , since the hypothesis that the u_s be monomorphisms implies that K reduces set-theoretically to the unit section of G .

Theorem 6.8. *Let $u : H \rightarrow G$ be a homomorphism of S -preschemes in groups, with H of multiplicative type and of finite type, and G separated over S . Suppose moreover S locally noetherian or G of finite presentation over S .*

<!-- label: III.IX.6.8 -->

Then $K = \text{Ker}(u)$ is a subgroup of multiplicative type and of finite type of H , and u factors as

```
```text
H → H/K → G,
```

\*where  $H/K$  is of multiplicative type and of finite type,  $u'$  is the canonical homomorphism and is faithfully flat (and affine), and  $u''$  is a monomorphism.\*

(N.B. As remarked in 6.6.1,  $u''$  is a closed immersion if  $G$  is affine over  $S$  or of finite presentation over  $S$ .) It suffices to prove that  $K$  is of multiplicative type, the rest of the proposition then following from 2.7 and IV 5.2.6.

Suppose first  $G$  of finite presentation over  $S$ . This hypothesis being stable under base change, one is reduced, to prove that  $K$  is of multiplicative type, to the case where  $H$  is diagonalizable, i.e.  $H = D_{\{S\}}(M)$ , where  $M$  is a commutative group of finite type. Let  $s \in S$ ; then  $K_s$  is a closed subgroup of  $H_s = D_{\{\kappa(s)\}}(M)$ , hence

<!-- original page 68 --> by 8.1[<sup>N.D.E-IX-45</sup>] is of the form  $D_{\{\kappa(s)\}}(N)$ , where  $N$  is a quotient group of  $M$ . Set

$K' = D_{\{S\}}(N)$ ; then  $K'$  is a subgroup of multiplicative type of  $H$ . Let  $v' : K' \rightarrow G$  be induced by  $u$ . [<sup>N.D.E-IX-46</sup>] Then  $v'_s$  is the unit homomorphism by construction, hence by 5.2 there exists an open neighborhood  $U$  of  $s$  such that  $v'|_U : K'|_U \rightarrow G|_U$  is the unit homomorphism. Hence, replacing  $S$  by  $U$  if necessary, one may suppose that  $v'$  is the unit homomorphism, hence that  $u$  factors as

```
```text
H → H/K' → G.
```

Now, since u'_s is deduced from u_s by factoring through $H_s \rightarrow H_s/\text{Ker}(u_s)$, then u'_s is a monomorphism (IV 5.2.6), hence by 6.6 there exists an open neighborhood U of s such that $u'|_U : (H/K')|_U \rightarrow G|_U$ is a monomorphism. Hence, restricting S if necessary, one sees that u'' is a monomorphism, hence $\text{Ker}(u) = \text{Ker}(u') = K'$, which proves that $\text{Ker } u$ is of multiplicative type.

The same proof is valid if, instead of supposing G of finite presentation over S , one supposes S locally noetherian – at least in the case where H is diagonalizable. In the case where one does not make this hypothesis on H , one must show that one can find a covering base change $S' \rightarrow S$, with S' locally noetherian, that trivializes H . This will indeed be seen in the following Exposé (X 4.6).

7. Algebraicity of formal homomorphisms into an affine group

Theorem 7.1. *Let A be a noetherian ring equipped with an ideal I such that A is separated and complete for the I -adic topology, $S = \text{Spec}(A)$, $S_n = \text{Spec}(A/I^{n+1})$, H, G S -preschemes in groups, with H of isotrivial multiplicative type, and G affine.*

<!-- label: III.IX.7.1 -->

Then the canonical map

```
```text
(*) θ : Hom_{S-gr.}(H, G) → lim_n Hom_{S_n-gr.}(H_n, G_n)
```

<!-- label: eq:III.IX.7.1-star -->

\*is bijective (where  $H_n, G_n$  are the  $S_n$ -groups deduced from  $H, G$  by the base change  $S_n \rightarrow S$ ).\*

<!-- original page 69 -->

Suppose first  $H$  diagonalizable, hence of the form

$H = \operatorname{Spec} A^{\{M\}},$

where  $B = A^{\{M\}}$  is the algebra of the commutative group  $M$  with coefficients in  $A$ . One also has  $G = \operatorname{Spec}(C)$ , where  $C$  is an  $A$ -algebra equipped with a diagonal map (satisfying the well-known axioms). Then the homomorphisms of  $S$ -groups  $H \rightarrow G$  correspond bijectively to the homomorphisms of  $A$ -algebras  $\varphi : C \rightarrow B$  compatible with the diagonal maps, i.e. such that, for every  $f \in C$ ,

$\Delta_H(\varphi(f)) = (\varphi \otimes \varphi)(\Delta_G(f))$

where  $\Delta_H$  and  $\Delta_G$  are the diagonal maps. One has an analogous description for the homomorphisms of  $S_n$ -groups  $H_n \rightarrow G_n$ , defined by certain homomorphisms of  $A_n$ -algebras  $\varphi_n : C_n \rightarrow B_n$  (where one sets  $A_n = A/I^{n+1}$ ,  $B_n = B \otimes_A A_n$ ,  $C_n = C \otimes_A A_n$ ). Set

$B^\wedge = \varprojlim B_n$  and  $C^\wedge = \varprojlim C_n$ ;

then  $\hat{B} = \varprojlim A^{\{M\}}_n$  identifies with a submodule of the product  $A^{\{M\}}$  (namely, that formed by the families  $(a_m)_{m \in M}$  of elements of  $A$  which tend to 0 (for the  $I$ -adic topology) along the filter of complements of finite parts of  $M$ ). This already implies that the canonical homomorphism  $B \rightarrow \hat{B}$  is injective, [N.D.E-IX-47] since the projective system  $\theta(\varphi) = (\varphi_n)_{n \geq 0}$  defines a homomorphism  $\hat{\varphi} : \hat{C} \rightarrow \hat{B}$  such that the diagram below is commutative:

$$\begin{array}{ccc} C & \xrightarrow{\varphi} & B \\ \downarrow & & \downarrow \\ C^\wedge & \xrightarrow{\varphi^\wedge} & B^\wedge \end{array}$$

Let us prove that  $\theta$  is surjective: take a projective system  $(\varphi_n)_{n \geq 0}$  and let us prove that it comes by reduction from a  $\varphi$  of the first member. A priori,  $(\varphi_n)$  defines a homomorphism on the completed algebras

$\hat{\varphi} : \hat{C} \rightarrow \hat{B},$

and all that remains is to see that its composite  $\Phi : C \rightarrow \hat{C} \xrightarrow{\hat{\varphi}} \hat{B}$  with the canonical homomorphism  $C \rightarrow \hat{C}$  sends  $C$  into  $B$ . Indeed, if this is the case, one finds a homomorphism <!-- original page 70 --> of  $A$ -algebras  $\varphi : C \rightarrow B$ , reducing along the  $\varphi_n$ , from which one concludes at once that it is compatible with the diagonal maps (since the  $\varphi_n$  are, and  $B \otimes_A B \rightarrow \hat{B} \otimes_{\hat{A}} \hat{B}$  is injective, as one sees, as above, by replacing  $M$  by  $M \otimes M$ ).

Note that the diagonal homomorphism  $\Delta_H$  of  $H$  defines, on passing to the completions, a homomorphism

$\Delta_H^\wedge : B^\wedge \rightarrow B^\wedge \otimes_A B,$

and one has a commutative diagram (deduced by passage to the projective limit from the analogous diagrams defined by the  $\varphi_n$ ):

$$\begin{array}{ccc} C & \xrightarrow{\varphi} & B^\wedge \\ \downarrow & & \downarrow \\ C^\wedge & \xrightarrow{\varphi^\wedge} & B^\wedge \end{array}$$

$$\downarrow \Delta\_G \quad \downarrow \Delta\_H$$

$$C \otimes A \ C \rightarrow B \otimes A \ B,$$

where  $\Psi$  is the composite

```

```text
C \otimes_A C \dashrightarrow B^{\wedge} \otimes_A B^{\wedge} \rightarrow B^{\wedge} \otimes^{\wedge}_A B
```

```

(the last arrow being the obvious canonical homomorphism). It follows that for every  $f \in C$ ,  $\Phi(f)$  is an element of  $\hat{B}$  whose image under  $\hat{\Delta}_H$  is a "decomposable" element of  $\hat{B} \otimes \hat{A}$ , i.e. is in the image of  $\hat{B} \otimes \{A\}$ .

Denote by  $\{e_{\mathbf{m}}\}_{\mathbf{m} \in M}$  the canonical basis of  $\Lambda^{\mathbf{M}}$  and  $\{e_{\mathbf{m},\mathbf{m}'}\}$  that of  $\Lambda^{\mathbf{M} \times \mathbf{M}} = \Lambda^{\mathbf{M}} \otimes \Lambda^{\mathbf{M}}$ . Since  $\Delta_H(e_{\mathbf{m}}) = e_{\mathbf{m}} \otimes e_{\mathbf{m}} = e_{\mathbf{m},\mathbf{m}}$  for every  $\mathbf{m}$ , it suffices now to apply the

**\*\*Lemma 7.2.\*\*** \*Let  $A$  be a noetherian ring,  $M$  a set,  $(a_{m,m'})$  a family of elements of  $A$  indexed by  $M \times M$ , such that\*

```
<!-- label: III.IX.7.2 -->
```

\*(i)  $\$a_{\{m,m'\}} = 0\$$  if  $\$m \neq m'\$$  (i.e. the support of the family is contained in the diagonal of  $\$M \times M\$$ ),\*

\*(ii) One has\*

```
```text
a_{m,m'} = \sum_i b^i_m c^i_{m'}
```

*where the b^i , c^i are finitely many elements of A^M (i.e. $(a_{m,m'})$ belongs to the image of the canonical homomorphism $A^M \otimes \{A\} \rightarrow A^M \otimes M$).

Under these conditions, the support of the family $(a_{m,m'})$ is finite.

<!-- original page 71 -->

By (i), the family $\{a_{\{m,m'\}}\}$ is determined by knowledge of the $a_{\{m\}} = a_{\{m,m\}}$. Set, for every $x = (x_{\{n\}})_{\{n \in M\}} \in A^{\{M\}}$:

```
```text
(u · x)_m = ∑_{m'} a_{m,m'} x_{m'},
```
```

i.e. interpret $(a_{\{m,m'\}})$ as the matrix of a homomorphism $u : A^{\{M\}} \rightarrow A^M$. Then by (i) one has simply

```

```text
(u · x)_m = a_m x_m.
```

```

On the other hand, by (ii) one has

```
```text
u · x ∈ ∑_i A · b^i,
```
```

hence $\mathfrak{u}(A^{\{M\}})$ remains in a finitely generated A -module. Consequently, denoting by $(e_m)_{m \in M}$ the canonical basis of $A^{\{M\}} \subset A^M$, the $a_m e_m$ remain in a finitely generated A -module. Since A is noetherian, the module they generate is itself of finite type, which implies (since the e_m are linearly independent) that all but finitely many of the a_m are zero. This proves 7.2 and consequently 7.1 in the case where H is diagonalizable.

Let us now prove the general case of 7.1, where one supposes only H isotrivial, i.e. there exists a finite étale surjective morphism $S' \rightarrow S$ such that $H' = H \times_{S'} S'$ is diagonalizable. We shall use only the fact that

S' $\rightarrow$ S is finite and covering (for the faithfully flat quasi-compact topology, or simply for the canonical topology of (S_{Sch})) – thus the "étale" hypothesis could be replaced by "flat".

<!-- original page 72 -->

Let $S' = S' \times_S S$; introduce likewise S'_n and $S'_n = S' \times_S S_n = S'_n \times_{S'_n} S'_n$, and $H', G', H'_n, G'_n, H'_n, G'_n$ deduced from H and G by the base changes one guesses. Note that H' and H'_n are now diagonalizable. Note also that S' hence S'_n is affine, and that if $S = \operatorname{Spec}(A)$, $S' = \operatorname{Spec}(A')$, then A and A' are separated and complete for the topology defined by IA resp. by IA' (since A and A' are finite over A). Since $S \rightarrow S$ and $S'_n \rightarrow S_n$ are covering, one obtains a commutative diagram of maps of sets whose two rows are exact:

```

```text
Hom_{S-gr.}(H, G) → Hom_{S'-gr.}(H', G') → Hom_{S"-gr.}(H'', G'')
 ↑u ↑u' ↑u''
lim_n Hom_{S_n-gr.}(H_n, G_n) → lim_n Hom_{S'_n-gr.}(H'_n, G'_n) → lim_n Hom_{S''_n-gr.}(H''_n, G''_n).
```

```

(N.B. The second row is exact as a projective limit of exact diagrams, relative to the various $S'_n \rightarrow S_n$.) By what has already been proved (the diagonalizable case), u and u' are bijective. The same therefore holds for u , which completes the proof of 7.1.

Corollary 7.3. Under the conditions of 7.1, suppose moreover G smooth over S , and let $u_0 : H_0 \rightarrow G_0$ be a homomorphism of S_0 -groups. Then there exists a homomorphism of S -groups $u : H \rightarrow G$ which lifts u_0 . Any two such liftings u, u' are conjugate by an element g of $G(S)$ reducing along the unit element of $G_0(S_0)$.

<!-- label: III.IX.7.3 -->

Follows from the conjunction of 3.6 and 7.1. To construct a u , one constructs step by step u_n , which is possible by 3.6, and by 7.1 the system (u_n) comes from a u . Given two liftings u and u' , to construct g such that $u' = \operatorname{int}(g) u$, $g_0 = 1$, <!-- original page 73 --> one constructs step by step g_n , such that $g_0 = 1$, g_n is deduced from g_{n+1} by reduction, $u'_n = \operatorname{int}(g_n) u_n$; this is possible thanks to 3.6. Since A is separated and complete, the g_n come from a $g \in G(S)$; and to prove that $u' = \operatorname{int}(g) u$, it suffices to use the injectivity in assertion 7.1.

Remark 7.4. One will compare 7.1 with EGA III 5.4.1, which implies that the statement 7.1 is valid if, instead of supposing H of multiplicative type and G affine, one supposes H proper over S , and G separated and locally of finite type over S . Having a statement like 7.1 without a properness hypothesis is rather exceptional, and must here be interpreted as one of the aspects of the great "rigidity" of the structure of a group of multiplicative type. The analogous statement with $G = H = G_a$ (additive group) is false in general, as one sees by taking A of characteristic $p > 0$, and defining the u_n by reduction mod I^{n+1} from an additive formal series*

<!-- label: III.IX.7.4 -->

```

```text
u(T) = ∑_{n ≥ 0} a_n T^{p^n},
```

```

where the a_n are elements of A that tend to 0 for the I -adic topology, but not for the discrete topology. Statement 7.1 also becomes false if one suppresses the hypothesis G affine, even for $H = G_m$ (multiplicative group); one sees an example of this (with A a complete discrete valuation ring) by starting from an elliptic curve over the field of fractions K of A , which reduces (in the Néron-Kodaira reduction theory, say) along the group G_m over the residue field k : [N.D.E-IX-48] *one will thus have a commutative smooth group scheme G over S , whose special fiber is $G_{m,k}$ (which, thanks to 3.6, allows one to define a projective system of isomorphisms* $u_n : H_n \rightarrow G_n$, where $H = G_{m,A}$), but whose generic fiber is an abelian variety, so that there exists no homomorphism of S -groups $H \rightarrow G$ other than 0.*

8. Subgroups, quotient groups, and extensions of groups of multiplicative type over a field [IX-8-1]

Scholium 8.0. [N.D.E-IX-49] *Let k be a field, H an affine k -group scheme. Denote by $k[H]$ its affine algebra and $X(H) = \operatorname{Hom}_{k\text{-gr.}}(H, G_{m,k})$ the group of characters of H . By the lemma of independence of characters, $X(H)$ is a free part of $k[H]$. It follows that H is diagonalizable if and only if $X(H)$ generates $k[H]$ as a k -vector space.*

<!-- label: III.IX.8.0 -->

<!-- original page 74 -->

Proposition 8.1. *Let G be a diagonalizable group scheme (resp. of multiplicative type) over a field k . *Then for every subgroup scheme H of G , H and G/H are diagonalizable (resp. of multiplicative type).*

<!-- label: III.IX.8.1 -->

Definition 1.1 reduces us at once to the non-resp. case. An easy passage to the limit, using VI_B 11.13 and VIII 3.1, reduces us to the case where G is of finite type over k . By VI_B 11.16, one can find a finite family of non-zero elements

$$f_i = \sum a_{im} m, \quad a_{im} \in k \quad (8.1.1)$$

<!-- label: eq:III.IX.8.1.1 -->

of the affine ring $k^{(M)}$ of $G = D_{\{k\}}(M)$, such that the points of H (with values in an arbitrary k -algebra k') are the points $g \in G(k')$ such that one has

$$\tau_g f_i = \lambda_i(g) f_i, \quad \text{with } \lambda_i(g) \in k', \quad (8.1.2)$$

<!-- label: eq:III.IX.8.1.2 -->

where τ_g denotes the translation by g . Now one has

$$\tau_g f_i = \sum a_{im} \chi_m(g) m, \quad (8.1.3)$$

<!-- label: eq:III.IX.8.1.3 -->

where $\chi_m : G \rightarrow G_{\{m,k\}}$ is the character associated with m , so that (8.1.2) is equivalent to the relation

$$\chi_m(g) = \chi_{m'}(g) \quad \text{if } m, m' \in Z_i, \quad (8.1.4)$$

<!-- label: eq:III.IX.8.1.4 -->

Z_i denoting the set of $m \in M$ such that $a_{im} \neq 0$. This relation may also be written

$$\chi_{m' - m}(g) = 1 \quad \text{if } m, m' \in Z_i.$$

<!-- original page 75 -->

Denoting by N the subgroup of M generated by all the $m' - m$ (i varying, and $m, m' \in Z_i$), one deduces from the definition of $D_{\{k\}}(M)$ ($\simeq G$) that H identifies with $D_{\{k\}}(M/N)$. It then follows from VIII 3.1 that G/H identifies with $D_{\{k\}}(N)$. QED.

Proposition 8.2. *Let k be a field, H, K k -group schemes of multiplicative type and of finite type, and G a k -group scheme such that one has an exact sequence*

<!-- label: III.IX.8.2 -->

$$1 \rightarrow H \rightarrow G \rightarrow K \rightarrow 1$$

(which entails that G is of finite type over k).

(i) If one supposes G commutative or K connected, then G is of multiplicative type.

(ii) If K and H are diagonalizable, with K a torus, then G is diagonalizable.

For the proof of (i), the reader is referred to XVII 7.1.1, of which 8.2 (i) is a special case; the case of a field is treated in part (i) of the proof of XVII 7.1.1 (not using the results of the following Exposés).

(ii) Suppose now K and H diagonalizable:

```
```text
K ≅ D_k(M) and H ≅ D_k(N).
```

[^N.D.E-IX-53] Suppose  $G$  of multiplicative type (which is the case by (i) if  $K$  is a torus). Then, by X 1.4,  $G$  is isotrivial over  $k$ , i.e. there exists a finite separable extension  $k'/k$  such that  $G' = G \times_k k'$  is diagonalizable, so  $G' = D_{k'}(E)$  for some commutative group  $E$ , and one has an exact sequence

$$0 \rightarrow D_{k'}(N) \rightarrow D_{k'}(E) \rightarrow D_{k'}(M) \rightarrow 0. \quad (1)$$

<!-- label: eq:III.IX.8.2.1 -->

Hence, by VIII, 3.1 and 3.2,  $M$  is a subgroup of  $E$  and one has an exact sequence

$$0 \rightarrow M \rightarrow E \rightarrow N \rightarrow 0. \quad (2)$$

<!-- label: eq:III.IX.8.2.2 -->

For a given extension  $E_0$  of  $N$  by  $M$ , consider the diagonalizable  $k$ -group  $G_{\{0\}} = D_{\{k\}}(E_{\{0\}})$ ; then the  $k$ -functor in groups  $A$  of automorphisms of the extension

$$1 \rightarrow H \rightarrow G_{\{0\}} \rightarrow K \rightarrow 1, \quad (3)$$

<!-- label: eq:III.IX.8.2.3 -->

i.e. the sub-functor in groups of  $\operatorname{Aut}_{\{k\}\text{-gr.}}(G_{\{0\}})$  whose points on a  $k$ -prescheme  $T$  are the  $\phi \in \operatorname{Aut}_{\{T\}\text{-gr.}}(G_T)$  inducing the identity on  $H_T$  and on  $K_T$ , identifies with  $\operatorname{Hom}_{\{k\}\text{-gr.}}(\bar{K}, H)$ , which is, by VIII 1.5, the constant  $k$ -group of value  $L = \operatorname{Hom}_{\{\text{gr.}\}}(N, M)$ .

One sees therefore that the classification of extensions  $G$  of  $K$  by  $H$  which, over a separable closure  $k_s$  of  $k$ , become isomorphic to the extension (3), is the same as that of the <!-- original page 76 -->  $k$ -torsors for the étale topology under the constant group  $L_{\{k\}}$ . Denoting  $\Gamma = \operatorname{Gal}(k_s/k)$ , these are classified by the Galois cohomology group ( $L$  being a trivial  $\Gamma$ -module):

$$H^1_{\text{ét}}(k, L_k) = H^1(\Gamma, L) = \operatorname{Hom}_{\{\text{gr. top.}\}}(\Gamma, L).$$

If moreover  $K$  is a torus,  $M$  is torsion-free, hence so is  $L$ , whence  $\operatorname{Hom}_{\{\text{gr. top.}\}}(\Gamma, L) = 0$ ; it follows that every extension of  $K$  by  $H$  is already diagonalizable.

**Remark 8.3.** \*As already pointed out in the proof of 8.2, the first assertion is stated and proved over an arbitrary base in XVII 7.1.1. On the other hand, the second assertion generalizes, with essentially the same proof, to the case of an integral normal base scheme (or more generally, geometrically unibranch), using X 5.13 below.\*

<!-- label: III.IX.8.3 -->

\*Finally, one can also consider 8.1 as a corollary of the (markedly less trivial) result 6.8, also valid over an arbitrary base scheme.\*[^N.D.E-IX-54]

[^IX-0]: Version 1.0 of 8 November 2009: additions in proof of 3.6 bis, 4.4–7, 5.0–6, 6.1, 7.1, 8.2. 8.1 and 4.5 to be revised.

[^N.D.E-IX-1]: \*N.D.E.\* Indeed, there exists by hypothesis an open neighborhood  $U$  of  $s$  and a faithfully flat quasi-compact morphism  $S' \rightarrow U$  such that  $G_{S'}$  is diagonalizable; then for every  $s' \in S'$  above  $s$ ,  $\kappa(s')$  is an extension of  $\kappa(s)$  and  $G_{s'} = G \times_S \operatorname{Spec}(\kappa(s'))$  is diagonalizable.

[^N.D.E-IX-2]: \*N.D.E.\* The number 1.4.1 has been added to the remarks that follow, for later references.

[^N.D.E-IX-3]: \*N.D.E.\* This definition has been added, since it appears in propositions 2.3 and 2.7.

[^N.D.E-IX-4]: \*N.D.E.\* Cf. also V, 9.1 or EGA IV<sub>2</sub>, 2.7.1.

[^N.D.E-IX-5]: \*N.D.E.\* and even a closed immersion.

[^N.D.E-IX-6]: \*N.D.E.\* The erroneous reference to IV 4.7.5 has been corrected. Note that N° 8 of the present Exposé is independent of N°s 3 to 7.

[^N.D.E-IX-7]: \*N.D.E.\* The original indicated: "by 2.1 b), since its fibers are so". The editors did not understand this argument, and substituted the one that follows.

[^N.D.E-IX-8]: \*N.D.E.\* The following sentence has been spelled out.

[^N.D.E-IX-9]: \*N.D.E.\* Note that X 2.3 depends in an essential way on Theorem 3.6 of the present Exposé.

[^N.D.E-IX-10]: \*N.D.E.\* The numbering of the original has been preserved: there is no N° 3.7.

[^IX-4-1]: All the results from 4.1 to 4.6 are contained in EGA IV<sub>3</sub>, 11.10, to which we refer the reader for an exposition in form of the notion of schematic density.

[^N.D.E-IX-11]: \*N.D.E.\* The "algebraicity" theorem 7.1.

[^N.D.E-IX-12]: \*N.D.E.\* All the results on schematic density stated in EGA IV<sub>3</sub>, § 11.10 follow from the results on "separating families of homomorphisms" proved in loc. cit., § 11.9, to which we shall refer in certain \*N.D.E.\* that follow.

[^N.D.E-IX-13]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-14]: \*N.D.E.\* For another proof, using a reduction to the case where  $S$  is locally noetherian (and 4.3 and 4.5 as here), see EGA IV<sub>3</sub>, 11.9.16 and 11.9.12 (N.B. in the last line of the proof of 11.9.16, replace 11.9.5 by 11.9.12).

[^N.D.E-IX-15]: \*N.D.E.\* The following sentence has been added, and the original spelled out in what follows.

[^N.D.E-IX-16]: \*N.D.E.\* The original added: "at least at every point  $x$  of  $X$  above  $s$ ", but this restriction seems unnecessary.

[^N.D.E-IX-17]: \*N.D.E.\* The original has been spelled out and corrected, to show that the projective limit of the rings  $\varprojlim_{i \geq n} T_i$  defines a closed formal subscheme of the formal scheme  $\mathrm{Spf}(\widehat{A})$ .

[^N.D.E-IX-18]: \*N.D.E.\* The original has been spelled out and corrected, distinguishing between  $S'_{(n)}$  and the subscheme  $S'_{(n)} = S'_{(n)}(s')$  introduced below.

[^N.D.E-IX-19]: \*N.D.E.\* This lemma has been inserted here, since it is used in the proof of 4.5 and 4.7.

[^N.D.E-IX-20]: \*N.D.E.\* This hypothesis is in fact superfluous, cf. EGA IV<sub>3</sub>, 11.10.6 and 11.9.13.

[^N.D.E-IX-21]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-22]: \*N.D.E.\* The original continued with: "Using 4.3 for the  $X_A$ , where  $A$  is a quotient of  $A$  by a power of a maximal ideal, and Hilbert's Nullstellensatz, one is reduced to the case where  $k$  is a finite extension of  $k$ ". One could spell out this reduction, and pursue this approach, since the case of a finite extension  $k'/k$  is somewhat simpler than the more general case treated in EGA IV<sub>3</sub>, 11.9.10 b).

[^N.D.E-IX-23]: \*N.D.E.\* Specify this ...

[^N.D.E-IX-24]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-25]: \*N.D.E.\* One will need in X 4.3 this result for  $S$  non locally noetherian (namely,  $S = \mathrm{operatorname{Spec}}(\widehat{A} \otimes_{\widehat{A}} \widehat{A})$ , where  $\widehat{A}$  is the completion of the noetherian local ring  $A$ ).

[^N.D.E-IX-26]: \*N.D.E.\* "Diagonalizable" has been replaced by "of multiplicative type".

[^N.D.E-IX-27]: \*N.D.E.\* This lemma has been made explicit, since it is used several times in the sequel (implicitly in the original).

[^N.D.E-IX-28]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-29]: \*N.D.E.\* Because  $K = H$  if  $K_{\hat{S}} = H_{\hat{S}}$ , cf. SGA 1, VIII 5.4; but the sequel does not use the hypothesis " $A$  complete".

[^N.D.E-IX-30]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-31]: \*N.D.E.\* And of finite presentation over  $S$ , cf. EGA IV<sub>3</sub>, 11.10.5 (ii) and 11.9.10 (ii).

[^N.D.E-IX-32]: \*N.D.E.\* "Morphism covering for the faithfully flat quasi-compact topology" has been replaced by "universal effective epimorphism", so as to be able to apply this to the morphism  $K \rightarrow S$  of 5.5; the beginning of the proof has been modified accordingly.

[^N.D.E-IX-33]: \*N.D.E.\* This is the case, for example, if  $S = \operatorname{Spec} k$  and  $S' = \operatorname{Spec} k'$ , where  $k$  is a field and  $k'$  a radical extension of  $k$ , cf. X, Prop. 1.4.

[^N.D.E-IX-34]: \*N.D.E.\* The following sentence has been added.

[^N.D.E-IX-35]: \*N.D.E.\* The hypothesis "locally of finite type" has been added to agree with the reference VI\_A, 2.4. In fact, one can show that over a field, every connected group scheme is geometrically connected.

[^N.D.E-IX-36]: \*N.D.E.\* The original has been spelled out in what follows.

[^N.D.E-IX-37]: \*N.D.E.\* The original has been spelled out in the proof of a).

[^N.D.E-IX-38]: \*N.D.E.\* The original has been spelled out and corrected, by replacing "unit section of  $(G_H)_n$  over  $H_n$ " by  $H_{S^{\{0\}}_n}$ .

[^N.D.E-IX-39]: \*N.D.E.\* The original has been spelled out in what follows, by making explicit the results of Exp. III that are used.

[^N.D.E-IX-40]: \*N.D.E.\* Since  $S$  is quasi-compact, it is covered by a finite number of affine opens, hence one is reduced to the case where  $S = \operatorname{Spec}(A)$ . Then, since  $G$  is of finite presentation over  $S$ , one can apply EGA IV<sub>3</sub>, 8.8.2.

[^N.D.E-IX-41]: \*N.D.E.\* Above,  $X - \{s\}$  has been corrected to  $S - \{s\}$ . Recall on the other hand that a quasi-finite morphism is supposed to be of finite type, cf. EGA II, 6.2.3 (and EGA III<sub>2</sub>, Err\_III 20 for the definition of "locally quasi-finite"). Hence here ( $S$  being noetherian),  $X$  is of finite presentation over  $S$ , each immersion  $X_{\{i\}} \hookrightarrow X$  is of finite type (by EGA I, 6.3.5), hence  $X_{\{i\}}$  is of finite presentation over  $S$ , and one may apply EGA IV<sub>3</sub>, 8.8.2.

[^IX-6-1]: Cf. VI\_B 2.5 (ii) for a more general statement.

[^N.D.E-IX-42]: \*N.D.E.\* Cf. EGA IV<sub>3</sub>, 13.1.4, and EGA IV<sub>4</sub>, 17.4.1. Moreover,  $t$  (instead of  $s$ ) has been used to denote the image of  $x$ .

[^N.D.E-IX-43]: \*N.D.E.\* It in fact suffices to suppose  $G$  locally of finite type over  $S$ ; by EGA IV<sub>4</sub>, 1.4.3 (v), this entails ( $H \rightarrow S$  being of finite presentation) that  $H \rightarrow G$  is locally of finite presentation, hence so is  $K \rightarrow S$ , which is deduced from it by base change.

[^N.D.E-IX-44]: \*N.D.E.\* The numbering 6.6.1 has been added, for later references.

[^N.D.E-IX-46]: \*N.D.E.\* "Induced by  $G$ " has been corrected to "induced by  $u$ ".

[^N.D.E-IX-47]: \*N.D.E.\* What follows has been spelled out.

[^N.D.E-IX-48]: \*N.D.E.\* One could spell out such an example ...

[^IX-8-1]: Added in July 1969. This regretful section is independent of N's 3 to 7.

[^N.D.E-IX-49]: \*N.D.E.\* This scholium has been added.

[^N.D.E-IX-50]: \*N.D.E.\* "Over a field  $k$ " has been added, being implicit in the original; on the other hand, "algebraic group" has been replaced by "group scheme", since  $G$  is not supposed to be of finite type.

[^N.D.E-IX-51]: \*N.D.E.\* Spell out this "passage to the limit": this uses 8.0 and also the equality  $G/H = \varinjlim_i G_i/H_i$ , cf. VI\_B, proof of 11.17. To see that  $H = \varinjlim_i (H \cap G_i)$ , does one use the fact that  $H$  is closed in  $G$ ? Using this, one can give a direct proof ...

[^N.D.E-IX-52]: \*N.D.E.\* It would doubtless be necessary to rewrite VI\_B 11.16 in the usual, more pleasant form. In particular, a single  $f_i$  suffices below ...

[^N.D.E-IX-53]: \*N.D.E.\* The statement, as well as its proof, has been spelled out.

[^N.D.E-IX-54]: \*N.D.E.\* Note however that the proof of 6.8 uses 8.1!

[^N.D.E-IX-55]: \*N.D.E.\* Additional references cited in this Exposé.

## 1. Classification of isotrivial groups. Case of a base field

<!-- original page 77 -->

Recall (IX 1.1) that the group of multiplicative type  $H$  over the prescheme  $S$  is said to be *isotrivial* if there exists an étale, finite, surjective morphism  $S' \rightarrow S$  such that  $H' = H \times_{S'} S'$  is diagonalizable. When  $S$  is connected,  $S'$  decomposes as a finite sum of connected components  $S'_i$ , and one can therefore (possibly by replacing  $S'$  by one of the  $S'_i$ ) assume  $S'$  connected. Finally, one knows that  $S'$  can be dominated by an  $S'_1$  finite, étale and connected, which is Galois, i.e. a principal homogeneous bundle over  $S$  with group  $\Gamma_S$ , where  $\Gamma_S$  is an ordinary finite group (cf. SGA 1, V N°s 7 & 3 when  $S$  is locally noetherian, and EGA IV<sub>4</sub>, 18.2.9 in the general case).[^N.D.E-X-1] We assume  $S'$  chosen in this way, and we propose to determine the groups of multiplicative type  $H$  over  $S$  which are "trivialized" by  $S'$ , i.e. such that  $H' = H \times_{S'} S'$  is diagonalizable.[^N.D.E-X-2] By descent theory (cf. SGA 1, VIII 5.4), the category of these  $H$  is equivalent to the category of diagonalizable groups  $H'$  over  $S'$ , equipped with operations of  $\Gamma_S$  on  $H'$  compatible with the operations of  $\Gamma_S$  on  $S'$ . (N.B. As the groups under consideration are affine over the base, the question of effectivity of a descent datum is answered in the affirmative, cf. SGA 1, VIII 2.1.) Now  $S'$  being connected, the contravariant functor

$$M \mapsto D_{S'}(M)$$

is an anti-equivalence of the category of ordinary commutative groups with the category <!-- original page 78 --> of diagonalizable groups over  $S'$  (cf. VIII 1.6), a quasi-inverse functor being  $H \mapsto \operatorname{Hom}_{S'\text{-gr.}}(H, G_{m,S'})$ .[^N.D.E-X-3]

**Proposition 1.1.** \*Let  $S$  be a connected prescheme,  $S'$  a connected principal cover of  $S$  with group  $\Gamma_S$  (finite). Then the category of groups of multiplicative type over  $S$  split[^N.D.E-X-4] by  $S'$  is anti-equivalent to the category of  $\Gamma_S$ -modules, i.e. of ordinary commutative groups  $M$  equipped with a homomorphism  $\Gamma_S \rightarrow \operatorname{Aut}_{\text{gr.}}(M)$ .\*

<!-- label: III.X.1.1 -->

One concludes from this in a standard manner:

**\*\*Corollary 1.2.\*\*** \*Let  $S$  be a connected prescheme,  $\xi : \operatorname{Spec}(\Omega) \rightarrow S$  a "geometric point" of  $S$ , i.e. a homomorphism into  $S$  of the spectrum of an algebraically closed field  $\Omega$ ; consider the fundamental group of  $S$  at  $\xi$  (cf. SGA 1 V, N° 7):\*

<!-- label: III.X.1.2 -->

$\pi = \pi_1(S, \xi).$

\*Then the category of isotrivial groups of multiplicative type  $H$  over  $S$  is anti-equivalent to the category of "Galois modules" under  $\pi$ , i.e. of  $\pi$ -modules  $M$  such that the stabilizer in  $\pi$  of every point of  $M$  is an open subgroup.\*

\*In this correspondence, to the isotrivial group of multiplicative type  $H$  is associated the group  $M = \operatorname{Hom}_{\Omega\text{-gr}}(H_{\xi}, G_{m, \Omega})$ , where  $H_{\xi}$  is the fiber of  $H$  at  $\xi$ ; this group is naturally equipped with operations of  $\pi_1(S, \xi)$ .\*

**\*\*Remark 1.3.\*\*** We shall see below (cf. 5.16) that if  $S$  is normal, or more generally geometrically unibranch, then every group of multiplicative type and of finite type over  $S$  is necessarily isotrivial, so that the classification principle 1.2 is applicable to groups of multiplicative type and of finite type over  $S$ , which correspond to <!-- original page 79 --> Galois  $\pi$ -modules that are of finite type over  $\mathbb{Z}$ . For the moment, let us confine ourselves to the following result:

<!-- label: III.X.1.3 -->

**\*\*Proposition 1.4.\*\*** \*Let  $k$  be a field,  $H$  a group of multiplicative type and of finite type over  $k$ ; then  $H$  is isotrivial, i.e. there exists a finite separable extension  $k'$  of  $k$  which splits  $H$ .\*

<!-- label: III.X.1.4 -->

\*Consequently, by 1.2, if  $\pi$  is the topological Galois group of an algebraic closure  $\Omega$  of  $k$ , the category of groups of multiplicative type and of finite type  $H$  over  $k$  is anti-equivalent to the category of Galois modules  $M$  under  $\pi$  that are of finite type as  $\mathbb{Z}$ -modules.\*

It follows first from the fact that  $H$  is of finite type over  $k$  and from the "principle of the finite extension" (cf. EGA IV<sub>3</sub>, 9.1.4) that there exists a finite extension  $k'$  of  $k$  which splits  $H$ . Let us recall the principle of the proof: by hypothesis there exist a diagonalizable group of finite type  $G$  over  $k$ , a faithfully flat  $S'$  over  $S = \operatorname{Spec}(k)$ , and an isomorphism of  $S'$ -groups  $H_{S'} \simeq G_{S'}$ . Possibly replacing  $S'$  by the residue field of a point of  $S'$ , we may suppose that  $S'$  is the spectrum of an extension  $K$  of  $k$ . The latter is the inductive limit of its finitely generated subalgebras  $A_i$ , from which it readily follows (cf. EGA IV<sub>3</sub>, 8.8.2.4) that  $u$  comes from an  $A_i$ -isomorphism  $u_i : H_{A_i} \simeq G_{A_i}$  for  $i$  large enough. By the Nullstellensatz, there exists a quotient ring  $k'$  of  $A_i$  which is a finite extension of  $k$ . The latter therefore splits  $H$ .

<!-- original page 65 -->

Then  $k'$  is a radical extension of a separable extension  $k'_s$  of  $k$ . By IX 5.4, the isomorphism  $u' : H_{k'} \simeq G_{k'}$  comes from an isomorphism  $H_{k'_s} \simeq G_{k'_s}$ , which proves that  $k'_s$  splits  $H$  and establishes 1.4.

**\*\*Remark 1.5.\*\*** Statement 1.2 yields in particular a characterization of isotrivial tori over  $S$  of relative dimension  $n$ : setting  $\pi = \pi_1(S, \xi)$ , they correspond to classes (up to "equivalence") of representations  $\rho : \pi \rightarrow \operatorname{GL}(n, \mathbb{Z})$  with kernel an open subgroup of  $\pi$ .

<!-- label: III.X.1.5 -->

**\*\*1.6.\*\*** Even when  $S$  is an algebraic curve, there can exist over  $S$  tori (of relative dimension  $\geq 2$ ) that are not locally isotrivial (and *a fortiori* not isotrivial); <!-- original page 80 --> there can also exist locally trivial tori that are not isotrivial. (Note however that such phenomena can present themselves only if  $S$  is not normal, as already signalled in 1.3.) Let for example  $S$  be an irreducible algebraic curve (over an algebraically closed field to fix ideas) having an ordinary double point  $a$ , let  $S'$  be its normalization, and  $b$  and  $c$  the two points of  $S'$  above  $a$ . One then constructs a principal homogeneous bundle  $P$  over  $S$ , with structural group  $\mathbb{Z}$ , connected, by attaching together an infinity of copies of  $S'$  along the diagram

<!-- label: III.X.1.6 -->

```

```text
.....      b      b      b      b      .....
      c      c      c
...

```

(N.B. This is a principal bundle in the sense of the étale topology.) Now one has a homomorphism

```

```text
φ : Z → GL(2, Z), φ(n) = (1 n)
 (0 1),
```

```

which permits the construction of a torus T over S , of relative dimension 2 , from the trivial torus $G^{\{2\}}_m$ over P and from the descent datum on the latter deduced from ϕ . (N.B. one will note that the projection $P \rightarrow S$ is covering for the étale topology and *a fortiori* for the canonical topology of (Sch) , and that the descent datum under consideration is necessarily effective, since $G^{\{2\}}_{m,P}$ is affine over P .) It is not difficult to prove that T is not isotrivial in a neighborhood of $a \in [N.D.E-X-5]$ (it is however trivial on $S - \{a\}$).

One finds a variant of this construction by taking for S a curve having two irreducible components S_1 and S_2 intersecting in two points a' and a'' , which permits the construction of a principal homogeneous bundle P over S with group $\mathbb{Z}_S$, connected and locally trivial, hence an associated torus T which is locally trivial, but not isotrivial.

2. Infinitesimal variations of structure

<!-- original page 81 -->

[^{N.D.E-X-6}] Let us begin by recalling the following result (cf. SGA 1, I 8.3 in the case S locally noetherian, EGA IV₄, 18.1.2 in general):

<!-- original page 66 -->

Recall 2.0. *Let S be a prescheme, S_0 a sub-prescheme having the same underlying set. Then the functor*

<!-- label: III.X.2.0 -->

```

```text
X ↦ X_0 = X ×_S S_0
```

```

is an equivalence between the category of étale preschemes over S and the analogous category over S_0 .

Proposition 2.1. *Let S be a prescheme, S_0 a sub-prescheme having the same underlying set (i.e. defined by a nilideal I). Then the functor*

<!-- label: III.X.2.1 -->

```

```text
H ↦ H_0 = H ×_S S_0
```

```

from the category of preschemes in groups of multiplicative type over S to the analogous category over S_0 , is fully faithful.

Moreover, it induces an equivalence between the category of quasi-isotrivial groups of multiplicative type over S and the analogous category over S_0 .

Let us first prove the full faithfulness, i.e. that if H, G over S are of multiplicative type, then

```

```text
Hom_{S-gr.}(H, G) → Hom_{S_0-gr.}(H_0, G_0)
```

```

is bijective. The question being local on S , we may suppose S affine; there then exists a faithfully flat

quasi-compact morphism $S' \rightarrow S$ which splits H and G . Let $S'' = S' \times_S S'$; denote by H', G' resp. H'', G'' the groups deduced from H, G by the base change $S' \rightarrow S$ resp. $S'' \rightarrow S$; define S'_0 and S''_0 similarly, the latter being also isomorphic to $S'_0 \times_{S'_0} S'_0$. One then finds a commutative diagram with exact rows:

$$\begin{array}{ccccc} \text{Hom}_{\{S\text{-gr.}\}}(H, G) & \rightarrow & \text{Hom}_{\{S'\text{-gr.}\}}(H', G') & \Rightarrow & \text{Hom}_{\{S''\text{-gr.}\}}(H'', G'') \\ \downarrow u & & \downarrow u' & & \downarrow u'' \\ \text{Hom}_{\{S_0\text{-gr.}\}}(H_0, G_0) & \rightarrow & \text{Hom}_{\{S'_0\text{-gr.}\}}(H'_0, G'_0) & \Rightarrow & \text{Hom}_{\{S''_0\text{-gr.}\}}(H''_0, G''_0), \end{array}$$

so to prove that u is bijective, it suffices to prove that u' and u'' are, which reduces us to the case where H and G are diagonalizable, hence of the form $D_{\{S\}}(M)$ and $D_{\{S\}}(N)$, where M and N are ordinary commutative groups. One will therefore have likewise $H_0 = D_{\{S_0\}}(M)$, $G_0 = D_{\{S_0\}}(N)$. One then has a commutative diagram

$$\begin{array}{ccc} \text{Hom}_{\{S\text{-gr.}\}}(N_S, M_S) & \square & \text{Hom}_{\{S\text{-gr.}\}}(D_S(M), D_S(N)) \\ \downarrow & & \downarrow \\ \text{Hom}_{\{S_0\text{-gr.}\}}(N_{S_0}, M_{S_0}) & \square & \text{Hom}_{\{S_0\text{-gr.}\}}(D_{S_0}(M), D_{S_0}(N)), \end{array}$$

<!-- original page 67 -->

where the horizontal arrows are isomorphisms by VIII 1.4, so we are reduced to proving that the homomorphism

$$(\times) \quad \text{Hom}_{\{S\text{-gr.}\}}(N_S, M_S) \rightarrow \text{Hom}_{\{S_0\text{-gr.}\}}(N_{S_0}, M_{S_0})$$

is bijective, i.e. to proving that the functor $M_{\{S\}} \mapsto M_{\{S_0\}}$, from preschemes in constant commutative groups over S to preschemes in constant commutative groups over S_0 , is fully faithful. Now $S \rightarrow S_0$ identifies also with the natural map

$$\text{Hom}_{\{\text{gr.}\}}(N, \Gamma(M_S)) \rightarrow \text{Hom}_{\{\text{gr.}\}}(N, \Gamma(M_{S_0}))$$

deduced from $\Gamma(M_{\{S\}}) \rightarrow \Gamma(M_{\{S_0\}})$; this latter map is obviously bijective (since $\Gamma(M_{\{S\}}) = \text{set of locally constant maps from } S \text{ to } M$, depends only on the topological space underlying S), whence the desired conclusion.

To prove the second assertion of 2.1, it remains to see that every group H_0 of multiplicative type over S_0 which is quasi-isotrivial comes from a quasi-isotrivial group of multiplicative type H over S . To see this, let $S' \rightarrow S_0$ be an étale surjective morphism which splits H_0 .

One knows (cf. 2.0) that there exists an étale morphism $S' \rightarrow S$ and an S_0 -isomorphism $S' \times_S S_0 \xrightarrow{\sim} S'_0$, so that one may suppose that S'_0 comes from S' by reduction. Since S'_0 is diagonalizable, one sees at once that it is isomorphic to the group deduced by base change $S'_0 \rightarrow S'$ from a diagonalizable group H' over S' (N.B. if $H'_0 = D_{\{S'_0\}}(M)$, one takes $H' = D_{\{S'\}}(M)$). Set as usual $S'' = S' \times_S S'$, $S''' = S' \times_S S' \times_S S'$, and define S''_0, S'''_0 similarly, deduced from the preceding by the base change $S_0 \rightarrow S$ and isomorphic also to the fibered square resp. cube of S'_0 over S_0 . Using the full faithfulness already proved, in the cases (S'', S''_0) and (S''', S'''_0) , one sees that the natural descent datum on H'_0 relative to $S'_0 \rightarrow S_0$ (cf. IV 2.1) comes from a well-determined descent datum on H' relative to $S' \rightarrow S$. This descent datum is effective since H' is affine over S' (SGA 1, VIII 2.1), so there exists an S -group H such that $H \times_S S' = H' = D_{\{S'\}}(M)$, and H is therefore of quasi-isotrivial multiplicative type.

One then verifies easily, using now the full-faithfulness result for (S', S'_0) , that the given isomorphism between H'_0 and $H' \times_{S'} S'_0$ comes from an isomorphism between H_0 and $H \times_S S_0$. (For a more formal exposition of results of this kind, see Giraud's article in preparation [X-2-1] on descent theory.)

Corollary 2.2. Let H be an S -group of multiplicative type, and $H_0 = H \times_S S_0$. For H to be quasi-isotrivial (resp. locally isotrivial, resp. isotrivial, resp. locally trivial, resp. trivial), it is necessary and sufficient that H_0 be so.*

<!-- label: III.X.2.2 -->

The "only if" is trivial; the "if" has already been seen in the quasi-isotrivial case, since thanks to the full faithfulness, it suffices to know that every quasi-isotrivial group over S_0 lifts to a quasi-isotrivial group over S . The same argument works for "trivial". For the case "isotrivial", one takes up the reasoning establishing the second assertion of 2.1, but taking $S_{\{0\}}$ to $S_{\{0\}}$ étale surjective and finite. The cases "locally isotrivial" and "locally trivial" follow at once from the cases "isotrivial" and "trivial".

One can generalize 2.2 somewhat when I is nilpotent, without supposing $\ast$ a priori $\ast$ of multiplicative type: [N.D.E-X-8]

<!-- original page 84 -->

<!-- original page 68 -->

Corollary 2.3. Suppose the ideal I defining S_0 locally nilpotent. Let H be a prescheme in groups over S , flat over S , and $H_{\{0\}} = H \times_S S_{\{0\}}$. For H to be of quasi-isotrivial multiplicative type, it is necessary and sufficient that H_0 be so.

<!-- label: III.X.2.3 -->

Indeed, suppose H_0 is of quasi-isotrivial multiplicative type; let us prove that H is so. The question being local for the étale topology, and the category of étale preschemes over S being equivalent to the category of étale preschemes over S_0 by the functor $S' \mapsto S' \times_S S_{\{0\}}$ (cf. 2.0), one is at once reduced to the case where H_0 is diagonalizable, hence isomorphic to a group $D_{S_{\{0\}}}(M)$. Let $G = D_S(M)$; one then has an isomorphism $u_{\{0\}} : H_{\{0\}} \xrightarrow{\sim} G_{\{0\}}$; I claim it comes from a unique homomorphism $u : H \rightarrow G$, which will therefore be an isomorphism since $u_{\{0\}}$ is one (H and G being flat over S , and I locally nilpotent [N.D.E-X-9]); this will establish 2.3. Now one has (cf. VIII 1 (xxx))

text
 $\text{Hom}_{\{S\text{-gr.}\}}(H, G) \simeq \text{Hom}_{\{S\text{-gr.}\}}(M_S, \text{Hom}_{\{S\text{-gr.}\}}(H, G_{\{m,S\}})),$

and the second member identifies also with

$\text{Hom}_{\{S\text{-gr.}\}}(M, \text{Hom}_{\{S\text{-gr.}\}}(H, G_{\{m,S\}})),$

so the homomorphism

text
 $(\times) \quad \text{Hom}_{\{S\text{-gr.}\}}(H, G) \rightarrow \text{Hom}_{\{S_0\text{-gr.}\}}(H_0, G_0)$

is isomorphic to the homomorphism

text
 $\text{Hom}_{\{S\text{-gr.}\}}(M, \text{Hom}_{\{S\text{-gr.}\}}(H, G_{\{m,S\}})) \rightarrow \text{Hom}_{\{S\text{-gr.}\}}(M, \text{Hom}_{\{S_0\text{-gr.}\}}(H_0, G_{\{m,S_0\}}))$

deduced from the restriction homomorphism

text
 $(\times\times) \quad \text{Hom}_{\{S\text{-gr.}\}}(H, G_{\{m,S\}}) \rightarrow \text{Hom}_{\{S_0\text{-gr.}\}}(H_0, G_{\{m,S_0\}});$

<!-- original page 85 -->

so to prove that $(\times)$ is bijective, it suffices to prove that $(\times\times)$ is. The question is local on S ; we may therefore suppose S affine. Now $G_{\{m,S\}}$ being commutative and smooth over S , the situation is governed by IX 3.6, which completes the proof.

Corollary 2.4. Let A be an artinian local ring with residue field k , $S = \text{Spec}(A)$, $S_{\{0\}} = \text{Spec}(k)$.

<!-- label: III.X.2.4 -->

(i)[^{N.D.E-X-10}] Let H be an S -prescheme in groups, flat and locally of finite type, such that $H_{\{0\}} = H \times_S S_{\{0\}}$ is of multiplicative type. Then H is of multiplicative type, of finite type and isotrivial. In particular, every S -prescheme in groups H of multiplicative type and of finite type is isotrivial.

(ii) The functor $H \mapsto H_{\{0\}}$ is an equivalence between the category of groups of multiplicative type of finite type over A and the analogous category over k .

Indeed, let H be as in (i). Then $H_{\{0\}}$ is of multiplicative type and locally of finite type, hence of finite type, hence isotrivial by 1.4. Therefore, by 2.3 and 2.2, H is of multiplicative type (hence of finite type) and isotrivial. Assertion (ii) then follows from 2.1.

Corollary 2.5. *Let $S' \rightarrow S$ be a faithfully flat and radicial morphism.*

<!-- label: III.X.2.5 -->

(i) The functor $H \mapsto H' = H \times_{S'} S'$, from the category of groups of multiplicative type over S to the analogous category over S' , is fully faithful.

Moreover, it induces an equivalence between the subcategories formed by the quasi-isotrivial groups of multiplicative type.*

(ii) If H is of multiplicative type, for it to be quasi-isotrivial (resp. locally isotrivial, resp. isotrivial, resp. locally trivial, resp. trivial) it is necessary and sufficient that H' be so.

Indeed, let $S' = S \times_S S'$ and $S'' = S' \times_{S'} S'$; then the hypothesis that $S' \rightarrow S$ is radicial implies that the diagonal immersions $S' \rightarrow S'$ and $S' \rightarrow S''$ are surjective, so the base change by either of these immersions is governed by 2.1 and 2.2. Taking into account that $S' \rightarrow S$ is a morphism of effective descent for the fibered category of groups of multiplicative type over preschemes (since it is faithfully flat and quasi-compact[^{N.D.E-X-11}]), our assertion follows formally from 2.1 and 2.2 (cf. for a formal argument the already-cited Giraud article).

3. Finite variations of structure: complete base ring

<!-- original page 86 -->

Lemma 3.1. *Let A be a noetherian ring, equipped with an ideal I such that A is separated and complete for the I -adic topology, $S = \operatorname{Spec}(A)$, $S_{\{0\}} = \operatorname{Spec}(A/I)$, G and H two S -group schemes, with G of multiplicative type and isotrivial, H affine over S , flat over S at the points of $H_{\{0\}} = H \times_S S_{\{0\}}$, $H_{\{0\}}$ of quasi-isotrivial multiplicative type. Then the natural map*

<!-- label: III.X.3.1 -->

```text  
 $\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H) \rightarrow \operatorname{Hom}_{\{S_{\{0\}}\text{-gr.}\}}(G_{\{0\}}, H_{\{0\}})$

\*is bijective.\*

For every integer  $n \geq 0$ , let  $S_n = \operatorname{Spec}(A/I^{n+1})$ , and let  $G_n$ ,  $H_n$  be the groups deduced from  $G$ ,  $H$  by the base change  $S_n \rightarrow S$ . Since  $G/S$  is of isotrivial multiplicative type and  $H$  affine over  $S$ , then, by IX 7.1, the natural homomorphism

```text  
 $\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H) \rightarrow \varinjlim_n \operatorname{Hom}_{\{S_n\text{-gr.}\}}(G_n, H_n)$

is bijective. On the other hand, by 2.3, the H_n are of quasi-isotrivial multiplicative type, and by 2.1, the transition homomorphisms in the projective system $(\operatorname{Hom}_{\{S_n\text{-gr.}\}}(G_n, H_n))_n$ are isomorphisms, whence 3.1 at once.

Theorem 3.2. *Let A be a noetherian ring equipped with an ideal I such that A is separated and complete for the I -adic topology, $S = \operatorname{Spec}(A)$, $S_{\{0\}} = \operatorname{Spec}(A/I)$. Then:*

<!-- label: III.X.3.2 -->

<!-- original page 70 -->

(i) The functor

```text  
 $H \mapsto H_0 = H \times_S S_0$   
```

is an equivalence between the category of isotrivial groups of multiplicative type over S and the analogous category over S_0 .

<!-- original page 87 -->

*(ii) Let H be an S -group of multiplicative type and of finite type; for H to be isotrivial, it is necessary and sufficient that H_0 be so.

Proof. For (i) one can either take up the proof of 2.1, or use 1.2, in either case using the fact that the functor

```text  
 $S' \mapsto S'_0 = S' \times_S S_0$   
```

from the category of finite étale schemes over S to the category of finite étale schemes over S_0 is an equivalence (SGA 1, I 8.4), which one can also state (reducing to the case S connected, i.e. S_0 connected), by choosing a geometric point ξ of S_0 , by saying that the canonical homomorphism

```text  
 $\pi_1(S_0, \xi) \rightarrow \pi_1(S, \xi)$   
```

is an isomorphism.

Let us prove (ii), i.e. that if H_0 is isotrivial, then H is so. By (i), there exists an isotrivial group of multiplicative type G over S and an S_0 -isomorphism

$u_0 : G_0 \xrightarrow{\sim} H_0$.

[^N.D.E-X-12] Since H is of finite type, so are H_0 and G_0 ; therefore, by IX 2.1 b), the type of G at each point of S is an abelian group of finite type, and so G is of finite type over S . On the other hand, by 3.1, u_0 comes from a homomorphism of S -groups

$u : G \rightarrow H$.

Finally, since G , H are of multiplicative type and of finite type over S , and since u_0 is an isomorphism, then, by IX 2.9, u is an isomorphism (taking into account that every neighborhood of S_0 in S equals S).

Corollary 3.3. *Let A be a complete noetherian local ring with residue field k .*

<!-- label: III.X.3.3 -->

<!-- original page 88 -->

(i) Every group of multiplicative type and of finite type over A is isotrivial.

(ii) The functor $H \mapsto H \otimes_A k = H_0$ is an equivalence between the categories of groups of multiplicative type and of finite type over A and over k .

[^N.D.E-X-12] First, (i) follows from 3.2 (ii) and 1.4; then (ii) follows from 3.2 (i), taking into account the fact

that H is of finite type if and only if H_0 is (cf. the proof of 3.2 (ii)).

Remark 3.3.1. One will note that 3.3 yields, by 1.4, a complete classification of groups of multiplicative type and of finite type over A in terms of the topological Galois group of an algebraic closure Ω of k .

<!-- label: III.X.3.3.1 -->

Remarks 3.4. Under the hypotheses of 3.2 (i.e. A noetherian, separated and complete for the I -adic topology, but without further hypothesis on A/I), it will follow from N° 5 that the functor $H \mapsto H_0$, from the category of groups of multiplicative type and of finite type over S to the analogous category over S_0 , is again fully faithful (without hypotheses of isotriviality). [N.D.E-X-13]

<!-- label: III.X.3.4 -->

However, it is not in general essentially surjective; in fact, there can exist an S_0 -group H_0 of multiplicative type and of finite type, locally trivial if one wishes (but not isotrivial), which does not come by reduction from a group of multiplicative type H over S .

To see this, let us take up either of the examples 1.6 of a non-isotrivial group of multiplicative type over a non-normal curve. One may obviously take this curve affine, say S_0 , and assume that it is embedded in the affine space of dimension 2, hence defined by an ideal J in $k[X, Y]$. We shall take for A the completion of this ring for the J -adic topology, so that A is a regular ring of dimension 2, *a fortiori* normal. We shall see in 5.16 that it follows that every group of multiplicative type and of finite type over $S = \operatorname{Spec}(A)$ is isotrivial; therefore H_0 , which is of finite type and not isotrivial, does not come from a group of multiplicative type H over S (since H would necessarily be of finite type, hence isotrivial).

Lemma 3.5. [X-3-1] Let S be a prescheme, $u : G \rightarrow H$ a homomorphism of S -preschemes in groups, locally of finite presentation and flat over S , U the set of $s \in S$ such that the induced homomorphism on fibers $u_s : G_s \rightarrow H_s$ is flat (resp. smooth, resp. unramified, resp. étale, resp. quasi-finite).*

<!-- label: III.X.3.5 -->

<!-- original page 89 -->

Then U is open, and the restriction $u|_U : G|_U \rightarrow H|_U$ is a flat (resp. smooth, resp. unramified, resp. étale, resp. quasi-finite) morphism.

Indeed, let V be the set of points at which u is flat (resp. ...). One knows that V is open (cf. SGA 1, I to IV in the locally noetherian case, EGA IV in general [N.D.E-X-14]), and that for $x \in G$ above $s \in S$, one has $x \in V$ if and only if $u_s : G_s \rightarrow H_s$ is flat (resp. ...) at x (same reference; in the flat, smooth, étale cases, one uses here the flatness of G and H over S). Since u_s is a homomorphism of locally algebraic groups, this also means that u_s is flat (resp. ...) everywhere (Exp. VI_B, 1.3), i.e. $s \in U$. Therefore U is the inverse image of the open set V by the unit section of G , hence open, and $V = G|_U$, so $G|_U \rightarrow H|_U$ is flat (resp. ...), which completes the proof. (N.B. In the "unramified" or "quasi-finite" case, the flatness hypothesis on G and H is unnecessary.)

Lemma 3.6. *Let H be a commutative algebraic group over a field k , admitting an open subgroup G of multiplicative type. Then the family of subschemes $\{H_n\}$ ($n > 0$) of H is schematically dense; in particular, if one has $\{H_n\} \cap G = \{1\}$ for every $n > 0$, then $H = G$.*

<!-- label: III.X.3.6 -->

Here $\{H_n\}$ denotes the kernel of $n \cdot \operatorname{id}_H$. [N.D.E-X-15] Let $\bar{k}$ be an algebraic closure of k ; it suffices to show that the family $\{H_n \otimes_{\bar{k}} \bar{k}\}_{n > 0}$ is schematically dense in $H \otimes_{\bar{k}} \bar{k}$, for then the family $\{H_n\}_{n > 0}$ will be so in H (cf. IX 4.5). Thus, one may suppose k algebraically closed, hence G of the form $D_{\{k\}}(M)$, M a finitely generated ordinary commutative group.

<!-- original page 72 -->

Let $M_0 = M/\operatorname{Torsion}(M)$; then $T = D_{\{k\}}(M_0)$ is the largest torus contained in G , and H/T is finite, so $H(k)/T(k)$ is annihilated by an integer $\nu > 0$. One can find a finite number of elements $g_i \in H(k)$ such that

```text  
H =  $\bigcup_i g_i \cdot G$ ,  
```

and one will have $g^{\nu}_i \in T(k)$. Since k is algebraically closed, $\nu \cdot \text{id}_T$ is surjective on $T(k) \simeq k^{\ast d}$, so up to replacing the g_i by $g_i t^{-1}_i$, where $t_i \in T(k)$ is such that $t^{\nu}_i = g^{\nu}_i$, $\leftarrow$ original page 90 $\rightarrow$ one may suppose that $g^{\nu}_i = 1$. If then n is a multiple of ν , one will have

```
```text
_n H \supseteq g_i \cdot _n G,
```

and since (for  $n > 0$  variable) the family of  $\{G_n\}$  is schematically dense in  $G$  by IX 4.7, conclusion 3.6 follows.

**Theorem 3.7.** \*Let  $A$  be a noetherian ring equipped with an ideal  $I$  such that  $A$  is separated and complete for the  $I$ -adic topology,  $S = \operatorname{Spec}(A)$ ,  $S_0 = \operatorname{Spec}(A/I)$ , and let  $H$  be an affine  $S$ -group scheme of finite type, flat over  $S$  at the points of  $H_0$ , such that  $H_0 = H \times_S S_0$  is of multiplicative type and isotrivial.\*

$\leftarrow$  label: III.X.3.7  $\rightarrow$

\*Then there exists an open and closed subgroup  $G$  of  $H$ , of isotrivial multiplicative type (and of finite type), such that  $G_0 = H_0$ .\*

By 3.2 (i), there exists an isotrivial group of multiplicative type  $G$  over  $S$  and an isomorphism

```

$
u_0 : G_0 \xrightarrow{\sim} H_0.
$
```

By 3.1,  $u_0$  comes from a unique homomorphism of  $S$ -groups

```

$
u : G \rightarrowtail H.
$
```

Using IX 6.6, one sees that  $u$  is a monomorphism (since if  $U$  is the set of  $s \in S$  such that  $u_s : G_s \rightarrowtail H_s$  is a monomorphism, then  $U$  is an open neighborhood of  $S_0$  hence identical to  $S$ , and  $G|_U \rightarrowtail H|_U$  is a monomorphism). By IX 2.5,  $u$  is even a closed immersion.

[^N.D.E-X-16] Therefore  $G$  is of finite type, hence of finite presentation over  $S$ . Then, by lemma 3.5 in the "étale" case, one sees that there exists an open set  $U$  neighborhood of  $S_0$ , hence identical to  $S$ , such that  $G|_U \rightarrowtail H|_U$  is étale, so  $u$  is étale, hence an open immersion (since it is an étale monomorphism[^N.D.E-X-17]), which completes the proof.

**Corollary 3.8.** \*Let  $A$  be a noetherian ring equipped with an ideal  $I$  such that  $A$  is separated and complete for the  $I$ -adic topology,  $S = \operatorname{Spec}(A)$ ,  $S_0 = \operatorname{Spec}(A/I)$ , and let  $H$  be an  $S$ -prescheme in groups of finite type, affine and flat over  $S$ .\*

$\leftarrow$  label: III.X.3.8  $\rightarrow$

$\leftarrow$  original page 91  $\rightarrow$

\*For  $H$  to be of multiplicative type and isotrivial, it is necessary and sufficient that  $H_0$  be so, and that  $H$  satisfy one of the following conditions a) and b) (which are therefore equivalent given the preceding conditions):\*

\*a) The fibers of  $H$  are of multiplicative type, and of constant type on each connected component of  $S$ .\*

\*b)  $H$  is commutative and the  $\{H_n\}$  ( $n > 0$ ) are finite over  $S$ .\*

\*These last conditions are also implied by the following:\*

\*c) The fibers of  $H$  are connected.\*

Of course, if  $H$  is of multiplicative type (and isotrivial), conditions a) and b) are verified by IX 1.4.1 a) and 2.1 c), so only the "if" requires proof. We shall use the subgroup  $G$  indicated in 3.7. When condition c) is satisfied, one

obviously has  $G = H$  and we are done.

In case b), one notes that the immersion  $u : G \rightarrow H$  induces an open immersion

```
```text
n u : n G → n H
```
```

which induces an isomorphism  $(\pi_n G)_0 \xrightarrow{\sim} (\pi_n H)_0$ ; since  $H$  is finite over  $S$ , this implies at once that  $\pi_n u$  is an isomorphism (the complement of its image is finite over  $S$  and reduces to  $\emptyset$ ). By 3.6 it follows that the morphisms induced on fibers  $u_s : G_s \rightarrow H_s$  are isomorphisms, so  $u$  is surjective, hence an isomorphism.

Finally, in case a), one may assume  $S$  connected, [N.D.E-X-18] and it follows that for every  $s \in S$ ,  $u_s : G_s \rightarrow H_s$  is a monomorphism of algebraic groups of multiplicative type and of the same type over  $\kappa(s)$ . [N.D.E-X-19] I claim that such a homomorphism is necessarily an isomorphism (which will again complete the proof [N.D.E-X-20]). Indeed, one may suppose, possibly extending the base field, that the two groups over  $\kappa(s)$  are diagonalizable, and then this follows from VIII 3.2 b) and from the fact that a surjective homomorphism of isomorphic finitely generated  $\mathbb{Z}$ -modules  $M \rightarrow N$  is necessarily bijective.

**Corollary 3.9.** \*Let  $A$  be a noetherian ring equipped with an ideal  $I$  such that  $A$  is separated and complete for the  $I$ -adic topology, and let  $H$  be an  $S$ -prescheme in groups of finite type, affine and flat over  $S$ , with connected fibers.\*

```
<!-- label: III.X.3.9 -->
```

```
<!-- original page 92 -->
```

\*For  $H$  to be an isotrivial torus, it is necessary and sufficient that  $H_0$  be so.\*

**4. Case of an arbitrary base. Quasi-isotriviality theorem**

Let  $A$  be a local ring. Recall that one says, after Nagata, that  $A$  is *henselian* if every algebra  $B$  finite over  $A$  is a product of local algebras  $B_i$  finite over  $A$ .

**Recall 4.0.** [N.D.E-X-21] \*Let  $A$  be a henselian local ring,  $k$  its residue field,  $S = \operatorname{Spec}(A)$ ,  $S_0 = \operatorname{Spec}(k)$ , and  $\xi$  a geometric point of  $S_0$ . Then, the functor\*

```
<!-- label: III.X.4.0 -->
```

```
```text
X ↦ X_0 = X ×_S S_0
```
```

is an equivalence between the category of étale covers of  $S$  and the analogous category over  $S_0$  (cf. EGA IV<sub>4</sub>, § 18.5). Consequently (cf. SGA 1, V), one has  $\pi_1(S_0, \xi) = \pi_1(S, \xi)$ .

Suppose moreover  $A$  noetherian and denote by  $A'$  its completion,  $S' = \operatorname{Spec}(A')$ . Then  $A'$  is a complete noetherian local ring, hence henselian (loc. cit., 18.5.14), and the functor

```
```text
X ↦ X' = X ×_S S'
```
```

from the category of étale covers of  $S$  to the analogous category over  $S'$ , fits into a commutative diagram

```
```text
      Rev.ét.(S) → Rev.ét.(S')
        ↘       ↗
        ≈       ≈
        ↘       ↗
      Rev.ét.(S_0)
```

so is also an equivalence of categories, whence $\pi_1(S_0, \xi) = \pi_1(S', \xi)$.

Remark 4.0.1. Since S is connected (A being local), it follows from 1.2 that the category of isotrivial groups of multiplicative type over S is equivalent to the analogous category over S_0 (and also over S' if moreover A is noetherian).

<!-- label: III.X.4.0.1 -->

Lemma 4.1. Let A be a henselian local ring with residue field k , $S = \operatorname{Spec}(A)$, $S_0 = \operatorname{Spec}(k)$.

<!-- label: III.X.4.1 -->

(i) The functor

$$H \mapsto H_0 = H \times_S S_0$$

is an equivalence between the category of finite groups of multiplicative type over S and* <!-- original page 93 --> the analogous category over S_0 .*

(ii) If moreover A is noetherian, denoting by A' its completion and $S' = \operatorname{Spec}(A')$, the functor

$$H \mapsto H' = H \times_S S'$$

is an equivalence between the category of finite groups of multiplicative type over S and the analogous category over S' .*

As in 4.0, the second assertion is a consequence of the first; let us prove the latter. One already knows that the functor under consideration is essentially surjective, since every group of multiplicative type H_0 over $S_0 = \operatorname{Spec}(k)$, finite hence of finite type over k , is isotrivial by 1.4, hence comes from an isotrivial group of multiplicative type over S by 4.0.1.

It remains to prove full faithfulness, i.e. that for two finite groups G, H of multiplicative type over S , the map below is bijective:

$$\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H) \rightarrow \operatorname{Hom}_{\{S_0\text{-gr.}\}}(G_0, H_0),$$

i.e., [N.D.E-X-22] denoting by F the S -functor $\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H)$, that the natural map

$$\operatorname{Hom}_S(S, F) \rightarrow \operatorname{Hom}_{S_0}(S_0, F_0)$$

induced by the base change $S_0 \rightarrow S$ is bijective. For this, given recall 4.0, it suffices to prove:

Lemma 4.2. Let G, H be two finite groups of multiplicative type over a prescheme S . Then $F = \operatorname{Hom}_{\{S\text{-gr.}\}}(G, H)$ is representable by a finite étale scheme over S .*

<!-- label: III.X.4.2 -->

[N.D.E-X-23] Let $f : S' \rightarrow S$ be a faithfully flat quasi-compact morphism such that G' and H' are diagonalizable. It suffices to show that $F_{S'}$ is representable by a prescheme X' étale and finite (hence affine) over S' , since the descent datum on X' relative to f (cf. VIII 1.7.2) will then be effective (by SGA 1 VIII, 2.1), whence the existence of an S -prescheme X such that $X \times_S S' = X'$, which represents F , and is étale and finite over S (cf. SGA 1, V 5.7 and EGA IV₄, 17.7.3 (ii)).

One may therefore suppose that $G = D_{\{S\}}(M)$ and $H = D_{\{S\}}(N)$, where M and N are finite commutative groups (cf. VIII 2.1 c)). Then, <!-- original page 94 --> $K = \operatorname{Hom}_{\{S\text{-gr.}\}}(N, M)$ is a finite abelian group and, by VIII 1.5, one has an isomorphism

S

$\operatorname{Hom}_{S\text{-gr.}}(G, H) \cong K_S,$
 $\square$

which completes the proof of 4.2 and hence of 4.1.

****Proposition 4.3.0.**** ^[^N.D.E-X-24] *Let S be a henselian local scheme, s its closed point, $g : X \rightarrow S$ a morphism locally of finite type, x an isolated point of the fiber X_s .*

<!-- label: III.X.4.3.0 -->

(i) Then $X_{X,x}$ is finite over S_s . (In particular, if the residue extension $k(x)/k(s)$ is trivial, then $S_s \rightarrow X_{X,x}$ is surjective, by Nakayama's lemma.)*

(ii) If moreover g is separated, then $X' = \operatorname{Spec}(0_{X,x})$ is an open and closed subscheme of X , i.e. one has a decomposition as a disjoint sum $X = X' \sqcup X''$.*

Proof. By the local form of Zariski's main theorem given in [Pes66], or [Ray70, Ch. IV, Th. 1], x has an affine open neighborhood $U = \operatorname{Spec}(B)$ of finite type and quasi-finite over $A = 0_{S,s}$, and there exists an open immersion $U \hookrightarrow Y = \operatorname{Spec}(C)$, where C is a finite A -algebra. (N.B. to reach this conclusion, one may also use Chevalley's semi-continuity theorem (EGA IV₃, 13.1.4), then the form of Zariski's main theorem given in loc. cit., 8.12.8.)

Since A is henselian, Y is the disjoint sum of local schemes $Y_1, \dots, Y_n$, each finite over S , and the points of Y above s are the closed points $y_1, \dots, y_n$. Therefore $x = y_i$ for some i , and $0_{X,x} = 0_{U,x} = C_i$ is finite over A . Moreover, $X' = C_i$ is an open subscheme of U hence of X .

Suppose moreover g separated. Then, since the morphism $X' \rightarrow S$ is finite (C_i being finite over A), so is the immersion $X' \rightarrow X$ (cf. EGA II, 6.1.5 (v)), so X' is also closed in X .

****Lemma 4.3.**** *Let A be a noetherian henselian local ring, A' its completion, $S = \operatorname{Spec}(A)$, $S' = \operatorname{Spec}(A')$, s the closed point of S , G and H two S -preschemes in groups, with G of multiplicative type and of finite type over S , H locally of finite type and separated over S , H_s of multiplicative type, and H flat over S at the points of H_s .*

<!-- label: III.X.4.3 -->

Let G_s, H_s be deduced from G, H by the base change $S' \rightarrow S$. Then the natural map below is bijective:

```text  
 $\operatorname{Hom}_{S\text{-gr.}}(G, H) \cong \operatorname{Hom}_{S'\text{-gr.}}(G', H').$

Since  $S'$  is faithfully flat and quasi-compact over  $S$ , one knows by SGA 1, VIII 5.2 that this map is a bijection of the first member onto the part of the second formed by the  $u' : G' \rightarrow H'$  such that the two inverse images  $u'^{-1}_1, u'^{-1}_2 : G' \rightarrow H'$  of  $u'$  on  $S' = S \times_S S'$  (by the projections  $\operatorname{pr}_1, \operatorname{pr}_2$  of  $S' \rightarrow S$ ) are equal.

Therefore everything reduces to proving that for every homomorphism of  $S'$ -groups  $u' : G' \rightarrow H'$ , one has  $u'^{-1}_1 = u'^{-1}_2$ . By the density theorem IX 4.8 it suffices to prove that  $u'^{-1}_1$  and  $u'^{-1}_2$  coincide on  $\{g_n\} \subset G'$  for every integer  $n > 0$ . (N.B. one needs here in an essential way the density theorem in a case where the base prescheme, here  $S'$ , is not locally noetherian.)

This reduces us, replacing  $G$  by  $\{g_n\} \subset G$ , to the case where there exists an integer  $n > 0$  such that  $n \cdot \operatorname{id}_G = 0$ , hence where  $G$  is finite over  $S$ . Let likewise  $H_n$  be the kernel of the  $n$ -th power morphism  $\phi_n$  in  $H$ . (N.B. we have not assumed  $H$  commutative, so  $\phi_n$  (resp.  $H_n$ ) is not necessarily a homomorphism of groups (resp. a subgroup of  $H$ ).) Since  $H_n$  is defined as the fibered product of  $\phi_n : H \rightarrow H$  <!-- original page 95 --> and the unit section  $\epsilon : S \rightarrow H$ , its formation commutes with every base change  $T \rightarrow S$ , i.e. one has  $(H_n)_T = H_n(H_T)$ .

<sup>[^N.D.E-X-25]</sup> We denote by an index  $m$  on the right the reductions modulo  $\mathfrak{m}^{m+1}$ , where  $\mathfrak{m}$  is the maximal ideal of  $A$ . Then  $H_m$  is flat over  $S_m$  (since  $H$  is so over  $S$  at the points of  $H_0$ ); therefore, by 2.4, since  $H_0$  is of multiplicative type and of finite type, so is  $H_m$ . Therefore each  $(H_n)_m = H_m(H_m)$  is a subgroup of  $H_m$ , of multiplicative type, finite and flat over  $S_m$ .

In particular,  $(H_n)_0 = H_0(H_0)$  is finite over  $S_0$ ; since  $S$  is henselian local and  $H$  is

(like  $H_S$ ) locally of finite type and separated over  $S_S$ , then, by 4.3.0, <!-- original page 77 --> the local rings of  $\{H_S\}_{S \in S}$  at the points of  $\{H_S\}_{S \in S}$  are finite over  $S_S$  and one has a decomposition as a disjoint sum of open sets

```

```text
(*)       $\bigcup_{S \in S} H_S = \bigcup_{S \in S} H_S^-$ ,
```

```

where  $Z = \{H_S\}_{S \in S}$  is finite over  $S_S$ , and  $\{H_S\}_{S \in S}^-$  lies above  $S - \{s\}$ .

Note that, for every finite  $S_S$ -scheme  $Y_S$  (such as  $G_S$ ), every  $S_S$ -morphism  $Y_S \rightarrow \{H_S\}_{S \in S}$  factors through  $Z_S$ , and that the formation of the decomposition  $(\ast)$  commutes with the base change  $S' \rightarrow S$  (where  $S' = \operatorname{Spec}(A')$ ,  $A'$  the completion of  $A$ ).

Then  $Z' = Z \times_{S_S} S'$  is a finite scheme over  $S'$ , as is  $P' = Z' \times_{S'} Z'$ . Denote by  $\nu$  the restriction to  $P'$  of the multiplication of  $H'$  and by  $\sigma$  the automorphism of  $P'$  which exchanges the two factors. Since  $P'$  is finite over  $S'$  and  $H'$  separated and locally of finite type over  $S'$ , then, by EGA II 5.4.3 and IV<sub>1</sub> 1.1.3,  $Y = \nu(P')$  is a closed subscheme of  $H'$ , universally closed and quasi-compact, hence of finite type, hence proper over  $S'$ . Moreover,  $Y \rightarrow S'$  has finite fibers (since  $P' \rightarrow S'$  does). Therefore, since  $S'$  is noetherian, the morphism  $Y \rightarrow S'$  is finite (cf. EGA III, 4.4.2). Since  $Z' \subset Y$  and  $Z'_m = Y'_m$  for every  $m$ , then  $Z' = Y$ , by lemma IX 5.0, so  $Z'$  is a subgroup of  $H'$ . Likewise, the kernel  $K = \operatorname{Ker}(\nu, \nu \circ \sigma)$  is a closed subscheme of  $P'$ , such that  $K_m = P'_m$  for every  $m$  (since  $Z'_m = \{H_m\}$  is commutative), so  $K = P'$ , i.e.  $Z'$  is a commutative subgroup of  $H'$ .

On the other hand, since each reduction  $Z'_m = \{H_m\}$  is flat over  $S_m$ , then, by the "local criterion of flatness" (cf. EGA 0\_III, 10.2.2 or [BAC], III § 5, Example 1 and Th. 1),  $Z'$  is flat over  $S'$ . Since moreover  $Z'_0 = \{H_0\}$  is a finite group of multiplicative type over  $S'_0$ , hence isotrivial by 1.4, then  $Z'$  is of multiplicative type (and isotrivial) over  $S'$ , by 3.8 b). Since  $S' \rightarrow S$  is faithfully flat and quasi-compact, one deduces that the multiplication  $Z \times_{S_S} Z \rightarrow H_S$  factors through  $Z_S$  and makes  $Z_S$  a subgroup of  $H_S$ , finite over  $S_S$  and of multiplicative type (since  $Z'$  is).

Finally, by the remarks made above on decomposition  $(\ast)$ ,  $Z'$  is the "finite part" of  $\{H_S\}_{S \in S}$ , and so the morphism  $u' : G' \rightarrow \{H_S\}_{S \in S}$  takes its values in  $Z'$ . Since  $Z_S$  is of multiplicative type and finite over  $S_S$ , as is  $G_S = \{G_S\}$ , then, by 4.1,  $u'$  comes from a  $u : G \rightarrow Z$ , and therefore  $u'_1 = u'_2$ . This completes the proof of 4.3.

**Lemma 4.4.0.** [N.D.E-X-26] \*Let  $A$  be a ring,  $S = \operatorname{Spec}(A)$ ,  $H_S$  an  $S_S$ -group scheme of multiplicative type and of finite type, quasi-isotrivial (resp. isotrivial),  $\{A_i\}$  a filtered family of subrings of  $A$  of which  $A$  is the inductive limit,  $S_i = \operatorname{Spec}(A_i)$ .\*

<!-- label: III.X.4.4.0 -->

\*Then there exist an index  $i$  and an  $S_i$ -group scheme  $H_{S_i}$  of multiplicative type and of finite type, quasi-isotrivial (resp. isotrivial), such that  $H_S = H_{S_i} \times_{S_i} S_S$ .\*

**Theorem 4.4.** \*Let  $S$  be a prescheme,  $H_S$  an  $S_S$ -prescheme in groups affine and of finite presentation over  $S_S$ , and  $s \in S$ . Assume:

<!-- label: III.X.4.4 -->

\* $\alpha$ )  $H_S$  is flat over  $S_S$  at the points of  $H_{S_s}$ .\*

\* $\beta$ )  $H_{S_s}$  is of multiplicative type.\*

\*Then there exist an étale morphism  $S' \rightarrow S$ , a point  $s'$  of  $S'$  above  $s$  such that the extension  $\kappa(s')/\kappa(s)$  is trivial, and an open and closed subgroup  $G'$  of  $H' = H \times_{S_S} S'$ ,\* <!-- original page 96 --> \*of multiplicative type and of finite type, isotrivial, such that  $G'_{s'} = H'_{s'}$ .\*

[N.D.E-X-27] **Proof.** Let us provisionally denote  $T = \operatorname{Spec}(0_{S,s})$  and show that, by "descent of conclusions", one can reduce to the case where  $S = T$ . Indeed, suppose we have found an étale morphism  $g : T' \rightarrow T$ , a point  $s' \in T'$  and a subgroup  $G'$  of  $H' = H \times_{T'} T'$  satisfying the conditions of the statement; replacing  $T'$  by an affine open neighborhood of  $s'$ , one may suppose  $T'$  of finite presentation over  $T$ .

Since  $G'$  is isotrivial, there exists an étale finite surjective morphism  $f : \tilde{T} \rightarrow T'$  such that  $\tilde{G} = G' \times_{T'} \tilde{T}$  is isomorphic to  $\mathcal{D}_{\tilde{T}}(M)$ , where  $M$  is a finitely generated abelian

group. Since  $T$ ,  $H$ , and  $\tilde{T}$ ,  $G$  are of finite presentation over  $T = \operatorname{Spec}(0_{\{S,s\}})$ , and  $0_{\{S,s\}}$  is the inductive limit of the subalgebras  $A_i = 0_{\{S\}}(S_i)$ , where  $S_i$  runs through the affine open neighborhoods of  $s$  in  $S$ , then, by EGA IV<sub>3</sub>, 8.8.2 (and Exp. VI\_B, 10.2 and 10.3), there exist an index  $i$ ,  $S_i$ -preschemes (resp. an  $S_i$ -prescheme in groups) of finite presentation  $S'_i$  and  $\tilde{T}_i$  (resp.  $G'_i$ ), and morphisms  $g_i : S'_i \rightarrow S_i$  and  $f_i : \tilde{T}_i \rightarrow S'_i$  (resp. a morphism of  $S_i$ -preschemes in groups  $u_i : G'_i \rightarrow H \times_{S_i} S'_i$ ), from which  $f$  and  $g$  (resp.  $u : G \rightarrow H$ ) come by the base change  $T' \rightarrow S_i$ . Moreover, taking  $i$  large enough,  $g_i$  will be étale,  $f_i$  étale finite surjective, and  $u_i$  an open and closed immersion (cf. EGA IV, 8.10.5 and 17.7.8).

Then,  $\tilde{G}$  comes from the groups  $\tilde{G}_i = G_i \times_{S_i} \tilde{T}_i$  and  $D_{\{\tilde{T}_i\}}(M)$ ; therefore, by EGA IV<sub>3</sub>, 8.8.2 (i) (and VI\_B, 10.2), there exists an index  $j$  such that  $\tilde{G}_j \simeq D_{\{\tilde{T}_j\}}(M)$ , so  $G_j$  is of isotrivial multiplicative type. Denote by  $s'_j$  the image of  $s$  in  $S'_j$ . Then the étale morphism  $S'_j \rightarrow S_j$   $\hookrightarrow$   $S$ , the point  $s'_j$  and the open and closed subgroup  $G'_j$  of  $H \times_{S_j} S'_j$ , verify the conditions of the statement. This shows that one may suppose  $S = \operatorname{Spec}(A)$  local, with closed point  $s$ .

**\*\*b)\*\*** Then,  $A$  is the inductive limit of local rings  $A_i$  which are localizations of  $\mathbb{Z}$ -algebras of finite type; denote  $S_i = \operatorname{Spec}(A_i)$ . Let us show that the hypotheses  $\alpha$ ) and  $\beta$ ) "descend" to some  $A_i$ . Since  $H \rightarrow S$  is of finite presentation, the set of  $x \in H$  such that  $H$  is flat over  $S$  at  $x$  is an open set  $W$ , which contains  $H_s$  by hypothesis, hence contains a quasi-compact open set  $V$  containing  $H_s$  (since  $H_s$  being affine, one can cover it by a finite number of affine open sets contained in  $W$ ). Then the open immersion  $\tau : V \hookrightarrow H$  is of finite presentation, so  $V \rightarrow S$  is too.

Therefore, by EGA IV<sub>3</sub>, 8.8.2 (and Exp. VI\_B, 10.2 and 10.3), there exist an index  $i$ , an  $S_i$ -prescheme  $V_i$  (resp. an  $S_i$ -prescheme in groups  $H_i$ ) of finite presentation over  $S_i$ , and an  $S_i$ -morphism  $\tau_i : V_i \rightarrow H_i$  from which  $V$ ,  $H$  and  $\tau$  come by base change  $S \rightarrow S_i$ ; moreover, taking  $i$  large enough,  $\tau_i$  will be an open immersion and  $V_i$  will be flat over  $S_i$ , by EGA IV<sub>3</sub>, 8.10.5 and 11.2.6. Denote by  $s_i$  the image of  $s$  in  $S_i$ ; since the open immersion  $(V_i)_{s_i} \hookrightarrow (H_i)_{s_i}$  gives, by the base change  $\kappa(s_i) \rightarrow \kappa(s)$ , the equality  $V_{s_i} = H_{s_i}$ , one already has  $(V_i)_{s_i} = (H_i)_{s_i}$ , i.e.  $(H_i)_{s_i} \subseteq V_i$ , so  $H_i$  is flat over  $S_i$  at the points of  $(H_i)_{s_i}$ . Finally,  $(H_i)_{s_i}$  is of multiplicative type, since  $H_{s_i} = (H_i)_{s_i} \otimes_{\kappa(s_i)} \kappa(s)$  is. Therefore the triple  $(S_i, H_i, s_i)$  verifies the hypotheses of 4.4, and if the desired assertion is verified for this triple, it will also be verified, by base change, for  $(S, H, s)$ . This reduces us to the case where  $A$  is local and noetherian. Let us now distinguish two cases.

**\*\*1°)\*\***  $A$  is local noetherian and henselian.\* <!-- original page 79 --> Let  $\hat{A}$  be its completion,  $\hat{S} = \operatorname{Spec}(\hat{A})$ , and  $\hat{H} = H \times_S \hat{S}$ . Applying theorem 3.7, one finds an  $\hat{S}$ -group  $\hat{G}$  of multiplicative type, isotrivial and of finite type, and a homomorphism of  $\hat{S}$ -groups

$$\begin{aligned} & s \\ \hat{u} : \hat{G} & \longrightarrow \hat{H} \\ & s \end{aligned}$$

which is an open immersion and a closed immersion, such that  $\hat{u}$  induces an isomorphism  $\hat{u}_{\{0\}} : \hat{G}_{\{0\}} \xrightarrow{\sim} \hat{H}_{\{0\}}$ .

By remark 4.0.1, the base change functor by  $\hat{S} \rightarrow S$  induces an equivalence between the category of isotrivial groups of multiplicative type over  $S$ , and over  $\hat{S}$ ; in particular  $\hat{G}$  "comes from" an  $S$ -group of multiplicative type  $G$ , isotrivial and of finite type. By 4.3,  $\hat{u}$  comes from a homomorphism

$$\begin{aligned} & s \\ u : G & \longrightarrow H \\ & s \end{aligned}$$

moreover  $u$  is an open and closed immersion and induces an isomorphism  $u_{\{0\}} : G_{\{0\}} \rightarrow H_{\{0\}}$ , since this is so after the faithfully flat quasi-compact base change  $\hat{S} \rightarrow S$ . This therefore proves 4.4 in this case (taking of course, in the conclusion of 4.4,  $S' = S$  and  $s' = s$ ).

**\*\*2°)\*\***  $A$  is local noetherian.\* The reduction to case 1°) is immediate, by applying 1°) to the "henselized" ring  $A^{\{h\}}$  of  $A$ . More precisely, one sees easily (using SGA 1, I § 5[<sup>X-4-1</sup>]) that the local rings  $0_{\{S',s'\}}$  of the  $S$ -preschemes étale  $S'$  equipped with a point  $s'$  above  $s$  such that  $\kappa(s')/\kappa(s)$  is trivial, form a filtered inductive system, whose inductive limit is a noetherian henselian local ring  $A^{\{h\}}$  (called the "henselized" ring of  $A$ ); for details of this construction (due to Nagata in the normal case), cf. SGA 4, VIII § 4[<sup>X-4-1</sup>]. The sorites of EGA IV<sub>3</sub> § 8 then allow, <!-- original page 97 --> as in part a) of the proof, to deduce from a known result

on the inductive limit  $A^{\{h\}}$  of the  $A_{S',s'}$ , an analogous result on one of the  $(S', s')$ , which proves 4.4.

**Corollary 4.5.** Let  $S$  be a prescheme,  $H$  an  $S$ -prescheme in groups of multiplicative type and of finite type. Then  $H$  is quasi-isotrivial, i.e. is split by an étale surjective morphism  $S' \rightarrow S$ .

<!-- label: III.X.4.5 -->

Indeed, let  $s$  in  $S$ . By 4.4, there exist an étale morphism  $S' \rightarrow S$ , an  $s'$  in  $S'$  above  $s$  such that  $\kappa(s) = \kappa(s')$ , and a subgroup  $G'$  of  $H'$ , of isotrivial multiplicative type and of finite type, such that  $G'_{\{s'\}} = H'_{\{s'\}}$ . Since  $G'$  and  $H'$  are of multiplicative type and of finite type, then, by IX 2.9, there exists an open neighborhood  $U'$  of  $s'$  such that  $G'|_{U'} = H'|_{U'}$ .

[^N.D.E-X-28] Suppose moreover  $S$  local henselian, with closed point  $s$ ; then, by EGA IV<sub>1</sub>, 18.5.11 b), there exists a section  $\sigma$  of  $S' \rightarrow S$  such that  $\sigma(s) = s'$ . (N.B. one can see directly that  $B = A_{S',s'}$  equals  $A = A_{S,s}$  as follows: by 4.3.0 (i), one has  $B \subseteq A/I$ , and since  $B$  is a finitely presented and flat  $A$ -algebra,  $I$  is a finitely generated ideal <!-- original page 80 --> (cf. EGA IV<sub>1</sub>, 1.4.7), and  $I = I_m$  (where  $m$  is the maximal ideal of  $A$ ), whence  $I = 0$ .) Therefore  $H$  is already isotrivial. One thus obtains:

**Corollary 4.6.** Let  $A$  be a henselian local ring,  $k$  its residue field, and  $\pi$  the topological Galois group of an algebraic closure of  $k$ .

<!-- label: III.X.4.6 -->

(i) Every group of multiplicative type and of finite type over  $S = \operatorname{Spec}(A)$  is isotrivial.

(ii) The category of these groups over  $S$  is equivalent (via the functor  $H \mapsto H \otimes_{\{A\}} k$ ) to the analogous category over  $S_{\{0\}} = \operatorname{Spec}(k)$ ; it is therefore anti-equivalent, by 1.4, to the category of Galois modules under  $\pi$  which are of finite type as  $\mathbb{Z}$ -modules.

**Corollary 4.7.** Under the conditions of 4.4 suppose moreover that one of the following conditions is verified:

<!-- label: III.X.4.7 -->

a) For every generization  $t$  of  $s$ ,  $H_t$  is of multiplicative type and of the same type as  $H_s$ .

b)  $H$  is commutative and the  $H_{\{n\}}$  ( $n > 0$ ) are finite over  $S$  in a neighborhood of  $s$ .

c) For every generization  $t$  of  $s$ , the fiber  $H_t$  is connected.

Then there exists an open neighborhood  $U$  of  $s$  such that  $H|_U$  is of multiplicative type.

<!-- original page 98 -->

Taking into account that an étale morphism is open, one is reduced to proving that there exists (with the notations of the conclusion of 4.4) an open neighborhood  $U$  of  $s$  such that  $G'|_U = H'|_U$ . Set  $S' = \operatorname{Spec}(A_{S',s'})$ ; since  $G'$  and  $H'$  are of finite presentation over  $S'$ , it suffices to show, by EGA IV<sub>3</sub>, 8.8.2, that  $G' = H'$ . We may therefore suppose  $S = S'$ , and then hypotheses (a), (b), (c) become those of the lemma below, whose proof is the same as that of 3.8:

**Lemma 4.7.1.** Let  $S$  be a local scheme,  $s$  its closed point,  $H$  an  $S$ -group scheme of finite type,  $G$  an open and closed subgroup of  $H$ , of multiplicative type, such that  $G_{\{s\}} = H_{\{s\}}$ . Suppose moreover one of the following conditions verified:

<!-- label: III.X.4.7.1 -->

a) The fibers of  $H$  are of multiplicative type and of the same type as  $H_s$ .

b)  $H$  is commutative and the  $H_{\{n\}}$  ( $n > 0$ ) are finite over  $S$ .

c) The fibers of  $H$  are connected.

Then  $G = H$ .

**Corollary 4.8.** Let  $S$  be a prescheme,  $H$  an  $S$ -prescheme in groups affine, flat and of finite presentation over  $S$ , with fibers of multiplicative type.

<!-- label: III.X.4.8 -->

\*For  $H_S$  to be of multiplicative type, it is necessary and sufficient that it satisfy one of the two following conditions (equivalent given the preceding conditions):\*

\*a) The type of  $H_{\{s\}}$  (cf. IX 1.4) is a locally constant function of  $s \in S$ .\*

\*b)  $H_S$  is commutative, and the  $H_{\{s\}}$  ( $s \in S$ ) are finite over  $S$ .\*

\*Moreover, these conditions a), b) are implied by the following:\*

\*c) The fibers of  $H_S$  are connected.\*

In particular, one finds:

**Corollary 4.9.** \*Let  $S$  be a prescheme,  $H_S$  an  $S$ -prescheme in groups flat and of finite presentation over  $S$ . Suppose moreover  $H_S$  affine over  $S$  and with connected fibers. [N.D.E-X-29] If  $s \in S$  is such that  $H_{\{s\}}$  is a torus, there exists an open neighborhood  $U$  of  $s$  such that  $H|_U$  is a torus.\*

<!-- label: III.X.4.9 -->

<!-- original page 81 -->

\*In particular, if all the fibers of  $H_S$  are tori,  $H_S$  is a torus.\*

**5. Scheme of homomorphisms from one group of multiplicative type to another. Twisted constant groups and groups of multiplicative type**

**Definition 5.1.** \*a) Let  $S$  be a prescheme,  $R_S$  a prescheme in groups over  $S$ . One says that  $R_S$  is a\* twisted constant group \*over  $S$  if it is locally isomorphic, in the sense of the faithfully flat quasi-compact topology, to a constant group scheme, i.e. of the form  $M_S$  with  $M$  an ordinary group.\*

<!-- label: III.X.5.1 -->

<!-- original page 99 -->

\*b) One says that the twisted constant group  $R_S$  over  $S$  is\* quasi-isotrivial, resp. isotrivial, resp. locally isotrivial, resp. locally trivial, resp. trivial, \*if in the definition above one can replace the faithfully flat quasi-compact topology by the étale topology, resp. the global finite étale topology, resp. the finite étale topology, resp. the Zariski topology, resp. the coarsest (or "chaotic") topology, cf. IX 1.1 and 1.2, and IV 6.6.\*

\*To say that  $R_S$  is quasi-isotrivial (resp. isotrivial) thus means that there exists an étale surjective (resp. and finite) morphism  $S' \rightarrow S$  such that  $R_{S'} = R_S \times_{S'} S'$  is a constant group over  $S'$ ; to say that it is trivial means that  $R_S$  is a constant group.\*

\*c) One defines as in VIII 1.4 the\* type \*of a twisted constant group  $R_S$  over  $S$  at an  $s \in S$ ; it is a class of ordinary groups up to isomorphism, which for variable  $s \in S$  is a locally constant function of  $s$ , hence constant if  $S$  is connected. One will also say that  $R_S$  is "of type  $M_S$ " if all the fibers of  $R_S$  are of type  $M_S$ .\*

\*Beware that  $R_S$  is quasi-compact over  $S$  only if it is finite over  $S$ , i.e. if its type at every  $s \in S$  is a finite group. [N.D.E-X-30]

\*d) The case most interesting for us is that where  $R_S$  is commutative. We shall then say that  $R_S$  is "finitely generated" if its type at each point  $s \in S$  is given by a finitely generated  $\mathbb{Z}$ -module, a notion which should not be confused with the schematic notion " $R_S$  of finite type over  $S$ " (cf. above).\*

**Remark 5.2.** We shall also have to consider  $S$ -preschemes  $X_S$  which are locally isomorphic (for the faithfully flat quasi-compact topology) to constant preschemes, independently of any group structure. We shall then say that  $X_S$  is a \*twisted constant bundle\* over  $S$ , and we extend to these preschemes the terminology introduced in 5.1. Of course one will note that when  $X_S$  is endowed with an  $S$ -group structure, the meaning of the expressions "twisted constant", "isotrivial" etc. changes, depending on whether one takes into account or not the group structure over  $S$ . The same holds if one considers <!-- original page 100 --> on  $X_S$  any other species of algebraic structure (for example that of Galois principal bundle that will be considered in the following number).

<!-- label: III.X.5.2 -->

**Proposition 5.3.** \*Let  $R$  be a commutative twisted constant group over  $S$ .\*

<!-- label: III.X.5.3 -->

(i) The functor  $H = D_{\{S\}}(R)$  (cf. VIII 1) is representable and is a group of multiplicative type over  $S$ .\*

(ii) For every  $s \in S$ , the type of  $R$  at  $s$  equals that of  $H$  at  $s$ .\*

(iii) For  $R$  to be quasi-isotrivial (resp. isotrivial, resp. trivial, resp. locally isotrivial, resp. locally trivial), it is necessary and sufficient that  $H$  be so.\*

**Remark 5.3.1.** [N.D.E-X-31] One may worry about seeing in 5.3 the term "type" used in two different senses depending on whether we speak of  $R$  or  $H$ ; fortunately, when an  $S$ -prescheme in groups  $G$  is at the same time a twisted constant group and of multiplicative type, its type in either sense is the same, thanks to the fact that a finite ordinary commutative group is isomorphic to its dual!

<!-- label: III.X.5.3.1 -->

**Proof.** Since the families covering for the faithfully flat quasi-compact topology are families of effective descent for the fibered category of affine preschemes in groups over variable base preschemes (SGA 1, VIII 2.1), one sees that  $H$  is representable (and is affine over  $S$ ), since it is so "locally" [N.D.E-X-32] (because it is so when  $R$  is constant, and then  $H$  is a diagonalizable group).

The fact that  $H$  is of multiplicative type is then evident by definition, as is the fact that the type of  $R$  and  $H$  at  $s \in S$  is the same. Finally, since  $H_{\{S\}} = D_{\{S\}}(R_{\{S\}})$ , the last assertion is reduced to the "trivial" case, i.e. to verifying that  $R$  is trivial if and only if  $H$  is, which follows at once from the biduality theorem VIII 1.2.

To finish making precise the correspondence between twisted constant groups and groups of multiplicative type, one must start from a group of multiplicative type  $H$ , and study  $R = D_{\{S\}}(H)$ . If the latter is representable, it is obviously a twisted constant group, and one will have  $H \simeq D_{\{S\}}(R)$ . In other words:

**Scholie 5.4.0.** \*The functor  $R \mapsto D_{\{S\}}(R)$  is an anti-equivalence [N.D.E-X-33] between the category of twisted constant groups over  $S$  and that of groups of multiplicative type  $H$  over  $S$  such that  $D_{\{S\}}(H)$  is representable.\*

<!-- label: III.X.5.4.0 -->

<!-- original page 101 -->

I do not know whether this condition on  $H$  is always satisfied; we shall see however that it is satisfied when  $H$  is quasi-isotrivial, in particular when  $H$  is of finite type.

**Lemma 5.4.** \*Let  $S' \rightarrow S$  be a faithfully flat morphism locally of finite presentation,  $X'$  an  $S'$ -prescheme separated, locally of finite presentation and locally quasi-finite over  $S'$ .\*

<!-- label: III.X.5.4 -->

Then every descent datum on  $X'$  relative to  $S' \rightarrow S$  is effective, i.e. there exists an  $S$ -prescheme  $X$ , and an  $S'$ -isomorphism  $X \times_{\{S\}} S' \simeq X'$  compatible with the descent datum.\*

We have already noted that the hypothesis on  $S' \rightarrow S$  implies that it is a morphism covering for the faithfully flat quasi-compact topology (IV 6.3.1 (iv)), *a fortiori* a morphism of effective descent.

When  $X' \rightarrow S'$  is quasi-compact, hence of finite presentation and quasi-finite, then it is a quasi-affine morphism (cf. SGA 1, VIII 6.2 [N.D.E-X-34]), and effectivity follows in this case from SGA 1, VIII 7.9. In the general case, one reduces at once to the case where  $S$  and  $S'$  are affine. One covers  $X'$  by affine open sets  $U'_i$ ; let  $V'_i$  be the saturation of  $U'_i$  for the equivalence relation in  $X'$  defined by the descent datum, i.e.  $V'_i = q_2(q_1^{-1} \cup \{1\}(U'_i))$ , where  $q_1, q_2$  are the two projections of  $X' \times_{\{S\}} S' = X' \times_{\{S\}} (S', p_1)$  onto  $X'$  ( $q_1 = pr_1$ , and  $q_2$  is deduced from the first projection of  $X' \times_{\{S\}} S' = X' \times_{\{S\}} (S', p_2)$  thanks to the given descent isomorphism  $X' \times_{\{S\}} S' \simeq X' \times_{\{S\}} S'$ ). Since  $S' \rightarrow S$  is faithfully flat quasi-compact locally of finite presentation, the same holds for  $p_1 : S' \rightarrow S = S \times_{\{S\}} S' \rightarrow S$ , hence also for  $q_1$  and  $q_2$ , which are consequently open morphisms (SGA 1 IV 6.6 [N.D.E-X-35]). Consequently,  $V'_i$  is an open and quasi-compact part of  $X'$ . By what we have already seen, the descent data induced on the  $V'_i$  are effective, whence it follows that the descent datum on  $X'$  is so (SGA 1, VIII 7.2).

**\*\*Corollary 5.5.\*\*** \*A faithfully flat morphism of finite presentation  $S' \rightarrow S$  is a morphism of effective descent for the fibered category of twisted constant groups (over variable base preschemes).\*

<!-- label: III.X.5.5 -->

<!-- original page 102 -->

Indeed, this amounts to asserting the effectivity of a descent datum under the conditions of 5.4, when  $X$  is a constant  $S$ -prescheme.

**\*\*Theorem 5.6.\*\*** \*Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -preschemes in groups of quasi-isotrivial multiplicative type, with  $G$  of finite type.\*

<!-- label: III.X.5.6 -->

Then  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  is representable by, and is a quasi-isotrivial twisted constant group over  $S$ ; \*for every  $s$  in  $S$ , if the type at  $s$  of  $G$  (resp.  $H$ ) is  $M$  (resp.  $N$ ), that of  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  is  $\operatorname{Hom}_{\text{gr.}}(M, N)$ .\*

One proceeds as in 4.2, using the fact that the assertion is established (VIII 1.5) when  $G$  and  $H$  are trivial. The necessary effectivity criterion is furnished by 5.5 (in the case of an étale surjective morphism  $S' \rightarrow S$ ).

In particular, taking  $G = G_{\{m, S\}}$ , one finds:

**\*\*Corollary 5.7.\*\*** \*(i) Let  $H$  be a quasi-isotrivial  $S$ -group of multiplicative type; then the  $S$ -group  $D_{\{S\}}(H)$  is representable and is a quasi-isotrivial twisted constant group over  $S$ .\*

<!-- label: III.X.5.7 -->

(ii) The functors  $R \mapsto D_{\{S\}}(R)$  and  $H \mapsto D_{\{S\}}(H)$  are anti-equivalences, quasi-inverse to one another, between the category of quasi-isotrivial twisted constant  $S$ -groups and that of quasi-isotrivial  $S$ -groups of multiplicative type.\*

(iii) These functors induce anti-equivalences between the subcategories formed by the isotrivial, resp. locally isotrivial, resp. locally trivial, resp. trivial groups.\*

The last assertion is included only for the record, being already contained in 5.3.

Moreover, since every  $S$ -group of multiplicative type and of finite type is quasi-isotrivial by 4.5, one deduces from 5.6:

**\*\*Corollary 5.8.\*\*** \*Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -preschemes in groups of multiplicative type and of finite type. Then  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  is representable and is a finitely generated quasi-isotrivial twisted constant  $S$ -group.\*

<!-- label: III.X.5.8 -->

Let us note also that in 5.3,  $R$  is finitely generated if and only if  $H = D_{\{S\}}(R)$  is of finite type (IX 2.1 b)). By 4.5,  $H$  is then quasi-isotrivial, hence  $R$  is quasi-isotrivial. One thus finds:

<!-- original page 103 -->

**\*\*Corollary 5.9.\*\*** \*The functors of 5.7 induce anti-equivalences quasi-inverse to one another between the category of  $S$ -groups  $H$  of multiplicative type of finite type, and that of finitely generated twisted constant  $S$ -groups  $R$ ; moreover, every such group  $R$  is quasi-isotrivial.\*

<!-- label: III.X.5.9 -->

**\*\*Corollary 5.10.\*\*** \*Let  $H$ ,  $G$  be two  $S$ -preschemes in groups of multiplicative type and of finite type.\*

<!-- label: III.X.5.10 -->

(i) Then  $\operatorname{Isom}_{S\text{-gr.}}(H, G)$  is representable by an open and closed subprescheme of  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$ , and it is a twisted constant  $S$ -prescheme.\*

\*(ii) In particular,  $\operatorname{Aut}_{\{S\text{-gr.}\}}(H)$  is representable and is a twisted constant  $S$ -group (in general non-commutative).\*

This follows from 5.8 and from VIII 1.6.[^N.D.E-X-38]

**Recall 5.11.0.**[^N.D.E-X-39] Recall that if  $X$  is a locally noetherian prescheme, its connected components (which are always closed) are open. Indeed, let  $C$  be a connected component of  $X$ ,  $x \in C$  and  $U$  a noetherian open neighborhood of  $x$ ; then  $U$  has only a finite number of connected components, hence the connected component  $U_x$  of  $x$  in  $U$  is open in  $U$  hence in  $X$ ; since  $U_x \subseteq C$ , this shows that  $C$  is open in  $X$ .

<!-- label: III.X.5.11.0 -->

**Proposition 5.11.** \*Let  $S$  be a prescheme,  $R$  a commutative twisted constant group over  $S$ ,  $H = D_{\{S\}}(R)$  the group of multiplicative type that it defines. Consider the following conditions:\*

<!-- label: III.X.5.11 -->

(i)  $H$  is isotrivial (i.e.  $R$  is isotrivial).\*

(ii)  $R$  is the union of subpreschemes both open and closed  $R_{\{i\}}$ , which are quasi-compact over  $S$  (and then necessarily finite over  $S$ ).\*

(iii) The connected components of  $R$  are finite over  $S$ .\*

a) Then (i)  $\Rightarrow$  (ii)  $\Rightarrow$  (iii).[^N.D.E-X-40]

b) One has (i)  $\Leftrightarrow$  (ii)  $\Leftrightarrow$  (iii) if  $S$  is locally noetherian.\*

c) Finally, (i)  $\Leftrightarrow$  (ii) if  $R$  is finitely generated (i.e. if  $H$  is of finite type over  $S$ ), at least if  $S$  is quasi-compact or if its connected components are open.\*

Decomposing first  $S$  into a prescheme sum of preschemes  $S_{\{i\}}$  on each of which  $H$  is of constant type (cf. IX 1.4.1), we are reduced to the case where  $H$  hence  $R$  is of constant type  $M$ . We shall need:

**Lemma 5.12.** \*Let  $S$  be a prescheme,  $R$  a twisted constant prescheme over  $S$ . Then every closed subprescheme  $Z$  of  $R$  which is quasi-compact over  $S$  is finite over  $S$ .\*

<!-- label: III.X.5.12 -->

Indeed, one reduces to the case where  $R$  is constant, hence of the form  $I_S$ , where  $I$  is a set, <!-- original page 104 --> hence the filtered increasing union of the  $J_S$ , where  $J$  runs through the finite subsets of  $I$ . One may moreover suppose  $S$  affine; then  $Z$  is quasi-compact, hence contained in one of the  $J_S$ . Since  $J_S$  is finite over  $S$ , the same holds for  $Z$ .

Lemma 5.12 already establishes the parenthesized assertion in 5.11 (ii).[^N.D.E-X-41] The implication (ii)  $\Rightarrow$  (iii) is then clear, since the connected components of  $R$  are closed; by 5.11.0 they are open and closed if  $S$  is locally noetherian ( $R$  being étale, hence locally of finite type over  $S$ ), whence (iii)  $\Rightarrow$  (ii) in this case.

Let us prove that (i)  $\Rightarrow$  (ii). For this, let  $S' \rightarrow S$  be an étale finite surjective morphism splitting  $H$  hence  $R$  (cf. 5.3), so that  $R'$  is isomorphic to  $\coprod_{\{m\} \in M} R'_{\{m\}}$ , where the  $R'_{\{m\}}$  are disjoint open sets of  $R'$ ,  $S' \rightarrow S$  isomorphic to  $S' \rightarrow S$ . Let  $g : R' \rightarrow R$  be the projection, which is a finite étale surjective morphism, hence an open and closed morphism; then the  $R_{\{m\}} = g(R'_{\{m\}})$  are open and closed parts of  $R$ , and obviously quasi-compact over  $S$  since the  $R'_{\{m\}}$  are so.

Finally, suppose  $H$  of finite type over  $S$ , and let us prove (ii)  $\Rightarrow$  (i). The case where the connected components of  $S$  are open reduces at once to the case where  $S$  is connected, so we may suppose  $S$  quasi-compact or connected. Since  $M$  is finitely generated, one can write  $M = \mathbb{Z}^r \times N$ , where  $r$  is an integer  $\geq 0$  and  $N$  a finite abelian group. Let  $G = D_{\{S\}}(M)$ ; consider the preschemes

```
```text
P = Isom_{S-gr.}(H, G) \subset Hom_{S-gr.}(H, G) = Q
```
```

(cf. 5.8 and 5.10). One has isomorphisms

```

```text

$$Q \simeq \operatorname{Hom}_{\{S\text{-gr.}\}}(M_S, R) \simeq \operatorname{Hom}_{\{S\text{-gr.}\}}(\mathbb{Z}^r_S, R) \times \operatorname{Hom}_{\{S\text{-gr.}\}}(N_S, R) \simeq R^r \times E,$$

```

```

where  $E = \operatorname{Hom}_{\{S\text{-gr.}\}}(N_{\{S\}}, R)$  is finite over  $S$ . It follows that  $Q$  is the union of subpreschemes both open and closed  $Q_i$  finite over  $S$ . Therefore  $P$  is the union of the subpreschemes both open and closed  $P_i = P \cap Q_i$ , finite over  $S$ . Since they are étale over  $S$ , their images in  $S$  are parts  $S_i$  both open and closed, and they cover  $S$ . If  $S$  is connected or quasi-compact, there therefore exists a finite set  $I$  of indices  $i$  such that the  $S_i$  cover  $S$ ; let  $S'$  be the union of the corresponding  $P_i$ . Then  $S' \rightarrow S$  is finite étale surjective, and setting  $P' = P \times_S S' = \operatorname{Isom}_{\{S\text{-gr.}\}}(H', G')$ , one sees that  $P'$  has a section over  $S'$ , hence there exists an isomorphism of  $S'$ -groups

```

```text

$$H' = H \times_S S' \rightarrow G' = G \times_S S' = D_{\{S'\}}(M),$$

```

```

which proves that  $S'$  splits  $H$ . This completes the proof of 5.11. [N.D.E-X-43]

**Remark 5.11 bis.** Let us note moreover that one can, when  $H$  is of finite type over  $S$  and of constant type, give the following isotriviality criterion (in which it is no longer necessary to make any restriction on  $S$ ):  $H = D_{\{S\}}(R)$  is isotrivial if and only if  $R$  is the union of a sequence of parts both open and closed finite over  $S$ . [N.D.E-X-44]

« label: III.X.5.11bis »

**Lemma 5.13.** Let  $S$  be a locally noetherian and connected prescheme,  $P$  a quasi-isotrivial twisted constant  $S$ -prescheme,  $Z$  a part both open and closed of  $P$ , such that there exists an  $s \in S$  with  $Z_s$  finite. Then  $Z$  is finite over  $S$ .

« label: III.X.5.13 »

Let us first not suppose  $S$  connected: let  $U$  be the set of  $s \in S$  such that  $Z_s$  is finite; we shall prove that  $U$  is both open and closed, and that  $Z|_U$  is finite over  $U$ . This is a statement essentially equivalent to 5.13 but has the advantage of being "of local nature" on  $S$  for the étale topology (say), which reduces us to the case where  $P$  is constant, i.e. of the form  $I_S$ , where  $I$  is a set. (N.B. the locally noetherian hypothesis is not lost by an étale base change; this is where we use the quasi-isotriviality of  $P$  over  $S$ .)

One may moreover suppose  $S$  connected, since its connected components are open ( $S$  being locally noetherian). But then one necessarily has  $Z = J_{\{S\}}$ , where  $J$  is a part of  $I$ , and one therefore has  $U = \emptyset$  or  $U = S$ , depending on whether  $J$  is infinite or finite, which gives the desired conclusion.

**Recalls 5.14.0.** [N.D.E-X-45] Let  $S$  be a locally noetherian prescheme, and let  $\tilde{S}$  be the normalization of  $S$  (cf. EGA II, 6.3.8). Recall that  $S$  is said to be *geometrically unibranch* (cf. EGA 0\_IV, § 23.2 and IV<sub>2</sub>, § 6.15) if the canonical morphism  $\tilde{S} \rightarrow S$  is radicial (and hence a universal homeomorphism); in particular, the connected components of  $S$  are irreducible.

« label: III.X.5.14.0 »

Suppose then  $S$  connected, hence irreducible, let  $\eta$  be its generic point and let  $f : P \rightarrow S$  be a flat and locally quasi-finite morphism. Let  $P_i$  be the irreducible components of  $P$ , and  $\xi_i$  the generic point of  $P_i$ . Since  $P$  is flat over  $S$ , each  $\xi_i$  lies above  $\eta$  (cf. EGA IV<sub>2</sub>, 2.3.4), and so  $(P_i)_{\eta} = P_i \cap P_{\eta}$  is the closure of  $\xi_i$  in  $P_{\eta}$ . Since the fiber  $P_{\eta}$  is discrete, one therefore has  $(P_i)_{\eta} = \{\xi_i\}$ . This applies in particular when  $f$  is étale; in this case,  $P$  is also locally noetherian and geometrically unibranch (cf. EGA IV<sub>4</sub>, 17.5.7), so its irreducible components are its connected components and are open (and closed).

**Corollary 5.14.** Let  $S$  be a locally noetherian and geometrically unibranch prescheme,  $P$  a quasi-isotrivial twisted constant  $S$ -prescheme. Then the connected components of  $P$  are finite over  $S$ .

« label: III.X.5.14 »

One may obviously suppose  $S$  connected hence irreducible, and let  $\eta$  be its generic point. By what precedes, each connected component  $P_i$  of  $P$  is open and closed, and meets the fiber  $P_{\eta}$  at a single point. Therefore 5.13 applies and shows that each  $P_i$  is finite over  $S$ .

**\*\*Theorem 5.16.\*\***[<sup>N.D.E-X-46</sup>] \*Let  $S$  be a locally noetherian and geometrically unibranch prescheme. Then every  $S$ -group of multiplicative type and of finite type is isotrivial.\*

<!-- label: III.X.5.16 -->

One may indeed suppose  $S$  connected, hence  $H$  of constant type  $M$ . It suffices to apply 5.14 to  $P = \text{Isom}_{\{S\text{-gr.}\}}(H, G)$ , where  $G = D_{\{S\}}(M)$ , then to argue as in the proof of 5.11 (ii)  $\Rightarrow$  (i). One may also apply 5.14 to  $P = R = D_{\{S\}}(H)$  (cf. 5.9), then use 5.11.

## ## 6. Infinite Galois principal covers and the enlarged fundamental group

(The results of the present N° and of the following will no longer be used in the sequel of this Seminar.)

Let  $S$  be a prescheme; we propose to determine the principal homogeneous bundles  $P$  over  $S$  with structural group of the form  $G_S$ , the constant  $S$ -group defined by an ordinary group  $G$  (not necessarily finite), which we shall also call *Galois principal bundles* over  $S$  with group  $G$ . <!-- original page 107 --> We take "principal bundle" in the sense of the faithfully flat quasi-compact topology (cf. Exp. IV, Def. 5.1.5), but we shall note that for such a  $P$ , the structural morphism  $P \rightarrow S$  is necessarily étale and surjective, hence covering for the étale topology; consequently  $P$  is also locally trivial for the étale topology (cf. IV, Prop. 5.1.6). [<sup>N.D.E-X-47</sup>]

We shall assume that  $S$  is a sum of connected preschemes, i.e. that its connected components are open, which reduces us at once to the case where  $S$  is connected. We shall then choose a "geometric point"  $\xi$  of  $S$ , i.e. an  $S$ -scheme  $\xi$  which is the spectrum of an algebraically closed field  $\Omega = \kappa(\xi)$ . Then for every Galois principal bundle  $P$  over  $S$  with group  $G$ ,  $P_{\xi}$  is a Galois principal bundle over the algebraically closed field  $\kappa(\xi)$ , hence is trivial. We shall therefore make the initial problem precise by proposing to determine the category of Galois principal bundles over  $S$  \*pointed\* above  $\xi$ , i.e. endowed with an  $S$ -homomorphism  $\xi \rightarrow P$ , i.e. with a trivialization of  $P_{\xi}$ . For fixed  $G$ , the set of classes of such bundles, up to an isomorphism respecting the base point, will be denoted by  $\bar{\pi}^1(S, \xi; G)$ . Then the set  $\bar{\pi}^1(S; G)$  of isomorphism classes of Galois principal bundles over  $S$  with group  $G$  (without a specified base point) is isomorphic to the set of orbits of  $G$  in  $\bar{\pi}^1(S, \xi; G)$  (taking into account the natural operations of  $G$  on this set, corresponding to translation by  $G$  of the marked point in a pointed Galois principal bundle  $P$ ):

```
``text

$$\pi^{-1}(S; G) = \pi^{-1}(S, \xi; G)/G.$$

````
```

For every morphism $S' \rightarrow S$ which is a morphism of universal effective descent for the fibered category of twisted constant preschemes over a variable base (for example $S' \rightarrow S$ faithfully flat and locally of finite presentation, cf. 5.4; for other examples cf. SGA 1 IX), we propose to determine the subsets of the preceding sets, denoted $\bar{\pi}^1(S'/S, \xi; G)$ and <!-- original page 108 --> $\bar{\pi}^1(S'/S; G)$, formed by the Galois principal bundles over S which become trivial on S' (or, as one says, are "split" by S'). One will in fact determine the category of Galois principal bundles P over S which are split by S' . Of course, one will then have

```
``text

$$\pi^{-1}(S, \xi; G) = \lim_{S'} \pi^{-1}(S'/S, \xi; G),$$

````
```

where in the second member,  $S'$  runs over a cofinal system in the set of  $S'/S$  covering for the étale topology (for example, when  $S$  is quasi-compact, the set of  $S'$  over  $S$  which are quasi-compact and with étale and surjective structural morphism). Likewise, the category of Galois principal bundles over  $S$  will be the inductive limit of the subcategories defined by the  $S'$  (formed of the bundles which are split over  $S'$ ).

Thanks to the hypothesis made on  $S'/S$ , the category of Galois principal bundles over  $S$  split by  $S'$  is equivalent to the category of trivial Galois principal bundles over  $S'$  (hence of the form  $G_{\{S'\}}$ , where  $G$  acts by right translations), endowed with a descent datum relative to  $S' \rightarrow S$ . The datum of a base point on a Galois principal bundle  $P$  over  $S$  split by  $S'$  amounts, in terms of the corresponding trivial bundle  $P'$  over  $S'$  and its descent datum, to the datum of a trivialization of  $P' \times_{S'} S'_{\xi}$  compatible with the induced descent datum, relative to  $S'_{\xi} \rightarrow \xi$  (N.B. we have set  $S'_{\xi} = S' \times_S \xi$ ), i.e. a section  $\sigma$  of  $P'_{\xi}$  over  $S'_{\xi}$  compatible with the descent datum. There is then advantage, for an arbitrary  $S$ -prescheme  $S'$  (for which one no longer supposes that  $S' \rightarrow S$  is a morphism of universal effective descent for the fibered category of twisted constant bundles...), in defining  $\bar{\pi}^1(S'/S; G)$  and  $\bar{\pi}^1(S'/S, \xi; G)$  as the set of classes, up to isomorphism, of the structures with descent data just specified. One then obtains, for these functors in  $G$ , a very simple simplicial description, in terms of the fibered square and cube  $S''$  and  $S'''$  of  $S'$  over  $S$ , which we shall sketch below (cf. 6.3).

<!-- original page 109 -->

The important conclusion to retain will be the following:

**\*\*Proposition 6.1.\*\*** \*Suppose that the connected components of  $S'$  and  $S''$  are open, and, for example, that the quotient set of  $\pi_0(S')$  by the equivalence relation induced by the two projections  $\pi_0(S'') \rightarrow \pi_0(S')$  is a single point.\*<sup>[N.D.E-X-48]</sup>

<!-- label: III.X.6.1 -->

(i) The functor  $G \mapsto \bar{\pi}_1(S'/S, \xi; G)$ , from the category of groups to the category of sets, is representable by a group, denoted  $\pi_1(S'/S, \xi)$  and called the fundamental group of  $S'$  at  $\xi$  relative to  $S'$ . One thus has a functorial bijection:

$$\pi_1(S'/S, \xi; G) \cong \text{Hom}_{\text{gr.}}(\pi_1(S'/S, \xi), G).$$

(ii) This group has a set of generators in bijection with  $\pi_0(S'')$ , and is described in terms of these generators by relations in bijection with the elements of  $\pi_0(S'')$ .<sup>[N.D.E-X-49]</sup> In particular,  $\pi_1(S'/S, \xi)$  is finitely generated (resp. of finite presentation) if  $\pi_0(S'')$  (resp. as well as  $\pi_0(S'')$ ) is finite.\*

(iii) The category of Galois principal bundles over  $S$  split by  $S'$ , with base point above  $\xi$ , is equivalent to the category of ordinary groups  $G$ , endowed with a homomorphism of  $\pi_1(S'/S, \xi)$  into  $G$ .\*

The proof is given below, cf. ....

**\*\*6.2.\*\*** When  $S$  is a connected locally noetherian prescheme, which implies that every étale prescheme  $S'$  over  $S$  is locally noetherian hence has its connected components open, one concludes from what precedes<sup>[N.D.E-X-50]</sup> that the functor  $G \mapsto \bar{\pi}_1(S, \xi; G)$ , from the category of ordinary groups to the category of sets, is strictly pro-representable (cf. \*Séminaire Bourbaki\*, February 1960, N° 195, §§ A.2 and A.3), i.e. there exists a projective system

<!-- label: III.X.6.2 -->

$$\Pi = \varprojlim \Pi_1(S; \xi) = (\pi_i)_{i \in I}$$

of ordinary groups over a filtered increasing index set  $I$ , which is "strict" <!-- original page 110 --> (i.e. with surjective transition morphisms  $\pi_j \rightarrow \pi_i$ ), and an isomorphism of functors in  $G$

$$\pi_1(S, \xi; G) \cong \varprojlim_i \text{Hom}_{\text{gr.}}(\pi_i, G).$$

The second member is also simply denoted  $\text{Hom}_{\text{pro-gr.}}(\Pi, G)$  (cf. loc. cit.).

In the case where the projective limit  $\Pi = \varprojlim \pi_i$  is "sufficiently large", more precisely when the canonical homomorphisms  $\Pi \rightarrow \pi_i$  are surjective, it is appropriate to endow  $\Pi$  with the projective limit topology of the discrete topologies of the  $\pi_i$ , and the preceding isomorphism is also written:

$$\pi_1(S, \xi; G) \cong \text{Hom}_{\text{gr. top.}}(\Pi, G),$$

where the second member denotes the set of homomorphisms of topological groups, it being understood that  $G$  is endowed with the discrete topology.

The hypothesis just formulated on the projective system  $\Pi$  is verified, as is well known, when the  $\pi_i$  are finite groups (cf. [BEns], III § 7.4, Th. 1). This last condition obviously also means that every Galois principal bundle over  $S$  is isotrivial, i.e. is split by an étale surjective finite morphism. This is the case when  $S$  is geometrically unibranch (for example normal), as follows at once from 5.14.<sup>[N.D.E-X-51]</sup> In the case where the  $\pi_i$  are finite, the group  $\pi$  coincides also with the fundamental group  $\pi_1(S, \xi)$  introduced in SGA 1, V.

Also, in the favorable case ( $\pi$  to  $\pi_i$  surjective) one could call  $\pi$  the \*enlarged fundamental group of  $S$  at  $\xi$ . Outside of this favorable case,  $\pi$  itself is hardly of interest, and the role of the usual fundamental group is played by the projective system  $\Pi$  itself, which one will call the \*enlarged fundamental pro-group of  $S$  at  $\xi$ . (Any terminological suggestion better than "enlarged" is welcome! [N.D.E-X-52]). One will note that knowledge of this pro-group is more precise than that of the usual fundamental group  $\pi_1(S, \xi)$  of SGA 1 V; more precisely, the latter is the projective limit of the projective system formed by the finite quotients of the  $\pi_i$ .

**6.3.** Let us indicate rapidly the "computation" of  $\pi_1(S'/S, \xi)$ . Let  $S_i$  be the  $(i + 1)$ -th fibered power of  $S'$  over  $S$  (i.e.  $S_0 = S'$ ,  $S_1 = S'^2$ , etc.). One has between the  $S_i$  obvious simplicial operations, which make  $(S_i)_{i \in \mathbb{N}}$  a simplicial object of  $(\text{Sch})/S$ .

<!-- label: III.X.6.3 -->

<!-- original page 111 -->

Transforming this simplicial object by the functor "set of connected components"

$$\pi_0 : (\text{Sch})/S \longrightarrow (\text{Ens}),$$

one finds a simplicial set  $K_{\bullet} = (K_i)_{i \in \mathbb{N}}$ , with  $K_i = \pi_0(S_i)$ .

Likewise, the  $S_i(\xi)$  ( $= (i + 1)$ -th fibered power of  $S'(\xi)$  over  $S(\xi)$ ) form a simplicial object of  $(\text{Sch})/\xi$  hence of  $(\text{Sch})/S$ , moreover endowed with a natural homomorphism of simplicial objects into  $(S_i)_{i \in \mathbb{N}}$ , whence a simplicial set  $k_{\bullet}$  (with  $k_i = \pi_0(S_i(\xi))$ ) and a canonical homomorphism

$$k_{\bullet} \longrightarrow K_{\bullet}.$$

We can form a new simplicial set by taking the cone of this morphism (cf. 9.5.1):

$$\tilde{K}_{\bullet} = \text{Cone}(k_{\bullet} \longrightarrow K_{\bullet}).$$

[N.D.E-X-53] In this way, one obtains a "pointed simplicial set"  $\tilde{K}_{\bullet}$  (i.e. a simplicial set endowed with a homomorphism  $\tilde{\xi} : \tilde{e}_{\bullet} \rightarrow \tilde{K}_{\bullet}$ , where  $\tilde{e}_{\bullet}$  is the final simplicial set). We can construct its well-known combinatorial invariants  $\pi_0(\tilde{K}_{\bullet})$ ,  $\tilde{\xi}$  and  $\pi_1(\tilde{K}_{\bullet}, \tilde{\xi})$ , whose construction involves only the components of degree  $\leq 1$  resp. of degree  $\leq 2$ . These invariants are defined without restriction on  $S$  or  $S'$ . One then verifies without difficulty, when the connected components of  $S_0$  and  $S_1$  are open and  $\tilde{K}_{\bullet}$  is connected, [N.D.E-X-54] that  $\pi_1(\tilde{K}_{\bullet}, \tilde{\xi})$  represents the functor  $G \mapsto \bar{\pi}_1^{\text{ét}}(S'/S, \xi; G)$ , i.e. one has:

```text  
 $\pi_1(S'/S; \xi) \cong \pi_1(K_{\bullet}, \xi).$

Let us also signal that when the morphism $S' \rightarrow S$ is "universally submersive" (cf. SGA 1, IV 2.1), and the connected components of S' are open, then [N.D.E-X-55] <!-- original page 112 --> the simplicial set $K_{\bullet}$, hence also $\tilde{K}_{\bullet}$, is connected.

Examples 6.4. It remains to give examples of enlarged fundamental groups. Let us take up the examples of 1.6, i.e. let k be an algebraically closed field, C_1 a complete rational curve over k , having exactly one singular point, this point being an ordinary double point, and C_2 a curve which is the union of two irreducible components, isomorphic to P^1_k and meeting at exactly two points, which are ordinary double points of C_2 . In either case, the enlarged fundamental group of the curve is isomorphic to $\mathbb{Z}$. [N.D.E-X-56]

<!-- label: III.X.6.4 -->

In general, there would be reason to take up (simplifying and rectifying them) the results of SGA 1 IX 5, in the

framework of the enlarged fundamental group. The examples of loc. cit., 5.5 would give as many examples of enlarged fundamental pro-groups which are not profinite. Thus, if instead of an ordinary double point, one took in the first example a double point with n distinct branches, [N.D.E-X-57] one would find as enlarged fundamental group the free (discrete!) group on $n - 1$ generators.

7. Classification of twisted constant preschemes and of groups of multiplicative type of finite type in terms of the enlarged fundamental group

7.0. Let S be a prescheme, which we still assume locally noetherian, to ensure that S and certain preschemes over S that we shall consider (original page 113) (notably those étale over S , more generally those locally of finite type over S) are locally connected.

Proposition 7.0.1. Every twisted constant prescheme X over S which is locally trivial for the (fppf) topology (i.e. which is split by a faithfully flat morphism locally of finite presentation $S' \rightarrow S$) is quasi-isotrivial (i.e. one can even choose $S' \rightarrow S$ étale surjective).

label: III.X.7.0.1

Indeed, one may suppose S connected, hence X of type I , where I is a fixed set. Therefore $X' = X \times_S S'$ is isomorphic to $I_{S'}$, hence $I_{S'}$ is endowed with a descent datum relative to $S' \rightarrow S$, i.e. one has an isomorphism $I_{S'} \xrightarrow{\sim} I_{S'}$ satisfying the usual transitivity condition. Now, $S' = S \times_S S'$ is locally noetherian hence locally connected, whence it follows that the automorphisms of $I_{S'}$ correspond to the sections of $G_{S'}$, where $G = \operatorname{Aut}(I)$ is the group of permutations of I .

In this way, one obtains a descent datum on $G_{S'}$ (considered as a trivial Galois principal bundle) relative to $S' \rightarrow S$. By 5.4 this descent datum is effective, whence a Galois principal bundle P over S , with group G . By construction, it represents the functor $\operatorname{Isom}_S(I_S, X)$ in the category of preschemes over S which are locally noetherian. Consequently, the étale surjective base change $P \rightarrow S$ splits X , so X is indeed quasi-isotrivial.

Remark 7.0.2. Beware that even if S is the spectrum of a field, it is not true in general that every twisted constant bundle over S is quasi-isotrivial. It suffices for example to take for X the scheme sum of a sequence of schemes of the form $\operatorname{Spec}(k_i)$, where the k_i are separable extensions of k of strictly increasing degrees.

label: III.X.7.0.2

The proof given above shows at the same time that the classification of twisted constant bundles X over S , quasi-isotrivial and of type I , is equivalent to that of Galois principal bundles over S with group $G = \operatorname{Aut}(I)$. It is even an equivalence of categories.

It can be put in a more convenient form as in SGA 1 V. For this, (original page 114) suppose S connected and equipped with a geometric point ξ . Consequently the enlarged fundamental pro-group $\Pi = \Pi_1(S, \xi)$ is defined. Moreover, for every quasi-isotrivial twisted constant bundle X over S , let $I = X(\xi)$ be its set-theoretic fiber at ξ . Therefore X is of type I , and consequently associated as we have just said with a Galois principal bundle $P = \operatorname{Isom}_S(I_S, X)$ over S , with group $G = \operatorname{Aut}(I)$.

By the definition of Π , one therefore obtains a canonical homomorphism of Π into G , i.e. of one of the Π_i into G . Since G is the group of permutations of $I = X(\xi)$, this means that Π "acts continuously on $I = X(\xi)$ ", it being understood that the Π_i (i large) act on I , in a way compatible with the transition morphisms.

We leave to the reader the verification that every S -morphism $X \rightarrow Y$ between quasi-isotrivial twisted constant bundles over S induces a map $X(\xi) \rightarrow Y(\xi)$ compatible with the operations of Π , and that the functor thus obtained is an equivalence of categories:

Proposition 7.0.3. Let S be a locally noetherian connected prescheme, ξ a geometric point of S , $\Pi = \Pi_1(S, \xi)$ the enlarged fundamental pro-group of S at ξ . Then the functor*

label: III.X.7.0.3

S
 $X \mapsto X(\xi)$
 S

is an equivalence between the category of quasi-isotrivial twisted constant bundles over S and the category of sets

on which π acts continuously.*

This functor is compatible with the operations of finite sums and finite inverse limits. It follows for example that the twisted constant groups (or rings etc.) quasi-isotrivial over S correspond to the ordinary groups (resp. rings etc.) on which the pro-group π acts continuously. In particular:

Corollary 7.0.4. *The category of commutative twisted constant groups quasi-isotrivial over S is equivalent to the category of " π -modules", i.e. of commutative groups M on which π acts continuously.*

<!-- label: III.X.7.0.4 -->

Using now 5.7 one concludes the:

Theorem 7.1. *Let S be a locally noetherian connected prescheme, ξ a geometric point of S , $\pi = \pi_1(S, \xi)$ the enlarged fundamental pro-group of S at ξ . Then the functor*

<!-- label: III.X.7.1 -->

$$G \mapsto \operatorname{Hom}_{\pi\text{-gr}}(G_{\xi}, G_{m, \xi})$$

*induces an anti-equivalence of the category of quasi-isotrivial groups of multiplicative type over S * <!-- original page 115 --> *with the category of π -modules.*

Using 4.5 one concludes:

Corollary 7.2. *The preceding functor induces an anti-equivalence of the category of groups of multiplicative type and of finite type over S with the category of π -modules which are of finite type over $\mathbb{Z}$.*

<!-- label: III.X.7.2 -->

Example 7.3. Take for example for S a complete rational curve over an algebraically closed field, having exactly one multiple point with $n + 1$ distinct branches. By 6.4, the enlarged fundamental group $\pi(S, \xi)$ is a free group on n generators. Therefore, by 7.2, the classification of tori of relative dimension m over S is equivalent to the classification of systems of n endomorphisms $A_1, \dots, A_n$ of the $\mathbb{Z}$ -module $\mathbb{Z}^m$, up to automorphism of $\mathbb{Z}^m$. Except for $n \leq m$ or $m \leq 1$, an explicit classification of such systems seems hopeless. One can at least define a multitude of non-trivial invariants for such a system, such as the characteristic polynomials of the A_i . [N.D.E-X-58]

<!-- label: III.X.7.3 -->

Remark 7.4. If one makes no hypothesis on S , it remains true that for a given ordinary commutative group M of finite type over $\mathbb{Z}$, the category of groups of multiplicative type of type M over S is anti-equivalent to the category of Galois principal bundles over S with group $G = \operatorname{Aut}_{\text{gr}}(M)$. This follows easily from 5.9 and 5.10.

<!-- label: III.X.7.4 -->

Remark 7.5. The theory of the fundamental pro-group that we have sketched in the present two numbers will be written more advantageously in the framework of general sites. In this form, it applies equally well, for example, to ordinary topological spaces, and gives a satisfactory theory at least for a locally connected topological space (not necessarily locally simply connected). In this case too it seems that one cannot be content with defining a fundamental group, and that a pro-group is needed. Finally, let us note that, once one has available the language of topologies and descent (which is really at the bottom of these questions), the exposition sketched here is also technically simpler than that of SGA 1 V, and should therefore in principle replace it.

<!-- label: III.X.7.5 -->

8. Appendix: Elimination of certain affineness hypotheses

<!-- original page 116 -->

Our aim is to prove the following generalization of 4.9.

****Theorem 8.1.**** *Let S be a prescheme, H an S -prescheme in groups flat and of finite presentation, with connected and affine fibers. [N.D.E-X-59] Let $s \in S$; suppose that H_s is a torus. Then there exists an open neighborhood U of s such that $H|_U$ is a torus.*

<!-- label: III.X.8.1 -->

One concludes immediately:

****Corollary 8.2.**** *Let H be an S -prescheme in groups, flat and of finite presentation over S . For H to be a torus, it is necessary and sufficient that its fibers be tori.*

<!-- label: III.X.8.2 -->

****Remark 8.3.**** Even when S is the spectrum of a discrete valuation ring, one cannot abandon in 8.1 the hypothesis that the fibers of H (here the generic fiber) be affine, since there are examples of smooth groups over S whose generic fiber is an elliptic curve, and whose special fiber is G_m .

<!-- label: III.X.8.3 -->

Proof of 8.1. One may obviously suppose $S = \operatorname{Spec}(A)$ affine, which reduces us by the standard procedure (cf. EGA IV₂, 8.8.2) to the case where S is moreover noetherian. We begin by proving 8.2 in this case.

By 4.9 we are reduced to proving that H is affine over S . We may therefore suppose [N.D.E-X-60] A noetherian local, and since the completion $\hat{A}$ is faithfully flat over A , we are reduced by descent to the case where A is a complete noetherian local ring. Let S' be the normalization of S ; one knows by Nagata that it is finite over S (EGA 0-IV, 23.1.5); moreover $S' \rightarrow S$ is surjective, so $H' = H \times_S S' \rightarrow H$ is finite and surjective, so to prove that H is affine, it suffices to show that H' is so (EGA II, 6.7.1).

<!-- original page 95 -->

[N.D.E-X-61] Replacing S by a connected component of S' , this reduces us to the case where A is a noetherian (semi-local) normal and integral ring. Moreover, possibly replacing A by its normalization in a finite separable extension of its field of fractions, <!-- original page 117 --> one may suppose that the generic fiber H_{η} of H is diagonalizable, i.e. that one has an isomorphism

$$u_{\eta} : H_{\eta} \rightarrow \sim T_{\eta},$$

where $T = G_{\{r\}}^{\{m, S\}}$. Now we have:

****Lemma 8.4.**** *Let S be a locally noetherian normal and irreducible prescheme, with generic point η , H a prescheme in groups over S smooth and with connected fibers, T a prescheme in groups of multiplicative type and of finite type over S , $u_{\eta} : H_{\eta} \rightarrow T_{\eta}$ a homomorphism of algebraic groups over $\kappa(\eta)$.*

<!-- label: III.X.8.4 -->

Then u_{η} extends to a homomorphism of groups $u : H \rightarrow T$.

Possibly replacing S by its normalization in a finite separable extension of its function field, one may suppose T diagonalizable (which is moreover the case in the application we have in view). Then T is a closed subgroup of a group of the form $G_{\{r\}}^{\{m, S\}}$, which reduces us to the case where $T = G_{\{m, S\}}$.

It all amounts to proving that u_{η} , considered as a rational map of H into $T = G_{\{m, S\}}$, is everywhere defined (since the morphism $u : H \rightarrow T$ extending it is then necessarily a homomorphism of groups). One may consider u_{η} as an invertible section f of the structural sheaf of H_{η} , and one must show that it extends to an invertible section of the structural sheaf of H . Now H , being smooth over the normal S , is normal (SGA 1, II 3.1), so it suffices to find a closed part Z of H of codimension ≥ 2 such that f extends to an invertible section of the structural sheaf of $H - Z$. This reduces us at once to the case where S is the spectrum of a discrete valuation ring A (by localizing at points of codimension 1 of S).

Let t be a uniformizer of A , t the section of $\mathcal{O}_H$ that it defines, so that the special fiber H_0 is equal to $V(t)$. By hypothesis H_0 is smooth over the residue field k , and connected. Then f is a rational function on H which has neither zeros nor poles in $H - H_0$; since $H_0 = V(t)$ is an irreducible divisor, there exists an integer $n \in \mathbb{Z}$ such that $t^{-n} f = t^n f$ has neither zeros nor poles, i.e. is an invertible section of $\mathcal{O}_H$. <!-- original

page 118 --> It therefore defines a morphism $v : H \rightarrow G_{m,S}$, and since $v_{\eta} = t'^{\{n\}} u_{\eta}$ and u_{η} is a homomorphism of groups, v transforms the unit section of H into a section of $G_{m,S}$ whose value at the generic point of S is $t^{\{n\}}$; since it is a question of a section of $G_{m,S}$, $t^{\{n\}}$ must be a unit, i.e. $n = 0$, so v extends u_{η} , which completes the proof of 8.4.

Applying this lemma to the present case, one finds a homomorphism of groups

```
```text
u : H → T = G^r_{m,S}
```

which induces on the generic fibers an isomorphism. Let us prove that  $u$  is an isomorphism.

**Lemma 8.5.** For every integer  $n > 0$  prime to the residual characteristic of  $A$ ,  $H = \text{Ker}(n \cdot \text{id}_H)$  is finite over  $S$ .

<!-- label: III.X.8.5 -->

If  $n$  is prime to the residual characteristic of  $A$ , it is prime to all the residual characteristics of points of  $S$ . Therefore  $n \cdot \text{id}_H$  induces on every fiber of  $H$  an étale morphism; consequently  $n \cdot \text{id}_H$  is étale (SGA 1, I 5.9), so its kernel  $H$  is étale over  $S$ . On the other hand,  $H$  is separated over  $S$  since  $H$  is is. [X-8-1] [N.D.E-X-62] Moreover, all its fibers have the same rank  $n^r$ , since the fibers of  $H$  are tori, all of the same dimension  $r$  ( $H$  being smooth over  $S$ ). One concludes that  $H$  is finite over  $S$  (SGA 1, I 10.9 or EGA IV<sub>4</sub>, 18.2.9).

Therefore, by the preceding lemma,  $u(H)$  is a closed part of  $T$ . Since on the generic fiber  $T_{\eta}$ , this part is identical to  $(T_{\eta})$ , it follows that it contains the closure of this part, namely  $(T)$ . Now for every  $s \in S$ , the  $(T_s)$  are dense in  $T_s$ ; since  $u_s(H_s)$  is a closed part (VI\_B 1.4.2) containing them, one sees that  $u_s(H_s) = T_s$ , so  $u$  is surjective. Since a surjective homomorphism of tori of the same dimension over a field is flat, [N.D.E-X-63] it follows that  $u$  induces on each fiber a flat morphism, so  $u$  is flat (SGA 1 I 5.9). Consequently,  $K = \text{Ker}(u)$  is flat over  $S$ , [N.D.E-X-64] hence equal to the closure of its generic fiber  $K_{\eta}$ . Now  $K_{\eta}$  is the unit group by construction, and since  $K$  is separated over  $S$  (since  $H$  is), its unit section is closed, whence it follows that  $K$  is the unit group. <!-- original page 119 --> Therefore  $u$  is a monomorphism; since we have seen that it is faithfully flat, it is therefore an isomorphism (cf. SGA 1, I 5.1 or EGA IV<sub>4</sub>, 17.9.1). This proves that  $H$  is a torus, hence completes the proof of 8.2. [N.D.E-X-65]

**Remark 8.5.1.** Instead of invoking 8.5 one can also invoke Zariski's "Main Theorem", which directly implies that  $u$  is an open immersion, hence an isomorphism. [N.D.E-X-66]

<!-- label: III.X.8.5.1 -->

To prove 8.1, we are reduced, thanks to the quasi-isotriviality theorem, to the case where  $S$  is local,  $s$  its closed point, [N.D.E-X-67] and to proving that, with the hypotheses made elsewhere,  $H$  is then a torus. By 8.2 already proved, we are reduced to proving that the fibers of  $H$  are tori. One may suppose  $S$  the spectrum of a complete noetherian local ring  $A$ . By 3.3 there exists for every  $n > 0$  a group of multiplicative type  $T_n$  finite over  $S$ , and an isomorphism  $(T_n)_s \simeq (H_s)$ , where  $s$  is the closed point of  $S$ . Proceeding as in 3.1 and using the fact that  $T_n$  is finite over  $S$ , [N.D.E-X-68] one sees that the preceding isomorphism comes from a homomorphism  $u_n : T_n \rightarrow H$ , moreover uniquely determined. (Pass to the limit over the artinian quotients of  $A$ .)

Moreover, by uniqueness properties,  $u_n : T_n \rightarrow H$  is deduced from  $u_m : T_m \rightarrow H$  by restriction to  $(T_n) \simeq T_n$  when  $m$  is a multiple of  $n$ . It follows from IX 6.6 that the  $u_n$  are monomorphisms, so the  $T_n$  are subgroups of  $H$ , and for  $m$  a multiple of  $n$ , one has  $T_n = (T_m)$ .

Therefore for every  $t \in S$ , the  $(T_n)_t$  are subgroups of  $H_t$ , of type  $(\mathbb{Z}/n\mathbb{Z})^r$  (where  $r = \dim H_s = \dim H_t$ ), such that for  $m$  a multiple of  $n$ , one has  $(T_n)_t = (T_m)_t$ . The fact that  $H_t$  is a torus now follows from:

**Lemma 8.6.** Let  $H$  be a smooth affine algebraic group over an algebraically closed field  $k$ ,  $(T_n)_{n > 0}$  a family of subgroups of multiplicative type of  $H$ , such that for every integer  $n > 0$ ,  $T_n$  is of type  $(\mathbb{Z}/n\mathbb{Z})^r$ , and for every multiple  $m$  of  $n$ , one has  $T_n = (T_m)$ .

<!-- label: III.X.8.6 -->

Under these conditions,  $H$  contains a torus of dimension  $\geq r$  containing the  $T_n$ , <!-- original page 120 --> so if  $H$  is connected of dimension  $\leq r$ ,  $H$  is a torus of dimension  $r$ .

This is an exercise on affine algebraic groups, which we shall treat by reference to \*Bible\*. We confine ourselves to considering the  $T_n$  for  $n$  prime to the characteristic. Let  $K$  be the closure of the union of the  $T_n$  in  $H$ , endowed with the induced reduced structure; then standard arguments show that  $K$  is a commutative algebraic subgroup of  $H$ . By \*Bible\*, § 4.5, Th. 4,  $K$  is therefore isomorphic to a product  $K_u \times K_s$ , with  $K_u$  "unipotent" and  $K_s$  diagonalizable. Every diagonalizable subgroup of  $K$  is contained in  $K_s$ , so the  $T_n$  are subgroups of  $K_s$ , hence  $K = K_s$ . Write  $K = D(M)$ , with  $M$  an ordinary commutative group of finite type over  $\mathbb{Z}$ ; then  $T_n \subseteq K$  means that  $M$  admits a quotient group isomorphic to  $(\mathbb{Z}/n\mathbb{Z})^r$ . Since this is true for every integer  $n$  prime to the characteristic of  $k$  (it would suffice for powers of a fixed prime number), it follows that  $M$  is of rank  $\geq r$ , so  $K$  contains a torus of dimension  $r$ , say  $T$ . When  $H$  is connected of dimension  $r$ , it follows that  $T = H$ , which completes the proof of 8.6. Thus 8.1 is proved.

**Remarks 8.7.** Using 8.1, it should not be difficult to give analogous generalizations of 4.7 and 4.8. A more interesting study would be that of the situation in 8.1 where one abandons the hypothesis that the fibers of  $H$  be affine. One can show that there then exists an open neighborhood  $U$  of  $s$  such that  $H|_U$  is commutative and that for every  $t$  in  $U$ , the geometric fiber  $H_t$  is an extension of an abelian variety by a torus. [N.D.E-X-69] Of course, in questions of this kind, one may restrict oneself to the case where  $S$  is the spectrum of a discrete valuation ring,  $s$  its closed point,  $t$  its generic point.

<!-- label: III.X.8.7 -->

One can generalize this result as follows. For every algebraic group  $G$  connected smooth over an algebraically closed field  $k$ , a well-known theorem of Chevalley <!-- original page 121 --> tells us that  $G$  is (in a unique way) an extension of an abelian variety  $A$  by a smooth connected affine group  $V$ . Let us denote by \*abelian rank\* (resp. \*reductive rank\*, resp. \*nilpotent rank\*, resp. \*semisimple dimension\*) of  $G$ , and denote by  $\rho_{\text{ab}}(G)$  (resp.  $\rho_r(G)$ , resp.  $\rho_n(G)$ , resp.  $d_s(G)$ ), the dimension of  $A$ , resp. the dimension of the maximal tori of  $G$ , resp. the dimension of the Cartan subgroups [N.D.E-X-70] of  $G$ , resp. the dimension of the quotient of  $G$  (or also of  $V$ ) by its radical (cf. \*Bible\* for all these notions). Let us also introduce the \*unipotent rank\*  $\rho_u(G) = \rho_u(V) = \rho_n(G) - \rho_r(G) - \rho_{\text{ab}}(G)$ . When  $G$  is not over an algebraically closed field, we still denote by the same names and the same notations the corresponding invariants for  $G_{\bar{k}}$ , where  $\bar{k}$  is the algebraic closure of  $k$ .

This being so, let  $G$  be a smooth group scheme over the spectrum  $S$  of a discrete valuation ring; let  $\rho_{\text{ab}}$  etc. (resp.  $\rho'_{\text{ab}}$  etc.) be the invariants associated with the special fiber (resp. with the generic fiber); then one has the inequalities:

$$\begin{cases} \rho_{\text{ab}} \leq \rho'_{\text{ab}} \\ \rho_r + \rho_{\text{ab}} \leq \rho'_r + \rho'_{\text{ab}} \\ d_s \leq d'_s \end{cases} \quad \begin{cases} \rho_n \leq \rho'_n \\ \rho_u \leq \rho'_u \end{cases}$$

It amounts to the same to say that if  $G$  is smooth of finite type over an arbitrary base  $S$ , the functions  $s \mapsto \rho_{\text{ab}}(s)$ ,  $s \mapsto \rho_r(s) + \rho_{\text{ab}}(s)$ ,  $s \mapsto d_s(s)$  are lower semi-continuous, and the functions  $s \mapsto \rho_n(s)$ ,  $s \mapsto \rho_u(s)$  are upper semi-continuous. [N.D.E-X-71]

The same results probably remain valid without supposing  $G$  smooth over  $S$ , but simply flat of finite presentation over  $S$ , by agreeing to denote, for an algebraic group  $G$  over an algebraically closed field  $k$ , by  $\rho_{\text{ab}}(G)$  etc. the corresponding invariants of  $G^0_{\text{red}}$ .

In this Seminar, we present some results of this kind for  $G$  affine over  $S$ , or more generally with affine fibers:

<!-- original page 122 --> in this case, we shall verify the semi-continuity properties for  $\rho_r$ ,  $\rho_n$  hence for

$\rho_u = \rho_n - \rho_r$ , and the continuity of  $\rho_s$  in a neighborhood of a point  $s$  whose fiber is a reductive group. [N.D.E-X-71]

One can generalize 8.2 when one supposes already  $G$  commutative, as follows:

**Theorem 8.8.** [N.D.E-X-72] \*Let  $G$  be an  $S$ -prescheme in commutative groups which is flat and of finite presentation over  $S$ , with affine connected fibers. Let  $s$  in  $S$ , and suppose that\*

<!-- label: III.X.8.8 -->

\*a) if  $\bar{k}$  denotes an algebraic closure of  $k(s)$ ,  $G_{\bar{k}}_{\text{red}}$  is a torus.\*

\*b) There exists a generization  $t$  of  $s$  such that  $G_t$  is smooth over  $k(t)$ .\*

\*Under these conditions, there exists an open neighborhood  $U$  of  $s$  such that  $G|_U$  is a torus.\*

\*(Note moreover that if one supposes only that for every generization  $t$  of  $s$ ,  $G_t$  is affine resp. connected, one easily derives that the same conclusion is valid for  $t$  in an open neighborhood of  $s$ ).\*

\*Proof of 8.8.\* It suffices to prove that  $G_s$  is smooth over  $k(s)$ . Indeed, since  $G$  is flat of finite presentation over  $S$ , it then follows that  $G$  is smooth over  $S$  above a neighborhood of  $s$  (cf. 3.5), but then one is under the conditions of 8.1.

To prove that  $G_s$  is smooth over  $k(s)$ , the usual procedure reduces us to the case where  $S$  is affine noetherian. Choosing a homomorphism  $S' \rightarrow S$  from a spectrum of a discrete valuation ring  $S'$  into  $S$ , sending the closed point to  $s$  and the generic point  $\eta$  to  $t$ , we are reduced to the case where  $S$  is itself the spectrum of a discrete valuation ring, which may be assumed moreover complete with algebraically closed residue field, and where  $s = \eta$  are respectively the closed point and the generic point of  $S$ .

Therefore  $G$  is flat, separated, of finite type over  $S$ , the generic fiber  $G_{\eta}$  is smooth and connected, <!-- original page 123 --> and the special fiber  $G_0$  is such that  $T_0 = (G_0)_{\text{red}}$  is a torus. Let  $m$  be an integer  $> 0$  prime to the residual characteristic at  $s$ , hence also to that at  $\eta$ ; one knows then that  $m \cdot \text{id}_{G_s}$  is a fiber-by-fiber étale morphism (VII\_A 8.4), hence an étale morphism since  $G$  is flat over  $S$  (SGA 1 I 5.9), so its kernel  $\{_{m}G\}$  is étale over  $S$ , and since  $G$  is separated [X-8-2] [N.D.E-X-73] of finite type over  $S$ , so is  $\{_{m}G$ . Since  $\{_{m}G\}_0 = \{_{m}(T_0)$ , its degree is  $m^r$ , where  $r = \dim T_0 = \dim G_0 = \dim G$ . It follows that the rank of  $\{_{m}G\}_{\eta} = \{_{m}(G_{\eta})$  is  $\geq m^r$ , which proves already (using 8.6) that  $G_{\eta}$  is a torus of dimension  $r$ , since the two fibers of  $\{_{m}G$  have the same rank, hence as in 8.5 that  $\{_{m}G$  is finite over  $S$ . [N.D.E-X-74]

Note that since  $S$  is complete with algebraically closed residue field, the finite étale cover  $\{_{m}G$  decomposes completely, so through every point of  $\{_{m}G_0$  passes a section of  $G$  over  $S$ ; in particular, the set of points of  $G_0$  through which passes a section of  $G$  over  $S$  is everywhere dense. Now we have this:

**\*Lemma 8.9.\*** \*Let  $S$  be a locally noetherian regular prescheme of dimension 1,  $G$  an  $S$ -prescheme in groups flat and locally of finite type, such that  $G_{\eta}$  is smooth over  $k(\eta)$  for every maximal point  $\eta$  of  $S$  (which implies that  $G$  is reduced). Suppose that the normalized scheme  $X$  of  $G$  is finite over  $G$  (this is the case, by Nagata, if  $S$  is the spectrum of a complete discrete valuation ring, cf. EGA IV<sub>2</sub>, 7.7.4), and let  $G'$  be the open set of  $X$  formed by the points at which  $X$  is smooth over  $S$ . With these notations:\*

<!-- label: III.X.8.9 -->

\*a) If the projection  $G' \rightarrow S$  is surjective, then there exists on  $G'$  a unique structure of  $S$ -prescheme in groups such that the canonical morphism  $G' \rightarrow G$  is a homomorphism of groups.\*

\*b) Suppose that for every closed point  $s$  of  $S$ , the set of points of  $G^{\wedge}_{\{s\}}$  through which passes an étale quasi-section is dense in  $G^{\wedge}_{\{s\}}$  for the Zariski topology. Then  $X$  is regular, one is under the conditions of a), and the map  $\Gamma(G'/S) \rightarrow \Gamma(G/S)$  is bijective.\*

<!-- original page 124 -->

In the case of interest to us, this lemma applies and gives us a homomorphism of groups  $u : G' \rightarrow G$ , where  $G'$  is smooth over  $S$ , and  $u_{\eta}$  is an isomorphism  $G'_{\eta} \xrightarrow{\sim} G_{\eta}$ . Possibly replacing  $G'$  by an open subgroup, one may suppose that  $G'_0$  is connected, and since  $u_0 : G'_0 \rightarrow G_0$  induces a surjective morphism  $G'_0 \rightarrow T_0$ , where  $T_0$  is a torus of the same dimension as  $G'_0$ , one easily concludes that  $G'_0$  is a torus (for example using 8.6, or by referring to \*Bible\*, § 7.3, Th. 3 a)). Consequently, by 8.2  $G'$  is a torus, but then by IX 6.8,  $\text{Ker } u$  is a subgroup of multiplicative type of  $G'$ , and since its generic fiber is reduced to the unit group, it is the unit group, hence  $u$  is a monomorphism. Using now VIII 7.9 it follows that  $u$  is an immersion. Being surjective, and  $G$  being reduced, it follows that  $u$  is an isomorphism, which completes the proof of 8.8.

It remains to prove 8.9. To prove a), note that the uniqueness of the group law on  $G'$  making  $u : G' \rightarrow G$  a homomorphism of groups is clear, since one knows the group law of  $G$  on the generic fiber (supposing  $S$  irreducible, which is permissible). For existence, one reduces easily to the case where  $S$  is local, the spectrum of a discrete valuation ring  $A$ , and thanks to uniqueness, and to the fact that the operation of integral closure commutes with an étale base extension, one can make étale base extensions on  $S$ , which reduces us to the case where  $A$  is "strictly

local" i.e. henselian with separably closed residue field. The same reduction applies for b), but under the hypothesis made in b), one can now replace "étale quasi-section" by "section".

Note that  $G'$  being smooth over  $S$  and  $X$  normal,  $G' \times_S X$  is normal (since smooth over  $X$  which is normal), so the composite morphism  $G' \times_S X \rightarrow G \times_S G \rightarrow G$  factors as

```

```text
p : G' x_S X → X.
```

```

<!-- original page 125 -->

Let us prove that this last morphism induces on the open set  $G' \times_S G'$  of  $G' \times_S X$  a morphism

```

```text
G' x_S G' → G'.
```

```

One must therefore show that  $G'_{\{0\}} \times_{G'} G'_{\{0\}}$  is mapped into the open set  $G'_{\{0\}}$  of  $X_0$ ; it suffices to see that for every point  $g'_{\{0\}}$  of  $G'_{\{0\}}$  with values in  $k$ , the morphism

```

$$
(\times) \quad h'_{\{0\}} \mapsto p_{\{0\}}(g'_{\{0\}}, h'_{\{0\}})
$$

```

from  $G'_{\{0\}}$  into  $X_0$  takes its values in  $G'_{\{0\}}$ . Now since  $G'$  is smooth over  $S$  and  $S$  is henselian, every  $g'_{\{0\}}$  as above is induced by a section  $g'$  of  $G'$  over  $S$ , and one sees at once that the morphism  $(\times)$  above is then induced by the morphism  $h' \mapsto p(g', h')$  of  $G'$  into  $X$ , itself deduced by transport of structure from the automorphism  $h \mapsto g \cdot h$  of  $G$ , left translation by the section  $g$  of  $G$  image of  $g'$ . So  $h' \mapsto p(g', h')$  is itself an automorphism of  $X$ , hence maps  $G'$  into  $G'$ , which proves our assertion.

It remains to prove that the composition law thus obtained on  $G'$  is a group law. Associativity follows at once from the associativity of the generic fiber (isomorphic to that of  $G$ ). On the other hand, the symmetry automorphism of the  $S$ -prescheme  $G$  induces an automorphism of  $X$ , which therefore leaves  $G'$  stable and induces an automorphism  $\sigma$  of  $G'$ . One then verifies that the latter has the properties of an inverse for the composition law on  $G'$ , since this again reduces to verifying the commutativity of certain diagrams involving fibered powers of  $G'$  over  $S$ , and the latter being smooth over  $S$ , it suffices to verify the commutativity on the generic fiber, which is clear. This proves part a) of 8.9.

Let us prove b). Let  $Z$  be the set of  $x \in X$  such that  $0_{\{X,x\}}$  is non-regular; it is a closed part by a theorem of Nagata (EGA IV<sub>2</sub>, 6.12.6), <!-- original page 126 --> obviously contained in  $X_0$ ; let  $Z$  be its image in  $G$ , which is therefore a closed part of  $G_0$ . Then  $Z$  is a rare part of  $G_0$ , i.e. contains no maximal point  $y$  of  $G_0$ . Indeed, since  $G_0$  is defined in  $G$  by an equation  $t = 0$  (where  $t$  is a uniformizer of the discrete valuation ring  $A$ ),  $0_{\{G,y\}}$  is of dimension 1 by the Hauptidealsatz, so for every  $x$  of  $X$  above  $y$ ,  $0_{\{X,x\}}$  is of dimension 1, hence a discrete valuation ring since  $X$  is normal hence regular in codimension 1. On the other hand, it is evident that for every section  $g$  of  $G$  over  $S$ ,  $Z$  is stable under the automorphism of  $X$  defined by transport of structure from the left translation by  $g$  in  $G$ , so  $Z$  is stable under the left translation in  $G_0$  defined by  $g_{\{0\}}$ . Now by hypothesis the set of such  $g_{\{0\}}$  is dense in  $G^{\{0\}}_{\{0\}}$ . Since  $Z$  is stable under translation by these  $g_{\{0\}}$ , and is a rare closed set, it follows at once that  $Z = \emptyset$ , whence  $Z' = \emptyset$ , so  $X$  is regular. Consequently,  $X$  is smooth over  $S$  at every point through which passes a section. Now every section of  $G$  over  $S$  lifts in a unique way to a section of  $X$  over  $S$  hence of  $G'$  over  $S$ . This is so in particular for the unit section, which proves that the image of  $G'$  in  $S$  is  $S$ , i.e. that one is under the conditions of (a). This completes the proof of 8.9 and hence of 8.8.

## 9. Addenda

[^N.D.E-X-75]

### 9.1. Simplicial sets, topoi, groupoids, and topological spaces

\*\*Notations 9.1.1.\*\*[^X-9-1] \*Let  $E$  be a simplicial set. One can associate with it the following objects:\*

<!-- label: III.X.9.1.1 -->

\*(2) a topos  $\mathcal{T} = E^{\sim}$ , obtained from the topos naturally associated with the sets  $E_i$ , by the procedure

described in [Del74], 6.3.1 (see also [Ill72], VI.5.2 and SGA 4 VI.7);\*

\*(3) a groupoid  $\mathcal{G} = \Pi(E)$ , whose objects are the elements of  $E_0$  (the "vertices"), and whose arrows are defined in [GZ67], II.7;\*

\*(4) a topological space  $X = |E|$  (a cellular complex), called the "geometric realization" (or "topological") (cf. loc. cit., III.1).\*

Let us note that a sheaf on  $\mathcal{T}$  is nothing other than a simplicial set over  $\mathcal{E}$ .

<!-- original page 102 -->

### 9.2. Locally constant sheaves; descent data

**Definitions 9.2.1.** \*One calls a\* locally constant sheaf \*on:\*

<!-- label: III.X.9.2.1 -->

\*(1) a simplicial set  $\mathcal{E}$ , every morphism of simplicial sets  $\mathcal{E}' \rightarrow \mathcal{E}$  such that for every  $i \in \mathbb{N}$  and every  $e \in E_i$ , the face operators  $d$  induce isomorphisms  $\mathcal{E}'_e \xrightarrow{\sim} \mathcal{E}'_{d(e)}$  between the fibers (cf. [AM69], § 10);\*

\*(2) a topos  $\mathcal{T}$ , every object  $F$  of  $\mathcal{T}$  such that there exists an epimorphism  $U \rightarrow 1$  and an isomorphism  $F \times U \xrightarrow{\sim} I \times U$ , where  $I$  is a set and  $f : T \rightarrow \text{Ens}$  is the final morphism (cf. SGA 4, IX.2);\*

\*(3) a groupoid  $\mathcal{G}$ , every presheaf on  $\mathcal{G}$ , that is, every contravariant functor from  $\mathcal{G}$  into the category of sets (cf. [GZ67], append. I.1.2);\*

\*(4) a topological space  $X$ , every sheaf of sets on  $X$ , locally constant in the usual sense.\*

\*Finally:\*

\*(5) one calls a\* descent datum \*on a simplicial set  $\mathcal{E}$  the datum of a sheaf  $F$  on  $\mathcal{E}^{\sim}_0$  (that is, a set-valued function on  $E_0$ ) and of an isomorphism  $\alpha : p^{\ast}_1 F \xrightarrow{\sim} p^{\ast}_2 F$ , where  $p_1, p_2 : \mathcal{E}^{\sim}_1 \rightarrow \mathcal{E}^{\sim}_0$  are the morphisms (deduced from the) faces, satisfying the usual cocycle relation (cf. Exp. IV, 2.1 (1) and infra).\*

The morphisms between these five types of objects, as well as the associated inverse-image functors, are defined in an obvious manner.

### 9.3. Some equivalences of categories

Let  $\mathcal{E}$  be a simplicial set and let  $\mathcal{T}$ ,  $\mathcal{G}$  and  $X$  be the associated topos, groupoid and topological space.

**Proposition 9.3.1.** \*The categories of locally constant sheaves on  $\mathcal{E}$ ,  $\mathcal{T}$ ,  $\mathcal{G}$ ,  $X$  as well as the category of descent data on  $\mathcal{E}$  are equivalent.\*

<!-- label: III.X.9.3.1 -->

**Sketch of proof.** Let us denote by (1) through (5) the categories of objects defined in the preceding paragraph.

– (1)  $\Leftrightarrow$  (5). This is a particular case of [AM69], 10.6 (see also [GZ67], append. I.2.3, [Fri82], ?5.6, or [Ill72], VI.8.1.6). An equivalence of categories is given by the functor associating with the object  $(\mathcal{E}' \rightarrow \mathcal{E})$  the pair  $(\mathcal{E}'_0, \alpha)$  where  $\mathcal{E}'_0$  is considered as a sheaf on  $E_0$  and where  $\alpha$  is the unique isomorphism  $p^{\ast}_1 \mathcal{E}'_0 \xrightarrow{\sim} p^{\ast}_2 \mathcal{E}'_0$  whose fiber at each  $y \in E_1$  – with images denoted  $x_1$  and  $x_2$  by the two projections – is given by the isomorphisms  $(\mathcal{E}'_0)_{x_1} \xrightarrow{\sim} (\mathcal{E}'_0)_{x_2}$ .

– (5)  $\Leftrightarrow$  (3). Evident: one of the two relations defining the morphisms in the groupoid  $\mathcal{G}$  associated with  $\mathcal{E}$  is a cocycle relation.

– (1)  $\Leftrightarrow$  (4). Cf. [GZ67], append. I.3.2.1.

– (1)  $\Leftrightarrow$  (2). One must show that an object over  $\mathcal{E}$  is a locally constant sheaf in the simplicial sense if and only if it

is so as a sheaf on  $T = E^{\sim}$ . This follows from the fact that the locally constant sheaves  $F_{\bullet}$  on  $T$  are nothing other than the cartesian sheaves, that is, those for which the arrows  $([n] \rightarrow [m])^{\ast} F_m \rightarrow F_n$  are isomorphisms. This last point is a particular case of a general fact on simplicial topoi <!-- original page 103 --> together with the fact that every sheaf on  $E^{\sim}_0$  is locally constant. (See also [Ill72], VI.8.1.6.) QED.

For every group  $H$ , the equivalences of categories above induce equivalences between the categories of  $H$ -torsors, these being locally constant sheaves equipped with an action of  $H$ , with fibers isomorphic to  $H$  acting on itself by translation.

#### 9.4. Fundamental groups and groupoids

It follows from the preceding equivalences of categories that for every group  $H$  and every simplicial set  $E$ , the sets of isomorphism classes of  $H$ -torsors  $H^1(E, H)$ ,  $H^1(E^{\sim}, H)$ ,  $\pi_0(\operatorname{Hom}(\pi(E), BH))$  and  $H^1(|E|, H)$  are naturally in bijection. Recall that one denotes by  $BH$  the punctual groupoid associated with  $H$  and by  $\pi_0$  the functor associating with a category the set of isomorphism classes of its objects.

Likewise, if  $e$  is a point of  $E$ , the preceding equivalences induce bijections between the sets of isomorphism classes of  $H$ -torsors trivialized over  $e$ , denoted respectively  $H^1(E \operatorname{rel} e, H)$ ,  $H^1(E^{\sim} \operatorname{rel} e^{\sim}, H)$ ,  $\pi_0(\operatorname{Hom}(\pi_1(\pi(E), e), H))$  and  $H^1(|E| \operatorname{rel} |e|, H)$ . Recall that one denotes by  $\pi_1(\pi(E), e)$  the group  $\operatorname{Isom}_{\pi(E)}(e, e)$ . For variable  $H$ , these functors are represented, in the connected case, by a group which one denotes by  $\pi_1(E, e)$ . The group  $\pi_1(E, e)$  is isomorphic to  $\pi_1(\pi(E), e)$  and  $\pi_1(|E|, |e|)$ , hence also to the fundamental group of a simplicial set as defined by Kan (cf. e.g. [May67], 16.1 or [Ill72], I.2.1.1). (Recall that the set  $H^1(E, H)$  is in turn isomorphic to the set  $H^1(\pi_1(E, e), H)$  of morphisms to  $H$  modulo conjugation, also denoted  $\operatorname{Hom} \operatorname{ext}(\pi_1(E, e), H)$ .)

#### 9.5. Cones

**Definitions 9.5.1.** (1) Let  $f : E' \rightarrow E$  be a morphism of simplicial sets. Recall (cf. for example [Del74], 6.3.1) that one denotes by  $C(f)$  the pointed simplicial set whose underlying set in degree  $n$  is

<!-- label: III.X.9.5.1 -->

```

```text
E_n \cup (\cup_{i < n} E'_i) \cup *,

```

where $\star$ is a singleton. We leave to the reader the task of defining the simplicial maps, the definition of the faces in rank less than or equal to two being recalled below. (See also [GZ67], VI.2 for a pointed variant.) The category of locally constant sheaves on $C(f)$ is equivalent to the category of locally constant sheaves on E equipped with a trivialization of the inverse image on E' . The simplicial set $C(f)$ is naturally pointed by $\star \rightarrow C(f)$.

(2) Let $f : T' \rightarrow T$ be a morphism of topoi. Denote by $C(f)$ the topos whose objects are quintuples $(F, F', A, \alpha : f^{\ast} F \rightarrow F', \beta : A \rightarrow \Gamma(T', F'))$, where F (resp. F') is an object of T (resp. T'), A is a set, and α (resp. β) is a morphism in T' (resp. Ens). (See also [Del80], 4.3.4 and [Ill72], III.4 for a variant of this construction.) The category of locally constant sheaves on $C(f)$ is equivalent to the category of locally constant sheaves on T equipped with a trivialization of the inverse image on T' . The topos $C(f)$ is naturally pointed by the fiber functor sending the quintuple $(F, F', A, \alpha : f^{\ast} F \rightarrow F', \beta : A \rightarrow \Gamma(T', F'))$ to the set A .

(3) Let $f : G' \rightarrow G$ be a morphism of groupoids. Denote by $C(f)$ the colimit of the diagram

```

G
G \leftarrow G' \rightarrow B_1
G

```

where B_1 is the punctual category (one object, one arrow). The category of locally constant sheaves on $C(f)$ is equivalent to the category of locally constant sheaves on G equipped with a trivialization of the inverse image on G' .

(4) Let $f : X' \rightarrow X$ be a morphism of topological spaces. Denote by $C(f)$ the colimit of the diagram

```

```text
* \leftarrow X' \times \{0\} \rightarrow X' \times [0, 1] \leftarrow X' \times \{1\} \rightarrow X.
```

```

The category of locally constant sheaves on $\mathcal{C}(f)$ is equivalent to the category of locally constant sheaves on X equipped with a trivialization of the inverse image on X' . The topological space $\mathcal{C}(f)$ is naturally pointed by $\star \in \mathcal{C}(f)$.

9.5.2. Descent data on the cone of a simplicial map

Let $f : E' \rightarrow E$ be a morphism of simplicial sets and $\mathcal{C}(f)$ its cone (cf. supra, (1)). Let us use the letter p (resp. q , r) to denote the face maps of E' (resp. E , $\mathcal{C}(f)$). Before stating the proposition below, let us explicit the faces r in degree less than or equal to two in terms of p and q . By convention, p_{ij} (resp. p_i) is the face map $E'_2 = E'_{\{1,2,3\}} \rightarrow E'_1 = E'_{\{1,2\}}$ (resp. $E'_1 = E'_{\{1,2\}} \rightarrow E'_0 = E'_{\{1\}}$) corresponding to the increasing map $\{1, 2\} \rightarrow \{1, 2, 3\}$ (resp. $\{1\} \rightarrow \{1, 2\}$) of image $\{i, j\}$ (resp. $\{i\}$) [^{X-9-2}]. The same convention is adopted for the faces of E and $\mathcal{C}(f)$.

The morphism

$$r_1 : \mathcal{C}(f)_1 = E_1 \amalg E'_0 \amalg \star \rightarrow \mathcal{C}(f)_0 = E_0 \amalg \star$$

(resp. r_2) is:

- $q_1 : E_1 \rightarrow E_0$ (resp. $q_2 : E_1 \rightarrow E_0$) on E_1 ;
- $E'_0 \rightarrow \star$ (resp. $f_0 : E'_0 \rightarrow E_0$) on E'_0 ;
- $\star \rightarrow \star$ on $\star$.

Likewise the morphism

$$r_{21} : \mathcal{C}(f)_2 = E_2 \amalg E'_1 \amalg E'_0 \amalg \star \rightarrow \mathcal{C}(f)_1 = E_1 \amalg E'_0 \amalg \star$$

(resp. r_{31}) is:

- $q_{21} : E_2 \rightarrow E_1$ (resp. q_{32} , q_{31}) on E_2 ;
- $p_1 : E'_1 \rightarrow E'_0$ (resp. $f_1 : E'_1 \rightarrow E_1$, $p_2 : E'_1 \rightarrow E'_0$) on E'_1 ;
- $E'_0 \rightarrow \star$ (resp. $\text{Id} : E'_0 \rightarrow E'_0$, $\text{Id} : E'_0 \rightarrow E'_0$) on E'_0 .

Let β be a descent datum on $\mathcal{C}(f)$, that is, a sheaf H_0 on $\mathcal{C}(f)_0 = E_0 \amalg \star$ equipped with an isomorphism $\gamma : r^{\ast}_1 H_0 \xrightarrow{\sim} r^{\ast}_2 H_0$ between its inverse images on $\mathcal{C}(f)_1 = E_1 \amalg E'_0 \amalg \star$ satisfying the cocycle relation $r^{\ast}_{31} \gamma = r^{\ast}_{32} \gamma \circ r^{\ast}_{21} \gamma$.

<!-- original page 105 -->

The restriction of the isomorphism γ to E_1 (resp. E'_0) is a descent datum $\beta : q^{\ast}_1 G_0 \xrightarrow{\sim} q^{\ast}_2 G_0$ where G_0 is the restriction of H_0 to E_0 (resp. a trivialization $t : H_0(\star) \xrightarrow{\sim} f^{\ast}_0 G_0 =: F_0$ where $H_0(\star)$ is the constant sheaf with stalk $H_0(\star)$). The restriction of the cocycle relation satisfied by γ to E_2 (resp. E'_1) is the cocycle relation for β (resp. $p^{\ast}_2(t) = f^{\ast}_1(\beta) \circ p^{\ast}_1(t)$). This latter relation means that the trivialization t is compatible with the descent datum $f^{\ast}_1(\beta)$ induced by β on F_0 . From this it follows:

****Proposition 9.5.3.**** *Let $f : E' \rightarrow E$ be a morphism of simplicial sets and $\mathcal{C}(f)$ its cone, pointed by $\star$. The category of descent data on $\mathcal{C}(f)$ trivialized over $\star$ is equivalent to the category of descent data on E equipped with a trivialization of the descent datum induced on E' .*

<!-- label: III.X.9.5.3 -->

9.6. Representability of the functor $\pi^{-1}(S'/S, \xi; -)$

The notations are those of page 90 and from now on we suppose the connected components of $S_{\{0\}} = S'$ and $S_{\{1\}} = S' \times_{S'} S'$ open. Under this hypothesis, one has the following explicit combinatorial description, which follows immediately from the recalls above.

Proposition 9.6.1. *For every group G , the set $\bar{\pi}^1(S'/S, \xi; G)$ of isomorphism classes of descent data equipped with a trivialization above ξ is in natural bijection with the relative non-abelian cohomology set*

`<!-- label: III.X.9.6.1 -->`

```
```text
H^1(K rel k, G) := H^1(K~ rel *, G).
```
```

It follows that this functor is representable by a group, denoted $\pi_1(K, k)$ (the "relative fundamental group"), as soon as the simplicial set $\tilde{K} = C(k \rightarrow K)$ is connected. One verifies immediately that this is so if and only if the map $\pi_0(k) \rightarrow \pi_0(K)$ is surjective. It suffices in particular that the simplicial set K be connected. As indicated in the text, this is the case if the scheme S is connected and the morphism $S' \rightarrow S$ is universally submersive.

9.7. Contractibility of k , counter-example to the injectivity of $k \rightarrow K$.

The two following propositions make the N.D.E. (53) more precise.

Proposition 9.7.1. *Let k be an algebraically closed field, and X a connected k -scheme. For every integer $i \geq 0$, denote by $X_{(i)}$ the $(i+1)$ -th fibered power of X over k . For every integer $i \geq 0$, the canonical map*

`<!-- label: III.X.9.7.1 -->`

```
$$
\pi_0(X_{(i)}) \rightarrow \pi_0(X)^{i+1}
$$
```

is a bijection. In particular, the simplicial set $\pi_0(X_{\bullet})$ is contractible.

It suffices to prove the following lemma, which follows by passage to the limit from the Künneth formula. [Spell out?]

Lemma 9.7.2. *Let k be an algebraically closed field and X, Y two connected k -schemes. Then the fibered product $X \times_k Y$ is connected.*

`<!-- label: III.X.9.7.2 -->`

Proposition 9.7.3. *Let X be a connected scheme, $X' \rightarrow X$ a finite étale morphism, and x a geometric point of X localized at a point x . The canonical morphism $\pi_0(X'_{(x)}) \rightarrow \pi_0(X')$ is surjective.*

`<!-- label: III.X.9.7.3 -->`

`<!-- original page 106 -->`

Indeed, every connected component of X' has image an open-closed of X hence meets the fiber $X'_{(x)}$. The morphism $\pi_0(X'_{(x)}) \rightarrow \pi_0(X')$ is therefore surjective, as is the morphism $\pi_0(X'^{\{x\}}_{(x)}) \rightarrow \pi_0(X'_{(x)})$.

[^X-0]: Version xy of 6 November 2009: Addenda placed in Section 9, reviewed through 8.8.

[^N.D.E-X-1]: *N.D.E.* More precisely, this follows from the "axiomatic conditions of a Galois theory", cf. SGA 1, V N° 4 g); when S is locally noetherian, the verification of the axioms is done in *loc. cit.*, N°s 7 & 3, in particular 3.7, which rests on SGA 1, I 10.9. This last result is proved, without noetherian hypotheses, in EGA IV₄, 18.2.9.

[^N.D.E-X-2]: *N.D.E.* In the sequel, one will say that an S -group of multiplicative type is "split" if it is "trivial" in the sense of IX 1.2, i.e., if it is a diagonalizable S -group.

[^N.D.E-X-3]: *N.D.E.* One has corrected S to S' .

[^N.D.E-X-4]: *N.D.E.* One has replaced, here and in the sequel, "splittés" by "déployés", "splitte" by "déploie", etc. (In English: "split".)

[^N.D.E-X-5]: *N.D.E.* See 7.3 below.

[^N.D.E-X-6]: *N.D.E.* One has added this "recall", for later references.

[^N.D.E-X-7]: *N.D.E.* One has corrected the original by exchanging M and N in the right-hand terms.

[^X-2-1]: Cf. J. Giraud, *Méthode de la descente*, Bull. Soc. Math. France, Mémoire 2 (1964).

[^N.D.E-X-8]: *N.D.E.* One recalls that 2.3 is used to prove Theorem IX 3.6 bis.

[^N.D.E-X-9]: *N.D.E.* Since u_0 is an isomorphism, it suffices to see that for every $h \in H$, the morphism $\phi : O_{G,u(h)} \rightarrow O_{H,h}$ is bijective. It is so by reduction modulo $I = I_s$ (where s is the image of h in S), so its cokernel C verifies $C = IC$, whence $C = 0$ since I is nilpotent. Then, since $O_{H,h}$ is flat over $O_{S,s}$, the kernel K of ϕ also verifies $K = IK$, whence $K = 0$.

[^N.D.E-X-10]: *N.D.E.* One has rewritten the statement keeping only the non-trivial implication, to bring it into focus.

[^N.D.E-X-11]: *N.D.E.* Spell out this point

[^N.D.E-X-12]: *N.D.E.* One has spelled out the original in what follows.

[^N.D.E-X-13]: *N.D.E.* Specify this reference, possibly adding a corollary in N° 5

[^X-3-1]: Cf. also VI_B 2.5 for more systematic developments of this nature.

[^N.D.E-X-14]: *N.D.E.* Specify these references: Since G , H are locally of finite presentation, u is locally of finite presentation (IV₁, 1.4.3 (v)); next one applies IV₃, 11.3.10 and 13.1.4 for flat and quasi-finite, IV₄, 17.4.1, 17.5.1 and 17.6.1 for unramified, smooth and étale; compare with VI_B 2.5.

[^N.D.E-X-15]: *N.D.E.* One has added the following sentence.

[^N.D.E-X-16]: *N.D.E.* One has added the following sentence.

[^N.D.E-X-17]: *N.D.E.* Cf. EGA IV₄, 17.9.1.

[^N.D.E-X-18]: *N.D.E.* The original indicated: "i.e. S_0 connected". Note that, since A is separated for the I -adic topology, S_0 meets every connected component of S (and since A is complete, the connected components of S_0 and S are in bijection).

[^N.D.E-X-19]: *N.D.E.* since G_s and H_s are of the same type for every $s \in S_0$, hence for every s .

[^N.D.E-X-20]: *N.D.E.* because u will once again be a surjective open immersion.

[^N.D.E-X-21]: *N.D.E.* One has spelled out this recall, and added remark 4.0.1.

[^N.D.E-X-22]: *N.D.E.* One has added what follows.

[^N.D.E-X-23]: *N.D.E.* One has spelled out the original in what follows.

[^N.D.E-X-24]: *N.D.E.* One has added this recall, used in the proof of 4.3 (the reference to EGA IV₄ 18.5.11 not being fully satisfactory).

[^N.D.E-X-25]: *N.D.E.* One has spelled out the original in what follows, on the basis of indications by M. Raynaud.

[^N.D.E-X-26]: *N.D.E.* One has added this lemma, used several times in the sequel.

[^N.D.E-X-27]: *N.D.E.* One has spelled out the reductions that follow (the original indicated: "One reduces at once to the case where S_S is the spectrum of a noetherian local ring A_S , and where s_S is the closed point of S_S ").

[^X-4-1]: Or EGA IV₄, § 18.6.

[^N.D.E-X-28]: *N.D.E.* One has spelled out the original in what precedes and what follows.

[^N.D.E-X-29]: *N.D.E.* This result is generalized in 8.1: it suffices in fact to suppose that the fibers of H_S are affine and connected.

[^N.D.E-X-30]: *N.D.E.* See lemma 5.12 below.

[^N.D.E-X-31]: *N.D.E.* One has moved this remark here, appearing in the original after the proof.

[^N.D.E-X-32]: *N.D.E.* cf. VIII § 1.7.

[^N.D.E-X-33]: *N.D.E.* One has corrected "equivalence" to "anti-equivalence".

[^N.D.E-X-34]: *N.D.E.* (when S'_S is locally noetherian, and EGA IV₃, 8.11.2 in general).

[^N.D.E-X-35]: *N.D.E.* (when S'_S is locally noetherian, and EGA IV₂, 2.4.6 in general).

[^N.D.E-X-36]: *N.D.E.* One has corrected H_S to G_S .

[^N.D.E-X-37]: *N.D.E.* One has added what follows.

[^N.D.E-X-38]: *N.D.E.* Correct this reference by treating the case of the functor $\text{Isom}_{\{S\text{-gr.}\}}(H, G)_S$ in an addition 1.5.1 in VIII ...

[^N.D.E-X-39]: *N.D.E.* One has added this recall, used several times in the sequel. (See also EGA I, 6.1.9; note however that the proof of *loc. cit.* seems unnecessarily complicated.)

[^N.D.E-X-40]: *N.D.E.* Compare with the examples of 1.6 ...

[^N.D.E-X-41]: *N.D.E.* One has spelled out the original in what follows.

[^N.D.E-X-42]: *N.D.E.* because it is a twisted constant group of type $\text{End}_{\{\text{gr.}\}}(N)_S$ (cf. 5.6 and 5.8).

[^N.D.E-X-43]: *N.D.E.* modulo the verification that (ii) $\Rightarrow$ (i) when S_S is locally noetherian and R_S is not finitely generated ...

[^N.D.E-X-44]: *N.D.E.* Spell out this point: M_S being a finitely generated $\mathbb{Z}$ -module, it is countable, and the proof of 5.11 (i) $\Rightarrow$ (ii) shows that R_S is the union of a countable family of open and closed parts, finite over S_S . One would need to see the converse ...

[^N.D.E-X-45]: *N.D.E.* The original treated in 5.14 the case where S_S is locally noetherian and normal, and signalled in Remark 5.15 that the reasoning applies, more generally, if one supposes only S_S geometrically unibranch instead of normal. One has modified the statement of 5.14 (and also 5.16) accordingly, and one has added these "recalls", drawn from EGA IV₄, 18.10.6 and 18.10.7, which show that the proof of 5.14 applies verbatim to the geometrically unibranch case.

[^N.D.E-X-46]: *N.D.E.* One has removed remark 5.15, rendered obsolete by the addition of 5.14.0 (cf. the preceding N.D.E.), and in 5.16 one has replaced "normal" by "geometrically unibranch".

[^N.D.E-X-47]: *N.D.E.* Note that P_S is supposed to be a prescheme – in the *a priori* more general case of a sheaf (fpqc) P_S which is a G_S -torsor, is P_S necessarily representable?

[^N.D.E-X-48]: *N.D.E.* One has added the hypothesis that the connected components of S'_S be open, as well as the second hypothesis. This latter means that the simplicial set $K_{\bullet} = \pi_0(S_{\bullet})$ defined in 6.3 is connected; in fact a weaker hypothesis suffices, namely that the cone $\tilde{K}_{\bullet}$ of a certain morphism of

simplicial sets $K_{\bullet}$ be connected (cf. *loc. cit.*).

[^N.D.E-X-49]: *N.D.E.* One has suppressed the superfluous hypothesis that the connected components of S'' be open. On the other hand, the description given later (cf. ...) gives as the natural set of generators the set $\pi_0(S'') \coprod \pi_0(S'_{\xi})$; one then reduces to $\pi_0(S'')$ by means of the relations between these generators arising from the 2-cells. See for example [Kan58], § 19 for a finer description.

[^N.D.E-X-50]: *N.D.E.* One could spell out this deduction; I_S is in bijection with a cofinal set of morphisms $S' \rightarrow S$ covering for the étale topology ...

[^N.D.E-X-51]: *N.D.E.* One has corrected 5.13 to 5.14.

[^N.D.E-X-52]: *N.D.E.* Some authors speak of the "true" fundamental group.

[^N.D.E-X-53]: *N.D.E.* One has corrected the original, which considers $\tilde{K}_{\bullet} = K_{\bullet}/k_{\bullet}$ whereas on the one hand $k_{\bullet}$ is already contractible (cf. 9.7.1) and on the other hand the morphism $k_{\bullet} \rightarrow K_{\bullet}$ is not in general injective. It is an epimorphism if S'/S is étale finite (cf. 9.7.3).

[^N.D.E-X-54]: *N.D.E.* One has added the hypothesis that $\tilde{K}_{\bullet}$ be connected; for the proof, see the addendum below (Section 9).

[^N.D.E-X-55]: *N.D.E.* One has modified the sequel, taking into account the correction made above, cf. N.D.E. (53). (The original was: " $\pi_0(\tilde{K}_{\bullet}, \tilde{\xi})$ is also canonically isomorphic to the set $\pi_0(S, \xi)$ of connected components of S , pointed by the connected component of ξ in S ".)

[^N.D.E-X-56]: *N.D.E.* One could spell this out: first, taking into account 5.14, the enlarged fundamental group of the projective line P^1_k is zero, i.e. P^1_k is "truly" simply connected. Next, one would have to extend to the case of the enlarged fundamental group and the category of principal bundles (not necessarily finite), Corollary 5.4 of SGA 1 IX and the discussion that follows. (Let Γ_1 and Γ_2 be two copies of P^1_k , a_i, b_i two distinct points of Γ_i , C'_2 the disjoint union of Γ_1 and Γ_2 , C'_2 the curve obtained by identifying a_1 with a_2 ; then C_2 is obtained from C'_2 by additionally identifying b_1 with b_2). The discussion following *loc. cit.* extended to the enlarged case, then shows that the enlarged fundamental group of C'_2 (resp. C_2) is zero (resp. $\mathbb{Z}$).

[^N.D.E-X-57]: *N.D.E.* This is an n -fold point with n distinct tangents, for example the curve $X^n - Y^n = X^{n+1}$.

[^N.D.E-X-58]: *N.D.E.* In particular, this shows that the tori of relative dimension 2 considered in 1.6 are not isotrivial.

[^N.D.E-X-59]: *N.D.E.* Note that the hypotheses entail that H_S is separated over S , by VI_B, Th. 5.3 or Cor. 5.5.

[^N.D.E-X-60]: *N.D.E.* by EGA IV₂, 8.8.2 again.

[^N.D.E-X-61]: *N.D.E.* One has spelled out the original in what follows.

[^X-8-1]: By Raynaud's theorem VI_B 5.3.

[^N.D.E-X-62]: *N.D.E.* Spell out this point, in connection with the modifications in VI_B § 5.

[^N.D.E-X-63]: *N.D.E.* This follows, for example, from VIII 3.2 a); more generally, if $f : G \rightarrow H$ is a surjective morphism of algebraic groups over a field k and if H is reduced, then f is flat (cf. VI_B 1.3).

[^N.D.E-X-64]: *N.D.E.* One has spelled out the original in what follows.

[^N.D.E-X-65]: *N.D.E.* At least in the case envisaged so far, namely S locally noetherian.

[^N.D.E-X-66]: *N.D.E.* The editors did not understand this remark, not understanding why u would *a priori* have finite fibers and be surjective ...

[^N.D.E-X-67]: *N.D.E.* Spell out this reduction ...

[^N.D.E-X-68]: *N.D.E.* Spell out this point ...

[^N.D.E-X-69]: *N.D.E.* Give a reference here?

[^N.D.E-X-70]: *N.D.E.* Recall the definition of "Cartan subgroup" ...

[^N.D.E-X-71]: *N.D.E.* Give a reference for these results?

[^N.D.E-X-72]: *N.D.E.* G. Prasad and J.-K. Yu have generalized (subject to some additional hypotheses) this result without supposing G commutative and replacing in hypothesis a) and the conclusion "torus" by "reductive group", cf. [PY06], Th. 6.2.

[^X-8-2]: By Raynaud's theorem VI_B 5.3.

[^N.D.E-X-73]: *N.D.E.* cf. N.D.E. (62) in 8.5.

[^N.D.E-X-74]: *N.D.E.* revise the preceding sentence ...

[^N.D.E-X-75]: *N.D.E.* This additional section was written by Fabrice Orgogozo (following indications by Ofer Gabber).

[^X-9-1]: PP: I have replaced "FGA, *Technique de descente* I, 1.6" by "Exp. IV, 2.1".

[^X-9-2]: This convention departs from the current simplicial norm but is closer to the notations used by Grothendieck in his theory of descent.

[^X-biblio]: *N.D.E.* additional references cited in this Exposé; the references [AM69] and following concern the Addenda.

<!-- SOURCE: 11-criteres-representabilite.md -->

Exposé XI. Representability criteria. Applications to multiplicative-type subgroups of affine group schemes

<!-- label: III.XI -->

by A. Grothendieck

0. Introduction

<!-- original page 127 -->

As we have already seen examples in Exp. X, N°s 4, 5, the representability of certain functors, such as certain functors of type $\operatorname{Hom}_{\{S\}}(X, Y)$ and various variants, plays an important role in many questions concerning preschemes in groups.

Among the results particularly useful in this theory, let us mention (in addition to the questions of representability of quotients, studied in Exposés V and VI_B and in Exp. VIII 5) the question of the representability of functors of the form $\prod_{X/S} Y/X$ (where Y is a subobject of X), studied in Exp. VIII 6 in a very elementary case, of which we shall give variants in N° 6 of the present Exposé; these results give us the representability of various centralizers, normalizers, transporters.

Less elementary representability criteria, using results that will appear in EGA VI, are indicated in 6.12 and in Exp. XV, XVI, where we shall give a criterion of representability of quotients G/H in cases not covered by the preceding Exposés (a criterion that was not developed in the oral Exposés).

Our principal object in the present Exposé is the proof of theorems 4.1 and 4.2, which furnish a typical example of a non-projective construction technique (close to the one that will be developed in EGA VI). It has indeed appeared, since the oral Exposé and the writing of the present text, that the affine hypotheses made in 4.1 <!-- original page 128 --> and 4.2 can to a large extent be eliminated (cf. XV), and that, on the other hand, one can, for the essential part of the theory developed in the following Exposé, do without 4.1 and 4.2. It might finally be interesting to prove the analogue of these results for a general reductive (for instance semisimple) group prescheme instead of a group of multiplicative type, in which case 4.1 and 4.2 will doubtless be the key result for the proof.

1. Reminders on smooth, étale, and unramified morphisms

The reader is referred to EGA IV §§ 17 & 18, and pending its publication, to SGA 1, I, II, III (where it is however appropriate to replace certain noetherian hypotheses, troublesome in applications, by hypotheses of finite

presentation).

Definition 1.1. Let S be a prescheme, F a functor $(\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$. One says that F is formally smooth (resp. formally unramified [XI-1-1], resp. formally étale) if for every S' -prescheme S' , affine (in the absolute sense), and every subscheme S'' of S' defined by a nilpotent ideal J , the map

$$F(S') \rightarrow F(S'')$$

is surjective (resp. injective, resp. bijective). A prescheme X over S is said to be formally smooth over S (resp. formally unramified over S , resp. formally étale over S) if the corresponding functor is formally smooth (resp. formally unramified, resp. formally étale); one says that X is smooth over S (resp. unramified over S , resp. étale over S) if it satisfies the preceding condition and if moreover X is locally of finite presentation over S .

<!-- label: III.XI.1.1 -->

<!-- original page 129 -->

The interest of these definitions for X resides in the fact that, on the one hand, they are expressed in a remarkably simple way in terms of the functor represented by X (and in practice, X is often given as the object over S representing some explicit functor), and that, on the other hand, they are also expressed by remarkable properties concerning the local structure of X , which we shall recall in the following statements (for the proof, we refer to loc. cit.).

Proposition 1.2. Let X be a prescheme locally of finite presentation over S . Then:

<!-- label: III.XI.1.2 -->

(i) For X to be smooth over S , it is necessary and sufficient that X be flat over S , and that its geometric fibers $X \times_S \text{Spec}(\kappa(s))$ be regular schemes. More generally, for X to be smooth over S in a neighborhood of the point $x \in X$ (one then says that X is smooth over S at x), it is necessary and sufficient that X be flat over S at x and $X_{(s)}$ be smooth over $\kappa(s)$ at x , i.e. $X_{(s)} \times_{\kappa(s)} \bar{\kappa}(s)$ be regular at the points (or simply, a point) above x .

(ii) Suppose S , and hence X , locally noetherian; let $x \in X$ and let $s \in S$ be its image in S . Then the smooth nature of X over S at x is detected on the local homomorphism $A = 0_{(S,s)} \rightarrow B = 0_{(X,x)}$ of noetherian local rings (or even on the local homomorphism $\hat{A} \rightarrow \hat{B}$ of their completions), by the following characteristic property: B is flat over A , and $B \otimes_A k$ is geometrically regular over k (the residue field of A), i.e. for every finite extension k' of k , $(B \otimes_A k) \otimes_k k' = B \otimes_A k'$ is a regular semi-local ring. When the residual extension $k(B)/k(A)$ is trivial, these conditions are equivalent also to the following: $\hat{B}$ is isomorphic as $\hat{A}$ -algebra to an algebra of formal power series $\hat{A}[[t_1, \dots, t_n]]$.

Thus, from the "formal" point of view, the structure of X over S is that of the typical affine space $S[t_1, \dots, t_n]$ over S .

Proposition 1.3. Let X be a prescheme locally of finite presentation over S . Then: <!-- original page 130 -->

<!-- label: III.XI.1.3 -->

(i) The following conditions are equivalent:

a) X is unramified over S .

b) The diagonal morphism $X \rightarrow X \times_S X$ is an open immersion.

c) $\Omega_{X/S}^1 = 0$.

d) The geometric fibers of X/S are discrete and reduced, i.e. isomorphic to sums of copies of the base field.

e) For every $s \in S$, the fiber $X \times_S \text{Spec}(\kappa(s)) = X_{(s)}$ is unramified over $\kappa(s)$, or equivalently is isomorphic to a sum of spectra of finite separable extensions of $\kappa(s)$.

(ii) One has analogous conditions of pointwise nature for X_S to be unramified over S_S at a given point x_S (i.e. in a neighborhood of the said point); for example, it is necessary and sufficient that 0_{X_S} , x_S be a finite separable extension of $\kappa(s)$, which is expressed also in terms of the local homomorphism $A = 0_{S,s} \rightarrow B = 0_{X,x}$ by the condition that $B \otimes_A k$ be a finite separable extension of k (residue field of A), i.e. $r(A) \otimes B = r(B)$ and $k(B)$ is a finite separable extension of $k(A)$. When A , and hence also B , is noetherian, and $k(A) \rightarrow k(B)$, this means also that $\hat{A} \rightarrow \hat{B}$ is surjective.

Thus, from the "formal" point of view, to say that X_S is unramified over S_S means that X_S is essentially a subscheme of S_S . Observe also that conditions d) and e) are expressed solely in terms of the fibers of X/S .

Proposition 1.4. *Let X_S be a prescheme locally of finite presentation over S_S . For X_S to be étale over S_S , it is necessary and sufficient that it be smooth over S_S and unramified over S_S (trivial by definition), which permits applying criteria 1.2 and 1.3. One finds in particular:*

<!-- label: III.XI.1.4 -->

*(i) For X_S to be étale over S_S , it is necessary and sufficient that it be flat over S_S and unramified over S_S .

<!-- original page 131 --> Analogous local criterion for X to be étale over S at a given point x .*

(ii) Suppose moreover S_S , and hence X_S , locally noetherian. Then the fact that X_S is étale over S_S at a point x_S is detected on the local homomorphism $A = 0_{S,s} \rightarrow B = 0_{X,x}$ (and even on the local homomorphism $\hat{A} \rightarrow \hat{B}$) by the following characteristic property: B is flat over A , and $B \otimes_A k$ is a finite separable extension of k (residue field $[\text{N.D.E-XI-1}]$ of A). When $k(A) \rightarrow k(B)$, this condition means simply that $\hat{A} \rightarrow \hat{B}$ is an isomorphism.

Thus, from the "formal" point of view, to say that X_S is étale over S_S means simply that X_S is locally isomorphic to S_S .

Remark 1.5. When X_S is locally of finite presentation over S_S and one is given a point $x \in X$, then the fact that X_S is smooth (resp. unramified, resp. étale) over S_S at x_S , i.e. in a neighborhood of x_S , is detected on the functor $X : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$ by the following characteristic property: for every S'_S over S_S , S'_S the spectrum of a local ring, every subscheme S''_S of S'_S defined by a nilpotent ideal, and every S_S -morphism $u'' : S'' \rightarrow X_S$ sending the closed point s''_S of S''_S to x_S , there exists at least one (resp. at most one, resp. exactly one) S_S -morphism $u : S' \rightarrow X_S$ which extends it. This statement shows in particular that in definition 1.1 one may restrict to S'_S which are local schemes (provided that the functor in question is representable by a prescheme locally of finite presentation over S_S). On the other hand, when S_S is locally noetherian, one may even, in the preceding pointwise criterion, restrict to S'_S which are local artinian schemes, and one may thus impose the same restriction on S'_S in definition 1.1 (provided that S_S is locally noetherian and the functor in question is represented by a prescheme locally of finite type over S_S).

<!-- label: III.XI.1.5 -->

<!-- original page 132 -->

Remark 1.6. Of course, given a morphism $f : X \rightarrow Y$ of preschemes, one will say that f is smooth (resp. ...) if f_S makes X_S into a smooth (resp. ...) S_S -prescheme. When X_S and Y_S are S_S -preschemes and f_S an S_S -morphism of finite presentation, then these properties of f_S are expressed immediately in terms of the morphism of functors $F, G : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$ defined by $f_S : f_S$ is smooth (resp. unramified, resp. étale) if for every S'_S -prescheme S'_S , S'_S affine (in the absolute sense), and every subscheme S''_S of S'_S defined by a nilpotent ideal J , the map

```text  
 $F(S') \rightarrow F(S'') \times_{G(S'')} G(S')$

deduced from the commutative square

$$\begin{array}{ccc} S_S & & \\ F(S') \searrow & \text{\scriptsize $\downarrow$} & \searrow G(S') \\ & \text{\scriptsize $\downarrow$} & \\ F(S'') \searrow & \text{\scriptsize $\downarrow$} & \searrow G(S'') \\ S_S & & \end{array}$$

is surjective (resp. injective, resp. bijective), i.e. for every commutative square of morphisms of functors over  $S_S$

(where  $S'$ ,  $S''$  are as above and  $i : S'' \rightarrow S'$  is the canonical immersion):

$$\begin{array}{ccc} S'' & \xrightarrow{i} & S' \\ u'' \downarrow & & \downarrow v \\ F & \xrightarrow{f} & G \end{array} \quad (Q)$$

<!-- label: III.XI.1.6 -->

there exists at least one (resp. at most one, resp. exactly one) morphism  $u : S' \rightarrow F$  making the two corresponding triangles commutative:  $u'' = u \circ i$  and  $v = f \circ u$ .

<!-- label: III.XI.1.6 -->

This property for a homomorphism of functors  $f : F \rightarrow G$  over  $S$  keeps its meaning even when the functors in question are not representable; one will say (if it is satisfied) that the homomorphism of functors  $f : F \rightarrow G$  is *formally smooth* (resp. *formally unramified*, resp. *formally étale*). One will note that this depends only on the homomorphism of functors  $(\text{Sch})^{\text{op}} \rightarrow (\text{Ens})$  defined by  $f$ ,  $G$  (cf. I 1.4.1), and not on the structural morphisms  $F \rightarrow S$  and  $G \rightarrow S$ . An equivalent way of expressing the preceding definition, somewhat more manageable in applications, is the following: the morphism of functors  $f : F \rightarrow G$  over  $S$  is said to be *formally smooth* (resp. *formally unramified*, resp. *formally étale*) when, for every  $S'$  over  $S$  and every morphism  $S' \rightarrow G$ , the functor  $F' = F \times_G S'$  over  $S'$  is *formally smooth* (resp. *formally unramified*, resp. *formally étale*).

**Remark 1.7.** Under the conditions of 1.6, when one is given a "point of  $F$ " with values in a field  $k$ , i.e. an element  $x$  of  $F(\text{Spec}(k))$  or, what amounts to the same, a morphism  $\text{Spec}(k) \rightarrow F$ , one says likewise that  $f$  is *formally smooth* (resp. *formally unramified*, resp. *formally étale*) *at*  $x$ , if the condition of the preceding definition is satisfied whenever  $S'$  is a local scheme and the morphism  $S' \rightarrow F$  in the diagram (Q) above is "compatible with the marked points" in the following sense: if  $k'$  denotes the residue field of  $S'$  and of  $S'$  at their closed point, the diagram

$$\begin{array}{ccc} \text{Spec}(k') & & \text{Spec}(k) \\ \downarrow j & & \downarrow x \\ S'' & \longrightarrow & F \end{array}$$

(where  $j : \text{Spec}(k') \rightarrow S''$  denotes the canonical immersion) can be completed in <!-- original page 134 --> a commutative diagram

$$\begin{array}{ccccc} & & \text{Spec}(k'') & & \\ & \swarrow & & \searrow & \\ \text{Spec}(k') & & & & \text{Spec}(k) \\ \downarrow & & & & \downarrow \\ S'' & \longrightarrow & & & F \end{array},$$

<!-- label: III.XI.1.7 -->

where  $k''$  is the spectrum of a field. When  $f$ ,  $G$  are representable by  $S$ -preschemes  $X$ ,  $Y$  and the  $S$ -morphism  $f : X \rightarrow Y$  is locally of finite presentation, this condition means precisely (by virtue of 1.5) that  $f : X \rightarrow Y$  is *smooth at the point* of  $X$  image of  $\text{Spec}(k)$  by  $x : \text{Spec}(k) \rightarrow X$ .

**Remark 1.8.** When the condition of the preceding definition is satisfied while restricting to local artinian  $S$ , one will say that  $f : F \rightarrow G$  is *infinitesimally smooth* (resp. *infinitesimally unramified*, resp. *infinitesimally étale*) *at*  $x$ , and one says that  $f : F \rightarrow G$  is *infinitesimally smooth* (resp. ...) if it is so at every point  $x$ , in other terms if the condition envisaged in 1.6 is satisfied whenever  $S'$  is local <!-- original page 90 --> artinian.

This variant of the preceding notions is technically useful, since it is often easier to verify, being a weaker notion, while being frequently sufficient (for example if  $f: X \rightarrow G$  is a morphism locally of finite presentation, with  $G$  representable by a prescheme locally noetherian...) to entail the strong condition.

<!-- label: III.XI.1.8 -->

Smooth morphisms of preschemes behave in a remarkably simple way with respect to differential calculus. We confine ourselves here to recalling the following property:

**Proposition 1.9.** \*Let  $f: X \rightarrow S$  be a smooth morphism of preschemes. Then  $\Omega^1_{X/S}$  is a locally free module of finite type over  $\mathcal{O}_X$ , and its rank at a point  $x \in X$  equals the dimension of the fiber  $X_s$  (where  $s = f(x)$ ) in a neighborhood of the point  $x$ .\*

<!-- label: III.XI.1.9 -->

<!-- original page 135 -->

This dimension is called the *relative dimension* of  $X$  over  $S$  at  $x$ . One will note that it is zero (when  $f$  is smooth at  $x$ ) if and only if  $f$  is étale at  $x$ . This dimension is computed in practice still in terms of the functor  $F$  represented by  $X$ , in the following way. Let  $\xi$  be a point of  $F$  with values in a field  $k$ , "localized at  $x$ ", i.e. a morphism  $\text{operatorname{Spec}}(k) \rightarrow F = X$  whose image is  $x$ . Consider the algebra  $D(k) = k[t]/(t^2)$  of dual numbers over  $k$ , considered as an  $S$ -prescheme, and consider the map

$$\begin{array}{c} S \\ F(D(k)) \longrightarrow F(k) \\ S \end{array}$$

deduced from the augmentation  $D(k) \rightarrow k$ , and let finally  $F(D(k), \xi)$  be the inverse image of  $\xi \in F(k)$  under this map. Then this set is naturally endowed with a structure of vector space over  $k$  (in fact, it is the vector space dual of  $\Omega^1_{X/S} \otimes_{\mathcal{O}_X} k$ ), whose dimension is the relative dimension of  $X$  over  $S$  at  $x$ .

To make explicit the vector law on  $F(D(k), \xi)$ , it is convenient to introduce more generally, as in Exp. II, for every vector space  $V$  over  $k$ , the algebra  $D_k(V) = k + V$  (with  $V$  an ideal of square zero), and to consider  $F(D_k(V), \xi)$ , the inverse image of  $\xi$  by  $F(D_k(V)) \rightarrow F(k)$ , as a covariant functor in  $V$ , with values in  $(\text{Ens})$ . It then suffices that this functor commute with products of two factors (which means that  $F$  transforms certain amalgamated sums of a very special type into fibered products, compare Exp. II – a condition always satisfied when  $F$  is representable), to conclude that the  $F(D_k(V), \xi)$  and in particular  $F(D(k), \xi)$  are endowed with vector structures over  $k$ . One can thus define the relative dimension of  $F$  over  $X$  at the "point"  $\xi$ , under conditions appreciably broader than the representability of  $F$ .

In the present Exposé, the fact that certain functors which we shall make explicit are representable by preschemes smooth over  $S$  will serve us mainly through the intermediary of the following result, which will be for us the technical intermediary to pass from constructions on the completion of the local ring  $A$  of a point  $s$  of a noetherian scheme  $S$  <!-- original page 136 --> to a local ring  $A'$  over  $A$  étale over  $A$ , which will yield in particular a means of passing from  $s$  to neighboring points:

**Proposition 1.10.** \*Let  $f: X \rightarrow S$  be a smooth morphism of preschemes,  $s$  a point of  $S$ , and  $x$  a point of  $X$  above  $s$  such that  $\kappa(x)$  be a finite separable extension of  $\kappa(s)$ . Then there exists a subscheme  $S'$  of  $S$ , étale over  $S$ , passing through  $x$ . Hence one can find an étale morphism  $S' \rightarrow S$ , a point  $s'$  of  $S'$  above  $s$  of residue extension equal to  $\kappa(x)/\kappa(s)$ , and an  $S'$ -morphism  $S' \rightarrow X$  sending  $s'$  to  $x$ .\*

<!-- label: III.XI.1.10 -->

To construct  $S'$ , one simply takes a system  $g_1, \dots, g_n$  of sections of  $\Omega^1_{X/S}$  on a neighborhood of  $x$ , which induce at  $x$  a regular system of parameters of the local ring of the fiber  $X_s$  at  $x$ ; the subscheme  $S'$  defined by the  $g_i$  is then étale over  $S$  at  $x$ , and provided one shrinks  $S'$ , it will then be étale over  $S$ .

We shall use 1.10 when  $\kappa(x) = \kappa(s)$ , i.e.  $x$  is rational over  $\kappa(s)$ , i.e.  $x$  can be considered as a section of  $X_s$  over  $\text{operatorname{Spec}}(\kappa(s))$ . Then 1.10 is in the nature of a theorem of extension of sections (after étale extension of the base). It takes a particularly simple form in the following special case:

**Corollary 1.11.** \*Under the conditions of 1.10, suppose that  $S$  is the spectrum of a henselian local ring, and that  $\kappa(x) = \kappa(s)$ . Then there exists a section of  $X$  over  $S$  passing through  $x$  (uniquely determined if  $X$  is in fact étale over  $S$  at  $x$ ).\*

<!-- label: III.XI.1.11 -->

Indeed,  $S$  being henselian, it follows under the conditions of 1.10 that  $S'$  contains an open subscheme which is finite over  $S$  and whose fiber at  $s$  is reduced to  $x$ . As it is étale over  $S$ , it follows that it is isomorphic to  $S$ , whence the conclusion. — One will note that when  $S$  is the spectrum of a complete local ring, 1.10 or 1.11 is more or less the equivalent of the classical "Hensel's lemma", and one sometimes refers to it by this name.

## 2. Examples of formally smooth functors drawn from the theory of multiplicative-type groups

<!-- original page 137 -->

We are going to interpret, in the language introduced in the preceding N°, the results stated in IX 3 concerning infinitesimal extensions of a homomorphism of a group of multiplicative type (consequences of the vanishing of the Hochschild cohomology of such a group, established in Exposé I).

**Proposition 2.1.** \*Let  $S$  be a prescheme,  $H$  a group of multiplicative type over  $S$ ,  $G$  an  $S$ -prescheme in groups smooth over  $S$ ; consider the functor over  $S$ \*

$M_H = \operatorname{Hom}_{\{S\text{-gr.}\}}(H, G)$

\*(whose value at  $S'$  over  $S$  is the set of homomorphisms of  $S'$ -groups from  $H_{S'}$  to  $G_{S'}$ ). This functor is formally smooth over  $S$ .\*

<!-- label: III.XI.2.1 -->

Cf. IX 3.6. More generally:

**Corollary 2.2.** \*Let  $S, G$  be as above, and consider a homomorphism  $u : H_1 \rightarrow H_2$  of group schemes of multiplicative type over  $S$ , whence with the preceding notation a morphism of functors over  $S$ .\*

$$M_{H_2} \rightarrow M_{H_1} \quad (M_{H_i} = \operatorname{Hom}_{\{S\text{-gr.}\}}(H_i, G)),$$

\*given by  $w \mapsto w \circ u$ . This homomorphism is formally smooth.\*

<!-- label: III.XI.2.2 -->

Indeed, by virtue of definitions 1.6, this is equivalent to the following statement: when  $S$  is affine,  $S'$  a subscheme defined by a nilpotent ideal, let

$$v : H_1 \rightarrow G$$

be a homomorphism of  $S$ -groups, and

$$w' : (H_2)_{S'} \rightarrow G_{S'}$$

<!-- original page 138 --> a homomorphism of  $S'$ -groups such that  $w' u_{S'} = v_{S'}$ ; there then exists a homomorphism of  $S$ -groups

$$w : H_2 \rightarrow G$$

extending  $w'$ , and such that  $w u = v$ . To see this, one begins by extending  $w'$  to a homomorphism of  $S$ -groups  $w_0 : H_2 \rightarrow G$ , which is possible by 2.1; consider then  $v' = w_0 u : H_1 \rightarrow G$ . It is such that  $v'_{S'} = v_{S'}$  by hypothesis on  $w'$ , hence by virtue of VIII 3.6 there exists an element  $g$  of  $G(S)$ , whose image in  $G(S')$  is the unit element, and such that  $v = \operatorname{int}(g) v'$ , whence  $v = (\operatorname{int}(g) w_0) u$ , and it will therefore

suffice to take  $w = \text{int}(g) w_{\{0\}}$ .

**Corollary 2.3.** With the notation of 2.1, consider  $M_{\{H\}} = M$  as a functor with group of operators  $G$  ( $G$  operating by  $(v, g) \mapsto \text{int}(g) \circ v$ ). Then the corresponding morphism

text  
 $R : G \times_S M \rightarrow M \times_S M$

defined by  $(g, v) \mapsto (\text{int}(g) \circ v, v)$  is a formally smooth morphism.

label: III.XI.2.3 -->

By means of a base change  $S' \rightarrow S$ , this is equivalent to the following statement:

**Corollary 2.4.** With the notation of 2.1, let  $v_{\{1\}}, v_{\{2\}} : H \rightarrow G$  be two morphisms of  $S$ -groups, and let  $\text{Transp}(v_{\{1\}}, v_{\{2\}})$  be the subfunctor of  $G$  formed of the  $g$  such that  $\text{int}(g) \circ v_{\{1\}} = v_{\{2\}}$ . Then this functor is formally smooth over  $S$ . In particular (if  $v_{\{1\}} = v_{\{2\}} = v$ ) the functor  $\text{Centr}(v)$ , subgroup of  $G$  formed of the  $h$  such that  $\text{int}(h) v = v$ , is formally smooth over  $S$ .

label: III.XI.2.4 -->

original page 139 -->

(N.B. The pair  $(v_{\{1\}}, v_{\{2\}})$  can be considered as a section over  $S$  of the second member in the morphism  $R$  of 2.3, and  $\text{Transp}(v_{\{1\}}, v_{\{2\}})$  as the inverse image functor of the said section under  $R$ .) Statement 2.4 itself is equivalent to the following: when  $S$  is affine and  $S'$  is a subscheme of  $S$  defined by a nilpotent ideal, for every  $g_{\{0\}} \in G(S')$  such that  $\text{int}(g_{\{0\}})(v_{\{1\}})_{\{S'\}} = (v_{\{2\}})_{\{S'\}}$ ,  $g_{\{0\}}$  extends to a  $g \in G(S)$  such that  $\text{int}(g) v_{\{1\}} = v_{\{2\}}$ . To prove this, one begins by extending  $g_{\{0\}}$  to a section  $g'$  of  $G$  over  $S$ , which is possible since  $G$  is smooth over  $S$ ; one sets  $v'_{\{2\}} = \text{int}(g') v_{\{1\}}$ , one notes that  $v_{\{2\}}$  and  $v'_{\{2\}}$  have the same restriction over  $S'$ , hence by the result already invoked IX 3.6 there exists a  $g'' \in G(S)$ , inducing the unit section over  $S'$ , and such that  $v_{\{2\}} = \text{int}(g'') v'_{\{2\}}$ , whence  $v_{\{2\}} = \text{int}(g'') \text{int}(g') v_{\{1\}} = \text{int}(g'' g') v_{\{1\}}$ , so that it suffices to take  $g = g'' g'$ .

**Proposition 2.1 bis.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups smooth over  $S$ , and consider the functor  $M : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$ :

text  
 $M(S') = \text{set of multiplicative-type subgroups of } G_{\{S'\}}.$

Then  $M$  is formally smooth over  $S$ .

label: III.XI.2.1bis -->

Cf. IX 3.6 bis.

**Corollary 2.2 bis.** Let  $n$  be an integer, and consider the morphism of functors

$\phi_n : M \rightarrow M$

defined by

text  
 $\phi_n(H) = {}_n H = \text{Ker}(n \cdot \text{id}_H).$

Then  $\phi_n$  is a formally smooth morphism. If for every integer  $p > 0$ ,  $M_{\{p\}}$  denotes the subfunctor of  $M$  such that  $M_{\{p\}}(S')$  is the set of multiplicative-type subgroups  $H$  of  $G_{\{S'\}}$  such that  $\phi_p(H) = H$ , then the morphism induced by  $\phi_n$ :

$M_{\{np\}} \rightarrow M_{\{n\}}$

\$\$

\*is formally smooth.\*

<!-- label: III.XI.2.2bis -->

<!-- original page 140 -->

The second assertion is trivially contained in the first and is included only for the convenience of a later reference. The proof of the first is analogous to that of 2.2, invoking this time IX 3.6 bis.

**Corollary 2.3 bis.** \*With the notation of 2.1 bis, consider  $M$  as a functor with group of operators  $G$  ( $G$  operating by  $(g, H) \mapsto \text{int}(g)(H)$ ). Then the corresponding morphism\*

``text  
 $R : G \times_S M \rightarrow M \times_S M$   
``

\*defined by  $(g, v) \mapsto (\text{int}(g)v, v)$  is formally smooth.\*

<!-- label: III.XI.2.3bis -->

This is equivalent to the following statement:

**Corollary 2.4 bis.** \*With the notation of 2.1 bis, let  $H_1, H_2$  be two multiplicative-type subgroups of  $G$ , and let  $\text{Transp}_G(H_1, H_2)$  be the subfunctor of  $G$  formed of the  $g$  such that  $\text{int}(g)H_1 = H_2$ . Then this functor is formally smooth over  $S$ . In particular, if  $H_1 = H_2 = H$ , the subfunctor  $\text{Norm}_G(H)$  of  $G$ , normalizer of  $H$ , is formally smooth over  $S$ .\*

<!-- label: III.XI.2.4bis -->

The proof is analogous to that of 2.4, invoking again IX 3.6 bis.

**Proposition 2.5.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups smooth over  $S$ ,  $K$  a sub- $S$ -prescheme in groups, smooth over  $S$  or of multiplicative type,  $H$  an  $S$ -prescheme in groups of multiplicative type,  $u : H \rightarrow G$  a homomorphism of  $S$ -groups, and denote by  $\text{Transp}_G(u, K)$  the subfunctor of  $G$  whose value, at an  $S'$  over  $S$ , is formed of the  $g \in G(S')$  such that  $\text{int}(g)u_{S'} : H_{S'} \rightarrow G_{S'}$  factors through  $K_{S'}$ . Then this functor is formally smooth over  $S$ .\*

<!-- label: III.XI.2.5 -->

The proof is analogous to that of 2.2, invoking IX 3.6 and X 2.1 (the latter in the case  $K$  of multiplicative type).

<!-- original page 141 -->

### ## 3. Auxiliary representability results

**Proposition 3.1.** \*Let  $F \rightarrow S$  be a functor over the prescheme  $S$ . The following conditions are equivalent:\*

<!-- label: III.XI.3.1 -->

(i)  $F$  is representable, and  $F \rightarrow S$  is an open immersion (one also says simply that  $F \rightarrow S$  is an open immersion).\*

(ii)  $F$  is a sheaf for the faithfully flat quasi-compact topology, "commutes with inductive limits of rings",  $F \rightarrow S$  is a monomorphism, and finally the following condition is satisfied: for every local prescheme  $S'$  over  $S$ , of residue field  $k$ , and every  $S$ -morphism  $\text{Spec}(k) \rightarrow S'$ , there exists an  $S$ -morphism  $S' \rightarrow S$  which extends it.\*

(iii) (When  $S$  is locally noetherian.)  $F$  is a sheaf for the faithfully flat quasi-compact topology, "commutes with inductive limits of rings", "commutes with adic projective limits of local artinian rings",  $F \rightarrow S$  is a monomorphism, and is infinitesimally étale (cf. 1.8).\*

Let us first make precise two points of terminology.

**\*\*Remark 3.2.\*\*** One says that a functor  $[^N.D.E-XI-2]$   $\mathcal{F}$  over  $\mathcal{S}$  "commutes with inductive (understood: filtered) limits of rings" if for every filtered projective system  $(S'_i)_{i \in I}$  of  $\mathcal{S}$ -affine schemes above an affine open of  $\mathcal{S}$ , with rings  $A'_i$ , the natural homomorphism

```

```text
(*)    $\lim_{\rightarrow} F(S'_i) \rightarrow F(S')$    (where  $S' = \text{Spec } A'$ ,  $A' = \lim_{\rightarrow} A'_i$ )
```

```

<!-- label: III.XI.3.2 -->

<!-- original page 142 -->

is bijective. One will note that  $\mathcal{S}$  is none other than the projective limit of  $(S'_i)$  in the category of preschemes (and even of all ringed spaces), so that the condition envisaged is in the nature of a right-exactness condition (commutation with certain inductive limits in  $(\text{Sch})^{\circ}/\mathcal{S}$ ), just as the condition of being a sheaf for some topology. One will pay attention to the fact that the condition envisaged is essentially relative, i.e. involves the morphism  $\mathcal{F} \rightarrow \mathcal{S}$  and not only the functor  $\mathcal{F} : (\text{Sch})^{\circ} \rightarrow (\text{Ens})$ ; more precisely, in  $(*)$ ,  $\mathcal{F}(S'_i)$  and  $\mathcal{F}(S')$  denote  $\text{Hom}_{\mathcal{S}}(S'_i, \mathcal{F})$ ,  $\text{Hom}_{\mathcal{S}}(S', \mathcal{F})$ . Thus, when  $\mathcal{F}$  is representable, the condition envisaged means that  $\mathcal{F}$  is locally of finite presentation over  $\mathcal{S}$ . (And we have used several times, in the last two Exposés, the fact that a functor represented by an  $\mathcal{S}$ -prescheme locally of finite presentation commutes with inductive limits of rings.)

**\*\*Remark 3.3.\*\*** One says that a functor  $[^N.D.E-XI-2]$   $\mathcal{F}$  over  $\mathcal{S}$  "commutes with adic projective limits of local artinian rings" if for every  $\mathcal{S}'$  over  $\mathcal{S}$  which is the spectrum of a complete noetherian local ring  $A'$ , setting  $S'_n = \text{Spec}(A'/\text{rad}(A')^{n+1})$ , the natural map

```

$$\mathcal{F}(S') \rightarrow \varprojlim \mathcal{F}(S'_n)$$

```

<!-- label: III.XI.3.3 -->

is bijective. One will note that this condition, which is in the nature of a left-exactness condition, is satisfied whenever  $\mathcal{F}$  is representable. One sees easily that, contrary to the condition of commutation with inductive limits of rings, it is intrinsic to  $\mathcal{F}$  as an element of  $\text{Ob}(\hat{\text{ch}})$ , i.e. it does not involve the morphism  $\mathcal{F} \rightarrow \mathcal{S}$ .

**\*\*Remark 3.4.\*\*** Let  $\mathcal{F}$  be a functor over  $\mathcal{S}$  which is a sheaf for the Zariski topology, or as one also says, which is "of local nature". (It suffices for this that  $\mathcal{F}$  be a sheaf for a finer topology, such as the faithfully flat quasi-compact topology.) Let  $(S_i)$  be a covering of  $\mathcal{S}$  by opens; then one easily verifies (by a method of gluing pieces) that  $\mathcal{F}$  is representable if and only if the  $\mathcal{F}_i = \mathcal{F}|_{S_i} = \mathcal{F} \times_{\mathcal{S}} S_i$  are, <!-- original page 143 --> which allows for example reduction to the case where  $\mathcal{S}$  is affine. Suppose that the functor  $\mathcal{F}$  of local nature commutes with inductive limits of rings. Then, for  $\mathcal{F}$  to be representable, it is necessary and sufficient that its restriction to the category of preschemes locally of finite presentation over  $\mathcal{S}$  be representable. The "necessary" was pointed out in 3.2; the "sufficient" amounts to this: if  $\mathcal{X}$  is a prescheme locally of finite presentation over  $\mathcal{S}$  and  $\mathcal{X} \rightarrow \mathcal{F}$  a morphism such that, for every  $\mathcal{S}'$  locally of finite presentation over  $\mathcal{S}$ , the induced morphism

```

```text
 $\text{Hom}_{\mathcal{S}}(S', \mathcal{X}) \rightarrow \text{Hom}_{\mathcal{S}}(S', \mathcal{F})$ 
```

```

<!-- label: III.XI.3.4 -->

is bijective, then  $\mathcal{X} \rightarrow \mathcal{F}$  is an isomorphism. Now this results easily from the fact that  $\mathcal{X}$  and  $\mathcal{F}$  are two functors of local nature which commute with inductive limits of rings.

Let us now prove 3.1. The implications (i)  $\Rightarrow$  (ii) and (i)  $\Rightarrow$  (iii) are evident; let us prove the inverse implications.

One has (ii)  $\Rightarrow$  (i). Let  $U$  indeed be the set of  $s \in \mathcal{S}$  such that the canonical monomorphism  $\text{Spec}(\kappa(s)) \rightarrow \mathcal{S}$  factors through  $\mathcal{F}$ . By virtue of the last condition (ii), for every  $s \in U$ , the canonical monomorphism  $\text{Spec}(\mathcal{O}_{\mathcal{S},s}) \rightarrow U$  factors through  $\mathcal{F}$ . Noting that  $\mathcal{O}_{\mathcal{S},s}$  is the inductive limit of the rings of affine neighborhoods of  $s$ , it follows from the fact that  $\mathcal{F}$  commutes with inductive limits of rings that for every  $s \in \mathcal{S}$ , there exists an open neighborhood  $U_s$  such that the canonical immersion  $U_s \rightarrow \mathcal{S}$  factors through  $\mathcal{F}$ . This implies  $U_s \subset U$ , so  $U$  is open. As  $\mathcal{F} \rightarrow \mathcal{S}$  is a monomorphism, and  $\mathcal{F}$  is of local nature, the  $\mathcal{S}$ -morphisms  $U_s \rightarrow \mathcal{F}$  glue on the intersections  $U_s \cap U_{s'}$  ( $s, s' \in U$ ), hence come from an  $\mathcal{S}$ -morphism  $U \rightarrow \mathcal{F}$ . It remains to prove that this is an isomorphism, hence that every  $\mathcal{S}$ -morphism  $S' \rightarrow \mathcal{F}$  factors uniquely through  $U$  (where  $S'$  is an  $\mathcal{S}$ -prescheme). As  $\mathcal{F} \rightarrow \mathcal{S}$  and

$U \rightarrow S$  are monomorphisms, it amounts to the same to say that the structural morphism  $S' \rightarrow S$  factors through  $U$ , which reduces us to the case where  $S'$  is the spectrum of a field, hence reduced to a single point <!-- original page 144 -->  $S'$ . Let  $s$  be the point of  $S$  below  $s'$ ; I say that the  $S$ -morphism  $S' \rightarrow F$  factors through  $\operatorname{Spec}(\kappa(s)) = S_0 \rightarrow F$  (which implies  $s \in U$  and will prove what we want).

It amounts to the same, since  $S' \rightarrow S_0$  is covering for fpqc and  $F$  is a sheaf for this topology, that the two composites

```

```text
S'' = S' x_{S_0} S' \rightrightarrows S' \rightarrow F
```

```

are the same, which follows from the fact that  $F \rightarrow S$  is a monomorphism.

One has (iii)  $\Rightarrow$  (ii) (when  $S$  is locally noetherian). It suffices to prove the last condition of (ii), and moreover (by virtue of the preceding proof) it suffices to do so when  $S'$  is of the form  $\operatorname{Spec}(0_{(S,s)})$ , with  $s \in S$ . Let  $A = 0_{(S,s)}$ ,  $A_n = A/m^{n+1}$ ,  $S_n = \operatorname{Spec}(A_n)$ . Then it follows from the hypothesis that  $F \rightarrow S$  is infinitesimally smooth, that the given morphism  $S_0 \rightarrow F$  extends to morphisms  $S_n \rightarrow F$ . As  $F \rightarrow S$  is a monomorphism, one thus obtains an element of  $\varprojlim F(S_n)$ , and since  $F$  commutes with adic projective limits of local artinian rings, the  $S_n \rightarrow F$  come from a morphism  $\operatorname{Spec}(\hat{A}) = \hat{S}' \rightarrow F$ . As  $F \rightarrow S$  is a monomorphism,  $F$  a sheaf for fpqc, and  $\hat{S}' \rightarrow S'$  covering for the said topology, this morphism  $\hat{S}' \rightarrow F$  factors through  $S' \rightarrow F$ , which completes the proof.

**Proposition 3.5.** \*Let  $S$  be a locally noetherian prescheme,  $F \rightarrow S$  a functor over  $S$ ,  $(X_i, u_i)_{i \in I}$  a family of  $S$ -morphisms  $u_i : X_i \rightarrow F$ , where the  $X_i$  are preschemes locally of finite type over  $S$ . Suppose the following conditions are satisfied:

<!-- label: III.XI.3.5 -->

a)  $F$  is a sheaf for the faithfully flat quasi-compact topology, commutes with inductive limits of rings, commutes with adic projective limits of local artinian rings.\*

b) The  $u_i : X_i \rightarrow F$  are monomorphisms, and are infinitesimally étale (cf. 1.8).\* <!-- original page 145 -->

c) The family of the  $u_i$  is "set-theoretically surjective".\*

Under these conditions,  $F$  is representable by a prescheme locally of finite type over  $S$  (and the  $u_i$  are open immersions, which make the family of the  $X_i$  into an open covering of  $F$ ).\*

**Remark 3.6.** Proceeding as at the end of Remark 1.7, one defines, for every functor  $F : (\operatorname{Sch})^{\circ} \rightarrow (\operatorname{Ens})$ , an "underlying set"  $\operatorname{set}(F)$  as a quotient set of the set of points of  $F$  with values in fields (for the equivalence relation made precise in 1.7). When  $F$  is representable by  $X$ , one recovers the underlying set of  $X$ . Evidently  $\operatorname{set}(F)$  depends functorially on  $F$ , so that if  $G \rightarrow F$  is a morphism of functors, one will say that this morphism is \*set-theoretically surjective\* if the induced map  $\operatorname{set}(G) \rightarrow \operatorname{set}(F)$  is surjective. This means therefore also that every point of  $F$  with values in a field  $k$  "comes from" a point of  $G$  with values in a suitable extension of  $k$ . This definition extends immediately to the case of a family of morphisms  $G_i \rightarrow F$ , which makes precise the meaning of c).

<!-- label: III.XI.3.6 -->

Let us prove 3.5. For this, let us introduce, for  $(i, j) \in I \times I$ ,

```

```text
X_{i,j} = X_i x_F X_j,
```

```

and consider the projections

```

```text
v_{i,j} : X_{i,j} \rightarrow X_i \quad \text{and} \quad w_{i,j} : X_{i,j} \rightarrow X_j.
```

```

I say that these last are representable by open immersions. To see it, one applies criterion 3.1 (iii):  $X_{i,j}$  satisfies the three exactness conditions (being a sheaf, commuting with  $\varinjlim$  of rings and with adic

$\varprojlim$  of local artinian rings), since  $\mathcal{F}$ ,  $X_i$ ,  $X_j$  satisfy them, and these conditions are stable under finite projective limits, in particular under fibered products; <!-- original page 146 --> since  $X_i \rightarrow \mathcal{F}$  is a monomorphism, so is  $v_{i,j} : X_{i,j} \rightarrow X_i$  deduced from it by base change  $X_j \rightarrow \mathcal{F}$ , and symmetrically  $v_{j,i}$  is a monomorphism; finally the "infinitesimally étale" condition is also preserved by base change. This proves that one is under the conditions of 3.1 (iii).

We may now use the  $X_i$ ,  $X_{i,j}$ ,  $v_{i,j}$  and  $w_{i,j}$  to construct in the usual way an  $\mathcal{S}$ -prescheme  $X$  such that the  $X_i$  are identified with opens of  $X$ , the  $X_{i,j}$  with the intersections  $X_i \cap X_j$ , and the  $v_{i,j}$ ,  $w_{i,j}$  with the canonical immersions. Note that  $X$  is also the quotient of

$\mathcal{S}$   
 $Y = \amalg_i X_i$   
 $\mathcal{S}$

by the equivalence relation  $R = \amalg_{i,j} X_{i,j}$  (the two projections  $v, w : R \rightarrow Y$  being defined by the  $v_{i,j}$  resp. the  $w_{i,j}$ ). More precisely,  $\mathcal{F}$  being a sheaf for fpqc, the  $u_i : X_i \rightarrow \mathcal{F}$  come from a  $u : Y \rightarrow \mathcal{F}$ , and  $\mathcal{R}$  is none other than the equivalence relation defined by  $u$ ,  $\mathcal{R} = Y \times_{\mathcal{F}} Y$ ; finally the quotient  $X = Y/\mathcal{R}$  is also a quotient in the category of fpqc-sheaves (and even, in the category of sheaves for the Zariski topology): it suffices to use the definitions of "quotient" and "sheaf" to convince oneself. Consequently,  $u$  factors uniquely through a morphism

$\mathcal{S}$   
 $\bar{u} : X \rightarrow F,$   
 $\mathcal{S}$

and this morphism is a monomorphism. It remains to show that it is an isomorphism. As  $\mathcal{F}$  is of local nature, one may suppose  $\mathcal{S}$  affine, and as moreover  $\mathcal{F}$  commutes with inductive limits of rings, it suffices to verify that for every  $T$  affine of finite type over  $\mathcal{S}$ , every morphism  $T \rightarrow \mathcal{F}$  factors through  $X$  (cf. 3.4). For this, consider  $G = X \times_{\mathcal{F}} T \rightarrow T$ . It suffices to prove that this is an isomorphism. Now,  $T$  being noetherian, one sees as above that this is an open immersion (N.B.  $X \rightarrow \mathcal{F}$  is infinitesimally étale, as follows at once from the fact that the induced morphisms  $u_i : X_i \rightarrow \mathcal{F}$  are). Now by hypothesis  $X \rightarrow \mathcal{F}$  is set-theoretically surjective, and one sees at once that this is a condition stable under base change, <!-- original page 147 --> hence  $G \rightarrow T$  is set-theoretically surjective, hence an isomorphism since it is an open immersion. QED.

**Proposition 3.7.** \*Let  $\mathcal{S}$  be a locally noetherian prescheme,  $I$  a filtered increasing index set,  $(T_i)_{i \in I}$  a projective system of  $\mathcal{S}$ -preschemes locally of finite type,  $T = \varprojlim T_i$  the projective limit functor,  $\mathcal{F}$  a functor over  $\mathcal{S}$ ,  $u : F \rightarrow T$  an  $\mathcal{S}$ -morphism. Suppose the following conditions are satisfied:

<!-- label: III.XI.3.7 -->

a)  $\mathcal{F}$  is a sheaf for the faithfully flat quasi-compact topology, commutes with inductive limits of rings, and with adic projective limits of local artinian rings.\*

b) The morphism  $u : F \rightarrow T$  is a monomorphism.\*

b') The morphism  $u : F \rightarrow T$  is infinitesimally étale.\*

c) For every point  $x$  of  $\mathcal{F}$  with values in the spectrum of a field  $k$ , denoting by  $x_i \in T_i(\operatorname{Spec}(k))$  its image and by  $t_i$  the corresponding element of  $T_i$ , there exists an  $i \in I$  such that for  $j \geq i$  the transition morphism  $p_{i,j} : T_j \rightarrow T_i$  is étale at  $t_j$ .\*

d) For every prescheme  $X$  locally of finite type over  $\mathcal{S}$ , and every  $\mathcal{S}$ -morphism  $X \rightarrow \mathcal{F}$ , the set of  $x \in X$  at which this morphism is infinitesimally étale is open.\*

Under these conditions,  $\mathcal{F}$  is representable by a prescheme locally of finite type over  $\mathcal{S}$ .\*

Let us note immediately that in the case which will occupy us in the following  $N^\circ$ , one will verify conditions c) and d) through the following corollary:

**Corollary 3.8.** \*Granting a), b), b'), conditions c) and d) are implied by the following:

<!-- label: III.XI.3.8 -->

<!-- original page 148 -->

\*c') The  $T_i$  are smooth over  $S$ , and the transition morphisms  $p_{i,j} : T_j \rightarrow T_i$  are smooth.\*

\*d') For every point  $x$  of  $F$  with values in the spectrum of a field  $k$ , let  $t_i(x)$  be the element of  $T_i$  defined by  $x$ ,  $d_i(x)$  the relative dimension of  $T_i$  over  $S$  at  $t_i(x)$ , and  $d(x) = \sup d_i(x)$ . Then:\*

\*1°) for every  $x$  as above, one has  $d(x) < +\infty$ , and\*

\*2°) for every prescheme  $X$  locally of finite type over  $S$  and every  $S$ -monomorphism  $v : X \rightarrow F$ , the function  $x \mapsto d(x)$  on  $X$  is locally constant (where for  $x$  in  $X$  one denotes by  $x$  the point of  $F$  with values in  $\kappa(x)$  induced by  $v$ ).

Let us prove 3.7. Let us place ourselves under the conditions of c); let  $t$  be the element of  $\text{set}(F)$  defined by  $x$  (cf. 3.6) and set

```
```text
0_t = lim_{\rightarrow} 0_{T_i, t_i}.
```

Then using the condition stated in c), one sees easily that 0_t is a noetherian local ring (EGA 0_IV 10.3.1.3). Its residue field $\kappa(t)$ is the inductive limit of the residue fields $\kappa(t_i)$, and k is an extension of it. If η denotes the spectrum of $\kappa(t)$, x that of k , one has a commutative diagram

```
```text
\xrightarrow{\quad} F
\downarrow \quad \downarrow
\eta \rightarrow T,
```

whose definition is evident and left to the reader. As  $x \rightarrow \eta$  is covering for the fpqc topology,  $F$  is a sheaf for it by virtue of a), and  $F \rightarrow T$  is a monomorphism by virtue of b), one sees at once that the morphism  $\eta \rightarrow T$  factors (uniquely) through a morphism  $\eta \rightarrow F$ . Let us note now the

<!-- original page 149 -->

**Lemma 3.9.** \*Under the conditions of 3.7, let  $T_0 = \text{Spec}(A)$  be a noetherian local scheme,  $T_0' = \text{Spec}(k(A))$ ,  $i : T_0' \rightarrow T_0$  the canonical immersion, and suppose given a commutative square of morphisms\*

```
```text
T_0' \rightarrow F
| \quad \quad |
i \downarrow \quad \downarrow
T_0 \rightarrow T.
```

Then there exists a unique T -morphism $T_0 \rightarrow T$.

<!-- label: III.XI.3.9 -->

The proof is that of 3.1 (iii) $\Rightarrow$ (ii) (where the fact that the S of the cited statement be representable was not used), using that F is a sheaf for the fpqc topology, commutes with adic projective limits of local artinian rings (in this case the $A/\text{rad}(A)^{n+1}$), and that $F \rightarrow T$ is a monomorphism and is infinitesimally étale.

We shall apply lemma 3.9 to the case where $T_0 = \text{Spec}(0_t)$, hence $T_0' = \text{Spec}(\kappa(t))$, noting that we have just constructed $T_0' \rightarrow F$, and that the canonical homomorphisms $0_{T_i}, t_i \rightarrow 0_t$ define a projective system of morphisms $\text{Spec}(0_t) \rightarrow T_i$, whence a canonical morphism $\text{Spec}(0_t) \rightarrow T$. The commutativity of the corresponding square ($\times$) is trivial (since by definition of T , it suffices to verify it with T replaced by T_i), whence a unique T -morphism

```
```text
v' : T_0 = Spec(0_t) \rightarrow F.
```

As  $\mathcal{F}$  commutes with inductive limits of rings, this morphism factors through

```
```text
v'_i : T'_i = Spec(O_{T_i, t_i}) → F
```

for i large. For such an i , one has

```
```text
T_0 ⊂ T'_i i.e. O_{T_i, t_i} ⊂ O_t.
```

Indeed, as  $T_0 \rightarrow T'_i$  is faithfully flat quasi-compact, hence an effective epimorphism, <!-- original page 150 --> it suffices to see that it is a monomorphism. Now if one has two morphisms  $R \rightrightarrows T_0$  (with  $R$  representable) having the same composite with  $T_0 \rightarrow T'_i$ , they have the same composite with  $T_0 \rightarrow T$  (which factors through  $T_0 \rightarrow T'_i$ ), hence the same composite with  $T_0 \rightarrow T_{\{j\}}$  for every  $j$ , hence with  $T_0 \rightarrow T'_{\{j\}}$  for every  $j$ , hence are equal because  $T_0$  is the projective limit of the  $T'_{\{j\}}$  in the category  $(\text{Sch})$ .

Consider the diagram

```
```text
      v'
T_0  -----> F
|           ^
|           v'_i
v           ^
T'_i -----> T_i
```

where the unspecified arrows are the obvious ones. The square is commutative and so is the upper triangle, hence as $T_0 \rightarrow T'_i$ is an epimorphism, it follows that the lower triangle is commutative. Now O_{T_i, t_i} is the inductive limit of the affine rings of affine open neighborhoods of t_i in T_i , hence as $\mathcal{F}$ commutes with inductive limits of rings, v'_i comes from a morphism

```
$$
v_{\{t\}} : U_{\{t\}} \rightarrow F
$$
```

from an open neighborhood $U_{\{t\}}$ of t_i in T_i . One sees at once that, restricting this neighborhood if necessary, $v_{\{t\}}$ is necessarily a $T_{\{i\}}$ -morphism ($T_{\{i\}}$ being locally of finite type over S , hence also commuting with inductive limits of rings). Then the composite of $v_{\{t\}}$ with $F \rightarrow T_i$ is a monomorphism, hence $v_{\{t\}}$ is a monomorphism. I say that it is infinitesimally étale at t_i . Since $F \rightarrow T$ is infinitesimally étale, it amounts to the same to say that the composite $T_{\{i\}} \rightarrow F \rightarrow T$ is infinitesimally étale at t_i , or again that the induced morphism $T'_{\{i\}} \rightarrow T$ is infinitesimally étale, or finally (since $T_0 \rightarrow T'_{\{i\}}$) that <!-- original page 151 --> $T_0 \rightarrow T$ is infinitesimally étale, which is immediate, this morphism being the projective limit of the infinitesimally étale morphisms $T'_{\{i\}} \rightarrow T_{\{i\}}$.

Let us now apply condition d), which had not yet been used; it follows that $v_{\{t\}}$ is infinitesimally étale in a neighborhood of t , hence, restricting $U_{\{t\}}$ to a smaller open if necessary, one may suppose that $v_{\{t\}}$ is a monomorphism infinitesimally étale.

For $t \in \text{set}(F)$ variable, the family of morphisms $v_{\{t\}}$ is amenable to 3.5, which implies the conclusion of 3.7.

Let us prove now 3.8, supposing satisfied conditions c') and d') of 3.8. Then with the notation of d'), one will have $d_{\{i\}}(\xi_i) = \text{constant}$ for i large, hence the relative dimension of $T_{\{j\}}$ over $T_{\{i\}}$ at $t_{\{j\}}$, equal to $d_{\{j\}}(\xi_j) - d_{\{i\}}(\xi_i)$, is zero, hence $T_{\{j\}} \rightarrow T_{\{i\}}$ is étale at $t_{\{j\}}$, which proves condition c). Consequently the preceding proof applies to give, for each $t \in \text{set}(F)$, an index i , an open neighborhood $U_{\{t\}}$ of t_i , and a morphism $U_{\{t\}} \rightarrow F$ which is a monomorphism, infinitesimally étale at t_i , and all reduces to proving that this morphism is infinitesimally étale in a neighborhood of t_i . Now with the notation of d') 2°), where one takes $X = U_{\{t\}}$, one may suppose, replacing $U_{\{t\}}$ by the connected component of t_i in $U_{\{t\}}$ if necessary, that for every $x \in U_{\{t\}}$, one has

```
```text
d(\xi_x) = d(\xi_{t_i}) for every x ∈ U_t.
```

Now  $d(\xi_{t_i}) = \text{relative dimension of } T_i \text{ over } S \text{ at } t_i$ , and as the relative dimension of  $T_i$  over  $S$  remains constant on  $U_t$ , one will have also, for every  $x \in U_t$ :

```
```text
(*)    d(ξ_x) = relative dimension of U_t over S at x.
```
```

On the other hand, with the notation of the proof of 3.7, one sees at once that for every  $x \in U_t$  (original page 152 --> local noetherian prescheme  $R_0 = \text{operatorname{Spec}}(A)$ , setting  $R_0' = \text{operatorname{Spec}}(k(A))$ , every morphism  $R_0 \rightarrow F$  such that the induced morphism  $R_0' \rightarrow F$  factors through  $F$  (i.e. sends the closed point of  $R_0$  to  $t$  in  $\text{set}(F)$ ) factors (uniquely in an obvious way) through  $T_0$ . (The proof is that of 3.1 or 3.9: one uses that  $T_0 \rightarrow F$  is a monomorphism infinitesimally étale at  $t$ , and that  $T_0$  is a sheaf for fpqc commuting with adic  $\varprojlim$ ). Applying this result to the morphism  $\text{operatorname{Spec}}(O_{U_t, x}) \rightarrow R_0 \rightarrow F$  induced by  $v_t$  and to the point  $x \in \text{set}(F)$  image of the closed point of  $R_0$ , i.e. image of  $x$  by  $v_t$ , one finds a factorization

```
```text
Spec(O_{U_t, x}) → Spec(O_{t_x}) → F
```
```

and as the second arrow is infinitesimally étale at  $x$ , to prove that the composite is so at  $x$ , it suffices to prove that the first is so at  $x$ . Now thanks to formula (\*) above, it is an  $S$ -homomorphism of localizations, at two points  $x$ ,  $t_x$ , of smooth  $S$ -preschemes  $U_t$ ,  $U_{t_x}$  of the same relative dimension  $d$  over  $S$  at  $t$ ,  $t_x$ . This morphism is induced by an  $S$ -morphism

```
$$
w : U \rightarrow V
$$
```

where  $U$  is an open neighborhood of  $x$  in  $U_t$ , and  $V = U_{t_x}$  (EGA I 6.5.1). It all reduces to proving that this morphism is étale at  $x$ . Moreover,  $U$  and  $V$  are equipped with monomorphisms  $U \rightarrow F$ ,  $V \rightarrow F$ , and one sees at once that, restricting  $U$  further if necessary,  $w$  is an  $F$ -morphism, hence  $w$  is a monomorphism. It now suffices to prove the

**Lemma 3.10.** \*Let  $U$ ,  $V$  be two smooth  $S$ -preschemes, of the same relative dimension  $d$  over  $S$ , and  $w : U \rightarrow V$  an  $S$ -morphism which is a monomorphism; then  $w$  is an open immersion (and a fortiori is étale).\*

<!-- label: III.XI.3.10 -->

By virtue of SGA 1, I 5.7, one is reduced to the case where  $S$  is the spectrum of a field, which one may suppose algebraically closed. By virtue of SGA 1, I 5.1, it suffices to prove that  $w$  is étale, and it suffices to prove this at the closed points of  $U$ . Let  $x$  be such a point, (original page 153 -->  $y = w(x)$ ); then, taking a regular system of parameters  $f_1, \dots, f_d$  of  $O_{V, y}$ , one sees that  $A = O_{U, x} / \sum f_i O_{U, x}$  is the trivial extension of  $k = O_{V, y} / \sum f_i O_{V, y}$  (for  $w$  being a monomorphism, so is the structural morphism  $\text{operatorname{Spec}}(A) \rightarrow \text{operatorname{Spec}}(k)$  deduced from it by base change). As  $O_{U, x}$  is a regular local ring of dimension  $d$ , it follows that the  $f_i$  form a regular system of parameters of this ring, which immediately implies that  $w$  is étale at  $x$  and completes the proof of 3.10, hence of 3.8.

**Corollary 3.11.** \*Under the conditions of 3.8, for every quasi-compact open  $U$  of  $F$  separated over  $S$ , there exists an  $i \in I$  such that for every  $j \geq i$  the morphism  $U_j \rightarrow U$  is an open immersion. In particular, if the  $T_i$  are quasi-affine over  $S$ , then every open  $U$  of  $F$  quasi-compact over  $S$ , i.e. of finite type over  $S$ , is quasi-affine over  $S$ .\*

<!-- label: III.XI.3.11 -->

The proof of 3.7 shows that for every  $t \in F$ , there exists an  $i \in I$  such that  $u_i : F \rightarrow T_i$  is a local isomorphism at  $t$ , and then  $u_j$  is a local isomorphism at  $x$  for every  $j \geq i$ . By reason of quasi-compactness, one may choose  $i$  independent of  $x \in U$ . It remains to prove that for  $i$  large,  $u_i|_U : U \rightarrow T_i$  is a monomorphism. Now as  $U \rightarrow T$  is a monomorphism, one sees that the intersection of the equivalence relations  $U \times_{T_i} U \subset U \times_S U$  is reduced to the diagonal, and as  $U \times_S U$  is a noetherian prescheme and the  $U \times_{T_i} U$  closed subpreschemes, it follows that one of these  $U \times_{T_i} U$  is already reduced to the diagonal, i.e.  $u_i|_U$  is a monomorphism. This proves the first assertion in 3.11, and the second is an immediate consequence of it.

**Proposition 3.12.** \*Let  $S$  be a prescheme,  $G$  an affine  $S$ -prescheme in groups.\*

<!-- label: III.XI.3.12 -->

<!-- original page 154 -->

\*a) Let  $F_S$  be the functor  $(\text{Sch})^{\text{circ}}/S \rightarrow (\text{Ens})_S$  such that, for every  $T_S$  over  $S_S$ ,

```text

$F(T) = \text{set of multiplicative-type subgroups of } G_T \text{ which are finite over } T.$

```

\*Suppose  $S_S$  locally noetherian or  $G_S$  of finite presentation over  $S_S$ . Then the functor  $F_S$  is representable and is affine over  $S_S$ . If  $G_S$  is of finite presentation over  $S_S$ , then  $F_S$  is locally of finite presentation over  $S_S$ .\*

\*b) Let  $H_S$  be an  $S_S$ -prescheme in groups of multiplicative type, and finite over  $S_S$ . Then  $\text{Hom}_{S\text{-gr.}}(H, G)_S$  is representable. It is affine over  $S_S$ , and if  $G_S$  is of finite type (resp. of finite presentation) over  $S_S$ , the same holds for  $\text{Hom}_{S\text{-gr.}}(H, G)_S$ .\*

**Remark 3.13.** Except for the precision that  $\text{Hom}_{S\text{-gr.}}(H, G)_S$  is affine, and in the case where  $G_S$  is of finite presentation over  $S_S$  (which will suffice for us), 3.12 is an immediate consequence of the theory of Hilbert schemes (A. Grothendieck, *Techniques de construction et théorèmes d'existence en Géométrie Algébrique: IV Les Schémas de Hilbert*, Séminaire Bourbaki, May 1961, N° 221). It even suffices that  $G_S$  be quasi-projective over  $S_S$ ; in case a), one may also represent the larger functor

```text

$F'(T) = \{ \text{set of subpreschemes in groups of } G_T, \\ \text{flat, proper and of finite presentation over } T \}$

```

(the canonical monomorphism  $F \rightarrow F'$  is an "open immersion", as follows from criterion 3.1 and from X 4.7 b), so that the representability of  $F'$  entails that  $F$  is representable by an open of  $F'$ ); in case b), one may restrict to supposing that  $H_S$  is projective and of finite presentation over  $S_S$ . In both cases, one obtains a functor locally of finite presentation over  $S_S$ . In the present Exposé, 3.12 is only a technical lemma for proving a key result in the following N°, so we shall sketch an easy direct proof of 3.12, not using Hilbert schemes.

<!-- label: III.XI.3.13 -->

Let us first prove b). It will suffice to prove that  $\text{Hom}_S(H, G)_S$  is representable (independently of any group structure on  $H_S, G_S$ ), and has the supplementary properties stated for  $\text{Hom}_{S\text{-gr.}}(H, G)_S$ , since using also the same result for  $\text{Hom}_S(H \times_S H, G)_S$ , one makes explicit the subfunctor  $\text{Hom}_{S\text{-gr.}}(H, G)_S$  of  $\text{Hom}_S(H, G)_S$  <!-- original page 155 --> by a finite projective limit (in fact, with the help of fibered products) involving  $G_S, \text{Hom}_S(H, G)_S$  and  $\text{Hom}_S(H \times_S H, G)_S$ , which we leave to the reader to make explicit. On the other hand, one will have

$S_S$

$H = \text{Spec}(B),$

$S_S$

where  $B_S$  is a sheaf of algebras over  $S_S$  which is locally free as a sheaf of modules (this is the only hypothesis on  $H_S$  that we shall need to retain). As the representability question envisaged is local on  $S_S$ , we may suppose  $S_S$  affine with ring  $A_S$ . On the other hand, one will have  $G = \text{Spec}(C)_S$ , where  $C_S$  is an  $A_S$ -algebra. When  $G = S[t] = G_{\{0\}}$ ,  $t$  an indeterminate, the functor  $\text{Hom}$  is none other than

$S_S$

$T \mapsto \Gamma(T, B_T),$

$S_S$

which is representable ( $B_S$  being locally free) by the vector bundle  $V(B^{\vee})_S$ , where  $B^{\vee}_S$  is the sheaf of modules dual to  $B_S$ . When  $G = S[(t_i)]_S$ , with  $(t_i)_S$  a (not necessarily finite) family of indeterminates, one will have therefore  $G = G^{\{I\}}_{\{0\}}$  (product over  $S_S$  of a family of copies of  $G_{\{0\}}$ ), which is representable by the affine scheme

```text

$\text{Hom}_S(H, G)^I = V(B^{\vee})^I = V(B^{\vee}(I)).$

```

In the general case,  $G_S$  will be isomorphic to a closed subscheme of a scheme of the form  $S[(t_i)]$ , i.e.  $C_S$  will be a quotient of an  $A_S$ -algebra of the form  $A[(t_i)]$ . Let  $\{F_j\}$  be a system of generators of the ideal by which one divides. Suppose  $B_S$  free of rank  $n_S$ , which is permissible by covering  $S_S$  by smaller affine opens. Choose a basis  $\{e_k\}_{1 \leq k \leq n_S}$  of  $B_S$ ; then writing the  $n_S$  components in this basis of  $F_j((x_i))$ , for  $x_i = \sum x_{ik} e_k$  ( $x_{ik}$  indeterminate coefficients, taken in an unspecified algebra  $A'$  over  $A_S$ ), one finds, for each  $F_j$ ,  $n_S$  polynomials  $F_{j,k}$  in the  $\{x_{i,k}\}_{i \in I, 1 \leq k \leq n_S}$ , with coefficients in  $A_S$ . One verifies at once that  $\operatorname{Hom}_S\{S\}(H, G)$  is represented by the spectrum of the quotient of the polynomial ring  $A[(x_{i,k})]$  by the ideal generated by the  $F_{j,k}$ . This proves at once b).

Let us prove a). For every ordinary finite commutative group  $M_S$ , let  $'F_M$  be the subfunctor of  $F_S$  obtained by restricting to subgroups of  $'G_T$  which are of multiplicative type <!-- original page 156 --> and of type  $M_S$ . One sees easily, by a gluing argument like the one which served in 3.5 (which we should have stated by unscrewing a bit more!), that it suffices to verify that the  $'F_M$  are representable; then  $F_S$  will be representable by the prescheme sum of the  $'F_M$ , where  $M_S$  runs over the set of classes of finite commutative groups up to isomorphism. ( $F_S$  is in fact the sum of the  $'F_M$  in the category of sheaves...).

From now on we suppose  $M_S$  fixed, and we shall write  $F_S$  instead of  $'F_M$ . Let  $H = D_S(M)$ ; consider the subfunctor  $F' = \operatorname{Imm}_{S\text{-gr.}}(H, G)$  of  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  whose value at  $T$  is the set of homomorphisms of  $T$ -groups  $H_T \rightarrow G_T$  which are closed immersions. We know already that  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  is representable by an affine  $S_S$ -prescheme by virtue of b), and using IX 6.8, one sees at once that  $F'$  is representable by an open and closed subscheme of the latter, hence it is also affine over  $S_S$ . Consider finally the canonical morphism  $F' \rightarrow F_S$ , which associates to each monomorphism  $H_T \rightarrow G_T$  the image group. One verifies at once, by virtue of the definitions, that in this way  $F'$  becomes a principal homogeneous bundle (in the category of fpqc sheaves) over  $F_S$ , with group  $\Gamma_F = \Gamma_S \times_{F_S} F_S$ , where  $\Gamma_S = \operatorname{Aut}_{S\text{-gr.}}(M)$ , whence it follows "by descent" that this morphism is representable (i.e. for every morphism  $T \rightarrow F_S$ , with  $T$  representable,  $T \times_{F_S} F'$  is representable – in fact, representable by a principal galois bundle under  $\Gamma_S$ ). Hence by virtue of IV 4.6.6,  $F_S$  is representable if and only if the quotient  $F'/F'$ , where  $F' = F' \times_{F_S} F'$ , exists in  $(\text{Sch})'$  and is universally effective for faithfully flat quasi-compact morphisms, or what amounts to the same, if and only if the quotient  $F'/\Gamma_S$  exists and is universally effective for the said morphisms. Now as  $F_S$  is affine over  $S_S$ , one has seen in V 4.1 that the condition in question is indeed satisfied. This proves the representability of  $F_S$  in a).

As for the complement, relative to the case where one supposes  $G_S$  of finite presentation over  $S_S$ , it follows at once from the preceding proof, taking into account that by virtue of b),  $F'$  is then locally of finite presentation over  $S_S$ , so that one may apply Exposé V[<sup>N.D.E.-XI</sup>-3]. <!-- original page 104 -->

#### ## 4. The scheme of multiplicative-type subgroups of a smooth affine group

<!-- original page 157 -->

The principal result of the present Exposé is constituted by

**Theorem 4.1.** \*Let  $S_S$  be a prescheme,  $G_S$  an  $S_S$ -prescheme in groups smooth and affine over  $S_S$ ,  $F_S$  the functor  $(\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$  defined by\*

```
```text
F(T) = set of multiplicative-type subgroups of G_T.
```
```

\*Then the functor  $F_S$  is representable, and is smooth and separated over  $S_S$ .\*

<!-- label: III.XI.4.1 -->

Let us signal at once the following variant:

**Corollary 4.2.** \*Let  $G_S, H_S$  be two  $S_S$ -preschemes in groups, with  $G_S$  smooth and affine over  $S_S$ ,  $H_S$  of multiplicative type and of finite type. Then  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  is representable, and is smooth and separated over  $S_S$ .\*

<!-- label: III.XI.4.2 -->

Indeed, when  $H_S$  is smooth over  $S_S$ , so is  $H \times_{S_S} G_S$ , and one may apply 4.1 to this latter. By the consideration of graph subgroups,  $\operatorname{Hom}_{S\text{-gr.}}(H, G)$  becomes a subfunctor  $F'$  of the functor  $F_S$  of "multiplicative-type subgroups of  $H \times_{S_S} G_S$ ", namely  $F'(T) = \text{set of multiplicative-type subgroups } K_T \text{ of}$

$(H \times_S G)_T = H_T \times_T G_T$  such that the homomorphism induced by the first projection

$$K \longrightarrow H_T$$

is an isomorphism. By virtue of IX 2.9, the canonical morphism  $F' \rightarrow F$  is an open immersion, hence  $F$  being representable, so is  $F'$ , which will be representable by an open of  $F$ ; and  $F$  being separated and smooth over  $S$ , so will  $F'$  be. In the case where  $H$  is finite over  $S$ , it suffices to apply 3.12 b) for the representability of  $\operatorname{Hom}_{\{S\text{-gr.}\}}(H, G)$ . When  $H$  is a product  $H_1 \times_S H_2$ , with  $H_1$  smooth over  $S$  and  $H_2$  finite over  $S$ , then  $\operatorname{Hom}_{\{T\text{-gr.}\}}(H_T, G_T)$  is identified with the subset of  $\operatorname{Hom}_{\{T\text{-gr.}\}}((H_1)_T, G_T) \times \operatorname{Hom}_{\{T\text{-gr.}\}}((H_2)_T, G_T)$  formed of pairs  $(u_1, u_2)$  such that  $u_1 \cdot u_2 = u_2 \cdot u_1$ , whence it follows that  $\operatorname{Hom}_{\{S\text{-gr.}\}}(H, G)$  is representable by a closed  $\llcorner$  original page 158  $\rightarrow$  subscheme of  $\operatorname{Hom}_{\{S\text{-gr.}\}}(H_1, G) \times_S \operatorname{Hom}_{\{S\text{-gr.}\}}(H_2, G) = X$ , as one sees by applying VIII 6.5 b), where one takes  $Y = H$ ,  $Z = G$ ,  $q_1$  and  $q_2$  being defined respectively by  $(u_1, u_2) \mapsto u_1 \cdot u_2$  and  $(u_1, u_2) \mapsto u_2 \cdot u_1$ .

In the general case, the question being local on  $S$  for the Zariski topology, one may suppose that  $S$  is affine, and  $H$  of constant type over  $S$ . Then  $H$  being quasi-isotrivial (X 4.5), one can find an étale surjective morphism  $S' \rightarrow S$ ,  $S'$  affine, that splits  $H$ , i.e. such that  $H' = H_{S'}$  is diagonalizable. Then the preceding result applies, since a diagonalizable group is the product of a diagonalizable torus by a diagonalizable finite group. It remains to see that the descent datum obtained on the  $S'$ -prescheme  $\operatorname{Hom}_{\{S'\text{-gr.}\}}(H', G') = X'$  is effective. This is seen by the reasoning of X 5.4, noting that in loc. cit., the hypothesis that  $X' \rightarrow S'$  was separated and locally quasi-finite served only to ensure that every open part of  $X'$  quasi-compact over  $S'$  was quasi-affine over  $S'$ . Now this property is still verified in the present case, as follows easily from the fact that this is so for the functor  $F$  of 4.1 (which will be seen in the course of the proof of 4.1). This (or any other variant of this little unscrewing) establishes the representability of  $\operatorname{Hom}_{\{S\text{-gr.}\}}(H, G)$ , and at the same time the fact that it is separated over  $S$ . It is locally of finite presentation over  $S$ , as one sees for example (as was pointed out in 3.2) thanks to the fact that this functor "commutes with inductive limits of rings". Finally, this functor being formally smooth over  $S$  (by virtue of 2.1), it is smooth over  $S$ .

**\*\*Remark 4.3.\*\*** We have here deduced 4.2 from 4.1, which is really immediate only when  $H$  is also smooth over  $S$ . For the deduction to be made without contortions for the general case, the representability result 4.1 would have to be established without supposing  $G$  smooth over  $S$ , but only affine of finite presentation over  $S$ . (Of course,  $\llcorner$  original page 159  $\rightarrow$  then  $F$  will no longer be smooth in general over  $S$ !) There is little doubt that 4.1 remains true under these more general hypotheses, but the proof appears to have to be more delicate (failing the possibility of invoking 3.8)  $[\text{XI-4-1}][\text{N.D.E-XI-4}]$ . Let us point out however that when  $G$  is a closed subgroup of an affine and smooth group  $G_0$  over  $S$ , then the functor  $F$  representing the multiplicative-type subgroups of  $G$  is representable by a closed subscheme of the prescheme representing the analogous functor  $F_0$  for  $G_0$  (amenable to 4.1), as one sees easily by applying VIII 6.4. This raises also the question: is an affine  $S$ -group scheme  $G$ , which is affine and of finite presentation over  $S$ , isomorphic to a subgroup scheme of some  $\operatorname{GL}(n)_S$ ,  $n$  suitable? This is true when  $S$  is the spectrum of a field, cf. VI\_B 11.11, but unfortunately false in general, even for tori, cf. 4.6. Finally, note that one could also prove 4.2 directly by exactly the same method as 4.1.

$\llcorner$  label: III.XI.4.3  $\rightarrow$

$\llcorner$  TRANSLATOR NOTE: In the source, the footnote (\*) is marked at this point of the text; the OCR has fused it with the N.D.E. (4). They are rendered here as XI-4-1 and N.D.E-XI-4.  $\rightarrow$

Let us now prove 4.1. Since the functor  $F$  is evidently of local nature, one may suppose  $S$  affine, so that  $S = \operatorname{Spec}(A)$ ,  $A$  a ring. Considering  $A$  as the inductive limit of its subrings of finite type over  $\mathbb{Z}$ , and noting that  $G$  comes from a smooth and affine group over such a subring (EGA IV 8), one is reduced to the case where  $S$  is noetherian. For every integer  $n > 0$ , let  $T_n$  be the functor defined as  $F$ , but restricting to subgroups  $H$  of multiplicative type of  $G_T$  such that  $n \cdot \operatorname{id}_H = 0$ , i.e. such that  $\{t\}_n H = H$ . Order the set  $I$  of integers  $> 0$  by the divisibility relation. When  $m$  is a multiple of  $n$ , define

$$p_{n,m} : T_m \longrightarrow T_n$$

$\llcorner$  original page 160  $\rightarrow$  by  $p_{n,m}(H) = {}_n H = \operatorname{Ker}(n \cdot \operatorname{id}_H)$ . In this way the  $T_n$  form a projective system of

functors over  $S$ . By virtue of 3.12 a), the functors  $T_n$  are representable, affine and of finite type over  $S$ . Define likewise morphisms

$$u_n : F \rightarrow T_n,$$

by the relation  $u_n(H) = \{u_n(H)\}$ . In this way, one obtains a morphism

$$u : F \rightarrow T = \varinjlim T_n,$$

where the  $\varinjlim$  is taken in the category of functors over  $S$ . But let us point out at once that, the  $T_n$  being representable and affine over  $S$ , so is  $T$  (it will be the spectrum of the inductive limit of the quasi-coherent algebras on  $S$  which define the  $T_n$ ). Of course,  $T$  is not in general of finite type over  $S$ .

We are going to apply 3.7 and are reduced to verifying conditions a) to d) of 3.7, which will imply that  $F$  is representable by a prescheme locally of finite type over  $S$ . It then follows from 2.1 bis that  $F$  is even smooth over  $S$ , and as  $F$  is a subfunctor of  $T$  which is affine over  $S$ , it follows that  $F$  is separated over  $S$  (being separated over  $T$ , which is separated over  $S$ ). Let us prove at once the complement invoked above, namely that every open  $U$  of  $F$  quasi-compact over  $S$  is quasi-affine over  $S$ : this follows from 3.11 and from the fact that the  $T_n$  are affine over  $S$ .

Let us verify therefore the conditions of 3.7.

a)  $F$  is a sheaf for the faithfully flat quasi-compact topology, by descent theory SGA 1, VIII, which applies here since multiplicative-type groups over  $T$  are affine over  $S$ . It commutes with inductive limits of rings by the general carpet [XI-4.2] EGA IV 8. Let us show that it commutes with adic projective limits of local artinian rings. When dealing with, instead of the functor  $F$ , the analogous functor envisaged in 4.2, this property is none other than that of IX 7.1 in the special case where  $A$  is a complete noetherian local ring, equipped with an ideal of definition for its usual topology (N.B. This is exactly where the hypothesis  $G$  affine intervenes in an essential way). In the present case, we are reduced to proving the

**Lemma 4.4.** \*Let  $A$  be a complete noetherian local ring, with maximal ideal  $\mathfrak{m}$ ,  $G$  a group scheme affine over  $S = \operatorname{Spec}(A)$ . For every integer  $n \geq 0$ , let  $S_n = \operatorname{Spec}(A/\mathfrak{m}^{n+1})$ ,  $G_n = G \times_S S_n$ . Let for every  $n$ ,  $H_n$  be a subgroup of multiplicative type and of finite type of  $G_n$ , such that for  $m \geq n$ ,  $H_n$  is deduced from  $H_m$  by reduction. Under these conditions, there exists a unique multiplicative-type subgroup  $H$  in  $G$  which reduces along the  $H_n$ .\*

<!-- label: III.XI.4.4 -->

<!-- original page 161 -->

By virtue of X 3.2 there exists a group of multiplicative type  $H$  over  $S$ , necessarily of finite type and isotrivial, determined up to unique isomorphism, equipped with an isomorphism  $H \times_S S_0 \simeq H_0$  (using the fact that  $H_0$  is isotrivial, being of finite type over a field, cf. X 1.4). By virtue of X 2.1, for every  $n$ , the isomorphism  $H \times_S S_0 \simeq H_0$  lifts to a unique isomorphism  $H \times_S S_n \simeq H_n$ . Having said this, by virtue of IX 7.1 already cited, the homomorphisms  $H_n \rightarrow G_n$  come from a unique homomorphism of  $S$ -groups  $u : H \rightarrow G$ . By virtue of IX 6.6, this last is a monomorphism since  $u_0 : H_0 \rightarrow G_0$  is one. This completes the proof of 4.4.

b) The morphism  $u : F \rightarrow T$  is a monomorphism. This follows from the density theorem IX 4.7, in the form of corollary 4.8 b). One will pay attention to the fact that it is essential, for the application we make of it here, to dispose of this result over a not necessarily noetherian base. (N.B. As the functor  $T$  does not commute with inductive limits of rings, it is not possible to reduce to that a priori.)

b') The morphism  $u : F \rightarrow T$  is infinitesimally étale; in other terms one has the

**Lemma 4.5.** \*Let  $A$  be an artinian local ring of residue field  $k$ ,  $S = \operatorname{Spec}(A)$ ,  $I$  an ideal  $\subset \operatorname{rad}(A)$ ,  $S_0 = \operatorname{Spec}(A/I)$ ,  $G$  an  $S$ -prescheme in groups smooth over  $S$ ,  $G_0 = G \times_S S_0$ ; let us give ourselves a multiplicative-type subgroup  $H_0$  of  $G_0$  and for every integer  $n \geq 0$ , a multiplicative-type subgroup  $H(n)$  of  $G$  such that\*

\*1°) for every multiple  $m$  of  $n$ ,  $H(n) = \{u_n(H(m))\}$ , and\*

\*2°)  $H(n)_0 = \{u_n(H_0)\}$ .\*

\*Under these conditions, there exists a multiplicative-type subgroup  $H_S$  of  $G_S$  and one only such that  $\{ \}_{n} H = H(n)_S$  for every  $n$ .

<!-- label: III.XI.4.5 -->

Uniqueness is already contained in b). For existence, an immediate recurrence reduces us to the case where  $J_m = 0_S$ ,  $\mathfrak{m}_S$  being the maximal ideal of  $A_S$ . Let  $\mathfrak{k} = A/\mathfrak{m}_S$ ,  $S_{\{0\}} = \text{operatorname{Spec}}(k)_S$ ,  $G_{\{0\}} = G \times_{S_{\{0\}}} S_{\{0\}}$ ,  $\mathfrak{g}_{\{0\}}$  the Lie algebra of  $G_{\{0\}}$ ,  $\mathfrak{h}_{\{0\}}$  that of  $H_{\{0\}}$ . One has a canonical isomorphism of groups: <!-- original page 162 -->

```
```text
g_{0} \otimes_k J = \text{Ker}(G(S) \rightarrow G(S_{\{0\}})),
```

cf. Exp. III. By virtue of IX 3.6 bis and 3.7, there exists a multiplicative-type subgroup H_S of G_S reducing along $H_{\{0\}}$, and such an H_S is determined modulo inner automorphism by an element of $N = \text{Ker}(G(S) \rightarrow G(S_{\{0\}}))_S$. Thus the set P_S of liftings H_S of $H_{\{0\}}$ is a principal homogeneous set under the group N/M_S , where M_S is the group of $\mathfrak{g} \in N_S$ such that $\text{int}(g) \cdot H = H_S$.

Now one sees easily (Exp. III) that this subgroup is none other than the vector subspace of $\mathfrak{g}_{\{0\}} \otimes_{\mathfrak{k}} J$ formed of the invariants under $H_{\{0\}}$, when $H_{\{0\}}$ operates on $\mathfrak{g}_{\{0\}} \otimes_{\mathfrak{k}} J$ by the representation induced by the adjoint representation of $G_{\{0\}}$. Likewise, the set $P(n)_S$ of liftings of $H(n)_{\{0\}} = \{ \}_{n} H_{\{0\}}$ is a principal homogeneous set under $N/M(n)_S$, where $M(n)_S$ is the vector subspace of $\mathfrak{g}_{\{0\}} \otimes_{\mathfrak{k}} J = N_S$ formed of the invariants under $\{ \}_{n} H_{\{0\}}$. Using the density theorem Exp. IX 4.7, one sees easily that for n large (in the sense of the order relation put on the set of integers $n > 0$, namely the divisibility relation) one has $M = M(n)_S$. Consequently, the natural map $H \mapsto \{ \}_{n} H_S$ from P_S to $P(n)_S$, which is compatible with the operations of N_S and hence with the homomorphism $N/M \rightarrow N/M(n)_S$ on the groups of operators, is bijective for n large. The conclusion of 4.5 results from this at once.

To verify c) and d) of 3.7, we use 3.8, which reduces us to verifying c') and d') below.

c') The $T_{\{n\}}$ are smooth over S_S , and the transition morphisms $p_{\{n,m\}} : T_{\{m\}} \rightarrow T_{\{n\}}$ are smooth.

This is none other than 2.2 bis.

d') With the notation of 3.8, a point ξ of F_S with values in a field k_S over S_S is none other than a multiplicative-type subgroup $H_{\{0\}}$ of $G_{\{0\}} = G_{\{k\}}$. Taking up again the reasoning of b') above, one sees that the integer $d(\xi)$ envisaged in 3.8 is none other than the dimension of $\mathfrak{g}_{\{0\}}/\mathfrak{g}^{H_{\{0\}}}_{\{0\}}$, <!-- original page 163 --> where $\mathfrak{g}_{\{0\}}$ is the Lie algebra of $G_{\{0\}}$ and $\mathfrak{g}^{H_{\{0\}}}_{\{0\}}$ is the vector subspace of invariants under $H_{\{0\}}$. It is therefore a finite integer, i.e. condition d') 1°) of 3.8 is verified. With the notation of d') 2°), the datum of a morphism $\nu : X \rightarrow F_S$ amounts to the datum of a multiplicative-type subgroup H_S of G_X . For $x \in X$, the integer $d(\xi_x)$ is then none other than the dimension of $(\mathfrak{g} \otimes_{\mathfrak{k}} \kappa(x))^{H_{\{x\}}}$, where $\mathfrak{g}_S$ is the sheaf of Lie algebras of G_X (which is locally free of finite type over X_S since G_X is smooth over X_S , and $\mathfrak{g} \otimes_{\mathfrak{k}} \kappa(x)$ is none other than the Lie algebra of the fiber $G_{\{x\}}$ of G_X at x_S), and $H_{\{x\}}$ is the fiber of H_S at x_S . Now $\mathfrak{g}_S$ being a locally free module on S_S on which the group of multiplicative type H_S operates, one sees at once that the subfunctor $\mathfrak{g}^{H_{\{x\}}}$ of invariants under H_S is given by a locally direct factor subsheaf, hence locally free, of $\mathfrak{g}_S$. (By descent, one is reduced to the case where H_S is diagonalizable, and where one applies Exp. I 4.7.3, noting that the subsheaf of invariants corresponds to the component of degree zero.) Consequently $d(\xi_x) = \text{rank at } x_S \text{ of } \mathfrak{g}^{H_{\{x\}}}$, hence it is a function locally constant in x_S . This completes the proof of condition d').

We have thus verified the conditions of 3.7, which completes the proof of 4.1.

Remark 4.6. When $G = \text{GL}(n)_S$, one can give a noticeably simpler and more explicit direct proof of 4.1, by using I 4.7.3. The proof shows moreover that in this case, the modular scheme is a scheme that is a sum of a family of affine schemes over S_S . Proceeding as was said in 4.3, one deduces the same result whenever G_S is a closed subgroup of a group of the form $\text{GL}(n)_S$. One should however beware of thinking that the preschemes which represent the functors in 4.1 or 4.2 are always sums of a family of affine schemes over S_S . Let for example H_S be a multiplicative-type group of finite type over a locally noetherian prescheme S_S ; then by virtue of X 5.11, H_S is isotrivial if and only if $\text{operatorname{Hom}}_{\{S\text{-gr.}\}}(H, G_{\{m\}})_S$ is a sum of a family of affine preschemes over S_S . Now one has pointed out (X 1.6) <!-- original page 164 --> that there can exist tori H_S (of relative dimension 2) which are not isotrivial; for such a torus, $\text{operatorname{Hom}}_{\{S\text{-gr.}\}}(H, G_{\{m\}})_S$ is therefore not a sum of S_S -preschemes affine over S_S , and one sees likewise that the twisted constant group "dual" $\text{operatorname{Hom}}_{\{S\text{-gr.}\}}(G_{\{m\}}, H)_S$ is not such a sum either (for if two twisted constant commutative groups of finite presentation $\mathbb{R}_S, \mathbb{R}'_S$ are dual to each other, $\mathbb{R}' = \text{operatorname{Hom}}_{\{S\text{-gr.}\}}(\mathbb{R}, \mathbb{Z}_S)$, one sees easily that one is isotrivial if and only if the other is). This last point shows also that such an H_S is not isomorphic to a subgroup of a group of the form $\text{GL}(n)_S$;

more precisely, one can show that a multiplicative-type group of finite type over S locally noetherian connected is isomorphic to a subgroup of a group of the form $\operatorname{Aut}_{\operatorname{Mod}(E)}(E)$ (with E a locally free module of finite type over S) if and only if it is isotrivial. Finally, taking $G = H \times G_m$ in the two preceding examples, one finds an example where the prescheme representing the functor F of 4.1 is not a sum of a family of S -preschemes affine over S (with G a torus of relative dimension 3 if one wishes).

<!-- label: III.XI.4.6 -->

5. First corollaries of the representability theorem

Let H , G be as in 4.2. Set

$M = \operatorname{Hom}_{S\text{-gr.}}(H, G)$,

which is an S -prescheme smooth, separated over S , by virtue of 4.2. Note that G operates on the functor $M = \operatorname{Hom}_{S\text{-gr.}}(H, G)$ by

$(g, u) \mapsto \operatorname{int}(g) \circ u$,

whence a canonical morphism

$(x) \quad G \times_S M \rightarrow M \times_S M$,

<!-- label: eq:III.XI.5-cross -->

whose components are the preceding morphism $G \times_S M \rightarrow M$, and the second projection $G \times_S M \rightarrow M$.

Corollary 5.1. *The preceding morphism $(\times)$ is smooth.*

<!-- original page 165 -->

<!-- label: III.XI.5.1 -->

This follows from 4.2 and 2.3. This statement is equivalent to the following:

Corollary 5.2. *Let $u_1, u_2 : H \rightarrow G$ be two homomorphisms of S -groups. Then the subfunctor $\operatorname{Transp}(u_1, u_2)$ of G (cf. 2.4) is representable by a closed subprescheme of G , smooth over S .*

<!-- label: III.XI.5.2 -->

It remains only to prove that $\operatorname{Transp}(u_1, u_2) \rightarrow G$ is indeed a closed immersion, which follows from the fact that it is the kernel of a pair of morphisms $G \rightarrow M$ (namely $g \mapsto \operatorname{int}(g) u_1$ and the "constant" morphism $g \mapsto u_2$), and from the fact that M is separated over S . In particular:

Corollary 5.3. *Let $u : H \rightarrow G$ be a morphism of S -groups. Then $\operatorname{Centr}_G(u) = \operatorname{Transp}(u, u)$ is representable by a closed subprescheme in groups of G , smooth over S . Moreover, $G/\operatorname{Centr}_G(u)$ is representable by an open subprescheme of M .*

<!-- label: III.XI.5.3 -->

It remains to prove this last point. Now the morphism

$g \mapsto \operatorname{int}(g) \circ u$

from G to M is smooth of finite type by virtue of 5.2; it is therefore an open morphism (EGA IV 6.6), and if U denotes its image, with the structure induced by M , the induced morphism $G \rightarrow U$ is smooth, surjective, of finite type, hence covering for the faithfully flat and quasi-compact topology. Moreover, it is evident that the preceding

morphism $\mathcal{G} \rightarrow \mathcal{M}$ makes $\mathcal{G}$ into a formally principal homogeneous sheaf under $\text{Centr}_{\mathcal{G}}(u)_{\mathcal{M}}$, which implies that the sheaf $\mathcal{G}/\text{Centr}_{\mathcal{G}}(u)$ is indeed representable by $\mathcal{U}$.

Corollary 5.4. Let $u_1, u_2 : H \rightarrow G$ be two homomorphisms of S -groups. The following conditions are equivalent:

III.XI.5.4

(i) u_1 and u_2 are conjugate locally for the étale topology.

original page 166

(i bis) u_1, u_2 are conjugate locally in the sense of the faithfully flat quasi-compact topology.

(ii) For every s in S , denoting by $\bar{s}$ the spectrum of an algebraic closure of $k(s)$, the morphisms $u_1|_{s^{-1}}, u_2|_{s^{-1}} : H_{s^{-1}} \rightarrow G_{s^{-1}}$ are conjugate by an element of $\mathcal{G}(\bar{k}(s))$.

(ii bis) The structural morphism $\text{Transp}(u_1, u_2) \rightarrow S$ is surjective.

(iii) $\text{Transp}(u_1, u_2)$ is a torsor under the action of the S -prescheme in groups smooth of finite type $\text{Centr}_{\mathcal{G}}(u_1)$.

(i) $\Rightarrow$ (i bis) and (ii) $\Rightarrow$ (ii bis) are trivial (the second thanks to the Nullstellensatz); on the other hand (i bis) $\Rightarrow$ (ii) by the "principle of finite extension" (EGA IV 9). On the other hand (ii bis) $\Rightarrow$ (iii) thanks to the fact that $\text{Transp}(u_1, u_2)$ is smooth over S hence flat over S , and of finite type hence quasi-compact over S ; it is therefore faithfully flat quasi-compact over S if and only if its structural morphism is surjective. As, on the other hand, it is formally principal homogeneous under $\text{Centr}_{\mathcal{G}}(u_1)$, which is faithfully flat and quasi-compact over S , one sees that this last condition is equivalent also to saying that $\text{Transp}(u_1, u_2)$ is a torsor under $\text{Centr}_{\mathcal{G}}(u_1)$ (understood: in the sense of the faithfully flat and quasi-compact topology). Finally (iii) $\Rightarrow$ (i) thanks to the fact that $\text{Transp}(u_1, u_2)$ is smooth over S and to "Hensel's lemma" in the form 1.10.

Remark 5.5. For $u : H \rightarrow G$ fixed, the functor $(\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$ which associates to every T over S the set of homomorphisms of T -groups $u_2 : H_T \rightarrow G_T$ which are conjugate to $u|_T : H|_T \rightarrow G|_T$ locally for the étale topology, is precisely representable by the open of $\mathcal{M}$, isomorphic to $\mathcal{G}/\text{Centr}_{\mathcal{G}}(u)$, envisaged in 5.3.

III.XI.5.5

Let us sketch the variants of the preceding results, obtained by application of 4.1 instead of 4.2. Let therefore $\mathcal{G}$ be a prescheme in groups smooth and affine over S , and let us now denote by $\mathcal{M}$ the S -prescheme smooth, separated over S , which represents the functor envisaged in 4.1. One has again operations of $\mathcal{G}$ on $\mathcal{M}$:

text
 $(g, H) \mapsto \text{int}(g)(H),$

whence as above a morphism

text
 $(x \text{ bis}) \quad G \times_S \mathcal{M} \rightarrow \mathcal{M} \times_S \mathcal{M}.$

eq:III.XI.5-cross-bis

Corollary 5.1 bis. The preceding morphism is smooth.

III.XI.5.1bis

This follows from 4.1 and 2.3 bis. One concludes again:

Corollary 5.2 bis. Let H_1, H_2 be two multiplicative-type subgroups of $\mathcal{G}$. Then the subfunctor $\text{Transp}_{\mathcal{G}}(H_1, H_2)$ of $\mathcal{G}$ is representable by a closed subprescheme of $\mathcal{G}$, smooth over S .

III.XI.5.2bis

In particular:

****Corollary 5.3 bis.**** *Let H be a multiplicative-type subgroup of G . Then the subfunctor in groups $\text{Norm}_{\{G\}}(H)$ of G is representable by a closed subscheme of G , smooth over S . Moreover, the quotient $G/\text{Norm}_{\{G\}}(H)$ is representable by an open subscheme of M .*

<!-- label: III.XI.5.3bis -->

****Corollary 5.4 bis.**** *Let H_1, H_2 be two multiplicative-type subgroups of G . The following conditions are equivalent:*

<!-- label: III.XI.5.4bis -->

(i) H_1 and H_2 are conjugate locally for the étale topology.*

(i bis) H_1 and H_2 are conjugate locally for the faithfully flat quasi-compact topology.*

(ii) For every $s \in S$, denoting by $\bar{s}$ the spectrum of an algebraic closure of $\kappa(s)$, the subgroups $H_1, \bar{s}$, $H_2, \bar{s}$ of $G_{\bar{s}}$ are conjugate by an element of $G(\kappa(\bar{s}))$.*

(ii bis) The structural morphism $\text{Transp}(H_1, H_2) \rightarrow S$ is surjective.* <!-- original page 168 -->

(iii) $\text{Transp}(H_1, H_2)$ is a principal homogeneous bundle under the action of the S -prescheme in groups smooth of finite type $\text{Norm}_{\{G\}}(H_1)$.*

****Remark 5.5 bis.**** Remark 5.5 transposes likewise to the present case.

<!-- label: III.XI.5.5bis -->

****Remark 5.6.**** Note that to establish the result 5.2, and consequently also the first assertion in 5.3, as well as 5.4, the reference to 4.2 can be replaced by a reference to VIII, 6.4, whose proof is much easier. This shows also that the hypothesis G affine over S is unnecessary there. Moreover, in N° 6, we shall show how a variant of this method permits extending these results to the case of certain groups H more general than groups of multiplicative type. These same observations extend to the variants 5.2 bis etc. On the other hand, the result 5.8 that follows uses in an essential way all the hypotheses made (notably G affine and smooth over S , H of multiplicative type), and the lecturer knows of no other proof of it than via the representability theorems 4.1 or 4.2[XI-5-1].

<!-- label: III.XI.5.6 -->

****5.7.**** Since the morphism $(\times)$ resp. $(\times \text{ bis})$ is smooth hence open, its image is open. Let R be this image, equipped with the structure induced by $M \times_S M$; one easily verifies that R is an equivalence relation in M , which is none other moreover than the one made explicit in 5.4 resp. 5.4 bis. It would be interesting to know whether the quotient sheaf M/R (which is formally étale over S) is representable (it is then representable by a prescheme étale over S); it is so for example when S is the spectrum of a field. One will note moreover that R may not be closed in $M \times_S M$ (even when G is quasi-finite over S), which means (when M/R is representable) that M/R is then not separated over S .

<!-- label: III.XI.5.7 -->

****Theorem 5.8.**** *Let S be a prescheme, G an S -prescheme smooth and affine over S , $s \in S$. Then:*

<!-- label: III.XI.5.8 -->

a) For every multiplicative-type subgroup $H^{\{0\}}$ of G_s , there exists an étale morphism $S' \rightarrow S$, a point s' of S' above s such that the residue extension $\kappa(s')/\kappa(s)$ be trivial, and a multiplicative-type subgroup H' of $G' = G \times_S S'$, such that $H'_{s'} = H^{\{0\}} \otimes_{\kappa(s)} \kappa(s')$.*

b) For every group homomorphism $u^{\{0\}} : H_s \rightarrow G_s$, where H is an S -prescheme in groups of multiplicative type and of finite type, there exists an étale morphism $S' \rightarrow S$, a point s' of S' above s such that the residue extension $\kappa(s')/\kappa(s)$ be trivial, and a group homomorphism $u' : H' \rightarrow G'$, such that $u'_{s'} : H'_{s'} \rightarrow G'_{s'}$ be equal to $u^{\{0\}} \otimes_{\kappa(s)} \kappa(s')$.*

This results from 4.1 resp. 4.2, and from Hensel's lemma in the form 1.10.

****Proposition 5.9.**** *Let S be a prescheme, G an S -prescheme smooth and affine over S , H a multiplicative-type

subgroup of G . Consider $\text{Centr}_G(H) \hookrightarrow \text{Norm}_G(H)$, which by 5.3 and 5.3 bis are closed subschemes in groups of G , smooth over S . Then the first group is an open and closed subscheme of the second, and the quotient sheaf*

$$W_G(H) = \text{Norm}_G(H) / \text{Centr}_G(H)$$

is representable by an open subscheme in groups of $\text{Aut}_{S\text{-gr}}(H)$; it is therefore an S -prescheme in groups quasi-finite, étale and separated over S .*

<!-- label: III.XI.5.9 -->

Consider indeed the evident homomorphism

$$\theta : \text{Norm}_G(H) \longrightarrow \text{Aut}_{S\text{-gr}}(H),$$

whose kernel is by definition $\text{Centr}_G(H)$. As $\text{Aut}_{S\text{-gr}}(H)$ is representable by an S -prescheme in groups étale and separated over S (X 5.10), its unit section is an open and closed immersion, <!-- original page 170 --> hence its inverse image under θ is an open and closed subgroup of $\text{Norm}_G(H)$. I say moreover that θ is a smooth morphism: this indeed results formally from the definitions, and from the fact that $\text{Norm}_G(H)$ is smooth over S and $\text{Aut}_{S\text{-gr}}(H)$ is étale over S . One concludes as in 5.3 that the image of θ is an open U of $\text{Aut}_{S\text{-gr}}(H)$ and that, equipped with the induced structure, U represents the quotient sheaf $\text{Norm}_G(H) / \text{Centr}_G(H)$. This latter is therefore étale and separated over S since $\text{Aut}_{S\text{-gr}}(H)$ is, and it is quasi-finite over S , being quasi-compact over S as image of $\text{Norm}_G(H)$ which is. This completes the proof of 5.9.

Corollary 5.10. *For every s in S , let*

$$w(s) = \text{rank } \text{Norm}_{G_s}(H_s) / \text{Centr}_{G_s}(H_s)$$

(which is also the index of $\text{Centr}_G(\bar{k}) / \text{Centr}_G(\bar{k})$ in $\text{Norm}_G(\bar{k}) / \text{Norm}_G(\bar{k})$, where $\bar{k}$ is an algebraic closure of $k(s)$). Then the function $s \mapsto w(s)$ is lower semicontinuous. For it to be constant in a neighborhood of the point s , it is necessary and sufficient that $W_G(H)$ be finite over S in a neighborhood of s .*

<!-- label: III.XI.5.10 -->

Indeed, for every S -prescheme W which is étale, of finite type and separated over S , it is true that the function $s \mapsto w(s) = \text{rank } [W_s : k(s)]$ is lower semicontinuous, and that it is constant in a neighborhood of the point s if and only if W is finite over S in a neighborhood of s (a fact pointed out in SGA 1, I 10.9, and whose proof, which offers no difficulty, will be found in EGA IV[N.D.E-XI-5-2]).

Remark 5.11. [N.D.E-XI-5] Let G be a prescheme in groups affine and smooth over S , H a multiplicative-type subgroup; then 5.3 and 5.3 bis imply that the quotients

$$G / \text{Centr}_G(H) \text{ and } G / \text{Norm}_G(H)$$

are preschemes smooth over S and quasi-affine over S , since in both cases, the modular prescheme M in which the quotient is embedded is such that every open U of M quasi-compact over S is quasi-affine over S (3.11). We shall see moreover in the following Exposé [N.D.E-XI-6] that for every U as above, the schematic closure $\bar{U}$ <!-- original page 171 --> of U in M is even affine over S , which shows that the quotients envisaged are affine over S provided the open U in the corresponding modular scheme (of homomorphisms of group from H to G , resp. of multiplicative-type subgroups of G) is closed in M . This is for example the case if H is a "maximal torus" in the second case envisaged, or when S is the spectrum of a field, cf. XII.5.4[N.D.E-XI-7]. I do not know whether the quotients envisaged are affine over S in general.

<!-- label: III.XI.5.11 -->

6. On a rigidity property for homomorphisms of certain group schemes, and the representability of certain transporters[^XI-6-0]

****Proposition 6.1.**** *Let S be a locally noetherian prescheme, H a commutative S -prescheme in groups, of finite type over S , E a set of integers > 0 , stable under multiplication, and suppose the following conditions satisfied:*

<!-- label: III.XI.6.1 -->

a) For every $n \in E$, the subgroup $H_n = \text{Ker}(n \cdot \text{id}_H)$ is finite and flat over S .

b) For every $s \in S$, the family of the $H_{n,s}$ ($n \in E$) is schematically dense in H_s .

Let Y be a closed subscheme of H . Then the subfunctor $\prod_{H/S} Y/H$ of S (compare VIII, 6) is representable by a closed subscheme T of S , and if S is noetherian, there exists an $n \in E$ such that

```text  
(x)  $\prod_{H/S} Y/H = \prod_{nH/S} Y \cap nH/S$ .  
```

<!-- label: eq:III.XI.6.1-cross -->

Indeed, by virtue of VIII 6.4, as by condition a) H_n is finite and flat and a fortiori "essentially free" over S , it follows that the second member of $(\times)$ is representable <!-- original page 172 --> by a closed subscheme T_n of T . Of course, for $n \in E$, with E ordered by divisibility, the T_n form a decreasing family of closed subschemes of S , hence if S is noetherian (which we may suppose) it is stationary for n large. Let T be the value of T_n for n large; I say that T indeed represents the first member of $(\times)$, which will complete the proof. One is reduced to proving that if S' is a prescheme over S such that $(Y \cap H_n)_{S'} = (H_n)_{S'}$ for every $n \in E$, i.e. such that $Y_{S'} \supset H_{S'}$ for every $n \in E$, then $Y_{S'} = H_{S'}$. Now this is indeed the case, for by virtue of IX 4.4 the family of the $H_{n,S'}$ is schematically dense in $H_{S'}$, taking conditions a) and b) into account.

****Theorem 6.2.**** *Let S be a prescheme, H, E as in 6.1 satisfying conditions a), b), $u : H \rightarrow G$ a homomorphism of S -groups from H to an S -prescheme in groups locally of finite type over S , finally K a closed subscheme in groups of H . Consider the subfunctor $\text{Transp}_G(u, K)$ of G (cf. 2.5). Then this last is representable by a closed subscheme of G , and if G is noetherian (for example S noetherian and G of finite type over S), there exists an integer $n \in E$ such that $\text{Transp}_G(u, K) = \text{Transp}_G(u|_{H_n}, K)$. If finally G is smooth over S , and K smooth over S or of multiplicative type, and if H, E satisfy the following condition stronger than a):*

<!-- label: III.XI.6.2 -->

a') For every $n \in E$, the subgroup H_n of H is of multiplicative type,

then $\text{Transp}_G(u, K)$ is smooth over S .

Consider indeed the G -group $H_G = H \times_S G$, which evidently satisfies the conditions of 6.1 (with S replaced by G , and H by H_G), and the closed subscheme Y of H_G , inverse image of $K \subset G$ under

```text  
 $H_G = H \times_S G \rightarrow G$   
```

<!-- original page 173 --> defined by $(h, g) \mapsto \text{int}(g) \cdot u(h)$. Then $\text{Transp}_G(u, K)$ is none other than

$\prod_{H_G/G} Y/H_G$ (compare VIII, examples 6.5 e)). Hence the first assertions result from 6.1, and moreover, one sees that for every quasi-compact open U of G , there exists $n \in E$ such that $\text{Transp}_G(u, K)$ and $\text{Transp}_G(u|_{H_n}, K)$ have the same trace on U . To verify the last assertion of 6.2, one can therefore replace H by an H_n , and then it suffices to apply 2.5, which applies since H_n is supposed of multiplicative type over S .

****Remark 6.3.**** The preceding proof uses only the very elementary result VIII 6.4, and moreover (for the last part) 2.5, that is, when K is smooth over S , the infinitesimal result IX 3.6, hence the vanishing of the cohomology of multiplicative-type groups. One will note that in the most important cases (cf. 6.7) one can suppose even the $n \in E$ prime to the residual characteristics of S , i.e. invertible in $\mathcal{O}_S$, hence the H_n finite étale over S , and then the cohomological result invoked is practically trivial, so that 6.2 is then independent of the theory of multiplicative-type groups.

<!-- label: III.XI.6.3 -->

****6.4.**** One sees as usual that 6.1 extends to the case where one has an S -prescheme S' over S (not necessarily locally noetherian), and a closed subprescheme Y' of $H' = H \times_S S'$, provided that $Y' \rightarrow H'$ is of finite presentation i.e. the ideal defining Y' is of finite type: then $\prod_{H'/S} Y'/H'$ is representable by a closed subprescheme T' of S' , such that $T' \rightarrow S'$ is of finite presentation, and if S' is quasi-compact, there exists $s \in S$ such that the relation analogous to $(*)$ is valid. It follows also that the first statement in 6.2 is valid without supposing G locally of finite type over S , provided that the immersion $K \rightarrow G$ is of finite presentation.

<!-- label: III.XI.6.4 -->

****6.5.**** As announced in 5.6, theorem 6.2 permits extending to the preschemes in groups satisfying a') and b) above, certain results established by another method and under more restrictive conditions for groups of multiplicative type. This is the case for results 5.2, for the beginning of 5.3, for 5.4, and for the bis variants of the preceding results 5.9 and 5.10. <!-- original page 174 --> This is also the case for the results of IX, N°s 5 and 6, with the exclusion of IX 6.8 (already false for a homomorphism of abelian schemes $u : H \rightarrow G$, over the spectrum S of a discrete valuation ring with residue characteristic $p > 0$: it can happen that $\text{Ker } u$ have as generic fiber the unit group, and as special fiber a radical group not reduced to the unit group).

<!-- label: III.XI.6.5 -->

****6.6.**** We have just given an example of a rigidity property for groups of multiplicative type which is not shared by abelian schemes. Another example, extremely important, is in the fact that the existence theorem of infinitesimal extensions of homomorphisms IX 3.6 is no longer valid when H is an abelian scheme. Thus, an abelian scheme $\neq 0$ over a field admits non-trivial infinitesimal variations, contrary to what occurs for a group of multiplicative type – which is the infinitesimal aspect of the fact that there exists a "theory of moduli" (moreover far from being completed) for abelian varieties, while the theory of moduli for groups of multiplicative type is empty. Another "global" aspect of this infinitesimal difference is that if H is an abelian scheme over S locally noetherian, and G is an S -prescheme in groups commutative locally of finite type over S , then one can show that $\text{Hom}_{S\text{-gr.}}(H, G)$ is representable by a prescheme locally of finite type over S , but contrary to what happens for H of multiplicative type, this prescheme is not étale over S , but only unramified over S . Thus, if S is for example the spectrum of a complete discrete valuation ring, H and G abelian schemes over S , there can exist homomorphisms $H_{\{0\}} \rightarrow G_{\{0\}}$ on the special fibers which do not come "by specialization" from a homomorphism on the generic fibers.

<!-- label: III.XI.6.6 -->

****6.7.**** Theorem 6.2 applies whenever H is an abelian scheme over S , or more generally an extension of such a scheme by a torus. Indeed, the question being local on S , one may suppose that there exists a prime number ℓ prime to the residue characteristics of S , <!-- original page 175 --> and one sees that it then suffices to take for E the set of powers of ℓ to satisfy conditions a') and b).

<!-- label: III.XI.6.7 -->

A reasoning analogous to that of 6.1 gives us the

****Theorem 6.8.**** *Let X be a prescheme smooth over S , with geometric fibers connected non-empty. Then for every closed subprescheme Y of X , the functor $\prod_{X/S} Y/X$ is representable by a closed subprescheme T of S . If Y is of finite presentation over X , then T is of finite presentation over S .*

<!-- label: III.XI.6.8 -->

As $f : X \rightarrow S$ is faithfully flat locally of finite presentation, it is covering for the fpqc topology. As on the other hand $T = \prod_{X/S} Y/X$ is evidently a subsheaf of S (for the fpqc topology), it follows that the question of representability of T by a closed subprescheme of S is of local nature on S for the fpqc topology, and the same holds for the question of deciding whether T is of finite presentation over S . Doing then the base change $S' \rightarrow S$, with $S' = X$, one is reduced to the case where X admits a section e over S . One may moreover suppose S affine and a fortiori quasi-compact. One then has:

****Corollary 6.9.**** *Under the conditions of 6.8, suppose that S be quasi-compact and that X admit a section e over S . Let, for every integer $n \geq 0$, $X_{\{n\}}$ be the subprescheme of X , infinitesimal neighborhood of order n of the section e . Suppose Y of finite presentation over X . Then there exists an integer $n \geq 0$ such that one has $\prod_{X/S} Y/X = \prod_{X_{\{n\}}/S} Y_{\{n\}}/X_{\{n\}}$ (where $Y_{\{n\}} = Y \cap X_{\{n\}}$).*

<!-- label: III.XI.6.9 -->

This corollary indeed implies 6.8 when Y is of finite presentation over X , thanks to VIII 6.4: for, X being smooth over S , $X_{/S}$ is finite and locally free over S and a fortiori is "essentially free" over S in the sense of VIII 6.1, hence $\prod_{n \geq 0} Y_n/X_n$ is representable by a closed subscheme of S . Moreover, the proof of loc. cit., or the reduction to the noetherian case, <!-- original page 176 --> immediately shows us that the said closed subscheme of S is of finite presentation over S .

Let us prove first 6.9, hence 6.8, when S is noetherian. Let $T_n = \prod_{n \geq 0} Y_n/X_n$. Then the T_n form a decreasing sequence of closed subschemes of S , and S being noetherian, this sequence is stationary. Let $R = \bigcap_{n \geq 0} T_n$ their common value for n large; one has evidently $T \subset R$, and it suffices to establish that one has $R \subset T$. Doing the base change $R \rightarrow S$, one is reduced to the case where $R = S$, i.e. $Y_n = X_n$ for every n i.e. $Y \subset X$ for every n , and to prove then $T = S$ i.e. $Y = X$. Now $Y \subset X$ for every n implies (thanks to the fact that X is locally noetherian) that Y is, in a neighborhood of each point of S , an induced open subscheme of X , hence there exists an induced open U of X , containing S , such that $U \subset Y$. By virtue of IX 4.3, the fibers of X/S being integral, U is schematically dense in X , hence (Y being a closed subscheme majorizing U) one has $Y = X$. This proves 6.9, hence 6.8, in this case.

The general case proceeds by reduction to the preceding case. For every $s \in S$, there exists an affine open neighborhood U of s and an affine open neighborhood V of s such that $f(V) \subset U$. Then $f(V)$ is an open neighborhood of s contained in U , and if S_0 is an affine open neighborhood of s contained in $f^{-1}(V) \cap f^{-1}(U)$, and $X_0 = V \cap f^{-1}(S_0)$, then X_0 and S_0 are affine opens of X resp. S , and X_0/S_0 admits a section. Because of the local nature of 6.8 and 6.9, one may suppose $S = S_0$. I say that one then has $\prod_{n \geq 0} Y_n/X_n = \prod_{n \geq 0} Y_n/S_n$, where $Y_0 = Y \cap X_0$; indeed, by virtue of IX 4.6, X_0 is schematically dense in X (at least when X is quasi-separated over S so that X_0 is retrocompact in X ; but in fact one can show without difficulty that IX 4.6 remains valid without the retrocompactness hypothesis), and likewise for every base change $S_1 \rightarrow S$, $X_0 \times_S S_1$ is schematically dense in $X \times_S S_1$, whence at once the announced equality. This reduces us to the case where $X = X_0$, so one may suppose S and X affine. <!-- original page 177 --> Moreover, if $X = \operatorname{Spec}(B)$ and if J is the ideal of B which defines Y , J is the inductive limit of its sub-ideals of finite type, hence Y is the intersection of closed subschemes Y_i of X which are of finite presentation over S , and consequently $\prod_{n \geq 0} Y_n/X_n = \bigcap_{i \geq 0} \prod_{n \geq 0} Y_{i,n}/X_n$, which reduces us, to prove 6.8, to the case where Y is of finite presentation over X . It then suffices to prove 6.9 with S and X affine. But then X and Y over S come by base change $S \rightarrow S_0$ from an analogous situation X_0 and Y_0 over S_0 , with S_0 noetherian, which reduces us to the case where S is noetherian, which has already been treated. This completes the proof of 6.8 and 6.9.

Corollary 6.10. *Let X be an S -prescheme in groups smooth of finite presentation, with connected fibers, Y a prescheme in groups of finite presentation over S , $i : Y \rightarrow X$ a monomorphism of S -preschemes in groups, making Y therefore a subgroup of X . Then $\prod_{n \geq 0} Y_n/X_n$ is representable by a closed subscheme of finite presentation of S . If S is quasi-compact, denoting for every integer $n \geq 0$ by X_n the infinitesimal neighborhood of order n of the unit section of X , and setting $Y_n = X_n \cap Y$, one has for n large enough: $\prod_{n \geq 0} Y_n/X_n = \prod_{n \geq 0} X_n/S_n$.*

<!-- label: III.XI.6.10 -->

The proof is essentially that of 6.9. Note that the unit sections of X and of Y induce bijective immersions $S \rightarrow X_0$ and $S \rightarrow Y_0$, hence induce isomorphisms of S_{red} with $(X_0)_{\text{red}}$ and $(Y_0)_{\text{red}}$, which implies that the injection $Y_0 \rightarrow X_0$ is proper, hence, being a monomorphism of finite presentation, is a closed immersion. Consequently, by virtue of VIII 6.4 already used, $\prod_{n \geq 0} Y_n/X_n$ is representable by a closed subscheme of S of finite presentation over S , and it remains therefore to prove the last assertion of 6.10 in the case where one supposes moreover S affine. One reduces immediately again to the case where S is noetherian, and one is reduced to proving that one then has $R = T$ (with the notation of the proof of 6.9), or again that $Y \subset X$ for every n implies $Y = X$. Now the hypothesis implies that $i : Y \rightarrow X$ is étale at the points of the unit section of Y over S , hence Y is smooth over S at the points of the unit section, whence it follows that the open Y_0 of points of Y at which Y is smooth <!-- original page 178 --> over S is an induced open subgroup of Y . Then $Y_0 \rightarrow X$ is a monomorphism étale by virtue of X 3.5, hence an open immersion; now the fibers of X being connected and every open subgroup of an algebraic group being also closed, it follows that this is a surjective open immersion i.e. an isomorphism. Hence $Y_0 = X$ and a fortiori $Y = X$, which completes the proof of 6.10.

Proceeding as in VIII 6.5, one concludes from 6.10:

Corollary 6.11. *Let G be an S -prescheme in groups locally of finite type and quasi-separated over S , H a prescheme in groups smooth of finite presentation over S with connected fibers, $i : H \rightarrow G$ a monomorphism of

S -groups, making H therefore a subgroup of G . Then:*

<!-- label: III.XI.6.11 -->

a) $\text{Centr}_G(H)$ and $\text{Norm}_G(H)$ are representable by closed subschemes of G of finite presentation over G , and likewise, for every monomorphism $j : K \rightarrow G$ of finite presentation of S -preschemes in groups, $\text{Transp}_G(H, K)$ is representable by a closed subscheme of G of finite presentation over G .

b) If G is quasi-compact, in the various cases envisaged in a), there exists an integer $n \geq 0$ such that (if H_n denotes the infinitesimal neighborhood of order n of the unit section of H) one has

```
``text
Centr_G(H) = Centr_G(H_n)
Norm_G(H) = Norm_G(H_n)
Transp_G(H, K) = Transp_G(H_n, K) = Transp_G(H_n, K_n).
``
```

One applies 6.10 to the prescheme in groups $X = H_G = H \times_S G$ above the base prescheme G , and to the subscheme in groups Y inverse image of the diagonal subgroup of $(G \times_S G)_G$ over G by a suitable homomorphism of G -groups of X into $(G \times_S G)_G$ (in the case of Centr), resp. the inverse image of K_G by a suitable homomorphism of G -groups of X into G_G (in the case of Transp). The case of Norm reduces to the transporter by taking $K = H$, the hypothesis on G ensuring that $H \rightarrow G$ is of finite presentation (hence $Y \rightarrow X$ is of finite presentation); <!-- original page 179 --> in the case of Centr , the hypothesis made on G ensures that the diagonal group of $G \times_S G$ is of finite presentation over $G \times_S G$, whence again the fact that Y is of finite presentation over X .

Remark 6.12. One can prove (using rather delicate results of EGA VI[^{XI-6-1}]) that if X is a prescheme flat of finite presentation over S , which is proper over S or with non-empty connected geometric fibers, then for every closed subscheme Y of X of finite presentation over S , $\prod_{X/S} Y/X$ is representable by a closed subscheme of S of finite presentation over S . Likewise, if X is an S -prescheme in groups flat of finite presentation with connected fibers, and $i : Y \rightarrow X$ a monomorphism of S -groups, with Y an S -prescheme in groups of finite presentation, then $\prod_{X/S} Y/X$ is representable by a closed subscheme of S of finite presentation over S . In particular, 6.11 a) remains valid by replacing the hypothesis " H smooth over S " by " H flat over S ".

Exposé XII. Maximal tori, the Weyl group, Cartan subgroups, the reductive center of smooth and affine group schemes

<!-- label: III.XII -->

by A. Grothendieck

<!-- original page 180 -->

From the present Exposé onwards, in contrast to the preceding Exposés, we make use of the known results on the structure of smooth algebraic groups over an algebraically closed field k , and above all of Borel's theory of affine algebraic groups, expounded in the Séminaire Chevalley 56/57: "Classification des groupes de Lie algébriques".[^N.D.E-XII-1] Following the usage in the theory of algebraic groups, we refer to this Séminaire by the sigil *BIBLE*. For the next Exposés, we shall need in particular the results of *BIBLE* 4, 5, 6, 7 (the number after *BIBLE* refers to the Exposé number). It seems, moreover, that the theory of schemes brings no notable simplification to Borel's theory as exposed in *BIBLE*. That is why it has not seemed useful to reproduce it in the present Séminaire, our aim here being to deduce, from results known over algebraically closed fields, analogous results valid over an arbitrary base prescheme. (Things will be different for Chevalley's structure theory of semisimple groups, which, it appears, is best treated *ab ovo* over an arbitrary base prescheme.)

In the oral Exposés (which we have followed in Nos. 1 to 4) we restricted ourselves to affine group preschemes over S , relying in an essential way on the representability theorems of Exp. XI N° 4. In the present notes (cf. Nos. 6 to 8) <!-- original page 181 --> we show rapidly how the affine hypotheses can be eliminated by a simpler method that does not use the most delicate results of Exposé XI. For other generalizations of the results contained in the present Exposé, see also Exposés XV and XVI. (It is evident that the content of Exposés XI, XII, XV, XVI ought to be completely rewritten.)

1. Maximal tori

<!-- label: III.XII.1 -->

1.0. Let first G be an algebraic group over an algebraically closed field k . By a *maximal torus of G * one

means an algebraic subgroup T of G which is a torus (meaning here, since k is algebraically closed, that it is isomorphic to a group of the form $G^{\{r\}}_m$), and which is maximal for this property. Note that, k being perfect, G_{red} is a subgroup of G , smooth over k , so it is essentially an algebraic group in the sense of *BIBLE*. Moreover, every reduced subgroup of G (such as a torus) is automatically a subgroup of G_{red} , so the maximal tori of G coincide with the maximal tori of G_{red} . When G is affine, hence G_{red} is affine, a fundamental theorem of Borel tells us that two maximal tori of G are conjugate by an element of $G(k) = G_{\text{red}}(k)$ (*BIBLE* 6, th. 4 c)); in particular they have the same dimension. We shall call the common dimension of the maximal tori of G the *reductive rank of G *. Note moreover that the restriction that G be affine is unnecessary, as follows from a known theorem of Chevalley, asserting that every connected smooth algebraic group over k is an extension of an abelian variety by an affine group; cf. N° 6. In Nos. 1 to 4 we shall mostly restrict ourselves to affine group preschemes over the base.

Let G be a smooth algebraic group over k , and T a maximal torus of G ; the centralizer $C(T)$ of T in G will be called the *Cartan subgroup of G associated with T *. For us this is a group subscheme defined thanks to (VIII, 6.7), but one will note that, G being smooth over k , the same holds for the Cartan subgroup C by (XI, 5.3); hence
 <!-- original page 182 --> in this case C is the unique group subscheme of G smooth over k (i.e. an algebraic subgroup of G in the sense of *BIBLE*) such that $C(k)$ is the subgroup of $G(k)$ centralizing $T(k)$, i.e. it is essentially the centralizer in the sense of *BIBLE*. By the conjugation theorem already cited, the Cartan subgroups associated with the various maximal tori are conjugate to each other, hence have the same dimension. We shall call their common dimension the *nilpotent rank of G *; it equals that of G_{red} . Let $\rho_r(G)$ and $\rho_n(G)$ denote the reductive and nilpotent ranks of G ; then one has

$$\rho_r(G) \leq \rho_n(G),$$

and the difference

$$\rho_u(G) = \rho_n(G) - \rho_r(G) = \dim C/T$$

might be called, when G is affine, the *unipotent rank of G *. When G is smooth, affine, and connected, then C is a nilpotent connected algebraic group (*BIBLE* 6, th. 6 a) and c)), hence (*BIBLE* 6, th. 2) isomorphic to the product $C_s \times C_u$, where $C_s = T$ is the maximal torus we started with (which is *a fortiori* a maximal torus in C), and where C_u is a smooth unipotent subgroup, i.e. a successive extension of groups isomorphic to G_a (*BIBLE* 6 th. 1 cor. 1 and 7, th. 4). One then has also, in this case:

$$\rho_u(G) = \dim C_u.$$

Remark 1.1. Besides the three notions of rank we have just made precise for an affine algebraic group, there are two others that are useful, namely the *semisimple rank $\rho_s(G)$ *, which is by definition the reductive rank of the quotient G/R , where R is the radical of G , and finally the *infinitesimal rank $\rho_i(G)$ *, which is by definition the nilpotent rank of the Lie algebra of G (which will be defined and studied in the following Exposé). We shall not use them in the present Exposé. Let us only signal the inequalities:*

$$\rho_s \leq \rho_r \leq \rho_n \leq \rho_i.$$

<!-- label: III.XII.1.1 -->

Lemma 1.2. Let G be an algebraic group over the algebraically closed field k , T an algebraic subgroup of G , k' an algebraically closed extension of k , G' and T' the groups obtained from G , T by extension of the base. For T' to be a maximal torus of G' , it is necessary and sufficient that T be a maximal torus of G .

<!-- label: III.XII.1.2 -->

<!-- original page 183 -->

This is an immediate consequence of the "principle of finite extension" (EGA IV, 9.1.1).

Definition 1.3. Let S be a prescheme, G an S -prescheme in groups of finite type, T a group subscheme of G . One says that T is a *maximal torus of G if*

a) T_S is a torus (IX, 1.3) and

b) for every $s \in S$, denoting by $\bar{S}_s$ the spectrum of an algebraic closure of $\kappa(s)$, $T_{\bar{S}_s}$ is a maximal torus in $G_{\bar{S}_s}$.

<!-- label: III.XII.1.3 -->

Remarks 1.4. *It follows from 1.2 that when S is the spectrum of an algebraically closed field one recovers the usual definition, and that property 1.3 is stable under any base change. Note that, by (X, 8.8), one may in Definition 1.3 replace condition a) by:*

a') T_S is of finite presentation and flat over S .

<!-- label: III.XII.1.4 -->

One should beware that a maximal torus in the sense of Definition 1.3 is indeed maximal among the subtori of G (as follows at once from (IX, 2.9)), but that the converse cannot be valid—the base S being, say, connected—unless G effectively admits a maximal torus in the sense of 1.3, which is not the case in general (even if $S = \operatorname{Spec}(\mathbb{Z})$ and G is "semisimple"; see also 1.6). We shall see however in XIV that the converse holds when S is artinian, or when S is a local scheme and G is "reductive": in this case, every torus of G is contained in a maximal torus.

Definition 1.5. *Let G be an algebraic group over a field k . The* reductive rank *(resp.* nilpotent rank*, resp.* unipotent rank*, etc.) of G is the reductive rank (resp. ...) of $G_{\bar{k}}$, where $\bar{k}$ is an algebraic closure of k .*

<!-- label: III.XII.1.5 -->

<!-- original page 184 -->

One will note that, in view of 1.2 and the commutation of the formation of $\operatorname{Centr}_G(T)$ with base extension, the notions of rank introduced in 1.5 are invariant under extension of the base field; on the other hand, for k algebraically closed, they coincide with those introduced at the beginning of the present number.

Remark 1.6. *It is not difficult to construct an affine smooth group scheme G over the spectrum S of a discrete valuation ring, whose generic fiber is isomorphic to G_m , and whose special fiber is isomorphic to G_a . Such a G contains no torus except the trivial torus T (reduced to the unit subgroup), which is evidently not a maximal torus. More precisely, in the special fiber $G_{\{0\}} = G_{\{a,k\}}$, T_0 is indeed a maximal torus, but in the generic fiber $G_{\{1\}} = G_{\{m,K\}}$, T_1 is no longer a maximal torus (k is the residue field, K the fraction field of the valuation ring under consideration). One sees also from this example that the reductive rank of G_S ($s \in S$) is not a continuous function of s . One has however the following results:*

<!-- label: III.XII.1.6 -->

Theorem 1.7. *Let S be a prescheme, G an affine smooth S -prescheme in groups over S . For every $s \in S$, consider $\rho_r(s) = \rho_r(G_s)$ and $\rho_n(s) = \rho_n(G_s)$, the reductive and nilpotent ranks of G_s (1.5). With these notations, one has the following:*

a) The function ρ_r on S is lower semicontinuous, the function ρ_n on S is upper semicontinuous, hence the function $\rho_u = \rho_n - \rho_r$ is upper semicontinuous.*

b) The following conditions (stable under arbitrary base change) are equivalent:*

(i) The function ρ_r on S is locally constant.*

<!-- original page 185 -->

(ii) There exists, locally for the étale topology, a maximal torus in G .*

(ii bis) There exists, locally for the faithfully flat quasi-compact topology, a maximal torus in G .*

c) Let T_1, T_2 be two maximal tori in G (which implies that one is under the conditions of b)). Then T_1, T_2 are conjugate locally for the étale topology, i.e. there exists an étale surjective morphism $S' \rightarrow S$ such that the subgroups $(T_1)_{S'}$ and $(T_2)_{S'}$ of $G_{S'}$ are conjugate by a section of $G_{S'}$ over S' .*

*d) Under the conditions of b), i.e. when ρ_r is locally constant, the same holds for ρ_n (hence also for $\rho_u = \rho_n - \rho_r$).

<!-- label: III.XII.1.7 -->

Proof. a) Note that for any morphism $S' \rightarrow S$, setting $G' = G \times_S S'$, the functions ρ'_r etc. on S' defined in terms of G' as ρ_r etc. in terms of G are obtained simply by composing the latter with $S' \rightarrow S$. When $S' \rightarrow S$ is faithfully flat quasi-compact, it follows that ρ' is continuous, resp. upper semicontinuous, resp. lower semicontinuous, if and only if ρ is, the Zariski topology of S' being in effect a quotient of that of S (SGA 1, VIII 4.3). Consequently, the assertions of a) are local for the faithfully flat quasi-compact topology. Let then $s \in S$; we wish to show that the set U of $t \in S$ such that $\rho_r(t) \leq \rho_r(s)$ (resp. $\rho_n(t) \leq \rho_n(s)$) is a neighborhood of s . By the principle of finite extension, there exists a finite extension k of $\kappa(s)$ such that G_k admits a maximal torus. There then exist an open neighborhood U of s , and a finite surjective locally free morphism $S' \rightarrow U$ such that the fiber S'_s is $\kappa(s)$ -isomorphic to $\operatorname{Spec}(k)$ (cf. EGA III, 10.3.2, where the noetherian hypothesis is manifestly unnecessary). Since $S' \rightarrow S$ is an open morphism (SGA 1, IV 6.6), we are reduced to the case where $S' = S$, i.e. to the case where there exists a maximal torus T_s in G_s . Furthermore, by (XI, 5.8 a)), possibly replacing S by an S' étale over S equipped with a point s' above s , <!-- original page 186 --> we may suppose that T_s is the fiber at s of a subtorus T of G . Then for every $t \in S$, $\rho_r(t) = \rho_r(G_t) \leq \dim T_t = \dim T_s = \rho_r(G_s) = \rho_r(s)$, which proves that ρ_r is lower semicontinuous. On the other hand, by (XI, 5.3), the functor

$C = \operatorname{Centr}_G(T)$

is representable by $C = \operatorname{Centr}_G(T)$, [N.D.E-XII-2] a closed group subscheme of G smooth over S . So there exists a neighborhood U of s such that $t \in U$ implies $\dim C_t = \dim C_s = \rho_n(s)$. The upper semicontinuity of ρ_n is then a consequence of the relation

$\rho_n(t) \leq \dim C_t$ for every $t \in S$,

which is itself contained in the following purely geometric lemma:

Lemma 1.8. *Let k be a field, G an affine smooth algebraic group over k , T a torus in G , C its centralizer; then one has*

$\rho_n(G) \leq \dim C$.

<!-- label: III.XII.1.8 -->

Indeed, one may suppose k algebraically closed, so that T is contained in a maximal torus T_0 . Let C_0 be the centralizer of the latter; then $C_0 \subset C$, hence $\dim C_0 \leq \dim C$. QED.

b) If ρ_r is locally constant, then for every torus T in G , and every $s \in S$, if T_s is a maximal torus in G_s , then there exists an open neighborhood U of s such that $T|_U$ is a maximal torus in $G|_U$. Using now the reasoning of a), one sees that (i) $\Rightarrow$ (ii bis). On the other hand (ii bis) $\Rightarrow$ (i), for when G admits a maximal torus T , then it is evident that $\rho_r(s) = \dim T_s$ is a locally constant function of s ; now we signaled at the beginning of the proof of a) that the question of continuity of ρ_r was local for the faithfully flat topology. Hence (i) $\Leftrightarrow$ (ii bis), and obviously (ii) $\Rightarrow$ (ii bis); it remains to prove the converse implication (i) $\Rightarrow$ (ii). <!-- original page 187 --> For this, introduce the functor F of (XI, 4.1), [N.D.E-XII-3] which is therefore a smooth separated prescheme over S , and consider the subfunctor $\mathcal{T}$ of F , whose value for an S' over S is the set of maximal tori in $G_{S'}$. Using the previous remark that, granted (i), a torus in $G_{S'}$ which is maximal in the fiber of some point $s \in S'$ is maximal above an open neighborhood of s , one sees that $\mathcal{T}$ is representable by an open subscheme of F , and is therefore smooth and separated over S . Since the structural morphism $\mathcal{T} \rightarrow S$ is evidently surjective, it admits a section locally for the étale topology by (XI, 1.10), which proves (i) $\Rightarrow$ (ii).

c) This is an immediate consequence of (XI, 5.4 bis), taking into account Borel's conjugation theorem recalled at the beginning of the number.

d) By the remark at the beginning of the proof in a), and taking into account b), we may suppose that there exists a maximal torus T in G . If C is its centralizer, then C is representable and smooth over S by (XI, 5.3), so the function $s \mapsto \rho_n(s) = \dim C_s$ is indeed locally constant.

The proof of 1.7 is complete. We shall refer to the conditions envisaged in 1.7 b) by saying that in this case G is of locally constant reductive rank*. Let us note:

Corollary 1.9. *Let G be as in 1.7, and let s in S be such that $\rho_u(s) = 0$, i.e. $\rho_r(s) = \rho_n(s)$ (i.e. the Cartan subgroups of $G_{\bar{k}}$ are tori, where $\bar{k}$ is an algebraic closure of $k(s)$). Then there exists an open neighborhood U of s over which ρ_r and ρ_n are constant; in particular, for every t in U , the unipotent rank $\rho_u(t)$ of G_t is zero.*

<!-- label: III.XII.1.9 -->

Indeed, this follows immediately from 1.7 a) and from the inequality $\rho_r(t) \leq \rho_n(t)$ for every t in S .

Note also that we have proved, at the same time as b), the

<!-- original page 188 -->

Corollary 1.10. *Let G be as in 1.7, and suppose G of locally constant reductive rank. Consider the functor*

$\mathcal{T} : (\text{Sch})^{\circ} \rightarrow (\text{Ens}),$

such that for every S over S , one has

``text
 $\mathcal{T}(S) = \text{the set of maximal tori of } G_S.$

Then $\mathcal{T}$ is representable by a smooth, separated prescheme of finite type over S .

<!-- label: III.XII.1.10 -->

It remains to verify that $\mathcal{T}$ is of finite type over S . The question being local for the faithfully flat quasi-compact topology, we may suppose that G admits a maximal torus T . By (XI, 5.3 bis) and the bis version of 5.5, $\text{Norm}_G(T)$ and $G/\text{Norm}_G(T)$ are representable by preschemes $\text{Norm}_G(T)$ and $G/\text{Norm}_G(T)$, and $\mathcal{T}$ is isomorphic to $G/\text{Norm}_G(T)$. [N.D.E-XII-4] The morphism $G \rightarrow \mathcal{T}$ defined by $g \mapsto \text{int}(g)(T)$ being surjective, and G quasi-compact over S , the same holds for $\mathcal{T}$, which completes the proof.

Remarks 1.11. *a) The prescheme $\mathcal{T}$ of 1.10 will rightly be called the prescheme of maximal tori of G . We shall see in N° 5 that it is in fact affine over S . One can verify this directly when G is isomorphic to a closed group subscheme of a prescheme of the form $\text{GL}(n)$, using (XI, 4.6) and remarking that, by the reasoning of the proof of 1.7 b), $\mathcal{T}$ identifies with a subscheme both open and closed of the prescheme $\mathcal{F}$ which represents the multiplicative-type subgroups of G .*

b) It is possible to give a proof of 1.7—and hence of 1.9—not using the delicate results of XI, but only the easy results (XI, 3.12) and (XI, 6.2), working only with multiplicative-type subgroups finite over the base (morally, the groups T_n where T is a maximal torus); compare N° 7. The same remark applies to the proof of 1.10.

<!-- label: III.XII.1.11 -->

<!-- original page 189 -->

We end this number by giving examples in which there exists a unique maximal torus.

Proposition 1.12. *Let G be an S -prescheme in groups of multiplicative type and of finite type. Then G admits a unique maximal torus, and every torus in G is contained in this maximal torus.*

<!-- label: III.XII.1.12 -->

Uniqueness obviously follows from the latter assertion, which characterizes the maximal torus as the largest subtorus of

G . From uniqueness it follows that the existence question is local for the faithfully flat quasi-compact topology, which allows us to suppose G diagonalizable, i.e. of the form $D_{\{S\}}(M)$, with M a finitely generated commutative group. Let M_0 be the quotient of M by its torsion subgroup; I claim that the torus $T = D_{\{S\}}(M_0)$ in G is a maximal torus and a largest subtorus. Indeed, a subtorus T' of G is locally diagonalizable for the fpqc topology, hence to prove $T' \subset T$ we may suppose T' diagonalizable, hence of the form $D_{\{S\}}(N)$, where N is a free quotient of M (VIII 1.4 and 3.2 b)), hence N is a quotient of M_0 , hence $T' \subset T$. Since the construction of T as $D_{\{S\}}(M_0)$ is compatible with any base extension, this shows at the same time that T is a maximal torus of G , and completes the proof. In the case where G is smooth over S , 1.12 may be generalized:

Proposition 1.13. *Let G be an S -prescheme in groups of finite presentation over S . Suppose that G admits, locally for the faithfully flat quasi-compact topology, a central maximal torus. Then G admits (globally) a unique maximal torus, [N.D.E-XII-5] and it is the largest subtorus of G .*

<!-- label: III.XII.1.13 -->

Here again, uniqueness is trivial from the last assertion, and renders existence a local question for fpqc, which allows us to suppose that G admits a central maximal torus T . We show that every torus R of G is contained in T .

This follows from the <!-- original page 190 -->

Lemma 1.14. *Let G be an S -prescheme in groups of finite presentation over S , T a maximal torus of G , R a subtorus of G , and suppose that T and R commute. Then $R \subset T$.*

<!-- label: III.XII.1.14 -->

Indeed, since R and T commute, the morphism $R \times_{\{S\}} T \rightarrow G$ defined by $(r, t) \mapsto r \cdot t$ is a group homomorphism, hence by (IX, 6.8) it admits an image subgroup T' in G , which is a multiplicative-type group quotient of $R \times_{\{S\}} T$, hence a torus, evidently containing T . Since T is a maximal torus, one has $T' = T$ (1.4), hence $R \subset T$, which proves 1.14 and hence 1.13. In particular, using 1.7 b):

Corollary 1.15. *Let G be a commutative, smooth, and affine S -prescheme in groups over S , of locally constant reductive rank. Then G admits a unique maximal torus, and this latter contains every subtorus of G .*

<!-- label: III.XII.1.15 -->

Corollary 1.16. *Let G be a smooth and affine S -prescheme in groups over S . Suppose that for every $s \in S$, denoting by $\bar{s}$ the spectrum of an algebraic closure $\bar{k}$ of $k(s)$, the geometric fiber $G_{\bar{s}}$ is a connected nilpotent algebraic group (in the sense of BIBLE, i.e. the group $G(\bar{k})$ of its $\bar{k}$ -valued points is nilpotent). Suppose moreover that the reductive rank of G is locally constant. Then G admits a unique maximal torus T ; moreover, T is central and is the largest subtorus of G .*

<!-- label: III.XII.1.16 -->

By 1.7 b), G admits a maximal torus locally for fpqc, and by 1.13 we are reduced to proving that a maximal torus of G is central. By (IX, 5.6 b)), we are reduced to the case where S is the spectrum of a field, which one may suppose algebraically closed. Then $T(k)$ lies in the center of $G(k)$ by *BIBLE* 6 th. 2, which implies that T lies in the center of G , since $\text{Centr}_G(T)$ is a closed subscheme of G (VIII 6.6) which contains the points of $G(k)$, hence is identical to G by the Nullstellensatz (since G is reduced).

<!-- original page 191 -->

Finally, for later reference, let us signal the following trivial proposition (of which we have already made implicit use):

Proposition 1.17. *Let $G \supset H \supset T$ be preschemes in groups of finite type over S . Equivalent conditions:*

(i) T is a maximal torus of G .*

(ii) T is a maximal torus of H , and for every $s \in S$, one has equality of the reductive ranks $\rho_r(G_s) = \rho_r(H_s)$.*

<!-- label: III.XII.1.17 -->

2. The Weyl group

<!-- label: III.XII.2 -->

Let first k be an algebraically closed field, and let G be a smooth affine algebraic group over k . If T is a maximal torus, C its centralizer and N its normalizer, then by (XI, 5.9) these are smooth closed subgroups of G , and C is an open subgroup of N , so that $W = N/C$ is a finite étale group over k , hence determined by the group $W(k)$ of its k -valued points, as $W = W(k)_k$ (constant group defined by the ordinary finite group $W(k)$). The finite group $W(k)$ will be called the *geometric Weyl group* (or simply the *Weyl group* if no confusion is to be feared) of G relative to T . By Borel's conjugation theorem, the Weyl groups relative to the various maximal tori are isomorphic to each other; this is why one sometimes speaks of "the" Weyl group of G , without specifying a maximal torus. Since the formation of C , N , and N/C commutes with any base extension, one sees that if k' is an algebraically closed extension of k , the geometric Weyl group of $G_{k'}$ relative to $T_{k'}$ is canonically isomorphic to that of G relative to T ; consequently, "the" geometric Weyl group of G (which is properly speaking an isomorphism class of ordinary finite groups) coincides with that of G' .

<!-- original page 192 -->

This allows one, when G is a smooth affine algebraic group over an arbitrary field k , to speak of the *geometric Weyl group* of G as the isomorphism class of the geometric Weyl group of $G_{k'}$, where k' is any algebraically closed extension of k . When G admits a maximal torus T , then one may evidently form as above $C = \text{Centr}_{\{G\}}(T)$, $N = \text{Norm}_{\{G\}}(T)$, $W = N/C$ which is a finite étale group over k , called the *Weyl group* of G relative to T ; the geometric Weyl group is then nothing other than the class of the group of points of W with values in any algebraically closed extension k' of k . Here, knowledge of the geometric Weyl group $W(k)$ evidently no longer suffices in general to reconstruct the algebraic group W : one must also know the operations on $W(k')$ of the Galois group of the separable algebraic closure of k in k' .

When finally G is an S -prescheme in groups over an arbitrary base S , G smooth and affine over S , and if T is a maximal torus of G , then (XI, 5.9) still allows us to form the group

```text  
 $W(T) = N(T)/C(T)$ ,  
```

which is an étale, separated, quasi-finite S -prescheme in groups over S . Its geometric fibers (relative to the algebraic closures of the residue fields $\kappa(s)$, $s \in S$) are the geometric Weyl groups of the fibers G_s . Consequently, (XI, 5.10) gives information on the variation of these groups with $s \in S$. We can make this information more precise and generalize it as follows:

Theorem 2.1. *Let S be a prescheme, G a smooth and affine S -prescheme in groups over S . For every $s \in S$, let $w(s)$ be the geometric Weyl group of G_s , which is therefore an isomorphism class of finite groups. In the set E of such classes, introduce the following preorder relation: $w \leq w'$ if and only if w and w' are represented by finite groups W and W' such that W is isomorphic to a quotient of a subgroup of W' . With this convention:*

a) The function $s \mapsto w(s)$ from S to E is lower semicontinuous.*

<!-- original page 193 -->

b) Suppose that the reductive rank of G is locally constant. Then the following conditions are equivalent:*

(i) The function $s \mapsto w(s)$ is locally constant.*

(i bis) The function $s \mapsto \text{card } w(s)$ is locally constant.*

(ii) There exists, locally for the étale topology (or merely for the fpqc topology), a maximal torus T , such that $W(T)$ is finite over its base.*

(ii bis) For every S' over S , and every maximal torus T of $G_{S'}$, the associated Weyl group $W(T)$ is finite over S' .*

<!-- label: III.XII.2.1 -->

Proof. a) Proceeding as in 1.7 a), one is reduced, in order to prove that for every $s \in S$ there exists an open neighborhood U of s such that $t \in U$ implies $w(t) \leq w(s)$, to the case where there exists a torus R in G such that R_s is a maximal torus in G_s . Let

$$W(R) = \text{Norm}_{\{G\}(R)} / \text{Centr}_{\{G\}(R)}$$

as in (XI, 5.9); this is an étale, separated, quasi-finite group prescheme over S . For every $t \in S$, let $w'(t) \in E$ be its geometric fiber at t . Since $R_{\{s\}}$ is a maximal torus in $G_{\{s\}}$, and the formation of Norm , Centr , Norm/Centr is compatible with any base extension, in particular with passage to the fibers, one sees that one has

$$w(s) = w'(s);$$

I claim moreover that, for t near s , one has the inequalities

$$w(t) \leq w'(t) \quad \text{and} \quad w'(t) \leq w'(s),$$

which will suffice to establish a). These two inequalities are contained in the two following lemmas:

<!-- original page 194 -->

Lemma 2.2. *Let S be a prescheme, W an étale, separated, quasi-finite S -prescheme in groups over S . For every $s \in S$, let $f(s)$ be the class of the geometric fiber of W at s , which is an element of the ordered set E of isomorphism classes of finite groups, introduced in 2.1. Then the function $f : S \rightarrow E$ is lower semicontinuous. For it to be constant in a neighborhood of $s \in S$, it is necessary and sufficient that the same hold for the function $s \mapsto \text{card } f(s)$, and for this it is necessary and sufficient that W be finite over S above an open neighborhood U of s .*

<!-- label: III.XII.2.2 -->

This result is a refinement, in terms of groups, of the one invoked in the proof of (XI, 5.10); we content ourselves with a sketch of the proof (which is of the most standard type). As usual, one is reduced to the case S affine noetherian. One sees at once that the function f is constructible (EGA 0_III, 9.3.1 and 9.3.2, and the sundries of EGA IV, 9), and by (EGA 0_III, 9.3.4) one is reduced, for the semicontinuity, to proving that if t is a generalization of s , one has $f(t) \geq f(s)$. This reduces us, thanks to (EGA II, 7.1.7), to the case where S is the spectrum of a discrete valuation ring, which one may suppose complete with algebraically closed residue field. But then, s denoting the closed point of S , since G is étale and separated over S , it contains a subscheme G' both open and closed, finite over S , such that $G'_{\{s\}} = G_{\{s\}}$ (EGA II, 6.2.6), and one sees at once that G' is here a subgroup of G . Moreover G' , being étale finite over $S = \text{Spec}(V)$, with V complete with algebraically closed residue field, is a constant group, hence of the form A_S , where $A = G'(\kappa(s)) = G(\kappa(s))$ has class $f(s)$. If B is the geometric fiber of G at the generic point t of S , one has therefore a canonical monomorphism $A \rightarrow B$, which proves $f(s) \leq f(t)$. (N.B. this proof in fact proves the semicontinuity for an order relation on E finer than the one indicated in 2.1.) The fact that f is continuous at s if and only if $s \mapsto \text{card } f(s)$ is, follows from the fact that for $w, w' \in E$, the relations $w \leq w'$ and $\text{card } w = \text{card } w'$ imply $w = w'$. The fact that this condition is equivalent to the finiteness of W on a neighborhood of s is then independent of the group structure <!-- original page 195 --> on W , and has been signaled after (XI, 5.10); its proof can moreover easily be carried out by the preceding arguments, using the valuative criterion of properness (EGA II, 7.3.8).

Lemma 2.3. *Let G be a smooth affine algebraic group over an algebraically closed field k , $R \subset T$ two subtori, $W(R)$ and $W(T)$ the two associated finite groups as in (XI, 5.9), quotients of the normalizer by the centralizer. Then $W(R)$ is isomorphic to a quotient of a subgroup of $W(T)$.*

<!-- label: III.XII.2.3 -->

Indeed, consider the diagram

$$\begin{array}{ccc} T & \hookrightarrow & C(T) \hookrightarrow C(R) \\ & \downarrow & \downarrow \\ N(T) \cap N(R) & \hookrightarrow & N(R) \\ & \downarrow & \\ N(T) & & \end{array}$$

...

then $(N(T) \cap N(R))/C(T)$ is a subgroup of $W(T) = N(T)/C(T)$, and one has an obvious homomorphism:

```
```text
(N(T) ∩ N(R))/C(T) → W(R) = N(R)/C(R),
```
```

and everything reduces to proving that this last is surjective, i.e. that for every k -valued point g of $N(R)$, there exists a k -valued point c of $C(R)$ such that cg normalizes T , i.e. such that

```
```text
int(c)(int(g)T) = T.
```
```

Now for this it suffices to note that $\text{int}(g)T$ is a torus of $N(R)$ hence of $C(R)$ (which is an open subgroup thereof). Then T and $\text{int}(g)T$ are maximal tori of $C(R)$, since they are maximal in G , and one concludes by Borel's conjugation theorem.

This proves 2.3 and thereby 2.1 a).

<!-- original page 196 -->

b) We have already signaled that (i) and (i bis) are trivially equivalent; they imply (ii bis) by the converse to 2.2 or to (XI, 5.10) at choice; (ii bis) $\Rightarrow$ (ii) thanks to 1.7 b); finally (ii) $\Rightarrow$ (i bis), for one sees as in 1.7 a) that the condition (i) is local for fpqc, which allows us to suppose that G admits a maximal torus T such that $W(T)$ is finite over S , and one concludes again by (XI, 5.10). This completes the proof of 2.1.

3. Cartan subgroups

<!-- label: III.XII.3 -->

Definition 3.1. Let G be a smooth S -prescheme in groups of finite type over the prescheme S . By a Cartan subgroup of G one means a group subscheme C of G , smooth over S , such that for every $s \in S$, denoting by $\bar{s}$ the spectrum of an algebraic closure of $k(s)$, $C_{\bar{s}}$ is a Cartan subgroup (cf. N° 1) of $G_{\bar{s}}$.

<!-- label: III.XII.3.1 -->

It is immediate that if C is a Cartan subgroup of G , then for every S' over S , $C_{S'}$ is a Cartan subgroup of $G_{S'}$. If S is the spectrum of an algebraically closed field, one recovers the notion recalled in N° 1. Finally, one verifies at once that the property for a group subscheme C of G to be a Cartan subgroup is local in nature for the faithfully flat quasi-compact topology.

Theorem 3.2. Let G over S be as in 3.1, and suppose that G is affine over S and of locally constant reductive rank. Then the map

```
```text
T → Cent_G(T)
```
```

induces a bijection from the set of maximal tori of G onto the set of Cartan subgroups [XII-3-1] of G . If C corresponds to T , then T is the unique maximal torus

<!-- original page 197 -->

of C .

<!-- label: III.XII.3.2 -->

If T is a maximal torus of G , the functor $\text{Cent}_G(T)$ is representable, by (XI, 5.3) or (XI, 6.2), by a closed smooth subscheme of G , $C = \text{Cent}_G(T)$, and it follows from the definitions that C is a Cartan subgroup of G . Moreover, T is obviously a maximal torus of C , and being central, it is the unique maximal torus of C (1.13). Hence the map $T \mapsto \text{Cent}_G(T)$ from the set of maximal tori into the set of Cartan subgroups is injective; it remains to prove that it is surjective. Let then C be a Cartan subgroup of G ; we prove that it is of the form

$\text{Centr}_{\{G\}}(T)$, for T a maximal torus of G . For this it suffices to find a maximal torus T of C , for then T will be a maximal torus of G (since for every $s \in S$, G_s and C_s have the same reductive rank). By (IX, 5.6 b)) T lies in the center of C , hence $C \subset C' = \text{Centr}_{\{G\}}(T)$, and then C is a smooth subgroup of the smooth group C' over S , coinciding with C' fiber by fiber, whence $C = C'$. Now since G is of locally constant reductive rank, the same holds for C , hence C admits a maximal torus locally for the étale topology by 1.7 b), and since this torus is central by the preceding reasoning, it follows by 1.13 that C does admit a maximal torus, which completes the proof.

Corollary 3.3. Let G be a smooth and affine S -prescheme in groups over S of locally constant reductive rank, and let $\mathcal{C} : (\text{Sch})^{\text{circ}}/S \rightarrow (\text{Ens})$ be the functor defined by*

text
 $\mathcal{C}(S') =$ the set of Cartan subgroups of $G_{\{S'\}}$.

Then the functor $\mathcal{C}$ is isomorphic to the functor $\mathcal{T}$ of 1.10, hence is representable by the same smooth, separated prescheme of finite type over S .

<!-- label: III.XII.3.3 -->

Corollary 3.4. Under the conditions of 3.2, if $C = \text{Centr}_{\{G\}}(T)$, one has*

$$\text{Norm}_{\{G\}}(C) = \text{Norm}_{\{G\}}(T).$$

<!-- label: III.XII.3.4 -->

<!-- original page 198 -->

Remark 3.5. When G is not of locally constant reductive rank, it is nevertheless possible that G admit Cartan subgroups (for example if G has connected nilpotent fibers, G is a Cartan subgroup of itself, but is not necessarily of locally constant reductive rank, cf. 1.6). In XV, we develop the theory of Cartan subgroups without supposing G affine over S or of locally constant reductive rank, using the theory of regular elements of the next Exposé. See also Nos. 6 and 7 for the elimination of the affine hypothesis.*

<!-- label: III.XII.3.5 -->

4. The reductive center

<!-- label: III.XII.4 -->

Definition 4.1. Let S be a prescheme, G an S -group of finite presentation over S , with affine fibers, Z a group subscheme of G . One says that Z is a reductive center of G if*

(i) Z is central, and of multiplicative type, and*

(ii) for every base change $S' \rightarrow S$ and every central homomorphism $u : H \rightarrow G_{\{S'\}}$, where H is a group of multiplicative type and of finite type over S' , u factors through $Z_{\{S'\}}$.*

<!-- label: III.XII.4.1 -->

(For a variant of this notion when the fibers of G are not supposed affine, cf. 8.6.)*

Note that such a Z is necessarily of finite type over S (since its fibers are), hence is uniquely determined as the largest central multiplicative-type subgroup of G . It is easy to give examples where G (smooth and affine over S) admits a largest central multiplicative-type subgroup Z , but where Z is not a reductive center (i.e. G does not admit a reductive center), cf. for example 1.6; it follows however easily from (IX, 6.8) that a subgroup Z of G is a reductive center of G if and only if it is a largest central multiplicative-type subgroup, and retains this property under any base change; see also 4.3 below.

<!-- original page 199 -->

It is evident from 4.1 that if Z is the reductive center of G , then for every base change $S' \rightarrow S$, $Z_{\{S'\}}$ is the reductive center of $G_{\{S'\}}$. From this, and from the uniqueness of the reductive center, follows, thanks to the

theory of faithfully flat quasi-compact descent (SGA 1, VIII):

Proposition 4.2. *Let G be an S -prescheme in groups of finite presentation over S and with affine fibers. If G admits a reductive center locally for the faithfully flat quasi-compact topology, then it admits a reductive center. For Z to be a reductive center of G , it is necessary and sufficient that it be so locally for the fpqc topology.*

<!-- label: III.XII.4.2 -->

Let us also note:

Proposition 4.3. *Let G be an S -prescheme in groups of finite presentation and with affine fibers, Z a group subscheme. For Z to be a reductive center of G , it is necessary and sufficient that it be of multiplicative type, and that for every $s \in S$, Z_s be a reductive center of G_s .*

<!-- label: III.XII.4.3 -->

Indeed, it follows first from (IX, 5.6 b)) that Z is then central. Since the conditions envisaged are stable under base change, it remains to prove that any central homomorphism $u : H \rightarrow G$, with H of multiplicative type and of finite type, factors through Z . Now, Z being central, u and the canonical immersion $v : Z \rightarrow G$ define a group homomorphism

```text  
w : H  $\times_S$  Z  $\rightarrow$  G.  
```

By (IX, 6.8) this last admits an image group K , which is a multiplicative-type subgroup of G , and everything reduces to proving that $K = Z$. Now this is true fiber by fiber by the hypothesis on Z , and it now suffices to apply (IX, 5.1 bis), which completes the proof of 4.3.

One will note that in criterion 4.3, the hypothesis that for every $s \in S$, Z_s is the reductive center of G_s is in fact purely geometric, i.e. it suffices to verify it on the algebraic closure of $\kappa(s)$, as follows from the second assertion of 4.2.

Theorem 4.4. *Let G be an affine algebraic group over a field k . Then G *

<!-- original page 200 -->

admits a reductive center.

<!-- label: III.XII.4.4 -->

Since the center of G is representable by a closed subgroup of G (VIII, 6.7), one is immediately reduced to the case where G is commutative. Furthermore, by 4.2 one may suppose k algebraically closed. We shall see in XVII that in this case G is written as a product $Z \times U$, where Z is of multiplicative type and U is "unipotent", from which it will follow at once that Z is indeed a reductive center of G . We shall give here a proof independent of the structure theorem for commutative algebraic groups in the general form just indicated.

Note that it follows from (IX, 6.8) that the set of multiplicative-type subgroups H of G is filtered upward. We show that it admits a largest element.

When G is smooth over k , one applies the structure theorem *BIBLE* 4 th. 4,

G
 $G = G_s \times G_u$,
 G

with G_s of multiplicative type and G_u "unipotent", which means here that G_u admits a composition series whose factors are subgroups (smooth if one insists) of G_a . (Indeed, $G_u/G_u^{(0)}$ is a unipotent group by *BIBLE* 4 cor. to th. 3, hence a p -group where p is the characteristic exponent, thanks to *BIBLE* 4 prop. 4; on the other hand, $G_u^{(0)}$ admits a composition series with connected smooth quotients of dimension 1 by *BIBLE* 6 th. 1 cor. 1, and these are isomorphic to G_a by *BIBLE* 7 th. 4.) Now one sees easily (cf. the lemma below) that every homomorphism from a multiplicative-type group to G_a , and hence also to G_u , is trivial, which proves indeed that every multiplicative-type subgroup of G is contained in G_s .

In the general case, consider the subgroup

$G_{\{0\}} = G_{\{\text{red}\}}$

of $G_{\mathbb{Z}}$, which is smooth over $k_{\mathbb{Z}}$, hence by the foregoing admits a largest $\langle \text{-- original page 201 --} \rangle$ multiplicative-type subgroup $Z_{\{0\}}$. The multiplicative-type subgroups of $G_{\mathbb{Z}}$ containing $Z_{\{0\}}$ correspond to multiplicative-type subgroups of $G^{\wedge}_{\{0\}} = G/Z_{\{0\}}$. Now one has an exact sequence

$$0 \rightarrow G_{\{0\}}/Z_{\{0\}} \rightarrow G/Z_{\{0\}} \rightarrow G/G_{\{0\}} \rightarrow 0,$$

where by the foregoing, $G_{\{0\}}/Z_{\{0\}}$ has no multiplicative-type subgroup except the unit group. Since a subgroup of a multiplicative-type group is of multiplicative type (IX, 8), it follows that for every multiplicative-type subgroup $H_{\mathbb{Z}}$ of $G/Z_{\{0\}}$, one has $H_{\mathbb{Z}} \cap (G_{\{0\}}/Z_{\{0\}}) = 0$, hence $H_{\mathbb{Z}} \rightarrow G/G_{\{0\}}$ is injective. Since $G/G_{\{0\}}$ is a radical algebraic group, hence finite over $k_{\mathbb{Z}}$, this implies that $H_{\mathbb{Z}}$ is itself radical and of rank bounded by that of $G/G_{\{0\}}$. This implies that the family of multiplicative-type subgroups of $G_{\mathbb{Z}}$ admits a largest element, say $Z_{\mathbb{Z}}$.

I claim that $G_{\mathbb{Z}}$ has no multiplicative-type subgroup other than the unit subgroup. This follows from the fact (proved in 7.1.1) that a commutative extension of two multiplicative-type algebraic groups is of multiplicative type: if then $Z'_{\mathbb{Z}}$ is the inverse image in $G_{\mathbb{Z}}$ of a multiplicative-type subgroup of $G/Z_{\mathbb{Z}}$, then $Z'_{\mathbb{Z}}$ is of multiplicative type, hence $Z' = Z_{\mathbb{Z}}$ by the maximal character of $Z_{\mathbb{Z}}$, hence $Z'/Z = 0$.

It now easily follows from the "principle of finite extension" that for any extension $K_{\mathbb{Z}}$ of $k_{\mathbb{Z}}$, $(G/Z)_{\{K\}} = G_{\{K\}}/Z_{\{K\}}$ likewise has no multiplicative-type subgroup except the unit group.

We can now prove that $Z_{\mathbb{Z}}$ is a reductive center of $G_{\mathbb{Z}}$. Indeed, let $\varphi : H \rightarrow G_{\{S\}}$ be a homomorphism of $S_{\mathbb{Z}}$ -groups, where $S_{\mathbb{Z}}$ is a prescheme over $k_{\mathbb{Z}}$ and $H_{\mathbb{Z}}$ a multiplicative-type group of finite type over $S_{\mathbb{Z}}$; we prove that φ factors through $Z_{\mathbb{Z}}$. This amounts to saying that the composite homomorphism $H \rightarrow G_{\{S\}} \rightarrow (G/Z)_{\{S\}} = G_{\{S\}}/Z_{\{S\}}$ is zero. Now setting $U = G/Z_{\mathbb{Z}}$, I claim that every homomorphism $\varphi : H \rightarrow U_{\{S\}}$ is zero. Indeed, by (IX, 5.2) one is reduced to the case where $S_{\mathbb{Z}}$ is the spectrum of a field, and by (IX, 6.8) this then follows from the fact that U_K has no multiplicative-type subgroup other than $\{0\}$. $\langle \text{-- original page 202 --} \rangle$ This completes the proof of 4.4. It only remains to give the proof of the

Lemma 4.4.1. *Let $H_{\mathbb{Z}}$ be a multiplicative-type $S_{\mathbb{Z}}$ -prescheme in groups; then every homomorphism of $S_{\mathbb{Z}}$ -groups $\varphi : H \rightarrow G_{\{a\}}$ is trivial.*

$\langle \text{-- label: III.XII.4.4.1 --} \rangle$

Indeed, consider the module $G^{\wedge}_{\{2\}}_{\{S\}} = E_{\mathbb{Z}}$ as an extension of $G_{\{S\}} = E'_{\mathbb{Z}}$ by $G^{\wedge}_{\{S\}} = E''_{\mathbb{Z}}$; then $G_{\{a\}}$ identifies with the prescheme of automorphisms of this extension, hence a homomorphism $\varphi : H \rightarrow G_{\{a\}}$ identifies with an $H_{\mathbb{Z}}$ -module structure on $E_{\mathbb{Z}}$ respecting the extension structure, i.e. such that $E'_{\mathbb{Z}}$ is stable under $H_{\mathbb{Z}}$ and the operations induced by $H_{\mathbb{Z}}$ on $E'_{\mathbb{Z}}$ and $E''_{\mathbb{Z}}$ are trivial. By (I, 4.7.3) it follows that $H_{\mathbb{Z}}$ operates trivially on $E_{\mathbb{Z}}$, hence φ is trivial. QED.

Remark 4.4.2. *If $G_{\mathbb{Z}}$ is a nonzero abelian variety over $k_{\mathbb{Z}}$, then $G_{\mathbb{Z}}$ does not admit a reductive center in the sense of 4.1 with the restriction " $G_{\mathbb{Z}}$ affine" omitted, because for $n_{\mathbb{Z}}$ coprime to the characteristic, $\{G_{\mathbb{Z}}^{\wedge n}\}_{n \in \mathbb{N}}$ is étale over $k_{\mathbb{Z}}$ of order prime to the characteristic, hence of multiplicative type; now the family of $\{G_{\mathbb{Z}}^{\wedge n}\}_{n \in \mathbb{N}}$ is schematically dense in $G_{\mathbb{Z}}$, so that if there were a reductive center, it would be identical to $G_{\mathbb{Z}}$, which is absurd, since $G_{\mathbb{Z}}$ is not of multiplicative type. This is the reason why it is appropriate in 4.1 to impose the restriction that $G_{\mathbb{Z}}$ have affine fibers.*

$\langle \text{-- label: III.XII.4.4.2 --} \rangle$

Lemma 4.5. *Let $S_{\mathbb{Z}}$ be a prescheme, $G_{\mathbb{Z}}$ a smooth $S_{\mathbb{Z}}$ -prescheme in groups over $S_{\mathbb{Z}}$, affine over $S_{\mathbb{Z}}$, with connected fibers, $T_{\mathbb{Z}}$ a maximal torus of $G_{\mathbb{Z}}$, $\varphi : H \rightarrow G_{\mathbb{Z}}$ a central homomorphism, with $H_{\mathbb{Z}}$ a multiplicative-type $S_{\mathbb{Z}}$ -prescheme in groups of finite type. Then φ factors through $T_{\mathbb{Z}}$.*

$\langle \text{-- label: III.XII.4.5 --} \rangle$

Indeed, let $C_{\mathbb{Z}}$ be the centralizer of $T_{\mathbb{Z}}$, which is a closed group subscheme of $G_{\mathbb{Z}}$ smooth over $S_{\mathbb{Z}}$ (XI, 5.3), hence affine over $S_{\mathbb{Z}}$. Since $T_{\mathbb{Z}}$ is in the center of $C_{\mathbb{Z}}$, it is invariant, and one may consider the quotient group $C/T = U_{\mathbb{Z}}$, which is representable (VIII, 5.1). Since φ is central, it factors through $C_{\mathbb{Z}}$, and everything reduces to proving that $\langle \text{-- original page 203 --} \rangle$ the composite homomorphism $H \rightarrow C \rightarrow U = C/T_{\mathbb{Z}}$ is trivial. By (IX, 5.2) one is reduced to the

case where S is the spectrum of a field, which one may suppose algebraically closed. But then by *BIBLE* 6, th. 2, S is a connected algebraic group (smooth over k) which is "unipotent", meaning, as we have already observed, that it admits a composition series with quotients isomorphic to G_a . Hence every homomorphism from a multiplicative-type group of finite type H to S is trivial. This proves 4.5.

Corollary 4.6. *Let G be as in 4.5. If G admits a reductive center, the latter is contained in every maximal torus of G .*

<!-- label: III.XII.4.6 -->

Theorem 4.7. *Let S be a prescheme, G an S -prescheme in groups, smooth over S , affine over S , with connected fibers.*

a) For every $s \in S$, let $z(s)$ be the type of the reductive center of G_s (which is defined by 4.4). Order the set E of isomorphism classes of finitely generated $\mathbb{Z}$ -modules, by declaring that the class of M is greater than that of M' if M' is*

<!-- original page 204 -->

isomorphic to a quotient of M . Then the map $S \rightarrow E, s \mapsto z(s)$, is lower semicontinuous.*

b) For G to admit a reductive center Z , it is necessary and sufficient that the preceding function $z : S \rightarrow E$ be locally constant. If this is so, G/Z is representable (cf. VIII, 5.1), and G/Z admits the unit subgroup as reductive center.*

c) Suppose that the reductive rank of G is locally constant (cf. 1.7 b)). Then G admits a reductive center Z . If G/Z is representable (for example, G affine over S), then moreover the maximal tori T of G (resp. the Cartan subgroups C of G) and T' (resp. C') of $G' = G/Z$ are in bijective correspondence, to T (resp. C) corresponding $T' = T/Z$ (resp. $C' = C/Z$), and to T' (resp. C') corresponding $T = \varphi^{-1}(T')$ (resp. $C = \varphi^{-1}(C')$), where $\varphi : G \rightarrow G'$ is the canonical homomorphism.*

d) Let T be a maximal torus of G , let $\mathfrak{g}$ denote the Lie algebra of G , and consider the homomorphism*

$$\theta : T \rightarrow \mathrm{GL}(\mathfrak{g}),$$

induced by the adjoint representation of G (II, 4). Then the kernel of θ is a reductive center of G .*

<!-- label: III.XII.4.7 -->

Proof. a) and b). The proof of a) and of the first assertion of b) is essentially identical to that of 1.7 a) and b), and we refrain from reproducing the reasoning here. We signal only that one must in a) appeal to (IX, 5.6) (using the fact that G has connected fibers). Let us prove the second assertion of b), i.e. that if Z is a reductive center of G , then $G' = G/Z$ admits the unit subgroup as reductive center. Note immediately that by (VIII, 5.1) the quotient group G/Z is indeed representable; it is affine over S , of finite presentation over S (VIII, 5.8) and even smooth over S (for it suffices to see this on the fibers, G' being flat of finite presentation over S ; now on the fibers we signaled in (VI_B, 9.2.(xii)) that a quotient of a smooth algebraic group over a field k is smooth); finally, G having connected fibers, the same holds for G' . Thus G' satisfies the same starting hypotheses as G . To see that the unit subgroup of G' is a reductive center, we may restrict if we wish to the case where S is the spectrum of a field (4.3). Let Z' be a central multiplicative-type subgroup of G' ; everything reduces to proving that Z' is reduced to the unit group. Let Z_1 be the inverse image of Z' in G , and consider the operations of Z_1 on G induced by inner automorphisms of G . Since Z is central, Z operates trivially, so Z_1 operates by way of operations of Z' on G . Moreover Z being in the center of G , Z_1 and hence Z' operate trivially on Z ; in addition Z' being in the center of G' , <!-- original page 205 --> the operations of Z' on the quotient $G/Z = G'$ are also trivial. Since Z is central, it follows at once that the operations of Z' on G come from a group homomorphism

text

$$u : Z' \rightarrow \mathrm{Hom}_{\{S\text{-gr}\}}(G', Z),$$
text

by

text

$$r(z') \cdot g = g \cdot u(z')(\phi(g)),$$

where $r : Z' \rightarrow \text{Aut}_{S\text{-gr}}(G)$ is the envisaged representation of Z' by automorphisms of G , and $\varphi : G \rightarrow G$ the canonical homomorphism. Now the datum of a group homomorphism u as above amounts to the datum of a group homomorphism

$$v : G' \rightarrow \text{Hom}_{S\text{-gr}}(Z', Z),$$

on the other hand by (X, 5.8) the right-hand side is representable and is an étale group over S , hence its unit section is an open immersion, hence $\text{Ker } v$ is an open subgroup of G' . Since G' has connected fibers, it is equal to G' , hence v is zero, hence u is zero, hence Z' operates trivially on G , hence the same holds for Z_1 , which is therefore central in G . Thus Z_1 is a commutative extension of a multiplicative-type group Z' by a multiplicative-type group Z , hence (since we are over a field) is a multiplicative-type group (7.1.1). Being central in G , it is contained in the reductive center Z , i.e. $Z_1 = Z$, whence $Z' = 1$, unit group, which completes the proof of b).

d) Let $Z = \text{Ker } \theta$, which is a multiplicative-type subgroup of T (e.g. by (IX, 6.8)). By 4.5, every central homomorphism $u : H \rightarrow G$, with H of multiplicative type and of finite type, factors through T , hence through Z . Since the formation of Z is compatible with any base change, it remains to prove that Z is central, i.e. that the centralizer C of Z equals G . Now by (XI, 5.3), C is a closed smooth subgroup of G ; on the other hand, since Z operates trivially on G , one sees that $\text{Lie}(C) = \mathfrak{g}$. One easily concludes that $C = G$: indeed, the immersion $C \rightarrow G$ is étale, since it is so fiber by fiber (being an unramified homomorphism of smooth algebraic groups of the same dimension, VI_B, 1.3), and one may apply (X, 3.5). Thus $C \rightarrow G$ is an étale closed immersion, hence an open immersion (SGA 1, I 5.1), and since it is also a closed immersion and G has connected fibers, it is an isomorphism.

c) By 1.7 b), G admits a maximal torus locally for the fpqc topology, hence by 4.2 and by d) which we have just proved, G admits a reductive center Z . We saw in d) that every maximal torus T of G contains Z . One sees at once that $T' = T/Z$ is a torus; to prove that it is a maximal torus in G' , one is reduced by Definition 1.3 to the case where S is the spectrum of an algebraically closed field, and then the assertion is contained in *BIBLE* 7 th. 3 a). Conversely, let T' be a maximal torus of G' , and let $T = \varphi^{-1}(T')$; we prove that T is a maximal torus of G . The question being local for the fpqc topology, we may suppose that G already admits a maximal torus, say T_0 , so that by the foregoing, $T'_0 = T_0/Z_0$ is a maximal torus of G' . By the conjugation theorem 1.7 c), T' and T'_0 are locally conjugate for the fpqc topology, hence (since $\varphi : G \rightarrow G'$ is covering for this topology, so every section of G' lifts locally to a section of G) T and T_0 are also locally conjugate. Since T_0 is a maximal torus, the same therefore holds for T . One proceeds analogously for the Cartan subgroups. This completes the proof.

Let us give a useful translation of d), in the case where T is diagonalizable, hence of the form $D_{\{S\}}(M)$, where M is a finitely generated free $\mathbb{Z}$ -module. Then (I, 4.7.3) the T -module $\mathfrak{g}$ decomposes as a direct sum of T -submodules $\mathfrak{g}_m$ ($m \in M$):

$$\mathfrak{g} = \bigoplus_{m \in M} \mathfrak{g}_m,$$

which are necessarily locally free. Suppose that for every $m \in M$, the rank of $\mathfrak{g}_m$ is constant (which is the case in particular if S is connected). Then the set R of $m \in M$ such that $\mathfrak{g}_m \neq 0$ ("roots") is finite. With this stated:

Corollary 4.8. Under the preceding conditions and with the preceding notations, the reductive center of G is the intersection of the kernels of the root characters χ_m on T . One thus has an isomorphism*

$$Z \simeq D_{\{S\}}(N),$$

where N is the quotient of M by the subgroup generated by R .

<!-- label: III.XII.4.8 -->

Corollary 4.9. Let G be an algebraic group over an algebraically closed field k . Suppose G smooth over k ,

connected affine, with reductive center reduced to the unit group, and that the Lie algebra $\mathfrak{g}$ of G is nilpotent. Then G is "unipotent", i.e. admits a composition series with quotients isomorphic to $\mathbb{G}_a$.*

<!-- label: III.XII.4.9 -->

By *BIBLE* 6, th. 4, cor. 3 it suffices to prove that a maximal torus T of G is reduced to the unit group, or equivalently that the Lie algebra $\mathfrak{t}$ of T is reduced to 0 . Now it follows from the fact that the T -module $\mathfrak{g}$ decomposes according to the characters α of T (I, 4.7.3) that for every $t \in T$, the operation $\text{ad}_{\{g\}}(t)$ on $\mathfrak{g}$ is semisimple. If then $\mathfrak{g}$ is nilpotent, $\text{ad}_{\{g\}}(t)$ is zero. Now by 4.7 d), the reductive center of G being reduced to the identity element, the homomorphism $T \rightarrow \text{GL}(\mathfrak{g})$ is a monomorphism, hence induces an injective application on the Lie algebras, which means (II, 4.5) that for $t \in T$, the relation $\text{ad}_{\{g\}}(t) = 0$ implies $t = 0$. This proves that $T = 0$ and completes the proof.

****Proposition 4.10.**** *Let G be an affine, smooth, connected algebraic group over an algebraically closed field k . Then the reductive center of G is the intersection of the maximal tori of G .*

<!-- label: III.XII.4.10 -->

<!-- original page 208 -->

Of course, this is the intersection in the schematic sense (or equivalently, in the sense of subfunctors of G), i.e. the largest closed subscheme of G majorized by the maximal tori of G . It follows from the noetherian character of G that this is also the intersection of a suitable finite set of maximal tori of G .

Let Z be the intersection in question; Z is a closed subgroup of a torus, hence of multiplicative type; on the other hand by 4.5 it contains the reductive center of G . To prove that it is equal, it remains to prove that it is central. Since G is connected, it suffices by (IX, 5.5) to prove that Z is invariant. Now by construction Z is invariant under the $\text{int}(g)$, with $g \in G(k)$, hence the normalizer N of Z (cf. VIII, 6.7) is a closed subgroup of G containing the rational points of G . Since G is reduced, one has $N = G$, which completes the proof.

****Proposition 4.11.**** *Let S be a prescheme, G a smooth S -prescheme in groups over S , affine over S , with connected fibers, and of zero unipotent rank, which implies* (1.9) *that*

<!-- original page 209 -->

G is of locally constant reductive rank, hence (1.10) that the "prescheme of maximal tori of G " is defined, say $\mathcal{T}$, and is smooth, separated, of finite type over S . Let G operate on $\mathcal{T}$ via inner automorphisms, whence a homomorphism of group functors*

$$u : G \rightarrow \text{Aut}_S(\mathcal{T}).$$

Under these conditions, the following three subfunctors of G are identical:

(i) The reductive center Z of G .

(ii) The center Z' of G .

(iii) The kernel $Z'' = \text{Ker } u$ of the preceding homomorphism.

In particular, the center of G is representable by a multiplicative-type subgroup of G .

<!-- label: III.XII.4.11 -->

Proof. One has trivially $Z \subset Z' \subset Z''$; it remains to prove that $Z'' \subset Z$, which amounts to proving (the hypotheses being stable under base change) that every section g of G over S which operates trivially on $\mathcal{T}$ is a section of Z . Introducing $G' = G/Z$ and using 4.7 b) and c), which imply in particular that the prescheme $\mathcal{T}'$ of maximal tori of G' is canonically isomorphic to $\mathcal{T}$, one is reduced to the case where $G = G'$, i.e. to the case where the reductive center Z of G is zero. (N.B. note that by 4.7 c), the unipotent rank of G' equals that of G , hence is zero since that of G is zero.) It thus remains to prove in this case that g is the unit section of G . The usual reduction procedure brings us to the case where S is noetherian, and even to the case where S is local artinian (since to verify that g is the unit section it suffices to verify when S is locally noetherian that this is so after any base change $S' \rightarrow S$ with S' local artinian). Now in this case the kernel Z'' of u is representable (VIII, 6.2 a) and 6.5 c)) (Note that Z'' is representable by (XI, 6.8)). To prove

that Z' is reduced to the unit subgroup, it suffices by Nakayama to prove that the same holds for its fiber Z'_0 . This thus reduces us to the case where S is the spectrum of a field k , which one may evidently suppose algebraically closed. Now Z' is contained in the stabilizer of every point of $\mathcal{T}(k)$, i.e. in the normalizer $N(T)$ of every maximal torus T of G . Since the reductive rank of G is zero, it follows by (XI, 5.9) that T is an open subgroup of $N(T)$, hence the Lie algebra of $N(T)$ is identical to that of T . Hence the Lie algebra of Z' is contained in that of T . On the other hand, it follows from 4.10 that the intersection of the Lie algebras of the maximal tori T of G is none other than the Lie algebra of the reductive center Z , hence here zero, since we have assumed $Z = 0$. Consequently, the Lie algebra of Z' is zero, i.e. Z' is étale over k . Moreover Z' is evidently invariant in G , and since G is connected it follows easily that Z' is in the center of G . It is therefore in $T = \text{Centr}_{\{G\}}(T)$ for every maximal torus T , hence in the intersection of the maximal tori, i.e. in $Z = 0$ by 4.10, which completes the proof.

5. Application to the scheme of multiplicative-type subgroups [XII-5-0]

<!-- label: III.XII.5 -->

<!-- original page 210 -->

Theorem 5.1. *Let S be a prescheme, G a smooth and affine S -prescheme in groups over S , M the "prescheme of multiplicative-type subgroups of G ", representing the *functor explicit in (XI, 4.1). For every integer $n > 0$, let T_n be the subfunctor of M such that $T_n(S') =$ the set of multiplicative-type group subpreschemata H of $G_{S'}$ such that $n \cdot \text{id}_H = 0$, so that T_n is representable, and is affine over S (XI, 3.12 a)). Let $u_n : M \rightarrow T_n$ be the morphism defined by $u_n(H) = \{t_n\} H$ (where $\{t_n\} H = \text{Ker}(n \cdot \text{id}_H)$). With these notations, one has the following:*

a) Every subprescheme U of M of finite type over S is contained in a closed subprescheme of finite type over S , and every closed subprescheme X of M of finite type over S is affine over S .*

b) Suppose S quasi-compact, and let X be a closed subprescheme of M of finite type over S . Then there exists an integer $n > 0$ such that for every multiple m of n , the induced morphism*

$$u_m|_X : X \rightarrow T_m$$

is a closed immersion.

<!-- label: III.XII.5.1 -->

Proof. a) To prove the first assertion of a), one takes for X the schematic closure of U (EGA I, 9.5.1 and 9.5.3), which is defined since the immersion $i : U \rightarrow M$ is quasi-compact (because U is of finite type over S and M is separated over S (4.1)). It therefore remains to prove that such an X is affine over S , which will prove at the same time the second assertion of a). In the foregoing form, one sees that the question is local on S , which one may therefore suppose affine. Then U , being of finite type over S , is contained in a quasi-compact open of M , and this brings us to the case where U itself is <!-- original page 211 --> an open, of finite type over S , i.e. quasi-compact. (N.B. A closed subscheme of a scheme affine over S is affine over S .)

It suffices to prove that such a U is majorized by a closed subprescheme of M which is affine. In this form, the usual reduction procedure brings us at once to the case where S is noetherian. One proceeds similarly for b), which reduces to the case where S is affine noetherian.

Let us take up again the inverse limit T of the T_n used in the proof of (XI, 4.1), which is an affine prescheme (but not of finite type) over S , and whose local rings are noetherian, as was seen at the beginning of the proof of (IX, 3.7). (N.B. For t in T , $t = (t_n)$, the transition morphisms $T_m \rightarrow T_n$ being smooth and the dimension of the T_m being bounded, there exists an n_0 such that the $T_n \rightarrow T_{n_0}$ are étale at t_n for every n multiple of n_0 .) The proof of *loc. cit.*, or (XI, 3.11), show that the canonical morphism

$$u : M \rightarrow T$$

is an immersion, and induces isomorphisms on the local rings (but one will note that u is not in general an open immersion nor a quasi-compact morphism). Let U be a quasi-compact open of M ; we shall prove that its closure in T is contained in M , which proves (if X denotes the schematic closure of U in M) that $u|_X : X \rightarrow T$ is a closed immersion, hence that X is affine, and that will prove a). Since U is noetherian, it has only finitely many

irreducible components, and every element $t \in T$ in the closure of U is a specialization of an element x of U . Since the local ring of t in T is noetherian, the same holds for the local ring A_t of t in $\bar{X}$ endowed with the induced reduced structure.

The canonical morphism of the noetherian integral local scheme $S' = \operatorname{Spec}(A)$ into T then sends the closed point of S' to t , the generic point to $x \in M$, and one must show under these conditions that $t \in M$. Possibly replacing A by the quotient of a suitable complete local A -algebra flat over A (EGA 0_III, 10.3.1) by a minimal prime ideal, we may suppose that A is complete with algebraically closed residue field, (and <!-- original page 212 --> we could even reduce to the case where it is moreover a discrete valuation ring thanks to EGA II, 7.1.7). One is thus reduced (making the change of notation: S' denoted by S) to the

Lemma 5.2. *Let S be the spectrum of a complete noetherian integral local ring with algebraically closed residue field, G a smooth and affine S -prescheme in groups over S , $H(n)$, $n > 0$ a system of multiplicative-type subgroups of G , indexed by the integers $n > 0$, η the generic point of S . Suppose:

a) If m is a multiple of n , one has $H(n) = \{ \}_{n} H(m)$.

b) There exists a multiplicative-type subgroup H_{η} of G_{η} such that one has $H(n)_{\eta} = \{ \}_{n} (H_{\eta})$ for every $n > 0$.

Under these conditions, there exists a multiplicative-type subgroup H of G such that for every $n > 0$, one has $H(n) = \{ \}_{n} H$.

<!-- label: III.XII.5.2 -->

For each n , let $C_n = \operatorname{Centr}_G(H(n))$, which is a closed group subscheme of G , smooth over S (XI, 5.3). The set of integers $n > 0$ being ordered by divisibility, the C_n form a decreasing family of closed subschemes of G , and since G is noetherian, this family is stationary. Let C be the common value of the C_n for n large. Then C satisfies the same conditions as G ; moreover the $H(n)$ are in fact subgroups of C . Hence, replacing G by C , we may suppose that the $H(n)$ are central subgroups of G .

Let then s be the closed point of S , and Z_s the reductive center of G_s (defined thanks to 4.4). By the definition (4.1) Z_s contains the $H(n)_s$. Since A is complete, Z_s comes from a multiplicative-type group subscheme Z of G (XI, 5.8). I claim that Z contains the $H(n)$. Indeed, since $H(n)$ is central, it commutes with Z in G , hence one deduces a group homomorphism $Z \times H(n) \rightarrow G$, which by (IX, 6.8) admits an image group which is a multiplicative-type subgroup K of G containing Z , and <!-- original page 213 --> everything reduces to proving that $K = Z$, which follows from $K_s = Z_s$ and (IX, 5.1 bis).

One is thus reduced to proving the analogue of 5.2, but with G replaced by a group Z of multiplicative type and of finite type over S (not necessarily smooth over S). Since A is complete with algebraically closed residue field, Z is diagonalizable (X, 3.3 and 1.4), hence of the form $D_S(M)$, with M a finitely generated commutative group. Consequently every multiplicative-type subgroup H of Z is diagonalizable (IX, 2.11 (i)), hence of the form $D_S(N)$, where N is a quotient group of M (VIII, 3.2). Thus the $H(n)$ correspond to quotient groups $M(n)$ of M , and the existence of a multiplicative-type subgroup H of Z such that $H(n) = \{ \}_{n} H$ for every n amounts to that of a quotient group N of M such that $M(n) = N/nN$ for every n . Now this follows at once from the fact that there exists a subgroup H_{η} of G_{η} such that $H(n)_{\eta} = \{ \}_{n} (H_{\eta})$ for every n . This completes the proof of 5.2 and hence of a).

b) We already know that $u|_X : X \rightarrow T$ is a closed immersion. It easily follows that for m large, the composite $u_m|_X : X \rightarrow T_m$ is also a closed immersion. Since we will not need this fact in the sequel, we omit the details of the proof.

Corollary 5.3. *With the notations of 5.1, let U be a part of M both open and closed, of finite type over S . Then U is affine over S for the structure induced by M , and if S is quasi-compact, there exists an integer $n > 0$ such that for every multiple m of n , the induced morphism $u_m|_U : U \rightarrow T_m$ is an open and closed immersion (i.e. an isomorphism onto an open and closed part of T_m , equipped with the induced structure).

<!-- label: III.XII.5.3 -->

The first assertion follows from 5.1 a), the second from 5.1 b), taking into account that $u_m : M \rightarrow T_m$ is smooth (XI, 2.2 bis) and that a smooth immersion, i.e. étale, is an open immersion.

<!-- original page 214 -->

Corollary 5.4. *Let S be a prescheme, G a smooth and affine S -prescheme in groups over S , of locally

constant reductive rank (1.7 b)), $\mathcal{T}$ the "prescheme of maximal tori of G " (1.10). Then $\mathcal{T}$ is smooth and affine over S . If T is a maximal torus of G , $N(T)$ its normalizer, then $G/N(T)$ (XI, 5.3 bis) is affine over S . The same holds for $G/C(T)$ (where $C(T)$ is the centralizer of T) provided that $W(T) = N(T)/C(T)$ is finite over S (cf. 2.1 b)).*

<!-- label: III.XII.5.4 -->

The second assertion is contained in the first, since by the conjugation theorem, $G/N(T)$ is isomorphic to $\mathcal{T}$ (XI, 5.5 bis). For the first assertion, one notes that by construction, $\mathcal{T}$ is isomorphic to an open and closed subscheme of M (for one may suppose the reductive rank of G constant and equal to r , and then $\mathcal{T}$ is the subscheme of M corresponding to the subtori of relative dimension r , i.e. the largest subscheme of M over which the "universal multiplicative-type subgroup" $H \subset G_M$ is a torus of relative dimension r). One may therefore apply 5.3. Finally, for the last assertion, one notes that $G/C(T)$ is finite over $G/N(T) \simeq (G/C(T))/W(T)$, hence is affine since $G/N(T)$ is.

Corollary 5.5. *Let G be a smooth and affine algebraic group over a field k . Then the scheme M of multiplicative-type subgroups of G is a direct sum of affine schemes over S . For every multiplicative-type subgroup H of G , if C and N denote respectively its centralizer and its normalizer, the quotients G/C and G/N are affine.*

<!-- label: III.XII.5.5 -->

Using (XI, 5.1 bis), one sees that the saturation under G operating on M of any finite closed part of M is open: indeed, one is reduced to the case where k is algebraically closed, hence to the case of the trajectory of a k -rational point x , but then by *loc. cit.* the morphism $g \mapsto g \cdot x$ from G to M is smooth hence open, hence its image is open. Let U be the union of the classes of the closed points of M for the equivalence relation defined by the operations of G . Then U is open and contains every closed point of M , <!-- original page 215 --> hence by the Nullstellensatz is identical to M . Thus M is a disjoint union of opens, which are therefore necessarily closed, hence M is the sum prescheme of preschemata M_i , each of which is a G -trajectory of a closed point, hence is quasi-compact, hence of finite type. By 5.3 the M_i are therefore affine. If H is a multiplicative-type subgroup of G , it corresponds to a k -rational point x of M , and G/N identifies with the trajectory of x under G (XI, 5.5 bis). It is therefore affine by the foregoing. Since C is an open subgroup of N (XI, 5.9), G/C is finite over G/N (since the latter is isomorphic to $(G/C)/(N/C)$), hence affine since G/N is.

This proof shows at the same time:

Corollary 5.6. *Under the conditions of 5.5 for G and H , the subscheme U of M "of multiplicative-type subgroups of G that are locally conjugate to H " is an open and closed subscheme of G .*

<!-- label: III.XII.5.6 -->

In picturesque language, every multiplicative-type subgroup H of G that is a limit of subgroups of G conjugate to H , is itself conjugate to H .

Remarks 5.7. *Let S be a prescheme, G a smooth and affine S -prescheme over S , H an S -prescheme of multiplicative type and of finite type, and set $M = \operatorname{Hom}_{S\text{-gr}}(H, G)$, which by (XI, 4.2) is representable and is smooth over S and separated over S . One can then prove for M a result entirely analogous to 5.1, either by reducing to 5.1 by an argument analogous to that of (XI, 4.2), or by proceeding directly by an argument modeled on that of 5.1. From this one deduces corresponding variants for 5.3, 5.5, 5.6, which the reader will formulate.*

<!-- label: III.XII.5.7 -->

6. Maximal tori and Cartan subgroups of not-necessarily-affine algebraic groups (algebraically closed base field)

<!-- label: III.XII.6 -->

<!-- original page 216 -->

Lemma 6.1. *Let G be a connected algebraic group over a field k , Z an algebraic subgroup of finite index in its center; then G/Z is affine.*

<!-- label: III.XII.6.1 -->

One may suppose that Z is the center of G , since a scheme finite over an affine scheme is affine. Consider the

vector spaces

```
```text
P_n = P_n(G) = 0_{G,e}/m_{G,e}^{n+1} (n an integer ≥ 0),
```
```

where $m_{G,e}$ is the maximal ideal; then G operates on the $P_n(G)$ by the adjoint representation, and if Z_n is the kernel of the corresponding homomorphism

```
$$
ad_n : G \longrightarrow GL(P_n),
$$
```

one verifies easily (using the fact that G is connected) that Z is the intersection of the Z_n , hence (G being noetherian) equal to one of the Z_n . But ad_n defines, on passage to the quotient, a monomorphism $G/Z_n \rightarrow GL(P_n)$, which is therefore a closed immersion, hence G/Z_n is affine, and consequently G/Z is.

Lemma 6.2. *Let G be a smooth algebraic group over the field k , Z a central algebraic subgroup, $G' = G/Z$, $u : G \rightarrow G'$ the canonical homomorphism, T a multiplicative-type subgroup in G , $T' = u(T)$ the image group, C the centralizer of T in G , C' that of T' in G' . Then one has*

```
$$
C'^{\{0\}} \subset u(C).
$$
```

<!-- label: III.XII.6.2 -->

One may suppose k algebraically closed. Let

```
$$
C_1 = (u^{-1}(C'))_{red},
$$
```

it suffices to prove that $C_1 \subset C$, since $u(C_1)$ is connected of finite index in C' <!-- original page 217 --> hence equal set-theoretically to $C'^{\{0\}}$, hence equal to $C'^{\{0\}}$ since C' and consequently $C'^{\{0\}}$ are smooth.

Consider the morphism

```
$$
(g, t) \mapsto gt^{-1}t^{-1}
$$
```

from $G \times G$ to G ; it induces a morphism

```
```text
φ : C_1 × T → Z_1, where Z_1 = Z_red,
```
```

since the left-hand side being reduced, it suffices to see that for $g \in C_1(k)$, $t \in T(k)$, one has $gtg^{-1}t^{-1} \in Z(k)$, which comes from the fact that g centralizes T modulo Z . One sees easily (by computing on k -rational points) that $\varphi(g, t)$ is additive in g and additive in t , hence is "bilinear"; I claim that (with Z_1 smooth and C_1 connected) this homomorphism is identically zero, which will prove indeed that $C_1 \subset C$. Using the density theorem for T , we are reduced to the case where T is finite, i.e. where there exists an integer $n > 0$ such that $n \cdot \text{id}_T = 0$. Note that φ is defined by a group homomorphism

```
$$
C_1 \longrightarrow \text{Hom}_{S\text{-gr}}(T, Z_1),
$$
```

now Z_1 being commutative and smooth, the right-hand side is representable by an étale algebraic group over k , and C_1 being connected, every group homomorphism from C_1 to the latter is zero. QED.

Corollary 6.3. *Under the preceding conditions, suppose C' connected; then one has*

```
```text
```

$C' = u(C), \quad C = u^{-1}(C').$

<!-- label: III.XII.6.3 -->

Indeed, then  $C' = C'^{\{0\}}$ ; on the other hand  $C$  obviously contains  $Z$ , hence is equal to  $u^{-1}(u(C))$ .

<!-- original page 218 -->

**Lemma 6.4.** \*Let  $G$  be an algebraic group over the field  $k$ ,  $Z$  a central algebraic subgroup such that  $G/Z = G'$  is a torus. Then  $G$  is commutative, and if  $k$  is algebraically closed, there exists a torus  $T$  in  $G$  such that  $u(T) = G'$ , where  $u$  is the canonical homomorphism  $G \rightarrow G/Z = G'$ .\*

<!-- label: III.XII.6.4 -->

One may suppose  $k$  algebraically closed. Consider again the morphism  $G \times G \rightarrow G$  defined by  $(g, h) \mapsto ghg^{-1}h^{-1}$ ; then (since  $Z$  is central) this morphism factors through a morphism  $G' \times G' \rightarrow G$ , and since  $G'$  is commutative, this latter takes its values in  $Z$ , and even in  $Z_1 = Z_{\text{red}}$ , since  $G' \times G'$  is reduced. One sees as above that the morphism  $\varphi : G' \times G' \rightarrow Z_{\text{red}}$  thus obtained is bilinear, hence zero, which proves that  $G$  is commutative. To find a torus  $T$  of  $G$  such that  $u(T) = G'$ , one may (replacing  $G$  by  $G^{\{0\}}_{\text{red}}$  if necessary) suppose  $G$  smooth and connected, and moreover (replacing  $Z$  by  $Z^{\{0\}}_{\text{red}}$  if necessary) <!-- original page 219 --> that  $Z$  is smooth and connected. By a well-known theorem of Chevalley, [N.D.E-XII-6]  $Z$  is an extension of an abelian variety by an affine group, which reduces us at once to proving our assertion in each of the two following cases: 1°)  $Z$  is affine, 2°)  $Z$  is an abelian variety. In case 1°),  $G$  is affine and the result is well known (\*BIBLE\* 7 th. 3 a)). Suppose then that  $Z$  is an abelian variety. Since every homomorphism from the additive group  $G_a$  to the torus  $G' = R$  or to the abelian variety  $Z$  is trivial, it follows that the same holds for every homomorphism from  $G_a$  to  $G$ , hence  $G$  does not contain a subgroup isomorphic to  $G_a$ . By Chevalley's structure theorem already invoked, one has an exact sequence

$$0 \rightarrow T \rightarrow G \rightarrow A \rightarrow 0,$$

where  $A$  is an abelian variety, and  $T$  an affine smooth connected group. Since the latter is commutative and contains no additive subgroup, it follows that  $T$  is a torus (and it is evidently the unique maximal torus of  $G$ ). Everything reduces to proving that every epimorphism

$$u : G \rightarrow R,$$

where  $R$  is a torus, satisfies  $u(T) = R$ . Set

text  
 $\text{Hom}_{\text{gr}}(T, G_m) = M, \quad \text{Hom}_{\text{gr}}(R, G_m) = P,$

(these are finitely generated free  $\mathbb{Z}$ -modules which recover  $T$ ,  $R$  up to isomorphism by  $T = D_{\{k\}}(M)$ ,  $R = D_{\{k\}}(P)$ ), and let

$$B = \text{Ext}^1_{k\text{-gr}}(A, G_m),$$

( $B$  is also the set of  $k$ -rational points of the abelian variety dual to  $A$ ). One evidently has

text  
 $(\times \times) \quad \text{Ext}^1(A, T) = \text{Hom}_{\text{gr}}(M, B), \quad \text{Ext}^1(A, R) = \text{Hom}_{\text{gr}}(P, B),$

in particular the extension  $G$  of  $A$  by  $T$  is given by a homomorphism

$$\theta : M \rightarrow B.$$

On the other hand the exact sequence (\*) gives the exact sequence

$$0 \rightarrow \operatorname{Hom}(A, R) \rightarrow \operatorname{Hom}(G, R) \rightarrow \operatorname{Hom}(T, R) \rightarrow \operatorname{Ext}^1(A, R),$$

moreover  $\operatorname{Hom}(A, R) = 0$ , and  $\operatorname{Hom}(T, R) \rightarrow \operatorname{Ext}^1(A, R)$  identifies with the homomorphism

$$\operatorname{Hom}(P, M) \rightarrow \operatorname{Hom}(P, B)$$

deduced from  $\theta : M \rightarrow B$ . Setting

$$N = \operatorname{Ker}(\theta),$$

one therefore finds a canonical bijection

$$\operatorname{Hom}(G, R) \simeq \operatorname{Hom}(P, N) \simeq \operatorname{Hom}(S, R), \quad \text{where } S = D_k(N),$$

which can be described geometrically at once as follows:

<!-- original page 220 -->

**Lemma 6.5.** \*Let  $G$  be an extension of an abelian variety  $A$  by a torus  $T = D_k(M)$ , defined by a homomorphism  $\theta : M \rightarrow B = \operatorname{Ext}^1(A, G_m)$  (base field  $k$  algebraically closed). Let  $N = \operatorname{Ker} \theta$ ,  $S = D_k(N)$  the corresponding torus, isomorphic to  $T/U$  where  $U = D_k(M/N)$ ; consider the extension  $H = G/U$  of  $A$  by  $S$ . This extension splits, [N.D.E-XII-7] hence one has a unique projection of  $H$  onto  $S$ , whence a unique homomorphism\*

$$v : G \rightarrow S$$

\*extending the canonical homomorphism  $T \rightarrow S$ . With this stated, for every torus  $R$  and every homomorphism  $u : G \rightarrow R$ , there exists a unique homomorphism  $u' : S \rightarrow R$  such that  $u = u'v$ . In particular, one has  $\operatorname{Im}(u) = \operatorname{Im}(u') = u(T)$ .\*

<!-- label: III.XII.6.5 -->

This shows in particular that if  $u$  is an epimorphism, the same holds for its restriction to  $T$ , which completes the proof of 6.4.

**Theorem 6.6.** \*Let  $G$  be a smooth and connected algebraic group over an algebraically closed field  $k$ .\*

a) The maximal tori of  $G$  are conjugate.\*

b) Let  $T$  be a torus in  $G$ ; then its centralizer is smooth and connected.\*

c) The map  $T \rightarrow \operatorname{Centr}_G(T)$  establishes a bijective correspondence between the set of maximal tori  $T$  of  $G$  and the set of Cartan subgroups ( $N^\circ 1$ ) of  $G$ . For an algebraic subgroup  $C$  of  $G$  to be a Cartan subgroup, it is necessary and sufficient that it be smooth, nilpotent, and set-theoretically equal to its connected normalizer (and then it is even equal to its connected normalizer); one then has  $C = \operatorname{Centr}_G(T)$ , where  $T$  is the unique maximal torus of  $C$ , and  $\operatorname{Norm}_G(C) = \operatorname{Norm}_G(T)$ .\*

d) Let  $v : G \rightarrow H$  be an epimorphism of smooth connected algebraic groups; then the maximal tori (resp. the Cartan subgroups) of  $H$  are the images of the maximal tori (resp. of the Cartan subgroups) of  $G$ . If  $T$  is a maximal torus of  $G$  and  $C$  its centralizer, then  $v(C)$  is the centralizer of  $v(T)$ .\*

<!-- original page 221 -->

\*e) Under the conditions of d), suppose that  $\text{Ker } v$  is a central subgroup of  $G$ ; then  $T \mapsto v(T)$  (resp.  $C \mapsto v(C)$ ) establishes a bijective correspondence between the set of maximal tori (resp. the Cartan subgroups) of  $G$  and the set of maximal tori (resp. Cartan subgroups) of  $H$ . The Cartan subgroups of  $G$  contain the center of  $G$  and a fortiori  $\text{Ker } v$ , and are the groups of the form  $v^{-1}(C')$ , where  $C'$  is a Cartan subgroup of  $H$ .

<!-- label: III.XII.6.6 -->

Let us also state at once the following immediate consequence of c):

**Corollary 6.7.** For  $G$  to be nilpotent (i.e. the group  $G(k)$  nilpotent) it is necessary and sufficient that the tori in  $G$  be central, or equivalently that  $G$  have only a single maximal torus (and then this latter is the largest subtorus of  $G$ ).

<!-- label: III.XII.6.7 -->

**Proof of 6.6.** Let  $Z$  be a central algebraic subgroup of  $G$ , let  $G' = G/Z$ , and  $u : G \rightarrow G'$  the canonical homomorphism. Then  $G'$  is a smooth and connected group. If  $T'$  is a subtorus of  $G'$ , it follows from 6.4 that  $u^{-1}(T')$  is commutative and that  $T'$  is the image of a subtorus of  $u^{-1}(T')$ , hence of a subtorus of  $G$ . Since  $u^{-1}(T')$  is commutative, it obviously admits a largest subtorus  $T$  (since the sum of two subtori gives a third containing both), and one therefore has  $u(T) = T'$ . From this it follows immediately that for every maximal torus  $T$  of  $G$ , its image  $T' = u(T)$  is a maximal torus of  $G'$ , and that  $T \mapsto u(T)$  is a bijective correspondence between maximal tori of  $G$  and maximal tori of  $G'$ .

We now make

```

Z = Centr(G)^{0}_{red},

```

then  $G'$  is affine by 6.1. Since the maximal tori of  $G'$  are then conjugate, the same holds for those of  $G$ , which proves a). <!-- original page 222 --> Moreover, for  $G$  to be nilpotent, resp. have only a single maximal torus, it is necessary and sufficient that  $G'$  satisfy the same condition; now  $G'$  being affine, the two conditions in question on  $G'$  are equivalent (\*BIBLE\* 6 th. 4 cor. 2), hence the same holds for the conditions in question on  $G$ . Moreover, if  $G$  has only a single maximal torus  $T$ , this latter is invariant hence central, and since every torus in  $G$  is contained in a maximal torus, it is central. Conversely, if every torus is central, the same holds for the maximal tori, and by the conjugation theorem a) there is only a single maximal torus. This proves 6.7.

Let  $T$  be any torus of  $G$ ,  $T' = u(T)$ ; then  $C' = \text{Centr}_{G'}(T')$  is connected (\*BIBLE\* 6 th. 6 a)), hence by 6.3 the centralizer  $C$  of  $T$  is equal to  $u^{-1}(C')$ , hence connected (since  $Z$  is connected), which proves b). If  $T$  is maximal, hence  $T'$  maximal, then we know that  $C'$  is nilpotent, hence  $C$  (which is a central extension of  $C'$ ) is nilpotent. Moreover,  $T$  is a maximal torus of  $C$ , hence by 6.7 it is the unique maximal torus of  $C$ ; consequently the map  $T \mapsto \text{Centr}_G(T)$  from the set of maximal tori of  $G$  into the set of Cartan subgroups is bijective. Moreover one has

```

text
Centr_G(T) = C ⊂ Norm_G(C) ⊂ Norm_G(T)

```

and since we know that the centralizer of  $T$  is of finite index in its normalizer (cf. XI, 5.9, whose reasoning is valid without affine hypothesis, using only the representability of the two functors in question, as was signaled in (XI, 6.5)), and that  $C$  is smooth and connected, we conclude

```

C = Norm_G(C)^{0}.

```

Moreover, by the bijective correspondence between maximal tori and Cartan subgroups, we see that  $\text{Norm}_G(C)$  and  $\text{Norm}_G(T)$  have the same  $k$ -valued points, and since the latter is smooth, one has

```

Norm_G(T) = Norm_G(C).

```

To complete the proof of c), it remains to prove that if  $C$  is a smooth nilpotent connected subgroup

<!-- original page 223 --> of  $G$  of finite index in its normalizer, then  $C$  is a Cartan subgroup. Now since  $Z$  is central, the normalizer of  $C$  contains  $Z$ , and since  $Z$  is smooth and connected, we conclude  $Z \subset C$ , whence  $C = u^{-1}(C')$ , where  $C' = u(C)$ . One then has

```

$$\text{Norm}_G(C) = u^{-1}(\text{Norm}_{G'}(C')),$$

```

which proves that  $C$  is nilpotent connected of finite index in its normalizer, hence <!-- original page 224 --> by \*BIBLE\* 7 th. 1 it is a Cartan subgroup of  $G$ , whence at once that  $C$  is a Cartan subgroup of  $G$ .

Let us prove e): we are under the conditions of the start of the proof (setting  $\text{Ker } u = Z$ ,  $G' = H$ ); we have already seen that  $T \mapsto u(T)$  is a bijective correspondence between maximal tori of  $G$  and maximal tori of  $G'$ . Taking into account the bijective correspondence between maximal tori and Cartan subgroups just proved, we deduce a bijective correspondence between Cartan subgroups  $C$  of  $G$  and Cartan subgroups  $C'$  of  $G'$ , by making correspond to  $C = \text{Centr}_G(T)$  the group  $C' = \text{Centr}_{G'}(T')$ , where  $T' = u(T)$ . Since  $C$  is connected by b), it follows by 6.3 that  $C' = u(C)$ , and  $C = u^{-1}(C')$ , which proves e).

It remains to prove d). Let  $T$  be a maximal torus of  $G$ ; we prove that  $v(T)$  is a maximal torus of  $H$  (which, taking into account the conjugation theorem a), will imply that the maximal tori of  $H$  are all of the form  $v(T)$  as above). Let then  $R$  be a torus in  $H$  containing  $v(T)$ ; we prove  $R = v(T)$ . Replacing  $H$  by  $R$  and  $G$  by  $v^{-1}(R)^{\{0\}}$ , we may suppose  $R = H$ , i.e. that  $H$  is a torus, and we are reduced to proving that then  $v(T) = H$ . Let again  $Z = \text{Centr}_G(\{0\})$ ,  $G' = G/Z$ , and  $H' = H/v(Z)$ :

```

$$\begin{array}{c} \text{e} \rightarrow Z \rightarrow G \xrightarrow{u} G' \rightarrow e \\ \quad \quad \quad \downarrow \quad \downarrow \quad \downarrow \\ \text{e} \rightarrow v(Z) \rightarrow H \xrightarrow{v} H' \rightarrow e. \end{array}$$

```

We already know that  $u(T)$  is a maximal torus of  $G'$ , and since  $G'$  is affine, so  $v' : G' \rightarrow H'$  is an epimorphism of affine smooth connected groups,  $v'(u(T))$  is a maximal torus of  $H'$  (\*BIBLE\* 7 th. 3 a)) hence equal to  $H'$ , i.e.  $u'(v(T)) = H'$ ; hence to prove  $v(T) = H$  it suffices to show that  $v(T) \supset v(Z)$ . Now  $v(Z)$  is a smooth connected subgroup of  $H$ , hence a torus, and  $v' : Z \rightarrow v(Z)$  is an epimorphism, hence by 6.4 one has  $v(Z) = v'(S)$ , where  $S$  is a torus of  $Z$ . Now  $S$ , being central in  $G$ , is evidently contained in the maximal torus  $T$ , whence  $v(Z) \subset v(T)$ . This proves assertion d) in the case of maximal tori.

Taking into account the bijective correspondence between maximal tori and Cartan subgroups, it remains to prove that if  $T$  is a maximal torus of  $G$  and  $C$  its centralizer, then  $v(C)$  is the centralizer of  $v(T)$ . For this, take up again the diagram (D) above (where of course  $H$  is no longer supposed to be a torus), let  $T' = u(T)$ ,  $C' = u(C)$ ; we have already seen in e) that  $C'$  is the centralizer of the maximal torus  $T'$ , hence ( $G'$  being affine, hence  $H'$  being affine)  $v'(C')$  is the centralizer of the maximal torus  $v'(T')$  of  $H'$  (\*BIBLE\* 7 th. 3 a)), i.e.  $u'(v(C))$  is the centralizer of  $u'(v(T))$ ; since  $C$  contains  $Z$ ,  $v(C)$  contains  $v(Z)$ ;  $v(C)$  is therefore the inverse image by  $u'$  of  $u'(v(C))$ , i.e. of the centralizer of  $u'(v(T))$ , hence is the centralizer of  $v(T)$  as follows from e) applied to  $u' : H \rightarrow H'$  and to the maximal torus  $v(T)$  of  $H$ . This completes the proof of 6.6.

## ## 7. Application to not-necessarily-affine smooth group preschemes

<!-- label: III.XII.7 -->

**Theorem 7.1.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups smooth, separated and of finite type over  $S$ . Suppose that  $G$  admits, locally for the faithfully flat quasi-compact topology, a maximal torus. Then:\*

a) The map\*

```

$$T \mapsto \text{Centr}_G(T)$$

```

\*induces a bijection from the set of maximal tori of  $G$  onto the set of Cartan\*

<!-- original page 225 -->

\*subgroups of  $G$ . If  $C$  corresponds to  $T$ , then  $T$  is the unique maximal torus of  $C$ .\*

\*b) Let  $T, T'$  be two maximal tori of  $G$ ,  $C, C'$  the corresponding Cartan subgroups; then one has\*

```
```text
Transp_G(T, T') = Transp_G(C, C') = Transp_G(T, C'),
```
```

\*the first two terms are also identical to the strict transporters; finally the functor in question is representable by a closed subscheme of  $G$  smooth over  $S$ . The tori  $T, T'$  and the Cartan subgroups  $C, C'$  are conjugate locally for the étale topology.\*

\*c) There exists, locally for the étale topology, a maximal torus of  $G$  and a Cartan subgroup of  $G$ .\*

\*d) Suppose that every finite part of a fiber  $G_{\{s\}}$  of  $G$  is contained in an affine open of  $G$  (for example  $G$  quasi-projective over  $S$ , or  $S$  artinian); then the functor  $\mathcal{T} : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$  defined in 1.10 (functor of maximal tori of  $G$ ), isomorphic to the functor  $\mathcal{C} : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$  of Cartan subgroups of  $G$ , is representable by a smooth, separated prescheme of finite type over  $S$ , which is quasi-projective over  $S$  when  $G$  is, and is affine over  $S$  when  $G$  is affine over  $S$ , or when  $S$  is artinian.\*

\*e) Let  $u : G \rightarrow G'$  be a morphism of  $S$ -preschemes in groups, where  $G'$  is smooth, separated of finite type over  $S$ , and suppose that for every  $s \in S$ , one has  $u_{\{s\}}(G_{\{s\}}) = G'_{\{s\}}$ , i.e.  $u_{\{s\}}$  is faithfully flat (Exp. VI<sup>N.D.E.-XII-8</sup>). Then for every maximal torus  $T$  of  $G$ ,  $u(T)$  is a maximal torus of  $G'$ ; if  $G'$  has connected fibers, then for every Cartan subgroup  $C$  of  $G$ ,  $u(C)$  is a Cartan subgroup of  $G'$ , and if  $C$  is the centralizer of  $T$ ,  $u(C)$  is the centralizer of  $u(T)$ . In either case, the induced morphism  $T \rightarrow u(T)$ , resp.  $C \rightarrow u(C)$ , is faithfully flat.\*

\*f) Under the conditions of e), suppose moreover that  $\text{Ker } u$  is a central\*

<!-- original page 226 -->

\*subgroup of  $G$ . Then  $T \mapsto u(T)$  is a bijective map from the set of maximal tori of  $G$  onto the set of maximal tori of  $G'$ , and if  $G'$  has connected fibers,  $C \mapsto u(C)$  is likewise a bijective map from the set of Cartan subgroups of  $G$  onto the set of Cartan subgroups of  $G'$ ; if  $C' = u(C)$ , one has  $C = u^{-1}(C')$ .\*

<!-- label: III.XII.7.1 -->

**Remarks 7.2.** We shall see in XV that the conclusion of d) remains valid without the restrictive condition on the finite parts of the  $G_{\{s\}}$ . We shall also prove there the conclusions concerning only the Cartan subgroups contained in b), c), d), e), when one supposes only that  $G$  admits, locally for the faithfully flat quasi-compact topology, a Cartan subgroup (but not necessarily a maximal torus). For this we shall moreover need to use 7.1 in the case where  $S$  is artinian. Moreover, the proof of c) and d) (in the case  $S$  not artinian) is considerably simplified by using the method of XV.\*

<!-- label: III.XII.7.2 -->

**Proof of 7.1.** a) Proceeding as in 3.2, one sees that for every maximal torus  $T$  of  $G$ ,  $C = \text{Centr}_G(T)$  is indeed a Cartan subgroup of  $G$ , and  $T$  is determined in terms of  $C$  as the unique maximal torus of  $C$ , so that it remains only to show that every Cartan subgroup  $C$  of  $G$  is defined by a maximal torus of  $G$ , or equivalently that  $C$  admits a central maximal torus. The question being still local for the fpqc topology, we may suppose that  $G$  admits a maximal torus  $T$ . Then by (XI, 6.2),  $\text{Transp}_G(T, C)$  is representable by a closed subscheme  $S'$  of  $G$  smooth over  $S$ ; moreover  $S' \rightarrow S$  is surjective, as follows from 6.6 c). Hence, replacing  $S$  by  $S'$ , we may suppose that there exists a section  $g$  of  $G$  such that  $\text{ad}(g) \cdot T \subset C$ ; but then  $\text{ad}(g) \cdot T$  is a maximal torus of  $C$ , which is central fiber by fiber by 6.6 c), hence central by (IX, 5.6 b)). QED.

<!-- original page 227 -->

b) Let  $T, T'$  be two maximal tori of  $G$ , and  $C, C'$  the corresponding Cartan subgroups of  $G$ . Then the following conditions are equivalent:

```
```text
(1)  $T \subset T'$  (2)  $T = T'$  (3)  $T \subset C'$  (4)  $C \subset C'$  (5)  $C = C'$ .
```
```

This follows trivially from a). Using the same result after arbitrary base change, one deduces the identity stated in b) between various transporters and strict transporters. Moreover, we already noted in a) that  $\text{Transp}_G(T, C)$  is representable by a closed subscheme of  $G$ , smooth over  $S$ , and that its structural morphism is surjective.

Consequently, by Hensel there exists locally for the étale topology a section of this prescheme over  $S$ , hence  $T$  and  $T'$  on the one hand,  $C$  and  $C'$  on the other hand, are conjugate locally for the étale topology, which proves b).

c) Suppose first that  $S$  is artinian, local. When  $G$  admits a maximal torus  $T$ , then it follows from the conjugation theorem proved in b) that the functor  $\mathcal{T}$  of maximal tori of  $G$  is representable by the homogeneous space  $G/N$ , where  $N$  is the normalizer of  $T$  in  $G$ , which is smooth by b). Moreover, as we noted in (VI\_A, 3.2.1), since  $\mathcal{T}$  is a homogeneous space under  $G$ , every finite part of  $\mathcal{T}$  is contained in an affine open. In the general case, there exists a finite extension  $k'$  of the residue field  $k$  of  $S$  such that  $G_{k'}$  has a maximal torus; then  $k'$  comes from  $k$  by a finite flat base change  $S' \rightarrow S$ , and the maximal torus of  $G_{k'}$  lifts to a maximal torus of  $G_{S'}$  (XI, 2.1 bis), so the functor  $\mathcal{T}_{S'}$  is representable by a prescheme over  $S'$ , smooth separated and of finite type over  $S'$ , every finite part of which is contained in an affine open. Hence the natural descent datum on  $\mathcal{T}_{S'}$  is effective, hence  $\mathcal{T}$  is representable, and by descent one sees that  $\mathcal{T}$  is smooth over  $S$ , separated and of finite type over  $S$ . From smoothness it follows, thanks to Hensel, that  $\mathcal{T}$  admits a section locally for the étale topology. This proves c) and d) in the case  $S$  artinian (N.B. we shall prove below that in this case,  $\mathcal{T}$  is in fact affine over  $S$ ).

Suppose now  $S$  arbitrary. To prove c) and d), which are assertions local on  $S$  for the Zariski topology, we may suppose that there exists a prime  $\ell$  prime to the residue characteristics of  $S$ , that  $S$  is affine, and that the reductive rank of the fibers of  $G$  (which is evidently locally constant, thanks to the hypothesis of local existence for fpqc of a maximal torus) is constant, say  $r$ . Let  $S' \rightarrow S$  be a faithfully flat and quasi-compact morphism,  $S'$  affine, such that  $G_{S'}$  admits a maximal torus  $T_0$ . Let  $C_0$  be its centralizer; I claim that there exists a suitable power  $n$  of  $\ell$  such that one has also  $C = \text{Centr}_{G(\{T\})}$ . Indeed, to see this, one is reduced at once to the case  $S'$  noetherian, where this was seen in (XI, 6.2). Fix  $n$  thus, set

```

text
M = (Z/nZ)^r, P = Hom_{S-gr}(M_S, G),

```

then  $P$  is evidently representable as a closed subprescheme of finite presentation of  $(\{T\}_{n} G)^r$ , where

```

text
n G = Hom{S-gr}((Z/nZ)_S, G),

```

which is also the kernel of the  $n$ -th power morphism on  $G$ , hence representable by a closed subprescheme of finite presentation of  $G$ . Moreover  $P$  is smooth over  $S$  by (XI, 2.1). Let  $s \in S$ ; by what was seen above, there exists a finite separable extension  $k'$  of  $k(s)$  such that there exists a maximal torus  $T'$  in  $G_{k'}$ ; moreover, since  $\{T\}_n$  is étale over  $k'$  ( $n$  being prime to the characteristic of  $k'$ ) we may suppose (replacing  $k'$  by a finite separable extension if necessary) that  $\{T\}_n$  is isomorphic to  $M_{k'}$ . Let  $S' \rightarrow S$  be an étale morphism such that there exists  $s' \in S'$  above  $s$  in  $S$ , giving rise to the residual extension  $k(s') \simeq k'$ . One thus has a section of  $P_{S'} \otimes k(s') \rightarrow \mathcal{K}(s')$ , hence by Hensel, replacing  $(S', s')$  by  $(S'', s'')$  étale over it if necessary, we may suppose that there exists a section of  $P_{S''}$  over  $S''$ , i.e. an element of  $P(S'')$ , extending the given section. In other words, one has a homomorphism  $M_{S''} \rightarrow G_{S''}$  which induces an isomorphism  $M_{k(s'')} \simeq \{T\}_n$ . By (IX, 6.4) (which here reduces to a simple application of Nakayama's lemma) this homomorphism is a closed immersion above an open neighborhood of  $s'$ , <!-- original page 229 --> which may be supposed equal to  $S''$ . Let  $H$  be its image, and consider its centralizer  $C'$  in  $G_{S''}$ , which is a closed smooth subprescheme of  $G$ , by (XI, 6.2). Let us also note:

**Lemma 7.3.** \*Under the preceding conditions for  $\ell$ ,  $n$ ,  $r$ , for every prescheme  $S''$  over  $S$  and every maximal torus  $T'$  of  $G_{S''}$ , one has\*

```

S
Centr_{G_{S''}}(T') = Centr_{G_{S''}}(\{T\}_n T').
S

```

<!-- label: III.XII.7.3 -->

Indeed, by faithfully flat descent from  $S' \times_S S''$ , one is reduced to the case where  $G_{S''}$  admits a maximal torus  $T'_1$  for which the preceding relation is true. But since  $T'$  is locally conjugate to  $T'_1$  for the étale topology by b), it follows that the same relation is true for  $T'$ .

Applying the foregoing result for  $\mathcal{K}(s'')$  instead of  $S''$ , one sees that the fiber  $C'_{s''}$  is a Cartan subgroup of  $G_s$ . Note now that  $G$  being smooth over  $S$ , the union of the neutral components of the fibers  $G_s$  is an open of  $G$  (by a general result of EGA IV on smooth morphisms [N.D.E-XII-9]), evidently stable

under the group law of  $G$ ; this is therefore a subgroup of  $G$  for the prescheme structure induced by  $G$ . Moreover,  $G^{\{0\}}$  satisfies the preliminary hypotheses of  $G$ , and there is an evident bijective correspondence between the maximal tori of  $G$  and those of  $G^{\{0\}}$ . Hence to prove c) and d), we may suppose  $G$  has connected fibers, which we shall do. Then the Cartan subgroups of  $G$  have connected fibers (6.6 a)). This being so, I claim that  $C'^{\{0\}}$  is a Cartan subgroup of  $G_{S'}$  above an open neighborhood of  $s'$  in  $S'$  (which will complete the proof of c)). This follows indeed from the

**Lemma 7.4.** \*Under the conditions of 7.1, suppose  $G$  has connected fibers; let  $C$  be a closed group subscheme of  $G$ , smooth over  $S$ , and  $s$  an element of  $S$  such that  $C_s$  is a Cartan subgroup of  $G_s$ ; then  $C^{\{0\}}$  is a Cartan subgroup of  $G$  above an open neighborhood of  $s$ .\*

<!-- label: III.XII.7.4 -->

One easily reduces to the case where  $S$  is local and  $s$  is its closed point, and to proving that then  $C$  is a Cartan subgroup of  $G$ ; then by flat descent to the case where  $G$  admits a maximal torus, say  $T$ . Then by (XI, 6.2),  $\text{Transp}_{\{G\}}(T, C)$  is representable by a closed subscheme of  $G$  smooth over  $S$ . Moreover, by the hypothesis on  $C_s$ , the fiber of the transporter at  $s$  is non-empty (taking into account the conjugation theorem 6.6 a)). This reduces us by faithfully flat descent to the case where this transporter admits a section over  $S$ , hence to the case where  $C$  contains a maximal torus  $T$  of  $G$ . But then  $T$  is central in  $C^{\{0\}}$  by (IX, 5.6 a)), hence  $C^{\{0\}} \subset \text{Centr}_{\{G\}}(T)$ , and since this is an inclusion of smooth group schemes over  $S$  having the same relative dimension (namely, the dimension of their common fiber at  $s$ ) and with connected fibers, it is an equality, which completes the proof.

d) We keep the preceding notations and hypotheses for  $\ell, n, r$ , and the connectedness of the fibers of  $G$ . Let  $Q : (\text{Sch})^{\text{circ}}/S \rightarrow (\text{Ens})$  be the functor defined by

```
```text
Q(S') = the set of multiplicative-type subgroups of  $G_{S'}$  of type equal to  $(\mathbb{Z}/n\mathbb{Z})^r = M$  (IX, 1.4).
```
```

Then

```
```text
 $T \rightarrow_n T$ 
```
```

is a morphism

```
$$
\varphi : \mathcal{T} \rightarrow Q,
$$
```

which is a monomorphism by 7.3. I claim that  $Q$  is representable by a separated prescheme of finite presentation over  $S$ . Indeed, as we signaled in the proof of (XI, 3.12 a)), one has an isomorphism

```
$$
Q \simeq P_{\{0\}}/\Gamma
$$
```

<!-- original page 231 -->

where  $P_0$  is the open and closed subscheme of the prescheme  $P = \text{Hom}_{\{S\}}(M_{\{S\}}, G)$  introduced in c) corresponding to the monomorphisms  $M_{\{S\}} \rightarrow G_{\{S\}}$  (cf. IX, 6.8), and where  $\Gamma = \text{Aut}_{\{gr\}}(M)_{\{S\}}$ . The hypothesis that every finite part of a fiber  $G_s$  is contained in an affine open of  $G$ , being stable under passage to a closed subscheme and under cartesian products, is evidently inherited by  $(\{n\} G)^r$  hence by  $P$ , hence by  $P_0$ , so that  $Q$  is representable by a prescheme of finite presentation over  $S$  (cf. V). [N.D.E-XII-10] One sees in the same way that if  $G$  is quasi-projective (resp. affine) over  $S$ , the same holds for  $Q$ . In any case,  $Q$  is separated over  $S$ . Now one has the

**Lemma 7.5.** \*The homomorphism  $\varphi : \mathcal{T} \rightarrow Q$  above is representable by an open immersion.\*

<!-- label: III.XII.7.5 -->

In other words, one must prove that if  $H$  is a multiplicative-type subgroup of  $G$ , of type  $M$ , then there exists an open part  $U$  of  $S$  such that for every  $s'$  over  $S$ ,  $H_{S'}$  is of the form  $(\{n\} T_{S'})$ , for a suitable maximal

torus  $T_{\{S\}}$  of  $G_{\{S\}}$ , if and only if  $S'$  \to  $S$  factors through  $U$ . One may evidently suppose that the nilpotent rank of the fibers of  $G$  is constant (since by b), it is locally constant), say  $r'$ . Let  $C = \text{Centr}_{\{G\}}(H)$ , which is a closed group subscheme of  $G$  smooth over  $S$  (XI, 6.2). Then replacing  $S$  by the open and closed part of the points at which  $C$  is of relative dimension  $r'$ , we may suppose  $C$  of relative dimension  $r'$  everywhere. One then sees at once that  $H$  is of the form  $\{_{\{n\}} T$ , for a maximal torus  $T$  of  $G$ , if and only if  $C^{\{0\}}$  admits a central maximal torus  $T$  of relative dimension  $r$  everywhere and  $H = \{_{\{n\}} T$ , which gives another expression of the subfunctor  $U$  of  $S$  we wish to represent (in replacing in the preceding criterion  $S$  by an  $S'$  over  $S$ ). Moreover by flat descent, we may suppose that  $G$  admits a maximal torus  $T_1$ . Let  $R$  be the subfunctor  $\text{Transp}_{\{G\}}(T_1, \text{Centr}_{\{C^{\{0\}}\}}(C^{\{0\}}))$  of  $\text{Transp}_{\{G\}}(T_1, C)$ ; the latter is representable by a smooth prescheme over  $S$  by (XI, 6.2), and the former is representable by an induced open subscheme, as follows at once from (IX, 5.6 a)); in particular it is smooth over  $S$ . Consequently its structural morphism into  $S$  is open, <!-- original page 232 --> hence its image is open, and replacing  $S$  by the said image (equipped with the induced structure) we may suppose the structural morphism surjective. Then by 1.13 applied to  $C^{\{0\}}$ ,  $C^{\{0\}}$  admits a central maximal torus  $T$  since it admits one locally for fpqc, which will evidently be of relative dimension equal to that of  $T_1$ , i.e.  $r$ . Thus, the condition to be expressed for  $H$  is the equality  $H = \{_{\{n\}} T$ , which by (IX, 2.10) amounts again to taking a suitable open (and closed) part of  $S$ .

Lemma 7.5 therefore implies that  $\mathcal{T}$  is representable by a separated prescheme locally of finite presentation over  $S$ , and even of finite presentation over  $S$ , as one sees by taking up again the proof of 7.5 to assure oneself that  $\varphi$  is in fact a quasi-compact open immersion, or by reducing by faithfully flat quasi-compact descent to the case where  $G$  admits a maximal torus, and where  $\mathcal{T}$  is therefore isomorphic to  $G/\text{Norm}_{\{G\}}(T)$ . This last expression, or at choice (XI, 2.1), show moreover that  $\mathcal{T}$  is smooth over  $S$ . Finally, if  $G$  is quasi-projective over  $S$ , the same holds for  $Q$  hence also for  $\mathcal{T}$ . If  $G$  is affine over  $S$ , the assertion that  $\mathcal{T}$  is then affine over  $S$  is recorded for memory, being established in 5.4 (N.B. I do not know whether without the affine hypothesis on  $G/S$ , it is possible to choose  $n$  in such a way that in 7.5 the open immersion is also a closed immersion). For the assertion that  $\mathcal{T}$  is affine over  $S$  if  $S$  is artinian, one is reduced to the case where  $S$  is the spectrum of a field (EGA I, 6.1.7), which one may suppose algebraically closed. Then thanks to f), which will be proved below, it suffices to prove the same assertion for  $G/\text{Centr}(G)$ ; now this last is affine by 6.1, so that one is under the preceding conditions. This completes the proof of d).

e) By (IX, 6.8), we know that there exists a subtorus  $T'$  of  $G'$  such that  $u$  induces a faithfully flat morphism  $T \rightarrow T'$  (which characterizes  $T'$  as the subsheaf  $u(T)$  of  $G'$ ). Let  $C$  be the centralizer of  $T$ ,  $C'$  that of  $T'$ ; we prove that the morphism <!-- original page 233 -->  $C \rightarrow C'$  is flat, and faithfully flat if  $G'$  has connected fibers. Since  $C$ ,  $C'$  are flat of finite presentation over  $S$ , one is reduced to the case of a base field (SGA 1, I 5.9), which one may evidently suppose algebraically closed. Moreover one may suppose  $G$ ,  $G'$  connected (replacing them by  $G^{\{0\}}$  and  $G'^{\{0\}}$  if necessary, which does not change  $C^{\{0\}}$  and  $C'^{\{0\}}$ ), and it then suffices to apply 6.6 d), taking into account a).

f) Taking into account a) and e), one may restrict to proving the assertion concerning the Cartan subgroups. Now since a Cartan subgroup of  $G$  is the centralizer of a maximal torus, it contains the center of  $G$  and a fortiori  $\text{Ker } u$ , hence is of the form  $u^{-1}(C')$ , where  $C' = u(C)$  is the Cartan subgroup of  $G'$  envisaged in e). Hence the map  $C \rightarrow u(C)$  is injective; to show that it is bijective, it suffices to see that for every Cartan subgroup  $C'$  of  $G'$ ,  $u^{-1}(C')$  is a Cartan subgroup of  $G$ . The question being local for fpqc, we may suppose that  $G$  admits a Cartan subgroup  $C_1$ , hence  $u(C_1) = C'_1$  is a Cartan subgroup of  $G'$ , hence locally conjugate to  $C'$  for fpqc by b), and since  $u^{-1}(C'_1) = C_1$  is a Cartan subgroup of  $G$ , it follows that  $u^{-1}(C')$  is a Cartan subgroup of  $G$ . QED.

One can also, to prove that  $u^{-1}(C)$  is a Cartan subgroup, note that it is flat over  $S$  since  $u$  is (SGA 1, I 5.9), which reduces us by definition to the case of a base field, and one may apply 6.6 e).

**\*\*Corollary 7.6.\*\*** \*Under the conditions of 7.1 e),  $G'$  admits, locally for the étale topology, a maximal torus, hence satisfies the preliminary conditions for  $G$ . If moreover  $\text{Ker } u$  is central, then the functors  $\mathcal{T}_{\{G\}}$ ,  $\mathcal{C}_{\{G\}}$  of maximal tori of  $G$  and Cartan subgroups of  $G$  are isomorphic to the analogous functors  $\mathcal{T}_{\{G'\}}$ ,  $\mathcal{C}_{\{G'\}}$  for  $G'$  (hence, in the case where they are representable, they are represented by isomorphic  $S$ -preschemes).\*

<!-- label: III.XII.7.6 -->

**\*\*Remark 7.7.\*\*** \*a) Contrary to what happens in the case where  $G$  is affine over  $S$  (it suffices, in fact, that  $G$  have affine fibers, as one will see in XVI), it is not true\* <!-- original page 234 --> \*that the fact that  $G$  has locally constant reductive rank implies that  $G$  admits, locally for fpqc, a maximal torus. For example, let  $S$  be the spectrum of a discrete valuation ring,  $G_1$  and  $G_2$  smooth separated group schemes of finite type over  $S$  such that the generic fiber of  $G_1$  is an elliptic curve, the special fiber a group  $G_{\{m\}}$ , and the generic fiber of  $G_2$  a group  $G_{\{m\}}$ , the special fiber a group  $G_{\{a\}}$ , and take  $G = G_1 \times_S G_2$ . Then the two fibers of  $G$  have reductive rank 1, but one sees at once that  $G$  does not admit a maximal torus locally for fpqc. It is on the other hand very plausible that the following condition (for a smooth separated group of finite type over a prescheme  $S$ ) is

sufficient for the existence of a maximal torus locally for the étale topology: the reductive rank and the abelian rank of the fibers of  $G_S$  are locally constant functions.\*

\*b) In the proof of 7.1 (notably a)) we have invoked (XI, 6.2) in cases where  $S_S$  is not supposed locally noetherian. However, in the cases of application of (XI, 6.2) envisaged, the reduction to the case  $S_S$  noetherian affine is immediate.\*

<!-- label: III.XII.7.7 -->

Here is a variant of 7.1 b):

**\*\*Proposition 7.8.\*\*** \*Let  $G_S$  be an  $S_S$ -prescheme in groups smooth of finite presentation with connected fibers,  $H_S$  a smooth  $S_S$ -prescheme in groups,  $i : H \rightarrow G_S$  a monomorphism of  $S_S$ -groups (making  $H_S$  an  $S_S$ -subgroup of  $G_S$ ). Then for every Cartan subgroup  $C_S$  of  $G_S$ ,  $\text{Transp}_G(C, H)_S$  is representable by a closed subprescheme of  $G_S$  smooth over  $S_S$ .\*

<!-- label: III.XII.7.8 -->

The fact that the transporter is representable by a closed subprescheme of  $G_S$  of finite presentation is contained in (XI, 6.11), taking into account that  $C_S$  has connected fibers since  $G_S$  does (6.6 b)). To show that the transporter is smooth over  $S_S$ , one is reduced by the standard procedure to the case where  $S_S$  is affine noetherian, then to the case where  $S_S$  is artinian local, and by descent to the case where the residue field of  $S_S$  is algebraically closed. But then

<!-- original page 235 -->  $C_S$  admits a maximal torus  $T_S$ , which is a maximal torus of  $G_S$ . We may suppose that the reductive rank and the nilpotent rank of the fiber  $H_0$  are equal to those of  $T_0$  (otherwise the transporter would be empty), but then one sees at once (using the connectedness of  $C_S$  and the fact that the centralizer in  $H_S$  of a maximal torus of  $H_S$  is smooth) that one has

```
```text
Transp_G(C, H) = Transp_G(T, H)
```
```

and since we know that the second member is smooth (XI, 2.5), the same holds for the first. The preceding reasoning shows more generally part b) of the

**\*\*Proposition 7.9.\*\*** \*Let  $G_S$  and  $i : H \rightarrow G_S$  be as in 7.8, suppose moreover that for every  $s \in S$ ,  $H_{\{s\}}$  is connected and has the same reductive rank and the same nilpotent rank as  $G_{\{s\}}$  (i.e.  $H_{\{s\}}$  contains a Cartan subgroup of  $G_{\{s\}}$ ). Then one has the following:\*

\*a)  $\text{Norm}_G(H)_S$  is representable by a closed subprescheme  $\text{Norm}_G(H)_S$  of  $G_S$  of finite presentation over  $S_S$ , and the canonical monomorphism  $H \rightarrow \text{Norm}_G(H)_S$  is an open immersion; consequently  $i_S$  is an immersion, and one has\*

```
$$
H = \text{Norm}_G(H)^{\{0\}}.
$$
```

\*b) For every Cartan subgroup  $C_S$  of  $G_S$ ,  $\text{Transp}_G(C, H)_S$  is a closed subprescheme of  $G_S$ , smooth over  $S_S$ , with surjective structural morphism. If  $C_S$  is the centralizer of a maximal torus  $T_S$  of  $G_S$ , one has moreover\*

```
```text
Transp_G(T, H) = Transp_G(C, H).
```
```

\*c) Let  $C_S$  be a group subprescheme of  $H_S$ . For it to be a Cartan subgroup of  $H_S$ , it is necessary and sufficient that it be a Cartan subgroup of  $G_S$ .\*

\*d) Suppose that  $G_S$  admits, locally for the étale topology, or for the fpqc topology, \*

<!-- original page 236 -->

\*a Cartan subgroup (resp. a maximal torus); then the same holds for  $H_S$ .\*

<!-- label: III.XII.7.9 -->

**\*Proof.\*** a) The representability of  $\text{Norm}_G(H)_S$  by a closed subprescheme  $\text{Norm}_G(H)_S$  of  $G_S$  of finite presentation over  $S_S$  is contained in (XI, 6.11). Since  $H_S$  is smooth hence flat locally of finite presentation over  $S_S$ , to verify

that  $\pi^{-1}(H)$  is an open immersion, one is reduced to verifying it on the fibers (VI\_B, 2.6), which reduces us to the case where  $S$  is the spectrum of an algebraically closed field  $k$ . One is then reduced (Exp. VII<sup>[N.D.E-XII-11]</sup>) to verifying that the corresponding homomorphism on the Lie algebras is an isomorphism, or equivalently that  $(g/h)^H = 0$ , where  $g$  and  $h$  are the Lie algebras of  $G$  and of  $H$ , and the exponent  $H$  denotes the invariants under  $H$  (cf. II, 5.2.3 (i)). Now  $H$  contains by hypothesis a Cartan subgroup  $C$  of  $G$ , the centralizer of the maximal torus  $T$  of  $G$ , and it suffices therefore to prove that one has

$$(g/h)^T = 0,$$

which follows, taking into account complete reducibility of the representations of  $T$  (I, 4.7.3), from the analogous relation  $(g/c)^T$ , where  $c = \text{Lie}(C)$ . As for this latter, equivalent to

$$g^T = c,$$

it means that the centralizer  $C$  and the normalizer  $N$  of  $T$  have the same Lie algebra, which follows from the fact that  $C$  is an open subgroup of  $N$  (XI, 5.9). This completes the proof of a).

b) As we have signaled, the proof was given in 7.8.

c) Taking into account the fact that  $H$  is a subprescheme of  $G$ , the assertion reduces trivially to the case where  $S$  is the spectrum of an algebraically closed field, in which case it follows at once from the hypothesis made on  $H$ .

<!-- original page 237 -->

d) One uses b), c), and the "Hensel lemma" (XI, 1.10).

**Corollary 7.10.** Let  $G$  and  $H$  be as in 7.9, and suppose that for every algebraically closed field  $k$  over  $S$ , every element of  $G_k(k)$  which normalizes  $H_k(k)$  is in  $H_k(k)$ . Then  $H$  is a closed subprescheme of  $G$ , and is its own normalizer.\*

<!-- label: III.XII.7.10 -->

This follows trivially from 7.9 a). We shall apply 7.10 in particular to the Borel subgroups (more generally, to the parabolic subgroups) of  $G$ .

**Corollary 7.11.** Let  $G$ ,  $H$  be as in 7.9. Then  $H$  contains every group subprescheme  $Z$  of  $G$  which is central in  $G$ , flat and of finite presentation over  $S$ .\*

<!-- label: III.XII.7.11 -->

One may as usual reduce to the case  $S$  affine noetherian, then to the case  $S$  artinian, which implies that one is under the conditions of 7.1. By 7.9 c) one may suppose that  $H$  contains a Cartan subgroup  $C$  of  $G$ , and one is reduced to proving that  $C \subset Z$ . Now since  $S$  is artinian,  $G' = G/Z$  is representable by a prescheme in groups of finite type over  $S$ , the canonical morphism  $u : G \rightarrow G'$  being faithfully flat and its kernel being  $Z$  (VI\_A, 3.2). Obviously  $G'$  is smooth over  $S$ , and one may apply 7.1 f), which implies that  $C$  is of the form  $u^{-1}(C')$ , hence contains  $Z$ .

**Corollary 7.12.** Let  $G$ ,  $G'$  be two  $S$ -preschemata in groups smooth of finite presentation,  $u : G \rightarrow G'$  a faithfully flat group homomorphism (i.e. for every  $s \in S$ ,  $u_s$  is faithfully flat); suppose  $\text{Ker } u$  central and  $G$  with connected fibers. Then the map\*

$$H' \rightarrow H = u^{-1}(H')$$

\*establishes a bijective correspondence between group subpreschemata  $H'$  of  $G'$ , smooth of finite presentation over  $S$ , having the same reductive rank and the same\*

<!-- original page 238 -->

\*nilpotent rank as  $G'$  at every  $s \in S$ , and the set of group subpreschemata  $H$  of  $G$ , smooth of finite

presentation over  $S$ , having the same reductive rank and the same nilpotent rank as  $G$  at every  $s \in S$ . For  $H$  to have connected fibers, it is necessary and sufficient that  $H'$  do.\*

<!-- label: III.XII.7.12 -->

Let  $H$  be a group subscheme of  $G$  having the properties just specified. Then by 7.10,  $H$  contains  $Z = \text{Ker } u$ , hence by the theory of faithfully flat descent, is of the form  $u^{-1}(H')$ , where  $H'$  is a well-determined group subscheme of  $G'$ , and one verifies at once, taking into account 6.6 e), that this latter has the properties stated above. Moreover, if  $H$  has connected fibers, the same evidently holds for  $H' = H/Z$ . It therefore remains to prove that if one starts from a subgroup  $H'$  of  $G'$  having the stated properties, then  $u^{-1}(H') = H$  has the same properties in  $G$ ; and that if  $H'$  has connected fibers, the same holds for  $H$ . Taking into account 6.6 e), one is reduced to proving that  $H$  is smooth over  $S$  (resp. and has connected fibers). Now  $H$  is already flat over  $S$  as the inverse image of  $H'$  which is, by the flat morphism  $u$ , hence one is reduced to verifying that the geometric fibers of  $H$  are smooth (resp. and connected) which reduces us to the case where  $S$  is the spectrum of an algebraically closed field. Then  $H'$  contains a Cartan subgroup  $C'$  of  $G'$ , hence  $H$  contains the inverse image  $C$  of  $C'$ , which is a Cartan subgroup of  $G$  by 6.6 e), hence  $C$  is smooth and connected. Consequently 7.11 follows from the following lemma:

**\*Lemma 7.13.\*** \*Let  $G, G'$  be two preschemes in groups flat of finite presentation over  $S$ ,  $u : G \rightarrow G'$  a group homomorphism which is faithfully flat,  $C'$  a group subscheme of  $G'$  of finite presentation over  $S$ , such that  $C = u^{-1}(C')$  is smooth over  $S$  (resp. has connected fibers). Then for every group subscheme  $H'$  of  $G'$  of finite presentation over  $S$ , containing  $C'$ , and such that  $H' = H/Z$  is smooth over  $S$  (resp. has connected fibers), its inverse image  $H = u^{-1}(H')$  is smooth over  $S$  (resp. has connected fibers).\*

<!-- label: III.XII.7.13 -->

As we have remarked above, this statement reduces at once to the case where  $S$  is the spectrum of a field. Note then that  $H$  is a principal bundle of base  $H/C$ , group  $C$  (Exp. VI\_B, 9); on the other hand  $H/C \cong H'/C'$  (cf. Exp. IV), and  $H'$  being smooth <!-- original page 239 --> (resp. connected) the same holds for  $H'/C'$  hence for  $H/C$ . Since the same holds for  $C$  by hypothesis, it follows at once that the same holds for the bundle  $H$ . QED.

## 8. Semisimple elements; union and intersection of maximal tori in not-necessarily-affine group schemes

<!-- label: III.XII.8 -->

Throughout this number,  $G$  denotes a smooth  $S$ -prescheme in groups of finite presentation over  $S$ , with connected fibers.

<!-- original page 240 -->

Suppose first that  $S$  is the spectrum of an algebraically closed field. When  $G$  is affine, one has defined in \*BIBLE\* 4 N° 4 the notion of semisimple element of  $G(k)$ ; one verifies at once that this notion is invariant under algebraically closed extension  $k'/k$  of the base field. Moreover, one has seen in \*BIBLE\* 6 th. 5 (c) that  $g \in G(k)$  is semisimple if and only if it is contained in a maximal torus of  $G$ . When  $G$  is no longer supposed affine,  $G$  is written canonically (thanks to Chevalley) as an extension of an abelian variety by a smooth and connected affine algebraic group:

```
``text
(*) e → V → G → A → e.
````
```

We shall say that an element g of $G(k)$ is *semisimple* if it is a semisimple element of $V(k)$. Since the maximal tori of V are obviously identical to the maximal tori of G , it amounts to the same to say that g belongs to a maximal torus of G . This is evidently still a notion invariant under algebraically closed extension k'/k of the base field k .

Suppose now that S is the spectrum of an arbitrary field k , and let $g \in G$. Then (choosing an algebraically closed extension K of k) one sees that g is the image of a geometric point g' of G with values in an algebraically closed extension K of k , and we shall say that g is *semisimple* if g' is semisimple, which is independent of the particular choice of g' , thanks to what was said above. If k' is an extension of k , then the set of semisimple elements of $G_{k'}$ is the inverse image of the set G^{ss} of semisimple elements of G .

Suppose finally S arbitrary; then a point $g \in G$ is said to be *semisimple* if it is semisimple in its fiber $G_{\{s\}}$. If $S' \rightarrow S$ is any morphism, then $G^{\text{ss}}_{S'}$ is the inverse image of G^{ss} . Suppose that the functor $\mathcal{T}$ defined in 1.10 (functor of maximal tori) is representable by a prescheme of finite presentation over S (which is the case for example if G admits locally for fpqc a maximal torus, by 7.1 d), at least if G is

quasi-projective over S). Consider the canonical maximal torus T of $G_{\mathcal{T}}$ ("universal maximal torus of G "), and the morphism

$$u : T \rightarrow G$$

induced by the projection $G_{\mathcal{T}} \rightarrow G$. Then it follows at once from the definition that G^{ss} is none other than the image of the preceding morphism. We shall conclude:

Proposition 8.1. *The set G^{ss} of semisimple elements of G is locally constructible (hence constructible if S , hence G , is quasi-compact and quasi-separated).*

<!-- label: III.XII.8.1 -->

One reduces as usual to the case where S is affine noetherian; moreover one may suppose (by the usual noetherian criterion of constructibility (EGA 0.III, 9.2.3)) that S is integral, and restrict to proving that there exists a nonempty open U of S such that $G^{\text{ss}}|_U$ is constructible. Taking U small enough, and replacing it if necessary by a finite covering, one may suppose that G is separated over S and contains a maximal torus

<!-- original page 241 --> T . But then by 7.1 d) the functor $G_{\mathcal{T}}$ is representable by a prescheme of finite presentation over S , and the same therefore holds for T , whose image in G is consequently constructible. QED.

Suppose again that k is a field, and consider the subgroup H of G generated by the preceding morphism (cf. VI_B, 1.2). It is a smooth group subscheme of G , connected since T is, whose formation is evidently compatible with any base field extension (cf. VI), that of T being so. When k is algebraically closed, one sees at once that H is also the algebraic subgroup of G generated by the maximal tori of G , or equivalently by the tori of G , and it is also the smallest algebraic subgroup of G that contains the semisimple elements of $G(k)$. (In fact, these characterizations of H remain valid as soon as k is an infinite field, thanks to the fact, proved in XIV, that the set of points of T rational over k is dense in T). Moreover, H is invariant in G , for to see this, one may restrict to the case where k is algebraically closed, and then (H and G being smooth over k) it suffices to verify that H is stable under the inner automorphisms $\text{int}(g)$, $g \in G(k)$, which is evident. (One could even show that H is a characteristic subgroup of G , i.e. stable under $\text{Aut}_{\text{gr}}(G)$.) It then follows at once from 6.6 d) that the reductive rank of G/H is zero; more precisely, if K is an invariant algebraic subgroup of G , it follows at once from the fact that for k algebraically closed, the maximal tori of G/K are the direct images of the maximal tori of G , that the reductive rank of G/K is zero if and only if K contains all the maximal tori of G (k being supposed algebraically closed), or equivalently if and only if K contains H (k arbitrary): hence H is the smallest invariant algebraic subgroup of G such that G/H is of zero reductive rank. Another evident characterization of H is the following: it is the smallest algebraic subgroup of G having the same reductive rank as G . Let us note finally that H is affine: indeed, to see this one may again suppose k algebraically closed, and taking up the exact sequence (*) at the beginning of the N° , one notes that the maximal tori of G are contained in V , hence the same holds for H , hence V <!-- original page 242 --> being affine, H is. Let us summarize the results obtained:

Proposition 8.2. *Let G be a smooth and connected algebraic group over the field k , and let $\bar{k}$ be an algebraic closure of k . There exists an algebraic subgroup H of G such that $H_{\bar{k}}$ is the algebraic subgroup of $G_{\bar{k}}$ generated by the maximal tori (or equivalently the tori) of $G_{\bar{k}}$. The group H is also characterized as the smallest algebraic subgroup of G having the same reductive rank as G , or the smallest invariant algebraic subgroup of G such that the reductive rank of G/H is zero. It is a smooth connected invariant and affine subgroup of G , whose formation commutes with any extension of the base field.*

<!-- label: III.XII.8.2 -->

In order to use the characterization of H in terms of G/H , it is appropriate to make explicit the

Corollary 8.3. *Let G be a smooth and connected algebraic group over an algebraically closed field k . For G to be of zero reductive rank (i.e. with the notations of 8.2, for one to have $H = \{e\}$) it is necessary and sufficient that G be an extension of an abelian variety by a smooth connected unipotent algebraic group (i.e. successive extension of groups isomorphic to the additive group G_a).*

<!-- label: III.XII.8.3 -->

Indeed, thanks to Chevalley's exact sequence (*), one is reduced to proving that the reductive rank of the smooth connected affine group V is zero if and only if V is <!-- original page 158 --> unipotent, which is contained in *BIBLE* 6.4 th. 4 cor. 3. Hence with the notations of 8.2, H is the smallest invariant algebraic subgroup of G such that $(G/H)_{\bar{k}}$ is an extension of an abelian variety by a smooth connected affine unipotent algebraic group. One

concludes also:

****Corollary 8.4.**** *With the notations of 8.2, for one to have $G = H$ (i.e. $G_{\{\bar{k}\}}$ generated by its maximal tori) it is necessary and sufficient that G be affine and that every homomorphism from $G_{\{\bar{k}\}}$ to the additive group be trivial.*

<!-- label: III.XII.8.4 -->

<!-- original page 243 -->

****Remarks 8.5.**** *a) Let V be the largest smooth connected affine algebraic subgroup of $G_{\{\bar{k}\}}$ (so that $G_{\{\bar{k}\}}$ is an extension of an abelian variety by V). It is well known (Rosenlicht^[N.D.E-XII-12]), if k is not perfect, that V is in general not "defined over k ", i.e. that there does not in general exist an algebraic subgroup V' of G such that $V_{\{\bar{k}\}} = V'$. However, when V is generated by its maximal tori, i.e. when V admits no quotient group isomorphic to the additive group $G_{\{a, \bar{k}\}}$, there exists such a V' , namely the group H of 8.2. One thus sees that in this question of rationality, as in many others (cf. for example XIV, N° 6), all the troubles come from the unipotent groups, i.e. from the additive group, while it is the presence of (enough) multiplicative-type groups that on the contrary ensures that things go well.*

b) One may also introduce, with the notations of 8.2, the inverse image H' in G of the commutator subgroup of G/H ; then H' is the smallest invariant algebraic subgroup of G such that $(G/H')_{\{\bar{k}\}}$ is a commutative extension of an abelian variety by a smooth connected affine unipotent algebraic group. H' is again a smooth connected affine subgroup of G . Let H'' be the inverse image in G of $p^n(G/H')$ for n large, p being the characteristic (assumed > 0); then one sees easily that H''/H' is an abelian variety, and H'' is the smallest invariant algebraic subgroup of G such that G/H'' is a commutative smooth connected affine unipotent algebraic group. This being so, one sees easily that for $V = H_{\{\bar{k}\}}$ (notations of a)), i.e. for every homomorphism from V to the additive group to be trivial, it is necessary and sufficient that $H'' = G$, or equivalently that every homomorphism from $G_{\{\bar{k}\}}$ to the additive group be trivial.

<!-- label: III.XII.8.5 -->

To finish, we shall generalize to smooth groups with connected fibers the notion of reductive center developed in N° 4, inspired by 4.10. Let $\mathcal{Z}$ be the subfunctor of G defined by

$\mathcal{Z}(S') = \text{Set of sections } g' \text{ of } G_{S'} \text{ over } S' \text{ such that for every } S'' \text{ over } S'$

<!-- original page 244 -->

S' and every maximal torus T' of $G_{S'}$, the inverse image g'' of g' by $S'' \rightarrow S'$ is a section of T' over S'' .*

Introducing the functors $\mathcal{T}(S') = \text{set of maximal tori of } G_{S'}$, and $\mathcal{T}(S') = \text{set of pairs } (T', g')$, where T' is a maximal torus of $G_{S'}$ and g' a section of T' over S' , one sees that $\mathcal{T}$ is a subfunctor of $\mathcal{Z} \times_S G = \mathcal{T} \times_S G$, and with these notations, one may also write

$$\mathcal{Z} = \prod_{\mathcal{T} \times_S G} \mathcal{T} / \mathcal{T} \times_S G.$$

Using (XI, 6.8) and 7.1 d) which ensures the representability of $\mathcal{T}$ by a smooth S -prescheme under certain conditions, one could conclude the representability of $\mathcal{Z}$ under certain conditions, which we shall however obtain by a more direct route below.

****Definition 8.6.**** *Let G be a smooth S -prescheme in groups of finite presentation with connected fibers. One says that G admits a* reductive center *if the preceding functor $\mathcal{Z}$ (which is evidently a subgroup of G) is representable by a multiplicative-type group. One then says that $\mathcal{Z}$ is the* reductive center of G .*

<!-- label: III.XII.8.6 -->

One will note that if Z is a reductive center of G , then for every base change $S' \rightarrow S$, $Z_{S'}$ is a reductive center of $G_{S'}$; on the other hand, the existence of a reductive center is evidently a local question for the fpqc topology. As for the terminology "reductive center", note that Z is in any case central, since evidently $\mathcal{Z}$ is invariant under

$\mathcal{Z}$

$\text{operatorname{Aut}}_{\{S\}}(G)$
 $\mathbb{A}^1_k$

and *a fortiori* it is an invariant subgroup of G , and one applies (IX, 5.5).

Lemma 4.5 must be replaced here by:

Lemma 8.7. *Let $\rho : H \rightarrow G$ be a central homomorphism, where H is of multiplicative*

<!-- original page 245 -->

type and of finite type over $\mathbb{A}^1_k$; suppose that for every algebraically closed field k over $\mathbb{A}^1_k$, $\rho_k(H_k)$ is contained in the largest affine smooth connected subgroup of G_k . Then ρ factors through every maximal torus T of G (hence ρ factors in fact through the subfunctor $\mathcal{Z}$ of G defined above).

<!-- label: III.XII.8.7 -->

Using an easy variant of (IX, 5.1 bis) (where the sign $\supseteq$ would be replaced by an inclusion sign), one is reduced to the case where $\mathbb{A}^1_k$ is the spectrum of a field k , which one may suppose algebraically closed. (Reduce to the case $\mathbb{A}^1_k$ affine noetherian, then artinian, then use (IX, 3.6).) Since T is contained in the largest affine smooth connected subgroup V of G , one is then reduced to the case where $G = V$, i.e. where G is affine, where the result was proved in 4.5.

Proposition 8.8. *Let G be a smooth $\mathbb{A}^1_k$ -prescheme in groups of finite presentation with connected fibers.*

a) If $\mathbb{A}^1_k$ is the spectrum of a field k , then G admits a reductive center Z . When G is an extension of an abelian variety by a smooth connected affine algebraic group V (for example if k is algebraically closed), then Z is also the reductive center of V , and is the largest central multiplicative-type subgroup of V .

b) Let Z be a multiplicative-type group subscheme of G . Then Z is a reductive center of G if and only if for every $s \in S$, Z_s is a reductive center of G_s . Then Z is the largest multiplicative-type subgroup K of G such that for every $s \in S$, K_s is contained in the reductive center of G_s ; more generally, for every homomorphism $\rho : H \rightarrow G$, with H of multiplicative type and of finite type over $\mathbb{A}^1_k$, such that for every algebraically closed field k over $\mathbb{A}^1_k$, $\rho_k(H_k) \subset G_k$ factors through the largest smooth connected affine subgroup of G_k , ρ factors through Z (and in particular, ρ is central).

<!-- original page 246 -->

c) If G admits, locally for the fpqc topology, a maximal torus, then G admits a reductive center.

d) Let T be a maximal torus of G . Then $T \cap \text{Centr}(G) = \text{Ker}(T \rightarrow \text{GL}(g))$ and this is a reductive center of G .

e) Let Z be a reductive center of G , and suppose $G' = G/Z$ representable (for example $\mathbb{A}^1_k$ artinian); then G' admits the unit subgroup as reductive center, and $T' \mapsto T = \varprojlim (T')$ establishes a bijective correspondence between maximal tori of G' and maximal tori of G .

<!-- label: III.XII.8.8 -->

Proof. a) Suppose that $\mathbb{A}^1_k$ is the spectrum of a field k . To prove the existence of a reductive center, one may suppose k algebraically closed, and one is reduced consequently to the case where G is an extension of an abelian variety by a smooth connected affine algebraic group V . Since for every S' over k , the maximal tori of $G_{S'}$ are those of $V_{S'}$ (by (IX, 5.2) and the fact that over an algebraically closed field, a homomorphism from a torus to an abelian variety is trivial), it follows that the functor $\mathcal{Z}$ defined above in terms of G is the same as the one defined in terms of V . One is thus reduced to the case G affine. Since $\mathcal{T}$ is representable and necessarily "essentially free" over k (VIII, 6.1), it follows that $\mathcal{T}_G$ is essentially free over G , and since T is a closed subscheme of $\mathcal{T}_G = G \backslash \mathcal{T}$ (by e.g. (VIII, 5.7)) it follows by (VIII, 6.4) that $\mathcal{Z} = \prod_{G/G} T/G$ is representable by a closed subscheme of G . It is therefore a group subscheme of G ; I claim that it is of multiplicative type: indeed one may suppose k algebraically closed; then G admits a maximal torus T , and by definition one will have $Z \subset T$, hence Z is of multiplicative type as an algebraic subgroup of a multiplicative-type group (IX, 8). This proves that Z is a reductive center of G . The fact that it is the largest central multiplicative-type subgroup of V is contained in 8.7.

b) The "only if" being trivial, let us prove that if Z is a multiplicative-type subgroup of G such that for every $s \in S$, Z_s is the reductive center of G_s , *<!-- original page 247 -->* then Z is a reductive center of G . One must first prove that Z is contained in every maximal torus of G (which will thus remain true after every base

change): this is an immediate consequence of 8.7. Next, one must prove that if g_S is a section of G_S over S_S such that for every S'_S over S_S and every maximal torus T' of $G_{S'}$, $g_{S'}$ is a section of T' , then g_S is a section of Z_S . Note that one could reduce as usual (taking into account that $\prod_{T \in \mathcal{T}} T/G = \mathcal{Z}_0$ is an fpqc sheaf that commutes with inductive limits of rings) to the case S_S affine, then S_S noetherian, and finally S_S artinian. Then $\mathcal{T}$ is representable by a smooth prescheme over S_S by 7.1 d), so proceeding as in a), one sees that $\prod_{T \in \mathcal{T}} T/G$ is representable by a closed subscheme Z_0 of G_S . We have already seen that $Z \subset Z_0$; on the other hand by hypothesis on Z_S one has $Z_k = Z_{0,k}$ (where k_S is the residue field); now Z_S being flat over S_S , it follows $Z = Z_0$, which proves that Z_S is a reductive center of G_S . The other assertions of b) are contained in 8.7.

c) Reduces immediately to d).

d) Of course, g_S denotes the Lie algebra of G_S , and $T \rightarrow \mathrm{GL}(g)$ the homomorphism induced by the adjoint representation of G_S . One has trivially

```
```text
T ∩ Centr_G ⊂ Ker(T → GL(g)),
```
```

the proof of the reverse inclusion is the same as in 4.7 d), we do not repeat it here. Let Z_S be the group in question; as $\mathrm{Ker}(T \rightarrow \mathrm{GL}(g))$ it is of multiplicative type (cf. for example (IX, 6.8)). To prove that it is a reductive center of G_S , one is reduced by b) to the case where S_S is the spectrum of a field. Let then Z_0 be the reductive center (which exists by a)); one has evidently $Z_0 \subset T \cap \mathrm{Centr}(G) = Z_S$; on the other hand since Z_S is a central multiplicative-type subgroup contained in the smooth connected affine subgroup T_S , it follows from a) that $Z_0 \subset Z_S$, hence $Z_0 = Z_S$. QED.

e) Under the conditions of 7.1 f) set $Z = \mathrm{Ker} \, u_S$ and suppose that for every algebraically closed field k_S over S_S , Z_{k_S} is contained in a maximal torus of G_{k_S} . Then one verifies easily that the map $T' \mapsto u^{-1}(T')$ induces a bijective correspondence between the set of maximal tori of G_S and the set of maximal tori of G_S . Applying this to the situation 8.8 e), the desired conclusion follows at once.

Remarks 8.9. a) The proof given of 8.8 is independent of the results of N° 4, and in particular that of 8.8 a) does not use 4.4 (whose proof is a little burdensome).*

b) One sees easily that the subgroup $\mathcal{Z}_S$ of G_S envisaged in 8.6 is always central (whether it is representable or not), and it may be tempting to call it the reductive center of G_S in all cases.*

c) One may also generalize 4.9; one finds the following statement: Let G_S be a smooth and connected algebraic group over an algebraically closed field. For G_S to be an extension of an abelian variety by a smooth connected unipotent algebraic group (i.e. for the reductive rank of G_S to be zero, cf. 8.3) it is necessary and sufficient that the reductive center of G_S be reduced to the unit group and that the Lie algebra of G_S be nilpotent.*

<!-- label: III.XII.8.9 -->

9. Complement: action of a group scheme and fixed points

<!-- label: III.XII.9 -->

The aim of this section, added in January 2008, is to study fixed points under the action of a group scheme.

9.1. Representability of the functor of fixed points

<!-- label: III.XII.9.1 -->

Let S_S be a scheme, G_S an S_S -group scheme acting on an S_S -scheme X_S . One defines the subfunctor X^G_S of X_S of fixed points of X_S under G_S : for every S_S -scheme T_S , $X^G_S(T_S)$ is the subset of $X(T_S)$ consisting of fixed points under G_S (VIII, 6.e).

Recall the notion of " S_S -pure scheme" introduced in ([G-R], § 3.3, [R]). Let G_S be a flat S_S -group scheme of finite presentation. Since the fibers of G_S have no embedded components, the notion of purity for G_S takes the following form. The scheme G_S is S_S -pure if for every strictly henselian local S_S -scheme T_S with closed point t_S , every generic point $\tilde{x}_S$ of a fiber of $G \times_{S_S} T_S$ specializes to a point of G_{t_S} , i.e. the closure of $\tilde{x}_S$ in $G \times_{S_S} T_S$ meets G_{t_S} .

<!-- original page 162 -->

Examples. (1) If G is quasi-finite and separated over S , G is S -pure if and only if G is finite over S .

(2) If $S = \operatorname{Spec}(R)$ and $G = \operatorname{Spec}(A)$, G is S -pure if and only if A is a projective R -module ([G-R], 3.3.5). In particular G is S -pure if G is diagonalizable.

(3) A multiplicative-type group scheme is S -pure since the notion of purity is local for the étale topology on S .

(4) The scheme G is S -pure if G is S -proper or if the fibers of G are irreducible or if S is semi-local artinian.

(5) In particular, an S -reductive group scheme G is S -pure.

Proposition 9.2. *Let G be an S -group scheme of finite presentation, S -flat and S -pure, acting on an S -scheme X of finite presentation. Then the functor X^G of fixed points of X under G is representable by a closed subscheme of X , of finite presentation over S .*

<!-- label: III.XII.9.2 -->

Indeed, let s in $X(S)$ and let H be the group subscheme of G fixing s . Then s is fixed under G if and only if $H = G$. Now the subfunctor C of S of coincidences (precisely, if T is an S -scheme, $C(T) = \{\emptyset\}$ if $H \times_S T \rightarrow G \times_S T$ is bijective, and $C(T) = \emptyset$ otherwise) of H with G is representable by a closed subscheme of S , defined by a finitely generated sheaf of ideals ([G-R], 4.1.1). One applies this result with $S = X$ taking for s the universal point of X (i.e. the identity in $X(X) = \operatorname{Hom}_S(X, X)$).

9.3. Infinitesimal obstruction

<!-- label: III.XII.9.3 -->

Under the hypothesis that G is a flat S -group scheme of finite presentation acting (on the left) on a smooth S -prescheme X , we shall now study the formal smoothness of the functor X^G .

One supposes here that S is equipped with a closed subscheme S_0 defined by a sheaf of quasi-coherent ideals $\mathcal{I}$ of square zero. One writes $j : S_0 \rightarrow S$, $G_0 = G \times_S S_0$, $X_0 = X \times_S S_0$.

Let ϵ be a point of $X^G(S_0)$ that lifts to a point of $X(S)$. We shall study the obstruction to lifting ϵ to a point of $X^G(S)$. Since X is smooth, one knows that the liftings of ϵ to $X(S)$ form a principal homogeneous space, trivial for the abelian group

$$\operatorname{Hom}_{\mathcal{O}_{S_0}}(\epsilon^*(\Omega_{X_0/S_0}), \mathcal{I})$$

(III, 0.2, 0.3). One sets

$$L_0 = \operatorname{Hom}_{\mathcal{O}_{S_0}}(\epsilon^*(\Omega_{X_0/S_0}), \mathcal{I}),$$

this is an $\mathcal{O}_{S_0}$ -module. Moreover, given that ϵ is fixed under G , L_0 is naturally a G_0 - $\mathcal{O}_{S_0}$ -module. One writes $\rho : G_0 \rightarrow \operatorname{Aut}_{\mathcal{O}_{S_0}}(L_0)$ (resp. $\rho : G \rightarrow \operatorname{Aut}_S(j_* L_0)$) for the associated representation.

Lemma 9.4. *There exists a certain class $c(\epsilon) \in H^1(G, j_* L_0) \simeq H^1(G_0, L_0)$, defined canonically by ϵ , such that ϵ lifts to $X^G(S)$ if and only if $c(\epsilon) = 0$.*

<!-- label: III.XII.9.4 -->

<!-- original page 163 -->

The adjunction $H^1(G, j_* L_0) \simeq H^1(G_0, L_0)$ is that of lemma (III, 1.1.2). We work with the small fppf site on S . For every flat scheme T of finite presentation over S , one writes $G_T = G \times_S T$, $X_T = X \times_S T$ for the corresponding objects over T . Consider the sheaf $\mathcal{A}$ on the small fppf site of S such that, for every T flat and of finite presentation over S , one has:

```

```text
\[\mathcal{A}\}(T) = \{\text{set of liftings of } \varepsilon_0 \times_S T \text{ in } X(T)\}.
```

```

Given that the formation of ε_0 commutes with flat base changes, the foregoing considerations indicate that $\mathcal{A}(T)$ is a trivial principal homogeneous space under the abelian group $H^0(T, j_{*} \varepsilon_{0*})$. Again from the fact that ε_0 is fixed, for every T flat and of finite presentation over S , and every g in $G(T)$, g acts by affine automorphisms on $\mathcal{A}(T)$, compatibly with the action of G on $j_{*} \varepsilon_{0*}$. That is to say:

```

```text
g(a_T + v) = g(a_T) + \rho(g)(v), \quad v \in H^1(T, j_{*} \varepsilon_{0*}).
```

```

Since G is flat of finite type one may apply these considerations taking $T = G$ and for g the universal point id_G of G . One thus obtains an action of the fppf sheaf G on $\mathcal{A}$.

Let a be a lifting of ε_0 in $X(S)$. One writes $g^{\sharp}$ for the universal point of G , and one defines $v^{\sharp} \in H^0(G, j_{*} \varepsilon_{0*})$ by

```

```text
\rho(g^{\sharp})(v^{\sharp}) = g^{\sharp} \cdot a_G - a_G.
```

```

For every S -prescheme Y , one sets $z(Y) : G(Y) \rightarrow H^0(Y, j_{*} \varepsilon_{0*})$, $g \mapsto v^{\sharp}(g)$. This defines the 1-cocycle z in $Z^1(G, L)$ (Exposé I, § 5).

Its class $c(\varepsilon_0)$ in $H^1(G, j_{*} \varepsilon_{0*})$ does not depend on the choice of a . In particular, if ε_0 lifts to $X^G(S)$, one has $c(\varepsilon_0) = 0$. Conversely, if $c(\varepsilon_0) = 0$, then there exists $w \in H^0(S, j_{*} \varepsilon_{0*})$ such that $z(Y)(g) = g.w - w$ for every S -prescheme Y and every $g \in G(Y)$. Applying this to $Y = G$ and to $g^{\sharp}$, one concludes that $a - w \in X^G(S)$. We have thus established that ε_0 lifts in $X^G(S)$ if and only if $c(\varepsilon_0) = 0$.

Remark 9.5. In the case where G is affine and flat of finite type over S affine, one can refine this obstruction into a class $\tilde{c}(\varepsilon_0) \in H^1_{G, L}(X, L)$ where $H^1_{G, L}(X, L)$ is the G -equivariant cohomology group defined by Wevers ([W], app. C). In this case, it is not necessary to suppose that ε_0 lifts to $X(S)$.

<!-- label: III.XII.9.5 -->

9.6. Smoothness of fixed points

<!-- label: III.XII.9.6 -->

Theorem 9.7. Let G be an S -group scheme flat, of finite type over a noetherian base S , acting on a smooth S -scheme X . Suppose that G is S -pure, and for every geometric point s above S (with algebraically closed residue field), one has*

```

$$
H^1(G_s, (\Omega^1_{X_s}))^* = 0.
$$

```

*Then the functor X^G of fixed points of X under G is representable by a closed subscheme of X smooth over S .

<!-- label: III.XII.9.7 -->

Let us prove Theorem 9.7. We know that X^G is representable by a closed subscheme of X of finite presentation over S . We may suppose $S = \text{Spec}(A)$ local. Following the smoothness criterion (SGA 1, III, 3.1.iii bis), it suffices to verify the formal smoothness of X^G <!-- original page 164 --> for $S' = \text{Spec}(A')$ and the closed subscheme $S'_0 = \text{Spec}(A'/I') = \text{Spec}(A'_0)$, where A' is an artinian local ring and I' an ideal of square zero of A' . By dévissage, one reduces to the case where I' is annihilated by the maximal ideal of A' . In particular, if k denotes the residue field of A' , I' is a k -vector space.

One is therefore given an element $\varepsilon'_0 \in X^G(S'_0)$ which one wishes to lift to $X^G(S')$. One then

writes $X_{\{0\}} = X \times_{S'} S'$, $G' = G \times_{S'} S'$, $X'_{\{0\}} = X \times_{S'} S'_{\{0\}}$, $G'_{\{0\}} = G \times_{S'} S'_{\{0\}}$. Given that S' is affine and that $X_{\{0\}}$ is smooth over S' , $\epsilon_{\{0\}} \in X^{\{G\}}(S'_{\{0\}})$ lifts to $X(S')$. By Lemma 9.4, the class

$c(\epsilon_{\{0\}}) \in H^1(G'_{\{0\}}, L'_{\{0\}})$

is the obstruction to lifting $\epsilon_{\{0\}}$ in $X^{\{G\}}(S')$, where $L'_{\{0\}} = \operatorname{Hom}_{\{0\}}(S'_{\{0\}})(\epsilon_{\{0\}} * (\Omega^1_{X'_{\{0\}}/S'_{\{0\}}), I')$. Given that $L'_{\{0\}}$ is a k -vector space, one has a canonical isomorphism $H^1(G'_{\{0\}}, L'_{\{0\}}) \simeq H^1(G'_{\{0\}} \times_{A'_{\{0\}}} k, L'_{\{0\}})$. It suffices to show that $H^1(G'_{\{0\}} \times_{A'_{\{0\}}} k, L'_{\{0\}}) = 0$. Writing $\bar{k}$ for an algebraic closure of k , one has an isomorphism (IX, 3.1 in the affine case, lemma 9.11 in general)

```text  
 $H^1(G''_{\{0\}} \times_{A''_{\{0\}}} k, L''_{\{0\}} \otimes_k k^-) = H^1(G''_{\{0\}} \times_{A''_{\{0\}}} k^-, L''_{\{0\}} \otimes_k k^-).$

One then remarks that the representation  $L'_{\{0\}} \otimes_k \bar{k}$  is a direct sum of  $(\Omega^1_{X_{\{0\}} \times_{S'} \bar{k}})^*$ . By hypothesis one has  $H^1(G'_{\{0\}} \times_{A'_{\{0\}}} \bar{k}, (\Omega^1_{X_{\{0\}} \times_{S'} \bar{k}})^*) = 0$ , which implies  $H^1(G'_{\{0\}} \times_{A'_{\{0\}}} k, L'_{\{0\}}) = 0$ .

**Corollary 9.8.** Let  $G$  be a flat  $S$ -group scheme of finite presentation acting on a smooth  $S$ -scheme  $X$  of finite presentation. Suppose that  $G$  admits a composition series whose factors are of one of the following types:

- (1)  $S$ -abelian scheme (i.e.  $G$  is smooth over  $S$  and its fibers are abelian varieties),
- (2)  $S$ -group scheme of multiplicative type,
- (3)  $S$ -group scheme finite, étale, of degree invertible on  $S$ ,
- (4)  $S$ -reductive group if  $S$  is a  $\mathbb{Q}$ -scheme.

Then the functor  $X^{\{G\}}$  of fixed points of  $X$  under  $G$  is representable by a closed subscheme of  $X$ , of finite presentation, smooth over  $S$ .

<!-- label: III.XII.9.8 -->

Indeed, if  $1 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 1$  is an exact sequence of  $S$ -groups satisfying the hypotheses of the theorem, the  $S$ -group  $G''$  acts on the functor  $X^{\{G'\}}$ , and the functor  $X^{\{G\}}$  is nothing other than that of fixed points of  $X^{\{G'\}}$  under  $G''$ . Thus one is reduced to the case of an  $S$ -group of one of the four types above. By passage to the limit, one may suppose  $S$  noetherian. We shall verify the cohomological criterion stated above for a fiber  $G_{\{s\}}$  above a geometric point  $s$  of  $S$  and a finite-dimensional linear representation  $V$  of  $G_{\{s\}}$ .

In the case of an abelian scheme, every map from  $G^{\{n\}}_{\{s\}}$  to  $V$  is constant, and consequently the  $H^i(G_{\{s\}}, V)$  are zero for  $i > 0$ .

In the case of a multiplicative-type group scheme,  $G_{\{s\}}$  is a diagonalizable group. Theorem (I, 5.3.3) shows that the  $H^i(G_{\{s\}}, V)$  are zero for  $i > 0$ .

In the two following cases, the argument is the same since it rests on the semisimplicity of the linear representations of  $G_{\{s\}}$ . Indeed in the case of an  $S$ -group scheme <!-- original page 165 --> finite, étale, of degree invertible on  $S$ ,  $G_{\{s\}}$  is a constant finite group of degree invertible in the residue field  $\kappa(s)$ ; it is well known that every linear representation of  $G_{\{s\}}$  is semisimple.

For the reductive case, the residue field  $\kappa(s)$  is supposed (algebraically closed) of characteristic zero. One knows then that every linear representation of  $G_{\{s\}}$  is semisimple (see [T-Y], theorem 27.3.3).

**Remark 9.9.** This applies in particular to the case of an action of  $G/S$  on a smooth  $S$ -group scheme  $H$ . If  $G$  is a multiplicative-type group acting by inner transformations on  $H$  smooth and affine over  $S$ , one recovers then the corollary (XI, 5.3) stating the smoothness of the centralizer of  $G$  in  $H$ .

<!-- label: III.XII.9.9 -->

**\*\*Remark 9.10.\*\*** \*In the case where  $S = \operatorname{Spec}(k)$  and  $G$  is a linearly reductive algebraic group defined over the algebraically closed field  $k$ , this result is due independently to Fogarty ([F], theorem 5.4) and Iversen ([I], proposition 1.3).\*

<!-- label: III.XII.9.10 -->

The proof of Theorem 9.7 uses the following lemma, well known in the case of an affine group scheme (IX, 3.1).

**\*\*Lemma 9.11.\*\*** \*Let  $G$  be a group scheme over an affine scheme  $S = \operatorname{Spec}(A)$ , and  $f : S' = \operatorname{Spec}(A') \rightarrow S$  a flat morphism. Set  $G' = G \times_S S'$ . Then for every quasi-coherent  $G$ -module  $M$ , one has canonical isomorphisms\*

```

```text
H^i(G, M) \otimes_A A' \cong H^i(G', M \otimes_A A') \quad (i \geq 0).
```

```

<!-- label: III.XII.9.11 -->

Given that the chains of degree  $n$  for Hochschild cohomology are determined by their value at the point  $(\operatorname{id}, \dots, \operatorname{id}) \in G(G) \times \dots \times G(G)$ , one has an isomorphism of  $A$ -modules  $H^n(G, M) \cong \Gamma(G^n, M \otimes_A \Omega_{G^n/A})$ . The cohomology group  $H^n(G, M)$  is the  $n$ -th cohomology group of the complex

```

```text
L \rightarrow \Gamma(G, M \otimes_A \Omega_G) \rightarrow \Gamma(G^2, M \otimes_A \Omega_{G^2}) \rightarrow \Gamma(G^3, M \otimes_A \Omega_{G^3}) \rightarrow \dots
```

```

Since  $A'$  is flat over  $A$ , by (EGA IV\_1, 1.7.21) one has

```

```text
\Gamma(G'^n, M \otimes_A \Omega_{G'^n/A'}) \cong \Gamma(G'^n, (M \otimes_A A') \otimes_{A'} \Omega_{G'^n/A'}).
```

```

This implies the required assertion by taking cohomology.

## 1. An auxiliary lemma on varieties with operators

<!-- label: III.XIII.1 -->

<!-- original page 249 -->

Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups acting on the left on an  $S$ -prescheme  $V$ ,  $W$  a closed  $S$ -subprescheme of  $V$ ,  $N$  its stabilizer in  $G$  — the subgroup of  $G$  whose points, with values in an  $S'$  over  $S$ , are the  $g \in G(S')$  such that  $g \cdot W_{S'} = W_{S'}$ . We endow  $(Sch)/S$  with the faithfully flat quasi-compact topology, and identify  $G$ ,  $V$ ,  $W$  with the corresponding sheaves (cf. IV). We shall therefore argue in the category of sheaves on  $(Sch)/S$ , and in this section the term "locally" refers to the topology we have just specified on  $(Sch)/S$ . Note that  $N$  is a sheaf; consider the quotient sheaf  $G/N$ . One sees at once that it is isomorphic to the following functor: to every  $S'$  over  $S$ , one associates the set of subsheaves  $W'$  of  $V_{S'}$  that are locally conjugate to  $W_{S'}$  by the group  $G$ . Let  $X$  be the subsheaf of  $G/N \times_S V$  whose value, for every  $S'$  over  $S$ , is the set of pairs  $(W', v)$ , where  $W'$  is as above and  $v$  is a section of  $W'$  over  $S'$  (hence a section of  $V_{S'}$  over  $S'$ ). Let  $Z$  be the inverse image of  $X$  in  $G \times_S V$ , so that we have the cartesian diagram

```

```text
      Z  -----> X
      |           | i
(*)   |           |
      v           v
      G x_S V -> G/N x_S V,
...

```

<!-- label: eq:III.XIII.1.star -->

where i is the canonical immersion, and the second horizontal arrow comes from the canonical morphism $G \rightarrow G/N$.

<!-- original page 250 --> Since this morphism sends the point $g \in G(S')$ to the subsheaf $g \cdot W_{S'}$ of $V_{S'}$, one

sees that $Z(S')$ is the set of pairs $(g, v) \in G(S') \times V(S')$ such that $v \in g \cdot W_{S'}(S')$. Consequently, Z is isomorphic to the sheaf $G \times_S W$, by means of the isomorphism

```

```text
G x_S W -> Z
...

```

defined by  $(g, w) \mapsto (g, g \cdot w)$ . Thus the preceding cartesian diagram gives the cartesian diagram

```

```text
      q
      G x_S W -----> X
      |               | i
(**)  |               |
      lambda         v
      G x_S V -> G/N x_S V
...

```

<!-- label: eq:III.XIII.1.doublestar -->

where $\lambda(g, w) = (g, g \cdot w)$, hence $q(g, w) = (\bar{g}, g \cdot w)$, where $\bar{g}$ denotes the image of g under the canonical map $G(S') \rightarrow (G/N)(S')$. One sees finally from diagram $(*)$ that $Z \rightarrow X$ makes Z into a principal bundle with base X and group N acting on the right by $(g, v) \cdot n = (gn, v)$, so that in $(**)$, $q : G \times_S W \rightarrow X$ makes $G \times_S W$ into a principal bundle with base X and group N acting on the right by

```

```text
(g, w) · n = (gn, n-1 · w).
...

```

We summarize the principal morphisms above in the following diagram:

```

```text
      G x_S W
      /   \
     q     \phi
     |       \
     v        \
G/N ← p-X → V
     |   ^   ^
    pr_1 i_! pr_2
     |
    G/N x_S V

(D)
```

```

<!-- label: eq:III.XIII.1.D -->

where  $\psi = \text{pr}_2 \circ i$  and  $\varphi = \psi \circ q$ , i.e.  $\varphi(g, w) = g \cdot w$ . If  $v$  is a section of  $V$  over  $S$ , the subsheaf  $X_v$  of  $X$ , inverse image of this section by  $\psi$ , is given by <!-- original page 251 -->  $X_v(S) =$  set of subsheaves  $W'$  of  $V_S$  which are locally conjugate to  $W_S$  by  $G$  and which contain the section  $v_S$  of  $V_S$ , while the subsheaf of  $G \times_S W$  inverse image of  $v$  by  $\varphi$  is isomorphic to the subsheaf  $M_v$  of  $G$  given by  $M_v(S) =$  set of  $g \in G(S)$  such that  $v_S \in g \cdot W(S)$ , i.e. such that  $g^{-1} v_S \in W(S)$ . If  $w$  is a section of  $W$  and not merely of  $V$ , then  $M_v$  evidently contains  $N$ .

In these explicit descriptions we have not used the fact that  $G$ ,  $V$ ,  $W$  are representable (nor that the site over which we work is defined in terms of preschemes!). But suppose now that  $N$  is representable and faithfully flat and quasi-compact over  $S$ , and that  $G/N$  is representable. When  $S$  is the spectrum of a field, and  $G$  is of finite type over  $k$ , one knows that this hypothesis is necessarily satisfied (VIII 6 and VI\_B.11.18). One then sees from the cartesian diagram  $(**)$ , using the theory of faithfully flat quasi-compact descent and the fact that  $Z \rightarrow G \times_S V$  is a closed immersion, that  $X$  is representable (it is obtained by descent of the closed subscheme  $Z$  of  $G \times_S V$  by the faithfully flat quasi-compact morphism  $G \times_S V \rightarrow G/N \times_S V$ ). Hence diagram (D) is a diagram of morphisms of preschemes over  $S$ .

We henceforth assume that  $S$  is the spectrum of a field  $k$ , and that  $G$ ,  $V$ ,  $W$  are of finite type over  $k$ . Let  $\mathfrak{n}$  be the Lie algebra of  $N$ , so that  $\dim N \leq \text{rank } \mathfrak{n}$ , with equality if and only if  $N$  is smooth over  $k$  (Exp VI [N.D.E-XIII-1]). Let  $a \in W(k)$ , and consider the subscheme  $M_a$  of  $G$  defined above, containing  $N$ , and isomorphic to  $\varphi^{-1}(a)$ ; we shall denote by  $\mathfrak{m}_a$  its Zariski tangent space at the identity element  $e$  of  $N$ , so that one has

```

```text
(1)   0 ≤ dim N ≤ rank N ≤ rank \mathfrak{m}_a.
```

```

<!-- label: eq:III.XIII.1.1 -->

**Lemma 1.1.** *With the preceding notation:*

<!-- label: III.XIII.1.1 -->

<!-- original page 252 -->

**a)** Consider the following conditions:

- (i)  $\mathfrak{n} = \mathfrak{m}_a$  and  $N$  is smooth over  $k$ .
- (i bis)  $\dim N = \text{rank } \mathfrak{m}_a$ .
- (ii) The morphism  $\psi : X \rightarrow V$  is unramified at  $(\bar{e}, a)$ .
- (iii)  $M_a$  and  $N$  coincide in a neighborhood of  $e$ .

Then one has the implications (i)  $\Leftrightarrow$  (i bis)  $\Leftrightarrow$  (ii)  $\Leftrightarrow$  (iii).

**b)** Suppose  $\varphi : G \times_S W \rightarrow V$  is smooth at  $(e, a)$ . Then  $M_a$  is smooth over  $k$  at  $e$ , and  $\psi$  is smooth at  $(\bar{e}, a)$ .

**Proof.** a) The equivalence of (i) and (i bis) follows at once from the relations (1) and from the fact already noted that  $N$  is smooth over  $k$  if and only if  $\dim N = \text{rank } \mathfrak{n}$ . On the other hand, consider the inclusion morphism  $N \rightarrow M_a$ ; it is well known [N.D.E-XIII-2] that if  $N$  is smooth over  $k$  at  $e$  and the tangent map at

$\pi$  is surjective, then  $N \rightarrow M_a$  is smooth at  $e$ , hence (being an immersion) is an isomorphism at  $e$ , which shows that (i) implies (iii). To prove the equivalence of (ii) and (iii), consider as above  $X_a = \pi^{-1}(a)$  and use the isomorphism  $M_a \xrightarrow{\sim} \varphi^{-1}(a) \xrightarrow{\sim} q^{-1}(X_a)$  to obtain a morphism  $p_a : M_a \rightarrow X_a$  which makes  $M_a$  a principal homogeneous bundle with group  $N_{X_a}$ . Consider the following diagram

```

```text
      j_a
      |
M_a  ←----- N
|      |
p_a|    |
↓      ↓
X_a  ←----- S = Spec(k),
...

```

where $\pi^{-1}(a) \rightarrow X_a$ is defined by the point $(\bar{e}, a)$ of X , and $j_a : N \rightarrow M_a$ is the canonical immersion. To say that π is unramified at $(\bar{e}, a)$ means that j_a 's is an open immersion, or equivalently that it induces an isomorphism $\pi^{-1}(a) \xrightarrow{\sim} \pi^{-1}(X_a) \xrightarrow{\sim} \pi^{-1}(X_a)$. <!-- original page 253 --> Since p_a is flat, it is equivalent to say that the morphism deduced from the preceding by the base change $\pi^{-1}(M_a, e) \rightarrow \pi^{-1}(X_a, \bar{e})$ is an isomorphism; now this deduced morphism is none other than the morphism $\pi^{-1}(N, e) \rightarrow \pi^{-1}(M_a, e)$, which proves the equivalence of (ii) and (iii).

One will note moreover that the proof shows that conditions (ii), (iii) imply the following condition, apparently stronger than (iii):

- (iii bis) N is an open and closed subscheme of M_a .

b) The first assertion follows from the fact that M_a is isomorphic to $\varphi^{-1}(a)$, the second from the fact that q is flat and $q(e, a) = (\bar{e}, a)$.

2. Density theorem and theory of the regular points of G

<!-- label: III.XIII.2 -->

We shall apply the constructions and notation of the preceding section to the case where G is a connected smooth algebraic group over k , where $V = G$ on which G acts by inner automorphisms, and where W is a connected smooth algebraic subgroup H of G . We shall denote by $\mathfrak{g}$ the Lie algebra of G , by $\mathfrak{h}$ that of H , by N the normalizer of H in G , and by $\mathfrak{n}$ the Lie algebra of N . If $a \in G(k)$, we shall denote, as in section 1, by M_a the symmetric of its transporter into H , so that if $a \in H(k)$, one has $N \subset M_a$; in this case, we denote by $\mathfrak{m}_a$ the Zariski tangent space of M_a at the identity element e of G . Note that

```

```text
□ ⊂ □ ⊂ □_a for a ∈ H(k).
...

```

We shall need the following:

<!-- original page 254 -->

**Lemma 2.0.** In order that  $H = N^{\{0\}}$ , it is necessary and sufficient that  $(\mathfrak{g}/\mathfrak{h})^H = 0$  (where the first member denotes the subspace of invariants under the action of  $H$  deduced from the adjoint representation). When this condition is satisfied,  $N$  is smooth and  $\dim X = \dim G$ . In any case,  $\dim X \leq \dim G$ , and this inequality is an equality if and only if  $H$  is of finite index in  $N$ .

<!-- label: III.XIII.2.0 -->

Indeed, one has seen (II 5.2.3 (i)) that  $\mathfrak{n}$  equals the inverse image of  $(\mathfrak{g}/\mathfrak{h})^H$  under the morphism  $\mathfrak{g} \rightarrow \mathfrak{g}/\mathfrak{h}$ , hence  $(\mathfrak{g}/\mathfrak{h})^H = 0$  is equivalent to  $\mathfrak{h} = \mathfrak{n}$ , which is also equivalent (since  $H$  is a smooth connected algebraic subgroup of the algebraic group  $N$ ) to  $H = N^{\{0\}}$  (cf. VI.2). This evidently implies that  $N$  is smooth. On the other hand, one has

```

```text
dim X = (dim G - dim N) + dim H = dim G - (dim N - dim H),
```

```

hence

```

```text
dim X ≤ dim G,
```

```

with equality if and only if  $\dim H = \dim N$ , i.e. if and only if  $H$  is of finite index in  $N$ . This is the case in particular if  $H = N^{\{0\}}$ , which completes the proof of 2.0.

**Theorem 2.1.** Let  $G$  be a smooth connected algebraic group over the algebraically closed field  $k$ ,  $H$  a connected smooth algebraic subgroup,  $N$  its normalizer,  $\mathfrak{g}$ ,  $\mathfrak{h}$ ,  $\mathfrak{n}$  the Lie algebras,  $X = G \times^N H$  the scheme (fibered over  $G/N$  with typical fiber  $H$ ) introduced in section 1,  $\psi : X \rightarrow G$  the canonical morphism (whose image is also the image of  $\varphi : G \times H \rightarrow G$  defined by  $\varphi(g, h) = \text{int}(g)h = ghg^{-1}$ ). The following conditions are all equivalent:

```

<!-- label: III.XIII.2.1 -->

```

- (i)  $H$  contains a Cartan subgroup  $C$  of  $G$ .
- (i bis)  $H$  has the same reductive rank and the same nilpotent rank (XII 1) as  $G$ .
- (ii)  $H$  contains a maximal torus  $T$  of  $G$ , and  $(\mathfrak{g}/\mathfrak{h})^T = 0$ .

```

<!-- original page 255 -->

```

- (iii) The set of conjugates of  $H$  containing a given maximal torus is finite and non-empty, and  $H$  is of finite index in its normalizer.
- (iv) There exists  $a \in H(k)$  contained only in finitely many conjugates of  $H$  (or merely such that  $\psi^{-1}(a)$  has an isolated point), and  $H$  is of finite index in its normalizer.
- (iv bis) The morphism  $\psi : X \rightarrow G$  is generically quasi-finite (i.e. there exists a dense open of  $X$  on which  $\psi$  is quasi-finite), and  $H$  is of finite index in its normalizer.
- (v) There exists a dense open  $U$  in  $G$  such that for every  $x \in U(k)$ , the set of conjugates of  $H$  containing  $x$  is finite and non-empty, i.e.  $\psi : X \rightarrow G$  is dominant and generically quasi-finite.
- (vi) There exists a dense open  $U$  of  $G$  such that every  $x \in U(k)$  is contained in a conjugate of  $H$ , i.e.  $\psi : X \rightarrow G$  is dominant.
- (vii) There exists  $a \in H(k)$  such that the subspace of  $\mathfrak{g}/\mathfrak{h}$  of fixed points of  $\text{ad}_{\mathfrak{g}/\mathfrak{h}}(a)$  is zero.

Furthermore, these conditions imply that  $H$  is its own connected normalizer, i.e.  $N$  is smooth and  $\dim H = \dim N$ , and that  $\psi : X \rightarrow G$  is generically étale.

**Proof.** By 2.0, one has  $\dim X \leq \dim G$ , with equality if and only if  $\dim H = \dim N$ , i.e.  $H$  of finite index in  $N$ . From the inequality  $\dim X \leq \dim G$  it follows that  $\psi$  is dominant if and only if it is dominant and generically quasi-finite, or again if and only if  $\psi$  is generically quasi-finite and  $\dim X = \dim G$ . As this latter equality means also, by 2.0, that  $H$  is of finite index in  $N$ , we have proved the equivalence of (vi), (v), (iv bis). The equivalence of (iv) and (iv bis) is immediate.

The equivalence of (i) and (i bis) is immediate from the definitions, and is left to the reader. On the other hand, if  $H$  contains a Cartan subgroup  $C$  of  $G$ , then it contains the maximal torus  $T$  of  $C$ , which is a maximal torus of  $G$ . <!-- original page 256 --> Since  $C$  is the centralizer of  $T$ , its Lie algebra  $\mathfrak{c}$  is given by

$$\mathfrak{c} = \mathfrak{g}^T$$

(II, 5.2.3 (ii)). Hence as  $H \supset C$ , so that  $\mathfrak{h} \supset \mathfrak{c}$ , it follows that  $\mathfrak{c} \subset \mathfrak{g}^T$ , which is equivalent (by I, 4.7.3) to the relation

$$(*) \quad (\mathfrak{c}/\mathfrak{h})^T = 0.$$

Conversely, suppose that  $H$  contains the maximal torus  $T$  and that the preceding relation holds, i.e. that

$\frac{h}{\supseteq} \frac{c}{}$ ; I claim that  $H$  contains the centralizer  $C$  of  $T$  (which will establish (i)  $\Rightarrow$  (ii)). This follows from the:

**Lemma 2.1.1.** \*Let  $G$  be a smooth algebraic group over the field  $k$ ,  $T$  a subgroup of multiplicative type of  $G$ ,  $C$  its connected centralizer (equal to the centralizer of  $T$  if  $G$  is connected and  $T$  is a torus, (XII 6.6 b)),  $H$  a smooth subgroup of  $G$  containing  $T$ . In order that  $H$  contain  $C$ , it is necessary and sufficient that its Lie algebra  $\frac{h}{}$  contain that  $\frac{c}{}$  of  $C$ .\*

<!-- label: III.XIII.2.1.1 -->

Indeed, one knows (XI 2.4) that  $\text{Centr}_G(T)$  is smooth over  $k$ , hence  $C$  is smooth over  $k$ ; similarly  $\text{Centr}_H(T)$  is smooth over  $k$ , and  $\text{Centr}_H(T) = \text{Centr}_G(T) \cap H$  has  $\frac{h}{\cap} \frac{c}{}$  as Lie algebra; hence the hypothesis implies that the smooth subgroup  $\text{Centr}_H(T)$  of the smooth group  $\text{Centr}_G(T)$  has the same Lie algebra, so it contains the connected component  $C$  of the latter, and thus  $H$  contains  $C$ . \*QED\*.

Let us prove the equivalence of (i) and (iii), which amounts to proving that if  $H$  contains the maximal torus  $T$  of  $G$ , then the condition  $H \supseteq C$  (which is also equivalent to  $(*)$  above, as we have just seen) is equivalent to the fact that  $H$  is of finite index in its normalizer <!-- original page 257 --> and that the set of conjugates of  $H$  containing  $T$  is finite. If  $H$  contains  $C$ , hence if one has  $(*)$ , then a fortiori

```
```text
(**)  (□/□)^H = 0,
```
```

and we know that  $\frac{n}{}$  is the inverse image of the first member of the preceding relation under the canonical homomorphism  $\frac{g}{\rightarrow} \frac{g}{\backslash} \frac{h}{}$  (II 5.2.3 (i)), so that the preceding relation means, by 2.0, that  $H = N^{\{0\}}$ , and a fortiori  $H$  is of finite index in its normalizer. Now consider the diagram of subgroups

```
```text
  T  →  N(T) ∩ H  →  H
      |           |
      ↓           ↓
  N(T) ∩ N(H)  →  N(H)
      |
      ↓
    N(T).
```
```

Using the theorem of conjugacy of maximal tori in  $H$  (XII 6.6 a)), one sees that every conjugate of  $H$  containing  $T$  is a conjugate of  $H$  by an element of  $N(T)(k)$ , so the set of conjugates of  $H$  containing  $T$  is in bijective correspondence with the set of points of  $N(T)/N(T) \cap N(H)$  with values in  $k$ ; but as  $H \supseteq C$ , one has  $N(T) \cap H \supseteq C$ , hence the preceding set is a quotient of  $N(T)/C(k)$ , which is a finite set, hence is finite. This proves (i)  $\Rightarrow$  (iii). Conversely, suppose (iii), i.e.  $N(T)/N(T) \cap N(H)$  finite and  $N(H)/H$  finite. Using again the conjugacy theorem in  $H$ , one sees again that the homomorphism

```
```text
N(T) ∩ N(H)/N(T) ∩ H → N(H)/H
```
```

induced by the preceding diagram is bijective on points with values in  $k$  (in fact, it is an isomorphism), hence as the latter is finite, so is the former, so  $N(T) \cap H$  is of finite index in  $N(T)$ , hence contains  $C = N(T)^{\{0\}}$ , hence  $H \supseteq C$ . Thus (i), (i bis), (ii), (iii) are equivalent conditions.

<!-- original page 258 -->

Let us prove that (ii)  $\Rightarrow$  (vii). One sees at once that conditions (ii) and (vii) are each invariant under an extension  $k \rightarrow k'$  of the base field, with  $k'$  algebraically closed, which allows us to assume that  $k$  has infinite transcendence degree over its prime subfield. Then it is well known (and easily verified) that there exists an element  $a$  of  $T(k)$  such that the subgroup of  $T(k)$  it generates is dense in  $T$  for the Zariski topology. One easily concludes that  $\frac{g}{\backslash} \frac{h}{\wedge} T = (\frac{g}{\backslash} \frac{h}{\wedge} \text{ad}(a))^T$ , and as the first member is zero by hypothesis, one concludes (vii).

Let us prove (vii)  $\Rightarrow$  (vi). This implication is contained in the following result, which sharpens 2.1:

**Corollary 2.2.** \*Let  $G$  be a smooth algebraic group over a field  $k$ ,  $H$  a smooth algebraic subgroup,  $N$  its

normalizer in  $G$ ,  $\varphi : G \times H \rightarrow G$  the morphism defined by  $\varphi(g, h) = \text{ad}(g)h = ghg^{-1}$ ,  
 $\psi : X = G \times^N H \rightarrow G$  the morphism deduced from  $\varphi$  by passage to the quotient (cf. section 1),  
 $a \in H(k)$ . The following conditions are equivalent:\*

<!-- label: III.XIII.2.2 -->

- \*(i)  $\varphi$  is smooth at  $(e, a)$ .
- \*(ii)  $\psi$  is étale at  $(\bar{e}, a)$ , and  $N$  is smooth over  $k$ .
- \*(iii)  $(\mathfrak{g}/\mathfrak{h})^{\text{ad}(a)} = 0$  (where  $\mathfrak{g}$ ,  $\mathfrak{h}$  are the Lie algebras of  $G$ ,  $H$ ).

\*These conditions imply  $H^0 = N^0$ .\*

We know that the smoothness of  $\varphi$  (which is a morphism between smooth  $k$ -preschemes) at a  $k$ -rational point is equivalent to the surjectivity of the tangent map at that point. Now an immediate calculation shows that this tangent map is written (using the usual identifications of the tangent spaces at points of  $G$  and  $H$  with the Lie algebras of  $G$  and  $H$ )

```
```text
dφ(ξ, η) = (id - ad(a)) · ξ + η,
```

regarded as a map from $\mathfrak{g} \times \mathfrak{h}$ to $\mathfrak{g}$. <!-- original page 259 --> Surjectivity therefore amounts to the surjectivity of $(\text{id} - \text{ad}(a))$ on $\mathfrak{g}/\mathfrak{h}$, i.e. to (iii). Now (iii) implies a fortiori $(\mathfrak{g}/\mathfrak{h})^H = 0$, i.e. (cf. 2.0, where the connectedness hypothesis at the beginning of the section is unnecessary) $H^0 = N^0$. From this we deduce that N is smooth, and $\dim H = \dim N$, whence $\dim X = \dim G$. Now since $q : G \times H \rightarrow X$ is flat and $\psi \circ q = \varphi$ is smooth at (e, a) , it follows that ψ is smooth at $q(e, a) = (\bar{e}, a)$, hence étale at this point by reasons of dimension. So we have proved (i) $\Leftrightarrow$ (iii) $\Rightarrow$ (ii); on the other hand (ii) $\Rightarrow$ (i), because the smoothness of N implies that of q . *QED*.

Let us finally prove (vi) $\Rightarrow$ (i), which, together with the implications already established, will prove the theorem. Suppose first that G is affine. Let U be a non-empty open of G such that $x \in U(k)$ implies that x is contained in a conjugate of H . Let C be a Cartan subgroup of G . Using the implication (i) $\Rightarrow$ (iv) for C in place of H (this is Borel's "density theorem"), it follows that one can find a conjugate of C which meets U , so one can assume $U \cap C \neq \emptyset$, i.e. that there exists a non-empty open V in C such that for every $x \in V(k)$, x is contained in a conjugate of H . Write C as a product

```
$$
C = T \cdot C_u
$$
```

where T is the maximal torus of C (which is a maximal torus of G) and C_u is the unipotent part of C , T being in the center of C (*Bible* 6 th. 2). We can again assume that k has infinite transcendence degree over its prime subfield, which allows us to find an element t of $T(k)$ that is in the projection of V onto T (which is a non-empty open of T), i.e. $t \in C_u \cap V \neq \emptyset$, and such that t "generates" T . Since every algebraic subgroup of G containing a product $t \cdot u$ ($t \in T(k)$, $u \in C_u(k)$) contains the two factors (*Bible* 4 th. 3), it follows, with the preceding choice of t , <!-- original page 260 --> and taking $t \cdot u \in V(k)$, that there exists a conjugate of H containing t , hence T . So we may already assume that one has

```
$$
T \subset H.
$$
```

If W is the open of C_u inverse image of V by $u \mapsto t \cdot u$, one sees therefore that for every element x of $(T \cdot W)(k)$, there exists a conjugate of H containing T and x . As we have already noted, such a conjugate is of the form $\text{int}(g) \cdot H$, where $g \in N(T)(k)$. Consider then the morphism

```
```text
f : N(T) × H → G
```
```

defined by $f(g, h) = \text{int}(g) \cdot h = ghg^{-1}$; then the image of f contains $T \cdot W$, so as $N(T)$ is a finite union of translates $C \cdot g_i$ (where $g_i \in N(T)(k)$) since C is of finite index in $N(T)$, it follows that there exists a dense open V_0 of $C = T \cdot C_u$ which is contained in the image of $(C \cdot g_i) \times H$

by $\$f\$$. Replacing $\$H\$$ by $\$int(g_{\{i\}}) \cdot \$H\$$ if necessary, we may assume $\$g_{\{i\}} = e\$$, i.e.
 $\$f(C \times H) \subset V_{\{0\}}\$$. So for every $\$u \in V_{\{0\}}(k)\$, there exist $\$v \in C(k)\$ and $\$h \in H(k)\$ such that$$$

```
```text
v-1 h v = u, whence vuv-1 ∈ H(k),
```
```

hence, setting

```
```text
C0 = C ∩ H = Centr_H(T),
```
```

$\$vuv^{-1} \in C_{\{0\}}\$$, whence $\$int(v) \cdot C_{\{0\}} \subset u\$$. This proves that the union of the conjugates of $\$C_{\{0\}}\$ in $\$C\$$ (by elements of $\$C(k)\$$) is dense, which implies (as we have seen for the pair $\$(G, H)\$$ instead of $\$(C, C_{\{0\}})\$$) that $\$C_{\{0\}}\$ is of finite index in its normalizer in $\$C\$$. By *Bible* 7, lemma of section 1, it follows that $\$C_{\{0\}} = C\$$, hence $\$C = H\$$, which proves (vi) ⇒ (i) when $\$G\$$ is affine.$$

In the general case, we proceed by induction on $\$n = \dim G\$$, the assertion being trivial if $\$n = 0\$$. Let $\$Z\$$ be the center of $\$G\$$, and distinguish two cases:

1°) $\dim Z \cap H > 0\$$: then setting $\$G' = G/(Z \cap H)\$, one has $\dim G' < n\$; <!-- original page 261 --> on the other hand the hypothesis (vi) on $\$H\$$ implies the same condition for the image $\$H'\$$ of $\$H\$$ in $\$G'\$, so $\$H'\$$ contains a Cartan subgroup $\$C'\$$ of $\$G'\$, hence $\$H\$$ contains the inverse image $\$C\$$ of $\$C'\$, which is a Cartan subgroup by XII 6.6 e).$$$$$

2°) $\dim Z \cap H = 0\$$: then the canonical morphism $\$H \rightarrow G/Z\$$ is a finite morphism, and as $\$G/Z\$$ is affine by virtue of XII 6.1, it follows that $\$H\$$ is affine, hence every homomorphism from $\$H\$$ into an abelian variety is zero (and even every morphism of preschemes from $\$H\$$ to an abelian variety is zero): this follows from the fact that an affine smooth connected algebraic group over an algebraically closed field is a rational variety, or simply that it is the union of its Borel subgroups (*Bible* 6 th. 5 b)), and it follows very easily from the structure theorems *Bible* 6.2 and 6.3 that an affine smooth connected solvable group is a rational variety. Now use Chevalley's structure theorem for $\$G\$$, according to which $\$G\$$ is an extension of an abelian variety $\$A\$$ by a smooth affine group. Then the image of $\$H\$$ in $\$A\$$ is zero, $\$H\$$ being affine; on the other hand it is identical to $\$A\$$, because the union of its conjugates in $\$A\$$ must be dense. So $\$A = 0\$$, hence $\$G\$$ is affine, and we are reduced to the case already treated. This completes the proof of 2.1.

****Corollary 2.3.**** Assume that the equivalent conditions of 2.1 hold.*

<!-- label: III.XIII.2.3 -->

a) Let $\$k(X)\$$ (resp. $\$k(G)\$$) be the field of rational functions of $\$X\$$ (resp. $\$G\$$); then $\$k(X)\$$ is a finite separable extension of $\$k(G)\$$. Denote its degree by $\$d\$$.

b) Let $\$T\$$ be a maximal torus of $\$G\$$ contained in $\$H\$$ (which exists by form 2.1 (ii)), and let $\$C\$$ be the corresponding Cartan subgroup of $\$G\$$. Then $\$C \subset H\$$. On the other hand, $\$Norm_{\{G\}}(T)\$$ is a smooth subgroup of $\$G\$$ and $\$Norm_G(T) \cap Norm_G(H) = Norm_{\{Norm_G(H)\}}(T)\$ is a smooth subgroup of it, of finite index equal to $\$d\$$ (defined in a)). The number of conjugates of $\$H\$$ containing a given maximal torus or a given Cartan subgroup is equal to $\$d\$$.$

c) Let $\$U\$$ be the largest open of $\$G\$$ such that <!-- original page 262 --> $\psi : X \rightarrow G$ induces a morphism $\psi^{-1}(U) \rightarrow U$ that is finite and étale. Then $\$U\$$ is a dense open, and for $\$g \in G(k)\$, one has $\$g \in U(k)\$ if and only if there exist exactly $\$d\$$ conjugates of $\$H\$$ containing $\$g\$$, or again if and only if there exist at least $\$d\$$ distinct conjugates $\$H_{\{i\}}\$ of $\$H\$$ containing $\$g\$ such that for every $\$i\$, $\frac{g}{h_{\{i\}}} \in ad(g) = 0\$ (where $\frac{h}{i} = Lie(H_{\{i\}})\$$).$$$$$$

Assertion a) comes from the fact that ψ is generically étale (which was stated at the end of 2.1); this also implies that the open $\$U\$$ introduced in c) is non-empty, i.e. dense, and the two characterizations stated for the elements of $\$U(k)\$ (taking into account that ψ is separated, $\$X\$ integral and $\$G\$ integral normal, SGA 1 I 10.11, and that $\frac{g}{h_{\{i\}}} \in ad(g) = 0\$ means that ψ is étale at the point $\$x_{\{i\}}\$ of $\psi^{-1}(g)\$ corresponding to $\$H_{\{i\}}\$). If $\$H\$$ contains the maximal torus $\$T\$$ of $\$G\$$, then the centralizers of $\$T\$$ in $\$H\$ and $\$G\$ have the same dimension, and are smooth and connected (XII 6.6 b)), hence are equal, which proves that $\$C \subset H\$$. Moreover, one knows that the normalizer of $\$T\$$ in a smooth group containing it is smooth (XI, 2.4 bis), so $\$Norm_{\{G\}}(T)\$ and $\$Norm_{\{Norm_{\{G\}}(H)\}}(T)\$ are smooth (N.B. we have noted that $\$N = Norm_{\{G\}}(H)\$ is smooth at the end of the statement of 2.1); also $\$Norm_{\{N\}}(T)\$ contains $\$C\$$, which is of finite index in $\$N(T)\$, so it is of finite index in $\$N(T)\$. Using the theorem of conjugacy for maximal tori in $\$H\$, one sees that the index in question equals the number of conjugates of $\$H\$$ containing $\$T\$, or what amounts to the same, containing $\$C\$$. Now since the union of the conjugates of $\$C\$$ in $\$G\$ is$$$$$$$$$$$$$$$$$$

dense (by 2.1 (i) $\Rightarrow$ (vi) applied to $\mathcal{C}$ instead of $\mathcal{H}$), and the open U defined in c) is evidently stable under inner automorphisms, one sees that $\mathcal{C} \cap U \neq \emptyset$. Proceeding as in the proof of the implication (vi) $\Rightarrow$ (ii) of 2.1, one concludes that (up to a harmless change of base field) there exists $g \in (C \cap U)(k)$ such that every conjugate of $\mathcal{H}$ containing g contains $\mathcal{T}$, and hence also $\mathcal{C}$. So the conjugates of $\mathcal{H}$ containing $\mathcal{C}$ are those containing g , and as $g \in U(k)$, their number equals d , which completes the proof of b). One will note that we have in fact shown that the set of conjugates of $\mathcal{H}$ containing $\mathcal{T}$ is a homogeneous set <!-- original page 263 --> under the group of rational points of

$W_G(T) = \text{Norm}_G(T)/\text{Centr}_G(T),$

which proves in particular that

``text
 d order of the Weyl group of G .
 ``

Corollary 2.4. With the notation of 2.1, the following conditions are equivalent:

<!-- label: III.XIII.2.4 -->

- (i) $\psi : X \rightarrow G$ is a birational morphism.
- (ii) There is exactly one conjugate of $\mathcal{H}$ containing a given Cartan subgroup of G .
- (iii) $\mathcal{H}$ contains a Cartan subgroup $\mathcal{C}$ of G , and $\text{Norm}_G(H) \supset \text{Norm}_G(C)$.
- (iv) There exists a non-empty open V of G such that $g \in V(k)$ implies that g is contained in exactly one conjugate of $\mathcal{H}$.

This is clear from 2.1 and 2.3.

Corollary 2.5. Assume that the conditions of 2.4 hold, and let $g \in G(k)$. The following conditions are equivalent:

<!-- label: III.XIII.2.5 -->

- (i) $g \in U(k)$, where U is defined in 2.3 c), i.e. g is contained in exactly one conjugate of $\mathcal{H}$.
- (ii) The set of conjugates of $\mathcal{H}$ containing g is finite and non-empty.
- (iii) The scheme $\psi^{-1}(g)$ of conjugates of $\mathcal{H}$ containing g has an isolated point.
- (iv) There exists a conjugate $\mathcal{H}'$ of $\mathcal{H}$ containing g , and one has $(\frac{g}{h})^{\text{ad}(g)} = 0$, where $\frac{g}{h} = \text{Lie}(H')$.

Finally, U is also the largest open of G such that ψ induces an isomorphism $\psi^{-1}(U) \xrightarrow{\sim} U$.

<!-- original page 264 -->

The equivalence of (i), (ii), (iii) and the last assertion follow from the "Main Theorem" [N.D.E-XIII-3] applied to the birational morphism $\psi : X \rightarrow G$, given that G is normal. The equivalence of these conditions with (iv) follows at once from the last assertion of 2.1 characterizing the set of points of X at which ψ is étale.

Theorem 2.6. Let G be a smooth connected algebraic group over an algebraically closed field k , $\mathcal{C}$ a Cartan subgroup, associated to a maximal torus $\mathcal{T}$, $N = \text{Norm}_G(C) = \text{Norm}_G(T)$ (cf. XII 8.4), let $X = G \times^N C$, where N acts on the left factor G by right translations, and on the right factor C by inner automorphisms, and let $\psi : X \rightarrow G$ be the canonical morphism.

<!-- label: III.XIII.2.6 -->

a) The morphism ψ is birational.

b) Let U be the largest open of G such that ψ induces an isomorphism $\psi^{-1}(U) \xrightarrow{\sim} U$ (cf. 2.5). Let

``text
 $\rho = \rho_V(G) = \dim C$
 ``

be the nilpotent rank of G . Then for every $g \in G(k)$, the multiplicity of the eigenvalue 1 in $\text{ad}(g)$ acting on $\mathfrak{g}$ is at least equal to ρ , and for it to equal ρ , it is necessary and sufficient that $g \in U(k)$.

Proof. Since condition 2.1 (i) is satisfied, one can apply 2.4 (iii) $\Rightarrow$ (i), which establishes a). In *Bible* 7 (in the case where G is affine) the points of $U(k)$ are called the *regular points* of $G(k)$, and we shall follow this terminology, calling U the *open of regular points* of G . (N.B. The proof given in the *Bible*

<!-- original page 265 --> that the set in question is itself open is incorrect, but we have obtained it in the present Exposé under more general conditions.)

Let us prove b); for this, introduce for every $g \in G(k)$ the characteristic polynomial

```
```text
P(ad(g), t) = t^n + c_1(g) t^{n-1} + ... + c_n(g);
```
```

one sees at once (replacing k by any algebra over k) that the $c_i(g)$ come from well-determined sections

```
$$
c_i \in \Gamma(G, \mathcal{O}_G^{\otimes i}).
$$
```

When $g \in G(k)$ is an element contained in a Cartan subgroup (for example a regular element), which we may assume to be $\mathbb{C}$, then by 2.5 (iv) one sees that $(\mathfrak{g}/\mathfrak{c})^{\text{ad}(g)} = 0$ if and only if g is regular (where $\mathfrak{c}$ denotes the Lie algebra of $\mathbb{C}$); on the other hand, since $\mathbb{C}$ is nilpotent, one sees at once that $\text{ad}_{\mathfrak{c}}(g)$ has only the eigenvalue 1 , which proves that the multiplicity of the eigenvalue 1 in $\text{ad}_{\mathfrak{g}}(g)$ is $\geq \rho$, and equal exactly to $\dim C = \rho$ if and only if g is regular. In particular, the polynomial above is divisible by $(t - 1)^{\rho}$. Since the relation of divisibility by $(t - 1)^{\rho}$ is expressed by linear relations (with integer coefficients) among the coefficients of the polynomial, and these relations are satisfied for $g \in U(k)$, U being a dense open, it follows (G being reduced) that they hold for all g ; in fact one has a relation

```
```text
(t) t^n + c_1 t^{n-1} + ... + c_n = (t - 1)^{\rho} (t^{n-\rho} + b_1 t^{n-\rho-1} + ... + b_{n-\rho})
```
```

<!-- label: eq:III.XIII.2.6.dagger -->

in the ring of polynomials over $\Gamma(G, \mathcal{O}_G^{\otimes i})$; in particular for every $g \in G(K)$, $\text{ad}(g)$ has the eigenvalue 1 with multiplicity at least ρ . Moreover, we have seen that equality holds if g is regular; let us prove the converse. To this end, suppose first G affine, and write g as a product

```
$$
g = g_s g_u
$$
```

of its semisimple part and its unipotent part (*Bible* 4 section 4); then <!-- original page 266 -->

```
$$
\text{ad}(g) = \text{ad}(g_s) \text{ad}(g_u)
$$
```

is the analogous decomposition of $\text{ad}(g)$ (loc. cit. cor. to th. 3), so $\text{ad}(g)$ and $\text{ad}(g_s)$ have the same eigenvalues (counted with multiplicity); in particular the eigenvalue 1 appears with the same multiplicity in $\text{ad}(g)$ and in $\text{ad}(g_s)$.

Moreover, by *Bible* 7 th. 2 cor. 1, g is regular if and only if g_s is. Hence to prove b), we may assume $g = g_s$, i.e. g semisimple, so contained in a maximal torus by *Bible* 6 th. 5 c), and a fortiori in a Cartan subgroup – the case already treated. This proves b) in the case G affine. In the general case, let $Z = \text{Centr}(G)_{\text{red}}$; then by XII 6.6 e) the Cartan subgroups of G are the inverse images of those of $G' = G/Z$, hence g is regular in G if and only if its image g' in G' is regular in G' . On the other hand, since Z is smooth, the Lie algebra $\mathfrak{g}'$ of G' is none other than $\mathfrak{g}/\mathfrak{z}$, where $\mathfrak{z} = \text{Lie}(Z)$, and $\text{ad}(g')$ is none other than $\text{ad}(g)|_{\mathfrak{g}/\mathfrak{z}}$; hence the multiplicity of the eigenvalue 1 in $\text{ad}(g)$ equals $d = \dim Z$ plus the multiplicity of the eigenvalue 1 in $\text{ad}(g')$, whence at

once the first is equal to the nilpotent rank of G if and only if the second is equal to the nilpotent rank of G' . Thus we are reduced to the case of G' ; now G' being affine by XII 6.1, this case has already been treated. This completes the proof of 2.6.

Corollary 2.7. With the notation of the preceding proof, let

$$b = 1 + b_1 + \dots + b_{n-p} \in \Gamma(G, \mathfrak{g}_G).$$

Then the open of regular points of G is given by

$$U = G_{\{b\}}$$

III.XIII.2.7 -->

(set of points of G at which b is invertible); in particular U is an affine open if G is affine.

original page 267 -->

Corollary 2.8. Let H be a smooth connected algebraic subgroup of G containing a Cartan subgroup of G .

III.XIII.2.8 -->

a) Let C be an algebraic subgroup of H . In order that C be a Cartan subgroup of H , it is necessary and sufficient that it be a Cartan subgroup of G .

b) Let $g \in G(k)$, and let d be the integer introduced in 2.3. In order that g be a regular point of G , it is necessary and sufficient that there exist exactly d conjugates H_i of H containing g , and that for each i , g be a regular element of H_i ; or again, that there be at most d conjugates of H containing g , and that g be regular in one of them. If so, and if C is the unique Cartan subgroup of G containing g , then the conjugates of H containing g are the conjugates of H containing C .

c) Let $g \in H(k)$; in order that g be regular in G , it is necessary and sufficient that it be regular in H , and that one have $(\mathfrak{g}/\mathfrak{h})^{\text{ad}(g)} = 0$.

Let us prove a). Under either hypothesis on C , the unique maximal torus T of C is a maximal torus of H and of G (H having the same reductive rank as G); hence as $\text{Centr}_H(T) \subset \text{Centr}_G(T)$ are smooth connected groups of the same dimension, they are equal, so it amounts to the same to say that C is equal to one or the other of these two groups, which proves a).

Let us prove b). Suppose first g regular in G , let C be the unique Cartan subgroup of G containing g . Then by 2.3 b) there exist exactly d conjugates H_i of H containing C . Since $(\mathfrak{g}/\mathfrak{c})^{\text{ad}(g)} = 0$, i.e. $\text{ad}(g)$ has no eigenvalue $+1$ on $\mathfrak{g}/\mathfrak{c}$, one has a fortiori $(\mathfrak{g}/\mathfrak{h}_i)^{\text{ad}(g)} = 0$, hence by 2.3 c) there are exactly d conjugates of H containing g , namely the H_i . For such an H_i , a Cartan subgroup of H_i containing g is a Cartan subgroup of G containing g by a), hence equals C , which proves that g is regular in H_i . Conversely, suppose that there are at most d conjugates H_i of H containing g , and that g is regular in one of them, which we may assume to be H . Let us prove that g is regular in G . Since g is regular in H , it is contained in a unique Cartan subgroup C' of H ; by a) this is a Cartan subgroup of G . Let C'' be a Cartan subgroup of G containing g ; let us prove $C' = C''$ (which will prove that g is regular in G). Indeed, by 2.3 b) there exist exactly d conjugates of H containing C' , and as these latter contain g , they are necessarily the H_i , hence the H_i and in particular H contain C' . Hence C , C' are two Cartan subgroups of H (by a)) that contain the same regular element g of H , so they are equal. *QED*.

Let us prove c). Denoting by $\nu(u)$ the nullity [N.D.E-XIII-5] of $\text{id} - u$, for an endomorphism of a finite-dimensional vector space, one has

$$\nu(\text{ad}(g)|_{\mathfrak{g}/\mathfrak{c}}) = \nu(\text{ad}(g)|_{\mathfrak{g}/\mathfrak{h}}) + \nu(\text{ad}(g)|_{\mathfrak{g}/\mathfrak{h}_i}),$$

and the two terms on the right-hand side are respectively $\geq$ nilpotent rank of H (equal to the nilpotent rank

ρ of G by a) and $\geqslant 0$; hence one has $\nu(\mathrm{ad}(g)_{\mathfrak{g}}) = \rho$ if and only if $\nu(\mathrm{ad}(g)_{\mathfrak{h}}) = \rho$ and $\nu(\mathrm{ad}(g)_{\mathfrak{g}/\mathfrak{h}}) = 0$, i.e. g is regular in G if and only if g is regular in H and $\mathrm{ad}(g)_{\mathfrak{g}/\mathfrak{h}}$ has no non-zero invariants. *QED*.

Remarks 2.9. In the statement of 2.1, one cannot weaken condition (iii) by assuming only that H contains a maximal torus and is of finite index in its normalizer, even if one further requires that this normalizer be smooth, i.e. that $H = N^{\{0\}}$, and even when G is affine solvable. An example is furnished by the group G of matrices of the form

<!-- label: III.XIII.2.9 -->

$$g = \begin{pmatrix} t & a & c \\ 0 & 1 & b \\ 0 & 0 & 1 \end{pmatrix},$$

and the subgroup H of matrices of the preceding form with $b = c = 0$ (N.B. the Cartan subgroup of G is here the matrices g with $a = c = 0$).

<!-- original page 269 -->

Remarks 2.10. Let G be a smooth algebraic group over k , H a smooth algebraic subgroup, but we no longer assume H and G connected. Suppose that $H^{\{0\}}$ contains a Cartan subgroup of $G^{\{0\}}$. Then $(\mathfrak{g}/\mathfrak{h})^H \subset (\mathfrak{g}/\mathfrak{h})^{H^{\{0\}}} = 0$, hence $H^{\{0\}} = N^{\{0\}}$ (N is the normalizer of H), in particular N is smooth. However, one easily constructs examples, with G connected, where H has a connected component H_i such that for no $h \in H_i(k)$ one has $(\mathfrak{g}/\mathfrak{h})^{\mathrm{ad}(h)} = 0$, i.e. the morphism $(g, h) \mapsto \mathrm{ad}(g) \cdot h$ from $G \times H_i$ to G is étale (nor even quasi-finite) at no point (take for example for H the normalizer of the maximal torus in $\mathrm{SL}(2)_k$). Similarly, even if the image H' of H in the finite group $G' = G/G^{\{0\}}$ equals G' , it is not necessarily true that the union of conjugates of H in G is dense (take for G the semidirect product of $\mathbb{Z}/2\mathbb{Z}$ with $G^{\{0\}} = \mathrm{SL}(2)_k$ on which it acts by "symmetry", and for H the semidirect product $\mathbb{Z}/2\mathbb{Z} \cdot T$, where T is a maximal torus of $G^{\{0\}}$). On the other hand, if one does not assume a priori that $H^{\{0\}}$ contains a Cartan subgroup of $G^{\{0\}}$, but that the union of conjugates of H in G is dense, then $H^{\{0\}}$ necessarily contains a Cartan subgroup of $G^{\{0\}}$: to verify this, one may evidently suppose G connected, and it suffices to redo the proof of 2.1 (vi) $\Rightarrow$ (i), which is valid without assuming H connected.

<!-- label: III.XIII.2.10 -->

3. The case of an arbitrary base prescheme

<!-- label: III.XIII.3 -->

<!-- original page 270 -->

Suppose first that we are over a base field k , not necessarily algebraically closed. Since conditions 2.1 (i bis), (iv bis), (v), (vi) are invariant under extension of the base field, one sees by passing to the algebraic closure $\bar{k}$ of k that they are equivalent to each other, and equivalent to the fact that $H_{\bar{k}}$ contains a Cartan subgroup of $G_{\bar{k}}$. When this condition is satisfied, then (with the notation of 2.3) it will still be true that $k(X)$ is a finite separable extension of $k(G)$, of degree d independent of any extension of the base. If U is the largest open of G such that ψ induces a morphism $\psi^{-1}(U) \rightarrow U$ that is finite and étale, then the formation of U commutes with extension of the base field. If ψ is birational, then U is also the largest open of G such that ψ induces an isomorphism $\psi^{-1}(U) \xrightarrow{\sim} U$, and if then $g \in U(k)$, there exists a subgroup H' of G and only one, conjugate to H over the algebraic closure $\bar{k}$ of k , such that $H' \cap g = \{1\}$.

A point $g \in G(k)$ is said to be *regular* if it is regular as an element of $G_{\bar{k}} = G_{\bar{k}}(\bar{k})$. More generally, the construction of 2.7 gives us an open of G , whose formation commutes with any extension of the base field, called the *open of regular points* of G , which is also characterized by the fact that for every algebraically closed extension K of k and every point $g \in G(K)$, g is a regular point of G_K if and only if $g \in U(K)$. If $g \in U(k)$, [N.D.E.-XIII-6] one sees that g is contained in one and only one Cartan subgroup of G , as we shall show under more general conditions below.

Let G be a smooth, separated, finite-type prescheme in groups with connected fibers over the prescheme S ; consider the functor $\mathcal{C} : (\mathrm{Sch})^{\mathrm{c}}/S \rightarrow (\mathrm{Ens})$ defined by

```

```text
□(S′) = set of Cartan subgroups (XII 3.1) of G_{S′}.
```

```

Suppose this functor is representable by a smooth prescheme over S ; we give in XV a necessary and sufficient condition for this to be so, but we already know that this hypothesis is satisfied if G is affine over S with locally constant reductive rank (XII 3.3), or more generally if G admits locally for the fpqc topology a maximal torus (XII 7.1 a)), for example if S is the spectrum of a field. <!-- original page 271 --> Let X be the Cartan subgroup of the $\mathcal{C}$ -prescheme in groups $G_{\mathcal{C}}$, the "universal Cartan subgroup" of G . As a prescheme over S , X therefore represents the functor

```

```text
X(S′) = set of pairs (C, g), C a Cartan subgroup of G_{S′} and g a section of C over S′.
```

```

Consider the canonical projection morphism $(C, g) \mapsto g$

```

$$
\psi : X \rightarrow G.
$$

```

One then has the:

Theorem 3.1. *Under the preceding conditions on G , and with the preceding notation, let U be the set of $g \in G$ such that g is a regular element of its fiber G_s .*

<!-- label: III.XIII.3.1 -->

Then U is open, and it is also the largest open U of G such that ψ induces an isomorphism $\psi^{-1}(U) \xrightarrow{\sim} U$.

Let us first prove that U is open. From the hypothesis of representability of $\mathcal{C}$ as a smooth prescheme over S , since its structural morphism is evidently surjective, one concludes at once that G admits locally for the étale topology a Cartan subgroup, and that the nilpotent rank of the fibers of G is locally constant. The same holds for the dimension of the fibers of G , and up to localizing on S , one may assume that both are constant, say ρ and n . Consider then the Killing polynomial

```

```text
P_G(t) = t^n + c_1 t^{n-1} + ... + c_n \in A[t], where A = \Gamma(G, \mathcal{O}_G).
```

```

The restriction of this polynomial to the fibers G_s of G , and in particular to the fibers at the maximal points of S , is divisible by $(t - 1)^\rho$, which is expressed by the fact that certain linear combinations with integer coefficients of the c_i vanish on the fibers G_s . <!-- original page 272 --> When S is reduced (which we may assume in order to establish that U is open), it follows that they are themselves zero, hence the Killing polynomial itself is divisible by $(t - 1)^\rho$, say

```

```text
P_G(t) = (t - 1)^\rho (t^{n-\rho} + b_1 t^{n-\rho-1} + ... + b_{n-\rho}).
```

```

Let b be the sum of the coefficients $b_0 = 1, b_1, \dots, b_{n-\rho}$ of the second factor; then by 2.7 applied to the fibers of G , one sees that

```

$$
U = G_b,
$$

```

which indeed proves that U is open.

To prove that $\psi^{-1}(U) \rightarrow U$ is an isomorphism, we are reduced by SGA 1, I 5.7 to verifying it fiber by fiber, which reduces to the case of a base field, which we may assume algebraically closed. Then there exists a Cartan subgroup C of G , and if N is its normalizer, $\mathcal{C}$ is identified by the conjugacy theorem XII 7.1 a) and b) with G/N , and the morphism $\psi : X \rightarrow G$ considered here is none other than that defined in section 2. One concludes then by 2.6 b). The same reasoning also shows that U is the largest open of G such that ψ induces an

isomorphism $\psi^{-1}(U) \rightarrow U$.

Corollary 3.2. Under the conditions of 3.1, let g be a regular section of G , i.e. such that for every s in S , $g(s)$ is a regular point of G_s . Then there exists one and only one Cartan subgroup C of G such that g is a section of C .

<!-- label: III.XIII.3.2 -->

Indeed, the hypothesis on g means that g is a section of U , and the conclusion means that there exists a unique section of X lifting it, which is just another way of expressing that $\psi^{-1}(U) \rightarrow U$ is an isomorphism.

Note now that the open $\psi^{-1}(U)$ of the Cartan subgroup X of $G_{\mathcal{C}}$ is none other than <!-- original page 273 --> the open of X consisting of the points of X that are regular in $G_{\mathcal{C}}$ (by which we mean: regular in their fiber). One thus obtains a natural "fibration" of the dense open U of regular points of G over the prescheme $\mathcal{C}$, the fibers being dense opens of Cartan subgroups of the fibers of $G_{\mathcal{C}}$ (namely the opens of regular points in G). One finds for example the following result (which will be considerably refined in the following Exposé):

Corollary 3.3. Let G be a smooth connected algebraic group over the field k , $\mathcal{T}$ the scheme of maximal tori of G (= the scheme of Cartan subgroups of G). Then the field of functions $k(G)$ of G is isomorphic to the field of functions of a smooth connected affine nilpotent algebraic group C over the field of functions $k(\mathcal{T})$ of $\mathcal{T}$, namely $C =$ "the generic Cartan subgroup of G ". If G is affine of zero unipotent rank, i.e. if the Cartan subgroups of G_K are tori, then $k(G)$ is a unirational extension of $k(\mathcal{T})$.

<!-- label: III.XIII.3.3 -->

Of course, by "generic Cartan subgroup" of G , we mean (by abuse of language) the Cartan subgroup of $G_{k(\mathcal{T})}$ generic fiber of X over $\mathcal{T}$. It remains only to prove the last assertion of 3.3, which is contained in the following well-known result (due to Chevalley):

Lemma 3.4. Let k be a field, T a torus over k , $k(T)$ the field of rational functions on T ; then $k(T)$ is a unirational extension of k , i.e. is contained in a pure transcendental extension of k .

<!-- label: III.XIII.3.4 -->

Indeed, let k' be a finite separable extension of k that splits T (X 1.4); then $T \otimes_k k'$ is a rational variety, i.e. admits a dense open isomorphic to a dense open of affine space $\mathbb{A}^n_{k'}$; hence $T' = \prod_{\text{Spec}(k')/\text{Spec}(k)} T_{k'}/\text{Spec}(k')$ is a rational variety (because it admits a dense open isomorphic to a dense open of <!-- original page 274 --> $\prod_{\text{operatorname{Spec}}(k')/\text{operatorname{Spec}}(k)} \mathbb{A}^n_{k'}$, which is isomorphic to affine space of dimension mn over k , where $m = [k' : k]$). Consider the norm homomorphism from T' to T (defined whenever T is a commutative group scheme over k); the composite $T \rightarrow T' \rightarrow T$ is the m -th power in T , hence dominant, hence $T' \rightarrow T$ is dominant, which proves that T is unirational.

Let us return to the conditions of 3.1, but assume further that G admits, locally for the fpqc topology, a maximal torus (XII 7.1). Let Y be the maximal torus of the Cartan subgroup X of $G_{\mathcal{C}}$, so that the morphism $\psi : X \rightarrow G$ induces a morphism $Y \rightarrow G$ whose image is set-theoretically the semisimple elements of the fibers of G (XII 8). Finally, it follows from 3.1 that the restriction of ψ to the open Y_{reg} of regular points of Y induces a closed immersion

$$Y_{\text{reg}} \rightarrow U = G_{\text{reg}}.$$

Making explicit the meaning of $Z = Y_{\text{reg}}$ as a functor on S , one finds:

Corollary 3.5. Let G be a smooth, separated, finite-type S -prescheme in groups with connected fibers over the prescheme S , admitting locally for the fpqc topology a maximal torus. Let $Z : (\text{Sch})^{\text{circ}}/S \rightarrow (\text{Ens})$ be the functor defined by*

<!-- label: III.XIII.3.5 -->

```
```text
Z(S') = set of regular sections of $G_{S'}$ over S' that are contained in
 a maximal torus of $G_{S'}$.
```
```

Then Z is representable by a closed sub-prescheme, smooth over S , of the open $U = G_{\text{reg}}$ of G introduced in 3.1.

To finish, let us note the following result, which sharpens the density theorem 2.1 (i) $\Rightarrow$ (vi):

Corollary 3.6. *Under the conditions of 3.5, let C be a Cartan subgroup of G , <!-- original page 275 --> and consider the morphism*

<!-- label: III.XIII.3.6 -->

```
```text
φ : Z × C → G
```
```

defined by $\varphi(g, h) = \text{ad}(g)h = ghg^{-1}$. Then φ is dominant.

It evidently suffices to prove this fiber by fiber, which reduces us to the case where S is the spectrum of an algebraically closed field. Let T be the maximal torus of C , t_0 an element of $T(k)$ regular in G , c_0 an element of $C(k)$ regular in G ; consider $\varphi^{-1}(\varphi(t_0, c_0))$, whose k -rational points are the pairs (t, c) with $t \in Z(k)$, $c \in C(k)$, such that

```
```text
ad(t) c = ad(t_0) c_0 i.e. c = ad(t^{-1} t_0) c_0,
```
```

which are therefore in bijective correspondence with the $t \in Z(k)$ such that $\text{ad}(t^{-1} t_0) c_0 \in C$, or equivalently (since c_0 is regular) such that $t^{-1} t_0 \in N$ (normalizer of C), i.e. $t \in N$. One obtains an open and closed part of this fiber by restricting to the $t \in Z(k)$ such that $t \in C(k)$. So we have found a connected component of $\varphi^{-1}(\varphi(t_0, c_0))$ isomorphic to T (N.B. that the preceding set-theoretic reasoning indeed gives an isomorphism of schemes is seen by replacing points with values in k by points with values in an arbitrary k -prescheme); hence the generic fiber of φ is of dimension $\leq \dim T$, so $\dim(\varphi)$ is of dimension $\geq \dim Z \times C - \dim T = \dim Z + \dim C - \dim T$; now one has $\dim Z = \dim Y = \dim G - \dim T$, whence finally $\dim \text{Im}(\varphi) \geq \dim G$, so φ is dominant. *QED*.

Remarks 3.7. *One will note that the reasoning shows moreover that the connected component at (t_0, c_0) of the fiber $\varphi^{-1}(\varphi(t_0, c_0))$ is isomorphic to T , in particular is smooth over k , and has the same dimension as the generic fiber, which implies that φ is in fact smooth <!-- original page 276 --> at (t_0, c_0) (which one ought to be able to verify also by calculating the tangent map). It follows that under the conditions of 3.6 the induced morphism $Z \times_{\text{reg}} C \rightarrow G_{\text{reg}}$ (where one has set $C_{\text{reg}} = C \cap G_{\text{reg}}$) is a smooth morphism. One sees similarly that the analogous morphism $Z \times_{\text{reg}} T \rightarrow Z$ (where T is a maximal torus of G) is smooth; more generally, for every smooth connected invariant algebraic subgroup H of C containing a regular element c_0 of $G(k)$, the image of $Z \times_{\text{reg}} H \rightarrow G$ is dense in that of $G \times_{\text{reg}} H \rightarrow G$.*

<!-- label: III.XIII.3.7 -->

4. Lie algebras over a field: rank, regular elements, Cartan subalgebras

<!-- label: III.XIII.4 -->

In what follows of this Exposé, we take up the theory developed by Chevalley in his book *Théorie des Groupes de Lie III* (Act. Sc. Ind. 1226, Paris 1955), the technique of schemes allowing us to eliminate the hypothesis of characteristic zero. We begin by recalling in the present section certain well-known notions and results.

Let $\mathfrak{g}$ be a Lie algebra over a ring k . For every $a \in \mathfrak{g}$, one denotes by $\text{ad}(a)$ the endomorphism

```
```text
ad(a) · x = [a, x]
```
```

of $\mathfrak{g}$, which is a derivation of the Lie algebra $\mathfrak{g}$. Now for any derivation D of the Lie algebra $\mathfrak{g}$, the nil-space of D , i.e. the union of the kernels of the iterates of D , is a Lie subalgebra of $\mathfrak{g}$, as one sees from the Leibniz formula

```

```text

$$D^m([x, y]) = \sum_{0 \leq p \leq m} (m \text{ choose } p) [D^p x, D^{m-p} y].$$

```

```

We shall set

```

```text

$$\text{Nil}(a, \mathfrak{g}) = \text{nil-space of } \text{ad}(a) = \bigcup_{m \geq 0} \text{Ker } \text{ad}(a)^m;$$

```

```

<!-- original page 277 -->

when no confusion need be feared, we shall denote it simply $\text{Nil}(a)$, and we shall call it the **nil-space of a* (in $\mathfrak{g}$).

****Proposition 4.1.**** *For every $a \in \mathfrak{g}$, its nil-space $\text{Nil}(a, \mathfrak{g})$ is a Lie subalgebra of $\mathfrak{g}$, equal to its own normalizer.**

<!-- label: III.XIII.4.1 -->

It remains to prove that it is its own normalizer, i.e. that every element of $\mathfrak{g} / \text{Nil}$ annihilated by the adjoint representation of Nil on $\mathfrak{g} / \text{Nil}$ is zero, which is trivial (since every element in this quotient annihilated by $\text{Ad}(a)$ is zero).

In what follows of this section, we suppose that k is a field, and that $\mathfrak{g}$ is of finite dimension over k . We shall denote by $W(\mathfrak{g})$ the scheme over k defined by $\mathfrak{g}$, whose points in the k -algebra A are the elements of $\mathfrak{g} \otimes_k A$. If $a \in \mathfrak{g}$, the characteristic polynomial of $\text{ad}(a)$ is also called the **characteristic polynomial** or **Killing polynomial** of a in $\mathfrak{g}$, namely

```

```text

$$P_{\mathfrak{g}}(a, t) = t^n + c_1(a) t^{n-1} + \dots + c_n(a),$$

```

```

where $n = \text{rank}_k \mathfrak{g}$, the $c_i(a) \in k$. Taking this polynomial also for $a \in \mathfrak{g} \otimes_k A$, [N.D.E-XIII-8] where A is any k -algebra, one sees that the $c_i(a)$ come from well-determined sections c_i of the structural sheaf of $W(\mathfrak{g})$, i.e. from elements of the symmetric algebra $A = \text{Sym}_k(\mathfrak{g}^{\vee})$, where $\mathfrak{g}^{\vee}$ is the dual of the k -module $\mathfrak{g}$. (When k is an infinite field, the c_i are determined by knowing the corresponding polynomial functions $\mathfrak{g} \rightarrow k$, but this is no longer the case if k is a finite field.) Let r be the largest integer such that the Killing polynomial

```

```text

$$P_{\mathfrak{g}}(t) = t^n + c_1 t^{n-1} + \dots + c_n \in A[t]$$

```

```

is divisible by t^r , i.e. one has:

```

```text

$$P_{\mathfrak{g}}(t) = t^n + c_1 t^{n-1} + \dots + c_{n-r} t^r, \quad c_{n-r} \neq 0.$$

```

```

<!-- original page 278 -->

The integer r is called the **nilpotent rank** of the Lie algebra $\mathfrak{g}$. It is invariant under extension of the base field.

****Proposition 4.2.**** *Let r be the nilpotent rank of $\mathfrak{g}$, and $a \in \mathfrak{g}$. Then one has**

<!-- label: III.XIII.4.2 -->

```

```text

$$\text{rank}_k \text{Nil}(a, \mathfrak{g}) \leq r,$$

```

```

with equality if and only if

$c_{n-r}(a) \neq 0$.

*In this case, $\mathfrak{Nil}(a, \mathfrak{g})$ is a nilpotent Lie algebra (and we shall see in 5.7 b) the converse, when $\mathfrak{g}$ is the Lie algebra of an algebraic group G smooth over k).

The first assertion is trivial, since by definition $\text{rank}_k \mathfrak{Nil}(a, \mathfrak{g}) =$ multiplicity of the zero root in $P_{\mathfrak{g}}(a, t)$. Let us prove that if $c_{n-r}(a) \neq 0$, then $\mathfrak{Nil}(a)$ is nilpotent, which also means that for every $x \in \mathfrak{Nil}(a)$, $\text{ad}_{\mathfrak{Nil}(a)}(x)$ is a nilpotent endomorphism. One may assume k algebraically closed; then as $\text{ad}_a : \mathfrak{g}/\mathfrak{Nil}(a) \rightarrow \mathfrak{g}/\mathfrak{Nil}(a)$ is injective, there exists a non-empty open U of $W(\mathfrak{Nil}(a))$ such that for every $x \in U(k)$, $\text{ad}(x) : \mathfrak{g}/\mathfrak{Nil}(a) \rightarrow \mathfrak{g}/\mathfrak{Nil}(a)$ is injective, hence $\mathfrak{Nil}(x) \subset \mathfrak{Nil}(a)$; one may further suppose U contained in the open of points where c_{n-r} does not vanish (since this open is non-empty by $c_{n-r}(a) \neq 0$), and then $\mathfrak{Nil}(x)$ having the same dimension as $\mathfrak{Nil}(a)$, one will have $\mathfrak{Nil}(x) = \mathfrak{Nil}(a)$. Consequently, for every $x \in U(k)$, $\text{ad}(x) : \mathfrak{g}/\mathfrak{Nil}(a) \rightarrow \mathfrak{g}/\mathfrak{Nil}(a)$ is nilpotent, and by the principle of extension of algebraic identities, this remains true for every $x \in \mathfrak{Nil}(a)$, hence $\mathfrak{Nil}(a)$ is nilpotent.

One says that the element a of $\mathfrak{g}$ is *regular* if $c_{n-r}(a) \neq 0$, i.e. if $\text{rank}_k \mathfrak{Nil}(a, \mathfrak{g}) = r$. When k is infinite, this also means that $\text{rank}_k \mathfrak{Nil}(a, \mathfrak{g})$ is the smallest possible (original page 279) (for a varying in $\mathfrak{g}$). In any case, the notion of regular element of $\mathfrak{g}$ is invariant under extension of the base field, and the set of points of $W(\mathfrak{g})$ that are regular (i.e. that come from regular points of $W(\mathfrak{g})$ with values in a suitable extension of k) is open, since identical to $W(\mathfrak{g})_{c_{n-r} \neq 0}$ (set of points where c_{n-r} is invertible).

Corollary 4.3. *Let a be a regular element of $\mathfrak{g}$, and $\mathfrak{h}$ a Lie subalgebra of $\mathfrak{g}$ containing a . Then $\mathfrak{h}$ is nilpotent if and only if $\mathfrak{h} \subset \mathfrak{Nil}(a, \mathfrak{g})$; in particular, $\mathfrak{Nil}(a, \mathfrak{g})$ is a maximal nilpotent subalgebra of $\mathfrak{g}$.*

<!-- label: III.XIII.4.3 -->

Since $\mathfrak{Nil}(a)$ is nilpotent, the relation $\mathfrak{h} \subset \mathfrak{Nil}(a)$ indeed implies that $\mathfrak{h}$ is nilpotent; and conversely, if $\mathfrak{h}$ is nilpotent, it is contained in the nil-space of its element a , i.e. $\mathfrak{h} \subset \mathfrak{Nil}(a)$.

Proposition 4.4. *Suppose k infinite. Let $\mathfrak{d}$ be a Lie subalgebra of $\mathfrak{g}$. Consider the following conditions:

<!-- label: III.XIII.4.4 -->

- (i) $\mathfrak{d}$ is maximal nilpotent and contains a regular element of $\mathfrak{g}$.*
- (i bis) $\mathfrak{d}$ is of the form $\mathfrak{Nil}(a, \mathfrak{g})$, where a is a regular element of $\mathfrak{g}$.*
- (ii) $\mathfrak{d}$ is nilpotent and of the form $\mathfrak{Nil}(a, \mathfrak{g})$, where $a \in \mathfrak{g}$.*
- (ii bis) $\mathfrak{d}$ is nilpotent, and there exists $a \in \mathfrak{d}$ such that $\text{ad}_a : \mathfrak{g}/\mathfrak{d} \rightarrow \mathfrak{g}/\mathfrak{d}$ is injective.*
- (iii) $\mathfrak{d}$ is nilpotent and identical to its own normalizer.*

*One has the implications:

$$(i) \Leftrightarrow (i \text{ bis}) \Rightarrow (ii) \Leftrightarrow (ii \text{ bis}) \Leftrightarrow (iii)$$

*(and we shall see in 5.7 a) that if $\mathfrak{g}$ is the Lie algebra of a smooth algebraic group, then all the preceding conditions are equivalent).

<!-- original page 280 -->

The equivalence of (i) and (i bis) is trivial by 4.3, and these conditions trivially imply (ii). The equivalence of (ii) and (ii bis) is also trivial, as is (ii bis) $\Rightarrow$ (iii) (cf. 4.1). It remains to prove the implication (iii) $\Rightarrow$ (ii bis), the only one moreover that uses the fact that k is infinite, and which follows at once from:

Lemma 4.5. *Let $\mathfrak{d}$ be a nilpotent Lie algebra over an infinite field k , acting on a finite-dimensional vector space V . Suppose that for every $x \in \mathfrak{d}$, the endomorphism $u(x)$ is non-injective. Then there

exists a non-zero element v of V annihilated by $\frac{d}{dx}$.

<!-- label: III.XIII.4.5 -->

One may suppose k algebraically closed and $\frac{d}{dx}$ of finite dimension. One knows then that V is a direct sum of finitely many non-zero stable subspaces V_i ($1 \leq i \leq n$), such that for every i , and every $x \in \frac{d}{dx}$, $u(x)|V_i$ has a single eigenvalue $\lambda_i(x)$ (cf. Bourbaki, *Groupes et Algèbres de Lie*, Chap. I, §4, Exercise 22). Let $c_i(x)$ be the constant term of the characteristic polynomial of $u(x)|V_i$, so that $\lambda_i(x) = 0$ if and only if $c_i(x) = 0$. Then c_i is a polynomial function on $\frac{d}{dx}$, and the hypothesis means that $\frac{d}{dx}$ is the union of the sets of zeros of the c_i . So one of the c_i is zero, which reduces us (replacing V by V_i) to the case where V is such that the $u(x)$ ($x \in \frac{d}{dx}$) are nilpotent. But then Engel's theorem (Bourbaki loc. cit. th. 1) implies that there exists a non-zero v in V annihilated by $\frac{d}{dx}$. *QED*.

One sees easily that (k being always an infinite field) conditions (i) (i bis) of 4.4 are invariant under any extension of the base field. If they are satisfied, one will say that $\frac{d}{dx}$ is a *Cartan subalgebra* of $\frac{d}{dx}$; in the general case (k not necessarily infinite) one will say that $\frac{d}{dx}$ is a Cartan subalgebra of $\frac{d}{dx}$ if it becomes a Cartan subalgebra under one (and hence any) extension of the base field k to k' , with k' infinite. This thus implies that $\frac{d}{dx}$ is nilpotent and equal to its own normalizer.

<!-- original page 281 -->

Proposition 4.6. *a) Let a be an element of $\frac{d}{dx}$. If a is regular, it is contained in one and only one Cartan subalgebra of $\frac{d}{dx}$ (and we shall see in 6.1 d) the converse when k is algebraically closed and $\frac{d}{dx}$ is the Lie algebra of a smooth algebraic group).*

<!-- label: III.XIII.4.6 -->

b) Let $\frac{d}{dx}$ be a Cartan subalgebra of $\frac{d}{dx}$, a an element of $\frac{d}{dx}$; then a is regular in $\frac{d}{dx}$ if and only if $\text{ad}(a)|_{\frac{d}{dx} \setminus \frac{d}{dx}}$ is injective.

Indeed, for a) one notes that if a is regular, then $\text{Nil}(a, \frac{d}{dx})$ is a Cartan subalgebra of $\frac{d}{dx}$ (because this is true over an infinite extension k' of k), and it follows then at once from 4.3 that every Cartan subalgebra of $\frac{d}{dx}$ containing a is identical to the preceding one. For b) one notes that the nullity [N.D.E-XIII-9] of $\text{ad}(a)|_{\frac{d}{dx}}$ is equal to the sum of the nullities of $\text{ad}(a)|_{\frac{d}{dx}}$ and of $\text{ad}(a)|_{\frac{d}{dx} \setminus \frac{d}{dx}}$, and as the first equals r , the sum is equal to r if and only if $\text{ad}(a)|_{\frac{d}{dx} \setminus \frac{d}{dx}}$ is injective. *QED*.

Corollary 4.7. *Let a be a regular element of $\frac{d}{dx}$, $\frac{d}{dx}$ a Cartan subalgebra of $\frac{d}{dx}$ containing a , A an algebra over k , $\frac{d}{dx}_A$ and $\frac{d}{dx}_A \subset \frac{d}{dx}_A$ the A -Lie algebras deduced from $\frac{d}{dx}$, $\frac{d}{dx}$ by base change, a_A the image of a in $\frac{d}{dx}_A$. Let u be an automorphism of $\frac{d}{dx}_A$. In order that $u(\frac{d}{dx}_A) = \frac{d}{dx}_A$, it is necessary and sufficient that one have $u(a_A) \in \frac{d}{dx}_A$.*

<!-- label: III.XIII.4.7 -->

The condition is trivially necessary; let us prove that it is also sufficient. If it is satisfied, then $\frac{d}{dx}' = u(\frac{d}{dx}_A)$ is a Lie subalgebra containing a_A , and every element b of which is such that $\text{ad}(b)|_{\frac{d}{dx}'}$ is nilpotent (because $\frac{d}{dx}'$ is isomorphic to $\frac{d}{dx}_A$, which has this property, as follows at once from the definition of "nilpotent" in Bourbaki, *Groupes et Algèbres de Lie*, Chap. I, §4, def. 1). Taking $b = a_A$, one sees that the nil-space $\text{Nil}(b, \frac{d}{dx}_A)$ contains $\frac{d}{dx}'$; on the other hand it is equal to $\frac{d}{dx}_A$, and as $\frac{d}{dx}$ is locally a direct factor in the module $\frac{d}{dx}_A$ ($\frac{d}{dx}$ being so), hence in $\frac{d}{dx}_A$, and as it is a projective module of the same rank r as the latter, one concludes that it equals it. *QED*.

Proposition 4.8. *Let $\frac{d}{dx}$ be a Lie subalgebra of $\frac{d}{dx}$.*

<!-- label: III.XIII.4.8 -->

<!-- original page 282 -->

a) The following conditions are equivalent if k is infinite:

- *(i) $\frac{d}{dx}$ contains a Cartan subalgebra $\frac{d}{dx}$ of $\frac{d}{dx}$.*
- *(ii) $\frac{d}{dx}$ contains a regular element a of $\frac{d}{dx}$, and an element b such that

$\text{ad}(b)_{\mathfrak{g}/\mathfrak{h}}$ is injective.*

(iii) $\mathfrak{h}$ has the same nilpotent rank as $\mathfrak{g}$, and contains a regular element of $\mathfrak{g}$.

These conditions are invariant under extension of the base field k .

b) Suppose these conditions are satisfied over a suitable infinite extension k' of k . Let $a \in \mathfrak{h}$; then a is regular in $\mathfrak{g}$ if and only if it is regular in $\mathfrak{h}$ and $\text{ad}(a)_{\mathfrak{g}/\mathfrak{h}}$ is injective, i.e. if and only if $\text{Nil}(a, \mathfrak{h}) = \text{Nil}(a, \mathfrak{g})$ and this is a Cartan subalgebra of $\mathfrak{h}$.*

c) Under the conditions of b), let $\mathfrak{d}$ be a Lie subalgebra of $\mathfrak{h}$; in order that it be a Cartan subalgebra of $\mathfrak{h}$, it suffices that it be a Cartan subalgebra of $\mathfrak{g}$ (and we shall see in 5.8 that the condition is also necessary if $\mathfrak{g}$ is the Lie algebra of a smooth algebraic group G , and $\mathfrak{h}$ the Lie algebra of a smooth algebraic subgroup H of G).*

One sees at once that conditions (ii) and (iii) of a) are invariant under extension of the base field k (assumed infinite), and that in statements b) and c), one may assume k infinite, which we shall do. If $\mathfrak{h}$ contains the Cartan subalgebra $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$, then a is a regular element of $\mathfrak{g}$ such that $\text{ad}(a)_{\mathfrak{g}/\mathfrak{h}}$ is injective, hence (i) $\Rightarrow$ (ii). Conversely, if (ii) is satisfied, then for an element a "sufficiently general" of $\mathfrak{h}$, a satisfies simultaneously the two conditions of (ii), hence $\text{Nil}(a, \mathfrak{g})$ is a Cartan subalgebra of $\mathfrak{g}$ and is contained in $\mathfrak{h}$, so one has (i). So (i) and (ii) are equivalent. Suppose them satisfied, let a be a variable element of $\mathfrak{h}$; then

<!-- original page 283 -->

```
```text
(*) rank_k Nil(a, $\mathfrak{h}$) = rank_k Nil(a, $\mathfrak{d}$) + rank_k Nil(ad(a)_{\mathfrak{g}/\mathfrak{h}}),
```

on the other hand, the two terms of the right-hand side are respectively  $\geq r_0 =$  nilpotent rank of  $\mathfrak{h}$ , and  $\geq 0$ , the equalities being moreover attained [N.D.E.-XIII-10] for an element "sufficiently general" of  $\mathfrak{h}$ . Moreover, one has also  $\text{rank}_k \text{Nil}(a, \mathfrak{g}) \geq r =$  nilpotent rank of  $\mathfrak{g}$ , with equality attained for an element "sufficiently general" of  $\mathfrak{h}$ , and attained if and only if  $a$  is regular in  $\mathfrak{g}$ . One concludes from this that one has  $r = r_0$ , and that  $a$  is regular if and only if the two terms of the right-hand side of (\*) equal respectively  $r_0$  and  $0$ , i.e. if and only if  $a$  is regular in  $\mathfrak{h}$  and  $\text{ad}(a)_{\mathfrak{g}/\mathfrak{h}}$  is injective, which proves b), and c) follows trivially by taking an element  $a$  in  $\mathfrak{d}$  regular in  $\mathfrak{g}$ , so that  $\text{Nil}(a, \mathfrak{g}) = \mathfrak{d}$ . Moreover, the preceding result shows that (i)  $\Rightarrow$  (iii); finally (iii)  $\Rightarrow$  (i), because under (iii), an element sufficiently general  $a$  of  $\mathfrak{h}$  is regular in  $\mathfrak{h}$  and in  $\mathfrak{g}$ , hence  $\text{Nil}(a, \mathfrak{h}) \subset \text{Nil}(a, \mathfrak{g})$  are respectively Cartan subalgebras of  $\mathfrak{h}$  and of  $\mathfrak{g}$ , and as they have the same rank over  $k$ , they are identical, which proves (i). This completes the proof of 4.8.

## 5. The case of the Lie algebra of a smooth algebraic group: density theorem

<!-- label: III.XIII.5 -->

Let  $G$  be a smooth algebraic group over the field  $k$ , and  $\mathfrak{g}$  its Lie algebra. Let  $\mathfrak{h}$  be a Lie subalgebra of  $\mathfrak{g}$ . Let  $G$  act on  $W(\mathfrak{g})$  by the adjoint representation, and consider the subscheme  $W(\mathfrak{h})$ . The construction of section 1 leads us to introduce

```
$$
N = \text{Norm}_{\mathfrak{g}}(\mathfrak{h}) = \text{Norm}_{\mathfrak{g}}(W(\mathfrak{h})),
$$
```

which is an algebraic subgroup of  $G$  (not necessarily smooth),

```
$$
\mathfrak{h} = \text{Lie}(N),
$$
```

<!-- original page 284 -->

and the scheme

```

```text
X = G ×N W(□)
```

```

quotient of  $\tilde{X} = G \times W(\mathfrak{h})$  by  $N$  acting on the right by  $(g, x) \cdot n = (gn, \text{Ad}(n^{-1})x)$ . We consider the canonical morphisms

```

```text
      G × W(□)
      |      \
      q       ϕ
      |       \
      v       ↘
      X  →  ψ  W(□).
```

```

**Theorem 5.1.** With the preceding notation, suppose  $k$  infinite. Consider the following conditions:

III.XIII.5.1

- (i)  $\mathfrak{h}$  contains a Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}$ .
- (ii) There exists  $a \in \mathfrak{h}$  such that  $\text{ad}(a)|_{\mathfrak{h}}$  is injective.
- (iii)  $\varphi : G \times W(\mathfrak{h}) \rightarrow W(\mathfrak{g})$  is generically smooth.
- (iv) The preceding morphism  $\varphi$  (or also  $\psi : X \rightarrow W(\mathfrak{g})$ ) is dominant, and  $\mathfrak{h}$  has the same nilpotent rank as  $\mathfrak{g}$ .
- (v)  $\psi : X \rightarrow W(\mathfrak{g})$  is generically smooth and  $\mathfrak{h} = \mathfrak{n}$ .
- (vi)  $\psi : X \rightarrow W(\mathfrak{g})$  is dominant, and  $\mathfrak{h} = \mathfrak{n}$ .
- (vii)  $\psi : X \rightarrow W(\mathfrak{g})$  is dominant.
- (viii)  $\psi : X \rightarrow W(\mathfrak{g})$  is dominant, and  $N$  is smooth.
- (ix)  $\psi : X \rightarrow W(\mathfrak{g})$  is dominant, and  $\mathfrak{h} = \mathfrak{n}$ , and  $\mathfrak{h}$  is the Lie algebra of a smooth algebraic subgroup  $H$  of  $G$ .
- (x)  $\psi : X \rightarrow W(\mathfrak{g})$  is generically quasi-finite, and  $\mathfrak{n} = \mathfrak{h}$ .
- (xi)  $\psi : X \rightarrow W(\mathfrak{g})$  is generically étale, and  $\mathfrak{n} = \mathfrak{h}$ .
- (xii) There exists a smooth algebraic subgroup  $H$  of  $G$  with Lie algebra  $\mathfrak{h}$ , and  $\mathfrak{h}$  contains a Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}$ .
- (xiii) There exists  $a \in \mathfrak{h}$  such that  $\mathfrak{N}$  and the transporter  $M_a$  of  $a$  to  $\mathfrak{h}$  (cf. section 1) coincide

One then has the following diagram of implications:

```

```text
(xi) ⇔ (xii) ⇔ (xiii) ⇔ (viii) ⇔ (ix) ⇔ (x)
      |
      v
(i) ⇔ (ii) ⇔ (iii) ⇔ (iv) ⇔ (v) ⇔ (vi) ⇔ (vii).
```

```

When  $k$  is of characteristic zero, all the conditions considered are equivalent. Finally, one has

```

```text
(xi) ⇔ [(i) and (viii)] ⇔ [(v) and (viii)].
```

```

Let us first note the trivial implications:

```

```text
(v) ⇔ (vi) ⇔ (vii),    (ix) ⇔ (vi),    (xi) ⇔ [(x) and (v)].
```

```

Let us prove the equivalence of conditions (i) to (iv) and that they imply (v). The implication (i)  $\Rightarrow$  (ii) is trivial. On the other hand (iii) means, when  $k$  is algebraically closed, that there exists a  $k$ -rational point of  $G \times W(\mathfrak{h})$  at which the tangent map to  $\varphi$  is surjective, and one sees at once that this point may be taken of the form  $(e, a)$ , where  $a \in \mathfrak{h}$  (up to transforming it by an operation of  $G(k)$ ). One concludes that if  $k$  is infinite (not necessarily algebraically closed) this condition (evidently sufficient) of generic smoothness is still necessary. Now the tangent map is easily calculated: identifying the tangent space to

$W(\frac{h}{g})$  at  $a$  with  $\frac{h}{g}$ , it is the map

```
```text
( $\xi$ ,  $x$ )  $\mapsto$  [ $\xi$ ,  $a$ ] +  $x$ 
```

from $\frac{g}{h} \times \frac{h}{g}$ to $\frac{g}{g}$. To say that it is surjective also means that $\text{ad}(a)_\frac{g}{h}$ is surjective, or what amounts to the same, injective. This proves the equivalence of conditions (ii) and (iii). Moreover, (ii) evidently implies $\frac{h}{g} = \frac{n}{g}$, and (iii) implies that ψ is generically smooth, <!-- original page 286 --> since if φ is smooth at a point u , it follows (q being flat) that ψ is smooth at $q(u)$. So (ii), (iii) imply (v). Let us prove that they imply (i). For this, note that since ψ is dominant, and the set of regular points of $\frac{g}{g}$ is open dense, it follows that $\frac{h}{g}$ contains regular elements of $\frac{g}{g}$, hence a "sufficiently general" element b of $\frac{h}{g}$ is regular in $\frac{g}{g}$ and satisfies $\text{ad}(b)_\frac{g}{h}$ injective, so $\text{Nil}(b, \frac{g}{g}) \subset \frac{h}{g}$, hence $\frac{h}{g}$ contains the Cartan subalgebra $\frac{d}{g} = \text{Nil}(b, \frac{g}{g})$. So (i), (ii), (iii) are equivalent; finally (i) $\Leftrightarrow$ (iv), since we have already noted that if $\frac{h}{g}$ contains a Cartan subalgebra, it has the same rank as $\frac{g}{g}$ (4.6), so (i) $\Rightarrow$ (iv); conversely, if (iv) is satisfied, then $\frac{h}{g}$ contains a regular element of $\frac{g}{g}$, and since it has the same rank as $\frac{g}{g}$, it contains a Cartan subalgebra by 4.6.

Let us prove the equivalence of conditions (viii) to (x). Let us first remark the following facts:

Lemma 5.2. a) If N is smooth, then*

```
<!-- label: III.XIII.5.2 -->
```

```
```text
dim $X \square$ dim G ,
```

\*with equality if and only if  $\frac{h}{g} = \frac{n}{g}$ .\*

b) If  $\frac{h}{g} = \frac{n}{g}$ , then\*

```
```text
dim  $X \square$  dim  $G$ ,
```

with equality if and only if N is smooth.

These assertions follow at once from the formula

```
```text
dim $X = \dim G - \dim N + \dim_k \square$,
```

and from the fact that  $\dim N = \dim_k \frac{n}{g}$  is equivalent to  $N$  smooth.

```
<!-- original page 287 -->
```

This established, (viii)  $\Rightarrow$  (x), since (viii) implies  $\dim X \geq \dim G$ , hence by 5.2 a) the equality of these dimensions and  $\frac{h}{g} = \frac{n}{g}$ , hence (x); and one sees similarly (x)  $\Rightarrow$  (viii) by applying 5.2 b). On the other hand, (viii) implies (ix), since it implies  $\frac{h}{g} = \frac{n}{g}$ , hence  $\frac{h}{g}$  is the Lie algebra of the smooth algebraic subgroup  $N$  of  $G$ ; and conversely (ix)  $\Rightarrow$  (viii), since  $H$  normalizes its Lie algebra  $\frac{h}{g}$ , so it is contained in  $N$ , and as  $H$  is smooth and has the same Lie algebra as  $N$ , it follows that  $N$  is smooth.

Let us finally prove the equivalence of conditions (xi), (xii), (xiii) and the fact that they entail (iii) (which will complete the establishment of our diagram of implications). One has (xi)  $\Leftrightarrow$  (xiii), since if  $\frac{n}{g} = \frac{h}{g}$ , then by 5.2 b) one has  $\dim X \geq \dim G$ , hence (xi) is then equivalent (given that  $W(\frac{g}{g})$  is normal) to the fact that  $\psi$  is generically unramified, which is equivalent also to (xiii) by (1.1 (ii)  $\Leftrightarrow$  (iii)), proceeding as above for the proof of (ii)  $\Leftrightarrow$  (iii). Since (xi)  $\Rightarrow$  (x)  $\Rightarrow$  (viii) by what we have seen, one sees that (xi) implies that  $N$  is smooth, i.e.  $q : G \times W(\frac{h}{g}) \rightarrow X$  is smooth, hence the composite  $\varphi = \psi \circ q$  is generically smooth, i.e. one has (iii). Since (iii)  $\Rightarrow$  (i), it also follows that (xi)  $\Rightarrow$  (xii). [N.D.E-XIII-11] Finally (xii)  $\Rightarrow$  (xi), since one evidently has (xii)  $\Rightarrow$  (i), so as one has seen (i)  $\Rightarrow$  (iii)

$\Rightarrow (v)$ , one has  $(xii) \Rightarrow (v)$ ; it follows that one has also  $(xii) \Rightarrow (ix)$ , and as one has seen  $(ix) \Rightarrow (x)$ , it follows that  $(xii) \Rightarrow ((v) \text{ and } (x))$ , hence  $(xii) \Rightarrow (xi)$  since generically étale = generically smooth + generically quasi-finite.

Finally, when  $k$  is of characteristic 0, then  $(vii) \Rightarrow (viii)$ , since by a theorem of Cartier,  $N$  is automatically smooth (VI.B 1.6.1), and  $[(viii) \text{ and } (x)] \Rightarrow (xi)$ , since in characteristic zero, for a morphism of integral preschemes, generically étale = dominant and generically quasi-finite. This shows that in this case, all the conditions (i) to (xiii) are equivalent.

<!-- original page 288 -->

**Corollary 5.3.** Under the equivalent conditions (viii) to (x), there exists a unique smooth connected algebraic subgroup  $H$  of  $G$  whose Lie algebra is  $\mathfrak{h}$ , and one has\*

<!-- label: III.XIII.5.3 -->

```
```text
Norm_G(H) = Norm_G(□) = N,    H = N°.
```
```

Indeed,  $H = N^{\{0\}}$  will satisfy the required conditions; on the other hand if  $H$  satisfies them, then (since  $H$  normalizes its Lie algebra  $\mathfrak{h}$ ) one has  $H \subset N$ , hence as this is an inclusion of smooth groups having the same Lie algebra, with  $H$  connected, one will have  $H = N^{\{0\}}$ . For the identity  $\text{Norm}_G(H) = \text{Norm}_G(\mathfrak{h})$ , one may assume  $k$  algebraically closed; then from what one has just seen, it follows immediately that the points of the two groups with values in  $k$  are the same; on the other hand the inclusions  $H \subset \text{Norm}_G(H) \subset N$  show that  $\text{Norm}_G(H)$  and  $N$  have the same Lie algebra, hence they are identical.

**Corollary 5.4.** Under the equivalent conditions (i) to (iv), let  $a \in \mathfrak{h}$ . Then the following conditions are equivalent, and are realized if  $a$  is regular in  $\mathfrak{g}$ :

<!-- label: III.XIII.5.4 -->

- (i)  $\varphi$  is smooth at  $(e, a)$ .
- (ii)  $M_a = \text{Transp}_G(a, \mathfrak{h})$  is smooth at  $e$ , and  $\dim_e(M_a) = \text{rank}_k \mathfrak{h}$ .
- (iii)  $\text{ad}(a)_{\mathfrak{h}}$  is injective (or again, bijective).

When one is under the equivalent conditions (xi) to (xiii), let  $H$  be the algebraic subgroup of  $G$  considered in 5.3. Then the preceding conditions are also equivalent to the following conditions:

- (iv)  $\psi$  is étale at  $(\bar{e}, a)$ .
- (v) Denoting by  $M^{\{0\}}_a$  the connected component of  $e$  in the transporter  $M_a$  of  $a$  to  $\mathfrak{h}$ ,  
 <!-- original page 289 --> endowed with the structure induced by  $M_a$ , one has\*

```
$$
H = M^{\{0\}}_a.
$$
```

Evidently (i)  $\Rightarrow$  (ii) since  $M_a$  is isomorphic to the fiber  $\varphi^{-1}(a)$ , the point  $e$  corresponding to  $(e, a)$ ; and one has (ii)  $\Rightarrow$  (i), since (ii) implies that  $\varphi$  is "equidimensional" at  $(e, a)$  (i.e. the dimension of the fiber passing through this point equals that of the generic fiber), which implies  $(G \times W(\mathfrak{h}))$  and  $W(\mathfrak{g})$  being regular) that it is flat at  $(e, a)$ , hence smooth since its fiber is at this point. The equivalence of (i) and (iii) has been seen in the proof of 5.1 as resulting from the simple calculation of the tangent map. Moreover, one has seen in 4.8 b) that " $a$  regular in  $\mathfrak{g}$ "  $\Rightarrow$  (iii). Under conditions (xi) to (xiii), since  $q : G \times W(\mathfrak{h}) \rightarrow X$  is smooth ( $N$  being smooth), it follows that (i) is equivalent to  $\psi$  smooth at  $(\bar{e}, a)$ , and as  $\psi$  is generically étale, this is equivalent to (iv). Finally, as was noted at the end of the proof of 1.1, (iv) implies that  $N$  is the prescheme induced on  $M_a$  by an open and closed part of  $M_a$ , whence (v); finally (v)  $\Rightarrow$  (ii) trivially (or again (v)  $\Rightarrow$  (iv) by 1.1, since  $\psi$  is dominant and  $W(\mathfrak{g})$  normal, "unramified" is here equivalent to "étale"). This completes the proof of 5.4.

**Corollary 5.5.** Let  $G$  be a smooth algebraic group over a field  $k$ ,  $H$  a smooth algebraic subgroup such that its Lie algebra  $\mathfrak{h}$  contains (at least over a suitable extension of  $k$ ) a Cartan subalgebra of the Lie algebra  $\mathfrak{g}$  of  $G$ . Let  $K$  be a connected algebraic subgroup of  $G$  (not necessarily smooth), with Lie algebra  $\mathfrak{k}$ ; suppose that  $\mathfrak{k}$  contains a regular element  $a$  of  $\mathfrak{g}$  (at least over a suitable extension of  $k$ ). Then  $H$  contains  $K$  if and only if  $\mathfrak{h}$  contains  $\mathfrak{k}$ .

<!-- label: III.XIII.5.5 -->

Indeed, by 5.4 (iii)  $\Rightarrow$  (v) one has  $H = M^{\{0\}}_a$  (N.B. of course, this relation being invariant under extension of the base field, it is valid without the hypothesis that the latter be infinite!); on the other hand  $\mathfrak{k} \subset \mathfrak{h}$  evidently implies  $K \subset M_a$ , hence as  $K$  is connected,  $K \subset M^{\{0\}}_a$ , whence  $K \subset H$ . \*QED\*.

<!-- original page 290 -->

**Corollary 5.6.** \*Let  $G$ ,  $H$  be as in 5.5, and let  $K$  be an algebraic subgroup of  $G$ ; suppose  $H$  connected and  $K$  smooth. Then  $K$  contains  $H$  if and only if  $\mathfrak{k}$  contains  $\mathfrak{h}$ .\*

<!-- label: III.XIII.5.6 -->

Indeed, if  $\mathfrak{k} \supset \mathfrak{h}$ , then  $K$  satisfies the hypothesis considered in 5.5 for  $H$ ; on the other hand  $H$  evidently satisfies the condition considered for  $K$  in 5.5. The conclusion then follows from 5.5.

**Corollary 5.7.** \*Let  $\mathfrak{g}$  be the Lie algebra of a smooth algebraic group  $G$  over a field  $k$ . Then:\*

<!-- label: III.XIII.5.7 -->

a) Let  $\mathfrak{d}$  be a Lie subalgebra of  $\mathfrak{g}$ . In order that  $\mathfrak{d}$  be a Cartan subalgebra, it is necessary and sufficient that  $\mathfrak{d}$  be nilpotent and equal to its own normalizer.\*

b) Let  $a$  be an element of  $\mathfrak{g}$ ; in order that  $a$  be regular, it is necessary and sufficient that  $\text{Nil}(a, \mathfrak{g})$  be nilpotent.\*

Up to making an extension of the base field, one may assume  $k$  infinite. Given 4.4, one is reduced for a) to proving that if  $\mathfrak{d}$  is nilpotent and contains an element  $a$  such that  $\text{ad}(a)|_{\mathfrak{g}/\mathfrak{d}}$  is injective, then  $\mathfrak{d}$  is a Cartan subalgebra. Now by 5.1 (ii)  $\Rightarrow$  (i),  $\mathfrak{d}$  contains a Cartan subalgebra  $\mathfrak{d}' = \text{Nil}(a, \mathfrak{g})$ , and by 4.3 one concludes from the fact that  $\mathfrak{d}$  is nilpotent that  $\mathfrak{d} = \mathfrak{d}'$ . To prove b), one notes that  $\text{Nil}(a, \mathfrak{g})$  is a Cartan subalgebra of  $\mathfrak{g}$  by a), hence  $a$  is regular.

**Corollary 5.8.** \*Let  $G$  be a smooth algebraic group over a field  $k$ ,  $H$  a smooth algebraic subgroup,  $\mathfrak{g}$ ,  $\mathfrak{h}$  the Lie algebras; suppose that after suitable extension of the base field,  $\mathfrak{h}$  contains a Cartan subalgebra of  $\mathfrak{g}$ . Let  $\mathfrak{d}$  be a Lie subalgebra of  $\mathfrak{h}$ ; then it is a Cartan subalgebra of  $\mathfrak{h}$  if and only if it is a Cartan subalgebra of  $\mathfrak{g}$ .\*

<!-- label: III.XIII.5.8 -->

<!-- original page 291 -->

Given 4.8 c), it remains to show that if  $\mathfrak{d}$  is a Cartan subalgebra of  $\mathfrak{h}$ , it is a Cartan subalgebra of  $\mathfrak{g}$ ; for this one is reduced to showing that  $\mathfrak{d}$  contains an element  $a$  regular in  $\mathfrak{g}$ , assuming (which is permissible)  $k$  algebraically closed. But since there is a dense open in  $\mathfrak{h}$  consisting of regular points of  $\mathfrak{g}$ , our assertion follows from 5.1 (i)  $\Rightarrow$  (vii) applied to  $(\mathfrak{h}, \mathfrak{d})$ .

**6. Cartan subalgebras and subgroups of type (C), relative to a smooth algebraic group**

<!-- label: III.XIII.6 -->

For simplicity, we restrict ourselves in the following theorem to the case of an algebraically closed base field (the case of an arbitrary base prescheme being treated in the next Exposé):

**Theorem 6.1.** \*Let  $G$  be a smooth algebraic group over an algebraically closed field  $k$ ,  $\mathfrak{g}$  its Lie algebra. Then:\*

<!-- label: III.XIII.6.1 -->

a) The Cartan subalgebras of  $\mathfrak{g}$  are conjugate.\*

b) Let  $\mathfrak{d}$  be a Cartan subalgebra of  $\mathfrak{g}$ . Then its normalizer  $N$  in  $G$  is smooth, and  $D = N^{\{0\}}$  is the only smooth connected subgroup of  $G$  whose Lie algebra is  $\mathfrak{d}$ . One has\*

```

```text
Norm_G(□) = Norm_G(D) = N,      hence D = Norm_G(D)0.
```

```

\*c) With  $\mathfrak{d}$  as in b), set as in section 5:  $X = G \times^N W(\mathfrak{d})$ , and consider the canonical morphism\*

```

$$
\psi : X \rightarrow W(\mathfrak{g}),
$$

```

\*(whose fiber at  $a \in \mathfrak{g}$  has as points with values in  $k$  the set of Cartan subalgebras of  $\mathfrak{g}$  containing  $a$ ). Then  $\psi$  is a birational morphism.\*

\*d) With the notation of c), let  $U$  be the largest open of  $W(\mathfrak{g})$  such that  $\psi$  induces an isomorphism\*  
 <!-- original page 292 -->

```

$$
\psi^{-1}(U) \xrightarrow{\sim} U.
$$

```

\*Then for  $a \in \mathfrak{g}$ , the following conditions are equivalent:\*

- \*(i)  $a \in U(k)$ .\*
- \*(ii)  $a$  is contained in one and only one Cartan subalgebra of  $\mathfrak{g}$ .\*
- \*(iii) The set of Cartan subalgebras of  $\mathfrak{g}$  containing  $a$  is finite and non-empty.\*
- \*(iv) The fiber  $\psi^{-1}(a)$  has an isolated point.\*
- \*(v) (If  $a \in \mathfrak{d}$ ) The morphism  $\psi$  is étale (or merely: quasi-finite) at the point  $(\bar{e}, a)$ .\*
- \*(vi)  $a$  is a regular element of  $\mathfrak{g}$ .\*
- \*(vii) With the notation of 5.4 (iii), one has  $N = M_a$ .\*

\*Proof.\* Let us apply 5.1 when  $\mathfrak{h}$  is a Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}$ ; let us show that the strongest conditions (xi) to (xiii) are then satisfied. This is evident, either in form (xiii) given 4.7 (which implies that for a regular element  $a$  of  $\mathfrak{g}$  contained in  $\mathfrak{d}$ , one has  $N = M_a$ ), or in form (xi) = (x) + (i), since condition (i) is trivial and condition (x) follows from the fact that a regular point of  $\mathfrak{g}$  is contained in a single Cartan subalgebra of  $\mathfrak{g}$  (4.6 a)), and a fortiori in a single conjugate of  $\mathfrak{d}$ . Then b) follows from 5.3, and c) follows from the fact that  $\psi$  is generically étale and that a sufficiently general point (more precisely, a regular point) of  $\mathfrak{g}$  is contained in a single Cartan subalgebra of  $\mathfrak{g}$ . Under these conditions, the equivalence of conditions (i) to (v) on  $a$  is an immediate consequence of Zariski's Main Theorem for the separated birational morphism  $\psi$ , given that  $W(\mathfrak{g})$  is normal and  $WX$  is integral. <!-- original page 293 --> The equivalence of (v) and (vi) is a particular case of 5.4 (iii)  $\Leftrightarrow$  (iv) (reducing to the case where  $a \in \mathfrak{d}$  by transforming  $a$  by a suitable element  $g \in G(k)$ ), given 4.6 b). Moreover, by 5.4, (v) and (vi) are also equivalent to  $N \supset M_{\{0\}}$ , and by 4.7 already invoked, this even implies  $N = M_a$ . This proves d).

Of course, b), c), and the equivalence of (i), (iv), (v), (vi), (vii) remain valid over an arbitrary base field. Let us now prove a) using the fact that  $k$  is algebraically closed. By 5.1 (i)  $\Rightarrow$  (vii),  $\psi : X \rightarrow W(\mathfrak{g})$  is dominant, hence there exists a dense open  $V$  of  $W(\mathfrak{g})$  such that every  $a \in V(k)$  is the image of an element of  $X(k)$ , i.e. is contained in a conjugate of  $\mathfrak{d}$ . Applying this result to a second Cartan subalgebra  $\mathfrak{d}'$  of  $\mathfrak{g}$ , one sees that one may take  $V$  such that every element of  $V(k)$  is a conjugate of an element of  $\mathfrak{d}$  and of an element of  $\mathfrak{d}'$ . Taking a regular element in  $V(k)$ , it follows that there is a conjugate  $\mathfrak{d}''$  of  $\mathfrak{d}$  which contains an element of  $\mathfrak{d}'$  regular in  $\mathfrak{g}$ , hence which equals  $\mathfrak{d}$  by 4.6 a). This completes the proof of 6.1.

**Definition 6.2.** \*Let  $G$  be a smooth algebraic group over a field  $k$ . One calls a\* subgroup of type (C) \*of  $G$  any smooth connected algebraic subgroup whose Lie algebra is a Cartan subalgebra of  $\mathfrak{g}$ . One calls the\* infinitesimal rank \*of  $G$  the nilpotent rank of its Lie algebra  $\mathfrak{g}$ , equal to the dimension of any subgroup of type (C) of  $G$ .\*

<!-- label: III.XIII.6.2 -->

From 6.1 b) one concludes at once:

**Corollary 6.3.** \*Under the conditions of 6.2, the map  $D \mapsto \text{Lie } D = \mathfrak{d}$  establishes a bijective correspondence between subgroups of type (C) of  $G$ , and Cartan subalgebras  $\mathfrak{d}$  of  $\mathfrak{g}$ . If  $D$  is

a subgroup of type (C) of  $G$ ,  $D$  is its own connected normalizer:\*

<!-- label: III.XIII.6.3 -->

$D = \text{Norm}_G(D)^{\{0\}}$ .

<!-- original page 294 -->

Combining 6.1 (a) and 6.3, one finds:

**Corollary 6.4.** \*If  $k$  is algebraically closed, the subgroups of type (C) of  $G$  are conjugate to each other.\*

<!-- label: III.XIII.6.4 -->

**Corollary 6.5.** \*Let  $G$  be a smooth algebraic group over algebraically closed  $k$ ,  $H$  a smooth algebraic subgroup of  $G$ ,  $\mathfrak{g}$  and  $\mathfrak{h}$  the Lie algebras. In order that  $\mathfrak{h}$  contain a Cartan subalgebra of  $\mathfrak{g}$ , it is necessary and sufficient that  $H$  contain a subgroup  $D$  of type (C) of  $G$ .\*

<!-- label: III.XIII.6.5 -->

This is evidently sufficient, and is also necessary, since in order that one have  $H \supset D$ , it is necessary and sufficient that  $\mathfrak{h} \supset \mathfrak{d}$ , by 5.5.

**Remarks 6.6.** \*a) One will note that the connected subgroups  $H$  of  $G$  described in 6.5 correspond bijectively to the Lie subalgebras  $\mathfrak{h}$  of  $\mathfrak{g}$  satisfying the strongest condition (xii) of 5.1 (and by 5.5, inclusion relations between such subgroups can already be recognized on their Lie algebras).\*

<!-- label: III.XIII.6.6 -->

\*b) Suppose still that  $k$  is algebraically closed, and let  $D$  be a subgroup of type (C) of  $G$ ; then it is easy to show that  $D$  contains a Cartan subgroup  $C$  of  $G$ : indeed, let  $V = \mathfrak{g}/\mathfrak{d}$ ; then for a "general" element  $a$  of  $\mathfrak{d}$ ,  $\text{ad}(a)$  acting on  $V$  is injective (it suffices that  $a$  be regular in  $\mathfrak{g}$ ); from this one easily concludes that for  $g \in D(k)$  "general",  $\text{Ad}(g)$  acting on  $V$  has no non-zero invariants, which allows one to apply 2.1 (vii)  $\Rightarrow$  (i). In fact, we shall see in the following Exposé a more precise result: every Cartan subgroup  $C$  of  $G$  is contained in one and only one subgroup of type (C) of  $G$ .\*

\*c) One should not confuse in general Cartan subgroups and subgroups of type (C): the subgroups of type (C) of  $G$  are Cartan subgroups <!-- original page 295 --> if and only if they are nilpotent (Cartan subgroups being indeed maximal nilpotent subgroups), and it may happen that  $\mathfrak{g}$  is nilpotent without  $G$  being so (example:  $\text{SL}(2)_k$  for  $k$  of characteristic 2); then the Cartan subalgebras of  $\mathfrak{g}$  are identical to  $\mathfrak{g}$ , i.e.  $G$  is a subgroup of type (C) of itself if  $G$  is connected, but it is not a Cartan subgroup of  $G$ ! On the other hand, we shall see in XIV that if  $G$  is a semisimple adjoint group, then its subgroups of type (C) are its Cartan subgroups. Similarly, in characteristic 0, without restriction on the smooth algebraic group  $G$  over  $k$ , the same conclusion is valid: this follows at once from the fact that in characteristic 0, a connected algebraic group is nilpotent if (and only if) its Lie algebra is. This follows at once from the fact that in characteristic zero, the center  $Z$  of the connected algebraic group  $G$  has as Lie algebra the center of  $\mathfrak{g}$  (for one obtains a priori the space of invariants of  $\mathfrak{g}$  under the adjoint representation of  $G$ ; now  $G$  being connected and  $k$  of characteristic zero, these are also the "invariants" in the infinitesimal sense of the adjoint representation of  $\mathfrak{g}$ , i.e. the center of  $\mathfrak{g}$ ), and that by Cartier's theorem (cf. VI\_B 1.6.1)  $Z$  is smooth.

# Exposé XIV. Regular elements (continuation). Applications to algebraic groups

<!-- label: III.XIV -->

\*by A. Grothendieck, with an Appendix by J.-P. Serre\*

## 1. Construction of Cartan subgroups and of maximal tori for a smooth algebraic group

<!-- label: III.XIV.1 -->

<!-- original page 296 -->

**Theorem 1.1.** \*Let  $G$  be a smooth algebraic group over a field  $k$ . Then  $G$  admits a maximal torus  $T$ , hence a Cartan subgroup  $C = \text{Centr}_{\{G\}}(T)$ .\*

<!-- label: III.XIV.1.1 -->

By virtue of (XII 3.2), it amounts to the same to find a maximal torus  $T$  of  $G$  or a Cartan subgroup  $C$  of  $G$ . Moreover, since the maximal tori of  $G$  are those of  $G^{\{0\}}$ , we may assume  $G$  connected. We distinguish two cases:

1°) \*The field  $k$  is finite.\* Let  $T$  be the scheme of maximal tori of  $G$  (Exp XII 1.10), which is a smooth scheme over  $k$ . Note that  $G$  operates on  $T$  via inner automorphisms, and by virtue of the conjugation theorem (XII 6.6 a)), two points of  $T_{\bar{k}}$  rational over  $\bar{k}$  are congruent under  $G_{\bar{k}}$ . Taking into account that  $T$  is smooth over  $k$ , hence  $T_{\bar{k}}$  smooth over  $\bar{k}$ , it follows that  $T_{\bar{k}}$  is isomorphic to  $G_{\bar{k}}/N$ , where  $N$  is the stabilizer of an element of  $T_{\bar{k}}$ , i.e. the normalizer of a maximal torus  $T$  of  $G_{\bar{k}}$ . Consequently,  $T$  is a "homogeneous space" under the action of the group  $G$ . A well-known theorem of Lang (Amer. J. Math. 78, 1956, pp. 555–563) tells us that every homogeneous space under a smooth connected algebraic group over a finite field  $k$  admits a rational point. In particular,  $T$  admits a rational point, i.e.  $G$  admits a maximal torus  $T$ . \*QED\*.

2°) \*The field  $k$  is infinite.\* We shall use the <!-- original page 297 -->

**Lemma 1.2.** \*Let  $G$  be a smooth algebraic group over a field  $k$ . Then  $G$  admits a subgroup of type (C) (XIII 6.2).\*

<!-- label: III.XIV.1.2 -->

By virtue of (XIII 6.3), this amounts to saying that  $\mathfrak{g}$  contains a Cartan subalgebra  $\mathfrak{d}$ . This is trivial if  $k$  is infinite, for then  $\mathfrak{g}$  contains a regular element  $a$ , and one takes  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$ . The case of finite  $k$  is handled exactly as in the proof of 1°) above, but requires the prior construction of the scheme  $\mathcal{D}$  of Cartan subalgebras of  $\mathfrak{g}$  and the fact that this scheme is smooth over  $k$ , which will be carried out below (2.16).

To establish 1.1 in case 2°), where we have placed ourselves, it suffices in any event to know 1.2 for  $k$  infinite. Let us also record for the record:

**Lemma 1.3.** \*Let  $G$  be a smooth, connected, affine algebraic group whose reductive center (XII 4.1 and 4.4) is reduced to the unit group. Then  $G$  is nilpotent if (and only if) its Lie algebra  $\mathfrak{g}$  is nilpotent.\*

<!-- label: III.XIV.1.3 -->

This is contained in (XII 4.9).

We can now give a procedure for constructing Cartan subgroups of  $G$  (also valid when  $k$  is finite, granting 1.2 in that case). Suppose first that  $G$  is affine. We proceed by induction on  $n = \dim G$ , the assertion being trivial if  $n = 0$ . So suppose  $n > 0$  and the assertion proved for dimensions  $n' < n$ . Let  $Z$  be the reductive center of  $G$ , and let

```
```text
u : G → G' = G/Z
```
```

be the canonical homomorphism. By virtue of (XII 4.7 c)), one has a bijective correspondence  $C' \mapsto C = u^{-1}(C')$  between Cartan subgroups of  $G'$  and Cartan subgroups of  $G$ . So, replacing  $G$  by  $G'$  if necessary, we may suppose that the reductive center  $Z$  of  $G$  is reduced to the unit element (since this is the case for that of  $G'$  by XII 4.7 b)).

<!-- original page 298 --> By virtue of 1.3,  $G$  admits a subgroup  $D$  of type (C). We know that over the algebraic

closure  $\bar{k}$  of  $k$ ,  $D_{\bar{k}}$  contains a Cartan subgroup of  $G_{\bar{k}}$  (XIII 6.6 b)), hence every Cartan subgroup of  $D$  is a Cartan subgroup of  $G$  (XIII 2.8 a)). So we are reduced to finding a Cartan subgroup of  $D$ . If  $\dim D = \dim G$ , i.e.  $D = G$ , then the Lie algebra of  $G$  is a Cartan subalgebra of itself, hence is nilpotent, hence by 1.3  $G$  is nilpotent, hence is a Cartan subgroup of itself. If  $\dim D < \dim G$ , then by the induction hypothesis there exists a Cartan subgroup of  $D$ , which is therefore a Cartan subgroup of  $G$ , which completes the proof in the case where  $G$  is affine. In the general case, let  $Z$  be the center of  $G$ ; then  $G/Z = G'$  is affine (XII 6.1) and for every Cartan subgroup  $C'$  of  $G'$ , its inverse image  $C$  in  $G$  is a Cartan subgroup of  $G$  (XII 6.6 e)). One is reduced to finding a Cartan subgroup of the smooth affine algebraic group  $G'$ , a case already treated.

**Corollary 1.4.** \*Let  $G$  be a smooth group scheme of finite type over an artinian scheme  $S$ . Then  $G$  admits a maximal torus  $T$ , hence a Cartan subgroup  $C = \text{Centr}_G(T)$ . Every torus  $S$  in  $G$  is contained in a maximal torus.\*

<!-- label: III.XIV.1.4 -->

One may indeed suppose  $S$  local of residue field  $k$ ; then by virtue of 1.1,  $G_{\{0\}} = G \times_S \text{Spec}(k)$  admits a maximal torus  $T_{\{0\}}$ , and by virtue of (IX 3.6 bis) and (X 2.3),

$T_0$  comes from a torus  $T$  of  $G$ , which is evidently a maximal torus. The last statement follows from this, applying the preceding result to the centralizer of  $S$ , which is indeed smooth over  $k$  (XI 2.4).

**Remarks 1.5.** a) We shall give below (3.20, 3.21 and XV) variants of 1.4 in the case where  $S$  is not assumed artinian.

<!-- label: III.XIV.1.5 -->

b) I do not know whether every algebraic group  $G$  (not necessarily smooth) over a field  $k$  admits a maximal torus. The question only arises in characteristic  $p > 0$ , and <!-- original page 299 --> using 1.1 for a smooth quotient group of the form  $G' = G/I$ , where  $I$  is a suitable radical subgroup of  $G$  (for example, the kernel of a sufficiently high power of the Frobenius homomorphism), one is reduced, by taking the inverse image in  $G$  of a maximal torus of  $G'$ , to the case where  $G_{\bar{k}}$  is a torus ( $\bar{k}$  always denoting the algebraic closure of  $k$ ). It is easy to see that the answer is affirmative when  $G$  is commutative (or more generally nilpotent): then  $G$  admits a unique maximal torus, which one may construct for example by descent from the maximal torus of  $G_{\bar{k}}$  [XIV-1-1].

c) In the case where  $G$  is affine, and  $k$  is perfect or  $G$  solvable, 1.1 is known and due to Rosenlicht; his proof is very different from the one given here.

d) When  $k$  is infinite, 1.1 is a consequence of the much more precise result that the scheme  $T$  of maximal tori of  $G$  is a rational variety, proved below (6.1). The method is essentially a combination of the proof of 1.1 and of the explicit description of the structure of the scheme  $\mathcal{D}$  of Cartan subalgebras of  $\mathfrak{g}$ . To reach the desired result, we must first generalize to the case of an arbitrary base prescheme certain results from (XIII 4 to 6) (this is the goal of the next two sections), and refine the previous construction proving 1.1, by using the fact that every Cartan subgroup of  $G$  is contained in one and only one subgroup of type (C) of  $G$  (Nos 4, 5).

**2. Lie algebras over an arbitrary prescheme: regular sections and Cartan subalgebras**

<!-- label: III.XIV.2 -->

**Lemma 2.1.** \*Let  $A$  be a ring,  $\mathfrak{d}$  a Lie algebra over  $A$ , and for every  $s \in \operatorname{Spec}(A)$ , let  $\mathfrak{d}(s) = \mathfrak{d} \otimes_A k(s)$  be the corresponding Lie algebra over the residue field  $k(s)$ . Suppose the  $A$ -module  $\mathfrak{d}$  is of finite presentation. The following conditions are equivalent:\*

<!-- label: III.XIV.2.1 -->

- \*(i) For every  $s \in \operatorname{Spec}(A)$ ,  $\mathfrak{d}(s)$  is nilpotent.\*
- \*(ii) For every  $x \in \mathfrak{d}$ ,  $\operatorname{ad}(x)$  is nilpotent.\*
- \*(iii) There exists an integer  $N \geq 0$  such that for every sequence  $x_1, \dots, x_N$  of elements of  $\mathfrak{d}$ , one has\*

<!-- original page 300 -->

$$\operatorname{ad}(x_1) \operatorname{ad}(x_2) \cdots \operatorname{ad}(x_N) = 0.$$

When  $A$  is a field, the equivalence of (i) and (iii) is the definition of "nilpotent", that of (ii) and (iii) is a well-known consequence of Engel's theorem (Bourbaki, \*Groupes et algèbres de Lie\*, Chap. I, § 4, N° 2). In the general case, one has trivially (iii)  $\Rightarrow$  (ii), and (ii)  $\Rightarrow$  (i) thanks to the preceding result and to the fact that (ii) is stable by passage to quotients and by localization. It remains to prove (i)  $\Rightarrow$  (iii). When  $A$  is local artinian with maximal ideal  $\mathfrak{m}$ , let  $n > 0$  be an integer such that  $\mathfrak{m}^n = 0$ , let  $N$  be an integer such that condition (iii) is satisfied for  $\mathfrak{d}(s) = \mathfrak{d} \otimes_A A/\mathfrak{m}(s)$ , and take  $N' = nN$ ; one sees at once that this integer satisfies (iii). When  $A$  is noetherian, there exist finitely many elements  $s_i \in \operatorname{Spec}(A)$  and ideals of definition  $\mathfrak{q}_i \subset A_{s_i}$  such that the natural map

$$\begin{aligned} & \text{``text} \\ & \mathfrak{d} \rightarrow \mathfrak{d}_i \otimes_{A_i} A, \quad \text{where } A_i = A_{s_i}/\mathfrak{q}_i, \end{aligned}$$

is injective; then by what precedes there exists for every  $i$  an integer  $N_i$  satisfying (iii) for the Lie algebra  $\mathfrak{d} \otimes_A A_i$ , and taking  $N$  to be the largest of the  $N_i$ , one satisfies (iii) for  $\mathfrak{d}$ . Finally, the general case reduces to the noetherian case by the usual procedure explained in (EGA IV 8).

**Definition 2.2.** Let  $S$  be a prescheme,  $\mathfrak{d}$  a quasi-coherent Lie algebra over  $S$  that is a module of finite presentation. One says that  $\mathfrak{d}$  is locally nilpotent if for every  $s \in S$ , the Lie algebra  $\mathfrak{d}(s)$  over  $k(s)$  is nilpotent. One says that  $\mathfrak{d}$  is strictly locally nilpotent if it is locally free, and if on every open  $U$  of  $S$  on which it is of constant rank  $r$ , its Killing polynomial reduces to  $P_{\mathfrak{d}}(t) = t^r$ .

!-- label: III.XIV.2.2 -->

Of course, if  $\mathfrak{d}$  is a locally free Lie algebra (as a module) over  $S$ , one defines its Killing polynomial as a polynomial

$$P_{\mathfrak{d}} \in A[t], \quad \text{where } A = \Gamma(\text{Sym}_{\mathfrak{d}}(\mathfrak{d})) \simeq \Gamma(W(\mathfrak{d}))$$

!-- original page 301 -->

is the ring of sections of the structure sheaf of the vector bundle  $W(\mathfrak{d})$  defined by  $\mathfrak{d}$ .

It is evident that the two notions just introduced in 2.2 are stable by base change, and of local nature for the fpqc topology. Let us note:

**Proposition 2.3.** If  $\mathfrak{d}$  is strictly locally nilpotent, it is locally nilpotent. The converse is true when  $\mathfrak{d}$  is locally free and  $S$  is reduced.

!-- label: III.XIV.2.3 -->

The proof is immediate.

**Definition 2.4.** Let  $S$  be a prescheme,  $\mathfrak{g}$  a Lie algebra over  $S$  that is a locally free module of finite type. Let  $\mathfrak{d}$  be a Lie subalgebra of  $\mathfrak{g}$ ; one says that it is a Cartan subalgebra if it satisfies the following conditions:

!-- label: III.XIV.2.4 -->

- (i)  $\mathfrak{d}$  is a locally direct factor submodule (hence also locally free of finite type).
- (ii) For every  $s \in S$ ,  $\mathfrak{d}(s)$  is a Cartan subalgebra of  $\mathfrak{g}(s)$ .

**Definition 2.5.** Let  $S$ ,  $\mathfrak{g}$  be as in 2.4. A section  $a$  of  $\mathfrak{g}$  is called quasi-regular if for every  $s \in S$ ,  $a(s) \in \mathfrak{g}(s)$  is a regular element of the Lie algebra  $\mathfrak{g}(s)$  over  $k(s)$ . One says that  $a$  is a regular section if it is quasi-regular and contained in a Cartan subalgebra of  $\mathfrak{g}$ .

!-- label: III.XIV.2.5 -->

Notions 2.4 and 2.5 are again stable by base change, and of local nature for the fpqc topology. Only the last assertion, and only for the notion "regular section", requires a proof, and follows from the fact that the Cartan subalgebra containing a given regular section is uniquely determined. More precisely:

!-- original page 302 -->

**Proposition 2.6.** Let  $S$ ,  $\mathfrak{g}$  be as in 2.4 and let  $a$  be a quasi-regular section of  $\mathfrak{g}$ . Then there exists at most one Cartan subalgebra of  $\mathfrak{g}$  containing  $a$ . For one to exist, i.e. for  $a$  to be a regular section, it is necessary and sufficient that  $a$  satisfy the following condition:  
 $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$  is a locally direct factor submodule of  $\mathfrak{g}$ , and  $\text{ad}(a)$  induces an automorphism of  $\mathfrak{g}/\mathfrak{d}$ . In this case,  $\mathfrak{d}$  is the unique Cartan subalgebra of  $\mathfrak{g}$  containing  $a$ .

!-- label: III.XIV.2.6 -->

Suppose indeed that  $a$  is contained in the Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}$ . Then  $\text{ad}(a)|_{\mathfrak{g}/\mathfrak{d}}$  is bijective on each fiber, hence (since  $\mathfrak{g}/\mathfrak{d}$  is locally free of finite type) it is an automorphism of  $\mathfrak{g}/\mathfrak{d}$ ; on the other hand by virtue of 2.1  $\text{ad}(a)|_{\mathfrak{d}}$  is locally nilpotent, hence  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$ , which proves the uniqueness of  $\mathfrak{d}$ , and the necessity of the stated regularity criterion. For sufficiency, note that the hypothesis made on  $a$  implies that the formation of  $\text{Nil}(a, \mathfrak{g})$  commutes with base extension and in particular with passage to

fibers, which shows in particular that the fibers  $\mathfrak{d}(s)$  of  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$  are Cartan subalgebras of the  $\mathfrak{g}(s)$ ; moreover  $\mathfrak{d}$  is a Lie subalgebra of  $\mathfrak{g}$  by virtue of (XIII 4.1), hence it is a Cartan subalgebra.

**Corollary 2.7.** Under the conditions of 2.4, let  $\mathfrak{d}$  be a Cartan subalgebra of  $\mathfrak{g}$ ,  $a$  a section of  $\mathfrak{d}$  that is regular in  $\mathfrak{g}$ ,  $u$  an automorphism of  $\mathfrak{g}$ . In order for  $u$  to preserve  $\mathfrak{d}$ , it is necessary and sufficient that  $u(a)$  be a section of  $\mathfrak{d}$ .

<!-- label: III.XIV.2.7 -->

Indeed, by transport of structure  $u(a)$  is then a regular section of  $\mathfrak{g}$ , contained in the two Cartan subalgebras  $\mathfrak{d}$  and  $u(\mathfrak{d})$ , which are therefore identical.

**Corollary 2.8.** Under the conditions of 2.4, let  $\mathfrak{d}$  be a Cartan subalgebra of  $\mathfrak{g}$ . Then for every  $s \in S$  such that  $k(s)$  is infinite, there exists an open neighborhood  $V$  of  $s$  and a regular section  $a$  of  $\mathfrak{g}$  over  $V$  such that  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g}|_V)$  (i.e. such that  $a$  is a section of  $\mathfrak{d}|_V$ ).

<!-- label: III.XIV.2.8 -->

Indeed, the fact that  $k(s)$  is infinite ensures the existence of a regular element  $a_0$  of <!-- original page 303 -->  $\mathfrak{g}(s)$  contained in  $\mathfrak{d}(s)$ ; one can extend it to a section  $a$  of  $\mathfrak{d}$  on an open neighborhood  $U$  of  $s$ , and since  $\text{ad}(a)|_{\mathfrak{g}/\mathfrak{d}}$  induces an automorphism of  $\mathfrak{g}(s)/\mathfrak{d}(s)$ , it follows that, on restricting  $V$ ,  $\text{ad}(a)|_{\mathfrak{g}/\mathfrak{d}}$  is an automorphism, which implies that  $a$  is a quasi-regular section of  $\mathfrak{g}|_V$  satisfying the desired condition.

Let  $\mathfrak{g}$  be as in 2.4; then examination of its Killing polynomial implies at once that the function

```
```text
s ↦ nilpotent rank of  $\mathfrak{d}(s)$ 
```
```

on  $S$  is upper semi-continuous. We are above all interested in the case when this function is in fact continuous, i.e. locally constant. Here are some variants of this property:

**Proposition 2.9.** Let  $S$ ,  $\mathfrak{g}$  be as in 2.4. Consider the following conditions:

<!-- label: III.XIV.2.9 -->

- $(C_0)$  The nilpotent rank of the  $\mathfrak{g}(s)$  ( $s \in S$ ) is a locally constant function of  $s$ .
- $(C_1)$  There locally exists, for the fpqc topology, a Cartan subalgebra of  $\mathfrak{g}$ .
- $(C_1')$  Like  $(C_1)$ , with "fpqc topology" replaced by "étale topology".
- $(C_2)$  Condition  $(C_0)$  is satisfied, and for every  $S'$  over  $S$ , every quasi-regular section of  $\mathfrak{g}_{S'} = \mathfrak{g} \otimes_S S'$  is regular.
- $(C_3)$  Every  $s \in S$  has an open neighborhood  $V$  on which the Killing polynomial of  $\mathfrak{g}$  is of the form

```
```text
tr(tn-r + c1 tn-r-1 + ... + cn-r)
```
```

where for every  $s \in V$ ,  $c_{n-r}(s) \in \text{Sym}(\mathfrak{g}(s)^{\vee})$  is non-zero.

With these notations, one has the implications

```
```text
(C3) ⇒ (C2) ⇒ (C1') ⇒ (C1) ⇒ (C0),
```
```

<!-- original page 304 -->

and when  $S$  is reduced, the five conditions considered are equivalent.

Let us also note that the conditions considered are manifestly stable by base change, and of local nature for the fpqc topology.

The implications  $(C_1') \Rightarrow (C_1) \Rightarrow (C_0)$  are trivial, the implication  $(C_0) \Rightarrow (C_3)$  when  $SS$  is reduced is immediate. Note moreover:

**Corollary 2.10.** Suppose condition  $(C_0)$  satisfied. Let  $U$  be the set of elements of  $W(\mathfrak{g})$  that are regular in their fiber. Then  $U$  is open; in particular, for every section  $a$  of  $\mathfrak{g}$  over  $SS$ , the set  $V$  of  $s \in SS$  such that  $a(s) \in \mathfrak{g}(s)$  is regular, is open.\*

<!-- label: III.XIV.2.10 -->

Indeed, the first assertion follows from the second (applied to  $\mathfrak{g}_{S'}$  for every base change  $S'$  over  $SS$ ). For the second, since one may suppose here  $SS$  reduced, hence  $(C_3)$  verified, it suffices to examine the Killing polynomial of  $a$  in  $\mathfrak{g}$ .

The implication  $(C_2) \Rightarrow (C_1')$  now follows easily from b) in the more precise statement that follows:

**Corollary 2.11.** Suppose condition  $(C_2)$  satisfied. Then:\*

<!-- label: III.XIV.2.11 -->

a) For every  $s \in SS$  and every Cartan subalgebra  $\mathfrak{d}_0$  of  $\mathfrak{g}(s)$  such that  $\mathfrak{d}_0$  contains a regular element of  $\mathfrak{g}(s)$  (condition automatically satisfied if  $k(s)$  is infinite), there exists an open neighborhood  $V$  of  $s$  and a subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}|_V$  whose fiber at  $s$  is  $\mathfrak{d}_0$ . If  $S_1$  is a subscheme of  $SS$  containing  $s$ , and if one has already extended  $\mathfrak{d}_0$  to a Cartan subalgebra  $\mathfrak{d}_1$  of  $\mathfrak{g}_{S_1}$ , then one can find an open neighborhood  $V$  of  $s$  in  $SS$  and a Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}|_V$  such that  $\mathfrak{d} \otimes_{S_1} (S_1 \cap V)$  is equal to  $\mathfrak{d}_1|_{(S_1 \cap V)}$ .\*

b) For every  $s \in SS$  such that  $\mathfrak{g}(s)$  contains a regular element (condition automatically satisfied if  $k(s)$  is infinite), <!-- original page 305 --> there exists an open neighborhood  $V$  of  $s$  and a Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}|_V$ .\*

Statement b) follows from a) by taking  $\mathfrak{d}_0 = \text{Nil}(a_0, \mathfrak{g}(s))$ ,  $a_0$  being a regular element of  $\mathfrak{g}(s)$ . To prove a), let us say the second formulation, one considers a regular element  $a_0$  of  $\mathfrak{g}(s)$  contained in  $\mathfrak{d}_0$ , one extends it to a neighborhood of  $s$  in  $S_1$  as a section of  $\mathfrak{d}_1$ , and one extends this last to a section of  $\mathfrak{g}$  in a neighborhood of  $s$ . By virtue of 2.10, this section is quasi-regular in an open neighborhood  $V$  of  $s$ , hence regular by virtue of  $(C_2)$ , hence by virtue of 2.6  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g}|_V)$  satisfies the required conditions.

**Remark 2.12.** I do not know if statement 2.11 a) and b) is valid without the hypothesis of existence of regular points (when  $k(s)$  is finite).

<!-- label: III.XIV.2.12 -->

It remains to prove the implication  $(C_3) \Rightarrow (C_2)$ . Let us also note the following equivalent form of  $(C_3)$ :

-( $C_3'$ ) One has  $(C_0)$ , i.e. the nilpotent rank of the  $\mathfrak{g}(s)$  ( $s \in SS$ ) is locally constant, and on every open  $V$  of  $SS$  where this rank has value  $r$ , the Killing polynomial of  $\mathfrak{g}|_V$  is divisible by  $t^r$ .

It is necessary to show that this condition implies that every quasi-regular section  $a$  of  $\mathfrak{g}$  is regular. Taking 2.6 into account, this is contained in the following lemma (applied to the endomorphism  $\text{ad}(a)$  of  $\mathfrak{g}$ ), (iv)  $\Rightarrow$  (iii):

**Lemma 2.13.** Let  $A$  be a ring,  $M$  a projective  $A$ -module of finite type,  $u$  an endomorphism of  $M$ . The following conditions are equivalent:\*

<!-- label: III.XIV.2.13 -->

- (i)  $M$  is the direct sum of two stable submodules  $M'$ ,  $M''$  such that  $u|_{M'}$  is nilpotent and  $u|_{M''}$  is an automorphism of  $M''$ .\*
- (ii) There exists an integer  $n > 0$  such that  $\text{Im } u^n + \text{Ker } u^n = M$ .\*
- (iii) The nil-space  $\text{Nil}(u) = \bigcup_{n>0} \text{Ker } u^n$  is a direct factor in  $M$ , and  $M = \text{Nil}(u) + u(M)$ .\*

\*These conditions are implied by the following (and are equivalent to it when  $A$  is reduced):\*

<!-- original page 306 -->

- \*(iv) Locally on  $\operatorname{Spec}(A)$  (for the Zariski topology) the characteristic polynomial  $P_u(t)$  of  $u$  can be put in the form\*

```
```text
t^r(t^{n-r} + c_1 t^{n-r-1} + ... + c_{n-r}),
```
```

\*where  $c_{n-r}$  is invertible.\*

The equivalence of (i) (ii) (iii) is immediate and is recorded for the record. The fact that (i) implies (iv) when  $A$  is reduced follows from the fact that in this case a nilpotent endomorphism of a projective module of rank  $r$  has characteristic polynomial  $t^r$ , while in any case the characteristic polynomial of an automorphism of a projective module of finite type has as constant term the determinant of  $u$  up to sign (locally on  $\operatorname{Spec}(A)$ ), hence an invertible element of  $A$ . Finally, to prove (iv)  $\Rightarrow$  (i), one notes that  $M$  is a module over the polynomial ring  $A[t]$ , by letting  $t$  act as  $u$ , and the well-known identity

```
```text
P(u) = 0
```
```

shows that  $M$  is annihilated by  $P A[t]$ , hence can be considered as a module over  $A[t]/P A[t]$ . Now writing  $P = t^r Q$ , where the constant term of  $Q$  is invertible, one sees at once that

```
```text
P A[t] = t^r A[t] \cap Q A[t],
```
```

hence  $A[t]/P A[t]$  decomposes into the product of the rings  $A[t]/t^r A[t]$  and  $A[t]/Q A[t]$ , whence a corresponding decomposition of  $M$  as a sum of two  $A[t]$ -modules, i.e. as a sum of two  $A$ -submodules  $M'$  and  $M''$  stable under  $u$ ; this is the decomposition envisaged in (i).

This completes the proof of 2.13, hence of 2.9.

<!-- original page 307 -->

**Corollary 2.14.** \*When condition  $(C_3)$  of 2.9 is satisfied, the Cartan subalgebras of  $\mathfrak{g}$  are strictly nilpotent (2.2).\*

<!-- label: III.XIV.2.14 -->

The proof is immediate.

**Remark 2.15.** a) Let us point out that one can prove a converse of 2.14:  $(C_3)$  is equivalent to the fact that for every  $S'$  over  $S$ , every quasi-regular section of  $\mathfrak{g}_{S'}$  is regular and every Cartan subalgebra of  $\mathfrak{g}_{S'}$  is strictly nilpotent, or again, every quasi-regular section of  $\mathfrak{g}_{S'}$  is contained in a strictly nilpotent Cartan subalgebra of  $\mathfrak{g}_{S'}$ .

<!-- label: III.XIV.2.15 -->

b) Contrary to the other conditions  $(C_0)$  to  $(C_2)$ , condition  $(C_3)$  is of "infinitesimal nature". More precisely, when  $S$  is locally noetherian,  $\mathfrak{g}$  satisfies condition  $(C_3)$  if and only if for every base change  $S' \rightarrow S$  with  $S'$  local artinian (if one wishes,  $S'$  the spectrum of an artinian quotient of a local ring of  $S$ ),  $\mathfrak{g}_{S'}$  satisfies the same condition. Similarly, when  $(C_0)$  is satisfied, the condition for a section of  $\mathfrak{g}$  to be regular is of infinitesimal nature.

c) When  $\mathfrak{g}$  is the Lie algebra of a smooth prescheme in groups of finite presentation over  $S$ , then we shall see that conditions  $(C_0)$ ,  $(C_1)$ ,  $(C_1')$ ,  $(C_2)$  on  $\mathfrak{g}$  are equivalent (5.2 a)); I do not know what is the case in general (except that, even for  $S$  local artinian,  $(C_0)$  does not imply  $(C_1)$ ). However, even in the case where  $\mathfrak{g}$  comes from a  $G$ , and  $S$  being local artinian, it is not true in general that  $(C_2)$  implies  $(C_3)$ , since  $\mathfrak{g}$  can be nilpotent without being strictly nilpotent. One obtains an example of this fact starting from a smooth affine group scheme  $G$  over the spectrum  $S$  of a discrete valuation ring such that the Lie algebra of the generic fiber is non-nilpotent (for example the generic fiber is an adjoint semisimple group), and that of the special fiber is nilpotent (for example, the special fiber being a vector group): then for  $n$  large enough, the Lie algebra of  $G_n = G \times_S S_n$  is not strictly nilpotent, however it is nilpotent.

<!-- original page 308 -->

Let us still place ourselves under the conditions of 2.4, and let

$$\mathcal{D} : (\text{Sch})^{\circ}/S \longrightarrow (\text{Ens})$$

be the functor defined by

$$\mathcal{D}(S') = \text{set of Cartan subalgebras of } \mathcal{D}_{S'}.$$

Let us also introduce the functor

$$X(S') = \text{set of pairs } (\mathcal{D}, a), \text{ where } \mathcal{D} \text{ is a Cartan subalgebra of } \mathcal{D}_{S'} \text{ and } a \text{ a section of } \mathcal{D}.$$

One thus has two projections  $(\mathcal{D}, a) \mapsto \mathcal{D}$  and  $(\mathcal{D}, a) \mapsto a$ :

$$p : X \rightarrow \mathcal{D} \quad \text{and} \quad \psi : X \rightarrow W(\mathcal{D}).$$

When  $(C_0)$  is satisfied, we also consider the open  $U$  of regular points of  $W(\mathcal{G})$  (cf. 2.10) and condition  $(C_2)$  is then expressed by the fact that the morphism

$$\psi^{-1}(U) \longrightarrow U$$

induced by  $\psi$  is an isomorphism (a priori, it is a monomorphism thanks to 2.6). Note that it is trivial that the morphism  $p : X \rightarrow \mathcal{D}$  is representable by a projection of vector bundles (i.e. for every  $S$ -morphism  $S' \rightarrow \mathcal{D}$ , corresponding to a Cartan subalgebra  $\mathcal{D}'$  of  $\mathcal{G}_{S'}$ ,  $X \times_{\mathcal{D}} \mathcal{D}'$  is representable by a vector bundle over  $S'$ , namely  $W(\mathcal{D}')$ ; so if  $\mathcal{D}$  is representable, the same is true of  $X$ . Now one has:

**Theorem 2.16.** \*Let  $S$  be a prescheme,  $\mathcal{G}$  a Lie algebra over  $S$  that is a locally free  $\mathcal{O}_S$ -module of finite type; suppose condition  $(C_0)$  of 2.9 is satisfied.\*

<!-- label: III.XIV.2.16 -->

a) The functor  $\mathcal{D}$  of Cartan subalgebras of  $\mathcal{G}$  defined above is representable by a quasi-projective prescheme of finite presentation over  $S$ . The same is true of the functor  $X$  defined above.\* <!-- original page 309 -->

b) When condition  $(C_2)$  of 2.9 is satisfied,  $\mathcal{D}$  and  $X$  are smooth over  $S$ , and the morphism  $\psi^{-1}(U) \rightarrow U$  induced by  $\psi$  is an isomorphism.\*

c) Still assuming condition  $(C_2)$  satisfied, let  $s \in S$ ,  $\mathcal{D}_s$  a Cartan subalgebra of  $\mathcal{G}(s)$ , corresponding to a point  $d$  of  $\mathcal{D}$  rational over  $k(s)$ . Suppose that  $\mathcal{D}_s$  contains a regular point of  $\mathcal{G}(s)$  (condition automatically satisfied if  $k(s)$  is infinite). Let  $r$  be the infinitesimal rank of  $\mathcal{G}(s)$ ,  $n$  its rank over  $k(s)$ ; then there exists an open neighborhood  $V$  of  $d$  in  $\mathcal{D}$  that is  $S$ -isomorphic to an open  $V'$  of  $S[t_1, \dots, t_{n-r}]$ .\*

**Proof.** One may suppose  $\mathcal{G}$  of constant rank  $n$  and of constant nilpotent rank  $r$ . The assertions made about  $X$  in a) and b) follow at once from the assertions made about  $\mathcal{D}$  and from the fact that  $X$  is a vector bundle over  $\mathcal{D}$  defined by a locally free module, and are stated only for the record.

a) The functor  $\mathcal{D}$  is a subfunctor of the functor  $\text{Grass}_{n-r}(\mathcal{G})$  whose value at  $S'$  is the set of locally free quotient modules of rank  $n - r$  of  $\mathcal{G}_{S'}$ , and it is well known that this latter functor is representable by a projective prescheme smooth over  $S$  (cf. for example Séminaire Cartan 1960/61, Exp. 12, Nos 2 and 3, whose constructions transpose as they stand to the case of preschemes) [XIV-2-1] [N.D.E-XIV-1]. So one is reduced to a relative problem, namely the following: given a locally free quotient module of rank  $n - r$  of  $\mathcal{G}$ , or

equivalently, a locally free submodule  $\mathfrak{d}$  of rank  $r$  that is locally a direct factor, represent the following functor:  $F(S) = \emptyset$  if  $\mathfrak{d}$  is not a Cartan subalgebra of  $\mathfrak{g}_S$ ,  $F(S) = \{\emptyset\}$  otherwise. In fact, we shall see that  $F$  is representable by a subscheme of finite presentation of  $S$  (which will show that  $\mathcal{D}$  to Grass is representable by an immersion of finite presentation, and will finish proving a)). One begins by expressing the condition that  $\mathfrak{d}_S$  is a Lie subalgebra of  $\mathfrak{g}_S$ ; one sees at once that this is expressed by the fact that  $S \rightarrow S$  factors through a certain closed subscheme  $S_1$  of  $S$ , of  $S$ , of  $S$ , of  $S$  original page 310  $\rightarrow$  finite presentation over  $S$  (whose local equations on  $S$  can be written immediately using a basis of  $\mathfrak{g}$  adapted to the submodule  $\mathfrak{d}$ ). One may therefore suppose that one has already  $S = S_1$ . One must then express that  $\mathfrak{d}_S$  contains locally for fpqc a quasi-regular section of  $\mathfrak{g}_S$ , and for this one considers  $V = W(\mathfrak{d}) \cap U$ , where  $U$  is the open of regular points of  $W(\mathfrak{g})$  (2.10); then the structure morphism  $V \rightarrow S$  being smooth and quasi-compact, its image  $S_1$  is an open part of  $S$  and the immersion morphism  $S_1 \rightarrow S$  is quasi-compact i.e. of finite presentation. The condition envisaged on  $S_1$  is then expressed by saying that  $S_1 \rightarrow S$  factors through  $S_1$ . So one is reduced to the case where  $S = S_1$ , and using the theory of descent, to the case where  $\mathfrak{d}$  admits a section  $a$  that is a quasi-regular section of  $\mathfrak{g}$ . It remains finally to express that the section  $a_S$  of  $\mathfrak{g}_S$  deduced from  $a$  satisfies  $\text{ad}(a_S)(\mathfrak{d}_S) \subset \mathfrak{d}_S$ , a direct factor of  $\mathfrak{g}_S$ , which amounts again to saying that  $S \rightarrow S$  factors through a certain open subscheme of finite presentation of  $S$ , namely  $S_D$ , where  $D$  is the determinant of  $\text{ad}(a)(\mathfrak{g}/\mathfrak{d})$ . But then one sees at once that  $\mathfrak{d}_S|_{S_D}$  is a Cartan subalgebra of  $\mathfrak{g}_S|_{S_D}$ , hence  $S_D$  represents the functor  $F$ , which proves a).

b) Is immediate thanks to 2.11 a) and (XI 1.5). Of course b) is also a consequence of the more precise statement c).

c) Let  $a_0$  be a regular point of  $\mathfrak{g}(s)$  contained in  $\mathfrak{d}_0$ ; extend it to a section  $a$  of  $\mathfrak{g}$  on an open neighborhood  $V$  of  $s$ ; one may evidently suppose  $V = S$ . On the other hand let  $M_0$  be a complement of the vector space  $\mathfrak{d}_0$  in  $\mathfrak{g}(s)$ ; then in an open neighborhood  $V$  of  $s$  there exists a submodule  $M$  of  $\mathfrak{g}_S$ , a direct factor of  $\mathfrak{g}_S|_V$ , such that  $M(s) = M_0$ , and one may again suppose  $V = S$ . Let now  $\mathcal{V}$  be the subfunctor of  $\mathcal{D}$  such that  $\mathcal{V}(S)$  is the set of Cartan subalgebras  $\mathfrak{d}'$  of  $\mathfrak{g}_S$  satisfying the two following conditions:

- 1°)  $\mathfrak{d}'$  is a complement of  $M_S$ , and
- 2°) the unique section of  $(a_S + M_S) \cap \mathfrak{d}'$  is a regular section of  $\mathfrak{g}_S$ .

$\leftarrow$  original page 311  $\rightarrow$

Condition 1°) corresponds to an open  $V_1$  of  $\mathcal{D}$  (induced by the open of  $\text{Grass}_{n-r}(\mathfrak{g})$  defined by the same condition 1°)); the conjunction of 1°) and 2°) corresponds to an open of  $V_1$  by virtue of 2.10 and (C<sub>2</sub>). Hence  $\mathcal{V}$  is represented by an open subscheme  $V$  of  $\mathcal{D}$ , evidently containing  $d$ .

On the other hand let  $\mathcal{V}'$  be the subfunctor of  $W(M)$  defined by

$\mathcal{V}'(S) = \text{set of sections } u' \text{ of } M_S \text{ such that:}$

- (i)  $a_S + u'$  is a regular section of  $\mathfrak{g}_S$ , and
- (ii) the unique Cartan subalgebra  $\mathfrak{d}'$  of  $\mathfrak{g}_S$  containing  $a_S + u'$  is a complement of  $M_S$ .

Then condition 1°) corresponds to an open subscheme  $V_1$  of  $W(M)$ , namely the inverse image of the open  $U$  of regular points of  $W(\mathfrak{g})$  (cf. 2.10) by the translation morphism  $m \mapsto a + m$ . The conjunction of (i) and (ii) corresponds to an open  $V'$  of  $V_1$ , namely the inverse image of  $V$  by the obvious morphism  $V_1 \rightarrow V$  (associating to  $u'$  the unique Cartan subalgebra  $\mathfrak{d}'$  of  $\mathfrak{g}_S$  containing  $a_S + u'$ ). The restriction of this last morphism to  $V'$  is a morphism

$V' \xrightarrow{\sim} V$

which is evidently an isomorphism. This proves c).

**Corollary 2.17.** Let  $\mathfrak{g}$  be a finite-dimensional Lie algebra over a field  $k$ . Then the scheme  $\mathcal{D}$  of Cartan subalgebras of  $\mathfrak{g}$  (2.16 a)) is quasi-projective, smooth and irreducible. When  $\mathfrak{g}$  contains a regular element (for example when  $k$  is infinite),  $\mathcal{D}$  is a rational variety, i.e. its function field is a pure extension of  $k$ .

$\leftarrow$  label: III.XIV.2.17  $\rightarrow$

The fact that  $\mathcal{D}$  is irreducible follows from the fact that one has a surjective morphism  $\psi^{-1}(U) \rightarrow \mathcal{D}$ , and  $\psi^{-1}(U)$  is irreducible, being isomorphic to the open  $U$  of  $W(\mathfrak{g})$ . The assertion on the function field is an immediate consequence of c).

**Remark 2.18.** I do not know if this conclusion remains valid if  $k$  is finite, without supposing that  $\mathfrak{g}$  contains a regular point; compare 2.12. One can prove that this is the case when  $\mathfrak{g}$  is the Lie algebra of an algebraic group  $G$  smooth over  $k$ , at least when  $G$  is an "adjoint" semisimple group, by using a result of Chevalley pointed out below (cf. Appendix). It is plausible that this result remains valid without restriction on  $G$ ; it would suffice for this that the cited result of Chevalley be proved for every (not necessarily adjoint) semisimple algebraic group.

<!-- label: III.XIV.2.18 -->

## 3. Subgroups of type (C) of group preschemes over an arbitrary prescheme

<!-- label: III.XIV.3 -->

**Theorem 3.1.** Let  $S$  be a prescheme,  $G$  a smooth  $S$ -prescheme in groups,  $\mathfrak{g}$  its Lie algebra (which is a locally free module of finite type over  $S$ ),  $\mathfrak{h}$  a Lie subalgebra of  $\mathfrak{g}$  that is (as a module) a locally direct factor in  $\mathfrak{g}$ , and such that for every  $s \in S$ , the geometric fiber  $\mathfrak{h}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ . Let  $a$  be a quasi-regular section of  $\mathfrak{g}$  (2.5). Then\*

$M_a = \text{Transp}_G(a, \mathfrak{h})$

is a subfunctor of  $G$  whose  $S$ -valued points are the  $g \in G(S)$  such that  $\text{ad}(g) \cdot a \in \mathfrak{h}$  is representable by a closed subprescheme  $[^{\text{N.D.E-XIV-2}}$  of  $G$  smooth over  $S$ , whose structure morphism to  $S$  is surjective.\*

<!-- label: III.XIV.3.1 -->

Consider the canonical morphism

$\phi : G \times_S W(\square) \rightarrow W(\square)$

given by  $(g, x) \mapsto \text{ad}(g) \cdot x$ ; then  $M_a$  is  $S$ -isomorphic to  $\varphi^{-1}(a)$ , the inverse image of  $a$  (considered as a section of  $W(\mathfrak{g})$  over  $S$ ) by  $\varphi$ . It will suffice for the smoothness of  $M_a$  to show that  $\varphi$  is smooth at points of  $G \times_S W(\mathfrak{h})$  lying over  $\text{Im}(a)$ ; more generally  $\varphi$  is smooth at every point lying over a point of  $W(\mathfrak{g})$  that is regular in its fiber  $W(\mathfrak{g}(s))$  over  $S$ . To see this, since the source and target of  $\varphi$  are smooth, hence flat locally of finite presentation over  $S$ , one is reduced to making the verification fiber by fiber, which reduces us to the case where  $S$  is the spectrum of an algebraically closed field,  $G$  thus being a locally algebraic group over  $k$ ,  $\mathfrak{h}$  a Lie subalgebra of its Lie algebra  $\mathfrak{g}$ , containing a Cartan subalgebra of  $\mathfrak{g}$ , and  $a$  a regular point  $\varphi^{-1}(a)$  (original page 313 --> of  $\mathfrak{g}$ ). One may evidently suppose (taking into account that  $\varphi$  is a  $G$ -morphism) that the point of  $G \times W(\mathfrak{h})$  envisaged is of the form  $(e, a)$ . One may evidently suppose  $G$  connected, hence of finite type over  $k$ , but then our assertion is none other than (XIII 5.4). Moreover, the fact that  $M_a$  is a closed subprescheme of  $G$  (of finite presentation over  $S$ ) is trivial, since  $M_a$  is the inverse image of  $W(\mathfrak{h})$  by the morphism  $g \mapsto \text{ad}(g) \cdot a$  of  $G$  into  $W(\mathfrak{g})$ . The surjectivity of the structure morphism  $M_a \rightarrow S$  also reduces to the case of an algebraically closed base field, but then  $\mathfrak{h}$  contains a Cartan subalgebra  $\mathfrak{d}$  by hypothesis, which is therefore conjugate to the Cartan subalgebra  $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$  by the conjugation theorem (XIII 6.1 a)), hence  $\mathfrak{h}$  contains a conjugate of  $a$ . This completes the proof of 3.1.

**Corollary 3.2.** Let  $G$ ,  $\mathfrak{g}$  be as in 3.1, with  $G$  of finite type over  $S$ ; let  $\mathfrak{k}$  and  $\mathfrak{h}$  be two Lie subalgebras of  $\mathfrak{g}$ , locally direct factors (as modules); suppose that one is under one of the two following hypotheses:\*

<!-- label: III.XIV.3.2 -->

a) For every  $s \in S$ , the geometric fiber  $\mathfrak{k}_s$  is nilpotent and contains a regular element of  $\mathfrak{g}_s$ ; the geometric fiber  $\mathfrak{h}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ .\*

\*b)  $\mathfrak{k}$  is a Cartan subalgebra of  $\mathfrak{g}$ .\*

\*Then  $\text{Transp}_G(\mathfrak{k}, \mathfrak{h})$  is a closed subscheme of  $G$  smooth over  $S$ ; moreover, in case a), its structure morphism to  $S$  is surjective.\*

The fact that the transporter is representable by a closed subscheme of finite presentation of  $G$  is immediate, and left to the reader. Let us first prove smoothness in case a). Suppose first that there exists a section  $a$  of  $\mathfrak{k}$  that is quasi-regular in  $\mathfrak{g}$ . Then it suffices to apply 3.1 and the

**Lemma 3.3.** \*Under the conditions of 3.2 a), if  $a$  is a section of  $\mathfrak{k}$  quasi-regular in  $\mathfrak{g}$ , then one has\*

<!-- label: III.XIV.3.3 -->

```text  
Transp_G($\square$, $\square$) = Transp_G(a, $\square$).
```

<!-- original page 314 -->

Indeed, taking the definitions into account, this amounts to showing that if  $a$  is moreover a section of  $\mathfrak{h}$ , then one has  $\mathfrak{k} \subset \mathfrak{h}$ . Now since by hypothesis  $\mathfrak{k}$  is locally nilpotent, it follows from 2.1 that  $\mathfrak{k} \subset \text{Nil}(a, \mathfrak{g})$ ; on the other hand  $\text{Nil}(a, \mathfrak{g}) \subset \mathfrak{h}$  because  $\text{ad}(a)|_{\mathfrak{g}/\mathfrak{h}}$  is injective (being so fiber by fiber by virtue of (XIII 4.8 b)). Whence the conclusion. In the general case, one reduces to the case where  $S$  is affine noetherian by the standard procedure, then to the case where  $S$  is local artinian (smoothness being a property of infinitesimal nature), and by flat descent to the case where its residue field is infinite, hence the fiber  $K_{\{0\}}$  admits an element that is regular in  $\mathfrak{g}_{\{0\}}$ . One lifts this element to an element of  $K = \Gamma(\mathfrak{k})$ , which reduces us to the preceding case. Thus, in case a) we have proved the smoothness of the transporter; as for the fact that its structure morphism is surjective, it reduces to the case where  $S$  is the spectrum of an algebraically closed field, hence where  $K$  contains a regular point of  $\mathfrak{g}$ , and one applies 3.3 and 3.1.

To prove b), one is reduced by the definition of smoothness (XI 1.1) to proving that if  $S$  is affine,  $S_{\{0\}}$  a subscheme defined by a quasi-coherent nilpotent ideal  $J$ ,  $g_{\{0\}}$  an element of  $G(S_{\{0\}})$  that transports  $\mathfrak{k}_{\{0\}}$  into  $\mathfrak{g}_{\{0\}}$ , then  $g_{\{0\}}$  lifts to an element  $g$  of  $G(S)$  that transports  $\mathfrak{k}$  into  $\mathfrak{g}$ . Now the hypothesis on  $g_{\{0\}}$  implies that one is under the conditions of a), already treated. This completes the proof.

Of course, when in 3.2 b)  $\mathfrak{h}$  satisfies the stronger hypothesis of 3.1, then (and only then) the structure morphism  $\text{Transp}_G(\mathfrak{d}, \mathfrak{h}) \rightarrow S$  is surjective. Using Hensel's lemma (XI 1.10), one concludes from 3.1 and 3.2:

**Corollary 3.4.** \*Under the conditions of 3.1 for  $G$  and  $\mathfrak{h}$ , and supposing  $G$  of finite type over  $S$ :\*

<!-- label: III.XIV.3.4 -->

\*a) For every quasi-regular section  $a$  of  $\mathfrak{g}$ , there locally exists for the étale topology a conjugate of  $a$  that is a section of  $\mathfrak{h}$ .\*

\*b) For every Cartan subalgebra  $\mathfrak{d}$  of  $\mathfrak{g}$ ,  $\mathfrak{d}$  is locally for the étale topology conjugate to a subalgebra of  $\mathfrak{h}$ .\*

In particular, when  $\mathfrak{h}$  is itself a Cartan subalgebra of  $\mathfrak{g}$ , one finds: <!-- original page 315 -->

**Corollary 3.5.** \*Let  $G$  be a smooth  $S$ -prescheme in groups of finite type,  $\mathfrak{g}$  its Lie algebra,  $\mathfrak{d}$  and  $\mathfrak{d}'$  two Cartan subalgebras of  $\mathfrak{g}$ . Then  $\text{Transp}_G(\mathfrak{d}, \mathfrak{d}')$  is identical to the strict transporter of  $\mathfrak{d}$  into  $\mathfrak{d}'$ , and is a closed subscheme of  $G$  smooth over  $S$ , with surjective structure morphism. Locally for the étale topology,  $\mathfrak{d}$  and  $\mathfrak{d}'$  are conjugate.\*

<!-- label: III.XIV.3.5 -->

The fact that the transporter is identical here to the strict transporter follows trivially from the fact that

$\mathfrak{d}$  and  $\mathfrak{d}'$  are locally direct factors in  $\mathfrak{g}$  and have the same rank at every point. Hence 3.5 is a particular case of 3.4. In particular, if  $\mathfrak{d} = \mathfrak{d}'$ :

**Corollary 3.6.** Let  $G$  be as in 3.5, and let  $\mathfrak{d}$  be a Cartan subalgebra of  $\mathfrak{g}$ . Then  $\text{Norm}_G(\mathfrak{d})$  is a closed subscheme in groups of  $G$  smooth over  $S$ , whose Lie algebra is identical to  $\mathfrak{d}$ .

<!-- label: III.XIV.3.6 -->

Indeed, this last assertion amounts to saying that  $\mathfrak{d}$  is its own normalizer in  $\mathfrak{d}$ , which follows at once from the fact that this is true fiber by fiber.

**Corollary 3.7.** Let  $G$ ,  $\mathfrak{g}$  be as in 3.5. Then conditions  $(C_2)$ ,  $(C_1')$ ,  $(C_1)$  of 2.9 are equivalent; in other words, if  $\mathfrak{g}$  admits locally for the fpqc topology a Cartan subalgebra, then every quasi-regular section of  $\mathfrak{g}$  is regular.

<!-- label: III.XIV.3.7 -->

Indeed, let  $s$  be a quasi-regular section; let us prove that it is regular. The question being local for the fpqc topology, one may suppose that  $\mathfrak{g}$  admits a Cartan subalgebra  $\mathfrak{d}$ . By virtue of 3.4 a),  $s$  is then locally for the étale topology conjugate to a section of  $\mathfrak{d}$ , which reduces us to the case where  $s$  is a section of  $\mathfrak{d}$ , where the conclusion is trivial from the definition.

**Definition 3.8.** Let  $G$  be a smooth prescheme in groups over a prescheme  $S$ . One calls a subgroup of type (C) of  $G$  a subscheme in groups  $D$  of  $G$ , smooth over  $S$ , with connected fibers, such that  $\mathfrak{d} = \text{Lie}(D)$  is a Cartan subalgebra (2.4) of  $\mathfrak{g} = \text{Lie}(G)$ , i.e. such that for every  $s \in S$ ,  $D_s$  is a subgroup of type (C) of the algebraic group  $G_s$  (XIII 6.2).

<!-- label: III.XIV.3.8 -->

<!-- original page 316 -->

**Theorem 3.9.** Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation,  $\mathfrak{g}$  its Lie algebra. Then:

<!-- label: III.XIV.3.9 -->

a) The map

$$D \mapsto \mathfrak{d} = \text{Lie}(D)$$

establishes a bijective correspondence between subgroups of type (C) of  $G$  and Cartan subalgebras of  $\mathfrak{g}$ .

b) If  $D$  and  $\mathfrak{d}$  correspond, one has

$$\text{Norm}_G(D) = \text{Norm}_G(\mathfrak{d}),$$

it is a closed subscheme of  $G$  smooth over  $S$ , and one has

$$D = \text{Norm}_G(D)^{\{0\}} = \text{Norm}_G(\mathfrak{d})^{\{0\}}.$$

c) Two subgroups of type (C)  $D$  and  $D'$  of  $G$  are conjugate locally for the étale topology.

**Proof.** Let  $D$  be a subgroup of type (C) of  $G$ , and  $\mathfrak{d}$  its Lie algebra; then  $D \subset \text{Norm}_G(\mathfrak{d})$ , and by virtue of Definition 3.8 and 3.6 this is an inclusion of preschemes in groups smooth over  $S$ , inducing an isomorphism on the Lie algebras. Since  $D$  has connected fibers, one therefore has  $D = \text{Norm}_G(\mathfrak{d})^{\{0\}}$ . Hence the map envisaged in a) is injective; let us prove that it is surjective. So let  $\mathfrak{d}$  be a Cartan subalgebra of  $\mathfrak{g}$ ; then by virtue of 3.6  $\text{Norm}_G(\mathfrak{d}) = N$  is a closed subscheme in groups of  $G$  smooth over  $S$ , admitting  $\mathfrak{d}$  as Lie algebra. Since  $G$  is of finite

presentation over  $S$ , the same is true of  $N$ , hence (as was pointed out in XII after 7.3) the union of the connected components of the fibers of  $N$  is the underlying set of an open subscheme in groups  $N^{\circ}$  of  $N$ , which is evidently a subgroup of type (C) of  $G$  having Lie algebra  $\mathfrak{d}$ . This proves a); the first assertion of b) follows from it at once;  $\leftarrow$  original page 317  $\rightarrow$  and the formula  $D = \text{Norm}_G(\mathfrak{d})^0$  has already been proved. Finally, c) follows from a) and 3.5.

**Corollary 3.10.** Suppose that  $\mathfrak{g}$  admits locally for the fpqc topology a Cartan subalgebra (or equivalently, by virtue of 3.9 a), that  $G$  admits locally for the fpqc topology a subgroup of type (C)). Consider the functor  $\mathcal{D} : (\text{Sch})^{\circ}/S \rightarrow (\text{Ens})$  defined by  $\mathcal{D}(S') =$  set of subgroups of type (C) of  $G_{S'}$ . Then this functor is representable by a quasi-projective and smooth prescheme over  $S$ , with connected geometric fibers. When  $S$  is the spectrum of a field  $k$ , hence  $G$  a smooth algebraic group over  $k$ , and  $\mathfrak{g}$  admits a regular point (condition automatically satisfied if  $k$  is infinite), then  $\mathcal{D}$  is a rational variety over  $k$ .

$\leftarrow$  label: III.XIV.3.10  $\rightarrow$

Indeed, by virtue of 3.9 a), the functor  $\mathcal{D}$  is canonically isomorphic to the functor envisaged in 2.16; on the other hand by virtue of 3.7 condition (C<sub>2</sub>) is satisfied. Hence 3.10 follows from 2.16 and 2.17.

**Corollary 3.11.** Let  $D$  be a subgroup of type (C) of  $G$ , and let  $N$  be its normalizer in  $G$ . Then the quotient sheaf  $G/N$  is canonically isomorphic to the functor  $\mathcal{D}$  of 3.10, hence representable by a quasi-projective and smooth prescheme over  $S$ , with connected geometric fibers.\*

$\leftarrow$  label: III.XIV.3.11  $\rightarrow$

**Proposition 3.12.** Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation over  $S$ ,  $H$ ,  $K$  two subschemes in groups, smooth of finite presentation over  $S$ , with  $K$  having connected fibers;  $\mathfrak{g}$ ,  $\mathfrak{k}$ ,  $\mathfrak{h}$  the corresponding Lie algebras. Suppose that one of the two following conditions is realized for the geometric fibers of these latter:\*

$\leftarrow$  label: III.XIV.3.12  $\rightarrow$

$\leftarrow$  original page 318  $\rightarrow$

a) For every  $s \in S$ ,  $\mathfrak{k}_s$  contains a regular element of  $\mathfrak{g}_s$ , and  $\mathfrak{h}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ .\*

b) For every  $s \in S$ ,  $\mathfrak{k}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ .\*

Under these conditions, in order to have  $H \supset K$ , it is necessary and sufficient that one have  $\mathfrak{h} \supset \mathfrak{k}$ .\*

Of course, we need only prove that if  $\mathfrak{h} \supset \mathfrak{k}$ , then  $H \supset K$ . In case b), the inclusion  $\mathfrak{h} \supset \mathfrak{k}$  shows that one is in fact under the conditions of a), so it suffices to prove a). Proceeding as in 3.2 a) by reduction to the case  $S$  local artinian, one is reduced to the case where there exists a section  $a$  of  $\mathfrak{k}$  that is quasi-regular in  $\mathfrak{g}$ . In this case, proceeding as in (XIII 5.5), one is reduced to the following statement:

**Corollary 3.13.** Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation over  $S$ ,  $H$  a subscheme in groups of  $G$  smooth of finite presentation over  $S$ ,  $\mathfrak{g}$  and  $\mathfrak{h}$  the Lie algebras,  $a$  a section of  $\mathfrak{h}$  that is quasi-regular in  $\mathfrak{g}$ . Suppose that for every  $s \in S$ , the geometric fiber  $\mathfrak{h}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ . Let\*

$\leftarrow$  label: III.XIV.3.13  $\rightarrow$

$$M_a = \text{Transp}_G(a, \mathfrak{h}),$$

which is a closed subscheme of  $G$  smooth over  $S$  (cf. 3.1), so that  $M^0_a$  (union of the connected components of the identity element in the fibers of  $M_a$ ) is an open part of  $M_a$ , which we shall endow with the structure induced by  $M_a$ . One then has  $H^0 = M^0_a$ .\*

Evidently one has  $H \subset M_a$ , whence  $H^0 \subset M^0_a$ . Since this is an inclusion of preschemes smooth over  $S$ , to prove that it is an equality, one is reduced to verifying it on the fibers, which reduces us to the case

where  $S$  is the spectrum of an algebraically closed field, a case treated in (XIII 5.4).

**Corollary 3.14.** Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation,  $D$  a subgroup of type (C) of  $G$ ,  $H$  a subprescheme in groups of  $G$  smooth over  $S$  and of finite presentation over  $S$ ,  $\mathfrak{d}$  and  $\mathfrak{h}$  their Lie algebras. Then one has\*

III.XIV.3.14 -->

text  
 $\text{Transp}_G(D, H) = \text{Transp}_G(\mathfrak{d}, \mathfrak{h}),$

\*and this functor is representable by a closed subprescheme of  $G$  smooth over  $S$ .\*

Indeed, the identity between the two transporters follows from 3.12 b), which allows one to apply 3.2.

**Corollary 3.15.** Let  $G$ ,  $H$  be as in 3.14 and suppose that for every  $s \in S$ , the geometric fiber  $\mathfrak{h}_s$  contains a Cartan subalgebra of  $\mathfrak{g}_s$ . Suppose moreover that  $\mathfrak{g}$  admits locally for the fpqc topology a Cartan subalgebra. Then locally for the étale topology,  $H$  contains a subgroup of type (C) of  $G$ .\*

III.XIV.3.15 -->

By virtue of 3.7 and 3.9 a),  $G$  admits locally for the étale topology a subgroup of type (C), so one may suppose that  $G$  admits such a subgroup, say  $D$ . Then the hypothesis on  $\mathfrak{h}$  means also that the structure morphism of the transporter considered in 3.14 is surjective (taking into account the conjugation theorem XIII 6.1 a)). One concludes by Hensel's lemma (XI 1.10).

**Corollary 3.16.** Let  $G$ ,  $H$ ,  $K$  be as in 3.12 a); suppose moreover that for every  $s \in S$ , the geometric fiber  $\mathfrak{k}_s$  is nilpotent (i.e.  $\mathfrak{k}$  is locally nilpotent). Then one has\*

III.XIV.3.16 -->

text  
 $\text{Transp}_G(K, H) = \text{Transp}_G(\mathfrak{k}, \mathfrak{h}),$

\*and this functor is representable by a closed subprescheme of  $G$  smooth over  $S$ , whose structure morphism to  $S$  is surjective.  $H$  contains locally for the étale topology a subgroup conjugate to  $K$ .\*

original page 320 -->

The identity of the two transporters is again contained in 3.12 a), the assertion on its structure is then none other than 3.2 a), and the last assertion of 3.16 is then a consequence of Hensel's lemma.

**Remarks 3.17.** a) In 3.12 and 3.16, one may replace the hypothesis that  $K$  is smooth over  $S$  by the following weaker hypothesis: the sheaf  $\mathcal{O}_K^*(\Omega^1_{K/S}) = \Omega^1_K$  of relative 1-differentials along the unit section is locally free. In this way, 3.12 contains (XIII 5.5).

III.XIV.3.17 -->

b) Let  $G$ ,  $\mathfrak{g}$ ,  $\mathfrak{h}$  be as in 3.1, with  $G$  of finite presentation over  $S$ . Then  $N = \text{Norm}_G(\mathfrak{h})$  is not necessarily smooth over  $S$  along the unit section, or equivalently, there does not necessarily exist a subprescheme in groups  $H$  of  $S$  smooth over  $S$  whose Lie algebra is  $\mathfrak{h}$ , even if  $S$  is the spectrum of a field. When such an  $H$  exists, so that one has (taking  $H$  with connected fibers)  $N = \text{Norm}_G(H)$ , I do not know whether  $N$  is smooth over  $S$ . In this question, one may evidently reduce to the case where  $S$  is local artinian.

To conclude this section, let us examine the case where  $G$  is "semisimple" over  $S$ :

**Theorem 3.18.** Let  $S$  be a prescheme,  $G$  a smooth  $S$ -prescheme in groups over  $S$ , whose geometric fibers are "adjoint" semisimple groups, i.e. semisimple with reductive center (XII 4.1 and 4.4) reduced to the unit group. Then the subgroups of type (C) of  $G$  are identical with its maximal tori, hence also with its Cartan subgroups (XII 3.1).\*

III.XIV.3.18 -->

Taking definitions into account, one is reduced to the case where  $S$  is the spectrum of an algebraically closed field, and to proving then that for a maximal torus  $T$  of  $G$ , the Lie algebra  $\mathfrak{t}$  of  $T$  is a Cartan subalgebra of  $\mathfrak{g}$ , that is to say (taking into account the inequality  $\text{nilpotent rank of } \mathfrak{t} \leq \text{nilpotent rank of } G = \dim T = \text{rank } G = r$ ) that there exists  $x \in \mathfrak{t}$  with  $\dim \text{Nil}(x, \mathfrak{g}) = r$ . Since  $\mathfrak{t}$  is abelian and *a fortiori* nilpotent, it amounts to the same to say that there exists  $a \in \mathfrak{t}$  such that  $\text{ad}(a)_{\mathfrak{g}/\mathfrak{t}}$  is injective <!-- original page 321 --> (XIII 5.7 a)). Now consider the characters  $\alpha$  of  $T$  that intervene in the representation of  $T$  induced by the adjoint representation of  $G$ . The structure theory of the semisimple group  $G$  (\*Bible\*, 13 th. 1 a) and th. 3, cor. 2), more precisely the "big cell" of  $G$ , semidirect product of  $T$  and subgroups  $P_{\alpha}$  isomorphic to the additive group  $G_{\alpha}$ , preserved by  $T$  and corresponding to the "root" characters of  $G$  for the torus  $T$ , shows that the eigenspace of  $\mathfrak{g}$  relative to the trivial character is none other than  $\mathfrak{t}$ , and the other eigenspaces are of dimension 1, the characters  $\alpha$  associated being none other than the roots of  $G$  for  $T$ . By virtue of the computation of the reductive center of  $G$  as the intersection of the kernels of the characters of  $T$  that intervene in the adjoint representation of  $G$  (XII 4.8), one sees that the fact that  $G$  is adjoint is interpreted as saying that the roots generate the lattice  $M = \text{Hom}(T, G_m)$ . Now a well-known lemma of the theory of roots tells us that every root is part of a system of simple roots, hence of a basis of the group generated by the roots, and consequently of a basis of the dual  $M^*$  of  $T$  [N.D.E-XIV-3]. We conclude:

**Corollary 3.19.** \*If  $G$  is an adjoint semisimple algebraic group over an algebraically closed field  $k$ ,  $T$  a maximal torus of  $G$ , then for every root  $\alpha$  of  $G$  with respect to  $T$ ,  $\alpha : T \rightarrow G_m$ , the corresponding homomorphism  $\alpha' : \mathfrak{t} \rightarrow k$  is non-zero.\*

<!-- label: III.XIV.3.19 -->

This result is essentially equivalent to Theorem 3.18, for given  $t \in \mathfrak{t}$ ,  $\text{ad}(t)$  is semisimple and its eigenvalues in  $\mathfrak{g}/\mathfrak{t}$  are none other than the  $\alpha'(t)$ , hence  $\text{ad}(t)_{\mathfrak{g}/\mathfrak{t}}$  is injective if and only if the  $\alpha'(t)$  are  $\neq 0$ , and there exists  $t \in \mathfrak{t}$  having this property if and only if all the  $\alpha'$  are  $\neq 0$ .

**Corollary 3.20.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups, smooth, of finite presentation over  $S$ , whose geometric fibers are connected reductive algebraic groups (i.e. extensions of a semisimple group by a torus). Then for every  $s \in S$  there exists an open neighborhood  $U$  of  $s$  such that  $G|_U$  admits a maximal torus.\* [XIV-3-1]

<!-- label: III.XIV.3.20 -->

We shall see indeed in XVI that the hypothesis just made on  $G$  implies <!-- original page 322 --> that  $G$  is affine over  $S$  and of locally constant reductive rank; hence (XII 4.7 c))  $G$  admits a reductive center  $Z$ ,  $G' = G/Z$  is a smooth and affine group over  $S$  whose reductive center is reduced to the unit group, and finally the maximal tori of  $G$  and of  $G'$  are in bijective correspondence. Moreover, one sees at once that the geometric fibers of  $G$  are connected semisimple groups, and moreover adjoint by definition (their reductive center being trivial). So it suffices to limit oneself to the case where  $G$  is semisimple and adjoint, and by virtue of 3.18 one is reduced to finding an open neighborhood  $U$  of  $s$  and a subgroup of type (C) of  $G|_U$ , or equivalently (3.9 a)) a Cartan subalgebra of  $\mathfrak{g}|_U$ . Now this is possible if  $k(s)$  is infinite, since by virtue of 3.7  $\mathfrak{g}$  satisfies condition (C<sub>2</sub>) of 2.9, hence one may apply 2.11 b). In fact, statement 3.20 remains valid without supposing  $k(s)$  infinite. Indeed, by the preceding argument, it suffices to know that for every adjoint semisimple group  $G$  over a finite field  $k$ , the Lie algebra  $\mathfrak{g}$  of  $G$  contains a regular element. Now this statement has been proved by Chevalley (using the properties of the Coxeter element of the Weyl group...), cf. the Appendix below by J.-P. Serre.

**Remarks 3.21.** a) Statement 3.20 remains valid, with essentially the same proof, replacing  $G$  by a closed subprescheme in groups  $H$  smooth over  $S$ , having everywhere the same rank as  $G$  (for example a "parabolic subgroup" of  $G$ ), provided that  $k(s)$  is infinite. I do not know if here again the hypothesis that  $k(s)$  is infinite is superfluous. One can show that this is the case at least if  $H$  is parabolic, thanks to the construction of the radical  $U$  of  $H$  and of the quotient  $H/U$ , which reduces us to the semisimple case. Unfortunately, the method of regular elements seems here powerless, since one easily constructs examples (for example with the projective group and its "standard" Borel subgroup) where the Lie algebra  $\mathfrak{h}$  of  $H$  does not contain any regular element.

<!-- label: III.XIV.3.21 -->

<!-- original page 323 -->

b) The proof of 3.20 in fact shows a more precise result (by invoking 3.9 b)) in the case where  $k(s)$  is infinite, namely that every maximal torus  $T_{\{s\}}$  of  $G_{\{s\}}$  comes from a maximal torus  $T$  on an open neighborhood of  $s$ . I do not know if this statement remains valid when  $k(s)$  is no longer supposed infinite; the difficulty obviously coming from the fact that the Lie algebra  $\mathfrak{t}_{\{s\}}$  of  $T_{\{s\}}$  does not in general contain a regular element of the

Lie algebra  $\mathfrak{g}_{\{0\}}$  of the fiber  $G_{\{s\}}$ . An affirmative answer to this problem would imply the following statement (which is proved only in the case of an infinite residue field or when  $A$  is separated and complete): Let  $A$  be a local ring, with residue field  $k$ ,  $M$  an "Azumaya algebra" over  $A$ , i.e. an algebra such that  $M$  is a free module of finite type over  $A$ , and  $M_{\{0\}} = M \otimes_A k$  a central simple algebra over  $k$ ,  $D_{\{0\}}$  a commutative subalgebra of  $M_{\{0\}}$  separable over  $k$ , such that  $[M_{\{0\}} : k] = ([D_{\{0\}} : k])^2$ ; then there exists a commutative subalgebra  $D$  of  $M$ , which is a direct factor module in  $M$  and such that  $D \otimes_A k = D_{\{0\}}$  (?). (Note that the datum of  $M$  is equivalent to the datum of a principal homogeneous bundle under the projective group  $\mathrm{PGL}(n)_A$ , whence an "inner" twisted form  $G$  of  $\mathrm{PGL}(n)$ , and the maximal tori of  $G$  correspond bijectively to the commutative subalgebras  $D$  of  $M$  étale over  $A$  of rank  $n$  over  $A$ .)

c) Applying 3.20 to the centralizer of a subtorus  $Q$  of  $G$  ( $G$  a reductive  $S$ -prescheme in groups), one deduces that every such  $Q$  is contained, locally for the Zariski topology, in a maximal torus of  $G$ .

## 4. A digression on Borel subgroups

<!-- label: III.XIV.4 -->

**Definition 4.1.** Let  $G$  be a smooth algebraic group over an algebraically closed field. One calls a Borel subgroup of  $G$  a smooth, solvable, connected algebraic subgroup that is maximal for these properties.\*

<!-- label: III.XIV.4.1 -->

When  $G$  is affine, one thus recovers the terminology of (\*Bible\* 6 def. 1). Let us note at once that if  $Z$  is a connected and smooth subgroup of  $G$  contained in the center <!-- original page 324 --> (or more generally, solvable and invariant), then for every Borel subgroup  $B$  of  $G$ , the image  $BZ$  of  $B \times Z$  by the morphism  $(b, z) \mapsto bz$  of  $B \times Z$  into  $G$  is a smooth, solvable, connected subgroup of  $G$  containing  $B$ , hence identical to  $B$ , hence  $B$  contains  $Z$ , hence  $B$  is the inverse image of an algebraic subgroup  $B'$  of  $G' = G/Z$ , and it is immediate that  $B'$  is a Borel subgroup of  $G'$ . Taking  $Z = \mathrm{Cent}(G^{\mathrm{circ}})$ ,  $G' = G/Z$  is affine (XII 6.1), hence the Borel subgroups of  $G'$  are conjugate and for such a  $B'$ ,  $G'/B'$  is a projective variety (\*Bible\* 6 th. 4). Consequently:

**Proposition 4.2.** Let  $G$  be as in 4.1. Then the Borel subgroups of  $G$  are conjugate. If  $B$  is a Borel subgroup, then  $G/B$  is a projective variety. The maximal tori of  $B$  (resp. the Cartan subgroups of  $B$ ,  $G$  being connected) are maximal tori of  $G$  (resp. Cartan subgroups of  $G$ ).\*

<!-- label: III.XIV.4.2 -->

It remains to prove the last assertion, and one may evidently suppose  $G = G^{\{0\}}$ . For the Cartan subgroups, it follows from the analogous assertion in  $G'$  (\*Bible\* 6 th. 4 cor. 4) and from (XII 6.6 e)). For the maximal tori, it follows from the preceding, since by (XII 6.6 c)) the maximal tori of a smooth algebraic group are the maximal tori of its Cartan subgroups.

**Corollary 4.3.** Suppose  $G$  connected. Then every element of  $G$  is contained in a Borel subgroup of  $G$ .\*

<!-- label: III.XIV.4.3 -->

One is reduced to the same statement in  $G'$ , which is well known (\*Bible\* 6 th. 5 d)).

**Corollary 4.4.** Let  $B$  be a Borel subgroup of  $G$ ,  $C$  a Cartan subgroup of  $B$ ,  $N$  its normalizer in  $G$ ; then  $N \cap B = C$ .\*

<!-- label: III.XIV.4.4 -->

Indeed,  $N \cap B = \mathrm{Norm}_B(C)$ , so one is reduced to showing that when  $G$  is connected and solvable, a Cartan subgroup  $C$  is its own connected <!-- original page 325 --> normalizer. Now with the preceding notations,  $C$  is the inverse image of a Cartan subgroup  $C'$  of  $G'$ , so one is reduced to the case where  $G$  is affine. Since one knows that the normalizer of a Cartan subgroup is smooth ( $C$  being its own connected normalizer, cf. for example XII 6.6 c)), it suffices to see that  $C$  and  $N$  have the same  $k$ -valued points, which is none other than (\*Bible\* th. 6 d)).

**Definition 4.5.** Let  $G$  be a smooth prescheme in groups of finite presentation over a prescheme  $S$ . One calls a Borel subgroup of  $G$  any subprescheme in groups  $B$  of  $G$ , smooth of finite presentation, such that for every  $s \in S$ , the geometric fiber  $B_{\{s\}}$  is a Borel subgroup of  $G_{\{s\}}$ .\*

<!-- label: III.XIV.4.5 -->

This is therefore, as one verifies at once, a notion stable by base change and of local nature for the fpqc topology (for if  $k'$  is an algebraically closed extension of an algebraically closed field  $k$ , then an algebraic subgroup  $B$  of the smooth algebraic group  $G$  over  $k$  is a Borel subgroup of  $G$  if and only if  $B_{k'}$  is one of  $G_{k'}$ ). It follows from this definition that if  $G$  is a smooth algebraic group over an arbitrary field  $k$ ,  $B$  a Borel subgroup of  $G$ , then  $G/B$  is a projective variety, every maximal torus  $T$  of  $B$  is a maximal torus of  $G$ , its normalizer in  $B$  is identical to its centralizer  $C$ , and is a Cartan subgroup of  $G$  when  $G$  is connected.

**Remarks 4.6.** Unfortunately, it is no longer true in general (even if  $G$  is affine over  $S$  and  $S$  is the spectrum of the algebra of dual numbers over an algebraically closed field  $k$ ) that two Borel subgroups of  $G$  are conjugate locally for the fpqc topology. As a consequence of this regrettable fact, let us point out that if  $G$  is a smooth, affine, connected algebraic group over a non-perfect field  $k$ , it is not possible in general to define in a natural way a homogeneous space  $\mathcal{D}$  under  $G$ , playing the role of a flag variety, i.e. of the variety of Borel subgroups of  $G$  (which, over the algebraic closure  $\bar{k}$  of  $k$ , would therefore be isomorphic to  $G_{\bar{k}}/B$ , where  $B$  is a Borel subgroup of  $G_{\bar{k}}$ ). Indeed, when the quotient of  $G_{\bar{k}}$  by its radical  $R$  is an adjoint semisimple group, then the kernel of  $G_{\bar{k}} \rightarrow \operatorname{Aut}(\mathcal{D})$  is the radical of  $G_{\bar{k}}$ , hence if  $\mathcal{D}$  came from a homogeneous space  $\mathcal{D}$  under  $G$ , the radical  $R$  would come from a subgroup  $R$  of  $G$ . Now one easily constructs examples where  $G_{\bar{k}}/R$  is adjoint but  $R$  is not "defined over  $k$ ". It is easy to see that under these conditions, the functor  $\mathcal{B} : (S) \rightarrow \text{Set}$  such that  $\mathcal{B}(S) = \text{set of Borel subgroups of } G_S$  is not representable by a smooth  $S$ -prescheme. From the infinitesimal point of view (III § 3), the non-validity of the conjugation theorem is expressed by the fact that if  $B$  is a Borel subgroup of the smooth algebraic group  $G$ , the cohomology group  $H^1(B, \mathcal{B})$  can be different from zero.

!-- label: III.XIV.4.6 -->

We shall see on the other hand in a later exposé that when  $G$  is semisimple, or more generally reductive, such unpleasant phenomena do not occur. It is these phenomena no doubt, as well as the absence of good existence theorems, that explain why Borel subgroups play only a relatively effaced role in the study of general group schemes from the scheme-theoretic point of view, while they will dominate the theory of semisimple group schemes in the later exposés.

**Proposition 4.8.** [N.D.E-XIV-5] \*Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation with connected fibers,  $B$  a Borel subgroup of  $G$ ; then  $B$  is identical to its own normalizer, and is a closed subprescheme of  $G$ .\*

!-- label: III.XIV.4.8 -->

Indeed, by virtue of (XII 7.10), one is reduced to proving that over an algebraically closed field  $k$ , every element of  $G(k)$  that normalizes  $B$  is in  $B(k)$ , which for  $G$  affine is a fundamental result of Chevalley (\*Bible\* 9 th. 1); the general case reduces to it at once by the reduction already used in 4.2.

**Remark 4.8.1.** One can generalize Definition 4.5 by also introducing the notion of parabolic subgroup of  $G$ : one calls thus a subprescheme in groups  $P$  of  $G$ , smooth and of finite presentation over  $S$ , such that for every  $s$  in  $S$ , the geometric fiber  $P_s$  is a parabolic subgroup of  $G_s$ , i.e. contains a Borel subgroup of  $G_s$ . --> Proposition 4.8 extends (with the same reduction proof to the "set-theoretic" statement, which is known) to the case of a parabolic subgroup  $P$  of  $G$ . Let us note the following consequence of this result (cf. XVI). If  $P$  is a parabolic subgroup of  $G$ , then  $G/P$  is representable by a quasi-projective prescheme of finite presentation over  $S$  (N.B. one assumes  $G$  to have connected fibers). Moreover  $G/P$  is evidently smooth over  $S$ , and moreover with connected and proper geometric fibers, whence one can conclude easily, using (EGA III 5.5.1), that  $\mathcal{D} = G/P$  is in fact proper, hence projective, over  $S$ . Moreover, if its relative dimension is  $n$ , it is known that the invertible sheaf  $\Omega_{\mathcal{D}/S}^n$  is such that its inverse induces on the geometric fibers of  $\mathcal{D}/S$  ample sheaves, hence (EGA III 4.7.1)  $\Omega_{\mathcal{D}/S}^{-1}$  is ample on  $\mathcal{D}$  relative to  $S$ .

!-- label: III.XIV.4.8.1 -->

One sees easily, by reduction to the affine case and to the case of an algebraically closed base field, that if  $u : G \rightarrow G'$  is an epimorphism of smooth algebraic groups, then for every Borel subgroup  $B$  of  $G$ ,  $u(B) = B'$  is a Borel subgroup of  $G'$ . We are interested in the case where one obtains in this way a bijective correspondence between Borel subgroups of  $G$  and of  $G'$ :

**Proposition 4.9.** \*Let  $G, G'$  be two smooth  $S$ -preschemes in groups of finite presentation with connected fibers,  $u : G \rightarrow G'$  a faithfully flat (i.e. surjective) homomorphism of groups [N.D.E-XIV-6]. Suppose one is in one of the following two cases (where one has set  $N = \operatorname{Ker} u$ ):\*

!-- label: III.XIV.4.9 -->

a)  $N$  is central in  $G$ .\*

\*b)  $S$  is the spectrum of a field  $k$ , and if  $\bar{k}$  denotes an algebraic closure of it,  $N_{\bar{k}} = \text{Ker } u_{\bar{k}}$  is contained in the radical of  $G_{\bar{k}}$ , i.e. in the largest smooth connected solvable invariant subgroup of  $G_{\bar{k}}$ .\*

\*Then the map  $B' \mapsto u^{-1}(B')$  induces a bijection of the set of Borel subgroups of  $G$  with the analogous set for  $G_{\bar{k}}$ .\*

Case b) follows at once from the correspondence between algebraic subgroups of  $G$  and algebraic subgroups of  $G_{\bar{k}}$  containing  $N_{\bar{k}}$ , and from the fact that when  $k$  is  $\leftarrow$  original page 328  $\rightarrow$  algebraically closed, the Borel subgroups of  $G_{\bar{k}}$  contain the radical of  $G_{\bar{k}}$  (which is immediate by the reasoning preceding 4.2).

Let us prove case a). By virtue of (XII 7.12), the map  $H' \mapsto H = u^{-1}(H')$  establishes a bijective correspondence between subschemes in groups  $H'$  of  $G'$  that are smooth of finite presentation over  $S$ , with connected fibers, and that have at every  $s \in S$  the same reductive rank and the same nilpotent rank as  $G'$ , and the subschemes in groups  $H$  of  $G$  having the analogous properties. Now Borel subgroups (of  $G'$ , or of  $G$ ) have the properties in question. It remains to prove that if  $H'$ ,  $H$  correspond, then  $H'$  is a Borel subgroup of  $G'$  if and only if  $H$  is one of  $G$ . By definition, this question reduces to the case where  $S$  is the spectrum of an algebraically closed field. Now since  $N$  is central in  $G$  hence in  $H$ , it follows that  $H$  is solvable if and only if  $H'$  is. Finally, taking the correspondence between algebraic subgroups of  $G'$  and algebraic subgroups of  $G$  containing  $N$  into account, one sees at once that  $H'$  has the maximal character of Definition 4.1 if and only if  $H$  does, which completes the proof.

**Corollary 4.10.** \*With the notations of 4.7, if  $B'$  and  $B$  are Borel subgroups of  $G'$  and  $G$  which correspond, one has\*

$\leftarrow$  label: III.XIV.4.10  $\rightarrow$

$$\mathfrak{b} = \text{Lie}(u^{-1}(\mathfrak{b}'))$$

\*where  $\mathfrak{g}$ ,  $\mathfrak{g}'$ ,  $\mathfrak{b}$ ,  $\mathfrak{b}'$  are the Lie algebras of  $G$ ,  $G'$ ,  $B$ ,  $B'$ , and where  $\text{Lie}(u) : \mathfrak{g} \rightarrow \mathfrak{g}'$  is the homomorphism deduced from  $u$ .\*

This statement follows trivially from the definitions and from the relation  $u^{-1}(B') = B$ .

We can now prove the principal result of the present section:

**Theorem 4.11.** \*Let  $G$  be a smooth algebraic group over an algebraically closed field  $k$ ,  $\mathfrak{g}$  its Lie algebra. Then  $\mathfrak{g}$  is equal to the union of the Lie algebras  $\mathfrak{b}$  of the Borel subgroups  $B$  of  $G$ .\*

$\leftarrow$  label: III.XIV.4.11  $\rightarrow$

$\leftarrow$  original page 329  $\rightarrow$

One may evidently suppose  $G$  connected. Let  $R$  be the radical of  $G$  and let  $G' = G/R$ . Then 4.9 b) and 4.10 reduce us to proving Theorem 4.11 for  $G'$  instead of  $G$ , i.e. one may suppose  $G$  semisimple. Let then  $Z$  be the center of  $G$ , identical to the reductive center, and let  $G' = G/Z$ . The same reasoning (now using 4.9 a)) reduces us to proving the theorem for  $G'$ , i.e. one may suppose  $G$  semisimple adjoint. Let  $B$  be a Borel of  $G$ ,  $T$  a maximal torus of  $B$  hence of  $G$ , and let  $\mathfrak{b}$  and  $\mathfrak{t}$  be the Lie algebras. By virtue of 3.18,  $T$  is a subgroup of type (C) of  $G$ , i.e.  $\mathfrak{t}$  is a Cartan subalgebra of  $\mathfrak{g}$ , hence the union of the conjugates of  $\mathfrak{t}$  is dense in  $\mathfrak{g}$  (XIII 5.1 (i)  $\Rightarrow$  (vii)). \*A fortiori\* the union of the conjugates of  $\mathfrak{b}$  is dense in  $\mathfrak{g}$ . Now let  $X$  be the closed subscheme of  $G/B \times W(\mathfrak{g})$  whose  $k$ -valued points are the  $(g, x)$  such that  $x \in \text{Ad}(g) \cdot \mathfrak{b}$  (cf. XIII 1). Then the morphism  $\psi : X \rightarrow W(\mathfrak{g})$  induced by the second projection is proper since  $G/B$  is proper over  $k$ ; on the other hand we have just seen that it is dominant, hence it is surjective, which proves 4.11.

The only result of the present section that we shall use in the rest of this exposé is the following corollary:

**Corollary 4.12.** \*Let  $k$  be an infinite field,  $G$  a smooth algebraic group over  $k$ ,  $T$  a maximal torus of  $G$ ,  $\mathfrak{g}$  and  $\mathfrak{t}$  the Lie algebras,  $u : G \rightarrow \text{GL}(V)$  a linear representation ( $V$  a finite-dimensional vector space over  $k$ ), whence a representation of Lie algebras  $u' : \mathfrak{g} \rightarrow \mathfrak{gl}(V)$ , making  $V$  into a  $\mathfrak{g}$ -module. Then the minimum of the nullity of  $u'(x)$  ( $x \in \mathfrak{g}$ ) is attained for an

element  $x \in \mathfrak{t}^*$

<!-- label: III.XIV.4.12 -->

One is reduced at once to the case where  $k$  is algebraically closed. One may evidently suppose  $G$  connected, and replacing  $G$  by  $G/(\text{Ker } u)_{\text{red}}$  if necessary, one may suppose  $G$  affine. Using 4.11 and the conjugation theorem of maximal tori of  $G$ , one is reduced to the case where  $G$  is moreover solvable. Then  $G$  is a semidirect product  $T \ltimes V$ , where  $V$  is the "unipotent part" of  $G$ , which is a smooth connected unipotent group (\*Bible\* 6 th. 3). Hence  $\mathfrak{g}$  is the direct sum (as a vector space) of the Lie subalgebras  $\mathfrak{t}$  and  $\mathfrak{v} = \text{Lie}(V)$ . <!-- original page 330 --> By virtue of the Lie-Kolchin theorem (\*Bible\* 6 th. 1),  $\mathfrak{v}$  admits a composition series by stable subspaces  $\mathfrak{v}_i$  such that  $\mathfrak{v}_i/\mathfrak{v}_{i+1} = \mathfrak{w}_i$  is of dimension 1. Then for each  $i$ , one has an induced representation  $\rho_i : G \rightarrow \text{GL}(\mathfrak{w}_i) = G_{\mathfrak{m}}$  and the corresponding homomorphism of Lie algebras  $\rho'_i : \mathfrak{g} \rightarrow \mathfrak{k}$ , so that for every  $x \in \mathfrak{g}$ , the nullity of  $\rho'_i(x)$  is equal to the number of  $j$  such that  $\rho'_i(x) = 0$ . Since  $V$  is unipotent, the  $\rho_i$  are trivial on  $V$ , hence the  $\rho'_i$  are trivial on  $\mathfrak{v}$ , which proves that if  $x = t + v$  ( $t \in \mathfrak{t}$ ,  $v \in \mathfrak{v}$ ), then  $\rho'_i(x) = \rho'_i(t) = \rho'_i(t)$  for all  $i$ , hence the nullity of  $\rho'_i(x)$  is equal to that of  $\rho'_i(t)$ . Assertion 4.12 follows at once.

## 5. Relations between Cartan subgroups and Cartan subalgebras

<!-- label: III.XIV.5 -->

Applying 4.12 to the adjoint representation of  $G$ , one finds:

**Theorem 5.1.** \*Let  $G$  be a smooth algebraic group over an infinite field,  $T$  a maximal torus of  $G$ ,  $\mathfrak{g} \supset \mathfrak{t}$  the Lie algebras; then  $\mathfrak{t}$  contains a regular element of  $\mathfrak{g}$ .\*

<!-- label: III.XIV.5.1 -->

**Corollary 5.2.** \*Let  $G$  be a smooth  $S$ -prescheme in groups of finite presentation,  $\mathfrak{g}$  its Lie algebra.\*

<!-- label: III.XIV.5.2 -->

a) Conditions  $(C_0)$  to  $(C_2)$  of 2.9 on  $\mathfrak{g}$  are equivalent; in particular, if the infinitesimal rank of the fibers of  $\mathfrak{g}$  at the points of  $S$  is locally constant, then  $\mathfrak{g}$  admits locally for the étale topology a Cartan subalgebra, hence (by 3.9 a))  $G$  admits locally for the étale topology a subgroup of type  $(C)$ .\*

b) Let  $H$  be a subscheme in groups of  $G$  smooth of finite presentation over  $S$ , with connected fibers having the same reductive rank as  $G$  at each  $s \in S$  (for example,  $H$  is a maximal torus or a Cartan subgroup of  $G$ ); let  $D$  be a subgroup of type  $(C)$  of  $G$ ; then one has  $H \subset D$  if and only if one has  $\mathfrak{h} \subset \mathfrak{d}$ .\*

c) Suppose condition  $(C_0)$  is satisfied, i.e. the infinitesimal rank of  $G$  is locally constant. Let  $H$  be a subscheme in groups of  $G$  smooth of finite presentation over  $S$ , with connected nilpotent fibers having the same reductive rank as  $G$  at each point (for example,  $H$  is a maximal torus or a Cartan subgroup of  $G$ ). Then  $H$  is contained in one and only one subgroup  $D$  of type  $(C)$  of  $G$ .\*

d) Suppose that  $G$  admits locally for fpqc a Cartan subgroup; then the same is true of every subgroup  $D$  of type  $(C)$  of  $G$ .\*

<!-- original page 331 -->

**Proof.** a) Suppose condition  $(C_0)$  is satisfied, and let us prove that the same is true of  $(C_2)$ , i.e. that every quasi-regular section  $s$  of  $\mathfrak{g}$  is regular. One reduces as usual to the case  $S$  affine noetherian, then, the question being "infinitesimal" (2.15 b)), to the case where  $S$  is local artinian (in which case  $(C_0)$  is moreover trivially satisfied). One may suppose moreover that the residue field  $k$  of  $S$  is infinite. Note that by virtue of 3.7 it suffices to establish that  $\mathfrak{g}$  admits a Cartan subalgebra. Let  $T$  be a maximal torus of  $G$ ; by virtue of 5.1 there exists a quasi-regular element  $t$  contained in the Lie algebra  $\mathfrak{t}$  of  $T$ ; let us prove that it is regular, which will complete the proof. Consider the linear representation of  $T$  in  $\mathfrak{g}$  induced by the adjoint representation of  $G$ ; there exists therefore a finite set  $\{u_i\}_{i \in I}$  of characters of  $T$ , such that  $\mathfrak{g}$  decomposes as a direct sum of submodules  $\mathfrak{g}_i$  stable under  $T$ ,  $T$  operating on  $\mathfrak{g}_i$  by  $u_i$  (cf. I § 4.7.3). Let  $\rho'_i : \mathfrak{t} \rightarrow A$  be the homomorphism of Lie algebras deduced from  $u_i : T \rightarrow G_{\mathfrak{m}}$  (N.B.  $A$  denotes the ring of  $S$ ). Consider the homomorphisms  $u_{i0}$  and  $\rho'_{i0}$  deduced from the preceding by passage to the fibers, i.e. by the base change  $A \rightarrow k$ . Let  $I'$  be the set of  $i \in I$  such that  $u_{i0} \neq 0$ , and let  $I'' = I - I'$ . The fact that  $t$  is regular is expressed by the condition

$\mathfrak{su}_{i0}(t_{0}) \neq 0$  for all  $i \in I$ , hence  $\mathfrak{su}_i(t)$  invertible for  $i \in I$ . The Cartan subalgebra of  $\mathfrak{g}_{00}$  defined by  $t$ , i.e. the kernel subspace of the semisimple endomorphism  $\text{ad}(t_{00})$  of  $\mathfrak{g}_{00}$ , is  $\sum_{i \in I'} (\mathfrak{g}_i)_{00}$ . Consider

```
```text
Q = \sum_{i \in I'} Q_i;
```

then $\text{ad}(t)$ is nilpotent in $\mathfrak{d}$; on the other hand it is an automorphism of $\mathfrak{g}/\mathfrak{d} \simeq \sum_{i \in I'} \mathfrak{g}_i$. <!-- original page 332 --> By virtue of 2.6, t is therefore regular.

b) Follows from 3.12 a), H satisfying the hypothesis that every geometric fiber of $\mathfrak{h}$ contains a regular element of that of $\mathfrak{g}$, thanks to 5.1.

c) By virtue of b), one is reduced to proving that $\mathfrak{h}$ is contained in one and only one Cartan subalgebra of $\mathfrak{d}$. By virtue of a) we know moreover that $\mathfrak{g}$ satisfies (C_2) . One is thus reduced to the:

Lemma 5.3. Let $\mathfrak{g}$ be a Lie algebra over S that is a locally free module of finite type and satisfies condition (C_2) of 2.9. Let $\mathfrak{h}$ be a Lie subalgebra of $\mathfrak{g}$ satisfying the following conditions: it is a locally direct factor module, it is locally nilpotent, and for every $s \in S$, the geometric fiber $\mathfrak{h}_s$ contains a regular element of $\mathfrak{g}_s$. Then $\mathfrak{h}$ is contained in one and only one Cartan subalgebra of $\mathfrak{g}$.

<!-- label: III.XIV.5.3 -->

(N.B. in the case of interest to us, $\mathfrak{h}$ satisfies the stated conditions: it is locally nilpotent because H has nilpotent fibers, and the condition on regular elements follows from 5.1.) Since 5.3 is local for the fpqc topology, it suffices to prove that at a point $s \in S$ such that $\kappa(s)$ is infinite, there exists an open neighborhood U of s such that existence and uniqueness hold for every base change $S' \rightarrow S$ factoring through U . Take a regular element of $\mathfrak{g} \otimes \kappa(s)$ contained in $\mathfrak{h} \otimes \kappa(s)$, extend it to a section a of $\mathfrak{h}$ on an open neighborhood U of s ; thanks to (C_2) one may suppose this section is regular (2.10). One may suppose $U = S$. A Cartan subalgebra of $\mathfrak{g}$ containing $\mathfrak{h}$ contains a , hence is identical to $\mathfrak{d} = \text{Nil}(a, \mathfrak{g})$ (2.6), whence uniqueness. Moreover since $\mathfrak{h}$ is locally nilpotent, one indeed has $\mathfrak{h} \subset \mathfrak{d}$, which proves existence.

d) Is a particular case of (XII 7.9 d)).

<!-- original page 333 -->

Corollary 5.4. Let G be a smooth and connected algebraic group over an algebraically closed field k , H a connected algebraic subgroup such that $\mathfrak{h}$ contains a Cartan subalgebra of $\mathfrak{g}$, i.e. such that H contains a subgroup of type (C) of G . Then the number of conjugates of H containing a regular element of $G(k)$ is equal to the number of conjugates of $\mathfrak{h}$ containing a regular element of $\mathfrak{g}$.

<!-- label: III.XIV.5.4 -->

Indeed, let g be a regular element of $G(k)$, C the unique Cartan subgroup of G containing g (XIII 2); then the conjugates of H containing g are those containing C (XIII 2.8 b)). Similarly, let x be a regular element of $\mathfrak{g}$; then if a conjugate $\mathfrak{h}'$ of $\mathfrak{h}$ contains x , then $\text{ad}(x)_{\mathfrak{g}/\mathfrak{h}'}$ is injective (XIII 5.4), hence $\mathfrak{h}'$ contains $\text{Nil}(x, \mathfrak{g}) = \mathfrak{d}$, hence the number of conjugates of $\mathfrak{h}$ containing x is equal to the number of conjugates containing the Cartan subalgebra $\mathfrak{d}$. Moreover $\mathfrak{d}$ is the Lie algebra of a subgroup D of type (C) of G . One may evidently suppose $C \subset D$, and assertion 5.4 will follow from this: in order for H to contain C , it is necessary and sufficient that $\mathfrak{h}$ contain $\mathfrak{d}$. Indeed, by virtue of (XIII 5.5) the relation $\mathfrak{h} \supset \mathfrak{d}$ implies $H \supset D$ and *a fortiori* $H \supset C$. Conversely, by 5.1 $\mathfrak{h}$ contains a regular element x of $\mathfrak{g}$; then $H \supset C$ implies $\mathfrak{h} \not\ni x$, hence as already pointed out, this implies $\mathfrak{h} \supset \mathfrak{d}$. This completes the proof.

Let G be as in 5.2 and suppose that the infinitesimal rank of the fibers of G remains locally constant (condition (C_0)). Then thanks to 5.2 c), one finds a homomorphism of functors on $(\text{Sch})^{\text{circ}}/S$:

$$S \rightarrow \mathcal{C} \rightarrow \mathcal{D}$$

\$\$

where

```text  
□(S') = set of Cartan subgroups of  $G_{\{S'\}}$   
□(S') = set of subgroups of type (C) of  $G_{\{S'\}}$ .  
```\n

<!-- original page 334 -->

By virtue of 3.10 and 5.2 a), $\mathcal{D}$ is representable by a smooth and quasi-projective prescheme over S . Consider the subgroup D of type (C) of $G_{\mathcal{D}}$ playing the universal role with respect to G/S ; one may then consider the functor $\mathcal{C}_{\mathcal{D}} : (\text{Sch})^{\circ}/\mathcal{D} \rightarrow (\text{Ens})$ defined in terms of the $\mathcal{D}$ -group D as $\mathcal{C}$ in terms of the S -group G . One then has the following result:

Proposition 5.5. *Under the preceding conditions, considering $\mathcal{C}$ as a functor over the prescheme $\mathcal{D}$, then $\mathcal{C}$ is $\mathcal{D}$ -isomorphic to the functor $\mathcal{C}_{\mathcal{D}}$ "of Cartan subgroups of D ".*

<!-- label: III.XIV.5.5 -->

This follows at once from the:

Corollary 5.6. *Let G be a smooth S -prescheme in groups of finite presentation, D a subgroup of type (C) of G . Then there is a bijective correspondence between Cartan subgroups of G contained in D , and Cartan subgroups of D (more precisely, for a subgroup H of G , H is a Cartan subgroup of G if and only if it is a Cartan subgroup of D).*

<!-- label: III.XIV.5.6 -->

Indeed, this is a particular case of (XII 7.9 c)), taking into account that over an algebraically closed field, a subgroup of type (C) of G contains a Cartan subgroup of G .

For the following section, the main result obtained here is 5.2 c) for H a Cartan subgroup of G , which permits stating 5.5 and thus furnishes a useful "dévissage" of $\mathcal{C}$.

6. Applications to the structure of algebraic groups

<!-- label: III.XIV.6 -->

Theorem 6.1. *Let G be a smooth algebraic group over a field k . Consider the scheme $\mathcal{T}$ of maximal tori of G , isomorphic to the scheme $\mathcal{C}$ of Cartan subgroups of G , which is a homogeneous space under G° , and a smooth affine connected algebraic scheme (XII 7.1 d)). Then $\mathcal{C}$ is a rational variety, i.e. the field of rational functions of $\mathcal{C}$ is a pure extension of k .*

<!-- label: III.XIV.6.1 -->

We shall first give the proof in the case where k is infinite. One may evidently <!-- original page 335 --> suppose G connected, since $\mathcal{T}$ hence $\mathcal{C}$ does not change on replacing G by G° . Moreover, by virtue of (XII 7.6), $\mathcal{C}$ does not change on dividing G by a central subgroup. This allows us, first dividing by the center of G , to suppose G affine (XII 6.1), then, dividing by its reductive center (XII 4.1 and 4.4), to suppose that the reductive center of G is trivial (XII 4.7 b)). Moreover we proceed by induction on $n = \dim G$, supposing the theorem proved for dimensions $n' < n$. If G is nilpotent, then $\mathcal{C}$ is reduced to a single point rational over k , and 6.1 is trivial. In the contrary case, the Lie algebra of G is non-nilpotent (1.3), hence the Cartan subalgebras of $\mathfrak{g}$ are of dimension $n' < n$, hence the subgroups of type (C) of G are of dimension $n' < n$. Consider then the morphism

\$\$
 $\mathcal{C} \rightarrow \mathcal{D}$
\$\$

envisaged in 5.5. We know by 3.10 (k being an infinite field, hence $\mathfrak{g}$ containing a regular element) that $\mathcal{D}$ is a rational variety, i.e. the field K of rational functions on $\mathcal{D}$ is a pure extension of k . Consider the fiber of $\mathcal{C}$ over the generic point x of $\mathcal{D}$; by virtue of 5.5 this is the

scheme of Cartan subgroups of a certain smooth and connected algebraic group $D_{\{x\}}$ over $K = \kappa(x)$ (namely $D_{\{x\}} =$ "the generic subgroup of type (C) of G "). The field L of rational functions on $\mathcal{C}$ is therefore isomorphic to the field of rational functions on $\mathcal{D}_{\{x\}}$, which by the induction hypothesis (since $\dim D_{\{x\}} = n' < n$) is a pure extension of K . So by transitivity L is a pure extension of k .

When k is finite, a different proof is needed. One may still suppose G is affine and connected. Note that k is perfect; it follows at once that the radical R of $G_{\bar{k}}$ is "defined over k ", i.e. comes from a subgroup R of G . Suppose first $R \neq G$, i.e. G non-solvable, and let

```
```text
u : G → G' = G/R
```
```

<!-- original page 336 -->

be the canonical morphism. Consider the corresponding morphism $\mathcal{C} \mapsto u(\mathcal{C})$

```
$$
v : \mathcal{C}_{\{G\}} \longrightarrow \mathcal{C}_{\{G'\}}
$$
```

(whose definition is immediate by virtue of (XII 7.1 e))). Let x be the generic point of $\mathcal{C}_{\{G'\}}$; then the fiber $v^{-1}(x)$ is identified with the scheme of Cartan subgroups of G_K (where $K = \kappa(x)$) whose image in G'_K is a certain Cartan subgroup $\mathcal{C}'_{\{x\}}$ (namely, "the generic Cartan subgroup of G' "). It is therefore also the scheme of Cartan subgroups of $H = u^{-1}_{\{K\}}(\mathcal{C}')$ (XII 7.9 c)), and since K is here an infinite extension of k , it follows from the already proved part of 7.1 that the field L of rational functions of $\mathcal{C}_{\{G\}}$, equal to that of $\mathcal{C}_{\{H\}}$, is a pure transcendental extension of K . To prove that it is a pure transcendental extension of k , it therefore suffices to prove that this is the case of K , i.e. one is reduced to the case where G is semisimple. One may moreover suppose that G is adjoint (dividing G by its reductive center if necessary). But then by virtue of 3.18 one has $\mathcal{C}_{\{G\}} \simeq \mathcal{D}_{\{G\}}$, and by virtue of 3.10 it suffices to prove that $\mathcal{D}_{\{G\}}$ admits a regular point, which (as was pointed out in 3.20) is an unpublished result of Chevalley [N.D.E-XIV-7].

It only remains to treat the case where k is finite, G connected affine solvable. One in fact has a more general result:

Corollary 6.2. *Let G be a smooth solvable algebraic group over a field k ; then the variety $\mathcal{C}$ of Cartan subgroups of G is isomorphic to an affine space $\operatorname{Spec} k[t_1, \dots, t_N]$.*

<!-- label: III.XIV.6.2 -->

One may still suppose G connected and affine. Let G_{∞} be the smallest of the groups appearing in the descending central series of G (by G_i such that $G_{i+1} = [G, G_i]$); it is thus the smallest invariant algebraic subgroup of G such that G/G_{∞} is nilpotent. Let $\mathcal{C}$ be a Cartan subgroup of G (it exists by virtue of 1.1); then the image of $\mathcal{C}$ in G/G_{∞} is a Cartan subgroup of it, hence is equal to G/G_{∞} , consequently the morphism $g \mapsto \operatorname{Ad}(g) \cdot \mathcal{C}$ of G_{∞} into $\mathcal{C}$ is an epimorphism, and identifies <!-- original page 337 --> $\mathcal{C}$ with the homogeneous space $G_{\infty}/N \cap G_{\infty}$, where N is the normalizer of $\mathcal{C}$ in G (moreover equal to $\mathcal{C}$ as we recalled in 4.4, but this is of little importance here). Note that $U = G_{\infty}$ is evidently a smooth connected "unipotent" algebraic group (since over the algebraic closure of k , it is contained in the unipotent part of G , by virtue of the known structure of smooth affine solvable groups, *Bible* 6 th. 3). When k is perfect (the only case needed to establish 6.1), it follows very easily that U is even k -unipotent, i.e. admits a composition series by algebraic subgroups U_i such that U_i/U_{i+1} is isomorphic to G_a . In fact, Rosenlicht has proved that this result remains valid for a group of the form G_{∞} as above, without restriction on k (M. Rosenlicht, *Questions of rationality for solvable algebraic groups over non perfect fields*, Annali di Matematica 1963, pp. 97–120, theorem 4 cor. 2), a result clearly more delicate which we shall admit here. It now suffices to apply the following lemma, doubtless well known to specialists:

Lemma 6.3. *Let U be a smooth connected algebraic group over a field k , $X = U/V$ a homogeneous space under U having a rational point over k . Suppose U is k -unipotent. Then as a k -scheme, X is isomorphic to an affine space $\operatorname{Spec} k[t_1, \dots, t_N]$.*

<!-- label: III.XIV.6.3 -->

Indeed, let $(U_i)_{0 \leq i \leq n}$ be a composition series of U by smooth connected subgroups, with

$U_{\{n\}} = (e)$, $U_{\{0\}} = U$, $U_{\{i\}}/U_{\{i+1\}} \simeq G_{\{a\}}$, the $U_{\{i\}}$ invariant in U . Then the $K_{\{i\}} = U_{\{i\}}^V$ are algebraic subgroups of U (not necessarily smooth nor connected if V is not, but no matter), and $K_{\{i+1\}}$ is invariant in $K_{\{i\}}$. One has a canonical morphism $U_{\{i\}}/U_{\{i+1\}} \rightarrow K_{\{i\}}/K_{\{i+1\}}$ that is an epimorphism, which proves that $K_{\{i\}}/K_{\{i+1\}}$ is either reduced to the unit group, or isomorphic to $G_{\{a\}}/H_{\{i\}}$, where $H_{\{i\}}$ is a finite subgroup of $G_{\{a\}}$, which by virtue of Rosenlicht (loc. cit., th. 2) implies that $K_{\{i\}}/K_{\{i+1\}} \simeq G_{\{a\}}$ (a result moreover immediate if k is perfect). Set now $X_{\{i\}} = U/K_{\{i\}}$; let us prove by induction on i that $X_{\{i\}}$ is isomorphic to an affine space. Indeed, if this is so for $X_{\{i\}}$, let us prove that the same is true of $X_{\{i+1\}}$. If $K_{\{i\}}/K_{\{i+1\}} = e$ one has $X_{\{i\}} = X_{\{i+1\}}$ and this is trivial. Otherwise, $X_{\{i+1\}}$ is a principal bundle with base $X_{\{i\}}$ and structure group $G_{\{a\}} \simeq K_{\{i\}}/K_{\{i+1\}}$. <!-- original page 338 --> So, $X_{\{i\}}$ being affine, $X_{\{i+1\}}$ is a trivial bundle, hence is isomorphic to $X_{\{i\}} \times G_{\{a\}}$, which again proves that $X_{\{i+1\}}$ is isomorphic to an affine space. This proves 6.2 and consequently completes the proof of 6.1.

Corollary 6.4. *Let G be a smooth algebraic group over an infinite field k . Then the set of k -rational points of $\mathcal{C}$ (notations of 6.1) is dense for the Zariski topology. The union of the Cartan subgroups of G is dense in G .*

<!-- label: III.XIV.6.4 -->

The first assertion is valid for any unirational variety over an infinite field, and is moreover the most important "arithmetic" consequence of the unirationality results for us here. The second assertion follows from the first and from the density theorem (XIII 2.1).

Corollary 6.5. *Let G be a smooth connected algebraic group over k . Then the variety Z of regular semisimple points of G (XIII 3.5) is a unirational variety. In particular, if k is infinite, the set of k -rational points of Z is dense in Z .*

<!-- label: III.XIV.6.5 -->

Indeed, Z is an open of a torus over $\mathcal{C}$, hence its function field L is the function field of a torus defined over the function field K of $\mathcal{C}$ (namely the "generic maximal torus" of G); it is therefore a unirational extension of K (XIII 3.4), and since K is a pure extension of k by virtue of 6.1, L is a unirational extension of k .

Corollary 6.6. *Let G be a smooth connected algebraic group over k , and let H be the subgroup of G generated by the subvariety Z of regular semisimple points, i.e. (XII 8.2) the smallest invariant algebraic subgroup of G such that G/H has reductive rank zero (i.e. is, over the algebraic closure of k , an extension of an abelian variety by a smooth connected unipotent group). Then H is a unirational variety. In particular, if $G = H$, i.e. (XII 8.4) if G is affine and if over the algebraic closure $\bar{k}$, <!-- original page 339 --> there exists no non-trivial homomorphism of $G_{\bar{k}}$ to $G_{\{a\}}$, then G is a unirational variety, hence if k is infinite, the set of its k -rational points is dense.*

<!-- label: III.XIV.6.6 -->

This follows at once from 6.5, for it is immediate that if one has smooth connected k -preschemes $Z_{\{i\}}$ that are unirational varieties and morphisms $u_{\{i\}} : Z_{\{i\}} \rightarrow G$, then the algebraic subgroup of G generated by the $u_{\{i\}}$ (VI_B 7.1) is a unirational variety.

As an interesting particular case of 6.5 or 6.6 (whichever one chooses), let us note:

Corollary 6.7. *Let G be a smooth connected affine algebraic group of unipotent rank zero; then G is a unirational variety.*

<!-- label: III.XIV.6.7 -->

One can refine 6.4 as follows:

Corollary 6.8. *Let G be a smooth connected algebraic group over the infinite field k , and let C be a Cartan subgroup of G . Then the union of the conjugates of C by regular semisimple elements of $G(k)$ is dense in G .*

<!-- label: III.XIV.6.8 -->

This follows at once from 6.4 and from (XIII 3.6), which says that the morphism $\varphi : Z \times \mathcal{C} \rightarrow G$ defined by $\varphi(t, c) = \text{ad}(t)c$ is dominant. This result also implies (without supposing k infinite):

Corollary 6.9. *Let G be a smooth connected algebraic group over k , H a smooth connected algebraic subgroup of

G such that H has the same reductive rank and the same nilpotent rank as G (i.e. over the algebraic closure $\bar{k}$ of k , $H_{\bar{k}}$ contains a Cartan subgroup of $G_{\bar{k}}$). If H is a unirational variety, the same is true of G . If $H(k)$ is dense in H , $G(k)$ is dense in G .

<!-- label: III.XIV.6.9 -->

Indeed, the morphism $\varphi : Z \times H \rightarrow G$ defined by $\varphi(t, h) = \text{ad}(t)h$ is dominant. Now by virtue of 6.5, Z is a unirational variety, and by hypothesis the same is true of H , hence of $Z \times H$, whence the first result. The second is proved analogously.

We now recover the following well-known result (due to Chevalley, in characteristic 0, to Rosenlicht in characteristic $p > 0$):

<!-- original page 340 -->

Corollary 6.10. Let G be a smooth connected affine algebraic group over a perfect field k . Then G is a unirational variety, hence if k is moreover infinite, $G(k)$ is dense in G .

<!-- label: III.XIV.6.10 -->

Indeed, by virtue of 1.1, G admits a Cartan subgroup C . By virtue of 6.9 it suffices to prove that this latter is a unirational variety. Now k being perfect, one sees at once by Galois descent from the case k algebraically closed (*Bible* 6 th. 2) that one has $C = T \times C_u$, where T is the maximal torus of C and C_u a smooth connected unipotent group. One already knows that T is a unirational variety (XIII 3.4); it remains to see that the same is true of C_u . Now k being perfect, C_u is even k -unipotent, and one may apply 6.3.

Remarks 6.11. a) One knows (Rosenlicht) examples of twisted forms of G_a over a non-perfect field that have only finitely many rational points, hence *a fortiori* are not unirational varieties. On the other hand, Chevalley has given an example of a torus over a field of characteristic zero that is not a rational variety. By contrast, it follows from Chevalley's theory of semisimple groups that over an algebraically closed field, every smooth connected affine algebraic group is a rational variety. Let us note moreover that the question of unirationality only arises in any event for affine algebraic groups, a unirational algebraic group being necessarily affine by Chevalley's structure theorem.

<!-- label: III.XIV.6.11 -->

b) With the notations of 6.6, it is tempting to try to give a unirationality condition on G in terms of the group G/H (which is unipotent if G is supposed affine). It is evidently necessary that this latter be unirational; is this condition also sufficient? Note that an example of Rosenlicht (loc. cit.) shows that a smooth connected unipotent algebraic group U may be a rational variety without being k -unipotent.

c) It would be interesting to study, over a finite field k , questions of the "density" type, such as the following (raised by Rosenlicht): Let G be a smooth and connected algebraic group <!-- original page 341 --> over k ; is G generated by its Cartan subgroups? [XIV-6-1] [N.D.E-XIV-8]

In this question, one can reduce to the case G affine, by dividing by the center. The answer would be affirmative in the semisimple case, if one could refine the existence result for regular points of Chevalley pointed out in 3.20, so as to obtain a regular element of $\mathfrak{g}$ that does not belong to $\mathfrak{h} = \text{Lie}(H)$, where H is a smooth algebraic subgroup of G and $H \neq G$ given in advance (G an adjoint semisimple group over the finite field k).

Appendix. Existence of regular elements over finite fields

<!-- label: III.XIV.7 -->

by J.-P. Serre

<!-- original page 342 -->

In all that follows, k denotes a finite field, and $\bar{k}$ its algebraic closure; the Galois group of $\bar{k}/k$ is denoted $\text{Gal}(\bar{k}/k)$; one recalls that, if $q = \text{Card}(k)$, $\text{Gal}(\bar{k}/k)$ is topologically generated by the "Frobenius" element $F : x \mapsto x^q$.

We propose to prove the following theorem [XIV-A-1]:

Theorem. Let G be an adjoint semisimple group defined over k , and let $\mathfrak{g}$ be its Lie algebra. The k -Lie algebra $\mathfrak{g}(k)$ contains a regular element.*

<!-- label: III.XIV.7.theorem -->

Remarks. (1) It is well to recall that "adjoint" means that the center of G is trivial (as a subgroup scheme of G). In view of the Chevalley seminar, this also means that, if T is a maximal torus of G , the group $X(T)$ of characters of T (defined over $\bar{k}$) is generated by the set R of roots. It follows in particular that the rank of the Lie algebra $\mathfrak{g}$ is equal to the dimension of T (i.e. to the rank of G).

(2) The editor does not know whether the hypothesis that G is adjoint is indispensable.

Lemma 1. It suffices to prove the theorem when G is geometrically simple.*

<!-- label: III.XIV.7.lemma-1 -->

(One says that G is geometrically simple if $G \otimes \bar{k}$ does not contain any normal subgroup scheme smooth over $\bar{k}$, apart from G and $\{e\}$; an equivalent condition: the associated root system R is irreducible.)

One may first suppose G indecomposable over k . The group $G \otimes \bar{k}$ is then a <!-- original page 343 --> product of geometrically simple components S that are permuted transitively by the Galois group $\mathcal{G}$. If H is the subgroup of $\mathcal{G}$ fixing one of these components S , this component is defined over the field K corresponding to H (i.e. comes by extension of scalars from a subscheme of $G \otimes K$), and a standard argument shows that $G = \prod_{K/k}(S)$ (i.e. $R_{K/k}(S)$, for readers used to the notation of Weil). Likewise, the Lie algebra $\mathfrak{g}$ of G is identified with $\prod_{K/k} \mathfrak{s}$, where $\mathfrak{s}$ is the Lie algebra of S . If the theorem is true for S , there exists $x \in \mathfrak{s}(K) = \mathfrak{g}(k)$ that is regular in $\mathfrak{s}$; one then verifies easily that it is regular in $\mathfrak{g}$. *QED*.

From now on, one supposes G geometrically simple and one chooses a maximal torus T of G (one knows this is possible). One denotes by X the group of characters of $T \otimes \bar{k}$, R its root system, W its Weyl group, and E the group of automorphisms of X preserving R . The group W is a normal subgroup of E .

If T' is another torus of G , one denotes by X' , R' , W' , E' the group of characters, root system, ..., corresponding. If one chooses $y \in G(\bar{k})$ such that $y \cdot (T \otimes \bar{k}) \cdot y^{-1} = T' \otimes \bar{k}$, one can identify X' , R' , W' , E' with X , R , W , E thanks to $\text{int}(y)$. Changing y modifies this identification by an automorphism of X corresponding to an element of W .

The canonical generator $x \mapsto x^q$ of $\mathcal{G}$ operates on X' while preserving R' ; it therefore defines an element $f_{T'}$ of E' . In particular one sets $f = f_T$. When one identifies E' with E as just stated, the element $f_{T'}$ is transformed into an element f' of E , defined up to replacement by $swf'w^{-1}$ with $w \in W$. We are going to compare this element to f :

Lemma 2. One has $f' \equiv f \pmod{W}$; conversely, every $f' \in E$ satisfying this condition can be obtained from a maximal torus T' of G .*

<!-- label: III.XIV.7.lemma-2 -->

Set $\bar{T} = T \otimes \bar{k}$, $\bar{T}' = T' \otimes \bar{k}$, and let $y \in G(\bar{k})$ be such that $\bar{yT}y^{-1} = \bar{T}'$; since $y^q \bar{T} y^{-q} = \bar{T}$,

<!-- original

page 344 --> one concludes that $n = y^{-1} y^q$ belongs to the normalizer $N(T)$ of T . The effect of f' on the points of $\bar{T}(\bar{k})$ is then the following:

```text

$f'(t) = y^{-1}(tyt^{-1})^q y = y^{-1} y^q t^q y^{-q} y = n t^q n^{-1}.$

```

If $w \in W$ is the element defined by n , this shows that f' and $f \circ w$ have the same effect on the points of $\bar{T}$, hence also on its characters, and one has $f' = f \circ w$, whence $f' \equiv f \pmod{W}$. Conversely, if $w \in W$ is given, one represents it by an element $n \in N(T)(\bar{k})$; thanks to a classical theorem of Lang, one can write n in the form $n = y^{-1} y^q$, with $y \in G(\bar{k})$; the torus $\bar{T}' = \bar{yT}y^{-1}$ is then defined over k , and the preceding calculation shows that the corresponding f' is equal to $f \circ w$.

Lemma 3. Let X , R , W , E be as above (R being irreducible), and let $\varphi \in E/W$. Then there exists an element $f \in E$ representing φ , and a family $\theta_1, \dots, \theta_n$ of roots enjoying the two following properties:

<!-- label: III.XIV.7.lemma-3 -->

(1) $\{\theta_1, \dots, \theta_n\}$ is a basis of X .

(2) R is the union of the orbits of the θ_i under the powers of f (i.e. every $a \in R$ can be written $a = f^m \theta_i$, with suitable m and i).

The proof will be given a little further on.

Here now is a lemma of linear algebra:

Lemma 4. Let V be a vector space over k , and let $\{\theta_1, \dots, \theta_n\}$ be a basis of the dual of $V \otimes \bar{k}$. There exists $x \in V$ such that $\theta_i(x) \neq 0$ for all i .*

<!-- label: III.XIV.7.lemma-4 -->

Let V^* be the dual of V , and let W_i be the subspace of $V^* \otimes \bar{k}$ generated by the conjugates of θ_i ; this subspace is defined over k , i.e. of the form $W_i \otimes \bar{k}$. The obvious application $W_1 \otimes \dots \otimes W_n \rightarrow \wedge^n V^*$ is not zero (otherwise its extension to $\bar{k}$ would be also, which is absurd since $\theta_i \in W_i$ and $\theta_1 \wedge \dots \wedge \theta_n \neq 0$). There exists therefore a basis of V^* formed of elements $u_i \in W_i$. Let $x \in V$ be such that $u_i(x) \neq 0$ for all i (for example $u_i(x) = 1$). The element x answers the question, for if one had $\theta_i(x) = 0$, the conjugates of θ_i would also vanish at x , and the same would be true of u_i , which is not the case.

<!-- original page 345 -->

End of the proof of the theorem.

By combining Lemmas 2 and 3, one can choose a torus T whose element f satisfies the properties of Lemma 3. If Y is the dual of X , the Lie algebra $\mathfrak{t}(\bar{k})$ of T [N.D.E-XIV-9] is canonically identified with $Y \otimes \bar{k}$, and this operation is compatible with the action of the Galois group (the latter operating on $Y \otimes \bar{k}$ thanks to its action on Y and on $\bar{k}$). Let $V = \mathfrak{t}(k)$ be the Lie algebra of T over k . An element $x \in V$ is regular if and only if it is not annihilated by any root $\alpha \in R$, or rather by any of the linear forms $\alpha \in V^* \otimes \bar{k}$ defined canonically by the $\alpha \in R$. By Lemma 4, one can find such an x not annihilated by any of the roots θ_i ; but every root is conjugate to a θ_i (this is what condition (2) of Lemma 3 expresses); it follows that x is not annihilated by any root, and it is indeed a regular element.

Proof of Lemma 3.

It relies on properties of Coxeter transformations. Let us briefly recall what this involves:

Let $a_1, \dots, a_n$ be a simple root system of R , and, for every i , let r_i be the symmetry corresponding to a_i . Set:

$c = r_1 \dots r_n$.

One has $c \in W$; of course the element c depends on the choice of the simple system $(a_1, \dots, a_n)$ as well as on the order of the a_i ; however one shows that its conjugacy class does not depend on any of these choices. One calls c the *Coxeter element* of the system considered. One shows (we shall admit it) that c does not have 1 as an eigenvalue.

Lemma 5. Set $\theta_i = r_n \dots r_{i+1}(a_i)$. Then:*

<!-- label: III.XIV.7.lemma-5 -->

(a) The θ_i form a basis of the group X generated by the roots.*

(b) One has $\theta_i > 0$ and $c(\theta_i) < 0$ for all i * [XIV-A-2].

(c) Every root $a \in R$ such that $a > 0$ and $c(a) < 0$ is equal to one of the θ_i .*

<!-- original page 346 -->

(d) R is the union of the orbits of the θ_i under the powers of c .

It is clear that θ_i is of the form $a_i + \sum_{j>i} m_{ij} a_j$, with $m_{ij} \in \mathbb{Z}$, which proves (a). Assertions (b) and (c) are consequences of the following remark: the symmetry r_i preserves the sign of every root distinct from $\pm a_i$, and changes the sign of $\pm a_i$.

Finally, for (d) one remarks that an orbit of c cannot be entirely formed of positive (resp. negative) roots, since, taking the sum of these roots one would find a non-zero element of X invariant under c , and we have admitted that c does not have 1 as an eigenvalue. There is therefore necessarily in every orbit an element $a > 0$ such that $c(a) < 0$, and one applies (c).

Remark. We have sketched the preceding proof only to facilitate the reader's task; one could have limited oneself to referring to the canonical texts on Coxeter (cf. for example Koszul, Séminaire Bourbaki, 1959/1960, exposé 191). Said texts contain other results: the orbits of c all have the same number h of elements, and each contains only one θ_i . In particular $h = \text{Card}(R)/n$.

Let us now return to the proof of Lemma 3. Distinguish three cases:

(1) The element $\varphi \in E/W$ given is equal to the identity element.

One must then take $f \in W$; one chooses $f = c$; it works by Lemma 5.

(2) The system R is of type A_n , with n even ≥ 2 , and φ is the unique non-trivial element of E/W .

One knows that $-1 \notin W$; one then takes $f = -c$. A simple calculation shows that c is of order $h = n + 1$; hence its order is odd. If $a \in R$ is any root, <!-- original page 347 --> one has $a = c^m \theta_i$ for a pair (m, i) , cf. Lemma 5; by adding h to m if necessary, one may suppose m even, and one sees that one has then $a = (-c)^m \theta_i = f^m \theta_i$. The orbits of the θ_i therefore indeed fill R .

(3) The element $\varphi \in E/W$ is non-trivial, and R is of one of the following types:

- A_n , n odd ≥ 3
- D_4
- D_n , $n \geq 5$
- E_6 .

(A glance at the classification shows that these are indeed all the cases (with A_n , n even) where E/W is non-trivial.)

Let S be a simple root system, which we shall not number for the moment. One knows that E is the semidirect product of W and the group Ψ of permutations of S that leave invariant the Cartan matrix (or the Dynkin diagram, it is the same thing). The group E/W is thereby identified with Ψ , and in particular φ corresponds to an element $\psi \in \Psi$. One observes by inspection of the Dynkin diagrams (cf. figures above) that every orbit of ψ in S is formed of roots that are pairwise orthogonal (i.e. not linked in the diagram). [Note that this would not be the case for A_n (n even), which obliged us to treat this case separately.] If σ is such an orbit, the symmetries r_a , $a \in \sigma$, commute with each other; their product will be denoted ρ_σ . It is clear that ρ_σ commutes with ψ .

This being so, let us choose on S a total order such that every orbit is a segment for this order relation; this amounts to numbering the elements of S : $S = \{a_1, \dots, a_n\}$. Let $\theta_1, \dots, \theta_n$ be the roots defined above, and $c = r_1 \cdots r_n$ the corresponding Coxeter element. The element c is the product of the ρ_σ , the σ being arranged in a certain order; it follows that it commutes with ψ . One then sets $f = c\psi$. One further remarks that ψ permutes the θ_i among themselves. Indeed, one has $\psi(\theta_i) > 0$ since $\theta_i > 0$ and $c(\psi(\theta_i)) = \psi(c(\theta_i)) < 0$, hence (Lemma 5, (c)), $\psi(\theta_i)$ is equal to some θ_j . It is now immediate <!-- original page 348 --> that $f = c\psi$ answers the question. Indeed, if $a \in R$, one has $a = c^m \theta_i$ for a pair (m, i) , whence $a = f^m (\psi^{-m} \theta_i) = f^m \theta_j$ for some j . *QED*.

Remark. One can prove that, except in case (2), every orbit of f has exactly $h = \text{Card}(R)/n$ elements and contains one and only one θ_i . In case (2), some of the θ_i are superfluous.

[^XIV-1-1]: M. Raynaud gave a negative answer to the question raised here, cf. (XVII Example 5.9.c)).

[^XIV-2-1]: Cf. also EGA I, 2nd edition (to appear in North Holland Publishing Co.).

[^N.D.E-XIV-1]: See § I.1.3 of M. Demazure and P. Gabriel, **Groupes algébriques**, Masson (1970).

[^N.D.E-XIV-2]: One has written $\text{Transp}_{\{G\}}(a, \mathfrak{h})$.

[^N.D.E-XIV-3]: One has replaced $\hat{T}$ by T .

[^XIV-3-1]: This result, as well as 2.11 on which it rests, generalizes immediately to the case where $\$s\$$ is replaced by a finite part of $\$S\$$ contained in an affine open.

[^N.D.E-XIV-4]: Where $\mathfrak{b}$ is the Lie algebra of B .

[^N.D.E-XIV-5]: There is no number 4.7.

[^N.D.E-XIV-6]: Add a reference here?

[^N.D.E-XIV-7]: Cf. the Appendix, by J.-P. Serre.

[^XIV-6-1]: This question has since been resolved affirmatively by Steinberg.

[^N.D.E-XIV-8]: Not having identified this result in the **Collected Papers** of R. Steinberg, we give a proof based on the Bruhat decomposition. Let G/K be a semisimple group defined over the finite field K . The point is to show that G is generated by its K -Cartan subgroups. This question is stable by central isogeny and by restriction of scalars; one is therefore reduced to the case where G is geometrically simple (in the same way as in Lemma 1 of the appendix below). Denote by $G^\sharp$ the subgroup of G generated by its K -subtori. The group G is quasi-split (Lang) and therefore admits a Killing couple (T, B) . By definition, one has $T \subset G^\sharp$; in particular T normalizes $G^\sharp$. The big cell $R_{\{u\}}(B)$ of G indicates that it suffices to verify that $R_{\{u\}}(B) \subset G^\sharp$. Let $\$S\$$ be the maximal split K -torus of T . One considers the relative root system $\Phi(G, S)$ and a basis Δ_K . Given $\alpha \in \Phi(G, S)$, denote by U_α the unipotent subgroup associated to α (cf. A. Borel, **Linear Algebraic Groups**, second edition (1991), Springer, Prop. 21.9). Since the K -group $R_{\{u\}}(B)$ is generated by the K -unipotent groups U_α ($\alpha \in \Delta_K$), one is reduced to verifying that $U_\alpha \subset G^\sharp$. A glance at the classification shows that there exists a semisimple group G_α of quasi-split type A_1 , A_2 , A_3 , or A_4 such that $U_\alpha \subset G_\alpha \subset G$. It is therefore permissible to suppose that $G = \text{PGL}_2$ or $G = \text{SU}_3(K)$, where K denotes the unique quadratic extension field of K . The group $\text{PGL}_2^\sharp$ containing the standard split torus T , the possibilities up to conjugation under $G(K)$ are the following: $\text{PGL}_2^\sharp = T$, $\text{PGL}_2^\sharp = B$, or $\text{PGL}_2^\sharp = \text{PGL}_2$. The case $\text{PGL}_2^\sharp = T$ is excluded since $\text{PGL}_2^\sharp$ contains the K -torus $R_{\{K/k\}}(G_m)/G_m$. The preceding discussion indicates that if $\text{PGL}_2^\sharp = B$, then $\text{PGL}_2^\sharp = \text{PGL}_2$. Hence $\text{PGL}_2^\sharp = \text{PGL}_2$. If $G = \text{SU}_3(K)$, $\Delta_K = \{\alpha\}$ and the possibilities for $G^\sharp$ (up to conjugation) are the following: $G^\sharp = T$, $G^\sharp = B$, $G^\sharp = U_{(2\alpha)} \sqcup T$, $G^\sharp = \langle U_{(2\alpha)}, U_{(-2\alpha)}, T \rangle = \text{SL}_2 \cdot T$, or $G^\sharp = G$. The case $G^\sharp = B$ is excluded as for PGL_2 . The case $\text{SL}_2 \cdot T$ is excluded because $G^\sharp$ contains the K -torus $R_{\{1\}}^{K/k}(R_{\{1\}}^{K_3/K}(G_m))$, K_3/K denoting the extension of degree 3 of K , and the isogeny class of this torus is irreducible. Moreover, this torus also excludes the cases $G^\sharp = T$ and $G^\sharp = U_{(2\alpha)} \sqcup T$. One concludes that $G^\sharp = G$.

[^XIV-A-1]: This theorem is due to Chevalley. The editor wishes to express his gratitude to American Express which, by misplacing a trunk of Chevalley manuscripts, obliged him to reconstruct the proof.

[^N.D.E-XIV-9]: One has changed $\bar{T}$ to T .

[^XIV-A-2]: For the order relation defined by $(a_1, \dots, a_n)$.

Exposé XV. Complements on sub-tori of a group scheme. Application to smooth groups

<!-- label: III.XV -->

by M. Raynaud [^XV-0-1]

0. Introduction

<!-- label: III.XV.0 -->

<!-- original page 349 -->

This Exposé complements and partially recasts Exposés XI and XII; the contents of Exposés XIII and XIV are not indispensable. Continuing the effort undertaken in XII, we shall work with S -preschemes in groups that are not necessarily affine and not necessarily separated over S .

Sections 1, 2, 3, 4 are devoted to the study of sub-tori of a group prescheme. We obtain theorems of infinitesimal lifting (§ 2) and global lifting (§ 4), in which an essential role is played by points of finite order (§ 1).

Sections 5, 6 and 7 are independent of the preceding ones. The consideration of infinitesimal neighborhoods leads to the representability of the functor of smooth subgroups equal to their connected normalizer (§ 5). In §§ 6 and 7, we turn more specifically to Cartan subgroups.

Finally, in § 8 we give a necessary and sufficient condition for the functor of sub-tori of a smooth group, or that of maximal tori, to be representable.

1. Lifting of finite subgroups

<!-- label: III.XV.1 -->

<!-- original page 350 -->

1.1. Finite, smooth and central subgroups of multiplicative type

<!-- label: III.XV.1.1 -->

Proposition 1.1. *Let S be an affine scheme, S_0 a closed subscheme of S defined by an ideal of square zero, G an S -prescheme in groups, H_0 a subgroup scheme of $G_0 = G \times_S S_0$ which is smooth over S_0 , of finite type, and of multiplicative type. Then, in order that there exist a subgroup scheme of G , of multiplicative type, which lifts H_0 , it is necessary and sufficient that there exist a subscheme H' of G , flat over S , which lifts H_0 .*

<!-- label: III.XV.1.1.statement -->

The necessity of the condition is clear; let us prove sufficiency. The group H_0 of multiplicative type is quasi-isotrivial (X 4.5); by Exp. X 2.1, there exist an S -group H of multiplicative type and an S_0 -isomorphism of groups:

```text  
u<sub>0</sub> : H ×<sub>S</sub> S<sub>0</sub> → H<sub>0</sub>.  
```

Since H' is flat over S and $H' \times_S S_0$ is of finite presentation over S_0 (Exp. IX 2.1 b)), H' is of finite presentation over S ; moreover, its fibers are smooth, so H' is smooth over S (EGA IV 17.5.1). Since S is affine, u_0 therefore lifts to an S -morphism of preschemes:

```  
u : H → H'.  
```

It then follows from Exp. III 2.1 and Exp. IX 3.1 that the composed morphism $v_0 : H \times_{S_0} S \rightarrow H_0 \rightarrow G_0$

<!-- original page 351 -->

also lifts to an S -morphism of groups:

```  
v : H → G.  
```

Since v_0 is an immersion, so is v . The image of H by v is therefore a subgroup scheme of G , of

multiplicative type, which lifts $H_{\{0\}}$.

Proposition 1.2. *Let S be a prescheme, $S_{\{0\}}$ a subprescheme of S defined by a locally nilpotent sheaf of ideals, G an S -prescheme in groups, flat and of finite presentation over S , and $H_{\{0\}}$ a subgroup scheme of $G_{\{0\}} = G \times_S S_{\{0\}}$ which is smooth, finite over $S_{\{0\}}$, of multiplicative type and central. Then there exists a unique subgroup scheme H of G , of multiplicative type, which lifts $H_{\{0\}}$. Moreover H is central. (See XVII App. III, 1).*

<!-- label: III.XV.1.2 -->

Proposition 1.2 bis. *Let S , G , $S_{\{0\}}$, $G_{\{0\}}$ be as above, H an S -group scheme of multiplicative type, smooth and finite over S , and $u_{\{0\}} : H_{\{0\}} = H \times_S S_{\{0\}} \rightarrow G_{\{0\}}$ a central homomorphism. Then $u_{\{0\}}$ lifts uniquely to a homomorphism $u : H \rightarrow G$. Moreover u is central.*

<!-- label: III.XV.1.2bis -->

The existence of the lifting u in 1.2 bis is easily deduced from 1.2 by considering the graph of $u_{\{0\}}$. The lifting u is unique and central by Exp. IX 3.4 and Exp. IX 5.1.

Proof of 1.2. The uniqueness of H and the fact that H is central follow from Exp. IX 5.6 b) and Exp. IX 3.4 bis. Given uniqueness, in order to prove the existence

<!-- original page 352 -->

of H we may assume S affine and $S_{\{0\}}$ defined by an ideal of square zero, and it suffices (1.1) to find a subscheme of G , flat over S , which lifts $H_{\{0\}}$.

Since $H_{\{0\}}$ is smooth and finite over $S_{\{0\}}$, we may assume – possibly after restricting S – that there exists an integer $n > 0$, invertible on S , such that $H_{\{0\}} = \{ \}_{n} H_{\{0\}}$. Consider the n -th power morphism in G :

```

```text
u : G → G, x ↦ x^n.
```

```

We still denote by $\{ \}_{n} G$ the "kernel of u ", that is, the inverse image under u of the unit section of G (N.B. u is not in general a group morphism). Granting for a moment the following lemma:

Lemma 1.3. *Let k be a field, G a group scheme locally of finite type over k , n an integer prime to the characteristic of k , u the n -th power morphism in G . Then u is étale at every point x of G belonging to the center of G .*

<!-- label: III.XV.1.3 -->

Since G is flat and of finite presentation over S , it follows from the preceding lemma and from EGA IV 17.8.2 that if x is a point of G projecting to s in S and belonging to the center of G_s , the morphism u is étale at x . If moreover x is a point of $\{ \}_{n} G$, then $\{ \}_{n} G$ is étale over S at x . By hypothesis, the group $H_{\{0\}}$ is central and contained in $\{ \}_{n} G_{\{0\}}$, so it is in fact contained in the largest open subset V of $\{ \}_{n} G$ which is étale over S . Since $H_{\{0\}}$ and $V \times_S S_{\{0\}} = V_{\{0\}}$ are étale over $S_{\{0\}}$, $H_{\{0\}}$ is an open subset of $V_{\{0\}}$ (EGA IV 17.8.7 and 17.9.1).

<!-- original page 353 -->

But then the open subprescheme of V having the same underlying space as $H_{\{0\}}$ is a subscheme of G , flat over S , which lifts $H_{\{0\}}$.

It remains to prove Lemma 1.3. For this, note that the largest open subset of G on which u is étale is invariant under base field extension (EGA IV 17.8.2); this allows us to reduce to the case where x is rational over k . Let t_x denote translation by x , which is a k -automorphism of the scheme G . Since x is in the center of G , we have the commutative diagram:

```

```text
G --u--> G
| |
t_x t_x^n
| |
```

```

▼
 $G \xrightarrow{u} G.$
 ▼

It therefore suffices to show that u is étale at the origin, but this was seen in VII_A 8.4.

1.2. Global lifting of finite groups

<!-- label: III.XV.1.2-global -->

Lemma 1.4. *Let A be a local ring, separated and complete for the topology defined by its maximal ideal $\mathfrak{m}$, let $S = \operatorname{Spec}(A)$, $S_n = \operatorname{Spec}(A/\mathfrak{m}^n)$. Then for every prescheme X (resp. every S -prescheme X), the canonical map*

```text  
 (\*)  $\operatorname{Hom}(S, X) \rightarrow \lim_{\leftarrow n} \operatorname{Hom}(S_n, X)$   
 ```

(resp.

```text  
 (\*\*)  $\Gamma(X/S) \rightarrow \lim_{\leftarrow n} \Gamma(X_n/S_n), \quad \text{where } X_n = X \times_S S_n$   
 ```

is bijective.

<!-- label: III.XV.1.4 -->

Statement (**) is an easy consequence of (*). Let us prove (*).

<!-- original page 354 -->

Let $u_n : S_n \rightarrow X$ ($n \in \mathbb{N}$) be a coherent system of morphisms. The image y of the closed point of S_n is therefore independent of n , and u_n factors through $\operatorname{Spec}(\mathcal{O}_{y,0})$. The morphisms u_n define, by passage to the projective limit, a ring morphism

```text  
 $\tilde{u} : \varprojlim \mathcal{O}_y \rightarrow \lim_{\leftarrow n} (A/\mathfrak{m}^n) = A.$   
 ```

This shows that (**) is surjective; it is injective as soon as A is separated for the $\mathfrak{m}$ -adic topology.

Corollary 1.5. *Let A be a complete noetherian local ring, $\mathfrak{m}$ its maximal ideal, $S = \operatorname{Spec}(A)$, $S_n = \operatorname{Spec}(A/\mathfrak{m}^n)$, X a finite scheme over S and Y an S -prescheme. Then the canonical map*

```text  
 $\operatorname{Hom}_S(X, Y) \rightarrow \lim_{\leftarrow n} \operatorname{Hom}_{S_n}(X_n, Y_n)$   
 ```

(where $X_n = X \times_S S_n$ and similarly $Y_n = \dots$) is bijective.

<!-- label: III.XV.1.5 -->

Indeed, it follows from EGA II 6.2.5 that X is a finite sum of local S -schemes finite over S . This reduces us to the case where X itself is the spectrum of a complete noetherian local ring. But $\operatorname{Hom}_S(X, Y) = \Gamma(Z/X)$ where Z is the X -prescheme $Y \times_S X$, and we apply the preceding proposition.

Proposition 1.6. *Let A , S , S_n be as above, and let G and M be two S -preschemes in groups, with M finite over S . Then:

a) The canonical map

```text

$\text{Hom}_{\{S\text{-gr}\}}(M, G) \rightarrow \lim_{\leftarrow n} \text{Hom}_{\{S_n\text{-gr}\}}(M_n, G_n)$

\*is bijective.\* <!-- original page 355 -->

\*b) If  $M$  is of multiplicative type and  $G$  is smooth over  $S$ , the canonical map\*

```text  
 $\varphi : \text{Hom}_{\{S\text{-gr}\}}(M, G) \rightarrow \text{Hom}_{\{S_0\text{-gr}\}}(M_0, G_0)$

is surjective. Moreover, if $\phi(u) = \phi(u') = u_0$, then u and u' are conjugate by an element of $G(S)$ reducing to the unit element of $G(S_0)$.

c) If M is of multiplicative type and smooth over S , if G is flat of finite type over S , and if $u_0 : M_0 \rightarrow G_0$ is a central homomorphism, then u_0 lifts uniquely to a homomorphism

$u : M \rightarrow G$.

Moreover u is central if G has connected fibers.

<!-- label: III.XV.1.6 -->

Proof. a) Follows from 1.5, from the fact that $M \times_S M$ is finite over S , and from the characterization of group morphisms as those rendering commutative the well-known diagram:

```text  

$$\begin{array}{ccc} M \times_S M & \xrightarrow{u \times u} & G \times_S G \\ \downarrow & & \downarrow \\ M & \xrightarrow{u} & G. \end{array}$$

b) By Exp. IX 3.6, one can construct a coherent system of homomorphisms  $u_n : M_n \rightarrow G_n$  lifting a homomorphism  $u_0 : M_0 \rightarrow G_0$ . Hence the first assertion of b), in view of a).

If now  $u$  and  $u'$  are two liftings of  $u_0$ , then  $u_n$  and  $u'_n$  are conjugate

<!-- original page 356 -->

by an element  $g_n$  of  $G(S_n)$  lifting the unit element of  $G(S_0)$  (Exp. IX 3.6); \*loc. cit.\* also implies that one may choose the  $g_n$  in a coherent way, and hence (1.4) coming from a section  $g$  of  $G(S)$ . The morphisms  $u$  and  $\int(g) \cdot u'$  then coincide modulo  $\mathfrak{m}^n$  for every  $n$ , so they coincide (1.5).

c) The existence and uniqueness of  $u$  follow from a) and 1.2 bis. If  $G$  has connected fibers,  $u$  is central by Exp. IX 5.6 a).

## ## 2. Infinitesimal lifting of sub-tori

<!-- label: III.XV.2 -->

<!-- original page 357 -->

### ### 2.1. Statement of the theorem

<!-- label: III.XV.2.statement -->

We shall give a theorem of infinitesimal lifting of sub-tori of a group prescheme which does not appeal to smoothness hypotheses (in contrast to Exp. IX 3.6 bis) and which moreover answers a very natural question [N.D.E-XV-1]: does it suffice to be able to lift "enough" points of finite order of a sub-torus  $T_0$  in order to be assured of being able to lift  $T_0$  (infinitesimally, of course)?

**Theorem 2.1.** Let  $S$  be a noetherian affine scheme,  $S_0$  a closed subscheme of  $S$  defined by an ideal  $J$  of square zero,  $G$  an  $S$ -prescheme in groups of finite type,  $G_0 = G \times_S S_0$ ,  $T_0$  a sub-torus of  $G_0$ ,  $q$  an integer  $> 0$  invertible on  $S$ . Suppose that for every integer  $n$  equal to a power of  $q$ , there exists a subscheme  $M_n$  of  $G$ , flat over  $S$ , such that  $M_n \times_S S_0 = \bigcup_{i=0}^{n-1} T_0^i$ . Then there exists a sub-torus  $T$  of  $G$  such that  $T \times_S S_0 = T_0$ .

<!-- label: III.XV.2.1 -->

Theorem 2.1 will be useful to us through the following two corollaries:

**Corollary 2.2.** Let  $S$  be a locally noetherian prescheme,  $S_0$  a closed subprescheme of  $S$  defined by a locally nilpotent sheaf of ideals,  $G$  an  $S$ -prescheme in groups of finite type,  $T_0$  a sub-torus of  $G_0 = G \times_S S_0$ ,  $q$  an integer  $> 0$  invertible on  $S$ ; finally, with the integer  $n$  ranging over powers of  $q$ , let  $(M_n)$  be a coherent system\*

<!-- original page 358 -->

of  $S$ -subgroup schemes of  $G$ , of multiplicative type, which lifts the  $\bigcup_{i=0}^{n-1} T_0^i$  (N.B. The system of subgroups of multiplicative type  $(M_n)$  is said to be coherent if  $M_m = \bigcup_{i=0}^{m-1} (M_n)^i$  whenever the integer  $m$  divides  $n$ .) Then there exists one and only one sub-torus  $T$  of  $G$  such that  $T \times_S S_0 = T_0$  and  $\bigcup_{i=0}^{n-1} T^i = M_n$  for every  $n$ .

<!-- label: III.XV.2.2 -->

**Corollary 2.3.** Let  $G$  be an  $S$ -prescheme in groups, flat and of finite presentation over  $S$ ,  $S_0$  a closed subprescheme of  $S$  defined by a sheaf of ideals of finite type and locally nilpotent,  $T_0$  a central torus of  $G_0 = G \times_S S_0$ . Then there exists one and only one sub-torus  $T$  of  $G$  lifting  $T_0$ . Moreover  $T$  is central.\*

<!-- label: III.XV.2.3 -->

**Remark 2.4.** We leave to the reader the task of formulating the analogue of statements 2.1, 2.2, 2.3 in which, instead of lifting a sub-torus of  $G_0$ , one is given a torus  $T$  over  $S$  and one proposes to lift a morphism

$$u_0 : T_0 \rightarrow G_0$$

(one reduces to the preceding cases by considering the graph of  $u_0$ ).

<!-- label: III.XV.2.4 -->

Let us show how Corollaries 2.2 and 2.3 are deduced from 2.1.

**Proof of Corollary 2.2.** The uniqueness of  $T$  follows from Exp. IX 4.8 b) and Exp. IX 4.10. To prove the existence of  $T$ , we may therefore reduce to the case where  $S$  is affine, hence noetherian, and where  $S_0$  is defined by an ideal of square zero.

<!-- original page 359 -->

**Lemma 2.5.** Let  $G$  be an  $S$ -prescheme in groups, of finite presentation, and  $H$  a subgroup scheme of  $G$ , of multiplicative type, smooth over  $S$ . Then  $\text{Cent}_G(H)$  is representable by a subgroup prescheme of  $G$ , of finite presentation.\*

<!-- label: III.XV.2.5 -->

The lemma follows from Exp. VIII 6.5 e), without smoothness hypothesis on  $H$ , when  $G$  is separated over  $S$ . In the present case, one notes that the assertion to be proved is local for the fpqc topology, which allows us to assume  $H$  diagonalizable, hence of the form  $D(S)(M)$ . We may also assume  $S$  affine, then  $S$  noetherian thanks to EGA IV 8. Since  $H$  is smooth over  $S$  and of finite type, the order  $q$  of the torsion subgroup of  $M$  is invertible on  $S$  (Exp. VIII 2.1 e)). It is then immediate (cf. Exp. IX 4.10) that the subgroups  $\bigcup_{i=0}^{n-1} H^i$ , where  $n$  ranges over powers of  $q$ , are schematically dense in  $H$  (Exp. IX 4.1). But  $\bigcup_{i=0}^{n-1} H^i$  is a completely decomposed covering of  $S$  (i.e. is isomorphic to a finite direct sum of copies of  $S$ ), so  $\text{Cent}_G(\bigcup_{i=0}^{n-1} H^i) = Z_n$  is representable as the intersection of the centralizers in  $G$  of the sections of  $\bigcup_{i=0}^{n-1} H^i$  over  $S$ . It then suffices to apply the lemma:

**\*\*Lemma 2.5 bis.\*\*** \*Let  $S$  be a noetherian prescheme,  $G$  an  $S$ -prescheme in groups of finite type,  $H$  a subgroup of  $G$  of multiplicative type,  $(H_i)$  an increasing filtered family of subgroups of  $G$  of multiplicative type, and suppose that  $Z_i = \text{Centr}_G(H_i)$  is representable by a subgroup prescheme of  $G$ . Then the family of  $Z_i$  is stationary.\*

<!-- original page 360 -->

\*If moreover the  $H_i$  are schematically dense in  $H$ , one has  $Z_i = \text{Centr}_G(H)$  for  $i$  large enough.\*

<!-- label: III.XV.2.5bis -->

To see that the family of  $Z_i$  is stationary, it suffices to show that the family of underlying sets  $\text{Sens}(Z_i)$  is stationary. Indeed, the stationary value will then be a closed subset of an open subset  $U$  of  $G$ ; and, possibly replacing  $G$  by  $U$ , we are reduced to studying a decreasing filtered family of closed subpreschemes of a noetherian prescheme. An easy constructibility argument reduces us to the case where  $S$  is integral. We must then show that the family of  $\text{Sens}(Z_i)$  is stationary above some non-empty open subset of  $S$ . Now the generic fiber of  $G$  is separated (Exp. VI A 0.3), so, possibly restricting  $S$ , we may assume  $G$  separated over  $S$  (EGA IV 8). But then  $Z_i$  is closed in  $G$  (Exp. VIII 6.5 e)).

To establish the last assertion of the lemma, denote by  $Z$  the stationary value of the family  $Z_i$ . It is clear that  $\text{Centr}_G(H)$  is a subfunctor of  $Z$ ; let us show that  $Z$  centralizes  $H$ . Let  $E$  be the subprescheme of  $H \times_S Z$  which is the kernel of the pair of morphisms:

```
```text
H x_S Z -> G
(h, c) -> c
(h, c) -> hch^{-1}.
```
```

The prescheme  $E$  majorizes  $H_i \times_S Z$  for every  $i$ . On the other hand, the  $H_i$  are flat over  $S$ , so (EGA IV 11.10.9) for every point  $s$  of  $S$ , the  $(H_i)_s$  are schematically dense in  $H_s$  and the  $H_i \times_S Z$  are schematically dense in  $H \times_S Z$ . Since  $G_s$  is separated,  $E_s$  is closed in  $(H \times_S Z)_s$  and therefore equal to it. But then  $E$  is closed in

<!-- original page 361 -->

$H \times_S Z$ , so equals  $H \times_S Z$ . This says that  $Z$  centralizes  $H$ .

Let us return to the proof of 2.2. By 2.5,  $Z_n = \text{Centr}_G(M_n)$  is representable, and by 2.5 bis the decreasing family of subpreschemes  $Z_n$  is stationary; let  $Z$  be its stationary value. The group  $Z$  majorizes  $T_0$  and the  $M_n$ . Possibly replacing  $G$  by  $Z$ , we may therefore assume the  $M_n$  central.

We are then in the conditions of application of Theorem 2.1, and there exists a sub-torus  $T$  of  $G$  lifting  $T_0$ . The groups  $T_n$  and  $M_n$  are then two liftings of  $T_0$ , hence are conjugate (Exp. IX 3.2 bis) and consequently coincide,  $M_n$  being central. The torus  $T$  answers the question.

**\*Proof of Corollary 2.3.\*** The uniqueness of  $T$  follows from Exp. IX 5.1 bis, and the fact that  $T$  is central follows from IX 5.6 b). This remark allows us, by the usual procedure, to reduce to the case where  $S$  is affine (so  $S_0$  is defined by a nilpotent ideal of finite type), then to the case where  $S$  is noetherian. Possibly restricting  $S$ , we may assume that there exists an integer  $q$  invertible on  $S$ . Corollary 2.3 is then a consequence of 2.2 and of 1.2.

**\*\*Remark 2.6.\*\*** One easily shows that Corollary 2.3 remains true if one replaces the torus  $T_0$  by a smooth central subgroup of multiplicative type of  $G_0$ .

<!-- label: III.XV.2.6 -->

### 2.2. Proof of 2.1

<!-- label: III.XV.2.proof -->

<!-- original page 362 -->

**\*\*a)** Reduction to the case  $T_0 = G_{\{m, S_0\}}$ .

Thanks to 1.1, we may assume that  $M_n$  is a subgroup of multiplicative type. Using Exp. IX 3.2 bis, we may assume

that the family of the  $\mathcal{M}_n$  is coherent (2.2). The centralizer  $\mathcal{Z}_n$  of  $\mathcal{M}_n$  in  $\mathcal{G}$  is representable (2.5), and the filtered family of  $\mathcal{Z}_n$  is stationary (2.5 bis). Possibly replacing  $\mathcal{G}$  by  $\mathcal{Z}_n$  for  $n$  large enough, we may therefore assume  $\mathcal{T}_0$  and the  $\mathcal{M}_n$  central. The uniqueness of the lifting of  $\mathcal{T}_0$  is then assured (Exp. IX 5.1 bis).

Proceeding as in the proof of 1.1, we may assume that there exist an  $\mathcal{S}$ -torus  $\mathcal{T}$  and an  $\mathcal{S}_0$ -isomorphism

```
```text
u_0 : T x_S S_0 -> T_0,
```

and it is equivalent to lift u_0 or to lift $\mathcal{T}_0$. In view of uniqueness, it suffices to prove the existence of a lifting of u_0 after performing a faithfully flat affine extension $\mathcal{S}' \rightarrow \mathcal{S}$ of finite type (fpqc descent), which allows us to assume $\mathcal{T} = \mathcal{G}^{(r)}_{\mathcal{M}, \mathcal{S}}$ (Exp. X 4.5). If the restriction of u_0 to each factor $\mathcal{G}_{\mathcal{M}}$ lifts to an $\mathcal{S}$ -morphism – necessarily central – one immediately deduces a lifting of u_0 . In short, we may assume $\mathcal{T}_0 = \mathcal{G}_{\mathcal{M}, \mathcal{S}_0}$.

****b) Definition of the obstruction to the existence of a lifting of $\mathcal{T}_0$.**

To prove 2.1, it suffices by 1.1 to find a subscheme of $\mathcal{G}$, flat over $\mathcal{S}$, which lifts $\mathcal{T}_0$. We shall see that one can define the obstruction to the existence of such a lifting as an element of a certain $\mathrm{Ext}^1(\cdot, \cdot)$ of sheaves of modules.

<!-- original page 363 -->

Let $\mathcal{U}$ be an open subset of $\mathcal{G}$ such that $\mathcal{T}_0$ is closed in $\mathcal{U}$, and let us still denote by $\mathcal{U}$ (resp. $\mathcal{U}_0$) the open subscheme of $\mathcal{G}$ (resp. $\mathcal{G}_0$) having $\mathcal{U}$ as underlying space. The sheaf $\mathcal{O}_{\mathcal{T}_0}$, viewed as a sheaf on $\mathcal{U}$, is therefore a quotient of $\mathcal{O}_{\mathcal{U}_0}$. Let h be the canonical epimorphism:

```
$$
h : \mathcal{O}_{\mathcal{U}_0} \longrightarrow \mathcal{O}_{\mathcal{T}_0}.
$$
```

****Lemma 2.7.**** *The canonical map*

```
```text
h~ = id_J \otimes h : J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{U}_0} \rightarrow J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{T}_0}
```

\*factors (evidently uniquely) as  $\phi_i \circ j_{\mathcal{U}}$ , where  $j_{\mathcal{U}}$  is the canonical epimorphism\*

```
```text
J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{U}_0} \rightarrow J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{U}} = J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{T}_0}.
```

<!-- label: III.XV.2.7 -->

We must show that $\tilde{h}(K) = 0$, where K is the kernel of $j_{\mathcal{U}}$. Now for every integer n equal to a power of q , we have an epimorphism

```
$$
h_n : \mathcal{O}_{\mathcal{T}_0} \longrightarrow \mathcal{O}_{\mathcal{T}_0^{(n)}}
$$
```

and since $\mathcal{O}_{\mathcal{T}_0^{(n)}}$ lifts to a scheme $\mathcal{M}_n$ flat over $\mathcal{S}$, the canonical morphism

```
```text
j_n : J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{T}_0^{(n)}} \rightarrow J \otimes_{\mathcal{S}_0} \mathcal{O}_{\mathcal{M}_n}
```

is an isomorphism.

<!-- original page 364 -->

The commutative diagram below:

```

```text
K → J ⊗_{S_0} Ω_{U_0} → J_{U_0} ⊂ Ω_U
      ↓ h~           ↗ i
      J ⊗_{S_0} Ω_{T_0}
      ↓ h~_n
      J ⊗_{S_0} Ω_{T_0} ≅ J_{M_n} ⊂ Ω_{M_n}
...

```

shows that $\tilde{h}(K)$ is contained in $\text{Ker } \tilde{h}_{\{n\}}$ for every n , hence is contained in $\bigcap_{\{n\}} \text{Ker } \tilde{h}_{\{n\}}$, and it suffices to show that this last intersection is zero. Now the sheaf $\mathcal{O}_{T_0}$ is equal to the sheaf $\mathcal{O}_{S_0}[\mathbb{Z}]$, the algebra of the group $\mathbb{Z}$ with coefficients in $\mathcal{O}_{S_0}$, while $\mathcal{O}_{\{n\}T_0}$ is the quotient algebra $\mathcal{O}_{S_0}[\mathbb{Z}/n\mathbb{Z}]$.

Let $a = \sum_{m \in \mathbb{Z}} a_m \otimes m$ be an element of $J \otimes_{S_0} \mathcal{O}_{T_0}$. The a_m are then sections of J , almost all zero. Take n large enough that the indices m for which a_m is non-zero have distinct images in $\mathbb{Z}/n\mathbb{Z}$. Then if $a \in \text{Ker } \tilde{h}_{\{n\}}$, one necessarily has $a = 0$. This proves that $\bigcap_{\{n\}} \text{Ker } \tilde{h}_{\{n\}} = 0$, and proves 2.7.

Let then K_0 be the kernel of h ; consider the following diagram:

```

```text
 0
 ↓
 K_0
 ↓
0 → J_{U_0} → Ω_U → Ω_{U_0} → 0
 ↓ i ↓ h ↓
 J ⊗_{S_0} Ω_{T_0} Ω_{T_0}
 ↓
 0.
...

```

The sheaf  $\mathcal{O}_U$  defines an element  $\Phi$  of the group  $\text{Ext}^1_{\mathcal{O}_U}(\mathcal{O}_{U_0}, J\mathcal{O}_{U_0})$ . Let  $\Psi$  be the element of

<!-- original page 365 -->

$\text{Ext}^1_{\mathcal{O}_U}(K_0, J \otimes_{S_0} \mathcal{O}_{T_0})$  deduced from  $\Phi$  by bifactoriality of  $\text{Ext}^1(\cdot, \cdot)$  through the morphisms  $K_0 \rightarrow \mathcal{O}_{U_0}$  and  $i : J\mathcal{O}_{U_0} \rightarrow J \otimes_{S_0} \mathcal{O}_{T_0}$ . It follows from Exp. III 4.1 and from the infinitesimal flatness criterion (cf. Exp. III 4.3) that there exists a subscheme of  $U$ , flat over  $S$ , which lifts  $T_0$ , if and only if  $\Psi$  is zero.

But note that  $T_0$  is affine, so it suffices (Exp. III 4.5 and 4.6) to show that there locally on  $U$  exists a subscheme flat over  $S$  lifting  $T_0$ . In short, it suffices to show that the image of  $\Psi$  in the sheaf

```

```text
Ω = Ext^1_{Ω_U}(K_0, J ⊗_{S_0} Ω_{T_0})
...

```

is zero. We shall still denote by Ψ this element of $\Gamma(U, \mathcal{O}_U)$.

c) Reduction to the case S local artinian with algebraically closed residue field.

Since K_0 and $J \otimes_{S_0} \mathcal{O}_{T_0}$ are coherent sheaves, so is the sheaf $\mathcal{O}_U$; moreover

$\mathcal{E}$ has its support in T_0 , since this is the case for $J \otimes_{S_0} \mathcal{O}_{T_0}$. To show that the section Ψ of $\mathcal{E}$ is zero, it suffices to see that for every point u of T_0 , the image of

<!-- original page 366 -->

Ψ in the fiber of $\mathcal{E}$ at the point u is zero. But the formation of the $\text{Ext}^i(\cdot, \cdot)$ of coherent sheaves commutes with flat extensions of the base [N.D.E-XV-2], so we are reduced to proving the existence of a lifting of $T_0 \cap \text{operatorname{Spec}} \mathcal{O}_{T_0}$ flat over S . Let s be the projection of u on S ; we may then replace S by $\text{operatorname{Spec}} \mathcal{O}_{S,s}$ and G by $G \otimes_{S_0} \mathcal{O}_{S,s}$.

Possibly again making a faithfully flat extension, we may assume that $\mathcal{O}_{S,s}$ has an algebraically closed residue field (EGA 0_III, 10.3.1).

Let $\mathfrak{m}$ be the maximal ideal of $\mathcal{O}_{S,s}$ and $S_n = \text{operatorname{Spec}} \mathcal{O}_{S,s} / \mathfrak{m}^n$. Suppose we have shown that for every $n > 0$ the obstruction to lifting $T_0 \otimes_{S_0} S_n = (T_0)_n$ to a subscheme of $G_n = G \otimes_{S_0} S_n$, flat over S_n , is zero, and let T_n be the unique flat lifting of $(T_0)_n$ over S_n which is a sub-torus of G_n . It is clear that if $n > n'$, one has

```
```text
(T_n) \times_{S_n} S_{n'} = T_{n'}.
```
```

If then u is a point of T_0 projecting onto s , it follows from the lemma below, applied to the coherent system of liftings $(T_n \cap \text{operatorname{Spec}} \mathcal{O}_{T_0,u})$ of $(T_0)_n \cap \text{operatorname{Spec}} \mathcal{O}_{T_0,u}$, that there indeed exists a lifting of $T_0 \cap \text{operatorname{Spec}} \mathcal{O}_{T_0,u}$ flat over $\mathcal{O}_{S,s}$. We are therefore reduced to proving that Ψ is zero when $S = S_n$ is the spectrum of an artinian local ring with algebraically closed residue field, and to proving:

Lemma 2.8. *Let $A \rightarrow B$ be a local homomorphism of noetherian local rings, $\mathfrak{m}$ the maximal ideal of A , J an ideal of square zero of A , M a B -module of finite type, $A_0 = A/J$, $B_0 = B/JB$, $M_0 = M/JM$, N_0 a quotient B_0 -module of M_0 which is flat over A_0 . For every integer $n > 0$, let A_n , $A_{0,n}$, etc., be the objects obtained by base extension*

<!-- original page 367 -->

$A \rightarrow A/\mathfrak{m}^n = A_n$, and let J_n be the image of J in A_n . For every integer $n > 0$, let N_n be a quotient B_n -module of M_n , flat over A_n , lifting N_0 , and suppose that for $n \geq n'$, N_n is obtained from $N_{n'}$ by base extension $A_{n'} \rightarrow A_n$. Then there exists a B -module N , quotient of M , flat over A , lifting N_0 .*

<!-- label: III.XV.2.8 -->

Proof of 2.8. * Let P_0 be the kernel of the epimorphism $M_0 \rightarrow N_0$. For every $n > 0$, we have the following commutative diagram in which the horizontal rows are exact:

```
```text
 0
 |
 v
 P_{0,n}
 |
 v
0 -> J_n M_n -> M_n -> M_{0,n} -> 0
 ^
 |
 J_n \otimes_{A_{0,n}} M_{0,n}
 |
 v
0 -> J_n \otimes_{A_{0,n}} N_{0,n} -> N_n -> N_{0,n} -> 0
 v v
 0 0
...
```
```

$\backslash (*_n *)$

Moreover, by hypothesis, the diagram $(*)_n$ reduces modulo $\mathfrak{m}^n$ to $(*)_n$.

The Artin-Rees lemma (Bourbaki, *Algèbre commutative*, Chap. 3 § 3 cor. 1) shows that the filtration defined on $\backslash JM$ (resp. $J \otimes_{A_0} M_0$ and $J \otimes_{A_0} N_0$) by the kernels of the morphisms

<!-- original page 368 -->

```

```text
JM → J_n M_n, (resp. J ⊗_{A_0} M_0 → J_n ⊗_{A_{0,n}} M_{0,n} and J ⊗_{A_0} N_0 → J_n ⊗_{A_{0,n}} N_{0,n})
```

```

is $\mathfrak{m}$ -good, so that, passing to the projective limit on the diagrams $(*)_n$ and denoting by $\hat{Q}$ the separated completion of a B -module Q for the $\mathfrak{m}$ -adic topology, one obtains the following commutative diagram, where the two horizontal rows are still exact:

```

```text
 0
 |
 ▼
 P^*_0
 |
 ▼

0 → JM → M^ → M^*_0 → 0
 ↗ ↘
 J ⊗_{A_0} M_0
 ↘ ↗
0 → J ⊗_{A_0} N_0 → lim_{←n} N_n → N^*_0 → 0
 ▼ ▼
 0 0
```

```

...

$(^{*})$

Now $(B, \mathfrak{m})$ is a Zariski ring and $J \otimes_{A_0} N_0$ is of finite type over B , so it is separated for the $\mathfrak{m}$ -adic topology. The diagram $(\hat{*})$ then shows that the morphism

```

```text
J ⊗_{A_0} M_0 → J ⊗_{A_0} N_0
```

```

deduced from the epimorphism $M_0 \rightarrow N_0$ factors through $\backslash JM$:

```

```text
J ⊗_{A_0} M_0 → can. → JM
 ↘ ↗
 J ⊗_{A_0} N_0.
```

```

Under these conditions, it follows from Exp. III 4.1 and Exp. III 4.3 that there exists a B -module quotient N of M , flat over A , lifting N_0 , if and only if a certain element g of $E = \text{Ext}^1_B(P_0, J \otimes_{A_0} N_0)$ is zero. More precisely, the exact sequence

```

$$
0 \rightarrow JM \rightarrow M \rightarrow M_0 \rightarrow 0
$$

```

defines an element f of F , where F is the B -module $\text{Ext}^1_B(M_0, JM)$, and g is the image of f

<!-- original page 369 -->

under the natural morphism $F \rightarrow E$ arising by bifactoriality from the morphisms

```

```text

```

$P_0 \rightarrow M_0$  and  $JM \rightarrow J \otimes_{A_0} N_0$ .

It follows from the diagram  $(\hat{*})$  and from Exp. III 4.1 that the image of  $g$  in  $\hat{E}$ , canonically identified with  $\text{Ext}^1_{\hat{B}}(\hat{P}_0, \hat{J} \otimes_{A_0} N_0)$ , is zero. But  $E$  is of finite type over  $B$ ,

<!-- original page 370 -->

so is separated for the  $\mathfrak{m}_B$ -adic topology, and consequently  $g$  is indeed equal to  $0$ , which completes the proof of 2.8.

**\*d)** Study of  $\mathcal{E}$ . We therefore suppose that  $S$  is the spectrum of a local artinian ring  $A$  with algebraically closed residue field  $k$ . Let  $A_0$  be the ring of  $S_0$ ,  $\mathfrak{m}_0$  the maximal ideal of  $A_0$ . Since  $S_0$  is artinian,  $T_0$  is closed in  $G$  (Exp. VI\_B 1.4.2); we may therefore take the open subset  $U$  equal to  $G$ , so that

$$\Gamma = \text{Ext}^1_{\Gamma(G)}(K_0, J \otimes_{S_0} \Gamma(T_0)).$$

Let  $B_0$  be the ring of the affine  $S_0$ -scheme  $T_0 = G_{\{m, S_0\}}$ , and  $B'_0$  the ring of the special fiber  $T_0 \times_{S_0} \text{Spec}(k) = G_{\{m, k\}}$  of  $T_0$ . The sheaf  $\mathcal{E}$  is a coherent  $\mathcal{O}_{T_0}$ -module, so is defined by a  $B_0$ -module of finite type which we shall denote  $E$ .

Consider the graded module associated to  $E$  and to the  $\mathfrak{m}_0$ -adic filtration:

$$E_r = \mathfrak{m}_0^r E / \mathfrak{m}_0^{r+1} E.$$

Each  $E_r$  is therefore a  $B'_0$ -module of finite type, and  $E_{-r} = 0$  for  $r$  large enough, since  $S_0$  is artinian.

Let then  $g$  be a section of  $G$  above  $S$  which on  $S_0$  induces a section  $g_0$  of  $T_0$ . Translation (on the left, to fix ideas) by the element  $g$  defines an "automorphism of the situation" from the viewpoint of the obstruction problem under consideration. In particular, to  $g$  corresponds an  $S_0$ -automorphism of the sheaf  $\mathcal{E}$  leaving the obstruction  $\Psi$  fixed. More precisely,  $g$  defines a semi-linear automorphism of the  $B_0$ -module  $E$  (relative to the  $A_0$ -automorphism of  $B_0$  defined by translation by  $g_0$  in the group  $T_0$ ). By reduction modulo  $\mathfrak{m}_0^{r+1}$ ,  $g$  then defines a semi-linear automorphism of  $E_r$  (relative to the  $k$ -automorphism of  $B'_0$  defined by translation by  $g_0$  in  $T_0 \times_{S_0} \text{Spec}(k)$ ).

**\*Lemma 2.9.\*** For every integer  $r \geq 0$ ,  $E_r$  is a locally free  $B'_0$ -module.

<!-- label: III.XV.2.9 -->

Let  $x$  be a point of  $T_0$ ,  $\kappa(x)$  its residue field,  $(E_r)_x$  "the fiber" of  $E_r$  at  $x$ , equal to  $E_r \otimes_{B'_0} \kappa(x)$ ,  $\ell(x)$  the rank of  $(E_r)_x$  over  $\kappa(x)$ ,  $\ell$  the maximum value of  $\ell(x)$  as  $x$  ranges over the points of  $T_0$ . Let  $L$  be the largest closed subscheme of  $\text{Spec} B'_0 = G_{\{m, k\}}$  above which  $E_r$  is locally free of rank  $\ell$  (TDTE IV Lemma 3.6). Let  $\beta$  be a point of  $L(k)$  (there is one,  $L$  being of finite type over  $k$  algebraically closed) and let  $\alpha$  be a point of  $G_{\{m, k\}}$  of order equal to a power  $n$  of  $q$ . The point  $\alpha$  is therefore rational

<!-- original page 371 -->

over  $k$ , and since by hypothesis  $T_0$  lifts to a subscheme  $M_n$  étale over  $S$ , there exists a section  $a$  of  $G$  above  $S$  which lifts  $\alpha$  and which, above  $S_0$ , is a section of  $T_0$ . The remarks made above then show that the fibers of  $E_r$  are  $k$ -isomorphic at the points  $\beta$  and  $\alpha \beta$  of  $G_{\{m, k\}}$ . But the points of order a power of  $q$  are dense in  $G_{\{m, k\}}$ , and similarly their translates by  $\beta$ . Since  $L$  is closed in  $G_{\{m, k\}}$  and  $G_{\{m, k\}}$  is reduced,  $L$  equals  $G_{\{m, k\}}$  and  $E_r$  is locally free over  $B'_0$  of rank  $\ell$ .

**\*e)** End of the proof of Theorem 2.1.

Let  $K_{(n)}$  be the sheaf of ideals of  $\mathcal{O}_{G_0}$  defining the closed subscheme  $T_{(n)}$ . The sheaf  $K_{(n)}^{\wedge N.D.E-XV-3}$  is therefore a subsheaf of  $K_{(n)}$ . Set, for simplicity,

```

```text

$$R = J \otimes_{S_0} \mathcal{O}_{T_0} \quad \text{and} \quad R(n) = J \otimes_{S_0} \mathcal{O}_{T_0}(n).$$

```

```

The sheaf  $R(n)$  is therefore a quotient of  $R$ , and one has the diagram of morphisms:

```

```text

$$\begin{array}{ccccccc}
 & & K_0 & & & & \\
 & & \downarrow & & & & \\
 & & K_0(n) & & & & \\
 & & \downarrow & & & & \\
 0 & \longrightarrow & J \otimes_{S_0} \mathcal{O}_{T_0} & \longrightarrow & \mathcal{O}_{T_0} & \longrightarrow & 0 \\
 & & \downarrow & & & & \\
 & & R & & & & \\
 & & \downarrow & & & & \\
 & & R(n) & & & & \\
 \dots & & & & & & 
 \end{array}$$

```

```

Using then the bifactoriality of  $\text{Ext}^1_{\mathcal{O}_{T_0}}(\mathcal{O}_{T_0}, \mathcal{O}_{T_0}(n))$ , one obtains the following commutative diagram:

```

```text

$$\begin{array}{ccc}
 \text{Ext}^1_{\mathcal{O}_{T_0}}(\mathcal{O}_{T_0}, J \otimes_{S_0} \mathcal{O}_{T_0}) & & \\
 \searrow & & \\
 \text{Ext}^1_{\mathcal{O}_{T_0}}(K_0(n), R) & \longrightarrow & \text{Ext}^1_{\mathcal{O}_{T_0}}(K_0, R) = 0 \\
 \downarrow & & \downarrow \\
 \text{Ext}^1_{\mathcal{O}_{T_0}}(K_0(n), R(n)) & \longrightarrow & \text{Ext}^1_{\mathcal{O}_{T_0}}(K_0, R(n)).
 \end{array}$$

```

```

Let us again denote by  $\Phi$  the element of  $\text{Ext}^1_{\mathcal{O}_{T_0}}(\mathcal{O}_{T_0}, J \otimes_{S_0} \mathcal{O}_{T_0})$  defined by the exact sequence

<!-- original page 372 -->

```

$$0 \longrightarrow J \otimes_{S_0} \mathcal{O}_{T_0} \longrightarrow \mathcal{O}_{T_0} \longrightarrow \mathcal{O}_{T_0} \longrightarrow 0,$$

```

so that  $\Psi$  is the image of  $\Phi$  in  $\mathcal{O}_{T_0}$ . Since  $\mathcal{O}_{T_0}(n)$  lifts to a subscheme  $M_n$  of  $G$ , flat over  $S$ , the image of  $\Phi$  in the sheaf  $\text{Ext}^1_{\mathcal{O}_{T_0}}(K_0(n), R(n))$  is zero (Exp. III 4.1); *a fortiori*, the image of  $\Phi$  in  $\text{Ext}^1_{\mathcal{O}_{T_0}}(K_0, R(n))$ , which is also the image of  $\Psi$ , is zero.

**Lemma 2.10.** *The canonical morphism*

```

```text

$$\text{Ext}^1_{\mathcal{O}_{T_0}}(K_0, R) \otimes_{B_0} \mathcal{O}_{T_0}(n) \rightarrow \text{Ext}^1_{\mathcal{O}_{T_0}}(K_0, R(n))$$

```

```

*is injective for every integer  $n$ .*

<!-- label: III.XV.2.10 -->

Indeed, the affine scheme  $T_0 = G_m, S_0$  has ring

```

$$B_0 = A_0[T, T^{-1}].$$

```

The subscheme  $\mathcal{O}_{T_0}(n)$  is defined by the vanishing of the following section of  $B_0$ :

$$h(n) = T^n - 1,$$

which is regular (EGA 0<sub>IV</sub> 15.2.2) and remains regular after any base change  $S'_0 \rightarrow S_0$ . We therefore have an exact sequence of sheaves:

$$0 \rightarrow \mathcal{O}_{T_0} \xrightarrow{h(n)} \mathcal{O}_{T_0} \rightarrow \mathcal{O}_{nT_0} \rightarrow 0.$$

<!-- original page 373 -->

Since  $\mathcal{O}_{T_0}$  is flat over  $S_0$ , one obtains, by tensoring with  $\mathcal{O}_{S_0}$  over  $\mathcal{O}_{S_0}$ , the exact sequence

$$0 \rightarrow R \xrightarrow{h(n)} R \rightarrow R(n) \rightarrow 0,$$

then the exact sequence of  $\text{Ext}$ :

$$\cdots \rightarrow \text{Ext}^1_{\mathcal{O}_G}(K_0, R) \xrightarrow{h(n)} \text{Ext}^1_{\mathcal{O}_G}(K_0, R) \rightarrow \text{Ext}^1_{\mathcal{O}_G}(K_0, R(n)),$$

which completes the proof of the lemma.

The foregoing shows that for every integer  $n$  equal to a power of  $q$ , the image of  $\Psi$  in  $\mathcal{O}_G/h(n)\mathcal{O}_G$  is zero. To show that  $\Psi$  is zero, it suffices to see that if  $\Psi \in \mathcal{O}_G/h(n)\mathcal{O}_G$ , then  $\Psi \in \mathcal{O}_G/h(n+1)\mathcal{O}_G$ . Let  $\bar{\Psi}$  be the image of  $\Psi$  in  $\mathcal{O}_G/h(n)\mathcal{O}_G$ . There exists an element  $\Psi(n)$  of  $\mathcal{O}_G$  such that one has

$$\Psi = \Psi(n) \cdot h(n) \quad (n \text{ equal to a power of } q).$$

We noted that the image  $\bar{h}(n)$  of  $h(n)$  in  $\mathcal{O}_{B'_0}$  is again  $\mathcal{O}_{B'_0}$ -regular. Since  $\mathcal{O}_{E_s}$  is locally free over  $\mathcal{O}_{B'_0}$  for every  $s$  (2.9), multiplication by  $\bar{h}(n)$  in  $\mathcal{O}_{E_r}$  is injective. One deduces immediately that  $\Psi(n)$  is in  $\mathcal{O}_G/h(n)\mathcal{O}_G$ . Let  $\bar{\Psi}(n)$  be its image in  $\mathcal{O}_{E_r}$ , so that one has the relation

$$\bar{\Psi} = \bar{h}(n) \bar{\Psi}(n) \quad (n \text{ equal to a power of } q).$$

This shows that the set  $F$  of points of  $G_{m,k}$  at which  $\bar{\Psi}$  takes the value  $0$  contains the dense set of points of order a power of  $q$ . Moreover  $F$  is a closed set (since  $\mathcal{O}_{E_r}$  is locally free over  $\mathcal{O}_{B'_0}$ ) and  $G_{m,k}$  is reduced, so  $\bar{\Psi}$  is zero.

This completes the proof of Theorem 2.1.

### ## 3. Characterization of a sub-torus by its underlying set

<!-- label: III.XV.3 -->

<!-- original page 374 -->

#### ### 3.1. Statement of the theorem

<!-- label: III.XV.3.statement -->

**\*\*Notation.\*\*** If  $X$  is a prescheme,  $\text{ens}(X)$  denotes the underlying set of  $X$ . If  $X$  and  $S$  are two  $S$ -preschemes,  $X_{\{S\}} = X \times_S S$ ,  $\pi : X_{\{S\}} \rightarrow X$  the canonical morphism,  $E$  a subset of  $\text{ens}(X)$ , one denotes by  $E_{\{S\}}$  (or  $E \times_S S$ ) the subset of  $\text{ens}(X_{\{S\}})$  equal to  $\pi^{-1}(E)$ .

**Theorem 3.1.** Let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -prescheme in groups of finite type,  $q$  an integer  $> 0$  invertible on  $S$ ,  $E$  a subset of  $\text{ens}(G)$ . Consider the following assertions concerning  $E$ :

- (i) The set  $E$  is the underlying set of a sub-torus  $T$  of  $G$ .
- (ii) a) For every point  $s$  of  $S$ , there exists a sub-torus  $T_s$  of  $G_s$  such that  $E \cap \text{ens}(G_s) = E_s$  is the underlying set of  $T_s$ .
- b) As the integer  $n$  ranges over powers of  $q$ , there exists a coherent family (cf. 2.2)  $M_n$  of subgroup schemes of  $G$ , of multiplicative type, such that for every point  $s$  of  $S$  one has

$$(M_n)_s = \{ T_s \}.$$

- (iii) a) As in (ii) a).
- b) The set  $E$  is locally closed in  $\text{ens}(G)$ , and the dimension of the fibers of  $E$  over  $S$  is locally constant.
- (iv) a) As in (ii) a).
- b) For every  $S$ -scheme  $S'$  which is the spectrum of a complete discrete valuation ring with algebraically closed residue field,  $E_{S'}$  is the underlying set of a sub-torus of  $G_{S'}$ .

Then one has the following implications:

- A) (i)  $\Leftrightarrow$  (ii)  $\Rightarrow$  (iii)  $\Rightarrow$  (iv).
- B) If  $G$  is separated over  $S$ , one has (iii)  $\Leftrightarrow$  (iv), and moreover  $E$  is closed.
- C) Conditions (i), (ii), (iii) (and also (iv) if  $G$  is separated over  $S$ ) are equivalent in the following two cases:
  - 1st case: a) The prescheme  $S$  is reduced, or  $G$  is flat over  $S$ , and
  - b) For every point  $s$  of  $S$ ,  $T_s$  is a central torus of  $G_s$ .
  - 2nd case:  $S$  is normal.

Moreover, in the two cases above, the torus  $T$  with underlying set  $E$  is unique.

**Remarks 3.2.** a) When  $S$  is reduced, it is unnecessary in (ii) to assume that the family  $M_n$  is coherent, this condition being entailed by the other hypotheses. Indeed, if the integer  $m$  divides  $n$ , the subgroups  $M_m$  and  $M_n$  are étale over  $S$ , hence reduced, and have the same underlying space, so they coincide.

b) If  $S$  is not assumed normal, it is no longer true in general that (iii)  $\Rightarrow$  (i), even when  $S$  is reduced, geometrically unbranched and  $G$  is a smooth group scheme over  $S$ . Indeed, consider the Borel subgroup of  $\text{SL}_{\{2, S\}}$  formed by matrices of the form

$$\begin{pmatrix} t & u \\ 0 & t^{-1} \end{pmatrix},$$

where  $S$  is the affine curve over a field  $k$  with ring

$$k[x, y]/(y^2 - x^3).$$

Consider then the set  $E$  obtained as follows: above the "cusp of  $S$ " ( $x = y = 0$ ) we take the diagonal torus ( $u = 0$ ). Above the complementary open subset ( $x \neq 0$ ) we take the torus deduced from the diagonal torus by conjugation by the element

\$\$  

$$\begin{pmatrix} 1 & y/x \\ 0 & 1 \end{pmatrix}.$$
  
 \$\$

The set  $E_S$  so obtained satisfies (iii) a); on the other hand it is closed in  $G_S$ , and the reduced subscheme having  $E_S$  as underlying set has equations

\$\$  

$$xu + y(t - t^{-1}) = 0$$
  

$$u^2 - x(t - t^{-1})^2 = 0.$$
  
 \$\$

<!-- original page 377 -->

This is therefore not a sub-torus of  $G_S$ , since the fiber above the cusp is not reduced.

<!-- label: III.XV.3.2 -->

**Plan of the proof of 3.1.** In a first part we shall establish the following "easy" implications:

```text  

$$\begin{array}{ccc} & (ii) & \\ (i) \nearrow & & \searrow (iv) \\ & (iii) & \nearrow \end{array}$$

 ...

and $[(iv) \Rightarrow (iii) \text{ and } E \text{ closed if } G \text{ is separated over } S]$.

The proof of the more delicate implications will be carried out in three stages:

- I) Reduction of the implication $(iii) \Rightarrow (i)$ (under the hypotheses of C), 1st case) to the case where S_S is normal.
- II) $(iii) \Rightarrow (ii)$ when S_S is normal.
- III) $(ii) \Rightarrow (i)$.

3.2. Proof of the "easy" assertions contained in 3.1

<!-- label: III.XV.3.easy -->

$(i) \Rightarrow (ii)$ and (iii) is trivial.

$(iii) \Rightarrow (iv)$. Possibly replacing S_S by S'_S , we may assume that S_S is the spectrum of a discrete valuation ring. Let t_S be the generic point of S_S and s_S the closed point.

Since E_S is locally closed, there exists a subprescheme of G_S which is reduced and whose underlying space is E_S ; we shall denote it E_S . The generic fiber E_{t_S} of E_S is therefore equal to the sub-torus T_{t_S} of rank r of G_{t_S} (by (iii) b)). Let E'_S be the schematic closure of E_{t_S} in E_S . The prescheme

<!-- original page 378 -->

E'_S is irreducible, and its closed fiber E'_{s_S} is non-empty (it contains the unit section of G_{s_S}), so E'_{s_S} is of dimension r (EGA IV 14.3.10). But then E'_{s_S} is a closed subscheme of E_{s_S} , and the latter is of dimension r (by (iii) b)) and irreducible (since it has the same underlying space as T_{s_S}), so E'_{s_S} has the same underlying space as E_{s_S} , and consequently $E' = E_S$, which proves that E_S is flat over S_S .

Let now E''_S be the schematic closure of E_{t_S} in G_S . Then E''_S is a subprescheme in groups of G_S , flat over S_S (Exp. VIII 7.1), which majorizes E'_S , hence E_S . The closed

<!-- original page 379 -->

fiber E''_{s_S} is an algebraic subgroup of G_{s_S} of dimension r (*loc. cit.*). Since T_{s_S} is a closed irreducible subset of G_{s_S} of dimension r , E_{s_S} has the same underlying set as the connected component $(E''_{s_S})^{\{0\}}$ of E''_{s_S} . Let $(E'')^{\{0\}}$ be the "connected component" of E''_S , i.e. the open subgroup of E''_S

complementary to the union of the irreducible components of $E'_{\{s\}}$ not containing the origin. One then has

```
$$
E = \text{ens}[(E')^{\{0\}}].
$$
```

Since E_S and E' are reduced, one has even $E = (E')^{\{0\}}$. Finally E_S is a subgroup prescheme of G_S , flat and of finite type over S_S , with connected fibers, hence separated (Exp. VI_B 5.2), whose generic fiber is a torus $T_{\{t\}}$, and whose reduced closed fiber is a torus $T_{\{s\}}$; but then E_S is a torus (Exp. X 8.8).

(ii) $\Rightarrow$ (iv). One may again assume that S_S is the spectrum of a discrete valuation ring, and we keep the notation introduced above. The schematic closure in G_S of $T_{\{t\}}$ is a subgroup prescheme T_S of G_S , flat over S_S , which majorizes $M_{\{n\}}$ for every integer n equal to a power of q . Consequently the closed fiber of T_S is a closed subscheme of $G_{\{s\}}$ majorizing $(M_{\{n\}})_{\{s\}}$ for every n , hence majorizing $T_{\{s\}}$. For dimension reasons, the "connected component" $T^{\{0\}}$ of T_S has E_S as underlying set, and one concludes as above that $T^{\{0\}}$ is a sub-torus of G_S .

(iv) $\Rightarrow$ [(iii) and E_S closed], if G_S is separated over S_S . Let us show that E_S is closed. [N.D.E-XV-4] First let us prove the lemma:

Lemma 3.3. *If the conditions stated in 3.1 (iv) are satisfied, E_S is a locally constructible part of $\text{ens}(G)_S$.*

```
<!-- label: III.XV.3.3 -->
```

By the usual method, we are reduced to studying the case where S_S is noetherian, integral, with generic point η . Possibly restricting S_S , we may assume (Exp. VI_B 10.10) that there exists a subgroup scheme H_S of G_S , flat over S_S , with connected fibers, whose generic fiber $H_{\{\eta\}}$ is equal to $T_{\{\eta\}}$. To prove 3.3 it then suffices to show that $\text{ens}(H) = E_S$. Now if s is a point of S_S , there exists, by EGA II 7.1.9, an S_S -scheme S' , the spectrum of a discrete valuation ring, that one may assume complete with algebraically closed residue field, whose generic point t' projects onto η and whose closed point s' projects onto s . By (iv) b), there exists a sub-torus $T_{\{S'\}}$ of $G_{\{S'\}}$ having $E_{\{S'\}}$ as underlying space. The two subprescheme in groups $T_{\{S'\}}$ and $H_{\{S'\}} = H \times_{S'} S'$ of $G_{\{S'\}}$ are flat over S' , have connected fibers, and the same generic fiber $T_{\{t'\}}$, so they coincide with the connected component of the schematic closure

```
<!-- original page 380 -->
```

of $T_{\{t'\}}$ in $G_{\{S'\}}$. Consequently $\text{ens}(H_{\{s\}}) = E_{\{s\}}$, so $\text{ens}(H) = E_S$, which proves the lemma.

This being so, knowing that E_S is locally constructible, in order to see that E_S is closed it suffices to show that every specialization in G_S of a point of E_S is a point of E_S . By the usual technique we are reduced to the case where S_S is the spectrum of a complete discrete valuation ring with algebraically closed residue field. But then the sub-torus of G_S of underlying space E_S ((iv) b)) is closed in G_S since G_S is separated (Exp. VIII 7.12).

3.3. Continuation of the proof of 3.1

```
<!-- label: III.XV.3.cont -->
```

I) Reduction of (iii) $\Rightarrow$ (i) (C, 1st case) to the case where S_S is normal.

a) Reduction to the case S_S affine reduced. We therefore assume that for every point s of S_S , $E_{\{s\}}$ is the underlying space of a central sub-torus of $G_{\{s\}}$. The uniqueness of T_S then follows from Exp. IX 5.1 bis, and moreover T_S will necessarily be central (*loc. cit.*). In view of uniqueness, to prove the existence of T_S we may assume S_S noetherian, affine of ring A_S . If S_S is not reduced, by hypothesis G_S is flat over S_S . By 2.3 it then suffices to solve the problem for $S_{\{\text{red}\}}$ and $G \times_{S_{\{\text{red}\}}} S_{\{\text{red}\}}$. We may therefore assume in addition that S_S is reduced.

b) Reduction to the case where the ring A_S is of finite type over $\mathbb{Z}$. Let us first prove two lemmas:

```
<!-- original page 381 -->
```

Lemma 3.4. *Let k be a field, G_k a k -algebraic group, E_k a subset of G_k , k' an extension of k , $T_{\{k'\}}$ a sub-torus of $G_{\{k'\}}$ having $E_{\{k'\}}$ as underlying space. Then, if $T_{\{k'\}}$ is central or if k is perfect, E_k is the underlying set of a sub-torus of $G_{\{k\}}$.*

```
<!-- label: III.XV.3.4 -->
```

Indeed, by fpqc descent it suffices to show that the two inverse images of $T_{k'}$ in $G_{k'}$, where $k' = k \otimes_{k'} k$, coincide. Now they have the same underlying space, namely the inverse image of E . If $T_{k'}$ is central, the lemma is a consequence of Exp. IX 5.1 bis. If k is perfect, k' is reduced and the two inverse images of $T_{k'}$, being smooth over k' , are reduced, hence coincide.

Remark 3.5. It follows from the preceding lemma that in the statement of 3.1 (iv), property (iv) a) is a consequence of (iv) b) in the two following cases:

1. One assumes that the residue fields of the points of S are perfect.
1. For every S' as in (iv) b), one assumes that the torus with underlying space $E_{S'}$ is central in $G_{S'}$.

<!-- label: III.XV.3.5 -->

Lemma 3.6. Let S be a prescheme projective limit of affine schemes S_i (cf. EGA IV 8), H an S -group scheme of multiplicative type and of finite type. Then there exist an index i , an S_i -group scheme H_i of multiplicative type and of finite type, and an S -isomorphism

```text  
 $H_i \times_{S_i} S \cong H$ .  
 ```

If moreover H is isotrivial, one may assume H_i isotrivial.

<!-- label: III.XV.3.6 -->

<!-- original page 382 -->

Since H is of finite type over S , H is in fact of finite presentation over S (Exp. IX 2.1 b)); there therefore exist an index ℓ and an S_ℓ -group scheme H_ℓ such that $H_\ell \otimes_{S_\ell} S$ is isomorphic to H (Exp. VI_B 10). Setting $H_i = H_\ell \otimes_{S_\ell} S_i$, one therefore has $H \cong \varinjlim H_i$ for every $i \geq \ell$.

Since H is of finite type over S , H is quasi-isotrivial (Exp. X 4.5), hence trivialized by an étale surjective morphism $S' \rightarrow S$. Using the quasi-compactness of S , one easily sees that there exist a covering of S by a finite number of affine open subsets S_α , and for every α an étale, surjective and finitely presented morphism $S'_\alpha \rightarrow S_\alpha$ trivializing $H|_{S_\alpha}$. This covering (S'_α) of S then comes from a covering (S_i, α_i) of S for i large enough (EGA IV 8). Possibly replacing S_i by S_{i, α_i} and S by S_α , we may therefore assume that H is trivialized by an étale surjective morphism $S' \rightarrow S$ of finite presentation. For i large enough, there then exist a prescheme S'_i , an étale surjective morphism $S'_i \rightarrow S_i$ of finite presentation, and an S -isomorphism $S'_i \otimes_{S_i} S \rightarrow S'$ (EGA IV 17.16). Set then for j large enough:

```text  
 $S'_j = S'_i \times_{S_i} S_j, \quad H'_j = H_j \times_{S_j} S'_j, \quad H' = H \times_S S'.$   
 ```

Given the choice of S' , there exist a finitely generated abelian group M and an S' -isomorphism of group schemes $D_{S'}(M) \xrightarrow{\sim} H'$. Since the S'_i are quasi-compact and $S' = \varinjlim S'_i$, it follows from Exp. VI_B 10 that there exist an index j and an S'_j -isomorphism of group schemes

$D_{S'_j}(M) \xrightarrow{\sim} H'_j$.
 S

But this says that H_j is a quasi-isotrivial group of multiplicative type.

<!-- original page 383 -->

When H is isotrivial, one proceeds analogously, using a trivialization of H by a finite étale morphism $S' \rightarrow S$.

This being so, we can carry out the announced reduction b). The ring A of S is a filtered inductive limit of its subrings A_i of finite type over $\mathbb{Z}$. Let $S_i = \operatorname{Spec} A_i$, $u_j : S \rightarrow S_j$ and $u_{jk} : S_k \rightarrow S_j$ ($k \geq j$) the transition morphisms. Since S is noetherian and G is of finite presentation over S , there exist an index i and an S_i -prescheme in groups G_i , of finite type over S_i , such

that G is S -isomorphic to $G_i \times_S S$. Similarly, since E is locally closed in G , we may assume that there exists a locally closed subset E_i of G_i such that $E = E_i \times_S S$ (EGA IV 8.3.11). For every $j > i$, let $G_{\{j\}} = G_{\{i\}} \times_S S_{\{j\}}$ and $E_{\{j\}} = E_{\{i\}} \times_S S_{\{j\}}$, and let $Q_{\{j\}}$ be the set of points s of $S_{\{j\}}$ such that $(E_{\{j\}})_s$ is the underlying set of a central sub-torus of $(G_{\{j\}})_s$.

It follows from 3.4 that $Q_{\{k\}} = u^{-1}_{\{j\}}(Q_{\{j\}})$ for $k \geq j$, and by hypothesis $\text{ens}(S) = u^{-1}_{\{j\}}(Q_{\{j\}})$ for $j \geq i$. Moreover, I claim that $Q_{\{j\}}$ is ind-constructible (EGA IV 1.9.4). Indeed, since $S_{\{j\}}$ is noetherian, it suffices (EGA IV 1.9.10) to see that if S is a noetherian integral scheme with generic point η , and if E_{η} is the underlying set of a central sub-torus T_{η} of G_{η} , there exists a neighborhood U of η such that for every point s of U , E_s has the same property. Now, possibly restricting S , we may assume that the

<!-- original page 384 -->

center Z of G is representable and that there exists a subgroup scheme T of G whose generic fiber is T_{η} (VI_B § 10). But then $\text{ens}(T)$ and E are two locally closed subsets of $\text{ens}(G)$ which coincide on the generic fiber; one may therefore find a neighborhood U of η such that, above U , $\text{ens}(T) = E$ (EGA IV 8.3.11). For the same reasons, one may assume that above U , T is central, since T is a torus (3.6).

Knowing now that $Q_{\{j\}}$ is ind-constructible, it follows from EGA IV 8.3.4 that $Q_{\{j\}} = \text{ens}(S_{\{j\}})$ for j large enough. We may then replace S , G , E by $S_{\{j\}}$, $G_{\{j\}}$, $E_{\{j\}}$, which reduces us to the case where S is an affine reduced scheme of finite type over $\mathbb{Z}$.

****c) Reduction to the case where S is the spectrum of a complete reduced noetherian local ring.**** Owing to the uniqueness of the torus of underlying set E , the usual technique (EGA IV 8) and Lemma 3.6 allow us to replace S by the spectrum of the local ring A of a point of S . Let $\hat{S}$ be the spectrum of the completion $\hat{A}$ of A for the topology defined by the maximal ideal. Since A is the localization of a finitely generated algebra over $\mathbb{Z}$, $\hat{S}$ is still

<!-- original page 385 -->

reduced (EGA IV 7.6.5). I claim that it suffices to solve the problem after the base change $\hat{S} \rightarrow S$. Indeed if $\hat{T}$ is the sub-torus of $G_{\hat{S}}$ with underlying space $E_{\hat{S}}$, its two inverse images in $G_{\hat{S}} \times_S \hat{S}$ are two central sub-tori with the same underlying space, so they coincide (Exp. IX 5.1 bis), and by fpqc descent, $\hat{T}$ comes from a torus T of G which answers the question (cf. 3.4).

****d) A descent lemma.**** Let us recall the following properties of finite morphisms which were noted in TDTE I: Let S and S' be two preschemes and $u : S' \rightarrow S$ a finite morphism. Then:

1. The morphism u is an epimorphism if and only if the canonical morphism of sheaves $\mathcal{O}_S \rightarrow u_* (\mathcal{O}_{S'})$ is injective.
1. The morphism u is an effective epimorphism (Exp. IV 1.3) if and only if the canonical diagram
$$0 \rightarrow \mathcal{O}_S \rightarrow u_* (\mathcal{O}_{S'}) \rightarrow u_* (\mathcal{O}_{S'}) \otimes_{\mathcal{O}_S} \mathcal{O}_S \rightarrow 0$$
 is exact.
1. If moreover S is noetherian and if u is an epimorphism, u is the composite of a finite sequence of effective finite epimorphisms.

We are then in a position to prove the following lemma, whose proof uses a technique of non-flat descent:

****Lemma 3.7.**** *Let S be a locally noetherian prescheme, G an S -prescheme in groups of finite type, S' a prescheme and $u : S' \rightarrow S$ a finite morphism. For every S -prescheme T , let $M(T)$ denote the set of subgroups of multiplicative type of G_T *

<!-- original page 386 -->

(resp. the set of central subgroups of multiplicative type of G_T), so that M is in a natural way a contravariant functor defined on Sch/S . Then, if u is an effective epimorphism (resp. an epimorphism), the diagram of sets

```

```text
(*) M(S) → M(S') ⇒ M(S' ×_S S')
```

```

is exact.

<!-- label: III.XV.3.7 -->

Proof. i) ****Reduction to the case where u is an effective epimorphism.**** We are then interested in the functor of central subgroups of multiplicative type of G . The injectivity of $M(S) \rightarrow M(S')$ is a local question on S , and, this injectivity being granted, the exactness of $(\ast)$ becomes a local problem on S . We may therefore assume S affine noetherian.

Let us study the case where $u : S' \rightarrow S$ is the composite of two finite epimorphisms:

```

```text
S' --v--> S'' --w--> S.
```

```

I claim that if the two diagrams

```

```text
(*)' M(S'') → M(S') → M(S' ×_{S''} S')
(*)'' M(S) → M(S'') → M(S' ×_S S'')
```

```

are exact, then so is $(\ast)$.

Indeed the injectivity of $M(S) \rightarrow M(S')$ is clear. If now T' is an element of $\text{Ker } M(S') \rightarrow M(S' \times_{S''} S')$, *a fortiori* T' belongs to $\text{Ker } M(S') \rightarrow M(S' \times_{S''} S')$, so by exactness of $(\ast)'$ comes from a unique element T'' of $M(S'')$. It suffices

<!-- original page 387 -->

to show that T'' belongs to $\text{Ker } M(S'') \rightarrow M(S' \times_S S'')$, since, by exactness of $(\ast)''$, T'' will descend to S . Let T''_1 and T''_2 be the two inverse images of T'' in $M(S' \times_{S''} S')$. Since these are two central subgroups of multiplicative type of $G_{S' \times_{S''} S'}$, to show that $T''_1 = T''_2$ it suffices to see that they have the same fibers (Exp. IX 5.1 bis). Consider the commutative diagram

```

```text
S' ←----- S' ×_{S''} S'
| |
v v × v
▼ ▼
S'' ←----- S'' ×_S S''.
```

```

The morphism v is a finite epimorphism, hence is dominant (property (a) above) and closed, hence is surjective, and the same is true of $v \times v$. Let x'' be a point of $S' \times_{S''} S'$ and x' a point of $S' \times_S S'$ above x'' . It follows from commutativity of the diagram above that the two inverse images of $(T''_1)_{x''}$ and $(T''_2)_{x''}$ in $G_{x'}$ coincide, so $(T''_1)_{x''} = (T''_2)_{x''}$ (EGA IV 2.2.15).

What precedes, and an immediate induction on the number of factors of a factorization of $u : S' \rightarrow S$ into effective epimorphisms (property (c) recalled above), show that to prove the exactness of $(\ast)$ in the case of central subgroups of multiplicative type, we may restrict to the case where u is an effective epimorphism. Finally, using once again Exp. IX 5.1 bis, one sees that it suffices to prove 3.7 when M is the functor of subgroups of multiplicative type of G and u an effective epimorphism.

ii) ****Injectivity of $M(S) \rightarrow M(S')$.** Since $u : S' \rightarrow S$ is an epimorphism, the canonical

<!-- original page 388 -->

morphism $\mathcal{O}_S \rightarrow \mathcal{O}_{S'}$ is injective; moreover an S -group of multiplicative type is flat over S ; the injectivity of $M(S) \rightarrow M(S')$ is therefore a consequence of the more general following lemma:

Lemma 3.8. Let $f : X \rightarrow S$ and $g : S' \rightarrow S$ be two morphisms of preschemes, $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$ -module, $X' = X \times_S S'$, $\mathcal{F}' = \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_{X'}$, $\mathcal{Q}(\mathcal{F})$ the set of quotient $\mathcal{O}_X$ -modules $\mathcal{G}$ of $\mathcal{F}$ which are quasi-coherent and flat over S , $\mathcal{Q}(\mathcal{F}')$ the analogue relative to $\mathcal{F}'$, X' and S' . Suppose g is quasi-compact and

$\mathcal{O}_S \rightarrow \mathcal{O}_{S'}$ injective; then the canonical map

```

```text

$$Q(\square) \rightarrow Q(\square')$$

$$\square \mapsto \square \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}$$

```

is injective.

<!-- label: III.XV.3.8 -->

Indeed, one may assume  $S$  affine, then  $X$  affine. The morphism  $g$  being quasi-compact,  $S'$  is then a union of a finite number of affine open subsets  $S'_i$ . Possibly replacing  $S'$  by  $\coprod S'_i$  (an operation which preserves the injectivity of  $\mathcal{O}_S \rightarrow \mathcal{O}_{S'}$ ), one may assume  $S'$  affine. One is then reduced to proving the following lemma, whose proof is immediate:

<!-- original page 389 -->

**Lemma 3.9.** Let  $A \rightarrow A'$  be an injective homomorphism of rings,  $M$  an  $A$ -module,  $N = M/P$  a quotient  $A$ -module flat over  $A$ ,  $M' = M \otimes_A A'$ ,  $N' = N \otimes_{A'} A' = M'/P'$ . Then  $P$  is the inverse image of  $P'$  under the canonical homomorphism  $M \rightarrow M'$  (so  $N$  and  $P$  are known when one knows  $N'$  and  $P'$ ).

<!-- label: III.XV.3.9 -->

iii) **Exactness of 3.7** (\*) at  $M(S')$ . Let  $T$  be an element of  $\text{Ker } M(S') \rightarrow M(S' \times_S S')$ . Suppose we have proved iii) when  $S$  is the spectrum of a noetherian local ring. For every point  $s$  of  $S$ , there then exists a subgroup of multiplicative type  $T_s$  of  $G \times_S \text{Spec}(\mathcal{O}_{S,s})$  which comes by descent from  $T' \times_S \mathcal{O}_{S,s}^{-1} \times_S \text{Spec}(\mathcal{O}_{S,s})$ . By (Exp. VI\_B § 10 and 3.6), there exist a neighborhood  $U$  of  $s$  in  $S$  and a subgroup scheme  $T'_U$  of  $G_U$  above  $U$  which is of multiplicative type and which extends  $T_s$ . Let  $U'$  be the inverse image of  $U$  in  $S'$ . One then knows two subschemes of  $G'|_{U'}$ :  $T'|_{U'}$  and  $T' \times_U U'$ , which coincide on  $U'^{-1} \times_U \text{Spec}(\mathcal{O}_{S,s})$ . If one regards  $U'^{-1} \times_U \text{Spec}(\mathcal{O}_{S,s})$  as the projective limit of the schemes  $U'^{-1}(V)$  where  $V$  ranges over the open neighborhoods of  $s$  in  $U$ , it follows from EGA IV 8 that there exists an open neighborhood  $V$  of  $s$  in  $U$  such that  $T' \times_U U'$  and  $T'_U$  coincide above  $U'^{-1}(V)$ . So with the hypotheses made,  $T'$  descends locally on  $S$ ; but, owing to the uniqueness proved in ii),  $T'$  then descends globally on  $S$ . In short, it suffices to prove iii) when  $S$  is the spectrum of a noetherian local ring.

<!-- original page 390 -->

Let then  $\hat{S}$  denote the spectrum of the completion of the ring of  $S$ , and let  $S'' = S' \times_S \hat{S}$ ,  $\hat{S}'' = \hat{S} \times_S S''$ ,  $\hat{S}''' = \hat{S} \times_S S'' = \hat{S} \times_{\hat{S}} \hat{S}''$ . I claim it suffices to show that the diagram

```

$$\begin{array}{ccc} S & \xrightarrow{\quad} & M(\hat{S}) \\ (*) & & \searrow \\ & & M(\hat{S}') \end{array}$$

```

is exact at  $M(\hat{S}')$ . This follows from the commutative diagram below, in which the second row is exact at  $M(\hat{S}')$  by hypothesis, the first two columns are exact (fpqc descent), and the map  $f$  is injective as follows from ii) applied to the finite epimorphism

```

```text

$$\hat{S}' \times_{\hat{S}} \hat{S} \rightarrow \hat{S} \times_S \hat{S}$$

```

deduced from $S' \rightarrow S$ by the flat base change $\hat{S} \times_S \hat{S} \rightarrow \hat{S}$:

```

```text

$$\begin{array}{ccccc} M(S) & \longrightarrow & M(S') & \longrightarrow & M(S'') \\ \downarrow & & \downarrow & & \downarrow \\ M(\hat{S}) & \longrightarrow & M(\hat{S}') & \longrightarrow & M(\hat{S}'') \\ \downarrow & & \downarrow & & \downarrow \\ M(\hat{S} \times_S \hat{S}) & \xrightarrow{f} & M(\hat{S}' \times_S \hat{S}') & & \end{array}$$

```

(the diagram-chase is left to the reader). It follows from the characterization (b) of effective finite epimorphisms that the morphism  $\hat{S}' \rightarrow \hat{S}$ , deduced from  $S' \rightarrow S$  by the flat base change  $\hat{S} \rightarrow S$ , is again an effective finite epimorphism. We are therefore reduced to the case where furthermore  $S$  is the spectrum of a complete noetherian local ring.

<!-- original page 391 -->

Let  $S_0$  denote the reduced subscheme of  $S$  whose underlying space is the closed point of  $S$ . Let  $T'$  be an element of  $\text{Ker } M(S') \rightarrow M(S'_0)$ ,  $T'_0$  its image in  $M(S'_0)$ . Since  $S'_0 = S'_0 \times_{S_0} S'_0$ ,  $S'_0$  is faithfully flat over  $S_0$ , there exists an  $S$ -subgroup of multiplicative type  $T'_{S_0}$  of  $G_{S_0}$  whose inverse image in  $G_{S'_0}$  is  $T'_{S'_0}$  (fpqc descent). But  $S$  is local complete noetherian, so there exist an  $S$ -group of multiplicative type  $T$  and an  $S_0$ -morphism  $u : T \times_{S_0} S'_0 \rightarrow T'_{S'_0}$  (Exp. X 3.3). The inverse image  $u'$  of  $u$  above  $S'_0$  extends uniquely to an  $S$ -isomorphism  $u' : T_{S'} \rightarrow T'$ , still by Exp. X 3.3 (note that  $S'$ , being finite over  $S$  local complete, is the sum of a finite number of complete local schemes). The two inverse images of  $u'$  above  $S'$  are two morphisms of  $T_{S'}$  into  $T'$  which coincide on  $S_0 \times_{S_0} S'_0$ , so they coincide (\*loc. cit.\*). Since  $T$  is flat over  $S$  and  $S' \rightarrow S$  is a finite effective epimorphism, it follows from TDTE I page 8 that the diagram

```

```text
Hom_S(T, G) → Hom_{S'}(T_{S'}, G_{S'}) ⇒ Hom_{S''}(T_{S''}, G_{S''})
```

```

is exact. So  $u'$  comes from a morphism of preschemes  $u : T \rightarrow G$ . Similarly  $T \times_{S_0} S'_0$  is flat over  $S$ , and consequently the map

```

```text
Hom_S(T ×_S T, G) → Hom_{S'}(T_{S'} ×_{S'} T_{S'}, G_{S'})
```

```

is injective. One deduces immediately that  $u$  is a morphism of groups, since this is so of  $u'$ . Moreover  $u$  is a monomorphism. Indeed, note first that  $\text{Ker } u$  is flat over  $S$ , since to establish this fact one may assume  $S$  artinian local (EGA 0\_III 10.2.2), hence  $G$  separated (Exp. VI\_A 0.3); but then  $\text{Ker } u$  is of multiplicative type (Exp. IX 6.8), hence is flat over  $S$ . Since  $\text{Ker}(u) \times_{S'} S' = \text{Ker}(u') = 0$ , one has  $\text{Ker}(u) = 0$  (3.8). But  $u$  being a monomorphism is an immersion (Exp. VIII, remarks 7.13), and the image group  $u(T)$  is indeed an element of  $M(S)$  whose image in  $M(S')$  is  $T'$ . This completes the proof of 3.7.

\*\*e) End of the proof of I).\*\*

<!-- original page 392 -->

We are reduced by reduction c) to the case where  $S$  is the spectrum of a complete reduced noetherian local ring  $A$ . Let  $S'$  be the spectrum of the normalization  $A'$  of  $A$ , which is finite over  $A$  by Nagata (EGA 0\_IV 23.1.5);  $S' \rightarrow S$  is an epimorphism since  $A$  embeds injectively into  $A'$ . Suppose then that there exists a torus  $T'$  of  $G_{S'}$  having  $E_{S'}$  as underlying space. The two inverse images of  $T'$  in  $G_{S' \times_S S'}$  are two central sub-tori with the same underlying space, so they coincide (Exp. IX 5 bis); hence, by 3.7,  $T'$  comes from a central sub-torus  $T$  of  $G_S$  which evidently has  $E$  as underlying space. It therefore suffices to prove the existence of  $T$ , which reduces us to the case where  $S$  is normal and completes the proof of I).

\*\*II) Proof of (iii)  $\Rightarrow$  (ii) when  $S$  is normal.\*\*

We may restrict to the case where  $S$  is integral; let  $t$  be its generic point. For every integer  $n$  equal to a power of  $q$ , let  $\{G_n\}$  be the subscheme of  $G$  "kernel" of the  $n$ -th power morphism in  $G$ . Since  $E$  is locally closed in  $G$  (by (iii) b)), the intersection of  $\{G_n\}$  with  $E$  is locally closed in  $G$ ; let us then denote by  $E(n)$  the reduced subscheme of  $G$  having  $\{G_n\} \cap E$  as underlying space.

Let us show that the structural morphism  $E(n) \rightarrow S$  is separated and universally open. For these two properties we have a valuative criterion (EGA II 7.2.3 and

<!-- original page 393 -->

EGA IV 14.5.8). Let then  $S'$  be an  $S$ -scheme which is the spectrum of a complete discrete valuation ring with algebraically closed residue field. We have shown that 3.1 (iii)  $\Rightarrow$  3.1 (iv), so there exists a sub-torus  $T'$  of  $G_{S'}$  having  $E_{S'}$  as underlying space. Now  $\{G_n\}T'$  is finite and étale over  $S'$ , hence separated and universally open over  $S'$ , and the same is true of  $E(n) \times_{S'} S'$ , which has the same underlying space as

$\pi_n^{-1}(T)$ .

Moreover, the fibers of  $E(n)$  have the same number of geometric points, namely  $r^n$  if  $r$  is the rank of the torus  $T$ . Finally, the generic fiber  $E(n)_t$ , being reduced, is equal to  $\pi_n^{-1}(T)_t$ , hence is étale over  $\mathrm{Spec}(t)$ . Since  $S$  is normal, it then follows from SGA I 10.11 that  $E(n)$  is an étale covering of  $S$ .

If  $s$  is a point of  $S$ ,  $E(n)_s$  is étale over  $\mathrm{Spec}(\kappa(s))$ , hence reduced, and consequently coincides with the group of multiplicative type  $\pi_n^{-1}(T)_s$ . Let us show that  $E(n)$  is a subgroup prescheme of  $G$ . Indeed, let  $m$  be the morphism

$$E(n) \times_S E(n) \rightarrow G$$

induced by the multiplication in  $G$ . The underlying map  $\mathrm{ens}(m)$  factors through  $E(n)$ , so  $m$  factors through the prescheme  $E(n)$ , since its source  $E(n) \times_S E(n)$  is étale over  $S$ , hence reduced. It then follows from Exp. X 4.8 a) that  $E(n)$  is a subgroup of multiplicative type. As already noted (3.2 a)), the family of subgroups  $E(n)$  is necessarily coherent. We have therefore proved that (iii)  $\Rightarrow$  (ii) when  $S$  is normal.

<!-- original page 394 -->

**III) Proof of (ii)  $\Rightarrow$  (i).**

In fact we shall show that there exists a unique sub-torus  $T$  of  $G$  with underlying space equal to  $E$  and such that  $\pi_n^{-1}(T) = M_n$  for every  $n$  equal to a power of  $q$ . The uniqueness of  $T$  follows simply from Exp. IX 4.8 b). To establish the existence of  $T$ , in view of uniqueness, we may successively assume:

a)  $S$  is noetherian.

b) The  $M_n$  are central subgroups. Indeed, it suffices to replace  $G$  by  $Z_n = \mathrm{Centr}_G(M_n)$  for  $n$  large enough (2.5 and 2.5 bis).

c)  $S$  is the spectrum of a local ring. Suppose indeed the problem solved after every base change  $\mathrm{Spec}(\mathcal{O}_{S,s}) \rightarrow S$  where  $s$  ranges over the points of  $S$ . Let  $T_s$  be the sub-torus of  $G \times_S \mathrm{Spec}(\mathcal{O}_{S,s})$  thus obtained. For every  $s$  there then exist an open neighborhood  $U$  of  $s$  and a sub-torus  $T$  of  $G|_U$  extending  $T_s$  (Exp. VI\_B § 10 and 3.6). We have shown that 3.1 (ii)  $\Rightarrow$  3.1 (iv); since  $S$  is noetherian,  $E$  is therefore constructible (3.3). Consequently, possibly restricting  $U$ , we may assume that  $\mathrm{ens}(T) = E \times_S U$  (EGA IV 9.5.2). But then, for every integer  $n$  equal to a power of  $q$ ,  $\pi_n^{-1}(T)$  and  $M_n \times_S U$  are two subgroups of multiplicative type of  $G|_U$  with the same fibers, hence which coincide,  $M_n$  being central (Exp. IX 5.3 bis). In short, with the hypotheses made, there exists a solution locally on  $S$ , hence by uniqueness, there exists a global solution.

<!-- original page 395 -->

d)  $S$  is the spectrum of a complete noetherian local ring, and if  $s$  is the closed point,  $T_s$  is trivial. This follows from EGA 0\_III 10.3.1 and from fpqc descent.

e)  $S$  is reduced. One applies 2.2.

f)  $S$  is normal. One applies Nagata's finiteness theorem (EGA 0\_IV 23.1.5) and Lemma 3.7 in the case of central sub-tori.

These reductions being made, since  $T_s$  is trivial,  $(M_n)_s$  is trivial, so  $M_n$  is trivial (Exp. X 3.3). If  $t$  is a point of  $S$ , the subgroups  $\pi_n^{-1}(T)_t$  of  $T_t$  are therefore trivial for every  $n$  equal to a power of  $q$ , and it follows easily from Exp. X 1.4 that  $T_t$  itself is trivial. It then suffices to prove the lemma:

**Lemma 3.10.** \*Under the hypotheses of 3.1 (ii), suppose in addition that  $S$  is noetherian and normal and that for every point  $s$  of  $S$ ,  $T_s$  is a trivial torus. Then there exists a unique sub-torus  $T$  of  $G$  with underlying space equal to  $E$ , such that  $\pi_n^{-1}(T) = M_n$  for every  $n$  equal to a power of  $q$ . Moreover  $T$  is trivial.\*

<!-- label: III.XV.3.10 -->

The uniqueness of  $T$  follows from the fact that  $T$ , being smooth over  $S$ , is reduced. To prove the existence, we may assume  $S$  irreducible with generic point  $\eta$ . Let  $r$  be the rank of  $T_\eta$ ,  $T^0 = G^r_{\eta,m}(S)$ ,  $u_\eta$  an isomorphism of  $T^0_\eta$  onto  $T_\eta$ ,  $\pi_n^{-1}(u_\eta)$  the restriction of  $u_\eta$  to

$\mathcal{T}^0_{\eta}$ . Since  $\mathcal{T}^0_{\eta}$  and  $M_{\eta}$  are trivial, there exists a unique extension  $\mathcal{U}_{\eta}$  of  $\mathcal{U}_{\eta}$  to an  $S$ -isomorphism of  $\mathcal{T}^0_{\eta}$  onto  $M_{\eta}$ . I claim that for every point  $s$  of  $S$  there exists a group isomorphism, necessarily unique:

$$\mathcal{U}_s : \mathcal{T}^0_s \xrightarrow{\sim} T_s$$

extending  $\mathcal{U}_s$  for every  $s$  equal to a power of  $q$ . Indeed, let  $S_1$  be an  $S$ -scheme,

← original page 396 →

spectrum of a complete discrete valuation ring with algebraically closed residue field, whose generic point  $t_1$  projects onto  $\eta$  and whose closed point  $s_1$  projects onto  $s$  (EGA II 7.1.9). It follows from the proof of 3.1 (ii)  $\Rightarrow$  3.1 (iv) that there exists a sub-torus  $T_1$  of  $G_{S_1}$  such that  $(M_{\eta})_{S_1} = \mathcal{T}^0_{t_1}$  for every  $s$  equal to a power of  $q$ . Since  $S_1$  is normal,  $T_1$  is isotrivial (Exp. X 5.16), and it follows from the classification of isotrivial tori (Exp. X 1.2) and from SGA 1 V 8.2 that  $T_1$ , having trivial generic fiber, is trivial. One may therefore extend the isomorphism  $\mathcal{U}_{\eta} \times_{\eta} t_1$  to an  $S_1$ -isomorphism of group schemes

```text  

$$\mathcal{U}_1 : T^0 \times_S S_1 \rightarrow T_1.$$
```

The restriction of  $\mathcal{U}_1$  to  $\mathcal{T}^0_{\eta} \times_S S_1$  on the one hand, and  $\mathcal{U}_{\eta} \times_S S_1$  on the other, coincide on the generic fiber by construction, hence coincide. The restriction  $\mathcal{U}_{1, s_1}$  of  $\mathcal{U}_1$  to the closed fiber thus realizes the desired extension after the residue field extension  $\kappa(s) \rightarrow \kappa(s_1)$ . It then follows from Exp. IX 4.8 a) and from fpqc descent that  $\mathcal{U}_{1, s_1}$  descends to  $\kappa(s)$  to a group isomorphism  $\mathcal{U}_s : \mathcal{T}^0_s \xrightarrow{\sim} T_s$  answering the question.

Moreover,  $\mathcal{T}^0$  is smooth over  $S$  which is normal, hence is normal. It then follows from an easy extension criterion for rational maps (EGA IV 20.4.6) that for the existence of an  $S$ -morphism  $\mathcal{U} : \mathcal{T}^0 \rightarrow G$  whose restriction to  $\mathcal{T}^0_s$ , for every point  $s$  of  $S$ , is the composite morphism

```text  

$$\mathcal{T}^0_s \xrightarrow{\mathcal{U}_s} T_s \rightarrow G_s,$$
```

it is necessary and sufficient that this be the case after every base change  $S_1 \rightarrow S$  where  $S_1$  is the spectrum

← original page 397 →

of a complete discrete valuation ring with algebraically closed residue field.

Now in the present case, a reasoning analogous to the one just made shows that the extension condition is indeed satisfied. Let  $\mathcal{U}$  denote the  $S$ -morphism  $\mathcal{T}^0 \rightarrow G$  thus obtained.

Let us show that  $\mathcal{U}$  is indeed a morphism of groups. Let  $m_{\mathcal{T}^0}$  (resp.  $m_G$ ) be the morphism defining the multiplication in  $\mathcal{T}^0$  (resp.  $G$ ). We must verify that  $m_G \circ (\mathcal{U} \times_S \mathcal{U}) = \mathcal{U} \circ m_{\mathcal{T}^0}$ . Now the subscheme of coincidences of these two morphisms is a subscheme of  $\mathcal{T}^0 \times_S \mathcal{T}^0$ , which majorizes the fibers (since  $\mathcal{U}_s$  is a group morphism), so has the same underlying space as  $\mathcal{T}^0 \times_S \mathcal{T}^0$ , hence is equal to it, since  $\mathcal{T}^0 \times_S \mathcal{T}^0$  is smooth over  $S$ , hence reduced.

Finally, note that  $\mathcal{U}$  is a monomorphism (since this is so on the fibers), hence is an immersion (Exp. VIII 7.9). The image of  $\mathcal{T}^0$  by  $\mathcal{U}$  is then a sub-torus of  $G$  having  $E$  as underlying set.

This completes the proof of Theorem 3.1.

## 4. Characterization of a sub-torus  $T$  by the subgroups  $\mathcal{T}_n$

← label: III.XV.4 →

← original page 398 →

### 4.1. Statement of the main theorem

<!-- label: III.XV.4.statement -->

**\*\*Theorem 4.1.\*\*** \*Let  $S$  be a locally noetherian connected prescheme,  $G$  an  $S$ -prescheme in groups of finite type over  $S$ ,  $q$  an integer  $> 1$  invertible on  $S$ ,  $r$  a positive integer. For every integer  $n$  equal to a power of  $q$ , let  $M(n)$  be a subgroup scheme of  $G$ , of multiplicative type and of type  $(\mathbb{Z}/n\mathbb{Z})^{\wedge r}$ . Suppose:

- \*a) The family of subgroups  $M(n)$  is coherent, that is, if the integer  $m$  divides  $n$ , one has\*

$$M(n) \cap M(m) = M(m).$$

- \*b) There exists a point  $s$  of  $S$  and a sub-torus  $T_s$  of  $G_s$  such that\*

$$M(n)_s = nT_s \quad \text{for every } n.$$

- \*c) For every point  $t$  of  $S$ , there exists a closed affine subscheme  $F_t$  of  $G_t$  majorizing  $M(n)_t$  for every  $n$ .\*

\*Then there exists one and only one sub-torus  $T$  of  $G$  such that  $M(n) = nT$  for every  $n$  equal to a power of  $q$ .\*

<!-- label: III.XV.4.1 -->

One has an analogous theorem concerning the lifting of morphisms:

**\*\*Theorem 4.1 bis.\*\*** \*Let  $S$ ,  $G$  and  $q$  be as above,  $T$  an  $S$ -torus, and for every integer  $n$  equal to a power of  $q$ , let  $u(n)$  be an  $S$ -group morphism  $u(n)_T : T \rightarrow G$ . Suppose:

- \*a) The family of morphisms  $u(n)$  is coherent, i.e., if  $m$  divides  $n$ , one has\*

<!-- original page 399 -->

$$u(m) = u(n)|_{n^{-1}mT}.$$

- \*b) There exists a point  $s$  of  $S$  and a group morphism  $u_s : T_s \rightarrow G_s$  such that

$u_s|_{n^{-1}T_s} = u(n)_s$  for every  $n$  equal to a power of  $q$ .\*

- \*c) For every point  $t$  of  $S$ , there exists a closed affine subscheme  $F_t$  of  $G_t$  majorizing  $u(n)_t(F_t)$  for every  $n$ .\*

\*Then there exists a unique group morphism  $u : T \rightarrow G$  such that for every  $n$  equal to a power of  $q$ , the restriction of  $u$  to  $nT$  is equal to  $u(n)$ .\*

<!-- label: III.XV.4.1bis -->

**\*\*Remark 4.2.\*\*** Using the lower semicontinuity of the abelian rank of a flat group prescheme of finite type over the spectrum of a discrete valuation ring (cf. Exp. X 8.7), one can, in the statements of 4.1 and 4.1 bis, weaken condition c) by simply requiring that the required closed affine subscheme  $F_t$  exists for every maximal point  $t$  of  $S$ .

<!-- label: III.XV.4.2 -->

Let us show how 4.1 bis follows from 4.1. Let  $G' = G \times_S T$ . For every integer  $n$  equal to a power of  $q$ , consider the group morphism

$$v(n) : nT \rightarrow G'$$

whose projections to  $G$  and  $T$  are respectively  $u(n)$  and the canonical immersion  $nT \rightarrow T$ . The morphism  $v(n)$  is therefore an immersion; let  $M(n)$  be the image subgroup. It is clear that the family of subgroups  $M(n)$  is

coherent in the sense of 4.1, that the group  $M(n)_S$  is equal to

<!-- original page 400 -->

$\Gamma'_S$ , where  $\Gamma'_S$  is the sub-torus of  $G'_S$  which is the graph of  $u_S$ , and that for every point  $t$  of  $S$ , the closed affine subscheme  $F_t \times \bar{T}_t$  of  $G'_t$  majorizes the subgroups  $M(n)_t$  for every  $n$ . By 4.1, there therefore exists a sub-torus  $\Gamma'_S$  of  $G'_S$  such that  $\Gamma'_S = M(n)_S$  for every  $n$  equal to a power of  $q$ . Let  $f$  be the restriction to  $\Gamma'_S$  of the projection of  $G'_S$  to  $T$ , and  $f(n)$  the restriction of  $f$  to  $M(n)_S$ . One has

$$f(n) \circ v(n) = \text{id}_{\Gamma'_S(n)}.$$

The fiber at  $s$  of  $\Gamma'_S$  is the torus already denoted  $\Gamma'_s$ , equal to the graph of  $u_s$  (this follows from Exp. IX 4.8 b)), so  $f_s$  is an isomorphism. But  $\text{Ker } f$  and  $\text{Coker } f$  are groups of multiplicative type (Exp. IX 2.7) of constant type,  $S$  being connected, hence reduced to the unit group, and  $f$  is an isomorphism. Let  $v$  be the inverse isomorphism of  $f$ . One has

$$v|_{\Gamma'_S(n)} = v(n).$$

Consequently, the composite of  $v$  and the projection of  $G'_S$  onto  $G_S$  is a morphism  $u : T \rightarrow G_S$  answering the question. The foregoing proves the existence of the morphism  $u$ ; as for uniqueness, it follows in any case from Exp. IX 4.8 a).

#### ### 4.2. Application

<!-- label: III.XV.4.app -->

We propose to generalize Theorem 7.1 of Exp. IX.

Let  $A$  be a complete noetherian local ring,  $I$  its maximal ideal,

<!-- original page 401 -->

$S = \text{Spec } A$ ,  $S_m = \text{Spec } (A/I^m)$ . For every prescheme  $X$ , set  $X_m = X \times_S S_m$ .

Let then  $G$  be an  $S$ -prescheme in groups of finite type,  $T$  an  $S$ -torus,  $q$  an integer invertible on  $S$ , and  $u_m : T_m \rightarrow G_m$  ( $m \in \mathbb{N}$ ) a coherent family of group morphisms. With  $n$  ranging over the powers of  $q$ , denote by  $u_m(n)$  the restriction of  $u_m$  to  $\Gamma'_m(n)$ , and by  $u(n)$  the unique group morphism

$$u(n) : \Gamma'_S(n) \rightarrow G$$

extending the morphisms  $u_m(n)$  for every  $m$  (1.6 a)). We shall say that the family  $(u_m)$ ,  $m \in \mathbb{N}$ , is \*admissible\* if for every point  $t$  of  $S$  there exists a closed affine subscheme  $F_t$  of  $G_t$  majorizing  $u(n)_t(\Gamma'_t(n))$  for every  $n$  equal to a power of  $q$  (this property is independent of  $q$ , as we shall see).

**Proposition 4.3.** \*With the notation above, the canonical map\*

$$\text{Hom}_{S\text{-gr}}(T, G) \rightarrow \varprojlim \text{Hom}_{S_m\text{-gr}}(T_m, G_m)$$

\*induces an isomorphism of the source onto the subset of the target consisting of "admissible" coherent families.\*

<!-- label: III.XV.4.3 -->

Indeed, it suffices to apply 4.1 bis, taking for  $s$  the closed point of  $S$ .

**Corollary 4.4.** \*With the notation above, suppose in addition that  $G$  has affine fibers; then the canonical map\*

```

```text
Hom_{S-gr}(T, G) → lim_{←m} Hom_{S_m-gr}(T_m, G_m)
```

```

\*is an isomorphism.\* <!-- original page 402 -->

<!-- label: III.XV.4.4 -->

Indeed, if  $G$  has affine fibers, every coherent family is "admissible".

**Remark 4.5.** When  $G$  is separated, one may in 4.3 replace the ring  $A$  by an  $\mathbb{I}$ -adic noetherian ring; one may indeed use EGA III 5.4.1 instead of 1.6 a).

<!-- label: III.XV.4.5 -->

### 4.3. Proof of 4.1

<!-- label: III.XV.4.proof -->

**Lemma 4.6.** \*Let  $k$  be a field,  $G$  a  $k$ -algebraic group,  $q$  an integer prime to the residue characteristic of  $k$ ,  $r$  an integer  $> 0$ ,  $M(n)$  ( $n$  ranging over the powers of  $q$ ) a coherent family of subgroups of  $G$ , of multiplicative type and of type  $\mathbb{Z}/n\mathbb{Z}$ . Then there exists a smallest closed subscheme  $H$  of  $G$  majorizing the  $M(n)$  for every  $n$ . Moreover,  $H$  is a smooth, connected and commutative algebraic subgroup of  $G$  whose formation is compatible with base field extension.\*

<!-- label: III.XV.4.6 -->

Let  $M$  be the subset of  $\text{ens}(G)$  which is the union of the underlying sets of the subgroups  $M(n)$  for every  $n$ , and  $H$  the reduced closed subscheme of  $G$  having the closure of  $M$  as underlying space. Since  $M(n)$  is étale over  $k$  hence reduced,  $M(n)$  is contained in  $H$ , and consequently  $H$  is the smallest closed subscheme of  $G$  majorizing  $M(n)$  for every  $n$ . Now let  $\bar{k}$  be an algebraically closed extension of  $k$ . By

<!-- original page 403 -->

construction the subschemes  $M(n)$  are schematically dense in  $H$  (Exp. IX 4.1); the  $M(n)_{\bar{k}}$  are therefore schematically dense in  $H_{\bar{k}}$  (Exp. IX 4.5); moreover  $M(n)_{\bar{k}}$  is reduced, and it follows that  $H_{\bar{k}}$  is necessarily equal to the closed reduced subscheme of  $G_{\bar{k}}$  having as underlying space the closure of  $M_{\bar{k}}$ . This proves that  $H$  is geometrically reduced (EGA IV 4.6.1). The family  $M(n)$  being coherent,  $M$  is stable under the group law; moreover  $M \times_{\bar{k}} M$  is dense in  $\text{ens}(H \times_{\bar{k}} H)$  and  $H \times_{\bar{k}} H$  is reduced (EGA IV 4.6.5); one immediately deduces that  $H$  is an algebraic subgroup of  $G$ . Moreover  $H$  is smooth over  $S$ , since it is geometrically reduced (Exp. VI A 1.3.1), and  $H$  is commutative since the  $M(n)$  are commutative. It remains to see that  $H$  is connected. Let  $H^{\{0\}}$  be the connected component of  $H$ ,  $m$  the number of geometric points of  $H/H^{\{0\}}$ ,  $q^{\{s\}}$  the exponent of  $q$  in the decomposition of  $m$  into prime factors. For every integer  $n$  equal to a power of  $q$ ,  $\{q^{\{s\}} M(n)\}$  is then contained in  $H^{\{0\}}$ . But the family  $M(n)$  is coherent and  $M(n)$  is of type  $\mathbb{Z}/n\mathbb{Z}$ , so  $\{q^{\{s\}} M(nq^{\{s\}}) = M(n)\}$ . Hence  $H^{\{0\}}$  majorizes  $M(n)$  for every  $n$  and consequently equals  $H$ .

This being so, we shall make condition c) of 4.1 more precise. Indeed, by what precedes, we may consider the smallest closed subscheme  $H_{\{t\}}$  of  $G_{\{t\}}$  majorizing  $M(n)_{\{t\}}$  for every  $n$ . The formation of  $H_{\{t\}}$  commuting with base field extension (4.6),  $H_{\{t\}} \times_{\bar{k}} \bar{k}$  is contained in the affine closed subset  $F_{\{t\}}$ , hence is affine. In short,  $H_{\{t\}}$  is affine. On the other hand, we know (4.6) that  $H_{\{t\}}$  is a smooth, connected, commutative algebraic group. It then follows from the structure of smooth, commutative, connected affine algebraic groups over an algebraically closed field (\*Bible\* 4 Th. 4),

<!-- original page 404 -->

that  $H_{\{t\}}$  is a direct product of a torus  $T_{\{t\}}$  and a unipotent group  $U_{\{t\}}$ . But then  $M(n)_{\{t\}}$  is necessarily contained in  $T_{\{t\}}$ , so  $H_{\{t\}} = T_{\{t\}}$ , and consequently  $H_{\{t\}}$  is a torus.

We can now begin the proof of 4.1.

a) **Uniqueness of the solution:** it suffices to apply Exp. IX 4.8 b).

b) **Case where  $S$  is the spectrum of a complete discrete valuation ring  $A$  with algebraically closed residue field**

$k_S$ . Denote by  $K_S$  the field of fractions of  $A_S$ ,  $s_S$  the closed point of  $S_S$ ,  $t_S$  the generic point,  $J_S$  the maximal ideal of  $A_S$ ,  $S_{\{m\}} = \operatorname{Spec}(A/J^{\{m\}})$ ,  $X_{\{m\}} = X \times_S S_{\{m\}}$ .

Let us distinguish two cases:

**1st case:** The point  $s_S$  of 4.1 b) is the generic point  $t_S$  of  $S_S$ . Let then  $T'$  be the schematic closure in  $G$  of the torus  $T_{\{t\}}$ . The closed fiber  $T'_{\{s\}}$  is therefore an algebraic subgroup of  $G_{\{s\}}$ , of dimension  $r$ , majorizing  $M(n)_{\{s\}}$  for every  $n$ , hence  $T'_{\{s\}}$  majorizes  $H_{\{s\}}$ . But  $H_{\{s\}}$  is a torus containing  $M(n)_{\{s\}}$ , so  $H_{\{s\}}$  has rank at least  $r$ . Consequently  $H_{\{s\}}$  has the same underlying space as the connected component of  $T'_{\{s\}}$ . The "connected component"  $(T')^{\{0\}}$  of  $T'$  is then a subgroup prescheme of  $G$ , flat, separated (VI B 5.2), whose generic fiber  $T_{\{t\}}$  is a torus and whose reduced closed fiber  $H_{\{s\}}$  is a torus. But then  $(T')^{\{0\}}$  is a torus (Exp. X 8.8) which we denote by  $T$ . The groups  $\{T_n\}$  and  $M_n$  are smooth over  $S_S$ , hence reduced, and since they have the same underlying space, they coincide. So the torus  $T$  is the solution of the problem.

**2nd case:** The point  $s_S$  of 4.1 b) is the closed point  $s_S$  of  $S_S$ . Possibly replacing  $G$  by

`<!-- original page 405 -->`

the schematic closure in  $G$  of the smallest algebraic subgroup  $H_{\{t\}}$  majorizing the family  $M(n)_{\{t\}}$  (4.6), we may assume  $G_{\{t\}}$  affine.

For every integer  $m \geq 0$ , it follows from 2.2 that there exists a unique sub-torus  $T_{\{m\}}$  of  $G_{\{m\}}$  lifting  $T_{\{s\}}$  and such that for every integer  $n$  equal to a power of  $q$ , one has  $\{T_n\} = M(n)_{\{m\}}$ . Moreover, let  $T^{\{0\}} = G^{\{r\}}_{\{m, S\}}$ . Since  $k$  is algebraically closed,  $T_{\{s\}}$  is trivial, and there exists a  $k$ -isomorphism  $u_{\{s\}} : T^{\{0\}}_{\{s\}} \xrightarrow{\sim} T_{\{s\}}$ . The morphism  $u_{\{s\}}$  lifts uniquely to an  $S_{\{m\}}$ -isomorphism  $u_{\{m\}} : T^{\{0\}}_{\{m\}} \rightarrow T_{\{m\}}$  (Exp. IX 3.3). The family of morphisms  $u_{\{m\}}$ ,  $m \in \mathbb{N}$ , defines in the limit a morphism  $\hat{u}$  of formal completions  $\hat{T}^{\{0\}}$  and  $\hat{G}$  of  $T^{\{0\}}$  and  $G$  along their closed fibers:

$$\begin{array}{ccc} \text{``text} & & \\ T^{\{0\}} & \xrightarrow{\hat{u}} & \hat{G} \\ | & & | \\ i & & j \\ \downarrow & & \downarrow \\ T^{\{0\}} & & G, \\ \text{````} & & \end{array}$$

where  $i$  and  $j$  denote the canonical morphisms.

We shall show that the morphism  $\hat{u}$  is algebraizable. For this we shall reduce to the case where the group  $G$  is affine.

**Lemma 4.7.** Let  $S$  be the spectrum of a discrete valuation ring  $A$ ,  $X$  and  $Y$  two  $S$ -preschemes, quasi-compact, quasi-separated and flat over  $S$ . Then the canonical map

$$\Gamma(X, \square_X) \otimes_A \Gamma(Y, \square_Y) \rightarrow \Gamma(X \times_S Y, \square_{X \times_S Y})$$

is an isomorphism.

`<!-- label: III.XV.4.7 -->`

Let  $f : X \rightarrow S$  (resp.  $g : Y \rightarrow S$ ) be the structural morphism. Since  $X$  (resp.  $Y$ )

`<!-- original page 406 -->`

is quasi-compact and quasi-separated, it follows from EGA I 9.2.2 and from EGA IV 1.7.4 that  $f_{\{*\}}(\mathcal{O}_X)$  (resp.  $g_{\{*\}}(\mathcal{O}_Y)$ ) is a quasi-coherent  $\mathcal{O}_S$ -algebra, which therefore corresponds to an affine  $S$ -scheme  $\tilde{X}$  (resp.  $\tilde{Y}$ ). By hypothesis  $Y$  is flat over  $S$ ; it then follows from EGA III 1.4.15, in view of EGA IV 1.7.21, that the canonical map (deduced from the canonical morphism  $X \rightarrow \tilde{X}$ )

$$\Gamma(\tilde{X} \times_S Y, \square_{\tilde{X} \times_S Y}) \rightarrow \Gamma(X \times_S Y, \square_{X \times_S Y})$$

is an isomorphism. But  $X$  being flat over  $S$ ,  $\tilde{X}$  is flat over  $S$  (since flat over  $A$  is equivalent to torsion-free). Applying once again EGA III 1.4.15 with the roles of  $X$  and  $Y$  exchanged, one obtains an isomorphism

$$\Gamma(\tilde{X}, \mathcal{O}_{\tilde{X}}) \otimes_A \Gamma(\tilde{Y}, \mathcal{O}_{\tilde{Y}}) = \Gamma(X \times_S \tilde{Y}, \mathcal{O}_{X \times_S \tilde{Y}}) \cong \Gamma(X \times_S Y, \mathcal{O}_{X \times_S Y}),$$

whence the lemma.

In the present case, the  $S$ -group  $G$  is flat over  $S$  and of finite type, hence quasi-compact and quasi-separated. One may therefore apply the lemma to  $G \times_S G$ :

$$\Gamma(G, \mathcal{O}_G) \otimes_A \Gamma(G, \mathcal{O}_G) \cong \Gamma(G \times_S G, \mathcal{O}_{G \times_S G}).$$

To the morphism  $\mu_G : G \times_S G \rightarrow G$  defining the multiplication in  $G$  there corresponds therefore a morphism

$$\Gamma(G, \mathcal{O}_G) \rightarrow \Gamma(G \times_S G, \mathcal{O}_{G \times_S G}) \cong \Gamma(G, \mathcal{O}_G) \otimes_A \Gamma(G, \mathcal{O}_G),$$

hence an  $S$ -morphism

$$\mu_{\tilde{G}} : \tilde{G} \times_S \tilde{G} \rightarrow \tilde{G},$$

<!-- original page 407 -->

where  $\tilde{G}$  denotes the affine  $S$ -scheme having  $\Gamma(G, \mathcal{O}_G)$  as  $A$ -algebra. It is formal, from there, to verify that  $\mu_{\tilde{G}}$  endows  $\tilde{G}$  with a structure of  $S$ -group scheme such that the canonical morphism  $\nu : G \rightarrow \tilde{G}$  is an  $S$ -group morphism.

**Remark 4.8.**  $\tilde{G}$  plays the role of a largest "affine quotient" of  $G$ ; moreover one can show that  $\tilde{G}$  is indeed a quotient of  $G$  for fpqc, hence is of finite type over  $S$  (XVII App. III, 2).

<!-- label: III.XV.4.8 -->

In the case at hand, the generic fiber  $G_t$  of  $G$  is affine; it then follows from EGA I 9.3.3 that  $\nu_t$  is an isomorphism. Since  $\tilde{G}$  is affine, the coherent family of morphisms

$$w_m = \nu_m u_m : T^0_m \rightarrow \tilde{G}_m \quad (m \in \mathbb{N})$$

comes from a unique  $S$ -group morphism (Exp. IX 7.1)

$$w : T^0 \rightarrow \tilde{G}.$$

Let  $T_t$  be the sub-torus of  $G_t$  equal to  $\nu_t^{-1}(w_t(T^0_t))$ . The torus  $T_t$  is therefore of rank at most  $r$  (as the image of a torus of rank  $r$ ). Let us show that  $T_t$  majorizes  $M(n)_t$  for every  $n$ . Indeed, let  $u(n)_m$  be the  $S_m$ -isomorphism  $(\{T^0\}_m) \rightarrow M(n)_m$  obtained by restriction of  $u_m$  to  $(\{T^0\}_m)$ . The coherent family of morphisms  $u(n)_m$  comes from a unique  $S$ -isomorphism  $u(n) : \{T^0\} \rightarrow M(n)$  (since  $M(n)$  is finite over  $S$ ). For every integer  $m \geq 0$ , one then has the equalities

$$w_m|_{(T^0)_m} = (\nu_m u_m)|_{(T^0)_m} = (\nu \circ u(n))_m.$$

Consequently,  $w|_{\{T^0\}} = \nu \circ u(n)$  (1.6 a)). In particular, one has  $w_t|_{(\{T^0\}_t)_t} = \nu_t \circ u(n)_t$ , so

$v^{-1}_{-1}\{t\} w_{\{t\}} (\{_{-n}T^{\{0\}})_{\{t\}} = u(n)_{\{t\}} (\{_{-n}T^{\{0\}})_{\{t\}} = M(n)_{\{t\}}.$

This indeed proves that  $T_{\{t\}}$  majorizes  $M(n)_{\{t\}}$ , and entails that  $T_{\{t\}}$  is of rank  $r$ . One concludes

<!-- original page 408 -->

as in the first case already studied, by considering the schematic closure in  $G$  of  $T_{\{t\}}$ , namely  $T''$ . Since  $T_{\{t\}}$  majorizes  $M(n)_{\{t\}}$ ,  $T''_{\{s\}}$  majorizes  $M(n)_{\{s\}}$ , hence majorizes  $T_{\{s\}}$  (density theorem). On the other hand  $T''$  is flat over  $S$  and  $T_{\{t\}}$  is of dimension  $r$ , so  $T''_{\{s\}}$  is of dimension  $r$  (Exp. VI\_B 4). In short,  $T_{\{s\}}$  has the same underlying space as the connected component of  $T''_{\{s\}}$ , and one concludes as in the first case that the connected component of  $T''$  is a sub-torus of  $G$  answering the question.

c) **End of the proof of 4.1.**

To prove the existence of the sub-torus  $T$ , we may assume  $S$  reduced (2.2). In view of 3.1 (ii)  $\Rightarrow$  (i), it then suffices to prove that the set  $U$  of points  $x$  of  $S$  such that there exists a sub-torus  $T_{\{x\}}$  of  $G_{\{x\}}$  with  $\{_{-n}T_{\{x\}} = M(n)_{\{x\}}$  for every  $n$  equal to a power of  $q$ , is equal to  $\text{Sens}(S)$ . The torus  $T_{\{x\}}$  in question is necessarily unique, and by fpqc descent, it suffices to prove its existence after extension of the residue field of  $x$  (Exp. IX 4.8 b)).

This being so, since  $S$  is locally noetherian and connected and since  $U$  is non-empty (it contains the point  $s$  of 4.1 b)), one is reduced, by an immediate argument, to proving that if  $x$  and  $x'$  are two points of  $S$ , with  $x$  a specialization of  $x'$ , and if one of the two points belongs to  $U$ , then both points are in  $U$ . By the usual technique (EGA II 7.1.9) one reduces to the case where  $S$  is the spectrum of a complete discrete valuation ring with algebraically closed residue field, a case which has been treated in b).

This completes the proof of Theorem 4.1.

**5. Representability of the functor of smooth subgroups identical to their connected normalizer**

<!-- label: III.XV.5 -->

<!-- original page 409 -->

**Proposition 5.1.** *Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation,  $H$  a subgroup prescheme of  $G$ , smooth with connected fibers. Then:*

- *a) The normalizer  $N$  of  $H$  in  $G$  is representable by a closed subprescheme of  $G$  of finite presentation over  $S$ .*
- *b) The following conditions are equivalent:*
  - *i) The canonical immersion  $H \rightarrow N$  is an open immersion.*
  - *ii) The group  $N$  is smooth along the unit section, and its connected component, which is then representable (Exp. VI\_B 3.10), is equal to  $H$ .*
  - *iii) For every point  $s$  of  $S$ , one has  $H_{\{s\}} = (N_{\{s\}})^{\{0\}}$ .*

<!-- label: III.XV.5.1 -->

**Proof.** The group prescheme  $H$  is locally of finite presentation over  $S$  ( $H$  is smooth over  $S$ ) and has connected fibers, hence is of finite presentation over  $S$  (Exp. VI\_B 5.3.3). Assertion a) is then a consequence of Exp. XI 6.11. The equivalence of the conditions appearing in b) is included here for the record and was proved in VI\_B 6.5.1.

This being so, we can state the main theorem of this section:

<!-- original page 410 -->

**Theorem 5.2.** *Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation over  $S$ ,  $\mathcal{L}_{\{G\}}$  (or simply  $\mathcal{L}$  if there is no ambiguity) the  $S$ -functor such that for every  $S$ -prescheme  $S'$  one has:*

- >  *$\mathcal{L}_{\{G\}}(S') =$  set of subgroup preschemes of  $G_{\{S'\}}$ , smooth over  $S'$ , with connected fibers, which are*
- > *identical to their connected normalizer.*

*Then the functor  $\mathcal{L}$  is representable by an  $S$ -prescheme, a union of an increasing family  $(U_i)_{i \in \mathbb{N}}$  of open subpreschemes, quasi-projective and of finite presentation over  $S$ , hence a fortiori separated over  $S$ .*

<!-- label: III.XV.5.2 -->

**\*\*Initial reductions.\*\***

For every integer  $r \geqslant 0$ , let  $\mathcal{L}^r$  be the subfunctor of  $\mathcal{L}$  such that for every  $S$ -prescheme  $S'$  one has:

>  $\mathcal{L}^r(S') =$  set of subgroup preschemes of  $G_{S'}$ , smooth, with connected fibers, identical to their  
> connected normalizer and of relative dimension  $r$ .

Since the dimension of the fibers of a smooth group is a locally constant function, the canonical monomorphism  $\mathcal{L}^r \rightarrow \mathcal{L}$  is representable by an immersion both open and closed. It therefore suffices to show that for every  $r$ ,  $\mathcal{L}^r$  is representable by an  $S$ -prescheme having the properties stated above, since  $\mathcal{L}$  will then be representable by the  $S$ -prescheme sum  $\coprod_{r \in \mathbb{N}} \mathcal{L}^r$ .

<!-- original page 411 -->

For every integer  $n \geqslant 0$ , every  $S$ -prescheme  $S'$  and every subgroup prescheme  $H$  of  $G_{S'}$ , we denote by  $H^{(n)}$  the  $n$ -th normal invariant of the unit section  $S' \rightarrow H$  of  $H$  (EGA IV 16.1.2), so that  $H^{(n)}$  is a sheaf of  $\mathcal{O}_{S'}$ -modules of finite type corresponding to the  $n$ -th infinitesimal neighborhood of the unit section of  $H$ . If  $H$  is smooth over  $S$  of relative dimension  $r$ ,  $H^{(n)}$  is a locally free  $\mathcal{O}_{S'}[0]$ -module whose rank  $\phi(n, r)$  depends only on  $n$  and  $r$ . Moreover, since  $H$  is a subprescheme of  $G_{S'}$ , one has a canonical epimorphism, compatible with base extension:

```
```text
G^{(n)} \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'} = G_{S'}^{(n)} \rightarrow H^{(n)}.
```

Introduce then the projective S -scheme

```
```text
P_{\phi(n, r)} = \text{Grass}_{\phi(n, r)}(G^{(n)})
```

(EGA I 2nd ed. 9.7; cf. also Séminaire Cartan 1960/61, Exp. N° 14 by A. Grothendieck). It then follows from the preceding remarks that the map

```
$$
H \mapsto H^{(n)}
$$
```

defines a canonical morphism

```
```text
u_{n, r} : \mathbb{A}^r \rightarrow P_{\phi(n, r)}.
```

The group G acts in a natural way on $G^{(n)}$, hence on $P_{\phi(n, r)}$, by means of the representation

```
```text
\text{int} : G \rightarrow \text{Aut}_{S\text{-gr}}(G), \quad g \mapsto \text{int}(g).
```

Moreover, if  $S'$  is a quasi-compact  $S$ -prescheme and  $H$  an element of  $\mathcal{L}^r(S')$ , one knows

<!-- original page 412 -->

(Exp. XI 6.11) that for  $n$  large enough,

```
$$
N = \text{Norm}_{G_{S'}}(H) = \text{Norm}_{G_{S'}}(H^{(n)}).
$$
```

For each integer  $n \geqslant 0$ , introduce the subfunctor  $\mathcal{L}^r_n$  of  $\mathcal{L}^r$  such that for

every  $\mathbb{A}^1$ -prescheme  $S$  one has:

>  $\mathcal{L}^r(S) = \text{set of subgroups } H \text{ of } G_S \text{ belonging to } \mathcal{L}^r(S) \text{ such that}$   
>  $\text{Norm}_{G_S}(H) = \text{Norm}_{G_S}(H^{\{n\}}).$

**Representability of  $\mathcal{L}^r$ .**

Since the integer  $r$  is fixed until the end of the proof of 5.2, we shall not repeat it in the notation. Thus we shall write  $\mathcal{L}$ ,  $\mathcal{L}_n$ ,  $\mathcal{P}_n$ ,  $\mathcal{U}_n$  instead of  $\mathcal{L}^r$ ,  $\mathcal{L}_n^r$ ,  $\mathcal{P}_n^r$ ,  $\mathcal{U}_n^r$ ,  $\mathcal{P}_{\phi(n, r)}$ ,  $\mathcal{U}_{(n, r)}$ .

Let  $v_n$  be the restriction of  $\mathcal{U}_n$  to the subfunctor  $\mathcal{L}_n$  of  $\mathcal{L}$ . It follows from the definition of  $\mathcal{L}_n$  and from 5.1 b) ii) that  $v_n$  is a monomorphism. In fact one has the following lemma:

**Lemma 5.3.** *The morphism  $v_n$  is an immersion of finite presentation. A fortiori,  $\mathcal{L}_n$  is representable by an  $\mathbb{A}^1$ -prescheme, quasi-projective and of finite presentation over  $\mathbb{A}^1$ .*

<!-- label: III.XV.5.3 -->

Possibly replacing  $\mathbb{A}^1$  by  $\mathcal{P}_n$ , we are reduced by the usual technique to proving the following assertion: Let  $Q \in \mathcal{P}_n(S)$  and consider the subfunctor  $F$  of the functor  $h_S$  represented by the final object  $S$  of  $\text{Sch}/S$ , such that for every  $\mathbb{A}^1$ -prescheme  $S$  one has:

<!-- original page 413 -->

-  $F(S) = h_S(S)$  (set with one element) if there exists  $H \in \mathcal{L}_n(S)$  such that  $H^{\{n\}} = Q_S$ ,  
-  $F(S) = \emptyset$  otherwise.\*

Then the canonical monomorphism  $F \rightarrow S$  is an immersion of finite presentation.

Let us first transform the definition of the functor  $F$ . For this, note that the normalizer of  $Q$  in  $G$  is representable by a subgroup prescheme  $N$  of finite presentation over  $\mathbb{A}^1$  (namely the inverse image of the point  $Q$  of  $\mathcal{P}_n(S)$  under the morphism  $G \rightarrow \mathcal{P}_n$ ,  $g \mapsto g \cdot Q$ ). I claim that the functor  $F$  coincides with the following subfunctor of  $h_S$ :

>  $F(S) = h_S(S)$  if:  
>  
> - (a)  $N_S$  is smooth along the unit section and of relative dimension  $r$ ,  
> - (b)  $N_S^{\{n\}}$  (which is then canonically an element of  $\mathcal{P}_n(S)$ ) is equal to  $Q_S$ .  
>  
>  $F(S) = \emptyset$  otherwise.\*

Indeed, denote temporarily by  $F_1$  the functor  $F$  in the first formulation, and  $F_2$  the functor  $F$  in the second formulation. Then:

i)  $F_1(S) = h_S(S) \rightarrow F_2(S) = h_S(S)$ .

<!-- original page 414 -->

Indeed, let  $H \in \mathcal{L}_n(S)$  be the subgroup of  $G_S$  such that  $H^{\{n\}} = Q_S$ . Then

```text  
Norm_{G_S}(H) = Norm_{G_S}(H^{\{n\}}) = Norm_{G_S}(Q_S) = N_S.
```

So by 5.1 b) ii),  $N_S$  is smooth along the unit section and its connected component is  $H$ . Consequently  $N_S$  is of relative dimension  $r$ ; and since  $H$  is open in  $N_S$  (by 5.1 b) i)), one has  $N_S^{\{n\}} = H^{\{n\}} = Q_S$ . In short,  $F_2(S) = h_S(S)$ .

ii)  $F_2(S) = h_S(S) \rightarrow F_1(S) = h_S(S)$ .

By hypothesis,  $N_S$  is smooth along the unit section, of relative dimension  $r$ ; its connected component is then representable (Exp. VI\_B 3.10) by a subgroup prescheme  $H$ , smooth over  $\mathbb{A}^1$ , with connected fibers of dimension  $r$ . Since  $H$  is invariant in  $N_S$  and open in  $N_S$ , one has the following inclusions:

```

```text

$$N_{S'} \subset \text{Norm}_{G_{S'}}(H) \subset \text{Norm}_{G_{S'}}(H^{\wedge(n)}) = \text{Norm}_{G_{S'}}((N_{S'})^{\wedge(n)}) = \text{Norm}_{G_{S'}}(Q_{S'}) = N_{S'}.$$

```

These inclusions are therefore equalities. The first inclusion then shows that H is equal to its connected normalizer, and the second shows that H is an element of $\mathcal{L}_n(S')$. This says that $F_1(S') = h_{S'}(S')$.

Implications i) and ii) entail $F_1 = F_2$. We keep the second definition of the functor F , and we shall first "represent condition a)" by an immersion of finite presentation. For this it suffices to apply the:

Lemma 5.4. *Let S be a prescheme, X an S -prescheme locally of finite presentation over S , $\sigma : S \rightarrow X$ a section of X , r an integer ≥ 0 , and $L : (\text{Sch}/S)^{\circ} \rightarrow (\text{Ens})$ the subfunctor of S defined as follows:*

```

<!-- original page 415 -->

```

```

-  $L(S') = h_{S'}(S')$  if  $X_{S'}$  is smooth along the section  $\sigma_{S'}$  and of relative dimension  $r$  at the points of  $\sigma_{S'}(S')$ .
-  $L(S') = \emptyset$  otherwise.

```

Then:

```

- *a) The monomorphism  $L \rightarrow S$  is an immersion of finite presentation.
- *b) Let  $\mathcal{J}$  be the conormal sheaf relative to the immersion  $S \rightarrow X$  (EGA IV 16.1.2); assume that for every point  $s$  of  $S$ ,  $\mathcal{J} \otimes_{\mathcal{O}_{S,s}} \kappa(s)$  is of rank at most  $r$ . Then the immersion  $L \rightarrow S$  is a closed immersion.

```

```

<!-- label: III.XV.5.4 -->

```

Proof. The functor L is of local nature on S , which reduces us to the case where S is affine. Possibly replacing X by a neighborhood of $\sigma(S)$, we may assume X of finite presentation over S , then (EGA IV 8.9) S noetherian (noting, in case b), that the formation of the conormal sheaf commutes with base extension (EGA IV 16.6.4) and that the rank of the fibers of $\mathcal{J}$ is a constructible function on S). This being so, for every S -prescheme S' , denote $\mathcal{J}_0 = \mathcal{J}_{S'}$ the conormal sheaf relative to the section $\sigma_{S'}$, $\mathcal{J}_0^\vee$ (canonically isomorphic to $\mathcal{J}_0$) the symmetric algebra of $\mathcal{J}_0$ over $\mathcal{O}_{S'}$, $\mathcal{G}_0^\vee$ the sheaf of graded $\mathcal{O}_{S'}$ -algebras associated to $\mathcal{J}_0^\vee$ (EGA IV 16), and for every integer $n \geq 0$ let $\sigma_n : S_n \rightarrow \mathcal{G}_0^\vee$ be the canonical epimorphism.

It follows from EGA IV 17.12.3 and from EGA IV 19.5.4 that, for $X_{S'}$ to be smooth along the section $\sigma_{S'}$ and of relative dimension r at the points of $\sigma_{S'}(S')$,

```

<!-- original page 416 -->

```

it is necessary and sufficient that:

```

- i)  $\mathcal{J}_0$  be a locally free  $\mathcal{O}_{S'}$ -sheaf of rank  $r$ .
- ii) For every integer  $n \geq 1$ ,  $\sigma_n$  be an isomorphism.

```

Now it follows from TDTE IV, Lemma 3.6, that "the functor that makes $\mathcal{J}$ locally free of rank r " is representable by a subscheme S_1 , closed in S in case b). Replacing S by S_1 , we are reduced to the case where $\mathcal{J}$ is locally free of rank r . Let us then proceed by induction on the integer n . Suppose that we have represented by a closed subscheme S_{n-1} of S the "functor that makes the morphisms $\sigma_{q,S'}$ injective for every integer $q \leq n-1$ ", and let us show that the "subfunctor [N.D.E.-XV-5] that makes $\sigma_{n,S'}$ injective" is representable by a closed subscheme S_n of S_{n-1} . Replacing S by S_{n-1} , we may assume that $\sigma_{q,S'}$ is bijective for $q \leq n-1$. But then the $(n-1)$ -st normal invariant $X^{(n-1)}$ relative to the section σ_S admits a composition series $X^{(0)}, \dots, X^{(n-1)}$ whose successive quotients $\mathcal{G}_0(\sigma_S), \dots, \mathcal{G}_{n-1}(\sigma_S)$ are locally free over $\mathcal{O}_{S'}$, hence flat; so $X^{(n-1)}$ is flat over $\mathcal{O}_{S'}$. Since the formation of $X^{(i)}$ commutes with base extension (EGA IV 16), one has, for every S -prescheme S' :

```

```text

$$\text{Gr}_n(\sigma_{S'}) = \text{Ker}(X_{S'}^{\wedge(n)} \rightarrow X_{S'}^{\wedge(n-1)}) = (\text{Gr}_n(\sigma))_{S'} \quad \text{and} \quad \sigma_{n,S'} = (\sigma_n)_{S'}.$$

```

So the functor that interests us is "the one that makes the morphism  $\sigma_n, S$  injective".

<!-- original page 417 -->

This functor is of local nature on  $S$ , which allows us to assume  $S$  affine and  $S_n(\mathcal{J})$  free over  $\mathcal{O}_S$ . But then it is clear that the functor in question is representable by the closed subscheme of  $S$  defined by the ideal generated by the coordinates of  $\text{Ker } \sigma_n, S$  with respect to a basis of  $S_n(\mathcal{J})$ .

Since  $S$  is noetherian, the decreasing sequence  $\{S_n\}$  of closed subschemes of  $S_1$  is stationary, and the stationary value represents the functor  $L$ , which completes the proof of 5.4.

Let us return to the question of representability of  $\mathcal{L}_n$ . Replacing  $S$  by a suitable subscheme  $S_1$ , we may therefore assume  $N$  smooth along the unit section and of relative dimension  $r$ . The functor  $\mathcal{L}_n$  is then the "functor of coincidences" of two sections of  $P_n$  above  $S$ ,  $h$  and  $g$ , corresponding to the sheaves  $\mathcal{O}_S$  and  $N^{(n)}$  (condition b) appearing in the definition of the functor  $F_2$  above). It is therefore representable by the closed subscheme of  $S$ , inverse image of the diagonal of  $P_n \times_S P_n$  by the morphism of finite presentation  $h \times_S g$ . This completes the proof of 5.3.

**\*\*Study of the transition morphisms  $\mathcal{L}_n \rightarrow \mathcal{L}_m$ .**

If a subgroup  $H$  of  $G_{S'}$  belongs to  $\mathcal{L}_n(S')$ , it belongs *a fortiori* to  $\mathcal{L}_m(S')$  for every  $m \geq n$ , whence natural monomorphisms

```text  
 $u^m_n : \mathcal{L}_n \rightarrow \mathcal{L}_m$ for $m \geq n$.
```

**\*\*Lemma 5.5.\*\*** \*The morphism  $u^m_n$  is an open immersion.\*

<!-- label: III.XV.5.5 -->

Possibly changing  $S$ , we are reduced to the following problem: Let  $H \in \mathcal{L}_m(S)$ ,

```text  
 $N = \text{Norm}_G(H) = \text{Norm}_G(H^{(m)})$, $N' = \text{Norm}_G(H^{(n)})$,
```

and let  $D : (\text{Sch}/S)^{\text{circ}} \rightarrow (\text{Ens})$  be the functor of coincidences of  $N$  and  $N'$ , defined by  $D(S') = h_{S'}(S')$  if  $N_{S'} = N'_{S'}$ , and  $D(S') = \emptyset$  otherwise. We must show that  $D \rightarrow S$

<!-- original page 418 -->

is an open immersion. Now I claim that  $D$  is also the subfunctor of  $S$  which "makes the immersion  $H \rightarrow N$  open". Indeed, if  $N_{S'} = N'_{S'}$ , then  $H_{S'} \rightarrow N'_{S'}$  is indeed an open immersion since this is so for  $H_{S'} \rightarrow N_{S'}$  (Prop. 5.1). Conversely, if  $H_{S'} \rightarrow N'_{S'}$  is an open immersion,  $H$  having connected fibers,  $H_{S'}$  is the connected component of  $N'_{S'}$  (Exp. VI\_B 3.10) and consequently is invariant in  $N'_{S'}$ , so  $N'_{S'} \subset N_{S'}$ . Since in any case  $N$  majorizes  $N'$ , one has  $N_{S'} = N'_{S'}$ . The group preschemes  $H$  and  $N$  are of finite presentation over  $S$  and  $H$  is flat over  $S$ ; the fact that  $D \rightarrow S$  is an open immersion then follows from Exp. VI\_B 2.6.

**\*\*End of the proof of 5.2.\*\***

The functors  $\mathcal{L}_n$  being representable and the transition morphisms  $u^m_n$  being compatible with one another and representable by open immersions, there exists a  $S$ -prescheme  $X$ , union of an increasing sequence of open subsets  $X_i$ ,  $i \in \mathbb{N}$ , such that  $X_i$  represents the functor  $\mathcal{L}_i$ , and such that if one identifies  $\mathcal{L}_i$  with  $X_i$ , the inclusion  $X_i \rightarrow X_j$  ( $j \geq i$ ) is identified with  $u^j_i$ . To conclude that  $X$  represents the functor  $\mathcal{L}$ , it then suffices to remark that in the category of sheaves on  $\text{Sch}/S$  equipped with the Zariski topology (Exp. IV 6.1) one has

<!-- original page 419 -->

```text  
 $X = \lim_{\rightarrow} X_i$ and $\mathcal{L} = \lim_{\rightarrow} \mathcal{L}_i$.
```

**\*\*Remark 5.6.\*\*** With the preceding notation, suppose in addition that  $S$  has all residue characteristics zero. Then, for every integer  $r \geqslant 0$ , the functor  $\mathcal{L}^{\{r\}}$  is equal to  $\mathcal{L}^{\{r\}}_1$ , hence is representable by an  $S$ -prescheme of finite presentation and quasi-projective over  $S$ . Indeed, it suffices to show that if  $H \in \mathcal{L}^{\{r\}}(S')$ , the canonical immersion

$$H \longrightarrow N = \text{Norm}_G(S')(H^{(1)})$$

is an open immersion (since this entails  $N = \text{Norm}_G(S')(H)$ , hence  $H \in \mathcal{L}^{\{r\}}_1(S')$ ). Since  $H$  is flat over  $S$ , and  $H$  and  $N$  are of finite presentation over  $S$ , it suffices (Exp. VI\_B 2.6) to show that for every point  $s$  of  $S$ ,  $H_s \rightarrow N_s$  is an open immersion. Now it follows easily [N.D.E-XV-6] from Cartier's theorem (Exp. VI\_B 1.6) that if  $G$  is an algebraic group over a field of characteristic 0 and  $H$  is a connected algebraic subgroup, one has

$$\text{Norm}_G(H) = \text{Norm}_G(\text{Lie } H) = \text{Norm}_G(H^{(1)}).$$

On the other hand, if  $S$  has non-zero residue characteristics, the subfunctors  $\mathcal{L}^{\{r\}}_n$  of  $\mathcal{L}^{\{r\}}$  may form a strictly increasing sequence (even when  $S$  is quasi-compact) and in this case  $\mathcal{L}^{\{r\}}$  is not representable by an  $S$ -prescheme quasi-compact over  $S$ . Take for example the algebraic group  $G$ , defined over a field  $k$  of characteristic  $p > 0$ , equal to the semidirect product of the torus  $T = G_m \times G_m$  by the unipotent group  $U = G_a \times G_a$ , the action of  $T$  on  $U$  being defined by  $(t, t', u, u') \mapsto (tu, t'u')$ . For every integer  $n > 0$ , consider the smooth connected subgroup  $U_n$  of  $U$  of equation  $u' = u^{p^n}$ , and the sub-torus  $T_n$  of  $T$  of equation  $t' = t^{p^n}$ . It is immediate to verify that  $T_n$  acts on  $U_n$  and that the subgroup  $G_n$  of  $G$ , equal to  $T_n \cdot U_n$ , is smooth, connected and equal to its normalizer in  $G$ . Now all the groups  $G_n$ , for  $n \geqslant m$ , are distinct but have the same infinitesimal neighborhood of order  $p^m$ .

<!-- label: III.XV.5.6 -->

**\*\*Remark 5.7.\*\*** There exists on  $\mathcal{L}$  a canonical invertible sheaf  $\mathcal{L}$ ,

<!-- original page 420 -->

whose restriction to every open subset  $U$  of  $\mathcal{L}$  quasi-compact over  $S$  is  $\mathcal{L}$ -ample. Indeed, consider the subgroup prescheme  $H$  of  $G_{\mathcal{L}}$  smooth over  $\mathcal{L}$ , with connected fibers, equal to its connected normalizer and universal for these properties. I claim that one may take for  $\mathcal{L}$  the sheaf  $(\det(\text{Lie } H))^{-1}$  (recall that if  $\mathcal{F}$  is a sheaf of  $\mathcal{O}_S$ -modules on a prescheme  $S$  that is locally free of finite rank,  $\det(\mathcal{F})$  denotes the invertible  $\mathcal{O}_S$ -module whose restriction to the open-closed subscheme  $S_r$  of  $S$  ( $r \geqslant 0$ ) where  $\mathcal{F}$  is of rank  $r$  is equal to  $\bigwedge^r(\mathcal{F})$ ). We keep the notation from the proof of 5.2. To prove the assertion made on  $\mathcal{L}$ , we may restrict to the functor  $\mathcal{L}^{\{r\}}_n$  and prove that  $\mathcal{L}|_{\mathcal{L}^{\{r\}}_n}$  is  $\mathcal{L}$ -ample. Consider the canonical immersion  $v_n : \mathcal{L}^{\{r\}}_n \rightarrow P_n$ , and let  $\mathcal{Q}$  be the locally free sheaf on  $P_n$  universal for the Grassmannian  $P_n$ . By construction, one has  $v_n^*(\mathcal{Q}) = H^{(n)}$  (where now  $H$  denotes the subgroup prescheme of  $G_{\mathcal{L}^{\{r\}}_n}$  universal for the functor  $\mathcal{L}^{\{r\}}_n$ ). Now  $\det(\mathcal{Q})$  is the canonical ample sheaf on  $P_n$  (EGA I 2nd ed. 9.7), so  $\det H^{(n)}$  is ample relative to  $\mathcal{L}^{\{r\}}_n$  (EGA II 4.6.13 i) bis). Let  $\mathcal{J}$  still denote the conormal sheaf, equal to  $H^{(1)}$ , and  $S^q(\mathcal{J})$  the homogeneous part of degree  $q$  of the symmetric algebra of  $\mathcal{J}$  over  $\mathcal{O}_{\mathcal{L}^{\{r\}}_n}$ . Since  $H$  is smooth over  $\mathcal{L}^{\{r\}}_n$ , it is immediate that one has a canonical isomorphism:

$$\det H^{(n)} \simeq \bigwedge_{1 \leq q \leq n} \det S^q(\mathcal{J}).$$

On the other hand, one proves that for every locally free sheaf  $\mathcal{J}$  of rank  $r$  and for every integer  $q > 0$ , there exists a canonical isomorphism:

<!-- original page 421 -->

$$\det S^q(\mathcal{J}) = (\det \mathcal{J})^{\otimes s},$$

where  $s > 0$  is an integer depending only on  $r$  and  $q$ . Finally, one obtains  $\det H^{\{n\}} \simeq (\det \mathcal{H})^{\otimes s}$  for a suitable integer  $s > 0$ , hence (EGA II 4.5.6),  $\det \square = (\det \text{Lie } H)^{-1}$  is indeed  $S$ -ample.

<!-- label: III.XV.5.7 -->

**Remark 5.8.** Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -preschemes in groups of finite presentation over  $S$ ,  $\iota : H \rightarrow G$  an  $S$ -homomorphism of groups which is a monomorphism. If  $H$  is smooth over  $S$  with connected fibers, one knows (Exp. XI 6.11) that  $N = \text{Norm}_G(H)$  is representable by a closed subgroup prescheme of  $G$ , of finite presentation over  $S$ . Suppose in addition that  $N$  is smooth along the unit section and has the same relative dimension over  $S$  as  $H$ . The connected component  $N^{\{0\}}$  of  $N$  is then representable by an open subgroup prescheme of  $N$ , smooth over  $S$  (Exp. VI\_B 3.10). The monomorphism  $\iota$  evidently factors through  $N^{\{0\}}$ . In fact one has  $H = N^{\{0\}}$ . Indeed, for every point  $s$  of  $S$ , one has  $H_s = (N^{\{0\}})_s$ , these two algebraic groups being connected, smooth, of the same dimension. Since  $H$  is flat over  $S$ , one deduces that  $H \rightarrow N^{\{0\}}$  is an isomorphism (EGA IV 17.9.5). Finally  $H$  is a subgroup prescheme of  $G$ . We have therefore shown that the functor  $\mathcal{H}$  introduced in this section is identical to the functor of subgroups  $H$  of  $G$ , smooth over  $S$ , with connected fibers and equal to their connected normalizer.

<!-- label: III.XV.5.8 -->

**6. Functor of Cartan subgroups and functor of parabolic subgroups**

<!-- label: III.XV.6 -->

<!-- original page 422 -->

When  $G$  is a smooth, connected algebraic group defined over an algebraically closed field  $k$ , one has defined the sub-tori of  $G$ , the maximal sub-tori, the Cartan subgroups (Exp. XII 1), the Borel subgroups (Exp. XIV 4.1), the parabolic subgroups (Exp. XIV 4.8 bis). We extend these notions to the case of a group prescheme over an arbitrary base, as follows:

**Definition 6.1.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation over  $S$ ,  $H$  an  $S$ -prescheme in groups,  $\iota : H \rightarrow G$  an  $S$ -monomorphism making  $H$  a subgroup of  $G$ . We say that  $H$  is a sub-torus of  $G$  (resp. a maximal sub-torus of  $G$ , a Cartan subgroup, a Borel subgroup, a parabolic subgroup) if:

- \*i)  $H$  is smooth over  $S$ .
- \*ii) For every geometric point  $s$  above  $S$ ,  $H_s$  is a sub-torus of  $(G_s)^{\{0\}_{\text{red}}}$  (resp. a maximal sub-torus, a Cartan subgroup, a Borel subgroup, a parabolic subgroup).

<!-- label: III.XV.6.1 -->

**Remarks 6.1 bis.**

a) If the  $S$ -group  $H$  is a sub-torus of  $G$  (resp. ...), its fibers are connected, and consequently  $H$  is of finite presentation over  $S$  (Exp. VI\_B 5.3.3).

<!-- original page 423 -->

b) If  $H$  is a sub-torus of  $G$ , then  $H$  is a torus in the sense of Exp. IX, as follows immediately from Exp. X 8.1. Moreover the monomorphism  $\iota : H \rightarrow G$  is an immersion (cf. 8.3 below).

c) If  $G$  is smooth over  $S$  with connected fibers and if  $H$  is a Cartan subgroup of  $G$  (resp. a Borel subgroup, a parabolic subgroup), the monomorphism  $\iota : H \rightarrow G$  is an immersion, so that our definitions coincide with those introduced in Exp. XII and Exp. XIV. Indeed,  $H$  is then identical to its connected normalizer (by XII 6.6 c), XIV 4.8 and 4.8 bis), and it suffices to apply 5.8.

<!-- label: III.XV.6.1bis -->

**Definition 6.1 ter.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups locally of finite type,  $s$  a point of  $S$ . The **nilpotent rank** of  $G$  at the point  $s$ , denoted  $\rho_n(s)$ , is the dimension of the Cartan subgroups of  $(G_s)^{\{0\}_{\text{red}}}$ . One similarly defines the **reductive rank**  $\rho_r(s)$ , the **unipotent rank**  $\rho_u(s)$ , the **abelian rank**  $\rho_{\text{ab}}(s)$  (cf. Exp. X 8.7).

<!-- label: III.XV.6.1ter -->

If now  $G$  is a smooth connected algebraic group defined over an algebraically closed field  $k$ , recall that the **radical** of  $G$ , denoted  $\text{rad}(G)$ , is the largest invariant, smooth, connected, solvable algebraic subgroup of  $G$ ;  $G/\text{rad}(G)$  is then semisimple (use Exp. XII 6.1 to reduce to the affine case). If  $G$  is moreover affine, one defines the **unipotent radical**  $\text{rad}_{\{u\}}(G)$  of  $G$  as the largest invariant, smooth, connected, unipotent algebraic subgroup of  $G$ ;  $G/\text{rad}_{\{u\}}(G)$  is then reductive.

<!-- original page 424 -->

**Proposition 6.2.** \*Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -preschemes in groups of finite presentation over  $S$ ,  $i : H \rightarrow G$  an  $S$ -monomorphism making  $H$  a subgroup of  $G$ , and let  $P(s)$  be one of the following properties concerning the point  $s$  of  $S$ :

- \*i)  $G_{\{s\}}^{\{0\}}$  is an abelian variety (resp. is affine, is a torus, is unipotent).\*
- \*ii)  $H_{\{s\}}^{\{0\}}$  is a maximal torus of  $G_{\{s\}}$ .\*
- \*iii)  $H_{\{s\}}^{\{0\}}$  is the centralizer in  $G_{\{s\}}^{\{0\}}$  of a torus of  $G_{\{s\}}$  (resp. is a Cartan subgroup of  $G_{\{s\}}$ ).\*
- \*iv)  $H_{\{s\}}^{\{0\}}$  is a Borel subgroup (resp. a parabolic subgroup) of  $G_{\{s\}}$ .\*
- \*v)  $H_{\{s\}}^{\{0\}}$  is the radical of  $G_{\{s\}}$  (resp.  $G_{\{s\}}^{\{0\}}$  is semisimple).\*
- \*vi)  $G_{\{s\}}$  is affine and  $H_{\{s\}}^{\{0\}}$  is the unipotent radical of  $G_{\{s\}}$  (resp.  $G_{\{s\}}^{\{0\}}$  is reductive).\*

\*Then the set  $E$  of points  $s$  of  $S$  for which  $P(s)$  is true is locally constructible (EGA 0\_III 9.1.11).\*

<!-- label: III.XV.6.2 -->

**Remark 6.2.1.** This proposition complements Exp. VI\_B § 10. Moreover, one can further specify the structure of  $E$  by using semi-continuity theorems (cf. Exp. X 8.7); we shall see an example a little later.

<!-- label: III.XV.6.2.1 -->

**Proof of 6.2.** <!-- original page 425 --> Note that if  $S$  is the spectrum of a field,  $E$  is invariant under extension of that field. A standard reduction (EGA IV 9) then allows us to reduce to the case where  $S$  is noetherian, integral, with generic point  $\eta$ . One must show that  $E$  or  $\text{ens}(S) \setminus E$  contains a neighborhood of  $\eta$  (EGA IV 9.2.1). One may assume  $S$  affine of ring  $A$  and field of fractions  $K$ . If  $L$  is a finite extension of  $K$ , it is immediate that there exists an  $A$ -subalgebra  $B$  of  $L$ , finite over  $A$ , having  $L$  as field of fractions. The canonical morphism  $S' \rightarrow S$ , where  $S' = \text{Spec } B$ , is dominant, of finite presentation, so the image of a non-empty open subset of  $S'$  contains a non-empty open subset of  $S$  (EGA IV 1.8.4). From the viewpoint that interests us, we may therefore replace  $S$  by  $S'$ , hence replace  $K$  by a finite extension  $L$ . Thus we may choose  $L$  so that  $G_{\{L\}}^{\{0\}}$  and  $H_{\{L\}}^{\{0\}}$  are smooth over  $L$  (EGA IV 4.6.6). Possibly restricting  $S'$ , we may assume that  $G_{\{red\}}$  and  $H_{\{red\}}$  are group preschemes smooth over  $S$  (Exp. VI\_B § 10 and EGA IV 17). In view of the properties to be proved, we may replace  $G$  and  $H$  by their reduced connected components (Exp. VI\_B 10.9), hence assume  $G$  and  $H$  smooth over  $S$  with connected fibers. Finally we may assume  $H$  is a closed subgroup prescheme of  $G$  (Exp. VI\_B 10.4).

**Proof of i).** \* Possibly after a finite extension of  $K$ , we may assume that  $G_{\{\eta\}}$  admits a "Chevalley decomposition", i.e. is an extension of an abelian variety  $D_{\{\eta\}}$  by a smooth connected linear algebraic group  $F_{\{\eta\}}$  (Séminaire Bourbaki 1956/57 N° 145). By Exp. VI\_B 10.16, there exists an open neighborhood  $U$  of  $\eta$

<!-- original page 426 -->

such that this generic extension comes from an extension  $l \rightarrow F \rightarrow G|_U \rightarrow D \rightarrow l$ . One may further assume  $F$  and  $D$  smooth over  $U$  with connected fibers,  $F$  affine over  $U$  and  $D$  proper over  $U$  (EGA IV 8, 9 and 17). For every point  $s$  of  $U$ ,  $(D_{\{s\}}, F_{\{s\}})$  is then the "Chevalley decomposition" of  $G_{\{s\}}$ . Consequently,  $G_{\{s\}}$  is an abelian variety (resp. is affine) if and only if  $F_{\{s\}}$  (resp.  $D_{\{s\}}$ ) is the unit group, which is a constructible property (EGA IV 9.2.6.1).

To establish the last two assertions of i), we may, by the preceding, assume  $G$  affine over  $S$ . Let  $q$  be a prime number invertible on  $S$  and  $\{q\}$  the "kernel" of the  $q$ -th power morphism in  $G$ . It follows easily from the structure of affine algebraic groups that  $G_{\{s\}}$  is a torus (resp. is unipotent) if and only if a)  $\text{`}_q G_s$  is quasi-finite, which is a constructible property (EGA IV 9.3.2), and b)  $\text{`}_q G_s$  has  $r^q$  geometric points, where  $r$  denotes the relative dimension of  $G$  over  $S$  (resp.  $\text{`}_q G_s$  has a single point). Now the function  $s \mapsto (\text{number of geometric points of } \text{`}_q G_s)$  is constructible (EGA IV 9.7.9). This completes the proof of (i).

**Proof of iii).** \* a) **Case of a centralizer of a torus.** \* Suppose  $H_{\{\eta\}} = \text{Centr}_{\{G_{\{\eta\}}\}}(T_{\{\eta\}})$ , where

$T_{\eta}$  is a torus of  $G_{\eta}$ , and let us show that  $H_s$  is the centralizer of a sub-torus of  $G_s$  for  $s$  in a neighborhood of  $\eta$ . By i), possibly restricting  $S$ ,

<!-- original page 427 -->

we may assume that  $T_{\eta}$  comes from a sub-torus  $T$  of  $G$ . But then  $Z = \text{Centr}_G(T)$  is representable (Exp. XI 6.11) by a subgroup prescheme of  $G$ . Since  $H$  and  $Z$  coincide generically, they coincide over a neighborhood of  $\eta$ . This proves to us that the set  $E$  of points  $s$  of  $S$  such that  $H_s$  is the centralizer in  $G_s$  of a sub-torus of  $G_s$  is ind-constructible (EGA IV 1), and this result will suffice for us to establish, in Lemma 6.6 below, that  $E$  is an open part of  $S$ ; *a fortiori*,  $E$  will indeed be a locally constructible part of  $S$ .

iii) b) **Case of a Cartan subgroup.** Suppose  $H_{\eta}$  is a Cartan subgroup of  $G_{\eta}$ , and let us show that  $H_s$  is a Cartan subgroup of  $G_s$  for every point  $s$  of a neighborhood of  $\eta$ . The group  $H_{\eta}$  is the centralizer in  $G_{\eta}$  of a torus of  $G_{\eta}$  and is nilpotent (Exp. XII 6.6). By a) and Exp. VI\_B 8.4,  $H_s$  has the same properties for every point  $s$  of a neighborhood  $U$  of  $\eta$ . For every point  $s$  of  $U$ , the group  $H_s$  thus has the same reductive rank as  $G_s$ , and its unique maximal torus is central (Exp. XII 6.7); it is therefore the centralizer of a maximal torus of  $G_s$ , i.e. a Cartan group of  $G_s$ .

Suppose now that  $H$  is not a Cartan subgroup of  $G$ , and let us show that  $H_s$  is not a Cartan subgroup of  $G_s$  for  $s$  in a neighborhood  $U$  of  $\eta$ . In view of the assertion provisionally admitted in (a) above, we may restrict to the case where  $H$  is the centralizer in  $G$  of a sub-torus  $T$ . But then  $H_{\eta}$  contains a Cartan subgroup  $C_{\eta}$  of  $H_{\eta}$ . We have just seen that, possibly restricting  $S$ ,  $C_{\eta}$  extends to a Cartan subgroup  $C_s$  of  $G_s$ , which one may assume contained in  $H_s$ . By hypothesis  $H_{\eta}$  strictly majorizes  $C_{\eta}$ , so  $H_s$  strictly majorizes  $C_s$  for  $s$  in a neighborhood  $U$  of  $\eta$  (EGA IV 9.5.2); *a fortiori*,  $H_s$  is not

<!-- original page 428 -->

a Cartan subgroup of  $G_s$  for  $s$  in  $U$ .

**Proof of ii).** Suppose  $H_{\eta}$  is a maximal torus of  $G_{\eta}$  and let  $C_{\eta}$  be its centralizer in  $G_{\eta}$ . By i) and iii),  $H$  is a torus over a neighborhood  $U$  of  $\eta$  and  $C = \text{Centr}_G(H)$  is a Cartan subgroup of  $G|U$ . To prove that  $H$  is a maximal torus of  $G$  over a neighborhood of  $\eta$ , we may then replace  $G$  by  $C$ , then by the linear component  $F$  of a Chevalley decomposition of  $C$  (cf. i)). Let  $q$  be an integer invertible on  $S$ ,  $\{_{qF}$  the kernel of the  $q$ -th power morphism in  $F$ . Since  $F_s$  is affine, nilpotent, smooth and connected,  $F_s$  is the direct product of its maximal torus  $T_s$  by a unipotent group (*Bible* 6-04), so  $qF_s = qT_s$ . Since  $H_{\eta}$  is a maximal torus,  $qH_{\eta} = qF_{\eta}$ , and consequently  $\{_{qH} = \{_{qF}$  over a neighborhood  $V$  of  $\eta$ . For every point  $s$  of  $V$ ,  $qH_s = qT_s$ , so  $H_s = T_s$  is a maximal torus.

Suppose now that  $H_{\eta}$  is not a maximal torus of  $G_{\eta}$ . By i), we may restrict to the case where  $H_{\eta}$  is a torus, then assume that it is contained in a strictly larger torus  $T_{\eta}$ . The latter extends to a torus  $T$  strictly majorizing  $H$  over a neighborhood  $U$  of  $\eta$ . *A fortiori*,  $H_s$  is not a maximal torus for  $s$  in  $U$ .

**Proof of iv).** Possibly restricting  $S$ , we may assume that the center  $Z$  of  $G$  is representable (Exp. VI\_B 10.11) and flat over  $S$ , as well as the quotient  $G/Z$  (*loc. cit.*). The property " $H_s$  majorizes  $Z_s$ " is constructible (EGA IV 9.5.2) and every parabolic subgroup of  $G_s$  contains  $Z_s$  (Exp. XIV 4.9 a)); this allows us to replace  $G$  by  $G/Z$ , hence assume  $G$  affine over  $S$  (Exp. XII 6.1 and i)). We may further

<!-- original page 429 -->

assume that  $G/H$  is representable, but then  $H_s$  is a parabolic subgroup of  $G_s$  if and only if  $(G/H)_s$  is proper (*Bible* 6 Th. 4 b)), which is an ind-constructible property (EGA IV 9.3.5). So  $E$  is ind-constructible, and this will suffice for us to prove that  $E$  is open (Lemma 6.6), hence locally constructible.

Let us now examine the case of Borel subgroups. If  $H_{\eta}$  is a Borel subgroup of  $G_{\eta}$ , i.e. a solvable parabolic subgroup of  $G_{\eta}$ , what precedes and Exp. VI\_B 8.4 entail that these properties remain true at every point  $s$  of a neighborhood of  $\eta$ . If now  $H_{\eta}$  is not a Borel subgroup of  $G_{\eta}$ , to prove that the same holds at points  $s$  of a neighborhood of  $\eta$ , we may restrict (in view of what precedes) to the case where  $H_{\eta}$  is a parabolic subgroup, then assume that  $H_{\eta}$  contains a Borel subgroup  $B_{\eta}$ . We have just shown that the latter extends to a Borel subgroup  $B_s$  of  $G_s$  over a neighborhood  $U$  of  $\eta$ . Since  $H_{\eta}$  strictly majorizes  $B_{\eta}$ ,  $H_s$  strictly majorizes  $B_s$  at every point of an open subset  $V$ , and  $H_s$  is not a Borel subgroup of  $G_s$  for  $s$  in  $V$ .

**Proof of v).** Suppose  $H_{\eta}$  is the radical of  $G_{\eta}$ . The group  $H_{\eta}$  is then invariant in  $G_{\eta}$ , solvable (smooth and connected); the same is therefore true for  $H_s$  for  $s$  belonging to a neighborhood  $U$  of  $\eta$  (Exp. VI\_B 8 and 10), so for  $s$  in  $U$ ,  $H_s$  is contained in the radical of  $G_s$ . Replacing  $G$  by  $G/H$

(Exp. VI\_B 10), we must

<!-- original page 430 -->

prove that if  $G_{\{\eta\}}$  is semisimple, then  $G_{\{s\}}$  is semisimple at every point of a neighborhood  $V_{\{s\}}$  of  $\eta_{\{s\}}$ . Using i) and ii), one may assume that  $G_{\{s\}}$  is affine over  $S_{\{s\}}$  and possesses a maximal torus  $T_{\{s\}}$ . Let  $W_{\{s\}}$  be the Weyl group of  $T_{\{s\}}$  (Exp. XII 2), which is quasi-finite and étale over  $S_{\{s\}}$ , hence finite and étale over an open subset  $V_{\{s\}}$ . It then follows from the elementary properties of roots (Exp. XIX 1.12) that  $G_{\{s\}}$  is semisimple over  $V_{\{s\}}$ .

Suppose now that  $H_{\{\eta\}}$  is not the radical of  $G_{\{\eta\}}$ . Possibly replacing  $K_{\{s\}}$  by a finite extension  $L_{\{s\}}$ , we may assume that  $G_{\{\eta\}}$  admits a radical  $R_{\{\eta\}}$ . By what precedes,  $R_{\{\eta\}}$  extends to a subgroup prescheme  $R_{\{s\}}$  of  $G_{\{s\}}$  such that for every  $s \in U$ ,  $R_{\{s\}}$  is the radical of  $G_{\{s\}}$ . By hypothesis,  $R_{\{\eta\}} \neq H_{\{\eta\}}$ . So  $R_{\{s\}} \neq H_{\{s\}}$  for  $s \in V$ . It remains to prove that if  $G_{\{\eta\}}$  is not semisimple, neither is  $G_{\{s\}}$  at neighboring points, but this is a particular case of what precedes (take  $H_{\{s\}} =$  unit group).

\*Proof of vi).\* The proof is entirely analogous to that of v), in view of i), and is left to the care of the reader.

**\*\*Corollary 6.3.\*\*** \*Let  $S_{\{0\}}$  be a quasi-compact prescheme,  $(S_{\{i\}})_{i \in L}$  a projective system of  $S_{\{0\}}$ -preschemes, affine over  $S_{\{0\}}$ ,  $S = \varprojlim S_{\{i\}}$  (EGA IV 8.2),  $G_{\{0\}}$  a group prescheme of finite presentation over  $S_{\{0\}}$ ,  $G_{\{i\}} = G_{\{0\}} \times_{S_{\{0\}}} S_{\{i\}}$ ,  $G = G_{\{0\}} \times_{S_{\{0\}}} S$ ,  $H_{\{0\}}$  a subgroup of  $G_{\{0\}}$ . Then, if  $H_{\{0\}}$  is a sub-torus of  $G_{\{0\}}$  (resp. a maximal sub-torus, a Cartan subgroup, a Borel subgroup, a parabolic subgroup), there exists an index  $i_1 \in L$  and a subgroup  $H_{i_1}$  of  $G_{i_1}$  such that  $H = H_{i_1} \times_{S_{i_1}} S$  and  $H_{i_1}$  is a sub-torus of  $G_{i_1}$  (resp. ...).\*

<!-- label: III.XV.6.3 -->

<!-- original page 431 -->

Indeed,  $H_{\{0\}}$  is smooth with connected fibers, hence of finite presentation over  $S_{\{0\}}$  (Exp. VI\_B 5.3.3). By Exp. VI\_B § 10, there exist  $i_1 \in L$  and a subgroup  $H_{i_1}$  of  $G_{i_1}$ , smooth over  $S_{i_1}$ , such that  $H = H_{i_1} \times_{S_{i_1}} S$ . Corollary 6.3 then follows from Definition 6.1, from 6.2, and from EGA IV 9.3.3.

**\*\*Corollary 6.3 bis.\*\*** \*Let  $S_{\{0\}}$  be a prescheme,  $G_{\{0\}}$  an  $S_{\{0\}}$ -prescheme in groups of finite presentation over  $S_{\{0\}}$ . Then the functions  $\rho_n$ ,  $\rho_r$ ,  $\rho_u$ ,  $\rho_{ab}$  (cf. 6.1 ter) are locally constructible functions on  $S_{\{0\}}$ .\*

<!-- label: III.XV.6.3bis -->

It suffices to show (EGA IV 9.) that if  $S_{\{0\}}$  is a noetherian integral scheme with generic point  $\eta_{\{0\}}$ , the functions in question are constant on a neighborhood of  $\eta_{\{0\}}$ . Possibly replacing  $S_{\{0\}}$  by a scheme  $S'_{\{0\}}$  finite over  $S_{\{0\}}$  and dominating  $S_{\{0\}}$ , we may assume that  $G_{\{\eta_{\{0\}}\}}$  admits a Cartan subgroup  $C_{\{\eta_{\{0\}}\}}$  with a Chevalley decomposition  $1 \rightarrow L_{\{\eta_{\{0\}}\}} \rightarrow C_{\{\eta_{\{0\}}\}} \rightarrow A_{\{\eta_{\{0\}}\}} \rightarrow 1$ . The argument made in 6.2 i) proves that this decomposition extends to a Chevalley decomposition over a neighborhood of  $\eta_{\{0\}}$ :

$$\begin{aligned} &S_{\{0\}} \\ &1 \rightarrow L_{\{\eta_{\{0\}}\}} \rightarrow C_{\{\eta_{\{0\}}\}} \rightarrow A_{\{\eta_{\{0\}}\}} \rightarrow 1. \\ &S_{\{0\}} \end{aligned}$$

Moreover, one may assume that  $C_{\{0\}}$  is a Cartan subgroup of  $G_{\{0\}}$  (6.3) and that the maximal torus  $T_{\{\eta_{\{0\}}\}}$  of  $L_{\{\eta_{\{0\}}\}}$  extends to a maximal torus  $T_{\{0\}}$  of  $L_{\{0\}}$  (6.3). The corollary follows immediately from this and from the definitions.

**\*\*6.4.0.\*\*** Let then  $S_{\{0\}}$  be a prescheme,  $G_{\{0\}}$  an  $S_{\{0\}}$ -prescheme in groups of finite presentation over  $S_{\{0\}}$ ,  $\mathcal{L}_{\{0\}}$  the functor of subgroups of  $G_{\{0\}}$ , smooth, with connected fibers and equal to their connected normalizer (cf. § 5);  $\mathcal{L}_{\{0\}}$  is representable (5.2 and 5.8). The remainder of this

<!-- original page 432 -->

section is devoted to the study of certain subfunctors of  $\mathcal{L}_{\{0\}}$ . More precisely, we introduce the subfunctors of  $\mathcal{L}_{\{0\}}$ , denoted  $\mathcal{L}_{\{0\}}^{\{C\}}$  (resp.  $\mathcal{L}_{\{0\}}^{\{CT\}}$ , resp.  $\mathcal{L}_{\{0\}}^{\{P\}}$ ), defined as follows: for every  $S_{\{0\}}$ -prescheme  $S'_{\{0\}}$ ,  $\mathcal{L}_{\{0\}}^{\{C\}}(S'_{\{0\}})$  (resp.  $\mathcal{L}_{\{0\}}^{\{CT\}}(S'_{\{0\}})$ , resp.  $\mathcal{L}_{\{0\}}^{\{P\}}(S'_{\{0\}})$ ) is the set of subgroups  $H_{\{s\}}$  of  $G_{\{s\}}$ , smooth over  $S'_{\{0\}}$ , with connected fibers, equal to their connected normalizer, and such that for every point  $s'_{\{0\}}$  of  $S'_{\{0\}}$ ,  $H_{\{s'\}}$  contains a Cartan subgroup (6.1) of  $G_{\{s'\}}$  (resp. is the centralizer in  $(G_{\{s'\}})^{\wedge_{\{0\}}}$  of a sub-torus of  $G_{\{s'\}}$ , resp. is a parabolic subgroup (6.1) of  $G_{\{s'\}}$ ).

<!-- label: III.XV.6.4.0 -->

**\*\*Theorem 6.4.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation over  $S$ . Then the  $S$ -functors  $\mathcal{L}_C$ ,  $\mathcal{CT}$ ,  $\mathcal{P}$  above (6.4.0) are representable by  $S$ -preschemes of finite presentation over  $S$ , quasi-projective over  $S$ .\*

<!-- label: III.XV.6.4 -->

**\*\*Remark 6.5.\*\*** If  $G$  has smooth fibers, for example if  $G$  is smooth over  $S$ , or if the residue characteristics of  $S$  are zero (Exp. VI\_B 1.6.1), every subgroup  $H$  of  $G$ , smooth over  $S$  with connected fibers, such that for every point  $s$  of  $S$ ,  $H_s$  contains a Cartan subgroup of  $G_s$ , is necessarily equal to its connected normalizer (and consequently is an element of  $\mathcal{L}_C(S)$ ). Indeed, using 5.1 iii), one may assume that  $S$  is the spectrum of a field, in which case the property was noted at the end of the statement of Exp. XIII 2.1.

<!-- label: III.XV.6.5 -->

Note that one has natural monomorphisms

```

```text
□ □  ↘
      □_C  →  □.
□ □  ↗
```

```

<!-- original page 433 -->

Let us show that these monomorphisms are open immersions of finite presentation (which will already prove, in view of 5.2, that  $\mathcal{L}_C$ ,  $\mathcal{CT}$ ,  $\mathcal{P}$  are representable by  $S$ -preschemes, union of an increasing sequence of open subpreschemes, quasi-projective and of finite presentation over  $S$ ). Now this will follow, by the usual technique, from the following lemma:

**\*\*Lemma 6.6.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation,  $H$  a subgroup of  $G$ , smooth with connected fibers. Then the set of points  $s$  of  $S$  such that  $H_s$  contains a Cartan subgroup of  $G_s$  (resp. is equal to the centralizer in  $G_s$  of a torus of  $G_s$ ) is an open subset of  $S$ . If moreover  $H$  is equal to its connected normalizer, the set of points  $s$  of  $S$  such that  $H_s$  is a parabolic subgroup of  $G_s$  is also an open subset of  $S$ .\*

<!-- label: III.XV.6.6 -->

The assertion to be proved is local on  $S$ , which allows us to assume  $S$  affine, then, by EGA IV 8.1 and 6.3,  $S$  noetherian. Denote by  $E$  the set of points of  $S$  having the property in question. It then follows from the assertions effectively proved in 6.2 that  $E$  is ind-constructible. But  $S$  is noetherian, so to prove that  $E$  is open, it suffices to show that  $E$  is stable under generizations (EGA IV 1.10.1). Using EGA II 7.1.9, we are finally led to prove that if  $S$  is the spectrum of a discrete valuation ring, and if the closed point  $s$  belongs to  $E$ , then so does the generic point  $t$ .

<!-- original page 434 -->

We shall need the following lemma:

**\*\*Lemma 6.7.\*\*** \*Let  $A$  be a complete noetherian local ring,  $S = \operatorname{Spec} A$ ,  $s$  the closed point of  $S$ ,  $H$  an  $S$ -prescheme in groups, smooth with connected fibers,  $T_s$  a sub-torus of  $H_s$ . Then:\*

- \*i) There exists a closed subgroup prescheme  $C$  of  $H$ , smooth, with connected fibers, such that  $C_s = \operatorname{Centr}_{H_s}(T_s)$ .\*
- \*ii) For every point  $t$  of  $S$ ,  $C_t$  is the centralizer in  $H_t$  of a sub-torus  $T_t$  of  $H_t$ .\*

<!-- label: III.XV.6.7 -->

**\*Proof of 6.7.\*** Let  $T^0$  be an  $S$ -torus such that there exists an isomorphism  $u_0 : T^0_s \xrightarrow{\sim} T_s$  (Exp. X 4.6). Let  $\mathfrak{m}$  be the maximal ideal of  $A$ ,  $A_n = A/\mathfrak{m}^n$ ,  $S_n = \operatorname{Spec} A_n$ ,  $H_n = H \times_S S_n$ , etc. Since  $H$  is smooth over  $S$ , for every integer  $n > 0$  there exists an  $S_n$ -group morphism  $u_n : T^0_n \rightarrow H_n$  lifting  $u_0$  (Exp. IX 3.6), and one may assume by induction on  $n$  that  $u_n$  lifts  $u_{n-1}$ . Moreover, let  $q$  be a prime number invertible on  $S$ ; for every integer  $\ell$  equal to a power of  $q$ , denote by  $\{u_n\}_\ell$  the restriction of  $u_n$  to the subgroup  $\{u_n\}_\ell T^0_n$ . For fixed  $\ell$  and variable  $n$ , the morphisms  $\{u_n\}_\ell$  form a projective system, hence come from a unique  $S$ -group morphism  $u_\ell : \{u_n\}_\ell T^0 \rightarrow H$  (1.6 a)).

Since  $H$  is separated (Exp. VI\_B 5.2) and  $u_0$  is a monomorphism,  $u$  is a monomorphism (Exp. IX 6.8), and even a closed immersion since it is finite,  $T^0$  being finite over  $S$ . Denote by  $M(\ell)$  the image group. It is clear that the family of subgroups of multiplicative type  $M(\ell)$  is coherent in the sense of 4.1. Let  $C_\ell = \text{Centr}_H(M(\ell))$ , which is representable by a subgroup prescheme (2.5), closed ( $H$  is separated),

<!-- original page 435 -->

smooth over  $S$  (Exp. XI 2.4). The  $C_\ell$  form a filtered decreasing family of closed subschemes, hence stationary,  $H$  being noetherian. The stationary value is a smooth closed subgroup  $C$  such that  $C_s = \text{Centr}_H(T_s)$  by the density theorem (Exp. IX 4.7). It remains to show that for every point  $s$  of  $S$ ,  $C_s$  is the centralizer in  $H_s$  of a sub-torus  $T_s$  (which will entail that  $C_s$  is connected). But this will follow from the more precise lemma below, applied to the family  $M(\ell)_s$  of subgroups of  $H_s$ :

**Lemma 6.8.** \*Let  $G$  be a connected algebraic group defined over a field  $k$ ,  $r$  an integer  $> 0$ ,  $q$  an integer prime to the characteristic  $[N.D.E-XV-7]$  of  $k$ ,  $M(\ell)$  ( $\ell$  ranging over the powers of  $q$ ) a coherent family of subgroups of  $G$ , of multiplicative type and of type  $(\mathbb{Z}/\ell\mathbb{Z})^r$  (cf. 4.6),  $M$  the algebraic subgroup of  $G$  generated by the  $M(\ell)$  (\*loc. cit.\*),  $T$  the unique maximal torus of  $M$  (cf. 3.4). Then\*

```
``text
Centr_G(T) = Centr_G(M) = Centr_G(M(\square)) for \square large enough.
```
```

<!-- label: III.XV.6.8 -->

The last equality is clear. To prove the first, introduce the center Z of G , $G' = G/Z$, M' (resp. T') the image of M (resp. T) in G' , K the inverse image of T' in G (i.e. the algebraic subgroup of G generated by T and Z). It evidently suffices to prove that $K \supseteq M$, hence that $T' = M'$. Now, M is smooth and connected (4.6) and G' is affine (Exp. XII 6.1), so M' is a direct product of its maximal torus

<!-- original page 436 -->

T' (Exp. XII 6.6 d)) and a unipotent group (*Bible* 4 Th. 4) (one may assume k algebraically closed). The image of $M(\ell)$ in M' is therefore necessarily contained in T' . So the inverse image of T' in M majorizes $M(\ell)$ for every ℓ , hence equals M . Consequently $M' = T'$. This proves 6.8 and hence 6.7.

This being so, let us prove 6.6. We have reduced to the case where S is the spectrum of a discrete valuation ring A , which one may further assume complete with algebraically closed residue field. Possibly replacing A by its normalization in a finite extension of its field of fractions, one may assume that $(G_t)_{\text{red}}$ is smooth [N.D.E-XV-8]. It is clear that to prove 6.6 one may replace G by the connected component of the schematic closure in G of $(G_t)^0_{\text{red}}$, hence assume G flat over S with connected fibers, and G_t smooth.

a) Suppose H_s is the centralizer in $(G_s)_{\text{red}}$ of a torus T_s , and let us show that H_t is then the centralizer in G_t of a sub-torus of G_t . By Lemma 6.7, there exists a subgroup scheme C_s of H_s , smooth over S , whose closed fiber is H_s and such that $C_t = \text{Centr}_H(T_t)$, where T_t is a sub-torus of H_t . Since H is smooth over S with connected fibers, one concludes for dimension reasons that $C = H$. Keeping the notation of 6.7, one has $H = C = C_\ell$ for ℓ large. Consider similarly $C'_\ell = \text{Centr}_G(M(\ell))$ (2.5), and let C' be the stationary value of C'_ℓ for ℓ large (2.5 bis). The group scheme C' majorizes H and is such that $C'_t = \text{Centr}_G(T_t)$ (6.8) and $C'_s = \text{Centr}_G(T_s)$. The hypothesis made on H_s implies $\dim H_s = \dim C'_s$. Moreover, $\dim H_s = \dim H_t$ (since H is smooth over S) and $\dim C'_t \leq \dim C'_s$ (Exp. VI_B 4.1),

<!-- original page 437 -->

so $\dim H_t = \dim C'_t$. But G_t being smooth and connected, $C'_t = \text{Centr}_G(T_t)$ is smooth and connected, so finally $H_t = C'_t = \text{Centr}_G(T_t)$.

b) Suppose H_s contains a Cartan subgroup C_s of G_s , i.e. the centralizer in $(G_s)_{\text{red}}$ of a maximal torus T_s of G_s . By 6.7, there exists a subgroup scheme C_s of H_s , smooth over S , with connected fibers, lifting C_s . It evidently suffices to prove that C_t contains a Cartan subgroup of G_t . Now by a) applied with $H = C$, C_t is the centralizer in G_t of a sub-torus of G_t , hence contains a Cartan subgroup of G_t .

c) Suppose H_s is a parabolic subgroup of G_s . Let $N = \text{Norm}_G(H)$. By hypothesis, H is equal to its connected normalizer, so N_s is smooth, and consequently equals $\text{Norm}_G((G_s)_{\text{red}}(H_s)) = H_s$ (Exp. XII 8 bis). But then N is flat over S . We shall see in Exp. XVI that, under these conditions, G/N is representable.

Since $H_{\{s\}} = N_{\{s\}}$ is a parabolic subgroup of G , $(G/N)_{\{s\}}$ is proper. Since (G/N) has connected fibers and is flat over S , it follows from EGA III 5.5.1 that (G/N) is proper over S . So $(G/N)_t = G_t/N_t$ is proper over t , and the same is true of G_t/H_t , since N_t/H_t is finite. It then suffices to apply the following lemma:

Lemma 6.9. Let k be a field, G a k -algebraic group, H a smooth connected algebraic subgroup of G ,

original page 438 -->

$N = \text{Norm}_G H$; then if $\dim H = \dim N$ and if G/H is proper, H is a parabolic subgroup of G .

label: III.XV.6.9 -->

Indeed, one may assume k algebraically closed and G smooth and connected. The center Z of G is contained in N , and the hypothesis $\dim H = \dim N$ entails that $Z^{\{0\}} = (Z^{\{0\}})^{\text{red}}$ is contained in H , so $G' = G/Z^{\{0\}}$ is affine (Exp. XII 6.1). Replacing G by G' and H by its image in G' , one is reduced to the case where G is affine (Exp. XIV 4.9), and Lemma 6.9 then follows from *Bible* 6 Th. 4. We have therefore proved Lemma 6.6.

To complete the proof of 6.4, we must prove that the S -preschemes representing $\mathcal{L}_{\{C\}}$ (resp. $\mathcal{L}_{\{CT\}}$, resp. $\mathcal{L}_{\{P\}}$) are of finite presentation over S . This assertion is local on S , which allows us to assume S affine, then, G being of finite presentation, S noetherian (EGA IV 8.9). We have just seen that the natural inclusions $\mathcal{L}_{\{CT\}} \rightarrow \mathcal{L}_{\{L\}}$ (resp. $\mathcal{L}_{\{P\}} \rightarrow \mathcal{L}_{\{L\}}$) are immersions, so the same is true of the inclusions $\mathcal{L}_{\{CT\}} \rightarrow \mathcal{L}_{\{C\}}$ (resp. $\mathcal{L}_{\{P\}} \rightarrow \mathcal{L}_{\{C\}}$), and consequently it suffices to prove that $\mathcal{L}_{\{C\}}$ is representable by an S -prescheme of finite presentation.

Let us resume the notation introduced in 5.2. For every integer $n \geq 0$, let $\mathcal{L}_{\{n\}}$ be the subfunctor of $\mathcal{L}$ such that

text
 $\mathcal{L}_n(S') = \{H \in \mathcal{L}(S') \text{ such that } \text{Norm}_G(S')(H) = \text{Norm}_G(S')(H^{\{n\}})\}.$

The S -functor $\mathcal{L}_{\{n\}}$ is therefore representable by an open subprescheme of $\mathcal{L}$, sum of the $\mathcal{L}^{\{r\}}_{\{n\}}$. Each $\mathcal{L}^{\{r\}}_{\{n\}}$ is of finite presentation over S (5.3) and is empty for $r > \sup_{s \in S} \dim G_{\{s\}}$ (which is a finite number, S being quasi-compact), so $\mathcal{L}_{\{n\}}$ is

original page 439 -->

of finite presentation over S . It suffices to prove that $\mathcal{L}_{\{C\}}$ is contained in $\mathcal{L}_{\{n\}}$ for n large enough.

For every point s of S , let $d(s)$ be the smallest integer n (finite or infinite) such that $\mathcal{L}_{\{C, G_{\{s\}}\}} \subset \mathcal{L}_{\{n, G_{\{s\}}\}}$. It suffices to show that the function d is bounded on S , since if M is an upper bound, $\mathcal{L}_{\{C\}}$ will be set-theoretically contained in $\mathcal{L}_{\{M\}}$, so $\mathcal{L}_{\{C\}}$ will be contained in $\mathcal{L}_{\{M\}}$, since the latter is an open subset of $\mathcal{L}$. An immediate constructibility argument reduces us to proving that if S is noetherian integral with generic point t , then d is bounded on a neighborhood of t .

a) **Reduction to the case where G is smooth over S .** Proceeding as in 6.2, one sees that, possibly changing S , one may assume that $(G)_{\text{red}}$ is a group prescheme smooth over S , which we shall denote G' . Set $X = \mathcal{L}_{\{C, G\}}$, $X' = \mathcal{L}_{\{C, G'\}}$ and let H (resp. H') be the subgroup prescheme of G_X (resp. $G_{X'}$) universal for the functor $\mathcal{L}_{\{C, G\}}$ (resp. $\mathcal{L}_{\{C, G'\}}$). Since H is smooth over X , $H \times_X X_{\text{red}}$ is reduced, hence contained in $G'_{X_{\text{red}}}$, and is an element of $\mathcal{L}_{\{C, G'\}}(X_{\text{red}})$, whence a canonical morphism $\rho : X_{\text{red}} \rightarrow X'$. It is clear that ρ is a monomorphism; let us show that ρ is even an immersion. Let N' be the normalizer of H' in $G_{X'}$. The set of points s of X' such that the immersion $H'_{\{s\}} \rightarrow N'_{\{s\}}$ is an open immersion is an open subset U , and $H'_{\{U\}} \rightarrow N'_{\{U\}}$ is an open immersion (Exp. VI_B 2.5 and EGA IV 17.9.5). It follows from 5.1 iii) that U is the largest open subset of X' above which H' is equal to its connected normalizer in $G_{X'}$, so $H'_{\{U\}} \subset N'_{\{U\}} \subset \mathcal{L}_{\{C, G'\}}(U)$. One immediately deduces that ρ is an isomorphism of X_{red} onto U_{red} . If one shows that $\mathcal{L}_{\{C, G\}}$ is of finite type when G is smooth, X' will be of finite type over S ,

original page 440 -->

so X_{red} will be of finite type (S is noetherian) and consequently will be contained in $\mathcal{L}^{\{M\}}_{\{G\}}$ for M large enough, and the same will hold of X .

b) **Case where S is the spectrum of an algebraically closed field k of characteristic $p > 0$ and G is a smooth algebraic group over k .** Instead of using the infinitesimal neighborhoods $H^{(n)}$ of a subgroup prescheme H of G , we shall use the radical subgroups $F_n(H)$, kernels of the iterates of the Frobenius morphism in H (Exp. VII A 4), which is legitimate here, since $F_n(H)$ is contained in the infinitesimal neighborhood of order p^n of the unit section of H . If T is a sub-torus of G , $F_n(T) = \{_{p^n}(T)$, and it is immediate by duality that $\text{Centr}_G(\{_{p^n}(T))$ is equal to $\text{Centr}_G(T)$ for n large enough. One then has the following more precise proposition:

Proposition 6.10. *Let k be a field of characteristic $p > 0$, G a smooth k -algebraic group, T a maximal torus of $G_{\bar{k}}$, m the smallest integer such that*

$$\text{Centr}_G(\{_{p^m}(T))^{\{0\}} = \text{Centr}_G(T)^{\{0\}}.$$

Then, for every k -prescheme S and every $H \in \mathcal{L}_C(S)$, one has*

$$\text{Norm}_{G_S}(H) = \text{Norm}_{G_S}(F_m(H)).$$

A fortiori, $\mathcal{L}_C$ is contained in $\mathcal{L}^{p^m}$.

<!-- label: III.XV.6.10 -->

Since H is smooth over S , of finite presentation over S and has a constant nilpotent rank (namely that of G), we shall see in the following section (7.3) that the functor $\mathcal{L}_H$

<!-- original page 441 -->

of Cartan subgroups of H is representable by an S -prescheme, smooth over S (the reader will verify that the proof given of this property does not use the fact that $\mathcal{L}_{C, H}$ is of finite type over S). It then follows from Exp. XIII 3.1 that one may consider the open subset U of regular points of H .

Let S' be an S -prescheme, g an element of $G(S')$ normalizing $F_m(H)_{S'}$. To prove that g normalizes $H_{S'}$, it suffices to prove that $\text{int}(g)U_{S'}$ is contained in $H_{S'}$; indeed, $H_{S'} \cap \text{int}(g)H_{S'}$ will then contain an open subgroup of $\text{int}(g)H$, hence will be equal to

<!-- original page 442 -->

$\text{int}(g)H$, since the latter has connected fibers. Possibly replacing S' by a suitable S'' , then S'' by S , we are reduced to proving that if $g \in G(S)$ normalizes $F_m(H)$ and if $u \in U(S)$, then $\text{int}(g)u \in H(S)$.

Now let C be the unique Cartan subgroup of H_S "containing" u (Exp. XIII 3.2). It suffices to show that $C = \text{int}(g)C \subset H$. Since $H \in \mathcal{L}_{C, G}(S)$, C is also a Cartan subgroup of G ; but the latter admits maximal tori, so (Exp. XII 7.1 (a)) C is the centralizer in $G^{\{0\}}_S$ of its unique maximal torus T . It follows from the definition of m (and from the fact that any two maximal tori of G are locally conjugate for fpqc (Exp. XII 7.1)) that

$$C = (\text{Centr}_G(T))^{\{0\}} = \text{Centr}_G(\{_{p^m}(T))^{\{0\}},$$

whence by conjugation by g :

$$C' = \text{Centr}_G(\text{int}(g)(\{_{p^m}(T)))^{\{0\}}.$$

But $\text{int}(g)(\{_{p^m}(T))$ is a subgroup of multiplicative type of $\text{int}(g)(F_m(H)) = F_m(H)$ (g normalizes $F_m(H)$), hence is contained in H . It then follows from Exp. XIII 2.1 (which is proved when the base is a field, but extends immediately to the case of an arbitrary base) that for C' to be contained in H it suffices that

```text

Lie  $C' \subset \text{Lie } H$ .

Now  $\text{Lie } C' = \text{int}(g)(\text{Lie } C) \subset \text{int}(g)(\text{Lie } H)$ .

On the other hand, if  $\mathfrak{m} \geqslant 1$ , which it is permissible to assume, one has (using Exp. VII\_A 4.1.2):

```
```text
Lie H = Lie(F_m(H)) = Lie(int(g)(F_m(H))) = int(g)(Lie H).
```
```

So  $\text{Lie } C' \subset \text{Lie } H$ , which completes the proof of 6.10.

We shall need another definition of the integer  $m$  introduced in 6.10.

**Lemma 6.11.** Let  $G$  be a smooth algebraic group defined over an algebraically closed field  $k$  of characteristic  $p > 0$ ,  $T$  a maximal torus of  $G$ ,  $\mathfrak{g} = \text{Lie } G$ , and  $R$  the family of non-zero characters of  $T$  appearing in the representation of  $T$  in  $\mathfrak{g}$  induced by the adjoint representation of  $G$ . For every element  $r \in R$ , denote by  $e_r$  the largest integer  $n$  such that  $p^n$  divides  $r$  in the group of characters of  $T$ . Then  $m = \sup_{r \in R} (e_r + 1)$  if  $R \neq \emptyset$ , and  $m = 0$  otherwise.

<!-- label: III.XV.6.11 -->

Indeed,  $\text{Centr}_G(T)$  is smooth and contained in  $\text{Centr}_G(\mathfrak{p}^m(T))$ , so

```
```text
(Centr_G T)^0 = (Centr_G(\mathfrak{p}^m(T)))^0 \Leftrightarrow \text{Lie}(\text{Centr}_G T) = \text{Lie}(\text{Centr}_G(F_m(T)))
\Leftrightarrow \mathfrak{p}^T = \mathfrak{p}^{\mathfrak{p}^m(T)} \quad (\text{Exp. II 5.2.3}).
```
```

<!-- original page 443 -->

Now with the usual notation,

```
```text
\mathfrak{p} = \mathfrak{p}_0 \oplus \bigoplus_{r \in R} \mathfrak{p}_r.
```
```

So  $\mathfrak{g}^T = \mathfrak{g}_0$  and  $\mathfrak{g}^{\mathfrak{p}^m(T)} = \mathfrak{g}_0 + \coprod_{r \in R_0} \mathfrak{g}_r$ , where  $R_0$  is the subset of  $R$  consisting of characters of  $T$  whose restriction to  $\mathfrak{p}^m(T)$  is zero. But a non-zero character  $r$  of  $T$  has trivial restriction to  $\mathfrak{p}^m(T)$  if and only if  $m \leq e_r$ , whence the lemma.

c) **Return to the proof of 6.4.** We have reduced (by point a) and the section preceding it) to the case where  $S$  is a noetherian integral scheme and  $G$  is smooth over  $S$ . We must show that the function  $d$  is bounded on a neighborhood of the generic point  $t$  of  $S$ . Possibly changing  $S$ , we may assume that  $G$  admits a trivial maximal torus (6.2)  $T = D_S(M)$ . Let then  $\mathfrak{g} = \coprod_{\lambda \in M} \mathfrak{g}_{\lambda}$  be the decomposition of the Lie algebra of  $G$  according to the characters of  $T$ , and let  $R$  be the finite set of non-zero characters of  $M$  such that  $\mathfrak{g}_{\lambda} \neq 0$ . Let us distinguish two cases:

**1st case:** the point  $t$ , and hence all points of  $S$ , have residue characteristic  $p > 0$ . It is clear, from what precedes, that the function  $d$  is then bounded by  $\mathfrak{p}^m$ , where  $m$  is defined as in 6.11.

**2nd case:** the point  $t$  has residue characteristic zero. For every  $\lambda \in R$ , let  $n_{\lambda}$  be the largest integer dividing  $\lambda$  in the group  $M$ , and set  $n = \prod n_{\lambda}$ ,  $\lambda \in R$ . For every prime number  $q$  dividing  $n$ , denote by  $S_q$  the closed subset of  $S$  consisting of points of  $S$  whose residue characteristic equals  $q$ , and let  $U$  be the non-empty open subset (it contains  $t$ ) complementary in  $S$  to the union of the  $S_q$ . If now  $s$  is a point of  $U$ , either  $s$

<!-- original page 444 -->

has residue characteristic zero, in which case  $d(s) = 1$  (5.6), or  $s$  has residue characteristic  $p > 0$  not dividing  $n$ , so the integer  $m$  relative to the group  $G_s$ , defined in 6.11, is at most one. Moreover, it follows from Exp. VII[N.D.E-XV-9] that

```

```text
Norm_{G_{S'}}(F_1(H)) = Norm_{G_{S'}}(Lie H) = Norm_{G_{S'}}(H^{\{1\}}).
```

```

Finally, it follows from 6.10 that if  $H \in \mathcal{L}_{\{C, G_s\}}(S')$ , one has  $\text{Norm}_{G_{S'}}(H) = \text{Norm}_{G_{S'}}(H^{\{1\}})$ , and consequently  $d(s) \leqslant 1$ , so  $d$  is bounded by  $1$  on  $U$ .

This completes the proof of 6.4.

**Corollary 6.12.** Let  $S$  be a prescheme and  $G$  an  $S$ -prescheme in groups of finite presentation. Suppose that the nilpotent rank (resp. the dimension of the Borel subgroups) of the fibers of  $G$  is a locally constant function on  $S$ . Then the functor  $\mathcal{C}$  of Cartan subgroups of  $G$  (resp. the functor  $\mathcal{B}$  of Borel subgroups of  $G$ ) is representable by an  $S$ -prescheme of finite presentation over  $S$ .

<!-- label: III.XV.6.12 -->

Indeed, possibly restricting  $S$ , we may assume that the nilpotent rank  $\nu$  of the fibers is constant. But then it is clear that  $\mathcal{C}$  is represented by the open-closed subscheme of the prescheme  $X$  representing  $\mathcal{L}_{\{C\}}$  (6.4) above which the universal subgroup of  $G_X$  relative to the functor  $\mathcal{L}_{\{C\}}$  is of relative dimension  $\nu$ . The proof is analogous for the functor  $\mathcal{B}$ , in view of the representability of the functor  $\mathcal{P}$ .

## 7. Cartan subgroups of a smooth group

<!-- label: III.XV.7 -->

<!-- original page 445 -->

**Proposition 7.1.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation, smooth over  $S$ , with connected fibers.

- \*i) Let  $\mathcal{CT}$  be the  $S$ -functor  $(\text{Sch}/S)^{\circ} \rightarrow \text{Ens}$  such that for every  $S$ -prescheme  $S'$ :  
 >  $\mathcal{CT}(S') = \text{set of subgroup preschemes } H \text{ of } G_{S'}, \text{ smooth over } S', \text{ such that for every point } s' \text{ of } S',$   
 >  $H_{s'}$  is the centralizer in  $G_{s'}$  of a sub-torus of  $G_{s'}$ .
- \*Then  $\mathcal{CT}$  is representable by an  $S$ -prescheme of finite presentation over  $S$ , smooth and quasi-projective over  $S$ .
- \*ii) If  $S$  is artinian and  $H \in \mathcal{CT}(S)$ , then  $H$  is the centralizer in  $G$  of a sub-torus of  $G$ . If  $S$  is the spectrum of a Henselian local ring and  $H \in \mathcal{CT}(S)$ , then  $H$  is the centralizer in  $G$  of a subgroup of multiplicative type of  $G$ , étale over  $S$ .
- \*iii) If  $L$  is an  $S$ -prescheme in groups, smooth and of finite presentation over  $S$ ,  $\iota : L \rightarrow G$  an  $S$ -group monomorphism, and  $H$  an element of  $\mathcal{CT}(S)$ , then  $\text{Transp}_G(H, L)$  and  $\text{Transp}^{\text{str}}_G(H, L)$  (cf. Exp. VIII 6.5 e)) are representable by closed subschemes of  $G$ , smooth over  $S$ .
- \*iv) If  $H \in \mathcal{CT}(S)$ ,  $H$  is closed in  $G$ ,  $N = \text{Norm}_G(H)$  is representable by a closed subgroup prescheme of  $G$ , smooth over  $S$ ;

<!-- original page 446 -->

$N/H$  is representable by an  $S$ -prescheme in groups, separated over  $S$ , étale and of finite type over  $S$ ;  $G/N$  is representable by an  $S$ -prescheme smooth and quasi-projective over  $S$ .

- \*v) Let  $G'$  be an  $S$ -prescheme in groups of finite presentation over  $S$  and  $u : G \rightarrow G'$  a faithfully flat  $S$ -group morphism, so that  $G'$  satisfies the same hypotheses as  $G$  (Exp. VI\_B 9). Then if  $H \in \mathcal{CT}_G(S)$ , the image of  $H$  by  $u$  is representable by a subgroup prescheme  $H'$  of  $G'$  which is an element of  $\mathcal{CT}_{G'}(S)$ . Moreover,  $H \rightarrow H'$  is faithfully flat, and if  $H$  is the centralizer in  $G$  of a torus  $T$ ,  $H'$  is the centralizer in  $G'$  of the torus  $T' = u(T)$ .
- \*vi) Under the conditions of v), consider the  $S$ -morphism\*

```

```text
ũ : □_G → □_{G'},    H ↦ H' = u(H).
```

```

- \*Then  $\tilde{u}$  is a quasi-compact faithfully flat morphism; if moreover  $\text{Ker } u$  is central,  $\tilde{u}$  is an isomorphism, the inverse isomorphism being  $H' \mapsto u^{-1}(H')$ .

<!-- label: III.XV.7.1 -->

\*Proof of ii).\* For the first assertion, we may assume  $S$  local artinian with closed point  $s$ . Let  $H \in \mathcal{CT}(S)$  and let  $T_s$  be the maximal central torus of  $H_s$ , which is already defined over  $\kappa(s)$  (cf. 3.4). Since  $H_s \in \mathcal{CT}(s)$ , one has  $H_s = \text{Centr}_{G_s}(T_s)$ . The group  $H$  is smooth, so  $T_s$  lifts uniquely to a sub-torus  $T$  of  $H$ , central

<!-- original page 447 -->

in  $H$  (Exp. IX 3.6 bis and Exp. IX 5.6). But then  $H' = \text{Centr}_G(T)$  majorizes  $H$  and has the same fiber as  $H$ ; since  $H$  is flat over  $S$ , one has  $H = H'$  (Exp. VI\_B 2.5).

Suppose now that  $S$  is the spectrum of a Henselian local ring, which one may assume noetherian by the usual reductions. Denote by  $s$  the closed point of  $S$ ,  $T_s$  the maximal central torus of  $H_s$ ,  $q$  an integer invertible on  $S$ ,  $\ell$  a power of  $q$ ,  $T$  an  $S$ -torus having a closed fiber isomorphic to  $T_s$  (Exp. X 4.6). Moreover, let  $\ell$  be the "kernel" of the  $\ell$ -th power morphism in  $H$ , and let  $U_\ell$  be the largest open subset of  $\ell$  étale over  $S$ . It then follows from 1.3 and from the fact that  $H$  is flat over  $S$  that  $U_\ell$  majorizes  $\ell T_s$ . Since  $S$  is Henselian, there exists a unique  $S$ -morphism

$$u_\ell : \ell T \rightarrow U_\ell$$

which, on the closed fiber, induces the canonical immersion  $\ell T_s \rightarrow (U_\ell)_s$ . By uniqueness, one easily sees that  $u_\ell$  is an  $S$ -group morphism, central (Exp. IX 5.6 a)). Proceeding then as in 6.6 and 6.7, one shows that  $u_\ell$  is an immersion, and that if  $M_\ell$  is the image group  $u_\ell(\ell T)$ , then  $\text{Centr}_G(M_\ell)$  is equal to  $H$  for  $\ell$  large enough (this is where the noetherian hypothesis on  $S$  is used).

\*Proof of i).\* The group  $G$  is smooth over  $S$  with connected fibers, so if  $H \in \mathcal{CT}(S)$ ,  $H$  has connected fibers (Exp. XII 6.6 b)) and is equal to its connected normalizer (6.5), so that the functor  $\mathcal{CT}$  defined in 7.1 i) coincides with the functor also denoted  $\mathcal{CT}$  defined in 6.4.0. So, by Theorem 6.4,  $\mathcal{CT}$  is representable by an  $S$ -prescheme of finite presentation and quasi-projective over  $S$ . It remains to show that this prescheme is smooth over  $S$ . One first reduces by EGA IV 8

<!-- original page 448 -->

to the case where  $S$  is affine noetherian. Thanks to Exp. XI 1.5, it then suffices to prove that if  $S$  is the spectrum of a local artinian ring,  $S_0$  a subscheme defined by a nilpotent ideal,  $H_0$  an element of  $\mathcal{CT}(S_0)$ , then  $H_0$  lifts to a subgroup prescheme  $H$  of  $G$ , smooth over  $S$ . Now by ii),  $H_0 = \text{Centr}_{G_0}(T_0)$ , where  $T_0$  is a sub-torus of  $G_0$ . Since  $G$  is smooth,  $T_0$  lifts to a sub-torus  $T$  of  $G$  (Exp. IX 3.6 bis), and it suffices to take  $H = \text{Centr}_G(T)$ , which is indeed smooth over  $S$  (Exp. XI 2.4 and Lemma 2.5).

\*Proof of iii).\* Since  $H$  is smooth with connected fibers, by Exp. XI 6.11,  $\text{Transp}_G(H, L)$  is representable by a closed subscheme of  $G$  of finite presentation over  $S$ . To show that this transporter is smooth, one reduces, as above, to proving that if  $S$  is local artinian,  $S_0$  a closed subscheme of  $S$ ,  $g_0 \in G(S_0)$  such that  $\text{int}(g_0)H_0 \subset L_0$ , then  $g_0$  lifts to  $g \in G(S)$  such that  $\text{int}(g)H \subset L$ . The group  $G$  being smooth over  $S$ , there exists a section  $g_1$  of  $G$  lifting  $g_0$ ; let  $H' = \text{int}(g_1)H$ . So this is an element of  $\mathcal{CT}(S)$  such that  $H'_0 \subset L_0$ . By ii),  $H'$  is the centralizer in  $G$  of a torus  $T'$  of  $G$ . Since  $L$  is smooth, the torus  $T'_0$  of  $L_0$  lifts to a torus  $T'$  of  $L$  (Exp. XI 3.6 bis). The group  $\text{Centr}_L(T')$  is contained in  $\text{Centr}_G(T')$ , has the same fiber as the latter (namely  $H'_0$ ) and is smooth, so equals  $\text{Centr}_G(T')$ . The sub-tori  $T'$  and  $T'_0$  of  $G$  are two liftings of  $T'_0$ , so are conjugate by an element  $h$  of  $G(S)$  reducing to the unit section of  $G_0$  (Exp. IX 3.3 bis); the same is therefore true of their centralizers  $H'$  and  $H'_0$  in  $G$ . The section  $g = h g_1$  lifts  $g_0$  and one has  $\text{int}(g)H \subset L$ .

<!-- original page 449 -->

If now  $g \in \text{Transp}_G(H, L)(S)$ , for  $\text{int}(g)H = L$  it is necessary and sufficient that for every  $s \in S$ ,  $\dim H_s = \dim L_s$ . It follows that if  $U$  denotes the open-closed subscheme of  $S$  above which the fibers of  $H$  have the same dimension as those of  $L$ , the strict transporter of  $H$  in  $L$ ,  $\text{Transp}^{\text{str}}_G(H, L)$ , is representable by the  $S$ -prescheme

$$U \times_S \text{Transp}_G(H, L).$$

\*Proof of iv).\* To see that if  $H \in \mathcal{CT}(S)$ ,  $H$  is closed in  $G$ , one may assume  $S$  affine noetherian, then  $S$  spectrum of a complete local ring (EGA IV 8); but then  $H$  is the centralizer in  $G$  of a subgroup of multiplicative type (by ii)), hence is closed since  $G$  is separated over  $S$  (Exp. VI\_B 5.2).

By iii),  $N = \text{Norm}_G(H) = \text{Transp}^{\text{str}}_G(H, H)$  is representable by a subgroup prescheme smooth over  $S$  and closed in  $G$ . Consider the  $S$ -morphism

```

```text
G → □□,    g ↦ int(g)H.
```

```

It follows from iii) that this morphism is smooth, so its image is an open subset  $U$  of  $\mathcal{CT}(S)$ . One then proves as in Exp. XI 5.3 that  $G/N$  is representable by  $U$ , hence in particular is quasi-projective.

Let us now study the quotient  $N/H$ . Thanks to EGA IV 8, to prove that  $N/H$  is representable, one may assume  $S$  affine noetherian, then  $S$  the spectrum of a local ring  $A$ , of finite (Krull[<sup>N.D.E-XV-10</sup>]) dimension.

<!-- original page 450 -->

We shall proceed by increasing induction on the dimension of  $S$ . If  $\dim S = 0$ , the property follows from Exp. VI\_A § 4. Note now that if  $N/H$  is representable, it is separated over  $S$  (since  $H$  is closed in  $N$  by iv)), of finite type and étale over  $S$  (since  $N$  is smooth over  $S$ , of finite type and  $H$  is open in  $N$ ), so  $N/H$  is necessarily quasi-affine over  $S$  (SGA 1 VIII.6.2). By effective descent of quasi-affine schemes (\*loc. cit.\* 7.9), one may replace  $A$  by its completion, hence assume  $S$  spectrum of a complete noetherian local ring. Let  $s$  be its closed point and  $U = S \setminus s$ . By induction hypothesis,  $(N|_U)/(H|_U)$  is representable by a  $U$ -group  $K$ . Let then  $T_s$  be the maximal central torus of  $H_s$ ,  $q$  an integer invertible on  $S$ ,  $\ell$  a power of  $q$ ,  $M_\ell$  the unique central subgroup of multiplicative type of  $H$  lifting  $\{\ell\}T_s$  (cf. ii)). Choose  $\ell$  large enough that  $\text{Centr}_G(M_\ell) = H$ , and let  $N' = \text{Norm}_G(M_\ell)$ . Since  $\text{Centr}_G(M_\ell) = H$ , one has  $N' \subset \text{Norm}_G(H)$ . Moreover, one immediately verifies that  $T_s$  (so also  $(M_\ell)_s$ ) is a characteristic subgroup of  $H_s$  (i.e. stable under  $\text{Aut}_{\text{gr}}(H_s)$ ), so  $N_s$  normalizes  $(M_\ell)_s$  and consequently  $N_s = N'_s$ . The proof of Exp. XI 5.9 then shows that the quotient  $N'/H = \text{Norm}_G(M_\ell)/\text{Centr}_G(M_\ell)$  is representable by an  $S$ -group  $K'$ . Since  $N'$  is smooth over  $S$  and  $N'_s = N_s$ ,  $N'$  is an open subgroup of  $N$  (Exp. VI\_B 2.5) containing  $H$ , so the image of  $N'|_U$  in  $K$  is an open subgroup, isomorphic to  $K'|_U$ . Let  $L$  be the  $S$ -prescheme obtained by gluing  $K$  and  $K'$  along the previous isomorphism, and let  $p$  be the  $S$ -morphism  $N \rightarrow L$  obtained by gluing the canonical projections  $N|_U \rightarrow K$  and  $N' \rightarrow K'$ .

<!-- original page 451 -->

It is clear that  $(L, p)$  represents the quotient  $N/H$ .

\*Proof of v).\* Suppose first that  $S$  is the spectrum of a field  $k$ . The image  $H'$  of  $H$  is then a smooth subgroup of  $G$ . We must show that  $H' \in \mathcal{CT}_G(S)$ , which will follow from the following more precise lemma:

**\*Lemma 7.2.\*** \*Let  $u : G \rightarrow G'$  be an epimorphism of smooth connected  $k$ -algebraic groups,  $T$  a torus of  $G$ ,  $T'$  its image in  $G'$ . Then\*

```

```text
u(Centr_G T) = Centr_{G'} T'.
```

```

<!-- label: III.XV.7.2 -->

Denote  $H = \text{Centr}_G T$ ,  $H' = \text{Centr}_{G'} T'$ ,  $H'' = u(H)$ . One has  $H'' \subset H'$ . To prove that  $H' = H''$ , one may assume the base field algebraically closed, and it suffices to prove that every Cartan subgroup of  $H'$  is contained in  $H''$ . Indeed,  $H''$  will then contain the open subset of regular points of  $H'$ , so  $H''$  will be an open subgroup of  $H'$  and consequently will be equal to  $H'$  since the latter has connected fibers. So let  $C$  be a Cartan subgroup of  $H'$ ;  $C$  is also a Cartan subgroup of  $G'$ , since  $H'$  is the centralizer of a torus  $T'$ , hence has the same reductive rank and the same nilpotent rank as  $G'$ . Set  $K = (u^{-1}(C))^{\{0\}}_{\text{red}}$ . Since  $T$  is in the center of  $H$ ,  $C$  contains  $T$ , so  $K$  contains  $T$ . Let then  $C$  be a Cartan subgroup of  $K$  containing  $T$ . The torus  $T$  is contained in the unique maximal torus of  $C$ , which is central in  $C$  (Exp. XII 6.6 c)), so  $C$  is contained in  $H = \text{Centr}_G T$ . Using now the fact that any two Cartan subgroups of  $G$  are conjugate and that the image of a Cartan subgroup of  $G$  is a Cartan subgroup of  $G'$  (Exp. XII 6.6), one

<!-- original page 452 -->

deduces that  $C$  is also a Cartan subgroup of  $G$ ; its image is therefore a Cartan subgroup of  $G'$ ; as it is contained in  $C'$ , one has  $u(C) = C'$ , so  $C$  is indeed contained in  $H'$ .

We have therefore established v) when  $S$  is the spectrum of a field  $k$ . Let us now study the general case. Since  $G$ ,  $H$  and  $G'$  are of finite presentation over  $S$ , to prove that  $u(H)$  is representable and is an element of  $\mathcal{CT}_G(S)$ , one reduces by the usual technique to the case where  $S$  is affine noetherian, then to the case where  $S$  is the spectrum of a local ring. By fpqc descent of subpreschemes of  $G'$ , one may even assume that  $S$  is the spectrum of a complete noetherian local ring  $A$ .

Let us resume the notation of ii), namely: let  $T$  be the maximal central torus of  $H$  ( $s$  is the closed point of  $S$ ),  $M_{\ell}$  a subgroup of multiplicative type of  $H$  lifting  $T_{\ell}$  such that  $H = \text{Centr}_G(M_{\ell})$ . Let  $T'$  be the image of  $T$  in  $G'$ . Since  $G'$  is separated over  $S$  (Exp. VI\_B 5.2), the image of  $M_{\ell}$  by  $u$  is a subgroup of multiplicative type  $M'_{\ell}$  of  $G'$  (Exp. IX 6.8). Set then  $H' = \text{Centr}_{G'}(M'_{\ell})$ , which is a smooth subgroup prescheme of  $G'$ . For every integer  $\ell$  equal to a power of  $q$ , there exists  $\ell$  such that  $(M'_{\ell})_{\ell}$  majorizes  $(T'_{\ell})_{\ell}$ , so we may assume  $\ell$  chosen large enough that  $H'_{\ell} = \text{Centr}_{G'}(T'_{\ell})$ ,  $T'_{\ell} = u_{\ell}(H_{\ell})$ , where the last equality follows from 7.2. The restriction of  $u$  to  $H$ , namely  $v$ , evidently factors through  $H'$ . Let us prove that  $v : H \rightarrow H'$  is a flat morphism. Since  $H$  and  $H'$  are flat over  $S$  and  $H_{\ell} \rightarrow H'_{\ell}$  is flat,  $v_{\ell}$  is flat on a neighborhood of  $H_{\ell}$  (EGA IV 11.3.10 and 11.3.1). The morphism  $v_{\ell}$  is therefore flat on an open subgroup of  $H$  (Exp. VI\_B 2.2), so  $v$  is flat,  $H$  having connected fibers.

<!-- original page 453 -->

The set-theoretic image of  $H$  is therefore an open subset of  $H'$  (necessarily equal to  $(H')^{\{0\}}$ ) which, equipped with its induced structure, represents the image sheaf  $u(H)$  (for the fpqc topology). The fact that  $u(H)$  is an element of  $\mathcal{CT}_G(S)$  then follows from 7.2.

Suppose now that  $H$  is the centralizer in  $G$  of a torus  $T$ , and let  $T'$  be the image of  $T$  by  $u$ , which is a sub-torus of  $G'$  (Exp. IX 6.8). The image of  $H$  by  $u$  is contained in  $\text{Centr}_{G'}(T')$ , coincides fiber by fiber with the latter (7.2), and is smooth over  $S$ , so  $u(H) = \text{Centr}_{G'}(T')$ .

\*Proof of vi).\* To show that  $\tilde{u}$  is a faithfully flat  $S$ -morphism, knowing that  $\mathcal{CT}_G$  and  $\mathcal{CT}_{G'}$  are smooth over  $S$  (by i)), it suffices to verify it on the geometric fibers. We are therefore reduced to the case where  $S$  is the spectrum of an algebraically closed field  $k$ . Let  $H' \in \mathcal{CT}_{G'}(k)$ ,  $T'$  its maximal central torus,  $T$  a sub-torus of  $G$  whose image is  $T'$ ,  $H = \text{Centr}_G(T)$ , so that  $H' = u(H)$  (7.2),  $N = \text{Norm}_G(H)$ ,  $N' = \text{Norm}_{G'}(H')$ . We have shown in iv) that  $G/N$  (resp.  $G'/N'$ ) canonically identifies with open neighborhoods of  $H$  in  $\mathcal{CT}_G$  (resp.  $\mathcal{CT}_{G'}$ ).

<!-- original page 454 -->

(resp. of  $H'$  in  $\mathcal{CT}_{G'}$ ). Under these identifications, the restriction of  $\tilde{u}$  to  $G/N$  coincides with the natural morphism

$$\begin{array}{c} S \\ w : G/N \longrightarrow G'/N' \\ S \end{array}$$

deduced from  $u$  by passage to the quotient. Now  $w$  is an epimorphism of homogeneous spaces under  $G$ , hence is faithfully flat. This proves that  $\tilde{u}$  is a flat morphism such that  $\tilde{u}(\mathcal{CT}_G)$ , which is therefore an open subset of  $\mathcal{CT}_{G'}$ , contains every point of  $\mathcal{CT}_{G'}(k)$ . Since  $\mathcal{CT}_{G'}$  is of finite type over  $k$ , one deduces that  $\tilde{u}$  is surjective, hence faithfully flat.

The complementary assertions contained in vi) in the case where  $\text{Ker } u$  is central follow from Exp. XII 7.12.

The following theorem generalizes Theorem 7.1 of Exp. XII:

**Theorem 7.3.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups of finite presentation over  $S$ , smooth, with connected fibers, and consider the  $S$ -functor  $\mathcal{C} : (\text{Sch}/S)^{\text{circ}} \rightarrow \text{Ens}$  such that:

>  $\mathcal{C}(S) = \text{set of Cartan subgroups of } G_S$ .

- \*i) The following conditions are equivalent:
  - \*a) The functor  $\mathcal{C}$  is representable.
  - \*b) The functor  $\mathcal{C}$  is representable by an  $S$ -prescheme, smooth, quasi-projective, of finite

presentation over  $S$ , with affine fibers.\*

- \*c) The group  $G$  admits locally for the étale topology a Cartan subgroup.\*
- \*d) The group  $G$  admits locally for the faithfully flat topology a Cartan subgroup.\*
- \*e) The nilpotent rank of the fibers of  $G$  is a locally constant function on  $S$ .\*

- \*ii) If the preceding conditions hold, any two Cartan subgroups of  $G$  are locally conjugate for the étale topology.\*

<!-- original page 455 -->

\*The set of regular points of the fibers of  $G$  (Exp. XIII 2.7) is an open subset  $G_{\text{reg}}$ , of finite presentation over  $S$ , and every section of  $G_{\text{reg}}$  over  $S$  is contained in a unique Cartan subgroup of  $G$ .\*

- \*iii) Let  $G$  be an  $S$ -prescheme in groups of finite presentation over  $S$  and  $u : G \rightarrow G'$  a faithfully flat  $S$ -group morphism, so that  $G'$  is smooth over  $S$  with connected fibers. Then if  $C$  is a Cartan subgroup of  $G$ ,  $u(C) = C'$  is representable by a Cartan subgroup of  $G'$ , and  $C \rightarrow C'$  is faithfully flat.\*
- \*iv) Under the conditions of i) and iii) the morphism\*

``text  

$$\tilde{u} : \square_G \rightarrow \square_{G'}, \quad C \mapsto u(C) = C'$$
``

\*is faithfully flat. If moreover  $\text{Ker}(u)$  is central,  $\tilde{u}$  is an isomorphism.\*

- \*v) For any complementary information concerning the transporters, or the relations with maximal tori, one may consult 7.1 and Exp. XII 7.1.\*

<!-- label: III.XV.7.3 -->

\*Proof.\* i) We shall show that  $b) \Rightarrow c) \Rightarrow d) \Rightarrow e) \Rightarrow b) \Rightarrow a) \Rightarrow d)$ .

$b) \Rightarrow c)$ . Let  $s$  be a point of  $S$ . Since  $C_s$  is smooth over  $\kappa(s)$ , there exist points of  $C_s$  whose residue field is a finite separable extension of  $\kappa(s)$ . Applying Exp. XI 1.10, one sees that there exist an open neighborhood  $U$  of  $s$  and an étale surjective morphism

<!-- original page 456 -->

$U' \rightarrow U$  such that  $G_{U'}$  admits a Cartan subgroup.

$c) \Rightarrow d)$  is clear.

$d) \Rightarrow e)$ . Let  $s \in S$ . By hypothesis, there exists an  $S$ -prescheme  $S'$ , flat over  $S$ , whose image contains  $s$ , such that  $G_{S'}$  admits a Cartan subgroup. Let  $s' \in S'$  be a point of  $S'$  above  $s$ . The nilpotent rank of the fibers of  $G_{S'}$  is therefore constant on  $\text{Spec } \mathcal{O}_{S', s'}$ , and consequently the nilpotent rank of the fibers of  $G$  is constant on  $\text{Spec } \mathcal{O}_{S, s}$  which is the image of  $\text{Spec } \mathcal{O}_{S', s'}$  (EGA IV 2.3.4 ii)). Let  $r$  be its value. It follows from 6.3 bis that the set  $E_r$  of points  $x$  of  $S$  such that the nilpotent rank of  $G_x$  equals  $r$  is an ind-constructible part of  $S$ , hence contains a neighborhood of  $s$  (EGA IV 1.10.1).

$e) \Rightarrow b)$ . The assertion is local on  $S$ , so one may assume that the nilpotent rank of the fibers of  $G$  is constant and equal to  $r$ . For every  $S$ -prescheme  $S'$  there is then identity between the Cartan subgroups of  $G_{S'}$  and the subgroup preschemes of  $G_{S'}$  smooth over  $S'$  of relative dimension  $r$ , whose geometric fibers are centralizers of a torus. Since  $\mathcal{C}$  is representable by 7.1,  $\mathcal{C}$  is representable by the open-closed subprescheme of  $\mathcal{C}$  representing the subfunctor of  $\mathcal{C}$  consisting of groups of relative dimension  $r$ . The other assertions in b) are contained in 7.1 i), except for the fact that the fibers of  $\mathcal{C}$  are affine, which itself follows from Exp. XII 7.1 d).

It is clear that  $b) \Rightarrow a)$ . Let us show that  $a) \Rightarrow d)$ . It follows from 6.2 iii) that the functor  $\mathcal{C}$

<!-- original page 457 -->

commutes with filtered inductive limits of rings, so if  $\mathcal{C}$  is representable, it is necessarily representable by an  $S$ -prescheme locally of finite presentation (EGA IV 8.14.2). To prove that  $\mathcal{C}$  is smooth over  $S$ , one is reduced to showing that if  $S$  is affine and if  $S_0$  is the closed subscheme defined by a nilpotent ideal  $J$ , then every Cartan subgroup  $C_0$  of  $G_0 = G \times_{S_0} S_0$  lifts to a Cartan subgroup  $C$  of  $G$ . But the existence of  $C_0$  entails that condition e) is satisfied for  $S_0$ , hence for  $S$  which has the same underlying space, and one concludes from the fact that  $d) \Rightarrow b)$ . Since  $\mathcal{C}$  is smooth over  $S$  and  $\mathcal{C} \rightarrow S$  is

surjective, one sees that a)  $\Rightarrow$  d).

ii) Let  $C$  and  $C'$  be two Cartan subgroups of  $G$ . Then  $\text{Trans}_G(C, C')$  is representable by a prescheme smooth over  $S$  (7.1 iii)) with non-empty fibers (cf. Exp. XII 6.6 a) and c)). The fact that  $C$  and  $C'$  are locally conjugate for the étale topology is then a consequence of Hensel's lemma (Exp. XI 1.10).

The other assertions of ii) are consequences of XIII 3.1 and XIII 3.2, in view of i).

iii) Let  $C$  be a Cartan subgroup of  $G$ . One knows (7.1 v)) that  $u(C)$  is representable by a smooth subgroup  $C'$  of  $G'$ . Since the fibers of  $C'$  are Cartan subgroups of the fibers of  $G'$  (Exp. XII 6.6 d)),  $C'$  is a Cartan subgroup of  $G'$ .

iv) To prove that the morphism  $\tilde{u}$  is faithfully flat, one proceeds as in 7.1 vi).

If now  $\text{Ker } u$  is central and  $C'$  is a Cartan subgroup of  $G'$ ,

<!-- original page 458 -->

$u^{-1}(C') = C$  is smooth, with connected fibers (7.1 vi)) and its fibers are Cartan subgroups (Exp. XII 6.6 f)), so  $C$  is a Cartan subgroup of  $G$ , which completes the proof of iv), in view of 7.1 vi).

## 8. Representability criterion for the functor of sub-tori of a smooth group

<!-- label: III.XV.8 -->

<!-- original page 459 -->

**8.0.** In this section, if  $S$  is a prescheme and  $G$  an  $S$ -prescheme in groups,  $\mathcal{T}_G$  (or simply  $\mathcal{T}$  if there is no ambiguity) denotes the  $S$ -functor  $(\text{Sch}/S)^{\circ} \rightarrow \text{Ens}$  such that, for every  $S$ -prescheme  $S'$ , one has

$\mathcal{T}(S') = \text{set of sub-tori of } G_{S'}.$

One similarly defines  $\mathcal{T}_C$  as the functor of central sub-tori of  $G$ .

**Proposition 8.1.** Let  $S$  be a locally noetherian prescheme and  $G$  an  $S$ -prescheme in groups of finite type. Then the following conditions are equivalent:

- i) The functor  $\mathcal{T}_G$  "commutes with adic limits of local artinian rings", i.e. for every  $S$ -prescheme of the form  $\text{Spec}(A) = S'$ , where  $A$  is a complete noetherian local ring for the topology defined by its maximal ideal  $\mathfrak{m}$ , the canonical map

$$\mathcal{T}(S') \rightarrow \varprojlim_n \mathcal{T}(S'_n) \quad (\text{where } S'_n = \text{Spec}(A/\mathfrak{m}^n))$$

is bijective.

- ii) As in i) but restricted to the case where  $A$  is a complete discrete valuation ring with algebraically closed residue field.
- iii) As in ii), but one restricts to the subfunctor  $\mathcal{T}^{(1)}$  of  $\mathcal{T}$  relative to sub-tori of  $G$  of relative dimension  $\leq 1$ .

<!-- original page 460 -->

- i bis) For every  $S$ -prescheme  $S'$  as in i) and every  $S'$ -torus  $T$ , the canonical map

$$\text{Hom}_{S'\text{-gr}}(T, G_{S'}) \rightarrow \varprojlim_n \text{Hom}_{S'_n\text{-gr}}(T_{S'_n}, G_{S'_n})$$

is bijective.

- ii bis) As i bis), but one restricts to the case where  $A$  is a complete discrete valuation ring with algebraically closed residue field.

- \*iii bis) As ii bis), but one restricts to the case where  $T$  is the multiplicative group  $G_m$ .\*

<!-- label: III.XV.8.1 -->

**Remark 8.2.** One has an analogous proposition restricting to central sub-tori of  $G$  and to central homomorphisms of a torus into  $G$ .

<!-- label: III.XV.8.2 -->

**Proof.** We shall use the following lemma:

**Lemma 8.3.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups,  $T$  an  $S$ -torus,  $u : T \rightarrow G$  an  $S$ -group morphism. Assume in addition that  $G$  is of finite presentation over  $S$ , or else that  $S$  is locally noetherian and  $G$  locally of finite type. Then:

- \*a)  $\text{Ker } u$  is a subgroup of multiplicative type of  $T$ .\*
- \*b) The quotient  $T' = T/\text{Ker } u$  is a torus.\*
- \*c) The canonical monomorphism  $T' \rightarrow G$  deduced from  $u$  by passage to the quotient is an immersion.\*

<!-- label: III.XV.8.3 -->

<!-- original page 461 -->

This lemma is a consequence of Exp. IX 6.8 when  $G$  is separated over  $S$ . In the general case, one reduces as usual to the case where  $S$  is noetherian. Let us first show that  $K = \text{Ker } u$  is flat. We may assume that  $S$  is the spectrum of a local artinian ring (EGA 0\_III 10.2.6), in which case  $G$  is separated (Exp. VI\_B 5.2), so  $K$  is of multiplicative type (Exp. IX 6.8) and  $\text{a fortiori}$  flat over  $S$ . Let us now prove that  $\text{Ker } u$  is closed in  $T$ , which reduces us to the case where  $S$  is the spectrum of a discrete valuation ring (EGA II 7.2.1). Since  $T$  is flat with connected fibers,  $u$  factors through the connected component of the schematic closure in  $G$  of the generic fiber of  $G$ . We may therefore assume  $G$  flat with connected fibers, but then  $G$  is separated (Exp. VI\_B 5.2), so  $K$  is closed. This being so, it follows from Exp. X 4.8 b) that  $K$  is a subgroup of multiplicative type of  $T$ . The quotient  $T' = T/K$  is then representable and  $T'$  is a group of multiplicative type (Exp. IX 2.7) whose fibers are tori, so it is a torus. The fact that the monomorphism  $T' \rightarrow G$  is an immersion then follows from Exp. VIII 7.9.

**Proof of 8.1.** i)  $\Rightarrow$  i bis). Set  $T_n = T_{S'_n}$ ,  $G_n = G_{S'_n}$ , and let  $(u_n)_{n \in \mathbb{N}}$  be an element of  $\varprojlim_{\leftarrow} \text{Hom}_{S'_n\text{-gr}}(T_n, G_n)$ . For every integer  $n$ ,  $u_n(T_n)$  is therefore a sub-torus  $T'_n$  of  $G_n$  (Lemma 8.3). By hypothesis, there exists a unique sub-torus  $T'$  of  $G$  lifting  $T'_n$  for every  $n$ . Since  $T'$  has affine fibers, one concludes thanks to 4.4.

i bis)  $\Rightarrow$  i). Let  $(T_n)_{n \in \mathbb{N}}$  be an element of  $\varprojlim_{\leftarrow} \square(S_n)$ . By Exp. X 4.6,

<!-- original page 462 -->

there exist an  $S'$ -torus  $T^0$  and an  $S'^0$ -isomorphism  $u_0 : T^0 \rightarrow T_0$ . Since  $T_n$  is smooth over  $S'_n$ ,  $u_0$  lifts to an  $S'_n$ -morphism  $u_n : T^0_n \rightarrow T_n$  (Exp. IX 3.6), and one may assume the family  $(u_n)_{n \in \mathbb{N}}$  coherent, hence coming from a morphism  $u : T^0 \rightarrow G$ . The image of  $T^0$  by  $u$  is then a sub-torus of  $G$  (Lemma 8.3) lifting  $T'_n$  for every  $n$ .

The implications i)  $\Rightarrow$  ii)  $\Rightarrow$  iii) on the one hand, and i bis)  $\Rightarrow$  ii bis)  $\Rightarrow$  iii bis) on the other, are evident. The implication iii)  $\Rightarrow$  iii bis) is proved as i)  $\Rightarrow$  i bis). It therefore suffices to prove: iii bis)  $\Rightarrow$  ii bis)  $\Rightarrow$  i bis).

ii bis)  $\Rightarrow$  i bis). With the terminology introduced in 4.3, assertion i bis) is true if and only if every element  $(u_n)_{n \in \mathbb{N}}$  of  $\varprojlim_{\leftarrow} \text{Hom}_{S_n\text{-gr}}(T_n, G_n)$  is "admissible". For every point  $t$  of  $S'$  distinct from the closed point  $s$  of  $S'$ , there exists an  $S'$ -scheme  $S''$ , spectrum of a complete discrete valuation ring with algebraically closed residue field, whose generic point projects to  $t$  and whose closed point projects to  $s$  (EGA II 7.1.9). One immediately deduces a valuative criterion for a family of morphisms to be admissible. This says that ii bis)  $\Rightarrow$  i bis).

iii bis)  $\Rightarrow$  ii bis). Let  $T$  be an  $S$ -torus, where  $S$  is the spectrum of a complete discrete valuation ring with algebraically closed residue field. The torus  $T$  is then trivial (Exp. X 4.6), i.e. isomorphic to  $(G_m, S)^r$  for a suitable integer  $r$ . Let  $(u_n)_{n \in \mathbb{N}}$  be an element of  $\varprojlim_{\leftarrow} \text{Hom}_{S_n\text{-gr}}((G_m)^r_{S_n}, G_n)$ . By hypothesis, the restrictions of  $u_n$  to each

<!-- original page 463 -->

factor of  $(G_m)^{\{r\}_S}$  come from a group morphism  $G_m \rightarrow G$ . Whence a product morphism  $(G_m)^{\{r\}_S} \rightarrow G^{\{r\}}$  which, composed with the morphism  $G^{\{r\}} \rightarrow G$  defined by the composition law in  $G$ , gives a morphism

$$v : (G_m)^{\{r\}_S} \rightarrow G.$$

Given the existence of the group morphism  $u_n$ , it is clear that  $u_n = v_n$ . It remains to see that  $v$  is a group morphism, which translates into the fact that two obvious morphisms  $f, g : X = (G_m)^{\{r\}_S} \times_S (G_m)^{\{r\}_S} \rightarrow G$  coincide. Let  $Z$  be the subscheme of coincidences of  $f$  and  $g$ . Since  $(G_m)^{\{r\}_S}$  has connected fibers and  $v((G_m)^{\{r\}_S})$  contains the unit section, one sees as in 8.3 that  $v$  factors through the connected component of  $G$ , which allows us to assume  $G$  separated (Exp. VI\_B 5.2), so  $Z$  is closed. On the other hand, since  $v_n$  is a group morphism, one has  $f_n = g_n$  for every  $n$ , so  $Z$  contains a neighborhood of the closed fiber of  $X$  (EGA I 10.9.4), hence is schematically dense in  $X$ ,  $X$  having smooth and irreducible fibers (Exp. IX 4.6), and consequently  $Z = X$ , so  $f = g$ .

**Definition 8.4.** Let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -prescheme in groups of finite type, and  $\mathcal{S}$  the set of  $S$ -schemes  $S'$ , spectrum of a complete discrete valuation ring with algebraically closed residue field, of closed point  $s$ , of generic point  $t$ ,

*original page 464*

such that  $(G_t)^{\{0\}_{\text{red}}}$  is smooth and admits a Chevalley decomposition, i.e. is an extension of an abelian variety by a smooth, connected linear algebraic subgroup  $L_t$  (this decomposition is then unique). If  $S' \in \mathcal{S}$ , denote by  $G'$  (resp.  $L$ ) the schematic closure in  $G_{S'}$  of  $G_t$  (resp.  $L_t$ ).

Under these conditions, we shall say that

"the abelian part of  $G$  does not degenerate into a toric part", or more briefly that  $G$  satisfies property AT,

if for every  $S' \in \mathcal{S}$ ,  $L_s$  has the same reductive rank as  $G'_s$ . (Intuitively, suppose that the quotient  $A = G'/L$  is representable, in which case  $A$  is a flat group prescheme such that  $(A_t)^{\{0\}_{\text{red}}}$  is an abelian variety. The condition "AT" then means that  $A_s$  has reductive rank zero, hence  $(A_s)^{\{0\}_{\text{red}}}$  is an extension of an abelian variety by a unipotent group.)

Similarly, assuming in addition  $G$  has connected fibers, we shall say that

$G$  satisfies property ATC

if for every  $S' \in \mathcal{S}$ , the schematic closure  $Z$  of the center  $Z_t$  of  $G_t$  satisfies AT.

*label: III.XV.8.4*

These technical definitions are justified by the following proposition:

**Proposition 8.5.** Let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -prescheme in groups of finite type. Then:

- a) For the functor  $\mathcal{T}$  of sub-tori of  $G$  to "commute with adic limits of local artinian rings" (cf. 8.1), it is necessary and sufficient that  $G$  satisfy property AT (8.4).
- b) If  $G$  has connected fibers, for the functor  $\mathcal{T}_C$  of central sub-tori of  $G$  to commute with adic limits of local artinian rings,

*original page 465*

it is necessary and sufficient that  $G$  satisfy property ATC (8.4).

*label: III.XV.8.5*

We shall need the following technical lemma:

**Lemma 8.6.** Let  $S$  be the spectrum of a discrete valuation ring,  $s$  the closed point of  $S$ ,  $G$  an  $S$ -prescheme in groups, flat and of finite type,  $T_s$  a sub-torus of  $G_s$ . Then there exists an  $S$ -scheme  $S'$ , spectrum of a discrete valuation ring faithfully flat over  $S$ , with closed point  $s'$ , and a subgroup scheme  $C$  of  $G_{S'}$ , flat over  $S'$ , commutative, with connected fibers, such that  $C_s$  majorizes  $T_s \times_{S'} s'$ .

<!-- label: III.XV.8.6 -->

Possibly replacing  $\mathbb{S}$  by  $\mathbb{S}'$ , spectrum of a discrete valuation ring faithfully flat over  $\mathbb{S}$ , we may assume that  $T_{\{s\}}$  is equal to  $(G_{\{m\}})^{r_{\{s\}}}$  and that the transcendence degree of  $\kappa(s)$  over the prime field is  $\geqslant r$  (EGA 0\_III 10.3.1 and EGA II 7.1.9). There then exists an element  $x$  of  $T_{\{s\}}(s)$  such that every algebraic subgroup of  $G_{\{s\}}$  "containing"  $x$  majorizes  $T_{\{s\}}$  (cf. Exp. XIII proof of 2.1 (ii)  $\Rightarrow$  (vii)). Since  $G$  is flat over  $\mathbb{S}$ , a quasi-section passes through  $x$  (EGA IV 14.5.8), and consequently, possibly replacing  $\mathbb{S}$  by the spectrum of a discrete valuation ring faithfully flat over  $\mathbb{S}$ , one may assume that there exists a section  $\tilde{x}$  of  $G$  above  $\mathbb{S}$  lifting  $x$ . Let  $C_{\{t\}}$  be the commutative algebraic subgroup of  $G_{\{t\}}$  generated by  $\tilde{x}_{\{t\}}$  (Exp. VI\_B 7), and let  $C$  be the schematic closure of  $C_{\{t\}}$  in  $G$ . It is clear that  $C_{\{s\}}$  contains  $x$ , hence majorizes  $T_{\{s\}}$ , and consequently, the "connected component" of  $C$  will be a flat and commutative group scheme answering the question.

\*Proof of 8.5 a).\* <!-- original page 466 --> Suppose the functor  $\mathcal{T}$  commutes with adic limits of artinian rings and let us show that  $G$  satisfies property AT. Let then  $\mathbb{S}' \in \mathcal{S}$ , and let  $T_{\{s\}}$  be a maximal torus of  $G'_{\{s\}}$ . We must prove that  $T_{\{s\}}$  is contained in  $L_{\{s\}}$ . The formation of  $L$  and  $G'$  evidently commutes with faithfully flat extensions  $\mathbb{S}' \rightarrow \mathbb{S}$  of discrete valuation rings. Possibly changing  $\mathbb{S}'$ , we may therefore, by Lemma 8.6, assume that there exists a subgroup scheme  $C$  of  $G'_{\{S\}}$ , flat and commutative, such that  $C_{\{s\}}$  majorizes  $T_{\{s\}}$ . But then  $T_{\{s\}}$  is a central sub-torus of  $C_{\{s\}}$ , and consequently lifts infinitesimally to a central sub-torus (Cor. 2.3). Given the hypothesis made on  $G$ ,  $T_{\{s\}}$  lifts to a sub-torus  $T$  of  $G$ . Evidently  $T_{\{t\}}$  is contained in the linear component  $L_{\{t\}}$  of  $G_{\{t\}}$ , so  $T$  is contained in  $L$ .

Suppose now that  $G$  satisfies property AT, and let us show that condition 8.1 iii bis) is verified. Let then  $\mathbb{S}$  be the spectrum of a complete discrete valuation ring  $A$  with algebraically closed residue field,  $\mathfrak{m}$  the maximal ideal of  $A$ ,  $\mathbb{S}_{\{n\}} = \operatorname{Spec}(A/\mathfrak{m}^n)$ ,  $u_n$ ,  $n \in \mathbb{N}$ , a coherent system of group morphisms  $u_n : (G_{\{m, S\}})_{\{n\}} \rightarrow G_{\{n\}} = G \times_{\mathbb{S}} \mathbb{S}_{\{n\}}$ . Let  $q$  be a prime number invertible on  $\mathbb{S}$ . The integer  $\ell$  ranging over the powers of  $q$ , there exists a unique  $\mathbb{S}$ -group morphism

```

```text
u : G{m, S} → G
```

```

lifting  $u_n|_{\{\ell\}}(G_{\{m, S\}})_{\{n\}}$  for every  $n$  (Prop. 1.6 a)). Consequently, if there exists an  $\mathbb{S}$ -group morphism  $u : G_{\{m, S\}} \rightarrow T$  lifting  $u_n$  for every  $n$ , its restriction to  $\{\ell\} G_{\{m, S\}}$  is uniquely determined. By the density theorem (Exp. IX 4.8 (a)), this proves

<!-- original page 467 -->

the uniqueness of  $u$  and the fact that to prove the existence of  $u$ , we may allow a faithfully flat extension of the base. Now  $(G_{\{t\}})^{0}_{\text{red}}$  admits a Chevalley decomposition, and this is already defined over a finite extension  $L$  of the field of fractions  $K$  of  $A$ . Possibly replacing  $\mathbb{S}$  by the normalization of  $\mathbb{S}$  in  $L$ , we may therefore assume  $\mathbb{S} \in \mathcal{S}$ . The morphism  $\{\ell\} u_{\{t\}}$  factors through  $(G_{\{t\}})_{\text{red}}$ , so  $\{\ell\} u$  factors through the schematic closure  $G'_{\{s\}}$  of  $(G_{\{t\}})_{\text{red}}$  in  $G'$ . Still by the density theorem, one deduces that  $u_n$  factors through  $G'_{\{n\}}$  for every  $n$ . Since  $G$  has property AT, every sub-torus of  $G'_{\{s\}}$ , and *a fortiori* of  $G'_{\{n\}}$ , is contained in  $L_{\{s\}}$ , so  $u_{\{s\}}$  factors through  $L_{\{s\}}$ . I claim that for every  $n$ ,  $u_n$  factors through  $L_{\{n\}}$ . Indeed, since  $L_{\{t\}}$  is invariant in  $(G')_{\{t\}}$ ,  $L$  is invariant in  $G'$ ; on the other hand,  $L$  is flat over  $\mathbb{S}$ , so for every integer  $n$ , the quotient  $H_{\{n\}} = G'_{\{n\}}/L_{\{n\}}$  is representable (Exp. VI\_A § 4). The image of  $(G_{\{m, S\}})_{\{n\}}$  in  $H_{\{n\}}$  is a sub-torus of  $H_{\{n\}}$  (Exp. IX 6.8) whose closed fiber is zero, so this image is zero and consequently  $u_n$  factors through  $L_{\{n\}}$ . But since  $L_{\{t\}}$  is affine, one deduces that the family  $u_n$  is admissible (Prop. 4.3), which completes the proof.

The proof of 8.5 b) is entirely analogous to that of 8.5 a), in view of 8.2 and Exp. IX 5.6 a).

**\*Proposition 8.7.\*** \*Let  $\mathbb{S}$  be a locally noetherian prescheme,  $G$  an  $\mathbb{S}$ -prescheme in groups of finite type. Then:\*

<!-- original page 468 -->

- \*i) If  $G$  has connected fibers and satisfies AT, it satisfies ATC.\*
- \*ii) If  $G$  satisfies AT, every subgroup prescheme of  $G$  satisfies AT.\*
- \*iii) If  $G$  is flat over  $\mathbb{S}$  and the abelian rank of the fibers of  $G$  is a locally constant function on  $\mathbb{S}$ , then  $G$  satisfies AT.\*

<!-- label: III.XV.8.7 -->

i) follows immediately from 8.5 and Exp. IX 5.6 a).

ii) Let  $H$  be a subgroup prescheme of  $G$ . To prove that  $H$  satisfies property AT, we may assume that  $S$  is the spectrum of a complete discrete valuation ring and we must show that every coherent family of  $S_n$ -group morphisms

```
```text
u_n : (G_{m, S})_n → H_n
```
```

is admissible (8.5 and 8.1 iii bis)). Now by hypothesis,  $G$  satisfies property AT, so there exists an  $S$ -group morphism

```
$$
u : (G_{\{m\}})_S \rightarrowtail G
$$
```

lifting  $u_n$  for every  $n$ . Proceeding as in the proof of 8.5, one sees that  $u|_{\bigcup_{\ell} G_{\{m, S\}}^\ell}$  (where  $\ell$  ranges over the powers of a prime  $q$  invertible on  $S$ ) factors through  $H$ . By density, one deduces that on the generic fiber,  $u_t$  factors through  $H_t$ . Since  $(G_{\{m\}})_S$  is reduced, it indeed follows that  $u$  factors through  $H$ .

iii) Let  $S' \in \mathcal{S}$  (notation of 8.4). <!-- original page 469 --> The group  $L$  is flat over  $S$ , its generic fiber  $L_t$  is affine; under these conditions, one can show that  $L_s$  is necessarily affine (XVII App. III, 2). Since  $G$  and  $L$  are flat, one has  $G = G'$  and the dimension of the fibers of  $G$  and  $L$  is constant on  $S$  (Exp. VI\_B 4), so that one has the inequalities:

```
```text
abelian rank  $G_s \leq \dim G_s - \dim L_s = \dim G_t - \dim L_t = \text{abelian rank } G_t$ .
```
```

The hypothesis entails that these inequalities are equalities. It follows that  $(G_s/L_s)^{0_{\text{red}}}$  is an abelian variety, hence has reductive rank zero, and consequently  $L_s$  has the same reductive rank as  $G_s$ .

We are now in a position to prove the main theorems of this section:

**Theorem 8.8.** \*Let  $G$  be a group prescheme of finite type over a locally noetherian prescheme  $S$ . Suppose  $G$  flat over  $S$  with connected fibers. Then:\*

- \*a) For the functor  $\mathcal{T}_C$  of central sub-tori of  $G$  to be representable, it is necessary and sufficient that  $G$  have property ATC (8.4). Moreover, in this case,  $\mathcal{T}_C$  is representable by an  $S$ -prescheme étale and separated over  $S$ .\*
- \*b) Under the conditions of a), for every  $S$ -torus  $T$ , the functor  $\operatorname{Hom}^{\text{cent}}_{\{S\text{-gr}\}}(T, G)$  of central homomorphisms of  $T$  into  $G$  is representable by an  $S$ -prescheme étale and separated over  $S$ .\*

<!-- label: III.XV.8.8 -->

**Theorem 8.9.** \*Let  $S$  be a locally noetherian prescheme and  $G$  an  $S$ -prescheme in groups of finite type, smooth over  $S$ .\*

- \*a) For the functor  $\mathcal{T}$  of sub-tori of  $G$  to be representable, it is necessary and sufficient\*

<!-- original page 470 -->

\*that  $G$  have property AT (8.4). Moreover, in this case,  $\mathcal{T}$  is representable by an  $S$ -prescheme smooth and separated over  $S$ ; more precisely, the structural morphism  $\mathcal{T} \rightarrow S$  admits a canonical factorization\*

```
```text
□  $\xrightarrow{u} Y \xrightarrow{v} S$ ,
```
```

\*where  $v$  is a smooth and quasi-projective morphism (hence of finite type) and  $u$  is an étale separated morphism.\*

- \*b) Under the conditions of a), for every  $S$ -torus  $T$ , the functor  $\operatorname{Hom}_{\{S\text{-gr}\}}(T, G)$  of homomorphisms of  $T$  into  $G$  is representable by an  $S$ -prescheme smooth and separated over  $S$ .\*

<!-- label: III.XV.8.9 -->

\*Proof of 8.8 a).\* If the functor  $\mathcal{T}_{\{C\}}$  is representable, it commutes with adic limits of artinian rings, and consequently (8.2 and 8.5 b))  $G$  has property ATC. To establish the converse, we shall use the following result, which will be proved in EGA VI, and is also found in Murre's exposé: Sémin. Bourbaki, May 1965, N° 294, Theorem 1, corollary 2.

**Lemma 8.10.** \*Let  $S$  be a locally noetherian prescheme and  $F$  a contravariant functor defined on  $Sch/S$  with values in the category of sets. For  $F$  to be representable by an étale separated  $S$ -prescheme, it is (necessary and) sufficient that  $F$  satisfy the following five properties:\*

- \*i)  $F$  is a sheaf for the fpqc topology (Exp. IV).\*

<!-- original page 471 -->

- \*ii)  $F$  commutes with inductive limits of rings (Exp. XI 3.2).\*

- \*iii)  $F$  commutes with adic limits of local artinian rings (8.1 i)).\*

- \*iv)  $F$  satisfies the "valuative criterion of separation", i.e. for every  $S$ -scheme  $S'$  which is the spectrum of a discrete valuation ring with generic point  $t$ , the canonical map  $F(S') \rightarrow F(t)$  is injective.\*

- \*v)  $F$  is infinitesimally étale (Exp. XI 1.8).\*

<!-- label: III.XV.8.10 -->

Let us show that the functor  $\mathcal{T}_{\{C\}}$  of 8.8 satisfies the five conditions of 8.10.

i) The functor  $\mathcal{T}$  (resp.  $\mathcal{T}_{\{C\}}$ ) is a sheaf for the fpqc topology as soon as  $G$  is of finite presentation over  $S$ . Indeed, every monomorphism of a torus into  $G$  is then an immersion (Exp. VIII 7.9), and the property follows from fpqc descent of subpreschemes.

ii) Corollary 6.3 proves that the functor  $\mathcal{T}$  commutes with inductive limits of rings if  $G$  is of finite presentation over  $S$ ; one immediately deduces that the same is true of  $\mathcal{T}_{\{C\}}$ .

iii) By 8.5, condition iii) is precisely equivalent to property ATC.

iv) follows simply from the fact that if  $S$  is the spectrum of a discrete valuation ring, two sub-tori of  $G$  having the same generic fiber coincide

<!-- original page 472 -->

and more precisely coincide with the connected component of the schematic closure in  $G$  of their generic fiber.

v) follows from 2.3 since  $G$  is flat over  $S$ .

\*Proof of 8.8 b).\* Proceeding as in Exp. XI 4.2, one sees that it suffices to prove that the product group  $T \times_S G$  again satisfies property ATC, which is immediate from the definition.

\*Proof of 8.9 a).\* Possibly replacing  $G$  by its connected component (Exp. VI\_B 3.10), we may assume  $G$  has connected fibers. If  $T$  is a sub-torus of  $G$ , its centralizer  $\text{Centr}_{\{G\}}(T)$  is then representable (Exp. XI 6.11) by a subgroup prescheme of  $G$ , smooth over  $S$  (Exp. XI 2.4), with connected fibers (Exp. XII 6.6 b)), hence is an element of  $\mathcal{CT}(S)$ , where  $\mathcal{CT}$  is the functor defined in 7.1 i). It is clear that the map

$$T \mapsto \text{Centr}_{\{G\}}(T)$$

defines an  $S$ -morphism

$$u : \mathcal{T} \rightarrow \mathcal{CT}.$$

Since  $\mathcal{CT}$  is representable by an  $S$ -prescheme smooth and quasi-projective over  $S$  (7.1 i)), it suffices to prove that the morphism  $u$  is representable by a separated and étale morphism.

After a suitable base change  $S' \rightarrow S$  (with  $S' = \mathcal{CT}$ ), hence  $S'$  locally noetherian),

<!-- original page 473 -->

we are reduced to the following problem: let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -prescheme in groups, smooth and of finite type over  $S$ , with connected fibers,  $H$  a subgroup of  $G$ , smooth over  $S$  with connected fibers. Consider the subfunctor  $X$  of  $\mathcal{T}_{C, H}$  such that, for every  $S$ -prescheme  $S'$ ,  $X(S')$  is the set of central sub-tori  $T$  of  $H_{S'}$  such that  $\text{Centr}_{G_{S'}}(T) = H_{S'}$ . We shall show that  $X$  is representable by an  $S$ -prescheme étale and separated over  $S$ .

Indeed, by hypothesis,  $G$  satisfies property AT, hence so does  $H$  (8.7 ii)); and since  $H$  has connected fibers,  $H$  also satisfies property ATC (8.7 i)). On the other hand  $H$  is smooth over  $S$ , hence flat. By 8.8 a),  $\mathcal{T}_{C, H}$  is representable by an  $S$ -prescheme étale and separated over  $S$ . It then suffices to show that the canonical monomorphism  $X \rightarrow \mathcal{T}_{C, H}$  is representable by an open immersion.

Set  $S' = \mathcal{T}_{C, H}$  and let  $K$  be the centralizer in  $G_{S'}$  of the "universal" central torus of  $H_{S'}$ . The group  $K$  is a smooth group scheme over  $S'$  with connected fibers, majorizing  $H_{S'}$ . By definition,  $X = \prod_{K/S'} H_{S'}/K$ , which is indeed representable by the open-closed subprescheme of  $S'$  above which  $H_{S'}$  and  $K$  have the same relative dimension.

One proves 8.9 b) analogously to 8.8 b).

**Corollary 8.11.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups smooth over  $S$  and of finite presentation. Then, if the abelian rank of the fibers of  $G$  is a locally constant function on  $S$  (in particular if the fibers of  $G$  are affine), the functor\*

<!-- original page 474 -->

\*of sub-tori of  $G$  is representable by an  $S$ -prescheme, smooth and separated over  $S$ , and the same is true of the functor  $\text{Hom}_{S\text{-gr}}(T, G)$  for every  $S$ -torus  $T$ .\*

<!-- label: III.XV.8.11 -->

Indeed, the assertion is local on  $S$ , so we may assume  $S$  affine and the abelian rank of the fibers of  $G$  constant. One may then find (Exp. VI\_B § 10) a noetherian affine scheme  $S_0$  and an  $S_0$ -prescheme in groups  $G_0$ , smooth and of finite type over  $S_0$ , such that  $G$  is  $S$ -isomorphic to  $G_0 \times_{S_0} S$ . Moreover, the abelian rank of the fibers of an  $S$ -prescheme in groups of finite presentation over  $S$  is an ind-constructible function (6.3 bis). By a standard argument (EGA IV 8), one concludes that in the present case, one may assume the abelian rank of the fibers of  $G_0$  constant on  $S_0$ . But then  $G_0$  has property AT (8.7 iii)), and consequently (8.10) the functor of sub-tori of  $G_0$  is representable by an  $S_0$ -prescheme smooth and separated over  $S_0$ , whence the announced property for  $G$ . As for the functor  $\text{Hom}_{S\text{-gr}}(T, G)$ , one proceeds analogously.

**Generalization of 8.9.**

The functor  $\mathcal{T}$  of sub-tori of a smooth group  $G$  not being necessarily representable, we shall state sufficient conditions for a subfunctor of  $\mathcal{T}$  to be representable.

**Proposition 8.12.** \*Let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -prescheme in groups, smooth over  $S$ , with connected fibers, and  $F$  an  $S$ -subfunctor of the functor  $\mathcal{T}$  of\*

<!-- original page 475 -->

\*sub-tori of  $G$ , satisfying the following properties:

- \*i)  $F$  is a sheaf for the fpqc topology (Exp. IV).\*
- \*ii)  $F$  commutes with inductive limits of rings (Exp. XI 3.2).\*
- \*iii)  $F$  commutes with adic limits of local artinian rings (Exp. XI 3.3).\*
- \*iv)  $F$  is infinitesimally smooth over  $S$  (Exp. XI 1.8).\*
- \*v)  $F$  is stable under inner automorphisms of  $G$ , i.e. for every  $S$ -prescheme  $S'$ , one has:\*

```text  
 $T \in F(S')$ and $g \in G(S') \Rightarrow \text{int}(g)T \in F(S')$.
 ```

\*Then  $F$  is representable by an  $S$ -prescheme, smooth and separated over  $S$ .\*

<!-- label: III.XV.8.12 -->

**\*\*Proposition 8.12 bis.\*\*** \*Let  $S$  and  $G$  be as above,  $T$  an  $S$ -torus, and  $F$  a subfunctor of  $\operatorname{Hom}_{S\text{-gr}}(T, G)$ , satisfying the following properties:

- $(i), (ii), (iii), (iv)$  as above.
- $(v)$   $F$  is stable under inner automorphisms of  $G$ , i.e. for every  $S$ -prescheme  $S'$ , one has:

``text  
 $u \in F(S')$  and  $g \in G(S') \Rightarrow \operatorname{int}(g) u \in F(S')$ .  
 ``

\*Then  $F$  is representable by an  $S$ -prescheme smooth and separated over  $S$ .

<!-- label: III.XV.8.12bis -->

\*Proof of 8.12.\* (The proof of 8.12 bis is entirely analogous and is left to the care of the reader.)

<!-- original page 476 -->

Let  $u : F \rightarrow \operatorname{mathcal{CT}}_S$  (7.1 i)) be the  $S$ -morphism which to every element  $T$  of  $F(S')$  associates the element  $\operatorname{Centr}_{G_{S'}}(T)$  of  $\operatorname{mathcal{CT}}_{S'}$ . Since  $\operatorname{mathcal{CT}}_S$  is representable by an  $S$ -prescheme smooth and quasi-projective (7.1 i)), we are reduced to proving the representability of  $u$ . After base change  $\operatorname{mathcal{CT}}_S \rightarrow S$ , we are reduced to the following problem: given  $S$  and  $G$  as above,  $H$  a smooth subgroup of  $G$  with connected fibers, we must represent the functor  $F_H$  such that  $F_H(S') = \text{set of elements } T \text{ in } F(S') \text{ such that}$

$H_{S'} = \operatorname{Centr}_{G_{S'}}(T)$ .  
 $F_H$

We shall show that  $F_H$  is étale and separated over  $S$ . To do this, it suffices to verify the five conditions of 8.10.

Conditions i), ii) and iii) of 8.10 follow easily from 8.12 i), ii) and iii). One has already remarked that  $\operatorname{mathcal{CT}}_S$  is a separated and infinitesimally étale functor, so  $F_H$ , which is a subfunctor of  $\operatorname{mathcal{CT}}_S$ , is separated and infinitesimally unramified (Exp. XI 1.8). It therefore suffices to show that  $F_H$  is infinitesimally smooth (\*loc. cit.\*). Let  $S$  be the spectrum of a local artinian ring,  $S_0$  a subscheme of  $S$  defined by a nilpotent ideal,  $T_0$  an element of  $F_H(S_0)$ ; let us prove that  $T_0$  lifts to an element  $T$  of  $F_H(S)$ . By hypothesis (8.12 iv)),  $T_0$  lifts to an element  $T'$  of  $F(S)$ . On the other hand,  $H$  being smooth,  $T_0$  lifts to a sub-torus  $T''$  of  $H_{S_0}$  (Exp. IX 3.6 bis), which is conjugate to  $T'$  by an element  $g \in G(S)$  (\*loc. cit.\*), so  $T'' \in F(S)$  (8.12 v)). Since  $\operatorname{Centr}_{G_{S'}}(T'')$  is smooth over  $S$  and coincides with  $H_{S_0}$  above  $S_0$ ,  $T''$  lies in the

<!-- original page 477 -->

center of  $H_{S_0}$  (Exp. IX 5.6 a)) and its centralizer in  $G$  is equal to  $H_{S_0}$ ; in short,  $T'' \in F_H(S)$ , and one takes  $T = T''$ .

**\*\*Corollary 8.13.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups smooth and of finite presentation over  $S$ , with connected fibers, and let  $\operatorname{mathcal{T}}_D$  be the subfunctor of  $\operatorname{mathcal{T}}_S$  whose set of points with values in an  $S$ -prescheme  $S'$  is the set of sub-tori  $T$  of  $G_{S'}$  such that for every point  $s$  of  $S'$ ,  $T_s$  is contained in the derived subgroup (Exp. VI\_B 7) of  $G_s$ . Then  $\operatorname{mathcal{T}}_D$  is representable by an  $S$ -prescheme smooth and separated over  $S$ .

<!-- label: III.XV.8.13 -->

**\*\*Corollary 8.13 bis.\*\*** \*Let  $S$  and  $G$  be as above,  $T$  an  $S$ -torus, and let  $\operatorname{Hom}^{\operatorname{der}}_{S\text{-gr}}(T, G)$  be the subfunctor of  $\operatorname{Hom}_{S\text{-gr}}(T, G)$  whose set of points with values in  $S'$  is the set of  $S'$ -morphisms  $u : T_{S'} \rightarrow G_{S'}$  such that for every point  $s$  of  $S'$ ,  $u_s$  factors through the derived group of  $G_s$ . Then this functor is representable by an  $S$ -prescheme smooth and separated over  $S$ .

<!-- label: III.XV.8.13bis -->

Corollary 8.13 and Corollary 8.13 bis are proved analogously; let us prove 8.13 bis for example. By the usual procedure, we reduce to the case where  $S$  is noetherian. Let us verify that the five conditions of 8.12 bis are satisfied:

Conditions i) and iv) follow immediately from the corresponding properties of the functor  $\operatorname{Hom}_{S\text{-gr}}(T, G)$ . Condition v) is satisfied since the derived group of an algebraic group is invariant (Exp. VI\_B § 7). To establish ii), we are reduced by a standard reduction (EGA IV 8) to proving that if  $S$  is a noetherian integral scheme with generic point  $\eta$  and  $u : T \rightarrow G$  is an  $S$ -group morphism which on the generic fiber

<!-- original page 478 -->

factors through the derived group of  $G_\eta$ , then there exists a neighborhood  $U$  of  $\eta$  such that, for every point  $s$  of  $U$ ,  $u_s$  factors through the derived group of  $G_s$ . But this follows immediately from Exp. VI\_B 10.12. To establish iii), let us resume the notation of 4.3. To show that an element  $(u_m)_m \in \varprojlim_{m \in \mathbb{N}} \operatorname{Hom}_{S\text{-gr}}(T_m, G_m)$  is "admissible", in the sense of 4.3, and comes from an element of  $\operatorname{Hom}_{S\text{-gr}}(T, G)$ , one reduces immediately to the case where  $S$  is the spectrum of a complete discrete valuation ring (cf. 8.1). Let  $t$  be the generic point and  $s$  the closed point of  $S$ ,  $D$  the schematic closure in  $G$  of the derived group  $D_t$  of  $G_t$ .

a)  $D_s$  contains the derived group of  $G_s$ . Indeed, since  $D_t$  is invariant in  $G_t$  and  $G$  is flat over  $S$ ,  $D$  is invariant in  $G$ . Moreover the morphism

```

```text
G x_S G -> G,      (x, y) -> x y x^{-1} y^{-1}
```

```

factors through  $D_t$  on the generic fiber, hence factors through  $D$ . Consequently the algebraic group  $G_s/D_s$  is commutative, whence assertion a).

b) If  $(u_m)_m \in \varprojlim_{m \in \mathbb{N}} \operatorname{Hom}_{S\text{-gr}}(T_m, G_m)$ , then  $u_m$  factors through  $D_m$ . Indeed, by hypothesis,  $u_s$  factors through the derived group of  $G_s$ , hence *a fortiori* factors through  $D_s$  by a). Since  $D_m$  is flat over  $S_m$  and invariant in  $G_m$ , the quotient group  $H_m = G_m/D_m$  is representable (Exp. VI\_A § 4). Since the image of  $T_m$  in  $H_m$  is a torus (Exp. IX 6.8) whose closed fiber is zero, the image of  $T_m$  is zero; this says that  $u_m$  factors through  $D_m$ .

c) The family  $(u_m)_m \in \varprojlim_{m \in \mathbb{N}} \operatorname{Hom}_{S\text{-gr}}(T, G)$  is "admissible" and lifts to a morphism  $T \rightarrow G$  belonging to  $\operatorname{Hom}_{S\text{-gr}}(T, G)$ .

<!-- original page 479 -->

By what precedes and 4.1 bis, it suffices to prove that  $D_t$  is an affine algebraic group, which follows from the following lemma:

**Lemma 8.14.** \*Let  $G$  be a smooth connected algebraic group defined over a field  $k$ . Then the derived group  $D$  of  $G$  is affine.\*

<!-- label: III.XV.8.14 -->

Since the formation of  $D$  commutes with base field extension (Exp. VI\_B 7), one may assume  $k$  algebraically closed. But then  $G$  is an extension of an abelian variety  $A$  by a linear group  $L$ . Since  $A$  is commutative,  $D$  is necessarily contained in  $L$ , hence is affine.

**Maximal tori.**

**Theorem 8.15.** \*Let  $S$  be a locally noetherian prescheme and  $G$  an  $S$ -prescheme in groups, smooth and of finite type over  $S$ . Then the following conditions are equivalent:\*

- \*i) The  $S$ -functor  $\mathcal{T}_M$ , whose set of points with values in an  $S$ -prescheme  $S'$  is the set of maximal tori of  $G_{S'}$  (Exp. XII 1.3), is representable.\*
- \*ii) The preceding functor  $\mathcal{T}_M$  is representable by an  $S$ -prescheme smooth and quasi-projective over  $S$  with affine fibers.\*
- \*iii) The group  $G$  admits locally for the étale topology a maximal torus.\*

<!-- original page 480 -->

- \*iv) The group  $G$  admits locally for the faithfully flat topology a maximal torus.\*
- \*v) The group  $G$  has property AT (8.4), and the reductive rank of its fibers is a locally constant function on  $S$ .\*

<!-- label: III.XV.8.15 -->

\*Proof.\* ii)  $\Rightarrow$  i) is clear.

i)  $\Rightarrow$  iii). Indeed, since  $G$  is of finite presentation over  $S$ , it follows from 6.3 that  $\mathcal{T}_M$  commutes with inductive limits of rings, hence is locally of finite presentation if it is representable (EGA IV 8.14). Moreover  $\mathcal{T}_M$  is formally smooth (Exp. XI 2.1 bis). So if it is representable, it is representable by a prescheme smooth over  $S$ , and iii) then follows from Hensel's lemma (Exp. XI 1.10).

iii)  $\Rightarrow$  iv) is clear.

iv)  $\Rightarrow$  v). Let  $s$  be a point of  $S$ . By hypothesis, there exists an  $S$ -prescheme  $S'$ , flat over  $S$ , whose image contains  $s$ , such that  $G_{S'}$  admits a maximal torus  $T'$ . Let  $s'$  be a point of  $S'$  above  $s$ . The reductive rank of the fibers of  $G_{S'}$  is therefore constant on  $\operatorname{Spec} \mathcal{O}_{S', s'}$ , and consequently the reductive rank of the fibers of  $G$  is constant on the image of  $\operatorname{Spec} \mathcal{O}_{S', s'}$ , which is  $\operatorname{Spec} \mathcal{O}_{S, s}$  (EGA IV 2.3.4 ii)). Now the reductive rank of the fibers of  $G$  is a locally constructible function on  $S$  (6.3 bis), so this rank is constant on a neighborhood of  $s$  (EGA IV 1.10.1).

To see that  $G$  has property AT, consider an  $S$ -scheme  $S_1$ , spectrum of a discrete valuation ring, with closed point  $s_1$  projecting to the point  $s$

<!-- original page 481 -->

above. The prescheme  $S'_1 = S_1 \times_S S'$  is faithfully flat over  $S_1$ , and  $G_{S'_1}$  admits a maximal torus. Let  $A$  (resp.  $A'$ ) be the ring of  $S_1$  (resp.  $S'_1$ ). Regarding  $A'$  as an inductive limit of its finitely generated  $A$ -subalgebras, it follows from 6.3 that there exists an  $S_1$ -scheme  $S''_1$  such that  $G_{S''_1}$  admits a maximal torus and the structural morphism  $S''_1 \rightarrow S_1$  is of finite type and surjective. Using now EGA II 7.1.9, we may assume that  $S'_1$  is the spectrum of a discrete valuation ring. But then it is clear that  $G_{S'_1}$ , hence also  $G_{S_1}$ , has property AT. Since this is true for every  $S$ -prescheme  $S_1$  spectrum of a discrete valuation ring,  $G$  has property AT.

v)  $\Rightarrow$  i). Indeed, by 8.9, the functor  $\mathcal{T}$  of sub-tori of  $G$  is representable, and it is clear that  $\mathcal{T}_M$  is representable by the open-closed subprescheme of  $\mathcal{T}$  representing the subfunctor of tori of rank  $r$ , where  $r$  denotes the reductive rank of  $G$  (which one may assume constant).

iii)  $\Rightarrow$  ii). Indeed, if condition iii) is realized, we may use the results of Exp. XII 7.1. The functor  $\mathcal{T}_M$  is therefore canonically isomorphic to the functor of Cartan subgroups of  $G$ , and it suffices to apply 7.3 i).

**Remark 8.16.** One can show that the prescheme  $\mathcal{T}_M$  of maximal tori of  $G$  is affine over  $S^{[XV-8-1]}$ , which generalizes Exp. XII 5.4.

<!-- label: III.XV.8.16 -->

**Corollary 8.17.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups,

<!-- original page 482 -->

smooth and of finite presentation over  $S$ . Suppose that the abelian rank and the reductive rank of the fibers of  $G$  are locally constant functions on  $S$ ; then  $G$  satisfies the (equivalent) properties i) to iv) of 8.15.\*

<!-- label: III.XV.8.17 -->

We may assume that the abelian rank and the reductive rank of the fibers of  $G$  are constant. Proceeding as in 8.11, and in view of 6.3 bis, we reduce to the case where  $S$  is noetherian. But then  $G$  has property AT (8.7), and one concludes by 8.15 v).

**Corollary 8.18.** Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups, smooth over  $S$ . Then the following conditions are equivalent:\*

- \*a) The unipotent rank  $\rho_u$  and the abelian rank  $\rho_{ab}$  (6.1 ter) of the fibers of  $G$  are locally constant functions on  $S$ .\*
- \*b) The unipotent rank  $\rho_u$  is locally constant and  $G$  admits locally for the fpqc topology maximal tori.\*
- \*c) The reductive rank  $\rho_r$  (6.1 ter) and the abelian rank  $\rho_{ab}$  of the fibers of  $G$  are locally constant functions on  $S$ .\*

<!-- label: III.XV.8.18 -->

**Remarks 8.19.** Under the hypotheses of 8.18, a more refined argument, using the lower semicontinuity of the abelian rank (announced in Exp. X 8.7), shows that if two of the three ranks  $\rho_u$ ,  $\rho_r$ ,  $\rho_{ab}$  are locally constant, then so is the third.

<!-- label: III.XV.8.19 -->

**Proof of 8.18.** Possibly replacing  $G$  by its connected component, we may assume  $G$  of finite presentation over  $S$  (Exp. VI\_B 5.3.3).

<!-- original page 483 -->

a)  $\Rightarrow$  c). Let  $s$  be a point of  $S$ . Since  $\rho_{ab}$  is locally constant, it follows from 8.11 that, possibly after an étale extension covering  $S$ , we may assume that there exists a sub-torus  $T$  of  $G$  whose fiber  $T_s$  is a maximal torus of  $G_s$ . Let  $C = \text{Centr}\{G\}(T)$ , which is a subgroup prescheme of  $G$ , smooth over  $S$  with connected fibers. For every point  $t$  of  $S$ ,  $C_t$  evidently contains a Cartan subgroup  $C'_t$  of  $G_t$ . Possibly restricting  $S$ , we may assume  $\rho_u$ ,  $\rho_{ab}$ , and the relative dimension of  $C$  over  $S$  are constant. One then has the inequalities

```
```text
dim C_s = dim C_t  $\square$  dim C'_t  $\square$   $\rho_u(t) + \rho_{ab}(t) + \dim T_t$ 
          =  $\rho_u(s) + \rho_{ab}(s) + \dim T_s = \rho_v(s) = \dim C_s$ .
```
```

One deduces that  $C_t = C'_t$ , hence that  $T$  is a maximal torus of  $G$ , and *a fortiori*  $\rho_r(t) = \rho_r(s)$ .

c)  $\Rightarrow$  b) by 8.17.

b)  $\Rightarrow$  a). Indeed, since  $G$  admits locally for the fpqc topology maximal tori, it admits locally for the fpqc topology Cartan subgroups, and consequently (Exp. XII 7.3) the nilpotent rank  $\rho_{\nu} = \rho_u + \rho_r + \rho_{ab}$  is locally constant. Since  $\rho_r$  and  $\rho_{ab}$  are locally constant,  $\rho_u$  is locally constant.

# Exposé XVI. Groups of zero unipotent rank

<!-- label: III.XVI -->

\*by M. Raynaud\*[^XVI-0]

## 1. An immersion criterion

<!-- label: III.XVI.1 -->

<!-- original page 484 -->

### 1.1. Examples of monomorphisms of group preschemes that are not immersions.

<!-- label: III.XVI.1.1 -->

We are going to construct a prescheme  $S$ , two  $S$ -group preschemes  $G$  and  $H$ , and an  $S$ -group monomorphism  $u : G \rightarrow H$  that is not an immersion. The groups  $G$  and  $H$  will be of finite presentation over  $S$ , flat over  $S$ , and  $G$  will even be smooth over  $S$  (cf. Exp. VIII, paragraph and footnote (\*) preceding 7.1; see also XVII App. III, 4).

a) Take first for  $S$  the spectrum of a discrete valuation ring  $A$ , of unequal characteristic and of residue characteristic equal to 2. Let  $t$  be the generic point of  $S$  and  $s$  the closed point. Take for  $G$  the open subgroup of the constant group  $G_{\{0\}} = (\mathbb{Z}/2\mathbb{Z})_S$  obtained by removing the point of the closed fiber  $(\mathbb{Z}/2\mathbb{Z})_s$  distinct from the identity element, and take for  $H$  the group of multiplicative type  $(\mu_2)_S$  of second roots of unity (Exp. I 4.4.4). In view of the choice of  $S$ ,  $H_t$  is isomorphic to  $(\mathbb{Z}/2\mathbb{Z})_t$  while  $H_s$  is a radicial group. One has an evident morphism  $G_{\{0\}} \rightarrow H$  defined by the section  $(-1)$  of  $H$ , whence a morphism  $u : G \rightarrow H$  which is a monomorphism but is not an immersion (otherwise it would necessarily be an isomorphism (cf. Exp. VIII 7)). Here, Exp. VIII 7.9 does not apply, since  $\pi_2 G = G$  is not finite over  $S$ .

b) Denote by  $K$  the  $S$ -group prescheme, étale and non-separated, obtained from the unit group <!-- original page 485 --> by "doubling" the unique point of the closed fiber. Take for  $H$  the product group  $(\mu_2)_S \times_S K$ . Let  $a$  (resp.  $b$ ) be the unique section of  $(\mu_2)$  (resp.  $K$ ) over  $S$  distinct from the unit section, and let  $h = (a, b)$  be the corresponding section of  $H$ . The datum of  $h$  defines an  $S$ -group morphism

```
```text
u : G = (Z/2Z)_S → H.
```

It is clear that u is a monomorphism and is not an immersion. Here, Exp. VIII 7.9 does not apply, since $\pi_2 H = H$ is not separated over S .

c) More interesting is the following example, in which G is a smooth group with connected fibers (and even $G = (\mathbb{G}_a)_S$) (cf. Exp. VIII 7.10).

Take for S the spectrum of a discrete valuation ring A of equal characteristic 2, and let π be a uniformizer of A and $\mathfrak{m}$ the maximal ideal of A .

Consider the additive group $(\mathbb{G}_a)_S$, the product group $(\mathbb{G}_a)_t \times (\mathbb{G}_a)_s$ of ring $A[X, Y]$, and let $G_{\{1\}}$ be the closed subgroup of equation

$$(1) \quad X^2 + X - \pi Y = 0.$$

<!-- label: eq:III.XVI.1.1.1 -->

The group $G_{\{1\}}$ is smooth over S , its generic fiber is isomorphic to $(\mathbb{G}_a)_t$ and its closed fiber is isomorphic to the product of $(\mathbb{G}_a)_s$ by $(\mathbb{Z}/2\mathbb{Z})_s$. One may take for the factor $(\mathbb{Z}/2\mathbb{Z})_s$ the subgroup N_s of $(G_{\{1\}})_s$ of equation

$$(2) \quad Y = X^2 + X = 0.$$

<!-- label: eq:III.XVI.1.1.2 -->

<!-- original page 486 -->

Let N' and N'' be two group subschemes of $G_{\{1\}}$, isomorphic to $(\mathbb{Z}/2\mathbb{Z})_t$, whose closed fibers coincide with N_s and whose generic fibers are distinct. The groups N' and N'' are therefore defined by the data of two sections of $G_{\{1\}}$ over S with coordinates (a', b') (resp. (a'', b'')) such that

```
```text
(3) a'^2 + a' - \pi b' = a''^2 + a'' - \pi b'' = 0,
```

$a' \text{ and } a'' \equiv 1 \pmod{\pi}, a' \neq a'',$   
 $b' \text{ and } b'' \equiv 0 \pmod{\pi}.$

<!-- label: eq:III.XVI.1.1.3 -->

(One may take, for example,  $(1, 0)$  and  $(1 + \pi^2, \pi + \pi^3)$ .)

The quotient groups  $G' = G_1/N$  and  $G'' = G_1/N''$  are representable (Exp. V 4.1). Let  $u$  be the canonical morphism

$$u : G_1 \rightarrow G' \times_S G'',$$

and let  $H$  be the group subscheme of  $G' \times_S G''$  equal to the schematic closure in  $G' \times_S G''$  of  $u^{-1}(G_1)$ , so that  $u$  factors through  $H$ . The kernel of  $u$  is  $K = N \cap N''$ , whose generic fiber is the unit group and whose closed fiber is equal to  $N_s$ ; in particular,  $K$  is not flat over  $S$ . On the generic fiber,  $u$  is therefore an isomorphism of  $G_1$  onto  $H$ . On the other hand, I claim that  $H_s$  is not smooth. Indeed, if  $H_s$  were smooth, then since  $u$  is a morphism with finite kernel and  $G_1$  and  $H_s$  have the same dimension (namely 1),  $u$  would be a flat morphism; since  $G_1$  and  $H$  are flat,  $u$  would be a flat morphism and consequently  $\text{Ker } u$  would be flat over  $S$ , which is not the case. It is clear that the restriction of  $u$  to the connected component  $G'_s$  of  $G_1$  is a monomorphism (the fibers of  $K \cap G'_s$  are unit groups, so  $K \cap G'_s$  is the unit group (Exp. VI\_B 2.9)), but it is not an immersion (otherwise it would be an open immersion and  $H_s$  would be smooth). <!-- original page 487 --> Here, Exp. VIII 7.9 does not apply, since  $G_2 = G$  is not finite over  $S$ .

For lovers of equations, let us say that in the example above one may take for  $H$  the closed subgroup of  $(\mathbb{G}_a \times_S \mathbb{G}_a)$  with ring  $A[V, W]/(F)$ , where

$$F = (a'b' - b'a')(a'^2V - a'^2W) - (a''V - a'W)^2$$

(where  $a', a'', b', b''$  satisfy (3)). For  $G$ , one takes the group  $(\mathbb{G}_a)$  with ring  $A[T]$ , and for morphism  $u : G \rightarrow H$  the  $S$ -morphism defined by the maps

$$V \mapsto a'(a'T + \pi T^2), \quad W \mapsto a''(a'T + \pi T^2).$$

**Remark 1.2.** The preceding construction is inspired by the method of Koizumi–Shimura.[^N.D.E-XVI-1] It does not apply when  $S$  is the spectrum of a ring of unequal characteristic, the points of finite order of  $G$  being then "too rigid".

<!-- label: III.XVI.1.2 -->

### 1.3. Statement of the immersion criterion.

<!-- label: III.XVI.1.3 -->

**Theorem 1.3.** Let  $S$  be a locally noetherian prescheme,  $G$  an  $S$ -group prescheme, smooth over  $S$ , of finite type, possessing locally for the fpqc topology Cartan subgroups (Exp. XV 6.1 and 7.3 (i)),  $H$  an  $S$ -group prescheme locally of finite type,  $u : G \rightarrow H$  an  $S$ -group monomorphism. Then:

a) If  $G$  has connected fibers, in order that  $u$  be an immersion, it is necessary and sufficient that for every  $S$ -scheme  $S'$  which is the spectrum of a complete discrete valuation ring with algebraically closed residue field, and for every Cartan subgroup  $C$  of  $G_{S'}$ , the restriction of  $u_{S'}$  to  $C$  be an immersion.\*

b) In order that  $u$  be an immersion (resp. a closed immersion), it is necessary and sufficient that for every  $S'$  as above and every Cartan subgroup  $C$  of the connected component  $(G_{S'})^0$  of  $G_{S'}$ , the restriction of  $u_{S'}$  to the normalizer (Exp. XI 6.11)  $N$  of  $C$  in  $G_{S'}$  be an immersion (resp. a closed immersion).\*

<!-- label: III.XVI.1.3 -->

<!-- original page 488 -->

Before proving 1.3, let us state some applications.

**Corollary 1.4.** Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth over  $S$ , of finite presentation over  $S$ , of zero unipotent rank (Exp. XV 6.1 ter) and possessing locally for the fpqc topology maximal tori,  $H$  an  $S$ -group prescheme,  $u : G \rightarrow H$  an  $S$ -group monomorphism. Suppose further that either  $H$  is of finite presentation over  $S$ , or  $S$  is locally noetherian and  $H$  locally of finite type. Then:

a) If  $G$  has connected fibers,  $u$  is an immersion.

b) If  $H$  is separated over  $S$  and if for every  $S'$  over  $S$  and every maximal torus  $T$  of  $G_{S'}$  the Weyl group

$$W = \text{Norm}_{G_{S'}}(T) / \text{Centr}^0_{G_{S'}}(T)$$

is representable (a condition always realized if  $G$  has connected fibers (Exp. XV 7.1 (iv))) and is finite over  $S$ , then  $u$  is a closed immersion.

<!-- label: III.XVI.1.4 -->

**Corollary 1.5.** Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth over  $S$ , of finite presentation over  $S$ , with connected fibers,  $H$  an  $S$ -group prescheme,  $u : G \rightarrow H$  an  $S$ -group monomorphism. Suppose either  $H$  of finite presentation over  $S$ , or  $S$  locally noetherian and  $H$  locally of finite type. Then:

<!-- original page 489 -->

a) If  $G$  is reductive, i.e. is affine over  $S$  with reductive fibers (cf. Exp. XIX),  $u$  is an immersion, and a closed immersion if  $H$  is separated.

b) If  $G$  has affine, solvable, connected fibers, of zero unipotent rank,  $u$  is an immersion, and a closed immersion if  $H$  is separated.

<!-- label: III.XVI.1.5 -->

**Proof of 1.4 from 1.3.**

**Reduction to the noetherian case.** If  $S$  is locally noetherian, the reduction is immediate, the properties to prove being local on  $S$ . In the second case,  $G$  and  $H$  are of finite presentation over  $S$ . Replacing  $S$  by a smaller open if necessary, we may assume  $S$  affine. By Exp. VI\_B § 10, there exist a noetherian scheme  $S_0$ , an  $S_0$ -group prescheme  $G_0$  smooth over  $S_0$  (with connected fibers in case a)), of finite type over  $S_0$ , an  $S_0$ -group prescheme  $H_0$  of finite type (separated in case b)), and an  $S_0$ -group morphism

$$u_0 : G_0 \rightarrow H_0,$$

such that  $G$ ,  $H$ ,  $u$  are obtained from  $G_0$ ,  $H_0$ ,  $u_0$  by a base extension  $S \rightarrow S_0$ . The fact that  $u$  is a monomorphism translates to  $\text{Ker } u = \text{unit group}$ ; we may therefore assume that  $u_0$  is a monomorphism. Since  $G$  has zero unipotent rank  $\rho_u$  and possesses, locally for the fpqc topology, maximal tori, the abelian rank  $\rho_{ab}$  of the fibers of  $G$  is locally constant (Exp. XV 8.18). But  $\rho_u$  and  $\rho_{ab}$  are locally constructible functions (Exp. XV 6.3 bis). A standard argument (cf. EGA IV 8.3.4) shows that one may choose  $S_0$  and  $G_0$  so that the unipotent rank (resp. the abelian rank) of the fibers of  $G_0$  is zero (resp. locally constant). But then  $G_0$  possesses locally maximal tori for the fpqc topology (Exp. XV 8.18), and <!-- original page 490 --> the functor  $\mathcal{TM}_{G_0}$  of maximal tori of  $G_0$  is representable by an  $S_0$ -scheme  $X_0$ , of finite type over  $S_0$  (Exp. XV 8.15). Let  $T_0$  be the "universal" maximal torus of  $(G_0)_{X_0}$ ,  $X_0$  the  $S_0$ -prescheme  $X_0 \times_{S_0} S$ ,  $T = T_0 \times_{S_0} S$  the universal maximal torus for  $G$ . By hypothesis, in case b), the Weyl group relative to  $T$  is representable and finite over  $X_0$ . These two properties are compatible with projective limits of preschemes (Exp. VI\_B 10.1 iii) and EGA IV 8.10.5). One may therefore choose  $S_0$  so that the Weyl group of  $T_0$  is finite over  $X_0$ . Under these conditions it is clear that to prove 1.4 we may replace  $S$ ,  $G$ ,  $u$ ,  $H$  by  $S_0$ ,  $G_0$ ,  $u_0$ ,  $H_0$ , hence assume  $S$  noetherian.

Let us use the valuative criterion provided by 1.3. We are reduced to the case where  $S$  is the spectrum of a discrete valuation ring and where  $G_0$  possesses a Cartan subgroup  $C_0$ .

\*Proof of 1.4 a).\* We must show that the restriction of  $u$  to  $C$  is an immersion (1.3 a)), which reduces us to the case where  $G = C$  has nilpotent connected fibers. Standard reductions (cf. Exp. VIII proof of 7.1) reduce us to the case where  $H$  is flat over  $S$ ,  $u$  is an isomorphism on the generic fiber, and  $u$  is an isomorphism of underlying spaces on the closed fiber. The group  $H$  is then with connected fibers, hence separated over  $S$  (Exp. VI\_B 5.2). Granting for a moment the lemma:

**Lemma 1.6.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth over  $S$ , with connected, nilpotent fibers, of zero unipotent rank. Then:

<!-- label: III.XVI.1.6 -->

i)  $G$  is commutative.

ii) For every integer  $n > 0$ ,  $G_n$  is a group prescheme, flat, quasi-finite over  $S$ , finite over  $S$  if and only if the abelian rank, or the reductive rank, of  $G$  is locally constant on  $S$ .

iii) For every integer  $q > 0$  invertible on  $S$ , the family of subgroups  $G_n^{(q)}$  is universally schematically dense in  $G$  relative to  $S$  (EGA IV 11.10.8).

<!-- original page 491 -->

Lemma 1.6 applies to the group  $G$ , and since  $G$  possesses locally maximal tori, the reductive rank of the fibers of  $G$  is locally constant; hence (1.6 ii)), for every integer  $n > 0$ ,  $G_n$  is finite over  $S$ . The fact that  $u$  is an immersion then follows from Exp. VIII 7.9.

**Proof of 1.6.** Let us first examine the case where  $S$  is the spectrum of a field:

**Lemma 1.7.** \*Let  $k$  be a field of characteristic  $p$ ,  $G$  an algebraic  $k$ -group, smooth, connected, nilpotent, of zero unipotent rank. Then  $G$  is a commutative group, extension of an abelian variety  $A$  by a torus  $T$ . For every integer  $n > 0$ ,  $G_n$  is a finite group, étale if  $(n, p) = 1$ , defined by a  $k$ -algebra of rank  $n^{\rho} + 2\rho_{ab}$ . If  $(q, p) = 1$ , the family of subgroups  $G_n^{(q)}$  ( $n \in \mathbb{N}$ ) is schematically dense in  $G$ .

<!-- label: III.XVI.1.7 -->

**Proof of 1.7.** Let  $Z$  be the center of  $G$ . The group  $G/Z$  is affine (Exp. XII 6.1), of zero unipotent rank, smooth and connected, hence is a torus (\*Bible\* 4 th. 4); but then  $G$  is commutative (Exp. XII 6.4). If  $T$  is the unique maximal torus of  $G$  (Exp. XV 3.4), it follows at once from Chevalley's theorem (Sém. Bourbaki 1956/57, No. 145) that  $G$  is an extension of an abelian variety  $A$  by  $T$ . For every integer  $n > 0$ , raising to the  $n$ th power is an epimorphism in  $T$ ; one deduces an exact sequence

```

```text
0 →  $n$  T →  $n$  G →  $n$  A → 0.
```

```

A classical theorem of Weil (A. Weil: *Variétés abéliennes et courbes algébriques*, § IX th. 33 cor. 1) tells us that  $A_n$  is a finite group defined by a  $k$ -algebra of rank  $n^{2\rho_{ab}}$ . Since  $T_n$  is a finite group of rank  $n^{\rho}$ , one deduces the announced structure of  $G_n$ .

Now let  $H$  be the smallest closed subscheme of  $G$  majorizing  $G_n^{(q)}$  for every  $n$ . It follows from the foregoing and from Exp. XV 4.6 that  $H$  is a smooth, connected subgroup, hence of the same type as  $G$ . Raising to the  $n$ th power in  $H$  is an epimorphism (since  $H_n^{(q)}$  is finite), so that one has the exact sequence

```

```text
0 →  $q$  H →  $q$  G →  $q$ (G/H) → 0.
```

```

It follows that  $G_n^{(q)}(G/H) = 0$ , hence  $G/H = 0$ . That is to say, the subgroups  $G_n^{(q)}$  are schematically dense in  $G$ .

<!-- original page 493 -->

\*Continuation of the proof of 1.6 i).\* To show that  $G$  is commutative, we reduce by the usual procedure to the case where  $S$  is noetherian, then to the case where  $S$  is the spectrum of a local ring with closed point  $s$ . The center of

$G_S$  is representable by a closed group subscheme  $Z_S$  of  $G_S$  (Exp. XI 6.11). To show that  $Z = G_S$ , it suffices to show that  $Z = G_S$  after reduction by every power of the maximal ideal of the ring of  $S_S$  (for  $Z_S$  will then be an open subgroup of  $G_S$ , hence equal to  $G_S$  since  $G_S$  has connected fibers). This reduces us to the case where  $S_S$  is local artinian.

Let  $q_S$  be an integer invertible on  $S_S$ . For every integer  $n_S$ ,  $\{q^{n_S}G_S\}$  is a subgroup of multiplicative type of  $G_S$ , étale and central (1.7). Since  $G_S$  is smooth,  $\{q^{n_S}G_S\}$  lifts to an  $S_S$ -group subscheme étale and central  $M_{n_S}$  of  $G_S$  (Exp. XV 1.2). The family of flat subgroups  $M_{n_S}$ ,  $n_S \in \mathbb{N}$ , is then schematically dense in  $G_S$  (1.7 and EGA IV 11.10.9). Since  $Z_S$  is closed in  $G_S$  and majorizes all the  $M_{n_S}$ , we have  $Z = G_S$ .

\*1.6 ii).\* To see that  $\{q^{n_S}G_S\}$  is flat and quasi-finite over  $S_S$ , it suffices to show that raising to the  $n_S$ th power in  $G_S$  is a flat and quasi-finite morphism. Since  $G_S$  is flat over  $S_S$ , we are reduced to the case where  $S_S$  is the spectrum of a field (EGA IV 11.3.10), and we noted in the proof of 1.7 that raising to the  $n_S$ th power was an epimorphism. Moreover  $\{q^{n_S}G_S\}$  is separated over  $S_S$ , since  $G_S$  is separated over  $S_S$  (Exp. VI\_B <!-- original page 494 --> 5.2). For  $\{q^{n_S}G_S\}$  to be finite over  $S_S$ , it is necessary and sufficient that the fibers of  $\{q^{n_S}G_S\}$  be the spectra of finite algebras, of locally constant rank (one sees this immediately by reducing to the case where  $S_S$  is the spectrum of a henselian local ring). But, by 1.7, this condition amounts to saying that the abelian rank, or the reductive rank, of the fibers of  $G_S$  is locally constant.

\*1.6 iii).\* To see that the family of subgroups  $\{q^{n_S}G_S\}$  ( $n_S \in \mathbb{N}$ ) is universally schematically dense in  $G_S$ , we again reduce to the case  $S_S$  noetherian. Taking 1.7 and 1.6 b) into account, it suffices to apply EGA IV 11.10.9.

**Proof of 1.4 b).** We have reduced to the case where  $S_S$  is the spectrum of a discrete valuation ring and where  $G_{\{0\}}$  possesses a Cartan subgroup  $C_S$ . Let  $N = \text{Norm}_{G_S} C_S = \text{Norm}_{G_S} T_S$ , where  $T_S$  is the unique maximal torus of  $C_S$  (Exp. XII 7.1 a) and b)). Since  $H_S$  is separated over  $S_S$ , it follows from 1.6 ii) and from Exp. VIII 7.12 that the restriction of  $\mathcal{U}_S$  to  $C_S$  is a closed immersion. On the other hand, to prove that  $\mathcal{U}_S$  is a closed immersion, it suffices to show that this is the case for  $\mathcal{U}_N$  (1.3 b)). Since by hypothesis  $\mathcal{W} = N/C_S$  is representable by a finite group scheme, this will follow from the following lemma, applied to the exact sequence

$$0 \rightarrow C \rightarrow N \rightarrow W \rightarrow 1$$

(note that a proper immersion is a closed immersion).

**Lemma 1.8.** \*Let  $S_S$  be a prescheme,  $G_S$  an  $S_S$ -group prescheme of finite presentation over  $S_S$ , extension of a group prescheme  $G''_S$ , proper and of finite presentation over  $S_S$ , by a group prescheme  $G'_S$ , of finite presentation and flat over  $S_S$ .\*

<!-- label: III.XVI.1.8 -->

<!-- original page 495 -->

$$1 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 1.$$

\*Let on the other hand  $H_S$  be an  $S_S$ -group prescheme of finite presentation over  $S_S$  (or locally of finite presentation if  $S_S$  is locally noetherian) and  $\mathcal{U} : G \rightarrow H_S$  an  $S_S$ -group morphism. Then if the restriction of  $\mathcal{U}_S$  to  $G'_S$  is proper,  $\mathcal{U}_S$  is proper.\*

**Proof of 1.8.** We reduce as usual to the case where  $S_S$  is noetherian (Exp. VI\_B § 10 and Exp. XV 6.2) and we may then apply the valuative criterion of properness (EGA II 7.3.8). We therefore suppose that  $S_S$  is the spectrum of a discrete valuation ring  $\mathcal{A}_S$ , with closed point  $s_S$  and generic point  $t_S$ . Let  $x_S \in G(t_S)$  and  $h_S \in H(s_S)$  be such that  $\mathcal{U}_{t_S}(x_S) = h_S$ . We must show that  $x_S$  comes from a unique element  $x_S$  of  $G(s_S)$ . It even suffices to prove the existence and uniqueness of  $x_S$  after a faithfully flat extension of the discrete valuation ring  $\mathcal{A}_S$ . Now let  $y_S$  be the projection of  $x_S$  in  $G''(t_S)$ . Since  $G''_S$  is proper over  $S_S$ ,  $y_S$  comes from a unique element  $y_S$  of  $G''(s_S)$ . Let  $X_S$  be the inverse image of  $y_S$  in  $G_S$ . The prescheme  $X_S$  is faithfully flat over  $S_S$  (since  $G'_S$  is faithfully flat over  $S_S$  as is the morphism  $G \rightarrow G''_S$  (Exp. VI\_B § 9)). Replacing if necessary the discrete valuation ring by a faithfully flat one, we may assume that  $X_S$  has a section  $\ell_S$  over  $S_S$  (EGA IV 14.5.8). Replacing  $x_S$  by  $x_S \ell_S^{-1}$ , we may assume that  $x_S \in G'(t_S)$ . But then the existence and uniqueness of  $x_S$  follow from the fact that  $\mathcal{U}|_{G'_S}$  is proper.

**Proof of 1.5.**

<!-- original page 496 -->

- a) We shall see in Exp. XIX that if  $G$  is reductive,  $G$  possesses locally for the faithfully flat topology maximal tori, has a finite Weyl group, and has zero unipotent rank. Assertion a) follows, in view of 1.4.
- b) If  $G$  has affine fibers of zero unipotent rank,  $G$  possesses maximal tori locally for the fpqc topology (Exp. XV 8.18). It then suffices to apply 1.4, taking into account the fact that  $G$ , having connected, smooth, affine, solvable fibers, has unit Weyl group (\*Bible\* 6 th. 1 cor. 3).

**\*\*Proof of 1.3 a).\*\***

Since the morphism  $u$  is already a monomorphism, in order to see that  $u$  is an immersion, it suffices to show that  $u$  is proper at the points of  $u(G)$  (EGA IV 15.7.1); for that we may use the valuative criterion of local properness (EGA IV 15.7.5). We are thus reduced to the case where  $S$  is the spectrum of a complete discrete valuation ring with algebraically closed residue field, with closed point  $s$  and generic point  $t$ . Since  $G$  is flat over  $S$ , standard reductions (cf. Exp. VIII proof of 7.1) allow us to reduce to the case where  $H$  is flat over  $S$ ,  $u_t$  is an isomorphism, and  $u_s$  is an isomorphism of underlying spaces. To say that  $u$  is an immersion is then equivalent to saying that  $u$  is an isomorphism.

By hypothesis, the group  $G$  possesses locally Cartan subgroups for the fpqc topology, so we may speak of the open set  $U$  of regular points of  $G$  <!-- original page 497 --> (Exp. XV 7.3 i) and ii)).

**\*\*Lemma 1.9.\*\*** \*With the preceding hypotheses, in order that  $u$  be an immersion, it suffices that  $u|_U$  be an immersion.\*

<!-- label: III.XVI.1.9 -->

Indeed, to say that  $u|_U$  is an immersion means that there exist an open  $V$  of  $H$  and a closed  $F$  of  $V$  such that  $u|_U$  factors through  $F$  and induces an isomorphism of  $U$  onto  $F$ . Since  $H_t$ , and hence also  $V_t$ , is irreducible, one necessarily has  $V_t = F_t$ . But then  $F_t$  majorizes the schematic closure of  $V_t$  in  $V$ , which is equal to  $V$  since  $H$  is flat over  $S$ . In short,  $\bar{V} = F$ . It follows that  $u|_U$  is an open immersion, hence  $u$  is an open immersion (VI\_B 2.6).

It remains to show that  $u|_U$  is an immersion, and for that we apply the valuative criterion of local properness. Replacing  $S$  by the spectrum of a faithfully flat discrete valuation ring, we must show that if  $h$  is a section of  $H$  over  $S$  whose image  $h(S)$  is contained in  $u(U)$ , then  $h$  is the image of a section  $g$  of  $U$  over  $S$ . It suffices to show that  $h$  is contained in the image of a Cartan subgroup  $C$  of  $G$ . Indeed, by hypothesis  $u|_C$  is an immersion, so  $h$  is the image of a section  $g$  of  $C$ , which is necessarily a section of  $U$ .

<!-- original page 498 -->

Let  $a \in U(s)$  (resp.  $b \in U(t)$ ) be such that  $u_s(a) = h(s)$  (resp.  $u_t(b) = h(t)$ ). Since  $u_t$  is an isomorphism,  $h(t)$  is a regular point of  $H_t$ , so is contained in a unique Cartan subgroup  $D_t$  of  $H_t$  (Exp. XIII 3.2). Let  $D$  be the schematic closure of  $D_t$  in  $H$ .

**\*\*Lemma 1.10.\*\*** \*i)  $D_s$  is a nilpotent algebraic group (Exp. VI\_B § 8).\*

<!-- label: III.XVI.1.10 -->

\*ii)  $\dim D_s = \nu = \text{nilpotent rank of } G = \text{nilpotent rank of } (H_s)_{\text{red}}$ .\*

\*iii)  $h(s) \in D_s(\kappa(s))$ .\*

i) Since  $H$  is separated (Exp. VI\_B 5.2), so is  $D$ . Moreover,  $D$  is flat over  $S$ , and its generic fiber is nilpotent. The fact that  $D_s$  is nilpotent then follows from Exp. VI\_B 8.4.

ii) Since  $(H_s)_{\text{red}} \not\subseteq G_s$ , these two groups have the same nilpotent rank. Since  $G$  possesses, locally for the fpqc topology, Cartan subgroups,  $G_s$  and  $G_t$  have the same nilpotent rank  $\nu$ . Finally, since  $D$  is flat over  $S$ , one has  $\dim D_s = \dim D_t = \nu$  (Exp. VI\_B § 4).

c) Since  $h_t$  factors through  $D_t$ ,  $h$  evidently factors through  $D$ , whence iii).

This being said, the following lemma proves that  $(D_s)_{\text{red}}$  is a Cartan subgroup of  $(H_s)_{\text{red}} \cong G_s$ :

**\*\*Lemma 1.11.\*\*** \*Let  $G$  be a smooth and connected algebraic group defined over an algebraically closed field  $k$ ,  $D$  a

smooth nilpotent algebraic subgroup containing a regular element  $a$  of  $G(k)$ . Then  $D^{\{0\}}$  is contained in a Cartan subgroup of  $G$ . If moreover  $\dim D$  is equal to the nilpotent rank of  $G$ , then  $D$  is a Cartan subgroup of  $G$  (and hence is connected).\*

<!-- label: III.XVI.1.11 -->

<!-- original page 499 -->

Let  $Z$  be the center of  $G$ ,  $G' = G/Z$  (which is affine, Exp. XII 6.1),  $a'$ ,  $D'$  the images of  $a$ ,  $D$  in  $G'$ . It follows immediately from the correspondence between Cartan subgroups of  $G$  and Cartan subgroups of  $G'$  (Exp. XII 6.6 e)) that  $a'$  is a regular element of  $G'$  and that it suffices to prove the lemma for the pair  $D'$ ,  $G'$ ; this allows us to assume  $G$  affine.

Let  $s$  then be the semisimple component of  $a$ , which belongs to  $D(k)$  (\*Bible\* 4 th. 3) and is regular (\*Bible\* 7 th. 2 cor. 1). By \*Bible\* 6 th. 2,  $s$  centralizes  $D^{\{0\}}$ , hence  $D^{\{0\}}$  is contained in the connected centralizer of  $s$ , which is a Cartan subgroup of  $G$  (\*Bible\* 7 th. 2). If now  $\dim D =$  nilpotent rank of  $G$ ,  $D^{\{0\}}$  is therefore a Cartan subgroup of  $G$ , equal to  $\text{Centr}_{\{G\}}(T)$ , where  $T$  is the unique maximal torus of  $D^{\{0\}}$  (Exp. XII 6.6). But  $D$  is nilpotent, hence centralizes  $T$  (\*Bible\* 6 th. 2), hence  $D = D^{\{0\}}$ .

Let us now work with the group  $G$ . The group  $C_{\{t\}} = u^{-1}_{\{t\}}(D_{\{t\}})$  is the unique Cartan subgroup of  $G_{\{t\}}$  containing  $b$ . Let  $C$  be the schematic closure of  $C_{\{t\}}$  in  $G$ .

By functoriality of the schematic closure,  $u|_C$  factors through  $D$ , so  $u_{\{s\}}(C_{\{s\}}) \subset D_{\{s\}}$ . Since  $u_{\{s\}}$  is an isomorphism of  $G_{\{s\}}$  onto  $(H_{\{s\}})_{\text{red}}$ , since  $\dim C_s = \dim C_t = v = \dim D_s$  (1.10), and since  $D_{\{s\}}$  is connected (1.11),  $u_{\{s\}}$  furnishes an isomorphism of  $(C_{\{s\}})_{\text{red}}$  onto  $(D_{\{s\}})_{\text{red}}$ , hence  $(C_{\{s\}})_{\text{red}}$  is a Cartan subgroup of  $G_{\{s\}}$ . <!-- original page 500 --> The following lemma shows that  $C$  is in fact a Cartan subgroup of  $G$ .

**\*Lemma 1.12.\*** \*Let  $S$  be the spectrum of a discrete valuation ring,  $G$  an  $S$ -group prescheme smooth, of finite type,  $C$  a group sub-prescheme of  $G$ , flat over  $S$ , such that the generic fiber  $C_{\{t\}}$  is a Cartan subgroup of  $G_{\{t\}}$  and the geometric reduced closed fiber  $(C_{\{s\}})_{\text{red}}$  is a Cartan subgroup of  $G_{\{s\}}$ . Then  $C$  is a Cartan subgroup of  $G$ .\*

<!-- label: III.XVI.1.12 -->

We must show that  $C$  is smooth over  $S$ , and it suffices to establish this point after a faithfully flat extension of the base. The hypotheses on  $C$  imply that the nilpotent rank of the fibers of  $G$  is constant, and we may therefore speak of the open set  $U$  of regular points of  $G$  (Exp. XV 7.3). Since  $(C_{\{s\}})_{\text{red}}$  is a Cartan subgroup of  $G_{\{s\}}$ ,  $C_{\{s\}}$  contains a regular point  $a_{\{s\}}$  of  $G_{\{s\}}$ . But  $C$  is flat over  $S$ , so (EGA IV 14.5.8), replacing the base by a faithfully flat extension if necessary, we may assume that  $a_{\{s\}}$  is an element of  $G(s)$  lifting to a section  $a$  of  $C(S)$ . Since  $U$  is open and contains  $a(s)$ ,  $U$  contains  $a$ . Let  $C'$  be the unique Cartan subgroup of  $G$  containing  $a$  (Exp. XV 7.3). One necessarily has  $C_{\{t\}} = C'_{\{t\}}$ , and consequently  $C'$  and  $C$  coincide with the connected component of the schematic closure of  $C_{\{t\}}$  in  $G$  (note that  $C'$  and  $C$  are flat over  $S$ ).

<!-- original page 501 -->

**\*\*End of the proof of 1.3 a).\*\*** By hypothesis, the restriction of  $u$  to the Cartan subgroup  $C$  of  $G$  is an immersion. It is clear that  $h(S)$  is contained in  $u(C) = D$ , hence  $h$  is the image of a section  $g$  of  $C(S)$ . QED.

**\*\*Proof of 1.3 b).\*\***

We shall again use the valuative criterion of local properness (EGA IV 15.5) in the case of an immersion (resp. the valuative criterion of properness (EGA II 7.3.6) in the case of a closed immersion). This reduces us to the case where  $S$  is the spectrum of a complete discrete valuation ring with algebraically closed residue field. Let  $s$  be the closed point and  $t$  the generic point of  $S$ . Replacing  $H$  by the schematic closure in  $H$  of  $u_{\{t\}}(G_{\{t\}})$ , we may assume that  $H$  is flat over  $S$  and that  $u_{\{t\}}$  is an isomorphism.

Let  $G^{\{0\}}$  be the connected component of  $G$ . By 1.2 a) [XVI-1],  $u|_{G^{\{0\}}}$  is an immersion; denote by  $H^{\{0\}}$  the group sub-prescheme of  $H$  image of  $G^{\{0\}}$ . One has therefore  $H^{\{0\}}_{\{s\}} = (H_{\{s\}})^{\{0\}}_{\text{red}}$ .

To verify the valuative criterion, we must show that every section  $h$  of  $H$  over  $S$  such that  $h(S)$  is contained in  $u(G)$  in the case of an immersion (resp. every section  $h$  of  $H$  over  $S$  in the case of a closed immersion) is the image of a section  $g$  of  $G$  over  $S$ .

Let  $C$  be a Cartan subgroup of  $G$ ,  $D = u(C)$  the Cartan subgroup of  $H^{\{0\}}$  image of  $C$ . <!-- original page 502 --> The  $S$ -group  $D' = \text{int}(h)D$  has connected fibers, hence its underlying space is contained in that of  $H^{\{0\}}$ ; moreover,

being smooth over  $S$ , it is reduced, and consequently  $D$  is a smooth group sub-prescheme of  $H^0$ . The fibers of  $D$  are Cartan subgroups of the fibers of  $H^0$ , so  $D$  is a Cartan subgroup of  $H^0$ , and  $C' = u^{-1}(D)$  is a Cartan subgroup of  $G$ . But  $\text{Transp}^{\text{str}}_G(C, C')$  is smooth and surjective over  $S$  (Exp. XII 7.1 b)). Since  $S$  is henselian with algebraically closed residue field, there exists  $g \in G(S)$  such that  $\text{int}(g)C = C'$ . Replacing  $h$  by  $u(g)^{-1}h$ , we may assume that  $h(t)$  normalizes  $D_t$  (and that  $h(s)$  is the image of an element of the normalizer of  $C_s$  in  $G_s$  in the case of an immersion). Let  $N = \text{Norm}_G(C)$ . By hypothesis  $u|_N$  is an immersion (resp. a closed immersion), so  $h$  is the image of a section of  $N$  over  $S$ , which completes the proof.

## 2. A representability theorem for quotients

<!-- label: III.XVI.2 -->

<!-- original page 503 -->

Let us "recall" the following result:

**Theorem 2.1.** \*Let  $S$  be a prescheme,  $X$  and  $Y$  two  $S$ -preschemes,  $f : X \rightarrow Y$  an  $S$ -morphism. Suppose we are in one of the following two cases:\*

<!-- label: III.XVI.2.1 -->

a) The morphism  $f$  is locally of finite presentation.\*

b) The prescheme  $S$  is locally noetherian and  $X$  is locally of finite type over  $S$ .\*

\*Then the following conditions are equivalent:\*

i) There exist an  $S$ -prescheme  $X'$  and a factorization of  $f$ :

```

```text
f : X →f'→ X' →f''→ Y,
```

```

\*where  $f'$  is a faithfully flat  $S$ -morphism, locally of finite presentation, and  $f''$  is a monomorphism.\*

ii) The (first) projection\*

```

```text
p1 : X ×Y X → X
```

```

\*is a flat morphism.\*

Moreover, if the preceding conditions are satisfied,  $(X', f')$  is a quotient of  $X$  by the equivalence relation defined by  $f$  (for the fpqc topology), so that the factorization  $f = f'' \circ f'$  of i) is unique up to isomorphism.\*

The proof of this delicate theorem will be found in EGA V; one may also consult the lecture by J.-P. Murre, \*Séminaire Bourbaki\*, May 1965, No. 294 th. 2 cor. 2, where the case  $Y$  locally noetherian,  $X$  of finite type over  $Y$  is treated. <!-- original page 504 --> We shall see that one may reduce to this case.

Let us first make some remarks:

a) i)  $\Rightarrow$  ii) is trivial. Indeed, the first projection

```

```text
p'1 : X ×{X'} X → X
```

```

factors through  $X \times_{\{Y\}} X$ :

```

```text
p'1 : X ×{X'} X →u→ X ×Y X →p1→ X.
```

```

The morphism  $u$  is an isomorphism, since  $f''$  is a monomorphism, and  $p'_1$  is flat, since  $f'$  is flat, so  $p_1$

is flat.

b) The assertions of 2.1 are local on  $Y$  (and so are local on  $S$ ); they are also local on  $X$ , as follows easily from the fact that a flat morphism locally of finite presentation is open (EGA IV 11.3.1).

c) Under the hypotheses of 2.1 a), in view of the foregoing, we are reduced to the case where  $X$  and  $Y$  are affine and  $f$  of finite presentation. Replacing  $S$  by  $Y$ , we may assume  $X$  and  $Y$  of finite presentation over  $S$ . We then reduce to the case  $S$  noetherian thanks to EGA IV 11.2.6.

d) Under the hypotheses of 2.1 b), we may assume  $S$ ,  $X$ ,  $Y$  affine,  $S$  noetherian and  $X$  of finite type over  $S$ . Consider  $Y$  as a filtered projective limit of affine schemes  $Y_{\{i\}}$  of finite type over  $S$ . The schemes  $X \times_{Y_{\{i\}}} X$  form a decreasing filtered family of closed subschemes of  $X \times_S X$ , whose projective limit is  $X \times_Y X$ . Since  $X \times_S X$  is noetherian, one has  $X \times_{Y_{\{i\}}} X = X \times_Y X$  for  $i$  large enough, so that

```
```text
f_i : X --f--> Y -> Y_i
```
```

satisfies the hypotheses of 2.1 ii) if  $f$  does. <!-- original page 505 --> Since the equivalence relation defined by  $f$  on  $X$  coincides with that defined by  $f_{\{i\}}$ , it is clear that it suffices to prove ii)  $\Rightarrow$  i) for  $f_{\{i\}}$ , which reduces us to the case where  $Y$  is of finite type over  $S$ .

### Application to group preschemes

**Theorem 2.2.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme locally of finite presentation over  $S$ , acting on an  $S$ -prescheme  $X$ . Let  $\xi \in X(S)$  be a section of  $X$  over  $S$  such that the stabilizer  $H$  of  $\xi$  in  $G$  is an  $S$ -group sub-prescheme of  $G$ , flat over  $S$ . Then, if  $X$  is locally of finite type over  $S$ , or if  $S$  is locally noetherian, the homogeneous space quotient  $G/H$  is representable by an  $S$ -prescheme, locally of finite presentation over  $S$ , and the  $S$ -morphism\*

<!-- label: III.XVI.2.2 -->

```
```text
f : G -> X,      g -> g . xi
```
```

\*factors as\*

```
```text
      G
     / \
    p   f
   /   \
  G/H --i--> X,
```
```

\*where  $p$  is the canonical projection, which is a faithfully flat morphism locally of finite presentation, and  $i$  is a monomorphism. (For definiteness, we have assumed that  $G$  acts on the left on  $X$ .)\*

**Proof.** The morphism  $f$  makes  $G$  into an  $X$ -prescheme. <!-- original page 506 --> By definition of the stabilizer of  $\xi$ , the morphism

```
```text
G x_S H -> G x_X G,      (g, h) -> (g, gh)
```
```

is an isomorphism. Since  $H$  is flat over  $S$ ,  $G \times_S H$  is flat over  $G$ , so the first projection  $p_{\{1\}} : G \times_S H \rightarrow G$  is a flat morphism. Furthermore, if  $X$  is locally of finite type over  $S$ ,  $f$  is locally of finite presentation (EGA IV 1.4.3 v)); otherwise  $S$  is assumed locally noetherian. It then suffices to apply 2.1 to the morphism  $f$ .

It remains to see that  $G/H$  is locally of finite presentation over  $S$ , but this follows immediately from Exp. V 9.1.

**\*\*Corollary 2.3.\*\*** \*Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -group preschemes,  $u : G \rightarrow H$  an  $S$ -homomorphism. Suppose  $G$  locally of finite presentation over  $S$  and that either  $H$  is locally of finite type over  $S$ , or  $S$  is locally noetherian. Then, if  $K = \text{Ker}(u)$  is flat over  $S$ , the quotient group  $G/K$  is representable by an  $S$ -group prescheme locally of finite presentation over  $S$ , and  $u$  factors as\*

<!-- label: III.XVI.2.3 -->

```

```text
      G  --u--> H
       \      ^
        p      i
         \      ^
          G/K
...

```

where p is the canonical projection and i a monomorphism.

****Proof.**** One applies 2.2 with $X = H$ and ξ the unit section of H .

****Corollary 2.4.**** *Let S be a prescheme, G an S -group prescheme of finite presentation over S , H an S -group prescheme smooth over S with connected fibers (hence of finite presentation over S , by VI_B 5.5), $i : H \rightarrow G$ a monomorphism of S -groups, so that H is a subgroup of G .*

<!-- label: III.XVI.2.4 -->

Suppose that $N = \text{Norm}_G(H)$ (which is representable by a closed group sub-prescheme of G , of finite presentation over S (Exp. XI 6.11)) is flat over S . Then G/N is representable by an S -prescheme of finite presentation over S and quasi-projective over S .

All the assertions to be proved, except the last, are local on S . To establish them, we may therefore assume S quasi-compact and the relative dimension of H over S constant and equal to r . Let us proceed as in XV § 5. For every integer $n > 0$, let $G_{(n)}$ (resp. $H_{(n)}$) be the n th normal invariant of the unit section of G (resp. of H) (EGA IV 16). The sheaf of $\mathcal{O}_S$ -modules $H_{(n)}$ is a quotient of $G_{(n)}$, and H being smooth over S of dimension r , $H_{(n)}$ canonically defines an element ξ_n of $X_n = \text{Grass}_{\varphi(n,r)} G_{(n)}$ (EGA I 2nd ed. § 9) for a suitable integer $\varphi(n, r)$. On the other hand, G acts naturally on $G_{(n)}$ (and hence also on X_n) via the representation

```

```text
G → Aut_{S-gr}(G), g ↦ int(g).
...

```

Since  $S$  is quasi-compact, there exists an integer  $m$  such that for  $n \geq m$  one has

```

```text
N = Norm_G(H) = Norm_G H_{(n)}    (Exp. XI 6.11 b)).
...

```

That is to say, N is the stabilizer of ξ_n for n large. <!-- original page 507 --> The representability of G/N therefore follows from 2.2. The fact that G/N is of finite presentation over S is a consequence of Exp. V 9.1. It remains to see that G/N is quasi-projective over S , and for that we shall exhibit a canonical invertible sheaf on G/N , S -ample. Consider the functor $F : (\text{Sch}/S)^{\circ} \rightarrow \text{Ens}$ such that for every S -prescheme T one has

```

```text
F(T) = set of T-subgroups H of G_T, representable, smooth over T,
 with connected fibers.
...

```

Such a group  $H$  is of finite presentation over  $S$  (Exp. VI\_B 5.5) and  $H \rightarrow G_T$  is a quasi-affine morphism (EGA IV 8.11.2). By effective descent of quasi-affine morphisms (SGA 1, VIII 7.9), one deduces that  $F$  is a sheaf for the fpqc topology. Since  $G/N$  is the sheaf associated to a subfunctor of  $F$ , one sees that there is a canonical monomorphism  $G/N \rightarrow F$ . There exists therefore a subgroup  $H_0$  of  $G \times_S (G/N)$ , representable, smooth over  $G/N$ , with connected fibers, "universal" for the functor  $G/N$ . I claim that the invertible sheaf  $\mathcal{L} = (\det(\text{Lie } H_0))^{-1}$  is  $S$ -ample. In this form, the assertion becomes local on  $S$ , and the proof is analogous to the one given in (Exp. XV 5.8).

The following corollary was announced in Exp. XIV 4.8 bis.

**\*\*Corollary 2.5.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with connected fibers,  $P$  a parabolic subgroup of  $G$  (Exp. XIV 4.8 bis). Then  $G/P$  is representable by an  $S$ -prescheme smooth and projective over  $S$ .\*

<!-- label: III.XVI.2.5 -->

<!-- original page 508 -->

It only remains to show (\*loc. cit.\*) that  $G/P$  is representable by an  $S$ -prescheme quasi-projective, of finite presentation, which follows from 2.4, given that  $P = \text{Norm}_G(P)$  (\*loc. cit.\*) is therefore flat over  $S$ .

## 3. Groups with flat center

<!-- label: III.XVI.3 -->

<!-- original page 509 -->

**\*\*Proposition 3.1.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with connected fibers. Suppose that the center  $Z$  of  $G$  (which is representable by Exp. XI 6.11) is flat over  $S$ . For every integer  $n > 0$ , let  $G_{(n)}$  denote the locally free  $\mathcal{O}_S$ -module equal to the  $n$ th normal invariant of  $G$  along the unit section, and let  $\rho_n$  be the natural "adjoint representation" of  $G$  in  $GL_S(G_{(n)})$ . Then:

<!-- label: III.XVI.3.1 -->

a) The quotient  $G' = G/Z$  is representable by an  $S$ -group prescheme, smooth, of finite presentation over  $S$ , quasi-affine, with affine connected fibers.\*

b) The representation  $\rho_n$  factors through  $G'$ :

```
```text
      G  --ρn--> GLS(G(n))
      /      ^
      /       in
      v
    G/Z  ---
...
```
```

If  $S$  is quasi-compact,  $i_n$  is a monomorphism for  $n$  large enough.\*

c) The functor  $\mathcal{T}_{G'}$  of subtori of  $G'$  is representable by an  $S$ -prescheme, smooth over  $S$ , which is a sum of a family of preschemes affine over  $S$  if  $S$  is quasi-compact.\*

**\*\*Proof.\*\*** The assertions of a) are local on  $S$ , which allows us to assume  $S$  quasi-compact. By Exp. XI 6.11 b),  $Z$  is equal to  $\text{Ker } \rho_n$  for  $n$  large enough, so this kernel is flat over  $S$ . The fact that  $G/Z$  is representable and that <!-- original page 510 -->  $i_n$  is a monomorphism therefore follows from 2.3. Since  $G$  is smooth and of finite presentation over  $S$ , the same is true of  $G'$  (Exp. VI B § 9). The group  $GL_S(G_{(n)})$  is affine over  $S$ , and a monomorphism of finite presentation is quasi-affine (EGA IV 8.11.2), hence  $G'$  is quasi-affine over  $S$  and has affine fibers. Since  $G'$  is smooth over  $S$ , the functor  $\mathcal{T}_{G'}$  is formally smooth (Exp. XI 2.1 bis). Taking into account Exp. XI 4.6 and 4.3, the assertions of 3.1 c) will therefore follow from the next lemma:

**\*\*Lemma 3.2.\*\*** \*Let  $S$  be a prescheme,  $G$  and  $H$  two  $S$ -group preschemes of finite presentation over  $S$ ,  $u : G \rightarrow H$  an  $S$ -group monomorphism,  $\mathcal{T}_G$  (resp.  $\mathcal{T}_H$ ) the functors of subtori of  $G$  (resp. of  $H$ ) (cf. Exp. XV § 8). Then the map  $\mathcal{T} \mapsto u(\mathcal{T})$  defines a monomorphism (XV 8.3 c))\*

<!-- label: III.XVI.3.2 -->

```
$$
\tilde{u} : \mathcal{T}_G \rightarrow \mathcal{T}_H
$$
```

\*which is representable by a closed immersion of finite presentation.\*

By the usual procedure, we are reduced to the following problem: let  $T$  be a subtorus of  $H$ ,  $T' = G \times_T H$  its

inverse image in  $G$ ,  $u_{\{T\}} : T' \rightarrow T$  the  $S$ -group monomorphism deduced from  $u$ . One must show that the  $S$ -functor  $\prod_{T/S}(T'/T)$  is representable by a closed sub-prescheme of  $S$ , of finite presentation. But  $T$ , being a torus, is smooth over  $S$  with connected fibers, and it suffices to apply Exp. XI 6.10.

<!-- original page 511 -->

**Theorem 3.3.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with connected fibers,  $Z$  the center of  $G$ . Suppose that  $Z$  is flat over  $S$  and that the unipotent rank (Exp. XV 6.1 ter) of  $G$  is equal to that of  $Z$ . Then:\*

<!-- label: III.XVI.3.3 -->

\*a) The group  $G' = G/Z$  is representable, and if  $S$  is quasi-compact, the canonical morphism  $i_{\{n\}} : G' \rightarrow \mathrm{GL}_S(G_{\{n\}})$  (cf. 3.1 b)) is an immersion for  $n$  large.\*

\*b) The group  $G'$  is quasi-affine over  $S$ , with affine fibers, the center of  $G'$  is the unit group, and  $G'$  has zero unipotent rank.\*

\*c) The group  $G'$  possesses locally for the étale topology maximal tori, and these are also Cartan subgroups of  $G'$ . The functor  $\mathcal{M}_{G'}$  of maximal tori of  $G'$  (Exp. XV § 8) is representable by an  $S$ -prescheme smooth and affine over  $S$ .\*

\*d) The group  $G$  possesses locally for the étale topology Cartan subgroups, and the functor  $\mathcal{C}_G$  of Cartan subgroups of  $G$  is representable by an  $S$ -prescheme, smooth and affine over  $S$ .\*

**Proof.** By 3.1, the group  $G'$  is representable by an  $S$ -prescheme, smooth and quasi-affine over  $S$ , with affine fibers. In view of the correspondence between Cartan subgroups of the fibers of  $G$  and of the fibers of  $G'$  (Exp. XII 6.6 e)), the hypothesis on the unipotent rank of  $Z$  implies that  $G'$  has zero unipotent rank. Using now <!-- original page 512 --> Exp. XV 8.18, one sees that  $G'$  possesses locally for the étale topology maximal tori. The fact that  $i_{\{n\}}$  is an immersion for  $n$  large then follows from 3.1 b) and 1.4 a). This completes the proof of a).

Let us now show c). Since  $G'$  has zero unipotent rank, it is clear that every maximal torus of  $G'$  is also a Cartan subgroup of  $G'$ . The functor of maximal tori of  $G'$  is representable by a sub-prescheme both open and closed of the functor of subtori of  $G'$ ; moreover it is of finite type over  $S$  (Exp. XV 8.15); it follows from 3.1 c) that this functor is representable by an  $S$ -prescheme, smooth and affine over  $S$ .

Since  $G'$  possesses, locally for the étale topology, Cartan subgroups, the same is true of  $G$ , and the functor of Cartan subgroups of  $G$  is canonically isomorphic to that of  $G'$  (Exp. XV 7.3 iv)), so c)  $\Rightarrow$  d).

It remains to show b), and more precisely, it remains to prove that the center  $Z'$  of  $G'$  is the unit group. Since  $Z'$  is representable (Exp. XI 6.11) and of finite presentation over  $S$ , it suffices to show that the fibers of  $Z'$  are reduced to the unit group (Exp. VI\_B 2.9), which reduces us to the case where  $S$  is the spectrum of an algebraically closed field. The center  $Z'$  is evidently contained in every Cartan subgroup of  $G'$ , hence in every maximal torus of  $G'$  by c), and is therefore of multiplicative type. Moreover, we shall see in Exp. XVII that if  $G$  is a connected algebraic group with center  $Z$ , the center  $Z'$  of  $G/Z$  is unipotent. In the present case,  $Z'$  being both of multiplicative type and unipotent, is reduced to the unit group (cf. Exp. XVII).

<!-- original page 513 -->

### Examples of groups whose center is flat

**Proposition 3.4.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme of finite presentation over  $S$ , smooth, with connected fibers,  $Z$  the center of  $G$ . Then  $Z$  is flat over  $S$  in the following two cases:\*

<!-- label: III.XVI.3.4 -->

\*a) The unipotent rank  $\rho_u$  (Exp. XV 6.1 ter) of the fibers of  $G$  is zero.\*

\*b) i)  $S$  is reduced.\*

\*ii) The dimension of the fibers of  $Z$  is a locally constant function on  $S$ .\*

\*iii) The unipotent rank of  $G$  is equal to the unipotent rank of  $Z$ .\*

**Proof of 3.4 a).** We shall prove at the same time:

**\*\*Proposition 3.5.\*\*** \*Under the hypotheses of 3.4 a), suppose moreover that  $G$  possesses a maximal torus  $T$  and let  $C = \text{Centr}_{\{G\}}(T)$  be the Cartan subgroup of  $G$  associated to  $T$  (Exp. XII 7.1). Then:\*

<!-- label: III.XVI.3.5 -->

(i)  $Z \cap T$  is a subgroup of multiplicative type of  $G$ .

(ii)  $C$  is commutative and equal to  $T \cdot Z$ .

(iii) If the quotients  $Z/Z \cap T$  and  $C/T$  are representable, they are representable by abelian preschemes (i.e.  $S$ -group preschemes, smooth over  $S$ , whose fibers are abelian varieties) and the canonical monomorphism  $Z/Z \cap T \rightarrow C/T$  is an isomorphism.\*

Using the general properties of passage to the limit proved in Exp. VI\_B § 10 and Exp. XV 6.2, 6.3, and 6.3 bis, we reduce as usual to the case <!-- original page 514 --> where  $S$  is noetherian (note that the assertions of 3.4 and 3.5 are local on  $S$ ). We noted in 3.1 that the hypotheses on  $G$  imply that  $Z$  is representable. To show that  $Z$  is flat over  $S$ , we reduce by EGA 0\_III 10.2.6 to the case where  $S$  is local artinian. But then,  $G$  being smooth,  $G$  possesses locally for the étale topology maximal tori (Exp. XV 8.17). Replacing  $S$  by a finite flat extension if necessary (which is allowable for proving that  $Z$  is flat), we may assume that  $G$  possesses a maximal torus  $T$ .

Let us show, in the same way, that to prove 3.5 we may reduce to the case  $S$  artinian.

i) Since  $Z$  is closed in  $G$  (Exp. XI 6.11),  $Z \cap T$  is a closed group subscheme of  $T$ . It follows from Exp. X 4.8 b) that  $Z \cap T$  is of multiplicative type if and only if it is flat over  $S$ . As before, it suffices to establish that  $Z \cap T$  is flat when  $S$  is artinian.

ii) Since  $G$  has zero unipotent rank, every Cartan subgroup  $C$  of  $G$  satisfies the hypotheses of Lemma 1.6, hence is commutative. The fact that  $C = T \cdot Z$  will follow from iii).

iii) If  $C/T$  is representable,  $C/T$  is smooth over  $S$  (Exp. VI\_B 9) and its fibers are abelian varieties (1.7), so  $C/T$  is an abelian prescheme. To show that the canonical monomorphism

```
```text
i : Z/Z ∩ T → C/T
```
```

is an isomorphism, it suffices to verify this when  $S$  is local artinian. <!-- original page 515 --> Indeed, one will then deduce in succession that  $Z/Z \cap T$  is flat over  $S$  (EGA 0\_III 10.2.6), then that  $i$  is flat (EGA IV 11.3.10), then that  $i$  is an open immersion (EGA IV 17.9.1), then that  $i$  is an isomorphism (since  $C/T$  has connected fibers).

We henceforth assume that  $S$  is local artinian with closed point  $s$  and that  $G$  possesses a maximal torus  $T$ . Let  $C = \text{Centr}_{\{G\}}(T)$ . The group  $C$  is a Cartan subgroup of  $G$  (Exp. XII 7.1) and majorizes  $Z$ .

The algebraic group  $M_{\{s\}} = Z_{\{s\}} \cap T_{\{s\}}$  is a subgroup of multiplicative type of  $G_{\{s\}}$  which is central. Since  $T$  is smooth over  $S$ ,  $M_{\{s\}}$  lifts to a group subscheme  $M$  of  $T$ , of multiplicative type (Exp. IX 3.6 bis) and contained in the center of  $G$  (Exp. IX 3.9), hence contained in  $Z \cap T$ . Since  $S$  is artinian and  $M$  and  $T$  are flat over  $S$ , the quotient groups  $Z \cap T/M$ ,  $Z' = Z/M$ , and  $A = C/T$  are representable (Exp. VI\_A §§ 4 and 5). By construction,  $(Z \cap T/M)_{\{s\}}$  is the unit group, so  $Z \cap T = M$  (Exp. VI\_B 2.9); a fortiori it is flat over  $S$ , which proves 3.5 i).

By passage to the quotient, one has a canonical monomorphism  $i : Z' \rightarrow A$ , which is therefore a closed immersion (Exp. VI\_B 1.4.2). We have already noted that  $A$  is an abelian scheme. It remains to show that  $i$  is an isomorphism. This will prove 3.5 iii) and will imply that  $Z'$  is flat over  $S$ , hence that  $Z$  is flat over  $S$  (as an extension of  $Z'$  by the flat group  $M$  (Exp. VI\_B § 9)). Since  $Z_{\{s\}}$  has the same abelian rank as  $G_{\{s\}}$  <!-- original page 516 --> (Exp. XII 6.1),  $i_{\{s\}}$  is an epimorphism, hence an isomorphism. Let  $q$  be an integer  $> 0$ , invertible on  $S$ . By the density theorem of 1.6 iii), to see that  $i(Z') = A$ , it suffices to show that for every integer  $n$  equal to a power of  $q$ ,  $i(Z')$  majorizes  $\{_{\{n\}} A$ . Now let  $M^{\{0\}}_{\{s\}}$  be the connected component of  $M_{\{s\}}$ . It is immediate by duality that raising to the  $q$ -th power in  $M^{\{0\}}_{\{s\}}$  is an epimorphism. One deduces immediately that if  $m_{\{0\}}$  is the exponent of  $q$  in the factorization into prime factors of  $\text{card}(M_{\{s\}} / M^{\{0\}}_{\{s\}})$ , the image of  $\{_{\{nm_{\{0\}}\}} Z_{\{s\}}$  in  $A_{\{s\}} \cong Z_{\{s\}}/M_{\{s\}}$  majorizes  $\{_{\{n\}} A_{\{s\}}$ . There exists therefore a subgroup of multiplicative type  $M_{\{s\}}(n)$  of  $Z_{\{s\}}$  whose image in  $A_{\{s\}}$  is  $\{_{\{n\}} A_{\{s\}}$ . As before, one sees that  $M_{\{s\}}(n)$  lifts to a subgroup of  $G$ , central and of multiplicative type,  $M(n)$ . The image of  $M(n)$  in  $A$  is a subgroup of multiplicative type (Exp. IX 6.8), hence necessarily equal to  $\{_{\{n\}} A$ , since it is so on the reduced fiber (Exp. IX 5.1 bis). This completes the proof of 3.4 a) and of 3.5.

**\*\*Proof of 3.4 b).\*\*** The assertion to be proved is local on  $S$ ; we may therefore assume  $S$  affine with ring  $A$ . Considering  $A$  as an inductive limit of its sub- $\mathbb{Z}$ -algebras of finite type, we reduce as above to the case where  $S$  is noetherian reduced.

To show that  $Z$  is flat, we have at our disposal a valuative criterion of flatness (EGA IV 11.8.1), which allows us to reduce to the case where  $S$  is the spectrum of a complete discrete valuation ring with algebraically closed residue field, with generic point  $t$  and closed point  $s$ . Let  $Z'$  be the schematic closure in  $Z$  of  $Z_t$ . We must show that  $Z' = Z$ , and it suffices even to show that  $Z_s = Z'_s$  (Exp. VI\_B 2.6). <!-- original page 517 --> By (Exp. VI\_B § 4), one has the inequalities

```
```text
dim Z_t = dim Z'_t = dim Z'_s ≤ dim Z_s.
```
```

But by hypothesis  $\dim Z_t = \dim Z_s$ , hence  $\dim Z'_s = \dim Z_s$  and consequently  $Z'_s$  majorizes  $(Z_s)^{\{0\}}$ . It follows that  $G'_s = G_s / Z'_s$  is affine (Exp. XII 6.1). In view of the correspondence between Cartan subgroups of  $G$  and of  $G'_s$  (Exp. XII 6.6 e), hypothesis 3.4 iii) implies that the unipotent rank of  $G'_s$  is zero, and consequently its Cartan subgroups are also its maximal tori. The image  $Z'_s$  of  $Z_s$  in  $G'_s$  is a central algebraic subgroup of  $G'_s$ , hence contained in every Cartan subgroup of  $G'_s$ , that is, in every maximal torus;  $Z'_s$  is therefore a subgroup of multiplicative type of  $G'_s$ . Under these conditions, we shall show in (Exp. XVII § 7) that there exists a finite subgroup of multiplicative type  $M_s$  of  $Z_s$  whose image in  $Z_s/Z'_s$  is  $Z'_s$  (we used this fact in the proof of 3.4 a) when  $Z'_s$  is étale). Since  $G$  is smooth over  $S$  and  $S$  is the spectrum of a complete local ring,  $M_s$  lifts to an  $S$ -subgroup of multiplicative type  $M$  of  $G$  (Exp. IX 3.6 bis and Exp. XV 1.6 b)) which is central (Exp. IX 5.6 a)). So  $M_t$  is contained in  $Z'_t = Z_t$ , and since  $M$  is flat,  $M$  is contained in  $Z'$ . The group  $M_s$  is therefore contained in  $Z'_s$ , but this implies that  $Z'_s$  is the unit group, i.e.  $Z_s = Z'_s$ . This completes the proof of 3.4 b).

### Example of a smooth group prescheme with connected fibers whose center is not flat

Let  $S$  be the spectrum of a discrete valuation ring  $A$ ,  $\pi$  a uniformizer of  $A$ , <!-- original page 518 -->  $t$  the generic point of  $S$ ,  $s$  the closed point. Let  $G$  be the smooth and affine  $S$ -group with ring  $B = A[T, T^{-1}, U]/F$  with  $F = 1 - T + \pi U$ , the composition law being defined by

```
```text
((t, u), (t', u')) ↦ (tt', πuu' + u + u').
```
```

The generic fiber  $G_t$  is therefore isomorphic to the multiplicative group  $(\mathbb{G}_m)_t$ , while the closed fiber  $G_s$  is isomorphic to the additive group  $(\mathbb{G}_a)_s$ . The function  $T$  is invertible in  $\Gamma(G, \mathcal{O}_G)$  and defines an  $S$ -group morphism  $\varphi : G \rightarrow (\mathbb{G}_m)_S$  which is an isomorphism on the generic fiber and the zero morphism on the closed fiber. The datum of  $\varphi$  allows one to construct the semidirect product group  $H = G \ltimes (\mathbb{G}_a)_S$  (note that  $(\mathbb{G}_m)_S$  acts on  $(\mathbb{G}_a)_S$ ). The center  $Z$  of  $H$  is the unit group on the generic fiber and is equal to  $H_s$  on the closed fiber, hence is not flat over  $S$ .

## 4. Groups with affine fibers, of zero unipotent rank

<!-- label: III.XVI.4 -->

<!-- original page 519 -->

**\*\*Theorem 4.1.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth over  $S$ , of finite presentation, with affine, connected fibers, of zero unipotent rank (Exp. XV 6.1 ter). Then:\*

<!-- label: III.XVI.4.1 -->

\*a) The center  $Z$  of  $G$  is a group of multiplicative type (and is therefore a reductive center of  $G$  (Exp. XII 4.1)).\*

\*b)  $G$  satisfies conditions a) to d) of 3.3.\*

\*c)  $G$  possesses locally for the étale topology maximal tori, and these are also Cartan subgroups of  $G$ . The functor  $\mathcal{TM}_G$  of maximal tori of  $G$  is representable by an  $S$ -prescheme smooth and affine over  $S$ .\*

\*d)  $G$  is quasi-affine over  $S$ . Moreover, if  $T$  is a maximal torus of  $G$ ,  $N = \text{Norm}_{\{G\}} T$  its normalizer in  $G$ ,  $W = N/T$  the Weyl group relative to  $T$ , the following conditions are equivalent:\*

\*(i)  $G$  is affine over  $S$ .\*

\*(ii)  $G' = G/Z$  is affine over  $S$ .\*

\*(iii)  $N$  is affine over  $S$ .\*

\*(iv)  $W$  is affine over  $S$ .\*

\*These conditions are always realized if  $S$  is locally noetherian of dimension  $\leq 1$ .\*

**\*\*Proof.\*\*** Since  $G$  has affine fibers (and so abelian rank zero) and zero unipotent rank,  $G$  possesses locally for the étale topology maximal tori (Exp. XV 8.18), and  $\leftarrow$  original page 520  $\rightarrow$  every maximal torus of  $G$  is evidently a Cartan subgroup of  $G$ , which proves the first part of c). To see that  $Z$  is of multiplicative type, we may assume, by what precedes, that  $G$  possesses a maximal torus  $T$ . Since  $T$  is also a Cartan subgroup,  $T$  majorizes  $Z$  (since  $T = \text{Centr}_{\{G\}}(T)$  by Exp. XII 7.1), and  $Z = Z \cap T$  is of multiplicative type by 3.5 i). This proves a). Assertion b) is clear, given a). On the other hand the functor  $\mathcal{TM}_{\{G\}}$  is isomorphic to the functor of Cartan subgroups of  $G$  (Exp. XII 7.1), hence is smooth and affine over  $S$  (3.3 c)), which completes the proof of c). It remains to prove d).

**\*\*Proof of d).\*\*** Since  $G'$  is quasi-affine (3.5 b)) and  $Z$  is of multiplicative type, hence affine over  $S$ ,  $G$  is quasi-affine (Exp. VI\_B § 9).

i)  $\Leftrightarrow$  ii). If  $G$  is affine,  $G'$  is affine by Exp. IX 2.3. If  $G'$  is affine,  $G$  is affine as an extension of an affine group by an affine group (Exp. VI\_B § 9).

i)  $\Leftrightarrow$  iii). If  $G$  is affine,  $N$  is affine since closed in  $G$  (Exp. XI 6.11 a)). Moreover  $G/N$  is isomorphic to the functor  $\mathcal{TM}_{\{G\}}$  (conjugacy of maximal tori, cf. Exp. XII 7.1 b)), so is affine over  $S$  by c). Hence if  $N$  is affine over  $S$ ,  $G$  is affine, as an "extension" of an affine homogeneous space by an affine group (Exp. VI\_B § 9).

iii)  $\Leftrightarrow$  iv). If  $N$  is affine,  $W = N/T$  is affine (Exp. IX 2.3) and conversely by Exp. VI\_B § 9.

$\leftarrow$  original page 521  $\rightarrow$

Moreover,  $N/T$  is representable by an  $S$ -group prescheme, étale, separated over  $S$ , of finite type (Exp. XV 7.1 iv)), hence quasi-finite over  $S$ . The last assertion of d) will therefore follow from the following lemma, applied with  $X = W$  and  $Y = S$ :

**\*\*Lemma 4.2.\*\*** \*Let  $S$  be a locally noetherian prescheme of dimension 1,  $X$  and  $Y$  two  $S$ -preschemes locally of finite type over  $S$ ,  $u : X \rightarrow Y$  an  $S$ -morphism quasi-finite and separated. Suppose that for every point  $s$  of  $S$  the morphism  $u_{\{s\}} : X_{\{s\}} \rightarrow Y_{\{s\}}$  deduced from  $u$  by the base change  $\text{operatorname{Spec}} \kappa(s) \rightarrow S$  is finite. Then  $u$  is an affine morphism.\*

$\leftarrow$  label: III.XVI.4.2  $\rightarrow$

The assertion to be proved is local on  $Y$ , which allows us to assume  $Y$  (and hence also  $X$ ) of finite type over  $S$ . By EGA IV 8, one sees that it suffices to prove 4.2 when  $S$  is the spectrum of a local ring  $A$ . By fpqc descent we may assume  $A$  complete, then  $A$  reduced (EGA II 1.6.4), then  $A$  normal (Nagata's theorem (EGA 0 IV 22) and Chevalley's theorem (EGA II 6.7.1)). If  $A$  is a field,  $u$  is finite by hypothesis, hence affine. Otherwise  $A$  is a discrete valuation ring; let  $s$  be the closed point of  $S$ ,  $t$  the generic point,  $\pi$  a uniformizer of  $A$ . Let  $y$  be a point of  $Y_{\{s\}}$ . Applying EGA IV 8 once more, we may replace  $y$  by the spectrum  $Y'$  of  $\mathcal{O}_{Y,y}$  and  $X$  by  $X' = X \times_{\{Y\}} Y'$ ; we may even assume  $\mathcal{O}_{Y,y}$  complete. Since  $u$  is quasi-finite and separated, by EGA II 6.2.6  $X'$  is a sum of two schemes  $X_1$  and  $X_2$  with  $X_1$  finite over  $Y'$  (hence affine) and  $X_2$  such that  $u(X_2)$  does not contain the closed point  $y$  of  $Y'$ . I claim that under these conditions  $X_2$  does not meet the closed fiber  $X'_{\{s\}}$ . Indeed, by hypothesis  $\leftarrow$  original page 522  $\rightarrow$   $X'_{\{s\}} \rightarrow Y'_{\{s\}}$  is finite, hence the restriction of this morphism to the closed subset  $(X_2)_{\{s\}}$  is finite and its image in  $(Y')_{\{s\}}$  is a closed subset. Since this image does not contain the closed point of the local scheme  $(Y')_{\{s\}}$ ,  $(X_2)_{\{s\}}$  is empty. Since  $u_{\{t\}}$  is finite, the restriction to  $(X_2)_{\{t\}} = X_2$  of the morphism  $X'_{\{t\}} \rightarrow Y'_{\{t\}}$  is finite. Moreover, one has  $Y'_{\{t\}} = Y'_{\{\pi\}}$ , so the open immersion  $Y'_{\{t\}} \rightarrow Y'$  is affine. In short, the composed morphism  $X_2 \rightarrow Y'_{\{t\}} \rightarrow Y'$  is affine, and it follows that the morphism  $X' = X_1 \sqcup X_2 \rightarrow Y'$  is affine.

**\*\*Corollary 4.3.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with affine, solvable, connected fibers, of zero unipotent rank. Then  $G$  is affine over  $S$ . If moreover the center of  $G$

is the unit group and if  $S$  is quasi-compact, the canonical morphism  $i_n : G \rightarrow GL_S(G_{(n)})$  (cf. 3.1 b)) is a closed immersion for  $n$  large enough.\*

<!-- label: III.XVI.4.3 -->

To prove that  $G$  is affine over  $S$ , we may assume that  $G$  possesses a maximal torus  $T$  (4.1 c)). Since  $G$  has solvable fibers, the Weyl group relative to  $T$  is the unit group (\*Bible\* 6 th. 1 cor. 3) and condition 4.1 d) iv) is satisfied. If the center of  $G$  is the unit group,  $i_n$  is a monomorphism for  $n$  large enough (3.1), hence is a closed immersion (1.5 b)).

## ## 5. Application to reductive and semisimple groups

<!-- label: III.XVI.5 -->

<!-- original page 523 -->

**Definition 5.1.** \*An  $S$ -group prescheme  $G$  is said to be reductive (resp. semisimple) if  $G$  is smooth and affine over  $S$ , with reductive (resp. semisimple) fibers.\*

<!-- label: III.XVI.5.1 -->

**5.1.1.** Reductive groups will be systematically studied from Exp. XIX onwards. In this section, we shall need the following properties, which will be proved in Exp. XIX (without using the developments of the present Exposé).

<!-- label: III.XVI.5.1.1 -->

a) \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and affine over  $S$ , with connected fibers,  $s$  a point of  $S$  such that  $G_s$  is reductive (resp. semisimple). Then there exists a neighborhood  $U$  of  $s$  such that  $G|_U$  is reductive (resp. semisimple).\*

b) \*If  $G$  is reductive,  $G$  possesses locally for the étale topology maximal tori, and if  $T$  is a maximal torus of  $G$ , the Weyl group  $W = \text{Norm}_G(T)/T$  is finite over  $S$ .\*

c) \*A reductive group has zero unipotent rank.\*

This being admitted, we propose to improve assertion a) above.

**Theorem 5.2.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with connected fibers,  $s$  a point of  $S$ . Then:\*

<!-- label: III.XVI.5.2 -->

(i) If the fibers of  $G$  are affine and  $G_s$  is reductive, there exists an open neighborhood  $U$  of  $s$  such that  $G|_U$  is reductive.\*

(ii) If  $G_s$  is semisimple, there exists an open neighborhood  $U$  of  $s$  such that  $G|_U$  is semisimple.\*

<!-- original page 524 -->

Using Exp. XV 6.2 i) and Exp. VI\_B § 10, one reduces to the case where  $S$  is noetherian.

In case (ii), consider the center  $Z$  of  $G$ , which is representable (Exp. XI 6.11 a)). Since  $G_s$  is semisimple, it is well known that  $Z_s$  is finite. Consequently (Exp. VI\_B § 4), there exists a neighborhood  $U$  of  $s$  such that  $Z$  is quasi-finite over  $U$ . For every point  $t$  of  $U$ ,  $G_t$  is then affine (Exp. XII 6.1). Replacing  $S$  by a smaller open if necessary, we may therefore assume that the fibers of  $G$  are affine, both in case (ii) and in case (i).

To prove 5.2 it suffices, by a), to prove that  $G$  is affine over  $S$ . Since  $G$  has affine fibers, we know that the functor of subtori of  $G$  is representable by a smooth  $S$ -prescheme (Exp. XV 8.11 and 8.9). Replacing  $S$  by an étale extension covering  $s$  (which is allowable), we may therefore assume that there exists a subtorus  $T$  of  $G$  such that  $T_s$  is a maximal torus of  $G_s$ . But then  $C = \text{Centr}_G(T)$  is a smooth subgroup of  $G$ , with connected fibers, majorizing  $T$ , such that  $C_s = T_s$  (since  $C_s$  is a Cartan subgroup of  $G_s$  and  $G_s$  has zero unipotent rank by c)). It follows that  $C = T$ , hence  $T$  is a Cartan subgroup and a maximal torus of  $G$ ; a fortiori, the unipotent rank of  $G$  is zero and one may apply 4.1.

By 4.1 d), it suffices to show that the Weyl group  $W$  relative to  $T$  is affine over a neighborhood  $U$  of  $s$ . In fact

we shall see that  $W$  is even finite over a neighborhood of  $s$ . Since  $W$  is quasi-finite over  $S$  (Exp. XV 7.1 iv)), to say that  $W$  is finite over a neighborhood  $U$  of  $s$  is equivalent to saying that the morphism  $W \rightarrow S$  is proper at  $s$  (EGA IV 15.7 and EGA III 4.4.2); to establish this we have at our disposal  $\leftarrow$  original page 525  $\rightarrow$  the valuative criterion of local properness (EGA IV 15.7), which reduces us to the case where  $S$  is the spectrum of a discrete valuation ring, with closed point  $s$ . But then, by the last assertion of 4.1 d),  $G$  is affine over  $S$ , and we may apply property a) recalled above to conclude that  $G$  is reductive (resp. semisimple). Using now property b), we conclude that  $W$  is indeed finite over  $S$ , which completes the proof of 5.2.

## 6. Applications: extension of certain rigidity properties of tori to groups of zero unipotent rank

$\leftarrow$  label: III.XVI.6  $\rightarrow$

$\leftarrow$  original page 526  $\rightarrow$

**Proposition 6.1.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth over  $S$ , of finite presentation, with connected affine fibers, and whose center is of multiplicative type (for example  $G$  of zero unipotent rank, cf. 4.1 a)). Then every closed normal subgroup  $K$  of  $G$ , of finite presentation over  $S$ , quasi-finite over  $S$ , is finite over  $S$ .\*

$\leftarrow$  label: III.XVI.6.1  $\rightarrow$

Indeed, for every geometric point  $s$  above  $S$ ,  $(K_s)_{\text{red}}$  is a finite étale subgroup of  $G_s$ , normal hence central (since  $G_s$  is connected). Consequently  $K_0 = Z \cap K$  (where  $Z$  denotes the center of  $G$ ) has the same underlying space as  $K$ , and it suffices to show that  $K_0$  is finite over  $S$ . Now  $K_0$  is a closed, quasi-finite subgroup of the multiplicative-type group  $Z$ , hence is finite, as one sees immediately (locally on  $S$ ,  $K_0$  will be majorized by  $\{z^n\}$  for a suitable integer  $n$ , and  $\{z^n\}$  is finite over  $S$ ).

**Corollary 6.2.** \*Let  $S$  and  $G$  be as above,  $K$  an  $S$ -group sub-prescheme of  $G$ , of finite presentation over  $S$ , normal and closed in  $G$ ,  $s$  a point of  $S$ . If  $K_s$  is finite (resp. is the unit group), there exists an open neighborhood  $U$  of  $s$  such that  $K|_U$  is finite over  $S$  (resp. is the unit group).\*

$\leftarrow$  label: III.XVI.6.2  $\rightarrow$

In view of the upper semi-continuity of the dimension of the fibers of  $K$  (Exp. VI\_B § 4), we may already assume, replacing  $S$  by a smaller open if necessary, that  $K$  is quasi-finite over  $S$ , hence finite (6.1).  $\leftarrow$  original page 527  $\rightarrow$  If moreover  $K_s$  is the unit group, one deduces easily by Nakayama's lemma that  $K$  is the unit group over  $\text{operatorname{Spec}} \mathcal{O}_s$ , hence over a neighborhood of  $s$ .

**Proposition 6.3.** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth and of finite presentation over  $S$ , with affine, connected fibers, of zero unipotent rank,  $H$  an  $S$ -group prescheme,  $s$  a point of  $S$ ,  $u : G \rightarrow H$  an  $S$ -group morphism such that  $\text{Ker } u_s$  is central. Suppose moreover that  $H$  is of finite presentation over  $S$  or that  $S$  is locally noetherian and  $G$  is locally of finite type over  $S$ . Then there exists an open neighborhood  $U$  of  $s$  such that if  $K = \text{Ker } u$ ,  $K|_U$  is central, of multiplicative type. Moreover,  $G' = (G|_U)/(K|_U)$  is representable and the morphism  $u' : G' \rightarrow H|_U$  deduced from  $u$  by passage to the quotient is an immersion.\*

$\leftarrow$  label: III.XVI.6.3  $\rightarrow$

**Proof.** Let  $Z$  be the center of  $G$ , and  $K_0 = K \cap Z$ .

a)  $K_0$  is a subgroup of multiplicative type over a neighborhood  $U$  of  $s$ . Indeed, replacing  $S$  by an étale extension over a neighborhood  $U$  of  $s$  if necessary (which is legitimate), we may assume that  $G$  possesses a maximal torus  $T$  (4.1 c)). But then  $T \cap K$  is a group of multiplicative type (Exp. XV 8.3) whose fiber at  $s$  is central by hypothesis, so  $T \cap K$  is central over a neighborhood of  $s$  (Exp. IX 5.6 a)) and consequently coincides with  $K_0$ .

b) Let us show that  $K_0 = K$  over a neighborhood  $U$  of  $s$ .  $\leftarrow$  original page 528  $\rightarrow$  By a) we may already assume that  $K_0$  is of multiplicative type, hence flat over  $S$ . Since  $K_0 = K \cap Z$ , the natural immersion  $K_0 \rightarrow K$  is then open over a neighborhood  $U$  of  $s$  (Exp. VI\_B 2.6). If  $t \in U$ , the image of  $K_t$  in the group  $G'_t = G_t/Z_t$  is then an étale finite group, normal in  $G'_t$  (since  $K_t$  is normal in  $G_t$ ), hence central, hence reduced to the unit group (3.3 b)). This says that  $K_t$  is contained in  $Z_t$ , hence is equal to  $K_0$ , whence  $K = K_0$  over  $U$ .

c) The representability of  $G'$  then follows from 2.3; the fact that  $u'$  is an immersion is contained in 1.3 a), taking 4.1 c) applied to  $G'$  into account.

**\*\*Proposition 6.4.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -group prescheme smooth, of finite presentation over  $S$ , with connected fibers,  $s$  a point of  $S$ , such that  $G_s$  is generated by its subtori (Exp. XII 8.2) (for example  $G_s$  affine of zero unipotent rank),  $H$  an  $S$ -group prescheme,  $u$  and  $v : G \rightarrow H$  two  $S$ -homomorphisms such that  $u_s = v_s$  and such that  $u_s$  is central. Suppose moreover that  $H$  is of finite presentation over  $S$ , or that  $S$  is locally noetherian. Then there exists a neighborhood  $U$  of  $s$  such that  $u|_U = v|_U$ .\*

<!-- label: III.XVI.6.4 -->

We reduce as usual to the case where  $S$  is noetherian (to study the condition " $G_s$  is generated by its subtori", one uses Exp. VI\_B 7.4). Since  $G$  has connected fibers, to show that  $u = v$  over a neighborhood  $U$  of  $s$ , it suffices

<!-- original page 529 --> to show that  $u = v$  after reduction by every power of the maximal ideal of the local ring

$\mathcal{O}_{\{S,s\}}$ , which reduces us to the case where  $S$  is local artinian.

But then, the functor of maximal subtori of  $G$  is representable by an  $S$ -scheme  $X$ , smooth of finite type over  $S$  (Exp. XV 8.17). Let  $T$  be the maximal subtorus of  $G_X$ , universal for the functor  $X$ . The hypothesis made on  $G_s$  means that the algebraic subgroup of  $G_s$  generated (Exp. VI\_B § 7) by the  $\kappa(s)$ -morphism  $f : T_s \rightarrow G_s$  (composite of the immersion  $T_s \rightarrow G_X$  and the canonical projection  $G_X \rightarrow G_s$ ) is equal to  $G_s$  itself. But  $X_s$  is geometrically connected (since if  $T$  is a maximal torus of  $G_s$ ,  $N$  its normalizer in  $G_s$ ,  $X_s$  is isomorphic to  $G_s/N$ ), and the image of  $T_s$  under  $f$  contains the unit section of  $G_s$ ; it then follows from Exp. VI\_B 7.4 that there exist an integer  $N > 0$  and an  $S$ -morphism  $f^N : T^N \rightarrow G$  (where  $T^N = T \times_S \cdots \times_S T$  ( $N$  factors) and  $f^N$  depends only on  $f$  and on the multiplication law of  $G$ ) such that  $(f^N)_s$  is surjective.

Consider the base change  $X \rightarrow S$  and the restrictions of  $u_X$  and  $v_X$  to the subtorus  $T$  of  $G_X$ . By hypothesis,  $u_X = v_X$  and  $u_X : T \rightarrow H_X$  is a central homomorphism. It then follows from Exp. IX 5.1 that  $u_X|_T = v_X|_T$ . Making explicit the definition of  $f^N$  and using the fact that  $u$  and  $v$  are homomorphisms, one deduces immediately that  $u^{f^N} = v^{f^N}$ . But the  $\kappa(s)$ -morphism  $f^N_s$  is surjective and  $G_s$  is smooth, hence reduced; consequently  $f^N_s$  is generically flat. Since  $T$  is smooth over  $S$ , hence flat, there exists a non-empty open set  $V$  of  $T$  such that  $f^N|_V$  is flat (EGA IV 11.3.10). The image of  $V$  is an open  $W$  of  $G$  (EGA IV 11.3.1) and  $f^N : V \rightarrow W$  is faithfully flat, of finite presentation, hence covering for the fpqc topology. <!-- original page 530 --> The equality  $u^{f^N} = v^{f^N}$  then implies  $u|_W = v|_W$ . Since  $W$  is schematically dense in  $G$  (EGA IV 11.10.10) and  $H$  is separated over  $S$  (Exp. VI\_A 0.3), one deduces immediately that  $u = v$ .

# Exposé XVII. Unipotent algebraic groups. Extensions between unipotent groups and groups of multiplicative type

<!-- label: III.XVII -->

\*by M. Raynaud\*[^XVII-0-0]

## 0. Some notations

<!-- label: III.XVII.0 -->

<!-- original page 531 -->

In the present chapter, we shall mostly consider algebraic groups defined over a field  $k$ . The number  $p \geqslant 0$  will always denote the characteristic of  $k$ ,  $F_p$  the prime field with  $p$  elements if  $p > 0$ ,  $\bar{k}$  an algebraically closed extension of  $k$ ,  $q$  a prime number distinct from  $p$ .

For every  $S$ -prescheme,  $(G_a)_S$  (resp.  $(G_m)_S$ ) denotes the additive group (resp. the multiplicative group) over  $S$  (cf. Exp. I, 4.3). For every integer  $n > 0$ ,  $(\mu_n)_S$  (resp.  $(\mathbb{Z}/n\mathbb{Z})_S$ ) denotes the group of  $n$ -th roots of unity (Exp. I, 4.4.4) (resp. the constant group over  $S$  associated with the abstract group  $\mathbb{Z}/n\mathbb{Z}$  (Exp. I, 4.1)). The group  $(\mathbb{Z}/n\mathbb{Z})_S$  is finite and étale over  $S$ ; the group  $(\mu_n)_S$  is flat and finite over  $S$ , and is étale over  $S$  if and only if  $n$  is invertible on  $S$  (Exp. VIII, 2.1).

If  $S$  is a prescheme of characteristic  $p > 0$ , for every integer  $n > 0$  and every  $S$ -prescheme in groups  $G$ , we denote by  $F_n(G)$  the radical sub- $S$ -prescheme in groups of  $G$  equal to the kernel of the  $n$ -th iterate of the Frobenius morphism relative to  $G$  (Exp. VII\_A). In particular, if  $G = (G_a)_S$  we set  $F_n(G) = (\alpha_{p^n})_S$ , which is a radical  $S$ -group, flat and finite over  $S$ , representing the following functor: for every  $S$ -prescheme  $S'$ ,  $(\alpha_{p^n})_S(S')$  is the set of  $x' \in \Gamma(S', 0_{S'})$  such that  $x'^{p^n} = 0$ .

The group  $(\mu_{p^n})_S$ , already defined, is canonically isomorphic to  $F_n(G_m)_S$ .

<!-- original page 532 -->

When there is no ambiguity about the base scheme  $S$ , we shall simply write  $G_a$ ,  $G_m$ ,  $\alpha_{p^n}$ , etc. instead of  $(G_a)_S$ ,  $(G_m)_S$ ,  $(\alpha_{p^n})_S$ , etc.

If  $G$  is an  $S$ -prescheme in commutative groups, for every integer  $n > 0$ ,  $\{ \}_n G$  is the sub-prescheme in groups of  $G$  equal to the kernel of raising to the  $n$ -th power in  $G$ .

For the convenience of the reader, we have gathered in an appendix some properties of algebraic groups proved in Exp. VI and VII, as well as elementary properties of Hochschild cohomology, which will be useful in this chapter.

## 1. Definition of unipotent algebraic groups

<!-- label: III.XVII.1 -->

<!-- original page 533 -->

**Definition 1.1.** \*An algebraic group  $G$  defined over an algebraically closed field  $k$  is said to be unipotent if  $G$  admits a composition series whose successive quotients are isomorphic to algebraic subgroups of  $(G_{\{a\}})_{\{k\}}$ .\*

<!-- label: III.XVII.1.1 -->

**Proposition 1.2.** \*Let  $k$  be an algebraically closed field,  $K$  an algebraically closed extension of  $k$ , and  $G$  an algebraic group defined over  $k$ . Then, in order that  $G$  be unipotent, it is necessary and sufficient that  $G_K$  be unipotent.\*

<!-- label: III.XVII.1.2 -->

The necessity of the condition is clear, since a composition series gives a composition series by extension of the base.

The proof of sufficiency is standard:  $K$  is the direct limit of its finitely generated  $k$ -subalgebras. By Exp. VI\_B § 10, one can find a finitely generated  $k$ -subalgebra  $A$  of  $K$ , a composition series  $G_{\{i\}}$  of  $G_S$  ( $S = \operatorname{Spec} A$ ), and immersions  $u_{\{i\}} : H_{\{i\}} = G_{\{i\}} / G_{\{i+1\}} \rightarrow (G_{\{a\}})_{\{S\}}$ . To prove that  $G$  is unipotent, it then suffices to make a  $k$ -base extension  $A \rightarrow k$ , which is possible because  $\operatorname{Hom}_{\{k\text{-alg}\}}(A, k)$  is non-empty, since  $A$  is a non-zero  $k$ -algebra of finite type over the algebraically closed field  $k$ .

**Definition 1.3.** \*Let  $G$  be an algebraic group defined over a field  $k$ . We shall say that  $G$  is unipotent if there exists an algebraically closed extension  $\bar{k}$  of  $k$  such that  $G_{\bar{k}}$  is unipotent (Definition 1.1).\*

<!-- label: III.XVII.1.3 -->

<!-- original page 534 -->

By 1.2, the property is independent of the chosen algebraically closed extension  $\bar{k}$ .

**Definition 1.4.** \*Let  $G$  be an algebraic group defined over a field  $k$  and  $H$  an algebraic group defined over an extension  $k'$  of  $k$ . We shall say that  $H$  is a form of  $G$  over  $k'$  if the algebraic groups  $G_{\bar{k}}$  and  $H_{\bar{k}}$  become isomorphic over  $\bar{k}$  (as above, one sees that the property does not depend on the choice of the algebraically closed extension  $\bar{k}$  of  $k'$ ). We shall also say that  $H$  is a twisted form of  $G$ .\*

<!-- label: III.XVII.1.4 -->

We are now in a position to describe the algebraic subgroups of  $G_{\{a\}}$ .

**Proposition 1.5.** \*Let  $k$  be a field of characteristic  $p \geq 0$ . Then an algebraic subgroup  $H$  of  $G_{\{a\}}$  is of one of the following types:\*

<!-- label: III.XVII.1.5 -->

(i)  $H = 0$ .

(ii)  $H = G_{\{a\}}$ .

(iii) (If  $p > 0$ )  $H$  is an extension of a twisted constant group  $(\mathbb{Z}/p\mathbb{Z})^r$  by a radical group  $\alpha_{p^n}$  ( $r$  and  $n$  integers  $\geq 0$ ,  $r + n > 0$ ). If moreover  $k$  is perfect, this extension is necessarily trivial.\*

**Proof.** If  $H$  is of dimension 1, it is clear that  $H = G_{\{a\}}$ . Otherwise  $H$  is of dimension 0 and consequently is an extension of an étale group  $H'$  by its identity component  $H''$ , which is a radical group. To describe  $H'_{\bar{k}}$ , it suffices to know the abstract group  $H'(\bar{k})$ , isomorphic to  $H(\bar{k})$ .

<!-- original page 535 -->

Now this latter is a finite subgroup of  $G_{\{a\}}(\bar{k})$ , hence is zero if  $p = 0$ , and of the form  $(\mathbb{Z}/p\mathbb{Z})^r$  otherwise, since it is annihilated by  $p$ . The group  $H'$  is closed in  $G_{\{a\}}$  and is defined by a single equation (the ring  $k[T]$  of  $G_{\{a\}}$  is principal), which over  $\bar{k}$  admits  $0$  as its only root, so this equation is of the form  $T^n = 0$ . Compatibility with the group law entails that  $(T + T')^n$  belongs to the ideal generated by  $T^n$  and  $T'^n$  in the ring  $k[T, T']$ , hence: if  $p = 0$ , one has  $n = 1$  and  $H'$  is

the trivial group; if  $p > 0$ , one has  $n = p^m$  and  $H' = \alpha_{p^m}$ .

The last assertion of 1.5 follows, more generally, from the lemma:

**Lemma 1.6.** *If  $k$  is a perfect field, every extension  $H$  of an étale algebraic group  $H'$  by a radicial group  $H'$  is trivial. Moreover, there is a unique lift of  $H'$  in  $H$ , namely  $H_{\text{red}}$ .*

<!-- label: III.XVII.1.6 -->

Indeed, since  $k$  is perfect, the reduced  $k$ -scheme  $H_{\text{red}}$  is an algebraic subgroup of  $H$  (Exp. VI\_A, 0.2) which is geometrically reduced, hence smooth over  $k$  (Exp. VI\_A, 1.3.1), hence étale, since  $H$  is of dimension 0. To see that the canonical projection  $H_{\text{red}} \rightarrow H'$  is an isomorphism, it suffices to verify it after base extension  $k \rightarrow \bar{k}$ , in which case it suffices to show that one has an isomorphism on the  $\bar{k}$ -valued points, which is clear. The last assertion follows from the fact that every lift of  $H'$  in  $H$ , being étale over  $k$ , is reduced, hence is necessarily contained in  $H_{\text{red}}$ .

<!-- original page 536 -->

Note that  $\alpha_{p^n}$  is a multiple extension of groups isomorphic to  $\alpha_p$ . From 1.5 we then deduce the corollary:

**Corollary 1.7.** *In order that an algebraic group  $G$  defined over an algebraically closed field  $k$  be unipotent, it is necessary and sufficient that it possess a composition series whose successive quotients are isomorphic to  $G_a$  if  $p = 0$ , and to one of the groups  $G_a$ ,  $\mathbb{Z}/p\mathbb{Z}$ ,  $\alpha_p$  if  $p > 0$ . (We shall call these the elementary unipotent groups.)*

<!-- label: III.XVII.1.7 -->

## ## 2. First properties of unipotent groups

<!-- label: III.XVII.2 -->

<!-- original page 537 -->

**Proposition 2.1.** *A unipotent algebraic group defined over a field  $k$  is affine over  $k$ .*

<!-- label: III.XVII.2.1 -->

By fpqc descent of affine morphisms, it suffices to prove 2.1 when  $k$  is algebraically closed. In this case,  $G$  is by definition a multiple extension of affine algebraic groups, hence is affine, by Exp. VI\_B, 9.2 (viii) applied to affine morphisms. [N.D.E-XVII-2]

**Proposition 2.2.**

<!-- label: III.XVII.2.2 -->

i) The property of being unipotent for an algebraic group is invariant under base field extension.

ii) Every algebraic subgroup of a unipotent group is unipotent.

iii) Every algebraic quotient group of a unipotent group is unipotent.

iv) Every extension of a unipotent algebraic group by a unipotent algebraic group is likewise unipotent.

*Proof.* i) follows immediately from 1.3 and 1.2. To establish the other properties, we may suppose the field  $k$  algebraically closed. Then iv) is evident from Definition 1.3.

<!-- original page 538 -->

Let then  $G$  be a unipotent algebraic group,  $G'$  an algebraic subgroup of  $G$ ,  $G'/G'$  an algebraic quotient group of  $G$ , and  $G_{\{i\}}$  ( $i = 1, \dots, n$ ) a composition series of  $G$  such that  $H_{\{i\}} = G_{\{i\}} / G_{\{i+1\}}$  is an elementary unipotent group (1.7).

To prove ii), consider the composition series of  $G'$  induced by that of  $G$ :  $G'_{\{i\}} = G_{\{i\}} \cap G'$ . The group  $G'_{\{i\}} / G'_{\{i+1\}}$  is identified with an algebraic subgroup of  $H_{\{i\}}$ , hence is isomorphic to a subgroup of  $G_a$ ,

and consequently  $G$  is unipotent.

To prove iii), consider the composition series of  $G$  image of that of  $G$ :  $G_{i+1} = \text{image of } G_i \text{ in } G$ . The group  $G_{i+1} / G_i$  is then a quotient of  $H_i$ , and it suffices to prove the lemma:

**Lemma 2.3.** \*If  $H$  is an elementary unipotent group (1.7) defined over a field  $k$ , every algebraic quotient group  $H'$  of  $H$  is zero or is isomorphic to  $H$  over  $k$ .\*

<!-- label: III.XVII.2.3 -->

**Proof.** If  $H = G_a$  in characteristic 0, or if  $H = \alpha_p$  or  $\mathbb{Z}/p\mathbb{Z}$  ( $p > 0$ ), it suffices to note that it follows from 1.5 that  $H$  has no algebraic subgroups other than 0 and  $H$  (observe that a non-zero algebraic subgroup of  $\alpha_p$  is defined by a  $k$ -algebra of  $k$ -rank at least  $p$  (1.5 iii)), hence is equal to  $\alpha_p$ .

Now let  $H = G_a$  ( $p > 0$ ), so that one has an exact sequence:

$$0 \rightarrow N \rightarrow G_a \rightarrow H' \rightarrow 0.$$

If  $N = G_a$ , then  $H' = 0$ . Otherwise, proceeding by induction on the length of a composition series of  $N$ , one may assume that  $N = \alpha_p$ , or that  $N$  is a form of  $\mathbb{Z}/p\mathbb{Z}$  (1.5).

<!-- original page 539 -->

a) If  $N \subseteq \alpha_p$ , the proof of 1.5 iii) shows that  $N$  is necessarily the kernel of the Frobenius morphism  $F$  in  $G_a$ , and one concludes using the exact sequence:

$$0 \rightarrow \alpha_p \rightarrow G_a \xrightarrow{F} G_a \rightarrow 0.$$

b) If  $N \subseteq \mathbb{Z}/p\mathbb{Z}$ , it is immediate that there exists  $a \in k^*$  such that  $N$  is the closed subscheme of  $G_a = \text{Spec } k[X]$  defined by the equation  $X^p - aX = 0$ . One then concludes using the exact sequence:

$$0 \rightarrow N \rightarrow G_a \xrightarrow{P} G_a \rightarrow 0,$$

where  $P$  is the Artin-Schreier morphism  $x \mapsto x^p - ax$ .

c) If  $N$  is a form of  $\mathbb{Z}/p\mathbb{Z}$ , there exists a finite Galois extension  $k'$  of  $k$  that trivializes  $N$ . By b) and an evident induction on  $r$ ,  $G_a / N$  is a form of  $G_a$  trivialized by  $k'$ . It then suffices to apply the following lemma:

**Lemma 2.3 bis.** \*Let  $k$  be a field,  $G$  a  $k$ -algebraic group which is a form of  $G_a$ , trivialized by a finite separable extension  $k'$  of  $k$ . Then  $G$  is isomorphic to  $G_a$ .\*

<!-- label: III.XVII.2.3bis -->

Indeed, the group of  $k'$ -automorphisms of the algebraic group  $(G_a)_{k'}$  is the group of non-zero homotheties  $(k')^\times$  (\*Bible\*, Exp. 9, Lemma 1), and the Galois cohomology group  $H^1(k'/k, G_m)$  is zero (one may suppose that  $k'$  is a Galois extension of  $k$ ), by Hilbert's Theorem 90. Lemma 2.3 bis then follows from the classification of  $k$ -forms of an algebraic group (cf. J.-P. Serre, \*Cohomologie galoisienne\*, Chap. III, 1.3).

This completes the proof of 2.2.

<!-- original page 540 -->

**Proposition 2.4.** \*Let  $k$  be a field,  $M$  a  $k$ -group of multiplicative type (Exp. VIII) and of finite type,  $U$  a unipotent  $k$ -algebraic group. Then:

<!-- label: III.XVII.2.4 -->

\*i)  $\operatorname{Hom}_{\{k\text{-gr}\}}(M, U) = e\$$  (a fortiori  $\operatorname{Hom}_{\{k\text{-gr}\}}(M, U) = e\$$ ).

\*ii)  $\operatorname{Hom}_{\{k\text{-gr}\}}(U, M) = e\$$ .

To prove i) we must establish that for every prescheme  $S\$$  over  $k\$$ ,  $\operatorname{Hom}_{\{S\text{-gr}\}}(M_{\{S\}}, U_{\{S\}}) = e\$$ . But this follows from the following lemma:

**Lemma 2.5.** Let  $S\$$  be a prescheme,  $M\$$  an  $S\$$ -group of multiplicative type and of finite type over  $S\$$ ,  $U\$$  an  $S\$$ -prescheme in groups of finite presentation over  $S\$$  with unipotent fibers. Then  $\operatorname{Hom}_{\{S\text{-gr}\}}(M, U) = e\$$ .

<!-- label: III.XVII.2.5 -->

Indeed, under the hypotheses made, in order that an  $S\$$ -morphism of groups  $u : M \rightarrow U$  be the unit homomorphism, it suffices that the restriction of  $u$  to the fibers of  $M$  over the points of  $S$  be the zero morphism (Exp. IX, 5.2). We are thus reduced to the case where  $S$  is the spectrum of a field, which we may further assume to be algebraically closed. In view of Definition 1.1, we may restrict to  $U = G_{\{a\}}$ , in which case the property has already been proved (Exp. XII, 4.4.1).

Let us now prove 2.4 ii). Let  $u : U \rightarrow M$  be a  $k$ -morphism of groups. The image  $u(U)$  is representable by an algebraic subgroup  $U''$  of  $M$  (Exp. VI\_B, 5.4). [N.D.E-XVII-3] The group  $U''$  is unipotent as a quotient of a unipotent group (2.2 iii)) and is of multiplicative type as a subgroup of a group of multiplicative type

<!-- original page 541 -->

(cf. \*Bible\*, Exp. 4, Th. 2 cor. 1, or Exp. IX, 6.8), so  $U''$  is the trivial group by 2.4 i).

**Remark 2.6.** Keeping the notations of 2.4, it is no longer true in general that the functor  $\operatorname{Hom}_{\{k\text{-gr}\}}(U, M)$  is equal to  $e$ . Thus, take a prescheme  $S$  such that  $\Gamma(S, \mathcal{O}_S)$  contains a non-zero element  $\epsilon$  such that  $\epsilon^2 = 0$  (for example the spectrum of the algebra of dual numbers of a ring  $A$ ). For every  $S'$  over  $S$ , the map  $u \mapsto 1 + \epsilon u$  defines a homomorphism, functorial in  $S'$ , from the additive group  $\Gamma(S', \mathcal{O}_{S'})$  to the multiplicative group  $\Gamma(S', \mathcal{O}_{S'}^\times)$ , hence defines an  $S$ -morphism of groups  $(G_{\{a\}})_S \rightarrow (G_{\{m\}})_S$ , and since  $\epsilon \neq 0$ , this morphism is not zero.

<!-- label: III.XVII.2.6 -->

Let us recall (Exp. VII\_A § 3) that when  $G$  is an  $S$ -prescheme in commutative groups, finite and flat over  $S$ , one has Cartier duality at one's disposal, and  $G$  is reflexive in the sense of Exp. VIII § 1. More precisely, the functor  $G \mapsto \operatorname{Hom}_{\{S\text{-gr}\}}(G, G_{\{m\}})$  is representable

<!-- original page 542 -->

by an  $S$ -prescheme in commutative groups  $D(G)$ , finite and flat over  $S$ , and the canonical morphism  $G \rightarrow D(D(G))$  is an isomorphism. In particular, one obtains:

(i)  $D(\mu_n) \simeq \mathbb{Z}/n\mathbb{Z}$  and consequently  $D(\mathbb{Z}/n\mathbb{Z}) \simeq \mu_n$ .

(ii) If  $S$  is of characteristic  $p > 0$ ,  $D(\alpha_p) \simeq \alpha_p$ .

## 3. Unipotent groups acting on a vector space

<!-- label: III.XVII.3 -->

<!-- original page 542 -->

Let us recall (Exp. I, 4.6.1) that if  $S$  is a prescheme and  $M$  a sheaf of  $\mathcal{O}_S$ -modules, one denotes by  $W(M)$  the  $S$ -functor  $(\operatorname{Sch}/S)^\circ \rightarrow (\operatorname{Ens})$  defined by the condition  $W(M)(S') = \Gamma(S', M \otimes \mathcal{O}_{S'})$  for every  $S$ -prescheme  $S'$ .

Moreover, let us recall that if an  $S$ -group acts on an  $S$ -functor  $V$ , one defines the  $S$ -functor  $V^G$  of invariants of  $V$  under  $G$  as the subfunctor of  $V$  whose set of points with values in some  $S'$  over  $S$  is the set of  $x \in V(S')$  such that  $x_{\{S'\}}$  is fixed under  $G(S')$  for every  $S'$  over  $S$ .

This being so, one has the following lemma:

**\*\*Lemma 3.1.\*\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups, affine over  $S$ , defined by the quasi-coherent  $\mathcal{O}_S$ -algebra  $A$ . Suppose that  $G$  acts on a quasi-coherent sheaf of  $\mathcal{O}_S$ -modules  $M$ , and let  $\mu : M \rightarrow A \otimes_{\mathcal{O}_S} M$  be the comorphism defining the action of  $G$  on  $M$  (Exp. I, 4.7.2), and  $\nu : M \rightarrow A \otimes_{\mathcal{O}_S} M$  the morphism  $x \mapsto \mu(x) - 1 \otimes x$ . Then:

<!-- label: III.XVII.3.1 -->

i)  $M^G(S) = \Gamma(\text{Ker}(\nu))$ .

ii) If  $S$  is the spectrum of a field  $k$ ,  $M^G$  is of the form  $W(N)$ , where  $N$  is a vector subspace of  $M$ .

iii) If  $S$  is the spectrum of a field  $k$ , every element  $x$  of  $M$  is contained in a finite-dimensional  $k$ -vector subspace of  $M$ , stable under the action of  $G$ .

<!-- original page 543 -->

**\*Proof.\*** iii) is included for the record and has already been proved in Exp. VI\_B, 11.2.

i) It is clear that  $M^G(S)$  contains  $\Gamma(\text{Ker}(\nu))$ . To establish the converse, one may suppose  $S$  affine with ring  $B$ . Let  $m \in M^G(S)$ . Then for every  $B$ -algebra  $B'$  and every  $u$  in  $\text{Hom}_{B\text{-alg}}(A, B')$  ( $u$  corresponds to an element of  $G(\text{Spec } B')$ ), one has:

```
```text
(u \otimes 1_M) v(m) = 0    in    B' \otimes_B M.
```

Taking in particular $B' = A$ and u the identity of A , one finds $\nu(m) = 0$.

ii) Let N be the kernel of ν , equal to $M^G(k)$ by i). Every k -prescheme S is flat over k , so one has:

```
```text
M^G(S) = \Gamma(\text{Ker}(\nu \otimes_k S)) = \Gamma(N \otimes_k S).
```

So  $M^G$  is isomorphic to the functor  $W(N)$ .

**\*\*Proposition 3.2.\*\*** \*Let  $G$  be a unipotent algebraic group defined over a field  $k$ , acting on a  $k$ -vector space  $V$ . Then if  $V \neq 0$ , one has  $V^G \neq 0$ .

<!-- label: III.XVII.3.2 -->

In view of 3.1 ii) and iii), one may suppose  $k$  algebraically closed and  $V$  of finite dimension over  $k$ .

Let  $0 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 0$  be an exact sequence of algebraic groups and suppose that  $G$  acts on a sheaf  $V$  (for the fpqc topology). Of course  $V^G \subset V^{G'}$ ,

<!-- original page 544 -->

and the quotient presheaf  $G/G'$  acts naturally on  $V^{G'}$ . But  $V^{G'}$  is a sheaf (as kernel of the well-known pair of morphisms  $V \rightarrow \text{Hom}(G', V)$ ); consequently, the sheaf associated with  $G/G'$ , that is,  $G''$ , acts on  $V^{G'}$ , and it is immediate to verify that  $(V^{G'})^{G''} = V^G = (V^{G'})^{G/G'}$ .

This remark allows us to reduce, in order to prove 3.2, to the case where  $G$  is an elementary unipotent group (1.7).

a)  $G = G_a$ ,  $p = 0$ . It follows from (\*Bible\* 4 prop. 4) that a morphism from  $G_a$  into the linear group  $GL(V)$  is given by an exponential map:

```
```text
T \mapsto \sum_{q=0}^{\infty} T^q n^q / q!
```

where n is a nilpotent endomorphism of V . But then $V \neq 0 \rightarrow \text{Ker } n \neq 0$, and it is clear that every vector of V annihilated by n is left fixed by G .

Suppose now $p > 0$.

b) $G = \alpha_p$. The group α_p being a radicial group of height 1 (Exp. VII_A § 7), giving a representation of α_p in V amounts to giving a representation of the p -Lie algebra α_p in $\mathfrak{gl}(V)$ (App. II 2.2), that is, here, to giving an element X of $\operatorname{End}(V)$ such that $X^p = 0$ (App. II 2.1). But then $V \neq 0 \Rightarrow W = \operatorname{Ker}(X) \neq 0$, and still by (App. II 2.2), one has $W = V^{\alpha_p}$.

c) $G = \mathbb{Z}/p\mathbb{Z}$. A representation of G in V is equivalent to giving an element x of $\operatorname{Aut}(V)$ such that $x^p = 1$, i.e. $(1 - x)^p = 0$, so x is of the form $1 + n$ with n nilpotent, and $W = \operatorname{Ker} n$ is left fixed by x .

<!-- original page 545 -->

d) $G = G_a$. Let G_i , $i \in I$, be the increasing filtered family of étale algebraic subgroups of G_a , hence isomorphic to $(\mathbb{Z}/p\mathbb{Z})^{r_i}$ (prop. 1.5), and let $V_i = V^{G_i}$. Since V is of finite, non-zero dimension, and V_i is non-zero by c), the decreasing filtered family of the V_i is stationary, and $W = \bigcap_{i \in I} V_i \neq 0$. Now one has the lemma:

Lemma 3.3. *The family of étale subgroups of $(G_a)_S$ (S an S -prescheme of characteristic $p > 0$) is schematically dense in G_S (Exp. IX, 4.1).*

<!-- label: III.XVII.3.3 -->

By Exp. IX, 4.4, it suffices to prove the lemma when S is the spectrum of the prime field F_p . In this case, it suffices to consider the family of étale subgroups G_n ($n \geq 1$) with equation $X^{p^n} - X = 0$, which is schematically dense in $(G_a)_{F_p}$ since it contains every closed point.

This being so, let us return to the proof of 3.2 d). If $w \in W$, its stabilizer in G is an algebraic subgroup of G_a that majorizes G_i for every $i \in I$, hence is equal to G_a (3.3), and consequently $W = V^{G_a}$.

One deduces immediately from 3.2 the

Corollary 3.4. *Let k be a field, G a unipotent k -algebraic group acting on a finite-dimensional k -vector space V . Then V possesses a sequence of vector subspaces V_i , defined over k , stable under G ,*

<!-- label: III.XVII.3.4 -->

<!-- original page 546 -->

``text
 $0 = V_0 \subset V_1 \subset \dots \subset V_n = V$,

such that G acts trivially on V_{i+1} / V_i . One may further suppose V_{i+1} / V_i of dimension 1.

We shall now summarize and complement the properties of unipotent groups already proved, in the following theorem:

Theorem 3.5. *Let G be an algebraic group defined over a field k . The following properties are equivalent:*

<!-- label: III.XVII.3.5 -->

i) G is unipotent.

ii) G possesses a composition series, defined over k , whose successive quotients are isomorphic to G_a if $p = 0$ (resp. to α_p , G_a , or twisted $(\mathbb{Z}/p\mathbb{Z})^r$ (1.4) if $p > 0$).

iii) As in ii), but one further assumes the composition series to be central.

iv) G possesses a characteristic composition series (Exp. VI_B) defined over k , whose successive quotients are isomorphic to $(G_a)^r$ if $p = 0$ (resp. to $(\alpha_p)^r$, twisted $(G_a)^s$, or twisted $(\mathbb{Z}/p\mathbb{Z})^t$, taken in this order, if $p > 0$).

v) G is isomorphic to an algebraic subgroup of the group $\operatorname{Trigstr}(n)_k$ of strictly upper-triangular matrices of the linear group $\operatorname{GL}(n)_k$, for some suitable integer $n \geq 0$.

vi) G is affine and, for every linear representation of G in a non-zero finite-dimensional k -vector space V , one has $V^G \neq 0$.

<!-- original page 547 -->

Proof.

i) $\Rightarrow$ vi) by 2.1 and 3.2.

vi) $\Rightarrow$ v). Since the algebraic group G is affine, G is an algebraic subgroup of a suitable linear group $GL(V)$ (Exp. VI_B, 11.3). Applying 3.4 to the representation of G in V defined by this embedding, one finds v).

v) $\Rightarrow$ iii). One knows that the algebraic group $\text{Trigstr}(n)$ possesses a central composition series with successive quotients isomorphic to G_a . The composition series induced on G gives property iii), taking 1.5 into account.

iii) $\Rightarrow$ ii) $\Rightarrow$ i) and iv) $\Rightarrow$ i) is clear.

We shall prove i) $\Rightarrow$ iv) shortly, but first let us note some consequences of what has been proved.

Definition 3.6. We shall say that a p -Lie algebra g ($p > 0$) (cf. Exp. VII_A § 5) is unipotent if the map $x \mapsto x^{(p)}$ is nilpotent, i.e. if for every $x \in g$, there exists an integer $n > 0$ such that $x^{(p^n)} = 0$.*

<!-- label: III.XVII.3.6 -->

Corollary 3.7. A unipotent algebraic group G is nilpotent (Exp. VI_B § 8); its Lie algebra g is nilpotent (Bourbaki, *Groupes et algèbres de Lie*, Chap. 1 § 4) and is isomorphic to a Lie algebra of nilpotent endomorphisms of a finite-dimensional vector space.*

<!-- label: III.XVII.3.7 -->

<!-- original page 548 -->

In characteristic $p > 0$, g is a unipotent p -Lie algebra (3.6).*

Since i) $\Rightarrow$ v), it suffices to prove 3.7 when $G = \text{Trigstr}(n)$. We have already used the fact that $\text{Trigstr}(n)$ is a nilpotent algebraic group. Moreover, the Lie algebra h of $\text{Trigstr}(n)$ consists of the upper-triangular endomorphisms of V having zeros on the principal diagonal. They are therefore nilpotent and consequently h is nilpotent (Bourbaki, *loc. cit.* Chap. 1 § 4 cor. 3). If $p > 0$, since the p -th power in the p -Lie algebra $g_l(V) = \text{operatorname{End}}(V)$ coincides with the p -th power of the endomorphisms of V (Exp. VII_A, 6.4.4), one sees that h is unipotent.

Corollary 3.8. Let k be an algebraically closed field and G a smooth and affine algebraic group over k . Then the following properties are equivalent:*

<!-- label: III.XVII.3.8 -->

i) G is unipotent.*

ii) $G(k)$ consists of unipotent elements (*Bible* 4 prop. 4 cor. 1), that is, G is unipotent in the sense of the *Bible*.*

i) $\Rightarrow$ ii) because G is isomorphic to an algebraic subgroup of a group $\text{Trigstr}(n)$ by 3.2 i) $\Rightarrow$ v).

ii) $\Rightarrow$ i). Let G be an algebraic group, unipotent in the sense of the *Bible*, and let G^0 denote its identity component. The maximal tori of G^0 , being made up of unipotent elements, are trivial, so G^0 is equal to its Cartan subgroups. Consequently, G^0 is solvable (*Bible* 6 Th. 6), hence triangularizable (*Bible* 6, Th. 1). In brief, G^0 is an algebraic subgroup of a group $\text{Trigstr}(n)$, and is therefore unipotent in the sense of the present Exposé.

The group $(G/G^0)(k)$ is a finite group made up of unipotent elements; it is therefore zero if $p = 0$ and equal to a finite p -group if $p > 0$ (*Bible* 4 prop. 4). But then G/G^0 is unipotent in the sense of the present Exposé as a multiple extension of groups isomorphic to $\mathbb{Z}/p\mathbb{Z}$. This proves that G is unipotent.

End of the proof of 3.5.* Let us prove that i) $\Rightarrow$ iv).

<!-- original page 549 -->

a) $p > 0$. Consider the increasing sequence of algebraic subgroups of G :

```
```text
{e} ⊂ F(G) ⊂ F2(G) ⊂ ... ⊂ Fn(G) ⊂ G0 ⊂ G.
```

One thus obtains a characteristic composition series of  $G$  (App. II 1), and for  $n$  large enough,  $G / F_n(G)$  is smooth (App. II 3.1), so that the successive quotients are, in order:

- (1) radical groups of height 1,
- (2) a smooth and connected group,
- (3) an étale group.

To prove i)  $\Rightarrow$  iv) it therefore suffices to prove the:

**Lemma 3.9.** \*Let  $G$  be a unipotent algebraic group defined over a field  $k$  of characteristic  $p > 0$ . Then  $G$  possesses a characteristic composition series, defined over  $k$ , whose successive quotients are isomorphic to:

<!-- label: III.XVII.3.9 -->

\*i)  $(\alpha_p)^r$  if  $G$  is radical.\*

\*ii) Twisted  $(G_a)^r$  if  $G$  is smooth and connected.\*

\*iii) Twisted  $(\mathbb{Z}/p\mathbb{Z})^r$  if  $G$  is étale.\*

**Proof.** i) The group  $G$  is radical. Filtering  $G$  by the  $F_n(G)$ , one reduces to the case where  $G$  is radical of height 1. Since  $G$  is nilpotent (3.5 i)  $\Rightarrow$  iii)), and since the center of an algebraic group is representable (Exp. VIII, 6.5 e)), one may consider the ascending central series of  $G$ , evidently characteristic in  $G$ , which reduces us to the case where  $G$  is moreover commutative.

<!-- original page 550 -->

Let  $g = \text{Lie}(G)$ . The  $p$ -th power morphism  $\pi$  is therefore additive on  $g$  (Exp. VII\_A); we shall reduce to the case where it is zero. For every prescheme  $S$  over  $k$ , set  $g_S = g \otimes_{\mathbb{Z}} \mathbb{Z}_S$ , and let  $h_S$  be the subsheaf of abelian groups of  $g_S$  image of  $g_S$  under  $\pi_S$ . Finally, let  $\bar{h}_S$  be the subsheaf of  $^0S$ -modules of  $g_S$  generated by  $h_S$ . It is clear that  $\bar{h}_S = \bar{h}_k \otimes_{\mathbb{Z}} \mathbb{Z}_S$  and that  $\bar{h}_S$  is a characteristic sub- $p$ -Lie algebra of  $g_S$  (i.e. is stable under the  $S$ -functor  $\text{Aut}_p(\text{Lie}(g))$ ). It then follows from App. II 2.2 that  $\bar{h}_k$  is the Lie algebra of an algebraic subgroup  $H$  of  $G$  that is characteristic in  $G$ .

Moreover, taking 3.7 and Lemma 3.9 bis below into account, if  $G \neq \{e\}$ ,  $H$  is distinct from  $G$ , because  $\bar{h}_k$  is distinct from  $g$ . On the other hand, if  $G/H = G'$ , one has  $\text{Lie } G' = g / \bar{h}_k$  (App. II 2.2), and consequently, the  $p$ -th power is zero in  $\text{Lie } G'$ . Proceeding by induction on  $\dim \text{Lie } G$ , we are thus reduced to the case where  $\text{Lie } G$  is a  $p$ -Lie algebra in which the  $p$ -th power is zero. But then  $\text{Lie } G$  is isomorphic to  $(\alpha_p)^r$  for some suitable integer  $r \geq 0$  (App. II 2.1), and consequently (App. II 2.2),  $G$  is isomorphic to  $(\alpha_p)^r$ . It remains to prove the:

**Lemma 3.9 bis.** \*Let  $k$  be a field of characteristic  $p > 0$ ,  $g$  a commutative, unipotent (3.6), finite-dimensional  $p$ -Lie algebra over  $k$ , and  $h$  the sub- $p$ -Lie algebra of  $g$  generated by the image of the  $p$ -th power in  $g$ . Then if  $g \neq 0$ , one has  $h \neq g$ .\*

<!-- label: III.XVII.3.9bis -->

Indeed, since  $g$  is commutative,  $h$  is simply the  $k$ -vector subspace of  $g$  generated by the  $X^{(p)}$  ( $X \in g$ ). If  $g \neq 0$  and is unipotent, there exists  $X \in g$ ,  $X \neq 0$ , such that  $X^{(p)} = 0$ .

<!-- original page 551 -->

Let  $X_1, \dots, X_n$  be a basis of a supplement in  $g$  of the line  $kX$ . The Lie algebra  $h$  is then the

$k$ -vector subspace of  $g$  generated by  $X^{(p)}_1, \dots, X^{(p)}_n$ , hence has dimension at most  $n = \dim g - 1$ .

*\*Proof of 3.9 ii)\*.*  $G$  is smooth and connected. In this case, the descending central series of  $G$  is representable by characteristic smooth connected algebraic subgroups  $G_i$  (Exp. VI\_B, 8.3 and 7.4), and  $G_i = 0$  for  $i$  large enough, since  $G$  is nilpotent (3.5 i)  $\Rightarrow$  iii)). It suffices to prove 3.9 for the groups  $G_i / G_{i+1}$ , which reduces us to the case where moreover  $G$  is commutative. For every integer  $n > 0$ , let  $G_n$  be the algebraic subgroup of  $G$  which is the image of  $G$  under the  $p^n$ -th power morphism. The group  $G_n$  is therefore smooth, connected and characteristic, and it follows from Definition 1.1 of unipotent groups that  $G_n = 0$  for  $n$  large enough. Replacing  $G$  by  $G_n / G_{n+1}$ , one may further suppose that  $G$  is annihilated by raising to the  $p$ -th power. But then, by (J.-P. Serre, *Groupes algébriques et corps de classes*, Chap. VII, prop. 11),  $G$  is a form of  $(G_a)^r$  for some suitable integer  $r$ .

*\*Proof of 3.9 iii)\*.*  $G$  is étale. Proceeding as in ii), one reduces to the case where  $G$  is commutative, then to the case where  $G$  is annihilated by  $p$ , but then  $G_{\bar{k}}$  is isomorphic to  $(\mathbb{Z}/p\mathbb{Z})^r$ .

*\*Proof of 3.5 i)  $\Rightarrow$  iv) in the case b)\**  $p = 0$ . The group  $G$  is then smooth and connected, and proceeding as in 3.9 ii), one reduces to the case where  $G$  is moreover commutative. One then has the following more precise result:

**Lemma 3.9 ter.** *\*Let  $k$  be a field of characteristic  $\neq 0$ ,  $G$  a commutative unipotent  $k$ -algebraic group,  $g = \text{Lie } G$ . Then there exists a canonical isomorphism:\**

<!-- label: III.XVII.3.9ter -->

<!-- original page 552 -->

$\exp : W(g) \rightarrow G$ .

*\*The morphism  $\exp$  is the unique homomorphism  $W(g) \rightarrow G$  that induces the identity on Lie algebras.\**

Since  $G$  is unipotent,  $G$  is realized as an algebraic subgroup of  $\text{Trigstr}(n)$  for some suitable integer  $n$  (3.5 i)  $\Rightarrow$  v)). The choice of such an embedding allows one to identify  $g$  with a Lie subalgebra of  $\mathfrak{gl}(n)$  consisting of nilpotent endomorphisms. Whence a  $k$ -morphism:

$\exp : W(g) \rightarrow GL(n), \quad T \mapsto \sum_{i \geq 0} T^i / i!$ .

Since  $G$  is commutative, the morphism  $\exp$  is a homomorphism. Let  $G'$  be the algebraic group image of  $W(g)$  under the morphism  $\exp$ . If one canonically identifies  $\text{Lie } W(g)$  with  $g$ , the linear tangent map of  $\exp$  is simply the injection  $g \rightarrow \mathfrak{gl}(n)$ . Consequently  $\text{Lie}(G \cap G') = g \cap g = g$ . Since  $G \cap G'$  is smooth (Exp. VI\_B, 1.6.1) and  $G$  is connected (being a multiple extension of groups  $G_a$  (3.5 i)  $\Rightarrow$  ii)), one necessarily has  $G = G'$ . The kernel  $\text{Ker}(\exp)$  is a unipotent étale group, hence is the trivial group, and consequently  $\exp$  is an isomorphism of  $W(g)$  onto  $G$ .

If  $h : W(g) \rightarrow G$  is another homomorphism such that  $\text{Lie}(h)$  is the identity map of  $g$ , the morphism  $h - \exp$  is a homomorphism ( $G$  being commutative) whose linear tangent map is therefore zero. Since  $k$  is of characteristic  $\neq 0$  and  $W(g)$  is connected, it again follows from Cartier's theorem that one necessarily has  $h = \exp$ .

<!-- original page 553 -->

**Proposition 3.10.** *\*Let  $G$  be an algebraic group defined over an algebraically closed field  $k$ . Then the following properties are equivalent:\**

<!-- label: III.XVII.3.10 -->

- \*i) Every morphism of a group of multiplicative type  $M$  into  $G$  is the zero morphism.\**
- \*i bis)  $G$  has no non-zero subgroups of multiplicative type.\**
- \*ii) a) if  $p = 0$ :  $G(k)$  contains no points of finite order other than  $e$ ;*
- \*b) if  $p \neq 0$ : for every prime number  $q \neq p$ ,  $x \in G(k)$  and  $x^q = e$  imply  $x = e$ ;*

```

...
for every $X \in \mathfrak{g} = \text{Lie } G$ such that $X^{(p)} = X$, one has $X = 0$.
...

ii bis) a) if $p = 0$: as in ii) a);
...
 b) if $p \neq 0$: every finite subgroup of $G(k)$ is a p -group,
...
 for every $X \in \mathfrak{g} = \text{Lie } G$ such that $X^{(p)} = X$, one has $X = 0$.
...

Proof.

i) $\Leftrightarrow$ i bis), since the image of a group of multiplicative type is of multiplicative type (Exp. IX, 2.7).

<!-- original page 554 -->

ii) $\Leftrightarrow$ ii bis). Because if an ordinary finite group H has order not a power of p , there exists a prime number
 $q \neq p$, and an element x of H distinct from e , such that $x^q = e$ (Sylow's theorem, cf. J.-P. Serre, Corps
locaux, Chap. IX § 2).

i) $\Rightarrow$ ii) follows from the following lemma:

Lemma 3.11. *Let G be an algebraic group defined over a field k .*

<!-- label: III.XVII.3.11 -->

a) If k contains the n -th roots of unity, with n an integer prime to p , one has:

```text
Hom_{k-gr}(\mu_n, G) \simeq Hom_{k-gr}(\mathbb{Z}/n\mathbb{Z}, G) \simeq {}_n G(k)
```

(points of order n of $G(k)$).

b) If $p > 0$, $\text{Hom}_{k-gr}(\mu_p, G) = \{X \in \mathfrak{g} = \text{Lie } G, \text{ such that } X^{(p)} = X\}$.*

Indeed, to prove a) we note that μ_n is then isomorphic over k to $\mathbb{Z}/n\mathbb{Z}$, and b) is a
consequence of App. II 2.1.

ii) $\Rightarrow$ i bis). By Lemma 3.11, ii) is equivalent to the fact that for every prime number r , G does not contain any
subgroups μ_r , which entails i bis) by reason of the:

Lemma 3.12. *Let G be a diagonalizable S -group, of finite type over S and distinct from the trivial group.
Then there exists a prime number r and a subgroup of G isomorphic to μ_r .*

<!-- label: III.XVII.3.12 -->

Let $G = D_S(M)$, where M is a finitely generated abelian group, hence extension of a free group M' by a finite
group M'' . If $M'' \neq 0$, it is clear that M admits quotients isomorphic to $\mathbb{Z}/r\mathbb{Z}$ for every
integer r . If $M'' = 0$, M admits a quotient isomorphic to $\mathbb{Z}/r\mathbb{Z}$ for every prime number r
dividing the order of M .

<!-- original page 555 -->

One then deduces the lemma by duality.

We have seen (Prop. 2.4) that a unipotent group satisfies the equivalent conditions of 3.10. The aim of the next section
is to prove the converse.

4. A characterization of unipotent groups

<!-- label: III.XVII.4 -->

```

<!-- original page 556 -->

As announced, we shall show that an algebraic group  $G$  defined over an algebraically closed field  $k$ , which does not contain any non-zero subgroup of multiplicative type, is unipotent. In fact, it suffices that it does not contain certain particular "elementary" subgroups of multiplicative type, which depend on the hypotheses made on  $G$ . Before stating the general theorem, let us study in detail some special cases.

### 4.1. Smooth, connected, affine algebraic groups

<!-- label: III.XVII.4.1 -->

**Proposition 4.1.1.** Let  $k$  be a field,  $G$  a smooth, connected, affine  $k$ -algebraic group,  $\mathfrak{g} = \text{Lie } G$ . Then the following properties are equivalent:

<!-- label: III.XVII.4.1.1 -->

- i)  $G$  is unipotent.
  - ii)  $G$  possesses a central composition series whose successive quotients are forms of  $G_a$ .
  - iii)  $G$  possesses a central, characteristic composition series whose successive quotients are forms of  $G_a^{(r)}$ .
  - iv) There exists an integer  $n > 1$  such that  $G_{\bar{k}}$  does not contain any subgroup isomorphic to  $\mu_n$ .
  - v) Every maximal torus of  $G$  is the trivial group.
- Suppose moreover that  $G$  is an algebraic subgroup of a linear group  $GL(n)$ . Then the preceding conditions are also equivalent to:

<!-- original page 557 -->

- vi)  $\mathfrak{g} \subset \mathfrak{gl}(n)$  consists of nilpotent endomorphisms.
  - vii)  $\mathfrak{g}$  is nilpotent and its center contains no non-zero semisimple endomorphism.
- Proof.** ii)  $\Rightarrow$  i) is clear, and i)  $\Rightarrow$  iii) was seen in 3.9. The implication iii)  $\Rightarrow$  ii) will follow from the following lemma:

**Lemma 4.1.2.** Let  $k$  be a field,  $G$  a  $k$ -algebraic group which is a form of  $G_a^{(r)}$ . Then:

<!-- label: III.XVII.4.1.2 -->

- a)  $G$  is realized as an algebraic subgroup of the group  $G_a^{(n)}$  for some suitable integer  $n$ .
- b)  $G$  possesses a composition series whose successive quotients are forms of  $G_a$ .

Indeed, by hypothesis, there exists an extension  $k'$  of  $k$  such that  $G_{k'}$  is isomorphic to  $(G_a, k')^{(r)}$ . By the principle of finite extension (EGA IV 9.1.1), one may suppose that  $k'$  is a finite extension of  $k$ . But then, for a), it suffices to consider the canonical closed immersion (EGA V[N.D.E-XVII-5]):

$$G \rightarrow \prod_{k'/k} (G_{k'})/k' \subset (G_a, k)^n \quad (\text{with } n = r \deg(k'/k)).$$

To prove b), in view of a), one may suppose that  $G$  is a closed subgroup of  $G' = (G_a)^{(n)}$ . If  $G \neq 0$ , there exists a hyperplane  $\mathfrak{h}$  of  $\mathfrak{g}' = \text{Lie } G'$  not containing  $\mathfrak{g}$ . Let  $\mathfrak{h}$  be the vector subgroup  $W(\mathfrak{h})$  of  $W(\mathfrak{g}') = G'$ . Since  $\mathfrak{h}$  is defined by an equation in  $G'$ ,  $\mathfrak{h} \cap \mathfrak{g}$  is defined by an equation in  $G$ , and one has the inequalities:

$$\begin{aligned} \dim G - 1 &\leq \dim(G \cap H) \\ &\leq \dim \text{Lie}(G \cap H) = \dim_k(\mathfrak{g} \cap \mathfrak{h}) = \dim_k(\mathfrak{g}) - 1 = \dim G - 1. \end{aligned}$$

Hence  $\dim(G \cap H) = \dim \text{Lie}(G \cap H)$ , and consequently  $G \cap H$  is smooth. The group  $G_1 = (G \cap H)^{(0)}$

<!-- original page 558 -->

is an algebraic subgroup of  $G$ , smooth and connected, such that  $G/G_1$  is smooth, connected, of dimension 1, hence a form of  $G_a$  (4.1 i)  $\Rightarrow$  iii)). One finishes by induction on the dimension of  $G$ .

Before continuing the proof of 4.1, let us note that the equivalence i)  $\Leftrightarrow$  ii) and 2.3 bis entail the following corollary:

**Corollary 4.1.3.** \*If  $k$  is a perfect field, a smooth and connected  $k$ -algebraic group is unipotent if and only if it possesses a composition series whose successive quotients are isomorphic to  $G_a$ .\*

<!-- label: III.XVII.4.1.3 -->

\*Continuation of the proof of 4.1.\*

i)  $\Rightarrow$  iv) by 2.4 i).

iv)  $\Rightarrow$  v). By Exp. XIV, 4.1,  $G$  possesses a maximal torus  $T$  defined over  $k$ . Now if  $r = \dim T$ ,  $(\bar{\mu}_n)_T$  is isomorphic to  $(\mu_n)^r$ . Hence  $r = 0$ .

v)  $\Rightarrow$  i) as remarked in the proof of 3.8.

i)  $\Rightarrow$  vi). By 3.4,  $G$  is in fact contained in an algebraic subgroup of  $GL(n)$  isomorphic to  $\text{Trigstr}(n)$ , hence  $g$  consists of nilpotent endomorphisms.

vi)  $\Rightarrow$  vii). Indeed,  $g$  is nilpotent by Engel's theorem (Bourbaki, \*Groupes et algèbres de Lie\*, Chap. I § 4 cor. 3).

vii)  $\Rightarrow$  v). Let  $T$  be a maximal sub-torus of  $G$  (Exp. XIV, 1.1),  $t$  its Lie algebra. The embedding of  $G$  in  $GL(n)$  defines a representation of  $T$  which is necessarily semisimple (this is seen on an algebraic closure  $\bar{k}$  of  $k$ , and one applies Exp. I, 4.7.3).

<!-- original page 559 -->

Hence if  $X \in t$ ,  $X$  is a semisimple endomorphism in  $gl(n)$ . One sees immediately that this entails that the map

```
``text
ad X : Y $\mapsto$ [X, Y]
``
```

is a semisimple endomorphism of  $gl(n)$ , hence of  $g$ . Since, moreover, this endomorphism is nilpotent ( $g$  being nilpotent),  $\text{ad } X$  is zero, so  $X$  is central. But then  $t$  is central and consists of semisimple endomorphisms, hence is zero by hypothesis; *a fortiori*,  $T$  is the trivial group.

**Remark 4.1.4.**

<!-- label: III.XVII.4.1.4 -->

\*a) We shall give below (4.3.1) an infinitesimal characterization of unipotent groups in characteristic  $p > 0$ , which is independent of an embedding in  $GL(n)$ .\*

\*b) When  $k$  is perfect, conditions ii) and iii) of 4.1.1 simplify by reason of the following lemma:\*

**Lemma 4.1.5.** \*If  $k$  is a perfect field, every  $k$ -algebraic group  $G$  which is a form of  $(G_a)^r$  is isomorphic to  $(G_a)^r$ .\*

<!-- label: III.XVII.4.1.5 -->

The lemma follows from 3.9 ter if the characteristic  $p$  of  $k$  is zero, and from 2.3 bis if  $r = 1$ . In the general case ( $p > 0$ ), realize  $G$  as an algebraic subgroup of  $(G_a)^n$  for some suitable integer  $n$  (4.1.2), and argue by induction on the integer  $n - r$ . If  $r = n$ , one indeed has  $G = (G_a)^r$ . Otherwise the quotient group  $G^n_a / G$  is a non-zero smooth connected unipotent group which, taking 4.1.1 i)  $\Rightarrow$  ii) and 2.3 bis into account,

<!-- original page 560 -->

possesses a composition series with quotients isomorphic to  $G_{\{a\}}$ . One deduces that there exists an algebraic subgroup  $G_1$  of  $(G_{\{a\}})^n$ , smooth and connected, containing  $G$ , such that  $G^n_{\{a\}} / G_1 = G_{\{a\}}$ . By induction it suffices to show that  $G_1$  is isomorphic to  $(G_{\{a\}})^{n-1}$ . Now it is immediate to verify that a homomorphism from  $\operatorname{Spec} k[X_1, \dots, X_n] = G^n_{\{a\}}$  to  $G_{\{a\}} = \operatorname{Spec} k[T]$  is defined by an additive polynomial of the form:

$$\sum_{i,j} a_{i,j} X^{p^j}_{\{i\}}.$$

Since  $G_1$  is smooth, the linear part of this polynomial is non-zero. Possibly making a linear change of the coordinates  $X_{\{i\}}$ , we may assume that  $G_1$  is an algebraic subgroup of  $(G_{\{a\}})^n$  defined by the equation:

$$\begin{aligned} (*) \quad P(X) = -X_1 + \sum_{j=1}^q a_j X^{p^j}_1 + Q(X_2, \dots, X_n) = 0, \\ \text{with } Q(X_2, \dots, X_n) = \sum_{i>1, j>0} b_{i,j} X^{p^j}_i. \end{aligned}$$

Proceed then by induction on the degree of  $P$ . If  $\deg P = 1$ , it is clear that  $G_1 \xrightarrow{\sim} G^{n-1}_{\{a\}}$ . Otherwise, since  $k$  is perfect, one has  $Q(X) = Q_1(X)^p$  and we may define an endomorphism  $v$  of  $G^n_{\{a\}}$  by the formulas:

$$\begin{aligned} X_i \mapsto X_i \quad \text{for } i > 1, \quad X_1 \mapsto \sum_{j=1}^q a_j^{1/p} X^{p^j}_1 + Q_1(X). \end{aligned}$$

It is clear that  $v$  induces an isomorphism on  $G_1$  and that  $v(G_1)$  has equation in  $G^n_{\{a\}}$ :

$$(*)_1 \quad P_1(X) = -X_1 + \sum_{j=1}^q a_j^{1/p} X^{p^j}_1 + Q_1(X_2, \dots, X_n) = 0.$$

Let us then distinguish two cases:

<!-- original page 561 -->

\*1st case.\*  $\deg(Q) = \deg P > p^q$ . Then  $\deg P_1 < \deg P$  and one wins by the induction hypothesis.

\*2nd case.\*  $\deg P = p^q$  ( $a_q \neq 0$ ). One then has  $\deg P_1 = \deg P = p^q$  and  $\deg Q_1 < p^q$ . (One cannot have  $Q = 0$ , otherwise  $G_1$  would not be connected.) If the polynomial  $Q_1$  has no linear part, one can iterate the preceding transformation. Continuing the process, one finally obtains an equation of the form:

$$(*)_s \quad P_s(X) = -X_1 + \sum_{j=1}^q a_j^{1/p^s} X^{p^j}_1 + Q_s(X),$$

where  $Q_s(X) = Q(X_2, \dots, X_n)^{1/p^s}$  is an additive polynomial having a non-zero linear part, and moreover  $\deg Q_s < p^q$ . Suppose, for example, that the coefficient of  $X_2$  in  $Q_s$  is non-zero, and let  $-L$  be the linear part of  $P_s(X)$ . Possibly making a linear change of coordinates, the equation of  $G_1$  becomes:

$$P'(X) = -L + \sum_{j=1}^q a_j^{1/p^s} X^{p^j}_1 + Q'(L, X_3, \dots, X_n),$$

where  $Q'$  is an additive polynomial without linear part, and  $\deg(Q') < p^q$ . But then we are reduced to the first case. [N.D.E-XVII-6]

### ### 4.2. Radicial groups

<!-- label: III.XVII.4.2 -->

**Proposition 4.2.1.** \*Let  $G$  be a radicial algebraic group defined over a field  $k$  of characteristic  $p > 0$ . Then the following conditions are equivalent:\*

<!-- label: III.XVII.4.2.1 -->

\*i)  $G$  is unipotent.\*

\*ii)  $G$  possesses a central composition series with successive quotients isomorphic to  $\alpha_p$ .\*

<!-- original page 562 -->

\*iii)  $G$  possesses a central and characteristic composition series with successive quotients isomorphic to  $\alpha_p^r$ .\*

\*iv)  $G_{\bar{k}}$  contains no subgroup isomorphic to  $\mu_p$ .\*

\*v)  $\mathfrak{g} = \text{Lie } G$  is a unipotent  $p$ -Lie algebra (3.6).\*

\*Proof.\* iii)  $\Rightarrow$  ii)  $\Rightarrow$  i) is clear, i)  $\Rightarrow$  iii) is 3.9 i), and i)  $\Rightarrow$  iv) by 2.4 i).

We shall need the following lemma on abelian  $p$ -Lie algebras:

**Lemma 4.2.2.** \*Let  $\mathfrak{g}$  be an abelian, finite-dimensional  $p$ -Lie algebra over a perfect field  $k$ . Then  $\mathfrak{g}$  can be written uniquely as a direct sum of a sub- $p$ -Lie algebra  $\mathfrak{r}$  on which the  $p$ -th power is bijective, and a sub- $p$ -Lie algebra  $\mathfrak{u}$ , unipotent (3.6). (The algebra  $\mathfrak{r}$  will be called the\* reductive part \*of  $\mathfrak{g}$  and  $\mathfrak{u}$  the\* unipotent part\*.) The formation of  $\mathfrak{r}$  and  $\mathfrak{u}$  is compatible with extension of the field  $k$ . If moreover  $k$  is algebraically closed,  $\mathfrak{r}$  admits a basis  $e_i$  such that  $e_i^{(p)} = e_i$ .\*

<!-- label: III.XVII.4.2.2 -->

The proof of this lemma is easy and left to the reader (cf. Bourbaki, \*Groupes et algèbres de Lie\*, Chap. I § 1 exercise 23). Let us simply say that  $\mathfrak{u}$  is the kernel of a suitable iterate of the map  $X \mapsto X^{(p)}$ , and that  $\mathfrak{r}$  is the image of the same iterate.

<!-- original page 563 -->

This being so, let us prove iv)  $\Rightarrow$  v). Possibly making an extension of the base field, one may suppose  $k$  algebraically closed.

Let then  $X$  be an element of  $\mathfrak{g}$  and  $\mathfrak{h}$  the sub- $p$ -Lie algebra generated by  $X$  in  $\mathfrak{g}$ . The algebra  $\mathfrak{h}$  is evidently commutative, and its reductive part (4.2.2) is zero, otherwise by \*loc. cit.\*,  $\mathfrak{h}$  would contain an element  $Y \neq 0$  such that  $Y^{(p)} = Y$ , and consequently (App. II 2.1 and 2.2)  $G$  would contain a subgroup isomorphic to  $\mu_p$  contrary to hypothesis. Hence  $\mathfrak{h}$ , and consequently  $\mathfrak{g}$ , is a unipotent  $p$ -Lie algebra.

v)  $\Rightarrow$  i). This is the least trivial implication of 4.2.1.

a) Case where  $G$  is of height 1 (Exp. VII A, 4.1.3). Since  $G$  is radical, it is affine, hence isomorphic to an algebraic subgroup of a linear group  $\text{GL}(V)$  (Exp. VI B, § 11). This embedding identifies  $\mathfrak{g}$  with a sub- $p$ -Lie algebra of  $\text{End}(V)$ , the  $p$ -th power of  $X$  in  $\mathfrak{g}$  coinciding with the  $p$ -th power of the endomorphism  $X$  (Exp. VII A, 6.4.4). Since  $\mathfrak{g}$  is unipotent by hypothesis,  $\mathfrak{g}$  is therefore an algebra of nilpotent endomorphisms of  $V$ , and by Engel's theorem (Bourbaki, \*Groupes et algèbres de Lie\*, Chap. I § 4 th. 1) is a Lie subalgebra of the Lie algebra  $\mathfrak{h}$  of the group of strictly upper-triangular matrices  $\text{Trigstr}(n)$  with respect to a suitable basis of  $V$ . Since  $G$  is of height 1, one then deduces from App. II 2.2 that  $G$  itself is an algebraic subgroup of  $\text{Trigstr}(n)$ , hence is unipotent (3.5 v)  $\Rightarrow$  i)).

b) General case. Proceed by induction on the height  $h$  of  $G$  [XVII-4-1]. The case  $h = 1$  has just been treated. Suppose  $h > 1$ , and set  $G' = F G$  and  $G'' = G/G'$ . The group  $G'$  is of height 1 and  $\text{Lie } G' = \mathfrak{g}'$  is unipotent, hence  $G'$  is unipotent by a).

<!-- original page 564 -->

To show that  $G$  is unipotent, it therefore suffices to prove that  $G''$  is unipotent (2.2). But  $G''$  is of height  $h - 1$ , hence, by induction hypothesis, it suffices to show that  $\text{Lie } G''$  is unipotent. Since iv)  $\Rightarrow$  v), it suffices to show that  $G''_{\bar{k}}$  does not contain any group isomorphic to  $\mu_p$ . Let then a subgroup of  $G''_{\bar{k}}$  isomorphic to  $\mu_p$ ,  $H$  its inverse image in  $G_{\bar{k}}$ . The group  $G'$  being unipotent, we shall prove in § 5 that the extension:

```text  
 $e \rightarrow G'_{\bar{k}} \rightarrow H \rightarrow \mu_p \rightarrow e$

...

is necessarily trivial (the proof given of this fact is independent of the results of the present section). Briefly, the group μ_p lifts in H , but being of height 1 it is necessarily contained in $G'_{\bar{k}} = F G_{\bar{k}}$, whence a contradiction, G' being unipotent.

4.3. Connected affine groups in characteristic $p > 0$

<!-- label: III.XVII.4.3 -->

Proposition 4.3.1. *Let G be a connected affine algebraic group over a field k of characteristic $p > 0$. Then the following conditions are equivalent:*

<!-- label: III.XVII.4.3.1 -->

i) G is unipotent.

ii) G possesses a composition series with successive quotients isomorphic to α_p and G_a (taken in this order).

iii) G admits a characteristic composition series with successive quotients isomorphic to α_p^r and G_a^s (taken in this order).

iv) $G_{\bar{k}}$ contains no subgroup isomorphic to μ_p .

v) $\mathfrak{g} = \text{Lie } G$ is unipotent (3.6).

<!-- original page 565 -->

vi) $\mathfrak{g}$ is nilpotent, and the reductive part of the center of $\mathfrak{g}$ (4.2.2) is trivial.

vi bis) $\mathfrak{g}$ is nilpotent, and every subgroup of multiplicative type of the identity component of the center of G is zero.

vi ter) G is nilpotent, and every subgroup of multiplicative type of the identity component of the center of G is zero.

Proof. It is clear that iii) $\Rightarrow$ ii) $\Rightarrow$ i). To establish i) $\Rightarrow$ iii), we shall need the following lemma:

Lemma 4.3.2. *Let k be a field of characteristic $p > 0$, $n \in \mathbb{N}$, k' a radical extension of k such that $(k')^{p^n}$ is contained in k ; for every k -prescheme X (resp. every k' -prescheme X'), denote by $X^{(p^n)}$ (resp. $X'^{(\phi)}$) the k -prescheme deduced from X (resp. X') by the base change:*

<!-- label: III.XVII.4.3.2 -->

```text

$F^n : k \rightarrow k, \quad x \mapsto x^{p^n}, \quad (\text{resp. } \phi : k' \rightarrow k, \quad x' \mapsto x'^{p^n}).$

```

Then, for every k -prescheme X , there exists a functorial isomorphism:

$$(X_{k'})^{(\phi)} \xrightarrow{\sim} X^{(p^n)}.$$

Consequently, if X and Y are two k -preschemes such that there exists a k' -isomorphism $u' : X_{k'} \xrightarrow{\sim} Y_{k'}$, then there exists a k -isomorphism $v : X^{(p^n)} \xrightarrow{\sim} Y^{(p^n)}$. If moreover X and Y are equipped with structures of k -preschemes in groups and if u is a k' -homomorphism, then v is a k -homomorphism.

<!-- original page 566 -->

The lemma follows simply from the transitivity of base changes and from the fact that the composite morphism $k \rightarrow k' \xrightarrow{\phi} k$ is equal to F^n .

Continuation of the proof of 4.3.1.

i) $\Rightarrow$ iii). Proceed by induction on $\dim G$. If $\dim G = 0$, since G is connected, it is radical, and one applies 3.9 i). If $\dim G > 0$, there exists an integer $m \geqslant 0$ such that the quotient $G / F_m G$ is a smooth group (App. II 3.1), evidently connected and non-zero. Applying 4.1.1 i) $\Rightarrow$ iii) to the latter, one sees that there exists an algebraic subgroup G' of G which is characteristic and connected, and such that the quotient $G' = G/G'$ is a form of $G^{\{r\}}_{\{a\}}$ ($r > 0$). By 4.1.5, if K is a perfect closure of k , one has $G'_{\{K\}} \xrightarrow{\sim} (G_{\{a, K\}})^{\{r\}}$. Since G' is of finite type over k , there exists a finite radical extension k' of k such that $G'_{\{k'\}} \xrightarrow{\sim} (G_{\{a, k'\}})^{\{r\}}$ (Exp. VI_B § 10). Let $n > 0$ be such that $(k')^{p^n} \subset k'$. Keeping the notations of 4.3.2, one deduces that there exists a k' -isomorphism of algebraic groups:

```
```text
(G_{a, k'})^r = (G_{a, k'})^{r\varphi} \square (G')^{(p^n)}.
```

Consider then the Frobenius homomorphism relative to  $G'$  (Exp. VII\_A § 4)

```
$$
F_n : G' \longrightarrow (G')^{(p^n)}.
$$
```

Since  $G'$  (and hence also  $(G')^{(p^n)}$ ) is smooth over  $k$ , and  $F_n$  is radical,  $F_n$  is an epimorphism for the fpqc topology, so that  $(G')^{(p^n)}$  is identified with  $G'/F_n(G')$ . Finally we have shown that  $G'/F_n(G')$  is isomorphic, as an algebraic group, to  $(G_a)^{\{r\}}$ .

<!-- original page 567 -->

The inverse image  $G'_n$  of  $F_n(G')$  in  $G$  is a subgroup of  $G$ , connected, characteristic, of dimension strictly less than that of  $G$ , to which we may apply the induction hypothesis.

i)  $\Rightarrow$  iv) by 2.4 i).

iv)  $\Rightarrow$  i). Consider  $G$  as an extension of a smooth connected group  $G'$  by a radical group  $G''$  (App. II 3.1). The group  $G''$  is unipotent (4.2.1 iv)  $\Rightarrow$  i)). It suffices to see that  $G'$  is unipotent, and for that it suffices to show that  $G'_{\{\bar{k}\}}$  does not contain a subgroup isomorphic to  $\mu_p$  (4.1.1 i)  $\Rightarrow$  iv)). Now if  $G'_{\{\bar{k}\}}$  contained a subgroup  $\mu_p$ , the latter would lift in  $G_{\{\bar{k}\}}$ , by the result (5.1) – already used – proved in § 5, whence a contradiction with iv).

i)  $\Rightarrow$  v) by 3.7.

v)  $\Rightarrow$  vi). Indeed, since  $(\text{ad } X)^{p^r} = \text{ad}(X^{(p^r)})$  (VII\_A, 5.2),  $\text{ad } X$  is nilpotent if  $g$  is unipotent, hence  $g$  is nilpotent by Engel's theorem (Bourbaki, \*Groupes et algèbres de Lie\*, Chap. I § 4). On the other hand, if  $g$  is unipotent, evidently so is its center, whose reductive part is then trivial (4.2.2).

vi)  $\Rightarrow$  iv). Indeed, if  $G_{\{\bar{k}\}}$  contains a subgroup isomorphic to  $\mu_p$ , there exists a non-zero element  $X$  of its Lie algebra such that  $X^{(p)} = X$  (App. II 2.1), hence  $X^{(p^r)} = X$  for every  $r > 0$ . Since  $\text{ad } X$  is nilpotent (because  $g$  is nilpotent and  $(\text{ad } X)^{p^r} = \text{ad } X^{(p^r)}$ ), necessarily  $\text{ad } X = 0$ , so  $X$  belongs to the reductive part of the center of  $g_{\{\bar{k}\}}$ , whence a contradiction with vi).

i)  $\Rightarrow$  vi ter) follows from 2.4 i) and from 3.5 i)  $\Rightarrow$  iii).

<!-- original page 568 -->

vi ter)  $\Rightarrow$  vi bis). Indeed, if  $G$  is nilpotent, so is its subgroup  $F G$ . It also follows from App. II 2.2 that  $F G$  is nilpotent if and only if  $\text{Lie } F G = \text{Lie } G$  (Exp. VII\_A) is nilpotent.

vi bis)  $\Rightarrow$  vi). Let  $Z$  be the identity component of the center of  $G$ , and let  $r$  be the reductive component of the center of  $g$ . We must show that  $r = 0$ . Now it is immediate that  $r$  is a characteristic sub- $p$ -Lie algebra of  $g = \text{Lie } F G$  (i.e. stable under the functor  $\text{Aut}_{p\text{-Lie}}(g)$ ); hence  $r$  is the Lie algebra of a characteristic radical subgroup  $R$  of  $F G$  (App. II 2.2). On the other hand, it follows from the last assertion of 4.2.2 and from App. II 2.1 that  $R$  is a form of  $\mu_p^{\{r\}}$ . The group  $R$  being characteristic in  $F G$ , which is itself a characteristic subgroup of  $G$  (App. II 1),  $R$  is  $\ast$ a fortiori $\ast$  invariant in  $G$ , hence is central,  $G$  being connected (Exp. IX, 5.5). Hence by hypothesis vi bis),  $R$  is zero, and so therefore is  $r$ .

### ### 4.4. Étale groups

<!-- label: III.XVII.4.4 -->

The following proposition is an easy consequence of Sylow's theorems and of the structure of finite  $q$ -groups (cf. J.-P. Serre, *\*Corps locaux\**, Chap. IX § 1).

**\*\*Proposition 4.4.1.\*\*** *Let  $G$  be a finite étale algebraic group defined over an algebraically closed field  $k$ . Then in order that  $G$  be unipotent, it is necessary and sufficient that for every prime number  $q$  distinct from the characteristic  $p$  of  $k$ ,  $G$  does not contain a subgroup isomorphic to  $\mu_q$ .*

<!-- label: III.XVII.4.4.1 -->

### ### 4.5. Abelian varieties

<!-- label: III.XVII.4.5 -->

<!-- original page 569 -->

Let  $G$  be an abelian variety defined over an algebraically closed field  $k$ . Then the following conditions are equivalent:

i)  $G$  is unipotent.

ii)  $G = 0$ .

iii) There exists an integer  $n$ , prime to the characteristic  $p$  of  $k$ , such that  $G$  does not contain a subgroup isomorphic to  $\mu_n$ .

Indeed, if  $G$  is an abelian variety of dimension  $d$ , one knows (cf. S. Lang, *\*Abelian varieties\**, Chap. IV § 3 th. 6) that the group  $G(k)$  ( $n$  an integer prime to  $p$ ) is isomorphic to  $(\mathbb{Z}/n\mathbb{Z})^{2d}$ , hence is isomorphic to  $\mu_n^{2d}$ . Whence iii)  $\Rightarrow$  ii), and ii)  $\Rightarrow$  i)  $\Rightarrow$  iii) are obvious.

### ### 4.6. General case

<!-- label: III.XVII.4.6 -->

If  $G$  and  $H$  are two algebraic groups defined over an algebraically closed field  $k$ , we shall denote by  $P(G, H)$  the property: "there is no algebraic subgroup of  $G$  isomorphic to  $H$ ". One then obtains the following characterizations of unipotent groups:

**\*\*Theorem 4.6.1.\*\*** *Let  $G$  be an algebraic group defined over an algebraically closed field  $k$  of characteristic  $p$ . Then:*

<!-- label: III.XVII.4.6.1 -->

\*i) If  $G$  is smooth, affine, and connected:

```text  
G is unipotent $\Leftrightarrow \exists n > 1$ such that $P(G, \mu_n)$ is true $\Leftrightarrow P(G, G_m)$ is true.
```

\*ii) If  $G$  is smooth and connected:

```text  
G is unipotent $\Leftrightarrow \exists n$ prime to p such that $P(G, \mu_n)$ is true.
```

<!-- original page 570 -->

\*iii) If  $G$  is smooth:

```text  
G is unipotent $\Leftrightarrow$ for every prime number $n \neq p$, $P(G, \mu_n)$ is true.
```

\*iv)  $G$  affine connected and  $p > 0$ : \*  $G$  unipotent  $\iff P(G, \mu_p)$  is true.\*

\*v)  $G$  connected and  $p > 0$ : \*

``text  
 $G$  unipotent  $\iff \exists n$  prime to  $p$  such that  $P(G, \mu_n)$  is true and  $P(G, \mu_p)$  is true.  
 ``

\*vi)  $G$  an arbitrary algebraic group: \*

``text  
 $G$  is unipotent  $\iff$  for every prime number  $n$ ,  $P(G, \mu_n)$  is true.  
 ``

\*Proof.\* i) follows from 4.1.1, and iv) from 4.3.1. We shall prove vi); ii), iii), v) are proved analogously and are left to the reader.

Let then  $G$  be an algebraic group. If  $G$  is unipotent,  $P(G, \mu_n)$  is true for every  $n > 1$  (2.4 i)). Conversely, suppose  $P(G, \mu_n)$  is true for every prime number  $n$ , and let us show that  $G$  is unipotent. Let  $G^0$  be the identity component of  $G$ . If  $G^0$  is smooth, it follows from a classical theorem of Chevalley[<sup>XVII-4-2</sup>] that  $G^0$  is an extension of an abelian variety  $A$  by an affine, connected, smooth group  $L$ . If  $G$  is not smooth, which presupposes  $p > 0$  (Exp. VI\_B, 1.6.1), there exists an integer  $n > 0$  such that  $G' = G^0 / F_n(G)$  is smooth (App. II 3.1). Then  $G'$  is an extension of an abelian variety  $A$  by a smooth connected linear group  $L'$ . Denote by  $L$  the inverse image of  $L'$  in  $G^0$ , which is still affine and connected, since  $F_n(G)$  is radicial. In all cases,  $G$  therefore possesses a composition series:

<!-- original page 571 -->

$\emptyset \subset L \subset G^0 \subset G$

such that  $L$  is affine and connected,  $G^0/L = A$  is an abelian variety, and  $G/G^0$  an étale group.

If  $P(G, \mu_n)$  is true, *a fortiori*  $P(L, \mu_n)$  is true, hence  $L$  is unipotent (4.1.1 and 4.3.1). If  $A$  is non-zero, there exists a prime number  $n$  and a subgroup of  $A$  isomorphic to  $\mu_n$  (4.5); by 5.1 below, this subgroup lifts in  $G$ , which contradicts the hypothesis  $P(G, \mu_n)$ ; hence  $A = \emptyset$ . Finally if  $G/G^0$  is not unipotent, there exists an integer  $q$  and a subgroup of  $G/G^0$  isomorphic to  $\mu_q$  (4.4.1). One deduces as above that  $P(G, \mu_q)$  is not true; hence  $G/G^0$  is unipotent, and consequently so is  $G$ .

## 5. Extension of a group of multiplicative type by a unipotent group

<!-- label: III.XVII.5 -->

<!-- original page 572 -->

### 5.1. Statement of the theorem

<!-- label: III.XVII.5.1 -->

**\*Definition 5.1.0.\*** Let  $k$  be a field,  $G$  a  $k$ -algebraic group. Following the terminology introduced by Rosenlicht (Questions of rationality for solvable algebraic groups over non perfect fields, Annali di Math. 61 (1963)), we shall say that  $G$  is " $k$ -solvable" if it satisfies the following equivalent conditions:

<!-- label: III.XVII.5.1.0 -->

i)  $G$  possesses a composition series with successive quotients isomorphic to  $G_a$ .

ii)  $G$  possesses a characteristic composition series  $G_i$  such that the successive quotients  $G_i / G_{i+1}$  are commutative and possess a composition series with successive quotients isomorphic to  $G_a$ .

The fact that i)  $\Rightarrow$  ii) is proved in *loc. cit.* In fact, one may take as composition series  $G_i$  the composition series introduced in the proof of 3.9 ii).

**\*\*Theorem 5.1.1.\*\*** \*Let  $k$  be a field,  $U$  a unipotent  $k$ -algebraic group,  $H$  a  $k$ -group of multiplicative type,  $E$  a  $k$ -algebraic group extension of  $H$  by  $U$ , so that one has the exact sequence:

<!-- label: III.XVII.5.1.1 -->

$$1 \longrightarrow U \longrightarrow E \longrightarrow H \longrightarrow 1.$$

\*Then:\*

<!-- original page 573-574 -->

\*i) The extension  $E$  is trivial in each of the following cases:\*

\*a)  $k$  is algebraically closed.\*

\*b)  $k$  is perfect and one of the groups  $U$  or  $H$  is connected.\*

\*c)  $U$  is  $k$ -solvable.\*

\*d)  $U$  is smooth and  $H$  is connected.\*

\*ii) If  $H'$  and  $H''$  are two lifts of  $H$  in  $E$ , then  $H'$  and  $H''$  are conjugate by an element of  $U(k)$  in each of the following cases:\*

\*a)  $k$  is algebraically closed and  $H$  is smooth.\*

\*b)  $k$  is algebraically closed and  $U$  is smooth.\*

(We shall indicate in the course of the proof other cases where the conclusion of ii) is true without assuming  $k$  algebraically closed.)

If  $U$  is an algebraic group (resp. a commutative algebraic group) defined over a field  $k$ , we denote by  $H^1(k, U)$  (resp.  $H^i(k, U)$ ,  $i \geq 1$ ) the pointed set (resp. the  $i$ -th group) of Galois cohomology of  $k$  with values in  $U$  (cf. J.-P. Serre, *Cohomologie Galoisienne*, Lecture Notes Maths. n° 5, Springer).

<!-- original page 575 -->

If  $S$  is a prescheme,  $H$  an  $S$ -prescheme in commutative groups,  $G$  an  $S$ -prescheme in groups acting on  $H$ , we denote by  $H^i(G, H)$  [N.D.E.-XVII-7] the  $i$ -th Hochschild cohomology group of  $G$  with values in  $H$  (App. I 1).

To prove 5.1.1, we shall proceed in several steps.

### 5.2. Proof of 5.1.1 i) and ii) in the case  $U$  smooth and  $H$  étale

<!-- label: III.XVII.5.2 -->

**\*\*Lemma 5.2.1.\*\*** \*With the notations of 5.1.1, if  $H$  is étale, the canonical morphism  $E \rightarrow H$  possesses a section  $s : H \rightarrow E$ , defined over  $k$ , in the following cases:\*

<!-- label: III.XVII.5.2.1 -->

\*a)  $k$  is algebraically closed.\*

\*b)  $k$  is perfect and  $U$  is smooth and connected.\*

\*c)  $U$  is " $k$ -solvable".\*

a) follows simply from the fact that  $E(k) \rightarrow H(k)$  is surjective. One has  $b) \Rightarrow c)$  by 4.1.2 b) and 2.3 bis. It therefore suffices to treat case c). Let  $x$  be a point of  $H$ ;  $x$  is both an open and closed part of  $H$ , and the induced subscheme is isomorphic to  $\operatorname{Spec} K$ , where  $K$  is a finite separable extension of  $k$ . Let  $X$  be the inverse image in  $E$  of the scheme  $x$ . The  $K$ -scheme  $X$  is a principal homogeneous  $K$ -space under the group  $U_K$ . But  $U_K$  possesses a composition series with successive quotients isomorphic to  $G_{a,K}$ , hence  $H^1(K, U_K) = 0$  (J.-P. Serre, *Cohomologie Galoisienne*, Chap. III, prop. 6), and consequently  $X$  is trivial,

hence has a  $k$ -rational point. One thus obtains a  $k$ -section of  $E \rightarrow H$  over  $x$ , for every point  $x$  of  $H$ , whence the existence of a section  $H \rightarrow E$ .

**Lemma 5.2.3.** [N.D.E-XVII-8] With the notations of 5.1.1, suppose  $H$  étale. Then:

<!-- label: III.XVII.5.2.3 -->

i) The extension  $E$  is trivial in each of the following cases:

a)  $U$  is commutative and  $E \rightarrow H$  possesses a section.

<!-- original page 576 -->

b)  $k$  is algebraically closed.

c)  $k$  is perfect and  $U$  is connected.

d)  $U$  is " $k$ -solvable".

Moreover, in each of the above cases, two lifts  $H'$  and  $H''$  of  $H$  in  $E$  are conjugate by an element of  $U(k)$ .

ii) Let  $R$  be the  $k$ -functor  $(\text{Sch}/k)^{\circ} \rightarrow (\text{Ens})$  such that, for every  $k$ -prescheme  $S$ ,  $R(S)$  is the set of lifts of  $H_S$  in  $E_S$ . Then if  $U$  is commutative,  $R$  is representable by a non-empty affine  $k$ -scheme. The group  $U$  acts by inner automorphisms on  $R$ , and this action makes  $R$  into a homogeneous space under  $U$  (for the fpqc topology (cf. Exp. IV)).

*Proof of i).* We shall reduce cases b), c), and d) to case a).

*Case b).* Since  $U$  possesses a characteristic composition series with successive commutative quotients (3.5 i)  $\Rightarrow$  iv)), one immediately reduces to the case where  $U$  is commutative. Moreover  $E \rightarrow H$  possesses a section by 5.2.1 a), and we are reduced to case a).

*Case d).* One proceeds similarly using 5.1.0 ii) and 5.2.1 c).

*Case c).* Let  $E_{\text{red}}$  be the reduced subgroup associated with  $E$ . Since  $H$  is smooth,  $E_{\text{red}}$  is an extension of  $H$  by  $U_0 = U \cap E_{\text{red}}$ , and one may replace  $E$  by  $E_{\text{red}}$ . But  $U$ , and therefore also  $U_0$ , is connected, and it is clear that  $U_0$  is the identity component of  $E_{\text{red}}$ , hence is smooth. But then  $U_0$  is smooth and connected,  $k$  is perfect, hence  $U_0$  is  $k$ -solvable (4.1.4 b)) and we are reduced to case d).

<!-- original page 577 -->

The preceding reductions show that in cases b), c), and d) one may suppose that  $U$  possesses a characteristic composition series  $(U_i)$  such that  $U_i / U_{i+1}$  is commutative and such that the maps  $U_i(k) \rightarrow (U_i / U_{i+1})(k)$  are surjective (in cases c) and d), this last point comes from  $H^1(k, G_a) = 0$ ). An immediate dévissage then shows that it suffices to prove the conjugacy of two lifts  $H'$  and  $H''$  in  $E$  when  $U$  is commutative. In short, it suffices to prove i) a). In this case, the triviality of the extension  $E$  is ensured if  $H^2(H, U) = 0$  (App. I 3.1), and the conjugacy of  $H'$  and  $H''$  if  $H^1(H, U) = 0$ . Now we have the following lemma:

**Lemma 5.2.4.** Let  $S$  be a prescheme,  $U$  an  $S$ -prescheme in commutative groups,  $H$  an  $S$ -prescheme in groups, étale, finite, of rank  $n$ , acting on  $U$ . Then the groups  $H^i(H, U)$  ( $i > 0$ ) are annihilated by  $n$  in the following two cases:

<!-- label: III.XVII.5.2.4 -->

a)  $H$  is a constant  $S$ -group (Exp. I 4.1).

b)  $S$  is the spectrum of a field.

*Proof of a).* The group  $H$  is by hypothesis the constant group associated with an ordinary group  $\{H\}$  of order  $n$ . It is clear [N.D.E-XVII-9] that  $H^i(H, U)$  is isomorphic to the  $i$ -th cohomology group  $H^i(\{H\}, U(S))$  of the group  $\{H\}$ , with values in the ordinary group  $U(S)$ , and it is classical that these groups are annihilated by  $n$  (J.-P. Serre, *Corps locaux*, Chap. VIII, prop. 4 cor. 1).

*Proof of b).* Let  $x \in H^i(H, U)$  ( $i > 0$ ), which one represents by an  $i$ -cocycle  $f : H^{\{i\}} \rightarrow U$

<!-- original page 578 -->

(where  $H^{\{i\}}$  denotes the product, over  $k$ , of  $i$  copies of  $H$ ). If  $K$  is a finite Galois extension of  $k$  that decomposes  $H$ , it follows from a) that  $\text{nf}_K$  is a coboundary. More precisely, an easy computation shows that if one defines the  $K$ -morphism  $F_K : H^{\{i-1\}}_K \rightarrow U_K$  by the formula:

```
```text
F_K(h_1, ..., h_{i-1}) = \sum_{h \in H(K)} f_K(h_1, ..., h_{i-1}, h),
```
```

one has, up to sign:

```
```text
d(F_K) = n f_K   (d coboundary operator).
```
```

Now an immediate Galois argument shows that  $F_K$  comes from a  $k$ -morphism  $F : H^{\{i-1\}} \rightarrow U$ , and consequently one has  $d(F) = \text{nf}$ .

**Corollary 5.2.4 bis.** \*With the notations of 5.2.4, suppose moreover that  $U$  is flat and of finite presentation over  $S$ , with unipotent fibers, and that  $n$  is prime to the residue characteristics of  $S$ . Then, in cases a) and b) above, one has  $H^{\{i\}}(H, U) = 0$  for  $i > 0$ .\*

<!-- label: III.XVII.5.2.4bis -->

It suffices to show that raising to the  $n$ -th power in  $U$  is an isomorphism, since this will entail that multiplication by  $n$  in  $H^{\{i\}}(H, U)$  is both an isomorphism and the zero morphism, hence  $H^{\{i\}}(H, U) = 0$ . Now, under the hypotheses on  $U$ , it suffices to verify that raising to the  $n$ -th power is an isomorphism on the fibers of  $U$  (EGA IV 17.9.5), which reduces us to the case where  $S$  is the spectrum of a field  $k$  of characteristic  $p$ . Since  $(n, p) = 1$ , raising to the  $n$ -th power in  $U$  is an étale morphism (Exp. VII), and is a monomorphism (2.4 i)), hence an open immersion (EGA IV 17.9.1).

<!-- original page 579 -->

This already proves that the restriction to the identity component  $U^{\{0\}}$  is an isomorphism; since  $U/U^{\{0\}}$  is a finite  $p$ -group, we are done.

This finishes the proof of 5.2.3 i) a), since  $H$ , being an étale group of multiplicative type, is of order prime to  $p$ .

**Proof of 5.2.3 ii).** It is clear that  $R$  is a sheaf for the fpqc topology. Moreover, taking the descent of affine schemes into account, the assertions of 5.2.3 ii) are local for the fpqc topology. We may therefore suppose  $k$  algebraically closed. The group  $H$  is then decomposed and the extension  $E$  is trivial (i b)); let  $H_0$  be a lift of  $H$  in  $E$ . For every  $k$ -prescheme  $S$ , and every lift  $H'$  of  $H_S$  in  $E_S$ ,  $H_{\{0,S\}}$  and  $H'$  are conjugate by an element of  $U(S)$ , since  $H^{\{1\}}(H_S, U_S) = 0$  (5.2.4 bis). Let then  $U^{\{H_0\}}$  be the sheaf of invariants of  $U$  under  $H_0$ , which is representable by an algebraic subgroup of  $U$  (Exp. VIII 6.5 d)). It follows from the preceding remarks that the  $k$ -morphism:

```
```text
U \rightarrow R,   u \mapsto \text{int}(u) H_0   (u \in U(S))
```
```

defines a  $k$ -isomorphism  $U / U^{\{H_0\}} \xrightarrow{\sim} R$ . This proves the representability of  $R$  and the fact that  $R$  is affine (2.1).

**Remark 5.2.5.** \*One can show that the assertions of 5.2.3 ii) remain true when  $U$  is not commutative, but we shall not need this to prove 5.1.1.\*

<!-- label: III.XVII.5.2.5 -->

<!-- original page 580 -->

### 5.3. Study of the case  $H$  smooth

<!-- label: III.XVII.5.3 -->

**\*\*Proposition 5.3.1.\*\*** \*The assertions contained in 5.2.3 i) remain true when one replaces the hypothesis "\$H\$ étale" by "\$H\$ smooth".\*

<!-- label: III.XVII.5.3.1 -->

Proceeding as in the proof of 5.2.3 i), one reduces to the case where moreover  $U$  is commutative.

Let  $N_0$  be the set of integers  $> 0$  prime to  $p$ , ordered by divisibility. For every  $n \in N_0$ ,  $H_n$  is an étale group and the family of  $H_n$  ( $n \in N_0$ ) is schematically dense in  $H$ , since  $H$  is smooth (Exp. IX, 4.10). Denote by  $E_n$  the inverse image of  $H_n$  in  $E$ , so that  $E_n$  is an extension of  $H_n$  by  $U$ , and finally let  $R_n$  be the  $k$ -functor of lifts of  $H_n$  in  $E_n$  (cf. 5.2.3 ii)). If  $n$  divides  $m$ , it is clear that one has a natural  $k$ -morphism  $R_m \rightarrow R_n$ , so the  $R_n$  form an inverse system of  $k$ -functors. Since  $R_n$  is representable by a non-empty affine  $k$ -scheme (5.2.3 ii)), and since a filtered direct limit of non-zero rings is non-zero, the functor  $R = \varprojlim R_n$  is representable by a non-empty affine  $k$ -scheme (EGA IV 8 and 1.9.1). There therefore exists an extension  $K$  of  $k$  and a point  $u \in R(K)$ . The image  $u_n$  of  $u$  in  $R_n(K)$  corresponds to a lift  $H'_n$  of  $H_n$  in  $E_n$ . By construction,  $H'_n = H'_m$  if  $n$  divides  $m$ . Set  $U_n = (U_n)^{H'_n}$ . The choice of  $H'_n$  allows one to identify  $(R_n)_K$  with  $U_n/K$ . But the family of  $H'_n$  is filtered increasing, hence the family of  $U_n$  is filtered decreasing and consequently is stationary for  $n$  large enough ( $U_K$  is noetherian). It follows that the family of  $(R_n)_K$  is stationary, and consequently so is the family of  $R_n$ .

<!-- original page 581 -->

In brief, one has  $R_n = R$  for  $n$  large enough.

Under the hypotheses made, it follows from 5.2.3 i) that  $R_n(k)$  is non-empty. One can therefore find a coherent system of lifts  $H'_n$  of  $H_n$  for  $n \in N_0$ . Denote by  $H'$  the smallest closed subscheme of  $E$  majorizing  $H'_n$  for every  $n$  (Exp. VI\_B § 7). The argument made in Exp. XV 4.6 shows that  $H'$  is a smooth commutative algebraic group whose formation commutes with base field extension. To show that  $H'$  is a lift of  $H$  in  $E$ , we may therefore suppose  $k$  algebraically closed. By \*Bible\* 4 th. 4,  $H'$  is then the direct product of a (smooth) group of multiplicative type  $M$  and a unipotent group  $V$ . The groups  $H'_n$  are then necessarily contained in  $M$  (2.4) and in view of the definition of  $H'$  this entails  $H' = M$ . So  $H'$  is of multiplicative type and consequently  $H' \cap U = \emptyset$ . The morphism  $H' \rightarrow H$  is therefore a monomorphism; moreover, it follows from the density theorem (Exp. IX, 4.10) that it is an epimorphism, hence an isomorphism.

Let now  $H'$  and  $H''$  be two lifts of  $H$  in  $E$ . For every  $n \in N_0$ , denote by  $T_n = \text{Transp}(\{H'_n, H''_n\})$  the transporter of  $H'_n$  into  $H''_n$ , which is representable by a closed subscheme of  $U$  (Exp. VIII 6.5 e)). The  $T_n$  form a decreasing filtered family of closed subschemes of  $U$ , non-empty by 5.2.3 i a). Let  $T$  be the stationary value. Under the hypotheses of 5.2.3 i),  $T_n(k)$  is non-empty. There therefore exists an element  $u$  of  $U(k)$  such that  $\{H'_n, H''_n\} = \text{int}(u) \{H'_n, H''_n\}$  for every  $n \in N_0$ . But then  $H'' = \text{int}(u) H'$  (Exp. IX, 4.8 b).

<!-- original page 582 -->

#### ### 5.4. Study of the case $U$ radical

<!-- label: III.XVII.5.4 -->

**\*\*Proposition 5.4.1.\*\*** \*If  $k$  is a perfect field of characteristic  $p > 0$ , and if  $U$  is radical, the extension  $E$  of 5.1.1 is trivial.\*

<!-- label: III.XVII.5.4.1 -->

Using a characteristic composition series of  $U$ , we may limit ourselves to the case where  $U$  is equal to  $(\alpha_p)^r$  (3.9).

It follows from App. II 2.2 and 2.1 that one has isomorphisms of  $k$ -functors:

```text  
Aut_{k-gr}(α_p)^r $\cong$ Aut_{p-Lie}(Lie(α_p)^r) $\cong$ GL(Lie(α_p)^r).
```

Consider then a  $k$ -vector space  $V$  of rank  $r$ , the  $k$ -scheme of vector groups  $W(V)$  (Exp. I 4.6), and identify

$(\alpha_p)^r$  with  $F V$ . The preceding remarks then show that the action of  $H$  on  $F V$ , defined by the extension  $E$ , comes from a linear representation  $\rho$  of  $H$  in  $V$ . Consider then the exact sequence:

```

```text
(*)      0 → F V → V → V^{(p)} → 0,
```

```

<!-- original page 583 -->

where  $F$  is the Frobenius morphism. Then  $(*)$  is an exact sequence of  $H$ -groups, provided one makes  $H$  act on the factor  $V^{(p)}$  via the linear representation  $H \rightarrow GL(V) \rightarrow GL(V^{(p)})$ .

Since the field  $k$  is perfect, the morphism  $F : V \rightarrow V^{(p)}$  induces a surjective map  $V(k) \rightarrow V^{(p)}(k)$ . It then follows from App. I 2.1 that the exact sequence  $(*)$  defines an exact sequence:

```

```text
(**)      H^1(H, V^{(p)}) → Ext_{alg}(H, F V) → Ext_{alg}(H, V).
```

```

Let us show that  $\text{Ext}_{\text{alg}}(H, V) = 0$ . Let then  $E_0$  be an algebraic group extension of  $H$  by  $V$ :

```

```text
1 → V → E_0 → H → 1.
```

```

The scheme  $E_0$  is a torsor with base  $H$  and group  $G^r_a$ , hence defines an element of  $H^1(H, 0^r_{H})$  (in the sense of the cohomology of coherent sheaves). Since  $H$  is affine, one has  $H^1(H, 0^r_{H}) = 0$  (EGA III § 1). That is to say,  $E_0 \rightarrow H$  possesses a section. Consequently, the group  $\text{Ext}_{\text{alg}}(H, V)$  is isomorphic to  $H^2(H, V)$  (App. I 3.1). Now  $H^i(H, V) = H^i(H, W(V)) = 0$  for  $i > 0$  (Exp. IX, 3.1). One then concludes, by the exact sequence  $(*)$ , that  $\text{Ext}_{\text{alg}}(H, F V) = 0$ , hence that  $E$  is a trivial extension.

### 5.5. Proof of 5.1.1 i)

<!-- label: III.XVII.5.5 -->

If  $k$  is of characteristic 0,  $U$  is  $k$ -solvable (4.1.3) and  $H$  is smooth; the fact that  $E$  is a trivial extension therefore follows from 5.3.1 and 5.2.3 d). One proves similarly that two lifts of  $H$  in  $E$  are conjugate by an element of  $U(k)$ .

Henceforth, we therefore suppose that  $k$  is a field of characteristic  $p > 0$ .

\*Proof of i) b)\*: \*Case  $k$  perfect,  $U$  connected.\*

We shall reduce to the case where  $U$  is radical. For this, note that since  $k$  is perfect,  $H_{\text{red}}$  is smooth; let  $E_0$  be its inverse image in  $E$ . It then follows from 5.3.1 and

<!-- original page 584 -->

5.2.3 i) c) that the extension:

```

$$
1 \rightarrow U \rightarrow E_0 \rightarrow H_{\text{red}} \rightarrow 1
$$

```

is trivial. Let  $H_1$  be a lift of  $H_{\text{red}}$  in  $E$ . By App. II 3.1, there exists an integer  $n > 0$  such that  $E^{(n)} = E / F_n(E)$  is smooth; let  $E''$  be the algebraic subgroup of  $E$  generated by  $H_1$  and  $F_n(E)$  (i.e. the inverse image in  $E$  of the image of  $H_1$  in  $E^{(n)}$ ). Denote by  $H'''$  the image of  $E''$  in  $H$ . Then I claim that  $H'' = H$ . Indeed, denote by  $R$  the image of  $F_n(E)$  in  $H$ , so that  $H'''$  is generated by  $R$  and  $H_{\text{red}}$ . The group  $H/R$  is a quotient of  $E^{(n)}$  hence is smooth; consequently the canonical morphism

```

$$
H_{\text{red}} \rightarrow H/R
$$

```

is an epimorphism, so  $H$  is generated by  $R$  and  $H_{\text{red}}$ , hence equals  $H'''$ . One thus obtains an exact sequence:

```

```text
(†)  $1 \rightarrow U' = U \cap E' \rightarrow E' \rightarrow H \rightarrow 1.$ 
```

```

But  $E'$  has the same underlying space as  $H_1$ , so  $U'$  is radical. Moreover, it is clear that it suffices to prove that the extension (†) is trivial, which follows from 5.4.1.

*\*Proof of i) b)\*: \*Case  $k$  perfect,  $H$  connected.\**

The group  $U$  is an extension of an étale group by its identity component  $U^0$ . The case  $U$  connected having just been treated, it suffices to examine the case  $U$  étale. One then has the more precise lemma:

*\*\*Lemma 5.5.1.\*\* \*With the notations of 5.1.1, suppose moreover  $U$  étale. Then:\**

<!-- label: III.XVII.5.5.1 -->

*\*i) If  $H$  is connected, there exists a unique lift of  $H$  in  $E$ , namely the identity component  $E^0$  of  $E$ .\**

<!-- original page 585 -->

*\*ii) If  $k$  is algebraically closed,  $E$  is trivial, and two lifts of  $H$  in  $E$  are conjugate by an element of  $U(k)$ .\**

i) The formation of the identity component commuting with base field extension, we may limit ourselves to the case  $k$  algebraically closed. If  $H$  is a torus,  $E$  is trivial (5.3.1 and 5.2.3 i b)), and it is clear that  $E^0$  is the unique lift of  $H$ . This already proves that, in the general case,  $E^0 \cap U$  is radical; since moreover it is étale ( $U$  being étale), it is zero. The morphism  $E^0 \rightarrow H$  is therefore a monomorphism, flat (since  $E^0$  is open in  $E$ ) and surjective ( $H$  is connected), hence an isomorphism. If now  $H'$  is another lift of  $H$ ,  $H'$  is connected, hence contained in  $E^0$ , and consequently equal to  $E^0$ .

ii) Let  $H_0$  be the identity component of  $H$ . By i),  $E^0$  is the unique lift of  $H_0$  in  $E$ . Set  $E_0 = E/E^0$ ,  $H_0' = H/H_0$ , so that one has the extension:

```

$$1 \rightarrow U \rightarrow E_0 \rightarrow H_0' \rightarrow 1.$$

```

$H_0'$  being étale, this extension is trivial (5.2.3 i b)). If  $H_1$  is a lift of  $H_0$  in  $E_0$ ,  $H_1$  its inverse image in  $E$ , it is clear that  $H_1$  lifts  $H$  in  $E$ . If  $H_2$  is a second lift of  $H$  in  $E$ , it contains  $E^0$ ; by 5.2.3 i b), the image of  $H_2$  in  $E_0$  is conjugate to  $H_1$  by an element  $u$  of  $U(k)$ , whence immediately  $H_2 = \text{int}(u) H_1$ .

*\*\*Remark 5.5.2.\*\* \*Under the hypotheses of 5.5.1 i), it is easy to see that  $E^0$  centralizes  $U$ .\**

<!-- label: III.XVII.5.5.2 -->

<!-- original page 586 -->

*\*Proof of 5.1.1 i) a)\*. Using the composition series*

```

$$1 \rightarrow U^0 \rightarrow U \rightarrow U/U^0 \rightarrow 1,$$

```

i) a) follows from the conjunction of i) b) and 5.5.1 ii).

Before proving 5.1.1 c) and d), we shall first establish 5.1.1 ii).

*\*Proof of 5.5.1 ii) a)\*. For lack of a satisfactory general statement, we shall describe a certain number of cases where, when  $H$  is smooth, two lifts of  $H$  in  $E$  are conjugate:*

*\*\*Proposition 5.6.1.\*\* \*With the notations of 5.1.1, suppose moreover  $H$  smooth, and let  $H'$  and  $H''$  be two lifts of  $H$  in  $E$ . Then  $H'$  and  $H''$  are conjugate by an element of  $U(k)$  in each of the following cases:\**

<!-- label: III.XVII.5.6.1 -->

\*a)  $k$  is algebraically closed.\*

\*b)  $U$  is commutative.\*

\*c)  $k$  is perfect and  $U$  is connected.\*

\*d)  $U$  is  $k$ -solvable.\*

\*e) The centralizer of  $H'$  in  $U$  is  $k$ -solvable.\*

\*f) The group of multiplicative type  $H$  is trivialized by a finite Galois extension  $K$  of  $k$  of degree prime to  $p$ .\*

<!-- original page 587 -->

\*Proof.\* a), b), c), d) follow from 5.3.1.

e) Let  $Z$  be the centralizer of  $H'$  in  $U$ ,  $T$  the transporter of  $H'$  into  $H''$ . By a),  $T$  is non-empty, so  $T$  is a principal homogeneous space under  $Z$ , and the hypothesis on  $Z$  entails that it is trivial.

f) Proceeding as in 5.3.1, one sees that it suffices to consider the case  $H$  étale. Suppose first  $H$  diagonalizable, defined by the ordinary group  $M$ , of order  $m$  prime to  $p$ . The data of the two lifts  $H'$  and  $H''$  defines a 1-cocycle of  $M$  with values in  $U(\bar{k})$ , that is, a map  $h$  from  $M$  to  $U(\bar{k})$  such that  $h(mn) = h(m) \cdot {}^m h(n)$  for every pair  $m, n$  of elements of  $M$ . The groups  $H'$  and  $H''$  are conjugate by an element of  $U(k)$  if and only if there exists  $a \in U(\bar{k})$  such that

```
```text
h(m) = a^{-1} ({}^m a).
```
```

Now the abstract group  $U(\bar{k})$  possesses a composition series with successive quotients commutative and annihilated by a power of  $p$  (one may suppose  $p > 0$  in view of 5.6.1 c)). One deduces immediately in this case that  $h$  is a coboundary.

Let us now examine the general case. Still denote by  $Z$  the centralizer of  $H'$  in  $U$ , and by  $T$  the transporter of  $H'$  into  $H''$ , which is a torsor under  $Z$ . By hypothesis, there exists a finite Galois extension  $K$  of  $k$ , with Galois group  $G$ , of order prime to  $p$ , that trivializes  $H$ . By the preceding study,  $H'_K$  and  $H''_K$  are conjugate by an element of  $U(K)$ ,

<!-- original page 588 -->

hence  $T_K$  is trivial. Consequently  $T$  is defined by an element of  $H^1(G, Z)$ . For the same reasons as above, the hypothesis on  $G$  entails that  $H^1(G, Z) = e$ , hence  $T$  is trivial.

### 5.7. Proof of 5.1.1 ii) b)

<!-- label: III.XVII.5.7 -->

**\*Lemma 5.7.1.\*** \*Let  $S$  be a prescheme,  $G$  an  $S$ -prescheme in groups, separated and smooth over  $S$ ,  $H$  an  $S$ -group of multiplicative type acting on  $G$ . Then the  $S$ -functor  $Z = G^H$  of invariants of  $G$  under  $H$  is representable by a sub- $S$ -prescheme in groups of  $G$ , closed and smooth over  $S$ .\*

<!-- label: III.XVII.5.7.1 -->

The fact that  $G^H$  is representable by a closed subprescheme in groups of  $G$  follows from Exp. VIII 6.5 d). Consider then the semidirect product  $K = G \times_S H$ . The centralizer of  $H$  in  $K$  is then equal to  $Z \times_S H$ . To prove that  $Z$  is smooth, we must verify that if  $S$  is affine,  $S$  is a closed subscheme of  $S$  defined by a square-zero ideal, and  $u_0$  is an element of  $Z(S')$ , then there exists an element  $u$  of  $Z(S)$  lifting  $u_0$ . Now since  $G$  is smooth over  $S$ , there exists an element  $u$  of  $G(S)$  lifting  $u_0$ . Let  $i$  be the canonical immersion of  $H$  into  $K$  and consider the two  $S$ -morphisms of groups

```
```text
H → K,    i    and    int(u) i = j.
```
```

Since  $u_0$  belongs to  $Z(S)$ , one has  $i_{S'} = j_{S'}$ . By Exp. IX, 3.2, there exists  $v \in K(S)$

<!-- original page 589 -->

lifting the unit section of  $K(S)$ , and such that

```
```text
i = int(v) j = int(vu) i.
```
```

So  $vu = (u, v)$  belongs to  $(Z \times_S H)(S)$ . So  $u$  belongs to  $Z(S)$  and lifts  $u_0$ .

**Lemma 5.7.2.** Let  $k$  be a field,  $H$  a  $k$ -algebraic group, and let  $P(H)$  be the following property:

<!-- label: III.XVII.5.7.2 -->

> "for every smooth unipotent  $k$ -group  $U$ , and for every extension  $E$  of  $H$  by  $U$ , two lifts of  $H$  in  $E$  are conjugate by an element of  $U(k)$ ."

Then if  $H$  is an algebraic group extension of a group of multiplicative type  $H'$  by a group of multiplicative type  $H''$ , and if  $P(H')$  and  $P(H'')$  are true,  $P(H)$  is true.

Indeed, let  $U$  be a smooth unipotent  $k$ -group,  $E$  an extension of  $H$  by  $U$ ,  $H_1$  and  $H_2$  two lifts of  $H$  in  $E$ ,  $H_1'$  and  $H_2'$  the corresponding lifts of  $H'$ . Since  $P(H')$  is true, there exists  $u \in U(k)$  such that  $H_2' = \text{int}(u) H_1'$ . Possibly replacing  $H_1$  by  $\text{int}(u) H_1$ , we may suppose  $H_1' = H_2'$ , which we allow ourselves to denote simply  $H_0'$ . Let  $E_0 = \text{Centr}_E(H_0)$ , which is equal to

```
```text
U^{H_0} \cdot H_1 = U^{H_0} \cdot H_2.
```
```

By 5.6.1,  $U^{H_0} = U_0$  is smooth. Consider then the extension

```

$
1 \longrightarrow U_0 \longrightarrow E_0 \longrightarrow H \longrightarrow 1.
$

```

By construction  $H_0$  is central in  $E_0$ , hence invariant. By passage to the quotient, one obtains the exact sequence:

```

$
1 \longrightarrow U_0 \longrightarrow E_0' \longrightarrow H' \longrightarrow 1.
$

```

Since  $U_0$  is smooth, and since  $P(H'')$  is true, the two images of  $H_1$  and  $H_2$

<!-- original page 590 -->

in  $E_0$  are conjugate by an element  $u$  of  $U_0(k)$ , but then  $H_1 = \text{int}(u) H_2$ .

To prove 5.1.1 ii) b), note then that, since  $k$  is algebraically closed,  $H$  possesses a composition series whose successive quotients are smooth or isomorphic to  $\mu_p$  when  $p > 0$ . By repeated use of 5.7.2, we are reduced to the case where  $H$  is smooth or equal to  $\mu_p$ . In the first case, it suffices to apply 5.1.1 ii) a). There remains the case  $H = \mu_p$ . Since  $U$  is smooth,  $U$  possesses a characteristic composition series with successive quotients étale or isomorphic to  $(G_a)^r$  (3.9). If  $U$  is étale, one applies 5.5.1. There finally remains the case  $H = \mu_p$ ,  $U = G_a^r$ .

We must show that  $H^1(\mu_p, U) = 0$ . The method used in 5.4.1 no longer applies here, since  $\mu_p$  does not in general act linearly on  $(G_a)^r$ . Let us fix the notations:  $H'$  denotes a lift of  $H$  in  $E$ ,  $\mathfrak{e} = \text{Lie } E$ ,  $\mathfrak{u} = \text{Lie } U$ ,  $\mathfrak{h} = \text{Lie } H$ ,  $\mathfrak{h}' = \text{Lie } H'$ . Let  $X$  be a non-zero element of  $\mathfrak{h}$  such that  $X^{(p)} = X$  (App. II 3.1), and let  $X'$  be its lift in  $\mathfrak{h}'$ .

Since  $\mu_p$  is a radical group of height 1, there is a bijective correspondence between the set of lifts of  $H$  in  $E$  and the set  $A$  of  $Y \in \mathfrak{e}$  such that  $Y^{(p)} = Y$  and which project to  $X$  (App. II 2.2). Likewise if  $Y \in A$  corresponds to the lift  $H'$  of  $H$  in  $E$ , and if  $u \in U(k)$ , then  $\text{int}(u) H' = H'$  if and only if  $\text{Ad}(u) X = Y$ . Let then  $B$  be the subset of  $Y \in \mathfrak{e}$  of the form  $\text{Ad}(u) X$ , where  $u \in U(k)$ . One has evidently  $B \subset A$ , and

everything reduces to showing that  $A = B$  if  $k$  is

<!-- original page 591 -->

algebraically closed.

a) \*Study of  $A$ .\* Since  $u$  is commutative and normalized by  $h$ , Jacobson's formula (Exp. VII\_A 5.2) gives simply, for  $u \in u$ :

```
```text
(X' + u)^{(p)} = X'^{(p)} + u^{(p)} + (ad X')^{p-1}(u) = X' + (ad X')^{p-1}(u),
```
```

so that  $X' + u \in A \xrightarrow{\text{Leftrightarrow}} u = (ad X')^{p-1}(u)$ .

Now let  $u = \sum_{n \in \mathbb{Z}/p\mathbb{Z}} u_n$  be the canonical decomposition of  $u$  under the action of  $h$ , which one may also write:

```
```text
u = u_0 \otimes \sum_{n \in (\mathbb{Z}/p\mathbb{Z})^\times} u_n.
```
```

If  $u \in u_0$ , one has  $ad X'(u) = 0$ . If  $u \in u_n$  ( $n \in (\mathbb{Z}/p\mathbb{Z})^\times$ ), one has  $(ad X')^{p-1}(u) = u$ . Finally,  $Y = X' + u$  is an element of  $A$  if and only if  $u \in \sum_{n \in (\mathbb{Z}/p\mathbb{Z})^\times} u_n$ . Note that  $A$  is the set of  $k$ -rational points of an irreducible subscheme of  $W(e)$ , of dimension equal to  $\dim u - \dim u_0 = \dim u - \dim \text{Centr}_u(X')$ .

b) \*Study of  $B$ .\* We shall need the following lemma:

**Lemma 5.7.3.** (Rosenlicht). Let  $U$  be a unipotent algebraic group over a field  $k$  acting on a quasi-affine  $k$ -scheme  $X$ . Then the orbit of every point  $x \in X(k)$  is closed in  $X$  (by orbit of  $x$  we mean the subset of  $\text{ens}(X)$  image of  $G$  under the morphism  $g \mapsto g \cdot x$ ).

<!-- label: III.XVII.5.7.3 -->

<!-- original page 592 -->

By functoriality,  $G$  acts on the affine envelope of  $X$  (that is,  $\text{Spec } \Gamma(X, \mathcal{O}_X)$ ), which allows us to suppose  $X$  affine. One may further suppose  $k$  algebraically closed,  $X$  reduced, and  $U$  smooth (note that  $U_{\text{red}}$  acts on  $X_{\text{red}}$  if  $k$  is perfect). Let  $Y$  be the schematic image of  $G$  (EGA I 9.5.1) under the morphism  $g \mapsto g \cdot x$ , which is a closed and reduced subscheme of  $X$  on which  $G$  acts. It follows easily from EGA IV 1.8.6 that the orbit of  $x$  is an open part  $Z$  of  $Y$ , dense in  $Y$ . We must show that  $Z = \text{ens}(Y)$ . Let  $F$  be the closed reduced subscheme of  $Y$  having  $Y \setminus Z$  as underlying space. One has therefore  $F = V(J)$ , where  $J$  is a non-zero ideal of  $\Gamma(Y, \mathcal{O}_Y)$ . Since  $G$  is smooth,  $G$  acts on  $F$ , hence on  $J$ , and consequently (3.2)  $J^G \neq 0$ . If  $a$  is a non-zero element of  $J^G$ ,  $a$  is necessarily constant on the orbit  $Z$ , hence is constant on  $Y$ ,  $Z$  being dense in  $Y$ . But then the ideal  $J$  contains  $k$ , and  $F = \emptyset$ .

This being so, let us apply the preceding lemma to the group  $U$  acting on the affine space  $W(e)$  via the adjoint representation. One obtains that the orbit of  $X'$  is the underlying set of a closed sub-prescheme of  $W(e)$ . Moreover, the stabilizer  $Z$  of  $X'$  is the centralizer of  $X'$  in  $U$ , and one has a closed immersion:

```
$$
U/Z \hookrightarrow W(e).
$$
```

Let us note that the orbit of  $X'$  is the underlying space of a closed subscheme of  $W(e)$  of dimension equal to  $\dim U - \dim Z$ .

c) \*End of the proof of 5.1.1 ii) b)\*. When  $k$  is algebraically closed, the canonical map  $U(k) \rightarrow (U/Z)(k)$  is surjective,

<!-- original page 593 -->

so that by point b) above,  $B$  is the set of  $k$ -rational points of a closed subscheme of  $W(e)$  of dimension  $\dim U - \dim Z$ . Taking point a) into account, to prove that  $A = B$ , it then suffices to show that one has:

```

```text
rg u - rg Centr_u(X') = dim U - dim Centr_U(X').
```

```

Now since  $U$  is smooth, one has  $\dim U = \text{rg } u$ . On the other hand, one has (Exp. II 5.3.3):

```

```text
dim Centr_U(X') = rg Centr_u(X'),
```

```

whence the result (note that one in fact has  $\dim \text{Centr}_U(X') = \text{rg Centr}_u(X')$ , which gives another proof that  $Z$  is smooth (5.7.1)).

### 5.8. End of the proof of 5.1.1 i)

<!-- label: III.XVII.5.8 -->

It remains to prove i) c) and i) d).

\*Proof of 5.1.1 i) d) ( $U$  smooth,  $H$  connected)\*. We shall need the following lemma:

**Lemma 5.8.1.** \*With the notations of 5.1.1, suppose  $U$  smooth and  $H$  radical, and let  $H_1$  be an algebraic subgroup of  $H$  that possesses a lift  $H_1'$  in  $E$ . Then  $H$  possesses a lift  $H'$  in  $E$  majorizing  $H_1'$ .\*

<!-- label: III.XVII.5.8.1 -->

By induction on the height of  $H/H_1$ , one may suppose  $H/H_1$  of height 1. Let  $C' = \text{Centr}_E(H_1')$ . I claim that the canonical morphism  $C' \rightarrow H$  is an epimorphism. To establish this point, we may suppose  $k$  algebraically closed; but then, the extension  $E$  is trivial (5.1.1 i a)); let  $H''$  be a lift of  $H$  in  $E$ ,  $H_1''$  the inverse image of  $H_1$  in  $H''$ .

<!-- original page 594 -->

The groups  $H_1'$  and  $H_1''$  are two lifts of  $H_1$  in  $E$ , hence are conjugate by an element of  $U(k)$ , since  $k$  is algebraically closed and  $U$  smooth (5.1.1 ii b)). It is clear then that to prove the assertion on  $C'$ , it suffices to prove it for  $C'' = \text{Centr}_E(H_1'')$ . But in this case,  $C''$  majorizes  $H''$ , and the property is clear. Moreover, it follows from 5.7.1 that  $C \cap U$  is smooth. It is clear then that we may replace  $E$  by  $C$ , hence suppose  $H_1'$  central. But then, possibly passing to the quotient by  $H_1'$ , we may suppose  $H_1 = 0$  and  $H$  of height 1.

Since  $U$  is smooth, one has the exact sequence of  $p$ -Lie algebras (App. II 3.2):

```

```text
(*) 0 → Lie U → Lie E → Lie H → 0.
```

```

Taking App. II 2.2 into account, saying that  $E$  is trivial is equivalent to saying that  $(*)$  is a trivial extension of  $p$ -Lie algebras. Suppose  $H \neq 0$  (hence  $\text{Lie } H \neq 0$ ) and suppose we have found a non-zero sub- $p$ -Lie algebra  $h$  of  $H$  such that  $h = \text{Lie } H$  that lifts to a sub- $p$ -Lie algebra  $h_1'$  of  $\text{Lie } E$ . By \*loc. cit.\*, there exists a subgroup  $H_1'$  of  $H$  such that  $\text{Lie } H_1' = h_1'$ , and a lift  $H_1''$  of  $H_1'$  in  $E$  such that  $\text{Lie } H_1'' = h_1'$ . Applying again the reduction described above, one is reduced to the same problem, where one has replaced  $H$  by  $H/H_1'$ . Since  $H$  is of height 1,  $\text{Lie}(H/H_1') = \text{Lie } H / \text{Lie } H_1'$  (\*loc. cit.\*), so  $\text{rg Lie}(H/H_1') \leq \text{rg Lie } H - 1$ . In brief, proceeding by induction on the rank of  $\text{Lie } H$ , one sees that it suffices, when  $H \neq 0$ ,

<!-- original page 595 -->

to find a non-zero Lie subalgebra of  $\text{Lie } H$  that lifts in  $\text{Lie } E$ . Now we have the following lemma:

**Lemma 5.8.2.** \*Let  $k$  be a field of characteristic  $p > 0$ , and  $\phi$  a surjective morphism of finite-rank  $p$ - $k$ -Lie algebras  $g \rightarrow h$ . Then:\*

<!-- label: III.XVII.5.8.2 -->

\*i) If  $\mathfrak{h}_{\bar{k}}$  is reductive (4.2.2) and  $\neq 0$ , there exists a reductive Lie subalgebra  $\mathfrak{h}_1$  of  $\mathfrak{g}$  whose image in  $\mathfrak{h}$  is non-zero.\*

\*ii) If  $\mathfrak{k}$  is perfect and if  $\mathfrak{u}$  is a unipotent element of  $\mathfrak{h}$  (i.e. there exists  $\mathfrak{n}$  such that  $\mathfrak{u}^{(p^n)} = 0$ ), then  $\mathfrak{u}$  lifts to a unipotent element of  $\mathfrak{g}$ .\*

Take  $\mathfrak{X}$  a non-zero element of  $\mathfrak{h}$  in case i) and  $\mathfrak{u}$  in case ii), and let  $\mathfrak{X}'$  be a lift of  $\mathfrak{X}$  in  $\mathfrak{g}$ . The sub- $\mathfrak{p}$ -Lie algebra of  $\mathfrak{g}$  generated by  $\mathfrak{X}'$  is an abelian  $\mathfrak{p}$ -Lie algebra (Exp. VII)  $\mathfrak{h}_0$ .

\*Case i)\*. It is clear from the description given in 4.2.2 that the reductive part (\*loc. cit.\*) of  $\mathfrak{h}_0, \bar{k}$  is already defined over  $\mathfrak{k}$ ; denote it  $\mathfrak{r}_0$ . I claim that the image of  $\mathfrak{r}_0$  in  $\mathfrak{h}$  is non-zero. To establish this point we may suppose  $\mathfrak{k}$  algebraically closed, so that  $\mathfrak{h}_0 = \mathfrak{r}_0 \oplus \mathfrak{u}_0$  ( $\mathfrak{u}_0$  the unipotent part of  $\mathfrak{h}_0$ ). If the image of  $\mathfrak{r}_0$  in  $\mathfrak{h}$  were zero, the image of  $\mathfrak{h}_0$  in  $\mathfrak{h}$  would be unipotent, hence would be zero since  $\mathfrak{h}$  is reductive (cf. 2.4 ii)); now by construction it contains  $\mathfrak{X}$ .

\*Case ii)\*. One proceeds similarly, exchanging the roles of  $\mathfrak{r}_0$  and  $\mathfrak{u}_0$ .

<!-- original page 596 -->

\*End of the proof of 5.8.1\*. Supposing  $\mathfrak{H} \neq 0$ , by 5.8.2 there exists a non-zero reductive Lie subalgebra  $\mathfrak{h}_1$  of 'Lie  $\mathfrak{E}$ '. Since 'Lie  $\mathfrak{U}$ ' is unipotent (4.3 i)), one necessarily has  $(\text{Lie } \mathfrak{U}) \cap \mathfrak{h}_1 = 0$ , so  $\mathfrak{h}_1$  is a lift of a sub- $\mathfrak{p}$ -Lie algebra of 'Lie  $\mathfrak{H}$ '.

\*End of the proof of 5.1.1 i d)\*. By 5.8.1, there exists a family of algebraic subgroups  $\mathfrak{H}_n$  ( $n \in \mathbb{N}$ ) of  $\mathfrak{E}$ , such that  $\mathfrak{H}_{n+1}$  majorizes  $\mathfrak{H}_n$  and  $\mathfrak{H}_n$  lifts  $\mathfrak{F}_n \cap \mathfrak{H}$ . The decreasing sequence of subgroups  $\text{Centr}_{\mathfrak{E}}(\mathfrak{H}_n)$  is stationary; let  $\mathfrak{C}$  be the stationary value. The center  $\mathfrak{Z}$  of  $\mathfrak{C}$  majorizes  $\mathfrak{H}_n$  for every  $n$ , hence the image of  $\mathfrak{Z}$  in  $\mathfrak{H}$  majorizes  $\mathfrak{F}_n \cap \mathfrak{H}$  for every  $n$ , and is consequently an open subgroup of  $\mathfrak{H}$  (Exp. VII\_A § 4), hence is equal to  $\mathfrak{H}$  since  $\mathfrak{H}$  is connected. To prove that  $\mathfrak{E}$  is trivial, we may therefore replace  $\mathfrak{E}$  by  $\mathfrak{Z}$ , hence suppose  $\mathfrak{E}$  commutative. We shall then see in 7.2.1 that  $\mathfrak{E}$  contains a maximal subgroup of multiplicative type  $\mathfrak{M}$ , whose formation commutes with base field extension. Since  $\mathfrak{E}_{\bar{k}}$  is a trivial extension (5.1.1 i) a) and  $\mathfrak{U}$  is unipotent, it is clear that  $\mathfrak{M}$  is the unique lift of  $\mathfrak{H}$  in  $\mathfrak{E}$ .

\*Proof of 5.1.1 i) c) ( $\mathfrak{U}$   $\mathfrak{k}$ -solvable)\*. Since  $(\mathfrak{H}/\mathfrak{H})^{(k)}$  is of order prime to  $\mathfrak{p}$ , it is immediate by duality that there exists an integer  $\mathfrak{n}$  such that  $\mathfrak{H}_n$  is an étale subgroup and the canonical morphism  $\mathfrak{H}_n \rightarrow \mathfrak{H}/\mathfrak{H}^{(0)}$  is an epimorphism, so that  $\mathfrak{H}/\mathfrak{H}_n$  is connected. By 5.2.3 d), there exists a lift  $\mathfrak{H}'$  of  $\mathfrak{H}_n$  in  $\mathfrak{E}$ . One shows, as at the beginning of the proof of 5.8.1, that  $\mathfrak{C} = \text{Centr}_{\mathfrak{E}}(\mathfrak{H}')$

<!-- original page 597 -->

is a subgroup of  $\mathfrak{E}$  such that  $\mathfrak{C} \rightarrow \mathfrak{H}$  is an epimorphism and such that  $\mathfrak{C} \cap \mathfrak{U}$  is smooth. Replacing  $\mathfrak{E}$  by  $\mathfrak{C}$  and passing to the quotient by  $\mathfrak{H}'$ , one is reduced to the case where  $\mathfrak{U}$  is smooth and  $\mathfrak{H}$  connected, that is, to case i) d).

This finishes the proof of 5.1.1.

### ### 5.9. Counterexamples

<!-- label: III.XVII.5.9 -->

Let us first indicate a procedure for obtaining non-trivial extensions of a  $\mathfrak{k}$ -group of multiplicative type  $\mathfrak{H}$  by a unipotent  $\mathfrak{k}$ -group  $\mathfrak{U}$ . Suppose given an action of  $\mathfrak{H}$  on  $\mathfrak{U}$ , and let  $\mathfrak{E}$  be the semidirect product  $\mathfrak{E} = \mathfrak{U} \ltimes \mathfrak{H}$ . Suppose moreover that one is given an element of  $\mathfrak{H}^1(k, \mathfrak{U})$  represented by a 1-cocycle  $\mathfrak{a}$ . The group  $\mathfrak{U}$  acts by inner automorphisms on  $\mathfrak{E}$ . The datum of  $\mathfrak{a}$  therefore defines a  $\mathfrak{k}$ -form of  $\mathfrak{E}$  denoted  $\mathfrak{E}_{\mathfrak{a}}$ . Suppose moreover that  $\mathfrak{U}$  is commutative; then  $\mathfrak{U}$  acts trivially on  $\mathfrak{U}$  and on the quotient  $\mathfrak{E}/\mathfrak{U} = \mathfrak{H}$ , so that  $\mathfrak{E}_{\mathfrak{a}}$  is still an extension of  $\mathfrak{H}$  by  $\mathfrak{U}$ . Suppose, for simplicity, that  $\mathfrak{H}$  is an étale diagonalizable group, so that the Galois group  $\mathfrak{G}$  of  $\bar{k}/k$  acts trivially on  $\mathfrak{H}(\bar{k})$ ; the action of  $\mathfrak{G}$  on the points of  $\mathfrak{E}_{\mathfrak{a}}(\bar{k})$  is then given by the formula:

```
```text
{}^g (u, h) = ({}^g u + a(g) - {}^h a(g), h)    (g ∈ G, u ∈ U(k̄), h ∈ H(k̄)).
```
```

If  $\mathfrak{h}$  is a point of  $\mathfrak{H}(k)$ ,  $\mathfrak{X}$  its inverse image in  $\mathfrak{E}_{\mathfrak{a}}$ ,  $\mathfrak{X}$  is therefore a torsor under  $\mathfrak{U}$  defined by the class of the 1-cocycle of  $\mathfrak{G}$  with values in  $\mathfrak{U}$ ,  $g \mapsto \mathfrak{a}(g) - {}^h \mathfrak{a}(g)$ . It follows that if there exists a point  $\mathfrak{h}$  of  $\mathfrak{H}(k)$  such that the preceding 1-cocycle is non-trivial,

<!-- original page 598 -->

the extension  $E_a$  is non-trivial. We shall apply this construction in two particular cases:

a) \*Non-trivial extension of an étale diagonalizable group  $H$  by  $\mathbb{Z}/p\mathbb{Z}$ .\*

Take for  $H$  the group  $(\mathbb{Z}/p\mathbb{Z})^{\times}$  acting by multiplication on  $U = \mathbb{Z}/p\mathbb{Z}$ . Let  $k$  be a field of characteristic  $p$ ,  $K$  an extension of  $k$  with Galois group  $G$  isomorphic to  $\mathbb{Z}/p\mathbb{Z}$ ,  $a$  a non-zero element of  $H^1(G, U) = \operatorname{Hom}(G, U)$ . The group  $E_a$  then answers the question.

b) \*Example of a non-trivial extension of an étale diagonalizable group  $H$  by a smooth connected unipotent group  $U$ .\*

Take for  $k$  a non-perfect field such that there exists a  $k$ -form  $U$  of  $G_a$  with  $H^1(k, U) \neq 0$ . For example (cf. J.-P. Serre, \*Cohomologie Galoisienne\*), one may take for  $k$  the field of fractions of a discrete valuation ring of equal characteristic  $p > 0$ , and for  $U$  the algebraic subgroup of  $G_a \times_k G_a$  with equation  $X^p + X + tY^p = 0$ , where  $t$  denotes a uniformizer of  $k$ . Indeed, supposing for simplicity that  $k$  contains the  $(p-1)$ -th roots of unity, one has an exact sequence of algebraic groups:

```
```text
0 → Z/pZ → U → G_a → 0,    (x, y) ↦ y,
```

hence an exact sequence of cohomology:

<!-- original page 599 -->

```
```text
G_a(k) → H^1(k, Z/pZ) → H^1(k, U) → 0,
```

where  $d$  sends  $x$  to the principal homogeneous space under  $\mathbb{Z}/p\mathbb{Z}$  with equation

```
```text
X^p + X + t x^p = 0.
```

Moreover, one knows that $H^1(k, \mathbb{Z}/p\mathbb{Z})$ is isomorphic to $k / P(k)$ (where $P(x) = x^p + x$), hence $H^1(k, U)$ is isomorphic to $k / (P(k) + t k^p)$. Suppose moreover $p \neq 2$; it is then clear that t^2 is an element of k not belonging to $P(k) + t k^p$, hence $H^1(k, U) \neq 0$.

On the other hand μ_{p-1} acts on U by the formula:

```
```text
(h, x, y) ↦ (hx, hy).
```

Denote by  $G$  the Galois group of the extension  $K$  defined by the equation

```
$$
X^p + X + t^2 = 0,
$$
```

and let  $a \in H^1(G, U)$  be the non-zero element described above. One verifies immediately that  $E_a$  is then a non-trivial extension of  $\mu_{p-1}$  by  $U$ .

c) \*Non-trivial extension of  $G_m$  by  $\alpha_p$ .\*

By 5.1.1 i) b), such an extension can only exist over a non-perfect field  $k$ . Let then  $k$  be a non-perfect field,  $G$  the semidirect product of  $U = G_a$  by  $H = G_m$ , with  $G_m$  acting on  $G_a$  by homotheties. Since  $U$  is invariant in  $G$ , so is  $U$ . Let  $G' = G / U$ . The group  $G'$  is isomorphic to  $G_a \cdot G_m$ , where  $G_m$  acts on  $G_a$  by the formula:

```
```text
```

$(h, u) \mapsto h^p u.$

<!-- original page 600 -->

The functor T_G (resp. $T_{G'}$) of subtori of G (resp. G') (cf. Exp. XV) is isomorphic to G_a , and the morphism $T_G \rightarrow T_{G'}$ deduced from the morphism $G \rightarrow G'$ is identified with the morphism $u \mapsto u^p$. It follows that if T' is a subtorus of G' corresponding to a point x of $k \simeq G_a(k)$ such that $x^{1/p}$ is not in k , the inverse image E of T' in G will be an extension of a torus T by $F U = \alpha_p$, will not possess maximal tori defined over k , hence will not be trivial. One finds for E the subgroup of $G = \operatorname{Spec} k[U, T, T^{-1}]$ with equation $U^p = x - x T^p$.

Remark 5.9.1. This last example shows that a non-smooth algebraic group defined over a non-perfect field does not necessarily possess maximal tori, and thus answers the question raised in Exp. XIV, 1.5 b).

<!-- label: III.XVII.5.9.1 -->

d) Let us now give an example of a trivial extension E of a group of multiplicative type H by a unipotent group U , and of two lifts H' and H'' of H that are not conjugate by an element of $U(k)$.

Take for E the semidirect product of $U = G_a$ by $\mu_p = \operatorname{Spec} k[T] / (T^p - 1)$, the action of μ_p on $G_a = \operatorname{Spec} k[U]$ being defined by the comorphism:

$$U \mapsto (U + U^p) T - U^p.$$

The centralizer of μ_p in E is then the étale group Z of equation $U + U^p = 0$. It follows that if k is not algebraically closed, the canonical map $U(k) \rightarrow (U/Z)(k)$ is not in general surjective,

<!-- original page 601 -->

hence, taking 5.1.1 ii) b) into account, two lifts of μ_p in E are not necessarily conjugate by an element of $U(k)$.

Here is another example, with k algebraically closed of characteristic $p > 0$. Let G be the radical group semidirect product of μ_p by α_p , where μ_p acts on α_p by "homotheties". One then has an exact sequence of algebraic groups, with μ_p as operator group:

$$0 \rightarrow \alpha_p \rightarrow G_a \rightarrow G_a \rightarrow 0, \quad x \mapsto x^p,$$

where μ_p acts by homotheties on the first term G_a , and trivially on the second. The exact cohomology sequence (App. I, prop. 11) furnishes here the exact sequence:

$$0 \rightarrow G_a(k) \rightarrow H^1(\mu_p, \alpha_p) \rightarrow H^1(\mu_p, G_a).$$

Since the last term is zero (I 5.3.3), one sees that $H^1(\mu_p, \alpha_p)$ is non-zero, hence two lifts of μ_p in G are not necessarily conjugate.

6. Extension of a unipotent group by a group of multiplicative type

<!-- label: III.XVII.6 -->

<!-- original page 602 -->

6.1. Statement of the theorem

<!-- label: III.XVII.6.1 -->

Theorem 6.1.1. Let k be a field, U a unipotent k -algebraic group, H a k -group of multiplicative type, E a k -algebraic group extension of U by H , so that one has the exact sequence

```

<!-- label: III.XVII.6.1.1 -->

$$
1 \longrightarrow H \longrightarrow E \longrightarrow U \longrightarrow 1.
$$

*Then the extension  $E$  is trivial and there exists a unique lift of  $U$  in  $E$  in each of the following cases:*

*A) The group  $U$  is smooth and one of the following conditions is satisfied:*

*i)  $U$  is connected and the canonical morphism  $E \rightarrow U$  possesses a section.*

*ii)  $U$  possesses a composition series with successive quotients isomorphic to  $G_a$ .*

*iii)  $H$  is étale.*

*iv)  $k$  is perfect.*

*B)  $U = \alpha_p$  and  $k$  is perfect.*

*C)  $E$  is commutative and  $k$  is perfect.*

### 6.2. Proof of 6.1.1 A)

<!-- label: III.XVII.6.2 -->

Let us first establish three lemmas.

**Lemma 6.2.1.** *Let  $S$  be a prescheme,  $E$  an  $S$ -prescheme in groups, extension of an  $S$ -prescheme in groups  $U$  with connected fibers, by an  $S$ -group of multiplicative type and of finite type  $H$  (i.e.  $U$  is the quotient of  $E$  by  $H$  for the fpqc topology). Then  $E$  is a central extension.*

<!-- label: III.XVII.6.2.1 -->

<!-- original page 603 -->

Indeed, since  $H$  is commutative, the group  $U$  acts by inner automorphisms on  $H$ , via an  $S$ -morphism of groups

$$u : U \longrightarrow \operatorname{Aut}_{S\text{-gr}}(H).$$

The functor  $\operatorname{Aut}_{S\text{-gr}}(H)$  is representable by an étale  $S$ -scheme (Exp. X 5.10), and consequently the unit section is both an open and closed immersion. Since  $U$  has connected fibers, one deduces that  $u$  is the unit morphism.

**Lemma 6.2.2.** *With the notations of 6.1.1, if  $E$  is trivial, there exists a unique lift of  $U$  in  $E$ .*

<!-- label: III.XVII.6.2.2 -->

Let  $U'$  and  $U''$  be two lifts of  $U$  in  $E$ . To show that  $U' = U''$ , we may suppose  $k$  algebraically closed, and it suffices to show that  $H^1(U, H) = 0$ . If  $U$  is connected,  $U$  centralizes  $H$  (6.2.1), hence

$$H^1(U, H) = \operatorname{Hom}_{k\text{-gr}}(U, H) = 0$$

by 2.4 ii). In the general case, denote by  $U_1$  the unique lift in  $E$  of the connected component  $U_0$  of  $U$ , and let  $N = \operatorname{Norm}_E(U_1)$ . If  $g \in E(k)$ ,  $\operatorname{int}(g) U_1$  is a lift of  $U_0$ , hence is equal to  $U_1$ , and consequently  $N(k) \supset E(k)$ . Moreover,  $N$  majorizes  $H$  (6.2.1) and  $U_1$ , whence immediately the fact that  $N = E$ . Passing to the quotient by  $U_1$ ,
```

one is reduced to the case where U is étale. In this case, k being algebraically closed, $H^1(U, H)$ is identified with the ordinary cohomology group $H^1(U(k), H(k))$ [N.D.E-XVII-10], and consequently is zero, since $U(k)$ is a finite p -group and $H(k)$ is uniquely p -divisible.

Corollary 6.2.3. *To prove that E is trivial, it suffices to show that E becomes trivial after a finite separable extension of the base field; in particular, one may suppose H diagonalizable.*

<!-- label: III.XVII.6.2.3 -->

Lemma 6.2.4. *For every central extension E of U by a diagonalizable k -group H to be trivial, it suffices that every central extension of U by G_m be trivial.*

<!-- label: III.XVII.6.2.4 -->

Indeed, by induction on r , one notes first that the hypothesis entails that E is trivial if $H = G^r_m$. In the general case, H embeds in G^r_m for a suitable integer r (this is immediate by duality); let $H'' = G^r_m / H$. One obtains the exact sequence (App. I 2.1):

```

```text
Z^1(U, H'') → Ext_{alg}(U, H) → Ext_{alg}(U, G_m^r) = 0
```

```

(where U acts trivially on H , H'' , G^r_m). But $Z^1(U, H'') = \operatorname{Hom}_{k\text{-gr}}(U, H'') = 0$ (2.4 ii)), hence $\operatorname{Ext}_{alg}(U, H) = 0$.

Proof of 6.1.1 A) i). Since $E \rightarrow U$ possesses a section, E defines an element f of $H^2(U, H)$ (App. I 3.1). We must show that f is zero, and for this, it suffices to show that a 2-cocycle $f : U \times_k U \rightarrow H$ is a constant morphism, which will follow from the following lemma:

<!-- original page 605 -->

Lemma 6.2.5. *Let U be a smooth connected unipotent k -algebraic group, H a k -group of multiplicative type; then every k -morphism (of preschemes)*

<!-- label: III.XVII.6.2.5 -->

```

f : U → H
f is constant.

```

To prove this lemma, we may suppose k algebraically closed. We proceed by increasing induction on $\dim U$. If $\dim U > 0$, U possesses a composition series (cf. 3.9):

```

1 → U' → U → π → U'' → 1
```

```

with  $U' \simeq G_a$  and  $\dim U' < \dim U$ . It suffices to show that  $f$  factors through  $U''$ . Since the graph of the equivalence relation defined by  $\pi$  is smooth over  $k$ , hence reduced, it suffices to show that if  $x, y \in U(k)$  have the same image  $z$  in  $U''(k)$ , then  $f(x) = f(y)$ . Now  $\pi^{-1}(z)$  is isomorphic to  $G_a$ , hence the restriction of  $f$  to  $\pi^{-1}(z)$  factors through a reduced irreducible component of  $H$ , hence through a  $k$ -scheme isomorphic to  $(G_m)^r$ . It then suffices to note that every morphism from  $G_a$  into  $(G_m)^r$  is constant, since every invertible regular function on  $G_a$  is constant.

**Proof of 6.1.1 A) ii).** Thanks to 6.2.1, 6.2.3, and 6.2.4, we may suppose that  $H = G_m$ . By hypothesis,  $U$  possesses a composition series  $U \supset U_1 \supset \dots$  such that  $U_i / U_{i+1}$  is isomorphic to  $G_a$ . Let  $E_1$  be the inverse image of  $U_1$  in  $E$ . By induction on  $\dim U$ , one may suppose the extension  $E_1$  is trivial; let  $U_1'$  be the unique

<!-- original page 606 -->

lift of  $U_1$ . Proceeding as in the proof of 6.2.4, one shows that  $U_1'$  is invariant in  $E$ . After passing to the quotient by  $U_1'$ , one is reduced to the case where  $U = G_a$ . The  $S$ -scheme  $E_S$  (where  $S = U$ ) is then a torsor

under the  $\$S$ -group  $G_{\{m\}} \times_k S$ , hence possesses a section, since  $\operatorname{Pic}(S) = 0$  (Exp. VIII 4.3). The extension  $E$  is then trivial by A) i).

\*Proof of 6.1.1 A) iii) ( $U$  smooth,  $H$  étale)\*. Suppose first  $U$  connected. The group  $U_{\{\bar{k}\}}$  then possesses a composition series with successive quotients isomorphic to  $G_{\{a\}}$ , hence  $E_{\{\bar{k}\}}$  is trivial by A) ii). Since  $H$  is étale, it is clear that the unique lift of  $U_{\{\bar{k}\}}$  in  $E_{\{\bar{k}\}}$  is the connected component of  $E_{\{\bar{k}\}}$ , hence this lift is already defined over  $k$ . In the general case, possibly passing to the quotient by the connected component of  $E$ , one is reduced to the case where  $E$  is étale, then to the case where  $E$  is completely decomposed (6.2.3). Since  $U(k)$  is a  $p$ -group and  $H(k)$  is of order prime to  $p$ , one may take as a lift of  $U(k)$  the Sylow  $p$ -subgroup of  $E(k)$ .

\*Proof of 6.1.1 A) iv) ( $U$  smooth,  $k$  perfect)\*. If  $U$  is connected,  $U$  possesses a composition series with successive quotients isomorphic to  $G_{\{a\}}$  (4.1.2 b)), and one applies A) ii). In the general case, what precedes allows us to reduce to the case where  $U$  is étale, then to the case where  $U$  is completely decomposed and  $H$  diagonalizable (6.2.3). Using now a characteristic composition series of  $H$  ( $H \supset H^{\{0\}} \supset F_n(H) \supset 0$ ), one reduces to the case where  $H$  is of one of the three following types:

<!-- original page 607 -->

a)  $H$  is étale.

b)  $H = G_{\{r\}_m}$ .

c)  $H$  is radical.

In case a), one applies A) iii); in case c), one applies 1.6. Finally in case b), one notes that by Hilbert's Theorem 90,  $E \rightarrow U$  possesses a section, so that it suffices to show that  $H^2(U, G_{\{r\}_m}) = H^2(U(k), G_{\{r\}_m}(k)) = 0$ . Now  $U(k)$  is a finite  $p$ -group, while  $G_{\{r\}_m}(k)$  is uniquely  $p$ -divisible (since  $k$  is perfect).

### 6.3. Proof of 6.1.1 B) and C)

<!-- label: III.XVII.6.3 -->

Thanks to 6.2.1, 6.2.3, 6.2.4, one sees that it suffices to prove B) when  $H = G_{\{m\}}$ . One therefore has an exact sequence:

$$1 \rightarrow G_{\{m\}} \rightarrow E \rightarrow \alpha_p \rightarrow 1.$$

Since  $G_{\{m\}}$  is smooth, one deduces an exact sequence of  $p$ -Lie algebras (App. II 3.2):

```
```text
(*) 0 → Lie G_m → Lie E → Lie α_p → 0.
```
```

The group  $\alpha_p$  being of height 1, the extension  $E$  is trivial if and only if (App. II 2.2) the exact sequence  $(*)$  of  $p$ -Lie algebras is split. One knows that  $\operatorname{Lie} \alpha_p$  is generated by an element  $X \neq 0$  such that  $X^{(p)} = 0$  (App. II 2.1); it therefore suffices to show that  $X$  lifts to an element  $Z$  of  $\operatorname{Lie} E$  such that  $Z^{(p)} = 0$ . Now by 5.8.2 ii), there exists a unipotent element  $Z$  of  $\operatorname{Lie} E$  lifting  $X$ . Since the unipotent part of  $\operatorname{Lie} E$  is clearly at most of dimension 1, one necessarily has  $Z^{(p)} = 0$ .

\*Proof of 6.1.1 C)\*. If  $U_{\{1\}}$  is a lift in  $E$  of an algebraic subgroup  $U_1$  of  $U$ ,  $U_{\{1\}}$  is invariant in  $E$ , since  $E$  is supposed commutative, and we may pass to the quotient by  $U_{\{1\}}$ . Using a composition series of  $U$  (3.5 ii)),

<!-- original page 608 -->

the preceding remark allows us to reduce to the case where  $U$  is smooth or equal to  $\alpha_p$ . But then  $E$  is trivial by A) iv) and B).

### 6.4. Examples of extensions of a unipotent group  $U$  by a group of multiplicative type  $H$  that are non-trivial

<!-- label: III.XVII.6.4 -->

In view of 6.1.1 A) iv), the problem only arises in characteristic  $p > 0$ .

a)  $H = G_m$ ,  $U$  is a non-trivial form of  $G_a$  (cf. App. III, § 5).

Let  $k$  be a non-perfect field of characteristic 2,  $u$  an element of  $k$  such that  $u^{1/2}$  does not belong to  $k$ . Consider the affine group  $E$  with ring  $k[X, Y, (X^2 + uY^2)^{-1}]$ , where multiplication is given by the comorphism:

```
```text
(X, Y) ↦ (XX' + uYY', XY' + YX').
```
```

The group  $E$  is smooth, connected, commutative, of dimension 2; the subscheme  $Y = 0$  defines a subgroup  $H \simeq G_m$ . The kernel  $K$  of squaring in  $E$  has equation:

```
$$
X^2 + uY^2 = 1,
$$
```

hence is of dimension 1. The group  $K$  contains the unipotent radical of  $E$  (defined over  $\bar{k}$ ) but also the contribution of  $H$  which is isomorphic to  $\mu_2$ . Since  $K$  is reduced over  $k$ , the unipotent radical of  $E$  is not defined over  $k$ ,

<!-- original page 609 -->

and  $U = E/H$  does not lift in  $E$ . (One verifies immediately that  $U$  is the form of  $G_a$  having ring  $k[V, W] / (V + uV^2 + W^2)$ , the morphism  $E \rightarrow U$  corresponding to the comorphism:  $V \mapsto Y^2 / (X^2 + Y^2 u)$ ,  $W \mapsto XY / (X^2 + Y^2 u)$ ).

b)  $H = G_m$ ,  $U = \mathbb{Z}/2\mathbb{Z}$ ,  $k$  non-perfect of characteristic 2.

Choosing  $k$  and  $u$  as in a), consider the subgroup  $E$  of  $\mathrm{GL}_2$  generated by the element  $X$  such that:

```
$$
X = \begin{pmatrix} 0 & 1 \\ u & 0 \end{pmatrix} = \begin{pmatrix} u^{1/2} & 0 \\ 0 & u^{1/2} \end{pmatrix} \begin{pmatrix} 0 & u^{-1/2} \\ u^{1/2} & 0 \end{pmatrix}.
$$
```

The group  $E$  is an extension of  $\mathbb{Z}/2\mathbb{Z}$  by  $G_m$ , but this extension is not trivial because the unipotent part of  $X$  is not defined over  $k$ .

c)  $H = \mu_p$ ,  $U = \alpha_p$ ,  $k$  non-perfect.

Let  $e$  be the commutative  $p$ -Lie algebra generated by two elements  $X$  and  $Y$  such that  $X^{(p)} = X$  and  $Y^{(p)} = aX$ . By App. II 2.2,  $e$  is the  $p$ -Lie algebra of an algebraic group  $E$  extension of  $\alpha_p$  by  $\mu_p$ , but this extension is trivial if and only if there exists  $b$  in  $k$  such that  $b^{(p)} = a$  (since one then has  $(bX + Y)^{(p)} = 0$ ).

d)  $H = \mu_2$ ,  $U = \alpha_2 \times \alpha_2$ ,  $E$  non-commutative,  $k$  a field of characteristic 2.

Consider the special linear group  $\mathrm{SL}_2(k)$  and let  $E = F(\mathrm{SL}_2(k))$ . The group  $E$  is a radical group of height 1, whose Lie algebra is generated by three elements

<!-- original page 610 -->

$X, Y, Z$  satisfying the following relations:

```
```text
[X, Y] = Z, [X, Z] = [Y, Z] = 0,
X^{(p)} = Y^{(p)} = 0, Z^{(p)} = Z.
```
```

Consequently,  $E$  is a central extension of  $U \simeq \alpha_2 \times \alpha_2$  by  $\mu_2$ . Each factor  $\alpha_2$  of  $U$  lifts uniquely in  $E$ , but  $U$  itself does not lift in  $E$ , because  $[X, Y] \neq 0$ .

## ## 7. Nilpotent affine algebraic groups

<!-- label: III.XVII.7 -->

<!-- original page 611 -->

### ### 7.1. Extensions of groups of multiplicative type

<!-- label: III.XVII.7.1 -->

**Proposition 7.1.1.** Let  $S$  be a prescheme,  $H$  and  $K$  two  $S$ -preschemes in groups of multiplicative type and of finite type,  $E$  a prescheme in groups extension of  $K$  by  $H$  (i.e.  $K$  is the quotient of  $E$  by  $H$  for the fpqc topology). Then  $E$  is of multiplicative type in the following two cases:

<!-- label: III.XVII.7.1.1 -->

a)  $E$  is commutative.

b) The fibers of  $K$  are connected.

**Proof.** i) **Case where  $S$  is the spectrum of a field  $k$ .**

The assertion to prove is local for the fpqc topology, which allows us to suppose  $k$  algebraically closed, hence  $H$  and  $K$  diagonalizable. Note that  $K$  acts trivially on  $H$  by inner automorphisms: this is clear in case a) and follows from 6.2.1 in case b). By induction on the length of a suitable composition series of  $K$ , one is reduced to the case where  $K$  is of one of three types: a)  $K = G_m$ , b)  $K = \mu_p$ , c)  $K = \mu_q$  with  $(q, p) = 1$ , and in this last case,  $E$  is commutative. Using now an embedding of  $H$  into  $G^{\{r\}}_m$ , one deduces that  $E$  embeds into an extension of  $K$  by  $G^{\{r\}}_m$ . One may therefore suppose  $H = G^{\{r\}}_m$ .

a) If  $K = G_m$ ,  $E$  is a smooth, connected, affine (Exp. VI\_B 9.2) algebraic group of unipotent rank zero, hence is a torus.

b)  $K = \mu_p$ . In this case  $E$  is a trivial extension.

<!-- original page 612 -->

Indeed, since  $H$  is smooth, the canonical morphism  $\mathrm{Lie} E \rightarrow \mathrm{Lie} \mu_p$  is surjective (App. II 3.2), and it suffices to apply 5.8.2 i), taking App. II 2.2 into account.

c)  $K = \mu_q$ , with  $(q, p) = 1$  and  $E$  commutative. Here again the extension  $E$  is trivial. Indeed, let  $x \in E(k)$  be a lift of a generator  $\bar{x}$  of  $\mu_q(k)$ . The element  $x^q$  is an element of  $H(k)$ , hence is of the form  $y^q$ ,  $y \in H(k)$  (note that  $G^{\{r\}}_m(k)$  is  $q$ -divisible). Since  $E$  is commutative,  $y^{-1}x$  is a lift of  $\bar{x}$  of order  $q$ .

ii) **General case.** The groups  $H$  and  $K$  are flat, affine, and of finite presentation over  $S$  (Exp. IX 2.1), and consequently so is  $E$  (Exp. VI\_B 9.2). Using then the general technique of VI\_B § 10, we reduce to the case where  $S$  is noetherian. To show that  $E$  is of multiplicative type, it suffices then to prove that  $E$  is commutative and that  $E_n$  is finite over  $S$  for every  $n$  (Exp. X 4.8 b).

a)  $E$  is commutative. One must verify that the morphism:

```text  
 $E \times_S E \rightarrow E, \quad (x, y) \mapsto [x, y] = xyx^{-1}y^{-1}$

factors through the unit section of E , and it suffices to verify this when S is the spectrum of a local Artinian ring. But then E is of multiplicative type by i) and Exp. X 2.3.

<!-- original page 613 -->

b) E_n is finite over S . Indeed, one has the exact sequence:

```text  
 $0 \rightarrow {}_n H \rightarrow {}_n E \rightarrow {}_n K \rightarrow {}_n H$

...

(where  $H_{\{n\}}$  is the cokernel of raising to the  $n$ -th power in  $H$ ). One knows that  $H_{\{n\}}$  is of multiplicative type (Exp. IX 2.7), hence separated, and that  $\{H_{\{n\}}\}$  and  $\{K_{\{n\}}\}$  are finite over  $S$ ;  $\text{Ker } u$  is a closed subgroup of  $\{K_{\{n\}}\}$ , hence is finite over  $S$ , and  $\{E_{\{n\}}\}$  is finite over  $S$ , as an extension of a finite group by a finite group (Exp. VI\_B 9.2).

### 7.2. Structure of commutative affine algebraic groups

<!-- label: III.XVII.7.2 -->

**Theorem 7.2.1.** Let  $k$  be a field,  $G$  a commutative affine  $k$ -algebraic group. Then:

<!-- label: III.XVII.7.2.1 -->

a)  $G$  contains a largest subgroup of multiplicative type  $M$ . The group  $M$  is characteristic in  $G$  and  $G/M$  is unipotent, and its formation commutes with extension of the field  $k$ .

b) If  $k$  is perfect,  $G$  is the direct product of  $M$  and a unipotent algebraic subgroup  $U$ , and this in a unique manner.

*Proof.* i)  $k$  algebraically closed.

When  $G$  is smooth, 7.2.1 b) is well-known (\*Bible\* § 4 Th. 4). If  $G$  is radical of height 1, to the decomposition of  $\text{Lie } G$  described in 4.2.2 corresponds, taking 4.3.1 v) and App. II 2.2 into account, a decomposition of  $G$  of the type 7.2.1 b). In the general case,  $G$  admits a composition series whose successive quotients are smooth or radical of height 1 (App. II 3.1). To prove 7.2.1 b), it then suffices to note that if one has an exact sequence of commutative algebraic groups:

$$0 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 0,$$

<!-- original page 614 -->

where  $G'$  (resp.  $G''$ ) is a product of a group of multiplicative type by a unipotent group,  $G' = M' \cdot U'$  (resp.  $G'' = M'' \cdot U''$ ), then so is  $G$ . Indeed, consider the exact sequence:

$$0 \rightarrow G'/U' \rightarrow G/U \rightarrow G''/U'' \rightarrow 0.$$

By 7.1.1 a), the inverse image in  $G/U$  of  $M''$  is a subgroup of multiplicative type  $M_1$ . The group  $M_1$  lifts to a subgroup  $M$  of  $G$  (5.1.1 i) a)). Likewise, using this time 6.1.1 C), one proves that there exists a unipotent subgroup  $U$  of  $G$ , extension of  $U''$  by  $U'$ . It is clear that  $G = M \cdot U$ .

ii) *General  $k$ .* By i),  $G_{\{\bar{k}\}}$  is a direct product of a group of multiplicative type  $M_{\{\bar{k}\}}$  by a unipotent group  $U_{\{\bar{k}\}}$ . Set  $S = \bar{k} \times \bar{k}$  and let  $M_1$  and  $M_2$  be the two inverse images of  $M_{\{\bar{k}\}}$  under the two projections  $S \rightarrow \bar{k}$ . The group  $G_{\{S\}} / M_{\{2\}} = (G/M_{\{\bar{k}\}})_{\{S\}}$  has unipotent fibers, so the image of  $M_1$  in  $G_{\{S\}} / M_{\{2\}}$  is zero (2.4 i)) and  $M_2$  majorizes  $M_1$ . Likewise  $M_1$  majorizes  $M_2$ , and finally  $M_{\{1\}} = M_{\{2\}}$ . By fpqc descent, it follows that  $M_{\{\bar{k}\}}$  comes from an algebraic subgroup  $M$  of  $G$ . It is clear that  $M$  is of multiplicative type, that  $G/M$  is unipotent, and that the formation of  $M$  is compatible with every extension of the field  $k$ . For every  $k$ -prescheme  $S$ , every subgroup of multiplicative type  $H$  of  $G_S$  is contained in  $M_S$ . Indeed, by 2.5, its image in the group with unipotent fibers  $(G/M)_{\{S\}} = G_{\{S\}} / M_{\{S\}}$  is zero. Taking in particular

<!-- original page 615 -->

for  $H$  the transform of  $M_S$  under an automorphism of  $G_S$ , one deduces that  $M$  is characteristic in  $G$ .

Finally if  $k$  is perfect,  $G/M$  lifts in  $G$  to a unipotent group, and this in a unique manner by 6.1.1 C).

**Remark 7.2.2.**

<!-- label: III.XVII.7.2.2 -->

\*i) If  $k$  is not perfect, the unipotent component of  $G_{\bar{k}}$  is not necessarily defined over  $k$ , as shown by the example 6.4 a).\*

\*ii) Unlike what happens for the multiplicative-type component  $M$ , the unipotent component  $U$  is not in general characteristic in  $G$  (whatever the characteristic of  $k$ ). Of course, the uniqueness of the decomposition 7.2.1 b) entails that  $U$  is invariant under every  $k$ -automorphism of  $G$ . But if  $U$  and  $M$  are such that there exists a  $k$ -prescheme  $S$  and a non-zero  $S$ -homomorphism  $h : U_S \rightarrow M_S$  (cf. 2.6), one deduces an  $S$ -automorphism of  $G_S$ ,  $(u, m) \mapsto (u, h(u) + m)$ , which does not leave  $U_S$  invariant.\*

\*iii) If  $G$  is finite over  $k$ ,  $G/M$  corresponds by Cartier duality (2.6) to the connected component of the dual  $D(G)$  of  $G$ .\*

### 7.3. Structure of nilpotent affine algebraic groups

<!-- label: III.XVII.7.3 -->

**Theorem 7.3.1.** \*Let  $k$  be a field,  $G$  a nilpotent (Exp. VI\_B § 8), affine, connected  $k$ -algebraic group. Then  $G$  possesses a largest subgroup of multiplicative type  $M$ . The group  $M$  is central and characteristic, and  $G/M$  is a unipotent algebraic group.\*

<!-- label: III.XVII.7.3.1 -->

Let  $Z$  be the center of  $G$ ,  $M$  the largest subgroup of multiplicative type of  $Z$  (7.2.1). Since  $Z$  is characteristic in  $G$  and  $M$  characteristic in  $Z$ ,  $M$  is characteristic in  $G$ . It suffices to show that  $G/M$  is unipotent. By induction on the length of the ascending central series of  $G$ , this will follow, more generally, from the following lemma:

<!-- original page 616 -->

**Lemma 7.3.2.** \*(Rosenlicht). Let  $G$  be a connected  $k$ -algebraic group,  $Z$  its center. Then the center  $Z'$  of  $G' = G/Z$  is unipotent.\*

<!-- label: III.XVII.7.3.2 -->

**Proof.** We may suppose  $k$  algebraically closed. It then suffices to show that  $Z'$  does not contain a subgroup isomorphic to  $\mu_{\ell}$  for every prime number  $\ell$  (4.6.1 vi)). Let then  $\mu_{\ell}$  be a subgroup of  $Z'$ ,  $N$  its inverse image in  $G$ . Since  $\mu_{\ell}$  is central in  $G'$ ,  $N$  is invariant in  $G$ .

i) \*Case where  $(\ell, p) = 1$ .\* One may find an element  $x$  of  $N(k)$  and an integer  $n$  having the following properties:

a)  $x$  lifts a generator  $\bar{x}$  of  $\mu_{\ell}$ .

b)  $x^{\ell^n} \in Z^0(k)$ ;

(it suffices to choose a lift of  $\bar{x}$  whose image in  $N/Z^0(k)$  belongs to the  $\ell$ -Sylow subgroup).

Raising to the  $\ell$ -th power in the commutative group  $Z^0$  is an étale morphism, hence  $Z^0(k)$  is  $\ell$ -divisible. Consequently, possibly multiplying  $x$  by an element of  $Z^0(k)$ , one may suppose  $x^{\ell^n} = 0$ . The group  $N$  is then generated by two commuting commutative groups ( $Z$  and the group generated by  $x$ ), hence is commutative. The group  $\mu_{\ell^n}$  is a group of multiplicative type, characteristic in  $N$ , hence invariant in  $G$ , and consequently central,  $G$  being connected (Exp. IX, 5.5). Hence  $\mu_{\ell^n}$  is contained in  $Z$ , which contradicts the fact that its image in  $G'$  contains  $\mu_{\ell}$ .

<!-- original page 617 -->

ii) \* $\ell = p$ .\* There then exists an integer  $n$  such that the image of  $F_n$  in  $G'$  contains  $\mu_p$ , so that one has the exact sequence:

```

```text
(*) 1 → K → F_n N → μ_p → 1.
```

```

The group  $K$  is contained in  $Z$ , hence is commutative; it then follows from 7.2.1 and from 7.1.1 b) and 5.5.1 that

there exists a subgroup of multiplicative type contained in  $F_n N$  whose image in the quotient by  $K$  is  $\mu_p$ . One deduces, as in i), that  $F_n N$  is commutative. The multiplicative-type component of  $F_n N$  (7.2.1) is characteristic in  $F_n N$ , hence invariant in  $G$ , hence central (Exp. IX, 5.5); since its image in  $G'$  contains  $\mu_p$ , one obtains a contradiction.

## A. Appendix I. Hochschild cohomology and extensions of algebraic groups

<!-- label: III.XVII.A -->

<!-- original page 618 -->

### A.1. Definition of cohomology groups

<!-- label: III.XVII.A.1 -->

Let  $k$  be a field,  $G$  a  $k$ -algebraic group,  $(\text{Ab})_G$  the abelian category of commutative  $k$ -algebraic groups on which  $G$  acts. If  $A \in \text{Ob}(\text{Ab})_G$ , the functor  $h_A : (\text{Sch}/k)^{\text{circ}} \rightarrow (\text{Ens})$  canonically defined by  $A$  is a  $G$ - $\mathbb{Z}$ -module in the sense of I 3.2. We may therefore consider the standard complex  $C^\bullet(G, A)$  of algebraic cochains of  $G$  with values in  $A$  (Exp. I 5.1), as well as the group of  $i$ -cocycles  $Z^i(G, A)$ , of  $i$ -coboundaries  $B^i(G, A)$ , and the  $i$ -th cohomology group  $H^i(G, A)$ . As usual,  $H^0(G, A)$  is identified with the group  $A^G(k)$ , where  $A^G$  is the  $k$ -functor of invariants of  $A$  under  $G$ . The group  $H^1(G, A)$  classifies the principal homogeneous spaces under  $A$ , trivial, on which  $G$  acts.

The functor  $A \mapsto H^\bullet(G, A)$  is not in general a cohomological functor from the category  $(\text{Ab})_G$  to  $\text{Ab}$ ; however, one has the following proposition:

**Proposition A.1.1.** \*Let  $0 \rightarrow A' \rightarrow A \rightarrow A'' \rightarrow 0$  be an exact sequence in  $(\text{Ab})_G$ . Then:

<!-- label: III.XVII.A.1.1 -->

a) If  $v$  possesses a section (that is, if there exists a  $k$ -morphism of preschemes  $s : A'' \rightarrow A$  such that  $svs = 1_{A''}$ ), one has the usual exact cohomology sequence:

```

```text
...  $H^i(G, A) \rightarrow H^i(G, A') \rightarrow H^{i+1}(G, A') \rightarrow \dots$ 
```

```

<!-- original page 619 -->

b) If  $A(k) \rightarrow A'(k)$  is surjective, one has the exact sequence:

```

```text
(1)  $0 \rightarrow A'^G(k) \rightarrow A^G(k) \rightarrow A''^G(k) \rightarrow H^1(G, A') \rightarrow H^1(G, A) \rightarrow H^1(G, A'')$ .
```

```

**Proof.** a) One notes that the existence of a section entails the exactness of the sequence of complexes:

```

```text
 $0 \rightarrow C^\bullet(G, A') \rightarrow C^\bullet(G, A) \rightarrow C^\bullet(G, A'') \rightarrow 0$ .
```

```

b) If  $x'' \in A''^G(k)$ , its inverse image in  $A$  is a principal homogeneous space under  $A'$ , trivial (since  $A(k) \rightarrow A'(k)$  is supposed surjective), on which  $G$  acts, hence defines an element  $d(x'') \in H^1(G, A')$ . The exactness of the sequence (1) is then immediate.

### A.2. The group  $\text{Ext}_{\text{alg}}(G, A)$

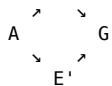

<!-- label: III.XVII.A.2 -->

Let  $A$  and  $G$  be two  $k$ -algebraic groups,  $E$  and  $E'$  two  $k$ -algebraic group extensions of  $G$  by  $A$ . These two extensions are said to be *isomorphic* if there exists a  $k$ -morphism of groups  $u : E \rightarrow E'$  making the diagram

```

```text
      E

```

commutative. The group E acts on A by inner automorphisms, and if A is commutative, this action factors through G , so G acts on A . Conversely, if $A \in \text{Ob}(\text{Ab})_G$, we denote by $\text{Ext}_{\text{alg}}(G, A)$ the set of classes of algebraic extensions E of G by A for which the action of G on A defined by E , and that coming from the structure

<!-- original page 620 -->

of object of $(\text{Ab})_G$, coincide.

$\text{Ext}_{\text{alg}}(G, A)$ is in a natural way a bifunctor, covariant in A and contravariant in G . More precisely:

a) If $f : A \rightarrow B$ is a morphism in $(\text{Ab})_G$, and if E represents an element of $\text{Ext}_{\text{alg}}(G, A)$, one defines $f_*(E) \in \text{Ext}_{\text{alg}}(G, B)$ as the class of the extension of G by B equal to the quotient of the semidirect product $B \rtimes E$ (E acting on B through G) by the algebraic subgroup image of A under the morphism (f, i) (this quotient is representable by Exp. VI_A § 5), so that one has a commutative diagram:

```

```text
1 → A → E → G → 1
 ↓f ↓ ↓1_G
1 → B → f_*(E) → G → 1.
```

```

b) If $g : H \rightarrow G$ is a k -morphism of k -algebraic groups, and if E is an extension of G by A , the fiber product $E \times_G H$ is naturally an extension of H by A , denoted $g^*(E)$. One therefore has a commutative diagram:

```

$$
1 \longrightarrow A \longrightarrow g^*(E) \longrightarrow H \longrightarrow 1
      \downarrow 1_A \qquad \downarrow \qquad \downarrow g
1 \longrightarrow A \longrightarrow E \longrightarrow G \longrightarrow 1.
$$

```

Adapting the proofs given in J.-P. Serre, *Groupes algébriques et corps de classes*, Chap. VII, one endows $\text{Ext}_{\text{alg}}(G, A)$ with a natural abelian group structure, functorial in A and G .

<!-- original page 621 -->

Proposition A.2.1. *Let $0 \rightarrow A' \rightarrow A \rightarrow A'' \rightarrow 0$ be an exact sequence in $(\text{Ab})_G$. Then:*

<!-- label: III.XVII.A.2.1 -->

a) One has a canonical exact sequence of abelian groups:

```

```text
Z^1(G, A) → Z^1(G, A'') → Ext_{alg}(G, A') → Ext_{alg}(G, A) → Ext_{alg}(G, A'').
```

```

b) If $A(k) \rightarrow A''(k)$ is surjective, one deduces from a) the exact sequence:

```

```text
(2) H^1(G, A) → H^1(G, A'') → Ext_{alg}(G, A') → Ext_{alg}(G, A) → Ext_{alg}(G, A'').
```

```

The exact sequence of a) generalizes the usual exact sequence of $\text{Hom}(\cdot, \cdot)$ valid in the framework of commutative extensions (*loc. cit.*) and is proved in the same way. Let us simply recall the definition of the coboundary $\delta : Z^1(G, A'') \rightarrow \text{Ext}_{\text{alg}}(G, A')$. For this, consider the extension

```

```text
1 → A' → A · G → A'' · G → 1,
```

```

...

deduced in the obvious way from the exact sequence $0 \rightarrow A' \rightarrow A \rightarrow A'' \rightarrow 0$. If $u \in Z^1(G, A')$, u defines in the usual way a section homomorphism $u : G \rightarrow A' \cdot G$. One then has $d(u) = u^*(A \cdot G)$.

A.3. Comparison of $H^2(G, A)$ and $\text{Ext}_{\text{alg}}(G, A)$

<!-- label: III.XVII.A.3 -->

It is well known, in the case of abstract groups, that there exists a functorial isomorphism between the abelian groups $H^2(G, A)$ and $\text{Ext}(G, A)$. Likewise in the present case, if A is an element of $(\text{Ab})_G$, to every 2-cocycle $u \in Z^2(G, A)$ one can associate a structure of algebraic group on the prescheme $A \times_k G$ which makes it an element of $\text{Ext}_{\text{alg}}(G, A)$. Moreover this extension is trivial if and only if $u \in B^2(G, A)$ (cf. Exp. III 1.2.2). Let us recall that the composition law on $A \times G$ is defined by the formula:

```
```text
(a, g)(a', g') = (a + {}^g a' + u(g, g'), gg').
```
```

<!-- original page 622 -->

It is clear that the extensions of G by A thus obtained are not arbitrary, since they possess a section. But conversely, if $E \in \text{Ext}_{\text{alg}}(G, A)$ possesses a section s , E is isomorphic to the extension of G by A associated with the 2-cocycle u such that:

```
```text
u(g, g') = s(g) s(g') s(gg')^{-1}.
```
```

One finally obtains the following proposition:

Proposition A.3.1. *There exists a functorial isomorphism between the bifunctors with values in abelian groups:*

<!-- label: III.XVII.A.3.1 -->

```
```text
(G, A) \mapsto H^2(G, A) \quad \text{and} \quad (G, A) \mapsto \text{Ext}_s(G, A),
```
```

where $\text{Ext}_s(G, A)$ denotes the subgroup of $\text{Ext}_{\text{alg}}(G, A)$ formed by the classes of extensions of G by A that possess a section.

B. Appendix II. Reminders and complements on radical groups

<!-- label: III.XVII.B -->

<!-- original page 623 -->

Let p be a prime number > 1 and let S be an F_p -prescheme.

B.1. The Frobenius morphism

<!-- label: III.XVII.B.1 -->

For every S -prescheme X and every integer $n > 0$, denote by $P_n : X \rightarrow X$ the F_p -endomorphism corresponding to raising to the p^n -th power in 0_X , and denote by $X^{(n)}$ the S -prescheme inverse image of X under the morphism $P_n : S \rightarrow S$. There then exists a unique S -morphism $F_n : X \rightarrow X^{(n)}$ making the diagram

```
```text
X -----> X
 \ /
 \ F_n /
 \ /
 X^{(n)}
 ↓
```
```

$$\begin{array}{ccc} & \downarrow P_n & \\ S & \xrightarrow{\quad} & S \\ & \downarrow P_n & \\ \dots & & \end{array}$$

commutative.

It is clear that F_n is identified with the " n -th iterate" of $F_1 = F$, called the Frobenius morphism of X/S .

If G is an S -prescheme in groups, $G^{(n)}$ is an S -prescheme in groups and $F_n : G \rightarrow G^{(n)}$ is an S -morphism of groups. Its kernel $F_n(G)$ is a characteristic sub-prescheme in groups of G (i.e. stable under the functor $\text{Aut}_S(G)$), and radicial over S . If G is an S -prescheme in groups that is radicial, one says that G is

<!-- original page 624 -->

of height $\leq h$ if $F_h(G) = G$.

B.2. Groups and p -Lie algebras

<!-- label: III.XVII.B.2 -->

If G is an S -prescheme in groups, $\text{Lie}(G)$ (Exp. II) is naturally a restricted p -Lie algebra (Exp. VII_A § 5 and 6). In particular one has the following result (cf. Exp. VII_A):

Proposition B.2.1. *i) $\text{Lie}(\alpha_p)_S = \text{Lie}(G_a)_S$ [N.D.E-XVII-11] is a sheaf of 0_S -modules, free over 0_S of rank 1, generated by an element X such that $X^{(p)} = 0$.*

<!-- label: III.XVII.B.2.1 -->

ii) $\text{Lie}(\mu_p)_S = \text{Lie}(G_m)_S$ is a sheaf of 0_S -modules, free over 0_S of rank 1, possessing a canonical basis X such that $X^{(p)} = X$.

Let us now recall the fundamental result proved in Exp. VII_A § 7:

Theorem B.2.2. *Suppose S affine with ring A . Then the functor*

<!-- label: III.XVII.B.2.2 -->

$G \mapsto \text{Lie } G$

establishes an equivalence of categories between, on the one hand, the category of S -preschemes in groups G of finite presentation and flat over S , of height 1, whose Lie algebra is locally free over 0_S ,

<!-- original page 625 -->

and, on the other hand, the category of restricted p - A -Lie algebras locally free of finite rank.

Moreover, if G is as above and if H is an S -prescheme in groups of finite presentation, the canonical morphism:

$\text{Hom}_S(G, H) \rightarrow \text{Hom}_{p\text{-Lie}}(\text{Lie } G(S), \text{Lie } H(S))$

is an isomorphism.

B.3. Radicial groups and smooth groups

<!-- label: III.XVII.B.3 -->

We now suppose that S is the spectrum of a field k of characteristic p .

Let us recall that in Exp. VI_A § 5, it was shown that if G is a k -algebraic group, H an algebraic subgroup of G , then the sheaf G/H (sheaf for the fpqc topology) is representable. Recall then (VII_A 8.3):

Proposition B.3.1. *Let G be a k -algebraic group. Then there exists an integer m such that for every $n \geq m$, the algebraic group $G / F_n(G)$ is smooth over k .*

<!-- label: III.XVII.B.3.1 -->

Proposition B.3.2. *Consider an exact sequence of k -algebraic groups:

<!-- label: III.XVII.B.3.2 -->

```text  
 $1 \rightarrow G' \rightarrow G \xrightarrow{u} G'' \rightarrow 1$   
 ```

and the following assertions:

i) The morphism u is smooth.

ii) G' is smooth over k .

iii) For every integer $n > 0$, one has the exact sequence:

$1 \rightarrow F_n(G') \rightarrow F_n(G) \rightarrow F_n(G'') \rightarrow 1$.

iv) The morphism $F_n(G) \rightarrow F_n(G'')$ is an epimorphism.

v) The morphism $(\text{Lie } G)(k) \rightarrow (\text{Lie } G'')(k)$ is surjective.

Then one has the following implications:

```text  
 i)  $\Leftrightarrow$  ii)  $\Rightarrow$  iii)  $\Rightarrow$  iv)  $\Leftrightarrow$  v).  
 ```

Moreover, if G is smooth, the five assertions are equivalent.

<!-- original page 626 -->

i) $\Leftrightarrow$ ii) by Exp. VI_B 9.2 vii).

ii) $\Rightarrow$ iii). If G' is smooth, $F_n : G' \rightarrow G'^{(n)}$ is an epimorphism and iii) follows from the snake lemma diagram.

iii) $\Rightarrow$ iv) is clear.

iv) $\Leftrightarrow$ v) by Theorem B.2.2.

v) $\Rightarrow$ ii) when G is smooth. Indeed G'' is then smooth, and v) entails that one has $\dim G' = \dim_k(\text{Lie } G')(k)$, hence G' is smooth.

C. Appendix III. Remarks and complements concerning Exposés XV, XVI, XVII

<!-- label: III.XVII.C -->

<!-- original page 627 -->

C.1.

<!-- label: III.XVII.C.1 -->

It may be that propositions 1.2 and 1.2 bis of XV remain true if one removes the hypothesis that H' is smooth over

S' . This is in particular the case if G is finite, flat, and commutative.

C.2. Complement to XV 4.8

<!-- label: III.XVII.C.2 -->

The following proposition, as well as Theorems C.3.1 and C.4.1 below, will appear in a paper in preparation by M. Raynaud on group schemes over a discrete valuation ring.[^N.D.E-XVII-12]

Proposition C.2.1. *Let S be the spectrum of a discrete valuation ring, t its generic point, G an S -prescheme in groups of finite type and flat, $\tilde{G} = \operatorname{Spec} \Gamma(G, \mathcal{O}_G)$, $u : G \rightarrow \tilde{G}$ the canonical morphism. Then:

<!-- label: III.XVII.C.2.1 -->

(1) $\tilde{G}$ is naturally an S -group scheme and u is a homomorphism.

(2) $\ker(u)$ is flat over S and $(\tilde{G}, u)$ is an fpqc quotient of G by $\ker(u)$, so that $\tilde{G}$ is the largest affine quotient of G .

(3) If G_t is affine, $\ker(u)$ is an étale group over S , equal to the trivial group if and only if G is separated over S . In particular, an S -group scheme G , flat, of finite type, separated, with affine generic fiber, is affine.

C.3.

<!-- label: III.XVII.C.3 -->

In the statement of XV 6.6, the hypothesis that H is equal to its connected normalizer is unnecessary for the set of points s of S such that H_s is a parabolic subgroup of G_s to be an open set. Indeed, taking up the proof given in paragraph c) preceding Lemma 6.9, and denoting by N the schematic closure of N_t in G . Then N is a closed subscheme in groups of G , flat over S , majorizing H and contained in N . It then follows from the theorem below

<!-- original page 628 -->

that G/N is representable. Since G_s / N_s is proper and connected, one finishes as in *loc. cit.*

Theorem C.3.1.[^N.D.E-XVII-13] *Let S be the spectrum of a henselian discrete valuation ring, G an S -prescheme in groups locally of finite type, H a closed sub-prescheme in groups of G , flat over S . Then G/H is representable.

<!-- label: III.XVII.C.3.1 -->

C.4. Complement to (XVI 1.1)

<!-- label: III.XVII.C.4 -->

The following theorem refines (VIII 7.9).

Theorem C.4.1. *Let S be the spectrum of a discrete valuation ring of residue characteristic $p > 0$, and let G be a commutative, smooth S -group scheme of finite type and separated over S . Then the following conditions are equivalent:

<!-- label: III.XVII.C.4.1 -->

(i) G_p is finite over S .

(ii) For every S -prescheme S' and for every S' -prescheme in groups H' , of finite presentation over S' , separated over S' , every S' -monomorphism $u : G_{S'} \rightarrow H'$ is an immersion.

C.5.

<!-- label: III.XVII.C.5 -->

The example (XVII 6.4 a)) provides an example of a smooth group over a field k , whose unipotent radical is not defined over k . The following proposition gives a general method for obtaining such groups:

<!-- original page 629 -->

Proposition C.5.1. *Let k be a field, K a finite radical extension of k of degree > 1 , H a connected, smooth K -algebraic group of dimension r , $G = \prod_{K/k} H/K$, which is a k -algebraic group, smooth, connected, of dimension $r[K : k]$. Let $u : G_K \rightarrow H$ be the canonical homomorphism, and $R = \text{Ker}(u)$. Then:

<!-- label: III.XVII.C.5.1 -->

i) The morphism u is an epimorphism and R is a smooth, unipotent, connected algebraic group.

ii) If U is a smooth algebraic subgroup of G such that U_K majorizes R , then $U = G$.

Corollary. *Keep the notations of the preceding proposition.*

a) If H is not unipotent, the unipotent radical of $G_{\bar{k}}$ is not defined over k .

b) If H is a non-zero abelian variety, G is not an extension of an abelian variety by a smooth linear group.

c) If H is not solvable, the solvable radical of $G_{\bar{k}}$ is not defined over k , and G does not possess a Borel subgroup defined over k .

Let us first show how the corollary follows from the proposition.

a) Let U be a unipotent radical of G . Then U_K is the unipotent radical of G_K , hence majorizes R , since R is smooth unipotent connected by i), hence $U = G$ by ii). Now G_K admits H as a quotient, and H is not unipotent by hypothesis, hence G is not unipotent, whence a contradiction.

b) If G is an extension of an abelian variety by a linear group L , smooth over k , necessarily L_K majorizes R , hence $L = G$. Now G cannot be a linear group since G_K possesses a quotient that is a non-zero abelian variety.

c) Let S (resp. B) be a solvable radical of G (resp. a Borel subgroup of G); then S_K (resp. B_K) majorizes R , hence $S = G$ (resp. $B = G$). But then G is solvable, which contradicts the fact that G_K possesses a quotient that is not solvable.

Proof of Proposition C.5.1.

i) Let us begin by describing the morphism u . The data of a K -scheme

S
 $f : S \rightarrow \text{Spec}(K)$
 S

<!-- original page 630 -->

allows one to construct the diagram:

$$\begin{array}{ccc} \text{Spec}(K) & \xleftarrow{h} T & \xrightarrow{j} X \\ \downarrow j & & \downarrow s \\ \text{Spec}(k) & \xleftarrow{g} S & \end{array} \quad (\text{where } g = j \circ f)$$

where $T = \text{Spec}(K) \times_{\text{Spec}(k)} S$, h and j are the two projections, and s is the section of T over S such that $h \circ s = f$. The map

S
 $u(S) : G_K(S) \rightarrow H(S)$
 S

is simply the composite map:

\$\$
 $G_{\{K\}}(S) \xrightarrow{\sim} H(T) \rightarrow H(S),$
 \$\$

where the last arrow is defined by the section ss .

Take in particular for SS the spectrum of an algebraic closure $\bar{k}$ of k and for f the unique k -morphism $K \rightarrow \bar{k}$, so that T is a local Artinian scheme. To prove i) it suffices to do so after extension $K \rightarrow \bar{k}$ of the base field. Now it is clear that $G_{\{S\}} = \prod_{T/S} H_{\{T\}} / T$ represents the Greenberg functor of $H_{\{T\}}$ relative to SS (M. J. Greenberg, *Schemata over local rings*, Ann. of Maths. 73, 1961, p. 624-648). The description made above then shows that, by means of this last identification, $u_{\{S\}}$ is the canonical transition morphism:

```text  
 Green( $H_T$ )  $\rightarrow$   $H_S = H_T \times_T S$ .  
 ```

Assertion i) then follows from the fact that H is smooth over K and from (M. J. Greenberg, *Schemata over local rings II*, Ann. of Maths. 78, 1963, p. 256-266).

ii) To establish ii) we may suppose k separably closed. Let U be a smooth algebraic subgroup of G such that $U_{\{K\}} \supset R$, and let us show that $U = G$.

<!-- original page 631 -->

Since G is connected, we may suppose U connected. Let V be the smooth connected algebraic subgroup $u_{\{U_{\{K\}}\}}$ of H , and $V' = \prod_{K/k} V/K$, which is a smooth connected algebraic subgroup of G . The group $V'_{\{K\}}$ is an algebraic subgroup of $G_{\{K\}}$, and the canonical morphism $V'_{\{K\}} \rightarrow V$ is simply the restriction of u to $V'_{\{K\}}$. By hypothesis, $U_{\{K\}}$ majorizes R , *a fortiori* $U_{\{K\}}$ majorizes $\text{Ker}(V'_{\{K\}} \rightarrow V)$; on the other hand, by construction, the image of $U_{\{K\}}$ in H is equal to V . One deduces that $U_{\{K\}}$ majorizes $V'_{\{K\}}$, hence U majorizes V' . On the other hand, the canonical isomorphism

```text  
 $G(k) \hookrightarrow G(K) \xrightarrow{u(K)} H(K)$   
 ```

evidently sends $U(k)$ into $V(K) = V'(k)$; that is to say, $U(k)$ is contained in $V'(k)$. Since U is smooth and k is separably closed, this entails $U \subset V'$, whence $U = V'$. One then has the equalities:

```text  
 $([K : k] - 1) \dim V = \dim \text{Ker}(V'_{\{K\}} \rightarrow V) = \dim R = ([K : k] - 1) \dim H$ .  
 ```

Since $K \neq k$, one concludes that $\dim V = \dim H$, whence $V = H$ and finally $U = V' = G$.

Exposé XVIII. Weil's theorem on the construction of a group from a rational law

<!-- label: III.XVIII -->

by Michael Artin

0. Introduction

<!-- label: III.XVIII.0 -->

<!-- original page 632 -->

This Exposé is devoted to the well-known theorem of Weil [1] which gives the construction of a group variety from a birational law. It seems that the generalization of this result to the case where the base is the spectrum of a discrete valuation ring was already known to several people; one may consult, for example, [2]. Here we shall prove the theorem for a flat group of finite presentation over an arbitrary base prescheme S . Since the hypotheses must be made with somewhat more care, the statement is not in the form given by Weil; but when S is the spectrum of a field, one sees that the form given here is essentially equivalent to Weil's. We use the following suggestion of Grothendieck: given a "group germ" X over a prescheme S , one is to construct the group as the quotient of $X \times_S X$ by a suitable equivalence relation.

1. "Recollections" on rational maps

<!-- label: III.XVIII.1 -->

<!-- original page 633 -->

Let X/S be a relative prescheme and $U \subseteq X$ an open subset. We say that U is *schematically dense* in X

relatively to S , or that $U \hookrightarrow X$ is *relatively schematically dense*, if for every base change $S' \rightarrow S$ the open subset $U \times_S S'$ is schematically dense in $X \times_S S'$. For the definition and properties of this notion we refer to Exp. IX, § 4.^[XVIII-1-1]

Proposition 1.1. (i) A finite intersection, as well as a union of a non-empty family of opens that are schematically dense relatively to S , is schematically dense relatively to S .

label: III.XVIII.1.1 -->

(ii) If $U \subseteq X$ is schematically dense relatively to S and if $S \rightarrow T$ is a morphism, then $U_T \subseteq X_T$ is schematically dense relatively to T .

(iii) Let $U \subseteq V \subseteq X$ be open immersions. For U to be schematically dense in X relatively to S , it is necessary and sufficient that it be so in V and that V be so in X .

(iv) If $U \subseteq X$ and $V \subseteq Y$ are relatively schematically dense, then $U \times_S V$ is schematically dense in $X \times_S Y$ relatively to S .

In Exp. IX one finds the following criterion:

Proposition 1.2. Let X/S be locally of finite presentation and flat, and let U be an open subset of X . If for each $s \in S$ the fiber U_s is schematically dense in X_s , then U is schematically dense in X relatively to S .

label: III.XVIII.1.2 -->

In particular:

Corollary 1.3. If X/S is locally of finite presentation and flat, and if each fiber X_s is "without embedded component", then U is schematically dense in X relatively to S if and only if for each $s \in S$, U_s is dense in X_s in the topological sense.

label: III.XVIII.1.3 -->

original page 634 -->

One easily deduces from the definition the following:

Proposition 1.4. Let $U \subseteq X$ be schematically dense relatively to S , and let $f, g : X \rightarrow Y$ be two morphisms of functors over S , where Y satisfies one of the following conditions:

label: III.XVIII.1.4 -->

(i) Y is a prescheme over S and each fiber Y_s is separated.

(ii) Y is a presheaf^[N.D.E-XVIII-1] on S such that the diagonal morphism $Y \rightarrow Y \times_S Y$ is representable by a closed immersion.^[N.D.E-XVIII-2]

Then if $f = g$ on U , one has $f = g$.

Proof. In case (i), the standard argument following IX 4.1 shows that f and g are equal on each fiber, so that the subscheme $\text{Ker}(f, g)$ of X is set-theoretically equal to U , hence closed; and since it majorizes U , it is equal to X , i.e. $f = g$. Case (ii) is proved as in *loc. cit.*^[N.D.E-XVIII-3]

Definition 1.5.^[XVIII-1-2] Let X be a prescheme over S and Y a presheaf over S . By a *rational map* $f : X \dashrightarrow Y$ over S we mean an equivalence class of morphisms $f : U \rightarrow Y$ over S , where U is an open of X that is schematically dense relatively to S , and where one sets $(f : U \rightarrow Y) \sim (f' : U' \rightarrow Y)$ if and only if there exists an open $U'' \subseteq U \cap U'$, schematically dense relatively to S , such that $f = f'$ on U'' .

label: III.XVIII.1.5 -->

This definition is made in such a way that one may define in the obvious way the rational map $f \times_S S'$ for any base change $S' \rightarrow S$.

If U is an open of X , we say that the rational map f is *defined* on U if there exists a morphism representing f whose set of definition contains U .

Definition 1.5.1. [N.D.E-XVIII-4] If Y satisfies one of the conditions (i), (ii) of 1.4, it is clear that there exists a largest open U of X on which f is defined, and this U is schematically dense relatively to S . It is called the *domain of definition* of f over S , and is denoted $\text{Dom}(f)$.

<!-- label: III.XVIII.1.5.1 -->

This notion does not commute with base change in general, but one has:

Proposition 1.6. Let X be an S -prescheme and Y an S -functor satisfying one of the hypotheses (i), (ii) of 1.4. Let $f : X \dashrightarrow Y$ be a rational map over S , let $S' \rightarrow S$ be a flat morphism locally of finite presentation, and set $f' = f \times_S S'$. Then*

<!-- label: III.XVIII.1.6 -->

<!-- original page 635 -->

``text
 $\text{Dom}(f') = \text{Dom}(f) \times_S S'$.
``

Proof. Set $U = \text{Dom}(f)$. It is clear that $V' = \text{Dom}(f')$ contains $U \times_S S'$. Let V be the image of V' , which is an open of X because $X' \rightarrow X$ is open. We must show that $V = U$, that is, we must find a morphism $V \rightarrow Y$ that represents f . Set $S'' = S' \times_S S'$, and

``text
 $X'' = X \times_S S''$, $U'' = U \times_S S''$, $V'' = V' \times_V V'$.
``

Then U'' is schematically dense in X'' relatively to S'' , hence U'' is schematically dense in V'' relatively to S'' , since $U'' \subseteq V'' \subseteq X''$. The restriction of $f' : V' \rightarrow Y$ to U' is deduced from $f : U \rightarrow Y$ by base change. The two morphisms $V'' \rightarrow Y$ deduced from g by base change are equal on U'' , hence are equal. Now since $V' \rightarrow V$ is flat and locally of finite presentation, it is fppf-covering (Exp. IV 6.3), and one finds the morphism $V \rightarrow Y$ by descent.

We shall make frequent use of the following triviality:

Proposition 1.7. Let X/S be faithfully flat, locally of finite presentation, and let $U \subseteq X$ be a relatively schematically dense open. Then there exists a base change $S' \rightarrow S$ which is fppf-covering, and a section $x \in X(S')$ which is contained in $U(S')$.

<!-- label: III.XVIII.1.7 -->

Indeed, U/S is fppf-covering. One takes $S' = U$ and the S -graph of the inclusion of U in X as the section.

2. Local determination of a group morphism

<!-- label: III.XVIII.2 -->

<!-- original page 636 (preceding) -->

Let G and H be groups and let $U \subseteq G$ be a subset such that $U \cdot U = G$. Then if f and g are homomorphisms from G to H such that $f = g$ on U , one has $f = g$. Similarly:

Proposition 2.1. Let S be a site (cf. Exp. IV [N.D.E-XVIII-5]), G a sheaf of groups on S , and $U \subseteq G$ a subsheaf of sets such that the morphism $U \times U \rightarrow G$ induced by multiplication is an epimorphism. Then if f and g are homomorphisms from G to a sheaf of groups H that are equal on U , one has $f = g$.

<!-- label: III.XVIII.2.1 -->

<!-- original page 636 -->

Corollary 2.2. Let G be an S -group prescheme locally of finite presentation and flat, let $U \subseteq G$ be an

open that is relatively schematically dense, and let $\mathcal{H}$ be a sheaf of groups on S for the fppf topology. Then every homomorphism $f : G \rightarrow \mathcal{H}$ is determined by its restriction to U .

<!-- label: III.XVIII.2.2 -->

Indeed, since G is flat over S , the composition law on G is a flat morphism (VI_B.9.2.xi), and it follows that $U \times_S U \rightarrow G$ is faithfully flat and locally of finite presentation, hence fppf-covering, hence an epimorphism.

Proposition 2.3. Let G be a group prescheme locally of finite presentation and flat over S , $U \subseteq G$ a relatively schematically dense open, and $\mathcal{H}$ a sheaf of groups for the fppf topology. Write m_G for the multiplication of G and m_H for that of $\mathcal{H}$.

<!-- label: III.XVIII.2.3 -->

Let $f : U \rightarrow \mathcal{H}$ be an S -morphism and assume that there exists a relatively schematically dense open V of $m_G^{-1}(U) \cap U \times_S U$ such that the diagram

$$\begin{array}{ccc} V & \xrightarrow{(f \times f)|_V} & H \times_S H \\ m_G \downarrow & & \downarrow m_H \\ U & \xrightarrow{f} & H \end{array}$$

is commutative. Then there exists a morphism of S -groups $\bar{f} : G \rightarrow \mathcal{H}$ (necessarily unique) extending f , in each of the following situations:

(i) $\mathcal{H}$ is representable.

(ii) The diagonal morphism $H \rightarrow H \times_S H$ is representable by a closed immersion. [N.D.E.-XVIII-6]

(iii) For each section $a \in U(S)$, the open $\text{pr}_2((a \times_S U) \cap V)$ is relatively schematically dense in U , and this statement remains true after every base change $S' \rightarrow S$.

Proof. Note first that V is relatively schematically dense in $G \times_S G$. Indeed, V is relatively schematically dense in

$$m_G^{-1}(U) \cap (U \times_S G) \cap (G \times_S U),$$

and the three factors are deduced from $U \subseteq G$ by an obvious base change $G \times_S G \rightarrow G$, which implies the assertion by 1.1.

To construct a morphism $\bar{f} : G \rightarrow \mathcal{H}$, it suffices, since $U \times_S U \rightarrow G$ is fppf-covering, to find a morphism from $U \times_S U$ to $\mathcal{H}$ such that the two morphisms induced on $(U \times_S U) \times_G (U \times_S U)$ are the same.

<!-- original page 637 -->

We take $m_H \circ (f \times f) : U \times_S U \rightarrow \mathcal{H}$. We must verify that whenever we have sections $a, b, c, d \in U(S')$, $S' \rightarrow S$ arbitrary, such that $ab = cd$, we also have $f(a)f(b) = f(c)f(d)$. By hypothesis, this is true if (a, b) and (c, d) are contained in $V(S')$, since in that case $f(a)f(b) = f(ab)$ and $f(c)f(d) = f(cd)$. Therefore it is true whenever $(a, b, c, d) \in (V \times_G V)(S')$.

I claim that $V \times_G V$ is an open of $(U \times_S U) \times_G (U \times_S U)$ schematically dense relatively to S . This will complete the proof in cases (i) and (ii) by 1.4, the facts that the morphism $\bar{f}$ so constructed extends f and that $\bar{f}$ is a homomorphism being evident, again by 1.4.

Indeed, we write

$$V \times_G V = (V \times_G (G \times_S G)) \cap ((G \times_S G) \times_G V).$$

...

By symmetry and 1.1, it suffices to verify that $V \times_{G'} (G \times_{S'} G)$ is relatively schematically dense in $(G \times_{S'} G) \times_{G'} (G \times_{S'} G)$. But this last prescheme is S' -isomorphic to $G \times_{S'} G \times_{S'} G$, the morphism being given by $(a, b, c, d) \mapsto (a, b, c)$. Thus what must be shown is that $V \times_{S'} G$ is schematically dense in $G \times_{S'} G \times_{S'} G$ relatively to S' , which is a consequence of the fact that V is relatively schematically dense in $G \times_{S'} G$.

It remains to treat case (iii). To prove $f(a)f(b) = f(c)f(d)$, it is permitted to make an fppf-covering base change. Suppose we have a section $x \in G(S')$, $S' \rightarrow S$ fppf-covering, such that (b, x) , (a, bx) , (d, x) , (c, dx) are all in V . Then one will have

```

```text
f(a)f(b)f(x) = f(a)f(bx) = f(abx) = f(cdx) = f(c)f(dx) = f(c)f(d)f(x),
```

```

whence the desired equality.

[^N.D.E-XVIII-7] To find such an x , set, for every $z \in U(S')$,

```

```text
V_z = pr_2((z \times_{S'} U_{S'}) \cap V_{S'}).
```

```

Then the hypotheses on x say that $x \in W$, where

```

```text
W = V_b(S') \cap V_d(S') \cap b^{-1} V_a(S') \cap d^{-1} V_c(S').
```

```

By (iii), W is relatively schematically dense in G . Hence the existence of a section x after an fppf-covering extension follows from Proposition 1.7.

<!-- original page 638 -->

Let us verify that the morphism so constructed is multiplicative. Let $a, b \in G(S')$, $S' \rightarrow S$ arbitrary, and write $S_{\{0\}} = S$. Choose an fppf-covering base change $S' \rightarrow S$ and a section $x \in G(S')$ such that $x \in U(S)$ and $ax^{-1} \in U(S')$, that is, $x \in (a^{-1}U)^{-1}(S')$. Choose moreover another fppf-covering extension $S'' \rightarrow S'$ and a section $y \in G(S'')$ such that

```

```text
y, by^{-1}, aby^{-1} \in U(S''),
```

```

and

```

```text
by^{-1} \in V_x, \quad xby^{-1} \in V_{\{ax^{-1}\}}.
```

```

Then by the definition of $\bar{f}$, one has on S''

```

```text
f^-(a) = f(ax^{-1})f(x), \quad f^-(b) = f(by^{-1})f(y), \quad f^-(ab) = f(aby^{-1})f(y).
```

```

Moreover,

```

$$
\bar{f}(a)\bar{f}(b) = f(ax^{-1})f(x)f(by^{-1})f(y) = f(ax^{-1})f(xby^{-1})f(y)
= f(aby^{-1})f(y) = \bar{f}(ab),
$$

```

whence multiplicativity.

The fact that $\bar{f}$ extends f is now easy. Let $a \in U(S')$, write $S_{\{0\}} = S$, and choose $S' \rightarrow S$ fppf-covering and sections $x, y \in G(S')$ such that (x, y) , (ax, y) , (a, xy) are in $V(S')$. Then

```
```text
f~(xy) = f(x)f(y) = f(xy), f~(axy) = f(ax)f(y) = f(axy).
```
```

Hence

```
```text
f~(a) = f~(axy)f~((xy)^{-1}) = f~(axy)f~(xy)^{-1} = f(axy)f(xy)^{-1} = f(a).
```
```

Remark 2.3.1. In many cases hypothesis (iii) is true, for it will even be true if one replaces U by a smaller open $U^{\{0\}}$, still relatively schematically dense in G . For example one has:

III.XVIII.2.3.1

Proposition 2.4. The situation being as in 2.3, suppose that each geometric fiber of G/S is irreducible. Let $U^{\{0\}} = \text{pr}_{\{1\}} V$ and

III.XVIII.2.4

```
```text
V^0 = V \cap m_{G^{-1}(U^0)} \cap (U^0 \times_S U^0).
```
```

Then $U^{\{0\}} \subseteq U$ is an open relatively schematically dense of G and the objects $U^{\{0\}}$, $f|_{U^{\{0\}}}$ and $V^{\{0\}}$ satisfy hypothesis (iii).

Proof. $U^{\{0\}}$ is open because $G \times_S G \rightarrow G$ is flat and locally of finite presentation. All the other verifications are trivial save hypothesis (iii).

Let $a \in U(S')$, write $S_{\{0\}} = S$. To verify that $\text{pr}_{\{2\}}((a \times_S U^{\{0\}}) \cap V^{\{0\}})$ is relatively schematically dense in $U^{\{0\}}$, it suffices to do so fiber by fiber by Corollary 1.3, that is, it suffices to treat the case where S is the spectrum of a field, and in that case it suffices to show that $U^{\{0\}}$ is non-empty, because G is irreducible and "without embedded components" (cf. VI_A, 1.1.1). Now

```
```text
pr_2((a \times_S U^0) \cap V^0) = pr_2((a \times_S U^0) \cap V) \cap pr_2((a \times_S U^0) \cap m_{G^{-1}(U^0)})
```
```

and the second term of the right-hand side is dense in G . Hence it suffices to show that $\text{pr}_{\{2\}}((a \times_S U^{\{0\}}) \cap V)$ is dense in G , that is, non-empty, which is clear because $a \in U^{\{0\}} = \text{pr}_{\{1\}} V$.

3. Construction of a group from a rational law

III.XVIII.3

original page 639

3.0.

III.XVIII.3.0

We are given a prescheme X/S and a rational map $X \times_S X \dashrightarrow X$ over S , and we seek a group G/S and a birational map relatively to S [N.D.E-XVIII-8]

```
$$
X \dashrightarrow G
$$
```

that commutes with the composition laws. We treat only the case where X/S satisfies the following hypothesis:

```

```text
(♦) X/S is faithfully flat, of finite presentation, and
 with separated fibers "without embedded components".
...

```

(Note that the latter two hypotheses are properties that hold for a group prescheme. [N.D.E-XVIII-9])

We shall often suppress the symbol  $S$  in fiber products.

Let  $X/S$  be a prescheme with the properties  $(♦)$  above, and let  $W$  be a subprescheme of finite presentation of  $X \times X \times X$  having the following property:

```

```text
(*) The three morphisms  $W \rightarrow X \times X$  given by the projections of  $X^3$  onto  $X^2$ 
    are open immersions, schematically dense relatively to  $S$ .
...

```

Notations. We shall use the following terminology. Given sections $a, b, c \in X(S)$, $S' \rightarrow S$ arbitrary, such that $(a, b, c) \in W(S')$, we write:

```

```text
 $c = ab, \quad b = a^{-1}c, \quad a = cb^{-1}.$
...

```

**Definition 3.0.1.** [N.D.E-XVIII-10] We say, given a section  $(a, b) \in X^2(S)$ , that  $ab$  is defined if and only if there exists a section  $c \in X(S)$  such that  $(a, b, c) \in W(S)$ , i.e. if and only if  $(a, b)$  lies in  $\text{pr}_{12} W(S)$ . Similarly, to say that  $a^{-1}b$  or  $ab^{-1}$  is defined has the analogous meaning, and one extends this terminology to products of several factors as well.\*

<!-- label: III.XVIII.3.0.1 -->

**Remark 3.0.2.** Let us note immediately the following fact: by (i),  $W$  defines a rational map  $X^2 \dashrightarrow X$  over  $S$  (the one given by  $(a, b) \mapsto ab$ ). It may well happen that this rational map has a domain of definition larger than  $\text{pr}_{12} W$ . Nevertheless, we say that  $ab$  is defined only if  $(a, b) \in \text{pr}_{12} W(S)$ .\*

<!-- label: III.XVIII.3.0.2 -->

**Definition 3.1.** A group germ is a prescheme  $X/S$  having the properties  $(♦)$  above together with a subprescheme  $W$  of finite presentation of  $X \times X \times X$  having the following properties:\*

<!-- label: III.XVIII.3.1 -->

<!-- original page 640 -->

(i)  $W$  satisfies the property  $(\ast)$  above.\*

(ii) For each section  $a \in X(S)$ , the sets\*

```

```text
 $\text{pr}_i((a \times X \times X) \cap W), \quad i = 2, 3,$ 
 $\text{pr}_i((X \times a \times X) \cap W), \quad i = 3, 1,$ 
 $\text{pr}_i((X \times X \times a) \cap W), \quad i = 1, 2,$ 
...

```

are schematically dense in X relatively to S , and this statement remains true after every base change $S' \rightarrow S$. (Hypothesis (i) implies that these sets are opens of X .) Intuitively, this says that " ax " is defined for x sufficiently general", etc.*

(iii) The law is associative, i.e. if $(a, b, c) \in X^3(S)$, $S' \rightarrow S$ arbitrary, is such that $(ab)c$ and $a(bc)$ are defined, one has $(ab)c = a(bc)$.*

Remarks. (a) In (i), the condition that W be schematically dense in X^2 relatively to S may be replaced by the condition that for each $s \in S$ the fiber W_s be dense in X^2_s in the topological sense, thanks to the hypotheses on X and to 1.2.*

(b) Condition (iii) is equivalent to the following: let $V_{\{1\}}$ (resp. $V_{\{2\}}$) be the open of $X^{\{3\}}$ where the rational map $(a, b, c) \mapsto a(bc)$ (resp. $(a, b, c) \mapsto (ab)c$) is defined [XVIII-3-1]. Then there exists an open $V \subseteq V_{\{1\}} \cap V_{\{2\}}$ which is schematically dense in $X^{\{3\}}$ relatively to S on which the two preceding maps coincide. This is a consequence of 1.4 because, of course, $V_{\{1\}}$ and $V_{\{2\}}$ are schematically dense in $X^{\{3\}}$ relatively to S .

(c) Hypothesis (ii) will serve below to ensure that X will be a subobject of the group prescheme that it defines. In many cases one may deduce (ii) from (i), provided that one replaces X by an open $X^{\{0\}}$ relatively schematically dense, and W by a relatively schematically dense open of $W \cap X^{\{0\}}$. In fact one has:

Proposition 3.2. *Suppose that each geometric fiber of X/S is irreducible, and let W be a subprescheme of $X^{\{3\}}$ satisfying condition (i) of 3.1. Then there exists an open $X^{\{0\}}$ of X relatively schematically dense and an open $W^{\{0\}}$ of $W \cap (X^{\{0\}} \times X^{\{0\}})$ relatively schematically dense such that the pair $(X^{\{0\}}, W^{\{0\}})$ satisfies conditions (i) and (ii). If (iii) is satisfied for (X, W) , it is satisfied for $(X^{\{0\}}, W^{\{0\}})$.*

<!-- label: III.XVIII.3.2 -->

<!-- original page 641 -->

Proof. Set $X^{\{0\}} = \bigcap_{i=1}^3 \text{pr}_i^{-1} W$. Each $\text{pr}_i^{-1} W$ is open in X because $W \rightarrow X^{\{2\}}$ is an open immersion and the projections $X^{\{2\}} \rightarrow X$ are flat and of finite presentation. Moreover, $\text{pr}_i^{-1} W$ is relatively schematically dense in X because W is so in $X^{\{2\}}$ and the projections $X^{\{2\}} \rightarrow X$ are surjective (it suffices to check density in the topological sense). Take $W^{\{0\}} = W \cap X^{\{0\}}$.

To verify that (i) holds, note that

$$W^0 = (W \cap (X^0 \times X^0 \times X)) \cap (W \cap (X \times X^0 \times X^0)) \cap (W \cap (X^0 \times X \times X^0)).$$

Now $W \cap (X^{\{0\}} \times X^{\{0\}} \times X) \subseteq \text{pr}_{12}^{-1} W \cap (X^{\{0\}} \times X^{\{0\}})$, hence is relatively schematically dense in W . Similarly, the other terms of the right-hand side are relatively schematically dense in W , and consequently $W^{\{0\}}$ is relatively schematically dense in W . Hence $\text{pr}_{ij}^{-1} W^{\{0\}}$ is relatively schematically dense in $\text{pr}_{ij}^{-1} W$, hence in $X \times X$, hence in $X^{\{0\}} \times X^{\{0\}}$.

To verify condition (ii), let $a \in X^{\{0\}}(S')$ and write $S_{\{0\}} = S$. We must show that, for example, $\text{pr}_2^{-1}((a \times X^{\{0\}} \times X^{\{0\}}) \cap W^{\{0\}})$ is schematically dense in $X^{\{0\}}$ relatively to S . By 1.3, it suffices to verify this fiber by fiber, that is, it suffices to treat the case where S is the spectrum of a field, and in that case it suffices to verify that the open is non-empty, because the fibers of X/S are irreducible and "without embedded components". Since $\text{pr}_2^{-1}((a \times X \times X) \cap W)$ is non-empty (as a is a section of $X^{\{0\}}$), this open is dense in X . One has

$$\text{pr}_2^{-1}((a \times X \times X) \cap W) = \text{pr}_2^{-1}((a \times X) \cap \text{pr}_{12}^{-1} W).$$

Hence,

$$\text{pr}_2^{-1}((a \times X) \cap \text{pr}_{12}^{-1} W) \cap X^0 = \text{pr}_2^{-1}((a \times X^0) \cap \text{pr}_{12}^{-1} W) = \text{pr}_2^{-1}((a \times X^0 \times X) \cap W)$$

is dense in X , hence in $X^{\{0\}}$.

Similarly, $\text{pr}_3^{-1}((a \times X \times X^{\{0\}}) \cap W)$ is dense in X , hence in $\text{pr}_3^{-1}((a \times X \times X) \cap W)$, i.e. $(a \times X \times X^{\{0\}}) \cap W$ is dense in $(a \times X \times X) \cap W$, i.e. $\text{pr}_2^{-1}((a \times X \times X^{\{0\}}) \cap W)$ is dense in $\text{pr}_2^{-1}((a \times X \times X) \cap W)$, hence dense in X , hence dense in $X^{\{0\}}$.

Now since

$$\begin{aligned} \text{pr}_2^{-1}((a \times X^0 \times X^0) \cap W^0) &= \text{pr}_2^{-1}((a \times X^0 \times X^0) \cap W) \\ &= \text{pr}_2^{-1}((a \times X^0 \times X) \cap W) \cap \text{pr}_2^{-1}((a \times X \times X^0) \cap W), \end{aligned}$$

...

it is indeed dense in $X^{\{0\}}$, as was to be shown. The other assertions of (ii) follow by symmetry, and the fact that condition (iii) is preserved is trivial. [N.D.E-XVIII-11] Proposition 3.2 is proved.

3.2.1.

<!-- label: III.XVIII.3.2.1 -->

[N.D.E-XVIII-12]

<!-- original page 642 -->

Let us now fix a group germ (X, W) over S . We must make some preliminary remarks on the situation, which we have gathered together below. We shall use these rules often without explicit mention in the sequel.

Let $a \in X(S')$, and write $S_{\{0\}} = S$. Then one obtains a (bi)rational map ϕ over S from X to itself by associating to a section x the section $\phi(x)$ if it is defined. By 3.1 (ii), the domain of definition of ϕ contains the relatively schematically dense open $U_{\{2\}}((a \times X \times X) \cap W)$, and ϕ defines an isomorphism of this open onto the open (where $a^{-1}x$ is defined) $U_{\{3\}}((a \times X \times X) \cap W)$. This remark is generalized in the obvious way in Rule 1.

Rule 1. Let $P = P(x, t_1, \dots, t_n)$ be a "product" of the symbols $x, t_1, \dots, t_n$ obtained recursively as follows: $P_{\{0\}} = x$; $P_{\{i+1\}}$ is one of the following expressions:

text
 $P_i t, \quad t P_i, \quad P_i^{-1} t, \quad t P_i^{-1}, \quad P_i t^{-1}, \quad t^{-1} P_i,$

where t is one of the t_j ; $P_{\{r\}} = P$. Let $a_{\{1\}}, \dots, a_{\{n\}} \in X(S')$. Then there exists a relatively schematically dense open U of $X_{\{S'\}}$ such that the product $P(x, a_{\{1\}}, \dots, a_{\{n\}})$ is defined (in the sense of Remark 3.0.2) for a section $x \in X(S')$ if and only if $x \in U(S')$, and the map $x \mapsto P(x, (a))$ gives an isomorphism of U onto another relatively schematically dense open, denoted $P(U, (a))$, of $X_{\{S'\}}$.

Rule 2. Let $a, b \in X(S')$. Then:

If ab is defined, so is $a^{-1}(ab)$, and $a^{-1}(ab) = b$.

If $a^{-1}b$ is defined, so is $a(a^{-1}b)$, and $a(a^{-1}b) = b$.

If ba^{-1} is defined, so is $(ba^{-1})a$, and $(ba^{-1})a = b$.

Rule 3. Let $a, b, b' \in X(S')$. If $ab = ab'$, if $ba = b'a$, if $a^{-1}b = a^{-1}b'$ or if $ba^{-1} = b'a^{-1}$, then $b = b'$. Here it is implicit that the equality relation implies that both sides are defined.

Rule 4. Let $a, b, c \in X(S')$. Then whenever both sides are defined, one has:

text
 $a((ba)^{-1}c) = b^{-1}c.$

<!-- original page 643 -->

Similarly:

text
 $(c(ab)^{-1})a = cb^{-1}, \quad a^{-1}(ab^{-1})c = b^{-1}c, \quad (c(b^{-1}a)^{-1})a = cb^{-1}.$

Rule 5. All the following associativity laws are true, whenever both sides are defined:

text
 $(a^{-1}b)c = a^{-1}(bc), \quad (ab^{-1})c = a(b^{-1}c), \quad (ab)c^{-1} = a(bc^{-1}),$
 $(ab)^{-1}c = b^{-1}(a^{-1}c), \quad (a^{-1}b)c^{-1} = a^{-1}(bc^{-1}), \quad (ab^{-1})c^{-1} = a(cb)^{-1}.$

3.2.2. Verification of the rules.

<!-- label: III.XVIII.3.2.2 -->

(1) is by an obvious induction on the length r of P , the case $r = 1$ being a direct consequence of 3.1 (ii).

(2) Trivial from the definition.

(3) Indeed, by Rule 2, for example in the first case, one has

```
```text
b = a-1(ab) = a-1(ab') = b'.
```
```

(4) Let us verify, for example, the first relation. On the right-hand side left multiplication by b is defined and gives bc , by Rule 2. Suppose it is also defined on the left-hand side. Then one will have

```
```text
b(a((ba)-1 c)) = (ba)((ba)-1 c) = c.
```
```

Indeed $(ba)^{-1}$ is defined by hypothesis because it figures in the expression. Hence the middle member is defined and equal to bc by Rule 2, and equal to the left-hand member by associativity (cf. 3.1 (iii)). Hence Rule 3 implies that the desired equality is true if this multiplication by b is defined.

Now fix a and b . Then Rule 1 implies that $b(a((ba)^{-1} c))$ is well defined for c "in" an open U of X relatively schematically dense; hence on this relatively schematically dense open the two rational maps $c \mapsto b^{-1}c$ and $c \mapsto a((ba)^{-1} c)$ are equal. By 1.4, they are equal on every common domain of definition, whence the desired result.

(5) The same kind of argument as the preceding. For example one verifies $(ab^{-1})c^{-1} = a(cb)^{-1}$ as follows. If right multiplication by c is defined on the right-hand side, one has equality by Rule 4. Since it suffices to verify such a formula on a relatively schematically dense open, one reduces to the case where this multiplication is well defined.

<!-- original page 644 -->

3.2.3.

<!-- label: III.XVIII.3.2.3 -->

Consider now the relation R on $X \times X$ obtained by setting, for $a, b, a', b' \in X(S)$, $(a, b) \sim (a', b') \bmod R(S)$ if and only if there exists $S' \rightarrow S$ fppf-covering and a section $x \in X(S')$ such that $(xa)b^{-1}$ and $(xa')b'^{-1}$ are defined and equal. Then R is an equivalence relation.

Indeed, this relation is evidently symmetric. By Rule 1, the product $(xa)b^{-1}$ is defined if x is "in" a suitable relatively schematically dense open. Hence 1.7 asserts that there exists $S' \rightarrow S$ fppf-covering and an $x \in X(S')$ such that $(xa)b^{-1}$ is defined. The relation is therefore reflexive, and transitivity is a consequence of the following lemma:

Lemma 3.3. Let x, y, a, b, a', b' be sections of $X(S')$ such that $(xa)b^{-1}$, $(xa')b'^{-1}$, $(ya)b^{-1}$, $(ya')b'^{-1}$ are defined. If $(xa)b = (xa')b'$ then $(ya)b = (ya')b'$.

<!-- label: III.XVIII.3.3 -->

Indeed, the lemma says that one may test $(a, b) \sim (a', b')$ with any $x \in X(S')$, $S' \rightarrow S$ fppf-covering, such that both products are defined. Given $a, b, a', b', a'', b'' \in X(S)$, one may, by Rule 1, 1.1 and 1.7, find an fppf-covering extension $S' \rightarrow S$ and a section $x \in X(S')$ such that the three products in question are defined, whence transitivity.

Proof of the lemma. Let us write formally to begin with:

```
```text
(za)b = ((zx-1)x) a b = ((zx-1)(xa)) b = (zx-1)((xa)b),
```
```

$(za')b' = ((zx^{-1})x) a' b' = ((zx^{-1})(xa')) b' = (zx^{-1})((xa')b').$

One verifies that these equalities are indeed true if the members are defined, by the appropriate rules [N.D.E-XVIII-13]. It follows that $(za)b = (za')b'$ if all these expressions are defined. Moreover, by Rule 1 and the hypotheses already made, these expressions are well defined if $z \in X(S')$ is in $V(S')$, where V is a certain open of X relatively schematically dense (we have taken $S_0 = S$). Hence the two rational maps from X to itself given by $z \mapsto (za)b$ and $z \mapsto (za')b'$ are equal, whence $(ya)b = (ya')b'$.

<!-- original page 645 -->

Lemma 3.4. Consider the rational map $\phi : X^3 \dashrightarrow X$ over S defined by $(a, b, c) \mapsto c^{-1}(ab)$. Let U be the domain of definition of ϕ and consider the graph Γ of the morphism $f : U \rightarrow X$ induced by ϕ , which is a subscheme of X^4 . Then a section $(a, b, c, d) \in X^4(S)$ is in $\Gamma(S)$ if and only if $(a, b) \sim (c, d)$.

<!-- label: III.XVIII.3.4 -->

Proof. Note first that the rational map ϕ is the same as the one given by the formula $(a, b, c) \mapsto (xc)^{-1}((xa)b)$ for an arbitrary section $x \in X(S)$. This is the same as saying that one has $xc^{-1}(ab) = (xc)^{-1}((xa)b)$ whenever both sides are defined. We leave the verification to the reader.

We show then that the map ϕ is defined at a section $(a, b, c) \in X^3(S)$ if and only if there exists d with $(a, b) \sim (c, d)$, and that one then has $d = \phi(a, b, c)$. Indeed, suppose that $(a, b) \sim (c, d)$. To verify that ϕ is defined, it is permitted to make an fppf-covering base change (Proposition 1.6), and one may therefore assume that there exists a section $x \in X(S)$ such that $(xa)b$ and $(xc)d$ are defined and equal. It follows (Rule 2) that $(xc)^{-1}((xa)b)$ is defined and equal to d .

Conversely, suppose ϕ is defined at the section (a, b, c) and let $d = \phi(a, b, c)$. Choose $S' \rightarrow S$ fppf-covering and a section $x \in X(S')$ such that $(xa)b$ and $(xc)d$ are defined. We want to show that they are equal. For this, it suffices to show that the two rational maps over S from X to itself, given by $b \mapsto (xa)b$ and $b \mapsto (xc)\phi(a, b, c)$, are the same, which follows from the remark of the first paragraph.

<!-- original page 646 -->

Proposition 3.5. The equivalence relation $R \rightarrow X^2$ is representable, and it is a flat relation of finite presentation, that is, the projections of R onto X^2 are flat morphisms of finite presentation.

<!-- label: III.XVIII.3.5 -->

Proof. We may suppose S affine. Since (X, W) is of finite presentation over S , we may descend the whole situation to an S of finite type over $\text{Spec } \mathbb{Z}$, hence noetherian. We may therefore suppose S noetherian. Then it is trivial that the graph Γ of (3.4) is of finite presentation over X^2 . The projection $\text{pr}_{12} : \Gamma \rightarrow X^2$ is flat because $\Gamma \rightarrow X^2$ is a closed immersion, which is an open of X^3 , and the projection $\text{pr}_{12} : X^3 \rightarrow X^2$ is flat because X is flat over S .

I claim that Γ represents R . Note that there is something to prove, because the domain of definition of a rational map does not in general commute with base change. Let $S' \rightarrow S$. What is clear, by (3.4) applied to S' , is that $R(S') \subset \Gamma(S')$, because $\phi|_{\times_S S'}$ is certainly defined on $U \times_S S'$. Let then $(a, b, c, d) \in R(S')$. We must show that $(a, b, c, d) \in \Gamma(S')$. The verification of this is done locally for, say, the étale topology. We may therefore suppose S' strictly local, i.e. the spectrum of a henselian ring with separably closed residue field. Moreover, by applying (1.6) and the usual passage-to-the-limit standard arguments, we reduce to the case S strictly local and $S' \rightarrow S$ local. Suppose we have a section $x \in X(S)$ such that over S' the products $(xa)b$ and $(xc)d$ are defined. This will imply that $(xc)^{-1}((xa)b)$ is defined, and equal to d . Now there exists an open V of X^3 relatively sch. dense such that $(xc)^{-1}((xa)b)$ is defined if and only if $(a, b, c) \in V$, and one has $V \subset U$. Hence $(a, b, c, d) \in \Gamma(S')$ if such an x exists. By (1.6) it is permitted to make a base change $S' \rightarrow S$ fppf-covering to find such an x . Since S is strictly local, one can [XVIII-3-2] find an $S' \rightarrow S$ faithfully flat, local, and finite and a section $x \in X(S')$ which "passes through" an arbitrary closed point of the closed fiber of X/S . Now to say that $(xa)b$ and $(xc)d$ are defined means that over S' , x lies in a certain relatively sch. dense open, which is verified on the closed fiber of $X_{S'}$. Hence it works.

<!-- original page 647 -->

Let now G be the quotient of X^2 by R as a sheaf for the fppf topology. We shall define a composition law on G

as follows. Let $(g, g') \in G(S')$ be represented by a section $((a, b), (c, d))$ of $X^2 \times X^2(S')$, $S' \rightarrow S$ fppf-covering. Suppose moreover that X admits a section x over S' such that $a(b(cx))$ and $x^{-1}d$ are defined, which is permitted by Rule 1 and (1.7), and we call gg' the class in $G(S')$ represented by the section $(a(b(cx)), x^{-1}d)$ of $X^2(S')$.

Let us verify that gg' does not depend on the choice of the section x and the representative $((a, b), (c, d))$. Indeed, let $(a', b') \sim (a, b)$, $(c', d') \sim (c, d)$, and x' be such that $a'(b'(c'x'))$ and $x'^{-1}d'$ are defined. We may suppose that all are sections over S' . We must show that

$$(a(b(cx)), x^{-1}d) \sim (a'(b'(c'x')), x'^{-1}d'),$$

that is, that for a suitable section $z \in X(S')$, $S' \rightarrow S$ suitably fppf-covering,

$$(z(a(b(cx))))(x^{-1}d) = (z(a'(b'(c'x'))))(x'^{-1}d').$$

Whenever all the products are defined, one has

$$\begin{aligned} (z(a(b(cx))))(x^{-1}d) &= ((za)(b(cx)))(x^{-1}d) = \\ &= (((za)b)(cx))(x^{-1}d) = (((za)b)c)x)(x^{-1}d) = \\ &= (((za)b)c)(x(x^{-1}d)) = ((za)b)c)d, \end{aligned}$$

and the same identities are true with the primes. Now by Rule 1 and (1.7) there exists such a z . One must therefore show that

$$(((za)b)c)d = (((za')b')c')d'.$$

But $(za)b = (za')b'$ because $(a, b) \sim (a', b')$ (3.3) and one has the desired equality because $(c, d) \sim (c', d')$.

<!-- original page 648 -->

Consider the natural morphism $i : X \rightarrow G$ defined as follows. For $a \in X(S')$, one chooses $S' \rightarrow S$ fppf-covering and a section $b \in X(S')$ such that ab^{-1} is defined, and one sets

$$i(a) = \text{class in } G \text{ of } (ab^{-1}, b).$$

One easily verifies that this class, which is a priori in $G(S')$, does not depend on the choice of b and so gives a well-determined element of $G(S)$.

The reader will give himself the pleasure of verifying the following:

Proposition 3.6. *The morphism i commutes with the composition laws of X and of G , i.e. if $a, b \in X(S)$ are sections such that ab is defined, one has $i(a)i(b) = i(ab)$.*

<!-- label: III.XVIII.3.6 -->

The goal of this section is the following theorem:

Theorem 3.7. [N.D.E.-XVIII-14] *Let (X, W) be a group germ over S , with X/S faithfully flat, of finite presentation, and with separated fibers without embedded component. Then with the notations above one has*

<!-- label: III.XVIII.3.7 -->

(i) G is a sheaf of groups.*

(ii) $\mathcal{G} : X \rightarrow G$ is representable by an open immersion.

(iii) G is representable locally on S for the fppf topology.

(iv) If G/S is representable, then it is a flat group of finite presentation, and $\mathcal{G} : X \rightarrow G$ is schematically dense relatively to S .

Note that G is evidently characterized by properties (i), ..., (iv); one may therefore forget the explicit construction of G .

The proof proceeds in several stages:

Lemma 3.8. (i) Let $\mathcal{C}$ be a section of $X(S)$; then the morphism from the prescheme $\mathcal{C} \times X$ (which is S -isomorphic to X) into G given by $\mathcal{C} \times X \rightarrow X \rightarrow G$ is a monomorphism.*

<!-- label: III.XVIII.3.8 -->

<!-- original page 649 -->

(ii) Let $\mathcal{C}_i, \mathcal{C}_j \in I$, be sections of $X(S)$, let $Z = \bigsqcup_i \mathcal{C}_i \times X$, and call $R^0 \rightarrow Z$ the equivalence relation induced on Z by the obvious morphism $Z \rightarrow X^2$. Then R^0 is a "gluing" of the $\mathcal{C}_i \times X \rightarrow X$.*

Proof.

(i) For two sections $(\mathcal{C}, a)$ and $(\mathcal{C}, a')$ of $(\mathcal{C} \times X)(S)$ to have the same image in G , one must have $(\mathcal{C}, a) \sim (\mathcal{C}, a')$, that is, $(\mathcal{C}a) \sim (\mathcal{C}a')$ for a suitable $x \in X(S')$, $S' \rightarrow S$ fppf-covering, whence $a = a'$ by Rule 3.

(ii) Let $\mathcal{C}_i, \mathcal{C}_j$ be two sections and consider the birational map ψ_j of X to itself over S given by the formula $x \mapsto \mathcal{C}_j^{-1}(\mathcal{C}_i x)$. This is the same map as the one given by $x \mapsto (\mathcal{C}_j^{-1})(\mathcal{C}_i x)$, for $y \in X(S)$, as one easily sees. Moreover, one verifies that ψ_j is defined at $\mathcal{C}_j \in I$ if and only if there exists $\mathcal{C}_i$ such that $(\mathcal{C}_i, \mathcal{C}_j) \sim (\mathcal{C}_j, \mathcal{C}_i)$, and then $\mathcal{C}_i = \psi_j(\mathcal{C}_j)$. Let U_j be the domain of definition over S of ψ_j . It remains to show that this domain of definition is universal, i.e. that if $\mathcal{C}_i \in I$, $S' \rightarrow S$ arbitrary, and if ψ_j is defined at $\mathcal{C}_i$, then $\mathcal{C}_i \in U_j(S')$. It comes to the same to show that if $\mathcal{C}_i, \mathcal{C}_j \in I$ are such that $(\mathcal{C}_i, \mathcal{C}_j) \sim (\mathcal{C}_j, \mathcal{C}_i)$, then $\mathcal{C}_i \in U_j(S')$. We leave the verification of this fact, which is analogous to that of (3.5), to the reader.

Lemma 3.9. Suppose that $\mathcal{C}_i \in I$, are sections of $X(S)$ such that $\bigsqcup_i \mathcal{C}_i \times X \rightarrow G$ is surjective as a morphism of sheaves. Then G is representable and flat, of finite presentation over S , and the structural morphism $X^2 \rightarrow G$ is flat and of finite presentation.*

<!-- label: III.XVIII.3.9 -->

Proof. The fact that G is representable is an immediate consequence of (3.8), and it follows that $\bigsqcup_i \mathcal{C}_i \times X \rightarrow G$ is an open covering. To show that $X^2 \rightarrow G$ is flat, it suffices to do so locally, hence to show that the rational map $X^2 \dashrightarrow \bigsqcup_i \mathcal{C}_i \times X$ induces a flat morphism on its domain of definition. Now this rational map is given by $(a, b) \mapsto (\mathcal{C}_i, ((\mathcal{C}_i^{-1})(a))b)$, x an arbitrary section, and if it is defined at $(a, b) \in X^2(S')$, one can find $S' \rightarrow S$ fppf-covering and a section $x \in X(S')$ such that $((\mathcal{C}_i^{-1})(a))b$ is defined. One sees easily that this is therefore a flat morphism.

<!-- original page 650 -->

It similarly follows that it is locally of finite presentation, hence fppf-covering. Now by construction, the relation R is effective. Hence by (3.5), the morphism $X^2 \rightarrow G$ becomes of finite presentation after the base change $G \leftarrow X^2$, which is fppf-covering; hence $X^2 \rightarrow G$ is of finite presentation. Let us show that $G \rightarrow S$ is flat and of finite presentation. It is flat and locally of finite presentation since G is covered by the $\mathcal{C}_i \times X \rightarrow X$. Now X^2/S is quasi-compact, and $X^2 \rightarrow G$ is surjective. This shows that G/S is quasi-compact. To show that $G \rightarrow S$ is quasi-separated, note that one has the following cartesian diagram

```text

$$\begin{array}{ccc} R & \xrightarrow{\alpha} & X^2 \times_S X^2 \\ | & & \downarrow \\ & & T \end{array}$$

$$\begin{array}{ccc} \gamma & & \beta \\ \downarrow & & \downarrow \\ G & \xrightarrow{\Delta} & G \times_S G. \end{array}$$

One has  $\gamma$  surjective and  $\alpha, \beta$  quasi-compact, hence  $\beta \circ \alpha$  is quasi-compact, hence  $\Delta$  is quasi-compact. [N.D.E-XVIII-15]

**Lemma 3.10.** Let  $\{c_i\}$ ,  $i \in I$ , be sections of  $X(S)$ . For  $\sqcup_i c_i \times X \rightarrow G$  to be surjective as a morphism of fppf-sheaves, it suffices that the following condition be satisfied:

!-- label: III.XVIII.3.10 -->

For each  $S' \rightarrow S$  and  $(a, b) \in X^2(S')$ , there exist an open covering  $\{S'_{\nu}\}$ ,  $\nu \in N$ , of  $S'$  and a function  $N \rightarrow I$  ( $\nu \mapsto i(\nu)$ ) such that  $(c_{i(\nu)}^{-1}(a)b)$  is defined on  $S'_{\nu}$ .

**Proof.** Let  $S' \rightarrow S$  be arbitrary, and  $g \in G(S')$ . Choose  $S' \rightarrow S'$  fppf-covering and a section  $(a, b) \in X^2(S')$  representing  $g$ . Take the open covering  $\{S'_{\nu}\}$  of  $S'$  that exists by the hypothesis of the lemma. Then on each  $S'_{\nu}$  one has  $(a, b) \sim (c_{i(\nu)}^{-1}(a)b)$ , hence  $g$  is represented by a section of  $\{c_{i(\nu)}\} \times X(S')$  on  $S'_{\nu}$ , which proves surjectivity, because the family of morphisms  $\{S'_{\nu} \rightarrow S'\}$  is fppf-covering.

**Lemma 3.11.** Let  $Y/S$  be a prescheme of finite presentation, and let  $\{a_i\}$ ,  $i \in I$ , be sections of  $Y(S)$ . Let  $s_0, s_1$  be points of  $S$  such that  $s_0$  is a specialization of  $s_1$ , and  $Y_j$  the fiber of  $Y/S$  at the point  $s_j$ . Let  $C_j$  be the closure in  $Y_j$  of the set of points  $\{a_i(s) \cap Y_j\}$ . Then one has  $\dim C_1 \geq \dim C_0$ .

!-- label: III.XVIII.3.11 -->

!-- original page 651 -->

**Proof.** It suffices to make the verification after a base change  $S' \rightarrow S$  with chosen points  $s'_0$  and  $s'_1$  such that  $s'_j \mapsto s_j$  and  $s'_0$  is a specialization of  $s'_1$ . One is

!-- original page 386 (continuing) -->

therefore (EGA II 7.1.4) reduced to the case where  $S$  is the spectrum of a valuation ring  $A$ ,  $s_0$  the closed point of  $S$ , and  $s_1$  the generic point of  $S$ . Now let  $V$  be the closure of  $C_1$  in  $Y$ . It is clear that  $C_0 \subseteq V$ , and so the lemma is a consequence of the "well-known" fact that an irreducible closed subscheme  $V$  of a prescheme  $Y/S$  of finite presentation satisfies  $\dim V \geq \dim V|_{s_1} \geq \dim V|_{s_0}$  if  $S$  is the spectrum of a valuation ring and if  $V|_{s_1} \neq \emptyset$  (EGA IV 13.1.6).

**Lemma 3.12.** Suppose that  $S$  is the spectrum of a local ring with closed point  $s_0$ , and let  $\{c_i\}$ ,  $i \in I$ , be sections such that the closure  $C_0$  of the set  $\{c_i(s) \cap X_0\}$  in the closed fiber  $X_0$  is of dimension equal to  $\dim X_0 = n$ . Then the condition of Lemma 3.9 is satisfied.

!-- label: III.XVIII.3.12 -->

**Proof.** Note first that the fibers of  $X/S$  all have the same dimension  $n$ , which results from EGA IV 12.1.1 (i) and from the fact that  $X$  has a rational composition law. Lemma (3.11) therefore implies that for each morphism  $S_1 \rightarrow S$  with  $S_1$  the spectrum of a field, the dimension of the closure of the set  $\{c_i\} \times_{S_1} S_1$  in  $X_{S_1}$  is equal to  $n$ . Let us verify the condition of (3.10). Let  $(a, b) \in X^2(S')$ . For  $(c_{i(\nu)}^{-1}(a)b)$  to be defined, it is necessary and sufficient that  $c_{i(\nu)}$  be contained in a certain open  $U \subseteq X_{S'}$  which is sch. dense relatively to  $S'$  (Rule 1). We must show that this is true for a suitable  $i$ , locally on  $S'$ . It therefore suffices to treat the case where  $S$  is the spectrum of a local ring, and then the fact that  $c_i \in U(S)$  is verified on the closed fiber. We are thus reduced to the case  $S' = \operatorname{Spec} k$ ,  $k$  a field. Now with the notations above, take  $S' = S_1$ .

!-- original page 652 -->

One has  $\dim C_1 = \dim X_{S_1}$ , and  $U$  is relatively sch. dense in  $X_{S_1}$ . Hence  $U \cap C_1 \neq \emptyset$ , whence  $U \cap \{c_p\} \times_{S_1} S_1 \neq \emptyset$ , and we are done.

The proof of the theorem is now easy. Note first the following consequence of the finiteness of Lemma (3.9): if  $\{A_i\}$  is an inductive system of rings over  $S$ , if  $\tilde{A} = \varinjlim A_i$ , and if the hypotheses of (3.9) are

satisfied for  $S = \operatorname{Spec} \tilde{A}$ , then one may descend the object that represents the quotient  $G$  of  $R \rightarrow X^2$  to one of  $S_i = \operatorname{Spec} A_i$  with the finiteness and flatness properties stated in (3.9). This is the usual passage to the limit (EGA IV 8 and 11). It follows that for the proof of (iii) and (iv) of (3.7), one may restrict to the case  $S = \operatorname{Spec} A$ , with  $A$  a strictly local ring. Let then  $x_0$  be a closed point of the closed fiber  $X_0$  of  $X/S$ . There exists<sup>[XVIII-3-3]</sup> an extension  $A'$  of  $A$ , local, free and finite, and a section of  $X' = X \times_S S'$  passing through the unique point  $x'_0$  of  $X'$  above  $x_0$ . Note that  $X'_0 \rightarrow X_0$  is radical since  $S$  is strictly local, hence the residue field of  $A$  separably closed. It follows that there exists an inductive system  $\{A_i\}$  of local rings, flat and finite over  $S$ , such that, setting  $\tilde{A} = \varinjlim A_i$  and  $\tilde{X} = X \times_S \operatorname{Spec} \tilde{A}$ ,  $\tilde{X}$  has a set of sections which induces a dense set on the closed fiber  $\tilde{X}_0$ . For each closed point  $x_0$  of  $X_0$  one takes an extension  $A(x_0)$  such that the corresponding base change of  $X$  admits a section "passing through  $x_0$ ", and one takes as inductive system the system of finite tensor products of the  $A(x_0)$ . Note that  $\tilde{A}$  is local, being a limit of local rings. Hence by (3.12) and (3.10) one has the quotient  $G$

<!-- original page 653 -->

over  $\operatorname{Spec} \tilde{A}$ , hence over one of  $\operatorname{Spec} A_i$  by the remarks above, hence locally for the fppf topology.

In fact it follows from the constructions that locally for the fppf topology one can find a finite set of sections  $\{c_i\}$  ( $i = 1, \dots, r$ ) such that  $G$  is covered by the  $c_i \times X$ . (ii) and (iv) follow easily from this fact, and we leave the verification of (i) to the reader.

**\*Corollary 3.13.\*** The sheaf of groups  $G$  determined by a group germ  $(X, W)$  over  $S$  is representable in each of the following situations:

<!-- label: III.XVIII.3.13 -->

(i)  $S$  is artinian.

(ii) For each local scheme  $S'$  to  $S$  at a closed point  $s$  of  $S$ ,  $X_{S'}$  has a set of sections that induces on the closed fiber a set whose closure is of dimension  $\dim X_s$ .

(iii)  $S$  is strictly local, and  $X/S$  is smooth.

(iv) There exists  $S' \rightarrow S$  fppf-covering such that  $G_{S'}$  is representable and affine over  $S$ .

Indeed, (ii) is a consequence of (3.10) and (3.12), (iii) follows directly from (ii) and "Hensel's lemma", (iv) from the descent of affine schemes, and (i) from the descent of group schemes, which is possible here because one knows that every finite subset of a group over a field is contained in an affine open (Exp. VI).

# Exposé XIX. Reductive groups: generalities

<!-- label: III.XIX -->

\*by M. Demazure\*

<!-- original page 1 -->

[^N.D.E-XIX-0] The remainder of this Séminaire is devoted to the study of reductive groups. Its principal aim is the generalization of Chevalley's classical results (\*Bible\* and \*Tôhoku\*)[^N.D.E-XIX-1] to arbitrary base schemes, the two central results being the uniqueness theorem (Exp. XXIII, Th. 4.1 and Cor. 5.1 to 5.10) and the existence theorem (Exp. XXV, Th. 1.1) for "pinned" reductive group schemes corresponding to prescribed "root data". The proofs employed are inspired by Chevalley's, the technique of schemes permitting one to lend them increased efficiency.

The results of the first volume of the \*Bible\* (Exp. 1 to 13) will be used systematically. By contrast, we shall prove directly over an arbitrary scheme the results of the second volume (in particular the isomorphism theorem); a knowledge of the proofs over an algebraically closed field is therefore not absolutely indispensable.

In the proof of these two fundamental results, we shall use only the most elementary results from the theory of groups of multiplicative type, contained essentially in Exp. VIII and IX; we shall, on the other hand, make essential use of the results of Exposé XVIII.[^N.D.E-XIX-2] The reader specifically interested in the existence and uniqueness theorems may, on a first reading, skip Exposés X to XVII.

## 1. Reminders on groups over an algebraically closed field

<!-- label: III.XIX.1 -->

<!-- original page 2 -->

**\*\*1.1.\*\*** In this number,  $k$  will always denote an algebraically closed field. As announced above, the only results from \*Bible\* used in what follows are found in volume 1 (Exposés 1 to 13). All the results of \*Bible\* (\*loc. cit.\*) concerning semisimple groups are valid more generally for reductive groups (definition below) and their proof is identical, with the following innocuous modifications:

- Exp. 9, § 4, Definition 3: see 1.6.1 below.
- Exp. 12, § 4, Theorem 2, e): suppress "finite".
- Exp. 13, § 3, Theorem 2: replace "rank" by "semisimple rank".
- Exp. 13, § 4, Corollary 2 to Theorem 3: replace "rank" by "reductive rank".

**\*\*1.2.\*\*** Let  $G$  be a smooth affine connected  $k$ -group. The \*radical\* of  $G$  (\*Bible\*, § 9.4, Prop. 2)[^N.D.E-XIX-3] is the reduced subgroup associated with the neutral component of the intersection of the Borel subgroups of  $G$ ; it is also the largest smooth connected solvable invariant subgroup of  $G$ ; we shall denote it  $\text{rad}(G)$ .

The \*unipotent radical\* of  $G$  is the unipotent part of the radical of  $G$ ; it is also the largest smooth connected unipotent invariant subgroup of  $G$ ; we shall denote it  $\text{rad}_u(G)$ .

**\*\*1.3.\*\*** Let  $G$  be a smooth affine connected  $k$ -group, and  $Q$  a torus of  $G$ . Then the centralizer  $\text{Centr}_G(Q)$  of  $Q$  in  $G$  is a closed subgroup of  $G$  (Exp. VIII, 6.7), smooth (Exp. XI, 2.4), and connected (cf. \*Bible\*, § 6.6, Th. 6 a) or [Ch05], § 6.7, Th. 7 a)).

<!-- original page 3 -->

One has the fundamental relation:

```text  
 $\text{rad}_u(\text{Centr}_G(Q)) = \text{rad}_u(G) \cap \text{Centr}_G(Q).$

<!-- label: eq:III.XIX.1.3.1 -->

First,[^N.D.E-XIX-4] $U = \text{rad}_u(G) \cap \text{Centr}_G(Q)$ is an invariant unipotent subgroup of $\text{Centr}_G(Q)$; let us show that it is smooth and connected. If we make Q operate on $\text{rad}_u(G)$ by inner automorphisms, U is none other

than the scheme of invariants of this operation. But this scheme is smooth and connected, by Lemma 1.4 below.

Consequently, U is a closed subgroup of $\text{rad}_u(\text{Centr}_G(Q))$. On the other hand, by *Bible*, Exp. 12, § 3, Cor. to Th. 1, one has $\text{rad}_u(\text{Centr}_G(Q))(k) \subset \text{rad}_u(G)(k)$. The equality (1.3.1) follows.

Let us signal a particular case of the foregoing result: if G is a smooth affine connected k -group and if T is a maximal torus of G , then

```
```text
Centr_G(T) = T · (Centr_G(T) ∩ rad_u(G)).
```
```

<!-- label: eq:III.XIX.1.3.2 -->

Indeed (cf. *Bible*, § 6.6, Th. 6 c) or [Ch05], § 6.7, Th. 7 c)), $\text{Centr}_G(T)$ is a solvable group, hence the semi-direct product of its maximal torus T and its unipotent radical.

<!-- original page 4 -->

By the density theorem (cf. *Bible*, § 6.5, Th. 5 a) or [Ch05], § 6.6, Th. 6 a)), the union of the $\text{Centr}_G(T)$, as T runs through the set of maximal tori of G , contains a dense open subset of G ; it therefore follows from (1.3.2):

Corollary 1.3.3. *If G is a smooth affine connected k -group, then the union of the $T \cdot \text{rad}_u(G)$, where T runs through the set of maximal tori of G , contains a dense open subset of G .*

<!-- label: III.XIX.1.3.3 -->

Notations 1.4.0. [N.D.E-XIX-5] *We shall systematically use the following notation: if S is a scheme and s a point of S , we denote by $\bar{s}$ the spectrum of an algebraic closure $\kappa_{\bar{s}}$ of $\kappa(s)$.*

<!-- label: III.XIX.1.4.0 -->

Lemma 1.4. [N.D.E-XIX-5] *Let S be a scheme, Q an S -torus operating on an S -group scheme H , separated and smooth over S .*

(i) The functor of invariants H^Q is representable by a closed subscheme of H , smooth over S .

(ii) If moreover H is affine over S , and has connected fibers, then H^Q does too.

<!-- label: III.XIX.1.4 -->

Proof. First, by VIII 6.5 (d), [N.D.E-XIX-6] since H is separated over S and Q essentially free over S , H^Q is representable by a closed subscheme of H . In particular, if H is affine over S , then so is H^Q .

Consider now the semi-direct product $G = H \cdot Q$; it is smooth and separated over S . Then, the centralizer $\text{Centr}_G(Q)$ is representable by a closed subscheme of G , of finite presentation over G , by Exp. XI 6.11 (a), [N.D.E-XIX-6] and it is smooth over S by Exp. XI 2.4.

Since $\text{Centr}_G(Q) = H^Q \cdot Q$, it follows that H^Q is smooth over S . (Indeed, using the section $\sigma : H^Q \rightarrow \text{Centr}_G(Q)$ deduced from the unit section ϵ_Q of Q , one sees at once that H^Q is formally smooth over S ; and since moreover ϵ_Q is of finite presentation, H^Q is locally of finite presentation over S .) This proves (i).

Finally, suppose H affine over S and with connected fibers. Then each geometric fiber $G_{\bar{s}}$ of G is a smooth affine connected $\kappa_{\bar{s}}$ -group, hence, by the first assertion of 1.3, so is

```
```text
Centr_{G_{s^-}}(Q_{s^-}) = (\text{Centr}_G(Q))_{s^-} = (H^Q)_{s^-} · Q_{s^-},
```
```

and this entails that $(H^Q)_{\bar{s}}$ is connected.

1.5. We recall that the *reductive rank* of the smooth affine k -group G is the common dimension of the maximal tori of G . We shall denote it $\text{rgred}(G/k)$ or $\text{rgred}(G)$. In order that $\text{rgred}(G/k) = 0$, it is necessary and sufficient that G be unipotent (i.e. that $G = \text{rad}_u(G)$), by *Bible*, § 6.4, Cor. 1 to Th. 4 or [Ch05], § 6.5, Cor.

1 to Th. 5.

If H is an invariant subgroup of the smooth affine k -group G , then the quotient G/H is affine and smooth (Exp. VI_B, 11.17 and VI_A, 3.3.2 (iii)). Moreover (*Bible*, § 7.3, Th. 3, a) and c)), one has

```
```text
rgred(G) = rgred(G/H) + rgred(H).
```

<!-- original page 4 (cont.) -->

**Definition 1.6.1.** [N.D.E-XIX-7] One says that the  $k$ -group  $G$  is reductive if it is smooth, affine, and connected, and if  $\text{rad}(G)$  is a torus, i.e. if  $\text{rad}_u(G) = \{e\}$ .

<!-- label: III.XIX.1.6.1 -->

**Lemma 1.6.2.** Let  $G$  be a reductive  $k$ -group.

(i) If  $Q$  is a torus of  $G$ , then  $\text{Centr}_G(Q)$  is reductive.

(ii) In particular, if  $T$  is a maximal torus of  $G$ , then  $\text{Centr}_G(T) = T$ .

(iii) The center of  $G$  is contained in every maximal torus, hence is diagonalizable.

(iv) The radical of  $G$  is the (unique) maximal torus of  $\text{Centr}(G)$ .

<!-- label: III.XIX.1.6.2 -->

**Proof.** Indeed, (i) follows from (1.3.1), (ii) from (1.3.2), and (iii) follows from (ii). Finally, the maximal torus of  $\text{Centr}(G)$  (i.e. the neutral component  $\text{Centr}(G)^{\{0\}}$ ) is a smooth connected solvable subgroup, invariant in  $G$ , hence contained in  $\text{rad}(G)$ ; conversely,  $\text{rad}(G)$  is an invariant torus in  $G$ , hence central (\*Bible\*, § 4.3, Cor. to Prop. 2), whence (iv).

<!-- original page 5 -->

**Remark 1.6.3.** If  $G$  is reductive and if  $\dim(G) \neq \text{rgred}(G)$ , then  $\dim(G) - \text{rgred}(G) \geq 2$ . Indeed, this difference is always even (cf. 1.10 below).

<!-- label: III.XIX.1.6.3 -->

**1.7.** Let  $G$  be a smooth affine connected  $k$ -group and  $H$  a smooth connected invariant subgroup. Then

```
```text
rad(H) = (rad(G) \cap H)^{\circ}_{\text{red}} \quad \text{and} \quad \text{rad}_u(H) = (\text{rad}_u(G) \cap H)^{\circ}_{\text{red}},
```

<!-- label: eq:III.XIX.1.7.1 -->

as one sees at once. In particular, if G is reductive, so is H .

Let $f : G \rightarrow G'$ be a surjective morphism of smooth affine connected k -groups. Then

```
$$
f(\text{rad}_u(G)) = \text{rad}_u(G').
$$
```

<!-- label: eq:III.XIX.1.7.2 -->

In particular, if G is reductive, so is G' .

Let us prove (1.7.2). First, f sends $\text{rad}_u(G)$ into $\text{rad}_u(G')$. Introducing $H = (f^{-1}(\text{rad}_u(G')))^{\{0\}_{\text{red}}}$, which contains $\text{rad}_u(G)$, one has $\text{rad}_u(H) = \text{rad}_u(G)$ and one is reduced to the case where $G = H$, i.e. where G' is unipotent. Since the union of the $T \cdot \text{rad}_u(G)$ (as T runs through the set of maximal tori of G) is dense in G , the union of the $f(T) \cdot f(\text{rad}_u(G))$ is dense in G' ; but $f(T)$ consists of semisimple elements, so $f(T) = \{e\}$, G' being unipotent; this shows that $f(\text{rad}_u(G))$ is dense

in G' . Therefore, by *Bible*, § 5.4, Lemma 4 or [Ch05], § 6.1, Lemma 1, [N.D.E-XIX-8] $\text{f}(\text{rad}_{\{u\}}(G))$ is an open subgroup of G' ; the latter being connected, it follows that $\text{f}(\text{rad}_{\{u\}}(G)) = G'$. (N.B.: one can prove under the same hypotheses that $\text{f}(\text{rad}(G)) = \text{rad}(G')$.)

****1.8.**** One says that the k -group G is *semisimple* if it is smooth, affine, and connected and if $\text{rad}(G) = \{e\}$, i.e. if G is reductive and $\text{Centr}(G)$ is finite. If G is an arbitrary smooth affine connected k -group, then $G / \text{rad}(G)$ is semisimple (*Bible*, § 9.4, Prop. 2), and $G / \text{rad}_{\{u\}}(G)$ is reductive. One calls the *semisimple rank* of G and denotes by $\text{rgss}(G/k)$ or $\text{rgss}(G)$ the reductive rank of $G / \text{rad}(G)$.

If G is reductive, one therefore has

<!-- original page 6 -->

```
```text
rgred(G) = rgss(G) + dim(rad(G)).
```
```

If G is a smooth affine connected k -group and if Q is a central subtorus of G , then G/Q is semisimple if and only if G is reductive and $Q = \text{rad}(G)$. Indeed, if G/Q is semisimple, $Q \subset \text{rad}(G)$, so $\text{rad}(G)$ is a torus, so G is reductive, so $\text{rad}(G)$ is the maximal torus of $\text{Centr}(G)$, so $\text{rad}(G) = Q$. If G is reductive and if Q is a central subgroup then (G/Q is reductive and) $\text{rgss}(G) = \text{rgss}(G/Q)$.

****1.9.**** If K is an algebraically closed extension of k and if G is a smooth affine connected k -group, then G is reductive (resp. semisimple) if and only if G_K is, and one has

```
$$
rgred(G/k) = rgred(G_K/K),
rgss(G/k) = rgss(G_K/K).
$$
```

****1.10.**** Let G be a smooth connected k -group and let T be a torus of G . [N.D.E-XIX-9] Denote by $\mathfrak{g}$ the k -Lie algebra of G , i.e. $\mathfrak{g} = \text{Lie}(G) = \text{Lie}(G/k)(k)$; likewise denote $\mathfrak{t} = \text{Lie}(T)$. Then $\mathfrak{g}$ decomposes under the action of T (via $T \curvearrowright G$ and the adjoint operation of G) as

```
```text
g = g_0 \oplus \bigoplus_{\alpha \in R} g_{-\alpha},
```
```

<!-- label: eq:III.XIX.1.10.1 -->

where the $\alpha \in R$ are non-trivial characters of T and the $g_{-\alpha}$ are $\neq 0$. The characters $\alpha \in R$ are called the *roots* of G with respect to T . By Exp. II, 5.2.3 (i), one has

<!-- original page 7 -->

```
$$
g_{\{0\}} = \text{Lie}(\text{Centr}_{\{G\}}(T)).
$$
```

<!-- label: eq:III.XIX.1.10.2 -->

In particular, [N.D.E-XIX-10] since $\text{Centr}_{\{G\}}(T)$ is connected (1.3 in the case where G is affine, and Exp. XII 6.6 b) in the general case), T is its own centralizer if and only if $g_{\{0\}} = \text{Lie}(T)$.

This condition entails that T is maximal and that $\text{Centr}(G) \subset T$, hence by Exp. XII 8.8 d) one has:

```
```text
Centr(G) = Ker(T \rightarrow GL(g)) = \bigcap_{\alpha \in R} Ker(\alpha);
```
```

<!-- label: eq:III.XIX.1.10.3 -->

moreover $\text{Centr}(G)$ is then affine, hence $G \curvearrowright G/\text{Centr}(G)$ is affine; since the latter group is affine (Exp. XII 6.1), [N.D.E-XIX-11] so is G .

When G is reductive and T maximal, the roots in the preceding sense coincide with the roots in the sense of *Bible*, § 12.2, Def. 1; the latter are indeed roots in the sense of this number (*Bible*, § 13.2, Th. 1, c)) and there are $\dim(G) - \dim(T)$ of them (*Bible*, § 13.4, Cor. 2 to Th. 3). Moreover, if α is a root, so is $-\alpha$ (*Bible*, § 12.2, Cor. to Prop. 1). (As usual, one writes the group structure of $\operatorname{Hom}_{\{k\text{-gr.}\}}(T, G_{\{m,k\}})$ indifferently additively or multiplicatively.) It follows that, for G reductive,

<!-- original page 8 -->

```
```text
dim(G) - rgred(G) = Card(R)
```
```

<!-- label: eq:III.XIX.1.10.4 -->

is always even.

The semisimple rank of the reductive group G is the rank of the subset R of the Q -vector space $\operatorname{Hom}_{\{k\text{-gr.}\}}(T, G_{\{m,k\}}) \otimes Q$ (*Bible*, § 13.3, Th. 2).

Lemma 1.11. Let k be an algebraically closed field, G a smooth affine connected k -group, T a torus of G , $W(T) = \operatorname{Norm}_G(T) / \operatorname{Centr}_G(T)$ the Weyl group of G with respect to T . The following conditions are equivalent:*

(i) G is reductive, T is maximal, $\operatorname{rgss}(G) = 1$.*

(ii) G is reductive, T is maximal, $G \not\supset T$; there exists a subtorus Q of T , of codimension 1 in T , central in G .*

(iii) G is not solvable and $\dim(G) - \dim(T) \leq 2$.*

(iv) $W(T) \not\supset e$ and $\dim(G) - \dim(T) \leq 2$.*

(v) $W(T) = (Z/ZZ)_k$ and $\dim(G) - \dim(T) = 2$.*

Moreover, under these conditions, there are exactly two roots of G with respect to T ; they are opposite. Under the conditions of (ii), $Q = \operatorname{rad}(G)$.*

<!-- label: III.XIX.1.11 -->

Proof. One has obviously (v) $\Rightarrow$ (iv). One has (iv) $\Rightarrow$ (iii) by *Bible*, § 6.1, Cor. 3 to Th. 1 or [Ch05], § 6.2, Cor. 3 to Th. 2. Let us prove (iii) $\Rightarrow$ (ii): let U be the unipotent radical of G ; one knows that G/U is reductive and is not a torus (otherwise G would be solvable); one therefore has, by (1.10.4),

```
```text
dim(G/U) - rgred(G/U) = Card(R) - 2;
```
```

but

```
```text
rgred(G) = rgred(G/U) + rgred(U) = rgred(G/U),
```
```

whence

```
```text
dim(G) - dim(U) - rgred(G) = dim(G/U) - rgred(G/U)
 = 2 = dim(G) - dim(T) = dim(G) - rgred(G).
```
```

This gives $\dim(U) = 0$, hence G is reductive, $\operatorname{rgred}(G) = \dim(T)$, hence T is maximal, $\dim(G) - \dim(T) = 2$. By *Bible*, § 10.4, Prop. 8, there exists a singular torus Q of codimension 1 in T ; then $\operatorname{Centr}_G(Q)$ is reductive (1.6.2 (i)), non-solvable (definition of a singular torus), hence $\dim(\operatorname{Centr}_G(Q)) - \operatorname{rgred}(G) \geq 2$, which proves that $G = \operatorname{Centr}_G(Q)$ and Q is central in G .

Let us prove (ii) $\Rightarrow$ (i). One knows that G/Q is reductive (1.7) and that $\text{rgred}(G/Q) = 1$, hence $\text{rgss}(G/Q) = 0$ or 1 . The first case is impossible, for it would entail $\text{rgss}(G) = 0$, hence $G = T$;

<!-- original page 9 -->

one therefore has $\text{rgred}(G/Q) = \text{rgss}(G/Q) = 1$, which proves that G/Q is semisimple; hence Q is the radical of G and $\text{rgss}(G) = 1$.

Let us finally prove (i) $\Rightarrow$ (v). If Q is the radical of G , one has $\dim(T) - \dim(Q) = 1$ and Q is central in G , hence $G = \text{Centr}_{\{G\}}(Q)$, which proves that Q is a singular torus; by *Bible*, § 11.3, Th. 2, one has $W_{\{G\}}(T) = (Z/2Z)_{\{k\}}$; by *Bible*, § 12.1, Lemma 1, one has $\dim(G) - \dim(T) = 2$. There are therefore at most two roots of G with respect to T ; but there are at least two, opposite to each other (1.10).

Proposition 1.12. *Let k be an algebraically closed field, G a smooth connected k -group, T a torus of G , R the set of roots of G with respect to T , and*

``text
 $g = g_0 \otimes \bigcup_{\alpha \in R} g_{-\alpha}, \quad \text{with } g_{-\alpha} \neq 0,$
 ``

the decomposition of g under $\text{Ad}(T)$. For each $\alpha \in R$, let T_{α} be the maximal torus of $\text{Ker}(\alpha)$ [N.D.E-IX-12] and $Z_{\alpha} = \text{Centr}_{\{G\}}(T_{\alpha})$. The following conditions are equivalent:

(i) G is affine, reductive; T is maximal.

(ii) $g_{\{0\}} = t$, each Z_{α} ($\alpha \in R$) is reductive.

(iii) $g_{\{0\}} = t$, each g_{α} ($\alpha \in R$) is of dimension 1 ; and if $\alpha, \beta \in R$ and $q \in Q$ are such that $\beta = q\alpha$, then $q = \pm 1$; for each $\alpha \in R$, there exists $w_{\alpha} \in G(k)$ which normalizes T , centralizes T_{α} , but does not centralize T .

Moreover, under these conditions, each Z_{α} is of semisimple rank 1 and one has $\text{Lie}(Z_{\alpha}) = t \oplus g_{\alpha} \oplus g_{-\alpha}$.

<!-- label: III.XIX.1.12 -->

Proof. *If G is affine and reductive and if T is maximal, each Z_{α} is affine and reductive (1.6.2 (i)), with maximal torus T ; moreover, T is its own centralizer (1.6.2 (ii)), hence $g_{\{0\}} = t$, which proves (i) $\Rightarrow$ (ii).

On the other hand $g_{\{0\}} = t$ entails that T is maximal and G affine (cf. 1.10), hence each Z_{α} is affine, smooth, and connected, by 1.3. In any case, one has, by Exp. II, 5.2.2,

<!-- original page 10 -->

``text
 $\text{Lie}(Z_{\alpha}) = g^{T_{\alpha}} = g_0 \otimes \bigcup_{\beta \in R \cap Q_{\alpha}} g_{\beta}.$
 ``

One therefore has

``text
 $\text{Lie}(Z_{\alpha}) \supset t \otimes g_{\alpha} \otimes g_{-\alpha},$
 ``

which entails $Z_{\alpha} \neq T$. Since T_{α} is a subtorus of codimension 1 in T , central in Z_{α} , one obtains by 1.11, applied to Z_{α} , the equivalence (ii) $\Leftrightarrow$ (iii) and the supplements.

It remains to prove (ii) $\Rightarrow$ (i); one already knows that (ii) entails that T is maximal and G affine. Let U be its unipotent radical; it is invariant in G , its Lie algebra is invariant under $\text{Ad}(T)$. One therefore has

``text
 $\text{Lie}(U) = (\text{Lie}(U) \cap g_0) \otimes \bigcup_{\alpha \in R} (\text{Lie}(U) \cap g_{\alpha}).$
 ``

By (1.3.1), one has

```

```text

$$U \cap T = U \cap \text{Centr}_G(T) = \text{rad}_U(\text{Centr}_G(T)) = \text{rad}_U(T) = \{e\},$$

$$U \cap Z_\alpha = U \cap \text{Centr}_G(T_\alpha) = \text{rad}_U(\text{Centr}_G(T_\alpha)) = \text{rad}_U(Z_\alpha) = \{e\}.$$

```

One therefore has[^N.D.E-XIX-13]

```

```text

$$\text{Lie}(U) \cap \mathfrak{g}_0 = \text{Lie}(U) \cap \mathfrak{t} = \text{Lie}(U \cap T) = 0,$$

$$\text{Lie}(U) \cap \mathfrak{g}_\alpha \subset \text{Lie}(U) \cap \text{Lie}(Z_\alpha) = \text{Lie}(U \cap Z_\alpha) = 0;$$

```

whence $\text{Lie}(U) = 0$ and $U = \{e\}$, i.e. G is reductive.

Corollary 1.13. *Let k be an algebraically closed field, G a smooth connected k -group, T a torus of G , R the set of roots of G with respect to T , and*

```

```text

$$\mathfrak{g} = \mathfrak{g}_0 \oplus \bigcup_{\alpha \in R} \mathfrak{g}_\alpha$$

```

as above. For each  $\alpha \in R$ , let  $T_{\{\alpha\}}$  be the maximal torus of  $\text{Ker}(\alpha)$  and  $Z_{\{\alpha\}} = \text{Centr}_G(T_{\{\alpha\}})$ . The following conditions are equivalent:\*

<!-- original page 11 -->

(i)  $G$  is affine, semisimple;  $T$  is maximal.\*

(ii)  $\mathfrak{g}_0 = \mathfrak{t}$ , each  $Z_{\{\alpha\}}$  is reductive, and  $\bigcap_{\alpha \in R} \text{Ker}(\alpha)$  is finite.\*

<!-- label: III.XIX.1.13 -->

[^N.D.E-XIX-14] This follows from the equalities  $\text{rad}(G) = \text{Centr}(G)^0$  and  $\text{Centr}(G) = \bigcap_{\alpha \in R} \text{Ker}(\alpha)$ , established in 1.6.2 (iv) and (1.10.3).

**2. Reductive group schemes. Definitions and first properties**

<!-- label: III.XIX.2 -->

**Scholie 2.1.** \*If  $G$  is a group scheme over  $S$ , the following properties are equivalent:\*

(i)  $G$  is affine and smooth over  $S$ , with connected fibers.\*

(ii)  $G$  is affine and flat over  $S$ , of finite presentation over  $S$ , with geometrically integral fibers.\*

\*These properties are stable under base change and local for (fpqc).\*

<!-- label: III.XIX.2.1 -->

[^N.D.E-XIX-15] Indeed, suppose (i) is satisfied. Since  $G$  is affine and smooth over  $S$ , it is of finite presentation over  $S$ ; and since its fibers are smooth and connected, they are geometrically integral, by VI\_A, 2.4.

Conversely, if (ii) is satisfied, the fibers of  $G$  are connected and geometrically reduced, hence smooth (VI\_A, 1.3.1); then  $G$  is smooth over  $S$ , by EGA IV\_4, 17.5.2.

Of course, these properties are stable under base change: cf. EGA II, 1.5.1 for "affine", IV\_1, 1.6.2 (iii) for "of finite presentation", IV\_2, 2.1.4 for "flat", and IV\_2, 4.6.5 (i) for "with geometrically integral fibers".

<!-- original page 9 -->

On the other hand, these properties are clearly local for the Zariski topology, so it suffices to verify that if  $S' \rightarrow S$  is a faithfully flat quasi-compact morphism and if  $G_{S'} \rightarrow S'$  has the indicated properties, then so does  $G \rightarrow S$ . This follows from EGA IV\_2, 2.5.1 for "flat", 2.7.1 (vi) and (xiii) for "of finite presentation" and "affine", and 4.6.5 (i) for "with geometrically integral fibers" (and also EGA IV\_4, 17.7.3 (ii) for "smooth").

**\*\*2.2.\*\*** Let  $G$  be an  $S$ -group scheme satisfying the preceding conditions, and  $Q$  a torus (cf. IX, Def. 1.3) of  $G$ . [N.D.E-XIX-16] Then, by XI, 6.11 a) and XI, 2.4,  $\text{Centr}_G(Q)$  is representable by a closed subgroup scheme of  $G$  (hence affine over  $S$ ), of finite presentation and smooth over  $S$ ; moreover, since each geometric fiber  $G_{\bar{s}}$  of  $G$  is a smooth affine connected  $\kappa_{\bar{s}}$ -group, then, by the first assertion of 1.3, so is

$\text{Centr}_{G_{\bar{s}}}(\bar{Q}_{\bar{s}}) = (\text{Centr}_G(Q))_{\bar{s}}$ .

**\*Lemma 2.3.\*** Let  $S$  be a scheme,  $G$  an  $S$ -group scheme smooth and affine over  $S$ , with connected fibers,  $T$  a torus of  $G$ . The set of  $s \in S$  such that  $G_s$  is a reductive  $s$ -group, of semisimple rank 1 and with maximal torus  $T_s$ , is an open subset  $U$  of  $S$ .

<!-- label: III.XIX.2.3 -->

<!-- original page 12 -->

**\*Proof.\*** Since  $G$  and  $T$  are flat over  $S$ , the function

$$s \mapsto \dim(G_s/s) - \dim(T_s/s)$$

is locally constant; let  $U_1$  be the open subset of points of  $S$  where it equals 2.

[N.D.E-XIX-17] By 6.3, the Weyl group

$$W_G(T) = \text{Norm}_G(T) / \text{Centr}_G(T)$$

is representable by an  $S$ -group scheme étale and separated over  $S$ , and the function

$$s \mapsto \text{number of points of } W_G(T)_s$$

is lower semicontinuous. Let  $U_2$  be the set of points of  $S$  where this function is  $\geq 1$ ; it is open. By 1.11, the set of  $s$  such that  $G_s$  is reductive, of semisimple rank 1, with maximal torus  $T_s$ , is  $U = U_1 \cap U_2$ ; moreover, for every  $s \in U$ ,  $W_G(T)_s$  has exactly two points.

Consequently (cf. SGA 1, I 10.9 and EGA IV<sub>3</sub>, 15.5.1 and IV<sub>4</sub>, 18.12.4),  $W_G(T)_U$  is étale and finite over  $U$ .

**\*Remark 2.4.\*** The group  $W_G(T)_U$  is isomorphic to  $(Z/2Z)_U$ .

<!-- label: III.XIX.2.4 -->

Indeed, by what precedes, it is étale and finite over  $U$ ; since the functor of automorphisms of  $(Z/2Z)_U$  is the trivial group, it suffices to verify the assertion locally; but the assertion is immediate if the algebra  $A$  defining  $W_G(T)_U$  is a free  $\mathcal{O}_U$ -module. [N.D.E-XIX-18]

**\*\*Notations and reminders 2.5.0.\*\*** [N.D.E-XIX-19] Let  $S$  be a scheme,  $G$  an  $S$ -group scheme,  $\epsilon : S \rightarrow G$  the unit section of  $G$ . One has seen in II, § 4.11 that the functor  $\text{Lie}(G/S)$  is representable by the vector fibration  $V(\omega^1_{G/S})$  (where  $\omega^1_{G/S} = \epsilon^*(\omega^1_{G/S})$ ), and one denotes\*

$$g = \text{Lie}(G/S) = (\omega^1_{G/S})^{\vee}$$

the sheaf of sections of this vector fibration. Suppose moreover that  $G$  is smooth over  $S$ ; then  $\omega^1_{G/S}$  and hence  $\text{Lie}(G/S)$  are locally free  $\mathcal{O}_S$ -modules of finite type, and one has (cf. I 4.6.5.1):\*

$$\text{Lie}(G/S) = W(\text{Lie}(G/S)),$$

...

\*i.e. for every  $S$ -scheme  $S'$ ,

```

```text
Lie(G/S)(S') = Γ(S', Lie(G/S) ⊗ 0_{S'}).
```

```

\*By II 4.1.1.1, the adjoint action of  $G$  endows  $\mathrm{Lie}(G/S) = W(\mathrm{Lie}(G/S))$  with a  $G$ - $0_S$ -module structure, hence  $\mathrm{Lie}(G/S)$  is a  $G$ - $0_S$ -module (cf. I 4.7.1). If moreover  $G$  is affine over  $S$ , this amounts to saying, by I 4.7.2, that  $\mathrm{Lie}(G/S)$  is an  $A(G)$ -comodule.\*

\*If  $T$  is a torus over  $S$  (IX Def. 1.3), one says that  $T$  is split ("trivial" in the original) if it is isomorphic to  $G^r_{m,S}$  for some integer  $r \geq 0$ , and one says that  $T$  is trivialized if one has fixed such an isomorphism or, more generally, an isomorphism  $T \simeq D_S(M)$ , where  $M$  is a free abelian group of rank  $r$ .\*

\*Let us finally recall (XII Def. 1.3) that a torus  $T$  of  $G$  is called maximal if, for every  $s \in S$ ,  $T_{\bar{s}}$  is a maximal torus of  $G_{\bar{s}}$ .\*

<!-- label: III.XIX.2.5.0 -->

**Theorem 2.5.** \*Let  $S$  be a scheme,  $G$  an  $S$ -group scheme affine and of finite presentation over  $S$ , with connected fibers, and  $s_0$  a point of  $S$ . Suppose  $G$  flat over  $S$  at  $\epsilon(s_0)$  and the geometric fiber  $G_{\bar{s}_0}$  (reduced and) reductive (resp. semisimple). Then there exists an open subset  $U$  of  $S$  containing  $s_0$  and an étale surjective morphism  $S' \rightarrow U$  such that:

<!-- original page 13 -->

(i)  $G_U$  is smooth over  $S$ , with geometrically reductive (resp. semisimple) fibers, of constant reductive rank and semisimple rank.\*

(ii)  $G_{S'}$  possesses a split  ${}^{\mathrm{N.D.E-XIX-20}}$  maximal torus  $T$ , and the Weyl group (cf. 6.3)\*

```

```text
W_{G_{S'}}(T) = Norm_{G_{S'}}(T) / Centr_{G_{S'}}(T) = Norm_{G_{S'}}(T) / T
```

```

\*is finite over  $S$ .\*

<!-- label: III.XIX.2.5 -->

**Proof.**  ${}^{\mathrm{N.D.E-XIX-21}}$  Denote by  $\pi : G \rightarrow S$  the structure morphism and  $\epsilon : S \rightarrow G$  the unit section. Since  $G$  is flat over  $S$  at  $\epsilon(s_0)$  and  $G_{\bar{s}_0}$  reduced (hence smooth over  $\bar{s}_0$ ), cf. VI\_A 1.3.1),  $G$  is smooth over  $S$  at the point  $\epsilon(s_0)$  (EGA IV<sub>4</sub>, 17.5.1), i.e. there exists an open neighborhood  $V$  of  $\epsilon(s_0)$  such that  $\pi|_V$  is smooth. Then,  $S' = \epsilon^{-1}(V)$  is an open subset of  $S$ , and  $G_{S'}$  is smooth over  $S'$  at the points of  $\epsilon(S')$ . Since  $G$  has connected fibers,  $G_{S'}$  is smooth over  $S'$ , by VI\_B, 3.10. So, replacing  $S$  by  $S'$ , one may assume  $G$  smooth over  $S$ .

By Exp. XI, Th. 4.1, the functor of subgroups of multiplicative type of  $G$  is representable by an  $S$ -scheme  $\mathcal{M}$ , smooth and separated over  $S$ . Denote by  $r_0$  the rank of  $G_{\bar{s}_0}$  and consider the open subscheme  $\mathcal{M}_{r_0}$  of  $\mathcal{M}$ , which represents the functor of subtori of rank  $r_0$  of  $G$  (IX 1.4). Smoothness entails that  $\mathcal{M}_{r_0}$  admits a rational point over a finite separable extension of  $k(s_0)$  (cf. EGA IV<sub>4</sub>, 17.15.10 (iii)). Thus there exists  $S' \rightarrow S$  étale equipped with a point  $s'_0$  mapping to  $s_0$  such that  $G_{S'}$  admits a torus of rank  $r_0$ . Therefore, replacing  $S$  by  $S'$ , one may assume that  $G_{s_0}$  admits a torus of rank  $r_0$ .

By "Hensel's lemma" (cf. XI, 1.10), the smoothness of  $\mathcal{M}_{r_0}$  permits one to lift this torus to an  $S'$ -torus  $T$  of  $G$ , where  $S' \rightarrow S$  is étale equipped with a point  $s'_0$  mapping to  $s_0$ . By Exp. X, 4.5 (see also 6.1  ${}^{\mathrm{N.D.E-XIX-22}}$ ), there exists an étale morphism  $f : S' \rightarrow S$  splitting  $T$  and such that  $f^{-1}(s'_0) \neq \emptyset$ . Since an étale morphism is open and the assertions of (i) are local for the étale topology, one may therefore assume that  $G$  possesses a split torus  $T$ ,  ${}^{\mathrm{N.D.E-XIX-23}}$  maximal at  $s_0$ . Write therefore  $T = D_S(M)$  and let

```

```text
g = \bigsqcup_{m \in M} g_m
```

```

...

be the decomposition of  $\mathfrak{g} = \text{Lie}(G/S)$  under  $\text{Ad}(T)$  (Exp. I, 4.7.3).

Put  $\mathfrak{t} = \text{Lie}(T)$  and, for every  $\mathfrak{m} \in M$ , denote  $\mathfrak{g}_{\mathfrak{m}}(s_0) = \mathfrak{g}_{\mathfrak{m}} \otimes_{\mathcal{O}_S} \kappa(s_0)$ .<sup>[N.D.E-XIX-24]</sup> Let  $R$  be the set of  $\mathfrak{m} \in M$ ,  $\mathfrak{m} \neq 0$ , such that  $\mathfrak{g}_{\mathfrak{m}}(s_0) \neq 0$ .<sup>[N.D.E-XIX-25]</sup> Since  $G_{\bar{s}_0}$  is reductive, one has  $\mathfrak{g}_0(s_0) = \mathfrak{t}(s_0)$ , hence

```text  
 $\mathfrak{g}(s_0) = \mathfrak{t}(s_0) \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha(s_0)$.
 ```

Since the modules in question are locally free, one may, by shrinking  $S$  if necessary, assume the  $\mathfrak{g}_{\alpha}$  free and

<!-- original page 14 -->

```text  
 $\mathfrak{g} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R} \mathfrak{g}_{\alpha}$.
 ```

One recalls, cf. Exp. XII, 1.12, that a group of multiplicative type possesses a unique maximal torus (this is moreover essentially trivial by descent, the diagonalizable case being evident). Let then  $T_{\alpha}$  be the maximal torus of the kernel of  $\alpha$  and  $Z_{\alpha} = \text{Centr}_G(T_{\alpha})$ .<sup>[N.D.E-XIX-26]</sup> By 2.2,  $Z_{\alpha}$  is affine and smooth over  $S$ , with connected fibers, and by 1.12, its fiber  $Z_{\alpha}(\bar{s}_0)$  is reductive, of semisimple rank 1, with maximal torus  $T_{\bar{s}_0}$ . By 2.3, there therefore exists an open subset  $U_{\alpha}$  of  $S$ , containing  $s_0$ , such that  $\bar{Z}_{\alpha}|_{U_{\alpha}}$  has reductive fibers.

<!-- original page 14 (cont.) -->

Set  $U = \bigcap_{\alpha \in R} U_{\alpha}$ . By 1.12, for every  $s \in U$ ,  $G_{\bar{s}}$  is reductive, with maximal torus  $T_{\bar{s}}$  and the set of roots of  $G_{\bar{s}}$  with respect to  $T_{\bar{s}}$  is identified with  $R$ , so that

```text  
 $\text{rgred}(G_{s^-}) = \dim(T) = \text{rg}(M), \quad \text{rgss}(G_{s^-}) = \text{rg}(R) \quad (\text{cf. 1.10}).$
 ```

One has therefore proved (i) and the first assertion of (ii); it remains to prove that the Weyl group  $W_{G_U}(T_U)$  is finite over  $U$ , i.e. "that it has the same number of points in each geometric fiber" (cf. SGA I, I 10.9 and EGA IV<sub>3</sub>, 15.5.1 and IV<sub>4</sub>, 8.12.4).

For this, it suffices to remark that the geometric fiber of this group at  $s \in U$  is determined by the situation  $R \subset M$ , as the constant group associated with the "abstract Weyl group of this root system", and in particular is independent of the point  $s$ , cf. \*Bible\*, § 11.3, Th. 2 (see also Exp. XXII, no. 3).

**Corollary 2.6.** \*Let  $G$  be an  $S$ -group affine and smooth over  $S$ , with connected fibers. The set of points  $s \in S$  such that  $G_{\bar{s}}$  is reductive (resp. semisimple) is an open subset  $U$  of  $S$ , and the functions\*

```text  
 $s \mapsto \text{rgred}(G_{s^-}/s^-), \quad s \mapsto \text{rgss}(G_{s^-}/s^-)$
 ```

\*are locally constant on  $U$ .\*

<!-- label: III.XIX.2.6 -->

<!-- original page 15 -->

**Definition 2.7.** \*An  $S$ -group (=  $S$ -group scheme)  $G$  is called\* reductive \*(resp.\* semisimple\*) if it is affine and smooth over  $S$ , with geometrically connected fibers, and reductive (resp. semisimple).\*

<!-- label: III.XIX.2.7 -->

The property of being reductive (resp. semisimple) for an  $S$ -group  $G$  is stable under base change and local for the (fpqc) topology.

**\*\*2.8.\*\*** Let  $G$  be a reductive  $S$ -group. For every torus (resp. maximal torus)  $Q$  of  $G$ ,  $Z(Q) = \text{Centr}_{\{G\}}(Q)$  is reductive (resp. equals  $Q$ ). This follows at once from 2.2 and 1.6. Applying 2.5 to  $\text{Centr}_{\{G\}}(Q)$ , one deduces from it that  $Q$  is contained (locally for the étale topology) in a maximal torus.

**\*\*Remark 2.9.\*\*** \*Using as usual the technique of EGA IV<sub>3</sub>, § 8, the finite-presentation hypotheses, and Theorem 2.5, one sees that if  $G$  is a reductive group over  $S$ , there exists an open covering of  $S$ , say  $\{U_i\}$ , such that each  $G_{U_i}$  comes by base change from a reductive group over a noetherian ring (in fact, a finitely generated algebra over  $Z$ ). Likewise, if  $G$  possesses a split maximal torus  $T$ , one may further assume that  $T_{U_i}$  comes from a split maximal torus of the preceding group, ...\*

<!-- label: III.XIX.2.9 -->

### ## 3. Roots and root systems of reductive group schemes

<!-- label: III.XIX.3 -->

<!-- original page 16 -->

**\*\*3.1.\*\*** Let  $S$  be a scheme,  $T$  an  $S$ -torus operating linearly on a locally free  $\mathcal{O}_S$ -module of finite type  $F$  (cf. I, § 4.7). For every character  $\alpha$  of  $T$  (i.e.  $\alpha \in \text{Hom}_{S\text{-gr.}}(T, G_{\{m,S\}})$ ), one defines a subfunctor of  $W(F)$  by

```text  
 $W(F)^{\alpha}(S') = \{ x \in W(F)(S') \mid t \cdot x = \alpha(t) \cdot x \text{ for all } t \in T(S'), S' \rightarrow S \}.$

****Lemma.**** [^{N.D.E-XIX-27}] *Then $W(F)^{\alpha} = W(F^{\alpha})$, where F^{α} is a submodule of F , locally a direct summand in F , hence also locally free.*

<!-- label: III.XIX.3.1 -->

Indeed, the assertion is local for the (fpqc) topology, and one may assume $T = D_{\{S\}}(M)$, where M is a (free) abelian group of finite type. Then α is identified with a locally constant function from S to M (Exp. VIII 1.3), and shrinking S if necessary, one may assume that this function is constant. One is then reduced to Exp. I, 4.7.3.

****Definition 3.2.**** *Let S be a scheme, G an S -group scheme smooth and with connected fibers, [^{N.D.E-XIX-28}] T a torus of G . Denote $\mathfrak{g} = \text{Lie}(G/S)$ and let T operate on $\mathfrak{g}$ through the adjoint representation of G .*

*One says that the character α of T is a root of G with respect to T if the following equivalent conditions are satisfied:

- *(i) For every $s \in S$, $\alpha_{\bar{s}}$ is a root of $G_{\bar{s}}$ with respect to $T_{\bar{s}}$ (1.10).*
- *(ii) α is non-trivial on each fiber and $\mathfrak{g}^{\alpha}(s) \neq 0$ for every $s \in S$.*

<!-- label: III.XIX.3.2 -->

****Lemma 3.3.**** *Let S be a scheme, T an S -torus, α a character of T . The following conditions are equivalent:*

<!-- original page 17 -->

- *(i) α is non-trivial on each fiber, that is to say: for every $s \in S$, $\alpha_{\bar{s}}$ is distinct from the unit character of $T_{\bar{s}}$.*
- *(ii) For every $S' \rightarrow S$, $S' \neq \emptyset$, $\alpha_{S'}$ is distinct from the unit character of $T_{S'}$.*
- *(iii) The morphism α is faithfully flat.*

<!-- label: III.XIX.3.3 -->

[^{N.D.E-XIX-29}] It is clear that (ii) $\Rightarrow$ (i), and one sees easily that (iii) $\Rightarrow$ (i). One has (i) $\Rightarrow$ (ii), for if $s' \in S$ lies over s and if $\alpha_{s'}$ is the unit character, then so is α_s . Finally, to prove (i) $\Rightarrow$ (iii), one reduces to the case where T is diagonalizable and concludes by Exp. VIII 3.2 a).

****3.4.**** [^N.D.E-XIX-30] Let G be a reductive S -group scheme, T a maximal torus of G . Let α be a root of G with respect to T . Then, by 2.5.0 and 1.12, g^α is a locally free ${}_{0_S}$ -module of rank one. Moreover, by 1.10, $-\alpha$ is also a root of G with respect to T . In particular, if G is of semisimple rank 1, one has by 1.11 and 1.12:

<!-- original page 14 (cont.) -->

****Lemma 3.5.**** *Let S be a scheme, G a reductive S -group of semisimple rank 1, T a maximal torus of G . If α is a root of G with respect to T , then $-\alpha$ is also one, and one has*

```
```text
g = t \otimes g^\alpha \otimes g^{-\alpha},
```

\*where  $g^\alpha$  and  $g^{-\alpha}$  are locally free of rank 1.\*

<!-- label: III.XIX.3.5 -->

**\*\*Definition 3.6.\*\*** \*Let  $S$  be a scheme,  $G$  a reductive  $S$ -group,  $T$  a maximal torus of  $G$ ,  $R$  a set of roots of  $G$  with respect to  $T$ . One says that  $R$  is a root system of  $G$  with respect to  $T$  if the following equivalent conditions are satisfied:\*

<!-- original page 18 -->

**\*(i)** For every  $s \in S$ ,  $\alpha \mapsto \alpha|_s$  is a bijection of  $R$  onto the set of roots of  $G_s$  with respect to  $T_s$ .\*

**\*(ii)** The elements of  $R$  are distinct on each fiber (i.e. if  $\alpha, \alpha' \in R$ ,  $\alpha \neq \alpha'$ , then  $\alpha - \alpha' (= \alpha \alpha'^{-1})$  is non-trivial on each fiber), and for every  $s \in S$ , one has\*

```
```text
dim(G_s/\kappa(s)) - dim(T_s/\kappa(s)) = Card(R).
```

***(iii)** One has $g = t \oplus \coprod_{\alpha \in R} g^\alpha$.*

<!-- label: III.XIX.3.6 -->

The equivalence of these various conditions is trivial.

****Lemma 3.7.**** *Let S be a scheme, G a reductive S -group, T a maximal torus of G , R a root system of G with respect to T . Every root of G with respect to T is locally on S equal to an element of R .*

<!-- label: III.XIX.3.7 -->

Proof. Visible on condition (iii).

Put $\mathcal{M} = \operatorname{Hom}_{S\text{-gr.}}(T, G_{(m,S)})$; it is a twisted constant S -group scheme (Exp. X 5.6). If G admits a root system R with respect to T , then the inclusion $R \hookrightarrow \mathcal{M}(S)$ defines a morphism $R_S \rightarrow \mathcal{M}$, where R_S is the constant S -scheme defined by R ; thanks to condition (ii), one sees easily that this morphism is an open and closed immersion whose image is none other than $\bigcup_{\alpha \in R} \alpha(S)$ (each $\alpha \in R$ being considered as a section $S \rightarrow \mathcal{M}(S)$).

Let $\mathcal{R}$ be the functor of roots of G with respect to T : by definition, $\mathcal{R}(S')$ is the set of roots of $G_{S'}$ with respect to $T_{S'}$ for every $S' \rightarrow S$; if $S' = \emptyset$, one sets $\mathcal{R}(\emptyset) = \{e\}$, and if $S' \neq \emptyset$ then the inclusion $R \hookrightarrow \mathcal{M}(S')$ identifies R with a root system of $G_{S'}$ with respect to $T_{S'}$, and therefore, by 3.7, one has

```
```text
\mathcal{R}(S') = \operatorname{Hom}_{\{\text{loc. const.}\}}(S', R),
```

which shows that  $\mathcal{R}$  is representable by  $R_S$ .

<!-- original page 19 -->

If one now no longer supposes necessarily that  $G$  possesses a root system relative to  $T$ ,  $\mathcal{R}$  is in any case a subsheaf of  $\mathcal{M}$  for (fpqc). Locally for this topology,  $G$  possesses a root system with respect to  $T$  (take for example  $T$  split and use the proof of Th. 2.5). By Exp. IV 4.6.8 and the theory of descent of open (resp. closed) subschemes, [N.D.E-XIX-31] one obtains:

**Proposition 3.8.** \*Let  $S$  be a scheme,  $G$  an  $S$ -group,  $T$  a maximal torus of  $G$ . The functor  $\mathcal{R}$  of roots of  $G$  with respect to  $T$  is representable by a twisted constant finite  $S$ -scheme (Exp. X 5.1) which is an open and closed subscheme of  $\operatorname{Hom}_{S\text{-gr.}}(T, G_{(m,S)})$ .\*

\*For  $R \subset \operatorname{Hom}_{S\text{-gr.}}(T, G_{(m,S)})$  to be a root system of  $G$  with respect to  $T$ , it is necessary and sufficient that the morphism  $R_{(S)} \rightarrow \operatorname{Hom}_{S\text{-gr.}}(T, G_{(m,S)})$  defined by the preceding inclusion induce an isomorphism  $R_{(S)} \xrightarrow{\sim} \mathcal{R}$ .\*

<!-- label: III.XIX.3.8 -->

**3.9.** Let  $S$  be a scheme,  $G$  a reductive  $S$ -group,  $T$  a maximal torus of  $G$ ,  $\alpha$  a root of  $G$  with respect to  $T$  (i.e. a section of  $\mathcal{R}$ ). Consider the kernel  $\operatorname{Ker}(\alpha)$  of  $\alpha$ , its unique maximal torus  $T_{\alpha}$ , and the centralizer of the latter,  $Z_{\alpha} = \operatorname{Centr}_G(T_{\alpha})$ . It is an  $S$ -group closed in  $G$ , reductive (2.8) of semisimple rank '1' (1.12). Moreover,

``text  
 $\operatorname{Lie}(Z_{\alpha}/S) = t \oplus g^{\alpha} \oplus g^{-\alpha},$   
 ``

so  $\{\alpha, -\alpha\}$  is a root system of  $Z_{\alpha}$  with respect to  $T$ .

**3.10.** Let  $S$  be a scheme,  $G$  a reductive  $S$ -group,  $T$  a maximal torus of  $G$ ,  $\alpha$  a root of  $G$  with respect to  $T$ . If  $q \in Q$  and if  $q\alpha$  is a root of  $G$  with respect to  $T$ , then  $q = 1$  or  $q = -1$ . This follows at once from 1.12.

#### ## 4. Roots and vector group schemes

<!-- label: III.XIX.4 -->

<!-- original page 20 -->

**4.1.** Let  $S$  be a scheme,  $F$  a locally free  $_0S$ -module of finite type. The  $S$ -scheme  $W(F)$  is smooth over  $S$ . Its Lie algebra is canonically isomorphic to  $F$ . Indeed, one has a canonical isomorphism

\$\$  
 W(F) \xrightarrow{\sim} \operatorname{Lie}(W(F)/S) = W(\operatorname{Lie}(W(F)/S))  
 \$\$

(Exp. II, 4.4.1 and 4.4.2). We shall always identify  $F$  and  $\operatorname{Lie}(W(F)/S)$ .

**Lemma 4.2.** \*Let  $S$  be a scheme,  $V$  a vector fibration over  $S$ , smooth over  $S$ . Then there exists a unique isomorphism of  $_0S$ -modules\*

\$\$  
 \exp : W(\operatorname{Lie}(V/S)) \xrightarrow{\sim} V  
 \$\$

\*inducing the identity on the Lie algebras.\* [N.D.E-XIX-32]

<!-- label: III.XIX.4.2 -->

\*Proof.\* Indeed,  $V = V(F)$  for some quasi-coherent  $_0S$ -module  $F$ . Since  $V$  is smooth over  $S$ , then  $F \simeq \omega^1_{V/S}$  is locally free of finite type, and therefore

\$\$  
 \operatorname{Lie}(V/S) = V(\omega^1\_{V/S}) \simeq W(\operatorname{Lie}(V/S)).  
 \$\$

Moreover, by Exp. II \*loc. cit.\*, one has a canonical isomorphism

$$V \xrightarrow{\sim} \text{Lie}(V/S) \simeq W(\text{Lie}(V/S))$$

and one has at once the uniqueness of  $\exp$ , since  $W$  is fully faithful.

**4.3. Notations.** If  $V$  is a vector bundle over  $S$ , one will denote by  $V^\times$  the open subset of  $V$  obtained by removing the zero section. Write the group law of  $V^\times$  in multiplicative notation. The action of  $0_S$  on  $V$  defining the module structure will then be written exponentially

$$0_S \times V \rightarrow V, \quad (x, v) \mapsto v^x.$$

$$\text{--- original page 21 ---}$$

One has  $(v v')^x = v^x v'^x$ ,  $v^{x+x'} = v^x v^{x'}$ ,  $v^{x x'} = (v^x)^{x'}$ . In particular, if one restricts the operator law to  $G_{m,S}$ , then  $V^\times$  is stable and is therefore endowed with a structure of object with group of operators  $G_{m,S}$ . We shall again write this law as  $(z, v) \mapsto v^z$ .

**Definition 4.4.1.** [N.D.E-XIX-33] Let  $L$  be an invertible module on  $S$  and  $W(L)$  the associated vector bundle. Then  $W(L)^\times$  is a principal homogeneous bundle (locally trivial) under  $G_{m,S}$ . One denotes  $\Gamma(S, L)^\times = W(L)^\times(S)$ .

$$\text{--- label: III.XIX.4.4.1 ---}$$

**Scholie 4.4.2.** There is a bijective correspondence between the isomorphisms of  $0_S$ -modules  $0_S \simeq L$ , the isomorphisms of  $0_S$ -modules  $0_S \simeq W(L)$ , [N.D.E-XIX-34] and the sections  $S \rightarrow W(L)^\times$ .

This correspondence is effected by  $f \mapsto W(f) \mapsto W(f)(1)$ . It is compatible with extension of the base. One may therefore consider  $W(L)^\times$  as the "scheme of trivializations of  $W(L)$ ".

$$\text{--- label: III.XIX.4.4.2 ---}$$

**4.5.** Let  $S$  be a scheme,  $T$  a torus over  $S$ ,  $P$  an  $S$ -group with group of operators  $G_{m,S}$  (for example a vector bundle),  $\alpha$  a character of  $T$ . One denotes  $T \cdot_\alpha P$  the semi-direct product of  $P$  by  $T$ , where  $T$  operates on  $P$  by the composite morphism

$$T \rightarrow G_{m,S} \rightarrow \text{Aut}_{\{S\text{-gr.}\}}(P).$$

**Definition 4.6.** Let  $S$  be a scheme,  $G$  an  $S$ -group scheme,  $T$  a subgroup of  $G$ ,  $\alpha$  a character of  $T$ ,  $L$  an  $0_S$ -module. Let

$$p : W(L) \rightarrow G \quad \text{[N.D.E-XIX-35]}$$

be a morphism of  $S$ -group functors. One says that  $p$  is normalized by  $T$  with multiplier  $\alpha$  if it satisfies the following equivalent conditions:

(i)  $p$  is a morphism of objects with group of operators  $T$ , if one makes  $T$  operate on  $W(L)$  by  $\alpha$  and on  $G$  by inner automorphisms. In other words, for every  $S' \rightarrow S$  and all  $t \in T(S')$  and  $x \in W(L)(S') = \Gamma(S', L \otimes 0_{S'})$ , one has

$$\text{--- original page 22 ---}$$

$$\text{int}(t) p(x) = p(\alpha(t) x).$$

(ii) The morphism  $T \cdot_\alpha W(L) \rightarrow G$  defined by the product in  $G$  (i.e. by  $(t, x) \mapsto t \cdot p(x)$ )

is a morphism of groups.\*

<!-- label: III.XIX.4.6 -->

**Lemma 4.7.** \*Under the conditions of 4.6, suppose moreover that  $G$  is smooth and has connected fibers, [N.D.E-XIX-36]  $T$  is a maximal torus of  $G$ ,  $L$  is invertible. If  $p$  is a monomorphism and  $\alpha$  non-zero on each fiber, then  $\alpha$  is a root of  $G$  with respect to  $T$ .\*

<!-- label: III.XIX.4.7 -->

**Proof.** Indeed  $\mathrm{Lie}(p) : L \rightarrow g$  is a monomorphism which factors through  $g^\alpha$ .

**Proposition 4.8.** \*Under the conditions of 4.7, suppose that  $G$  is reductive, and that  $p$  is a monomorphism. Then  $\alpha$  is a root of  $G$  with respect to  $T$  and  $\mathrm{Lie}(p)$  induces an isomorphism\*

$$\mathrm{Lie}(p) : L \xrightarrow{\sim} g^\alpha.$$

<!-- label: III.XIX.4.8 -->

**Proof.** Indeed, by virtue of 4.7 and the fact that  $g^\alpha$  is invertible, it suffices to prove that  $\alpha$  is non-zero on each fiber. Let then  $s \in S$  be such that  $\alpha_s = 0$  ( $= 1$  in multiplicative notation). If  $X$  is a non-zero section of  $L \otimes_S \kappa(s)$ , then  $p(X)$  is a unipotent element  $\neq e$  of  $G(\bar{s})$  which centralizes  $T_{\bar{s}}$ , which is impossible, since the latter is its own centralizer.

**Corollary 4.9.** \*Under the conditions of 4.8, there exists a monomorphism of groups with operators  $T$  (i.e. normalized by  $T$  with multiplier  $\alpha$ )\*

$$W(g^\alpha) \rightarrow G$$

which induces on the Lie algebras the canonical morphism  $g^\alpha \rightarrow g$ .\*

<!-- label: III.XIX.4.9 -->

We shall see shortly that 4.9 is verified in fact whenever  $G$  is a reductive group and  $\alpha$  a root of  $G$  with respect to  $T$ , and that such a morphism is unique.

<!-- original page 23 -->

**Reminder 4.10.** \*Let  $k$  be an algebraically closed field,  $G$  a reductive  $k$ -group,  $T$  a maximal torus of  $G$ ,  $\alpha$  a root of  $G$  with respect to  $T$ . There exists a monomorphism\*

$$p : G_{\alpha,k} \rightarrow G$$

normalized by  $T$  with multiplier  $\alpha$ .\*

<!-- label: III.XIX.4.10 -->

See *Bible*, § 13.1, Th. 1.

**4.11.** Let us conclude this section with a technical result that will be useful to us. Let  $S$  be a scheme, and  $L$  an invertible  $\mathcal{O}_S$ -module. Let  $q$  be an integer  $> 0$  such that  $x \mapsto x^q$  is an endomorphism of the  $S$ -group  $G_{\alpha,S}$ . (If  $S \neq \emptyset$ , one has  $q = 1$ , or  $q = p^n$ ,  $p$  being a prime number that is zero on  $S$ ; this follows at once from the elementary fact: the gcd of the binomial coefficients  $\binom{q}{i}$ , for  $i \neq 0, q$ , is  $p$  if  $q = p^n$ ,  $p$  prime, and  $1$  in the contrary case.) The morphism defined by the  $q$ -th power

$$L \rightarrow L^{\otimes q}$$

is a morphism of sheaves of abelian groups. It defines by base change a morphism of  $S$ -group schemes:

$$W(L) \rightarrow W(L \otimes q).$$

In particular, if  $L$  is another invertible module and if one has a morphism of  $0_S$ -modules

$$h : L \otimes q \rightarrow L',$$

one deduces from it a morphism of  $S$ -group schemes:

<!-- original page 24 -->

$$W(L) \rightarrow W(L'), \quad x \mapsto h(xq).$$

These notations laid down, one has:

**Proposition 4.12.** \*Let  $S$  be a scheme,  $T$  (resp.  $T'$ ) an  $S$ -torus,  $L$  (resp.  $L'$ ) an invertible  $0_S$ -module,  $\alpha$  (resp.  $\alpha'$ ) a character of  $T$  (resp.  $T'$ ). [N.D.E-XIX-37] Let  $f : T \rightarrow T'$  be a morphism of groups and  $g : W(L) \rightarrow W(L')$  a morphism of  $S$ -schemes (not necessarily a morphism of  $S$ -groups) satisfying the following condition:\*

$$(*) \quad g(\alpha(t) x) = \alpha'(f(t)) g(x)$$

\*for all  $x \in W(L)(S')$ ,  $t \in T(S')$ ,  $S' \rightarrow S$ . Let  $s_0 \in S$  be such that  $\alpha_{s_0} \neq 0$ .\*

\*a) Suppose that  $g$  sends the zero section to the zero section and that for every integer  $n > 0$ , one has  $(\alpha' \circ f)_{s_0} \neq n \alpha_{s_0}$ . Then  $g = 0$  in a neighborhood of  $s_0$ .\*

\*b) Suppose that  $g$  is a morphism of groups such that  $g_{s_0} \neq 0$ . Then there exist an open subset  $U$  of  $S$  containing  $s_0$  and an integer  $q > 0$  such that  $x \mapsto x^q$  is an endomorphism of  $G_{a,U}$  and  $(\alpha' \circ f)_U = q \alpha_U$ .\*

\*c) Suppose that  $(\alpha' \circ f)_{s_0} = q \alpha_{s_0}$ , where  $q$  is an integer  $> 0$  such that  $x \mapsto x^q$  is an endomorphism of  $G_{a,S}$ . Then there exist an open subset  $U$  of  $S$  containing  $s_0$  and a unique morphism of  $0_S$ -modules\*

$$h : L \otimes q|_U \rightarrow L'|_U$$

\*such that  $g_U$  is the composite morphism\*

$$W(L)_U \xrightarrow{x \mapsto x^q} W(L \otimes q)_U \xrightarrow{W(h)} (L')_U.$$

<!-- label: III.XIX.4.12 -->

**Proof.** Let us prove (a). Since the conclusion is local on  $S$ , one may assume that

<!-- original page 25 -->

$W(L) = W(L') = G_{a,S}$  and therefore that  $g$  is expressed as a polynomial

$$g(X) = \sum_{n \geq 0} a_n X^n, \quad a_n \in \Gamma(S, 0_S).$$

The condition  $(*)$  linking  $f_S$  and  $g_S$  is written as an identity in  $\Gamma(S', 0_{S'})[X]$ :

$$\sum_{n \in \mathbb{Z}} a_n \alpha'(f(t)) X^n = \sum_{n \in \mathbb{Z}} a_n \alpha(t)^n X^n,$$

that is, for every  $n \geq 0$ , every  $S' \rightarrow S$  and every  $t \in T(S')$ ,

$$a_n (\alpha'(f(t)) - \alpha(t)^n) = 0.$$

For each  $n \geq 0$ , let  $S_n$  be the set of  $S$  such that  $(\alpha' \circ f)_S = n \alpha_S$ . One knows (Exp. IX 5.3) that the  $S_n$  are open and closed, and that  $(\alpha' \circ f)_{S_n} = n \alpha_{S_n}$ . Moreover, since  $\alpha_{S_0} \neq 0$ , one may, shrinking  $S$  if necessary, assume that  $\alpha$  is non-zero on each fiber (same reference), which entails that the  $S_n$  are disjoint. Shrinking  $S$  if necessary, one may therefore assume that one is in one of the two following cases: there exists an  $n$  such that  $S = S_n$ , or all the  $S_n$  are empty.

Let  $m \geq 0$  be such that  $S_m = \emptyset$ ; I claim that then  $a_m = 0$ ; indeed  $\alpha' \circ f$  and  $m \alpha$  are distinct on each fiber of  $S$ , and one has:

**Lemma 4.13.** \*Let  $S$  be a scheme,  $T$  an  $S$ -torus,  $\alpha$  and  $\alpha'$  two characters of  $T$  distinct on each fiber; there exists a family  $\{S_i \rightarrow S\}$  covering for (fpqc), and for each  $i$  a  $t_i \in T(S_i)$ , such that  $\alpha(t_i) - \alpha'(t_i) = 1$ .\*

*Proof.* The lemma is trivial, by reduction to the diagonalizable case, then to the case  $T = G_m$ .

Let us resume the proof of Proposition 4.12; we have just proved (a). In cases (b) and (c), there exists an  $n$  such that  $S = S_n$  (with  $n = q$  in (c)). By the preceding result, one has therefore  $a_m = 0$  for  $m \neq n$ , which proves that  $g_S$  is written

original page 26

$$g(X) = a_n X^n, \quad a_n \in \Gamma(S, 0_S).$$

This proves (c) at once. In case (b), one knows that  $a_n(s_0) \neq 0$ , one may therefore assume  $a_n$  invertible on  $S$ , which entails that  $x \mapsto x^n$  is an endomorphism of  $G_{A,S}$  (by virtue of the hypothesis of (b)) and completes the proof.

## 5. An instructive example

III.XIX.5

**5.1.** Let  $k$  be an algebraically closed field of characteristic 0. Put  $A = k[t]$ , the polynomial ring in one variable over  $k$ , and  $S = \operatorname{Spec}(A)$ . Consider the following Lie algebra  $g_S$  over  $0_S$ : as a module, it is free of dimension 3, with basis  $\{X, Y, H\}$ ; the multiplication table is

$$[X, Y] = 2tH, \quad [H, X] = X, \quad [H, Y] = -Y.$$

For  $s \in S$ ,  $s \neq s_0$  (the point defined by  $t = 0$ ), the fiber  $g(s) = g \otimes_A \kappa(s)$  is isomorphic to the Lie algebra of the group  $\operatorname{PGL}_2(\kappa(s))$ . For  $s = s_0$ , it is a solvable Lie algebra.

**5.2.** Let  $G_1$  be the group scheme of automorphisms of  $g_S$ : for every  $S' \rightarrow S$ ,  $G_1(S')$  is the group of automorphisms of the  $0_{S'}$ -Lie algebra  $g \otimes_{0_S} 0_{S'}$ . It is a closed subscheme of the group  $\operatorname{GL}(g)_S$  of automorphisms of the  $0_S$ -module  $g_S$ . Let  $S' \rightarrow S$  and  $u \in M_3(\Gamma(S', 0_{S'}))$  considered as an endomorphism of the  $0_{S'}$ -module  $g \otimes_{0_S} 0_{S'}$ :

<!-- original page 27 -->

```
```text
u(X) = a X + b Y + e H,
u(Y) = b' X + a' Y + e' H,
u(H) = c X + c' Y + d H.
```
```

One sees at once that  $u$  is a section of  $G_1$  if and only if  $\det(u)$  is invertible and one has the relations: [N.D.E-XIX-38]

```
```text
(1) a(d - 1) = e c,           (1') a'(d - 1) = e' c',
(2) b(d + 1) = e c',         (2') b'(d + 1) = e' c,
(3) e = 2t(b c - a c'),      (3') e' = 2t(b' c' - a' c),
(4) 2t c = e b' - a e',      (4') 2t c' = b e' - e a',
(5) 2t(a a' - b b') = 2t d.
```
```

**Lemma 5.3.** \*The relations (1), (1'), (2), (2') imply\*

```
```text
det(u) = a a' (2 - d) + b b' (d + 2),
a a' - b b' = d · det(u).
```
```

<!-- label: III.XIX.5.3 -->

**Proof.** \*Indeed, the first assertion is obtained at once by inserting the relations (1), (1'), (2), (2') into the expansion of  $\det(u)$ :

```
```text
det(u) = a a' d + b e' c + b' c' e - a' e c - a e' c' - b b' d
        = a a' d + b b' (d + 1) + b b' (d + 1) - a a' (d - 1) - b b' d - a a' (d - 1)
        = a a' (d - d + 1 - d + 1) + b b' (d + 1 + d + 1 - d)
        = a a' (2 - d) + b b' (d + 2).
```
```

Multiplying this relation by  $d$ , one obtains

```
```text
d · det(u) = a a' (2d - d²) + b b' (d² + 2d).
```
```

But the relation  $(1) \times (1') = (2) \times (2')$  gives at once

<!-- original page 28 -->

```
```text
a a' (d - 1)² = b b' (d + 1)².
```
```

Combining the two preceding relations, one finds at once the second sought formula.

**5.4.** Consider then  $G = G_1 \cap \mathrm{SL}(g)$ . It is the closed subgroup of  $G_1$  defined by the equation  $\det(u) = 1$ . It is therefore an affine group over  $S$ .

**Proposition 5.5.** \*The group  $G$  is smooth over  $S$ .\*

<!-- label: III.XIX.5.5 -->

To prove the proposition, we shall need the following lemmas.

**Lemma 5.6.** \*Let  $U$  be the open subset of  $\mathrm{End}_A(g) \simeq W(M_3(O_S))$  defined by the condition "the product  $a d$  is invertible", i.e. the open subset  $\mathrm{End}_A(g)_f$ , where  $f$  is the

function defined by  $f(u) = a \, d$ . Then  $U \cap G$  is the closed subscheme of  $U$  defined by the six equations:\*

```
```text
(1), (2), (2'), (3), (3') and (D) :  $a \, a' - b \, b' = d$ .
```
```

<!-- label: III.XIX.5.6 -->

*\*Proof.\** It is first clear that these six relations are verified by every "point" of  $G$  (Lemma 5.3), in particular by every "point" of  $U \cap G$ . Conversely, it must be shown that if  $u \in U(S')$  (for every  $S' \rightarrow S$ ), and if  $u$  verifies the six conditions of the statement, then  $\det(u) = 1$  and  $u$  also verifies (1'), (4), (4') and (5).

One has first  $(D) \Rightarrow (5)$ . By (2) and (2'), one has

```
```text
 $b \, b' (d + 1) = b \, c \, e' = b' \, c' \, e$ .
```
```

But by (3) and (3'), writing  $2t(b \, c - a \, c')(b' \, c' - a' \, c)$  in two ways:

```
```text
 $(b \, c - a \, c') \, e' = (b' \, c' - a' \, c) \, e$ .
```
```

Combining with the preceding relation, this gives  $a \, c' \, e' = a' \, c \, e$ . But by (1),  $a' \, c \, e = a' \, a (d - 1)$ , which proves  $a (a' (d - 1) - e' \, c') = 0$  and entails (1'), since  $a$  is supposed invertible.

Thus, (1), (2), (2') and (1') are verified, hence by Lemma 5.3 and (D) one has  $d(\det(u) - 1) = 0$ . Since  $d$  is supposed invertible, this entails  $\det(u) = 1$ .

Let us prove (4) and (4'). Let us do it for example for (4'), the other calculation being deduced from it by symmetry.

<!-- original page 29 -->

By (3), (3') and (D), one has at once

```
```text
 $a' \, e + b \, e' = -2t(a \, a' - b \, b') \, c' = -2t \, d \, c'$ .
```
```

Combining (1') and (2), one has also<sup>[N.D.E-XIX-39]</sup>

```
```text
 $a' \, e + b \, e' = -d(b \, e' - e \, a')$ ,
```
```

which completes the proof of (4'),  $d$  being supposed invertible.

**\*Lemma 5.7.\***  $G$  is smooth over  $S$  along the unit section.\*

<!-- label: III.XIX.5.7 -->

*\*Proof.\** By 5.6 and SGA 1, II 4.10, it suffices to prove that the differentials of the functions

```
```text
 $a(d - 1) - e \, c, \quad b(d + 1) - e \, c', \quad b'(d + 1) - e' \, c,$ 
 $e - 2t(b \, c - a \, c'), \quad e' - 2t(b' \, c' - a' \, c), \quad a \, a' - b \, b' - d,$ 
```
```

at the points of the unit section of  $G$  are linearly independent. But denoting by a capital letter the differential of the corresponding lower-case, these are<sup>[N.D.E-XIX-40]</sup>

```
```text
 $D, \quad 2B, \quad 2B', \quad E + 2t \, C', \quad E' + 2t \, C, \quad A + A' - D,$ 
```
```

which are indeed linearly independent modulo every  $(t - \lambda)$ ,  $\lambda \in k$ .<sup>[N.D.E-XIX-41]</sup>

**Lemma 5.8.** For  $s \in S$ ,  $s \neq s_0$ , the fiber  $G_s$  is connected and semisimple.

<!-- label: III.XIX.5.8 -->

**Proof.** <sup>[N.D.E-XIX-42]</sup> Indeed, since  $s \neq s_0$ ,  $\mathfrak{g}(s)$  is isomorphic to the Lie algebra of  $\mathrm{PGL}_2(\kappa(s))$  and, on the other hand, one has  $G_s = (G_1)_s$ ; but it is known that the group of automorphisms of the Lie algebra of  $\mathrm{PGL}_2$  over a field of characteristic 0 is  $\mathrm{PGL}_2$  itself, which is connected and semisimple.

**Lemma 5.9.** The fiber  $G_{s_0}$  is solvable and has two connected components which are of the following form:

```

```text

$$G_{s_0}^+ = \begin{pmatrix} a & 0 & 0 \\ 0 & a^{-1} & 0 \\ c & c' & 1 \end{pmatrix} \quad \text{and} \quad G_{s_0}^- = \begin{pmatrix} 0 & b & 0 \\ b^{-1} & 0 & 0 \\ c & c' & -1 \end{pmatrix}.$$

```

```

<!-- label: III.XIX.5.9 -->

<!-- original page 30 -->

**Proof.** Indeed, one has  $e = e' = 0$ , since  $t = 0$  at  $s_0$ . One then solves immediately the equations (1), (1'), ... (5) and (D).

**Lemma 5.10.** The matrix

```

```text

$$w = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

```

```

is a section of  $G$  over  $S$ , such that  $w(s_0) \in G_{s_0}^-$ .

<!-- label: III.XIX.5.10 -->

Let us now prove 5.5.<sup>[N.D.E-XIX-43]</sup> Denote by  $G^0$  the union of the neutral components of the fibers of  $G$  (that is to say the complement of  $G_{s_0}^-$ ); since  $G$  is smooth over  $S$  along the unit section (5.7),  $G^0$  is an open subgroup of  $G$ , smooth over  $S$ , by VI\_B, 3.10. Since, by translation,  $G$  is evidently smooth at the points of  $w(S)$ ,  $G^0$  is smooth over  $S$ .

**5.11.** Consider the morphism  $G_{m,S} \rightarrow G^0$  defined by

```

```text

$$z \mapsto \begin{pmatrix} z & 0 & 0 \\ 0 & 1/z & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

```

```

It is a monomorphism that defines a torus  $T$  of  $G^0$ . I claim that one has

```

$$
T = \mathrm{Centr}_{\{G\}}(T) = \mathrm{Centr}_{\{G^0\}}(T).
$$

```

It suffices indeed to verify the first equality. Since these are smooth subgroups of  $G$  over  $S$ , it suffices to verify that they have the same geometric points. For the fibers at points  $s \neq s_0$ , this follows from the fact that  $\mathrm{PGL}_2(\kappa(s))$  is reductive and that  $T_s$  is a maximal torus of it for reasons of dimensions (cf. 1.11). On the fiber at  $s_0$ , the computation is done immediately. It follows in particular that  $T$  is a maximal torus of  $G$  and of  $G^0$ .

**5.12.** The section  $w$  of  $G$  defined in 5.9 normalizes  $T$ . It follows at once (cf. 2.4) that the Weyl group of  $G$  is isomorphic to  $(\mathbb{Z}/2\mathbb{Z})_S$ , and in particular finite over  $S$ .

<!-- original page 31 -->

```
```text
W_G(T) = Norm_G(T) / T = (Z/2Z)_S.
```

On the other hand, $W_{G^{\{0\}}}(T)$ is not finite over S : it "lacks a point" above $s_{\{0\}}$.

****5.13.**** The open immersion $G^{\{0\}} \rightarrow G$ is not a closed immersion (since $G^{\{0\}}$ is dense in G); it is however an affine morphism (and therefore $G^{\{0\}}$ is affine over S). Indeed, since $G^{\{0\}}_{s_{\{0\}}}$ is closed in $G_{s_{\{0\}}}$, which is closed in G , the complement U of $G^{\{0\}}_{s_{\{0\}}}$ in G is open; $G^{\{0\}}$ and U form an open covering of G and it suffices to verify that the immersions $G^{\{0\}} \rightarrow G^{\{0\}}$ and $G^{\{0\}} \cap U \rightarrow U$ are affine; for the first this is trivial, for the second, one notes that $U \cap G^{\{0\}}$ is defined in U by the equation $b \neq 0$.

We have therefore constructed an affine smooth S -group, with connected fibers, $G^{\{0\}}$, possessing a maximal torus T which is its own centralizer and whose Weyl group $W_{G^{\{0\}}}(T)$ is not finite (compare with Theorem 2.5).

6. Local existence of maximal tori. The Weyl group

<!-- label: III.XIX.6 -->

In the course of the proof of 2.5, we used a result from Exp. XI on the local existence for the étale topology of maximal tori; the proof of Exp. XI uses a fine representability result (XI 4.1). In the particular case which occupies us, one may give another proof, based on the ideas of Exp. XII no. 7, and of a much more elementary nature.

****Proposition 6.1.**** *Let S be a scheme, G a smooth, affine S -group scheme with connected fibers over S , $s_{\{0\}}$ a point of S such that the maximal tori of the geometric fiber $G_{\bar{s}_{\{0\}}}$ are their own centralizer. There exists an étale morphism $S' \rightarrow S$ covering $s_{\{0\}}$, and a split maximal torus T of $G_{S'}$.*

<!-- label: III.XIX.6.1 -->

<!-- original page 32 -->

Proof. First, one may assume S affine. [N.D.E-XIX-44] Since G is of finite presentation over S , one may assume S noetherian, then local, then henselian with separably closed residue field (cf. EGA IV, 8.12, § 8.8, and § 18.8). Set therefore $S = \operatorname{Spec}(A)$, A henselian with separably closed residue field $k = \kappa(s_{\{0\}})$. Choose a maximal torus $T_{\{0\}}$ of $G_{\{0\}}$ ($= G_{\{k\}}$) (one exists, for example because the scheme of maximal tori of $G_{\{0\}}$ is smooth over k , Exp. XII, 7.1 c)); since k is separably closed, $T_{\{0\}}$ is split (cf. X 1.4) and is therefore given by a monomorphism of groups

```
$$
f_{\{0\}} : G^{\{r\}}_{m,k} \rightarrow G_{\{0\}}.
$$
```

Let m be an integer > 1 prime to the characteristic of k . By Exp. VIII 6.7, for every $h > 0$, $\operatorname{Centr}_{G_{\{0\}}}(\{m^h\}T_{\{0\}})$ is representable by a closed subscheme of $G_{\{0\}}$. Since the $\{m^h\}T_{\{0\}}$ are schematically dense in $T_{\{0\}}$ (cf. Exp. IX 4.10) and $G_{\{0\}}$ is noetherian, there exists an h such that

```
$$
\operatorname{Centr}_{G_{\{0\}}}(\{m^h\}T_{\{0\}}) = \operatorname{Centr}_{G_{\{0\}}}(T_{\{0\}}) = T_{\{0\}}.
$$
```

Put $n = m^h$; since n is invertible on S , $\{n\} G_{\{m,S\}}$ is isomorphic to $(Z/nZ)_{\{S\}}$; $f_{\{0\}}$ therefore defines a monomorphism of groups

```
$$
u_{\{0\}} : (Z/nZ)^{\{r\}}_{\{k\}} \rightarrow G_{\{0\}}
$$
```

such that $\operatorname{Centr}_G(u_{\{0\}}) = T_{\{0\}}$. Now the S -functor

```
$$
\mathcal{P} = \operatorname{Hom}_{S\text{-gr.}}((Z/nZ)^{\{r\}}_{\{S\}}, G)
$$
```

is representable by an S -scheme of finite type (as a closed subscheme of r copies of $\{G = \operatorname{Hom}_{S\text{-gr.}}((Z/nZ)_S, G) = \operatorname{Ker}(G \xrightarrow{n} G)\}$). But $\mathcal{P}$ is smooth over S (Exp. IX 3.6), hence $u_0 \in \mathcal{P}(k)$ lifts to a section $u \in \mathcal{P}(S)$ (Hensel's lemma, Exp. XI 1.11):

<!-- original page 33 -->

S
 $u : (Z/nZ)^r_S \rightarrow G.$
 S

Consider $H = \operatorname{Centr}_G(u)$; it is a closed subgroup scheme of G , by Exp. VIII 6.5 e), and one has $H_0 = T_0$ by hypothesis. [N.D.E.-XIX-45] Moreover, H is smooth over S : indeed, let $S' = \operatorname{Spec}(A)$ be an affine scheme over S , $u' : (\{G_{m,S'}\})^r \rightarrow G_{S'}$ the morphism deduced from u by base change, $S'_J = \operatorname{Spec}(A/J)$, where J is an ideal of square zero, and let $x \in H(S'_J)$; since G is smooth, x lifts to an element g of $G(S')$; then $v = \operatorname{int}(g)(u')$ verifies $v_J = u'_J$ and therefore, by IX 3.2, there exists an element g' of $G(S')$ such that $g'_J = e$ and $\operatorname{int}(g')(v) = u'$; then $h = g'g$ belongs to $H(S')$ and verifies $h_J = x$.

Let then H^0 be the neutral component of H ; it is a subgroup scheme of G , smooth and with connected fibers, whose special fiber is a torus. By Exp. X 8.1, it is a torus, necessarily split (Exp. X 4.6). Put $H^0 = T$ and let $C = \operatorname{Centr}_G(T)$, which is a closed subgroup of G (Exp. VIII 6.5 e)), smooth (Exp. XI 2.4). Consider C^0 (in fact $C^0 = C$, but we do not need to know it); then $C^0 \supset T$ and these are two smooth groups with connected fibers. They coincide at s_0 , hence in a neighborhood. Shrinking S if necessary, one may therefore assume $C^0 = T$, hence *a fortiori* T maximal.

Remark 6.2. The proof shows in particular that the reductive rank of $G_{\bar{s}}$ is constant in a neighborhood of $s = s_0$.

<!-- label: III.XIX.6.2 -->

Proposition 6.3. Let S be a scheme, G an S -group scheme smooth and of finite presentation over S , Q a subtorus of G .

(i) $\operatorname{Centr}_G(Q)$ and $\operatorname{Norm}_G(Q)$ are representable by closed subgroup schemes, smooth (and therefore of finite presentation) over S .

(ii) $\operatorname{Centr}_G(Q)$ is an open and closed subscheme of $\operatorname{Norm}_G(Q)$. The quotient $W_G(Q) = \operatorname{Norm}_G(Q) / \operatorname{Centr}_G(Q)$ is representable by an open subgroup scheme of $\operatorname{Aut}_{S\text{-gr.}}(Q)$; it is therefore an S -group scheme quasi-finite, étale and separated over S .

<!-- original page 34 -->

(iii) For every $s \in S$, put*

S
 $w(s) = \operatorname{Norm}_{G_{\bar{s}}}(Q_{\bar{s}}) / \operatorname{Centr}_{G_{\bar{s}}}(Q_{\bar{s}}).$
 S

Then $s \mapsto w(s)$ is lower semicontinuous, and is constant in a neighborhood of s if and only if $W_G(Q)$ is finite over S in a neighborhood of s .

<!-- label: III.XIX.6.3 -->

Proof. By Exp. XI 6.11, $\operatorname{Centr}_G(Q)$ and $\operatorname{Norm}_G(Q)$ are representable by closed subschemes of finite presentation of G . These are smooth by Exp. XI 2.4 and 2.4 bis, which proves (i). Assertions (ii) and (iii) are then proved as in Exp. XI 5.9 and 5.10, whose proof uses in fact only (i) and not the fine theorems Exp. XI 4.1 and 4.2.

[^N.D.E-XIX-1]: **N.D.E.**: See the bibliographical references at the end of this Exposé. In particular, a re-edition of the **Séminaire Chevalley 1956–58**, cited [Bible], revised by P. Cartier, was published in 2005, cf. [Ch05].

[^N.D.E-XIX-2]: **N.D.E.**: More precisely, Proposition XVIII 2.3 (extension of a "generic homomorphism" between groups) is used in XXII 4.1.11 and then in Exp. XXIII (proof of the uniqueness theorem), and also in Exp. XXIV; Theorem XVIII 3.7 (construction of a group from a group germ) is used only in Exp. XXV.

[^N.D.E-XIX-3]: **N.D.E.**: The reference 9-06 (= Exp. 9, p. 6) has been replaced by § 9.4 (= Exp. 9, § 4), which applies equally well to [Bible] and to [Ch05]. When the numbering of [Ch05] differs from [Bible], which is the case in Exp. 6, both references will be indicated explicitly.

[^N.D.E-XIX-4]: **N.D.E.**: The following has been detailed.

[^N.D.E-XIX-5]: **N.D.E.**: These notations, which figured in 2.3 of the original, have been inserted here; on the other hand, the statement and proof of 1.4 have been detailed.

[^N.D.E-XIX-6]: **N.D.E.**: See also the additions made in VI_B, 6.2.4 (d) and 6.5.5 (a).

[^N.D.E-XIX-7]: **N.D.E.**: 1.6 has been transformed into 1.6.1 to 1.6.3. Note that in this Séminaire every reductive (resp. semisimple, cf. 1.8) k -group is, by definition, connected.

[^N.D.E-XIX-8]: **N.D.E.**: The following has been detailed.

[^N.D.E-XIX-9]: **N.D.E.**: The following sentence has been added.

[^N.D.E-XIX-10]: *N.D.E.*: The following has been detailed.

[^N.D.E-XIX-11]: *N.D.E.*: See also the addition VI_B, 6.2.6.

[^N.D.E-XIX-12]: *N.D.E.*: i.e., the connected component of $\text{\$Ker}(\alpha)$.

[^N.D.E-XIX-13]: *N.D.E.*: Note that if $\text{\$U}$, $\text{\$L}$ are two subgroup schemes of $\text{\$G}$, one has $\text{\`Lie}(\text{\$U} \cap \text{\$L}) = \text{\`Lie}(\text{\$U} \cap \text{\$L})$.

[^N.D.E-XIX-14]: *N.D.E.*: The following sentence has been added.

[^N.D.E-XIX-15]: *N.D.E.*: The following has been added.

[^N.D.E-XIX-16]: *N.D.E.*: The following has been detailed.

[^N.D.E-XIX-17]: *N.D.E.*: The following has been detailed. Note, on the other hand, that section 6 is independent of the rest of this Exposé.

[^N.D.E-XIX-18]: *N.D.E.*: The hypothesis entails that $\text{\$A}$ is locally free of rank 2 , and since the augmentation ideal $\text{\$I}$ is a direct factor of $\text{\$A}$, then, replacing $\text{\$U}$ by a sufficiently small affine open subset $\text{\$operatorname{Spec}}(R)$, one may assume that $\text{\$I} = \Gamma(U, \text{\$I})$ is a free $\text{\$R}$ -module of rank 1 . If $\text{\$x}$ is a generator of $\text{\$I}$, one then has $\text{\$x}^2 = a \text{\$x}$ for a certain $a \in \text{\$R}$, and the hypothesis that $\text{\$A} = \Gamma(U, \text{\$A})$ be étale entails that a is invertible in $\text{\$R}$, and one then sees easily that $\text{\$A}$ is the affine algebra of the constant $\text{\$R}$ -group $\text{\$Z}/2\text{\$Z}$ (compare with the first lines of [T070]).

[^N.D.E-XIX-19]: *N.D.E.*: This paragraph of notations and reminders has been added.

[^N.D.E-XIX-20]: *N.D.E.*: "Split" has been added.

[^N.D.E-XIX-21]: *N.D.E.*: The proof has been detailed.

[^N.D.E-XIX-22]: *N.D.E.*: which is independent of the rest of this Exposé.

[^N.D.E-XIX-23]: *N.D.E.*: In all this volume, "trivial torus" has been replaced by "split torus".

[^N.D.E-XIX-24]: *N.D.E.*: The preceding sentence has been added.

[^N.D.E-XIX-25]: *N.D.E.*: Note that, $\text{\$g}$ being a finite locally free $\text{\`O}_S$ -module, $\text{\$R}$ is a finite set.

[^N.D.E-XIX-26]: *N.D.E.*: The following sentence has been detailed.

[^N.D.E-XIX-27]: *N.D.E.*: This statement has been made into a lemma, in order to put it in evidence.

[^N.D.E-XIX-28]: *N.D.E.*: The original added the hypothesis that $\text{\$G}$ be of finite presentation over $\text{\$S}$, which does not seem to be used in what follows. In any case, $\text{\$G}$ being smooth over $\text{\$S}$ and with connected fibers, it is quasi-compact and separated over $\text{\$S}$ (VI_B, 5.5), hence of finite presentation over $\text{\$S}$.

[^N.D.E-XIX-29]: *N.D.E.*: The original has been simplified; it invoked Exp. IX, 5.2. Let us note, however, that *loc. cit.*, 5.3 shows that if $\text{\$S}$ is connected, then the conditions of the lemma are verified as soon as (i) is verified at one point s of $\text{\$S}$.

[^N.D.E-XIX-30]: *N.D.E.*: The following has been modified, in order to recall the hypotheses of 3.2 and to add that $\text{\$T}$ is a maximal torus.

[^N.D.E-XIX-31]: *N.D.E.*: see SGA 1, VIII 4.4 or EGA IV₂, 2.7.1.

[^N.D.E-XIX-32]: *N.D.E.*: We have kept the original proof; one can also detail it as follows. Let $\text{\$F}$ be a quasi-coherent $\text{\`O}_S$ -module, $\text{\$V} = V(\text{\$F})$. Denote by π the projection $\text{\$V} \rightarrow \text{\$S}$ and ϵ the zero section $\text{\$S} \rightarrow \text{\$V}$. Then $\omega^1_{V/S} = \pi^* F$, whence

(1) $\omega^1_{V/S} = \epsilon^* \Omega^1_{V/S} \simeq \pi^* F = F$,

and therefore $\text{\$Lie}(V/S) = (\omega^1_{V/S})^{V/S} \simeq F^{V/S}$. If one supposes $\text{\$V}$ smooth over $\text{\$S}$ then, by (1), $\text{\$F}$ is locally free

of finite type, and therefore

```
```text
(2) $V = V(F) = W(F^\vee) = W(\mathrm{Lie}(V/S)).$
```
```

Now, if U is an S -scheme equipped with a section $\tau : S \rightarrow U$, and if one is given an isomorphism $\phi : V \rightarrowtail U$ of "pointed" S -schemes, i.e. such that $\phi \circ \epsilon = \tau$ (for example if U is an S -group), then ϕ induces an isomorphism $d\phi : F^{\vee}\{V\} \rightarrowtail \mathrm{Lie}(U/S)$, whence an isomorphism $\psi : W(F^{\vee}\{V\}) \rightarrowtail W(\mathrm{Lie}(U/S))$ making the appropriate diagram commute, which permits one to identify U with $W(\mathrm{Lie}(U/S))$. Since the functor W is fully faithful, there exists a unique isomorphism $\exp : W(\mathrm{Lie}(U/S)) \rightarrowtail U$ such that $\mathrm{Lie}(\psi^{-1} \circ \exp) = \mathrm{id}$. In fact, one can see directly that $\mathrm{Lie}(\psi) = \mathrm{id}$, so that $\exp = \psi$.

[^N.D.E-XIX-33]: *N.D.E.*: For later references, 4.4 has been transformed into 4.4.1 and 4.4.2.

[^N.D.E-XIX-34]: *N.D.E.*: Here, one identifies the vector bundle $W(L)$ with the functor in 0_S -modules that it represents.

[^N.D.E-XIX-36]: *N.D.E.*: cf. N.D.E. (28).

[^N.D.E-XIX-37]: *N.D.E.*: "consider the semi-direct product $T \cdot_{\alpha} W(L)$, resp. $T' \cdot_{\alpha'} W(L')$ " has been removed. On the other hand, the hypothesis in (b) that g be a morphism of groups, combined with $(*)$, amounts to saying that the morphism $(t, x) \mapsto (f(t), g(x))$ is a morphism of groups from $T \cdot_{\alpha} W(L)$ to $T' \cdot_{\alpha'} W(L')$.

[^N.D.E-XIX-38]: *N.D.E.*: The equality $[u(X), u(Y)] = 2 \, t \, u(H)$ (resp. $[u(H), u(X)] = u(X)$, resp. $[u(H), u(Y)] = -u(Y)$) gives the relations (4), (4'), and (5) (resp. (1)–(3), resp. (1')–(3')).

[^N.D.E-XIX-39]: *N.D.E.*: The sign has been corrected.

[^N.D.E-XIX-40]: *N.D.E.*: $A + A' + B$ has been corrected to $A + A' - D$.

[^N.D.E-XIX-41]: *N.D.E.*: " $(t - a)$, $a \in A$ " has been corrected to " $(t - \lambda)$, $\lambda \in k$ ".

[^N.D.E-XIX-42]: *N.D.E.*: The following sentence has been slightly modified.

[^N.D.E-XIX-43]: *N.D.E.*: The following sentence has been modified, by adding the reference to VI_B, 3.10.

[^N.D.E-XIX-44]: *N.D.E.*: The preceding sentence as well as the reference to EGA IV in what follows have been added.

[^N.D.E-XIX-45]: *N.D.E.*: The reference VIII 6.5 e) has been added in what precedes, and the following sentence has been detailed.

[^N.D.E-XIX-35]: *N.D.E.*: Here, one has written $W(L)$ (with W in boldface) since, for an arbitrary 0_S -module L , $W(L)$ is not necessarily representable. But in what follows, L will be assumed locally free of finite rank (and even invertible), in which case the functor is representable by the vector bundle $V(L^{\vee}\{V\})$, and one will denote it simply $W(L)$.

Exposé XX. Reductive groups of semisimple rank 1

<!-- label: III.XX -->

by M. Demazure

<!-- N.D.E.: Version of 13/10/2024 -->

1. Elementary systems. The groups U_{α} and $U_{-\alpha}$

<!-- label: III.XX.1 -->

<!-- original page 35 -->

****Recollection 1.1.**** *Let $S = \operatorname{Spec}(k)$, where k is an algebraically closed field, and let G be a reductive S -group of semisimple rank 1, T a maximal torus (necessarily split) of G . One then has*

$$g = t \otimes g_{\alpha} \otimes g_{-\alpha},$$

where α and $-\alpha$ are the roots of G with respect to T . Moreover, there exist two group monomorphisms

$$p_{\alpha} : G_{\alpha}(S) \rightarrow G \quad \text{and} \quad p_{-\alpha} : G_{-\alpha}(S) \rightarrow G$$

such that

$$t p_{\alpha}(x) t^{-1} = p_{\alpha}(\alpha(t) x) \quad \text{and} \quad t p_{-\alpha}(x) t^{-1} = p_{-\alpha}(\alpha(t)^{-1} x),$$

for every $S' \rightarrow S$ and all $t \in T(S')$, $x \in G_{\alpha}(S')$, and such that the morphism

$$G_{\alpha}(S) \times_S T \times_S G_{-\alpha}(S) \rightarrow G,$$

*defined by $(y, t, x) \mapsto p_{-\alpha}(y) t p_{\alpha}(x)$, is radical and dominant (*Bible*, § 13.4, cor. 2 to th. 3).*

<!-- label: III.XX.1.1 -->

Since the tangent map at the identity is bijective, this morphism is also separable, hence birational; by Zariski's "Main Theorem" (EGA III₁, 4.4.9), it is therefore an open immersion.

****Lemma 1.2.**** *Let S be a scheme, G an S -group scheme, T a torus of G , Q a subtorus of T , α a character of T inducing on Q a non-trivial character on each fiber. Let $p_{\alpha} : G_{\alpha}(S) \rightarrow G$ (resp. $p_{-\alpha} : G_{-\alpha}(S) \rightarrow G$) be a group morphism normalized by T with multiplier α (resp. $-\alpha$). Suppose that the morphism*

<!-- original page 36 -->

$$u : G_{\alpha}(S) \times_S T \times_S G_{-\alpha}(S) \rightarrow G,$$

defined set-theoretically by $u(y, t, x) = p_{-\alpha}(y) t p_{\alpha}(x)$, is an open immersion. Let finally q be an integer ≥ 0 and

$$p : G_{\alpha}(S) \rightarrow G$$

a group morphism such that for every $S' \rightarrow S$ and all $t \in Q(S')$, $x \in G_{\alpha}(S')$ one has

$$\operatorname{int}(t)(p(x)) = p(\alpha(t)^q x).$$

Then there exists a unique $\nu \in G_{\alpha}(S)$ such that $p(x) = p_{\alpha}(\nu x^q)$.

<!-- label: III.XX.1.2 -->

Indeed, let Ω be the image of u and $U = \Omega \setminus \{0\}$. This is an open subset of $G_{\alpha}(S)$ containing the zero section. For every section t of Q , the automorphism of $G_{\alpha}(S)$ defined by multiplication by $\alpha(t)$ leaves U globally fixed. We have $U = G_{\alpha}(S)$; indeed, it suffices to check this when S is the spectrum of an

algebraically closed field k ; then $\alpha : Q(k) \rightarrow k^*$ is surjective, which proves at once that $U(k) \supset k^*$, hence $U = G_{\{a, k\}}$. There therefore exist three morphisms

$$a : G_{\{a, S\}} \rightarrow G_{\{a, S\}}, \quad b : G_{\{a, S\}} \rightarrow T, \quad c : G_{\{a, S\}} \rightarrow G_{\{a, S\}},$$

such that

$$p(x) = p_{-\alpha}(a(x)) b(x) p_{\alpha}(c(x)).$$

The condition on p translates to

$$\begin{aligned} a(\alpha(t) x) &= \alpha(t)^{-q} a(x), \\ b(\alpha(t) x) &= b(x), \\ c(\alpha(t) x) &= \alpha(t)^q c(x). \end{aligned}$$

<!-- original page 37 -->

For the same reason as before, one therefore has for every $S' \rightarrow S$ and every $z \in G_{\{m\}}(S')$,

$$a(z x) = z^{-q} a(x), \quad b(z x) = b(x), \quad c(z x) = z^q c(x),$$

hence

$$z^q a(z) = a(1), \quad b(z) = b(1), \quad c(z) = z^q c(1).$$

Since $G_{\{m, S\}}$ is schematically dense in $G_{\{a, S\}}$, one has at once for every $x \in G_{\{a\}}(S')$, $S' \rightarrow S$:

$$\begin{aligned} x^q a(x) &= a(1) = a(0) = 0, & \text{hence } a &= 0, \\ c(x) &= x^q c(1) = v x^q, & \text{for some } v &\in G_a(S), \\ b(x) &= b(1) = b(0) = e, & \text{hence } b &= e, \end{aligned}$$

which completes the proof.

Definition 1.3. Let S be a scheme. By an S -elementary system* one means a triple (G, T, α) where*

- (i) G is a reductive S -group of semisimple rank 1 (Exp. XIX 2.7),*
- (ii) T is a maximal torus of G ,*
- (iii) α is a root of G with respect to T (Exp. XIX 3.2).*

<!-- label: III.XX.1.3 -->

One thus has a direct sum decomposition (Exp. XIX 3.5)[^{N.D.E-XX-1}]

$$g = t \otimes g_{\alpha} \otimes g_{-\alpha},$$

g_{α} and $g_{-\alpha}$ being locally free of rank one.

1.4. If (G, T, α) is an S -elementary system, then $(G_{\{S'\}}, T_{\{S'\}}, \alpha_{\{S'\}})$ is an S' -elementary system for every $S' \rightarrow S$. If (G, T, α) is an S -elementary system, then $(G, T, -\alpha)$ is also one.

<!-- original page 38 -->

If S is a scheme, G a reductive S -group, T a maximal torus of G , α a root of G with respect to T , then (Exp. XIX 3.9), (Z_{α}, T, α) is an S -elementary system.

Let (G, T, α) be an S -elementary system. The invertible module $\mathcal{O}_G(\alpha)$ is canonically endowed with a T -module structure. One therefore has also a T -module structure on the vector bundle $\mathcal{O}_G(\alpha)$. On the other hand, the inner automorphisms of T define on G a structure of group with group of operators T .

Theorem 1.5. Let (G, T, α) be an S -elementary system.

(i) There exists a unique morphism of groups with group of operators T

$\exp : \mathcal{O}_G(\alpha) \rightarrow G$

which induces on the Lie algebras the canonical morphism $\mathcal{O}_G(\alpha) \rightarrow \mathfrak{g}$.

In other words, $\exp$ is the unique morphism satisfying the following conditions: for every $S' \rightarrow S$ and every $t \in T(S')$, $X, X' \in \mathcal{O}_G(\alpha)(S')$, one has

text
 $\exp(X + X') = \exp(X) \exp(X')$,
 $\text{int}(t)(\exp(X)) = \exp(\alpha(t) X)$,
 $\text{Lie}(\exp)(X) = X$.

(ii) If one defines analogously (in the S -elementary system $(G, T, -\alpha)$)

$\exp : \mathcal{O}_G(-\alpha) \rightarrow G$

then the morphism

text
 $\mathcal{O}_G(-\alpha) \times_S T \times_S \mathcal{O}_G(\alpha) \rightarrow G$

defined set-theoretically by $(Y, t, X) \mapsto \exp(Y) \cdot t \cdot \exp(X)$ is an open immersion.

<!-- label: III.XX.1.5 -->

Suppose we have proved the existence of the desired $\exp$ morphisms, and let us prove the other assertions of the theorem. We first prove (ii). Since both sides are of finite presentation and flat over S , it suffices to do so when S is the spectrum of an algebraically closed field (SGA 1, I 5.7 and VIII 5.5). Let then $S = \text{Spec } k$. Let $X \in \Gamma(S, \mathcal{O}_G(\alpha)^{\otimes n})$, $Y \in \Gamma(S, \mathcal{O}_G(-\alpha)^{\otimes n})$. It suffices to prove that the morphism

<!-- original page 39 -->

text
 $\mathcal{O}_G(\alpha, k) \times_k T \times_k \mathcal{O}_G(-\alpha, k) \rightarrow G, \quad (y, t, x) \mapsto \exp(y) t \exp(x)$

is an open immersion. Now by 1.1 and 1.2, there exist $a, b \in k$ such that

text
 $\exp(y) = p_{-\alpha}(a y) \quad \text{and} \quad \exp(x) = p_{\alpha}(b x)$.

Since $\exp : \mathcal{O}_G(-\alpha) \rightarrow G$ induces a monomorphism on Lie algebras, one has $a \neq 0$; likewise $b \neq 0$, and one is reduced to 1.1.

The uniqueness of the morphism $\exp$ may be proved locally on S ; one then reduces to the case where g_{α} and $g_{-\alpha}$ are free, and one has only to apply 1.2 (with $Q = T$ and $q = 1$).

It remains then to prove the existence of the desired morphism $\exp$. Let us first remark that, by virtue of the theory of faithfully flat descent and the uniqueness assertion just proved, it suffices to demonstrate this existence locally on S for the (fpqc) topology. By the usual arguments using finite presentation, one reduces to the case where S is noetherian, then to the case where it is noetherian local. By virtue of the preceding remark, one can therefore content oneself with proving the existence of the desired morphism $\exp$ when $S = \operatorname{Spec}(A)$, with A a complete noetherian local ring with algebraically closed residue field k . Let then $p_0 : G_{\{a, k\}} \rightarrow G_{\{k\}}$ be a monomorphism of k -groups normalized by $T_{\{k\}}$ with multiplier $\alpha_0 = \alpha \otimes_A k$ (one exists by 1.1). One knows (1.1 and 1.2) that the corresponding morphism $T_{\{k\}} \times_{\alpha_0} G_{\{a, k\}} \rightarrow G_{\{k\}}$ is an immersion, hence in particular a monomorphism. Let us provisionally admit the following two lemmas:

<!-- original page 40 -->

Lemma 1.6. *Let S be a scheme, G an S -group of finite presentation, T an S -torus, α a character non-trivial on each fiber of T , s_0 a point of S . Let*

```
```text
f : T \times_{\alpha} G_{\{a, S\}} \rightarrow G
```
```

be an S -group morphism such that f_{s_0} is a monomorphism and the restriction of f to T is a monomorphism. There exists an open neighborhood U of s_0 such that $f|_U$ is a monomorphism.

<!-- label: III.XX.1.6 -->

Lemma 1.7. *Let A be a complete noetherian local ring with algebraically closed residue field k , (G, T, α) an A -elementary system, $p_0 : G_{\{a, k\}} \rightarrow G_{\{k\}}$ a morphism of k -groups normalized by $T_{\{k\}}$ with multiplier $\alpha \otimes_A k$. There exists a group morphism $p : G_{\{a, A\}} \rightarrow G$ normalized by T with multiplier α .*

<!-- label: III.XX.1.7 -->

Let p be the morphism whose existence is asserted by 1.7. Let $f : T \times_{\alpha} G_{\{a, S\}} \rightarrow G$ be the corresponding morphism. It satisfies the hypotheses of 1.6, hence is a monomorphism; in particular p is a monomorphism. One then concludes by Exp. XIX 4.9.

Proof of 1.6. Denote by $\epsilon : S \rightarrow T \times_{\alpha} G_{\{a, S\}}$ the unit section. Since f is unramified at $\epsilon(s_0)$, it is so at $\epsilon(s)$ for all s in an open neighborhood U of s_0 ; $f|_U$ is therefore unramified (Exp. X 3.5) [N.D.E-XX-3], hence its kernel $\operatorname{Ker}(f)|_U$ is unramified over U . To prove that $f|_U$ is a monomorphism, it suffices therefore [N.D.E-XX-4] to prove that $\operatorname{Ker}(f)|_U$ is radicial over U , which is a set-theoretic question. One is thus reduced to proving:

<!-- original page 41 -->

Lemma 1.8. *Let k be an algebraically closed field; let N be an invariant subgroup of $T \times_{\alpha} G_{\{a, k\}}$ (α a non-trivial character of the torus T), étale over k and such that $N \cap T = \{e\}$. Then $N = \{e\}$.*

<!-- label: III.XX.1.8 -->

One has $\operatorname{int}(t')(t, x) = (t, \alpha(t')x)$. If (t, x) is a point of N , with $x \neq 0$, then $(t, z x)$ is also a point of N for $z \in k^*$, and (t, x) is not isolated; hence N is not quasi-finite. One therefore has set-theoretically $N \subset T$, and we are done.

Proof of 1.7. Let $\mathfrak{m}$ be the radical of A , and $S_n = \operatorname{Spec}(A/\mathfrak{m}^{n+1})$, $n \geq 0$. We first show, by induction on n , that p_0 can be extended for each n to a morphism of S_n -groups

```
```text
p_n : G_{\{a, S_n\}} \rightarrow G_{\{S_n\}}
```
```

normalized by $T_{\{S_n\}}$ with multiplier $\alpha_{\{S_n\}}$, the p_n further satisfying the condition

$p_{n+1} \cdot S_{n+1} \cdot S_n = p_n$.

Let $H = T \cdot_{\alpha} G_{\{a, S\}}$. The morphism $H_{\{S_n\}} \rightarrow G_{\{S_n\}}$ defined by p_n is denoted f_n . Let us admit the following lemma:

Lemma 1.9. *If (G, T, α) is a k -elementary system, k algebraically closed, and if $p : G_{\{a, k\}} \rightarrow G$ is a monomorphism normalized by T with multiplier α , one has*

```text  
 $H^2(T \cdot_{\alpha} G_{\{a, k\}}, g) = 0$ .  
 ```

(One lets $T \cdot_{\alpha} G_{\{a, k\}}$ act on g through the morphism $T \cdot_{\alpha} G_{\{a, k\}} \rightarrow G$ defined by p , and the adjoint representation of G).

<!-- label: III.XX.1.9 -->

Then, by virtue of Exp. III 2.8, f_n extends to a morphism of S_{n+1} -groups

\$\$
 $f'_{n+1} : H_{\{S_{n+1}\}} \rightarrow G_{\{S_{n+1}\}}$.
 \$\$

<!-- original page 42 -->

Now f'_{n+1} and the canonical immersion of $T_{\{S_{n+1}\}}$ into $G_{\{S_{n+1}\}}$ have the same restriction to $T_{\{S_n\}}$. By Exp. III 2.5, there exists an element $g \in G_{\{S_{n+1}\}}$ such that $g \cdot S_{n+1} \cdot S_n = e$ and such that $f_{n+1} = \text{int}(g) \circ f'_{n+1}$ restricts to $T_{\{n+1\}}$ along the canonical immersion of $T_{\{n+1\}}$. Let p_{n+1} be the restriction of f_{n+1} to $G_{\{a, S_{n+1}\}}$. It is a morphism normalized by $T_{\{S_{n+1}\}}$ with multiplier $\alpha_{\{S_{n+1}\}}$, which extends p_n .

One has thus constructed a coherent system (f_n) and one must now algebraize it. Now one has:

Lemma 1.10. *Let A be a complete noetherian local ring, $\mathfrak{m}$ its maximal ideal, $S = \text{operatorname{Spec}}(A)$, $S_n = \text{operatorname{Spec}}(A/\mathfrak{m}^{n+1})$, T an S -torus, α a non-zero character of T , X an affine S -scheme on which T acts. Let T act on $G_{\{a, S\}}$ via α . Let q be an integer ≥ 0 , and let $(f_n)_{n \geq 0}$ be a coherent system of morphisms*

```text  
 $f_n : G_{\{a, S_n\}}^q \rightarrow X_{\{S_n\}}$   
 ```

*of objects with operators $T_{\{S_n\}}$. There exists a unique morphism of objects with operators T *

```text  
 $f : G_{\{a, S\}}^q \rightarrow X$   
 ```

which induces the f_n (compare with Exp. IX 7.1).

<!-- label: III.XX.1.10 -->

Corollary 1.11. *If X is a group with group of operators T and if the f_n are group morphisms, then f is one too.*

<!-- label: III.XX.1.11 -->

It suffices to apply the uniqueness assertion of the lemma to the two morphisms $G^{\{2q\}}_{\{a, S\}} \rightarrow X$ deduced from f in the usual way.

<!-- original page 43 -->

Proof of 1.10. Suppose T split, which is moreover the case in the application of 1.10 to the proof of 1.5. One knows (Exp. I 4.7.3.1) that $X \mapsto A(X)$ realizes an equivalence between the category of affine S -schemes equipped with a T -operation and the opposite category of S -graded algebras of type $M = \text{operatorname{Hom}}_{\{S\text{-gr.}\}}(T, G_{\{m, S\}})$.

One therefore has gradings

```
```text
B = A(X) = \bigoplus_{m \in M} B_m \quad \text{and} \quad C = A(G_{\{a, S\}}^q) = \bigoplus_{m \in M} C_m.
```

One sees at once that each  $C_{\{m\}}$  is free of finite type over  $A$ . (Indeed, one has  $C_{\{m\}} = 0$  if  $m$  is not a multiple of  $\alpha$ , and if  $m = d \alpha$ ,  $C_{\{m\}}$  is isomorphic to the  $A$ -module of homogeneous polynomials of degree  $d$ , in  $q$  variables.) Set

```
```text
B^_m = \lim_n B_m \otimes_A (A/m^{n+1}),
C^_m = \lim_n C_m \otimes_A (A/m^{n+1}),
B^ = \bigoplus_{m \in M} B^_m, \quad C^ = \bigoplus_{m \in M} C^_m.
```

One then has canonical morphisms of M -graded algebras

```
```text
g_B : B \rightarrow B^ \quad \text{and} \quad g_C : C \rightarrow C^.
```

It follows from the remark made above that  $g_{\{C\}}$  is an isomorphism. To give a coherent system  $(f_{\{n\}})$  as in the statement is equivalent to giving a morphism of graded  $A$ -algebras

```
$$
\hat{F} : \hat{B} \rightarrow \hat{C}.
$$
```

To find a morphism  $f$  as in the statement is equivalent to finding a morphism of graded  $A$ -algebras  $F : B \rightarrow C$  rendering commutative the diagram

```
```text
B  \xrightarrow{F}  C
|               |
g_B             g_C
\downarrow       \downarrow
B^ \xrightarrow{F^} C^.
```

Since $g_{\{C\}}$ is an isomorphism, the existence and uniqueness of F are immediate. This proves 1.10.

<!-- original page 44 -->

To complete the proof of 1.5, it remains only to prove 1.9.

1.12. Proof of 1.9. One has $g = t \oplus g_{\{\alpha\}} \oplus g_{\{-\alpha\}}$. As explained in 1.9, consider g as a $(T \cdot_{\{\alpha\}} G_{\{a, k\}})$ -module. It is clear that $t \oplus g_{\{\alpha\}}$ is a submodule of g , the quotient being isomorphic to $g_{\{-\alpha\}}$ as a k -vector space and even as a T -module. It is clear that $G_{\{a, k\}}$ acts trivially on this quotient, which is of dimension 1 (for every group morphism from $G_{\{a, k\}}$ to $G_{\{m, k\}}$ is trivial). Similarly $g_{\{\alpha\}}$ is a submodule of $t \oplus g_{\{\alpha\}}$, the quotient being isomorphic to t as a T -module, $G_{\{a, k\}}$ acting trivially on it. To summarize:

<!-- label: III.XX.1.12 -->

Lemma 1.13. Under the conditions of 1.9, g admits a composition series as $(T \cdot_{\{\alpha\}} G_{\{a, k\}})$ -module whose successive quotients are*

```
$$
g_{\{-\alpha\}}, t, g_{\{\alpha\}},
$$
```

viewed as $(T \cdot_{\{\alpha\}} G_{\{a, k\}})$ -modules via the projection $T \cdot_{\{\alpha\}} G_{\{a, k\}} \rightarrow T$.

<!-- label: III.XX.1.13 -->

One is therefore reduced to computing the cohomology of $T \cdot_{\alpha} G_a, k$ acting via the projection $T \cdot_{\alpha} G_a, k \rightarrow T$ and the character β of T (here $\beta = 0$, α , or $-\alpha$) on $W(k)$.^[^N.D.E-XX-5] Let $k[x_1, \dots, x_n]$ denote the algebra of polynomials over k in n variables and $k_q[x_1, \dots, x_n]$ the subspace of homogeneous polynomials of degree q .

Lemma 1.14. With the preceding notations, one has $H^n(T \cdot_{\alpha} G_a, k) = H^n(C^*_{\alpha, \beta})$, where the complex $C^*_{\alpha, \beta}$ is defined by

<!-- original page 45 -->

```
```text
C^n_{\alpha, \beta} = { k_q[x_1, ..., x_n] if \beta = q \alpha, with q \in \mathbb{N};
 { 0 otherwise,
...

```

\*and\*

```
```text
\delta f(x_1, x_2, ..., x_{n+1}) = f(x_2, ..., x_{n+1})
                                + \sum_{i=1}^n (-1)^i f(x_1, ..., x_i x_{i+1}, ..., x_{n+1})
                                + (-1)^{n+1} f(x_1, ..., x_n).
...

```

<!-- label: III.XX.1.14 -->

Indeed, the functor $M \mapsto H^0(T, M)$ is exact on the category of T -modules (and the $H^q(T, -)$ vanish), by Exp. I 5.3.2. It follows, as in the usual case of group cohomology, that $H^n(T \cdot_{\alpha} G_a, k)$ can be computed as the n -th cohomology group of the complex of cochains of G_a, k in k , invariant under T , i.e. satisfying

```
```text
f(\alpha(t) x_1, ..., \alpha(t) x_n) = \beta(t) f(x_1, ..., x_n).
...

```

This indeed gives the announced complex.

To prove 1.9, it therefore suffices to prove that  $H^2(C^*_{\alpha, \beta}) = 0$  for  $\beta = 0, \alpha, -\alpha$ , which is done at once.

**Remark 1.15.** One can explicitly compute the groups  $H^n(C^*_{\alpha, \beta})$  for  $\beta = q\alpha$  (see M. Lazard, *Lois de groupes et analyseurs*, Annales E.N.S., 1955). In particular, one finds  $H^n(C^*_{\alpha, q\alpha}) = 0$  for  $n > q$ .

<!-- label: III.XX.1.15 -->

**Notations 1.16.** The image of the canonical immersion

```
```text
W(g_{-\alpha}) \times_S T \times_S W(g_{\alpha}) \rightarrow G
...

```

<!-- original page 46 -->

will be denoted Ω . It is an open subset of G containing the unit section. The image of

```
```text
W(g_{-\alpha}), resp. W(g_{\alpha}), resp. W(g_{-\alpha}) \times_S T, resp. T \times_S W(g_{\alpha})
...

```

will be denoted<sup>[^N.D.E-XX-6]</sup>

```
```text

```

$U_{-\alpha}$, resp. U_α , resp. $U_{-\alpha} \cdot T$, resp. $T \cdot U_\alpha$.

Then U_{α} (resp. $U_{-\alpha}$) is a subgroup of G canonically endowed with a vector bundle structure, and one has

$\text{int}(t)(x) = x^{\alpha(t)}$ (resp. $x^{-\alpha(t)}$),

*for every $S' \rightarrow S$, $t \in T(S')$, $x \in U_{\alpha}(S')$ (resp. $x \in U_{-\alpha}(S')$).

<!-- label: III.XX.1.16 -->

One has canonical isomorphisms

$T \cdot U_\alpha \cong T \cdot U_\alpha$ and $T \cdot U_{-\alpha} \cong T \cdot U_{-\alpha}$.

The open set Ω is stable under $\text{int}(T)$: one has

$\text{int}(t')(y \cdot t \cdot x) = y^{-\alpha(t')} \cdot t \cdot x^{\alpha(t')}$.

Corollary 1.17. *One has $\text{Lie}(U_{\alpha} / S) = \mathfrak{g}_{\alpha}$ and $\text{Lie}(U_{-\alpha} / S) = \mathfrak{g}_{-\alpha}$. The isomorphisms*

$W(\mathfrak{g}_{\alpha}) \xrightarrow{\exp} U_{\alpha}$ and $W(\mathfrak{g}_{-\alpha}) \xrightarrow{\exp} U_{-\alpha}$

are those of Exp. XIX 4.2.

<!-- label: III.XX.1.17 -->

Corollary 1.18. *The open set Ω is relatively schematically dense in G (cf. XVIII, § 1).*

<!-- label: III.XX.1.18 -->

Clear by Exp. XVIII, 1.3.[N.D.E-XX-7]

Corollary 1.19. *The center of G is $\text{Centr}(G) = \text{Ker}(\alpha)$. It is therefore a closed subgroup of G , of multiplicative type and of finite type.*

<!-- label: III.XX.1.19 -->

The second assertion follows from the first by Exp. IX 2.7. Let us therefore prove the first. The inner automorphism defined by a section of $\text{Ker}(\alpha)$ acts trivially on Ω (last formula of 1.16), hence on G by 1.18. Conversely, if $g \in G(S)$ centralizes G , then it centralizes T and U_{α} , hence is a section of T (Exp. XIX 2.8) annihilating α ; since this also holds after any base change, one indeed has $\text{Centr}(G) = \text{Ker}(\alpha)$.

Corollary 1.20. *For there to exist a monomorphism $p_{\alpha} : G_{\alpha, S} \rightarrow G$ normalized by T with multiplier α , it is necessary and sufficient that the 0_S -module $\mathfrak{g}_{\alpha}$ be free. More precisely, one has a bijection given by*

$X_{\alpha} \mapsto (x \mapsto \exp(x X_{\alpha}))$ and $p_{\alpha} \mapsto \text{Lie}(p_{\alpha})$

<!-- original page 47 -->

between $\Gamma(S, \mathfrak{g}_{\alpha})^{\times}$ and the set of monomorphisms p_{α} as above (which is also the set of isomorphisms of vector group schemes $G_{\alpha, S} \xrightarrow{\sim} U_{\alpha}$).[N.D.E-XX-8]

<!-- label: III.XX.1.20 -->

****Corollary 1.21.**** *The subgroups U_{α} and $U_{-\alpha}$ of G commute on no fiber.*

<!-- label: III.XX.1.21 -->

Indeed, if $(U_{\alpha})_s$ and $(U_{-\alpha})_s$ commute, then Ω_s is a subgroup of G_s , hence $\Omega_s = G_s$ [N.D.E-XX-9] and G_s is solvable, which contradicts the hypothesis that G_s is reductive of semisimple rank 1.

2. Structure of elementary systems

<!-- label: III.XX.2 -->

****Theorem 2.1.**** *Let S be a scheme, (G, T, α) an S -elementary system. There exists a morphism of 0_S -modules*

$$g_{\alpha} \otimes_{0_S} g_{-\alpha} \rightarrow 0_S, \quad (X, Y) \mapsto \langle X, Y \rangle,$$

and a morphism of S -groups

$$\alpha^* : G_{\{m, S\}} \rightarrow T$$

such that for every $S' \rightarrow S$ and all $X \in \Gamma(S', g_{\alpha} \otimes 0_{S'})$, $Y \in \Gamma(S', g_{-\alpha} \otimes 0_{S'})$ one has the equivalence:

$$\exp(X) \cdot \exp(Y) \in \Omega(S') \iff 1 + \langle X, Y \rangle \in G_m(S'),$$

and under these conditions one has the formula:

$$(F) \quad \exp(X) \cdot \exp(Y) = \exp\left(\frac{Y}{1 + \langle X, Y \rangle}\right) \cdot \alpha^*(1 + \langle X, Y \rangle) \cdot \exp\left(\frac{X}{1 + \langle X, Y \rangle}\right).$$

<!-- label: eq:III.XX.2.1.F -->

Moreover, the morphisms $(X, Y) \mapsto \langle X, Y \rangle$ and α^* are uniquely determined, the former is an isomorphism, hence puts the modules g_{α} and $g_{-\alpha}$ in duality, and one has $\alpha^* \circ \alpha^* = 2$ (squaring in $G_{\{m, S\}}$).

<!-- label: III.XX.2.1 -->

<!-- original page 48 -->

In view of the uniqueness assertions of the theorem, it suffices to do the proof locally on S . One can therefore assume g_{α} and $g_{-\alpha}$ free on S . Take then $X \in \Gamma(S, g_{\alpha}^{\otimes n})$, $Y \in \Gamma(S, g_{-\alpha}^{\otimes n})$ and set $p_{\alpha}(x) = \exp(xX)$, $p_{-\alpha}(y) = \exp(yY)$, for $x, y \in G_{\{a\}}(S')$, $S' \rightarrow S$. By 1.5 and 1.21, it suffices to prove:

****Proposition 2.2.**** *Let S be a scheme, G an S -group, T a torus of G , α a character of T non-trivial on each fiber, $p_{\alpha} : G_{\{a, S\}} \rightarrow G$ (resp. $p_{-\alpha} : G_{\{a, S\}} \rightarrow G$) a group monomorphism normalized by T with multiplier α (resp. $-\alpha$). Suppose that:*

(i) The morphism $G_{\{a, S\}} \times_S T \times_S G_{\{a, S\}} \rightarrow G$ defined by $(y, t, x) \mapsto p_{-\alpha}(y) t p_{\alpha}(x)$ is an open immersion. Denote its image by Ω .

(ii) For every $s \in S$, $(p_{\alpha})_s(G_{\{a, \kappa(s)\}})$ and $(p_{-\alpha})_s(G_{\{a, \kappa(s)\}})$ do not commute.*

Then there exist $\alpha \in \text{Hom}_{S\text{-gr}}(G_m, S)$, uniquely determined, having the following properties: for every $S' \rightarrow S$ and all $x, y \in G_a(S')$, one has

```

```text
p_α(x) p_{-α}(y) ∈ Ω(S') ⇔ 1 + a x y ∈ G_m(S'),
```

```

<!-- original page 49 -->

and, under this condition, one has the formula

```

```text
p_α(x) p_{-α}(y) = p_{-α}(y / (1 + a x y)) · α(1 + a x y) · p_α(x / (1 + a x y)).
```

```

Moreover, α is invertible (i.e. $\alpha \in \text{Hom}_{S\text{-gr}}(G_m, S)$ and $\alpha \circ \alpha^ = 2\text{id}$).

<!-- label: III.XX.2.2 -->

Proof:

A) Consider the morphism

```

G^2_{a, S} → G
```

```

defined by  $(x, y) \mapsto p_\alpha(x) p_{-\alpha}(y)$ . Let  $U$  be the inverse image of  $\Omega$  under this morphism. It is an open subset of  $G^2_{a, S}$  containing  $\emptyset \times_S G_{a, S}$  and  $G_{a, S} \times_S \emptyset$ . There therefore exist uniquely determined  $S$ -scheme morphisms

```

```text
A : U → G_{a, S},    C : U → G_{a, S},    B : U → T
```

```

satisfying the set-theoretic relation:

```

```text
p_α(u) p_{-α}(v) = p_{-α}(A(u, v)) B(u, v) p_α(C(u, v)).
```

```

One has immediately the relations

```

```text
A(0, v) = v,    A(u, 0) = 0,    C(u, 0) = u,    C(0, v) = 0,
B(u, 0) = B(0, v) = e.
```

```

Let  $S'$  be a separated  $S$ -scheme and let  $t \in T(S')$  be a point of  $T$ . Since  $\Omega_{S'}$  is stable under  $\text{int}(t)$ , then, by the last formula of 1.16,  $U_{S'}$  is stable under the automorphism  $(x, y) \mapsto (\alpha(t)x, \alpha(t)^{-1}y)$  of  $G^2_{a, S'}$ , and one has the relations:

```

```text
A(α(t) u, α(t)^{-1} v) = α(t)^{-1} A(u, v),
C(α(t) u, α(t)^{-1} v) = α(t) C(u, v),
B(α(t) u, α(t)^{-1} v) = B(u, v).
```

```

Since  $\alpha$  is faithfully flat, one deduces that for every  $S' \rightarrow S$  and every  $z \in G_m(S')$ ,  $U_{S'}$  is stable under the transformation  $(x, y) \mapsto (zx, z^{-1}y)$  and one has

```

```text
A(z u, z^{-1} v) = z^{-1} A(u, v),
C(z u, z^{-1} v) = z C(u, v),
```

```

$$B(z u, z^{-1} v) = B(u, v).$$

Suppose first that  $v$  is invertible; setting  $z = v$ , one deduces that if  $(u, v)$  is a section of  $U$ , then  $(u v, 1)$  is also one, and one has

$$A(u v, 1) = v^{-1} A(u, v), \quad B(u v, 1) = B(u, v).$$

Let then  $V$  be the open set of  $G^2_{\{a, S\}}$  defined by [N.D.E-XX-10]

$$(u, v) \in V(S') \iff (u, v), (u v, 1) \text{ and } (1, u v) \text{ belong to } U(S').$$

<!-- original page 50 -->

Since  $U$  is an open set of  $G^2_{\{a, S\}}$  containing  $0 \times G_{\{a, S\}}$  and  $G_{\{a, S\}} \times 0$ , then  $V$  is a neighborhood of the zero section of  $G^2_{\{a, S\}}$  and we have just seen that the morphisms

$$(u, v) \mapsto A(u, v) \text{ and } (u, v) \mapsto v A(u v, 1) \\ \text{resp. } (u, v) \mapsto B(u, v) \text{ and } (u, v) \mapsto B(u v, 1)$$

coincide on  $V \cap (G_{\{a, S\}} \times G_{\{m, S\}})$ . Since  $G_{\{a, S\}} \times G_{\{m, S\}}$  is schematically dense in  $G^2_{\{a, S\}}$ , these morphisms therefore coincide on  $V$ .

One knows that  $A(0, 1) = 1$ ; it follows that there exists an open set  $W_1$  of  $G_{\{a, S\}}$  containing the zero section such that for every section  $x$  of  $W_1$ ,  $A(x, 1)$  is invertible; setting  $A(x, 1)^{-1} = F(x)$ , one obtains that if  $(u, v) \in V(S')$  [N.D.E-XX-11] and  $u v \in W_1(S')$ ,  $S' \rightarrow S$ , then  $A(u, v) = v A(u v, 1) = v F(u v)^{-1}$ . Arguing similarly for  $C$ , one obtains that there exists an open set  $W_2$  of  $G_{\{a, S\}}$  containing the zero section, and an element  $E$  [N.D.E-XX-12] of  $0(W_2)^{\times}$ , such that  $C(u, v) = u C(1, u v) = u E(u v)^{-1}$ , if  $(u, v) \in V(S')$  and  $u v \in W_2(S')$ . Consequently, setting  $W = W_1 \cap W_2$ , one obtains:

There exists an open set  $W$  of  $G_{\{a, S\}}$  containing the zero section, and  $S$ -morphisms

$$F : W \rightarrow G_{\{m, S\}}, \quad F(0) = 1, \\ H : W \rightarrow T, \quad H(0) = e, \\ E : W \rightarrow G_{\{m, S\}}, \quad E(0) = 1,$$

such that if  $(u, v) \in V(S')$  and  $u v \in W(S')$ ,  $S' \rightarrow S$ , one has

$$(+)\quad p_{\alpha}(u) p_{-\alpha}(v) = p_{-\alpha}(v F(u v)^{-1}) H(u v) p_{\alpha}(u E(u v)^{-1}).$$

B) Let us now use the associativity of  $G$  to write

$$p_{\alpha}(u) p_{-\alpha}(v) p_{-\alpha}(w) = p_{\alpha}(u) p_{-\alpha}(v + w).$$

There exists an open set  $L$  of  $G^3_{\{a, S\}}$ , containing the unit section, such that  $(u, v, w) \in L(S')$  is equivalent to

$$(u, v) \in V(S'), \quad (u E(u v)^{-1}, w) \in V(S'), \quad (u, v + w) \in V(S'), \\ u v \in W(S'), \quad u w E(u v)^{-1} \in W(S'), \quad u(v + w) \in W(S').$$

Using then the formula (+), one writes at once for  $(u, v, w) \in L(S')$  the relations:

<!-- original page 51 -->

```

```text
(1)  $E(uv + u w) = E(u w E(uv)^{-1}) E(uv),$ 
(2)  $H(uv + u w) = H(u w E(uv)^{-1}) H(uv),$ 
(3)  $(v + w) F(uv + u w)^{-1} = \alpha(H(uv)^{-1}) w F(u w E(uv)^{-1})^{-1} + v F(uv)^{-1}.$ 
```

```

It is immediate from the definition of  $L$  that  $(1, 0, 0) \in L(S)$ . Consider therefore

```

```text
 $L \cap T(1 \times_S G_{\{a, S\}} \times_S G_{\{a, S\}}) = 1 \times_S M;$ 
```

```

$M$  is an open set of  $G^2_{\{a, S\}}$ , containing the section  $(0, 0)$ , and for  $(v, w) \in M(S')$ , one has  $v, w E(v)^{-1}, v + w \in W(S')$  and

```

```text
(1')  $E(v + w) = E(w E(v)^{-1}) E(v),$ 
(2')  $H(v + w) = H(w E(v)^{-1}) H(v),$ 
(3')  $(v + w) F(v + w)^{-1} = \alpha(H(v))^{-1} w F(w E(v)^{-1})^{-1} + v F(v)^{-1}.$ 
```

```

Consider finally the morphism from  $M$  to  $G^2_{\{a, S\}}$  defined set-theoretically by  $(v, w) \mapsto (v, w E(v)^{-1})$ . [N.D.E-XX-13] It preserves the section  $(0, 0)$  and induces an isomorphism of  $M$  onto an open set  $N$  of  $G^2_{\{a, S\}}$  containing the zero section (the inverse isomorphism being given by  $(x, y) \mapsto (x, y E(x))$ ). [N.D.E-XX-14] One has thus proved the following assertion:

There exists an open set  $N$  of  $G^2_{\{a, S\}}$ , containing the zero section, such that if  $(x, y) \in N(S')$ , then  $x, y$  and  $x + y E(x)$  [N.D.E-XX-15] belong to  $W(S')$  and:

```

```text
(1'')  $E(x + y E(x)) = E(x) E(y),$ 
(2'')  $H(x + y E(x)) = H(x) H(y),$ 
(3'')  $(x + y E(x)) F(x + y E(x))^{-1} = x F(x)^{-1} + \alpha(H(x))^{-1} y E(x) F(y)^{-1}.$ 
```

```

C) Arguing similarly with left associativity, one demonstrates the following assertion: [N.D.E-XX-16]

There exists an open set  $N'$  of  $G^2_{\{a, S\}}$ , containing the zero section, such that if  $(x, y) \in N'(S')$ , then  $x, y$  and  $x + y F(x)$  [N.D.E-XX-17] belong to  $W(S')$ , and

<!-- original page 52 -->

```

```text
(4'')  $F(x + y F(x)) = F(x) F(y),$ 
(5'')  $H(x + y F(x)) = H(x) H(y),$ 
(6'')  $(x + y F(x)) E(x + y F(x))^{-1} = x E(x)^{-1} + \alpha(H(x))^{-1} y F(x) E(y)^{-1}.$ 
```

```

We are therefore led to solve the "functional equation" (1'').

**Lemma 2.3.** \*Let  $S$  be a scheme,  $W$  an open set of  $G_{\{a, S\}}$  containing the unit section,  $F : W \rightarrow G_{\{m, S\}}$  an  $S$ -morphism. Suppose that  $F(0) = 1$  and that there exists an open set  $N$  of  $G^2_{\{a, S\}}$  containing the zero section such that for  $(x, y) \in N(S')$ ,  $x, y$ , and  $x + y F(x)$  [N.D.E-XX-17] belong to  $W(S')$  and that one has:

```

```text
(†)  $F(x + y F(x)) = F(x) F(y).$ 
```

```

(i) If  $S$  is the spectrum of a field  $k$ , there exists  $a \in k$  such that  $F(x) = 1 + a x$ .

(ii) If  $a = F'(0) \in \Gamma(S, 0_S)$  is invertible, then  $F(x) = 1 + a x$ .

<!-- label: III.XX.2.3 -->

By the hypotheses, we can differentiate the given equation at  $x = 0$  (resp. at  $y = 0$ ) and we find that

```
```text
(*)      F'(y) (1 + y F'(0)) = F'(0) F(y)      for (0, y) ∈ N(S'),
```
```

resp.

```
```text
F'(x) F(x) = F(x) F'(0)      for (x, 0) ∈ N(S').
```
```

Since  $F$  takes its values in  $G_m$ , the second relation gives us

```
```text
(*')     F'(x) = F'(0)      for (x, 0) ∈ N(S');
```
```

whence, by the first,

```
```text
F'(0)(1 + y F'(0)) = F'(0) F(y)      for (y, 0), (0, y) ∈ N(S').
```
```

If  $a = F'(0)$  is invertible, this gives us

<!-- original page 53 -->

```
```text
F(y) = 1 + a y,
```
```

for  $y$  a section of an open set of  $W$  containing the unit section, hence schematically dense in  $W$ , which proves (ii). This also proves (i) when  $F'(0) \neq 0$ .

If  $F'(0) = 0$ , then, by (\*'),  $F'(x) = 0$  when  $x$  is "near 0", hence  $F' = 0$  by schematic density. If  $k$  is of characteristic 0,  $F$  is a rational fraction with zero derivative, hence constant and equal to  $F(0) = 1$ .

If  $k$  is of characteristic  $p$ , and if  $F$  is not constant, [N.D.E-XX-18] there exists an integer  $n > 0$  and a rational fraction  $F_1 \in k(X)$  such that  $F'_1(X) \neq 0$  and

```
$$
F(X) = F_1(X^{p^n}) = F_1(X)^{p^n}.
$$
```

Substituting in the functional equation, one finds

```
```text
(†_1)    F_1(x + y F_1(x)^{p^n}) = F_1(x) F_1(y).
```
```

Differentiating at  $x = 0$ , one finds

```
$$
(\ast_1) F'_1(y) = F'_1(0) F_1(y),
$$
```

and differentiating (†<sub>1</sub>) at  $y = 0$ , one obtains

```
```text
(*'_1)    F'_1(x) F_1(x)^{p^n} = F_1(x) F'_1(0).
```
```

Since, by hypothesis,  $F'_{1}(X)$  is an invertible element of  $k(X)$ , one deduces from these two equalities that

$$F_{1}(X)^{p^n} = 1,$$

hence  $F_1$  is a constant, contradicting the initial hypothesis. This shows that  $F$  is constant, and equal to  $1 = F(0)$ .

D) Suppose  $S$  is the spectrum of a field. If  $F'(0) = 0$ , then  $F = 1$ . Formula (5') then gives us  $H(x + y) = H(x) H(y)$ , which shows that  $H$  extends to a group morphism  $G_a, S \rightarrow T$  (Exp. XVIII 2.3), which is necessarily constant of value  $e$ . On the other hand, by Lemma 2.3, one will also have  $E(x) = 1 + b x$  for some  $b \in k$ . But then (6'') gives, for  $(x, y) \in N(S')$ ,

$$(x + y) E(x + y)^{-1} = x E(x)^{-1} + y E(y)^{-1},$$

hence, [N.D.E-XX-19] by Exp. XVIII 2.3 again,  $x \mapsto x E(x)^{-1}$  extends to a morphism of  $k$ -groups  $G_a, k \rightarrow G_a, k$ , hence  $x/(1 + b x) = c x$  for some  $c \in k$ , whence  $b = 0$  (and  $c = 1$ ).

<!-- original page 54 -->

This shows that  $F, H, E$  are constant of value  $(1, e, 1)$  in a neighborhood of the unit section, hence everywhere, which by (+) shows that  $U_{\alpha}$  and  $U_{-\alpha}$  commute, contrary to hypothesis (ii).

If  $S$  is now arbitrary, one has therefore proved that  $F'(0)$  is non-zero on no fiber, hence is invertible. The same evidently holds for  $E'(0)$ , which by Lemma 2.3 shows that there exist  $a, b \in G_m(S)$  such that

$$(\clubsuit_1) \quad F(x) = 1 + a x, \quad E(x) = 1 + b x, \quad \text{for } x \in W(S').$$

E) The rest is now easy. Substituting the preceding results into (3''), one finds

$$y \alpha(H(x)) (1 + a y) = y (1 + a x + a y(1 + b x)) (1 + a x).$$

This formula is valid for every section  $(x, y)$  of  $N$ . But since  $G_a, S \times_S G_m, S$  is schematically dense in  $G^2_a, S$ , one deduces

$$(1 + a y) \alpha(H(x)) = (1 + a x + a y(1 + b x)) (1 + a x).$$

Setting  $y = 0$ , this gives  $\alpha(H(x)) = (1 + a x)^2$ . Substituting this into the preceding equality, one finds [N.D.E-XX-20]

$$a^2 x y = a b x y.$$

Since  $G_m, S$  is schematically dense in  $G_a, S$ , one deduces  $a^2 = a b$ , whence, since  $a$  is invertible,

$$(\clubsuit_2) \quad a = b \quad \text{and} \quad \alpha(H(x)) = (1 + a x)^2.$$

Since  $a$  is invertible,  $x \mapsto 1 + a x$  is an automorphism of  $G_a, S$ ; one can therefore find an open set  $W'$  of  $G_a, S$  containing the section  $1$  and a morphism

$$P : W' \rightarrow T$$

such that  $P(1 + a x) = H(x)$ . [N.D.E-XX-21]

Substituting in the relation (2'), one finds at once for  $(x, y) \in N(S)$ ,

```
```text
P(1 + a x + a y) = P((1 + a x + a y) / (1 + a x)) P(1 + a x),
```
```

which proves that there exists an open neighborhood of  $1$  in  $G_{\{m, S\}}$  such that one has for  $x$  and  $y$  in this neighborhood  $P(x) P(y) = P(x y)$ . By Exp. XVIII 2.3, there exists a group morphism

```
```text
(♦3)  $\alpha : G_{\{m, S\}} \rightarrow T$ 
```
```

<!-- original page 55 -->

extending  $P$ . Since  $\alpha(H(x)) = (1 + a x)^2$  near the section  $0$ , one has  $\alpha(\alpha^*(z)) = z^2$  near the section  $1$ , hence

```
```text
(♦4)  $\alpha \circ \alpha^* = 2.$ 
```
```

F) [N.D.E-XX-22] Assembling the results (+) and  $(\diamond_1 - \diamond_4)$ , one sees that there exist  $a \in G_{\{m\}}(S)$  and  $\alpha^* \in \operatorname{Hom}_{\{S\text{-gr.}\}}(G_{\{m, S\}}, T)$  such that  $\alpha \circ \alpha^* = 2$  and that, if  $(u, v) \in V(S)$  and  $u v \in W(S)$ , then  $1 + a u v$  is invertible and

```
```text
p- $\alpha(u)$  p- $\alpha(v)$  = p- $\alpha(v / (1 + a u v)) \cdot \alpha^*(1 + a u v) \cdot p_{-}\alpha(u / (1 + a u v)).$ 
```
```

Consider the open set  $V'$  of  $G^2_{\{a, S\}}$  defined by " $1 + a u v$  invertible", i.e.  $V' = (G^2_{\{a, S\}})_{\{f\}}$  where  $f(u, v) = 1 + a u v$ . The two sides of the preceding formula define morphisms from  $V'$  to  $G$  which coincide in a neighborhood of the section  $0$ , hence coincide on  $V'$ . The preceding formula is therefore valid for every section  $(u, v)$  of  $V'$ . In particular, it follows that  $V' \subset U$ , where  $U$  is the open set introduced at the beginning of A).

Let us prove that  $U = V'$ . Returning to the notations of A), one has a morphism

```
```text
A : U → G{a, S}
```
```

which, on  $V'$ , is defined by  $A(u, v) = v (1 + a u v)^{-1}$ . To show that  $U = V'$ , which is a set-theoretic question, one is reduced to the case where  $S$  is the spectrum of a field  $k$ , hence to the obvious assertion: the domain of definition of the rational map  $G^2_{\{a, k\}} \rightarrow G_{\{a, k\}}$  defined by the rational fraction  $Y / (1 + a X Y)$  is the open set defined by the function  $1 + a X Y$ .

G) One has thus proved the existence of  $a$  and  $\alpha^*$ , as well as the two additional properties announced. It remains to prove uniqueness. Let then  $a'$  and  $\alpha'^*$  also satisfy the required conditions. If  $u, v \in G_{\{a\}}(S)^2$ , one has at once:

<!-- original page 56 -->

```
```text
1 + a u v invertible ⇒ 1 + a' u v invertible and v / (1 + a u v) = v / (1 + a' u v);
```
```

one therefore has for every section  $u$  of  $G_{\{a\}}(S)$

```
```text
1 + a u invertible ⇒ 1 + a u = 1 + a' u,
```
```

which proves at once  $a = a'$ .

With the same notations, one then has

```
```text
1 + a u invertible  $\Rightarrow \alpha(1 + a u) = \alpha'(1 + a u),$ 
```
```

hence also  $\alpha' = \alpha$ .

**Corollary 2.4.** Let  $\exp(Y) t \exp(X)$  and  $\exp(Y') t' \exp(X')$  be two elements of  $\Omega(S)$ . Then their product is in  $\Omega(S)$  if and only if  $u = 1 + \langle X, Y' \rangle$  is invertible, and one has then\*

```
```text
(F')  $\exp(Y) t \exp(X) \cdot \exp(Y') t' \exp(X') =$ 
 $\exp(Y + u^{-1} \alpha(t)^{-1} Y') \cdot t t' \alpha(u) \cdot \exp(u^{-1} \alpha(t')^{-1} X + X').$ 
```
```

<!-- label: III.XX.2.4 -->

**Remark 2.5.** One can also write formula (F) of Theorem 2.1 without invoking the morphisms  $\exp$ . Indeed, transporting through these morphisms the duality  $g_{\alpha} \otimes g_{-\alpha} \rightarrow 0_S$ , one obtains a canonical pairing of vector bundles:\*

```
```text
 $U_{\alpha} \times_S U_{-\alpha} \rightarrow G_{\alpha}, S,$ 
```
```

which we shall still denote  $(x, y) \mapsto \langle x, y \rangle$ . One therefore has\*

```
```text
 $\langle \exp X, \exp Y \rangle = (X, Y).$ 
```
```

If  $x \in U_{\alpha}(S)$ ,  $y \in U_{-\alpha}(S)$  and if  $1 + \langle x, y \rangle \in G_m(S)$ , one has\*

```
```text
(F)  $x \cdot y = y^{\{(1 + \langle x, y \rangle)^{-1}\}} \cdot \alpha(1 + \langle x, y \rangle) \cdot x^{\{(1 + \langle x, y \rangle)^{-1}\}}.$ 
```
```

<!-- label: III.XX.2.5 -->

**Corollary 2.6.** The pairing\*

```
```text
 $W(g_{\alpha}) \times_S W(g_{-\alpha}) \rightarrow G_{\alpha}, S$ 
```
```

<!-- original page 57 -->

defines a pairing of principal  $G_m, S$ -bundles\*

```
```text
 $W(g_{\alpha})^{\times} \times_S W(g_{-\alpha})^{\times} \rightarrow G_m, S.$ 
```
```

This pairing will be denoted  $(X, Y) \mapsto \langle X, Y \rangle$ , or more simply  $(X, Y) \mapsto X Y$ .

<!-- label: III.XX.2.6 -->

For every section  $X \in \Gamma(S, g_{\alpha})^{\otimes}$ , there therefore exists a unique section  $X^{-1}$  of  $\Gamma(S, g_{-\alpha})^{\otimes}$  such that  $X X^{-1} = 1$ . One has  $(z X)^{-1} = z^{-1} X^{-1}$ . The morphism

\$\$

$s : W(g_{-\alpha})^{\times} \rightarrow W(g_{-\alpha})^{\times}$   
 $s$

thus defined is therefore an isomorphism of schemes, compatible with the isomorphism  $s : z \mapsto z^{-1}$  on the operator groups.

**Definition 2.6.1.** One says that  $X$  and  $s(X) = X^{-1}$  are paired.

<!-- label: III.XX.2.6.1 -->

Apply Corollary 2.4 to  $Y = 0 = X'$  and  $Y' = a X^{-1}$ ,  $a \in O_S(S)$ . Then  $u = 1 + a$  and  $u^{-1} Y' = u^{-1}(u - 1) X^{-1} = (1 - u^{-1}) X^{-1}$ , whence:

**Corollary 2.7.** Let  $X \in \Gamma(S, g_{-\alpha})^{\times}$  and  $u \in \Gamma(S, O_S)^{\times}$ . One has\*

text  
 $\alpha^*(u) = \exp((u^{-1} - 1) X^{-1}) \exp(X) \exp((u - 1) X^{-1}) \exp(-u^{-1} X).$   
 text

<!-- label: III.XX.2.7 -->

**Definition 2.8.** The morphism  $\alpha$  is called the coroot associated with the root  $\alpha$ .

<!-- label: III.XX.2.8 -->

**Remark 2.9.** If  $(G, T, \alpha)$  is an  $S$ -elementary system,  $(G, T, -\alpha)$  is also one. By Theorem 2.1 one therefore has a duality between  $g_{-\alpha}$  and  $g_{\alpha}$ , and a coroot  $\alpha(-\alpha)$ . Taking the inverse of formula (F), one proves at once\*

text  
 $\langle X, Y \rangle = \langle Y, X \rangle, \quad (-\alpha)^* = -\alpha^*.$   
 text

<!-- label: III.XX.2.9 -->

Let us now pass to the Lie algebra of  $G$ . The root  $\alpha$  and the coroot  $\alpha^*$  define the linear forms

text  
 $O_S \xrightarrow{\alpha^*} t \xrightarrow{\alpha} O_S.$   
 text

<!-- original page 58 -->

One will denote  $H_{\alpha} = \alpha^*(1)$ . One calls  $\alpha$  the infinitesimal root associated with  $\alpha$ , and  $H_{\alpha}$  the corresponding infinitesimal coroot\*.

**Lemma 2.10.** Let  $S' \rightarrow S$  and  $X, X' \in W(g_{\alpha})(S')$ ,  $H \in W(t)(S')$ ,  $Y, Y' \in W(g_{-\alpha})(S')$ ,  $t \in T(S')$ . One has\*

text  
 (1)  $\text{Ad}(t) H = H, \quad \text{Ad}(t) X = \alpha(t) X, \quad \text{Ad}(t) Y = \alpha(t)^{-1} Y.$   
 text

text  
 (2)  $\begin{cases} \text{Ad}(\exp(X)) H = H - \alpha(H) X, & \text{Ad}(\exp(X)) X' = X', \\ \text{Ad}(\exp(X)) Y = Y + \langle X, Y \rangle H_{\alpha} - \langle X, Y \rangle X. \end{cases}$   
 text

text  
 (2')  $\begin{cases} \text{Ad}(\exp(Y)) H = H + \alpha(H) Y, & \text{Ad}(\exp(Y)) Y' = Y', \\ \text{Ad}(\exp(Y)) X = X + \langle X, Y \rangle H_{-\alpha} - \langle X, Y \rangle Y. \end{cases}$   
 text

text  
 (3)  $[H, X] = \alpha(H) X, \quad [H, Y] = -\alpha(H) Y, \quad [X, Y] = \langle X, Y \rangle H_{\alpha}.$

...

\$\$  
(4)  $H_{-\alpha} = -H_{\alpha}$ .  
\$\$

\$\$  
(5)  $\alpha(H_{\alpha}) = 2$ .  
\$\$

<!-- label: III.XX.2.10 -->

The proof of these various formulas is either trivial or an immediate consequence of formula (F) of 2.1.

**Corollary 2.11.** Suppose  $H_{\alpha}$  is non-zero on every fiber (which is in particular the case if  $\alpha^2$  is invertible on  $S$ , by (5)). Then  $X_{\alpha} \in \Gamma(S, g_{\alpha}^{\otimes 2})$  and  $X_{-\alpha} \in \Gamma(S, g_{-\alpha}^{\otimes 2})$  are paired if and only if  $[X_{\alpha}, X_{-\alpha}] = H_{\alpha}$ .

<!-- label: III.XX.2.11 -->

<!-- original page 59 -->

**2.12.** Let  $(G, T, \alpha)$  be an elementary system. We know (1.19) that the center of  $G$  is  $\text{Centr}(G) = \text{Ker}(\alpha)$ , a group of multiplicative type and of finite type. If  $Q$  is a subgroup of multiplicative type of  $\text{Centr}(G)$ , the quotient  $G/Q$  is affine over  $S$  (Exp. IX 2.5), smooth over  $S$  (Exp. VI\_B 9.2) with connected reductive fibers of semisimple rank 1 (Exp. XIX 1.8).

Set  $G' = G/Q$ ; this is a reductive group of semisimple rank 1;  $T' = T/Q$  is a maximal torus of it. The open set  $U_{-\alpha} \cdot T \cdot U_{\alpha}$  of  $G$  is stable under  $Q$ , and one sees at once that the quotient is isomorphic to  $U_{-\alpha} \cdot T' \cdot U_{\alpha}$  of  $G'$ . If one denotes by  $\alpha'$  the character of  $T'$  induced by  $\alpha$ , it follows that the morphism derived from the canonical morphism  $G \rightarrow G'$  induces isomorphisms

text  
 $g_{\alpha} \longrightarrow g'_{\alpha}$  and  $g_{-\alpha} \longrightarrow g'_{-\alpha}$ .

In particular,  $\alpha'$  is a root of  $G'$  with respect to  $T'$ . Hence, denoting by  $\alpha/Q$  the character  $T/Q \rightarrow G_m$  induced by  $\alpha$ , one has:

**Lemma 2.13.** If  $Q$  is a subgroup of multiplicative type of  $\text{Ker}(\alpha)$ , then

\$\$  
(G/Q, T/Q, \alpha/Q)  
\$\$

is an elementary system.

<!-- label: III.XX.2.13 -->

<!-- original page 60 -->

**Lemma 2.14.** Under the preceding conditions, the following diagrams are commutative:

text  

$$\begin{array}{ccccc} W(g_{\alpha}) & \xrightarrow{\text{exp}} & G & \xleftarrow{\text{exp}} & W(g_{-\alpha}) \\ \downarrow \text{can } \square & & \downarrow \text{can} & & \downarrow \text{can } \square \\ W(g'_{\alpha}) & \xrightarrow{\text{exp}} & G' & \xleftarrow{\text{exp}} & W(g'_{-\alpha}) \end{array}$$

text  

$$\begin{array}{ccc} g_{\alpha} \otimes g_{-\alpha} & \longrightarrow & 0_S \\ \downarrow \text{can } \square & & \downarrow \text{id} \end{array}$$

$$g'_{\alpha'} \otimes g'_{-\alpha'} \xrightarrow{\quad} 0_S$$

```

```text

      |               \nearrow  \searrow
G_{m, S}  \downarrow  can  \uparrow  G_{m, S}
      \alpha^* \searrow \nearrow \alpha'
      T'
```

```

<!-- label: III.XX.2.14 -->

### ## 3. The Weyl group

<!-- label: III.XX.3 -->

<!-- original page 60 -->

**Notations 3.0.** <sup>[N.D.E-XX-23]</sup> If  $(G, T, \alpha)$  is an  $S$ -elementary system, one will denote

```

```text
N = Norm_G(T),    W = Norm_G(T) / T,
```

```

(cf. Exp. XIX 6.3);  $N$  is a closed subgroup of  $G$ , smooth over  $S$ . One will denote by  $N^{\times} = N - T$  the open subscheme of  $N$  induced on the complement of  $T$ . <sup>[N.D.E-XX-24]</sup> Let  $R$  be the (unique) maximal torus of  $\text{Ker}(\alpha)$ , and  $T'$  the image of  $\alpha^* : G_{m, S} \rightarrow T$ , which is a subtorus of dimension 1 of  $T$ .

The morphism

```

```text
T' \times_S R \rightarrow T
```

```

induced by the product in  $T$  is surjective (hence faithfully flat); indeed, one is reduced to checking this on the geometric fibers, and this follows at once from the formula  $\alpha \circ \alpha^* = 2$ .

**Theorem 3.1.** \*With the preceding notations:\*

(i)  $W$  is isomorphic to the constant group  $(\mathbb{Z}/2\mathbb{Z})_S$ .

<!-- original page 61 -->

(ii)  $N^{\times}$  is a principal homogeneous bundle locally trivial under  $T$ , on the left by the law  $(t, q) \mapsto tq$  (resp. on the right by the law  $(q, t) \mapsto qt$ ).

(iii) One has the formula\*

```

```text
int(w) t = t \cdot \alpha(\alpha(t)^{-1})
```

```

\*for  $w \in N^{\times}(S)$ ,  $t \in T(S)$ ,  $S' \rightarrow S$ . In the decomposition  $T_{S'} = T'_{S'} \cdot R_{S'}$ ,  $\text{int}(w)$  induces the identity on  $R_{S'}$  and the symmetry on  $T'_{S'}$ . One has the relations\*

```

```text
\alpha \circ \text{int}(w) = \alpha^{-1},    \text{int}(w) \circ \alpha^* = (\alpha^*)^{-1}.
```

```

(iv) For  $X \in W(g_{\alpha})^{\times}(S)$ ,  $S' \rightarrow S$ , set\*

```

```text
w_α(X) = exp(X) exp(-X⁻¹) exp(X).

*Then $w_{\alpha}(X) \in N^{\times}(S')$ and the morphism $w_{\alpha} : W(g_{\alpha})^{\times} \to N^{\times}$ thus
defined satisfies*

```text
w_α(z X) = α*(z) w_α(X) = w_α(X) α*(z)⁻¹,

for $z \in G_m(S')$, $X \in W(g_{\alpha})^{\times}(S')$, $S' \to S$.

(v)[^N.D.E-XX-25] For $X, Y \in W(g_{\alpha})^{\times}(S')$, $S' \to S$, one has, with the notations of 2.6,

```text
w_α(X) w_α(Y) = αv(-X Y⁻¹).

*In particular,*

```text
w_α(X)² = α*(-1) ∈ ₂T(S) ∩ Centr(G)(S),
w_α(X)⁻¹ = w_α(-X) = α*(-1) w_α(X).

(vi) If one defines analogously, for $Y \in W(g_{-\alpha})^{\times}(S')$,

```text
w_{-α}(Y) = exp(Y) exp(-Y⁻¹) exp(Y),

*one has (in addition to formulas analogous to the preceding)*

```text
w_{-α}(X⁻¹) = w_α(X)⁻¹ = w_α(-X),
w_α(X) w_{-α}(Y) = α*(X Y).

<!-- label: III.XX.3.1 -->

Proof. (i) has already been seen in Exp. XIX 2.4; it follows at once that $N^{\times}$ is indeed a principal
homogeneous bundle under T for the laws defined in (ii); the fact that it is locally trivial (for the Zariski
topology) follows notably from (iv).

<!-- original page 62 -->

Let us prove (iii); if $w \in N^{\times}(S)$, it is clear that $\alpha \circ \text{int}(w)$ is a root of G with respect to
T, hence is locally equal to α or $-\alpha$; since on each fiber it is $-\alpha$ (*Bible*, 12-05, proof of the
corollary to prop. 1), one has $\alpha \circ \text{int}(w) = -\alpha$. By transport of structure, one deduces

```text
-α* = int(w)⁻¹ ∘ α* = int(w) ∘ α*,

since $\text{int}(w)^2 = \text{int}(w^2)$ and $w^2$ is a section of $T$. Therefore $\text{int}(w)$ induces the symmetry on $T'$; since
$R$ is central, $\text{int}(w)$ induces the identity on $R$. The formula of (iii) defines a morphism $T \to T$ which satisfies
the same properties, hence coincides with $\text{int}(w)$.

Let us prove (iv). One has successively

```text
w_α(X) t w_α(X)⁻¹ = exp(X) exp(-X⁻¹) exp(X) t exp(-X) exp(X⁻¹) exp(-X)
= exp(X) exp(-X⁻¹) exp(X - α(t) X) exp(α(t)⁻¹ X⁻¹) exp(-α(t) X) t.
```

```

By application of formula (F), one has

```
```text
exp(-X^{-1}) exp((1 - \alpha(t)) X) = exp((\alpha(t)^{-1} - 1) X) \alpha^*(\alpha(t)^{-1}) exp(-\alpha(t)^{-1} X^{-1}).
```
```

Substituting in the preceding relation, one finds

```
```text
int(w_{\alpha}(X)) t = exp(\alpha(t)^{-1} X) \alpha^*(\alpha(t)^{-1}) exp(-\alpha(t) X) t
 = exp(a X) \alpha^*(\alpha(t)^{-1}) t,
```
```

where

```
```text
a = \alpha(t)^{-1} - (\alpha \circ \alpha^*)(\alpha(t)^{-1}) \alpha(t),
```
```

but $\alpha \circ \alpha^* = \text{id}$, which gives at once $a = 0$ and $w_{\alpha}(X) \in N^{\times}(S)$.

Let us prove the second assertion of (iv). One has [N.D.E-XX-26]

```
```text
\alpha^*(z) w_{\alpha}(X) = exp(z^2 X) exp(-z^{-2} X^{-1}) exp(z^2 X) \alpha^*(z)
 = exp(z X) exp((z^2 - z) X) exp(-z^{-2} X^{-1}) exp(z^2 X) \alpha^*(z)
 = exp(z X) exp(-z^{-1} X^{-1}) \alpha^*(z)^{-1} exp((z^3 - z^2) X) exp(z^2 X) \alpha^*(z)
 = exp(z X) exp(-z^{-1} X^{-1}) exp(z X) = w_{\alpha}(z X).
```
```

<!-- original page 63 -->

Let us prove (v). By virtue of the preceding result, the first formula of (v) follows at once from the second; let us prove the second:

```
```text
w_{\alpha}(X)^2 = exp(X) exp(-X^{-1}) exp(2 X) exp(-X^{-1}) exp(X)
 = exp(X) exp(-X^{-1}) exp(X^{-1}) \alpha^*(-1) exp(-2 X) exp(X)
 = exp(X) \alpha^*(-1) exp(-X) = \alpha^*(-1),
```
```

since $\alpha(\alpha^*(-1)) = (-1)^2 = 1$, which proves that $\alpha^*(-1) \in \text{Centr}(G)(S)$.

Let us prove (vi). The first assertion is a particular case of the second; let us prove the second. Both sides of this formula define morphisms $W(g_{\alpha})^{\times} \times_S W(g_{-\alpha})^{\times} \rightarrow G$. To prove that they coincide, it suffices to do so on a non-empty open set on each fiber (Exp. XVIII 1.4); it therefore suffices to verify the relation when $1 + X Y$ is invertible. One then has successively:

```
```text
w_{\alpha}(X) w_{-\alpha}(Y) = exp(X) exp(-X^{-1}) exp(X) exp(Y) exp(-Y^{-1}) exp(Y)
 = exp(X) exp(-X^{-1}) exp(Y / (1 + X Y)) \alpha^*(1 + X Y) exp(X / (1 + X Y)) exp(-Y^{-1}) exp(Y)
 = exp(X) exp(-X^{-1} / (1 + X Y)) \alpha^*(1 + X Y) exp(-Y^{-1} / (1 + X Y)) exp(Y)
 = exp(-X^{-2} Y^{-1}) \alpha^*(X Y / (1 + X Y)) exp(X + Y^{-1}) \alpha^*(1 + X Y) exp(-Y^{-1} / (1 + X Y)) exp(Y)
 = exp(-X^{-2} Y^{-1}) \alpha^*(X Y) exp((Y^{-1} + X) / (1 + X Y)^2) exp(-Y^{-1} / (1 + X Y)) exp(Y)
 = \alpha^*(X Y) exp(-Y) exp(Y) = \alpha^*(X Y).
```
```

<!-- original page 64 -->

Corollary 3.2. *Let $n \in \mathbb{Z}$, $n \neq 0$. For every $w \in G(S)$, the following conditions are equivalent:*

(i) $w \in N^{\times}(S)$,

*(ii) one has $\int(w) \circ n \alpha = -n \alpha$ (recall that $(n \alpha)(z) = \alpha(z)^n$).

<!-- label: III.XX.3.2 -->

One has (i) $\Rightarrow$ (ii) (assertion (iii) of Theorem 3.1); conversely, one may suppose that $N^\times$ admits a section, and one is reduced to proving:

Lemma 3.3. One has $\text{Centr}_G(n \alpha) = T$ for $n \neq 0$.

<!-- label: III.XX.3.3 -->

Indeed, the image T' of $n \alpha$ is a subtorus of G . It follows (Exp. XIX 2.8) that $\text{Centr}_G(n \alpha)$ is a reductive subgroup of G containing T . Since on each fiber one has $\text{Centr}_{G_s}(n \alpha_s) \neq G_s$, then $\text{Centr}_{G_s}(n \alpha_s) = T_s$ (Exp. XIX 1.6.3) [N.D.E-XX-27], hence $\text{Centr}_G(n \alpha) = T$, since these are smooth subgroups of G .

Remark 3.4. The construction of w_α and the fact that $w_\alpha(X)$ normalizes T rely only on formula (F). In particular, if G is an S -group satisfying the conditions of 2.2, $\text{Norm}_G(T)$ differs from T on each fiber. It follows that if G is an affine S -group with connected fibers satisfying the conditions of 2.2, it is reductive of semisimple rank 1. Indeed, it is smooth in a neighborhood of the unit section, hence smooth, and one can apply the criterion of Exp. XIX 1.11.

<!-- label: III.XX.3.4 -->

3.5. Before stating the following theorem, let us make a few remarks. We identify as usual $g_{-\alpha}$ with $(g_\alpha)^{\otimes -1}$. Similarly, we shall identify $\text{Hom}_{\{0\}}(g_{-\alpha}, g_\alpha)$ with $(g_\alpha)^{\otimes 2}$ and hence

<!-- original page 65 -->

$$\text{Isom}_{\{0\}\text{-mod.}}(W(g_{-\alpha}), W(g_\alpha)) \cong W((g_\alpha)^{\otimes 2})^{\otimes}.$$

If $w \in N^\times(S)$, then $\text{Ad}(w)$ permutes g_α and $g_{-\alpha}$ (3.1, (iii)), hence defines an isomorphism:

$$a_\alpha(w) : g_{-\alpha} \longrightarrow g_\alpha,$$

which we shall therefore identify with a section $a_\alpha(w) \in \Gamma(S, (g_\alpha)^{\otimes 2})^{\otimes}$. This construction is compatible with base change and therefore defines a morphism

$$a_\alpha : N^\times \rightarrow W((g_\alpha)^{\otimes 2})^{\otimes},$$

such that $a_\alpha(w) Y = \text{Ad}(w) Y$ for all $w \in N^\times(S')$, $Y \in \Gamma(S', (g_{-\alpha})^{\otimes})$, $S' \rightarrow S$.

Theorem 3.6. (i) One has

$$\int(w) \exp(Y) = \exp(a_\alpha(w) Y)$$

for every $S' \rightarrow S$ and all $w \in N^\times(S')$, $Y \in W(g_{-\alpha})(S')$.

(ii) One has

$$a_\alpha(t w) = \alpha(t) a_\alpha(w), \quad a_\alpha(w t) = \alpha(t)^{-1} a_\alpha(w).$$

(iii) If one defines analogously $a_{-\alpha} : N^{\times} \rightarrow W((g_{-\alpha})^{\otimes 2})^{\times}$, one has

$$a_{-\alpha}(w) = a_{\alpha}(w)^{-1}.$$

[^N.D.E-XX-28]

(iv) For every $X \in W(g_{\alpha})^{\times}(S')$, $S' \rightarrow S$, one has

$$a_{\alpha}(w_{\alpha}(X)) = -X^2.$$

<!-- label: III.XX.3.6 -->

<!-- original page 66 -->

Assertion (i) is trivial, by the characterization of the morphisms $\exp$ given in 1.5. Assertion (ii) is immediate, as is (iii). Let us prove (iv): let $X \in \Gamma(S', g_{\alpha})^{\times}$, $Z \in \Gamma(S', g_{\alpha})$; by definition[^N.D.E-XX-29]

$$a_{\alpha}(w_{\alpha}(X))^{-1}(Z) = \text{Ad}(w_{\alpha}(X))(Z) = \text{Ad}(\exp(X)) \text{Ad}(\exp(-X^{-1})) \text{Ad}(\exp(X))(Z).$$

Applying formulas (2') and (2) of Lemma 2.10, as well as the equalities $H_{-\alpha} = -H_{\alpha}$, $\alpha(H_{\alpha}) = 2$ (*loc. cit.* (4) and (5)) and $\langle X, X^{-1} \rangle = 1$ (2.6), one obtains that the right-hand side equals successively:

$$\begin{aligned} \text{Ad}(\exp(X)) \text{Ad}(\exp(-X^{-1}))(Z) &= \text{Ad}(\exp(X))(Z + \langle X^{-1}, Z \rangle (H_{\alpha} - X^{-1})) \\ &= Z + \langle X^{-1}, Z \rangle (H_{\alpha} - 2X - X^{-1} - H_{\alpha} + X) \\ &= Z - \langle X^{-1}, Z \rangle X - \langle X^{-1}, Z \rangle X^{-1}. \end{aligned}$$

But $Z = \langle X^{-1}, Z \rangle X$ and $\langle X^{-1}, Z \rangle X^{-1} = X^{-2} Z$, hence this shows that $a_{\alpha}(w_{\alpha}(X))^{-1} = -X^{-2}$, whence $a_{\alpha}(w_{\alpha}(X)) = -X^2$.

Corollary 3.7. *One has in particular*

$$\text{int}(w_{\alpha}(X)) \exp(X) = \exp(-X^{-1}),$$

whence (by the definition of $w_{\alpha}(X)$):

$$w_{\alpha}(X) \exp(X) w_{\alpha}(X)^{-1} = \exp(-X) w_{\alpha}(X) \exp(-X),$$

or, by an immediate calculation,

$$(w_{\alpha}(X) \exp(X))^3 = e.$$

<!-- label: III.XX.3.7 -->

Corollary 3.8. *Let $X \in \Gamma(S, g_{\alpha})^{\times}$ and $n \in \mathbb{Z}$, $n \neq 0$. Then $w_{\alpha}(X)$ is the unique section $w \in G(S)$ satisfying*

$$\text{int}(w) \circ n \alpha = -n \alpha.$$

$$(w \exp(X))^3 = e.$$

<!-- label: III.XX.3.8 -->

<!-- original page 67 -->

One knows that $w_{\alpha}(X)$ does satisfy these conditions. Conversely, let $w \in G(S)$ satisfy (i) and (ii). By 3.2 and 3.1 (ii), one knows that there exists $t \in T(S)$ such that $w = w_{\alpha}(X) t$. Set $u = \exp(X)$. One then has

```
```text
w u w^{-1} = w_{\alpha}(X) t \exp(X) t^{-1} w_{\alpha}(X)^{-1} = \exp(-\alpha(t) X^{-1}),
```
```

and on the other hand

```
```text
u^{-1} w u^{-1} = \exp(-X) w_{\alpha}(X) t \exp(-X)
 = \exp(-X) w_{\alpha}(X) \exp(-X) \exp(X - \alpha(t) X) t
 = \exp(-X^{-1}) \exp(X - \alpha(t) X) t = \exp(-X^{-1}) t \exp(H).
```
```

Now $(w u)^3 = e \rightarrow w u w^{-1} = u^{-1} w u^{-1}$; comparing the two decompositions of this element on $U_{-\alpha} \cdot T \cdot U_{\alpha}$, one extracts $t = e$.

Remark 3.9. One can summarize a number of results of this number by the following diagram of principal homogeneous (left) bundles*

```
```text
W(g_{\alpha})^{\times} \xrightarrow{w_{\alpha}} N^{\times} \xrightarrow{a_{\alpha}} W((g_{\alpha})^{\otimes 2})^{\times}
 \downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow
G_{\alpha}(m, S) \xrightarrow{\alpha^*} T \xrightarrow{\alpha} G_{\alpha}(m, S).
```
```

Note that a_{α} is faithfully flat (α being so) and that w_{α} is a monomorphism if and only if α is a monomorphism. We leave the reader the task of writing the corresponding diagrams for the right principal bundle structures, as well as the analogous diagrams for the root $-\alpha$, and of studying the relations between these various diagrams.

<!-- label: III.XX.3.9 -->

Lemma 3.10. Let S be a scheme, $q \geq 0$ such that $x \mapsto x^q$ defines an endomorphism of $G_{\alpha}(a, S)$, (G, T, α) and (G', T', α') two S -elementary systems, $f : G \rightarrow G'$ an S -group morphism. Let

<!-- original page 68 -->

```
```text
h : (g_{\alpha})^{\otimes q} \longrightarrow g'_{\alpha'}
```
```

be an isomorphism of ${}_{0_S}$ -modules and

```
```text
h^{\vee} : (g_{-\alpha})^{\otimes q} \longrightarrow g'_{-\alpha'}
```
```

the contragredient isomorphism. For every $S' \rightarrow S$ and every $X \in W(g_{\alpha})(S')$, suppose:

```
$$
f(\exp(X)) = \exp(h(X^q)).
$$
```

Then the following conditions are equivalent:

(i) $f(\alpha(z)) = \alpha'(z)^q$.

(ii) $f(w_{\alpha}(Z)) = w_{\alpha'}(h(Z^q))$.

(iii) $f(\exp(Y)) = \exp(h^{\vee}(Y^q))$.

(Each condition is to be read: for every $S' \rightarrow S$ and every $z \in G_m(S')$, $Z \in W(g_{\alpha})^{\times}(S')$, $Y \in W(g_{-\alpha})(S')$, one has ...).

<!-- label: III.XX.3.10 -->

Indeed, (i) $\Rightarrow$ (ii) by 3.8, (ii) $\Rightarrow$ (iii) by 3.7, (iii) $\Rightarrow$ (i) by 2.7.

Proposition 3.11. *Let S be a scheme, $q \in \mathbb{Z}$, $q > 0$, such that $x \mapsto x^q$ defines an endomorphism of $G_{\alpha, S}$, (G, T, α) and (G', T', α') two S -elementary systems, $f : G \rightarrow G'$ an S -group morphism. The following conditions on f are equivalent:*

(i) The restriction of f to T factors through a morphism $f_T : T \rightarrow T'$ making the diagram

$$\begin{array}{ccccc} G_{\alpha, S} & \xrightarrow{\alpha^*} & T & \xrightarrow{\alpha} & G_{\alpha', S} \\ \downarrow q & & \downarrow f_T & & \downarrow q \\ G_{-\alpha, S} & \xrightarrow{\alpha'^*} & T' & \xrightarrow{\alpha'} & G_{-\alpha', S} \end{array}$$

commutative.

<!-- original page 69 -->

(ii) There exists an (unique) isomorphism of 0_S -modules

$$h : (g_{\alpha})^{\otimes q} \rightarrow g_{-\alpha'}$$

such that $f(\exp(X)) = \exp(h(X^q))$, $f(\exp(Y)) = \exp(h^{\vee}(Y^q))$ for all $X \in W(g_{\alpha})(S')$, $Y \in W(g_{-\alpha})(S')$, $S' \rightarrow S$ (it follows that f also satisfies the equivalent conditions of 3.10).

<!-- label: III.XX.3.11 -->

One has (ii) $\Rightarrow$ (i). Indeed, by 3.10, condition (ii) entails $f \circ \alpha^* = q \alpha'^*$, hence, by 3.3, $f|_T$ factors through T' . It remains to prove $\alpha'(f(t)) = \alpha(t)^q$, which follows at once from the fact that f induces a morphism of groups $T \rightarrow T'$.

Let us prove (i) $\Rightarrow$ (ii). Let $X \in \Gamma(S, g_{\alpha})$, $Y \in \Gamma(S, g_{-\alpha})$. Set $p^+(x) = f(\exp(x X))$ and $p^-(y) = f(\exp(y Y))$; these are group morphisms

$$p^+, p^- : G_{\alpha, S} \rightarrow G.$$

Now one has

$$\begin{aligned} \int (\alpha'^*(z))^q (p^+(x)) &= \int (f_T(\alpha^*(z))) (f(\exp(x X))) \\ &= f(\int (\alpha^*(z))(\exp(x X))) \\ &= f(\exp(z^2 \times X)) = p^+(z^2 \times X). \end{aligned}$$

Applying Lemma 1.2 (with $Q = \alpha^*(G_{\alpha, S})$), one deduces that there exists a section $X' \in \Gamma(S, g_{-\alpha'})$ such that

$$f(\exp(x X)) = p^+(x) = \exp(x^q X').$$

Similarly, there exists a section $Y' \in \Gamma(S, g'^{-1}\alpha')$ such that

```
```text
f(exp(y Y)) = exp(y^q Y').
```
```

Writing now that f is a group morphism, hence that it respects formula (F), one obtains at once

```
```text
X^q Y^q = (X Y)^q = X' Y'.
```
```

<!-- original page 70 -->

One concludes easily that $X^{\{q\}} \mapsto X'$ and $Y^{\{q\}} \mapsto Y'$ define isomorphisms h and $h^{\vee}$ as announced.

Proposition 3.12. *Let (G, T, α) be an S -elementary system, $w \in N^{\times}(S)$; set*

```
$$
\Omega_0 = \Omega \cap \text{int}(w^{-1})(\Omega).
$$
```

Let d be the function on Ω defined by

```
```text
d(exp(Y) \cdot t \cdot exp(X)) = \alpha(t)^{-1} + X Y.
```
```

Then $\Omega_0 = \Omega_d$, and one has for $\exp(Y) \cdot t \cdot \exp(X) \in \Omega_0(S)$ the following formula (set $z = d(\exp(Y) \cdot t \cdot \exp(X))$):

```
```text
(*) \int(w)(\exp(Y) \cdot t \cdot \exp(X)) = \exp(z^{-1} a_{\alpha}(w)^{-1} X) \cdot t \alpha^*(z) \cdot \exp(z^{-1} a_{\alpha}(w) Y).
```

*Moreover, one has  $d \circ \text{int}(w) = d^{-1}$ .*

<!-- label: III.XX.3.12 -->

Indeed, one has at once [N.D.E-XX-30]

```
```text
\int(w)(\exp(Y) \cdot t \cdot \exp(X)) = \exp(a_{\alpha}(w) Y) \cdot t \alpha^*(\alpha(t)^{-1}) \cdot \exp(a_{\alpha}(w)^{-1} X)
= \exp(a_{\alpha}(w) Y) \cdot \exp(\alpha(t) a_{\alpha}(w)^{-1} X) \cdot t \alpha^*(\alpha(t)^{-1}).
```
```

By 2.1, this is a section of  $\Omega$  if and only if  $1 + \alpha(t) X Y$  is invertible, which proves indeed the equality  $\Omega_0 = \Omega_d$ ; applying then formula (F) of *loc. cit.*, one deduces by an immediate calculation the announced formula (\*). Finally, it follows from (\*) that one has

```
```text
(d \circ \int(w))(\exp(Y) \cdot t \cdot \exp(X)) = \alpha(t \alpha^*(z))^{-1} + z^{-2} X Y = z^{-2} (\alpha(t)^{-1} + X Y) = z^{-1},
```
```

whence the last assertion.

**N.B.** One notes that the function  $d$  is independent of the choice of  $w$ .

**4.** The isomorphism theorem

<!-- label: III.XX.4 -->

<!-- original page 71 -->

**\*\*Theorem 4.1.\*\*** \*Let  $S$  be a scheme,  $q \in \mathbb{Z}$ ,  $q > 0$ , such that  $x \mapsto x^q$  is an endomorphism of  $G_{\{a, S\}}$ ,  $(G, T, \alpha)$  and  $(G', T', \alpha')$  two  $S$ -elementary systems. Let\*

```
```text
h : (g_α)^{⊗q} → g_{α'}    and    h^v : (g_{-α})^{⊗q} → g_{-α'}
```

be two isomorphisms contragredient to each other. Let $f_T : T \rightarrow T'$ be an S -group morphism making the diagram*

```
```text
G_{m, S} --q--> G_{m, S}
 | |
 α* α'^*
 ↓ ↓
 T T'
 | |
 α α'
 ↓ ↓
G_{m, S} --q--> G_{m, S}
f_T
```

\*commutative.\*

<!-- original page 72 -->

\*There exists a unique morphism of  $S$ -groups  $f : G \rightarrow G'$  which extends  $f_T$  and satisfies\*

```
$$
f(\exp(X)) = \exp(h(X^q))
$$
```

\*for every  $X \in W(g_{\{\alpha\}}(S'))$ ,  $S' \rightarrow S$ . Moreover, this morphism also satisfies\*

```
```text
f(exp(Y)) = exp(h^v(Y^q))    and    f(w_α(Z)) = w_α(h(Z^q)),
```
```

\*for every  $S' \rightarrow S$  and all  $Y \in \Gamma(S', g_{\{-\alpha\}})$ ,  $Z \in \Gamma(S', g_{\{\alpha\}})^{\otimes q}$ .\*

<!-- label: III.XX.4.1 -->

If  $f : G \rightarrow G'$  extends  $f_T$ , then  $f \circ \alpha^* = (\alpha')^q$ . If moreover  $f$  satisfies the second condition, then it satisfies the two others as well by 3.10. It follows that  $f$  is determined on  $\Omega$  by the relation

```
```text
f(exp(Y) t exp(X)) = exp(h^v(Y^q)) f_T(t) exp(h(X^q)).
```
```

Since  $\Omega$  is schematically dense in  $G$ , this already proves the uniqueness of  $f$ . To prove its existence, it suffices, by virtue of Exp. XVIII 2.3, to prove that the preceding formula defines a "generically multiplicative" morphism from  $\Omega$  to  $G'$ . Now, by 2.4, this amounts to verifying that  $\alpha' \circ f = \alpha^q$ , which follows from the fact that  $f$  extends  $f_T$ .

**\*\*Scholie 4.2.\*\*** \*One can also interpret 4.1 as follows: consider the category  $E$  of  $S$ -elementary systems and the category  $D$  of tuples\*

```
```text
(G_{m, S}  --α*-->  T  --α-->  G_{m, S},  L),
```
```

\*where  $T$  is a torus,  $\alpha$  and  $\alpha^*$  are group morphisms such that  $\alpha \circ \alpha^* = 2$ , and  $L$  is an invertible  $\mathcal{O}_S$ -module (the reader will specify the morphisms of the two categories under consideration). One defines a functor  $E \rightarrow D$  by\*

```

```text

$$(G, T, \alpha) \mapsto (G_{\{m, S\}} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} G_{\{m, S\}}, g_\alpha).$$

```

The preceding theorem says that this functor is fully faithful. It is in fact an equivalence of categories, as one will see in the next number. One already has:

```

<!-- label: III.XX.4.2 -->

```

Corollary 4.3. If $q = 1$ and if f_T is an isomorphism, then f is an isomorphism.

```

<!-- label: III.XX.4.3 -->

```

Corollary 4.4. If $q = 1$ and if f_T is faithfully flat with kernel Q (cf. Exp. IX 2.7), then f is faithfully flat (quasi-compact) with kernel Q , hence identifies G' with G/Q .

```

<!-- label: III.XX.4.4 -->

```

Indeed, if f_T is faithfully flat with kernel Q , then

```

```text

$$Q = \text{Ker}(f_T) \subset \text{Ker}(f_T \circ \alpha') = \text{Ker}(\alpha).$$

```

Introducing the elementary system  $(G/Q, T/Q, \alpha/Q)$  of 2.13, one is reduced by 2.14 to proving that  $f/Q$  induces an isomorphism of  $G/Q$  onto  $G'$ , which follows at once from 4.3.

## 5. Examples of elementary systems, applications

```

<!-- label: III.XX.5 -->

```

```

<!-- original page 73 -->

```

**5.1.** Let  $S$  be a scheme,  $L$  an invertible  $\mathcal{O}_S$ -module. Consider the group  $GL$  over  $S$  defined by

```

```text

$$GL(S') = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mid a, d \in G_a(S'), b \in W(L)(S'), c \in W(L^{-1})(S'), a d - b c \in G_m(S') \right\}$$

```

equipped with the usual matrix multiplication law. It is locally isomorphic to $GL_2(S)$. It is therefore an S -group scheme, affine and smooth over S , with connected fibers.

Remark. Let L' and L'' be two invertible sheaves on S , such that $L = L' \otimes L''^{-1}$. [N.D.E-XX-31] Then one has an isomorphism of S -groups:

```

```text

$$GL \longrightarrow GL(L' \oplus L'')$$

```

defined as follows: if  $x$  (resp.  $y$ ) is a section of  $L'$  (resp.  $L''$ ) on an open set  $V$  of  $S$ , one has

```

```text

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} a x + b y \\ c x + d y \end{pmatrix}.$$

```

5.2. One will denote by SL the closed subgroup of GL defined by the relation $a d - b c = 1$. It is also an S -group scheme, affine and smooth over S , with connected fibers (isomorphic to $SL(L' \oplus L'')$ by the preceding isomorphism).

Likewise, consider the morphism $G_{\{m, S\}} \rightarrow GL$ defined by $z \mapsto (z \otimes 1 / 1 \otimes z)$. It is a central monomorphism; by passage to the quotient, one deduces a group PL , smooth and affine over S , with connected fibers (cf. Exp. VIII 5.7).

One can see that, by passage to the quotient from the isomorphism of the preceding remark, 'PL' is identified with the group of automorphisms of the projective bundle $\mathbb{P}(L' \oplus L'')$ (cf. EGA, II 4.2.7). One will denote by σ and ρ the canonical morphisms

<!-- original page 74 -->

```

```text
SL $\xrightarrow{\sigma}$ GL $\xrightarrow{\rho}$ PL;
```

```

σ is a closed immersion, ρ is faithfully flat and affine.

5.3. Consider the group morphisms

```

```text
t_G : G^2_{m, S} \to GL, t_G(z, z') = \begin{pmatrix} z & 0 \\ 0 & z' \end{pmatrix},
t_S : G_{m, S} \to SL, t_S(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix},
t_P : G_{m, S} \to PL, t_P(z) = p(t_G(z, 1)).
```

```

These are group monomorphisms, which define in each group a (split) torus of relative codimension 2. For every $s \in S$, let

```

```text
X \in \Gamma(s, L \otimes s)^{\times};
```

```

then the section $(0 \ X \ -X^{-1} \ 0)$ of GL_s normalizes $t_G(G^2_{m, s})$ and does not centralize it; one concludes from Exp. XIX 1.6 that 'GL' is reductive, of semisimple rank 1, with maximal torus $t_G(G^2_{m, S})$.

One argues similarly for 'SL' and 'PL' , and one sees that 'SL' (resp. 'PL') is reductive, of semisimple rank 1, with maximal torus $t_S(G_{m, S})$ (resp. $t_P(G_{m, S})$).

<!-- original page 74 -->

5.4. Reasoning as usual, one determines at once the Lie algebra of these various groups and the adjoint action of the chosen maximal torus. Let us do it for 'GL' ; this is immediate by Exp. II 4.8: $\text{Lie}(\text{'GL'}/S)$ is the Lie algebra of the matrices below:

```

```text
Lie(GL/S) = \{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \mid a \text{ and } d \text{ sections of } 0_S, b \text{ section of } L, c \text{ section of } L^{-1} \}
```

```

with the usual bracket; one has

```

```text
Ad(t_G(z, z')) \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & z z'^{-1} b \\ z' z^{-1} c & d \end{pmatrix}.
```

```

<!-- original page 75 -->

Denote $\text{Lie}(\text{'GL'}/S) = \mathfrak{g}$. Let $\alpha_G : t_G(G^2_{m, S}) \rightarrow G_{m, S}$ be the character defined by

```

```text
\alpha_G(t_G(z, z')) = z z'^{-1}.
```

```

One sees at once from the preceding relation that α_G is a root of 'GL' with respect to $t_G(G^2_{m, S})$ and that the morphism

```

```text
```

```

$u : L \rightarrow g \quad (\text{resp. } u^{-1} : L^{-1} \rightarrow g)$

defined by $u(X) = \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix}$ (resp. $u^{-1}(X) = \begin{pmatrix} 0 & 0 \\ X & 0 \end{pmatrix}$) is an isomorphism of L onto g_{α_G} (resp. of L^{-1} onto $g_{-\alpha_G}$).

One has thus proved that $(G, t_G(G^2_m, S), \alpha_G)$ is an S -elementary system.

Setting likewise

$\alpha_S(t_S(z)) = z^2, \quad \alpha_P(t_P(z)) = z,$

one proves that $(SL, t_S(G_m, S), \alpha_S)$ and $(PL, t_P(G_m, S), \alpha_P)$ are elementary systems, and one defines isomorphisms of L (resp. L^{-1}) with the corresponding direct summands of the Lie algebras of SL and PL .

5.5. Set $\exp \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix}$. One has thus defined a morphism

$W(g_{\alpha_G}) \rightarrow GL$

which induces on the Lie algebras the canonical morphism, hence is the unique morphism of this type (1.5). Similarly, one sets $\exp \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix}$. Carrying out the explicit calculation of formula (F), one finds

$\begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix} = X Y, \quad \alpha^*_G(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix} = t_G(z, z^{-1}).$

[^N.D.E-XX-32]

<!-- original page 76 -->

The open set $N^{\times} = N^{\times}_G$ (defined before 3.1) is:

$N^{\times}_G(S') = \left\{ \begin{pmatrix} 0 & P \\ Q & 0 \end{pmatrix} \mid P \in W(g_{\alpha})^{\times}(S'), Q \in W(g_{-\alpha})^{\times}(S') \right\},$

the morphism w_{α_G} (cf. 3.1 (iv)) is given, for every $X \in W(g_{\alpha})^{\times}(S')$, by

$w_{\alpha_G}(X) = \begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix}$

the morphism a_{α_G} (cf. 3.5) is given by:

if $w = \begin{pmatrix} 0 & P \\ Q & 0 \end{pmatrix} \in N^{\times}_G(S')$, then $a_{\alpha_G}(w) = P Q^{-1} \in W((g_{\alpha})^{\otimes 2})^{\times}(S'),$

that is, for every $Y \in W(g_{-\alpha})^{\times}(S')$, one has $a_{\alpha_G}(w)(Y) = P Q^{-1} Y \in W(g_{\alpha})^{\times}(S').$

5.6. We leave the reader the task of carrying out the same computations in SL and PL . One finds the same duality formula and the coroots

$\alpha^*_S(z) = t_S(z), \quad \alpha^*_P(z) = t_P(z^2).$

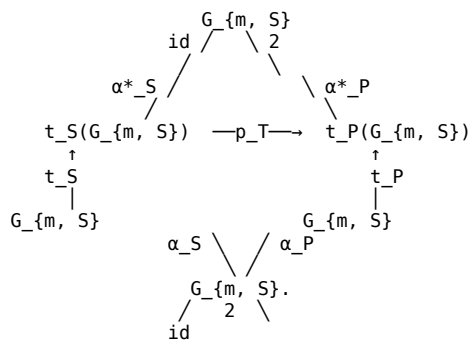

...

Denote by $p_{\{T\}}$ the morphism induced by $p : GL \rightarrow PL$ on $t_{\{S\}}(G_{\{m, S\}})$, i.e.

$$p_{\{T\}}(t_{\{S\}}(z)) = t_{\{P\}}(z^{\{2\}}).$$

One therefore has the commutative diagram:[^N.D.E-XX-33]

```text

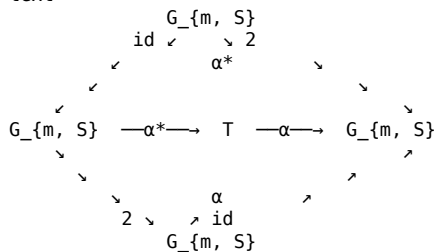

...

One recognizes in the central part the commutative diagram of 4.1[^N.D.E-XX-34] relative to the canonical morphism  $p \circ i : SL \rightarrow PL$ , which induces a morphism of the preceding  $\mathbb{S}$ -elementary systems.

<!-- original page 76 -->

**5.7.** Let now  $(G, T, \alpha)$  be any  $\mathbb{S}$ -elementary system. Consider the commutative diagram:

```text

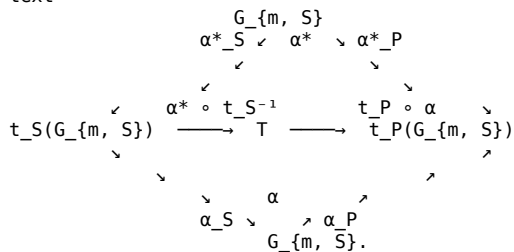

...

<!-- original page 77 -->

Combining the two preceding diagrams, one obtains a commutative diagram:

```text

...

Using 4.1, one therefore has:

**Proposition 5.8.** Let  $S$  be a scheme,  $(G, T, \alpha)$  an  $S$ -elementary system. Set  $L = g_{\alpha}$  (and hence  $L^{-1} = g_{-\alpha}$ ).

(i) There exists a unique group morphism  $f : SL \rightarrow G$  satisfying the following equivalent conditions:

text  
 (a)  $f \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix} = \alpha(z)$ ,  $f \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X)$ ;  
 (b)  $f \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X)$ ,  $f \begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix} = \exp(Y)$ ;  
 (c)  $f \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X)$ ,  $f \begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix} = w_{\alpha}(X)$ .  
 ...

(ii) There exists a unique group morphism  $g : G \rightarrow PL$  satisfying

text  
 $g(t) = \begin{pmatrix} \alpha(t) & 0 \\ 0 & 1 \end{pmatrix}$ ,  $g(\exp(X)) = p \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix}$ .  
 ...

Moreover, one has

text  
 $g(\exp(Y)) = p \begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix}$ ,  $g(w_{\alpha}(X)) = p \begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix}$ .  
 ...

<!-- original page 78 -->

The morphism  $g$  is faithfully flat quasi-compact with kernel  $\text{Ker}(\alpha) = \text{Centr}(G)$ , and  $g \circ f$  is the canonical morphism  $SL \rightarrow PL$ .

<!-- label: III.XX.5.8 -->

Note that conditions (b) of (i) give an explicit description of the duality between  $g_{\alpha}$  and  $g_{-\alpha}$ .

**Corollary 5.9.** Let  $(G, T, \alpha)$  be an  $S$ -elementary system. The subgroups  $T \cdot U_{\alpha}$ ,  $T \cdot U_{-\alpha}$ ,  $U_{\alpha}$  and  $U_{-\alpha}$  are closed.

<!-- label: III.XX.5.9 -->

Since  $U_{\alpha}$  is a closed subgroup scheme of  $T \cdot U_{\alpha}$ , it suffices to make the verification for the latter. By Noether's theorem (Exp. IV 5.3.1 and 6.4.1), it suffices to prove that  $(T \cdot U_{\alpha})/\text{Ker}(\alpha)$  is a closed subgroup of  $G/\text{Ker}(\alpha)$ . By virtue of 5.8, one is therefore reduced to proving that the subgroup of  $PL$  (or of  $GL$ , which amounts to the same by a new application of Noether's theorem) defined by  $c = 0$  is closed, which is trivial.

Consequently, the morphisms  $\exp$  of Theorem 1.5 (i) are closed immersions.

**N.B.** The corollary also follows from the fact that  $T \cdot U_{\alpha}$  and  $T \cdot U_{-\alpha}$  are "Borel subgroups" of  $G$  (cf. Exp. XII 7.10).

**5.10.** Let  $L$  be an invertible  ${}_{O_S}$ -module and

text  
 $G_{\{m, S\}} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} G_{\{m, S\}}$   
 ...

a diagram of groups [N.D.E-XX-35] such that  $\alpha \circ \alpha^* = 2$ . Let  $R$  be the maximal torus of  $\text{Ker}(\alpha)$  and  $K = \alpha^{*-1}(R)$ . Then  $K$  is a subgroup of multiplicative type of  $G_{\{m, S\}}$ ; by virtue of  $\alpha \circ \alpha^* = 2$ , it is even a subgroup of  $\mu_{\{2, S\}}$ . In particular the morphism

```

```text
K → SL,      z ↦ ( z   0 )
                  ( 0   z⁻¹)
```

```

is central. One has therefore a central group monomorphism:

<!-- original page 79 -->

```

```text
K → R × SL,      z ↦ (α*(z), ( z   0 )).
                  ( 0   z⁻¹)
```

```

Consider the group  $G = (R \times SL)/K$  obtained by passage to the quotient. It is an affine and smooth group over  $S$ , with connected fibers. It is immediate that the sequence

```

```text
1 → K → R × t_S(G_{\{m, S\}}) → T → 1
```

```

where  $u(x, t_S(z)) = x \alpha^*(z)$  is exact. The image of  $R \times t_S(G_{\{m, S\}})$  in  $G$  is therefore a torus  $T'$  isomorphic to  $T$ . One then shows without difficulty that if  $\alpha$  is the character of  $T'$  deduced from  $\alpha$  by the preceding isomorphism,  $(G, T', \alpha)$  is an  $S$ -elementary system, that  $g'_{\{\alpha\}}$  is isomorphic to  $L$ , and that  $\alpha^*$  is obtained from  $\alpha$  by the isomorphism  $T \xrightarrow{\sim} T'$ . One has therefore constructed an  $S$ -elementary system  $(G, T', \alpha)$  such that the corresponding object

<!-- original page 80 -->

```

```text
(G_{\{m, S\}} →_{α*} T' →_{α'} G_{\{m, S\}}, g'_{\{α'\}})
```

```

of the category  $\mathcal{D}$  defined in 4.2 is isomorphic to

```

```text
(G_{\{m, S\}} →_{α*} T →_{α} G_{\{m, S\}}, L).
```

```

One has therefore proved the

**Theorem 5.11.** \*In the notations of 4.2, the functor\*

```

```text
(G, T, α) ↦ (G_{\{m, S\}} →_{α*} T →_{α} G_{\{m, S\}}, g_α)
```

```

\*is an equivalence of categories between  $\mathcal{E}$  and  $\mathcal{D}$ .\*

<!-- label: III.XX.5.11 -->

## 6. Generators and relations for an elementary system

<!-- label: III.XX.6 -->

<!-- original page 80 -->

**6.1.** Let  $S$  be a scheme,  $(G, T, \alpha)$  an  $S$ -elementary system. Let  $X \in W(g_{\{\alpha\}}^{\times}(S))$  and  $u = \exp(X)$ ; one has seen in 3.8 that the element  $w = w_{\{\alpha\}}(X)$  satisfies in particular the relation

$S$

$(w u)^{\{3\}} = e.$

\$\$

[^N.D.E-XX-36]

One denotes by  $s_{\alpha}$  the automorphism of  $T$  induced by  $\text{int}(w)$ ; according to Theorem 3.1 (iii), for every  $S' \rightarrow S$  and  $t \in T(S')$ , one has

```text  
 $s_{\alpha}(t) = \text{int}(w)(t) = t \cdot \alpha(\alpha(t)^{-1}).$

Theorem 6.2. Let H be an S -sheaf of groups for (fppf). Let

```text  
 $f_T : T \rightarrow H, \quad f_{\alpha} : U_{\alpha} \rightarrow H$

be group morphisms and  $h \in H(S)$  a section of  $H$ . For there to exist a (necessarily unique) group morphism

\$\$  
 $f : G \rightarrow H$   
 \$\$

extending  $f_T$  and  $f_{\alpha}$  and satisfying  $f(w) = h$ , it is necessary and sufficient that the following conditions be satisfied:

(i) For every  $S' \rightarrow S$ , every  $t \in T(S')$  and every  $x \in U_{\alpha}(S')$ , one has

```text  
 (1) $f_T(t) f_{\alpha}(x) f_T(t)^{-1} = f_{\alpha}(t \times t^{-1}) = f_{\alpha}(x^{\alpha(t)}).$

(in other words, f_T and f_{α} extend to a group morphism from the semidirect product $T \cdot U_{\alpha}$ into H).

(ii) For every $S' \rightarrow S$ and every $t \in T(S')$, one has

```text  
 (2)  $h f_T(t) h^{-1} = f_T(s_{\alpha}(t)) = f_T(t \cdot \alpha(\alpha(t)^{-1})).$

<!-- original page 81 -->

(iii) One has the two relations in  $H(S)$ :

\$\$  
 (3)  $h^2 = f_T(\alpha^{-1}),$   
 (4)  $(h f_{\alpha}(u))^3 = e.$   
 \$\$

<!-- label: III.XX.6.2 -->

**Proof.** Denote additively  $U_{\alpha}$  and  $U_{-\alpha}$  and multiplicatively their vector structure. If  $f$  satisfies the conditions of the statement, one necessarily has for every  $y \in U_{-\alpha}(S)$ ,

```text  
 $f(y) = f(w^{-1} y w) = h f_{\alpha}(w^{-1} y w) h^{-1}.$

Let then $f_{-\alpha} : U_{-\alpha} \rightarrow H$ be the morphism defined by

```text  
 (\*\_1)  $f_{-\alpha}(y) = h f_{\alpha}(w^{-1} y w) h^{-1}.$

It is a group morphism. On the other hand,  $f$  is determined on the big cell  $\Omega$  by

$$f(y \cdot t \cdot x) = f_{-\alpha}(y) f_T(t) f_{\alpha}(x).$$

This shows the uniqueness of  $f$ ; since the conditions of the statement are manifestly necessary, let us show that they are sufficient.

One has by (4)

$$h f_{\alpha}(u) h^{-1} h^2 = f_{\alpha}(-u) h^{-1} f_{\alpha}(-u).$$

Now, by (3) and (1),  $h^2 = f_T(\alpha(-1))$  commutes with  $f_{\alpha}(-u)$ , which gives

$$h f_{\alpha}(u) h^{-1} = f_{\alpha}(-u) h f_{\alpha}(-u).$$

But, by definition,  $h f_{\alpha}(u) h^{-1} = f_{-\alpha}(w u w^{-1})$ ; by 3.7, since  $u = \exp(X)$  and  $w = w_{\alpha}(X)$ , one has

<!-- original page 82 -->

$$w u w^{-1} = -\tilde{u},$$

where  $\tilde{u}$  denotes the element paired with  $u$ . One obtains therefore:

$$f_{-\alpha}(-\tilde{u}) = f_{\alpha}(-u) h f_{\alpha}(-u).$$

Let now  $t$  be a section of  $T$  over a variable  $s$  to  $S$ . Apply  $f_T(t)$  to the preceding formula. One obtains on the left-hand side [N.D.E-XX-37]

$$\begin{aligned} f_T(t) f_{-\alpha}(-\tilde{u}) f_T(t)^{-1} &= f_T(t) h f_{\alpha}(u) h^{-1} f_T(t)^{-1} \\ &= h (h^{-1} f_T(t) h) f_{\alpha}(u) (h^{-1} f_T(t)^{-1} h) h^{-1} \\ &= h f_T(s_{\alpha}(t)) f_{\alpha}(u) f_T(s_{\alpha}(t))^{-1} h^{-1} = h f_{\alpha}(\alpha(s_{\alpha}(t)) u) h^{-1} \end{aligned}$$

by (2) and (1); then since  $s_{\alpha}(t) = t \cdot \alpha(\alpha(t)^{-1})$  and  $\alpha \circ \alpha = 2$ , this equals

$$h f_{\alpha}(\alpha(t)^{-1} u) h^{-1}.$$

Finally, by  $(*)_1$  and  $(*)_2$  one has

$$h f_{\alpha}(\alpha(t)^{-1} u) h^{-1} = f_{-\alpha}(\alpha(t)^{-1} w u w^{-1}) = f_{-\alpha}(-\alpha(t)^{-1} \tilde{u}).$$

The right-hand side of  $(*)_3$  gives

$$f_{\alpha}(-\alpha(t) u) \cdot f_T(t) h f_T(t)^{-1} h^{-1} \cdot h \cdot f_{\alpha}(-\alpha(t) u)$$

and since  $h f_T(t)^{-1} h^{-1} = f_T(s_{\alpha}(t)^{-1}) = f_T(t \cdot \alpha(\alpha(t)))$ , this equals

```

```text
f_{-\alpha}(-\alpha(t) u) \cdot f_T(\alpha^*(\alpha(t))) \cdot h \cdot f_{-\alpha}(-\alpha(t) u).
```

```

Comparing the two expressions obtained, one obtains

```

```text
f_{-\alpha}(-\alpha(t)^{-1} \tilde{u}) = f_{-\alpha}(-\alpha(t) u) \cdot f_T(\alpha^*(\alpha(t))) \cdot h \cdot f_{-\alpha}(-\alpha(t) u).
```

```

Since  $\alpha : T \rightarrow G_{\{m, S\}}$  is faithfully flat and  $\mathcal{H}$  is a separated presheaf, one can replace  $\alpha(t)^{-1}$  by an arbitrary section of  $G_{\{m, S\}}$ , and one obtains the

**Lemma 6.2.1.** *For every  $z \in G_{\{m\}}(S')$ ,  $S' \rightarrow S$ , one has*

```

```text
f_{-\alpha}(z \tilde{u}) = f_{-\alpha}(z^{-1} u) \cdot f_T(\alpha^*(-z^{-1})) \cdot h \cdot f_{-\alpha}(z^{-1} u).
```

```

<!-- label: III.XX.6.2.1 -->

<!-- original page 83 -->

Let now  $x, y \in G_{\{a\}}(S')$ ,  $S' \rightarrow S$ ; suppose  $y$  and  $(1 + x y)$  invertible. Applying the lemma first to  $z = y$ , one obtains<sup>[N.D.E-XX-38]</sup>

```

```text
f_{-\alpha}(x u) f_{-\alpha}(y \tilde{u}) = f_{-\alpha}((x + y^{-1}) u) \cdot f_T(\alpha^*(-y^{-1})) \cdot h \cdot f_{-\alpha}(y^{-1} u).
```

```

Now  $x + y^{-1} = y^{-1}(1 + x y)$ . Applying the lemma to  $z = y / (1 + x y)$ , one finds

```

```text
f_{-\alpha}((x + y^{-1}) u) = f_{-\alpha}(y / (1 + x y) \cdot \tilde{u}) f_{-\alpha}(-(x + y^{-1}) u) \cdot h \cdot f_T(\alpha^*(-y / (1 + x y))).
```

```

Substituting in the preceding equality, one obtains

```

```text
f_{-\alpha}(x u) f_{-\alpha}(y \tilde{u}) = f_{-\alpha}(y / (1 + x y) \cdot \tilde{u}) f_{-\alpha}(-(x + y^{-1}) u) \cdot h^{-1} \cdot f_T(\alpha^*(1 + x y)^{-1}) \cdot h \cdot f_{-\alpha}(y^{-1} u).
```

```

Since  $h^{-1} f_T(t) h = f_T(s_{\{\alpha\}}(t))$  by (2) (note that  $s_{\{\alpha\}}^2 = \text{id}$ ) and since  $s_{\{\alpha\}} \circ \alpha^* = -\alpha^* \circ s_{\{\alpha\}}$  (cf. 6.2.1), this equals

```

```text
f_{-\alpha}(y / (1 + x y) \cdot \tilde{u}) f_{-\alpha}(-(x + y^{-1}) u) \cdot f_T(\alpha^*(1 + x y)) \cdot f_{-\alpha}(y^{-1} u).
```

```

Finally, since for all  $x' \in U_{\{\alpha\}}(S')$  and  $z \in G_{\{m\}}(S')$  one has

```

```text
f_{-\alpha}(x') f_T(\alpha^*(z)) = f_T(\alpha^*(z)) f_{-\alpha}(z^{-2} x'),
```

```

one obtains

```

```text
f_{-\alpha}(x u) f_{-\alpha}(y \tilde{u}) = f_{-\alpha}(y / (1 + x y) \cdot \tilde{u}) \cdot f_T(\alpha^*(1 + x y)) \cdot f_{-\alpha}(-y^{-1} (1 + x y)^{-1} / (1 + x y)^2 + y^{-1} \cdot u)
= f_{-\alpha}(y / (1 + x y) \cdot \tilde{u}) \cdot f_T(\alpha^*(1 + x y)) \cdot f_{-\alpha}(x / (1 + x y) \cdot u).
```

```

One has thus proved:

**\*\*Lemma 6.2.2.\*\*** \*Let  $S' \rightarrow S$ . If  $a \in U_{\alpha}(S')$ ,  $b \in U^{\times}_{-\alpha}(S')$ , and  $1 + a b \in G_m(S')$ , one has\*

```
```text
f_{\alpha}(a) f_{-\alpha}(b) = f_{-\alpha}( b / (1 + a b) ) f_T(\alpha(1 + a b)) f_{\alpha}( a / (1 + a b) ).
```

<!-- label: III.XX.6.2.2 -->

<!-- original page 84 -->

By schematic density, this formula remains valid when $b \in U_{-\alpha}(S')$, $1 + a b$ being always invertible. Consider then the morphism

```
$$
f : \Omega \rightarrow H
$$
```

defined by $f(y \cdot t \cdot x) = f_{-\alpha}(y) f_T(t) f_{\alpha}(x)$.

It follows at once from 6.2.2, from condition 6.2 (i), and from formula (F') of 2.4 that if $g, g' \in \Omega(S')$ and $g g' \in \Omega(S')$, one has $f(g g') = f(g) f(g')$. By Exp. XVIII 2.3 (iii) and 2.4[^{N.D.E-XX-39}], there therefore exists a group morphism $G \rightarrow H$ extending f . Denote it also by f ; it answers the question; it suffices to prove, indeed, that $f(w_{\alpha}) = h$. Now $w_{\alpha} = u \cdot \tilde{u}$, whence, by (^{*_3}):[^{N.D.E-XX-40}]

```
```text
f(w_{\alpha}) = f_{\alpha}(u) f_{-\alpha}(-\tilde{u}) f_{\alpha}(u) = h.
```

**\*\*Remark 6.3.\*\*** \*We shall complete these results in Exp. XXIII 3.5.\*

[^N.D.E-XX-1]: N.D.E.: of  $0_S$ -modules.

[^N.D.E-XX-2]: N.D.E.: We shall see later (Cor. 5.9) that  $\text{exp}$  is an isomorphism of  $W(g_{\alpha})$  onto a closed subgroup of  $G$ .

[^N.D.E-XX-3]: N.D.E.: see also VI<sub>B</sub>, 2.5.

[^N.D.E-XX-4]: N.D.E.: by EGA IV<sub>4</sub>, 17.9.1.

[^N.D.E-XX-5]: N.D.E.: We have added the sentence that follows.

[^N.D.E-XX-6]: N.D.E.: We have replaced  $P_{-\alpha}$  and  $P_{\alpha}$  by  $U_{-\alpha}$  and  $U_{\alpha}$ .

[^N.D.E-XX-7]: N.D.E.: see also EGA IV<sub>3</sub>, 11.10.10.

[^N.D.E-XX-8]: N.D.E.: Indeed, on the one hand,  $\text{Lie}(G_{\{a, S\}}) = 0_{\{S\}}$  and  $\text{Lie}(p_{\alpha})$  is an element of  $\text{Hom}_{\{0_{\{S\}}\}}(0_{\{S\}}, g_{\alpha}) = \Gamma(S, g_{\alpha})$ .

[^N.D.E-XX-9]: N.D.E.: by 1.18.

[^N.D.E-XX-10]: N.D.E.: We have added the condition " $(1, u v) \in U(S)$ ".

[^N.D.E-XX-11]: N.D.E.: here and in what follows, we have replaced  $U(S)$  by  $V(S)$ .

[^N.D.E-XX-12]: N.D.E.: We have denoted by  $E$  the element denoted  $G$  in the original, since  $G$  already denotes the  $S$ -group under consideration.

[^N.D.E-XX-13]: N.D.E.: We have corrected what follows.

[^N.D.E-XX-14]: N.D.E.: that is, we have made the "change of variables"  $x = v$ ,  $y = w E(v)^{-1}$ , i.e.  $v = x$ ,  $w = y E(x)$ .

[^N.D.E-XX-15]: N.D.E.: We have corrected  $y E(x)$  to  $x + y E(x)$ .

[^N.D.E-XX-16]: N.D.E.: that is, one writes the equalities resulting from  $p_{\alpha}(t) p_{\alpha}(u) p_{-\alpha}(v) = p_{\alpha}(t + u) p_{-\alpha}(v)$  and sets  $v = 1$  and  $x = u$ ,  $t = y F(u)$  (i.e.  $y = t F(u)^{-1}$ ).

[^N.D.E-XX-17]: N.D.E.: We have corrected  $y F(x)$  to  $x + y F(x)$ .

[^N.D.E-XX-18]: N.D.E.: We have corrected what follows.

[^N.D.E-XX-19]: N.D.E.: We have added the sentence that follows. One can also see by a direct calculation that the preceding equality entails  $0 = x y b (2 + (x + y) b)$ , hence  $0 = b(2 + (x + y) b)$ , and finally  $b = 0$ .

[^N.D.E-XX-20]: N.D.E.: In the three preceding equalities, we have corrected the original by replacing the factor  $(1 + b x)$  on the right by  $1 + a x$ . Substituting the third equality into the second and taking into account that  $1 + a x$  is invertible, one obtains the equality  $a^2 x y = a b x y$ .

[^N.D.E-XX-21]: N.D.E.: that is, we have made the change of variables  $x' = 1 + a x$ , i.e.  $x = (x' - 1)/a$ .

[^N.D.E-XX-22]: N.D.E.: We have slightly modified what follows, since an open set  $V$  was already introduced in A).

[^N.D.E-XX-23]: N.D.E.: We have added the numbering 3.0, for later references.

[^N.D.E-XX-24]: N.D.E.: We have replaced  $Q$  by the more suggestive notation  $N^{\times}$ .

[^N.D.E-XX-25]: N.D.E.: We have corrected the first formula of the original.

[^N.D.E-XX-26]: N.D.E.: The first equality follows from 1.5 (i) which, combined with the equality  $\alpha \circ \alpha^* = 2$ , gives the formulas

$$\begin{aligned} \text{(``text} \\ (\dagger) \quad \alpha^*(z) \exp(X) \alpha^*(z)^{-1} = \exp(z^2 X), \quad \alpha^*(z) \exp(X^{-1}) \alpha^*(z)^{-1} = \exp(z^{-2} X), \\ \text{````)} \end{aligned}$$

the third equality follows from formula (F), and the fourth from ( $\dagger$ ), again. Finally, an analogous calculation shows that  $w_{\alpha}(X) \alpha^*(z^{-1}) = w_{\alpha}(z X)$ .

[^N.D.E-XX-27]: N.D.E.: The hypothesis  $\text{Centr}_{G_s}(n \alpha^*_s) \neq G_s$  entails that  $\dim \text{Centr}_{G_s}(n \alpha^*_s) - \dim T_s < 2$ , but this difference is even, by *loc. cit.*

[^N.D.E-XX-28]: N.D.E.: that is,  $a_{-\alpha}(w)$  and  $a_{\alpha}(w)$  are paired, cf. 2.6.1.

[^N.D.E-XX-29]: N.D.E.: We have detailed what follows.

[^N.D.E-XX-30]: N.D.E.: We have corrected the original by swapping  $a_{\alpha}(w)$  and  $a_{\alpha}(w)^{-1}$ , and we have detailed the proof of the equality  $d \circ \text{int}(w) = d^{-1}$ .

[^N.D.E-XX-31]: N.D.E.: We have corrected  $L' \otimes L'^{-1}$  to  $L' \otimes L'^{-1}$  and we have detailed the sentence that follows.

[^N.D.E-XX-32]: N.D.E.: We have detailed what follows.

[^N.D.E-XX-33]: N.D.E.: where  $t_S$  and  $t_P$  are isomorphisms.

[^N.D.E-XX-34]: N.D.E.: with  $q = 1$ .

[^N.D.E-XX-35]: N.D.E.:  $T$  being a torus.

[^N.D.E-XX-36]: N.D.E.: We have added the sentence that follows.

[^N.D.E-XX-37]: N.D.E.: We have corrected what follows.

[^N.D.E-XX-38]: N.D.E.: We have detailed the calculations that follow.

[^N.D.E-XX-39]: N.D.E.: Note that each geometric fiber of  $G$  is connected, for example by 1.1.

[^N.D.E-XX-40]: N.D.E.: We have simplified the original by invoking  $(*_3)$ .

# Exposé XXI. Root data

<!-- label: III.XXI -->

\*by M. Demazure\*

<!-- original page 85 -->

[^N.D.E-XXI-0] This Exposé collects, in the absence of a suitable reference,[^N.D.E-XXI-1] some known results on root data (= "abstract" root systems), most of which will be used in what follows.

**Notations.** – We denote by  $Q_+$  the set of positive (or zero) rational numbers; one has  $\mathbb{Z} \cap Q_+ = \mathbb{N}$ . Let  $V$  be a  $\mathbb{Q}$ -vector space; if  $A$  (resp.  $B$ ) is a subset of  $\mathbb{Q}$  (resp.  $V$ ), we denote by  $A \cdot B$  the image of  $A \otimes B$  under the morphism  $\mathbb{Q} \otimes V \rightarrow V$ , in other words the set of linear combinations of elements of  $B$  with coefficients in  $A$ . We write  $-B = \{-1\} \cdot B$ . We denote by  $E - F$  the set of elements of  $E$  that do not belong to  $F$ .

```

1. Generalities

<!-- label: III.XXI.1 -->

1.1. Definitions, first properties

<!-- label: III.XXI.1.1 -->

Definition 1.1.1. *Let M and M^* be two free $\mathbb{Z}$ -modules of finite type in duality. Write
 $V = M \otimes \mathbb{Q}$, $V^* = M^* \otimes \mathbb{Q}$; these are two $\mathbb{Q}$ -vector spaces in duality. We
identify M (resp. M^*) with a subset of V (resp. V^*). The canonical bilinear form on $M^* \times M$ (resp.
 $V^* \times V$) is denoted $(\ , \)$.*

<!-- label: III.XXI.1.1.1 -->

<!-- original page 86 -->

Let R be a finite subset of M . Suppose we are given a map $\alpha \mapsto \alpha^$ of R into M^* ; the set of α^* , for $\alpha \in R$,
is denoted R^* . To each $\alpha \in R$ we associate the endomorphism s_α (resp. s^*_α) of M and V (resp. M^* and V^*)
given by the formulas:*
```

$$\begin{aligned} (1) \quad s_\alpha(x) &= x - (\alpha^*, x)\alpha, & \text{i.e.} \quad s_\alpha &= \text{id} - \alpha^* \otimes \alpha; \\ (1^*) \quad s^*_\alpha(u) &= u - (u, \alpha)\alpha^*, & \text{i.e.} \quad s^*_\alpha &= \text{id} - \alpha \otimes \alpha^*. \end{aligned}$$

```

```text
One says that the pair  $(R, R^*)$  (more precisely the pair  $(R, R \rightarrow M^*)$ ) is a root datum in  $(M, M^*)$ , or that
 $(M, M^*, R, R^*)$  is a root datum, if the following axioms are satisfied:*
```

$$\begin{aligned} \text{(DR I)} \quad & \text{For each } \alpha \in R, \text{ one has } (\alpha^*, \alpha) = 2. \\ \text{(DR II)} \quad & \text{For each } \alpha \in R, \text{ one has } s_\alpha(R) \subset R, \quad s^*_\alpha(R^*) \subset R^*. \end{aligned}$$

```

```text
One says that R is the root system of the root datum $\mathcal{R} = (M, M^*, R, R^*)$. The elements of R (resp. R^*) are
called the roots (resp. coroots) of the root datum.*

Remark 1.1.2. *Axiom (DR I) is equivalent to any of the following properties:*
```

<!-- label: III.XXI.1.1.2 -->

```

```text
(2)  $s_\alpha s_\alpha = \text{id}$ , (2*)  $s^*_\alpha s^*_\alpha = \text{id}$ ,
(3)  $s_\alpha(\alpha) = -\alpha$ , (3*)  $s^*_\alpha(\alpha^*) = -\alpha^*$ .
```

```

**Remark 1.1.3.** *Axioms (DR I) and (DR II) entail*
```

<!-- label: III.XXI.1.1.3 -->

```

```text
 $R = -R, \quad R^* = -R^*, \quad 0 \notin R, \quad 0 \notin R^*.$
```
```

<!-- original page 87 -->

```

**Lemma 1.1.4.** *The map  $R \rightarrow R^*$  is a bijection. More generally, if  $\alpha, \beta \in R$  and  $(\alpha^*, x) = (\beta^*, x)$  for all
 $x \in R$ , then  $\alpha = \beta$ .*

<!-- label: III.XXI.1.1.4 -->

*Proof.* Indeed, one then has  $s_\beta(\alpha) = \alpha - 2\beta$ ,  $s_\alpha(\beta) = \beta - 2\alpha$ . One deduces
at once
```

```

```text
s_β s_α(α) = 2β - α = α + 2(β - α), s_β s_α(β - α) = s_β(β - α) = β - α,

whence $(s_{\beta} s_{\alpha})^n(\alpha) = \alpha + 2n(\beta - \alpha) \in R$ by (DR II). Since R is finite, one has
$\beta - \alpha = 0$.

Corollary 1.1.5. *The inverse map $R \to R$ defines a root datum*

<!-- label: III.XXI.1.1.5 -->

```text
□* = (M*, M, R*, R)

called the* dual *of $\mathcal{R}$.*[^N.D.E-XXI-2]

**Definition 1.1.6.** *We denote by $\Gamma_0(R)$ the subgroup of $M$ generated by $R$. We denote by $V(R)$ the vector
subspace of $V$ generated by $R$, that is to say $\Gamma_0(R) \otimes \mathbb{Q}$. Applying these definitions to
$\mathcal{R}$, one constructs similarly $\Gamma_0(R^*)$ and $V(R^*)$.*

<!-- label: III.XXI.1.1.6 -->

One calls* reductive rank *of $\mathcal{R}$ the number*

```text
rgred(□) = rank(M) = dim(V) = dim(V*) = rank(M*) = rgred(□*).

One calls* semisimple rank *of $\mathcal{R}$ the number*

```text
rgss(□) = rank(R) = rank(Γ_0(R)) = dim(V(R)).

One thus has $rgss(\mathcal{R}) \leqslant rgred(\mathcal{R})$.

We shall see below that $rgss(\mathcal{R}) = rgss(\mathcal{R}^*)$, that is to say that $V(R)$ and $V(R^*)$ have the same
dimension.*

<!-- original page 88 -->

**Definition 1.1.7.** *One says that $\mathcal{R}$ is* semisimple *(resp.* trivial*) if
$rgss(\mathcal{R}) = rgred(\mathcal{R})$ (resp. $rgss(\mathcal{R}) = 0$). For $\mathcal{R}$ to be trivial it is
therefore necessary and sufficient that $R$ be empty. The trivial root datum of reductive rank zero is denoted
$0 = (\{0\}, \{0\}, \emptyset, \emptyset)$.*

<!-- label: III.XXI.1.1.7 -->

**Definition 1.1.8.** *We denote by $W(\mathcal{R})$ the group of transformations of $M$ generated by the $s_{\alpha}$,
$\alpha \in R$. We call it the* Weyl group *of $\mathcal{R}$. We write*

<!-- label: III.XXI.1.1.8 -->

$W(\mathcal{R}) = W(\mathcal{R}^*)$.

Then $W(\mathcal{R})$ operates on $R$, $\Gamma_0(R)$, $V(R)$, $M$ and $V$. If $w \in W(\mathcal{R})$ and $x \in M$
(resp. $x \in V$), one has $wx - x \in \Gamma_0(R)$ (resp. $wx - x \in V(R)$); this is immediate from formula (1).
Likewise for $W(\mathcal{R}^*)$.

**Lemma 1.1.9.** *For all $\alpha \in R$, $x \in V$, $u \in V^*$, one has*

<!-- label: III.XXI.1.1.9 -->

```

```

```text
(4) (s*_α(u), s_α(x)) = (u, x).
```

*Proof.* Indeed, taking the scalar product of (1) and (1*), one finds that the left-hand side equals
$(u, x) + (u, \alpha)(\alpha^*, x)((\alpha^*, \alpha) - 2) = (u, x)$.

**Remark 1.1.10.** *If one assumes $\alpha \notin R$ and $\alpha^* \notin R^*$, then 1.1.9 is equivalent to (DR I).*

<!-- label: III.XXI.1.1.10 -->

**Corollary 1.1.11.** *Denote by $h \mapsto h^{\vee}$ the isomorphism of $GL(M)$ onto $GL(M^*)$ that associates to $h$
its contragredient. Then formula (4) is also written*

<!-- label: III.XXI.1.1.11 -->

$$
(5)      (s_{\{\alpha\}})^{\vee} = s_{\{\alpha\}}.
$$

**Corollary 1.1.12.** *The preceding isomorphism induces an isomorphism of $W(\mathcal{R})$ onto $W^*(\mathcal{R})$.*

<!-- label: III.XXI.1.1.12 -->

<!-- original page 89 -->

**Scholie 1.1.13.** *By virtue of the preceding result, we shall identify $W$ and $W^*$, and we shall regard $W$ as a
group of transformations of $R$, $R^*$, $M$, $M^*$, $\Gamma_0(R)$, $\Gamma_0(R^*)$, $V$, $V^*$, $V(R)$, $V(R^*)$. We
shall write $s_{\{\alpha\}}$ for $s^*_{\{\alpha\}}$.*

<!-- label: III.XXI.1.1.13 -->

### 1.2. The map $p$

<!-- label: III.XXI.1.2 -->

**Lemma 1.2.1.** *Let $p : M \to M^*$ (resp. $V \to V^*$) be the linear map defined by*

<!-- label: III.XXI.1.2.1 -->

```text
(6) p(x) = $\sum_{u \in R^*}$ (u, x) u.
```

*Write $\ell(x) = (p(x), x)$. One has the following properties:*

```text
(7) $\ell(x) \ge 0$, $\ell(\alpha) > 0$ for $\alpha \in R$.
(8) $\ell(w x) = \ell(x)$, for $w \in W$.
(9) $(p(x), y) = (p(y), x)$, for $x, y \in V$.
(10) $\ell(\alpha) \alpha^* = 2 p(\alpha)$, for $\alpha \in R$.
```

*Proof.* The first three relations are immediate.[^N.D.E-XXI-3] Let us prove the last. By (1), for $u \in V^*$:

```text
(u, α)^2 α^* = (u, α) u - (u, α) s_{α}(u)
 = (u, α) u + (u, s_{α}(α)) s_{α}(u)
 = (u, α) u + (s_{α}(u), α) s_{α}(u) (since $s_{\alpha^2} = id$).
```

```

<!-- original page 90 -->

Since s_{α} is a permutation of R^* (by (DR II)), it remains only to sum over $u \in R^*$ to conclude.

Scholie 1.2.2. Relation (10) says that $\alpha \mapsto \ell(\alpha) \alpha$ is the restriction to R of a linear map from M into M . In particular, one has*

<!-- label: III.XXI.1.2.2 -->

$$(-\alpha)^* = -\alpha^*.$$

Corollary 1.2.3. The map p induces an isomorphism of $V(R)$ onto $V(R)^*$.

<!-- label: III.XXI.1.2.3 -->

Proof. Indeed, p sends $V(R)$ into $V(R)^*$. We thus have

$$\dim(V(R)) \geq \dim(V(R)^*).$$

Applying this inequality to the dual root datum, we deduce

$$\dim(V(R)) = \dim(V(R)^*),$$

so p , being surjective, is also bijective.

Corollary 1.2.4. One has $\dim(V(R)) = \dim(V(R)^*)$, hence*

<!-- label: III.XXI.1.2.4 -->

$$\text{rgs}(\mathcal{R}) = \text{rgs}(\mathcal{R}^*).$$

Corollary 1.2.5. The bilinear form (u, x) is nondegenerate on $V(R^*) \times V(R)$, and so puts these $\mathbb{Q}$ -vector spaces in duality.*

<!-- label: III.XXI.1.2.5 -->

Proof. Indeed, if $(u, x) = 0$ for all $u \in R^*$, then $p(x) = 0$.

Corollary 1.2.6. The symmetric bilinear form $(p(x), y)$ is positive nondegenerate on $V(R)^*$.

<!-- label: III.XXI.1.2.6 -->

<!-- original page 91 -->

Corollary 1.2.7. W operates faithfully on R (and hence on the other sets of 1.1.13).*

<!-- label: III.XXI.1.2.7 -->

Proof. Indeed, let $u \in V^*$. Let $w \in W$; suppose that $w(\alpha) = \alpha$ for all $\alpha \in R$, and let us prove that $w(u) = u$. One has

$$(w(u) - u, \alpha) = (w(u), \alpha) - (u, \alpha) = (u, w^{-1}(\alpha)) - (u, \alpha) = 0.$$

But $w(u) - u \in V(R^*)$. If it is orthogonal to all the roots, it is zero by 1.2.5.

Corollary 1.2.8. The group W is finite.

III.XXI.1.2.8

Proposition 1.2.9. The operations of W respect the correspondence between roots and coroots. In other words, for $\alpha \in R$ and $w \in W$, one has

III.XXI.1.2.9

$$w(\alpha^\vee) = w(\alpha)^\vee.$$

Proof. It suffices to verify this for $w = s_\beta$, $\beta \in R$, that is to say to verify the formula

$$s_\beta(\alpha^\vee) = s_\beta(\alpha)^\vee.$$

Now $\ell(s_\beta(\alpha)) \leq \ell(\alpha) + 1$ equals:

$$p(s_\beta(\alpha)) = \sum_{u \in R^+} (u, s_\beta(\alpha)) u = \sum_{u \in R^+} (s_\beta(u), \alpha) u = \sum_{u \in R^+} (u, \alpha) s_\beta(u) = s_\beta(p(\alpha));$$

since $\ell(s_\beta(\alpha)) = \ell(\alpha)$, one obtains $s_\beta(\alpha)^\vee = s_\beta(\alpha^\vee)$.

original page 92

Corollary 1.2.10. If $\alpha \in R$ and $w \in W$, one has

III.XXI.1.2.10

$$w s_\alpha w^{-1} = s_{w(\alpha)}.$$

Proof. Indeed, $w s_\alpha w^{-1}(x) = x - (w(\alpha), w^{-1}(x)) w(\alpha) = x - (w(\alpha), x) w(\alpha)$, and this last term equals, by 1.2.9:

$$x - (w(\alpha), x) w(\alpha) = s_{w(\alpha)}(x).$$

Corollary 1.2.11. Let $R' \subset R$. For (M, M^*, R', R'^*) to be a root datum, it is necessary and sufficient that $\alpha, \beta \in R'$ imply $s_\alpha(\beta) \in R'$.

III.XXI.1.2.11

2. Relations between two roots

III.XXI.2

2.1. Proportional roots

III.XXI.2.1

Proposition 2.1.1. Let α and β be two roots. The following conditions are equivalent:

III.XXI.2.1.1

- (i) There exists $k \in \mathbb{Q}$ such that $\alpha = k\beta$.
- (ii) $s_\alpha = s_\beta$.

Moreover, under these conditions one has $\alpha^ = k^{-1} \beta^*$, and k is equal to one of the numbers $1, -1, 2, -2, 1/2, -1/2$.*

Proof. Suppose first (i). One has first

$$\alpha^* = \alpha(\alpha)^{-1} \cdot 2 p(\alpha) = k^{-2} \alpha(\beta)^{-1} \cdot 2 k p(\beta) = k^{-1} \beta^*.$$

This entails at once $s_{\alpha} = s_{\beta}$. Conversely, if $s_{\alpha} = s_{\beta}$, then

$$\alpha = s_{\alpha}(-\alpha) = s_{\beta}(-\alpha) = (\beta^*, \alpha) \beta - \alpha,$$

whence $2\alpha = (\beta^*, \alpha)\beta$, with $(\beta^*, \alpha) \in \mathbb{Z}$, so (ii) entails (i). Finally, if $\alpha = k\beta$, then $\alpha^* = k^{-1}\beta^*$, whence

$$(\alpha^*, \beta) = 2k^{-1}, \quad (\beta^*, \alpha) = 2k,$$

so $2k$ and $2k^{-1}$ are integers and we are done.

<!-- original page 93 -->

Application 2.1.2. *The root data $\mathcal{R}$ with $\text{rgss}(\mathcal{R}) = 1$ are of one of the following two types:

<!-- label: III.XXI.2.1.2 -->

(i) *Type A_1 : *there exists $\alpha \in M$ such that the roots are α and $-\alpha$. The coroots are then α^* and $-\alpha^*$.*

(ii) *Type A_1 ': *there exists $\alpha \in M$ such that the roots are $\alpha, -\alpha, 2\alpha, -2\alpha$. The coroots are then $\alpha^*, -\alpha^*, \alpha^*/2, -\alpha^*/2$.*

Definition 2.1.3. *One says that $\alpha \in R$ is* indivisible *if $\alpha/2 \notin R$. One says that $\mathcal{R}$ is* reduced *if every root is indivisible.*

<!-- label: III.XXI.2.1.3 -->

For $\mathcal{R}$ to be reduced it is necessary and sufficient that $\mathcal{R}^$ be so. If α is indivisible and if $w \in W$, then $w(\alpha)$ is indivisible.*

Definition 2.1.4. *Let $\alpha \in R$. If α is indivisible, set $\text{ind}(\alpha) = \alpha$. Otherwise, set $\text{ind}(\alpha) = \alpha/2$.*

<!-- label: III.XXI.2.1.4 -->

Corollary 2.1.5. *If $\alpha \in R$ is indivisible and if $k\alpha \in R$, where $k \in \mathbb{Q}$, then $k \in \mathbb{Z}$.*

<!-- label: III.XXI.2.1.5 -->

Proposition 2.1.6. *Let $\mathcal{R}$ be a root datum. Then*

<!-- label: III.XXI.2.1.6 -->

$$\text{ind}(\square) = (M, M^*, \text{ind}(R), \text{ind}(R)^*)$$

is a reduced root datum, and one has

$W(\text{ind}(\mathcal{R})) = W(\mathcal{R}).$

Proof. Indeed, $\text{ind}(\mathcal{R})$ is a root datum by 1.2.11, since the Weyl group permutes indivisible roots. The second assertion follows from 2.1.1.

<!-- original page 94 -->

Remark 2.1.7. If $\mathcal{R}$ is not reduced, one has $\text{ind}(\mathcal{R}) \neq \text{ind}(\mathcal{R}^*)$ and so $\text{ind}(\mathcal{R}^*) \neq \text{ind}(\mathcal{R})^*$.

<!-- label: III.XXI.2.1.7 -->

2.2. Orthogonal roots

<!-- label: III.XXI.2.2 -->

Lemma 2.2.1. Let α and β be two roots. One has

<!-- label: III.XXI.2.2.1 -->

$$(11) \quad \langle \alpha, \beta^* \rangle = \langle \beta, \alpha^* \rangle.$$

Proof. This follows at once from 1.2.1, formulas (9) and (10).

Corollary 2.2.2. Let $\alpha, \beta \in R$. The following conditions are equivalent:

<!-- label: III.XXI.2.2.2 -->

- (i) $\langle \alpha^*, \beta \rangle = 0$, (i bis) $\langle \beta^*, \alpha \rangle = 0$,
- (ii) $\langle \alpha, \beta^* \rangle = 0$,
- (iii) $s_{\alpha}(\beta) = \beta$, (iii bis) $s_{\beta}(\alpha) = \alpha$,
- (iv) $s_{\alpha}(\beta^*) = \beta^*$, (iv bis) $s_{\beta}(\alpha^*) = \alpha^*$,
- (v) $s_{\alpha} \neq s_{\beta}$ and s_{α} and s_{β} commute.

Proof. All the equivalences are immediate, except those involving (v). Let us show that (i) (and (i bis)) entail (v). One has

$$s_{\alpha} s_{\beta}(x) = x - \langle \beta^*, x \rangle \beta - \langle \alpha^*, x \rangle \alpha + \langle \beta^*, x \rangle \langle \alpha^*, \beta \rangle \alpha.$$

If $\langle \alpha^*, \beta \rangle = 0$, then $\langle \beta^*, \alpha \rangle = 0$ and $s_{\alpha} s_{\beta}(x) = s_{\beta} s_{\alpha}(x)$.

Suppose conversely (v). One has

$$s_{\alpha} = s_{\beta} s_{\alpha} s_{\beta} = s_{\beta(\alpha)} \quad (\text{by 1.2.10}).$$

By 2.1, there exists $k \in \mathbb{Q}$ such that $\alpha = k s_{\beta}(\alpha) = k \alpha - k \langle \beta^*, \alpha \rangle \beta$. Since $s_{\alpha} \neq s_{\beta}$, β and α are not proportional by 2.1.1, hence $\langle \beta^*, \alpha \rangle = 0$.

Definition 2.2.3. Two roots satisfying the equivalent conditions of 2.2.2 are called orthogonal.

<!-- label: III.XXI.2.2.3 -->

<!-- original page 95 -->

Remark 2.2.4. The roots α and β are orthogonal if and only if the coroots α^* and β^* are orthogonal.

`<!-- label: III.XXI.2.2.4 -->`

Lemma 2.2.5. If α and β are two orthogonal roots, then $\alpha + \beta \in R$ if and only if $\alpha - \beta \in R$.

`<!-- label: III.XXI.2.2.5 -->`

Proof. Indeed, $s_{\beta}(\alpha + \beta) = s_{\beta}(\alpha) + s_{\beta}(\beta) = \alpha - \beta$.

Lemma 2.2.6. Let α and β be two non-orthogonal roots. If one defines $\ell(\gamma)$ for a coroot γ as ℓ of the root γ of $\mathcal{R}$, one has the relation

`<!-- label: III.XXI.2.2.6 -->`

$$(12) \quad \ell(\alpha) \ell(\alpha^*) = \ell(\beta) \ell(\beta^*).$$

Proof. Indeed, multiplying formula (11) by the corresponding formula for $\mathcal{R}$, and using the equality $\ell(\gamma)^* = \gamma$ for all $\gamma \in R$, one finds:

$$(\beta^*, \alpha) (\alpha^*, \beta) \ell(\alpha) \ell(\alpha^*) = (\beta^*, \alpha) (\alpha^*, \beta) \ell(\beta) \ell(\beta^*).$$

2.3. General case

`<!-- label: III.XXI.2.3 -->`

Proposition 2.3.1. If α and β are any two roots, one has

`<!-- label: III.XXI.2.3.1 -->`

$$(13) \quad 0 \leqslant (\alpha^*, \beta)(\beta^*, \alpha) \leqslant 4.$$

If α and β are neither proportional nor orthogonal, one has

$$1 \leqslant (\alpha^*, \beta)(\beta^*, \alpha) \leqslant 3.$$

Proof. Indeed, one has $(p(\alpha), \beta)^2 = \ell(\alpha) \ell(\beta) (\alpha^*, \beta)(\beta^*, \alpha)$. On the other hand, by 1.2.6 the symmetric bilinear form $(p(x), y)$ is positive nondegenerate on $V(R)$, whence $(p(x), y)^2 \leqslant \ell(x) \ell(y)$. [N.D.E-XXI-4]

`<!-- original page 96 -->`

Corollary 2.3.2. Let α and β be two non-orthogonal roots. If $\ell(\alpha) = \ell(\beta)$, there exists $w \in W$ such that $w(\alpha) = \beta$.

`<!-- label: III.XXI.2.3.2 -->`

Proof. Indeed, if α and β are proportional, then since $\ell(\alpha) = \ell(\beta)$, one has $\alpha = \beta$ or $\alpha = -\beta$; in this case one takes $w = 1$ or $w = s_{\alpha}$. If α and β are neither proportional nor orthogonal, then by formula (11) and 2.3.1:

$$(\beta^*, \alpha) = (\alpha^*, \beta) = \pm 1.$$

If $(\beta^*, \alpha) = (\alpha^*, \beta) = 1$, one takes $w = s_{\beta} s_{\alpha} s_{\beta}$. If $(\beta^*, \alpha) = (\alpha^*, \beta) = -1$, one takes $w = s_{\alpha} s_{\beta}$.

Corollary 2.3.3. *If α and β are two roots, if $\alpha \neq \beta$ and $(\beta^*, \alpha) > 0$ (resp. if $\alpha \neq -\beta$ and $(\beta^*, \alpha) < 0$), then $\alpha - \beta$ (resp. $\alpha + \beta$) is a root.*

<!-- label: III.XXI.2.3.3 -->

Proof. The second case is deduced from the first by changing β into $-\beta$. If α and β are proportional and $(\beta^*, \alpha) > 0$, then $\beta = \alpha$, $2\beta = \alpha$, or $\beta = 2\alpha$. The first case is excluded. In the others, one has respectively $\alpha - \beta = \beta \in R$ or $\alpha - \beta = -\alpha \in R$. If α and β are not proportional, (α^*, β) and (β^*, α) are two strictly positive integers whose product is at most 3. One of them is therefore equal to 1. If $(\beta^*, \alpha) = 1$, one has $\alpha - \beta = s_{\beta}(\alpha) \in R$; if $(\alpha^*, \beta) = 1$, one has $\alpha - \beta = -s_{\alpha}(\beta) \in R$.

Lemma 2.3.4. *Let α and β be two non-proportional roots. If $\beta - \alpha$ is not a root, then $\beta + k\alpha \in R$ for $k = -(\alpha^*, \beta)$, but not for $k = -(\alpha^*, \beta) + 1$.*

<!-- label: III.XXI.2.3.4 -->

Proof. Indeed, $\beta - (\alpha^*, \beta)\alpha = s_{\alpha}(\beta) \in R$, but $\beta + (-(\alpha^*, \beta) + 1)\alpha = s_{\alpha}(\beta - \alpha) \notin R$.

Proposition 2.3.5. *Let α and β be two non-proportional roots. The set of integers k such that $\beta + k\alpha \in R$ is an interval $[p, q]$ ($p \leq 0$, $q \geq 0$), and one has $p + q = -(\alpha^*, \beta)$.*

<!-- label: III.XXI.2.3.5 -->

<!-- original page 97 -->

Proof. For the first assertion it suffices, for example, to prove that if $\beta + k\alpha \in R$, k integer > 0 , then $\beta + (k - 1)\alpha \in R$. If $k = 1$, this is trivial. If $k \geq 2$, one has

$$(\alpha^*, \beta + k\alpha) = (\alpha^*, \beta) + 2k \geq -3 + 4 > 0,$$

and one concludes by 2.3.3. Let then $[p, q]$ be the interval in question. Applying 2.3.4 to $\beta + p\alpha$, one finds

$$q - p = -(\alpha^*, \beta + p\alpha) = -(\alpha^*, \beta) - 2p.$$

[^N.D.E-XXI-5]

Remark 2.3.6. *The previous formula contains the qualitative statements 2.2.5 and 2.3.3.*

<!-- label: III.XXI.2.3.6 -->

Complements 2.3.7. [^N.D.E-XXI-6] *By 1.2.1 (9) and 1.2.6, the bilinear form on $V(R)$ defined by*

<!-- label: III.XXI.2.3.7 -->

$$(x, y) = (p(x), y)$$

is symmetric and positive definite. By 1.2.1 (10), for any $\alpha \in R$ and $y \in V(R)$,

$$(\alpha, y) = (\alpha/2)(\alpha^*, y),$$

```

'''
*where  $\ell(\alpha) = \langle \alpha, \alpha \rangle$ . Consequently, one deduces from 2.3.3 the following corollary.*

**Corollary.** *Let  $\alpha \neq \beta$  in  $R$ . If  $\alpha - \beta \notin R$ , then  $\langle \alpha, \beta \rangle \leq 0$ .*

## 3. Simple roots, positive roots

<!-- label: III.XXI.3 -->

### 3.1. Systems of simple roots

<!-- label: III.XXI.3.1 -->

**Lemma 3.1.1.** *Let  $\alpha$  and  $\alpha_i$ ,  $i = 1, \dots, n$ , be roots. Assume  $\alpha$  is distinct from the  $\alpha_i$ . If one has a relation*

<!-- label: III.XXI.3.1.1 -->

'''text
 $\alpha = \sum_i q_i \alpha_i, \quad q_i \in \mathbb{Q}_+,$ 
'''

*there exists an index  $i$  such that  $q_i \neq 0$ ,  $\langle \alpha, \alpha_i \rangle > 0$ , and  $\alpha - \alpha_i \in R$ .*

*Proof.* Indeed, one writes  $2 = \langle \alpha, \alpha \rangle = \sum_i q_i \langle \alpha, \alpha_i \rangle$ , which proves the first two assertions. The third then follows from 2.3.3.

**Proposition 3.1.2.** *Let  $\alpha$  and  $\alpha_i$ ,  $i = 1, \dots, n$ , be roots. If*

<!-- label: III.XXI.3.1.2 -->

'''text
 $\alpha = \sum_i m_i \alpha_i, \quad m_i \in \mathbb{N}_+,$ 
'''

<!-- original page 98 -->

*there exists a sequence  $\beta_1, \dots, \beta_m$  of roots taken from the  $\alpha_i$  (not necessarily pairwise distinct) such that if one denotes*

'''text
 $\gamma_p = \sum_{i=1}^p \beta_i, \quad p = 1, \dots, m,$ 
'''

*one has  $\gamma_p \in R$  and  $\gamma_m = \alpha$ .*

*Proof.* We argue by induction on the integer  $\sum m_i = m$ . If  $\alpha$  equals one of the  $\alpha_i$ , say  $\alpha_{i_0}$  (which is automatic if  $m = 1$ ), one takes  $m = 1$ ,  $\beta_1 = \alpha_{i_0}$ . Otherwise, one applies the previous lemma and there exists an index  $i$  such that  $m_i \neq 0$  and  $\alpha - \alpha_i$  is a root. One then has  $(m_i - 1) \in \mathbb{N}$  and

'''text
 $\alpha - \alpha_i = (m_i - 1) \alpha_i + \sum_{j \neq i} m_j \alpha_j.$ 
'''

It remains only to apply the induction hypothesis to  $\alpha - \alpha_i$ .

**Corollary 3.1.3.** *Let  $R' \subset R$ . The following conditions are equivalent:*

<!-- label: III.XXI.3.1.3 -->

*(i) If  $\alpha, \beta \in R'$  and  $\alpha + \beta \in R$ , then  $\alpha + \beta \in R'$ .*

```

(ii) $(\mathbb{N} \cdot R) \cap R \subset R$.

Proof. Indeed, one has clearly (ii) $\Rightarrow$ (i). The converse follows at once from the proposition.

Definition 3.1.4. A set of roots satisfying the conditions of 3.1.3 is called closed.

<!-- label: III.XXI.3.1.4 -->

Proposition 3.1.5. Let $\Delta \subset R$ be a set of roots. The following conditions are equivalent:

<!-- label: III.XXI.3.1.5 -->

(i) The elements of Δ are indivisible, linearly independent, and

<!-- original page 99 -->

``text
 $R \subset (Q_+ \cdot \Delta) \cup (-Q_+ \cdot \Delta)$.
 ``

(ii) The elements of Δ are linearly independent and

``text
 $R \subset (\mathbb{N} \cdot \Delta) \cup (-\mathbb{N} \cdot \Delta)$.
 ``

(iii) Every root is written in a unique way as a linear combination of the elements of Δ , with integer coefficients all of the same sign.*

[N.D.E-XXI-7] One has obviously (ii) $\Rightarrow$ (iii). Denote by $\alpha_1, \dots, \alpha_n$ the (distinct) elements of Δ .

Proof of (i) $\Rightarrow$ (ii). Let $\alpha \in R$. One has thus a unique expression

``text
 $\alpha = \sum_i q_i \alpha_i \quad q_i \in Q_+, \varepsilon = \pm 1$.
 ``

Let us show that the q_i are integers. This is certainly true if all but one of them are zero (cf. 2.1.5). Otherwise, α is distinct from the α_i and, applying 3.1.1, one finds i_0 such that $\alpha' = \varepsilon \alpha - \alpha_{i_0} \in R$ and $q_{i_0} \neq 0$. This gives

``text
 $\alpha' = (q_{i_0} - 1) \alpha_{i_0} + \sum_{i \neq i_0} q_i \alpha_i$.
 ``

<!-- original page 100 -->

Since at least one of the q_i , $i \neq i_0$, is nonzero, (i) entails $q_{i_0} - 1 \geq 0$. One repeats the operation for α' and after finitely many steps one has shown that the q_i are integers.

Proof of (iii) $\Rightarrow$ (i). Let us show that $\alpha_1, \alpha_2, \dots, \alpha_n$ are linearly independent over $\mathbb{Q}$. In the contrary case, one would have an equality

``text
 $x = \sum_{i \in I} a_i \alpha_i = \sum_{j \in J} b_j \alpha_j$,
 ``

where I, J are two disjoint subsets of $\{1, \dots, n\}$, at least one of them, say I , being nonempty, and $a_i, b_j \in \mathbb{N}$. By Corollary 2.3.7, one has $\langle \alpha_i, \alpha_j \rangle \leq 0$ if $i \in I$ and $j \in J$, whence $\langle x, x \rangle \leq 0$ and so $x = 0$. Let $i_0 \in I$; then the equalities

``text
 $\alpha_{i_0} = \alpha_{i_0} + \sum_{i \in I} a_i \alpha_i = \alpha_{i_0} + \sum_{j \in J} b_j \alpha_j$
 ``

entail (by (iii)) $a_i = 0 = b_j$ for all i, j , a contradiction. This shows that the elements of Δ are linearly independent over $\mathbb{Q}$; let us show they are also indivisible.

So let $\beta \in \Delta$ be divisible. One has $\beta/2 \in R$, whence

$$\beta/2 = \sum_{\alpha \in \Delta} m_\alpha \alpha, \quad m_\alpha \in \mathbb{N}, \quad \varepsilon = \pm 1,$$

so also $\beta = 2 \sum_{\alpha \in \Delta} m_\alpha \alpha$, whence by uniqueness $m_\alpha = 0$ if $\alpha \neq \beta$ and $2 m_\beta = 1$, a contradiction.

Definition 3.1.6. A set Δ of roots satisfying the conditions of 3.1.5 is called a system of simple roots, or a base of R .

III.XXI.3.1.6 -->

If $w \in W$ and if Δ is a system of simple roots, then $w(\Delta)$ is a system of simple roots.

Remark 3.1.7. This definition involves only R and not $\mathcal{R}$, and in fact involves only $\text{ind}(R)$.

III.XXI.3.1.7 -->

Remark 3.1.8. If Δ is a system of simple roots, Δ is a basis of the free abelian group $\Gamma_0(R)$. One has thus $\text{Card}(\Delta) = \text{rgss}(\mathcal{R})$.

III.XXI.3.1.8 -->

Remark 3.1.9. The conditions of 3.1.5 are then evidently equivalent to:

III.XXI.3.1.9 -->

(i') The elements of Δ are indivisible, of number $\leq \text{rgss}(\mathcal{R})$, and $R \subset (Q_+ \cdot \Delta) \cup (-Q_+ \cdot \Delta)$.

(ii') $\text{Card}(\Delta) \leq \text{rgss}(\mathcal{R})$ and $R \subset (\mathbb{N} \cdot \Delta) \cup (-\mathbb{N} \cdot \Delta)$.

original page 101 -->

Corollary 3.1.10. If Δ is a system of simple roots, then $\text{ind}(\Delta)$ is a system of simple coroots (i.e. a system of simple roots of $\mathcal{R}^*$).

III.XXI.3.1.10 -->

Proof. Indeed, if $\beta = \sum_{\alpha \in \Delta} a_\alpha \alpha$ ($a_\alpha \in \mathbb{N}$), then $p(\beta) = \sum_{\alpha \in \Delta} a_\alpha p(\alpha)$, whence, by 1.2.1 (10):

$$\beta^* = \sum_{\alpha \in \Delta} a_\alpha \left(\frac{\alpha}{\langle \alpha \rangle} \right)^*,$$

which shows that $\text{ind}(\Delta^*)$ satisfies (i').

[^N.D.E-XXI-8] By 2.1.1, if α^* is not indivisible, then $\alpha^* = 2 u^*$, where $u^* \in \text{ind}(\Delta^*)$ (and $u = 2\alpha$). One deduces:

Corollary 3.1.11. If Δ is a system of simple roots and if $\beta = \sum_{\alpha \in \Delta} a_\alpha \alpha$ ($a_\alpha \in \mathbb{Z}$) is the expression of β along Δ , then $2 a_\alpha \ell(\alpha)$ is divisible by $\ell(\beta)$ (and even by $2 \ell(\beta)$ if α^* is indivisible).

III.XXI.3.1.11 -->

Before continuing to state the properties of systems of simple roots, let us show that such systems exist.

3.2. Systems of positive roots

<!-- label: III.XXI.3.2 -->

Definition 3.2.1. A subset $R_+ \subset R$ is called a system of positive roots of R (or of $\mathcal{R}$, cf. Remark 3.2.2) if it satisfies the following conditions:

<!-- label: III.XXI.3.2.1 -->

(P 1) $R_+ \cap -R_+ = \emptyset$.

(P 2) $R_+ \cup -R_+ = R$.

(P 3) $(Q_+ \cdot R_+) \cap R \subset R_+$.

In particular, such a set is closed. We shall see later (3.3.8) that in fact a closed subset satisfying (P 1) and (P 2) also satisfies (P 3), and hence is a system of positive roots. If $w \in W$ and if R_+ is a system of positive roots, then $w(R_+)$ is a system of positive roots.

<!-- original page 102 -->

Remark 3.2.2. This definition involves only R . One will also say that R_+ is a system of positive roots of $\mathcal{R}$.

<!-- label: III.XXI.3.2.2 -->

Remark 3.2.3. From (P 1) and (P 2), one obtains at once

<!-- label: III.XXI.3.2.3 -->

$$\begin{aligned} \text{Card}(R_+) &= \text{Card}(R)/2. \end{aligned}$$

It follows that if R_+ and R'_+ are two systems of positive roots with $R_+ \subset R'_+$, then $R_+ = R'_+$.

Remark 3.2.4. If R_+ is a system of positive roots, R^*_+ is a system of positive coroots (i.e. a system of positive roots of $\mathcal{R}^*$).

<!-- label: III.XXI.3.2.4 -->

This follows at once from 1.1.4 and 1.2.2.

Definition 3.2.5. Let Δ be a system of simple roots. Set

<!-- label: III.XXI.3.2.5 -->

$$P(\Delta) = (Q_+ \cdot \Delta) \cap R = (\mathbb{N}_+ \cdot \Delta) \cap R.$$

Proposition 3.2.6. If Δ is a system of simple roots, $P(\Delta)$ is a system of positive roots. If Δ is a system of simple roots and R_+ is a system of positive roots, one has the equivalence:

<!-- label: III.XXI.3.2.6 -->

$$\Delta \subset R_+ \iff R_+ = P(\Delta).$$

Proof. The first assertion is immediate. If $\Delta \subset R_+$, then $P(\Delta) \subset R_+$ by (P 3), so $P(\Delta) = R_+$ by 3.2.3. The rest is trivial.

Remark 3.2.7. Systems of positive roots exist: let $\mathfrak{g}$ be a structure of totally ordered vector space on $V(R)$. The set of roots θ for this order relation is a system of positive roots.

!-- label: III.XXI.3.2.7 -->

!-- original page 103 -->

Theorem 3.2.8. Let R_+ be a system of positive roots. There exists a unique system of simple roots S such that $\mathcal{S}(R_+) \subset R_+$, i.e. such that $R_+ = P(\mathcal{S}(R_+))$.

!-- label: III.XXI.3.2.8 -->

Proof. Uniqueness follows at once from:

Lemma 3.2.9. Let Δ be a system of simple roots. Then for $\alpha \in P(\Delta)$ to belong to Δ , it is necessary and sufficient that α not be a sum of two elements of $P(\Delta)$.

!-- label: III.XXI.3.2.9 -->

Proof. This lemma follows at once from the definitions and from 3.1.2.

Let us now prove the existence of $\mathcal{S}(R_+)$. Consider the set of subsets T of R_+ such that $T = \text{ind}(T)$ and $(Q_+ \cdot T) \supset R_+$. This set is nonempty, since it contains $\text{ind}(R_+)$. Let Δ be a minimal element of this set for the inclusion relation. We show that Δ is a system of simple roots, that is to say, by 3.1.5 (i), that Δ is a free subset of $M \otimes \mathbb{Q}$.

Lemma 3.2.10. If $\alpha, \beta \in \Delta$ and $q\alpha + q'\beta \in R$, where $q, q' \in \mathbb{Q}$, then $q, q' \geq 0$.

!-- label: III.XXI.3.2.10 -->

Proof. Indeed, if $q, q' < 0$, one can write (possibly exchanging α and β)

$$\alpha - \beta \in R_+, \quad \alpha, \beta \in Q_+,$$

so by hypothesis there exists a relation

$$\alpha - \beta = \sum_{\gamma \in \Delta} c(\gamma) \gamma, \quad c(\gamma) \in Q_+.$$

If $a \leq c(\alpha)$, it is written

$$-\beta = ((c(\alpha) - a)/b) \alpha + \sum_{\gamma \neq \alpha} (c(\gamma)/b) \gamma.$$

Then this element belongs to $(Q_+ \cdot \Delta) \cap R$, which is contained in R_+ by (P 3). But then $\beta \in R_+ \cap -R_+$, which contradicts (P 1).

If, on the contrary, $a > c(\alpha)$, one writes

$$(a - c(\alpha)) \alpha = b \beta + \sum_{\gamma \neq \alpha} c(\gamma) \gamma,$$

!-- original page 104 -->

which proves $\Delta \subset Q_+ \cdot (\Delta - \{\alpha\})$, contrary to the minimal character of Δ .

Recall (cf. 2.3.7) that the bilinear form on $V(R)$ defined by $\langle x, y \rangle = (p(x), y)$ is a Euclidean inner product; moreover, for $\alpha \in R$ one has $\langle \alpha, y \rangle = \ell(\alpha) (\alpha^*, y) / 2$, so that

$\langle \alpha, y \rangle$ and $\langle \alpha^*, y \rangle$ have the same sign.

Lemma 3.2.11. *If $\alpha, \beta \in \Delta$, then $\langle \beta^*, \alpha \rangle \leq 0$ and so $\langle \beta, \alpha \rangle \leq 0$.*

<!-- label: III.XXI.3.2.11 -->

Proof. *Indeed, $s_{\beta}(\alpha) = \alpha - \langle \beta^*, \alpha \rangle \beta \in R$, whence $\langle \beta^*, \alpha \rangle \leq 0$ by 3.2.10.*

Let us now prove that Δ is free. In the contrary case, 3.2.11 entails, as in the proof of 3.1.5, the existence of a non-trivial relation

$$\sum_{\alpha \in \Delta} m(\alpha) \alpha = 0, \quad m(\alpha) \in \mathbb{N},$$

whence $-\alpha_0 = (m(\alpha_0) - 1) \alpha_0 + \sum_{\alpha \neq \alpha_0} m(\alpha) \alpha$, if $m(\alpha_0) \geq 1$. Then, by (P 3), α_0 belongs to $R_+ \cap -R_+$, contradicting (P 1).

This shows that Δ is a base of $\mathcal{R}$ and completes the proof of Theorem 3.2.8.

Corollary 3.2.12. *Let R_+ be a system of positive roots, Δ a base of $\mathcal{R}$, and $w \in W$. One has:*

<!-- label: III.XXI.3.2.12 -->

$$\begin{aligned} \Delta \subset R_+ \quad \square \quad R_+ = P(\Delta) \quad \square \quad \Delta = \square(R_+) \\ P(\text{ind}(\Delta^*)) = P(\Delta)^*, \quad \square(R_+^*) = \text{ind}(\square(R_+)^*); \\ \square(w(R_+)) = w(\square(R_+)), \quad P(w(\Delta)) = w(P(\Delta)). \end{aligned}$$

<!-- original page 105 -->

Definition 3.2.13. *If one has chosen a system of simple roots Δ , the elements of $P(\Delta)$ will be called* positive. *If one has chosen a system of positive roots R_+ , the elements of $\mathcal{S}(R_+)$ will be called* simple.

<!-- label: III.XXI.3.2.13 -->

Corollary 3.2.14. *Let R_+ be a system of positive roots. Let $\alpha \in R_+$. The following conditions are equivalent:*

<!-- label: III.XXI.3.2.14 -->

- *(i) α is simple (i.e. $\alpha \in \mathcal{S}(R_+)$).*
- *(ii) α is not a sum of two elements of R_+ .*
- *(iii) $R_+ - \{\alpha\}$ is closed (cf. 3.1.4).*

Proof. *The equivalence of (i) and (ii) follows at once from 3.2.9. The equivalence of (ii) and (iii) is immediate.*

Definition 3.2.15. *Let Δ be a system of simple roots. The sum of the coefficients of the decomposition of a root α along Δ is called the* order of α *relative to Δ and is denoted $\text{ord}_{\Delta}(\alpha)$.*

<!-- label: III.XXI.3.2.15 -->

One has the equivalences:

```text

$\alpha \in P(\Delta) \implies \text{ord}_\Delta(\alpha) > 0, \quad \alpha \in \Delta \implies \text{ord}_\Delta(\alpha) = 1.$

<!-- original page 106 -->

**Lemma 3.2.16.** \*Let  $\Delta$  be a system of simple roots and  $\alpha \in P(\Delta)$ . There exists a sequence  $\alpha_i \in \Delta, i = 1, \dots, m$ , such that\*

<!-- label: III.XXI.3.2.16 -->

```text  
 $\alpha_1 + \alpha_2 + \dots + \alpha_p \in P(\Delta) \quad \text{for } p = 1, \dots, m,$
 $\alpha_1 + \alpha_2 + \dots + \alpha_m = \alpha.$
 ```

\*Moreover, for every such sequence  $\alpha_i$ , one has  $m = \text{ord}_\Delta(\alpha)$ .\*

\*Proof.\* Trivial by 3.1.2.

### 3.3. Characterization and conjugacy of systems of positive roots

<!-- label: III.XXI.3.3 -->

**Lemma 3.3.1.** \*If  $\alpha \in P(\Delta)$ ,  $\beta \in \Delta$ , and if  $\alpha$  and  $\beta$  are not proportional, then  $s_\beta(\alpha) \in P(\Delta)$ .\*

<!-- label: III.XXI.3.3.1 -->

\*Proof.\* Indeed,  $s_\beta(\alpha) = \alpha - (\beta^*, \alpha) \beta$ . Since at least one simple root other than  $\beta$  appears in the decomposition of  $\alpha$  with a nonzero (hence strictly positive) coefficient, it also appears in the decomposition of  $s_\beta(\alpha)$  with the same coefficient, so  $s_\beta(\alpha)$  is also positive.

**Corollary 3.3.2.** \*If  $\beta \in \Delta$ , the symmetry  $s_\beta$  interchanges the elements of  $P(\Delta)$  not proportional to  $\beta$ .\*

<!-- label: III.XXI.3.3.2 -->

**Lemma 3.3.3.** \*If  $\alpha \in P(\Delta) - \Delta$ ,  $\alpha$  indivisible, there exists  $\beta \in \Delta$  such that  $s_\beta(\alpha) \in P(\Delta)$  and  $\text{ord}_\Delta(s_\beta(\alpha)) < \text{ord}_\Delta(\alpha)$ .\*

<!-- label: III.XXI.3.3.3 -->

\*Proof.\* Indeed, by 3.1.1 there exists  $\beta \in \Delta$  such that  $(\beta^*, \alpha) > 0$ . Since  $\alpha \notin \Delta$  and is indivisible,  $\alpha$  cannot be proportional to  $\beta$ . Hence  $s_\beta(\alpha) \in P(\Delta)$ , by 3.3.1, and one has  $\text{ord}_\Delta(s_\beta(\alpha)) = \text{ord}_\Delta(\alpha) - (\beta^*, \alpha) < \text{ord}_\Delta(\alpha)$ .

**Corollary 3.3.4.** \*If  $\alpha \in P(\Delta)$  is indivisible, there exists a sequence  $\beta_p \in \Delta, p = 1, \dots, q$ , such that\*

<!-- label: III.XXI.3.3.4 -->

```text  
 $\alpha = s_{\beta_p} \dots s_{\beta_1}(\alpha) \in P(\Delta) \quad \text{for } p = 1, \dots, q,$
 ```

\*and  $\alpha_q \in \Delta$ .\*

\*Proof.\* This follows from 3.3.3 by induction on  $\text{ord}_\Delta(\alpha)$ .

**Proposition 3.3.5.** \*The Weyl group is generated by the  $s_\alpha$ , for  $\alpha \in \Delta$ . Every indivisible root is conjugate to a simple root by an element of the Weyl group.\*

<!-- label: III.XXI.3.3.5 -->

<!-- original page 107 -->

\*Proof.\* The second assertion follows at once from 3.3.4. The first follows from it by 1.2.10 and 2.1.1.

**Proposition 3.3.6.** \*Let  $R_+$  be a system of positive roots. Let  $P' \subset R$  satisfy (P 2) and be closed. Then there exists  $w \in W$  such that  $w(R_+) \subset P'$ .\*

Let us state the corollaries at once.

**Corollary 3.3.7.** \*The Weyl group operates transitively on the set of systems of positive roots (resp. of systems of simple roots).\*

**Corollary 3.3.8.** \*For a subset of  $R$  to be a system of positive roots, it is necessary and sufficient that it satisfy (P 1) and (P 2) and be closed.\*

**Corollary 3.3.9.** \*If one endows  $\Gamma(R)$  with a structure of ordered group such that every root is  $> 0$  or  $< 0$ , the set of positive roots for this order structure is a system of positive roots.\*

\*Proof of 3.3.6.\* One can find  $w \in W$  such that  $\text{Card}(w(R_+) \cap P')$  is maximal, hence by replacing  $R_+$  by  $w(R_+)$  one may assume that

$$\text{Card}(R_+ \cap P') \geq \text{Card}(R_+ \cap s_{\alpha}(P'))$$

for all  $\alpha \in \mathcal{S}(R_+) = \Delta$ . Let us show that  $R_+ \subset P'$ . Otherwise,  $P'$  being closed, there exists  $\alpha \in \Delta$ ,  $\alpha \notin P'$ . But  $P'$  satisfying (P 2), one has then  $-\alpha \in P'$  (so  $-2\alpha \in P'$  if  $2\alpha$  is a root). For every  $\beta \in R_+ \cap P'$ , one has  $\beta \neq \alpha$ ; if  $2\alpha$  is not a root, then  $s_{\alpha}(\beta) \in R_+ \cap P'$  (by 3.3.1), so

$$s_{\alpha}(R_+ \cap P') \subset R_+ \cap s_{\alpha}(P');$$

but  $R_+ \cap s_{\alpha}(P')$  also contains  $\alpha = s_{\alpha}(-\alpha)$ , contradicting inequality (\*). If  $2\alpha$  is a root, one argues similarly.

To study sets of roots satisfying (P 2) and closed, one is therefore reduced to the case where they contain a set of positive roots.

**Proposition 3.3.10.** \*Let  $R_+$  be a system of positive roots and  $P'$  a closed subset of  $R$  containing  $R_+$ . If one denotes  $\Delta = \mathcal{S}(R_+)$  and  $\Delta' = \Delta \cap -P'$ , then  $P'$  is the union of  $R_+$  and the set of roots that are linear combinations with negative coefficients of the elements of  $\Delta'$ .\*

\*Proof.\* We prove the assertion by induction on the order of a root  $\gamma \in P' - R_+$ . If  $\text{ord}_{\Delta}(\gamma) = -1$ , then  $-\gamma \in \Delta$  and  $\gamma \in -\Delta'$ . If  $\text{ord}_{\Delta}(\gamma) < -1$ , there exists, by 3.1.2,  $\beta \in \Delta$  such that  $-\gamma = \beta - \gamma_1$  with  $\gamma_1 \in R$ ; then

$$0 < \text{ord}_{\Delta}(-\gamma - \beta) = \text{ord}_{\Delta}(-\gamma) - 1 < \text{ord}_{\Delta}(-\gamma)$$

and the first inequality shows that  $-\gamma - \beta \in R_+$ . Hence, since  $R_+ \cap -R_+ = \emptyset$  and  $\gamma + \beta$  is a sum of two roots of  $P'$ , it is an element of  $P' - R_+$  with

$\text{ord}_{\{\Delta\}(\gamma + \beta)} > \text{ord}_{\{\Delta\}(\gamma)}$ . So, by the induction hypothesis,  $\gamma + \beta$  is a linear combination with negative coefficients of the elements of  $\Delta'$ . Since  $\gamma = (\gamma + \beta) - \beta$ , it suffices to verify that  $\beta \in -P'$ . Now  $\gamma \in P'$  and  $-(\gamma + \beta) \in R_{\{+\}} \subset P'$ , so  $-\beta = \gamma - (\gamma + \beta)$  belongs to  $P'$ .

**Definition 3.3.10.1.** [N.D.E-XXI-9] One says that a subset  $R'$  of  $R$  is symmetric if  $-R' = R'$ .

III.XXI.3.3.10.1 -->

**Scholie 3.3.11.** Let  $P'$  be a set of roots satisfying (P 2) and closed. There exists a system of simple roots  $\Delta$  and a subset  $\Delta'$  of  $\Delta$  such that

III.XXI.3.3.11 -->

```text  
 $P' = R \cap (\mathbb{N} \cdot \Delta \cup -\mathbb{N} \cdot \Delta')$.
 ```

If one denotes  $R_{\{\Delta'\}} = (\mathbb{Z} \cdot \Delta') \cap R$ , which is a closed and symmetric subset of  $R$ , then  $P'$  is the disjoint union of  $R_{\{\Delta'\}}$  and of the closed part of  $P(\Delta)$  formed by the  $\alpha \in P(\Delta) - \mathbb{N} \cdot \Delta'$ , i.e. the positive roots which in the decomposition along  $\Delta$  contain at least one root of  $\Delta - \Delta'$ .

### 3.4. Closed and symmetric sets of roots

III.XXI.3.4 -->

**Proposition 3.4.1.** Let  $\mathcal{R} = (M, M^*, R, R')$  be a root datum and  $R'$  a closed and symmetric subset of  $R$ . Then:

III.XXI.3.4.1 -->

(i)  $\mathcal{R}' = (M, M^*, R', R'^*)$  is a root datum;

original page 109 -->

(ii) for every system of positive roots  $R_{\{+\}}$  of  $R$ ,  $R'_{\{+\}} = R_{\{+\}} \cap R'$  is a system of positive roots of  $R'$ ;

(iii) the Weyl group  $W(\mathcal{R}')$  of  $\mathcal{R}'$  is the subgroup of  $W(\mathcal{R})$  generated by the  $s_{\alpha}$ , for  $\alpha \in R'$ .

**Proof.** The first assertion is trivial by 1.2.11, the second follows from 3.3.8, the third is evident.

**Corollary 3.4.2.** Let  $w \in W(\mathcal{R}')$ . The order of  $w$  is the smallest integer  $n > 0$  such that  $w^n(\alpha') = \alpha'$  for every  $\alpha' \in R'$ .

III.XXI.3.4.2 -->

**Proof.** It suffices to apply 1.2.7 to the root datum  $\mathcal{R}'$ .

**Corollary 3.4.3.** Let  $\alpha$  and  $\beta$  be two non-proportional roots. Let  $n$  be the smallest integer  $> 0$  such that  $(s_{\alpha} s_{\beta})^n(\alpha) = \alpha$  and  $(s_{\alpha} s_{\beta})^n(\beta) = \beta$ . Then the subgroup  $W_{\{\alpha, \beta\}}$  of  $W$  generated by  $s_{\alpha}$  and  $s_{\beta}$  is defined by the relations:

III.XXI.3.4.3 -->

```text  
 $s_{\alpha}^2 = 1, \quad s_{\beta}^2 = 1, \quad (s_{\alpha} s_{\beta})^n = 1.$
 ```

**Proof.** Taking 3.4.2 into account, it suffices to verify:

**Lemma 3.4.4.** Let  $G$  be the group generated by two elements  $x$  and  $y$  subject to the relations  $x^2 = y^2 = 1$ . Every normal subgroup of  $G$  containing neither  $x$  nor  $y$  is generated (as a normal subgroup) by

an element of the form  $(xy)^n$ , where  $n > 0$ .

<!-- label: III.XXI.3.4.4 -->

[^N.D.E-XXI-10] \*Proof.\* Indeed, every element of  $G$  is written  $(xy)^n$ , or  $(yx)^n = (xy)^{-n}$ , or:

```

```text
(a)   x (yx)^{2n}    or    y (xy)^{2n+1}

(b)   y (xy)^{2n}    or    x (yx)^{2n+1},
```

```

where  $n \in \mathbb{N}$ . Now the elements of type (a) (resp. (b)) are conjugate to  $x$  (resp. to  $y$ ).

**Remark 3.4.5.** One computes the integer  $n$  immediately: if one sets

<!-- label: III.XXI.3.4.5 -->

```

```text
(α*, β) = p,    (β*, α) = q,
```

```

<!-- original page 110 -->

one has[^N.D.E-XXI-11]

```

```text
(s_α s_β)(α) = (pq - 1) α - q β,    (s_α s_β)(β) = p α - β.
```

```

The integer  $n$  is therefore the order of the matrix

```

```text
(pq - 1  p)
(-q    -1).
```

```

If  $pq = 0$ , then  $p = q = 0$ , by 2.2.2, whence  $n = 2$ . Otherwise, by 2.3.1,  $pq$  equals  $1$ ,  $2$ , or  $3$ , and one finds, respectively,  $n = 3$ ,  $4$ , or  $6$ .

N.B. By writing that the order of the previous matrix is finite, one recovers inequality (13) of 2.3.1.

**Definition 3.4.6.** Let  $\Delta$  be a system of simple roots and  $\Delta' \subset \Delta$ . We write

<!-- label: III.XXI.3.4.6 -->

```

```text
R_{Δ'} = R ∩ (Q · Δ') = R ∩ (Z · Δ').
```

```

**Lemma 3.4.7.**  $R_{\Delta'}$  is closed and symmetric,  $\Delta'$  is a system of simple roots of the root datum  $(M, M^*, R_{\Delta'}, R_{\Delta'}^*)$ , whose Weyl group is the subgroup  $W_{\Delta'}$  of  $W$  generated by the  $s_{\alpha}$ , for  $\alpha \in \Delta'$ . One has  $\Delta \cap R_{\Delta'} = \Delta'$ .

<!-- label: III.XXI.3.4.7 -->

**Proof.** Trivial.

**Proposition 3.4.8.** Let  $R' \subset R$ . The following conditions are equivalent:

<!-- label: III.XXI.3.4.8 -->

(i) There exists a vector subspace  $V'$  of  $V$  (or of  $V(R)$ ) such that  $R' = R \cap V'$ .

(ii) There exists a system of simple roots  $\Delta'$  of  $R$  and a subset  $\Delta'$  of  $\Delta$  such that

$R' = R_{\{\Delta\}}.$

\*More precisely, under these conditions, every system of simple roots  $\Delta'$  of  $(M, M^*, R', R'^*)$  is contained in a system of simple roots  $\Delta$  of  $R$ , and one has  $R' = R_{\{\Delta\}}.$

<!-- original page 111 -->

\*Proof.\* One has obviously (ii)  $\Rightarrow$  (i). Suppose (i) verified: then  $R'$  is closed and symmetric, so  $(M, M^*, R', R'^*)$  is a root datum. Let  $\Delta'$  be a system of simple roots of this datum and  $R'_{\{+\}} = P(\Delta')$ . If  $V' = V$ , then  $\Delta'$  is a system of simple roots of  $\text{mathcal{R}}$  and we are done. Otherwise, there exists  $x \in V^*$  such that

```text  
(x, V') = {0}, (x, α) $\neq$ 0 for all $\alpha \in R - R'$.
```

Put  $R_{\{+\}}(x) = \{\alpha \in R \mid (x, \alpha) > 0\}$  and  $R_{\{+\}} = R_{\{+\}}(x) \cup R'_{\{+\}}.$  For every  $\alpha \in R$ , one has the equivalences

```text  
(x, α) > 0 $\iff \alpha \in R_{\{+\}}(x),$
(x, α) < 0 $\iff \alpha \in -R_{\{+\}}(x),$
(x, α) = 0 $\iff \alpha \in R'.$
```

It follows at once from 3.3.8 that  $R_{\{+\}}$  is a system of positive roots of  $R$ . Put  $\Delta = \text{mathcal{S}}(R_{\{+\}}).$  It evidently suffices to prove  $\Delta' \subset \Delta.$  Otherwise let  $\alpha \in \Delta' - \Delta.$  Then, by 3.2.14, there exist  $\beta, \gamma \in R_{\{+\}}$  such that  $\alpha = \beta + \gamma.$  If  $\beta, \gamma \in R_{\{+\}}(x),$  one has  $\alpha \in R_{\{+\}}(x),$  which is absurd since  $(x, \Delta') = 0.$  If  $\beta$  or  $\gamma,$  say  $\beta,$  belongs to  $R'_{\{+\}},$  then, since  $R'$  is symmetric and closed,  $\gamma = \alpha - \beta$  belongs to  $R_{\{+\}} \cap R' = R'_{\{+\}};$  but then  $\alpha$  is not simple in  $R'_{\{+\}}.$

**Lemma 3.4.9.** \*Under the preceding conditions, let  $\alpha \in P(\Delta) - R'.$  For every  $w \in W_{\{\Delta'\}},$  one has  $w(\alpha) \in P(\Delta) - R'.$ \*

<!-- label: III.XXI.3.4.9 -->

<!-- original page 112 -->

\*Proof.\* It indeed suffices to verify this for  $w = s_{\{\beta\}}, \beta \in \Delta',$  in which case it follows from 3.3.1 and from the fact that  $s_{\{\beta\}}(R') = R'.$

**Lemma 3.4.10.** \*Let  $w \in W.$  Under the conditions of 3.4.8, the following conditions are equivalent:\*

<!-- label: III.XXI.3.4.10 -->

(i)  $w \in W_{\{\Delta'\}}.$

(ii) For every  $m \in M, w(m) - m \in V'.$

(iii) For every  $\alpha \in R, w(\alpha) - \alpha \in V'.$

\*Proof.\* One has obviously (i)  $\Rightarrow$  (ii)  $\Rightarrow$  (iii). Let us prove (iii)  $\Rightarrow$  (i). Let then  $w \in W$  be such that  $w(\alpha) - \alpha \in V'$  for all  $\alpha \in R.$  Write  $w = s_{\{\alpha_n\}} \cdots s_{\{\alpha_1\}},$  with  $\alpha_i \in \Delta,$  and let us prove by induction on  $n$  that each  $\alpha_i \in \Delta'.$  One may assume that  $w' = s_{\{\alpha_{n-1}\}} \cdots s_{\{\alpha_1\}} \in W_{\{\Delta'\}}.$  One has then, for all  $\alpha \in R,$

```text  
 $w(\alpha) - \alpha = w'(\alpha) - \alpha - (\alpha_n^*, w'(\alpha)) \alpha_n.$
```

Taking  $\alpha = w'^{-1}(\alpha_n),$  one finds  $\alpha_n \in V',$  whence  $\alpha_n \in \Delta',$  so  $w = s_{\{\alpha_n\}} w'$  belongs to  $W_{\{\Delta'\}}.$

### 3.5. Miscellaneous remarks

```

<!-- label: III.XXI.3.5 -->

Proposition 3.5.1. *Let R_+ be a system of positive roots. Denote*

<!-- label: III.XXI.3.5.1 -->

```text

$$\rho_{R_+} = (1/2) \sum_{\alpha \in \text{ind}(R_+)} \alpha.$$

```

Then $(\beta, \rho_{R_+}) = 1$ for every $\beta \in \mathcal{S}(R_+)$.

Proof. Indeed, one can write

```text

$$2\rho_{R_+} = \beta + \sum_{\alpha \in \text{ind}(R_+), \alpha \neq \beta} \alpha,$$

```

so $s_\beta(2\rho_{R_+}) = 2\rho_{R_+} - 2\beta$, by 3.3.2.

Corollary 3.5.2. *Put $\rho_{R_+} = (1/2) \sum_{\alpha \in \text{ind}(R_+)} \alpha$. Then*(\rho_{R_+}, \alpha) > 0 for every $\alpha \in R_+$ (i.e. $\rho_{R_+} \in \mathcal{C}(R_+)$, cf. 3.6.8).*
```

\*(ii) For every  $\alpha \in R$ , one has  $\text{ord}_{\mathcal{S}(R_+)}(\alpha) = (\rho_{R_+}, \alpha)$ .<sup>[N.D.E-XXI-12]</sup>

```

Remark 3.5.3. *If $w \in W$, one has $\rho_{w(R_+)} = w(\rho_{R_+})$ and $\rho_{w(R_+)} = w(\rho_{R_+})$.*

<!-- label: III.XXI.3.5.3 -->

Proposition 3.5.4. *Let α and γ be two non-proportional roots, with α indivisible. There exists a system of simple roots containing α and a root β such that $\gamma = a\alpha + b\beta$, with $a, b \in \mathbb{N}$.*

<!-- label: III.XXI.3.5.4 -->

Proof. Indeed, let us construct a basis of the vector space $V(R)$ containing $\alpha_1 = \alpha$, $\alpha_2 = \gamma$. Consider the lexicographic order with respect to this basis. Denoting by R_+ the set of roots > 0 , it is clear that R_+ is a system of positive roots and[N.D.E-XXI-13] that the smallest element of R_+ not proportional to α is simple. This element is of the form

```text

$$\beta = p\alpha + q\gamma, \quad 0 < q \leq 1.$$

```

One thus has $\gamma = q^{-1}\beta - q^{-1}p\alpha$, and since $q > 0$, one has $q^{-1} \in \mathbb{N}$ and $-q^{-1}p \in \mathbb{N}$.

Let us finally make two remarks about the group $\Gamma_0(R)$.

Proposition 3.5.5. *Let G be an abelian group and $f : R \rightarrow G$ a map satisfying the following two conditions*
```

<!-- label: III.XXI.3.5.5 -->

```

(i) If $\alpha \in R$, $f(-\alpha) = -f(\alpha)$.

(ii) If $\alpha, \beta, \alpha + \beta \in R$, $f(\alpha + \beta) = f(\alpha) + f(\beta)$.

Then there exists a unique group homomorphism $\bar{f} : \Gamma_0(R) \rightarrow G$ such that $\bar{f}(\alpha) = f(\alpha)$ for $\alpha \in R$.

```

\*Proof.\* Indeed, if  $\Delta$  is a system of simple roots of  $R$ , and if  $\beta \in R$  is written  $\sum_{\alpha \in \Delta} a(\alpha) \alpha$ , it follows at once from 3.2.16 that  $f(\beta) = \sum_{\alpha \in \Delta} a(\alpha) f(\alpha)$ . Now  $\Delta$  is a basis of  $\Gamma(R)$ .

<!-- original page 114 -->

**Proposition 3.5.6.** \*Let  $\Delta$  be a system of simple roots. There exists on  $\Gamma(R)$  a structure of totally ordered group such that the roots  $> 0$  are the elements of  $P(\Delta)$  and  $\alpha \mapsto \text{ord}_{\Delta}(\alpha)$  is an increasing function.\*

<!-- label: III.XXI.3.5.6 -->

\*Proof.\* Indeed, let  $\alpha_1, \alpha_2, \dots, \alpha_n$  ( $n = \text{rgss}(\mathcal{R})$ ) be the elements of  $\Delta$ . For  $x \in \Gamma(R)$ , one has a decomposition

$$x = \sum_i m_i(x) \alpha_i.$$

It suffices to take the lexicographic order with respect to the functions  $\sum m_i$ ,  $m_n$ ,  $m_{n-1}$ , ...,  $m_2$ .

**Remark 3.5.7.** \*The first roots are in order:\*

<!-- label: III.XXI.3.5.7 -->

$$\alpha_1, \alpha_2, \dots, \alpha_n;$$

one then has (if these are roots)  $2\alpha_1, \alpha_1 + \alpha_2, \alpha_1 + \alpha_3, \dots$ .

### 3.6. Weyl chambers

<!-- label: III.XXI.3.6 -->

**Lemma 3.6.1.** \*Let  $V$  be a finite-dimensional  $\mathbb{R}$ -vector space. [N.D.E-XXI-14] Let  $f_i$  be independent linear forms. Set\*

<!-- label: III.XXI.3.6.1 -->

$$C = \{x \in V \mid f_i(x) > 0\}.$$

\*Then  $C$  is a maximal convex subset of  $X = V - \bigcup_i f_i^{-1}(0)$ .\*

\*Proof.\* Trivial.

<!-- original page 115 -->

**Definition 3.6.2.** \*A subset  $C$  of  $V$  describable by the procedure of 3.6.1 will be called (here) a chamber of  $V$ .\*

<!-- label: III.XXI.3.6.2 -->

**Definition 3.6.3.** \*One says that the hyperplane  $H$  of  $V$  is a wall of  $C$  if  $H \cap (\bar{C} - C)$  contains a nonempty open subset of  $H$ .\*

<!-- label: III.XXI.3.6.3 -->

**Remark 3.6.4.** \*For a convex subset, the closure is described without appeal to the topology of  $V$ : it is the set of endpoints of all open segments contained in the given subset.\*

```

<!-- label: III.XXI.3.6.4 -->

Lemma 3.6.5. *Under the conditions of 3.6.1, one has*

<!-- label: III.XXI.3.6.5 -->

```text

$$C^- = \{x \in V \mid f_i(x) \leq 0\}.$$

```

The walls of C are the hyperplanes $f^{-1}_i(0)$.

Proof. The first assertion is clear. The second then follows from the fact that
 $\bar{C} \subset \bigcup_i f^{-1}_i(0)$ and that the $f^{-1}_i(0)$ are obviously walls of C .

Proposition 3.6.6. *Let C be a chamber of V . If H_i , $i = 1, 2, \dots, n$, are the distinct walls of C , then
for every system of linear forms u_i such that $H_i = u^{-1}_i(0)$, there exist $\epsilon_i \in \{-1, +1\}$
such that C is defined by*

<!-- label: III.XXI.3.6.6 -->

```text

$$C = \{x \in V \mid \epsilon_i u_i(x) > 0\}.$$

```

*For every wall H of C , one has $H \cap C = \emptyset$ and $H \cap \bar{C} = C_H$, where C_H is a chamber in
 H . The walls of C_H are the $H_j \cap H_i$, for $j \neq i$.*

Proof. This follows trivially from the lemma.

Definition 3.6.7. *The C_H are the faces of C .*

<!-- label: III.XXI.3.6.7 -->

Let now $\mathcal{R} = (M, M^*, R, R^*)$ be a root datum. We put $V^*(\mathbb{R}) = M^* \otimes \mathbb{R}$.

Definition 3.6.8.[N.D.E-XXI-15] *For every $\alpha \in R$, set*

<!-- label: III.XXI.3.6.8 -->

```text

$$H_\alpha = \{x \in V^*_\mathbb{R} \mid (x, \alpha) = 0\}.$$

```

<!-- original page 116 -->

We denote $X = V^(\mathbb{R}) - \bigcup_{\alpha \in R} H_\alpha$. For every $x \in X$, set*

```text

$$R_+(x) = \{\alpha \in R \mid (x, \alpha) > 0\}.$$

```

For every system of positive roots R_+ , denote

```text

$$\square(R_+) = \{x \in V^*_\mathbb{R} \mid (x, \alpha) > 0 \text{ for all } \alpha \in R_+\}.$$

```

Proposition 3.6.9. *(i) For every $x \in X$, $R_+(x)$ is a system of positive roots. For every system of positive
roots R_+ , $\mathcal{C}(R_+)$ is a chamber in $V^*(\mathbb{R})$. The $\mathcal{C}(R_+)$ are the maximal convex
subsets of X .*

<!-- label: III.XXI.3.6.9 -->

(ii) Let Δ be a system of simple roots. One has
```

```

```text
□(P(Δ)) = {x ∈ V*_ℝ | (x, α) > 0 for all α ∈ Δ}.
```

```

\*The walls of  $\mathcal{C}(P(\Delta))$  are the hyperplanes  $H_{\alpha} = \alpha^{-1}(0)$ , for  $\alpha \in \Delta$ ; its faces are the\*

```

```text
C_α = {x ∈ V*_ℝ | (x, α) = 0, (x, β) > 0 for β ∈ Δ, β ≠ α}.
```

```

\*(iii) One has the equivalence\*

```

```text
R_+(x) = R_+ □ x ∈ □(R_+).
```

```

\*Proof.\* It is first clear that  $R_{\{+}(x)$  is a system of positive roots. Since  $x \in \mathcal{C}(R_{\{+}(x))$ , the union of the  $\mathcal{C}(R_{\{+}(x))$  is  $X$ . Property (iii) is immediate; it follows that the  $\mathcal{C}(R_{\{+})$  form a partition of  $X$ . The first assertion of (ii) is evident. It follows at once that  $\mathcal{C}(R_{\{+})$  is a chamber in  $V$ , which proves the rest of (i). Putting  $C = \mathcal{C}(P(\Delta))$ , it remains only to remark that

```

```text
C^- ∩ (V*_ℝ - ∪_{α ∈ R} α^{-1}(0)) = C^- ∩ (V*_ℝ - ∪_{α ∈ Δ} α^{-1}(0))
```

```

to complete the proof of (ii) by 3.6.1.

**Definition 3.6.10.** \*The  $\mathcal{C}(R_{\{+})$  are called the Weyl chambers of the root datum. On the other hand, for every Weyl chamber  $C$ , one sets  $R_{\{+}(C) = R_{\{+}(x)$  for any  $x \in C$ .\*

<!-- label: III.XXI.3.6.10 -->

<!-- original page 117 -->

**Corollary 3.6.11.** \*The maps  $R_{\{+} \mapsto \mathcal{C}(R_{\{+})$  and  $C \mapsto R_{\{+}(C)$  realize a bijective correspondence between systems of positive roots and Weyl chambers.\*

<!-- label: III.XXI.3.6.11 -->

This correspondence is invariant under the Weyl group:

**Lemma 3.6.12.** \*If  $w \in W(\mathcal{R})$ , one has  $\mathcal{C}(w(R_{\{+})) = w(\mathcal{C}(R_{\{+}))$ .\*

<!-- label: III.XXI.3.6.12 -->

**Corollary 3.6.13.** \*The correspondences  $\Delta \xrightarrow{\quad} R_{\{+} \xrightarrow{\quad} C$  are isomorphisms of homogeneous spaces under  $W(\mathcal{R})$ .\*

<!-- label: III.XXI.3.6.13 -->

We shall see later that these homogeneous spaces are principal (5.5).

**Remark 3.6.14.** \*If  $C$  is a Weyl chamber, then  $-C$  is also one, called the opposite of  $C$ . There exists therefore a  $w_{\{0} \in W$  (and in fact a unique one, cf. 5.5) such that  $w_{\{0}(C) = -C$ ; one calls it the symmetry of the root datum with respect to the Weyl chamber  $C$  (or with respect to  $R_{\{+}(C)$  or  $\mathcal{C}(R_{\{+}(C))$ ...)\*

<!-- label: III.XXI.3.6.14 -->

## 4. Reduced root data of semisimple rank 2

<!-- label: III.XXI.4 -->

**4.0.**^[N.D.E-XXI-16] Let  $\mathcal{R}$  be a root datum of semisimple rank 2. Let  $\{\alpha, \beta\}$  be a system of

simple roots. Assume  $\ell(\alpha) \leq \ell(\beta)$ . One then has by 2.3.1 and 3.2.1 four possibilities:

<!-- label: III.XXI.4.0 -->

<!-- original page 84 -->

| Type             | $\ell(\beta)/\ell(\alpha)$ | $\ell(\beta^*)/\ell(\alpha^*)$ | $(\beta^*, \alpha)$ | $(\alpha^*, \beta)$ |
|------------------|----------------------------|--------------------------------|---------------------|---------------------|
| $A_1 \times A_1$ | —                          | —                              | 0                   | 0                   |
| $A_2$            | 1                          | 1                              | -1                  | -1                  |
| $B_2$            | 2                          | 1/2                            | -1                  | -2                  |
| $G_2$            | 3                          | 1/3                            | -1                  | -3                  |

<!-- original page 118 -->

It follows from 3.4.5 that the order of  $s_\alpha s_\beta$  is respectively 2, 3, 4, 6.

Let us study each of these systems separately and give the list of indivisible roots.

**Type  $A_1 \times A_1$ .** The indivisible roots are  $\alpha, \beta, -\alpha, -\beta$ . The corresponding coroots are  $\alpha^*, \beta^*, -\alpha^*, -\beta^*$ .

**Type  $A_2$ .** The indivisible positive roots are as follows:

| root $\gamma$                  | $\alpha$   | $\beta$   | $\alpha + \beta$     |
|--------------------------------|------------|-----------|----------------------|
| $\ell(\gamma)/\ell(\alpha)$    | 1          | 1         | 1                    |
| coroot $\gamma^*$              | $\alpha^*$ | $\beta^*$ | $\alpha^* + \beta^*$ |
| $\ell(\gamma^*)/\ell(\beta^*)$ | 1          | 1         | 1                    |

The half-sum of the indivisible positive roots is  $\rho = \alpha + \beta$ .

**Type  $B_2$ .** The indivisible positive roots are as follows:

| root $\gamma$                  | $\alpha$   | $\beta$   | $\alpha + \beta$      | $2\alpha + \beta$    |
|--------------------------------|------------|-----------|-----------------------|----------------------|
| $\ell(\gamma)/\ell(\alpha)$    | 1          | 2         | 1                     | 2                    |
| coroot $\gamma^*$              | $\alpha^*$ | $\beta^*$ | $2\alpha^* + \beta^*$ | $\alpha^* + \beta^*$ |
| $\ell(\gamma^*)/\ell(\beta^*)$ | 2          | 1         | 2                     | 1                    |

The half-sum of the indivisible positive roots is  $\rho = (4\alpha + 3\beta)/2$ .

**Type  $G_2$ .** The indivisible positive roots are as follows:

| root $\gamma$                  | $\alpha$   | $\beta$   | $\alpha + \beta$      | $2\alpha + \beta$      | $3\alpha + \beta$    | $3\alpha + 2\beta$    |
|--------------------------------|------------|-----------|-----------------------|------------------------|----------------------|-----------------------|
| $\ell(\gamma)/\ell(\alpha)$    | 1          | 3         | 1                     | 1                      | 3                    | 3                     |
| coroot $\gamma^*$              | $\alpha^*$ | $\beta^*$ | $\alpha^* + 3\beta^*$ | $2\alpha^* + 3\beta^*$ | $\alpha^* + \beta^*$ | $\alpha^* + 2\beta^*$ |
| $\ell(\gamma^*)/\ell(\beta^*)$ | 3          | 1         | 3                     | 3                      | 1                    | 1                     |

<!-- original page 119 -->

The half-sum of the indivisible positive roots is  $\rho = 5\alpha + 3\beta$ .

**Proposition 4.1.** Let  $n$  be the order of  $s_\alpha s_\beta$ . Set  $u_0 = 0$  and, for  $p \in \mathbb{N}$ ,

<!-- label: III.XXI.4.1 -->

```

\text
u_{2p+1} = u_{2p} + (s_\alpha s_\beta)^p(\alpha);
u_{2p+2} = u_{2p+1} + (s_\alpha s_\beta)^p s_\alpha(\beta).

```

Then: [N.D.E-XXI-17]

\*(i)  $u_{k+2n} = u_k$ , for every  $k \in \mathbb{N}$ .\*

\*(ii)  $u_0 = 0$ ,  $u_1 = \alpha$ ,  $u_{2n-1} = \beta$ ,  $u_{2n} = 0$ .\*

\*(iii) If  $1 < k < 2n - 1$ , one has  $u_k = a_k \alpha + b_k \beta$ , with  $a_k, b_k \in \mathbb{N}$ .\*

\*Proof.\* Assertion (i) follows from  $(s_\alpha s_\beta)^n = 1$  and  $u_{2n} = 0$ .

Let us prove (ii) and (iii). Direct computation gives, in the four cases, the following sequences of values: [N.D.E-XXI-18]

```

```text
(A1 × A1)    0, α, β + α, β, 0.

(A2)          0, α, β + 2α, 2β + 2α, 2β + α, β, 0.

(B2)          0, α, β + 3α, 2β + 4α, 3β + 4α, 3β + 3α, 2β + α, β, 0.

(G2)          0, α, β + 4α, 2β + 6α, 4β + 9α, 5β + 10α, 6β + 10α, 6β + 9α, 5β + 6α,
               4β + 4α, 2β + α, β, 0.
...

```

Lemma 4.2. Set $w_{2p} = (s_\beta s_\alpha)^p$, $w_{2p+1} = s_\alpha (s_\beta s_\alpha)^p$, so that $w_0, \dots, w_{2n-1}$ are the distinct elements of W . Let $u_0, \dots, u_{2n-1}$ be the elements of V defined in 4.1. For every $x \in V$, one has*

!-- label: III.XXI.4.2 -->

!-- original page 120 -->

```

```text
x - wk(x) = nk α + mk β,
...

```

with  $n_k, m_k \in \mathbb{Q}$  and  $n_k + m_k = (x, u_k)$ . [N.D.E-XXI-19]

\*Proof.\* The proof is by induction on  $k$ . If  $k = 0$ , the formula is trivially verified. Let us carry out, for example, the passage from  $w_{2p}$  to  $w_{2p+1}$ . One has  $w_{2p+1} = s_\alpha w_{2p}$ , whence

```

```text
x - w2p+1(x) = x - w2p(x) + w2p(x) - sα w2p(x) = n2p α + m2p β + (w2p(x), α) α.
...

```

So

```

```text
n2p+1 + m2p+1 = n2p + m2p + ((sβ sα)p(x), α)
 = (x, u2p) + (x, (sα sβ)p(α)) = (x, u2p+1).
...

```

**Corollary 4.3.** [N.D.E-XXI-20] Let  $x \in V$ . For every  $w \in W$ , set\*

!-- label: III.XXI.4.3 -->

```

```text
x - w(x) = aw α + bw β.
...

```

If $(x, \alpha) \geq 0$ and $(x, \beta) \geq 0$, then $a_w + b_w \geq 0$. If moreover $(x, \alpha) > 0$ (resp. $(x, \beta) > 0$), then $a_w + b_w > 0$ for $w \neq 1, s_\beta$ (resp. for $w \neq 1, s_\alpha$).

Proof. This follows at once from 4.1 and 4.2.

****Corollary 4.4.**** *Let $\mathcal{R}$ be any root datum and Δ a system of simple roots. Let γ be a positive root and α, β two simple roots; let $W_{\alpha, \beta}$ be the subgroup of W generated by s_{α} and s_{β} . If*

<!-- label: III.XXI.4.4 -->

```
```text
ord_Δ(s_α(γ)) < ord_Δ(γ), ord_Δ(s_β(γ)) ⊆ ord_Δ(γ),
```
```

<!-- original page 121 -->

then, for every $w \in W_{\alpha, \beta}$, one has $\text{ord}_{\Delta}(w(\gamma)) \leq \text{ord}_{\Delta}(\gamma)$; moreover $\text{ord}_{\Delta}(w(\gamma)) < \text{ord}_{\Delta}(\gamma)$ if $w \neq 1$, $w \neq s_{\beta}$.

Proof. Indeed, consider the dual root datum $\mathcal{R}^*$, then the datum (M^*, M, R^*, R') , where R' is the set of roots which are rational linear combinations of α and β . Applying 4.3 to this datum, one finds the announced corollary. [N.D.E-XXI-21]

5. The Weyl group: generators and relations

<!-- label: III.XXI.5 -->

Let $\mathcal{R}$ be a root datum. Since the Weyl group is the same for this datum and for the corresponding reduced datum, one may assume $\mathcal{R}$ reduced to study the Weyl group.

Let $\Delta = \{\alpha_1, \dots, \alpha_n\}$ be a system of simple roots ($n = \text{rgss}(\mathcal{R})$). Let n_{ij} be the order of the element $s_{\alpha_i} s_{\alpha_j}$ of W . In particular, one has $n_{ii} = 1$, and we saw in 3.4.2 and 3.4.3 that the subgroup W_{ij} of W generated by s_{α_i} and s_{α_j} was defined by the relations:

```
```text
s_α_i^2 = s_α_j^2 = (s_α_i s_α_j)^{n_ij} = 1.
```
```

****Theorem 5.1.**** *The group W is the group generated by the elements s_{α_i} , $i = 1, 2, \dots, n$, subject to the relations $(s_{\alpha_i} s_{\alpha_j})^{n_{ij}} = 1$.*

<!-- label: III.XXI.5.1 -->

Proof. We have already seen that the theorem is true when $n = 2$; we shall use this remark in the course of the proof. Introduce the group $\tilde{W}$ generated by elements T_i , $i = 1, 2, \dots, n$, subject to the relations $(T_i T_j)^{n_{ij}} = 1$. One has in particular $n_{ii} = 1$, whence $T_i^2 = 1$. Let $\rho : \tilde{W} \rightarrow W$ be the group morphism that sends T_i to s_{α_i} . One knows that ρ is surjective; we shall show it is injective.

<!-- original page 122 -->

****Lemma 5.2.**** *One can define in a unique manner for each $\alpha \in P(\Delta)$ an element $T_{\alpha} \in \tilde{W}$ such that one has the following properties:*

<!-- label: III.XXI.5.2 -->

(i) $\rho(T_{\alpha}) = s_{\alpha}$,

(ii) $T_{\alpha_i} = T_i$,

(iii) if β and α are two positive roots such that $s_{\alpha}(\beta) = \beta$, then $T_{\alpha} T_{\beta} T_{\alpha} = T_{\beta}$.*

<!-- original page 87 -->

Proof. Remark first that it follows from 1.2.10 and 3.3.6 that (i) is a consequence of (ii) and (iii), and that (ii) and (iii) completely determine the T_{α} . We shall make the construction by induction on $\text{ord}_{\Delta}(\alpha)$. If $\text{ord}_{\Delta}(\alpha) = 1$, then $\alpha \in \Delta$ and one sets $T_{\alpha} = T_i$ if $\alpha = \alpha_i$.

Consider the hypothesis:

(H_p) *there exist T_{α} , for $\alpha \in P(\Delta)$, $\text{ord}_{\Delta}(\alpha) \leq p$, satisfying (ii) and condition (iii) whenever $\text{ord}_{\Delta}(\alpha) \leq p$, $\text{ord}_{\Delta}(\beta) \leq p$.*

This is verified for $p = 1$: indeed, if α and $s_{\alpha}(\alpha) = \beta$ are simple, α_i and α are orthogonal, so if one denotes $\alpha_j = \alpha = \beta$, one has $n_{ij} = 2$, whence

```
```text
T_i T_j T_i = T_j.
```

Suppose  $p > 1$  and  $(H_{p-1})$  verified.

\*A) Construction of the  $T_{\alpha}$  for  $\text{ord}_{\Delta}(\alpha) \leq p$ . It evidently suffices to do this for  $\text{ord}_{\Delta}(\alpha) = p$ . There then exists  $\alpha_i \in \Delta$  such that  $s_{\alpha_i}(\alpha) \in P(\Delta)$  and  $\text{ord}_{\Delta}(s_{\alpha_i}(\alpha)) < p$  (3.3.3). One then sets

<!-- original page 123 -->

```
```text
(*)   Tα = Ti Tsαi(α) Ti.
```

Let us verify that T_{α} depends only on α . Let $\alpha_j \in \Delta$ be such that $s_{\alpha_j}(\alpha) \in P(\Delta)$ and $\text{ord}_{\Delta}(s_{\alpha_j}(\alpha)) < p$. Let us prove that

```
```text
(+) Ti Tsαi(α) Ti = Tj Tsαj(α) Tj.
```

Let us distinguish two cases.

(1)\* Suppose  $\alpha$  is a linear combination of  $\alpha_i$  and  $\alpha_j$ . Then the same is true of  $s_{\alpha_i}(\alpha)$  and  $s_{\alpha_j}(\alpha)$ , and by  $(H_{p-1})$ ,  $T_{s_{\alpha_i}(\alpha)}$  and  $T_{s_{\alpha_j}(\alpha)}$  are written as words in  $T_i$  and  $T_j$ . Since the projection of (+) in  $W$  is verified, and since the theorem is true for  $n = 2$ , so  $p$  is injective on the subgroup of  $\tilde{W}$  generated by  $T_i$  and  $T_j$ , (+) is indeed verified.

(2)\* Suppose  $\alpha$  is not a linear combination of  $\alpha_i$  and  $\alpha_j$ . Then if  $w \in W_{\alpha_i, \alpha_j}$ , the  $w(\alpha)$  will all be positive (cf. 3.4.9). The relation to be verified is also written

```
```text
(+++) (Ti Tj)nij - 1 Tsαi(α) (Tj Ti)nij - 1 = Tsαj(α).
```

Now it follows from 4.4 that the $w(\alpha)$ are all of order $< p$ for $w \in W_{\alpha_i, \alpha_j}$, $w \neq 1$. One can therefore apply hypothesis (H_{p-1}) $2(n_{ij} - 1)$ times, and we are done.

*B) Verification of (H_p) . [N.D.E-XXI-22] One must verify that if $\alpha_j \in \Delta$ and if $\beta = s_{\alpha_j}(\alpha)$ satisfies $\text{ord}_{\Delta}(\beta) \leq p$, then $T_j T_{\alpha} T_j = T_{\beta}$. If $\text{ord}_{\Delta}(\beta) < p$, this follows from what precedes (since $T^2_j = 1$), so one may suppose $\text{ord}_{\Delta}(\beta) = p = \text{ord}_{\Delta}(\alpha)$. In this case, α and α_j are orthogonal, so $\beta = \alpha$, and it is a matter of seeing that one has

<!-- original page 124 -->

```
```text
(†) Tj Tα Tj = Tα.
```

By  $(\star)$  above, one has  $T_{\alpha} = T_i T_{s_{\alpha_i}(\alpha)} T_i$ , so it remains only to verify the following equality:

```

```text
(+++)  $T_j T_i T_{\{s_{\alpha_i}(\alpha)\}} T_i T_j = T_{\alpha} = T_i T_{\{s_{\alpha_i}(\alpha)\}} T_i.$ 
```

Write $m = n_{ij}$ and $s_i = s_{\{\alpha_i\}}$, $s_j = s_{\{\alpha_j\}}$. One has $T_j T_i = (T_i T_j)^{m-1}$ and, by 4.4, one has $\text{ord}_{\Delta}(w(\alpha)) < p$ for every $w \in W_{ij}$ distinct from $1 = (s_i s_j)^m$ and from $s_j = s_i (s_i s_j)^{m-1}$. One deduces, by the induction hypothesis, that

```text

$$T_j (T_i T_j)^{m-2} T_{\{s_i(\alpha)\}} (T_j T_i)^{m-2} T_j = T_{\{s_j (s_i s_j)^{m-2} s_i(\alpha)\}} = T_{\{s_i s_j(\alpha)\}} = T_{\{s_i(\alpha)\}}$$

```

(the last equality since $s_j(\alpha) = \alpha$), whence finally

```text

$$(T_i T_j)^{m-1} T_{\{s_i(\alpha)\}} (T_j T_i)^{m-1} = T_i T_{\{s_i(\alpha)\}} T_i$$

```

which proves (+++).

Lemma 5.3. *Let $h \in \tilde{W}$. Write it*
```

```

<!-- label: III.XXI.5.3 -->

$$h = T_{\{\alpha_1\}} \cdots T_{\{\alpha_m\}}$$

with the $\alpha_i \in \Delta$, not necessarily distinct, in such a way that m is minimal. Then

$$p(h)(\alpha_m) \in -P(\Delta).$$

Proof. Indeed, since $p(T_{\{\alpha_m\}})(\alpha_m) = s_{\{\alpha_m\}}(\alpha_m) = -\alpha_m$, if $p(h)(\alpha_m)$ were positive, there would exist an index k , $1 \leq k \leq m-1$, such that

```text

$$u = s_{\{\alpha_{k+1}\}} \cdots s_{\{\alpha_m\}}(\alpha_m) = -s_{\{\alpha_{k+1}\}} \cdots s_{\{\alpha_{m-1}\}}(\alpha_m) \in -P(\Delta),$$

```

and $s_{\{\alpha_k\}}(u) \in P(\Delta)$. But then one has necessarily $u = -\alpha_k$ (3.3.1), whence

$$s_{\{\alpha_{k+1}\}} \cdots s_{\{\alpha_{m-1}\}}(\alpha_m) = \alpha_k,$$

which entails by (iii)

```text

$$T_{\{\alpha_k\}} T_{\{\alpha_{k+1}\}} \cdots T_{\{\alpha_{m-1}\}} T_{\{\alpha_m\}} = T_{\{\alpha_{k+1}\}} \cdots T_{\{\alpha_{m-1}\}},$$

```

and this contradicts the minimal character of m .

<!-- original page 125 -->

Let now $h \in \tilde{W}$ be such that $p(h)(P(\Delta)) \subset P(\Delta)$. By Lemma 5.3, one has $p(h) = 1$, which proves Theorem 5.1 and moreover the

Corollary 5.4. *If R_+ is a system of positive roots and if $w \in W$ is such that $w(R_+) = R_+$, then $w = 1$.*

<!-- label: III.XXI.5.4 -->

```

**\*\*Corollary 5.5.\*\*** \*The Weyl group operates freely and transitively on the set of systems of positive roots (resp. of systems of simple roots, resp. of Weyl chambers).\*

<!-- label: III.XXI.5.5 -->

Let us now choose a system of simple roots  $\Delta$ . Put  $R^+ = P(\Delta)$ . [N.D.E-XXI-23]

For every pair of simple roots  $(\alpha, \beta) \in \Delta \times \Delta$ , denote by  $R_{\alpha, \beta}$  the set of roots that are linear combinations of  $\alpha$  and  $\beta$ . Write  $R^+_{\alpha, \beta} = R^+ \cap R_{\alpha, \beta}$  and let  $W_{\alpha, \beta}$  be the Weyl group of  $R_{\alpha, \beta}$ , that is to say, the subgroup of  $W$  generated by  $s_{\alpha}$  and  $s_{\beta}$ .

**\*\*Theorem 5.6 (Tits).\*\*** \*Let  $\alpha$  and  $\beta$  be two simple roots and let  $w \in W$  be such that  $w(\alpha) = \beta$ . There exists a sequence of simple roots  $\alpha_0, \dots, \alpha_m$  and a sequence  $w_0, \dots, w_{m-1}$  of elements of  $W$  satisfying the following conditions:\*

<!-- label: III.XXI.5.6 -->

<!-- original page 89 -->

(i)  $\alpha_0 = \alpha$ ,  $\alpha_m = \beta$ .

(ii)  $w = w_{m-1} w_{m-2} \dots w_0$ .

(iii)  $w_i(\alpha_i) = \alpha_{i+1}$ , for  $0 \leq i \leq m-1$ .

(iv) For every  $i$ ,  $0 \leq i \leq m-1$ , such that  $\alpha_i \neq \alpha_{i+1}$ , one has  $w_i \in W_{\alpha_i, \alpha_{i+1}}$ .

(v) For every  $i$ ,  $0 \leq i \leq m-1$ , such that  $\alpha_i = \alpha_{i+1}$ , there exists a simple root  $\beta_i$  such that  $w_i \in W_{\alpha_i, \beta_i}$ .

**\*Proof.\*** Set [N.D.E-XXI-24]

<!-- original page 126 -->

```text  
M(w) = Card($R^+ \cap w^{-1}(-R^+)$) = Card($\{\alpha \in R^+ \mid w(\alpha) \in -R^+\}$).
```

If  $M(w) = 0$ , then  $w(R^+) = R^+$ , so  $w = 1$  by 5.4 and the theorem is trivial ( $m = 0$ ; assertions (iii) to (v) are empty). We argue by induction on  $M(w)$ . If  $M(w) > 0$ , there exists  $\beta_0 \in \Delta$  such that  $w(\beta_0) \in -R^+$ . Set  $\alpha_0 = \beta_0$ . Consider the set

```text  
 $A = w^{-1}(R^+) \cap R_{\alpha_0, \beta_0}$.
```

This is a system of positive roots of  $R_{\alpha_0, \beta_0}$ . There thus exists  $w_0 \in W_{\alpha_0, \beta_0}$  such that

$w_0^{-1}(R^+_{\alpha_0, \beta_0}) = A$ .

Put  $w' = w w_0^{-1}$ . By 3.4.9, one has at once

```text  
 $R^+ - R^+_{\alpha_0, \beta_0} = w_0(R^+ - R^+_{\alpha_0, \beta_0})$,
```

whence

```text  
(1) $(R^+ - R^+_{\alpha_0, \beta_0}) \cap w^{-1}(-R^+) = w_0((R^+ - R^+_{\alpha_0, \beta_0}) \cap w'^{-1}(-R^+))$.

...

On the other hand,

```
```text
(2) $\beta_0 \in R^+_{\alpha_0, \beta_0} \cap w^{-1}(-R^+),$
```
```

and, since $w_{\{0\}}(R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}}) = R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}}$, one has $w_{\{0\}}(-A) = R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}} \cap w'^{-1}(-R^+)$, whence

```
```text
(2') $R^+_{\alpha_0, \beta_0} \cap w'^{-1}(-R^+) = R^+_{\alpha_0, \beta_0} \cap w_{\{0\}}(-A) = R^+_{\alpha_0, \beta_0} \cap -R^+_{\alpha_0, \beta_0} = \emptyset.$
```
```

It follows from (1), (2), (2') that $M(w') < M(w)$.

Set $\alpha_{\{1\}} = w_{\{0\}}(\alpha_{\{0\}})$; let us show that $\alpha_{\{1\}} \in \Delta$, that is to say $\alpha_{\{0\}} \in w_{\{0\}}^{-1}(\Delta)$. One knows that $w_{\{0\}}(\alpha_{\{0\}}) \in \Delta$, so $\alpha_{\{0\}} \in w_{\{0\}}^{-1}(\Delta)$, hence also $\alpha_{\{0\}} \in w_{\{0\}}^{-1}(\Delta) \cap R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}}$; so $\alpha_{\{0\}}$ is a simple root of $A = w_{\{0\}}^{-1}(R^+) \cap R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}} = w_{\{0\}}^{-1}(\Delta \cap R_{\{\alpha_{\{0\}}, \beta_{\{0\}}\}})$, hence belongs to

```
```text
 $w_{\{0\}}^{-1}(\Delta \cap R^+_{\alpha_0, \beta_0}) = w_{\{0\}}^{-1}(\alpha_0, \beta_0)$
```
```

(see 3.4.8). So $\alpha_{\{1\}} = w_{\{0\}}(\alpha_{\{0\}})$ equals $\alpha_{\{0\}}$ or $\beta_{\{0\}}$. If $\alpha_{\{1\}} \neq \alpha_{\{0\}}$, one has $\alpha_{\{1\}} = \beta_{\{0\}}$ and $w_{\{0\}} \in W_{\{\alpha_{\{0\}}, \alpha_{\{1\}}\}}$.

Finally, one has $\beta_{\{1\}} = w'(\alpha_{\{1\}})$, with $M(w') < M(w)$, and one concludes by induction.

<!-- original page 90 -->

6. Morphisms of root data

<!-- label: III.XXI.6 -->

<!-- original page 127 -->

6.1. Definition

<!-- label: III.XXI.6.1 -->

Let $\mathcal{R} = (M, M^*, R, R^*)$ and $\mathcal{R}' = (M', M'^*, R', R'^*)$ be two root data. Let $f : M' \rightarrow M$ be a linear map and $f^t : M^* \rightarrow M'^*$ the transposed map.

Definition 6.1.1. One says that f is a morphism from $\mathcal{R}'$ to $\mathcal{R}$ and writes $f : \mathcal{R}' \rightarrow \mathcal{R}$, if f induces a bijection of R' onto R and f^t a bijection of R'^* onto R^* .

<!-- label: III.XXI.6.1.1 -->

Then f^t is a morphism of the dual root data:

```
$$
f^t : \mathcal{R}'^* \rightarrow \mathcal{R}^*
$$
```

One sees easily that if f is a morphism from $\mathcal{R}'$ to $\mathcal{R}$, and if one writes $\alpha = f(\alpha')$ for $\alpha' \in R'$, one has $\alpha^* = f^t(\alpha'^*)$. Indeed, one sees immediately that if one writes p and p' for the maps of 1.2.1 relative to $\mathcal{R}$ and $\mathcal{R}'$, one has $p' = f^t \circ p \circ f$, and the assertion sought follows at once. We leave to the reader the task of proving the statements that follow, which are almost all trivial.

Proposition 6.1.2. Let $f : \mathcal{R}' \rightarrow \mathcal{R}$ be a morphism of root data. If $\alpha' \in R'$ and

$\alpha = f(\alpha')$, then $\alpha^* = \{t\}f(\alpha^*)$. Moreover, f induces isomorphisms:

<!-- label: III.XXI.6.1.2 -->

$$R' \sqsubset R, \quad \Gamma_0(R') \sqsubset \Gamma_0(R), \quad V(R') \sqsubset V(R),$$

and f induces isomorphisms:

$$R^* \sqsubset R'^*, \quad \Gamma_0(R^*) \sqsubset \Gamma_0(R'^*), \quad V(R^*) \sqsubset V(R'^*),$$

<!-- original page 128 -->

the last being the transpose of the corresponding morphism induced by f . The map $s_{\alpha'} \mapsto s_{f(\alpha')}$ extends to an isomorphism $W(\mathcal{R}') \xrightarrow{\sim} W(\mathcal{R})$ compatible with the operations of these two groups on the sets of 1.1.13.

Proposition 6.1.3. The maps

<!-- label: III.XXI.6.1.3 -->

$$\Delta' \mapsto f(\Delta'), \quad R'_+ \mapsto f(R'_+), \quad C' \mapsto ({}^t f \otimes \mathbb{R})^{-1}(C')$$

define bijective correspondences between systems of simple roots, systems of positive roots, and Weyl chambers for $\mathcal{R}'$ and $\mathcal{R}$. These correspondences are compatible with the action of the Weyl groups and with the correspondences

$$\mathcal{S}(\mathcal{R}_+) \xleftrightarrow{\quad} \mathcal{R}_+ \xleftrightarrow{\quad} \mathcal{C}(\mathcal{R}_+).$$

Lemma 6.1.4. Morphisms compose. For the morphism $f : \mathcal{R}' \rightarrow \mathcal{R}$ to be an isomorphism, it is necessary and sufficient that $f : M' \rightarrow M$ be bijective.

<!-- label: III.XXI.6.1.4 -->

6.2. Isogenies

<!-- label: III.XXI.6.2 -->

Definition 6.2.1. A morphism $f : \mathcal{R}' \rightarrow \mathcal{R}$ of root data is called an *isogeny* if $f : M' \rightarrow M$ is injective with finite cokernel.

<!-- label: III.XXI.6.2.1 -->

If f is an isogeny, then f is an isogeny.

Definition 6.2.2. Let $f : \mathcal{R}' \rightarrow \mathcal{R}$ be an isogeny. Set $K(f) = \text{Coker}(M' \rightarrow M)$.

<!-- label: III.XXI.6.2.2 -->

Lemma 6.2.3. One has a natural pairing

<!-- label: III.XXI.6.2.3 -->

$$K(f) \times K({}^t f) \rightarrow \mathbb{Q}/\mathbb{Z},$$

which puts these two finite groups in duality.

Proof. This is classical.

Lemma 6.2.4. *If $f : \mathcal{R}' \rightarrow \mathcal{R}$ is a morphism, then $\text{rgss}(\mathcal{R}') = \text{rgss}(\mathcal{R})$. If moreover f is an isogeny, one has also $\text{rgred}(\mathcal{R}') = \text{rgred}(\mathcal{R})$.*

<!-- label: III.XXI.6.2.4 -->

<!-- original page 129 -->

Proof. Trivial.

Lemma 6.2.5. *Every morphism of semisimple root data is an isogeny.*

<!-- label: III.XXI.6.2.5 -->

Proof. This follows at once from the fact that f must induce an isomorphism of $V' = V(\mathcal{R}')$ onto $V = V(\mathcal{R})$.

If $\mathcal{R}'$ and $\mathcal{R}$ are semisimple, every isogeny $f : \mathcal{R}' \rightarrow \mathcal{R}$ defines a commutative diagram:

```

```text
Γ0(R') □ Γ0(R)
 ↓ ↓
 M' → M.
 f
```

```

If $M = \Gamma_0(\mathcal{R})$, then f is necessarily an isomorphism.

Definition 6.2.6. *A root datum is called* adjoint *(resp. simply connected) if $M = \Gamma_0(\mathcal{R})$, resp. $M^* = \Gamma_0(\mathcal{R}^*)$.*

<!-- label: III.XXI.6.2.6 -->

An adjoint or simply connected root datum is therefore semisimple. On the other hand, $\mathcal{R}$ is adjoint (resp. simply connected) if and only if $\mathcal{R}^*$ is simply connected (resp. adjoint). By virtue of the preceding result, one has:

Proposition 6.2.7. *Let $\mathcal{R}$ be a semisimple root datum. The following conditions are equivalent:

<!-- label: III.XXI.6.2.7 -->

(i) $\mathcal{R}$ is adjoint (resp. simply connected).

(ii) Every isogeny $\mathcal{R}' \rightarrow \mathcal{R}$ (resp. $\mathcal{R} \rightarrow \mathcal{R}'$) is an isomorphism.

Proposition 6.2.8. *Let $\mathcal{R}$ be an adjoint (resp. simply connected) root datum. Every indivisible root (resp. coroot) is an indivisible element of M (resp. M^*).*

<!-- label: III.XXI.6.2.8 -->

Proof. Indeed, every indivisible root is part of a basis of $\Gamma_0(\mathcal{R})$, by 3.3.5.

<!-- original page 130 -->

6.3. Radical and coradical

<!-- label: III.XXI.6.3 -->

Let $\mathcal{R}$ be a root datum. Set

```

```text
N = {x ∈ M | (α*, x) = 0 for all α* ∈ R*};
```

```

$$N^* = M^*/(V(R^*) \cap M^*).$$

Lemma 6.3.1. *Consider the canonical morphisms:*

III.XXI.6.3.1

$$N \rightarrow M, \quad M^* \rightarrow N^*.$$

They are transposes of each other and N^ is identified with the dual of N .*

Proof. This is immediate, taking 1.2.5 into account.

Definition 6.3.2. *One calls coradical of $\mathcal{R}$ and denotes by $\text{corad}(\mathcal{R})$ the trivial root datum*

III.XXI.6.3.2

$$\text{corad}(\mathcal{R}) = (N, N^*, \emptyset, \emptyset).$$

If one sets $\mathcal{R}_0 = (M, M^, \emptyset, \emptyset)$ (this is a trivial root datum), one has therefore a morphism*

$$\text{corad}(\mathcal{R}) \longrightarrow \mathcal{R}_0.$$

Definition 6.3.3. *One calls radical of $\mathcal{R}$ and denotes by $\text{rad}(\mathcal{R})$ the trivial root datum:*

III.XXI.6.3.3

$$\text{rad}(\mathcal{R}) = \text{corad}(\mathcal{R}^*).$$

[^{N.D.E}-XXI-25]

One thus has a diagram

$$\begin{array}{ccc} \text{corad}(\square) & \longrightarrow & \text{rad}(\square) \\ & \searrow & \swarrow \\ & \square_0 & \end{array}$$

original page 131

whose transpose is the corresponding diagram for $\mathcal{R}^*$.

Lemma 6.3.4. *The canonical morphism $u : \text{corad}(\mathcal{R}) \rightarrow \text{rad}(\mathcal{R})$ is an isogeny.*

III.XXI.6.3.4

Definition 6.3.5. *Set $N(\mathcal{R}) = K(u) = M / ((V(R) \cap M) + \bigcap_{\alpha \in R} \text{Ker}(\alpha))$. One then has a canonical pairing*

III.XXI.6.3.5

$$N(\mathcal{R}) \times N(\mathcal{R}^*) \longrightarrow \mathbb{Q}/\mathbb{Z}.$$

Lemma 6.3.6. *One has $\text{rgred}(\text{rad}(\square)) = \text{rgred}(\text{corad}(\square)) = \text{rgred}(\square) - \text{rgss}(\square)$, and the following conditions are equivalent:*

<!-- label: III.XXI.6.3.6 -->

- *(i) $\mathcal{R}$ is semisimple,*
- *(ii) $\text{rad}(\mathcal{R}) = 0$,*
- *(iii) $\text{corad}(\mathcal{R}) = 0$.*

6.4. Products of root data

<!-- label: III.XXI.6.4 -->

Definition 6.4.1. *Let $\mathcal{R} = (M, M^*, R, R^*)$ and $\mathcal{R}' = (M', M'^*, R', R'^*)$ be two root data. One calls* product root datum *of $\mathcal{R}$ and $\mathcal{R}'$ and denotes by $\mathcal{R}'' = \mathcal{R} \times \mathcal{R}'$ the root datum (M'', M''^*, R'', R''^*) where*

<!-- label: III.XXI.6.4.1 -->

```text  
 $M'' = M \times M', \quad M''^* = M^* \times M'^*,$   
 $R'' = (R \times \emptyset) \cup (\emptyset \times R'), \quad R''^* = (R^* \times \emptyset) \cup (\emptyset \times R'^*),$   
 ```

the map $\alpha \mapsto \alpha$ being the obvious map.

Proposition 6.4.2. *Under the preceding conditions, one has canonical isomorphisms*

<!-- label: III.XXI.6.4.2 -->

```text  
 $\Gamma_\emptyset(\mathcal{R}'') \simeq \Gamma_\emptyset(\mathcal{R}) \times \Gamma_\emptyset(\mathcal{R}'), \quad V(\mathcal{R}'') \simeq V(\mathcal{R}) \times V(\mathcal{R}'),$   
 $W(\square'') \simeq W(\square) \times W(\square'),$   
 ```

etc., and the equalities

<!-- original page 132 -->

```text  
 $\text{rgred}(\square'') = \text{rgred}(\square) + \text{rgred}(\square'), \quad \text{rgss}(\square'') = \text{rgss}(\square) + \text{rgss}(\square').$   
 ```

One also has a canonical isomorphism of root data

```text  
 $(\square \times \square')^* \simeq \square^* \times \square'^*.$   
 ```

The preceding definitions extend at once to a product of several factors. One has at once:

Proposition 6.4.3. *Let $\mathcal{R} = \mathcal{R}_1 \times \mathcal{R}_2 \times \cdots \times \mathcal{R}_n$ be a product of root data. The following conditions are equivalent:*

<!-- label: III.XXI.6.4.3 -->

- *(i) $\mathcal{R}$ is semisimple (resp. simply connected, resp. adjoint, resp. reduced).*
- *(ii) Each $\mathcal{R}_i$ is semisimple (resp. simply connected, resp. adjoint, resp. reduced).*

Let us consider the following special case: let $\mathcal{R}_0$ be a trivial root datum and $\mathcal{R}_1$ a semisimple root datum. One then has a commutative diagram

```

```text
 0 1
 ×
 ↗ ↘
 1 id → 1.
```

```

Lemma 6.4.4. One has canonical isomorphisms

`<!-- label: III.XXI.6.4.4 -->`

```

```text
corad(0 × 1) ≅ rad(0 × 1)
 ≅ ≅
 0.
```

```

In particular, $\mathcal{R}_0 \times \mathcal{R}_1 = 0$.

`<!-- original page 94 -->`

We shall see later that if conversely $\mathcal{R} = 0$, then the root datum $\mathcal{R}$ is a product of a semisimple datum by a trivial datum.

`<!-- original page 133 -->`

6.5. Induced and coinduced root data

`<!-- label: III.XXI.6.5 -->`

Let $\mathcal{R} = (M, M^*, R, R^*)$ be a root datum. Let $N \subset M$ be a subgroup containing the roots, i.e. such that

```

$
\Gamma_0(R) \subset N \subset M.
$

```

The canonical linear map $i_N : N \rightarrow M$ gives by transposition a linear map

```

$
{}^{t}i_N : M^* \rightarrow N^*.
$

```

Set $\mathcal{R}_N = \mathcal{R}$ and $\mathcal{R}_N^* = {}^{t}i_N(\mathcal{R}^*)$.

Lemma 6.5.1. $\mathcal{R}_N = (N, N^*, \mathcal{R}_N, \mathcal{R}_N^*)$ is a root datum, and i_N a morphism.

`<!-- label: III.XXI.6.5.1 -->`

Proof. Let us first show that ${}^{t}i_N$ induces an isomorphism of $\mathcal{R}$ onto $\mathcal{R}_N^*$. If $\alpha, \beta \in R$ and ${}^{t}i_N(\alpha) = {}^{t}i_N(\beta)$, one has $(\alpha, x) = (\beta, x)$ for all $x \in N$, in particular for $x \in R$, which gives $\alpha = \beta$ by 1.1.4. The rest follows without difficulty.

Definition 6.5.2. $\mathcal{R}_N$ is called the root datum induced by $\mathcal{R}$ on N .

`<!-- label: III.XXI.6.5.2 -->`

Lemma 6.5.3. Let $f : \mathcal{R}' \rightarrow \mathcal{R}$ be a morphism. Set $N = f(M') \subset M$. Then f factors uniquely through i_N .

`<!-- label: III.XXI.6.5.3 -->`

In particular, isogenies $\mathcal{R}' \rightarrow \mathcal{R}$, up to isomorphism, correspond bijectively to the subgroups of finite index of $M/\Gamma_0(R)$, which makes 6.2.7 more precise.

Let now N^* be a subgroup of M^* containing R^* . One defines the root datum *coinduced* by $\mathcal{R}$ on N^* by

$$\mathcal{R}^{N^*} = (\mathcal{R}_{N^*})^*,$$

<!-- original page 134 -->

and one has a canonical morphism:

$$p_{N^*} : \mathcal{R} \rightarrow \mathcal{R}^{N^*}.$$

Lemma 6.5.4. *Let $f : \mathcal{R}' \rightarrow \mathcal{R}$ be a morphism. There exist subgroups $N \subset M$ and $N'^* \subset M'^*$ such that f factors as*

<!-- label: III.XXI.6.5.4 -->

$$\begin{array}{ccc} \mathcal{R}' & \xrightarrow{f} & \mathcal{R} \\ \downarrow & & \uparrow \\ p_{N'^*} & & i_N \\ \downarrow & \xrightarrow{f_0} & \uparrow \\ \mathcal{R}'^{N'^*} & \longrightarrow & \mathcal{R}_N, \end{array}$$

where f_0 is an isomorphism.

Proof. Indeed, one takes $N = f(M')$ as in 6.5.3. The morphism $M' \rightarrow N$ obtained is surjective, so its transpose is injective. One takes the image of the latter as N'^* .

Let us now treat certain special cases. If one takes $N = \Gamma_0(R)$, one writes $\mathcal{R}_N = \text{ad}(\mathcal{R})$. If one takes $N = V(R) \cap M$, one writes $\mathcal{R}_N = \text{ss}(\mathcal{R})$. One thus has a diagram:

$$\text{ad}(\mathcal{R}) \rightarrow \text{ss}(\mathcal{R}) \rightarrow \mathcal{R}.$$

Set $d\acute{e}r(\mathcal{R}) = \text{ss}(\mathcal{R}^*)$ and $sc(\mathcal{R}) = \text{ad}(\mathcal{R}^*)$; by duality, one obtains a diagram:

$$\mathcal{R} \rightarrow d\acute{e}r(\mathcal{R}) \rightarrow sc(\mathcal{R}).$$

Proposition 6.5.5. (i) In the first row of the diagram

<!-- label: III.XXI.6.5.5 -->

$$\begin{array}{ccccccc} \text{ad}(\square) & \rightarrow & \text{ss}(\square) & \rightarrow & d\acute{e}r(\square) & \rightarrow & sc(\square) \\ & & & & \searrow & & \nearrow \\ & & & & \square & & \end{array}$$

the four data are semisimple and the three morphisms are isogenies.

(ii) $\text{ad}(\mathcal{R})$ is an adjoint datum, and $\mathcal{R}$ is adjoint if and only if $\text{ad}(\mathcal{R}) \rightarrow \mathcal{R}$ is an isomorphism.

<!-- original page 135 -->

(iii) $\mathcal{R}$ is a simply connected datum, and $\mathcal{R}$ is simply connected if and only if $\mathcal{R} \rightarrow \mathcal{S}(\mathcal{R})$ is an isomorphism.

(iv) The following conditions are equivalent:

(a) $\mathcal{R}$ is semisimple,

(b) $\mathcal{S}(\mathcal{R}) \rightarrow \mathcal{R}$ is an isomorphism,

(c) $\mathcal{R} \rightarrow \mathcal{D}(\mathcal{R})$ is an isomorphism.

Let us pause briefly on the morphism $\mathcal{S}(\mathcal{R}) \rightarrow \mathcal{D}(\mathcal{R})$. Referring to the construction of $\mathcal{S}(\mathcal{R})$ and $\mathcal{D}(\mathcal{R})$, it is easy to prove the

Lemma 6.5.6. *Let $h : \mathcal{S}(\mathcal{R}) \rightarrow \mathcal{D}(\mathcal{R})$ be the canonical isogeny. One has $K(h) \leq N(\mathcal{R})$.*

<!-- label: III.XXI.6.5.6 -->

6.5.7. Consider other special cases of induced data. Set

<!-- label: III.XXI.6.5.7 -->

$$N = \{x \in M \mid (\alpha^*, x) = 0 \text{ for } \alpha \in R\} \times \Gamma_0(R);$$

one knows that the sum is direct by 1.2.5. It follows that the root datum $\mathcal{R}_N$ is identified with the product $\mathcal{A}(\mathcal{R}) \times \text{corad}(\mathcal{R})$.

One can do the same by replacing $\Gamma_0(R)$ by $V(R) \cap M$, then dualize these two constructions. One thus obtains a diagram of root data:

$$\begin{array}{ccccccc} \mathcal{A}(\square) & \rightarrow & \mathcal{S}(\square) & \rightarrow & \mathcal{D}(\square) & \rightarrow & \mathcal{S}(\square) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \mathcal{A}(\square) \times \text{corad}(\square) & \rightarrow & \mathcal{S}(\square) \times \text{corad}(\square) & \rightarrow & \square & \rightarrow & \mathcal{D}(\square) \times \text{rad}(\square) \rightarrow \mathcal{S}(\square) \times \text{rad}(\square) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow \\ \mathcal{A}(\square) & \rightarrow & \mathcal{S}(\square) & \rightarrow & \mathcal{D}(\square) & \rightarrow & \mathcal{S}(\square); \end{array}$$

<!-- original page 136 -->

which is commutative, as one verifies at once. This diagram is self-dual in an obvious sense. The horizontal morphisms are isogenies. The composites of the vertical arrows are the identity.

Lemma 6.5.8. *Let h_1 and h_2 be the canonical isogenies:*

<!-- label: III.XXI.6.5.8 -->

$$\mathcal{S}(\square) \times \text{corad}(\square) \xrightarrow{h_1} \square \xrightarrow{h_2} \mathcal{D}(\square) \times \text{rad}(\square).$$

One has $K(h_1) \leq K(h_2) \leq N(\mathcal{R})$.

Proof. This is trivial from the definitions.

Corollary 6.5.9. *Let $\mathcal{R}$ be a root datum. The following conditions are equivalent:*

<!-- label: III.XXI.6.5.9 -->

(i) $N(\mathcal{R}) = 0$, i.e. $\text{corad}(\mathcal{R}) \rightarrow \text{rad}(\mathcal{R})$ is an isomorphism.

(ii) $\mathfrak{h} : \mathfrak{ss}(\mathcal{R}) \rightarrow \mathcal{R}$ is an isomorphism.
 (iii) $\mathfrak{h}_1 : \mathfrak{ss}(\mathcal{R}) \times \text{corad}(\mathcal{R}) \rightarrow \mathcal{R}$ is an isomorphism.
 (iv) $\mathfrak{h}_2 : \mathcal{R} \rightarrow \mathcal{R} \times \text{rad}(\mathcal{R})$ is an isomorphism.
 (v) $\mathcal{R}$ is the product of a semisimple datum and a trivial datum.

Let us also state a trivial consequence of the preceding remarks:

Corollary 6.5.10. For every root datum $\mathcal{R}$, there exist isogenies

$$\text{ad}(\square) \times \square_0 \rightarrow \square \rightarrow \text{sc}(\square) \times \square_0,$$

where $\mathcal{R}_0$ is "the" trivial root datum of rank $\text{rgred}(\mathcal{R}) - \text{rgss}(\mathcal{R})$.

Let us finally note a result that may be useful:

Lemma 6.5.11. Let $\mathcal{R}$ be a root datum, Δ a system of simple roots, Δ' a subset of Δ ; consider the root datum (cf. 3.4.7)

$$\square_{\Delta'} = (M, M^*, R_{\Delta'}, R^*_{\Delta'}).$$

original page 137

(i) If $\mathcal{R}$ is simply connected, then $\mathcal{R}_{\Delta'}$ is simply connected.*
 (ii) If $\mathcal{R}$ is adjoint, then $\mathfrak{ss}(\mathcal{R}_{\Delta'})$ is adjoint.*

Proof. The two assertions are evidently equivalent by duality. The second reduces to verifying the formula:

$$M \cap V(R_{\Delta'}) = \Gamma_0(R_{\Delta'});$$

now, if $M = \Gamma_0(\mathcal{R})$, the two sides are equal to the subgroup of M generated by Δ' .

6.6. Weights

Definition 6.6.1. Let $\mathcal{R}$ be a root datum. Set [N.D.E-XXI-26]

$$\Lambda(\square) = \{x \in V(\mathcal{R}) \mid (\alpha^*, x) \in \mathbb{Z} \text{ for all } \alpha^* \in R^*\}.$$

The elements of $\Lambda(\mathcal{R})$ are called the weights of $\mathcal{R}$. The weights of $\mathcal{R}^*$ are called the coweights of $\mathcal{R}$.

One has $\Gamma_0(\mathcal{R}) \subset \Lambda(\mathcal{R})$ and $\Lambda(\mathcal{R})$ is stable under $W(\mathcal{R})$.

Lemma 6.6.2. The bilinear map $V^* \times V \rightarrow \mathbb{Q}$ induces a duality

$$\Gamma_0(R^*) \times \Lambda(\mathcal{R}) \xrightarrow{\quad} \mathbb{Z}.$$

Proof. Trivial.

Corollary 6.6.3. Let $\Delta = (\alpha_1, \dots, \alpha_n)$ be a system of simple coroots. Let p_i , $i = 1, 2, \dots, n$, be the elements of $V(R)$ defined by*

$$(\alpha_i, p_j) = \delta_{ij},$$

$$(\alpha_i, p_j) = \delta_{ij},$$

(whence $s_{\alpha_i}(p_i) = p_i - \alpha_i$ and $s_{\alpha_i}(p_j) = p_j$ for $i \neq j$).^[XXI-6-1]
 Then $\Lambda(\mathcal{R})$ is the free abelian group generated by the p_i .*

$$(\alpha_i, p_j) = \delta_{ij},$$

The p_i are called the *fundamental weights* corresponding to the system of simple coroots Δ .

Corollary 6.6.4. For every $\alpha \in \Delta$, one has therefore $(\alpha, \sum p_i) = 1$, hence $\sum p_i = \rho_{R^+}$ (cf. 3.5.1), where $R_+ = P(\text{ind}(\Delta))$.*

$$(\alpha_i, p_j) = \delta_{ij},$$

Corollary 6.6.5. For every $x \in V(R)$, one has $x = \sum (\alpha_i, x) p_i$.*

$$(\alpha_i, p_j) = \delta_{ij},$$

Remark that $R^* \subset \Gamma_0(R^*)$ and $R \subset \Lambda(\mathcal{R})$, so $(\Lambda(\mathcal{R}), \Gamma_0(R^*), R, R^*)$ is a root datum.

Corollary 6.6.6. The canonical morphism $\Gamma_0(R^*) \rightarrow M^*$ is the transpose of the morphism $x \mapsto \sum (\alpha_i, x) p_i$, which defines a morphism of root data, and one has a commutative diagram:*

$$(\alpha_i, p_j) = \delta_{ij},$$

$$\begin{array}{ccc} & & \text{sc}(\square) \\ & \nearrow & \square \\ \square & & \\ & \searrow & \\ & & (\Lambda(\square), \Gamma_0(R^*), R, R^*). \end{array}$$

One thus has an explicit description of $\text{sc}(\mathcal{R})$ in terms of the weights of $\mathcal{R}$. Similarly, one finds a commutative diagram:

$$\begin{array}{ccc} & & \text{ad}(\square) \\ & \searrow & \square \\ \square & & \\ & \nearrow & \\ & & (\Gamma_0(R), \Lambda(\square^*), R, R^*). \end{array}$$

Corollary 6.6.7. For $\mathcal{R}$ to be simply connected, it is necessary and sufficient that $M = \Lambda(\mathcal{R})$.*

$$(\alpha_i, p_j) = \delta_{ij},$$

<!-- original page 139 -->

Remark 6.6.8. One has $\Lambda(\mathcal{R}) \cap M = V(\mathcal{R}) \cap M$. For $\mathcal{R}$ to be semisimple, it is therefore necessary and sufficient that $M \subset \Lambda(\mathcal{R})$.

<!-- label: III.XXI.6.6.8 -->

From the results of 6.5 there also follows:

Corollary 6.6.9. For $\mathcal{R}$ to be the product of a simply connected datum by a trivial datum, it is necessary and sufficient that $M \supset \Lambda(\mathcal{R})$.

<!-- label: III.XXI.6.6.9 -->

Consider now the canonical isogeny

$$f : \text{ad}(\mathcal{R}) \rightarrow \text{sc}(\mathcal{R}),$$

and set $Z(\mathcal{R}) = K(f)$. One has $Z(\mathcal{R}) \simeq Z(\text{sc}(\mathcal{R})) \simeq Z(\text{ad}(\mathcal{R}))$.

Corollary 6.6.10. One has a canonical isomorphism $Z(\mathcal{R}) = \Lambda(\mathcal{R})/\Gamma_0(\mathcal{R})$. More precisely, one has an exact sequence of $W(\mathcal{R})$ -modules:

<!-- label: III.XXI.6.6.10 -->

$$0 \rightarrow \Gamma_0(\mathcal{R}) \rightarrow \Lambda(\mathcal{R}) \rightarrow Z(\mathcal{R}) \rightarrow 0.$$

Corollary 6.6.11. One has a canonical pairing*

<!-- label: III.XXI.6.6.11 -->

$$Z(\mathcal{R}^*) \times Z(\mathcal{R}) \rightarrow \mathbb{Q}/\mathbb{Z}$$

which puts these groups in duality.

Remark 6.6.12. One has $Z(\mathcal{R} \times \mathcal{R}') \simeq Z(\mathcal{R}) \times Z(\mathcal{R}')$. Consider in particular simply connected data $\mathcal{R}_i$, $i = 1, 2, \dots, n$, and a trivial datum $\mathcal{R}_0$. Set $\mathcal{R} = \mathcal{R}_0 \times \mathcal{R}_1 \times \dots \times \mathcal{R}_n$. Let $\mathcal{R} = (M, M^*, R, R^*)$, $\mathcal{R}_0 = (M_0, M_0^*, \emptyset, \emptyset)$. One has*

<!-- label: III.XXI.6.6.12 -->

$$M/\Gamma_0(\mathcal{R}) \simeq M_0 \times Z(\mathcal{R}_1) \times \dots \times Z(\mathcal{R}_n).$$

6.7. Automorphisms

<!-- label: III.XXI.6.7 -->

An automorphism of $\mathcal{R}$ is, by 6.1.4, an automorphism of M , say u , such that $u(\mathcal{R}) = \mathcal{R}$ and $u^t(\mathcal{R}^*) = \mathcal{R}^*$. In particular, every element w of $W(\mathcal{R})$ defines an automorphism of $\mathcal{R}$.

<!-- original page 140 -->

Lemma 6.7.1. $W(\mathcal{R})$ is a normal subgroup of $\text{Aut}(\mathcal{R})$. More precisely, if $u \in \text{Aut}(\mathcal{R})$ and $\alpha \in R$, one has*

<!-- label: III.XXI.6.7.1 -->

```

```text
u s_{\alpha} u^{-1} = s_{\{u(\alpha)\}}.
```

```

Proof. The proof is the same as that of 1.2.10.

Proposition 6.7.2. *Let Δ be a system of simple roots. Set*

```

<!-- label: III.XXI.6.7.2 -->

```

```

```text
E_{\Delta}(\square) = \{u \in \operatorname{Aut}(\square) \mid u(\Delta) = \Delta\}.
```

```

Then $\operatorname{Aut}(\mathcal{R})$ is the semidirect product of $W(\mathcal{R})$ by $E_{\Delta}(\mathcal{R})$.

Proof. This follows at once from the fact that $W(\mathcal{R})$ operates simply transitively on the systems of simple roots, and from the fact that if Δ is a system of simple roots of $\mathcal{R}$, then $u(\Delta)$ is a system of simple roots for every automorphism u of $\mathcal{R}$.

We shall see later a simpler description of $E_{\Delta}(\mathcal{R})$ in the case of reduced and irreducible root data. [N.D.E-XXI-27]

Definition 6.7.3. *One denotes by $\operatorname{Aut}_{\{s\}}(\mathcal{R})$ [N.D.E-XXI-28] the set of $u \in \operatorname{Aut}(\mathcal{R})$ such that the following diagram is commutative:*

```

<!-- label: III.XXI.6.7.3 -->

```

```

```text
 u
 \square \longrightarrow \square
 \swarrow \quad \searrow
 \operatorname{rad}(\square).
```

```

One writes $E^{\{s\}}_{\Delta}(\mathcal{R}) = E_{\Delta}(\mathcal{R}) \cap \operatorname{Aut}_{\{s\}}(\mathcal{R})$.

```

<!-- original page 141 -->

```

Remark 6.7.4. *If $u \in \operatorname{Aut}(\mathcal{R})$, one has therefore $u \in \operatorname{Aut}_{\{s\}}(\mathcal{R})$ if and only if $(u - \operatorname{id})(M) \subset V(R)$. In particular $W(\mathcal{R}) \subset \operatorname{Aut}_{\{s\}}(\mathcal{R})$. It follows at once:*

```

<!-- label: III.XXI.6.7.4 -->

```

Proposition 6.7.5. *The group $\operatorname{Aut}_{\{s\}}(\mathcal{R})$ is the semidirect product of $W(\mathcal{R})$ by $E^{\{s\}}_{\Delta}(\mathcal{R})$, for every system of simple roots Δ .*

```

<!-- label: III.XXI.6.7.5 -->

```

To every automorphism of $\mathcal{R}$ is associated by functoriality an automorphism of $\operatorname{ad}(\mathcal{R})$. One thus has a canonical morphism

```

$$
\operatorname{Aut}(\mathcal{R}) \longrightarrow \operatorname{Aut}(\operatorname{ad}(\mathcal{R})).
$$

```

Lemma 6.7.6. *The morphism $\operatorname{Aut}_{\{s\}}(\mathcal{R}) \rightarrow \operatorname{Aut}(\operatorname{ad}(\mathcal{R}))$ is injective.*

```

<!-- label: III.XXI.6.7.6 -->

```

Proof. Let u be an automorphism of M such that $(u - \operatorname{id})(M) \subset V(R)$ and $\{^t u(\alpha^*) = \alpha^*$ for $\alpha^* \in R^*$. For every $x \in M$, one has

```

```text
(α^* , $u(x) - x$) = (${}^tu(\alpha^*) - \alpha^*$, x) = 0,
```

so  $u(x) - x = 0$ , by 1.2.5.

**Lemma 6.7.7.** *The group  $\operatorname{Aut}_s(\mathcal{R})$  is finite.*

<!-- label: III.XXI.6.7.7 -->

*Proof.* Indeed, it suffices for us to prove that  $\operatorname{Aut}(\mathcal{R})$  is finite if  $\mathcal{R}$  is adjoint. Since  $M$  is then generated by  $R$ , every automorphism of  $\mathcal{R}$  is determined by the permutation of  $R$  that it defines.

**Remark 6.7.8.** *One sees at once that  $\operatorname{Aut}(\mathcal{R})$  (resp.  $E_{\Delta}(\mathcal{R})$ ) is finite if and only if  $\operatorname{rgred}(\mathcal{R}) - \operatorname{rgss}(\mathcal{R}) \leq 1$ .*

<!-- label: III.XXI.6.7.8 -->

### 6.8.  $\mathcal{P}$ -morphisms of reduced root data

<!-- label: III.XXI.6.8 -->

<!-- original page 142 -->

In this number,  $p$  is an integer  $> 0$  fixed once and for all.

**Definition 6.8.1.** *Let  $\mathcal{R} = (M, M^*, R, R^*)$  and  $\mathcal{R}' = (M', M'^*, R', R'^*)$  be two reduced root data. One says that a group morphism*

<!-- label: III.XXI.6.8.1 -->

$$f : M' \rightarrow M$$

*is a  $\mathcal{P}$ -morphism from  $\mathcal{R}'$  to  $\mathcal{R}$ , if the following conditions are satisfied: there exist a bijection*

$$u : R \xrightarrow{\sim} R'$$

*and a map  $q : R \rightarrow \{p^n, n \in \mathbb{N}\}$  such that:*

(i)  $f(u(\alpha)) = q(\alpha) \alpha$  for every  $\alpha \in R$ .

(ii)  $f(u(\alpha)^*) = q(\alpha) u(\alpha)^*$  for every  $\alpha \in R$ .[N.D.E-XXI-29]

**Corollary 6.8.2.** *A  $\mathcal{P}$ -morphism is nothing other than a morphism.*

<!-- label: III.XXI.6.8.2 -->

**Corollary 6.8.3.** *The transpose of a  $\mathcal{P}$ -morphism is a  $\mathcal{P}$ -morphism.*

<!-- label: III.XXI.6.8.3 -->

**Lemma 6.8.4.** *If  $w \in W(\mathcal{R})$ ,  $\alpha \in R$ , one has  $q(w(\alpha)) = q(\alpha)$ . The map  $s_{\alpha} \mapsto s_{u(\alpha)}$  extends to an isomorphism  $u : W(\mathcal{R}) \rightarrow W(\mathcal{R}')$  such that*u(w(\alpha)) = u(w)(u(\alpha)).

```

\$\$

Proof. It suffices to prove that for $\alpha, \beta \in R$, one has $u(s_{\alpha}(\beta)) = s_{\alpha} u(\beta)$ and $q(s_{\alpha}(\beta)) = q(\beta)$. Now one has successively:

```
```text
f(s_{\alpha} u(\beta)) = f(u(\beta)) - (u(\alpha)*, u(\beta)) f(u(\alpha))
 = q(\beta) \beta - q(\beta) q(\alpha)^{-1} (\alpha*, \beta) q(\alpha) \alpha
 = q(\beta) (\beta - (\alpha*, \beta) \alpha) = q(\beta) s_{\alpha}(\beta).
```
```

<!-- original page 143 -->

If $\gamma = u^{-1}(s_{\alpha} u(\beta))$, one has therefore $q(\gamma) \gamma = f(u(\gamma)) = q(\beta) s_{\alpha}(\beta)$. The two roots γ and $s_{\alpha}(\beta)$ are therefore proportional (over $\mathbb{Q}$), so equal or opposite, but $q(\gamma)$ and $q(\beta)$ are positive. One thus has $q(\gamma) = q(\beta)$ and $\gamma = s_{\alpha}(\beta)$.

Definition 6.8.5. The $q(\alpha)$ are called the radical exponents of f .

<!-- label: III.XXI.6.8.5 -->

Example 6.8.6. Let R be a reduced root datum and $q = p^n$ ($n \in \mathbb{N}$). Then the multiplication by $q : M \rightarrow M$, $x \mapsto qx$ is a p -morphism whose radical exponents are all equal to q (and $u = \text{id}$); one denotes it

<!-- label: III.XXI.6.8.6 -->

\$\$
 $q : R \rightarrow R$.
\$\$

Proposition 6.8.7. In the notation of 6.8.1, u realizes an isomorphism of the set of systems of simple roots (resp. of positive roots) of R onto the corresponding set for R' .

<!-- label: III.XXI.6.8.7 -->

Proof. This follows at once from 3.1.5 (resp. 3.2.1).

7. Structure

<!-- label: III.XXI.7 -->

<!-- original page 144 -->

7.1. Decomposition of a root datum

<!-- label: III.XXI.7.1 -->

Proposition 7.1.1. Let R be a root datum, Δ a system of simple roots.

<!-- label: III.XXI.7.1.1 -->

(i) Let R' and R'' be two closed and symmetric sets of roots forming a partition of R . If one denotes $\Delta' = \Delta \cap R'$, $\Delta'' = \Delta \cap R''$, then $R' = R_{\Delta'}$, $R'' = R_{\Delta''}$, and every root of Δ' is orthogonal to every root of Δ'' .

(ii) Let Δ' and Δ'' be two subsets of Δ forming a partition of Δ and orthogonal. Then $R' = R_{\Delta'}$ and $R'' = R_{\Delta''}$ form a partition of R .

Proof. Let us first prove (i).

Lemma 7.1.2. Under the conditions of (i), if α , β , and $\alpha + \beta$ are roots, they all three belong to R' or all three to R'' .

<!-- label: III.XXI.7.1.2 -->

Proof. Suppose for example $\alpha + \beta \in R'$. Then one cannot have $\alpha, \beta \in R''$, since R'' is closed; suppose therefore $\alpha \in R'$. Then $-\alpha \in R'$ and $\beta = (\beta + \alpha) - \alpha \in R'$.

Let us now show that $R' = R_{\Delta}$ by induction on the order of a positive root $\alpha \in R' \cap P(\Delta)$. If $\text{ord}_{\Delta}(\alpha) = 1$, then $\alpha \in R' \cap \Delta = \Delta$. If $\text{ord}_{\Delta}(\alpha) > 1$, there exists $\beta \in \Delta$ such that $\alpha - \beta \in R$. By the lemma, one has $\beta \in \Delta$, $\alpha - \beta \in R'$, so $\alpha - \beta \in R_{\Delta}$ by induction, and finally $\alpha = (\alpha - \beta) + \beta \in R_{\Delta}$.

Let us finally show that Δ and Δ' are orthogonal. If $\alpha \in \Delta$ and $\beta \in \Delta'$, then $(\beta, \alpha) \leq 0$. If $(\beta, \alpha) \neq 0$, then $\beta + \alpha$ is a root, contrary to the lemma.

Let us prove (ii). If Δ or Δ' is empty, this is immediate. Otherwise, if R_{Δ} and $R_{\Delta'}$ do not form a partition of R , there exists a root α of the form

<!-- original page 145 -->

$$\alpha = \sum_i m_i \alpha_i + \sum_j m'_j \alpha'_j, \quad m_i \in \mathbb{Z}_+, m'_j \in \mathbb{Z}_+,$$

where one denotes by α_i (resp. α'_j) elements of Δ (resp. Δ'). Applying 3.1.2, one deduces a relation of the form (possibly inverting Δ and Δ'):

$$\delta = \gamma + \beta, \quad \gamma \in R_{\Delta}, \quad \beta \in \Delta', \quad \delta \in R.$$

But since $(\beta, \gamma) = 0$, $\gamma - \beta$ is also a root by 2.2.5, which is impossible.

****Proposition 7.1.3.**** Let R be a root datum. The following conditions are equivalent:

<!-- label: III.XXI.7.1.3 -->

(i) There exists no non-trivial partition of R into two closed and symmetric subsets.

(ii) For some (resp. every) system of simple roots Δ of R , there exists no partition of Δ into two non-empty orthogonal subsets.

<!-- original page 102 -->

(iii) The natural representation of $W(R)$ in $V(R)$ is irreducible.

(iv) For every pair (α, β) of roots, there exists a sequence of roots $\alpha_0, \alpha_1, \alpha_2, \dots, \alpha_n$, with $\alpha = \alpha_0$, $\alpha_n = \beta$, such that the roots α_i and α_{i+1} ($i = 0, \dots, n-1$) are non-orthogonal.

Proof. One has (i) $\Leftrightarrow$ (ii) by 7.1.1. One has obviously (iv) $\Rightarrow$ (ii). Conversely, if (ii) is verified for Δ , condition (iv) is verified for $\alpha, \beta \in \Delta$. Now for every root, there exists a simple root not orthogonal to it (3.1.1 for example). On the other hand (iii) $\Rightarrow$ (i): in effect, under the conditions of 7.1.1, $V(R')$ is stable under $W(R)$. It remains to prove (i) $\Rightarrow$ (iii).

<!-- original page 146 -->

So let H be a vector subspace of $V(R)$, stable under $W(R)$. For every $\alpha \in R$, the equation $s_{\alpha}(H) = H$ gives at once $\alpha \in H$, or $\alpha \in H^{\perp}$ (orthogonal of H in $V(R)$), which is in duality with $V(R)$. If one sets $R' = \{\alpha \in R \mid \alpha \in H\}$ and $R'' = \{\alpha \in R \mid \alpha \in H^{\perp}\}$, one has realized a partition of R into two closed and symmetric subsets.

****Definition 7.1.4.**** A root datum (resp. a root system) satisfying the equivalent conditions of 7.1.3 and of semisimple rank $\neq 0$ is called irreducible.

<!-- label: III.XXI.7.1.4 -->

Corollary 7.1.5. For every root datum $\mathcal{R}$, there exists a unique partition (up to order) of R into closed, symmetric, and irreducible subsets.

<!-- label: III.XXI.7.1.5 -->

Corollary 7.1.6. Every adjoint (resp. simply connected) root datum is a product of irreducible adjoint (resp. simply connected) root data.

<!-- label: III.XXI.7.1.6 -->

Proof. It suffices to see this in the adjoint case. The assertion then follows from the fact that under the conditions of 7.1.1, one has

$$\Gamma_0(R) = \Gamma_0(R') \times \Gamma_0(R'').$$

Corollary 7.1.7. For every root datum (resp. reduced root datum) $\mathcal{R}$, there exists an isogeny $\mathcal{R} \rightarrow \mathcal{R}'$, where $\mathcal{R}'$ is a product of a trivial root datum and of irreducible simply connected root data (resp. and reduced).

<!-- label: III.XXI.7.1.7 -->

7.2. Properties of irreducible root data

<!-- label: III.XXI.7.2 -->

<!-- original page 147 -->

Definition 7.2.1. Let $\mathcal{R}$ be an irreducible root datum. For every $\alpha \in R$, set

<!-- label: III.XXI.7.2.1 -->

$$\text{long}(\alpha) = \frac{\ell(\alpha)}{\ell(\alpha_0)},$$

where $\alpha_0 \in R$ is such that $\ell(\alpha_0)$ is minimal; one says that $\text{long}(\alpha)$ is the length of α .

Lemma 7.2.2. Let $\mathcal{R}$ be an irreducible root datum. The Weyl group operates transitively on the set of roots of the same length.

<!-- label: III.XXI.7.2.2 -->

Proof. Indeed, let $\alpha, \beta \in R$. Since the representation of W on $V(R)$ is irreducible, α cannot be orthogonal to all the $w(\beta)$, $w \in W$. There exists therefore $w \in W$ with $w(\beta)$ non-orthogonal to α . Now $\ell(w(\beta)) = \ell(\beta)$, and one concludes by 2.3.2.

Lemma 7.2.3. If $\mathcal{R}$ is irreducible and reduced, then $\text{long}(R)$ is $\{1\}$, $\{1, 2\}$, or $\{1, 3\}$.

<!-- label: III.XXI.7.2.3 -->

<!-- original page 103 -->

Proof. By virtue of the remark used above, for every $\alpha, \beta \in R$, there always exists $w \in W$ such that $w(\beta)$ is not orthogonal to α . One thus has $\frac{\ell(\alpha)}{\ell(\beta)} = 1, 2, 3, 1/2$, or $1/3$ (by 2.3.1). One has therefore $\text{long}(\alpha) = 1, 2$, or 3 , but if $\text{long}(\alpha) = 2$, $\text{long}(\beta) = 3$, then $\frac{\ell(\alpha)}{\ell(\beta)} = 2/3$, which is impossible.

Remark 7.2.4. Reasoning similarly, one proves the following result: if $\mathcal{R}$ is irreducible and not reduced with $\text{rgss}(\mathcal{R}) > 1$, one has $\text{long}(R) = \{1, 2, 4\}$. If one sets $\text{long}^{-1}(i) = R_i$, then $\text{ind}(R) = R_1 \cup R_2$, $R_4 = 2R_1$, and two non-proportional roots of R_1 are orthogonal. Conversely, if R is an irreducible and reduced system such that $\text{long}(R) = \{1, 2\}$, set $\text{long}^{-1}(i) = R_i$ and suppose that two

non-proportional roots of R_1 are orthogonal; then $R \cup R_1$ is irreducible, not reduced, and $\text{ind}(R \cup R_1) = R$.

<!-- label: III.XXI.7.2.4 -->

Lemma 7.2.5. If R is an irreducible root datum, R also is, and the product $\text{long}(\alpha) \text{long}(\alpha^*)$ is constant as α runs over R .

<!-- label: III.XXI.7.2.5 -->

<!-- original page 148 -->

Proof. This follows at once from 7.1.3 (iv) and 2.2.6.

Definition 7.2.6. Let R be any root datum. One calls length of $\alpha \in R$ and denotes by $\text{long}(\alpha)$ the length of α in its irreducible component.

<!-- label: III.XXI.7.2.6 -->

Lemma 7.2.7. There exists a unique group homomorphism $u : \Gamma(R) \rightarrow \Gamma(R^*)$ such that $u(\alpha) = \text{long}(\alpha) \alpha^*$ for $\alpha \in R$.

<!-- label: III.XXI.7.2.7 -->

Proof. By 3.5.5, it suffices to verify that if $\alpha, \beta, \alpha + \beta \in R$, one has

$$\text{long}(\alpha) \alpha^* + \text{long}(\beta) \beta^* = \text{long}(\alpha + \beta) (\alpha + \beta)^*.$$

But α, β , and $\alpha + \beta$ are in the same irreducible component of R by 7.1.2, and one is reduced to 1.2.2.

Remark 7.2.8. Let u be as in 7.2.7. For $\alpha, \beta \in R$, one has $(u(\alpha), \beta) = (u(\beta), \alpha)$. Indeed, this amounts to seeing that

<!-- label: III.XXI.7.2.8 -->

$$\text{long}(\alpha) (\alpha^*, \beta) = \text{long}(\beta) (\beta^*, \alpha),$$

which is obviously verified if α and β are orthogonal. If α and β are not orthogonal, then they are in the same irreducible component of R , and one is reduced to 1.2.1, formula (9).

Remark 7.2.9. The symmetric bilinear form $(u(x), y)$ is positive nondegenerate on $\Gamma(R)$.

<!-- label: III.XXI.7.2.9 -->

Proof. Indeed, let R_i be the irreducible components of R . One has

$$\Gamma(R) = \prod_i \Gamma(R_i),$$

and the bilinear form $(u(x), y)$ is the product of the forms

$$2^{-1} \ell(\alpha_i)^{-1} (p(x), y)$$

<!-- original page 149 -->

on the $\Gamma(R_i)$, where $\ell(\alpha_i)$ is the minimum of $\ell(\alpha)$ for $\alpha \in R_i$. Now these various symmetric bilinear forms are positive nondegenerate (1.2.6).

<!-- original page 104 -->

7.3. Cartan matrix

<!-- label: III.XXI.7.3 -->

Let $\mathcal{R}$ be a root datum. If Δ is a system of simple roots, one calls *Cartan matrix* of $\mathcal{R}$ relative to Δ the square matrix on the index set Δ defined by

$$a_{\alpha, \beta} = (\alpha^*, \beta), \quad \text{for } \alpha, \beta \in \Delta.$$

Let us first remark that if Δ' is another system of simple roots and w an element of $W(\mathcal{R})$ such that $w(\Delta) = \Delta'$, one has

$$(w(\alpha)^*, w(\beta)) = (\alpha^*, \beta),$$

so the Cartan matrix of $\mathcal{R}$ relative to Δ' is obtained from that relative to Δ by the isomorphism $\Delta \rightarrow \Delta'$ on the index set defined by w . It follows that, up to isomorphism on the index set, the Cartan matrix depends only on $\mathcal{R}$.

Proposition 7.3.1. *The Cartan matrix has the following properties:*

<!-- label: III.XXI.7.3.1 -->

- (i) $a_{\alpha, \alpha} = 2$, $a_{\alpha, \beta} \leq 0$ for $\alpha \neq \beta$.
- (ii) $a_{\alpha, \beta} = 0$ entails $a_{\beta, \alpha} = 0$.
- (iii) There exist strictly positive integers m_{α} ($= \text{long}(\alpha)$) such that the matrix

$$(m_{\alpha} a_{\alpha, \beta})$$

is symmetric, positive, and nondegenerate.

<!-- original page 150 -->

- (iv) The diagonal minors of the matrix $(a_{\alpha, \beta})_{\alpha, \beta \in \Delta'}$, i.e. the determinants

$$\det(a_{\alpha, \beta})_{\alpha, \beta \in \Delta'} \quad \text{for } \Delta' \subset \Delta,$$

are strictly positive.

- (v) One has $s_{\alpha}(\beta) = \beta - a_{\alpha, \beta} \alpha$ and $s_{\alpha}(\beta^*) = \beta^* - a_{\beta, \alpha} \alpha^*$.

Proof. Indeed, (v) is a definition, (i) follows from 3.2.11, (ii) from 2.2.2, (iii) from 7.2.9, (iv) follows at once from (iii) by the relation

$$\det(m_{\alpha} a_{\alpha, \beta})_{\alpha, \beta \in \Delta'} = (\prod_{\alpha \in \Delta'} m_{\alpha}) \det(a_{\alpha, \beta})_{\alpha, \beta \in \Delta'}.$$

Proposition 7.3.2. *Let $\mathcal{R}$ and $\mathcal{R}'$ be two simply connected (resp. adjoint) reduced root data, Δ (resp. Δ') a system of simple roots of $\mathcal{R}$ (resp. $\mathcal{R}'$), and $\varphi : \Delta \rightarrow \Delta'$ an isomorphism such that if one denotes by $a_{\alpha, \beta}$ and $a'_{\alpha, \beta}$ the Cartan matrices of $\mathcal{R}$ and $\mathcal{R}'$ relative to Δ and Δ' , one has:*

```

<!-- label: III.XXI.7.3.2 -->

$$
a'_{\{u(\alpha), u(\beta)\}} = a_{\{\alpha, \beta\}}.
$$

*Then there exists a unique isomorphism of  $\mathcal{R}$  onto  $\mathcal{R}'$  that induces  $u$  on  $\Delta$ .*

*Proof.* It evidently suffices to make the proof in the adjoint case. Then  $M = \Gamma_0(R)$  and  $M' = \Gamma_0(R')$  are the free abelian groups generated by  $\Delta$  and  $\Delta'$ . There exists therefore a unique isomorphism of groups of  $M$  onto  $M'$  that induces  $u$  on  $\Delta$ . Denote it also  $u$ . Let us show that  $u(R) \subset R'$ . Every root  $\alpha$  of  $R$  is written  $s_{\alpha_1} \cdots s_{\alpha_n}(\alpha_{n+1})$  with  $\alpha_i \in \Delta$ . One has obviously

$$
u(\alpha) = s_{\alpha_1} \cdots s_{\alpha_n}(u(\alpha_{n+1})),
$$

<!-- original page 151 -->

by virtue of the hypothesis on  $u$  and the relations (v) of 7.3.1.

It remains to prove that  $u(R') \subset R$ , which follows from the fact that the elements of  $M$  (resp.  $M'$ ) are determined by the duality with  $R$  or  $\Delta$  (resp.  $R'$  or  $\Delta'$ ), by 1.2.5.

**Corollary 7.3.3.** *A reduced simply connected or adjoint root datum is determined up to isomorphism by its Cartan matrix.*

<!-- label: III.XXI.7.3.3 -->

**Corollary 7.3.4.** *Let  $\mathcal{R}$  be a reduced simply connected (resp. adjoint) root datum, and  $\Delta$  a system of simple roots. The group  $E_{\Delta}(\mathcal{R})$  is identified with the group of automorphisms of the set  $\Delta$  that leave the Cartan matrix invariant.*

<!-- label: III.XXI.7.3.4 -->

**Remark 7.3.5.** *The question of the existence of a root datum corresponding to a given Cartan matrix satisfying (i), (ii), and (iv) (for example) is not easily resolved directly, without using the classification.*

<!-- label: III.XXI.7.3.5 -->

### 7.4. Dynkin diagrams

<!-- label: III.XXI.7.4 -->

**Definition 7.4.1.** *One calls a Dynkin diagram structure (the word "schéma" having been banished for obvious reasons) on a finite set  $\Delta$  the data of a set of pairs of distinct elements of  $\Delta$ , called linked pairs, and of a map from  $\Delta$  to the set  $\{1, 2, 3\}$ . The notion of isomorphism of such structures is obvious.*

<!-- label: III.XXI.7.4.1 -->

**Definition 7.4.2.** *Let  $\mathcal{R}$  be a root datum and  $\Delta$  a system of simple roots. One calls Dynkin diagram of  $\mathcal{R}$  relative to  $\Delta$  the set  $\Delta$ , two simple roots being linked if and only if they are non-orthogonal, with each root being assigned its length.*

<!-- label: III.XXI.7.4.2 -->

<!-- original page 152 -->

**Proposition 7.4.3.** *Dynkin diagram and Cartan matrix determine each other biuniquely.*

<!-- label: III.XXI.7.4.3 -->

*Proof.* Indeed, the equivalence

```

```

```text
 α and β are not linked $\square \quad a_{\{\alpha,\beta\}} = 0,$
```

```

and the relation

```

```text
 $\text{long}(\alpha) \, a_{\{\alpha,\beta\}} = \text{long}(\beta) \, a_{\{\beta,\alpha\}},$
```

```

(with $\inf \text{long}(\alpha) = 1$ in each connected component of the diagram) determine the $a_{\{\alpha,\beta\}}$ as a function of the linkages and lengths, and conversely (the details of the verification are left to the reader).

Corollary 7.4.4. *A reduced simply connected or adjoint root datum is determined by its Dynkin diagram.*

<!-- label: III.XXI.7.4.4 -->

Corollary 7.4.5. *Let $\mathcal{R}$ be a reduced simply connected or adjoint root datum and Δ a system of simple roots. The group $E_{\{\Delta\}}(\mathcal{R})$ is identified with the group of automorphisms of the Dynkin diagram of $\mathcal{R}$ relative to Δ , that is to say with the group of permutations of Δ preserving lengths and linkages.*

<!-- label: III.XXI.7.4.5 -->

Remark 7.4.6. *One classifies, with the usual method, [XXI-7-1][N.D.E-XXI-30] the various connected Dynkin diagrams, and one shows that each effectively corresponds to an irreducible reduced simply connected root datum. One finds the well-known types:*

<!-- label: III.XXI.7.4.6 -->

<!-- original page 153 -->

```

```text
1 - 1 - 1 - ... - 1 - 1 - 1 $A_n, \quad n \geq 1.$

2 - 2 - 2 - ... - 2 - 2 $\Rightarrow$ 1 $B_n, \quad n \geq 2.$

1 - 1 - 1 - ... - 1 - 1 $\Leftarrow$ 2 $C_n, \quad n \geq 3.$

 1
 /
1 - 1 - 1 - ... - 1 - 1 \
 1
 1 $D_n, \quad n \geq 4.$

 1
 |
1 - 1 - 1 - 1 - 1 - 1 $E_n, \quad n = 6, 7, 8.$

1 - 1 $\Rightarrow$ 2 - 2 $F_4.$

... 1 $\Rightarrow$ 3 $G_2.$
```

```

By 7.4.5, one finds at once the corresponding group $E_{\{\Delta\}}(\mathcal{R})$; one has:

```

```text
 $E_{\Delta}(\square) = \{e\}$ for $A_1, B_n, C_n, E_7, E_8, F_4, G_2.$
 $E_{\Delta}(\square) = \mathbb{Z}/2\mathbb{Z}$ for $A_n \ (n \geq 2), D_n \ (n \geq 5), E_6.$
 $E_{\Delta}(\square) = S_3$ for $D_4.$
```

```

7.5. Complements on p -morphisms

<!-- label: III.XXI.7.5 -->

Let $f : \mathcal{R} \rightarrow \mathcal{R}'$ be a p -morphism (cf. 6.8). It is clear from the definitions that the bijection $u : \mathcal{R} \xrightarrow{\sim} \mathcal{R}'$ associated with f makes systems of simple roots, systems of positive roots, irreducible components (etc.) of $\mathcal{R}$ and $\mathcal{R}'$ correspond. Suppose therefore, for simplicity, $\mathcal{R}$ and $\mathcal{R}'$ irreducible.

Lemma 7.5.1. *If $\mathcal{R}$ and $\mathcal{R}'$ are irreducible, there exists $k \in \mathbb{Q}$ such that for every $\alpha \in R$*

<!-- label: III.XXI.7.5.1 -->

```
```text
k long(u(α)) = q(α)2 long(α).
```
```

<!-- original page 154 -->

Proof. Indeed, one has $\text{long}(\alpha) (\alpha^*, \beta) = \text{long}(\beta) (\beta^*, \alpha)$ and, similarly,

```
```text
long(u(α)) (u(α)*, u(β)) = long(u(β)) (u(β)*, u(α)).
```
```

One deduces at once that for non-orthogonal α and β , one has

```
```text
q(α)2 long(α) / long(u(α)) = q(β)2 long(β) / long(u(β))
```
```

and one concludes then by 7.1.3 (iv).

Remark 7.5.2. *It follows from 7.2.2 and 6.8.4 that $q(\alpha)$ depends only on $\text{long}(\alpha)$. One then sees easily that if $q(\alpha)$ is not constant, then $q(\alpha) \text{long}(\alpha)$ is constant, which shows that then $p = 2$ or 3 . A glance at the diagrams of the preceding number shows that there are four possible cases (we denote by the same letter a Dynkin diagram and the corresponding simply connected reduced root datum):*

<!-- label: III.XXI.7.5.2 -->

```
```text
p = 2, Bn $\xrightarrow{f_1}$ Cn, Cn $\xrightarrow{f_2}$ Bn (with C2 = B2).
p = 2, F4 $\xrightarrow{g}$ F4.
p = 3, G2 $\xrightarrow{h}$ G2.
```
```

The reader will note that $f_1 \circ f_2$, $f_2 \circ f_1$, $g \circ g$, and $h \circ h$ are p -morphisms of the form described in 6.8.6.*

7.5.3. One sees at once from the preceding description that if $\mathcal{R}$ and $\mathcal{R}'$ are two reduced root data of semisimple rank ≤ 2 and if one has a p -morphism from $\mathcal{R}'$ to $\mathcal{R}$, then $\mathcal{R}$ and $\mathcal{R}'$ are of the same type. More precisely, one has the following table.

<!-- label: III.XXI.7.5.3 -->

Notations. Let $f : \mathcal{R}' \rightarrow \mathcal{R}$ be a p -morphism. We denote by q (resp. q_1) any positive power of p . We use for the rank-2 systems the notations of number 4 (we denote by α, β the simple roots, with $\ell(\alpha) \leq \ell(\beta)$).

<!-- original page 155 -->

| Type | p | values of f | values of f^t |
|------------------|-----|------------------------|----------------------------|
| Trivial | any | — | — |
| A_1 | any | $f(\alpha) = q \alpha$ | $f^t(\alpha) = q \alpha^*$ |
| $A_1 \times A_1$ | any | $f(\alpha) = q \alpha$ | $f^t(\alpha) = q \alpha^*$ |
| | | $f(\beta) = q_1 \beta$ | $f^t(\beta) = q_1 \beta^*$ |
| A_2, B_2, G_2 | any | $f(\alpha) = q \alpha$ | $f^t(\alpha) = q \alpha^*$ |

| | | | |
|---------------|-------------|--|--|
| | | | |
| $\$B_{\{2\}}$ | $\$p = 2\$$ | $\$f(\backslash\beta') = q \backslash\beta\$$ | $\${}^{\{t\}}f(\backslash\beta^*) = q \backslash\beta'^*\$$ |
| | | | |
| $\$G_{\{2\}}$ | $\$p = 3\$$ | $\$f(\backslash\alpha') = q \backslash\beta\$$ | $\${}^{\{t\}}f(\backslash\alpha^*) = 2 q \backslash\beta'^*\$$ |
| | | | |

[$\backslash$ N.D.E-XXI-0]: N.D.E.: Version of 13/10/2024.

[$\backslash$ N.D.E-XXI-1]: N.D.E.: For the results on root systems (§§ 1–5), one may consult [BLie], Chap. VI.

[$\backslash$ N.D.E-XXI-2]: N.D.E.: Note that $\$(\backslash\alpha^*)^* = \backslash\alpha\alpha\$$.

[$\backslash$ N.D.E-XXI-3]: N.D.E.: (8) follows from (4), (2) and (DR II).

[$\backslash$ N.D.E-XXI-4]: N.D.E.: with equality if and only if $\$x\$$ and $\$y\$$ are proportional.

[^N.D.E-XXI-5]: N.D.E.: We have corrected $\$+ 2p\$$ to $\$- 2p\$$.

[^N.D.E-XXI-6]: N.D.E.: We have added these complements, useful for the proof of 3.1.5.

[^N.D.E-XXI-7]: N.D.E.: In what follows, we have modified the order and detailed the proof of the implication (iii) $\Rightarrow$ (i).

[^N.D.E-XXI-8]: N.D.E.: We have added the following sentence, and in 3.1.11 we have replaced $\$a_{\alpha} \ell(\alpha)\$$ by $\$a_{\alpha} \ell(\alpha)\$$.

[^N.D.E-XXI-9]: N.D.E.: We have inserted this definition here.

[^N.D.E-XXI-10]: N.D.E.: We have corrected the original in what follows.

[^N.D.E-XXI-11]: N.D.E.: We have corrected the original in what follows.

[^N.D.E-XXI-12]: N.D.E.: Indeed, by 3.1.5, it suffices to verify the formula for $\alpha \in \Delta$. Now, by 3.5.1 applied to $\mathcal{R}^*$, one has in this case $(\rho_{R^*}, \alpha) = 1 = \text{ord}_{\mathcal{S}(R^*)}(\alpha)$.

[^N.D.E-XXI-13]: N.D.E.: We have modified the original, to take into account the case where 2α could be a root.

[^N.D.E-XXI-14]: N.D.E.: We have replaced $\mathbb{Q}$ by $\mathbb{R}$.

[^N.D.E-XXI-15]: N.D.E.: We have added the definition of the hyperplanes H_{α} .

[^N.D.E-XXI-16]: N.D.E.: We have added the numbering 4.0 for later references.

[^XXI-4-1]: The following numbers 4.1 to 4.4 are used in the proof of 5.1. There exist nowadays simpler proofs of 5.1 (see [BLie], § V.3, Th. 1). *N.D.E.: we have specified the reference and placed here this Note, which in the original appeared in 4.2.*

[^N.D.E-XXI-17]: N.D.E.: Let ρ be the half-sum of the positive roots (cf. 3.5.1); if one sets, as in 4.2 below, $w_0 = 1$, $w_1 = s_{\alpha}$, $w_2 = s_{\beta} s_{\alpha}$, $w_3 = s_{\alpha} s_{\beta} s_{\alpha}$, etc., then s_k is nothing other than $\rho - w_{k-1}(\rho)$, which proves (i) since $w_{2n} = \text{id}$.

[^N.D.E-XXI-18]: N.D.E.: We have corrected the original, to be in agreement with the convention $\ell(\alpha) \leq \ell(\beta)$ of 4.0.

[^N.D.E-XXI-19]: N.D.E.: Taking into account N.D.E. (17), this follows immediately from 3.5.1 and 1.1.9: one has $n_k + m_k = (x - w_k(x), \rho) = (x, \rho - w_{k-1}(\rho)) = (x, u_k)$.

[^N.D.E-XXI-20]: N.D.E.: We have corrected the statement.

[^N.D.E-XXI-21]: N.D.E.: Indeed, the hypotheses are equivalent to saying that $(\gamma, \alpha^*) > 0$ and $(\gamma, \beta^*) \leq 0$; then $\gamma - w(\gamma)$ belongs to $\mathbb{N}\alpha + \mathbb{N}\beta$ for every $w \in W_{\alpha, \beta}$, and is $\neq 0$ if $w \notin \{1, s_{\beta}\}$.

[^N.D.E-XXI-22]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-XXI-23]: N.D.E.: We have written R^+ here instead of R_+ , in order to be able to write $R^+_{\alpha, \beta} = R_{\alpha, \beta} \cap R^+$.

[^N.D.E-XXI-24]: N.D.E.: In what follows, we have detailed the original, and we have corrected equality (1).

[^N.D.E-XXI-25]: N.D.E.: That is, if one denotes $P = \{y \in M^* \mid (y, \alpha) = 0 \text{ for all } \alpha \in R\}$ and $P^* = M/(V(R) \cap M)$, one has $\text{rad}(\mathcal{R}) = (P^*, P, \emptyset, \emptyset)$.

[^N.D.E-XXI-26]: N.D.E.: We have replaced $\Gamma(\mathcal{R})$ by $\Lambda(\mathcal{R})$, to avoid any risk of confusion with $\Gamma_0(R)$.

[^XXI-6-1]: Warning: if the datum is not reduced, the α_i do not form a system of simple roots.

[^N.D.E-XXI-27]: N.D.E.: when $\mathcal{R}$ is simply connected or adjoint, see 7.4.5.

[^N.D.E-XXI-28]: N.D.E.: The exponent s is meant to suggest "semisimple".

[^N.D.E-XXI-29]: N.D.E.: Note that these two conditions entail
 $q(\alpha)(u(\alpha)^*, u(\beta)) = q(\beta)(\alpha^*, \beta)$, for all $\alpha, \beta \in R$.

[^XXI-7-1]: Cf. Bourbaki, **Groupes et algèbres de Lie**, Chap. VI N° 4.2 or **Séminaire Sophus Lie**.

[^N.D.E-XXI-30]: N.D.E.: For a slightly different proof, see also [De80].

Exposé XXII. Reductive groups: splittings, subgroups, quotient groups

<!-- label: III.XXII -->

by M. Demazure

<!-- original page 109 -->

[^N.D.E-XXII-0] This Exposé consists of two parts. The first (1 through 5.5) gathers the technical results needed for the proof of the uniqueness and existence theorems. The second (5.6 to the end) will not be used in that proof; the end of section 5 will be used in particular in Exposé XXVI on parabolic subgroups; section 6 establishes, in the scheme-theoretic setting, the classical results on the derived group of a reductive group.

1. Roots and coroots. Split groups and root data

<!-- label: III.XXII.1 -->

Theorem 1.1. *Let S be a scheme, G an S -reductive group, T a maximal torus of G , α a root of G relative to T .*

<!-- label: III.XXII.1.1 -->

(i) There exists a unique morphism of groups with operator group T

$$\exp \alpha : W(\alpha) \rightarrow G$$

inducing on the Lie algebras the canonical morphism $\mathfrak{g}(\alpha) \rightarrow \mathfrak{g}$. This morphism is a closed immersion. The corresponding morphism

$$T \times_{\alpha} W(\alpha) \rightarrow G$$

is also a closed immersion.

If $\rho : G \rightarrow T$ is a monomorphism normalized by T with multiplier α , there exists a unique $X \in \Gamma(S, \mathfrak{g}(\alpha))$ such that $\rho(x) = \exp \alpha(\rho(x))$; one has $\text{Lie}(\rho)(1) = X$, and the two preceding formulas set up a bijective correspondence between $\Gamma(S, \mathfrak{g}(\alpha))$ and the set of monomorphisms $G \rightarrow T$ normalized by T with multiplier α .

(ii) There exists a unique duality (denoted $(X, Y) \mapsto XY$)

$$\mathfrak{g} \otimes_{\mathbb{Z}} \mathbb{Z} \rightarrow \mathfrak{g}$$

and a unique morphism of groups

$$\alpha : G \rightarrow T,$$

\$\$

such that formula (F) of Exp. XX 2.1 holds. One has

```

```text
 $\alpha \circ \alpha^* = 2, \quad (-\alpha)^* = -\alpha^*,$
```

```

and α is given by the formula of Exp. XX 2.7.

Indeed, a morphism normalized by T with multiplier α factors necessarily through the closed subgroup $Z_\alpha = \text{Centr}_G(T_\alpha)$ of G (cf. Exp. XIX 3.9). Now (Z_α, T, α) is an S -elementary system (Exp. XX 1.4), and one is reduced to the results of Exposé XX (1.5, 2.1, and 5.9).

Remark 1.2. Part (i) of Theorem 1.1 remains valid if one only assumes that α is a character of T , non-trivial on each fiber. Indeed, one then has a decomposition $S = S' \amalg S''$ such that $\alpha|_{S'}$ is a root of $G_{S'}$ relative to $T_{S'}$ and $\alpha|_{S''} = 0$. If $S = S'$, one is reduced to 1.1; if $S = S''$ the result is trivial; the general case follows immediately.*

<!-- label: III.XXII.1.2 -->

Notations 1.3. As in Exposé XX, we denote by U_α the image of $W(g_\alpha)$; it is a closed subgroup of G , equipped canonically with a vector-space structure. We shall call it the vector group associated with the root α . We say that α is the coroot associated with α . Sections $X_\alpha \in \Gamma(S, g_\alpha)$ and $X_{-\alpha} \in \Gamma(S, g_{-\alpha})$ are said to be paired if $X_\alpha \cdot X_{-\alpha} = 1$. Then $X_\alpha \in \Gamma(S, g_\alpha)$ and likewise for $X_{-\alpha}$. The corresponding morphisms p_α and $p_{-\alpha}$ are contragredient to one another in the sense of XX, 1.5, [N.D.E-XXII-2] and one has*

<!-- label: III.XXII.1.3 -->

```

```text

$$p_\alpha(x) p_{-\alpha}(y) = p_{-\alpha}(y / (1 + xy)) \cdot \alpha(1 + xy) \cdot p_\alpha(x / (1 + xy)).$$

```

```

Proposition 1.4. Under the conditions of 1.1, let $w \in \text{Norm}_G(T)(S)$. Then $\beta = \alpha \circ \text{int}(w)^{-1} : T \rightarrow G, S$ is a root of G relative to T , $\beta^* = \text{int}(w) \circ \alpha^*$ is the corresponding coroot, and the following diagram is commutative:

<!-- label: III.XXII.1.4 -->

```

```text

$$\begin{array}{ccc} W(g_\alpha) & \xrightarrow{\exp \alpha} & G \\ | & & | \\ \text{Ad}(w) & & \text{int}(w) \\ \downarrow & & \downarrow \\ W(g_\beta) & \xrightarrow{\exp \beta} & G. \end{array}$$

```

```

Trivial: transport of structure.

Definitions 1.5. (a) Under the conditions of 1.1, we denote by s_α the automorphism of T defined by*

<!-- label: III.XXII.1.5 -->

```

```text

$$s_\alpha(t) = t \cdot \alpha(\alpha(t))^{-1}.$$

```

```

We denote by $(,)$ the canonical pairing:*

```

```text

$$\text{Hom}_{S\text{-gr.}}(G_m, S, T) \times \text{Hom}_{S\text{-gr.}}(T, G_m, S) \rightarrow \text{Hom}_{S\text{-gr.}}(G_m, S, G_m, S) = \mathbb{Z}_S.$$

```

```

Then s_α operates on $\text{Hom}_{S\text{-gr.}}(T, G_m, S)$, resp. $\text{Hom}_{S\text{-gr.}}(G_m, S, T)$, by the following formulas, where

χ denotes an arbitrary section of $\operatorname{Hom}_{S\text{-gr.}}(T, G_m, S)$ (resp. of $\operatorname{Hom}_{S\text{-gr.}}(G_m, S, T)$):*

$$s\alpha(\chi) = \chi - (\alpha^*, \chi) \alpha,$$

$$s\alpha(u) = u - (u, \alpha) \alpha^*.$$

One has $s\alpha \circ s\alpha = \operatorname{id}$ and $s_{-\alpha} = s\alpha$.

(b) If $X \in \Gamma(S, g\alpha)\backslash \times$, then the inner automorphism $w\alpha(X)$ of T defined by*

$$w\alpha(X) = \exp\alpha(X) \exp_{-\alpha}(-X^{-1}) \exp\alpha(X)$$

(cf. Exp. XX 3.1) coincides with $s\alpha$ (loc. cit.). One then concludes from 1.4:*

Corollary 1.6. *Let S be a scheme, G an S -reductive group, T a maximal torus of G , α and β two roots of G relative to T . Then*

$$s\alpha(\beta) = \beta - (\alpha^*, \beta) \alpha$$

is a root of G relative to T , and the corresponding coroot is*

$$s\alpha(\beta)^* = s\alpha(\beta^*) = \beta^* - (\beta^*, \alpha) \alpha^*.$$

Corollary 1.7. *Under the preceding conditions, $\alpha^* = \beta^*$ implies $\alpha = \beta$.

$$s\beta(\alpha) = \alpha - 2\beta, \quad s\alpha(\beta) = \beta - 2\alpha,$$

and from this one deduces immediately

$$(s\beta \circ s\alpha)^n(\alpha) = \alpha + 2n(\beta - \alpha).$$

If $\beta \neq \alpha$, there exists $s \in S$ such that $\alpha_s \neq \beta_s$. But then the preceding formula shows that there exist infinitely many distinct roots of G_s relative to T_s , which is impossible.

Definitions 1.8.0. [N.D.E-XXII-3] *If $u : G_m, S \rightarrow T$ is a morphism of groups, we shall say that u is a coroot of G relative to T if there exists a root α of G relative to T such that $\alpha^* = u$. Consider the functor R^* of coroots of G relative to T defined as follows:*

$$R^*(S') = \text{the set of coroots of } G_{S'} \text{ relative to } T_{S'}.$$

If R is the functor of roots of G relative to T (Exp. XIX 3.8), one has a canonical morphism $R \rightarrow R^*$. By virtue of 1.7 and Exp. XIX 3.8, one has:*

****Corollary 1.8.**** *The canonical morphism $R \rightarrow R^*$ is an isomorphism. In particular, R^* is representable by a finite twisted constant S -scheme, which is an open and closed subscheme of $\operatorname{Hom}_{\{S\text{-gr}\}}(G_m, S, T)$.*

<!-- label: III.XXII.1.8 -->

This leads us to the following definition:

****Definition 1.9.**** *Let S be a scheme, T an S -torus. We call a twisted root datum in T the data:

<!-- label: III.XXII.1.9 -->

- (i) a finite subscheme R of $\operatorname{Hom}_{\{S\text{-gr}\}}(T, G_m, S)$,
 - (ii) a finite subscheme R^* of $\operatorname{Hom}_{\{S\text{-gr}\}}(G_m, S, T)$,
 - (iii) an isomorphism $R \xrightarrow{\sim} R^*$ denoted $\alpha \mapsto \alpha^*$,
- satisfying the following conditions:

```

```text
(DR 1) For every $S' \rightarrow S$ and every $\alpha \in R(S')$, one has $\alpha \circ \alpha^* = 2$.
(DR 2) For every $S' \rightarrow S$ and every $\alpha, \beta \in R(S')$, one has
 $\alpha - (\beta^*, \alpha) \beta \in R(S')$, $\alpha^* - (\alpha^*, \beta) \beta^* \in R^*(S')$.
...

```

Moreover, if for  $\alpha \in R(S)$  ( $S \neq \emptyset$ ) one has  $2\alpha \notin R(S)$ , the root datum is said to be reduced.

**\*\*Proposition 1.10.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ ,  $R$  (resp.  $R^*$ ) the scheme of roots (resp. of coroots) of  $G$  relative to  $T$ . Then  $(R, R^*)$  is a reduced twisted root datum in  $T$ .\*

<!-- label: III.XXII.1.10 -->

The only thing that remains to be checked is that this twisted root datum is reduced. This was done in Exp. XIX 3.10.

### 1.11.

<!-- label: III.XXII.1.11 -->

Let  $T = D_{\{S\}}(M)$  be a trivialized torus. If we denote by  $M^*$  the abelian group dual to  $M$ , we have canonical isomorphisms (cf. Exp. VIII 1.5):

```

$$
\operatorname{Hom}_{\{S\text{-gr}\}}(T, G_m, S) \xrightarrow{\sim} M_{\{S\}},
\operatorname{Hom}_{\{S\text{-gr}\}}(G_m, S, T) \xrightarrow{\sim} M^*_{\{S\}},
$$

```

hence isomorphisms of groups:

```

```text
Hom_{\{S\text{-gr}\}}(T, G_m, S) \rightarrow \operatorname{Hom}_{\{\text{loc.const.}\}}(S, M),
Hom_{\{S\text{-gr}\}}(G_m, S, T) \rightarrow \operatorname{Hom}_{\{\text{loc.const.}\}}(S, M^*).
...

```

A character of T (resp. a morphism of groups $G_m, S \rightarrow T$) will be called *constant* (relative to the given trivialization) if the preceding isomorphism transforms it into a constant map from S to M (resp. M^*).

1.12.

<!-- label: III.XXII.1.12 -->

With the same notations, let (M, M^*, R, R^*) be a root datum (Exp. XXI). Then $(R_{\{S\}}, R^*_{\{S\}})$ is a twisted root datum in T . Conversely, if (R, R^*) is a twisted root datum in a torus T , a *splitting* of this root datum is the data of an ordinary root datum (M, M^*, R, R^*) together with an isomorphism $T \xrightarrow{\sim} D_{\{S\}}(M)$ that transforms (R, R^*) into $(R_{\{S\}}, R^*_{\{S\}})$.

Definition 1.13. Let S be a scheme, G an S -reductive group, T a maximal torus of G . We call a splitting of G relative to T the data

(i) of an abelian group M and an isomorphism $T \simeq D_{\{S\}}(M)$,
 (ii) of a system of roots R of G relative to T (Exp. XIX 3.6),
 satisfying the following two conditions:

(D_1) S is non-empty and the roots $\alpha \in R$ (resp. the corresponding coroots) are identified with constant functions from S to M (resp. M^*).
 (D_2) The $\mathfrak{g}_\alpha$ ($\alpha \in R$) are free $\mathcal{O}_S$ -modules.

We say that G is splittable relative to T if there exists a splitting of G relative to T . By a splitting of G we mean the data of a maximal torus T of G and a splitting of G relative to T . We say that G is splittable if there exists a splitting of G . By an S -split group we mean an S -reductive group equipped with a splitting; we denote it by a symbol of the form (G, T, M, R) , or simply G when there is no risk of confusion.

Condition (D_1) entails that R (resp. R^*) is canonically identified with a subset of M (resp. M^*).

Proposition 1.14. Let S be a scheme (non-empty), (G, T, M, R) an S -split group. Then

$R(G, T, M, R) = (M, M^*, R, R^*)$

is a reduced root datum (Exp. XXI 1.1 and 2.1.3); it is a splitting of the twisted root datum of 1.10.

This is a trivial consequence of 1.10 and Exp. XIX 3.7.

We shall sometimes write, for simplicity, $R(G, T, M, R) = R(G)$. We shall systematically use the notations V , $V(R)$, W , ... of Exp. XXI.

Remark 1.15. (a) If S is connected non-empty (resp. if $\pi_0(S) = 0$), the condition (D_1) (resp. (D_2)) is automatically satisfied.

(b) If (G, T, M, R) is an S -split group, then for every $S' \rightarrow S$, $S' \neq \emptyset$, $(G_{S'}, T_{S'}, M, R)$ is an S' -split group, and $R(G, T, M, R) = R(G_{S'}, T_{S'}, M, R)$.

1.16.

Let $T = D_{\{S\}}(M)$ be a trivialized torus. The Lie algebra $\mathfrak{t}$ of T is canonically identified (Exp. II 5.1.1) with

$$\mathfrak{t} \simeq M^* \otimes \mathcal{O}_S.$$

For every morphism of groups $u : T \rightarrow G_{m,S}$, $\text{Lie}(u)$ is a linear form

$$\text{Lie}(u) : \mathfrak{t} \rightarrow \mathcal{O}_S = \text{Lie}(G_{m,S}/S).$$

In particular, if u is defined by an element $\alpha \in M$, then $\text{Lie}(u)$ is the linear form α on $M^* \otimes \mathcal{O}_S$ defined by α :

```

```text
 $\alpha(m \otimes x) = (m, \alpha) x.$
```

```

Symmetrically, for every morphism of groups $h : G_m, S \rightarrow T$, $\text{Lie}(h)$ is an 0_S -morphism $0_{\{S\}} = \text{Lie}(G_m, S/S) \rightarrow t$, canonically defined by the section

```

```text
 $H = \text{Lie}(h)(1) \in \Gamma(S, t).$
```

```

In particular, if h is defined by an element $m \in M^*$, one has

```

$$H = \text{Lie}(h)(1) = m \otimes 1.$$

```

Comparing the two definitions, one finds in particular

```

```text
 $\alpha(H) = (h, \alpha) \cdot 1 \in \Gamma(S, 0_S).$
```

```

1.17.

<!-- label: III.XXII.1.17 -->

These definitions apply in particular to the case where T is the maximal torus of a split group. Each root $\alpha \in R$ defines an *infinitesimal root* $\alpha \in \text{Hom}_{0_{\{S\}}}(t, 0_{\{S\}})$ with

```

```text
 $\alpha(m \otimes x) = (m, \alpha) x.$
```

```

Each coroot $\alpha^* \in R^*$ defines an *infinitesimal coroot*

```

```text
 $H\alpha \in \Gamma(S, t), \quad H\alpha = \alpha^* \otimes 1.$
```

```

For $\alpha, \beta \in R$, one has the relation

```

$$\alpha(H\beta) = (\beta^*, \alpha) \cdot 1,$$

```

and in particular

```

$$\alpha(H\alpha) = 2.$$

```

In particular, if 2 is invertible on S , then α and $H\alpha$ are non-zero on each fiber.

2. Existence of a splitting. Type of a reductive group

<!-- label: III.XXII.2 -->

<!-- original page 114 -->

Proposition 2.1. *Let S be a scheme, G an S -reductive group, T a maximal torus of G . Suppose T is split. Then G is locally splittable relative to T : for every $s_0 \in S$, there exists an open neighborhood U of s_0 such that the U -group G_U is splittable relative to T_U .*

<!-- label: III.XXII.2.1 -->

Indeed, write $T \simeq D_{\{S\}}(M)$ and

$$g = \prod_{m \in M} g^m.$$

Let $R = \{ m \in M \mid m \neq 0, g^m(s_{\{0\}}) \neq 0 \}$. Shrinking S if necessary (replacing it by an open neighborhood of $s_{\{0\}}$), we may suppose that the g_{α} , $\alpha \in R$, are free, and that the g^m , $m \neq 0$, are zero. We then have

$$g = \prod_{\alpha \in R} g_{\alpha},$$

with the g_{α} free of rank 1. It follows that R is a system of roots of G relative to T (Exp. XIX 3.6). The coroots α corresponding to the $\alpha \in R$ are then identified with locally constant functions on S with values in M^* . Shrinking S further, we may take them constant, and we are done.

Note that the proof gives immediately:

Proposition 2.2. *Let S be a non-empty connected scheme with $\pi_1(S) = 0$, for example $\text{Spec}(\mathbb{Z})$ or a local scheme (in particular the spectrum of a field). If G is an S -reductive group possessing a split maximal torus T , then G is splittable relative to T .*

<!-- label: III.XXII.2.2 -->

We deduce immediately from 2.1 and the fact that a reductive group locally possesses maximal tori for the étale topology (Exp. XIX 2.5):

Corollary 2.3. *Let S be a scheme, G an S -reductive group (resp. and T a maximal torus of G). Then G is locally splittable (resp. locally splittable relative to T) for the étale topology on S .*

<!-- label: III.XXII.2.3 -->

Corollary 2.4. *Let k be a field, G a k -reductive group. There exists a finite separable extension K/k such that G_K is splittable.*

<!-- label: III.XXII.2.4 -->

Remark 2.5. *Using 2.1 and the remark Exp. XIX 2.9, one immediately proves the following result: let $G = (G, T, M, R)$ be an S -split group; there exists a cover of S by open sets U_i such that each split group G_{U_i} arises by base change from a split group over a noetherian ring (in fact, a finitely generated $\mathbb{Z}$ -algebra). We will furthermore prove that every split group over S already arises from a $\mathbb{Z}$ -split group (Exp. XXV).*

<!-- label: III.XXII.2.5 -->

2.6.

<!-- label: III.XXII.2.6 -->

Let k be an algebraically closed field and G a k -reductive group. One knows (e.g. by 2.4) that there exist splittings of G . Let (G, T, M, R) and (G, T', M', R') be two splittings of G ; the root data $R(G, T, M, R)$ and $R(G, T', M', R')$ are then isomorphic.

Indeed, one sees first that one can reduce to the case where $T = T'$ (because there exists $g \in G(k)$ such that $T' = \text{int}(g)T$, and one verifies easily that if one transports a splitting by an automorphism of G , one obtains a root datum isomorphic to the initial datum); but since $S = \text{Spec}(k)$ is connected, the isomorphism $D_{\{k\}}(M) \xrightarrow{\sim} T \xrightarrow{\sim} D_{\{k\}}(M')$ arises from a unique isomorphism $M \simeq M'$; for the same reason, there is at most one system of roots of G relative to T .

Definition 2.6.1. [N.D.E-XXII-4] *If G is a k -reductive group (k an algebraically closed field), we call* type of G *the isomorphism class of the root datum defined by an arbitrary splitting of G ; if G is a torus, of type M *

in the sense of Exp. IX 1.4, then the type of G as reductive group is given by the trivial root datum $(M, M^*, \emptyset, \emptyset)$.

<!-- label: III.XXII.2.6.1 -->

By 1.15 (b), [N.D.E-XXII-5] the type is invariant under (algebraically closed) extension of the base field.

Definition 2.7. If G is an S -reductive group and $s \in S$, we call the type of G at s the type of the s -reductive group G_s .

<!-- label: III.XXII.2.7 -->

For every $S' \rightarrow S$ and every $s' \in S'$ projecting to $s \in S$, the type of $G_{S'}$ at s' is equal to the type of G at s .

If G is splittable, and if (G, T, M, R) is a splitting of G , then the type of G at s is the isomorphism class of (G, T, M, R) by 1.15 (b). [N.D.E-XXII-5] It then follows immediately from 2.3:

Proposition 2.8. Let G be an S -reductive group ($S \neq \emptyset$). The function

<!-- label: III.XXII.2.8 -->

text
 $s \mapsto$ type of G at s

is locally constant on S . In particular, there is a partition of S into non-empty open subschemes such that on each of them G is of constant type. More precisely, let E be the set of types of the fibers of G ; for every $t \in E$, let S_t be the set of points $s \in S$ where G is of type t ; then $(S_t)_{t \in E}$ is a partition of S and each S_t is open and closed (and non-empty).

3. The Weyl group

<!-- label: III.XXII.3 -->

<!-- original page 118 -->

3.1.

<!-- label: III.XXII.3.1 -->

Let S be a scheme, G an S -reductive group, T a maximal torus of G . Then

$$W_G(T) = \text{Norm}_G(T)/T$$

is a finite étale S -group (Exp. XIX 2.5). The morphism $n \mapsto \text{int}(n)$ induces, by passage to the quotient, a canonical monomorphism (which is in fact an open immersion):

$$W_G(T) \rightarrow \text{Aut}_{S\text{-gr.}}(T).$$

3.2.

<!-- label: III.XXII.3.2 -->

Suppose now that G is splittable relative to T . Choose a splitting, say (G, T, M, R) . We then have a canonical isomorphism (Exp. VIII 1.5)

$$\text{Aut}_{S\text{-gr.}}(T) \cong (\text{Aut}_{\text{gr.}}(M))_S.$$

In particular, if W is the Weyl group of the root datum $R(G)$ (Exp. XXI 1.1.8), we have a monomorphism

$$W_S \rightarrow \operatorname{Aut}_{S\text{-gr.}}(T).$$

3.3.

<!-- label: III.XXII.3.3 -->

For each root $\alpha \in R$, the symmetry $s_\alpha \in W$ operates on M by

$$s_\alpha(x) = x - (\alpha^*, x) \alpha,$$

hence on T (via the preceding morphism) by

$$s_\alpha(t) = t \cdot \alpha^*(\alpha(t))^{-1}.$$

On the other hand, since g_α is assumed free, there exists $X \in \Gamma(S, g_\alpha) \times S$. Consider $w_\alpha(X) \in \operatorname{Norm}_G(T)(S)$ (Exp. XX 3.1). One has (loc. cit.)

$$\operatorname{int}(w_\alpha(X))(t) = s_\alpha(t).$$

Since W is generated by the s_α , $\alpha \in R$, it follows from the preceding remarks that if we regard W and $\operatorname{Norm}_G(T)(S)/T(S)$ as groups of automorphisms of T , we have

$$W \subset \operatorname{Norm}_G(T)(S)/T(S) \subset W_G(T)(S).$$

By definition of the constant group W_S associated with W (cf. I 1.8), we thus have a commutative diagram

$$\begin{array}{ccc} W_S & \xrightarrow{\quad} & W_G(T) \\ & \searrow & \swarrow \\ & \operatorname{Aut}_{S\text{-gr.}}(T) & \end{array}$$

Proposition 3.4. *Let S be a scheme, (G, T, M, R) an S -split group, W the Weyl group of the root datum $R(G)$. Then the canonical monomorphism*

<!-- label: III.XXII.3.4 -->

$$W_S \rightarrow W_G(T) = \operatorname{Norm}_G(T)/T$$

is an isomorphism.

These are both étale groups over S ; it therefore suffices to check that for every $s \in S$, $W_S(s) \rightarrow W_G(T)(s)$ is an isomorphism. [N.D.E-XXII-6] The latter assertion follows, for example, from *Bible*, § 11.3, th. 2.

Remark 3.5. *Using 2.3, the preceding proposition gives a new proof of the fact that the Weyl group of a maximal torus of an S -reductive group G is finite over S (Exp. XIX 2.5 (ii)).* [N.D.E-XXII-7]

<!-- label: III.XXII.3.5 -->

3.6.

<!-- label: III.XXII.3.6 -->

Under the conditions of 3.1, for every $w \in W_{\{G\}}(T)(S)$, we denote by $N_{\{w\}}^{\wedge N.D.E-XXII-8}$ the fiber product of the following diagram:

$$\begin{array}{ccc} \text{\texttt{N_w}} & \longrightarrow & \text{\texttt{Norm_G(T)}} \\ \downarrow & & \downarrow \scriptstyle w \\ \text{\texttt{S}} & \longrightarrow & \text{\texttt{W_G(T)}}. \end{array}$$

This is an open and closed subscheme of $\text{Norm}_{\{G\}}(T)$, which is a principal homogeneous bundle under T on the left (resp. on the right) by the law $(t, q) \mapsto tq$ (resp. $(q, t) \mapsto qt$). If $n \in N_{\{w\}}(S)$, one has

$$N_{\{ww'\}} = n \cdot N_{\{w'\}}, \quad N_{\{w'w\}} = N_{\{w'\}} \cdot n.$$

3.7.

<!-- label: III.XXII.3.7 -->

In particular, if α is a root of G relative to T , $N_{\{s\alpha\}}$ is none other than what was denoted $N \times$ in Exp. XX 3.0. If $g\alpha$ is free on S , one then has $N_{\{s\alpha\}}(S) \neq \emptyset$.

By 3.4 and condition (D₂) of the splitting, we deduce:

Corollary 3.8. *Under the conditions of 3.4, the morphism*

<!-- label: III.XXII.3.8 -->

$$\text{Norm}_G(T)(S) \rightarrow W_G(T)(S) = \text{Hom}_{\{\text{loc.cons.}\}}(S, W)$$

is surjective. In particular, for every $w \in W$, there exists $n_{\{w\}} \in \text{Norm}_{\{G\}}(T)(S)$ such that $\text{int}(n_{\{w\}})|_T = w$.

4. Homomorphisms of split groups

<!-- label: III.XXII.4 -->

<!-- original page 121 -->

4.1. The "big cell"

<!-- label: III.XXII.4.1 -->

4.1.1.

<!-- label: III.XXII.4.1.1 -->

Let (G, T, M, R) be a split S -reductive group. Choose a system of positive roots (Exp. XXI 3.2.1) R^+ of the root datum $R(G)$. Set $R^- = -R^+$.

Choose a total ordering on R^+ (resp. R^-) and consider the morphism induced by the product in G

$$u: \prod_{\alpha \in R^-} U_{\alpha} \times_S T \times_S \prod_{\alpha \in R^+} U_{\alpha} \rightarrow G.$$

This is an open immersion. Indeed, since both sides are flat and of finite presentation over S , it suffices to verify this on each geometric fiber (SGA 1, I 5.7 and VIII 5.4); one is thus reduced to the case where S is the spectrum of

an algebraically closed field; but, by *Bible*, § 13.4, cor. 2 to th. 3, u is radical and dominant; since the tangent map of u at the origin is an isomorphism (definition of a system of roots), u is birational; but G being normal, one may apply Zariski's "Main Theorem" (EGA III₁, 4.4.9) and u is an open immersion.

Let us show that the image Ω of this open immersion is independent of the ordering chosen on R_+ (resp. R_-). Since this is a question of comparing open subsets of G , one is reduced to proving that they have the same geometric points, so one may again assume that S is the spectrum of an algebraically closed field. Then the assertion is none other than *Bible*, § 13, prop. 1 (c) and th. 1 (a).

We have thus proved:

Proposition 4.1.2. *Let (G, T, M, R) be an S -split group. Let R_+ be a system of positive roots of R . There exists an open subset Ω_{R_+} of G such that for every total ordering on R_+ (resp. R_-), the morphism induced by the product in G*

(label: III.XXII.4.1.2 -->)

(text)

$$\prod_{\alpha \in R_-} U_{\alpha} \times_S T \times_S \prod_{\alpha \in R_+} U_{\alpha} \rightarrow G$$

is an open immersion with image Ω_{R_+} .

Remark 4.1.3. *One can translate 4.1.2 as follows: choose, for every $\alpha \in R$, an isomorphism of vector groups $\phi_{\alpha} : \mathfrak{g}_{\alpha} \xrightarrow{\sim} U_{\alpha}$ (cf. 1.19); then the morphism (set $N = \text{Card}(R_+) = \text{Card}(R_-)$)*

(label: III.XXII.4.1.3 -->)

(text)

$$\mathfrak{g}_S \times_S \prod_{\alpha \in R_-} \mathfrak{g}_{\alpha} \times_S \prod_{\alpha \in R_+} \mathfrak{g}_{\alpha} \rightarrow G$$

defined set-theoretically by

(text)

$$((x_{\alpha})_{\alpha \in R_-}, t, (x_{\alpha})_{\alpha \in R_+}) \mapsto \prod_{\alpha \in R_-} \phi_{\alpha}(x_{\alpha}) \cdot t \cdot \prod_{\alpha \in R_+} \phi_{\alpha}(x_{\alpha})$$

is an open immersion whose image depends only on R_+ (and not on the choice of the ϕ_{α} or the orderings on R_+ and R_-).

Notation 4.1.4. *We write*

$$\Omega_{R_+} = \prod_{\alpha \in R_-} U_{\alpha} \cdot T \cdot \prod_{\alpha \in R_+} U_{\alpha}.$$
 (N.D.E-XXII-9)

(label: III.XXII.4.1.4 -->)

Proposition 4.1.5. *The scheme Ω_{R_+} is of finite presentation over S (hence retrocompact in G) and is universally schematically dense in G relative to S (cf. Exp. XVIII 1).*

(label: III.XXII.4.1.5 -->)

The first assertion is trivial. Then, [N.D.E-XXII-10] Ω_{R_+} is flat and of finite presentation over S , and contains the unit section, hence meets each fiber of G in a non-empty open subset, hence in a dense one; the second assertion follows from Exp. XVIII 1.3. [N.D.E-XXII-11]

Corollary 4.1.6. *Let (G, T, M, R) be a split S -reductive group. Then*

(label: III.XXII.4.1.6 -->)

(text)

$$\text{Centr}(G) = \bigcap_{\alpha \in R} \text{Ker}(\alpha).$$

(N.D.E-XXII-12)

Consequently, $\text{Centr}(G)$ is representable by a closed diagonalizable subgroup of G .

The second assertion follows immediately from the first. To prove the latter, one may invoke Exp. XII 4.8 and 4.11; one may also proceed directly as follows.[^N.D.E-XXII-13]

Let $S' \rightarrow S$. If $t \in T(S')$ and $\alpha(t) = 1$ for every $\alpha \in R$, then $\text{int}(t)$ induces the identity on $T_{S'}$ and on each $(U_\alpha)_{S'}$, $\alpha \in R$, hence also on $(\Omega_{R+})_{S'}$, hence on $G_{S'}$ by schematic density, whence $t \in \text{Centr}(G)(S')$.

Conversely, since $\text{Centr}_{G_{S'}}(T_{S'}) = T_{S'}$ (cf. Exp. XIX 2.8), if $g \in G(S')$ centralizes $T_{S'}$ and the $(U_\alpha)_{S'}$, it is a section of $T_{S'}$ that annihilates the $\alpha \in R$.

****Corollary 4.1.7.**** *Let S be a scheme, G an S -reductive group. Then the center of G is representable by a closed subgroup of G , of multiplicative type; it is also "the intersection of the maximal tori of G " in the following sense: for every $S' \rightarrow S$, $\text{Centr}(G)(S')$ is the set of $g \in G(S')$ whose inverse image in $G(S')$, for every $S'' \rightarrow S'$, is contained in all the $T(S'')$, where T runs through the set of maximal tori of $G_{S''}$.*

<!-- label: III.XXII.4.1.7 -->

Taking into account 2.3, the first assertion follows from 4.1.6 by descent.[^N.D.E-XXII-14] Let us prove the second assertion. Let H be "the intersection of the maximal tori of G " in the preceding sense. One obviously has $\text{Centr}(G) \subset H$.[^N.D.E-XXII-15] Then, by descent, it suffices to prove $\text{Centr}(G) = H$ in the case where G is split. Since H is contained in the intersection of the maximal tori of G in the usual sense, this follows from the following remark: if (G, T, M, R) is a splitting, $\alpha \in R$ and $X \in \Gamma(S, g_\alpha)^\times$, then $\text{int}(\exp(\alpha(X))(T) \cap T = \text{Ker}(\alpha)$, as a trivial computation shows. (Cf. also Exp. XII 8.6 and 8.8 for a more general statement.)

****Remark 4.1.8.**** *In what follows, we shall systematically identify, in the split case, T with $D_{\{S\}}(M)$. Then $\text{Centr}(G)$ is none other than $D_{\{S\}}(M/\Gamma_{\{0\}}(R))$, where $\Gamma_{\{0\}}(R)$ is the subgroup of M generated by R (cf. Exp. XXI 1.1.6). If $\{\alpha_1, \alpha_2, \dots, \alpha_n\}$ is a system of simple roots of R , one immediately has (cf. Exp. XX 1.19):*

<!-- label: III.XXII.4.1.8 -->

```
```text
Centr(G) = \bigcap \text{Ker}(\alpha_i) = \bigcap \text{Centr}(Z_{\{\alpha_i\}}).
```

**\*\*Proposition 4.1.9.\*\*** \*Let  $S$  be a scheme,  $(G, T, M, R)$  an  $S$ -split group,  $Q$  an  $S$ -torus,  $\alpha_0$  a character of  $Q$ ,  $L$  an invertible  $\mathcal{O}_S$ -module,\*

<!-- label: III.XXII.4.1.9 -->

```
```text
f : Q \to T,      p : W(L) \to G
```
```

\*morphisms of groups satisfying the set-theoretic relation\*

```
```text
p(\alpha_0(q) \cdot x) = \text{int}(f(q)) \cdot p(x),
```
```

\*for all  $q \in Q(S)$ ,  $x \in W(L)(S)$ ,  $S' \rightarrow S$ . Suppose that  $f$  separates the elements of  $R$  in the following sense: if  $\alpha, \alpha' \in R$  and  $m, m' \in \mathbb{Z}$ , then  $m\alpha \circ f = m'\alpha' \circ f$  implies  $m\alpha = m'\alpha'$ .[^N.D.E-XXII-16] Finally, let  $s \in S$  be such that  $(\alpha_0)_{\{s\}} \neq e$  and  $p_{\{s\}} \neq e$ .\*

\*There then exist an open set  $U$  of  $S$  containing  $s$ , an integer  $q > 0$  such that  $x \mapsto x^q$  is an endomorphism of  $G_{U, \alpha}$ , a root  $\alpha \in R$ , and an isomorphism of  $\mathcal{O}_U$ -modules\*

```
```
h : (L|U)^{\otimes q} \xrightarrow{\sim} g_\alpha|U
```
```

\*such that\*

\*(i)  $(\alpha \circ f)|_U = (q \circ \alpha)|_U$ ,

\*(ii)  $p(X) = \exp(\alpha(h(X^q)))$  for every  $X \in W(L)(S)$ ,  $S' \rightarrow S$ .

Moreover, once  $U$  is chosen,  $q$ ,  $\alpha$  and  $h$  are uniquely determined.

Shrinking  $S$  if necessary, we may suppose that  $\alpha$  is non-zero on every fiber of  $S$ . Choose a system of positive roots  $R$  of  $\mathfrak{g}$  and let  $V = p^{-1}(\Omega_{R+})$ . This is an open subset of  $W(L)$  containing the zero section and stable under multiplication by every  $\alpha(q)$ ,  $q \in Q(S)$ ,  $S' \rightarrow S$ . Since  $\alpha$  is non-trivial on every fiber, it follows immediately that  $V = W(L)$ , hence that  $p$  factors through  $\Omega_{R+}$ . Choose an arbitrary ordering on  $R$  and  $-R$ ; all products will be taken in this ordering. We thus have unique morphisms

```

```text
a : W(L) -> Ua,    a in R,
b : W(L) -> T
```

```

such that

```

```text
p(x) = \prod_{a in R-} a(x) \cdot b(x) \cdot \prod_{a in R+} a(x).
```

```

Writing the covariance condition under  $q$ , one obtains immediately

```

```text
a(a(q) x) = a(f(q)) a(x),    a in R,
b(a(q) x) = b(x)
```

```

for all  $x \in W(L)(S)$ ,  $q \in Q(S)$ ,  $S' \rightarrow S$ . The second condition gives at once  $b = e$ .

Now let  $\alpha \in R$  be such that  $\alpha|_S \neq e$  (we know such an  $\alpha$  exists, since  $p|_S$  is supposed  $\neq e$ ). Applying Exp. XIX 4.12 (a), one deduces that there exists an integer  $n > 0$  such that  $(\alpha \circ f)|_S = (n \circ \alpha)|_S$ . Shrinking  $S$ , one can assume  $\alpha \circ f = n \circ \alpha$  (Exp. IX 5.3). But then, for every  $\alpha' \in R$ ,  $\alpha' \neq \alpha$ , one has  $(\alpha' \circ f)|_S \neq m \circ \alpha'$  for every integer  $m > 0$ , by virtue of the hypothesis made on  $f$  (and the fact that the only roots proportional to  $\alpha$  are  $\alpha$  and  $-\alpha$ ). Applying again Exp. XIX 4.12 (a), this time to  $\alpha'$ , one deduces that  $\alpha'$  is zero in a neighborhood of  $S$ ; since  $R$  is finite, one may, shrinking  $S$  again, suppose the  $\alpha'$  zero for  $\alpha' \in R$ ,  $\alpha' \neq \alpha$ . One then has  $p = \alpha$ , and one may apply Exp. XIX 4.12 (b), then (c), which gives the announced result (the uniqueness assertions are obvious).

**Remark 4.1.10.** The condition imposed on  $f$  in 4.1.9 is satisfied in particular when  $f$  is surjective (= faithfully flat).

<!-- label: III.XXII.4.1.10 -->

**Proposition 4.1.11.** Let  $(G, T, M, R)$  be an  $S$ -split group,  $R$  a system of positive roots of  $\mathfrak{g}$ ,  $\Omega_{R+}$  the corresponding "big cell".

<!-- label: III.XXII.4.1.11 -->

(i) Let  $H$  be a separated  $S$ -group functor [N.D.E-XXII-17] for (fppf). If  $f, g : G \rightarrow H$  are two morphisms of groups that coincide on  $\Omega_{R+}$ , then  $f = g$ .

(ii) Let  $H$  be an  $S$ -sheaf of groups for (fppf) and  $f : \Omega_{R+} \rightarrow H$  an  $S$ -morphism satisfying the following condition: for every  $S' \rightarrow S$  and every  $x, y \in \Omega_{R+}(S')$  such that  $xy \in \Omega_{R+}(S')$ , one has  $f(xy) = f(x) f(y)$ . There then exists a (unique, by (i)) morphism of groups  $\bar{f} : G \rightarrow H$  extending  $f$ .

Indeed, by 4.1.5, (i) (resp. (ii)) follows immediately from Exp. XVIII 2.2 (resp. 2.3 and 2.4).

**Remark 4.1.12.** If  $\alpha \in R$ , one has

<!-- label: III.XXII.4.1.12 -->

```text  
(†) $\Omega_{R+} \cap Z\alpha = U_{-\alpha} \cdot T \cdot U\alpha.$

[^N.D.E-XXII-18] Indeed, for every $S' \rightarrow S$, if $g = \prod_{\beta \in R-} p_{\beta}(x_{\beta}) \cdot t \cdot \prod_{\beta \in R+} p_{\beta}(x_{\beta})$ is an element of $\Omega_{R+}(S')$ and if $t' \in T \setminus \alpha(S')$, then

```text  
 $t' g t'^{-1} = \prod_{\beta \in R-} p_{\beta}(\beta(t')) x_{\beta} \cdot t \cdot \prod_{\beta \in R+} p_{\beta}(\beta(t')) x_{\beta}$

and since  $\alpha$  and  $-\alpha$  are the only two elements of  $R$  that take the value 1 on  $T \setminus \alpha$ , we obtain that  $g$  belongs to  $Z \setminus \alpha = \text{Centr}(T \setminus \alpha)$  if and only if  $x_{\beta} = 0$  for  $\beta \neq \pm \alpha$ .

By (†), one deduces from XX 2.1 that if  $X \in \Gamma(X, g_{\alpha})$  and  $Y \in \Gamma(S, g_{-\alpha})$ , one has:

```text  
 $\exp_{\alpha}(X) \exp_{-\alpha}(Y) \in \Omega_{R+}(S) \Leftrightarrow 1 + XY$ invertible.

4.2. Morphisms of split groups

<!-- label: III.XXII.4.2 -->

Definition 4.2.1. Let S be a scheme (non-empty), (G, T, M, R) and (G', T', M', R') two S -split groups. We say that the morphism of S -groups $f : G \rightarrow G'$ is compatible with the splittings, or defines a morphism of split groups, if the restriction of f to T factors through a morphism $f_T : T \rightarrow T'$ of the form $f_T = D_S(h)$, where $h : M \rightarrow M'$ is a morphism of groups satisfying the following condition:

<!-- label: III.XXII.4.2.1 -->

there exists a bijection $d : R \xrightarrow{\sim} R'$ [^N.D.E-XXII-19] and for each $\alpha \in R$ an integer $q(\alpha) > 0$ such that $x \mapsto x^{q(\alpha)}$ is an endomorphism of $G_{\alpha, S}$ and that

```text  
 $h(d(\alpha) \alpha) = q(\alpha) \alpha, \quad t h(\alpha) = q(\alpha) d(\alpha) t.$

**Remark 4.2.2.** It is immediate that  $h, d, q(\alpha)$  for  $\alpha \in R$ , are uniquely determined by  $f$ . One writes  $h = R(f)$ . The  $q(\alpha)$  are the root exponents of  $f$  (or of  $h$ ).

<!-- label: III.XXII.4.2.2 -->

Let  $p$  be the prime number (if it exists) that is zero on  $S$ ; set  $p = 1$  if there is no prime number zero on  $S$ . Then  $R(f)$  is a  $p$ -morphism of reduced root data in the sense of Exp. XXI 6.8. One has thus defined a functor  $R$  from the category of  $S$ -split groups to that of reduced root data (equipped with  $p$ -morphisms).

**Proposition 4.2.3.** Under the conditions of 4.2.1, one has the following properties:

<!-- label: III.XXII.4.2.3 -->

(i) For every  $\alpha \in R$ , there exists a unique isomorphism of  ${}_{0_S}$ -modules

$f_{\alpha} : (g_{\alpha})^{\otimes q(\alpha)} \xrightarrow{\sim} g'_{d(\alpha)}$

such that

$f(\exp_{\alpha}(X)) = \exp_{d(\alpha)}(f_{\alpha}(X^{q(\alpha)}))$

\*for every  $X \in W(g\alpha)(S')$ ,  $S' \rightarrow S$ .\*

\*(ii) For every  $\alpha \in R$ , one has  $q(-\alpha) = q(\alpha)$  and  $f_\alpha$  and  $f_{-\alpha}$  are contragredient to one another.\*

\*(iii) For every  $\alpha \in R$ , every  $Z \in W(g\alpha)^*(S')$ ,  $S' \rightarrow S$ , one has\*

$$f(w_\alpha(Z)) = w_{\{d(\alpha)\}}(Z^{q(\alpha)}).$$

By hypothesis the diagram

$$\begin{array}{ccccc} \text{Gm}, S & \xrightarrow{-\alpha} & T & \xrightarrow{-\alpha} & \text{Gm}, S \\ | & & | & & | \\ q(\alpha) & & f_T & & q(\alpha) \\ \downarrow & & \downarrow & & \downarrow \\ \text{Gm}, S & \xrightarrow{-d(\alpha)} & T' & \xrightarrow{-d(\alpha)} & \text{Gm}, S \end{array}$$

is commutative. It follows that  $f$  maps  $\text{Ker}(\alpha)$  into  $\text{Ker}(d(\alpha))$ , hence  $T_\alpha$  into  $T'_{d(\alpha)}$ , hence  $Z_\alpha$  into  $Z'_{d(\alpha)}$ . There is then nothing more to do than apply Exp. XX 3.10 and 3.11 to the groups  $Z_\alpha$  and  $Z'_{d(\alpha)}$ .

**Proposition 4.2.4.** \*The morphism  $f$  induces a morphism  $f_N$  of  $\text{Norm}(T)$  into  $\text{Norm}_{G'}(T')$ , hence a morphism  $f_W$  of  $W_{G'}(T)$  into  $W_{G'}(T')$ ; the latter is an isomorphism. More precisely, if we denote by  $d : W(R(G)) = W \rightarrow W' = W(R(G'))$  the isomorphism extending  $s_\alpha \mapsto s_{d(\alpha)}$  (Exp. XXI 6.8.4), we have a commutative diagram of isomorphisms:\*

<!-- label: III.XXII.4.2.4 -->

$$\begin{array}{ccc} W_{G'}(T) & \xrightarrow{-f_W} & W_{G'}(T') \\ \uparrow & & \uparrow \\ \square & & \square \\ | & & | \\ W_S & \xrightarrow{-d_S} & W'_S. \end{array}$$

This follows immediately from 3.4, Exp. XXI 6.8.4, and (iii) above.

**Remark 4.2.5.** \*With the notations of 4.2.3, the restriction of  $f$  to  $\Omega_{R+}$  (for a system of positive roots  $R+$ ) is written explicitly: it maps  $\Omega_{R+}$  to  $\Omega'_{d(R+)}$  ( $d(R+)$  is a system of positive roots of  $R'$  by Exp. XXI 6.8.7) and is given by the set-theoretic formula:\*

<!-- label: III.XXII.4.2.5 -->

$$\begin{aligned} f(\prod_{\alpha \in R-} \exp(\lambda \alpha) \cdot t \cdot \prod_{\alpha \in R+} \exp(\lambda \alpha)) \\ = \prod_{\alpha \in R-} \exp_{d(\alpha)}(f(\lambda \alpha^{q(\alpha)})) \cdot f_T(t) \cdot \prod_{\alpha \in R+} \exp_{d(\alpha)}(f(\lambda \alpha^{q(\alpha)})). \end{aligned}$$

**Proposition 4.2.6.** \*(i)  $f$  is surjective (= faithfully flat in the present case, cf. VI\_B 3.11) if and only if  $f_T$  is.\*

<!-- label: III.XXII.4.2.6 -->

\*(ii) One has  $\text{Ker}(f) \subset \Omega_{R+}$ .\*

Let us prove (i): if  $f$  is surjective, then  $f_T(T) = f(T)$  is a maximal torus of  $G'$  (indeed  $f(T)$  is a subtorus of a maximal torus  $T'$  (Exp. IX 6.8); to verify that  $f(T) = T'$ , one reduces to the case of an algebraically closed field, where this is \*Bible\*, § 7.3, th. 3 (a)).

If  $f_T$  is surjective, the preceding formula shows that  $f$  induces a surjection from  $\Omega = \Omega_{R+}$  onto  $\Omega' = \Omega'_{d(R+)}$ .<sup>[^N.D.E-XXII-20]</sup> Since the fibers of  $G$  are connected, it follows (cf. Exp. VI\_A, 0.5) that  $f$  is surjective.

Let us prove (ii) and for this admit a result to be proved below (5.7.4): choose for each  $w \in W$  an  $n_w \in \text{Norm}_G(T)(S)$  representing it; then the open sets  $\Omega_w = \Omega$  ( $w \in W$ ) form a cover of  $G$ . It is then enough to prove that  $\text{Ker}(f) \cap n_w \Omega \neq \emptyset$  implies  $w = 1$ . If  $x \in \Omega(S')$ ,  $S' \rightarrow S$  and  $f(n_w x) = 1$ , then  $f(x) = f(n_w)^{-1}$ ; but  $f(x) \in \Omega'(S')$  and  $f(n_w)^{-1} \in \text{Norm}_{G'}(T')(S')$ . By 4.2.4, one is reduced to proving:

**Lemma 4.2.7.** \*Under the conditions of 4.1.2, one has  $\Omega \cap \text{Norm}_G(T) = T$ .\*

<!-- label: III.XXII.4.2.7 -->

Let

$$x = \prod_{\alpha \in R-} p_\alpha(x_\alpha) \cdot t \cdot \prod_{\alpha \in R+} p_\alpha(x_\alpha) = v \cdot t \cdot u \in \Omega(S').$$

If  $x$  normalizes  $T_{S'}$ , one has for every  $t' \in T(S')$ ,

$$x t' x^{-1} = t'' \in T(S'),$$

that is,  $x t' = t'' x$ , which is written

$$v (t t') (t'^{-1} u t') = (t'' v t'^{-1}) (t'' t) u,$$

which gives  $t'^{-1} u t' = u$ , hence  $u \in \text{Centr}_G(T)(S') = T(S')$ , that is  $u = 1$ . Similarly  $v = 1$ .

**Corollary 4.2.8.** \*One has\*

<!-- label: III.XXII.4.2.8 -->

$$\text{Ker}(f) = \prod_{\alpha \in R-} K_\alpha \cdot \text{Ker}(f_T) \cdot \prod_{\alpha \in R+} K_\alpha,$$

where for each  $\alpha \in R$ ,  $K_\alpha$  denotes the finite  $S$ -group

$$K_\alpha = \text{Ker}(U_\alpha \rightarrow U_\alpha^{\otimes q(\alpha)}) = \alpha_{q(\alpha)}, S.$$

To apply this corollary, let us set:

**Definition 4.2.9.** \*Let  $S$  be a scheme,  $G$  and  $G'$  two  $S$ -reductive groups. A morphism of  $S$ -groups  $f : G \rightarrow G'$  that is faithfully flat and finite (i.e. surjective with finite kernel over  $S$ ) is called an  $*$  isogeny. \*If moreover  $\text{Ker}(f)$  is a central subgroup of  $G$ , one says that  $f$  is a  $*$  central isogeny.

<!-- label: III.XXII.4.2.9 -->

**Proposition 4.2.10.** \*Let  $f : G \rightarrow G'$  be a morphism of split groups. For  $f$  to be an isogeny (resp. a central isogeny) it is necessary and sufficient that  $f_T$  be an isogeny, i.e. that  $R(f)$  be injective with finite cokernel (resp. and that for every  $\alpha \in R$ , one has  $q(\alpha) = 1$ ).\*

<!-- label: III.XXII.4.2.10 -->

Indeed, by 4.2.8,  $\text{Ker}(f)$  is finite over  $S$  if and only if  $\text{Ker}(f_T)$  is finite over  $S$ , and  $\text{Ker}(f) \subset T$  if and only if each  $q(\alpha) = 1$  ( $\text{Ker}(f)$  is then central since of multiplicative type and invariant, cf. Exp. IX 5.5).

**\*\*Remark 4.2.11.\*\*** (a) One thus sees that  $f : G \rightarrow G'$  is a central isogeny if and only if  $R(f) : R(G) \rightarrow R(G')$  is an isogeny in the sense of Exp. XXI 6.2; moreover one has in this case (with the notations of loc. cit.):\*

<!-- label: III.XXII.4.2.11 -->

```
```text
Ker(f) = D_S(K(R(f))),    K(R(f)) = Coker(R(f)).
```
```

(b) If  $G$  and  $G'$  are semisimple, every morphism of split groups  $f : G \rightarrow G'$  is an isogeny.\*[<sup>N.D.E-XXII-21</sup>]

(c) If  $f : G \rightarrow G'$  is faithfully flat and finite and if  $G$  is reductive (resp. semisimple), then  $G'$  is also. It is indeed of finite presentation over  $S$  (Exp. V 9.1), affine over  $S$  (EGA II 6.7.1), smooth over  $S$  (Exp. VI 9.2), with connected reductive (resp. semisimple) geometric fibers by Exp. XIX 1.7.\*

Definition 4.2.1 may seem arbitrary. It is justified by the following proposition (which we state, for simplicity, for semisimple groups).

We say that a morphism  $f : G \rightarrow G'$  of  $S$ -reductive groups is *splittable* if there exist splittings of  $G$  and  $G'$  with which  $f$  is compatible. One then has:

**\*\*Proposition 4.2.12.\*\*** Let  $S$  be a scheme,  $G$  and  $G'$  two semisimple  $S$ -groups,  $f : G \rightarrow G'$  a morphism of groups. Let  $s \in S$ . The following conditions are equivalent:\*

<!-- label: III.XXII.4.2.12 -->

(i)  $\text{Ker } f_s$  is finite ( $\Leftrightarrow e_s$  is isolated in  $\text{Ker } f(s)$ ) and  $f_s$  is surjective, i.e.  $f_s$  is an isogeny.\*

(ii)  $f_s$  is splittable.\*

(iii) There exists an étale morphism  $S' \rightarrow S$  covering  $s$  such that  $f_{S'} : G_{S'} \rightarrow G'_{S'}$  is splittable.\*

One has obviously (iii)  $\Leftrightarrow$  (ii); (ii)  $\Rightarrow$  (i) follows from 4.2.11 (b) (this is where the hypothesis that  $G$  and  $G'$  are semisimple intervenes – the other implications are valid for reductive groups).

Let us now prove (i)  $\Rightarrow$  (iii). One may suppose  $G$  and  $G'$  split in such a way that  $f$  induces a morphism  $f_T : T \rightarrow T'$  (2.3 and Exp. XIX 2.8); shrinking  $S$ , one may suppose that  $f_T = D_S(h)$ , where  $h$  is a morphism of groups  $M' \rightarrow M$ . Let  $\alpha \in R$ , and consider the composite morphism

```
```text
p : W(gα) --expα--> G --f--> G'.
```
```

Since  $\text{Ker}(p_s)$  is finite,  $p_s \neq e_s$ . On the other hand  $f_{T_s}$  is surjective; one may therefore apply 4.1.9, and there exist an open subset  $V_\alpha$  of  $S$  containing  $s$ , a root  $\alpha' \in R'$ , an integer  $q(\alpha)$  such that  $x \mapsto x^{q(\alpha)}$  is an endomorphism of  $G_\alpha, V_\alpha$ , and an isomorphism of  $0_{V_\alpha}$ -modules

```
$$
f_\alpha : (g_\alpha)^{\otimes q(\alpha)}|_{V_\alpha} \xrightarrow{\sim} g'_{\alpha'}|_{V_\alpha}
$$
```

such that  $f(\exp_\alpha(X_\alpha)) = \exp_{d(\alpha)}(f_\alpha(X_\alpha^{q(\alpha)}))$  and  $\alpha' \circ f_T = h(\alpha') = q(\alpha)\alpha$ . One may replace  $S$  by the intersection of the  $V_\alpha$ , for  $\alpha \in R$ . Set  $\alpha' = d(\alpha)$ . It is clear that  $d : R \rightarrow R'$  is a bijection, because the kernel of  $h$  is finite ( $f_{T_s}$  being surjective). It only remains to prove that  $f_T \circ \alpha' = q(\alpha)\alpha$ , which is done by a trivial modification of the argument used in Exp. XX 3.11.

In any case, as one has seen in the course of the demonstration, one has (i)  $\Rightarrow$  (iii). Therefore:

**\*\*Corollary 4.2.13.\*\*** Let  $S$  be a scheme,  $f : G \rightarrow G'$  an isogeny of reductive groups. Then  $f$  is locally splittable for the étale topology.\*

<!-- label: III.XXII.4.2.13 -->

### ### 4.3. Central quotients of reductive groups

<!-- label: III.XXII.4.3 -->

Let us first consider a particular case.

**\*\*Proposition 4.3.1.\*\*** \*Let  $S$  be a scheme,  $(G, T, M, R)$  an  $S$ -split group,  $N$  a subgroup of  $M$  containing  $R$ ,  $Q = D_S(M/N) \subset \text{Centr}(G)$ . Then:\*

<!-- label: III.XXII.4.3.1 -->

(i)  $G' = G/Q$  is an  $S$ -reductive group, and  $T' = T/Q$  is a maximal torus of it;\*

(ii) if one identifies  $T'$  with  $D_S(N)$ , then  $R \subset N$  is a system of roots of  $G'$  relative to  $T'$ ,  $(G', T', N, R)$  is a splitting of  $G'$ , and  $R(G')$  is canonically identified with the induced root datum (Exp. XXI 6.5)  $R(G)^N$ ;

(iii) the canonical morphism  $G \rightarrow G'$  is compatible with the splittings, with root exponents 1, and gives by functoriality the canonical morphism (loc. cit.)  $R(G)^N \rightarrow R(G)$ .

One knows that  $G' = G/Q$  is representable by an affine group scheme over  $S$  (Exp. VIII 5.7), smooth over  $S$  (Exp. VI\_B 9.2), with connected reductive geometric fibers (as quotients of reductive groups, cf. Exp. XIX 1.7);  $G'$  is therefore an  $S$ -reductive group.

It is clear that  $T' = T/Q \simeq D_S(N)$  is a maximal torus of it. Note next that, choosing a system of positive roots  $R^+$  of  $R$ , the open set  $\Omega_{R^+}$  of 4.2 is stable under  $Q$  and that one has a canonical isomorphism

$$\Omega_{R^+}/Q \simeq \coprod_{\alpha \in R^-} U_{\alpha} \times_S (T/Q) \times_S \coprod_{\alpha \in R^+} U_{\alpha},$$

and that  $\Omega_{R^+}/Q$  is an open subset of  $G'$  containing the unit section (cf. Exp. IV, 4.7.2 and 6.4.1).

It follows that, if one denotes by  $\mathfrak{g}'$  the Lie algebra of  $G'$  and by  $\bar{\alpha}$  the character of  $T/Q$  induced by  $\alpha$  (or, which amounts to the same, defined by  $\alpha \in N$  in the identification  $T/Q = D_S(N)$ ), the canonical morphism  $G \rightarrow G'$  induces for each  $\alpha \in R$  an isomorphism

$$\mathfrak{g}_{\alpha} \xrightarrow{\sim} \mathfrak{g}'_{\bar{\alpha}}.$$

One has thus proved that  $R$  is a system of roots of  $G'$  relative to  $T'$ , and one finishes the proof without difficulty.

**\*\*Corollary 4.3.2.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $Q$  a normal subgroup of multiplicative type of  $G$ . Then  $Q$  is central in  $G$ , the quotient  $G/Q$  is representable by an  $S$ -reductive group, and the canonical morphism  $G \rightarrow G/Q$  is locally splittable for the étale topology (with root exponents equal to 1).\*

<!-- label: III.XXII.4.3.2 -->

The first assertion follows from Exp. IX 5.5; the others are local for the étale topology and one is reduced to 4.3.1.

**\*\*Definition 4.3.3.\*\*** \*Let  $G$  be an  $S$ -reductive group. We say that  $G$  is\* adjoint \*(resp. simply connected) if for every  $s \in S$ , the type of  $G_s$  at  $s$  is given by an adjoint (resp. simply connected) root datum, i.e. (Exp. XXI 6.2.6) such that  $M_s$  be generated by  $R_s$  (resp.  $M_s^*$  generated by  $R_s^*$ ).\*

<!-- label: III.XXII.4.3.3 -->

**\*\*Proposition 4.3.4.\*\*** (i) An adjoint (resp. simply connected) reductive group is semisimple.\*

<!-- label: III.XXII.4.3.4 -->

(ii) If  $T$  is a maximal torus of the adjoint (resp. simply connected) reductive group  $G$  and  $\alpha$  is a root of  $G$  relative to  $T$ , then the infinitesimal root  $\alpha$  is non-zero on every fiber (resp.  $\alpha^*$  is a monomorphism and the infinitesimal coroot  $H_{\alpha}$  is non-zero on every fiber).\*

Indeed, (i) is trivial; (ii) is checked on geometric fibers and follows immediately from Exp. XXI 6.2.8.

**Proposition 4.3.5.** (i) For the reductive group  $G$  to be adjoint, it is necessary and sufficient that  $\text{Centr}(G) = \{e\}$ .

<!-- label: III.XXII.4.3.5 -->

(ii) For every reductive group  $G$ , the quotient group  $G/\text{Centr}(G)$  is an adjoint reductive group.

Indeed, one may suppose  $G$  split; then (i) is trivial (since  $\text{Centr}(G) = D_{\{S\}}(M/\Gamma_0(R))$ ), and (ii) follows from 4.3.1.

**Definition 4.3.6.** Let  $G$  be an  $S$ -reductive group. We call\* adjoint group of  $G$  and denote by  $\text{ad}(G)$  the group  $G/\text{Centr}(G)$ . We call\* radical of  $G$  and denote by  $\text{rad}(G)$  the maximal torus (unique by Exp. XII 1.12) of  $\text{Centr}(G)$ . We call\* semisimple group associated with  $G$  the quotient  $G/\text{rad}(G)$ .

<!-- label: III.XXII.4.3.6 -->

The preceding definitions are compatible with base change. If  $s \in S$ ,  $\text{rad}(G)_s$  is indeed the radical of  $G_s$  in the usual sense (Exp. XIX 1.6).

### 4.3.7.

<!-- label: III.XXII.4.3.7 -->

If  $(G, T, M, R)$  is a split group, then  $\text{rad}(G) = D_{\{S\}}(M/N)$ , where  $N = M \cap V(R)$ , so the semisimple group associated with  $G$  (and similarly the adjoint group of  $G$ ) is equipped with a canonical splitting (4.3.1) and one has a diagram of split groups

$$\begin{array}{ccc} G & \twoheadrightarrow & \text{ss}(G) \twoheadrightarrow \text{ad}(G) \\ & & \downarrow \\ & & G_s \end{array}$$

corresponding to the canonical diagram of root data (Exp. XXI 6.5.5)

$$\begin{array}{ccc} \text{ad}(R(G)) & \twoheadrightarrow & \text{ss}(R(G)) \twoheadrightarrow R(G) \\ & & \downarrow \\ & & R_s \end{array}$$

**Remark 4.3.8.** Let  $(G, T, M, R)$  be an  $S$ -split adjoint (resp. simply connected) group,  $\Delta$  a system of simple roots of  $R$ . Then the family  $\{\alpha_{\alpha} \mid \alpha \in \Delta\}$ , resp.  $\{\alpha_{\alpha}^* \mid \alpha \in \Delta\}$ , induces an isomorphism\*

<!-- label: III.XXII.4.3.8 -->

$$\begin{array}{ccc} T & \twoheadrightarrow & (G, S)^{\Delta} \\ & & \downarrow \\ & & (G, S)^{\Delta} \twoheadrightarrow T. \end{array}$$

Indeed,  $M = \Gamma_0(R)$  (resp. ...) and  $\Delta$  is a basis of the free abelian group  $\Gamma_0(R)$  (Exp. XXI 3.1.8).

**Remark 4.3.9.** The radical of a reductive group is a characteristic subgroup (i.e. stable under  $\text{Aut}_S\text{-gr.}(G)$ ), by its very definition.\*

<!-- label: III.XXII.4.3.9 -->

## 5. Subgroups of type (R)

<!-- label: III.XXII.5 -->

<!-- original page 128 -->

We are especially interested in reductive groups, but some of the results we shall establish are valid more generally

for a wider class of groups: groups of type (RR).

### ### 5.1. Groups of type (RR)

<!-- label: III.XXII.5.1 -->

**Definition 5.1.1.** \*Let  $S$  be a scheme,  $G$  an  $S$ -group scheme. We say that  $G$  is of type (RR) if it satisfies the following conditions:

<!-- label: III.XXII.5.1.1 -->

(i)  $G$  is smooth and of finite presentation over  $S$  and has connected fibers.

(ii)  $G$  locally possesses maximal tori for the (fpqc) topology.

(iii) For every  $s \in S$ , every maximal torus  $T$  of  $G_s$ , and every root of  $G_s$  relative to  $T$  (Exp. XIX 1.10),  $\mathrm{Lie}(G_s)^{\alpha}$  is of rank 1 (as a vector space over  $k(s)$ ).

(iv) For every  $s \in S$  and every maximal torus  $T$  of  $G_s$ , let  $R$  denote the set of roots of  $G_s$  relative to  $T$  and  $\Gamma(R)$  the subgroup of  $\mathrm{Hom}_{s\text{-gr.}}(T, G_m)$  generated by  $R$ ; then the content [N.D.E-XXII-22] of every root  $\alpha \in R$  in the free abelian group  $\Gamma(R)$  (which is therefore a positive integer) is invertible on  $S$ .

**Recall 5.1.1.1.** [N.D.E-XXII-23] Let us recall that if  $G$  is a smooth connected algebraic group over an algebraically closed field  $k$ , a Cartan subgroup of  $G$  is the centralizer of a maximal torus of  $G$  (XII 1.0), and such a subgroup is smooth and connected: for this, as well as for other characterizations of Cartan subgroups, see Bible, § 7.1, Th. 1 in the affine case and Exp. XII Th. 6.6 in the general case. If  $S$  is an arbitrary scheme and  $G$  an  $S$ -smooth group of finite type, a Cartan subgroup of  $G$  is an  $S$ -smooth subgroup  $C$  of  $G$  such that, for every  $s \in S$ ,  $C_s$  is a Cartan subgroup of  $G_s$  (XII Def. 3.1).

<!-- label: III.XXII.5.1.1.1 -->

**Remark 5.1.2.** (a) By virtue of Exp. XII 7.1 (where the hypothesis that  $G$  is separated holds here since  $G$  has connected fibers, cf. Exp. VI\_B 5.5), (i) and (ii) entail that  $G$  locally possesses, for the étale topology, maximal tori (resp. Cartan subgroups), conjugate locally for the étale topology.

<!-- label: III.XXII.5.1.2 -->

(b) The Cartan subgroups of  $G$  have connected fibers (Exp. XII 6.6).

(c) If  $G$  is affine over  $S$ , (i) and (ii) are respectively equivalent to

(i')  $G$  is smooth over  $S$  with connected fibers.

(ii') The reductive rank of the fibers of  $G$  is locally constant (Exp. XII 1.7).

(d) By Exp. XII 8.8 (c) and (d),  $G$  has a reductive center  $Z$  and, for every  $s \in S$ , with the notations of (iv), one has [N.D.E-XXII-24]  $Z_s = \bigcap_{\alpha \in R} \mathrm{Ker}(\alpha)$ , whence

$$\mathrm{Hom}_{s\text{-gr.}}(T/Z_s, G_m) \simeq \Gamma(R).$$

(e) Condition (iv) holds in particular in the following two cases:

(1)  $S$  is of characteristic 0;

(2) every root is an indivisible element of the group generated by the roots.

(f) Being of type (RR) is stable under base change and is local for the (fpqc) topology.

From remarks (c) and (e), one immediately deduces:

**Proposition 5.1.3.** \*A reductive group is of type (RR).

<!-- label: III.XXII.5.1.3 -->

**\*\*Proposition 5.1.4.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -group of type (RR),  $Q$  a central subgroup of  $G$  of finite presentation over  $S$  such that the quotient  $G/Q$  is representable (for instance  $G$  affine over  $S$  and  $Q$  of multiplicative type (IX 2.3) or else  $S$  artinian (VI\_A 3.3.2)); then  $G/Q$  is an  $S$ -group of type (RR).\*

<!-- label: III.XXII.5.1.4 -->

Indeed,  $G/Q$  is smooth over  $S$  (Exp. VI\_B 9.2), of finite presentation over  $S$  (Exp. V 9.1) and with connected fibers, so condition (i) holds. On the other hand, condition (ii) follows from Exp. XII 7.6; it remains to verify conditions (iii) and (iv).

Let  $G' = G/Q$ ,  $u : G \rightarrow G'$  the canonical morphism,  $T' = u(T)$  the maximal torus of  $G'$  image of  $T$  (cf. Exp. XII 7.1 (e)); for each  $\alpha \in R$ , denote again by  $\alpha$  the character of  $T'$  defined by  $\alpha$  (one has  $Q \cap T \subset \bigcap_{\alpha \in R} \text{Ker}(\alpha)$  according to 5.1.2 (d)). Let us first prove:

**\*\*Lemma 5.1.5.\*\*** \*Under the conditions of 5.1.4, let  $T = D_{\{S\}}(M)$  be a trivialized maximal torus of  $G$ , and suppose that the decomposition of  $\mathfrak{g} = \text{Lie}(G)$  under  $\text{Ad}(T)$  is of the form\*

<!-- label: III.XXII.5.1.5 -->

```
```text
g = g^0 \oplus \bigoplus_{\alpha \in R} g_{\alpha}, \quad R \subset M - \{0\},
```
```

\*where for every  $s \in S$ ,  $g_{\alpha}(s) \neq 0$  for  $\alpha \in R$  (so  $g_{\alpha}$  is an invertible  $0_S$ -module for every  $\alpha \in R$  and  $R$  is the set of roots of  $G_{\{s\}}$  relative to  $T_{\{s\}}$  for every  $s \in S$ ).\*

\*Then the Lie algebra  $\mathfrak{g}'$  of  $G'$  decomposes under  $\text{Ad}(T')$  as follows:\*

```
```text
g' = g'^0 \oplus \bigoplus_{\alpha \in R} g'^{\alpha},
```
```

\*and  $\text{Lie}(u)$  induces an isomorphism of  $g_{\alpha}$  onto  $g'^{\alpha}$ .\*

Indeed, let  $p = \text{Lie}(u) : \mathfrak{g} \rightarrow \mathfrak{g}'$ . One immediately has  $p(g_{\alpha}) \subset g'^{\alpha}$  for every  $\alpha \in R$ , and  $p(g^0) \subset g'^0$ . Since

```
```text
Ker(p) = \text{Lie}(Q) \subset \text{Lie}(\text{Centr}_G(T)) = g^0,
```
```

$p$  induces a monomorphism from  $g_{\alpha}$  into  $g'^{\alpha}$ , for every  $\alpha \in R$ .

To prove the lemma, it suffices to do so when  $S$  is the spectrum of an algebraically closed field, and by virtue of the preceding remarks, it then suffices to prove that  $\text{rg}(g') = \text{rg}(g'^0) + \text{Card}(R)$ . Now set  $C = \text{Centr}_{\{G\}}(T)$ ,  $C' = \text{Centr}_{\{G'\}}(T')$ ; by Exp. XII 7.1 (e),  $u$  induces a faithfully flat morphism  $C \rightarrow C'$  of kernel  $Q$ . One thus has

```
```text
\dim C' + \dim Q = \dim C.
```
```

But  $G$ ,  $G'$ ,  $C$  and  $C'$  are smooth, so

```
```text
\dim G = \text{rg}(g) = \text{rg}(g^0) + \text{Card}(R) = \dim C + \text{Card}(R)
           = \dim Q + \dim C' + \text{Card}(R) = \dim Q + \text{rg}(g'^0) + \text{Card}(R)
\text{rg}(g') = \dim G' = \dim G - \dim Q
```
```

which entails

$\square$

$\mathrm{rg}(g') = \mathrm{rg}(g'^{\{0\}}) + \mathrm{Card}(R),$   
 $\$ \$$

that is, the desired relation.

Let us return to the proof of 5.1.4; one may suppose that  $\$ \$$  is the spectrum of an algebraically closed field. Let  $\$ T \$$  be a maximal torus of  $\$ G \$$ ; applying 5.1.5, one immediately has (iii) and (iv) for  $\$ G / Q \$$ .

To use the preceding proposition, let us introduce a definition:

**Definition 5.1.6.** We say that the  $\$ \$$ -group scheme  $\$ G \$$  is\* of type (RA) \*if it is of type (RR) and if it further satisfies the following condition (iv') (stronger than (iv)):

<!-- label: III.XXII.5.1.6 -->

(iv') For every  $\$ s \in \$ S$  and every maximal torus  $\$ T \$$  of  $\$ G_{\{s\}} \$$ , every root of  $\$ G_{\{s\}} \$$  relative to  $\$ T \$$  has a content in  $\$ \operatorname{Hom}_{\{s\}\text{-gr.}}(T, G_{m,s}) \$$  that is invertible on  $\$ S \$$ .

**Remarks 5.1.7.** (a) An  $\$ \$$ -reductive adjoint group is of type (RA).

<!-- label: III.XXII.5.1.7 -->

(b) If  $\$ S \$$  is of characteristic 0, every group of type (RR) is of type (RA).

(c) Being of type (RA) is stable under base change and is local for the (fpqc) topology.

Remark (a) above generalizes to:

**Proposition 5.1.8.** Let  $\$ S \$$  be a scheme,  $\$ G \$$  an  $\$ \$$ -group of type (RR),  $\$ Z \$$  its reductive center, suppose the quotient  $\$ G / Z \$$  representable (for instance  $\$ G \$$  affine over  $\$ S \$$ , or  $\$ S \$$  artinian); then  $\$ G / Z \$$  is of type (RA).

<!-- label: III.XXII.5.1.8 -->

Indeed, this follows immediately from 5.1.4, 5.1.5, and 5.1.2 (d).

**Remark 5.1.9.** If  $\$ G \$$  is of type (RR) and if  $\$ T \$$  is a maximal torus of  $\$ G \$$ , one may apply Exp. XIX 6.3. In particular  $\$ W_{\{G\}}(T) \$$  is étale, quasi-finite and separated over  $\$ S \$$ .

<!-- label: III.XXII.5.1.9 -->

### 5.2. Subgroups of type (R)

<!-- label: III.XXII.5.2 -->

**Definition 5.2.1.** Let  $\$ S \$$  be a scheme,  $\$ G \$$  a smooth  $\$ \$$ -group scheme of finite presentation with connected fibers, [N.D.E-XXII-25]  $\$ H \$$  a group subscheme of  $\$ G \$$ . We say that  $\$ H \$$  is\* of type (R) \*if:

<!-- label: III.XXII.5.2.1 -->

(i)  $\$ H \$$  is smooth, of finite presentation over  $\$ S \$$  and with connected fibers. [N.D.E-XXII-25]

(ii) For every  $\$ s \in \$ S$ ,  $\$ H_{\{s\}} \$$  contains a Cartan subgroup of  $\$ G_{\{s\}} \$$ .

This notion is stable under base change and local for the (fpqc) topology.

**Recall 5.2.2.** (cf. Exp. XII 7.9) Under the preceding conditions:

<!-- label: III.XXII.5.2.2 -->

(a)  $\$ H = \operatorname{Norm}_{\{G\}}(H)^{\{0\}} \$$ .

(b) If  $\$ G \$$  locally possesses, for the étale topology, Cartan subgroups (resp. maximal tori), so does  $\$ H \$$ , and the Cartan subgroups (resp. maximal tori) of  $\$ H \$$  are Cartan subgroups (resp. maximal tori) of  $\$ G \$$ .

**Examples 5.2.3.** (a) Borel subgroups: a Borel subgroup\* of  $\$ G \$$  is a subgroup  $\$ H \$$  of type (R) whose geometric fibers

are Borel subgroups of those of  $G$ .<sup>[^N.D.E-XXII-26]</sup>

<!-- label: III.XXII.5.2.3 -->

**(b) Parabolic subgroups:** a parabolic subgroup of  $G$  is a subgroup of type (R) whose geometric fibers contain Borel subgroups.

Other examples are given by the following propositions.

**Proposition 5.2.4.** Let  $G$  be as in 5.2.1,  $K \subset H$  two group subschemes of  $G$ ,  $H$  assumed to be of type (R). Then  $K$  is a subgroup of type (R) of  $H$  if and only if it is a subgroup of type (R) of  $G$ .

<!-- label: III.XXII.5.2.4 -->

<sup>[^N.D.E-XXII-27]</sup> Indeed, let  $s \in S$ . Since  $H$  is of type (R), every maximal torus of  $H_s$  is a maximal torus of  $G_s$ , and so likewise for Cartan subgroups.

**Proposition 5.2.5.** Let  $G$  be as in 5.2.1,  $T$  a maximal torus of  $G$ ,  $Q$  a subtorus of  $T$ ,  $Z = \text{Centr}_G(Q)$ . If  $H$  is a subgroup of type (R) of  $G$  containing  $T$ , then  $H \cap Z$  is a subgroup of type (R) of  $Z$ .

<!-- label: III.XXII.5.2.5 -->

Let us first recall that  $Z$  is a closed group subscheme of  $G$ , of finite presentation (Exp. XI 6.11), with connected fibers (Exp. XII 6.6), smooth over  $S$  (Exp. XI 2.4), so it satisfies the conditions imposed in Definition 5.2.1. Similarly,  $H \cap Z$  is of finite presentation, smooth and has connected fibers (since  $H \cap Z = \text{Centr}_H(Q)$ ); moreover  $H \cap Z \supset \text{Centr}_G(T)$ .

**Proposition 5.2.6.** Let  $S$  be a scheme,  $G$  an  $S$ -group of type (RR) (resp. (RA)),  $H$  a subgroup of type (R) of  $G$ . Then  $H$  is an  $S$ -group of type (RR) (resp. (RA)).

<!-- label: III.XXII.5.2.6 -->

Indeed, (i) is clear, (ii) follows from 5.2.2 (b), (iii) and (iv) (resp. (iv')) are to be verified when  $S$  is the spectrum of an algebraically closed field. Then  $H$  contains a maximal torus  $T$  of  $G$  (and hence also  $C = \text{Centr}_G(T)$ ),<sup>[^N.D.E-XXII-28]</sup> and the assertions to be proved follow immediately from:

**Lemma 5.2.7.** Let  $S$  be a scheme,  $G$  an  $S$ -group of type (RR),  $T$  a maximal torus of  $G$  equipped with a trivialization  $T \simeq D_S(M)$ , and suppose that

<!-- label: III.XXII.5.2.7 -->

text  
 $g = g^0 \prod_{\alpha \in R} g_{\alpha}$

(the  $g_{\alpha}$  being then invertible  $0_S$ -modules).

Let  $H$  be a subgroup of type (R) containing  $C = \text{Centr}_G(T)$  (i.e. containing  $T$ ). Then  $h = \text{Lie}(H/S)$  is locally on  $S$  of the form

text  
 $g^0 + \prod_{\alpha \in R'} g_{\alpha} = g_{R'}$

more precisely, let, for each  $s \in S$ ,  $R'(s) = \{\alpha \in R \mid g_{\alpha}(s) \subset h(s)\}$ . Then  $R'(s)$  is a locally constant function of  $s$ ; if  $U$  is an open subset of  $S$  on which  $R'(s) = R'$ , one has

text  
 $h_U = g^0_U \prod_{\alpha \in R'} g_{\alpha_U}$

Indeed,  $h$  is a submodule of  $g$ , locally a direct factor, containing  $g^0$  and stable under  $T$ .

### 5.3. Strict transporter of two subgroups of type (R). Applications

<!-- label: III.XXII.5.3 -->

**\*\*Recall 5.3.0.\*\***[<sup>N.D.E-XXII-29</sup>] \*Let  $S$  be a scheme,  $G$  an  $S$ -smooth group,  $g = \mathrm{Lie}(G/S)$  and  $h$  a sub- $0_S$ -module of  $g$  that is locally a direct factor. The  $0_S$ -algebra  $A = \mathrm{Sym}(\omega^1_{G/S})$  is locally free, so the  $S$ -scheme  $\mathrm{Lie}(G/S) = W(g) = \mathrm{Spec}(A)$  is essentially free in the sense of Exp. VIII, 6.1. Since  $W(h)$  is a closed subscheme of  $\mathrm{Lie}(G/S)$ , of finite presentation over  $\mathrm{Lie}(G/S)$ , then  $N = \mathrm{Norm}_G(h)$  is representable by a closed group subscheme of  $G$ , of finite presentation over  $G$ , by Exp. VIII, 6.5 (a). (See also the additions 6.2.3 and 6.2.4 (a) in Exp. VI\_B.) On the other hand, by Exp. II 5.3.1, one has  $\mathrm{Lie}(N/S) = \mathrm{Norm}_{\mathrm{Lie}(G/S)}(h)$ .\*

\*Finally, by Exp. VI\_B 3.10, if  $N$  is smooth over  $S$  at the points of the unit section, then the group subfunctor  $N^{\{0\}}$  (defined in VI\_B 3.1) is represented by an open group subscheme of  $N$ , smooth over  $S$ .\*

**\*\*Proposition 5.3.1.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -group of type (RA) (5.1.6),  $H$  a subgroup of type (R) of  $G$ ,  $g \supseteq h$  their Lie algebras.\*

<!-- label: III.XXII.5.3.1 -->

\*Then  $\mathrm{Norm}_G(h)$  (which is representable by a closed subscheme of  $G$  of finite presentation over  $S$  according to 5.3.0) is smooth over  $S$  at every point of the unit section, and one has\*

$$\mathrm{Norm}_G(h)^{\{0\}} = H.$$

[<sup>N.D.E-XXII-30</sup>] Proof. Set  $N = \mathrm{Norm}_G(h)$  and  $n = \mathrm{Lie}(N/S)$ . One has  $H \subset N$  and, by Exp. II 5.3.1, one has for every  $s \in S$

$$h(s) \subset n(s) = \mathrm{Norm}_{g(s)}(h(s)).$$

Now, by 5.3.2 below, one has  $h(s) = \mathrm{Norm}_{g(s)}(h(s))$ , and since  $H$  is smooth over  $S$ , one has  $\dim_{\kappa(s)} h(s) = \dim H_s$  (cf. [DG70], § II.5, Th. 2.1). One thus obtains

```text  
dim_{\kappa(s)} n(s) = dim_{\kappa(s)} h(s) = \dim H_s \leq \dim N_s

whence $N^{\{0\}}_s = H^{\{0\}}_s = H_s$ (H having connected fibers). It follows that the group subfunctor $N^{\{0\}}$ (defined in VI_B, 3.1) is represented by the smooth S -group H . This proves 5.3.1, modulo the following lemma:

****Lemma 5.3.2.**** *Under the conditions of 5.2.7, if G is of type (RA), one has, for every $s \in S$,*

<!-- label: III.XXII.5.3.2 -->

$$\mathrm{Norm}_{g(s)}(h(s)) = h(s).$$

Indeed, one is reduced to the case where S is the spectrum of a field, so where $h = g_{R'}$ for some $R' \subset R$. But one already has

$$\mathrm{Transp}_g(t, h) = h.$$

Indeed, if $H \in t$ and $X \in g_{\alpha}$, one has $[H, X] = \alpha(H)X$, where $\alpha : t \rightarrow 0_S$ is the derived morphism of α . Now condition (iv') says precisely that $\alpha \neq 0$ for every $\alpha \in R$.

****Corollary 5.3.3.**** *Let S be a scheme, G an S -group of type (RA), H and H' two subgroups of type (R) of G , h and h' their Lie algebras. Then*

<!-- label: III.XXII.5.3.3 -->

```
```text
H = H' ⇔ h = h'.
```
```

Corollary 5.3.4. Under the conditions of 5.2.7, with G of type (RA), the maps

```
<!-- label: III.XXII.5.3.4 -->
```

```
```text
H ↦ Lie(H/S), h ↦ Norm_G(h)°
```
```

realize a bijective correspondence between the set of subgroups of type (R) of G containing T and the set of Lie subalgebras of $\mathfrak{g}$ containing $\mathfrak{g}^{\{0\}}$, stable under T , and whose normalizer in G is smooth over S at every point of the unit section.*

[^N.D.E-XXII-31] Indeed, let $\mathfrak{h}$ be a Lie subalgebra of $\mathfrak{g}$ having the above properties. By 5.3.0, $H = \text{Norm}_G(\mathfrak{h})^{\{0\}}$ is a smooth S -group scheme. Moreover, since $C = \text{Centr}_G(T)$ stabilizes each $\mathfrak{g}^\alpha$ and has connected fibers (XII 6.6), one has $C \subset H$. Therefore H is a subgroup of G of type (R). By Exp. II 5.3.1, one has $\text{Lie}(H) = \text{Norm}_{\mathfrak{g}}(\mathfrak{h})$. Finally, by the proof of 5.3.2, one has $\text{Norm}_G(\mathfrak{h}) = h$.

Corollary 5.3.5. Let S be a scheme, G an S -group of type (RR) (5.1.1), T a maximal torus of G , H and H' two subgroups of type (R) of G , both containing T . Then

```
<!-- label: III.XXII.5.3.5 -->
```

```
```text
H = H' ⇔ h = h'.
```
```

By virtue of the finite presentation hypotheses, one reduces as usual (cf. EGA IV₃, § 8 and Exp. VI_B § 10) to the case where S is noetherian; it suffices then to verify that $h = h'$ implies $H_{\{S'\}} = H'_{\{S'\}}$ for every S' spectrum of an artinian quotient of a local ring of S ;[^N.D.E-XXII-32] one is thus reduced to the case where S is artinian, and one may apply 5.1.8. Let $u : G \rightarrow G' = G/Z$ be the canonical morphism and $T' = T/Z$ the maximal torus of G' corresponding to T . By Exp. XII 7.12, there exist subgroups of type (R) $H_{\{1\}}$ and $H'_{\{1\}}$ of G' , containing T' , such that $H = u^{-1}(H_{\{1\}})$ and $H' = u^{-1}(H'_{\{1\}})$. It suffices to prove that $H_{\{1\}} = H'_{\{1\}}$. But by 5.2.7 and 5.1.5, one has

```
$$
\text{Lie}(H_{\{1\}}) = \text{Lie}(H'_{\{1\}}),
$$
```

and one reduces to 5.3.3.

Remark 5.3.6. The fact that H and H' contain the same maximal torus is essential for the validity of 5.3.5 when G is not of type (RA). Example: maximal tori of SL_2 , k for k of characteristic 2.[^N.D.E-XXII-33]

```
<!-- label: III.XXII.5.3.6 -->
```

Corollary 5.3.7. Let S be a scheme, G an S -group of type (RR), T a maximal torus of G , H and H' two subgroups of type (R) of G , both containing T . The set U of $s \in S$ such that $H_{\{s\}} = H'_{\{s\}}$ is open and closed in S and $H_{\{U\}} = H'_{\{U\}}$.*

```
<!-- label: III.XXII.5.3.7 -->
```

Indeed, this follows immediately from 5.3.5 and 5.2.7.

Corollary 5.3.8. The "functor of subgroups of type (R) containing T ", where T is a given maximal torus in a group G of type (RR), is formally unramified (Exp. XI 1.1).*

```
<!-- label: III.XXII.5.3.8 -->
```

Theorem 5.3.9. Let G be an S -group of type (RR) (5.1.1), H and H' two subgroups of type (R) (5.2.1). Let $\text{Transt}_G(H, H')$ be the strict transporter of H into H' defined by

<!-- label: III.XXII.5.3.9 -->

```
```text
Transt_G(H, H')(S') = {g ∈ G(S') | int(g) H_{S'} = H'_{S'}}.
```

\*Then  $\text{Transt}_G(H, H')$  is representable by a closed subscheme of  $G_S$ , which is smooth and of finite presentation over  $S_S$ .\*

The fact that  $\text{Transt}_G(H, H')$  is representable by a closed subscheme of  $G_S$ , of finite presentation over  $S_S$ , follows from Exp. XI 6.11 (a). To prove that it is smooth over  $S_S$ , we must show that if  $S_S$  is affine and  $S_{\{0\}}$  is the closed subscheme defined by a nilpotent ideal  $J_S$ , and if  $g_{\{0\}} \in G(S_{\{0\}})$  and  $\text{int}(g_{\{0\}}) H_{\{0\}} = H'_{\{0\}}$ , there exists  $g \in G(S)$  projecting to  $g_{\{0\}}$  and such that  $\text{int}(g) H = H'$ . Since the question of smoothness is local for the étale topology, we may suppose that  $H_S$  contains a maximal torus  $T_S$  of  $G_S$ .

Then  $T_{\{0\}}$  is a maximal torus of  $H_{\{0\}}$ , hence  $\text{int}(g_{\{0\}}) T_{\{0\}}$  is a maximal torus of  $H'_{\{0\}}$ . By Exp. IX 3.6 bis, there exists a torus  $T'$  of  $H'$  such that  $T'_{\{0\}} = \text{int}(g_{\{0\}}) T_{\{0\}}$ ; by Exp. IX 3.3 bis, there thus exists  $g \in G(S)$  projecting to  $g_{\{0\}}$  and such that  $\text{int}(g) T = T'$ . Replacing  $H_S$  by  $\text{int}(g) H$  if necessary, we may therefore suppose that  $H_S$  and  $H'_S$  contain the same maximal torus  $T_S$  and that  $H_{\{0\}} = H'_{\{0\}}$ . But then  $H = H'$  by 5.3.7. QED.

**Corollary 5.3.10.** \*Let  $G_S$  be an  $S_S$ -group of type (RR),  $H_S$  a subgroup of type (R) of  $G_S$ . Then  $\text{Norm}_G(H)$  is representable by a closed group subscheme of  $G_S$ , of finite presentation and smooth over  $S_S$ .\*

<!-- label: III.XXII.5.3.10 -->

Using now the reasoning that, in Exp. XI, served to deduce 5.4 bis from 5.2 bis, one obtains:

**Corollary 5.3.11.** \*Under the hypotheses of 5.3.9, the following conditions are equivalent:\*

<!-- label: III.XXII.5.3.11 -->

(i)  $H_S$  and  $H'_S$  are locally conjugate in  $G_S$  for the étale topology.\*

(i bis) idem for the (fpqc) topology.\*

(ii) For every  $s \in S$ ,  $H_{\{s\}}$  and  $H'_{\{s\}}$  are conjugate by an element of  $G(s)_S$ .\*

(ii bis) The structural morphism  $\text{Transt}_G(H, H') \rightarrow S$  is surjective.\*

(iii)  $\text{Transt}_G(H, H')$  is a principal homogeneous bundle under the action of the smooth  $S_S$ -group scheme of finite presentation  $\text{Norm}_G(H)_S$ .\*

Let us simply remark that the non-trivial assertion (iii)  $\Rightarrow$  (i) is Hensel's lemma.

Using now Bible, § 6.4, th. 4 (= [Ch05], § 6.5 th. 5) and § 9.3, th. 1, one obtains by 5.3.10 and 5.3.11:

**Corollary 5.3.12.** \*Let  $G_S$  be an  $S_S$ -group of type (RR). The Borel subgroups of  $G_S$  are closed in  $G_S$ , equal to their normalizer, and conjugate locally for the étale topology.\*

<!-- label: III.XXII.5.3.12 -->

**Definition 5.3.13.** \*Let  $S_S$  be a scheme,  $G_S$  a smooth  $S_S$ -group scheme of finite presentation with connected fibers. [N.D.E-XXII-34] By a Killing couple of  $G_S$  we mean a couple  $T \subset B$ , where  $T_S$  is a maximal torus of  $G_S$  and  $B_S$  a Borel subgroup of  $G_S$  containing  $T_S$ .\*

<!-- label: III.XXII.5.3.13 -->

Using now the conjugacy of the maximal tori in  $B_S$  (cf. 5.1.2 (a) and 5.2.6, for example), one has:

**Corollary 5.3.14.** \*Let  $G_S$  be an  $S_S$ -group of type (RR). The Killing couples of  $G_S$  are conjugate locally for the étale topology.\*

<!-- label: III.XXII.5.3.14 -->

**\*\*Corollary 5.3.15.\*\*** \*Let  $G$  be an  $S$ -group of type  $(RR)$ . Let  $T$  be a maximal torus of  $G$ ,  $W_{\{G\}}(T) = \text{Norm}_{\{G\}}(T)/\text{Centr}_{\{G\}}(T)$  the corresponding Weyl group (Exp. XIX 6.3). The "functor of Borel subgroups of  $G$  containing  $T$ " is formally principal homogeneous under  $W_{\{G\}}(T)$ .\*

<!-- label: III.XXII.5.3.15 -->

This follows immediately from 5.3.14 and from the fact that if  $B$  is a Borel subgroup of  $G$  containing  $T$ , one has

$$\text{Norm}_{\{G\}}(T) \cap B = \text{Centr}_{\{G\}}(T),$$

cf. Exp. XIV 4.4.

**\*\*Proposition 5.3.16.\*\*** \*Let  $G$  be an  $S$ -group of type  $(RR)$ ,  $H$  a subgroup of type  $(R)$ ,  $N = \text{Norm}_{\{G\}}(H)$  its normalizer (5.3.10). Let  $T$  be a maximal torus of  $H$ ,  $W_{\{H\}}(T)$  and  $W_{\{N\}}(T)$  the corresponding Weyl groups (étale, quasi-finite, separated by Exp. XIX 6.3). One has the following exact sequence of sheaves (for the étale topology) (the morphisms are induced by the morphisms  $\text{Norm}_{\{H\}}(T) \rightarrow \text{Norm}_{\{N\}}(T) \rightarrow N/H$ ):\*

<!-- label: III.XXII.5.3.16 -->

$$1 \rightarrow W_{\{H\}}(T) \rightarrow W_{\{N\}}(T) \rightarrow N/H \rightarrow 1.$$

The only non-trivial point is that the last arrow is an epimorphism. So let  $n \in N(S')$ ,  $S' \rightarrow S$ . The two maximal tori  $T$  and  $\text{int}(n)T$  of  $H$  are conjugate in  $H$  locally for the étale topology. There thus exists a covering family  $\{S'_i \rightarrow S'\}$  and for each  $i$  an  $h_i \in H(S'_i)$  such that  $\text{int}(h_i)T = \text{int}(n)T$ . Hence  $n h_i^{-1} \in \text{Norm}_{\{N\}}(T)$ , which gives the desired result.

**\*\*Remark 5.3.17.\*\*** \*One can describe  $W_{\{N\}}(T)$  as follows: suppose we are reduced to the situation of 5.2.7, with  $h = g_{\{R\}}$ . Then  $W_{\{N\}}(T)$  equals  $\text{Norm}_{\{W\}}(R)$ , the sheaf of sections of  $W = W_{\{G\}}(T)$  that, acting on  $R$ , normalize  $R$ . Indeed, by 5.3.5, one has\*

<!-- label: III.XXII.5.3.17 -->

$$\text{Norm}_N(T) = \text{Norm}_G(H) \cap \text{Norm}_G(T) = \text{Norm}_G(h) \cap \text{Norm}_G(T).$$

**\*\*Corollary 5.3.18.\*\*** \*Let  $G$  be an  $S$ -group of type  $(RR)$ ,  $H$  a subgroup of type  $(R)$ . Suppose that "the Weyl groups of  $G$  are finite", i.e. that for every  $S' \rightarrow S$  and every maximal torus  $T$  of  $G_{\{S'\}}$ , the étale  $S'$ -scheme  $\text{Norm}_{\{G_{\{S'\}}\}}(T)/\text{Centr}_{\{G_{\{S'\}}\}}(T)$  is finite (cf. Exp. XIX 6.3 (iii)). The following conditions are equivalent:\*

<!-- label: III.XXII.5.3.18 -->

- \*(i)  $H$  is closed in  $G$ .\*
- \*(ii)  $\text{Norm}_{\{G\}}(H)/H$  is representable by a finite étale  $S$ -scheme.\*
- \*(iii) "The Weyl groups of  $H$  are finite".\*

Indeed, one may suppose that  $H$  possesses a maximal torus  $T$ . By 5.3.10,  $N = \text{Norm}_{\{G\}}(H)$  is closed in  $G$ , so  $W_{\{N\}}(T)$  is closed in  $W_{\{G\}}(T)$  and hence finite over  $S$ . One obviously has (i)  $\Rightarrow$  (iii), and (iii)  $\Rightarrow$  (ii) by the exact sequence of 5.3.16. Finally, (ii)  $\Rightarrow$  (i), because if  $N/H$  is finite, it is separated, so  $H$  is closed in  $N$ , hence in  $G$ .

**\*\*Remark 5.3.19.\*\*** \*When  $G$  is reductive, the preceding conditions on  $H$  seem always satisfied. We prove them below in most cases.\*

<!-- label: III.XXII.5.3.19 -->

### 5.4. Subgroups of type  $(R)$  of a split reductive group (generalities)

<!-- label: III.XXII.5.4 -->

### 5.4.1.

<!-- label: III.XXII.5.4.1 -->

If  $H$  is a subgroup of type (R) of the reductive group  $G$ , then  $H$  contains locally, for the étale topology, a maximal torus of  $G$  (5.2.2). By 2.3, one may, locally for the étale topology, suppose  $G$  split relative to this torus. Let then  $(G, T, M, R)$  be an  $S$ -split group,  $H$  a subgroup of type (R) of  $G$  containing  $T$ . By 5.3.5, such a subgroup is characterized by its Lie algebra, which (5.2.7) is locally on  $S$  of the form  $\mathfrak{g}_{R'}$ :

```
```text
 $\mathfrak{g}_{R'} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R'} \mathfrak{g}_{\alpha}.$ 
```

Definition 5.4.2. Let (G, T, M, R) be an S -split group. We shall say that the subset R' of R is of type (R) if $\mathfrak{g}_{R'}$ is the Lie algebra of a subgroup of type (R) of G containing T . This subgroup, uniquely determined by R' , is denoted $H_{R'}$.

<!-- label: III.XXII.5.4.2 -->

Lemma 5.4.3. Under the preceding conditions, one has the following equivalences:

<!-- label: III.XXII.5.4.3 -->

```
```text

$$\begin{aligned} H \cap Z_{\alpha} = T &\Leftrightarrow \alpha \notin R', \quad -\alpha \notin R', \\ H \supset U_{\alpha} &\Leftrightarrow \alpha \in R', \\ H \cap U_{\alpha} = e &\Leftrightarrow \alpha \notin R', \\ H \supset Z_{\alpha} &\Leftrightarrow \alpha \in R', \quad -\alpha \in R'. \end{aligned}$$

```

Indeed,  $H \cap Z_{\alpha}$  is a subgroup of type (R) of  $Z_{\alpha}$ , by 5.2.5; but a subgroup of type (R) of  $Z_{\alpha}$  containing  $T$  is locally equal to one of the following subgroups:  $T$ ,  $T \cdot U_{\alpha}$ ,  $T \cdot U_{-\alpha}$ ,  $Z_{\alpha}$ , by 5.3.5.

**Lemma 5.4.4.** Under the conditions of 5.4.2, let  $R_+$  be a system of positive roots; choose orderings on  $R' \cap R_+$  and  $R' \cap -R_+$ . The morphism

<!-- label: III.XXII.5.4.4 -->

```
```text

$$\Omega_{R_+, R'} = \prod_{\alpha \in R' \cap -R_+} U_{\alpha} \times_S T \times_S \prod_{\alpha \in R' \cap R_+} U_{\alpha} \rightarrow G$$

```

induced by the product in G induces an open immersion

```
$$
\Omega_{R_+, R'} \rightarrow H_{R'}.
$$
```

Indeed, by 5.4.3, this morphism factors through $H_{R'}$ and thus induces an immersion $\Omega_{R_+, R'} \rightarrow H_{R'}$. One then argues as in 4.1.1.

Proposition 5.4.5. Let (G, T, M, R) be an S -split group. Let R' and R'' be two subsets of R of type (R).

<!-- label: III.XXII.5.4.5 -->

(i) $H_{R'} \cap H_{R''}$ is smooth at every point of the unit section, $R' \cap R''$ is of type (R), and one has

```
```text

$$(H_{R'} \cap H_{R''})^{\circ} = H_{R' \cap R''}.$$

```

(ii) One has the equivalence

```

```text

$$H_{\mathbb{A}^1}(\mathcal{R}') \subset H_{\mathbb{A}^1}(\mathcal{R}'') \iff \mathcal{R}' \subset \mathcal{R}''.$$

```

Indeed, (ii) follows immediately from (i). To prove (i), it suffices to show that $H_{\mathbb{A}^1}(\mathcal{R}') \cap H_{\mathbb{A}^1}(\mathcal{R}'')$ is smooth at every point of the unit section: its neutral component (cf. Exp. VI_B 3.10) will then be a subgroup of type (R) containing $\mathcal{T}$, hence equal to $H_{\mathbb{A}^1}(\mathcal{R}' \cap \mathcal{R}'')$; but $\Omega_{\mathbb{A}^1}(\mathcal{R}^+, \mathcal{R}') \cap \Omega_{\mathbb{A}^1}(\mathcal{R}^+, \mathcal{R}'') = \Omega_{\mathbb{A}^1}(\mathcal{R}^+, \mathcal{R}' \cap \mathcal{R}'')$ is an open subset of $H_{\mathbb{A}^1}(\mathcal{R}') \cap H_{\mathbb{A}^1}(\mathcal{R}'')$ containing the unit section and smooth over $\mathcal{S}$.

Corollary 5.4.6. Let $\mathcal{S}$ be a scheme, G an $\mathcal{S}$ -reductive group, T a maximal torus of G , s a point of $\mathcal{S}$. If H and H' are two subgroups of type (R) of G containing T such that $H_{\mathbb{A}^1}(s) \subset H'_{\mathbb{A}^1}(s)$, there exists an open subset U of $\mathcal{S}$ containing s such that $H_{\mathbb{A}^1}(U) \subset H'_{\mathbb{A}^1}(U)$.

```

<!-- label: III.XXII.5.4.6 -->

```

Indeed, one may suppose G split relative to T . The assertion then follows immediately from 5.4.5 (ii).

One is led to ask which subsets $\mathcal{R}'$ of $\mathcal{R}$ are of type (R). One may suppose the group adjoint; one then has to verify that $\mathfrak{g}_{\mathbb{A}^1}(\mathcal{R}')$ is a Lie algebra and that its normalizer is smooth at every point of the unit section. The most important case is given by:

Theorem 5.4.7. Every closed subset $\mathcal{R}'$ of $\mathcal{R}$ is of type (R). (Recall, cf. Exp. XXI 3.1.4, that $\mathcal{R}' \subset \mathcal{R}$ is called closed if $\alpha, \beta \in \mathcal{R}'$, $\alpha + \beta \in \mathcal{R}$ entail $\alpha + \beta \in \mathcal{R}'$.)

```

<!-- label: III.XXII.5.4.7 -->

```

Remark 5.4.8. We shall see later (Exp. XXIII 6.6) that if $\ell \equiv 1 \pmod{N.D.E-XXII-35}$ (for example, if $\mathcal{S}$ has residue characteristic distinct from 2 and 3), the fact that $\mathfrak{g}_{\mathbb{A}^1}(\mathcal{R}')$ is a Lie algebra already entails that $\mathcal{R}'$ is closed, so $\mathcal{R}'$ is of type (R) if and only if it is closed. Theorem 5.4.7 thus gives all subsets of type (R) "independent of the characteristic".

```

<!-- label: III.XXII.5.4.8 -->

```

Let us first prove:

Lemma 5.4.9. Choose for each $\alpha \in \mathcal{R}$ an $X_{\alpha} \in \Gamma(S, \mathcal{G}_{\alpha})$. Let $\alpha, \beta \in \mathcal{R}$, with $\alpha + \beta \neq 0$ and let q be the largest integer i such that $\alpha + i\beta \in \mathcal{R}$. There exist sections $M_{\alpha, \beta, i} \in \Gamma(S, \mathcal{O}_{\mathcal{S}})$, uniquely determined, such that

```

<!-- label: III.XXII.5.4.9 -->

```

```

```text

$$\mathrm{Ad}(\exp(xX_{\alpha}))(X_{\beta}) = X_{\beta} + \sum_{i=1}^q M_{\alpha, \beta, i} x^i X_{\beta+i\alpha},$$

```

for every  $x \in \mathcal{G}(S')$ ,  $S' \rightarrow S$ .

Indeed,  $x \mapsto \mathrm{Ad}(\exp(xX_{\alpha}))(X_{\beta})$  defines a morphism  $\mathcal{G}_{\alpha, S} \rightarrow W(g) \simeq \mathcal{G}_{m_{\alpha, S}}$ . There thus exist sections  $Y_n \in \Gamma(S, \mathcal{G}_{\alpha, S})$ , uniquely determined, such that

```

```text

$$\mathrm{Ad}(\exp(xX_{\alpha}))(X_{\beta}) = \sum_{n \geq 0} x^n Y_n.$$

```

Applying the inner automorphism defined by a section t of T , one finds immediately

```

```text

$$\mathrm{Ad}(t)(Y_n) = \beta(t) \alpha(t)^n Y_n,$$

```

which entails  $Y_n \in \Gamma(S, \mathcal{G}^{\beta+n\alpha})$ . Since  $\alpha$  and  $\beta$  are not proportional, none of the  $\beta + n\alpha$  is zero; one thus has  $Y_n = 0$  for  $n > q$ ,  $Y_n = M_{\alpha, \beta, n} X_{\beta+n\alpha}$  for  $n \leq q$ , where  $M_{\alpha, \beta, n} \in \mathcal{G}_{\alpha, S}$  is uniquely determined. Setting  $x = 0$  in the formula obtained, one finds  $Y_0 = X_{\beta}$ , which completes the proof.

**\*\*Remark 5.4.10.\*\*** \*Differentiating the preceding formula at  $x = 0$ , one finds\*

<!-- label: III.XXII.5.4.10 -->

```

```text

$$[X_\alpha, X_\beta] = \begin{cases} N_{\alpha,\beta} X_{\alpha+\beta}, & \text{where } N_{\alpha,\beta} = M_{\alpha,\beta}, 1, \text{ if } \alpha + \beta \in R, \\ 0 & \text{if } \alpha + \beta \notin R, \alpha + \beta \neq 0. \end{cases}$$

```

```

Let us now prove 5.4.7. If  $R'$  is a closed subset of  $R$ , then  $\mathfrak{g}_{R'}$  is a Lie subalgebra of  $\mathfrak{g}$ , by 5.4.10 and Exp. XX 2.10, formula (3). By 5.4.9 and Exp. XX 2.10, formula (2),  $U_\alpha$  normalizes  $\mathfrak{g}_{R'}$  for each  $\alpha \in R'$ . Choose a system of positive roots  $R_+$  and consider the open set  $\Omega_{R_+}$  of 4.1.2; let  $\Omega_{R_+, R'}$  be the closed subscheme of  $\Omega_{R_+}$  defined as follows:

```

```text

$$\Omega_{R_+, R'} = \bigcap_{\alpha \in R' \cap -R_+} U_\alpha \cdot T \cdot \bigcap_{\alpha \in R' \cap R_+} U_\alpha.$$

```

```

The canonical immersion  $\Omega_{R_+, R'} \rightarrow G$  factors through  $\mathfrak{i} : \Omega_{R_+, R'} \rightarrow \text{Norm}_G(\mathfrak{g}_{R'})$ . Suppose  $G$  adjoint; the tangent map of  $\mathfrak{i}$  at the points of the unit section is bijective by 5.3.2; in particular, the morphism  $\mathfrak{i}$  is étale at every point of the unit section, hence is a local immersion [N.D.E-XXII-36] at every point of the unit section, hence  $\text{Norm}_G(\mathfrak{g}_{R'})$  is smooth at every point of the unit section, as was to be shown.

### ### 5.5. Borel subgroups of a split reductive group

<!-- label: III.XXII.5.5 -->

**\*\*Proposition 5.5.1.\*\*** \*Let  $(G, T, M, R)$  be an  $S$ -split group. For every system of positive roots  $R_+$  of  $R$ ,  $H_{R_+}$  (which exists by 5.4.7) is a Borel subgroup of  $G$  and, for every ordering on  $R_+$ , the morphism induced by the product in  $G$ \*

<!-- label: III.XXII.5.5.1 -->

```

```text

$$T \times_S \bigcap_{\alpha \in R_+} U_\alpha \rightarrow G$$

```

```

\*is a closed immersion with image  $H_{R_+}$ . One writes  $B_{R_+} = H_{R_+}$ .\*

By definition of the Borel subgroups, the first assertion may be verified by replacing  $S$  by the spectrum of an algebraically closed field. Let  $B$  be the Borel subgroup of  $G$  containing  $T$  and corresponding to the system of positive roots  $R_+$  (Bible, § 10.4, prop. 9); the Lie algebra of  $B$  is  $\mathfrak{g}_{R_+}$ ; one therefore has  $B = H_{R_+}$  by 5.3.5.

Let us prove the second assertion: the morphism in the statement induces an open immersion  $\mathfrak{i} : T \times_S \prod_{\alpha \in R_+} U_\alpha \rightarrow H_{R_+}$  (5.4.4). Now  $\mathfrak{i}$  is surjective (Bible, § 15.1, cor. 1 to prop. 1).

**\*\*Corollary 5.5.2.\*\*** \*Choose an arbitrary ordering on  $R_+$  and for each  $\alpha \in R_+$  an  $X_\alpha \in \Gamma(S, \mathfrak{g}_\alpha)$ . Let  $\alpha, \beta \in R_+$ . For each pair  $(i, j) \in \mathbb{N}^*$  such that  $i\alpha + j\beta \in R$ , there exists a unique section\*

<!-- label: III.XXII.5.5.2 -->

```

$$C_{i,j,\alpha,\beta} \in \Gamma(S, \mathcal{O}_S)$$

```

\*such that, for all  $x, y \in \mathfrak{g}_{S'}$ ,  $S' \rightarrow S$ , one has\*

```

```text

$$\exp_\alpha(xX_\alpha) \exp_\beta(yX_\beta) \exp_\alpha(xX_\alpha)^{-1} = \exp_\beta(yX_\beta) \prod_{i,j \in \mathbb{N}^*, i\alpha+j\beta \in R} \exp_{i\alpha+j\beta}(C_{i,j,\alpha,\beta} x^i y^j X_{i\alpha+j\beta}).$$

```

```

If  $\alpha = \beta$ , the assertion is trivial. Suppose therefore  $\alpha \neq \beta$ ; then, by virtue of the proposition, there exist unique morphisms

```

```text
F0 : G2{a,S} → T,      Fγ : G2{a,S} → Ga,S      (γ ∈ R+)
```

```

such that one has

```

```text
exp(xXα) exp(yXβ) exp(xXα)-1 = F0(x, y) ∏{γ ∈ R+} exp(Fγ(x, y) Xγ).
```

```

Let  $t \in T(S')$ ,  $S' \rightarrow S$ . Let  $\text{int}(t)$  act on this formula; one immediately has the relations

```

```text
(1)  F0(α(t) x, β(t) y) = F0(x, y),
(2)  Fγ(α(t) x, β(t) y) = γ(t) Fγ(x, y).
```

```

Since  $\alpha$  and  $\beta$  are two linearly independent characters (over  $\mathbb{Q}$ ) of  $T$ , one concludes as usual from the first relation that  $F_0$  is constant, so  $F_0(x, y) = e$ . Write next

```

```text
Fγ(x, y) = ∑ aij xi yj,      with aij ∈ Γ(S, 0S).
```

```

Substituting in relation (2) and identifying the polynomials of the two sides, one finds

```

```text
aij (α(t)i β(t)j - γ(t)) = 0.
```

```

If  $\gamma \neq i\alpha + j\beta$ , one knows (Exp. XIX 4.13) that there exists an  $S' \rightarrow S$  faithfully flat quasi-compact and a  $t \in T(S')$  such that  $\alpha(t)^i \beta(t)^j - \gamma(t) = 1$ . One thus has  $a_{ij} = 0$  on  $S'$ , hence on  $S$ . If  $\gamma = i\alpha + j\beta$ , one sets  $a_{ij} = C_{i,j,\alpha,\beta}$ . Setting  $x = 0$  (resp.  $y = 0$ ), one finds  $C_{0,1,\alpha,\beta} = 1$  (resp.  $C_{1,0,\alpha,\beta} = 0$ ).

**Remark 5.5.3.** Differentiating at  $y = 0$  and comparing with 5.4.9, one finds\*

<!-- label: III.XXII.5.5.3 -->

```

$$
C_{i,1,\alpha,\beta} = M_{\alpha,\beta,i}.
$$

```

**Corollary 5.5.4.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ ,  $\alpha \neq \beta$  two roots of  $G$  relative to  $T$  such that  $\alpha + \beta$  is non-trivial on every fiber. Order the set of  $i\alpha + j\beta$  ( $i, j \in \mathbb{N}$ ) in an arbitrary way. For all  $i, j \in \mathbb{N}$  such that  $i\alpha + j\beta \in R$ , there exists a unique morphism of  $0_S$ -modules\*

<!-- label: III.XXII.5.5.4 -->

```

```text
fα,β,i,j : (gα){i} ⊗ (gβ){j} → g{iα+jβ}
```

```

\*such that for every  $S' \rightarrow S$  and every  $X \in W(g\alpha)(S')$ ,  $Y \in W(g\beta)(S')$  one has (the 'exp' on the right being taken in the sense of 1.2[N.D.E-XXII-37]):\*

```

```text
expα(X) expβ(Y) expα(-X) = expβ(Y) ∏{(i,j)} expiα+jβ(fα,β,i,j(Xi ⊗ Yj)).
```

```

The assertion is local for (fpqc). By § 2, one may therefore suppose  $G$  split relative to  $T$ , and  $\alpha$  and  $\beta$

constant in the splitting. Since  $\alpha + \beta \neq 0$ , there exists a system of positive roots  $R^+$  containing  $\alpha$  and  $\beta$  (Exp. XXI 3.5.4), and one is reduced to 5.5.2.

**Corollary 5.5.5.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group.\*

<!-- label: III.XXII.5.5.5 -->

(i)  $G$  possesses Borel subgroups locally for the étale topology. If  $T$  is a maximal torus of  $G$ , then  $G$  also possesses Borel subgroups containing  $T$  locally for the étale topology.\*

(ii) If  $T$  is a maximal torus of  $G$ , the "functor of Borel subgroups of  $G$  containing  $T$ " is representable by a principal homogeneous bundle under  $W_G(T)$ .\*

(iii) If  $(G, T, M, R)$  is split, every Borel subgroup  $B$  of  $G$  containing  $T$  is locally on  $S$  of the form  $B_{R^+}$ , where  $R^+$  is a system of positive roots of  $R$ .\*

(iv) If  $T \subset B$  is a Killing couple of  $G$ , there exists a covering family  $\{S_i \rightarrow S\}$  for the étale topology, and for each  $i$  a splitting  $(G_{S_i}, T_{S_i}, M_i, R_i)$  and a system of positive roots  $R_{i+}$  of  $R_i$  such that  $B_{S_i} = B_{R_{i+}}$ .\*

Indeed, (i) follows from 2.3 and 5.5.1, (ii) from (i) and 5.3.15, (iii) from (ii) and 5.5.1, (iv) from (iii) and 2.3.

**Lemma 5.5.6.** Choose on the group  $\Gamma(R)$  generated by the roots a structure of totally ordered group such that the positive roots are the elements of  $R^+$  (cf. Exp. XXI 3.5.6). [N.D.E-XXII-38] Let  $\alpha_1 < \dots < \alpha_N$  be the elements of  $R^+$ . Consider the isomorphism\*

<!-- label: III.XXII.5.5.6 -->

text  
 $f : T \times_S U_{\alpha_1} \times_S \dots \times_S U_{\alpha_N} \rightarrow B_{R^+}$

induced by the product in  $G$ . Set for  $i = 1, \dots, N$ :

text  
 $U_{[i]} = f(U_{\alpha_1} \times_S \dots \times_S U_{\alpha_N})$ .

(i) Each  $U_{\geq i}$  is a normal subgroup of  $B_{R^+}$ .\*

(ii) For  $1 \leq i \leq N - 1$ ,  $U_{\geq i}$  is identified with the semi-direct product\*

$$U_{\geq i} = U_{\alpha_i} \cdot U_{\geq i+1}.$$

(iii)  $B_{R^+}$  is identified with the semi-direct product\*

$$B_{R^+} = T \cdot U_{\geq 1}.$$

(iv) For  $1 \leq i \leq N - 1$ , the inner automorphisms of  $U_{\geq 1}$  act trivially on  $U_{\geq i}/U_{\geq i+1}$  (which is identified with  $U_{\alpha_i}$  by (ii)).\*

Let us first prove by induction on  $i$  the following assertion:

$U_{\geq i}$  is a normal subgroup of  $B_{R^+}$ , semi-direct product of  $U_{\alpha_i}$  and  $U_{\geq i+1}$ .

The assertion is true for  $i = N$ ; suppose it for  $i + 1$  and let us prove it for  $i$ . One has (as schemes)

$$U_{\geq i} = U_{\alpha_i} \cdot U_{\geq i+1};$$

it is clear first that  $U_{\geq i}$  is stable under the inner automorphisms of  $B_{R+}$ . This is clear for  $\int(t)$ ,  $t \in T(S)$ ; it suffices to verify it for  $\int(x)$ ,  $x \in U_{\alpha}(S)$ ,  $\alpha \in R+$ . Now  $U_{\geq i+1}$  is supposed normal, so it suffices to see that  $\int(x) U_{\alpha_i} \subset U_{\geq i}$ . By 5.5.2, if  $y \in U_{\alpha_i}(S')$ , one has  $y^{-1} x y^{-1} \in U_{\geq i+1}(S')$ , which entails  $\int(x)(y) \in U_{\geq i}(S')$ .

Let us now prove that  $U_{\geq i}$  is a subgroup of  $B_{R+}$ . If  $x, y \in U_{\geq i}(S)$ , one may write  $x = p x'$ ,  $y = q y'$ , with  $p, q \in U_{\alpha_i}(S)$ , and  $x', y' \in U_{\geq i+1}(S)$ . One has

```

```text
xy = p x' q y' = pq(q^{-1} x' q) y' \in U_{\alpha_i}(S') U_{\geq i+1}(S');
```

```

similarly  $x^{-1} = p^{-1} (p x'^{-1} p^{-1}) \in U_{\alpha_i}(S') U_{\geq i+1}(S')$ . We have thus proved (i) and (ii), as well as (iv) along the way. As for (iii), it is a trivial consequence of 5.5.1.

**Lemma 5.5.7.** \*With the preceding notations, choose for each  $1 \leq i \leq N$  an  $X_i \in \Gamma(S, g_{\alpha_i})$  and consider the isomorphism\*

<!-- label: III.XXII.5.5.7 -->

```

$$
a : G^N_{a,S} \rightarrow U_{\geq 1}
$$

```

\*defined set-theoretically by\*

```

```text
a(x_1, ..., x_N) = exp_{\alpha_1}(x_1 X_1) \cdots exp_{\alpha_N}(x_N X_N).
```

```

\*There exists a unique family  $(Q_i)$ ,  $i = 1, \dots, N$ , of polynomials\*

```

```text
Q_i = Q_i(x_1, ..., x_N, y_1, ..., y_N)
```

```

\*with coefficients in  $\Gamma(S, 0_S)$  such that one has set-theoretically\*

```

```text
a(x_1, ..., x_N) a(y_1, ..., y_N) = a(Q_1(x_1, ..., y_N), ..., Q_N(x_1, ..., y_N)).
```

```

\*Furthermore, the  $Q_i$  have coefficients in the subring of  $\Gamma(S, 0_S)$  generated by the  $C_{i,j,\alpha,\beta}$  of 5.5.2 ( $\alpha, \beta \in R+$ ,  $i, j \in \mathbb{N}^*$ ) and each  $Q_i$  is of the form\*

```

```text
Q_i(x_1, ..., y_N) = x_i + y_i + Q'_i(x_1, ..., x_{i-1}, y_1, ..., y_{i-1}).
```

```

The existence and uniqueness of the  $Q_i$  follow immediately from the fact that  $a$  is an isomorphism of schemes. Denoting  $z, z', z''$  sections of  $U_{\geq i+1}$ , one has

```

```text
a(x_1, ..., x_N) a(y_1, ..., y_N) =
  a(x_1, ..., x_{i-1}, 0, ..., 0) exp(x_i X_i) z \cdot a(y_1, ..., y_{i-1}, 0, ..., 0) exp(y_i X_i) z';
```

```

using 5.5.6 (i) and (iv), the right-hand side is written

```

```text
a(x_1, ..., x_{i-1}, 0, ..., 0) a(y_1, ..., y_{i-1}, 0, ..., 0) exp((x_i + y_i) X_i) z'';
```

```

which gives, reusing 5.5.6,

```

```text

$$Q_i(x_1, \dots, x_N, y_1, \dots, y_N) = x_i + y_i + Q'_i(x_1, \dots, x_{i-1}, y_1, \dots, y_{i-1}),$$

```

```

with

```

```text

$$Q'_i(x_1, \dots, x_{i-1}, y_1, \dots, y_{i-1}) = Q_i(x_1, \dots, x_{i-1}, 0, \dots, 0, y_1, \dots, y_{i-1}, 0, \dots, 0);$$

```

```

that is, the precise form requested.

Let us prove finally the assertion on the coefficients of the polynomials  $Q_i$ . Let  $A$  be the subring of  $\Gamma(S, \mathcal{O}_S)$  generated by the  $C_{i,j,\alpha,\beta}$  ( $\alpha, \beta \in R$ ,  $i, j \in \mathbb{N}$ ). Let us prove by descending induction on  $i$  that if  $x_1 = \dots = x_{i-1} = 0$  and  $y_1 = \dots = y_{i-1} = 0$ , that is, if  $a(x_1, \dots, x_N)$  and  $a(y_1, \dots, y_N)$  are sections of  $\mathcal{O}_{\geq i}$ , then the polynomials

```

```text

$$R_j(x_1, \dots, x_N, y_1, \dots, y_N) = Q_j(x_1, \dots, x_N, y_1, \dots, y_N)$$

```

```

have coefficients in  $A$ . This is trivial for  $i = N$  and also for  $j < i$  (because  $R_j = 0$  for  $j < i$ ). Let  $i < N$ , suppose the assertion verified for  $i + 1$ , and let us prove it for  $i$  (and  $j \geq i$ ). One has

```

```text

$$a(0, \dots, 0, x_i, \dots, x_N) = \exp(x_i X_i) a(0, \dots, 0, x_{i+1}, \dots, x_N) = \exp(x_i X_i) Z_i.$$

```

```

Similarly write

```

```text

$$a(0, \dots, y_i, \dots, y_N) = \exp(y_i X_i) T_i.$$

```

```

One has

```

```text

$$a(0, \dots, x_i, \dots, x_N) a(0, \dots, y_i, \dots, y_N) = \exp((x_i + y_i) X_i) \int \exp(-y_i X_i) (Z_i) \cdot T_i.$$

```

```

Now

```

```text

$$\int \exp(-y_i X_i) (Z_i) = \int \exp(-y_i Y_i) (\exp(x_{i+1} X_{i+1}) \cdots \exp(x_N X_N))$$

```

```

is a product of  $N - i - 1$  sections of  $\mathcal{O}_{\geq i+1}$  whose coefficients in the decomposition  $\mathcal{O}_{\geq i+1} = \mathcal{O}_{\alpha_{i+1}} \cdots \mathcal{O}_{\alpha_N}$  are polynomials in  $y_i$  and  $x_{i+1}, \dots, x_N$  with coefficients in  $A$  (by 5.5.2). Applying the induction hypothesis, one deduces that the coefficients of

```

$$
\int \exp(-y_i X_i) (Z_i) \cdot T_i
$$

```

are also polynomials with coefficients in  $A$ , which finishes the proof.

Let us remark that the preceding induction immediately gives a proof of:

**Lemma 5.5.8.** With the notations of 5.5.6, let, for each  $i = 1, \dots, N$ , a morphism of groups\*

<!-- label: III.XXII.5.5.8 -->

```

$$
f_i : \mathcal{O}_{\alpha_i} \rightarrow H,

```

\$\$

\*where  $H$  is an  $S$ -group functor. For the morphism\*

\$\$

$f : U_{\backslash \text{geqslant } 1} \rightarrow H$

\$\$

\*defined by\*

```text

$f(\exp(x_1 X_1) \cdots \exp(x_N X_N)) = f_1(\exp(x_1 X_1)) \cdots f_N(\exp(x_N X_N))$

```

\*to be a morphism of groups, it is necessary and sufficient that for every pair  $i < j$ , one has\*

```text

$f_j(\exp(x_j X_j)) f_i(\exp(x_i X_i)) f_j(\exp(-x_j X_j)) = f(\exp(x_j X_j) \exp(x_i X_i) \exp(-x_j X_j)).$

```

### 5.6. Subgroups of type (R) with solvable fibers

<!-- label: III.XXII.5.6 -->

**Proposition 5.6.1.** \*Let  $(G, T, M, R)$  be an  $S$ -split group,  $R'$  a subset of  $R$  of type (R) (5.4.2),  $H_{\{R'\}}$  the corresponding subgroup of  $G$ . The following conditions are equivalent:\*

<!-- label: III.XXII.5.6.1 -->

(i)  $H_{\{R'\}}$  has solvable geometric fibers.\*

(ii) There exists a system of positive roots  $R_+$  such that  $R' \subset R_+$ , hence  $H_{\{R'\}} \subset B_{\{R_+\}}$  (cf. 5.4.5).\*

(iii)  $R' \cap -R' = \emptyset$ .\*

(iv) For every ordering on  $R$ , the morphism induced by the product in  $G$  is\*

```text

$T \times_S \prod_{\alpha \in R'} U_\alpha \rightarrow H_{\{R'\}}$

```

\*is an isomorphism.\*

(v)  $H_{\{R'\}} \cap \text{Norm}_{\{G\}}(T) = T$ .\*

(vi) For every subset  $R''$  of  $R$ , of type (R), one has (cf. 5.4.5)\*

```text

$H_{\{R'\}} \cap \text{Norm}_G(H_{\{R''\}}) = H_{\{R' \cap R''\}}.$

```

We shall prove these equivalences according to the logical scheme

\$\$

(iii)  $\Leftrightarrow$  (ii)  $\Rightarrow$  (vi)  $\Rightarrow$  (v)  $\Rightarrow$  (vi)  $\Rightarrow$  (iv)  $\Rightarrow$  (v)  $\Rightarrow$  (i)  $\Rightarrow$  (iii).

\$\$

One obviously has (ii)  $\Rightarrow$  (iii) and (vi)  $\Rightarrow$  (v) (take  $R'' = \emptyset$ ). By 5.4.6, it suffices to verify (i)  $\Rightarrow$  (ii) on geometric fibers; now if  $S$  is the spectrum of an algebraically closed field,  $H_{\{R'\}}$  is contained in a Borel subgroup containing  $T$ , so of the form  $H_{\{R_+\}}$  (5.5.5 (iii)).

Similarly (iii)  $\Rightarrow$  (i) is verified on geometric fibers; suppose (iii) is satisfied; if  $H_{\{R'\}}$  were not solvable, there

would exist a subtorus  $Q$  of  $T$ , of codimension 1 in  $T$ , such that  $\text{Centr}_{H_{R'}}(Q)$  is not solvable (Bible, § 10.4, prop. 8); now  $\text{Centr}_{H_{R'}}(Q)$  has Lie algebra  $\mathfrak{g}_{R'}$ , where  $R'$  is the set of roots of  $R$  vanishing on  $Q$ , so  $R' = \emptyset$  or  $\alpha$  (by virtue of (iii)); hence  $\text{Centr}_{H_{R'}}(Q)$ , which is a subgroup of type (R) of  $G$ , is  $T$  or  $T \cdot U_\alpha$ , hence solvable, contrary to the hypothesis.

Similarly (ii)  $\Rightarrow$  (iv) is verified on geometric fibers (since these are flat  $S$ -schemes of finite presentation); by Bible, § 13.2, th. 1 d), the morphism in question is bijective; it induces an isomorphism on the tangent spaces at the origin, and one concludes as usual (cf. 4.1.1).

One has (iv)  $\Rightarrow$  (v) by 4.2.7. To prove (v)  $\Rightarrow$  (i), one is again reduced to the case where  $S$  is the spectrum of an algebraically closed field, and one concludes by Bible, § 10.3, cor. to prop. 6 and § 9.3, cor. 3 to th. 1.

It thus remains only to prove the assertion (ii)  $\Rightarrow$  (vi). One may reduce to the case where  $G$  is adjoint. One then has, by 5.3.3,

```
```text
Norm_G(H_{R'}) = Norm_G(g_{R'}) \subset Transp_G(t, g_{R'}).
```

[^N.D.E-XXII-39] By 5.4.5, it suffices to prove

```
```text
(x) H_{R'}(S) \cap Transp_{G(S)}(t, g_{R'}) \subset H_{R' \cap R''}(S).
```

Let us first prove a lemma.

**\*Lemma 5.6.2.\*** \*In the notations of 5.5.7, let\*

<!-- label: III.XXII.5.6.2 -->

```
```text
u = exp(x_1 X_1) \cdots exp(x_N X_N)
```

where $x_i \in \mathfrak{g}_\alpha(S)$. Let m be an integer, $1 \leq m \leq N$, such that $x_i = 0$ for $i < m$.

***(a)** If $H \in \Gamma(S, t)$, the component of $\text{Ad}(u) H$ on $\mathfrak{g}^{\alpha_m}$ is*

```
$$
-\alpha_m(H) x_m X_m.
$$
```

***(b)** If $Y \in \Gamma(S, \mathfrak{g}^{-\alpha_m})$, the component of $\text{Ad}(u) Y$ on t is (with the notations of Exp. XX 2.6)*

```
```text
x_m \langle X_m, Y \rangle H_{\alpha_m}.
```

Denote indeed  $u = \mathfrak{g}^{\alpha_{m+1}} + \cdots + \mathfrak{g}^{\alpha_N}$ . By 5.4.9, one has

```
```text
Ad(exp(x_i X_i)) u \subset u,   for i > m.
```

By Exp. XX 2.10, one has

```
```text
Ad(exp(x_i X_i)) H = H - \alpha_i(H) x_i X_i.
```

This immediately gives, modulo  $u$ ,

```
```text
Ad(u) H = Ad(exp(x_m X_m)) H = H - \alpha_m(H) x_m X_m,
```

...

which entails the first result.

Likewise denote^[^N.D.E-XXII-40] $g_n = g^{\alpha_1} + \cdots + g^{\alpha_N}$ and $u_1 = \exp(x_{m+1} X_{m+1}) \cdots \exp(x_N X_N)$. For $i > m$, one has $\alpha_i > \alpha_m$ so, by 5.4.9, one has, modulo g_n ,

$$\text{Ad}(u_1) Y \equiv Y, \quad \text{whence} \quad \text{Ad}(u) Y \equiv \text{Ad}(\exp(x_m X_m)) Y.$$

Applying Exp. XX 2.10, one therefore obtains, modulo g_n ,

$$\text{Ad}(u) Y - Y \equiv x_m \langle X_m, Y \rangle H_{\alpha_m}$$

whence the second result.

Let us return to the proof of inclusion (x). Suppose that there exists $h \in H_{R'}(S)$, $h \notin H_{R' \cap R''}(S)$, such that

$$\text{Ad}(h) t \subset g_{R''}.$$

One may write

$$h = t \exp(x_1 X_1) \cdots \exp(x_N X_N).$$

Since $h \notin H_{R' \cap R''}(S)$, there exists a smallest m such that

$$t \exp(x_1 X_1) \cdots \exp(x_{m-1} X_{m-1}) \in H_{R' \cap R''}(S) \quad \text{and} \quad \alpha_m \notin R'', \quad x_m \neq 0.$$

Then $h' = \exp(x_m X_m) \cdots \exp(x_N X_N)$ also satisfies the conditions imposed on h above. But by 5.6.2, for every $H \in \Gamma(S, t)$ the component of $\text{Ad}(h') H$ on g^{α_m} is $-\alpha_m(H) x_m X_m$. By virtue of the hypothesis on h and on m , one has therefore $\alpha_m(H) = 0$ for every $H \in \Gamma(S, t)$, which is impossible (because G is supposed adjoint and α_m is therefore non-zero on every fiber).

Remark 5.6.2. bis. Resume the notations of 5.6.2. If $\text{Ad}(u)$ is the identity on t and on g^{α_m} , one has $x_m = 0$. Indeed, one has $x_m \alpha_m = 0$ and $x_m H_{\alpha_m} = 0$; if $\alpha_m \notin 2M$, then α_m is non-zero on every fiber; if $\alpha_m \in 2M$, then $\alpha_m^* \notin 2M^*$ and H_{α_m} is non-zero on every fiber; in each case, this entails $x_m = 0$. It follows that $u = e$ if $\text{Ad}(u)$ operates trivially on g .

<!-- label: III.XXII.5.6.2.bis -->

Remark 5.6.3. If H is a subgroup of type (R) of the reductive group G , with solvable geometric fibers, then H is closed in G and $\text{Norm}_G(H)/H$ is representable by a separated finite étale S -scheme.

<!-- label: III.XXII.5.6.3 -->

This follows from 5.3.18 and, at one's choice, 3.5 or Exp. XIX 2.5 (ii).

Corollary 5.6.4. Let (G, T, M, R) be a split reductive group. If $R' \subset R$ is closed and $R' \cap -R' = \emptyset$, then R' is contained in a system of positive roots.^[^N.D.E-XXII-41]

<!-- label: III.XXII.5.6.4 -->

Indeed, R' is of type (R) by 5.4.7, so the result follows from 5.6.1.

****Corollary 5.6.5.**** *Under the conditions of 5.6.1, the product in G induces an isomorphism*

<!-- label: III.XXII.5.6.5 -->

```text  
 $\prod_{\alpha \in R'} U_{\alpha} \cong U_{R'},$

\*where  $U_{R'}$  is a closed group subscheme of  $G$ , smooth over  $S$ , with connected and unipotent geometric fibers, independent of the choice of ordering on  $R'$ . Moreover,  $H_{R'}$  is the semi-direct product  $T \cdot U_{R'}$  ( $U_{R'}$  normal).\*

Indeed, if  $R' \subset R$ , then  $H_{R'} \cap U_{\geqslant 1}$  (notations of 5.5.6) is a closed subgroup of  $G$  of finite presentation, normal in  $H_{R'}$ . By 5.6.1 (iv), one has  $H_{R'} = T \cdot U_{R'}$ , which entails the other assertions.

**\*\*Remark 5.6.6.\*\*** \*In particular,  $U_{R+}$  is the group  $U_{\geqslant 1}$  of 5.5.6.\*

<!-- label: III.XXII.5.6.6 -->

Let us extract some corollaries of the preceding results concerning groups of type  $U_{R'}$ .

**\*\*Corollary 5.6.7.\*\*** \*Let  $(G, T, M, R)$  be a split reductive group,  $R'$  and  $R''$  two subsets of  $R$  of type  $(R)$ , with  $R' \cap R'' = \emptyset$ .\*

<!-- label: III.XXII.5.6.7 -->

**\*(i)** One has\*

```text  
 $U_{R'} \cap \text{Norm}_G(H_{R''}) = U_{R' \cap R''}.$

***(ii)** Suppose R' closed. If the conditions $\alpha \in R'$, $\beta \in R''$ and $\alpha + \beta \in R$ entail $\alpha + \beta \in R'$, then $H_{R''}$ normalizes $U_{R'}$.*

Indeed, (i) follows immediately from 5.6.5 and 5.6.1 (vi). To prove (ii), it suffices, by 5.4.4, to show that T and each U_{β} , $\beta \in R''$, normalize $U_{R'}$. [N.D.E-XXII-42] For T , this is trivial; for U_{β} , it follows from 5.5.2 and Exp. XXI 3.1.2. [N.D.E-XXII-43]

****Corollary 5.6.8.**** *Let (G, T, M, R) be an S -split group, $R+$ a system of positive roots, α a simple root of $R+$ (i.e. an element of $R+$ such that $R+ - \{\alpha\}$ is closed). Denote*

<!-- label: III.XXII.5.6.8 -->

\$\$
 $U_{\hat{\alpha}} = U_{R+ - \{\alpha\}}.$
 \$\$

Then

***(i)** $U_{\hat{\alpha}}$ is a normal subgroup of B_{R+} .*

***(ii)** U_{R+} is the semi-direct product of $U_{\hat{\alpha}}$ by U_{α} .*

***(iii)** $U_{-\alpha}$ normalizes $U_{\hat{\alpha}}$.*

***(iv)** Z_{α} normalizes $U_{\hat{\alpha}}$.*

If one defines similarly $U_{-\hat{\alpha}} = U_{R- - \{-\alpha\}}$ (where $R- = -R+$), one has

```text  
 $U_{R+} = U_{-\alpha^{\vee}} \cdot U_{-\alpha} \cdot T \cdot U_{\alpha} \cdot U_{\alpha^{\vee}}.$

Indeed, (ii) follows from 5.6.5, and (i) from 5.6.7 (ii). Similarly, (iii) follows from 5.5.2 (indeed, if  $\beta \in R$ ,  $\beta \neq \alpha$ , no combination  $i(-\alpha) + j\beta$ , with  $i, j > 0$ , can be negative because  $\beta$  contains at least one simple root  $\neq \alpha$ ). Then (iv) follows from (i) and (iii), because  $U_{-\alpha} \cdot T \cdot U_{\alpha}$  is schematically dense in  $Z_{\alpha}$ . Finally, the last assertion follows from (ii) and its analogue for  $U_{-R}$ .

Let us return to the general situation.

**Proposition 5.6.9.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $H$  a subgroup of type (R) with solvable geometric fibers.\*

<!-- label: III.XXII.5.6.9 -->

(i)  $D_{\{S\}}(H) = \operatorname{Hom}_{\{S\text{-gr}\}}(H, G_m, S)$  is representable by a twisted constant  $S$ -group, whose type at  $s \in S$  is  $\mathbb{Z}^{\operatorname{rg}_{\text{red}}(\bar{G}_s)}$ . The biduality morphism (Exp. VIII § 1)\*

$f : H \rightarrow D_{\{S\}}(D_{\{S\}}(H))$   
 $f$

is smooth and surjective.\*

(ii) The kernel  $H_u$  of  $f$  is the largest closed normal group subscheme of  $H$ , smooth over  $S$ , with connected and unipotent geometric fibers. We call it the\* unipotent part \*of  $H$  and write also  $H_u = \operatorname{rad}_u(H)$ .\*

Then  $H_u$  is also the sheaf of commutators of  $H$ : every morphism of groups from  $H$  to an  $S$ -presheaf of commutative groups separated for (fppf) vanishes on  $H_u$  and thus factors through  $H/H_u = D_{\{S\}}(D_{\{S\}}(H))$ .\*

(iii) If  $T$  is a maximal torus of  $H$ , the morphism  $T \rightarrow H$  induces isomorphisms  $D_{\{S\}}(H) \xrightarrow{\sim} D_{\{S\}}(T)$  and  $T \xrightarrow{\sim} D_{\{S\}}(D_{\{S\}}(H))$ . Furthermore,  $H$  is identified with the semi-direct product of  $H_u$  by  $T$ .\*

(iv) In the situation of 5.6.1, if  $H = H_{R'}$ , then  $H_u = U_{R'}$ .\*

The assertions of the proposition are local for the étale topology (Exp. X 5.5). One may therefore reduce to the case of 5.6.1. One then knows (5.6.5) that  $H_{R'}$  is the semi-direct product of  $U_{R'}$  by  $T$ . Let us show that  $U_{R'}$  is the sheaf of commutators of  $H_{R'}$ : since  $H_{R'}/U_{R'} = T$  is commutative, it suffices to prove that every morphism of groups  $\phi : H_{R'} \rightarrow V$  as in (ii) vanishes on  $U_{R'}$ . It suffices to prove that  $\phi$  vanishes on each  $U_{\alpha}$ ,  $\alpha \in R'$ . Now if  $t \in T(S)$ ,  $X \in W(g(\alpha)(S))$ , one has

text  
 $1 = \phi(t \exp(X) t^{-1} \exp(-X)) = \phi(\exp((\alpha(t) - 1) X)).$   
 text

Since  $\alpha : T \rightarrow G_m, S$  is faithfully flat, one deduces immediately that  $\phi$  vanishes on  $U_{\alpha}$ ; but every section of  $U_{\alpha}$  is locally the sum of two sections of  $U_{\alpha}$ . One thus has

text  
 $\operatorname{Hom}_{\{S\text{-gr}\}}(H, V) = \operatorname{Hom}_{\{S\text{-gr}\}}(H/U_{R'}, V)$   
 text

for every  $V$  as above. Applying this result to  $V = G_m, S$ , one deduces immediately (i) and (iii), then (iv) and the second assertion of (ii). It now suffices to prove the first assertion of (ii); the only non-trivial fact is that every closed normal subgroup  $U$  of  $H$ , smooth over  $S$  with connected unipotent geometric fibers, is a subgroup of  $H_u$ . Now one first has:

**Lemma 5.6.10.** \*Let  $G$  be an  $S$ -reductive group,  $T$  a maximal torus,  $U$  a group subscheme of  $G$ , smooth over  $S$ , with unipotent geometric fibers, normalized by  $T$ . Then  $U \cap T = e$ .\*

<!-- label: III.XXII.5.6.10 -->

Indeed, since  $T = \operatorname{Centr}_G(T)$ , one has  $U \cap T = U^T$  (invariants under  $\operatorname{int}(T)$ ). Applying Exp. XIX 1.4, one deduces that  $U \cap T$  is smooth over  $S$ , but it is also radicial over  $S$ : for every  $s \in S$ ,  $U(s) \cap T(s)$  consists of elements that are simultaneously unipotent and semisimple. This proves the lemma.

Let us return to the proof of 5.6.9 (ii). If  $U$  is a normal subgroup of  $H$  as above, then the semi-direct product  $T \cdot U$  is a subgroup of type (R) of  $G$ , with solvable geometric fibers. One may therefore suppose it of the form  $H_{R'}$ , with  $R' \subset R$ . It suffices to prove  $U = U_{R'}$  and one is therefore reduced to the case where  $H = T \cdot U$ ; but the quotient  $H/U$  being commutative,  $U$  is a subsheaf of the sheaf of commutators of  $H$ , which is  $H_u$ . QED.

Let us remark that we have in fact just proved:

**Proposition 5.6.11.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ . The maps\*

<!-- label: III.XXII.5.6.11 -->

```
```text
H ↦ H_u,    U ↦ T · U
```
```

\*are mutually inverse bijections between the set of subgroups  $H$  of type (R) of  $G$  containing  $T$  and having solvable geometric fibers, and the set of subgroups  $U$  of  $G$ , smooth over  $S$ , normalized by  $T$ , with connected and unipotent geometric fibers.\*[N.D.E-XXII-44]

In particular, when  $(G, T, M, R)$  is split, the groups  $H_{R'}$  and  $U_{R'}$  correspond.

**Corollary 5.6.12.** \*Let  $S$  be a scheme,  $(G, T, M, R)$  an  $S$ -split group (resp. and  $R$  a system of positive roots of  $R$  defining the Borel subgroup  $B$ ).\*

<!-- label: III.XXII.5.6.12 -->

\*Every smooth group subscheme of  $G$  with connected and unipotent geometric fibers (resp. every smooth group subscheme of  $B_u$ ) normalized by  $T$  is locally on  $S$  of the form  $U_{R'}$ , where  $R'$  is a subset of  $R$  contained in a system of positive roots (resp. a subset of  $R$ ) of type (R).\*

For the "resp." case, it suffices to note that the geometric fibers of the given group are unipotent and connected, by Bible, § 13.2, th. 1 (d).

Proposition 5.6.9 has moreover the following corollary:

**Corollary 5.6.13.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $H$  a subgroup of type (R) with solvable geometric fibers,  $\text{Tor}(H)$  the functor of maximal tori of  $H$ :\*

<!-- label: III.XXII.5.6.13 -->

```
```text
Tor(H)(S') = {maximal tori of H_{S'}}.
```
```

\*Then  $\text{Tor}(H)$  is representable by an affine and smooth  $S$ -scheme, which is a principal homogeneous bundle under  $H_u$  for the law  $(h, T) \mapsto \text{int}(h) T$ .\*[N.D.E-XXII-45]

Indeed, if  $T$  and  $T'$  are two maximal tori of  $H_{S'}$ , there exists a unique section  $h \in H_u(S')$  such that  $\text{int}(h) T = T'$ . The uniqueness of  $h$  follows immediately from the equality

```
$$
\text{Norm}_G(T) \cap H_u = e
$$
```

(cf. for example 5.6.1); it therefore suffices to prove the existence of  $h$  locally for the étale topology. By 5.2.6 and 5.1.2 (a), one may suppose  $T$  and  $T'$  conjugate by a section of  $H$ , whence the desired conclusion since  $H = H_u \cdot T$  by 5.6.9 (iii). It follows that  $\text{Tor}(H)$  is a principal homogeneous sheaf under  $H_u$ , which is affine and smooth over  $S$ , which immediately entails the statement.\*[N.D.E-XXII-46]

### 5.7. Bruhat's theorem

<!-- label: III.XXII.5.7 -->

**\*\*Recall 5.7.1.\*\*** \*Let  $k$  be an algebraically closed field,  $G$  a  $k$ -reductive group,  $B$  a Borel subgroup of  $G$ ,  $T$  a maximal torus of  $B$ ,  $N = \text{Norm}_G(T)$ . Then\*

<!-- label: III.XXII.5.7.1 -->

```text  
 $G(k) = B(k) N(k) B(k);$
 ```

\*this is Bruhat's theorem (Bible, § 13.4, cor. 1 to th. 3); more precisely, with the notations of 3.6, the sets\*

```text  
 $B(k) N_w(k) B(k) = B_u(k) N_w(k) B_u(k)$
 ```

\*form, as  $w$  runs through  $(N/T)(k)$ , a partition of  $G(k)$ . If  $B'$  is another Borel subgroup of  $G$  containing  $T$ , the sets  $B'(k) N_w(k) B(k)$  also form a partition of  $G(k)$ . Indeed, if  $y \in N(k)$  is such that  $\text{int}(y) B = B'$ , one has\*

```text  
 $y B(k) N_w(k) B(k) = B'(k) N_{\{yw\}}(k) B(k).$
 ```

**\*\*Definition 5.7.2.\*\*** \*Let  $(G, T, M, R)$  be an  $S$ -split group,  $R^-$  a system of positive roots of  $R$ ,  $B' = B_{\{R^-\}}$  the Borel group it defines. For  $w \in W$ , one writes (cf. 5.6.5):\*

<!-- label: III.XXII.5.7.2 -->

```text  
 $R_w^- = R^- \cap w(R^-), \quad B'_u w = U_{\{R_w^-\}} = \bigcap_{\alpha \in R_w^-} U_\alpha.$
 ```

\*If  $n_w \in \text{Norm}_G(T)(S)$  is a representative of  $w$  (3.8), one may also write\*

```text  
 $B'_u w = B'_u n_w \text{int}(n_w) B'_u.$
 ```

**\*\*Lemma 5.7.3.\*\*** \*Let  $(G, T, M, R)$  be an  $S$ -split group,  $R^+$  a system of positive roots of  $R$ ,  $R^- = -R^+$ ,  $B$  (resp.  $B'$ ) the Borel subgroup of  $G$  defined by  $R^+$  (resp.  $R^-$ ). Let  $w \in W$ ,  $N_w$  and  $B'_u w$  the corresponding subschemes of  $G$  (3.8 and 5.7.2).\*

<!-- label: III.XXII.5.7.3 -->

\*(i) The sheaf  $B' \cdot N_w \cdot B$ , image of the morphism\*

```text  
 $B' \times_S N_w \times_S B \rightarrow G$
 ```

\*induced by the product in  $G$ , is representable by a subscheme of  $G$  (in fact a closed subscheme of the open set  $N_w \setminus \Omega_{R^+}$ ).

\*(ii) The morphism\*

```text  
 $B'_u w \times_S N_w \times_S B^u \rightarrow G,$
 ```

\*induced by the product in  $G$ , is an immersion with image the preceding subscheme.\*

Let us first show that the morphism of (ii) is an immersion. By definition,  $\text{int}(n_w)^{-1}$  induces a closed immersion of  $B'_u w$  into  $B^u$ , so the morphism

```text

$(u, b) \mapsto n_w^{-1} u n_w b$

induces a closed immersion

```text  
 $B'_w \times_S B \rightarrow \Omega_{R+}$ .

This immediately entails that the morphism of (ii) induces a closed immersion of the first member into the open set  $\Omega_w \setminus \Omega_{R+}$ . To prove (i), it suffices to see that

```text  
 $B'(S) N_w(S) B(S) = B'_w(S) N_w(S) B^u(S)$.

Now, if $\alpha \in R$, one has $\text{int}(n_w) U_\alpha(S) = U_w(\alpha)(S)$, so if $w^{-1}(\alpha) \in R_+$,

```text  

$$\begin{aligned} U_\alpha(S) N_w(S) B(S) &= U_\alpha(S) n_w T(S) B^u(S) \\ &= n_w U_{w^{-1}(\alpha)}(S) T(S) B^u(S) \\ &= n_w B(S) = N_w(S) B^u(S). \end{aligned}$$

This immediately entails, in view of the definition of  $R^w_{-}$ , the desired assertion.

**Theorem 5.7.4.** \*Let  $S$  be a scheme,  $(G, T, M, R)$  an  $S$ -split group,  $B$  the Borel subgroup defined by the system of positive roots  $R_+$ ,  $B'$  the Borel subgroup defined by  $R_- = -R_+$ .\*

<!-- label: III.XXII.5.7.4 -->

**(i)** (Bruhat's theorem) The schemes  $B'_w \cdot N_w \cdot B$  form, as  $w$  runs through  $W$ , a partition of the underlying set of  $G$ .\*

**(ii)** For each  $w \in W$ , let  $n_w$  be a representative of  $w$  in  $\text{Norm}_G(T)(S)$  (3.8); then the open sets  $\Omega_w = n_w B'_w \cdot T \cdot B^u$  form, as  $w$  runs through  $W$ , a cover of  $G$ .\*

The two assertions are verified on geometric fibers, where one concludes by 5.7.1 and 5.7.3.

**Remark 5.7.5.** **(i)** entails that if  $S$  is the spectrum of a field,  $G(S)$  is the disjoint union of the  $B'_w \cdot T(S) \cdot B^u(S)$ . The corresponding assertion for an arbitrary  $S$  (even local or artinian) is obviously false. Note however that **(ii)** entails that if  $S$  is local,  $G(S)$  is the union of the  $\Omega_w$ . In fact:\*

<!-- label: III.XXII.5.7.5 -->

**Corollary 5.7.6.** \*Let  $\Delta$  be a system of simple roots of the split group  $G$  over the local scheme  $S$ .\*

<!-- label: III.XXII.5.7.6 -->

**(i)** Then  $G(S)$  is generated by  $T(S)$  and the  $U_\alpha(S)$ ,  $\alpha \in \Delta \cup -\Delta$ .\*

**(ii)** If  $G$  is simply connected (4.3.3),  $G(S)$  is already generated by the  $U_\alpha(S)$ ,  $\alpha \in \Delta \cup -\Delta$ .\*

Indeed, let  $H$  be the subgroup of  $G(S)$  generated by the  $U_\alpha(S)$ ,  $\alpha \in \Delta \cup -\Delta$ . Let us first remark that  $H$  contains a representative of each  $s_\alpha$  ( $\alpha \in \Delta$ ) in  $\text{Norm}_G(T)(S)$  (Exp. XX 3.1), hence a representative  $n_w$  of each  $w \in W$ .

Since every  $\alpha \in R$  is written  $w(\alpha_0)$  with  $w \in W$ ,  $\alpha_0 \in \Delta$ , one has

```text  
 $U_\alpha(S) = \text{int}(n_w) U_{\alpha_0}(S) \subset H$.

The subgroup generated by H and $T(S)$ thus contains $\Omega(S)$ and is therefore the whole of $G(S)$, by the remark made above.

If now G is simply connected, let us prove that $H \supset T(S)$. By Exp. XX 2.7, H contains $\alpha^*(G_m(S))$ for every $\alpha \in \Delta$, and it suffices to apply 4.3.8.

Remark 5.7.6.1. *Instead of taking, for each $\alpha \in \Delta$, $U_\alpha(S)$ and $U_{-\alpha}(S)$, one may content oneself with taking $U_\alpha(S)$ and a representative w_α of the symmetry s_α , or else $U_\alpha(S)$ and a section of $U_{-\alpha}$, ...*

<!-- label: III.XXII.5.7.6.1 -->

Corollary 5.7.7. *If G is of semisimple rank 1, choose a $u_\alpha \in U_{-\alpha}(S)$. Then Ω and $u_\alpha \Omega$ form a cover of G .*

<!-- label: III.XXII.5.7.7 -->

Indeed, if $u_{-\alpha}$ is the section of $U_{-\alpha}$ paired with u_α (cf. 1.3), one has, by 5.7.4 (ii),

$$G = \Omega \cup u_{-\alpha}^{-1} \Omega \cup u_{-\alpha}^{-1} \Omega,$$

whence

$$G = u_{-\alpha} \Omega \cup \Omega \cup u_\alpha u_{-\alpha}^{-1} \Omega = \Omega \cup u_\alpha \Omega.$$

Corollary 5.7.8. *Let S be a scheme, G an S -reductive group. Then G is essentially free over S (Exp. VIII 6.1).*

<!-- label: III.XXII.5.7.8 -->

Indeed, the assertion is local for the (fpqc) topology; one may suppose G split. Then G admits a cover by open subsets isomorphic to $G^N_{a,S} \times_S G^m_{n,S}$, which are essentially free.

Lemma 5.7.9. *Under the conditions of 5.7.4, let α be a simple root of R_+ and $u_\alpha \in U_{-\alpha}(S)$. For every $v \in U_{-\alpha}(S)$, one has*

<!-- label: III.XXII.5.7.9 -->

$$\Omega \cdot v \subset \Omega \cup u_\alpha \cdot \Omega.$$

We have to compare two open subsets of G ; it suffices to do so when S is the spectrum of a field k . One thus has to prove

$$\Omega(k) \cdot v \subset \Omega(k) \cup u_\alpha \Omega(k).$$

Now

$$\begin{aligned} \Omega(k) \cdot v &= B^u(k) T(k) B^u(k) \cdot v = U_{-\alpha^*}(k) U_{-\alpha}(k) T(k) U_\alpha(k) U_{\alpha^*}(k) \cdot v \\ &\subset U_{-\alpha^*}(k) Z_\alpha(k) U_{\alpha^*}(k) \cdot v. \end{aligned}$$

(One uses the decomposition of 5.6.8.) Applying now 5.6.8 (iii) and using 5.7.7 for the group Z_α , one obtains

$$\begin{aligned} \Omega(k) \cdot v &\subset U_{-\alpha^*}(k) Z_\alpha(k) \cdot v \subset U_{-\alpha^*}(k) Z_\alpha(k) U_{\alpha^*}(k) \\ &\subset U_{-\alpha^*}(k) U_{-\alpha}(k) T(k) U_\alpha(k) U_{\alpha^*}(k) \cup U_{-\alpha^*}(k) u_\alpha U_{-\alpha}(k) T(k) U_\alpha(k) U_{\alpha^*}(k). \end{aligned}$$

...

Using again 5.6.8 (iii) (for R instead of R^+), one obtains the result.

Proposition 5.7.10. Under the conditions of 5.7.4, choose for each simple root α a $u_\alpha \in U_{\alpha}(S)$. Let U_1 be the submonoid of $B^u(S)$ generated by the u_α . The open sets U_Ω , for $u \in U_1$, form a cover of G .

III.XXII.5.7.10

Once again, one may suppose that S is the spectrum of a field k ; by virtue of 5.7.6, it suffices to prove that $\bigcup_{u \in U_1} u \Omega(k)$ is stable under right multiplication by $T(k)$, $U_\alpha(k)$, $U_{-\alpha}(k)$ (for α simple). In the first two cases, this is trivial. In the last, it follows from the lemma.

Remark 5.7.11. Let us point out a particular case of 5.7.2. If $w = s_\alpha$ is the symmetry with respect to the simple root α , then

III.XXII.5.7.11

text
 $R_n s_\alpha(R^-) = R^- - \{-\alpha\}$

(Exp. XXI 3.3.1), and, in the notations of 5.6.8, one therefore has

$B^u_{s_\alpha} = U_{-\hat{\alpha}}$.

Remark 5.7.12. In fact, the proof of 5.7.10 immediately gives the following statement: under the conditions of 5.7.10, let Γ be a submonoid of $G(S)$; for the open sets U_Ω ($U \in \Gamma$) to form a cover of G , it is necessary and sufficient that for every $s \in S$ and every simple root α , one has

III.XXII.5.7.12

text
 $(u\alpha)_s B^u(s) \subset \Gamma \cdot B^u(s) \cdot T(s) \cdot B^u(s)$.

Remark 5.7.13. By 5.5.5 (iii), reasoning as in 5.7.1, one obtains immediately the following variant of 5.7.4: let (G, T, M, R) be an S -split group, B and B' two Borel subgroups of G containing T ; for every $w \in W$, the sheaf $B' \cdot N_w \cdot B$ is representable by a subscheme of G ; these subschemes form, for $w \in W$, a partition of the underlying set of G . One may also give the analogue of 5.7.3 (ii): one must set

III.XXII.5.7.13

text
 $B^u_w = B^u \cap \text{int}(n_w) B^u$

where $\tilde{B}$ is the Borel subgroup "opposite" to B relative to T (cf. 5.9.2).

Proposition 5.7.14. Let S be a scheme, G an S -reductive group, and

III.XXII.5.7.14

$\text{Ad} : G \rightarrow \text{GL}_{\{0\}}(g)$

its adjoint representation. Then $\text{Ker}(\text{Ad}) = \text{Centr}(G)$ (in other words, the canonical homomorphism deduced from Ad by passage to the quotient:

text
 $\text{Ad} : G/\text{Centr}(G) = \text{ad}(G) \rightarrow \text{GL}_{\{0\}}(g)$

...

is a monomorphism).[^N.D.E-XXII-48]

One may suppose G split. Choose on $\Gamma(S)$ a total ordering structure compatible with the group structure and let R_+ be the set of positive roots. By virtue of 5.7.4 (ii) and 4.1.6, it suffices to prove that if n_w is a representative of the element w of W , if $u \in U(S)$, $t \in T(S)$, $v \in U_{-}(S)$, and if $\text{Ad}(n_w) v t u = \text{id}$, then $w = e$, $v = e$, $u = e$. For each $m \in R \setminus \cup \{0\}$, set

```
```text
g_{>m} = \prod_{n > m} g^n, g_{<m} = \prod_{n < m} g^n.
```

Let  $X \in \Gamma(S, g_{\{m\}})$ ; write  $\text{Ad}(tu) X = \text{Ad}(v^{-1} n^{-1}_{-w}) X$ . Now

```
```text
Ad(t) Ad(u) X - m(t) X \in \Gamma(S, g_{>m}),
Ad(v^{-1} n_w^{-1}) X - Ad(n_w^{-1}) X \in \Gamma(S, g_{<w^{-1}(m)}).
```

If $w \neq e$, there exists $\alpha \in R$ such that $w^{-1}(\alpha) < \alpha$, and setting $m = \alpha$, one obtains a contradiction because

```
```text
Ad(tu) X \in \Gamma(S, g^\alpha + g_{>\alpha}) \cap \Gamma(S, g^{w^{-1}(\alpha)} + g_{<w^{-1}(\alpha)}) = \emptyset.
```

Hence  $w = e$ , and one may choose  $n_w = e$ ; one then has

```
```text
Ad(v^{-1}) X - X \in \Gamma(S, g_{<m} \cap (g^m + g_{>m})) = \emptyset,
```

whence $\text{Ad}(v) X = X$ for every $X \in \Gamma(S, g_{\{m\}})$, so $\text{Ad}(v) = \text{id}$. Similarly $\text{Ad}(u) = \text{id}$. One concludes by 5.6.2 bis.

5.8. Schemes associated with a reductive group

<!-- label: III.XXII.5.8 -->

Theorem 5.8.1. *Let S be a scheme, G an S -reductive group. Let H be the functor of subgroups of type (R) of G : for every $S' \rightarrow S$, $H(S')$ is the set of subgroups of type (R) of $G_{S'}$ (cf. 5.2.1). Then H is representable by a quasi-projective S -scheme of finite presentation over S .*

<!-- label: III.XXII.5.8.1 -->

[^N.D.E-XXII-49] Let $G' = G/\text{Centr}(G)$ be the adjoint group of G (4.3.6) and u the morphism $G \rightarrow G'$. By Exp. XII 7.12, the map $H' \mapsto u^{-1}(H')$ establishes a bijection between the set of subgroups of type (R) of G' and of G (and this remains valid after any base change). Thus, replacing G by G' , one may suppose that G is adjoint. Consider then the morphism

```
$$
u : H \rightarrow \text{Grass}(g)
$$
```

which associates with each subgroup of type (R) its Lie algebra (which is a sub- $\mathcal{O}_S$ -module of $\mathfrak{g}$ that is locally a direct factor. [^N.D.E-XXII-50]). Then u is a monomorphism by 5.3.3. It suffices to prove that it is representable by an immersion of finite presentation, in other words to prove the following assertion: for every $S_1 \rightarrow S$, given a sub- $\mathcal{O}_S$ -module locally a direct factor $\mathfrak{h}$ of $\mathfrak{g}_{S_1}$, the $S' \rightarrow S_1$ such that $\mathfrak{h}_{S'}$ is the Lie algebra of a subgroup of type (R) of $G_{S'}$ are exactly those that factor through some subscheme Σ of finite presentation of S_1 . Replacing S_1 by S , we reduce to $S_1 = S$, and we may furthermore suppose S affine; then there exists a noetherian affine scheme S_0 such that G (resp. $\mathfrak{h}$) arises by base change from an adjoint S_0 -reductive group G_0 (resp. a sub- $\mathcal{O}_{S_0}$ -module locally a direct factor $\mathfrak{h}_0$ of $\mathfrak{g}_0 = \text{Lie}(G_0/S_0)$). It suffices to show that there exists a subscheme Σ_0 of S_0 with the required properties (because one will then have $\Sigma = \Sigma_0 \times_{S_0} S$). Replacing S by S_0 , one may

therefore suppose S affine and noetherian (note that then every subscheme of S is of finite presentation over S). Finally, replacing S by a sufficiently small open set, one may suppose that g is free of rank n and that h is a direct factor, free of rank r .

One must first write that $h_{S'}$ is a Lie subalgebra of $g_{S'}$, i.e. that the morphism induced by the Lie bracket:

```

```text
φ : h ⊗ h --[,]--> g
```

```

factors through h . If $(e_1, \dots, e_n)$ is a basis of g such that $(e_1, \dots, e_r)$ is a basis of h , then ϕ is given by sections a^{ij}_k of $\mathcal{O}_S$ (where $i, j = 1, \dots, r$ and $k = 1, \dots, n$), and the preceding condition is equivalent to saying that $S^1 \times_S S$ factors through the closed subscheme of S defined by the equations $a^{ij}_k = 0$ for $k = r + 1, \dots, n$ and $i, j = 1, \dots, r$. Replace S by this closed subscheme.

Then, by 5.3.0, $N = \text{Norm}_G(h)$ is a closed group subscheme of G of finite presentation over G . One must now write (cf. 5.3.1) that $N_{S'}$ is smooth at every point of the unit section, of relative dimension $r = \text{rank}(h)$, and that the inclusion of $h_{S'}$ in $\text{Lie}(N_{S'}/S')$ is an equality.

[^N.D.E-XXII-51] Since N is affine over S (being closed in G), the unit section $\epsilon : S \rightarrow N$ is a closed immersion, so $\epsilon(S)$ is defined by a quasi-coherent ideal J of $\mathcal{O}_S(N)$. Note that $n_{S/N} = J/J^2$ is identified with $\epsilon^*(\Omega^1_{N/S})$, so its formation commutes with every base change $S' \rightarrow S$. By the equivalence (c') $\Leftrightarrow$ (a) in EGA IV₄, 17.12.1 (applied to $f : N \rightarrow S$ and $j = \epsilon$), $N_{S'} \rightarrow S'$ is smooth, of relative dimension r , at every point of $\epsilon(S')$ if and only if $n_{S'/N'} = n_{S/N} \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'}$ is locally free of rank r and the morphism $\phi_{\{n\}}(S') : \text{Sym}^{\{n\}}(n_{S'/N'}) \rightarrow J^{\{n\}}_{S'}/J^{\{n+1\}}_{S'}$ is an isomorphism for every $n \geq 1$. Denote $K_{\{n\}}(S') = \text{Ker } \phi_{\{n\}}(S')$. By TDTE I, Lemma 3.6, $n_{S/N} \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'} = K_{\{0\}}(S) \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'}$ is locally free of rank r if and only if $S' \rightarrow S$ factors through some subscheme Z of S . Replacing S by Z , we may therefore suppose that $n_{S/N} = J/J^2$ is locally free of rank r . Then, for every $S' \rightarrow S$, one has $(J^2/J^3) \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'} = J^2_{S'}/J^3_{S'}$ and hence $K_{\{2\}}(S') = K_{\{2\}}(S) \otimes_{\mathcal{O}_{S'}} \mathcal{O}_{S'}$. It follows that $\phi_{\{2\}}(S')$ is an isomorphism if and only if $S' \rightarrow S$ factors through the closed subscheme S_2 of S defined by the ideal generated by the image of $\text{Sym}^2(n_{S/N}) \otimes_{\mathcal{O}_{S'}} K_{\{2\}}(S)$ in $\mathcal{O}_S$. Then, over S_2 , J^2/J^3 is isomorphic to $\text{Sym}^2(n_{S/N})$, hence locally free, and the same argument shows that $\phi_{\{3\}}(S')$ is an isomorphism if and only if $S' \rightarrow S$ factors through some closed subscheme S_3 of S , etc. One obtains thus that $N_{S'} \rightarrow S'$ is smooth, of relative dimension r , at every point of $\epsilon(S')$ if and only if $S' \rightarrow S$ factors through the closed subscheme Z intersection of the S_n . But then, for every $S' \rightarrow Z$, $\text{Lie}(N_{S'}/S')$ is locally a direct factor of rank r of $g_{S'}$, and so the inclusion $h_{S'} \subset \text{Lie}(N_{S'}/S')$ is an equality. One then sets $H = N^0$.

Replacing S by Z , it remains only to express that $H_{S'}$ is of the same reductive rank as $G_{S'}$ at every point $s' \in S'$, or, equivalently, that H_s is of the same reductive rank as G_s at every point s of the (set-theoretic) image of S in S . Now this condition defines an open subset of S (Exp. XIX 6.2).

Remark. In general, the scheme H is not smooth over S . It is however smooth if ϵ^* is invertible on S , or if there exists a prime number p such that $p \cdot \mathcal{O}_S = 0$ (i.e. if S is of characteristic $p > 0$).

Corollary 5.8.2. Let S be a scheme, G an S -reductive group, H a subgroup of type (R) of G . (Recall (5.3.10) that $\text{Norm}_G(H)$ is representable by a closed group subscheme of G , smooth over S .)

<!-- label: III.XXII.5.8.2 -->

Then the quotient sheaf $G/\text{Norm}_G(H)$ is representable by a quasi-projective S -scheme, smooth and of finite presentation over S (which is in fact an open subset of H).

Indeed, consider the morphism

$$f : G \rightarrow H,$$

defined set-theoretically by $f(g) = \text{int}(g)H$. By 5.3.9, this morphism is smooth and of finite presentation, hence open. Let $V = f(G)$ equipped with its structure of open subscheme of H . The morphism $f : G \rightarrow V$ is covering and of kernel $\text{Norm}_G(H)$, which proves that $G/\text{Norm}_G(H)$ is representable by V (cf. Exp. IV 4.6.5).

Corollary 5.8.3. Let S be a scheme, G an S -reductive group. Consider the functors $\text{Tor}(G)$, $\text{Bor}(G)$, $\text{Kil}(G)$ defined by

<!-- label: III.XXII.5.8.3 -->

```

```text
Tor(G)(S') = {maximal tori of G_{S'}},
Bor(G)(S') = {Borel subgroups of G_{S'}},
Kil(G)(S') = {Killing couples of G_{S'}} (cf. 5.3.13)}.
```

```

(i) $\text{Tor}(G)$, $\text{Bor}(G)$, $\text{Kil}(G)$ are representable by smooth S -schemes of finite presentation, with integral geometric fibers, and respectively affine, projective, affine over S .

(ii) The canonical morphism $\text{Kil}(G) \rightarrow \text{Tor}(G)$ (resp. $\text{Kil}(G) \rightarrow \text{Bor}(G)$) is finite étale surjective (resp. affine smooth surjective).

(iii) Let T be a maximal torus of G (resp. B a Borel subgroup of G , resp. $B \supset T$ a Killing couple of G). The morphism

```

```text
G → Tor(G), resp. G → Bor(G), resp. G → Kil(G)
```

```

defined by

```

```text
g ↦ int(g) T, resp. g ↦ int(g) B, resp. g ↦ (int(g) B, int(g) T)
```

```

induces an isomorphism

```

```text
G/Norm_G(T) ≅ Tor(G), resp. G/B ≅ Bor(G), resp. G/T ≅ Kil(G).
```

```

One sees first that (iii) follows from the conjugacy theorem for maximal tori (resp. Borel subgroups, resp. Killing couples) and the fact that

```

```text
Norm_G(B) = B, Norm_G(B) ∩ Norm_G(T) = T,
```

```

all results previously established (5.1.2, 5.3.12, 5.3.14, 5.6.1).

It follows first that the canonical morphisms

```

```text
Tor(G) → H, Bor(G) → H
```

```

are representable, locally for the étale topology, by open immersions (5.8.2 and 5.1.2, resp. 5.5.5), hence by descent that $\text{Tor}(G)$ and $\text{Bor}(G)$ are representable by open subsets of H . Similarly $\text{Kil}(G)$ is locally (for the étale topology) representable by a scheme affine over the base (Exp. IX 2.3), hence representable by an affine S -scheme, by descent of affine schemes.[N.D.E-XXII-52]

The assertions of (ii) follow immediately from 5.5.5 (ii) and 5.6.13. It already follows that $\text{Tor}(G)$ is affine over S (EGA II 6.7.1). It thus remains only to prove the fact that $\text{Bor}(G)$ is projective over S . We already know that it is quasi-projective; it remains to prove that it is proper;[N.D.E-XXII-53] but it has connected fibers, so by EGA IV₃, 15.7.10, one is reduced to proving it on geometric fibers; if S is the spectrum of an algebraically closed field, one has $\text{Bor}(G) = G/B$ by (iii) and one concludes by Borel, § 6.4, th. 4 (or [Ch05], § 6.5, th. 5).

Remark 5.8.4. *Under the conditions of 5.8.3, let Q be a central subgroup of multiplicative type of G . The obvious morphisms define isomorphisms*

<!-- label: III.XXII.5.8.4 -->

```

```text
Tor(G) = Tor(G/Q), Bor(G) = Bor(G/Q), Kil(G) = Kil(G/Q).
```

**Corollary 5.8.5.** *Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a group subscheme of  $G$ , smooth and of finite presentation over  $S$ . The following conditions are equivalent:*

<!-- label: III.XXII.5.8.5 -->

*(i) For each  $s \in S$ ,  $P_s$  is a parabolic subgroup of  $G_s$  (i.e. the quotient scheme  $G_s/P_s$  is proper over  $s$ , or equivalently  $\bar{P}_s$  contains a Borel subgroup of  $G_s$ , cf. Bible, § 6.4, th. 4 or [Ch05], § 6.5, th. 5).*

*(ii) The quotient sheaf  $G/P$  is representable by an  $S$ -scheme that is smooth and projective over  $S$ .*P is closed in  $G$ , with connected fibers, and one has  $P = \text{Norm}_G(P)$ .

One obviously has (ii)  $\Rightarrow$  (i). If (i) holds, then  $P(s) = \text{Norm}_G(s)(P_s)$  and  $P_s$  is connected (for the first point, cf. Bible, § 12.3, lemme 4; [N.D.E-XXII-54] the second point follows from this, because  $P' = P^{\{0\}}_s$  is a parabolic subgroup of  $G_s$  normalized by  $P_s$ , whence  $P'(s) = P(s)$  and thus  $P' = P_s$ ); it follows that  $P$  is of type (R), and that  $P$  equals  $\text{Norm}_G(P)$ , hence is closed in  $G$ . By 5.8.2,  $G/P = G/\text{Norm}_G(P)$  is representable by a quasi-projective  $S$ -scheme. Its fibers are connected and proper, hence it is projective by the reasoning of 5.8.3.

**Remark 5.8.6.** *The statements 5.8.1, 5.8.2, 5.8.5 are valid for an  $S$ -group of type (RA), or for an  $S$ -group of type (RR) satisfying 5.1.8.* [N.D.E-XXII-55]

<!-- label: III.XXII.5.8.6 -->

**Remark 5.8.7.** *Through the inner automorphisms of  $G$ , one has canonical operations:*

<!-- label: III.XXII.5.8.7 -->

```text
G → Aut_S(Tor(G)), G → Aut_S(Bor(G)), G → Aut_S(Kil(G)),
```

*which, in the situation of 5.8.3 (iii), are identified with the canonical operations*

```text
G → Aut_S(G/Norm_G(T)), G → Aut_S(G/B), G → Aut_S(G/T).
```

*One concludes in particular that*

```text
Ker(G → Aut_S(Tor(G))) = Ker(G → Aut_S(Bor(G))) = Ker(G → Aut_S(Kil(G))) = Centr(G).
```

It is indeed clear that  $\text{Centr}(G)$  operates trivially on each of the three schemes. Conversely, the kernel of  $G \rightarrow \text{Aut}_S(\text{Kil}(G))$  is "the intersection of the maximal tori of  $G$ " in the sense of 4.1.7, hence equals  $\text{Centr}(G)$  (loc. cit.). For  $\text{Bor}(G)$ , one notes that "the intersection of the Borel subgroups of  $G$ " is also "the intersection of its maximal tori" (see the following section). For  $\text{Tor}(G)$ , one uses Exp. XII 4.11.

### 5.9. Properties peculiar to Borel subgroups

<!-- label: III.XXII.5.9 -->

Most of these properties will be generalized in Exp. XXVI to parabolic subgroups.

**Definition 5.9.1.** *Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $B$  and  $B'$  two Borel subgroups of  $G$ . We say that  $B$  and  $B'$  are in* general position *(or that  $B'$  is in general position relative to  $B$ ) if  $B \cap B'$  is a torus (necessarily maximal) of  $G$ .*

```

*If T is a maximal torus of G contained in B and B' , we say that B and B' are *opposite* (relative to T) if $B \cap B' = T$.*

Proposition 5.9.2. *Let S be a scheme, G an S -reductive group, B a Borel subgroup of G , T a maximal torus of B . There exists a unique Borel subgroup B' of G , opposite to B relative to T .*

<!-- label: III.XXII.5.9.2 -->

If (G, T, M, R) is a splitting of G relative to T and if $B = B_{R+}$ (5.5.1), then $B' = B_{-R+}$.

By faithfully flat descent, it suffices to prove the proposition in the split case, when $B = B_{R+}$ (5.5.5 (iv)). Then B_{-R+} is indeed opposite to B (4.1.2); let us show that it is the only Borel subgroup of G containing T that is opposite to B . If B' is a Borel subgroup of G containing T , then B' is locally on S of the form $B_{R'+}$, where $R'+$ is another system of positive roots of R (5.5.5 (iii)). If $R' + \neq -R +$, there exists $\alpha \in R' + \cap R +$, so that $\alpha \subset B_{R+} \cap B_{R'+}$.

Proposition 5.9.3. *Let S be a scheme, G an S -reductive group, B a Borel subgroup of G .*

<!-- label: III.XXII.5.9.3 -->

(i) If B' is a Borel subgroup of G , the following conditions are equivalent:

(a) B' is in general position relative to B (5.9.1).*

(b) $B' \cap B^u = e$.*

(b') $B' \cap B = e$.*

(c) The product in G induces an open immersion $B' \times_S B \rightarrow G$.*

(c') The canonical morphism $B' \rightarrow G/B$ is an open immersion.*

(ii) The functor $\text{Opp}(B)$:

text
 $S' \mapsto \{\text{Borel subgroups of } G_{S'} \text{ in general position relative to } B_{S'}\}$
 is

representable by an open subscheme of $\text{Bor}(G)$ (5.8.3). The morphism

$\text{Opp}(B) \rightarrow \text{Tor}(B)$

defined by $B' \mapsto B \cap B'$ is an isomorphism. In particular (5.6.13) the inner automorphisms of B^u equip $\text{Opp}(B)$ with a structure of principal homogeneous bundle under B^u .*

Let us first examine (i). One has (a) $\Rightarrow$ (c): indeed, (c) is local for the étale topology; by 5.5.5 (iv), one reduces to the case where G is split relative to $B \cap B'$ and B of the form B_{R+} ; by 5.9.2, one then has $B' \cap B^u = B_{-R+}$ and one is reduced to 4.1.2.

One trivially has (c') $\Leftrightarrow$ (c) $\Rightarrow$ (b') $\Rightarrow$ (b). It therefore remains to prove (b) $\Rightarrow$ (a). Let us first prove (ii): the second assertion is a formal consequence of 5.9.2, the third follows immediately from this by 5.6.13; let us prove the first; it is local for the étale topology and one may therefore suppose that B possesses a maximal torus T ; let $B_{\{0\}}$ be opposite to B relative to T (5.9.2).

By what precedes, the morphism $B^u \rightarrow \text{Bor}(G)$ induced by the canonical morphism $G \rightarrow G/B_{\{0\}} \rightarrow \text{Bor}(G)$ (5.8.3) induces an isomorphism $B^u \xrightarrow{\sim} \text{Opp}(B)$. One thus has a commutative diagram

text

$$\begin{array}{ccc} B^u & \longrightarrow & G/B_{\{0\}} \\ \square & & \square \\ \downarrow & & \downarrow \\ \text{Opp}(B) & \longrightarrow & \text{Bor}(G). \end{array}$$

...

Now the morphism $B^u \rightarrow G/B_{\{0\}}$ is an open immersion (by (i) (a) $\Rightarrow$ (c')), which finishes the proof of (ii). Let us immediately note the corollary:

Corollary 5.9.4. *Let G be an S -reductive group and B and B' two Borel subgroups of G . If $s \in S$ is such that $B_{\{s\}}$ and $B'_{\{s\}}$ are in general position, there exists an open subset V of S containing s such that B_V and B'_V are in general position.*

<!-- label: III.XXII.5.9.4 -->

It only remains to prove (b) $\Rightarrow$ (a). By virtue of the preceding corollary, it suffices to do so when S is the spectrum of an algebraically closed field k . One may suppose G split relative to a maximal torus T of B . Let $B_{\{0\}}$ be the Borel subgroup opposite to B . Since the Borel subgroups of G are conjugate under $G(k)$, there exists $g \in G(k)$ such that $\text{int}(g) B_{\{0\}} = B'$. By Bruhat's theorem (5.7.4), one may write $g = b n b'$, with $b \in B(k)$, $b' \in B'_{\{0\}}(k)$, $n \in \text{Norm}_{\{G\}}(T)(k)$. One thus has

```
```text
B' = int(b) int(n) B'_0
```
```

and $B' \cap B = \text{int}(b) (\text{int}(n) B_{\{0\}} \cap B)$. If $n \notin T(k)$, $\text{int}(n) B_{\{0\}} \cap B \neq e$ (cf. proof of 5.9.2); it follows that (b) entails $B' \cap B = \text{int}(b) (B_{\{0\}} \cap B) = \text{int}(b) \bar{T}$. QED.

Proposition 5.9.5. *Let S be a scheme, G an S -reductive group, B a Borel subgroup of G , B^u its unipotent part. There exists a sequence of subgroups of B :

<!-- label: III.XXII.5.9.5 -->

```
```text
U_0 = B^u \supset U_1 \supset \dots \supset U_n \supset \dots
```
```

possessing the following properties:

(i) Each $U_{\{i\}}$ is smooth, with connected fibers, characteristic in B ; the inner automorphisms of B^u act trivially on the (sheaf) quotients $U_{\{i\}}/U_{\{i+1\}}$.*

(ii) For each $i \geq 0$, there exists a locally free $\mathcal{O}_S$ -module $\mathcal{E}_{\{i\}}$ and an isomorphism of S -sheaves of groups*

```
$$
U_{\{i\}}/U_{\{i+1\}} \xrightarrow{\sim} W(\mathcal{E}_{\{i\}}).
$$
```

(iii) For every $s \in S$, $(U_{\{n\}})_s = e$ for $n \geq \dim(B^u_s)$.*

Suppose first that there exists a splitting (G, T, M, R) of G and a system of positive roots R^+ of R such that $B = B_{\{R^+\}}$. We denote by Δ the set of simple roots of R^+ ; for each $\alpha \in R^+$, we write $\text{ord}(\alpha)$ for the sum of the coefficients of α in the basis Δ of $\Gamma(R)$; it is the *order* of α relative to R^+ . One has $\text{ord}(\alpha) \leq \text{Card}(R^+)$. For every $i \geq 0$, let $R^{\{i\}}$ be the set of roots of order $\geq i$; it is a closed set of positive roots, so one may construct (5.6.5)

```
$$
U_{\{i\}} = U_{\{R^{\{i\}}\}}.
$$
```

If $\alpha \in R^+$ and $\beta \in R^{\{i\}}$, then $\alpha + \beta \in R^{\{i+1\}}$. It follows, by 5.5.2, that each $U_{\{i\}}$ is a normal subgroup of B and that the inner automorphisms of B^u operate trivially on $U_{\{i\}}/U_{\{i+1\}}$. This group is moreover identified with

```
$$
\prod_{\text{ord}(\alpha) = i+1} U_{\alpha}
$$
```

and is thus equipped with a vector-space structure.

If B is of the form $B_{\{R'\}}$ for another splitting (G, T', M', R') of G , let us show that the groups $U'_{\{i\}}$ constructed as above using the new splitting coincide with the $U_{\{i\}}$ and that the vector-space structures on the successive quotients also coincide. By 5.6.13, there exists $b \in B^{\{u\}}(S)$ such that $T' = \text{int}(b) T$; the assertion to be proved is local on S and one may therefore suppose that the isomorphism $T \xrightarrow{\sim} T'$ induced by $\text{int}(b)$ arises by duality from an isomorphism of root data

```
```text
h : (M', M'^*, R', R'^*) → (M, M*, R, R*).
```
```

It is clear that the roots of $R'+$ are the $\alpha \circ \text{int}(b) = h(\alpha)$, $\alpha \in R+$, and that the simple roots of $R'+$ are the $\alpha \circ \text{int}(b) = h(\alpha)$, $\alpha \in \Delta$, hence $\text{ord}(h(\alpha)) = \text{ord}(\alpha)$ for $\alpha \in R+$. On the other hand, it is clear by transport of structure that the vector groups $U'_{\{h(\alpha)\}}$ are none other than the $\text{int}(b) U_{\alpha}$. One thus has $\text{int}(b) U_{\{i\}} = U'_{\{i\}}$; but $U_{\{i\}}$ being invariant, this gives $U_{\{i\}} = U'_{\{i\}}$.

Similarly the isomorphism of vector groups

```
```
int(b) : U_{\{i\}}/U_{\{i+1\}} → U'_{\{i\}}/U'_{\{i+1\}}
```
```

is the identity, by virtue of what has already been proved.

Let us now treat the general case. There exists a covering family for the étale topology $\{S_{\{i\}} \rightarrow S\}$ and for each i a splitting $(G_{\{i\}}, T_{\{i\}}, M_{\{i\}}, R_{\{i\}})$ and a system of positive roots $R_{\{i+\}}$ of $R_{\{i\}}$ such that $B \times_{\{S\}} S_{\{i\}} = B_{\{R_{\{i+\}}\}}$ (5.5.5, (iii)). For each i , one thus has a family

```
```text
B_{\{S_{\{i\}}\}} = U_{\{i,0\}} ⊃ U_{\{i,1\}} ⊃ ... ⊃ U_{\{i,j\}} ⊃ ...
```
```

and vector-space structures on the $U_{\{i,j\}}/U_{\{i,j+1\}}$. By descent, it suffices to prove that for every pair (i, i') and every j , one has

```
```text
U_{\{i,j\}} ×_{S_{\{i\}}} S_{\{ii'\}} = U_{\{i',j\}} ×_{S_{\{i'\}}} S_{\{ii'\}}
```
```

(one writes $S_{\{ii'\}} = S_{\{i\}} \times_{\{S\}} S_{\{i'\}}$) and that the vector-space structures on the quotients

```
```text
(U_{\{i,j\}}/U_{\{i,j+1\}}) ×_{S_{\{i\}}} S_{\{ii'\}} and (U_{\{i',j\}}/U_{\{i',j+1\}}) ×_{S_{\{i'\}}} S_{\{ii'\}}
```
```

coincide. Now if $S_{\{ii'\}} = \emptyset$, this is trivial; if $S_{\{ii'\}} \neq \emptyset$, then one is in the situation studied above: $B \times_{\{S\}} S_{\{ii'\}}$ is defined by the system of positive roots $R_{\{i+\}}$ (resp. $R_{\{i'+\}}$) in the splitting $(G_{\{S_{\{ii'\}}\}}, T_{\{i\}} \times_{\{S_{\{i\}}\}} S_{\{ii'\}}, M_{\{i\}}, R_{\{i\}})$ (resp. in the splitting $(G_{\{S_{\{ii'\}}\}}, T_{\{i'\}} \times_{\{S_{\{i'\}}\}} S_{\{ii'\}}, M_{\{i'\}}, R_{\{i'\}})$.

****Corollary 5.9.6.**** *If S is affine, $H^1(S, B^{\{u\}}) = e$, i.e. every principal bundle under $B^{\{u\}}$ possesses a section.*

<!-- label: III.XXII.5.9.6 -->

Indeed, S decomposes as a direct sum of subschemes on each of which $B^{\{u\}}$ is of constant relative dimension. One may therefore, by 5.9.5 (iii), suppose that there exists an n such that $U_{\{n\}} = e$. Since, by TDTE I, B.1.1, [N.D.E-XXII-56]

```
```text
H^1(S, U_{\{i\}}/U_{\{i+1\}}) = H^1(S, W(E_{\{i\}})) = 0,
```
```

one has $H^1(S, B^u) = 0$.

Corollary 5.9.7. *If S is affine, B possesses maximal tori. If T is a maximal torus of B , one has $H^1(S, T) = H^1(S, B)$.*

label: III.XXII.5.9.7 -->

The first assertion follows immediately from 5.9.6 and 5.6.13; the second follows in standard fashion. [N.D.E-XXII-57]

Corollary 5.9.8. *If G is an S -reductive group, the canonical morphism (cf. 5.8.3)*

label: III.XXII.5.9.8 -->

$$\text{Kil}(G) \rightarrow \text{Bor}(G)$$

possesses sections over every affine open subset.

Corollary 5.9.9. *Under the conditions of 5.9.5, suppose S affine; then there exists a locally free $\mathcal{O}_S$ -module $\mathcal{E}$ such that B^u is, as a scheme, S -isomorphic to $W(E)$.*

label: III.XXII.5.9.9 -->

Let us show by induction on i that B^u/U_i is S -isomorphic to $W(E_0 \oplus \cdots \oplus E_{i-1})$. This is clear for $i = 0$; suppose $i \geq 1$. Then B^u/U_i is a principal homogeneous bundle of base $X = B^u/U_{i-1}$ under the group $(U_{i-1}/U_i)_X$. Since B^u/U_{i-1} is affine, by the induction hypothesis, and since $U_{i-1}/U_i = W(E_{i-1})$, this bundle is trivial. One thus has (at least) an isomorphism of S -schemes

$$B^u/U_i \cong (B^u/U_{i-1}) \times_S W(E_{i-1}) = W(E_0 \oplus \cdots \oplus E_{i-1}).$$

One concludes immediately by condition (iii) of 5.9.5.

Corollary 5.9.10. *Let S be a semi-local scheme, s_i its closed points, B a Borel subgroup of the S -reductive group G . The canonical map*

label: III.XXII.5.9.10 -->

$$B^u(S) \rightarrow \prod_i B^u(\text{Spec } \kappa(s_i))$$

is surjective.

Indeed, if $S = \text{Spec}(A)$, $\kappa(s_i) = A/p_i$ and if $\mathcal{E}$ is given by the A -module $\mathcal{E}$, one has

$$B^u(S) = E \otimes A, \quad B^u(\text{Spec } \kappa(s_i)) = E \otimes_{A/p_i} A.$$

The assertion then follows immediately from the fact that $A \rightarrow \prod_i A/p_i$ is surjective.

5.10. Subgroups of type (R) with reductive fibers

label: III.XXII.5.10 -->

Proposition 5.10.1. *Let (G, T, M, R) be an S -split group, R' a subset of R of type (R) (5.4.2), $H_{R'}$ the corresponding subgroup of G . The following conditions are equivalent:*

label: III.XXII.5.10.1 -->

(i) $H_{R'}$ is reductive (i.e. has reductive geometric fibers).

(ii) One has $\$R' = -R'$, i.e. $\$R'$ is symmetric.

Moreover, under these conditions, $(H_{\{R'\}}, T, M, R')$ is a splitting of $H_{\{R'\}}$; for every system of positive roots $\$R+\$$ of $\$R\$$, $\$R'+ = R' \cap R+\$$ is a system of positive roots of $\$R'$ and*

$$B_{\{R+\}} \cap H_{\{R'\}} = H_{\{R'+\}}$$

is a Borel subgroup of $H_{\{R'\}}$, whose unipotent part is*

$$U_{\{R+\}} \cap H_{\{R'\}} = U_{\{R'+\}}.$$

One has obviously (i) $\Rightarrow$ (ii) (it suffices to check it fiber by fiber and $\$R'$ is a system of roots of $H_{\{R'\}}$ relative to $\$T\$$). To prove (ii) $\Rightarrow$ (i), one remarks by 5.4.3 that

$$H_{\{R'\}} \cap Z\alpha = \text{Centr}_{\{H_{\{R'\}}\}}(T\alpha) = Z\alpha$$

for every $\alpha \in R'$ and one applies the criterion of Exp. XIX 1.12.

If $\$R+\$$ is a system of positive roots of $\$R\$$, then $\$R'+ = R+ \cap R'$ is obviously a closed subset of $\$R'$ such that $\$R'+ \cup -R'+ = R'$ and $\$R'+ \cap -R'+ = \emptyset$, hence a system of positive roots of $\$R'$. The other two assertions follow respectively from 5.6.1 (vi) and 5.6.7 (i).

Corollary 5.10.2. Let $\$S\$$ be a scheme, $\$G\$$ an $\$S\$$ -reductive group, $\$H\$$ an $\$S\$$ -reductive subgroup such that for every $s \in S$, $\$G_{\{s\}}$ and $\$H_{\{s\}}$ have the same reductive rank. Then $\$H\$$ is closed in $\$G\$$, $\$Norm_{\{G\}}(H)\$$ is smooth over $\$S\$$, $\$Norm_{\{G\}}(H)/H\$$ is representable by a finite étale $\$S\$$ -scheme.*

<!-- label: III.XXII.5.10.2 -->

If $\$T\$$ is a maximal torus of $\$H\$$ and $\$B\$$ a Borel subgroup of $\$G\$$ containing $\$T\$$, then $\$B \cap H\$$ is a Borel subgroup of $\$H\$$, whose unipotent part is $(B \cap H)_u = B^u \cap H$.*

The first assertions follow immediately from 5.3.10 and 5.3.18, via the fact that the Weyl groups of $\$G\$$ and $\$H\$$ are finite (Exp. XIX 2.5). The other assertions are local for the étale topology and reduce to the case studied in 5.10.1.

Proposition 5.10.3. Let $\$S\$$ be a scheme, $\$G\$$ an $\$S\$$ -reductive group.*

<!-- label: III.XXII.5.10.3 -->

(a) If $\$Q\$$ is a torus of $\$G\$$, $\$Centr_{\{G\}}(Q)\$$ is a subgroup of type (R) of $\$G\$$ with reductive fibers. If $\$Q \subset Q'\$$ are two tori of $\$G\$$, then $\$Centr_{\{G\}}(\bar{Q}) \supseteq Centr_{\{G\}}(Q')\$$.*

(b) If $\$H\$$ is a subgroup of type (R) of $\$G\$$ with reductive fibers, then $\$rad(H)\$$ (4.3.6) is a torus of $\$G\$$. If $\$H \subset H'\$$ are two subgroups of type (R) of $\$G\$$ with reductive fibers, then $\$rad(H) \supseteq rad(H')\$$.*

(c) If $\$Q\$$ is a torus of $\$G\$$, one has*

$$rad(Centr_G(Q)) \supset Q \quad \text{and} \quad Centr_G(rad(Centr_G(Q))) = Centr_G(Q).$$

(d) If $\$H\$$ is a subgroup of type (R) of $\$G\$$ with reductive fibers, one has*

$$Centr_G(rad(H)) \supset H \quad \text{and} \quad rad(Centr_G(rad(H))) = rad(H).$$

Indeed, (a) follows immediately from Exp. XIX 2.8. To prove (b), it suffices to note that $\$rad(H') \subset H\$$, because $\$H\$$ contains (locally for (fpqc)) a maximal torus of $\$G\$$, hence of $\$H'\$$. The first assertion of (c) (resp. (d)) is trivial, the second follows by the usual reasoning.

This proposition leads to the following definition:

Definition 5.10.4. Let S be a scheme, G an S -reductive group, H a reductive subgroup of type (R) of G , and Q a subtorus of G .^[N.D.E-XXII-58]

<!-- label: III.XXII.5.10.4 -->

1) We say that H is a critical subgroup if it is the centralizer of its radical.

2) We say that Q is a C-critical torus if it is the radical of its centralizer.

It then follows from Proposition 5.10.3:

Corollary 5.10.5. (i) For every subtorus Q of G , $\text{Centr}_G(Q)$ is critical.

<!-- label: III.XXII.5.10.5 -->

(ii) For every subgroup of type (R) with reductive fibers H of G , $\text{rad}(H)$ is a C-critical torus of G .

(iii) The maps

$$\begin{aligned} & \text{Centr}_G(Q), \quad H \mapsto \text{rad}(H) \\ & \text{rad}(H), \quad H \mapsto \text{Centr}_G(H) \end{aligned}$$

are mutually inverse bijections between the set of C-critical tori of G and the set of its critical reductive subgroups of type (R).

(iv) If Q is a torus of G , $\text{rad}(\text{Centr}_G(Q))$ is the smallest C-critical torus of G containing Q .

(v) If H is a reductive subgroup of type (R) of G , $\text{Centr}_G(\text{rad}(H))$ is the smallest critical reductive subgroup of type (R) of G containing H .

Remark 5.10.5.1.^[N.D.E-XXII-58] (1) A torus T of G is a critical subgroup of G if and only if it is a maximal torus.

<!-- label: III.XXII.5.10.5.1 -->

(2) In what follows, "critical torus" means "C-critical torus".

Proposition 5.10.6. Let (G, T, M, R) be an S -split group, R' a subset of R . The following conditions are equivalent:

<!-- label: III.XXII.5.10.6 -->

(i) R' is of type (R), $H_{R'}$ is reductive and critical.

(ii) There exists a system of simple roots Δ of R and a subset Δ' of Δ such that R' is the set of elements of R that are linear combinations of elements of Δ' .

(iii) R' is closed, symmetric, and every system of simple roots of R' is the intersection with R' of a system of simple roots of R .

Indeed, by Exp. XXI 3.4.8, (ii) and (iii) are equivalent and are also equivalent to the fact that R' is the intersection of R with a $\mathbb{Q}$ -subspace of $M \otimes \mathbb{Q}$. Now this last condition is entailed by (i): if $H_{R'} = \text{Centr}_G(Q)$, then R' is the set of elements of R that vanish on Q (Exp. II 5.2.3 (ii)). Finally, this condition entails (i), because $\text{rad}(H_{R'})$ is the maximal torus of $\bigcap_{\alpha \in R'} \text{Ker}(\alpha)$, hence $\text{Centr}_G(\text{rad}(H_{R'}))$ is none other than $H_{R'}$ where R' is the intersection of R with the subspace generated by R' .

5.10.7.

<!-- label: III.XXII.5.10.7 -->

Let us summarize some of the preceding results: let (G, T, M, R) be an S -split group, and let Δ be a system of simple roots of R and R^+ the corresponding system of positive roots; choose a subset Δ' of Δ , denote R' the set of elements of R that are linear combinations of elements of Δ' and set $R^+ = R' \cap R^+$. Let $T_{\Delta'}$ be the maximal torus of $\bigcap_{\alpha \in \Delta'} \text{Ker}(\alpha)$ and $Z_{\Delta'} = \text{Centr}_G(T_{\Delta'})$.

Then $Z_{\Delta'}$ is a reductive subgroup of G , with radical $T_{\Delta'}$; $(Z_{\Delta'}, T, M, R')$ is an S -split group; $B_{R^+} \cap Z_{\Delta'}$ is the Borel subgroup of $Z_{\Delta'}$ defined by the system of positive roots R'^+ (or by the system of simple roots Δ') and its unipotent part is $U_{R^+} \cap Z_{\Delta'} = U_{R'^+}$.

Remark 5.10.8. Under the conditions of 5.10.4, let Q be a critical torus of G , $L = \text{Centr}_G(Q)$ its centralizer. Since $Q = \text{rad}(L)$, then Q is a characteristic subgroup of L ; it follows immediately that

`<!-- label: III.XXII.5.10.8 -->`

$$\text{Norm}_G(L) = \text{Norm}_G(Q),$$

hence also

$$\text{Norm}_G(L)/L = \text{Norm}_G(Q)/\text{Centr}_G(Q) = W_G(Q).$$

By 5.10.2, one deduces:

Proposition 5.10.9. Let S be a scheme, G an S -reductive group, Q a critical torus of G . The Weyl group $W_G(Q)$ is (étale) finite over S .

`<!-- label: III.XXII.5.10.9 -->`

Remark 5.10.10. Under the conditions of 5.10.7, one may make explicit

`<!-- label: III.XXII.5.10.10 -->`

$$W_G(T_{\Delta'}) = \text{Norm}_G(Z_{\Delta'})/Z_{\Delta'}.$$

It is the constant group associated with the quotient W_1/W_2 , where W_1 is the subgroup of W formed by the elements that normalize the subgroup of M generated by Δ' , and W_2 is the subgroup of W generated by the $\alpha \in \Delta'$.

5.11. Subgroups of type (RC)

`<!-- label: III.XXII.5.11 -->`

Definition 5.11.1. Let S be a scheme, G an S -reductive group. A group subscheme H of G is called of type (RC) if it is of type (R), i.e. (5.2.1) satisfies the following two conditions:

`<!-- label: III.XXII.5.11.1 -->`

(i) H is smooth over S , with connected fibers;

(ii) for every $s \in S$, H_s contains a maximal torus of G_s ;

and if it further satisfies the following condition:

(iii) for every $s \in S$ and every maximal torus T of H_s , the set of roots of H_s relative to T is a closed subset of the set of all roots of G_s relative to T .

Remark 5.11.2. As we have already noted in 5.4.8, condition (iii) is a consequence of the others when 6 is invertible on S . [N.D.E-XXII-59]

<!-- label: III.XXII.5.11.2 -->

****Lemma 5.11.3.**** *Let (G, T, M, R) be an $\mathbb{A}^1$ -split group and R' a closed subset of R . Let*

<!-- label: III.XXII.5.11.3 -->

``text
 $R_1 = \{\alpha \in R' \mid -\alpha \in R'\}$ and $R_2 = \{\alpha \in R' \mid -\alpha \notin R'\}$.
 ``

Then $R_{\{1\}}$ and $R_{\{2\}}$ are closed. Consider the groups $H_{\{R'\}}$, $H_{\{R_{\{1\}}\}}$ and $U_{\{R_{\{2\}}\}}$ (5.4.7 and 5.6.5), which are smooth with connected fibers.

(i) The group $U_{\{R_{\{2\}}\}}$ is normal in $H_{\{R'\}}$ and $H_{\{R'\}}$ is the semi-direct product of $U_{\{R_{\{2\}}\}}$ by $H_{\{R_{\{1\}}\}}$.

(ii) $H_{\{R_{\{1\}}\}}$ is reductive, $U_{\{R_{\{2\}}\}}$ has connected and unipotent geometric fibers; every normal subgroup of $H_{\{R'\}}$, smooth over $\mathbb{A}^1$ and with connected and unipotent geometric fibers, is contained in $U_{\{R_{\{2\}}\}}$, and every reductive subgroup of $H_{\{R'\}}$ containing T is contained in $H_{\{R_{\{1\}}\}}$.

(iii) One has $U_{\{R_{\{2\}}\}} \cap \text{Norm}_{\{G\}}(H_{\{R_{\{1\}}\}}) = e$.

One first has (iii) by 5.6.7 (i). The first assertion of (i) follows from 5.6.7 (ii). Since $U_{\{R_{\{2\}}\}} \cap H_{\{R_{\{1\}}\}} = e$ by (iii), the semi-direct product $H_{\{R_{\{1\}}\}} \cdot U_{\{R_{\{2\}}\}}$ is a subgroup of $H_{\{R'\}}$; but these are two subgroups of type (R) of G , containing T , and they have the same Lie algebra $\mathfrak{g}_{\{R'\}}$; they thus coincide by 5.3.5, finishing the proof of (i).

Let us now prove (ii); the first two assertions are simply 5.10.1 and 5.6.5. Let U be a group subscheme of $H_{\{R'\}}$, smooth and of finite presentation, normal (hence normalized by T), with connected and unipotent geometric fibers; by 5.6.12, one has, locally on $\mathbb{A}^1$, $U = U_{\{R''\}}$, where R'' is a subset of R such that $R'' \cap -R'' = \emptyset$. If $U \not\subset U_{\{R_{\{2\}}\}}$, then $R'' \not\subset R_{\{2\}}$, so there exists $\alpha \in R''$ such that $-\alpha \in R'$. Then $Z\alpha \subset H_{\{R'\}}$ (5.4.3), so $Z\alpha$ normalizes U . But U contains $U\alpha$ and $Z\alpha$ possesses a section w such that $\text{int}(w) U\alpha = U_{\{-\alpha\}}$; this entails $-\alpha \in R''$, contradicting the hypothesis $R'' \cap -R'' = \emptyset$.

Finally, if L is a reductive subgroup of $H_{\{R'\}}$ containing T , one has locally on $\mathbb{A}^1$, $L = H_{\{R'''\}}$, with R''' symmetric contained in R , hence contained in $R_{\{1\}}$.

****Proposition 5.11.4.**** *Let S be a scheme, G an $\mathbb{A}^1$ -reductive group, H a group subscheme of G of type (RC).*

<!-- label: III.XXII.5.11.4 -->

(i) H is closed in G , $\text{Norm}_{\{G\}}(H)/H$ is representable by a finite étale $\mathbb{A}^1$ -group scheme.

(ii) H possesses a largest normal group subscheme that is smooth and of finite presentation over S , with connected and unipotent geometric fibers; we call it the unipotent radical *of H and denote it $\text{rad}_{\{u\}}(H)$. The quotient sheaf $H/\text{rad}_{\{u\}}(H)$ is representable by an $\mathbb{A}^1$ -reductive group.*

(iii) If T is a maximal torus of H , H possesses a reductive subgroup L containing T of type (RC) possessing the two following properties:

(a) Every reductive subgroup of H containing T is contained in L .

(b) H is the semi-direct product $H = L \cdot \text{rad}_{\{u\}}(H)$, i.e. the canonical morphism $L \rightarrow H/\text{rad}_{\{u\}}(H)$ is an isomorphism.

Furthermore, L is the unique reductive subgroup of H containing T and satisfying one or the other of the two preceding conditions. Finally, one has the following equalities:

``text
 $\text{Norm}_H(L) = L, \quad \text{Norm}_H(T) = \text{Norm}_L(T), \quad W_H(T) = W_L(T),$
 ``

in particular $W_H(T)$ is finite over S .

Proof. Let us first note that (i) is local for the étale topology. Therefore, by Corollary 5.3.18, (i) is a

consequence of the last assertion of (iii).

The assertions of (ii) are local for the étale topology. One may therefore suppose to be in the situation of 5.11.3, where one concludes immediately by (i) and (ii).

By virtue of the uniqueness assertions contained in it, (iii) is also local for the étale topology and one may again reduce to the situation of 5.11.3, where properties (a) and (b) have been verified. The uniqueness of an L satisfying (a) is trivial; the uniqueness of an L satisfying (b) is obvious, given (a). The equality $\text{Norm}_H(L) = L$ is none other than 5.11.3 (iii); if a section of H normalizes T , then it normalizes L , by uniqueness of L , hence is a section of L by what was just demonstrated, which proves the second equality; the third is then trivial.

Proposition 5.11.5. *Let S be a scheme, G an S -reductive group, H_c the functor of subgroups of type (RC) of G , which is a subfunctor of the functor H of 5.8.1.*

<!-- label: III.XXII.5.11.5 -->

(i) H_c is representable by an open subscheme of H , smooth, quasi-projective, and of finite presentation over S .*

(ii) There exists a finite étale S -scheme C_{ell} and a morphism*

$$C_{\text{ell}} : H_c \rightarrow C_{\text{ell}},$$

smooth, quasi-projective, of finite presentation, surjective, with connected geometric fibers, possessing the following property:*

For every $S' \rightarrow S$ and every H , $H' \in H_c(S')$, $C_{\text{ell}}(H) = C_{\text{ell}}(H')$ if and only if H and H' are conjugate in G locally for the étale topology (or, equivalently by 5.3.11, if for every $s \in S$, H_s and H'_s are conjugate by an element of $G(s)$).*

(iii) C_{ell} and C_{ell} are determined (up to unique isomorphism) by the preceding conditions.*

(iv) If (G, T, M, R) is a splitting of G , let E be the set of conjugacy classes modulo W of closed subsets of R ; then there exists an isomorphism $C_{\text{ell}} \xrightarrow{\sim} E_S$ such that, for every closed subset R' of R , $C_{\text{ell}}(H_{R'})$ corresponds to the canonical image of R' in $E_S(S) = \text{Hom}_{\{\text{loc.const.}\}}(S, E)$.*

It is first clear that H_c is a sheaf for the étale topology and that (ii) entails that C_{ell} is none other than the quotient sheaf of H_c by the equivalence relation defined by conjugation.

This entails first (iii), as well as the fact that it suffices to verify (i) and (ii) locally for the étale topology. One thus reduces to the situation of (iv); let us first construct a morphism

$$f : H_c \rightarrow E_S.$$

It suffices to construct an application $H_c(S) \rightarrow E_S(S)$ functorial in S ; so let H be a subgroup of type (RC) of G ; since H locally for the étale topology possesses maximal tori, and since the maximal tori of G are conjugate locally for the étale topology, there exists a covering family $\{S_i \rightarrow S\}$ and for each i a $g_i \in G(S_i)$ and a closed subset R_i of R such that $\text{int}(g_i)(H \times_{S_i} S_i) = H_{R_i} \times_{S_i} S_i$; each R_i defines a section η_i of E_{S_i} , i.e. an element of $E_S(S_i)$; it now suffices to prove that the family (η_i) arises from a section $\eta = f(H)$ of E_S over S , and that the latter depends only on H .

For this, one is reduced to proving that $H_{R'}$ and $H_{R''}$ are conjugate locally for the étale topology if and only if R' and R'' are conjugate by an element of the Weyl group W , which is trivial.

For every $\eta \in E$, there exists an $H_0 \in H_c(S)$ such that $f(H_0) = \eta$: it suffices to take $H_0 = H_{R'}$ where R' is a closed subset of R whose image in E is η . If $H \in H_0(S')$, $S' \rightarrow S$, H is conjugate to H_0 locally for the étale topology if and only if $f(H) = \eta$ (as one sees immediately by the preceding argument), which shows that $f^{-1}(\eta)$ is identified with the quotient $G/\text{Norm}_G(H_0)$, which by 5.8.2 is an open subset of H , smooth, quasi-projective of finite presentation over S , with connected and non-empty fibers. Since E_S is the sum of the open subschemes images of the sections corresponding to the $\eta \in E$, H_c is identified with the sum of the $f^{-1}(\eta)$, $\eta \in E$, which proves (i) and (ii). Finally, (iv) holds by construction.

****Corollary 5.11.6.**** *If $u \in \mathrm{C\ell}_c(S)$, $S' \rightarrow S$, $c\ell^{-1}(u)$ is an S' -scheme that is smooth, quasi-projective, of finite presentation, with non-empty connected fibers; it is an open subset of H_c and a "homogeneous" scheme under $G_{S'}$ (by inner automorphisms). In particular, if $H \in c\ell^{-1}(u)(S)$, the morphism $G_{S'} \rightarrow (Hc)_{S'}$ defined by $g \mapsto \mathrm{int}(g)H$ identifies $G_{S'}/\mathrm{Norm}_{G_{S'}}(H)$ with $c\ell^{-1}(u)$.*

<!-- label: III.XXII.5.11.6 -->

****Examples 5.11.7.**** *In particular, one has two canonical sections u_t , u_b of $\mathrm{C\ell}_c$ corresponding respectively to maximal tori ($R' = \emptyset$) and to Borel subgroups ($R' = \text{system of positive roots}$). The S -schemes $c\ell^{-1}(u_t)$ and $c\ell^{-1}(u_b)$ are none other than the S -schemes $\mathrm{Tor}(G)$ and $\mathrm{Bor}(G)$ introduced in 5.8.3. We will see other examples in Exp. XXVI.*

<!-- label: III.XXII.5.11.7 -->

****Remark 5.11.8.**** *One may construct an S -scheme $\mathrm{C\ell}$, of finite presentation and unramified, and a morphism $H \rightarrow \mathrm{C\ell}$ smooth and surjective, with connected geometric fibers, enjoying properties analogous to 5.11.5 (ii) and (iii).*

<!-- label: III.XXII.5.11.8 -->

6. The derived group

<!-- label: III.XXII.6 -->

6.1. Preliminaries

<!-- label: III.XXII.6.1 -->

In this section, we fix a scheme S , an S -split group (G, T, M, R) , a system of positive roots R_+ of R , and write

```text  
 $B = B_{R_+}$ ,  $B_- = B_{R_-}$ ,  $U = B^u$ ,  $U_- = (B_-)^u$ ,  
 $\Omega = \Omega_{R_+} = U_- \cdot T \cdot U$ .  
 ```

6.1.1.

<!-- label: III.XXII.6.1.1 -->

We denote by T' the subtorus of T "image of the family α , $\alpha \in R$ "; in other words, T' is the image of the morphism of groups

$G^{\{R\}}_{\{m, S\}} \rightarrow T$
 S

defined by $(z_{\alpha})_{\alpha \in R} \mapsto \prod_{\alpha \in R} \alpha(z_{\alpha})$. One sees immediately that if Δ denotes the set of simple roots of R_+ , the morphism

$G^{\{\Delta\}}_{\{m, S\}} \rightarrow T'$
 S

defined in the same way is surjective with finite kernel. If we identify T with $D_{\{S\}}(M)$, then T' is identified with $D_{\{S\}}(M/N)$, where

S
 $N = M \cap V(R^*)^{\perp}$
 S

(we denote by $V(R^*)^{\perp}$ the orthogonal of $V(R^*)$ in the duality between V and V^*).

****Lemma 6.1.2.**** *The morphism defined by the product in T' *

<!-- label: III.XXII.6.1.2 -->

```
```text
rad(G) ×S T' → T
```
```

is an isogeny (cf. 4.2.9).

Indeed, the canonical morphism $\text{rad}(T) \rightarrow T/T'$ arises by duality from the morphism of commutative groups

```
```text
M n V(R*)^1 → M/(M n V(R)),
```
```

which one sees immediately to be injective with finite cokernel (cf. Exp. XXI 6.3).

Definition 6.1.3. *One writes $\Omega' = U_{\{-\}} \cdot T' \cdot U$; it is a closed subscheme of $\Omega = U_{\{-\}} \cdot T \cdot U$.*

<!-- label: III.XXII.6.1.3 -->

Lemma 6.1.4. *Let α be a simple root and $w_{\alpha} \in \text{Norm}_G(T)(S)$ lifting s_{α} . One has*

<!-- label: III.XXII.6.1.4 -->

```
```text
int(w_α) Ω' n Ω ⊂ Ω'.
```
```

It suffices for us to prove that if $g \in \Omega'(S)$ and $\text{int}(w_{\alpha}) g \in \Omega(S)$, then $\text{int}(w_{\alpha}) g \in \Omega'(S)$. By 5.6.8, write

```
```text
g = a · exp_{-α}(Y) · t · expα(X) · b,
```
```

with $a \in U_{\{-\hat{\alpha}\}}(S)$, $Y \in \Gamma(S, g^{-\alpha})$, $t \in T'(S)$, $X \in \Gamma(S, g^{\alpha})$, $b \in U_{\{\hat{\alpha}\}}(S)$. One then has

```
```text
int(w_α) g = int(w_α) a · int(w_α)(exp_{-α}(Y) t expα(X)) · int(w_α) b.
```
```

By virtue of 5.6.8 (iv), one has

```
```text
int(w_α) a ∈ U_{-α^}(S), int(w_α) b ∈ U_{α^}(S).
```
```

It follows that one has the following equivalences (setting $h = \exp_{-\alpha}(Y) t \exp \alpha(X)$):

```
```text
int(w_α) g ∈ Ω(S) ⇔ int(w_α) h ∈ Ω(S)
int(w_α) g ∈ Ω'(S) ⇔ int(w_α) h ∈ Ω'(S).
```
```

One is therefore reduced to the case where $g = h$. Since one has (4.1.12)

```
```text
Zα n Ω = U_{-α} · T · Uα, Zα n Ω' = U_{-α} · T' · Uα,
```
```

one is reduced to proving the following assertion:

```

```text
int(w_α) h ∈ (U_{-α} · T · U_α)(S) ⇒ int(w_α) h ∈ (U_{-α} · T' · U_α)(S).
```

```

Now this latter follows immediately from Exp. XX 3.12, which shows that the component on T of $\text{int}(w_{\alpha})h$ is of the form $t \cdot \alpha(z) \in T'(S)$.

Lemma 6.1.5. *For every $w \in \text{Norm}_{\{G\}}(T)(S)$, there exists an open subset V_w of G containing the unit section, such that*

```

<!-- label: III.XXII.6.1.5 -->

```

```

```text
int(w) Ω' ∩ V_w ⊂ Ω'.
```

```

Choose, for each simple root α , an $n_{\alpha} \in \text{Norm}_{\{G\}}(T)(S)$ lifting s_{α} . For every point $s \in S$, there exist an open subset V_s of S containing s , a $t \in T(V)$ and over V_s a relation

```

```text
w = n_{α_1} ... n_{α_p} t, with the α_i simple.
```

```

One may obviously content oneself with making the demonstration for $V = S$; it is done by induction on p . If $p = 0$, then $w \in T(S)$ and one takes $V_w = G$; suppose therefore $w = n_{\alpha} \cdot w'$, w' satisfying the conclusion of the lemma; there thus exists an open subset $V_{w'}$ of G , containing the unit section, such that $\text{int}(w') \cap \Omega' \cap V_{w'} \subset \Omega'$. One may then write

```

```text
int(w) Ω' ∩ (int(n_α) V_{w'} ∩ Ω) = int(n_α)(int(w') Ω' ∩ V_{w'}) ∩ Ω
 ⊂ int(n_α) Ω' ∩ Ω ⊂ Ω',
```

```

by 6.1.4. One then takes $V_w = \text{int}(n_{\alpha}) V_{w'} \cap \Omega$ and we are done.

Lemma 6.1.6. *There exists an open subset $V_{\{0\}}$ of G , containing the unit section, such that for every $S' \rightarrow S$, one has*

```

<!-- label: III.XXII.6.1.6 -->

```

```

```text
U(S') U_{-}(S') ∩ V_{\theta}(S') ⊂ Ω'(S').
```

```

Let $n_{\{0\}}$ be an element of $\text{Norm}_{\{G\}}(T)(S)$ lifting the symmetry $w_{\{0\}}$ of the Weyl group, [N.D.E-XXII-60] that is, such that $\text{int}(n_{\{0\}}) U = U_{\{-\}}$ (cf. Exp. XXI 3.6.14); then $n_{\{2\}_{\{0\}}} \in T(S)$. Let us show that the open set $V_{\{0\}} = V_{\{n_{\{0\}}\}}$ of 6.1.5 answers the question. Indeed

```

```text
U(S') U_{-}(S') = int(n_{\theta})(int(n_{\theta})^{-1} U(S') · int(n_{\theta})^{-1} U_{-}(S'))
 = int(n_{\theta})(U_{-}(S') · U(S')) ⊂ int(n_{\theta}) Ω'(S').
```

```

Whence

```

```text
U(S') U_{-}(S') ∩ V_{\theta}(S') ⊂ int(n_{\theta}) Ω'(S') ∩ V_{\theta}(S') ⊂ Ω'(S').
```

```

Lemma 6.1.7. *Consider the morphism*

```

<!-- label: III.XXII.6.1.7 -->

```

```

```text
f : Ω = U_{-} · T · U → T/T'
```

```

...

composite of the second projection and the canonical morphism of T into T/T' . Then f is "generically multiplicative": there exists an open subset V of $\Omega \times_S \Omega$, containing the unit section (and hence relatively schematically dense, Exp. XVIII 1.3) such that for every $S' \rightarrow S$ and every $(x, y) \in V(S')$, one has $xy \in \Omega(S')$ and $f(xy) = f(x) f(y)$.

Let x and y be two sections of Ω over S' . Write

```

$$x = u \cdot t \cdot v, \quad y = u' \cdot t' \cdot v', \quad \text{with } u, u' \in U_-(S'), \quad t, t' \in T(S'), \quad v, v' \in U(S').$$

```

Let V_0 be the open set of 6.1.6 and V the open subset of $\Omega \times_S \Omega$ defined by " $v \cdot u' \in V_0(S')$ " (it is the inverse image of V_0 by the morphism $\Omega \times_S \Omega$ written set-theoretically $(x, y) \mapsto v \cdot u'$). Then V answers the question. Indeed, for $(x, y) \in V(S')$, one has

```

$$xy = (u \cdot t \cdot v)(u' \cdot t' \cdot v') = (u \cdot t)(v \cdot u')(t' \cdot v').$$

```

But $v \cdot u' \in \Omega(S')$, whence

```

$$xy \in U_-(S') \cdot t \cdot \Omega(S') \cdot t' \cdot U(S') \subset U_-(S') \cdot t \cdot T'(S') \cdot U(S'),$$

```

which shows that $xy \in \Omega(S')$ and that

```

$$f(xy) = f(tt') = f(t) f(t') = f(x) f(y).$$

```

Proposition 6.1.8. *There exists a morphism of groups*

<!-- label: III.XXII.6.1.8 -->

```

$$f : G \rightarrow T/T'$$

```

inducing on T the canonical projection. The kernel $\text{Ker}(f)$ of f is a closed group subscheme of G smooth over S and with connected fibers. Every morphism of groups from G to a presheaf of commutative groups on S , separated for (fppf), vanishes on $\text{Ker}(f)$.

The first assertion follows immediately from 4.1.11. One has immediately $\text{Ker}(f) \cap \Omega = \Omega'$, which proves that $\text{Ker}(f)$ is smooth over S at every point of the unit section.[^N.D.E-XXII-61] By 5.6.9 (ii), every morphism ϕ from G to a presheaf of commutative groups separated for (fppf) vanishes on U and U_- . By Exp. XX 2.7, ϕ therefore vanishes also on T' , hence on Ω' . Taking the notations of 5.7.10, one sees that the monoid U_1 is contained in $\text{Ker}(f)(S)$, which shows that

```

$$\text{Ker}(f) = \bigcup_{u \in U_1} u \cdot \Omega'.$$

```

It follows on the one hand that every ϕ as above vanishes on $\text{Ker}(f)$, and on the other hand that $\text{Ker}(f)$ has connected fibers, hence is smooth over S by Exp. VI_B 3.10.

6.2. Derived group of a reductive group

<!-- label: III.XXII.6.2 -->

Theorem 6.2.1. *Let S be a scheme, G an S -reductive group.*

<!-- label: III.XXII.6.2.1 -->

(i) $D_{\{S\}}(G) = \operatorname{Hom}_{\{S\text{-gr.}\}}(G, \operatorname{Gm}(S))$ is representable by a twisted constant S -group, whose type at $s \in S$ is $\mathbb{Z}^{\operatorname{rg}_{\text{red}}(G_s)} - \operatorname{rg}_{\text{ss}}(G_s)$.

(ii) Write $\operatorname{corad}(G) = D_{\{S\}}(D_{\{S\}}(G))$, which is therefore an S -torus. The biduality morphism (cf. Exp. VIII § 1)

$f_{\{0\}} : G \rightarrow \operatorname{corad}(G)$

is smooth and surjective.*

(iii) The composite morphism

$\operatorname{rad}(G) \rightarrow G \rightarrow \operatorname{corad}(G)$

is an isogeny (cf. 4.2.9).*

(iv) The kernel of $f_{\{0\}}$, denoted

$d\operatorname{acute}{e}r(G) = \operatorname{Ker}(f_{\{0\}})$

is a closed group subscheme of G , semisimple over S , called the* derived group *of G . If G is semisimple, one has $d\operatorname{acute}{e}r(G) = G$.*

(v) Every morphism of groups from G to an S -presheaf of commutative groups, separated for (fppf), vanishes on $d\operatorname{acute}{e}r(G)$ and thus factors through $f_{\{0\}}$.

Proof. All assertions of the theorem are local for the étale topology; one may thus reduce to the case where G is split over S . Consider then the morphism f of 6.1.8. By the last assertion of 6.1.8, one immediately has an isomorphism

$\operatorname{Hom}_{\{S\text{-gr.}\}}(G, \operatorname{Gm}(S)) \cong \operatorname{Hom}_{\{S\text{-gr.}\}}(T/T', \operatorname{Gm}(S)),$

which proves (i), then (ii) and gives a commutative diagram

$$\begin{array}{ccc} G & \xrightarrow{f_0} & \operatorname{corad}(G) \\ \searrow & & \downarrow \\ f & & \\ \searrow & \rightarrow & T/T'. \end{array}$$

One then has (v) by 6.1.8, and (iii) by 6.1.2. One also has $\operatorname{Ker}(f) = \operatorname{Ker}(f_{\{0\}})$, which by 6.1.8 entails that $d\operatorname{acute}{e}r(G)$ is smooth over S and has connected fibers; it remains to verify that its fibers are semisimple; now they are reductive by Exp. XIX 1.7, as invariant subgroups of reductive groups. By (iii), $\operatorname{rad}(G) \cap d\operatorname{acute}{e}r(G)$ is finite, which indeed entails that the fibers of $d\operatorname{acute}{e}r(G)$ are semisimple.

Remark 6.2.2. (a) By construction, in the case where G is split, $d\operatorname{acute}{e}r(G)$ is the (fppf) subsheaf of G generated by the $U\alpha$, $\alpha \in R$. (It even suffices to take the $U\alpha$, $\alpha \in \Delta \cup -\Delta$, where Δ is a basis of R .)*

<!-- label: III.XXII.6.2.2 -->

(b)[^{N.D.E-XXII-62}] *Let C be the presheaf of commutators of G , i.e. the S -group functor that associates with every $S' \rightarrow S$ the group of commutators of $G(S')$ (i.e. the subgroup of $G(S')$ generated by the elements $xyx^{-1}y^{-1}$, for $x, y \in G(S')$), and let $\tilde{C}$ be the associated (fppf) sheaf. Since the quotient $G/d\operatorname{acute}{e}r(G) = T/T'$ is commutative, then $d\operatorname{acute}{e}r(G)$ contains C and hence $\tilde{C}$ (cf. Exp. IV 4.3.12).*

On the other hand, the quotient presheaf $\mathcal{G}/\tilde{\mathcal{C}}$ is separated (Exp. IV 4.4.8.1), and therefore by (v) one has $d\acute{e}r(G) \subset \tilde{\mathcal{C}}$, whence $d\acute{e}r(G) = \tilde{\mathcal{C}}$, i.e. $d\acute{e}r(G)$ is the (fppf) sheaf of commutators of $\mathcal{G}$.

Let us finally note that $\mathcal{C}$, being a subpresheaf of $\mathcal{G}$, is separated, but is not equal to $d\acute{e}r(G)$ in general: for example, $d\acute{e}r(SL_2) = SL_2$ but $SL_2(F_2) \not\subseteq S_3$ is not equal to its derived group.

(c) When S is the spectrum of an algebraically closed field k , $d\acute{e}r(G)(k)$ is the group of commutators of $G(k)$ (Exp. VI_B 7.10).

6.2.3.

<!-- label: III.XXII.6.2.3 -->

Consider now the two exact sequences

$$\begin{array}{c} \mathcal{G} \\ 1 \rightarrow \text{rad}(G) \rightarrow G \rightarrow \text{ss}(G) \rightarrow 1, \\ 1 \rightarrow d\acute{e}r(G) \rightarrow G \rightarrow \text{corad}(G) \rightarrow 1. \\ \mathcal{G} \end{array}$$

Since $\text{rad}(G)$ is central in $\mathcal{G}$, the product in $\mathcal{G}$ defines a morphism of groups

$$\begin{array}{l} \text{``text} \\ u : \text{rad}(G) \times_S d\acute{e}r(G) \rightarrow G \\ \text{``} \end{array}$$

which is covering by virtue of 6.2.1 (iii), hence surjective and flat (Exp. VI_B 9.2 (xi)).^[^N.D.E-XXII-63] Its kernel is isomorphic to $\text{rad}(G) \cap d\acute{e}r(G)$, which is also the kernel of $\text{rad}(G) \rightarrow \text{corad}(G)$, hence is a finite subgroup of multiplicative type of $\text{rad}(G)$.

One reasons similarly for the morphism

$$\begin{array}{l} \text{``text} \\ G \rightarrow \text{corad}(G) \times_S \text{ss}(G), \\ \text{``} \end{array}$$

whose kernel is $d\acute{e}r(G) \cap \text{rad}(G)$. One thus has:

Proposition 6.2.4. *Let $\mathcal{G}$ be an S -reductive group. The morphisms*

<!-- label: III.XXII.6.2.4 -->

$$\begin{array}{l} \text{``text} \\ \text{rad}(G) \times_S d\acute{e}r(G) \rightarrow G, \quad G \rightarrow \text{corad}(G) \times_S \text{ss}(G), \quad \text{rad}(G) \rightarrow \text{corad}(G) \\ \text{``} \end{array}$$

are central isogenies, and their kernels are isomorphic.

Corollary 6.2.5. *The following conditions are equivalent:*

<!-- label: III.XXII.6.2.5 -->

- *(i) $\mathcal{G}$ is the product of a semisimple group and a torus.*
- *(ii) $\text{rad}(G) \times_S d\acute{e}r(G) \xrightarrow{\sim} \mathcal{G}$.*
- *(iii) $\mathcal{G} \xrightarrow{\sim} \text{corad}(G) \times_S \text{ss}(G)$.*
- *(iv) $\text{rad}(G) \cap d\acute{e}r(G) = e$.*

6.2.6.

<!-- label: III.XXII.6.2.6 -->

Let us return provisionally to the case of a split group. Let us keep the notations of 6.1. Set $N = M \cap V(R)^{\perp}$. One thus has $T' = D_{\{S\}}(M/N)$. One has seen that $U_{\{-\}} \cdot T' \cdot U$ was an open neighborhood of the unit section of $d\text{-}e\text{-}r(G)$. One thus has

```text  
 $\text{Lie}(\text{dér}(G)/S) = t' \cap \bigcap_{\alpha \in R} g^{\alpha}.$   
 ```

Since the characters induced on T' by the $\alpha \in R$ are non-zero and distinct (cf. Exp. XXI 1.2.5 – one has moreover already used this fact in 6.1.2), R is a system of roots of $d\text{-}e\text{-}r(G)$ relative to T' . It is then immediate (since $U \cap d\text{-}e\text{-}r(G)$) that the ‘exp’ morphisms of $d\text{-}e\text{-}r(G)$ “are” those of G and similarly for the coroots.

It follows:

Proposition 6.2.7. In the preceding notations, $(d\text{-}e\text{-}r(G), T', M/N, R)$ is a split group with root datum $d\text{-}e\text{-}r(R(G))$. The canonical morphism $d\text{-}e\text{-}r(G) \rightarrow G$ gives by functoriality the canonical morphism of root data $R(G) \rightarrow d\text{-}e\text{-}r(R(G))$ of Exp. XXI 6.5.*

<!-- label: III.XXII.6.2.7 -->

N. B. The reader may, as an exercise, construct the diagram of split groups corresponding to the three left columns of the diagram of root data of Exp. XXI 6.5.7.

Proposition 6.2.8. Let S be a scheme, G an S -reductive group, $d\text{-}e\text{-}r(G)$ its derived group.*

<!-- label: III.XXII.6.2.8 -->

(i) For every maximal torus T of G , $T \cap d\text{-}e\text{-}r(G)$ is a maximal torus of $d\text{-}e\text{-}r(G)$. For every maximal torus T' of $d\text{-}e\text{-}r(G)$, $\text{Centr}_{\{G\}}(T') = \text{rad}(G) \cdot T'$ is a maximal torus of G . The two preceding constructions are inverse to one another and set up a bijective correspondence between maximal tori of G and of $d\text{-}e\text{-}r(G)$.*

(ii) For every Borel subgroup B of G , $B \cap d\text{-}e\text{-}r(G)$ is a Borel subgroup B' of $d\text{-}e\text{-}r(G)$. One has $B^u = B'^u$. For every Borel subgroup B' of $d\text{-}e\text{-}r(G)$, $\text{Norm}_{\{G\}}(B') = \text{rad}(G) \cdot B'$ is a Borel subgroup of G . The preceding applications are inverse to one another and set up a bijective correspondence between Borel subgroups of G and of $d\text{-}e\text{-}r(G)$.*

By the local conjugacy theorem for maximal tori and the construction of the derived group, the only assertion that remains to prove in (i) is the following: if T is a maximal torus of G , then

```text  
 $T = (T \cap \text{dér}(G)) \cdot \text{rad}(G) = \text{Centr}_G(T \cap \text{dér}(G)).$   
 ```

The first equality is trivial (one reduces to the split case); the second follows from this immediately, because $\text{rad}(G)$ is central in G , so $T = \text{Centr}_G(T) = \text{Centr}_G(T \cap d\text{-}e\text{-}r(G))$. One reasons similarly for (ii).

6.3. Subgroups with commutative quotients

<!-- label: III.XXII.6.3 -->

6.3.1.

<!-- label: III.XXII.6.3.1 -->

Let G be an S -reductive group. If H is a group subsheaf of G , the following conditions are equivalent:

- H contains $d\text{-}e\text{-}r(G)$.
- H is normal and G/H is commutative.

In this case, the canonical morphism $f_{\{0\}} : G \rightarrow \text{corad}(G)$ sends H to a subsheaf $f_{\{0\}}(H)$ of $\text{corad}(G)$; one has

```

```text

$$\begin{aligned} G/H &\cong \text{corad}(G)/f_0(H), & H/\text{dér}(H) &\cong f_0(H), \\ \text{dér}(G) &= \text{dér}(H), & H &= f_0^{-1}(f_0(H)). \end{aligned}$$

```

```

Since $\text{d}\acute{e}r(G)$ is smooth over S and has connected fibers, [N.D.E-XXII-64] by Exp. IV, 5.3.1 and 6.3.1, and Exp. IV_B 9.2, the map $H \mapsto f_0(H)$ establishes a bijective correspondence between group subschemes (resp. closed group subschemes) of G containing $\text{d}\acute{e}r(G)$, smooth over S and with connected fibers, and group subschemes (resp. closed group subschemes) of $\text{corad}(G)$, smooth over S and with connected fibers.

Now, if H is a group subscheme of $\text{corad}(G)$, smooth over S with connected fibers, then H is of finite presentation over S (Exp. VI_B 5.5) and its fibers are tori (since those of $\text{corad}(G)$ are), so by Exp. X 8.2, H is a subtorus of $\text{corad}(G)$, hence is closed in $\text{corad}(G)$ (Exp. IX 2.6).

Consequently, every subgroup of G , smooth with connected fibers and containing $\text{d}\acute{e}r(G)$, is closed in G . [N.D.E-XXII-64]

6.3.2.

<!-- label: III.XXII.6.3.2 -->

If H is a closed group subscheme of G , smooth over S , with connected fibers, and normal in G , then H is reductive. If furthermore $H \supset \text{d}\acute{e}r(G)$, then $\text{d}\acute{e}r(H) = \text{d}\acute{e}r(G)$ and $f_0(H)$ is identified with $\text{corad}(H)$. One has thus proved:

Proposition 6.3.3. *Let G be an S -reductive group. Every group subscheme H of G , normal in G , with commutative quotient (i.e. containing $\text{d}\acute{e}r(G)$), smooth over S , with connected fibers, [N.D.E-XXII-65] is closed and reductive. One has $\text{d}\acute{e}r(H) = \text{d}\acute{e}r(G)$ and $f_0(H)$ is identified with $\text{corad}(H)$; one has*

<!-- label: III.XXII.6.3.3 -->

```

```text

$$G/H \cong \text{corad}(G)/\text{corad}(H), \quad H = (H \cap \text{rad}(G)) \cdot \text{dér}(G).$$

```

```

Furthermore, $H \mapsto f_0(H)$ defines a bijection between the set of subgroups H of G possessing the preceding properties and the set of subtori of $\text{corad}(H)$.

By a further application of Noether's theorem (Exp. IV, 5.3.1 and 6.3.1), one deduces:

Proposition 6.3.4. *Let S be a scheme, G an S -reductive group, T a maximal torus of G . For every subgroup H of G as above, $T \cap H$ is a maximal torus of G and one has*

<!-- label: III.XXII.6.3.4 -->

```

```text

$$G/H \cong T/(T \cap H), \quad H = (T \cap H) \cdot \text{dér}(G).$$

```

```

Furthermore, $H \mapsto T \cap H$ is a bijection between the set of subgroups H of G as above and the set of subtori of T containing $T \cap \text{d}\acute{e}r(G)$.

[^N.D.E-XXII-0]: Version of 13/10/2024.

[^N.D.E-XXII-1]: The set $\Gamma(S, g\alpha)\times$ is defined in XIX 4.4.1.

[^N.D.E-XXII-2]: That is, if one denotes by $\langle , \rangle$ the duality between $g\alpha$ and $g_{-\alpha}$ and if one identifies $g\alpha$ with $U\alpha$ via $p\alpha(x) = \exp(x\alpha)$, and similarly for $g_{-\alpha}$, then $\langle p\alpha(x), p_{-\alpha}(y) \rangle = xy$.

[^N.D.E-XXII-3]: We have added the numbering 1.8.0 to highlight these definitions.

[^N.D.E-XXII-4]: We have added the number 2.6.1 for later references.

[^N.D.E-XXII-5]: We have corrected the original, which referred to 1.17.

[^N.D.E-XXII-6]: Indeed, since W_S and $W_G(T) = \text{Norm}_G(T)/T$ are étale over S , the morphism $f : W_S \rightarrow W_G(T) = \text{Norm}_G(T)/T$ is étale (EGA IV₄, 17.3.4); if furthermore each f_s is an isomorphism, then, by loc. cit., 17.9.1, f is a surjective open immersion, hence an isomorphism.

[^N.D.E-XXII-7]: Indeed, let T be a maximal torus of G . The fact that $W_G(T)$ is finite over S is local for the (fpqc) topology (EGA IV₂, 2.7.1), so a fortiori for the étale topology. By 2.3, one may therefore suppose that G is split relative to T , in which case the assertion follows from 3.4.

[^N.D.E-XXII-8]: We have replaced Q_w by N_w , just as in XX 3.0 we had replaced Q by $N\times$.

[^N.D.E-XXII-9]: And we call it the "big cell" corresponding to $R+$.

[^N.D.E-XXII-10]: We have expanded the original in what follows.

[^N.D.E-XXII-11]: See also EGA IV₃, 11.10.10.

[^N.D.E-XXII-12]: We have added the following sentence.

[^N.D.E-XXII-13]: We have expanded the original in what follows.

[^N.D.E-XXII-14]: Indeed, the representability of the center by a closed subscheme of G is local for the (fpqc) topology (SGA 1, VIII 5.2 and 5.4), so a fortiori for the étale topology, and the same holds for the property "of multiplicative type".

[^N.D.E-XXII-15]: We have expanded the original in what follows.

[^N.D.E-XXII-16]: Note that this is equivalent to the hypothesis: if $\alpha, \alpha' \in R$, $m, m' \in \mathbb{Z}$ and if $(m\alpha \circ f)_s = (m'\alpha' \circ f)_s$ for every geometric point s of S , then $m\alpha = m'\alpha'$. In particular, this separation hypothesis is stable under base change.

[^N.D.E-XXII-17]: Recall (cf. Exp. IV, 4.3.5) that an S -prefunctor H is separated for a topology T if for every $S' \rightarrow S$ and every family of S -morphisms $(S'_i \rightarrow S')_{i \in I}$ covering for T , the map $H(S') \rightarrow \prod_{i \in I} H(S'_i)$ is injective.

[^N.D.E-XXII-18]: We have expanded the original in what follows.

[^N.D.E-XXII-19]: We have replaced the notation $u : R \rightarrow R'$ by $d : R \rightarrow R'$.

[^N.D.E-XXII-20]: We have expanded the reference to Exp. VI in what follows.

[^N.D.E-XXII-21]: Indeed, since G and G' are semisimple, f_T is surjective with finite kernel, so f is faithfully flat with finite kernel by 4.2.6 (i) and 4.2.8.

[^N.D.E-XXII-22]: The content of the root α is the positive generator of the ideal $\{f(\alpha), f \in \Gamma_0(R)^*\}$ of $\mathbb{Z}$; it is the largest integer $c > 0$ such that $\alpha/c \in \Gamma_0(R)$.

[^N.D.E-XXII-23]: We have added this recall.

[^N.D.E-XXII-24]: The original stated "under the conditions of (iv)", but the last condition of (iv) does not seem to be used here.

[^N.D.E-XXII-25]: The hypothesis that G (resp. H) be of finite presentation over S is automatically verified because G (resp. H) being smooth over S with connected fibers, is quasi-compact and separated over S (VI_B 5.5), so of finite presentation over S .

[^N.D.E-XXII-26]: This amounts to saying that H is a smooth subgroup of G , each of whose geometric fibers H_s is a Borel subgroup of G_s (since every Borel subgroup of G_s is connected and contains a Cartan subgroup of G_s).

[^N.D.E-XXII-27]: We have expanded what follows.

[^N.D.E-XXII-28]: By hypothesis, H contains $\text{Centr}_G(T')$ for some maximal torus T' of G ; then T and T' are conjugate in H , so H also contains $C = \text{Centr}_G(T)$.

[^N.D.E-XXII-29]: We have added this recall, which is used in the proofs of 5.3.1 and 5.3.4.

[^N.D.E-XXII-30]: We have expanded the original in what follows.

[^N.D.E-XXII-31]: We have added the following proof.

[^N.D.E-XXII-32]: Indeed, let $g \in G$, s its image in S , m the maximal ideal of $\mathcal{O}_{G,g}$, n that of $\mathcal{O}_{S,s}$, and I (resp. I') the kernel of the morphism of $\mathcal{O}_{G,g}$ into $\mathcal{O}_{H,g}$ (resp. $\mathcal{O}_{H',g}$) (the latter being the zero ring if $g \notin H$, resp. $g \notin H'$). Since $\mathcal{O}_{G,g}$ is noetherian, I and I' are closed for the m -adic topology, so a fortiori for the n -adic topology, so it suffices to show that $I + n^n \mathcal{O}_{G,g} = I' + n^n \mathcal{O}_{G,g}$ for every $n \in \mathbb{N}$.

[^N.D.E-XXII-33]: Indeed, if k is algebraically closed, all the maximal tori of $G = \text{SL}_2, k$ are conjugate under $G(k)$, and all have for Lie algebra the line $k \cdot \text{id} \subset M_2(k)$ (which is invariant under the adjoint action).

[^N.D.E-XXII-34]: Cf. footnote (25).

[^N.D.E-XXII-35]: In fact, it suffices (cf. loc. cit.) that 2 and 3 be non-zero on S .

[^N.D.E-XXII-36]: By EGA IV₄, 17.11.2, $\mathcal{S}$ is étale at every point of the unit section (and $\mathrm{Norm}_G(g_{R'})$ is smooth at every point of the unit section). Furthermore, let V be the largest open subset of $\Omega_{R+, R'}$ on which $\mathcal{S}$ is étale; since $\mathcal{S}$ is a monomorphism, $\mathcal{S}_V$ is an open immersion (ibid., 17.9.1).

[^N.D.E-XXII-37]: That is, if $g^{\alpha+j\beta} = 0$ on a connected component of $\mathcal{S}$, the corresponding exponential is 1 on this component.

[^N.D.E-XXII-38]: Note that such an ordering is necessarily compatible with ord_{Δ} , where $\Delta = S(R+)$ (cf. XXI 3.2.15).

[^N.D.E-XXII-39]: The inclusion follows from $t \subset g_{R'}$.

[^N.D.E-XXII-40]: We have corrected the original in what follows.

[^N.D.E-XXII-41]: This is in fact a statement about root systems, completing Exposé XXI (cf. [BLie], VI § 1.7, Prop. 22) and proved here by an indirect route.

[^N.D.E-XXII-42]: Indeed, G having connected fibers is separated over S by VI_B 5.5, so by XI 6.11 (see also the addition 6.5.5 in VI_B), $\mathrm{Norm}_G(U_{R'})$ is represented by a closed group subscheme N of G . If N contains T and the U_{β} , for $\beta \in R'$, it then contains the big cell $\Omega_{R+, R'}$; now this is schematically dense in $H_{R'}$ by 5.4.4 and EGA IV₃, 11.10.10 (the fibers of $H_{R'}$ are integral and $\Omega_{R+, R'}$ contains a non-empty open subset of each fiber). It follows that $H_{R'} \subset N$, hence $H_{R'}$ normalizes $U_{R'}$.

[^N.D.E-XXII-43]: One must see that, under the hypotheses of (ii), if $\alpha \in R'$ and $\beta \in R'$, then all roots of the form $i\alpha + j\beta$ with $i, j \in \mathbb{N}$ belong to R' , and for this we have replaced the reference XXI 2.3.5 by XXI 3.1.2. This may also be seen directly by inspection of the rank 2 root systems.

[^N.D.E-XXII-44]: We have removed the hypothesis that U be closed, which is automatically verified. Indeed, for such a U , one has $U \cap T = e$ by 5.6.10, so the semi-direct product $H = T \cdot U$ is a subgroup of type (R) of G (cf. 5.2.1), with solvable geometric fibers. So, by 5.6.3, H is closed in G , and since U is closed in H , it is closed in G .

[^N.D.E-XXII-45]: This re-proves and refines XII 1.10 (for G reductive).

[^N.D.E-XXII-46]: By SGA 1, VIII 2.1 and EGA IV₄, 17.7.1.

[^N.D.E-XXII-47]: See also the additions made in VI_B, 6.2.1 to 6.2.6 and 6.5.2 to 6.5.5.

[^N.D.E-XXII-48]: It is in fact a closed immersion, by Exp. XVI 1.5 (a).

[^N.D.E-XXII-49]: We have expanded the original in what follows.

[^N.D.E-XXII-50]: Cf. Exp. II 4.11.8.

[^N.D.E-XXII-51]: The original next indicated that, denoting $n_{N/G}$ the inverse image of the conormal sheaf $N_{N/G}$ by the unit section $\mathcal{S} \rightarrow N$, the condition that $n_{N_{S'}/G_{S'}}$ $\rightarrow$ $\omega^1_{G_{S'}/S'}$ be universally injective is equivalent to the fact that $\mathcal{S}' \rightarrow \mathcal{S}$ factors through some open subscheme of $\mathcal{S}$. We were unable to justify this point, in view of the fact that the formation of $N_{N/G}$ does not commute with base change, and we have replaced this argument with the one that follows, indicated by O. Gabber.

[^N.D.E-XXII-52]: Cf. SGA 1, VIII 2.1.

[^N.D.E-XXII-53]: One may suppose $\mathcal{S}$ affine and, since $\mathrm{Bor}(G)$ is of finite presentation over S by (i), reduce to the case where $\mathcal{S}$ is noetherian; one is then under the hypotheses of EGA IV₃, 15.7.10.

[^N.D.E-XXII-54]: We have expanded what follows.

[^N.D.E-XXII-55]: Indeed, the proof of 5.8.1 only uses 5.3.3 (valid for a group of type (RA)) and XIX 6.2 which, by XII 1.7 (b), is also valid for groups of type (RR).

[^N.D.E-XXII-56]: This is the corollary on page 18 of TDTE I.

[^N.D.E-XXII-57]: Indeed, one has an exact sequence

$H^1(S, B^u) \rightarrow H^1(S, B) \xrightarrow{\pi} H^1(S, B/B^u) = H^1(S, T)$, see [Se64], I § 5.5, Prop. 38 or [Gi71], III Prop. 3.3.1. Now $H^1(S, T) \rightarrow H^1(S, B)$ is a section of π , so π is surjective; on the other hand $H^1(S, B^u) = 0$ by 5.9.6.

[^N.D.E-XXII-58]: We have modified the original, introducing the terminology "C-critical torus" instead of "critical torus", in order to avoid confusions in later references (cf. Exp. XXVI, 3.9). We have also expanded the statement of 5.10.5 and added Remark 5.10.5.1.

[^N.D.E-XXII-59]: I.e. when every residue characteristic of S is > 3 .

[^N.D.E-XXII-60]: The symmetry w_0 is defined in XXI 3.6.14.

[^N.D.E-XXII-61]: We have added "at every point of the unit section" as well as the reference to VI_B 3.10 at the end of the proof. Furthermore, in the next sentence we have replaced "prescheme" with "presheaf".

[^N.D.E-XXII-62]: In what follows, we have expanded the original, and suppressed the assertion that " $d\acute{e}r(G)$ is the separated (fppf) presheaf of commutators of G ".

[^N.D.E-XXII-63]: Indeed, G is the (fppf) quotient of $\text{rad}(G) \times_S d\acute{e}r(G)$ by $\text{Ker}(u)$, which is a group of multiplicative type, hence flat over S . Therefore, by VI_B 9.2 (xi), the morphism u is flat.

[^N.D.E-XXII-64]: We have expanded the original in what follows. In particular, we have added the conclusion (implicit in the original) that every subgroup of G , smooth with connected fibers and containing $d\acute{e}r(G)$, is closed in G .

[^N.D.E-XXII-65]: We have removed the hypothesis that H be retrocompact in G , which is automatically verified because, by VI_B 5.5, G and H are separated and quasi-compact over S , so $H \hookrightarrow G$ is quasi-compact by EGA IV₁, 1.1.2 (v).

Exposé XXIII. Reductive groups: uniqueness of pinned groups

<!-- label: III.XXIII -->

by M. Demazure

<!-- original page 263 -->

[^N.D.E-XXIII-0]

The aim of this Exposé is the proof of the uniqueness theorem (Theorem 4.1). This was proved by Chevalley in the case of an algebraically closed field; the method of reduction to rank two used here is also due to Chevalley (see *Bible*, Exp. 23 and 24). Along the way, we obtain an explicit description of reductive groups by generators and relations (3.5).

1. Pinnings

<!-- label: III.XXIII.1 -->

Definition 1.1. *Let S be a scheme and (G, T, M, R) an S -split group (XXII, 1.13). One calls*
pinning[^N.D.E-XXIII-butterfly] *of this split group the datum of a system Δ of simple roots of R and, for each $\alpha \in \Delta$, a section $X_\alpha \in \Gamma(S, g_\alpha)^{\times}$.*[^N.D.E-XXIII-butterfly-anchor]

<!-- label: III.XXIII.1.1 -->

In other words, a pinning of the reductive group G over the nonempty scheme S is the datum of:

- (i) a maximal torus T ,
- (ii) an abelian group M and an isomorphism $T \simeq D_S(M)$,
- (iii) a system of roots R of G with respect to T ,
- (iv) a system of simple roots Δ of R ,

(v) an $X_{\alpha} \in \Gamma(S, g_{\alpha})^{\times}$ for every $\alpha \in \Delta$, that is, of a

```

```text
u_α = exp_α(X_α) ∈ U_α^×(S) for every α ∈ Δ,
```

```

<!-- original page 264 -->

satisfying condition (D 1) of Exp. XXII, 1.13 (indeed condition (D 2) of *loc. cit.* is automatically satisfied [N.D.E-XXIII-1]).

Every split group admits a pinning; in particular, every reductive group is locally pinnable for the étale topology.

1.2.

<!-- label: III.XXIII.1.2 -->

If G is a pinned S -group – that is, an S -split group equipped with a pinning – it is canonically endowed with the system of positive roots R^{+} defined by Δ , the corresponding Borel subgroup $B = B_{R^{+}}$, the opposite Borel subgroup $B^{-} = B_{R^{-}}$, the unipotent groups $U = B_{\{u\}}$, $U^{-} = (B^{-})_{\{u\}}$, the open set $U^{-} \cdot T \cdot U$, etc. Likewise, for each $\alpha \in \Delta$, one has a canonical isomorphism of vector groups

```

```text
p_α : G_{[a, S]} ⊂ U_α, x ↦ exp_α(x X_α) = u_α x,
```

```

normalized by T with multiplier α , and whose datum is equivalent to that of X_{α} (Exp. XXII, 1.1).

By duality, one deduces an $X_{-\alpha} \in \Gamma(S, g_{-\alpha})^{\times}$ and an isomorphism

```

```text
p_{-α} : G_{[a, S]} ⊂ U_{-α}
```

```

which is the contragredient of the preceding one (Exp. XXII, 1.3). We shall set (Exp. XX, 3.1)

```

```text
w_α = w_α(X_α) = p_α(1) p_{-α}(-1) p_α(1) = p_{-α}(-1) p_α(1) p_{-α}(-1).
```

```

One then has (*loc. cit.* 3.1, 3.7)

```

```text
w_α^2 = α^*(-1), int(w_α) t = s_α(t) = t · α^*(α(t)^{-1}),
```

```

```

```text
int(w_α) p_α(x) = p_{-α}(-x) = p_{-α}(x)^{-1},
Ad(w_α) X_α = -X_{-α},
```

```

```

```text
int(w_α) p_{-α}(x) = p_α(-x) = p_α(x)^{-1},
Ad(w_α) X_{-α} = -X_α.
```

```

<!-- original page 265 -->

We shall use the preceding notation systematically in what follows.

Definition 1.3. Let S be a scheme and $(G, T, M, R, \Delta, (X_{\alpha}))$ and $(G', T', M', \cdots)$ two pinned S -groups. One says that the morphism of split groups (Exp. XXII, 4.2.1)*

S

$f : G \rightarrow G'$
 $\$ \$$

$\ast$ is compatible with the pinnings, $\ast$ or that it defines a $\ast$ morphism of pinned groups, $\ast$ if the bijection $\$d : R \rightarrow R'$ associated with it (cf. loc. cit.) satisfies $\$d(\Delta) = \Delta'$ and if, for every $\alpha \in \Delta$, one has $\ast$

$$f(\exp_{\alpha}(X_{\alpha})) = \exp_{\{d(\alpha)\}}(X'_{\{d(\alpha)\}}), \quad \text{i.e.} \quad f(u_{\alpha}) = u'_{\{d(\alpha)\}}.$$

$[\text{N.D.E-XXIII-2}]$

$\text{<!-- label: III.XXIII.1.3 -->}$

$\text{<!-- original page 178 source / page 179 source -- heading transition -->}$

1.4.

$\text{<!-- label: III.XXIII.1.4 -->}$

If we denote by $\$q(\alpha)\$$ the integer of $\ast$ loc. cit. $\ast$, we therefore have

$$f(p_{\alpha}(x)) = p'_{\{d(\alpha)\}}(x^{\{q(\alpha)\}}) \quad \text{for} \quad \alpha \in \Delta,$$

and consequently

$$f(p_{-\alpha}(x)) = p'_{\{-d(\alpha)\}}(x^{\{q(\alpha)\}}), \quad f(w_{\alpha}) = w'_{\{d(\alpha)\}}.$$

Recall (Exp. XXII, 4.2) that, for every $\alpha \in R$ and all $z \in G_m(S')$, $t \in T(S')$,

$$f(\alpha^{\ast}(z)) = d(\alpha)^{\ast}(z)^{\{q(\alpha)\}} = d(\alpha)^{\ast}(z^{\{q(\alpha)\}}), \quad d(\alpha)(f(t)) = \alpha(t)^{\{q(\alpha)\}}.$$

1.5.

$\text{<!-- label: III.XXIII.1.5 -->}$

$\text{<!-- original page 266 -->}$

We shall call a $\ast$ pinned root datum $\ast$ a root datum endowed with a system of simple roots, and a $\ast$ $\$p\$$ -morphism of pinned root data $\ast$ a $\$p\$$ -morphism of root data (Exp. XXI, 6.8) sending simple roots to simple roots.

If $\$G\$$ is a pinned $\$ \$$ -group, we denote by $\$R(G)\$$ the corresponding pinned root datum (this is the root datum of Exp. XXII, 1.14 equipped with Δ). Let $\$p\$$ be the integer defined in Exp. XXII, 4.2.2. One then has:

$\ast$ **Scholium 1.6.** $\ast$ $\ast$ The correspondence $\$G \mapsto R(G)\$$ defines a functor from the category of pinned reductive $\$ \$$ -groups to that of pinned root data (with $\$p\$$ -morphisms as morphisms). $\ast$

$\text{<!-- label: III.XXIII.1.6 -->}$

$\text{### 1.7. The pinned groups } Z_{\{\Delta_1\}}\$$

$\text{<!-- label: III.XXIII.1.7 -->}$

Let Δ_1 be a subset of the system of simple roots Δ of the pinned group $\$G\$$. Let $T_{\{\Delta_1\}}$ be the maximal torus of $\bigcap_{\alpha \in \Delta_1} \text{Ker}(\alpha)$; set

$\$ \$$
 $Z_{\{\Delta_1\}} = \text{Centr}_G(T_{\{\Delta_1\}}).$
 $\$ \$$

Set $R' = \mathbb{Z} \cdot \Delta_1 \cap R$; one knows (Exp. XXII, 5.10.7) that Z_{Δ_1} is a reductive S -group with radical T_{Δ_1} , that (T, M, R') is a splitting of it, and Δ_1 a system of simple roots. It follows that $(Z_{\Delta_1}, T, M, R', \Delta_1, (X_{\alpha})_{\alpha \in \Delta_1})$ is a pinned S -group. We shall always equip Z_{Δ_1} with this pinning. In particular, we shall consider the groups

```
```text
Z_α = Z_{α}, Z_{αβ} = Z_{α, β}.
```

We denote by  $B_{\Delta_1} = B \cap Z_{\Delta_1}$ ; one knows (\*loc. cit.\*) that this is the canonical Borel subgroup [N.D.E-XXIII-3] of  $Z_{\Delta_1}$ , and that its unipotent part is  $U_{\Delta_1} = U \cap Z_{\Delta_1}$ . In particular,

```
$$
B_{\alpha} = T \cdot U_{\alpha}.
$$
```

<!-- original page 267 -->

We shall denote

```
```text
U_{αβ} = U_{α, β} = U \cap Z_{αβ} = \bigcap_{\gamma \in R^+_{αβ}} U_{\gamma},
```

where $R^+_{\alpha \beta}$ denotes the set of positive roots that are linear combinations of α and β .

Now let $f : G \rightarrow G'$ be a morphism of pinned S -groups. If $d : R \rightarrow R'$ is the corresponding bijection and if Δ_1 is a subset of Δ , then $d(\Delta_1) = \Delta'_1$ is a subset of Δ' , and it is clear that f sends T_{Δ_1} into $T'_{\Delta'_1}$, hence Z_{Δ_1} into $Z'_{\Delta'_1}$. The corresponding S -morphism

```
$$
f_{\Delta_1} : Z_{\Delta_1} \rightarrow Z'_{d(\Delta_1)}
$$
```

is compatible with the canonical pinning; it defines a morphism of pinned root data

```
```text
R(f_{\Delta_1}) : R(Z_{\Delta_1}, T, M, ...) \rightarrow R(Z_{\Delta'_1}, T', M', ...)
```

and the underlying morphisms  $M' \rightarrow M$  of  $R(f)$  and  $R(f_{\Delta_1})$  coincide.

### 1.8. Study of the group  $\text{Norm}_G(T)$

<!-- label: III.XXIII.1.8 -->

For each pair  $(\alpha, \beta)$  of simple roots, denote by  $n_{\alpha \beta}$  the order of the element  $s_{\alpha} s_{\beta}$  of the Weyl group  $W$ . In particular,  $n_{\alpha \alpha} = 1$ . One has therefore  $(w_{\alpha} w_{\beta})^{n_{\alpha \beta}} \in T(S)$ .

**Definition 1.8.1.** For every  $(\alpha, \beta) \in \Delta \times \Delta$ , one sets

```
```text
t_{αβ} = (w_α w_β)^{n_{αβ}} \in T(S).
```

Moreover, one sets (Exp. XX, 3.1)

```
```text
t_α = t_{αα} = w_α^2 = α^{(-1)} \in T(S).
```

<!-- label: III.XXIII.1.8.1 -->

<!-- original page 268 -->

**Proposition 1.8.2.** \*Let  $H$  be an  $S$ -functor in groups transforming direct sums of schemes into products (for example a sheaf for the Zariski topology). Let\*

$f_T : T \rightarrow H$

be a morphism of groups and  $h_\alpha$  ( $\alpha \in \Delta$ ) elements of  $H(S)$ . In order that there exist a morphism of groups (necessarily unique)\*

$f_N : \text{Norm}_G(T) \rightarrow H$

inducing  $f_T$  on  $T$  and such that  $f(w_\alpha) = h_\alpha$  for  $\alpha \in \Delta$ , it is necessary and sufficient that the following two conditions be satisfied:

(i) For every  $\alpha \in \Delta$ ,

$f_T(s_\alpha(t)) = h_\alpha f_T(t) h_\alpha^{-1}$

for every  $t \in T(S)$ ,  $S' \rightarrow S$  (i.e.  $f_T \circ s_\alpha = \text{int}(h_\alpha) \circ f_T$ ).

(ii) For every  $(\alpha, \beta) \in \Delta \times \Delta$ ,

$f_T(t_{\alpha\beta}) = (h_\alpha h_\beta)^{n_{\alpha\beta}}$ .

<!-- label: III.XXIII.1.8.2 -->

**Proof.** \* Indeed, equip  $(Sch)$  with the topology  $\mathcal{T}$  generated by the pretopology whose covering families are the direct sums; the hypothesis of the statement says that  $H$  is a  $\mathcal{T}$ -sheaf. Let  $L$  be the free group with generators  $m_\alpha$  ( $\alpha \in R$ ) and  $L_1$  the invariant subgroup generated by the elements  $m_\alpha m_\beta^{n_{\alpha\beta}}$ ,  $(\alpha, \beta) \in \Delta \times \Delta$ . Let  $g : L \rightarrow W$  be the morphism defined by  $g(m_\alpha) = s_\alpha$ ; one knows (Exp. XXI, 5.1) that  $g$  induces an isomorphism  $\bar{g}$  of  $L/L_1$  onto  $W$ . Make  $L$  act on  $T$  through  $g$  (or, equivalently, by  $m_\alpha \cdot t = s_\alpha(t)$ ). Let  $L_S$  be the constant group defined by  $L$ ; consider the semidirect product  $T \cdot L_S = N$  for the preceding operation. One has a morphism of  $S$ -groups

$h : T \cdot L_S = N \rightarrow \text{Norm}_G(T)$

unique such that  $h(m_\alpha) = w_\alpha$ ,  $h(t) = t$  for every  $t \in T(S)$ ,  $S' \rightarrow S$ . Let  $N_1$  be the invariant subsheaf of groups of  $N$  generated by the

<!-- original page 269 -->

$t_{\alpha\beta}^{-1} \cdot (m_\alpha m_\beta)^{n_{\alpha\beta}}$ ,  $(\alpha, \beta) \in \Delta \times \Delta$ .

One evidently has  $N_1 \subset \text{Ker } h$ ; consider the induced morphism

$h_1 : N/N_1 \rightarrow \text{Norm}_G(T)$ .

Let us prove that  $h_1$  is an isomorphism. Since  $h$  induces on  $T$  the canonical immersion, which is a monomorphism, the canonical morphism

$$T \rightarrow N/N_1$$

is also a monomorphism, hence induces an isomorphism of  $T$  onto  $TN_1/N_1$ . For the same reason,  $h_1$  induces an isomorphism of  $TN_1/N_1$  onto  $T$ ; to prove that  $h_1$  is an isomorphism, it therefore suffices to verify that the corresponding morphism

$$h_2 : N/TN_1 \rightarrow \text{Norm}_G(T)/T$$

is an isomorphism. Now  $TN_1$  is the invariant  $\mathcal{T}$ -subsheaf of groups of  $N$  generated by  $T$  and the  $(m_\alpha m_\beta)^{n_\alpha n_\beta}$ , that is, the  $\mathcal{T}$ -subsheaf generated by  $T$  and  $L_1$ , that is,  $T \cdot (L_1)_S$ . The morphism  $h_2$  is therefore identified with the morphism

$$\bar{g} : L_S / (L_1)_S \rightarrow W_S$$

which is an isomorphism by construction.

The proof of 1.8.2 is now easy; the conditions are evidently necessary. Let us prove that they are sufficient. Condition (i) shows that there exists a morphism

$$u : N \rightarrow H$$

such that  $u(m_\alpha) = h_\alpha$  for  $\alpha \in \Delta$ , and  $u|_T = f_T$ . Condition (ii) says that  $u$  vanishes on  $N_1$ , which yields the result at once.

### 1.9. Faithfulness of the functor  $R$

<!-- label: III.XXIII.1.9 -->

<!-- original page 270 -->

**Proposition 1.9.1.** *The functor  $R$  of 1.6 is faithful: if*

$$f, g : G \rightarrow G'$$

*are two morphisms of pinned groups such that  $R(f) = R(g)$ , then  $f = g$ .*

<!-- label: III.XXIII.1.9.1 -->

Indeed,  $f$  and  $g$  coincide on  $T$ ,  $U_\alpha$  ( $\alpha \in \Delta$ ) and  $U_{-\alpha}$  ( $\alpha \in \Delta$ ); it therefore suffices to apply:

**Lemma 1.9.2.** *Let  $S$  be a scheme,  $G$  a pinned reductive  $S$ -group,  $H$  an  $S$ -presheaf in groups, separated for (fppf). Let*

$$f, g : G \rightarrow H$$

*be two morphisms of  $S$ -groups. The following conditions are equivalent:*

*(i)  $f = g$ .*

\*(ii)  $f$  and  $g$  coincide on  $T$ , on each  $U_{\alpha}$  ( $\alpha \in \Delta$ ), on each  $U_{-\alpha}$  ( $\alpha \in \Delta$ ).

\*(iii)  $f$  and  $g$  coincide on  $T$ , on each  $U_{\alpha}$  ( $\alpha \in \Delta$ ), and  $f(w_{\alpha}) = g(w_{\alpha})$  for each  $\alpha \in \Delta$ .

<!-- label: III.XXIII.1.9.2 -->

Indeed, (i)  $\Rightarrow$  (ii) is trivial, (ii)  $\Rightarrow$  (iii) follows at once from the definition of  $w_{\alpha}$  (1.2). It remains to prove (iii)  $\Rightarrow$  (i). If  $\alpha \in R$ , there exists a sequence  $\{\alpha_i\} \subset \Delta$  with  $\alpha = s_{\alpha_1} s_{\alpha_2} \cdots s_{\alpha_n}(\alpha_{n+1})$ , hence

```

```text
U_{\alpha} = \text{int}(w_{\alpha_1} \cdots w_{\alpha_n}) U_{\alpha_{n+1}},
```

```

which shows that  $f$  and  $g$  coincide on each  $U_{\alpha}$ . It follows that  $f$  and  $g$  coincide on  $\Omega$ , hence coincide (Exp. XXII, 4.1.11).

**Remark 1.9.3.** If  $G$  is semisimple, one may, in (ii) and (iii), drop the hypothesis that  $f$  and  $g$  coincide on  $T$ . Indeed,  $G$  is generated as an (fppf) sheaf by the  $U_{\alpha}$ ,  $\alpha \in R$  (Exp. XXII, 6.2.2 (a)).

<!-- label: III.XXIII.1.9.3 -->

## 2. Generators and relations for a pinned group

<!-- label: III.XXIII.2 -->

<!-- original page 271 -->

In this section, we fix a pinned  $S$ -group  $G$ . If  $\alpha, \beta \in \Delta$ , we shall use the notation  $Z_{\alpha}$ ,  $Z_{\alpha\beta}$ ,  $U_{\alpha\beta}$ ,  $R^+_{\alpha\beta}$  of 1.7.

**Theorem 2.1.** Let  $S$  be a scheme,  $G$  a pinned  $S$ -group,  $\mathcal{H}$  an  $S$ -sheaf in groups for (fppf). Let

```

```text
f_N : \text{Norm}_G(T) \rightarrow H, \quad f_{\alpha} : U_{\alpha} \rightarrow H, \quad \alpha \in R,
```

```

be morphisms of groups. In order that there exist a morphism of groups (necessarily unique)

```

f : G \rightarrow H
```

```

extending f_N and the f_{α} ($\alpha \in R$), it is necessary and sufficient that the following conditions be satisfied:

(i) For every $\alpha \in \Delta$ and every $\beta \in R$,

```

```text
\text{int}(f_N(w_{\alpha})) \circ f_{\beta} = f_{s_{\alpha}(\beta)} \circ \text{int}(w_{\alpha}).
```

```

(ii) For every $\alpha \in \Delta$, there exists a morphism of groups

```

F_{\alpha} : Z_{\alpha} \rightarrow H
```

```

extending  $f_{\alpha}$ ,  $f_{-\alpha}$  and  $f_N|_{\text{Norm}(Z_{\alpha})(T)}$ .

(iii) For every pair  $(\alpha, \beta) \in \Delta \times \Delta$ , there exists a morphism of groups  $U_{\alpha\beta} \rightarrow H$  inducing  $f_{\gamma}$  on  $U_{\gamma}$  for every  $\gamma \in R^+_{\alpha\beta}$  (i.e.  $U_{\gamma} \subset U_{\alpha\beta}$ ).

<!-- label: III.XXIII.2.1 -->

### 2.1.1. Proof

<!-- label: III.XXIII.2.1.1 -->

The conditions of the statement are evidently necessary. Choose on the other hand a structure of totally ordered group on  $\Gamma_0(R)$  such that the roots  $> 0$  are the elements of  $R^{+}$  (Exp. XXI, 3.5.6); every product indexed by a subset of  $R$  will be taken relative to this order.

<!-- original page 272 -->

Denote by  $f_T$  the restriction of  $f_N$  to  $T$ , and consider the morphism

$f : \Omega \rightarrow H$

defined set-theoretically by

```text  
f($\prod_{\alpha \in R^+} y_\alpha \cdot t \cdot \prod_{\alpha \in R^+} x_\alpha$) = $\prod f_\alpha(y_\alpha) \cdot f_T(t) \cdot \prod f_\alpha(x_\alpha)$.

Any morphism satisfying the conditions of the statement must extend f ; on the other hand any morphism of groups $f : G \rightarrow H$ extending f also extends f_N : indeed, extending f_α and $f_{-\alpha}$, it satisfies $f(w_\alpha) = F_\alpha(w_\alpha) = f_N(w_\alpha)$, and it extends f_T by hypothesis. By Exp. XXII, 4.1.11 (ii), one is therefore reduced to proving:

Proposition 2.1.2. The morphism $f : \Omega \rightarrow H$ defined above is "generically multiplicative"; more precisely, for every $S' \rightarrow S$ and all $x, y \in \Omega(S')$ such that $xy \in \Omega(S')$, one has $f(xy) = f(x) f(y)$.

<!-- label: III.XXIII.2.1.2 -->

Lemma 2.1.3. Let $n \in \text{Norm}_G(T)(S')$, $S' \rightarrow S$, and let $\alpha, \beta \in R$ be such that $\text{int}(n) U_\alpha = U_\beta$ (i.e. $n(\alpha) = \beta$); then

```text  
 $\text{int}(f_N(n)) \circ f_\alpha = f_\beta \circ \text{int}(n)$ .

<!-- label: III.XXIII.2.1.3 -->

Indeed, it suffices to verify the formula for a system of generators of the sheaf  $\text{Norm}_G(T)$ ; it is true for each  $w_\alpha$ ,  $\alpha \in \Delta$  (by 2.1 (i)), so it suffices to do it for  $n \in T(S')$ . This is trivial by 2.1 (ii) if  $\alpha$  is simple; otherwise, one takes a  $w \in W$  such that  $w^{-1}(\alpha) \in \Delta$ ; writing  $w$  as a product of simple reflections, [N.D.E-XXIII-4] one is reduced to proving that if the formula is true for  $\alpha$  and for every  $n$ , it is also true for  $w_\alpha(\alpha)$  and  $t \in T(S')$ , where  $\alpha_0 \in \Delta$ . Now, by 2.1 (i),

```text  
 $\text{int}(f_N(t)) \circ f_{w_\alpha(\alpha)} = \text{int}(f_N(t w_{\alpha_0})) \circ f_\alpha \circ \text{int}(w_{\alpha_0}^{-1})$
 $= f_{w_\alpha(\alpha)} \circ \text{int}(t w_{\alpha_0}) \circ \text{int}(w_{\alpha_0}^{-1})$.

Lemma 2.1.4. The restriction of f to U (resp. U^{-}) is a morphism of groups. In particular, this restriction is independent of the order chosen on the roots.

<!-- label: III.XXIII.2.1.4 -->

<!-- original page 273 -->

It suffices to give the proof for U . By virtue of Exp. XXII, 5.5.8, it suffices to verify that for every pair $\alpha < \beta$ of positive roots, one has for all $x_\alpha \in U_\alpha(S')$, $x_\beta \in U_\beta(S')$, $S' \rightarrow S$,

```

```text
f_{\beta}(x_{\beta}) f_{\alpha}(x_{\alpha}) f_{\beta}(x_{\beta}^{-1}) = f(x_{\beta} x_{\alpha} x_{\beta}^{-1}).

```

By Exp. XXII, 5.5.2, there exist  $x_{\gamma} \in U_{\gamma}(S)$  ( $\gamma = i\alpha + j\beta \in R$ ,  $i > 0$ ,  $j \in \mathbb{Z}$ ) such that

```

```text
x_{\beta} x_{\alpha} x_{\beta}^{-1} = \prod_{\gamma} x_{\gamma},

```

and we must therefore verify the relation

```

```text
f_{\beta}(x_{\beta}) f_{\alpha}(x_{\alpha}) f_{\beta}(x_{\beta}^{-1}) = \prod_{\gamma} f_{\gamma}(x_{\gamma}).

```

By Exp. XXI, 3.5.4, there exists  $w \in W$  such that  $w(\alpha) = \alpha_0 \in \Delta$ ,  $w(\beta) \in A_{\alpha_0 \beta_0}$  (notation of 1.7), where  $\beta_0 \in \Delta$ . Lifting  $w$  to an  $n \in \text{Norm}_G(T)(S)$  (by Exp. XXII, 3.8), it suffices to verify the preceding relation after conjugation by  $f_N(n)$ . By 2.1.3, one is therefore reduced to the case  $\alpha, \beta \in R^+_{\alpha_0 \beta_0}$ , a case in which we conclude by condition 2.1 (iii).

**\*Lemma 2.1.5.\*** Let  $n \in \text{Norm}_G(T)(S)$  be such that  $\text{int}(n) U = U^{-}$  (i.e.  $n$  is the symmetry of the Weyl group [N.D.E-XXIII-6] (Exp. XXI, 3.6.14)). For every  $u \in U(S)$ ,  $S' \not\rightarrow S$  (resp.  $u \in U^{-}(S)$ ,  $S' \rightarrow S$ ), one has\*

```

```text
f(n u n^{-1}) = f_N(n) f(u) f_N(n^{-1}).

```

<!-- label: III.XXIII.2.1.5 -->

Immediate by 2.1.3 and 2.1.4.

<!-- original page 274 -->

Lemma 2.1.6. Let $u \in B(S)$, $v \in B^{-}(S)$, $g \in \Omega(S)$, $S' \rightarrow S$. Then*

```

```text
f(v g u) = f(v) f(g) f(u).

```

<!-- label: III.XXIII.2.1.6 -->

Indeed, set  $v = v_1 t_1$ ,  $g = v_2 t_2 u_2$ ,  $u = t_3 u_3$ , with  $v_i \in U^{-}(S)$ ,  $t_i \in T(S)$ ,  $u_i \in U(S)$ . One has

```

```text
f(v) f(g) f(u) = f(v_1) f_T(t_1) f(v_2) f_T(t_2) f(u_2) f_T(t_3) f(u_3),

```

on the one hand, and

```

```text
f(v g u) = f(v_1 t_1 v_2 t_1^{-1} t_1 t_2 t_3 t_3^{-1} u_2 t_3 u_3)
 = f(v_1 \cdot t_1 v_2 t_1^{-1}) f_T(t_1 t_2 t_3) f(t_3^{-1} u_2 t_3 \cdot u_3).

```

Using 2.1.4 to decompose the two extreme terms of this last expression, one obtains

```

```text
f(v g u) = f(v_1) f(t_1 v_2 t_1^{-1}) f_T(t_1 t_2 t_3) f(t_3^{-1} u_2 t_3) f(u_3).

```

One is then reduced to the obvious formulas

```
```text
f(t_1 v_2 t_1^{-1}) = f_T(t_1) f(v_2) f_T(t_1)^{-1}, f(t_3^{-1} u_2 t_3) = f_T(t_3)^{-1} f(u_2) f_T(t_3),
```
```

which follow from the definition of f and from 2.1.3.

Lemma 2.1.7. *Let $\alpha \in \Delta$ and $g \in \Omega(S') \cap \text{int}(w_{\alpha})^{-1} \Omega(S')$, $S' \rightarrow S$. Then*

```
```text
f(w_{\alpha} g w_{\alpha}^{-1}) = f_N(w_{\alpha}) f(g) f_N(w_{\alpha})^{-1}.
```
```

<!-- label: III.XXIII.2.1.7 -->

Indeed, let $g \in \Omega(S')$, $S' \rightarrow S$. Write, by Exp. XXII, 5.6.8,

```
```text
g = a x_{-\alpha} t x_{\alpha} b,
```
```

<!-- original page 275 -->

with $a \in U_{\hat{\alpha}}(S')$, $x_{-\alpha} \in U_{-\alpha}(S')$, $t \in T(S')$, $x_{\alpha} \in U_{\alpha}(S')$, $b \in U_{\hat{\alpha}}(S')$. By 2.1.3, 2.1.4 and the fact that s_{α} permutes the positive roots $\neq \alpha$ (cf. Exp. XXI, 3.3.2), one has

```
```text
int(w_{\alpha}) a \in U_{-\alpha}^{\wedge}(S'), int(w_{\alpha}) b \in U_{\alpha}^{\wedge}(S')
```
```

and the formula to be proved is true for $g = a$ or $g = b$. By 2.1.6, one is therefore reduced to proving the asserted formula when $g = x_{-\alpha} t x_{\alpha} \in Z_{\alpha}(S')$. But then "everything happens in Z_{α} ", and one concludes by condition (ii) of 2.1.

Lemma 2.1.8. *Let $n \in \text{Norm}_{\{G\}}(T)(S)$. For every $S' \rightarrow S$ and every $g \in \Omega(S')$ such that $\text{int}(n) g \in \Omega(S')$, one has*

```
```text
f(n g n^{-1}) = f_N(n) f(g) f_N(n)^{-1}.
```
```

<!-- label: III.XXIII.2.1.8 -->

This is trivial if $n \in T(S)$ (by 2.1.3). The two sides of the preceding formula define morphisms of $\Omega \cap \text{int}(n)^{-1} \Omega$ into H ; to verify that they coincide, it suffices to verify that there exists an open V_n of Ω containing the unit section such that $\text{int}(n) V_n \subset \Omega$, and that $f \circ \text{int}(n)$ and $\text{int}(f_N(n)) \circ f$ coincide on V_n . By virtue of the structure of $\text{Norm}_{\{G\}}(T)$, it suffices to prove that if the preceding assertion is true for an $n' \in \text{Norm}_{\{G\}}(T)(S)$ and if $\alpha \in \Delta$, it is true for $n = n' w_{\alpha}$. Set

```
```text
V_n = \Omega n \text{int}(w_{\alpha})^{-1} V_{n'}.
```
```

One has $\text{int}(n) V_n \subset \text{int}(n') V_{n'} \subset \Omega$. If $g \in V_n(S')$, then

```
```text
int(n) g = int(n') int(w_{\alpha}) g.
```
```

Now $\text{int}(w_{\alpha}) g \in V_{n'}(S')$, hence by hypothesis

```
```text
```

```
f(int(n') int(w_α) g) = int(f_N(n')) f(int(w_α) g);
```

since  $\text{int}(w_{\alpha}) g \in \Omega(S)$ , one may apply 2.1.7, which gives

```
```text
f(int(w_α) g) = int(f_N(w_α)) f(g),
```

and one concludes at once.

<!-- original page 276 -->

Let us now prove 2.1.2. Let $x, x' \in \Omega(S)$; write as usual

```
```text
x = v t u, x' = v' t' u',
```

whence

```
```text
x x' = v t (u v') t' u'.
```

By 2.1.6 and the relation $U^{-1}(S) \Omega(S) U(S) = \Omega(S)$, one is reduced to proving that if $u v' \in \Omega(S)$, then $f(u v') = f(u) f(v')$. Let $n \in \text{Norm}_G(T)(S)$ be as in 2.1.5 (ii). One has

```
```text
f(u) = f_N(n)^{-1} f(n u n^{-1}) f_N(n), f(v') = f_N(n)^{-1} f(n v' n^{-1}) f_N(n),
```

by \*loc. cit.\*, whence

```
```text
f(u) f(v') = f_N(n)^{-1} f(n u n^{-1}) f(n v' n^{-1}) f_N(n).
```

But $n u n^{-1} \in U^{-1}(S)$, $n v' n^{-1} \in U(S)$, so that

```
```text
f(n u n^{-1}) f(n v' n^{-1}) = f((n u n^{-1})(n v' n^{-1})) = f(n u v' n^{-1}),
```

which gives

```
```text
f(u) f(v') = f_N(n)^{-1} f(n u v' n^{-1}) f_N(n).
```

If $u v' \in \Omega(S)$, one may apply 2.1.8 and one is done.

****Remark 2.2.**** *Instead of giving oneself f_N , one may give oneself a morphism of groups $f_T : T \rightarrow H$ and sections $h_{\alpha} \in H(S)$ ($\alpha \in \Delta$) satisfying the conditions of 1.8.2. One must then replace condition (ii) of the theorem by:*

(ii') There exists a morphism of groups $F_{\alpha} : Z_{\alpha} \rightarrow H$ extending

```
```text
f_α, f_T and satisfying F_α(w_α) = h_α.
```

<!-- label: III.XXIII.2.2 -->

<!-- original page 277 -->

We shall now give the preceding theorem a more explicit form. Keep the preceding notation.

```text
int(h_α) f_{αβ}(x) = f_{αβ}(int(w_α) x),
(resp. int(h_β) f_{αβ}(x) = f_{αβ}(int(w_α) x)).
```
```

(6)

<!-- label: III.XXIII.2.3 -->

\*Proof.\* The uniqueness is clear by 1.9.2. Let us prove existence.

**Lemma 2.3.1.** \*There exists a morphism of groups\*

```
$$
f_{N} : \text{Norm}_{\{G\}}(T) \rightarrow H
$$
```

extending  $f_T$  and satisfying  $f_N(w_{\alpha}) = h_{\alpha}$ .

<!-- label: III.XXIII.2.3.1 -->

This is precisely what is asserted by 1.8.2, taking into account conditions (2) and (3).

<!-- original page 279 -->

**Lemma 2.3.2.** \*There exists a morphism of groups\*

```
```text
F_α : Z_α → H,      α ∈ Δ,
```
```

extending  $f_T$ ,  $f_{\alpha}$  and satisfying  $F_{\alpha}(w_{\alpha}) = h_{\alpha}$ , hence extending  $f_N|_{\text{Norm}_{Z_{\alpha}}(T)}$ .

<!-- label: III.XXIII.2.3.2 -->

This is clear from Exp. XX, 6.2 and conditions (1), (3) and (4).

**Lemma 2.3.3.** \*For every  $(\alpha, \beta) \in \Delta \times \Delta$ ,  $\alpha \neq \beta$ , every  $n \in \text{Norm}_{Z_{\alpha \beta}}(T)(S)$  such that  $n(\alpha) = \alpha$  (resp.  $n(\alpha) = \beta$ ), i.e.  $\text{int}(n) U_{\alpha} = U_{\alpha}$  (resp.  $\text{int}(n) U_{\alpha} = U_{\beta}$ ), every  $S' \rightarrow S$  and every  $x \in U_{\alpha}(S')$ ,

```
```text
int(f_N(n)) f_α(x) = f_α(int(n) x)
```
```

\*(resp.\*

```
```text
int(f_N(n)) f_α(x) = f_β(int(n) x)).
```
```

<!-- label: III.XXIII.2.3.3 -->

Indeed, there exist a  $t \in T(S)$  and a sequence  $\{\alpha_i\} \subset \{\alpha, \beta\}$  such that  $n = t w_{\alpha_k} \cdots w_{\alpha_1}$ . The condition is satisfied for  $n = t$  by condition (1). One may therefore suppose  $n = w_{\alpha_k} \cdots w_{\alpha_1}$ . We proceed by induction on  $k$ , i.e. we suppose the assertion proved for every  $n$  which can be written as a product of fewer than  $k - 1$  simple reflections (and satisfies the hypotheses of the lemma). Consider the roots

```
$$
\gamma_i = s_{\alpha_i} \cdots s_{\alpha_1}(\alpha).
$$
```

If all the  $\gamma_i$  are positive, i.e. belong to  $R^+_{-\alpha-\beta}$ , one may apply condition (v) of 2.3; using the notation of 2.3 (v), one concludes at once by induction that

```

```text
int(f_N(w_{\alpha_i} \cdots w_{\alpha_1})) f_{\alpha}(x) = f_{\alpha\beta}(int(w_{\alpha_i} \cdots w_{\alpha_1}) x),
```

```

which for  $i = k$  is the desired property. If not all the  $\gamma_i$  are positive, there exists an index  $j < k$  such that

```

```text
\gamma_j \in R^+, \quad \gamma_{j+1} \notin R^+.
```

```

<!-- original page 280 -->

Since  $\gamma_{j+1} = s_{-\alpha_j}(\gamma_j)$ , it follows at once that  $\gamma_j = \alpha_j$ , by Exp. XXI, 3.3.2, hence that  $\gamma_j$  is  $\alpha$  or  $\beta$ , and one may decompose  $n$  as

```

$$
n = n' \cdot n'',
n' = w_{\alpha_k} \cdots w_{\alpha_{j+1}},
n'' = w_{\alpha_j} \cdots w_{\alpha_1},
$$

```

$n'$  and  $n''$  satisfying the hypotheses of the lemma and being a product of fewer than  $k - 1$  reflections, hence satisfying by the induction hypothesis the conclusion of the lemma.

**Lemma 2.3.4.** \*Let  $\alpha \in R$ . If  $n, n' \in \text{Norm}_G(T)(S)$  and  $\beta, \beta' \in \Delta$  satisfy  $n(\alpha) = \beta$  and  $n'(\alpha) = \beta'$ , one has\*

```

```text
int(f_T(n)^{-1}) f_{\beta}(n \times n'^{-1}) = int(f_T(n')^{-1}) f_{\beta'}(n' \times n'^{-1}),
```

```

\*for every  $x \in U_{\alpha}(S)$ ,  $S' \rightarrow S$ .\*

<!-- label: III.XXIII.2.3.4 -->

It suffices to verify that if  $n(\alpha) = \beta$ ,  $\alpha, \beta \in \Delta$ , then  $\text{int}(f_T(n)) \circ f_{\alpha} = f_{\beta} \circ \text{int}(n)$ . Now, by Tits's lemma (Exp. XXI, 5.6), there exists a sequence of simple roots  $\alpha_0 = \alpha, \alpha_1, \dots, \alpha_m = \beta$ , and a sequence of elements  $w_i \in W$ ,  $i = 0, 1, \dots, m - 1$ , with

```

```text
n = w_{m-1} \cdots w_0,
w_i(\alpha_i) = \alpha_{i+1}, \quad i = 0, 1, \dots, m - 1,
```

```

<!-- original page 281 -->

the following condition being moreover satisfied: for every  $i = 0, 1, \dots, m - 1$ , there exists a simple root  $\beta_i$  such that

```

```text
w_i \in W_{\alpha_i \beta_i}, \quad \alpha_{i+1} = \alpha_i \quad \text{or} \quad \beta_i.
```

```

One is then reduced by induction to the case treated in the preceding lemma.

**Lemma 2.3.5.** \*There exists a family of morphisms of groups  $f'_{-\gamma} : U_{\gamma} \rightarrow H$ ,  $\gamma \in R$ , satisfying\*

(i) For  $\alpha \in \Delta$ ,  $f'_{\alpha} = f_{\alpha}$  and  $f'_{-\alpha} = F_{\alpha}|_{U_{-\alpha}}$ , where

$f_{\alpha}$  is defined in 2.3.2.\*

(ii) For  $\alpha, \beta \in \Delta$  and  $\gamma \in R^{+}_{\alpha\beta}$ ,  
 $f'_{\gamma} = f_{\alpha\beta}|_{U_{\gamma}}$ .\*

(iii) For every  $n \in \text{Norm}_G(T)(S)$  and  $\alpha, \beta \in R$  such that  $n(\alpha) = \beta$ ,\*

```text  
int(f_N(n)) f'_{\alpha}(x) = f'_{\beta}(int(n) x)
```

\*for every  $x \in U_{\alpha}(S')$ ,  $S' \rightarrow S$ .\*

<!-- label: III.XXIII.2.3.5 -->

For every root  $\alpha \in R$ , there exists an  $n \in \text{Norm}_G(T)(S)$  such that  $n(\alpha) \in \Delta$ . Then define  $f'_{\alpha}(x)$  as the expression of 2.3.4. This is independent of the choice of  $n$ , and  $f'_{\alpha}$  is indeed a morphism of groups. Property (iii) is satisfied by construction. The first assertion of (i) is clear (take  $n = e$ ), the second too (take  $n = w_{\alpha}$  and apply 2.3.2); if  $\gamma \in R^{+}_{\alpha\beta}$  ( $\alpha, \beta \in \Delta$ ), there exists  $n \in \text{Norm}_{Z_{\alpha\beta}}(T)(S)$  such that  $n(t) = \alpha$  or  $\beta$ ; one then applies (iii) and conditions (5) and (6) and has proved (ii).

### 2.3.6.

<!-- label: III.XXIII.2.3.6 -->

<!-- original page 282 -->

Let us now prove the theorem by showing that the conditions of 2.1 are satisfied, for the morphisms  $f_N$  and  $f'_{\alpha}$ ,  $\alpha \in R$ .

- 2.1 (i) follows from 2.3.5 (iii),
- 2.1 (ii) follows from 2.3.5 (i) and 2.3.2,
- 2.1 (iii) follows from 2.3.5 (ii) and from the fact that  $f_{\alpha\beta}$  is a morphism of groups.

An obvious corollary is:

**Corollary 2.4.** \*Let  $S$  be a scheme,  $G$  a pinned  $S$ -group of semisimple rank  $\geq 1$ ,  $\mathcal{H}$  an (fppf)  $S$ -sheaf in groups. For each  $(\alpha, \beta) \in \Delta \times \Delta$ , let\*

$$F_{\alpha\beta} : Z_{\alpha\beta} \rightarrow \mathcal{H}$$

\*be a morphism of groups. In order that there exist a morphism of groups\*

$$f : G \rightarrow \mathcal{H}$$

\*inducing the  $f_{\alpha\beta}$ , it is necessary and sufficient that for every  $(\alpha, \beta) \in \Delta \times \Delta$ ,

$$F_{\alpha\beta}|_{Z_{\alpha}} = F_{\alpha\alpha}.$$

<!-- label: III.XXIII.2.4 -->

The condition is evidently necessary. Suppose it satisfied. Set  $f_T = F_{\alpha\alpha}|_T$  (which does not depend on  $\alpha$ , since  $F_{\alpha\alpha}|_T = F_{\alpha\beta}|_T = F_{\beta\beta}|_T$ ). Set

```text  
 $p_{\alpha} = F_{\alpha\alpha}|_{U_{\alpha}}, \quad h_{\alpha} = F_{\alpha\alpha}(w_{\alpha}), \quad f_{\alpha\beta} = F_{\alpha\beta}|_{U_{\alpha\beta}}.$
```

The conditions of 2.3 are evidently satisfied: (1), (2), (4) "are verified" in  $Z_{\{\alpha\}}$ , (3), (5) and (6) in  $Z_{\{\alpha\}\beta}$ . There therefore exists a morphism  $f : G \rightarrow H$  extending  $f_T$ , the  $f_{\{\alpha\}}$  ( $\alpha \in \Delta$ ) and satisfying  $f(w_{\{\alpha\}}) = h_{\{\alpha\}}$ ; it coincides with  $F_{\{\alpha\}\beta}$  on generators of  $Z_{\{\alpha\}\beta}$ , hence satisfies  $f|_{Z_{\{\alpha\}\beta}} = F_{\{\alpha\}\beta}$ .

One also has the following technical corollary.

<!-- original page 283 -->

**Corollary 2.5.** Let  $S$  be a scheme,  $G$  and  $G'$  two pinned  $S$ -groups of semisimple rank 2,  $q$  an integer  $> 0$  such that  $x \mapsto x^q$  is an endomorphism of  $G_{\{a, S\}}$ ,  $h : R(G') \rightarrow R(G)$  a  $q$ -morphism of pinned root data. Choose for each  $\alpha \in R^+$  an  $X_{\{\alpha\}} \in \Gamma(S, g_{\{\alpha\}}^{\otimes q})$  and an  $X'_{\{d(\alpha)\}} \in \Gamma(S, g'_{\{d(\alpha)\}}^{\otimes q})$  (extending the canonical choices for  $\alpha \in \Delta$ ). Suppose the following conditions are realized:

(i) If  $\Delta = \{\alpha, \beta\}$ , then  $D_{\{S\}}(h)(t_{\{\alpha\}\beta}) = t'_{\{d(\alpha)\}\beta}$ .

(ii) For every  $\alpha \in \Delta$  and every  $\beta \in R^+$ ,  $\beta \neq \alpha$  (whence  $s_{\{\alpha\}}(\beta) \in R^+$ ), if  $z \in G_{\{m\}}(S)$  is defined by

```
```text
Ad(w_α) X_β = z X_{s_α(β)},
```
```

one has also

```
```text
Ad(w'_{d(α)}) X'_{d(β)} = z^{q(β)} X'_{d(s_α(β))}.
```
```

(iii) There exists a morphism of groups  $f : U \rightarrow U'$  such that for every  $\alpha \in R^+$ ,

```
```text
f(exp(x X_α)) = exp(x^{q(α)} X'_{d(α)})
```
```

for every  $x \in G_{\{a\}}(S)$ ,  $S' \rightarrow S$ .

Then there exists a morphism of pinned groups  $g : G \rightarrow G'$  such that  $R(g) = h$ .

<!-- label: III.XXIII.2.5 -->

Indeed, one defines  $f_{\{\alpha\}} : U_{\{\alpha\}} \rightarrow G'$  by

```
```text
f_α(exp(x X_α)) = exp(x^{q(α)} X'_{d(α)});
```
```

one sets  $f_T = D_{\{S\}}(h)$ ,  $h_{\{\alpha\}} = w'_{\{d(\alpha)\}}$ . The conditions of 2.3 are satisfied (note that  $q(s_{\{\alpha\}}(\beta)) = q(\beta)$  (Exp. XXI, 6.8.4) and that one always has  $D_{\{S\}}(h)(t_{\{\alpha\}}) = t'_{\{d(\alpha)\}}$ ), and one concludes at once.

**Remark 2.6.** One may make condition (v) of 2.3 more precise as follows. One must first verify:

(a) For every word in  $w_{\{\alpha\}}$  and  $w_{\{\beta\}}$  such that the corresponding word transforms  $\alpha$  or  $\beta$  into  $\alpha$  or  $\beta$ , the relation of type 2.3.3 corresponding is satisfied. In fact the proof of 2.3.3 shows that it suffices to verify it for the words in  $w_{\{\alpha\}}$  and  $w_{\{\beta\}}$  that are minimal (in the sense that any nontrivial initial sub-word does not satisfy the imposed conditions).

<!-- original page 284 -->

If condition (a) is satisfied, one may now define for each  $\gamma \in R^+_{\{\alpha\}\beta}$  an  $f_{\{\gamma\}} : U_{\{\gamma\}} \rightarrow H$  as in 2.3.5; one must then write:

\*(b) The morphism defined by the  $f_{\gamma}$ \*

```
```text
U_{\alpha\beta} = \prod_{\gamma \in R^+_{\alpha\beta}} U_{\gamma} \rightarrow H
```

is a morphism of groups. By Exp. XXII, 5.5.8, (b) is entailed by:

(b') The preceding morphism respects the commutation relations between U_{γ} and U_{δ} for $\gamma, \delta \in R^+_{\alpha\beta}$, $\gamma > \delta$ (i.e. the relations in $C_{i,j,\gamma,\delta}$ of Exp. XII, 5.5.2).

<!-- label: III.XXIII.2.6 -->

It is clear that conversely the set of conditions (a) and (b') is equivalent to (v).

One may even reduce the preceding conditions to conditions bearing only on the elements h_{α} , h_{β} , $f_{\alpha}(u_{\alpha})$, $f_{\beta}(u_{\beta})$ of H . A condition of type (a) will be written for example, if $s_{\alpha} s_{\beta} s_{\alpha}(\beta) = \alpha$:

```
```text
int(h_{\alpha} h_{\beta} h_{\alpha}) f_{\beta}(x) = f_{\alpha}(int(w_{\alpha} w_{\beta} w_{\alpha}) x); (1)
```

for every  $x \in U_{\alpha}(S)$ ,  $S' \rightarrow S$ . In particular, for  $x = u_{\beta}$ , one has  $int(w_{\alpha} w_{\beta} w_{\alpha}) u_{\beta} = u^z_{\beta}$  for a certain section  $z$  of  $G_m(S)$ , and the preceding relation will give

```
```text
int(h_{\alpha} h_{\beta} h_{\alpha}) f_{\beta}(u_{\beta}) = f_{\alpha}(u_{\alpha})^z.          (1')
```

<!-- original page 285 -->

Let us show that, conversely, taking into account conditions (i) to (iv) of 2.3, (1') entails (1). If $t \in T(S)$, $S' \rightarrow S$, make $int(t)$ act on (1'); taking into account conditions (i) and (ii), one obtains (1) for $x = int(t) u_{\beta} = u^{\beta(t)}_{\beta}$. It suffices to remark now that $\beta : T \rightarrow G_m(S)$ is faithfully flat, hence that condition (1) is certainly true for $x \in U_{\alpha}(S)^{\times}$, $S' \rightarrow S$. Since it is additive in x , and every section of U_{α} can be locally written as a sum of two sections of $U^{\times}_{\alpha}$, one concludes that (1') + (i) + (ii) $\Rightarrow$ (1).

One reasons similarly with conditions of type (b). It is then necessary to use the fact that if γ and γ' are two distinct (hence linearly independent over $\mathbb{Q}$) positive roots, the morphism $T \rightarrow G^2_{m,S}$ of components γ and γ' is faithfully flat. We leave the details of this transposition to the reader.

3. Groups of semisimple rank 2

<!-- label: III.XXIII.3 -->

3.1. Generalities

<!-- label: III.XXIII.3.1 -->

Lemma 3.1.1. *Let S be a scheme, G a pinned S -group, α and β two roots of G , with $\alpha + \beta \neq 0$.*

(i) If $\alpha + \beta \notin R$, then

```
```text
exp(X_{\alpha}) exp(X_{\beta}) = exp(X_{\beta}) exp(X_{\alpha})
```

\*for all  $X_{\alpha} \in \mathfrak{g}_{\alpha}(S)$ ,  $X_{\beta} \in \mathfrak{g}_{\beta}(S)$ ,  $S' \rightarrow S$ .\*

\*(ii) If  $\alpha + \beta$  and  $\alpha - \beta$  are not roots, then\*

```

```text
w_α(z_α) exp(X_β) w_α(z_α)^{-1} = exp(X_β)
```

<!-- original page 286 -->

for all $X_{\beta} \in W(g_{\beta})(S)$, $z_{\alpha} \in W(g_{\alpha})^{\times}(S)$, $S' \rightarrow S$, and

```text
w_α(z_α) w_β(z_β) = w_β(z_β) w_α(z_α)
```

for all $z_{\alpha} \in W(g_{\alpha})^{\times}(S)$ and $z_{\beta} \in W(g_{\beta})^{\times}(S)$, $S' \rightarrow S$.

(iii) Let $X_{\alpha} \in W(g_{\alpha})^{\times}(S)$, $X_{\beta} \in W(g_{\beta})^{\times}(S)$, and $w \in \text{Norm}_{\{G\}}(T)(S)$ such that $w(\alpha) = \beta$; define $z \in G_m(S)$ by

```text
Ad(w) X_α = z X_β.
```

Then

```text
int(w) exp(x X_α) = exp(x z X_β),
int(w) exp(y X_α^{-1}) = exp(y z^{-1} X_β^{-1}),
int(w) w_α(X_α) = β^*(z) w_β(X_β).
```

In particular, if $z = \pm 1$, then

$$\int(w) w_{\alpha}(X_{\alpha}) = w_{\beta}(X_{\beta})^z.$$

(iv) If one sets $t_{\alpha} = \alpha^{}(-1)$, $t_{\beta} = \beta^{*}(-1)$, then*

```text
s_α(t_β) = t_β t_α^{(β^*, α)},    β(t_α) = (-1)^{(α^*, β)}.
```

<!-- label: III.XXIII.3.1.1 -->

Proof. (i) follows at once from Exp. XXII, 5.5.2; (ii) from Exp. XX, 3.1 and from (i) applied to (β, α) , $(\beta, -\alpha)$, $(-\beta, \alpha)$, $(-\beta, -\alpha)$; (iii) is evident from the definitions. For the last assertion of (iii), note that $\beta^{*}(-1) = w_{\beta}(X_{\beta})^{-2}$. Finally, (iv) is trivial.

**Proposition 3.1.2 (Groups of type $A_1 \times A_1$). ** *Let S be a scheme, G a pinned S -group of type $A_1 \times A_1$, and denote $\Delta = R^{+} = \{\alpha, \beta\}$.*

(i) One has

<!-- original page 287 -->

```text
t_{αβ} = (w_α w_β)^2 = t_α t_β = (w_β w_α)^2 = t_{βα}.
```

(ii) One has

```text
Ad(w_α) X_β = X_β,    Ad(w_β) X_α = X_α.
```

```

```

(iii) U_{α} and U_{β} commute (i.e. U is commutative).

<!-- label: III.XXIII.3.1.2 -->

Indeed, by assertion (ii) of the lemma, $w_{\alpha} w_{\beta} = w_{\beta} w_{\alpha}$, whence
 $(w_{\alpha} w_{\beta})^2 = w_{\alpha}^2 w_{\beta}^2 = t_{\alpha} t_{\beta}$, which is (i). By assertion (ii) of
the lemma, one has also (ii); finally, (iii) is assertion (i) of the lemma.

3.1.3.

<!-- label: III.XXIII.3.1.3 -->

Let us make condition (v) of 2.3 explicit here. Using the method exposed in 2.6, one obtains the two following groups of
conditions, setting $v_{\alpha} = f_{\alpha}(u_{\alpha})$ for $\alpha \in \Delta$:

```text
(A)    $h_{\alpha} v_{\beta} h_{\alpha}^{-1} = v_{\beta}$ ,           (B)    $v_{\alpha} v_{\beta} = v_{\beta} v_{\alpha}$ .
       $h_{\beta} v_{\alpha} h_{\beta}^{-1} = v_{\alpha}$ 
...

### 3.2. Groups of type  $A_2$ 

<!-- label: III.XXIII.3.2 -->

**Proposition 3.2.1.** *Let  $S$  be a scheme,  $G$  a pinned  $S$ -group of type  $A_2$ , and denote
 $\Delta = \{\alpha, \beta\}$ ,  $R^+ = \{\alpha, \beta, \alpha + \beta\}$ .*

<!-- original page 288 -->

*(i) One has*

```text
 $t_{\alpha\beta} = (w_{\alpha} w_{\beta})^3 = e = (w_{\beta} w_{\alpha})^3 = t_{\beta\alpha}$.
```

*(ii) Set  $\text{Ad}(w_{\beta}) X_{\alpha} = X_{\alpha + \beta}$ . Then*

```text
 $\text{Ad}(w_{\alpha}) X_{\beta} = -X_{\alpha + \beta}$, $\text{Ad}(w_{\alpha}) X_{\alpha + \beta} = X_{\beta}$, $\text{Ad}(w_{\beta}) X_{\alpha + \beta} = -X_{\alpha}$.
```

*(iii) Set  $p_{\alpha + \beta}(x) = \exp(x X_{\alpha + \beta}) = \text{int}(w_{\beta}) p_{\alpha}(x)$ . Then*

```text
 $p_{\beta}(y) p_{\alpha}(x) = p_{\alpha}(x) p_{\beta}(y) p_{\alpha + \beta}(x y)$.
```

<!-- label: III.XXIII.3.2.1 -->

### 3.2.2.

<!-- label: III.XXIII.3.2.2 -->

The proof occupies Nos. 3.2.2 to 3.2.7. First,  $(\beta^*, \alpha) = (\alpha^*, \beta) = -1$ , whence
 $\alpha(t_{\beta}) = \beta(t_{\alpha}) = -1$ .

Set  $\text{Ad}(w_{\beta}) X_{\alpha} = X_{\alpha + \beta}$ ; one has at once

```text
 $\text{Ad}(w_{\beta}) X_{\alpha + \beta} = \alpha(t_{\beta}) X_{\alpha} = -X_{\alpha}$.
```

Set

```text
```

```

$$\text{Ad}(w_\alpha) X_\beta = z X_{\alpha + \beta}, \quad z \in G_m(S),$$

whence

$$\text{Ad}(w_\alpha) X_{\alpha + \beta} = \beta(t_\alpha) z^{-1} X_\beta = -z^{-1} X_\beta.$$

We know (Exp. XXII, 5.5.2) that there exists a unique section $A \in G_a(S)$ such that

$$p_\beta(y) p_\alpha(x) = p_\alpha(x) p_\beta(y) p_{\alpha + \beta}(A \times y). \quad (+)$$

To prove (ii) and (iii), it therefore remains to show that $A = -z = 1$.

<!-- original page 289 -->

3.2.3.

<!-- label: III.XXIII.3.2.3 -->

Make $\text{int}(w_{\beta})$ act on the preceding formula (+); one obtains:

$$p_{-\beta}(-y) p_{\alpha + \beta}(x) = p_{\alpha + \beta}(x) p_{-\beta}(-y) p_\alpha(-A \times y). \quad (++)$$

3.2.4.

<!-- label: III.XXIII.3.2.4 -->

By definition of $p_{\alpha + \beta}$,

$$w_\beta p_\alpha(x) w_\beta^{-1} = p_{\alpha + \beta}(x),$$

which is written

$$p_\beta(1) p_{-\beta}(-1) p_\beta(1) p_\alpha(x) p_\beta(-1) p_{-\beta}(1) p_\beta(-1) = p_{\alpha + \beta}(x).$$

Since p_β and $p_{\alpha + \beta}$ commute, $\alpha + 2\beta$ not being a root, this is also written

$$p_\beta(1) p_\alpha(x) p_\beta(-1) = p_{-\beta}(1) p_{\alpha + \beta}(x) p_{-\beta}(-1).$$

Using now (+) in the left member and (++) in the right, one obtains:

$$p_\alpha(x) p_\beta(1) p_{\alpha + \beta}(A \times) p_\beta(-1) = p_{\alpha + \beta}(x) p_{-\beta}(1) p_\alpha(A \times) p_{-\beta}(-1).$$

Since $\alpha + 2\beta$ (resp. $\alpha - \beta$) is not a root, the left (resp. right) member is written

$$p_\alpha(x) p_{\alpha + \beta}(A \times) \quad \text{resp.} \quad p_{\alpha + \beta}(x) p_\alpha(A \times)$$

and the right-hand term equals $p_{\alpha}(A \times) p_{\alpha + \beta}(x)$, since $2\alpha + \beta$ is not a root. Therefore

```

```text
p_{\alpha}(x) p_{\alpha + \beta}(A x) = p_{\alpha}(A x) p_{\alpha + \beta}(x),

```

which gives (by XXII 4.1.3)  $A = 1$ .

### 3.2.5.

<!-- label: III.XXIII.3.2.5 -->

Now make  $\text{int}(w_{\alpha})$  act on formula (+); using the fact that  $A = 1$ , one finds

```

```text
p_{\alpha + \beta}(z y) p_{-\alpha}(-x) = p_{-\alpha}(-x) p_{\alpha + \beta}(z y) p_{\beta}(-z^{-1} x y).      (+++)

```

3.2.6.

<!-- label: III.XXIII.3.2.6 -->

<!-- original page 290 -->

Write now, as a moment ago,

```

```text
w_{\alpha} p_{\beta}(y) w_{\alpha}^{-1} = p_{\alpha + \beta}(z y),

```

whence, since  $p_{\alpha}$  and  $p_{\alpha + \beta}$  commute,

```

```text
p_{\alpha}(1) p_{\beta}(y) p_{\alpha}(-1) = p_{-\alpha}(1) p_{\alpha + \beta}(z y) p_{-\alpha}(-1).

```

Using now (+) and (+++), this is also written

```

```text
p_{\beta}(y) p_{\alpha + \beta}(-y) = p_{\alpha + \beta}(z y) p_{\beta}(-z^{-1} y),

```

and since  $p_{\beta}$  and  $p_{\alpha + \beta}$  commute, this gives  $z = -1$ .

### 3.2.7.

<!-- label: III.XXIII.3.2.7 -->

We have therefore proved (ii) and (iii). Let us prove (i). One has

```

```text
w_{\alpha} w_{\beta} w_{\alpha} = w_{\alpha} w_{\beta} w_{\alpha}^{-1} w_{\alpha}^2 = w_{\alpha + \beta}^{-1} t_{\alpha},

```

whence

```

```text
w_{\beta} w_{\alpha} w_{\beta} w_{\alpha} w_{\beta} = w_{\beta} w_{\alpha + \beta}^{-1} t_{\alpha} w_{\beta} = w_{\beta} w_{\alpha + \beta}^{-1} w_{\beta}^{-1} \cdot s_{\beta}(t_{\alpha}) \cdot t_{\beta}
= w_{\alpha} \cdot t_{\alpha} t_{\beta} \cdot t_{\beta} = w_{\alpha} t_{\alpha} = w_{\alpha}^{-1},

```

which gives

```

```text
(w_{\alpha} w_{\beta})^3 = (w_{\beta} w_{\alpha})^3 = e,

```

which completes the proof.

****Remark 3.2.8.**** *Condition (v) of 2.3 translates here as (setting $v_{\alpha} = f_{\alpha}(u_{\alpha})$):*

```
```text
(A) int(h_α h_β h_α) v_β = v_β → h_α v_β h_α^{-1} = h_β v_α h_β^{-1} (B)
 int(h_β h_α h_β) v_α = v_α
 v_β v_α = v_α v_β · h_β v_α h_β^{-1},
 v_β · h_β v_α h_β^{-1} = h_β v_α h_β^{-1} · v_β,
 v_α · h_β v_α h_β^{-1} = h_β v_α h_β^{-1} · v_α.
```
```

<!-- label: III.XXIII.3.2.8 -->

<!-- original page 291 -->

Setting $v_{\alpha + \beta} = \text{int}(h_{\beta}) v_{\alpha}$, the three last conditions are also written

```
```text
(B) v_β v_α = v_α v_β v_{α + β},
 v_α v_{α + β} = v_{α + β} v_α,
 v_β v_{α + β} = v_{α + β} v_β.
```
```

3.3. Groups of type B_2

<!-- label: III.XXIII.3.3 -->

****Proposition 3.3.1.**** *Let S be a scheme, G a pinned S -group of type B_2 , and denote $\Delta = \{\alpha, \beta\}$, $R^+ = \{\alpha, \beta, \alpha + \beta, 2\alpha + \beta\}$.*

(i) One has

```
```text
t_{αβ} = (w_α w_β)^4 = t_α = (w_β w_α)^4 = t_{βα}.
```
```

<!-- original page 194 source / 294 reedition – heading transition -->

(ii) If one sets

```
```text
Ad(w_β) X_α = X_{α + β}, Ad(w_α) X_β = X_{2α + β},
```
```

one has:

```
```text
Ad(w_α) X_{α + β} = -X_{α + β},
Ad(w_α) X_{2α + β} = X_β,
Ad(w_β) X_{α + β} = -X_α,
Ad(w_β) X_{2α + β} = X_{2α + β}.
```
```

(iii) Set

```
```text
p_{α + β}(x) = exp(x X_{α + β}) = \text{int}(w_β) p_α(x),
p_{2α + β}(x) = exp(x X_{2α + β}) = \text{int}(w_α) p_β(x).
```
```

Then:

```
```text
p_β(y) p_α(x) = p_α(x) p_β(y) p_{α + β}(x y) p_{2α + β}(x^2 y),
p_{α + β}(y) p_α(x) = p_α(x) p_{α + β}(y) p_{2α + β}(2 x y).
```
```

```

$$\alpha(t_{\beta}) = -1, \alpha(t_{\alpha}) = -2, \text{ whence } \alpha(t_{\beta}) = -1, \alpha(t_{\alpha}) = 1.$$

```

original page 292

Note in passing that $\alpha(t_{\alpha}) = \alpha(t_{\alpha}) = 1$, which shows that t_{α} is a section of $\text{Centr}(G)$. Set

$$\text{Ad}(w_{\beta}) X_{\alpha} = X_{\alpha + \beta}, \quad \text{Ad}(w_{\alpha}) X_{\beta} = X_{2\alpha + \beta}.$$

One has at once

$$\begin{aligned} \text{Ad}(w_{\beta}) X_{\alpha + \beta} &= \alpha(t_{\beta}) X_{\alpha} = -X_{\alpha}, \\ \text{Ad}(w_{\alpha}) X_{2\alpha + \beta} &= \beta(t_{\alpha}) X_{\beta} = X_{\beta}. \end{aligned}$$

Since $(2\alpha + \beta) + \beta$ and $(2\alpha + \beta) - \beta$ are not roots,

$$\text{Ad}(w_{\beta}) X_{2\alpha + \beta} = X_{2\alpha + \beta}.$$

There exists a scalar $k \in G_m(S)$ such that

$$\text{Ad}(w_{\alpha}) X_{\alpha + \beta} = k X_{\alpha + \beta}.$$

On the other hand, by Exp. XXII, 5.5.2, there exist sections $A, B, C \in G_a(S)$ such that

$$\begin{aligned} p_{\beta}(y) p_{\alpha}(x) &= p_{\alpha}(x) p_{\beta}(y) p_{\alpha + \beta}(A \times y) p_{2\alpha + \beta}(B \times^2 y), & (1) \\ p_{\alpha + \beta}(y) p_{\alpha}(x) &= p_{\alpha}(x) p_{\alpha + \beta}(y) p_{2\alpha + \beta}(C \times y). & (2) \end{aligned}$$

It is therefore necessary, in (ii) and (iii), to prove that $A = B = 1$, $C = 2$, $k = -1$.

3.3.3.

label: III.XXIII.3.3.3

Make $\text{int}(w_{\alpha})$ act on formula (2). One finds

$$p_{2\alpha + \beta}(y) p_{-\alpha}(-x) = p_{-\alpha}(-x) p_{2\alpha + \beta}(y) p_{\alpha + \beta}(A k \times y) p_{\beta}(B \times^2 y). \quad (3)$$

Transforming (2) likewise, one obtains

$$p_{\alpha + \beta}(k y) p_{-\alpha}(-x) = p_{-\alpha}(-x) p_{\alpha + \beta}(k y) p_{\beta}(C \times y). \quad (4)$$

original page 293

Transforming (1) by $\text{int}(w_{\beta})$,

$$p_{-\beta}(-y) p_{\alpha + \beta}(x) = p_{\alpha + \beta}(x) p_{-\beta}(-y) p_{\alpha}(-A x y) p_{2\alpha + \beta}(B x^2 y). \quad (5)$$

3.3.4.

<!-- label: III.XXIII.3.3.4 -->

Write

$$w_{\beta} p_{\alpha}(x) w_{\beta}^{-1} = p_{\alpha + \beta}(x).$$

Since $\alpha + 2\beta$ is not a root, this gives

$$p_{\beta}(1) p_{\alpha}(x) p_{\beta}(-1) = p_{-\beta}(1) p_{\alpha + \beta}(x) p_{-\beta}(-1).$$

Using (1) in the left member and (5) in the right, one obtains

$$p_{\alpha}(x) p_{\beta}(1) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) p_{\beta}(-1) = p_{\alpha + \beta}(x) p_{-\beta}(1) p_{\alpha}(A x) p_{2\alpha + \beta}(-B x^2) p_{-\beta}(-1).$$

Since p_{β} commutes with $p_{\alpha + \beta}$ and $p_{2\alpha + \beta}$ on the one hand, and $p_{-\beta}$ commutes with p_{α} and $p_{2\alpha + \beta}$ on the other hand, this is written

$$p_{\alpha}(x) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) = p_{\alpha + \beta}(x) p_{\alpha}(A x) p_{2\alpha + \beta}(-B x^2).$$

Transforming the right member by (2), one obtains

$$p_{\alpha}(x) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) = p_{\alpha}(A x) p_{\alpha + \beta}(x) p_{2\alpha + \beta}((A C - B) x^2),$$

which gives

$$A = 1, \quad C = 2 B.$$

3.3.5.

<!-- label: III.XXIII.3.3.5 -->

Write now

$$w_{\alpha} p_{\beta}(y) w_{\alpha}^{-1} = p_{2\alpha + \beta}(y).$$

Since $3\alpha + \beta$ is not a root, this gives

$$p_{\alpha}(1) p_{\beta}(y) p_{\alpha}(-1) = p_{-\alpha}(1) p_{2\alpha + \beta}(y) p_{-\alpha}(-1).$$

<!-- original page 294 -->

Using (1) in the left member, (3) in the right, one obtains

```

```text
p_{\beta}(y) p_{\alpha + \beta}(-A y) p_{2\alpha + \beta}(B y) = p_{2\alpha + \beta}(y) p_{\alpha + \beta}(A k y) p_{\beta}(B y).
```

```

Since $p_{\alpha + \beta}$, $p_{2\alpha + \beta}$ and p_{β} commute, this gives at once

```

```text
B = 1, -A = A k,
```

```

whence finally

```

```text
A = 1, B = 1, C = 2, k = -1.
```

```

3.3.6.

<!-- label: III.XXIII.3.3.6 -->

We have therefore proved (ii) and (iii). Let us prove (i). Taking into account the equality $s_{\beta}(t_{\alpha}) = t_{\alpha} t^{\beta} s_{\beta}(t_{\alpha})$ (since $s_{\beta}(t_{\alpha}) = 2$), [XXIII-3-1] one has successively:

```

```text
w_{\alpha} w_{\beta} w_{\alpha} = w_{\alpha} w_{\beta} w_{\alpha}^{-1} t_{\alpha} = w_{2\alpha + \beta} t_{\alpha},
w_{\beta} w_{\alpha} w_{\beta} w_{\alpha} w_{\beta} = w_{\beta} w_{2\alpha + \beta} w_{\beta}^{-1} \cdot s_{\beta}(t_{\alpha}) \cdot t_{\beta} = w_{2\alpha + \beta} t_{\alpha} t_{\beta},
w_{\alpha} w_{\beta} w_{\alpha} w_{\beta} w_{\alpha} w_{\beta} w_{\alpha} = w_{\alpha} w_{2\alpha + \beta} w_{\alpha}^{-1} \cdot s_{\alpha}(t_{\alpha} t_{\beta}) \cdot t_{\alpha} = w_{\beta} \cdot t_{\alpha} \cdot t_{\beta} t_{\alpha} \cdot t_{\alpha}
= w_{\beta}^{-1} t_{\alpha},
```

```

whence

```

$$
(w_{\beta} w_{\alpha})^4 = t_{\alpha},
$$

```

and

```

```text
(w_{\alpha} w_{\beta})^4 = s_{\beta}(t_{\alpha}) = t_{\alpha},
```

```

which completes the proof.

Remark 3.3.7. Condition (v) of 2.3 translates here as follows, setting $v_{\alpha + \beta} = \text{int}(h_{\beta}) v_{\alpha}$ and $v_{2\alpha + \beta} = \text{int}(h_{\alpha}) v_{\beta}$:

<!-- original page 295 -->

```

```text
(A) int(h_{\alpha} h_{\beta} h_{\alpha}) v_{\beta} = v_{\beta}, (B) v_{\beta} v_{\alpha} = v_{\alpha} v_{\beta} v_{\alpha + \beta} v_{2\alpha + \beta},
 int(h_{\beta} h_{\alpha} h_{\beta}) v_{\alpha} = v_{\alpha}, v_{\alpha + \beta} v_{\alpha} = v_{\alpha} v_{\alpha + \beta} v_{2\alpha + \beta}^2,
 v_{\alpha + \beta} v_{\beta} = v_{\beta} v_{\alpha + \beta},
 v_{2\alpha + \beta} v_{\alpha} = v_{\alpha} v_{2\alpha + \beta},
 v_{2\alpha + \beta} v_{\beta} = v_{\beta} v_{2\alpha + \beta},
 v_{2\alpha + \beta} v_{\alpha + \beta} = v_{\alpha + \beta} v_{2\alpha + \beta}.
```

```

<!-- label: III.XXIII.3.3.7 -->

3.4. Groups of type `G<sub>2</sub>`

<!-- label: III.XXIII.3.4 -->

Proposition 3.4.1. Let S be a scheme, G a pinned S -group of type G_2 , and denote $\Delta = \{\alpha, \beta\}$, $R^+ = \{\alpha, \beta, \alpha + \beta, 2\alpha + \beta, 3\alpha + \beta, 3\alpha + 2\beta\}$.

(i) One has

$$t_{\alpha\beta} = (w_{\alpha} w_{\beta})^6 = e = (w_{\beta} w_{\alpha})^6 = t_{\beta\alpha}.$$

(ii) If one sets

$$\begin{aligned} \text{Ad}(w_{\beta}) X_{\alpha} &= X_{\alpha + \beta}, & \text{Ad}(w_{\alpha}) X_{\alpha + \beta} &= X_{2\alpha + \beta}, \\ \text{Ad}(w_{\alpha}) X_{\beta} &= -X_{3\alpha + \beta}, & \text{Ad}(w_{\beta}) X_{3\alpha + \beta} &= X_{3\alpha + 2\beta}, \end{aligned}$$

one has:

$$\begin{aligned} \text{Ad}(w_{\alpha}) X_{2\alpha + \beta} &= -X_{\alpha + \beta}, & \text{Ad}(w_{\alpha}) X_{3\alpha + \beta} &= X_{\beta}, \\ \text{Ad}(w_{\alpha}) X_{3\alpha + 2\beta} &= X_{3\alpha + 2\beta}, & \text{Ad}(w_{\beta}) X_{\alpha + \beta} &= -X_{\alpha}, \\ \text{Ad}(w_{\beta}) X_{2\alpha + \beta} &= X_{2\alpha + \beta}, & \text{Ad}(w_{\beta}) X_{3\alpha + 2\beta} &= -X_{3\alpha + \beta}. \end{aligned}$$

(iii) If one sets

$$\begin{aligned} p_{\alpha + \beta}(x) &= \exp(x X_{\alpha + \beta}) = \text{int}(w_{\beta}) p_{\alpha}(x), \\ p_{2\alpha + \beta}(x) &= \exp(x X_{2\alpha + \beta}) = \text{int}(w_{\alpha} w_{\beta}) p_{\alpha}(x), \\ p_{3\alpha + \beta}(x) &= \exp(x X_{3\alpha + \beta}) = \text{int}(w_{\alpha}) p_{\beta}(-x), \\ p_{3\alpha + 2\beta}(x) &= \exp(x X_{3\alpha + 2\beta}) = \text{int}(w_{\beta} w_{\alpha}) p_{\beta}(-x), \end{aligned}$$

<!-- original page 296 -->

one has:

$$\begin{aligned} p_{\beta}(y) p_{\alpha}(x) &= p_{\alpha}(x) p_{\beta}(y) p_{\alpha + \beta}(x y) p_{2\alpha + \beta}(x^2 y) p_{3\alpha + \beta}(x^3 y) p_{3\alpha + 2\beta}(x^3 y^2), \\ p_{\alpha + \beta}(y) p_{\alpha}(x) &= p_{\alpha}(x) p_{\alpha + \beta}(y) p_{2\alpha + \beta}(2 x y) p_{3\alpha + \beta}(3 x^2 y) p_{3\alpha + 2\beta}(3 x y^2), \\ p_{2\alpha + \beta}(y) p_{\alpha}(x) &= p_{\alpha}(x) p_{2\alpha + \beta}(y) p_{3\alpha + \beta}(3 x y), \\ p_{3\alpha + \beta}(y) p_{\beta}(x) &= p_{\beta}(x) p_{3\alpha + \beta}(y) p_{3\alpha + 2\beta}(-x y), \\ p_{2\alpha + \beta}(y) p_{\alpha + \beta}(x) &= p_{\alpha + \beta}(x) p_{2\alpha + \beta}(y) p_{3\alpha + 2\beta}(3 x y). \end{aligned}$$

<!-- label: III.XXIII.3.4.1 -->

3.4.2.

<!-- label: III.XXIII.3.4.2 -->

The proof occupies Nos. 3.4.2 to 3.4.9. One has $\beta(\alpha^*) = -1$, $\alpha(\beta^*) = -3$, whence $\beta(t_{\alpha}) = \alpha(t_{\beta}) = -1$. Define $X_{\alpha + \beta}$, $X_{2\alpha + \beta}$, $X_{3\alpha + \beta}$ and $X_{3\alpha + 2\beta}$ as in (ii). One has at once

$$\begin{aligned} \text{Ad}(w_{\beta}) X_{\alpha + \beta} &= \alpha(t_{\beta}) X_{\alpha} = -X_{\alpha}, \\ \text{Ad}(w_{\alpha}) X_{2\alpha + \beta} &= \alpha(t_{\alpha}) \beta(t_{\alpha}) X_{\alpha + \beta} = -X_{\alpha + \beta}, \\ \text{Ad}(w_{\alpha}) X_{3\alpha + \beta} &= -\beta(t_{\alpha}) X_{\beta} = X_{\beta}, \\ \text{Ad}(w_{\beta}) X_{3\alpha + 2\beta} &= \alpha(t_{\beta})^3 \beta(t_{\beta}) X_{3\alpha + \beta} = -X_{3\alpha + \beta}. \end{aligned}$$

...

Finally, since $(3\alpha + 2\beta) \pmod{\alpha}$ and $(2\alpha + \beta) \pmod{\beta}$ are not roots,

$$\text{Ad}(w_\alpha) X_{3\alpha + 2\beta} = X_{3\alpha + 2\beta}, \quad \text{Ad}(w_\beta) X_{2\alpha + \beta} = X_{2\alpha + \beta},$$

which completes the proof of (ii).

3.4.3.

<!-- label: III.XXIII.3.4.3 -->

<!-- original page 297 -->

By virtue of Exp. XXII, 5.5.2, there exist scalars^[N.D.E-XXIII-7]

$$A, B, C, D, E, F, G, H, J \in G_a(S),$$

such that

$$\begin{aligned} p_\beta(y) p_\alpha(x) &= p_\alpha(x) p_\beta(y) p_{\alpha+\beta}(A \times y) p_{2\alpha+\beta}(B x^2 y) p_{3\alpha+\beta}(C x^3 y) p_{3\alpha+2\beta}(D x^3 y^2), & (1) \\ p_{\alpha+\beta}(y) p_\alpha(x) &= p_\alpha(x) p_{\alpha+\beta}(y) p_{2\alpha+\beta}(E x y) p_{3\alpha+\beta}(F x^2 y) p_{3\alpha+2\beta}(G x y^2), & (2) \\ p_{2\alpha+\beta}(y) p_\alpha(x) &= p_\alpha(x) p_{2\alpha+\beta}(y) p_{3\alpha+\beta}(H x y), & (3) \\ p_{3\alpha+\beta}(y) p_\beta(x) &= p_\beta(x) p_{3\alpha+\beta}(y) p_{3\alpha+2\beta}(J x y). & (4) \end{aligned}$$

3.4.4.

<!-- label: III.XXIII.3.4.4 -->

Make $\text{int}(w_{\beta})$ act on (1), (3) and (4):

$$\begin{aligned} p_{-\beta}(-y) p_{\alpha+\beta}(x) &= \\ p_{\alpha+\beta}(x) p_{-\beta}(-y) p_\alpha(-A x y) p_{2\alpha+\beta}(B x^2 y) p_{3\alpha+2\beta}(C x^3 y) p_{3\alpha+\beta}(-D x^3 y^2), & (5) \\ p_{2\alpha+\beta}(y) p_{\alpha+\beta}(x) &= p_{\alpha+\beta}(x) p_{2\alpha+\beta}(y) p_{3\alpha+2\beta}(H x y), & (6) \\ p_{3\alpha+2\beta}(y) p_{-\beta}(-x) &= p_{-\beta}(-x) p_{3\alpha+2\beta}(y) p_{3\alpha+\beta}(-J x y). & (7) \end{aligned}$$

Making $\text{int}(w_\alpha)$ act on (1), one finds

$$\begin{aligned} p_{3\alpha+\beta}(-y) p_{-\alpha}(-x) &= \\ p_{-\alpha}(-x) p_{3\alpha+\beta}(-y) p_{2\alpha+\beta}(A x y) p_{\alpha+\beta}(-B x^2 y) p_\beta(C x^3 y) p_{3\alpha+\beta}(D x^3 y^2). & (8) \end{aligned}$$

3.4.5.

<!-- label: III.XXIII.3.4.5 -->

Write

$$w_\beta p_\alpha(x) w_{\beta^{-1}} = p_{\alpha+\beta}(x),$$

that is, $\alpha + 2\beta$ not being a root,

<!-- original page 298 -->

$$p_{\beta}(1) p_{\alpha}(x) p_{\alpha}(-1) = p_{-\beta}(1) p_{\alpha + \beta}(x) p_{-\beta}(-1). \quad (9)$$

Transforming the left member of (9) by (1), then (4), one obtains:

$$\begin{aligned} p_{\beta}(1) p_{\alpha}(x) p_{\beta}(-1) &= p_{\alpha}(x) p_{\beta}(1) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) p_{3\alpha + \beta}(C x^3) p_{\alpha + 2\beta}(D x^3) p_{\beta}(-1) \\ &= p_{\alpha}(x) p_{\beta}(1) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) p_{\beta}(-1) p_{3\alpha + \beta}(C x^3) p_{\alpha + 2\beta}((D - C J) x^3) \\ &= p_{\alpha}(x) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) p_{3\alpha + \beta}(C x^3) p_{\alpha + 2\beta}((D - C J) x^3). \end{aligned} \quad (10)$$

Transforming the right member of (9) by (5), then (7):

$$\begin{aligned} p_{-\beta}(1) p_{\alpha + \beta}(x) p_{-\beta}(-1) &= p_{\alpha + \beta}(x) p_{-\beta}(1) p_{\alpha}(A x) p_{2\alpha + \beta}(-B x^2) p_{3\alpha + 2\beta}(-C x^3) p_{3\alpha + \beta}(-D x^3) p_{-\beta}(-1) \\ &= p_{\alpha + \beta}(x) p_{\alpha}(A x) p_{2\alpha + \beta}(-B x^2) p_{3\alpha + 2\beta}(-C x^3) p_{3\alpha + \beta}((C J - D) x^3). \end{aligned} \quad (11)$$

Using now (2), this right member becomes

$$\begin{aligned} p_{\alpha}(A x) p_{\alpha + \beta}(x) p_{2\alpha + \beta}(A E x^2) p_{3\alpha + \beta}(A^2 F x^3) p_{3\alpha + 2\beta}(A G x^3) \times \\ p_{2\alpha + \beta}(-B x^2) p_{3\alpha + 2\beta}(-C x^3) p_{3\alpha + \beta}((C J - D) x^3) \\ = p_{\alpha}(A x) p_{\alpha + \beta}(x) p_{2\alpha + \beta}((A E - B) x^2) p_{3\alpha + \beta}((A^2 F + C J - D) x^3) p_{3\alpha + 2\beta}((A G - C) x^3). \end{aligned} \quad (12)$$

So (9) rewrites:

$$\begin{aligned} p_{\alpha}(x) p_{\alpha + \beta}(A x) p_{2\alpha + \beta}(B x^2) p_{3\alpha + \beta}(C x^3) p_{3\alpha + 2\beta}((D - C J) x^3) = \\ p_{\alpha}(A x) p_{\alpha + \beta}(x) p_{2\alpha + \beta}((A E - B) x^2) p_{3\alpha + \beta}((A^2 F + C J - D) x^3) p_{3\alpha + 2\beta}((A G - C) x^3), \end{aligned}$$

which gives

$$A = 1, \quad E = 2 B, \quad C + D = F + C J, \quad F = G.$$

3.4.6.

<!-- label: III.XXIII.3.4.6 -->

Write now

$$w_{\alpha} p_{\beta}(y) w_{\alpha}^{-1} = p_{3\alpha + \beta}(-y),$$

<!-- original page 299 -->

that is, $\alpha + \beta$ not being a root,

$$p_{\alpha}(1) p_{\beta}(y) p_{\alpha}(-1) = p_{-\alpha}(1) p_{3\alpha + \beta}(-y) p_{-\alpha}(-1). \quad (13)$$

Transform the left member by (1):

$$p_{\alpha}(1) p_{\beta}(y) p_{\alpha}(-1) = p_{\beta}(y) p_{\alpha + \beta}(-A y) p_{2\alpha + \beta}(B y) p_{3\alpha + \beta}(-C y) p_{3\alpha + 2\beta}(-D y^2).$$

Transform the right member of (13) successively by (8), (6) and (4):

```

```text
p_{-α}(1) p_{3α + β}(-y) p_{-α}(-1)
= p_{3α + β}(-y) p_{2α + β}(A y) p_{α + β}(-B y) p_β(C y) p_{3α + 2β}(D y^2)
= p_{3α + β}(-y) p_{α + β}(-B y) p_{2α + β}(A y) p_{3α + 2β}(-A B H y^2) p_β(C y) p_{3α + 2β}(D y^2)
= p_β(C y) p_{3α + β}(-y) p_{α + β}(-B y) p_{2α + β}(A y) p_{3α + 2β}((D - C J - A B H) y^2)
= p_β(C y) p_{α + β}(-B y) p_{2α + β}(A y) p_{3α + β}(-y) p_{3α + 2β}((D - C J - A B H) y^2).
```

```

So (13) rewrites:

```

```text
p_β(C y) p_{α + β}(-B y) p_{2α + β}(A y) p_{3α + β}(-y) p_{3α + 2β}((D - C J - A B H) y^2) =
p_β(y) p_{α + β}(-A y) p_{2α + β}(B y) p_{3α + β}(-C y) p_{3α + 2β}(-D y^2),
```

```

whence

```

```text
C = 1, A = B, D - C J - A B H = -D.
```

```

Taking into account the results already obtained:

```

```text
A = B = C = 1, E = 2, F = G, D + 1 = F + J, 2 D = H + J.
```

```

3.4.7.

<!-- label: III.XXIII.3.4.7 -->

Write

```

```text
w_β p_{3α + β}(x) w_β^{-1} = p_{3α + 2β}(x),
```

```

that is,

```

```text
p_β(1) p_{3α + β}(x) p_β(-1) = p_{-β}(1) p_{3α + 2β}(x) p_{-β}(-1).
```

```

Transforming the left member by (4), the right by (7), one obtains:

<!-- original page 300 -->

```

```text
p_{3α + β}(x) p_{3α + 2β}(-J x) = p_{3α + 2β}(x) p_{3α + β}(-J x),
```

```

so $J = -1$.

3.4.8.

<!-- label: III.XXIII.3.4.8 -->

Write finally

```

```text
w_α p_{α + β}(y) w_α^{-1} = p_{2α + β}(y),
```

```

that is,

```
```text
p_{\alpha}(1) p_{\alpha + \beta}(y) p_{-\alpha}(-1) = p_{-\alpha}(1) p_{-\alpha}(-1) p_{2\alpha + \beta}(y) p_{\alpha}(1) p_{-\alpha}(-1).
```

Transforming the left member by (2), the right by (3), one obtains:

```
```text
p_{\alpha + \beta}(y) p_{2\alpha + \beta}(-E y) p_{3\alpha + \beta}(F y) p_{3\alpha + 2\beta}(-G y^2) =
... p_{-\alpha}(1) p_{2\alpha + \beta}(y) p_{3\alpha + \beta}(H y) p_{-\alpha}(-1).
```

It is immediate to see that, if one makes $p_{-\alpha}(-1)$ commute with $p_{3\alpha + \beta}(H y)$, then $p_{2\alpha + \beta}(y)$, one does not introduce in the right member any new terms in $p_{3\alpha + \beta}$. The latter therefore writes, denoting by empty parentheses quantities whose exact value does not matter to us:

```
```text
p_{\alpha + \beta}(\) p_{2\alpha + \beta}(\) p_{\beta}(\) p_{3\alpha + \beta}(H y) p_{3\alpha + 2\beta}(\).
```

Comparing with the left member, one has at once  $F = H$ , whence by the previous results  $2D = D + 1$ , so  $D = 1$ , and finally  $F = G = H = 2D - J = 3$ , which completes the determination of the coefficients  $A, \dots, J$  and the proof of (iii).

### 3.4.9.

<!-- label: III.XXIII.3.4.9 -->

Let us prove (i) finally, in the usual manner. One has successively:

```
```text
w_{\alpha} w_{\beta} w_{\alpha} = w_{\alpha} w_{\beta} w_{\alpha}^{-1} t_{\alpha} = w_{3\alpha + \beta}^{-1} \cdot t_{\alpha},
w_{\beta} (w_{\alpha} w_{\beta})^2 = w_{\beta} w_{3\alpha + \beta}^{-1} w_{\beta}^{-1} \cdot s_{\beta}(t_{\alpha}) \cdot t_{\beta} = w_{3\alpha + 2\beta}^{-1} \cdot t_{\alpha} t_{\beta} \cdot t_{\beta} = w_{3\alpha + 2\beta}^{-1} \cdot t_{\alpha},
w_{\alpha} (w_{\beta} w_{\alpha})^3 = w_{\alpha} w_{3\alpha + 2\beta}^{-1} w_{\alpha}^{-1} = w_{3\alpha + 2\beta}^{-1},
w_{\beta} (w_{\alpha} w_{\beta})^4 = w_{\beta} w_{3\alpha + 2\beta}^{-1} w_{\beta}^{-1} \cdot t_{\beta} = w_{3\alpha + \beta} \cdot t_{\beta},
w_{\alpha} (w_{\beta} w_{\alpha})^5 = w_{\alpha} w_{3\alpha + \beta} w_{\alpha}^{-1} \cdot s_{\alpha}(t_{\beta}) \cdot t_{\beta} = w_{\beta} \cdot t_{\beta} t_{\alpha} \cdot t_{\alpha} = w_{\beta}^{-1}.
```

<!-- original page 301 -->

Whence

```
```text
(w_{\alpha} w_{\beta})^6 = (w_{\beta} w_{\alpha})^6 = e.
```

**Remark 3.4.10.** Condition (v) of 2.4 is composed of

```
```text
(A)   int(h_{\alpha} h_{\beta} h_{\alpha} h_{\beta} h_{\alpha}) v_{\beta} = v_{\beta},
...   int(h_{\beta} h_{\alpha} h_{\beta} h_{\alpha} h_{\beta}) v_{\alpha} = v_{\alpha},
```

and, setting

```
```text
v_{\alpha + \beta} = int(h_{\beta}) v_{\alpha}, v_{2\alpha + \beta} = int(h_{\alpha} h_{\beta}) v_{\alpha},
v_{3\alpha + \beta} = int(h_{\alpha}) v_{\beta}^{-1}, v_{3\alpha + 2\beta} = int(h_{\beta} h_{\alpha}) v_{\beta}^{-1},
```

<!-- original page 302 -->

the commutation relations:

```

```text
(B)  $v_{\beta} v_{\alpha} = v_{\alpha} v_{\beta} v_{\{\alpha + \beta\}} v_{\{2\alpha + \beta\}} v_{\{3\alpha + \beta\}} v_{\{3\alpha + 2\beta\}},$ 
 $v_{\{\alpha + \beta\}} v_{\alpha} = v_{\alpha} v_{\{\alpha + \beta\}} v_{\{2\alpha + \beta\}}^2 v_{\{3\alpha + \beta\}}^3 v_{\{3\alpha + 2\beta\}}^3,$ 
 $v_{\{2\alpha + \beta\}} v_{\alpha} = v_{\alpha} v_{\{2\alpha + \beta\}} v_{\{3\alpha + \beta\}}^3,$ 
 $v_{\{3\alpha + \beta\}} v_{\alpha} = v_{\alpha} v_{\{3\alpha + \beta\}},$ 
 $v_{\{3\alpha + 2\beta\}} v_{\alpha} = v_{\alpha} v_{\{3\alpha + 2\beta\}},$ 
 $v_{\{\alpha + \beta\}} v_{\beta} = v_{\beta} v_{\{\alpha + \beta\}},$ 
 $v_{\{2\alpha + \beta\}} v_{\beta} = v_{\beta} v_{\{2\alpha + \beta\}},$ 
 $v_{\{3\alpha + \beta\}} v_{\beta} = v_{\beta} v_{\{3\alpha + \beta\}} v_{\{3\alpha + 2\beta\}}^{-1},$ 
 $v_{\{3\alpha + 2\beta\}} v_{\beta} = v_{\beta} v_{\{3\alpha + 2\beta\}},$ 
 $v_{\{2\alpha + \beta\}} v_{\{\alpha + \beta\}} = v_{\{\alpha + \beta\}} v_{\{2\alpha + \beta\}} v_{\{3\alpha + 2\beta\}}^3,$ 
 $v_{\{3\alpha + \beta\}} v_{\{\alpha + \beta\}} = v_{\{\alpha + \beta\}} v_{\{3\alpha + \beta\}},$ 
 $v_{\{3\alpha + 2\beta\}} v_{\{\alpha + \beta\}} = v_{\{\alpha + \beta\}} v_{\{3\alpha + 2\beta\}},$ 
 $v_{\{3\alpha + \beta\}} v_{\{2\alpha + \beta\}} = v_{\{2\alpha + \beta\}} v_{\{3\alpha + \beta\}},$ 
 $v_{\{3\alpha + 2\beta\}} v_{\{2\alpha + \beta\}} = v_{\{2\alpha + \beta\}} v_{\{3\alpha + 2\beta\}},$ 
 $v_{\{3\alpha + 2\beta\}} v_{\{3\alpha + \beta\}} = v_{\{3\alpha + \beta\}} v_{\{3\alpha + 2\beta\}}.$ 
...

<!-- label: III.XXIII.3.4.10 -->

### 3.5. Explicit form of the generators-and-relations theorem

<!-- label: III.XXIII.3.5 -->

**Theorem 3.5.1.** *Let  $S$  be a scheme,  $G$  a pinned  $S$ -group,  $T$  its maximal torus,  $\Delta$  its system of simple roots,  $U_{\alpha} \in U_{\alpha}(S)^{\times}$  and  $w_{\alpha} \in \text{Norm}_G(T)(S)$  the elements defined by the pinning  $(\alpha \in \Delta)$ . Let*
```

$$f_T : T \rightarrow H, \quad f_{\alpha} : U_{\alpha} \rightarrow H, \quad \alpha \in \Delta$$

```

```text
<!-- original page 303 -->

be morphisms of groups, H being an S -sheaf in groups for (fppf); let $h_{\alpha} \in H(S)$, $(\alpha \in \Delta)$ be sections of H , and set $v_{\alpha} = f_{\alpha}(u_{\alpha})$, $\alpha \in \Delta$. In order that there exist a morphism of groups

 $f : G \rightarrow H$

extending f_T , f_{α} $(\alpha \in \Delta)$ and satisfying $f(w_{\alpha}) = h_{\alpha}$ $(\alpha \in \Delta)$ (and then necessarily unique), it is necessary and sufficient that the following conditions be satisfied:

*(i) For every $S' \rightarrow S$, every $\alpha \in \Delta$, every $t \in T(S')$ and every $x \in U_{\alpha}(S')$,\text{int}(f_T(t)) f_{\alpha}(x) = f_{\alpha}(\text{int}(t) x) = f_{\alpha}(x^{\alpha(t)}).
(1)

*(ii) For every $\alpha \in \Delta$, every $S' \rightarrow S$ and every $t \in T(S')$,\text{int}(h_{\alpha}) f_T(t) = f_T(s_{\alpha}(t)) = f_T(t \cdot \alpha^{\alpha(t)}).
(2)

(iii) For every $\alpha \in \Delta$, [N.D.E-XXIII-8]

$$h_{\alpha}^2 = f_T(\alpha^{\alpha(t)}), \quad (3_{11})$$

$$(h_{\alpha} v_{\alpha})^3 = e. \quad (4)$$

```

\*(iv) For all  $\alpha, \beta \in \Delta$ ,  $\alpha \neq \beta$ , such that  $(\alpha^*, \beta) = 0$  (resp.  $(\alpha^*, \beta) = -1$ , resp.  $(\alpha^*, \beta) = -2$ , resp.  $(\alpha^*, \beta) = -3$ ):\*

<!-- original page 304 -->

\*(a) the relation\*

```

```text
(h_α h_β)^2 = f_T(α^*(-1) β^*(-1))    if (α^*, β) = 0;
(h_α h_β)^3 = e,                      if (α^*, β) = -1;      (3z)
(h_α h_β)^4 = f_T(α^*(-1)),            if (α^*, β) = -2;
(h_α h_β)^6 = e,                      if (α^*, β) = -3.
```

```

\*(b) The relations (A) and (B) of 3.1.3 (resp. 3.2.8, resp. 3.3.7, resp. 3.4.10).\*

<!-- label: III.XXIII.3.5.1 -->

This follows at once from 2.3, 2.6 and the calculations done in each particular case.

**Remark 3.5.2.** \*One may present the preceding results in a slightly different way: one gives oneself morphisms, for  $\alpha \in \Delta$ ,\*

```

```text
a_α : T · U_α → H,    b_α : Norm_{Z_α}(T) → H,
```

```

\*and one sets\*

```

```text
h_α = b_α(w_α),    v_α = a_α(u_α);
```

```

\*then the conditions to be verified are the following:\*

\*(1) all the  $a_{\alpha}$  ( $\alpha \in \Delta$ ) and all the  $b_{\alpha}$  ( $\alpha \in \Delta$ ) have the same restriction to  $T$ ;

\*(2) conditions (4) and (iv) of 3.5.1 above are satisfied.\*

<!-- label: III.XXIII.3.5.2 -->

### 3.5.3.

<!-- label: III.XXIII.3.5.3 -->

<!-- original page 305 -->

Various applications of this theorem will be given in the following Exposé. Let us mention one here: Theorem 3.5.1 gives a description by generators and relations of  $G$  in the category of  $S$ -sheaves for (fppf); in other words, consider for each  $S' \rightarrow S$  the group  $H(S')$  generated by  $T(S')$ ,  $U_{\alpha}(S')$ ,  $\alpha \in R$ , and  $w_{\alpha}$ ,  $\alpha \in R$ , subjected to relations analogous to (1), (2), (3<sub>1</sub>), (4), (3<sub>2</sub>), (A), (B); then  $G$  is none other than the sheaf associated with the presheaf  $S' \mapsto H(S')$ .

In particular, if  $S$  is the spectrum of an algebraically closed field  $k$ , one has  $G(S) = H(S)$  (an immediate consequence of the Nullstellensatz in the form: "a sieve over an algebraically closed field, covering for (fppf), is trivial"), so that 3.5.1 yields at once an explicit description by generators and relations of the "abstract" group  $G(k)$ . [N.D.E-XXIII-9]

## 4. Uniqueness of pinned groups: fundamental theorem

<!-- label: III.XXIII.4 -->

**Theorem 4.1.** \*Let  $S$  be a nonempty scheme. The functor  $R$  of 1.6 is fully faithful: let  $G$  and  $G'$  be two pinned  $S$ -groups,  $p$  [N.D.E-XXIII-10] an integer  $> 0$  such that  $x \mapsto x^p$  is an endomorphism of  $G_{\{a, S\}}$ , and

$h : R(G') \rightarrow R(G)$  a  $p$ -morphism of pinned root data. There exists a unique morphism of pinned groups\*

$f : G \rightarrow G'$

\*such that  $R(f) = h$ .

*III.XXIII.4.1*

The uniqueness is proved in 1.9. It suffices to prove existence. By hypothesis, one has a bijection  $d : R \xrightarrow{\sim} R'$  and a map  $q : R \rightarrow \{p^n \mid n \in \mathbb{N}\}$  such that

$h(d(\alpha)) = q(\alpha) \alpha$  and  $h(\alpha^*) = q(\alpha) d(\alpha)^*$

*original page 306*

for every  $\alpha \in R$ . In particular, the semisimple ranks of  $G$  and  $G'$  coincide.

### 4.1.1.

*III.XXIII.4.1.1*

Suppose  $\text{rg}_{\text{ss}}(G) = \text{rg}_{\text{ss}}(G') = 0$ . Then  $G$  and  $G'$  are tori: one has  $G = T = D_S(M)$ ,  $G' = T' = D_S(M')$  and  $h$  is simply a morphism of ordinary groups  $h : M' \rightarrow M$ . One then takes  $f = D_S(h)$ .

### 4.1.2.

*III.XXIII.4.1.2*

Suppose  $\text{rg}_{\text{ss}}(G) = \text{rg}_{\text{ss}}(G') = 1$ . Consider then

$f_T = D_S(h) : T \rightarrow T'$ .

By hypothesis, one has a commutative diagram, where  $\alpha' = d(\alpha)$ :

$$\begin{array}{ccccc} G_{\{m, S\}} & \xrightarrow{\alpha^*} & T & \xrightarrow{\alpha} & G_{\{m, S\}} \\ \downarrow q(\alpha) & & \downarrow f_T & & \downarrow q(\alpha) \\ G_{\{m, S\}} & \xrightarrow{\alpha'^*} & T' & \xrightarrow{\alpha'} & G_{\{m, S\}} \end{array}$$

One then applies Exp. XX, 4.1.

### 4.1.3.

*III.XXIII.4.1.3*

Suppose  $\text{rg}_{\text{ss}}(G) = \text{rg}_{\text{ss}}(G') = 2$ . Then, by Exp. XXI, 7.5.3, one knows all the possibilities for  $h : R(G') \rightarrow R(G)$ . Let us examine them successively, verifying each time the conditions of 2.5.

Denote  $\Delta = \{\alpha, \beta\}$ ,  $\Delta' = \{\alpha', \beta'\}$  in such a way that  $d(\alpha) = \alpha'$ ,  $d(\beta) = \beta'$ .

### 4.1.4.  $G$  and  $G'$  of type  $A_1 \times A_1$

*III.XXIII.4.1.4*

One has

```
```text
h(α') = q α,    h(β') = q_1 β.
```

Let us show that the conditions of 2.5 are satisfied: (ii) and (iii) follow from 3.1.2 (ii) and (iii); let us prove (i).

<!-- original page 307 -->

One has[^N.D.E-XXIII-11]

```
```text
D_S(h) t_{αβ} = D_S(h)(t_α t_β) = ^t h(α^*)(-1) · ^t h(β^*)(-1) = α'^*((-1)^q) · β'^*((-1)^{q_1}).
```

Now, the hypothesis that  $x \mapsto x^p$  is an endomorphism of  $G_{\{a, S\}}$  (and  $S \neq \emptyset$ ) entails that  $p = 1$  or that  $S$  is of characteristic  $p$ ; in all cases  $(-1)^q = -1$  (if  $q$  is even,  $p = 2$  and  $-1 = -1$ ). Consequently,

```
```text
D_S(h) t_{αβ} = α'^*(-1) · β'^*(-1) = t'_{α' β'}.
```

This shows that condition 2.5 (i) is satisfied.

4.1.5. G and G' of type A_2

<!-- label: III.XXIII.4.1.5 -->

One has

```
```text
h(α') = q α, h(β') = q β.
```

Set  $X_{\{\alpha + \beta\}} = \text{Ad}(w_{\{\beta\}}) X_{\{\alpha\}}$  and  $X'_{\{\alpha' + \beta'\}} = \text{Ad}(w_{\{\beta'\}}) X_{\{\alpha'\}}$ . Let us verify the conditions of 2.5. For (i), one reasons as above, using 3.2.1 (i); for (ii), it is immediate by 3.2.1 (ii); it remains to verify (iii). We must check that

```
```text
p_α(x) p_β(y) p_{α + β}(z) ↦ p'_{α'}(x^q) p'_{β'}(y^q) p'_{α' + β'}(z^q)
```

is a morphism of groups. The only nontrivial commutation relation is that of 3.2.1 (iii), which is written

```
```text
p_β(y) p_α(x) = p_α(x) p_β(y) p_{α + β}(x y),
p'_{β'}(y^q) p'_{α'}(x^q) = p'_{α'}(x^q) p'_{β'}(y^q) p'_{α' + β'}(x^q y^q).
```

### 4.1.6.

<!-- label: III.XXIII.4.1.6 -->

One reasons similarly for  $G$  and  $G'$  of type  $B_2$  (resp.  $G_2$ ), when the radical exponents are equal, using 3.3.1 (resp. 3.4.1); it remains, therefore, to treat – in order to complete the case of groups of rank 2 – the two exceptional cases of Exp. XXI, 7.5.3.

### 4.1.7.  $G$  and  $G'$  of type  $B_2$ ,  $S$  of characteristic 2,  $q(\alpha) = 2q$ ,  $q(\beta) = q$

<!-- label: III.XXIII.4.1.7 -->

<!-- original page 308 -->

The positive roots are  $\{\alpha, \beta, \alpha + \beta, 2\alpha + \beta\}$  and  $\{\alpha', \beta', \alpha' + \beta', \alpha' + 2\beta'\}$  (note that the "short" simple roots are  $\alpha$  and  $\beta'$ ). One has

$$h(\alpha') = 2q\alpha, \quad h(\beta') = q\beta, \quad h(\alpha' + \beta') = q(2\alpha + \beta), \quad h(\alpha' + 2\beta') = 2q(\alpha + \beta),$$

which gives

$$\begin{aligned} d(\alpha + \beta) &= \alpha' + 2\beta', & q(\alpha + \beta) &= 2q, \\ d(2\alpha + \beta) &= \alpha' + \beta', & q(2\alpha + \beta) &= q. \end{aligned}$$

Set

$$\begin{aligned} X_{\alpha + \beta} &= \text{Ad}(w_\beta) X_\alpha, & X_{2\alpha + \beta} &= \text{Ad}(w_\alpha) X_\beta, \\ X_{\alpha' + \beta'} &= \text{Ad}(w'_{\alpha'}) X'_{\beta'}, & X_{\alpha' + 2\beta'} &= \text{Ad}(w'_{\beta'}) X'_{\alpha'}. \end{aligned}$$

Let us now verify the conditions of 2.5.

(i) Since  $\mathbb{S}$  is of characteristic 2, one has  $-1 = 1$  on  $\mathbb{S}$ , hence  $t_{\alpha\beta} = t_{\alpha\beta} = \alpha^{*}(-1) = e = \beta^{*}(-1) = t_{\beta\alpha} = t_{\alpha\beta}$  (cf. 3.3.1 (i)).

(ii) One has by construction

$$\begin{aligned} \text{Ad}(w_\alpha) X_\beta &= X_{2\alpha + \beta}, & \text{Ad}(w'_{\alpha'}) X'_{\beta'} &= X'_{\alpha' + \beta'} = X'_{d(2\alpha + \beta)}; \\ \text{Ad}(w_\beta) X_\alpha &= X_{\alpha + \beta}, & \text{Ad}(w'_{\beta'}) X'_{\alpha'} &= X'_{\alpha' + 2\beta'} = X'_{d(\alpha + \beta)}. \end{aligned}$$

By 3.3.1 (ii) and the fact that  $-1 = 1$  on  $\mathbb{S}$ , one has on each side

$$\begin{aligned} \text{Ad}(w_\alpha) X_{\alpha + \beta} &= X_{\alpha + \beta}, & \text{Ad}(w'_{\alpha'}) X'_{d(\alpha + \beta)} &= \text{Ad}(w'_{\alpha'}) X'_{\alpha' + 2\beta'} = X'_{\alpha' + 2\beta'} = X'_{d(\alpha + \beta)}; \\ \text{Ad}(w_\alpha) X_{2\alpha + \beta} &= X_\beta, & \text{Ad}(w'_{\alpha'}) X'_{d(2\alpha + \beta)} &= \text{Ad}(w'_{\alpha'}) X'_{\alpha' + \beta'} = X'_{\beta'} = X'_{d(\beta)}; \\ \text{Ad}(w_\beta) X_{\alpha + \beta} &= X_\alpha, & \text{Ad}(w'_{\beta'}) X'_{d(\alpha + \beta)} &= \text{Ad}(w'_{\beta'}) X'_{\alpha' + 2\beta'} = X'_{\alpha'} = X'_{d(\alpha)}; \\ \text{Ad}(w_\beta) X_{2\alpha + \beta} &= X_{2\alpha + \beta}, & \text{Ad}(w'_{\beta'}) X'_{d(2\alpha + \beta)} &= \text{Ad}(w'_{\beta'}) X'_{\alpha' + \beta'} = X'_{\alpha' + \beta'} = X'_{d(2\alpha + \beta)}. \end{aligned}$$

<!-- original page 309 -->

(iii) By 3.3.1 (iii), one sees that the only nontrivial commutation relation in  $\mathbb{U}$  (resp.  $\mathbb{U}'$ ) is

$$p_\beta(y) p_\alpha(x) = p_\alpha(x) p_\beta(y) p_{\alpha + \beta}(x y) p_{2\alpha + \beta}(x^2 y),$$

resp.

$$p'_{\alpha'}(y') p'_{\beta'}(x') = p'_{\beta'}(x') p'_{\alpha'}(y') p'_{\alpha' + \beta'}(x' y') p'_{\alpha' + 2\beta'}(x' y'^2).$$

We must verify that the morphism

$$p_\alpha(x) p_\beta(y) p_{\alpha + \beta}(z) p_{2\alpha + \beta}(t) \mapsto p'_{\alpha'}(x^{2q}) p'_{\beta'}(y^q) p'_{\alpha' + 2\beta'}(z^{2q}) p'_{\alpha' + \beta'}(t^q)$$

is a morphism of groups; one sees at once that this amounts to seeing that

```

```text
p'_{\beta'}(y^q) p'_{\alpha'}(x^{2q}) = p'_{\alpha'}(x^{2q}) p'_{\beta'}(y^q) p'_{\alpha' + 2\beta'}((x y)^{2q}) p'_{\alpha' + \beta'}((x^2 y)^q),

```

which is none other than the second relation above (setting $y' = x^{2q}$, $x' = y^q$).

4.1.8. G and G' of type G_2 , S of characteristic 3, $q(\alpha) = 3q$, $q(\beta) = q$

<!-- label: III.XXIII.4.1.8 -->

<!-- original page 310 -->

The positive roots are $\{\alpha, \beta, \alpha + \beta, 2\alpha + \beta, 3\alpha + \beta, 3\alpha + 2\beta\}$ on the one hand, $\{\alpha', \beta', \alpha' + \beta', \alpha' + 2\beta', \alpha' + 3\beta', 2\alpha' + 3\beta'\}$ on the other (as in the preceding case, the short simple roots are α and β). One has

```

```text
h(\alpha') = 3 q \alpha, h(\beta') = q \beta, h(\alpha' + \beta') = q(3\alpha + \beta),
h(\alpha' + 2\beta') = q(3\alpha + 2\beta), h(\alpha' + 3\beta') = 3 q(\alpha + \beta),
h(2\alpha' + 3\beta') = 3 q(2\alpha + \beta),
```

```

which gives

```

```text
d(\alpha + \beta) = \alpha' + 3\beta', q(\alpha + \beta) = 3 q,
d(2\alpha + \beta) = 2\alpha' + 3\beta', q(2\alpha + \beta) = 3 q,
d(3\alpha + \beta) = \alpha' + \beta', q(3\alpha + \beta) = q,
d(3\alpha + 2\beta) = \alpha' + 2\beta', q(3\alpha + 2\beta) = q.
```

```

Set

```

```text
X_{\alpha + \beta} = Ad(w_{\beta}) X_{\alpha}, X_{2\alpha + \beta} = Ad(w_{\alpha}) X_{\alpha + \beta},
X_{3\alpha + \beta} = -Ad(w_{\alpha}) X_{\beta}, X_{3\alpha + 2\beta} = Ad(w_{\beta}) X_{3\alpha + \beta};
X'_{\alpha' + \beta'} = -Ad(w'_{\alpha'}) X'_{\beta'}, X'_{\alpha' + 2\beta'} = Ad(w'_{\beta'}) X'_{\alpha' + \beta'},
X'_{\alpha' + 3\beta'} = Ad(w'_{\beta'}) X'_{\alpha'}, X'_{2\alpha' + 3\beta'} = Ad(w'_{\alpha'}) X'_{\alpha' + 3\beta'}.
```

```

Let us now verify the conditions of 2.5.

(i) $t_{\alpha\beta} = e$ and $t'_{\alpha'\beta'} = e$ by 3.4.1 (i).

(ii) One has by construction

```

```text
Ad(w_{\beta}) X_{\alpha} = X_{\alpha + \beta}, Ad(w'_{\beta'}) X'_{\alpha'} = X'_{\alpha' + 3\beta'} = X'_{d(\alpha + \beta)};
Ad(w_{\alpha}) X_{\beta} = -X_{3\alpha + \beta}, Ad(w'_{\alpha'}) X'_{\beta'} = -X'_{\alpha' + \beta'} = -X'_{d(3\alpha + \beta)};
Ad(w_{\beta}) X_{3\alpha + \beta} = X_{3\alpha + 2\beta}, Ad(w'_{\beta'}) X'_{d(3\alpha + \beta)} = Ad(w'_{\beta'}) X'_{\alpha' + \beta'} = X'_{\alpha' + 2\beta'} = X'_{d(3\alpha + 2\beta)};
Ad(w_{\alpha}) X_{\alpha + \beta} = X_{2\alpha + \beta}, Ad(w'_{\alpha'}) X'_{d(\alpha + \beta)} = Ad(w'_{\alpha'}) X'_{\alpha' + 3\beta'} = X'_{2\alpha' + 3\beta'} = X'_{d(2\alpha + \beta)}.
```

```

<!-- original page 311 -->

By 3.4.1 (ii), one has on each side:

```

```text
Ad(w_{\alpha}) X_{2\alpha + \beta} = -X_{\alpha + \beta}, Ad(w'_{\alpha'}) X'_{d(2\alpha + \beta)} = Ad(w'_{\alpha'}) X'_{2\alpha' + 3\beta'} = -X'_{\alpha' + 3\beta'} = -X'_{d(\alpha + \beta)};
Ad(w_{\beta}) X_{3\alpha + 2\beta} = -X_{3\alpha + \beta}, Ad(w'_{\beta'}) X'_{d(3\alpha + 2\beta)} = Ad(w'_{\beta'}) X'_{\alpha' + 2\beta'} = -X'_{\alpha' + \beta'} = -X'_{d(3\alpha + \beta)}.
```

```

(The dots replace four verifications of the same kind.)

(iii) The only nontrivial commutation relations in U and U' are, by 3.4.1 (iii) (and taking into account $3 = 0$ on S):

```

```text
p_β(y) p_α(x) = p_α(x) p_β(y) p_{α+β}(x y) p_{2α+β}(x^2 y) p_{3α+β}(x^3 y) p_{3α+2β}(x^3 y^2),
p_{α+β}(y) p_α(x) = p_α(x) p_{α+β}(y) p_{2α+β}(-x y),
p_{3α+β}(y) p_β(x) = p_β(x) p_{3α+β}(y) p_{3α+2β}(-x y);

p'_{α'}(y') p'_{β'}(x') =
p'_{β'}(x') p'_{α'}(y') p'_{α'+β'}(-x' y') p'_{α'+2β'}(-x'^2 y') p'_{α'+3β'}(-x'^3 y') p'_{2α'+3β'}(-x'^3 y'^2),
p'_{α'+β'}(y') p'_{β'}(x') = p'_{β'}(x') p'_{α'+β'}(y') p'_{α'+2β'}(x' y'),
p'_{α'+3β'}(y') p'_{α'}(x') = p'_{α'}(x') p'_{α'+3β'}(y') p'_{2α'+3β'}(x' y').
```

```

<!-- original page 312 -->

We must verify that the morphism $\phi : U \rightarrow U'$ defined by

```

```text
φ(p_α(x) p_β(y) p_{α+β}(t) p_{2α+β}(u) p_{3α+β}(v) p_{3α+2β}(w))
= p'_{α'}(x^3q) p'_{β'}(y^q) p'_{α'+3β'}(t^3q) p'_{2α'+3β'}(u^3q) p'_{α'+β'}(v^q) p'_{α'+2β'}(w^q)
```

```

is a morphism of groups. Now one verifies immediately that the three last commutation relations are also written

```

```text
p'_{β'}(y^q) p'_{α'}(x^3q) =
p'_{α'}(x^3q) p'_{β'}(y^q) p'_{α'+3β'}((x y)^3q) p'_{2α'+3β'}((x^2 y)^3q) p'_{α'+β'}((x^3 y)^q) p'_{α'+2β'}((x^3 y^2)^q),
p'_{α'+3β'}(y^3q) p'_{α'}(x^3q) = p'_{α'}(x^3q) p'_{α'+3β'}(y^3q) p'_{2α'+3β'}(-(x y)^3q),
p'_{α'+β'}(y^q) p'_{β'}(x^q) = p'_{β'}(x^q) p'_{α'+β'}(y^q) p'_{α'+2β'}(-(x y)^q);
```

```

which shows that ϕ is indeed a morphism of groups and completes the proof of 4.1.7.

4.1.9. Case where G and G' are of semisimple rank > 2

<!-- label: III.XXIII.4.1.9 -->

For each root $\alpha \in \Delta$, denote $\alpha' = d(\alpha) \in \Delta' = d(\Delta)$. For each $(\alpha, \beta) \in \Delta \times \Delta$, consider the pinned groups of semisimple rank ≤ 2 , $Z_{\alpha\beta}$ and $Z'_{\alpha'\beta'}$. The morphism of groups $M \rightarrow M'$ underlying h defines a ϕ -morphism of root data

```

```text
h_{αβ} : R(Z_{αβ}) → R(Z'_{α' β'}).
```

```

By virtue of the preceding results, there exists therefore a morphism of pinned groups

```

```text
f_{αβ} : Z_{αβ} → Z'_{α' β'}
```

```

<!-- original page 313 -->

such that $R(f_{\alpha\beta}) = h_{\alpha\beta}$. Let us prove that the $f_{\alpha\beta}$ satisfy the gluing condition of 2.5; indeed $f_{\alpha\beta}|_{Z_{\alpha}}$ and $f_{\alpha\alpha}$ are two morphisms of pinned groups

```

$$
Z_{\alpha} \rightarrow Z'_{\alpha'}
$$

```

corresponding to the same morphism of pinned root data, and therefore coincide by the uniqueness result already proved. By 2.5 there exists therefore a morphism of groups

\$\$
 $f : G \rightarrow G'$
 \$\$

extending the $f_{\{\alpha, \beta\}}$. This is evidently a morphism of pinned groups such that $R(f) = h$, which completes the proof of Theorem 4.1.

5. Corollaries of the fundamental theorem

<!-- label: III.XXIII.5 -->

The most important is:

Corollary 5.1. *Let S be a nonempty scheme, G and G' two pinned S -groups, h an isomorphism of pinned root data*

\$\$
 $h : R(G') \xrightarrow{\sim} R(G)$.
 \$\$

There exists a unique isomorphism of pinned S -groups

\$\$
 $f : G \xrightarrow{\sim} G'$
 \$\$

such that $R(f) = h$.

<!-- label: III.XXIII.5.1 -->

Note that 5.1 also follows from 3.5.1 (the relations of 3.5.1 may be written using only the datum of $R(G)$); note also that 5.1 follows from the most elementary part of the proof of 4.1 (one does not need to consider the "exceptional isogenies" of 4.1.7 and 4.1.8).

<!-- original page 314 -->

Corollary 5.2 ("Uniqueness theorem"). *Let S be a scheme, G and G' two splittable S -groups (Exp. XXII, 1.13). If G and G' are of the same type (Exp. XXII, 2.6), they are isomorphic.*

<!-- label: III.XXIII.5.2 -->

Corollary 5.3. *Let S be a scheme, G and G' two splittable S -groups. The following conditions are equivalent:*

- (i) G and G' are isomorphic.*
- (ii) G and G' are isomorphic locally for the (fpqc) topology.*
- (iii) There exists an $s \in S$ such that the s -groups G_s and G'_s are of the same type.*

<!-- label: III.XXIII.5.3 -->

Indeed, one evidently has (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii). On the other hand, (iii) entails that $R(G) = R(G_s) = R(G'_s) = R(G')$, hence that G and G' satisfy the condition of 5.2.

Corollary 5.4 ("Uniqueness of the Chevalley schemes"). *Let G and G' be two reductive groups over $\mathbb{Z}$ possessing split maximal tori. [XXIII-5-1] The following conditions are equivalent:*

- (i) G and G' are isomorphic.*
- (ii) There exists $s \in \operatorname{Spec}(\mathbb{Z})$ such that G_s and G'_s are of the same type.*
- (iii) $G_{\mathbb{C}}$ and $G'_{\mathbb{C}}$ are of the same type.*

<!-- label: III.XXIII.5.4 -->

Indeed, G and G' are splittable by Exp. XXII, 2.2.

Corollary 5.5 ("Existence of outer automorphisms"). **Let S be a scheme, G a pinned S -group, h an automorphism of the pinned root datum $R(G)$. There exists a unique automorphism u of G respecting its pinning and such that $R(u) = h$.**

<!-- label: III.XXIII.5.5 -->

Let us make the preceding corollary explicit.

Corollary 5.5.bis. **Let S be a scheme, G a split reductive S -group, R^+ a system of positive roots of G .**

<!-- original page 315 -->

Choose for each simple root α an isomorphism of vector groups $p_\alpha : G_\alpha \rightarrow U_\alpha$. Let h be an automorphism of M permuting the positive roots and the corresponding coroots: if $\alpha \in R^+$, $h(\alpha) \in R^+$ and $h^\vee(\alpha^*) = h(\alpha)^*$. There exists a unique automorphism u of G inducing $D_S(h)$ on T and such that $u \circ p_\alpha = p_{h(\alpha)}$ for every simple root α .

<!-- label: III.XXIII.5.5.bis -->

Corollary 5.6. **Let G and G' be two reductive S -groups. The following conditions are equivalent:**

(i) G and G' are isomorphic locally for the (fpqc) topology.

(i bis) G and G' are isomorphic locally for the étale topology.

(ii) For every $s \in S$, G_s and G'_s are isomorphic.

(iii) The functions $s \mapsto$ type of G_s and $s \mapsto$ type of G'_s are equal.

<!-- label: III.XXIII.5.6 -->

<!-- original page 208 source -->

Indeed (i bis) $\Rightarrow$ (i) trivially, (i) $\Rightarrow$ (ii) by the principle of finite extension (EGA IV₃, 9.1.4), (ii) $\Rightarrow$ (iii) trivially; it remains to prove (iii) $\Rightarrow$ (i bis). Now one may suppose G and G' splittable (Exp. XXII, 2.3), in which case the assertion follows from 5.3.

Corollary 5.7. **Let S be a scheme, G a reductive S -group, G' an S -group that is affine, smooth, and with connected fibers. Let $s \in S$ be such that G_s and G'_s are isomorphic; there exists then an étale $S' \rightarrow S$ covering s such that $G_{S'}$ and $G'_{S'}$ are isomorphic.**

<!-- label: III.XXIII.5.7 -->

Indeed, by Exp. XIX 2.5 and Exp. XXII 2.1, one may suppose G and G' reductive splittable and one is reduced to 5.3.

In the case where S is the spectrum of a field, one deduces from 5.6 and 5.7:

<!-- original page 316 -->

Corollary 5.8. **Let k be a field and G and G' two reductive k -groups. The following conditions are equivalent:** [N.D.E-XXIII-12]

(i) G and G' are of the same type.

(ii) $G \otimes_k \bar{k}$ and $G' \otimes_k \bar{k}$ are isomorphic.

(iii) There exists a finite separable extension K of k such that $G \otimes_k K$ and $G' \otimes_k K$ are isomorphic.

<!-- label: III.XXIII.5.8 -->

****Corollary 5.9.**** *Let S be a nonempty scheme and R a root datum. The following conditions are equivalent:*

(i) There exists a pinned S -group of type R .

(ii) There exists an S -group of type R .

(iii) There exists locally for (fpqc) a reductive S -group of type R .

<!-- label: III.XXIII.5.9 -->

It is evidently a matter of proving (iii) $\Rightarrow$ (i). To simplify the proof, suppose that there exist a faithfully flat quasi-compact morphism $S' \rightarrow S$ and a reductive S' -group G' of type R . One may suppose G' splittable; fix a pinning E' of G' ; denote $R = R(G', E')$. The two pullbacks of (G', E') to $S'' = S' \times_S S'$ are pinned groups (G''_1, E''_1) , (G''_2, E''_2) ; one has canonical isomorphisms $p_i : R(G''_i, E''_i) \xrightarrow{\sim} R$, whence an isomorphism

$$p_2^{-1} \circ p_1 : R(G''_1, E''_1) \rightarrow R(G''_2, E''_2).$$

By the uniqueness theorem, there exists a unique isomorphism

$$f : (G''_1, E''_1) \rightarrow (G''_2, E''_2)$$

such that $R(f) = p_2$. One has therefore on G' a gluing datum; this is a descent datum.

<!-- original page 317 -->

Indeed, one must verify a compatibility condition between the pullbacks of f on S'' , but it suffices to make this verification on the transforms of these arrows by the functor R , since the latter is fully faithful. Now p_2 is indeed a descent datum, by construction, which shows that f is one too. Since G' is affine, this descent datum is effective; since the pinning of G' is stable under the descent datum, one verifies easily that there exists a pinned S -group (G, E) which gives (G', E') by base extension and which is therefore of type R .

N.B. Naturally, in the language of fibered categories, the preceding proof simplifies (and becomes intelligible).

****Corollary 5.10.**** *Let S be a nonempty scheme. Let R be a pinned root datum such that there exists a reductive S -group of type R . Then there exists a pinned S -group of type R , unique up to a unique isomorphism.*

<!-- label: III.XXIII.5.10 -->

****Definition 5.11.**** *Under the preceding conditions, we shall denote by $\acute{e}_p(S)(R)$ the unique pinned S -group of type R , by $T(S)(R)$ its canonical maximal torus, by $B(S)(R)$ its canonical Borel subgroup, etc.*

<!-- label: III.XXIII.5.11 -->

If one has a morphism $S' \rightarrow S$ (S nonempty), one may identify $\acute{e}_p(S')(R)$ with $\acute{e}_p(S)(R) \times_{\operatorname{Spec}(\mathbb{Z})} S'$, etc. In particular, if $\acute{e}_p(\operatorname{Spec}(\mathbb{Z}))(R)$ exists (we shall see that this is always the case), one denotes it $\acute{e}_p(R)$, and one has

$$\acute{e}_p(S)(R) = \acute{e}_p(R) \times_{\operatorname{Spec}(\mathbb{Z})} S.$$

One says that $\acute{e}_p(R)$ is the *Chevalley group scheme* of type R .

5.12.

<!-- label: III.XXIII.5.12 -->

It therefore comes to the same thing to say that the $\mathcal{G}$ -sheaf in groups $\mathcal{G}$ is a reductive $\mathcal{G}$ -group of type R , or to say that it is locally isomorphic (for the étale or (fpqc) topology) to $E_p(R)$. Likewise, by virtue of the conjugation theorems, it comes to the same thing to say that (G, T) is a reductive $\mathcal{G}$ -group of type R equipped with a maximal torus, or to say that it is locally isomorphic to $(E_p(R), T(R))$; likewise with Borel subgroups or Killing couples.

6. Chevalley systems

<!-- label: III.XXIII.6 -->

<!-- original page 318 -->

The explicit calculations of No. 3 have important numerical consequences. We first lay down the following definition.

Definition 6.1. Let $\mathcal{G}$ be a scheme, (G, T, M, R) a split $\mathcal{G}$ -group. One calls a Chevalley system of $\mathcal{G}$ a family $(X_\alpha)_{\alpha \in R}$ of elements

$\mathcal{G}$
 $X_\alpha \in \Gamma(S, g_\alpha)^{\otimes \infty}$
 $\mathcal{G}$

<!-- original page 210 source -->

satisfying the following condition:

(SC) for every pair $\alpha, \beta \in R$,

$\mathcal{G}$
 $\text{Ad}(w_\alpha(X_\alpha)) X_\beta = \pm X_{s_\alpha(\beta)}.$
 $\mathcal{G}$

<!-- label: III.XXIII.6.1 -->

Recall (Exp. XX, 3.1) that

text
 $w_\alpha(X_\alpha) = \exp(X_\alpha) \exp(-X_\alpha^{-1}) \exp(X_\alpha).$

Note that (SC) entails in particular $X_{-\alpha} = \pm X_\alpha$ for $\alpha \in R$, by virtue of the relation (Exp. XX, 3.7) $\text{Ad}(w_\alpha(X_\alpha)) X_{-\alpha} = -X_{-\alpha}$.

Proposition 6.2. Every split group admits a Chevalley system. More precisely, let $(\Delta, (X'_\alpha)_{\alpha \in \Delta})$ be a pinning (1.1) of the split group (G, T, M, R) ; there exists then a Chevalley system $(X_\alpha)_{\alpha \in R}$ of $\mathcal{G}$ such that $X_\alpha = X'_\alpha$ for $\alpha \in \Delta$.

<!-- label: III.XXIII.6.2 -->

Let us first show that it suffices to verify condition (SC) for $\alpha \in \Delta$; for every $\alpha \in R$, there exists a sequence $\{\alpha_i\} \subset \Delta$ such that $\alpha = s_{\alpha_1} \cdots s_{\alpha_n}(\alpha_{n+1})$, whence, applying condition (SC) for each of the α_i ,

text
 $X_\alpha = \pm \text{Ad}(w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n})) X_{\alpha_{n+1}}.$

<!-- original page 319 -->

By 3.1.1 (iii),

text
 $w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n}) w_{\alpha_{n+1}}(X_{\alpha_{n+1}}) w_{\alpha_n}(X_{\alpha_n})^{-1} \cdots w_{\alpha_1}(X_{\alpha_1})^{-1}$
 $= \alpha^{\pm 1} w_\alpha(X_\alpha).$
 ...

Now, it suffices to note that $w_{\alpha_i}(X_{\alpha_i})^{-1} = \alpha_i^{*}(-1) w_{\alpha_i}(X_{\alpha_i})$ and that for every pair of roots (β, γ) , $\beta(\gamma^{*}(-1)) = (-1)^{\langle \gamma^{*}, \beta \rangle} = \pm 1$, which entails that if (SC) is satisfied for the pairs (α_i, γ) ($\gamma \in R$), it is so for every pair (α, β) , ($\beta \in R$).

Let us now construct a system $(X_{\alpha})_{\alpha \in R}$ in the following manner. For every $\alpha \in R$, choose a sequence $\{\alpha_i\} \subset \Delta$ as above, and define X_{α} by

```
```text
X_{\alpha} = Ad(w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n})) X'_{\alpha_{n+1}}.
```

To verify (SC), it suffices to prove:

**Lemma 6.3.** \*Let  $(G, T, M, R, \Delta, (X_{\alpha})_{\alpha \in \Delta})$  be a pinned  $\mathbb{S}$ -group; let  $\{\alpha_i\}$  ( $0 \leq i \leq n+1$ ) be a sequence of simple roots such that\*

```
$$
int(s_{\alpha_1} \cdots s_{\alpha_n})(\alpha_{n+1}) = \alpha_0.
$$
```

\*Then\*

```
```text
Ad(w_{\alpha_1} \cdots w_{\alpha_n}) X_{\alpha_{n+1}} = \pm X_{\alpha_0}.
```

<!-- label: III.XXIII.6.3 -->

Reasoning as in 2.3.4 with the help of Tits's lemma (Exp. XXI 5.6), one is reduced to verifying lemma 6.3 in the two following cases:

a) $\mathbb{S}$ is of semisimple rank at most 2, or b) $w_{\alpha_1} \cdots w_{\alpha_n}$ is a section of T .

In case a), note that 6.3 is a consequence of 6.2 and that 6.2 has been verified in part (i) of 3.1.2 (resp. 3.2.1, resp. 3.3.1, resp. 3.4.1).

<!-- original page 320 -->

It therefore remains to prove 6.3 in case b), or, what amounts to the same thing, that if $\{\alpha_i\}$ is a sequence of simple roots such that $s_{\alpha_1} \cdots s_{\alpha_n} = \text{id}$, then $t = w_{\alpha_1} \cdots w_{\alpha_n}$ satisfies $\alpha(t) = \pm 1$ for every root $\alpha \in R$. By virtue of the structure of the Weyl group (Exp. XXI, 5.1), the word $s_{\alpha_1} \cdots s_{\alpha_n}$ in the free group generated by the s_{α} , $\alpha \in \Delta$, is in the invariant subgroup generated by the $(s_{\alpha} s_{\beta})^{n_{\alpha\beta}}$, $(\alpha, \beta) \in \Delta \times \Delta$. One is therefore reduced to the case where $s_{\alpha_1} \cdots s_{\alpha_n}$ is of the form

```
```text
s_{\alpha_1} \cdots s_{\alpha_i} (s_{\alpha_{i+1}} s_{\alpha_{i+2}})^{n_{\alpha_{i+1}\alpha_{i+2}}} s_{\alpha_i} \cdots s_{\alpha_1}.
```

Then

```
```text
t = s_{\alpha_1} \cdots s_{\alpha_i} (t_{\alpha_{i+1}\alpha_{i+2}}),
```

and one is reduced to verifying that for every pair of simple roots (α_1, α_2) and every root $\beta \in R$, $\beta(t_{\alpha_1\alpha_2}) = \pm 1$, which is trivial, in view of the values of $t_{\alpha_1\alpha_2}$ calculated in No. 3 (part (i) of 3.1.2, 3.2.1, 3.3.1, 3.4.1).

Proposition 6.4. *Let (G, T, M, R) be a split $\mathbb{S}$ -group, $(X_{\alpha})_{\alpha \in R}$ a Chevalley system of $\mathbb{S}$. Let α and β be two non-proportional roots; suppose*

```
```text
```

$\text{long}(\alpha) \leq \text{long}(\beta)$ , i.e.  $|(\beta^*, \alpha)| \leq |(\alpha^*, \beta)|$ .

\*Let  $q$  and  $p - 1$  be the integers  $\geq 0$  such that the set of roots of the form  $\beta + k\alpha$ ,  $k \in \mathbb{Z}$ , is

$\{\beta - (p - 1)\alpha, \dots, \beta, \dots, \beta + q\alpha\}$ .

(cf. Exp. XXI, 2.3.5; by loc. cit., one has therefore  $-(\alpha^*, \beta) = q - p + 1$ ). Then the commutation relation between  $U_{\alpha}$  and  $U_{\beta}$  is given by the following table (which exhausts the possible cases, since the length of the preceding root chain is  $p + q - 1 \leq 3$ ),\*

<!-- original page 321 -->

\*where, for each  $\gamma \in R$ , one writes  $p_{\gamma}(x) = \exp(x X_{\gamma})$ .\*

$$\begin{array}{ll} (p, q) & p_{\beta}(y) p_{\alpha}(x) p_{\beta}(-y) p_{\alpha}(-x) \\ (-, 0) & = e \\ (1, 1) & = p_{\alpha + \beta}(\pm x y) \\ (1, 2) & = p_{\alpha + \beta}(\pm x y) p_{2\alpha + \beta}(\pm x^2 y) \\ (1, 3) & = p_{\alpha + \beta}(\pm x y) p_{2\alpha + \beta}(\pm x^2 y) p_{3\alpha + \beta}(\pm x^3 y) p_{3\alpha + 2\beta}(\pm x^3 y^2) \\ (2, 1) & = p_{\alpha + \beta}(\pm 2 x y) \\ (2, 2) & = p_{\alpha + \beta}(\pm 2 x y) p_{2\alpha + \beta}(\pm 3 x^2 y) p_{\alpha + 2\beta}(\pm 3 x y^2) \\ (3, 1) & = p_{\alpha + \beta}(\pm 3 x y). \end{array}$$

<!-- label: III.XXIII.6.4 -->

\*Proof.\* By virtue of Exp. XXI, 3.5.4, there exists a system of simple roots  $\Delta$  of  $R$  satisfying:  $\alpha \in \Delta$ , and there exist  $\alpha' \in \Delta$  and  $a, b \in \mathbb{Q}_{+}$  such that  $\beta = a\alpha + b\alpha'$ . Consider the pinning  $(\Delta, (X_{\alpha})_{\alpha \in \Delta})$  of  $G$ . The commutation relation to be verified is a relation between elements of  $U_{\alpha\alpha'}$ ; one is therefore reduced to the explicit calculations of No. 3, and one concludes at once by condition (SC).

**Corollary 6.5 (Chevalley's rule).** \*Let  $S$  be a scheme,  $(X_{\alpha})_{\alpha \in R}$  a Chevalley system of the split  $S$ -group  $G$ . If  $(\alpha, \beta, \alpha + \beta \in R)$ , then\*

$$[X_{\alpha}, X_{\beta}] = \pm p X_{\alpha + \beta},$$

\*where  $p$  is the smallest integer  $> 0$  such that  $\beta - p\alpha$  is not a root.\*

<!-- label: III.XXIII.6.5 -->

<!-- original page 322 -->

Indeed, since the assertion is symmetric in  $\alpha$  and  $\beta$ , one may suppose  $\text{long}(\alpha) \leq \text{long}(\beta)$ , and one is reduced to 6.4.

**Corollary 6.6.** \*Let  $S$  be a scheme such that  $6 \cdot 1_S \neq 0$  and  $(G, T, M, R)$  a split  $S$ -group. If  $R'$  is a subset of  $R$  such that\*

$$g_{R'} = t \oplus \bigoplus_{\alpha \in R'} g_{\alpha} \quad (*)$$

\*is a Lie subalgebra of  $g$ , then  $R'$  is a closed subset of  $R$  (Exp. XXI, 3.1.4).\*

<!-- label: III.XXIII.6.6 -->

[^N.D.E-XXIII-15] Indeed, let  $(X_{\gamma})_{\gamma \in R^{+}}$  be a Chevalley system of  $g$ , and let

$\alpha, \beta \in R$  be such that  $\alpha + \beta \in R$ . By 6.5 and 6.4,

```
```text
[X_α, X_β] = ± p X_{α + β},    with p ∈ {1, 2, 3}
```

and since neither 2 nor 3 are zero on S , this entails, by $(*)$, that $\mathfrak{g}_{R'}$ contains $\mathfrak{g}_{\alpha + \beta}$, hence $\alpha + \beta \in R$. [N.D.E-XXIII-16]

6.7.

<!-- label: III.XXIII.6.7 -->

It is possible to make explicit the exact value of the various $\pm$ of this section, thanks to the study of the group $\text{Norm}_{\{G\}}(T)$, and more precisely of the "extended Weyl group":

```
```text
W^* = N(Z), where N = Norm_{Ép_Z(R)}(T_Z(R))
```

(cf. 5.11), which is an extension of  $W(R)$  by an abelian group of type  $(2, 2, \dots, 2)$ , which is "responsible for the signs". [XXIII-6-1] [N.D.E-XXIII-17]

**Remark 6.7.1.** [N.D.E-XXIII-18] \*Note that, by point (i) of 3.1.2 and 3.n.1 ( $n = 2, 3, 4$ ), the elements  $w_{\alpha}$  and  $w_{\beta}$  of  $N(\mathbb{Z})$  satisfy the "braid relations":\*

```
```text
w_α w_β ... = w_β w_α ...    (n_{αβ} factors in each term).
```

[^N.D.E-XXIII-0]: N.D.E.: Version of 13/10/2024.

[^N.D.E-XXIII-1]: N.D.E.: It is implied by condition (v), i.e. the existence of a section
 $X_{\{\alpha\}} \in \Gamma(S, g_{\{\alpha\}}^{\otimes \infty})$.

[^N.D.E-XXIII-2]: N.D.E.: We have denoted by d the bijection $R \xrightarrow{\sim} R'$ (instead of su), in order to
 avoid the notation $u_{\{\alpha\}}$.

[^N.D.E-XXIII-3]: N.D.E.: i.e., the Borel subgroup of $Z_{\{\Delta_1\}}$ corresponding to $R'_+ = R' \cap R_+$.

[^N.D.E-XXIII-4]: N.D.E.: We have replaced "fundamental symmetries" by "simple reflections".

[^N.D.E-XXIII-5]: N.D.E.: We have corrected $i, j > 0$ to $i > 0$, $j \geqslant 0$ (since $x_{\{\alpha\}}$ appears in the
 product on the right).

[^N.D.E-XXIII-6]: N.D.E.: relative to Δ .

[^XXIII-3-1]: In the source: "since $(\alpha^*, \beta) = 2$ ". The correct expression $(\alpha^*, \beta) = -2$ was
 used in the previous section; here Demazure exploits the resulting formula
 $s_{\beta}(t_{\alpha}) = t_{\alpha} t_{\beta}^{-2} t_{\alpha} = t_{\alpha}$ (using $t_{\beta}^{-2} = e$, which holds in B_2).

<!-- TRANSLATOR NOTE: the source displays " $(\alpha^*, \beta) = 2$ "; this is a sign-convention discrepancy that does not
 affect the conclusion $s_{\beta}(t_{\alpha}) = t_{\alpha}$ since $t_{\beta}^{(\alpha^*, \beta)}$ is computed via the involution $t_{\beta}^2 = e$. -->

[^N.D.E-XXIII-7]: N.D.E.: We introduce here absolute constants $A, B, \dots, J$. These constants will be determined in
 the pages that follow; their values are $A = B = C = D = 1$, $E = 2$, $J = -1$, $F = G = H = 3$, cf. 3.4.8.

[^N.D.E-XXIII-8]: N.D.E.: The relations (3_1) and (3_2) form the description of the normalizer of the torus, (3_1) being,
 like (4) , in a group of rank 1, while (3_2) is in a group of rank 2.

[^N.D.E-XXIII-9]: N.D.E.: For an arbitrary field k and G simply connected, R. Steinberg gave a presentation of the
 group $G(k)$ in [St62], Th. 3.2, see also [St67], § 6, Th. 8.

[^N.D.E-XXIII-10]: N.D.E.: To avoid a notational problem later on, we have replaced q by p , so that in what follows,
 q (resp. q_1) is an arbitrary power of p .

[^N.D.E-XXIII-11]: N.D.E.: We have spelled out what follows.

[^XXIII-5-1]: In fact, one may prove that every $\mathbb{Z}$ -torus is split.[^N.D.E-XXIII-14]

[^N.D.E-XXIII-12]: N.D.E.: Another proof of this corollary, not using the reduction to the case of groups of rank 2, was
 given by M. Takeuchi ([Ta83], Th. 4.6); see also [Ja87], II 1.14.

[^N.D.E-XXIII-13]: N.D.E.: This corollary is rendered superfluous by Exp. XXV, which shows the existence of a split

group of type R over $\operatorname{Spec}(\mathbb{Z})$, hence over any base S . (In fact, after XXV 1.3 one finds a reference to the present corollary to ensure that the reductive $\mathbb{Z}$ -group obtained is split, but this already follows from XXII 2.2; cf. N.D.E. (3) of XXV.)

[^N.D.E-XXIII-15]: N.D.E.: We have added the following proof. Note that it suffices that 2 and 3 be nonzero on S ; for example the result is valid for $S = \operatorname{Spec}(\mathbb{Z}/6\mathbb{Z})$.

[^N.D.E-XXIII-16]: N.D.E.: On the other hand, let us point out that if $2 = 0$ on S and R is of type C_n , then the set R of short roots (which is a root system of type D_n) is not closed in R , but is a part of type (R) of R , symmetric (cf. XXII 5.4.2 and 5.4.10), i.e. it corresponds to a subgroup $H_{\{R\}}$ of type (R) of G with reductive fibers: this is in particular the case for the natural embedding (in characteristic 2) of $SO(2n)$ into $Sp(2n)$. Likewise, if $2 = 0$ on S and R is of type F_4 (resp. if $3 = 0$ on S and R is of type G_2), the set R of short roots (which is a root system of type D_4 (resp. A_2)) is not closed in R , but corresponds to a subgroup $H_{\{R\}}$ of type (R) of G , with reductive fibers.

[^XXIII-6-1]: Cf. J. Tits, *Sur les constantes de structure et le théorème d'existence des algèbres de Lie semi-simples*, Publ. Math. I.H.É.S. **31** (1966), 21–58.

[^N.D.E-XXIII-17]: N.D.E.: see also [Ti66].

[^N.D.E-XXIII-18]: N.D.E.: We have added this remark.

[^N.D.E-XXIII-19]: N.D.E.: additional references cited in this Exposé.

[^N.D.E-XXIII-14]: N.D.E.: this follows from the fact that every $\mathbb{Z}$ -torus is isotrivial (Exp. X, 5.16) and from the fact that every étale covering of $\operatorname{Spec}(\mathbb{Z})$ is trivial.

Exposé XXIV. Automorphisms of reductive groups

<!-- label: III.XXIV -->

by M. Demazure

<!-- original page 215 -->

[^N.D.E-XXIV-0]

The first part of this Exposé (nos 1 to 5) is a direct consequence of the existence, for a reductive group, of "sufficiently many outer automorphisms", a result which is itself a consequence of the weakest form of the isomorphism theorem for pinned groups. The second part (nos 6 and 7) presents two applications of the more precise results of the preceding Exposé; in particular, no 7 uses the theorem of generators and relations in its explicit form. Finally, we have given in an appendix (no 8) some results on "Galois" cohomology used in the text.

Let us specify our cohomological notation: if S is a scheme and G an S -group scheme, we write $H^1(S, G)$ for the first cohomology set of S with coefficients in G , computed for the (fpqc) topology; this is also the set of isomorphism classes of (fpqc) principal homogeneous sheaves under G . We write $H^1_{\acute{e}t}(S, G)$ for the corresponding set for the étale topology; this is therefore the part of $H^1(S, G)$ formed by classes of homogeneous sheaves under G which are quasi-isotrivial (= locally trivial for the étale topology). We write $\operatorname{Fib}(S, G)$ for the part of $H^1(S, G)$ formed by classes of representable sheaves (principal homogeneous bundles). We thus have the inclusions

<!-- original page 216 -->

```
```text
H^1_{\acute{e}t}(S, G) \subset H^1(S, G),
\operatorname{Fib}(S, G) \subset H^1(S, G).
```
```

If every principal homogeneous sheaf under G is representable (for example if G is quasi-affine over S , cf. SGA 1, VIII 7.9), then $\operatorname{Fib}(S, G) = H^1(S, G)$.

If $S' \rightarrow S$ is a covering morphism for the (fpqc) topology, we write $H^1(S'/S, G)$ for the kernel of the canonical

$\mathrm{map} \, H^1(S, G) \rightarrow H^1(S', G_{S'})$. It is known that $H^1(S'/S, G)$ can be computed simplicially (TDTE I, § A.4), which implies that when $S' \rightarrow S$ is covering for the étale topology, $H^1(S'/S, G)$ is also the kernel of $H^1_{\acute{e}t}(S, G) \rightarrow H^1_{\acute{e}t}(S', G_{S'})$.

Finally, following Exp. VIII, 4.5, we call "theorem 90" the following assertion: "every principal homogeneous sheaf under G_m, S is representable and locally trivial", an assertion equivalent to " $H^1(S, G_m, S) = \mathrm{operatorname{Pic}}(S)$ ", or again to " $H^1(S, G_m, S) = 0$ for S local (or more generally semi-local)".

1. The automorphism scheme of a reductive group

<!-- label: III.XXIV.1 -->

1.0.

<!-- label: III.XXIV.1.0 -->

It is convenient first to make certain definitions of the preceding Exposé more precise. Let S be a nonempty scheme, G an S -reductive group, $R = (M, M^*, R, R^*, \Delta)$ a pinned reduced root datum (Exp. XXIII 1.5). We call *pinning of G of type R^* , or R^* -pinning of G^* , the datum:

(i) of an isomorphism of $D_{\{S\}}(M)$ onto a maximal torus T of G (or, what amounts to the same, of a monomorphism $D_{\{S\}}(M) \rightarrow G$ whose image is a maximal torus T of G), identifying R with a root system of G relative to T (Exp. XIX, 3.6) and R^* with the corresponding set of coroots,

<!-- original page 217 -->

(ii) for each $\alpha \in \Delta$, of an $X_{\alpha} \in \Gamma(S, g_{\alpha})^{\times}$.

For G to possess an R -pinning, it is necessary and sufficient that it be splittable and of type R (Exp. XXII, 2.7).

If $u : G \rightarrow G'$ is an isomorphism of S -reductive groups, to every R -pinning E of G there corresponds by "transport of structure" an R -pinning $u(E)$ of G' . If $v : R' \rightarrow R$ is an isomorphism of pinned root data, to every R' -pinning E' of G' there corresponds by transport of structure an R -pinning $v(E')$ of G .

Let us call a *pinned group* a triple (G, R, E) where G is an S -reductive group, R is a pinned reduced root datum, and E is a pinning of G of type R . We call an *isomorphism of the pinned group (G, R, E) onto the pinned group (G', R', E') * a pair (u, v) where u is an isomorphism $u : G \rightarrow G'$ and v is an isomorphism of pinned root data $v : R' \rightarrow R$, such that $u(E) = v(E')$. [N.D.E-XXIV-1]

N. B. If S is nonempty, v is uniquely determined by u , and we shall also say by abuse of language that u is an isomorphism of pinned groups. In particular, if (G, R, E) is a pinned group, an automorphism of (G, R, E) is therefore an automorphism u of G such that there exists an automorphism v of R with $u(E) = v(E)$; it is therefore an automorphism of G normalizing T , inducing on T an automorphism of the form $D_{\{S\}}(h)$ where h is an automorphism of M , and permuting among themselves the elements X_{α} , $\alpha \in \Delta$. (As is easily seen, the preceding conditions moreover characterize the automorphisms of (G, R, E) .)

<!-- original page 218 -->

One has an obvious contravariant functor

```
```text
Φ : (G, R, E) ↦ R, (u, v) ↦ v
```
```

and the principal result of the preceding Exposé (Exp. XXIII, 4.1) shows us that this is a fully faithful functor (we shall moreover see in the next Exposé that it is an equivalence of categories). It follows in particular that the group of automorphisms of (G, R, E) is canonically isomorphic to the group of automorphisms of the pinned root datum R (cf. Exp. XXIII, 5.5).

1.1.

<!-- label: III.XXIV.1.1 -->

Let S be a scheme; endow $(\text{Sch})/S$ with the (fpqc) topology and consider the S -group sheaf $\text{Aut}_{\{S\text{-gr.}\}}(G)$, where G is an S -group scheme. One has an exact sequence of S -group sheaves

```
```text
1 → Centr(G) → G →int→ Aut_{S-gr.}(G)
```
```

which defines a monomorphism

```
```text
j : G / Centr(G) → Aut_{S-gr.}(G).
```
```

The image sheaf of j is the sheaf of *inner automorphisms* of G ; for an automorphism u of G to be inner, it is necessary and sufficient that there exist a covering family $\{S_i \rightarrow S\}$ and for each i a $g_i \in G(S_i)$ such that $\text{int}(g_i) = u|_{S_i}$. In this case, if v is another automorphism of G , one sees at once that $\text{int}(v)u = v \circ u \circ v^{-1}$ is the inner automorphism defined by the family $g'_i = v(g_i)$. It follows that the image of j is normal in $\text{Aut}_{\{S\text{-gr.}\}}(G)$. The quotient group sheaf, denoted $\text{Autext}(G)$, is the sheaf of *outer automorphisms* of G . One thus has an exact sequence

```
```text
1 → G / Centr(G) → Aut_{S-gr.}(G) → Autext(G) → 1.
```
```

The preceding definitions are all compatible with base change. They are naturally valid in any site.

1.2.

<!-- label: III.XXIV.1.2 -->

Let S be a scheme and (G, R, E) a pinned S -reductive group. Let E be the (abstract) group of automorphisms of the pinned root datum R , i.e. the group of automorphisms of R normalizing Δ . By Exp. XXIII, 5.5, one has a canonical monomorphism

```
$$
E \rightarrow \text{Aut}_{\{S\text{-gr.}\}}(G)
$$
```

which associates to $h \in E$ the unique automorphism u of the pinned group G such that $\Phi(u) = h$. This monomorphism canonically defines a monomorphism of sheaves

```
$$
(*) \quad a : E_{\{S\}} \rightarrow \text{Aut}_{\{S\text{-gr.}\}}(G).
$$
```

For an automorphism u of G to be a section of the image sheaf of a , it is necessary and sufficient that the following conditions be satisfied:

(i) u normalizes T . One then knows that u permutes the roots of G relative to T . If $\alpha \in R$, then $u(\alpha) : t \mapsto \alpha(u^{-1}(t))$ is locally on S of the form $t \mapsto \beta(t)$, with $\beta \in R$. The second condition is then written as follows:

<!-- original page 219 -->

(ii) If $\alpha \in \Delta$ and if U is an open set of S such that $u(\alpha)_U \in R$, then $u(\alpha)_U \in \Delta$ and

```
$$
\text{Lie}(u_U)(X_{\{\alpha\}})_U = (X_{u(\alpha)})_U.
$$
```

It follows at once from the definitions that the sections of $a(E_{\{S\}})$ normalize the subgroups of G defined by the pinning: T , B , B^{-} , U , U^{-} .

These definitions being set, one has:

Theorem 1.3. Let S be a scheme, G an S -reductive group. Consider the canonical exact sequence of S -group sheaves^{N.D.E-XXIV-2}

$$1 \rightarrow \mathrm{ad}(G) \rightarrow \mathrm{Aut}_{\{S\text{-gr.}\}}(G) \rightarrow \mathrm{Aut}(G) \rightarrow 1.$$

(i) $\mathrm{Aut}_{\{S\text{-gr.}\}}(G)$ is representable by a smooth and separated S -scheme.

(ii) $\mathrm{Aut}(G)$ is representable by a finitely generated twisted constant S -scheme (Exp. X, 5.1).

(iii) If G is splittable, the preceding exact sequence splits. More precisely, for every pinning of G , the morphism (cf. 1.2 (*))

$$p \circ a : E_S \rightarrow \mathrm{Aut}(G)$$

is an isomorphism.

label: III.XXIV.1.3

Let us first show how the theorem follows from the following lemma:

Lemma 1.4. Under the hypotheses of (iii), $\mathrm{Aut}_{\{S\text{-gr.}\}}(G)$ is the semi-direct product $\mathrm{ad}(G) \ltimes \mathrm{Aut}(G)$ ^{N.D.E-XXIV-3}

label: III.XXIV.1.4

The lemma immediately implies the theorem when G is splittable. Since G is locally splittable for the étale topology (Exp. XXII, 2.3), hence also for the (fppf) topology, and since the latter is "of effective descent" for the fibered category of twisted constant morphisms (Exp. X, 5.5), one deduces (ii) in the general case (cf. Exp. IV, 4.6.8). To deduce (i), one notes that $\mathrm{ad}(G)$ is affine over S , hence the morphism p is affine when $\mathrm{Aut}_{\{S\text{-gr.}\}}(G)$ is representable, and one concludes by descent of affine schemes.^{N.D.E-XXIV-4}

original page 220

It therefore remains only to prove 1.4. For this, it suffices to prove:

Lemma 1.5. If (R, E) and (R', E') are two pinnings of the S -reductive group G , there exists a unique inner automorphism u of G over S transforming one pinning into the other (i.e. such that there exists $v : R' \rightarrow R$ with $u(E) = v(E')$, cf. 1.0).

label: III.XXIV.1.5

1.5.1. Uniqueness.

It suffices to prove that if G is a pinned S -group and if $\mathrm{int}(g)$ is an automorphism of pinned group $(g \in G(S))$, then $\mathrm{int}(g) = \mathrm{id}$. Now one has first $\mathrm{int}(g) T = Tg$, $\mathrm{int}(g) B = Bg$, so $g \in \mathrm{Norm}_G(T)(S) \cap \mathrm{Norm}_G(B)(S) = T(S)$ (cf. for example Exp. XXII, 5.6.1). It follows that $\mathrm{int}(g)$ normalizes each U_α and that

$$\mathrm{Lie}(\mathrm{int}(g)) X_\alpha = \mathrm{Ad}(g) X_\alpha = \alpha(g) X_\alpha$$

for every $\alpha \in \Delta$. One thus has $\alpha(g) = 1$ for $\alpha \in \Delta$, so $g \in \bigcap_{\alpha \in \Delta} (\mathrm{Ker} \alpha)(S) = \mathrm{Centr}(G)(S)$ (Exp. XXII, 4.1.8). QED

1.5.2. Existence.

It suffices to prove this locally for the (fpqc) topology. Let

$(T, M, R, \Delta, (X_\alpha)_{\alpha \in \Delta})$ and $(T', M', R', \Delta', (X'_{\alpha'})_{\alpha' \in \Delta'})$

be the two pinnings. By conjugacy of maximal tori, one may assume $T = T'$. Up to restricting S , one may assume that the isomorphism $D_S(M) \xrightarrow{\sim} D_S(M')$ comes from an isomorphism $M \xrightarrow{\sim} M'$ carrying R onto R' , and one is reduced to the situation $T = T'$, $M = M'$, $R = R'$. Since the systems of simple roots are conjugate by the Weyl group (Exp. XXI, 3.3.7), one may also assume $\Delta = \Delta'$. There then exists for each $\alpha \in \Delta$ a scalar $z_\alpha \in G_m(S)$ such that $X'_\alpha = z_\alpha X_\alpha$, and it suffices to construct locally for (fpqc) a section t of T such that $\alpha(t) = z_\alpha$ for each $\alpha \in \Delta$. But the morphism $T \rightarrow (G_m, S)^{\Delta}$ with components $\alpha, \alpha \in \Delta$ is the dual of an injection $\mathbb{Z}^{\Delta} \rightarrow M$, hence faithfully flat, which completes the proof of 1.5.2 and so of 1.3.

<!-- original page 221 -->

Corollary 1.6. Let S be a scheme, G an S -reductive group. The following conditions are equivalent:

(i) $\operatorname{Aut}_S(G)$ is affine (resp. of finite type, resp. of finite presentation, resp. quasi-compact) over S .

(ii) $\operatorname{Aut}(G)$ is finite over S .

(iii) For every $s \in S$, one has $\operatorname{rg}(G_s) - \operatorname{rg}(G_s) \leq 1$.

<!-- label: III.XXIV.1.6 -->

Indeed, since $\operatorname{ad}(G)$ is affine, flat and of finite presentation over S , the morphism $\operatorname{Aut}_S(G) \rightarrow \operatorname{Aut}(G)$ is affine, faithfully flat and of finite presentation.

If $\operatorname{Aut}(G)$ is finite over S , it is affine over S , hence so is $\operatorname{Aut}_S(G)$, which proves (ii) $\Rightarrow$ (i). If $\operatorname{Aut}_S(G)$ is quasi-compact over S , it is of finite presentation over S (being in any case locally of finite presentation and separated over S); by Exp. V, 9.1, $\operatorname{Aut}(G)$ is then of finite presentation over S , hence finite, which proves (i) $\Rightarrow$ (ii). Finally, to prove the equivalence of (ii) and (iii), one may assume G split, and one is reduced to Exp. XXI, 6.7.8.

Corollary 1.7. Let S be a scheme and G an S -reductive group. Then $\operatorname{Aut}_S(G)^0 \xrightarrow{\sim} \operatorname{ad}(G)$.

<!-- label: III.XXIV.1.7 -->

Corollary 1.8. Let S be a scheme, G an S -reductive group, H an S -group scheme smooth, affine and with connected fibers over S . Then the S -functor

$$\operatorname{Isom}_S(G, H)$$

is representable by a smooth and separated S -scheme (which is affine over S if G is semisimple).

<!-- label: III.XXIV.1.8 -->

Indeed, let U be the set of points s of S such that H_s is reductive; this is open (Exp. XIX, 2.6); if S is an S -scheme, $H_{S'}$ is reductive if and only if $S' \rightarrow S$ factors through U . It follows that the canonical morphism $\operatorname{Isom}_S(G, H) \rightarrow S$ factors through U . One may therefore assume $S = U$ and one is reduced to:

<!-- original page 222 -->

Corollary 1.9. Let S be a scheme, G and G' two S -reductive groups. Then

$$F = \operatorname{Isom}_S(G, G')$$

is representable by a smooth and separated S -scheme (affine if G or G' is semisimple). Moreover, S decomposes as a sum of two open subschemes S_1 and S_2 such that $F_{S_1} = \emptyset$ and such that F_{S_2} is a principal homogeneous bundle on the left (resp. right) under $\operatorname{Aut}_S(G_2\text{-gr.})(G'_{S_2})$ (resp.

$\operatorname{Aut}_{S_2\text{-gr.}}(G_{S_2})$.

<!-- label: III.XXIV.1.9 -->

Indeed, let S_2 be the set of points of S where G and G' are of the same type, and let S_1 be its complement.

Since the type of a reductive group is a locally constant function, S_1 and S_2 are open. It is clear that $F_{S_1} = \emptyset$, and one may assume $S = S_2$. By Exp. XXIII, 5.6, F is a principal homogeneous sheaf under $\operatorname{Aut}_{S\text{-gr.}}(G)$, locally trivial for the étale topology. It follows that $F_0 = F / \operatorname{ad}(G)$ is a principal homogeneous sheaf under $\operatorname{Aut}(G)$, locally trivial for the étale topology, hence representable (Exp. X, 5.5). Since $\operatorname{ad}(G)$ is affine, F is therefore also representable.

Let us remark that in the course of the proof, we have obtained:

Corollary 1.10. Let S be a scheme, G and G' two S -reductive groups of the same type at each $s \in S$. Then $\operatorname{ad}(G)$ operates freely (on the right) in $\operatorname{Isom}_{S\text{-gr.}}(G, G')$, the quotient sheaf

$$\operatorname{Isomext}(G, G') = \operatorname{Isom}_{S\text{-gr.}}(G, G') / \operatorname{ad}(G)$$

is representable by a twisted constant S -scheme, which is a principal homogeneous bundle under $\operatorname{Aut}(G)$ (and which is therefore finite over S if G is semisimple). Moreover, the isomorphism

$$\operatorname{Isom}_{S\text{-gr.}}(G, G') \simeq \operatorname{Isom}_{S\text{-gr.}}(G', G)$$

defined by $u \mapsto u^{-1}$ induces an isomorphism

$$\operatorname{Isomext}(G, G') \simeq \operatorname{Isomext}(G', G).$$

<!-- label: III.XXIV.1.10 -->

<!-- original page 223 -->

Remark 1.11. If $\operatorname{Isomext}(G, G')(S) \neq \emptyset$, one says that G is an *inner twisted form* of G' ; then G' is an inner twisted form of G ; one can then reduce the structure group of $\operatorname{Isom}_{S\text{-gr.}}(G, G')$ to $\operatorname{ad}(G)$. More precisely, let $u \in \operatorname{Isomext}(G, G')(S)$, considered as a section $u : S \rightarrow \operatorname{Isomext}(G, G')$. Write

$$\operatorname{Isomint}_u(G, G')$$

for the inverse image under the canonical morphism $\operatorname{Isom}_{S\text{-gr.}}(G, G') \rightarrow \operatorname{Isomext}(G, G')$ of the closed subscheme of $\operatorname{Isomext}(G, G')$ image of u . The natural operation of $\operatorname{ad}(G)$ on $\operatorname{Isomint}_u(G, G')$ endows this scheme with a structure of principal homogeneous bundle; by extension of the structure group [N.D.E-XXIV-5] $\operatorname{ad}(G) \rightarrow \operatorname{Aut}(G)$, $\operatorname{Isomint}_u(G, G')$ recovers $\operatorname{Isom}_{S\text{-gr.}}(G, G')$.

<!-- label: III.XXIV.1.11 -->

By Hensel's lemma (Exp. XI, 1.11), 1.8 gives at once:

Corollary 1.12. Let S be a henselian local scheme, G an S -reductive group, G' a smooth affine S -group with connected fibers, s the closed point of S . If G_s and G'_s are isomorphic $\kappa(s)$ -algebraic groups, then G and G' are isomorphic. More precisely, every $\kappa(s)$ -isomorphism $G_s \simeq G'_s$ comes from an S -isomorphism $G \simeq G'$.

<!-- label: III.XXIV.1.12 -->

Applying now 1.7 (resp. 1.12) to the scheme of dual numbers over a field, one deduces from Exp. III, 2.10 (resp. 3.10) point (i) (resp. (ii)) of the following corollary.

****Corollary 1.13.**** *Let k be a field and G a k -reductive group.*

***(i)** If G is adjoint, one has $H^1(G, \text{Lie}(G/k)) = 0$. [N.D.E-XXIV-6]*

***(ii)** One has $H^2(G, \text{Lie}(G/k)) = 0$.*

<!-- label: III.XXIV.1.13 -->

****Remark 1.14.**** (i) The assertion concerning H^1 was known (Chevalley); the one concerning H^2 had been proved in most cases of the classification by Chevalley.

<!-- original page 224 -->

(ii) In fact, the conjunction of 1.13 and the uniqueness theorem over an algebraically closed field is essentially equivalent to the uniqueness theorem. A direct proof of 1.13 would therefore give a way to deduce the general uniqueness theorem from Chevalley's uniqueness theorem over a field.

The existence of reductive groups of all types over all schemes (Exp. XXV) shows that the obstructions to lifting a k -reductive group G over Artinian rings with residue field k (which by Exp. III, 3.8 are elements of

```text  
 $H^3(G, \text{Lie}(G/k) \otimes V) \simeq H^3(G, \text{Lie}(G/k)) \otimes V,$   
```

where V is a certain k -vector space (equipped with the trivial action of G) are zero. This seems to suggest that $H^3(G, \text{Lie}(G/k)) = 0$. Here too, a direct proof of this fact (if it is true) would doubtless give a way to deduce the general existence theorem from the existence theorem over a field (Chevalley's Tôhoku).

<!-- label: III.XXIV.1.14 -->

****Corollary 1.15.**** *Let k be a field, [N.D.E-XXIV-7] G a k -reductive group. Consider k as a trivial G -module. Then*

```text  
 $H^1(G, k) = H^2(G, k) = 0.$   
```

<!-- label: III.XXIV.1.15 -->

[N.D.E-XXIV-8] Since $H^i(G_{\bar{k}}, \bar{k}) = H^i(G, k) \otimes \bar{k}$, one may assume k algebraically closed. An element of $H^1(G, k)$ is nothing but a morphism of k -groups $\phi : G \rightarrow G_{\{a, k\}}$. Then $\phi(G) = G / \text{Ker}(\phi)$ is a smooth, connected and reductive subgroup (cf. XIX 1.7) of $G_{\{a, k\}}$, hence trivial. So $H^1(G, k) = 0$.

<!-- original page 225 -->

Consider now the k -reductive group $H = G \times_k G_{\{m, k\}}$. One has $\text{Lie}(H/k) = \text{Lie}(G/k) \oplus k$, a decomposition stable under H . For any H -module V , one has

```text  
 $H^i(H, V) = H^i(G, H^0(G_{\{m, k\}}, V))$   
```

(this follows from the characterization of $H^i(H, -)$ as derived functors of $H^0(H, -) = H^0(G, H^0(G_{\{m, k\}}, -))$, and from the fact that the functor $H^0(G_{\{m, k\}}, -)$ is exact, cf. Exp. I, 5.3.1 and 5.3.3). In particular, one has for every i

```text  
 $H^i(H, \text{Lie}(H/k)) = H^i(G, \text{Lie}(G/k)) \oplus H^i(G, k)$   
```

whence $H^2(G, k) = 0$ by applying 1.13 (ii) to the reductive group H .

****Corollary 1.15.1.**** [N.D.E-XXIV-9] *Let k be a field, G a k -reductive group, Z its center and $R = (M, M^*, R, R^*)$ the type of G . Then one has*

```

```text

$$H^1(G, \operatorname{Lie}(G/k)) = \operatorname{Ext}^1_{\mathbb{Z}}(M / \Gamma_0(R), k).$$

```

```

In particular, $H^1(G, \operatorname{Lie}(G/k)) = 0$ if and only if Z is smooth over k .

<!-- label: III.XXIV.1.15.1 -->

Indeed, let g (resp. z , resp. g_{ad}) be the Lie algebra of G (resp. Z , resp. $G_{\operatorname{ad}} = G/Z$). It follows from 1.15 (and from its proof) that

```

```text

$$H^1(G, g) = H^1(G_{\operatorname{ad}}, g) = H^1(G_{\operatorname{ad}}, g/z).$$

```

```

Set $C = \operatorname{Coker}(g \rightarrow g_{\operatorname{ad}})$; one has an exact sequence

```

$$0 \rightarrow g/z \rightarrow g_{\operatorname{ad}} \rightarrow C \rightarrow 0.$$

```

Since $H^1(G_{\operatorname{ad}}, g_{\operatorname{ad}}) = 0$ (1.13) and $H^0(G_{\operatorname{ad}}, g_{\operatorname{ad}}) = 0$ (cf. Exp. II, 5.2.3), one obtains

```

```text

$$H^1(G_{\operatorname{ad}}, g/z) = H^0(G_{\operatorname{ad}}, C).$$

```

```

To compute the right-hand term, one may assume k algebraically closed. Let (G, T, M, R) be a splitting of G ; then $Z = D_{\{k\}}(M / \Gamma_0(R))$ and C is identified with

```

```text

$$\operatorname{Coker}(\operatorname{Hom}_{\mathbb{Z}}(M, k) \rightarrow \operatorname{Hom}_{\mathbb{Z}}(\Gamma_0(R), k)) \simeq \operatorname{Ext}^1_{\mathbb{Z}}(M / \Gamma_0(R), k),$$

```

```

equipped with the trivial action of G_{ad} . The corollary follows, since Z is not smooth over k if and only if $\operatorname{schar}(k) = p > 0$ and $M / \Gamma_0(R)$ has p -torsion (Exp. IX, 2.1).

Definition 1.16. *Let S be a scheme, G an S -reductive group. We call a* form of G over S *an S -group scheme G' locally isomorphic to G for the (fpqc) topology (it amounts to the same to say (cf. Exp. XXIII, 5.6) that G' is locally isomorphic to G for the étale topology, or again that G' is an S -reductive group of the same type as G at every point of S).*

<!-- label: III.XXIV.1.16 -->

Corollary 1.17. *Let S be a scheme, G an S -reductive group.*

(i) The functor*

```

$$G' \mapsto \operatorname{Isom}_{\{S\text{-gr.}\}}(G, G')$$

```

is an equivalence between the category of forms of G over S and the category of principal homogeneous bundles under $\operatorname{Aut}_{\{S\text{-gr.}\}}(G)$.

<!-- original page 226 -->

(ii) If $S' \rightarrow S$ is a covering morphism, forms of G trivialized by S' and bundles trivialized by S' correspond.*

(iii) Every principal homogeneous sheaf under $\operatorname{Aut}_{\{S\text{-gr.}\}}(G)$ is representable and quasi-isotrivial (i.e. locally trivial for the étale topology).*

<!-- label: III.XXIV.1.17 -->

The first assertion is formal in the category of sheaves (for (fpqc) for example). On the other hand, every sheaf locally isomorphic to G (for (fpqc)) is representable (since G is affine over S) and locally isomorphic to G for the étale topology. Finally, for every form G of G , the S -sheaf $\text{Isom}_{\{S\text{-gr.}\}}(G, G')$ is representable, by 1.8. The corollary follows at once.

Corollary 1.18. The set of isomorphism classes of forms of the reductive group G over S is isomorphic to

$$H^1(S, \text{Aut}_{\{S\text{-gr.}\}}(G)) = H^1_{\text{ét}}(S, \text{Aut}_{\{S\text{-gr.}\}}(G)) = \text{Fib}(S, \text{Aut}_{\{S\text{-gr.}\}}(G)).$$

If $S' \rightarrow S$ is a covering morphism, the subset formed by forms trivialized by S' is isomorphic to $H^1(S'/S, \text{Aut}_{\{S\text{-gr.}\}}(G))$.

<!-- label: III.XXIV.1.18 -->

Corollary 1.19. Let S be a scheme, R a pinned reduced root datum such that $\text{E}_p(S)(R)^{\text{N.D.E-XXIV-10}}$ exists (condition automatically satisfied, cf. Exp. XXV). Write

$$A_S(R) = \text{Aut}_{\{S\text{-gr.}\}}(\text{Ép}_S(R)) = \text{ad}(\text{Ép}_S(R)) \cdot E(R)_S.$$

(i) The set of isomorphism classes of S -reductive groups of type R (Exp. XXII, 2.7) is isomorphic (by Exp. XXIII, 5.12) to

$$H^1(S, A_S(R)) = H^1_{\text{ét}}(S, A_S(R)) = \text{Fib}(S, A_S(R)).$$

(ii) If $S' \rightarrow S$ is a covering morphism, the subset formed by the classes of groups splittable over S' is isomorphic to $H^1(S'/S, A_S(R))$.

<!-- label: III.XXIV.1.19 -->

Remark 1.20. With the preceding notation, to every S -reductive group of type R is canonically associated a right principal homogeneous bundle under $A_S(R)$:

$$\text{Isom}_{\{S\text{-gr.}\}}(\text{Ép}_p(S)(R), G) = P.$$

Note that P is to be interpreted as the "scheme of pinnings of G of type R " (cf. 1.0). Moreover P is also a principal homogeneous bundle (on the left) under $\text{Aut}_{\{S\text{-gr.}\}}(G)$, a structure that appears at once in the description above.

<!-- label: III.XXIV.1.20 -->

Proposition 1.21. Let S be a henselian local scheme, s its closed point. The functor

$$G \mapsto G_s$$

induces a bijection of the set of isomorphism classes of S -reductive groups onto the set of isomorphism classes of $k(s)$ -reductive groups.

In particular, for every S -reductive group G , there exists a finite surjective étale morphism $S' \rightarrow S$ such that $G_{S'}$ is splittable.

<!-- label: III.XXIV.1.21 -->

<!-- original page 227 -->

Using the existence of the $\text{p}_{\{S\}(R)}$ (Exp. XXV), one is reduced to proving that if one writes $H = A_{\{S\}(R)}$, the canonical map

```
```text
Fib(S, H) → Fib(κ(s), H_s)
```
```

is bijective (and that every element of $\text{Fib}(S, H)$ has the property indicated above). Now, every finite part of H is contained in an affine open set (it is indeed trivial for a constant group, and H is affine above a constant group); one may therefore use the result proved in the appendix (8.1).

2. Automorphisms and subgroups

<!-- label: III.XXIV.2 -->

<!-- original page 228 -->

Let us introduce a notation: if $H = \text{operatorname{Aut}}_{\{S\}\text{-gr.}}(G)$, and if X is a subfunctor of G , we write

```
```text
Aut_{S-gr.}(G, X) = Norm_H(X), Aut_{S-gr.}(G, id_X) = Centr_H(X).
```
```

If Y is a second subfunctor of G , one defines similarly $\text{Aut}_{\{S\}\text{-gr.}}(G, X, Y) = \text{Aut}_{\{S\}\text{-gr.}}(G, X) \cap \text{Aut}_{\{S\}\text{-gr.}}(G, Y)$, and if G' is a second S -group and X' a subfunctor of G' , one writes $\text{Isom}_{\{S\}\text{-gr.}}(G, X; G', X')$ for the subfunctor of $\text{Isom}_{\{S\}\text{-gr.}}(G, G')$ defined by: for every $S' \rightarrow S$,

```
```text
Isom_{S-gr.}(G, X; G', X')(S') = { u ∈ Isom_{S-gr.}(G, G')(S') | u(X_{S'}) = X'_{S'} }
```
```

and one defines similarly $\text{Isom}_{\{S\}\text{-gr.}}(G, X, Y; G', X', Y')$, etc. [N.D.E-XXIV-11]

Proposition 2.1. *Let S be a scheme, G an S -reductive group, T a maximal torus of G (resp. B a Borel subgroup of G , resp. $B \supset T$ a Killing couple of G). Write T_{ad} (resp. B_{ad}) for the maximal torus (resp. Borel subgroup) of $\text{ad}(G)$ corresponding to T (resp. B):*

```
```text
B_ad = B / Centr(G) = B / Centr(B),
T_ad = T / Centr(G).
```
```

Then $\text{operatorname{Aut}}_{\{S\}\text{-gr.}}(G, T)$ (resp. $\text{operatorname{Aut}}_{\{S\}\text{-gr.}}(G, B)$), resp. $\text{operatorname{Aut}}_{\{S\}\text{-gr.}}(G, B, T)$ is representable by a closed subscheme of $\text{operatorname{Aut}}_{\{S\}\text{-gr.}}(G)$, smooth over S , and the exact sequence of Theorem 1.3 induces exact sequences:

```
```text
1 → Norm_{ad(G)}(T_ad) → Aut_{S-gr.}(G, T) → Autext(G) → 1;
1 → B_ad → Aut_{S-gr.}(G, B) → Autext(G) → 1;
1 → T_ad → Aut_{S-gr.}(G, B, T) → Autext(G) → 1.
```
```

<!-- label: III.XXIV.2.1 -->

By descent of closed subschemes, [N.D.E-XXIV-12] one is at once reduced to the case where G is pinned and where $B \supset T$ is its canonical Killing couple (cf. Exp. XXII, 5.5.5 (iv)). Since the group E of 1.2 normalizes B and T , the result follows at once from the normalization theorems in $\text{ad}(G)$ (Exp. XXII, 5.3.12 and 5.6.1).

<!-- original page 229 -->

Using now the conjugation theorems (cf. Exp. XXIII, 5.12), and arguing as in no 1, one deduces:

Corollary 2.2. *Let S be a scheme, G and G' two S -reductive groups of the same type at each point. Let $B \supset T$ (resp. $B' \supset T'$) be a Killing couple of G (resp. G').*

*(i) The $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, T; G', T')$ is representable by a closed smooth subscheme of $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, G')$ which is principal homogeneous under $\text{Aut}_{\{S\text{-gr.}\}}(G, T)$.

Moreover, $\text{Norm}_{\text{ad}(G)}(T_{\text{ad}})$ operates freely on this scheme, and one has a canonical isomorphism

$$\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, T; G', T') / \text{Norm}_{\text{ad}(G)}(T_{\text{ad}}) \simeq \text{Isomext}(G, G').$$

*(ii) The $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B; G', B')$ is representable by a closed smooth subscheme of $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, G')$ which is principal homogeneous under $\text{Aut}_{\{S\text{-gr.}\}}(G, B)$.

Moreover, B_{ad} operates freely on this scheme and one has a canonical isomorphism

$$\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B; G', B') / B_{\text{ad}} \simeq \text{Isomext}(G, G').$$

*(iii) The $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B, T; G', B', T')$ is representable by a closed smooth subscheme of $\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, G')$, principal homogeneous under $\text{Aut}_{\{S\text{-gr.}\}}(G, B, T)$.

Moreover, T_{ad} operates freely on this scheme and one has a canonical isomorphism

$$\mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B, T; G', B', T') / T_{\text{ad}} \simeq \text{Isomext}(G, G').$$

<!-- label: III.XXIV.2.2 -->

Arguing again as in no 1, one deduces:

Corollary 2.3. Let S be a scheme, G an S -reductive group, $B \supset T$ a Killing couple of G . The functor

$$(G', T') \mapsto \mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, T; G', T'),$$

resp.

$$(G', B') \mapsto \mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B; G', B'),$$

resp.

$$(G', B', T') \mapsto \mathcal{I} \text{som}_{\{S\text{-gr.}\}}(G, B, T; G', B', T'),$$

is an equivalence between the category of pairs (G', T') (resp. of pairs (G', B') , resp. of triples (G', B', T')), where G' is a form of G and T' a maximal torus of G' (resp. B' a Borel subgroup of G' , resp. $B' \supset T'$ a Killing couple of G'), and the category of principal homogeneous bundles under the S -group H , where $H = \text{Aut}_{\{S\text{-gr.}\}}(G, T)$ (resp. $H = \text{Aut}_{\{S\text{-gr.}\}}(G, B)$, resp. $H = \text{Aut}_{\{S\text{-gr.}\}}(G, B, T)$).

<!-- original page 230 -->

Moreover, every principal homogeneous sheaf under H is representable and quasi-isotrivial, so that one has

$$H^1(S, H) = H^1_{\text{ét}}(S, H) = \text{Fib}(S, H).$$

<!-- label: III.XXIV.2.3 -->

Remark 2.4. Under the conditions of 2.2, the morphism noted set-theoretically $u \mapsto u(T)$ (resp. $u \mapsto u(B)$, resp. $u \mapsto (u(B), u(T))$) induces an isomorphism

```
```text
Isom_{S-gr.}(G, G') / Aut_{S-gr.}(G, T) = Tor(G')
```

```
```text
resp. Isom_{S-gr.}(G, G') / Aut_{S-gr.}(G, B) = Bor(G'),
```

```
```text
resp. Isom_{S-gr.}(G, G') / Aut_{S-gr.}(G, B, T) = Kil(G').
```

The proof is immediate: it suffices to do it locally for (fpqc), so one may assume  $G \simeq G'$ , and one is reduced to Exp. XXII, 5.8.3 (iii).

<!-- label: III.XXIV.2.4 -->

**Remark 2.5.** The preceding results are at once interpreted in terms of restriction of the structure group: if  $G$  is a form of  $G_0$ , corresponding to the principal bundle  $\text{Isom}_{S\text{-gr.}}(G, G_0)$ , to give a restriction of the structure group of this bundle to  $\text{Aut}_{S\text{-gr.}}(G, T)$  amounts to giving a maximal torus  $T$  of  $G$ , the bijections suggested above being that of 2.4 on the one hand, the map  $T \mapsto \text{Isom}_{S\text{-gr.}}(G, T; G', T')$  on the other. Similarly for Borel subgroups and Killing couples.

<!-- label: III.XXIV.2.5 -->

**Proposition 2.6.** Let  $S$  be a scheme,  $G$  and  $G'$  two  $S$ -reductive groups of the same type at each point,  $T$  (resp.  $T'$ ) a maximal torus of  $G$  (resp.  $G'$ ). Then  $T_{\text{ad}}$  operates freely on  $\text{Isom}_{S\text{-gr.}}(G, T; G', T')$ , the quotient\*

```
```text
P = Isom_{S-gr.}(G, T; G', T') / T_{ad}
```

is representable; it is a principal homogeneous bundle under

```
```text
A = Aut_{S-gr.}(G, T) / T_{ad},
```

\*where  $A$  is representable by a twisted constant  $S$ -scheme, extension of  $\text{Aut}(G)$  by  $W_{\text{ad}}(G)(T_{\text{ad}}) = \text{Norm}_{\text{ad}}(G)(T_{\text{ad}}) / T_{\text{ad}}$ . Moreover, if one makes  $A$  operate on  $T$  in the obvious way, the bundle associated to  $P$  is none other than  $T^*$ . [N.D.E-XXIV-13]\*

<!-- label: III.XXIV.2.6 -->

The first part of the proposition follows at once from the preceding results. To prove the second, one notes that there is an obvious morphism  $P \times_{S\text{-gr.}} T \rightarrow T$  (defined by  $(u, t) \mapsto u(t)$ ); to show that after passage to the quotient by  $A$  it induces an isomorphism, one may once again assume  $(G, T) \simeq (G', T')$ , in which case it is immediate.

In an entirely analogous way, one has:

**Proposition 2.7.** Let  $S$  be a scheme,  $G$  and  $G'$  two  $S$ -reductive groups of the same type at each point,  $B \supset T$  (resp.  $B' \supset T'$ ) a Killing couple of  $G$  (resp.  $G'$ ). If one makes  $\text{Aut}_{S\text{-gr.}}(G, B, T) / T_{\text{ad}}$   $\simeq \text{Aut}(G)$  operate in the obvious way on  $T$ , the bundle associated to  $\text{Isom}_{S\text{-gr.}}(G, G')$  is none other than  $T^*$ .

<!-- label: III.XXIV.2.7 -->

**Corollary 2.8.** Let  $G$  and  $G'$  be two  $S$ -reductive groups that are inner twisted forms of each other; let  $B \supset T$  (resp.  $B' \supset T'$ ) be a Killing couple of  $G$  (resp.  $G'$ ). Then  $T$  and  $T'$  are

isomorphic. [N.D.E-XXIV-14]\*

<!-- label: III.XXIV.2.8 -->

<!-- original page 231 -->

**Remark 2.9.** It is not true in general that  $B$  and  $B'$  are isomorphic; they are however inner twisted forms of each other (cf. no 5).

<!-- label: III.XXIV.2.9 -->

One can develop "Isomint" variants [N.D.E-XXIV-15] of the preceding results. Let us point out one:

**Proposition 2.10.** Let  $S$  be a scheme,  $G$  and  $G'$  two  $S$ -reductive groups of the same type at each point,  $B \supset T$  (resp.  $B' \supset T'$ ) a Killing couple of  $G$  (resp.  $G'$ ). Let  $u \in \text{Isomext}(G, G')(S)$ ; consider\*

```text  
 $\text{Isomint}_u(G, B, T; G', B', T') = \text{Isom}_{\{S\text{-gr.}\}}(G, B, T; G', B', T') \cap \text{Isomint}_u(G, G').$
 ```

It is a smooth and affine  $S$ -scheme which is a principal homogeneous bundle under  $T_{\text{ad}}$ . In particular,  $\text{Isomint}_{\{u\}}(G, B, T; G', B', T')(S) \neq \emptyset$  if and only if the corresponding element of  $H^1(S, T_{\text{ad}})$  is zero.\*

<!-- label: III.XXIV.2.10 -->

To conclude this section, let us prove two results which will be useful later:

**Proposition 2.11.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ . The obvious morphism\*

$T_{\text{ad}} \rightarrow \varinjlim \text{Aut}_{\{S\text{-gr.}\}}(G, \text{id}_T)$   
 $S$

is an isomorphism.\*

<!-- label: III.XXIV.2.11 -->

This follows from the preceding statements; moreover, one has given a direct proof in the course of the proof of 1.5.2.

**Corollary 2.12.** Under the preceding conditions, there exists an equivalence between the category of pairs  $(G', f)$ , where  $G'$  is a form of  $G$  and  $f$  is an isomorphism of  $T$  onto a maximal torus of  $G'$ , and the category of principal homogeneous bundles under  $T_{\text{ad}}$ .\*

<!-- label: III.XXIV.2.12 -->

**Corollary 2.13.** If  $H^1(S, T_{\text{ad}}) = 0$ , and if  $G'$  is a form of  $G$  possessing a maximal torus isomorphic to  $T$ , then  $G'$  is isomorphic to  $G$ .\*

<!-- label: III.XXIV.2.13 -->

**Corollary 2.14.** Let  $S$  be a scheme such that  $\text{Pic}(S) = 0$ , and  $G$  an  $S$ -reductive group of constant type. For  $G$  to be splittable, it is necessary and sufficient that  $G$  possess a split maximal torus.\*

<!-- label: III.XXIV.2.14 -->

<!-- original page 232 -->

Let  $G$  be a reductive group,  $\text{rad}(G)$  its radical (Exp. XXII, 4.3.9); since  $\text{rad}(G)$  is central and characteristic in  $G$ , one has a canonical morphism

```text  
 $q : \text{Aut}(G) \rightarrow \text{Aut}_{\{S\text{-gr.}\}}(\text{rad}(G)).$
 ```

**Proposition 2.15.** Let  $G$  be an  $S$ -reductive group. The following sequence is exact:

$$1 \rightarrow \mathrm{ad}(G) \rightarrow \mathrm{Aut}_{\{S\text{-gr.}\}}(G, \mathrm{id}_{\mathrm{rad}(G)}) \rightarrow \mathrm{Aut}(G) \rightarrow \mathrm{Aut}_{\{S\text{-gr.}\}}(\mathrm{rad}(G))$$

and  $\mathrm{Ker}(q) = \mathrm{Im}(p)$  is an open and closed subscheme of  $\mathrm{Aut}(G)$ , finite over  $S$ .

One may assume  $G$  split. The first assertion is immediate; the second follows from Exp. XXI, 6.7.5 and 6.7.7.

Writing  $H = \mathrm{operatorname{Aut}}_{\{S\text{-gr.}\}}(G, \mathrm{id}_{\mathrm{rad}(G)})$ , one deduces:

**Corollary 2.16.** There exists an equivalence between the category of pairs  $(G', f)$ , where  $G'$  is a form of  $G$  and  $f$  is an isomorphism of  $\mathrm{rad}(G)$  onto the radical of  $G'$ , and the category of principal bundles under a certain  $S$ -group scheme  $H$ , where  $H$  is such that there exists an exact sequence

$$1 \rightarrow \mathrm{ad}(G) \rightarrow H \rightarrow F \rightarrow 1,$$

where the  $S$ -group  $F$  is étale and finite over  $S$ .

### 3. Dynkin scheme of a reductive group. Quasi-split groups

#### 3.1.

Recall (Exp. XXI, 7.4.1) that a *Dynkin diagram* is a finite set endowed with the structure defined by a set of pairs of distinct elements (*bonds*) and a map to  $\{1, 2, 3\}$  (*lengths*). To each pinned reduced root datum  $R$  is associated a Dynkin diagram  $\Delta(R)$ , whose underlying set is the set of simple roots.

#### 3.2.

Let  $S$  be a scheme. An  $S$ -*Dynkin scheme* is a finite twisted constant  $S$ -scheme  $\Delta$ , equipped with the structure defined by a subscheme  $L$  of  $\Delta \times_S \Delta$  having empty intersection with the diagonal, and by a morphism  $\Delta \rightarrow \{1, 2, 3\}$ . If  $S'$  is a connected  $S$ -scheme,  $\Delta(S')$  is naturally endowed with a structure of Dynkin diagram.

One defines at once the following notions: isomorphism of two Dynkin schemes, base change of a Dynkin scheme, constant Dynkin scheme associated to a Dynkin diagram.

#### 3.3.

We propose to associate to each  $S$ -reductive group  $G$  an  $S$ -Dynkin scheme. Suppose first that  $G$  is splittable over  $S$ ; for every pinning  $E$  of  $G$ , write  $\Delta(E)$  for the constant Dynkin scheme associated to the pinned root datum defined by  $E$ ; if  $E$  and  $E'$  are two pinnings of  $G$ , there exists by 1.5 a unique inner automorphism of  $G$  over  $S$  transforming  $E$  into  $E'$ ; this automorphism of  $G$  defines an isomorphism  $\Delta(E) \rightarrow \Delta(E')$ ; the  $\Delta(E)$  evidently form a transitive system, so that one may identify the  $\Delta(E)$  (i.e. take the inductive limit); the result is a constant Dynkin scheme denoted  $\mathrm{Dyn}(G)$ . If

now  $G$  is an arbitrary  $S$ -reductive group, there exists a covering family for the étale topology  $\{S_i \rightarrow S\}$  such that  $G_{S_i}$  is splittable. Arguing as previously, one therefore has a canonical descent datum on the  $\text{Dyn}(G_{S_i})$ , allowing one to construct by descent an  $S$ -Dynkin scheme  $\text{Dyn}(G)$ .

### 3.4.

<!-- label: III.XXIV.3.4 -->

This construction satisfies the following properties (which moreover essentially characterize it):

(i) To each  $S$ -reductive group is associated a Dynkin scheme  $\text{Dyn}(G)$ ; to every isomorphism  $u : G \rightarrow G'$  is functorially associated an isomorphism  $\text{Dyn}(u) : \text{Dyn}(G) \rightarrow \text{Dyn}(G')$ .

(ii) If  $S$  is an  $S$ -scheme and  $G$  an  $S$ -reductive group, one has

```text  
 $\text{Dyn}(G \times_S S') \simeq \text{Dyn}(G) \times_S S'$.
 ```

(iii) If  $E$  is a pinning of  $G$ , defining the pinned root datum with Dynkin diagram  $\Delta$ , one has

```text  
 $\text{Dyn}(G) \simeq \Delta_S$.
 ```

(iv) If  $u$  is an inner automorphism of  $G$ ,  $\text{Dyn}(u)$  is the identity automorphism of  $\text{Dyn}(G)$ .

### 3.5.

<!-- label: III.XXIV.3.5 -->

Let  $S$  be a scheme,  $G$  an  $S$ -reductive group. It is clear that the functor  $\text{Aut}_{\text{Dyn}}(\text{Dyn}(G))$  of automorphisms of  $\text{Dyn}(G)$  for the structure of Dynkin scheme is representable by a finite twisted constant  $S$ -scheme. By 3.4 (i) and (ii), one has a canonical morphism

```text  
 $\text{Aut}_{S\text{-gr.}}(G) \rightarrow \text{Aut}_{\text{Dyn}}(\text{Dyn}(G))$,
 ```

which, by (iv), factors through a morphism

```text  
 $\text{Aut}(G) \rightarrow \text{Aut}_{\text{Dyn}}(\text{Dyn}(G))$.
 ```

More generally, if  $G$  and  $G'$  are two  $S$ -reductive groups, one has a canonical morphism

```text  
 $\text{Isomext}(G, G') \rightarrow \text{Isom}_{\text{Dyn}}(\text{Dyn}(G), \text{Dyn}(G'))$;
 ```

in particular, if  $G$  is an inner twisted form of  $G$  (1.11), the Dynkin schemes  $\text{Dyn}(G)$  and  $\text{Dyn}(G')$  are isomorphic.

### 3.6.

<!-- label: III.XXIV.3.6 -->

<!-- original page 234 -->

If  $G$  is semisimple (resp. adjoint or simply connected), the morphism

```text  
 $\text{Aut}(G) \rightarrow \text{Aut}_{\text{Dyn}}(\text{Dyn}(G))$
 ```

is a monomorphism (resp. an isomorphism). Indeed, one may assume  $G$  pinned and one is reduced to the corresponding result for pinned reduced root data (cf. Exp. XXI, 7.4.5).

One has an analogous result for 'Isom's; whence it follows in particular that two semisimple adjoint (resp. simply connected)  $S$ -groups are inner twisted forms of each other if and only if their Dynkin schemes are isomorphic.

### 3.7.

<!-- label: III.XXIV.3.7 -->

One can give a different construction of the Dynkin scheme associated to a reductive group. Let  $R$  be a pinned reduced root datum,  $G$  an  $S$ -reductive group of type  $R$ ; write  $\Delta(R)$  for the Dynkin diagram defined by the root datum  $R$ . One has (3.5) a canonical morphism

$$A_S(R) = \text{Aut}_{\{S\text{-gr.}\}}(\acute{E}p_S(R)) \rightarrow \text{Aut}_{\text{Dyn}}(\Delta(R)_S).$$

The  $S$ -reductive group  $G$  corresponds (1.17) to a bundle  $\text{Isom}_{\{S\text{-gr.}\}}(\acute{E}p_S(R), G)$ , principal homogeneous under  $A_S(R)$ . The bundle under  $\text{operatorname{Aut}}_{\text{Dyn}}(\Delta(R)_S)$  associated corresponds to a form on  $S$  of  $\Delta(R)_S$ : this is  $\text{Dyn}(G)$ ; in other words, this associated bundle is none other than  $\text{Isom}_{\text{Dyn}}(\Delta(R)_S, \text{Dyn}(G))$ . In this last form, the proof is immediate.

### 3.8. Dynkin scheme and Killing couples.

<!-- label: III.XXIV.3.8 -->

Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $B \supset T$  a Killing couple of  $G$ . There exists a canonical morphism

$$i : \text{Dyn}(G) \rightarrow \text{Hom}_{\{S\text{-gr.}\}}(T, G_{\{m, S\}})$$

which identifies  $\text{Dyn}(G)$  with the "scheme of simple roots of  $B$  relative to  $T$ "; this morphism is defined at once by descent from the pinned case. Note moreover that the datum of  $T$  and of  $i$  allows one to reconstruct  $B$  ("biunivocal correspondence between systems of simple roots and systems of positive roots").

It follows from the preceding description of  $D = \text{Dyn}(G)$  that there exists a canonical root of  $B_D$  with respect to  $T_D$ : this root  $\alpha_D$  is the image under  $i(D)$  of the identity morphism of  $D$ . One thereby deduces a canonical invertible  $0_D$ -module  $g_D$ :

$$g_D = (g \otimes_{0_S} 0_D)^{\alpha_D}.$$

<!-- original page 235 -->

In the pinned case, one has

$$D = \coprod_{\alpha \in \Delta} S_{\alpha},$$

where each  $S_{\alpha}$  is a copy of  $S$ , and  $g_D$  is then the  $0_D$ -module which induces  $g_{\alpha}$  on  $S_{\alpha}$ , for every  $\alpha \in \Delta$ .

### 3.9. Quasi-pinnings. Quasi-pinned groups.

<!-- label: III.XXIV.3.9 -->

If  $G$  is an  $S$ -reductive group, we call \*quasi-pinning of  $G$ \* the datum:

(i) of a Killing couple  $B \supset T$  of  $G$ ,

(ii) of a section  $\mathcal{X}$  in  $\Gamma(\mathrm{Dyn}(G), g_D)^{\times}$ .

We say that an  $S$ -reductive group is *quasi-splittable* if it possesses a quasi-pinning. We call *quasi-pinned group* a reductive group equipped with a quasi-pinning.

Let  $B \supset T$  be a Killing couple of the  $S$ -reductive group  $G$ ; then  $G$  is quasi-pinnable relative to this Killing couple if and only if  $g_D$  possesses a non-zero section at every point, i.e. if the element of  $\mathrm{Pic}(\mathrm{Dyn}(G))$  defined by  $g_D$  is zero. Suppose in particular that  $S$  is semi-local; then  $\mathrm{Dyn}(G)$  is also semi-local, so  $\mathrm{Pic}(\mathrm{Dyn}(G)) = 0$ . One deduces:

**Proposition 3.9.1.** *Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group. For  $G$  to be quasi-splittable, it is necessary and sufficient that it possess a Borel subgroup.*

<!-- label: III.XXIV.3.9.1 -->

[^N.D.E-XXIV-17] Indeed,  $S$  is affine so, by the first assertion of Exp. XXII, 5.9.7, if  $G$  possesses a Borel subgroup  $B$ , it also possesses a Killing couple  $B \supset T$ . Then, since  $\mathrm{Pic}(D) = 0$ ,  $g_D$  possesses a section  $X$  nowhere zero.

Let still  $A$  be a semi-local ring and  $S = \mathrm{Spec}(A)$ ; remark now that for every  $S$ -reductive group  $G$  the morphism  $\mathrm{Bor}(G) \rightarrow S$  is surjective (since  $g_s$  possesses Borel subgroups, for every  $s \in S$ ) and smooth and projective (Exp. XXII, 5.8.3), so it possesses sections after a finite surjective étale extension of the base.[^N.D.E-XXIV-18] One deduces:

**Corollary 3.9.2.** *Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group. There exists an étale, finite and surjective morphism  $S' \rightarrow S$  such that  $G_{S'}$  is quasi-splittable.*

<!-- label: III.XXIV.3.9.2 -->

**Remark 3.9.3.** Under the preceding conditions, let  $T$  be a maximal torus of  $G$  (cf. Exp. XIV, 3.20); then one may moreover assume that  $G_{S'}$  is quasi-splittable relative to  $T_{S'}$ : it suffices to apply the preceding argument to the "scheme of Borel subgroups containing  $T$ ", which is finite and étale over  $S$  (Exp. XXII, 5.5.5 (ii)).

<!-- label: III.XXIV.3.9.3 -->

### 3.10.

<!-- label: III.XXIV.3.10 -->

Let  $E$  and  $E'$  be two quasi-pinnings of the  $S$ -reductive group  $G$ . There exists a unique inner automorphism of  $G$  transforming  $E$  into  $E'$ . Indeed, one is at once reduced to the split case, where the assertion has already been proved (1.5; it suffices indeed to note that for an inner automorphism of  $G$  it amounts to the same to respect a pinning or the underlying quasi-pinning). One concludes as in no 1 that a

<!-- original page 236 -->

quasi-pinning of the  $S$ -reductive group  $G$  defines a splitting  $h$  of the exact sequence:

```

```text
1 → ad(G) → Aut_{S-gr.}(G) → Aut_{S-gr.}(G) / ad(G) → 1,
```

```

the image of  $h$  being the subgroup of  $\mathrm{Aut}_{S\text{-gr.}}(G)$  which leaves invariant the quasi-pinning.

Similarly if  $G$  and  $G'$  are two quasi-pinned  $S$ -groups, one defines in a natural way the subfunctor

```

$$
\mathrm{Isom}_{S\text{-gr. q-acute{e}p.}}(G, G')
$$

```

of  $\mathrm{Isom}_{S\text{-gr.}}(G, G')$ ; the projection of  $\mathrm{Isom}_{S\text{-gr.}}(G, G')$  onto  $\mathrm{Isomext}(G, G')$  induces an isomorphism

```

```text
(*)  \mathrm{Isom}_{S\text{-gr. q-acute{e}p.}}(G, G') \xrightarrow{\sim} \mathrm{Isomext}(G, G').
```

```

**Theorem 3.11.** Let  $S$  be a scheme,  $R$  a pinned reduced root datum such that  $\acute{e}p_{\{S\}}(R)$  exists (cf. Exp. XXV),  $E$  the group of its automorphisms. Consider the three following categories:

- (i) The category  $\text{Rev}$  of principal Galois coverings of  $S$  with group  $E$  (the morphisms are isomorphisms of  $E$ -bundles).
- (ii) The category  $\text{Redext}$  whose objects are the  $S$ -reductive groups of type  $R$  (Exp. XXII, 2.7), the morphisms from  $G$  to  $G'$  being the elements of  $\text{Isomext}(G, G')(S)$ .
- (iii) The category  $\text{Qép}$  of quasi-pinned  $S$ -reductive groups of type  $R$  (the morphisms are the isomorphisms respecting the quasi-pinnings).

These three categories are equivalent: more precisely, one has a diagram of functors, commutative up to functorial isomorphisms

```

```text
      qép
    ----->
Rev  /         \ Qép
    /           \
rev /             \ i
    \             /
     \           /
      Redext
...

```

<!-- label: III.XXIV.3.11 -->

We shall describe below these three functors, leaving to the reader the task of verifying the commutativity of the diagram. [N.D.E-XXIV-19]

3.11.1. The functor i .

It is the obvious functor: $i(G) = G$, $i(f) = f$ image of f under the isomorphism of 3.10 (*).

3.11.2. The functor $qép$.

Let S' be a principal Galois covering of S with group E . Let $(G, T, M, R, \Delta, (X_{\alpha})_{\alpha \in \Delta})$ be a pinning of $G = \acute{e}p_{\{S\}}(R)$ and $(X'_{\alpha})_{\alpha \in \Delta}$ the corresponding pinning of $G' = G_{\{S'\}} = \acute{e}p_{\{S'\}}(R)$. By Exp. XXIII 5.5 bis, there exists a unique morphism of groups

```

```text
θ : E → Aut_{S-gr.}(Ép_S(R)) = A(R)(S)
...

```

<!-- original page 237 -->

such that, for every  $h \in E$ ,  $\theta(h)$  induces  $D_{\{S\}}(h)$  on  $T$  and  $\text{Lie}(\theta(h))(X_{\alpha}) = X_{\theta(h)(\alpha)}$  for every  $\alpha \in \Delta$ . Taking into account the action of  $E$  on  $S'$ , one thereby obtains an action of  $E$  on  $G'$ , compatible with the action of  $E$  on  $S'$  and respecting the canonical quasi-pinning of  $G'$ . [N.D.E-XXIV-20] Since  $S' \rightarrow S$  is covering for the (fpqc) topology, it is an effective descent morphism for the fibered category of affine morphisms, and one writes

```

$$
q\acute{e}p(S') = Q\text{-}\acute{e}p_{\{S'/S\}}(R)
$$

```

for the quasi-pinned  $S$ -group obtained by Galois descent. [N.D.E-XXIV-21]

### 3.11.3. The functor  $\text{rev}$ .

Let  $G$  be an  $S$ -reductive group of type  $R$ . One writes

```

$$
\text{rev}(G) = \text{Isomext}(\acute{e}p_{\{S\}}(R), G);

```

\$\$

this is a principal homogeneous bundle under  $\text{'E\_S'}$  (cf. 1.10 and 1.19), that is, an object of  $\text{'Rev'}$ .

### 3.11.4. [N.D.E-XXIV-22]

It is clear, by the isomorphism 3.10 (\*), that the functor  $i$  is fully faithful. On the other hand, if  $G_0$ ,  $G$ ,  $G'$  are  $S$ -reductive groups, the natural morphism

$$\text{Isom}(G_0, G) \times_S \text{Isom}(G, G') \rightarrow \text{Isom}(G_0, G')$$

induces a morphism

$$(*) \quad \text{Isomext}(G_0, G) \times_S \text{Isomext}(G, G') \rightarrow \text{Isomext}(G_0, G')$$

since, for every  $S' \rightarrow S$ , if  $g_0 \in G_0(S')$ ,  $g \in G(S')$ ,  $u \in \text{Isom}(G_0, G)(S')$ , and  $v \in \text{Isom}(G, G')(S')$ , one has the equality  $v \circ \text{int}(g) \circ u \circ \text{int}(g_0) = v \circ u \circ \text{int}(u^{-1}(g) \cdot g_0)$ . Taking  $G_0 = \text{acute}[E]_p(S)(R)$ , one obtains a map

$$\text{Isomext}(G, G')(S) \rightarrow \text{Hom}_{\{\text{Rev}\}}(\text{Isomext}(\acute{E}p_S(R), G), \text{Isomext}(\acute{E}p_S(R), G'))$$

and to show that this is a bijection, one may assume by (fpqc) descent that  $G$  and  $G'$  are pinned, in which case it is evident.

<!-- original page 238 -->

Similarly, if  $S_1$ ,  $S_2$  are two objects of  $\text{'Rev'}$  and if one writes  $S_i \times^E \text{acute}[E]_p(S)(R)$  for the  $S$ -group  $q\text{acute}[e]_p(S_i)$  obtained by twisting  $\text{acute}[E]_p(S)(R)$  by the  $E$ -torsor  $S_i$  (cf. N.D.E. (21)), one has a natural map

$$\text{Hom}_{\{\text{Rev}\}}(S_1, S_2) \rightarrow \text{Hom}_{\{Q\acute{e}p\}}(S_1 \times^E \acute{E}p_S(R), S_2 \times^E \acute{E}p_S(R)),$$

and to show that this is a bijection, one may assume by (fpqc) descent that  $S_1$  and  $S_2$  are trivial  $E$ -bundles, in which case it is evident.

Thus the three functors of the diagram are fully faithful. Moreover, for every object  $S'$  of  $\text{'Rev'}$ , one has a natural morphism

$$S' \rightarrow \text{Isomext}(\acute{E}p_S(R), S' \times^E \acute{E}p_S(R))$$

and to see that this is an isomorphism, one may assume by (fpqc) descent that  $S'$  is a trivial  $E$ -bundle, in which case it is evident.

One thus has an isomorphism of functors  $\text{Id}_{\{\text{Rev}\}} \rightarrow \text{rev} \circ \text{acute}[e]_p$ . Since the functor  $\text{'rev'}$  is fully faithful one obtains therefore, for every  $S$ -reductive group  $H$  (not necessarily quasi-split), a bijection

$$\text{Isomext}(Q\text{-}\acute{E}p_{\{\text{rev}(H)/S\}}(R), H)(S) = \text{Aut}_{\{\text{Rev}\}}(\text{rev}(H))$$

functorial in  $H$ . In particular, the identity morphism of  $\text{rev}(H)$  corresponds to a "canonical" element  $u_0$  of  $\text{Isomext}(Q\text{-}\text{acute}[E]_p_{\{\text{rev}(H)/S\}}(R), H)(S)$ ; moreover, every  $u \in \text{Isomext}(Q\text{-}\text{acute}[E]_p_{\{\text{rev}(H)/S\}}(R), H)(S)$  corresponds to an automorphism  $\phi_u$  of  $\text{rev}(H)$ , and  $q\text{acute}[e]_p(\phi_u)$  is the unique automorphism of pinned  $S$ -group of  $Q\text{-}\text{acute}[E]_p_{\{\text{rev}(H)/S\}}(R)$  such that  $u_0 \circ \text{acute}[e]_p(\phi_u) = u$ . We have thus proved theorem 3.11.

Let us develop one of the corollaries of 3.11:

**\*\*Corollary 3.12.\*\*** \*For every  $S$ -reductive group  $G$ , there exists a quasi-pinned  $S$ -group  $G_{\{q\text{-}\acute{e}p\}}$  and an "outer isomorphism"  $u \in \text{Isomext}(G_{\{q\text{-}\acute{e}p\}}, G)(S)$ . The pair  $(G_{\{q\text{-}\acute{e}p\}}, u)$  is unique up to a unique isomorphism.\*

<!-- label: III.XXIV.3.12 -->

Indeed, one may assume  $G$  of constant type  $R$ , and one takes  $G_{\{q\text{-}\acute{e}p\}} = Q\text{-}\acute{e}p_{\{\text{rev}(G)/S\}}(R)$ .

### 3.12.1.

<!-- label: III.XXIV.3.12.1 -->

Note that the datum of the pair  $(G_{\{q\text{-}\acute{e}p\}}, u)$  allows one to define canonically the  $S$ -scheme (cf. 1.11)

$S$   
 $Q = \text{Isomint}(G_{\{q\text{-}\acute{e}p\}}, G), [\{^N\}.D.E\text{-XXIV-23}]$   
 $S$

which is a principal homogeneous bundle under  $\text{ad}(G_{\{q\text{-}\acute{e}p\}})$ , and whose datum "is equivalent" to that of the inner twisted form  $G$  of  $G_{\{q\text{-}\acute{e}p\}}$ . Moreover,  $Q$  is none other than the "scheme of quasi-pinnings of  $G$ ", a definition which accounts for its structure of principal homogeneous bundle (on the left) under  $\text{ad}(G)$  (3.10) – compare with 1.20.

**\*\*Proposition 3.13.\*\*** \*Let  $S$  be a scheme,  $G$  a semisimple adjoint (resp. simply connected)  $S$ -group,  $B \supset T$  a Killing couple of  $G$ ,  $\text{Dyn}(G)$  the Dynkin  $S$ -scheme\*

<!-- original page 239 -->

\*of  $G$ . There exists a canonical isomorphism of  $S$ -group schemes\*

```text  
 $T \sqsubset \prod_{\text{Dyn}(G)/S} G_m, \text{Dyn}(G)$.
 ```

\*(Recall (cf. Exp. II, § 1) that the right-hand side is by definition the  $S$ -functor which to  $S' \rightarrow S$  associates  $G_m(\text{Dyn}(G) \times_{S'} S')$ , or, what amounts to the same,  $G_m(\text{Dyn}(G_{\{S'\}}))$ .)\*

<!-- label: III.XXIV.3.13 -->

\*First proof.\* Let us do it for simplicity in the adjoint case. Consider the composite morphism

```text  
 $T \rightarrow \prod_{D/S} T_D \rightarrow \prod_{D/S} G_m(D)$,
 ```

where the first morphism is the canonical morphism, the second is  $\prod_{D/S} \alpha_D$  (we have written  $D = \text{Dyn}(G)$ ). To verify that this morphism is an isomorphism, one may assume  $G$  split; now, in this case, this is none other than the morphism  $T \rightarrow (G_m, S)^{\Delta}$  with components  $\alpha$ , for  $\alpha \in \Delta$ , and the latter is an isomorphism (Exp. XXII, 4.3.8).

\*Second proof.\* By 2.8, 3.5 and 3.11, one may assume that  $G = Q\text{-}\acute{e}p_{\{S'/S\}}(R)$ ,  $T$  being the canonical maximal torus. On  $S'$ , one has by Exp. XXII 4.3.8, an isomorphism  $T_{\{S'\}} \xrightarrow{\sim} (G_m, S')^{\Delta}$ , defined by the simple roots (resp. the simple coroots). The group  $E$  operates on the right-hand side by permutation of  $\Delta$ . Now the bundle associated to  $S'/S$  by  $E \rightarrow \text{Opérateurname}\{Aut\}(\Delta)$  is  $\text{Dyn}(G)$  (3.7), and one concludes at once.

Using Prop. 8.4 of the appendix, one deduces:

**\*\*Corollary 3.14.\*\*** \*Under the preceding conditions, one has\*

```text  
 $H^1(S, T) \sqsubset H^1(\text{Dyn}(G), G_m) \sqsubset \text{Pic}(\text{Dyn}(G))$.
 ```

\*In particular,  $H^1(S, T) = 0$  when  $S$  is semi-local.\*

<!-- label: III.XXIV.3.14 -->

<!-- original page 240 -->

**Remark 3.15.** Let  $S$  be a scheme,  $G$  (resp.  $G'$ ) an  $S$ -reductive group,  $B \supset T$  (resp.  $B' \supset T'$ ) a Killing couple of  $G$  (resp.  $G'$ ),  $\mathfrak{u} \in \text{Isomext}(G, G')(S)$ . Set (cf. 2.10)

```text  
P = Isomint_u(G, B, T; G', B', T');
```

this is a principal homogeneous bundle under  $T_{\text{ad}}$  (by  $(f, t) \mapsto f \circ \text{int}(t)$ ).

Let on the other hand  $D = \text{Dyn}(G) = \text{Dyn}(G')$  (identified via  $\mathfrak{u}$  (3.5)), and let  $L = \text{Isom}_D(g_D, g'_D)$  be the principal homogeneous bundle under  $G_{\{m, D\}}$  defined by the invertible  ${}_{0_D}$ -module

```text  
Hom_{0_D}(g_D, g'_D) = g'_D \otimes (g_D)^v.
```

Each  $f \in P(S)$  defines an isomorphism of  $g_D \otimes_{0_S} 0_{S'}$  onto  $g'_D \otimes_{0_S} 0_{S'}$ , whence a canonical morphism

\$\$  
P \rightarrow \text{prod}\_{D/S} L.  
\$\$

This morphism is an isomorphism, compatible with the isomorphism of operator groups

```text  
T_ad \rightarrow \prod_{D/S} G_{\{m, D\}}
```

defined above. Indeed, it suffices to verify it in the case where the two groups are pinned, where it is easy.

<!-- label: III.XXIV.3.15 -->

It follows in particular that in the isomorphism

\$\$  
H^1(S, T\_{\text{ad}}) \xrightarrow{\sim} \text{operatorname{Pic}}(\text{Dyn}(G))  
\$\$

of 3.14, the class of the bundle  $P$  is transformed into  $c_{\text{ell}}(g'^D) - c_{\text{ell}}(g_D)$ . The bundle  $P$  is therefore trivial if and only if  $g'^D$  and  $g_D$  are isomorphic.

If  $(G, B, T)$  is quasi-splittable, for example if one takes for  $G$  the group  $G'_{\{q\text{-}\acute{e}\text{p.}\}}$ , with its canonical Killing couple, it follows that the image of the class of  $P$  is none other than the obstruction to the quasi-splitting of  $G$  defined in 3.9.

### 3.16. Symmetries

<!-- label: III.XXIV.3.16 -->

### 3.16.1.

<!-- label: III.XXIV.3.16.1 -->

Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $B \supset T$  a Killing couple of  $G$ . Write  $D = \text{Dyn}(G)$ . Recall (Exp. XXII, 5.9.1) that there exists a unique Borel subgroup  $B^{\{-\}}$  of  $G$  such that  $B \cap B^{\{-\}} = T$ . If  $X \in \Gamma(D, g_D)^{\times}$  defines a quasi-pinning of  $G$  relative to  $(B, T)$  (3.9), then  $Y = -X^{-1} \in \Gamma(D, (g_D)^{\vee})^{\times}$  defines a quasi-pinning of  $G$  relative to  $(B^{\{-\}}, T)$ ; one says

that this is the *opposite quasi-pinning*.

If  $R$  is a pinned reduced root datum and if  $E$  is an  $R$ -pinning of the  $S$ -reductive group  $G$ , one defines an  $R$ -pinning  $E^{\{-\}}$  said to be *opposite* to  $E$  in the following way: one keeps the same maximal torus  $T$ , one takes the opposite of the isomorphism  $D_S(M) \xrightarrow{\sim} T$ , and one "pins" by  $Y_{\alpha} = -X_{-1}_{\alpha} \in \Gamma(S, g^{-\alpha}^{\times})$ , for  $\alpha \in \Delta$ . The quasi-pinning underlying  $E^{\{-\}}$  is the quasi-pinning opposite to the quasi-pinning underlying  $E$ .

**Remark.** In the notation of Exp. XIX, 3.1, if one sets

$w_{\alpha}(X_{\alpha}) = \exp(X_{\alpha}) \exp(-X_{\alpha}^{-1}) \exp(X_{\alpha}),$

one has  $w_{\alpha}(X_{\alpha}) = w_{-\alpha}(Y_{\alpha})$  (loc. cit., 3.1 (vi)).

<!-- original page 241 -->

**Proposition 3.16.2.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group.\*

(i) Let  $T$  be a maximal torus of  $G$ ; there exists a unique\*

$i_T \in (\text{Aut}_{S\text{-gr.}}(G, T) / T_{\text{ad}}(S)) \subset \text{Aut}_{S\text{-gr.}}(T)$

such that  $i_T(t) = t^{-1}$  for every section  $t$  of  $T$ .\*

(ii) Let  $(B, T)$  be a Killing couple of  $G$ ; there exists a unique section\*

$w_{\{B, T\}} \in (\text{Norm}_G(T) / T)(S) = W_G(T)(S)$

such that  $\text{int}(w_{\{B, T\}})(B) = B^{\{-\}}$  (with the obvious abuse of language).\*

(iii) Let  $Q = (B, T, X)$  be a quasi-pinning of  $G$ ,  $Q^{\{-\}} = (B^{\{-\}}, T, Y)$  the opposite quasi-pinning; there exists a unique inner automorphism of  $G$ \*

$n_Q \in \text{Norm}_{\text{ad}}(G)(T_{\text{ad}})(S) \subset \text{Aut}_{S\text{-gr.}}(G)$

such that  $n_Q(Q) = Q^{\{-\}}$ , that is,  $n_Q(T) = T$ ,  $n_Q(B) = B^{\{-\}}$ ,  $n_Q(X) = Y$ .\*

(iv) Let  $(R, E)$  be a pinning of  $G$ ,  $(R, E^{\{-\}})$  the opposite pinning; there exists a unique automorphism of  $G$ \*

$u_E \in \text{Aut}_{S\text{-gr.}}(G, T) \subset \text{Aut}_{S\text{-gr.}}(G)$

such that  $u_E(E) = E^{\{-\}}$ , i.e.  $u_E(t) = t^{-1}$  for every section  $t$  of  $T$ , and  $\text{Ad}(u_E) X_{\alpha} = Y_{\alpha}$  for every  $\alpha \in \Delta$ .\*

<!-- label: III.XXIV.3.16.2 -->

**Proof.** (ii) follows from Exp. XXII, 5.5.5 (ii), then (iii) follows from 3.10, and (iv) follows from Exp. XXIII, 4.1. Finally to prove (i), one may assume  $G$  pinned. Existence follows from (iv) for example, uniqueness from the fact that an automorphism of  $G$  inducing the identity on  $T$  is given by a section of  $T_{\text{ad}}$  (2.11).

**Corollary 3.16.3.** One has\*

$i_T^2 = w_{\{B, T\}}^2 = n_Q^2 = u_E^2 = e.$

\*Moreover,  $i_T$  (resp.  $u_E$ ) is  $\neq e$  if  $G \neq e$ , and  $w_{B, T}$  (resp.  $n_Q$ ) is  $\neq e$  if  $G$  is not a torus.\*

<!-- label: III.XXIV.3.16.3 -->

\*\*Corollary 3.16.4.\*\* \*In the situation of (iii) (resp. (iv)),  $n_Q$  projects onto  $w_{B, T}$  (resp.  $u_E$ ) projects onto  $i_T$ ) by the canonical morphism\*

$$\text{Norm}_{\text{ad}(G)(T_{\text{ad}})} \rightarrow W_{\text{ad}(G)(T_{\text{ad}})} \simeq W_G(T),$$

\*resp.\*

```text  
 $\text{Aut}_{S\text{-gr.}}(G, T) \rightarrow \text{Aut}_{S\text{-gr.}}(G, T) / T_{\text{ad}}.$

<!-- label: III.XXIV.3.16.4 -->

Corollary 3.16.5. *The preceding definitions are compatible with base change, and are functorial under isomorphism (in an obvious sense).*

<!-- label: III.XXIV.3.16.5 -->

<!-- original page 242 -->

Proposition 3.16.6. *(i) One can define uniquely for each reductive group G over a scheme S an element*

$$s_G \in \text{Aut}_{\text{ext}}(G)(S)$$

in such a way that this construction is functorial in G under isomorphism, is compatible with base change, and is such that whenever T is a maximal torus of the S -reductive group G , s_G is the image of i_T under the canonical morphism

```text  
 $\text{Aut}_{S\text{-gr.}}(G, T) / T_{\text{ad}} \rightarrow \text{Aut}_{\text{ext}}(G).$

\*(ii) One has  $s_G^2 = e$ , and  $s_G$  is a central element of  $\text{Aut}_{\text{ext}}(G)$ .\*

\*(iii) Under the conditions of 3.16.2 (ii), if one identifies  $\text{Aut}_{S\text{-gr.}}(G, B, T) / T_{\text{ad}}$  with  $\text{Aut}_{\text{ext}}(G)$  (2.2), one has\*

```text  
 $w_{B, T} i_T = i_T w_{B, T} = s_G.$

(iv) Under the conditions of 3.16.2 (iv), if one identifies $\text{Aut}_{S\text{-gr.}}^{\text{p}}(G, R, E)$ with $\text{Aut}_{\text{ext}}(G)$ (1.3 (iii)), one has

```text  
 $n_E u_E = u_E n_E = s_G.$

<!-- label: III.XXIV.3.16.6 -->

\*Proof.\* (i) is proved without difficulty by descent. On the other hand, since  $i_T$  is evidently a central section of square  $e$  in  $\text{Aut}_{S\text{-gr.}}(T)$ , (ii) follows immediately; (iii) is a consequence of (iv) by descent. Finally, under the conditions of (iv), it is clear that  $n_E u_E = u_E n_E$  and that this automorphism of  $G$  respects the pinning; modulo the identification made, it is therefore equal to its image in  $\text{Aut}_{\text{ext}}(G)$ ; but  $n_E$  is inner and  $u_E$  projects onto  $s_G$ .

**Remark 3.16.7.** (i) One determines  $s_G$  explicitly in each case of the classification thanks to (iii): for each irreducible pinned root datum it suffices to compose the symmetry through the origin with the symmetry in the Weyl group (i.e. the element  $w_0$  of the Weyl group such that  $w_0(\Delta) = -\Delta$ ). One finds the following results: one has  $s_G = e$  except for  $A_n$  ( $n \geq 2$ ),  $D_n$  ( $n$  odd) and  $E_6$ , in which case  $s_G$  is the unique non-trivial "outer automorphism".

(ii) The automorphism  $u_E$  is the one used to construct "the compact real forms" in the theory of semisimple Lie algebras.

<!-- label: III.XXIV.3.16.7 -->

<!-- original page 243 -->

**Remark 3.16.8.** We defined in 3.16.1 an involution in the  $S$ -scheme  $Q = \text{Isomint}(G_{q-\acute{e}p}, G)$  of quasi-pinnings of  $G$  (cf. 3.12.1); by transport of structure from  $G_{q-\acute{e}p}$  to  $G$ , one sees at once that this involution is given by the action of an element of  $\text{ad}(G_{q-\acute{e}p})(S)$ : the element  $n_0$  defined (3.16.2 (iii)) by the canonical quasi-pinning of  $G_{q-\acute{e}p}$ .

In the same way, one has defined an involution in the  $S$ -scheme

$$P = \text{Isom}_{\{S\text{-gr.}\}(\acute{e}p_S(R), G)$$

of  $R$ -pinnings of  $G$  (cf. 1.20). Arguing as before, one sees that this involution is given by the action of the automorphism  $u_0$  of  $\acute{e}p_S(R)$  defined (3.16.2 (iv)) by the canonical pinning of  $\acute{e}p_S(R)$ .

<!-- label: III.XXIV.3.16.8 -->

**4. Isotriviality of reductive groups and of principal bundles under reductive groups**

<!-- label: III.XXIV.4 -->

**4.1. Definitions. Isotriviality theorem**

<!-- label: III.XXIV.4.1 -->

**Definition 4.1.1.** Let  $S$  be a scheme,  $G$  an  $S$ -group scheme,  $P$  a principal homogeneous bundle under  $G$ . One says that  $P$  is locally isotrivial (resp. semi-locally isotrivial) if for every point  $s \in S$  (resp. every finite set  $F$  of points of  $S$  contained in an affine open set) there exist an open set  $U$  of  $S$  containing  $s$  (resp.  $F$ ) and a finite surjective étale morphism  $S' \rightarrow U$  such that  $P_{S'}$  is trivial.

<!-- label: III.XXIV.4.1.1 -->

**Definition 4.1.2.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group. One says that  $G$  is locally isotrivial (resp. semi-locally isotrivial) if for every point  $s \in S$  (resp. every finite set  $F$  of points of  $S$  contained in an affine open set) there exist an open set  $U$  of  $S$  containing  $s$  (resp.  $F$ ) and a finite surjective étale morphism  $S' \rightarrow U$  such that  $G_{S'}$  is splittable.

<!-- label: III.XXIV.4.1.2 -->

**Remark 4.1.3.** (i) The equivalence of categories 4.1.1 of 1.17 respects by definition local (resp. semi-local) isotriviality.

<!-- original page 244 -->

(ii) Add to the conditions of 4.1.1:  $G$  locally of finite presentation over  $S$ . Then the principal bundle  $P$  (or the reductive group  $G$ ) is locally isotrivial (resp. semi-locally isotrivial) if and only if for every  $S' \rightarrow S$ ,  $S'$  local (resp. semi-local),  $P_{S'}$  is isotrivial (or  $G_{S'}$  isotrivial), that is to say, if there exists  $S'' \rightarrow S'$  finite surjective étale such that  $P_{S''}$  is trivial (or  $G_{S''}$  split).

(iii) In the case of tori, definition 4.1.2 coincides with that of Exp. IX, 1.1.

<!-- label: III.XXIV.4.1.3 -->

### 4.1.4.

<!-- label: III.XXIV.4.1.4 -->

Recall (Exp. XXII, 4.3 and 6.2) that for every reductive group  $G$ , we have introduced the groups  $\text{rad}(G)$ ,  $\text{corad}(G)$  and  $\text{d}\text{rad}(G)$ . The groups  $\text{rad}(G)$  and  $\text{corad}(G)$  are tori, which are split when  $G$  is split; moreover, there exists an isogeny  $\text{rad}(G) \rightarrow \text{corad}(G)$ . The  $G$ -group  $\text{d}\text{rad}(G)$  is semisimple, one has  $G / \text{d}\text{rad}(G) = \text{corad}(G)$ ; it follows that for every principal homogeneous bundle  $P$  under  $G$ ,  $P / \text{d}\text{rad}(G)$  is a principal homogeneous bundle under  $\text{corad}(G)$ . This said, one has:

**Theorem 4.1.5.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group of constant type.\*

(i) The following conditions are equivalent:

(a)  $G$  is locally (resp. semi-locally) isotrivial.

(b) The torus  $\text{rad}(G)$  is.

(b') The torus  $\text{corad}(G)$  is.

(c) The Galois covering of  $S$  associated to  $G$  (3.11) is.

If  $T$  is a maximal torus of  $G$ , these conditions are also equivalent to

(d) The torus  $T$  is locally (resp. semi-locally) isotrivial.

(ii) Let  $P$  be a principal homogeneous bundle under  $G$ ; for  $P$  to be locally (resp. semi-locally) isotrivial, it is necessary and sufficient that the  $\text{corad}(G)$ -principal bundle  $P / \text{d}\text{rad}(G)$  be so.

<!-- label: III.XXIV.4.1.5 -->

**Corollary 4.1.6.** \*The conditions of (i) are satisfied when  $G$  is semisimple or when  $S$  is locally noetherian and normal (or more generally geometrically unibranch). The conditions of (ii) are satisfied when  $G$  is locally (resp. semi-locally) isotrivial.\*

<!-- label: III.XXIV.4.1.6 -->

For (i), the first assertion is trivial from (b), the second follows from (c) and Exp. X, 5.14 and 5.15. For (ii), it suffices to note that by virtue of theorem 90, a principal bundle under a split torus is semi-locally isotrivial.

### 4.2. Proof: the semisimple case

<!-- label: III.XXIV.4.2 -->

Let us first prove, for later reference:

**Proposition 4.2.1.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$  (resp.  $B$  a Borel subgroup, resp.  $B \supset T$  a Killing couple of  $G$ ),  $P$  a principal homogeneous bundle under  $G$ ,  $G'$  the twisted form of  $G$  associated to  $P$  (via the morphism  $\text{int} : G \rightarrow \text{Aut}_{S\text{-gr.}}(G)$ ). One has canonical isomorphisms\*

$$P / \text{Norm}_G(T) \cong \text{Tor}(G'), \quad P / B \cong \text{Bor}(G'), \quad P / T \cong \text{Kil}(G').$$

<!-- label: III.XXIV.4.2.1 -->

<!-- original page 245 -->

By construction,  $G'$  is the quotient of  $P \times_S G$  by a certain action of  $G$  ( $(p, g) \sim (pg, g^{-1}g'g)$ ); one therefore has a morphism  $P \times_S G \rightarrow G'$ , that is, a morphism

$$P \rightarrow \text{Hom}_S(G, G'),$$

\$\$

which, as one sees at once, factors through a morphism

```
```text
f : P → Isom_{S-gr.}(G, G'),
```
```

(to verify this assertion, one may assume  $G = P$ , in which case one has  $G' = G$ ,  $f = \text{id}$ ). The set-theoretic map  $\varphi \mapsto f(\varphi)(T)$  defines a morphism

\$\$  
P \rightarrow \text{Tor}(G').  
\$\$

To verify that this morphism induces an isomorphism  $P / \text{Norm}_G(T) \xrightarrow{\sim} \text{Tor}(G')$  as announced, one may again assume  $P = G$  in which case one is reduced to Exp. XXII, 5.8.3 (iii). (In fact, \*loc. cit.\* should be replaced by the statement above.) One argues similarly for  $\text{Bor}$  and  $\text{Kil}$ .

**Proposition 4.2.2.** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -semisimple group of constant type.\*

(i)  $G$  is isotrivial.\*

(ii) Every principal bundle under  $G$  is isotrivial.\*

<!-- label: III.XXIV.4.2.2 -->

Let us prove (i). Up to making a finite surjective étale extension of the base, one may, by 3.9.2, assume  $G$  quasi-split. But then  $G$  is isotrivial by construction (3.11, the group  $E$  being finite). To prove (ii), one may, by (i), assume  $G$  split; one is then reduced to:

**Lemma 4.2.3.** \*Let  $S$  be a semi-local scheme. Every principal bundle under a split reductive group is isotrivial.\*

<!-- label: III.XXIV.4.2.3 -->

Indeed, with the notation of 4.2.1, where  $B \supset T$  denotes the canonical Killing couple of the split  $G$ , the  $S$ -scheme  $\text{Kil}(G)$  possesses a section, after finite surjective étale extension of the base, by 3.9.2. One may therefore reduce the structure group of  $G$  to  $T$ ; but  $T$  is split, so  $H^1(S, T) = 0$  (theorem 90).

**Corollary 4.2.4.** \*Let  $S$  be a scheme and\*

\$\$  
1 \rightarrow G \rightarrow G' \rightarrow G'' \rightarrow 1  
\$\$

\*an exact sequence of  $S$ -group schemes (for  $(\text{fpqc})$ ),  $G$  being semisimple of constant type. Let  $P$  be a principal homogeneous bundle under  $G$ , suppose the sheaf  $[^{\text{N.D.E-XXIV-24}} P / G]$  associated representable (for example  $G$  affine over  $S$ ). For  $P$  to be locally isotrivial (resp. semi-locally isotrivial), it is necessary and sufficient that  $P / G$  be so (as bundle under  $G''$ ).\*

<!-- label: III.XXIV.4.2.4 -->

<!-- original page 246 -->

If  $P$  is trivial,  $P / G$  is too, which shows that the condition is necessary. Conversely, suppose  $S$  local (resp. semi-local) and  $P / G$  isotrivial, so trivialized by a finite surjective étale extension  $S'$  of  $S$ . Extending the base to  $S'$ , one may reduce the structure group of  $P_{S'}$  to  $G_{S'}$ . But  $S'$  is still semi-local and  $G_{S'}$  semisimple of constant type, so the obtained bundle is isotrivial (4.2.2).

### 4.3. Proof: general case.

<!-- label: III.XXIV.4.3 -->

Let us first note that 4.1.5 (ii) follows at once from the application of 4.2.4 to the exact sequence

$$1 \rightarrow \mathrm{d}\mathrm{r}(G) \rightarrow G \rightarrow \mathrm{corad}(G) \rightarrow 1.$$

Let us therefore prove (i). If  $G$  is split,  $\mathrm{rad}(G)$  and  $\mathrm{corad}(G)$  are split, as is  $\mathrm{rev}(G)$ ; so (a) implies (b), (b'), and (c).

### 4.3.1.

<!-- label: III.XXIV.4.3.1 -->

One has  $(c) \Rightarrow (a)$ . Let  $R$  be the type of  $G$ ; one has an exact sequence

$$1 \rightarrow \mathrm{ad}(\mathrm{E}_p(R)) \rightarrow A_S(R) \rightarrow E_S \rightarrow 1.$$

Applying 4.2.4 to the bundle  $P = \mathrm{Isom}_S(\mathrm{E}_p(R), G)$  and to the associated bundle  $\mathrm{rev}(G) = P / \mathrm{ad}(\mathrm{E}_p(R))$ , one has  $(c) \Rightarrow (a)$ .

### 4.3.2.

<!-- label: III.XXIV.4.3.2 -->

One has  $(b) \Rightarrow (a)$ . It suffices to prove that if  $\mathrm{rad}(G)$  is split,  $G$  is semi-locally isotrivial. Now let  $G_0 = \mathrm{E}_p(R)$ ; consider the category of pairs  $(G, f)$ , where  $G$  is a form of  $G_0$  and  $f$  is an isomorphism of  $\mathrm{rad}(G_0)$  onto  $\mathrm{rad}(G)$ .

One knows (2.16) that this category is equivalent to the category of principal homogeneous bundles under a certain  $S$ -group  $H$  extension of a finite twisted constant group by a semisimple group. It suffices to prove that every principal bundle under  $H$  is semi-locally isotrivial; this follows at once from 4.2.4.

### 4.3.3.

<!-- label: III.XXIV.4.3.3 -->

One has  $(b') \Rightarrow (a)$ . One can argue as previously (it will moreover be the same group  $H$  that arises). One can also see that (b) and (b') are equivalent: a torus isogenous to a locally split torus is also locally split (cf. Exp. IX, 2.11 (iii)).

### 4.3.4.

<!-- label: III.XXIV.4.3.4 -->

One has  $(d) \Rightarrow (a)$ . It suffices to prove that a group of constant type possessing a split maximal torus is semi-locally isotrivial; this follows at once from 2.14.

### 4.3.5.

<!-- label: III.XXIV.4.3.5 -->

One has  $(a) \Rightarrow (d)$ . It suffices to prove that a maximal torus of a split group is semi-locally isotrivial. More precisely:

**\*Lemma 4.3.6.\*** Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $T_0$  a split maximal torus of  $G$ ,  $W_0 = \mathrm{Norm}_G(T_0) / T_0$  (this is a locally constant  $S$ -group, constant if  $G$  is of constant type, by 2.14),  $T$  a maximal torus of  $G$ .

There exists a morphism  $S' \rightarrow S$  which is principal homogeneous under  $W_0$  (hence étale finite and surjective, and even principal Galois if  $G$  is of constant type) such that  $T_{S'}$  is conjugate to  $(T_0)_{S'}$  by an element of  $G(S')$  (and so in particular split).

<!-- label: III.XXIV.4.3.6 -->

<!-- original page 247 -->

Indeed, one knows that  $\text{Transp}_{\{G\}}(T_{\{0\}}, T)$  is a principal homogeneous bundle under  $\text{Norm}_{\{G\}}(T_{\{0\}})$  (cf. for example Exp. XI, 5.4 bis). Set  $S' = \text{Transp}_{\{G\}}(T_{\{0\}}, T) / T_{\{0\}}$ ; this is a principal homogeneous bundle under  $W_{\{0\}}$ . Extending the base from  $S$  to  $S'$ , one can reduce the structure group of  $\text{Transp}_{\{G\}}(T_{\{0\}}, T)$  to  $T_{\{0\}}$ . Now  $S'$  is semi-local and  $T_{\{0\}}$  split, so  $\text{Transp}_{\{G\}}(T_{\{0\}}, T)$  possesses a section over  $S'$ . [N.D.E-XXIV-25] QED

### 4.4. Use of the existence of maximal tori

<!-- label: III.XXIV.4.4 -->

Using Grothendieck's existence theorem for maximal tori (Exp. XIV, 3.20), one can considerably sharpen the preceding results. Let us state at once:

**Theorem 4.4.1.** \*Let  $S$  be a semi-local scheme,  $R$  a pinned reduced root datum,  $W$  its Weyl group,  $E$  the group of its automorphisms. (Recall that  $E$  operates naturally on  $W$  and that the semi-direct product  $A = W \cdot E$  is identified with the group of automorphisms of  $R$  non-pinned, cf. Exp. XXI, 6.7.2).\*

(i) Every principal homogeneous bundle under  $\text{acute}\{E\}_p(S)(R)$  is trivialized by a principal Galois covering  $S' \rightarrow S$  of group  $W$ .\*

(ii) Let  $G$  be an  $S$ -reductive group of type  $R$ ; let  $\text{rev}(G) = \text{Isomext}(\text{acute}\{E\}_p(S)(R), G)$  be the associated Galois covering of  $S$  with group  $E$ . Let  $W_0$  be the form of  $W_S$  associated to  $\text{rev}(G)$ . There exists a morphism  $S' \rightarrow S$ , which is a principal homogeneous bundle under  $W_0$ , such that  $G_{S'}$  is quasi-splittable (i.e. possesses a Borel subgroup).\*

(iii) Every  $S$ -reductive group of type  $R$  is split by a principal Galois covering  $\tilde{S} \rightarrow S$  with group  $A$ .\*

<!-- label: III.XXIV.4.4.1 -->

Let us first state:

**Proposition 4.4.2.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ ,  $P$  a principal homogeneous bundle under  $G$ ,  $G'$  the twisted form of  $G$  associated to  $P$  (one then has, cf. 4.2.1, a canonical isomorphism  $P / \text{Norm}_{\{G\}}(T) \xrightarrow{\sim} \text{Tor}(G')$ ). Let  $T'$  be a maximal torus of  $G'$ , defining a composite morphism\*

$$S \rightarrow \text{Tor}(G') \square P / \text{Norm}_G(T).$$

\*Consider the canonical morphisms\*

$$P \rightarrow P/T \rightarrow P / \text{Norm}_G(T)$$

\*and take their inverse images by the preceding morphism:\*

$$\begin{array}{ccccc} P & \rightarrow & P/T & \rightarrow & P / \text{Norm}_G(T) \\ \uparrow & & \uparrow & & \uparrow \\ H & \rightarrow & S' & \rightarrow & S. \end{array}$$

<!-- original page 248 -->

\*Then  $S'$  (resp.  $H$ ) is a principal homogeneous bundle over  $S$  (resp.  $S'$ ) under  $W_{\{G\}}(T)$  (resp.  $T_{\{S'\}}$ ). Moreover, if one makes  $W_{\{G\}}(T)$  operate on  $T$  in the obvious way, the bundle associated to  $S'$  is isomorphic to  $T'$ .\*

<!-- label: III.XXIV.4.4.2 -->

The first two assertions are trivial, the last is proved like the corresponding assertion of 2.6.

**Corollary 4.4.3.** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ . Suppose

one of the two following conditions is satisfied:\*

\*(i)  $T_S$  is split.\*

\*(ii)  $T_S$  is contained in a Borel subgroup of  $G_S$ , and  $G_S$  is either adjoint, or simply connected.\*

\*Let moreover  $P_S$  be a principal homogeneous bundle under  $G_S$ . There exists an  $S$ -scheme  $S'$ , which is a principal homogeneous bundle under  $W_G(T_S)$ , such that  $P_{S'}$  is trivial.\*

<!-- label: III.XXIV.4.4.3 -->

Indeed, if  $G'$  is the form of  $G_S$  associated to  $P_S$ , then  $G'$  possesses a maximal torus  $T'$  (Exp. XIV, 3.20). Resuming the notation of the preceding proposition, one sees that  $H^1(S', T_{S'}) = 0$  (by theorem 90 for (i), by 3.14 for (ii)). The morphism  $H \rightarrow S'$  possesses a section, so  $P_{S'}$  also possesses a section over  $S'$ . QED

Let us now prove the theorem. Assertion (i) is a particular case of the preceding corollary (take  $G = \text{acute}\{E\}_p(S)(R)$ , endowed with its canonical split torus). Let us prove (ii). One knows (3.12) that  $G_S$  is an inner twisted form of

$G_0 = Q \cdot \text{acute}\{E\}_p(\text{rev}(G)/S)(R)$ .

If  $T_0$  is the canonical maximal torus of  $G_0$ ,  $W_{G_0}(T_0)$  is the group  $W_0$  described in the statement. The form  $G_S$  of  $G_0$  corresponds to a principal homogeneous bundle  $P_S$  under  $\text{ad}(G_0)$  ( $P = \text{Isomint}(G_0, G)$ ). The group  $W_{\text{ad}(G_0)}(T^{\text{ad}}_0)$  is canonically isomorphic to  $W_0$ , and one obtains the wanted result by applying 4.4.3 to the situation  $(\text{ad}(G_0), T^{\text{ad}}_0, P)$ , hypothesis (ii) of 4.4.3 being well verified. Let us finally prove (iii). Resume the notation of (ii); one has a diagram

```

```text
      rev(G)
      ^   ^
    E_S   W_0
      ^   ^
      S'
```

```

<!-- original page 249 -->

One knows that  $G_{S'}$  is isomorphic to  $(G_0)_{S'}$  and that  $(G_0)_{\text{rev}(G)}$  is splittable. If one sets  $\tilde{S} = S' \times_S \text{rev}(G)$ ,  $G_{\tilde{S}}$  is splittable, and it only remains to verify that  $\tilde{S}$  is indeed a principal Galois covering of  $S$  with group  $A$ , which follows from the following more general lemma (naturally valid in any site):

**Lemma 4.4.4.** \*Let  $S$  be a scheme,  $G_S$  and  $H_S$  two  $S$ -group schemes,  $G \rightarrow \text{Aut}_{S\text{-gr.}}(H)$  an action of  $G_S$  on  $H_S$ ,  $E_S$  a  $G_S$ -principal homogeneous bundle,  $F_S$  an  $H_0$ -principal homogeneous bundle, where  $H_0$  is the form of  $H_S$  associated to  $E_S$ . Then  $E \times_S F$  is endowed naturally with a structure of principal homogeneous bundle under the semi-direct product  $H \ltimes G$ .\*

<!-- label: III.XXIV.4.4.4 -->

Write  $(e, g) \mapsto eg$  (resp.  $(f, u) \mapsto fu$ ) for the action (on the right) of  $G_S$  on  $E_S$  (resp. of  $H_0$  on  $F_S$ ). Write

```

```text
p : E x_S H -> H_0
```

```

for the canonical projection ( $H_0$  is by definition the quotient of  $E \times_S H$  by  $G_S$  acting on it by the formula  $(e, h)g = (eg, g^{-1}h)$ ). Consider the morphism

```

```text
r : E x_S F x_S H x_S G -> E x_S F
```

```

defined set-theoretically by

```
```text
r(e, f, h, g) = (eg, f · p(e, h)).
```
```

The morphism  $r$  indeed defines an action of the semi-direct product  $H \cdot G$  on  $E \times_S F$ . Indeed, one has set-theoretically

```
```text
r(r(e, f, h, g), h', g') = (egg', f p(e, h) p(eg, h'));
```
```

but

```
```text
p(e, h) p(eg, h') = p(e, h) p(e, g h' g^{-1}) = p(e, h g h' g^{-1}),
```
```

whence

```
```text
r(r(e, f, h, g), h', g') = r(e, f, h g h' g^{-1}, g g'),
```
```

which had to be proved.

To prove now that this law is indeed a law of principal homogeneous bundle, one may assume that  $E$  and  $F$  are trivial, in which case one sees at once that  $E \times_S F$  is also a trivial bundle.

### 4.5. Isotriviality of maximal tori of semisimple groups<sup>N.D.E-XXIV-26</sup>

<!-- label: III.XXIV.4.5 -->

Let us bring out here the following result, contained implicitly in 2.6 (cf. the N.D.E. (13)) and which was mentioned at the end of Exp. IX 1.2. Recall (XXIII 5.11) that, for every scheme  $S$  and every reduced root datum  $R$ , one writes  $\acute{e}p_S(R)$  for the unique pinned  $S$ -group of type  $R$  (which exists by Exp. XXV) and  $T_S(R)$  its canonical maximal torus.

**Proposition 4.5.1.** \*Let  $G$  be an  $S$ -semisimple group of constant type  $R$ ; assume that  $G$  possesses a maximal torus  $T$  (which is the case if  $S$  is semi-local, by XIV 3.20).\*

**(i)** Then  $P = \text{Isom}_{S\text{-gr.}}(\acute{e}p_S(R), T_S(R)) / T_S(R)_{\text{ad}}$  is a principal  $S$ -bundle under the finite group  $\text{Aut}(R)$ , and  $T_P$  is a split maximal torus of  $G_P$ . Consequently,  $T$  is isotrivial.\*

**(ii)** Moreover, for every finite set  $F$  of points of  $P$  contained in an affine open set, there exists an open set  $U$  of  $S$  containing  $F$  such that  $G_U$  is split.\*

<!-- label: III.XXIV.4.5.1 -->

<!-- original page 250 -->

**Proof.** \* The exact sequence

```
```text
1 → T_S(R)_{ad} → Aut_{S-gr.}(Ép_S(R), T_S(R)) → Aut_{S-gr.}(T_S(R))
```
```

induces for every  $S' \rightarrow S$  a morphism of bundles  $P_{S'} \rightarrow \text{Isom}_{S'\text{-gr.}}(T_{S'}(R), T_{S'}(R))$ , so if  $P_{S'}$  possesses a section, then  $T_{S'}(R)$  and  $T_{S'}$  are isomorphic. This is in particular the case for  $S' = P$ .

Note moreover that  $\text{Aut}_{S\text{-gr.}}(\acute{e}p_S(R), T_S(R)) / T_S(R)_{\text{ad}}$  is none other than the constant  $S$ -group  $\text{Aut}(R)_S$ , and that  $P$  is identified with the  $\text{Aut}(R)_S$ -torsor  $\text{Isom}(R, \tilde{R}(G, T))$ , where  $\tilde{R}(G, T)$  denotes the twisted root datum associated to  $(G, T)$  (cf. XXII 1.10).

Then (ii) follows from (i) and from 2.14, taking into account the fact that the  $g_{\alpha}$  ( $\alpha$  ranging over the roots of  $R$ ) are free  $U$ -modules of rank 1 on a sufficiently small affine open set  $U$  containing  $F$ .

## 5. Canonical decomposition of an adjoint or simply connected group

<!-- label: III.XXIV.5 -->

In this section, we shall use the results of no 1 to generalize to the case of schemes a classical decomposition of adjoint (resp. simply connected) groups. So as not to overburden the exposition indefinitely, the proofs are sketched and the details are left to the reader; in fact it is always a matter of absolutely standard proofs in the theory of principal bundles: reduction of the structure group, twisting, etc.

### 5.1.

<!-- label: III.XXIV.5.1 -->

Recall (Exp. XXI, 7.4) that a Dynkin diagram is a disjoint union of its connected components, which are Dynkin diagrams. Moreover, every non-empty connected Dynkin diagram corresponding to a root datum is isomorphic to one of the standard diagrams ( $A_n$ ,  $B_n$ , ...,  $G_2$ ) which were exhibited in Exp. XXI, 7.4.6. In the sequel, we shall be interested only in Dynkin diagrams whose connected components are of one of the preceding types. Let  $T$  be the set of these standard diagrams. For every Dynkin diagram  $D$ , let  $n(t) = n_D(t)$  be the number of connected components of  $D$  isomorphic to  $t$ , where  $t \in T$ . The \*type\* of  $D$  is by definition  $\sum_{t \in T} n_D(t) \cdot t$ .

A Dynkin diagram of type  $t$  is said to be \*simple of type  $t$ \*, a Dynkin diagram of type  $n \cdot t$  is said to be \*isotypic of type  $t$ \*. Let  $D_0$  be the set of connected components of  $D$  and let

$a : D_0 \rightarrow T$

be the obvious map. The type of  $D$  is none other than  $\sum_{x \in D_0} a(x)$ .

### 5.2.

<!-- label: III.XXIV.5.2 -->

Let  $S$  be a scheme,  $D$  an  $S$ -Dynkin scheme (verifying the restrictive condition stated above). The cokernel of the pair of morphisms  $L \rightarrow D$  ( $L = \wedge^N D.E-XXIV-27$  scheme of bonds of  $D$ ) is written  $D_0$ . This is the "scheme of connected components" of  $D$  (it

<!-- original page 251 -->

exists trivially when  $D$  is constant; the general case is deduced from this by descent); it is a finite twisted constant  $S$ -scheme. One has a canonical morphism

$a : D_0 \rightarrow T$ .

For  $t \in T$ , set  $a^{-1}(t) = D_{0,t}$ ; this is a subscheme of  $D_0$ , whose inverse image in  $D$ , written  $D_t$ , is the \*isotypic component of type  $t$ \* of the Dynkin scheme  $D$ . Each  $D_t$  is a subscheme of  $D$ , and one has

$$D = \coprod_{t \in T} D_t.$$

Note that the degree of  $D_{0,t}$  at  $s \in S$  is  $n(s, t)$ , if the type of  $D$  at  $s$  is  $\sum_t n(s, t) \cdot t$ .

### 5.3.

<!-- label: III.XXIV.5.3 -->

In what follows, we shall consider only semisimple adjoint (resp. simply connected) groups. To simplify the language, we shall state the results for adjoint groups; all statements will remain valid if one substitutes everywhere "simply

connected" for "adjoint".

Recall that an adjoint reduced root datum is determined up to isomorphism by the type of its Dynkin diagrams. We shall therefore say that an adjoint root datum  $R$  (resp. a semisimple adjoint group  $G$ ) is \*of type  $\sum n(t) \cdot t$ \* if its Dynkin diagrams are (resp. if its type is given by an adjoint root datum of type  $\sum n(t) \cdot t$ ). We shall say that  $R$  or  $G$  is \*simple of type  $t$ \* (resp. \*isotypic of type  $t$ \*) if its type is  $t$  (resp.  $n \cdot t$ ,  $n > 0$ ).

If  $G$  is a semisimple adjoint group, we shall use the symbols  $\text{Dyn}_{\{0\}}(G)$  and  $\text{Dyn}_{\{0, t\}}(G)$  in the sense defined in 5.2.

### 5.4.

<!-- label: III.XXIV.5.4 -->

Let  $t_i$ ,  $i = 1, 2, \dots, n$ , be distinct elements of  $T$ , and let  $R_i$  be a pinned adjoint root datum isotypic of type  $t_i$ . Consider the product  $R = R_1 \times \dots \times R_n$  (Exp. XXI, 6.4.1). Let  $S$  be a scheme such that the different  $\acute{e}_p(R_i)$  exist (cf. Exp. XXV). One verifies at once that there exists a canonical isomorphism

$$(*) \quad \acute{e}_p(R) = \acute{e}_p(R_1) \times_S \dots \times_S \acute{e}_p(R_n).$$

<!-- original page 252 -->

Moreover, if  $E_i$  denotes the group of automorphisms of  $R_i$ ,  $E$  the group of automorphisms of  $R$ ,  $D_i$  (resp.  $D$ ) the Dynkin diagram of  $R_i$  (resp.  $R$ ), one has isomorphisms:

$$E_i \simeq \text{Aut}(D_i), \quad D = \coprod D_i, \quad E \simeq \prod E_i \simeq \text{Aut}(D).$$

Combining with  $(*)$  and 1.4, one sees that  $(*)$  induces an isomorphism

$$A_S(R) \simeq A_S(R_1) \times_S \dots \times_S A_S(R_n).$$

**Proposition 5.5.** \*Let  $S$  be a scheme,  $G$  an  $S$ -semisimple adjoint group. There exists a unique decomposition\*

$$G \simeq \prod_{t \in T} G_t,$$

where  $G_t$  is an  $S$ -semisimple adjoint group isotypic of type  $t$ . Moreover, the preceding decomposition induces isomorphisms\*

$$\text{Dyn}_t(G) \simeq \text{Dyn}(G_t), \quad \text{Aut}_{\{S\text{-gr.}\}}(G) \simeq \prod_{t \in T} \text{Aut}_{\{S\text{-gr.}\}}(G_t).$$

<!-- label: III.XXIV.5.5 -->

This has indeed been proved above when  $G$  is split. In the general case, one may assume  $G$  of constant type  $R$ . Using the preceding decomposition of  $A_S(R)$  and 1.17, one deduces the wanted decomposition of  $G$ . The other results are then proved by descent.

**Remark 5.6.** More generally, if  $G$  and  $H$  are two semisimple adjoint groups, one has canonical isomorphisms as follows (the diagram is commutative):

$$\begin{array}{ccc} \text{Isom}_{\{S\text{-gr.}\}}(G, H) & \simeq & \prod_{t \in T} \text{Isom}_{\{S\text{-gr.}\}}(G_t, H_t) \\ \downarrow & & \downarrow \\ \text{Isomext}(G, H) & \simeq & \prod_{t \in T} \text{Isomext}(G_t, H_t) \\ \square & & \square \end{array}$$

$$\begin{array}{ccc} \downarrow & & \downarrow \\ \text{Isom}_{\{\text{Dyn}\}}(\text{Dyn}(G), \text{Dyn}(H)) & \square & \prod_{\{t \in T\}} \text{Isom}_{\{\text{Dyn}\}}(\text{Dyn}(G_t), \text{Dyn}(H_t)). \end{array}$$

<!-- label: III.XXIV.5.6 -->

**Remark 5.7.** One can give an intrinsic characterization of  $G_t$ , which we state below without proof: it is the largest reductive subgroup of  $G$  invariant (and moreover characteristic) and isotypic of type  $t$ .

<!-- label: III.XXIV.5.7 -->

The preceding proposition allows one to reduce the study of semisimple adjoint groups to that of isotypic semisimple adjoint groups. It is this study that we shall now undertake.

### 5.8.

<!-- label: III.XXIV.5.8 -->

Let  $R$  be a pinned reduced adjoint simple root datum of type  $t$ ,  $I$  a nonempty finite set,  $R^I$  the product root datum of copies  $R_i$  of  $R$ , for  $i \in I$ . Write  $E$  for the group of automorphisms of  $R$ , which is identified with the group of automorphisms of the Dynkin diagram  $D$  of  $R$ . The Dynkin diagram of  $R^I$  is identified with  $D^I$ , which shows that one has an exact sequence:

$$1 \rightarrow \text{Aut}(D)^I \rightarrow \text{Aut}(D^I) \rightarrow \text{Aut}(I) \rightarrow 1,$$

where  $\text{Aut}(I)$  denotes the group of permutations of  $I$ . It follows that the canonical isomorphism

$$E_p(R)^I \simeq E_p(R^I)$$

induces an exact sequence

$$1 \rightarrow A_p(R)^I \rightarrow A_p(R^I) \rightarrow \text{Aut}(I_p) \rightarrow 1,$$

the last group being the  $E$ -constant group associated to  $\text{Aut}(I)$ . Note moreover that  $I$  is canonically identified with the set of connected components of  $D^I$ .

<!-- original page 253 -->

<!-- original page 254 -->

If  $G$  is an  $E$ -semisimple group of type  $R^I$ , defining (cf. 1.17) a principal homogeneous bundle  $P$  under  $A_p(R^I)$ , the definition of  $\text{Dyn}(G)$  by descent (3.7), and that of  $\text{Dyn}_0(G)$  (5.2), shows that the bundle associated to  $P$  by the morphism  $A_p(R^I) \rightarrow \text{Aut}(I_p)$  is none other than  $\text{Isom}(I_p, \text{Dyn}_0(G))$ , corresponding to the form  $\text{Dyn}_0(G)$  of  $I_p$ . Using again the equivalence of categories 1.17 and the preceding exact sequence, one deduces by a formal argument that there exists a  $\text{Dyn}_0(G)$ -reductive group of type  $R$ , say  $G_0$ , and an  $E$ -isomorphism  $G \simeq \prod_{\text{Dyn}_0(G)/S} G_0$ .

**Proposition 5.9.** Let  $S$  be a scheme,  $G$  an  $E$ -semisimple adjoint group isotypic of type  $t$ . There exist a  $\text{Dyn}_0(G)$ -semisimple adjoint group  $G_0$  simple of type  $t$ , and an  $E$ -isomorphism (unique)\*

$$G \simeq \prod_{\text{Dyn}_0(G)/S} G_0.$$

\*Moreover, this isomorphism induces an exact sequence\*

$$1 \rightarrow \prod_{\text{Dyn}_0(G)/S} \text{Aut}_{S\text{-gr.}}(G_0) \rightarrow \text{Aut}_{S\text{-gr.}}(G) \rightarrow \text{Aut}_S(\text{Dyn}_0(G)) \rightarrow 1.$$

<!-- label: III.XXIV.5.9 -->

One may evidently assume  $G$  of constant type  $n \cdot t$ . The first assertion has already been proved (the uniqueness assertion is evident). The second is then deduced from the split case by descent.

One can combine 5.5 and 5.9:

**Proposition 5.10.** \*Let  $S$  be a scheme,  $G$  an  $S$ -semisimple adjoint group,  $D = \text{Dyn}(G)$  its Dynkin scheme.\*

(i) There exists a canonical decomposition\*

$$G \simeq \coprod_{t \in T} \coprod_{D_{\{0, t\}}/S} G_{\{0, t\}} \simeq \coprod_{\text{Dyn}_0(G)/S} G_0,$$

where each  $G_{\{0, t\}}$  is a  $\text{Dyn}_{\{0, t\}}(G)$ -simple adjoint group of type  $t$  (resp. where  $G_0$  is a  $\text{Dyn}_0(G)$ -semisimple adjoint group whose type at  $x \in \text{Dyn}_0(G)$  is  $a(x) \in T$  (the morphism  $a : \text{Dyn}_0(G) \rightarrow T$  was defined in 5.2)).\*

(ii) The preceding decompositions induce isomorphic exact sequences (written vertically), where  $\text{Aut}_S(D_{\{0\}})$  denotes the scheme of automorphisms of  $\text{Dyn}_0(G)$  which commute with the morphism  $a : \text{Dyn}_0(G) \rightarrow T$ :

<!-- original page 255 -->

$$\begin{array}{ccc} & 1 & 1 \\ & \downarrow & \downarrow \\ \coprod_{t \in T} \coprod_{D_{\{0, t\}}/S} \text{Aut}_{\text{gr.}}(G_{\{0, t\}}) & \square & \coprod_{\text{Dyn}_0(G)/S} \text{Aut}_{\text{gr.}}(G_0) \\ & \downarrow & \downarrow \\ \text{Aut}_{\{S\text{-gr.}\}}(G) & \rightarrow & \text{Aut}_{\{S\text{-gr.}\}}(G) \\ & \downarrow & \downarrow \\ \coprod_{t \in T} \text{Aut}_S(\text{Dyn}_{\{0, t\}}(G)) & \square & \text{Aut}_S(a)(\text{Dyn}_0(G)) \\ & \downarrow & \downarrow \\ & 1 & 1 \end{array}$$

<!-- label: III.XXIV.5.10 -->

**Corollary 5.11.** \*Under the preceding conditions, the three following categories are equivalent:\*

(i) the category of principal homogeneous bundles under  $G$ .\*

(ii) the category of principal homogeneous bundles under  $G_0$ .\*

(iii) the product category, for  $t \in T$ , of the categories of principal homogeneous bundles under the  $G_{\{0, t\}}$ .\*

<!-- label: III.XXIV.5.11 -->

This is deduced formally from the preceding decompositions and from 8.4.

**Corollary 5.12.** \*One has canonical isomorphisms\*

$$\text{Tor}(G) \simeq \coprod_{t \in T} \coprod_{D_{\{0, t\}}/S} \text{Tor}(G_{\{0, t\}}) \simeq \coprod_{\text{Dyn}_0(G)/S} \text{Tor}(G_0),$$

and similarly replacing  $\text{Tor}$  by  $\text{Bor}$  (resp.  $\text{Kil}$ ).

<!-- label: III.XXIV.5.12 -->

Trivial starting from the split case.

**Remark 5.13.** The canonical morphism

\$\$  
 $\text{Dyn}(G) \rightarrow \text{Dyn}_{\{0\}}(G)$   
 \$\$

allows one to consider  $\text{Dyn}(G)$  as a  $\text{Dyn}_{\{0\}}(G)$ -Dynkin scheme; in fact it is the Dynkin scheme  $\text{Dyn}(G_{\{0\}})$  of  $G_0$ .

Similarly if  $T \subset B$  is a Killing couple of  $G$ , corresponding canonically to the Killing couple  $T_{\{0\}} \subset B_{\{0\}}$  of  $G_0$ , one verifies that the obstructions to the quasi-splitting of  $G$  and  $G_0$ , which lie (3.9) in  $\text{Pic}(\text{Dyn}(G)) = \text{Pic}(\text{Dyn}(G_0))$  coincide. One deduces:

<!-- label: III.XXIV.5.13 -->

**Corollary 5.14.** The following conditions are equivalent:

(i)  $G$  is quasi-splittable,

<!-- original page 256 -->

(ii)  $G_0$  is quasi-splittable,

(iii) each  $G_{\{0, t\}}$ ,  $t \in T$ , is quasi-splittable.

<!-- label: III.XXIV.5.14 -->

## 6. Automorphisms of Borel subgroups of reductive groups

<!-- label: III.XXIV.6 -->

**Lemma 6.1.** Let  $S$  be a scheme,  $(G, T, M, R)$  a split  $S$ -group,  $\Delta$  a system of simple roots of  $R$ , and  $B$  the corresponding Borel subgroup. Then  $B_u$  is generated as (fppf) group sheaf by the  $U_{\alpha}$ ,  $\alpha \in \Delta$ .

<!-- label: III.XXIV.6.1 -->

Let  $H$  be the group subsheaf of  $B_u$  generated by the  $U_{\alpha}$ ,  $\alpha \in \Delta$ . Let us prove  $H \supset U_{\beta}$  ( $\beta \in R^+$ ) by induction on the integer  $\text{ord}(\beta) = \text{ord}_{\Delta}(\beta) > 0$  (cf. Exp. XXI, 3.2.15). The assertion is verified by hypothesis for  $\text{ord}(\beta) = 1$ . Suppose then  $\text{ord}(\beta) > 1$  and  $U_{\gamma} \subset H$  as soon as  $\text{ord}(\gamma) < \text{ord}(\beta)$ . There exists  $\alpha \in \Delta$  such that  $\beta - \alpha \in R^+$  (Exp. XXI, 3.1.1). Let  $p$  be the largest integer such that  $\beta - p\alpha \in R$ . One has  $U_{\alpha}$ ,  $U_{\beta-p\alpha} \subset H$ ,  $\beta - p\alpha \notin R$ . One is therefore reduced to proving:

**Lemma 6.2.** Resume the notation of Exp. XXIII, 6.4. Suppose  $p = 1$ , that is,  $\beta - \alpha$  not a root. If  $H$  is a group subsheaf of  $B_u$  such that  $U_{\alpha}$ ,  $U_{\beta} \subset H$ , then  $U_{i\alpha + j\beta} \subset H$  whenever  $i\alpha + j\beta \in R$ ,  $i > 0$ ,  $j > 0$ .

<!-- label: III.XXIV.6.2 -->

Let us distinguish four cases according to the value of  $q = 0, 1, 2, 3$ . In the sequel  $x$  and  $y$  denote two arbitrary sections of  $G_{\{a, S'\}}$ ,  $S' \rightarrow S$ .

If  $q = 0$ , there is nothing to prove.

<!-- original page 257 -->

If  $q = 1$ , one has  $p_{\alpha+\beta}(\pm xy) = p_{\beta}(-y) p_{\alpha}(-x) p_{\beta}(y) p_{\alpha}(x) \in H(S')$ , so  $U_{\alpha+\beta} \subset H$ .

If  $q = 2$ , one similarly has

```text  
 $p_{\alpha+\beta}(\pm xy) p_{2\alpha+\beta}(\pm x^2y) = p_{\beta}(-y) p_{\alpha}(-x) p_{\beta}(y) p_{\alpha}(x) \in H(S'),$

whence, up to changing certain signs,

```
```text
F(x, y) = p_{\alpha+\beta}(xy) p_{2\alpha+\beta}(x^2y) \in H(S').
```

Since  $p_{\alpha+\beta}$  and  $p_{2\alpha+\beta}$  commute, one then has  
 $F(x, 1) F(1, -x) = p_{2\alpha+\beta}(x^2 - x)$ . [N.D.E-XXIV-28] If  $a \in G_a(S)$ , the equation  $X^2 - X = a$  defines a free surjective extension of  $S$  (this is  $\operatorname{Spec} 0_S[X]/(X^2 - X - a)$ ); one therefore has  $p_{2\alpha+\beta}(a) \in H(S')$  so  $U_{2\alpha+\beta} \subset H$ , hence also  $U_{\alpha+\beta} \subset H$  (since  $F(1, a) \in H(S')$ ).

If  $q = 3$ , one similarly has

```
```text
F(x, y) = p_{\alpha+\beta}(xy) p_{2\alpha+\beta}(x^2y) p_{3\alpha+\beta}(x^3y) p_{3\alpha+2\beta}(x^3y^2) \in H(S');
```

and since

```
```text
p_{3\alpha+2\beta}(\pm x) = F(1, 1)^{-1} p_{\beta}(-x) F(1, 1) p_{\beta}(x) \in H(S'),
```

one obtains that  $U_{3\alpha+2\beta} \subset H$  and so

```
```text
K(x, y) = p_{\alpha+\beta}(xy) p_{2\alpha+\beta}(x^2y) p_{3\alpha+\beta}(x^3y) \in H(S').
```

Computing then

```
```text
K(x + y, 1) K(-x, 1) K(1, y)^{-1}
```

modulo  $U_{3\alpha+2\beta}$ , one finds

```
```text
p_{2\alpha+\beta}(2x^2 + y^2 + 2xy - y) p_{3\alpha+\beta}(y^3 + 3xy^2 + 3x^2y - y) \in H(S').
```

If $a \in G_a(S)$, the "equations"

```
```text
x^2 = -xy - y + 1 - a
y^2 = 3y - 2 + 3a
```

define a free surjective extension of  $S$ ; one then has  $y^3 + 3xy^2 + 3x^2y - y = 0$  and the preceding expression gives  $p_{2\alpha+\beta}(a) \in H(S')$ . [N.D.E-XXIV-29] One has thus proved that  $H$  contains  $U_{2\alpha+\beta}$  and  $U_{3\alpha+2\beta}$  and that

<!-- original page 258 -->

```
```text
E(x, y) = p_{\alpha+\beta}(xy) p_{3\alpha+\beta}(x^3y) \in H(S').
```

Since $p_{\alpha+\beta}(xy)$ and $p_{3\alpha+\beta}$ commute, one is reduced to the preceding computation, i.e.
 $E(1, x) E(1, -x) = p_{3\alpha+\beta}(x^3 - x)$, whence $U_{3\alpha+\beta} \subset H$, then
 $U_{\alpha+\beta} \subset H$.

****Remark 6.2.1.**** The preceding proof shows that one could have replaced the hypothesis " H contains U_{α} and U_{β} " by " H contains U_{α} or U_{β} ", and H is invariant under $\operatorname{int}(U_{\alpha})$ and

$\text{int}(U_{\{\beta\}})$.

<!-- label: III.XXIV.6.2.1 -->

Theorem 6.3. *Let S be a scheme, G and G' two S -semisimple groups, B (resp. B') a Borel subgroup of G (resp. G'). Every isomorphism $B \xrightarrow{\sim} B'$ is induced by a unique isomorphism $G \xrightarrow{\sim} G'$.*

<!-- label: III.XXIV.6.3 -->

The assertion is local for the étale topology and one may assume G split: $G = (G, T, M, R)$, B being defined by the system of positive roots R^+ of R . The given isomorphism $u : B \xrightarrow{\sim} B'$ induces an isomorphism of T onto a maximal torus T' of B' , hence of G' . The given isomorphism $T \simeq D_S(M)$ gives an isomorphism $T' \simeq D_S(M)$ in which the elements of R^+ become the constant roots of B' with respect to T' , hence the elements of R the constant roots of G' with respect to T' . Since G and G' are semisimple, the coroots are determined by duality (Exp. XXI, 1.2.5), which proves that (T', M, R) is a splitting of G' such that $R(G) = R(G')$.

Applying Exp. XXIII, 5.1 (uniqueness theorem), one deduces that there exists a unique isomorphism $G \xrightarrow{\sim} G'$ coinciding with u on T and the U_{α} , $\alpha \in \Delta$. By 5.1, the restriction of this isomorphism to B is u . QED

Remark 6.3.1. (i) Using Exp. XXII, 4.1.9 and arguing as in *loc. cit.* 4.2.12, one can in the statement of the theorem replace "isomorphism" by "isogeny" (resp. "central isogeny").

(ii) The theorem is false for reductive groups. Take for example $G = G' = \text{SL}_2 \times G_m$ identified with the group of matrices below:

```

```text
{ (a b 0)
 (c d 0) : ad - bc = 1, h invertible };
 (0 0 h)
```

```

<!-- original page 259 -->

take for $B = B'$ the Borel subgroup defined by $c = 0$ and for u the automorphism of B below:
 $u(a, b, d, h) = (a, b, d, ah)$.

<!-- label: III.XXIV.6.3.1 -->

Corollary 6.4. *The functor $(G, B) \mapsto B$ from the category formed by pairs (G, B) , where G is an S -semisimple group and B a Borel subgroup of G , to the category of S -group schemes (morphisms being isomorphisms) is fully faithful.*

<!-- label: III.XXIV.6.4 -->

Corollary 6.5. *Let S be a scheme, G an S -semisimple group, B a Borel subgroup of G , B' an S -group locally isomorphic to B for (fpqc). Then B' is locally isomorphic to B for the local finite étale topology [N.D.E-XXIV-30] and there exists an S -semisimple group G' of which B' is a Borel subgroup; G' is unique up to a unique isomorphism inducing the identity on B' .*

<!-- label: III.XXIV.6.5 -->

Corollary 6.6. *Let S be a scheme, G an S -semisimple group, B a Borel subgroup of G . Then $\text{Aut}_{S\text{-gr.}}(B)$ is representable by an affine and smooth S -scheme, $\text{Aut}(B)$ is representable by an étale and finite S -scheme, and the obvious morphisms induce an isomorphism of exact sequences*

```

```text
1 → B_ad → Aut_{S-gr.}(G, B) → Aut(G) → 1
 ↓ ↓ ↓
1 → B_ad → Aut_{S-gr.}(B) → Aut(B) → 1.
```

```

<!-- label: III.XXIV.6.6 -->

This follows at once from 2.1 and from the preceding results. The reader is left the task of developing the analogues of

the results of nos 1, 2, 3, 4 in the framework above.

Remark 6.7. If S is a scheme and B an S -group, B can therefore be a Borel subgroup only of a unique semisimple group, well determined by B . It therefore remains to characterize the S -groups B that are Borel subgroups of semisimple groups. [N.D.E-XXIV-31]

<!-- label: III.XXIV.6.7 -->

<!-- original page 260 -->

7. Representability of the functors $\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H)$, for G reductive

<!-- label: III.XXIV.7 -->

7.1. The split case

<!-- label: III.XXIV.7.1 -->

7.1.1.

<!-- label: III.XXIV.7.1.1 -->

Let S be a scheme, G a pinned S -group, T its maximal torus, Δ the set of simple roots and, for $\alpha \in \Delta$,

$$u_\alpha \in U_\alpha(S), \quad w_\alpha \in \operatorname{Norm}_G(T)(S),$$

the elements defined by the pinning.

Let on the other hand H be an S -group scheme; we are interested in the functor $\operatorname{Hom}_{\{S\text{-gr.}\}}(G, H)$, and more precisely in the morphism

$$q : \operatorname{Hom}_{\{S\text{-gr.}\}}(G, H) \rightarrow \operatorname{Hom}_{\{S\text{-gr.}\}}(T, H).$$

Let then

$$f_T : T \rightarrow H$$

be a morphism of S -groups; consider $q^{-1}(f_T) = F$. This is the functor defined by

$$F(S') = \{ f \in \operatorname{Hom}_{\{S'\text{-gr.}\}}(G_{S'}, H_{S'}) \mid f = (f_T)_{S'} \text{ on } T_{S'} \}.$$

One has a morphism of S -functors

$$i : F \rightarrow H^{2n},$$

where $n = \operatorname{Card}(\Delta)$, defined set-theoretically by $i(f) = (f(u_\alpha), f(w_\alpha))_{\alpha \in \Delta}$. By Exp. XXIII, 1.9, i is moreover a monomorphism.

Proposition 7.1.2. *If H is separated over S , F is representable and i is a closed immersion.*

<!-- label: III.XXIV.7.1.2 -->

The usual technique of relative representability [N.D.E-XXIV-32] shows us that it suffices to prove that, given sections

```

```text
 $v_\alpha, h_\alpha \in H(S), \quad \text{for } \alpha \in \Delta,$

```

the  $S$ -schemes  $S'$  such that there exists an  $S'$ -homomorphism

```

 $f : G_{S'} \rightarrow H_{S'}$

```

extending  $(f_T)_{S'}$  and verifying  $f(u_\alpha) = v_\alpha$ ,  $f(w_\alpha) = h_\alpha$ , are exactly those that factor through a certain closed subscheme of  $S$ . One may evidently assume  $S$  affine.

To simplify the sequel, let us say that a morphism  $Y \rightarrow X$  of affine schemes verifies condition (L) if  $Y$  is the spectrum of an  $O(X)$ -algebra which is a free  $O(X)$ -module. It is clear that if one restricts to the category of affine schemes, a product, or a composite of morphisms verifying (L) verifies (L), and that (L) is stable under base change.

**Lemma 7.1.3.** Suppose  $S$  affine, and let  $\alpha \in \Delta$ . Consider the morphism

```

```text
 $a : T \times_S T \rightarrow G_{\alpha, S}$ 

```

defined set-theoretically by $a(t, t') = \alpha(t) + \alpha(t')$.

!-- original page 261 -->

(i) a is faithfully flat and of finite presentation.

(ii) Let R be the fibered square of a . The structure morphism $R \rightarrow S$ verifies (L).

!-- label: III.XXIV.7.1.3 -->

It is first clear that the morphism a is surjective, since $\alpha : T \rightarrow G_{\alpha, S}$ is. It is trivial that a is of finite presentation. Since α verifies (L), it suffices, to prove (i) and (ii), to show that the morphism

```

```text
 $u : G_{\alpha, S}^2 \rightarrow G_{\alpha, S}$

```

defined set-theoretically by  $u(x, y) = x + y$  verifies (L). In other words, it suffices to verify that for every ring  $A$ , the ring  $A[X, Y, X^{-1}, Y^{-1}]$  is a free module over its subring  $A[X + Y]$ . [N.D.E-XXIV-34] Now  $A[X, Y]$  is a free module with basis  $\{1, X\}$  over the subring  $B = A[X + Y, XY]$  (one has  $X^2 - (X + Y)X + XY = 0$ ), so  $A[X^{\pm 1}, Y^{\pm 1}] = A[X, Y]_{XY}$  is free over  $B_{XY} = A[X + Y, (XY)^{\pm 1}]$  with basis  $\{1, X\}$ , and free over  $A[X + Y]$  with basis the elements  $(XY)^p$  and  $X(XY)^p$ , for  $p \in \mathbb{Z}$ .

**Lemma 7.1.4.** Let  $\alpha \in \Delta$ , and let  $b : T \times_S T \rightarrow H$  be the morphism defined set-theoretically by

```

```text
 $b(t, t') = \int(f_T(t)) v_\alpha \cdot \int(f_T(t')) v_\alpha.$ 

```

Let $f_\alpha : U_\alpha \rightarrow H$ be an S -morphism. The following conditions are equivalent: [N.D.E-XXIV-35]

(i) f_α is a morphism of groups; one has $f_\alpha(u_\alpha) = v_\alpha$ and

```

```text
 $f_T(t) f_\alpha(x) f_T(t)^{-1} = f_\alpha(\alpha(t) x)$

```

for all  $t \in T(S)$ ,  $x \in U_\alpha(S)$ ,  $S' \rightarrow S$ .

(ii) One has  $f_\alpha(u_\alpha) = v_\alpha$  and the relation

```

```text
f_α(a(t, t') u_α) = b(t, t')
```

```

\*for all  $t, t' \in T(S)$ ,  $S' \rightarrow S$ .\*

<!-- label: III.XXIV.7.1.4 -->

If  $f_{\alpha}$  verifies (i), one has  $f_{\alpha}(\alpha(t) u_{\alpha}) = \text{int}(f_T(t)) v_{\alpha}$ , which entails (ii) at once. Conversely, suppose (ii) verified and let us prove the various conditions of (i); let us first prove the last. Since  $S$  is covering for (fpqc), it suffices to prove that if  $t, t', t' \in T(S)$ , one has

```

```text
f_T(t) f_α(a(t', t'') u_α) f_T(t)^{-1} = f_α(α(t) a(t', t'') u_α);
```

```

<!-- original page 262 -->

now this also reads

```

```text
f_T(t) b(t', t'') f_T(t)^{-1} = b(t t', t t''),
```

```

an evident property from the definition of  $b$ . It remains to prove that  $f_{\alpha}$  is a morphism of groups. Now the preceding property gives at once

```

```text
f_α(α(t) u_α) f_α(α(t') u_α) = (f_T(t) f_α(u_α) f_T(t)^{-1}) · (f_T(t') f_α(u_α) f_T(t')^{-1})
= b(t, t') = f_α(α(t) u_α + α(t') u_α).
```

```

One therefore has  $f_{\alpha}(x + x') = f_{\alpha}(x) f_{\alpha}(x')$ , whenever  $x$  and  $x'$  are sections of the open subset  $U^{\times}_{\alpha}$  of  $U_{\alpha}$ , which is schematically dense; one concludes then by Exp. XVIII, 1.4.

### 7.1.5.

<!-- label: III.XXIV.7.1.5 -->

Let us fix provisionally an  $\alpha \in \Delta$ . The morphism  $S \rightarrow S$  is faithfully flat quasi-compact, so  $G_{\alpha, S}$  is identified with the quotient of  $T \times_S T$  by the equivalence relation  $R$  defined by  $S$ . Let

```

```text
R = \rhd_{i_1, i_2} T \times_S T
```

```

be this equivalence relation.

For the morphism  $S \rightarrow S$  to factor through  $S$ , [N.D.E-XXIV-36] it is necessary and sufficient that  $b \circ i_1 = b \circ i_2$ ; that is, if one writes  $K$  for the kernel of the pair of morphisms

```

```text
R = \rhd_{b \circ i_1, b \circ i_2} H,
```

```

it is necessary and sufficient that  $K = R$ . Now  $H$  is assumed separated over  $S$ , so  $K$  is a closed subscheme of  $R$ . Recall, on the other hand, that  $R$  is essentially free over  $S$  (7.1.3).

### 7.1.6.

<!-- label: III.XXIV.7.1.6 -->

By the foregoing, if  $S'$  is an  $S$ -scheme, for there to exist over  $S'$  an  $f_{\alpha}$  verifying the conditions of 7.1.4 (i) (and then necessarily unique), it is necessary and sufficient that  $K_{S'} = R_{S'}$ , and that the morphism

$f_{\alpha}$  obtained verify  $f_{\alpha}(u_{\alpha}) = v_{\alpha}$ .

The first condition is equivalent to the fact that  $S' \rightarrow S$  factors through a certain closed subscheme of  $S$  (Exp. VIII, 6.4[N.D.E-XXIV-37]); if one replaces  $S$  by this closed subscheme, the second condition defines once again a closed subscheme of  $S$  (equality of two sections of  $H$ , now  $H$  is assumed separated over  $S$ ).

Up to replacing  $S$  by this closed subscheme, one may therefore assume that there exists a morphism  $f_{\alpha} : U_{\alpha} \rightarrow H$  verifying the conditions of 7.1.4 (i). Taking the intersection of the subschemes of  $S$  obtained for each  $\alpha \in \Delta$ , one may assume this condition verified for every  $\alpha \in \Delta$ .

### 7.1.7.

<!-- label: III.XXIV.7.1.7 -->

Similarly, consider for each  $\alpha \in \Delta$  the two morphisms of  $S$ -groups

$$f_T \circ \text{int}(w_{\alpha}), \text{int}(h_{\alpha}) \circ f_T : T \rightarrow H.$$

Since  $H$  is separated over  $S$  and  $T$  essentially free over  $S$ , the same reasoning as previously shows that, up to replacing  $S$  by a closed subscheme, one may assume that for every  $\alpha \in \Delta$  one has

$$f_T \circ \text{int}(w_{\alpha}) = \text{int}(h_{\alpha}) \circ f_T.$$

### 7.1.8.

<!-- label: III.XXIV.7.1.8 -->

Using now the theorem of generators and relations (Exp. XXIII, 3.5), one sees that there exists a homomorphism of groups  $f : G \rightarrow H$  verifying the required conditions if and only if a certain finite set of algebraic relations between the sections  $h_{\alpha}, v_{\alpha}, f_T(\alpha^{(-1)})$  ( $\alpha \in \Delta$ ) of  $H$  is satisfied:

<!-- original page 263 -->

$$R_i(h_{\alpha}_{\alpha}, (v_{\alpha})_{\alpha}, (f_T(\alpha^{(-1)}))_{\alpha}) = e, \quad i = 1, \dots, n.$$

Since  $H$  is separated over  $S$ , this defines once again a closed subscheme of  $S$ , and one is done.

**\*Corollary 7.1.9.\*** Let  $S$  be a scheme,  $G$  a split  $S$ -reductive group,  $T$  its maximal torus,  $H$  an  $S$ -group scheme separated over  $S$ . Let further  $P$  be a property of morphisms such that:

- (i) A closed immersion verifies  $P$ .
  - (ii) The composite of two morphisms verifying  $P$  also verifies  $P$ .
  - (iii)  $P$  is stable under base change.
  - (iv) The structure morphism  $H \rightarrow S$  verifies  $P$ .
- Then the canonical morphism

$$\text{Hom}_{\{S\text{-gr.}\}}(G, H) \rightarrow \text{Hom}_{\{S\text{-gr.}\}}(T, H)$$

is relatively representable by a separated morphism verifying  $P$ . [N.D.E-XXIV-38]

<!-- label: III.XXIV.7.1.9 -->

Indeed, one may assume  $G$  pinned; the structure morphism  $H^{2n} \rightarrow S$  verifies  $P$  and one concludes by 7.1.2.

**\*\*Corollary 7.1.10.\*\*** \*Let  $S$  be a scheme,  $G$  a split  $S$ -reductive group, and  $H$  an  $S$ -group scheme smooth and with affine fibers. [N.D.E-XXIV-39] Then the functor  $\operatorname{Hom}_{S\text{-gr.}}(G, H)$  is representable by an  $S$ -scheme locally of finite presentation and separated over  $S$ .\*

<!-- label: III.XXIV.7.1.10 -->

Indeed, since  $H$  is smooth over  $S$ , one can consider its neutral component  $H^{\{0\}}$ , which has affine fibers, is smooth, separated and of finite presentation over  $S$  (Exp. VI\_B, 3.10 and 5.5). Since  $G$  has connected fibers, one may replace  $H$  by  $H^{\{0\}}$ . Since  $G$  and  $H$  are then of finite presentation, one may assume  $S$  noetherian, and one applies 7.1.9 taking for  $P$  the property "of finite type". But, by Exp. XV, 8.9, one knows that  $\operatorname{Hom}_{S\text{-gr.}}(T, H)$  is representable by a separated  $S$ -scheme locally of finite type.

**\*\*Remark 7.1.11.\*\*** If  $H$  is affine over  $S$ , one can replace the reference to Exp. XV by Exp. XI, 4.2.

<!-- label: III.XXIV.7.1.11 -->

### 7.2. General case

<!-- label: III.XXIV.7.2 -->

**\*\*Proposition 7.2.1.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ . Let on the other hand  $H$  be an  $S$ -group scheme, such that the structure morphism  $H \rightarrow S$  verifies the following condition:\*

\*(+) Each point  $s \in S$  possesses an open neighborhood  $U$  such that the morphism  $H_U \rightarrow U$  is quasi-projective.\*

\*Then the canonical morphism\*

```text  
 $\operatorname{Hom}_{S\text{-gr.}}(G, H) \rightarrow \operatorname{Hom}_{S\text{-gr.}}(T, H)$
 ```

\*is relatively representable by a morphism verifying (+).\*

<!-- label: III.XXIV.7.2.1 -->

<!-- original page 264 -->

When  $G$  is splittable relative to  $T$ , one applies 7.1.9 taking for  $P$  the property (+) above. When  $G$  is locally isotrivial, for example semisimple (4.2.2), one notes that the assertion of the theorem is local for the local finite étale topology (indeed, the property of being quasi-projective is local for the global finite étale topology and ensures the effectiveness of descent for this topology, cf. SGA 1, VIII, 7.7). Finally, in the general case, one uses the following lemma:

**\*\*Lemma 7.2.2.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $T$  a maximal torus of  $G$ ,  $G'$  the derived group of  $G$  (Exp. XXII, 6.2),  $T' = T \cap G'$  the maximal torus of  $G'$  corresponding to  $T$  (Exp. XXII, 6.2.8). Then the diagram\*

$$\begin{array}{ccc} G & \twoheadrightarrow & G' \\ \uparrow & & \uparrow \\ T & \twoheadrightarrow & T' \end{array}$$

\*is an amalgamated sum in the category of  $S$ -group sheaves: that is, for every  $S$ -group sheaf  $H$ , the following square is cartesian:\*

```text  
 $\operatorname{Hom}_{S\text{-gr.}}(G, H) \rightarrow \operatorname{Hom}_{S\text{-gr.}}(G', H)$
 $\downarrow \qquad \qquad \downarrow$
 $\operatorname{Hom}_{S\text{-gr.}}(T, H) \rightarrow \operatorname{Hom}_{S\text{-gr.}}(T', H).$
 ```

<!-- label: III.XXIV.7.2.2 -->

Indeed, if  $\text{rad}(G)$  is the radical of  $G$ , then  $\text{rad}(G) \subset T$ , so

```
```text
rad(G) ∩ G' = rad(G) ∩ T' = K,
```

and the product in G induces isogenies (Exp. XXII, 6.2)

```
```text
i : G' ×_S rad(G) → G, j : T' ×_S rad(G) → T.
```

Let  $f_{G'} : G' \rightarrow H$ ,  $f_T : T \rightarrow H$ , and  $f_{T'} : T' \rightarrow H$  be morphisms of  $S$ -groups such that  $f_{G'}|_{T'} = f_T|_{T'} = f_{T'}$ . Let us show that there exists a unique morphism of  $S$ -groups  $f : G \rightarrow H$  inducing  $f_{G'}$  and  $f_T$ . Let  $f_{\text{rad}} = f_T|_{\text{rad}(G)}$  [N.D.E-XXIV-40] and let

```
```text
f_1 = f_{G'} · f_{rad} : G' ×_S rad(G) → H.
```

For f to exist (and it will evidently be unique), it is necessary and sufficient that f_1 induce the identity on the kernel of i , that is, that $f_{G'}$ and f_{rad} coincide on K ; but the existence of f_T shows by the same argument that $f_{T'}$ and f_{rad} coincide on K . It only remains to note that $f_{G'}$ and $f_{T'}$ evidently coincide on $K \subset T$.

Arguing now as in 7.1.10, one deduces from 7.2.1:

Corollary 7.2.3. Let S be a scheme, G an S -reductive group, H an S -group scheme smooth and quasi-projective over S with affine fibers. Then $\text{Hom}_{\{S\text{-gr.}\}}(G, H)$ is representable by an S -scheme locally of finite presentation and separated over S .

<!-- label: III.XXIV.7.2.3 -->

7.3. Phenomena specific to characteristic 0

<!-- label: III.XXIV.7.3 -->

If G and H are two smooth S -groups, $\mathfrak{g}$ and $\mathfrak{h}$ their Lie algebras, one has a canonical morphism

```
```text
Lie : Hom_{S-gr.}(G, H) → Hom_{0_S\text{-Lie alg.}}(\mathfrak{g}, \mathfrak{h}),
```

where the right-hand side has an obvious definition.

<!-- original page 265 -->

**Proposition 7.3.1.** Let  $S$  be a scheme of characteristic 0 (i.e. a  $\mathbb{Q}$ -scheme),  $G$  an  $S$ -reductive group,  $H$  an  $S$ -group scheme smooth and quasi-projective over  $S$  with affine fibers.

(i)  $\text{Hom}_{\{S\text{-gr.}\}}(G, H)$  is representable by a smooth and separated  $S$ -scheme over  $S$ .

(ii) If  $G$  is semisimple, this scheme is affine and of finite presentation over  $S$ .

(iii) If  $G$  is simply connected (Exp. XXII, 4.3.3), the canonical morphism

```
```text
Lie : Hom_{S-gr.}(G, H) → Hom_{0_S\text{-Lie alg.}}(\mathfrak{g}, \mathfrak{h})
```

is an isomorphism.

<!-- label: III.XXIV.7.3.1 -->

Lemma 7.3.2. Let k be a field of characteristic 0, G a k -reductive group, V a finite-dimensional k -vector

space, $\rho: \mathrm{GL}(V) \rightarrow G$ a linear representation of G in V . One has*

```

```text

$$H^0(G, V) = H^0(\mathfrak{g}, V), \quad H^i(G, V) = 0, \quad \text{for } i > 0.$$

```

```

<!-- label: III.XXIV.7.3.2 -->

The first equality is true in general for a smooth connected group; [N.D.E-XXIV-41] in the case of a reductive group, one can prove it as follows: one may assume k algebraically closed, hence G splittable, hence G generated by subgroups isomorphic to GL_m , [N.D.E-XXIV-42] and it suffices to verify the assertion for this group, which is easy.

From this first equality it follows that $H^0(G, V)$ is an exact functor in V when G is semisimple; $\mathfrak{g}$ is indeed then a semisimple Lie algebra and one applies [BLie], § 1.6, exercise 1 (b). The assertion remains true when G is reductive; indeed, if one introduces the radical R of G [N.D.E-XXIV-43] and the quotient G/R which is semisimple, one has $H^0(G, V) = H^0(G/R, H^0(R, V))$, and $H^0(G, -)$ is composed of two exact functors. Applying then Exp. I, 5.3.1, one deduces $H^i(G, V) = 0$ for $i > 0$.

Remark 7.3.3. Under the preceding conditions, if G is semisimple, one has $H^1(\mathfrak{g}, V) = H^2(\mathfrak{g}, V) = 0$, cf. [BLie], *loc. cit.* (b) and (d).

<!-- label: III.XXIV.7.3.3 -->

7.3.4.

<!-- label: III.XXIV.7.3.4 -->

Let us now prove the proposition. Already, by 7.2.3, $\mathrm{Hom}_{\mathrm{S-gr.}}(G, H)$ is representable by an S -scheme locally of finite presentation and separated over S ; to show that it is smooth, it suffices to prove that it is infinitesimally smooth (Exp. XI, 1.8), [N.D.E-XXIV-44] which follows from Exp. III, 2.8 (i) by 7.3.2. We have thus proved (i).

Let us show that (ii) follows from (iii). It suffices first to prove that $\mathrm{Hom}_{\mathrm{S-gr.}}(G, H)$ is affine over S ; it will then be of finite presentation over S , since it is smooth over S by (i); in any case $\mathrm{Hom}_{0_S}(\text{Lie alg.})(\mathfrak{g}, \mathfrak{h})$ is representable by a closed subscheme of

```

```text

$$\mathrm{Hom}_{0_S}(\text{Lie alg.})(\mathfrak{g}, \mathfrak{h}) = W(\mathfrak{g}^V \otimes_{0_S} \mathfrak{h})$$

```

```

which is an affine S -scheme, and the desired conclusion appears when G is simply connected.

<!-- original page 266 -->

In the general case, one may assume G split, so $G \simeq \mathrm{P}_1(R)$; introducing the simply connected root datum $\mathrm{sc}(R)$ (Exp. XXI, 6.5.5), and using the existence theorem (Exp. XXV, 1.1), one constructs a simply connected S -group $\tilde{G}$ and a central isogeny $\tilde{G} \rightarrow G$. The kernel K of this isogeny is a finite diagonalizable S -group (so a twisted constant S -group, S being of characteristic 0) and $\mathrm{Hom}_{\mathrm{S-gr.}}(K, H)$ is (trivially) representable by a separated S -scheme (if $K \simeq (\mathbb{Z}/n\mathbb{Z})_S$, then $\mathrm{Hom}_{\mathrm{S-gr.}}(K, H)$ is isomorphic to $\mathrm{Ker}(H \rightarrow^n H)$). One has an exact sequence of "pointed S -schemes":

```

```text

$$1 \rightarrow \mathrm{Hom}_{\mathrm{S-gr.}}(G, H) \rightarrow \mathrm{Hom}_{\mathrm{S-gr.}}(\tilde{G}, H) \rightarrow \mathrm{Hom}_{\mathrm{S-gr.}}(K, H),$$

```

```

so ρ is a closed immersion, hence $\mathrm{Hom}_{\mathrm{S-gr.}}(G, H)$ is affine over S .

7.3.5.

<!-- label: III.XXIV.7.3.5 -->

Let us finally prove (iii). Arguing as in the proof of (i) and using 7.3.3, one can show that the S -scheme $\mathrm{Hom}_{0_S}(\text{Lie alg.})(\mathfrak{g}, \mathfrak{h})$ is smooth over S . To prove (iii), one may therefore assume

$S = \operatorname{Spec}(k)$, where k is an algebraically closed field of characteristic 0; it even suffices to prove that the morphism Lie is bijective on k -valued points and that it induces a bijection on tangent spaces at two corresponding points. Let us first show that

```
```text
Hom_{k-gr.}(G, H) → Hom_{k\text{-Lie alg.}}(g, h)
```
```

is bijective.

If $u : G \rightarrow H$ is a morphism of k -groups, the graph of u is a connected subgroup of $G \times_k H$ which is determined by its Lie algebra which is the graph of $\text{Lie}(u)$; the map is therefore injective. Conversely, if $v : g \rightarrow h$ is a morphism of Lie algebras, the graph k of v is a Lie subalgebra of $g \times h$, isomorphic to g . In particular, since g is its own derived algebra, the same is true of k and so, by a theorem of Chevalley ([Ch51], § 14, Th. 15), k is the Lie algebra of a connected subgroup K of $G \times_k H$. [N.D.E-XXIV-45] Moreover, since $k \subseteq g$ is semisimple, G is a semisimple k -group. Since

```
```text
dim(K) = dim(k) = dim(g) = dim(G)
```
```

and since $K \cap H$ is finite (because its Lie algebra is zero), the canonical morphism $\text{pr}_1 : K \rightarrow G$ is finite and dominant; since G is connected, pr_1 is surjective; it is therefore an isogeny. Since G is simply connected and K semisimple then, by Exp. XXI 6.2.7, pr_1 is an isomorphism, so K is the graph of a morphism of k -groups $u : G \rightarrow H$ such that $\text{Lie}(u) = v$.

Finally, let $u : G \rightarrow H$ be a morphism of k -groups. The tangent space to $\operatorname{Hom}_{k\text{-gr.}}(G, H)$ at u is identified with $Z^1(G, h)$ (cf. Exp. II, 4.2; G operates on h by $\text{Ad}_H \circ u$); similarly, one can prove that the tangent space to $\text{Hom}_{k\text{-Lie alg.}}(g, h)$ at $\text{Lie}(u)$ is identified with $Z^1(g, h)$. We must therefore prove that the canonical map $Z^1(G, h) \rightarrow Z^1(g, h)$ is bijective. Now one has a commutative diagram

```
```text
0 → h^G → h → Z^1(G, h) → H^1(G, h)
 ↓ ↓ ↓ ↓
0 → h^g → h → Z^1(g, h) → H^1(g, h)
```
```

and by 7.3.2 and 7.3.3 one has $h^G = h^g$ and $H^1(G, h) = 0 = H^1(g, h)$, whence the desired conclusion.

Remark 7.3.6. It is presumably the case that if S is a locally noetherian scheme, G an S -semisimple simply connected group, H an S -group scheme smooth, $\hat{G}$ and $\hat{H}$ their formal completions along the unit section, every homomorphism $\hat{G} \rightarrow \hat{H}$ comes from a unique homomorphism of G into H , which would generalize 7.3.1 (iii). When S is the spectrum of a field k and H is affine and of finite type, this follows from a theorem of Dieudonné ([Di57], § 15, th. 4). [N.D.E-XXIV-46]

<!-- label: III.XXIV.7.3.6 -->

7.4. An example

<!-- label: III.XXIV.7.4 -->

By way of example, we shall determine

```
```text
Hom_{S-gr.}(SL_2, S), SL_2(S)).
```
```

7.4.1.

<!-- label: III.XXIV.7.4.1 -->

Recall (Exp. XX, no 5) that $SL_2(S)$ is the S -group scheme formed by the matrices $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$ over S satisfying $ad - bc = 1$. A maximal torus T is defined by the monomorphism $\alpha : G_m(S) \rightarrow SL_2(S)$

S

$$\alpha^{\{*\}}(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix}.$$

\$\$

A root of G with respect to T is defined by $\alpha(\alpha^{\{*\}}(z)) = z^2$, a corresponding monomorphism

$$p : G_{\{a, S\}} \rightarrow SL_{\{2, S\}}$$

being defined by

$$p(x) = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}.$$

Finally, the representative of the Weyl group corresponding to $u = p(1)$ is

$$w = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

<!-- original page 267 -->

Recall on the other hand (Exp. XX, 6.2) that $SL_{\{2, S\}}$ is generated by T , $p(G_{\{a, S\}})$ and w , subject to the relations

$$\begin{aligned} \alpha^{\{*\}}(z) p(x) \alpha^{\{*\}}(z^{-1}) &= p(z^2 x), \\ w \alpha^{\{*\}}(z) w^{-1} &= \alpha^{\{*\}}(z^{-1}), \\ w^2 &= \alpha^{\{*\}}(-1), \\ (w u)^3 &= 1. \end{aligned}$$

7.4.2.

<!-- label: III.XXIV.7.4.2 -->

Let f be an endomorphism of $SL_{\{2, S\}}$. It defines first a homomorphism $f \circ \alpha^{\{*\}} : G_{\{m, S\}} \rightarrow SL_{\{2, S\}}$. The kernel $\text{Ker}(f \circ \alpha^{\{*\}})$ is a closed subgroup of $G_{\{m, S\}}$, hence is locally on S equal to a μ_n ($n \geq 1$) or to $G_{\{m, S\}}$. Up to restricting f , one may therefore assume that there exists an $n \in \mathbb{N}$ and a monomorphism

$$f' : G_{\{m, S\}} \rightarrow SL_{\{2, S\}}$$

such that $f \circ \alpha^{\{*\}}(z) = f'(z^n)$.

By the conjugacy of monomorphisms $G_{\{m, S\}} \rightarrow SL_{\{2, S\}}$, one can, after an étale-covering extension of the base, find a section g of G such that $f \circ \alpha^{\{*\}}(z) = \text{int}(g) \circ \alpha^{\{*\}}(z^n)$. Transforming f by $\text{int}(g)$, one is therefore reduced to the case where there exists an $n \in \mathbb{N}$ such that $f \circ \alpha^{\{*\}}(z) = \alpha^{\{*\}}(z^n)$.

7.4.3.

<!-- label: III.XXIV.7.4.3 -->

Consider now the morphism

$$f \circ p : G_{\{a, S\}} \rightarrow SL_{\{2, S\}}.$$

It verifies the condition

```
```text
 $\alpha^*(z^n) (f \circ p)(x) \alpha^{*(z^n)^{-1}} = (f \circ p)(z^2 x).$
```
```

If $n = 0$, it follows at once that $f \circ p$ is invariant under the homotheties of $G_{\{a, S\}}$, hence constant. If $n \neq 0$, one can apply Exp. XXII, 4.1.9; $x \mapsto x^n$ is an endomorphism of $G_{\{a, S\}}$, there exists a $\lambda \in G_{\{m, S\}}$ such that

```
```text
 $f \circ p(x) = p(\lambda x^n);$
```
```

this relation is moreover valid for $n = 0$, taking $\lambda = 1$. Up to again extending S , one can find a $z \in G_{\{m, S\}}$ such that $z^2 = \lambda$. Replacing f by $\text{int}(\alpha^*(z)) \circ f$, one is therefore reduced to the case where one has

```
```text
 $f \circ \alpha^*(z) = \alpha^*(z^n), \quad f \circ p(x) = p(x^n).$
```
```

<!-- original page 268 -->

7.4.4.

<!-- label: III.XXIV.7.4.4 -->

Finally, one must have $f(w) \alpha^{*(z^n)} f(w)^{-1} = \alpha^{*(z^n)^{-1}}$ and $(f(w) u)^3 = 1$. By Exp. XX, 3.8, this entails $f(w) = w^n$. Since G is generated by T , $p(G_{\{a, S\}})$ and w , this entails that for every $(a, b, c, d) \in G(S)$, $S' \rightarrow S$, one has

```
```text
 $f \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a^n & b^n \\ c^n & d^n \end{pmatrix}.$
```
```

7.4.5.

<!-- label: III.XXIV.7.4.5 -->

Summarizing the preceding discussion, one sees that locally on S for the étale topology, one can find for every endomorphism f of $SL_{\{2, S\}}$ an (inner) automorphism ϕ of $SL_{\{2, S\}}$, and an integer $n \geq 0$ such that $f = \phi \circ F_n$, where

```
```text
 $F_n \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a^n & b^n \\ c^n & d^n \end{pmatrix}.$
```
```

Note that if $f = \phi \circ F_n$, the integer n is well determined by a fiber f_s of f , for example by $\text{Ker}(f_s)$. It follows that n is a locally constant function on S .

7.4.6.

<!-- label: III.XXIV.7.4.6 -->

One deduces at once that if f is an endomorphism of $SL_{\{2, S\}}$, then S decomposes canonically as a sum of open and closed subschemes S_0, S_1, S_{p^n} (where p^n ranges over the set of positive powers of prime numbers) such that:

- (i) f_{S_0} is the zero morphism,
- (ii) f_{S_1} is an isomorphism (= an inner automorphism),

(iii) S_{p^n} is of characteristic p and $f_{S_{p^n}}$ decomposes uniquely in the form $\phi \circ F^n_p$, where ϕ is an inner automorphism and F_p the Frobenius endomorphism of SL_2, F_p .

7.4.7.

<!-- label: III.XXIV.7.4.7 -->

In other words, $\operatorname{Hom}_{\mathbb{Z}\text{-gr.}}(SL_2, \mathbb{Z}), SL_2, \mathbb{Z})$ is the sum scheme:

(i) of a scheme isomorphic to $\operatorname{Spec}(\mathbb{Z})$,

(ii) of a scheme isomorphic to $\operatorname{Aut}_{\mathbb{Z}\text{-gr.}}(SL_2, \mathbb{Z}) \simeq \operatorname{ad}(SL_2, \mathbb{Z})$,

(iii) for each prime number p and each integer $n > 0$, of a scheme isomorphic to $\operatorname{Aut}_{F_p\text{-gr.}}(SL_2, F_p) \simeq \operatorname{ad}(SL_2, F_p)$.

7.4.8.

<!-- label: III.XXIV.7.4.8 -->

It follows in particular that

(i) $\operatorname{Hom}_{F_p\text{-gr.}}(SL_2, F_p), SL_2, F_p)$ has an infinite number of connected components, and so is not quasi-compact.

(ii) If S is a scheme of unequal characteristics, $\operatorname{Hom}_{S\text{-gr.}}(SL_2, S), SL_2, S)$ is not flat over S .

8. Appendix: Cohomology of a smooth group over a henselian ring. Cohomology and the functor $\prod$

<!-- label: III.XXIV.8 -->

<!-- original page 269 -->

Proposition 8.1. *Let S be a henselian local scheme, s its closed point, G an S -group scheme smooth such that every finite subset of G is contained in an affine open set.[^XXIV-8-star] Then*

(i) If P is a principal homogeneous bundle under G , there exists an $S' \rightarrow S$ finite, surjective étale that trivializes P . One has $\operatorname{Fib}(S, G) \simeq H^1_{\acute{e}}(S, G)$.*

(ii) For every finite surjective étale morphism $S' \rightarrow S$, the canonical map*

```text  
 $H^1(S'/S, G) \rightarrow H^1(S' \otimes_S \kappa(s) / \kappa(s), G_s)$   
 ```

is bijective.

(iii) The canonical map*

```text  
 $\operatorname{Fib}(S, G) \rightarrow \operatorname{Fib}(\kappa(s), G_s)$   
 ```

is bijective.

<!-- label: III.XXIV.8.1 -->

8.1.2.

<!-- label: III.XXIV.8.1.2 -->

If K is a finite separable extension of $\kappa(s)$, there exists an $S' \rightarrow S$ finite surjective étale such that $K \simeq S' \otimes_S \kappa(s)$.[^N.D.E-XXIV-47] If P is a principal homogeneous bundle under G , then P is

smooth over S , hence $P_{\{s\}}$ smooth over $\kappa(s)$; there therefore exists a finite separable extension K of $\kappa(s)$ such that P_K possesses a section (cf. EGA IV₄, 17.15.10). Representing K as said above, one sees that $P_{\{S\}}$ possesses a section by "Hensel's lemma" (cf. EGA IV₄, 18.5.17), which proves the first part of (i).

Conversely, if P is a principal homogeneous sheaf under G for the étale topology, there exists an $S' \rightarrow S$ finite surjective étale that trivializes P (indeed every covering family of a henselian local scheme for the étale topology is dominated by a family reduced to a morphism $S' \rightarrow S$ of the wanted form).

By virtue of the descent hypothesis made on G , P is representable (SGA 1, VIII, 7.6), which completes the proof of (i), and shows that (ii) entails (iii). It only remains to prove (ii).

<!-- original page 270 -->

8.1.3.

<!-- label: III.XXIV.8.1.3 -->

The map of (ii) is injective: let P and Q be two principal homogeneous bundles under G trivialized by S' . Consider the S -group sheaf $H = \text{Isom}_{G\text{-bundles}}(P, Q)$; since $H_{\{S'\}}$ is isomorphic to $G_{\{S'\}}$, H is representable, by the second hypothesis on G , cf. above. If $H(\kappa(s)) \neq \emptyset$, then $H(S) \neq \emptyset$ by Hensel's lemma, so P and Q are isomorphic.

8.1.4.

<!-- label: III.XXIV.8.1.4 -->

Let us finally prove that the map of (ii) is surjective, or equivalently that the canonical map

$$Z^1(S'/S, G) \rightarrow Z^1(S' \otimes_S \kappa(s) / \kappa(s), G_s)$$

is surjective. Let Z^1 be the S -functor defined by

$$Z^1(T) = Z^1(S' \times_S T / T, G_T);$$

the preceding map is identified with the map

$$Z^1(S) \rightarrow Z^1(\kappa(s));$$

by a further application of Hensel's lemma, it suffices to prove that Z^1 is representable by a smooth S -scheme.

8.1.5.

<!-- label: III.XXIV.8.1.5 -->

Let us prove that Z^1 is representable by an S -scheme locally of finite presentation. Let C_i , $i = 0, 1, \dots$, be the S -functor defined by

$$C_i(T) = C_i(S' \times_S T / T, G_T),$$

that is

$$C_i(T) = G((S' \times_S T / T)^{i+1}) = G((S'/S)^{i+1} \times_S T),$$

or again

$$C_i = \text{operatorname{Hom}}_S((S'/S)^{i+1}, G).$$

Since Z^1 is obtained from C_1 and C_2 by fibered products, it suffices to prove that C_i , $i = 1, 2$, is representable by an S -scheme locally of finite presentation.

8.1.6.

<!-- label: III.XXIV.8.1.6 -->

If $T \rightarrow S$ is a finite surjective étale morphism that decomposes S , then

$$C_i \times_S T = \text{Hom}_T((S' \times_S T / T)^{i+1}, G_T)$$

is representable by a product of n copies of G_T , where n is the degree of $(S'/S)^{i+1}$. Applying once more the hypothesis on G , one deduces that C_i is indeed representable by an S -scheme locally of finite presentation (SGA 1, VIII, *loc. cit.*).

8.1.7.

<!-- label: III.XXIV.8.1.7 -->

To prove that Z^1 is smooth, we must now, by definition, prove that if T is an affine S -scheme, T_0 the closed subscheme defined by an ideal J of square zero, the canonical map

$$Z^1(T) \rightarrow Z^1(T_0)$$

is surjective. Since G is smooth, the canonical map $G(T) \rightarrow G(T_0)$ is surjective,

<!-- original page 271 -->

and it suffices to prove that the canonical map

$$H^1(S' \times_S T / T, G_T) \rightarrow H^1(S' \times_S T_0 / T_0, G_{T_0})$$

is bijective.

Changing notation slightly and generalizing the hypotheses, it now suffices for us to prove:

Lemma 8.1.8. *Let S and S' be two affine schemes, $S' \rightarrow S$ a faithfully flat morphism, J an ideal of square zero on S , T_0 the closed subscheme it defines, G a smooth S -group. Set $S'_0 = S' \times_S S_0$, $G_0 = G \times_S S_0$. The canonical map*

$$H^1(S'/S, G) \rightarrow H^1(S'_0/S_0, G_0)$$

is bijective.

<!-- label: III.XXIV.8.1.8 -->

Remark 8.1.9. If one assumes G commutative, the same assertion is valid for all H^i , $i > 0$, with an analogous proof.

<!-- label: III.XXIV.8.1.9 -->

Proof. Let M_0 be the quasi-coherent S_0 -module $M_0 = \text{Lie}(G_0/S_0) \otimes_{S_0} J$. For each S_0 -prescheme T_0 , set $M_0(T_0) = H^0(T_0, M_0 \otimes_{S_0} \mathcal{O}_{T_0})$, and let

```

```text

$$M = \prod_{S_0/S} M_{0_0} \quad \text{and} \quad \bar{G} = \prod_{S_0/S} G_{0_0}$$

```

```

be the $\mathbb{S}$ -group functors defined by $M(T) = M_{0_0}(T_{0_0})$ and $\bar{G}(T) = G_{0_0}(T_{0_0})$, where $T_{0_0} = T \times_S S_{0_0}$. By Exp. III, 0.9 and (0.6.2), there exists for every affine $\mathbb{S}$ -scheme T an exact sequence, functorial in T :

```

$$1 \rightarrow M(T) \rightarrow G(T) \rightarrow \bar{G}(T) \rightarrow 1.$$

```

We have to study the map

```

```text

$$H^1(S'/S, G) \rightarrow H^1(S'_0/S_{0_0}, G_{0_0}) = H^1(S'/S, \bar{G}).$$

```

```

Suppose first G commutative. One then has an exact cohomology sequence

```

```text

$$H^1(S'/S, M) \rightarrow H^1(S'/S, G) \rightarrow H^1(S'/S, \bar{G}) \rightarrow H^2(S'/S, M);$$

```

```

but

```

```text

$$H^i(S'/S, M) = H^i(S'_0/S_{0_0}, M_{0_0}) = H^i(S'_0/S_{0_0}, M_{0_0}),$$

```

```

and one knows (TDTE I, B, Lemma 1.1) that $H^i(S'_0/S_{0_0}, M_{0_0}) = 0$ for $i \neq 0$.

If now G is not commutative, we must use the exact sequence of non-abelian cohomology. If $u \in Z^1(S'/S, \bar{G})$, one knows that the elements of $H^1(S'/S, G)$ having the same image in $H^1(S'/S, \bar{G})$ as the class of u are in the image of the corresponding coboundary map:

```

```text

$$H^1(S'/S, M_u) \rightarrow H^1(S'/S, G),$$

```

```

where M_u is the $\mathbb{S}$ -functor M "twisted by u ". Similarly, if v is an element of $Z^1(S'/S, \bar{G})$, there exists a "coboundary"

```

$$\Delta(v) \in H^2(S'/S, M_v),$$

```

<!-- original page 272 -->

where M_v is the $\mathbb{S}$ -functor M "twisted by v ", such that $\Delta(v) = 0$ if and only if the class of v is in the image of $H^1(S'/S, G)$. It suffices to prove that one has $H^1(S'/S, M_u) = H^2(S'/S, M_v) = 0$.

Now recall (Exp. III 0.8) that the action of G on M defined by the exact sequence is none other than that which is deduced functorially from the adjoint representation of G_{0_0} :

```

$$\text{ad} : G_{0_0} \rightarrow \text{Aut}_{0_0(S_{0_0})}(\text{Lie}(G_{0_0}/S_{0_0})).$$

```

The element u (resp. v) therefore acts in $M_{S' \times_S S'}$ via an $S'_{0_0} \times_{S_{0_0}} S'_{0_0}$ -automorphism of $\text{Lie}(G_{0_0}/S_{0_0})$. Since u (resp. v) is a cocycle, this automorphism is a descent datum; write L_u (resp. L_v) for the quasi-coherent $M_{S_{0_0}}$ -module obtained. One verifies at once that for $T \rightarrow S$, one has

```

```text

```

$M_u(T) = H^0(T_0, L_u \otimes_{\mathcal{O}_{S_0}} J \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_{T_0})$

and the same relation replacing  $u$  by  $v$ . One therefore has

```

```text
H1(S'/S, Mu) = H1(S'0/S0, Lu ⊗ J),
H2(S'/S, Mv) = H2(S'0/S0, Lv ⊗ J),
```

```

and both are indeed zero by virtue of the result already used.

**Proposition 8.2.** \*Let  $\mathcal{C}$  be a category possessing fibered products, equipped with a topology coarser than the canonical topology,  $S' \rightarrow S$  a morphism of  $\mathcal{C}$ ,  $G'$  an  $S'$ -group sheaf,  $G$  the  $S$ -group sheaf  $\prod_{S'/S} G'$ . Let  $H^1_{S'}(S', G') \subset H^1(S', G')$  be the set of classes of principal homogeneous sheaves under  $G'$  which are trivialized by a sieve of  $S'$  obtained by base change from a suitable covering sieve of  $S$ . The canonical map  $H^1_{S'}(S, G) \rightarrow H^1_{S'}(S', G')$  defined by the functor\*

```

```text
P ↦ P ×S S'
```

```

\*induces a bijection\*

```

```text
H1(S, G) ≅ H1S(S', G');
```

```

\*the inverse bijection is defined by the functor  $P' \mapsto \prod_{S'/S} P'$ .\*

<!-- label: III.XXIV.8.2 -->

For every object  $X$  of  $\mathcal{C}/S$ , one has by definition a functorial isomorphism in  $X$

```

```text
HomS(X, G) ≅ HomS'(X ×S S', G').
```

```

One therefore has for each  $S$ -object  $T$  a functorial bijection in  $T$

```

```text
H1(T/S, G) ≅ H1(T'/S', G').
```

```

Replacing now the unique morphism  $T \rightarrow S$  by an arbitrary covering family of  $S$  and passing to the inductive limit, one deduces the first part of the statement. The second part is deduced without difficulty.

**Lemma 8.3.** \*Under the conditions of 8.2, the assertion  $H^1_{S'}(S', G') = H^1(S', G')$  is local on  $S$ : suppose there exists a covering family  $\{S_i \rightarrow S\}$  such that for every  $i$ , one has  $H^1_{S'}(S_i, G') = H^1(S_i, G')$ . Then  $H^1_{S'}(S, G) = H^1(S, G)$ .\*

<!-- label: III.XXIV.8.3 -->

<!-- original page 273 -->

Indeed, let  $P$  be a principal homogeneous sheaf under  $G$ . Set

```

```text
P'_i = P ×S S_i;
```

```

by hypothesis, there exists a covering family  $\{S_{ij} \rightarrow S_i\}$  such that for each  $j$ ,  $P' \times_{S'} S_{ij}$  possesses a section. But  $\{S_{ij} \rightarrow S\}$  is a covering family of  $S$ , and  $P'$  is indeed trivialized by the covering family of  $S$  obtained from this one by base change.

**\*\*Proposition 8.4.\*\*** \*Let  $S' \rightarrow S$  be a finite étale morphism of schemes. Let  $G'$  be an  $S'$ -group sheaf,  $G$  the  $S$ -group sheaf  $\prod_{S'/S} G'$ . For the étale (resp. local finite étale, resp. (fpqc)) topology, the functors\*

```

```text
P      ↔      P ×S S'
↓_{S'/S} ↓      ↔      ↓
P'      ↔      P'

```

induce inverse bijections of each other:

```

```text
H1(S, G) = H1(S', G').
```

```

<!-- label: III.XXIV.8.4 -->

By 8.2, it suffices to show that $H^1(S')(S', G') = H^1(S', G')$. By 8.3, it suffices to do this locally for the local finite étale topology; one may therefore assume that S' is a finite direct sum of copies of S , say $\coprod_{i \in I} S$, where I is a suitable finite set. Then G' is given by a family $(G_i)_{i \in I}$ of sheaves on S and

```

```text
H1(S', G') = ∏_{i ∈ I} H1(S, G_i).
```

```

On the other hand

```

```text
H1(S, G) = ∏_{i ∈ I} H1(S, G_i),
```

```

whence, by 8.2, $H^1(S')(S', G') = H^1(S', G')$. QED

****Remarks 8.5.**** One can interpret 8.2 and 8.3 by the following exact sequence (f is the given morphism $S' \rightarrow S$)

```

```text
1 → H1(S, f*(G')) → H1(S', G') → H0(S, R1f*(G')).
```

```

<!-- label: III.XXIV.8.5 -->

In the commutative case, this exact sequence follows from the Leray spectral sequence; it is still valid in the non-commutative case (cf. Giraud's thesis [N.D.E-XXIV-48]).

In this form, one sees that the result is still valid if f is only assumed finite, or simply integral, the topology being the étale topology, because for every G' , one has

```

```text
R1f*(G') = \text{final sheaf},
```

```

by SGA 4, VIII, 5.3. [N.D.E-XXIV-49]

On the other hand, this result becomes false if one takes a topology such as (fpqc) or (fppf), even if $S = \operatorname{Spec}(k)$, k algebraically closed field of characteristic $p \neq 0$, $S' = \operatorname{Spec}(k[t]/t^2)$, $G' = \mu_p$ or α_p .

<!-- original page 274 -->

Similarly, 8.2 becomes false, even for the étale topology, if one suppresses in it the hypothesis that f is finite, as one sees by taking for f an open immersion; for example if $S = \operatorname{Spec}(V)$, V a complete discrete valuation ring with algebraically closed residue field, S' being the open subset induced at the generic point, and G' the constant group $(\mathbb{Z}/n\mathbb{Z})_{S'}$, with n prime to the residue characteristic of V , one has $H^1(S, G) = 0$, $H^1(S', G') \neq 0$. Moreover, replacing S' by $S \coprod S'$, one deduces an analogous example, with $S' \rightarrow S$ étale surjective, hence covering for the topology considered.

[^N.D.E-XXIV-0]: N.D.E.: Version of 13/10/2024.

[^N.D.E-XXIV-1]: N.D.E.: Hence $\mathrm{Lie}(u)(X'_{\{v(\alpha)\}}) = X_{\{\alpha\}}$, for every $\alpha \in R$.

[^N.D.E-XXIV-2]: N.D.E.: One recalls that $\mathrm{ad}(G) = G / \mathrm{Centr}(G)$ denotes the adjoint group of G , cf. XXII 4.3.6.

[^N.D.E-XXIV-3]: N.D.E.: We have replaced here and in the sequel the notation $\mathrm{int}(G)$ by $\mathrm{ad}(G)$.

[^N.D.E-XXIV-4]: N.D.E.: cf. SGA 1, VIII 2.1.

[^N.D.E-XXIV-5]: N.D.E.: We have corrected $\mathrm{ad}(G) \rightarrow \mathrm{Aut}(G)$ to $\mathrm{ad}(G) \rightarrow \mathrm{operatorname{Aut}}(G)$.

[^N.D.E-XXIV-6]: N.D.E.: We have corrected the original, which stated (i) without assuming G adjoint. Following the characterization of the $H^i(G, -)$ as derived functors of $\operatorname{Hom}_G(k, -)$ (Exp. I, 5.3.1; see also [Ja87], I 4.16), one has $H^i(G, V) = \operatorname{Ext}_G^i(k, V)$ for every G -module V ; now if $\operatorname{char}(k) = p > 0$ and $G = \operatorname{SL}_p(k)$, then $\operatorname{Lie}(G_{\mathbb{A}}/k)$ is a non-trivial extension of k by $\mathfrak{g} = \operatorname{Lie}(\operatorname{SL}_p(k))$, so $H^1(G, \mathfrak{g}) \neq 0$. See also the addition 1.15.1 below.

[^N.D.E-XXIV-7]: N.D.E.: We have replaced "scheme" by "field".

[^N.D.E-XXIV-8]: N.D.E.: Because of the correction made in 1.13, we have given another proof in the case of H^1 . On the other hand, it follows from a theorem of G. Kempf that $H^i(G, k) = 0$ for every $i > 0$, cf. [Ja87], II 4.5 and 4.11.

[^N.D.E-XXIV-9]: N.D.E.: We have added this corollary, drawn from remarks of O. Gabber, which makes 1.13 (i) more precise.

[^N.D.E-XXIV-10]: N.D.E.: cf. XXIII, Definition 5.11.

[^N.D.E-XXIV-11]: N.D.E.: We have made explicit the preceding definitions (the original indicated "One defines similarly $\operatorname{Aut}_{S\text{-gr}}(G, X, Y)$, ..., $\operatorname{Isom}_{S\text{-gr}}(G, X; G', X')$, ...").

[^N.D.E-XXIV-12]: N.D.E.: cf. SGA 1, VIII 1.9.

[^N.D.E-XXIV-13]: N.D.E.: Therefore, if P possesses a section, then T and T' are isomorphic; in particular T_P and T'_P are isomorphic. See the addition 4.5.1 where this remark is developed in the case where $G = \operatorname{acute}\{E\}_p(S)(R)$.

[^N.D.E-XXIV-14]: N.D.E.: by 2.7, since $\operatorname{Isomext}(G, G')$ possesses a section (cf. the preceding N.D.E.).

[^N.D.E-XXIV-15]: N.D.E.: Recall that $\operatorname{Isomint}_u(G, G')$ is defined in 1.11.

[^N.D.E-XXIV-16]: N.D.E.: We have added the hypothesis that S be connected.

[^N.D.E-XXIV-17]: N.D.E.: We have detailed the reference to Exp. XXII, 5.9.7.

[^N.D.E-XXIV-18]: N.D.E.: The original referred to EGA IV, § 24, which has not appeared. The point is to use "Bertini's theorem". Let us detail the argument, which was indicated to us by O. Gabber. Let $X \rightarrow S$ be a surjective, smooth and projective morphism; replacing S by a connected component, one may assume that X/S has constant relative dimension d at every point (cf. EGA IV₄, 17.10.2). One may also assume that X is a closed subscheme of a projective space $\mathbb{P}^n_S = \mathbb{P}(E)_S$, where E is a free $\mathcal{A}$ -module of rank $n + 1$ (cf. EGA II, 5.3.3). Let $s_1, \dots, s_r$ be the closed points of S ; by Bertini's theorem (see for example [Jou83], I 6.10), there exists an open set U of the product $P = (E^*)^d$, with non-empty fibers, such that for every point $u = (f_1, \dots, f_d)$ of $U_{\{s_i\}}$, the intersection of $X_{\{\kappa(u)\}}$ with the d hyperplanes of $\mathbb{P}^n_{\{\kappa(u)\}}$ defined by u is étale over $\kappa(u)$. Up to shrinking U , one may assume that U is the complement in the affine space $\mathbb{A}^n_S$ of the locus of zeros $V(Q)$ of a certain polynomial Q of degree $m > 0$. One then sees easily (by induction on the number of variables) that $V(Q)$ cannot contain all rational points of $\mathbb{A}^n_{\{\kappa(s_i)\}}$ if $|\{\kappa(s_i)\}| > m$. Since the morphism $\mathcal{A} \rightarrow \prod_i \kappa(s_i)$ is surjective, one can find a monic polynomial $R \in \mathcal{A}[X]$ of degree m whose image in $\kappa(s_i)[X]$ is irreducible if $\kappa(s_i)$ is finite, and possesses m distinct roots if $\kappa(s_i)$ is infinite. Put $\mathcal{A}' = \mathcal{A}[X]/(R)$ and $S' = \operatorname{operatorname{Spec}}(\mathcal{A}')$; then $S' \rightarrow S$ is étale, finite and surjective, and the residue field at each of its closed points $s'_1, \dots, s'_t$ is of cardinality $\geq 2m$. Then U possesses a rational point u_i over each closed point of S' , and since $\mathcal{A}' \rightarrow \prod_i \kappa(s'_i)$ is surjective, these lift to a section u of $P_{\{S'\}}$. Write Z for the intersection of $X_{\{S'\}}$ with the d hyperplanes of $\mathbb{P}^n_{\{S'\}}$ defined by u , and V for the open set of Z formed by the points at which Z is étale over S' . By EGA IV₃, 11.3.8, V contains the fibers $Z_{\{s'_i\}}$ for every i ; since $\pi : Z \rightarrow S'$ is proper, it follows that the closed set $\pi(Z - V)$ is empty, whence $V = Z$. Then $Z \rightarrow S'$ is surjective, étale and proper, hence finite, as is the composite $Z \rightarrow S$, and this yields the desired section of $X \rightarrow S$.

[^N.D.E-XXIV-19]: N.D.E.: We have sketched in 3.11.4 the verification of the fact that the functors i_* , rev and $\operatorname{qép}$ are fully faithful, and that the composite $\operatorname{rev} \circ i \circ \operatorname{qép}$ is isomorphic to the identity functor of Rev .

[^N.D.E-XXIV-20]: N.D.E.: We have expanded the original in the foregoing, to show that the action of E on G' is obtained by combining the natural action of E on $\operatorname{acute}\{E\}_p(S)(R)$ and the given action on S' . The canonical Killing couple of G' is preserved by this action, as is the quasi-pinning given by the element $\tilde{X}$ of

$\Gamma(\Delta_S)$, $\text{Lie}(G'/S)_{\Delta_S}$, equal to X'_{α} on the copy of S indexed by α (indeed, since E acts on Δ_S by permutation of the copies of S , one has indeed $h(\tilde{X}) = \tilde{X}$ for every $h \in E$).

[^N.D.E-XXIV-21]: N.D.E.: see, for example, TDTE I, p. 22, Example 1. One can also describe $\mathcal{O}_p(S)$ as the twist of $\mathcal{O} = \mathcal{O}_p(R)$ by the E -torsor S'/S , i.e. the (fpqc) sheaf quotient of $S' \times_S G$ by the right action of E defined by $(s', g) \cdot h = (s' h, h^{-1}(g))$. Since G is affine over S and since E acts on G by group automorphisms, this sheaf is representable by an S -group $G^{\sharp}$, which is a "twisted" form of G , and $\mathcal{O}^{\sharp} = \text{Dyn}(G^{\sharp})$ is the twist of the constant Dynkin scheme Δ_S by the torsor S'/S . Since E normalizes B and T , one obtains likewise a pair $(B^{\sharp}, T^{\sharp})$ which is a Killing couple of $G^{\sharp}$. On the other hand, let $\mathfrak{g} = \text{Lie}(G/S)$ and $\mathfrak{g}^{\sharp} = \text{Lie}(G^{\sharp}/S)$; for every $U \rightarrow S$, the sections of $\mathfrak{g}^{\sharp}$ on U are the E -equivariant S -morphisms $U \times_S S' \rightarrow W(\mathfrak{g})$. Since $\mathcal{O}^{\sharp} \times_S S' = \mathcal{O}$ is E -isomorphic to $\Delta_S \times S$, equipped with the action $(\alpha, s') \cdot h = (h^{-1}(\alpha), s' h)$, one obtains that the morphism given by $(\alpha, s') \mapsto X_{\alpha}$ is a section of $\mathfrak{g}^{\sharp}$ on $\mathcal{O}^{\sharp}$ which is a quasi-pinning, i.e. a section nowhere zero of $(\mathfrak{g}^{\sharp} \otimes_{\mathcal{O}^{\sharp}} 0_{\mathcal{O}^{\sharp}})^{\wedge D^{\sharp}}$ (cf. 3.8).

[^N.D.E-XXIV-22]: N.D.E.: We have added this number.

[^N.D.E-XXIV-24]: N.D.E.: We have replaced "bundle" by "sheaf", and then G by G' .

[^N.D.E-XXIV-25]: N.D.E.: by "theorem 90".

[^N.D.E-XXIV-26]: N.D.E.: We have added this no 4.5.

[^N.D.E-XXIV-27]: N.D.E.: We have replaced R by L , as in 3.2.

[^N.D.E-XXIV-28]: N.D.E.: We have corrected $F(-1, x)$ to $F(1, -x)$.

[^N.D.E-XXIV-29]: N.D.E.: We have corrected $p_{\{3\alpha+\beta\}}(a)$ to $p_{\{2\alpha+\beta\}}(a)$, and detailed the end of the argument.

[^N.D.E-XXIV-30]: N.D.E.: denoted (étf) in Exp. IV 6.3. In other words, for every $s \in S$ there exist an open neighborhood U of s and a finite surjective étale morphism $V \rightarrow U$ such that $B' \times_S V \simeq B \times_S V$.

[^N.D.E-XXIV-31]: N.D.E.: One can ask whether every smooth affine S -group, each of whose geometric fibers is a Borel subgroup of a semisimple group, is a Borel subgroup of a semisimple S -group. (We have suppressed the "counter-example" given in the original, for $S = \text{scheme of dual numbers over a field } k$, which was erroneous, as M. Demazure pointed out to us.)

[^N.D.E-XXIV-32]: N.D.E.: See for example the proof of XXII 5.8.1.

[^N.D.E-XXIV-33]: N.D.E.: We have corrected $X \rightarrow Y$ to $Y \rightarrow X$.

[^N.D.E-XXIV-34]: N.D.E.: We have simplified the proof of the original.

[^N.D.E-XXIV-35]: N.D.E.: In what follows, the group law of U_{α} is written additively, that is, if one writes $p_{\alpha} : G_{\alpha, S} \rightarrow U_{\alpha}$ for the isomorphism such that $p_{\alpha}(1) = u_{\alpha}$ and if $x = p_{\alpha}(z)$, then $\alpha(t) x$ (resp. $\alpha(t, t')$) denotes $p_{\alpha}(\alpha(t) z)$ (resp. $p_{\alpha}(\alpha(t, t')) = \alpha(t) u_{\alpha} + \alpha(t') u_{\alpha}$).

[^N.D.E-XXIV-36]: N.D.E.: i.e. for condition (ii) of 7.1.4 to be satisfied.

[^N.D.E-XXIV-37]: N.D.E.: see also the addition in Exp. VI_B, 6.2.3.

[^N.D.E-XXIV-38]: N.D.E.: i.e. for every $S' \rightarrow \text{Hom}_{S\text{-gr.}}(T, H)$, with S representable, $\text{Hom}_{S\text{-gr.}}(G, H) \times_S S'$ is representable and the morphism of S -schemes $\text{Hom}_{S\text{-gr.}}(G, H) \times_S S' \rightarrow S'$ is separated and verifies $\mathcal{P}$.

[^N.D.E-XXIV-39]: N.D.E.: We have suppressed the hypothesis that H be quasi-separated, which is superfluous.

[^N.D.E-XXIV-40]: N.D.E.: We have replaced f_r by f_{rad} .

[^N.D.E-XXIV-41]: N.D.E.: Indeed, it is clear that $V^{\{G\}} \subset V^{\{g\}}$. On the other hand, $H = \text{Centr}_{\{G\}}(V^{\{g\}})$ is a

closed subgroup of G , smooth since $\text{char}(k) = 0$; by Exp. II 5.3.1, one has $\text{Lie}(H) = \text{Centr}_{\{g\}}(V^{\wedge\{g\}}) = g$, and since H is smooth and G connected this entails $H = G$, whence $V^{\wedge\{g\}} \subset V^{\wedge\{G\}}$ (see also [DG70], § II.6, Prop. 2.1 (c)).

[^N.D.E-XXIV-42]: N.D.E.: Indeed, the union of the maximal tori of G is dense in G , cf. *Bible*, § 6.5, Th. 5 (= [Ch05], § 6.6, Th. 6).

[^N.D.E-XXIV-43]: N.D.E.: Note that R is a torus.

[^N.D.E-XXIV-44]: N.D.E.: i.e. that for every S -scheme S' local artinian, with closed point s' , every morphism of $\kappa(s')$ -groups $G_{\{s'\}} \rightarrow H_{\{s'\}}$ lifts to a morphism of S' -groups $G_{\{S'\}} \rightarrow H_{\{S'\}}$. By Exp. III 2.8, this follows from the vanishing of $H^2(G_{\{s'\}}, V)$, where $V = \text{Lie}(H_{\{s'\}}/\kappa(s'))$.

[^N.D.E-XXIV-45]: N.D.E.: see also [Bo91], II 7.9. Moreover, we have added the sentence that follows.

[^N.D.E-XXIV-46]: N.D.E.: See Exp. VII_B for the definition of the formal groups $\hat{G}$ and $\hat{H}$. Suppose that $S = \text{operatorname{Spec}}(k)$, where k is a field. By *loc. cit.*, 2.2.1, to give a morphism of k -formal groups $v : \hat{G} \rightarrow \hat{H}$ is equivalent to giving a morphism of k -Hopf algebras $\phi : \text{Dist}(G) \rightarrow \text{Dist}(H)$, where $\text{Dist}(G)$ denotes the algebra of distributions (at the origin) of G , cf. Exp. VII_A, 2.1 or [DG70], § II.4, 6.1 or [Ja87], I 7.7 (it is called the "hyperalgebra" of G in [Di57] and [Ta75]). Theorem 4 of [Di57] (see also [Ta75], 0.3.4 (f) and (g)) generalizes in this context the theorem of Chevalley used in 7.3.5; one thereby obtains that there exists a closed connected k -subgroup K of $G \times H$ such that $\hat{K}$ equals the graph of v ; since $\text{Dist}(K) \rightarrow \text{Dist}(G)$ is an isomorphism, $K \rightarrow G$ is a finite étale morphism. One then deduces that K is semisimple and then, by Exp. XXI 6.2.7, that $K \rightarrow G$ is an isomorphism (since G is simply connected); see also [Ta75], 1.8 and 2.2. More generally, *loc. cit.* studies the k -groups G having the property (SC): every finite étale morphism of k -groups $G' \rightarrow G$, with G' connected, is an isomorphism. Note finally that what precedes shows that every $\text{Dist}(G)$ -module V of finite dimension is, uniquely, a G -module; for an extension to the case of a split reductive k -group G (or even of a Borel subgroup of G) see [Ja87], II 1.20 (and the references therein).

[^XXIV-8-star]: This last condition is in fact unnecessary (cf. A. Grothendieck, *Groupe de Brauer III*, in *Dix Exposés sur la cohomologie des schémas*, North-Holland, 1968, theorem 11.7 and remarks 11.8.3).

[^N.D.E-XXIV-47]: N.D.E.: Note that S' is still local and henselian. Furthermore, we have kept the numbering of the original: there is no 8.1.1.

[^N.D.E-XXIV-48]: N.D.E.: See § V 3.1.4 of [Gi71].

[^N.D.E-XXIV-49]: N.D.E.: This reference also refers to § V 3.1.4 of [Gi71].

[^N.D.E-XXIV-50]: N.D.E.: We have added to these three references, figuring in the original, the following references.

[^N.D.E-XXIV-23]: N.D.E.: We write $\text{Isomint}(G_{\{q\text{-}\acute{e}\text{p}\}}, G)$ instead of $\text{Isomint}_{\{u\}}(G_{\{q\text{-}\acute{e}\text{p}\}}, G)$ (cf. 1.11), since the pair $(G_{\{q\text{-}\acute{e}\text{p}\}}, u)$ is unique up to a unique isomorphism.

Exposé XXV. The existence theorem

<!-- label: III.XXV -->

by M. Demazure

<!-- original page 269 -->

[^N.D.E-XXV-0] For the sake of completeness, we give in this Exposé a proof of the existence theorem for split groups. Like Chevalley's original proof ("Sur certains schémas de groupes semi-simples", *Séminaire Bourbaki*, May 1961, no. 219), it rests on the existence of complex semisimple algebraic groups of all possible types. The principle of a more satisfactory proof, establishing directly the existence of a simply connected split semisimple $\mathbb{Z}$ -group corresponding to a given Cartan matrix, was given by Cartier (unpublished).[^N.D.E-XXV-1] Let us point out, however, that the difficulty is not to give an explicit construction of a group scheme, but to verify that the group thus constructed really meets the required conditions, that is, essentially, that its fibers are indeed smooth and reductive.

1. Statement of the theorem

<!-- label: III.XXV.1 -->

Theorem 1.1. *Let S be a non-empty scheme. The functor*

S
 $G \mapsto R(G)$
 S

is an equivalence of the category of pinned S -reductive groups with the category of pinned reduced root data.

<!-- label: III.XXV.1.1 -->

<!-- original page 269 (cont., page 411 of original) -->

By virtue of the uniqueness theorem (Exp. XXIII, 4.1), the preceding statement is equivalent to:

Corollary 1.2 (Existence of split groups). *For every reduced root datum R , there exists a split reductive $\mathbb{Z}$ -group G such that $R(G) \simeq R$.* [N.D.E-XXV-2]

<!-- label: III.XXV.1.2 -->

<!-- original page 270 -->

In particular:

Corollary 1.3. *Let k be a field. For every splittable reductive k -group G_k , there exists a reductive $\mathbb{Z}$ -group G such that $G \otimes_{\mathbb{Z}} k \simeq G_k$.*

<!-- label: III.XXV.1.3 -->

Conversely, let us remark first that to prove 1.2 it suffices, by Exp. XXII 4.3.1 and Exp. XXI 6.5.10, to consider the case where the root datum R is simply connected (and even irreducible if one insists, by Exp. XXI, 7.1.6).

On the other hand, under the conditions of 1.3, the group scheme G is of constant type (since $\operatorname{Spec}(\mathbb{Z})$ is connected), hence of type $R(G_k)$; by Exp. XXIII, 5.9, it follows that the validity of 1.3 for a given group G_k entails the existence of a split $\mathbb{Z}$ -group of type $R(G_k)$. [N.D.E-XXV-3]

To prove 1.2, and hence 1.1, it therefore suffices to prove 1.3 when k is of characteristic zero (for example $k = \mathbb{C}$) and G_k is simply connected (and in particular semisimple), as well as:

Proposition 1.4. *For every simply connected reduced root datum R , there exists a semisimple algebraic $\mathbb{C}$ -group of type R .*

<!-- label: III.XXV.1.4 -->

One may prove 1.4 in the following way. One knows first that there exists a complex semisimple Lie algebra $\mathfrak{g}$ of type R , cf. for example N. Jacobson, *Lie Algebras*, ch. VII, Th. 5. [N.D.E-XXV-4] Then $G = \operatorname{Aut}(g)^0$ is a semisimple algebraic $\mathbb{C}$ -group of type $\operatorname{ad}(R)$. [N.D.E-XXV-5] By *Bible*, § 23.1, Prop. 1, one deduces from this the existence of a semisimple $\mathbb{C}$ -group of type R .

The rest of this Exposé is devoted to the proof of 1.3 for k of characteristic zero and G_k semisimple. It will be carried out in two stages: construction of a "piece of $\mathbb{Z}$ -group scheme" ($n^\circ 2$), and study of the group obtained by application of the "theorem of Weil" ($n^\circ 3$).

<!-- original page 271 -->

To avoid confusion, we shall not use in $n^\circ 2$ the abbreviated notation X_k to denote the k -scheme $X \otimes_{\mathbb{Z}} k$, where X is a $\mathbb{Z}$ -scheme.

2. Existence theorem: construction of a piece of group

<!-- label: III.XXV.2 -->

2.1.

<!-- label: III.XXV.2.1 -->

Let us choose, once and for all, a splitting of G_k , denoted

```text  
( $G_k$ ,  $T_k$ ,  $M$ ,  $R$ )  
```

(cf. Exp. XXII, 1.13), a system of simple roots Δ of R (defining the system of positive roots R^+), a Chevalley system $(X_{\alpha,k})_{\alpha \in R}$ of G_k (Exp. XXIII, 6.1 and 6.2) satisfying the following supplementary condition (cf. XX 2.6): for every $\alpha \in R$, one has

\$\$
 $X_{\alpha,k} X_{-\alpha,k} = 1$.
\$\$

Finally, let us choose on the subgroup of M generated by R a total order relation compatible with the group structure, such that the roots > 0 are the elements of R^+ . We then denote the roots

```text  
 $-\alpha_n < -\alpha_{n-1} < \dots < -\alpha_1 < \alpha_1 < \alpha_2 < \dots < \alpha_n$ .  
```

For $\alpha \in R$, we denote by $U_{\alpha,k}$ the vector group corresponding to the root α , and by

\$\$
 $p_{\alpha,k} : \mathbb{G}_{a,k} \rightarrow U_{\alpha,k}$
\$\$

the isomorphism of vector groups defined by $X_{\alpha,k}$.

2.2.

<!-- label: III.XXV.2.2 -->

The splitting of G_k includes in particular an isomorphism of k -groups

\$\$
 $T_k \simeq D_k(M)$.
\$\$

Put $T = D(M)$; this is a $\mathbb{Z}$ -torus, and the previous isomorphism may be regarded as an isomorphism

```text  
 $T_k = T \otimes_{\mathbb{Z}} k$ .  
```

<!-- original page 271 (cont., page 413 of original) -->

One has

\$\$
 $\operatorname{Hom}_{\mathbb{Z}\text{-gr.}}(T, \mathbb{G}_m) = M$,
\$\$

and one will regard the elements of $R \subset M$ as characters of T . Likewise, one will regard the elements of R^* as morphisms of $\mathbb{Z}$ -groups $\mathbb{G}_m \rightarrow T$.

2.3.

<!-- label: III.XXV.2.3 -->

For each $\alpha \in R^+$, let $\mathbb{G}_a(\alpha)$ be a copy of the group $\mathbb{G}_a$; consider the

$\mathbb{Z}$ -scheme

$U = \mathbb{G}_a(\alpha_1) \times \cdots \times \mathbb{G}_a(\alpha_n).$

If U_k denotes the unipotent part of the Borel group B_k of G_k defined by R^+ , denote by

$a : U \otimes_{\mathbb{Z}} k \rightarrow U_k$

the isomorphism of k -schemes defined by

$a(x_1, \dots, x_n) = p_{\alpha_1, k}(x_1) \cdots p_{\alpha_n, k}(x_n).$

2.4.

<!-- label: III.XXV.2.4 -->

<!-- original page 272 -->

The group law of U_k translates into relations of the form

$a(x_1, \dots, x_n) \cdot a(y_1, \dots, y_n) = a(z_1, \dots, z_n),$

where each z_h ($h = 1, \dots, n$) is expressed as a polynomial

$z_h = x_h + y_h + Q_h(x_1, \dots, x_{h-1}, y_1, \dots, y_{h-1}),$

the coefficients of Q_h being integers (Exp. XXII, 5.5.8 and Exp. XXIII, 6.4). Moreover $Q_h(x_1, \dots, x_{h-1}, 0, \dots, 0) = 0$.

<!-- original page 272 (cont., page 414 of original) -->

Let us equip U with the composition law defined by the preceding formulas (which are indeed "defined over $\mathbb{Z}$ "). Since this law induces on U_k its group law, it is associative, and (0) is a unit element (indeed, the two preceding assertions are expressed by relations between the polynomials Q_h , and $\mathbb{Z} \rightarrow k$ is injective). Let us show that this is a group law: if (x_i) is a section of U (over some S), one computes the inverse (y_i) of (x_i) by the recurrence formulas

$y_i = -x_i - Q_i(x_1, \dots, x_{i-1}, y_1, \dots, y_{i-1})$

which are still "defined over $\mathbb{Z}$ ".

In summary, we have constructed on U a group law such that the previous isomorphism a is an isomorphism of groups.

For each $\alpha \in R^+$, consider the morphism

$p_{\alpha} : \mathbb{G}_a \rightarrow U$

defined by $p_{\alpha}(x) = (x_i)$ where

$x_i = x$ if $\alpha_i = \alpha,$

$x_i = 0$ if $\alpha_i \neq \alpha$.

This is a closed immersion and a group homomorphism; we denote its image by $U_{\{\alpha\}}$. One has $\phi(x_i) = p_{\{\alpha_1\}}(x_1) \cdots p_{\{\alpha_n\}}(x_n)$, which proves that U is identified with the product

$$U = U_{\{\alpha_1\}} \cdot U_{\{\alpha_2\}} \cdots U_{\{\alpha_n\}}.$$

2.5.

<!-- label: III.XXV.2.5 -->

Let $T = D(M)$ act on each $U_{\{\alpha\}}$ through the character α ; one verifies at once that this defines an action of T on the group U , and one can construct the semi-direct product $B = T \ltimes U$. One has a canonical isomorphism of k -groups

$$B \otimes_{\mathbb{Z}} k \cong B_k.$$

<!-- original page 272 (cont., page 415 of original) -->

If we now take any order on R^+ , the morphism

$$\prod_{\alpha \in R^+} U_{\{\alpha\}} \rightarrow U$$

defined by the product in U is still an isomorphism. Indeed, since both sides are flat $\mathbb{Z}$ -schemes of finite presentation, it suffices to verify the assertion on geometric fibers; one is then reduced to Lazard's theory (*Bible*, § 13.1, Prop. 1): one considers U as a group with operators T , and one uses the fact that the $U_{\{\alpha\}}$ are pairwise non-isomorphic as groups with operators (since the characters $\alpha \in R^+$ of T are pairwise distinct on each fiber).

2.6.

<!-- label: III.XXV.2.6 -->

<!-- original page 273 -->

Replacing R^+ by $R^- = -R^+$, one constructs similarly the groups U^{-} , B^{-} , $U_{\{\alpha\}}$ ($\alpha \in R^{-}$) and the isomorphisms

$$p_{\alpha} : U_{\alpha} \rightarrow U_{\alpha}, \quad \alpha \in R^{-}.$$

Let us finally introduce the product scheme

$$\Omega = U^{-} \times T \times U;$$

one has a canonical isomorphism of k -schemes

$$\Omega \otimes_{\mathbb{Z}} k \cong U_k \times_k T_k \times_k U_k = \Omega_k,$$

where Ω_k is the "big cell" of G_k (Exp. XXII, 4.1.2).

From now on, we identify $\Omega \otimes_{\mathbb{Z}} \mathbb{Z}$ with Ω_k by the previous isomorphism; we regard U^{-} , T , U as subschemes of Ω , through their unit sections. We denote by $e = (0)$, e , (0) the "unit

section" of Ω .

Our goal now is to put a piece-of-group law on Ω .

Lemma 2.7. *Let $\alpha \in \Delta$, and let $w_{\alpha,k}$ be the element of $\text{Norm}_G(T)(k)$ defined by $X_{\alpha,k}$ (recall that by definition*

$w_{\alpha,k} = p_{-\alpha,k}(-1) p_{\alpha,k}(1) p_{-\alpha,k}(-1)$).

There exist an open subset V_{α} of Ω containing the section e , and a morphism

$h_{\alpha} : V_{\alpha} \rightarrow \Omega$,

satisfying the following conditions:

(i) $h_{\alpha}(e) = e$,

(ii) $h_{\alpha} \circ \text{int}(w_{\alpha,k})$ coincides with the restriction of $\text{int}(w_{\alpha,k})$ to $V_{\alpha} \cap G_k$.

(iii) One has $T \subset V_{\alpha}$, and h_{α} sends T into T . For every $\beta \in R$, one has $U_{\beta} \subset V_{\alpha}$ and h_{α} sends U_{β} into $U_{s_{\alpha}(\beta)}$.

<!-- label: III.XXV.2.7 -->

<!-- original page 273 (cont., page 416 of original) -->

By virtue of the definition of a Chevalley system (Exp. XXIII, 6.1), there exists for each $\beta \in R$ an integer e_{β} such that

$\text{int}(w_{\alpha,k}) p_{\beta,k}(x) = p_{s_{\alpha}(\beta),k}(e_{\beta} x)$

for every $x \in G_a(S)$, $S \rightarrow \text{Spec}(k)$.

Let S be any scheme, and write an arbitrary element of $\Omega(S)$ in the form

$u = (\prod_{\beta \in R^-} p_{\beta}(x_{\beta}) \cdot p_{-\alpha}(x_{-\alpha}), \quad t, \quad p_{\alpha}(x_{\alpha}) \cdot \prod_{\beta \in R^+} p_{\beta}(x_{\beta}))$,

where one has chosen some (arbitrary) order on $R^- - \{-\alpha\}$ and $R^+ - \{\alpha\}$ (cf. 2.5).

One defines a morphism $d : \Omega \rightarrow \text{Spec}(\mathbb{Z})$ by

$d(u) = \alpha(t) + x_{\alpha} x_{-\alpha}$.

<!-- original page 273 (cont., page 417 of original) -->

<!-- original page 274 -->

Let V_{α} be the open subset Ω_d (that is, the open subset of Ω defined by " $d(u)$ invertible"); it contains e , T , and each U_{β} , $\beta \in R$. Let

$h_{\alpha} : V_{\alpha} \rightarrow \Omega$

be the morphism defined by $h_{\alpha}(u) = (a(u), b(u), c(u))$ where

```

```text
a(u) = ([_{\beta \in -, \beta \neq -\alpha} p_{s_{\alpha}(\beta)}(e_{\beta} x_{\beta})] \cdot p_{-\alpha}(-x_{\alpha} d(u)^{-1}),
b(u) = t \cdot \alpha(d(u)),
c(u) = p_{\alpha}(-x_{-\alpha} d(u)^{-1}) \cdot ([_{\beta \in R^+, \beta \neq \alpha} p_{s_{\alpha}(\beta)}(e_{\beta} x_{\beta})]).
```

```

Since s_{α} permutes the positive roots (resp. negative roots) distinct from α (resp. $-\alpha$), $c(u)$ (resp. $a(u)$) is a section of U (resp. $U^{\{-\}}$) and the previous morphism is well-defined. It satisfies (i) and (iii) trivially. As for (ii), this follows at once from the definition of the e_{β} , $\beta \in R$, and from Exp. XX, 3.12.

Lemma 2.8. *There exist open subsets V and V' of Ω and morphisms*

```

```text
h : V → Ω, h' : V' → Ω,
```

```

satisfying the following conditions:

(i) V and V' contain e , and $h(e) = h'(e) = e$.

(ii) The morphism induced by $h' \circ h : h^{-1}(V') \rightarrow \Omega$ is the restriction of the identity morphism.

(iii) The k -morphisms $h \circ \text{id}_{\mathbb{Z}}$ and $h' \circ \text{id}_{\mathbb{Z}}$ are the restrictions to $V \circ \text{id}_{\mathbb{Z}}$ and $V' \circ \text{id}_{\mathbb{Z}}$ of automorphisms of the group G_k .

(iv) V and V' contain U , T and $U^{\{-}}$; h and h' send U into $U^{\{-}}$, $U^{\{-}}$ into U , and T into T .

<!-- label: III.XXV.2.8 -->

<!-- original page 274 (cont., page 418 of original) -->

Let w^0 be the element of the Weyl group of G_k that transforms $R^{\{+\}}$ into $R^{\{-}}$. Write

```

```text
w^0 = s_{\alpha_n} \cdots s_{\alpha_1}, \alpha_i \in \Delta
```

```

(no relation to the numbering of 2.1). Put

```

```text
w_{\theta} = w_{\alpha_n, k} \cdots w_{\alpha_1, k} \in \text{Norm}_{G_k}(T_k)(k).
```

```

Define by recursion on $i \leq n$ an open subset V_i of Ω and a morphism $h_i : V_i \rightarrow \Omega$ by $V_0 = \Omega$, $h_0 = \text{id}$, and, for $i = 0, \dots, n-1$,

```

```text
V_{i+1} = h_i^{-1}(V_{\alpha_{i+1}}), h_{i+1} = h_{\alpha_{i+1}} \circ h_i,
```

```

where the notations V_{α_j} and h_{α_j} are those of 2.7.

<!-- original page 275 -->

Take $V = V_n$ and $h = h_n$. The conditions in (i), (iii) and (iv) bearing on V and h are indeed verified; for (i) and (iii) this follows at once from 2.8, for (iv) from the fact that $h \circ \text{id}_{\mathbb{Z}}$ is the restriction of id_{w^0} to $V \circ \text{id}_{\mathbb{Z}}$.

Since $(w^0)^2 = 1$, one also has

```

```text
 $w^0 = s_{\{\alpha_1\}} \cdots s_{\{\alpha_n\}} = (s^3_{\{\alpha_1\}}) \cdots (s^3_{\{\alpha_n\}}).$
```

```

Setting

```

$$
w'_{\{0\}} = (w_{\{\alpha_1\},k})^{\{3\}} \cdots (w_{\{\alpha_n\},k})^{\{3\}},
$$

```

<!-- original page 275 (cont., page 419 of original) -->

and carrying out the same construction as above, one deduces from it an open subset V' and a morphism h' also satisfying (i), (iii), (iv). Moreover, $h' \otimes_{\mathbb{Z}} k$ is the restriction of $\text{int}(w'_{\{0\}})$ to $V' \otimes_{\mathbb{Z}} k$. But for each simple root $\alpha \in \Delta$, one has $(w_{\{\alpha,k\}})^{\{4\}} = e$ (cf. Exp. XX, 3.1), hence $w'_{\{0\}} \cdot w_{\{0\}} = e$, which shows that $h' \circ h$ induces the identity morphism on a non-empty open subset of $\Omega \otimes_{\mathbb{Z}} k$. But since Ω is smooth and of finite presentation over $\mathbb{Z}$, $\Omega \otimes_{\mathbb{Z}} k$ is schematically dense in Ω , which proves (ii).

Proposition 2.9. *There exist an open subset V_1 of $\Omega \times \Omega$, an open subset V_2 of Ω , and morphisms*

```

```text
 $\pi : V_1 \rightarrow \Omega, \quad \sigma : V_2 \rightarrow \Omega,$
```

```

having the following properties:

(i) If $x \in \Omega(S)$, then (e, x) and (x, e) are sections of V_1 , and

```

```text
 $\pi(e, x) = \pi(x, e) = x.$
```

```

(ii) V_2 contains e and $\sigma(e) = e$.

(iii) π_k and σ_k are the restrictions of the morphisms $G_k \times_k G_k \rightarrow G_k$ and $G_k \rightarrow G_k$ defined by the product (resp. the inverse).

<!-- label: III.XXV.2.9 -->

Proof. Let (v, t, u) and (v', t', u') be two sections of Ω . Then $h(u)$ is a section of $U^{\{-\}}$, $h(v')$ is a section of U by 2.8 (iv), and one can therefore regard $(h(u), e, h(v'))$ as a section of Ω . Let V_1 be the open subset of $\Omega \times \Omega$ defined by the condition:

```

```text
 $((v, t, u), (v', t', u')) \in V_1(S) \iff (h(u), e, h(v')) \in V'(S)$
```

```

(notation of 2.8). If $((v, t, u), (v', t', u'))$ is a section of V_1 , then $h'(h(u), e, h(v'))$ is defined; it is a section of Ω which one can decompose:

<!-- original page 275 (cont., page 420 of original) -->

```

```text
 $h'(h(u), e, h(v')) = (v'', t'', u'').$
```

```

One then sets

```

```text
 $\pi((v, t, u), (v', t', u')) = (v \cdot {}^t v''^{-1} t^{-1}, t {}^{t''} t', t'^{-1} u'' {}^{t'} u').$
```

```

<!-- TRANSLATOR NOTE: source has $v \cdot tv'' t^{-1}$ and $t'^{-1} u'' t' \cdot u''$; the leading t' (resp. t'^{-1}) denotes conjugation, rendered here with a leading raised t'/t'^{-1} to indicate the conjugation action. -->

The verification of (i) is immediate (by 2.8 (ii)). To verify the condition in (iii) bearing on π , one sees that

```

```text
h'(h(u), e, h(v')) = u v' = v'' t'' u''
```

```

when $u \in U(S)$, $v \in U^{-1}(S)$, $S \rightarrow k$, by virtue of 2.8 (iii) and (ii). One constructs σ similarly: if (v, t, u) is a section of Ω , $h(u^{-1})$ is a section of U^{-1} ,

<!-- original page 276 -->

$h(v^{-1})$ is a section of U , $h(t^{-1})$ is a section of T , so $(h(u^{-1}), h(t^{-1}), h(v^{-1}))$ is a section of Ω and one can define an open subset V_2 of Ω by

```

```text
(v, t, u) ∈ V_2(S) ⇔ (h(u^{-1}), h(t^{-1}), h(v^{-1})) ∈ V'(S)
```

```

and a morphism $\sigma : V_2 \rightarrow \Omega$ by

```

```text
σ(v, t, u) = h'(h(u^{-1}), h(t^{-1}), h(v^{-1})).
```

```

One verifies the conditions on σ as above.

Corollary 2.10. π is "generically associative" and σ is a "generic inverse": if $x, y, z \in \Omega(S)$ and if the expressions below are defined (which always happens over an open subset of Ω containing the unit section), one has:

```

```text
π(x, π(y, z)) = π(π(x, y), z), π(x, σ(x)) = e = π(σ(x), x).
```

```

<!-- label: III.XXV.2.10 -->

<!-- original page 276 (cont., page 421 of original) -->

Indeed, the two sides of each of these formulas define morphisms between smooth $\mathbb{Z}$ -schemes of finite presentation, which coincide on the generic fibers, by 2.10 (iii).

<!-- TRANSLATOR NOTE: source says "par 2.10 (iii)" but the reference should be to 2.9 (iii); kept as in source. -->

Corollary 2.11. Let $\alpha \in R$. For all S and all $x, y \in \mathbb{G}_a(S)$ such that $(p_\alpha(x), p_{-\alpha}(y)) \in V_1(S)$ and $1 + xy \in \mathbb{G}_m(S)$ (which defines an open subset of $\mathbb{G}_a^2(S)$ containing the section $(0, 0)$), one has:

```

```text
π(p_α(x), p_{-α}(y)) = (p_{-α}(y / (1 + xy)), α*(1 + xy), p_α(x / (1 + xy))).
```

```

<!-- label: III.XXV.2.11 -->

The proof is the same as before, by Exp. XX, 2.1.

3. Existence theorem: end of the proof

<!-- label: III.XXV.3 -->

To simplify language, let us pose the following definition.

Definition 3.1. Let S be a scheme and G an S -group scheme. One says that G is *admissible* if there exists

an open immersion of Ω -schemes $i : \Omega_S = \Omega \times S \rightarrow G$ satisfying the following conditions:

(i) The diagram

$$\begin{array}{ccc} (V_1)_S & \xrightarrow{i \times_S i} & \Omega_S \times_S \Omega_S \xrightarrow{i \times_S i} G \times_S G \\ \downarrow \pi & & \downarrow \pi_G \\ \Omega_S & \xrightarrow{i_S} & G, \end{array}$$

where π_G denotes the multiplication morphism in G , is commutative.

(ii) There exists a finite set of sections $a_{\{j\}} \in \Omega(S)$ such that the $i(a_{\{j\}}) \cdot i(\Omega_S)$ cover G .

<!-- label: III.XXV.3.1 -->

<!-- original page 276 (cont., page 422 of original) -->

By Weil's "theorem" (Exp. XVIII, 3.13 (iii) and (iv)), one has:

Lemma 3.2. *If for every scheme S étale and of finite type over $\mathbb{Z}$, every admissible S -group is affine, then there exists an admissible affine $\mathbb{Z}$ -group.*

<!-- label: III.XXV.3.2 -->

<!-- original page 277 -->

Now one has:

Lemma 3.3. *Let S be a scheme and G an admissible S -group. Then G is smooth and of finite presentation over S , with affine connected semisimple fibers.*

<!-- label: III.XXV.3.3 -->

Since Ω_S is smooth and of finite presentation over S , with connected fibers, the same holds for G , by condition (ii). To verify 3.3, one may therefore suppose that S is the spectrum of a field K . Let us identify Ω_K with its image in G . It is clear that Ω_K is the product

$$\prod_{\alpha \in R^-} U_{\alpha, K} \cdot T_K \cdot \prod_{\alpha \in R^+} U_{\alpha, K}$$

of the subgroups T_K and $U_{\alpha, K}$ ($\alpha \in R$) of G . The Lie algebra of G is therefore identified with the direct sum

$$\text{Lie}(T_K) \oplus \bigoplus_{\alpha \in R} \text{Lie}(U_{\alpha, K}).$$

Since the inner automorphism defined by a section of T_K acts on $U_{\alpha, K}$, and therefore on $\text{Lie}(U_{\alpha, K})$, through the character

$$\alpha \in R \subset M = \text{Hom}_{K\text{-gr.}}(T_K, \prod_{\alpha \in R} U_{\alpha, K}),$$

the previous decomposition of $\text{Lie}(G)$ is exactly the decomposition under the adjoint action of T . The roots of G_K with respect to T_K are therefore the $\alpha \in R$. Apply Exp. XIX, 1.13. Let T_{α} be the maximal torus of $\text{Ker}(\alpha) \subset T_K$, and let $Z_{\alpha} = \text{Cent}_G(T_{\alpha})$; it suffices for us to prove that each Z_{α} is reductive. Now $Z_{\alpha} \cap \Omega_K$ is none other than

```

```text

$$\bigcap_{\beta \in R^-} \{ \beta|_{T_\alpha} = e \} \cup_{\beta, K} \cdot T_K \cdot \bigcap_{\beta \in R^+} \{ \beta|_{T_\alpha} = e \} \cup_{\beta, K};$$

```

<!-- original page 277 (cont., page 423 of original) -->

but the roots vanishing on  $T_{\alpha}$  are the rational multiples of  $\alpha$ , hence  $\alpha$  and  $-\alpha$ ; this proves

```

```text

$$Z_{\alpha} \cap \Omega_K = U_{-\alpha, K} \cdot T_K \cdot U_{\alpha, K}.$$

```

To prove that Z_{α} is reductive, it suffices, by Exp. XX 3.4, to prove that $U_{\alpha, K}$ and $U_{-\alpha, K}$ do not commute, which follows at once from 2.11.

It follows from 3.2 and 3.3 that the proof will be complete if we prove:

Lemma 3.4. *If S is a locally noetherian scheme of dimension ≤ 1 , and if G is a smooth S -group of finite type with affine connected semisimple fibers, then G is affine (and therefore semisimple).*

<!-- label: III.XXV.3.4 -->

Nota. In Exp. XVI, it was seen that 3.4 is true without hypothesis on S , but the proof is relatively delicate; since here we need only the particular case 3.4, we give a direct proof of it.

Consider the Lie algebra $\mathfrak{g}$ of G , which is a locally free $\mathcal{O}_S$ -module, and the adjoint representation of G

```

$$\text{Ad} : G \rightarrow \text{GL}_{\mathcal{O}_S}(g).$$

```

<!-- original page 278 -->

To prove that G is affine over S , it suffices to prove that the morphism Ad is affine. Since G is smooth with connected fibers, it is separated over S (VI_B 5.5), so the morphism Ad is separated. Using a result proved in the appendix (see 4.1), it suffices to prove that the morphism Ad is quasi-finite. One is thus reduced to the case where S is the spectrum of a field; in this case G is affine, hence semisimple, and one is reduced to Exp. XXII 5.7.14.

4. Appendix

<!-- label: III.XXV.4 -->

<!-- original page 278 (cont., page 424 of original) -->

We used in the course of the proof the following proposition:

Proposition 4.1. *Let S be a locally noetherian scheme of dimension ≤ 1 , let G and H be two S -group schemes of finite type, and $f : G \rightarrow H$ a quasi-finite separated group morphism. If G is flat over S , [N.D.E-XXV-6] then f is affine.*

<!-- label: III.XXV.4.1 -->

We shall give the proof only in the case where G is smooth over S , a hypothesis which is indeed verified in the application we have made of the proposition.

4.2.

<!-- label: III.XXV.4.2 -->

By EGA II, 1.6.4, one may suppose S reduced. By the usual techniques of passage to the limit, [N.D.E-XXV-7] one may suppose S local. If $\dim(S) = 0$, the assertion is trivial, [N.D.E-XXV-8] suppose $\dim(S) = 1$. By faithfully flat descent, one may suppose that S is complete with algebraically closed residue field. Replacing S by its normalization $\tilde{S}$ if necessary, one may (EGA II, 6.7.1 and EGA 0_IV 23.1.5) suppose S normal. [N.D.E-XXV-9]

One is therefore reduced to the case where S is the spectrum of a complete discrete valuation ring A with algebraically closed residue field.

4.3.

<!-- label: III.XXV.4.3 -->

Let η (resp. s) be the generic (resp. closed) point of S . Consider the image $f_{\eta}(G_{\eta})$ of G_{η} in H_{η} . It is a closed subgroup scheme of H_{η} . Let H' be the schematic closure in H of $f_{\eta}(G_{\eta})$. Since $H' \rightarrow H$ is affine (it is a closed immersion), one may replace H by H' and so suppose H flat over S and f_{η} surjective. Since f_{η} is finite, and G and H are flat over S , one has

```
```text
dim(G_s) = dim(G_η) = dim(H_η) = dim(H_s).
```

### 4.4.

<!-- label: III.XXV.4.4 -->

Let  $H^0_s, \dots, H^n_s$  be the irreducible components of  $H_s$ , where  $H^0_s$  denotes the neutral component, and let  $z_0, \dots, z_n$  be their generic points. Since each local ring  $\mathcal{O}_{H,z_i}$  is of dimension  $\leq 1$ , the morphism  $G \times_H \mathcal{O}_{H,z_i} \rightarrow \mathcal{O}_{H,z_i}$  is affine because quasi-finite and separated (cf. Exp. XVI, Lemma 4.2), so  $G$  is affine over  $H$  in a neighborhood of  $z_i$ . Denoting by  $V$  the largest open subset of  $H$  such that  $G|_V$  is affine over  $V$ , it follows

<!-- original page 278 (cont., page 425 of original) -->

<!-- original page 279 -->

that  $V$  contains all the  $z_i$ , [N.D.E-XXV-10] so contains at least one closed point  $y_i \in H^0_s$  (and one has  $\kappa(y_i) = \kappa(s)$  since  $\kappa(s)$  is algebraically closed).

On the other hand,  $V$  is obviously stable under the translation defined by any element  $g \in G(S)$ . But one has  $\dim(G_s) = \dim(H_s)$  and  $f_s$  is finite, so

```
$$
f(s) : G^0_s(s) \rightarrow H^0_s(s)
$$
```

is surjective. Since  $A$  is complete and  $G$  smooth over  $S$ , the canonical map  $G^0(S) \rightarrow G^0_s(s)$  is surjective; since  $H^0_s(s)$  acts transitively on each  $H^i_s(s)$ , it follows that  $V \supset H_s(s)$ , hence (since  $\kappa(s)$  is algebraically closed)  $V \supset H_s$ . [N.D.E-XXV-11]

Since one obviously has  $V \supset H_{\eta}$ , since  $f_{\eta}$  is finite, one therefore has  $V = H$ . \*QED\*.

[^N.D.E-XXV-0]: N.D.E.: Version of 13/10/2024.

[^N.D.E-XXV-1]: N.D.E.: Such a principle was also sketched by B. Kostant [Ko66]; a complete proof, using quantum groups, has been given recently by G. Lusztig [Lu09].

[^N.D.E-XXV-2]: N.D.E.: Let us also point out that the work [BT84] of F. Bruhat and J. Tits contains a variant of Chevalley's construction (\*loc. cit.\*, 2.2.3–2.2.5 and § 3.2), which yields in particular a smooth affine  $\mathbb{Z}$ -group  $G$  with connected fibers, possessing a split maximal torus, and whose generic fiber is a reductive  $\mathbb{Q}$ -group of type  $R$ ; the fact that the geometric fibers of  $G$  are reductive follows from the study of the unipotent radical of a special fiber carried out in \*loc. cit.\*, 4.6.12 and 4.6.15 (valid for more general  $G$ , associated with a valued root datum), but it is simpler to deduce it from the description of  $g = \mathrm{Lie}(G)$ , from Exp. XIX 1.12 (iii), and from the existence of the elements  $s_{w_{\alpha}(X)}$  of Exp. XX 3.1 (iv) (cf. [BT84], 3.2.1).

[^N.D.E-XXV-3]: N.D.E.: In fact, Exp. XXIII, 5.9 is not necessary because the present Exposé constructs, for every semisimple  $\mathbb{Q}$ -group  $G_{\mathbb{Q}}$ , a semisimple  $\mathbb{Z}$ -group  $G$  of the same type as  $G_{\mathbb{Q}}$  and equipped with a split maximal torus  $T$ ; hence, by Exp. XXII 2.2,  $G$  is split.

[^N.D.E-XXV-4]: N.D.E.: Let  $\Delta$  be a base of  $R$  and  $\tilde{g}$  the complex Lie algebra generated by generators  $(e_{\alpha}, f_{\alpha}, h_{\alpha})_{\alpha \in \Delta}$  subject to the relations  $[h_{\alpha}, h_{\beta}] = 0$ ,  $[e_{\alpha}, f_{\beta}] = h_{\alpha}$  if  $\beta = \alpha$  and  $= 0$  otherwise,  $[h_{\alpha}, e_{\beta}] = (\alpha, \beta) e_{\beta}$  and  $[h_{\alpha}, f_{\beta}] = -(\alpha, \beta) f_{\beta}$ . In \*loc. cit.\*,  $g$  is defined as the quotient of  $\tilde{g}$  by the intersection of the kernels of the finite-dimensional irreducible representations of  $\tilde{g}$ ; in [Se66], § VI.5, Th. 9 (see also [BLie], VIII, § 4.3, Th. 1) it is shown that  $g$  is the quotient of  $\tilde{g}$  by the relations  $\mathrm{ad}(e_{\alpha})^{1-(\alpha, \beta)}(e_{\beta}) = 0$  and  $\mathrm{ad}(f_{\alpha})^{1-(\alpha, \beta)}(f_{\beta}) = 0$ . For an explicit description of the structure constants (in particular the choice of signs), see Exp. XXIII 6.5 and 6.7 as well as [Ti66], § 4, Th. 1 and (for types A, D, E) [Sp98], 10.2.5.

[^N.D.E-XXV-5]: N.D.E.: One may suppose  $R$  irreducible, hence  $g$  simple. By a general argument, one knows that  $\mathrm{Lie}(G)$  is the complex Lie algebra of derivations of  $g$  (cf. [DG70], § II.4, Prop. 2.3); but these are all inner

(cf. [BLie], I § 6.1, Cor. 3 of Prop. 1), hence  $\mathrm{Lie}(G) = \mathfrak{g}$ ; consequently  $G$  has no invariant subgroup of dimension  $> 0$ , hence  $G$  is semisimple. Its root system is then the same as that of  $\mathfrak{g}$ ; moreover, the center of  $G$  acts simultaneously trivially and faithfully on  $\mathfrak{g}$ , hence is trivial, hence  $G$  is adjoint.

[^N.D.E-XXV-6]: N.D.E.: We have added the flatness hypothesis, which had been omitted.

[^N.D.E-XXV-7]: N.D.E.: cf. EGA IV\_3, 8.10.5 (viii).

[^N.D.E-XXV-8]: N.D.E.: Indeed, if  $S = \operatorname{Spec}(k)$  ( $k$  a field), then  $f$  is the composite of the projection  $p : G \rightarrow G/\operatorname{Ker}(f)$  and a closed immersion  $i$ , and since  $\operatorname{Ker}(f)$  is finite over  $k$ ,  $p$  is finite (VI\_B 9.2).

[^N.D.E-XXV-9]: N.D.E.: Indeed, the irreducible components  $S_1, \dots, S_r$  of  $S$  are complete integral noetherian local schemes, hence, by a theorem of Nagata (cf. EGA 0\_IV, 23.1.5) the normalization  $\tilde{S}_i$  is finite over  $S_i$ , and therefore  $\tilde{S}$  is finite over  $S$ . Then, by a theorem of Chevalley (cf. EGA II, 6.7.1), if  $f \times_S \tilde{S}$  is an affine morphism, then so is  $f$ .

[^N.D.E-XXV-10]: N.D.E.: The following sentence has been added.

[^N.D.E-XXV-11]: N.D.E.: When  $G$  is not assumed smooth over  $S$ , one may proceed as follows. Let  $h_0$  be a rational point of  $H^0_s$  and  $g_0$  a rational point of  $G^0_s$  such that  $f(g_0) = h_0$ . By VI\_B 5.6.1, there exists a commutative diagram

```text

$$\begin{array}{ccc} S'' & \xrightarrow{g} & G \\ \downarrow \pi & \searrow \varphi & \downarrow \\ S' & \xrightarrow{w} & S \end{array}$$

...

where w is étale and surjective, π finite and surjective, and $\varphi^{-1}(s)$ is formed of a single point s'' such that $g(s'') = g_0$. Then the morphism $G_{S''} \rightarrow H_{S''}$ is affine above a neighborhood of $h_0 y_i$, and the same holds for $G_{S'} \rightarrow H_{S'}$ (EGA II, 6.7.1), and then for $G \rightarrow H$ by faithfully flat descent (EGA IV_2, 2.7.1 (xiii)). Hence $h_0 y_i \in V$, and it follows that V contains $H_s(s)$, and therefore H_s .

Exposé XXVI. Parabolic subgroups of reductive groups

<!-- label: III.XXVI -->

by M. Demazure

<!-- original page 281 -->

[^N.D.E-XXVI-0]

This Exposé studies the parabolic subgroups of an S -reductive group G . Its essential result is the conjugacy theorem (5.4). The essential tool is the notion of *transversal position* of two parabolic subgroups, a notion studied systematically in §4. Another fact plays an important role: the decomposition of the unipotent radical $\operatorname{rad}^u(P)$ of a parabolic subgroup P as successive extensions of vector groups (2.1)[^N.D.E-XXVI-1].

Various schemes associated with G are studied in §3; §6 deals with the split subtori[^N.D.E-XXVI-2] of G and their relations with parabolic subgroups.

Finally, in §7, we briefly expound how, over a semi-local base, one formulates the "relative theory" of reductive groups as presented over fields in the article of A. Borel and J. Tits, *Groupes réductifs*, Publications Mathématiques de l'IHÉS, no. 27. In that article, cited [BT65] in what follows, the reader will moreover find, in the case of a base field, other results that have not been touched on here.

1. Recollections. Levi subgroups

<!-- label: III.XXVI.1 -->

****Definition 1.1.**** *Let S be a scheme, G an S -reductive group, P a sub- S -group-scheme of G . One says that P is a* parabolic subgroup *of G if*

(i) P is smooth over S ,

<!-- original page 282 -->

(ii) for each $s \in S$, the s -quotient-scheme G_s/P_s is proper (i.e. Bible, §6.4, Th. 4 (= [Ch05], §6.5, Th. 5), P_s contains a Borel subgroup of G_s).

<!-- label: III.XXVI.1.1 -->

****Proposition 1.2**** (Exp. XXII, 5.8.5). *Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G . Then P is closed in G , with connected fibers, and*

S
 $P = \text{Norm}_G(P)$.
 S

Moreover, the quotient sheaf G/P is representable by an S -scheme that is smooth and projective over S .

<!-- label: III.XXVI.1.2 -->

****Proposition 1.3**** (Exp. XXII, 5.3.9 and 5.3.11). *Let S be a scheme, G an S -reductive group, P and P' two parabolic subgroups of G . The following conditions are equivalent:*

(i) P and P' are conjugate in G , locally for the étale (resp. (fpqc)) topology.

(ii) For each $s \in S$, P_s and P'_s are conjugate by an element of $G(s)$.

(iii) The strict transporter $\text{Transt}_G(P, P')$ of P into P' (defined by

```text  
 $\text{Transt}_G(P, P')(S) = \{ g \in G(S) \mid \text{int}(g) P = P' \}$  )  
```)

for every $S' \rightarrow S$) is a closed subscheme of G , smooth and of finite presentation over S , which is a principal homogeneous bundle on the right under P and on the left under P' .

<!-- label: III.XXVI.1.3 -->

****Proposition 1.4.**** *Let S be a nonempty scheme, (G, T, M, R) an S -split reductive group, R' a subset of R . The following conditions on R' are equivalent:*

<!-- original page 428 -->

(i) $\mathfrak{g}_{R'} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R'} \mathfrak{g}^{\alpha}$ is the Lie algebra of a parabolic subgroup of G containing T (necessarily unique, Exp. XXII, 5.3.5).

(ii) R' is of type (R) (Exp. XXII, 5.4.2) and contains a system of positive roots.

(iii) R' is a closed subset of R and satisfies: if $\alpha \in R - R'$, then $-\alpha \in R'$ (that is, $R = R' \cup (-R')$).

(iv) There exist a system of simple roots Δ , and a subset A of Δ such that R' is the union of the set of positive roots and the set of negative roots that are linear combinations of the elements of A .

(v) R' contains a system of simple roots of R ; moreover, if $\Delta \subset R'$ is a system of simple roots of R and one sets

S
 $A = (-R') \cap \Delta$,

\$\$

then R' is the union of the set of positive roots and the set of negative roots that are linear combinations of the elements of A .

<!-- label: III.XXVI.1.4 -->

One has (i) $\Rightarrow$ (ii) by Exp. XXII, 5.4.5 (ii) and 5.5.1. One has (iii) $\Rightarrow$ (ii) by Exp. XXI, 3.3.6 and Exp. XXII, 5.4.7. One trivially has (v) $\Rightarrow$ (iv) $\Rightarrow$ (iii). One has (iii) $\Rightarrow$ (v) by Exp. XXI, 3.3.6 and 3.3.10.

It therefore remains to prove that (i) implies that R' is a closed subset of R . But this last assertion can be verified on any geometric fiber; one may therefore assume that S is the spectrum of an algebraically closed field.

Let P be the parabolic subgroup of G containing T whose Lie algebra is $\mathfrak{g}_{R'}$. Since the Borel subgroups of P are the Borel subgroups of G contained in P , it follows from Bible, §12.3, Th. 1, and from Exp. XXII, 5.4.5 (i), that if one denotes by U the unipotent radical of P , then $T \cdot U$ is the subgroup of G containing T whose Lie algebra is

```
```text
 $\mathfrak{g}_{R'} = \mathfrak{t} \oplus \sum_{\alpha \in R'} \mathfrak{g}^\alpha,$
```

<!-- original page 429 -->

where  $R''$  is the intersection of the systems of positive roots of  $R$  contained in  $R'$ . In particular, it follows that  $R''$  is closed and that  $R'' \cap (-R') = \emptyset$ . On the other hand, the group  $H = P/U$  is reductive, the canonical image  $\bar{T}$  of  $T$  is a maximal torus of it ( $T \rightarrow \bar{T}$  is an isomorphism), and one has an isomorphism of  $\bar{T}$ -modules, i.e. of  $M$ -graded vector spaces,

```
```text
 $\text{Lie}(H) = \mathfrak{t} \oplus \sum_{\alpha \in R_s} \mathfrak{g}^\alpha,$ 
```

where R_s is the complement of R'' in R . It follows that R_s is naturally identified with the set of roots of H relative to $\bar{T}$, and in particular satisfies $R_s = -R_s$. One immediately deduces that

```
```text
 $R' = \{ \alpha \in R \mid -\alpha \notin R' \}, \quad R_s = \{ \alpha \in R \mid -\alpha \in R' \}.$
```

Let us now show that  $R'$  is closed. Let  $\alpha, \beta \in R'$  such that  $\alpha + \beta \in R$ ; let us prove that  $\alpha + \beta \in R'$ . If  $\alpha, \beta \in R'$ , then  $\alpha + \beta \in R'$  because  $R''$  is closed. If  $\alpha \in R_s$ ,  $\beta \in R'$ , and if  $\alpha + \beta \in R$ , then  $\alpha + \beta \in -R'$ , and one has  $-\alpha = -(\alpha + \beta) + \beta \in R'$  because  $R''$  is closed, which entails  $-\alpha \in R' \cap R_s$  and contradicts the fact that  $R_s \cap R' = \emptyset$ . It therefore remains to study the case where  $\alpha, \beta \in R_s$ . If  $\alpha + \beta \notin R$ , then  $\alpha + \beta \in -R'$ . But, as  $\alpha + \beta \neq 0$ , there exists a system of positive roots of the root system  $R_s$  containing  $\alpha$  and  $\beta$ , hence a Borel subgroup of  $H = P/U$  containing the canonical image of  $U_\alpha$  and  $U_\beta$ . Its inverse image in  $P$  is a Borel subgroup containing  $U_\alpha$ ,  $U_\beta$  and  $U$ , hence  $U_\alpha$ ,  $U_\beta$  and  $U_{-(\alpha+\beta)}$ , which is impossible.

**Corollary 1.5.** \*A parabolic subgroup of a reductive group is of type (RC) (Exp. XXII, 5.11.1).\*

<!-- original page 430 -->

<!-- label: III.XXVI.1.5 -->

**Proposition 1.6** (Exp. XXII, 5.11.4). \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a subgroup of  $G$  of type (RC) (\*N.D.E.-XXVI-3).

(i)  $P$  possesses a largest invariant sub-group-scheme that is smooth and of finite presentation over  $S$ , with connected unipotent geometric fibers. It is a characteristic subgroup of  $P$ , called the unipotent radical of  $P$ , denoted  $\text{rad}^u(P)$ . The quotient sheaf  $P/\text{rad}^u(P)$  is representable by an  $S$ -reductive group.\*

(ii) If  $T$  is a maximal torus of  $P$ ,  $P$  possesses a reductive subgroup  $L$  containing  $T$  such that:

\*(a) Every reductive subgroup of  $P$  containing  $T$  is contained in  $L$ .\*

\*(b)  $P$  is the semidirect product  $L \cdot \text{rad}^u(P)$ , i.e. the canonical morphism  $L \rightarrow P/\text{rad}^u(P)$  is an isomorphism.\*

Moreover,  $L$  is the unique subgroup (resp. reductive subgroup) of  $P$  containing  $T$  and satisfying (b) (resp. (a)). Finally, one has\*

```text  
Norm_P(L) = L, Norm_P(T) = Norm_L(T).
```

<!-- label: III.XXVI.1.6 -->

### 1.7.

<!-- label: III.XXVI.1.7 -->

A subgroup  $L$  of  $P$  satisfying condition (b) above is called a *Levi subgroup* of  $P$ . It is a maximal reductive subgroup of  $P$ ; indeed, it is reductive, since isomorphic to  $P/\text{rad}^u(P)$ . Let us show that it is maximal for this property. Let  $L'$  be a reductive subgroup of  $P$  containing  $L$ ; to prove that  $L' = L$ , one may reason locally for the (fpqc) topology, and hence assume that  $L$  has a maximal torus  $T$ , and one is reduced to 1.6 (ii).

<!-- original page 431 -->

If  $L$  and  $L'$  are two Levi subgroups of  $P$ , then  $L$  and  $L'$  are conjugate in  $P$ , locally for the (fpqc) topology. Indeed, locally for this topology, one may assume that  $L$  (resp.  $L'$ ) has a maximal torus  $T$  (resp.  $T'$ ); since  $T$  and  $T'$  are conjugate in  $P$  locally for the (fpqc) topology, one may assume  $T = T'$ , and one then has  $L = L'$ , by 1.6 (ii). But since  $P = L \cdot \text{rad}^u(P)$  and  $\text{Norm}_P(L) = L$ , one immediately deduces:

**\*\*Corollary 1.8.\*\*** \*Let  $P$  be a subgroup of type (RC)[<sup>N.D.E-XXVI-4</sup>] of the  $S$ -reductive group  $G$ . If  $L$  and  $L'$  are two Levi subgroups of  $P$ , there exists a unique  $u \in \text{rad}^u(P)(S)$  such that  $\text{int}(u) L = L'$ .\*

<!-- label: III.XXVI.1.8 -->

Let us denote by  $\text{Lev}(P)$  the functor of Levi subgroups of  $P$ : for  $S' \rightarrow S$ ,  $\text{Lev}(P)(S')$  is the set of Levi subgroups of  $P_{S'}$ . From 1.8 one deduces:

**\*\*Corollary 1.9.\*\*** \*Let  $P$  be a subgroup of type (RC)[<sup>N.D.E-XXVI-4</sup>] of the  $S$ -reductive group  $G$ . Then  $\text{Lev}(P)$  is a principal homogeneous bundle under the  $S$ -group  $\text{rad}^u(P)$ , and in particular is representable by an  $S$ -scheme that is smooth and affine over  $S$ , with integral geometric fibers.\*

<!-- label: III.XXVI.1.9 -->

It follows immediately from 1.6:

**\*\*Corollary 1.10.\*\*** \*Let  $P$  be a subgroup of type (RC)[<sup>N.D.E-XXVI-4</sup>] of the  $S$ -reductive group  $G$ . The functor  $\text{Tor}(P)$  of maximal tori of  $P$  is representable by an  $S$ -scheme that is smooth and affine, the "relation  $L \supseteq T$ " defines a morphism\*

$$\text{Tor}(P) \rightarrow \text{Lev}(P),$$

\*the fiber of which over  $L \in \text{Lev}(P)(S)$  is identified with  $\text{Tor}(L)$  (Exp. XXII, 5.8.3).\*

<!-- label: III.XXVI.1.10 -->

The first assertion of 1.10 is a consequence of the other two and of Exp. XXII, 5.8.3.

<!-- original page 432 -->

**\*\*Definition 1.11.\*\*** \*Let  $S$  be a nonempty scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ ,  $E = (T, M, R, \Delta, (X_{\alpha})_{\alpha \in \Delta})$  a pinning of  $G$ . One says that  $E$  is\* adapted \*to  $P$ , or

that  $E$  is a pinning of the pair  $(G, P)$ , if  $P \subset T$  and if the Lie algebra of  $P$  is of the form  $t \oplus \bigoplus_{\alpha \in R'} g^{\alpha}$ , where  $R'$  is a subset of  $R$  containing  $R^+$ .

<!-- label: III.XXVI.1.11 -->

In particular, if  $T \subset B$  is the Killing pair defined by the pinning, one has  $T \subset B \subset P$ .

Under the preceding conditions, one sets  $\Delta(P) = \Delta \cap (-R')$ ; then, by Exp. XXII, 5.4.3, one has:

$$\alpha \in \Delta(P) \iff \alpha \in \Delta \text{ and } U_{-\alpha} \subset P \iff \alpha \in \Delta \text{ and } U_{-\alpha} \cap P \neq e.$$

It follows immediately from 1.4 (v) and Exp. XXII, 5.11.3 and 5.10.6:

**Proposition 1.12.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ ,  $(T, M, R, \Delta, (X_{\alpha})_{\alpha \in \Delta})$  a pinning of  $G$  adapted to  $P$ ,  $\Delta(P)$  the subset of  $\Delta$  defined above.

(i) The unipotent radical  $\text{rad}^u(P)$  of  $P$  is none other than

$$U_{R''} = \prod_{\alpha \in R''} U_{\alpha},$$

where  $R''$  is the set of positive roots that, in their decomposition along  $\Delta$ , involve at least one element of  $\Delta - \Delta(P)$  with a nonzero coefficient.

(ii) The unique Levi subgroup  $L$  of  $P$  containing  $T$  is none other than

$$Z_{\Delta(P)} = \text{Centr}_G(T_{\Delta(P)}),$$

where  $T_{\Delta(P)}$  is the maximal torus of  $\bigcap_{\alpha \in \Delta(P)} \text{Ker}(\alpha)$ ; moreover, one has  $T_{\Delta(P)} = \text{rad}(L)$ .

<!-- label: III.XXVI.1.12 -->

**Corollary 1.13.** Every Levi subgroup  $L$  of the parabolic subgroup  $P$  of the reductive group  $G$  is a critical subgroup of  $G$ , i.e. satisfies (Exp. XXII, 5.10.4):

$$L = \text{Centr}_G(\text{rad}(L)).$$

<!-- original page 433 -->

<!-- label: III.XXVI.1.13 -->

This follows immediately from 1.12 and from the following lemma, which is contained in 1.4 and Exp. XXII, 5.4.1:

**Lemma 1.14.** Locally for the étale topology, every pair  $(G, P)$ , where  $P$  is a parabolic subgroup of the reductive group  $G$ , may be pinned (1.11).

<!-- label: III.XXVI.1.14 -->

Let us note:

**Proposition 1.15.** Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ ,  $E$  and  $E'$  two pinnings of  $G$  adapted to  $P$ . The unique inner automorphism of  $G$  over  $S$  that transforms  $E$  into  $E'$  (Exp. XXIV, 1.5) comes from  $P$ , via the morphism

$$P \rightarrow P/\text{Centr}(P) = P/\text{Centr}(G) \rightarrow G/\text{Centr}(G).$$

...

<!-- label: III.XXVI.1.15 -->

Indeed, it suffices to reason as in Exp. XXIV, 1.5, using:

**\*\*Lemma 1.16\*\*** (Exp. XXII, 5.3.14 and 5.2.6). *\*The maximal tori (resp. Borel subgroups, resp. Killing pairs) of a parabolic subgroup  $P$  of the  $S$ -reductive group  $G$  are conjugate in  $P$ , locally for the étale topology.\**

<!-- label: III.XXVI.1.16 -->

**\*\*Proposition 1.17.\*\*** *\*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  and  $P'$  two parabolic subgroups of  $G$ ,  $B$  a Borel subgroup contained in  $P$  and  $P'$ . If  $P$  and  $P'$  are conjugate in  $G$  locally for the étale topology, then  $P = P'$ .\**

<!-- label: III.XXVI.1.17 -->

<!-- original page 434 -->

Indeed, one may assume that there exists  $g \in G(S)$  such that  $\text{int}(g) P = P'$ . Then  $B$  and  $\text{int}(g)^{-1} B$  are two Borel subgroups of  $P$ . Possibly after extending  $S$ , by 1.16 one may assume that there exists  $p \in P(S)$  such that  $\text{int}(p) \text{int}(g)^{-1} B = B$ . Then

```text  
 $p \cdot g^{-1} \in \text{Norm}_G(B)(S) = B(S),$

and $g \in B(S) \cdot p \subset P(S)$, hence $P' = \text{int}(g) P = P$.

****Remark 1.18.**** **If P and P' are two parabolic subgroups of G containing a common Borel subgroup, then $P \cap P'$ is again a parabolic subgroup of G . Indeed, it is smooth along the unit section (Exp. XXII, 5.4.5), and it contains a Borel subgroup.**

<!-- label: III.XXVI.1.18 -->

****Proposition 1.19.**** **Let S be a scheme, G an S -reductive group, G' its derived group (Exp. XXII, 6.2.1).**

(i) The maps

```text  
 $P \mapsto P' = P \cap G' \quad \text{and} \quad P \mapsto P' \cdot \text{rad}(G) = \text{Norm}_G(P')$   
 ```

are mutually inverse bijections between the set of parabolic subgroups of G and the set of parabolic subgroups of G' . One has $\text{rad}^u(P) = \text{rad}^u(P')$.

(ii) Let P be a parabolic subgroup of G and $P' = P \cap G'$. The maps

```text  
 $L \mapsto L' = L \cap G' = L \cap P'$   
 $L' \mapsto L' \cdot \text{rad}(G) = \text{Centr}_G(\text{rad}(L'))$   
 ```

are mutually inverse bijections between the set of Levi subgroups of P and the set of Levi subgroups of P' . Moreover, one has $\text{rad}(L') = (\text{rad}(L) \cap G')^{\{0\}}$.

<!-- label: III.XXVI.1.19 -->

<!-- original page 435 -->

The proof (by reduction to the split case, for example) is straightforward and is left to the reader, together with that, immediate, of:

****Proposition 1.20.**** **Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G , L a Levi subgroup of P . The maps**

```

```text

$$Q \mapsto Q \cap L = Q', \quad Q' \mapsto Q' \cdot \text{rad}^u(P)$$

```

```

are mutually inverse bijections between the set of parabolic subgroups of G contained in P and the set of parabolic subgroups of L . Moreover, the Levi subgroups of Q' are the Levi subgroups of Q contained in L .

<!-- label: III.XXVI.1.20 -->

One may complete 1.6 as follows:

Proposition 1.21. *Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G .*

(i) P possesses a largest invariant subgroup that is smooth and of finite presentation over S , with connected solvable geometric fibers. It is a characteristic subgroup of P , called the radical of P , and denoted $\text{rad}(P)$. The quotient sheaf $P/\text{rad}(P)$ is representable by an S -semisimple group.*

(ii) If L is a Levi subgroup of P , $\text{rad}(P)$ is the semidirect product of $\text{rad}^u(P)$ and $\text{rad}(L)$; one has $\text{rad}(L) = L \cap \text{rad}(P)$, hence $L = \text{Centr}_G(L \cap \text{rad}(P))$, and $P/\text{rad}(P) \simeq L/\text{rad}(L)$.*

<!-- label: III.XXVI.1.21 -->

Indeed, assertion (i) being local, one may assume that G has a Levi subgroup L , and one is reduced to proving that $R = \text{rad}^u(P) \cdot \text{rad}(L)$ has the properties announced in (i), which is immediate. For (ii), it only remains to show that $\text{rad}(L) = L \cap \text{rad}(P)$, which follows immediately from the fact that $L \cap \text{rad}(P)$ is smooth and has connected fibers, L being the centralizer of a torus [N.D.E-XXVI-6].

<!-- original page 436 -->

2. Structure of the unipotent radical of a parabolic subgroup

<!-- label: III.XXVI.2 -->

Proposition 2.1. *Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G , $\text{rad}^u(P)$ its unipotent radical. There exists a sequence of sub-group-schemes of $\text{rad}^u(P)$ *

```

```text

$$\text{rad}^u(P) = U_0 \supset U_1 \supset U_2 \supset \cdots \supset U_n \supset \cdots$$

```

```

possessing the following properties:

(i) Each U_i is smooth, with connected fibers, characteristic and closed in P . The commutator of a section of U_i and a section of U_j is a section of U_{i+j+1} (over a varying $S' \rightarrow S$).*

(ii) For each $i \geq 0$, there exists a locally free $\mathcal{O}_S$ -module $\mathcal{E}_i$ and an isomorphism of S -group sheaves*

```

$$U_i / U_{i+1} \xrightarrow{\sim} W(\mathcal{E}_i).$$

```

Moreover, the automorphisms of P (over a varying $S' \rightarrow S$) act linearly on $W(\mathcal{E}_i)$.*

(iii) For every $s \in S$, one has $U_{n,s} = e$ for $n > \dim(\text{rad}^u(P)_s)$.*

<!-- label: III.XXVI.2.1 -->

2.1.1.

<!-- label: III.XXVI.2.1.1 -->

Suppose first that the pair (G, P) is pinnable. Let $(T, M, R, \Delta, \dots)$ be a pinning of G adapted to P ; let $\Delta(P)$ be the part of Δ defined by P . Let $\alpha_1, \dots, \alpha_p$ be

<!-- original page 437 -->

the elements of $\Delta(P)$, and $\beta_1, \dots, \beta_q$ the elements of $\Delta - \Delta(P)$. Every root $\gamma \in R$ is written uniquely as

$$\gamma = a_1 \alpha_1 + \dots + a_p \alpha_p + b_1 \beta_1 + \dots + b_q \beta_q.$$

Set

$$a(\gamma) = b_1 + \dots + b_q. \quad [\text{N.D.E-XXVI-7}]$$

It follows immediately from the definitions that the following properties hold (cf. 1.12):

- (i) $U_\gamma \subset P \xrightarrow{\text{Leftrightarrow}} a(\gamma) \geq 0$.
- (ii) $U_\gamma \subset \text{rad}^u(P) \xrightarrow{\text{Leftrightarrow}} a(\gamma) > 0$.
- (iii) $a(n\gamma + m\gamma') = n a(\gamma) + m a(\gamma')$ for all $n, m \in \mathbb{Z}$.

For $i > 0$, let R_i be the set of roots $\gamma \in R$ such that $a(\gamma) > i$. Each R_i is a closed set of roots satisfying $R_i \cap (-R_i) = \emptyset$. Consider (Exp. XXII, 5.6.5) the S -group

$$U_i = U_{R_i} = \prod_{\gamma \in R_i} U_\gamma.$$

It is a closed sub-group-scheme of G , smooth over S , with connected fibers.

Let $\alpha, \beta \in R$; consider the commutation relation of Exp. XXII, 5.5.2

$$p_\alpha(x) p_\beta(y) p_\alpha(-x) = p_\beta(y) \prod_{n, m \in \mathbb{N}^*} p_{n\alpha + m\beta}(C_{n, m, \alpha, \beta} x^n y^m),$$

<!-- original page 438 -->

where each p_γ is an isomorphism of vector groups $G_{\{a, S\}} \xrightarrow{\sim} U_\gamma$. Let us first remark that if $a(\alpha) > i$ and $a(\beta) > j$, one has

$$a(n\alpha + m\beta) = n a(\alpha) + m a(\beta) \geq n(i+1) + m(j+1) > i + j + 1$$

when n, m are > 0 . It follows that the commutator of a section of U_α and a section of U_β is a section of U_{i+j+1} (over a varying S to S), which indeed entails $(U_i, U_j) \subset U_{i+j+1}$. For each $i \geq 0$, the quotient U_i / U_{i+1} is therefore commutative; it is naturally identified with

$$U_i / U_{i+1} \cong \prod_{a(\gamma) = i+1} U_\gamma \cong W(E_i),$$

where E_i is the direct sum of the g^γ for $a(\gamma) = i + 1$.

Let us return to the above commutation formula, and suppose $a(\alpha) \geq 0$, $a(\beta) > i$. If $n, m \in \mathbb{N}^*$,

- either $a(n\alpha + m\beta) > i + 1$,
- or $a(n\alpha + m\beta) = i + 1$, in which case one necessarily has $m = 1$.

This proves first that $\int(p_{\alpha}(x))$ respects U_i (hence also U_{i+1}), and then that, in the expression of $\int(p_{\alpha}(x)) p_{\beta}(y)$, only terms of the form $p_{\alpha+\beta}(C_{n,1,\alpha,\beta} x^n y)$ occur modulo U_{i+1} , which are therefore linear in y . It follows that the inner automorphisms defined by sections of U_{α} act linearly on the quotient U_i / U_{i+1} identified with $W(E_i)$. As this is also trivially true for the inner automorphisms defined by sections of T , and as P is generated by T and the U_{α} , $\mathfrak{a}(\alpha) \not\subseteq 0$, one deduces that:

(i) each U_i is invariant in P ,

(ii) the inner automorphisms defined by sections of P act linearly on $U_i / U_{i+1} \simeq W(E_i)$.

2.1.2.

<!-- label: III.XXVI.2.1.2 -->

Now let $(T', M', R', \Delta, \dots)$ be a new pinning of G adapted to P .

<!-- original page 439 -->

By 1.15, there exists an inner automorphism of G coming from P that transforms the old pinning into the new one. Possibly after extending S , one may assume that this inner automorphism is of the form $\int(p)$, $p \in P(S)$. If one takes up the preceding constructions using the new pinning, it is clear that the groups U'_i and the isomorphisms $U'_i / U'_{i+1} \simeq W(E'_i)$ obtained are deduced from U_i and $U_i / U_{i+1} \simeq W(E_i)$ by transport of structure via $\int(p)$. It follows from remarks (i) and (ii) above that one therefore has $U'_i = U_i$, and that the two vector structures constructed on $U_i / U_{i+1} = U'_i / U'_{i+1}$ coincide.

This shows that the groups U_i and the vector structures on the quotients U_i / U_{i+1} are independent of the pinning considered (and in particular invariant under every automorphism of P , as one sees easily).

We have therefore proved the proposition when the pair (G, P) is pinnable (part (iii) is trivial, since by Exp. XXI 3.1.2, the set $\{\alpha(\gamma) \mid \gamma \in R\}$ is an interval of $\mathbb{Z}$, hence one cannot have $\dim(U_i, s) = \dim(U_{i+1}, s)$ unless $U_i, s = e$).

2.1.3.

<!-- label: III.XXVI.2.1.3 -->

In the general case, there exists a covering family for the (fpqc) topology $\{S_j \rightarrow S\}$ such that each pair (G_{S_j}, P_{S_j}) is pinnable (1.14). By the preceding, one has descent data on the $\text{rad}^u(P_{S_j})_i$, compatible with the vector structures of the quotients, and one concludes by descent of closed subschemes (resp. locally free modules) [N.D.E-XXVI-8].

Corollary 2.2. *Let S be an affine scheme, G an S -reductive group, P a parabolic subgroup of G . One has*

$$H^1(S, \text{rad}^u(P)) = 0,$$

i.e. every principal homogeneous bundle under $\text{rad}^u(P)$ is trivial.*

<!-- label: III.XXVI.2.2 -->

Indeed, S decomposes as a sum of subschemes on each of which $\text{rad}^u(P)$ is of constant relative dimension. One may

<!-- original page 440 -->

therefore, by (iii), assume that there exists n such that $U_n = e$. Since $H^1(S, U_i / U_{i+1}) = H^1(S, W(E_i)) = 0$ by TDTE I, B, 1.1 (or SGA 1, XI 5.1), one concludes at once.

Corollary 2.3. *Under the preceding conditions, P possesses a Levi subgroup L . If L is a Levi subgroup of P , the canonical map*

$$H^1(S, L) \rightarrow H^1(S, P)$$

*is bijective (cf. the introduction of Exp. XXIV for the definition of $H^1(S, -)$).

<!-- label: III.XXVI.2.3 -->

The first assertion follows from 2.2 and 1.9. The canonical map $H^1(S, L) \rightarrow H^1(S, P)$ is surjective, because P is the semidirect product $L \rtimes \text{rad}^u(P)$. To prove that it is injective, it suffices to see that for every principal homogeneous bundle Q under L , one has $H^1(S, \text{rad}^u(P)_Q) = 0$, where the subscript Q denotes twisting by the L -bundle Q . This can be proved in two ways: one may take up the proof of 2.2, using the fact that the vector structures on the U_i / U_{i+1} are invariant under L ; one may also remark that $\text{rad}^u(P)_Q$ is identified with the unipotent radical of the parabolic subgroup P_Q of G_Q , and apply 2.2 to P_Q .

Corollary 2.4. *Let S be a semi-local scheme, G an S -reductive group, P a parabolic subgroup of G . There exists a maximal torus T of G contained in P .

<!-- label: III.XXVI.2.4 -->

Indeed, in view of 2.3, P has a Levi subgroup L , and it suffices to prove that L has a maximal torus, which follows from Exp. XIV, 3.20.

<!-- original page 441 -->

Corollary 2.5. *Let S be an affine scheme, G an S -reductive group, P a parabolic subgroup of G . There exists a locally free $\mathcal{O}_S$ -module E such that $\text{rad}^u(P)$ is isomorphic as an S -scheme to $W(E)$.

<!-- label: III.XXVI.2.5 -->

Indeed, let us prove by induction on i that one has an isomorphism of S -schemes

```

```text
rad^u(P) / U_i = W(E_0 \otimes E_1 \otimes \cdots \otimes E_{i-1}).
```

```

This is clear for $i = 0$. Assume $i > 0$; then $\text{rad}^u(P) / U_i$ is a principal homogeneous bundle with base $\text{rad}^u(P) / U_{i-1}$, under the group

```

```text
(U_{i-1} / U_i)_{\text{rad}^u(P) / U_{i-1}} = W(E_{i-1} \otimes \mathcal{O}_{\text{rad}^u(P) / U_{i-1}}).
```

```

Now the base is affine (e.g. by the induction hypothesis), so this bundle is trivial (TDTE I or SGA 1 XI, *loc. cit.*), and there exists an isomorphism of S -schemes $\text{rad}^u(P) / U_i \simeq (\text{rad}^u(P) / U_{i-1}) \times (U_{i-1} / U_i)$, which completes the proof.

Corollary 2.6. *Let S be a semi-local scheme, S_i the set of its closed points, G an S -reductive group, P a parabolic subgroup of G . The canonical map*

```

```text
rad^u(P)(S) \rightarrow \prod_i \text{rad}^u(P)(\text{Spec } \kappa(s_i))
```

```

is surjective.

<!-- label: III.XXVI.2.6 -->

Indeed, if $S = \text{Spec}(A)$, $\kappa(s_i) = A/p_i$, and if E is given by the projective (hence flat) module E , we must prove that the map

```

```text
E \rightarrow \prod_i E \otimes_A A/p_i
```

```

is surjective. It suffices to do this when $E = A$, in which case it is well known (cf. Bourbaki, *Alg. Comm.* Chap. II, §1, no. 2, Proposition 5).

<!-- original page 442 -->

****Corollary 2.7.**** *Let k be an infinite field, G a k -reductive group, P a parabolic subgroup of G ; then $\text{rad}^u(P)(k)$ is dense in $\text{rad}^u(P)$.*

<!-- label: III.XXVI.2.7 -->

****Corollary 2.8.**** *Let S be a semi-local scheme, s_i the set of its closed points, G an S -reductive group, P a parabolic subgroup of G , and L_i a Levi subgroup of P_{s_i} for each i . There exists a Levi subgroup L of P inducing L_i for each i .*

<!-- label: III.XXVI.2.8 -->

Indeed, let L_0 be a Levi subgroup of P (2.3). For each i , let $u_i \in \text{rad}^u(P)(\text{Spec}(k(s_i)))$ be such that $\text{int}(u_i) L_0 = L_i$ (1.8); if $u \in \text{rad}^u(P)(S)$ induces u_i for each i (2.6), then $L = \text{int}(u) L_0$ answers the question.

****Corollary 2.9.**** *In the situation of 2.1, let moreover H be a sub-group-scheme of G , smooth and of finite presentation over S , with connected fibers, such that $P \cap H$ contains locally for the (fpqc) topology a maximal torus of G . Then for each i ≥ 0 , there exists a locally direct factor submodule F_i of E_i such that the isomorphism $U_i / U_{i+1} \xrightarrow{\sim} W(E_i)$ induces an isomorphism of groups*

```
```text
(U_i \cap H) / (U_{i+1} \cap H) \cong W(F_i).
```

<!-- label: III.XXVI.2.9 -->

Indeed,  $H$  is a subgroup of type (R) of  $G$  (Exp. XXII, 5.2.1). On the other hand, the assertion to be proved is local for the (fpqc) topology, and one may assume  $G$  split relative to a maximal torus of  $P \cap H$ ; one may even reduce to the situation of 2.1.1, with  $H$  defined by a subset  $R'$  of  $R$ . Taking up the notation of \*loc. cit.\*, one sees by Exp. XXII, 5.6.7 (ii) that  $U_i \cap H = \prod_{\alpha \in R'_i} U_{\alpha}$ , hence that  $(U_i \cap H) / (U_{i+1} \cap H)$  is identified with  $\prod_{\alpha \in R'_i} U_{\alpha}$ ,  $a(\alpha) = i+1$   $U_{\alpha}$ , which yields the result.

**\*\*Corollary 2.10.\*\*** \*In the situation of 2.9, the conclusions of 2.2, 2.5, 2.6, 2.7 are also valid when  $\text{rad}^u(P)$  is replaced by  $\text{rad}^u(P) \cap H$ .\*

<!-- original page 443 -->

<!-- label: III.XXVI.2.10 -->

**\*\*Corollary 2.11.\*\*** <sup>[N.D.E-XXVI-9]</sup> \*Let  $G$  be an  $S$ -reductive group,  $P$  a parabolic subgroup,  $H$  a subgroup of type (RC) of  $P$  such that  $\text{rad}^u(H) = \text{rad}^u(P) \cap H$ . Then statements 2.2 to 2.8 are also valid when  $P$  is replaced by  $H$ .\*

<!-- label: III.XXVI.2.11 -->

**## 3. Scheme of parabolic subgroups of a reductive group**

<!-- label: III.XXVI.3 -->

**### 3.1.**

<!-- label: III.XXVI.3.1 -->

Let  $E$  be a finite twisted constant  $S$ -scheme (Exp. X, 5.1). Consider the  $S$ -functor  $\text{Of}(E)$ , where  $\text{Of}(E)(S')$  is the set of open and closed subschemes of  $E_{S'}$  (or, equivalently, the set of open and closed subsets of  $E_{S'}$ ); then  $\text{Of}(E)$  is representable by a finite twisted constant  $S$ -scheme. Indeed, if  $E = A_S$ , where  $A$  is a finite set, one has immediately  $\text{Of}(E) \cong \text{P}(A_S)$  (where  $\text{P}(A)$  denotes the power set of  $A$ ), and one concludes by descent of open and closed subschemes. One trivially has:

```
```text
Of(E_{S'}) = Of(E)_{S'},      Of(E \times_S E') = Of(E) \times_S Of(E').
```

3.2.

<!-- label: III.XXVI.3.2 -->

Let S be a scheme, G an S -reductive group. The functor $\text{Par}(G)$ of parabolic subgroups of G is defined by

$\text{Par}(G)(S)$ = the set of parabolic subgroups of G_S .

In particular, $G \in \text{Par}(G)(S)$, $\text{Bor}(G) \subset \text{Par}(G)$. We propose to define a morphism

$t : \text{Par}(G) \rightarrow \text{Of}(\text{Dyn}(G))$

possessing the following properties:

(i) t is functorial in G (with respect to isomorphisms) and commutes with base change.

<!-- original page 444 -->

(ii) If (T, M, R, Δ) is a pinning of G adapted to the parabolic subgroup P (1.11), the canonical isomorphism $\text{Dyn}(G) \xrightarrow{\sim} \Delta_S$ (Exp. XXIV, 3.4 (iii)) transforms $t(P)$ into $\Delta(P)_S$ (notations of 1.11, 1.12).

Let first P be a parabolic subgroup of G and (T, M, R, Δ) a pinning of G adapted to P . One defines $t(P)$ by (ii); the subscheme $t(P)$ of $\text{Dyn}(G)$ thus constructed is independent of the pinning chosen. Indeed, if (T', M', R', Δ') is another pinning of G adapted to P , the unique inner automorphism of G transforming the first pinning into the second comes from P (1.15); the canonical isomorphism $\Delta \xrightarrow{\sim} \Delta'$ therefore transforms $\Delta(P)$ into $\Delta'(P)$, which entails the announced result.

If now one no longer assumes (G, P) to be pinnable, it follows immediately from 1.14 and the definition of $\text{Dyn}(G)$ (Exp. XXIV, 3.3) that one may define by descent an open and closed subscheme $t(P)$ of $\text{Dyn}(G)$, unique, such that for every $S \rightarrow S'$ for which $(G, P)_S$ is pinnable, one has $t(P)_S = t(P)_{S'}$.

Theorem 3.3. *Let S be a scheme, G an S -reductive group,*

$t : \text{Par}(G) \rightarrow \text{Of}(\text{Dyn}(G))$

the morphism defined above.

(i) For two parabolic subgroups P and P' of G to be conjugate locally for the (fpqc) topology (cf. 1.3), it is necessary and sufficient that $t(P) = t(P')$.

(ii) $\text{Par}(G)$ is representable, and the morphism t is smooth, projective, with integral geometric fibers.*

<!-- label: III.XXVI.3.3 -->

By 3.2 (i), and the fact that inner automorphisms of G act trivially on $\text{Dyn}(G)$ (Exp. XXIV, 3.4 (iv)), one indeed has $t(P) = t(P')$ when P and P' are conjugate. Conversely, let P and P' be two parabolic subgroups of G such that $t(P) = t(P')$; let us prove that P and P' are conjugate in G , locally for the (fpqc) topology; one may first

<!-- original page 445 -->

assume that the pairs (G, P) and (G, P') are pinnable (1.14); by conjugacy of pinnings in G (Exp. XXIV, 1.5), one may assume that there exists a pinning (T, M, R, Δ) of G adapted to P and P' . Then $t(P) = t(P')$ implies $\Delta(P) = \Delta(P')$, hence $P = P'$ (cf. 1.4 (v)). We have therefore proved (i). To demonstrate (ii), let us take up the notation of Exp. XXII, 5.11.5[^{N.D.E-XXVI-10}].

We have a canonical morphism $\text{Par}(G) \rightarrow H_c$, and it is clear (e.g. by reduction to the pinned case) that it fits

into a cartesian square (where the vertical arrows are monomorphisms)

$$\begin{array}{ccc} \text{Par}(G) & \xrightarrow{t} & \text{Of}(\text{Dyn}(G)) \\ \downarrow & & \downarrow \\ H_c & \xrightarrow{c} & C_c. \end{array}$$

Now (*loc. cit.*) H_c is representable and the morphism c is smooth, quasi-projective, of finite presentation, with integral geometric fibers, hence the same holds for t .

It remains to prove that t is proper; but this is now a local assertion for the (fpqc) topology, and one may reduce to the pinned case $G = (G, T, M, R, \Delta)$. One then has $\text{Dyn}(G) \simeq \Delta$, and it suffices to prove that for every subset Δ_1 of Δ , the S -scheme $t^{-1}(\Delta_1)$ is proper over S . Now if P_1 is the parabolic subgroup of G containing T such that $\Delta(P_1) = \Delta_1$, it follows from (i) that the morphism $G \rightarrow \text{Par}(G)$ defined set-theoretically by $g \mapsto \text{int}(g) P_1$ induces an isomorphism of $G / \text{Norm}_G(P_1)$ onto $t^{-1}(\Delta_1)$. Now, by 1.2, $G / \text{Norm}_G(P_1) = G / P_1$ is projective over S .

Definition 3.4. $\text{Of}(\text{Dyn}(G))$ is called the scheme of types of parabolics of G ; $t(P)$ is called the type of P .

!-- label: III.XXVI.3.4 -->

Corollary 3.5. The S -functor $\text{Par}(G)$ is representable by an S -scheme that is smooth and projective over S . The decomposition

$$\text{Par}(G) \rightarrow \text{Of}(\text{Dyn}(G)) \rightarrow S$$

is the Stein factorization (EGA III, 4.3.3) of the structural morphism $\text{Par}(G) \rightarrow S$.

!-- original page 446 -->

!-- label: III.XXVI.3.5 -->

Corollary 3.6. For each $t \in \text{Of}(\text{Dyn}(G))(S)$, the S -scheme

$$\text{Par}_t(G) = t^{-1}(t)$$

of parabolic subgroups of G of type t is smooth and projective over S , homogeneous under G . If P is a parabolic subgroup of G , one has a canonical isomorphism $G/P \xrightarrow{\sim} \text{Par}_t(P)(G)$. One has $\text{Par}_{\emptyset}(G) = \text{Bor}(G)$, $\text{Par}_{\text{Dyn}(G)}(G) \xrightarrow{\sim} S$.

!-- label: III.XXVI.3.6 -->

Remark 3.7. The S -scheme $\text{Of}(\text{Dyn}(G))$ is equipped with a natural order structure (the relation of domination, here set-theoretic inclusion, between subschemes). This order structure is a lattice; in particular, the infimum of two open and closed subschemes of $\text{Dyn}(G)_S$ is obviously their intersection. Let us moreover remark that if B is a Borel subgroup of G , one may define the functor X of parabolic subgroups of G containing B . The morphism $X \rightarrow \text{Of}(\text{Dyn}(G))$ induced by t is an isomorphism (for the structure of "ordered scheme"), by virtue of the assertion $P \subset Q \Rightarrow t(P) \subset t(Q)$ and of:

!-- label: III.XXVI.3.7 -->

Lemma 3.8. Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G , t' a section of $\text{Of}(\text{Dyn}(G))$ over S , such that $t(P) \subset t'$. There exists a unique parabolic subgroup P' of G , containing P , and such that $t(P') = t'$.

!-- label: III.XXVI.3.8 -->

Possibly after extending the base, one may assume that P contains a Borel subgroup B of G . The uniqueness of P then follows from 1.17. To demonstrate existence, one may place oneself in the split case, in which case the assertion is evident, cf. §1.

<!-- original page 447 -->

Remarks 3.8.1. (i) The assertion analogous to 3.8 obtained by reversing the inclusions is obviously false. It would, for instance, entail that every group of type A_1 has a Borel subgroup, which is not the case, cf. Exp. XX, §5.

(ii) It follows immediately from the preceding that $t(P) \subset t(Q)$ means that locally for (fpqc) or (ét), P is conjugate to a subgroup of Q (it suffices moreover to verify the assertion on geometric fibers). Moreover, one shall see in §5 that the étale topology may be replaced by the Zariski topology.*

<!-- label: III.XXVI.3.8.1 -->

3.9.

<!-- label: III.XXVI.3.9 -->

The preceding discussions may be taken up in the case of critical subgroups. Let us recall (Exp. XXII, 5.10.4 and 5.10.5) that a reductive subgroup H of the reductive group G is *critical* if $H = \text{Centr}_G(\text{rad}(H))$, that a subtorus Q of G is a *C-critical torus* if $Q = \text{rad}(\text{Centr}_G(Q))$, and that critical subgroups and C-critical tori [N.D.E-XXVI-11] are in bijective correspondence (via $H \mapsto \text{rad}(H)$ and $Q \mapsto \text{Centr}_G(Q)$).

If (G, T, M, R) is a split S -group, the subgroup of G containing T corresponding to the part R of R (Exp. XXII, 5.4.2) is critical if and only if R is "vectorial" (that is, the intersection of R with a vector subspace of $M \otimes \mathbb{Q}$), cf. Exp. XXII, 5.10.6.

If G is an arbitrary S -reductive group, one defines, as in Exp. XXII, 5.11.5, an étale finite S -scheme $\mathcal{C}_{\text{ell}}^{\text{crit}}$, which in the split case will be the constant scheme associated with the set of vectorial parts of R modulo the action of the Weyl group. If $\text{Crit}(G)$ denotes the "functor of critical subgroups" of G , one has a canonical morphism $\text{Crit}(G) \rightarrow \mathcal{C}_{\text{ell}}^{\text{crit}}$, which fits into a cartesian diagram [N.D.E-XXVI-12]

```

```text
Crit(G) --c--> C_crit
 | |
 v v
 H_c --c--> C_c.
```

```

<!-- original page 448 -->

Proposition 3.10. Let S be a scheme, G an S -reductive group, $\text{Crit}(G)$ the functor of its critical subgroups, $\mathcal{C}_{\text{ell}}^{\text{crit}}$ and $\mathcal{C}_{\text{ell}} : \text{Crit}(G) \rightarrow \mathcal{C}_{\text{ell}}^{\text{crit}}$ the étale finite S -scheme and the morphism defined above.*

(i) For critical subgroups H and H' of G to be conjugate (locally for the (fpqc) topology), it is necessary and sufficient that $\mathcal{C}_{\text{ell}}(H) = \mathcal{C}_{\text{ell}}(H')$.*

(ii) $\text{Crit}(G)$ is representable and the morphism $\mathcal{C}_{\text{ell}}$ is smooth, affine, with integral geometric fibers.*

<!-- label: III.XXVI.3.10 -->

This is proved as 3.3, with the exception of the assertion " $\mathcal{C}_{\text{ell}}$ is affine". It suffices to prove that $\text{Crit}(G)$ is affine over S . Now $\text{Crit}(G)$ is naturally identified with the S -functor of critical tori of G , and one therefore has a canonical monomorphism

```

S
Crit(G) --> M
S

```

where M is the scheme of subgroups of multiplicative type of G (Exp. XI, 4.1). To prove that $\text{Crit}(G)$ is affine over S , it suffices, by Exp. XII 5.3, to show that this morphism is an open and closed immersion, or equivalently, by

making the base change $S \rightarrow S'$, to prove the following assertion: if Q is a subgroup of multiplicative type of the reductive group G , the $S' \rightarrow S$ such that $Q_{S'}$ is a critical torus of $G_{S'}$ are those that factor through a certain open and closed subscheme of S . Now to say that Q is a critical torus is to say:

(1) that Q is a torus,

(2) Q being a torus, that $\text{rad}(\text{Centr}_G(0))$, which is also a torus, is of the same relative dimension as Q .

These two conditions are indeed of the type envisaged.

Corollary 3.11. The S -functor $\text{Crit}(G)$ is representable by an S -scheme that is smooth and affine over S .

<!-- original page 449 -->

<!-- label: III.XXVI.3.11 -->

Corollary 3.12. Let H be a critical subgroup of the S -reductive group G . Then $G / \text{Norm}_G(H)$ and G / H are representable by S -schemes that are affine and smooth over S .

<!-- label: III.XXVI.3.12 -->

The first assertion follows from 3.11, the second from the first and from Exp. XXII, 5.10.2.

Corollary 3.13. Let Q be a subtorus of the S -reductive group G . Then $G / \text{Centr}_G(Q)$ is representable by an S -scheme that is smooth and affine over S . The same holds for $G / \text{Norm}_G(Q)$ if Q is a critical subtorus of G .

<!-- label: III.XXVI.3.13 -->

Indeed, $H = \text{Centr}_G(Q)$ is critical (Exp. XXII, 5.10.5), and one has $\text{Norm}_G(H) = \text{Norm}_G(Q)$ if Q is critical (*loc. cit.* 5.10.8).

3.14.

<!-- label: III.XXVI.3.14 -->

By the conjugacy of Levi subgroups of parabolic subgroups of G , there exists a unique morphism

$$u : \text{Of}(\text{Dyn}(G)) \rightarrow \text{ell}_{\text{crit}}$$

such that for every parabolic subgroup P of G , and every Levi subgroup L of P , one has $\text{c}_{\text{ell}}(L) = u(t(P))$, and such that this holds after every base change.

3.15.

<!-- label: III.XXVI.3.15 -->

Let S be a scheme, G an S -reductive group. Consider the S -functors [N.D.E-XXVI-13]:

```

```text
PL(S') = { pairs P ⊃ L, P parabolic of G_{S'}, L Levi subgroup of P };
PT(S') = { pairs P ⊃ T, P parabolic of G_{S'}, T maximal torus of P };
CT(S') = { pairs C ⊃ T, C critical subgroup of G_{S'}, T maximal torus of C };
PLT(S') = { triples P ⊃ L ⊃ T, (P, T) ∈ PT(S'), L Levi subgroup of P }.
```

```

One has evident morphisms between these functors and the functors $\text{Par}(G)$, $\text{Crit}(G)$,

<!-- original page 450 -->

$\text{Tor}(G)$ already introduced, and one has a commutative diagram in the form of a truncated cube (see the following figure):

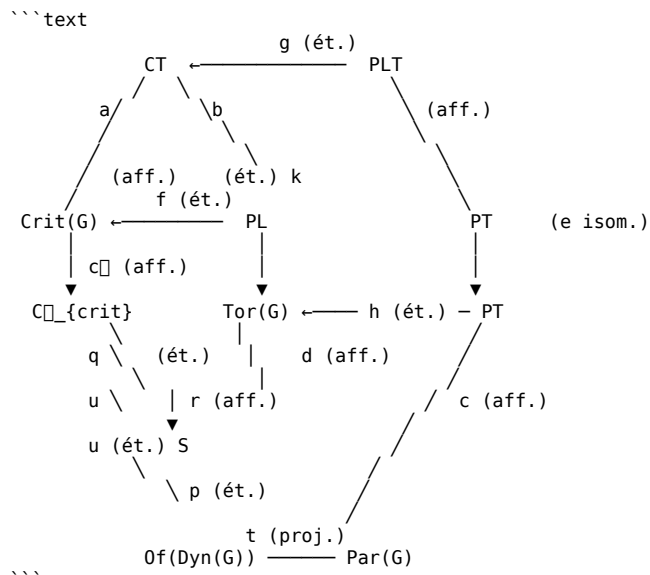

Figure 3.15.1.

<!-- TRANSLATOR NOTE: The cube diagram in the source has many visual lines/arrows that are difficult to render in plain text; the labels and key adjacencies are preserved above. -->

<!-- original page 451 -->

Theorem 3.16. *(cf. Figure 3.15.1).*

(i) All the morphisms of the diagram are smooth, surjective, and of finite presentation.

(ii) All the morphisms of the diagram, with the exception of t , are affine; the morphism t is projective.

(iii) All the morphisms of the diagram are either étale finite or with integral geometric fibers: the morphisms f , g , h , k , p , q and u are étale finite, the morphisms a , b , c , d , r and ℓ are with integral geometric fibers, the morphism e is an isomorphism.

(iv) The square (a, b, f, g) is cartesian.

<!-- label: III.XXVI.3.16 -->

Proof. It is first clear that e is an isomorphism, by 1.6 (ii). On the other hand, (iv) is evident.

The morphism a is smooth, affine, with integral geometric fibers: indeed, by base change $\text{Crit}(G) \rightarrow S$, it suffices to verify that the morphism $\text{Tor}(L_0) \rightarrow S$, where L_0 is the universal critical subgroup, has these properties; but L_0 is reductive (by definition), and one is reduced to Exp. XXII, 5.8.3. The morphism b therefore has the same properties, by virtue of (iv).

<!-- original page 452 -->

The morphism d is also smooth, affine, with integral geometric fibers, by 1.9; the same therefore holds for $c = d \circ b \circ e^{-1}$. The morphism r has these same properties (Exp. XXII, 5.8.3), as does the morphism ℓ (3.10).

On the other hand, we have already proved that the morphisms p and q are étale finite surjective (3.1 and 3.9). If we prove that f and k are étale finite surjective, the same properties will hold for g (by (iv)) and for h (since $h = k \circ g \circ e^{-1}$); as the properties stated for t were established in 3.3 (ii), it therefore only remains to prove that f (resp. k) is étale finite surjective; let us give the proof for k , that for f being analogous.

It suffices to prove that if T is a maximal torus of G , the functor C of critical subgroups of G containing T is representable by an étale finite S -scheme with non-empty fibers; one may assume G split with respect to T ; let then E be the set of vectorial parts of R (root system of the splitting); C is representable by E_S (3.9), which completes the proof.

Corollary 3.17. All the functors of the preceding diagram are representable by S -schemes that are smooth over S , and they are all affine over S , with the exception of $\text{Par}(G)_S$.

`<!-- label: III.XXVI.3.17 -->`

Remark 3.18. (i) The fact that the morphism $f : \text{PL} \rightarrow \text{Crit}(G)_S$ is étale surjective implies that a subgroup of G is critical if and only if it is, locally for the étale topology, a Levi subgroup of a parabolic subgroup of G .

On the other hand, one should not believe that in general the map $f(S) : \text{PL}(S) \rightarrow \text{Crit}(G)(S)$ is surjective: it may very well happen that a critical subgroup C of G does not come on S from a parabolic subgroup of G ; for example, a maximal torus is not always contained in a Borel subgroup (example: a non-split form of SL_2 , cf. Exp. XX, §5).

(ii) Similarly, it may happen that the morphism $u : \text{Of}(\text{Dyn}(G)) \rightarrow \text{C}\ell_{\text{crit}}$ is not an isomorphism: two parabolic subgroups of distinct types may have Levi subgroups of the same type; for example: in a group of type A_2 , there are two types of parabolic subgroups whose Levi subgroups are of semisimple rank 1 (corresponding to the two vertices of the diagram), whereas there is only one type of critical subgroup of rank 1.

The analogous example with a group of type A_3 shows that, even over an algebraically closed field, non-isomorphic parabolic subgroups may have Levi subgroups of the same type. [N.D.E-XXVI-14]

`<!-- label: III.XXVI.3.18 -->`

Let us close this section with an application to the theory of principal bundles.

`<!-- original page 453 -->`

Lemma 3.20. [N.D.E-XXVI-15] Let S be a scheme, G an S -reductive group, F a principal homogeneous bundle under G , G_F the corresponding twisted form of G . Identify $\text{Dyn}(G)_S$ and $\text{Dyn}(G_F)_S$ (Exp. XXIV, 3.5). Let P be a parabolic subgroup of G . One has a canonical isomorphism

$$F/P \xrightarrow{\sim} \text{Par}_{\{t(P)\}(G_F)}.$$

In particular, for the structural group of F to reduce to P , it is necessary and sufficient that G_F have a parabolic subgroup of type $t(P)$.

`<!-- label: III.XXVI.3.20 -->`

The proof goes exactly as in Exp. XXIV, 4.2.1.

3.21.

`<!-- label: III.XXVI.3.21 -->`

If S is a scheme, G an S -reductive group, and if $t \in \text{Of}(\text{Dyn}(G))(S)$, one denotes by $H^1_t(S, G)$ the subset of $H^1(S, G)$ formed of classes of principal bundles F under G such that the associated group G_F has a parabolic subgroup of type t . If G itself has a parabolic subgroup P of type t , $H^1_t(S, G)$ is none other than the image of $H^1(S, P)$ in $H^1(S, G)$, an image which therefore does not depend on the P chosen.

4. Relative position of two parabolic subgroups

`<!-- label: III.XXVI.4 -->`

4.1. A preliminary result

`<!-- label: III.XXVI.4.1 -->`

Lemma 4.1.1. Let k be a field, G a k -reductive group, P and P' two parabolic subgroups of G .

(i) Then $P \cap P'$ is smooth, of the same reductive rank as G , and contains a maximal torus T of G .

(ii) The set R of roots of $P \cap P'$ with respect to T is a closed subset of the set R of roots of G with respect to T .[^{N.D.E-XXVI-16}]

<!-- label: III.XXVI.4.1.1 -->

Suppose first k algebraically closed. Let B (resp. B') be a Borel subgroup

<!-- original page 454 -->

of P (resp. P'). One knows that there exists $g \in G(k)$ such that $\text{int}(g) B = B'$. On the other hand, if T_0 is a maximal torus of B and one sets $N = \text{Norm}_G(T_0)$, one knows (Bruhat's theorem, Bible, §13.4, Cor. 1 to Th. 3) that $G(k) = B(k) N(k) B(k)$. One therefore sees that there exist $b, b_{-1} \in B(k)$ and $n \in N(k)$ such that $g = b n b_{-1}$, hence $\text{int}(b) \text{int}(n) B = B'$. One then has

```
```text
P ∩ P' ⊃ B ∩ B' = int(b)(B ∩ int(n) B') ⊃ int(b) T_0.
```
```

Now suppose k arbitrary. Applying the preceding result, one sees that $P_{\bar{k}} \cap P'_{\bar{k}}$ contains a maximal torus of $G_{\bar{k}}$; by Exp. XXII, 5.4.5, one deduces that $(P \cap P')_{\bar{k}}$ is smooth "along the unit section", hence smooth since one is over a field (Exp. VI_A 1.3.1), hence $P \cap P'$ is smooth. By Exp. VI_A 2.3.1, the neutral component $(P \cap P')^0$ of $P \cap P'$ is therefore an open subgroup of $P \cap P'$, smooth over S . One may then apply Exp. XIV, 1.1 to it, whence (i).

Finally, the set R_P (resp. $R_{P'}$) of roots of P (resp. P') with respect to T is closed and one has $R' = R_P \cap R_{P'}$, whence (ii).

Remark 4.1.2. *One may prove ([BT65], 4.5) that $P \cap P'$ is connected;[^{N.D.E-XXVI-17}] this will be used in 4.5.1.*

<!-- label: III.XXVI.4.1.2 -->

Remark 4.1.3. *The preceding lemma is not true over an arbitrary scheme. Indeed, let G be, for example, a reductive group over an algebraically closed field k , and let B be a Borel subgroup of G . Take $S = X$ as base and consider the Borel subgroups B_1 and B_2 of G_X , where $B_1 = B_X$ and $B_2 = \text{int}(g_0) B_1$, g_0 being the canonical (diagonal) section of G_X . For each $g \in X(k)$, the fiber of $B_1 \cap B_2$ at g is none other than $B \cap \text{int}(g) B$. If one assumes $B \neq G$, the dimension of this fiber varies with g , hence $B_1 \cap B_2$ cannot be smooth over X .*

<!-- label: III.XXVI.4.1.3 -->

4.2. Transversal position

<!-- label: III.XXVI.4.2 -->

Theorem 4.2.1. *Let S be a scheme, G an S -reductive group, P and Q two parabolic subgroups of G . The following conditions on the pair (P, Q) are equivalent:*

(i) $\text{Lie}(P/S) + \text{Lie}(Q/S) = \text{Lie}(G/S)$.

<!-- original page 455 -->

(ii) The canonical morphism $P \times_S Q \rightarrow G$ is smooth.

(ii') The canonical morphism $P \rightarrow G/Q$ is smooth.

(iii) The canonical morphism $P \times_S Q \rightarrow G$ is open.

(iii') The canonical morphism $P \rightarrow G/Q$ is open.

(iv) The canonical morphism $P \times_S Q \rightarrow G$ is fiberwise dominant.

(iv') The canonical morphism $P \rightarrow G/Q$ is fiberwise dominant.

(v) For every $s \in S$, " $P_s \cap Q_s$ is of minimum dimension", i.e. one has

```
```text
dim(P_s ∩ Q_s) = dim P_s + dim Q_s - dim G_s.
```
```

(vi) There exists a covering family for the étale topology $\{S_i \rightarrow S\}$, and for each i a Borel subgroup B_i of P_{S_i} and a Borel subgroup B'_i of Q_{S_i} , such that $B_i \cap B'_i$ is a maximal torus of G_{S_i} .

(vii) There exists a covering family for the étale topology $\{S_i \rightarrow S\}$, and for each i a splitting $(T_i, \dots, R_i)$ of G_{S_i} and a system of positive roots R^+_i of R_i , such that P_{S_i} (resp. Q_{S_i}) is the subgroup of type (R) of G_{S_i} containing T_i and defined by a subset $R^{\{(1)\}}_i$ (resp. $R^{\{(2)\}}_i$) of R containing R^+_i (resp. $-R^+_i$) (see Exp. XXII, 5.4.2 and 5.2.1 for the definitions).

<!-- label: III.XXVI.4.2.1 -->

Proof. We shall prove the theorem following the logical diagram

```
```text
(i) ⇔ (vii) ⇔ (vi)
 \
(ii') ⇒ (iii') ⇒ (iv') ⇒ (v)
 /
(ii) ⇒ (iii) ⇒ (iv)
```
```

<!-- original page 456 -->

One trivially has $(ii) \Rightarrow (iii)$ and $(ii') \Rightarrow (iii')$. If (iii) holds, the set-theoretic image of the morphism $P \times_S Q \rightarrow G$ is an open set of G containing the unit section; since the fibers of G are connected, this image is dense on each fiber, which proves (iv) . One similarly has $(iii') \Rightarrow (iv')$.

One has $(ii') \Rightarrow (ii)$, by the cartesian diagram

```
```text
P ×_S Q → G
 | |
pr_1 |
 v v
 P → G/Q.
```
```

On the other hand (iv) or (iv') implies (v) , by the theory of dimension (cf. EGA IV₂, 5.6.6). One notes that one may indeed assume $S = \operatorname{Spec}(k)$, k an algebraically closed field, and that every non-empty fiber of the morphism (iv) , resp. (iv') , at a point of $G(k)$, resp. of $(G/Q)(k)$, is isomorphic to $P \cap Q$ (as an immediate computation shows).

One has $(vi) \Rightarrow (vii)$, by Exp. XXII, 5.5.1 (iv) and 5.9.2.

One has $(vii) \Rightarrow (i)$, because to verify that $\operatorname{Lie}(P) + \operatorname{Lie}(Q) = \operatorname{Lie}(G)$, one may reason locally for (fpqc); thus if (vii) is satisfied one may assume G split, $P \supset B_{R^+}$ and $Q \supset B_{-R^+}$ (usual notations), in which case one already has

```
```text
Lie(B_{R^+}) + Lie(B_{-R^+}) = Lie(G).
```
```

Let us prove that (i) implies (ii') .

Let $u : P \rightarrow G/Q$ be the canonical morphism; to prove that u is smooth, it suffices to do so on the geometric fibers

of U , since P and G/Q are smooth over S , and one may therefore assume that S is the spectrum of an algebraically closed field. As the morphism U is compatible with the obvious action of P (one has $u(p \cdot p') = p \cdot u(p')$) it suffices, by a translation argument (cf. the proof of VI_B 1.3), to verify that U is smooth at e in $P(k)$, i.e. (SGA 1, II 4.7) that the tangent map to U at e is surjective; but the latter is naturally

<!-- original page 457 -->

identified with the canonical map $\text{Lie}(P) \rightarrow \text{Lie}(G)/\text{Lie}(Q)$, which is surjective if (i) is satisfied.

It therefore only remains to verify the last assertion, namely $(v) \Rightarrow (vi)$. Suppose first that S is the spectrum of an algebraically closed field. By 4.1.1, there exists a maximal torus T contained in P and Q ; let R (resp. R_1 , resp. R_2) be the set of roots of G (resp. P , resp. Q) relative to T .

One has:

```
```text
dim(G) = dim(T) + Card(R), dim(P) = dim(T) + Card(R_1),
dim(Q) = dim(T) + Card(R_2), dim(P ∩ Q) = dim(T) + Card(R_1 ∩ R_2),
```
```

by Exp. XXII, 5.4.4 and 5.4.5 for example. The condition of (v) is therefore equivalent to

```
```text
Card(R_1 ∩ R_2) = Card(R_1) + Card(R_2) - Card(R),
```
```

that is $R_1 \cup R_2 = R$. To demonstrate (vi), it suffices, by Exp. XXII, 5.9.2 and 5.4.5, to prove that $R_1 \cap R_2$ contains a system of positive roots of R . We are therefore reduced to proving:

Lemma 4.2.2. *Let R be a "root system" (e.g. the set of roots of a root datum in the sense of Exposé XXI). Let R_1 and R_2 be two closed subsets of R each containing a system of positive roots. If $R_1 \cup R_2 = R$, then $R_1 \cap R_2$ contains a system of positive roots.*

<!-- label: III.XXVI.4.2.2 -->

Indeed, since $R_1 \cap R_2 = R_3$ is evidently closed, and by Exp. XXI, 3.3.6, it suffices to show that $R_3 \cup R_3 = R$. Now one knows that $R_1 \cup R_1 = R = R_2 \cup R_2$, and one concludes thanks to the following elementary fact: if A, A', B, B' are four subsets of a set E , and if $A \cup A' = B \cup B' = A \cup B = A' \cup B' = E$, then $(A \cap B') \cup (A' \cap B) = E$.

This completes the proof of $(v) \Rightarrow (vi)$ in the case where the base is the spectrum of an algebraically closed field. Let

<!-- original page 458 -->

us now return to the general case and assume (v) is satisfied. Let s in S ; by the preceding, one may find a Borel subgroup $\bar{B}$ (resp. $\bar{B}'$) of P_s (resp. Q_s) such that $\bar{B} \cap \bar{B}'$ is a maximal torus of G_s .

Since the S -scheme $\text{Bor}(P) = \text{Bor}(P/\text{rad}^u(P))$ of Borel subgroups of P is smooth, one may, applying "Hensel's lemma" (cf. Exp. XI 1.10) and reasoning locally for the étale topology (i.e. replacing S by an S' to S that is étale and covering S , and s by a point of its fiber in S'), assume that there exists a Borel subgroup B of P projecting onto $\bar{B}$; one may similarly assume that there exists a Borel subgroup B' of Q projecting onto $\bar{B}'$. Since $B_s \cap B'_s$ is a maximal torus of G_s , there exists an open neighborhood U of s in S such that $B_U \cap B'_U$ is a maximal torus of G_U (Exp. XXII, 5.9.4), which proves (vi). QED.

Definition 4.2.3. *A pair (P, Q) satisfying the equivalent conditions (i) to (vii) of Theorem 4.2.1 is said to be in transversal position. *One also says that P is in transversal position relative to Q , or, by abuse of language, that P and Q are in (mutual) transversal position.*

<!-- label: III.XXVI.4.2.3 -->

In view of (vi), this definition coincides in the case of Borel subgroups with that of Exp. XXII, 5.9.1.

Corollary 4.2.4. *Let S be a scheme, G an S -reductive group, P and Q two parabolic subgroups of G .*

(ii) The canonical morphism $P \times_S Q \rightarrow G$ induces a smooth and surjective morphism $P \times_S Q \rightarrow \text{Gen}(Q/P)$, and an isomorphism

```
```text
(P x_S Q) / (P n Q) = Gen(Q/P)
```
```

(where $P \times_S Q = R$ operates on $P \times_S Q$ by $(p, q) \mapsto (p \cdot r, r^{-1} \cdot q)$).

(iii) The canonical morphism $P \rightarrow \text{Par}_{\{t(Q)\}}(G)$ (defined set-theoretically by $p \mapsto \text{int}(p) \cdot Q$) induces a smooth and surjective morphism $P \rightarrow \text{Gen}(P) \times \text{Par}_{\{t(Q)\}}(G)$, and an

<!-- original page 461 -->

isomorphism

```
```text
P / (P n Q) = Gen(P) n Par_{t(Q)}(G).
```
```

(iv) The canonical morphism $G \rightarrow \text{Par}_{\{t(P)\}}(G) \times \text{Par}_{\{t(Q)\}}(G)$ (defined set-theoretically by $g \mapsto (\text{int}(g) \cdot P, \text{int}(g) \cdot Q)$) induces a smooth and surjective morphism $G \rightarrow \text{Gen}(G) \times (\text{Par}_{\{t(P)\}}(G) \times_S \text{Par}_{\{t(Q)\}}(G))$ and an isomorphism

```
```text
G / (P n Q) = Gen(G) n (Par_{t(P)}(G) x_S Par_{t(Q)}(G)).
```
```

<!-- label: III.XXVI.4.2.5 -->

Let us demonstrate (i). It is clear that the condition is sufficient; let us prove that it is necessary. Let then (P', Q') be in transversal position. Since P and P' are conjugate locally for the étale topology, we may assume $P = P'$, and it suffices to prove that if Q and Q' are two parabolic subgroups of G , in transversal position relative to P , and of the same type, then they are conjugate, locally for the étale topology, by a section of P . Using 4.2.1 (vi), one may assume that there exist Borel subgroups $B, B', B_{\{1\}}, B'_{\{1\}}$ of P, P, Q, Q' respectively, such that $B \times B_{\{1\}} = T$ and $B' \times B'_{\{1\}} = T'$ are maximal tori of G . Now the Killing pairs (B, T) and (B', T') of P are conjugate locally in P for the étale topology (1.16), and one may assume $B = B', T = T'$, in which case one has $B_{\{1\}} = B'_{\{1\}}$ by Exp. XXII, 5.9.2, hence $Q = Q'$ by 3.8.

Assertions (ii), (iii) and (iv) are proved in a parallel fashion. Let us demonstrate, for instance, (ii); let $g \in \text{Gen}(Q/P)(S)$, i.e. let $g \in G(S)$ be such that $\text{int}(g) \cdot Q$ is in transversal position relative to P . By the preceding proof, Q and $\text{int}(g) \cdot Q$ are conjugate locally for the étale topology, by a section of P . Reasoning

<!-- original page 462 -->

locally for this topology, one may assume that there exists $p \in P(S)$ such that $\text{int}(g) \cdot Q = \text{int}(p) \cdot Q$, hence $p^{-1} \cdot g \in \text{Norm}_G(Q)(S) = Q(S)$; which proves the existence of $q \in Q(S)$ such that $g = p \cdot q$. We have therefore proved that the morphism considered in (ii) is covering for the étale topology. Comparing with 4.2.1 (ii), one deduces that it is smooth and surjective. On the other hand, an immediate reasoning shows that the equivalence relation defined on $P \times_S Q$ by the morphism $P \times_S Q \rightarrow G$ is the equivalence relation associated with the action of the group $R = P \times_S Q$ (operating by $(p, q) \mapsto (p \cdot r, r^{-1} \cdot q)$), which demonstrates the last assertion of (ii) (since a smooth surjective morphism is an effective epimorphism, for example).

Remark 4.2.6. *If P and Q are in transversal position, one will often denote by $P \cdot Q$ the open subset $\text{Gen}(Q/P)$ of G , a notation justified by 4.2.5 (ii).*

<!-- label: III.XXVI.4.2.6 -->

Proposition 4.2.7. *Let S be a scheme, G an S -reductive group, P and Q two parabolic subgroups of G , the pair (P, Q) being in transversal position.*

(i) The group $P \times_S Q$ is smooth over S (and in fact has connected fibers by 4.1.2); introducing then $(P \times_S Q)^{\{0\}}$ (cf. Exp. VI_B 3.10), this is a subgroup of type (RC) of G (Exp. XXII, 5.11.1), whose unipotent radical (loc. cit. 5.11.4) decomposes as a direct product*

```

```text
rad^u((P ∩ Q)^0) = (rad^u(P) ∩ Q) ×_S (P ∩ rad^u(Q)).
```

```

(ii) If S is affine, $H^1(S, \text{rad}^u((P \cap Q)^0)) = 0$. If S is semi-local, $P \cap Q$ contains a maximal torus of G .

<!-- label: III.XXVI.4.2.7 -->

Indeed, $P \cap Q$ is smooth by 4.2.1 (ii) and the cartesian diagram

```

```text
P ×_S Q → G
 ↑ ↑
 P ∩ Q → S.
```

```

<!-- original page 463 -->

To verify the announced assertions on $(P \cap Q)^0$, one may reason locally for the étale topology, hence by 4.2.1 (vii) assume to have chosen a splitting (G, T, M, R) of G , such that P and Q contain T and are defined respectively by subsets R_1 and R_2 of R , R_1 containing a system of positive roots R^+ , and R_2 containing the opposite system R^- . Let Δ be the set of simple roots of R^+ ; denote

```

```text
A_1 = Δ ∩ -R_1, A_2 = Δ ∩ R_2, A = A_1 ∩ A_2.
```

```

By 1.4 (v) and 1.12, one has

```

```text
R_1 = R^+ ∪ (R^- ∩ -A_1), R_2 = (R^+ ∩ A_2) ∪ R^-,
rad^u(P) = ∩_{α ∈ R_1, α ∉ -R_1} U_α, rad^u(Q) = ∩_{α ∈ R_2, α ∉ -R_2} U_α.
```

```

By Exp. XXII, 5.6.7, one therefore has

```

```text
rad^u(P) ∩ Q = ∩_{α ∈ R_1 ∩ R_2, α ∉ -R_1} U_α = ∩_{α ∈ K_2} U_α,
rad^u(Q) ∩ P = ∩_{α ∈ R_1 ∩ R_2, α ∉ -R_2} U_α = ∩_{α ∈ K_1} U_α,
```

```

where K_2 is the set of positive roots that are linear combinations of the elements of A_2 , but not linear combinations of the elements of A , and K_1 the set of negative roots that are linear combinations of the elements of A_1 , but not linear combinations of the elements of A . It is clear that if $\alpha \in K_2$, $\beta \in K_1$, $\alpha + \beta$ is never a root, nor zero, which entails that the two groups above commute.

On the other hand, one knows by Exp. XXII, 5.4.5, that $H = (P \cap Q)^0$ is defined by the set of roots $R_1 \cap R_2$, namely

<!-- original page 464 -->

```

```text
R_1 ∩ R_2 = (R^+ ∩ A_2) ∪ (R^- ∩ -A_1).
```

```

Since $R_1 \cap R_2$ is closed, H is of type (RC) by definition (Exp. XXII 5.11.1), and by *loc. cit.* 5.11.3 and 5.11.4, one has

```

```text
rad^u(H) = ∩_{α ∈ K} U_α,
```

```

where K is the set of $\alpha \in R_1 \cap R_2$ such that $\alpha \notin -(R_1 \cap R_2)$. As the symmetric part of $R_1 \cap R_2$ is evidently $R \cap \mathbb{A}^1$, one sees at once that $K = K_1 \cup K_2$, which completes the proof of (i).

The first assertion of (ii) then follows from (i) and 2.10; let us demonstrate the second. Since $(P \cap Q)^0 / \text{rad}^u((P \cap Q)^0)$ is reductive, it has a maximal torus $\bar{T}$ if the base is semi-local. The inverse image of $\bar{T}$ in $(P \cap Q)^0$ is a subgroup N of type (R) of G with solvable fibers, and one has $N^u = \text{rad}^u((P \cap Q)^0)$ (Exp. XXII, 5.6.9). The scheme of maximal tori of N is a principal homogeneous bundle under N^u (*loc. cit.* 5.6.13), hence has a section, since $H^1(S, N^u) = 0$.

4.3. Opposite parabolic subgroups

<!-- label: III.XXVI.4.3 -->

4.3.1.

<!-- label: III.XXVI.4.3.1 -->

If G is an S -reductive group, one has defined in Exp. XXIV, 3.16.6, a canonical "outer automorphism" s_G of order ≤ 2 [N.D.E.-XXVI-20] of G , hence a canonical automorphism of order ≤ 2 of $\text{Dyn}(G)$, hence also an automorphism of order ≤ 2 of $0f(\text{Dyn}(G))$, which we shall also denote s_G or simply s . Two types of parabolic subgroups $t, t' \in 0f(\text{Dyn}(G))(S)$ will be said to be *opposite* when $t = s_G(t')$.

Theorem 4.3.2. *Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G .*

(a) If L is a Levi subgroup of P , there exists a unique parabolic subgroup P' of G such that $P \cap P' = L$.*

<!-- original page 465 -->

(b) For every parabolic subgroup Q of G , the following conditions are equivalent:*

(i) For every $s \in S$, $(P \cap Q)_s^0$ (which is smooth by 4.1.1) is reductive.*

(ii) $P \cap Q$ is a Levi subgroup of P and of Q .*

(iii) P and Q are of opposite types, and the pair (P, Q) is in transversal position (cf. 4.2.3).*

(iv) P and Q are of opposite types and $\text{rad}^u(P) \cap Q = e$.*

(v) $\text{rad}^u(P) \cap Q = \text{rad}^u(Q) \cap P = e$.*

(vi) The canonical morphism $\text{rad}^u(P) \times_S Q \rightarrow G$ is an open immersion.*

(vi') The canonical morphism $\text{rad}^u(P) \rightarrow G/Q$ is an open immersion.*

(vii) There exists a covering family for the étale topology $\{S_i \rightarrow S\}$, and for each i a splitting (T_i, M_i, R_i) of G_{S_i} , and a subset $R_i^{(1)}$ of R_i such that P_{S_i} (resp. Q_{S_i}) is the subgroup of type (R) of G_{S_i} containing T_i and defined by $R_i^{(1)}$ (resp. by $R_i^{(2)}$) = $-R_i^{(1)}$.*

<!-- label: III.XXVI.4.3.2 -->

Proof. *Let us first demonstrate the second part of the theorem; one sees first that (iii) $\Leftrightarrow$ (vii) by 4.2.1 (vii) and the definition of s_G in the split case (Exp. XXII, 3.16.2 (iv)); one trivially has (ii) $\Rightarrow$ (i); one has (vi') $\Rightarrow$ (vi) by base change $G \rightarrow G/Q$.

<!-- original page 466 -->

Now suppose (vii) holds, and let us prove all the other conditions; as they are local for the étale topology, one may assume $G = (G, T, M, R)$ split, P defined by the part R' of R and Q by the part $-R'$. If L is the subgroup of type (R) of G containing T defined by $R' \cap -R'$, it is clear by Exp. XXII, 5.11.3 that L is a Levi subgroup common to P and Q . But $P = L \cdot \text{rad}^u(P)$, $Q = L \cdot \text{rad}^u(Q)$, and by Exp. XXII, 5.6.7, $\text{rad}^u(P) \cap Q = Q \cap \text{rad}^u(P) = e$; hence $P \cap Q = L$, and we have proved (ii) and (v). Since P and Q are in transversal position, the canonical morphism $P \rightarrow G/Q$ induces an open immersion $P / P \cap Q \rightarrow G/Q$ (4.2.1); but the canonical morphism $\text{rad}^u(P) \rightarrow P / P \cap Q = P / L$ is an isomorphism, so we have proved (vi'). In

view of what was already seen, all assertions are therefore consequences of (vii).

It now suffices to prove that any one of the assertions (i), (iv), (v), (vi) implies (vii); as we have already proved the equivalence of (ii) and (iii), it suffices to give the proof on geometric fibers, and one may assume that S is the spectrum of an algebraically closed field. By 4.1.1, there exists a maximal torus T of G contained in $P \cap Q$. Let R (resp. R_1 , resp. R_2) be the set of roots of G (resp. P , resp. Q) relative to T .

Let $R^{\{a\}}_1$ be the asymmetric part of R_1 (i.e. $R^{\{a\}}_1 = \{ \alpha \in R_1 \mid -\alpha \notin R_1 \}$). Introduce $R^{\{a\}}_2$ similarly. We must prove that $R_1 = -R_2$.

– Condition (i) entails that $R_1 \cap R_2$ is symmetric; let $\alpha \in R_1$; if $\alpha \notin R_2$, then $\alpha \in -R_2$, and if $\alpha \in R_2$, then $\alpha \in R_1 \cap R_2 = -(R_1 \cap R_2) \subset -R_2$; one therefore has $R_1 \subset -R_2$, hence by symmetry $R_1 = -R_2$.

– Condition (iv) entails $\text{Card}(R_1) = \text{Card}(R_2)$ and $R^{\{a\}}_1 \cap R_2 = \emptyset$; the second condition is equivalent to $R_2 \subset -R_1$; the first then gives $R_2 = -R_1$.

– Condition (v) entails $R^{\{a\}}_1 \cap R_2 = R^{\{a\}}_2 \cap R_1 = \emptyset$, hence $R_2 \subset -R_1$ and $R_1 \subset -R_2$, which again gives $R_2 = -R_1$.

– Condition (vi) entails $\text{Lie}(\text{rad}^u(P)) \oplus \text{Lie}(Q) = \text{Lie}(G)$, which entails that R is the disjoint union of R_2 and

<!-- original page 467 -->

$R^{\{a\}}_1$, hence that $R_2 = -R_1$.

This completes the proof of the second part of the theorem. Let us prove the first; let us first remark that, by virtue of (vii) $\Rightarrow$ (ii), we have already proved the existence locally for the étale topology of the sought group P' ; it therefore remains to prove its uniqueness, and this can also be done locally for the étale topology. One may therefore assume G split relative to a maximal torus T of L , and P (resp. P') defined by a part R_1 (resp. R'_1) of the root system R .

By hypothesis $R_1 \cap R'_1$ is symmetric; reasoning as above, one derives $R'_1 = -R_1$, which proves that P' is determined by P and L and completes the proof.

Definition 4.3.3. Two parabolic subgroups of G satisfying the equivalent conditions (i) to (vii) of 4.3.2 are said to be *opposite*. If P is a parabolic subgroup of G , and if L is a Levi subgroup of P (resp. and if T is a maximal torus of P), one calls *parabolic subgroup opposite to P relative to L (resp. T)* the unique parabolic subgroup Q of G such that $P \cap Q = L$ (resp. such that $P \cap Q$ is the unique Levi subgroup of P containing T , cf. 1.6, or, equivalently, such that $P \cap Q$ contains T and that P and Q are opposite).

<!-- label: III.XXVI.4.3.3 -->

By 4.3.2 (iii), one derives from 4.2.4 and 4.2.5 parallel results; let us give one sample.

Corollary 4.3.4. Let S be a scheme, G an S -reductive group, P and Q two parabolic subgroups of G .

<!-- original page 468 -->

(i) For P and Q to be opposite, it is necessary and sufficient that for every point $s \in S$, P_s and Q_s be opposite. If $S' \rightarrow S$ is a surjective morphism, and if $P_{S'}$ and $Q_{S'}$ are opposite, then P and Q are opposite.

(ii) The functor $\text{Opp}(G)$, such that for $S' \rightarrow S$, $\text{Opp}(G)(S')$ is the set of pairs of opposite parabolic subgroups of $G_{S'}$, is representable by an open subscheme of $\text{Par}(G)^2$. The functor $\text{Opp}(P)$ such that for $S' \rightarrow S$, $\text{Opp}(P)(S')$ is the set of parabolic subgroups of $G_{S'}$ opposite to $P_{S'}$, is representable by a universally schematically dense open subscheme over $S[\text{N.D.E-XXVI-21}]$ of $\text{Par}_{\{s(t(P))\}}(G)$.

(iii) Suppose P and Q are opposite; let P' and Q' be two parabolic subgroups of G , P' being of the same type as P . For P' and Q' to be opposite, it is necessary and sufficient that locally for the étale topology, the pair (P', Q') be conjugate to the pair (P, Q) . (N. B. One shall see in §5 that the étale topology can be replaced by the Zariski topology.)

<!-- label: III.XXVI.4.3.4 -->

****Corollary 4.3.5.**** *Let S be a scheme, G an S -reductive group, P a parabolic subgroup of G .*

<!-- original page 469 -->

(i) The morphism $\text{Opp}(P) \rightarrow \text{Lev}(P)$ (cf. 1.9) defined set-theoretically by $Q \mapsto P \cap Q$, is an isomorphism; $\text{Opp}(P)$ is a principal homogeneous bundle under $\text{rad}^u(P)$ ($\text{rad}^u(P)$ operating by inner automorphisms). If S is affine, there exists a parabolic subgroup of G opposite to P .*

(ii) Suppose S semi-local; let S_i be the set of its closed points; for each i , let Q_i be a parabolic subgroup of G_{S_i} , opposite to P_{S_i} . There exists a parabolic subgroup Q of G , opposite to P , and such that $Q_{S_i} = Q_i$ for each i .*

(iii) The morphism $\text{Opp}(G) \rightarrow \text{PL}$ (cf. 3.15) defined set-theoretically by $(P, Q) \mapsto (P, P \cap Q)$ is an isomorphism.*

<!-- label: III.XXVI.4.3.5 -->

All this follows from the first part of the theorem and from 1.9, 2.3 and 2.8.

****Remark 4.3.6.**** *Let P and Q be two opposite parabolic subgroups of G , and let $P \cdot Q$ be the open subscheme of G , sheaf-theoretic image of $P \times_S Q$, introduced in 4.2.6. The "product morphism" $G \times_S G \rightarrow G$ induces isomorphisms:*

```

```text
rad^u(P) ×_S Q → P · Q → P ×_S rad^u(Q).
```

```

<!-- label: III.XXVI.4.3.6 -->

This follows indeed from 4.3.2 (or 4.2.5 (ii)) and from the fact that $P \cap Q$ is a Levi subgroup of P and of Q , hence that $P = \text{rad}^u(P) \cdot (P \cap Q)$ and $Q = \text{rad}^u(Q) \cdot (P \cap Q)$.

<!-- original page 470 -->

One has similarly a commutative diagram

```

```text
rad^u(P) → G/Q
 ↓ ↓
Opp(P) → Par_{t(Q)}(G),
```

```

where the vertical arrows are induced by $g \mapsto \text{int}(g)Q$.

4.4. Osculating position

<!-- label: III.XXVI.4.4 -->

****Proposition 4.4.1.**** *Let S be a scheme, G an S -reductive group, P and Q two parabolic subgroups of G . The following conditions are equivalent:*

(i) $P \cap Q$ is a parabolic subgroup of G .*

(ii) $P \cap Q$ contains locally for the étale topology a Borel subgroup of G .*

(iii) $P \cap Q$ contains locally for the étale topology a maximal torus of G , and, for every $S' \rightarrow S$ and every maximal torus T of $G_{S'}$ contained in $P_{S'}$ and $Q_{S'}$, the opposite of $P_{S'}$ relative to T is in transversal position relative to $Q_{S'}$.*

(iv) There exists a covering family for the étale topology $\{S_i \rightarrow S\}$, and for each i a maximal torus T_i of G_{S_i} contained in P_{S_i} and Q_{S_i} , and such that the opposite of P_{S_i} relative to T_i is in transversal position relative to Q_{S_i} .*

<!-- original page 471 -->

*(v) There exists a covering family for the étale topology $\{S_i \rightarrow S\}$, and for each i a splitting (T_i, M_i, R_i) of G_{S_i} such that P_{S_i} (resp. Q_{S_i}) is the subgroup of type (R) of G_{S_i} containing T_i and defined by a set of roots $R^{(1)}_i$ (resp. $R^{(2)}_i$), $R^{(1)}_i \cap R^{(2)}_i$ containing a system of positive roots of R .

Moreover, if these conditions are satisfied, one has $t(P \cap Q) = t(P) \cap t(Q)$ (with the notations of 3.2).

<!-- label: III.XXVI.4.4.1 -->

One has (v) $\Rightarrow$ (ii) and (iii) $\Rightarrow$ (iv) trivially. On the other hand, (ii) $\Rightarrow$ (i) by 1.18. One has (iv) $\Rightarrow$ (v): indeed, one may assume G split, P (resp. Q) defined by the set of roots R_1 (resp. R_2); the opposite of P is then defined by $-R_1$, and one is reduced to Lemma 4.2.2. One proves (i) $\Rightarrow$ (iii) by splitting, in the same way. Finally, the last assertion of the theorem can be proved locally for the étale topology; one may assume that $P \cap Q$ contains a Borel subgroup B of G , and one is reduced to 3.7.

Definition 4.4.2. Two parabolic subgroups of G satisfying conditions (i) to (v) of 4.4.1 are said to be in osculating position.

<!-- label: III.XXVI.4.4.2 -->

Corollary 4.4.3. Let P and Q be two parabolic subgroups in osculating position, and let P' and Q' be two parabolic subgroups of G , of the same type as P and Q respectively. For P' and Q' to be in osculating position, it is necessary and sufficient that the pair (P', Q') be conjugate to the pair (P, Q) , locally for the étale topology.

<!-- original page 472 -->

<!-- label: III.XXVI.4.4.3 -->

It suffices to prove that if P and P' are in osculating position with respect to Q , they are conjugate, locally for (ét), by a section of Q . Now $P \cap Q$ and $P' \cap Q$ are two parabolic subgroups of the same type contained in Q , hence are conjugate locally for (ét) by a section of Q , by part (ii) of the lemma below. One may therefore assume $P \cap Q = P' \cap Q$; one then has $P = P'$, by part (i) of the same lemma:

Lemma 4.4.4. Let P , P' and Q be three parabolic subgroups of the S -reductive group G .

(i) For $P = P'$, it is necessary and sufficient that P and P' be in osculating position and of the same type.

(ii) If $P \subset Q$, $P' \subset Q$, and if $g \in G(S)$ is such that $\text{int}(g) P$ and P' are in osculating position, then $g \in Q(S)$.

<!-- label: III.XXVI.4.4.4 -->

Part (i) follows trivially from the last assertion of 4.4.1. Let us demonstrate (ii): Q and $\text{int}(g) Q$ contain $P' \cap \text{int}(g) P$, hence are in osculating position; they coincide by (i), hence $g \in \text{Norm}_G(Q)(S) = Q(S)$.

Let us remark that assertions (iii) and (iv) of the theorem immediately yield:

<!-- original page 473 -->

Corollary 4.4.5. Let P , P' and Q be three parabolic subgroups of the S -reductive group G , containing the same maximal torus T of G . Suppose P and P' opposite relative to T . For Q to be in osculating position relative to P , it is necessary and sufficient that it be in transversal position relative to P' . Under these conditions $P \cap Q$ is also in transversal position relative to P' .

<!-- label: III.XXVI.4.4.5 -->

Corollary 4.4.6. Let P and Q be two parabolic subgroups of G containing the same maximal torus T . For P and Q to be in transversal position, it is necessary and sufficient that there exist two parabolic subgroups $P' \subset P$ and $Q' \subset Q$ of G , opposite relative to T ; one may even choose $t(P') = t(P) \cap s(t(Q))$. [N.D.E-XXVI-22]

<!-- label: III.XXVI.4.4.6 -->

The condition is evidently sufficient (4.2.1 (i) and 4.3.2 (iii)). Let us show that it is necessary; let $P^\vee$ (resp.

$Q^{\sim}$ be the opposite of P (resp. Q) relative to T . By 4.4.5, $P \cap Q$ is in transversal position relative to P and $Q^{\sim}$, hence also relative to $P \cap Q^{\sim}$ by a further application of 4.4.5; moreover

```
```text
t(P^~ n Q) = t(P^~) n t(Q) = s(t(P)) n s(t(Q^~)) = s(t(P) n t(Q^~)) = s(t(P n Q^~)),
```
```

<!-- original page 474 -->

hence $P \cap Q = P'$ and $P \cap Q^{\sim} = Q'$ are opposite (4.3.2 (iii)); but $P' \cap Q' \supset T$, hence they are indeed opposite relative to T .

4.5. Standard position

<!-- label: III.XXVI.4.5 -->

In this section, we briefly indicate how some of the preceding results generalize.

Proposition 4.5.1. *If P_1 and P_2 are two parabolic subgroups of the S -reductive group G , the following conditions are equivalent: [N.D.E-XXVI-23]

- (i) $P_1 \cap P_2$ is smooth.*
 - (ii) $P_1 \cap P_2$ is a subgroup of type (R) (or of type (RC)) of G .*
 - (iii) $P_1 \cap P_2$ contains locally for the (fpqc) topology a maximal torus of G .*
 - (iv) $P_1 \cap P_2$ contains locally for the Zariski topology a maximal torus of G .*
- *When S is semi-local, these conditions are moreover equivalent to:*
- (v) $P_1 \cap P_2$ contains a maximal torus of G .*

<!-- label: III.XXVI.4.5.1 -->

Proof. [N.D.E-XXVI-23] Evidently, (iv) $\Rightarrow$ (iii) (and (v) $\Rightarrow$ (iv) when S is semi-local), and (ii) $\Rightarrow$ (i) according to Exp. XXII, Def. 5.2.1. We shall show (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii), then that (iii) entails (i) and (iv) (and also (v) when S is semi-local). Set $K = P_1 \cap P_2$. By 4.1.1 and [BT65], 4.5, each geometric fiber K_s contains a maximal torus T_s of G_s and is connected, and the set of roots of K_s with respect to T_s is a closed subset of the set of roots of G_s with respect to T_s . Hence, if K is smooth over S , then it is a subgroup of type (RC) (hence a fortiori of type (R)), cf. Exp. XXII 5.2.1 and 5.11.1. We therefore have (i) $\Leftrightarrow$ (ii).

If K is a subgroup of type (R), it contains locally for the étale topology a maximal torus of G , by Exp. XXII 2.2 and Exp. XIX 6.1. So (ii) $\Rightarrow$ (iii).

Suppose (iii) holds and let us show that K is smooth. By (fpqc) descent, one may assume that $G = (G, T, M, R)$ is split, where T is a maximal torus contained in $P \cap Q$, and that there exist two closed subsets R_1 and R_2 of R such that $P = H_{R_1}$ and $Q = H_{R_2}$.

<!-- original page 311 source / page 475 -->

Since K has connected fibers, it follows from Exp. XXII 5.4.5 that K equals $H_{R_1 \cap R_2}$, hence is smooth over S and of type (RC).

Let $R^{\{s\}}_1$ be the symmetric part of R_1 and $R^{\{a\}}_1 = R_1 - R^{\{s\}}_1$; then $\text{rad}^{\{u\}}(P_1) = H_{R^{\{a\}}_1}$. As noted in the proof of [BT65], 4.4, $R' = (R^{\{s\}}_1 \cap R_2) \cup R^{\{a\}}_1$ is a closed subset of R such that $R' \cup (-R') = R$; hence, by Exp. XXI 3.3.6, R' contains a system of positive roots of R . Moreover, the symmetric part of R' is $R^{\{s\}}_1 \cap R^{\{s\}}_2$, which is contained in $R_1 \cap R_2$.

It follows from the preceding that $P' = K \cdot \text{rad}^{\{u\}}(P)$ is a parabolic subgroup of G , and that K is a subgroup of type (RC) of P' such that $\text{rad}^{\{u\}}(K) = K \cap \text{rad}^{\{u\}}(P')$. Hence, by 2.11, K has a Levi subgroup L . It then follows from Exp. XIV 3.20 and 3.21 that K satisfies assertion (iv), as well as assertion (v) when S is semi-local. This proves 4.5.1.

Definition 4.5.1.1. [N.D.E-XXVI-24] *When the preceding conditions are satisfied, one says that P and Q are in*

mutual standard position; *this is, for instance, the case if P and Q are in transversal position, or in osculating position, or if the base is the spectrum of a field. It is a notion stable under base extension and local for the (fpqc) topology.*

<!-- label: III.XXVI.4.5.1.1 -->

4.5.2.

<!-- label: III.XXVI.4.5.2 -->

Let (P, Q) and (P', Q') be two pairs of parabolic subgroups of G , in standard position, and let H be the subfunctor of G defined as follows: $H(S)$ is the set of $g \in G(S)$ such that $\text{int}(g) P = P'$ and $\text{int}(g) Q = Q'$. It is a closed subscheme of G , smooth over S and formally principal homogeneous under $P \cap Q$. One deduces that the following conditions are equivalent:

- (i) (P, Q) and (P', Q') are conjugate locally for the (fpqc) topology,
- (ii) (P, Q) and (P', Q') are conjugate locally for the étale topology.
- (iii) (P, Q) and (P', Q') are conjugate on each geometric fiber.

One then says that the pairs (P, Q) and (P', Q') have the same *type of mutual position*. This is a notion stable under base change and local for the (fpqc) topology.

4.5.3.

<!-- label: III.XXVI.4.5.3 -->

Let $\text{Stand}(G)$ be the subfunctor of $\text{Par}(G) \times_S \text{Par}(G)$ "formed of pairs in mutual standard position". Then $\text{Stand}(G)$ is representable, there exists an étale finite S -scheme TypeStand ("scheme of types of mutual standard position"), and a morphism, smooth, of finite presentation, with irreducible geometric fibers (and hence in particular faithfully flat)

```

```text
t_2 : Stand(G) → TypeStand
```

```

<!-- original page 476 -->

which is a quotient of $\text{Stand}(G)$ by the action of G : two sections of $\text{Stand}(G)$ (over an arbitrary $S' \rightarrow S$) have the same type of mutual position if and only if they have the same image under t_2 . One has a commutative diagram

```

```text
Stand(G) ———— t_2 ———→ TypeStand
 | |
 ↓ ↓ q
Par(G) ×_S Par(G) →_t × t→ Of(Dyn(G)) ×_S Of(Dyn(G)),
```

```

where the morphism q may be described by descent as follows: if (P, Q) is a pair of parabolic subgroups of G in mutual standard position, and if T is a maximal torus of $P \cap Q$, then the morphism $\text{Norm}_G(T) \rightarrow \text{Stand}(G)$ defined set-theoretically by $n \mapsto (P, \text{int}(n) Q)$ induces an isomorphism

```

```text
W_P(T) \ W_G(T) / W_Q(T) ≅ q^{-1}(t(P), t(Q)).
```

```

(The left-hand side denotes the sheaf of double cosets ...). These assertions are proved without difficulty (remark in particular that $t^{-1}_2(t_2(P, Q)) \simeq G / (P \cap Q)$).

4.5.4.

<!-- label: III.XXVI.4.5.4 -->

Now let P be a fixed parabolic subgroup of G , and let $\text{Par}(G; P)$ be the functor of parabolic subgroups of G in standard position relative to P . For each $t \in \text{Of}(\text{Dyn}(G))(S)$, set similarly $\text{Par}_t(G; P) = \text{Par}(G; P) \cap \text{Par}_t(G)$. One sees at once that the two preceding functors are obtained from $\text{Stand}(G)$ by

<!-- original page 477 -->

fibered products, and are therefore representable by S -schemes that are smooth and of finite presentation over S , with non-empty fibers. One has a canonical morphism t_P induced by t_2 (i.e. $t_P(Q) = t_2(P, Q)$)

```

```text
t_P : Par_t(G; P) → q^{-1}(t(P), t)
```

```

which is smooth and of finite presentation, with irreducible geometric fibers. The canonical morphism $\text{Par}_t(G; P) \rightarrow \text{Par}_t(G)$ is a surjective monomorphism, and may therefore be considered as a *cellular decomposition* of $\text{Par}_t(G)$ (indexed by the set of connected components of $q^{-1}(t(P), t)$).

4.5.5.

<!-- label: III.XXVI.4.5.5 -->

Suppose now that the type t is of the form $t(Q)$, where Q is a parabolic subgroup of G in standard position relative to P , and that $P \cap Q$ contains a maximal torus T .

Then $\text{Par}_t(G) \simeq G/Q$ and $q^{-1}(t(P), t) \simeq W_P(T) \setminus W_G(T) / W_Q(T)$, which gives a diagram

```

```text
Par_{t(Q)}(G; P) →f→ W_P(T) \ W_G(T) / W_Q(T)
 |
 i
 ↓
Par_{t(Q)}(G) →□→ G/Q
```

```

where i is a surjective monomorphism, and where f is smooth and of finite presentation, with irreducible geometric fibers. Moreover, if Q_1 and Q_2 are two sections of $\text{Par}_t(G; P)$ (over an $S' \rightarrow S$), i.e. two parabolic

<!-- original page 478 -->

subgroups of $G_{S'}$ conjugate (locally for (fpqc)) to Q , and in standard position relative to $P_{S'}$, then Q_1 and Q_2 are conjugate by a section of P (locally for (fpqc)) if and only if $f(Q_1) = f(Q_2)$. If S is the spectrum of an algebraically closed field k , one thereby finds the relation

```

```text
P(k) \ G(k) / Q(k) = W_P(T)(k) \ W_G(T)(k) / W_Q(T)(k).
```

```

More generally, if one assumes that the scheme $W_P(T) \setminus W_G(T) / W_Q(T)$ is constant and of the form E_S (which happens, for instance, when G is split relative to T and S is connected), the $f^{-1}(e)$, $e \in E$, form a decomposition of $\text{Par}_t(G; P)$ into open and closed subschemes, which are homogeneous spaces under P , smooth and of finite presentation over S , with irreducible geometric fibers.

4.5.6.

<!-- label: III.XXVI.4.5.6 -->

Let us return to the general situation of 4.5.4. The scheme $q^{-1}(t(P), t)$ [N.D.E-XXVI-25] always has two distinguished sections, corresponding respectively to the types "transversal position" and "osculating position". The inverse image of the first section is a relatively dense open subscheme of $\text{Par}_t(G; P)$, as one has seen above; it is the cell of maximum relative dimension of the decomposition.

The inverse image of the second section is presumably a closed subscheme of $\text{Par}_t(G; P)$; it is the cell of minimum relative dimension of the decomposition.

5. Conjugacy theorem

<!-- label: III.XXVI.5 -->

<!-- original page 479 -->

Theorem 5.1. *Let S be a semi-local scheme, G an S -reductive group, P and P' two opposite parabolic subgroups (4.3.3) of G . Then*

$$\text{rad}^u(P)(S) \cdot P' \cdot P = G,$$

i.e. the union of the open subsets $U_P' \cdot P$ (4.3.6), for U running through $\text{rad}^u(P)(S)$, is all of G .

<!-- label: III.XXVI.5.1 -->

The proof is carried out in several steps:

5.1.1.

<!-- label: III.XXVI.5.1.1 -->

It suffices to give the proof in the case where S is the spectrum of a field k ; this follows at once from 2.6.

5.1.2.

<!-- label: III.XXVI.5.1.2 -->

Let $L = P \cap P'$. Suppose L has a Borel subgroup B_L ; let T be a maximal torus of B_L (Exp. XXII, 5.9.7); one verifies at once that $B = B_L \cdot \text{rad}^u(P)$ is a Borel subgroup of P ; let B' be the Borel subgroup of G opposite to B relative to T (i.e. such that $B \cap B' = T$). One has $B' \subset P'$ as one verifies at once by splitting G relative to T . Let us prove that

$$(x) \quad B^u(S) \cdot B' \cdot B \subset \text{rad}^u(P)(S) \cdot P' \cdot P.$$

Since one has $B^u(S) \subset P(S) = \text{rad}^u(P)(S) \cdot L(S) \subset \text{rad}^u(P)(S) \cdot P'(S)$, it suffices to prove that $B' \cdot B \subset P' \cdot P$, which is evident. It follows from (x) that it suffices to prove 5.1

<!-- original page 480 -->

for the pair (B, B') .

5.1.3.

<!-- label: III.XXVI.5.1.3 -->

The theorem is true if k is algebraically closed; indeed, the condition of 5.1.2 is satisfied, and one concludes by Exp. XXII, 5.7.10.

5.1.4.

<!-- label: III.XXVI.5.1.4 -->

The theorem is true when k is an infinite field. Indeed, $\text{rad}^u(P)(k)$ is dense in $\text{rad}^u(P)(\bar{k})$ by 2.7, and the theorem is true for $\bar{k}$.

5.1.5.

<!-- label: III.XXVI.5.1.5 -->

We are therefore reduced to the case where k is a finite field. Now $\text{Bor}(L)$ is a smooth homogeneous space of L ; it follows from Lang's theorem (Am. J. of Maths., 78, 1956 [N.D.E-XXVI-26]) that L has a Borel subgroup B_L . By 5.1.2, one may therefore assume that $P = B$ and $P' = B'$ are Borel subgroups. One writes $T = B \cap B'$.

5.1.6.

<!-- label: III.XXVI.5.1.6 -->

Let K be the algebraic closure of k ; choose a pinning of the triple (G_K, B_K, T_K) , let R^+ (resp. Δ) be the set of positive roots (resp. simple). By Exp. XXII, 5.7.2, it suffices to prove that for every $\alpha \in \Delta$, one has

$$(1) \quad u_\alpha B^u(K) \subset B^u(k) \cdot B^u(K) \cdot B(K).$$

Let α_i be the various roots conjugate to α over k (these are elements of Δ , since B is "defined over k "), and let R' be the set of roots that are linear combinations of the α_i . Set $R'^- = R'^- \cap R'$. As " R' " is defined

<!-- original page 481 -->

over k , there exists a subtorus Q of T such that Q_K is the maximal torus of the common kernel of the α_i .

Set $Z = \text{Centr}_G(Q)$, $B_Z = B \cap Z$, $B'_Z = B' \cap Z$ (cf. Exp. XXII, 5.10.2). Let us show that it suffices to verify the sought assertion in Z , that is

$$(2) \quad u_\alpha \cdot B^u_Z(K) \subset B^u_Z(k) \cdot B^u_Z(K) \cdot B_Z(K).$$

One has $(B'^u_Z)_K = \prod_{\alpha \in R'^-} U_\alpha$; let R'' be the complement of R' in R , and set

$$V = \prod_{\alpha \in R''} U_\alpha.$$

One immediately has $(B'^u)_K = (B'^u_Z)_K \cdot V$, and $(B_Z)_K$ normalizes V (Exp. XXII, 5.6.7). One therefore derives from (2) successively

$$\begin{aligned} u_\alpha \cdot B^u(K) &= u_\alpha \cdot B^u_Z(K) \cdot V(K) \subset B^u_Z(k) \cdot B^u_Z(K) \cdot B_Z(K) \cdot V(K) \\ &\subset B^u_Z(k) \cdot B^u_Z(K) \cdot V(K) \cdot B_Z(K), \end{aligned}$$

which yields (1) at once.

We are therefore reduced to the case where $G = Z$, that is, where the Galois group of K over k acts transitively on the simple roots.

5.1.7.

<!-- label: III.XXVI.5.1.7 -->

<!-- original page 482 -->

The assertion to be proved is equivalent to the fact that G/B is the union of the translates by $B^u(k)$ of the open image of B'^u , an assertion that does not change if one replaces G by its adjoint group (or by any group yielding the same adjoint group). One may therefore assume G adjoint.

5.1.8.

<!-- label: III.XXVI.5.1.8 -->

Consider then the Dynkin diagram of G_K . The Galois group acts transitively on this Dynkin diagram. But this Galois group has only cyclic quotients, and the Dynkin diagram has no cycles. It follows immediately that this diagram is of type A_1 , A_n with $n \geq 0$, or A_2 , A_m with $m \geq 0$. Using the canonical decomposition of Exp. XXIV, 5.9, one

may write

```
$$
G = \prod_{D/K} G_{\{0\}},
$$
```

where D is a finite k -scheme and $G_{\{0\}}$ is either a torus, of type A_1 , or of type A_2 .

By Exp. XXIV, 5.12, B comes from a Borel subgroup $B_{\{0\}}$ of $G_{\{0\}}$, T from a maximal torus $T_{\{0\}}$ of $G_{\{0\}}$; B' comes from the Borel subgroup $B'_{\{0\}}$ of $G_{\{0\}}$ opposite to $B_{\{0\}}$ relative to $T_{\{0\}}$. One has

```
```text
B'^u(k) = B^u_{\{0\}}(D),
B'^u \cdot T \cdot B^u = \prod_{D/k} B'^u_{\{0\}} \cdot T_{\{0\}} \cdot B^u_{\{0\}},
```
```

and it suffices to prove the sought assertion for the triple $(G_{\{0\}}, B_{\{0\}}, T_{\{0\}})$.

5.1.9.

<!-- label: III.XXVI.5.1.9 -->

<!-- original page 483 -->

One may therefore assume that G is of type $\emptyset$, A_1 , or A_2 . Since G has a Borel subgroup B , G is quasi-splittable relative to B (Exp. XXIV, 3.9.1), hence splittable if it is of type $\emptyset$ or A_1 . Since the theorem has already been proved in the split case (Exp. XXII 5.7.10), only the case A_2 remains to be treated. By Exp. XXIV, 3.11 there exists a morphism $E \rightarrow \operatorname{Spec}(k)$, principal Galois bundle under the group $\mathbb{Z}/2\mathbb{Z}$ of automorphisms of the Dynkin diagram of type A_2 , such that $G = Q_{\text{acute}}(E)_p \times_{E/\operatorname{Spec}(k)} (A_2)$. If E has a section, G is splittable and the theorem is proved. Otherwise, one necessarily has $E = \operatorname{Spec}(k')$, where k' is a quadratic extension of k . Finally, as one saw in 5.1.7, one may assume G simply connected (i.e. that G is a form of $SL_3(k)$).

5.1.10.

<!-- label: III.XXVI.5.1.10 -->

One is therefore in the following situation: one has a finite field k , a quadratic extension k' of k . The group $SL_3(k')$ of 3×3 matrices of determinant 1 is pinned as follows: the maximal torus is the group of diagonal matrices, the Borel subgroup is the group of upper triangular matrices, the "pins" are the elements:

```
$$
u_{\{\alpha\}} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad u_{\{\beta\}} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.
$$
```

One sees at once that the big cell Ω is defined by

```
```text
(a b c)
(d e f) \in \Omega(S) \Leftrightarrow a \text{ and } ae - bd \text{ are invertible,}
(g h i)
```
```

<!-- original page 484 -->

and that

```
```text
B^u(k) = { (1 x z)
 { (0 1 x^-) : x, z \in k', z + z^- = x x^- }
 { (0 0 1)
...
 }.
```

We must prove inclusion (1) of 5.1.6, that is to say, show that for all  $a, b, c \in K$  (algebraic closure of  $k$ ), there exist  $x, z \in k'$  such that  $z + \bar{z} = x \bar{x}$  and

$$(1) \quad \begin{pmatrix} 1 & x & z \\ 0 & 1 & \bar{x} \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ a & 1 & 0 \\ b & c & 1 \end{pmatrix} \in \Omega(K).$$

– If  $a \neq -1$ , one takes  $x = z = 0$ .

– If  $a = -1$ , the conditions to be realized are written

$$\begin{cases} z + z^{-1} = x x^{-1}, \\ b z - x \neq 0, \\ (b + c) z + b x - 1 \neq 0. \end{cases}$$

Let  $q$  be the number of elements of  $k$  ( $q \geq 2$ ). One knows that for every  $m \in k$ , the equation  $z + \bar{z} = m$ , with  $z \in k'$ , has  $q$  solutions.

– If  $b = 0$ , take  $x = 1$ ; one must solve  $z + \bar{z} = 1$ ,  $z \neq 1$ , which is always possible by the preceding remark.

– If  $b \neq 0$ , take  $x = 0$ ; one must solve

$$z + z^{-1} = 0, \quad z \neq 0, \quad (b + c) z \neq 1.$$

This is always possible if  $q \geq 3$ . If  $k = \mathbb{F}_2$ , it is possible if  $b + c \neq 1$ ; one may take  $z = 1$ .

<!-- original page 485 -->

– It remains to treat the case  $k = \mathbb{F}_2$ ,  $b + c = 1$ ,  $b \neq 0$ . The system is then written

$$z + z^{-1} = x x^{-1}, \quad b z \neq x, \quad z + b x \neq 1.$$

If  $b = 1$  (resp.  $b \notin k'$ ), let us take  $x = 1$ ; then the last two conditions are written  $z \neq b^{-1}$ ,  $1 - b$ , and they are consequences of  $z + \bar{z} = 1$ , which has solutions. Finally, if  $b \in k' - k$ , one may take  $x = b$ ,  $z = \bar{b}$ . QED.

**Corollary 5.2.** Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $P$  and  $P'$  two opposite parabolic subgroups of  $G$ . The canonical map

$$\text{rad}^u(P)(S) \cdot \text{rad}^u(P')(S) \rightarrow (G/P)(S)$$

is surjective (in particular, one has  $(G/P)(S) = G(S) / P(S)$ ). Every parabolic subgroup  $Q$  of  $G$ , of the same type as  $P$ , is of the form  $\int (u \ u') P$  with  $u \in \text{rad}^u(P)(S)$  and  $u' \in \text{rad}^u(P')(S)$ .

<!-- label: III.XXVI.5.2 -->

The second assertion is evidently equivalent to the first; let us demonstrate the latter. Let  $s_i$  be the closed points of  $S$ , let  $V$  be the open subscheme of  $G/P$  image of  $P'$  (and isomorphic to  $\text{rad}^u(P')$ , cf. 4.3.6), and let  $x \in (G/P)(S)$ . By 5.1, there exists for each  $i$  a section  $u_i \in \text{rad}^u(P)(\kappa(s_i))$  such that  $u_i x_{s_i}$  is a section of  $V_{s_i}$ . If  $u \in \text{rad}^u(P)(S)$  lifts the  $u_i$  (2.6),  $u x$  is a section of  $V$ , since such an assertion is verified on the closed fibers. But  $\text{rad}^u(P')(S) \xrightarrow{\sim} V(S)$  is bijective, and one concludes at once.

<!-- original page 486 -->

**\*\*Corollary 5.3.\*\*** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $P, P'$  and  $Q$  three parabolic subgroups of  $G$ . There exists  $g \in G(S)$  such that  $\text{int}(g) Q$  is in transversal position relative to  $P$  and  $P'$ .\*

<!-- label: III.XXVI.5.3 -->

With the notation of 4.2.4 (ii), one must verify that the universally schematically dense open subscheme over  $S \setminus \{N.D.E-XXVI-27\}$   $\text{Gen}(Q/P) \cap \text{Gen}(Q/P')$  of  $G$  has a section over  $S$ . Let us in fact choose a parabolic subgroup of  $G$  opposite to  $Q$  (4.3.5 (i)), say  $Q_1$ , and set  $U = \text{rad}^u(Q)$ ,  $U' = \text{rad}^u(Q_1)$ . We shall show that there exists  $g \in U(S)$  answering the question; in this form, it follows from 4.2.4 (i) and 2.6 that it suffices to verify the assertion on the fibers at the closed points of  $S$ , and one may therefore assume that  $S$  is the spectrum of a field  $k$ .

If  $k$  is algebraically closed, there exists  $g \in G(k)$  answering the question; now  $g$  is written  $u^{-1} q$  with  $u \in U(k)$ ,  $u' \in U'(k)$ ,  $q \in Q(k)$  (5.2), and one has  $\text{int}(u^{-1}) Q = \text{int}(g) Q$ .

If  $k$  is infinite, consider the open subset  $V$  of  $U \times_k U'$  defined by the cartesian diagram

$$\begin{array}{ccc} U \times_k U' & \longrightarrow & G \\ \uparrow & & \uparrow \\ V & \longrightarrow & \text{Gen}(Q/P) \cap \text{Gen}(Q/P'); \end{array}$$

since  $V \setminus \{\emptyset\} \neq \emptyset$  by what was just seen,  $V$  is dense in  $U \times_k U'$ , hence has a section by 2.7.

If  $k$  is finite,  $P$  (resp.  $P'$ ) has a Borel subgroup  $B$  (resp.  $B'$ ), by virtue of

<!-- original page 487 -->

Lang's theorem (cf. 5.1.5), since the schemes  $\text{Bor}(P) \simeq \text{Bor}(P/\text{rad}^u(P))$  and  $\text{Bor}(Q) \simeq \text{Bor}(Q/\text{rad}^u(Q))$  are smooth. If  $B_1$  is a Borel subgroup opposite to  $B$  (4.3.5 (i)), there exist  $a \in B^u(k)$  and  $a_1 \in B^u_1(k)$  such that  $\text{int}(a a_1) B = B'$  (5.2); then  $B_0 = \text{int}(a a_1) B_1 = \text{int}(a) B_1$  is opposite to  $B'$  and to  $B$ ; if  $Q_0$  is the unique parabolic subgroup of  $G$  containing  $B_0$  and of the same type as  $Q$  (3.8),  $Q_0$  is in transversal position relative to  $P$  and  $P'$  (4.2.1 (vi)). On the other hand, by 5.2,  $Q_0$  is written  $\text{int}(u^{-1}) Q$  with  $u \in U'(k)$ ,  $u \in U(k)$ , which is what was to be demonstrated.

**\*\*Corollary 5.4.\*\*** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $P$  and  $Q$  two parabolic subgroups of  $G$ . There exists  $g \in G(S)$  such that  $\text{int}(g) P$  is in osculating position relative to  $Q$ , i.e. (4.4.2) that  $\text{int}(g) P \cap Q$  is a parabolic subgroup of  $G$ .\*

<!-- label: III.XXVI.5.4 -->

Indeed, by 4.3.5 (i), there exists a parabolic subgroup  $P'$  of  $G$  opposite to  $P$ . By 5.3, there exists a parabolic subgroup  $P'_1$  of  $G$  of the same type as  $P'$ , in transversal position relative to  $P$  and  $Q$ . If  $T$  is a maximal torus of  $P'_1 \cap Q$  (4.2.7 (ii)), and if  $P_1$  is the opposite of  $P'_1$  relative to  $T$ , then  $P_1$  and  $Q$  are in osculating position, by 4.4.5. On the other hand,  $P$  and  $P_1$  being opposite to  $P'_1$ , there exists  $g \in \text{rad}^u(P'_1)(S)$  such that  $\text{int}(g) P = P_1$  (4.3.5 (i)). QED.

<!-- original page 488 -->

Let us remark, moreover, that for the same reason there exists  $u \in \text{rad}^u(P)(S)$  such that  $\text{int}(u) P = P'_1$ , hence  $g$  is written  $\text{int}(u) u^{-1}$  with  $u' \in \text{rad}^u(P')(S)$ , which gives  $P_1 = \text{int}(u u'^{-1}) P = \text{int}(u u') P$  and re-proves 5.2 in passing.

Statements 5.3 and 5.4 are the essential results of this section. Let us first state some consequences of 5.4.

**\*\*Corollary 5.5.\*\*** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group.\*

(i) If  $P$  and  $Q$  are two parabolic subgroups of  $G$  and if  $t(P) \subset t(Q)$  (cf. 3.3), there exists  $g \in G(S)$  such that  $\text{int}(g) P \subset Q$ .\*

(ii) Let\*

```

```text
P_1 \supset P_2 \supset \cdots \supset P_n \quad \text{and} \quad P'_1 \supset P'_2 \supset \cdots \supset P'_n
```

```

\*be two chains of parabolic subgroups of  $G$  such that  $t(P_{\{i\}}) = t(P'_{\{i\}})$ . There exists  $g \in G(S)$  such that  $\text{int}(g) P_{\{i\}} = P'_{\{i\}}$  for each  $i$ .\*

\*(iii) Let  $P, Q, P', Q'$  be four parabolic subgroups of  $G$  such that  $t(P) = t(P')$  and  $t(Q) = t(Q')$ . If the pairs  $(P, P')$  and  $(Q, Q')$  are in transversal (resp. osculating) position, there exists  $g \in G(S)$  such that  $\text{int}(g) P = P'$  and  $\text{int}(g) Q = Q'$ .\*

<!-- original page 489 -->

\*(iv) Let  $P$  and  $P'$  be two parabolic subgroups of the same type,  $L$  (resp.  $L'$ ) a Levi subgroup of  $P$  (resp.  $P'$ ). There exists  $g \in G(S)$  such that  $\text{int}(g) P = P'$  and  $\text{int}(g) L = L'$ .\*

<!-- label: III.XXVI.5.5 -->

\*Proof:\* (i) follows at once from 5.4; (ii) is proved by induction on  $n$ , the case  $n = 0$  being trivial; one may therefore assume  $P_{\{i\}} = P'_{\{i\}}$  for  $i = 1, \dots, n-1$ ; by 5.2 there exists  $g \in G(S)$  such that  $\text{int}(g) P_{\{n\}} = P'_{\{n\}}$ ; but then  $P_{\{n\}}$  and  $\text{int}(g) P_{\{n\}}$  are contained in  $P_{\{n-1\}} = P'_{\{n-1\}}$ , hence  $g \in P_{\{n-1\}}(S)$  (4.4.4 (ii)) and  $\text{int}(g) P_{\{i\}} = P'_{\{i\}}$  for  $i = 1, \dots, n$ .

On the other hand, (iv) follows at once from 5.2 and 1.8. Let us demonstrate (iii) in the case of "transversal position"; the assertion is a consequence of (iv) when the types of  $P$  and  $Q$  are opposite (4.3.3 (iii)); in the general case, by 4.2.7 (iii) and 4.4.6, one may find parabolic subgroups  $P_{\{1\}}, P'_{\{1\}}, Q_{\{1\}}, Q'_{\{1\}}$  of  $P, P', Q, Q'$  respectively, such that  $P_{\{1\}}$  and  $P'_{\{1\}}$  are opposite, as are  $Q_{\{1\}}$  and  $Q'_{\{1\}}$ , and such that  $t(P_{\{1\}}) = t(P'_{\{1\}})$ ; there therefore exists  $g \in G(S)$  such that  $\text{int}(g) P_{\{1\}} = P'_{\{1\}}$ ,  $\text{int}(g) Q_{\{1\}} = Q'_{\{1\}}$ , and one may assume  $P_{\{1\}} = P'_{\{1\}}$  and  $Q_{\{1\}} = Q'_{\{1\}}$ ; but then  $P$  and  $P'$  are in osculating position and of the same type, hence  $P = P'$  (4.4.4 (i)); for the same reason  $Q = Q'$ .

It remains to demonstrate assertion (iii) in the case of "osculating position". By the conjugacy theorem (5.2), one may assume  $P = P'$ ; by the same theorem, one may find  $g \in G(S)$  such that  $\text{int}(g) Q = Q'$ ; but then  $g \in P(S)$  by 4.4.4 (ii) and one has  $\text{int}(g) P = P = P'$ .

<!-- original page 490 -->

**Definition 5.6.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ . One says that  $P$  is minimal \*if whenever  $Q$  is a parabolic subgroup of  $G$  contained in  $P$ , one has  $Q = P$ .\*

<!-- label: III.XXVI.5.6 -->

One should note that this is not in general a notion stable under passage to fibers.

**Corollary 5.7.** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group.\*

\*(i) Let  $t, t' \in \text{Of}(\text{Dyn}(G))(S)$ . If there exist in  $G$  a parabolic subgroup of type  $t$  and a parabolic subgroup of type  $t'$ , there exists a parabolic subgroup of type  $t \cap t'$ . In particular, there exists a smallest element  $t_{\{\min\}}$  in the set of  $t(P)$ ,  $P$  running through the set of parabolic subgroups of  $G$ .\*

\*(ii) Every parabolic subgroup of  $G$  contains a minimal parabolic subgroup. For a parabolic subgroup of  $G$  to be minimal, it is necessary and sufficient that it be of type  $t_{\{\min\}}$ . Two minimal parabolic subgroups of  $G$  are conjugate by an element of  $G(S)$ .\*

<!-- label: III.XXVI.5.7 -->

This follows at once from 5.4 and 5.5 (i).

**Remark 5.8.** \*A parabolic subgroup opposite to a minimal parabolic subgroup is also minimal; this entails  $s(t_{\{\min\}}) = t_{\{\min\}}$ .\*

<!-- label: III.XXVI.5.8 -->

<!-- original page 491 -->

**\*\*Corollary 5.9.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ . The canonical morphism\*

$$G \twoheadrightarrow G/P = X$$

\*makes  $G$  an  $X$ -bundle locally trivial (in the sense of Zariski) with group  $P_X$ . If  $L$  is a Levi subgroup of  $P$ , the canonical morphism (cf. 3.12)\*

$$G \twoheadrightarrow G/L = Y$$

\*makes  $G$  a  $Y$ -bundle locally trivial (in the sense of Zariski) with group  $L_Y$ .\*

<!-- label: III.XXVI.5.9 -->

It suffices to prove that if one has a morphism  $S' \rightarrow S$ , where  $S'$  is local and a morphism  $S' \rightarrow X$  (resp.  $S' \rightarrow Y$ ), it lifts to a morphism  $S' \rightarrow G$ . In other words, one may assume  $S$  local, and one must show that the map  $G(S) \rightarrow X(S)$  (resp.  $G(S) \rightarrow Y(S)$ ) is surjective.

The first assertion was demonstrated in 5.2; let us demonstrate the second. Let  $y \in Y(S)$ ; its canonical image in  $X(S)$  comes from a  $g \in G(S)$ ; the projection  $y'$  of  $g$  in  $Y(S)$  therefore has the same projection as  $y$  in  $X(S)$ . There exists therefore a unique  $u \in \text{rad}^u(P)(S)$  such that  $y' u = y$ , and the projection of  $g u$  in  $Y(S)$  is indeed  $y$ .

<!-- original page 492 -->

**\*\*Corollary 5.10.\*\*** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group.\*

(i) Let  $P$  be a parabolic subgroup of  $G$ ,  $L$  a Levi subgroup of  $P$ . The canonical maps (cf. 3.21) induce bijections\*

$$\begin{aligned} & \text{``text} \\ & H^1(S, L) \cong H^1(S, P) \cong H^1_{\{t(P)\}}(S, G). \end{aligned}$$

(ii) Let  $t, t' \in \text{Of}(\text{Dyn}(G))(S)$ ; one has (cf. 3.21)\*

$$\begin{aligned} & \text{``text} \\ & H^1_t(S, G) \cap H^1_{t'}(S, G) = H^1_{t \cap t'}(S, G). \end{aligned}$$

(iii) If  $P$  and  $Q$  are two parabolic subgroups of  $G$  in osculating position, the following canonical diagram is cartesian and composed of injections:\*

$$\begin{array}{ccc} \text{``text} & & \\ H^1(S, P) & \longrightarrow & H^1(S, G) \\ \uparrow & & \uparrow \\ H^1(S, P \cap Q) & \longrightarrow & H^1(S, Q). \end{array}$$

<!-- label: III.XXVI.5.10 -->

Let us demonstrate (i). The map  $H^1(S, L) \rightarrow H^1(S, P)$  is bijective by 2.3; the map  $H^1(S, P) \rightarrow H^1_{\{t(P)\}}(S, G)$  is surjective (3.21); let us show that it is injective, i.e. that the canonical map  $H^1(S, P) \rightarrow H^1_{\{t(P)\}}(S, G)$  is injective. Let  $Q$  be a principal bundle under  $P$ ,  $Q_1$  the associated principal bundle under  $G$ ,  $P'$  and  $G'$  the corresponding twisted forms of  $P$  and  $G$ . It is clear that  $G'$  is an  $S$ -reductive group and that  $P'$  is a parabolic

<!-- original page 493 -->

subgroup of it. The set of elements of  $H^1(S, P)$  that have the same image as the class of  $Q$  in  $H^1(S, G)$  is naturally identified with the kernel of the canonical map  $H^1(S, P) \rightarrow H^1(S, G)$ , and this, by the exact sequence of cohomology, with the set of orbits of  $G(S)$  in  $(G'/P')(S)$  (for these arguments of non-abelian cohomology, see Giraud's thesis [N.D.E-XXVI-28]). But  $G'(S)$  acts transitively on  $(G'/P')(S)$  by 5.2.

Let us demonstrate (ii): let  $Q$  be a principal homogeneous bundle under  $G$  and  $G_Q$  the corresponding twisted form of  $G$ . By definition (3.21), we must prove that  $G_Q$  has a parabolic subgroup of type  $t \cap t'$  if and only if it has parabolic subgroups of type  $t$  and  $t'$ , which is none other than the conjunction of 3.8 and 5.7 (i). Finally, (iii) follows at once from (i) and (ii).

Let us now state a consequence of 5.3.

**Corollary 5.11.** \*Let  $S$  be a semi-local scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ . If  $P \neq G$ , there exist at least three distinct parabolic subgroups of  $G$  of the same type as  $P$ ; in other words,  $P \neq G$  entails  $(G(S) : P(S)) \geqslant 3$ .\*

<!-- label: III.XXVI.5.11 -->

Indeed, let  $P$  be a parabolic subgroup of  $G$  opposite to  $P$  (4.3.5 (i)). Since  $P \neq G$ , one has  $\text{rad}^u(P) \neq e$  (by 4.3.2 for example). By 2.1,  $\text{rad}^u(P)(S) \neq e$ ; let then  $u \in \text{rad}^u(P)(S)$ ,  $u \neq e$ . Then  $\text{int}(u)P \neq P$ , and by 5.3, there exists a  $P_1$ , of the same type as  $P$ , and opposite to  $P$  and  $\text{int}(u)P$ ; then  $P_1$ ,  $P$  and  $\text{int}(u)P$  are three distinct parabolic subgroups of  $G$ , of the same type as  $P$ .

## 6. Parabolic subgroups and split tori

<!-- label: III.XXVI.6 -->

<!-- original page 494 -->

**Proposition 6.1.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $g = \text{Lie}(G/S)$ , and  $Q$  a split subtorus of  $G$ . Write  $Q = D_S(M)$  and let\*

```text  
 $g = \bigoplus_{\alpha \in M} g^\alpha$

be the decomposition of g under the action of Q . Let M_1 be a subset of M such that $0 \in M_1$ and that $\alpha, \beta \in M_1 \Rightarrow \alpha + \beta \in M_1$.

(i) There exists a unique smooth subgroup H_{M_1} of G , with connected fibers, containing $\text{Centr}_G(Q)$, and whose Lie algebra is $\bigoplus_{\alpha \in M_1} g^\alpha$.

(ii) One has the following implications:

```text  
 $M_1 = \{0\}$                        $H_{M_1} = \text{Centr}_G(Q)$ ,  
 $M_1 = -M_1$                      $H_{M_1}$  is reductive,  
 $M_1 \cup (-M_1) = M$             $H_{M_1}$  and  $H_{-M_1}$  are parabolic subgroups of  $G$ ,  
                                                                                 opposite, with common Levi subgroup  $H_{M_1 \cap -M_1}$ .  
...`

<!-- label: III.XXVI.6.1 -->

To demonstrate (i) and (ii), which are local for the (fpqc) topology, one may assume that  $Q$  is contained in a maximal

<!-- original page 495 -->

torus  $T$  of  $G$ ; one may furthermore split  $G$  relative to  $T$ . Assertion (i) then follows at once from Exp. XXII, 5.3.5, 5.4.5 and 5.4.7; the assertions of (ii) follow from Exp. XXII, 5.3.5, 5.10.1, 5.11.3 and, in this Exposé, 1.4 and 4.3.2.

**Corollary 6.2.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $Q$  a split subtorus of  $G$ . There exists a parabolic subgroup of  $G$  of which  $\text{Centr}_G(Q)$  is a Levi subgroup.\*

<!-- label: III.XXVI.6.2 -->

Indeed, writing  $Q = D_{\{S\}}(M)$ , one chooses a total order structure on the group  $M$ , one calls  $M_1$  the set of positive elements of  $M$ ; the group  $H_{\{M_1\}}$  answers the question.

**Corollary 6.3.** \*If the  $S$ -reductive group  $G$  has a non-central split subtorus, it has a proper parabolic subgroup (i.e.  $\neq G$ ).\*

<!-- label: III.XXVI.6.3 -->

By 5.9 and 5.10, one derives from 6.2:

**Corollary 6.4.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $Q$  a split subtorus of  $G$ . The canonical morphism  $G \rightarrow G / \text{Centr}_{\{G\}}(Q)$  is a locally trivial fibration.\*

\*If  $S$  is semi-local, the map  $G(S) \rightarrow (G / \text{Centr}_{\{G\}}(Q))(S)$  is surjective, and the map  $H^1(S, \text{Centr}_{\{G\}}(Q)) \rightarrow H^1(S, G)$  is injective.\*

<!-- label: III.XXVI.6.4 -->

### 6.5.

<!-- label: III.XXVI.6.5 -->

Suppose  $S$  connected. If  $T$  is an  $S$ -torus and  $T'$  and  $T''$  are two split subtori of  $T$ , their product  $T' \cdot T''$  is also a split subtorus of  $T$ . Indeed,

<!-- original page 496 -->

it is identified with the quotient of  $T' \times T''$  by  $T' \cap T''$ , a quotient that is split by Exp. IX, 2.11. It follows that  $T$  has a largest split subtorus; one denotes it  $T_{\text{spl}}$ .

**Lemma 6.6.** \*Let  $S$  be a connected scheme,  $T$  an isotrivial  $S$ -torus,  $T_{\text{spl}}$  its largest split subtorus. The following conditions are equivalent:\*

(i) There exists a homomorphism  $T \rightarrow G_{\{m, S\}}$  distinct from  $e$ .\*

(ii)  $T_{\text{spl}} \neq e$ .\*

<!-- label: III.XXVI.6.6 -->

Since  $T$  is assumed isotrivial, there exist a finite group  $\Gamma$ , a connected principal Galois covering  $S' \rightarrow S$  of group  $\Gamma$ , and an isomorphism  $T_{\{S'\}} \simeq D_{\{S'\}}(M)$ ;  $M$  is then endowed with a structure of  $\Gamma$ -module, and one has a natural isomorphism  $\text{Hom}_{\{S\}}(T, G_{\{m, S\}}) = H^0(\Gamma, M)$ .

On the other hand, let  $V$  be the vector subspace of  $M \otimes \mathbb{Q}$  generated by elements of the form  $g(m) - m$ ,  $g \in \Gamma$ ,  $m \in M$ . One verifies at once that  $(T_{\text{spl}})_{\{S'\}}$  is identified with  $D_{\{S'\}}(M / M \cap V)$ . Assertion (i) is therefore equivalent to  $H^0(\Gamma, M) \neq 0$ , or equivalently to  $H^0(\Gamma, M \otimes \mathbb{Q}) \neq 0$ , whereas assertion (ii) is equivalent to  $M \neq M \cap V$ , or equivalently to  $M \otimes \mathbb{Q} \neq V$ . Now one has  $M \otimes \mathbb{Q} = H^0(\Gamma, M \otimes \mathbb{Q}) \oplus V$ , as one verifies at once (consider the projector  $M \otimes \mathbb{Q} \rightarrow H^0(\Gamma, M \otimes \mathbb{Q})$  that sends  $x$  to the average of the transforms of  $x$  by  $\Gamma$ ).

<!-- original page 497 -->

**Lemma 6.7.** \*Let  $S$  be a scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$  such that  $P \neq G$ ,  $L$  a Levi subgroup of  $P$ ,  $Q$  its radical. There exists a homomorphism  $Q \rightarrow G_{\{m, S\}}$  distinct from  $e$ .\*

<!-- label: III.XXVI.6.7 -->

Consider the unipotent radical  $U$  of  $P$ ; it is invariant under  $\text{int}(P)$ , hence under  $\text{int}(Q)$ . Consider the invertible  $U$ -module  $\det(\text{Lie}(U))$ , the "maximum exterior power" of the locally free  $U$ -module  $\text{Lie}(U)$ . The adjoint representation defines a homomorphism of groups

text  
 $f : Q \rightarrow \text{Aut}(\det(\text{Lie}(U))) = G_{\{m, S\}}.$

...

If  $P \not\subset G$ , then  $U \not\subset e$ . Let us choose  $s \in S$  such that  $U_s \not\subset e$ . Splitting  $G_s$  relative to a maximal torus containing  $Q_s$ , one sees at once that  $f_s \not\subset e$ .

**Proposition 6.8.** \*Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group,  $P$  a parabolic subgroup of  $G$ ,  $L$  a Levi subgroup of  $P$ ,  $Q$  its radical,  $Q_{\text{spl}}$  the largest split subtorus of  $Q$  (i.e. the largest central split subtorus of  $L$ ). Then\*

$L = \text{Centr}_G(Q_{\text{spl}})$ .

!-- label: III.XXVI.6.8 -->

Set  $L' = \text{Centr}_G(Q_{\text{spl}})$ ; this is a reductive subgroup of  $G$  containing  $L$ ; moreover,  $P' = P \cap L'$  is a parabolic subgroup of  $L'$ , of Levi subgroup  $L$  (1.20). If  $L' \not\subset L$ , then  $L' \not\subset P$  (since  $L$  is a maximal reductive subgroup of

!-- original page 498 -->

$P$ , cf. 1.7), hence  $P' \not\subset L'$ .

Let  $G_1$  be the derived group of  $G$ , and  $P_1 = P \cap G_1$ . By 1.19,  $P_1$  is a parabolic subgroup of the semisimple group  $G_1$ ,  $L_1 = L \cap G_1$  is a Levi subgroup of it, and

text  
 $Q_1 = \text{rad}(L_1) = (\text{rad}(L) \cap G_1)^0 = (Q \cap G_1)^0$ .

Since  $L_1$  has a maximal torus  $T_1$  (Exp. XIV, 3.20), and the latter is isotrivial (Exp. XXIV, 4.1.5),  $Q_1$ , being a subtorus of  $T_1$ , is also isotrivial (Exp. IX, 2.11); since  $P_1 \not\subset G_1$ , one may apply 6.7 and 6.6, and one therefore has  $(Q_1)_{\text{spl}} \not\subset e$ , whence  $(Q_{\text{spl}} \cap G_1)^0 \not\subset e$ , hence  $Q_{\text{spl}} \not\subset \text{rad}(L')$  (since  $\text{rad}(L') \cap G_1$  is finite), which is contradictory with the definition of  $L'$ .

**Corollary 6.9.** \*Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group,  $Q$  a critical subtorus of  $G$  (i.e. such that  $\text{rad}(\text{Centr}_G(Q)) = Q$ ). For  $\text{Centr}_G(Q)$  to be a Levi subgroup of a parabolic subgroup of  $G$ , it is necessary and sufficient that  $\text{Centr}_G(Q) = \text{Centr}_G(Q_{\text{spl}})$ , that is,  $\text{Lie}(G)^Q = \text{Lie}(G)^{Q_{\text{spl}}}$ .\*

!-- label: III.XXVI.6.9 -->

This follows from 6.2 and 6.8.

**Corollary 6.10.** \*Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group,  $L$  a subgroup of  $G$ . The following conditions are equivalent:\*

- (i) There exists a parabolic subgroup of  $G$  of which  $L$  is a Levi subgroup.\*
- (ii) There exists a split subtorus of  $G$  of which  $L$  is the centralizer.\*
- (iii) There exists a homomorphism  $G_m \times S \rightarrow G$  of which  $L$  is the centralizer.\*

!-- label: III.XXVI.6.10 -->

!-- original page 499 -->

Indeed, one has (i)  $\Rightarrow$  (ii) by 6.8, and (iii)  $\Rightarrow$  (i) by 6.1; it remains to prove (ii)  $\Rightarrow$  (iii). Suppose then  $L = \text{Centr}_G(Q)$ , with  $Q = D_S(M)$ ; write  $\mathfrak{g} = \text{Lie}(G/S)$  and

text  
 $\mathfrak{g}_\alpha = \bigoplus_{\alpha \in M} \mathfrak{g}^\alpha$ ,

and let  $R$  be the set of  $\alpha \in M - \{0\}$  such that  $\mathfrak{g}^\alpha \not\subset 0$ .

Since  $R$  is finite and does not contain  $0$ , there exists a homomorphism  $u : M \rightarrow \mathbb{Z}$  such that  $u(\alpha) \neq 0$  for each  $\alpha \in R$ . By duality,  $u$  gives a homomorphism  $G_{\{m, S\}} \rightarrow Q$ , hence a homomorphism  $f : G_{\{m, S\}} \rightarrow G$ . One has  $\text{Centr}_{\{G\}}(f) \supset \text{Centr}_{\{G\}}(Q)$ ; these are two smooth subgroups of  $G$ , with connected fibers; their Lie algebras coincide (since both are equal to  $\mathfrak{g}^0$ ); they therefore coincide, by a customary argument.

**Corollary 6.11.** Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group. The maps

$$L \mapsto \text{rad}(L)_{\text{spl}}, \quad Q \mapsto \text{Centr}_G(Q)$$

are mutually inverse bijections, which reverse the natural order structures, between the set of subgroups  $L$  of  $G$  that are Levi subgroups of parabolic subgroups of  $G$  and the set of split subtori  $Q$  of  $G$  such that  $\text{rad}(\text{Centr}_G(Q))_{\text{spl}} = Q$ .

<!-- label: III.XXVI.6.11 -->

**Corollary 6.12.** Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group. Consider the following assertions:

<!-- original page 500 -->

- (i) There exists a parabolic subgroup of  $G$  distinct from  $G$ .
  - (ii)  $G$  has a non-central split subtorus.
  - (ii bis)  $G$  has a non-central split subtorus of relative dimension 1.
  - (iii) There exists a homomorphism of groups  $G_{\{a, S\}} \rightarrow G$  that is a closed immersion.
- Then one has (i)  $\Leftrightarrow$  (ii)  $\Leftrightarrow$  (ii bis)  $\Rightarrow$  (iii).

<!-- label: III.XXVI.6.12 -->

The only new assertion is (i)  $\Rightarrow$  (iii). Let then  $P$  be a parabolic subgroup of  $G$ , distinct from  $G$ . Then  $U = \text{rad}^u(P) \neq e$ . Consider the last non-trivial subgroup  $U_{\{n\}}$  of the composition series of  $U$  (2.1). One has an isomorphism  $U_{\{n\}} \simeq W(E_{\{n\}})$ , where  $E_{\{n\}}$  is a locally free  $0_S$ -module, hence free [N.D.E-XXVI-30]. Since  $E_{\{n\}} \neq 0$ , there exists a locally direct-factor monomorphism  $0_S \rightarrow E_{\{n\}}$ , hence a closed immersion  $G_{\{a, S\}} = W(0_S) \hookrightarrow W(E_{\{n\}}) \simeq U_{\{n\}}$ , which yields (iii) at once.

**Remark 6.12.1.** When  $S$  is the spectrum of a field of characteristic  $0$ , it follows from the Jacobson–Morozov theorem that (iii)  $\Rightarrow$  (ii bis). The preceding four conditions are then equivalent ("Godement's criterion", cf. [BT65, 8.5]).

<!-- label: III.XXVI.6.12.1 -->

<!-- original page 501 -->

**Definition 6.13.** Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group. One says that  $G$  is *anisotropic* if  $G$  contains no split subtorus not reduced to  $e$ .

<!-- label: III.XXVI.6.13 -->

**Corollary 6.14.** Let  $S$  be a connected semi-local scheme. For the  $S$ -reductive group  $G$  to be anisotropic, it is necessary and sufficient that it have no parabolic subgroup  $P \neq G$ , and that its radical be anisotropic.

<!-- label: III.XXVI.6.14 -->

Using now 6.6, Exp. XXIV, 4.1.5, and Exp. XXII, 6.2, one deduces:

**Corollary 6.15.** Let  $S$  be a connected semi-local scheme,  $G$  an isotrivial  $S$ -reductive group (e.g.  $G$  semisimple, or  $S$  normal (Exp. X 5.16)). For  $G$  to be anisotropic, it is necessary and sufficient that  $G$  have no parabolic subgroup  $P \neq G$ , and that  $\text{Hom}_{\{S\text{-gr.}\}}(G, G_{\{m, S\}}) = e$ .

<!-- label: III.XXVI.6.15 -->

**\*\*Proposition 6.16.\*\*** \*Let  $S$  be a connected semi-local scheme,  $G$  an  $S$ -reductive group. The maximal split subtori of  $G$  are the largest central split subtori of the Levi subgroups of the minimal parabolic subgroups of  $G$ . Two such tori are conjugate by an element of  $G(S)$ .\*

<!-- label: III.XXVI.6.16 -->

Let  $Q$  be a maximal split subtorus of  $G$ . [N.D.E-XXVI-32] Then, by 6.2,  $L = \text{Centr}_G(Q)$  is a Levi subgroup of a parabolic subgroup  $P$  of  $G$ , and since  $Q \subset \text{rad}(\text{Centr}_G(Q))_{\text{spl}}$ , the maximality of  $Q$  entails  $Q = \text{rad}(\text{Centr}_G(Q))_{\text{spl}}$ . By 6.11,  $L$  is a minimal element of the set of Levi subgroups of parabolic

<!-- original page 502 -->

subgroups of  $G$ , hence  $P$  is a minimal parabolic subgroup of  $G$  by 1.20. It then follows from 5.7 and 5.5 (iv) that two subtori such as  $Q$  are conjugate by a section of  $G(S)$ . The conjugacy of the  $Q$  and of the pairs  $(P, L)$  then entails the first assertion of 6.16.

**\*\*Corollary 6.17.\*\*** \*Let  $S$  be a connected semi-local scheme,  $P$  and  $P'$  two minimal parabolic subgroups in standard position (4.5.1.1). Then  $P \cap P'$  contains a common Levi subgroup of  $P$  and  $P'$ .\*

<!-- label: III.XXVI.6.17 -->

Indeed,  $P \cap P'$  contains a maximal torus  $T$  of  $G$ , by 4.5.1 (v); let  $L$  be the unique Levi subgroup of  $P$  containing  $T$ . One has

```
```text
rad(P) ∩ T = rad(P) ∩ L = rad(L)
```
```

by 1.21, hence  $\text{rad}(P) \cap T$  contains  $\text{rad}(L)_{\text{spl}}$ , which is a maximal split subtorus of  $G$ , hence is necessarily equal to  $T_{\text{spl}}$ . One therefore has  $L = \text{Centr}_G(T_{\text{spl}})$ , and by symmetry  $L$  is also a Levi subgroup of  $P'$ .

**\*\*Remark 6.18.\*\*** \*It follows from 1.21 that the parabolic subgroup  $P$  of  $G$  is minimal if and only if  $\text{rad}(P)$  contains a maximal split subtorus of  $G$ ; then, by the proof of 6.17, if  $T$  is a maximal torus of  $P$ ,  $T_{\text{spl}}$  is a maximal split torus of  $G$  and of  $\text{rad}(P)$ , and  $\text{Centr}_G(T_{\text{spl}})$  is a Levi subgroup of  $P$ . Moreover, every Levi subgroup of  $P$  is obtained in this way.\*

<!-- label: III.XXVI.6.18 -->

## 7. Relative root datum

<!-- label: III.XXVI.7 -->

<!-- original page 503 -->

In this section,  $S$  will denote a non-empty connected semi-local scheme,  $G$  an  $S$ -reductive group,  $Q$  a maximal split subtorus of  $G$ , and  $L$  the centralizer of  $Q$  in  $G$ , i.e.  $L = \text{Centr}_G(Q)$ .

### 7.1.

<!-- label: III.XXVI.7.1 -->

Since  $Q$  is the largest central split subtorus of  $L$ , every section of  $G(S)$  that normalizes  $L$  also normalizes  $Q$ . One therefore has (cf. 7.1.1)

```
$$
\text{Norm}_G(L)(S) = \text{Norm}_G(Q)(S).
$$
```

On the other hand, one saw in 6.4 that the map  $G(S) \rightarrow (G/L)(S)$  is surjective. It follows that one has a canonical identification

```
```text
W_G(Q)(S) = (\text{Norm}_G(Q) / \text{Centr}_G(Q))(S) \cong \text{Norm}_G(L)(S) / L(S).
```
```

One will denote by  $M$  the group  $\operatorname{Hom}_{S\text{-gr.}}(Q, G_{\{m, S\}})$ , so that one has a canonical isomorphism  $Q \simeq D_{\{S\}}(M)$ . One will denote by  $W$  the group of automorphisms of  $M$  defined by  $W_{\{G\}}(Q)(S)$ . One therefore has isomorphisms

```
```text
W ≅ W_G(Q)(S) = Norm_G(L)(S) / L(S).
```
```

### 7.1.1.

<!-- label: III.XXVI.7.1.1 -->

One does not in general have  $\operatorname{Norm}_{\{G\}}(L) = \operatorname{Norm}_{\{G\}}(Q)$ . Take, for example, for  $S$  the spectrum of a field  $k$ , having a quadratic extension  $k'$ , for  $G$  the unitary group  $Q\text{-}\acute{E}_{p_{k'}/k}(A_{\{2\}})$  (cf. Exp. XXIV, 3.11.2).

<!-- original page 504 -->

Since the minimal parabolic subgroups of  $G$  are its Borel subgroups, their Levi subgroups are maximal tori, and one has  $(\operatorname{Norm}_{\{G\}}(L)/L)(k) = S_{\{3\}}$ .

On the other hand, since  $G$  is not split, the maximal split tori of  $G$  are of dimension  $\leq 1$ , hence isomorphic to  $G_{\{m, k\}}$ . Since  $\operatorname{Norm}_{\{G\}}(Q)/L$  acts faithfully on  $Q$ , one has  $(\operatorname{Norm}_{\{G\}}(Q)/Q)(k) = \mathbb{Z}/2\mathbb{Z}$ .

### 7.2.

<!-- label: III.XXVI.7.2 -->

If  $P$  is a parabolic subgroup of  $G$  with Levi group  $L$  (one exists by 6.2),  $P$  is necessarily minimal (cf. 6.18). By the conjugacy of minimal parabolic subgroups of  $G$  (5.7), of that of Levi subgroups of a parabolic subgroup (1.8), and of the equalities  $P = \operatorname{Norm}_{\{G\}}(P)$  and  $\operatorname{Norm}_{\{G\}}(L) \cap P = L$  (1.6), one obtains: the set of (minimal) parabolic subgroups of  $G$  with Levi group  $L$  is principal homogeneous under the group  $W$ .

### 7.3.

<!-- label: III.XXVI.7.3 -->

The Lie algebra of  $G$  decomposes under the action of  $Q$  as

```
```text
Lie(G) = Lie(L) ⊕ ⨆_{α ∈ R} Lie(G)^α,
```
```

where  $R$  is the set of non-zero characters of  $Q$  such that  $\operatorname{Lie}(G)^{\alpha} \neq 0$  (roots of  $G$  relative to  $Q$ ).

Let us denote by  $M^{\{*\}}$  the group  $\operatorname{Hom}_{S\text{-gr.}}(G_{\{m, S\}}, Q)$ , which is in duality with  $M$  and on which  $W$  acts naturally by transport of structure.

<!-- original page 505 -->

**Theorem 7.4.** With the notations of 7.3, there exists a unique map  $\alpha \mapsto \alpha^{\{*\}}$  from  $R$  to  $M^{\{*\}}$  that defines on  $(M, M^{\{*\}})$  a root datum (Exp. XXI, 1.1) whose Weyl group is  $W$ .

Moreover, the parabolic subgroups  $P$  of  $G$  with Levi group  $L$  and the systems of positive roots  $R^{\{+\}}$  of  $R$  correspond bijectively via the relation\*

```
```text
Lie(P) = Lie(L) ⊕ ⨆_{α ∈ R^+} Lie(G)^α.
```
```

<!-- label: III.XXVI.7.4 -->

### 7.4.1.

<!-- label: III.XXVI.7.4.1 -->

Suppose first that the existence of the map  $\alpha \mapsto \alpha^*$  sought has been proved. By Exp. XXI, 3.4.10,  $s_\alpha$  is the unique element of  $W$  such that for every  $m \in M$ ,  $s_\alpha(m) - m$  is a rational multiple of  $\alpha$ , which shows that  $s_\alpha$  is determined by  $\alpha$ ; as one then has [N.D.E-XXVI-33]  $\alpha^*(m) \alpha = m - s_\alpha(m)$ , one sees that  $\alpha^*$  is determined by  $\alpha$ , which proves the uniqueness of the map  $\alpha \mapsto \alpha^*$ .

### 7.4.2.

<!-- label: III.XXVI.7.4.2 -->

Let  $\alpha \in R$  and let  $L_\alpha$  (resp.  $H_\alpha$ , resp.  $H_{-\alpha}$ ) be the unique smooth subgroup of  $G$  with connected fibers containing  $L$  and such that (cf. 6.1 (i))

```

```text
Lie(L_α)   = Lie(L) ⊗ ⨁_{γ ∈ Zα ∩ R} Lie(G)^γ,
Lie(H_α)   = Lie(L) ⊗ ⨁_{γ ∈ Nα ∩ R} Lie(G)^γ,
Lie(H_{-α}) = Lie(L) ⊗ ⨁_{γ ∈ -Nα ∩ R} Lie(G)^γ.
```

```

<!-- original page 506 -->

$L_\alpha$  is a reductive subgroup of  $G$ ,  $H_\alpha$  and  $H_{-\alpha}$  are parabolic subgroups of it with Levi subgroup  $L$ , and  $H_\alpha$  and  $H_{-\alpha}$  are opposite relative to  $L$  (cf. 6.1 (ii)).

By 7.2, there therefore exists  $s_\alpha \in \text{Norm}_{L_\alpha}(Q)(S) / L(S) \subset W$  such that  $s_\alpha(H_\alpha) = H_{-\alpha}$ . One has  $s_\alpha(\alpha) = -\alpha$  (because  $\alpha$  (resp.  $-\alpha$ ) is the common divisor of the elements of  $R$  occurring in  $H_\alpha$  (resp.  $H_{-\alpha}$ )), and one has  $s_\alpha^2 = \text{id}$  (since  $s_\alpha(H_\alpha) = H_{-\alpha}$  and  $H_{-\alpha}$  are both opposite to  $H_\alpha$  relative to  $L$ ). One has therefore constructed an  $s_\alpha \in W$  satisfying the following properties:

```

```text
(x)      s_α(α) = -α,      s_α^2 = id;
(xx)     s_α can be represented by an element of L_α(S).
```

```

Let us moreover remark that  $s_\alpha$  is constructed canonically from  $\alpha$ , and in particular that

```

```text
(xxx)    for every  $w \in W$ , one has  $w s_\alpha w^{-1} = s_{w(\alpha)}$ .
```

```

### 7.4.3.

<!-- label: III.XXVI.7.4.3 -->

We now propose to prove the assertion:

```

```text
(xxxx)    for every  $m \in M$ ,  $s_\alpha(m) - m \in \mathbb{Z}\alpha$ .
```

```

Since  $S$  is connected, this assertion is local for the (fpqc) topology. One may therefore assume that  $L_\alpha = G_1$  is splittable relative to a maximal torus  $T_1$  of  $L$ . Let then  $(G_1, T_1, M_1, R_1)$  be such a splitting. The monomorphism  $Q \rightarrow T_1$  identifies  $M$  with a quotient of  $M_1$ ; let  $p: M_1 \rightarrow M$  be the canonical map.

The image of  $R_1$  under  $p$  consists, possibly with the inclusion of zero, of the roots of  $G_1$  with respect to  $Q$

<!-- original page 507 -->

(hence of the elements of  $R$  that are integer multiples of  $\alpha$ ); one therefore has  $p(R_1) \subset \mathbb{Z}\alpha$ . By (xx), there exists an element of  $\text{Norm}_{G_1}(L)(S)$  that induces  $s_\alpha$  on  $Q$ . By Exp. XXII, 5.10.10, there therefore exists a section  $w \in (W_1)_S(S)$  that induces  $s_\alpha$  on  $Q$

(one denotes by  $W_1$  the Weyl group of the root datum  $(M_1, R_1, \dots)$ ). Possibly after restricting  $S$ , one may therefore assume that there exists  $w \in W_1$  inducing  $s_\alpha$  on  $Q$ , hence satisfying  $\rho(w(m_1)) = s_\alpha(\rho(m_1))$  for every  $m_1 \in M_1$ . But, by definition of  $W_1$ ,  $w$  is a product of reflections with respect to elements of  $R_1$ , hence  $w(m_1) - m_1$  is a linear combination with integer coefficients of elements of  $R_1$ . It follows that  $s_\alpha(\rho(m_1)) - \rho(m_1)$  is a linear combination with integer coefficients of the elements of  $\rho(R_1) \subset \mathbb{Z}\alpha$ , hence an integer multiple of  $\alpha$ , as was to be proved.

### 7.4.4.

<!-- label: III.XXVI.7.4.4 -->

One may therefore define an element  $\alpha^* \in M^*$  by [^N.D.E-XXVI-34]

```
```text
 $\alpha^*(m) = m - s_\alpha(m).$ 
```
```

By (x), one has  $(\alpha^*, \alpha) = 2$ ; on the other hand, it follows from (xxx) that for every pair  $(\alpha, \alpha') \in R \times R$ , one has  $s_\alpha(\alpha') \in R$  and  $s_\alpha(\alpha'^*) = s_\alpha(\alpha')^*$ , which proves (cf. Exp. XXI, 1.1) that the constructed map  $\alpha \mapsto \alpha^*$  indeed defines a root datum on  $(M, M^*)$ .

### 7.4.5.

<!-- label: III.XXVI.7.4.5 -->

Let  $W$  be the Weyl group of this root datum (the group of transformations of  $M$  generated by the  $s_\alpha$ ); one has  $W \subset W$ .

Let on the other hand  $\geq$  be a total order relation on the free abelian group  $M$ ; set  $R^+ = \{ \alpha \in R \mid \alpha \geq 0 \}$ . One knows that  $R^+$  is a system of positive roots of  $R$ . Let  $w \in W$ , represented by an  $n \in \text{Norm}_G(L)(S) = \text{Norm}_G(Q)(S)$ . Set  $P = H_{R^+}$

<!-- original page 508 -->

(notation of 6.1); by \*loc. cit.\*,  $P$  is a parabolic subgroup of  $G$  with Levi subgroup  $L$ . One obviously has  $\text{int}(n) P = H_{w(R^+)}$ . It then follows from 7.3 that  $w(R^+) = R^+$  entails  $w = e$ . As the group  $W$  acts transitively on the systems of positive roots of  $R$  (Exp. XXI, 3.3.7) and the stabilizer in  $W$  of  $R^+$  is the identity, one concludes immediately that  $W = W$ . One also concludes that  $W = W$  acts in a simply transitive way both on the set of systems of positive roots of  $R$  and on the set of parabolic subgroups of  $G$  with Levi group  $L$ , which entails the last assertion of 7.4. QED.

### 7.5.

<!-- label: III.XXVI.7.5 -->

If  $P$  and  $P_1$  are two minimal parabolic subgroups of  $G$ , with Levi subgroups  $L$  and  $L_1$ , and if one denotes by  $Q$  and  $Q_1$  the maximal central split tori of  $L$  and  $L_1$ , then the pairs  $(P, Q)$  and  $(P_1, Q_1)$  are conjugate: there exists  $g \in G(S)$  such that  $\text{int}(g) P = P_1$  and  $\text{int}(g) Q = Q_1$ .

Indeed,  $P$  and  $P_1$  are conjugate (5.7) and one may therefore assume  $P = P_1$ ; then  $L$  and  $L_1$  are conjugate by a section of  $P(S)$  (1.8). Moreover, if  $g$  and  $g'$  are two sections of  $G$  conjugating the pairs  $(P, Q)$  and  $(P_1, Q_1)$ , then  $g'^{-1}g$  normalizes  $P$  and  $Q$ , hence  $P$  and  $L$ ; but

```
```text
 $\text{Norm}_G(P) \cap \text{Norm}_G(L) = P \cap \text{Norm}_G(L) = L = \text{Centr}_G(Q).$ 
```
```

<!-- original page 509 -->

The isomorphism  $Q \xrightarrow{\sim} Q_1$  induced by  $\text{int}(g)$  is therefore independent of  $g$ .

Let  $R$  and  $R_1$  be the root data defined thanks to 7.4 in  $\text{Hom}_{S\text{-gr.}}(Q, G_m, S)$  and  $\text{Hom}_{S\text{-gr.}}(Q_1, G_m, S)$ , and let  $R^+$  and  $R_1^+$  be the systems of positive roots

corresponding to  $P$  and  $P_1$ . The canonical isomorphism  $Q \xrightarrow{\sim} Q_1$  defined above transforms  $(R, R^+)$  into  $(R_1, R^+_1)$ . One immediately deduces that one may define the \*pinned relative root datum\* [N.D.E-XXVI-35] of  $G$  over  $S$ , by identifying the various  $(R, R^+)$  by means of the transitive system of isomorphisms described above.

From now on, we shall denote  $(M, M^*, R, R^+) = R(G/S)$  this pinned root datum; for each pair  $P \supset Q$  as above, one therefore has a canonical isomorphism  $M \xrightarrow{\sim} \operatorname{Hom}_{S\text{-gr.}}(Q, G_{(M, S)})$  transforming  $R$  (resp.  $R^+$ ) into the set of roots of  $G$  (resp. of  $P$ ) relative to  $Q$ , and  $W(R)$  into  $W_G(Q)(S)$ .

### 7.6.

<!-- label: III.XXVI.7.6 -->

Let still  $Q$  be a maximal split torus of  $G$ ,  $P$  a (minimal) parabolic subgroup of  $G$  with Levi group  $\operatorname{Centr}_G(Q)$ ,  $(M, M^*, R, R^+)$  the corresponding pinned root datum (7.4), and  $\Delta$  the set of simple roots of  $R^+$ . For every  $A \subset \Delta$ , let  $R_A \subset R$  be the set

```
```text
R_A = R^+ \cup (\mathbb{Z}A \cap R^-)
```

consisting of positive roots and negative roots that are linear combinations of elements of A . It is a closed set (Exp. XXI, 3.1.4) of roots, and every closed set containing R^+ is uniquely of this form (Exp. XXI, 3.3.10). By 6.1,

<!-- original page 510 -->

there exists a unique subgroup P_A of G , smooth and with connected fibers, containing $\operatorname{Centr}_G(Q)$ and such that

```
```text
Lie(P_A) = Lie(G)^0 \oplus \bigoplus_{\alpha \in R_A} \operatorname{Lie}(G)^\alpha.
```

It then follows at once from 6.1, from the conjugacy of minimal parabolics, and from the fact that the set of roots of a parabolic subgroup of  $G$  containing  $Q$  is closed (which is deduced at once from 1.4 by splitting), that:

**\*\*Proposition 7.7.\*\*** (i) The map  $A \mapsto P_A$  is a bijection of the set of subsets of  $\Delta$  onto the set of parabolic subgroups of  $G$  containing  $P$ . This bijection preserves the natural order relations of inclusion.\*

(ii) Every parabolic subgroup of  $G$  is conjugate by a section of  $G(S)$  to a unique  $P_A$ .\*

<!-- label: III.XXVI.7.7 -->

### 7.8.

<!-- label: III.XXVI.7.8 -->

Let  $P \supset Q$  be as above. Consider the relative root datum (7.5) of  $G$  over  $S$  and the canonical isomorphism

```
```text
f : (M, M^*, R, R^+, R^+) \rightarrow (M, M^*, R, R^+, R^+).
```

<!-- TRANSLATOR NOTE: The source writes f as an automorphism of (M, M^*, R, R^+, R^+) with itself; presumably the identifications are over different bases or models. -->

The set Δ of simple roots of R^+ is transformed into the set Δ of simple roots of R^+ , hence every subset A of Δ into a subset $f(A) \subset \Delta$.

****Definition 7.9.0.**** [N.D.E-XXVI-36] *Let H be an arbitrary parabolic subgroup of G . By 7.7 (ii), it is conjugate to a unique P_A . Let us denote $t_r(H) = f(A) \subset \Delta$. One verifies at once using the conjugacy theorems that $t_r(H)$ is independent of the choice of the pair $P \supset Q$. One says that it is the* relative type *of H .*

<!-- original page 511 -->

<!-- label: III.XXVI.7.9.0 -->

****Proposition 7.9.**** (i) The map $H \mapsto t_r(H)$ induces a bijection between the set of conjugacy classes (under $G(S)$) of parabolic subgroups of G , and the set of subsets of Δ .

(ii) Let H be a parabolic subgroup of G , P a minimal parabolic subgroup contained in H , Q the maximal central split torus of a Levi subgroup of P , Δ the set of simple roots of P relative to Q , and $f : \Delta \xrightarrow{\sim} \Delta$ the canonical isomorphism. Then, for every $\alpha \in \Delta$, one has the equivalence:

$$f(\alpha) \in t_r(H) \iff \text{Lie}(H)^{-\alpha} \neq 0$$

and one has $H = P_A$, where $A = f^{-1}(t_r(H))$.

(iii) If H and H' are two parabolic subgroups of G containing P , then (see 3.8.1 (ii) and 5.5 (i) for other equivalent conditions):

$$t_r(H) \subset t_r(H') \iff t(H) \subset t(H')$$

<!-- label: III.XXVI.7.9 -->

7.10.

<!-- label: III.XXVI.7.10 -->

One can study the relative positions of two minimal parabolic subgroups; the results are as follows (one refers to

<!-- original page 512 -->

4.5.2 for the notation $t_2(P, P_1)$):

(1) If P, P_1, P', P'_1 are four minimal parabolic subgroups of G , then $t_2(P, P_1) = t_2(P', P'_1)$ (i.e. (P, P_1) and (P', P'_1) are conjugate locally for (fpqc)) if and only if there exists $g \in G(S)$ such that $\text{int}(g)P = P'$ and $\text{int}(g)P_1 = P'_1$.

(2) Let us fix in particular a minimal parabolic subgroup P of G of Levi subgroup L , and let T be a maximal torus of L . Consider the scheme $\text{Par}_{t_{\min}}(G; P)$ of minimal parabolic subgroups of G in standard position relative to P . One has a morphism (cf. 4.5.5)

$$f : \text{Par}_{t_{\min}}(G; P) \rightarrow W_P(T) \backslash W_G(T) / W_P(T)$$

whose fibers are "the orbits of P in $\text{Par}_{t_{\min}}(G; P)$ ". By (1), f therefore induces a monomorphism

$$P(S) \backslash \text{Par}_{t_{\min}}(G; P)(S) \hookrightarrow (W_P(T) \backslash W_G(T) / W_P(T))(S).$$

The image of this morphism is identified with W ; this is the Bruhat theorem: each orbit of $P(S)$ in $\text{Par}_{t_{\min}}(G; P)(S)$ contains one and only one parabolic subgroup of G with Levi group L (that is, of the form $\text{int}(n)P$, where $n \in \text{Norm}_G(L)$).

(3) In other words, let $E(S)$ be the set of $g \in G(S)$ such that $\text{int}(g)P$ and P are in mutual standard position. Then $E(S)$ has a partition into double cosets modulo $P(S)$ indexed by W :

$$E(S) = P(S) \cdot W \cdot P(S)$$

<!-- original page 513 -->

(obvious notation). Setting $U = \text{rad}^{\{u\}}(P)(S)$, one may also write

```
```text
E(S) = U(S) · Norm_G(L)(S) · U(S),
```
```

thereby exhibiting a partition of $E(S)$ into double cosets modulo $U(S)$, indexed by $\text{Norm}_G(L)(S)$.

(4) If S is the spectrum of a field, then $E(S) = G(S)$, and one recovers [BT65], 5.15.

```
**Counterexamples 7.11.** *Let  $S = \text{operatorname{Spec}}(\mathbb{Z}/4\mathbb{Z})$ ,  $G = \text{SL}_2(S)$ . Let  $B$  be the
standard Borel subgroup formed of matrices  $\begin{pmatrix} a & b \\ c & d \end{pmatrix}$  with  $c = 0$ . Let  $g = \begin{pmatrix} 1 & -2 \\ 1 & 1 \end{pmatrix} \in G(S)$  [scil.:  $g = (1, 1, -2, 1)$ ]; set  $B' = \text{int}(g) B$ . Then  $B(S) = B'(S)$ , and  $B \cap B'$  does not contain a maximal torus [N.D.E-XXVI-37]. This shows on the one hand that two distinct minimal parabolic subgroups may have the same group of sections, and on the other hand that there exists no general criterion allowing one to recognize whether two minimal parabolic subgroups  $P$  and  $P'$  are in standard position, using only the groups  $P(S)$  and  $P'(S)$ . In particular, the part  $E(S)$  of  $G(S)$  does not seem to be definable using only the situation  $(G(S), P(S), \text{Norm}_G(L)(S))$  (in the preceding case, this part is defined by  $c \neq 2$  [N.D.E-XXVI-38]).*
```

```
<!-- label: III.XXVI.7.11 -->
```

```
### 7.12.
```

```
<!-- label: III.XXVI.7.12 -->
```

```
<!-- original page 514 -->
```

One now proposes to study the variation of $R(G/S)$ with S . Let then S be an S -scheme, also semi-local connected and non-empty. Let Q be a maximal split torus of G ; then $Q_{\{S\}}$ is a split torus of $G_{\{S\}}$; let Q' be a maximal split torus of $G_{\{S\}}$ containing $Q_{\{S\}}$. Set

```
```text
M = Hom_{S-gr.}(Q, G_{\{m, S\}}) = Hom_{S'-gr.}(Q_{\{S'\}}, G_{\{m, S'\}}),
M' = Hom_{S'-gr.}(Q', G_{\{m, S'\}}).
```
```

The monomorphism $Q_{\{S'\}} \rightarrow Q'$ induces an epimorphism $u : M' \rightarrow M$. Denote

```
```text
L = Centr_G(Q), L' = Centr_{G_{\{S'\}}}(Q'),
```
```

one has $L' \subset L_{\{S'\}}$.

If H is a subgroup of G containing L , then $H_{\{S'\}}$ contains L' , and one has

```
```text
Lie(H) = Lie(L) * \sum_{\alpha \in R_H} Lie(H)^{\alpha},
Lie(H_{\{S'\}}) = Lie(L') * \sum_{\alpha' \in R'_{H_{\{S'\}}}} Lie(H_{\{S'\}})^{\alpha'},
```
```

where R_H (resp. $R'_{H_{\{S'\}}}$) denotes the set of roots of H (resp. $H_{\{S'\}}$) relative to Q (resp. Q'). One immediately derives that

```
$$
R_{\{H\}} \subset u(R'_{H_{\{S'\}}}) \subset R_{\{H\}} \cup \{0\}.
$$
```

Taking $H = G$, one sees first that $R \subset u(R') \subset R \cup \{0\}$; taking then for H a minimal parabolic subgroup P of Levi subgroup L , one sees that $R'_{H_{\{S'\}}}$ contains a system of positive roots of R' , hence (7.4) that there exists a minimal parabolic subgroup P' of $G_{\{S'\}}$ of Levi subgroup L' contained in $P_{\{S'\}}$. One has therefore constructed a diagram

```
$$
```

$$\begin{array}{ccccc} Q_{\{S'\}} & \subset & L_{\{S'\}} & \subset & P_{\{S'\}} \\ & \cap & & \cap & \\ Q' & \subset & L' & \subset & P'. \end{array}$$

\$\$

If $R^{\{+ \}}$ (resp. Δ) is the system of positive roots (resp. simple) of R defined by P ,

<!-- original page 515 -->

and if one defines similarly $R'^{\{+ \}}$ and Δ' , one easily verifies that

$$R^{\{+ \}} \subset u(R'^{\{+ \}}) \subset R^{\{+ \}} \cup \{0\}, \quad \Delta \subset u(\Delta') \subset \Delta \cup \{0\}.$$

Let now $w \in W$ $\backslash \text{meq Norm}_{\{G\}}(Q)(S) / \text{Centr}_{\{G\}}(Q)(S)$, and $n \in \text{Norm}_{\{G\}}(Q)(S)$ a representative of w . One has $\text{int}(n) Q = Q$ hence $\text{int}(n) L = L$, hence $\text{int}(n) L_{\{S'\}} = L_{\{S'\}}$. Then Q' and $\text{int}(n) Q'$ are two maximal split tori of $L_{\{S'\}}$, hence are conjugate by a section $x \in L(S')$, and one has $\text{int}(n x) Q' = Q'$, hence $n x \in \text{Norm}_{\{G_{\{S'\}}\}}(Q')(S')$. Let w' be the image of $n' = n x$ in $W' \backslash \text{meq Norm}_{\{G_{\{S'\}}\}}(Q')(S') / \text{Centr}_{\{G_{\{S'\}}\}}(Q')(S')$. It is clear that the operation of w' on M' is compatible with the projection $u : M' \rightarrow M$ and that the induced operation on M coincides with that defined by w .

Using now the definition of relative root data and the conjugacy theorems, one proves without difficulty:

Theorem 7.13. *Let S and S' be two non-empty connected semi-local schemes, $S' \rightarrow S$ a morphism of S -schemes, G an S -reductive group,*

$$R(G/S) = (M, M^*, R, R^*, R^{\{+ \}}), \quad R(G_{\{S'\}}/S') = (M', M'^*, R', R'^*, R'^{\{+ \}})$$

the pinned relative root data. There exists a canonical homomorphism

$$u : M' \rightarrow M$$

\$\$

<!-- original page 516 -->

satisfying the following conditions:

(i) u is surjective.*

(ii) For every $w \in W$, there exists an element w' of W' compatible with u and which induces w on M .*

(iii) For every subset X of M , denote $X^{\wedge} = X \cap (M - \{0\})$. Then*

$$u(R'^{\{+ \}})^{\wedge} = R^{\{+ \}}, \quad u(\Delta')^{\wedge} = \Delta.$$

(iv) For every parabolic subgroup H , consider $t_r(H) \subset \Delta$ and $t_r(H_{\{S'\}}) \subset \Delta'$. Then*

$$t_r(H_{\{S'\}}) = (u^{-1}(t_r(H) \cup \{0\})) \cap \Delta' = \{ \alpha' \in \Delta' \mid u(\alpha') \in t_r(H) \text{ or } u(\alpha') = 0 \}.$$

<!-- label: III.XXVI.7.13 -->

Remark 7.14. *If G is splittable over S , its maximal split tori are maximal tori, and the relative notions introduced here then coincide with the absolute notions already introduced. The preceding theorem therefore gives a description of the relative root datum $R(G/S)$ and of the relative type t_r , via the absolute root datum and the absolute type of the group $G_{\{S'\}}$, S' being chosen in such a way that $G_{\{S'\}}$ is splittable (cf. Exp. XXIV, 4.4.1). We refer to [BT65], 6.12 et seq. for this description.*

<!-- label: III.XXVI.7.14 -->

7.15.

<!-- label: III.XXVI.7.15 -->

<!-- original page 517 -->

Let S be a Henselian local scheme, s its closed point, S_0 the spectrum of the residue field of s , identified with a closed subscheme of S ; for every object X above S , let us denote by X_0 the object above S_0 deduced from X by base change. Let finally G be an S -reductive group. For every parabolic subgroup $\bar{P}$ of G , $\bar{P}_0$ is a parabolic subgroup of G_0 ; conversely, for every parabolic subgroup P of G_0 , there exists a parabolic subgroup $\bar{P}$ of G such that $\bar{P}_0 = P$ (this follows from Hensel's lemma and from the fact that $\text{Par}(G)$ is a smooth S -scheme); in particular (cf. 5.7), a parabolic subgroup $\bar{P}$ of G is minimal if and only if $\bar{P}_0$ is minimal. Such a subgroup $\bar{P}$ of G being chosen, an analogous reasoning shows that the maximal split subtori of $\bar{P}_0$ are of the form T_0 , where T is a maximal split subtorus of $\bar{P}$. It follows without difficulty that the relative root data of G over S and of G_0 over S_0 are canonically isomorphic, so that the theory of parabolic subgroups of G reduces to that of parabolic subgroups of G_0 .

Let us remark, moreover, that every S_0 -reductive group is of the form G_0 (Exp. XXIV, Prop. 1.21), which conversely allows one to reduce the study of parabolic subgroups of an S_0 -reductive group to the corresponding study over S .

[^N.D.E-XXVI-0]: *N.D.E.* Version of 13/10/2024.

[^N.D.E-XXVI-1]: *N.D.E.* Since the Levi subgroups of $\$P\$$ form a torsor under $\$rad^{\{u\}}(P)\$$ (1.9), this entails, when $\$S\$$ is semi-local, that $\$P\$$ has a Levi subgroup and hence a maximal torus (2.4).

[^N.D.E-XXVI-2]: *N.D.E.* The terminology "trivial torus" has been replaced by that of "split torus".

[^N.D.E-XXVI-3]: *N.D.E.* "Parabolic subgroup" has been replaced by "subgroup of type (RC)", as in Exp. XXII, 5.11.4, because it will be useful later on (4.5.1, 6.17) to be able to apply this statement to $\$P \backslash cap P'\$,$ when $\`P, P'\`$ are two parabolic subgroups such that $\$P \backslash cap P'\$$ is of type (RC).

[^N.D.E-XXVI-4]: *N.D.E.* cf. N.D.E. (3).

[^N.D.E-XXVI-5]: *N.D.E.* $\$ \Delta(P)\$$ has been corrected to $\$ \Delta - \Delta(P)\$$.

[^N.D.E-XXVI-6]: *N.D.E.* cf. XIX 1.4.

[^N.D.E-XXVI-8]: *N.D.E.* cf. SGA 1, VIII 1.3, 1.9 and 1.10.

[^N.D.E-XXVI-9]: *N.D.E.* Corollary 2.11 has been added; it will be used in 4.5.1 and 6.17.

[^N.D.E-XXVI-10]: *N.D.E.* One recalls (cf. *loc. cit.*) that $\$H_{\{c\}} = H_{\{c\}}(G)\$$ denotes the functor of subgroups of $\$G\$$ of type (RC), $\$C\ell_{\{c\}} = C\ell_{\{c\}}(G)\$$ the functor of "conjugacy classes" of such subgroups, and that $\$c\ell : H_{\{c\}} \rightarrow C\ell_{\{c\}}\$$ is the canonical projection.

[^N.D.E-XXVI-11]: *N.D.E.* "Critical torus" has been replaced here by "C-critical torus", cf. *loc. cit.*. In the sequel, we shall simply write "critical torus" instead of "C-critical torus".

[^N.D.E-XXVI-12]: *N.D.E.* cf. 3.3, N.D.E. (10) for the notations $\$H_{\{c\}}\$$ and $\$C\ell_{\{c\}}\$$.

[^N.D.E-XXVI-13]: *N.D.E.* $\`LT\`$ has been changed to $\`CT\`$.

[^N.D.E-XXVI-14]: *N.D.E.* i.e. the parabolic subgroups $\$P = ((* * * *), (0 * * *), (0 0 * *), (0 0 0 *))\$$ and $\$P' = ((* * * *), (0 * * *), (0 * * *), (0 0 0 *))\$$ of $\`GL_4\`$ are not isomorphic (because $\`rad^u(P) \neq rad^u(P')\`$), but their Levi subgroups $\$L = ((* * 0 0), (* * 0 0), (0 0 * 0), (0 0 0 *))\$$ and $\$L' = ((* 0 0 0), (0 * * 0), (0 * * 0), (0 0 0 *))\$$ are conjugate by the element $\`((0 0 1 0), (0 1 0 0), (1 0 0 0), (0 0 0 1))\`$.

[^N.D.E-XXVI-15]: *N.D.E.* The numbering of the original has been preserved: there is no §3.19.

[^N.D.E-XXVI-16]: *N.D.E.* Point (ii) has been added; it will be useful in 4.5.1.

[^N.D.E-XXVI-17]: *N.D.E.* In view of the details added in 4.5.1, the original has been modified here (which stated "we shall not use this fact").

[^N.D.E-XXVI-18]: *N.D.E.* "Relatively dense" has been replaced by "universally schematically dense over $\$S\$$ ", cf. EGA IV₃, Def. 11.10.8.

[^N.D.E-XXVI-19]: *N.D.E.* cf. EGA IV₃, 11.10.10.

[^N.D.E-XXVI-20]: *N.D.E.* "Of order 2" has been replaced by "of order $\$ \leqslant 2\$$ " because $\$s_{\{G\}}\$$ may be trivial

(for example, if G is of type A_1 , B_n , C_n , ...).

[^N.D.E-XXVI-21]: *N.D.E.* "Relatively dense" has been replaced by "universally schematically dense over S ", cf. EGA IV₃, Def. 11.10.8.

[^N.D.E-XXVI-22]: *N.D.E.* Recall that the involution s was defined in 4.3.1.

[^N.D.E-XXVI-23]: *N.D.E.* The proof of the equivalence of these conditions has been added (as well as condition (v), used implicitly in 6.17 of the original); consequently, 4.5.1 has been transformed into Proposition 4.5.1 plus Definition 4.5.1.1.

[^N.D.E-XXVI-24]: *N.D.E.* see N.D.E. (23). Moreover, for an example of parabolic subgroups P, Q that are not in standard position, see 7.11 below.

[^N.D.E-XXVI-25]: *N.D.E.* $t^{-1}(t(P), t)$ has been corrected to $q^{-1}(t(P), t)$ and, lower down, $\text{Par}_t(G)$ to $\text{Par}_t(G; P)$ (twice).

[^N.D.E-XXVI-26]: *N.D.E.* See also [DG70], §III.5, 7.4.

[^N.D.E-XXVI-27]: *N.D.E.* "Relatively dense" has been replaced by "universally schematically dense over S ", cf. EGA IV₃, Def. 11.10.8.

[^N.D.E-XXVI-28]: *N.D.E.* See [Gi71], §III.3.

[^N.D.E-XXVI-29]: *N.D.E.* Multiplicative notation has been adopted, i.e. "their sum $T' + T''$ " has been replaced by "their product $T' \cdot T''$ ".

[^N.D.E-XXVI-30]: *N.D.E.* Since S is assumed semi-local and connected.

[^XXVI-1]: This is more generally true when S is the spectrum of a perfect field (Tits).[^N.D.E-XXVI-31]

[^N.D.E-XXVI-32]: *N.D.E.* The following sentence has been spelled out.

[^N.D.E-XXVI-33]: *N.D.E.* $\alpha^{*(m)}$ has been corrected to $\alpha^{*(m)} \alpha$.

[^N.D.E-XXVI-34]: *N.D.E.* $\alpha^{*(m)}$ has been corrected to $\alpha^{*(m)} \alpha$.

[^N.D.E-XXVI-35]: *N.D.E.* Recall (Exp. XXIII 1.5) that a pinned root datum is a root datum endowed with the choice of a system of positive roots (or of simple roots).

[^N.D.E-XXVI-36]: *N.D.E.* The numbering 7.9.0 has been added to highlight the definition of "relative type".

[^N.D.E-XXVI-38]: *N.D.E.* More generally, for every S -scheme S' , $E(S')$ is defined by the condition: " c is zero or invertible".

[^N.D.E-XXVI-39]: *N.D.E.* The references that follow have been added to this reference, which appears in the original.

[^N.D.E-XXVI-31]: *N.D.E.* This is Corollary 3.7 of the article [BT71].

[^N.D.E-XXVI-7]: *N.D.E.* $a_1 + \dots + a_p$ has been corrected to $b_1 + \dots + b_q$.

SGA 3: Group Schemes

Séminaire de Géométrie Algébrique du Bois-Marie, 1962–1964.

M. Demazure and A. Grothendieck, with collaborators J.-E. Bertin, P. Gabriel, M. Raynaud, M. Artin, J.-P. Serre. 2011
SMF *Documents Mathématiques* re-edition by Demazure (Tomes I, II, III, with N.D.E. footnotes).

Abstract

This Séminaire develops the theory of group schemes over an arbitrary base prescheme, in two complementary parts. Part I (Exposés I–VII_B, Tome I) lays foundations: schematic and categorical syntax, faithfully flat quasi-compact descent,

fibered categories and sheaves, the construction of quotient schemes, generalities on algebraic groups and group schemes, and the infinitesimal study of differential operators and formal groups, including the correspondence between height-1 radical group schemes and restricted $\mathfrak{p}$ -Lie algebras. Part II (Exposés VIII–XXVI, Tomes II and III) develops the structure theory: groups of multiplicative type (VIII–XII); regular elements in algebraic groups and Lie algebras (XIII–XIV); smoothness and maximal tori (XV); groups of zero unipotent rank, unipotent algebraic groups, and extensions (XVI–XVII); Weil's theorem on the construction of a group from a rational law (XVIII); and, in Tome III, the structure theory of reductive group schemes – generalities (XIX), the rank-1 case (XX), root data (XXI), splitting and subgroup structure (XXII), uniqueness of pinned groups (XXIII), automorphisms (XXIV), the existence theorem (XXV), and parabolic subgroups (XXVI). The Séminaire generalizes the Borel–Chevalley structure theory of affine algebraic groups to arbitrary base preschemes, with Chevalley's "Tôhoku" groups over $\mathbb{Z}$ as a guiding example.

Reading order

Files are numbered so alphanumeric order matches reading order.

Reference convention

Following the source's §7 convention (see the [Introduction](00-i-avertissement-introduction.md#introduction)), SGA 3 is cited as `(Exp. N, M.K)` where N is the Exposé Roman numeral and $M.K$ is the decimal numbering inside that Exposé –

for example `(XII, 3.2)` for statement 3.2 of Exposé XII. A bare `5.7.11` refers to the proposition of that name in the same Exposé. The split Exposés are cited as `VI\_A`, `VI\_B`, \$VII_{A}\$, \$VII_{B}\$ (matching the source's typeset subscript notation).

Cross-volume citations follow the source's abbreviations: `EGA X, x.y.z` for the **Éléments de Géométrie Algébrique**, `SGA n, X y.z` for other SGA volumes, **Bible** for the **Séminaire Chevalley** 1956/58, and TDTE for Grothendieck's **Techniques de descente et théorèmes d'existence** (Bourbaki, 1959–62). See the [glossary](glossary.md) for the full list.

Editorial conventions

- **Terminology.** SGA 3 retains the historical SGA/EGA distinction between **prescheme** (**préschéma**) and **scheme** (**schéma**), in the older sense of separated prescheme), matching SGA 1 and SGA 2 (Exposés I–XIII). The translation honors this throughout all 26 Exposés. As Grothendieck notes in the Introduction (§ 6), SGA 3 also deliberately replaces the usual hypothesis "of finite type" by "of finite presentation"; the translation preserves this distinction.
- **Editor footnotes (N.D.E.).** The 2011 SMF **Documents Mathématiques** re-edition (M. Demazure, ed.) added footnotes recording corrections, updates, modern references, and the current status of questions raised in the original 1962–1964 seminar. In this translation, original footnotes from the Séminaire authors (Demazure, Grothendieck, Bertin, Gabriel, Raynaud, Artin, Serre) use slugs like $\{I\}^3\text{-}1$, while editor footnotes use $\{N\}^{\text{D.E-I-3}}$ so the two are visibly distinct.
- **Page marks.** HTML comments `<!-- original page N -->` mark the start of page N in the 2011 SMF re-edition, whose pagination is the reference for the errata sheets.
- **Mathematics.** Mathematics is written with Unicode and wrapped in backticks where formatter mangling is a risk (most identifier-rich expressions). Displayed equations use fenced ````text```` blocks, optionally pinned with `<!-- label: eq:III.<Exp>.X.Y -->`.
- **Split Exposés (VI and VII).** Exposés VI and VII are split into A and B parts in the source. Filenames keep the split (`06A-`, `06B-`, `07A-`, `07B-`); cross-references use `VI_A`, `VI_B`, `$VII_{A}$`, `$VII_{B}$`.

Provenance

This is a translation, not a critical edition. The authoritative text remains the French 2011 SMF **Documents Mathématiques** re-edition, derived from the SLN 151, 152, 153 of 1970 as re-typeset by M. Demazure. For any claim that matters mathematically, consult the source: this English version exists to make the volume readable, not to replace it.

Glossary and Translation Ledger – SGA 3

This file records the translation choices made for the SGA 3 Markdown translation. It is the authoritative reference for the parallel translators of individual Exposés; every translator must consult it before drafting and must obey it where it applies.

Core terminology

| French | English | Note |
|----------------------------------|------------------------|---|
| ----- | ----- | ----- |
| préschéma | prescheme | Historical SGA/EGA term. Used throughout SGA 3, |
| matching SGA 1 and SGA 2 I–XIII. | | |
| schéma | scheme | Older sense: separated prescheme. The 2011 re-edition |
| retains this. | | |
| \$S\$-préschéma | \$S\$-prescheme | A prescheme over \$S\$. Sometimes typeset |
| `S-préschéma`; preserve hyphen. | | |
| \$S\$-schéma en groupes | \$S\$-group scheme | The relative form. Title-level for the whole |
| Séminaire. | | |
| faisceau | sheaf | Standard. |
| | | |
| faisceau (quasi-)cohérent | (quasi-)coherent sheaf | Standard. |

| | | |
|--|---|---|
| espace annelé | ringed space | Standard. |
| application | map | "Function" only in elementary set-theoretic contexts. |
| morphisme | morphism | Standard. |
| morphisme étale / lisse / plat / propre | étale / smooth / flat / proper morphism | Standard; matches SGA 1 glossary. |
| de présentation finie
présentation finie* (cf. Intro §6); preserve. | of finite presentation | SGA 3 deliberately replaces *de type fini* by *de |
| de type fini | of finite type | Use only when the source uses *de type fini*. |
| revêtement étale | étale covering | Per SGA 1 glossary. |
| immersion / immersion fermée / ouverte | immersion / closed immersion / open immersion | Standard. |
| ouvert / fermé / localement fermé | open / closed / locally closed | Standard. |
| voisinage | neighborhood | American spelling. |
| recouvrement | covering | "Cover" only in casual prose. |
| corps | field | False friend: not "body". |
| anneau | ring | Commutative by SGA convention unless stated. |
| anneau local (noethérien) | (noetherian) local ring | Standard. |
| anneau local régulier | regular local ring | Standard. |
| corps résiduel | residue field | Denoted $\kappa(x)$ or $\kappa(A)$ (per SGA 1). |
| catégorie | category | Standard. |
| foncteur / foncteur dérivé | functor / derived functor | Standard. |
| foncteur exact / exact à gauche / à droite | exact / left exact / right exact functor | Standard. |
| sous-foncteur | subfunctor | Standard. |
| foncteur représentable | representable functor | Central to SGA 3. |
| représentation (d'un groupe par un foncteur)
representable functors and for representations of groups; pick by context. | representation | Be careful: SGA 3 uses *représenter* both for |
| catégorie abélienne | abelian category | Standard. |
| limite projective / inductive | inverse / direct limit | Modern English. |
| fibre | fiber | American spelling. |
| fibre géométrique
groups.) | geometric fiber | Standard. (Used heavily in Tome III for reductive |
| spécialisation | specialization | American spelling. |
| canonique
specifically appeals to naturality. | canonical | Do *not* translate as "natural" unless the source |
| fonctoriel | functorial | Standard. |
| naturel | natural | Reserve for genuine naturality. |
| à isomorphisme près | up to isomorphism | Standard. |
| nécessaire et suffisant | necessary and sufficient | Sometimes "if and only if" in theorem statements. |

| | | |
|--------------------|----------------|------------------------------------|
| si et seulement si | if and only if | "Iff" only if local idiom permits. |
|--------------------|----------------|------------------------------------|

SGA 3 topics: foundations (Tome I)

| French | English | Note |
|---|--|--|
| ----- | ----- | ----- |
| schéma en groupes | group scheme | Title-level term. |
| \$\$-groupe | \$\$-group | Shorthand for *\$\$-schéma en groupes*. Preserve. |
| schéma en monoïdes | monoid scheme | Standard. |
| schéma en anneaux | ring scheme | Standard. |
| structure algébrique | algebraic structure | Per Exposé I title. |
| cohomologie des groupes | group cohomology | Per Exposé I title. |
| univers (Univers) | universe | Set-theoretic universe (Grothendieck universe). |
| catégorie `(Ens)` | category of sets `(Ens)` | Keep the source notation `(Ens)`. Gloss only at first use. |
| catégorie `(Sch)` | category of schemes `(Sch)` | Keep notation. The source writes \$(Sch)/S\$ for \$\$-schemes. |
| catégorie `(Ann)` | category of rings `(Ann)` | Keep notation. |
| catégorie `(Gr)` | category of groups `(Gr)` | Keep notation. |
| `Ĉ`
`Cb`; restore the hat. | `Ĉ` | Notation for $\operatorname{Hom}(C^{\circlearrowleft}, (Ens))$. OCR may produce |
| $C^{\circlearrowleft}$ | $C^{\circlearrowleft}$ (opposite category) | Keep $\{C^{\circlearrowleft}\}$ Unicode; OCR may give so or $\emptyset$. |
| foncteur contravariant | contravariant functor | Standard. |
| topologie fpqc
per Exposé. | fpqc topology | "Faithfully flat quasi-compact." Acronym kept; spell out on first use |
| topologie fppf | fppf topology | "Faithfully flat of finite presentation." Same convention. |
| topologie étale | étale topology | Standard. |
| topologie de Zariski | Zariski topology | Standard. |
| descente fidèlement plate | faithfully flat descent | Matches SGA 1 glossary. |
| catégorie fibrée | fibered category | American spelling. |
| faisceau (au sens d'une topologie) | sheaf (in the sense of a topology) | Standard. |
| faisceau associé | associated sheaf | Standard. |
| sous-foncteur représentable | representable subfunctor | Standard. |
| objet en groupes
groupes*. | group object | When the source uses *objet en groupes* rather than *schéma en |
| algèbre de Hopf | Hopf algebra | Standard. |
| algèbre affine | affine algebra | Standard. |
| spectre | spectrum | Standard. |
| $\operatorname{Spec}(A)$
without parens. | $\operatorname{Spec}(A)$ | Keep as-is; the source sometimes writes $\operatorname{Spec} A$ |

| | | |
|---|-----------------------------------|--|
| extension infinitésimale | infinitesimal extension | Per Exposé III title. |
| déformation infinitésimale | infinitesimal deformation | Standard. |
| fibré tangent
occurrence. | tangent bundle | Per Exposé II title. Context may favor "tangent sheaf"; flag first |
| fibré normal | normal bundle | Standard. |
| fibré principal | principal bundle | Standard. |
| algèbre de Lie | Lie algebra | Standard. $\text{Lie}(G/S)$ notation preserved. |
| $\mathfrak{g}$ -algèbre de Lie
de Lie*. Keep it; flag with a one-time gloss. | $\mathfrak{g}$ -Lie algebra | Modern: *restricted Lie algebra*; the source's term is $\mathfrak{g}$ -algèbre |
| schéma en groupes radiciel de hauteur 1 | radicial group scheme of height 1 | Per Intro §1. *Radiciel* = purely inseparable. |
| radiciel | radicial | Loanword (per EGA); not "radical". |
| opérateur différentiel | differential operator | Per Exposé VII_A title. |
| groupe formel | formal group | Per Exposé VII_B title. |
| $\mathbb{S}$ -foncteur | $\mathbb{S}$ -functor | A functor from $\text{Sch}^{\circ}/\mathbb{S}$ to Ens . Preserve. |
| passage au quotient | passage to the quotient | Standard. |
| schéma quotient | quotient scheme | Per Exposé V title. |
| relation d'équivalence | equivalence relation | Standard. |
| groupoïde | groupoid | Standard. |
| sous-groupe distingué / normal | normal subgroup | Standard (English does not distinguish). |
| centralisateur / normalisateur | centralizer / normalizer | American spelling. |
| transporteur | transporter | Standard. |
| stabilisateur | stabilizer | American spelling. |

SGA 3 topics: multiplicative-type and Lie-algebra material (Tome II)

| French | English | Note |
|---------------------------------|--------------------------------|--|
| ----- | ----- | ----- |
| groupe diagonalisable | diagonalizable group | American spelling. Per Exposé VIII title. |
| groupe de type multiplicatif | group of multiplicative type | Per Exposé IX–X titles. |
| caractère / cocaractère | character / cocharacter | Standard. |
| $\mathcal{D}(M)$ | $\mathcal{D}(M)$ | The Cartier dual of the abstract group M . Notation preserved. |
| groupe constant | constant group | Standard. |
| groupe tordu | twisted group | Standard. |
| forme tordue | twisted form | Standard. |
| critère de représentabilité | representability criterion | Per Exposé XI title. |
| tore | torus | Standard. Plural: *tori*. |
| tore maximal | maximal torus | Standard. |
| sous-tore | subtorus | Standard. |
| variété des tores maximaux | variety of maximal tori | Standard. |
| groupe de Weyl | Weyl group | Standard. |
| sous-groupe de Cartan | Cartan subgroup | Standard. |
| centre / centre réductif | center / reductive center | American spelling. $Z(G)$, $\text{rad}(G)$, $\text{rad}_u(G)$ notations preserved. |
| élément régulier | regular element | Per Exposés XIII–XIV titles. |
| élément semi-simple / unipotent | semisimple / unipotent element | "Semisimple" one word, no hyphen. |
| polynôme caractéristique | characteristic polynomial | Standard. |
| sous-groupe lisse | smooth subgroup | Standard. |
| groupe (algébrique) lisse | smooth (algebraic) group | Standard. |

| | | | |
|------------------------------------|---------------------------------|---|--|
| groupe de rang unipotent nul | group of zero unipotent rank | Per Exposé XVI title. | |
| groupe algébrique unipotent | unipotent algebraic group | Per Exposé XVII title. | |
| extension (de groupes algébriques) | extension (of algebraic groups) | Standard. | |
| loi rationnelle | rational law | Per Exposé XVIII title (Weil's theorem on rational laws). | |
| théorème de Weil | Weil's theorem | Standard. | |

SGA 3 topics: reductive groups (Tome III)

| French | English | Note |
|--------------------------------------|---|--|
| ----- | ----- | |
| groupe réductif | reductive group | Per Tome III title and Exposés XIX–XXVI. |
| groupe semi-simple | semisimple group | One word, no hyphen. |
| groupe résoluble | solvable group | American spelling. |
| groupe à rang semi-simple 1 | group of semisimple rank 1 | Per Exposé XX title. |
| déploiement / déployé | splitting / split | Standard. |
| groupe déployable | splittable group | Standard. |
| sous-groupe parabolique | parabolic subgroup | Per Exposé XXVI title. |
| sous-groupe de Borel | Borel subgroup | Standard. |
| sous-groupe radiciel | root subgroup | The U_{α} of a reductive group. |
| donnée radicielle | root datum | Per Exposé XXI title. Plural: *root data*. |
| système de racines | root system | Standard. |
| racine | root | Standard. (Not "radical" – that is *radical*.) |
| coracine | coroot | Standard. |
| poids | weight | Standard. |
| groupe épinglé | pinned group | Per Exposé XXIII title. *Épinglage* = *pinning*; "framed group" |
| only in passing. | | |
| épinglage | pinning | Standard (in this translation). |
| unicité des groupes épinglés | uniqueness of pinned groups | Per Exposé XXIII title. |
| automorphisme (d'un groupe réductif) | automorphism | Per Exposé XXIV title. |
| isogénie | isogeny | Standard. |
| groupe simplement connexe / adjoint | simply connected / adjoint group | Standard. |
| théorème d'existence | existence theorem | Per Exposé XXV title. |
| théorème d'unicité | uniqueness theorem | Standard. |
| groupes « de Tôhoku » | "Tôhoku" groups | Chevalley's groups over $\mathbb{Z}$. Italics on *Tôhoku* in |
| journal references. | | |
| Bible (Séminaire Chevalley 1956/58) | the *Bible* (Chevalley Seminar 1956–58) | SGA 3 cites the Chevalley Seminar as "Bible". Render the same way. |
| Bourbaki | Bourbaki | Standard. |
| théorie de Borel-Chevalley | Borel–Chevalley theory | Use en-dash between author names. |
| théorie de Demazure | Demazure's theory | Standard. |

Proof movement

These follow \$references/french-math-idiom.md\$ of the translation skill, with SGA-specific tweaks (inherited from SGA 1/SGA 2).

| French | English | Note |
|---------------------------------------|---|--|
| Soit / Soient X / X et Y | Let X / X and Y be | Match singular / plural. |
| Supposons (que) | Suppose (that) / Assume | "Assume" if the sentence is a hypothesis register. |
| Posons
definitions. | Set / Put | "Put" for variable assignments; "Set" for ad-hoc |
| Notons | Denote / Write / Note | Choose by what follows; *Notons que* is "Note that". |
| On a | We have | Not "one has" except for register. |
| On en déduit | We deduce | "It follows" if the inference is non-trivial. |
| Montrons (que) | We show (that) | "It remains to show" if it closes a reduction. |
| Il suffit de | It suffices to | Standard. |
| Il reste à montrer | It remains to show | Standard. |
| Il en résulte (que) / Il résulte (de) | It follows (that) / It follows (from) | Choose by structure; "hence" in compact proof prose. |
| Par suite | Consequently / hence | Avoid "as a result of this". |
| D'où | Hence / whence | "Whence" only if register supports it. |
| En effet | Indeed | Standard introduces a justification. |
| Or | Now | Pivot conjunction; "but" only if the sentence really |
| contrasts. /
Donc | Thus / hence / so | Choose by rhythm. |
| D'une part ... d'autre part | On the one hand ... on the other hand | Keep both clauses. |
| Cela achève la démonstration | This completes the proof | Standard. |
| CQFD | QED | Or "This proves the claim." |
| à savoir | namely | Standard. |
| compte tenu de | taking into account / in view of | Choose by clause weight. |
| en vertu de | by virtue of / by | "By" usually suffices. |
| moyennant | by means of / using | Standard. |
| quitte à | (possibly) by ... / replacing X by Y if necessary | A standard French move. |
| à condition que | provided that | Standard. |
| dès que | as soon as | Standard. |
| chaque fois que | whenever | Standard. |

Modality and certainty

Preserve modality exactly; do **not** upgrade certainty.

| French | English |
|--------------------------------------|--|
| il est clair que | it is clear that |
| il est évident que | it is evident that |
| manifestement / il est manifeste que | manifestly / it is manifest that |
| il semble que | it seems that |
| on s'attend à ce que | one expects that |
| il est probable que | it is probable that |
| sans doute | doubtless / probably (context-dependent) |
| conjecturalement | conjecturally |
| il y a tout lieu de penser que | there is every reason to think that |
| on peut conjecturer | one may conjecture |
| il n'est pas exclu que | it is not excluded that |
| il se peut que | it may be that |
| vraisemblablement | presumably |

Cross-volume citations

| Source | English citation form |
|--|---|
| EGA I, II, III, IV (with chapter and number) | `EGA I, 1.2.3` / `EGA IV, 1.4`, etc. Preserve the chapter Roman numeral. |
| SGA 1 (with Exposé and number) | `SGA 1, I 5.1` / `SGA 1, VIII 1.7`, etc. Match the source's spacing. |
| SGA n in general | `SGA n, X y.z` per the Introduction §7 convention. |
| Bible = Séminaire Chevalley 1956/58 | *Bible* (italicised) or \$S\acute{e}minaire Chevalley 1956/58\$. Keep the source's wording. |
| TDTE | Grothendieck's *Techniques de descente et théorèmes d'existence* (Bourbaki 1959–62). |
| Mumford GIT | Mumford, *Geometric Invariant Theory*. Italics. |
| Demazure–Gabriel | *Groupes algébriques* (Demazure–Gabriel). Italics, en-dash between author names. |

Common OCR repairs

The 2011 SMF re-edition is modern LaTeX, so OCR is high quality. Most math symbols survive. These items still recur:

- ****Dropped sub/superscripts on big operators.**** Γ , H^i , Ext^i , $R^i f_*$, ${}_0X$, Lie , $T_e G$, μ_n , G_m , G_a , α_p , $D(M)$, $w\alpha(X)$, root operators U_α , T_α may lose their indices. Recover from context.
- ****Cb` instead of `C`.** Hat on category symbol drops. Restore.
- ****\$(\text{ast})\$ / \$(\text{ast}\text{ast})\$ / \$(\text{ast}\text{ast}\text{ast})\$ for original footnote markers.**** Render as $\{\}^{\{<\}\text{expos}\acute{e}\}>\text{--}\text{<sec>--}\text{<n>}$ slugs ($\{\}^{\{I\}-1-1}$, $\{\}^{\{I\}-1-2}$, ...).
- ****`N` for N.D.E. footnote markers**** (small Arabic digit in parentheses). Render as $\{\}^{\{N\}.D.E.\text{--}\text{<expos}\acute{e}\}>\text{--}N$ ($\{\}^{\{N\}.D.E.-I-3}$, etc.) and translate the body of the note.
- ****\$\ddot{i}\$ or `i`**** (dotless i with floating diacritic) – restore to $\dot{i}$.
- ****Backslash escapes**** surviving from LaTeX: $\&$ → $\&$, $\#$ → $\#$.
- ****Arrows.**** $\rightarrow$ → to , $\mapsto$ → mapsto , $\sim$ → sim (often broken across lines) → cong , $\leadsto$ (OCR artefact) → $\xrightarrow{\text{sim}}$ or to annotated $\sim$.
- ****Greek subscripts.**** π_1 , H_0 , G_m etc. should be π_1 , H^0 , G_m (with backticks).
- ****`°` for opposite category**** drops to $\circ$ or θ . Restore $\circ^{\circ}$ or θ° (degree sign), matching local convention.
- ****VIB, VIIA, VIIB citations.**** Render as VI_B , VII_A , VII_B . Preserve subscript via underscore.
- ****« » guillemets.**** Translate to English quotes ($\cdots$) unless the source uses them to mark a Grothendieckian coinage, in which case keep them as quotation marks in the translation too.
- ****Hat across line break**** for formal completions: $\text{Et}(b/X)$ → $\hat{E}t(\hat{X})$. Same as SGA 2.
- ****Math run-ons.**** Restore displayed equations as fenced `text` blocks.
- ****Embedded N.D.E. footnotes.**** Source convention is (N) N.D.E. : `<text>` at page bottom. Recover the whole footnote (which may span lines) and translate as $\{\}^{\{N\}.D.E.\text{--}\text{<expos}\acute{e}\}>\text{--}N$.

Style anchors (non-negotiable for cross-volume consistency)

Inherited from SGA 1 / SGA 2. Deviate only if the SGA 1/2 corpus is itself inconsistent.

- ****File naming.**** `\00-i-errata.md`, `\00-i-avis-avertissement-introduction.md`, `\00-ii-preface.md`, `\00-iii-errata.md`, `\NN-<slug>.md` for each Exposé (using `\06A`, `\06B`, `\07A`, `\07B` for the split Exposés), `\glossary.md`, `\README.md`, `\zz-i-index-notations.md`, `\zz-iii-index-notations.md`, `\zz-iii-index-terminologique.md`.

- **Heading hierarchy.** ``# Exposé N. <English Title>`` (with ``_A`` / ``_B`` suffix where applicable), then numbered ``## 1. <Section Title>``, then sub-sections ``### 1.1. <Subsection>``. The Exposé heading carries a ``<!-- label: III.<Roman> -->`` comment on the next line.
- **Statement blocks.** ``**Proposition.**``, ``**Lemma.**``, ``**Theorem.**``, ``**Corollary.**``, ``**Definition.**``, ``**Remark.**``, ``**Example.**``, ``**Scholie.**`` on their own line. Statement numbers go inline: ``**Proposition 3.1.2.**`` ``**Statement...``. The label ``<!-- label: III.<Roman>.X.Y -->`` follows on the next line.
- **Math.** Unicode math wrapped in backticks for inline. Displayed math in fenced ``~~~`text`~~~`` blocks. Numbered displayed equations get ``<!-- label: eq:III.<Roman>.X.Y -->``.
- **Footnotes.** Markdown ``${{}}^{slug}`` syntax. Original footnotes: ``${{}}^{<expos\acute{e}>-<sec>-<n>}`` (e.g. ``${{}}^{I}-1-1``). Editor footnotes: ``${{}}^{N}.D.E-<expos\acute{e}>-<n>`` (e.g. ``${{}}^{N}.D.E-I-3``).
- **Page marks.** ``<!-- original page N -->`` at page boundaries (page numbers from the 2011 re-edition).
- **Cross-references.** Source's own convention: ``${VI}_{B}, 5.3``, ``${EGA III}, 4.1.5``, ``${SGA 1}, IV 3.8``, ``${Bible}, XIV``.
- **Bibliographies.** Each Exposé's own bibliography section is preserved as ``## Bibliography``, entries as a numbered (or ``[Key]``-keyed) list, journal titles in italics.

``## Cross-Exposé additions (discovered during translation)``

Each translated Exposé file ends with a fenced HTML-comment block titled ``LEDGER DELTA – Exposé <N>`` recording new terminology choices that the translator encountered beyond what this glossary already covers. Those deltas are kept in place at the foot of each Exposé rather than copied here, both to preserve the audit trail and because consolidating the deltas (which span ~500–1,500 terms across the 26 Exposés) into a single table would make the glossary harder to scan than the per-Exposé tables. A future cleanup pass may de-duplicate the most cross-cutting entries (e.g. ``*dévissage*``, the ``prescheme`/`scheme`` split, Demazure's ``épinglage*`` → ``pinning*``, Bertin's "anti-affine" envelope) into the tables above; until then, consult the deltas in the Exposé files for the authoritative per-Exposé terminology choices.

``<!-- SOURCE: zz-i-index.md -->``

``# Index – Tome I``

``<!-- label: III.index-i -->``

A combined index of notation and terminology for Tome I. Page numbers refer to the 2011 SMF re-edition.
