Avertissement and Introduction

<!-- label: III.avertissement-introduction -->

Avertissement

<!-- label: III.avertissement -->

We present here a slightly revised re-edition of the original Séminaire, whose aim and content are indicated in the Introduction. The revision consisted essentially in the correction of typographical errors, the addition (in footnotes) of some supplementary remarks or references, the present subdivision into three volumes each equipped with a detailed table of contents and an index of notation, and the adjunction of a terminological index at the end of Volume 3. In addition, Exposé VI B by J.-E. Bertin has been partially rewritten by him, in particular §§ 5 and 10, so that some references to that Exposé differ from references to the original Exposé. The reader will find a list of the Séminaire's Exposés at the beginning of the present volume.

Since the first edition of the present Séminaire appeared, the *Éléments de Géométrie Algébrique*, Chap. IV, have appeared in their entirety, which renders certain passages of the Séminaire unnecessary; we have occasionally indicated in footnotes the relevant references to EGA IV that allow such passages to be short-circuited.

For another exposition on algebraic groups using systematically the language of schemes, we point to the book by M. Demazure and P. Gabriel, *Groupes algébriques* (North-Holland & Masson et Cie). Unlike the present Séminaire, this book assumes no knowledge of algebraic geometry, but contains all the necessary preliminaries from the theory of schemes, and its reading can therefore serve as an introduction to the study of our Séminaire. (It also contains themes not covered in the Séminaire, such as the Dieudonné-style structure theory of commutative affine algebraic groups, in *loc. cit.* Chap. V.)

Bures-sur-Yvette, March 1970

Introduction

<!-- label: III.introduction -->

<!-- original page xxi -->

1. The aim of the present seminar is twofold.

On the one hand, we aim to give convenient foundations for the theory of group schemes in general. Exposés I to IV will provide for this purpose the indispensable preliminary exercises in schematic and categorical syntax. To obtain a language that "fits" geometric intuition effortlessly, and to avoid eventually unbearable circumlocutions, we always identify a prescheme X over another S with the functor $(\text{Sch})^{\{\circ\}}/S \rightarrow (\text{Ens})$ that it represents, [I-intro-1] and it is necessary to give many definitions in such a way that they apply to arbitrary functors, representable or not. Moreover, nearly all the functors we shall have to use will be "sheaves" (for the "faithfully flat quasi-compact topology"); Exposé IV, which treats groups only incidentally, gives a sketch of the language of "localization" and sheaves, which turns out to be very convenient for questions of representability of functors as well. Above all, this Exposé will provide us, for questions of passage to the quotient, with the most convenient framework for what follows.

Exposé V gives some general results on the existence of quotients, taken up in Exposé VI_A in the case of the quotient of an algebraic group over a field (or more generally, over an Artinian ring) by a subgroup. [I-intro-2] The latter Exposé and Exposé VI_B which follows it also contain various elementary results specific to algebraic groups over a field, used routinely thereafter.

Exposé VII studies certain facts linked to the characteristic of the base field, and in particular develops with appropriate generality the correspondence between radicial group schemes of height 1 and restricted p -Lie algebras.

<!-- original page xxii -->

Finally, Exposé XVIII contains the generalization, in the theory of schemes, of Weil's theorem on the "birational" definition of algebraic groups.

On the other hand, we propose to generalize to groups over an arbitrary base prescheme the Borel–Chevalley structure theory of affine algebraic groups. It has moreover become apparent in the course of writing up the seminar notes that the affine hypothesis is unnecessary for many results of the theory. The most complete results are obtained, evidently, in the case of "semisimple group schemes", or more generally "reductive" ones, with which we shall be exclusively concerned from Exposé XIX onwards. Chevalley himself had already given the construction of the "Tôhoku" groups over the ring of integers, a construction that will be taken up in the present seminar. The principal uniqueness theorem^[I-intro-3] gives a simple characterization of the "twisted" variants of these Tôhoku groups over a base prescheme S : they are the affine and smooth groups over S whose geometric fibers are connected semisimple groups in the usual sense.^[I-intro-4]

****2.**** As in the case of the theory known over an algebraically closed field, a crucial role is played by the sub-tori of the group schemes under consideration. The preliminary study of tori – and, more generally, of "group schemes of multiplicative type" (both from the intrinsic viewpoint and from the viewpoint of multiplicative-type subgroups of a given group) – therefore takes up a fairly large place in this seminar (Exposés VIII to XII). Their remarkable rigidity (in certain respects greater even than that of abelian schemes, or of semisimple group schemes) makes them very effective working instruments for the study of certain more general groups.

****3.**** From Exposé XII onwards (with the exception of Exposé XVIII already mentioned) we shall routinely use the theory of affine algebraic groups over an algebraically closed field, which the reader will find in the *Séminaire Chevalley* 1956, in particular in Exposés IV to IX of that seminar. We shall also use, but to a lesser extent, the later Exposés of the *Séminaire Chevalley*, devoted to the structure of semisimple algebraic groups. Indeed, we shall take up Chevalley's theory directly in the framework of schemes: it will be seen that in this way (even over a base field) the exposition gains in simplicity and in precision.

****4.**** The principal object of the present seminar is evidently to develop techniques that apply to the study of group schemes over an arbitrary base, i.e. essentially to the study of families of algebraic groups. As such, the infinitesimal properties of such families, and in particular the case of an Artinian base scheme, play an important role. These properties intervene even for the study

<!-- original page xxiii -->

of algebraic groups over a field k , in the case where the latter is not perfect, in order in particular to apply the technique of descent in the non-Galois case. Among the new results obtained in this case, let us mention the existence of maximal tori and Cartan subgroups in any smooth algebraic group, the rationality of the variety of maximal tori, and various related results (Exp. XIV^[I-intro-5]), or the correspondence between the "forms" of a semisimple group and the principal homogeneous bundles under a suitable (in general non-connected) semisimple algebraic group (Exp. XXIV, 1.16–1.20). In general, one may say that the methods required to work over a non-perfect base field are essentially those used for arbitrary base preschemes, and thereby fall outside the framework of classical algebraic geometry.

****5.**** It has not seemed useful to indicate at the head of the written-up Exposés the date or dates of the corresponding oral presentations at the Séminaire. Let us merely say that the order of the mimeographed Exposés (from I to XXVI) does correspond to the order of the oral presentations. On the other hand, the writing-up of the final text is sometimes notably later than the oral presentation, and often differs from it fairly substantially, the written text being generally more detailed and more complete (such as Exp. IV and VII_B), or indeed substantially more general (such as Exp. XII or VII_B) than the oral presentation. Other written Exposés correspond to no oral presentation (VI_B, VII_A, XV, XVI, XVII, and essentially XXVI), and were written up and inserted into the mimeographed seminar either to provide convenient references for various other Exposés (this is notably the case of VI_B), or because they constitute a natural extension of the notions and techniques already developed. One should note as a consequence that the reading of Exposés VII_A, VII_B, XV, XVI, XVII is not necessary for the study of the rest of the seminar, and in particular for the part of this seminar devoted to reductive group schemes.

****6.**** From the theory of schemes, we shall mainly use the general language of schemes, expounded in EGA I; the notions of flat morphism, étale morphism, smooth morphism, expounded in SGA 1, I to V; and finally the theory of faithfully flat descent of SGA 1, VIII. We have as far as possible avoided formulating unnecessary noetherian hypotheses, which has required us in return to replace the usual hypothesis "of finite type" by the hypothesis "of finite presentation". For the notion of morphism of finite presentation, the reader is referred to EGA IV, 1.4 and 1.6. The results of SGA 1, I to IV, most often stated in the noetherian context, will be developed in the general case in EGA IV,^[I-intro-6] where standard methods for reducing certain types of statements (involving hypotheses of finite presentation) to the noetherian case will also be developed in detail (EGA IV, §§ 8, 9, 11). The reader who does not wish to admit these results from EGA IV can simplify certain statements or their proofs by assuming the base prescheme to be locally

noetherian. He will, however, expose himself to difficulties in cases where the proof

<!-- original page xxiv -->

proceeds by descent from $\hat{A}$ to A , where $\hat{A}$ is the completion of a noetherian local ring A , since this method leads to the introduction of the (in general non-noetherian) ring $\hat{A} \otimes_{\hat{A}} \hat{A}$.

****7.**** References will be made following the usual decimal system: the reference 5.7.11 refers to the proposition (or lemma, definition, etc.) of that name in the same Exposé; in the reference XVII 7.8 the Roman numeral indicates the number of the Exposé. We shall use the following abbreviations for our standard references:

| Abbreviation | Expansion

[^I-intro-1]: Such a viewpoint seems to have been envisaged for the first time eight or nine years ago, in connection with the theory of formal groups, by P. Cartier, who unfortunately did not take the trouble to make it precise and systematic as it deserved.

[^I-intro-2]: For a more thorough study of passage to the quotient, in particular by reductive groups, see the important study by D. Mumford, *Geometric Invariant Theory*, Ergebnisse der Mathematik, Bd. 34, Springer, 1965. Let us observe that, on an important point, the terminology of this book does not agree with ours: over a field of characteristic $p > 0$, the groups that Mumford calls "reductive" [^{N.D.E-I}-intro-1] are the smooth groups of multiplicative type in the sense of the seminar (cf. Exp. IX). One may presumably consider that Mumford's acceptance of the word "reductive", which loses its meaning over a base that is not a field, was adopted by him on a provisional basis and as a kind of stopgap (and this is also roughly what Mumford explains, for other motives, from the second paragraph of his preface!).

[^I-intro-3]: *N.D.E.* This refers to Corollary XXIII.5.6, which is easily deduced from the uniqueness theorem for split reductive groups (cf. XXIII, Th. 4.1 and Cor. 5.2), given that every semisimple S -group is a "twisted form" (for the étale topology) of a "Tôhoku" group (cf. XXII, Cor. 2.3).

[^I-intro-4]: This is the essential result of M. Demazure's thesis (*Schémas en groupes réductifs*, Bull. Soc. Math. France ****93**** (1965), 369–413).

[^I-intro-5]: *N.D.E.* In particular, Theorems 1.1 and 6.1.

[^I-intro-6]: Since the writing of this introduction, the four parts (§§ 1 to 21) of EGA IV have appeared.

[^N.D.E-I-intro-1]: *N.D.E.* Concerning the quotient by a reductive group, the situation has evolved considerably since A. Grothendieck wrote Note (**). Indeed, for an affine algebraic group over an arbitrary field k , the "good" notion, introduced by Mumford, is that of "geometrically reductive" group. (One says, on the other hand, that G is "linearly reductive" if every rational representation of G is completely reducible; but, as pointed out in Note (**), this condition is too restrictive if $\text{char}(k) > 0$.) By the results of M. Nagata and W. J. Haboush ([Na64], [NM64], [Ha75]), the geometrically reductive k -groups are exactly the reductive k -groups in the sense of the present seminar. For all this, see the subsequent editions of Mumford's book ([MF82]). Moreover, the extension to the case of an arbitrary base of the notion of "geometric reductivity", and of its consequences for passage to the quotient, was carried out by C. S. Seshadri ([Se77]), and additions, due to M. Raynaud, are to be found in the article [CTS79] of J.-L. Colliot-Thélène and J.-J. Sansuc. Finally, for more recent developments concerning passage to the quotient by an algebraic group or, more generally, by a groupoid (cf. Exposé V of the present seminar), we point to the articles [Ko97] and [KM97] by J. Kollár and by S. Keel and S. Mori.

Errata – Tome I

<!-- label: III.errata-i -->

Misprints and errors in the new edition of SGA 3, Tome 1.

13 October 2024.

1. SGA 3, Tome 1

Page numbers refer to the version published in 2011. The new compilation compressed the pages to remove the final (odd-numbered) page of Exposés 3 and 6A, so the pagination of the 2024 version is shifted by $\$-2\$$ (resp. $\$-4\$$) starting from Exposé 4 (resp. Exposé 6B).

1.1. Exposé I

- p. 18, in the added Proposition 3.1.2, the proof that 0 is a generator is incorrect. This has been corrected in the 13/10/2024 version.
- p. 29, N.D.E. (40): $\dot{I}_B$ should be: Cf. VI_B .

1.2. Exposé II

- p. 82: the 2nd sentence of N.D.E. 71 should appear in N.D.E. 72.

1.3. Exposé IV

- p. 182, proof of Prop. 1.8: in the diagram, on the upper-left arrow, vu should be uv , and likewise in the 1st line below the diagram. This has been corrected in the 13/10/2024 version.

1.4. Exposé VI_A

- p. 302, the proof of Lemma 2.1.3 contained an unwarranted simplification; one must revert to the original proof. This has been corrected in the 13/10/2024 version.
- p. 329, in the proof of Lemma 6.1, the word "à droite" (on the right) is missing after "resp."

1.5. Exposé VI_B

- p. 359, end of Cor. 4.4. There was a slip in N.D.E. (31): keeping the same notation, one must consider the subgroup $G = \operatorname{Spec} A[X]/(\Delta X)$ of the additive group over S , which to every A -algebra R associates the subgroup of $r \in R$ such that $\Delta r = 0$. This has been corrected in the 13/10/2024 version.
- p. 374, Th. 6.2.3: in the proof, line 2 of the 3rd paragraph, replace "free module" by "projective module".

1.6. Exposé VII_B

- p. 587, line 6 of 5.0: $\Delta(A)$ should be $\Delta(a)$.

Preface to Tome II

<!-- label: III.preface-ii -->

A note from the translator.

Tome II of the 2011 SMF re-edition of SGA 3 contains Exposés VIII through XVIII, with no separate front matter, errata sheet, or notation index of its own – the editors chose to consolidate the volume-level apparatus into Tomes I and III only. Reading-order navigation for the Tome II Exposés can be found in the [README](README.md); references to the Avertissement, Introduction, and reference convention all live with [Tome I's front matter](00-i-avertissement-introduction.md); and the translation glossary applies uniformly across the three Tomes. The Tome I errata sheet flags Exposé II only (§ 1.2), and the Tome III errata sheet does not concern this Tome.

Topically, Tome II spans three threads. Exposés VIII–XII (Grothendieck) develop the theory of groups of multiplicative type – diagonalizable groups (VIII), homomorphisms between groups of multiplicative type (IX), characterization and classification (X), representability criteria (XI), and the foundational structure theorems on maximal tori, the Weyl group, Cartan subgroups, and the reductive center (XII), which together provide the language used throughout Tome III. Exposés XIII–XV (Grothendieck, with Serre's appendix in XIV, and Raynaud in XV) develop the theory of regular elements in algebraic groups and Lie algebras and apply it to the construction and parametrization of maximal tori, in particular in smooth group schemes over a non-perfect field. Exposés XVI–XVIII close the Tome with Raynaud's treatment of groups of zero unipotent rank and of unipotent algebraic groups and their extensions (XVI–XVII), and Artin's writing-up of Weil's theorem on the construction of a group from a rational law (XVIII).

Several of the Exposés in this Tome were inserted into the mimeographed Séminaire without a corresponding oral presentation, as Grothendieck notes in §5 of the Introduction: VII_A and VII_B from Tome I, and XV, XVI, XVII from this Tome, may be read as natural extensions of the techniques developed in the surrounding material rather than as steps in the main line; the reader heading for the reductive-group material of Tome III need not pause on them.

The Exposés in this Tome are listed below; for the full reading order across all three Tomes, see the [README](README.md).

- [Exposé VIII – Diagonalizable groups (Grothendieck)](08-groupes-diagonalisables.md)
- [Exposé IX – Groups of multiplicative type: homomorphisms (Grothendieck)](09-groupes-type-multiplicatif-homomorphismes.md)
- [Exposé X – Characterization and classification of groups of multiplicative type (Grothendieck)](10-caracterisation-classification-groupes-multiplicatif.md)
- [Exposé XI – Representability criteria (Grothendieck)](11-criteres-representabilite.md)
- [Exposé XII – Maximal tori, the Weyl group, Cartan subgroups, the reductive center (Grothendieck)](12-tores-maximaux-weyl-cartan-centre-reductif.md)
- [Exposé XIII – Regular elements: algebraic groups and Lie algebras (Grothendieck)](13-elements-reguliers-groupes-algebres-lie.md)
- [Exposé XIV – Regular elements: continuation, applications (Grothendieck, app. Serre)](14-elements-reguliers-suite-applications.md)
- [Exposé XV – Complements on sub-tori. Application to smooth groups (Raynaud)](15-sous-tores-applications-groupes-lisses.md)
- [Exposé XVI – Groups of zero unipotent rank (Raynaud)](16-groupes-rang-unipotent-nul.md)
- [Exposé XVII – Unipotent algebraic groups; extensions (Raynaud)](17-groupes-algebriques-unipotents-extensions.md)
- [Exposé XVIII – Weil's theorem on the construction of a group from a rational law (Artin)](18-theoreme-weil-loi-rationnelle.md)

Errata – Tome III

<!-- label: III.errata-iii -->

Misprints and errors in the new edition of SGA 3, Tome 3.

13 October 2024.

1. SGA 3, Tome 3

1.1. Exposé XIX

- p. 15, line 4: after "take $\$T\$$ split", add: "and use the proof of Th. 2.5".

- p. 23, line -4 of 5.13: $t \neq 0$ should be $b \neq 0$.
- p. 24, at the level of page 33 of the original: add "of r copies" before "of n $G =$ ". And, 6 lines below, replace $G_{m,S}$ by $G_{m,S}^r$.

1.2. Exposé XX

- p. 29, 2 lines below original page 39: x should be X .
- p. 37, 3 lines above B), $G(0) = 1$ should be $E(0) = 1$.
- p. 38, line above C), r should be α .
- p. 38, 2 lines below C), $N(S)$ should be $N'(S)$.
- p. 40, 1st formula in D): $E(x)$ should be $E(x)^{-1}$. (This formula was not written in the original.)
- p. 40, paragraph E): in the 3 first formulas with $\alpha(H)$ on the left, replace on the right $(1 + bx)$ by $(1 + ax)$. The proof is unchanged.
- p. 45, Th. 3.1 (v): the 1st formula is incorrect and Y is undefined. (This error appears in the original.) One should understand that $Y = zX$, with $z \in G_m(S)$; then by (iv) one has $w_\alpha(Y) = w_\alpha(X) \alpha^{\vee}(z^{-1})$, hence $w_\alpha(X)^2 = \alpha^{\vee}(-1)$ gives

$$w_\alpha(X) w_\alpha(Y) = \alpha^{\vee}(-z^{-1}).$$

Finally, X^{-1} and Y^{-1} are defined in Corollary 2.6: one has $XX^{-1} = 1$ and $Y^{-1} = z^{-1} X^{-1}$, hence indeed $z^{-1} = -X Y^{-1}$.

- p. 51, Prop. 3.12: replace $Q(S)$ by $N^{\times}(S)$.

1.3. Exposé XXI

- p. 85, N.D.E. (19): a closing parenthesis is missing after $w_{k-1}(\rho)$.

1.4. Exposé XXII

- p. 122, last line of 4.1.12: $\exp_\alpha(Y)$ should be $\exp_{-\alpha}(Y)$.

1.5. Exposé XXIII

- p. 210, line above 6.2: replace $-X^{-1}_{-\alpha}$ by $-X^{-1}_\alpha$.

1.6. Exposé XXIV

- p. 245, line 8 of the proof of 4.5.1: $\circ\sim$ should be $\circ\grave{u}$.

1.7. Exposé XXVI

- p. 311, diagram of 4.5.3: extra parenthesis before the last 0_f .

<!-- SOURCE: 01-structures-algebriques-cohomologie-groupes.md -->

Exposé I. Algebraic structures. Group cohomology

<!-- label: III.I -->

by M. Demazure

<!-- original page 1 -->

[^I-0-0] This Exposé consists of two parts; the first gathers a certain number of general definitions and sets up notations that will often be used in the sequel, while the second treats group cohomology and culminates in Theorem

5.3.3 (vanishing of the cohomology of diagonalizable groups).

We choose once and for all a Universe.^[^N.D.E-I-1] All the definitions stated and all the constructions carried out will be relative to this Universe. We shall systematically allow ourselves the following abuse of language: in order to define a functor $f : C \rightarrow C'$, we shall content ourselves with defining the object $f(S)$ of C' for every object S of C , each time that there is no ambiguity about the way to define $f(h)$ for an arrow h of C . In practice, we shall say: let $f : C \rightarrow C'$ be the functor defined by $f(S) = \cdots$.

1. Generalities

1.1.

Let C be a category. We shall denote by $\hat{C}$ the category $\operatorname{Hom}(C^{\circ}, (\operatorname{Ens}))$ of contravariant functors from C to the category (Ens) of sets.^[^N.D.E-I-2] There exists a canonical functor $h : C \rightarrow \hat{C}$ which associates to every $X \in \operatorname{Ob}(C)$ the functor hX such that

$$hX(S) = \operatorname{Hom}(S, X).$$

For every functor $F \in \operatorname{Ob}(\hat{C})$, one defines (cf. for example EGA 0_III, 8.1.4) a bijection

$$\operatorname{Hom}(hX, F) \xrightarrow{\sim} F(X).$$

^[^N.D.E-I-3]

<!-- original page 2 -->

In particular, for every pair X, Y of objects of C , the following canonical map is bijective:

$$\operatorname{Hom}_C(X, Y) \cong \operatorname{Hom}_{\hat{C}}(hX, hY);$$

i.e. the functor h is fully faithful. It thus defines an isomorphism of C onto a full subcategory of $\hat{C}$, and an equivalence of C with the full subcategory of $\hat{C}$ formed by the representable functors (i.e. those isomorphic to a functor of the form hX). In the sequel, we shall often identify X and hX . The following numbers aim to show that this identification can be made without danger.

Remark 1.1.1.^[^N.D.E-I-4] We sometimes need the following variant. Let D be a full subcategory of C and let $X, Y \in \operatorname{Ob}(D)$; denote by h'_X and h'_Y the restrictions to D of hX and hY . Then one has*

$$\operatorname{Hom}_C(X, Y) = \operatorname{Hom}_D(X, Y) = \operatorname{Hom}_D(h'_X, h'_Y)$$

and therefore: to give a morphism $X \rightarrow Y$ "is the same thing" as to give, functorially in T , a map $\phi(T) : \operatorname{Hom}(T, X) \rightarrow \operatorname{Hom}(T, Y)$, for every $T \in \operatorname{Ob}(D)$.

<!-- label: III.I.1.1.1 -->

1.2.

^[^N.D.E-I-5] We shall say that F is a *subobject* (or a *subfunctor*) of G if $F(S)$ is a subset of $G(S)$ for each S .

In $\hat{C}$, "arbitrary" inverse limits exist and are computed by:

$$(\lim_{\leftarrow i} F_i)(S) = \lim_{\leftarrow i} F_i(S).$$

^[^N.D.E-I-6] In particular, fiber products are defined by:

```

```text

$$(F \times_G F')(S) = F(S) \times_{\{G(S)\}} F'(S).$$

```

```

[^N.D.E-I-7]

<!-- original page 3 -->

We shall choose as final object of $\hat{C}$ the functor e such that $e(S) = \{\emptyset\}$ [^N.D.E-I-8]. Every $F \in \text{Ob}(\hat{C})$ has a unique morphism into e , and one sets

```

```text

$$F \times F' = F \times_e F'.$$

```

```

The functor h commutes with inverse limits; in particular, for $X \times X'$ to exist ($X, X' \in \text{Ob}(C)$), resp. for C to admit a final object e , it is necessary and sufficient that $hX \times hX'$ be representable, resp. that e be representable, and one has

```

```text

$$hX \times hX' = h_{\{X \times X'\}} \quad \text{and} \quad he = e.$$

```

```

A monomorphism of $\hat{C}$ is nothing other than a morphism $F \rightarrow G$ such that, for every $S \in \text{Ob}(C)$, the corresponding map of sets $F(S) \rightarrow G(S)$ is injective. [^N.D.E-I-9]

*The functor Γ . For every $F \in \text{Ob}(\hat{C})$, one sets

```

$$\Gamma(F) = \text{Hom}(e, F);$$

```

an element of $\Gamma(F)$ is therefore a family $(\gamma_S)_{S \in \text{Ob}(C)}$, $\gamma_S \in F(S)$, such that for every arrow $f : S' \rightarrow S$ of C one has $F(f)(\gamma_{S'}) = \gamma_S$.

One sets $\Gamma(hX) = \Gamma(X)$ for $X \in \text{Ob}(C)$. If C has a final object e , one therefore has an isomorphism $\Gamma(X) \cong \text{Hom}(e, X)$.

1.3.

Let $S \in \text{Ob}(C)$. We denote by C/S the category of objects of C over S , i.e. the category whose objects are the arrows $f : T \rightarrow S$ of C , with $\text{Hom}(f, f')$ being the subset of $\text{Hom}(T, T')$ formed by those u such that $f = f' \circ u$. If C has a final object e , then C/e is isomorphic to C . The category C/S has a final object: the identity arrow $S \rightarrow S$.

If $f : T \rightarrow S$ is an object of C/S , then one can form the category $(C/S)/f$, which by abuse of language one denotes $(C/S)/T$, and one has a canonical isomorphism

```

$$C/T \cong (C/S)/T.$$

```

This construction also applies to the category $\hat{C}$; one defines in particular the category $\hat{C}/hS$. On the other hand, one can form the category $\hat{C}_{/S}$.

If $f : T \rightarrow S$ is an object of C/S , then $\Gamma(f)$ is identified with the set $\Gamma(T/S)$ of sections of T over S , that is, of arrows $S \rightarrow T$ which are right inverses of f . Note that $hf : hT \rightarrow hS$ is then an object of $\hat{C}/hS$, and one has:

<!-- original page 4 -->

```

```text

$$\Gamma(hf) = \Gamma(hT/hS) = \Gamma(T/S) = \Gamma(f).$$

```

```

1.4.

We now propose to define an equivalence of categories $\hat{C}/S$ and $\hat{C}/hS$, that is, to prove that "to give a functor on the category of objects of C over S is 'the same thing' as to give a functor on C endowed with a morphism into hS ".

(i) Construction of $\alpha S : \hat{C}/hS \rightarrow \hat{C}/S$.

Let first $H : F \rightarrow hS$ be an object of $\hat{C}/hS$. We must define a functor $\alpha S(H)$ on C/S . Let first $f : T \rightarrow S$ be an object of C/S ; we define $\alpha S(H)(f)$ as the inverse image of f in $hS(T)$ by the map $H(T) : F(T) \rightarrow hS(T)$. [N.D.E-I-10]

Next, let $u : f \rightarrow f'$ be an arrow of C/S ; then $F(u) : F(T') \rightarrow F(T)$ induces a map from $\alpha S(H)(f)$ into $\alpha S(H)(f')$, which we denote $\alpha S(H)(u)$. One verifies at once that the maps

```
```text
f ↦ αS(H)(f) and u ↦ αS(H)(u)
```
```

do define a functor on C/S , hence an object $\alpha S(H)$ of $\hat{C}/S$.

Finally, let $H : F \rightarrow hS$ and $H' : F' \rightarrow hS$ be two objects of $\hat{C}/hS$ and $U : H \rightarrow H'$ a morphism of $\hat{C}/hS$:

```
```text
 U
 F ----> F'
 | |
 H H'
 | |
 hS hS
```
```

<!-- original page 5 -->

Then for every $f : T \rightarrow S$, the map $U(T) : F(T) \rightarrow F'(T)$ induces a map

```
$$
\alpha S(U)(f) : \alpha S(H)(f) \rightarrow \alpha S(H')(f),
$$
```

which defines a morphism of functors

```
$$
\alpha S(U) : \alpha S(H) \rightarrow \alpha S(H').
$$
```

One verifies easily that the maps

```
```text
H ↦ αS(H) and U ↦ αS(U)
```
```

do define a functor $\alpha S : \hat{C}/hS \rightarrow \hat{C}/S$.

(ii) Proposition 1.4.1. The functor $\alpha S : \hat{C}/hS \rightarrow \hat{C}/S$ is an equivalence of categories.*

<!-- label: III.I.1.4.1 -->

We only indicate the principle of the construction of a quasi-inverse functor $\beta S : \hat{C}/S \rightarrow \hat{C}/hS$. Let G be a functor on C/S ; for every object T of C , one sets

```
```text
βS(G)(T) = sum of the sets G(f) for f ∈ Hom(T, S) = hS(T),
```
```

...

which defines a functor $\beta_S(G)$ on $\mathcal{C}_S$, equipped with an obvious projection onto $\mathcal{H}_S$.

1.5.

The equivalence α_S commutes with the functors Γ_S . In other words, if $H : F \rightarrow \mathcal{H}_S$ is an object of $\hat{\mathcal{C}}/\mathcal{H}_S$ and $\alpha_S(H)$ the corresponding object of $\hat{\mathcal{C}}_S$, one has

$$\Gamma_S(\alpha_S(H)) \simeq \Gamma_S(H) \simeq \Gamma_S(F/\mathcal{H}_S).$$

The equivalence α_S commutes with the functors h_S , i.e. if $f : T \rightarrow S$ is an object of $\mathcal{C}/S$, then $hf : \mathcal{H}_T \rightarrow \mathcal{H}_S$ is an object of $\hat{\mathcal{C}}/\mathcal{H}_S$ whose transform by α_S is nothing other than $h_{C/S}(f)$, where

$$h_{C/S} : \mathcal{C}/S \rightarrow \hat{\mathcal{C}}_S$$

is the canonical functor. [N.D.E-I-11] As a consequence:

<!-- original page 6 -->

Proposition 1.5.1. *Let $H : F \rightarrow \mathcal{H}_S$ be an object of $\hat{\mathcal{C}}/\mathcal{H}_S$. For $\alpha_S(H) : (C/S)^{\circ} \rightarrow (\text{Ens})$ to be representable, it is necessary and sufficient that $F : \hat{\mathcal{C}}^{\circ} \rightarrow (\text{Ens})$ be representable; if $F \simeq h_T$, then $\alpha_S(H)$ is representable by the object $T \rightarrow S$ of $\mathcal{C}/S$.*

<!-- label: III.I.1.5.1 -->

The equivalence α_S is transitive in $\mathcal{C}_S$: if $f : T \rightarrow S$ is an object of $\mathcal{C}/S$, one has a commutative diagram of equivalences

$$\begin{array}{ccccc} \hat{\mathcal{C}}/\mathcal{H}_S & \xrightarrow{\alpha_{S/\mathcal{H}_T}} & (\hat{\mathcal{C}}_S)/\mathcal{H}_T & \xrightarrow{\alpha_f} & \hat{\mathcal{C}}_{C/S}/T \\ \simeq \swarrow & & & & \searrow \simeq \\ & \xrightarrow{\quad} & \hat{\mathcal{C}}/\mathcal{H}_T & \xrightarrow{\alpha_T} & \hat{\mathcal{C}}_T/T \end{array}$$

where $\alpha_{S/\mathcal{H}_T}$ denotes (provisionally) the restriction (cf. 1.6) of the functor α_S to objects above $\mathcal{H}_T$.

1.6. Base change in a functor

For every $S \in \text{Ob}(\mathcal{C})$, one has a canonical functor

$$i_S : \mathcal{C}/S \rightarrow \mathcal{C}$$

defined by $i_S(f) = T$ if f is the arrow $T \rightarrow S$. If $f : T \rightarrow S$ is an object of $\mathcal{C}/S$, one denotes by $i_{T/S} = i_{\{f\}}$ the functor:

$$i_{T/S} : (C/S)/T \rightarrow C/S,$$

and one has the commutative diagram:

$$(C/S)/T \xrightarrow{i_{T/S}} C/S \xrightarrow{i_S} C$$

$$= \frac{\quad}{C/T} \quad \frac{\quad}{iT}$$

that is, identifying $(C/S)/T$ with C/T as we shall do henceforth,

<!-- original page 7 -->

$i_S \circ i_{T/S} = iT.$

In the same way, if one identifies C_S and C/e_S when C_S has a final object e_S , then $i_{S/e} : C/S \rightarrow C/e_S$ is identified with i_S .

For $X \in \text{Ob}(C)$ (resp. $Y \in \text{Ob}(C/S)$), let $p_S(X)$ (resp. $p_{T/S}(Y)$) denote the object of C/S (resp. of C/T), when it exists, defined by $X \times_S S$ (resp. $Y \times_{T/S} T$) equipped with its second projection:

$$\begin{array}{ccc} \begin{array}{c} X \times S \\ | \\ p_S(X) \downarrow \\ S \end{array} & \text{resp.} & \begin{array}{c} Y \times_{T/S} T \\ | \\ p_{T/S}(Y) \downarrow \\ T \end{array} \end{array}$$

The (partially defined) functor p_S (resp. $p_{T/S}$) is called the *base change functor*. It is by definition of the product (resp. of the fiber product) the right adjoint of the functor i_S (resp. $i_{T/S}$). [N.D.E-I-12] One also denotes

$$p_S(X) = XS \quad \text{and} \quad p_{T/S}(Y) = YT.$$

The functor i_S defines a functor (restriction)

$$i_S^* : \hat{C} \rightarrow \hat{C}_S;$$

one denotes $i_S^* F = i_S^*(F) = F \circ i_S$. One has obviously

$$i_{T/S}^* \circ i_S^* = i_T^*,$$

that is, for every functor $F \in \text{Ob}(\hat{C})$,

$$(i_S^* F)_T = FT.$$

The notation requires a justification, which is the following:

Proposition 1.6.1. For the functor $(hX)_S : (C/S)^{\circ} \rightarrow (\text{Ens})$ to be representable, it is necessary and sufficient that the product $X \times_S S$ exist. One then has

$$(hX)_S \simeq h_{X \times_S S}.$$

<!-- label: III.I.1.6.1 -->

This shows that FS has two interpretations: restriction of the functor F to $\mathcal{C}/S$, and functor obtained by base change $e \rightarrow S$. This leads to the following notation:

```

```text
 F FS FT
 | | |
 e ← S ← T
```

```

which renders both of the preceding interpretations. Note that one has

```

```text
Γ(FS) = Hom(hS, F) = F(S),
```

```

in particular

```

$$
\Gamma(XS) \simeq \operatorname{Hom}(S, X).
$$

```

1.7.0.

[^N.D.E-I-13] Let E be an object of $\hat{\mathcal{C}}$. Consider the category $\mathcal{C}_E$ of objects of $\mathcal{C}$ above E : its objects are the pairs (V, ρ) formed by an object V of $\mathcal{C}$ and a $\hat{\mathcal{C}}$ -morphism $\rho : hV \rightarrow E$, i.e. $\rho \in E(V)$; a morphism from (V, ρ) to (V', ρ') is

<!-- original page 8 -->

the datum of a $\mathcal{C}$ -morphism $f : V \rightarrow V'$ such that $\rho' \circ f = \rho$ (i.e. $E(f)(\rho') = \rho$). Denote by L the functor

```

$$
\lim_{\rightarrow} \{(V, \rho) \in \mathcal{C}_E\} \rightarrow hV,
$$

```

i.e. for every $S \in \operatorname{Ob}(\mathcal{C})$, $L(S) = \lim_{\rightarrow} \{(V, \rho) \in \mathcal{C}_E\} \rightarrow hV(S)$ is the set of equivalence classes of triples (V, ρ, v) , where $v : S \rightarrow V$ is a $\mathcal{C}$ -morphism, and where one identifies (V, ρ, v) with $(V', \rho', f \circ v)$ for every $\mathcal{C}$ -morphism $f : V \rightarrow V'$ such that $\rho' \circ f = \rho$.

Then the map $\phi_E(S)$ which to the class of (V, ρ, v) associates the element $\rho \circ v$ of $E(S)$ is well defined, and defines a morphism of functors

```

```text
φ_E : lim_{→} {(V, ρ) ∈ C_E} → E.
```

```

Lemma. ϕ_E is an isomorphism.

Indeed, let $S \in \operatorname{Ob}(\mathcal{C})$. Every $x \in E(S)$ is the image under $\phi_E(S)$ of the triple $(S, x, \operatorname{id}_S)$; this shows that $\phi_E(S)$ is surjective. On the other hand, let $\ell_1 = (V_1, \rho_1, v_1)$ and $\ell_2 = (V_2, \rho_2, v_2)$ be two elements of $L(S)$ having the same image in $E(S)$; set $\gamma = \rho_1 \circ v_1 = \rho_2 \circ v_2$. Then ℓ_1 and ℓ_2 are both equal, in $L(S)$, to the class of the triple $(S, \gamma, \operatorname{id}_S)$. This shows that $\phi_E(S)$ is injective.

Corollary. For every object F of $\hat{\mathcal{C}}$, one has

```

```text
Hom(E, F) = lim_{←} {(V, ρ) ∈ C_E} F(V).
```

```

1.7. Objects Hom, Isom, etc.

Let F and G be two objects of $\hat{\mathcal{C}}$. We shall define another object of $\hat{\mathcal{C}}$ in the following way:

```

```text
Hom(F, G)(S) = Hom_{\hat{C}/S}(FS, GS) \simeq Hom_{\hat{C}/hS}(F \times hS, G \times hS) \simeq Hom_{\hat{C}}(F \times hS, G).
```

```

The object $\operatorname{Hom}(F, G)$ defined above has the following properties:

(i) $\operatorname{Hom}(e, G) \simeq G$. [N.D.E-I-14]

(ii) The formation of Hom commutes with base extension:

<!-- original page 9 -->

```

```text
Hom(FS, GS) \simeq Hom(F, G)_S.
```

```

(iii) $(F, G) \mapsto \operatorname{Hom}(F, G)$ is a bifunctor, contravariant in F and covariant in G .

These three properties are obvious from the definitions.

We shall show that, for every object E of $\hat{C}$, one has

```

```text
Hom(E, Hom(F, G)) \simeq Hom(E \times F, G).
```

```

Let $\phi : E \times F \rightarrow G$; we must associate to it a morphism of E into $\operatorname{Hom}(F, G)$. So let $S' \rightarrow S$ be an arrow of $\hat{C}$. One has maps

```

```text
E(S) \times F(S') \rightarrow E(S') \times F(S') \xrightarrow{\phi(S')} G(S').
```

```

Every element e of $E(S)$ therefore defines, for every $S' \rightarrow S$, a map $F(S') \rightarrow G(S')$ functorial in S' , i.e. an element $\theta_\phi(e)$ of $\operatorname{Hom}(F, G)(S)$. One has thus obtained a map

```

```text
\phi \mapsto \theta_\phi, \quad \operatorname{Hom}(E \times F, G) \rightarrow \operatorname{Hom}(E, \operatorname{Hom}(F, G)),
```

```

which is "functorial in E ".

Proposition 1.7.1. [N.D.E-I-15] Let $E, F, G \in \operatorname{Ob}(\hat{C})$.

(a) The map $\phi \mapsto \theta_\phi$ is a bijection:

```

```text
Hom(E \times F, G) \xrightarrow{\sim} Hom(E, Hom(F, G)).
```

```

(b) Moreover, one has an isomorphism of functors:

```

```text
Hom(E, Hom(F, G)) \simeq Hom(E \times F, G).
```

```

<!-- label: III.I.1.7.1 -->

(a) Consider both members as functors in E . The asserted result is true if $E = hX$; indeed, in that case it is nothing other than the definition of the functor $\operatorname{Hom}(F, G)$. On the other hand, both members as functors in E transform direct limits into inverse limits. Finally, by Lemma 1.7.0, every object E of $\hat{C}$ is isomorphic to the direct limit of the hX , where X runs over the category $\hat{C}_E$. This proves (a).

[N.D.E-I-15-alt] Let us sketch a direct proof of (a). To every

$\theta \in \text{Hom}(E, \text{Hom}(F, G))$, one associates the element ϕ_θ of $\text{Hom}(E \times F, G)$ defined as follows. For every $S \in \text{Ob}(\mathcal{C})$, one has a map

```
```text
θ(S) : E(S) → Hom(F × S, G),
```
```

functorial in S . If $(e, f) \in E(S) \times F(S)$, then f is a morphism $S \rightarrow F$, hence $f \times \text{id}_S$ is a morphism $S \rightarrow F \times S$; on the other hand, $\theta(S)(e)$ is a morphism $F \times S \rightarrow G$, so by composition one obtains a morphism:

```
```text
θ(S)(e) ∘ (f × id_S) : S → G,
```
```

i.e. an element $\phi_\theta(S)(e, f)$ of $G(S)$. One verifies easily that the correspondence $S \mapsto \phi_\theta(S)$ is functorial in S , hence defines a morphism ϕ_θ from $E \times F$ to G . We leave to the reader the verification that the maps $\theta \mapsto \phi_\theta$ and $\phi \mapsto \theta_\phi$ are mutually inverse bijections.

<!-- original page 10 -->

Let us prove (b). If $S \in \text{Ob}(\mathcal{C})$, one has, by 1.7 (ii) and (a) applied to $\mathcal{C}/S$:

```
```text
Hom(E, Hom(F, G))(S) ≃ Hom_S(ES, Hom_S(FS, GS))
 ≃ Hom_S(ES ×_S FS, GS)
 ≃ Hom(E × F × S, G)
 ≃ Hom(E × F, G)(S)
```
```

and these isomorphisms are functorial in S .

Corollary 1.7.2. One has:

```
```text
Hom(E, Hom(F, G)) ≃ Hom(F, Hom(E, G)),
Hom(E, Hom(F, G)) ≃ Hom(F, Hom(E, G)).
```
```

<!-- label: III.I.1.7.2 -->

In particular, taking $E = e$, and taking into account $\text{Hom}(e, G) \simeq G$, one has

```
```text
Γ(Hom(F, G)) ≃ Hom(F, G).
```
```

Note that the composition of Hom 's provides functorial morphisms

```
```text
Hom(F, G) × Hom(G, H) → Hom(F, H).
```
```

If F and G are two objects of $\hat{\mathcal{C}}$, one denotes by $\text{Isom}(F, G)$ the subset of $\text{Hom}(F, G)$ formed by the isomorphisms of F onto G . One then defines a subobject $\text{Isom}(F, G)$ of $\text{Hom}(F, G)$ by:

```
```text
Isom(F, G)(S) = Isom(FS, GS).
```
```

One then has isomorphisms

```
```text
Γ(Isom(F, G)) ≃ Isom(F, G),
```
```

$\text{Isom}(F, G) \simeq \text{Isom}(G, F)$.

In the particular case where $F = G$, one sets

```

```text
End(F) = Hom(F, F), End(F) = Hom(F, F) ≃ Γ(End(F)),
Aut(F) = Isom(F, F), Aut(F) = Isom(F, F) ≃ Γ(Aut(F)).
```

```

The formation of the objects Hom , Isom , Aut , End commutes with base change.

Remark 1.7.3. [N.D.E-I-16] One can construct an object isomorphic to $\text{Isom}(F, G)$ in the following manner: one has a morphism

```

```text
Hom(F, G) × Hom(G, F) → End(F);
```

```

permuting F and G , one deduces a morphism

```

```text
Hom(F, G) × Hom(G, F) → End(F) × End(G).
```

```

<!-- original page 11 -->

On the other hand, the identity morphism of F is an element of $\text{End}(F)$ and therefore defines a morphism $e \rightarrow \text{End}(F)$. Doing the same with G and forming the product, one finds a morphism

```

$$
e \rightarrow \text{End}(F) \times \text{End}(G).
$$

```

It is then immediate that the fiber product of e and of $\text{Hom}(F, G) \times \text{Hom}(G, F)$ over $\text{End}(F) \times \text{End}(G)$ is isomorphic to $\text{Isom}(F, G)$.

<!-- label: III.I.1.7.3 -->

All these definitions apply in particular to the case where $F = hX$, $G = hY$. In the case where $\text{Hom}(hX, hY)$ is representable by an object of $\mathcal{C}$, one denotes this object by $\text{Hom}(X, Y)$. It has the following property: if $Z \times X$ exists, then

```

```text
Hom(Z, Hom(X, Y)) ≃ Hom(Z × X, Y).
```

```

This property characterizes it when the products exist in $\mathcal{C}$.

One defines similarly (when they happen to exist) objects

```

```text
Isom(X, Y), End(X), Aut(X);
```

```

we simply note that, by the construction given above, $\text{Isom}(X, Y)$ exists whenever fiber products exist in $\mathcal{C}$ and $\text{Hom}(X, Y)$, $\text{Hom}(Y, X)$, $\text{End}(X)$ and $\text{End}(Y)$ exist.

All that precedes applies equally to categories of the form $\mathcal{C}/S$. The corresponding objects will be denoted as explicitly as possible by appropriate symbols: for example, if T and T' are two objects of $\mathcal{C}$ above S , one will denote by $\text{Hom}_S(T, T')$ the object $\text{Hom}_{\mathcal{C}/S}(T/S, T'/S)$.

1.8. Constant objects

Let $\mathcal{C}$ be a category in which direct sums and fiber products exist, and in which direct sums commute with base change

(for example, the category of schemes^[^N.D.E-I-17]). For every set E and every object S of $\mathcal{C}$, we set

```
```text
(1.8.1) ES = the direct sum of a family (Si){i∈E}
 of objects of C all isomorphic to S.
```
```

This object is characterized by the formula:

```
```text
(1.8.2) HomC(ES, T) = Hom(E, HomC(S, T)),
```
```

for every $T \in \text{Ob}(\mathcal{C})$, where the second Hom is taken in the category of sets.

The object ES is equipped with a canonical projection onto S , in such a way that $E \mapsto ES$ is in fact a functor from (Ens) to $\mathcal{C}/S$.

[^N.D.E-I-18] If $S' \rightarrow S$ is an arrow of $\mathcal{C}$, one has, since direct sums commute with base change,

```
$$
E_{\{S'\}} = (ES)_{\{S'\}}.
$$
```

In particular, if $\mathcal{C}$ has a final object e , one has

```
$$
ES = (Ee)_{\{S\}}.
$$
```

<!-- original page 12 -->

The functor $E \mapsto ES/S$, from (Ens) to $\mathcal{C}/S$, commutes with finite products. For this, it suffices to see that

```
```text
(×) ES ×S FS = (E × F)S.
```
```

<!-- label: eq:III.I.1.8-cross -->

Now, by the results of 1.7 applied to $\mathcal{C}/S$, one has, for every $T \in \text{Ob}(\mathcal{C}/S)$, natural isomorphisms (all unspecified Hom 's being taken in $\mathcal{C}/S$):

```
```text
Hom((E × F)S, T) ≅ Hom{(Ens)}(E × F, Hom(S, T)) ≅
Hom{(Ens)}(E, Hom{(Ens)}(F, Hom(S, T))) ≅ Hom{(Ens)}(E, Hom(FS, T))
```
```

and

```
```text
Hom(ES ×S FS, T) ≅ Hom(ES, Hom(FS, T)) ≅ Hom{(Ens)}(E, Hom(S, Hom(FS, T))).
```
```

Now $\text{Hom}(S, \text{Hom}(FS, T)) \cong \text{Hom}(FS, T)$, hence $(\times)$.

Suppose that, with $\emptyset$ denoting an initial object of $\mathcal{C}$, the diagram

```
```text
 ∅ → S
 | |
 ↓ ↓
 S → S ∪ S
```
```

$\ast$ is cartesian.

(This is the case for the category of schemes.)^{N.D.E-I-19} Then the functor $E \rightarrow ES$ commutes with finite inverse limits.

Indeed, taking $\times$ into account, it suffices to see that $E \rightarrow ES$ commutes with fiber products. Let $u : E \rightarrow G$ and $v : F \rightarrow G$ be two maps of sets. Since in C direct sums commute with base change, one has

```

```text
(1) $F \times_{GS} E \cong \coprod_{f \in F} S_f \times_{GS} E \cong \coprod_{f \in F, x \in E} S_f \times_{GS} S_x.$
```

```

If $v(f) \neq u(x)$, there exists in C/S a morphism

```

```text
 $S_f \times_{GS} S_x \rightarrow S_f \times_{S_{v(f)}} \cup S_{u(x)} S_x;$
```

```

now by hypothesis $\ast$ the right-hand term is $\emptyset$. Consequently,

```

```text
(2) $S_f \times_{GS} S_x \cong \emptyset \quad \text{if } v(f) \neq u(x).$
```

```

On the other hand, if $v(f) = u(x)$, there exists in C/S a morphism

```

```text
 $S \rightarrow S_f \times_{GS} S_x;$
```

```

since $S \rightarrowtail S$ is the final object of C/S , it follows that

```

```text
(3) $S_f \times_{GS} S_x \cong S \quad \text{if } v(f) = u(x).$
```

```

<!-- original page 13 -->

Combining (1), (2), and (3) one obtains an isomorphism functorial in S

```

```text
 $F \times_{GS} E \cong \coprod_{F \times_G E} S = (F \times_G E)_S.$
```

```

An object of the form ES will be called a *constant object*. Note that one has a morphism functorial in E :

```

 $E \rightarrowtail \Gamma(ES/S)$ 

```

which associates to each $i \in E$ the section of ES over S defined by the isomorphism of S onto S_i . Suppose condition $\ast$ is satisfied for every object S of C ; then the morphism $E \rightarrowtail \Gamma(ES/S)$ is a monomorphism for every $S \neq \emptyset$.

If C is the category of schemes, then $\Gamma(ES/S)$ is identified with the locally constant maps from the topological space S to the set E , the preceding map associating to each element of E the corresponding constant map. Note that, by what was just said, ES may also be defined as representing the functor which to every S over S associates the set of locally constant functions from the topological space S to the set E .^{N.D.E-I-20}

2. Algebraic structures

Given a species of algebraic structure in the category of sets, we propose to extend it to the category C . Let us first treat one example: the case of groups.

2.1. Group structures

We retain the notations of the preceding paragraph.

Definition 2.1.1. Let $G \in \text{Ob}(\hat{C})$. By a $\hat{C}$ -group structure on G , we mean the datum, for every $S \in \text{Ob}(C)$, of a group structure on the set $G(S)$, in such a way that for every arrow $f : S' \rightarrow S$ of C , the map $G(f) : G(S') \rightarrow G(S)$ is a group homomorphism. If G and H are two $\hat{C}$ -groups, by a morphism of $\hat{C}$ -groups from G into H we mean any morphism $u \in \text{Hom}(G, H)$ such that for every $S \in \text{Ob}(C)$, the map of sets $u(S) : G(S) \rightarrow H(S)$ is a group homomorphism.

<!-- label: III.I.2.1.1 -->

One denotes by $\text{Hom}_{\hat{C}\text{-Gr.}}(G, H)$ the set of morphisms of $\hat{C}$ -groups from G into H , and by $\hat{C}\text{-Gr.}$ the category of $\hat{C}$ -groups.

Examples. Let $E \in \text{Ob}(\hat{C})$; the object $\text{Aut}(E)$ is endowed in an obvious manner with a $\hat{C}$ -group structure. The final object e has a unique $\hat{C}$ -group structure which makes it a final object of $\hat{C}\text{-Gr.}$

For every $S \in \text{Ob}(C)$, let $e_G(S)$ be the identity element of $G(S)$. The family of the $e_G(S)$

<!-- original page 14 -->

defines an element $e_G \in \Gamma(G) = \text{Hom}(e, G)$ which is a morphism of $\hat{C}$ -groups $e \rightarrow G$, and which is called the *unit section* of G .

Note that to give a $\hat{C}$ -group structure on G amounts to giving a composition law on G , i.e. a $\hat{C}$ -morphism

```
```text
π_G : G × G → G
```

such that, for every  $S \in \text{Ob}(C)$ ,  $\pi_G(S)$  endows  $G(S)$  with a group structure.

In the same way,  $f : G \rightarrow H$  is a morphism of  $\hat{C}$ -groups if and only if the following diagram is commutative:

```
```text
      π_G
  G × G -----> G
  |               |
  (f,f)           f
  |               |
  ↓               ↓
  H × H -----> H
  π_H
```
```

A subobject  $H$  of  $G$  such that, for every  $S \in \text{Ob}(C)$ ,  $H(S)$  is a subgroup of  $G(S)$ , obviously has a  $\hat{C}$ -group structure induced by that of  $G$ : it is the only one for which the monomorphism  $H \rightarrow G$  is a morphism of  $\hat{C}$ -groups. The  $\hat{C}$ -group  $H$  endowed with this structure is called a *sub- $\hat{C}$ -group* of  $G$ .

If  $G$  and  $H$  are two  $\hat{C}$ -groups, the product  $G \times H$  is endowed with an obvious  $\hat{C}$ -group structure: for every  $S \in \text{Ob}(C)$ , one endows  $G(S) \times H(S)$  with the product group structure of the group structures given on  $G(S)$  and  $H(S)$ . The  $\hat{C}$ -group  $G \times H$  endowed with this structure will be called the *product  $\hat{C}$ -group* of  $G$  and  $H$  (it is indeed the product in the category of  $\hat{C}$ -groups).

If  $G$  is a  $\hat{C}$ -group, then for every  $S \in \text{Ob}(C)$ ,  $G_S$  is a  $\hat{C}_S$ -group. If  $G$  and  $H$  are two  $\hat{C}$ -groups, one defines the object  $\text{Hom}_{\hat{C}\text{-Gr.}}(G, H)$  of  $\hat{C}$  by:

```
```text
Hom_{\hat{C}\text{-Gr.}}(G, H)(S) = Hom_{\hat{C}_S\text{-Gr.}}(G_S, H_S)
```
```

(Note:  $\text{Hom}_{\hat{C}\text{-Gr.}}$  is not in general a  $\hat{C}$ -group, nor a fortiori the  $\text{Hom}$  object in

<!-- original page 15 -->

the category  $\hat{C}\text{-Gr.}$ ).

One defines similarly the objects

```
```text
Isom_{C-Gr.}(G, H),    End_{C-Gr.}(G),    Aut_{C-Gr.}(G).
```

Definition 2.1.2. Let $G \in \text{Ob}(C)$. By a C -group structure on G , we mean a $\hat{C}$ -group structure on $\hat{h}G \in \text{Ob}(\hat{C})$. By a morphism of the C -group G into the C -group H , we mean an element $u \in \text{Hom}(G, H) \simeq \text{Hom}(\hat{h}G, \hat{h}H)$ which defines a morphism of $\hat{C}$ -groups from $\hat{h}G$ into $\hat{h}H$.

<!-- label: III.I.2.1.2 -->

One denotes by $(C\text{-Gr.})$ the category of C -groups. Note that there exists in (Cat) a cartesian square

```
```text
(C-Gr.) -----> (C-hat-Gr.)
 | |
 | |
 h h
 | |
 C -----> C-hat
...```
```

All the preceding definitions and constructions therefore transport at once to  $(C\text{-Gr.})$  whenever the functors they involve (products,  $\text{Hom}$  objects, etc.) are representable. They also apply to the categories  $C/S$ . In that case, we shall write  $\text{Hom}_{S\text{-Gr.}}$  for  $\text{Hom}_{\hat{C}_{/S}\text{-Gr.}}$ , etc.

### 2.2.

More generally, if  $(T)$  is a species of structure on  $n$  base sets defined by finite inverse limits (for example, by commutativities of diagrams constructed with cartesian products: structures of monoid, group, set with operators, module over a ring, Lie algebra over a ring, etc.), the preceding construction permits one to define the notion of "structure of species  $(T)$  on  $n$  objects  $F_1, \dots, F_n$  of  $\hat{C}$ ":

<!-- original page 16 -->

such a structure will be the datum, for each  $S$  of  $C$ , of a structure of species  $(T)$  on the sets  $F_1(S), \dots, F_n(S)$  in such a way that for every arrow  $S' \rightarrow S$  of  $C$ , the family of maps  $(F_i(S')) \rightarrow (F_i(S))$  is a polyhomomorphism for the species of structure  $(T)$ . One defines similarly the morphisms of the species of structure  $(T)$ , whence a category  $\hat{C} \times \hat{C} \times \dots \times \hat{C}^{\wedge (T)}$ . The fully faithful functor  $(h \times h \times \dots \times h)$  then allows one to define by inverse image the category  $(C \times C \times \dots \times C)^{\wedge (T)}$ , and then, as it commutes with inverse limits, to transport to it all the properties, notions, and notations of a functorial kind introduced in  $\hat{C}$ . Suppose now that in  $C$  fiber products exist, and let  $(T)$  be a species of algebraic structure defined by the datum of certain morphisms between cartesian products satisfying axioms consisting of certain commutativities of diagrams constructed using the preceding arrows. A structure of species  $(T)$  on a family of objects of  $C$  will therefore be defined by certain morphisms between cartesian products satisfying certain commutation conditions. It follows that if  $C$  and  $C'$  are two categories possessing products and  $f: C \rightarrow C'$  is a functor commuting with products, then for every family of objects  $(F_i)$  of  $C$  endowed with a structure of species  $(T)$ , the family  $(f(F_i))$  of objects of  $C'$  will thereby also be endowed with a structure of species  $(T)$ . Every  $C$ -group will be transformed into a  $C'$ -group, every pair  $(C\text{-ring}, C\text{-module over this } C\text{-ring})$  into an analogous pair in  $C'$ , etc.

In particular, let  $C$  be a category satisfying the conditions of 1.8; [N.D.E-I-21] the functor  $E \mapsto ES$  defined in *loc. cit.* commutes with finite inverse limits; it therefore transforms group into  $S$ -group (i.e.  $C/S$ -group), ring into  $S$ -ring, etc.

**Remark.** It is good to note that the preceding construction procedure applied to the category  $\hat{C}$  does give back the notions already defined there; in other words, it amounts to the same thing to give on an object of  $\hat{C}$  a structure of species  $(T)$  when one considers this object as a functor on  $C$ , or to give a structure of species  $(T)$  on the representable functor on  $\hat{C}$  defined by this object. [N.D.E-I-22]

<!-- original page 17 -->

We shall still treat two particular cases of the preceding construction, the case of structures with operator groups and the case of modules.

### ### 2.3. Structures with operator groups

**Definition 2.3.1.** \*Let  $E \in \text{Ob}(\hat{C})$  and  $G \in \text{Ob}(\hat{C}\text{-Gr.})$ . A structure of  $E$  object with  $\hat{C}$ -operator group  $G$  (\*or of  $G$ -object\*) on  $E$  is the datum, on  $E(S)$ , for every  $S \in \text{Ob}(C)$ , of a structure of set with operator group  $G(S)$  in such a way that, for every arrow  $S' \rightarrow S$  of  $C$ , the map of sets  $E(S') \rightarrow E(S)$  is compatible with the operator homomorphism  $G(S') \rightarrow G(S)$ .\*

<!-- label: III.I.2.3.1 -->

As usual, it amounts to the same thing to give a morphism

$$\mu : G \times E \rightarrow E$$

which for each  $S$  endows  $E(S)$  with a structure of set with operators  $G(S)$ . But  $\text{Hom}(G \times E, E) \cong \text{Hom}(G, \text{End}(E))$ , so  $\mu$  defines a morphism  $G \rightarrow \text{End}(E)$ , and it is immediate that this maps  $G$  into  $\text{Aut}(E)$  and is a morphism of  $\hat{C}$ -groups. Consequently: to give on  $E$  a structure of object with  $\hat{C}$ -operator group  $G$  is equivalent to giving a morphism of  $\hat{C}$ -groups

$$\rho : G \rightarrow \text{Aut}(E).$$

In particular, every element  $g \in G(S)$  defines an automorphism  $\rho(g)$  of the functor  $E$ , that is, an automorphism of  $E \times hS$  commuting with the projection  $E \times hS \rightarrow hS$ , and in particular an automorphism of the set  $E(S')$  for every  $S' \rightarrow S$ .

**Definition 2.3.2.** \*One denotes by  $E^G$  the subobject of  $E$  defined as follows:

$$E^G(S) = \{x \in E(S) \mid x_{S'} \text{ invariant under } G(S') \text{ for every } S' \rightarrow S\},$$

\*where  $x_{S'}$  denotes the image of  $x$  by  $E(S) \rightarrow E(S')$ .\*

<!-- label: III.I.2.3.2 -->

Then  $E^G$  (\*subobject of invariants of  $G$ \*)

<!-- original page 18 -->

is the largest subobject of  $E$  on which  $G$  operates trivially.

**Definition 2.3.3.** \*Let  $F$  be a subobject of  $E$ . One denotes by  $\text{Norm}_G F$  and  $\text{Centr}_G F$  the sub- $\hat{C}$ -groups of  $G$  defined by\*

[^N.D.E-I-23]

$$\begin{aligned} (\text{Norm}_G F)(S) &= \{g \in G(S) \mid \rho(g) F S = F S\} \\ &= \{g \in G(S) \mid \rho(g) F(S') = F(S'), \text{ for every } S' \rightarrow S\}, \\ (\text{Centr}_G F)(S) &= \{g \in G(S) \mid \rho(g)|F S = \text{identity}\} \\ &= \{g \in G(S) \mid \rho(g)|F(S') = \text{identity}, \text{ for every } S' \rightarrow S\}, \end{aligned}$$

\*where the vertical bar after  $\rho(g)$  denotes restriction.\*

<!-- label: III.I.2.3.3 -->

**Scholium 2.3.3.1.** [^N.D.E-I-24] \*In particular, let  $x \in \Gamma(E)$ , i.e. (cf. 1.2) a collection of elements  $x_S \in E(S)$ ,  $S \in \text{Ob}(C)$ , such that for every arrow  $f : S' \rightarrow S$  one has  $E(f)(x_{S'}) = x_S$  (if  $C$  has a final object  $S_0$  one has  $\Gamma(E) = E(S_0)$ ). Then  $x$  defines a subfunctor of  $E$ , which we shall denote

$\bar{x}$ , and one has  $\text{Norm}_G(\bar{x}) = \text{Centr}_G(\bar{x})$ . We shall denote by  $\text{Stab}_G(x)$  and call it stabilizer of  $x$  this functor; for every  $S \in \text{Ob}(C)$  one therefore has:

```

```text
Stab_G(x)(S) = {g ∈ G(S) | ρ(g) x_S = x_S}.
```

```

Suppose that fiber products exist in  $C$ ; if  $G = hG^*$  (resp.  $E = hE^*$ ), where  $G^*$  is a  $C$ -group (resp.  $E^* \in \text{Ob}(C)$ ), and if  $C$  has a final object  $S_0$ , so that  $x$  is a morphism  $S_0 \rightarrow E^*$ , then  $\text{Stab}_G(x)$  is representable by the fiber product  $G \times_{S_0} E^*$ , where  $G \rightarrow E^*$  is the composite of  $\text{id}_G \times x : G = G \times S_0 \rightarrow G \times E^*$  and of  $\mu : G \times E \rightarrow E^*$ .

<!-- label: III.I.2.3.3.1 -->

**Remark 2.3.3.2.** [N.D.E-I-24] The formation of  $E^*$ ,  $\text{Norm}_G F$  and  $\text{Centr}_G F$  commutes with base change, i.e. for every  $S \in \text{Ob}(C)$  one has

```

```text
(E^*)_S = (E^*)^{{}_S},      (Norm_G F)_S = Norm_{{}_S} F_S,      (Centr_G F)_S = Centr_{{}_S} F_S.
```

```

<!-- label: III.I.2.3.3.2 -->

**Definition 2.3.4.** If  $G^*$  is a  $C$ -group and  $E^*$  an object of  $\hat{C}$  (resp.  $E^*$  an object of  $C$ ) a structure of  $G^*$ -object on  $E^*$  (resp. on  $E^*$ ) is a structure of  $hG^*$ -object on  $E^*$  (resp.  $hE^*$ ).

<!-- label: III.I.2.3.4 -->

In view of this definition, all the notions and notations defined above transport to  $C$  when they involve only representable functors: for example, if  $\text{Norm}_G(hF)$  is representable, then there exists one and only one subobject of  $G^*$  that represents it, and which is then a sub- $C$ -group of  $G^*$ ; one denotes it  $\text{Norm}_G(F)$ , etc.

**Definition 2.3.5.** a) One says that the  $\hat{C}$ -group  $G^*$  operates on the  $\hat{C}$ -group  $H^*$  if  $H^*$  is endowed with a structure of  $G^*$ -object such that, for every  $g \in G(S)$ , the automorphism of  $H(S)$  defined by  $g$  is a group automorphism.

It amounts to the same thing to say that for every  $g \in G(S)$ , the automorphism  $\rho(g)$  of  $H^*$

<!-- original page 19 -->

is an automorphism of  $\hat{C}/S$ -groups, or that the morphism of  $\hat{C}$ -groups  $G \rightarrow \text{Aut}(H)$  maps  $G$  into  $\text{Aut}_\hat{C}\text{-Gr}(H)$ .

b) In the situation above, there exists on the product  $H \times G$  a unique  $\hat{C}$ -group structure such that, for every  $S$ ,  $(H \times G)(S)$  is the semidirect product of the groups  $H(S)$  and  $G(S)$  relative to the given operation of  $G(S)$  on  $H(S)$ . We shall denote this  $\hat{C}$ -group  $H \cdot G$  and call it the semidirect product of  $H$  by  $G$ . One therefore has by definition

```

```text
(H · G)(S) = H(S) · G(S).
```

```

<!-- label: III.I.2.3.5 -->

Let  $G^*$  be a  $\hat{C}$ -group. For every arrow  $S' \rightarrow S$  of  $C$  and every  $g \in G(S)$ , let  $\text{Int}(g)$  be the automorphism of  $G(S')$  defined by  $\text{Int}(g) h = g h g^{-1}$ . This definition extends into that of a morphism of  $\hat{C}$ -groups

```

```text
Int : G → Aut_{{}_\hat{C}\text{-Gr}}(G) ⊂ Aut(G).
```

```

Definition 2.3.3 therefore applies, and one has sub- $\hat{C}$ -groups of  $G^*$

```

```text
Norm_G(E) and Centr_G(E)
```

```

...

for every subobject  $E$  of  $G$ .

**Definition 2.3.6.** One calls\* center of  $G$  and one denotes by  $\text{Centr}(G)$  the sub- $\hat{C}$ -group  $\text{Centr}_{\{G\}}(G)$  of  $G$ . One says that  $G$  is\* commutative\* if  $\text{Centr}(G) = G$ , or, what amounts to the same thing, if  $G(S)$  is commutative for every  $S$ .

One says that the sub- $\hat{C}$ -group  $H$  of  $G$  is\* invariant\* in  $G$  (or\* normal\*) if  $\text{Norm}_{\{G\}}(H) = G$ , or, what amounts to the same thing, if  $H(S)$  is invariant in  $G(S)$  for every  $S$ .<sup>[N.D.E-I-25]</sup>

<!-- label: III.I.2.3.6 -->

**Definition 2.3.6.1.**<sup>[N.D.E-I-26]</sup> Let  $f : G \rightarrow G'$  be a morphism of  $\hat{C}$ -groups. One calls\* kernel of  $f$ , and one denotes by  $\text{Ker } f$ , the sub- $\hat{C}$ -group of  $G$  defined by\*

``text  
 $(\text{Ker } f)(S) = \{x \in G(S) \mid f(S)(x) = 1\} = \text{Ker } f(S)$   
``

\*for every  $S \in \text{Ob}(C)$ ; it is an invariant sub- $\hat{C}$ -group.\*

\*Note that if  $G = hG$  and  $G' = hG'$ , if  $C$  has a final object  $S_0$  and if fiber products exist in  $C$ , then  $\text{Ker}(f)$  is representable by  $S_{\{0\}} \times_{G'} G$ .\*

<!-- label: III.I.2.3.6.1 -->

**Definition 2.3.6.2.**<sup>[N.D.E-I-26]</sup> Let  $E \in \hat{C}$  and  $G$  a  $\hat{C}$ -group operating on  $E$ . One says that the operation of  $G$  on  $E$  is\* faithful\* if the kernel of the morphism  $G \rightarrow \text{operatorname{Aut}}(E)$  is trivial, i.e. if for every  $S \in \text{Ob}(C)$  and  $g \in G(S)$ , the condition  $g_S \cdot x = x$  for every  $S' \rightarrow S$  and  $x \in E(S')$  entails  $g = 1$ .\*

<!-- label: III.I.2.3.6.2 -->

Many definitions and propositions of the elementary theory of groups transpose easily. Let us simply point out the following, which will be useful to us:

**Proposition 2.3.7.** Let  $f : W \rightarrow G$  be a morphism of  $\hat{C}$ -groups. Set  $H(S) = \text{Ker } f(S)$ . Let  $u : G \rightarrow W$  be a morphism of  $\hat{C}$ -groups which is a section of  $f$ \*

<!-- original page 20 -->

\*(and which is then necessarily a monomorphism). Then  $W$  is identified with the semidirect product of  $H$  by  $G$  for the operation of  $G$  on  $H$  defined by  $(g, h) \mapsto \text{Int}(u(g)) \cdot h$  for  $g \in G(S)$ ,  $h \in H(S)$ ,  $S \in \text{Ob}(C)$ .\*

<!-- label: III.I.2.3.7 -->

The set of these definitions and propositions transports as usual to  $C$ . One defines in particular the semidirect product of two  $C$ -groups  $H$  and  $G$  (with  $G$  operating on  $H$ ) when the cartesian product  $H \times G$  exists, and one has the analogue of Proposition 2.3.7 in the following form:

**Proposition 2.3.8.** Let  $H \rightarrowtail W \rightarrowtail G$  be a sequence of morphisms of  $C$ -groups such that for every  $S \in \text{Ob}(C)$ ,  $\text{Int}(H(S), i(S))$  is a kernel of  $f(S) : W(S) \rightarrow G(S)$ . Let  $u : G \rightarrow W$  be a morphism of  $C$ -groups which is a section of  $f$ . Then  $W$  is identified with the semidirect product of  $H$  by  $G$  for the operation of  $G$  on  $H$  such that if  $S \in \text{Ob}(C)$ ,  $g \in G(S)$  and  $h \in H(S)$ , one has  $\text{Int}(u(g)) \cdot i(h) = i(\{g\} \cdot h)$ .\*

<!-- label: III.I.2.3.8 -->

## 3. The category of 0-modules, the category of  $G$ -0-modules

**Definition 3.1.** Let  $0$  and  $F$  be two objects of  $\hat{C}$ . One says that  $F$  is a\*  $\hat{C}$ -module\* over the  $\hat{C}$ -ring  $0$ , or in abbreviated form an\*  $0$ -module\*, if, for every  $S \in \text{Ob}(C)$ , one has endowed  $0(S)$  with a ring structure and  $F(S)$  with a structure of module over this ring in such a way that, for every arrow  $S' \rightarrow S$  of  $C$ ,  $0(S') \rightarrow 0(S)$  is a ring homomorphism and  $F(S') \rightarrow F(S)$  is a homomorphism of abelian groups compatible with this ring homomorphism.\*

<!-- label: III.I.3.1 -->

If  $\mathcal{F}$  is fixed, one defines in the usual way a morphism of the  $\mathcal{F}$ -modules  $F$  and  $F'$ , whence the commutative group  $\operatorname{Hom}_{\mathcal{F}}(F, F')$ , and the category of  $\mathcal{F}$ -modules, denoted  $(\mathcal{F}\text{-Mod})$ .

**Lemma 3.1.1.** <sup>[N.D.E-I-27]</sup>  $(\mathcal{F}\text{-Mod})$  is endowed with a structure of abelian category, defined "argument by argument". Moreover,  $(\mathcal{F}\text{-Mod})$  verifies the axiom (AB 5) (cf. [Gr57, 1.5]), i.e. arbitrary direct sums exist, and if  $M$  is an  $\mathcal{F}$ -module,  $N$  a submodule, and  $(F_i)_{i \in I}$  a directed family of submodules of  $M$ , then\*

text  

$$\bigcup_{i \in I} (F_i \cap N) = (\bigcup_{i \in I} F_i) \cap N.$$

<!-- label: III.I.3.1.1 -->

Indeed, let  $f : F \rightarrow F'$  be a morphism of  $\mathcal{F}$ -modules. One defines the  $\mathcal{F}$ -modules  $\operatorname{Ker} f$  (resp.  $\operatorname{Im} f$  and  $\operatorname{Coker} f$ ) by setting, for every  $S \in \operatorname{Ob}(\mathcal{C})$ ,  $(\operatorname{Ker} f)(S) = \operatorname{Ker} f(S)$  (resp.  $\rightarrow$ ). Then  $\operatorname{Ker} f$  (resp.  $\operatorname{Coker} f$ ) is a kernel (resp. cokernel) of  $f$ , and one has an isomorphism of  $\mathcal{F}$ -modules  $F / \operatorname{Ker} f \xrightarrow{\sim} \operatorname{Im} f$ . This proves that  $(\mathcal{F}\text{-Mod})$  is an abelian category.

Arbitrary direct sums exist and are defined "argument by argument". Finally, if  $M$  is an  $\mathcal{F}$ -module,  $N$  a submodule, and  $(F_i)_{i \in I}$  a directed family of submodules of  $M$ , then the inclusion

text  

$$\bigcup_{i \in I} (F_i \cap N) \subset (\bigcup_{i \in I} F_i) \cap N$$

is an equality: indeed, if  $S \in \operatorname{Ob}(\mathcal{C})$  and  $x \in N(S) \cap \bigcup_{i \in I} F_i(S)$ , there exists  $i \in I$  such that  $x \in N(S) \cap F_i(S)$ .

**Proposition 3.1.2.** <sup>[N.D.E-I-27]</sup> Suppose the category  $\mathcal{C}$  is small, i.e. that  $\operatorname{Ob}(\mathcal{C})$  is a set. Then  $(\mathcal{F}\text{-Mod})$  has a generator, and therefore enough injective objects.\*

<!-- label: III.I.3.1.2 -->

**Proof.** For every object  $S$  of  $\mathcal{C}$ , one defines the  $\mathcal{F}$ -module  $0_S$  as follows. For every object  $S'$ ,  $0_S(S')$  is a direct sum of copies of  $0(S')$  indexed by  $\operatorname{Hom}_{\mathcal{C}}(S', S)$ , i.e.

text  

$$0_S(S') = \bigoplus_{g : S' \rightarrow S} 0(S') \cdot g.$$

For every morphism  $f : S' \rightarrow S'$ , denoting  $f^*$  the ring homomorphism  $0(S') \rightarrow 0(S')$ , the morphism  $0_S(f) : 0_S(S') \rightarrow 0_S(S')$  sends each element  $a \cdot g$  of  $0_S(S')$  (where

<!-- original page 19 -->

$a \in 0(S')$  and  $g : S' \rightarrow S$ ) to the element  $f^*(a) \cdot g$  of  $0_S(S')$ . One verifies easily that this does define a functor in  $\mathcal{F}$ -modules.

Since, by hypothesis,  $\operatorname{Ob}(\mathcal{C})$  is a set, one can consider the direct sum  $G = \bigoplus_{S \in \operatorname{Ob}(\mathcal{C})} 0_S$ .

**Lemma 3.1.2.1.** Let  $F$  be an  $\mathcal{F}$ -module. For every  $S \in \operatorname{Ob}(\mathcal{C})$ , every element  $x$  of  $F(S)$  defines a unique morphism of  $\mathcal{F}$ -modules  $\tilde{x} : 0_S \rightarrow F$  such that  $\tilde{x}(1 \operatorname{id}_S) = x$ .

<!-- label: III.I.3.1.2.1 -->

**Proof.** Let  $\phi$  be a morphism of  $\mathcal{F}$ -modules  $0_S \rightarrow F$  such that  $\phi(1 \operatorname{id}_S) = x$ . Let  $g : S' \rightarrow S$  and  $a \in 0(S')$ . The  $0(S')$ -linearity and the commutativity of the diagram

text  

$$\begin{array}{ccc} 0_S(S) & \xrightarrow{\quad \phi \quad} & F(S) \\ | & & | \end{array}$$

$$\begin{array}{ccc} 0_S(g) & & F(g) \\ \downarrow & \varphi & \downarrow \\ 0_{S'} & \longrightarrow & F(S') \end{array}$$

entail that  $\phi(ag) = a \phi(1g) = a F(g)(\phi(1_{id_S})) = a F(g)(x)$ . So  $\phi$ , if it exists, is determined by the previous equality. Conversely, if one defines  $\phi$  thus, then for every  $f : S' \rightarrow S$  one has

$$\phi \circ 0_S(f)(ag) = \phi(f^*(a) g \circ f) = f^*(a) F(g \circ f)(x) = F(f)(a F(g)(x)) = F(f) \circ \phi(ag)$$

i.e. the diagram

$$\begin{array}{ccc} 0_{S'} & \xrightarrow{\phi} & F(S') \\ \downarrow 0_S(f) & & \downarrow F(f) \\ 0_S(f) & & F(f) \\ \downarrow & \varphi & \downarrow \\ 0_{S''} & \longrightarrow & F(S'') \end{array}$$

is commutative. This proves the lemma.

Now, let  $F$  be an  $0_S$ -module. For every  $S \in \text{Ob}(C)$ , let  $F_{\{0\}}(S)$  be a system of generators of the  $0(S)$ -module  $F(S)$ , and let  $L_S$  be the direct sum indexed by  $F_{\{0\}}(S)$  of copies of  $0_S$ . By the lemma, one obtains a morphism of  $0_S$ -modules  $L_S \rightarrow F$ , such that the morphism  $L_S(S) \rightarrow F(S)$  is surjective, hence an epimorphism in the category of  $0(S)$ -modules.

Set  $I = \bigsqcup_{S \in \text{Ob}(C)} F_{\{0\}}(S)$ . Then one obtains a morphism of  $0_S$ -modules

$$G^{\{\emptyset I\}} \longrightarrow \oplus_{S \in \text{Ob}(C)} L_S \longrightarrow F$$

which is "argument by argument" an epimorphism, hence an epimorphism of  $(0\text{-Mod.})$ . This shows that  $G$  is a generator of  $(0\text{-Mod.})$  (cf. [Gr57, 1.9.1]). Since  $(0\text{-Mod.})$  verifies (AB 5), it then follows from [Gr57, 1.10.1] that  $(0\text{-Mod.})$  has enough injective objects.

**Remark 3.1.3.** If  $0_0$  is the  $\hat{C}$ -ring defined by  $0_{\{0\}}(S) = \mathbb{Z}$  (which should not be confused with the functor associated to the constant object  $\mathbb{Z}$ ), then the category of  $0_0$ -modules is isomorphic to the category of commutative  $\hat{C}$ -groups.\*

<!-- label: III.I.3.1.3 -->

<!-- original page 20 -->

**Definition 3.1.4.** Note that, if  $F$  is an  $0_S$ -module, then for every  $S \in \text{Ob}(C)$ ,  $F_S$  is an  $0_S$ -module. One can therefore define a  $\hat{C}$ -abelian group  $\text{Hom}_{\{0\}}(F, F)$  by\*

$$\text{Hom}_0(F, F')(S) = \text{Hom}_{0_S}(F_S, F'_S).$$

\*One defines similarly the objects\*

$$\text{Isom}_0(F, F'), \quad \text{End}_0(F) \quad \text{and} \quad \text{Aut}_0(F),$$

\*the last being a  $\hat{C}$ -group for the structure induced by the composition of automorphisms.\*

<!-- label: III.I.3.1.4 -->

**Definition 3.2.** Let  $R$  be a  $\mathbb{C}$ -ring,  $M$  an  $R$ -module and  $G$  a  $\mathbb{C}$ -group. By a structure of  $G$ - $M$ -module on  $M$  we mean a structure of  $G$ -object such that for every  $S \in \text{Ob}(\mathcal{C})$  and every  $g \in G(S)$ , the automorphism of  $M(S)$  defined by  $g$  is an automorphism of its  $M(S)$ -module structure.

<!-- label: III.I.3.2 -->

It amounts to the same thing to say that the morphism of  $\mathbb{C}$ -groups

$$\rho : G \rightarrow \text{Aut}(M)$$

defined in 2.3 maps  $G$  into the sub- $\mathbb{C}$ -group  $\text{Aut}_0(M)$  of  $\text{Aut}(M)$ . To give a structure of  $G$ - $M$ -module on the  $M$ -module  $M$  is therefore to give a morphism of  $\mathbb{C}$ -groups

$$\rho : G \rightarrow \text{Aut}_0(M).$$

One defines in a natural way the abelian group  $\text{Hom}_0(M, M')$ , hence the additive category of  $G$ - $M$ -modules denoted  $(G\text{-Mod})$ .

**Remark 3.2.1.** The reader will note that  $(G\text{-Mod})$  may also be defined as the category of  $0[G]$ -modules, where  $0[G]$  is the algebra of the  $\mathbb{C}$ -group  $G$  over the  $\mathbb{C}$ -ring  $R$ , whose definition is clear. [N.D.E-I-28] Consequently, by 3.1.1 and 3.1.2,  $(G\text{-Mod})$  is an abelian category verifying the axiom (AB 5); moreover, if  $R$  is small,  $(G\text{-Mod})$  has enough injective objects.

<!-- label: III.I.3.2.1 -->

<!-- original page 22 -->

All the constructions of this paragraph specialize at once to the case where  $G$  (or  $R$ , or both) are representable by objects of  $\mathcal{C}$ , which are thereby endowed with the corresponding algebraic structures.

We have treated succinctly the case of the principal algebraic structures encountered in the rest of this seminar. For the others (structure of  $R$ -Lie algebra for example), we believe that the reader will have had enough examples in this paragraph to make the general mechanism sketched in 2.2 work himself in each particular case.

We shall now apply what we have just done to the category of schemes, denoted  $(\text{Sch})$ , and more generally to the categories  $(\text{Sch})/S$  (also denoted  $(\text{Sch}/S)$ ).

#### ## 4. Algebraic structures in the category of schemes

We shall allow ourselves, whenever there is no ambiguity, the following abuses of language: one will designate by  $T$  the object  $T \rightarrow S$  of  $(\text{Sch}/S)$ , the datum of  $f$  ("structural morphism of  $T$ ") being understood, and one will identify  $\mathcal{C}$  with a subcategory of  $\mathbb{C}$ . Given the compatibilities stated in the preceding paragraphs, these identifications can be made without danger.

We shall further simplify the terminology along the following model: a  $(\text{Sch})$ -group will also be called a *group scheme*, a  $(\text{Sch})/S$ -group a *group scheme over  $S$* , or  *$S$ -group scheme*, or  *$S$ -group*, or  *$A$ -group* when  $S$  is the spectrum of the ring  $A$ .

##### ### 4.1. Constant schemes

The category of schemes satisfies the conditions required in 1.8. One can therefore define constant objects in it; for every set  $E$ , one has a scheme  $E_{\mathbb{Z}}$ , and for every scheme  $S$ , an  $S$ -scheme  $E_S = (E_{\mathbb{Z}})_S$ . Recall (cf. \*loc. cit.\*) that for every  $S$ -scheme  $T$ ,  $\text{Hom}_S(T, E_S)$  is the set of locally constant maps

<!-- original page 23 -->

from the topological space  $T$  to  $E$ .

The functor  $E \mapsto E_S$  commutes with finite inverse limits. In particular if  $G$  is a group,  $G_S$  is an  $S$ -group scheme; if  $R$  is a ring,  $R_S$  is an  $S$ -ring scheme, etc.

### ### 4.2. Affine S-groups

Let us recall a certain number of things about affine  $S$ -schemes (EGA II, § 1). One says that the  $S$ -scheme  $T$  is *affine over  $S$*  if the inverse image of every affine open subset of  $S$  is affine. The  $S$ -algebra  $\Gamma(T)$ , which one denotes  $A(T)$ , is then quasi-coherent ( $f^*$  denotes the structural morphism of  $T$ ). Conversely, to every quasi-coherent  $S$ -algebra  $A$ , one can associate an  $S$ -scheme affine over  $S$ , denoted  $\operatorname{Spec}(A)$ . These functors  $T \mapsto A(T)$  and  $A \mapsto \operatorname{Spec}(A)$  are quasi-inverse equivalences between the category of  $S$ -schemes affine over  $S$  and the category opposite to that of quasi-coherent  $S$ -algebras.

It follows that to give an algebraic structure on an  $S$ -scheme  $T$  affine over  $S$  is equivalent to giving the corresponding structure on  $A(T)$  in the category opposite to that of quasi-coherent  $S$ -algebras. In particular, if  $G$  is an  $S$ -group affine over  $S$ ,  $A(G)$  is endowed with a structure of augmented  $S$ -bialgebra, that is, one has two morphisms of  $S$ -algebras

<!-- original page 24 -->

```
```text
Δ : A(G) → A(G) ⊗_S A(G)    and    ε : A(G) → S
```
```

corresponding to the morphisms of  $S$ -schemes

```
```text
π : G × G → G    and    e_G : S → G.
```
```

The maps  $\Delta$  and  $\epsilon$  satisfy the following conditions (which express that  $G$  is an  $S$ -monoid): [N.D.E-I-29]

\*\*(HA 1)\*\*  $\Delta$  is co-associative: the following diagram is commutative\*

```
```text
      A(G) ⊗_S A(G)
      /      \
Δ /            \ id ⊗ Δ
A(G)             A(G) ⊗_S A(G) ⊗_S A(G)
Δ \            \ Δ ⊗ id
      A(G) ⊗_S A(G)
```
```

\*\*(HA 2)\*\*  $\Delta$  is compatible with  $\epsilon$ : the two following composites are the identity\*

```
```text
A(G)  --Δ--> A(G) ⊗_S A(G)  --id ⊗ ε--> A(G) ⊗_S S  ~> A(G),
A(G)  --Δ--> A(G) ⊗_S A(G)  --ε ⊗ id--> S ⊗_S A(G)  ~> A(G).
```
```

Let us take this opportunity to note once more that it follows from the definition of an  $S$ -group structure that to give such a structure on an  $S$ -scheme  $G$  affine over  $S$ , it is not necessary to verify anything on  $A(G)$ , but simply to endow each  $G(S')$  for  $S'$  above  $S$  with a group structure functorial in  $S'$ .

<!-- original page 25 -->

This remark applies *mutatis mutandis* to morphisms.

### ### 4.3. The groups $G_a$ and $G_m$ . The ring $0$

#### #### 4.3.1.

Let  $G_a$  be the functor from  $(Sch)^{\circ}$  to  $(Ens)^{\circ}$  defined by

```

$$
G_a(S) = \Gamma(S, \mathcal{O}_S)
$$

```

endowed with the  $\hat{Sch}$ -group structure defined by the additive group structure of the ring  $\Gamma(S, \mathcal{O}_S)$ . It is representable by an affine scheme, which we shall denote  $G_a$ , which is therefore a group scheme

```

$$
G_a = \operatorname{Spec} \mathbb{Z}[T].
$$

```

Indeed,  $G_a(S) = \operatorname{Hom}(S, G_a) = \operatorname{Hom}_{\{Alg.\}}(\mathbb{Z}[T], \Gamma(S, \mathcal{O}_S)) \cong \Gamma(S, \mathcal{O}_S)$ .

For every scheme  $S$ , one therefore has an  $S$ -group affine over  $S$ , denoted  $G_{a,S}$ , which corresponds to the  $\mathcal{O}_S$ -bialgebra  $\mathcal{O}_S[T]$ , with the diagonal map and the augmentation defined by:

```

```text
Δ(T) = T ⊗ 1 + 1 ⊗ T,    ε(T) = 0.
```

```

### 4.3.2.

Let  $G_m$  be the functor from  $(Sch)^{\circ}$  to  $(Ens)^{\circ}$  defined by

```

$$
G_m(S) = \Gamma(S, \mathcal{O}_S)^{\times},
$$

```

where  $\Gamma(S, \mathcal{O}_S)^{\times}$  denotes the multiplicative group of invertible elements of the ring  $\Gamma(S, \mathcal{O}_S)$ , endowed with its natural  $\hat{Sch}$ -group structure. It is representable by an affine scheme denoted  $G_m$

```

```text
G_m = Spec Z[T, T^{-1}] = Spec Z[Z],
```

```

where  $\mathbb{Z}[\mathbb{Z}]$  denotes the algebra of the group  $\mathbb{Z}$  over the ring  $\mathbb{Z}$ . Indeed,

<!-- original page 26 -->

```

```text
G_m(S) = \operatorname{Hom}_{\{Alg.\}}(\mathbb{Z}[T, T^{-1}], \Gamma(S, \mathcal{O}_S)) \cong \Gamma(S, \mathcal{O}_S)^{\times}.
```

```

For every scheme  $S$ , one therefore has an  $S$ -group affine over  $S$  denoted  $G_{m,S}$ , which corresponds to the  $\mathcal{O}_S$ -algebra  $\mathcal{O}_S[\mathbb{Z}]$ , with the diagonal map and augmentation defined by:

```

```text
Δ(x) = x ⊗ x    and    ε(x) = 1,    for x ∈ Z.
```

```

### 4.3.3.

Let  $\mathcal{O}$  be the functor  $G_a$  endowed with its  $\hat{Sch}$ -ring structure. It is represented by the scheme  $\operatorname{Spec} \mathbb{Z}[T]$ , which we shall denote  $\mathcal{O}$  when considering it as endowed with its ring scheme structure.

For every scheme  $S$ ,  $\mathcal{O}_S = S \times_{\operatorname{Spec} \mathbb{Z}} \operatorname{Spec} \mathbb{Z}[T] = \operatorname{Spec}(\mathcal{O}_S[T])$  is therefore an  $S$ -ring scheme, affine over  $S$ . (Note: in EGA II 1.7.13,  $\mathcal{O}_S$  is denoted  $S[T]$ ).

### 4.3.3.1.

[^N.D.E-I-30] For every object  $X$  of  $\hat{Sch}$ ,  $\mathcal{O}(X) = \operatorname{Hom}(X, \mathcal{O})$  is endowed with a ring structure,

functorial in  $X$ . In particular, if  $X'$  is a scheme and one is given morphisms  $x : X' \rightarrow X$  and  $f : X \rightarrow 0$  (i.e.  $f \in O(X)$ ), then  $f(x) = f \circ x$  is an element of  $O(X') = \Gamma(X', O_{X'})$ .

**Definition.** Let  $\pi : M \rightarrow X$  be a morphism of  $\text{Sch}$ , and let  $OX = O \times X$ . One says that  $M$  is an  $OX$ -module if one has given, for every  $X$ -scheme  $X'$ , a structure of  $O(X')$ -module on  $\text{Hom}_X(X', M)$ , functorial in  $X'$ .

This amounts to giving a law of  $X$ -abelian group  $\mu : M \times_X M \rightarrow M$  and an "external law"

```

```text
O \times M = OX \times_X M \rightarrow M, \quad (f, m) \mapsto f \cdot m
```

```

which is an  $X$ -morphism (i.e.  $\pi(f \cdot m) = \pi(m)$ ) and which, for every  $x \in X(S)$ , endows  $M(x) = \{m \in M(S) \mid \pi(m) = x\}$  with a structure of  $O(S)$ -module.

In this case, for every  $Y \in \text{Ob } \hat{\text{Sch}}_X$  (not necessarily representable),  $\text{Hom}_X(Y, M) = \Gamma(M_Y/Y)$  is an  $O(Y)$ -module, functorially in  $Y$ .

### 4.4. Diagonalizable groups

#### 4.4.1.

The construction of  $G_m$  generalizes as follows: let  $M$  be a commutative group and  $M_{\mathbb{Z}}$  the group scheme associated to it by the procedure of 4.1. Consider the functor defined by

```

```text
D(M)(S) = Hom_{groups}(M, G_m(S)) \simeq Hom_{S-Gr.}(MS, G_{m,S}).
```

```

<!-- original page 27 -->

It is a commutative  $\text{Sch}$ -group representable by a group scheme that one will denote  $D(M)$ ; one will therefore have by definition:

```

$$
D(M) \simeq \text{Hom}_{(\text{Sch})\text{-Gr.}}(M_{\mathbb{Z}}, G_m).
$$

```

Set in fact

```

$$
D(M) = \text{Spec } \mathbb{Z}[M],
$$

```

where  $\mathbb{Z}[M]$  is the algebra of the group  $M$  over the ring  $\mathbb{Z}$ ; one has

```

```text
D(M)(S) = Hom_{Alg.}(\mathbb{Z}[M], \Gamma(S, O_S)) \simeq Hom_{groups}(M, \Gamma(S, O_S)^\times)
```

```

by the very definition of the algebra  $\mathbb{Z}[M]$ .

#### 4.4.2.

For every scheme  $S$  one therefore has an  $S$ -group scheme affine over  $S$

```

```text
D_S(M) = D(M)_S = Hom_{(\text{Sch})\text{-Gr.}}(M_{\mathbb{Z}}, G_m)_S = Hom_{S\text{-Gr.}}(MS, G_{m,S}).
```

```

It is associated to the  $O_S$ -bialgebra  $O_S[M]$ , endowed with the diagonal map and augmentation defined by

```

```text
\Delta(x) = x \otimes x \quad \text{and} \quad \varepsilon(x) = 1, \quad \text{for } x \in M.
```

```

...

#### ### 4.4.3.

If  $f : M \rightarrow N$  is a homomorphism of commutative groups, one defines in an obvious manner a morphism of  $S$ -groups

$$D_S(f) : D_S(N) \rightarrow D_S(M),$$

whence a functor

$$D_S : M \rightarrow D_S(M)$$

from the category of abelian groups to the category of  $S$ -groups affine over  $S$ , which one may also define as the composite of the functor  $M \mapsto MS$  and of the functor  $MS \mapsto \operatorname{Hom}_S(MS, G_{m,S})$ . This functor commutes with extensions of the base.

<!-- original page 28 -->

An  $S$ -group isomorphic to a group of the form  $D_S(M)$  is said to be *diagonalizable*. Note that the elements of  $MS$  are interpreted as certain characters of  $D_S(M)$ , that is, certain elements of  $\operatorname{Hom}_S(D_S(M), G_{m,S})$ . (Confer VIII 1).

#### ### 4.4.4.

Let us give some examples of diagonalizable groups. One has first

$$D(\mathbb{Z}) = G_m \quad \text{and} \quad D(\mathbb{Z}^r) = (G_m)^r.$$

One sets

$$\mu_n = D(\mathbb{Z}/n\mathbb{Z}),$$

and calls it the *group of  $n$ -th roots of unity*. Indeed, one has

$$\mu_n(S) = \operatorname{Hom}_{\text{groups}}(\mathbb{Z}/n\mathbb{Z}, \Gamma(S, \mathcal{O}_S^\times)) = \{f \in \Gamma(S, \mathcal{O}_S) \mid f^n = 1\}.$$

The  $S$ -group  $\mu_{n,S}$  corresponds to the  $\mathcal{O}_S$ -algebra  $\mathcal{O}_S[T]/(T^n - 1)$ . Suppose in particular that  $S$  is the spectrum of a field  $k$  of characteristic  $p = n$ . Setting  $T - 1 = s$ , one finds

$$k[T]/(T^p - 1) = k[s]/(s^p),$$

which shows that the underlying topological space of  $\mu_{p,k}$  reduces to a point, the local ring of this point being the artinian  $k$ -algebra  $k[s]/(s^p)$ . (In the same vein, let us note that the  $S$ -schemes  $G_{a,S}$ ,  $G_{m,S}$ ,  $\mathcal{O}_S$  are smooth over  $S$ , that  $D_S(M)$  is

<!-- original page 29 -->

flat over  $S$  and that it is formally smooth (resp. smooth) over  $S$  if and only if no residue characteristic of  $S$  divides the torsion of  $MS$  (resp. and if moreover  $MS$  is of finite type), cf. Exp. VIII, 2.1).

#### ### 4.5. Other examples of groups

The preceding procedure applies to the "classical groups" (linear groups  $GL_n$ , symplectic  $Sp_n$ , orthogonal

$GL_n(S)$ , etc.). One defines for example  $GL_n(S)$  as representing the functor  $GL_n(S)$  such that:

```
```text
GL_n(S) = GL(n, Γ(S, OS)) = Aut_{OS}(OS^n).
```

One can construct it for example as the open subscheme of $\operatorname{Spec} \mathbb{Z}[T_{ij}]$ ($1 \leq i, j \leq n$) defined by the function $f = \det((T_{ij})^{n-i+j})$, that is, $\operatorname{Spec} \mathbb{Z}[T_{ij}, f^{-1}]$.

4.6. Functor-modules in the category of schemes

We propose to associate to every OS -module on the scheme S an OS -module (where OS denotes the functor-ring introduced in 4.3.3). This can be done in two different ways. Precisely:

Definition 4.6.1. *Let S be a scheme. For every OS -module F one denotes by $V(F)$ and $W(F)$ the contravariant functors on $(Sch)/S$ defined by:*

```
```text
V(F)(S') = Hom_{OS}(F ⊗_{OS} O_{S'}, O_{S'}),
W(F)(S') = Γ(S', F ⊗_{OS} O_{S'})
```

(where  $F \otimes_{OS} O_{S'}$  denotes the inverse image on  $S'$  of the  $OS$ -module  $F$ ).

<!-- label: III.I.4.6.1 -->

Then  $V(F)$  and  $W(F)$  are endowed in an obvious manner with a structure of  $OS$ -modules (recall that  $OS(S') = \Gamma(S', O_{S'}) = W(OS)(S')$ ), in such a way that one has in fact defined two functors  $V$  and  $W$  from the category of  $OS$ -modules to the category of  $OS$ -modules, with  $V$  contravariant and  $W$  covariant.

We restrict ourselves in the rest of this paragraph to the case where the  $OS$ -modules in question are quasi-coherent, that is, we consider  $V$  and  $W$  as

<!-- original page 30 -->

functors from the category  $(OS\text{-}Mod.q.c.)$  of quasi-coherent  $OS$ -modules to the category of  $OS$ -modules

```
$$
V : (OS-Mod.q.c.)^{\circ} \rightarrow (OS-Mod.),
W : (OS-Mod.q.c.) \rightarrow (OS-Mod.).
$$
```

**Remark 4.6.1.1.** [N.D.E-I-31] \*The reader will note that, in what follows, all the propositions involving only the functor  $W$  are valid for arbitrary  $OS$ -modules, not necessarily quasi-coherent.\*

<!-- label: III.I.4.6.1.1 -->

**Proposition 4.6.2.** (i) The functors  $V$  and  $W$  commute with base extension: if  $S'$  is above  $S$  and if  $F$  is a quasi-coherent  $OS$ -module, one has\*

```
```text
V(F ⊗ O_{S'}) = V(F)_{S'}    and    W(F ⊗ O_{S'}) = W(F)_{S'}.
```

(ii) The functors V and W are fully faithful: the canonical maps*

```
```text
Hom_{OS}(F, F') → Hom_{OS}(V(F'), V(F))
Hom_{OS}(F, F') → Hom_{OS}(W(F), W(F'))
```

\*are bijective.\*

(iii) The functors  $V$  and  $W$  are additive:\*

```

```text

$$V(F \otimes F') = V(F) \times_S V(F') \quad \text{and} \quad W(F \otimes F') = W(F) \times_S W(F').$$

```

```

<!-- label: III.I.4.6.2 -->

Parts (i) and (iii) are obvious from the definitions. For (ii), one takes for  $S'$  open subschemes of  $S$ . We leave the proof to the reader (for  $V$ , use EGA II, 1.7.14).

Recall (cf. 3.1.4) that if  $F, F'$  are  $\mathcal{O}_S$ -modules,  $\text{Hom}_{\mathcal{O}_S}(F, F')$  denotes the  $\mathcal{O}_S$ -functor (in abelian groups) which to every  $S' \rightarrow S$  associates  $\text{Hom}_{\mathcal{O}_{S'}}(F_{S'}, F'_{S'})$ .

**Proposition 4.6.3.** [N.D.E-I-32] One has canonical morphisms in  $(\mathcal{O}_S\text{-Mod})^*$ :

```

```text
      W(Hom_{\mathcal{O}_S}(F, F'))
      /      \
Hom_{\mathcal{O}_S}(W(F), W(F'))  Hom_{\mathcal{O}_S}(V(F'), V(F))
```

```

<!-- label: III.I.4.6.3 -->

<!-- original page 31 -->

This follows immediately from 4.6.2 (i) and (ii).

**Notation 4.6.3.1.** Let  $F$  be a quasi-coherent  $\mathcal{O}_S$ -module. One knows (EGA II, 1.7.8) that the  $\mathcal{O}_S$ -functor  $V(F)$  is representable by an  $S$ -scheme affine over  $S$  which one denotes  $V(F)$  and calls the *vector fibration* [N.D.E-I-33] defined by  $F$ :

```

$$V(F) = \text{Spec}(S(F)),$$

```

where  $S(F)$  denotes the symmetric algebra of the  $\mathcal{O}_S$ -module  $F$ . [N.D.E-I-34]

<!-- label: III.I.4.6.3.1 -->

**Proposition 4.6.4.** Let  $F$  and  $F'$  be two quasi-coherent  $\mathcal{O}_S$ -modules,  $A$  a quasi-coherent  $\mathcal{O}_S$ -algebra. One has a functorial isomorphism:

```

```text

$$\text{Hom}_S(\text{Spec}(A), \text{Hom}_{\mathcal{O}_S}(W(F'), W(F))) \cong \text{Hom}_{\mathcal{O}_S}(F', F \otimes_{\mathcal{O}_S} A).$$

```

```

<!-- label: III.I.4.6.4 -->

Indeed, denoting  $X = \text{Spec}(A)$ , the first member is canonically isomorphic to  $\text{Hom}_{\mathcal{O}_S}(W(F'), W(F))(X)$ , that is, by definition, to

```

```text

$$\text{Hom}_{\mathcal{O}_X}(W(F')_X, W(F)_X) = \text{Hom}_{\mathcal{O}_X}(W(F' \otimes_{\mathcal{O}_S} \mathcal{O}_X), W(F \otimes_{\mathcal{O}_S} \mathcal{O}_X))$$

```

```

(cf. 4.6.2 (i)), which by 4.6.2 (ii) can also be written

<!-- original page 32 -->

```

```text

$$\text{Hom}_{\mathcal{O}_X}(F' \otimes_{\mathcal{O}_S} \mathcal{O}_X, F \otimes_{\mathcal{O}_S} \mathcal{O}_X) = \text{Hom}_{\mathcal{O}_S}(F', \pi_*(\pi^*(F))),$$

```

```

where one denotes  $\pi : X \rightarrow S$  the structural morphism. But, by EGA II, 1.4.7, one has

$\pi_*(\pi^*(F)) \simeq F \otimes A$ , which completes the proof.

**Corollary 4.6.4.1.** One has a canonical isomorphism

text  
 $W(F \otimes A) \simeq \text{Hom}_S(\text{Spec}(A), W(F)).$

<!-- label: III.I.4.6.4.1 -->

Indeed, [N.D.E-I-35] let  $f : S' \rightarrow S$  be an  $S$ -scheme and  $X' = X \times_S S'$ ; one has a cartesian square

text  

$$\begin{array}{ccc} X' & \xrightarrow{f'} & X \\ | & & | \\ \pi' & & \pi \\ \downarrow & f & \downarrow \\ S' & \xrightarrow{\quad} & S \end{array}$$

and by EGA II, 1.5.2,  $X'$  is affine over  $S'$  and  $\pi'_*(\mathcal{O}_{X'}) = f^*(A)$ . One has therefore

text  
 $\text{Hom}_S(\text{Spec}(A), W(F))(S') = \text{Hom}_{S'}(\text{Spec}(f^*(A)), W(f^*(F)))$

and by 4.6.4 applied to  $f^*(F)$ ,  $f^*(F) = \mathcal{O}_{S'}$  and  $f^*(A)$ , this equals

text  
 $\Gamma(S', f^*(F) \otimes f^*(A)) = \Gamma(S', f^*(F \otimes A)) = W(F \otimes A)(S').$

**Proposition 4.6.5.** If  $F$  and  $F'$  are two  $\mathcal{O}_S$ -modules locally free of finite type, the morphisms of 4.6.3 are isomorphisms.

<!-- label: III.I.4.6.5 -->

Indeed, for every  $S' \rightarrow S$ , one has

text  
 $W(\text{Hom}_{\mathcal{O}_S}(F, F'))(S') = \Gamma(S', \text{Hom}_{\mathcal{O}_S}(F, F') \otimes \mathcal{O}_{S'}) = \text{Hom}_{\mathcal{O}_{S'}}(F \otimes \mathcal{O}_{S'}, F' \otimes \mathcal{O}_{S'}).$

But the second member is indeed isomorphic to  $\text{Hom}_{\mathcal{O}_S}(W(F), W(F'))(S')$  and to  $\text{Hom}_{\mathcal{O}_S}(V(F'), V(F))(S')$ , by 4.6.2 (i) and (ii).

**Corollary 4.6.5.1.** Let  $F$  be an  $\mathcal{O}_S$ -module locally free of finite type. Set  $F^{\vee} = \text{Hom}_{\mathcal{O}_S}(F, \mathcal{O}_S)$ . One has canonical isomorphisms:

<!-- original page 33 -->

text  
 $W(F^{\vee}) \simeq \text{Hom}_{\mathcal{O}_S}(W(F), \mathcal{O}_S) \simeq V(F),$   
 $V(F^{\vee}) \simeq \text{Hom}_{\mathcal{O}_S}(V(F), \mathcal{O}_S) \simeq W(F).$

<!-- label: III.I.4.6.5.1 -->

One has finally the following proposition:

**Proposition 4.6.6.** Let  $f : F \rightarrow F'$  be a morphism of  $\mathcal{O}_S$ -modules locally free of finite rank. For  $W(f) : W(F) \rightarrow W(F')$  to be a monomorphism, it is necessary and sufficient that  $f$  identify  $F$  locally with a direct factor of  $F'$ .

<!-- label: III.I.4.6.6 -->

The direct proposition is essentially contained in EGA 0\_I, 5.5.5.[^N.D.E-I-36] Conversely, if  $\mathcal{F}$  is locally a direct factor of  $\mathcal{F}'$ , then for every  $\pi : S' \rightarrow S$ ,  $\pi^* \mathcal{F}$  is a submodule of  $\pi^* \mathcal{F}'$  (because locally a direct factor), so  $W(\mathcal{F})(S') = \Gamma(S', \pi^* \mathcal{F})$  is a submodule of  $W(\mathcal{F}')(S') = \Gamma(S', \pi^* \mathcal{F}')$ .

### 4.7. The category of  $G$ - $\mathcal{O}_S$ -modules

Let  $G$  be an  $S$ -group and  $\mathcal{F}$  an  $\mathcal{O}_S$ -module;  $W(\mathcal{F})$  is endowed with a structure of  $\mathcal{O}_S$ -module.

**Definition 4.7.1.** By a structure of  $G$ - $\mathcal{O}_S$ -module on  $\mathcal{F}$  we mean a structure of  $hG$ - $\mathcal{O}_S$ -module on  $W(\mathcal{F})$  (cf. 3.2). A morphism of  $G$ - $\mathcal{O}_S$ -modules is by definition a morphism of the associated  $hG$ - $\mathcal{O}_S$ -modules. One thus obtains the category  $(G\text{-}\mathcal{O}_S\text{-Mod.})$ , and one denotes  $(G\text{-}\mathcal{O}_S\text{-Mod.q.c.})$  the full subcategory formed by the  $G$ - $\mathcal{O}_S$ -modules that are quasi-coherent as  $\mathcal{O}_S$ -modules.\*

<!-- label: III.I.4.7.1 -->

To give a structure of  $G$ - $\mathcal{O}_S$ -module on  $\mathcal{F}$  is therefore, by 3.2, to give a morphism of  $\hat{\text{Sch}}_S$ -groups

$\rho : hG \rightarrow \text{Aut}_{\mathcal{O}_S}(W(\mathcal{F})).$

**Remark 4.7.1.0.** [^N.D.E-I-37] Since by 4.6.2 one has an anti-isomorphism of  $S$ -functors in groups\*

text  
(†)  $\text{Aut}_{\mathcal{O}_S}(W(\mathcal{F})) \simeq \text{Aut}_{\mathcal{O}_S}(V(\mathcal{F})),$

one sees that it is equivalent to give a structure of  $hG$ - $\mathcal{O}_S$ -module on  $W(\mathcal{F})$  or on  $V(\mathcal{F})$ .\* Indeed, let  $\rho : hG \rightarrow \text{Aut}_{\mathcal{O}_S}(W(\mathcal{F}))$  be as above. For every  $T \rightarrow S$  and  $g \in G(T)$ , denote by  $\rho(g)$  the image of  $\rho(g)$  by the anti-isomorphism (†); one has therefore  $\rho(gh) = \rho(h) \circ \rho(g)$ , i.e.  $\rho$  defines a structure of  $hG$ - $\mathcal{O}_S$ -module "on the right" on  $V(\mathcal{F})$ . Setting  $\rho^{\vee}(g) = \rho(g^{-1})$ , one obtains indeed a structure of  $hG$ - $\mathcal{O}_S$ -module on  $V(\mathcal{F})$ , the datum of which is equivalent to that of  $\rho$ .

<!-- label: III.I.4.7.1.0 -->

**Remark 4.7.1.1.** One can say that one has constructed the categories one has just defined by the cartesian squares:

text  

$$\begin{array}{ccccc} & & \longrightarrow & (G\text{-}\mathcal{O}_S\text{-Mod.}) & \longrightarrow & (hG\text{-}\mathcal{O}_S\text{-Mod.}) \\ & & & & & \downarrow \text{forget} \\ (G\text{-}\mathcal{O}_S\text{-Mod.q.c.}) & \longrightarrow & & & & \\ & & \xrightarrow{W} & & & \\ & & (\mathcal{O}_S\text{-Mod.}) & \longrightarrow & & (\mathcal{O}_S\text{-Mod.}). \end{array}$$

<!-- label: III.I.4.7.1.1 -->

[^N.D.E-I-38] The categories  $(\mathcal{O}_S\text{-Mod.})$  and  $(\mathcal{O}_S\text{-Mod.})$  are abelian, but one should be careful that in general the functor  $W$  is neither left nor right exact.

<!-- original page 34 -->

**Remark 4.7.1.2.** [^N.D.E-I-39] Let  $\mathcal{F}$  be a  $G$ - $\mathcal{O}_S$ -module. The subsheaf of invariants  $\mathcal{F}^G$  is defined as follows: for every open subset  $U$  of  $S$ ,

text  
 $\mathcal{F}^G(U) = W(\mathcal{F})^G(U) = \{x \in \mathcal{F}(U) \mid g \cdot x_{S'} = x_{S'} \text{ for every } S' \xrightarrow{f} U, g \in G(S')\},$

where  $x_{S'}$  denotes the image of  $x$  in  $\Gamma(S', f^*(\mathcal{F})) = \Gamma(U, f_* f^*(\mathcal{F}))$ .

One should be careful that the natural morphism  $W(\mathcal{F}^G) \rightarrow W(\mathcal{F})^G$  is not in general an isomorphism. For example,

if  $S = \operatorname{Spec}(\mathbb{Z})$  and  $G$  is the constant group  $\mathbb{Z}/2\mathbb{Z} = \{1, \tau\}$  acting on  $F = \mathcal{O}_S$  by  $\tau \cdot 1 = -1$ , one has  $F^G = 0$  but, if  $R$  is an  $F_2$ -algebra,  $W(F)^G(\operatorname{Spec}(R)) = R$ .

<!-- label: III.I.4.7.1.2 -->

### 4.7.2.

We suppose from now until the end of n° 4.7 that  $G$  is affine over  $S$ . [N.D.E-I-40] Then, by virtue of 4.6.4, the datum of a morphism of  $S$ -functors

$\rho : h_G \rightarrow \operatorname{End}_{\mathcal{O}_S}(W(F))$

is equivalent to that of a morphism of  $\mathcal{O}_S$ -modules

$\mu : F \rightarrow F \otimes_{\mathcal{O}_S} A(G).$

To say that  $\rho$  is a morphism of  $\hat{\operatorname{Sch}}_S$ -groups is then equivalent to saying that  $\mu$  satisfies the following axioms:

**(CM 1)** the following diagram is commutative

$$\begin{array}{ccc} F & \xrightarrow{\mu} & F \otimes_{\mathcal{O}_S} A(G) \\ \downarrow \mu & & \downarrow \operatorname{id} \otimes \Delta \\ F \otimes_{\mathcal{O}_S} A(G) & \xrightarrow{\mu \otimes \operatorname{id}} & F \otimes_{\mathcal{O}_S} A(G) \otimes_{\mathcal{O}_S} A(G). \end{array}$$

**(CM 2)** the following composite is the identity

$$F \xrightarrow{\mu} F \otimes A(G) \xrightarrow{\operatorname{id} \otimes \varepsilon} F \otimes \mathcal{O}_S \xrightarrow{\sim} F.$$

These axioms (CM 1) and (CM 2) are those of a (right) comodule structure [N.D.E-I-41] over the bialgebra  $A(G)$ .

Set  $A = A(G)$ . If  $F$  and  $F'$  are  $A$ -comodules, a morphism of comodules  $f : F \rightarrow F'$  is a morphism of  $\mathcal{O}_S$ -modules such that the following diagram is

<!-- original page 30 -->

commutative:

$$\begin{array}{ccc} F & \xrightarrow{f} & F' \\ \downarrow \mu_F & & \downarrow \mu_{F'} \\ F \otimes A & \xrightarrow{f \otimes \operatorname{id}} & F' \otimes A. \end{array}$$

One thus obtains the category  $(A\text{-Comod})$ , and one will denote by  $(A\text{-Comod.q.c.})$  the full subcategory formed by the  $A$ -comodules that are quasi-coherent as  $\mathcal{O}_S$ -modules. One has thus obtained:

**Proposition 4.7.2.** Let  $G$  be an  $S$ -group affine over  $S$ . One has equivalences of categories:

\$\$  
 (G-OS-Mod.) \cong (A(G)-Comod.)  
 (G-OS-Mod.q.c.) \cong (A(G)-Comod.q.c.)  
 \$\$

<!-- label: III.I.4.7.2 -->

[^N.D.E-I-42] \*If moreover  $\mathcal{S} = \operatorname{Spec}(\Lambda)$  is affine and if one denotes  $\Lambda[G] = \Gamma(S, A(G))$ , one has an equivalence of categories\*

\$\$  
 (A(G)-Comod.q.c.) \cong (\Lambda[G]-Comod.).  
 \$\$

[^N.D.E-I-43] Suppose moreover that  $A = A(G)$  is a flat  $\mathcal{O}_S$ -module. Let  $E$  be an  $A$ -comodule and  $F$  a sub- $\mathcal{O}_S$ -module of  $E$ . Since  $A$  is flat over  $\mathcal{O}_S$ , one can identify  $F \otimes A$  (resp.  $F \otimes A \otimes A$ ) with a sub- $\mathcal{O}_S$ -module of  $E \otimes A$  (resp.  $E \otimes A \otimes A$ ). Suppose that  $\mu_E$  maps  $F$  into  $F \otimes A$ ; then its restriction  $\mu_F : F \rightarrow F \otimes A$  endows  $F$  with a structure of  $A$ -comodule; one says that  $F$  is a \*subcomodule\* of  $E$ . By passage to the quotient,  $\mu_E$  defines a morphism of  $\mathcal{O}_S$ -modules  $E/F \rightarrow E/F \otimes A$ , which endows  $E/F$  with a structure of  $A$ -comodule. If  $f : E \rightarrow E'$  is a morphism of  $A$ -comodules,  $\operatorname{Ker} f$  (resp.  $\operatorname{Im} f$ ) is a sub- $A$ -comodule of  $E$  (resp.  $E'$ ), and  $f$  induces an isomorphism of  $A$ -comodules:  $E/\operatorname{Ker} f \xrightarrow{\sim} \operatorname{Im} f$ . Moreover, if  $E$  and  $E'$  are quasi-coherent  $\mathcal{O}_S$ -modules, so are  $\operatorname{Ker} f$  and  $\operatorname{Im} f$ . Consequently,  $(A\text{-Comod})$  and  $(A\text{-Comod.q.c.})$  are abelian categories.

**\*Corollary 4.7.2.1.\*** \*Suppose that  $G$  is affine and flat over  $\mathcal{S}$ . Then the category  $(G\text{-OS-Mod.q.c.})$  (resp.  $(G\text{-OS-Mod.})$ ), equivalent to the category of  $A(G)$ -comodules quasi-coherent over  $\mathcal{O}_S$  (resp.  $A(G)$ -comodules), is abelian.\*

<!-- label: III.I.4.7.2.1 -->

### 4.7.3.

Suppose now that  $G$  is a diagonalizable group, that is, that  $A(G)$  is the algebra of a commutative group  $M$  over the sheaf of rings  $\mathcal{O}_S$ . If  $F$  is an  $\mathcal{O}_S$ -module, one has

```text  
 $F \otimes A(G) = \bigoplus_{m \in M} F \otimes m \mathcal{O}_S$.
 ```

To give a morphism of  $\mathcal{O}_S$ -modules

```text  
 $\mu : F \rightarrow F \otimes A(G)$
 ```

<!-- original page 31 -->

is therefore equivalent to giving  $\mathcal{O}_S$ -endomorphisms  $\mu_m$  of  $F$ , such that for every section  $x$  of  $F$  on an open subset of  $\mathcal{S}$ ,  $\mu_m(x)$  is a section of the direct sum  $\bigcup_{m \in M} F$  (this means that on every sufficiently small open subset, there are only finitely many restrictions of the  $\mu_m(x)$  that are nonzero).

For  $\mu$  defined by

```text  
 $\mu(x) = \sum_{m \in M} \mu_m(x) \otimes m$
 ```

to satisfy (CM 1) (resp. (CM 2)) it is necessary and sufficient that one have

```text  
 $\mu_m \circ \mu_{m'} = \delta_{mm'} \mu_m$, (resp. $\sum_{m \in M} \mu_m = \operatorname{Id}_F$),
 ```

which means that the  $\mu_m$  are pairwise orthogonal projectors with sum the identity. One has thus proved:

**Proposition 4.7.3.** If  $G = D_{\{S\}}(M)$  is a diagonalizable  $S$ -group, the category of quasi-coherent  $G$ - $\mathcal{O}_S$ -modules (resp. of  $G$ - $\mathcal{O}_S$ -modules) is equivalent to the category of quasi-coherent  $\mathcal{O}_S$ -modules (resp. of  $\mathcal{O}_S$ -modules) graded of type  $M$ .

<!-- label: III.I.4.7.3 -->

**Remark.** If  $S$  is endowed with a structure of  $\mathcal{O}_S$ -algebra preserved by the operations of  $G$ , then the gradation of  $S$  is a gradation of algebra. More precisely:

**Corollary 4.7.3.1.** The functor  $A \mapsto \operatorname{Spec} A$  induces an equivalence between the category of quasi-coherent  $\mathcal{O}_S$ -algebras graded of type  $M$  and the category opposite to that of  $S$ -schemes affine over  $S$  with  $S$ -operator group  $G = D_{\{S\}}(M)$ .

<!-- label: III.I.4.7.3.1 -->

**Proposition 4.7.4.** Let  $G$  be a diagonalizable  $S$ -group. If  $0 \rightarrow F_1 \rightarrow F_2 \rightarrow F_3 \rightarrow 0$  is an exact sequence of quasi-coherent  $G$ - $\mathcal{O}_S$ -modules that splits as a sequence of  $\mathcal{O}_S$ -modules, then it also splits as a sequence of  $G$ - $\mathcal{O}_S$ -modules.

<!-- label: III.I.4.7.4 -->

Indeed, if  $G = D_{\{S\}}(M)$ , each  $F_i$  is graded by the  $(F_i)_m$ , and for each  $m \in M$  the sequence

$$0 \rightarrow (F_1)_m \rightarrow (F_2)_m \rightarrow (F_3)_m \rightarrow 0$$

of  $\mathcal{O}_S$ -modules is split. The preceding proposition then entails the result.

## 5. Group cohomology

<!-- original page 37 -->

### 5.1. The standard complex

[^N.D.E-I-44] Let  $\mathcal{C}$  be a category,  $G$  a  $\hat{\mathcal{C}}$ -group,  $\mathcal{O}$  a  $\hat{\mathcal{C}}$ -ring, and  $F$  a  $G$ - $\mathcal{O}$ -module. One sets, for  $n \geq 0$ ,

$$C^n(G, F) = \operatorname{Hom}(G^n, F) \quad \text{and} \quad C^n(G, F) = \operatorname{Hom}(G^n, F),$$

where  $G^0$  is the final object  $e$ . Then  $C^n(G, F)$  (resp.  $C^n(G, F)$ ) is endowed in an obvious manner with a structure of  $\mathcal{O}$ -module (resp. of  $\Gamma(0)$ -module), and one has

$$C^n(G, F) \cong \Gamma(C^n(G, F)) \quad \text{and} \quad C^n(G, F)(S) = C^n(GS, FS).$$

<!-- original page 32 -->

To give an element of  $C^n(G, F)$  is to give for each  $S \in \operatorname{Ob}(\mathcal{C})$  an  $n$ -cochain of  $G(S)$  in  $F(S)$ , functorially in  $S$ . The boundary operator

$$\partial : C^n(G(S), F(S)) \rightarrow C^{n+1}(G(S), F(S)),$$

which, recall, is given by the formula

$$\begin{aligned} \partial(g_1, \dots, g_{n+1}) &= g_1 f(g_2, \dots, g_{n+1}) \\ &\quad + \sum_{i=1}^n (-1)^i f(g_1, \dots, g_i g_{i+1}, \dots, g_{n+1}) \\ &\quad + (-1)^{n+1} f(g_1, \dots, g_n), \end{aligned}$$

is functorial in  $S$  and therefore defines a homomorphism:

```
```text
∂ : C^n(G, F) → C^{n+1}(G, F)
```
```

<!-- original page 38 -->

such that  $\partial \circ \partial = 0$ . One has thus defined a complex of abelian groups (and even of  $\Gamma(0)$ -modules) denoted  $C^*(G, F)$ . One defines in the same way the complex of  $S$ -modules  $C^*(G, F)_S$ , and one has:

```
```text
C^*(G, F) = \Gamma(C^*(G, F)).
```
```

One denotes by  $H^n(G, F)$  (resp.  $H^n(G, F)_S$ ) the groups (resp. the  $\hat{C}$ -groups) of cohomology of the complex  $C^*(G, F)$  (resp.  $C^*(G, F)_S$ ).

One has in particular

```
```text
H^0(G, F) = F^G    and    H^0(G, F)_S = \Gamma(F^G).
```
```

**Remark 5.1.1.** [N.D.E-I-45] The "set-theoretic" description of  $\partial$  given above is convenient for verifying that  $\partial \circ \partial = 0$ . One can also define  $\partial$  in terms of the multiplication  $m : G \times G \rightarrow G$  and the action  $\mu : G \times F \rightarrow F$  as follows: for every  $f \in C^n(G, F)$ ,

```
```text
∂f = μ ∘ (id_G × f) + \sum_{i=1}^n (-1)^i f ∘ (id_{G^{i-1}} × m × id_{G^{n-i}}) + (-1)^{n+1} f ∘ pr_{[1,n]},
```
```

where  $pr_{[1,n]}$  denotes the projection of  $G^{n+1} = G^n \times G$  onto  $G^n$ . Similarly, for every  $S \in \text{Ob}(C)$  and  $f \in C^n(G, F)(S) = C^n(GS, FS)_S$ , one has\*

```
```text
∂f = μ_S ∘ (id_{GS} × f) + \sum_{i=1}^n (-1)^i f ∘ (id_{GS^{i-1}} × m_S × id_{GS^{n-i}}) + (-1)^{n+1} f ∘ pr_{[1,n]_S},
```
```

where  $m_S$  and  $\mu_S$  are deduced from  $m$  and  $\mu$  by base change.\*

<!-- label: III.I.5.1.1 -->

### 5.2.

[N.D.E-I-46] Recall (cf. § 3) that  $(G\text{-}0\text{-}\text{Mod.})$  is endowed with a structure of abelian category, defined "argument by argument"; thus,

```
$$
0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0
$$
```

is an exact sequence of  $G$ - $S$ -modules if and only if the sequence of abelian groups

```
$$
0 \rightarrow F'(S) \rightarrow F(S) \rightarrow F''(S) \rightarrow 0
$$
```

is exact, for every  $S \in \text{Ob}(C)$ .

<!-- original page 33 -->

[N.D.E-I-47] Suppose  $C$  small; then, by 3.2.1,  $(G\text{-}0\text{-}\text{Mod.})$  has enough injective objects, so that the derived functors of the left exact functors  $H^0$  and  $H^0$  are defined. We now propose to show that the functors  $H^n$  (resp.

$H^n$  are indeed the derived functors of  $H^0$  (resp.  $H^0$ ).

**Definition 5.2.0.** [N.D.E-I-48] For every  $A$ -module  $P$ , one denotes by  $E(P)$  the object  $\text{Hom}(G, P)$  of  $\hat{C}$  endowed with the structure of  $A$ -module defined as follows: for every  $S \in \text{Ob}(C)$  one has  $\text{Hom}(G, P)(S) = \text{Hom}_S(G_S, P_S)$ , and one makes  $g \in G(S)$  and  $\phi \in \text{Hom}_S(G_S, P_S)$  operate on  $\phi \in \text{Hom}_S(G_S, P_S)$  by the formulas

$$(g \cdot \phi)(h) = \phi(hg) \quad \text{and} \quad (a \cdot \phi)(h) = a \phi(h),$$

for every  $h \in G(S')$ ,  $S' \rightarrow S$ . Moreover, for every  $\phi \in \text{Hom}_S(G_S, P_S)$  one sets

$$\epsilon(\phi) = \phi(1) \in P(S)$$

(where  $1$  denotes the unit element of  $G(S)$ ).

$\text{III.I.5.2.0} \rightarrow$

This defines a functor  $E : (0\text{-Mod.}) \rightarrow (G\text{-}0\text{-Mod.})$  and a natural transformation  $\epsilon : E \rightarrow \text{Id}$ , where  $\text{Id}$  denotes the identity functor of  $(0\text{-Mod.})$ .

**Remark 5.2.0.1.** [N.D.E-I-48] In what follows, let us denote by  $G_1$  and  $G_2$  two copies of  $G$ . Then the morphism

$$G_1 \times E(P) \rightarrow E(P), \quad (g_1, \phi) \mapsto (g_2 \mapsto \phi(g_2 g_1))$$

corresponds via the isomorphisms

$$\begin{aligned} \text{Hom}(G_1 \times E(P), E(P)) &\simeq \text{Hom}(E(P), \text{Hom}(G_1, \text{Hom}(G_2, P))) \\ &\simeq \text{Hom}(E(P), \text{Hom}(G_2 \times G_1, P)) \end{aligned}$$

to the morphism  $\phi \mapsto ((g_2, g_1) \mapsto \phi(g_2 g_1))$ , i.e. to the morphism

$$\text{Hom}(G, P) \rightarrow \text{Hom}(G_2 \times G_1, P)$$

induced by the multiplication  $\mu_G : G \times G \rightarrow G$ ,  $(g_2, g_1) \mapsto g_2 g_1$ .

$\text{III.I.5.2.0.1} \rightarrow$

**Lemma 5.2.0.2.** [N.D.E-I-48] (i) The functor  $E$  is right adjoint to the forgetful functor  $(G\text{-}0\text{-Mod.}) \rightarrow (0\text{-Mod.})$ ; more precisely,  $\epsilon : E \rightarrow \text{Id}$  induces for every  $M \in (G\text{-}0\text{-Mod.})$  and  $P \in \text{Ob}(0\text{-Mod.})$  a bijection

$$\text{Hom}_{(G\text{-}0\text{-Mod.})}(M, E(P)) \cong \text{Hom}_{(0\text{-Mod.})}(M, P)$$

functorial in  $M$  and  $P$ .

(ii) Consequently, if  $I$  is an injective object of  $(0\text{-Mod.})$  then  $E(I)$  is an injective object of  $(G\text{-}0\text{-Mod.})$ .

$\text{III.I.5.2.0.2} \rightarrow$

$\text{original page 34} \rightarrow$

**Proof.** To every  $A$ -morphism  $f : M \rightarrow P$ , one associates the element  $\phi_f$  of  $\text{Hom}_0(M, E(P))$

defined as follows. For every  $S \in \text{Ob}(\mathcal{C})$  and  $m \in M(S)$ ,  $\phi_f(m)$  is the element of  $\text{Hom}_{\mathcal{S}}(GS, PS)$  defined by: for every  $g \in G(S')$ ,  $S' \rightarrow S$ ,

```

```text

$$\phi_f(m)(g) = f(g \cdot m) \in P(S').$$

```

Then, for every $h \in G(S)$, one has $\phi_f(h \cdot m) = h \cdot \phi_f(m)$, i.e. ϕ_f is an element of

```

$$\text{Hom}_{G\text{-}\mathcal{O}\text{-Mod.}}(M, E(P)).$$

```

If $\phi \in \text{Hom}_{G\text{-}\mathcal{O}\text{-Mod.}}(M, E(P))$ and if one denotes, for every $m \in M(S)$, $f(m) = \phi(m)(1)$, then

```

```text

$$\phi_f(m)(g) = f(g \cdot m) = \phi(g \cdot m)(1) = (g \cdot \phi(m))(1) = \phi(m)(g),$$

```

i.e.  $\phi_f = \phi$ . Conversely, it is clear that  $\phi_f(m)(1) = f(m)$ . This proves (i), and (ii) follows at once.

**Definition 5.2.0.3.** \*Let  $M$  be a  $G$ - $\mathcal{O}$ -module; the identity map of  $M$  (considered as an  $\mathcal{O}$ -module) corresponds by adjunction to the morphism of  $G$ - $\mathcal{O}$ -modules\*

```

$$\mu_M : M \rightarrow E(M)$$

```

\*such that for every  $S \in \text{Ob}(\mathcal{C})$  and  $m \in M(S)$ ,  $\mu_M(m)$  is the morphism  $GS \rightarrow MS$  defined by: for every  $S' \rightarrow S$  and  $g \in G(S')$ ,  $\mu_M(m)(g) = g \cdot m_{S'} \in M(S')$ .\*

<!-- label: III.I.5.2.0.3 -->

Note that  $\mu_M$  is a monomorphism. Indeed,  $\epsilon_M : E(M) \rightarrow M$  is a morphism of  $\mathcal{O}$ -modules such that  $\epsilon_M \circ \mu_M = \text{id}_M$ ; consequently  $M$  is a direct factor, as an  $\mathcal{O}$ -module, of  $E(M)$ .

<!-- original page 39 -->

**Proposition 5.2.1.** \*Suppose that  $\mathcal{C}$  is small, that finite products exist in it, and that  $G$  is representable. Then, the functors  $H^n(G, -)$  (resp.  $H^n(G, -)$ ) are the derived functors of the left exact functor  $H^0(G, -)$  (resp.  $H^0(G, -)$ ) on the category of  $G$ - $\mathcal{O}$ -modules.\*

<!-- label: III.I.5.2.1 -->

By virtue of the well-known general results, [N.D.E-I-49] it suffices to verify that the  $H^n(G, -)$  (resp.  $H^n(G, -)$ ) form an effaceable cohomological functor in degrees  $> 0$ .

Let

```

$$0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0$$

```

be an exact sequence of  $G$ - $\mathcal{O}$ -modules, and let  $S \in \text{Ob}(\mathcal{C})$ . By hypothesis,  $G$  is representable by an object  $G \in \text{Ob}(\mathcal{C})$ , and finite products exist in  $\mathcal{C}$ ; in particular  $\mathcal{C}$  has a final element  $e$ . Hence each  $G^n \times S$  is representable by  $G^n \times S$  (with  $G^0 = e$ ), and the sequence

```

```text

$$0 \rightarrow F'(G^n \times S) \rightarrow F(G^n \times S) \rightarrow F''(G^n \times S) \rightarrow 0$$

```

is exact. This shows that the sequence of $\mathcal{O}$ -modules

```

```text

```

$$0 \rightarrow C^n(hG, F') \rightarrow C^n(hG, F) \rightarrow C^n(hG, F'') \rightarrow 0$$

is exact. It follows that  $C^*(G, -)$ , considered as a functor on  $(G\text{-}0\text{-Mod})$  with values in the category of complexes of  $(0\text{-Mod})$ , is exact. This shows that the

<!-- original page 35 -->

$H^n(G, -)$  indeed form a cohomological functor. Since the functor  $\Gamma$  is exact, the same is true for the  $H^n(G, -)$ . It will now suffice to prove:

**Lemma 5.2.2.** *For every  $P \in \text{Ob}(0\text{-Mod})$ , one has:*

$$H^n(G, \text{Hom}(G, P)) = 0 \quad \text{and} \quad H^n(G, \text{Hom}(G, P)) = 0, \text{ for } n > 0.$$

<!-- label: III.I.5.2.2 -->

It suffices to prove that  $C^*(G, \text{Hom}(G, P))$  and  $C^*(G, \text{Hom}(G, P))$  are homotopically trivial in degrees  $> 0$ . It suffices even to do this for the second, the corresponding result for the first being deduced from it by base change. [N.D.E-I-50] Now, one defines for every  $n \geq 0$  a morphism

$$\sigma : C^{n+1}(G, \text{Hom}(G, P)) \rightarrow C^n(G, \text{Hom}(G, P))$$

as follows. Let  $f \in C^{n+1}(G, \text{Hom}(G, P))$ ; for every  $S \in \text{Ob}(C)$  and  $g_1, \dots, g_n \in G(S)$ ,  $\sigma(f)(g_1, \dots, g_n)$  is the element of  $\text{Hom}_S(G, P)$  defined by: for every  $S' \rightarrow S$  and  $x \in G(S')$ ,

$$\sigma(f)(g_1, \dots, g_n)(x) = f(x, g_1, \dots, g_n)(e) \in P(S')$$

(where  $e$  denotes the unit element of  $G(S')$ ). Then,  $\sigma$  is a homotopy operator in degrees  $> 0$ . Indeed, for every  $g_1, \dots, g_{n+1} \in G(S)$  and  $x \in G(S')$  one has, on the one hand:

$$\begin{aligned} \partial \sigma(f)(g_1, \dots, g_{n+1})(x) &= f(x, g_1, g_2, \dots, g_{n+1})(e) \\ &\quad + \sum_{i=1}^n (-1)^i f(x, g_1, \dots, g_i, g_{i+1}, \dots, g_{n+1})(e) \\ &\quad + (-1)^{n+1} f(x, g_1, \dots, g_n)(e), \end{aligned}$$

and on the other hand:

$$\begin{aligned} \sigma(\partial f)(g_1, \dots, g_{n+1})(x) &= (x f(g_1, g_2, \dots, g_{n+1}))(e) - f(x, g_1, g_2, \dots, g_{n+1})(e) \\ &\quad + \sum_{i=1}^n (-1)^{i+1} f(x, g_1, \dots, g_i, g_{i+1}, \dots, g_{n+1})(e) \\ &\quad + (-1)^{n+2} f(x, g_1, \dots, g_n)(e), \end{aligned}$$

whence

$$(\partial \sigma(f) + \sigma(\partial f))(g_1, \dots, g_{n+1})(x) = f(g_1, \dots, g_{n+1})(x),$$

i.e.  $\partial \sigma + \sigma \partial$  is the identity map of  $C^{n+1}(G, \text{Hom}(G, P))$ , for every  $n \geq 0$ .

**Remark 5.2.3.** [N.D.E-I-51] The hypothesis " $C$  small" is used only to ensure the existence of the derived functors  $R^n H^0$  and  $R^n H^1$ . In any case, the foregoing shows that the functors  $H^n(G, -)$  (resp.  $H^n(G, -)$ ) form a cohomological functor, effaceable in degrees  $> 0$ , hence they are the (right) satellite functors of the left exact functor  $H^0(G, -)$  (resp.  $H^0(G, -)$ ), in the sense of [Gr57, 2.2]; if  $(G\text{-}0\text{-Mod})$  has enough injective

objects (which is the case if  $S$  is small), they coincide with the derived functors (\*loc. cit.\* 2.3).\*

<!-- label: III.I.5.2.3 -->

<!-- original page 36 -->

### 5.3. Cohomology of $G$ - $\mathcal{O}_S$ -modules

Let  $S$  be a scheme,  $G$  an  $S$ -group, and  $F$  a quasi-coherent  $G$ - $\mathcal{O}_S$ -module. One defines the cohomology groups of  $G$  with values in  $F$  by

```
```text
H^n(G, F) = H^n(hG, W(F)).
```
```

(for the notations, cf. 4.6).

<!-- original page 40 -->

Suppose  $G$  is affine over  $S$ . Then, in view of Proposition 4.6.4, this cohomology is computed as follows:  $H^n(G, F)$  is the  $n$ -th homology group of the complex  $C^*(G, F)$  whose  $n$ -th term is:

```
```text
C^n(G, F) = \Gamma(S, F \otimes A(G) \otimes \dots \otimes A(G))
               \underbrace{\hspace{1cm}}_{n \text{ times}}
```
```

If  $f_i$  (resp.  $a_i$ ) is a section of  $F$  (resp. of  $A(G)$ ) on an open subset of  $S$ , one has

```
```text
\partial(f \otimes a_1 \otimes \dots \otimes a_n) = \mu_F(f) \otimes a_1 \otimes a_2 \otimes \dots \otimes a_n
      + \sum_{i=1}^n (-1)^i f \otimes a_1 \otimes \dots \otimes \Delta a_i \otimes \dots \otimes a_n
      + (-1)^{n+1} f \otimes a_1 \otimes a_2 \otimes \dots \otimes a_n \otimes 1,
```
```

where  $\Delta : A(G) \rightarrow A(G) \otimes A(G)$  and  $\mu_F : F \rightarrow F \otimes A(G)$  describe the coalgebra structure of  $A(G)$  and the comodule structure of  $F$ . Note in passing that the cohomology of  $G$  with values in  $F$  therefore depends only on the comodule structure of  $F$ , and in particular only on the  $S$ -monoid structure of  $G$ .

One has in particular

```
```text
H^0(G, F) = \Gamma(S, F^G),
```
```

where  $F^G$ , the \*sheaf of invariants of  $F$ , is defined as the sheaf whose sections on the open subset  $U$  of  $S$  are the sections of  $F$  on  $U$  whose inverse image in any  $S'$  over  $U$  is invariant under  $g(S')$  (cf. 4.7.1.2).

<!-- original page 41 -->

**Theorem 5.3.1.** \*Let  $S$  be an affine scheme,  $G$  an  $S$ -group affine and flat over  $S$ . The functors  $H^n(G, -)$  are the derived functors of  $H^0(G, -)$  on the category of quasi-coherent  $G$ - $\mathcal{O}_S$ -modules.\*

<!-- label: III.I.5.3.1 -->

*Proof.* [N.D.E-I-52] Since  $G$  is affine and flat over  $S$ , by 4.7.2.1, the category  $(G\text{-}\mathcal{O}_S\text{-Mod.q.c.})$  is equivalent to the category  $(A(G)\text{-Comod.q.c.})$  of  $A(G)$ -comodules quasi-coherent over  $\mathcal{O}_S$ , and is therefore abelian. On the other hand,  $A(G)$  being a flat  $\mathcal{O}_S$ -module, each functor  $F \mapsto F \otimes_{\mathcal{O}_S} A(G)^{\otimes n}$  is exact; since moreover  $S$  is affine, one obtains that  $C^*(G, -)$  is an exact functor on  $(G\text{-}\mathcal{O}_S\text{-Mod.q.c.})$ .

Denote by  $\Delta$  (resp.  $\eta$ ) the comultiplication (resp. the augmentation) of  $A(G)$ . For every quasi-coherent  $\mathcal{O}_S$ -module  $P$ , one denotes  $\text{Ind}(P) = P \otimes_{\mathcal{O}_S} A(G)$  endowed with the structure of  $A(G)$ -comodule defined by

```
```text
id_P \otimes \Delta : P \otimes_{\mathcal{O}_S} A(G) \rightarrow P \otimes_{\mathcal{O}_S} A(G) \otimes_{\mathcal{O}_S} A(G);
```
```

...

<!-- original page 37 -->

this defines a functor  $\text{Ind} : (\mathcal{O}\mathcal{S}\text{-Mod.q.c.}) \rightarrow (\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$ .

It follows from 4.6.4.1, 5.2.0, and 5.2.0.1 that one has an isomorphism of  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -modules:

```text  
(*) $W(\text{Ind}(P)) \simeq E(W(P)) = \text{Hom}(G, W(P))$.
```

<!-- label: eq:III.I.5.3.1-star -->

Via this identification, the morphism  $\epsilon : E(W(P)) \rightarrow W(P)$  corresponds to the morphism of  $\mathcal{O}\mathcal{S}'$ -modules  $\text{id}_P \otimes \eta : \text{Ind}(P) \rightarrow P$ .

One has already used that the functor  $W : (\mathcal{O}\mathcal{S}\text{-Mod.}) \rightarrow (\mathcal{O}\mathcal{S}\text{-Mod.})$  is fully faithful; the same is true, by Definition 4.7.1, of its restriction to  $(\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.})'$ , i.e. if  $M, M'$  are  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -modules, one has a functorial isomorphism

```text  
 $\text{Hom}_{\{\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.}\}}(M, M') \simeq \text{Hom}_{\{\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.}\}}(W(M), W(M'))$.
```

Consequently, one deduces from Lemma 5.2.0.2 the following:

**Corollary 5.3.1.1.** (i) The functor  $\text{Ind}$  is right adjoint to the forgetful functor  $(\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.q.c.}) \rightarrow (\mathcal{O}\mathcal{S}\text{-Mod.q.c.})$ . More precisely, the map  $\text{id}_P \otimes \eta : \text{Ind}(P) \rightarrow P$  induces for every object  $M$  of  $(\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$  a bijection

```text  
 $\text{Hom}_{\{\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.}\}}(M, \text{Ind}(P)) \cong \text{Hom}_{\{\mathcal{O}\mathcal{S}\}}(M, P)$.
```

(ii) Consequently, if  $I$  is an injective object of  $(\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$  then  $\text{Ind}(I)$  is an injective object of  $(\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$ .

<!-- label: III.I.5.3.1.1 -->

Let  $F$  be a  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -module and  $\mu_F : F \rightarrow \text{Ind}(F)$  the map defining the structure of  $A(G)$ -comodule. It follows from 5.2.0.3 (or from axioms (CM 1) and (CM 2) of 4.7.2) that  $\mu_F$  is a morphism of  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -modules, and that  $(\text{id}_F \otimes \eta) \circ \mu_F = \text{id}_F$ , hence that  $F$  is a direct factor of  $\text{Ind}(F)$  as  $\mathcal{O}\mathcal{S}'$ -module; in particular,  $\mu_F$  is a monomorphism. Since, by (ast) and 5.2.2,

```text  
 $H^n(G, W(\text{Ind}(F))) \simeq H^n(G, \text{Hom}_S(G, W(F))) = 0 \quad \text{for } n > 0,$
```

one therefore obtains that  $H^n(G, -)$  is effaceable for  $n > 0$ .

Finally,  $S$  being affine,  $(\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$  has enough injective objects. So let  $F \hookrightarrow I$  be a monomorphism of  $\mathcal{O}\mathcal{S}'$ -modules, where  $I$  is an injective object of  $(\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$ ; then,  $A(G)$  being flat over  $\mathcal{O}\mathcal{S}'$ ,  $\text{Ind}(F)$  is a sub- $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -module of  $\text{Ind}(I)$ , whence:

**Corollary 5.3.1.2.** The abelian category  $(\mathcal{G}\text{-}\mathcal{O}\mathcal{S}\text{-Mod.q.c.})'$  has enough injective objects.

<!-- label: III.I.5.3.1.2 -->

Taking [Gr57, 2.2.1 and 2.3] into account (already used in the proof of 5.2.1), this completes the proof of Theorem 5.3.1.

**Remark 5.3.1.3.** One can also prove 5.3.1.1 by the following computation. To every morphism of  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -modules  $\phi : M \rightarrow P \otimes_{\mathcal{O}\mathcal{S}} A(G)$  one associates the  $\mathcal{O}\mathcal{S}'$ -morphism  $(\text{id}_P \otimes \eta) \circ \phi : M \rightarrow P$ . Conversely, to every  $\mathcal{O}\mathcal{S}'$ -morphism  $f : M \rightarrow P$  one associates the morphism of  $\mathcal{G}\text{-}\mathcal{O}\mathcal{S}'$ -modules  $(f \otimes \text{id}_{A(G)}) \circ \mu_M : M \rightarrow P \otimes_{\mathcal{O}\mathcal{S}} A(G)$ . One sees at once that

```

```text
(id_P ⊗ η) ∘ (f ⊗ id_{A(G)}) ∘ μ_M = (f ⊗ id_{OS}) ∘ (id_P ⊗ η) ∘ μ_M = f.
```

```

<!-- label: III.I.5.3.1.3 -->

<!-- original page 38 -->

\*On the other hand, for every  $\varphi$  the following diagram is commutative:\*

```

```text
      φ
      |
M  -----> P ⊗_{OS} A(G)
      |
      | μ_M      id_P ⊗ Δ
      |          |
      | φ ⊗ id_{A(G)}  ↓
      |          |
M ⊗_{OS} A(G)  -----> P ⊗_{OS} A(G) ⊗_{OS} A(G).
```

```

\*It follows that\*

```

```text
((id_P ⊗ η) ∘ φ ⊗ id_{A(G)}) ∘ μ_M = (id_P ⊗ η ⊗ id_{A(G)}) ∘ (φ ⊗ id_{A(G)}) ∘ μ_M
                                = (id_P ⊗ η ⊗ id_{A(G)}) ∘ (id_P ⊗ Δ) ∘ φ = φ.
```

```

\*This proves 5.3.1.1 (i) (and (ii) follows).\*

Let  $F$  be a  $G$ - $OS$ -module; one has seen above that axiom (CM 2) of 4.7.2 shows that, considered as  $OS$ -module,  $F$  is a direct factor of  $E(F)$ . This entails:

**Proposition 5.3.2.** \*Let  $S$  be an affine scheme and  $G$  an  $S$ -group affine and flat; suppose that every exact sequence  $0 \rightarrow F_1 \rightarrow F_2 \rightarrow F_3 \rightarrow 0$  of quasi-coherent  $G$ - $OS$ -modules that splits as a sequence of  $OS$ -modules also splits as a sequence of  $G$ - $OS$ -modules.\*

\*Then, the functors  $H^n(G, -)$  are zero for  $n > 0$  (or what amounts to the same, the functor  $H^0(G, -)$  is exact).\*

<!-- label: III.I.5.3.2 -->

Indeed, by hypothesis, the sequence of  $G$ - $OS$ -modules

```

0 → F → E(F) → E(F)/F → 0

```

is split;  $F$  is therefore a direct factor, as  $G$ - $OS$ -module, of  $E(F)$ , whose cohomology is zero.

One immediately deduces from this and from Proposition 4.7.4:

<!-- original page 42 -->

**Theorem 5.3.3.** \*Let  $S$  be an affine scheme and  $G$  a diagonalizable  $S$ -group. For every quasi-coherent  $G$ - $OS$ -module  $F$ , one has  $H^n(G, F) = 0$ , for  $n > 0$ .\*

<!-- label: III.I.5.3.3 -->

**Remark.** \*Proposition 5.3.2 remains valid when  $G$  is not necessarily flat over  $S$ ; the proof then appeals to relative cohomology.[^N.D.E-I-53]\*

## ## 6. $G$ -equivariant objects and modules

[^N.D.E-I-54] Let  $\mathcal{C}$  be a category having a final object and in which fiber products exist. Let  $G$  be a  $\hat{\mathcal{C}}$ -group,  $\pi : M \rightarrow X$  a morphism of  $\hat{\mathcal{C}}$ , and  $\lambda = \lambda_X : G \times X \rightarrow X$  an action of  $G$  on  $X$ . In the

sequel, one will denote  $Y \times_{\{f\}} M$  the fiber product of  $\pi : M \rightarrow X$  and an  $X$ -functor  $f : Y \rightarrow X$ .

For every  $U \in \text{Ob}(C)$  and  $x \in X(U)$ , one will denote  $M_{\{x\}} = U \times_{\{x\}} M$ , i.e. for every  $\phi : U' \rightarrow U$ , one has

```

```text
M_x(U') = {m ∈ M(U') | π(m) = x_{U'} = φ*(x)}.
```

```

Finally, if  $g \in G(U)$  one will also denote  $gx$  the element  $\lambda(g, x)$  of  $X(U)$ .

**Definition 6.1.** (a) One says that  $M$  is a  $G$ -equivariant  $X$ -object if one has given an action  $\lambda : G \times M \rightarrow M$  of  $G$  on  $M$  lifting  $\lambda$ , i.e. such that the square below is commutative:

```

```text
      G × M  -----> M
      |           |
      id_G × π    π
      |           |
      G × X  -----> X
      λ
```

```

This amounts to giving for every morphism  $(g, x) : U \rightarrow G \times X$  maps

```

```text
λ_x^{U(g)} : M_x(U) → M_{gx}(U),    m ↦ g · m
```

```

verifying  $1 \cdot m = m$  and  $g \cdot (h \cdot m) = (gh) \cdot m$  and functorial in the  $(G \times X)$ -object  $U$ . This still amounts to giving morphisms of  $U$ -objects:

```

$$
\lambda_{\{x\}}(g) : M_{\{x\}} \rightarrow M_{\{gx\}}
$$

```

verifying  $\lambda_{\{x\}}(1) = \text{id}$  and  $\lambda_{\{hx\}}(g) \circ \lambda_{\{x\}}(h) = \lambda_{\{x\}}(gh)$ .

(b) Let now  $O$  be a  $\hat{C}$ -ring and let  $OX = O \times X$ . Under the conditions of (a), one says that  $M$  is a  $G$ -equivariant  $OX$ -module if it is an  $OX$ -module (cf. Definition 4.3.3.1, valid for any ring functor on a category  $C$ ) and if the action  $\lambda$  is compatible with the  $OX$ -module structure of  $M$ , i.e. if for every  $(g, x) \in G(U) \times X(U)$  ( $U \in \text{Ob}(C)$ ), the map  $\lambda_{\{x\}}(g) : M_{\{x\}} \rightarrow M_{\{gx\}}$ ,  $m \mapsto g \cdot m$  is a morphism of  $OU$ -modules.

<!-- label: III.I.6.1 -->

**Remark 6.2.** (i) In (a) above, the conditions  $\lambda_{\{x\}}(1) = \text{id}$  and  $\lambda_{\{hx\}}(g) \circ \lambda_{\{x\}}(h) = \lambda_{\{x\}}(gh)$  evidently entail that each  $\lambda_{\{x\}}(g)$  is an isomorphism, with inverse  $\lambda_{\{gx\}}(g^{-1})$ . Conversely, if one assumes that each  $\lambda_{\{x\}}(g)$  is an isomorphism, the condition  $\lambda_{\{hx\}}(g) \circ \lambda_{\{x\}}(h) = \lambda_{\{x\}}(gh)$  applied to  $h = 1$  gives  $\lambda_{\{x\}}(1) = \text{id}$ .

(ii) Let  $M$  be an  $OX$ -module. First, one sees that giving a morphism  $\lambda : G \times M \rightarrow M$  making the diagram of 6.1 commutative and such that each morphism

<!-- original page 40 -->

$\lambda_{\{x\}}(g) : M_{\{x\}} \rightarrow M_{\{gx\}}$ ,  $m \mapsto g \cdot m$ , is an isomorphism of  $OU$ -modules, is equivalent to giving an isomorphism of  $O_{G \times X}$ -modules:

```

```text
θ : G × M = (G × X) ×_{pr_X} M ⊕ (G × X) ×_λ M
      (g, x, m) ↦ (g, x, g · m).
```

```

Since one has assumed that each  $\lambda_{\{x\}}(g)$  is an isomorphism, the equality  $\lambda_{\{x\}}(1) = \text{id}$  will be a

consequence of the equality  $\Lambda_{\{hx\}}(g) \circ \Lambda_{\{x\}}(h) = \Lambda_{\{x\}}(gh)$  applied to  $h = 1$ . One therefore obtains that  $\Lambda$  is an action of  $G$  on  $M$  (i.e.  $g \cdot (h \cdot m) = (gh) \cdot m$ ) if and only if the diagram of  $(G \times G \times X)$ -isomorphisms below is commutative (where one denotes  $\mu$  the multiplication of  $G$  and  $f \circ (\theta)$  the isomorphism deduced from  $\theta$  by a base change  $f : G \times G \times X \rightarrow G \times X$ ):

$$\begin{array}{ccc} & \text{pr}_{\{2,3\}}^*(\theta) & \\ (G \times G \times X) \times_{\{\text{pr}_X \circ \text{pr}_{\{2,3\}}\}} M & \square & (G \times G \times X) \times_{\{\lambda \circ \text{pr}_{\{2,3\}}\}} M \\ (\mu \times \text{id}_X) \circ (\theta) & & (\text{id}_G \times \lambda) \circ (\theta) \\ \dots & & \dots \\ (G \times G \times X) \times_{\{\lambda \circ (\mu \times \text{id}_X)\}} M & & (G \times G \times X) \times_{\{\lambda \circ (\text{id}_G \times \lambda)\}} M. \end{array}$$

One sees therefore that giving a  $G$ -equivariant  $OX$ -module structure on  $M$  is equivalent to giving an isomorphism  $\theta$  of  $(G \times X)$ -modules as above, such that the diagram above is commutative.\*

(iii) All that precedes extends to the case where  $G$  is only a  $\hat{C}$ -monoid: in that case, giving an action  $\Lambda : G \times M \rightarrow M$  lifting  $\lambda$  and such that each  $\Lambda_{\{x\}}(g) : M_{\{x\}} \rightarrow M_{\{gx\}}$  is a morphism of  $OU$ -modules is equivalent to giving a morphism  $\theta$  of  $(G \times X)$ -modules as in (ii), such that the diagram above (without the  $\sim$  under the arrows) is commutative, and such that  $p_M \circ \theta \circ (\epsilon_G \times \text{id}_M) = \text{id}_M$ , where  $\epsilon_G$  denotes the unit section of  $G$  and  $p_M$  the projection onto  $M$ .\*

<!-- label: III.I.6.2 -->

### 6.3. $G$ -equivariant morphisms

Let  $Y$  be a second object of  $\hat{C}$ , endowed with an action  $\lambda_{\{Y\}} : G \times Y \rightarrow Y$  of  $G$ , and let  $N$  be a second  $G$ -equivariant  $OX$ -module. One says that a  $\hat{C}$ -morphism  $f : Y \rightarrow X$  (resp. a morphism of  $OX$ -modules  $\phi : M \rightarrow N$ ) is  $G$ -equivariant if it commutes with the action of  $G$ , i.e. if one has set-theoretically  $f(g \cdot y) = g \cdot f(y)$  (resp.  $\phi(g \cdot m) = g \cdot \phi(m)$ ), which is equivalent to saying that  $f \circ \lambda_{\{Y\}} = \lambda_{\{X\}} \circ (id_G \times f)$  (resp.  $\phi \circ \lambda_{\{M\}} = \lambda_{\{N\}} \circ (id_G \times \phi)$ ).

One then obtains at once the following lemma:

<!-- original page 41 -->

**Lemma 6.3.1.** \*Let  $f : Y \rightarrow X$  be a  $G$ -equivariant morphism and  $M$  a  $G$ -equivariant  $OX$ -module. Then the inverse image  $f^*(M) = Y \times_{\{f\}} M$  is a  $G$ -equivariant  $OU$ -module.\*

<!-- label: III.I.6.3.1 -->

On the other hand,  $G$  acts on  $\text{Hom}_{\{\hat{C}\}}(Y, X)$ . Indeed, let  $T \in \text{Ob}(C)$ ,  $g \in G(T)$  and  $\phi$  a  $T$ -morphism  $Y_T \rightarrow X_T$ ; then  $g$  defines automorphisms  $\lambda_{\{Y\}}(g)$  and  $\lambda_{\{X\}}(g)$  of  $Y_T$  and  $X_T$ , and one will denote  $g \cdot \phi$  (or also  $\phi \circ g^{-1}$ ) the morphism  $\lambda_{\{X\}}(g) \circ \phi \circ \lambda_{\{Y\}}(g^{-1})$ . This defines an action of  $G(T)$  on  $\text{Hom}_{\{T\}}(Y_T, X_T)$ , functorial in  $T$ .

**Definition 6.3.2.** \*If  $\phi : Y \rightarrow X$  is an arbitrary  $\hat{C}$ -morphism, one can therefore consider its stabilizer  $\text{Stab}_{\{G\}}(\phi)$  (cf. 2.3.3.1): for every  $T \in \text{Ob}(C)$ ,  $\text{Stab}_{\{G\}}(\phi)(T)$  is the subgroup  $G(T)$  formed by the  $g$  such that  $g \circ \phi_T = \phi_T \circ g$ , i.e. such that the diagram\*

$$\begin{array}{ccc} & \phi_T & \\ Y_T & \xrightarrow{\quad} & X_T \\ \downarrow g & & \downarrow g \\ Y_T & \xrightarrow{\quad \phi_T \quad} & X_T \end{array}$$

\*commutes. Then, the morphism  $\phi : Y \rightarrow X$  is equivariant under  $\text{Stab}_{\{G\}}(\phi)$ .\*

<!-- label: III.I.6.3.2 -->

### ### 6.4. Global sections

Let  $M$  be a  $G$ -equivariant  $OX$ -module. Denote by  $S_0$  the final object of  $C$ , and (cf. Exp. II, 1.1) by  $\prod_{X/S_0} M$  the "functor of sections of  $M$  over  $X$ ": it is the functor which to every  $T \in \text{Ob}(C)$  associates

$\text{Hom}_{X(T)}(X_T, M_T) = \Gamma(M_T/X_T)$ .

Recall, on the other hand, that every morphism  $g : Z \rightarrow Y$  of  $\hat{C}$ -objects above  $X$  induces a morphism of abelian groups  $M(g) : M(Y) \rightarrow M(Z)$ , which is compatible with the ring morphism  $g^* : O(Y) \rightarrow O(Z)$ . In particular, when  $Z = Y$  (with  $g$  then an  $X$ -endomorphism of  $Y$ ), one obtains a morphism of abelian groups

$M(g) : M(Y) \rightarrow M(Y)$

which is not in general a morphism of  $O(Y)$ -modules, but which verifies, for every  $m \in M(Y)$  and  $\alpha \in O(Y)$ :

$M(g)(\alpha \cdot m) = g^*(\alpha) \cdot M(g)(m)$ .

This said, one will write simply, in the sequel,  $g^*$  instead of  $M(g)$ .

Let  $T \in \text{Ob}(C)$  and let  $X_T = X \times T$  and  $\text{pr}_X$  the projection  $X_T \rightarrow X$ . For every  $\alpha \in O(X_T)$  and  $g \in G(T)$ , set  $g(\alpha) = (g^{-1})^*(\alpha)$ : it is the element of  $O(X_T)$  defined set-theoretically by: for every  $S \in \text{Ob}(C)$  and  $x \in X(S)$ ,  $t \in T(S)$ ,

$g(\alpha)(x, t) = \alpha(g^{-1}x, t)$ .

One thus obtains a (left) action of  $G(T)$  by ring automorphisms on  $O(X_T)$ , functorial in  $T$ , and such that  $g(\alpha) = \alpha$  if  $\alpha$  is the image in  $O(X_T)$  of an element of  $O(T)$ .

Now denote by  $\phi$  the identity morphism of  $X_T$  (cf. 6.3 and the generalization further below to a morphism  $\phi : Y \rightarrow X$ ) and designate  $\text{Hom}_{X_T}(X_T, M)$  by  $M(\phi, g^{-1})$  resp.  $M(\phi)$ , according as  $X_T$  is regarded as an  $X$ -object via  $\text{pr}_X \circ \lambda(g^{-1})_T$ , resp.  $\text{pr}_X$ .

<!-- original page 42 -->

Then  $\lambda(g^{-1})_T$  is an  $X$ -morphism between these two  $X$ -objects, hence, by the preceding, one obtains a morphism of abelian groups

$(g^{-1})^* : M(\phi) \rightarrow M(\phi, g^{-1}), \quad m \mapsto m \circ \lambda(g^{-1})_T$

which verifies  $(g^{-1})^*(\alpha \cdot m) = (g \alpha) \cdot (g^{-1})^*(m)$  for every  $m \in M(\phi)$  and  $\alpha \in O(X_T)$ . (If  $m$  is a section of  $M_T$  on  $X_T$  then  $(g^{-1})^*(m)$  is the section defined set-theoretically by  $(x, t) \mapsto m(g^{-1}x, t)$ .) In particular,  $(g^{-1})^*$  is a morphism of  $O(T)$ -modules.

By the functoriality of the morphisms of  $O(X_T)$ -modules  $\lambda_x(g)$ , one obtains a commutative diagram:

$$\begin{array}{ccc} M(\phi) & \xrightarrow{(g^{-1})^*} & M(\phi, g^{-1}) \\ \downarrow \Lambda_\phi(g) & & \downarrow \Lambda_{\phi, g^{-1}}(g) \\ M(g, \phi) & \xrightarrow{(g^{-1})^*} & M(g, \phi, g^{-1}) \end{array}$$

and  $g \cdot \phi^{-1} = \phi$ , since  $\phi$  is the identity map. Setting  $A(g) = (g^{-1})^* \circ \Lambda_{\phi}(g)$ , one therefore obtains a morphism of abelian groups

$$A(g) : M(\phi) \rightarrow M(\phi)$$

which is "compatible with the action of  $G(T)$  on  $\mathcal{O}(X_T)$ ", i.e. which verifies

$$A(g)(\alpha \cdot m) = (g \cdot \alpha) \cdot A(g)(m).$$

Finally, if  $h$  is a second element of  $G(T)$ , it follows from the functoriality of  $M$  and of the morphisms  $\Lambda_{\phi}(g)$  that one has a commutative diagram

$$\begin{array}{ccccc}
 & M(\phi) & & & \\
 & \downarrow \Lambda_{\phi}(g) & & \Lambda_{\phi}(hg) & \\
 \Lambda_{\phi}(h) & & & & \\
 & \downarrow & & \searrow & \\
 M(g \cdot \phi) & \xrightarrow{\Lambda_{\phi}(h)} & M(hg \cdot \phi) & \xrightarrow{(hg)^{-1}*} & M(\phi) \\
 (g^{-1})^* & & & & ((hg)^{-1})^* \\
 M(\phi) & \xrightarrow{\Lambda_{\phi}(h)} & M(h \cdot \phi) & \xrightarrow{(h^{-1})^*} & M(\phi)
 \end{array}$$

whence  $A(h) \circ A(g) = A(hg)$ . Consequently, one has obtained the following proposition:

**Proposition 6.4.1.** For every  $T$ , the  $\mathcal{O}(X_T)$ -module  $(\prod_{X/S_0} M)(T) = \Gamma(M_T/X_T)$  is endowed, in a way functorial in  $T$ , with an action of  $G(T)$  "compatible with the action of  $G(T)$  on  $\mathcal{O}(X_T)$ ", i.e. which verifies

$$A(g)(\alpha \cdot m) = g(\alpha) \cdot A(g)(m).$$

<!-- label: III.I.6.4.1 -->

Since  $g(\alpha) = \alpha$  for  $\alpha \in \mathcal{O}(T)$ , this gives in particular that  $\prod_{X/S_0} M$  is a  $G$ - $\mathcal{O}_{S_0}$ -module.

More generally, let, as in 6.3,  $Y$  be a second  $G$ -equivariant  $\hat{C}$ -object,  $\phi : Y \rightarrow X$  a  $\hat{C}$ -morphism and  $H = \text{Stab}_G(\phi)$ . Then the fiber product  $M_{\phi} = Y \times_{\phi} M$  is an  $H$ -equivariant  $\mathcal{O}_Y$ -module. One therefore obtains:

<!-- original page 43 -->

**Corollary 6.4.2.** The functor  $\prod_{Y/S_0} M_{\phi}$  is a  $\text{Stab}_G(\phi)$ - $\mathcal{O}_{S_0}$ -module.

<!-- label: III.I.6.4.2 -->

### 6.5. $G$ -equivariant $\mathcal{O}_X$ -modules

Let us apply what precedes in the following situation. Let  $S$  be a scheme,  $G$  an  $S$ -group scheme acting on an  $S$ -scheme  $X$ , and  $F$  an  $\mathcal{O}_X$ -module (not necessarily quasi-coherent).

**Definition 6.5.1.** One says that  $F$  is a  $G$ -equivariant  $\mathcal{O}_X$ -module if the  $\mathcal{O}_X$ -module  $M = W(F)$  is

$G$ -equivariant, i.e. if one has given, for every morphism  $(g, x) : U \rightarrow G \times_S X$ , isomorphisms of  $\mathcal{O}_U$ -modules

$$\Lambda_x(g) : W(x^*(F)) \xrightarrow{\sim} W((gx)^*(F)),$$

functorial in  $U$  and verifying  $\Lambda_{hx}(g) \circ \Lambda_x(h) = \Lambda_x(gx)$ . Since the functor  $W$  is fully faithful (cf. 4.6.1.1 and 4.6.2), one therefore obtains isomorphisms of  $\mathcal{O}_U$ -modules

$$\Lambda_x(g) : x^*(F) \xrightarrow{\sim} (gx)^*(F),$$

where one recalls that  $gx$  denotes the morphism  $\lambda \circ (g, x) : U \rightarrow X$ . In particular, applying this to the identity morphism of  $G \times_S X$ , one obtains an isomorphism of  $\mathcal{O}_{G \times_S X}$ -modules

$$(\star) \quad \theta : pr_X^*(F) \xrightarrow{\sim} \lambda^*(F)$$

*label: eq:III.I.6.5.1-star -->*

such that the diagram  $(\star)$  of morphisms of sheaves on  $G \times_S G \times_S X$  below is commutative:

$$\begin{array}{ccc} pr_{\{2,3\}}^* \circ pr_X^*(F) & \xrightarrow{pr_{\{2,3\}}^*(\theta)} & pr_{\{2,3\}}^* \circ \lambda^*(F) \\ & & (id_G \times \lambda)^* \circ pr_X^*(F) \\ & & (**) \quad \square \quad (id_G \times \lambda)^*(\theta) \\ (\mu \times id_X)^* \circ pr_X^*(F) & \longrightarrow & (\mu \times id_X)^* \circ \lambda^*(F) \quad (id_G \times \lambda)^* \circ \lambda^*(F). \end{array}$$

*label: III.I.6.5.1 -->*

Moreover, if  $E$  is a second  $G$ -equivariant  $\mathcal{O}_X$ -module, one says that a morphism of  $\mathcal{O}_X$ -modules  $\phi : E \rightarrow F$  is  $G$ -equivariant if the morphism  $W(\phi) : W(E) \rightarrow W(F)$  is. With the above notations, this is equivalent to saying that  $\theta_F \circ pr_X^*(\phi) = \lambda^*(\phi) \circ \theta_E$ .

**Remark 6.5.2.** If  $f : Y \rightarrow X$  is a  $G$ -equivariant morphism, it follows from 6.3.1 that  $f^*(F)$  is a  $G$ -equivariant  $\mathcal{O}_Y$ -module.

*label: III.I.6.5.2 -->*

**Remark 6.5.3.** Suppose moreover  $F$  quasi-coherent. Then it follows from what precedes that giving a  $G$ -equivariant  $\mathcal{O}_X$ -module structure on  $M = W(F)$  is equivalent to giving such a structure on  $V(F)$ , which is itself equivalent to giving an action of  $G$  on the vector fibration  $V(F)$ , compatible with the action on  $X$  and "linear" on the fibers.

Indeed, denote by  $\phi$  the isomorphism  $\lambda^*(F) \xrightarrow{\sim} pr_X^*(F)$  inverse of  $\theta$ . For every morphism  $(g, x) : U \rightarrow G \times_S X$ , one has an isomorphism of  $\mathcal{O}_U$ -modules  $\phi_x(g) = \Lambda_x(g)^{-1} = \Lambda_{gx}(g^{-1})$  from  $(gx)^*(F)$  to  $x^*(F)$ ; it induces an isomorphism of  $\mathcal{O}_U$ -modules

$$V((gx)^*(F)) \xrightarrow{\sim} V(x^*(F))$$

*original page 44 -->*

which one will denote  $t \phi_x(g)$ . One then has

$$t \phi_{gx}(h) \circ t \phi_x(g) = t (\Lambda_{gx}(h) \circ \phi_x(g))^{-1} = \Lambda_x(hg)^{-1} = t \phi_x(hg).$$

Since, for every  $X$ -scheme  $f : Y \rightarrow X$ , one has  $V(F) \times_{\{f\}} Y \simeq V(f^*(F))$  (cf. 4.6.2), one therefore obtains that the isomorphism

```

```text
t φ : G ×_S V(F) = (G ×_S X) ×_{pr_X} V(F) = V(pr_*_X(F))
      V(λ*(F)) = (G ×_S X) ×_λ V(F)
```

```

endows  $V(F)$  with a  $G$ -equivariant  $\mathcal{O}_X$ -module structure. Finally, identifying each functor  $V(-)$  with the vector fibration that represents it, and composing  $t \circ \phi$  with the projection onto  $V(F)$ , one obtains an action of  $G$  on the vector fibration  $V(F)$ , compatible with the action on  $X$  and "linear" on the fibers.

<!-- label: III.I.6.5.3 -->

One thus recovers the definition given, for example, in [GIT, Chap. 1, § 3], up to the fact that in *loc. cit.* Mumford considers a locally free  $\mathcal{O}_X$ -module of finite rank  $E$ , and defines an action of  $G$  on  $V(E) = W(E^{\vee})$ . Indeed, the diagram  $(\star)$  above, with  $\theta$  replaced by  $\phi$  and the direction of the arrows reversed, is exactly the one one finds in *loc. cit.*, Def. 1.6, and the isomorphism  $t \circ \phi$  above coincides with the isomorphism  $\Phi$  of *loc. cit.*, p. 31.

**Remark 6.5.4.** Consider in particular the case where  $X = S$ , endowed with the trivial action of  $G$ . In this case, a  $G$ -equivariant  $\mathcal{O}_S$ -module  $F$  is the same thing as a  $G$ - $\mathcal{O}_S$ -module (cf. 4.7.1). Moreover, if one denotes  $f$  the morphism  $G \rightarrow S$  (equal here to  $\text{pr}_X$  and to  $\lambda$ ), then the isomorphism

```

G
(⋆) θ : f*(F) →_{sim} f*(F)
G

```

is an element of

```

```text
Hom_{OG}(f*(F), f*(F)) = Hom_{OG}(W(f*(F)), W(f*(F))) = End_{OS}(W(F))(G)
```

```

which is nothing other than the morphism  $\rho : G \rightarrow \text{End}_{\mathcal{O}_S}(W(F))$  defining the operation of  $G$  on  $W(F)$ . Moreover,  $\theta$  corresponds by adjunction to the morphism of  $\mathcal{O}_S$ -modules  $f_{\circ}(\theta) \circ \tau : F \rightarrow f_{\circ} f^*(F)$ , where  $\tau : F \rightarrow f_{\circ} f^*(F)$  is the "unit" morphism of the adjunction. (This will be used in `VI_B`, 11.10.bis.)

<!-- label: III.I.6.5.4 -->

### 6.6. The functors  $\prod_{X/S} W(F)$  and  $W(p_{\circ}^*(F))$

Let  $S$  be a scheme,  $G$  an  $S$ -group scheme acting on  $S$ -schemes  $X$  and  $Y$  via the morphisms  $\lambda : G \times_S X \rightarrow X$  and  $\mu : G \times_S Y \rightarrow Y$ , and let  $p : X \rightarrow Y$  be a  $G$ -equivariant morphism. Suppose that the morphisms  $p : X \rightarrow Y$  and  $\nu : Y \rightarrow S$  are quasi-compact and quasi-separated, and that  $p$  is flat.

Then the projection  $\text{pr}_Y : G \times_S Y \rightarrow Y$  is flat, as is  $\mu$  (since  $\mu$  is the composite of  $\text{pr}_Y$  and of the automorphism  $(g, y) \mapsto (g, gy)$ ). Finally, for a variable  $S$ -scheme  $f : T \rightarrow S$ , one will denote by  $p_T : X_T \rightarrow T$  and  $f_X : X_T \rightarrow X$  the morphisms deduced from  $p$  and  $f$  by base change.

Let  $F$  be a quasi-coherent and  $G$ -equivariant  $\mathcal{O}_X$ -module, and let  $\theta$  be the isomorphism  $\text{pr}_X^*(F) \rightarrow_{\sim} \lambda^*(F)$  of 6.5.1  $(\star)$ . Since  $p$  is quasi-compact and quasi-separated,

<!-- original page 45 -->

$p_{\circ}^*(F)$  is quasi-coherent (cf. EGA I, 9.2.1).

**Lemma 6.6.1.** The quasi-coherent  $\mathcal{O}_Y$ -module  $p_{\circ}^*(F)$  is  $G$ -equivariant.

<!-- label: III.I.6.6.1 -->

Indeed, one has the two cartesian squares below:

$$\begin{array}{ccc}
G \times_S X & \xrightarrow{\text{pr}_X} & X \\
& & \downarrow p \\
G \times_S Y & \xrightarrow{\text{pr}_Y} & Y
\end{array}
\quad
\begin{array}{ccc}
& & \xleftarrow{\lambda} G \times_S X \\
& & \downarrow \mu \\
& & G \times_S Y.
\end{array}$$

Since  $p$  is quasi-compact and quasi-separated and  $\text{pr}_X$  and  $\mu$  are flat, it follows from EGA III, 1.4.15 (completed by EGA IV\_1, 1.7.21) that one has  $q_* \text{pr}_X^*(F) = \text{pr}_Y^* p_*(F)$  and  $q_* \lambda^*(F) = \mu_* p_*(F)$ . Consequently,  $\theta$  induces an isomorphism:

$$\theta_Y : \text{pr}_Y^* p_*(F) \xrightarrow{\sim} \mu_* p_*(F),$$

and one obtains similarly that  $\theta_Y$  verifies the "cocycle condition" 6.5.1  $(\star)$  (since the morphisms  $G \times_S G \times_S Y \rightarrow G \times_S Y$  involved are flat). This proves the lemma.

In particular, take  $Y = S$  endowed with the trivial action of  $G$ . Taking Remark 6.5.4 into account, one then obtains that  $p_*(F)$  is a  $G$ - $\mathcal{O}_S$ -module. If moreover  $G$  is affine over  $S$  and if one denotes  $A(G) = \pi_*(\mathcal{O}_G)$ , then  $p_*(F)$  is therefore an  $A(G)$ -comodule, by 4.7.2.

On the other hand, by 6.4.1, the functor  $\prod_{X/S} W(F)$ , which to every  $f : T \rightarrow S$  associates

$$W(f_X^*(F))(X_T) = \Gamma(X_T, f_X^*(F)) = \Gamma(T, p_{T*} f_X^*(F))$$

is a  $G$ - $\mathcal{O}_S$ -module. Moreover, one has a canonical morphism  $\tau : W(p_*(F)) \rightarrow \prod_{X/S} W(F)$ , which is given for every  $f : T \rightarrow S$  by the canonical morphism:

$$\Gamma(T, f^* p_*(F)) \rightarrow \Gamma(T, p_{T*} f_X^*(F))$$

and which is an isomorphism when restricted to the full subcategory of schemes  $T$  flat over  $S$ , and one verifies without difficulty that  $\tau$  is a morphism of  $G$ - $\mathcal{O}_S$ -modules. Consequently, one has obtained the following proposition (for point (ii), compare with [GIT], p. 32).

**Proposition 6.6.2.** \*Let  $S$  be a scheme,  $G$  an  $S$ -group scheme acting on an  $S$ -scheme  $X$ , and  $F$  a quasi-coherent and  $G$ -equivariant  $\mathcal{O}_X$ -module. Suppose that  $\pi : G \rightarrow S$  is flat and that  $p : X \rightarrow S$  is quasi-compact and quasi-separated.\*

(i) Then  $p_*(F)$  is a quasi-coherent  $G$ - $\mathcal{O}_S$ -module. Moreover, the canonical morphism  $W(p_*(F)) \rightarrow \prod_{X/S} W(F)$  is a morphism of  $G$ - $\mathcal{O}_S$ -modules, and these two functors coincide on the category of flat  $S$ -schemes.\*

(ii) If moreover  $G$  is affine over  $S$  and if one denotes  $A(G) = \pi_*(\mathcal{O}_G)$ , then  $p_*(F)$  is endowed with a structure of  $A(G)$ -comodule. [N.D.E-I-55]\*

<!-- label: III.I.6.6.2 -->

<!-- original page 46 -->

### 6.7. Stabilizers

Let  $S$  be a scheme,  $G$  an  $S$ -group scheme acting on an  $S$ -scheme  $X$ , and let  $F$  be a quasi-coherent  $G$ -equivariant  $\mathcal{O}_X$ -module. Let  $Y$  be a second  $S$ -scheme endowed with an action of  $G$  (possibly trivial), let  $\phi : Y \rightarrow X$  be an  $S$ -morphism, not necessarily  $G$ -equivariant, and let  $\text{Stab}_G(\phi)$  be the stabilizer in  $G$  of  $\phi$  (cf. 6.3.2).

Let us point out at once (see Exp. VI\_B, § 6) that  $\text{Stab}_G(\phi)$  is representable by a closed sub-group scheme  $H$

of  $G$  if  $X$  is separated over  $S$  and if  $Y$  is essentially free over  $S$  (cf. \*loc. cit.\*, Déf. 6.2.1). Indeed, consider the morphism  $r : G \times_S Y \rightarrow X \times_S X$  given set-theoretically by  $r(g, y) = (\phi(y), g \phi(g^{-1}y))$ , and let  $P = G \times_S Y$  and  $P'$  the inverse image by  $r$  of the diagonal  $\Delta_{X/S}$ . Then one has (cf. \*loc. cit.\*, 6.2.4 (a))

$$\begin{aligned} & \\ \text{Stab}_G(\phi) &= \prod_{P/G} P' \\ & \end{aligned}$$

and therefore, by \*loc. cit.\*,  $\text{Stab}_G(\phi)$  is representable by a closed sub-group scheme  $H$  of  $G$  if  $X$  is separated over  $S$  and if  $Y$  is essentially free over  $S$ ; this second condition being automatically verified if  $S$  is the spectrum of a field, or if  $Y = S$ . Under these hypotheses,  $\phi^*(F)$  is then a quasi-coherent  $H$ -equivariant  $\mathcal{O}_Y$ -module (cf. 6.5.2).

Hence, if moreover  $\pi : G \rightarrow S$  and  $p : Y \rightarrow S$  are quasi-compact and quasi-separated over  $S$ , and  $\pi$  flat, then  $p_* \phi^*(F)$  is an  $H$ - $\mathcal{O}_S$ -module, by 6.6.2. In particular, one obtains:

**\*\*Corollary 6.7.1.\*\*** \*Let  $S$  be a scheme,  $G$  an  $S$ -group scheme acting on an  $S$ -scheme  $X$ , and  $F$  a quasi-coherent  $G$ -equivariant  $\mathcal{O}_X$ -module. Suppose that  $\pi : G \rightarrow S$  is flat and that  $X \rightarrow S$  is quasi-compact and separated. Let  $\tau : S \rightarrow X$  be a section of  $X$  over  $S$ .\*

**\*(i)** The stabilizer  $H = \text{Stab}_G(\tau)$  is a closed sub-group scheme of  $G$ , and  $\tau^*(F)$  is a quasi-coherent  $H$ - $\mathcal{O}_S$ -module.\*

**\*(ii)** If moreover  $H$  is affine over  $S$  (for example, if  $G$  is) and if one denotes  $A(H) = \pi_*(\mathcal{O}_H)$ , then  $\tau^*(F)$  is an  $A(H)$ -comodule.\*

<!-- label: III.I.6.7.1 -->

### ### 6.8. $G$ -equivariant sheaves on $G$

To conclude, let us point out two results (6.8.1 and 6.8.6 below) that will be used in Exposés II and III (cf. in particular III, 4.25).

**\*\*Proposition 6.8.1.\*\*** \*Let  $S$  be a scheme,  $\pi : G \rightarrow S$  an  $S$ -group scheme,  $\epsilon : S \rightarrow G$  the unit section. Consider the action by left translations of  $G$  on itself. Then the functors  $E \mapsto \pi^*(E)$  and  $F \mapsto \epsilon^* \pi^*(F)$  induce equivalences, quasi-inverse to one another, between the category of quasi-coherent  $\mathcal{O}_S$ -modules and that of quasi-coherent  $G$ -equivariant  $\mathcal{O}_G$ -modules.\*

<!-- label: III.I.6.8.1 -->

**\*Proof.\*** Denote by  $\mu$  the multiplication of  $G$  and by  $\text{pr}_2$  the second projection  $G \times_S G \rightarrow G$ . Since  $\pi \circ \mu = \pi \circ \text{pr}_2$ , then, for every quasi-coherent  $\mathcal{O}_S$ -module  $E$ , one has a canonical isomorphism  $\mu^* \pi^*(E) = \text{pr}_2^* \pi^*(E)$ , and one verifies easily that this isomorphism satisfies the "cocycle condition" 6.5.1  $(\star)$ , i.e.  $\mu^* \pi^*(E)$  is a  $G$ -equivariant  $\mathcal{O}_G$ -module. Since  $\epsilon^* \pi^*(E) = E$ , the functor  $E \mapsto \pi^*(E)$  is

<!-- original page 47 -->

fully faithful; it remains therefore to see that for every  $G$ -equivariant  $\mathcal{O}_G$ -module  $F$ , one has  $F \simeq \pi^* \epsilon^* \pi^*(F)$ . By hypothesis, one has an isomorphism  $\theta : \text{pr}_2^*(F) \xrightarrow{\sim} \mu^*(F)$ ; taking the inverse image of  $\theta$  by the morphism  $\tau : G \rightarrow G \times_S G$  of components  $(\text{id}_G, \epsilon \circ \pi)$ , one obtains an isomorphism  $F \xrightarrow{\sim} \pi^* \epsilon^* \pi^*(F)$ .

**\*\*Remarks 6.8.2.\*\*** **\*(a)** Consider the action of  $G \times_S G$  on  $G$  defined by  $(g_1, g_2) \cdot g = g_1 g_2^{-1} g$ ; then the stabilizer of the unit section  $\epsilon : S \rightarrow G$  is the diagonal subgroup  $H$  of  $G \times_S G$ . Consequently, if  $F$  is a quasi-coherent  $(G \times_S G)$ -equivariant  $\mathcal{O}_G$ -module then, by 6.5.2,  $E = \epsilon^* \pi^*(F)$  is endowed with a structure of  $H$ - $\mathcal{O}_S$ -module.\*

**\*(b)** One can show that  $F \mapsto \epsilon^* \pi^*(F)$  is an equivalence of categories, between the category of quasi-coherent  $(G \times_S G)$ -equivariant  $\mathcal{O}_G$ -modules and that of quasi-coherent  $H$ - $\mathcal{O}_S$ -modules. This is a particular case of more general "descent" results (cf. Exp. IV, § 2 and SGA 1, VIII), see for example [Th87], 1.2–1.3.\*

<!-- label: III.I.6.8.2 -->

**\*\*Remark 6.8.3.\*\*** \*One retains the notations of 6.8.1. For every quasi-coherent  $\mathcal{O}_S$ -module  $\mathcal{E}$ , denote by  $\pi_{G,*} \pi^*(\mathcal{E})$  the sub- $\mathcal{O}_S$ -module of  $\pi_{G,*} \pi^*(\mathcal{E})$  whose sections on every open subset  $V$  of  $S$  are the  $\gamma \in \Gamma(V, \pi^*(\mathcal{E}))$  such that  $g \cdot \gamma = \gamma$  for every  $g \in G|_V$  and  $g \in G(S)$ . Then the natural morphism  $\mathcal{E} \rightarrow \pi_{G,*} \pi^*(\mathcal{E})$  is an isomorphism: this is immediate if  $\pi_{G,*} \pi^*(\mathcal{E}) = \mathcal{E} \otimes_{\mathcal{O}_S} \pi_{G,*}(\mathcal{O}_G)$  (for example if  $G \rightarrow S$  is affine, or if  $G \rightarrow S$  is quasi-compact and quasi-separated and  $\mathcal{E}$  flat), and it is verified without difficulty in the general case.\*

<!-- label: III.I.6.8.3 -->

**\*\*Remark 6.8.4.\*\*** \*Let  $S$  be a scheme,  $H$  an  $S$ -group scheme acting on an  $S$ -scheme  $X$ ,  $\mathcal{F}$  an  $\mathcal{O}_X$ -module. Suppose  $H$  flat over  $S$  and denote by  $\mathcal{W}_P(\mathcal{F})$  the restriction of the functor  $\mathcal{W}(F)$  to the full subcategory formed by the  $S$ -schemes that are flat. Since, by 6.5.1, endowing  $\mathcal{F}$  with a structure of  $H$ -equivariant module is equivalent to giving an isomorphism  $\theta : \pi^*(X)(F) \rightarrow \lambda^*(F)$  of sheaves on  $G \times_S X$ , verifying the "cocycle condition"  $(\star)$ , one sees that to give an  $H$ -equivariant module structure on  $\mathcal{F}$ , it suffices to give such a structure on  $\mathcal{W}_P(\mathcal{F})$ .\*

<!-- label: III.I.6.8.4 -->

**\*\*Recollection 6.8.5.\*\*** \*Let  $X$  be an  $S$ -scheme and  $Y$  a sub- $S$ -scheme of  $X$ . One denotes by  $\mathcal{N}_{Y/X}$  the conormal sheaf of the immersion  $i : Y \hookrightarrow X$  (cf. EGA IV<sub>4</sub>, 16.1.2). If  $S' \rightarrow S$  is a flat morphism and if one denotes  $i' : Y' \hookrightarrow X'$  the immersion deduced from  $i$  by base change, then by\* loc. cit., \*16.2.2 (iii), one has  $\mathcal{N}_{Y'/X'} \otimes_{\mathcal{O}_{Y'}} \mathcal{O}_{Y'} = \mathcal{N}_{Y/X}$ .\*

<!-- label: III.I.6.8.5 -->

**\*\*Proposition 6.8.6.\*\*** \*Let  $S$  be a scheme,  $X$  an  $S$ -group scheme,  $Y$  a sub- $S$ -group scheme of  $X$ . Suppose  $Y$  flat over  $S$ . Then the conormal sheaf  $\mathcal{N}_{Y/X}$  is a  $(Y \times_S Y)$ -equivariant  $\mathcal{O}_Y$ -module.\*

<!-- label: III.I.6.8.6 -->

Indeed,  $H = Y \times_S Y$  is flat over  $S$ , so by Remark 6.8.4, it suffices to endow  $\mathcal{W}_P(\mathcal{N}_{Y/X})$  with an  $H$ -equivariant module structure. Let  $S'$  be a flat  $S$ -scheme, let  $Y' \hookrightarrow X'$  be the immersion obtained by base change, and let  $\mathcal{N}' = \mathcal{N}_{X'/Y'} \otimes_{\mathcal{O}_{Y'}} \mathcal{O}_{Y'}$ . By 6.8.5, one has  $\mathcal{N}' = \mathcal{N}_{Y'/X'}$ .

Every  $h \in H(S')$  induces an automorphism of  $Y'$ , and one therefore obtains, for every  $y \in Y'(S')$ , isomorphisms

```
```text
Γ(S', y*(N')) ⊂ Γ(S', y* h*(N'))
```
```

<!-- original page 48 -->

which endow  $\mathcal{W}_P(\mathcal{N})$  with a structure of  $H$ -equivariant module (cf. 6.1).

[^I-0]: Version of 13/10/2024.

[^N.D.E-I-1]: N.D.E.: Cf. SGA 4, Exp. I, § 0 and Appendix; see also the discussion in [DG70], p. xxvi.

[^N.D.E-I-2]: N.D.E.: One calls it the category of presheaves on  $\mathcal{C}$ , cf. IV 4.3.1.

[^N.D.E-I-3]: N.D.E.: This result is often called the "Yoneda Lemma"; we shall use this terminology in other N.D.E.

[^N.D.E-I-4]: N.D.E.: This remark has been added.

[^N.D.E-I-5]: N.D.E.: The order has been modified, in order to introduce fiber products before monomorphisms, cf. N.D.E. (9).

[^N.D.E-I-6]: N.D.E.: Likewise, "arbitrary" direct limits exist and are computed "argument by argument", i.e.  
 $(\varinjlim F_i)(S) = \varinjlim F_i(S)$ ; but in general the functor  $h$  does not commute with direct limits.

[^N.D.E-I-7]: N.D.E.: In particular, the kernel of a pair of morphisms  $u, v : F \rightarrow G$  is the subfunctor  
 $\text{Ker}(u, v)$  of  $F$  defined by  $\text{Ker}(u, v)(S) = \{x \in F(S) \mid u(x) = v(x)\}$ .

[^N.D.E-I-8]: N.D.E.:  $\{\emptyset\}$  (the set of subsets of the empty set) denotes the one-element set.

[^N.D.E-I-9]: N.D.E.: If  $F(S) \rightarrow G(S)$  is injective for every  $S$ , it is clear that  $F \rightarrow G$  is a monomorphism; the converse is seen by considering the diagram  $F \times_{\{S\}} F \rightarrow F \rightarrow G$ . One thus obtains that: " $F \rightarrow G$  is a monomorphism if and only if the diagonal morphism  $F \rightarrow F \times_{\{S\}} F$  is an isomorphism" (cf. EGA I, 5.3.8). Likewise, it is clear that if  $F(S) \rightarrow G(S)$  is surjective for every  $S$ , then  $F \rightarrow G$  is an epimorphism, and the converse is seen by considering the amalgamated sum  $G \amalg_{\{F\}} G$ , cf. the proof of Lemma 4.4.4 in Exp. IV.

[^N.D.E-I-10]: N.D.E.: For example, if  $F = hX$  then  $h$  corresponds to a morphism  $h : X \rightarrow S$  and  
 $h(T) : \text{Hom}_{\{T\}}(T, X) \rightarrow \text{Hom}_{\{T\}}(T, S)$  is the map  $g \mapsto h \circ g$ , whence  
 $\alpha_S(hX) = \text{Hom}_{\{C/S\}}(-, X)$ .

[^N.D.E-I-11]: N.D.E.: Cf. N.D.E. (10).

[^N.D.E-I-12]: N.D.E.: I.e. if  $g : U \rightarrow S$  (resp.  $h : V \rightarrow T$ ) is an object of  $\mathcal{C}/S$  (resp.  $\mathcal{C}/T$ ) then  $i_S(g) = U$   
 and  $i_{T/S}(h)$  is the object  $f \circ h : V \rightarrow S$  of  $\mathcal{C}/S$ , and one has:

```

```text
Hom_{C/S}(U, X \times S) \simeq Hom_C(U, X) \quad \text{resp.} \quad Hom_{\{C/T\}}(V, X \times_S T) \simeq Hom_{\{C/S\}}(V, X).
```

```

[^N.D.E-I-13]: N.D.E.: The following lemma has been added (cf. SGA 4, I.3.4); it is used in the proof of 1.7.1 and will be useful several times in the sequel.

[^N.D.E-I-14]: N.D.E.: And, if  $E$  is a third object of  $\hat{C}$ , one has  $\text{Hom}(E, F \times G) \cong \text{Hom}(E, F) \times \text{Hom}(E, G)$ .

[^N.D.E-I-15]: N.D.E.: Point (b) has been added, which will be useful in II.1 and II.3.11. On the other hand, a second, more direct, proof of (a) has been sketched.

[^N.D.E-I-15-alt]: (continuation of the proof of Proposition 1.7.1, sketching a direct argument)

[^N.D.E-I-16]: N.D.E.: The numbering 1.7.3 has been added, for subsequent references.

[^N.D.E-I-17]: N.D.E.: The former terminology "pré-schémas/schémas" has been replaced by the current terminology "schémas/schémas séparés".

[^N.D.E-I-18]: N.D.E.: In the three paragraphs that follow, the order of the sentences has been modified and some clarifications added concerning the role of the hypothesis  $(\ast)$  below.

[^N.D.E-I-19]: N.D.E.:  $(\ast)$  is not verified if  $C$  is the category whose arrows are  $A \rightarrow B$  and  $\text{id}_A, \text{id}_B$ ; in this case  $B \sqcup B = B$  and  $B \times_B B = B \neq A$ .

[^N.D.E-I-20]: N.D.E.: Note also that the diagonal morphism  $E \rightarrow E \times_S E = (E \times E)_S$  is a closed immersion, i.e.  $E$  is separated over  $S$ .

[^N.D.E-I-21]: N.D.E.: Including the condition  $(\ast)$ .

[^N.D.E-I-22]: N.D.E.: For example, for group structures: let  $G \in \text{Ob}(\hat{C})$ ; if the functor  $\hat{C} \rightarrow (\text{Ens})$ ,  $F \mapsto \text{Hom}_{\hat{C}}(F, G)$  is endowed with a group structure, the same is true of its restriction to  $C$ ,  $X \mapsto G(X)$ . Conversely, if  $G$  is a  $\hat{C}$ -group, then the "multiplication" morphism  $\pi_G : G \times G \rightarrow G$  induces for every  $F \in \text{Ob}(\hat{C})$  a group structure on  $\text{Hom}_{\hat{C}}(F, G)$ , functorial in  $F$ .

[^N.D.E-I-23]: N.D.E.: We have corrected the original, replacing the inclusion  $\rho(g) \text{ FS} \subset \text{FS}$  by an equality, in order to ensure that  $\text{Norm}_G(F)$  is indeed a group (see VI\_B 6.4 for conditions under which the "transporter" coincides with the "strict transporter").

[^N.D.E-I-24]: N.D.E.: Scholium 2.3.3.1 and Remark 2.3.3.2 have been added.

[^N.D.E-I-25]: N.D.E.: Moreover, one says that  $H$  is *\*central\** in  $G$  if  $\text{Centr}_G(H) = G$ , or, what amounts to the same thing, if  $H(S)$  is central in  $G(S)$  for every  $S$ .

[^N.D.E-I-26]: N.D.E.: Definitions 2.3.6.1 and 2.3.6.2 have been added.

[^N.D.E-I-27]: N.D.E.: Statements 3.1.1 and 3.1.2 have been added to make explicit that the category  $(0\text{-Mod})$  is abelian and verifies the axiom (AB 5), and moreover has enough injective objects if the category  $C$  is small. An error in 3.1.2, reported in 2016 by Linyuan Liu, has been corrected here.

[^N.D.E-I-28]: N.D.E.: The following sentence has been added; this will be used in section 5.

[^N.D.E-I-29]: N.D.E.: And, of course, the inversion morphism  $G \rightarrow G$  induces a morphism of  $\mathcal{O}_S$ -algebras  $\tau : A(G) \rightarrow A(G)$  which, together with  $\Delta$  and  $\epsilon$ , makes  $A(G)$  an  $\mathcal{O}_S$ -Hopf algebra.

[^N.D.E-I-30]: N.D.E.: This paragraph has been added, which will be useful later (cf. II 1.3).

[^N.D.E-I-31]: N.D.E.: The numbering 4.6.1.1 has been added, for subsequent references.

[^N.D.E-I-32]: N.D.E.: The isomorphism  $\text{Hom}_{\mathcal{O}_S}(W(F), W(F')) \cong \text{Hom}_{\mathcal{O}_S}(V(F'), V(F))$  has been added.

[^N.D.E-I-33]: N.D.E.: "vector bundle" has been replaced by "vector fibration"; current usage being to call a vector

fibration that is locally trivial of rank  $r$  a "vector bundle of rank  $r$ ", i.e. one whose sheaf of sections is locally isomorphic to  $\mathcal{O}_S^{\oplus r}$ .

[^N.D.E-I-34]: N.D.E.: Let us point out here the articles [Ni04] (resp. [Ni02]), which show that if  $S$  is noetherian and  $F$  is a coherent  $\mathcal{O}_S$ -module, then  $W(F)$  (resp. the  $S$ -group which to every  $T \rightarrow S$  associates  $\operatorname{Aut}_{\mathcal{O}_T}(F \otimes \mathcal{O}_T)$ ) is representable if and only if  $F$  is locally free.

[^N.D.E-I-35]: N.D.E.: The original has been detailed in what follows.

[^N.D.E-I-36]: N.D.E.: The following sentence has been detailed.

[^N.D.E-I-37]: N.D.E.: This remark has been added, taken from [DG], II, § 2, 1.1.

[^N.D.E-I-38]: N.D.E.: The original has been corrected by suppressing the assertion that the category  $(G\text{-}\mathcal{O}_S\text{-Mod.})$  is abelian, see 4.7.2.1 below.

[^N.D.E-I-39]: N.D.E.: This remark has been added.

[^N.D.E-I-40]: N.D.E.: Cf.  $\text{VI}_B$ , §§ 11.1–11.6 for the extension of the results of 4.7.2 to the case where  $G$  is not necessarily affine, but where  $G$  and  $F$  are assumed to be flat over  $S$ .

[^N.D.E-I-41]: N.D.E.: Left  $G$ - $\mathcal{O}_S$ -modules correspond in a natural way to right  $A(G)$ -comodules.

[^N.D.E-I-42]: N.D.E.: The following sentence has been added.

[^N.D.E-I-43]: N.D.E.: The following paragraph has been added, taken from [Se68, § 1.3].

[^N.D.E-I-44]: N.D.E.: This complex is often called the "Hochschild complex"; see for example § II.3 of [DG70].

[^N.D.E-I-45]: N.D.E.: This remark has been added.

[^N.D.E-I-46]: N.D.E.: The following recollection has been added.

[^N.D.E-I-47]: N.D.E.: The following sentence has been added.

[^N.D.E-I-48]: N.D.E.: The original has been modified, in order to introduce 5.2.0.1 and 5.2.0.2, which will be useful in the proof of Theorem 5.3.1.

[^N.D.E-I-49]: N.D.E.: Cf. [Gr57], 2.2.1 and 2.3. Moreover, the original has been detailed in what follows.

[^N.D.E-I-50]: N.D.E.: The original has been detailed in what follows.

[^N.D.E-I-51]: N.D.E.: This remark has been added.

[^N.D.E-I-52]: N.D.E.: The original has been modified to show that the category  $(G\text{-}\mathcal{O}_S\text{-Mod.q.c.})$  is abelian and has enough injective objects. One may compare with [Ja03], Part I, 3.3-3.4, 3.9, 4.2 and 4.14-4.16 (where one should be aware that " $k$ -group scheme" means "affine  $k$ -group scheme", cf. \*loc. cit.\*, 2.1).

[^N.D.E-I-53]: N.D.E.: The editors did not seek to develop this remark.

[^N.D.E-I-54]: N.D.E.: This section has been added.

[^N.D.E-I-55]: N.D.E.: The same is true if  $G$  is flat, quasi-compact and quasi-separated over  $S$  and if  $p_*(F)$  is a flat  $\mathcal{O}_S$ -module, cf. Exp.  $\text{VI}_B$ , 11.6.1 (ii).

[^N.D.E-I-56]: N.D.E.: additional references cited in this Exposé.

# Exposé II. Tangent bundles, Lie algebras

<!-- label: III.II -->

\*by M. Demazure\*

<!-- original page 43 -->

[^N.D.E-II-0] We propose in this Exposé to construct the analogue, in the theory of schemes, of the tangent bundles and Lie algebras of the classical theory. It will however be useful not to restrict ourselves to schemes properly speaking, but also to consider certain functors on the category of schemes which are not necessarily representable (for example the functors  $\text{Hom}$ ,  $\text{Norm}$ , etc.). As announced in the preceding Exposé (cf. I 1.1), we shall identify a scheme with the functor associated to it.

On the other hand, the constructions presented below go beyond the framework of the theory of schemes. They are equally valid, for example, in the theory of analytic spaces with nilpotent elements, modulo a few modifications of detail.

Before beginning this construction, we must lay down a few general definitions that complement those of I 1.7.

## 1. The functors  $\text{Hom}_{Z/S}(X, Y)$

<!-- label: III.II.1 -->

Let us resume the notations of I 1.1. We identify the category  $\mathcal{C}$  with a full subcategory of  $\hat{\mathcal{C}} = \text{Hom}(\mathcal{C}^{\text{circ}}, (\text{Ens}))$  (in particular we suppress the underlines[^N.D.E-II-1] that allowed us to distinguish graphically an object of  $\hat{\mathcal{C}}$  from an object of  $\mathcal{C}$ ).

Consider the following situation: four objects of  $\hat{\mathcal{C}}$ , denoted  $S, X, Y, Z$ , the first being in fact an object of  $\mathcal{C}$ , with  $X$  and  $Y$  above  $Z$ , and  $Z$  above  $S$ :

<!-- original page 44 -->

```

```text
      X           Y
      \         /
      pX        pY
       \       /
        \     /
         Z
         |
         S
...

```

Definition 1.1. We define an object of $\hat{\mathcal{C}}/S$, denoted $\text{Hom}_{Z/S}(X, Y)$, by:

<!-- label: III.II.1.1 -->

```

```text
(1) $\text{Hom}_{Z/S}(X, Y)(S') = \text{Hom}_{Z/S'}(X_{S'}, Y_{S'}) = \text{Hom}_Z(X \times_S S', Y),$
```

```

for every object S' of $\mathcal{C}/S$. One sees at once that $\text{Hom}_{Z/S}(X, Y)$ is nothing other than the subobject of $\text{Hom}_S(X, Y)$ formed by the morphisms compatible with p_X and p_Y , that is to say, the kernel of the pair of morphisms

```

```text
Hom_S(X, Y) $\rightrightarrows$ Hom_S(X, Z)
```

```

defined: the first by composition with p_Y ; the second as the constant morphism whose "image" is p_X .

On the other hand, one sees as in I 1.7 that, for every object T of $\hat{\mathcal{C}}$ above S , one has a natural bijection:[^N.D.E-II-2]

```

```text
(2) $\text{Hom}_S(T, \text{Hom}_{Z/S}(X, Y)) \cong \text{Hom}_Z(X \times_S T, Y).$
```

```

Moreover, by I 1.7.1, if E, F are objects of $\hat{\mathcal{C}}$ above Z , one has:

```

$$\mathrm{Hom}_Z(E, \mathrm{Hom}_Z(F, Y)) \cong \mathrm{Hom}_Z(E \times_Z F, Y) \cong \mathrm{Hom}_Z(F, \mathrm{Hom}_Z(E, Y)).$$

```

Applying this with $E = X$ and $F = Z \times_S T$, one obtains natural bijections, for every object T of $\hat{C}/S$:

```

$$(3) \quad \mathrm{Hom}_S(T, \mathrm{Hom}_{Z/S}(X, Y)) \cong \mathrm{Hom}_Z(X \times_S T, Y) \cong \begin{cases} \mathrm{Hom}_Z(Z \times_S T, \mathrm{Hom}_Z(X, Y)) \\ \mathrm{Hom}_Z(X, \mathrm{Hom}_Z(Z \times_S T, Y)) \end{cases}.$$

```

Moreover, these bijections are functorial in T , so one obtains isomorphisms of S -functors:

```

$$(4) \quad \mathrm{Hom}_S(T, \mathrm{Hom}_{Z/S}(X, Y)) \cong \mathrm{Hom}_{Z/S}(X, \mathrm{Hom}_Z(Z \times_S T, Y)) \\ \cong \mathrm{Hom}_{Z/S}(X \times_S T, Y).$$

```

Let us point out two particular cases of the definition. If $Z = S$, one has:

```

$$\mathrm{Hom}_{S/S}(X, Y) = \mathrm{Hom}_S(X, Y).$$

```

<!-- original page 45 -->

On the other hand, when $X = Z$, one sets

```

$$(5) \quad \prod_{Z/S} Y = \mathrm{Hom}_{Z/S}(Z, Y),$$

```

so that by definition

```

$$(\prod_{Z/S} Y)(S') = \mathrm{Hom}_Z(Z \times_S S', Y) \cong \Gamma(Y_{S'}/Z_{S'}).$$

```

The functor $\mathrm{prod}_{Z/S} : \hat{C}/Z \rightarrow \hat{C}/S$ is right adjoint to the base-change functor from S to Z : for every S -functor U one has

```

$$\mathrm{Hom}_S(U, \prod_{Z/S} Y) = \mathrm{Hom}_Z(U \times_S Z, Y).$$

```

(If $C = (\mathrm{Sch})$ and if Z is an S -scheme, the functor $\mathrm{prod}_{Z/S}$ is called *"Weil restriction of scalars"*.)^[N.D.E-II-3] Let us note also that one has an isomorphism:

```

$$(6) \quad \mathrm{Hom}_{Z/S}(X, Y) \cong \mathrm{Hom}_{X/S}(X, Y \times_Z X) = \prod_{X/S}(Y \times_Z X),$$

```

which gives in particular, for $Z = S$, an isomorphism:

```

$$(7) \quad \mathrm{Hom}_S(X, Y) \cong \prod_{X/S} Y_X.$$

```

Remark 1.2. The functor $Y \mapsto \mathrm{Hom}_{Z/S}(X, Y)$ commutes with products in the following sense: one has a functorial isomorphism

<!-- label: III.II.1.2 -->

```

```text
(*) $\text{Hom}_{\{Z/S\}}(X, Y \times_Z Y') = \text{Hom}_{\{Z/S\}}(X, Y) \times_S \text{Hom}_{\{Z/S\}}(X, Y')$.
```

```

It follows that if Y is a Z -group, resp. a Z -ring, etc., then $\text{Hom}_{\{Z/S\}}(X, Y)$ is an S -group, resp. an S -ring, etc.

Remark 1.3. [N.D.E-II-4] Moreover, let $\pi : M \rightarrow Y$ be a Y -functor of 0_Y -modules (cf. I, 4.3.3.1). Set $H = \text{Hom}_{\{Z/S\}}(X, Y)$. Then $\text{Hom}_{\{Z/S\}}(X, M)$ is equipped with a natural structure of 0_H -module; more precisely, for every H' above H , $\text{Hom}_{\{H'\}}(H', \text{Hom}_{\{Z/S\}}(X, M))$ is equipped with a natural structure of $0(H' \times_S X)$ -module.

<!-- label: III.II.1.3 -->

Indeed, denote by $m : M \times_S Y \rightarrow M$ and $\lambda : 0_Y \times_S Y \rightarrow M$ the morphisms defining the structures of Y -(abelian) group and of 0_Y -module. Let H' be an S -scheme above $H = \text{Hom}_{\{Z/S\}}(X, Y)$, i.e. one has been given a Z -morphism $f : X \times_S H' \rightarrow Y$, which therefore makes $X \times_S H'$ a Y -object. Then,

```

$$\text{Hom}_{\{H'\}}(H', \text{Hom}_{\{Z/S\}}(X, M))$$

```

is the set of Z -morphisms $\phi : X \times_S H' \rightarrow M$ such that $\pi \circ \phi = f$, i.e. of Y -morphisms $X \times_S H' \rightarrow M$.

<!-- original page 52 -->

If ϕ, ψ are two such morphisms, one defines $\phi + \psi$ as the Y -morphism composite

```

```text

$$X \times_S H' \xrightarrow{(\phi \times \psi)} M \times_Y M \xrightarrow{m} M$$

```

```

and one verifies that this equips $\text{Hom}_{\{Z/S\}}(X, M)$ with a structure of abelian group above $H = \text{Hom}_{\{Z/S\}}(X, Y)$. [N.D.E-II-5]

Likewise, if a is an element of $0(X \times_S H')$, i.e. an S -morphism $a : X \times_S H' \rightarrow 0_Y$, one defines $a\phi$ as the composite $\lambda \circ (a \times \phi)$, where $a \times \phi$ denotes the Y -morphism from $X \times_S H' \times_S 0_Y$ to $0_Y \times_S Y \times_S M \times_S 0_Y \times_S M$ with components a and ϕ ; one verifies that this equips $\text{Hom}_{\{H'\}}(H', \text{Hom}_{\{Z/S\}}(X, M))$ with a structure of $0(X \times_S H')$ -module, functorial in the H -object H' .

2. The schemes $I_{\{S\}}(M)$

<!-- label: III.II.2 -->

Definition 2.1. Let S be a scheme and M a quasi-coherent 0_S -module. We denote by $D_{\{0_S\}}(M)$ the quasi-coherent 0_S -algebra $0_S \oplus M$ (where M is considered as an ideal of square zero). We denote by $I_{\{S\}}(M)$ the S -scheme $\text{Spec } D_{\{0_S\}}(M)$. [N.D.E-II-6]

<!-- label: III.II.2.1 -->

In particular we set $D_{\{0_S\}} = D_{\{0_S\}}(0_S)$, $I_{\{S\}} = I_{\{S\}}(0_S)$, and we call them respectively the algebra of dual numbers over S and the scheme of dual numbers over S .

Then $M \mapsto I_{\{S\}}(M)$ is a contravariant functor from the category of quasi-coherent 0_S -modules to that of S -schemes. In particular the morphisms $0 \rightarrow M$ and $M \rightarrow 0$ define respectively the structural morphism $\rho : I_{\{S\}}(M) \rightarrow I_{\{S\}}(0) = S$ and a section ϵ_M of it, which we call the *zero section*. [N.D.E-II-7]

<!-- original page 46 -->

2.1.1. [N.D.E-II-8] Since $M \mapsto I_{\{S\}}(M)$ is a contravariant functor, every $a \in \text{Hom}_{\{S\}}(I_{\{S\}}(M), I_{\{S\}}(M))$ defines an S -endomorphism a^* of $I_{\{S\}}(M)$, and one has $1^* = \text{id}$, $(ab)^* = b^* \circ a^*$, $0^* = \epsilon_M \circ \rho$ and $a^* \circ \epsilon_M = \epsilon_M$.

Consequently, the S -scheme $I_{\{S\}}(M)$ is equipped with a right action of the multiplicative monoid of $\operatorname{End}_{\{0\}}(M)$, which commutes with the S -morphisms $I_{\{S\}}(M) \rightarrow I_{\{S\}}(M')$ arising from morphisms $M' \rightarrow M$; in particular, the operators a^* preserve the zero section of $I_{\{S\}}(M)$.

For every $a \in \operatorname{End}_{\{0\}}(M)$ and $f : S' \rightarrow S$ and $m \in I_{\{S\}}(M)(S')$, we shall write $m \cdot a = a^*(m)$; then $m \cdot 1 = m$, $(m \cdot a) \cdot b = m \cdot (ab)$, $m \cdot 0 = \epsilonpsilon_M(\rho(m))$ and, if $m = \epsilonpsilon_M(f)$, then $m \cdot a = m$. [N.D.E-II-9]

Remark 2.1.2. The formation of the $I_{\{S\}}(M)$ commutes with base extension: one has canonical isomorphisms

!-- label: III.II.2.1.2 -->

text
 $I_{\{S\}}(M)_{\{S'\}} = I_{\{S'\}}(M \otimes_{\{0\}} \{0\}_{\{S'\}}).$

To simplify, we shall write $I_{\{S'\}}(M) = I_{\{S\}}(M)_{\{S'\}}$; more generally, if X is an S -functor (not necessarily representable), we shall write $I_{\{X\}}(M) = I_{\{S\}}(M) \times_S X$.

2.1.3. [N.D.E-II-10] By what precedes, the multiplicative monoid of $0(S')$ acts on the S' -scheme $I_{\{S'\}}(M)$, functorially in M , i.e. the S -scheme $I_{\{S\}}(M)$ is equipped with a structure of object with monoid of operators $\{0\}_S$, this structure being functorial in M . One thus has a morphism of S -schemes

text
 $\lambda : I_S(M) \times_S \{0\}_S \rightarrow I_S(M),$

verifying obvious conditions. For every S -functor X , one obtains by base change a morphism of X -functors:

text
 $\lambda_X : I_X(M) \times_S \{0\}_S \rightarrow I_X(M)$

which makes the S -functor $I_{\{X\}}(M)$ into an object with monoid of operators $0(X)$: every element a of $0(X) = \operatorname{Hom}_{\{S\}}(X, \{0\}_S)$ defines an X -endomorphism $a^* = \lambda_X \circ (\operatorname{id}_{I_X(M)} \times a \circ \operatorname{pr}_X)$ of $I_{\{X\}}(M)$; explicitly, if $x \in X(S')$ and $m \in I_{\{S\}}(M)(S') = I_{\{S'\}}(M)(S')$, then $a(x) = a \circ x$ belongs to $0(S')$ and one has:

text
 $(m, x) \cdot a = (m \cdot a(x), x).$

This operation is functorial in M and preserves the zero section $\epsilonpsilon_M : X \rightarrow I_{\{X\}}(M)$, i.e. $a^* \circ \epsilonpsilon_M = \epsilonpsilon_M$ for every $a \in 0(X)$.

Moreover, this operation is "functorial in X " in the following sense: if $\pi : Y \rightarrow X$ is a morphism of S -functors and $u : 0(X) \rightarrow 0(Y)$ the corresponding ring morphism (i.e. $u(a) = a \circ \pi \in 0(Y)$ for every $a \in 0(X) = \operatorname{Hom}_{\{S\}}(X, \{0\}_S)$), then the following diagram is commutative:

text

$$\begin{array}{ccc} I_X(M) & \xrightarrow{a^*} & I_X(M) \\ \uparrow \pi & & \uparrow \pi \\ I_Y(M) & \xrightarrow{u(a)^*} & I_Y(M) \end{array}$$

2.2. Let now M and N be two quasi-coherent $\{0\}_S$ -modules. The commutative diagram

text

$$\begin{array}{ccc} & M \otimes N & \\ \nearrow & \uparrow & \searrow \\ M & & N \end{array}$$

$$\begin{array}{c} \searrow \quad \downarrow \quad \swarrow \\ \quad \quad 0 \end{array}$$

<!-- original page 54 -->

defines a commutative diagram of S -schemes

```

``text
      I_S(M ⊗ N)
      /   |   \
    ↗     |     ↖
  I_S(M) ε_{M⊗N} I_S(N)
    ↖     |     ↗
    ε_M   |   ε_N
      \   |   /
        S
(*)

```

Proposition 2.2. For every S -scheme X , the diagram of functors over S obtained by applying the functor $\operatorname{Hom}_S(-, X)$ to diagram (*) is cartesian:

<!-- label: III.II.2.2 -->

<!-- original page 47 -->

```

``text
      Hom_S(I_S(M ⊗ N), X)
      /   |   \
    ↗     |     ↖
Hom_S(I_S(M), X) Hom_S(I_S(N), X)
    ↖     |     ↗
    Hom_S(S, X) = X

```

It must be verified that for every $S' \rightarrow S$, the diagram of sets obtained by taking the value of the functors on S' is cartesian. Since the formation of $I_S(P)$ commutes with base extension in the sense explained above, it suffices to do it for $S' = S$, hence to verify that the following diagram of sets is cartesian:

```

``text
      X(I_S(M ⊗ N))
      /   |   \
    ↗     |     ↖
  X(I_S(M)) X(I_S(N))
    ↖     |     ↗
    X(ε_M) X(ε_N)
      \   |   /
        X(S)

```

Now, if $x \in X(S)$, it follows from SGA 1, III 5.1 [N.D.E-II-11], that $X(\epsilon_M)^{-1}(x)$ is isomorphic, functorially in M , to

$$\operatorname{Hom}_{0_S}(x^* (\Omega^1_{X/S}), M),$$

where $\Omega^1_{X/S}$ denotes the sheaf of relative differentials of X with respect to S . Now this latter functor (in M) evidently transforms a direct sum of 0_S -modules into the product of the corresponding sets, whence the result.

Corollary 2.2.1. Let X be an S -scheme and M a free 0_S -module of finite type. The functor $\operatorname{Hom}_S(I_S(M), X)$ is isomorphic (as functor above X) to a finite product (above X) of copies of $\operatorname{Hom}_S(I_S, X)$.

<!-- label: III.II.2.2.1 -->

<!-- original page 48 -->

****Nota 2.2.2.**** *It follows from the proof of the proposition that $\operatorname{Hom}_{\{S\}}(I_{\{S\}}, X)$ is isomorphic as $\mathcal{X}$ -functor to $V(\Omega^1_{X/S})$ (I 4.6.1), hence representable by the vector fibration^[^N.D.E-II-12]
 $V(\Omega^1_{X/S})$.

<!-- label: III.II.2.2.2 -->

3. The tangent bundle, condition (E)

<!-- label: III.II.3 -->

In this section, unless otherwise stated, the letters M, M', N , etc., will always denote free $\mathcal{O}_S$ -modules of finite type (that is to say, isomorphic to a finite direct sum of copies of $\mathcal{O}_S$).

We shall systematically use the identifications justified in Exposé I; thus we shall say "functor above S " to designate indifferently a functor equipped with a morphism into S ($= h_S$) or a functor on the category of objects above S . Likewise we shall say "group-functor above S ", etc.

****Definition 3.1.**** *Let S be a scheme and M a free $\mathcal{O}_S$ -module of finite type. Let $\mathcal{X}$ be a functor above S . One calls ****tangent bundle to $\mathcal{X}$ above S relative to the $\mathcal{O}_S$ -module M **** and denotes by $T_{X/S}(M)$ the S -functor*

<!-- label: III.II.3.1 -->

$$T_{X/S}(M) = \operatorname{Hom}_{\{S\}}(I_{\{S\}}(M), X).$$

*In particular, one calls ****tangent bundle to $\mathcal{X}$ above S **** and denotes by $T_{X/S}$ the functor^[^N.D.E-II-13]

$$T_{X/S} = T_{X/S}(\mathcal{O}_S) = \operatorname{Hom}_S(I_S, X).$$

Then $M \mapsto T_{X/S}(M)$ is a covariant functor from the category of free $\mathcal{O}_S$ -modules of finite type to the category of S -functors. In particular the morphisms^[^N.D.E-II-14] $M \mapsto 0$ and $0 \mapsto M$ define respectively an S -morphism

<!-- original page 49 -->

$$\pi_M : T_{X/S}(M) \rightarrow T_{X/S}(0) = X$$

and a section τ_0 of it, called the ***zero section*** (or ***null section***).

****Remark 3.1.1.****^[^N.D.E-II-15] One should note that the projection $\pi_M : T_{X/S}(M) \rightarrow X$ is induced by the zero section $\epsilon_M : S \rightarrow I_{\{S\}}(M)$, while the null section $\tau_0 : X \rightarrow T_{X/S}(M)$ is induced by the structural morphism $\rho : I_{\{S\}}(M) \rightarrow S$; i.e., for every point $t \in T_{X/S}(M)(S')$ (resp. $x \in X(S')$), corresponding to an S -morphism $f : S' \rightarrow I_{\{S\}}(M)$ (resp. $g : S' \rightarrow X$), one has $\pi(t) = f \circ (\operatorname{id}_{S'} \times \epsilon_M)$ (resp. $\tau_0(x) = g \circ (\operatorname{id}_{S'} \times \rho)$).

<!-- label: III.II.3.1.1 -->

It follows from 3.1 that $M \mapsto T_{X/S}(M)$ is a covariant functor from the category of free $\mathcal{O}_S$ -modules of finite type to that of functors above X . In particular $0(S)$ is a monoid of operators of the $\mathcal{X}$ -functor $T_{X/S}(M)$ which respects "functoriality in M ".

****Scholie 3.1.2.****^[^N.D.E-II-15] What precedes means, in particular, the following. For every S -morphism $\phi : X' \rightarrow X$, set

<!-- label: III.II.3.1.2 -->

```

```text

$$\Sigma(X', M) = \text{Hom}_X(X', T_{X/S}(M)).$$

```

```

One has an action of the multiplicative monoid $\text{End}_{\{0\}}(M)$ on $\Sigma(X', M)$, denoted $(\lambda, x) \mapsto \lambda \ast x$, such that $(\lambda \mu) \ast x = (\lambda \mu) \ast x$, $1 \ast x = x$, and $0 \ast x = \tau_0 \circ \phi$, where τ_0 is the null section $X \rightarrow T_{X/S}(M)$. One has likewise an action of $\text{End}_{\{0\}}(M \oplus M)$ on $\Sigma(X', M \oplus M)$. [^N.D.E-II-16]

Moreover, let $m : M \oplus M \rightarrow M$ (resp. $\delta : M \rightarrow M \oplus M$) be the addition (resp. the diagonal map) of M , and denote by $m_{X'} : \Sigma(X', M \oplus M) \rightarrow \Sigma(X', M)$ and $\delta_{X'} : \Sigma(X', M) \rightarrow \Sigma(X', M \oplus M)$ the morphisms induced by m and δ . For $\lambda, \mu \in 0(S)$, denote by ℓ_{λ} (resp. $\ell_{\lambda, \mu}$) multiplication by λ in M (resp. by (λ, μ) in $M \oplus M$). Since $m \circ \ell_{\lambda, \lambda} = \ell_{\lambda} \circ m$ and $m \circ \ell_{\lambda, \mu} \circ \delta = \ell_{\lambda + \mu}$, one has, for every $z \in \Sigma(X', M \oplus M)$ and $x \in \Sigma(X', M)$:

```

```text
(†) $\lambda \ast m(z) = m((\lambda, \lambda) \ast z), \quad m((\lambda, \mu) \ast \delta(x)) = (\lambda + \mu) \ast x.$
```

```

Definition 3.2. Let $u \in X(S) = \text{Hom}_{\{S\}}(S, X) = \Gamma(X/S)$. One calls **tangent space** to X above S at the point u relative to M , and denotes by $L^u_{X/S}(M)$, the S -functor obtained from the X -functor $T_{X/S}(M)$ by pullback along the morphism $u : S \rightarrow X$:

<!-- label: III.II.3.2 -->

```

```text

$$\begin{array}{ccc} L^u_{X/S}(M) & \xrightarrow{\quad} & T_{X/S}(M) \\ \downarrow & & \downarrow \pi \\ S & \xrightarrow{\quad u \quad} & X. \end{array}$$

```

```

In particular $L^u_{X/S}(0_{\{S\}})$ is denoted $L^u_{X/S}$. It is the **tangent space** to X above S at the point u .

Remark 3.2.1. [^N.D.E-II-17] It follows from 3.1.1 that, for every $t : S' \rightarrow S$, $L^u_{X/S}(M)(S')$ is the set of S -morphisms $f : I_{\{S'\}}(M) \rightarrow X$ such that $f \circ \epsilon_M = u \circ t$, where $\epsilon_M : S' \rightarrow I_{\{S'\}}(M)$ is the zero section.

<!-- label: III.II.3.2.1 -->

Let us note immediately the

Proposition 3.3. If X is representable by an S -scheme denoted $\tilde{X}$, then $T_{X/S}(M)$ and $L^u_{X/S}(M)$ are representable. In particular $T_{X/S}$ and $L^u_{X/S}$ are representable by vector fibrations on $\tilde{X}$ and on S , which are respectively $V(\Omega^1_{\tilde{X}/S})$ and $V(u^*(\Omega^1_{\tilde{X}/S}))$.

<!-- label: III.II.3.3 -->

It clearly suffices to prove the proposition for $T_{X/S}(M)$; the analogous results for $L^u_{X/S}(M)$ follow by pullback. By Corollary 2.2.1, it even suffices to do it for $T_{X/S}$, and in that case, the proposition is nothing other than the remark noted in 2.2.2.

Remark 3.3.1. From this proposition follows a particularly simple description of the vector fibration representing $L^u_{X/S}$: the image of the section u of X over S is locally closed [^N.D.E-II-18], hence defined by a quasi-coherent ideal $\mathfrak{m}$ of a scheme induced on an open subset of X . The quotient $\mathfrak{m}/\mathfrak{m}^2$ can be considered as a quasi-coherent module on S . It is this module that defines the sought-after vector fibration.

<!-- label: III.II.3.3.1 -->

<!-- original page 50 -->

Take for example X an algebraic scheme over a field k and u a k -rational point of X . Let $\mathfrak{m}$ be the maximal ideal of the local ring $\mathcal{O}_{X,u}$ and let t be the k -vector space dual to $\mathfrak{m}/\mathfrak{m}^2$; it is the Zariski tangent space of $\mathcal{O}_{X,u}$ at the point u . Then, with the notations of I 4.6.5.1, one has:

$$L^u_{X/k} = V(\mathfrak{m}/\mathfrak{m}^2) = W(t).$$

Having closed this parenthesis, let us return to the general situation. Let us remark first that $L^u_{X/S}(M)$ is a covariant functor from the category of free $\mathcal{O}_S$ -modules of finite type to that of functors above S . In particular $\mathcal{O}(S)$ is a set of operators of the S -functor $L^u_{X/S}(M)$ which respects functoriality in M . [N.D.E-II-19]

Proposition 3.4. *The formation of $T_{X/S}(M)$ and $L_{X/S}(M)$ commutes with base extension: for every S -scheme S' , one has isomorphisms functorial in M *

<!-- label: III.II.3.4 -->

$$\begin{aligned} & T_{X_{S'}/S'}(M \otimes \mathcal{O}_{S'}) \cong T_{X/S}(M)_{S'}, \\ & L^{u'}_{X_{S'}/S'}(M \otimes \mathcal{O}_{S'}) \cong L^u_{X/S}(M)_{S'}, \quad \text{where } u' = u_{S'}. \end{aligned}$$

This results immediately from the fact that Hom commutes with base extension.

Corollary 3.4.1. *The S -functor $T_{X/S}(M)$ (resp. the S -functor $L^u_{X/S}(M)$) is naturally equipped with a structure of object with operators $\mathcal{O}_X$ (resp. $\mathcal{O}_S$), this structure being functorial in M .*

<!-- label: III.II.3.4.1 -->

Let us show this first for $L^u_{X/S}(M)$. For each S' above S , $\mathcal{O}(S')$ acts on $M \otimes \mathcal{O}_{S'}$ hence on $L^{u'}_{X_{S'}/S'}(M \otimes \mathcal{O}_{S'}) = L^u_{X/S}(M)_{S'}$; now one verifies that this action is functorial in S' . It thus equips $L^u_{X/S}(M)$, as announced, with a structure of functor with operators $\mathcal{O}_S$.

For $T_{X/S}(M)$ it is a little more complicated. For each X' above X , set $T_{X/S}(M)_{X'} = T_{X/S}(M) \otimes_{\mathcal{O}_X} \mathcal{O}_{X'}$; one must equip $T_{X/S}(M)_{X'}(X') = \text{Hom}_{\mathcal{O}_X}(X', T_{X/S}(M))$ with a structure of set with monoid of operators $\mathcal{O}(X')$ in a manner functorial in X' . For this one constructs the following diagram, where $X_{X'}$ denotes $X \otimes_{\mathcal{O}_S} \mathcal{O}_{X'}$ and f' denotes the section of $X_{X'}$ over X' defined by $f' : X' \rightarrow X_{X'}$:

<!-- original page 58 -->

$$\begin{array}{ccccc} & & T_{X_{X'}/X'}(M) & & \\ & \swarrow & & \searrow & \\ T_{X/S}(M) & \xleftarrow{\quad} & T_{X/S}(M)_{X'} & & \\ \downarrow & & \downarrow & & \\ & & X_{X'} & & \\ & \swarrow & & \searrow & \\ X & \xleftarrow{\quad f \quad} & & & X' \\ & \searrow & & \swarrow & \\ & & S & & \end{array}$$

[N.D.E-II-20] This diagram, joined with 3.2.1, shows that $T_{X/S}(M)_{X'}(X')$ is identified with

$$L^{f'}_{X_{X'}/X'}(M)(X') = \{ X' \text{-morphisms } \psi : I_{X'}(M) \rightarrow X_{X'} \text{ such that } \psi \circ \varepsilon_M = f' \},$$

on which every $a \in \mathcal{O}(X')$ acts via its action on $I_{X'}(M)$, i.e., with the notations of 2.1.1, one has: $a\psi = \psi \circ a$, i.e. for every $X'' \rightarrow X'$ and $x \in I_{X'}(M)(X'')$, $(a\psi)(x) = \psi(x \cdot a)$. One then verifies easily that this construction is functorial in X' .

The isomorphisms of Proposition 3.4 are then, by construction, isomorphisms for the structures of $\mathcal{O}_{X/S}$ -objects, resp. $\mathcal{O}_{S'}$ -objects.

Remark 3.4.2. [N.D.E-II-21] The action of $\mathcal{O}_X$ on $\mathcal{T}_{X/S}(M)$ can be seen, more simply, as follows. For every $f : X' \rightarrow X$, one has

<!-- label: III.II.3.4.2 -->

```

```text
Hom_X(X', T_{X/S}(M)) = { φ ∈ Hom_S(I_{X'}(M), X) | φ ∘ ε_M = f },
```

```

and one saw in 2.1.3 that $I_{X'}(M)$, considered as S -functor, is equipped with an action of the monoid $\mathcal{O}(X')$ which preserves the zero section $\epsilon_M : X' \rightarrow I_{X'}(M)$. Consequently, if one denotes by a^* the X' -endomorphism of $I_{X'}(M)$ defined by $a \in \mathcal{O}(X')$, one has: $a\phi = \phi \circ a^*$, i.e., for every $S' \rightarrow S$ and $(m, x') \in \operatorname{Hom}_S(I_{S'}(M), I_{X'}(M) \times_S X')$,

```

```text
(aφ)(m, x') = φ(m · a(x'), x')
```

```

(note that $a^* \circ \epsilon_M = \epsilon_M$, whence $a\phi \circ \epsilon_M = \phi \circ \epsilon_M = f$).

Likewise, the action of $\mathcal{O}_S$ on $\mathcal{L}^u_{X/S}(M)$ can be described as follows. For every $t : S' \rightarrow S$, $\mathcal{L}^u_{X/S}(M)(S')$ is the set of S -morphisms $\phi : I_{S'}(M) \rightarrow X$ such that $\phi \circ \epsilon_M = u \circ t$; for such a ϕ and $a \in \mathcal{O}(S')$, one has: $a\phi = \phi \circ a^*$.

Remark 3.4.3. [N.D.E-II-21] The observations of 3.1.2 hold equally for the action of $\mathcal{O}_S$ on $\mathcal{L}^u_{X/S}(M)$ and that of $\mathcal{O}_X$ on $\mathcal{T}_{X/S}(M)$.

<!-- label: III.II.3.4.3 -->

Definition 3.5. Let S be a scheme and X an S -functor. One says that X satisfies **condition (E)** relative to S if, for every $S' \rightarrow S$ and all free $\mathcal{O}_{S'}$ -modules M and N of finite type, the diagram of sets

<!-- label: III.II.3.5 -->

```

```text
 X(I_{S'}(M ⊗ N))
 / \
X(I_{S'}(M)) X(I_{S'}(N))
 \ /
 X(S') ,
```

```

obtained by applying X to the diagram () defined in 2.1, is cartesian.* [N.D.E-II-22]

<!-- original page 52 -->

3.5.1. [N.D.E-II-23] It comes to the same thing to say that the functor $M \mapsto \mathcal{T}_{X/S}(M)$ transforms direct sums of free $\mathcal{O}_S$ -modules of finite type into products of X -functors; in this case, the same holds for the functor $M \mapsto \mathcal{L}^u_{X/S}(M) = S \times_X \mathcal{T}_{X/S}(M)$, for every $u \in \Gamma(X/S)$.

Proposition 2.2 shows that every representable functor satisfies condition (E).

Abbreviation: instead of saying " X satisfies condition (E) with respect to S ", we shall sometimes say " X/S satisfies condition (E)".

If X/S satisfies condition (E), the functor $M \mapsto \mathcal{T}_{X/S}(M)$ commutes with products and therefore transforms groups into groups. In particular $\mathcal{T}_{X/S}(M)$ is a commutative X -group. For the same reason, $\mathcal{L}^u_{X/S}(M)$ is a commutative S -group.

Proposition 3.6. If X/S satisfies (E), the abelian group structure on $\mathcal{T}_{X/S}(M)$ (resp. $\mathcal{L}^u_{X/S}(M)$) and

the action of $'0_X'$ (resp. $'0_S'$) equip $T_{X/S}(M)$ (resp. $L^u_{X/S}(M)$) with a structure of $'0_X'$ -module (resp. $'0_S'$ -module).*

<!-- label: III.II.3.6 -->

The action of $'0_X'$ (resp. $'0_S'$) is functorial in M ; it therefore respects the abelian group structure that is deduced by functoriality from that of M .^[^N.D.E-II-24] Indeed, let us resume the notations of 3.1.2. The structure of (abelian) X -group on $T_{X/S}(M)$ is defined by the composite:

$$T_{X/S}(M) \times_X T_{X/S}(M) = T_{X/S}(M \otimes M) \longrightarrow T_{X/S}(M),$$

and on the other hand the morphism

$$T_{X/S}(M) \longrightarrow T_{X/S}(M \otimes M) = T_{X/S}(M) \times_X T_{X/S}(M)$$

is the diagonal morphism. Taking into account Remark 3.4.3, one deduces from the equalities (†) of 3.1.2 that

$$\lambda(x + y) = \lambda x + \lambda y, \quad (\lambda + \mu)x = \lambda x + \mu x,$$

for every $f : X' \rightarrow X$, $x, y \in \operatorname{Hom}_X(X', T_{X/S}(M))$ and $\lambda, \mu \in 0(X')$.

Remark 3.6.1. *If X is representable, in which case it satisfies (E) and $T_{X/S}$ and $L^u_{X/S}$ are representable by vector fibrations, the preceding laws are the same as those deduced from the vector fibration structures (cf. I 4.6).^[^N.D.E-II-25]

<!-- label: III.II.3.6.1 -->

Proposition 3.4 bis. *If X/S satisfies (E), then $X_{S'}/S'$ satisfies (E) and the isomorphisms of 3.4 respect the structures of $0_{X_{S'}}$ -modules, resp. of $0_{S'}$ -modules.*

<!-- label: III.II.3.4-bis -->

Without comment.

<!-- original page 53 -->

Proposition 3.7. *The functors $T_{X/S}(M)$ and $L^u_{X/S}(M)$ are functorial in X , i.e., if $f : X \rightarrow X'$ is an S -morphism, one has commutative diagrams:*

<!-- label: III.II.3.7 -->

$$\begin{array}{ccc} T_{X/S}(M) & \xrightarrow{T(f)} & T_{X'/S'}(M) \\ \downarrow & & \downarrow \\ X & \xrightarrow{\quad} & X' \end{array}, \quad \begin{array}{ccc} L^u_{X/S}(M) & \xrightarrow{L(f)} & L^{u,f \circ u}_{X'/S'}(M) \\ \downarrow & & \downarrow \\ S & & S \end{array}.$$

Moreover,^[^N.D.E-II-26] if f is a monomorphism, so are $T(f)$ and $L(f)$.

The existence of $T(f)$ and $L(f)$, as well as the last assertion, follow immediately from the definitions. The commutativity of the diagrams then follows from the functoriality of these morphisms with respect to M and from the fact that $T_{X/S}(0) = X$.

Remark 3.7.1.^[^N.D.E-II-27] Suppose X and X' representable and let r be the rank of the free $'0_S'$ -module M . Then, by 2.2.2, $T_{X/S}(M)$ is isomorphic to the product over X of r copies of $V(\Omega^1_{X/S})$, and likewise for $T_{X'/S'}(M)$. Consequently, the above square is cartesian when f is an open immersion, more generally when $f^*(\Omega^1_{X'/S'}) = \Omega^1_{X/S}$, for example if f is étale; under these conditions, one has an isomorphism of S -functors

<!-- label: III.II.3.7.1 -->

\$\$
 $L^{\{u\}}_{\{X/S\}}(M) \xrightarrow{\sim} L^{\{f \circ u\}}_{\{X'/S\}}(M).$
 \$\$

In general, the cartesian square of 3.7 defines a morphism of $\mathcal{X}$ -functors:

```text  

$$\begin{array}{ccc} T_{\{X/S\}}(M) & \longrightarrow & T_{\{X'/S\}}(M) \times_{X'} X \\ & \searrow & \swarrow \\ & X & \end{array}$$
  
 ...

**Proposition 3.7 bis.** \*Let  $f : X \rightarrow X'$  be an  $\mathcal{S}$ -morphism; if  $\mathcal{X}$  and  $\mathcal{X}'$  satisfy (E) with respect to  $\mathcal{S}$ , then\*

<!-- label: III.II.3.7-bis -->

```text  

$$T_{\{X/S\}}(M) \xrightarrow{T(f)} T_{\{X'/S\}}(M)_X \quad \text{resp.} \quad L^u_{\{X/S\}}(M) \xrightarrow{L(f)} L^{\{f \circ u\}}_{\{X'/S\}}(M)$$

is a morphism of $\mathcal{O}_X$ -modules (resp. of $\mathcal{O}_S$ -modules).

This follows from Proposition 3.7 by functoriality in $\mathcal{M}$.

Proposition 3.8. *Let $\mathcal{X}$ and $\mathcal{Y}$ be two functors above $\mathcal{S}$. One has isomorphisms functorial in $\mathcal{M}$:

<!-- label: III.II.3.8 -->

```text  
 (3.8.1)  $T_{\{X/S\}}(M) \times_S T_{\{Y/S\}}(M) \cong T_{\{(X \times_S Y)/S\}}(M),$   
 (3.8.2)  $L^u_{\{X/S\}}(M) \times_S L^v_{\{Y/S\}}(M) \cong L^{\{(u,v)\}}_{\{(X \times_S Y)/S\}}(M).$   
 ...

[^N.D.E-II-28] The first isomorphism follows from 1.2 (\*); the second is deduced from it by the base change  $(u, v) : S \rightarrow X \times_S Y$ .

**Remark 3.8.0.** Note that (3.8.1) can also be interpreted as an isomorphism of  $\mathcal{X} \times_S \mathcal{Y}$ -functors

<!-- label: III.II.3.8.0 -->

```text  

$$T_{\{X/S\}}(M) \times_X (X \times_S Y) \times T_{\{Y/S\}}(M) \times_Y (X \times_S Y) \cong T_{\{(X \times_S Y)/S\}}(M).$$

 ...

Corollary 3.8.1. *If $\mathcal{X}/\mathcal{S}$ is equipped with an algebraic structure defined by finite cartesian products, then $T_{\{X/S\}}(M)$ is equipped with a structure of the same kind and the projection $T_{\{X/S\}}(M) \rightarrow X$ is a morphism of this kind of structure.*

<!-- label: III.II.3.8.1 -->

Proposition 3.8 bis. *If $\mathcal{X}/\mathcal{S}$ and $\mathcal{Y}/\mathcal{S}$ satisfy (E), then $(\mathcal{X} \times_S \mathcal{Y})/S$ satisfies (E) and (3.8.1) (resp. (3.8.2)) is an isomorphism of $\mathcal{O}_{\mathcal{X} \times_S \mathcal{Y}}$ -modules (resp. $\mathcal{O}_S$ -modules).*

<!-- label: III.II.3.8-bis -->

Proof. [^N.D.E-II-29] Suppose that $\mathcal{X}/\mathcal{S}$ and $\mathcal{Y}/\mathcal{S}$ satisfy (E). Then, by 3.5.1 and (3.8.1), so does $(\mathcal{X} \times_S \mathcal{Y})/S$. Let us show that (3.8.1) is an isomorphism of $\mathcal{O}_{\mathcal{X} \times_S \mathcal{Y}}$ -modules.

<!-- original page 62 -->

Let $(x, y) : Z \rightarrow X \times_S Y$ be an S -morphism; taking into account 3.4.2, it suffices to see that the map

```

```text
{ $\varphi \in \text{Hom}_S(I_Z(M), X) \mid \varphi \circ \varepsilon_M = x \}$ $\times$ $\{ \psi \in \text{Hom}_S(I_Z(M), Y) \mid \psi \circ \varepsilon_M = y \}$
 $\rightarrow \{ \theta \in \text{Hom}_S(I_Z(M), X \times_S Y) \mid \theta \circ \varepsilon_M = (x, y) \}$
...

```

which to  $(\varphi, \psi)$  associates  $\varphi \times \psi$  is a morphism of  $0(Z)$ -modules. But this is clear, because if  $a \in 0(Z)$  then  $a \cdot (\varphi, \psi) = (\varphi \circ a^*, \psi \circ a^*)$  is sent to

```

```text
 $(\varphi \circ a^*) \times (\psi \circ a^*) = (\varphi \times \psi) \circ a^* = a \cdot (\varphi \times \psi).$ 
...

```

Likewise, using 3.2.1, one shows that (3.8.2) is an isomorphism of 0_S -modules.

3.9.0. If X is an S -group and if $e : S \rightarrow X$ denotes its unit section, one writes:

```

$$
\text{Lie}(X/S, M) = L^e_{X/S}(M),
$$

```

i.e., $\text{Lie}(X/S, M)$ is defined by the cartesian square:

```

```text
 Lie(X/S, M) $\xrightarrow{\quad i \quad}$ T_{X/S}(M)
 | | |
 | | | p
 v | v
 S $\xrightarrow{\quad e \quad}$ X .
...

```

By Corollary 3.8.1, the projection  $p : T_{X/S}(M) \rightarrow X$  is a morphism of  $S$ -groups, and it follows that  $\text{Lie}(X/S, M)$  is equipped with a structure of  $S$ -group, and is isomorphic via  $i$  to the kernel of  $p$ .

If, moreover,  $X/S$  satisfies condition (E), we shall see in Proposition 3.9 that the  $S$ -group structure on  $\text{Lie}(X/S, M)$ , induced by that of  $X$ , coincides with the abelian group structure induced by functoriality in  $M$  (cf. 3.5.1). In fact, this result is valid under the weaker hypothesis that  $X$  be an  $S$ -functor of monoids or, more generally, an  $S$ -functor of  $H$ -sets (cf. the definition below).

**Definitions 3.9.0.1.** a) Let us introduce the following terminology: **an  $H$ -set** is a set  $X$  equipped with a composition law with two-sided unit, denoted  $e_X$  or simply  $e$ . If  $f : X \rightarrow Y$  is a morphism of  $H$ -sets, its kernel  $\text{Ker } f$  is  $f^{-1}(e_Y)$ ; it is a sub- $H$ -set of  $X$ .

**III.II.3.9.0.1**

b) An  **$H$ -object** in a category  $\mathcal{C}$  is defined in the usual manner: it is therefore an object  $X$  of  $\mathcal{C}$ , equipped with a morphism  $X \times X \rightarrow X$  such that there exists a section of  $X$  (above the final object) possessing the properties of a two-sided unit. Every  $\mathcal{C}$ -monoid, in particular every  $\mathcal{C}$ -group, is therefore a  $\mathcal{C}$ - $H$ -object. In particular, an  $H$ -object of the category of functors above the scheme  $S$  will be called an  **$S$ - $H$ -functor**.

c) If  $X$  is an  $S$ - $H$ -functor (for example, an  $S$ -group), and if  $e : S \rightarrow X$  denotes the unit section of  $X$ , one writes:

```

```text
Lie(X/S, M) = L^e_{X/S}(M)    and    Lie(X/S) = Lie(X/S, 0_S).
...

```

Let us make explicit the following particular case of 3.8.1.

Corollary 3.9.0.2. If X is an S - H -functor (resp. an S -group), then $T_{X/S}(M)$ and $\text{Lie}(X/S, M)$ are also S - H -functors (resp. S -groups), and one has morphisms of S - H -functors (resp. of S -groups):

III.II.3.9.0.2

```

```text
 i
Lie(X/S, M) —————> T_{X/S}(M) $\overset{p}{\neq} X$,
 s
```

```

where i is an isomorphism of $\text{Lie}(X/S)(M)$ onto $\text{Ker } p$ and s is a section of p .

<!-- original page 55 -->

Proposition 3.9. *Let X be an S - H -functor satisfying (E) with respect to S . The S - H -functor structure of $\text{Lie}(X/S, M)$ coming from that of X coincides with the S -group structure defined in 3.5.1.*

<!-- label: III.II.3.9 -->

It follows from what was said above that $\text{Lie}(X/S, M)$ is an H -object in the category of $_0 S$ -modules. The proposition will then follow from the following lemma: [N.D.E-II-33]

Lemma 3.10. *Let C be a category. Let G be an H -object in the category of C - H -objects; G is therefore a C - H -object (whose composition law we shall denote $f : G \times G \rightarrow G$) equipped with a morphism of C - H -objects $h : G \times G \rightarrow G$. [N.D.E-II-34] *Then $f = h$ and f is commutative.*

<!-- label: III.II.3.10 -->

By taking the values of the functors on a variable argument, one reduces, in the usual manner, to verifying the lemma when C is the category of sets. One thus has a set G and two maps $f, h : G \times G \rightarrow G$ such that

```

```text
h(f(x, y), f(z, t)) = f(h(x, z), h(y, t)).
```

```

One has on the other hand two elements of G , namely e and u , with $f(e, x) = f(x, e) = x$, $h(u, x) = h(x, u) = x$. One sees first that

```

```text
h(f(u, y), f(x, u)) = f(x, y) = h(f(x, u), f(u, y)).
```

```

In particular, for $y = e$, resp. $x = e$, one obtains, respectively,

```

```text
x = f(x, e) = h(f(u, e), f(x, u)) = h(u, f(x, u)) = f(x, u),
y = f(e, y) = h(f(e, u), f(u, y)) = h(u, f(u, y)) = f(u, y),
```

```

whence, on substituting in the original equality,

```

```text
h(y, x) = f(x, y) = h(x, y).
```

```

This proves the lemma, and thus Proposition 3.9. From 3.9 one then deduces the following corollaries.

Corollary 3.9.1. *If X is an S - H -functor satisfying (E) with respect to S , every element of $X(I_{\{S\}}(M))$ which projects onto the unit element of $X(S)$ is invertible.*

<!-- label: III.II.3.9.1 -->

Corollary 3.9.2. *If X is an S -monoid satisfying (E) with respect to S , an element of $X(I_{\{S\}}(M))$ is invertible if and only if its image in $X(S)$ is.*

<!-- label: III.II.3.9.2 -->

<!-- original page 56 -->

****Corollary 3.9.3.**** *If X is an S -group satisfying (E) with respect to S , the two S -group laws on $\text{Lie}(X/S, M)$ coincide.*

<!-- label: III.II.3.9.3 -->

****Corollary 3.9.4.**** [^{N.D.E-II-35}] *Let G be an S -group satisfying (E) with respect to S . For $n \in \mathbb{Z}$, let $n_{\{G\}} : G \rightarrow G$ be the morphism of S -functors defined by $g \mapsto g^n$. Then the derived morphism $L(n_{\{G\}}) : \text{Lie}(G/S) \rightarrow \text{Lie}(G/S)$ is "multiplication by n ", i.e. the map that to every $x \in \text{Lie}(G/S)(S')$ associates $n \cdot x$.*

<!-- label: III.II.3.9.4 -->

Let us first remark that $n_{\{G\}}$ is not in general a morphism of groups, but it preserves the unit section $e : S \rightarrow G$, so the derived morphism $L(n_{\{G\}})$ indeed sends $\text{Lie}(G/S) = L^{\{e\}}(X/S)$ into itself. If one denotes by i the inclusion $\text{Lie}(G/S) \hookrightarrow T_{\{G/S\}}$, then $L(n_{\{G\}})$ is defined by the equality $i(L(n_{\{G\}})(x)) = i(x)^n$, for every $S' \rightarrow S$ and $x \in \text{Lie}(G/S)(S')$. Now, by 3.9, the two group laws on $\text{Lie}(G/S)$ (coming from condition (E) and coming from the law of G) coincide, i.e. one has $i(x)^n = i(n \cdot x)$, whence $L(n_{\{G\}})(x) = n \cdot x$.

Before drawing other consequences of Proposition 3.9, let us prove another functoriality result:

****Proposition 3.11.**** *In the situation of Section 1, one has an isomorphism functorial in M .*

<!-- label: III.II.3.11 -->

$$T_{\{\text{Hom}_{\{Z/S\}}(X, Y)/S\}}(M) \xrightarrow{\sim} \text{Hom}_{\{Z/S\}}(X, T_{\{Y/Z\}}(M)).$$

Indeed, by definition (cf. 3.1):

$$T_{\{\text{Hom}_{\{Z/S\}}(X, Y)/S\}}(M) = \text{Hom}_S(I_S(M), \text{Hom}_{\{Z/S\}}(X, Y)).$$

By the isomorphism (4) of 1.1, applied to $T = I_S(M)$, one has:

$$\text{Hom}_S(I_S(M), \text{Hom}_{\{Z/S\}}(X, Y)) \simeq \text{Hom}_{\{Z/S\}}(X, \text{Hom}_Z(Z \times_S I_S(M), Y)).$$

Taking into account the isomorphism $Z \times_S I_S(M) \simeq I_Z(M)$, this gives

$$T_{\{\text{Hom}_{\{Z/S\}}(X, Y)/S\}}(M) \simeq \text{Hom}_{\{Z/S\}}(X, \text{Hom}_Z(I_Z(M), Y)) = \text{Hom}_{\{Z/S\}}(X, T_{\{Y/Z\}}(M)).$$

****Corollary 3.11.1.**** *If Y/Z satisfies (E), then $\text{Hom}_{\{Z/S\}}(X, Y)/S$ satisfies (E) and the isomorphism of 3.11 respects the S -module structures above $\text{Hom}_{\{Z/S\}}(X, Y)$.* [^{N.D.E-II-36}]

<!-- label: III.II.3.11.1 -->

Proof. Let M, N be two free S -modules of finite type. If Y/Z satisfies (E), then

$$T_{\{Y/Z\}}(M \otimes N) = T_{\{Y/Z\}}(M) \times_Y T_{\{Y/Z\}}(N).$$

The right-hand term is a subfunctor of $T_{\{Y/Z\}}(M) \times_S T_{\{Y/Z\}}(N)$ and via the isomorphism of 1.2 (*), one obtains an isomorphism

$$\text{Hom}_{\{Z/S\}}(X, T_{\{Y/Z\}}(M \otimes N)) \simeq \text{Hom}_{\{Z/S\}}(X, T_{\{Y/Z\}}(M)) \times_{\{\text{Hom}_{\{Z/S\}}(X, Y)\}} \text{Hom}_{\{Z/S\}}(X, T_{\{Y/Z\}}(N)).$$

...

Combined with 3.11, this implies:

```

```text
T_{Hom_{Z/S}(X,Y)/S}(M \otimes N) \simeq
... T_{Hom_{Z/S}(X,Y)/S}(M) \times_{Hom_{Z/S}(X,Y)} T_{Hom_{Z/S}(X,Y)/S}(N),

```

so  $\operatorname{Hom}_{Z/S}(X, Y)$  satisfies (E) with respect to  $S$ . This proves the first assertion of the corollary.

Let us see the second. Denote by  $H = \operatorname{Hom}_{Z/S}(X, Y)$  and give ourselves an  $S$ -morphism  $\Delta : H' \rightarrow \operatorname{Hom}_{Z/S}(X, Y)$ , i.e., a  $Z$ -morphism  $\delta : H' \times_S X \rightarrow Y$ , which therefore makes  $H' \times_S X$  a  $Y$ -object.

On the one hand, one has a commutative diagram:

```

```text
Hom_H(H', Hom_{Z/S}(X, T_{Y/Z}(M))) \longrightarrow Hom_S(H', Hom_{Z/S}(X, T_{Y/Z}(M)))
Hom_Y(H' \times_S X, T_{Y/Z}(M)) \longrightarrow Hom_Z(H' \times_S X, T_{Y/Z}(M))
... { \psi \in Hom_Z(I_{H' \times_S X}(M), Y) \mid \psi \circ \varepsilon_M = \delta } \longrightarrow Hom_Z(I_{H' \times_S X}(M), Y) .

```

By 1.3, the action of $\alpha \in O(H' \times_S X)$ on $\Psi \in \operatorname{Hom}_{Y/Z}(H' \times_S X, T_{Y/Z}(M))$ is given by: for every $U \rightarrow S$ and $(h, x) \in \operatorname{Hom}_{Z/S}(U, H' \times_S X)$ (U being then above Y via $\delta \circ \text{circ}(h, x)$),

```

```text
(\alpha\Psi)(h, x) = \alpha(h, x) \Psi(h, x),
...

```

where  $\alpha(h, x) \in O(U)$  acts on  $\Psi(h, x) \in T_{Y/Z}(M)(U)$  via the structure of  $O_Y$ -module of  $T_{Y/Z}(M)$ . By 3.4.2, this last is given, via the identification

```

```text
Hom_Y(H' \times_S X, T_{Y/Z}(M)) = { \psi \in Hom_Z(I_{H' \times_S X}(M), Y) \mid \psi \circ \varepsilon_M = \delta },
...

```

by: for every $(m, h, x) \in \operatorname{Hom}_{Z/S}(U, I_S(M) \times_S H' \times_S X)$,

```

```text
(1) (\alpha\psi)(m, h, x) = \psi(m \cdot \alpha(h, x), h, x).
...

```

<!-- original page 66 -->

On the other hand, consider the tangent space  $T_{H/S}(M) = \operatorname{Hom}_{Z/S}(I_S(M), H)$ ; one has a commutative diagram:

```

```text
Hom_H(H', T_{H/S}(M)) \longrightarrow Hom_S(H', T_{H/S}(M))
{ \Phi \in Hom_S(I_{H'}(M), H) \mid \Phi \circ \varepsilon_M = \Delta } \longrightarrow Hom_S(I_{H'}(M), H)
... { \varphi \in Hom_Z(I_{H' \times_S X}(M), Y) \mid \varphi \circ \varepsilon_M = \delta } \longrightarrow Hom_Z(I_{H' \times_S X}(M), Y) ,

```

where the bijection (*) is given as follows (cf. 1.1 (2) and I 1.7.1): for every $U \rightarrow S$ and $(m, h, x) \in \operatorname{Hom}_{Z/S}(U, I_S(M) \times_S H' \times_S X)$ (so that U is above Z via $U \rightarrow X \rightarrow Z$), one has $\Phi(m, h) \in \operatorname{Hom}_{Z/S}(X \times_S U, Y)$ and

```

```text
(\dagger) \varphi(m, h, x) = \Phi(m, h) \circ (x \times \text{id}_U) \in Hom_Z(U, Y).

```

...

By 3.4.2 (where one replaces  $X$  by  $\operatorname{Hom}_{Z/S}(X, Y)$  and  $X'$  by  $H'$ ), the action of  $a \in O(H')$  on  $\Phi \in \operatorname{Hom}_S(I_{H'}(M), H)$  is given by: for every  $U \rightarrow S$  and  $(m, h) \in \operatorname{Hom}_S(U, I_S(M) \times_S H')$ ,

```
```text
(aΦ)(m, h) = Φ(m · a(h), h).
```
```

Consequently, if  $\phi$  (resp.  $a\phi$ ) is the element of  $\operatorname{Hom}_{Z/I_{H'} \times_S X}(M, Y)$  associated with  $\Phi$  (resp.  $a\Phi$ ), one has, by (†),

```
```text
(2) (aφ)(m, h, x) = Φ(m · a(h), h) ◦ (x × id_U) = φ(m · a(h), h, x).
```
```

Combined with (1), this shows that the isomorphism  $T_{H/S}(M) \xrightarrow{\sim} \operatorname{Hom}_{Z/S}(X, T_{Y/Z}(M))$  of 3.11.1 is an isomorphism of  $O(H)$ -modules; moreover, for every  $H' \rightarrow H$ , the structure of  $O(H')$ -module on  $\operatorname{Hom}_H(H', T_{H/S}(M))$  extends, in a manner functorial in  $H'$ , to a structure of  $O(H' \times_S X)$ -module.

In particular, for  $Z = S$ , one obtains the following corollary.

**Corollary 3.11.2.** One has an isomorphism functorial in  $M$ :

!-- label: III.II.3.11.2 -->

```
$$
T_{\operatorname{Hom}_S(X,Y)/S}(M) \xrightarrow{\sim} \operatorname{Hom}_S(X, T_{Y/S}(M)).
$$
```

Moreover, if  $Y/S$  satisfies (E), then  $\operatorname{Hom}_S(X, Y)/S$  satisfies (E) and the preceding isomorphism respects the  $O_S$ -module structures above  $\operatorname{Hom}_S(X, Y)$ .

[^N.D.E-II-37] Let  $u : X \rightarrow Y$  be an  $S$ -morphism; one identifies it with the constant morphism  $u : S \rightarrow \operatorname{Hom}_S(X, Y)$  such that  $u(f) = u$  for every  $f : S' \rightarrow S$ . One sees at once that the fiber product of  $u$  and of  $\operatorname{Hom}_S(X, T_{Y/S}(M)) \rightarrow \operatorname{Hom}_S(X, Y)$  is identified with  $\operatorname{Hom}_S(Y/S, X, T_{Y/S}(M))$ , where  $X$  is above  $Y$  via  $u$ . Consequently, from the definition of  $L^u_{\operatorname{Hom}_S(X,Y)/S}(M)$  and the preceding corollary one deduces:

**Corollary 3.11.3.** Let  $u : X \rightarrow Y$  be an  $S$ -morphism. One has an isomorphism functorial in  $M$  (where in the right-hand term  $X$  is above  $Y$  via  $u$ ):

!-- label: III.II.3.11.3 -->

```
$$
L^u_{\operatorname{Hom}_S(X,Y)/S}(M) \xrightarrow{\sim} \operatorname{Hom}_{Y/S}(X, T_{Y/S}(M)).
$$
```

[^N.D.E-II-38] It is an isomorphism of  $O_S$ -modules if  $Y/S$  satisfies (E).

In particular, for  $Y = X$ ,  $\operatorname{End}_S(X)$  is an  $S$ -functor of monoids, hence a fortiori an  $S$ - $H$ -functor; recalling that  $\operatorname{Lie}(\operatorname{End}_S(X)/S, M)$  denotes  $L^e_{\operatorname{End}_S(X)/S}(M)$ , where  $e$  is the unit section (cf. 3.9.0.1), one obtains:

**Corollary 3.11.4.** One has an isomorphism functorial in  $M$ :

!-- label: III.II.3.11.4 -->

!-- original page 57 -->

```
```text
Lie(End_S(X)/S, M) ≅ L_{X/S} T_{X/S}(M);
```
```

[^N.D.E-II-38] \*it is an isomorphism of  $0_S$ -modules if  $X/S$  satisfies (E).\*

**Remark 3.11.5.** [^N.D.E-II-39] Suppose that  $X/S$  satisfies (E). Then  $\prod_{X/S} T_{X/S}(M) = \operatorname{Hom}_{X/S}(X, T_{X/S}(M))$  is equipped with a structure of  $(\prod_{X/S} 0_X)$ -module, i.e. for every  $S' \rightarrow S$ ,

<!-- label: III.II.3.11.5 -->

```

$$\operatorname{Hom}_{X/S}(X, T_{X/S}(M))(S') = \{ \psi \in \operatorname{Hom}_X(I_{S'}(M) \times_S X, X) \mid \psi \circ (\epsilon_M \times \operatorname{id}_X) = \operatorname{pr}_X \}$$

```

is equipped with a structure of  $0(X \times_S S')$ -module, functorial in  $S'$ . This follows, at one's choice, from 3.6 and the properties of the functor  $\prod_{X/S}$  (cf. 1.2), or from the proof of 3.11.1.

We shall now interpret geometrically the definition of the tangent bundle.

[^N.D.E-II-40] Let  $U$  be an  $S$ -functor; by I 1.7.2, one has isomorphisms functorial in  $M$

```

$$T_{X/S}(U) = \operatorname{Hom}_S(U, \operatorname{Hom}_S(I_S(M), X)) = \operatorname{Hom}_S(I_S(M), \operatorname{Hom}_S(U, X)) \\ = \operatorname{Hom}_{\{I_S(M)\}(U_{I_S(M)}, X_{I_S(M)})}.$$

```

In particular, the morphism  $M \rightarrow 0$  gives a commutative diagram:

```

$$\begin{array}{ccc} \operatorname{Hom}_S(U, T_{X/S}(M)) & \square & \operatorname{Hom}_{\{I_S(M)\}(U_{I_S(M)}, X_{I_S(M)})} \\ \downarrow \pi_M & & \downarrow \text{identity} \\ \operatorname{Hom}_S(U, X) & \longrightarrow & \operatorname{Hom}_S(U, X) \end{array}$$

```

where the second vertical arrow is obtained by the base change  $\epsilon_M : S \rightarrow I_S(M)$ . [^N.D.E-II-41]

In consequence:

**Proposition 3.12.** \*Let  $h_0 : U \rightarrow X$  be an  $S$ -morphism. Then  $\operatorname{Hom}_X(U, T_{X/S}(M))$  is identified with the set of  $I_S(M)$ -morphisms from  $U_{I_S(M)}$  to  $X_{I_S(M)}$  which restrict to  $h_0$  on  $U$  (viewed as a subobject of  $U \times_S I_S(M)$  via  $\operatorname{id}_U \times \epsilon_M$ ).

<!-- label: III.II.3.12 -->

[^N.D.E-II-42] In particular, for  $U = X$  and  $h_0 = \operatorname{id}_X$ , one obtains the

**Corollary 3.12.1.** \*The set  $\Gamma(T_{X/S}(M)/X)$  is identified with the set of  $I_S(M)$ -endomorphisms  $\phi$  of  $X_{I_S(M)}$  which induce the identity on  $X$ , i.e. such that the following diagram be commutative: [^N.D.E-II-43]

<!-- label: III.II.3.12.1 -->

```

$$\begin{array}{ccc} I_X(M) & \xrightarrow{\phi} & I_X(M) \\ \uparrow \epsilon_M & & \uparrow \epsilon_M \\ X & \xrightarrow{\operatorname{id}} & X \end{array}$$

```

<!-- original page 58 -->

[^N.D.E-II-44] On the other hand, by 3.11.2,  $\Gamma(T_{X/S}(M)/X) \simeq \operatorname{Lie}(\operatorname{End}_S(X/S, M)(S))$ ; if moreover  $X/S$  satisfies (E), then  $\operatorname{End}_S(X/S)$  satisfies (E), so  $\operatorname{Lie}(\operatorname{End}_S(X/S, M))$

is an  $'0_S$ -module by 3.6 (and in fact a  $(\prod_{X/S} 0_X)$ -module, by 3.11.5). Applying 3.9, one deduces the

**Proposition 3.13.** *If  $X/S$  satisfies (E), the abelian group  $\Gamma(T_{X/S}(M)/X)$  is identified with the set of  $I_S(M)$ -endomorphisms of  $X_{I_S(M)}$  inducing the identity on  $X$ . Consequently, every  $I_S(M)$ -endomorphism of  $X_{I_S(M)}$  which induces the identity on  $X$  is an automorphism.*

<!-- label: III.II.3.13 -->

**Corollary 3.13.1.** *Let  $u : X \rightarrow Y$  be an  $S$ -isomorphism,  $Y/S$  satisfying (E). Every  $I_S(M)$ -morphism from  $X_{I_S(M)}$  into  $Y_{I_S(M)}$  which extends  $u$  is an isomorphism.*

<!-- label: III.II.3.13.1 -->

**Corollary 3.13.2.** *If  $Y/S$  satisfies (E), then the monomorphism  $\text{Isom}_S(X, Y) \rightarrow \text{Hom}_S(X, Y)$  induces, for every  $u \in \text{Isom}_S(X, Y)$ , an isomorphism*

<!-- label: III.II.3.13.2 -->

$$L^u_{\text{Isom}_S(X, Y)/S}(M) \xrightarrow{\sim} L^u_{\text{Hom}_S(X, Y)/S}(M).$$

**Proof.** [N.D.E-II-45] One must see that  $L^u_{\text{Isom}_S(X, Y)/S}(M)(S') \rightarrow L^u_{\text{Hom}_S(X, Y)/S}(M)(S')$  is a bijection, for every  $S' \rightarrow S$ . By base change (cf. 3.4), it suffices to do it for  $S' = S$ . In this case,  $L^u_{\text{Hom}_S(X, Y)/S}(M)(S)$  (resp.  $L^u_{\text{Isom}_S(X, Y)/S}(M)(S)$ ) is the set of  $I_S(M)$ -morphisms (resp. automorphisms)  $X_{I_S(M)} \rightarrow Y_{I_S(M)}$  which extend  $u$ , and one applies the preceding corollary.

<!-- original page 69 -->

**Corollary 3.13.3.** *If  $X/S$  satisfies (E), the monomorphism  $\text{Aut}_S(X) \rightarrow \text{End}_S(X)$  induces, for every  $u \in \text{Aut}_S(X)$ , an isomorphism  $L^u_{\text{Aut}_S(X)/S}(M) \xrightarrow{\sim} L^u_{\text{End}_S(X)/S}(M)$ . In particular, one has*

<!-- label: III.II.3.13.3 -->

$$\text{Lie}(\text{Aut}_S(X)/S, M) \cong \text{Lie}(\text{End}_S(X)/S, M) \cong \prod_{X/S} T_{X/S}(M),$$

[N.D.E-II-46] *so that  $\text{Lie}(\text{Aut}_S(X)/S, M)$  is equipped with a structure of  $(\prod_{X/S} 0_X)$ -module.*

**3.14.** Suppose to conclude that  $X$  is representable. [N.D.E-II-47] In this case, one saw in 2.2.2 that the  $X$ -functor  $T_X/S$  is representable by  $V(\Omega^1_{X/S})$ , whence bijections:

$$\Gamma(T_X/S/X) \cong \text{Hom}_X(\Omega^1_{X/S}, 0_X) \cong \text{Dér}_{0_S}(0_X).$$

This is also deduced from what precedes, as follows. By 3.13,  $\Gamma(T_{X/S}/X)$  is identified with the set of infinitesimal endomorphisms of  $X$  (i.e. of  $I_S$ -endomorphisms of  $X_{I_S}$  inducing the identity on  $X$ ). Now  $X$  and  $X_{I_S}$  have the same underlying topological space, the corresponding rings of sheaves being  $'0_X$  and  $D_{0_X} = 0_X \oplus M$ , where  $M = 0_X$  is considered as ideal of square zero. Denoting by  $\pi : D_{0_X} \rightarrow 0_X$  the morphism of  $'0_X$ -algebras that vanishes on  $M$ , one deduces that to give an infinitesimal endomorphism of  $X$  is equivalent to giving a morphism of  $'0_S$ -algebras  $\phi : 0_X \rightarrow D_{0_X}$  such that  $\pi \circ \phi = \text{id}_{0_X}$ , which is equivalent to giving an  $'0_S$ -derivation of the sheaf of rings  $'0_X$ .

Moreover, one sees easily that if  $D, D' \in \text{Dér}_{0_S}(0_X)$  and if one denotes by  $\phi_D$  the infinitesimal endomorphism corresponding to  $D$ , then

$$\phi_{D+D'} = \phi_D \circ \phi_{D'}.$$

This shows that the identification

```
```text
{ infinitesimal endomorphisms of X } = Dér_{0_S}(0_X)
```

is an isomorphism of abelian groups. Taking into account 3.13 (and 3.11.5), one has therefore constructed an isomorphism of abelian groups (and even of $\mathcal{O}(X)$ -modules)

<!-- original page 59 -->

```
$$
\Gamma(T_{X/S}/X) \xrightarrow{\sim} D\acute{e}r_{0_S}(0_X),
$$
```

which recovers the classical interpretation of tangent vector fields in terms of derivations of the structure sheaf. [N.D.E-II-48] Let us remark in passing that $\Gamma(T_{X/S}/X)$ is equal to $H^0(X, g_{X/S})$, where $g_{X/S}$ is the dual of $\Omega^1_{X/S}$.

4. Tangent space to a group – Lie algebras

<!-- label: III.II.4 -->

4.1. Let G be a group-functor above S . By 3.9.0.2, $T_{G/S}(M)$ and $\text{Lie}(G/S, M)$ are equipped with structures of groups above S and one has morphisms of groups

```
```text
 i
Lie(G/S, M) -----> T_{G/S}(M) \cong G ;
 s
...
```
```

by definition i is an isomorphism of $\text{Lie}(G/S)(M)$ onto the kernel of p and s is a section of p . It then follows from I 2.3.7 that this sequence of morphisms allows one to identify $T_{G/S}(M)$ with the semi-direct product of G by $\text{Lie}(G/S, M)$.

Definition 4.1.A. [N.D.E-II-49] The corresponding action of G on $\text{Lie}(G/S, M)$ is denoted*

<!-- label: III.II.4.1.A -->

```
```text
Ad : G \rightarrow \text{Aut}_{S\text{-gr.}}(\text{Lie}(G/S, M))
...
```
```

and called the **adjoint representation** (relative to M) of G ; one has therefore by definition, for $x \in G(S')$ and $X \in \text{Lie}(G/S, M)(S')$:

```
```text
Ad(x) X = i^{-1}(s(x) i(X) s(x)^{-1}).
...
```
```

If G is commutative, then $T_{G/S}(M)$ is also commutative and $\text{Ad}(x) X = X$.

Definition 4.1.B. [N.D.E-II-49] If G and H are two group-functors above S and if $f : G \rightarrow H$ is a morphism of groups, by functoriality there is deduced a morphism of exact sequences compatible with the canonical sections:*

<!-- label: III.II.4.1.B -->

```
```text
1 \rightarrow \text{Lie}(G/S, M) \rightarrow T_{G/S}(M) \rightarrow G \rightarrow 1
 | L(f) | T(f) | f
 v v v
1 \rightarrow \text{Lie}(H/S, M) \rightarrow T_{H/S}(M) \rightarrow H \rightarrow 1 ;
...
```
```

<!-- original page 60 -->

* $L(f)$, which we shall also write $\text{Lie}(f)$, is the* **derived morphism** *of f .*[^{N.D.E-II-50}]

Remark 4.1.C.[^{N.D.E-II-51}] *If G/S and H/S satisfy (E), then $L(f)$ respects the 0_S -module structures deduced from "functoriality in M " (cf. 3.6).*

<!-- label: III.II.4.1.C -->

Proposition 4.1.1. *Let $g \in G(S)$. Then $\text{Ad}(g) : \text{Lie}(G/S, M) \rightarrow \text{Lie}(G/S, M)$ is the derived morphism of $\text{Int}(g) : G \rightarrow G$.*

<!-- label: III.II.4.1.1 -->

Indeed $\text{Ad}(g) X = i^{-1}(\text{Int}(g) i(X))$, which is nothing other than $L(\text{Int}(g))(X)$ by the very definition of the derived morphism.

Suppose that G/S satisfies (E). Then, by Proposition 3.9, the group structure on $\text{Lie}(G/S, M)$ defined as above is nothing other than the structure induced by its 0_S -module structure (defined thanks to (E)). One then deduces from the preceding proposition and the functoriality of the action of 0_S (cf. 3.6) the corollary:

Corollary 4.1.1.1. *Suppose that G/S satisfies (E). Then Ad sends G into the subgroup*

<!-- label: III.II.4.1.1.1 -->

``text
 $\text{Aut}_{0_S\text{-mod.}}(\text{Lie}(G/S, M))$
 ```

\*of  $\text{Aut}_{S\text{-gr.}}(\text{Lie}(G/S, M))$ , i.e., for every  $g \in G(S')$ ,  $\text{Ad}(g)$  respects the  $0_{S'}$ -module structure of  $\text{Lie}(G'/S', M)$  (where  $G' = G \times_S S'$ ). In other words,  $\text{Ad}$  is a **linear representation** (cf. I, 3.2) of  $G$  in the  $0_S$ -module  $\text{Lie}(G/S, M)$ .\*

**Remarks 4.1.1.2.** \*a) For  $G/S$  to satisfy (E), it is necessary and sufficient that for every pair  $(M, N)$  of free  $0_S$ -modules of finite type, the diagram\*

<!-- label: III.II.4.1.1.2 -->

``text  

$$\begin{array}{ccc} & \text{Lie}(G/S, M \otimes N) & \\ \swarrow & & \searrow \\ \text{Lie}(G/S, M) & & \text{Lie}(G/S, N) \\ \searrow & & \swarrow \\ & \text{Lie}(G/S, 0) = S & \end{array}$$
  
 ```

obtained by applying the functor $\text{Lie}(G/S, -)$ to the diagram () of 2.1, be cartesian.*

b) Suppose that G/S satisfies (E). Then the derived morphism of the group law $\pi : G \times_S G \rightarrow G$ is nothing other than the addition law in $\text{Lie}(G/S, M)$. (N.B. π is not a morphism of groups, but $\pi(e, e) = e$, so the derived morphism $L(\pi)$ sends $T^{\wedge}\{(e, e)\}_{(G \times_S G)/S}(M) = \text{Lie}(G/S, M) \times_S \text{Lie}(G/S, M)$ into $\text{Lie}(G/S, M)$, cf. 3.7 and 3.8.) For every $n \in \mathbb{Z}$, one shows likewise that if one denotes by $\eta_n : G \rightarrow G$ the morphism of S -functors defined by $g \mapsto g^n$, then the derived morphism $L(\eta_n)$ is multiplication by n on $\text{Lie}(G/S)$, cf. 3.9.4.

<!-- original page 61 -->

4.1.2.0.[^{N.D.E-II-52}] Consider now the S -functor $\text{Hom}_{G/S}(G, T_{G/S}(M))$; for every $S' \rightarrow S$, one has $T_{G/S}(M)_{S'} \simeq T_{G/S'}(M)$ (cf. 3.4) and therefore:

``text
 $\text{Hom}_{G/S}(G, T_{G/S}(M))(S') \simeq \text{Hom}_{G/S'}(G_{S'}, T_{G/S'}(M)) = \Gamma(T_{G/S'}(M)/G_{S'})$.
 ```

One then obtains the:

**Proposition 4.1.2.** [II-4-1] \*The map  $\text{Lie}(G/S, M)(S) \rightarrow \Gamma(T_{G/S}(M)/G)$  which to  $X \in \text{Lie}(G/S, M)(S)$  associates the section  $x \mapsto X \cdot x$  is a bijection of  $\text{Lie}(G/S, M)(S)$  onto the part of  $\Gamma(T_{G/S}(M)/G)$  formed by the sections invariant under right translation.\*

<!-- label: III.II.4.1.2 -->

<!-- original page 73 -->

Likewise, one makes  $G$  act on the right on  $\text{Hom}_{G/S}(T_{G/S}(M)/G, T_{G/S}(M)/G)$  as follows: for every  $S' \rightarrow S$ ,  $x \in G(S')$  and  $u \in \text{Hom}_{G/S}(T_{G/S}(M)/G, T_{G/S}(M)/G)(S') = \text{Hom}_{G/S}(T_{G/S}(M)/G, T_{G/S}(M)/G)(S')$ ,

text  
 $(u \cdot x)(g) = u(g \cdot x^{-1}) \cdot x,$

for every  $g \in G(S')$ ,  $S' \rightarrow I_{S'}(M)$ . Then the morphism of 3.12.1

$\text{Hom}_{G/S}(G, T_{G/S}(M)) \rightarrow \text{Hom}_{G/S}(T_{G/S}(M)/G, T_{G/S}(M)/G)$

respects the actions of  $G$  and therefore induces, for every  $S' \rightarrow S$ , a bijection between  $\Gamma(T_{G/S}(M)/G)(S')$  and the set of  $I_{S'}(M)$ -endomorphisms  $u$  of  $T_{G/S}(M)(S')$  which induce the identity on  $G$  and "commute with right translations", i.e. which verify  $u_{S'} \cdot x = u_{S'}$  for every  $S' \rightarrow S$  and  $x \in G(S')$ . One obtains therefore:

**Proposition 4.1.3.** [II-4-1] \*There exists a bijection functorial in  $G$  between the set  $\text{Lie}(G/S, M)(S)$  and the set of  $I_{S'}(M)$ -endomorphisms of  $T_{G/S}(M)(S')$  inducing the identity on  $G$  and commuting with the right translations of  $G$  (in the sense indicated above).\*

<!-- label: III.II.4.1.3 -->

Taking now into account 3.13:

**Theorem 4.1.4.** [II-4-1] \*Let  $G$  be an  $S$ -functor of groups; suppose that  $G/S$  satisfies (E). Then the group  $\text{Lie}(G/S, M)(S)$  is identified, functorially in  $G$ , with the group of  $I_{S'}(M)$ -automorphisms of  $T_{G/S}(M)(S')$  inducing the identity on  $G$  and commuting with the right translations of  $G$  (in the sense indicated above).\*

<!-- label: III.II.4.1.4 -->

One thus recovers (in the case  $M = 0_S$ ) one of the classical definitions of the Lie algebra of a group.

**4.2.0.** [N.D.E-II-54] Before going further, let us establish new corollaries of 3.11. Let  $X, Y$  be above  $Z$ , with  $Z$  above  $S$ , as in Section 1. As one saw in 3.11, the isomorphisms 1.1 (4):

text  

$$(1) \quad \text{Hom}_S(I_S(M), \text{Hom}_{Z/S}(X, Y)) \cong \text{Hom}_{Z/S}(X, \text{Hom}_Z(I_Z(M), Y)) \\ \cong \text{Hom}_{Z/S}(X \times_S I_S(M), Y)$$

induce the isomorphism  $\theta$  below:

text  

$$(2) \quad T_{\text{Hom}_{Z/S}(X, Y)}(M) \cong \text{Hom}_{Z/S}(X, T_{Y/Z}(M)) \\ \cong \text{Hom}_{Z/S}(X \times_S I_S(M), Y) .$$

<!-- original page 74 -->

By 1.3, if  $Y$  is a  $Z$ -group, so is  $\text{Hom}_{Z/S}(V, Y)$  for every  $V \rightarrow Z$  (in particular for  $V = I_Z(M)$ ); explicitly, if  $Z' \rightarrow Z$  and  $\phi, \psi \in \text{Hom}_{Z/S}(V_{Z'}, Y)$ , then

$\phi \cdot \psi$  is defined by  $(\phi \cdot \psi)(v) = \phi(v) \psi(v)$ , for every  $v \in V_{Z'}(Z')$ .

Suppose now that  $X$  and  $Y$  are  $Z$ -groups and let us pose the following definition.

**Definition 4.2.0.1.** Let  $\text{Hom}_{(Z/S)\text{-gr.}}(X, Y)$  be the subfunctor of  $\text{Hom}_{Z/S}(X, Y)$  defined by: for every  $S' \rightarrow S$ ,

`<!-- label: III.II.4.2.0.1 -->`

```

```text
(3)  $\text{Hom}_{(Z/S)\text{-gr.}}(X, Y)(S') = \text{Hom}_{Z_{S'}\text{-gr.}}(X_{S'}, Y_{S'})$ .
```

```

This definition applies equally when one replaces  $Y$  by the  $Z$ -group  $T_{Y/Z}(M)$ .

One then sees easily that  $T_{\text{Hom}_{(Z/S)\text{-gr.}}(X, Y)/S}(M)(S')$  corresponds, in the preceding isomorphisms (2), to the  $Z_{S'}$ -morphisms

```

```text
 $\varphi : X_{S'} \times_{S'} I_{S'}(M) \rightarrow Y_{S'}$ 
```

```

which are "multiplicative in  $X$ ", i.e. which verify  $\phi(x_1 \times x_2, m) = \phi(x_1, m) \phi(x_2, m)$ , and these correspond to the morphisms of  $Z_{S'}$ -groups  $X_{S'} \rightarrow T_{Y/Z}(M)_{S'}$ . One has thus obtained:

**Proposition 4.2.0.2.** Let  $X, Y$  be  $Z$ -groups, with  $Z$  above  $S$ . One has isomorphisms of  $S$ -functors, functorial in  $M$ :

`<!-- label: III.II.4.2.0.2 -->`

```

$$

$$T_{\text{Hom}_{(Z/S)\text{-gr.}}(X, Y)/S}(M) \xrightarrow{\sim} \text{Hom}_{(Z/S)\text{-gr.}}(X, T_{Y/Z}(M)).$$

$$

```

In particular, for  $Z = S$ , one obtains the following corollary. Before stating it, let us remark that if  $Y$  is a commutative  $S$ -group, so is  $T_{Y/S}(M)$ , then  $H = \text{Hom}_{S\text{-gr.}}(X, Y)$  and  $\text{Hom}_{S\text{-gr.}}(X, T_{Y/S}(M))$ , and finally  $T_{H/S}(M)$ .

**Corollary 4.2.0.3.** Let  $X, Y$  be  $S$ -groups. One has isomorphisms of  $S$ -functors, functorial in  $M$ :

`<!-- label: III.II.4.2.0.3 -->`

```

$$

$$T_{\text{Hom}_{S\text{-gr.}}(X, Y)/S}(M) \xrightarrow{\sim} \text{Hom}_{S\text{-gr.}}(X, T_{Y/S}(M)).$$

$$

```

If  $Y$  is commutative, these are moreover isomorphisms of abelian  $S$ -groups.

**Definition 4.2.0.4.** [N.D.E-II-55] If  $Y$  is an  $0_S$ -module, the functor  $T_{Y/S}(M)$  (resp.  $\text{Lie}(Y/S, M)$ ) is equipped with an  $0_S$ -module structure deduced from that of  $Y$ . Equipped with this structure, it will be denoted  $T'_{Y/S}(M)$  (resp.  $\text{Lie}'(Y/S, M)$ ).

`<!-- label: III.II.4.2.0.4 -->`

Consequently, if  $X, Y$  are  $0_S$ -modules, then  $T'_{Y/S}(M) = \text{Hom}_S(I_S(M), Y)$  and  $H = \text{Hom}_{0_S\text{-mod.}}(X, Y)$ , then  $\text{Hom}_{0_S\text{-mod.}}(X, T'_{Y/S}(M))$  and  $T'_{H/S}(M)$ , are equipped with an  $0_S$ -module structure, and one obtains the:

`<!-- original page 75 -->`

**Corollary 4.2.0.5.** If  $X, Y$  are  $0_S$ -modules, one has isomorphisms of  $0_S$ -modules, functorial in  $M$ :

`<!-- label: III.II.4.2.0.5 -->`

```

```text

```

$T'_{\{Y/S\}}(X, Y)/S(M) \cong \text{Hom}_{\{Y/S\}}(X, T'_{\{Y/S\}}(M)).$

Definition 4.2.A. [N.D.E-II-56] Let X, L be S -groups, with S acting on L by group automorphisms (cf. I 2.3.5). One defines the subfunctor $Z^1_{\{S\}}(X, L)$ of $\text{Hom}_{\{S\}}(X, L)$ as follows: for every $S' \rightarrow S$,

III.II.4.2.A

$$Z^1_{\{S\}}(X, L)(S') = \{ \varphi \in \text{Hom}_{\{S'\}}(X_{\{S'\}}, L_{\{S'\}}) \mid \varphi(x_1 x_2) = \varphi(x_1) (\varphi(x_2)), \\ \text{for all } x_1, x_2 \in X(S'), S' \rightarrow S \}.$$

It is called the "functor of crossed homomorphisms" from X to L .

Remark 4.2.B. [N.D.E-II-56] a) If L' is a second S -group on which S acts by group automorphisms, one has

III.II.4.2.B

$$Z^1_{\{S\}}(X, L \times_S L') \cong Z^1_{\{S\}}(X, L) \times_S Z^1_{\{S\}}(X, L').$$

b) If L is a G - S -module, $Z^1_{\{S\}}(X, L)$ coincides with the kernel of the differential $\partial : \text{Hom}_{\{S\}}(X, L) \rightarrow \text{Hom}_{\{S\}}(X^2, L)$ defined in I 5.1; in particular, $Z^1_{\{S\}}(X, L)$ is in this case an S -module.

4.2. Let $u : X \rightarrow Y$ be a morphism of S -groups; then $L^u_{\{S\}}(X, Y)/S(M)$ is described as follows. First, one saw in 3.11.3 that one has an isomorphism of S -functors, functorial in M :

original page 63

$$L^u_{\{S\}}(X, Y)/S(M) \cong \text{Hom}_{\{Y/S\}}(X, T_{\{Y/S\}}(M)).$$

On the other hand, since Y is an S -group, one has

$$T_{\{Y/S\}}(M) = \text{Lie}(Y/S, M) \cdot Y = \text{Lie}(Y/S, M)_Y;$$

there follows an isomorphism of S -functors, functorial in M :

$$L^u_{\{S\}}(X, Y)/S(M) \cong \text{Hom}_S(X, \text{Lie}(Y/S, M)).$$

For every $S' \rightarrow S$, let $u' : X' \rightarrow Y'$ denote the morphism deduced from u by base change. Consider the S -functor defined as follows: [N.D.E-II-57] for every $S' \rightarrow S$,

$$\text{Hom}_{\{(Y/S)\text{-gr.}\}}(X, \text{Lie}(Y/S, M) \cdot Y)(S') = \text{Hom}_{\{(Y'/S)\text{-gr.}\}}(X', (\text{Lie}(Y/S, M) \cdot Y)_{\{S'\}}) \\ = \text{Hom}_{\{(Y'/S)\text{-gr.}\}}(X', \text{Lie}(Y'/S', M) \cdot Y').$$

Then one sees easily that the isomorphism (†) induces an isomorphism

$$L^u_{\{S\}}(X, Y)/S(M) \cong \text{Hom}_{\{(Y/S)\text{-gr.}\}}(X, \text{Lie}(Y/S, M) \cdot Y).$$

On the other hand, the morphism

```

```text
X $\xrightarrow{u}$ Y $\xrightarrow{\text{Ad}}$ Aut_{S-gr.}(Lie(Y/S, M))
```

```

<!-- original page 76 -->

defines an action of X on $L = \text{Lie}(Y/S, M)$ by group automorphisms.

If $\Phi \in \text{Hom}_{Y/S}(X, \text{Lie}(Y/S, M) \cdot Y)$, then, for every $S' \rightarrow S$ and $x \in X(S')$, one can write in a unique manner

```

```text
 $\Phi(S')(x) = \phi(S')(x) \cdot u'(x), \quad \text{where } \phi(S')(x) \in \text{Lie}(Y'/S', M)(S');$
```

```

this determines an element ϕ of $\text{Hom}_S(X, \text{Lie}(Y/S, M))$. Then $\Phi(S')$ is a morphism of groups if, and only if, for all $x_1, x_2 \in X(S')$ one has:

```

```text
 $\phi(S')(x_1 x_2) = \phi(S')(x_1) (u(x_1) \phi(S')(x_2) u(x_1)^{-1})$
 $= \phi(S')(x_1) (x_1 \cdot \phi(S')(x_2)),$
```

```

i.e., if and only if $\phi \in Z^1_S(X, \text{Lie}(Y/S, M))$. One has thus obtained the:

Proposition 4.2. *Let $u : X \rightarrow Y$ be a morphism of S -groups. One has an isomorphism of S -functors, functorial in M :

<!-- label: III.II.4.2 -->

```

```text
 $L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M) \cong Z^1_S(X, \text{Lie}(Y/S, M)).$
```

```

[^N.D.E-II-58] Suppose further that Y/S satisfies (E). Then it follows from 4.2.0.3, exactly as in the proof of 3.11.1, that $\text{Hom}_{S\text{-gr.}}(X, Y)/S$ satisfies (E). So one has (cf. 3.5.1):

```

```text
 $L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M \otimes N) \cong L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M) \times_S L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(N).$
```

```

(This also follows from 4.2 and 4.2.B a.) Consequently, $L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M)$ is equipped, like $Z^1_S(X, \text{Lie}(Y/S, M))$ (cf. 4.2.B b)), with an ${}_0S$ -module structure, deduced from functoriality in M . One deduces that the isomorphism of 4.2 is, in this case, an isomorphism of ${}_0S$ -modules:

Proposition 4.2 bis. [^N.D.E-II-58] *Let $u : X \rightarrow Y$ be a morphism of S -groups; suppose that Y/S satisfies (E). One has an isomorphism of ${}_0S$ -modules, functorial in M :

<!-- label: III.II.4.2-bis -->

```

```text
 $L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M) \cong Z^1_S(X, \text{Lie}(Y/S, M)).$
```

```

Moreover, when Y/S satisfies (E), one deduces from 3.13.1, exactly as in the proof of 3.13.2, that for every $u \in \text{Isom}_{S\text{-gr.}}(X, Y)$ one has an isomorphism functorial in M :

```

$$L^u_{\text{Isom}_{S\text{-gr.}}(X,Y)/S}(M) \xrightarrow{\sim} L^u_{\text{Hom}_{S\text{-gr.}}(X,Y)/S}(M).$$

```

One deduces from this the following two corollaries.

Corollary 4.2.1. *Let $u : X \rightarrow Y$ be a morphism of S -groups; if Y/S satisfies (E), one has an isomorphism of ${}_0S$ -modules, functorial in M :

<!-- label: III.II.4.2.1 -->

```
```text
L^u_{Isom_{S-gr.}(X,Y)/S}(M) \cong Z^1_S(X, Lie(Y/S, M)).
```
```

<!-- original page 77 -->

****Corollary 4.2.2.**** *Let X be an S -group; if X/S satisfies (E), one has an isomorphism of 0_S -modules, functorial in M .*

<!-- label: III.II.4.2.2 -->

```
```text
Lie(Aut_{S-gr.}(X)/S, M) \cong Z^1_S(X, Lie(X/S, M)).
```
```

[^N.D.E-II-59] Moreover, if Y is commutative, the adjoint action of Y on $L = Lie(X/S, M)$ is trivial, whence $Z^1_S(X, L) = \operatorname{Hom}_{S-gr.}(X, L)$. Therefore:

****Corollary 4.2.3.**** *Let Y be a commutative S -group; one has an isomorphism of S -functors, functorial in M .*

<!-- label: III.II.4.2.3 -->

```
```text
L^u_{Hom_{S-gr.}(X,Y)/S}(M) \cong Hom_{S-gr.}(X, Lie(Y/S, M)).
```
```

****4.3.**** Consider now the case where X and Y are 0_S -modules. Recall (cf. 4.2.0.4) that one writes $T'_{Y/S}(M)$ (resp. $Lie'(Y/S, M)$) for the functor $T_{Y/S}(M)$ (resp. $Lie(Y/S, M)$) equipped with the 0_S -module structure deduced from that of Y .

When Y/S satisfies (E), we shall always write $Lie(Y/S, M)$ for the functor $Lie(Y/S, M)$ equipped with the 0_S -module structure defined for every functor satisfying (E). In this case, we know (cf. 3.9) that the abelian-group structures of $Lie(Y/S, M)$ and $Lie'(Y/S, M)$ coincide, but the same is not a priori true for those of module (see a counterexample in §6.3). For every $S' \rightarrow S$ and $a \in O(S')$, we shall write $a \cdot m$ (resp. $a \cdot m$) for the action of a on $m \in Lie'(Y/S, M)(S')$ (resp. on $m \in Lie(Y/S, M)(S')$), and similarly for the action of a on $T'_{Y/S}(M)$ and $T_{Y/S}(M)$.

One has $T'_{Y/S}(M) \simeq Lie'(Y/S, M) \oplus Y$ as 0_S -modules; consequently one obtains, exactly as for Propositions 4.2 and 4.2 bis, the:

****Proposition 4.3.**** *Let $u : X \rightarrow Y$ be a morphism of 0_S -modules. One has an isomorphism of S -functors, functorial in M .*

<!-- label: III.II.4.3 -->

```
```text
(*) L^u_{Hom_{^0_S-mod.}(X,Y)/S}(M) \cong Hom_{^0_S-mod.}(X, Lie'(Y/S, M)).
```
```

[^N.D.E-II-60] *If Y/S satisfies (E), then $\operatorname{Hom}_{^0_S-mod.}(X, Y)/S$ satisfies (E) and (*) is an isomorphism of 0_S -modules when one equips both sides with the 0_S -module structure deduced from functoriality in M .*[^N.D.E-II-61]

****Remark 4.3 bis.****[^N.D.E-II-62] Let $u : X \rightarrow Y$ be a morphism of 0_S -modules; denote by τ_u the map which to every morphism of 0_S -modules $\phi : X \rightarrow Lie'(Y/S, M)$ associates the morphism

<!-- label: III.II.4.3-bis -->

```
```text
u \oplus \phi : X \rightarrow T'_{Y/S}(M) = Y \oplus Lie'(Y/S, M).
```
```

<!-- original page 78 -->

Then the isomorphism of 4.3 fits into the following commutative diagram, functorial in M :

$$\begin{array}{ccc} \text{``text} \\ L^u_{\text{Hom}_{\{0_S\text{-mod.}\}}(X,Y)/S}(M) & \square & \text{Hom}_{\{0_S\text{-mod.}\}}(X, \text{Lie}'(Y/S, M)) \\ \downarrow & & \downarrow \tau_u \\ T_{\text{Hom}_{\{0_S\text{-mod.}\}}(X,Y)/S}(M) & \square & \text{Hom}_{\{0_S\text{-mod.}\}}(X, T'_{Y/S}(M)). \end{array}$$

Moreover, when Y/S satisfies (E), one deduces from 3.13.1, exactly as in the proof of 3.13.2, that for every $u \in \text{Isom}_{\{0_S\text{-mod.}\}}(X, Y)$, one has

$$\text{``text} \\ (*) \quad L^u_{\text{Isom}_{\{0_S\text{-mod.}\}}(X,Y)/S}(M) = L^u_{\text{Hom}_{\{0_S\text{-mod.}\}}(X,Y)/S}(M).$$

Corollary 4.3.1. *Let X be an 0_S -module satisfying (E) with respect to S . One has an isomorphism functorial in M :

<!-- label: III.II.4.3.1 -->

$$\text{``text} \\ \text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S, M) \square \text{Hom}_{\{0_S\text{-mod.}\}}(X, \text{Lie}'(X/S, M))$$

which respects the 0_S -module structures deduced from functoriality in M . *In particular, $\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S$ satisfies (E).

Proof. The first assertion follows from (*) and 4.3; let us prove the second. As X/S satisfies (E), one has isomorphisms of 0_S -modules $\text{Lie}'(X/S, M \otimes N) \simeq \text{Lie}'(X/S, M) \times_S \text{Lie}'(X/S, N)$, and thus:

$$\text{``text} \\ \text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S, M \otimes N) \simeq \text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S, M) \times_S \text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S, N).$$

Taking 4.1.1.2 a) into account, this proves that $\text{Aut}_{\{0_S\text{-mod.}\}}(X)/S$ satisfies (E).

4.3.2. Before continuing in this direction, let us examine more closely the relations between Y , $\text{Lie}(Y/S)$ and $\text{Lie}'(Y/S)$. Let us remark first that

$$\text{``text} \\ (1) \quad \text{Lie}(0_S/S, M) = \text{Lie}'(0_S/S, M) = W(M)$$

(where $W(M)$ is defined in I 4.6) and that one therefore has a canonical isomorphism

$$\begin{array}{l} \\ (2) \quad d : 0_S \xrightarrow{\sim} \text{Lie}(0_S/S). \\ \end{array}$$

<!-- original page 65 -->

Let now F be an 0_S -module. For every $S_2 \rightarrow S_1 \rightarrow S$, one has a dihomomorphism

$$\text{``text} \\ (3) \quad \begin{array}{l} \square F(S_1) \rightarrow F(S_2) \\ \square 0(S_1) \rightarrow 0(S_2), \end{array}$$

whence a morphism of $0(S_2)$ -modules

``text

$F(S_1) \otimes_{O(S_1)} O(S_2) \rightarrow F(S_2).$

In particular, setting $S_1 = S'$ and $S_2 = I_{S'}(M)$, one deduces morphisms of $O(S')$ -modules, functorial in M ,

$$F(S') \otimes_{O(S')} T_{O/S}(M)(S') \rightarrow T'_{F/S}(M)(S');$$

letting S' vary, one obtains morphisms of O_S -modules, functorial in M ,

$$(4) \quad F \otimes_{O_S} T_{O/S}(M) \rightarrow T'_{F/S}(M).$$

These morphisms are functorial in M , hence compatible with the projections of the tangent bundles onto their bases; they therefore define morphisms of O_S -modules

$$(5) \quad F \otimes_{O_S} \text{Lie}(O_S/S, M) \rightarrow \text{Lie}'(F/S, M)$$

such that one has the commutative diagram:

$$\begin{array}{ccccccc} 0 & \rightarrow & F \otimes_{O_S} \text{Lie}(O_S/S, M) & \rightarrow & F \otimes_{O_S} T_{O/S}(M) & \rightarrow & F \rightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & \text{Lie}'(F/S, M) & \longrightarrow & T'_{F/S}(M) & \longrightarrow & F \rightarrow 0 \end{array}$$

One may consider the morphisms (5) as morphisms of abelian S -groups

$$(6) \quad F \otimes_{O_S} \text{Lie}(O_S/S, M) \rightarrow \text{Lie}(F/S, M);$$

tensoring F with the isomorphism $d : O_S \rightarrow \text{Lie}(O_S/S)$, one deduces (for $M = O_S$) a morphism of abelian S -groups

<!-- original page 66 -->

$$(7) \quad F \otimes_{O_S} \text{Lie}(O_S/S) \rightarrow \text{Lie}(F/S)$$

also denoted $d : F \rightarrow \text{Lie}(F/S)$.

Remark 4.3.3. [N.D.E-II-65] When F/S satisfies (E), the morphisms (6) and (7) are not necessarily morphisms of O_S -modules, when one equips both sides with the module structures deduced from that of M thanks to condition (E).

<!-- label: III.II.4.3.3 -->

For example, let k be a field of characteristic $p > 0$, $S = \text{Spec}(k)$, and let F be the O_S -module which to every S -scheme T associates $F(T) = \Gamma(T, O_T)$ equipped with the $O(T)$ -module structure obtained by making scalars act through the p -th power, i.e., $r \cdot \bar{f} = r^p f$, for $r \in O(T)$, $f \in F(T)$. As F -functor of groups, F is isomorphic to $G_{\{a, S\}}$. Therefore F satisfies (E) and $\text{Lie}(F/S)$ is identified with $\text{Lie}(G_{\{a, S\}}/S) \cong O_S$. Then, the canonical morphism $d : F \rightarrow \text{Lie}(F/S)$ is, for every $T \rightarrow S$, the identity map $F(T) \rightarrow O(T)$: it indeed respects the abelian-group structure but not the O_S -module structure.

Remark 4.3.4. [N.D.E-II-66] One can make the morphisms (4) and (5) explicit as follows. The morphism $\Theta : F \otimes_{O_S} T_{O/S}(M) \rightarrow T'_{F/S}(M) = \text{Hom}_S(I_S(M), F)$ is defined by: for every $S' \rightarrow S$, $\alpha \in O(I_{S'}(M))$, and $f : S' \rightarrow F$,

<!-- label: III.II.4.3.4 -->

```

```text
 $\theta(f \otimes \alpha) = \alpha \cdot (\tau_\theta \circ f) = \alpha \cdot (f \circ \rho),$
```

```

where $\tau_{\{0\}}$ is the null section $F \rightarrow T_{\{F/S\}}(M)$ and ρ the structural morphism $I_{\{S'\}}(M) \rightarrow S'$. Then θ induces a morphism $\theta : F \otimes_{\{0\}} \text{Lie}(0_{\{S\}}/S, M) \rightarrow \text{Lie}'(F/S, M)$; this follows from the "functoriality in M " already mentioned after (4), and can be seen explicitly as follows. On the one hand, one has

```

```text
 $\text{Lie}'(F/S, M)(S') = \{ \varphi \in \text{Hom}_S(I_{\{S'\}}(M), F) \mid \varphi \circ \varepsilon_M = e \},$
```

```

where e denotes the unit section $S' \rightarrow F$. On the other hand, $\text{Lie}(0_{\{S\}}/S, M)(S') = \Gamma(S', M)$ is the kernel of the augmentation $\eta : \mathcal{O}(I_{\{S'\}}(M)) \rightarrow \mathcal{O}(S')$, and it is therefore a question of seeing that if $f \in F(S')$ and $\alpha \in \Gamma(S', M)$, then $\alpha \cdot (f \circ \rho) \circ \varepsilon_M = e$.

Consider the dihomomorphism (3), in the case where $S_2 \rightarrow S_1$ is the S -morphism $\varepsilon_M : S' \rightarrow I_{\{S'\}}(M)$; one has then a commutative diagram

```

```text

$$\begin{array}{ccc} F(I_{\{S'\}}(M)) & \xrightarrow{F(\varepsilon_M)} & F(S') \\ \downarrow \alpha & & \downarrow \eta(\alpha) \\ F(I_{\{S'\}}(M)) & \xrightarrow{F(\varepsilon_M)} & F(S') \end{array}$$

```

```

For every $\phi : I_{\{S'\}}(M) \rightarrow F$, one therefore has $(\alpha \cdot \phi) \circ \varepsilon_M = \eta(\alpha) \cdot (\phi \circ \varepsilon_M)$, whence $(\alpha \cdot \phi) \circ \varepsilon_M = e$ if $\eta(\alpha) = 0$.

In particular, taking $M = t_{0_{\{S\}}}$, one has $\text{Lie}(0_{\{S\}}/S) = t_{0_{\{S\}}}$ and the morphism $F \rightarrow \text{Lie}'(F/S)$ is given by $f \mapsto t \cdot (f \circ \rho)$.

Remark 4.3.5. [N.D.E-II-67] Let F be an 0_S -module, set $E = \text{End}_{0_S\text{-mod.}}(F)$ and denote by d_F and d_E the morphisms of 0_S -modules given by 4.3.2 (5):

<!-- label: III.II.4.3.5 -->

```

```text
 $d_F : F \otimes_{0_S} \text{Lie}(0_S/S, M) \rightarrow \text{Lie}'(F/S, M),$
 $d_E : E \otimes_{0_S} \text{Lie}(0_S/S, M) \rightarrow \text{Lie}'(E/S, M).$
```

```

One deduces from 4.3.4 the following commutative diagram of morphisms of 0_S -modules:

```

```text

$$\begin{array}{ccc} E \otimes_{0_S} \text{Lie}(0_S/S, M) & \xrightarrow{d_E} & \text{Lie}'(E/S, M) \\ & \uparrow \simeq (*) & \\ \text{Hom}_{0_S}(F, F \otimes_{0_S} \text{Lie}(0_S/S, M)) & \xrightarrow{d_F} & \text{Hom}_{0_S}(F, \text{Lie}'(F/S, M)) \end{array}$$

```

```

where the right vertical arrow is the isomorphism $(*)$ of 4.3. Therefore (loc. cit.), if F/S satisfies (E), then E/S satisfies (E) and $(*)$ is also an isomorphism of 0_S -modules when one equips the right-hand terms with the 0_S -module structure deduced from (E).

<!-- original page 81 -->

Remark 4.4.0. [N.D.E-II-68] In 4.3.2, the morphisms (4) are isomorphisms if and only if the morphisms (5) are. Moreover, if these conditions are verified, then F/S satisfies (E). Indeed, it suffices to verify that $\text{Lie}'(F/S, M \otimes N) \simeq \text{Lie}'(F/S, M) \times_S \text{Lie}'(F/S, N)$. Now one has the commutative diagram below, where by hypothesis the horizontal arrows are isomorphisms:

<!-- label: III.II.4.4.0 -->

```

```text
 F ⊗_{0_S} Lie(0_S/S, M ⊗ N) ⊆ Lie'(F/S, M ⊗ N)
 | ⊆ |
 ↓ ↓
 F ⊗_{0_S} (Lie(0_S/S, M) ×_S Lie(0_S/S, N)) ⊆ Lie'(F/S, M) ×_S Lie'(F/S, N);
```

```

the second vertical arrow is therefore also an isomorphism, i.e. F/S satisfies (E).

Definition 4.4. One says that F is a **good 0_S -module** if the morphisms

<!-- label: III.II.4.4 -->

```

```text
F ⊗_{0_S} T_{0_S/S}(M) → T_{F/S}(M)
or, equivalently,
F ⊗_{0_S} Lie(0_S/S, M) → Lie(F/S, M),
```

```

are isomorphisms of abelian S -groups (so that F/S satisfies (E)) and if moreover they respect the 0_S -module structures deduced from condition (E).

Corollary 4.4.1. [N.D.E-II-69] Let F be an 0_S -module. Consider the following conditions:

<!-- label: III.II.4.4.1 -->

(i) F is a good 0_S -module.

(ii) F/S satisfies (E) and $d : F \rightarrow \text{Lie}(F/S)$ is an isomorphism of 0_S -modules.

(iii) $\text{Lie}(F/S, M) = \text{Lie}'(F/S, M)$.

Then one has (i) $\Leftrightarrow$ (ii) $\Rightarrow$ (iii).

Proof. (i) $\Rightarrow$ (ii) follows from the definition. To prove (ii) $\Rightarrow$ (i), one must show that the morphisms of abelian S -groups (functorial in M)

```

```text
F ⊗_{0_S} Lie(0_S/S, M) ⊆ Lie(F/S, M)
```

```

are isomorphisms of 0_S -modules. Since F/S satisfies (E), both sides transform finite direct sums of copies of 0_S into finite products of abelian S -groups. This reduces us to the case $M = 0_S$, which follows from the hypothesis.

Finally, (i) $\Rightarrow$ (iii) follows from the definition and from the fact that the isomorphisms

```

```text
F ⊗_{0_S} Lie(0_S/S, M) ⊆ Lie'(F/S, M)
```

```

of 4.3.2 (5) are morphisms of 0_S -modules.

Examples 4.4.2. For every quasi-coherent 0_S -Module E , the 0_S -modules $V(E)$ and $W(E)$ defined in I 4.6 are good.

<!-- label: III.II.4.4.2 -->

<!-- original page 67 -->

[N.D.E-II-70] Indeed, for every $f : S' \rightarrow S$, the morphisms

```

```text

```

$$\begin{aligned} V(E)(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}(M)) &\rightarrow T_{\{V(E)/S\}}(M)(S') \\ W(E)(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}(M)) &\rightarrow T_{\{W(E)/S\}}(M)(S') \end{aligned}$$

correspond, respectively, to the morphisms:

$$\begin{aligned} &\text{Hom}_{\{0_{\{S'\}}\text{-mod.}\}}(f^*(E), 0_{\{S'\}} \otimes_{\{0(S')\}} \Gamma(S', D_{\{0_{\{S'\}}\}}(M))) \\ &\rightarrow \text{Hom}_{\{0_{\{S'\}}\text{-mod.}\}}(f^*(\bar{E}), D_{\{0_{\{S'\}}\}}(M)) \\ &\Gamma(S', f^*(E)) \otimes_{\{0(S')\}} \Gamma(S', D_{\{0_{\{S'\}}\}}(M)) \\ &\rightarrow \Gamma(S', f^*(\bar{E}) \otimes_{\{0_{\{S'\}}\}} D_{\{0_{\{S'\}}\}}(M)); \end{aligned}$$

these are isomorphisms, since  $D_{\{0_{\{S'\}}\}}(M)$  is isomorphic, as  $\{0_{\{S'\}}\}$ -module, to a finite direct sum of copies of  $\{0_{\{S'\}}\}$ .

**Proposition 4.5.** *Let  $F$  be a good  $\{0_S\}$ -module. Then:*

*III.II.4.5*

(i)  $\text{Aut}_{\{0_S\text{-mod.}\}}(F)/S$  satisfies (E) and one has a functorial isomorphism

$$\text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(F)/S, M) \cong \text{Hom}_{\{0_S\text{-mod.}\}}(F, \text{Lie}(F/S, M))$$

which respects the  $\{0_S\}$ -module structures deduced from condition (E). In particular, one has an isomorphism of  $\{0_S\}$ -modules

$$\text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(F)/S) \cong \text{End}_{\{0_S\text{-mod.}\}}(F).$$

(ii) *[N.D.E-II-71] Moreover,  $\text{End}_{\{0_S\text{-mod.}\}}(F)$  is a good  $\{0_S\}$ -module.*

Indeed, by 4.4.1,  $F/S$  satisfies (E) and

$$(1) \quad \text{Lie}(F/S, M) = \text{Lie}'(F/S, M) \cong F \otimes_{\{0_S\}} \text{Lie}(0_S/S, M).$$

Assertion (i) then follows from 4.3.1. Set  $E = \text{End}_{\{0_S\text{-mod.}\}}(F)$ . By (1) and Remark 4.3.5, one has the following commutative diagram of morphisms of abelian  $\{S\}$ -groups:

$$\begin{array}{ccc} \text{End}_{\{0_S\text{-mod.}\}}(F) \otimes_{\{0_S\}} \text{Lie}(0_S/S, M) & \xrightarrow{d_E} & \text{Lie}(\text{End}_{\{0_S\text{-mod.}\}}(F)/S, M) \\ & \uparrow \cong (*) & \\ \text{Hom}_{\{0_S\}}(F, F \otimes_{\{0_S\}} \text{Lie}(0_S/S, M)) & \xrightarrow{d_F} & \text{Hom}_{\{0_S\}}(F, \text{Lie}(F/S, M)) \end{array}$$

where  $d_F$  and  $(*)$  are isomorphisms of  $\{0_S\}$ -modules; consequently, so is  $d_E$ . This proves (ii).

**Scholie 4.5.1.** *[N.D.E-II-72] Set (cf. 2.1)  $\{0_{\{I_{\{S'\}}\}}\} = 0_{\{S'\}} \oplus t \{0_{\{S'\}}\}$  (with  $t^2 = 0$ ), and let  $F$  be a good  $\{0_S\}$ -module. Then, for every  $S' \rightarrow S$ , the morphism*

*III.II.4.5.1*

$$F(S') \otimes t F(S') = F(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}) \rightarrow F(I_{\{S'\}}) = F(S') \otimes \text{Lie}(F/S)(S')$$

original page 82

(which is the identity on  $F(S')$ ) induces an isomorphism of  $0(S')$ -modules  $t : F(S') \xrightarrow{\sim} \text{Lie}(F/S)(S')$ . Letting  $S'$  vary, one obtains an isomorphism which one may write  $\text{Lie}(F/S) \xrightarrow{\sim} t F$ .

For every  $S' \rightarrow S$ , one has therefore, by 4.5, a commutative diagram:

$$\begin{array}{ccccc} \text{End}_{0\{S'\}\text{-mod.}}(F_{\{S'\}}) & \cong & \text{Hom}_{0\{S'\}\text{-mod.}}(F_{\{S'\}}, t F_{\{S'\}}) & \cong & \text{Lie}(\text{Aut}_{0\{S'\}\text{-mod.}}(F)/S)(S') \\ \downarrow & & \downarrow & & \downarrow \\ \dots & & \text{Aut}_{0\{I_{S'}\}\text{-mod.}}(F_{\{I_{S'}\}}) & & T_{\text{Aut}_{0\{S'\}\text{-mod.}}(F)/S}(S') \end{array}$$

and one deduces from 4.3 bis that every  $X \in \text{End}_{0\{S'\}\text{-mod.}}(F_{\{S'\}})$  corresponds to the element  $\text{id} + t X$  of  $\text{Aut}_{0\{I_{S'}\}\text{-mod.}}(F_{\{I_{S'}\}})$ .

**Definition 4.6.** One says that the  $G/S$ -functor of groups  $G$  is **good** if  $G/S$  satisfies condition (E) and if  $\text{Lie}(G/S)$  is a good  $0_S$ -module.

<!-- label: III.II.4.6 -->

[^N.D.E-II-73] Note that if  $F$  is a good  $0_S$ -module, it is a good  $G/S$ -group; indeed  $F/S$  satisfies (E) and  $\text{Lie}(F/S) \xrightarrow{\sim} F$  is a good  $0_S$ -module.

**Example 4.6.1.** If  $G$  is representable, it is good. Indeed,  $G/S$  satisfies (E) and  $\text{Lie}(G/S)$  is of the form  $V(E)$ , hence good, by 4.4.2.

<!-- label: III.II.4.6.1 -->

**Lemma 4.6.2.** [^N.D.E-II-74] Let  $G$  be a  $G/S$ -functor of groups such that  $G/S$  satisfies (E), and let  $F = \text{Lie}(G/S)$ . Then  $F$  satisfies (E) and the morphism of abelian groups  $d : F \rightarrow \text{Lie}(F/S)$  respects the  $0_S$ -module structures.

<!-- label: III.II.4.6.2 -->

Consequently,  $G$  is good if and only if  $F \rightarrow \text{Lie}(F/S)$  is bijective.

**Proof.** Suppose that  $G/S$  satisfies (E). Let  $M, N$  be free  $0_S$ -modules of finite rank. Write  $F(N) = \text{Lie}(G/S, N)$  and  $e$  the unit section of  $G$ .

For every  $S' \rightarrow S$ , one has  $F(N)(S') = \{ g \in \text{Hom}_S(I_{S'}(N), G) \mid g \circ \text{id}_{I_{S'}(N)} = e \}$  and  $\text{Lie}(F(N)/S, M)(S') = \text{Hom}_S(I_{S'}(M), F(N))$  is identified with

$$\begin{array}{l} \{ \phi \in \text{Hom}_S(I_{S'}(N) \times_{S'} I_{S'}(M), G) \mid \\ \quad \phi \circ (\text{id}_N \times \text{id}_{I_{S'}(M)}) = e \in G(I_{S'}(M)), \\ \quad \phi \circ (\text{id}_{I_{S'}(N)} \times \text{id}_M) = e \in G(I_{S'}(N)) \} \end{array}$$

This shows that

$$(1) \quad \text{Lie}(F(N)/S, M) \cong \text{Lie}(F(M)/S, N).$$

As  $G/S$  satisfies (E), one deduces:

$$\begin{array}{l} \text{Lie}(F(N)/S, M_1 \otimes M_2) \cong \text{Lie}(F(M_1 \otimes M_2)/S, N) \\ \quad \cong \text{Lie}((F(M_1) \times_S F(M_2))/S, N). \end{array}$$

By 3.8, the right-hand term is isomorphic to

$$\text{Lie}(F(M_1)/S, N) \times_S \text{Lie}(F(M_2)/S, N) \cong \text{Lie}(F(N)/S, M_1) \times_S \text{Lie}(F(N)/S, M_2).$$

...

<!-- original page 84 -->

It follows that

```

```text
(2)  Lie(F(N)/S, M_1 \otimes M_2) \approx Lie(F(N)/S, M_1) \times_S Lie(F(N)/S, M_2),
```

```

so  $F(N)/S$  satisfies (E), by Remark 4.1.1.2 a).

Let us now show that the morphism of abelian groups  $d : F(N) \rightarrow Lie(F(N)/S)$  respects the  $0_S$ -module structures. Consider the free  $0_S$ -module  $M = t \cdot 0_S$ , so that

```

```text
0(I_{S'}(M)) = 0(S')[t]/(t^2) = 0(S') \otimes t \cdot 0(S')
```

```

and  $Lie(0_S/S) \simeq t \cdot 0_S$ . We denote by  $\rho_t$  the structural morphism  $I_{S'}(M) \rightarrow S$ , which corresponds to the injection  $u_t : 0_S \hookrightarrow D_{0_S}(M) = 0_S \oplus t \cdot 0_S$ . Recall (cf. 3.4.2) that, for every  $S$ -functor  $X$ ,  $F(N)(X) = Lie(G/S, N)(X)$  is the set of  $S$ -morphisms  $\phi : I_X(N) \rightarrow G$  such that  $\phi \circ \epsilon_N = e$ , and that the action of  $a \in O(X)$  is given by  $a \cdot \phi = \phi \circ a^*$ , where  $a^*$  is the endomorphism of  $I_X(N)$  associated with  $a$ , cf. 2.1.3.

Consequently, by 4.3.4, the morphism  $d : F(N) \rightarrow Lie(F(N)/S)$  is given by: for every  $S' \rightarrow S$  and  $f \in \operatorname{Hom}_S(S', F(N))$ ,

```

```text
f \mapsto f \otimes t \mapsto t \cdot (f \circ \rho_t) = f \circ \rho_t \circ t^*,
```

```

where, in the last term,  $f \circ \rho_t \in F(N)(I_{S'}(M))$  is considered as an  $S$ -morphism  $\phi : I_{I_{S'}(M)}(N) \rightarrow G$  (such that  $\phi \circ \epsilon_N = e$ ). It is a question of seeing that  $d$  is a morphism of  $0_S$ -modules, i.e., that  $d(a \cdot f) = u_t(a) \cdot d(f)$  for every  $a \in O(S)$ .

Considering  $f \in F(N)(S')$  as a morphism  $I_{S'}(N) \rightarrow G$ , one has likewise  $a \cdot f = f \circ a^*$ . On the other hand, by the functoriality in  $X$  of the action of  $O(X)$  on  $I_X(N)$  (cf. 2.1.3), one has the commutative diagram below:

```

```text
      I_{S'}(N)  \xrightarrow{a^*}  I_{S'}(N)
      \uparrow \rho_t \quad \uparrow \rho_t
      I_{I_{S'}(M)}(N) \xrightarrow{u_t(a)^*} I_{I_{S'}(M)}(N) .
```

```

One has therefore

```

```text
d(a \cdot f) = f \circ a^* \circ \rho_t \circ t^* = f \circ \rho_t \circ u_t(a)^* \circ t^* = f \circ \rho_t \circ t^* \circ u_t(a)^* = u_t(a) \cdot d(f)
```

```

(the second-to-last equality resulting from the fact that  $0_S$  is commutative). This completes the proof of Lemma 4.6.2.

**Theorem 4.7.** *If  $F$  is a good  $0_S$ -module, the  $S$ -group  $\operatorname{Aut}_{0_S\text{-mod.}}(F)$  is good.*

<!-- label: III.II.4.7 -->

<!-- original page 68 -->

[^N.D.E-II-75] Indeed, by 4.5,  $\operatorname{Aut}_{0_S\text{-mod.}}(F)/S$  satisfies (E) and  $Lie(\operatorname{Aut}_{0_S\text{-mod.}}(F)/S) \approx \operatorname{End}_{0_S\text{-mod.}}(F)$  is a good  $0_S$ -module.

**4.7.1.** Let now  $G$  be an  $S$ -group and  $F$  a good  $0_S$ -module. Suppose given a linear representation of  $G$  in  $F$ , that is to say (I 4.7.1), a morphism of  $S$ -groups

$$\rho : G \rightarrow \text{Aut}_{0_S\text{-mod.}}(F).$$

If  $G/S$  satisfies (E), one deduces from 4.1.C and 4.5 a morphism of  $0_S$ -modules, denoted  $\rho'$  or  $d\rho$ :

$$\text{Lie}(G/S) \rightarrow \text{Lie}(\text{Aut}_{0_S\text{-mod.}}(F)/S) = \text{End}_{0_S\text{-mod.}}(F).$$

Moreover, setting  $0_{I_S} = 0_S \oplus t \cdot 0_S$  (with  $t^2 = 0$ ), one deduces from 4.5.1 that, if  $S' \rightarrow S$  and  $X \in \text{Lie}(G/S)(S') \subset G(I_S')$ , then one has in  $\text{Aut}_{0_{I_S'}\text{-mod.}}(F_{I_S'})$  the following equality:

$$(*) \quad \rho(X) = \text{id} + t \rho'(X),$$

i.e. for every  $S' \rightarrow I_S$  and  $f \in F(S')$ , one has in  $F(S')$  the equality  $\rho(X)(f) = f + t \rho'(X)(f)$ .

**Definition 4.7.2.** Let  $G$  be a good  $S$ -group. Then  $\text{Lie}(G/S)$  is a good  $0_S$ -module, and one has a morphism of  $S$ -groups  $\text{Ad} : G \rightarrow \text{Aut}_{0_S\text{-mod.}}(\text{Lie}(G/S))$ . One deduces from 4.7.1 a morphism of  $0_S$ -modules\*

label: III.II.4.7.2 -->

$$\text{ad} : \text{Lie}(G/S) \rightarrow \text{End}_{0_S\text{-mod.}}(\text{Lie}(G/S)),$$

or, what amounts to the same, an  $0_S$ -bilinear morphism:

$$\text{Lie}(G/S) \times_S \text{Lie}(G/S) \rightarrow \text{Lie}(G/S), \quad (x, y) \mapsto [x, y] = \text{ad}(x) \cdot y$$

(where  $x$  and  $y$  denote two arbitrary elements of  $\text{Lie}(G/S)(S') = \text{Lie}(G_{S'}/S')(S')$ ). If  $G$  is commutative, then  $[x, y] = 0$ .\*

original page 69 -->

**4.7.3.** One can give an equivalent definition of the bracket as follows: let us remark first that it suffices to do it for  $x, y \in \text{Lie}(G/S)(S)$ . Let us remark next that there is a canonical isomorphism

$I_S \times_S I_S \simeq I_{I_S}$ ; to avoid confusions, let us denote by  $I$  and  $I'$  two copies of  $I_S$  and set  $0_{I'} = 0_S[t]$ ,  $0_{I'} = 0_S[t']$ , where  $t^2 = 0 = t'^2$ . One has then a commutative diagram

$$\begin{array}{ccc} I \times I' & \longrightarrow & I' \\ | & & | \\ I & \longrightarrow & S \end{array},$$

the two arrows starting from  $I \times I'$  identifying it with the scheme of dual numbers over  $I$  or over  $I'$ . There follows a commutative diagram of groups (where one writes  $L = \text{Lie}(G/S)$ ):

$$\begin{array}{ccccc} & 1 & & 1 & \\ & | & & | & \\ L(I) & \longrightarrow & L(S) & \twoheadrightarrow & 1 \\ & | & & | & \end{array}$$

$$\begin{array}{ccccccc}
 1 & \rightarrow & L(I') & \rightarrow & G(I \times I') & \rightarrow & G(I') \rightarrow 1 \\
 (1) & & \downarrow & & \downarrow & & \downarrow \\
 1 & \rightarrow & L(S) & \rightarrow & G(I) & \rightarrow & G(S) \rightarrow 1 \\
 & & & & \downarrow & & \downarrow \\
 & & & & 1 & & 1 .
 \end{array}$$

The ninth piece of the puzzle is nothing other than  $\text{Lie}(L(S)(S))$ . If  $G$  is good, this is  $L(S)$  and one has therefore the following commutative diagram, where the lines and columns are exact sequences of groups, the five  $L(-)$  are commutative, [N.D.E-II-78] and where, taking into account the identification  $L(I) = L(S) \oplus L(S)$  (resp.  $L(I') = L(S) \oplus L(S)$ ), the injection  $L(S) \hookrightarrow L(I)$  (resp.  $L(S) \hookrightarrow L(I')$ ) is given by  $u \mapsto t \oplus u$  (resp.  $u \mapsto t' \oplus u$ ):

<!-- original page 86 -->

$$\begin{array}{ccccccc}
 & & & & t & & \\
 z \in L(S) & \xrightarrow{\quad} & L(I) & \xrightarrow{\quad} & L(S) & \ni & x \\
 \downarrow t' & & & & \downarrow & & \\
 L(I') & \xrightarrow{\quad} & G(I \times I') & \xrightarrow{\quad} & G(I') & & \\
 \downarrow & & & & \downarrow & & \\
 y \in L(S) & \xrightarrow{\quad} & G(I) & \xrightarrow{\quad} & G(S) & . & 
 \end{array}$$

Now in such a diagram, if one takes two elements  $x$  and  $y$  as marked, and one lifts arbitrarily  $x$  resp.  $y$  to an element  $\tilde{x} \in L(I)$  resp.  $y' \in L(I')$ , the commutator  $\tilde{x} y' \tilde{x}^{-1} y'^{-1}$  in  $G(I \times I')$  does not depend on the chosen lifts and is the image of an element  $z$  as marked. The reader will verify that one has  $z = [x, y]$ . [N.D.E-II-79]

Indeed, if one still denotes by  $x$  the image of  $\tilde{x}$  by the canonical section  $L(S) \rightarrow L(I)$  (and likewise for  $y$ ), then  $\tilde{x} = xu$  and  $y' = yv$ , with  $u, v \in L(S) = L(I) \cap L(I')$ , and since  $L(I)$  and  $L(I')$  are commutative one has

$$\begin{aligned}
 x y' x^{-1} y'^{-1} &= x u y v u^{-1} x^{-1} v^{-1} y'^{-1} \\
 &= x u y u^{-1} v x^{-1} v^{-1} y'^{-1} \\
 &= x y x^{-1} y'^{-1}.
 \end{aligned}$$

Moreover, this element is sent to the unit element of  $G(I)$  and of  $G(I')$ , hence comes from a (unique)  $z$  as indicated. Finally, considering  $y$  (resp.  $x$ ) as an element of  $L_{I'}(I')$  (resp. of  $L(S) \subset G(I')$ ), one has by 4.7.1 (\*):

$$x y x^{-1} = \text{Ad}(x)(y) = (\text{id} + t' \text{ad}(x))(y) = y + t' [x, y],$$

so the element  $x y x^{-1} y^{-1}$  of  $L(I')$  is the image of the element  $z = [x, y]$  of  $L(S)$ .

On this construction the following two properties appear:

(i) the bracket is "functorial in  $G$ ": precisely,  $G \mapsto \text{Lie}(G/S)$  is a functor from the category of good  $S$ -groups to the category of good  $0_S$ -modules equipped with an  $0_S$ -bilinear composition law.

(ii) One has  $[x, y] + [y, x] = 0$ : indeed the diagram is symmetric with respect to the first diagonal. [N.D.E-II-80]

**Proposition 4.8.** \*Let  $F$  be a good  $0_S$ -module. Via the identification\*

<!-- label: III.II.4.8 -->

text

$\text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(F)/S) = \text{End}_{\{0_S\text{-mod.}\}}(F)$

\*one has\*

```text  
 $\text{Ad}(g) \cdot Y = g \circ Y \circ g^{-1}$ and $[X, Y] = X \circ Y - Y \circ X,$
 ```

\*for every  $S' \rightarrow S$ ,  $g \in \text{operatorname{Aut}}_{\{0_{S'}\text{-mod.}\}}(F_{S'})$ , and  $X, Y \in \text{Lie}(\text{Aut}_{\{0_S\text{-mod.}\}}(F)/S)(S') = \text{End}_{\{0_{S'}\text{-mod.}\}}(F_{S'})$ .\*

\*Proof.\*[<sup>N.D.E-II-81</sup>] By base change, one reduces to  $S' = S$ , which permits one to lighten the notation. Set  $I = I_S$  and  $0_I = 0_S[t]$  (with  $t^2 = 0$ ). Recall (cf. 4.5.1) that the inclusion  $i : \text{End}_{\{0_S\text{-mod.}\}}(F) \hookrightarrow \text{Aut}_{\{0_I\text{-mod.}\}}(F_I)$  sends  $Y$  to  $\text{id} + t Y$ . Then, by definition of  $\text{Ad}(g)$  (cf. 4.1.A), one has:

```text  
 $\text{id} + t \text{Ad}(g)(Y) = g \circ (\text{id} + t Y) \circ g^{-1} = \text{id} + t (g \circ Y \circ g^{-1}),$
 ```

whence  $\text{Ad}(g)(Y) = g \circ Y \circ g^{-1}$ .

Let  $I'$  be a second copy of  $I_S$ , set  $0_{I'} = 0_S[t']$  (with  $t'^2 = 0$ ). Apply the results of 4.7.3 to  $G = \text{operatorname{Aut}}_{\{0_S\text{-mod.}\}}(F)$  and  $L = \text{Lie}(G/S) = \text{Aut}_{\{0_S\text{-mod.}\}}(F)$ . One identifies  $X$  with its image under the canonical section  $L(S) \hookrightarrow L(I)$ ; its image in  $G(I \times I')$  is then  $\text{id} + t' X$ , whose inverse is  $\text{id} - t' X$ . Likewise,  $Y$  lifts to  $\text{id} + t Y$ , whose inverse is  $\text{id} - t Y$ . Then, the commutator

```text  
 $(\text{id} + t' X) \circ (\text{id} + t Y) \circ (\text{id} - t' X) \circ (\text{id} - t Y) = \text{id} + t t' (X \circ Y - Y \circ X)$
 ```

is the image in  $G(I \times I')$  of the element  $Z = X \circ Y - Y \circ X$  of  $L(S)$  (indeed,  $Z$  is sent to  $t Z$  in  $L(I)$ , then to  $\text{id} + t' t Z$  in  $G(I \times I')$ ). By 4.7.3, this shows that  $[X, Y] = X \circ Y - Y \circ X$ .

<!-- original page 71 -->

**\*Corollary 4.8.1.\*** \*Let  $G$  be a good  $S$ -group and  $x, y, z \in \text{Lie}(G/S)(S')$ . One has:\*

<!-- label: III.II.4.8.1 -->

```text  
 $[x, [y, z]] + [y, [z, x]] + [z, [x, y]] = 0.$
 ```

[<sup>N.D.E-II-82</sup>] Indeed, since  $G$  is good,  $\text{Lie}(G/S)$  is a good  $0_S$ -module and therefore, by 4.7,  $\text{operatorname{Aut}}_{\{0_S\text{-mod.}\}}(\text{Lie}(G/S))$  is a good  $S$ -group. Then, the morphism of  $S$ -groups

```text  
 $\text{Ad} : G \rightarrow \text{Aut}_{\{0_S\text{-mod.}\}}(\text{Lie}(G/S))$
 ```

gives, by the functoriality 4.7.3 (i):  $\text{ad}[x, y] = [\text{ad } x, \text{ad } y]$ . Combined with 4.8, this gives:

```text  
 $\text{ad}[x, y] = [\text{ad } x, \text{ad } y] = \text{ad } x \circ \text{ad } y - \text{ad } y \circ \text{ad } x,$
 ```

which, applied to an element  $z$ , gives the Jacobi relation.

**\*Corollary 4.8.2.\*** \*Let  $G$  be a good  $S$ -group acting linearly on a good  $0_S$ -module  $F$  (i.e. let  $F$  be a  $G$ - $0_S$ -module, with  $G$  and  $F$  good). Then the linear map  $\rho : \text{Lie}(G/S) \rightarrow \text{End}_{\{0_S\text{-mod.}\}}(F)$  is a representation, i.e. one has\*

<!-- label: III.II.4.8.2 -->

```

```text

$$\rho'([x, y]) = \rho'(x) \circ \rho'(y) - \rho'(y) \circ \rho'(x).$$

```

```

**Scholie 4.9.** To every good  $S$ -group (for example representable), one has associated a good  ${}_{0_S}$ -module  $\text{Lie}(G/S)$  functorially equipped with a bilinear map satisfying\*

<!-- label: III.II.4.9 -->

```

```text

$$[x, y] + [y, x] = 0, \quad [x, [y, z]] + [y, [z, x]] + [z, [x, y]] = 0.$$

```

```

We shall call  $\text{Lie}(G/S)$  equipped with this structure the "Lie algebra" of  $G$  over  $S$  (the quotation marks being justified by the fact that one does not know whether  $\text{Lie}(G/S)$  is, strictly speaking, an  ${}_{0_S}$ -Lie algebra\*[N.D.E-II-83]\*). To every linear representation of  $G$  in a good  ${}_{0_S}$ -module  $F$  is associated a representation of its "Lie algebra". In particular, to the adjoint representation of  $G$  is associated the adjoint representation of its "Lie algebra".\*

**Definition 4.10.** A group-functor  $G$  above  $S$  is said to be **very good** if it is good and if  $\text{Lie}(G/S)$  is an  ${}_{0_S}$ -Lie algebra (i.e. if one has identically  $[x, x] = 0$ ).

<!-- label: III.II.4.10 -->

**Examples 4.10.1.** The following  $S$ -groups are very good:  $\text{Aut}_{0_S\text{-mod.}}(F)$  for every good  ${}_{0_S}$ -module  $F$  (cf. 4.7 and 4.8), every representable group (see below), every good  $S$ -group admitting a monomorphism into a very good  $S$ -group, for example every good subgroup-functor of a representable group, or every good  $S$ -group admitting a faithful linear representation in a good  ${}_{0_S}$ -module, for example every good  $S$ -group such that  $\text{Ad}$  is a monomorphism . . .\*

<!-- label: III.II.4.10.1 -->

<!-- original page 89 -->

**4.11.** Suppose now that  $G$  is a group scheme over  $S$ . By 4.1.4,  $\text{Lie}(G/S)(S)$  is identified with the group of infinitesimal automorphisms of  $G/S$  right-invariant, that is to say, by 3.14, with the group of derivations of  ${}_{0_G}$  over  ${}_{0_S}$  invariant by right translation. Moreover this identification respects the module structure and is an\*[N.D.E-II-84]\* anti-isomorphism of Lie algebras, as one sees by reasoning as in 4.7.3: set  $0_{\{I\}} = 0_{\{S\}[t]}$  and  $0_{\{I'\}} = 0_{\{S\}[t']}$  and let  $x \in L(I)$  and  $y \in L(I')$ . The left translation  $\lambda_x$  (resp.  $\lambda_y$ ) is an  $S$ -automorphism of  $G_{I \times I'}$  which induces the identity on  $G_{I'}$  (resp.  $G_I$ ) and which corresponds to an  ${}_{0_S}$ -automorphism

```

```text

$$u = \text{id} + t d_x \quad \text{resp.} \quad v = \text{id} + t' d_y$$

```

```

of  $G_{I \times I'} = 0_{\{G\}[t, t']/(t^2, t'^2)}$ , where  $d_x, d_y$  are  ${}_{0_S}$ -derivations of  ${}_{0_G}$  invariant by right translation. Since the correspondence between  $S$ -automorphisms of  $G_{I \times I'}$  and  ${}_{0_S}$ -automorphisms of  $0_{\{G_{I \times I'}\}}$  is contravariant,  $\lambda_x \lambda_y \lambda_x^{-1} \lambda_y^{-1}$  corresponds to  $v^{-1} u^{-1} v u = \text{id} + t t' (d_y d_x - d_x d_y)$ . One deduces, by 4.7.3, that the map  $x \mapsto -d_x$  is an isomorphism of Lie algebras (for more details, see [DG70], § II.4, 4.4 and 4.6). What precedes is valid for  $\text{Lie}(G/S)(S) = \text{Lie}(G_{S'}/S')(S)$  for every  $S' \rightarrow S$ . One thus recovers the classical definition:[N.D.E-II-85]

**Scholie 4.11.1.** Via the isomorphism  $x \mapsto -d_x$ ,  $\text{Lie}(G/S)$  is identified with the functor that to every  $S'$  above  $S$  associates the  $0(S')$ -Lie algebra of derivations of  $G_{S'}$  with respect to  $S'$  invariant by right translation.\*

<!-- label: III.II.4.11.1 -->

Since one knows already, by 4.6.1, that every representable group is good, it follows from what precedes:

**Corollary 4.11.2.** Every representable group is very good.\*

<!-- label: III.II.4.11.2 -->

Let  $\epsilon : S \rightarrow G$  be the unit section of  $G$ . Set  $\omega^1_{G/S} = \epsilon^*(\omega^1_{G/S})$  and recall (cf. 3.3) that  $\mathrm{Lie}(G/S)$  is representable by the vector fibration  $V(\omega^1_{G/S})$ .

**Scholie 4.11.3.** One has therefore associated functorially to every  $S$ -group scheme  $G$  a vector fibration  $\mathrm{Lie}(G/S) = V(\omega^1_{G/S})$  over  $S$ , which represents the functor  $\mathrm{Lie}(G/S)$ , hence is equipped with a structure of  $S$ -scheme of  $0_S$ -Lie algebras. Moreover (cf. 3.4 and 3.8), this construction commutes with base extension and finite products.

!-- label: III.II.4.11.3 -->

**Remarks 4.11.4.** Denote by  $\pi$  the morphism  $G \rightarrow S$ .

!-- label: III.II.4.11.4 -->

a) The  $0_S$ -module  $\omega^1_{G/S}$  is evidently  $(G \times_S G)$ -equivariant (cf. I, § 6) and therefore, by I 6.8.1, one has  $\omega^1_{G/S} \simeq \pi^*(\omega^1_{G/S})$ . It follows for example that  $\omega^1_{G/S}$  is locally free (resp. locally free of finite type) if  $\omega^1_{G/S}$  is, which is in particular the case if  $S$  is the spectrum of a field (resp. if  $S$  is the spectrum of a field and  $G$  locally of finite type over  $S$ ).

!-- original page 90 -->

b) Moreover, by I 6.8.2,  $\omega^1_{G/S}$  is equipped with a canonical structure of  $G$ - $0_S$ -module, which induces on  $V(\omega^1_{G/S}) = \mathrm{Lie}(G/S)$  the adjoint action. [N.D.E-II-87]

c) On the other hand (cf. EGA I, 5.3.11 and 5.4.6),  $\epsilon$  is an immersion, and is a closed immersion if  $G$  is separated over  $S$ . Therefore  $\omega^1_{G/S}$  is identified with  $I/I^2$ , where  $I$  is the quasi-coherent ideal defining  $\epsilon(S)$  in an open subset  $U$  of  $G$  in which  $\epsilon(S)$  is closed (if  $G \rightarrow S$  is separated, one may take  $U = G$ , and if  $G = \mathrm{Spec} A(G)$  is affine over  $S$ ,  $I$  is nothing other than the augmentation ideal of  $A(G)$ , i.e. the kernel of  $\epsilon^{\mathrm{natural}} : A(G) \rightarrow 0_S$ , cf. I 4.2). [N.D.E-II-88]

**Remark 4.11.5.** One can deduce from the isomorphism  $\omega^1_{G/S} \simeq \pi^*(\omega^1_{G/S})$  that the  $0_S$ -module  $\omega^1_{G/S}$  is identified with the sheaf  $\pi^*(\omega^1_{G/S})^G$  of "differentials of  $G$  with respect to  $S$  invariant on the right", that is to say, with the sheaf whose sections on an open subset  $U$  of  $S$  are the sections of  $\omega^1_{G/S}$  on  $\pi^{-1}(U)$  invariant by right translation (cf. I, 6.8.3, compare also with VII\_A, 2.4). [N.D.E-II-89]

!-- label: III.II.4.11.5 -->

!-- original page 74 -->

**Notation 4.11.6.** One denotes by  $\mathrm{Lie}(G/S)$  the sheaf of sections of the vector fibration  $\mathrm{Lie}(G/S) \rightarrow S$ ; it is the  $0_S$ -module  $(\omega^1_{G/S})^{\vee} = \mathrm{Hom}_{0_S}(\omega^1_{G/S}, 0_S)$  dual to  $\omega^1_{G/S}$  (cf. EGA II 1.7.9). It is equipped with a structure of  $0_S$ -Lie algebra.

!-- label: III.II.4.11.6 -->

Since this construction does not commute with base extension (in general), the Lie algebra structure on this module does not allow one to reconstruct the structure of  $S$ -scheme of  $0_S$ -Lie algebras on  $\mathrm{Lie}(G/S)$ . [N.D.E-II-90]

However one has:

**Lemma 4.11.7.** Suppose  $\omega^1_{G/S}$  locally free of finite type (which is the case in particular if  $G$  is smooth over  $S$  (cf. EGA IV\_4, 17.2.4), or if  $S$  is the spectrum of a field and  $G$  locally of finite type over  $S$ ). Then  $\mathrm{Lie}(G/S)^{\vee} \cong (\omega^1_{G/S})^{\vee\vee} \cong \omega^1_{G/S}$  and therefore\*

!-- label: III.II.4.11.7 -->

```
```text
Lie(G/S) = V(ω1G/S) = V(Lie(G/S)∨) = W(Lie(G/S))
```
```

\*(the last equality following from I 4.6.5.1).\*

Finally, let  $G \rightarrow H$  be a monomorphism of group-functors. Then  $\mathrm{Lie}(G/S) \rightarrow \mathrm{Lie}(H/S)$  is also a monomorphism (cf.

3.7). Since every vector monomorphism of vector fibrations is a closed immersion [N.D.E-II-91] one obtains:

**Corollary 4.11.8.** *Let  $G \hookrightarrow H$  be a monomorphism of  $S$ -group schemes.*

*III.II.4.11.8 -->*

*(i)  $\mathrm{Lie}(G/S) \rightarrow \mathrm{Lie}(H/S)$  is a closed immersion and therefore  $\omega^1_{H/S} \rightarrow \omega^1_{G/S}$  is an epimorphism.*

*(ii) If  $\omega^1_{G/S}$  is locally free of finite type, then the corresponding morphism  $\mathrm{Lie}(G/S) \rightarrow \mathrm{Lie}(H/S)$  is an isomorphism of  $\mathrm{Lie}(G/S)$  onto a sub-module of  $\mathrm{Lie}(H/S)$  locally direct factor.*

**5. Computation of some Lie algebras**

*III.II.5 -->*

**5.1. Examples of Lie algebras: diagonalizable groups**

*III.II.5.1 -->*

Let  $G = D_{\{S\}}(M)$  be a diagonalizable group over  $S$  (I 4.4). Since the formation of  $\mathrm{Lie}(G/S)$  commutes with base extension, it suffices to make the construction for  $G = D(M)$ . One has then:

$$G(I_S) = \mathrm{Hom}_{\mathrm{gr.}}(M, \Gamma(I_S, \mathcal{O}_{I_S}^{\wedge \times})) = \mathrm{Hom}_{\mathrm{gr.}}(M, \Gamma(S, D_{\{0_S\}}^{\wedge \times})).$$

Now one has a split exact sequence

$$1 \rightarrow \Gamma(S, \mathcal{O}_S) \rightarrow \Gamma(S, D_{\{0_S\}}^{\wedge \times}) \rightarrow \Gamma(S, \mathcal{O}_S^{\wedge \times}) \rightarrow 1,$$

which gives that  $\mathrm{Lie}(G)(S)$  is identified with  $\mathrm{Hom}_{\mathrm{gr.}}(M, \mathcal{O}(S))$  equipped with its obvious  $\mathcal{O}(S)$ -module structure. One thus obtains, after base change:

*original page 75 -->*

**Proposition 5.1.** *One has isomorphisms*

*III.II.5.1 -->*

$$\mathrm{Hom}_{S\text{-gr.}}(M_S, \mathcal{O}_S) \cong \mathrm{Lie}(D_S(M)/S) \quad \text{and} \quad \mathrm{Hom}_{\mathrm{gr.}}(M^{\sim}_S, \mathcal{O}_S) \cong \mathrm{Lie}(D_S(M)/S),$$

*(where, in the second isomorphism,  $\tilde{M}_S$  denotes the constant sheaf of groups on  $S$  defined by  $M$ , and  $\mathrm{Hom}_{\mathrm{gr.}}$  the sheaf of homomorphisms of sheaves of groups).*

**Corollary 5.1.1.** *If  $M$  is free of finite type (or, as we shall say later, if  $D_{\{S\}}(M)$  is a split torus), then (see I, 4.6.5 for the definition of  $W$ )*

*III.II.5.1.1 -->*

$$W(\mathrm{Lie}(D_S(M)/S)) \cong \mathrm{Lie}(D_S(M)/S),$$
  

$$M^{\vee} \otimes_{\mathbb{Z}} \mathcal{O}_S \cong \mathrm{Lie}(D_S(M)/S),$$

*where  $M^{\vee}$  denotes the dual of the abelian group  $M$ . In particular*

$$\mathcal{O}_S \cong \mathrm{Lie}(G_{\{m,S\}}/S) \quad \text{and} \quad \mathcal{O}_S \cong \mathrm{Lie}(G_{\{m,S\}}/S).$$

### ### 5.2. Normalizers and centralizers

<!-- label: III.II.5.2 -->

Let us first prove a few lemmas. Recall (cf. I 3.1.1) that a sequence  $0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0$  of  ${}_{0_S}$ -modules is said to be exact if for every  $S' \rightarrow S$  the sequence  $0 \rightarrow F'(S') \rightarrow F(S') \rightarrow F''(S') \rightarrow 0$  of  ${}_0(S')$ -modules is exact.

<!-- original page 76 -->

Likewise, a sequence  $1 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 1$  of  $\$S$ -groups is said to be exact if for every  $S' \rightarrow S$  the sequence of groups  $1 \rightarrow G'(S') \rightarrow G(S') \rightarrow G''(S') \rightarrow 1$  is exact.

**Lemma 5.2.1.** <sup>[^N.D.E-II-92]</sup> \*Let  $1 \rightarrow G' \rightarrow G \rightarrow G'' \rightarrow 1$  be an exact sequence of  $\$S$ -groups.\*

<!-- label: III.II.5.2.1 -->

**(i)** The sequences  $1 \rightarrow T_{\{G'/S\}}(M) \rightarrow T_{\{G/S\}}(M) \rightarrow T_{\{G''/S\}}(M) \rightarrow 1$  and\*

```
```text
1 → Lie(G'/S, M) → Lie(G/S, M) → Lie(G''/S, M) → 1
```
```

\*are then exact.\*

**(ii)** Let  $1 \rightarrow H' \rightarrow H \rightarrow H'' \rightarrow 1$  be a second sequence of groups; it is exact if and only if the sequence below is exact:\*

```
```text
1 → G' ×_S H' → G ×_S H → G'' ×_S H'' → 1.
```
```

**(iii)** If two of the  $\$S$ -groups  $G', G, G''$  satisfy (E), the third also satisfies (E).\*

**(iv)** If  $0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0$  is an exact sequence of  ${}_{0_S}$ -modules and if two of the modules  $F', F, F''$  are good, the third is also.\*

**(v)** If two of the  $\$S$ -groups  $G', G, G''$  are good, the third is also.\*

<sup>[^N.D.E-II-93]</sup> The first part of (i) is immediate, and the second part follows. Likewise, (ii) is immediate. Let us prove (iii). To abbreviate, write  $L(M) = \text{Lie}(G, M)$ ,  $L'(M) = \text{Lie}(G', M)$ , etc. Then one has the following commutative diagram

```
```text
1 → L'(M ⊗ N) → L(M ⊗ N) → L''(M ⊗ N) → 1
    |           |           |
    ↓           ↓           ↓
1 → L'(M) ×_S L'(N) → L(M) ×_S L(N) → L''(M) ×_S L''(N) → 1
```
```

in which the first (resp. the second) row is exact by (i) (resp. (i) and (ii)). Assertion (iii) follows.

Let us prove (iv). One has a commutative diagram

```
```text
0 → F' ⊗_{0_S} T_{\{0_S/S\}}(M) → F ⊗_{0_S} T_{\{0_S/S\}}(M) → F'' ⊗_{0_S} T_{\{0_S/S\}}(M) → 0
    |           |           |
    ↓           ↓           ↓
0 → T_{\{F'/S\}}(M) → T_{\{F/S\}}(M) → T_{\{F''/S\}}(M) → 0
```
```

with exact rows (the first, because  $T_{\{0_S/S\}}(M)$  is a free  ${}_{0_S}$ -module hence flat, the second by (i)). It follows that if two of the modules  $F', F, F''$  are good, the third is also. Finally, (v) follows from (iii) and (iv).

**Lemma 5.2.2.** \*Let  $G$  be an  $\$S$ -group,  $E, H$  two  $G$ -objects,  $F$  a  $G$ - ${}_{0_S}$ -module.\*

<!-- label: III.II.5.2.2 -->

\*(i) The canonical homomorphism  $E^{\{G\}} \times_{\{H\}} H^{\{G\}} \rightarrow (E \times_{\{H\}} H)^{\{G\}}$  is an isomorphism.\*

\*(ii) If  $F$  is a good  ${}_0S$ -module, so is  $F^{\{G\}}$ .\*

<!-- original page 92 -->

[^N.D.E-II-94] The first assertion is immediate; let us prove the second. For every  $S' \rightarrow S$ , one has a commutative diagram

$$\begin{array}{ccc} F^G(I_{\{S'\}}(M)) & \xrightarrow{\quad} & F(I_{\{S'\}}(M)) \\ \uparrow \varphi & & \uparrow \varphi_1 \\ F^G(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}(M)) & \xrightarrow{\quad} & F(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}(M)) \end{array}$$

and one must show that  $\varphi$  is bijective; now it is evidently injective; let us show that it is surjective. Let  $(t_0, \dots, t_n)$  be a basis of the free  ${}_0(S')$ -module  $0(I_{\{S'\}}(M))$  and let

$$u = \sum_{i=0}^n f_i \otimes t_i$$

be an element of  $F(S') \otimes_{\{0(S')\}} 0(I_{\{S'\}}(M))$  such that  $\varphi_1(u)$  belongs to  $F^{\{G\}}(I_{\{S'\}}(M))$ . Let us show that the  $f_i$  belong to  $F^{\{G\}}(S')$ .

Let  $S'' \rightarrow S'$ ; one can consider  $S''$  as above  $I_{\{S'\}}(M)$  via the zero section  $\epsilon_M$ . Then, for every  $g \in G(S'')$ , one has:

$$u_{\{S''\}} = g \cdot u_{\{S''\}} = \sum_{i=0}^n g \cdot (f_i)_{\{S''\}} \otimes (t_i)_{\{S''\}}.$$

Since the  $(t_i)_{\{S''\}}$  form a basis of  $0(I_{\{S''\}}(M)) \simeq 0(I_{\{S'\}}(M)) \otimes_{\{0(S')\}} 0(S'')$  over  ${}_0(S'')$ , it follows that  $g \cdot (f_i)_{\{S''\}} = (f_i)_{\{S''\}}$ , whence  $f_i \in F^{\{G\}}(S')$  for every  $i$ .

\*Notations.\*[^N.D.E-II-95] If  $E$  is an  $S$ -group and  $F$  a sub- $S$ -group of  $E$ , one denotes by  $E/F$  the  $S$ -functor that to every  $S' \rightarrow S$  associates the set  $E(S')/F(S')$  of classes  $\bar{x} = x F(S')$ ,  $x \in E(S')$ . If  $E$  is a commutative  $S$ -group then  $E/F$  is a commutative  $S$ -group.

Let now  $G$  be an  $S$ -group and  $K$  a sub- $S$ -group of  $G$ ; set  $E = \text{Lie}(G/S, M)$  and  $F = \text{Lie}(K/S, M)$ . The adjoint action of  $K$  on  $E$  stabilizes  $F$ , hence induces an action of  $K$  on the  $S$ -functor  $E/F$ . Then, for every  $S' \rightarrow S$ , one has:

$$(E/F)^K(S') = \{ \bar{x} \in E(S')/F(S') \mid \text{for every } f : S'' \rightarrow S' \text{ and } k \in K(S''), \\ f^*(\bar{x}^{-1}) \text{ Ad}(k)(f^*(\bar{x})) \in F(S'') \},$$

where  $f^*(\bar{x})$  denotes the image of  $\bar{x}$  in  $E(S'')$ .

**Theorem 5.2.3.** \*Let  $G$  be an  $S$ -group,  $K$  a sub- $S$ -group of  $G$ . Write (I 2.3.3)\*

<!-- label: III.II.5.2.3 -->

<!-- original page 77 -->

$$N = \text{Norm}_G(K), \quad Z = \text{Centr}_G(K).$$

\*Make  $K$  act on  $\text{Lie}(G/S, M)$  through the adjoint representation of  $G$ .\*

\*(i) If the group law of  $\text{Lie}(G/S, M)$  is commutative<sup>[^II-5-1]</sup> <sup>[^N.D.E-II-96]</sup>, then\*

```
```text
Lie(N/S, M) / Lie(K/S, M) = ( Lie(G/S, M) / Lie(K/S, M) )^K.
```
```

\*(ii) If the group law of  $\text{Lie}(G/S, M)$  is commutative<sup>[^II-5-1]</sup>, then\*

```
```text
Lie(Z/S, M) = Lie(G/S, M)^K.
```
```

\*(iii) If  $G$  satisfies (E) (resp. if  $G$  and  $K$  satisfy (E)), then  $Z$  satisfies (E) (resp.  $N$  satisfies (E)).\*

\*(iv) Suppose  $G$  is good; then  $Z$  is good; if moreover  $G$  is very good, then  $Z$  is very good.\*

\*(v) Suppose  $G$  and  $K$  are good; then  $N$  is good; if moreover  $G$  is very good, then  $N$  is very good.\*

To prove (i) and (ii)<sup>[^N.D.E-II-97]</sup> we shall use the following lemma, which follows from the diagram of exact sequences considered in 4.1.B (with  $G$  and  $H$  interchanged).

**Lemma 5.2.3.0.** \*Let  $G$  be an  $S$ -group,  $H$  a sub- $S$ -group of  $G$ , and  $M$  a free  ${}_0S$ -module of finite type. Then  $T_{H/S}(M)$  and  $\text{Lie}(G/S, M)$  are sub- $S$ -groups of  $T_{G/S}(M)$  and one has:\*

<!-- label: III.II.5.2.3.0 -->

```
```text
T_{H/S}(M) \cap T_{G/S}(M) = Lie(H/S, M),
```
```

\*where one has set  $T_{H/S}(M) \cap T_{G/S}(M) := \text{def } T_{H/S}(M) \times_{T_{G/S}(M)} \text{Lie}(G/S, M)$ .\*

Since the functors considered in (i) and (ii) commute with base extension, it suffices to show the equalities of  $S$ -points.

Set  $H = N$  (resp.  $H = Z$ ) and let  $\alpha = \pm 1$ . By the preceding lemma and the definition of  $N$  and  $Z$  (cf. I 2.3.3), one has:  $\text{Lie}(H/S, M)(S) =$

```
```text
{ X \in Lie(G/S, M)(S) \mid
  for every f : S' \to I_S(M) and u \in K(S'),
    f^{*\alpha}(X) \cdot u \cdot f^{*}(X^{-\alpha}) \cdot u^{-1} \in K(S'),
  resp. f^{*}(X) \cdot u \cdot f^{*}(X^{-1}) \cdot u^{-1} = 1 \quad (*) },
```
```

where  $f^{*}(X)$  denotes the image of  $X$  in  $G(S')$ .

To simplify the writing, let us write

```
```text
g = Lie(G/S, M), \quad k = Lie(K/S, M), \quad n = Lie(N/S, M), \quad z = Lie(Z/S, M).
```
```

If  $X \in \text{Lie}(H/S, M)(S)$ , the equalities (\*) are valid for every  $f : S' \rightarrow S$ , since  $f = \rho \circ \epsilon_M \circ f$  factors through  $I_S(M)$  (where  $\rho : I_S(M) \rightarrow S$  is the structural morphism and  $\epsilon_M : S \rightarrow I_S(M)$  the zero section). One deduces that

```
```text
n(S)/k(S) \subset (g/k)^K(S) \quad \text{and} \quad z(S) \subset g^K(S).
```
```

<!-- original page 95 -->

To prove the reverse inclusions, suppose henceforth  $g = \text{Lie}(G/S, M)$  commutative; then  $g^K$  and  $(g/k)^K$  are commutative  $S$ -groups. Let  $X \in g(S)$  and  $\bar{X}$  its image in  $(g/k)(S)$ , suppose that  $\bar{X} \in (g/k)^K(S)$

(resp.  $X \in g^{\{K\}}(S)$ ) and let us show that  $X \in n(S)$  (resp.  $X \in z(S)$ ).

Let  $f : S' \rightarrow I_{\{S\}}(M)$ ; let us show that the preceding condition (\*) is verified for every  $u \in K(S')$ . Consider the cartesian square

$$\begin{array}{ccc} I_{\{S'\}}(M) & \xrightarrow{p} & I_S(M) \\ \downarrow \rho' & \searrow \rho \circ f & \downarrow \rho \\ S' & \xrightarrow{f} & S \end{array}$$

and let  $h$  be the section of  $\rho$  defined by  $f$ . It suffices to show that, for every  $v \in K(I_{\{S'\}}(M))$ , one has

$$\begin{aligned} (**) \quad & p^*(X^\alpha) \cdot v \cdot p^*(X^{-\alpha}) \cdot v^{-1} \in K(I_{\{S'\}}(M)), \\ & \text{resp. } p^*(X) \cdot v \cdot p^*(X^{-1}) \cdot v^{-1} = 1. \end{aligned}$$

Indeed, taking  $v = \rho'^{-1}(u)$  and applying  $h^*$  to (\*\*), one obtains (\*), since  $\rho' \circ h = \text{id}_{S'}$  and  $p \circ h = f$ .

Let us now show (\*\*); for simplicity, we shall write  $X$  instead of  $p^*(X)$ . Every  $v \in K(I_{\{S'\}}(M))$  is written in a unique manner  $Y \cdot k$  where  $Y \in \text{Lie}(K/S, M)(S')$  and  $k \in K(S')$ . The expression  $X^\alpha \cdot u \cdot X^{-\alpha} \cdot u^{-1}$  then becomes  $X^\alpha \cdot k \cdot Y \cdot k \cdot X^{-\alpha} \cdot k^{-1} \cdot Y^{-1}$  which, since  $\text{Lie}(G/S, M)$  is commutative, is written  $X^\alpha \cdot \text{Ad}(k)(X^{-\alpha})$ . Now this is a priori in  $\text{Lie}(G/S, M)(S')$ ; taking into account Lemma 5.2.3.0, the condition (\*\*) for  $X$  therefore becomes: for every  $k \in K(S')$ ,

$$\begin{aligned} \square \quad & \text{Ad}(k)(X) = X, & \text{if } H = Z; \\ \square \quad & X^\alpha \text{Ad}(k)(X^{-\alpha}) \in \text{Lie}(K/S, M)(S'), & \text{if } H = N. \end{aligned}$$

When  $H = Z$ , this condition is indeed a consequence of the hypothesis  $X \in g^{\{K\}}(S)$ . When  $H = N$ , the condition is also written:

$$(*)' \quad \text{Ad}(k)(X) = X \quad \text{and} \quad \text{Ad}(k)(X^{-1}) = X^{-1},$$

now the second condition of (\*)' is a consequence of the first, since the action of  $K$  on  $g/k$  respects the group structure of this latter. Therefore, when  $H = N$ , the condition (\*\*) for  $X$  is indeed a consequence of the hypothesis  $X \in (g/k)^{\{K\}}(S)$ . This proves (i) and (ii).

To prove (iii)–(v), let us write  $g(M) = \text{Lie}(G/S, M)$  and define similarly  $k(M)$ ,  $z(M)$  and  $n(M)$ . If  $G/S$  satisfies (E), then  $g(M \oplus N) \simeq g(M) \times_S g(N)$  and therefore, by 5.2.2 (i),

$$g(M \otimes N)^K \simeq g(M)^K \times_S g(N)^K,$$

<!-- original page 96 -->

whence  $z(M \oplus N) \simeq z(M) \times_S z(N)$ , so  $Z$  satisfies (E). If moreover  $K/S$  satisfies (E), one obtains successively isomorphisms:

$$\begin{aligned} (g/k)(M \otimes N) & \simeq (g/k)(M) \times_S (g/k)(N), \\ (g/k)^K(M \otimes N) & \simeq (g/k)^K(M) \times_S (g/k)^K(N), \end{aligned}$$

then a commutative diagram:

```

```text
  0 → k(M ⊗ N) → n(M ⊗ N) → (n/k)(M ⊗ N) → 0
      ↓           ↓           ↓
  0 → k(M) ×_S k(N) → n(M) ×_S n(N) → (n/k)(M) ×_S (n/k)(N) → 0
```

```

from which it follows that  $n(M \oplus N) \simeq n(M) \times_S n(N)$ , so  $N$  satisfies (E).

Henceforth, write  $g = g(0_S) = \text{Lie}(G/S)$  and define similarly  $k, z, n$ . If  $G$  is good,  $g$  is a good  $0_S$ -module so, by 5.2.2 (ii),  $z \simeq g^K$  is also, so  $Z$  (which satisfies (E) by (iii)) is good. If moreover  $K$  is good, then  $k$  is a good  $0_S$ -module so, by 5.2.1 (iv) and 5.2.2 (ii), so are  $g/k$  and  $(g/k)^K$ . Taking into account the exact sequence

```

g
0 → k → n → (g/k)^K → 0,
g

```

one obtains, by 5.2.1 (iv) again, that  $n$  is good. Finally, if in addition to the preceding conditions,  $G$  is very good, i.e., if one has identically  $[x, x] = 0$  for every  $x \in g$ , it is clear that  $Z$  and  $N$  are very good. This proves (iii), (iv) and (v).

**Corollary 5.2.3.1.** One has  $\text{Lie}(\text{Centr}(G)/S) = \text{Lie}(G/S)^K$  if the group law of  $\text{Lie}(G/S)$  is commutative.

<!-- label: III.II.5.2.3.1 -->

**Corollary 5.2.3.2.** If the group law of  $\text{Lie}(G/S)$  is commutative and if  $K$  is a normal subgroup of  $G$ , then

<!-- label: III.II.5.2.3.2 -->

```

```text
( Lie(G/S) / Lie(K/S) )^K = Lie(G/S) / Lie(K/S).
```

```

### 5.3. Linear representations

<!-- label: III.II.5.3 -->

<!-- original page 79 -->

Let  $G$  be a good  $S$ -group acting linearly on a good  $0_S$ -module  $F$  via

```

g
\rho : G → \operatorname{Aut}_{0_S\text{-mod.}}(F).
g

```

One has defined (4.7.1 and 4.8.2) a corresponding linear representation

```

```text
\rho' : \text{Lie}(G/S) → \text{End}_{0_S\text{-mod.}}(F).
```

```

The sub- $S$ -groups  $\text{Norm}_G(E)$  and  $\text{Centr}_G(E)$  are defined for every part  $E$  of  $F$ , for example for every sub- $0_S$ -module  $E$  of  $F$ .

<!-- original page 97 -->

**Definition 5.3.0.** One will pose analogously: for every  $S'$  to  $S$ ,

<!-- label: III.II.5.3.0 -->

```

```text
\text{Norm}_{\text{Lie}(G/S)}(E)(S') = \{ X \in \text{Lie}(G/S)(S') \mid \rho'(X) E_{S'} \subset E_{S'} \};
\text{Centr}_{\text{Lie}(G/S)}(E)(S') = \{ X \in \text{Lie}(G/S)(S') \mid \rho'(X) E_{S'} = 0 \}.
```

```

\*(Note that this construction can be made for any linear representation of an  $\mathfrak{O}_S$ -Lie algebra" (in the sense of 4.9) and that the two subobjects constructed are sub- $\mathfrak{O}_S$ -modules stable under the bracket.)\*

**Theorem 5.3.1.** \*Let  $G$  be a good  $S$ -group acting linearly on a good  $\mathfrak{O}_S$ -module  $F$  and let  $E$  be a sub- $\mathfrak{O}_S$ -module of  $F$ .\*

<!-- label: III.II.5.3.1 -->

(i) One has  $\text{Lie}(\text{Centr}_G(E)/S) = \text{Centr}_{\{\text{Lie}(G/S)\}}(E)$  and  $\text{Centr}_G(E)$  is a good  $S$ -group; it is very good if  $G$  is.\*

(ii) Suppose that  $E$  is a good  $\mathfrak{O}_S$ -module. Then\*[^N.D.E-II-98]  $\text{Lie}(\text{Norm}_G(E)/S) = \text{Norm}_{\{\text{Lie}(G/S)\}}(E)$  and  $\text{Norm}_G(E)$  is a good  $S$ -group; it is very good if  $G$  is.\*

The proof is left to the reader.

**5.3.2.** Let  $G$  be a good  $S$ -group; what precedes applies in particular to the case where one takes for  $\rho$  the adjoint representation of  $G$ . Let  $E$  be a good[^N.D.E-II-99] sub-module of  $\text{Lie}(G/S)$ ; to it one therefore associates two subgroups of  $G$ , its centralizer and its normalizer. By 5.3.1, their Lie algebras are respectively the centralizer and the normalizer of  $E$  in  $\text{Lie}(G/S)$  computed as usual by means of the bracket:

```
```text
Centr_{Lie(G/S)}(E)(S') = { X ∈ Lie(G/S)(S') | [X, E_{S'}] = 0 },
Norm_{Lie(G/S)}(E)(S') = { X ∈ Lie(G/S)(S') | [X, E_{S'}] ⊂ E_{S'} }.
```

5.3.3. Let K be a sub- S -group of G , then $\text{Lie}(K/S)$ is a sub- $\mathfrak{O}_S$ -module of $\text{Lie}(G/S)$; suppose that $\text{Lie}(K/S)$ is a good $\mathfrak{O}_S$ -module[^N.D.E-II-99] (which is the case if K is a good S -group). One evidently has

```
```text
Centr_G(K) ⊂ Centr_G(Lie(K/S)),
Norm_G(K) ⊂ Norm_G(Lie(K/S)),
```
```

whence, by 5.3.1,

```
```text
Lie(Centr_G(K)/S) ⊂ Centr_{Lie(G/S)}(Lie(K/S)),
Lie(Norm_G(K)/S) ⊂ Norm_{Lie(G/S)}(Lie(K/S)),
```
```

but none of these four inclusions is a priori an equality; we shall see by the sequel many examples.

It follows in particular from these inclusions that if K is a normal subgroup of G , then $\text{Lie}(K/S)$ is an ideal of $\text{Lie}(G/S)$.

6. Miscellaneous remarks

<!-- label: III.II.6 -->

<!-- original page 98 -->

6.1. One can define the bracket of two infinitesimal automorphisms for an S -functor X which is not necessarily a group. It suffices to apply the results of this Exposé to the group $\text{Aut}_{\{S\}}(X)$. To arrive at an agreeable formalism, one is led to suppose X good, i.e. to suppose that the $\mathfrak{O}_X$ -module $\mathcal{T}_{X/S}$ is good (if X is an S -group, this definition evidently coincides with Definition 4.6).

6.2. There exist functors possessing infinitesimal endomorphisms that are not automorphisms, hence a fortiori not satisfying condition (E).[^N.D.E-II-100] For every pointed set (E, x_0) , let $\mathcal{M}(E)$ be the free abelian monoid generated by E and let $\text{MAP}(E, x_0)$ be the abelian monoid obtained by quotienting $\mathcal{M}(E)$ by the equivalence relation generated by the relation $m \sim x_0 + m$. Then $(E, x_0) \mapsto \text{MAP}(E, x_0)$ is the left adjoint of the forgetful functor from the category of abelian monoids to that of pointed sets; one will say that $\text{MAP}(E, x_0)$ is the "free abelian monoid on the pointed set (E, x_0) ".

Take then for X the functor that to every scheme S associates the free abelian monoid on the set $0(S)$, pointed by the zero element. Every morphism $f : S \rightarrow I_{\mathbb{Z}} = \operatorname{Spec}(\mathbb{Z}[\epsilon])$ corresponds to an element of square zero u_f of $0(S)$, and hence defines an endomorphism of $X(S)$ by $x \mapsto x + u_f$ (sum in $\operatorname{MAP}(0(S), 0)$). One thus obtains an endomorphism ϕ of $X_{I_{\mathbb{Z}}} = X \times_{I_{\mathbb{Z}}} I_{\mathbb{Z}}$, defined as follows. For every $f \in I_{\mathbb{Z}}(S)$ and $x \in X(S)$,

```

```text
phi((x, f)) = (x + u_f, f).
```

```

If $f_0 : S \rightarrow I_{\mathbb{Z}}$ is the composite of the structural morphism $S \rightarrow \operatorname{Spec}(\mathbb{Z})$ and the zero section of $I_{\mathbb{Z}}$, the corresponding element is $u_{f_0} = 0$, and so $\phi((x, f_0)) = (x, f_0)$, since $x + 0 = x$ in $\operatorname{MAP}(0(S), 0)$. This shows that ϕ induces the identity on X ; it is therefore an infinitesimal endomorphism of X which is evidently not an automorphism.

6.3. There exist modules that are not good. On the one hand, one can modify the preceding counterexample slightly: [N.D.E-II-101] take for $F(S)$ the free $0(S)$ -module with basis the elements of $0(S)$; then F does not satisfy condition (E) with respect to $\operatorname{Spec}(\mathbb{Z})$; moreover, let G be the $\mathbb{Z}$ -group defined by $G(S) = \operatorname{GL}_n(R(S))$, where $n \geq 2$ and $R(S)$ is the $0(S)$ -algebra of the abelian group $0(S)$; then the $\mathbb{Z}$ -group $\operatorname{Lie}(G/\mathbb{Z})$ is not commutative.

[N.D.E-II-102] On the other hand, one can give the following counterexamples. Let $S = \operatorname{Spec}(k)$, with k a field of characteristic $p > 0$.

a) Let F be the 0_S -module which to every S -scheme T associates $F(T) = \Gamma(T, 0_T)$ equipped with the $0(T)$ -module structure obtained by making scalars act through the p -th power, that is to say, $r \cdot f = r^p f$, for $r \in 0(T)$, $f \in F(T)$. As S -functor of groups, F is isomorphic to $G_{\{a, S\}}$. Therefore F/S satisfies (E) and $\operatorname{Lie}(F/S)$ is identified with $\operatorname{Lie}(G_{\{a, S\}}/S) \cong 0_S$. Then, the canonical morphism $F \rightarrow \operatorname{Lie}(F/S)$ is,

```

<!-- original page 99 -->

```

for every $T \rightarrow S$, the identity map $F(T) \rightarrow 0(T)$: it respects the abelian-group structure but not the module structure. Therefore F is not good (cf. 4.4.1).

b) Let $\alpha_{p,k}$ be the k -functor of groups which to every S -scheme T associates

```

```text
alpha_{p,k}(T) = { x in 0(T) | x^p = 0 };
```

```

it is represented by $\operatorname{Spec}(k[X]/(X^p))$ so it is a very good S -group; it is also equipped with an 0_S -module structure, but it is not a good 0_S -module, because the canonical morphism $\alpha_{p,k} \rightarrow \operatorname{Lie}(\alpha_{p,k}/k) = G_{\{a,k\}}$ is not bijective.

6.4. Let G be a group-functor on S . One has by definition the following implications

```

<!-- original page 82 -->

```

```

```text
(G/S satisfies (E)) = (G is good) = (G is very good).
```

```

[N.D.E-II-103] It would be interesting to prove or counter-exemplify the implications in the reverse direction.

6.5. [N.D.E-II-104] Let Nil be the $\mathbb{Z}$ -functor of groups defined as follows: for every scheme S , $\operatorname{Nil}(S)$ is the ideal of $0(S)$ formed by the nilpotent elements, i.e.

```

```text
Nil(S) = { x in 0(S) | there exists n in N such that x^n = 0 }.
```

```

(Nil is very good but is not representable.) Let Nil^2 , 0_{rad} and F be the $\mathbb{Z}$ -functors of groups that to every scheme S associate, respectively, the ideal $\operatorname{Nil}(S)^2$ and

```

```text

$$O_{\text{red}}(S) = O(S) / \text{Nil}(S), \quad F(S) = O(S) / \text{Nil}(S)^2.$$

```

One sees easily that  $\text{Lie}(O_{\text{red}}/\mathbb{Z}) = 0$ , so the  $O_{\text{red}}/\mathbb{Z}$ -module  $O_{\text{red}}$  is not good (although it is a good  $\mathbb{Z}$ -group). If  $M, N$  are  $\mathbb{Z}$ -modules free of finite rank, one has

```

```text

$$\text{Nil}^2(I_S(M \otimes N)) = \text{Nil}^2(S) \otimes \text{Nil}(S) \otimes_{\mathbb{Z}} M \otimes \text{Nil}(S) \otimes_{\mathbb{Z}} N$$

```

and therefore

```

```text

$$F(I_S(M \otimes N)) \simeq F(S) \otimes O_{\text{red}}(S) \otimes_{\mathbb{Z}} M \otimes O_{\text{red}}(S) \otimes_{\mathbb{Z}} N.$$

```

One deduces, on the one hand, that the  $\mathbb{Z}$ -functor of groups  $F$  satisfies condition (E) and, on the other hand, that  $\text{Lie}(F/\mathbb{Z}) = O_{\text{red}}$ ; since this latter is not a good  $\mathbb{Z}$ -module, this shows that  $F$  is an example of a  $\mathbb{Z}$ -group that satisfies (E) but is not good.

**6.5.1.** Let us also give the counterexamples mentioned in 5.3.1–5.3.3. Let  $S$  be a scheme,  $F$  the good  $O_S$ -module  $O^{\oplus 2}_S$  equipped with the natural action of the good  $S$ -group  $G = \text{GL}_2(S)$ , and  $E$  the sub- $O_S$ -module of  $F$  formed by the pairs  $(x_1, x_2)$  such that  $x_2$  is nilpotent. Set  $N = \text{Norm}_G(E)$ . Then  $\text{Lie}(N/S) = \text{Lie}(G/S)$  while, for every  $S' \rightarrow S$ , one has

```

```text

$$\text{Norm}_{\{\text{Lie}(G/S)\}(E)}(S') = \left\{ \begin{bmatrix} a & b \\ x & c \end{bmatrix} \mid a, b, c, x \in O(S'), x \text{ nilpotent} \right\},$$

```

so $\text{Lie}(\text{Norm}_G(E)/S) \neq \text{Norm}_{\{\text{Lie}(G/S)\}(E)}$.

<!-- original page 100 -->

By considering the semi-direct product $G_1 = F \cdot G$, one obtains an analogous counterexample where E is a sub- O_S -module of $\text{Lie}(G_1/S)$; moreover, with the notations introduced above, $E = \text{Lie}(K/S)$ where K is the subgroup $O_S \oplus \text{Nil}^2$ of F (i.e., for every $S' \rightarrow S$, $K(S')$ is formed by the pairs (x_1, x_2) such that $x_2 \in \text{Nil}(S')^2$).

[^N.D.E-II-0]: Version of 14/10/2024.

[^N.D.E-II-1]: Rendered in this edition by boldface characters $\mathbf{F}$, $\mathbf{G}$, $\mathbf{V}$, $\mathbf{W}$, cf. Exposé I. However, for functors such as $\mathbf{Norm}$ and $\mathbf{Centr}$ (cf. 5.2) the underlines have been kept in the original, and they have been added for the functor $\mathbf{Lie}$, this to distinguish the functor $\mathbf{Lie}(G/S)$ from the $\Gamma(S, O_S)$ -Lie algebra $\mathbf{Lie}(G/S) = \mathbf{Lie}(G/S)(S)$, used for example in Exposé VII_A.

[^N.D.E-II-2]: One has detailed the points (2), (3), (4); in particular, (4) will be used in 3.11.

[^N.D.E-II-3]: One has added the two preceding sentences.

[^N.D.E-II-4]: One has added this remark, useful for Corollary 3.11.1.

[^N.D.E-II-5]: Of course, if M is a G -group (not necessarily abelian) and if one sets $\phi \cdot \psi = m \circ (\phi \times \psi)$, this makes $\operatorname{Hom}_{Z/S}(X, M)$ a group above $\operatorname{Hom}_{Z/S}(X, Y)$.

[^N.D.E-II-6]: Note that $I_S(M)$ has the same underlying space as S .

[^N.D.E-II-7]: Compare with 3.1.1.

[^N.D.E-II-8]: One has detailed the original in what follows, and one has added the numbering 2.1.1 to 2.1.3.

[^N.D.E-II-9]: In the sequel, one will be principally interested in the case where $a \in O(S)$, acting by homotheties on M . For example, if M is a free O_S -module of rank r , then, for every $S' \rightarrow S$, $\operatorname{Hom}_S(S', I_S(M))$ is identified with the set of r -tuples $(\epsilon_1, \dots, \epsilon_r) \in O(S')$ such that $\epsilon_i \epsilon_j = 0$ for all i, j , and one has $(\epsilon_1, \dots, \epsilon_r) \cdot a = (a \epsilon_1, \dots, a \epsilon_r)$ for every $a \in O(S)$.

[^N.D.E-II-10]: One has added this paragraph, which will be useful in 3.4.2 and 4.6.2.

[^N.D.E-II-11]: See also the addition 0.1.8 in Exp. III.

[^N.D.E-II-12]: Cf. N.D.E. (33) of Exp. I.

[^N.D.E-II-13]: When $S = \operatorname{Spec}(k)$ and X is a k -scheme, one has $T_{X/S}(S) = \operatorname{Hom}_S(S' \otimes_{\epsilon} k[\epsilon], X) = X(S' \otimes_{\epsilon} k[\epsilon])$; one thus recovers one of the usual definitions of the tangent bundle.

[^N.D.E-II-14]: One has corrected " $0 \rightarrow M$ and $M \rightarrow 0$ " to: " $M \rightarrow 0$ and $0 \rightarrow M$ ".

[^N.D.E-II-15]: One has added the paragraphs 3.1.1 and 3.1.2.

[^N.D.E-II-16]: In fact, one is interested only in the action of $0(S)$ (resp. $0(S) \otimes 0(S)$) on $\Sigma(X', M)$ (resp. $\Sigma(X', M \oplus M)$), cf. below and the proof of 3.6.

[^N.D.E-II-17]: One has added this remark.

[^N.D.E-II-18]: Cf. EGA I, 5.3.11.

[^N.D.E-II-19]: Cf. 3.1.2.

[^N.D.E-II-20]: One has detailed the original in what follows.

[^N.D.E-II-21]: One has added Remarks 3.4.2 and 3.4.3.

[^N.D.E-II-22]: For examples of S -functors and S -groups not satisfying (E), see 6.2 and 6.3.

[^N.D.E-II-23]: One has added what follows.

[^N.D.E-II-24]: One has detailed what follows.

[^N.D.E-II-25]: I.e., for every S -morphism $f : X' \rightarrow X$, the action of $0(X')$ on $\operatorname{Hom}_X(X', T_{X/S}(M))$ corresponds, via the identification $\operatorname{Hom}_X(X', T_{X/S}(M)) \simeq \operatorname{Hom}_{0_X}(f^*(\Omega^1_{X/S}), M \otimes_{0_S} 0_{X'})$, to the natural action of $0(X')$ on the right-hand term; this follows from the proof of SGA 1, III 5.1 (see also the addition 0.1.8 in Exp. III).

[^N.D.E-II-26]: One has added the sentence that follows.

[^N.D.E-II-27]: One has added the hypothesis that X and X' be representable, and one has detailed what follows.

[^N.D.E-II-28]: One has detailed what follows.

[^N.D.E-II-29]: One has added this proof.

[^N.D.E-II-30]: One has added this paragraph, in order to explain the introduction of the notion of S - H -functor.

[^N.D.E-II-31]: This is inspired by the notion of H -space in topology.

[^N.D.E-II-32]: One has added Corollary 3.9.0.2, which will be useful in 4.1.

[^N.D.E-II-33]: Inspired by the standard proof showing that the fundamental group of an H -space is abelian.

[^N.D.E-II-34]: $G \otimes G$ is equipped with the law $(G \otimes G) \otimes (G \otimes G) \rightarrow G \otimes G$, $((x, z), (y, t)) \mapsto (f(x, y), f(z, t))$.

[^N.D.E-II-35]: One has added this corollary, which amplifies Remark 4.1.1.2 below.

[^N.D.E-II-36]: Setting $H = \operatorname{Hom}_{Z/S}(X, Y)$, this implies in particular that $T_{H/S}(M)$ is equipped with a natural structure of module over $\prod_{X \otimes_S H/H} 0_H$. This result has seemed somewhat surprising to the editors; for this reason one has detailed the proof.

[^N.D.E-II-37]: One has added the sentences that follow.

[^N.D.E-II-38]: One has added the sentence that follows.

[^N.D.E-II-39]: One has added this remark.

[^N.D.E-II-40]: One has simplified the original in what follows.

[^N.D.E-II-41]: Via the isomorphism $\operatorname{Hom}_{\mathcal{I}_{\{S\}}(M)}(U_{\mathcal{I}_{\{S\}}(M)}, X_{\mathcal{I}_{\{S\}}(M)}) \simeq \operatorname{Hom}_{\mathcal{S}}(U \times_{\mathcal{S}} \mathcal{I}_{\{S\}}(M), X)$, this is equivalent to Remark 3.1.1. Likewise, 3.12 is equivalent to the first part of Remark 3.4.2.

[^N.D.E-II-42]: One has detailed the original in what follows.

[^N.D.E-II-43]: When $\mathcal{M} = 0_X$, these are called "infinitesimal endomorphisms" of X ; see 6.2 at the end of this Exposé.

[^N.D.E-II-44]: One has detailed the original in what follows.

[^N.D.E-II-45]: One has added the proof that follows.

[^N.D.E-II-46]: One has added what follows.

[^N.D.E-II-47]: One has added the reminder of 2.2.2, and detailed the sequel.

[^N.D.E-II-48]: Moreover, this isomorphism is functorial in S : if $S' \rightarrow S$, setting $X' = X_{S'}$, one has $\operatorname{Lie}(\operatorname{Aut}_{\mathcal{S}}(X)/S)(S') \simeq \Gamma(T_{X'/S}/X') \simeq D_{\operatorname{acute}\{e\}r_{0_{S'}}}(0_{X'})$.

[^N.D.E-II-49]: One has added the numbering 4.1.A and 4.1.B to highlight these definitions.

[^N.D.E-II-50]: If f is a monomorphism, so are $L(f)$ and $T(f)$, cf. 3.7.

[^N.D.E-II-51]: One has added this remark.

[^N.D.E-II-52]: One has detailed the original in what follows, in order to show the action of G on the functors $\operatorname{Hom}_{G/S}(G, T_{G/S}(M))$ and $\operatorname{Hom}_{G/S}(G, \operatorname{Lie}(G/S, M))$.

[^II-4-1]: The statements 4.1.2, 4.1.3 and 4.1.4 are obtained more simply by remarking that the automorphisms of G invariant by right translations are the left translations.[^N.D.E-II-53]

[^N.D.E-II-54]: One has added paragraph 4.2.0, whose results are used implicitly in 4.2 and 4.7 of the original.

[^N.D.E-II-55]: One has inserted here this definition, which in the original appeared in 4.3.

[^N.D.E-II-56]: One has detailed the original in what follows; in particular, one has added Definition 4.2.A and Remark 4.2.B.

[^N.D.E-II-57]: This is Definition 4.2.0.1 applied to $Z = Y$ and to the Y -groups $u : X \rightarrow Y$ and $T_{Y/S}(M)$.

[^N.D.E-II-58]: One has added the sentences that follow and Proposition 4.2 bis, implicit in the original.

[^N.D.E-II-59]: One has added the sentence that follows.

[^N.D.E-II-60]: One has added the sentence that follows.

[^N.D.E-II-61]: Note that on the right-hand term, this is the structure defined by $(a \cdot \phi)(x) = a \cdot \phi(x)$, where $a \cdot \phi(x)$ denotes the action of a on $\phi(x) \in \operatorname{Lie}(Y/S, M)$. This differs from the action $(a \cdot \phi')(x) = a \cdot \phi'(x) = \phi(ax)$, but coincides with it if $\operatorname{Lie}(Y/S, M) = \operatorname{Lie}'(Y/S, M)$.

[^N.D.E-II-62]: One has added this remark, which will be useful in 4.5.1.

[^N.D.E-II-63]: Cf. N.D.E. (61). Moreover, one has added the sentence that follows, as well as its proof.

[^N.D.E-II-64]: One has changed $S' \rightarrow S$ to $S_{-2} \rightarrow S_{-1} \rightarrow S$, because one must let S_{-2} and S_{-1} vary (cf. below). Moreover, one has detailed the original in what follows.

[^N.D.E-II-65]: One found in the original the assertion that when F/S satisfies (E), the morphisms (6) (and hence (7)) are morphisms of 0_S -modules, assertion contradicted by a counterexample given in 6.3. One has deleted this assertion, inserted here the example just mentioned, and modified Definition 4.4 accordingly. This is without consequence for the sequel.

[^N.D.E-II-66]: One has added this remark, which will be useful in 4.6.2.

[^N.D.E-II-67]: One has added this remark, which will be useful in 4.5 and 4.7.

[^N.D.E-II-68]: Taking into account the modifications in Definition 4.4 (cf. N.D.E. (65)), one has inserted here this remark, which in the original figured in the proof of 4.4.1.

[^N.D.E-II-69]: The original showed that (i) implies (ii) and (iii); one has added the implication (ii) $\Rightarrow$ (i).

[^N.D.E-II-70]: One has added what follows.

[^N.D.E-II-71]: One has added the point (ii), immediate consequence of what precedes.

[^N.D.E-II-72]: One has added this scholie, implicit in the original, which will be useful in 4.7.1. (Here and in the sequel, one writes $\$t$, t' , etc. for variables of square zero, the letter ϵ being reserved for the unit section of groups.)

[^N.D.E-II-73]: One has added the sentence that follows.

[^N.D.E-II-74]: One has added this lemma.

[^N.D.E-II-75]: One has simplified the original, using the additions made in 4.3.1 and 4.5.

[^N.D.E-II-76]: One has added the numbering 4.7.1, 4.7.2, 4.7.3.

[^N.D.E-II-77]: One has added the sentence that follows.

[^N.D.E-II-78]: One has detailed the original in what follows.

[^N.D.E-II-79]: The original indicated in a footnote: "(*) The author acknowledges, at Gabriel's request, that the exercise is not immediate; this is moreover the reason why it is not in the text". One has given the details, taking into account the addition made in 4.7.1; see also [DG70], § II.4, 4.2.

[^N.D.E-II-80]: I.e. $\$x$ and $\$y$ play symmetric roles: the image in $\$G(I \times I)$ of $[y, x]$ equals the commutator $y' \tilde{x} y'^{-1} \tilde{x}^{-1}$, which is the inverse of $\tilde{x} y' \tilde{x}^{-1} y'^{-1} = [x, y]$. On the other hand (cf. 4.10 below), one does not know whether one necessarily has $[x, x] = 0$: if one considers $\$x$ as an element $\tilde{x} \in L(I)$ (resp. $\$x' \in L(I')$) it is not a priori clear that $\tilde{x}$ and $\$x'$ commute. .

[^N.D.E-II-81]: One has detailed and simplified the original in what follows.

[^N.D.E-II-82]: One has detailed the original in what follows.

[^N.D.E-II-83]: Because one does not know whether $[x, x] = 0$, see 4.10 which follows.

[^N.D.E-II-84]: One has corrected a sign error in the original, cf. [DG70], § II.4, 4.4 and 4.6.

[^N.D.E-II-85]: One has detailed the original in what follows; in particular, one has added, for later references, the numbering 4.11.1 to 4.11.8.

[^N.D.E-II-86]: One has detailed what follows, taking into account the additions made in Exp. I, § 6.8.

[^N.D.E-II-87]: For this reason, the linear action of $\$G$ on $\omega^1_{G/S}$ could be called the "pre-adjoint action"; in fact, by abuse of language, one will still speak of "the adjoint action" on $\omega^1_{G/S}$. Let us point out here a slightly more general construction, which will be used in Exp. III (cf. in particular III 0.8). Suppose given, for every $Y \rightarrow S$, an $\mathcal{O}_Y$ -module $\mathcal{N}(Y)$, and for every $\$S$ -morphism $\phi : Z \rightarrow Y$, a morphism of $\mathcal{O}_Z$ -modules $\mathcal{N}(\phi) : \phi^* \mathcal{N}(Y) \rightarrow \mathcal{N}(Z)$, which is functorial in ϕ (this is the case, for example, if J is a quasi-coherent ideal of $\mathcal{O}_S$ and if one sets $\mathcal{N}(Y) = J \mathcal{O}_Y$, cf. Exp. III); then the action of $\$G$ on $\omega^1_{G/S}$ induces a (generalized) "adjoint action" of $\$G$ on the $\$S$ -functor of abelian groups that to every $f : Y \rightarrow S$ associates $\text{Hom}_{\mathcal{O}_Y}(\phi^* (\omega^1_{G/S}), \mathcal{N}(Y))$.

[^N.D.E-II-88]: One has added the preceding description of $\omega^1_{G/S}$, which will be useful later (for example, in VII_A, 5.5).

[^N.D.E-II-89]: This description of $\omega^1_{G/S}$ in terms of invariant differentials will not be used in the

sequel.

[^N.D.E-II-90]: Because $\mathrm{Lie}(G/S) \cong (\omega^1_{G/S})^{\vee}$ does not necessarily determine $\omega^1_{G/S}$. For example, if $S = \mathbb{A}^1_k$ (k a field) and if G_S is the S -group whose fiber at $s = 0$ is $G_{\{a,k\}}$ and the other fibers are the unit group, then $\mathrm{Lie}(G/S) = 0$ but $\mathrm{Lie}(G_s/k)(k) = k$.

[^N.D.E-II-91]: Let $f : M \rightarrow N$ be a morphism of $\mathcal{O}_S$ -modules and $P = \mathrm{Coker}(f)$. If $V(N) \rightarrow V(M)$ is a monomorphism, the surjective morphism $\mathrm{Sym}(N) \rightarrow \mathrm{Sym}(P)$ factors through $\mathcal{O}_S$, so $P = 0$.

[^N.D.E-II-92]: One has detailed the statement of the lemma (and its proof); this will be useful in 5.3.1.

[^N.D.E-II-93]: One has added the proof of points (iii) and (v).

[^N.D.E-II-94]: One has detailed the original in what follows.

[^N.D.E-II-95]: One has detailed these notations.

[^II-5-1]: Condition automatically verified if G_S satisfies (E) (cf. 3.9), for example if G_S is representable.

[^N.D.E-II-96]: For an example where the S -group $\mathrm{Lie}(G/S)$ is not commutative, see 6.3.

[^N.D.E-II-97]: One has detailed the proof, adding in particular Lemma 5.2.3.0, implicit in the original.

[^N.D.E-II-98]: One has corrected the original, which stated the equality that follows without hypotheses on E ; see 6.5.1 for counterexamples.

[^N.D.E-II-99]: One has added this hypothesis; cf. 6.5.1.

[^N.D.E-II-100]: One has detailed the original in what follows. In particular, the correct definition of the "free abelian monoid on a pointed set" was pointed out to us by O. Gabber.

[^N.D.E-II-101]: One has added what follows.

[^N.D.E-II-102]: In what follows, one has detailed example a) and added example b).

[^N.D.E-II-103]: And G_S is very good if it is representable (4.11). For representability criteria, see for example [M067]. On the other hand, for the automorphisms of an affine algebraic group (over an algebraically closed field of characteristic 0), let us cite [HM69].

[^N.D.E-II-104]: One has added this paragraph.

[^N.D.E-II-105]: Additional references cited in this Exposé.

[^N.D.E-II-53]: See for example the proof of Propositions 4.6 and 2.5 of [DG70], § II.4.

Exposé III. Infinitesimal extensions

<!-- label: III.III -->

by M. Demazure

<!-- original page 83 -->

[^N.D.E-III-0] In this Exposé, we place ourselves in the following general situation. We have a scheme S and a coherent nilpotent ideal I on S . We denote by S_n the closed subscheme of S defined by the ideal I^{n+1} ($n \geq 0$). In particular S_0 is defined by I . Since I is nilpotent, S_n is equal to S for n large enough, and the S_i have the same underlying topological space. A typical example of this situation is the following: S is the spectrum of a local Artinian ring A , I is the ideal defined by the radical of A , so that S_0 is the spectrum of the residue field of A .

In the preceding situation, one is given a certain number of data above S_0 , and one looks above S for data which lift them, that is to say, which give them back by base change from S to S_0 . This is done step by step, by way of

the $S_{\{n\}}$. At each step, we propose to define the obstructions encountered, and to classify, when they exist, the solutions obtained.

The passage from $S_{\{n\}}$ to $S_{\{n+1\}}$ can be generalized as follows: one has a scheme S , two ideals I and J with $I \supset J$, and $I \cdot J = 0$ (in the preceding case S , I and J are respectively $S_{\{n+1\}}$, I/I^{n+2} , I^{n+1}/I^{n+2}). We denote by $S_{\{0\}}$ (resp. S_J) the closed subscheme of S defined by I (resp. J), and we pose a problem of extension from S_J to S .

<!-- original page 84 -->

In (SGA 1, III), problems of extension of morphisms of schemes and of extension of schemes were treated. We pose here the problems of extension of morphisms of groups, of extension of group structures, and of extension of subgroups.

We have gathered in a § 0 the results of (SGA 1, III) which will be useful to us, in order to put them in the most convenient form for our purpose, and to spare the reader from having to refer constantly to (SGA 1, III).^[N.D.E-III-1] § 1 collects some computations of group cohomology which will be useful in what follows and which have nothing to do with scheme theory. §§ 2 and 3 treat respectively of the extension of group morphisms and the extension of group structures. In § 4, we have briefly recalled the proof of a result stated in (TDTE IV) concerning the extension of subschemes, and applied this result to the problem of extension of subgroups. For the rest of the Seminar, only the result of § 2, concerning the extension of morphisms of groups, will be indispensable.^[N.D.E-III-2]

The idea of reducing infinitesimal extension problems to the usual computations of cohomology in extensions of groups was suggested by J. Giraud at the oral exposé (whose computations were notably more complicated and less transparent). Unfortunately, it seems that this method only applies well to the first two problems studied, and we have been unable to escape rather painful computations in the case of extensions of subgroups.

To simplify the language, we shall call a Y -functor, resp. Y -scheme, etc., a functor, resp. scheme, etc., equipped with a morphism into the functor Y , thus extending the definitions of Exposé I (which concerned only the case of a representable Y).

0. Reminders from SGA 1 III and various remarks

<!-- label: III.III.0 -->

<!-- original page 85 -->

Let us first state a general definition.

Definition 0.1. Let C be a category, X an object of C , G a C -group acting on X . We say that X is **formally principal homogeneous**^[N.D.E-III-3] under G if the following equivalent conditions are satisfied:

<!-- label: III.III.0.1 -->

(i) for each object S of C , the set $X(S)$ is empty or principal homogeneous under $G(S)$;

(ii) the morphism of functors $G \times X \rightarrow X \times X$ defined set-theoretically by $(g, x) \mapsto (gx, x)$ is an isomorphism.

This being so, we shall put the results of (SGA 1, III, § 5)^[N.D.E-III-4] in the form which will be most useful to us. We shall employ the following general notations throughout this section. We have a scheme S and on S two quasi-coherent ideals I and J such that

```
```text
I ⊃ J and I · J = 0.
```
```

In particular we shall therefore have $J^2 = 0$. We shall denote by $S_{\{0\}}$ (resp. S_J) the closed subscheme of S defined by the ideal I (resp. J). For every S -functor X , we shall systematically denote by $X_{\{0\}}$ and X_J the functors obtained by base change from S to $S_{\{0\}}$ and S_J . Same notation for a morphism.

<!-- original page 86 -->

Definition 0.1.1.^[N.D.E-III-5] Let X be an S -functor. Define a functor X^+ above S by the formula:

<!-- label: III.III.0.1.1 -->

```

```text
Hom_S(Y, X^+) = Hom_{S_J}(Y_J, X_J) = Hom_S(Y_J, X)
```

```

*for a variable S -scheme Y . In the notations of (Exp. II, 1), one has

```

```
X^{+} \simeq \prod_{S_J/S} X_J .
```

```

The identity morphism of X_J defines by construction an S -morphism

```

```
p_X : X \to X^{+} .
```

```

[^N.D.E-III-6] Explicitly, for every S -scheme Y , the map

```

```text
p_X(Y) : Hom_S(Y, X) \to Hom_S(Y, X^+) = Hom_S(Y_J, X)
```

```

is the map induced by the morphism $Y_J \to Y$.

Remark 0.1.2. Let us now observe that if X is an S -group functor, then X_J is an S_J -group functor; then the formula defining X^{+} endows it with a structure of S -group functor, and the description of p_X above shows that $p_X : X \to X^{+}$ is a morphism of S -group functors.*

<!-- label: III.III.0.1.2 -->

Remark 0.1.3. On the other hand, for every S -group functor Y , one has:

<!-- label: III.III.0.1.3 -->

```

```text
Hom_{S-gr.}(Y, X^+) = Hom_{S_J-gr.}(Y_J, X_J) .
```

```

Indeed, let $f \in \operatorname{Hom}_{S_J}(Y, X^{+})$, corresponding to $f_J \in \operatorname{Hom}_{S_J}(Y_J, X_J)$; the condition that $f \in \operatorname{Hom}_{S-gr.}(Y, X^{+})$ is that, for every $T \to S$ and $y, y' \in Y(T)$, one has $f(y \cdot y') = f(y) \cdot f(y')$, and this is equivalent to*

```

```text
f_J(y_J) \cdot f_J(y'_J) = f_J((y \cdot y')_J) ;
```

```

since $(y \cdot y')_J = y_J \cdot y'_J$ (because $Y(T) \to Y(T_J) = Y_J(T_J)$ is a morphism of groups), this is the condition for f_J to be a morphism of groups. Applying this to $Y = X$, we recover that p_X , which corresponds to id_{X_J} , is a morphism of S -group functors.

Let us now return to the general case, but assume that X is an S -scheme. Since an S -morphism of a variable S -scheme Y into X^{+} is by definition an S_J -morphism g_J of Y_J into X_J , we shall define an X^{+} -functor in abelian groups L_X as follows.

Scholie 0.1.4. [^N.D.E-III-7] If $\pi : Y \to S$ is a morphism of schemes and M an O_S -module, we denote by $M \otimes_{O_S} O_Y$ the inverse image $\pi^*(M)$. If $\mathfrak{f}$ is an ideal of O_S , we denote by $\mathfrak{f} \cdot O_Y$ the ideal of O_Y image of the morphism*

<!-- label: III.III.0.1.4 -->

```

```text
\pi^*(\mathfrak{f}) = \mathfrak{f} \otimes_{O_S} O_Y \to O_Y .
```

```

Note that, for every morphism of S -schemes $f : Z \rightarrow Y$, one has an epimorphism of $\mathcal{O}_Z$ -modules:

$$f^*(J \cdot \mathcal{O}_Y) \rightarrow J \cdot \mathcal{O}_Z, \quad (0.1.4)$$

as follows from the commutative diagram below:

$$\begin{array}{ccc} J \otimes_{\mathcal{O}_S} \mathcal{O}_Y \otimes_{\mathcal{O}_Y} \mathcal{O}_Z & \longrightarrow & J \otimes_{\mathcal{O}_S} \mathcal{O}_Z \\ \downarrow & & \downarrow \\ f^*(J \cdot \mathcal{O}_Y) = (J \cdot \mathcal{O}_Y) \otimes_{\mathcal{O}_Y} \mathcal{O}_Z & \longrightarrow & J \cdot \mathcal{O}_Z. \end{array}$$

<!-- original page 87 -->

Definition 0.1.5. [N.D.E-III-8] Let X be an S -scheme. For every X^+ -scheme Y , given by a morphism $g_J : Y_J \rightarrow X_J$, we set:

<!-- label: III.III.0.1.5 -->

$$\mathrm{Hom}_{X^+}(Y, L_X) = \mathrm{Hom}_{\mathcal{O}_{Y_0}}(g_0^*(\Omega^1_{X_0/S_0}), J \cdot \mathcal{O}_Y),$$

where $\Omega^1_{X_0/S_0}$ denotes the module of relative differentials of X_0 with respect to S_0 (cf. SGA 1, I.1 or EGA IV₄, 16.3), and where $J \cdot \mathcal{O}_Y$ is regarded as an $\mathcal{O}_{Y_0}$ -module thanks to the fact that it is annihilated by $\mathcal{I}$.

Then L_X is an X^+ -functor in abelian groups. [N.D.E-III-9] Indeed, for every X^+ -morphism $f : Z \rightarrow Y$, the functor f_0^* and the morphism $f_0^*(J \cdot \mathcal{O}_Y) \rightarrow J \cdot \mathcal{O}_Z$ of (0.1.4) induce a natural morphism of abelian groups $L_X(f)$:

$$\begin{aligned} \mathrm{Hom}_{\mathcal{O}_{Y_0}}(g_0^*(\Omega^1_{X_0/S_0}), J \cdot \mathcal{O}_Y) \\ \rightarrow \mathrm{Hom}_{\mathcal{O}_{Z_0}}(f_0^* g_0^*(\Omega^1_{X_0/S_0}), f_0^*(J \cdot \mathcal{O}_Y)) \\ \rightarrow \mathrm{Hom}_{\mathcal{O}_{Z_0}}(f_0^* g_0^*(\Omega^1_{X_0/S_0}), J \cdot \mathcal{O}_Z). \end{aligned}$$

Let us finally note that $L_X(f)$ is described locally as follows. Note first that Y and Y_J have the same underlying topological space, and similarly for S and S_J if S is an open subset of Y . Let then $U = \mathrm{Spec}(A)$ be an affine open of X above an affine open $U = \mathrm{Spec}(A)$ of S , $V = \mathrm{Spec}(B)$ an affine open of Y such that $g_J(V_J) \subset U$, and $W = \mathrm{Spec}(C)$ an affine open of $f^{-1}(V)$. Let J and $\mathcal{I}$ be the ideals of Λ corresponding to J and $\mathcal{I}$. Then f_0^* (resp. g_J) induces a morphism of Λ -algebras $\theta : B \rightarrow C$ (resp. $\phi : A \rightarrow B/JB$), and one obviously has $\theta(JB) \subset JC$. On the other hand, $\sum \mathrm{Hom}_{\mathcal{O}_{Y_0}}(g_0^*(\Omega^1_{X/S}), J \cdot \mathcal{O}_Y)$ induces an element D of

$$\mathrm{Hom}_{\mathcal{O}_{V_0}}(g_0^*(\Omega^1_{U/S}), J \cdot \mathcal{O}_V) = \mathrm{Hom}_{B/IB}(\Omega^1_{A/\Lambda} \otimes_A B/IB, JB) = \mathrm{Der}_\Lambda(A, JB),$$

and the image of $L_X(f)(m)$ is in

$$\mathrm{Hom}_{\mathcal{O}_{W_0}}(f_0^* g_0^*(\Omega^1_{U/S}), J \cdot \mathcal{O}_Z) = \mathrm{Hom}_{C/IC}(\Omega^1_{A/\Lambda} \otimes_A C/IC, JC) = \mathrm{Der}_\Lambda(A, JC)$$

is none other than $\theta \circ D$.

<!-- original page 88 -->

Remark 0.1.6. [N.D.E-III-10] Let $f : X \rightarrow W$ be an S -morphism. It induces an S -morphism $f^+ : X^+ \rightarrow W^+$ defined as follows: if g is an element of $\mathrm{Hom}_S(Y, X^+)$, corresponding

to an S -morphism $g_{\{J\}} : Y_{\{J\}} \rightarrow X$, then $f^+(g)$ is the element $f \circ g_{\{J\}}$ of $\operatorname{Hom}_{\{S\}}(Y, W^{\{+\}})$. It is clear that the following diagram is commutative:*

<!-- label: III.III.0.1.6 -->

$$\begin{array}{ccc} & & f \\ X & \longrightarrow & W \\ p_X \downarrow & & \downarrow p_W \\ X^+ & \xrightarrow{f^+} & W^+ \end{array}$$

Reminders 0.1.7. [N.D.E-III-11] In this paragraph, given an S -scheme X , we "recall" certain functorial properties of the module of differentials $\Omega^1_{X/S}$ and of the first infinitesimal neighborhood of the diagonal $\Delta^{\{1\}}_{X/S}$, properties which follow easily from (EGA IV₄, §§ 16.1–16.4), but which do not figure there explicitly.*

<!-- label: III.III.0.1.7 -->

a) Let us begin by recalling the following facts (cf. EGA II, §§ 1.2–1.5). Let $g : Y \rightarrow X$ be a morphism of schemes, $\pi : X' \rightarrow X$ an affine X -scheme, B the quasi-coherent $\mathcal{O}_{X'}$ -algebra $\pi_*(\mathcal{O}_{X'})$; then the Y -scheme $Y \times_X X'$ is affine and corresponds to the quasi-coherent $\mathcal{O}_Y$ -algebra $g^*(B)$, and one has a commutative diagram of bijections:

$$\begin{array}{ccc} \operatorname{Hom}_X(Y, X') & \xrightarrow{\quad} & \operatorname{Hom}_Y(Y, Y \times_X X') \\ \downarrow \square & & \downarrow \square \\ \operatorname{Hom}_{\{\mathcal{O}_X\text{-alg.}\}}(B, g_*(\mathcal{O}_Y)) & \xrightarrow{\quad} & \operatorname{Hom}_{\{\mathcal{O}_Y\text{-alg.}\}}(g^*(B), \mathcal{O}_Y). \end{array}$$

Moreover, these bijections are functorial in the pair (X, X') , i.e., if W is an affine S -scheme, corresponding to the quasi-coherent $\mathcal{O}_W$ -algebra A , if one has a commutative diagram of morphisms of schemes

$$\begin{array}{ccccc} & & X' & \xrightarrow{f'} & W' \\ & \nearrow g' & & & \downarrow \\ Y & \xrightarrow{g} & X & \xrightarrow{f} & W \end{array},$$

and if we denote by $\phi : A \rightarrow f_*(B)$ and $\phi^\sharp : f^*(A) \rightarrow B$ (resp. $\theta : B \rightarrow g_*(\mathcal{O}_Y)$ and $\theta^\sharp : g^*(B) \rightarrow \mathcal{O}_Y$) the algebra morphisms associated to f' (resp. to a variable X -morphism $g' : Y \rightarrow X'$), then one has the following commutative diagram (where Y is viewed as a W -scheme via $f \circ g$):

<!-- original page 89 (cont.) -->

$$\begin{array}{ccc} \operatorname{Hom}_X(Y, X') & \xrightarrow{g' \mapsto f' \circ g'} & \operatorname{Hom}_W(Y, W') \\ & & \downarrow \cong \\ & & \operatorname{Hom}_{\{\mathcal{O}_W\text{-alg.}\}}(A, f_* g_*(\mathcal{O}_Y)) \\ & & \downarrow \cong \\ \operatorname{Hom}_{\{\mathcal{O}_X\text{-alg.}\}}(B, g_*(\mathcal{O}_Y)) & \xrightarrow{\quad} & \operatorname{Hom}_{\{\mathcal{O}_X\text{-alg.}\}}(f^*(A), g_*(\mathcal{O}_Y)) \\ \downarrow \square & & \downarrow \square \\ \psi \mapsto \psi \circ g^*(\phi^\sharp) & & \end{array}$$

$\text{Hom}_{\{0_Y\text{-alg.}\}}(g^*(B), 0_Y) \longrightarrow \text{Hom}_{\{0_Y\text{-alg.}\}}(g^* f^*(A), 0_Y).$

****b)**** Let now X be an S -scheme. Let $\Omega^1_{X/S}$ be the module of differentials of X over S , and $\Delta^{(1)}_{X/S}$ the first infinitesimal neighborhood of the diagonal immersion $\delta_X : X \rightarrow X \times_S X$; it is a subscheme of $X \times_S X$, of which the diagonal $\Delta_{X/S}$ is a closed subscheme. We denote by $\text{pr}^i_{X/S}$ ($i = 1, 2$) the two projections $X \times_S X \rightarrow X$, and by π_X the restriction of $\text{pr}^1_{X/S}$ to $\Delta^{(1)}_{X/S}$.

On the one hand, every morphism $f : X \rightarrow W$ of S -schemes induces an S -morphism $\Delta^{(1)}_{X/S} \rightarrow \Delta^{(1)}_{W/S}$ such that the following diagram is commutative:

$$\begin{array}{ccccccc} & \delta_X & & \text{pr}_X & & & \\ X & \xrightarrow{\quad} & \Delta^{(1)}_{X/S} & \xrightarrow{\quad} & X \times_S X & \xrightarrow{\quad} & X \\ f \downarrow & & \Delta^{(1)}_{X/S} \downarrow & & f \times f \downarrow & & f \downarrow \\ W & \xrightarrow{\quad} & \Delta^{(1)}_{W/S} & \xrightarrow{\quad} & W \times_S W & \xrightarrow{\quad} & W \end{array}$$

On the other hand, $\Delta^{(1)}_{X/S}$ is, via the projection π_X , an affine X -scheme, spectrum of the augmented quasi-coherent $\mathcal{O}_X$ -algebra

$\mathcal{P}^1_{X/S} = \mathcal{O}_X \oplus \Omega^1_{X/S},$

where $\Omega^1_{X/S}$ is an ideal of square zero; the augmentation is the morphism of $\mathcal{O}_X$ -algebras $\epsilon_X : \mathcal{P}^1_{X/S} \rightarrow \mathcal{O}_X$ which vanishes on $\Omega^1_{X/S}$ and which corresponds to the closed immersion $\delta_X : X \rightarrow \Delta^{(1)}_{X/S}$. Then, every morphism of S -schemes $f : X \rightarrow W$ induces a morphism of augmented $\mathcal{O}_X$ -algebras

$f^*(\mathcal{P}^1_{W/S}) = \mathcal{O}_X \oplus f^*(\Omega^1_{W/S}) \rightarrow \mathcal{P}^1_{X/S} = \mathcal{O}_X \oplus \Omega^1_{X/S}$

that is, equivalently, a morphism of $\mathcal{O}_X$ -modules

$f_{X/W/S} : f^*(\Omega^1_{W/S}) \rightarrow \Omega^1_{X/S},$

cf. (EGA IV₄, 16.4.3.6) (and (16.4.18.2) for the notation $f_{X/W/S}$).

<!-- original page 90 -->

Since $\pi_X : \Delta^{(1)}_{X/S} \rightarrow X$ is affine, then, by a), $\Delta^{(1)}_{X/S} \xrightarrow{f}$ is entirely determined by $f_{X/W/S}$ and, for every X -scheme $g : Y \rightarrow X$, the set

$\text{Hom}_X(Y, \Delta^{(1)}_{X/S}) \simeq \text{Hom}_{\{0_Y\text{-alg.}\}}(0_Y \oplus g^*(\Omega^1_{X/S}), 0_Y)$

is identified with a subset of $\text{Hom}_{\{0_Y\text{-alg.}\}}(g^*(\Omega^1_{X/S}), 0_Y)$, namely the subset

$\tilde{\text{Hom}}_{\{0_Y\text{-alg.}\}}(g^*(\Omega^1_{X/S}), 0_Y)$

formed by the $\mathcal{O}_Y$ -morphisms $\psi : g^*(\Omega^1_{X/S}) \rightarrow 0_Y$ such that $\text{Im}(\psi)$ is an ideal of $\mathcal{O}_Y$ of square zero. [N.D.E-III-12]

Consequently, applying a) to the diagram

```

```text
 Δ(1) f
 ↓
Δ(1)X/S → Δ(1)W/S
 ↑
 g'
 |
Y →g X →f W
...

```

and taking into account that  $\Delta^{(1)} f$  is the restriction to  $\Delta^{(1)}_{X/S}$  of  $f \times f$ , one obtains the following commutative diagram, functorial in the  $S$ -scheme  $Y \rightarrow X$ :

```

```text
Hom_X(Y, X ×_S X)  →(g, g') ↦ (f ∘ g, f ∘ g') Hom_W(Y, Δ(1)W/S)
    ↑                               ↑
Hom_X(Y, Δ(1)X/S) →g' ↦ Δ(1) f ∘ g' Hom_W(Y, Δ(1)W/S)    (0.1.7 (*))
    ↓                               ↓
Hom~_{0_Y}(g*(Ω1X/S), 0_Y) →ψ ↦ ψ ∘ g*(f_{X/W/S}) Hom~_{0_Y}(g* f*(Ω1W/S), 0_Y).

...

```

Remark 0.1.7.1. Let us end this paragraph with the following remark, which will be useful later (cf. 0.1.10). If we denote by $\tilde{L}_X$ the S -functor which to every S -scheme $g : Y \rightarrow X$ associates $\operatorname{Hom}_{0_Y}(g^*(\Omega^1_{X/S}), 0_Y)$, and $\tilde{L}_f : \tilde{L}_X \rightarrow \tilde{L}_W$ the morphism of functors defined above (which to every $\psi \in \tilde{L}_X(Y)$ associates $\psi \circ g^*(f_{X/W/S})$), what precedes shows that we have a commutative diagram of functors:

<!-- label: III.III.0.1.7.1 -->

```

```text
X ×~ X L~_X ← Δ(1)X/S → X ×_S X
f ×~ | Δ(1) f | f × f |
W ×~ W L~_W ← Δ(1)W/S → W ×_S W.
...

```

<!-- original page 91 -->

**Theorem 0.1.8.** (SGA 1, III 5.1) [N.D.E-III-13] Let  $Y, X$  be two  $S$ -schemes,  $J$  a quasi-coherent ideal of  $0_Y$  of square zero,  $Y_J$  the closed subscheme of  $Y$  defined by  $J$ , and  $g_J : Y_J \rightarrow X$  an  $S$ -morphism.

<!-- label: III.III.0.1.8 -->

a) The set  $P(g_J)$  of  $S$ -morphisms  $g : Y \rightarrow X$  which extend  $g_J$  is either empty, or principal homogeneous under the abelian group

$\operatorname{Hom}_{0_{Y_J}}(g_J^*(\Omega^1_{X/S}), J)$ .

b) If  $i : Y_{\{0\}} \rightarrow Y_J$  is the closed immersion defined by a quasi-coherent ideal  $I \subset J$  such that  $I \cdot J = 0$ , and if  $g_{\{0\}} = g_J \circ i$ , the preceding abelian group is isomorphic to

$\operatorname{Hom}_{0_{Y_{\{0\}}}}(g_{\{0\}}^*(\Omega^1_{X/S}), J)$ .

**Proof.** (b) follows at once from (a). Indeed,  $J$ , being annihilated by  $I$ , can be considered as an  $0_{Y_{\{0\}}}$ -module, whence, by adjunction:

```

```text
Hom_{0_{Y_J}}(g_J^*(\Omega^1_{X/S}), J) = Hom_{0_{Y_0}}(i^* g_J^*(\Omega^1_{X/S}), J).
```

```

To prove (a), we may assume  $P(g_J) \neq \emptyset$ , i.e. that there exists an  $\mathbb{A}^1$ -morphism  $g : Y \rightarrow X$  extending  $g_J$ . Let us denote by  $j$  the immersion  $Y_J \hookrightarrow Y$ . Then  $P(g_J)$  is the set of  $\mathbb{A}^1$ -morphisms  $g' : Y \rightarrow X$  such that  $g' \circ j = g_J$ . The datum of such a  $g'$  is equivalent to the datum of an  $\mathbb{A}^1$ -morphism

```

```text
h : Y \rightarrow X \times_S X
```

```

such that  $\text{pr}_1 \circ h = g$  and  $h_J = \delta \circ g_J$ , where  $h_J = h \circ j$  and  $\delta$  is the diagonal immersion  $X \hookrightarrow X \times_S X$ :

```

```text
      X \times_S X \xleftarrow{h_J = \delta \circ g_J} Y_J
      | \nearrow h \qquad \qquad \qquad | \downarrow j
pr_1 | \searrow \qquad \qquad \qquad | \downarrow
      X \xleftarrow{g} \qquad \qquad \qquad Y .
```

```

Since  $h_J$  factors through  $\delta$  and  $Y$  is in the first infinitesimal neighborhood of the immersion  $j : Y_J \rightarrow Y$  (since  $J^2 = 0$ ), then, by functoriality (cf. EGA IV<sub>4</sub>, 16.2.2 (i)), the  $h$ 's sought factor uniquely through  $\Delta^{(1)}_{X/S}$  (cf. 0.1.7). Set

```

```text
Y' = \Delta^{(1)}_{X/S} \times_X Y \quad \text{and} \quad Y_J' = Y' \times_Y Y_J = \Delta^{(1)}_{X/S} \times_X Y_J .
```

```

Then the  $h$ 's sought are in bijection with the sections  $u$  of  $Y' \rightarrow Y$  which extend the section  $u_J = (\delta \circ g_J, \text{id})$  of  $Y_J' \rightarrow Y_J$ . On the other hand,  $Y'$  (resp.  $Y_J'$ ) is an affine scheme over  $Y$  (resp.  $Y_J$ ), corresponding to the quasi-coherent algebra

```

```text
A = 0_Y \otimes g^*(\Omega^1_{X/S}), \quad \text{resp.} \quad A_J = A \otimes_{0_Y} 0_{Y_J} = 0_{Y_J} \otimes g_J^*(\Omega^1_{X/S}).
```

```

Let us denote by  $\epsilon : A \rightarrow 0_Y$  the canonical augmentation of  $A$  (i.e. the morphism of  $0_Y$ -algebras  $A \rightarrow 0_Y$  which vanishes on  $g^*(\Omega^1_{X/S})$ ), and likewise define  $\epsilon_J : A_J \rightarrow 0_{Y_J}$ . Then,

```

```text
\Gamma(Y'/Y) \simeq \text{Hom}_{0_Y\text{-alg.}}(A, 0_Y), \quad \Gamma(Y_J'/Y_J) \simeq \text{Hom}_{0_{Y_J}\text{-alg.}}(A_J, 0_{Y_J})
```

```

<!-- original page 92 -->

and, via these isomorphisms, the section  $u = (\delta \circ g, \text{id})$  (resp.  $u_J$ ) corresponds to  $\epsilon$  (resp.  $\epsilon_J$ ). Consequently,  $P(g_J)$  is in bijection with the set of algebra morphisms  $A \rightarrow 0_Y$  which reduce to  $\epsilon_J$ , and via this bijection,  $g$  corresponds to  $\epsilon$ .

Set  $M = g^*(\Omega^1_{X/S})$ . Then  $\text{Hom}_{0_Y\text{-alg.}}(A, 0_Y)$  is identified with the set of  $0_Y$ -morphisms  $\psi : M \rightarrow 0_Y$  such that  $\text{Im}(\psi)$  is an ideal of square zero, and we are interested in those which induce the null morphism  $M \rightarrow 0_{Y_J} = 0_Y/J$ , i.e. which send  $M$  into  $J$ . Conversely, since  $J^2 = 0$ , every  $0_Y$ -morphism  $\phi : M \rightarrow J$  comes from a (unique) algebra morphism  $A \rightarrow 0_Y$ , reducing to  $\epsilon_J$ . Finally, we have  $\text{Hom}_{0_Y\text{-alg.}}(g^*(\Omega^1_{X/S}), J) = \text{Hom}_{0_{Y_J}\text{-alg.}}(g_J^*(\Omega^1_{X/S}), J)$  since  $J^2 = 0$  (cf. the proof of (b) already seen). One thus obtains a bijection

```

$$
P(g_J) \simeq \text{Hom}_{0_{Y_J}\text{-alg.}}(g_J^*(\Omega^1_{X/S}), J)
$$

```

by which  $g$  corresponds to the null morphism.

For every  $m \in \operatorname{Hom}_{\mathcal{O}_Y(J)}(g_* \Omega^1_{X/S}, J)$ , denote by  $m \cdot g$  the element of  $\mathcal{P}(g_*)$  associated to  $g$  and  $m$  by the preceding bijection. We have already seen that  $0 \cdot g = g$ ; it remains to see that

$$m' \cdot (m \cdot g) = (m + m') \cdot g. \quad (0.1.8 \quad *)$$

This is verified locally. [N.D.E-III-14] Indeed, the two preceding morphisms  $Y \rightarrow X$  induce the same continuous map as  $g$  between the underlying topological spaces; it therefore suffices to verify that for every affine open  $U = \operatorname{Spec}(A)$  of  $X$  above an affine open  $\operatorname{Spec}(\Lambda)$  of  $S$ , and every affine open  $V = \operatorname{Spec}(B)$  of  $g^{-1}(U)$ , they induce the same morphism of  $\Lambda$ -algebras  $A \rightarrow B$ .

Let  $J = \Gamma(V, J)$  and let  $\phi, \psi$  and  $\eta$  be the morphisms  $A \rightarrow B$  induced by  $g$ ,  $m \cdot g$  and  $m' \cdot (m \cdot g)$  respectively; they coincide modulo  $J$ . One can uniquely write  $\psi = \phi + D$  (resp.  $\eta = \psi + D'$ ), where  $D$  (resp.  $D'$ ) is an element of

$$\operatorname{Der}_{\phi}(A, J) = \{ \delta \in \operatorname{Hom}_{\Lambda}(A, J) \mid \delta(ab) = \phi(a) \delta(b) + \phi(b) \delta(a) \}$$

(resp.  $\operatorname{Der}_{\psi}(A, J)$ ). But  $\operatorname{Der}_{\phi}(A, J) = \operatorname{Der}_{\psi}(A, J)$  since  $J^2 = 0$ , and both are identified with

$$\operatorname{Hom}_{B/J}(\Omega^1_{A/\Lambda} \otimes_A B/J, J),$$

and via this identification  $D$  corresponds to  $m$  and  $D'$  to  $m'$ . Then  $\eta = \phi + D + D'$  and  $D + D'$  corresponds to  $m + m'$ , whence the equality  $(*)$ .

**\*Corollary 0.1.9.\*** [N.D.E-III-15] \*Let  $X$  be an  $S$ -scheme; resume the notations of 0.1.5. Then  $X$  is endowed with a (left) action of the  $X^+$ -abelian group  $L_X$ , which makes  $X$  into a formally principal homogeneous object under  $L_X$  above  $X^+$ , i.e. one has an isomorphism of  $X^+$ -functors:\*

<!-- label: III.III.0.1.9 -->

$$L_X \times X \xrightarrow{X^+} X \times X$$

\*(defined set-theoretically by  $(m, x) \mapsto (x, m \cdot x)$ ).\*

**\*Proof.\*** Let  $i_0$  be the immersion  $X_0 \hookrightarrow X$ . Note first that, since  $X_0 = X \times_S S_0$ , one has  $i_0^*(\Omega^1_{X/S}) \simeq \Omega^1_{X_0/S_0}$  (cf. EGA IV, 16.4.5).

Let  $Y$  be an  $X^+$ -scheme, given by an  $S$ -morphism  $g_J : Y_J \rightarrow X$ , and let  $g_0 : Y_0 \rightarrow X_0$  be the morphism obtained by base change. By 0.1.8, if  $\operatorname{Hom}_{X^+}(Y, X)$  is non-empty, it is a principal homogeneous set under the group

$$\operatorname{Hom}_{\mathcal{O}_Y}(g_0^* i_0^*(\Omega^1_{X/S}), J \cdot \mathcal{O}_Y),$$

which is identified with  $\operatorname{Hom}_{\mathcal{O}_Y}(g_0^*(\Omega^1_{X_0/S_0}), J \cdot \mathcal{O}_Y) = L_X(Y)$ . One therefore has a bijection

$$L_X(Y) \times \operatorname{Hom}_{X^+}(Y, X) \longrightarrow \operatorname{Hom}_{X^+}(Y, X \times_{X^+} X)$$

given by  $(m, g) \mapsto (g, m \cdot g)$ . Let us show that this is "functorial in  $Y$ ".

Let  $f : Z \rightarrow Y$  be a morphism of  $S$ -schemes. It is a question of showing that the diagram below is commutative:

$$\begin{array}{ccc} L_X(Y) \times \text{Hom}_{X^+}(Y, X) & \longrightarrow & \text{Hom}_{X^+}(Y, X \times_{X^+} X) \\ \downarrow L_X(f) \times f & & \downarrow f \times f \\ L_X(Z) \times \text{Hom}_{X^+}(Z, X) & \longrightarrow & \text{Hom}_{X^+}(Z, X \times_{X^+} X). \end{array}$$

If  $\text{Hom}_{X^+}(Y, X) = \emptyset$ , there is nothing to show. It therefore suffices to see that, for every  $S$ -morphism  $g : Y \rightarrow X$  extending  $g_{|J}$  and every  $m \in L_X(Y)$ , one has:

$$(m \cdot g) \circ f = L_X(f)(m) \cdot (g \circ f). \quad (0.1.9 \quad *)$$

These two  $S$ -morphisms  $Z \rightarrow X$  coincide on  $Z_J$  with  $g_{|J} \circ f_{|J}$ ; in particular, they induce the same continuous map as  $g \circ f$  between the underlying topological spaces. Consequently, it suffices to see that, if  $z \in Z$ ,  $y = f(z)$ ,  $x = g(y)$ , and if  $A, B, C$  denote respectively the local rings  $\mathcal{O}_{X,x}$ ,  $\mathcal{O}_{Y,y}$ ,  $\mathcal{O}_{Z,z}$ , then the morphisms  $A \rightarrow C$  induced by  $(m \cdot g) \circ f$  and  $L_X(f)(m) \cdot (g \circ f)$  coincide. Denote by  $s$  the image of  $x$  in  $S$ ,  $\Lambda = \mathcal{O}_{S,s}$ ,  $J$  and  $I$  the ideals of  $\Lambda$  corresponding to  $J$  and  $I$ , and let  $\phi, \psi : A \rightarrow B$  and  $\theta : B \rightarrow C$  be the morphisms of  $\Lambda$ -algebras induced by  $g, m \cdot g$ , and  $f$ . Then  $m \cdot g$  induces an element  $D$  of

$$\text{Hom}_{B/I}(\Omega^1_{A/\Lambda} \otimes_A B/I, B/I) = \text{Der}_\Lambda(A, B/I)$$

and one has  $\psi = \phi + D$ ; hence  $(m \cdot g) \circ f$  corresponds to  $\theta \circ \psi = \theta \circ \phi + \theta \circ D$ . Now, we have seen in 0.1.5 that  $\theta \circ D$  is the image of  $L_X(f)(m)$  in

$$\text{Hom}_{C/I}(\Omega^1_{A/\Lambda} \otimes_A C/I, C/I) = \text{Der}_\Lambda(A, C/I);$$

consequently,  $\theta \circ \psi = \theta \circ \phi + \theta \circ D$  is the image of  $L_X(f)(m) \cdot (g \circ f)$ . This proves the equality (0.1.9 (\*)).

**Corollary 0.1.10.** [N.D.E-III-16] a)  $L_X$  depends functorially on  $X$ : for every  $S$ -morphism  $f : X \rightarrow W$ , there exists an  $S$ -morphism  $L_f : L_X \rightarrow L_W$  which is a morphism of abelian groups "above  $f^+$ ", i.e., the diagram

<!-- label: III.III.0.1.10 -->

$$\begin{array}{ccc} L_X & \xrightarrow{L_f} & L_W \\ \downarrow & & \downarrow \\ X^+ & \xrightarrow{f^+} & W^+ \end{array}$$

is commutative, and for every  $Y \rightarrow X^+$ ,

$$L_f(Y) : \text{Hom}_{X^+}(Y, L_X) \rightarrow \text{Hom}_{W^+}(Y, L_W)$$

(where  $Y$  is above  $W^+$  via  $f^+$ ) is a morphism of abelian groups.

b) Moreover, the following diagram is commutative:

```

```text
L_X × X → X ×_{X^+} X
  |           |
L_f × f       f × f
  ▼           ▼
L_W × W → W ×_{W^+} W .
```

```

\*Proof.\* a)  $L_{\{f\}}$  is induced by the morphism of  $0_{\{X_0\}}$ -modules  $f_{\{X_0\}/W_0/S_0} : f_{\{0\}}(\omega^1_{\{W_0\}/S_0}) \rightarrow \omega^1_{\{X_0\}/S_0}$  (cf. 0.1.7 b)): for every  $X^+$ -scheme  $Y$ , given by an  $S$ -morphism  $g_J : Y_J \rightarrow X$ , one has a commutative diagram, functorial in  $Y$ :

```

```text
Hom_{0_{Y_0}}(g_*(\Omega^1_{X_0/S_0}), J \cdot 0_Y) \xrightarrow{L_f(Y)} Hom_{0_{Y_0}}(g_*(\Omega^1_{W_0/S_0}), J \cdot 0_Y)
  |                               |
  \{g_J\}                       \{f_J \circ g_J\}
```

```

where  $L_{\{f\}}(Y)$  is the map  $\psi \mapsto \psi \circ g_J^*(f_{X_0/W_0/S_0})$ , which is indeed a morphism of abelian groups. [N.D.E-III-17]

Let us prove (b). Let  $Y$  be an  $X^+$ -scheme; if  $\operatorname{Hom}_{X^+}(Y, X) = \emptyset$  there is nothing to show. So let  $g \in \operatorname{Hom}_{X^+}(Y, X)$ ; it must be seen that for every  $m \in L_X(Y)$ , one has:

```

```text
f \circ (m \cdot g) = L_f(Y)(m) \cdot (f \circ g).
```
(0.1.10 (*))

```

Now,  $g$  being fixed,  $\operatorname{Hom}_X(Y, X \times_{X^+} X)$  is a subset of  $\operatorname{Hom}_X(Y, \Delta^{(1)}_{X/S})$  and

```

```text
L_X(Y) = Hom_{0_{Y_0}}(g_*(\Omega^1_{X_0/S_0}), J \cdot 0_Y) = Hom_{0_Y}(g^*(\Omega^1_{X/S}), J \cdot 0_Y)
```

```

a subset of  $\tilde{L}_X(Y)$  (cf. 0.1.7); finally,  $L_{\{f\}}(Y)$  is the restriction to  $L_X(Y)$  of the map  $\tilde{L}_{\{f\}}(Y)$ . Moreover, the bijection

```

```text
L_X(Y) \xrightarrow{\sim} Hom_X(Y, X \times_{X^+} X), \quad m \mapsto (g, m \cdot g)
```

```

is (the inverse of) the restriction to  $L_X(Y) \subset \tilde{L}_X(Y)$  of the bijection  $\operatorname{Hom}_X(Y, \Delta^{(1)}_{X/S}) \xrightarrow{\sim} \{g\} \times L_X(Y)$  considered in 0.1.7.1. Consequently, the equality (0.1.10 (\*)) results from (0.1.7 (\*)); indeed, if we denote by  $g'$  the  $X$ -morphism  $Y \rightarrow \Delta^{(1)}_{X/S}$  defined by  $(g, m \cdot g)$ , then the element of  $\tilde{L}_W(Y)$  corresponding to  $(f \circ g, f \circ g')$  is  $\tilde{L}_{\{f\}}(Y)(m) = L_{\{f\}}(Y)(m)$ , i.e., one indeed has

```

```text
L_f(m) \cdot (f \circ g) = f \circ (m \cdot g).
```

```

**Lemma 0.1.11.** \*Let  $X, X'$  be two  $S$ -schemes. One has a commutative diagram:

<!-- label: III.III.0.1.11 -->

```

```text
L_X \times_S L_{X'} \xrightarrow{\sim} L_{X \times_S X'}
  |               |
  \downarrow       \downarrow
X^+ \times_S X'^+ \xrightarrow{\sim} (X \times_S X')^+ .
```

```

[^N.D.E-III-18] \*Proof.\* First, for every  $S$ -scheme  $Y$ ,  $\operatorname{Hom}_S(Y, X^+ \times_S X'^+)$  equals  $\operatorname{Hom}_S(Y, X^+) \times \operatorname{Hom}_S(Y, X'^+)$  and this is isomorphic to

```
```text
Hom_S(Y_J, X) × Hom_S(Y_J, X') = Hom_S(Y, (X ×_S X')^+);
```
```

this proves that  $X^+ \times_S X'^+ \simeq (X \times_S X')^+$ .

Next, let  $Y$  be a scheme above  $X^+ \times_S X'^+$  via a morphism  $h : Y_J \rightarrow X \times_S X'$ ; set  $f = p \circ h$  and  $g = q \circ h$ , where we have denoted by  $p, q$  the projections of  $X \times_S X'$  to  $X$  and  $X'$ . Since  $\Omega^1_{(X_0 \times_S X'_0)/S_0} \cong p_0^*(\Omega^1_{X_0/S_0}) \oplus q_0^*(\Omega^1_{X'_0/S_0})$  (cf. EGA IV<sub>4</sub>, 16.4.23), one obtains a natural isomorphism:

```
```text
Hom_{0_{Y_0}}(f_0^*(\Omega^1_{X_0/S_0}), J \cdot 0_Y) × Hom_{0_{Y_0}}(g_0^*(\Omega^1_{X'_0/S_0}), J \cdot 0_Y)
= Hom_{0_{Y_0}}(h_0^*(\Omega^1_{(X_0 \times_S X'_0)/S_0}), J \cdot 0_Y)
```
```

i.e.,  $L_X(Y) \times L_{X'}(Y) \simeq L_{X \times_S X'}(Y)$ .

**Remark 0.1.12.** [^N.D.E-III-19] \*Let  $\mathcal{C}$  be a category stable under fibered products,  $S$  an object of  $\mathcal{C}$ ,  $T_1, T_2$  two objects above  $S$  and, for  $i = 1, 2$ ,  $L_i$  and  $X_i$  two objects above  $T_i$ .\*

<!-- label: III.III.0.1.12 -->

```
```text
L_1 → T_1 ← X_1      L_2 → T_2 ← X_2
      \      /          \      /
       ▼      ▼          ▼      ▼
        S              S
```
```

\*Then one has a natural isomorphism:\*

```
```text
(L_1 ×_{T_1} X_1) ×_S (L_2 ×_{T_2} X_2) = (L_1 ×_S L_2) ×_{T_1 ×_S T_2} (X_1 ×_S X_2).
```
```

Consequently, from the preceding lemma one deduces the:

**Corollary 0.1.13.** \*Let  $X_1, X_2$  be two  $S$ -schemes. One has a commutative diagram of isomorphisms:\*

<!-- label: III.III.0.1.13 -->

```
```text
L_{X_1 ×_S X_2} ×_{(X_1 ×_S X_2)^+} (X_1 ×_S X_2)
(0.1.11) ≈ ▼ (L_{X_1} ×_S L_{X_2}) ×_{(X_1^+ ×_S X_2^+)} (X_1 ×_S X_2)
              ≈ (L_{X_1} ×_{X_1^+} X_1) ×_S (L_{X_2} ×_{X_2^+} X_2) .
              (0.1.12)
```
```

We can now state:

<!-- original page 88 (cont.) -->

**Proposition 0.2.** \*For every  $S$ -scheme  $X$ , one can define a (left) action of the  $X^+$ -abelian group  $L_X$  on the  $X^+$ -object  $X$ , such that:\*

<!-- label: III.III.0.2 -->

\*(i) this action makes  $X$  into a formally principal homogeneous object under  $L_X$  above  $X^+$ , i.e. the morphism\*

$$\begin{array}{ccc} L_X \times X & \longrightarrow & X \times X \\ & \searrow & \swarrow \\ & X^+ & X^+ \end{array}$$

is an isomorphism of  $X^+$ -functors;\*

\*(ii) this action is functorial in the  $S$ -scheme  $X$ , i.e., for every  $S$ -morphism  $f : X \rightarrow W$ , the following diagram is commutative:\*

$$\begin{array}{ccc} L_X \times_{X^+} X & \longrightarrow & X \\ \downarrow L_f \times f & & \downarrow f \\ L_W \times_{W^+} W & \longrightarrow & W \end{array}$$

\*(iii) this action "commutes with fibered product", i.e. for all  $S$ -schemes  $X_1$  and  $X_2$ , the following diagram is commutative:\*

$$\begin{array}{ccc} L_{X_1 \times_S X_2} \times_{(X_1 \times_S X_2)^+} (X_1 \times_S X_2) & \longrightarrow & X_1 \times_S X_2 \\ \downarrow \cong & & \uparrow \\ (L_{X_1} \times_{X_1^+} L_{X_2}) \times_{(X_1^+ \times_S X_2^+)} (X_1 \times_S X_2) & \longrightarrow & (L_{X_1} \times_{X_1^+} X_1) \times_S (L_{X_2} \times_{X_2^+} X_2). \end{array}$$

<!-- original page 89 -->

\*Proof.\*[<sup>N.D.E-III-20</sup>] (i) and (ii) follow respectively from Corollaries 0.1.9 and 0.1.10. To prove (iii), denote  $P(X) = L_X \times_{X^+} X$ , for every  $S$ -scheme  $X$ . Then, by (ii) applied to the projections  $p_i : X_1 \times_S X_2 \rightarrow X_i$ , one obtains commutative squares

$$\begin{array}{ccc} P(X_1 \times_S X_2) & \longrightarrow & X_1 \times_S X_2 \\ \downarrow L_{p_i} \times p_i & & \downarrow p_i \\ P(X_i) & \longrightarrow & X_i \end{array}$$

<!-- original page 90 -->

for  $i = 1, 2$ , and hence a commutative square:

$$\begin{array}{ccc} P(X_1 \times_S X_2) & \longrightarrow & X_1 \times_S X_2 \\ \downarrow & & \downarrow \\ P(X_1) \times_S P(X_2) & \longrightarrow & X_1 \times_S X_2. \end{array}$$

Combining this with Corollary 0.1.13, one obtains that the vertical arrow is an isomorphism, and that one has the commutative diagram announced in (iii).

<!-- original page 90 -->

**Remark 0.3.** Suppose the  $X^+$ -scheme  $Y$  flat over  $S$  (cf. SGA 1, IV). Then one can write\*

<!-- label: III.III.0.3 -->

```

```text
Hom_{X^+}(Y, L_X) = Hom_{0_{Y_0}}(g_0^*(\Omega^1_{X_0/S_0}), J \otimes_{0_{S_0}} 0_{Y_0}).
```

```

**Remark 0.4.** Denote by  $\pi_0 : X_0 \rightarrow S_0$  the structural morphism and suppose there exists an  $\Omega^1_{S_0}$ -module  $\Omega^1_{X_0/S_0}$  such that  $\Omega^1_{X_0/S_0} \simeq \pi_0^*(\Omega^1_{X_0/S_0})$  (the case will arise in particular when  $X_0$  is an  $S_0$ -group, cf. II, 4.11). If one defines a functor  $L'_{X_0}$  above  $S_0$  by the formula\*

```

<!-- label: III.III.0.4 -->

```

```

```text
Hom_S(Y, L'_X) = Hom_{0_{Y_0}}(\omega^1_{X_0/S_0} \otimes_{0_{S_0}} 0_{Y_0}, J \cdot 0_Y), \quad (0.4.1)
```

```

one then has  $\operatorname{Hom}_{X^+}(Y, L_X) = \operatorname{Hom}_S(Y, L'_X)$  for every  $X^+$ -scheme  $Y$ , that is to say\*

```

```text
L_X = L'_X \times_{S_0} X^+.
```

```

[N.D.E-III-21] Then, since  $L_X \times_{X^+} X = L'_X \times_{S_0} X$ , the action of  $L'_X$  on  $X$  induces an action of  $L'_X$  on  $X$ , and this action respects the morphism  $p_X : X \rightarrow X^+$ ; indeed, if  $Y$  is an  $S_0$ -scheme,  $h : Y \rightarrow X$  an  $S_0$ -morphism and  $m$  an element of  $L'_X(Y)$ , then  $h$  and  $m \cdot h$  have the same restriction to  $Y_J$ , i.e.  $p_X(m \cdot h) = p_X(h)$ .

```

<!-- original page 91 -->

```

**Remark 0.5.** Keep the hypotheses and notations of 0.4 and suppose moreover that  $Y$  is an  $S_0$ -scheme flat over  $S_0$ . Then we have\*

```

<!-- label: III.III.0.5 -->

```

```

```text
Hom_{X^+}(Y, L_X) = Hom_S(Y, L'_X) = Hom_{S_0}(Y_0, L^0_X),
```

```

where the  $S_0$ -functor in abelian groups  $L^0_{X_0}$  is defined by the following identity (with respect to the variable  $S_0$ -scheme  $T$ ):\*

```

```text
Hom_{S_0}(T, L^0_X) = Hom_{0_T}(\omega^1_{X_0/S_0} \otimes_{0_{S_0}} 0_T, J \otimes_{0_{S_0}} 0_T). \quad (0.5.1)
```

```

In the notations of (II, 1), we have therefore shown that the functors  $L'_X$  and  $\prod_{S_0/S} L^0_{X_0}$  have the same restriction to the full subcategory of  $(\operatorname{Sch})/S_0$  whose objects are the  $S_0$ -schemes  $Y$  flat over  $S_0$ .\*

**Remark 0.6.** Keep the hypotheses and notations of 0.5 [N.D.E-III-22] and suppose moreover that there exists a section  $\epsilon_0$  of  $\pi_0 : X_0 \rightarrow S_0$ ; one then has  $\Omega^1_{X_0/S_0} \simeq \epsilon_0^*(\Omega^1_{X_0/S_0})$ .\*

```

<!-- label: III.III.0.6 -->

```

First, one has (independently of the preceding hypothesis):

```

```text
Hom_{S_0}(T, L^0_X) = \Gamma(T, Hom_{0_T}(\omega^1_{X_0/S_0} \otimes_{0_{S_0}} 0_T, J \otimes_{0_{S_0}} 0_T)).
```

```

Now suppose that  $\Omega^1_{X_0/S_0}$  admits a finite presentation (cf. EGA 0\_I, 5.2.5), which will in particular be the case if  $X_0$  is locally of finite presentation over  $S_0$  (cf. EGA IV<sub>4</sub>, 16.4.22). Then, if  $T$  is flat over  $S_0$ , it follows from (EGA 0\_I, 6.7.6) that

```

```text
Hom_{0_T}(\omega^1_{X_0/S_0} \otimes_{0_{S_0}} 0_T, J \otimes_{0_{S_0}} 0_T) = Hom_{0_{S_0}}(\omega^1_{X_0/S_0}, J) \otimes_{0_{S_0}} 0_T ,
```

```

whence

```

```text
Hom_{S_0}(T, L^0_X) = \Gamma(T, Hom_{0_{S_0}}(\omega^1_{X_0/S_0}, J) \otimes_{0_{S_0}} 0_T).
```

```

Introducing the notation  $W(\cdot)$  of (I, 4.6.1), we have therefore proved that for every  $S_0$ -scheme  $T$  flat over  $S_0$ , one has

```

```text
Hom_{S_0}(T, L^0_X) = Hom_{S_0}(T, W(Hom_{0_{S_0}}(\omega^1_{X_0/S_0}, J))).
```

```

<!-- original page 92 -->

In summary, if  $\omega^1_{X_0/S_0}$  admits a finite presentation, and if one restricts to the category of  $S_0$ -schemes flat over  $S_0$ , one has

```

```text
L'_X = \prod_{S_0/S} W(Hom_{0_{S_0}}(\omega^1_{X_0/S_0}, J)), \tag{0.6.1}
```

```

and  $\text{Hom}_{0_{S_0}}(\omega^1_{X_0/S_0}, J)$  is a quasi-coherent  $0_{S_0}$ -module, by EGA I, 9.1.1.

Note finally that if  $\omega^1_{X_0/S_0}$  is moreover locally free (of finite rank), for example if  $X_0$  is smooth over  $S_0$  (in which case it is automatically locally of finite presentation over  $S_0$ ), one has

```

```text
Hom_{0_{S_0}}(\omega^1_{X_0/S_0}, J) = \text{Lie}(X_0/S_0) \otimes_{0_{S_0}} J, \tag{0.6.2}
```

```

where, by abuse of language ( $X_0$  not being necessarily an  $S_0$ -group), we denote by  $\text{Lie}(X_0/S_0)$  the dual of the  $0_{S_0}$ -module  $\omega^1_{X_0/S_0}$ . [N.D.E-III-23]

Proposition 0.2 (and its proof) has two important corollaries. [N.D.E-III-24]

**Corollary 0.7.** \*Let  $X$  be an  $S_0$ -scheme.\*

<!-- label: III.III.0.7 -->

a) Every  $S_0$ -endomorphism of  $X$  inducing the identity on  $X_J$  is an automorphism.\*

b) One has an exact sequence of groups:\*

```

```text
0 \longrightarrow Hom_{0_{X_0}}(\Omega^1_{X_0/S_0}, J \cdot 0_X) \xrightarrow{i} \text{Aut}_{S_0}(X) \longrightarrow \text{Aut}_{S_J}(X_J) .
```

```

c) Moreover, if one makes  $\text{Aut}_{S_0}(X)$  act on the first group by transport of structure, one has, for all  $u \in \text{Aut}_{S_0}(X)$  and  $m \in \text{Hom}_{0_{X_0}}(\Omega^1_{X_0/S_0}, J \cdot 0_X)$ :

```

```text
i(u \cdot m) = u \cdot i(m) \cdot u^{-1}.
```

```

<!-- original page 93 -->

**Proof.** By 0.2 (i),  $\text{Hom}_{X^+}(X, X)$  is a principal homogeneous set under

$\text{Hom}_{X^+}(X, L_X)$ , since it is certainly non-empty: it contains a marked point, namely the identity automorphism of  $X$ . [N.D.E-III-25] Consequently, the map  $m \mapsto m \cdot \text{id}_X$  induces a bijection

$$\text{Hom}_{X^+}(X, L_X) \xrightarrow{\sim} \text{Hom}_{X^+}(X, X).$$

Let  $m \in \text{Hom}_{X^+}(X, L_X)$  and let  $f = m \cdot \text{id}_X$  be an element of  $\text{Hom}_{X^+}(X, X)$ . Applying 0.2(ii) to  $f$ , one obtains:

$$f \circ (m \cdot \text{id}_X) = L_f(X)(m) \cdot f = L_f(X)(m) \cdot (m' \cdot \text{id}_X).$$

On the other hand, since  $f$  is an  $X^+$ -endomorphism of  $X$ , one has  $f \circ J = \text{id}_{X \circ J}$  and therefore  $f \circ 0 = \text{id}_{X \circ 0}$ ; since  $L_f$  depends only on  $f \circ 0$  (cf. N.D.E. (17) in 0.1.10), one therefore has  $L_f(X)(m) = m$ . Consequently, the equality above rewrites as:

$$(m' \cdot \text{id}_X) \circ (m \cdot \text{id}_X) = m \cdot (m' \cdot \text{id}_X) = (m + m') \cdot \text{id}_X.$$

This shows that the bijection  $m \mapsto m \cdot \text{id}_X$  transforms the group law of  $\text{Hom}_{X^+}(X, L_X)$  into the composition law of  $X^+$ -endomorphisms of  $X$ .

It follows first that every element of  $\text{Hom}_{X^+}(X, X)$  is invertible, which is the first assertion of the statement, and then that one has an exact sequence

$$0 \rightarrow \text{Hom}_{X^+}(X, L_X) \xrightarrow{i} \text{Aut}_S(X) \rightarrow \text{Aut}_{\{S_J\}}(X_J),$$

which is the second.

Let us now note that the morphism  $i$  defined above is functorial in  $X$  for isomorphisms, because it is defined in structural terms from the action of  $L_X$  on  $X$  above  $X^+$ , itself functorial in  $X$  by assertion (ii) of Proposition 0.2. [N.D.E-III-26] Hence every automorphism  $u$  of  $X$  above  $S$  induces by transport of structure isomorphisms

$$h : \text{Hom}_{X^+}(X, L_X) \xrightarrow{\sim} \text{Hom}_{X^+}(X, L_X)$$

and  $f : \text{Aut}_S(X) \xrightarrow{\sim} \text{Aut}_S(X)$  such that the following diagram is commutative:

$$\begin{array}{ccc} \text{Hom}_{X^+}(X, L_X) & \xrightarrow{i} & \text{Aut}_S(X) \\ \downarrow h & & \downarrow f \\ \text{Hom}_{X^+}(X, L_X) & \xrightarrow{i} & \text{Aut}_S(X) \end{array}$$

<!-- original page 94 -->

i.e. such that  $f \circ i = i \circ h$ . On the other hand,  $f$  is given by the commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{a} & X \\ u \downarrow & & \downarrow u \\ X & \xrightarrow{f(a)} & X \end{array},$$

...

that is,  $f(a) = u \circ a \circ u^{-1}$  for every  $a \in \operatorname{Aut}_S(X)$ . Writing  $i(h(m)) = f(i(m))$ , one finds the desired formula.

**\*\*Corollary 0.7.bis.\*\*** \*Let  $X$  be an  $S$ -scheme such that  $X_J$  is an  $S_J$ -monoid. Then  $L_X$  is endowed with a structure of  $S$ -monoid, one has a split exact sequence of  $S$ -monoids:\*

<!-- label: III.III.0.7.bis -->

```text

$$1 \longrightarrow L'_X \xrightarrow[\quad s]{\quad i \quad} L_X \xrightarrow{\quad p \quad} X^+ \longrightarrow 1$$

...

and the monoid law induced on L'_X coincides with its abelian group structure. In particular, if X_J is an S_J -group, then L_X is an S -group and is the semidirect product of X^+ and L'_X .

Proof. Indeed, since X_J is an S_J -monoid, then $X^+ = \prod_{S_J/S} X_J$ is an S -monoid (indeed, one has $X^+(Y) = X_J(Y_J)$ for every $Y \in S$). For every S -scheme Y , denote by $\tilde{Y}_J$ the Y_J -affine scheme corresponding to the quasi-coherent S_{Y_J} -algebra $S_{Y_J} \oplus J \cdot 0_Y$ (i.e. the graded algebra associated to the filtration $S_{Y_J} \supset J \cdot 0_Y$). Then $L_X(Y)$ is identified with $X_J(\tilde{Y}_J)$ and $L'_X(Y)$ with the kernel of the morphism $p : X_J(\tilde{Y}_J) \rightarrow X_J(Y_J)$ induced by the "zero section" $Y_J \rightarrow \tilde{Y}_J$ (i.e. by the morphism of S_{Y_J} -algebras $S_{Y_J} \rightarrow 0_{Y_J}$ vanishing on the ideal $J \cdot 0_Y$). One has therefore, for every $Y \in S$, a split exact sequence of monoids, functorial in Y :

```text

$$1 \longrightarrow L'_X(Y) \xrightarrow[\quad s]{\quad i \quad} L_X(Y) \xrightarrow{\quad p \quad} X^+(Y) \longrightarrow 1 .$$

...

It remains to see that the monoid law induced on  $L'_X$  coincides with its abelian group structure. Denote by  $\mu$  the monoid law of  $L_X$  and  $e$  its unit section; one must show that for all  $m, m' \in L'_X(Y)$ , one has

```text

$$\mu(m \cdot e, m' \cdot e) = (m + m') \cdot e .$$

This can be seen in either of the following ways. On the one hand, one can revisit the proof of equality (0.1.10 (*)) by replacing the morphism $f : X \rightarrow W$ appearing there with the morphism $\mu : L_X \times_S L_X \rightarrow L_X$. Identifying $X^+(Y) = X_J(Y_J)$ with its image by s in $L_X(Y) = X_J(\tilde{Y}_J)$, one obtains that, for all $g, g' \in X_J(Y_J)$ and $m, m' \in L'_X(Y)$, one has

```text

$$\mu(m \cdot g, m' \cdot g') = L_\mu((g, g'))(m, m') \cdot \mu(g, g'), \quad (*)$$

where  $L_\mu((g, g'))$  denotes the morphism derived from  $\mu$  at the point  $(g, g')$  (i.e.  $\tilde{Y}_J$  is above  $L_X \times_S L_X$  via  $(g, g')$ ). In particular, one has  $\mu(m \cdot e, m' \cdot e) = L_\mu((e, e))(m, m') \cdot e$ ; now  $L_\mu((e, e))(m, m') = L_{\square_e}(m) + L_{r_e}(m')$ , where  $\ell_e$  (resp.  $r_e$ ) denotes left (resp. right) translation by  $e$ , which is the identity map of  $X_J$ , whence  $L_\mu((e, e))(m, m') = m + m'$ .

Alternatively, one can proceed as follows (cf. the proof of [DG70], § II.4, Th. 3.5). By Lemma 0.1.11, the formation of  $X^+$  and of  $L_X$  "commutes with products", and hence the same holds for  $L'_X$ ; it follows that the morphism  $\mu' : L'_X \times L'_X \rightarrow L'_X$  induced by  $\mu$  is a homomorphism for the abelian-group structure. One then deduces from Lemma 3.10 of Exp. II that  $\mu'$  coincides with the abelian-group law.

<!-- original page 95 -->

**\*\*0.8.\*\***[^N.D.E-III-27] Let now  $X$  be an  $S$ -scheme such that  $X_J$  is an  $S_J$ -group. Suppose there exists an  $S$ -morphism

<!-- label: III.III.0.8 -->

```

```text
P : X × X → X
    S
```

```

such that the morphism obtained by base change

```

```text
P_J : X_J × X_J → X_J
    S_J
```

```

is the group law of  $X_J$ . (An important particular case of the preceding situation will be the case where  $X$  is an  $S$ -group and one takes for  $P$  its group law.) From this one deduces a morphism

```

```text
L_P : L_X × L_X = L_{X ×_S X} → L_X
```

```

which, in fact, does not depend on  $P$ , because it is computed by means of the group law  $P_J$  of  $X_J$ , as we shall now see. [N.D.E-III-28] Indeed, by (ii) and (iii) of 0.2, for every  $Y \rightarrow S$  and  $x, x' \in X(Y)$ ,  $m, m' \in L_{\{X\}}(Y)$ , one has

```

```text
P(m · x, m' · x') = L_P^{(x, x')}(m, m') · (x, x') = L_P^{(x, x')}(m, m') · μ(g, g')
```

```

where  $g$  (resp.  $g'$ ) is the image of  $x$  (resp.  $x'$ ) in  $X^{+}(Y)$ . Moreover (cf. the proof of 0.10),  $L^{(x, x')}_P$  equals  $L_{\mu^{(g, g')}}^{(x, x')}$  and, by 0.7.bis (\*), this is the element of  $L_{\{X\}}(Y)$  defined by the following equality in  $L_{\{X\}}(Y)$ :

```

```text
L_{\mu^{(g, g')}}^{(x, x')}(m, m') · μ(g, g') = μ(m · g, m' · g'),
```

```

that is, if we denote by  $\times$  (instead of  $\mu$ ) the group law of  $L_X$  and  $\text{Ad}$  the "adjoint action" of  $X^{+}$  on  $L_{\{X\}}$  (which factors through  $X_0$  and is induced by the adjoint action of  $X_0$  on  $\omega^1_{X_0/S_0}$ ), one obtains that

```

```text
L_{\mu^{(g, g')}}^{(x, x')}(m, m') × g × g' = m × g × m' × g' = (m × \text{Ad}(g)(m')) × g × g'
```

```

hence finally  $L^{(x, x')}_P(m, m') = m \times \text{Ad}(g)(m')$ . We therefore obtain:

**\*\*Proposition 0.8.\*\*** \*Let  $P : X \times_S X \rightarrow X$  be an  $S$ -morphism such that  $P_J$  endows  $X_J$  with a structure of  $S_J$ -group. Denote by  $\times$  the group law of  $L_{\{X\}}$  and by  $(m, x) \mapsto m \cdot x$  the morphism  $L_{\{X\}} \times_S X \rightarrow X$  defining the action of  $L_{\{X\}}$  on  $X$ , and let  $\text{Ad} : X^{+} \rightarrow \text{Aut}_{S\text{-gr.}}(L_{\{X\}})$  be the "adjoint action" of  $X^{+}$  on  $L_{\{X\}}$  (which is induced by the adjoint action of  $X_0$  on  $\omega^1_{X_0/S_0}$ ). Then, for every  $S' \rightarrow S$  and  $x, x' \in X(S')$ ,  $m, m' \in L_{\{X\}}(S')$ , one has:\*

```

```text
P(m · x, m' · x') = (m × \text{Ad}(p_X(x))(m')) · P(x, x').      (0.8.1)
```

```

\*If  $X$  is an  $S$ -group, we shall denote by  $\ast$  its law,  $e$  its unit section, and  $i$  the  $S$ -morphism defined by:\*

```

$$
i(m) = m \cdot e,
$$

```

\*for every  $S' \rightarrow S$  and  $m \in L'_X(S)$ .\*

<!-- original page 96 -->

**Corollary 0.9.** \*Let  $X$  be an  $S$ -group. Then  $X^+$  is naturally endowed with a structure of  $S$ -group, and  $p_X$  is a morphism of  $S$ -groups. Moreover, the  $S$ -morphism\*

<!-- label: III.III.0.9 -->

$$i : L'_X \longrightarrow X, \quad m \mapsto m \cdot e$$

is an isomorphism of  $S$ -groups from  $L'_X$  onto  $\text{Ker}(p_X)$ , and one has, for all  $S' \rightarrow S$ ,  $x' \in X(S')$ ,  $m \in L'_X(S)$ :

$$m \cdot x' = (m \cdot e) * x' = i(m) * x'. \quad (0.9.1)$$

The first two assertions have already been proved in 0.1.2. Since  $X$  is formally principal homogeneous over  $X^+$  under  $L_X = L'_X \times X^+$ , the morphism  $i$  is indeed an isomorphism of  $S$ -functors from  $L'_X$  onto the kernel of  $p_X$ . The fact that  $i$  is a morphism of groups and the formula (0.9.1) follow from formula (0.8.1) applied respectively to  $x = x' = e$ , and to  $x = e$ ,  $m' = 1$ .

**Corollary 0.10.** \*Let  $X$  be an  $S$ -group. With the preceding notations, for every  $S' \rightarrow S$  and all  $x \in X(S')$  and  $m' \in L'_X(S')$ , one has\*

<!-- label: III.III.0.10 -->

$$x * i(m') * x^{-1} = i(\text{Ad}(p_X(x))(m')). \quad (0.10.1)$$

This follows from the equality  $i(m') \text{ast } x^{-1} = m' \cdot x^{-1}$  and from (0.8.1) applied to  $m = 1$  and  $x' = x^{-1}$ .

When  $X$  is an  $S$ -group, we have therefore explicitly determined the kernel of  $X \rightarrow X^+$  and the action of the inner automorphisms of  $X$  on this kernel. We shall now see that one can do the same for certain  $S$ -group functors not necessarily representable. One case will be useful to us, namely that of the  $\text{Aut}$  functors (I, 1.7). Let us state at once:

**Proposition 0.11.** \*Let  $E$  be an  $S$ -scheme. Denote  $X = \text{Aut}_S(E)$ . The kernel of the morphism of  $S$ -group functors\*

<!-- label: III.III.0.11 -->

$$p_X : X \longrightarrow X^+$$

is canonically identified with the  $S$ -functor in commutative groups  $L'_X$  defined by\*

$$\text{Hom}_S(Y, L'_X) = \text{Hom}_{\{0_{\{E_0 \times_{S_0} Y_0\}}(\Omega^1_{E_0/S_0} \otimes_{0_{\{S_0\}}} 0_{\{Y_0\}}, J \cdot 0_{\{E \times_S Y\}}\}},$$

where  $Y$  denotes a variable  $S$ -scheme.\*

Indeed, if  $Y$  is a variable  $S$ -scheme, one has  $\text{Hom}_S(Y, X) = \text{Aut}_Y(E \times_S Y)$ , and

$$\text{Hom}_S(Y, X^+) = \text{Hom}_S(Y_J, X) = \text{Aut}_{Y_J}(E \times_S Y_J) = \text{Aut}_{Y_J}((E \times_S Y) \times_Y Y_J).$$

<!-- original page 97 -->

Applying 0.7 b) to the  $S$ -scheme  $E \times_S Y$ , one obtains an isomorphism of groups:

```

```text
Hom_S(Y, L'_X) = Ker(Hom_S(Y, X) → Hom_S(Y, X^+)),

```

an isomorphism that one verifies easily to be functorial in the S -scheme Y . One thus obtains an isomorphism of S -groups

```

```text
L'_X = Ker(X → X^+),

```

which completes the proof of Proposition 0.11.

**Corollary 0.12.** [N.D.E-III-29] We keep the notations of 0.11:  $S$  is an  $S$ -scheme and  $X = \text{Aut}_S(E \times_S Y)$ . One has a natural action  $f$  of  $X$  on  $L'_X$  defined as follows. For every  $S$ -scheme  $Y$ , one has\*

<!-- label: III.III.0.12 -->

```

```text
Hom_S(Y, X) = Aut_Y(E ×_S Y)
and Hom_S(Y, L'_X) = Hom_{O_{E_0 ×_{S_0} Y_0}}(Ω^1_{E_0 ×_{S_0} Y_0 / Y_0}, J · O_{E ×_S Y})

```

(N. B. $\Omega^1_{E_0/S_0} \otimes_{S_0} O_{Y_0} \simeq \Omega^1_{E_0/S_0} \times_{S_0} O_{Y_0} / Y_0$, cf. EGA IV₄, 16.4.5); the first group acts on the second by transport of structure and this action is indeed functorial in Y . One then has the formula:*

```

```text
x · i(m) · x-1 = i(f(x) m),
(0.12.1)

```

for every  $Y \rightarrow S$  and all  $x \in \text{Hom}_S(Y, X)$ ,  $m \in \text{Hom}_S(Y, L'_X)$ .

Indeed, this follows from 0.7 c) applied to the  $S$ -scheme  $E \times_S Y$ .

**Reminder 0.13.** The direct image of a quasi-coherent module by a morphism of finite presentation is quasi-coherent. Under the same conditions, the formation of the direct image commutes with flat base change: in the situation\*

<!-- label: III.III.0.13 -->

```

```text
T ←g' T' = T ×_S S'
|      |
f      f'
▼      ▼
S ←g S' ,

```

<!-- original page 98 -->

if one supposes f (and therefore f') of finite presentation and g (and therefore g') flat, one has for every quasi-coherent $\mathcal{O}_T$ -module $\mathcal{F}$ *

```

```text
f_*(F) ⊗_{O_S} O_{S'} = f'_*(F ⊗_{O_S} O_{S'}),

```

\*where, more elegantly,\*

\$\$  
 $g^*(f_{\{*\}}(F)) = f'_{\{*\}}(g^*(F)).$   
 \$\$

These two facts hold more generally for a quasi-compact and quasi-separated morphism  $f$ , cf. (EGA I, 9.2.1) and (EGA III<sub>1</sub>, 1.4.15) in the quasi-compact separated case (taking into account EGA III<sub>2</sub>, Err\_III 25) and (EGA IV<sub>1</sub>, 1.7.4 and 1.7.21).

**Remark 0.14.** [N.D.E-III-30] Resume the notations of 0.11: let  $S$  be an  $S$ -scheme,  $X = \operatorname{Aut}_S(E)$  and  $L'_X$  the  $S$ -functor in commutative groups defined by:

<!-- label: III.III.0.14 -->

```text  
 $L'_X(Y) = \operatorname{Hom}_{\{0_{\{E_0 \times_{S_0} Y_0\}}(\Omega^1_{E_0/S_0}) \otimes_{0_{\{S_0\}}} 0_{\{Y_0\}}, J \cdot 0_{\{E \times_S Y\}}\}} \\ = \operatorname{Hom}_{\{0_{\{E \times_S Y\}}(\Omega^1_{E/S}) \otimes_{0_S} 0_Y, J \cdot 0_{\{E \times_S Y\}}\}} \\ = \Gamma(E \times_S Y, \operatorname{Hom}_{\{0_{\{E \times_S Y\}}(\Omega^1_{E/S}) \otimes_{0_S} 0_Y, J \cdot 0_{\{E \times_S Y\}}\}}).$
 ```

Suppose  $Y$  flat over  $S$ ; then one has isomorphisms:

```text  
 $J \cdot 0_{\{E \times_S Y\}} \longleftarrow (J \cdot 0_E) \otimes_{0_S} 0_Y \longrightarrow (J \cdot 0_E) \otimes_{0_{\{S_0\}}} 0_{\{Y_0\}}.$
 ```

Suppose moreover  $E$  of finite presentation over  $S$ ; then  $\Omega^1_{E/S}$  is an  $0_E$ -module of finite presentation (cf. EGA IV<sub>4</sub>, 16.4.22), and hence, by (EGA 0\_I, 6.7.6),

```text  
 $\operatorname{Hom}_{\{0_{\{E \times_S Y\}}(\Omega^1_{E/S}) \otimes_{0_S} 0_Y, (J \cdot 0_E) \otimes_{0_S} 0_Y\}} = \operatorname{Hom}_{0_E}(\Omega^1_{E/S}, J \cdot 0_E) \otimes_{0_S} 0_Y.$
 ```

Denote by  $\pi : E \rightarrow S$  and  $g : Y \rightarrow S$  the structural morphisms; applying 0.13 to the diagram

```text  

$$\begin{array}{ccc} E & \xleftarrow{g'} & E \times_S Y \\ | & & | \\ \pi & & \pi' \\ \downarrow & g & \downarrow \\ S & \xleftarrow{\quad} & Y \end{array},$$

 ```

and to the  $0_E$ -module  $F = \operatorname{Hom}_{0_E}(\Omega^1_{E/S}, J \cdot 0_E)$ , one obtains

```text  
 $\Gamma(E \times_S Y, g'^*F) = \Gamma(Y, \pi'^* g'^* F) = \Gamma(Y, g^* \pi_* F) = W(\pi_* F)(Y).$
 ```

<!-- original page 99 -->

We have therefore shown that, if  $S$  is of finite presentation over  $S$ , one has

```text  
 $L'_X = W(\pi_* \operatorname{Hom}_{0_E}(\Omega^1_{E/S}, J \cdot 0_E)) \quad (0.14.1)$
 ```

on the category of  $S$ -schemes flat over  $S$ . Note moreover that the module of which we take the  $W$  is quasi-coherent, by (EGA I, 9.1.1 and 9.2.1).

[N.D.E-III-31] Denote by  $L_{\{0\}}$  the  $S_{\{0\}}$ -functor

```text  
 $W(\pi_{\{0\}}^* \operatorname{Hom}_{0_{\{E_0\}}}(\Omega^1_{E_0/S_0}, J \cdot 0_E)).$
 ```

Then, returning to the definition of  $L'_X(Y)$  and taking into account the isomorphism

$$J \cdot 0_{\{E \times_S Y\}} = (J \cdot 0_E) \otimes_{0_{\{S_0\}}} 0_{\{Y_0\}},$$

one obtains, by arguing as above, that

$$L'_X(Y) = L_0(Y_0) = L_0(Y \times_S S_0) = \prod_{S_0/S} L_0(Y).$$

Hence, on the category of  $S$ -schemes flat over  $S$ , one has:

$$L'_X = \prod_{S_0/S} W(\pi_{0*} \operatorname{Hom}_{0_{\{E_0\}}}(\Omega^1_{\{E_0/S_0\}}, J \cdot 0_E)).$$

It is not obvious that the action of  $X$  on  $L'_X$  defined in 0.12 comes from an action of  $X_{\{0\}} = \operatorname{Aut}_{S_{\{0\}}}(E_{\{0\}})$  on  $L_{\{0\}}$ ; this is however the case when, moreover,  $E$  is flat over  $S$ .

<!-- original page 100 -->

Indeed, in this case one has canonical isomorphisms:

$$J \cdot 0_E = J \otimes_{0_S} 0_E = J \otimes_{0_{\{S_0\}}} 0_{\{E_0\}}.$$

$$L_0 = W(\pi_{0*} \operatorname{Hom}_{0_{\{E_0\}}}(\Omega^1_{\{E_0/S_0\}}, J \otimes_{0_{\{S_0\}}} 0_{\{E_0\}})),$$

$$L'_X = \prod_{S_0/S} W(\pi_{0*} \operatorname{Hom}_{0_{\{E_0\}}}(\Omega^1_{\{E_0/S_0\}}, J \otimes_{0_{\{S_0\}}} 0_{\{E_0\}})). \quad (0.14.2)$$

Then, for every  $S_{\{0\}}$ -scheme  $T$ , one has

$$L_0(T) = \operatorname{Hom}_{0_{\{E_0 \times_{S_0} T\}}}(\Omega^1_{\{E_0 \times_{S_0} T / T\}}, J \otimes_{0_{\{S_0\}}} 0_{\{E_0 \times_{S_0} T\}})$$

and  $\operatorname{Hom}_{S_{\{0\}}}(T, X_{\{0\}}) = \operatorname{Aut}_T(E_{\{0\}} \times_{S_{\{0\}}} T)$  acts by transport of structure on  $L_{\{0\}}(T)$ , functorially in  $T$ ; finally, for every  $S$ -scheme  $Y$  flat over  $S$ , the action by transport of structure of  $\operatorname{Hom}_S(Y, X) = \operatorname{Aut}_Y(E \times_S Y)$  on  $L'_X(Y) = L_{\{0\}}(Y_{\{0\}})$  factors through  $\operatorname{Aut}_{Y_{\{0\}}}(E_{\{0\}} \times_{S_{\{0\}}} Y_{\{0\}})$ .

Let us finally extract from (SGA 1, III) the following two propositions.

**Proposition 0.15.** (SGA 1, III, 6.8) [N.D.E-III-32] For every  $S_J$ -scheme  $Y$  smooth over  $S_J$  and affine, there exists an  $S$ -scheme  $X$  smooth over  $S$  such that  $X \times_S S_J \simeq Y$ , and such an  $X$  is unique up to (non-unique) isomorphism.\*

<!-- label: III.III.0.15 -->

**Proposition 0.16.** (SGA 1, III, 5.5) [N.D.E-III-33] Let  $X$  be an  $S$ -scheme smooth over  $S$ . For every affine  $S$ -scheme  $Y$ , the canonical map\*

<!-- label: III.III.0.16 -->

$$p_X(Y) : \operatorname{Hom}_S(Y, X) \longrightarrow \operatorname{Hom}_S(Y, X^+) = \operatorname{Hom}_{S_J}(Y_J, X_J)$$

\*is surjective.\*

**\*\*Corollary 0.17.\*\*** \*Let  $E$  be an  $S$ -scheme smooth over  $S$  and affine; denote  $X = \operatorname{Aut}_S(E)$ . For every affine  $S$ -scheme  $Y$ , the canonical map\*

<!-- label: III.III.0.17 -->

```text  
 $\operatorname{Aut}_Y(E \times_S Y) = \operatorname{Hom}_S(Y, X) \longrightarrow \operatorname{Hom}_S(Y, X^*) = \operatorname{Aut}_{Y_J}(E_J \times_{S_J} Y_J)$

is surjective.

Indeed, $Y \times_S E$ is affine over Y , itself affine, so affine. Applying 0.16, one deduces that every S_J -morphism $Y_J \times_{S_J} E_J \rightarrow E_J$ extends to an S -morphism $Y \times_S E \rightarrow E$. [^N.D.E-III-34] In other words, every Y_J -endomorphism of $Y_J \times_{S_J} E_J$ lifts to a Y -endomorphism of $Y \times_S E$. Then, 0.7 a) shows that every Y_J -automorphism of $Y_J \times_{S_J} E_J$ lifts to a Y -automorphism of $Y \times_S E$, which is the announced property.

1. Extensions and cohomology

<!-- label: III.III.1 -->

<!-- original page 101 -->

1.1.

<!-- label: III.III.1.1 -->

Let C be a category stable under fibered products. [^N.D.E-III-35] Let S be an object of C , G an (representable) S -group, and F an S -functor in commutative groups on which G acts. We defined in (I, 5.1) the cohomology groups $H^n(G, F)$. Recall that these are the homology groups of a complex denoted $C^*(G, F)$ where, denoting $(G/S)^n = G \times_S \cdots \times_S G$ (n factors),

```text  
 $C^n(G, F) = \operatorname{Hom}_S((G/S)^n, F)$ .

Since  $G$ , and hence the  $(G/S)^n$ , are representable, one has also

\$\$  
 $C^n(G, F) = F((G/S)^n);$   
\$\$

from this, and from the definition of the boundary operator, one sees that the complex  $C^*(G, F)$  depends only on the restriction of  $F$  to the full subcategory of  $C/S$  whose objects are the cartesian powers of  $G$  over  $S$ . Consequently, one has the:

**\*\*Lemma 1.1.1.\*\*** \*Let  $C$  be a category stable under fibered products, [^N.D.E-III-35]  $S$  an object of  $C$ ,  $G$  a representable  $S$ -group. Denote by  $C(G)$  the full subcategory of  $C/S$  whose objects are the cartesian powers of  $G$  over  $S$ . Let  $F$  and  $F'$  be two  $S$ -functors in commutative groups on which  $G$  acts. If  $F$  and  $F'$  have the same restriction to  $C(G)$ , one has a canonical isomorphism\*

<!-- label: III.III.1.1.1 -->

```text  
 $H^*(G, F) \xrightarrow{\sim} H^*(G, F')$.

1.1.2. Cohomology and restriction of scalars.

<!-- label: III.III.1.1.2 -->

[^N.D.E-III-36] Let us state another comparison result. Let now $T \rightarrow S$ be a morphism in C . If F is a T -functor in commutative groups, then the functor obtained by "restriction of scalars" (cf. Exp. II, 1)

$$F_{\{1\}} = \prod_{T/S} F$$

is an $\mathcal{S}$ -functor in commutative groups and one has a morphism of $\mathcal{S}$ -group functors

$$u : \prod_{T/S} \text{Aut}_{\{T\text{-gr.}\}}(F) \longrightarrow \text{Aut}_{\{S\text{-gr.}\}}(F_1) \quad [^{\wedge}\text{N.D.E-III-37}]$$

Let now G be an $\mathcal{S}$ -group functor and let

$$G_T \longrightarrow \text{Aut}_{\{T\text{-gr.}\}}(F)$$

be an action of G_T on F . By definition of the functor $\prod_{T/S}$, one deduces a morphism of $\mathcal{S}$ -group functors

$$G \longrightarrow \prod_{T/S} \text{Aut}_{\{T\text{-gr.}\}}(F)$$

whence, by composition with u , an action of G on $F_{\{1\}} = \prod_{T/S} F$. [$^{\wedge}\text{N.D.E-III-38}$]

<!-- original page 102 -->

Lemma 1.1.2. *Under the preceding conditions, one has a canonical isomorphism**

<!-- label: III.III.1.1.2 -->

$$H^*(G, \prod_{T/S} F) \simeq H^*(G_T, F).$$

Indeed, by the definition of cohomology, the standard complexes are canonically isomorphic.

1.2. Lifting of group morphisms.

<!-- label: III.III.1.2 -->

[$^{\wedge}\text{N.D.E-III-39}$] Following the general principles, we lay down the following definition:

Definition 1.2.1. *Let $1 \rightarrow M \xrightarrow{u} E \xrightarrow{v} G$ be a sequence of morphisms of $\hat{\mathcal{C}}$ -groups. We say that it is **exact** if the following equivalent conditions are verified:*

<!-- label: III.III.1.2.1 -->

(i) for every $S \in \mathcal{O}b \mathcal{C}$, the following sequence of ordinary groups is exact:

$$1 \longrightarrow M(S) \xrightarrow{u(S)} E(S) \xrightarrow{v(S)} G(S)$$

(ii) for every object H of $\hat{\mathcal{C}}$, the following sequence of ordinary groups is exact:

$$1 \longrightarrow \text{Hom}(H, M) \xrightarrow{u(H)} \text{Hom}(H, E) \xrightarrow{v(H)} \text{Hom}(H, G)$$

Taking in particular $H = G$ in (ii), one sees that the set of sections of v (not respecting *a priori* the group structures) is empty or principal homogeneous under $\text{Hom}(G, M)$. Suppose it is non-empty; so let

$$s : G \longrightarrow E$$

...

be a section of ν . Then for every $S \in \mathcal{O} C$ and every $x \in G(S)$, the element $s(x)$ of $E(S)$ defines an inner automorphism of E_S which normalizes M_S (more correctly, the image of M_S by u_S), hence an automorphism of M_S .

<!-- original page 103 -->

Scholie 1.2.1.1. ^[N.D.E-III-40] If M is commutative, one sees "set-theoretically" that this automorphism does not depend on the chosen section, but only on x , and depends multiplicatively on it. In summary, to every exact sequence

<!-- label: III.III.1.2.1.1 -->

$$\begin{array}{ccccccc} & & & & & & \\ (E) & 1 & \longrightarrow & M & \xrightarrow{u} & E & \xrightarrow{\nu} & G \\ & & & & & & \end{array}$$

such that M is commutative and that ν admits a section, is associated a morphism of $\hat{C}$ -groups

$$G \longrightarrow \text{Aut}_{\{\hat{C}\text{-gr.}\}}(M)$$

which is called the **action** of G on M defined by the extension (E) .

Definition 1.2.1.2. We saw in (I, 2.3.7) that ν admits a section which is a morphism of $\hat{C}$ -groups if and only if the extension (E) is isomorphic ("as an extension") to the semidirect product of M by G relative to the preceding action. Such a section of ν will be called a **section** of the extension (E) , or simply a **section** of (E) .

<!-- label: III.III.1.2.1.2 -->

If s is a section of (E) and if $m \in \Gamma(M) \cap \text{Ker}(\Gamma(E) \rightarrow \Gamma(G))$ (for the definition of Γ , see I, 1.2), then the morphism $G \rightarrow E$ defined by ^[N.D.E-III-41]

$$x \mapsto u(m) s(x) u(m)^{-1}$$

is also a section of (E) , said to be **deduced** from s by the inner automorphism defined by m (or by $u(m)$).

Lemma 1.2.2. Let $(E) : 1 \rightarrow M \xrightarrow{u} E \xrightarrow{\nu} G$ be an exact sequence of $\hat{C}$ -groups such that M is commutative and ν admits a section. Let G act on M in the manner defined by (E) .

<!-- label: III.III.1.2.2 -->

(i) The extension (E) canonically defines a class $c(E) \in H^2(G, M)$ whose vanishing is necessary and sufficient for the existence of a section of (E) .

<!-- original page 104 -->

(ii) If $c(E) = 0$, the set of sections of (E) is principal homogeneous under the group $Z^1(G, M)$, and the set of sections of (E) modulo the action of the inner automorphisms defined by the elements of $\Gamma(M)$ is principal homogeneous under the group $H^1(G, M)$.

^[N.D.E-III-42] (iii) Let s be a section of (E) ; the set of conjugates of s by the inner automorphisms defined by $\Gamma(M)$ is in bijection with $\Gamma(M)/H^0(G, M)$.

Proof. It proceeds exactly as in the case of ordinary groups, the fact that one starts from a section of ν ensuring the functoriality of the set-theoretic computations. Let us briefly indicate the principal steps.

a) To each section s of ν , one associates the morphism

$$D_s : G \times G \longrightarrow M,$$

defined set-theoretically by

```
```text
u(Ds(x, y)) = s(xy) s(y)-1 s(x)-1.
```
```

One shows that Ds is a 2-cocycle by the following computation.[^{N.D.E-III-43}] By the definition of the differential of the standard complex (I, 5.1), one has:

```
```text
(∂2 Ds)(x, y, z) = (s(x) Ds(y, z) s(x)-1) · Ds(x, y)-1 · Ds(xy, z)-1 · Ds(x, yz);
```
```

it suffices to substitute the definition of Ds into this formula to find (without using any commutativity) $Ds \in Z^2(G, M)$.

****b)**** If s and s' are two sections of v , there exists $f : G \rightarrow M$ such that $s(x) = f(x) s'(x)$. One then has

```
```text
Ds'(x, y) = f-1(xy) Ds(x, y) s(x) f(y) s(x)-1 f(x),
 = Ds(x, y) · f-1(xy) · (s(x) f(y) s(x)-1) · f(x),
```
```

<!-- original page 105 -->

i.e.

```
$$
Ds' = Ds \cdot \partial^1 f.
$$
```

[^{N.D.E-III-44}] This shows that the class of Ds in $H^2(G, M)$ does not depend on the chosen section s of v ; it is the class $c(E)$ of the extension (E) .

****c)**** Let s and s' be two sections of v and let $m \in \Gamma(M)$. Then, the equality $s(x) = m^{-1} s'(x) m$ (for every $x \in G(S)$, $S \in \text{Ob } C$) is equivalent to

```
```text
s(x) = m-1 s'(x) m s'(x)-1 s'(x), i.e. s = ∂0 m · s'.
```
```

In particular, the stabilizer of s in $\Gamma(M)$ is the subgroup of $m \in \Gamma(M)$ such that $\partial^0 m = e_M$, i.e. the subgroup $H^0(G, M)$. This already proves (iii).

****d)**** The reasoning is now habitual.[^{N.D.E-III-45}] Let s_0 be an arbitrary section of v ; there exists a section s , necessarily of the form $s = f \cdot s_0$, which is a morphism of groups, i.e. which satisfies $Ds = 0$, if and only if $(Ds_0)^{-1} = \partial^1 f$, i.e., if and only if the class $c(E)$ is zero. This proves (i).

In this case, the set of sections of (E) consists of the sections $s' = h \cdot s$, where $h : G \rightarrow M$ satisfies $\partial^1 h = 0$, i.e. $h \in Z^1(G, M)$. Moreover, by point c), two such sections $h_1 \cdot s$ and $h_2 \cdot s$ are conjugate under $\Gamma(M)$ if and only if h_1 and h_2 have the same image in $H^1(G, M)$. This proves (ii).

Let still

```
```text
(E) 1 → M →u E →v G
```
```

be an exact sequence of $\hat{C}$ -groups with M commutative. Let

```
```text
f : H → G
```
```

be a morphism of $\hat{C}$ -groups. Consider $E_{\{f\}} = H \times_{\{G\}} E$; it is a $\hat{C}$ -group and the projection $v_{\{f\}} : E_{\{f\}} \rightarrow H$ is a morphism of $\hat{C}$ -groups. Likewise for $e_{\{f\}} : E_{\{f\}} \rightarrow E$. On the other hand, if one sends M into E via u and into H via the unit morphism, one defines a morphism of $\hat{C}$ -groups $u_{\{f\}} : M \rightarrow E_{\{f\}}$. We have thus constructed a commutative diagram of $\hat{C}$ -groups:

$$\begin{array}{ccccccc} \text{``text} \\ (E) & 1 & \longrightarrow & M & \xrightarrow{u} & E & \xrightarrow{v} & G \\ & & & \parallel & & \uparrow e_{\{f\}} & & \uparrow f \\ & & & \text{id} & & \downarrow u_{\{f\}} & & \downarrow v_{\{f\}} \\ (E_{\{f\}}) & 1 & \longrightarrow & M & \xrightarrow{u_{\{f\}}} & E_{\{f\}} & \xrightarrow{v_{\{f\}}} & H. \end{array}$$

One has immediately:

<!-- original page 106 -->

Lemma 1.2.3. (i) The sequence $(E_{\{f\}})$ is exact.*

<!-- label: III.III.1.2.3 -->

(ii) The map $s \mapsto e_{\{f\}} \circ s = f \circ s$ realizes a bijective correspondence between the morphisms*

$s : H \rightarrow E_{\{f\}}$

such that $v_{\{f\}} \circ s = \text{id}$ (that is, the sections of $v_{\{f\}}$) and the morphisms*

$f' : H \rightarrow E$

such that $v \circ f' = f$ (that is, the morphisms f' "lifting" f).

(iii) In the preceding correspondence, sections of $(E_{\{f\}})$ and morphisms of groups f' lifting f correspond.*

Applying Lemma 1.2.2 to the extension $(E_{\{f\}})$ and taking into account 1.2.3, one obtains the following proposition (which formally contains 1.2.2):

Proposition 1.2.4. Let $(E) : 1 \rightarrow M \rightarrow E \xrightarrow{v} G$ be an exact sequence of $\hat{C}$ -groups with M commutative. Let*

<!-- label: III.III.1.2.4 -->

$f : H \rightarrow G$

be a morphism of $\hat{C}$ -groups; suppose it lifts to a morphism (not necessarily of groups) $f' : H \rightarrow E$. Let H act on M by the composite morphism (multiplicative and independent of the choice of f'),*

$H \xrightarrow{f'} E \xrightarrow{\text{int}} \text{Aut}_{\{\hat{C}\text{-gr.}\}}(M).$

(i) The morphism f canonically defines a class $c(f) \in H^2(H, M)$ whose vanishing is necessary and sufficient for the existence of a morphism of $\hat{C}$ -groups*

$f' : H \rightarrow E$

lifting f .

<!-- original page 107 -->

(ii) If $\phi(f) = \theta$, the set of morphisms of $\hat{C}$ -groups f' lifting f , modulo the action of the inner automorphisms defined by elements of $\Gamma(M)$ (i.e. by elements m of $\Gamma(E)$ such that $v(m) = e$), is principal homogeneous under $H^1(H, M)$.

(iii) If $f' : H \rightarrow E$ is a morphism of groups lifting f , the set of transforms of f' by the inner automorphisms defined by the elements of $\Gamma(M)$ is isomorphic to $\Gamma(M) \backslash \Gamma(M \backslash H) = \Gamma(M) / H^1(H, M)$.

1.3. Extensions of group laws.

<!-- label: III.III.1.3 -->

Consider the following situation: one has a morphism of $\hat{C}$

```
```text
(†) p : X → Y
```
```

and a commutative $\hat{C}$ -group M acting on X , such that X is formally principal homogeneous above Y under M_Y .

If $g : Y \rightarrow Z$ is an arbitrary morphism of $\hat{C}$, then $g \circ p : X \rightarrow Z$ is invariant under M : for each $S \in \text{Ob } C$, $(g \circ p)(S)$ is invariant under the action of $M(S)$ acting on $X(S)$. Conversely, we shall assume the following condition verified for $n = 1, 2, 3, 4$.

$(+)_n$: Every morphism from X^n to M , invariant under the action of M^n on X^n , factors uniquely through $p^n : X^n \rightarrow Y^n$ (where the powers n denote cartesian powers).

Lemma 1.3.1. (i) If h is a morphism from Y to M , the automorphism u_h of X defined set-theoretically by $x \mapsto h(p(x)) \cdot x$ preserves the fibers of p and commutes with the actions of M on X , [N.D.E-III-46] i.e. for all $S \in \text{Ob } C$ and $x \in X(S)$, $m \in M(S)$, one has*

<!-- label: III.III.1.3.1 -->

```
```text
p(h(p(x)) · x) = p(x), m · (h(p(x)) · x) = h(p(m · x)) · (m · x) .
```
```

(ii) This construction realizes a bijective correspondence between morphisms from Y to M and automorphisms of X preserving the fibers of p and commuting with the actions of M .

The first part is clear, since $p(m \cdot x) = p(x)$ and M is commutative.

<!-- original page 108 -->

Conversely, an automorphism u of X preserving the fibers of p is written set-theoretically $x \mapsto g(x) \cdot x$, where g is some morphism from X to M . If u commutes with the actions of M , the morphism g is invariant under M [N.D.E-III-47] and one concludes by condition $(+)_1$.

We now suppose given in addition a group law on Y and an action of Y on M , that is, a morphism of $\hat{C}$ -groups:

```
```text
(‡) f : Y → Aut_{\hat{C}-gr.}(M) .
```
```

Definition 1.3.2. A composition law on X is

<!-- label: III.III.1.3.2 -->

```
```text
P : X × X → X
```
```

is said to be **admissible** if it verifies the following two conditions:*

(i) P lifts the group law of Y , i.e. the diagram

$$\begin{array}{ccc} X \times X & \xrightarrow{P} & X \\ (p,p) \downarrow & & \downarrow p \\ Y \times Y & \xrightarrow{\quad} & Y \end{array}$$

is commutative.

(ii) For every $S \in \mathcal{C}$ and all $x, y \in X(S)$, $m, n \in M(S)$, one has the following relation:

$$P(m \cdot x, n \cdot y) = m \cdot f(p(x))(n) \cdot P(x, y).$$

Proposition 1.3.3. *For a group law $\ast$ on X to be admissible, it is necessary and sufficient that the following four conditions be satisfied:*

<!-- label: III.III.1.3.3 -->

(i) $p : X \rightarrow Y$ is a morphism of groups.

<!-- original page 109 -->

(ii) The morphism $i : M \rightarrow X$ defined by $i(m) = m \cdot e_X$ is an isomorphism of groups from M onto $\text{Ker}(p)$, that is to say: one has set-theoretically $(m \cdot e_X) \ast (n \cdot e_X) = (mn) \cdot e_X$.

(iii) One has $m \cdot x = (m \cdot e_X) \ast x = i(m) \ast x$ for each $m \in M(S)$, $x \in X(S)$.

(iv) The inner automorphisms of X act on $\text{Ker}(p)$ by the set-theoretic formula

$$x \ast i(m) \ast x^{-1} = i(f(p(x)) m).$$

The proof is immediate.

Lemma 1.3.4. [N.D.E.-III-48] *Let h be a morphism $Y \rightarrow M$ and u_h the automorphism $x \mapsto h(p(x)) \cdot x$ of X (cf. 1.3.1). Let P be an admissible composition law (resp. an admissible group law) on X and let P' be the composition law on X deduced from P by means of u_h , i.e. $P'(x, y) = u_h^{-1}(P(u_h(x), u_h(y)))$. Then:*

<!-- label: III.III.1.3.4 -->

(i) P' is an admissible composition law (resp. an admissible group law).

(ii) For every $x, y \in X(S)$ ($S \in \mathcal{C}$), setting $v = p(x)$ and $w = p(y)$, one has

$$P'(x, y) = (h(vw)^{-1} \cdot h(v) \cdot f(v)(h(w))) \cdot P(x, y) = (\partial^1 h)(p(x), p(y)) \cdot P(x, y).$$

Proof. *One has $u_h^{-1} = u_{h^{\vee}}$, where $h^{\vee} : Y \rightarrow M$ is defined by $h^{\vee}(y) = h(y)^{-1}$. By 1.3.2 (i) and (ii), one has $P(h(v) \cdot x, h(w) \cdot y) = h(v) \cdot f(v)(h(w)) \cdot P(x, y)$ and $p(P(x, y)) = vw$, whence

$$P'(x, y) = (h(vw)^{-1} \cdot h(v) \cdot f(v)(h(w))) \cdot P(x, y) = (\partial^1 h)(p(x), p(y)) \cdot P(x, y).$$

It is then immediate that P' verifies conditions (i) and (ii) of 1.3.2.

Definition 1.3.5. Two admissible composition laws deduced from one another by the procedure of 1.3.4 are said to be **equivalent**. [N.D.E-III-49]

<!-- label: III.III.1.3.5 -->

<!-- original page 110 -->

Proposition 1.3.6. Suppose there exists an admissible composition law on X . Then:

<!-- label: III.III.1.3.6 -->

(i) There exists a class $\mathcal{H}^3(Y, M)$ (canonically determined), whose vanishing is necessary and sufficient for the existence of an admissible **associative** composition law on X .

(ii) If $\mathcal{H}^3(Y, M) = \emptyset$, the set of admissible and associative composition laws (resp. of equivalence classes of admissible and associative composition laws) on X is principal homogeneous under $\mathcal{Z}^2(Y, M)$ (resp. $\mathcal{H}^2(Y, M)$).

The proof proceeds in several steps.

a) Let P be an admissible composition law on X . Since P lifts the composition law of Y which is associative, there exists a unique morphism $a : X^3 \rightarrow M$ such that

```

```text
(*) P(x, P(y, z)) = a(x, y, z) · P(P(x, y), z).
```

```

By applying conditions 1.3.2 (i) and (ii), one sees at once that a is invariant under the action of M^3 on X^3 , [N.D.E-III-50] whence, by applying hypothesis $(+)_3$, the following result:

(1) There exists a unique morphism $DP : Y^3 \rightarrow M$ such that

```

```text
P(x, P(y, z)) = DP(p(x), p(y), p(z)) · P(P(x, y), z),
```

```

and P is associative if and only if $DP = 0$.

b) Compute step by step $P(P(P(x, y), z), t)$ by means of the preceding formula. Setting $p(x) = u$, $p(y) = v$, $p(z) = w$, $p(t) = h$, one obtains [N.D.E-III-51] the following pentagonal diagram, where an arrow $a \xrightarrow{\quad} b$ means that $b = m \cdot a$:

```

```text
 DP(u,v,wh) ✓ P(x, P(y, P(z, t))) ✓ f(u)(DP(v,w,h))
 | | |
P(P(x, y), P(z, t)) P(x, P(P(y, z), t))
 | |
DP(uv,w,h) DP(u,vw,h)
 | |
P(P(P(x, y), z), t) ← DP(u,v,w) P(P(x, P(y, z)), t)
```

```

so one finds

```

```text
DP(u, v, w) · DP(u, vw, h) · f(u)(DP(v, w, h)) · DP(u, v, wh)-1 · DP(uv, w, h)-1 = e_M
```

```

i.e., $\partial^3 DP(u, v, w, h) = e_M$. As moreover the first member of the preceding formula can be written, by means of P and a , as the expression in (x, y, z, t) of a certain morphism $X^4 \rightarrow M$, it follows from the uniqueness hypothesis in $(+)_4$ that $\partial^3 DP$ and e_M , which factor through the same morphism, are equal, hence

(2) DP is a cocycle, i.e. one has $DP \in \mathcal{Z}^3(Y, M)$.

****c)**** If P and P' are two admissible composition laws on X , there exists a unique morphism

```
```text
b : X^2 → M
```
```

such that $P'(x, y) = b(x, y) \cdot P(x, y)$. Applying 1.3.2 (ii) to P and P' , one sees that b is invariant under M^2 , whence, by $(+)_2$:

<!-- original page 111 -->

(3)** For every pair of admissible composition laws (P, P') , there exists a unique $d(P, P') : Y^2 \rightarrow M$ such that

```
```text
P'(x, y) = d(P, P')(p(x), p(y)) · P(x, y),
```
```

and the set of admissible composition laws becomes in this way principal homogeneous under $\operatorname{Hom}(Y^2, M) = C^2(Y, M)$.

****d)**** Under the preceding conditions, one has the formula:

```
```text
(4) DP' - DP = ∂^2 d(P, P').
```
```

****e)**** P and P' are equivalent if and only if there exists a morphism $h \in C^1(Y, M) = \operatorname{Hom}(Y, M)$ such that $d(P, P') = \partial^1 h$; this follows from the definition of equivalence and from 1.3.4 (ii).

****f)**** It now only remains to conclude: one seeks a P that is associative, i.e. such that $DP' = e_M$. Now DP is a cocycle whose class in $H^3(Y, M)$ does not depend on the chosen admissible composition law P (by (3) and (4)). This class is the desired obstruction c . One will be able to choose a P answering the conditions if and only if $c = 0$; indeed, choosing an arbitrary P , one will have to solve, by (1):

```
```text
0 = DP' = DP + ∂^2 d(P, P'),
```
```

which is possible by (3) and (4) if and only if $c = 0$. The set of associative P is principal homogeneous under $Z^2(Y, M)$, again by (3) and (4). The set of associative P up to equivalence is principal homogeneous under $H^2(Y, M)$ by (e).

2. Infinitesimal extensions of a morphism of group schemes

<!-- label: III.III.2 -->

<!-- original page 112 -->

Resume the notations of § 0. Let Y and X be two S -group functors. Let M be the kernel of the morphism of groups $p_X : X \rightarrow X^+$. One thus has an exact sequence of S -group functors

```
```text
1 → M → X →p_X→ X^+ .
```
```

By definition of X^+ , one has isomorphisms

```
```text
Hom_S(Y, X^+) → Hom_{S_J}(Y_J, X_J)
Hom_{S-gr.}(Y, X^+) → Hom_{S_J-gr.}(Y_J, X_J),
```
```

and the morphism

```

```text
Hom_S(Y, p_X) : Hom_S(Y, X) → Hom_S(Y, X^+)
```

```

associates to an S -morphism $f : Y \rightarrow X$ the S -morphism $f^+ : Y \rightarrow X^+$ corresponding by the preceding isomorphisms to the S_J -morphism $f_J : Y_J \rightarrow X_J$ obtained by base change from f . If M is commutative, one can apply to this situation Proposition 1.2.4.

2.0.

<!-- label: III.III.2.0 -->

[^N.D.E-III-52] In what follows, we shall be interested in the following case: Y is flat over S , and X is an S -group functor of one of the following two species:

a) X is an S -group scheme,

b) $X = \operatorname{Aut}_S(E)$ where E is an S -scheme, of finite presentation over S .

Denote by $(\operatorname{Flat})/S$ the category of S -schemes flat over S . In case (a) (resp. (b)), the S -group functor $M = \operatorname{Ker}(X \rightarrow X^+)$, its restriction L to $(\operatorname{Flat})/S$, and the actions of the inner automorphisms of X on M , have been computed in 0.9, 0.5, and 0.10 (resp. 0.11, 0.14, and 0.12). That is to say, in case (a), let $L_{\{0\}}$ be the $S_{\{0\}}$ -functor in commutative groups defined by: for every $S_{\{0\}}$ -scheme $T_{\{0\}}$,

```

```text
Hom_{S_0}(T_0, L_0) = Hom_{0_{T_0}}(\omega^1_{X_0/S_0} \otimes_{0_{T_0}} 0_{T_0}, J \otimes_{0_{T_0}} 0_{T_0}),
```

```

on which $X_{\{0\}}$ acts via its adjoint representation in $\omega^1_{X_{\{0\}}/S_{\{0\}}}$; then $L = \prod_{S_{\{0\}}/S} L_{\{0\}}$, i.e. for every S -scheme T , one has $L(T) = L_{\{0\}}(T \times_S S_{\{0\}})$.

In case (b), denote by π the structural morphism $E \rightarrow S$; then L is the functor in abelian groups on $(\operatorname{Flat})/S$ defined by

```

```text
Hom_S(T, L) = \Gamma(T, \pi^*(\operatorname{Hom}_{0_E}(\Omega^1_{E/S}, J \cdot 0_E)) \otimes_{0_S} 0_T),
```

```

on which X , considered as a functor on $(\operatorname{Flat})/S$, acts as we saw in 0.12.

Then, one has an exact sequence of functors in groups on $(\operatorname{Flat})/S$:

```

```text
(E) 1 → L → X → X^+ .
```

```

On the other hand, Y being supposed flat over S , the groups $H^i(Y, M)$ depend, by 1.1.1, only on the restriction L of M to $(\operatorname{Flat})/S$. Since $L = \prod_{S_{\{0\}}/S} L_{\{0\}}$ in case (a), then by 1.1.2, one has in this case isomorphisms $H^i(Y, L) \simeq H^i(Y_{\{0\}}, L_{\{0\}})$.

<!-- original page 113 -->

Then, taking the preceding into account, one deduces from Proposition 1.2.4 the:[^N.D.E-III-53]

Theorem 2.1. *Let S be a scheme, I and J two quasi-coherent ideals such that $I \supset J$ and $I \cdot J = 0$, defining the closed subschemes $S_{\{0\}}$ and S_J , and let:

<!-- label: III.III.2.1 -->

<!-- original page 114 -->

— X an S -group functor of type (a) or (b), and $L_{\{0\}}$, L as above;*

— Y an S -group scheme flat over S and $f_J : Y_J \rightarrow X_J$ a morphism of S_J -groups.*

Then:

(i) For f_J to lift to a morphism of S -groups $Y \rightarrow X$, it is necessary and sufficient that the following two conditions be satisfied:

(i₁) f_J lifts to a morphism of S -functors $Y \rightarrow X$ (by 1.2.4, this defines an action of Y on L , which does not depend on the chosen lift; moreover, in case (a), the action thus obtained of Y_0 on L_0 comes from the morphism $f_0 : Y_0 \rightarrow X_0$ and from "the adjoint action" of X_0 on L_0);

(i₂) A certain obstruction $c(f_J)$, defined canonically by f_J , vanishes, where $c(f_J)$ is a class in $H^2(Y, L) \cong H^2(Y_0, L_0)$ in case (a)).

(ii) If the conditions of (i) are satisfied, the set E of morphisms of S -group functors $Y \rightarrow X$ extending f_J is principal homogeneous under $Z^1(Y, L) \cong Z^1(Y_0, L_0)$ in case (a)), and E modulo the action of the inner automorphisms of X defined by the sections of X over S inducing the unit section of X_J over S_J , is principal homogeneous under $H^1(Y, L) \cong H^1(Y_0, L_0)$ in case (a)).

(iii) If $f : Y \rightarrow X$ is a morphism of S -group functors extending f_J , the set of morphisms $Y \rightarrow X$ transforms of f by the inner automorphisms defined by the sections of X over S inducing the unit section of X_J over S_J is isomorphic to $\Gamma(L)/H^0(Y, L) \cong \Gamma(L_0)/H^0(Y_0, L_0)$ in case (a)).

Remark 2.1.1. [N.D.E-III-54] *If $f, f' : Y \rightarrow X$ are morphisms of S -group functors extending f_J , one therefore obtains a cocycle $d(f, f') \in Z^1(Y, L) \cong Z^1(Y_0, L_0)$ in case (a)), such that*

<!-- label: III.III.2.1.1 -->

```text  
(\*)  $f' = d(f, f') \cdot f$ . [N.D.E-III-55]  
```

We shall denote by $\bar{d}(f, f')$ the image of $d(f, f')$ in $H^1(Y, L) \cong H^1(Y_0, L_0)$ in case (a)).

<!-- original page 115 -->

Remark 2.2. *We keep the preceding notations; in particular, Y is flat over S . In case (b), L is, by (0.14.1), the restriction to $(\text{Flat})/S$ of the functor*

<!-- label: III.III.2.2 -->

$$W(\pi_*(\operatorname{Hom}_{0_E}(\Omega_{E/S}^1, J \cdot 0_E))),$$

where $\pi : E \rightarrow S$ is the structural morphism. In case (a), suppose moreover that X is locally of finite presentation over S ; then by (0.6.1), L is the restriction to $(\text{Flat})/S$ of the functor

$$\prod_{S_0/S} W(\operatorname{Hom}_{0_{S_0}}(\Omega_{X_0/S_0}^1, J)).$$

In both cases, the module of which we take the W is quasi-coherent, by (EGA I, 9.1.1). Suppose moreover Y affine over S . [N.D.E-III-56] Then, by (I, 5.3), one obtains:

a) $H^i(Y, L) = H^i(Y_0, L_0) = H^i(Y_0, \operatorname{Hom}_{0_{S_0}}(\Omega_{X_0/S_0}^1, J))$,

b) $H^i(Y, L) = H^i(Y, \pi_*(\operatorname{Hom}_{0_E}(\Omega_{E/S}^1, J \cdot 0_E)))$.

<!-- original page 116 -->

Remark 2.3. *1) By 0.16 and 0.17, condition (i_1) is automatically verified when Y is an affine scheme and*

<!-- label: III.III.2.3 -->

```

```text
(*) { in case (a), X is smooth over S;
 in case (b), E is smooth and affine over S.
...

```

\*2) Moreover, under these conditions (\$Y\$ always being supposed flat over \$S\$, cf. 2.0), one can write in case (a), by 2.2 a) and (0.6.2),\*

```

```text
H^i(Y, L) = H^i(Y_0, L_0) = H^i(Y_0, Lie(X_0/S_0) \otimes_{O_{S_0}} J),
...

```

[^ND.E-III-57] and in case (b), by (0.14.2), 1.1.2 and (I, 5.3),

```

```text
H^i(Y, L) = H^i(Y_0, \pi_{0*} Hom_{O_{S_0}}(\Omega^1_{E_0/S_0}, J \otimes_{O_{S_0}} O_{E_0})).
...

```

Let us now state a certain number of corollaries concerning the case where \$Y\$ is an \$S\$-diagonalizable group (I, 4.4); one knows then (loc. cit. 5.3.3) that if \$S\$ is affine, \$H^n(Y, F) = 0\$ for \$n > 0\$ and every quasi-coherent \$O\_S\$-module \$F\$. First, a particular case:

**\*\*Corollary 2.4.\*\*** \*Let \$S\$ be a scheme and \$S\_0\$ a closed subscheme defined by a nilpotent ideal. Let \$Y\$ be a diagonalizable \$S\$-group and let:\*

<!-- label: III.III.2.4 -->

\*a) \$X\$ an \$S\$-group locally of finite presentation over \$S\$,\*

\*b) \$X = \operatorname{Aut}\_S(E)\$ where \$E\$ is an \$S\$-scheme locally of finite presentation.\*

\*Let \$f : Y \to X\$ be a morphism of \$S\$-groups such that the morphism \$f\_0 : Y\_0 \to X\_0\$ obtained by base change is the unit morphism. Then \$f\$ is the unit morphism.\*

Indeed, the question is local on \$S\$ and (in (b)) on \$E\$. We may therefore suppose \$S\$ affine and (in (b)) \$E\$ of finite presentation over \$S\$. Now introducing the closed subschemes \$S\_n\$ of \$S\$ defined by the powers of the ideal defining \$S\_0\$, one is reduced to the case where \$S\_0\$ is defined by an ideal of square zero, and in that case the asserted statement follows from the theorem, via 2.2.

In the case where one does not necessarily suppose that \$f\_0\$ is the unit morphism, one has:

**\*\*Corollary 2.5.\*\*** \*Let \$S\$ and \$S\_0\$ be as in 2.4. Suppose moreover \$S\$ affine. Let \$Y\$ be a diagonalizable \$S\$-group, \$X\$ an \$S\$-group functor, and \$f\_0 : Y\_0 \to X\_0\$ a morphism of \$S\_0\$-group functors.\*

<!-- label: III.III.2.5 -->

\*(i)[<sup>N</sup>D.E-III-58]\*

<!-- original page 117 -->

\*(ii) Suppose that one of the following two properties holds:\*

\*a) \$X\$ is an \$S\$-group smooth over \$S\$;\*

\*b) \$X = \operatorname{Aut}\_S(E)\$ where \$E\$ is smooth and affine over \$S\$.\*

\*Then \$f\_0\$ extends to a morphism of \$S\$-groups \$Y \to X\$; two such extensions are conjugate by an inner automorphism of \$X\$ defined by a section of \$X\$ over \$S\$ inducing the unit section of \$X\_0\$ over \$S\_0\$.\*

Introduce the \$S\_n\$ as above.[<sup>N</sup>D.E-III-59] For (ii), note first that a scheme smooth over \$S\$ is necessarily locally of finite presentation over \$S\$; hence, in case (b), \$E\$ being smooth and affine over \$S\$ is necessarily of finite presentation over \$S\$, i.e. we are indeed under hypothesis (b) of 2.0.

Then, under the hypotheses of (ii), condition \$(i\_1)\$ of 2.1 is automatically verified by 0.16 and 0.17; moreover every section of \$X\_{S\_n}\$ over \$S\_n\$ lifts to a section of \$X\_{S\_{n+1}}\$ over \$S\_{n+1}\$, by the definition of

"smooth over  $S$ " in case (a), and by 0.17 in case (b). Consequently, if  $f$  and  $f'$  are two lifts of  $f_0$ , one can suppose step by step that  $f_n = f'_n$  by lifting the inner automorphism whose existence is asserted by part (ii) of the theorem, which completes the proof.

By reasoning likewise, taking into account Remark 2.3, one obtains:

**Corollary 2.6.** Let  $S$  be a scheme,  $I$  a nilpotent ideal defining the closed subscheme  $S_0$ ,  $Y$  an  $S$ -group flat over  $S$  and affine,  $X$  an  $S$ -group smooth over  $S$ .

III.III.2.6

(i) If, for every  $n \geq 0$ , one has  $H^2(Y_0, \text{Lie}(X_0/S_0) \otimes_{0_{S_0}} I^{n+1}/I^{n+2}) = 0$ , every morphism of  $S_0$ -groups  $f_0 : Y_0 \rightarrow X_0$  lifts to a morphism of  $S$ -groups  $f : Y \rightarrow X$ .

(ii) If, for every  $n \geq 0$ , one has  $H^1(Y_0, \text{Lie}(X_0/S_0) \otimes_{0_{S_0}} I^{n+1}/I^{n+2}) = 0$ , two such lifts are conjugate by an inner automorphism of  $X$  defined by a section of  $X$  over  $S$  inducing the unit section of  $X_0$  over  $S_0$ .

Now one has the following lemma:

**Lemma 2.7.** Let  $S$  be an affine scheme,  $G$  an affine  $S$ -group,  $F$  a quasi-coherent  $0_S$ -module,  $L$  a locally free  $0_S$ -module. Suppose one has an action of  $G$  on  $F$  in the sense of Exposé I, which defines an action of  $G$  on  $F \otimes_{0_S} L$  [N.D.E-III-60]. Denote by  $\Lambda$  the ring of  $S$ ,  $L$  the  $\Lambda$ -module defining  $L$  (which is therefore a projective module). One has a canonical isomorphism\*

III.III.2.7

original page 118

text  
 $H^*(G, F \otimes_{0_S} L) \simeq H^*(G, F) \otimes_{\Lambda} L$ .

[N.D.E-III-61] Indeed, denote by  $A$  the  $0_S$ -algebra  $A(G)$  and consider the complex  $C$  of quasi-coherent  $0_S$ -modules:

text  
 $0 \rightarrow F \rightarrow F \otimes_{0_S} A \rightarrow F \otimes_{0_S} A \otimes_{0_S} A \rightarrow \dots$

By (I, 5.3),  $H^*(G, F)$  (resp.  $H^*(G, F \otimes_{0_S} L)$ ) is the cohomology of the complex  $\Gamma(S, C)$  (resp.  $\Gamma(S, C \otimes_{0_S} L)$ ). Now, since  $S$  is affine, one has (cf. EGA I, 1.3.12)

text  
 $\Gamma(S, C \otimes_{0_S} L) \simeq \Gamma(S, C) \otimes_{\Lambda} L$ .

Since  $L$  is a projective  $\Lambda$ -module (hence flat), one has also  $H^*(\Gamma(S, C) \otimes_{\Lambda} L) \simeq H^*(\Gamma(S, C)) \otimes_{\Lambda} L$ , whence the announced result.

By using the lemma, one transforms 2.6 into:

**Corollary 2.8.** Let  $S$  be an affine scheme,  $I$  a nilpotent ideal on  $S$  defining the closed subscheme  $S_0$ . Suppose the  $I^{n+1}/I^{n+2}$  locally free on  $S_0$ . Let  $Y$  be an  $S$ -group flat over  $S$  and affine,  $X$  an  $S$ -group smooth over  $S$ , and  $f_0 : Y_0 \rightarrow X_0$  a morphism of  $S_0$ -groups.\*

III.III.2.8

(i) If  $H^2(Y_0, \text{Lie}(X_0/S_0)) = 0$ ,  $f_0$  lifts to a morphism of  $S$ -groups  $f : Y \rightarrow X$ .

(ii) If  $H^1(Y_0, \text{Lie}(X_0/S_0)) = 0$ , two such lifts are conjugate by an inner automorphism of  $X$  defined by a section of  $X$  over  $S$  inducing the unit section of  $X_0$  over  $S_0$ .

In particular, taking  $Y = X$ :

**\*\*Corollary 2.9.\*\*** \*Let  $S$  and  $S_0$  be as above. Let  $X$  be an  $S$ -group smooth over  $S$  and affine.\*

<!-- label: III.III.2.9 -->

(i) If  $H^1(X_0, \text{Lie}(X_0/S_0)) = 0$ , every endomorphism of  $X$  over  $S$  inducing the identity on  $X_0$  is the inner automorphism defined by a section of  $X$  over  $S$  inducing the unit section of  $X_0$  over  $S_0$ .\*

<!-- original page 119 -->

(ii) If  $H^2(X_0, \text{Lie}(X_0/S_0)) = 0$ , every  $S_0$ -automorphism of  $X_0$  extends to an  $S$ -automorphism of  $X$ . [N.D.E-III-62]\*

**\*\*Remark 2.10.\*\*** \*The assertions concerning  $H^1$  have converses by the theorem. Let us signal as an example the following: if  $S = \mathbb{A}^1$  is the scheme of dual numbers over  $S_0$  (II, 2.1) and if  $X$  is a flat  $S$ -group such that every automorphism of  $X$  over  $S$  inducing the identity on  $S_0$  is the inner automorphism defined by a section of  $X$  over  $S$  inducing the unit section of  $X_0$  over  $S_0$ , then  $H^1(X_0, \text{Lie}(X_0/S_0)) = 0$ . [N.D.E-III-63]\*

<!-- label: III.III.2.10 -->

**\*\*Corollary 2.11.\*\*** \*Let  $S$ ,  $I$  and  $J$  be as in 2.1. Let  $Y$  be an  $S$ -group scheme flat over  $S$ ,  $X$  an  $S$ -group scheme,  $f : Y \rightarrow X$  a morphism of  $S$ -groups. The set of morphisms from  $Y$  to  $X$  deduced from  $f$  by conjugation by elements  $x \in X(S)$  inducing the unit of  $X(S_0)$  is isomorphic to the quotient\*

<!-- label: III.III.2.11 -->

``text  

$$E = \text{Hom}_{\{0\}}(\omega^1_{X_0/S_0}, J) / \text{Hom}_{\{0\}}(\omega^1_{X_0/S_0}, J)^{\text{ad}(Y_0)},$$
 ``

\*where the second group consists of the  $\{0\}$ -morphisms  $\omega^1_{X_0/S_0} \rightarrow J$  which by every base change  $S' \rightarrow S_0$  give morphisms  $\omega^1_{X_0/S_0} \otimes_{\{0\}} 0_{S'} \rightarrow J \otimes_{\{0\}} 0_{S'}$  invariant under the action of  $Y_0(S')$  on the first factor.\*

By 2.1 (iii), one knows that the set sought is isomorphic to  $\Gamma(L_0)/H^0(Y_0, L_0)$ . Now  $\Gamma(L_0) = \text{Hom}_{\{0\}}(\omega^1_{X_0/S_0}, J)$  and  $H^0(Y_0, L_0)$  is evidently none other than  $\Gamma(L_0)^{\text{ad}(Y_0)}$  in the sense of the preceding statement.

<!-- original page 120 -->

**\*\*Corollary 2.12.\*\*** \*Under the conditions of 2.11, suppose moreover  $\omega^1_{X_0/S_0}$  locally free of finite rank. Then\*

<!-- label: III.III.2.12 -->

``text  

$$E \cong \Gamma(S_0, \text{Lie}(X_0/S_0) \otimes_{\{0\}} J) / H^0(Y_0, \text{Lie}(X_0/S_0) \otimes_{\{0\}} J).$$
 ``

[N.D.E-III-64] Indeed, if  $\omega^1_{X_0/S_0}$  is locally free of finite rank, one has  $\text{Hom}_{\{0\}}(\omega^1_{X_0/S_0}, J) \cong \text{Lie}(X_0/S_0) \otimes_{\{0\}} J$ .

**\*\*Corollary 2.13.\*\*** \*Suppose moreover  $Y_0$  diagonalizable. Then\*

<!-- label: III.III.2.13 -->

``text  

$$E \cong \Gamma(S_0, \text{Lie}(X_0/S_0) \otimes_{\{0\}} J) / \Gamma(S_0, \text{Lie}(X_0/S_0)^{\text{ad}(Y_0)} \otimes_{\{0\}} J)$$
 ``

\*where  $\text{Lie}(X_0/S_0)^{\text{ad}(Y_0)}$  can be constructed as the factor of the decomposition of (I, 4.7.3) corresponding to the null character of  $Y_0$ .\*

Indeed, if  $Y_0 \cong D_{\{0\}}(M)$ , one has by loc. cit. a decomposition into direct sum:

```

```text

$$\mathrm{Lie}(X_0/S_0) = \mathrm{Lie}(X_0/S_0)_0 \oplus \bigoplus_{m \in M, m \neq 0} \mathrm{Lie}(X_0/S_0)_m.$$

```

```

By tensoring with  $J$ , one finds an analogous decomposition for  $\mathrm{Lie}(X_{\{0\}}/S_{\{0\}}) \otimes_{\{0\}} J$ , whence the relation

```

```text

$$H^0(Y_0, \mathrm{Lie}(X_0/S_0) \otimes J) \simeq \Gamma(S_0, \mathrm{Lie}(X_0/S_0)_0 \otimes_{\{0\}} J).$$

```

```

**Corollary 2.14.** *Suppose moreover  $S_{\{0\}}$  affine. Then*

*III.III.2.14*

```

```text

$$E \simeq \Gamma(S_0, [\mathrm{Lie}(X_0/S_0) / \mathrm{Lie}(X_0/S_0)^{\mathrm{ad}(Y_0)}] \otimes_{\{0\}} J).$$

```

```

### 3. Infinitesimal extensions of a group scheme

*III.III.3*

*original page 121*

Still in the notation of  $n^\circ 0$  ( $S$ ,  $I$ ,  $J$ , etc.), let us give ourselves an  $S$ -scheme  $X$  and suppose  $X_J$  endowed with a group structure. We propose to find the  $S$ -group structures on  $X$  inducing on  $X_J$  the given structure.

From now on, we assume  $X$  flat over  $S$ . Let  $\mathcal{C}$  be the category of  $S$ -schemes flat over  $S$ . We have therefore  $X \in \mathrm{Ob} \mathcal{C}$ . We shall denote by  $Y$ , resp.  $M$ , the functor on  $\mathcal{C}$  defined by  $X^+$ , resp.  $L'_X$ . The canonical morphism  $p_X : X \rightarrow X^+$  defines a morphism of  $\hat{\mathcal{C}}$

```

$$p : X \rightarrow Y$$

```

*original page 122*

and the action of  $L'_X$  on  $X$  in  $(\mathrm{Sch})/S$  defines an action of  $M$  on  $X$  in  $\hat{\mathcal{C}}$ . One verifies at once that  $X$  thus becomes formally principal homogeneous under  $M_Y$  above  $Y$  (cf. 0.2 (i) and 0.4).

The action of  $X^+$  on  $L'_X$  defined in 0.8 (denoted  $\mathrm{Ad}$  in loc. cit.) defines an action denoted  $f$  of  $Y$  on  $M$ . One knows, on the other hand (0.5), that

```

```text

$$\mathrm{Hom}_{\hat{\mathcal{C}}}(Z, M) \simeq \mathrm{Hom}_{\{S_0\}}(Z_0, L_0), \quad Z \in \mathrm{Ob} \mathcal{C},$$

```

```

where  $L_{\{0\}}$  is the functor defined in 0.5.

**Lemma 3.1.** (i) Condition  $(+)_n$  of 1.3 is satisfied for every positive integer  $n$ .

*III.III.3.1*

(ii) If one makes the  $S_{\{0\}}$ -group  $X_{\{0\}}$  act on the  $S_{\{0\}}$ -functor  $L_{\{0\}}$  through its adjoint representation, one has a canonical isomorphism

```

```text

$$H^*(X_0, L_0) \simeq H^*(Y, M),$$

```

```

(the first cohomology being computed in  $(\mathrm{Sch})/S_{\{0\}}$ , the second in  $\mathcal{C}$ ).

Both parts of the lemma follow from the relation:

```

```text
Hom_C(Y, M) = Hom_{(Sch)/S_0}(X^+ \times_S S_0, L_0)
            = Hom_{S_0}(X_0, L_0)
            = Hom_C(X, M),
...

```

which arises at once from the definition of M_S as a $\prod_{S_0/S} S_0$. This relation being more generally satisfied on replacing X_S, Y_S by $X_{\{n\}}, Y_{\{n\}}$, one deduces that every morphism $X_{\{n\}} \rightarrow M_S$ factors in a unique manner through $Y_{\{n\}}$, which entails $(+)_n$. One also deduces from it the relation $C^*(Y, M) = C^*(X_{\{0\}}, L_{\{0\}})$, which entails (ii).

We may therefore apply the constructions of 1.3. In particular:

Lemma 3.2. *Let $P : X \times_S X \rightarrow X_S$ be a morphism. In order for P_S to induce the group law of X_J , it is necessary and sufficient that P_S be an admissible composition law (cf. 1.3.2) on X_S .*

`<!-- label: III.III.3.2 -->`

Indeed, in order for P_S to induce the group law of X_J , it is necessary and sufficient that P_S lift the group law of $X^{(+)}_S$, or equivalently that of Y_S . It therefore only remains to show that every morphism P_S lifting the group law of X_J satisfies the identity $(++)$ of 1.3.2 (ii), and this is exactly what was seen in 0.8.

Proposition 3.3. *Let S_S be a scheme and $S_{\{0\}}$ a closed subscheme defined by a nilpotent ideal. Let X_S be a flat S_S -scheme, quasi-compact or locally of finite presentation over S_S . Let $P : X \times_S X \rightarrow X_S$ be a composition law on X_S . In order for P_S to be a group law, it is necessary and sufficient that the two following conditions be satisfied:*

`<!-- label: III.III.3.3 -->`

(i) P_S is associative.*

(ii) P_S induces on $X_{\{0\}} = X \times_{S_S} S_{\{0\}}$ a group law.*

These conditions are obviously necessary. Let us show that they are sufficient. Suppose first that $X \rightarrow S_S$ has a section. Since $X(S'_i)$ is then non-empty for each $S'_i \rightarrow S_S$, it suffices [N.D.E-III-65] to show that, for every $x \in X(S'_i)$, the left and right translations by x_S are isomorphisms of $X_{\{S'_i\}}$. [N.D.E-III-66]

`<!-- original page 123 -->`

One may evidently suppose $S'_i = S_S$; the translation in question t_S induces on $X_{\{0\}}$ a translation $t_{\{0\}}$ of $X_{\{0\}}$, which is therefore an automorphism since $X_{\{0\}}$ is a group. One concludes by flatness (SGA 1 III 4.2). [N.D.E-III-67]

No longer supposing now that X_S has a section over S_S , suppose that there exists an $S'_i \rightarrow S_S$ such that $X_{\{S'_i\}}$ has a section over S'_i . Then $X_{\{S'_i\}}$ is an S'_i -group according to what we have just seen; consider its unit section e'_i . The inverse image of e'_i by $\text{pr}_{\{i\}} : S' \times_S S' \rightarrow S'_i$ ($i = 1, 2$) is the unit section of $X_{\{S''\}}$ for the group law inverse image of $P_{\{S'_i\}}$ by $\text{pr}_{\{i\}}$. But since P_S is "defined over S_S ", these two group laws coincide, and therefore so do their unit sections. One has therefore $\text{pr}_{\{1\}}^*(e') = \text{pr}_{\{2\}}^*(e')$.

If $S'_i \rightarrow S_S$ is a descent morphism (cf. Exp. IV n° 2), there will exist a section of X_S giving e'_i by base extension, and we shall be done. Since X_J has a section over X_S (the diagonal section), one sees that it now suffices to prove that $X \rightarrow S_S$ is a descent morphism. Now it is flat and surjective, and quasi-compact or locally of finite presentation, hence covering for (fpqc), hence a descent morphism (Exp. IV, n° 6).

Remark. *In fact the hypothesis $X \rightarrow S_S$ quasi-compact or locally of finite presentation is superfluous, by virtue of the following result which the reader will prove as an exercise on Exposé IV:*

Under the conditions of the text on S_S and $S_{\{0\}}$, if $X \rightarrow S_S$ is a flat morphism and $X_{\{0\}} \rightarrow S_{\{0\}}$ a morphism covering for (fpqc), then $X \rightarrow S_S$ is a descent morphism.

`<!-- original page 124 -->`

Lemma 3.4. *In order for two admissible composition laws on X_S to be equivalent (cf. 1.3.5), it is necessary and sufficient that they be deduced from one another by an automorphism of X_S over S_S inducing the identity on X_J .*

<!-- label: III.III.3.4 -->

Indeed, the morphisms constructed in 1.3.1 are exactly those of the preceding statement (by 0.7).^[^N.D.E-III-68]

Taking all the preceding results into account, Proposition 1.3.6 gives:

Theorem 3.5. *Let S be a scheme, I and J two ideals on S such that $I \supset J$, $I \cdot J = 0$, $S_{\{0\}}$ and S_J the closed subschemes of S which they define. Let X be an S -scheme flat over S (and locally of finite presentation or quasi-compact over S), $X_{\{0\}}$ and X_J the schemes obtained by base change. Suppose X_J endowed with an S_J -group structure and denote by $L_{\{0\}}$ the $S_{\{0\}}$ -functor in commutative groups defined by the formula*

<!-- label: III.III.3.5 -->

```
```text
Hom_{S_0}(T, L_0) = Hom_{0_T}(\omega^1_{X_0/S_0} \otimes_{0_{\{S_0\}}} 0_T, J \otimes_{0_{\{S_0\}}} 0_T)
```

\*on which  $X_{\{0\}}$  acts through its adjoint representation.\*

(i) For there to exist an  $S$ -group structure on  $X$  inducing the given structure on  $X_J$ , it is necessary and sufficient that the following conditions be satisfied:\*

(i<sub>1</sub>) There exists a morphism of  $S$ -schemes  $X \times_S X \rightarrow X$  inducing the group law of  $X_J$ .\*

(i<sub>2</sub>) A certain obstruction class belonging to  $H^3(X_{\{0\}}, L_{\{0\}})$  (defined canonically by the data of  $X$  and the group law of  $X_J$ ) is zero.\*

(ii) If the conditions of (i) are satisfied, the set  $E$  of group laws on  $X$  inducing the given law of  $X_J$  is a principal homogeneous set under  $Z^2(X_{\{0\}}, L_{\{0\}})$ , and  $E$  modulo the  $S$ -automorphisms of  $X$  inducing the identity on  $X_J$ , is a principal homogeneous set under  $H^2(X_{\{0\}}, L_{\{0\}})$ .\*

<!-- original page 125 -->

<sup>[^N.D.E-III-69]</sup> Indeed, every morphism of  $S$ -schemes  $f : X \times_S X \rightarrow X$  inducing the group law of  $X_J$  is, by 3.2, an admissible composition law on  $X$ ; then, by 1.3.6 (i), the existence of an associative admissible composition law  $P : X \times_S X \rightarrow X$  is equivalent to the vanishing of a certain class  $c(f) \in H^3(X_{\{0\}}, L_{\{0\}})$ , and in this case, by 3.3,  $P$  is a group law. This proves (i), and (ii) then follows from 3.3 and 1.3.6 (ii).

**Remark 3.5.1.**<sup>[^N.D.E-III-70]</sup> \*If  $\mu, \mu'$  are group laws on  $X$  inducing the given law of  $X_J$ , one therefore obtains a cocycle  $\delta(\mu, \mu') \in Z^2(X_{\{0\}}, L_{\{0\}})$ , the sign convention chosen being that  $\mu' = \delta(\mu, \mu') \cdot \mu$ , that is, for every  $S' \rightarrow S$  and  $x, y \in X(S')$ ,\*

<!-- label: III.III.3.5.1 -->

```
```text
μ'(x, y) = δ(μ, μ')(x_0, y_0) · μ(x, y).
```

^[^N.D.E-III-71]

We shall denote by $\bar{\delta}(\mu, \mu')$ the image of $\delta(\mu, \mu')$ in $H^2(X_{\{0\}}, L_{\{0\}})$. Finally, if X endowed with the group law μ (resp. μ') is designated simply by X (resp. X'), one will write $\delta(X, X')$ instead of $\delta(\mu, \mu')$, and likewise for $\bar{\delta}(X, X')$.

Remark 3.6. *Let X_J be an S_J -scheme smooth over S_J and affine. By 0.15, there exists up to isomorphism a unique S -scheme X , smooth over S , reducing to X_J . If X_J is endowed with an S_J -group structure, it follows from 0.16 that condition (i₁) is automatically satisfied. Moreover, by 0.6 the definition of $L_{\{0\}}$ simplifies and one obtains:*

<!-- label: III.III.3.6 -->

Corollary 3.7. *Let S, I and J be as in 3.1. Let X_J be an S_J -group smooth over S_J and affine.*

<!-- label: III.III.3.7 -->

(i) The set of S -groups smooth over S and reducing to X_J , up to isomorphism (inducing the identity on X_J), is empty or principal homogeneous under the group

```text  
 $H^2(X_0, \text{Lie}(X_0/S_0) \otimes_{\{S_0\}} J)$ .  
 ```

(ii) There exists an S -group smooth over S reducing to X_J if and only if a certain obstruction in

```text  
 $H^3(X_0, \text{Lie}(X_0/S_0) \otimes_{\{S_0\}} J)$   
 ```

is zero.

One deduces as usual the following corollaries:

Corollary 3.8. *Let S be a scheme and S_0 a closed subscheme defined by a nilpotent ideal I . Let X_0 be an S_0 -group smooth over S and affine.*

<!-- label: III.III.3.8 -->

(i) If $H^2(X_0, \text{Lie}(X_0/S_0) \otimes_{\{S_0\}} I^{n+1}/I^{n+2}) = 0$ for every $n \geq 0$, two S -groups smooth over S reducing to X_0 are isomorphic (by an isomorphism inducing the identity on X_0).

<!-- original page 126 -->

(ii) If $H^3(X_0, \text{Lie}(X_0/S_0) \otimes_{\{S_0\}} I^{n+1}/I^{n+2}) = 0$ for every $n \geq 0$, there exists an S -group smooth over S , reducing to X_0 .

Corollary 3.9. *Let S be an affine scheme and S_0 a closed subscheme defined by a nilpotent ideal I . Suppose the I^{n+1}/I^{n+2} locally free on S_0 . Let X_0 be an S_0 -group smooth and affine over S_0 .*

<!-- label: III.III.3.9 -->

(i) If $H^2(X_0, \text{Lie}(X_0/S_0)) = 0$, two S -groups smooth over S reducing to X_0 are isomorphic.

(ii) If $H^3(X_0, \text{Lie}(X_0/S_0)) = 0$, there exists an S -group smooth over S reducing to X_0 .

Corollary 3.10. *Let S_0 be a scheme and $S = \text{IS}_0$ the scheme of dual numbers over S_0 . Let X_0 be an S_0 -group smooth over S_0 . In order for every S -group Y , smooth over S , such that Y_0 be S_0 -isomorphic to X_0 , to be S -isomorphic to $X = X_0 \times_{S_0} S$, it is necessary and sufficient that $H^2(X_0, \text{Lie}(X_0/S_0)) = 0$. [N.D.E-III-72]*

<!-- label: III.III.3.10 -->

Indeed, by virtue of 3.5 the set of classes, up to an S -group isomorphism "inducing the identity on X_0 ", of such groups Y , is in bijection with $H^2(X_0, \text{Lie}(X_0/S_0))$; hence the set of classes, up to an arbitrary S -group isomorphism, is in bijection with

$$H^2(X_0, \text{Lie}(X_0/S_0)) / \Gamma_{X_0},$$

where

$$\Gamma_{X_0} = \text{operatorname{Aut}}_{S_0\text{-gr.}}(X_0)$$

(which acts in the evident manner on the $H^2(X_0)$). The conclusion follows at once. [N.D.E-III-73]

4. Infinitesimal extensions of closed subgroups

<!-- label: III.III.4 -->

<!-- original page 127 -->

Let us first state a result valid in an arbitrary abelian category.

Lemma 4.1. *Let $0 \rightarrow A' \xrightarrow{i} A \xrightarrow{p} A'' \rightarrow 0$ be an exact sequence, $\phi : A' \rightarrow Q$ a morphism and $\pi : A'' \rightarrow P$ an epimorphism with kernel C . Let E be the set (up to isomorphism) of quadruples (B, f, g, h) such that the sequence*

<!-- label: III.III.4.1 -->

```

```text
0 → Q →f→ B →g→ P → 0
```

```

be exact and the diagram below commutative:

```

```text
0 → A' →i→ A →p→ A'' → 0
 | | |
 φ h π
 ↓ ↓ ↓
0 → Q →f→ B →g→ P → 0.
```

```

(i) For E to be non-empty, it is necessary and sufficient that the image in $\text{Ext}^1(C, Q)$ of the element A of $\text{Ext}^1(A'', A)$ be zero.*

(ii) Under these conditions, E is a principal homogeneous set under the abelian group $\text{Hom}(C, Q)$.*

Introduce the amalgamated sum $B' = A \sqcup_{A'} Q$. One then has a commutative diagram with exact rows:[^N.D.E-III-74]

```

```text
0 → A' →i→ A →p→ A'' → 0
 | | |
 φ j ||
0 → Q → B' → A'' → 0,
```

```

<!-- original page 128 -->

and it is clear that the category of solutions of the problem posed is canonically isomorphic to the category of solutions of the corresponding problem for the sequence

```

```text
0 → Q → B' → A'' → 0
```

```

and the morphisms id_Q and $\pi : A'' \rightarrow P$.[^N.D.E-III-75] In this case, the set E is in bijection with the set of subobjects N of B' such that $B' \rightarrow A''$ induces an isomorphism of N with the kernel C of $A'' \rightarrow P$, that is to say, the set of morphisms $e : C \rightarrow B'$ lifting the canonical morphism $C \rightarrow A''$. The abelian group $G = \text{Hom}(C, Q)$ acts on E by $g \cdot e = g + e$ (addition in $\text{Hom}(C, B')$), and if $E \neq \emptyset$ this makes E into a principal homogeneous set under G .

One deduces from this:

Proposition 4.2.[^N.D.E-III-76] *Let S be a scheme, S_J the closed subscheme defined by a quasi-coherent ideal J of square zero, X an S -scheme, F an $\mathcal{O}_X$ -module, $X_J = X \times_S S_J$, $F_J = F \otimes_{\mathcal{O}_X} \mathcal{O}_{X_J}$, and $G_J = F_J / H_J$ a quotient module of F_J . Suppose given a morphism of $\mathcal{O}_{X_J}$ -modules*

<!-- label: III.III.4.2 -->

```

```text
f : J \otimes_{\mathcal{O}_{S_J}} G_J \rightarrow Q.
```

```

<!-- label: III.III.4.3 -->

For every open U of X , let $\mathcal{E}(U)$ be the set of quasi-coherent $[\wedge^{\text{N.D.E-III-77}}]$ quotient modules $\mathcal{G}$ of $\mathcal{F}|_U$, flat over $\mathcal{S}$, and such that $\mathcal{G}/J\mathcal{G} \simeq G_{\{J\}}|_U$. Then the $\mathcal{E}(U)$ form a sheaf of sets $\mathcal{E}$ on X , which is formally principal homogeneous under the sheaf in commutative groups

```
```text
A = Hom_{O_{X_J}}(H_J, J \otimes_{O_{S_J}} G_J).
```

\*Proof.\* Denote by  $\pi : X \rightarrow S$  the structural morphism. Let  $U$  be an open of  $X$  and  $\mathcal{G}$  an  $\mathcal{O}_U$ -module flat over  $\mathcal{S}$  and such that  $\mathcal{G}/J\mathcal{G} \simeq G_{\{J\}}|_U$ . Then, for every  $x \in U$ ,  $\mathcal{G}_x$  is a flat module over the local ring  $\mathcal{O}_{S,s}$  (where  $s = \pi(x)$ ), and therefore the morphism

```
```text
J_s \otimes_{O_{S,s}} (G/JG)_x = J_s \otimes_{O_{S,s}} G_x \rightarrow (JG)_x
```

is bijective; one has therefore an exact sequence

```
```text
0 \rightarrow J \otimes_{O_S} (G_J|_U) \rightarrow G \rightarrow G_J|_U \rightarrow 0
```

<!-- original page 130 -->

and since  $J \otimes_{O_S} (G_J|_U)$  and  $G_J|_U$  are quasi-coherent  $\mathcal{O}_U$ -modules, so is  $\mathcal{G}$  (cf. EGA III, 1.4.17).

Conversely, since one has supposed  $G_J$  flat over  $S_J$ , if  $\mathcal{G}$  is a quasi-coherent  $\mathcal{O}_U$ -module such that  $\mathcal{G}/J\mathcal{G} \simeq G_{\{J\}}$  and such that the morphism  $J \otimes_{O_S} G_{\{J\}} \rightarrow JG_{\{J\}}$  is bijective, then  $\mathcal{G}$  is flat over  $\mathcal{S}$ , by the "fundamental criterion of flatness" (cf. SGA I IV, 5.5 [N.D.E-III-78]).

Consequently, the set  $\mathcal{E}(U)$  considered here coincides with the set considered in 4.2, taking for  $\mathcal{F}$  the identity morphism of  $J \otimes_{O_S} G_{\{J\}}$ , and the conclusion follows therefore from 4.2. QED.

[N.D.E-III-79] Let us preserve the preceding notation. Let  $Y_J$  be a closed subscheme of  $X_J$ , defined by a quasi-coherent ideal  $\mathcal{I}_{Y_J}$ . We assume  $Y_J$  flat over  $S_J$ . Then, applying 4.3 to  $\mathcal{F} = \mathcal{O}_{X_J}$  and  $G_{\{J\}} = \mathcal{O}_{Y_J} = \mathcal{O}_{X_J}/\mathcal{I}_{Y_J}$ , one obtains the following corollary.

**\*\*Corollary 4.3.1.\*\*** \*Let  $\mathcal{S}$ ,  $S_J$ ,  $J$ ,  $X$ ,  $X_J$ ,  $Y_J$  and  $\mathcal{I}_{Y_J}$  be as above; one assumes  $Y_J$  flat over  $S_J$ . Denote by  $\mathcal{A}_J$  the sheaf in commutative groups\*

<!-- label: III.III.4.3.1 -->

```
```text
Hom_{O_{X_J}}(\mathcal{I}_{Y_J}, J \otimes_{O_{S_J}} \mathcal{O}_{Y_J})
```

on X_J and $\mathcal{A} = i_{X_J^}(\mathcal{A}_J)$, where i_X is the immersion $X_J \hookrightarrow X$.*

For every open U of X , let $\mathcal{E}(U)$ be the set of closed subschemes Y of U , flat over $\mathcal{S}$, such that $Y \times_{\mathcal{S}} S_J = Y_J \cap U$. Then $\mathcal{E}$ is an $\mathcal{A}$ -pseudo-torsor.

If moreover a Y exists locally (that is, if every $x \in X$ has an open neighborhood U such that $\mathcal{E}(U) \neq \emptyset$), then $\mathcal{E}$ is an $\mathcal{A}$ -torsor. Now one knows (see for example EGA IV₄, 16.5.15) that the $\mathcal{A}$ -torsors on X are parametrized by the group $H^1(X, \mathcal{A}) = H^1(X_J, \mathcal{A}_J)$, and that $\mathcal{E}$ has a global section (i.e. $\mathcal{E}(X) \neq \emptyset$) if and only if the cohomology class corresponding to $\mathcal{E}$ is zero. One thus obtains:

****Corollary 4.4.**** *Let $\mathcal{S}$, S_J , J , X , X_J , Y_J and $\mathcal{I}_{Y_J}$ be as above; one assumes Y_J flat over S_J . Let $\mathcal{E}$ be the set of closed subschemes Y of X , flat over $\mathcal{S}$, such that $Y \times_{\mathcal{S}} S_J = Y_J$.*

<!-- label: III.III.4.4 -->

(i) The set E is empty or principal homogeneous under the abelian group

```
```text
H^0(X, A) = H^0(X_J, A_J) = Hom_{0_{X_J}}(I_{Y_J}, J \otimes_{0_{S_J}} 0_{Y_J}).
```
```

<!-- original page 131 -->

(ii) For E to be non-empty, it is necessary and sufficient that the two following conditions be satisfied:

(a) There exists locally on X a solution of the problem.

(b) A certain obstruction is zero, lying in

```
```text
H^1(X_J, Hom_{0_{X_J}}(I_{Y_J}, J \otimes_{0_{S_J}} 0_{Y_J})).
```
```

Complement 4.4.1. [N.D.E-III-80] *Let us keep the notation of 4.4 and suppose that E contains an element Y . Denote by I_Y the ideal of 0_X defining Y , and I_{Y_J} its image in 0_{X_J} . Then, as was seen in the proof of 4.2, one has a commutative diagram*

<!-- label: III.III.4.4.1 -->

```
```text
J \otimes_{0_{S_J}} 0_{X_J} \longrightarrow J0_X
\downarrow \qquad \qquad \downarrow
J \otimes_{0_{S_J}} 0_{Y_J} \longrightarrow J0_Y
```
```

hence an epimorphism of 0_X -modules $\phi : J0_X \rightarrow J \otimes_{0_{S_J}} 0_{Y_J}$; denote by K its kernel. Then, for every element Y of E , the morphism $0_X \rightarrow 0_{Y'}$ factors through $0_X/K$ (which is the amalgamated sum B of the proof of Lemma 4.1) and, denoting by $I_{Y'}$ the ideal of Y in 0_X , one has a commutative diagram:

```
```text
 0 0
 \downarrow \downarrow
 I_{Y'}/K \longrightarrow I_{Y_J}
 \downarrow \downarrow
0 \longrightarrow (J0_X)/K \longrightarrow 0_X/K \longrightarrow 0_{X_J} \longrightarrow 0
 \downarrow \downarrow \downarrow \downarrow
0 \longrightarrow J \otimes_{0_{S_J}} 0_{Y_J} \longrightarrow 0_{Y'} \longrightarrow 0_{Y_J} \longrightarrow 0
 \downarrow \downarrow
 0 0.
```
```

Therefore, replacing X by the closed subscheme defined by K , one reduces to $K = 0$. Then, the datum of Y is equivalent to that of the sub- 0_X -module $I_{Y'}$ of 0_X , sending bijectively onto I_{Y_J} by the projection $p : 0_X \rightarrow 0_{X_J}$; denote by $f' : I_{Y_J} \rightarrow I_{Y'}$ (resp. $f : I_{Y_J} \rightarrow I_Y$) the inverse isomorphism. Then $f' - f$ is an element of

```
```text
Hom_{0_{X_J}}(I_{Y_J}, J \otimes_{0_{S_J}} 0_{Y_J}) = Hom_{0_{X_J}}(I_{Y_J}, J0_Y)
```
```

which we shall denote $d(Y', Y)$. (Note that $d(Y, Y') = -d(Y', Y)$.)

<!-- original page 132 -->

For our fixed Y and variable Y' , consider the morphism:

```

```text

$$I_{Y'} \rightarrow 0_X \rightarrow 0_Y = 0_X/I_Y;$$

```

since the composition with  $0_{Y'} \rightarrow 0_{Y_J}$  is zero, one knows that it takes values in  $J \otimes_{0_{S_J}} 0_{Y_J}$ . More precisely, if  $V$  is an open of  $X$ ,  $x'$  a section of  $I_{Y'}$  on  $V$  and  $x_J$  its image in  $\Gamma(V, I_{Y_J})$ , then

```

```text

$$x' = f'(x_J) = f(x_J) + (f' - f)(x_J) = f(x_J) + d(Y', Y)(x_J).$$

```

Consequently: the morphism $I_{Y'} \rightarrow J \otimes_{0_{S_J}} 0_{Y_J}$ is given by $d(Y', Y)$.

4.5.0. [N.D.E-III-81] Let us keep the notation of 4.3.1 and 4.4 and carry out a certain number of transformations: $I_{Y_J}/I_{Y_J}^2$ is a quasi-coherent 0_{X_J} -module annihilated by I_{Y_J} , hence is the direct image of a quasi-coherent 0_{Y_J} -module denoted N_{Y_J/X_J} , called the *conormal sheaf* to Y_J in X_J . [N.D.E-III-82] Since $J \otimes_{0_{S_J}} 0_{Y_J}$ is annihilated by I_{Y_J} , the sheaf in commutative groups A_J of 4.3.1 identifies with:

```

```text

$$\text{Hom}_{0_{Y_J}}(I_{Y_J}/I_{Y_J}^2, J \otimes_{0_{S_J}} 0_{Y_J}) = \text{Hom}_{0_{Y_J}}(N_{Y_J/X_J}, J \otimes_{0_{S_J}} 0_{Y_J}),$$

```

whence, for every  $i \geq 0$ :

```

```text

$$H^i(X_J, A_J) = H^i(Y_J, \text{Hom}_{0_{Y_J}}(N_{Y_J/X_J}, J \otimes_{0_{S_J}} 0_{Y_J})).$$

```

[N.D.E-III-83] One can then suppress the hypothesis " Y closed", as follows. Let us first note that every open U_J of X_J comes by base change from the open subscheme U of X having the same underlying topological space as U_J . Let now Y_J be a closed subscheme of U_J , flat over S_J , and I_{Y_J} the quasi-coherent ideal of 0_{U_J} defining Y_J . If Y_J lifts to a subscheme Y of X , then Y , having the same underlying topological space as Y_J , is a closed subscheme of U ; consequently, the obstruction to lifting Y_J to a subscheme, flat over S , of X or of U is "the same", it resides in

```

```text

$$H^1(Y_J, \text{Hom}_{0_{Y_J}}(N_{Y_J/X_J}, J \otimes_{0_{S_J}} 0_{Y_J})).$$

```

Finally, let us return to the notation of  $n^\circ 0$ : let  $I$  be a quasi-coherent ideal of  $0_S$  such that  $J \subset I$  and  $IJ = 0$ , and let  $S_\emptyset$  be the closed subscheme of  $S_J$  defined by  $I$ . For every  $S$ -scheme  $Z$ , one denotes  $Z_J = Z \times_S S_J$  and  $Z_\emptyset = Z \times_S S_\emptyset$ . Then, since  $J$  is annihilated by  $I$ , one has, with the notation of 4.4:

```

```text

$$J \otimes_{0_{S_J}} 0_{Y_J} = J \otimes_{0_{S_\emptyset}} 0_{Y_\emptyset}$$

$$\text{Hom}_{0_{Y_J}}(N_{Y_J/X_J}, J \otimes_{0_{S_J}} 0_{Y_J}) = \text{Hom}_{0_{Y_\emptyset}}(N_{Y_J/X_J} \otimes_{0_{Y_J}} 0_{Y_\emptyset}, J \otimes_{0_{S_\emptyset}} 0_{Y_\emptyset}),$$

```

etc. One thus obtains:

<!-- original page 133 -->

Proposition 4.5. *Let S be a scheme, $S_\emptyset$ and S_J the closed subschemes defined by the quasi-coherent ideals I and J , such that $I \supset J$ and $I \cdot J = 0$. **Definition 4.6.1.** \*(cf. SGA 6, VII 1.1) Let  $B_\$$  be a commutative ring,  $f : E \rightarrow B_\$$  a  $B_\$$ -linear morphism, where  $E_\$$  is a free  $B_\$$ -module of finite rank  $d_\$$ , and  $I_\$$  the ideal  $f(E)_\$$  (if one chooses a basis of  $E_\$, f_\$$  is given by a  $d_\$$ -tuple  $(f_1, \dots, f_d)$  of elements of  $B_\$, and  $I_\$$  is the ideal generated by the  $f_i$ ). The **Koszul complex**  $K_\bullet(f)_\$$  is the graded  $B_\$$ -module  $\bigwedge^\bullet E_\$, equipped with the differential (of degree  $-1$ ):*$$

```
<!-- label: III.III.4.6.1 -->
```

```
```text
x_1 ∧ ⋯ ∧ x_i ↦ ∑_{j=1}^i (-1)^{j-1} f(x_j) x_1 ∧ ⋯ ∧ x^{j-1} ∧ ⋯ ∧ x_i.
```
```

```
<!-- original page 134 -->
```

One has therefore an augmented chain complex ( $B/I_\$$  being in degree  $-1$ ):

```
```text
⋯ → Ⓚ² E → E → B → B/I → 0
```
```

which by definition is exact in degree  $0$ , since  $I = f(E)$ . One says that  $f_\$$  is **regular** if  $K_\bullet(f)_\$$  is acyclic in degrees  $> 0$ , that is, if the augmented complex above is a resolution of  $C = B/I_\$$ .

In this case, the proof of SGA 6, VII 1.2 b) shows that the  $C_\$$ -modules  $I^{n+1}/I^n$  ( $n \in \mathbb{N}$ ) are free,  $I/I^2$  being of rank  $d_\$$ .

**Definition 4.6.2.** \*(cf. SGA 6, VII 1.4) Let  $X_\$$  be a scheme,  $Y_\$$  a subscheme,  $U_\$$  an open of  $X_\$$  such that  $Y_\$$  is a closed subscheme of  $U_\$, defined by the quasi-coherent ideal  $I_{Y'}$ .*$

```
<!-- label: III.III.4.6.2 -->
```

\*One says that  $Y$  is **locally complete intersection** in  $X$  if  $Y \hookrightarrow X$  is a regular immersion in the sense of SGA 6, VII 1.4, that is, if for every  $y \in Y$  there exists an affine open neighborhood  $V$  of  $y$  in  $U$ , a finite free  $\mathcal{O}_V$ -module  $\mathcal{E}$ , and a regular morphism  $f : E \rightarrow \mathcal{O}_V$  of image  $I_Y|_V$ , i.e. such that  $\bullet(f)$  be a resolution of  $\mathcal{O}_Y \cap V$ .\*

This implies that the immersion  $Y \hookrightarrow X$  is locally of finite presentation, and, by 4.6.1, that the conormal sheaf  $\mathcal{N}_{Y/X} = I_Y/I_Y^2$  is a finite locally free  $\mathcal{O}_Y$ -module.

**Lemma 4.6.3.** [N.D.E-III-88] Let  $A$  be a ring,  $J$  an ideal of  $A$  of square zero,  $\bar{A} = A/J$ ,  $B$  a flat  $A$ -algebra,  $E$  a free  $B$ -module of finite rank,  $f : E \rightarrow B$  a morphism of  $B$ -modules. One supposes that the morphism  $g : \bar{E} = E \otimes_A \bar{A} \rightarrow \bar{B} = B \otimes_A \bar{A}$  induced by  $f$  is regular and that  $\bar{B}/\bar{g}(\bar{E})$  is flat over  $\bar{A}$ .\*

<!-- label: III.III.4.6.3 -->

Then  $f$  is regular and  $B/f(E)$  is flat over  $A$ .\*

**Proof.** Set  $C = B/f(E)$  and  $\bar{C} = C \otimes_A \bar{A} = \bar{B}/\bar{g}(\bar{E})$ . First, the  $\bigwedge^i_B(E)$  are free  $B$ -modules, hence flat  $A$ -modules, since  $B$  is flat over  $A$ . As  $\bigwedge_{\bullet} B \otimes_A \bar{A} \simeq \bigwedge_{\bullet} \bar{B}$ , one obtains therefore an exact sequence of complexes:

```

$$0 \rightarrow J \otimes_A \bullet_B E \rightarrow \bullet_B E \rightarrow \bullet_B \bar{E} \rightarrow 0.$$

```

Moreover, since  $J^2 = 0$ , one has  $J \otimes_A M = J \otimes_A \bar{A} \otimes_A M$  for every  $A$ -module  $M$ . Denoting by dashed arrows the augmentation morphisms, and by  $d$  the rank of  $E$ , one therefore obtains the bicomplex that follows, where the rows are exact:

<!-- original page 135 -->

```

$$\begin{array}{ccccccc}
 & & \begin{array}{c} \downarrow \theta \\ 0 \end{array} & & \begin{array}{c} \downarrow \theta \\ 0 \end{array} & & \begin{array}{c} \downarrow \theta \\ 0 \end{array} \\
 0 \rightarrow & J \otimes_A \bullet_B \bar{E} & \xrightarrow{\quad} & \bullet_B E & \xrightarrow{\quad} & \bullet_B \bar{E} & \xrightarrow{\quad} 0 \\
 & \downarrow \square & & \downarrow \square & & \downarrow \square & \\
 0 \rightarrow & J \otimes_A \bar{E} & \xrightarrow{\quad} & E & \xrightarrow{\quad} & \bar{E} & \xrightarrow{\quad} 0 \\
 & \downarrow \text{Id} \otimes g & & \downarrow f & & \downarrow \bar{g} & \\
 0 \rightarrow & J \otimes_A B^- & \xrightarrow{\quad} & B & \xrightarrow{\quad} & B^- & \xrightarrow{\quad} 0 \\
 & \downarrow \square & & \downarrow \square & & \downarrow \square & \\
 & J \otimes_A C^- & \xrightarrow{\quad} & C & \xrightarrow{\quad} & C^- & \xrightarrow{\quad} 0 \\
 & \downarrow \theta & & \downarrow \theta & & \downarrow \theta & \\
 & 0 & & 0 & & 0 &
 \end{array}$$

```

Moreover, the right and left columns are exact, since  $\bullet(g)$  is a resolution of  $\bar{C}$  and the latter is flat over  $\bar{A}$ . Hence, considering the long exact homology sequence associated with the exact sequence of unaugmented complexes, one obtains that  $\bullet(f)$  is acyclic in degrees  $> 0$ , and that one has in degree  $0$  an exact sequence:

```

$$0 \rightarrow J \otimes_A C^- \rightarrow C \rightarrow C^- \rightarrow 0.$$

```

Hence  $C$  is flat over  $A$ , by the "fundamental criterion of flatness" (cf. [BAC], § III.5, th. 1).

**Lemma 4.6.4.** [N.D.E-III-88] Let  $A$  be a commutative ring,  $J$  a nilpotent ideal,  $N \subset M$  two  $A$ -modules such that  $M/N$  is flat over  $A$ . If  $x_1, \dots, x_n$  are elements of  $N$  whose images generate the image  $\bar{N}$  of  $N$  in  $M/JM$ , then they generate  $N$ .\*

<!-- label: III.III.4.6.4 -->

Indeed, denote by  $N'$  the submodule of  $N$  generated by the  $x_i$ , and  $Q = N/N'$ . Then the morphism  $N' \otimes (A/J) \rightarrow \bar{N}$  is surjective. On the other hand, since  $M/N$  is flat over  $A$ , the morphism  $N \otimes (A/J) \rightarrow \bar{N}$  is bijective. One thus obtains that  $Q \otimes (A/J) = 0$ , whence  $Q = 0$  by the "nilpotent Nakayama lemma" (one has  $Q = JQ = J^2Q = \cdots = 0$ ).

One can now prove:

**Proposition 4.6.5** [N.D.E-III-88] Let  $S, I, J$  and  $X, Y_J$  be as in 4.5. Suppose moreover  $X$  flat over  $S$  and  $Y_J$  locally complete intersection in  $X_J$ .

!-- label: III.III.4.6.5 -->

!-- original page 136 -->

a) Then condition (a) of 4.5 (i) is satisfied; moreover, every  $Y$  flat over  $S$  lifting  $Y_J$  is locally complete intersection in  $X$ .

b) If moreover  $Y_0$  is affine, condition (b) of loc. cit. is likewise satisfied.

**Proof.** The first assertion of (a) follows from Lemma 4.6.3; the second then results from Lemma 4.6.4. On the other hand, the hypothesis entails (cf. 4.6.2) that  $N_{Y_J/X_J}$  is a finite locally free  $O_{Y_J}$ -module, hence the  $O_{Y_0}$ -module

$$N_0 = \text{Hom}_{O_{Y_0}}(N_{Y_J/X_J} \otimes_{O_{Y_J}} O_{Y_0}, J \otimes_{O_{S_0}} O_{Y_0}).$$

is quasi-coherent (cf. EGA I, 1.3.12), whence  $R^1\Gamma(Y_0, N_0) = 0$  if  $Y_0$  is affine.

**Remark 4.6.6** [N.D.E-III-88] Let us conclude this paragraph by the following example, which shows that, under the hypotheses of Lemma 4.6.3, if  $(\bar{g}_1, \bar{g}_2)$  is a regular sequence generating the ideal  $\bar{I} = \bar{g}(\bar{E})$ , it does not necessarily lift to a regular sequence in  $B$ .

!-- label: III.III.4.6.6 -->

Let  $k$  be a field,  $\bar{A} = k[X, Y]$ , denote by  $k[\epsilon]$  the  $\bar{A}$ -module  $\bar{A}/(X, Y)$  (i.e.  $P \cdot \epsilon = P(0, 0)$  for every  $P \in \bar{A}$ ), and let  $A = \bar{A} \oplus k[\epsilon]$ , where  $J = k[\epsilon]$  is an ideal of square zero. One has  $A/J = \bar{A}$ .

The algebra  $B = A \otimes_k k[Z, T]$  is free over  $A$ , hence flat; one has  $\bar{B} = k[X, Y, Z, T]$ . Set  $\bar{g}_1 = XZ - YT$  and  $\bar{g}_2 = XZ - 1$ . Since the polynomial  $\bar{g}_1$  is irreducible,  $\bar{B}/(\bar{g}_1)$  is integral, and therefore  $(\bar{g}_1, \bar{g}_2)$  is a regular sequence in  $\bar{B}$ , generating the ideal  $\bar{I} = (XZ - 1, YT - 1)$ . Hence

$$C = \bar{B}/\bar{I} = k[X, Y, X^{-1}, Y^{-1}] = \bar{A}[X^{-1}, Y^{-1}]$$

is a flat  $\bar{A}$ -algebra (and also a flat  $A$ -algebra). But every lift in  $B$  of  $\bar{g}_1$  is of the form  $XY - ZT + \lambda \epsilon$ , where  $\lambda \in k[Z, T]$ , hence annihilates  $\epsilon$ .

**4.7.** One has suppressed here Remark 4.7, placed in 4.5.1.

**Remark 4.8.0** [N.D.E-III-89] Let  $S$  be a scheme,  $S'$  a closed subscheme,  $X$  an  $S$ -scheme,  $Y$  a sub- $S$ -scheme of  $X$ , and  $X' = X \times_S S'$ ,  $Y' = Y \times_S S'$ . Then, one has a surjective morphism of  $O_{Y'}$ -modules

!-- label: III.III.4.8.0 -->

$$N_{Y/X} \otimes_{O_Y} O_{Y'} \rightarrow N_{Y'/X'}.$$

Indeed, up to replacing  $X$  by a certain open, one may suppose that  $Y$  is closed, defined by an ideal  $I_Y$  of  $O_X$ ; then the image of  $I_Y$  in  $O_{X'}$  is the ideal  $I_{Y'}$  defining  $Y'$ , and one has a surjective morphism of  $O_{Y'}$ -modules

```

```text
 $\pi : (I_Y/I_{Y^2}) \otimes_{O_Y} O_{Y'} \twoheadrightarrow I_{Y'}/I_{Y'}^2.$ 
```

```

Suppose moreover that  $O_Y = O_X/I_Y$  is flat over  $S$ ; then the natural morphism

```

```text
 $I_Y \otimes_{O_X} O_{X'} \rightarrow I_{Y'}$ 
```

```

<!-- original page 137 -->

is bijective (cf. EGA IV<sub>2</sub>, 2.1.8). One then has the following commutative diagram with exact rows:

```

```text

$$\begin{array}{ccccccc}
 I_{Y^2} \otimes_{O_X} O_{X'} & \rightarrow & I_Y \otimes_{O_X} O_{X'} & \rightarrow & (I_Y/I_{Y^2}) \otimes_{O_Y} O_{Y'} & \rightarrow & 0 \\
 \downarrow \text{surj.} & & \downarrow \square & & \downarrow \pi \text{ surj.} & & \\
 0 & \rightarrow & I_{Y'}^2 & \rightarrow & I_{Y'} & \rightarrow & I_{Y'}/I_{Y'}^2 \rightarrow 0
 \end{array}$$

```

```

whence one deduces, by the snake lemma: [N.D.E-III-90]

```

```text
 $N_{Y/X} \otimes_{O_Y} O_{Y'} \simeq N_{Y'/X'} \quad \text{if } Y \text{ is flat over } S. \quad (4.8.0)$ 
```

```

**Proposition 4.8.** \*Let  $S, S_0, S_J$  and  $I, J$  be as in 4.5. [N.D.E-III-91] Let  $X$  be an  $S$ -scheme,  $Y$  a subscheme of  $X$ , and  $i$  the immersion  $Y \hookrightarrow X$ .\*

<!-- label: III.III.4.8 -->

**(i)** For every  $S$ -morphism  $f : T \rightarrow X$  such that  $f_J : T_J \rightarrow X_J$  factors through  $Y_J$ , one can define an obstruction\*

```

```text
(*)  $c(X, Y, f) \in \text{Hom}_{O_{T_0}}(f_0^*(N_{Y/X} \otimes_{O_Y} O_{Y_0}), J_{0,T})$ 
```

```

\*whose vanishing is equivalent to the existence of a factorization of  $f$  through  $Y$ .\*

**(ii)** Let  $Y'$  be a second subscheme of  $X$ . Suppose that  $Y_J' = Y_J$  and that  $Y, Y'$  are flat over  $S$ . One then has isomorphisms (cf. 4.8.0):\*

```

```text
 $J_{0,Y} \simeq J \otimes_{O_{S_0}} O_{Y_0} \simeq J_{0,Y'} \quad \text{and} \quad N_{Y/X} \otimes_{O_Y} O_{Y_J} \simeq N_{Y_J/X_J}$ 
```

```

\*whence an isomorphism:\*

```

```text
 $u : \text{Hom}_{O_{Y_0}}(N_{Y_J/X_J} \otimes_{O_{Y_J}} O_{Y_0}, J_{0,Y}) \simeq \text{Hom}_{O_{Y_0}}(N_{Y/X} \otimes_{O_Y} O_{Y_0}, J_{0,Y'}).$ 
```

```

\*Denoting by  $i' : Y' \rightarrow X$  the canonical immersion and  $d(Y, Y')$  the deviation of 4.5.1, one has: [N.D.E-III-92]\*

```

```text
(**)  $c(X, Y, i') = u(d(Y, Y'))$ .
```

```

**(iii)** The canonical morphism  $N_{Y/X} \xrightarrow{D} i^*(\Omega^1_{X/S})$  (cf. SGA 1 II, formula 4.3) [N.D.E-III-93] induces a morphism:\*

```

```text
```

```

$D_0 : N_{\{Y/X\}} \otimes_{\{0_Y\}} 0_{\{Y_0\}} \rightarrow \Omega^1_{\{X_0/S_0\}} \otimes_{\{0_{\{X_0\}}\}} 0_{\{Y_0\}}$

<!-- original page 138 -->

\*and hence, for every  $S$ -morphism  $f : T \rightarrow X$  as in (i), a morphism:

```text  
 $v_{\{f_0\}} : \text{Hom}_{\{0_{\{T_0\}}\}}(f_0^*(\Omega^1_{\{X_0/S_0\}}), J0_T) \rightarrow \text{Hom}_{\{0_{\{T_0\}}\}}(f_0^*(N_{\{Y/X\}} \otimes_{\{0_Y\}} 0_{\{Y_0\}}), J0_T),$
 $a \mapsto a \circ f_0^*(D_0)$
 ```

\*where above the first group is  $\text{Hom}_{X^+}(T, L_X)$ , cf. 0.1.5. For  $a \in \text{Hom}_{X^+}(T, L_X)$ , one has:

```text  
 (***) $c(X, Y, a \cdot f) - c(X, Y, f) = v_{\{f_0\}}(a),$
 ```

\*where  $a \cdot f$  denotes the composite morphism  $T \xrightarrow{a \times f} L_X \times_{X^+} X \rightarrow X$ .

We shall prove part (i) of the proposition, leaving the reader to (not) verify assertions (ii) and (iii); this verification is done by reduction to the affine case, then by comparison of explicit definitions. [N.D.E-III-94]

Let us therefore prove (i). The morphism  $f : T \rightarrow X$  defines a morphism of sheaves of rings  $\phi : 0_X \rightarrow f_*(0_T)$ . [N.D.E-III-95] Let  $U$  be an open subscheme of  $X$  in which  $Y$  is closed; since  $T$  (resp.  $Y_J$ ) has the same underlying space as  $T_J$  (resp.  $Y$ ), the continuous map underlying  $f$  sends  $T$  into  $U$ , and since  $U$  is an open of  $X$ ,  $\phi$  induces a morphism of sheaves of rings  $0_U = 0_X|_U \rightarrow f_*(0_T)$ , i.e.  $f$  factors through  $U$ .

Therefore, one may restrict to the case where  $Y$  is closed, hence defined by a sheaf of ideals  $I_Y$ . For  $f$  to factor through  $Y$ , it is necessary and sufficient that the composite map  $I_Y \rightarrow 0_X \rightarrow f_*(0_T)$  be zero. Since  $f_J$  factors through  $Y_J$ , the composite map  $I_{Y_J} \rightarrow 0_{X_J} \rightarrow f_J^*(0_{T_J})$  is zero. Considering the commutative diagram, where the first row is exact:

```text  
 $0 \rightarrow f_*(J0_T) \rightarrow f_*(0_T) \rightarrow f_*(0_{T_J})$
 $\quad \quad \quad \nwarrow \quad \quad \quad \uparrow \quad \quad \quad \uparrow$
 $\quad \quad \quad \nwarrow \quad \quad \quad \phi \quad \quad \quad \phi_J$
 $\quad \quad \quad \nwarrow \quad \quad \quad \downarrow \quad \quad \quad \downarrow$
 $\quad \quad \quad \nwarrow \quad \quad \quad 0_X \rightarrow 0_{X_J}$
 $\quad \quad \quad \nwarrow \quad \quad \quad \uparrow \quad \quad \quad \uparrow$
 $\quad \quad \quad \nwarrow \quad \quad \quad I_Y \rightarrow I_{Y_J}$
 ```

<!-- original page 139 -->

one deduces that  $\phi$  sends  $I_Y$  into  $f_*(J0_T)$ . [N.D.E-III-96] Since  $J^2 = 0$ , it follows that  $f_*(J0_T)$ , viewed as  $0_X$ -module via  $\phi$ , is annihilated by  $I_Y$ ; consequently,  $\phi$  induces a morphism of  $0_X$ -modules

```text  
 $h : i_*(N_{\{Y/X\}}) = I_Y/I_Y^2 \rightarrow f_*(J0_T).$
 ```

On the other hand, one has cartesian squares:

```text  
 $T_0 \xrightarrow{f_0} X_0 \xleftarrow{i_0} Y_0$
 $\downarrow \tau_{\{T_0\}} \quad \downarrow \tau_{\{X_0\}} \quad \downarrow \tau_{\{Y_0\}}$
 $T \xrightarrow{f} X \xleftarrow{i} Y.$
 ```

where  $i_{T_0}$  etc. are the closed immersions deduced by base change from  $S_{\{0\}} \rightarrow S$ . Since  $J0_T$  is a

quasi-coherent  $\mathcal{O}_T$ -module annihilated by  $\mathcal{I}$ , one has an isomorphism

$$\mathcal{O}_T \simeq (\tau_{T_0})_* \tau_{T_0}^* (\mathcal{O}_T),$$

whence  $f_*(\mathcal{O}_T) \simeq (\tau_{X_0})_*(f_{T_0})_* \tau_{T_0}^* (\mathcal{O}_T)$ . Therefore  $h$  corresponds, by adjunction, to a morphism of  $\mathcal{O}_{T_0}$ -modules

$$h_0 : f_{0*} \tau_{X_0}^* \mathcal{I} \rightarrow \tau_{T_0}^* (\mathcal{O}_T).$$

Now,  $\tau_{X_0}^* \mathcal{I} \simeq \tau_{X_0}^* (\mathcal{O}_T) \simeq (\tau_{X_0})_*(\tau_{X_0})^* (\tau_{X_0})^* (\mathcal{O}_T) = \mathcal{O}_{Y/X} \otimes_{\mathcal{O}_Y} \mathcal{O}_{Y_0}$ . Hence, returning to the abuse of notation  $\tau_{T_0}^* (\mathcal{O}_T) = \mathcal{O}_T$  constantly used,  $h_0$  identifies with a morphism of  $\mathcal{O}_{T_0}$ -modules

$$h_0 : f_{0*} (\mathcal{O}_{Y/X} \otimes_{\mathcal{O}_Y} \mathcal{O}_{Y_0}) \rightarrow \mathcal{O}_T$$

which is the obstruction  $c(X, Y, f)$  sought. This proves (i).

When  $f$  is the immersion  $i' : Y' \hookrightarrow X$ , one sees that  $c(X, Y, i')$  comes from the morphism  $\mathcal{I}_Y \hookrightarrow \mathcal{O}_X \rightarrow \mathcal{O}_{Y'}$  hence corresponds, by 4.4.1 and 4.5.1, to the class  $d(Y, Y')$ . This proves (ii).

Let us prove (iii). First,  $D : \mathcal{O}_{Y/X} \rightarrow \tau_{X_0}^* (\Omega_{X/S}^1)$  induces a morphism

$$D_0 : \tau_{Y_0}^* (\mathcal{O}_{Y/X}) \rightarrow \tau_{Y_0}^* \mathcal{I} \rightarrow \tau_{Y_0}^* (\Omega_{X/S}^1) = \mathcal{I}_0 \tau_{X_0}^* (\Omega_{X/S}^1)$$

and, since  $\mathcal{O}_X = X \times_S S$ , one has  $\tau_{X_0}^* (\Omega_{X/S}^1) \simeq \Omega_{X_0/S_0}^1$  (cf. EGA IV<sub>4</sub>, 16.4.5). One thus obtains the announced morphism

$$D_0 : \mathcal{O}_{Y/X} \otimes_{\mathcal{O}_Y} \mathcal{O}_{Y_0} \rightarrow \Omega_{X_0/S_0}^1 \otimes_{\mathcal{O}_{X_0}} \mathcal{O}_{Y_0}.$$

Finally, we shall verify equality  $c(X, Y, f)$  after the remark below.

**Remark 4.9.** The obstruction  $c(X, Y, f)$  is computed locally on  $T$ . Let  $U = \operatorname{Spec}(C)$  be an affine open of  $T$  above an affine open  $\operatorname{Spec}(A)$  of  $X$ , itself above an affine open  $\operatorname{Spec}(\Lambda)$  of  $S$ ; let  $J \subset I \subset \Lambda$  (resp.  $\mathcal{I}_Y \subset \mathcal{A}$ ) be the ideals corresponding to  $J \subset I$  (resp. to  $\mathcal{I}_Y$ ), let  $B = A/I$  and let  $\phi : A \rightarrow C$  be the morphism of  $\Lambda$ -algebras corresponding to  $f : T \rightarrow X$ ; since  $f(T_J) \subset Y_J$  one has  $\phi(\mathcal{I}_Y) \subset \mathcal{I}_C$  and therefore  $\phi$  induces a morphism of  $\Lambda$ -algebras  $B \rightarrow C/JC \rightarrow C_0 = C/IC$ . Then the obstruction  $c = c(X, Y, f)$  is computed by the following commutative diagram:

<!-- label: III.III.4.9 -->

$$\begin{array}{ccccc} \mathcal{I}_Y & \longrightarrow & A & \xrightarrow{\phi} & C \\ & & & & \uparrow c \\ \mathcal{I}_Y/\mathcal{I}_Y^2 & \longrightarrow & \mathcal{I}_Y/\mathcal{I}_Y^2 \otimes_B C_0 & \longrightarrow & JC, \end{array}$$

<!-- original page 140 -->

that is, it is defined, above the open  $U$ , as the unique element of

$$\operatorname{Hom}_{C_0}(\mathcal{I}_Y/\mathcal{I}_Y^2 \otimes_B C_0, JC) = \operatorname{Hom}_{B_0}(\mathcal{I}_Y/\mathcal{I}_Y^2 \otimes_B B_0, JC)$$

...

\*such that, with the evident notation, one has  $c(x \otimes_{\mathcal{B}} 1) = \phi(x)$ , for every  $x \in I_Y$ .\*

[^N.D.E-III-97] One can now complete the proof of 4.8 (iii). The equality  $(\ast\ast\ast)$  is verified locally on  $T$ , so one is reduced to the affine situation described above. Let us denote by  $d_{A/\Lambda}$  the differential  $A \rightarrow \Omega^1_{A/\Lambda}$ . Then  $a$  corresponds, above  $U$ , to an element  $a_U$  of

text  
 $\text{Hom}_{\mathcal{C}_0}(\Omega^1_{A_0/\Lambda_0} \otimes_{A_0} \mathcal{C}_0, \mathcal{J}\mathcal{C}) \simeq \text{Hom}_{\mathcal{B}_0}(\Omega^1_{A/\Lambda} \otimes_A \mathcal{B}_0, \mathcal{J}\mathcal{C}) \simeq \text{Hom}_A(\Omega^1_{A/\Lambda}, \mathcal{J}\mathcal{C}).$

Then, on the one hand,  $v_{f_0}(a)$  corresponds above  $U$  to the element  $a_U \circ \bar{D}_U$ , where  $\bar{D}_U$  is the morphism of  $\mathcal{B}_U$ -modules[^N.D.E-III-98]

text  
 $I_Y/I_{Y^2} \rightarrow \Omega^1_{A/\Lambda} \otimes_A \mathcal{B}_0, \quad x + I_{Y^2} \mapsto d_{A/\Lambda}(x) \otimes 1.$

On the other hand (cf. the proofs of 0.1.8 and 0.1.9), the morphism of  $\Lambda$ -algebras  $\phi' : A \rightarrow C$  corresponding to  $a \cdot f$  differs from  $\phi$  by the  $\Lambda$ -derivation  $A \rightarrow \mathcal{J}\mathcal{C}$  associated with  $a_U$ , i.e. one has:

text  
 $\phi' = \phi + a_U \circ d_{A/\Lambda} = \phi + a_U \circ (d_{A/\Lambda} \otimes 1).$

Consequently, denoting  $c' = c(X, Y, a \cdot f)$ , one has for every  $x \in I_Y$ , denoting by  $\bar{x}$  its image in  $I_Y/I_{Y^2}$ :

text  
 $(c' - c)(x \otimes 1) = a_U(d_{A/\Lambda}(x) \otimes 1) = (a_U \circ D_U)(x) = v_{f_0}(a)(x).$

This shows that  $c' - c = v_{f_0}(a)$ .

**4.10.** One has suppressed Remark 4.10 of the original, made obsolete by the addition of Remark 4.8.0.

**4.11.** We now propose to study the following situation. Let  $S, S_J$  and  $S_0$  be as in 4.8; one has three  $S$ -schemes  $X, X', T$ , a subscheme  $Y$  of  $X$  (resp.  $Y'$  of  $X'$ ), and morphisms  $f : T \rightarrow X$  and  $g : X' \rightarrow X$ .

<!-- original page 141 -->

text  

$$\begin{array}{ccccc} & & Y' & & Y \\ & & \downarrow c & & \downarrow c \\ T & \xrightarrow{f} & X' & \xrightarrow{g} & X. \\ & & \downarrow i' & & \downarrow i \end{array}$$

One supposes that by reduction modulo  $J$ , this diagram completes into a commutative diagram

text  

$$\begin{array}{ccccc} & & Y_J' & \longrightarrow & Y_J \\ & & \downarrow c & & \downarrow c \\ & & i_J' & & i_J \\ T_J & \xrightarrow{f_J} & X_J' & \xrightarrow{g_J} & X_J. \end{array}$$

One has therefore by 4.8 obstructions:

text  
 $c(X, Y, g \circ i') \in \text{Hom}_{\{0\}}(i_0'^* g_0^*(N_{Y/X} \otimes_{\{0\}} \mathcal{O}_{Y_0}), \mathcal{J}\mathcal{O}_Y),$   
 $c(X', Y', f) \in \text{Hom}_{\{0\}}(f_0^*(N_{Y'/X'} \otimes_{\{0\}} \mathcal{O}_{Y_0'}), \mathcal{J}\mathcal{O}_T),$

$c(X, Y, g \circ f) \in \text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}} 0_{\{Y_0\}}), J0_T),$

whose relations one seeks to compute. [N.D.E-III-99]

**Lemma 4.12.** *Suppose  $Y'$  flat over  $S$ , so that  $J \otimes_{\{0_{\{S_0\}}\}} 0_{\{Y_0'\}} = J0_{\{Y'\}}.$*

<!-- label: III.III.4.12 -->

**(i)** One has a natural morphism

$$b_{\{f_0\}} : \text{Hom}_{\{0_{\{Y_0'\}}\}}(i_0^*g_0(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), J0_{\{Y'\}}) \rightarrow \text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), J0_T).$$

**(ii)** One has also a natural morphism, functorial in  $T$ , [N.D.E-III-100]

$$a_{\{g_0\}}(f_0) : \text{Hom}_{\{0_{\{T_0\}}\}}(f_0^*(N_{\{Y'/X'\}} \otimes_{\{0_{\{Y_0'\}}\}}), J0_T) \rightarrow \text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), J0_T).$$

**Proof.** [N.D.E-III-101] Let us first note that,  $X, X', Y, Y'$  being fixed, to give a  $T$  as above is equivalent to giving a morphism  $(f, f_J) : T \rightarrow X' \times_{X'} Y'^{+}$ . Set  $Z = X' \times_{X'} Y'^{+}$  and denote by  $M$  and  $M'$  the  $Z$ -functors defined by: for every  $f : T \rightarrow Z$ ,

$$\begin{aligned} M(T) &= \text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), J0_T) \\ M'(T) &= \text{Hom}_{\{0_{\{T_0\}}\}}(f_0^*(N_{\{Y'/X'\}} \otimes_{\{0_{\{Y_0'\}}\}}), J0_T). \end{aligned}$$

[N.D.E-III-102]

One has in any case a commutative diagram:

$$\begin{array}{ccc} f_0^*(J \otimes_{\{0_{\{S_0\}}\}} 0_{\{Y_0'\}}) & \xrightarrow{\quad} & J \otimes_{\{0_{\{S_0\}}\}} 0_{\{T_0\}} \\ \downarrow & & \downarrow \\ f_0^*(J0_{\{Y'\}}) & \xrightarrow{\quad} & J0_T \end{array}$$

<!-- original page 142 -->

and since  $Y'$  is flat over  $S$ , the left arrow is an isomorphism, hence one obtains a morphism of  $\{0_{\{T_0\}}\}$ -modules  $f_{\{0\}}^*(J0_{\{Y'\}}) \rightarrow J0_T$ . The latter induces a morphism of abelian groups

$$\text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), f_0^*(J0_{\{Y'\}})) \rightarrow M(T)$$

and, composing with the morphism

$$M(Y') \rightarrow \text{Hom}_{\{0_{\{T_0\}}\}}(f_*g_*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}}), f_0^*(J0_{\{Y'\}})),$$

induced by  $f_{\{0\}}$ , one obtains the morphism  $b_{\{f_0\}} : M(Y') \rightarrow M(T)$ .

Likewise, one has in any case a diagram

$$\begin{array}{ccc} g_0^*(N_{\{Y/X\}} \otimes_{\{0_{\{Y_0\}}\}} 0_{\{Y_0'\}}) & \xrightarrow{\quad} & N_{\{Y'/X'\}} \otimes_{\{0_{\{Y_0'\}}\}} 0_{\{Y_0'\}} \\ \downarrow & & \downarrow \\ g_0^*(N_{\{Y_0/X_0\}}) & \xrightarrow{\quad} & N_{\{Y_0'/X_0'\}} \end{array}$$

...

and since  $Y'$  is flat over  $S$ , the second vertical arrow is an isomorphism by 4.8.0. One thus obtains an  $0_{Y'}-morphism$

```

```text
i_0' * g_0 * (N_{Y/X} \otimes_{0_Y} 0_{Y'}) \rightarrow N_{Y'/X'} \otimes_{0_{Y'}} 0_{Y'}
```

```

which induces a morphism  $a_{g_0}(id_{Y'}) : M'(Y') \rightarrow M(Y')$  and, for every  $f : T \rightarrow Z$ , a morphism  $a_{g_0}(f) : M'(T) \rightarrow M(T)$  such that one has a commutative diagram

```

```text
M'(Y') --{a_{g_0}(id_{Y'})}--> M(Y')
|                               |
b'_{f_0}                       b_{f_0}
|                               |
M'(T) --{a_{g_0}(f_0)}--> M(T)
```

```

(where  $b'_{f_0}$  is defined like  $b_{f_0}$ ). QED.

**Remark 4.12.1.** [N.D.E-III-103] Denote by  $M_0$  and  $M_0'$  the  $Y_0$ -functors defined by: for every  $f : T_0 \rightarrow Y_0'$ ,

<!-- label: III.III.4.12.1 -->

```

```text
M_0(T) = Hom_{0_{T_0}}(f_0 * g_0 * (N_{Y/X} \otimes_{0_{Y_0}}), J \otimes_{0_{S_0}} 0_{T_0})
M_0'(T) = Hom_{0_{T_0}}(f_0 * (N_{Y'/X'} \otimes_{0_{Y_0'}}), J \otimes_{0_{S_0}} 0_{T_0}).
```

```

<!-- original page 143 -->

\*Note immediately that  $Z_0 = Y_0'$  and that on the category of  $S$ -schemes  $T$  which are flat over  $S$ ,  $M$  and  $M'$  coincide, respectively, with the functors  $\prod_{S_0/S} M_0$  and  $\prod_{S_0/S} M_0'$ . In this case,  $b_{f_0}$  is simply the morphism

```

f_0 * : M_0(Y_0') \longrightarrow M(T_0)
f_0

```

\*induced by  $f_0$ , and for every morphism  $u : U \rightarrow T$ , setting  $h = f \circ u$ , one has a commutative diagram

```

```text
M_0'(T_0) --{a_{g_0}(f_0)}--> M_0(T_0)
|                               |
u_0 *                           u_0 *
|                               |
M_0'(U_0) --{a_{g_0}(h_0)}--> M_0(U_0)
```

```

\*i.e.  $a_{g_0}$  becomes a morphism of functors  $\prod_{S_0/S} M_0' \rightarrow \prod_{S_0/S} M_0$ .

**Proposition 4.13.** \*Suppose  $Y'$  flat over  $S$ . One has then the formula:

<!-- label: III.III.4.13 -->

```

```text
c(X, Y, g \circ f) = a_{g_0}(c(X', Y', f)) + b_{f_0}(c(X, Y, g \circ i')).
```

```

Since the definition of the different obstructions and of the morphisms  $a_{g_0}$  and  $b_{f_0}$  is local, one easily sees that it suffices to verify the given formula when the different schemes in play are affine. Let us thus denote  $S = \operatorname{Spec}(\Lambda)$ ,  $S_J = \operatorname{Spec}(\Lambda/J)$ ,  $S_I = \operatorname{Spec}(\Lambda/I)$ ,

$T = \text{operatorname{Spec}}(C)$ ,  $X = \text{operatorname{Spec}}(A)$ ,  $Y = \text{operatorname{Spec}}(A/I_{\{Y\}}) = \text{operatorname{Spec}}(B)$ ,  
 $X' = \text{operatorname{Spec}}(A')$ ,  $Y' = \text{operatorname{Spec}}(A'/I_{\{Y'\}}) = \text{operatorname{Spec}}(B')$ .

One has therefore a diagram of rings and ideals [N.D.E-III-104]

```text

$$\begin{array}{ccccc} & & B' & & B \\ & & \uparrow & & \uparrow \\ & & \pi' & & \pi \\ & & | & & | \\ C & \xleftarrow{f} & A' & \xleftarrow{g} & A \\ & & \uparrow & & \uparrow \\ & & I_{\{Y'\}} & & I_Y. \end{array}$$

```

Let us study the different terms of the formula to be proved. In what follows, if  $x \in I_{\{Y\}}$  (resp.  $u \in I_{\{Y'\}}$ ), we denote by  $\bar{x}$  (resp.  $\bar{u}$ ) its image in  $I_{\{Y\}}/I_{\{Y\}}^2$  (resp.  $I_{\{Y'\}}/I_{\{Y'\}}^2$ ); on the other hand, if  $m$  belongs to a  $\Lambda$ -module  $M$ , we denote by  $\bar{m}_0$  its image in  $M_0 = M/IM$ .

One has seen that  $c = c(X, Y, g \circ f)$  is the unique  $C_0$ -morphism  $I_{\{Y\}}/I_{\{Y\}}^2 \otimes_{\{B\}} C_0 \rightarrow JC$  such that  $c(\bar{x} \otimes 1) = f(g(x))$ , for every  $x \in I_{\{Y\}}$ .

<!-- original page 144 -->

Fix  $x \in I_{\{Y\}}$ ; one has  $g(x) \in I_{\{Y'\}} + JA'$  since  $g_{\{J\}}(Y_{\{J\}}') \subset Y_{\{J\}}$ . Write  $g(x) = x' + \sum \lambda_i a'_i$ , with  $x' \in I_{\{Y'\}}$ ,  $\lambda_i \in J$ ,  $a'_i \in A'$ . One therefore has

```text

(1) $c(X, Y, g \circ f)(x \otimes 1) = f(g(x)) = f(x') + \sum \lambda_i f(a'_i).$

```

Now consider  $a_{\{g_0\}}(c(X', Y', f))$ . According to the definitions laid down, it is defined by the diagram

```text

$$\begin{array}{ccccc} & & & f & \\ & & & \longrightarrow & C \\ & & & \uparrow & | \\ & & & & c(X', Y', f) \\ I_{\{Y_0'\}}/I_{\{Y_0'\}}^2 \otimes_{\{B_0'\}} C_0 & \xleftarrow{\cong} & I_{\{Y'\}}/I_{\{Y'\}}^2 \otimes_{\{B'\}} C_0 & \longrightarrow & JC \\ \uparrow g_0 & & & \nearrow & \nearrow \\ I_{\{Y_0\}}/I_{\{Y_0\}}^2 \otimes_{\{B_0\}} C_0 & \xleftarrow{\quad} & I_Y/I_Y^2 \otimes_{\{B\}} C_0 & & a_{\{g_0\}}(c(X', Y', f)) \end{array}$$

One has therefore $a_{\{g_0\}}(c(X', Y', f))(\bar{x} \otimes 1) = f(u)$, where u is an element of $I_{\{Y'\}}$ whose image $\bar{u}$ in $I_{\{Y_0'\}}/I_{\{Y_0'\}}^2$ satisfies $\bar{u} \otimes 1 = \bar{g}_0(\bar{x} \otimes 1) \otimes 1 = \bar{g}_0(\bar{x} \otimes 1) \otimes 1$. One can therefore take $u = x'$ and one finds

```text

(2)  $a_{\{g_0\}}(c(X', Y', f))(x \otimes 1) = f(x').$

```

Consider finally $b_{\{f_0\}}(c(X, Y, g \circ i'))$. By hypothesis, the morphism of Λ_0 -algebras $f_0 : A_0' \rightarrow C_0$ factors through B_0' , and therefore, since $J \otimes_{\Lambda_0} B_0' \xrightarrow{\sim} JB'$ (B' being flat over Λ), one obtains a morphism of B_0' -modules $\psi : JB' \rightarrow JC$ such that one has a commutative diagram:

```text

$$\begin{array}{ccc} J \otimes_{\Lambda_0} A_0' & \xrightarrow{\text{id} \otimes \pi'} & J \otimes_{\Lambda_0} B_0' \xrightarrow{\text{id} \otimes f_0} J \otimes_{\Lambda_0} C_0 \\ \downarrow & & \downarrow \square \end{array}$$

$$\dots JA' \xrightarrow{\pi'} JB' \xrightarrow{\psi} JC.$$

Denote  $\phi : JB' \otimes_{B_0'} C_0 \rightarrow JC$  the morphism of  $C_0$ -modules deduced from  $\psi$ ; then one has, for every  $a' \in A'$ ,  $\lambda \in J$ ,

$$\text{``text} \\ (\dagger) \quad \phi(\lambda \pi'(a') \otimes 1) = \lambda f(a'). \\ \text{```}$$

<!-- original page 145 -->

Then,  $b_{f_0}(c(X, Y, g \circ i'))$  is defined by the commutative diagram:

$$\begin{array}{ccc} I_Y & \xrightarrow{\pi' \circ g} & B' \\ & & \uparrow c(X, Y, g \circ i') \\ I_Y/I_{Y^2} \otimes_{B_0} B_0' & \longrightarrow & JB' \\ \downarrow & & \downarrow \\ I_Y/I_{Y^2} \otimes_{B_0} C_0 & \longrightarrow & JB' \otimes_{B_0'} C_0 \\ & \searrow \varphi & \searrow \varphi \\ & b_{f_0}(c(X, Y, g \circ i')) & \\ & \searrow & \searrow \\ & & JC. \end{array}$$

...

One has therefore at once

$$\text{``text} \\ (3) \quad b_{f_0}(c(X, Y, g \circ i'))(x^- \otimes 1) = \phi(\sum \lambda_i \pi'(a'_i) \otimes 1) = \sum \lambda_i f(a'_i), \\ \text{```}$$

the last equality following from  $(\dagger)$  above. The comparison of the three explicit results (1), (2), (3) gives the formula sought.

**Corollary 4.14.** \*Let  $Y, Y'$  be two flat subschemes of  $X$ , reducing to  $Y_J$ ; suppose  $Y_0$  locally complete intersection in  $X_0$ . If  $f : T \rightarrow X$  is an  $S$ -morphism such that  $f_J$  factors through  $Y_J \rightarrow X_J$ , one has the formula\*

<!-- label: III.III.4.14 -->

$$\text{``text} \\ c(X, Y, f) - c(X, Y', f) = b_{f_0}(d(Y, Y')). \\ \text{```}$$

Indeed, applying the preceding formula to the diagram

$$\begin{array}{ccccc} & Y' & & Y & \\ & \downarrow & & \downarrow & \\ & i' & & i & \\ T \xrightarrow{f} X & \xrightarrow{\text{id}} & X & & X \end{array}$$

...

one finds  $c(X, Y, f) - c(X, Y', f) = b_{f_0}(c(X, Y, i'))$ . Moreover, by 4.8 (ii), one has  $c(X, Y, i') = d(Y, Y')$ .

**Proposition 4.15.** \*Let  $X$  be an  $S$ -group smooth over  $S$  and  $Y$  a sub- $S$ -group flat and locally of finite presentation over  $S$ . Then  $Y$  is locally complete intersection (cf. 4.6.2) in  $X$ .\*

<!-- label: III.III.4.15 -->

<!-- original page 146 -->

\*Proof.\*[<sup>N.D.E-III-105</sup>] We shall show that the immersion  $Y \rightarrow X$  is regular in the sense of EGA IV<sub>4</sub>, 16.9.2, which implies that it is also regular in the sense of 4.6.2, by EGA IV<sub>4</sub>, 19.5.1 (moreover, by loc. cit., the two definitions are equivalent if  $S$  is locally noetherian). Therefore, in what follows, we take "regular immersion" in the sense of EGA IV<sub>4</sub>, 16.9.2. Since  $X$  and  $Y$  are flat and locally of finite presentation over  $S$ , then, by EGA IV<sub>4</sub>, 19.2.4, it suffices to show that, for every  $s \in S$ ,  $Y_s \rightarrow X_s$  is a regular immersion. By EGA IV<sub>4</sub>, 19.1.5 (ii), one is reduced to verifying the assertion on the geometric fibers of  $S$ , that is, when  $S$  is the spectrum of an algebraically closed field  $k$ .

Then, by VI<sub>A</sub>, 3.2, the quotient  $X/Y$  exists and is smooth, the morphism  $\pi : X \rightarrow X/Y$  is flat, and one has a cartesian square

$$\begin{array}{ccc} Y & \xrightarrow{f} & X \\ | & & | \\ i & & \pi \\ \downarrow & & \downarrow \\ e & \longrightarrow & X/Y \end{array}$$

(where  $e$  is the image in  $X/Y$  of the unit point of  $X$ ). Therefore, by flat base change (cf. EGA IV<sub>4</sub>, 19.1.5 (ii)), it suffices to see that  $i$  is a regular immersion, which is immediate since the noetherian local ring  $\mathcal{O}_{X/Y, e}$  is smooth, hence its maximal ideal is generated by a regular sequence.

\*\*4.16.\*\*[<sup>N.D.E-III-106</sup>] Let  $X$  be an  $S$ -group smooth over  $S$ , denote  $\mu : X \times_S X \rightarrow X$  its group law. Suppose given a sub- $S$ -group  $Y$  of  $X$ , flat and locally of finite presentation over  $S$ . By 4.15,  $Y$  is locally complete intersection in  $X$ .

Hence, by 4.6.5, every flat  $S$ -scheme [<sup>N.D.E-III-107</sup>]  $Y'$  lifting  $Y$  is locally complete intersection in  $X$ . For such a  $Y'$  one has, by 4.8.0,

<!-- label: III.III.4.16.1 -->

$$(4.16.1) \quad N_{Y/X} \otimes_{\mathcal{O}_Y} \mathcal{O}_{Y_0} = N_{Y_0/X_0} = N_{Y/X} \otimes_{\mathcal{O}_Y} \mathcal{O}_{Y_0}.$$

On the other hand, denote by  $\epsilon : S \rightarrow Y$  the unit section of  $Y$  and  $n_{Y/X}$  the quasi-coherent  $\mathcal{O}_S$ -module:

$$\begin{aligned} n_{Y/X} &= \epsilon^*(N_{Y/X}) \\ n_{Y/X} &= \epsilon^*(N_{Y/X}) \end{aligned}$$

Since  $Y$  and  $X$  are  $S$ -groups, one sees easily that  $n_{Y/X}$  is invariant under the (say left) translations of  $Y$ , hence [<sup>N.D.E-III-108</sup>] is the inverse image by  $Y \rightarrow S$  of  $n_{Y/X}$ , i.e. one has

<!-- label: III.III.4.16.2 -->

$$(4.16.2) \quad N_{Y_0/X_0} = n_{Y_0/X_0} \otimes_{\mathcal{O}_S} \mathcal{O}_{Y_0}.$$

<!-- original page 147 -->

Taking (4.16.1) and (4.16.2) into account, one deduces on the one hand from 4.5 that the set of sub- $S$ -schemes  $Y'$  of  $X$ , flat over  $S$ , lifting  $Y$ , is empty or principal homogeneous under

<!-- label: III.III.4.16.3 -->

$$(4.16.3) \quad \text{Hom}_{\mathcal{O}_S}(n_{Y_0/X_0} \otimes_{\mathcal{O}_S} \mathcal{O}_{Y_0}, J \otimes_{\mathcal{O}_S} \mathcal{O}_{Y_0}),$$

...

and one deduces on the other hand from 4.8 (i) that, for every such  $Y$  and every  $S$ -morphism  $f : T \rightarrow X$  such that  $f_{\{J\}} : T_{\{J\}} \rightarrow X_{\{J\}}$  factors through  $Y_{\{J\}}$ , the obstruction  $c(X, Y, f)$  to  $f$  factoring through  $Y$  is an element of

$\text{Hom}_{\{0\}}(n_{\{Y_0/X_0\}} \otimes_{\{0\}} 0_{\{T_0\}}, J_{0,T})$ ;

if moreover  $T$  is flat over  $S$ , this last group equals

$\text{Hom}_{\{0\}}(n_{\{Y_0/X_0\}} \otimes_{\{0\}} 0_{\{T_0\}}, J \otimes_{\{0\}} 0_{\{T_0\}})$ .

This leads to introducing the group functor  $N_{\{0\}}$  below:

**Definition 4.16.1.** Let  $N_{\{0\}}$  be the  $S_{\{0\}}$ -functor in commutative groups defined by: for every  $Z \in \text{Ob}(S_{\{0\}})$ ,

!-- label: III.III.4.16.1d -->

$(*) \quad \text{Hom}_{\{S_0\}}(Z, N_0) = \text{Hom}_{\{0,Z\}}(n_{\{Y_0/X_0\}} \otimes_{\{0\}} 0_Z, J \otimes_{\{0\}} 0_Z)$ .

Then, the set of sub- $S$ -schemes  $Y$  of  $X$ , flat over  $S$ , lifting  $Y_{\{J\}}$ , is empty or principal homogeneous under

$\text{Hom}_{\{S_0\}}(Y_0, N_0) = C^1(Y_0, N_0)$ .

For each such  $Y$ , consider the following diagram:

$$\begin{array}{ccc} Y \times_S Y & & Y \\ \downarrow & & \downarrow \\ (i,i) & & i \\ \downarrow & \mu & \downarrow \\ X \times_S X & \longrightarrow & X \end{array}$$

and denote  $DY = c(X, Y, \mu \circ (i, i))$  the obstruction to  $\mu \circ (i, i)$  factoring through  $Y$ , i.e. to  $Y$  being stable under the group law of  $X$ ; by what precedes,  $DY$  is an element of

$N_0(Y_0 \times_{\{S_0\}} Y_0) = C^2(Y_0, N_0)$ .

**Lemma 4.17.** [N.D.E-III-109] Let  $X$  be an  $S$ -group smooth over  $S$  and  $Y_{\{J\}}$  a sub- $S_{\{J\}}$ -group of  $X_{\{J\}}$ , flat and locally of finite presentation over  $S_{\{J\}}$ . For each subscheme  $Y$  of  $X$ , flat over  $S$  and lifting  $Y_{\{J\}}$ , consider the obstruction defined in 4.16.1:

!-- label: III.III.4.17 -->

$DY \in \text{Hom}_{\{S_0\}}(Y_0 \times_{\{S_0\}} Y_0, N_0) = C^2(Y_0, N_0)$

(i) For  $Y$  to be a sub- $S$ -group of  $X$ , it is necessary and sufficient that  $DY = 0$ .

!-- original page 148 -->

(ii) If one makes  $Y_{\{0\}}$  act on  $N_{\{0\}}$  by functoriality from the inner automorphisms of  $Y_{\{0\}}$ , then

```

```text
(‡) 
$$\begin{cases} a_j : \text{Hom}_{\{S_0\}}(Y_0^3, N_0 \otimes N_0) \rightarrow \text{Hom}_{\{S_0\}}(Y_0^3, N_0) \\ b_j : \text{Hom}_{\{S_0\}}(Y_0^2, N_0) \rightarrow \text{Hom}_{\{S_0\}}(Y_0^3, N_0). \end{cases}$$

```

```

Applying 4.13 twice to  $c(X, Y, \mu_{2,Y}) = u$ , one obtains:

```

```text

$$a_1(c(X^2, Y^2, f_1)) + b_1(c(X, Y, \mu_Y)) = u = a_2(c(X^2, Y^2, f_2)) + b_2(c(X, Y, \mu_Y)).$$

```

```

Now,  $c(X, Y, \mu_Y) = DY$  and, since  $f_1 = (1, \mu)$  and  $f_2 = (\mu, 1)$ , one has, with evident notations:

```

```text

$$c(X^2, Y^2, f_1) = (0, DY) \quad \text{and} \quad c(X^2, Y^2, f_2) = (DY, 0).$$

```

```

Hence, one obtains:

```

```text

$$u = a_1((0, DY)) + b_1(DY) = a_2((DY, 0)) + b_2(DY).$$

```

```

The first thing one notes is that  $b_j$  is nothing other than  $\text{Hom}_{\{S_0\}}((f_{j,Y})_{0}, N_{0})$ , that is to say, the morphism deduced from  $(f_{j,Y})_{0}$  by functoriality.

The identity above therefore becomes:

```

```text

$$a_1((0, DY)) - \text{Hom}((\mu, 1), N_0)(DY) + \text{Hom}((1, \mu), N_0)(DY) - a_2((DY, 0)) = 0.$$

```

```

One recognizes the two middle terms: they are the parts " $DY(xy, z)$ " and " $DY(x, yz)$ " of the 2-coboundary formula. It only remains, then, to identify the two other terms.

We must first compute the map  $a_j$ . Now it comes, by inverse image by  $(f_{j,Y})_{0}$ , from the morphism of  $S_0^{Y^2}$ -modules

```

```text

$$P : n_{Y_0/X_0} \otimes 0_{Y_0^2} \rightarrow (n_{Y_0/X_0} \otimes n_{Y_0/X_0}) \otimes 0_{Y_0^2}$$

```

```

induced by the product in  $Y_0$ . Now this morphism is described in the following way: consider the vector bundle  $V = V(n_{Y_0/X_0})$ ;  $P$  gives by duality a morphism

```

```text

$$V(P) : V \times_{S_0} V \times_{S_0} Y_0 \times_{S_0} Y_0 \rightarrow V \times_{S_0} Y_0 \times_{S_0} Y_0$$

```

```

<!-- original page 150 -->

which is expressed set-theoretically by [N.D.E-III-112]

```

```text

$$V(P)(u, v, a, b) = (u + \text{Ad}(a)v, ab, b).$$

```

```

This is proved exactly like the corresponding fact on Lie algebras, that is, on the module  $\omega^1_{Y_0/S_0}$ . One first notes that  $V$  is endowed by functoriality in  $Y_0$  with a group structure in the category of vector bundles on  $S_0$ ; by virtue of the lemma already used for Lie algebras (Exposé II, 3.10), this structure coincides with the group structure underlying its  $0_{S_0}$ -module structure. One then sees that  $V(n_{Y_0/X_0}) \otimes_{0_{S_0}} 0_{Y_0} = V(n_{Y_0/X_0})$  is also endowed with a structure of  $S_0$ -group which is none other than the semi-direct product of that of  $V$  by that of  $Y_0$ . It only remains to identify the operations of  $Y_0$  on  $V$  to establish the desired formula.

Let us now compute the two remaining terms. Consider first  $a_1((0, DY))$ . One computes it by the diagram (where  $n$  denotes  $n_{Y_0}/X_0$ ):

$$\begin{array}{ccc} n \otimes 0_{Y_0^2} & \xrightarrow{P} & (n+n) \otimes 0_{Y_0^2} \\ \downarrow (f_1, Y)_0^* & & \downarrow (f_1, Y)_0^* \\ n \otimes 0_{Y_0^3} & & (n+n) \otimes 0_{Y_0^3} \\ & \searrow & \downarrow (0, DY) \\ & a_1((0, DY)) & J \otimes 0_{Y_0^3}. \end{array}$$

Considering now the vector bundles defined by these different modules as so many schemes over  $S_0$  and taking points with values in anything, one has, denoting  $(u, x, y, z)$  a point of  $V(J) \times Y_0^3$ :

$$\begin{array}{ccc} (Ad(x)DY_{\{y,z\}}(u), x, yz) & \xleftarrow{\quad} & (0 + DY_{\{y,z\}}(u), x, yz) \\ \uparrow & & \uparrow \\ & & (0 + DY_{\{y,z\}}(u), x, y, z) \\ (Ad(x)DY_{\{y,z\}}(u), x, y, z) & \xleftarrow{\quad} & (u, x, y, z). \end{array}$$

One has thus obtained  $a_1((0, DY))(x, y, z) = Ad(x)DY(y, z)$ , which is indeed the first term of the coboundary. One would have likewise  $a_2((DY, 0))(x, y, z) = DY(x, y)$ , whence [N.D.E-III-113]

$$0 = Ad(x)DY(y, z) - DY(xy, z) + DY(x, yz) - DY(x, y) = (\partial^2 DY)(x, y, z).$$

<!-- original page 151 -->

**4.20.** **Proof of 4.17 (iii).** [N.D.E-III-114] This is done by comparing the two values of  $v = c(X, Y, \mu \circ (i', i'))$  computed in the two following diagrams

$$(*) \quad \begin{array}{ccc} & Y' & Y \\ & \downarrow c & \downarrow c \\ & i' & i \\ Y' \times_S Y' & \xrightarrow{\quad} & X \xrightarrow{\mu \circ (i', i')} X \end{array} \quad |$$

$$(\dagger) \quad \begin{array}{ccccc} & & Y \times_S Y & Y & \\ & & \downarrow c & \downarrow c & \\ & & (i, i) & i & \\ Y' \times_S Y' & \xrightarrow{(i', i')} & X \times_S X & \xrightarrow{\mu} & X. \end{array}$$

Denote  $f = \mu \circ (i', i')$ ; then  $f$  gives

$$(1) \quad v = DY' + f_0^*(c(X, Y, i')).$$

Now  $Y_0' = Y_0$  and  $f_0$  is the multiplication  $Y^2_0 \rightarrow Y_0$ ; one deduces from this that

...

$$(2) \quad f_0*(c(X, Y, i'))(x_0, y_0) = c(X, Y, i')(x_0 y_0).$$

Set  $c = c(X, Y, i')$ ; via the identification  $N_{\{0\}}' \simeq N_{\{0\}} \oplus N_{\{0\}}$ ,  $c(X \times_S X, Y \times_S Y, (i', i'))$  identifies with the pair  $(c, c)$ . Then, denoting  $h = (i', i')$ ,  $\tau(t)$  gives

$$(3) \quad v = h_0*(DY) + a_{\{\mu_0\}}(c, c).$$

Now  $h_{\{0\}}$  is the identity map of  $Y^{\{2\}}_{\{0\}}$ , whence  $h_{\{0\}}*(DY) = DY$ . Finally, by the computation of  $a_{\{\mu_0\}}$  done previously, one has for every  $S' \rightarrow S$  and  $x_{\{0\}}, y_{\{0\}} \in Y_{\{0\}}(S_{\{0\}}')$ ,

$$(4) \quad a_{\{\mu_0\}}(c, c)(x_0, y_0) = c(x_0) + \text{Ad}(x_0)(c(y_0)).$$

One thus obtains:

$$(DY' - DY)(x_0, y_0) = \text{Ad}(x_0)c(X, Y, i')(y_0) - c(X, Y, i')(x_0 y_0) + c(X, Y, i')(x_0) \\ = (\partial^1 c(X, Y, i'))(x_0, y_0).$$

Since  $c(X, Y, i') = d(Y, Y')$  (cf. 4.8 (ii)), this shows that  $DY' - DY = \partial^1 d(Y, Y')$ .

**Theorem 4.21.** \*Let  $S$  be a scheme,  $I$  and  $J$  two ideals [N.D.E-III-115] on  $S$  such that  $I \supset J$  and  $I \cdot J = 0$ . Let  $X$  be an  $S$ -group smooth over  $S$  and  $Y_J$  a sub- $S_J$ -group of  $X_J$ , flat and locally of finite presentation over  $S_J$ . Consider the  $S_{\{0\}}$ -functor in commutative groups  $N_{\{0\}}$  defined by\*

<!-- label: III.III.4.21 -->

$$\text{Hom}_{\{S_0\}}(T, N_0) = \text{Hom}_{\{0_T\}}(n_{\{Y_0/X_0\}} \otimes_{\{0_{S_0}\}} 0_T, J \otimes_{\{0_{S_0}\}} 0_T), \quad T \in \text{Ob}(\text{Sch})/S_0,$$

\*on which  $Y_{\{0\}}$  acts via the inner automorphisms of  $X_{\{0\}}$ .\*

(i) For there to exist a sub- $S$ -group of  $X$ , flat over  $S$ , which reduces to  $Y_J$ , it is necessary and sufficient that the two following conditions be verified:\*

<!-- original page 152 -->

(i<sub>1</sub>) There exists a subscheme  $Y$  of  $X$ , flat over  $S$ , lifting  $Y_J$  (condition automatically satisfied if  $Y_{\{0\}}$  is affine, cf. 4.6.5).\*

(i<sub>2</sub>) A certain canonical obstruction, element of  $H^2(Y_{\{0\}}, N_{\{0\}})$ , is zero.\*

(ii) If the conditions of (i) are satisfied, the set of sub- $S$ -groups  $Y$  of  $X$ , flat over  $S$  and reducing to  $Y_J$  is a principal homogeneous set under the group  $Z^1(Y_{\{0\}}, N_{\{0\}})$ . [N.D.E-III-116]\*

Indeed, condition (i<sub>1</sub>) is necessary. Suppose it satisfied and let  $Y$  be flat over  $S$  lifting  $Y_J$ . We must seek a  $Y'$  flat over  $S$  lifting  $Y_J$  as well such that  $DY' = 0$ , [N.D.E-III-117] cf. 4.17 (i). By 4.17 (iii), this amounts to seeking a  $d(Y', Y) \in C^1(Y_{\{0\}}, N_{\{0\}})$  such that  $DY = \partial^1 d(Y', Y)$ . [N.D.E-III-118]

Let  $c \in H^2(Y_{\{0\}}, N_{\{0\}})$  be the image class of  $DY$ , which is a cocycle by 4.17 (ii). It does not depend on the choice of  $Y$  by 4.17 (iii), and its vanishing is necessary and sufficient for the existence of a  $d(Y', Y)$  satisfying the preceding equation. This proves (i).

If one has now chosen  $Y$  such that  $DY = 0$ , the equation to solve becomes  $\partial^1 d(Y', Y) = 0$ , which proves (ii).

**Remark 4.22.** \*Let us keep the notation of 4.21. By 4.15,  $Y_{\{0\}}$  is locally complete intersection in  $X_{\{0\}}$ , hence  $N_{\{Y_{\{0\}}/X_{\{0\}}\}}$  is a finite locally free  $0_{\{Y_{\{0\}}\}}$ -module, and consequently

$n_{Y_0/X_0} = \epsilon_0(N_{Y_0/X_0})$  is a finite locally free  $\mathcal{O}_{S_0}$ -module. Hence, denoting  $n^{\vee}_{Y_0/X_0} = \operatorname{Hom}_{\mathcal{O}_{S_0}}(n_{Y_0/X_0}, \mathcal{O}_{S_0})$ , one has\*

<!-- label: III.III.4.22 -->

```

```text
Hom_{\mathcal{O}_T}(n_{Y_0/X_0} \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_T, J \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_T) = n_{Y_0/X_0}^{\vee} \otimes_{\mathcal{O}_{S_0}} J \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_T.
```

```

\*for every  $T \rightarrow S_0$ . [N.D.E-III-119] Consequently, the  $\mathcal{O}_{S_0}$ -functor  $n_{\mathcal{O}_T}$  is isomorphic to the functor\*

```

```text
W(n_{Y_0/X_0}^{\vee} \otimes_{\mathcal{O}_{S_0}} J) = W(\operatorname{Hom}_{\mathcal{O}_{S_0}}(n_{Y_0/X_0}, J)).
```

```

\*It results in isomorphisms: [N.D.E-III-120]\*

```

```text
H^2(Y_0, N_0) = H^2(Y_0, \operatorname{Hom}_{\mathcal{O}_{S_0}}(n_{Y_0/X_0}, J)) = H^2(Y_0, n_{Y_0/X_0}^{\vee} \otimes_{\mathcal{O}_{S_0}} J),
Z^1(Y_0, N_0) = Z^1(Y_0, \operatorname{Hom}_{\mathcal{O}_{S_0}}(n_{Y_0/X_0}, J)) = Z^1(Y_0, n_{Y_0/X_0}^{\vee} \otimes_{\mathcal{O}_{S_0}} J).
```

```

**4.23.** Still under the hypotheses of 4.21, we are now going to study how the set of  $Y$  lifting  $Y_J$  behaves with respect to conjugation by sections of  $X$ . If  $x$  is a section of  $X$  over  $S$  inducing the unit section of  $X_J$ , the inner automorphism  $\operatorname{Int}(x)$  defined by  $x$  transforms flat subgroups of  $X$  lifting  $Y_J$  into flat subgroups of  $X$  lifting  $Y_J$ . Now, under the conditions of 4.21 (ii), the set of these subgroups is principal homogeneous under  $Z^1(Y_0, N_0)$ ; we shall see that there then exists a subgroup  $\Gamma$  of  $B^1(Y_0, N_0)$  [N.D.E-III-121] such that two subgroups of  $X$ , flat over  $S$ , and lifting  $Y_J$ , are conjugate (by  $x \in X(S)$  inducing the unit of  $X(S_J)$ ) if and only if their "difference" in  $Z^1(Y_0, N_0)$  is an element of  $\Gamma$ . In the best cases, we shall show that  $\Gamma$  equals  $B^1(Y_0, N_0)$ , hence that the set of flat subgroups of  $X$  lifting  $Y_J$ , modulo conjugation by  $x \in X(S)$  inducing the unit of  $X(S_J)$ , is empty or principal homogeneous under  $H^1(Y_0, N_0)$  (cf. 4.29 and 4.36).

<!-- original page 153 -->

**4.24.** We keep the notation of 4.21. Let  $Y$  be a flat subgroup of  $X$ , reducing to  $Y_J$ . Recall that we introduced in 0.5 the functor  $L^{\{X\}}_0$  (resp.  $L^{\{Y\}}_0$ ) defined by the identity with respect to the variable  $\mathcal{O}_{S_0}$ -scheme  $T$ :

```

```text
Hom_{\mathcal{O}_T}(T, L_0^{\{X\}}) = Hom_{\mathcal{O}_T}(\omega^1_{X_0/S_0} \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_T, J \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_T)
```

```

(resp. similarly on replacing  $X$  by  $Y$ ), as well as the functor  $L'_X = \prod_{S_0/S} L^{\{X\}}_0$ .

Now one has:

**Lemma 4.25.** \*There exists a canonical exact sequence of  $Y_0$ - $\mathcal{O}_{S_0}$ -modules\*

<!-- label: III.III.4.25 -->

```

```text
(+) n_{Y_0/X_0} \xrightarrow{d} \omega^1_{X_0/S_0} \rightarrow \omega^1_{Y_0/S_0} \rightarrow 0
```

```

\*possessing the following properties:\*

(i) By inverse image on  $Y_0$ ,  $d$  gives the morphism  $\bar{D}_0$  of 4.8 (iii).\*

(ii) If  $X_0$  and  $Y_0$  are smooth over  $S_0$ , then  $d$  is injective. Since the two  $\omega^1$  are then locally free of finite type, so is  $n_{Y_0/X_0}$  and the sequence is locally split.\*

**Proof.** [N.D.E-III-122] Denote by  $\pi_0$  the morphism  $Y_0 \rightarrow S_0$ . By SGA 1 II, formula (4.3) (see also EGA IV<sub>4</sub>, 16.4.21), one has a canonical exact sequence of  $\mathcal{O}_{Y_0}$ -modules

```

```text
(†)  $N_{\{Y_0/X_0\}} \xrightarrow{D^0} \Omega^1_{\{X_0/S_0\}} \otimes_{\{O_{\{X_0\}}\}} O_{\{Y_0\}} \xrightarrow{\quad} \Omega^1_{\{Y_0/S_0\}} \xrightarrow{\quad} 0.$ 
```

```

Since this sequence is formed of  $(Y_0 \times_S Y_0)$ -equivariant modules and morphisms, its inverse image  $(+)$  by  $\epsilon_{\{Y_0\}}$  is an exact sequence of  $Y_0$ -modules, and  $(†)$  is the inverse image of  $(+)$  by  $\pi_{\{Y_0\}}$  (cf. Exp. I, § 6.8). This proves (i).

<!-- original page 154 -->

Suppose moreover  $X_0$  and  $Y_0$  smooth over  $S_0$ . Then, by SGA 1 II 4.10 (see also EGA IV<sub>4</sub>, 17.2.3 (i) and 17.2.5),  $D^0$  is injective and the sequence  $(†)$  is formed of  $O_{\{Y_0\}}$ -modules locally free of finite type (hence is locally split). By the equivalence of categories I, 6.8.1,  $D^0$  is also injective, and therefore the sequence  $(+)$  has the indicated properties.

**4.26.** [N.D.E-III-123] For every  $S_0$ -scheme  $f : T \rightarrow S_0$ ,  $(+)$  gives an exact sequence of  $Y_0(T)$ -modules

```

```text
 $0 \rightarrow \text{Hom}_{\{O_T\}}(f^*(\omega^1_{\{Y_0/S_0\}}), f^*(J)) \rightarrow \text{Hom}_{\{O_T\}}(f^*(\omega^1_{\{X_0/S_0\}}), f^*(J)) \rightarrow \text{Hom}_{\{O_T\}}(f^*(n_{\{Y_0/X_0\}}), f^*(J)),$ 
```

```

hence one has an exact sequence of  $Y_0$ - $O_{\{S_0\}}$ -modules:

<!-- label: III.III.4.26.1 -->

```

```text
(4.26.1)  $0 \rightarrow L_0^0 Y \rightarrow L_0^0 X \xrightarrow{D^0} N_0.$ 
```

```

From this one deduces an exact sequence of complexes of abelian groups:

```

```text
 $0 \rightarrow C^*(Y_0, L_0^0 Y) \rightarrow C^*(Y_0, L_0^0 X) \xrightarrow{D^*} C^*(Y_0, N_0),$ 
```

```

and in particular, a commutative diagram with exact rows

```

```text

$$\begin{array}{ccccc} 0 \rightarrow C^0(Y_0, L_0^0 Y) & \rightarrow & C^0(Y_0, L_0^0 X) & \xrightarrow{D^0} & C^0(Y_0, N_0) \\ \downarrow \partial & & \downarrow \partial & & \downarrow \partial \\ 0 \rightarrow C^1(Y_0, L_0^0 Y) & \rightarrow & C^1(Y_0, L_0^0 X) & \xrightarrow{D^1} & C^1(Y_0, N_0). \end{array}$$

```

```

Note that  $C^0(Y_0, L^0_{\{Y_0\}})$  (resp.  $C^0(Y_0, L^0_{\{X_0\}})$ ) is none other than  $\text{Hom}_{\{S_0\}}(S_0, L^0_{\{Y_0\}})$  (resp.  $\text{Hom}_{\{S_0\}}(S_0, L^0_{\{X_0\}})$ ) (resp.  $\dots$ ), i.e. (cf. 0.9) the group of sections of  $Y_0$  (resp.  $X_0$ ) over  $S_0$  inducing the unit section of  $X_J$ . Note also that  $D^1$  is none other than the morphism  $v_{\{i_{Y_0}\}}$  of 4.8 (iii), where  $i_{Y_0} : Y_0 \rightarrow X_0$  is the canonical immersion. [N.D.E-III-124]

**Lemma 4.27.** \*Under the conditions of 4.21 for  $S, I, J$  and  $X$ , let  $Y$  be a subgroup of  $X$ , flat over  $S$  and lifting  $Y_J$ . Denote  $i : Y \rightarrow X$  the canonical immersion. [N.D.E-III-125]\*

<!-- label: III.III.4.27 -->

(i) Let  $i' : Y \rightarrow X$  be a morphism of  $S$ -schemes lifting  $i_J$  (so that  $i'$  is also an immersion), let  $Y' = i'(Y)$  and let  $d(i, i')$  be the element of  $C^1(Y_0, L^0_{\{X_0\}})$  such that  $i' = d(i, i') \cdot i$  (cf. 1.2.4). Then the deviation  $d(Y, Y') \in C^1(Y_0, N_0)$  (cf. 4.5.1) is given by the formula:

```

```text
 $d(Y, Y') = d^1(d(i, i')).$ 
```

```

(ii) Let  $x \in C^0(Y_0, L^0_{\{X_0\}})$  be a section of  $X$  over  $S$  inducing the unit section of  $X_J$  over  $S_J$ .

Then the deviation  $d(Y, \text{Int}(x)Y) \in C^1(Y_0, N_0)$  (cf. 4.5.1) is given by the formula:

<!-- original page 155 -->

```
```text
-d(Y, Int(x)Y) = d^1\partial x = \partial d^0x.
```
```

Indeed,  $Y'$  is the image of  $Y$  by the composite morphism: [N.D.E-III-126]

```
```text
Y \xrightarrow{\{(d(i, i'), i)\}} L'_X \times_S X \rightarrow X,
```
```

which is denoted  $d(i, i') \cdot i$  in 4.8 (iii); by loc. cit. and the equality  $v_{i_0} = d^1$ , one has therefore:

```
```text
c(X, Y', d(i, i') \cdot i) - c(X, Y', i) = v_{i_0}(d(i, i')) = d^1(d(i, i')).
```
```

But  $d(i, i') \cdot i = i'$  factors through  $Y'$  by definition, hence the first term is zero; moreover, by 4.8 (ii), one has  $c(X, Y', i) = d(Y', Y) = -d(Y, Y')$ . Hence  $d(Y, Y') = d^1(d(i, i'))$ , which proves (i).

Let now  $x$  be as in (ii). By the formula

```
```text
xyx^{-1} = xyx^{-1}y^{-1}y = (x - \text{Ad}(y)x)y = (-\partial x)(y) \cdot y,
```
```

one sees that  $Y'$  is the image of  $Y$  by the immersion  $i' = (-\partial x) \cdot i_Y$ . Hence, by (i) one obtains

```
```text
-d(Y, \text{Int}(x)Y) = d^1\partial x = \partial d^0x.
```
```

**Corollary 4.28.** For two subgroups  $Y$  and  $Y'$  of  $G$ , flat over  $S$  and lifting  $Y_J$ , to be conjugate by a section of  $X$  over  $S$  inducing the unit section of  $X_J$ , it is necessary and sufficient that  $d(Y, Y') \in \partial C^0(Y_0, L^1X_0) \subset \partial C^0(Y_0, N_0) = B^1(Y_0, N_0)$ .

<!-- label: III.III.4.28 -->

**Corollary 4.29.** If  $d^0$  is surjective,  $Y$  and  $Y'$  as above are conjugate by a section of  $X$  over  $S$  inducing the unit section of  $X_J$  if and only if  $d(Y, Y') \in B^1(Y_0, N_0)$ .

<!-- label: III.III.4.29 -->

<!-- original page 156 -->

**Corollary 4.30.** Let  $Y$  be as in 4.27; the set of conjugates of  $Y$  by sections of  $X$  over  $S$  inducing the unit section of  $X_J$  is isomorphic to:

<!-- label: III.III.4.30 -->

```
```text
d^1\partial(C^0(Y_0, L^0X)) = C^0(Y_0, L^0X) / \text{Ker } d^1\partial.
```
```

Note now that  $C^0(Y_0, L^1X_0)/\text{Ker } d^1\partial$  is computed solely with the help of the left square of the commutative diagram of 4.26. It follows in particular that one can also compute it in any diagram of the same type having the same left square. Consider in particular the functor  $L^1X_0/L^1Y_0$  above  $S_0$  defined by

```
```text
\text{Hom}_{S_0}(T, L^0X/L^0Y) = \text{Hom}_{S_0}(T, L^0X) / \text{Hom}_{S_0}(T, L^0Y).
```
```

One has a commutative diagram

$$\begin{array}{ccccccc} \text{\texttt{````text}} \\ 0 \rightarrow C^0(Y_0, L_0^*Y) & \rightarrow & C^0(Y_0, L_0^*X) & \rightarrow & C^0(Y_0, L_0^*X/L_0^*Y) & \rightarrow & 0 \\ & \downarrow \partial & \downarrow \partial & & \downarrow \partial & & \\ 0 \rightarrow C^1(Y_0, L_0^*Y) & \rightarrow & C^1(Y_0, L_0^*X) & \rightarrow & C^1(Y_0, L_0^*X/L_0^*Y) & \rightarrow & 0, \\ \text{\texttt{````}} \end{array}$$

whence by the preceding remark:

**Corollary 4.31.** *Let  $Y$  be as in 4.27; the set of conjugates of  $Y$  by sections of  $X$  over  $S$  inducing the unit section of  $X_J$  is isomorphic to*

*III.III.4.31*

$$\text{\texttt{````text}} \\ E = \partial(C^0(Y_0, L_0^*X/L_0^*Y)) = C^0(Y_0, L_0^*X/L_0^*Y) / H^0(Y_0, L_0^*X/L_0^*Y).$$

**Corollary 4.32.** *Suppose moreover  $S_0$  affine and  $\omega^{11}_{Y_0/S_0}$  finite locally free. [N.D.E-III-127] If one denotes  $F_0 = [\text{Lie}(X_0/S_0)/\text{Lie}(Y_0/S_0)] \otimes_{0_{S_0}} J$ , one has  $E = \Gamma(S_0, F_0)/H^0(Y_0, F_0)$ .*

*III.III.4.32*

[N.D.E-III-128] Indeed, since  $\omega^{11}_{Y_0/S_0}$  is finite locally free, as is  $\omega^{11}_{X_0/S_0}$  (since  $X$  is supposed smooth over  $S$ ), one has, by 0.6:

$$\text{\texttt{````text}} \\ L_0^*Y = W(\text{Lie}(Y_0/S_0) \otimes_{0_{S_0}} J) \quad \text{and} \quad L_0^*X = W(\text{Lie}(X_0/S_0) \otimes_{0_{S_0}} J).$$

On the other hand, by 4.25, one has an exact sequence of  $Y_0 - 0_{S_0}$ -modules:

$$\text{\texttt{````text}} \\ 0 \rightarrow K \rightarrow \omega^1_{X_0/S_0} \xrightarrow{\phi} \omega^1_{Y_0/S_0} \rightarrow 0$$

(where  $K = \text{Ker}(\phi)$ ). Since  $\omega^{11}_{Y_0/S_0}$  and  $\omega^{11}_{X_0/S_0}$  are finite locally free, one has a locally split exact sequence:

$$\text{\texttt{````text}} \\ 0 \rightarrow \text{Lie}(Y_0/S_0) \otimes_{0_{S_0}} J \rightarrow \text{Lie}(X_0/S_0) \otimes_{0_{S_0}} J \rightarrow F_0 \rightarrow 0.$$

*original page 157*

It follows that one has an exact sequence of  $Y_0 - 0_{S_0}$ -modules:

$$\begin{array}{l} \\ 0 \xrightarrow{\quad} L^1_{Y_0} \xrightarrow{\quad} L^1_{X_0} \xrightarrow{\quad} W(F_0). \\ \end{array}$$

By the reasoning that served us to prove 4.31, we can compute  $E$  as the image of the composite map

$$\text{\texttt{````text}} \\ C^0(Y_0, L_0^*X) \xrightarrow{\pi} C^0(Y_0, W(F_0)) \xrightarrow{\partial} C^1(Y_0, W(F_0)).$$

Now the map  $\pi$  above is the map  $\Gamma(S_0, \text{Lie}(X_0/S_0) \otimes_{0_{S_0}} J) \rightarrow \Gamma(S_0, F_0)$ . Hence,  $S_0$  being affine,  $\pi$  is surjective and one finds indeed the announced result.

**Corollary 4.33.** *Let  $S, I, J$  and  $X$  be as in 4.21, and let  $Y$  be a diagonalizable subgroup of  $X$ . Suppose  $\omega^{11}_{Y_0/S_0}$  finite locally free and  $S_0$  affine. [N.D.E-III-129] The set of subgroups of  $X$  conjugate*

to  $Y$  by a section of  $X$  over  $S$  inducing the unit section of  $X_J$  is isomorphic to\*

<!-- label: III.III.4.33 -->

```

```text
E = Γ(S₀, [Lie(X₀/S₀) / Lie(X₀/S₀)^{ad(Y₀)}] ⊗_{Γ(S₀, O_{S₀})} Γ(S₀, J))
```

```

\*[<sup>N.D.E-III-130</sup>] that is, isomorphic to  $L^{\{X\}_0}(Y_0)/H^{\{0\}}(Y_0, L^{\{X\}_0})$ .\*

Indeed, one writes by I 4.7.3 (cf. 2.13):

```

$$
Lie(X_0/S_0) = Lie(X_0/S_0)^{ad(Y_0)} \oplus R.
$$

```

Since  $Y_0$  is commutative one has  $Lie(Y_0/S_0) \subset Lie(X_0/S_0)^{ad(Y_0)}$ , hence

```

```text
F₀ = [Lie(X₀/S₀)^{ad(Y₀)} / Lie(Y₀/S₀)] ⊗ J ⊗ R ⊗ J,
F₀^{ad(Y₀)} = [Lie(X₀/S₀)^{ad(Y₀)} / Lie(Y₀/S₀)] ⊗ J.
```

```

<!-- original page 158 -->

By 4.32, one has therefore  $E \simeq \Gamma(S_0, R \otimes J)$ . Returning to the definition of  $R$ , one is done.

**Corollary 4.34.** \*Let  $S, I, J$  and  $X$  be as in 4.21, and let  $Y$  be a diagonalizable subgroup of  $X$ . Suppose  $\omega^1_{Y_0/S_0}$  finite locally free and  $S_0$  affine.[<sup>N.D.E-III-131</sup>] If  $x \in X(S)$  induces the unit section of  $X_J$  and normalizes  $Y$ , then it centralizes  $Y$ .\*

<!-- label: III.III.4.34 -->

This results immediately from comparison of the preceding corollary and 2.14. Indeed, 4.33 shows that the elements of  $C^0(Y_0, L^{\{X\}_0})$  which globally preserve  $Y$  are the elements of  $H^{\{0\}}(Y_0, L^{\{X\}_0})$ , and one has seen in 2.14 that these are precisely those which act trivially on the canonical immersion  $Y \rightarrow X$ .

**4.35.** Let us return to the general situation of 4.21 and suppose  $Y_J$  smooth over  $S_J$ . Then, by 4.25 (ii), one has an exact sequence of  $Y_0$ - $S_0$ -modules:

```

$$
(\ast) \quad 0 \rightarrow Lie(Y_0/S_0) \rightarrow Lie(X_0/S_0) \rightarrow n^{\vee}_{Y_0/X_0} \rightarrow 0
$$

```

and they are finite locally free  $S_0$ -modules.

On the other hand, by SGA 1, II 4.10, every subscheme  $Y$  of  $X$  lifting  $Y_J$  and flat over  $S$  will be smooth over  $S$ . [<sup>N.D.E-III-132</sup>] Suppose moreover  $S_0$  and  $Y_J$  affine. Then, since  $n^{\vee}_{Y_0/X_0}$  is a locally free  $S_0$ -module, the sequence  $(\ast)$  remains exact when one applies  $\otimes_{S_0} J$  to it, and then takes the inverse image on  $Y^n$ , and as the  $Y^n$  are affine, one therefore obtains an exact sequence of complexes of abelian groups:

```

```text
0 → C*(Y₀, L₀^Y) → C*(Y₀, L₀^X) → d* → C*(Y₀, N₀) → 0
```

```

and in particular, a commutative diagram with exact rows

```

```text
0 → C¹(Y₀, L₀^Y) → C¹(Y₀, L₀^X) → d¹ → C¹(Y₀, N₀) → 0
    | ∂          | ∂          | ∂
    ↓            ↓            ↓
0 → C²(Y₀, L₀^Y) → C²(Y₀, L₀^X) → d² → C²(Y₀, N₀) → 0.
```

```

Let now  $Y, Y'$  be two subgroups of  $X$  lifting  $Y_J$  and flat, hence smooth, over  $S$ . As  $Y_J$  is affine, then, by 0.15,  $Y$  and  $Y'$  are isomorphic as schemes extending  $Y_J$ , i.e. there exists an isomorphism of  $S$ -schemes

$$f : Y \xrightarrow{\sim} Y'$$

<!-- original page 159 -->

inducing the identity on  $Y_J$ . On the one hand, by 1.2.4,  $f$  defines an element  $a$  of  $C^1(Y_0, L^X_0)$  such that  $f(y) = a(y_0)y$ , for every  $y \in Y(S)$ ,  $S' \rightarrow S$ , and by 4.27 (i), one has

$$d^1(a) = d(Y, Y').$$

Moreover, since  $Y, Y'$  are subgroups of  $X$ , the above element belongs to  $Z^1(Y_0, N_0)$  (cf. 4.21). Then  $\partial a$  is an element of  $Z^2(Y_0, L^Y_0)$  whose image  $\bar{\partial}a$  in  $H^2(Y_0, L^Y_0)$  depends only on the class  $\bar{d}(Y, Y') \in H^1(Y_0, N_0)$ ; this being the definition of the connecting map  $\partial^1 : H^1(Y_0, N_0) \rightarrow H^2(Y_0, L^Y_0)$ , one has therefore:

$$\partial^1(\bar{d}(Y, Y')) = \bar{\partial}a.$$

On the other hand, let us transport by  $f$  the group structure of  $Y'$  and let  $Y_1$  be the group obtained (which thus has  $Y$  as underlying scheme), that is, the group law  $\mu_1$  of  $Y_1$  is defined by: for every  $S' \rightarrow S$  and  $x, y \in Y(S')$ ,

$$\mu_1(x, y) = f^{-1}(f(x)f(y)).$$

By 3.5.1,  $Y_1$  defines a cocycle  $\delta(Y, Y_1) \in Z^2(Y_0, \text{Lie}(Y_0/S_0))$  such that, for every  $S' \rightarrow S$  and  $x, y \in Y(S')$ , one has

$$\delta(Y, Y_1)(x_0, y_0)xy = \mu_1(x, y) = f^{-1}(f(x)f(y)).$$

Set  $b = \delta(Y, Y_1)$ . For every  $S' \rightarrow S$  and  $x, y \in Y(S')$ , one has  $(b(x_0, y_0)xy)_0 = x_0y_0$  and therefore one obtains that  $f(b(x_0, y_0)xy)$  equals, on the one hand,  $a(x_0y_0)b(x_0, y_0)xy$  and, on the other hand,

$$f(x)f(y) = a(x_0)x a(y_0)y = a(x_0) \text{Ad}(x_0)(a(y_0))xy.$$

Comparing the two expressions, one obtains that  $b(x_0, y_0)$  equals

$$a(x_0y_0)^{-1} a(x_0) \text{Ad}(x_0)(a(y_0)) = \text{Ad}(x_0)(a(y_0)) - a(x_0y_0) + a(x_0) = (\partial a)(x_0, y_0),$$

i.e.  $\delta(Y, Y_1) = \partial a$ . We have thus obtained:

**Proposition 4.35.1.** [N.D.E-III-132] \*Under the hypotheses of 4.21, suppose moreover  $S_0$  affine and  $Y_J$  smooth over  $S_J$  and affine. Let  $Y, Y'$  be two subgroups of  $X$  lifting  $Y_J$  and flat (hence smooth) over  $S$ , let  $f : Y \xrightarrow{\sim} Y'$  be an isomorphism of  $S$ -schemes inducing the identity on  $Y_J$ , denote by  $Y_1$  the group obtained by transporting via  $f$  the group structure of  $Y'$ . Then one has\*

<!-- label: III.III.4.35.1 -->

$$\partial^1(d^-(Y, Y')) = \delta(Y, Y_1).$$

...

**\*\*Proposition 4.36.\*\*** \*Under the hypotheses of 4.21, suppose moreover  $Y_J$  smooth over  $S_J$  and  $S_{\{0\}}$  affine. The set of sub- $S$ -groups  $Y$  of  $X$  flat (or smooth) over  $S$ , reducing to  $Y_J$ , modulo conjugation by sections of  $X$  over  $S$  inducing the unit section of  $X_J$ , is either empty, or a principal homogeneous set under the group\*

```

\*for every  $n \geq 0$ , there exists a sub- $S$ -group of  $X$ , flat over  $S$ , reducing to  $Y_{\{0\}}$ .\*

**\*\*4.38.\*\*** It remains to relate the three constructions which we have made in this Exposé. To avoid inessential complications, we shall place ourselves in the following situation:  $S_{\{0\}}$  is the spectrum of a field  $k$ ,  $S$  is the spectrum of the dual numbers  $D(k)$ ,  $G$  is an  $S$ -group smooth over  $S$ ,  $K$  a sub- $S$ -group, smooth over  $S$  and affine.

<!-- original page 161 -->

[<sup>N.D.E-III-136</sup>] Denote  $g_{\{0\}} = \text{Lie } G_{\{0\}}$  (which here equals  $\Gamma(S_{\{0\}}, \text{Lie } G_{\{0\}}) = \text{Lie}(G_{\{0\}}/S_{\{0\}})(S_{\{0\}})$ ) and  $k_{\{0\}} = \text{Lie } K_{\{0\}}$ . One has an exact sequence of  $k$ -vector spaces[<sup>N.D.E-III-137</sup>]:

```

```text
0 → k0 → g0 → d → n{K0/G0}v → 0,
```

```

giving rise to an exact cohomology sequence:

```

```text

```

$$\begin{array}{ccccccc} 0 & \rightarrow & H^0(K_0, k_0) & \xrightarrow{i^0} & H^0(K_0, g_0) & \xrightarrow{d^0} & H^0(K_0, g_0/k_0) \\ & & \xrightarrow{\partial^0} & H^1(K_0, k_0) & \xrightarrow{i^1} & H^1(K_0, g_0) & \xrightarrow{d^1} & H^1(K_0, n_{\{K_0/G_0\}^v}) & \xrightarrow{\partial^1} & H^2(K_0, k_0). \end{array}$$

Now these various groups all have a geometric meaning.

a) $H^0(K_0, k_0) = \text{Lie Centr}(K_0)$ [N.D.E-III-138] by II 5.2.3.

b) $H^0(K_0, g_0) = \text{Lie Centr}_{G_0}(K_0)$ [N.D.E-III-138] (idem).

c) $H^0(K_0, g_0/k_0) = \text{Lie Norm}_{G_0}(K_0)/k_0$ [N.D.E-III-138] (idem).

d) $H^1(K_0, k_0) = \text{Lie } \operatorname{Aut}_{S_0\text{-gr.}}(K_0) / \operatorname{Im}(k_0)$, where $\operatorname{Im}(k_0)$ denotes the image of k_0 by the morphism $\text{Lie } \operatorname{Int}_0$ deduced from $\operatorname{Int}_0 : K_0 \rightarrow \operatorname{Aut}_{S_0\text{-gr.}}(K_0)$. Indeed, it follows from 2.1 (ii), applied to $Y = X = K$ and $f_0 = \operatorname{id}_{K_0}$, that $Z^1(K_0, k_0)$ is the group of infinitesimal automorphisms of the S_0 -group K_0 , and that $H^1(K_0, k_0)$ is obtained by quotienting by inner infinitesimal automorphisms, i.e. by the image of k_0 . Moreover, by II 4.2.2, one also has $Z^1(K_0, k_0) = \text{Lie } \operatorname{Aut}_{S_0\text{-gr.}}(K_0)$ [N.D.E-III-139].

<!-- original page 162 -->

e) $H^1(K_0, g_0)$ is, by 2.1 (ii), the group of deviations between homomorphisms $K \rightarrow G$ extending the canonical immersion $i_0 : K_0 \rightarrow G_0$, modulo the deviations obtained by the action of the inner automorphisms of G defined by elements of $G(S)$ giving the unit of $G(S_0)$ (that is, elements of g_0).

f) $H^1(K_0, n_{\{K_0/G_0\}})$ is, by 4.36, the group of deviations between subgroups K' of G extending K_0 and flat over S (hence smooth over S , cf. SGA 1, II 4.10), modulo the deviations obtained by the action of the inner automorphisms of G constructed as previously.

g) $H^2(K_0, k_0)$ is, by 3.5 (ii), the group of deviations between group structures on K extending that of K_0 , modulo the S -automorphisms of K inducing the identity on K_0 .

We now propose to show how one can make explicit the six morphisms of the preceding exact sequence in the geometric interpretation we have just given.

1. i^0 and d^0 are nothing other than the morphisms obtained by passage to the Lie algebra (then by passage to the quotient for d^0), starting from the canonical monomorphisms:

$$\begin{array}{l} \text{``text} \\ \text{Centr}(K_0) \rightarrow \text{Centr}_{G_0}(K_0) \rightarrow \text{Norm}_{G_0}(K_0). \\ \text{``} \end{array}$$

This indeed results immediately from the definition of the identifications (a), (b), and (c).

1. One constructs ∂^0 as follows. Let $\bar{x} \in \text{Lie Norm}_{G_0}(K_0)/k_0$. Lift it to $x \in \text{Lie Norm}_{G_0}(K_0) \subset \text{Norm}_{G_0}(K)(S)$. Then $\operatorname{Int}(x)$ defines an automorphism of K inducing the identity on K_0 , hence an element of $\operatorname{Aut}_{S_0\text{-gr.}}(K_0)$. Denote $\operatorname{Int}(\bar{x})$ the image of this element in $\operatorname{Aut}_{S_0\text{-gr.}}(K_0)/\operatorname{Im}(k_0)$. Then one has:

<!-- original page 163 -->

$$\begin{array}{l} \$\$ \\ (\text{last}) \quad \partial^0(\bar{x}) = -\operatorname{Int}(\bar{x}) = \operatorname{Int}(\bar{x}^{-1}). \\ \$\$ \end{array}$$

Indeed, let us compute the element of $\operatorname{Aut}_{S_0\text{-gr.}}(K_0)$ defined by $\operatorname{Int}(x)$. It will correspond by definition to an element a of $Z^1(K_0, k_0)$ such that

$$\begin{array}{l} \text{``text} \\ x y x^{-1} = a(y_0) y, \quad \text{for every } y \in K(S'), S' \rightarrow S. \\ \text{``} \end{array}$$

But this can also be written $a(y_0) = x y x^{-1} y^{-1} = x - \operatorname{Ad}(y)x = -\partial^0(x)(y_0)$, whence $a = -\partial^0(x)$.

[N.D.E-III-140] On the other hand, the image of $x \in \text{Lie Norm}_{G_0}(K_0) \subset g_0$ by ∂^0 is an

element of $Z^1(K_0, k_0)$, whose image $\bar{\partial}(x)$ in $H^1(K_0, k_0)$ depends only on $\bar{x}$, and by definition of the connecting map ∂ , one has

$$\partial(\bar{\partial}(x)) = \bar{\partial}(\partial(x));$$

combined with the equality $\partial = -\partial(x)$, this proves $(\ast)$.

[^N.D.E-III-141] Denote $i : K \rightarrow G$ the canonical immersion. Let $\bar{u}$ be an element of $H^1(K_0, k_0)$, image of a

$$u \in \text{Lie Aut}_{S_0\text{-gr.}}(K_0) \subset \text{Aut}_{S\text{-gr.}}(K).$$

Then one has:

$$(**) \quad i^1(\bar{u}) = d^-(i, i \circ u),$$

where $\bar{d}(i, i \circ u)$ is the class defined in 2.1.1.

Indeed, u is the image of an element $v \in Z^1(K_0, k_0)$ such that $u(y) = v(y_0)y$, and $i^1(\bar{u})$ is the image in $H^1(K_0, g_0)$ of the cocycle $i \circ v \in Z^1(K_0, g_0)$.

Now, since i is a morphism of groups, the equality $u(y) = v(y_0)y$ entails $iu(y) = iv(y_0)i(y)$. It follows that $i \circ v = d(i, i \circ u)$, whence $(\ast)$.

1. Let $i' : K \rightarrow G$ be a morphism of groups lifting i_0 , let $d(i, i')$ be the class defined in 2.1.1, and let $d(K, i'(K)) \in C^1(K_0, n_{K_0/X_0})$ be the deviation defined in 4.5.1; by 4.21, $d(K, i'(K))$ belongs to $Z^1(K_0, n_{K_0/X_0})$. Denote $\bar{d}(K, i'(K))$ its image in $H^1(K_0, n_{K_0/X_0})$. Then, by 4.27 (i), one has:

<!-- original page 164 -->

$$(\dagger) \quad d^1(d^-(i, i')) = d^-(K, i'(K)).$$

1. Finally, let K' be a subgroup of G lifting K_0 and flat, hence smooth, over S . We have supposed that K_0 is affine. Then one knows that K and K' are isomorphic as schemes extending K_0 (cf. 0.15), hence there exists an isomorphism of S -schemes

$$f : K \xrightarrow{\sim} K'$$

inducing the identity on K_0 . Let us transport by f the group structure of K' and let K_1 be the group obtained (which thus has K as underlying scheme), that is, the group law μ_1 of K_1 is defined by: for every $S' \rightarrow S$ and $x, y \in K(S')$,

$$\mu_1(x, y) = f^{-1}(f(x)f(y)).$$

[^N.D.E-III-142] By 3.5.1, K_1 defines a cocycle $\delta(K, K_1) \in Z^2(K_0, k_0)$ such that, for every $S' \rightarrow S$ and $x, y \in K(S')$, one has

$$\delta(K, K_1)(x_0, y_0) \cdot xy = \mu_1(x, y) = f^{-1}(f(x)f(y)).$$

Then, by 4.35.1, one has:

```

```text
(‡) $\partial^1(d^-(K, K')) = \delta^-(K, K_1).$
```

```

[^N.D.E-III-65]: N.D.E.: We have corrected the original by suppressing the inadequate reference to an exercise of Bourbaki on semigroups (cf. [BAlg], § I.2, Exercises 9–13) and by indicating the role of left and right translations; see the following N.D.E.

[^N.D.E-III-66]: N.D.E.: Let $\$E\$$ be a non-empty set equipped with an associative composition law, such that every left

translation ℓ_x is bijective; fix $x_0 \in E$. There exists a unique $e \in E$ such that $x_0 \cdot e = x_0$; then $x_0 \cdot e \cdot x = x_0 \cdot x$ entails $e \cdot x = x$, for every $x \in E$. On the other hand, for every x there exists a unique x' such that $x \cdot x' = e$. Suppose moreover that there exists $b \in E$ such that the right translation r_b is injective. Then, for every x , the equality $x \cdot e \cdot b = x \cdot b$ gives $x \cdot e = x$ (i.e. e is a neutral element), and $x \cdot x' \cdot x = x = x \cdot e \cdot x'$ entails $x' \cdot x = e$, i.e. x' is the inverse of x from the left and the right, hence E is a group. Note that the hypothesis " r_b is injective" is necessary: on every set E one can define a composition law by $x \cdot y = y$, for all $x, y \in E$; then every left translation is the identity (whence the associativity of the law), but for every y one has $r_y(E) = \{y\}$, hence E is not a group if $|E| > 1$.

[^N.D.E-III-67]: N.D.E.: Since X and X_0 have the same underlying topological space and t_0 is an automorphism, t_0 is a homeomorphism, hence an affine morphism, cf. Exp. VI_B, 2.9.1 or EGA IV₄, 18.12.7.1. It thus suffices to see that if J is a nilpotent ideal of a ring Λ , and $\phi : A \rightarrow B$ a morphism of Λ -algebras, with B flat over Λ , such that $\phi \otimes_{\Lambda} (\Lambda/J)$ is bijective, then ϕ is bijective. By the "nilpotent Nakayama lemma", ϕ is surjective; moreover, B being flat over Λ , one also has $\text{Ker}(\phi) \otimes_{\Lambda} (\Lambda/J) = 0$, whence $\text{Ker}(\phi) = 0$, hence ϕ is bijective.

[^N.D.E-III-68]: N.D.E.: Indeed, by the proof of 0.7, the S -endomorphisms of X inducing the identity on X_J are the automorphisms $m \cdot \text{id}_X$, for m ranging over $M(X) = \text{Hom}_S(X, M)$ (for every $S' \rightarrow S$ and $x \in X(S')$, one has $(m \cdot \text{id}_X)(x) = m(x) \cdot x$). Now, by the proof of 3.1, each $m : X \rightarrow M$ factors in a unique manner through a morphism h from $Y = X^{(+)}$ to M , and therefore $m \cdot \text{id}_X$ is the automorphism u_h introduced in 1.3.1. The lemma then follows from the definition of equivalence, cf. 1.3.4 and 1.3.5.

[^N.D.E-III-69]: N.D.E.: We have added what follows.

[^N.D.E-III-70]: N.D.E.: We have added this remark, analogue of 4.5.1, to introduce the notation $\delta(\mu, \mu')$ (or $\delta(X, X')$), used in 4.38; consequently, we have also added in 3.5 (ii) above the part concerning E itself.

[^N.D.E-III-71]: N.D.E.: We have conformed to the sign conventions of the original, in order to have in 4.38 (5) the equality $\partial^1 \bar{d}(X, X') = \bar{\delta}(X, X')$ (see also N.D.E. (54)).

[^N.D.E-III-72]: N.D.E.: This is used in XXIV, 1.13.

[^N.D.E-III-73]: N.D.E.: Indeed, $\text{Aut}_{S_0\text{-gr.}}(X_0)$ acts by group automorphisms on the abelian group $H^2(X_0, \text{Lie}(X_0/S_0))$, hence the orbit of 0 is the singleton $\{0\}$; consequently the quotient set is a singleton if and only if $H^2(X_0, \text{Lie}(X_0/S_0)) = \{0\}$.

[^N.D.E-III-74]: N.D.E.: One has $\text{Coker}(j) = B' \sqcup_{\emptyset} 0 = A \sqcup_{A'} 0 = A'$, and one sees that $\text{Ker}(j) \simeq \text{Ker}(i) = 0$ by reasoning "as if $\mathcal{C}$ were a category of modules"; for a proof solely in terms of arrows, see for example [Fr64], Th. 2.5.4 (*).

[^N.D.E-III-75]: N.D.E.: In what follows, we have replaced A by B and detailed the end of the argument.

[^N.D.E-III-76]: N.D.E.: We have rewritten the statement to be exactly in the setting of the application made of it in 4.3; moreover, we have detailed the proof, following the indications given by M. Demazure.

[^N.D.E-III-77]: N.D.E.: To lighten the statement, we have added here the hypothesis that G be quasi-coherent, and deferred to the proof the remark that this hypothesis is automatically satisfied; we have detailed the proof accordingly.

[^N.D.E-III-78]: N.D.E.: See also [BAC], § III.5, th. 1.

[^N.D.E-III-79]: N.D.E.: We have detailed what follows and added Corollary 4.3.1. Recall that "pseudo-torsor" is synonymous with "formally principal homogeneous".

[^N.D.E-III-80]: N.D.E.: We have added this complement, useful to prove point (ii) of Proposition 4.8.

[^N.D.E-III-81]: N.D.E.: We have added the numbering 4.5.0 to mark the return to the original.

[^N.D.E-III-82]: N.D.E.: We have corrected the following sentence.

[^N.D.E-III-83]: N.D.E.: We have detailed what follows.

[^N.D.E-III-84]: N.D.E.: Here, we have denoted $H^1(Y_0, A_0)$ the "coherent" cohomology group $H^1(Y_0, A_0)$ of the $S_0(Y_0)$ -module A_0 , in order to distinguish it from the "Hochschild" cohomology groups $H^i(Y_0, M_0)$ (S_0 an S_0 -group, M_0 an S_0 -module) which will be considered starting from 4.16.

[^N.D.E-III-85]: N.D.E.: We have placed here this remark, which replaces Remark 4.7 of the original.

[^N.D.E-III-86]: N.D.E.: We have corrected "closed subschemes" to "subschemes".

[^N.D.E-III-87]: N.D.E.: We have kept, for the record, Remark 4.6 of the original, in which the definition of "locally complete intersection" does not appear. We have added next the "good" definition, drawn from SGA 6, VII 1.4 (which replaces that of EGA IV₄, 16.9.2), and the proof of the three results stated in the remark.

[^N.D.E-III-88]: N.D.E.: In order to prove the results stated in Remark 4.6, we have added Lemmas 4.6.3, 4.6.4 and Proposition 4.6.5, as well as Remark 4.6.6.

[^N.D.E-III-89]: N.D.E.: We have inserted here this remark, used in the following proposition; it appeared in 4.10 of the original.

[^N.D.E-III-90]: N.D.E.: In the original, this was indicated in Remark 4.10, under the additional hypothesis that Y' was locally complete intersection in X' . This hypothesis figured also, consequently, in statements 4.12–4.14; it seems in fact superfluous, and we have suppressed it from the above-mentioned statements.

[^N.D.E-III-91]: N.D.E.: We have suppressed the hypothesis that I be nilpotent, which appears superfluous (cf. the proof).

[^N.D.E-III-92]: N.D.E.: See also 4.27 further on.

[^N.D.E-III-93]: N.D.E.: See also EGA IV₄, 16.4.21. Recall that if U is an affine open of X such that $Y \cap U$ is defined by the ideal I of $A = 0_X(U)$, if one denotes by d the differential $A \rightarrow \Gamma(U, \Omega^1_{X/S})$, and if $x \in I$, then $d(x + I^2)$ is the element $d(x) \otimes 1$ of $\Gamma(U, \Omega^1_{X/S}) \otimes_A (A/I)$.

[^N.D.E-III-94]: N.D.E.: We have done these verifications below.

[^N.D.E-III-95]: N.D.E.: On the one hand, we have suppressed the hypothesis that I be nilpotent, i.e. that X_0 have the same underlying topological space as X ; on the other hand, we have detailed the following sentence.

[^N.D.E-III-96]: N.D.E.: We have detailed what follows.

[^N.D.E-III-97]: N.D.E.: We have added what follows.

[^N.D.E-III-98]: N.D.E.: Cf. N.D.E. (93).

[^N.D.E-III-99]: N.D.E.: From 4.17 on, we shall apply this to the case where X is an S -group, $g : X \times_S X \rightarrow X$ the multiplication, Y a subscheme of X such that Y_J is a subgroup of X_J , $Y' = Y \times_S Y$, and to the two morphisms $Y^3 \rightarrow X^2$ which send (y_1, y_2, y_3) to $(y_1 y_2, y_3)$, resp. $(y_1, y_2 y_3)$. In this case, the comparison of the above obstructions will show that the obstruction to Y being a subgroup of X resides in a certain cohomology group (Hochschild) $H^2(Y_0, N_0)$.

[^N.D.E-III-100]: N.D.E.: We have suppressed the hypothesis " Y_0 's locally complete intersection in X_0 '", superfluous by 4.8.0; on the other hand, we have added that $a_{g_0}(f_0)$ is "functorial in T ", this playing a crucial role in the proof of 4.17.

[^N.D.E-III-101]: N.D.E.: We have detailed the proof, to make visible the "functoriality in T " of a_{g_0} .

[^N.D.E-III-102]: N.D.E.: The situation will simplify from 4.16 on: one will restrict to schemes flat over S , Y will be a flat S -group and $Y' = Y \times_S Y$; one will then obtain S_0 -functors N_0 and N_0' .

[^N.D.E-III-103]: N.D.E.: We have added this remark, used in the proof of 4.17.

[^N.D.E-III-104]: N.D.E.: We have kept the notation of the original, denoting $f : A' \rightarrow C$ and $g : A \rightarrow A'$ the morphisms of rings corresponding to $f : T \rightarrow X'$ and $g : X' \rightarrow X$. This explains the formula

$\mathcal{C}(X, Y, g \circ f)(\bar{x} \otimes 1) = f(g(x))$, for $x \in I_Y$.

[^N.D.E-III-105]: N.D.E.: We have added in the statement the hypothesis that Y be locally of finite presentation over S , and have given the following proof, more direct than the one sketched in the original. To be complete, let us also detail the latter. As in the proof given above, one reduces first to the case where $S = \operatorname{Spec}(k)$, k being an algebraically closed field. By EGA IV₄, 16.9.10 and 19.3.2, it suffices to see that, for every $y \in Y$, the completion of the local ring $\hat{O}_{Y,y}$ is the quotient of a complete noetherian local ring by a regular sequence. By loc. cit., 19.3.3, the set of $y \in Y$ satisfying this property is an open U of Y ; since Y is of finite type over k , it suffices to show that U contains every closed point. Since Y is a k -group it suffices, by a translation argument, to show that the property is true for the completion of $\hat{O}_{Y,e}$, that is, for the "formal group" $\hat{Y}$ corresponding to Y (cf. Exp. VII_B). Now, since X is smooth, the affine algebra $\hat{A}(\hat{X})$ is an algebra of formal power series $k[[X_1, \dots, X_n]]$, and one concludes with the help of the Dieudonné structure theorem which shows that $\hat{A}(\hat{Y})$ is isomorphic to a quotient $k[[X_1, \dots, X_{r+s}]]/(X^{p^{n_1}}_1, \dots, X^{p^{n_r}}_r)$, where p is the characteristic exponent of k and $r + s \leq n$, cf. VII_B, Remark 5.5.2 (b).

[^N.D.E-III-106]: N.D.E.: We have reorganized 4.16 by regrouping there, on the one hand, the hypotheses stated at the end of 4.15 and, on the other hand, the definition of the obstruction δY .

[^N.D.E-III-107]: N.D.E.: We have corrected the original by adding "flat".

[^N.D.E-III-108]: N.D.E.: See 4.25 further on.

[^N.D.E-III-109]: N.D.E.: We have modified 4.17 and 4.18 taking into account the additions made in 4.16.

[^N.D.E-III-110]: N.D.E.: In the original, one finds $\delta Y' - DY = -\partial d(Y, Y')$, but their ∂ is the opposite of the differential ∂^1 defined in I, 5.1.

[^N.D.E-III-111]: N.D.E.: We have slightly modified the notations, and detailed the beginning of the argument.

[^N.D.E-III-112]: N.D.E.: We have replaced a, b by ab, b to make visible that $V(P)$ comes by inverse image on Y^2_0 from the multiplication morphism $V_{Y_0} \times_{S_0} V_{Y_0} \rightarrow V_{Y_0}$.

[^N.D.E-III-113]: N.D.E.: We have changed the signs to make them compatible with I 5.1.

[^N.D.E-III-114]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-III-115]: N.D.E.: We have suppressed the hypothesis that I be nilpotent, which appears superfluous.

[^N.D.E-III-116]: N.D.E.: The question of whether the preceding set, modulo conjugation by the $x \in X(S)$ inducing the unit of $X(S_J)$, is principal homogeneous under $H^1(Y_0, N_0)$, occupies nos 4.23 to 4.36.

[^N.D.E-III-117]: N.D.E.: We have corrected $\partial DY'$ to $\delta Y'$.

[^N.D.E-III-118]: N.D.E.: Cf. N.D.E. (110).

[^N.D.E-III-119]: N.D.E.: We have detailed what precedes; this shows that the following isomorphism is valid without flatness hypothesis; on the other hand, since 4.16, we have restricted ourselves to S -schemes $f: T \rightarrow S$ flat over S to ensure that the group $\operatorname{Hom}_{\{0, T\}}(n_{Y_0/X_0} \otimes_{\{0, S_0\}} 0_{T_0}, j_{0,T})$, in which the obstruction $\mathcal{C}(X, Y, f)$ resides, coincides with $N_0(T_0)$ (cf. the end of 4.16).

[^N.D.E-III-120]: N.D.E.: With the notation of I 5.3, assuming Y_0 affine over S_0 .

[^N.D.E-III-121]: N.D.E.: We have replaced $Z^1(Y_0, N_0)$ by $B^1(Y_0, N_0)$, since the proof shows that Γ is a subgroup of $B^1(Y_0, N_0)$, cf. 4.27–4.29.

[^N.D.E-III-122]: N.D.E.: We have detailed the proof, taking into account the additions made in Exp. I, § 6.8.

[^N.D.E-III-123]: N.D.E.: We have detailed the original, to make visible that one has an exact sequence of Y_0 - S_0 -modules.

[^N.D.E-III-124]: N.D.E.: This results from the definition of $d: n_{Y_0/X_0} \rightarrow \Omega^1_{X_0/S_0}$ (cf. 4.25) and from that of $v_{i_{Y_0}}$ (cf. 4.8).

[^N.D.E-III-125]: N.D.E.: We have added point (i) below, which will be useful in 4.35.1 and then in 4.38 (4) and (5).

[^N.D.E-III-126]: N.D.E.: Recall that $L'_X = \prod_{S \in S} L^X_S$.

[^N.D.E-III-127]: N.D.E.: We have corrected $\text{Lie}(Y_S/S)$ to $\omega^1_{Y_S/S}$.

[^N.D.E-III-128]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-III-129]: N.D.E.: We have added the hypothesis on $\omega^1_{Y_S/S}$ and replaced the hypothesis "\$S\$ affine" by "\$S\$ affine".

[^N.D.E-III-130]: N.D.E.: We have added what follows, cf. 4.34.

[^N.D.E-III-131]: N.D.E.: Cf. N.D.E. (129).

[^N.D.E-III-132]: N.D.E.: We have added what follows and Proposition 4.35.1, implicit in the original, cf. 4.38 (5).

[^N.D.E-III-133]: N.D.E.: This also follows from the proof of 4.32.

[^N.D.E-III-134]: N.D.E.: For example, 4.37 is used in Exposé IX to prove statements 3.2 bis and 3.6 bis.

[^N.D.E-III-135]: N.D.E.: We have replaced $\text{Hom}_0(n_{Y/X}, I^{n+1}/I^{n+2})$ by $n^{\vee}_{Y/X} \otimes_0 I^{n+1}/I^{n+2}$, in accordance with Remark 4.22.

[^N.D.E-III-136]: N.D.E.: We have slightly modified the original in what follows. In particular, we have replaced X by G and Y by K , and we have denoted g and k their Lie algebras. On the other hand, we have written explicitly $H^i(K, \cdot)$ instead of the abbreviation $H^i(\cdot)$ of the original.

[^N.D.E-III-137]: N.D.E.: Equipped with the adjoint action of K .

[^N.D.E-III-138]: N.D.E.: Since the formation of centralizers and normalizers commutes with base change (cf. I 2.3.3.1), we have written $\text{Centr}(K)$ instead of $\text{Centr}(K)_0$ in the original, and similarly $\text{Centr}_G(K)$ and $\text{Norm}_G(K)$ instead of $\text{Centr}_G(K)_0$ and $\text{Norm}_G(K)_0$.

[^N.D.E-III-139]: N.D.E.: And this is the Lie algebra $\text{Der}_k(k)$ of derivations of k ; hence $H^1(K, k)$ is the quotient of $\text{Der}_k(k)$ by inner derivations (i.e. by the image of $\text{ad} : k \rightarrow \text{Der}_k(k)$).

[^N.D.E-III-140]: N.D.E.: We have added the following sentence.

[^N.D.E-III-141]: N.D.E.: We have detailed the original in what follows, and in $(\ast\ast)$ we have corrected $u \circ i$ to $i \circ u$.

[^N.D.E-III-142]: N.D.E.: We have modified the original in what follows, taking into account the additions made in 3.5.1 and 4.35.1.

[^N.D.E-III-143]: N.D.E.: Additional references cited in this Exposé.

Exposé IV. Topologies and sheaves

<!-- label: IIII.IV -->

by M. Demazure[^IV-0-1]

<!-- original page 160 -->

[^N.D.E-IV-0]

This Exposé is intended to acquaint the reader with the essentials of the language of topologies and sheaves (without cohomology), particularly convenient in questions of passage to the quotient (among others).

The first three sections develop the language of passage to the quotient. The fourth, which is the central part, is the

exposition of the theory of sheaves, oriented principally towards the application to questions of quotients; the fifth is an application to passage to the quotient in groups and to principal homogeneous fibered objects. The last section concerns more specifically the category of schemes, and defines various useful topologies on this category.

The reader will profitably refer to [AS], [MA], [D], and SGA 4; [D] in particular as regards the applications of topologies to the theory of descent, and SGA 4 for questions of universes (particularly mistreated in this Exposé).

1. Universal effective epimorphisms

<!-- original page 161 -->

In what follows in this Exposé, we suppose fixed a category $\mathcal{C}$.

Definition 1.1. A morphism $u : T \rightarrow S$ is called an *epimorphism* if, for every object X , the corresponding map

$$X(S) = \text{Hom}(S, X) \rightarrow X(T) = \text{Hom}(T, X)$$

is injective. One says that u is a *universal epimorphism* if for every morphism $S' \rightarrow S$, the fiber product $T' = T \times_S S'$ exists, and $u' : T' \rightarrow S'$ is an epimorphism.

<!-- label: III.IV.1.1 -->

<!-- original page 178 -->

Definition 1.2. A diagram

$$A \xrightarrow{u} B \rightrightarrows_{\{v_1, v_2\}} C$$

of maps of sets is said to be *exact* if u is injective and if its image is formed by the elements b of B such that $v_1(b) = v_2(b)$. A diagram of the same type in $\mathcal{C}$ is said to be *exact* if for every object X of $\mathcal{C}$, the corresponding diagram of sets

$$A(X) \rightarrow B(X) \rightrightarrows C(X)$$

is exact; one then also says that u makes A into a *kernel* of the pair of arrows (v_1, v_2) . Dually, a diagram

$$C \rightrightarrows_{\{v_1, v_2\}} B \xrightarrow{u} A$$

in $\mathcal{C}$ is said to be *exact* if it is exact as a diagram in the opposite category $\mathcal{C}^{\text{op}}$, i.e. if for every object X of $\mathcal{C}$, the corresponding diagram of sets

$$X(A) \rightarrow X(B) \rightrightarrows X(C)$$

<!-- original page 162 -->

is exact. One also says that u makes A into a *cokernel* of the pair of arrows (v_1, v_2) .

<!-- label: III.IV.1.2 -->

Definition 1.3. A morphism $u : T \rightarrow S$ is called an *effective epimorphism* if the fiber square $T \times_S T$ exists, and if the diagram

$$T \times_S T \rightrightarrows T \xrightarrow{u} S$$

$T \times_S T \rightrightarrows_{\{pr_1, pr_2\}} T \rightarrow S$

is exact, i.e. if u makes S into a cokernel of (pr_1, pr_2) . One says that u is a universal effective epimorphism *if for every morphism $S' \rightarrow S$, the fiber product $T' = T \times_S S'$ exists, and the morphism $u' : T' \rightarrow S'$ is an effective epimorphism.*

<!-- label: III.IV.1.3 -->

One evidently has the implications:

```

```text
universal effective epimorphism ⇔ effective epimorphism
 ↓ ↓
universal epimorphism ⇔ epimorphism,
```

```

but in general no other implication holds.[^N.D.E-IV-3]

Definition 1.4.0.[^N.D.E-IV-4] *We "recall" that a morphism $u : T \rightarrow S$ is said to be* squarable *if for every morphism $S' \rightarrow S$, the fiber product $T \times_S S'$ exists.*

<!-- label: III.IV.1.4.0 -->

Lemma 1.4. *Consider morphisms $U \rightarrowtail T \rightarrowtail S$. Then*

a) u, v epimorphisms $\Rightarrow uv$ epimorphism $\Rightarrow u$ epimorphism,*

b) u, v universal epimorphisms $\Rightarrow uv$ universal epimorphism, and u squarable $\Rightarrow u$ universal epimorphism.*

<!-- label: III.IV.1.4 -->

Lemma 1.4 is trivial from the definitions. From it we conclude:

Corollary 1.5. *Let $u : X \rightarrow Y$ and $u' : X' \rightarrow Y'$ be universal epimorphisms, such that $Y \times Y'$ exists; then $X \times X'$ exists and $u \times u' : X \times X' \rightarrow Y \times Y'$ is a universal epimorphism.*

<!-- label: III.IV.1.5 -->

Let us also note:

<!-- original page 163 -->

Definition 1.6.0.[^N.D.E-IV-5] *One says that an object S of $\mathcal{C}$ is* squarable *if its product with every object of $\mathcal{C}$ exists. (If $\mathcal{C}$ has a final object e , this is equivalent to saying that the morphism $S \rightarrow e$ is squarable, cf. 1.4.0.)*

<!-- label: III.IV.1.6.0 -->

Lemma 1.6. *Let $u : X \rightarrow Y$ be a morphism in $\mathcal{C}/S$; for it to be an epimorphism (resp. universal epimorphism, resp. effective epimorphism, resp. universal effective epimorphism), it suffices that the corresponding morphism in $\mathcal{C}$ be such, and this is also necessary if one supposes that S is a squarable object of $\mathcal{C}$.*

<!-- label: III.IV.1.6 -->

Immediate proof left to the reader. One uses the hypothesis " S squarable" in order to interpret the $\mathcal{C}/S$ -morphisms from an object Y of $\mathcal{C}/S$ into an object Z of $\mathcal{C}$ as the $\mathcal{C}/S$ -morphisms from Y into $Z \times S$.

Lemma 1.7. *With the notation of 1.4: u, v effective epimorphisms and v universal epimorphism $\Rightarrow uv$ effective epimorphism.*

<!-- label: III.IV.1.7 -->

To see this, one considers the diagram

```

```text
S = T = T x_S T
 ↑ ↑v ↑vx_S v
 U = U x_S U
 ^
 U x_T U
...

```

<!-- original page 164 -->

One notes that by hypothesis, row 1 and column 1 are exact, and that by virtue of 1.5 and 1.6,  $v \times_S v$  is an epimorphism ( $v$  being a universal epimorphism). The conclusion follows by an evident diagram-chase: if an element of  $X(U)$  has the same images in  $X(U \times_S U)$ , it has *a fortiori* the same images in  $X(U \times_S T)$ , hence comes from an element of  $X(T)$  since column 1 is exact. As row 1 is exact, it suffices to verify that the element under consideration has the same images in  $X(T \times_S T)$ , and since  $v \times_S v$  is an epimorphism, it suffices to verify that the images in  $X(U \times_S U)$  are the same, which is indeed the case.

**Proposition 1.8.** \*Consider morphisms  $U \rightarrow T \rightarrow S$ . Then  $u, v$  universal effective epimorphisms  $\Rightarrow uv$  universal effective epimorphism, and  $u$  squarable  $\Rightarrow u$  universal effective epimorphism.\*

<!-- label: III.IV.1.8 -->

The first implication follows at once from 1.7. For the second, one looks at the diagram (of "bisimplicial" type):

```

```text
S = T = T x_S T
↑uv  ↑   ↑
U = U x_S T = U x_S T x_S T
↑   ↑   ↑
U x_S U = U x_S U x_S T = U x_S U x_S T x_S T.
...

```

Columns 1, 2, 3 are exact by virtue of the hypothesis " uv universal effective epimorphism", row 2 is exact, since $U \times_S T \rightarrow U$ is an effective epimorphism (because it has a section over U), and the same holds for row 3 (same reason). An evident diagram-chase then shows that row 1 is exact, i.e. u is an effective epimorphism. As the hypotheses made are invariant under any change of base $S' \rightarrow S$, it follows that u is in fact a universal effective epimorphism.

Corollary 1.9. *Let $u : X \rightarrow Y$ and $u' : X' \rightarrow Y'$ be universal effective epimorphisms, such that $Y \times Y'$ exists; then $X \times X'$ exists and $u \times u' : X \times X' \rightarrow Y \times Y'$ is a universal effective epimorphism.*

<!-- label: III.IV.1.9 -->

Proof as for 1.5 by the diagram

```

```text
Y' = X'
 ↑ ↑u'
X = X x Y' = X x X'
 ↑ ↘ u x u'
 Y = Y x Y'.
...

```

<!-- original page 165 -->

**Corollary 1.10.** \*Consider a squarable morphism  $u : T \rightarrow S$ , and a change-of-base morphism  $S' \rightarrow S$  which is a universal effective epimorphism. For  $u$  to be a universal effective epimorphism, it is necessary and sufficient that  $u' : T' = T \times_S S' \rightarrow S'$  be one:\*

```

```text
T =v' T'
↑u   ↓u'
S =v  S'.

```

...

<!-- label: III.IV.1.10 -->

<!-- original page 181 -->

Only the "it suffices" requires a proof. Now if u is a universal effective epimorphism, so is vu by 1.8, and since $vu = uv$, one concludes by 1.8 that u is a universal effective epimorphism.

Remark 1.11. The same reasoning shows that in 1.10 one can replace "universal effective epimorphism" by "universal epimorphism" or "universal and effective epimorphism", or simply by "epimorphism" (and in this last case, the hypothesis " u squarable" is evidently unnecessary).

<!-- label: III.IV.1.11 -->

In the proof of 1.8 we used the following result, which deserves to be made explicit:

Proposition 1.12. Let $u : T \rightarrow S$ be a morphism that admits a section. Then u is an epimorphism, and if $T \times_S T$ exists, it is an effective epimorphism, and a universal effective epimorphism if moreover u is squarable.

<!-- label: III.IV.1.12 -->

The first assertion is contained in 1.4 a), and the third will follow at once from the second, which it will therefore suffice to establish. In fact we have a stronger conclusion: for every functor $F : C^{\circ} \rightarrow \text{Ens}$ (not necessarily representable), the diagram of sets

text
$$F(S) \rightarrow F(T) \rightrightarrows F(T \times_S T)$$

is exact. This may be considered as a particular case of the formalism of Čech cohomology (in dimension 0!), which we content ourselves with recalling here. Suppose simply that $T \times_S T$ exists; one then sets

text
$$\check{H}^0(T/S, F) = \text{Ker}(F(T) \rightrightarrows F(T \times_S T)).$$

<!-- original page 166 -->

One may evidently regard $\check{H}^0(T/S, F)$ as a contravariant functor in the argument T varying in C/S , every S -morphism $T' \rightarrow T$ defining a map

text
(+)
$$\check{H}^0(T/S, F) \rightarrow \check{H}^0(T'/S, F).$$

Fix T and T' in C/S . A well-known calculation shows that if there exists an S -morphism from T' into T , the corresponding map (+) is in fact independent of the choice of this morphism, [N.D.E-IV-6] so that $\check{H}^0(T/S, F)$ may be regarded as a functor on the category associated to the set C/S preordered by the relation of "domination" (T' dominates T if there exists an S -morphism from T' into T). In particular, if T and T' are isomorphic in this latter category, i.e. if each dominates the other, then (+) is an isomorphism of sets. This applies in particular to the case where T is the final object of C/S , i.e. essentially S itself; in any case T dominates $T' = S$, and the converse is true precisely if T/S has a section. This establishes 1.12 in the strengthened form announced.

Remark 1.13. For various applications, the notions introduced in the present Exposé, and the results stated, must be developed more generally relative to a family of morphisms $u_i : T_i \rightarrow S$ with the same target (instead of a single morphism $u : T \rightarrow S$). Thus, such a family will be said to be *epimorphic* if for every object X of C , the corresponding map

$$X(S) \rightarrow \prod_i X(T_i)$$

is injective, and one introduces in the same way the notion of an effective epimorphic *family and the "universal" variants of these notions. We shall admit, if need be, in what follows, that the results of the present Exposé extend to this more general situation.*

<!-- label: III.IV.1.13 -->

Remark 1.14. Every morphism that is at once a monomorphism and an effective epimorphism is an isomorphism.*

<!-- label: III.IV.1.14 -->

<!-- original page 167 -->

Indeed, in the notation of 1.3, the fact that $T \rightarrow S$ be a monomorphism entails that the two morphisms

```
```text
pr1, pr2 : T ×S T → T
```
```

are equal (and are isomorphisms). Now a diagram

```
```text
C →pr1 {v,v} B →u A
```
```

is exact only if u is an isomorphism, as follows immediately from the definition. [N.D.E-IV-7]

2. Descent morphisms

Let us recall the following definitions:

Definition 2.1. Let $f : S' \rightarrow S$ be a morphism such that $S'' = S' \times_S S'$ exists, and let $u' : X' \rightarrow S'$ be an object over S' . One calls* gluing datum *on X'/S' , relative to f , an S'' -isomorphism*

```
$$
c : X''_{\{1\}} \xrightarrow{\sim} X''_{\{2\}}
$$
```

where $X''_{\{i\}}$ ($i = 1, 2$) denotes the inverse image (supposed to exist) of X'/S' under the projection $\text{pr}_{\{i\}} : S'' \rightarrow S'$. One says that the gluing datum c is a* descent datum *if it satisfies the "cocycle condition"

```
$$
\text{pr}_{\{3\},\{1\}}(c) = \text{pr}_{\{3\},\{2\}}(c) \text{pr}_{\{2\},\{1\}}(c)
$$
```

<!-- label: III.IV.2.1 -->

<!-- original page 168 -->

where $\text{pr}_{\{i\},\{j\}}$ ($1 \leq j < i \leq 3$) are the canonical projections from $S'' = S' \times_S S' \times_S S'$ into S'' (N.B. one now supposes that S'' also exists), where $\text{pr}_{\{i\},\{j\}}(c)$ is the inverse image of c , considered as an S'' -morphism from $X''_{\{j\}}$ into $X''_{\{i\}}$, and where for every integer k between 1 and 3, $X''_{\{k\}}$ denotes the inverse image (supposed to exist) of X'/S' under the projection of index k , $q_{\{k\}} : S'' \rightarrow S'$.*

In the second part of the definition, we have therefore used identifications and abuses of writing in current use, [N.D.E-IV-8] which experience proves to be harmless, but which it is evidently fitting to avoid in a rigorous exposition of the theory of descent (which must precisely justify to a certain extent these common abuses of language). Such a formal exposition ([D]) has been written by Giraud (with the aim of justifying and making precise SGA 1, VII, which was never written). For a detailed exposition of the results of faithfully flat descent of which constant use will be made in the present Séminaire, one may consult SGA 1, VIII.

Let $f : S' \rightarrow S$ still be a morphism such that $S'' = S' \times_S S'$ exists, and let X be an object over S such that $X' = X \times_S S'$ and $X'' = X \times_S S''$ exist; then the inverse images of X under pr_i ($i = 1, 2$) exist and are canonically isomorphic, and consequently X'/S' is endowed with a canonical gluing datum relative to f . When S'' and $X'' = X \times_S S''$ exist, this is even a descent datum. If Y is another object over S ,

satisfying the same conditions as X/S , then for every S -morphism $X \rightarrow Y$, the corresponding S' -morphism $X' \rightarrow Y'$ is "compatible with the canonical gluing data" on X', Y' . If in particular $S' \rightarrow S$ is a squarable morphism, then

```

$$X \times_{S'} X' = X \times_S S'$$

```

is a functor from the category $\mathcal{C}/S$ into the "category of objects over S' equipped with a descent datum relative to f " – a category whose definition is left to the reader, and which is a full subcategory of the "category of objects over S' equipped with a gluing datum relative to f ".

This being so:

Definition 2.2. One says that a morphism $f : S' \rightarrow S$ is a *descent morphism* (resp. an *effective descent morphism*) if f is squarable (i.e. for every $X \rightarrow S$, the fiber product $X \times_{\{S\}} S'$ exists), and if the preceding functor $X \times_{S'} X' = X \times_S S'$ from the category $\mathcal{C}/S$ of objects over S , into the category of objects over S' equipped with a descent datum relative to f , is fully faithful (resp. an equivalence of categories).

III.IV.2.2 -->

original page 169 -->

One notes that the first of these two notions can be expressed using only the notion of gluing datum (hence without involving the triple fiber product S''), f being a descent morphism if f is squarable and $X \times_{S'} X'$ is a fully faithful functor from the category $\mathcal{C}/S$ into the category of objects over S' equipped with a gluing datum relative to f . When one makes this definition explicit, one finds that it means that for two objects X, Y over S , the following diagram of sets

```

$$(*) \quad \text{Hom}_S(X, Y) \rightarrow \text{Hom}_{S'}(X', Y') \rightrightarrows_{\{p_1, p_2\}} \text{Hom}_{S''}(X'', Y'')$$

```

original page 170 -->

is exact, where $p_i(u)$ denotes the inverse image of u in $\text{Hom}_{S'}(X', Y')$ under the projection $\text{pr}_i : S'' \rightarrow S'$, for $i = 1, 2$; indeed, the kernel of the pair (p_1, p_2) is by definition none other than the set of S' -morphisms $X' \rightarrow Y'$ compatible with the canonical gluing data.

Note that, by definition of the inverse images Y', Y'' , one has canonical bijections

```

$$\text{Hom}_{S'}(X', Y') \simeq \text{Hom}_S(X', Y) \quad \text{and} \quad \text{Hom}_{S''}(X'', Y'') \simeq \text{Hom}_S(X'', Y),$$

```

so that the exactness of the diagram $(*)$ is equivalent to that of

```

$$(**) \quad \text{Hom}_S(X, Y) \rightarrow \text{Hom}_S(X', Y) \rightrightarrows \text{Hom}_S(X'', Y),$$

```

obtained by applying $\text{Hom}_S(-, Y)$ to the diagram in $\mathcal{C}/S$:

```

$$(***) \quad X'' \rightrightarrows X' \rightarrow X$$

```

which is deduced from

```

$$S'' \rightrightarrows S' \rightarrow S$$

```

by the base change $X \rightarrow S$. This proves, taking account of 1.6, the first part of the following proposition:

****Proposition 2.3.**** *Let $f : S' \rightarrow S$ be a morphism. If it is a universal effective epimorphism, it is a descent morphism, and the converse is true if S is a squarable object of $\mathcal{C}$ (i.e. its product with every object of $\mathcal{C}$ exists).*

<!-- label: III.IV.2.3 -->

It remains to prove that if f is a descent morphism, it is a universal effective epimorphism, that is, that for every morphism $X \rightarrow S$, the diagram (xxx) is exact, i.e. for every object Z of $\mathcal{C}$, the transform of this diagram by $\text{Hom}(-, Z)$ is an exact diagram of sets. Now by hypothesis $Z \times S$ exists; let Y be the object of $\mathcal{C}/S$ that it defines; then the transform of (xxx) by $\text{Hom}(-, Z)$ is isomorphic to the transform by $\text{Hom}_{\mathcal{C}}(-, Y)$, and this last is exact by the hypothesis on f .

One may therefore apply to universal effective epimorphisms the results on descent morphisms, such as the following:

****Proposition 2.4.**** *Let $f : S' \rightarrow S$ be a descent morphism (for example a universal effective epimorphism). Then:*

a) For every S -morphism $u : X \rightarrow Y$, u is an isomorphism (resp. a monomorphism) if and only if $u' : X' \rightarrow Y'$ is.

b) Let X, Y be two subobjects of S , X' and Y' the subobjects of S' inverse images of the preceding ones. For X to be contained in Y (resp. to be equal to Y), it is necessary and sufficient that the same hold for X', Y' .

<!-- label: III.IV.2.4 -->

<!-- original page 185 -->

For (a), it follows from the definition that if u' is an isomorphism in the category of objects with gluing datum, then u is an isomorphism; now one notes at once that every isomorphism of objects over S' compatible with gluing data is an isomorphism of objects with gluing datum, i.e. its inverse is also compatible with the gluing data. For b), one is reduced to proving that if X' is contained in Y' , i.e. if there exists an S' -morphism $X' \rightarrow Y'$, then the same holds for X, Y over S . Now since $Y' \rightarrow S'$, and hence also $Y'' \rightarrow S''$, is a monomorphism, one sees that $X' \rightarrow Y'$ is automatically compatible with the gluing data, hence comes from an S -morphism $X \rightarrow Y$. Note that the proof holds more generally when one has two objects X, Y over S , with $Y \rightarrow S$ a monomorphism, and one asks whether the morphism $X \rightarrow S$ factors through Y : it suffices that $X' \rightarrow S'$ factor through Y' .

****Corollary 2.5.**** *Let $f : S' \rightarrow S$ be a universal effective epimorphism and $g : S \rightarrow T$ a morphism such that $S \times_{\{T\}} S$ exists. Suppose that $S'' = S' \times_{\{S\}} S'$ is also a fiber product of S' with itself over T , i.e. $S' \times_{\{S\}} S' \xrightarrow{\sim} S' \times_{\{T\}} S'$. Then $g : S \rightarrow T$ is a monomorphism (and conversely, of course).*

<!-- label: III.IV.2.5 -->

Indeed, consider the cartesian diagram

```

``text
S' x_S S'  □  S' x_T S'
   ↓       ↓ f
   S      →  S x_T S,
...

```

where the second horizontal arrow is the diagonal morphism. By virtue of 1.9 the second vertical arrow f is a universal effective epimorphism, by hypothesis the first horizontal arrow is an isomorphism, hence by virtue of 2.4 a) or b) at one's choice, [N.D.E-IV-9] the same holds for $S \rightarrow S \times_{\{T\}} S$, which means precisely that $g : S \rightarrow T$ is a monomorphism.

****Remark 2.6.**** *The notions introduced in 2.1, in terms of morphisms between certain inverse limits, become explicit in an obvious way in terms of the contravariant functors defined by the objects S, S', X under consideration: subject to the existence of the fiber products envisaged in 2.1, there is a one-to-one correspondence between gluing data (resp. descent data) on X'/S' relative to $S' \rightarrow S$, and gluing data (resp. descent data) for the corresponding objects in $\hat{\mathcal{C}} = \text{Hom}(\mathcal{C}^{\text{circ}}, (\text{Ens}))$. This allows one, if one wishes, to extend these notions to the case where one makes no hypothesis of existence of fiber products in $\mathcal{C}$.*

<!-- label: III.IV.2.6 -->

<!-- original page 172 -->

Remark 2.7. The notions introduced in this number generalize to the case of families of morphisms. They can on the other hand be presented in a more intrinsic manner using the notion of sieve (4.1). For these questions, the reader is referred to [D].

III.IV.2.7 -->

3. Universal effective equivalence relations

3.1. Equivalence relations: definitions

Definition 3.1.1. One calls a $\mathcal{C}$ -equivalence relation in $\mathcal{X}$ a representable subfunctor R of the functor $\mathcal{X} \times \mathcal{X}$, such that for every S in $\mathcal{C}$, $R(S)$ is the graph of an equivalence relation in $\mathcal{X}(S)$.

III.IV.3.1.1 -->

This definition applies in particular to the category $\hat{\mathcal{C}}$. If one considers $\mathcal{X}$ as an object of $\hat{\mathcal{C}}$, one then sees that a $\hat{\mathcal{C}}$ -equivalence relation in $\mathcal{X}$ is nothing other than a subfunctor R of $\mathcal{X} \times \mathcal{X}$ such that $R(S)$ is the graph of an equivalence relation in $\mathcal{X}(S)$ for every object S of $\mathcal{C}$. [N.D.E-IV-10]

If R is a $\mathcal{C}$ -equivalence relation in $\mathcal{X}$, one denotes by p_1 the morphism from R into $\mathcal{X}$ induced by the projection $\text{pr}_1 : \mathcal{X} \times \mathcal{X} \rightarrow \mathcal{X}$. One thus has a diagram

```

```text
p1, p2 : R → X.
```

```

original page 173 -->

Definition 3.1.2. A morphism $u : X \rightarrow Z$ is said to be compatible with R if $u \circ p_1 = u \circ p_2$. An object of $\mathcal{C}$ that is a cokernel of the pair (p_1, p_2) is also called a quotient object of $\mathcal{X}$ by R and denoted $\mathcal{X}/R$.

III.IV.3.1.2 -->

One thus has an exact diagram

```

```text
R →_{p1, p2} X → X/R
```

```

and $\mathcal{X}/R$ represents the covariant functor

```

```text
Hom_{\mathcal{C}}(X/R, Z) = \{ \text{morphisms from } X \text{ into } Z \text{ compatible with } R \}.
```

```

Since quotient objects have been chosen in $\mathcal{C}$, the quotient $\mathcal{X}/R$ is unique (when it exists).

These definitions generalize at once to the case of a $\hat{\mathcal{C}}$ -equivalence relation in $\mathcal{X}$, but one will notice that the identification of objects of $\mathcal{C}$ with their images in $\hat{\mathcal{C}}$ does not commute with the formation of quotients, that is, the quotient $\mathcal{X}/R$ of $\mathcal{X}$ by R in $\mathcal{C}$ is not *a priori* a quotient of $\mathcal{X}$ by R in $\hat{\mathcal{C}}$. One should therefore guard against rashly identifying $\mathcal{C}$ with its image in $\hat{\mathcal{C}}$ in questions involving passages to the quotient. [N.D.E-IV-11]

In what follows, we shall say simply *equivalence relation* for $\hat{\mathcal{C}}$ -equivalence relation; we shall specify, when appropriate, whether we are dealing with $\mathcal{C}$ -equivalence relations. [N.D.E-IV-12]

Definition 3.1.3. If $\mathcal{X}$ is an object of $\mathcal{C}$ over S , one calls an equivalence relation in $\mathcal{X}$ over S an equivalence relation R in $\mathcal{X}$ such that the structural morphism $\mathcal{X} \rightarrow S$ is compatible with R .

III.IV.3.1.3 -->

The canonical monomorphism $R \rightarrow \mathcal{X} \times \mathcal{X}$ then factors through the monomorphism

```

```text
X ×_S X → X × X
```

```

...

and defines an equivalence relation in the object X to S of C/S . When the quotient X/R exists, it is endowed with a canonical morphism into S and the corresponding object of C/S is a quotient of X in $\text{Ob } C/S$ by the preceding equivalence relation.

<!-- original page 174 -->

Conversely, if S is a squarable object of C and if Y to S is a quotient of X by this equivalence relation (in C/S), then Y is a quotient of X by R in C . In any case, we shall never have to consider quotients in C/S that are not already quotients in C .

Definition 3.1.4. *If X (resp. X') is an object of C equipped with an equivalence relation R (resp. R'), a morphism*

$u : X \rightarrow X'$

*is said to be compatible with R and R' *if the following equivalent conditions are satisfied:*

(i) for every S in $\text{Ob } C$, two points of $X(S)$ congruent modulo $R(S)$ are transformed by u_S into two points of $X'(S)$ congruent modulo $R'(S)$;

(ii) there exists a morphism $R \rightarrow R'$ (necessarily unique) making commutative the diagram*

```

```text
R → R'
↓ ↓
X × X → X' × X'.
 (u × u)
...

```

<!-- label: III.IV.3.1.4 -->

By the universal property of  $X/R$ , there then exists (when the quotients  $X/R$  and  $X'/R'$  exist) a unique morphism  $v$  making commutative the diagram

```

X \xrightarrow{p} X/R
\downarrow u \downarrow v
X' \xrightarrow{p'} X'/R'.

```

<!-- original page 175 -->

**Definition 3.1.5.** \*A subobject (= a representable subfunctor)  $Y$  of  $X$  is said to be stable under the equivalence relation  $R$  \*if the following equivalent conditions are satisfied:\*

(i) For every  $S$  in  $\text{Ob } C$ , the subset  $Y(S)$  of  $X(S)$  is stable under  $R(S)$ .

(ii) The two subobjects of  $R$  inverse images of  $Y$  under  $p_1$  and  $p_2$  are identical.

<!-- label: III.IV.3.1.5 -->

An important particular case of stable subobject of  $X$  is the following: the quotient  $X/R$  exists and  $Y$  is the inverse image on  $X$  of a subobject of  $X/R$ .

**Definition 3.1.6.** \*Let  $R$  be an equivalence relation in  $X$  and  $X' \rightarrow X$  a morphism. The equivalence relation  $R'$  in  $X'$  obtained by the cartesian diagram\*

```

```text
R'   →   R
↓       ↓
X' × X' → X × X

```

...

*is said to be the equivalence relation in X' 's inverse image of the equivalence relation R in X . In particular, if X' is a subobject of X , one says it is the equivalence relation induced in X' by R , and one denotes it $R_{X'}$.

<!-- label: III.IV.3.1.6 -->

The morphism $X' \rightarrow X$ is compatible with R and R ; one thus has, when the quotients exist, a morphism $X'/R \rightarrow X/R$ (3.1.4). If X' is a subobject of X , we shall see later that in certain cases one can prove that $X'/R \rightarrow X/R$ is a monomorphism, hence identifies X'/R with a subobject of X/R . When this is so, the inverse image of this subobject in X will be a subobject of X containing X' and stable under R : the *saturation* of X' for the equivalence relation R .

<!-- original page 176 -->

Proposition 3.1.7. If the subobject Y of X is stable under R , one has two cartesian squares, for $i = 1, 2$:

$$\begin{array}{ccc} R_Y & \rightarrow & R \\ \downarrow p_i & & \downarrow p_i \\ Y & \rightarrow & X. \end{array}$$

<!-- label: III.IV.3.1.7 -->

Immediate proof.

3.2. Equivalence relation defined by a group acting freely

Definition 3.2.1. Let X be an object of $\mathcal{C}$ and H a $\mathcal{C}$ -group acting on X (that is, equipped with a morphism of $\mathcal{C}$ -groups

$$H \rightarrow \text{Aut}(X)).$$

One says that H acts freely on X if the following equivalent conditions are satisfied:

(i) For every S in $\text{Ob } \mathcal{C}$, the group $H(S)$ acts freely on $X(S)$;

(ii) The morphism of functors

$$H \times X \rightarrow X \times X$$

defined set-theoretically by $(h, x) \mapsto (hx, x)$ is a monomorphism.

<!-- label: III.IV.3.2.1 -->

(In the preceding definition, one supposed that the group H acted "on the left" on X . One evidently has an analogous notion in the case where the group acts "on the right", that is, when one is given a morphism of groups from the group H^{op} into $\text{Aut}(X)$).

If H acts freely on X , the image of $H \times X$ under the morphism of (ii) is an equivalence relation in X called the *equivalence relation defined by the action of H on X* . When the quotient of X by this equivalence relation exists, it is denoted $H \backslash X$.

<!-- original page 177 -->

(X/H when H acts on the right). It represents the following covariant functor: if Z is an object of $\mathcal{C}$, one has

$$\text{Hom}(H \backslash X, Z) = \{\text{morphisms from } X \text{ into } Z \text{ invariant under } H\}$$

...

where the morphism $f : X \rightarrow Z$ is said to be *invariant under H* if for every $S \in \mathcal{C}$, the corresponding morphism $X(S) \rightarrow Z(S)$ is invariant under the group $H(S)$.

Lemma 3.2.2. Under the conditions of 3.2.1, let Y be a subobject of X . The following conditions are equivalent:

- (i) Y is stable under the equivalence relation defined by H (3.1.5);
- (ii) For every $S \in \mathcal{C}$, the subset $Y(S)$ of $X(S)$ is stable under $H(S)$;
- (iii) There exists a morphism f , necessarily unique, making commutative the diagram

$$\begin{array}{ccc} H \times Y & \xrightarrow{\quad} & Y \\ \downarrow & & \downarrow \\ H \times X & \rightarrow & X. \end{array}$$

Under these conditions, f defines a morphism of $\hat{\mathcal{C}}$ -groups

$$H \rightarrow \text{Aut}(Y)$$

and the equivalence relation defined in Y by this action of H is none other than the equivalence relation induced in Y by the equivalence relation defined in X by the action of H .

!-- label: III.IV.3.2.2 -->

Immediate proof. One evidently has an analogous statement for a "right action". The action of H on Y defined above will be called the *action induced in Y by the given action of H on X* .

!-- original page 178 -->

Let us now consider the following situation: H and G are two $\mathcal{C}$ -groups and one is given a morphism of groups

$$u : H \rightarrow G.$$

Then H acts on G by translations (one sets set-theoretically $hg = u(h)g$) and acts freely there if and only if u is a monomorphism. The quotient of G by this action of H is denoted, when it exists, $H \backslash G$. One defines similarly a right action of H on G and a quotient G/H . These quotients are functorial with respect to the groups in question; more precisely, one has the following lemma, stated for right quotients:

Lemma 3.2.3. Let $u : H \rightarrow G$ and $u' : H' \rightarrow G'$ be two monomorphisms of $\mathcal{C}$ -groups. Suppose given a morphism of $\mathcal{C}$ -groups

$$f : G \rightarrow G'.$$

The following conditions are equivalent:

- (i) f is compatible with the equivalence relations defined in G and G' by H and H' .
- (ii) For every $S \in \mathcal{C}$, one has $f(u(H(S))) \subset u'(H'(S))$.
- (iii) There exists a morphism $g : H \rightarrow H'$, necessarily unique and multiplicative, such that the following diagram is commutative

$$H \rightarrowtail H'$$

$$\begin{array}{ccc} \downarrow u & & \downarrow u' \\ G & \xrightarrow{f} & G' \\ \downarrow p & & \downarrow p' \\ G/H & \xrightarrow{\bar{f}} & G'/H' \end{array}$$

Under these conditions, if the quotients G/H and G'/H' exist, there exists a unique morphism $\bar{f}$ making commutative the diagram

$$\begin{array}{ccc} G & \xrightarrow{f} & G' \\ \downarrow p & & \downarrow p' \\ G/H & \xrightarrow{\bar{f}} & G'/H' \end{array}$$

<!-- label: III.IV.3.2.3 -->

<!-- original page 179 -->

The first part is proved by reduction to the set-theoretic case. The second follows at once from (i).

One could translate to the present situation the notions introduced above for general equivalence relations. Let us simply signal the following lemma, whose proof is immediate by reduction to the set-theoretic case:

Lemma 3.2.4. *Let $u : H \rightarrow G$ be a monomorphism of C -groups and G' a sub- C -group of G . For the subobject G' of G to be stable under the equivalence relation defined by H , it is necessary and sufficient that u factor through the canonical monomorphism $G' \rightarrow G$, and under this condition the action of H on G' induced by the action of H on G defined by u is none other than the action deduced from the monomorphism $H \rightarrow G'$ that factors u .*

<!-- label: III.IV.3.2.4 -->

3.3. Universal effective equivalence relations

Definition 3.3.1. *Let $f : X \rightarrow Y$ be a morphism. One calls the equivalence relation defined by f in X , and denotes by $R(f)$, the $\bar{\cdot}$ -equivalence relation in X image of the canonical monomorphism*

$$X \times_Y X \rightarrow X \times X.$$

<!-- label: III.IV.3.3.1 -->

Definition 3.3.2. *Let R be an equivalence relation in X . One says that R is effective if*

(i) R is representable (i.e. is a C -equivalence relation);*

(ii) the quotient $Y = X/R$ exists in C ;*[^{N.D.E-IV-13}]

(iii) the diagram*

<!-- original page 180 -->

$$R \rightrightarrows_{\{p_1, p_2\}} X \xrightarrow{p} Y$$

makes R the fiber square of X over Y , that is, R is the equivalence relation defined by p .

<!-- label: III.IV.3.3.2 -->

Scholie 3.3.2.1.[^{N.D.E-IV-14}] *If R is an effective equivalence relation in X , then p is an effective epimorphism (1.3). If $f : X \rightarrow Y$ is an effective epimorphism, then $R(f)$ is an effective equivalence relation in X a quotient of which is Y . There is therefore a "Galois" one-to-one correspondence between effective equivalence relations in X and effective quotients of X (i.e. equivalence classes of effective epimorphisms with source X).*

<!-- label: III.IV.3.3.2.1 -->

****Definition 3.3.3.**** *One says that the equivalence relation R in X is* universally effective *if the quotient $Y = X/R$ exists, and if, for every $Y' \rightarrow Y$, the fiber products $X' = X \times_{Y'} Y'$ and $R' = R \times_{Y'} Y'$ exist and R' is a fiber square of X' over Y' . It amounts to the same to say that R is effective and that $p : X \rightarrow X/R$ is a universal effective epimorphism.*

<!-- label: III.IV.3.3.3 -->

****Remark 3.3.3.2.****[^N.D.E-IV-14] *Suppose that $\mathcal{C}$ is the category of S -schemes and let $\mathbb{A}^1_S$ denote the affine space of dimension 1 over S . Let $R \subset X \times_S X$ be a universal effective equivalence relation and $p : X \rightarrow Y$ the quotient. Then, for every open U of Y , $0(U) = \operatorname{Hom}_S(U, \mathbb{A}^1_S)$ is the set of elements ϕ of $0(p^{-1}(U)) = \operatorname{Hom}_S(p^{-1}(U), \mathbb{A}^1_S)$ such that $\phi \circ \operatorname{pr}_1 = \phi \circ \operatorname{pr}_2$. In particular, if R is given by the action of a group H acting freely on the right on X (cf. 3.2.1), then $0(U)$ is the set of $\phi \in 0(p^{-1}(U))$ such that $\phi(xh) = \phi(x)$, for every $S' \rightarrow S$ and $x \in X(S')$, $h \in H(S')$.*

<!-- label: III.IV.3.3.3.2 -->

****Proposition 3.3.4.**** *Let R be a universal effective equivalence relation in X . Let $f : X \rightarrow Z$ be a morphism compatible with R , hence factoring through $g : X/R \rightarrow Z$. The following conditions are equivalent:*

(i) g is a monomorphism;

(ii) R is the equivalence relation defined by f .*

<!-- label: III.IV.3.3.4 -->

Indeed, (i) trivially entails (ii); the converse is none other than 2.5.

<!-- original page 181 -->

****Definition 3.3.5.**** *Let H be a $\mathcal{C}$ -group acting freely on X . One says that H acts* effectively, *or that the action of H on X is* effective *(resp.* universally effective*), if the equivalence relation defined in X by the action of H is effective (resp. universally effective).*

<!-- label: III.IV.3.3.5 -->

3.4. (M)-effectivity

In practice, it is most often difficult to characterize universal effective epimorphisms. One often disposes, nevertheless, of a certain number of morphisms of this type, for example in scheme theory, of faithfully flat quasi-compact morphisms. This leads to the developments below.

****3.4.1.**** Let us first state a certain number of conditions bearing on a family (M) of morphisms of $\mathcal{C}$:

(a) (M) is stable under extension of the base, i.e., every $u : T \rightarrow S$ element of (M) is squarable (cf. 1.4.0) and for every $S' \rightarrow S$, $u' : T \times_S S' \rightarrow S'$ is an element of (M) .

(b) The composite of two elements of (M) is in (M) .

(c) Every isomorphism is an element of (M) .

(d) Every element of (M) is an effective epimorphism.

Note that (a) and (b) entail:

(a') The cartesian product of two elements of (M) is in (M) : let $u : X \rightarrow Y$ and $u' : X' \rightarrow Y'$ be two S -morphisms, elements of (M) . If $Y \times_{Y'} Y'$ exists, then $X \times_{X'} X'$ exists and $u \times_{u'} u'$ is an element of (M) .

<!-- original page 182 -->

This follows from the diagram

$$\begin{array}{ccccc}
 & & & & \\
 & & & & \\
 Y' & \xrightarrow{\quad} & X' & & \\
 \uparrow & & \uparrow u' & & \\
 X & \xrightarrow{\quad} & X \times_S Y' & \xrightarrow{\quad} & X \times_S X' \\
 \uparrow u & & \searrow u \times_S u' & & \\
 Y & \xrightarrow{\quad} & Y \times_S Y' & &
 \end{array}$$

Likewise (a) and (d) entail:

(d') Every element of $\mathcal{M}$ is a universal effective epimorphism.

3.4.2. The family $\{M_i\}$ of universal effective epimorphisms satisfies the conditions (a) through (d) of 3.4.1. Indeed, (a), (c) and (d) are satisfied by definition, (b) follows from 1.8. In what follows, we shall suppose given a family $\mathcal{M}$ of morphisms of $\mathcal{C}$ satisfying these conditions: our results will therefore apply in particular to the family $\{M_i\}$.

Definition 3.4.3. One says that the equivalence relation R in X is of type $\mathcal{M}$ if it is representable and if $p_1 \in (M)$ (which by (b) and (c) entails that $p_2 \in (M)$).

One says that R is $\mathcal{M}$ -effective if it is effective and if the canonical morphism $X \rightarrow X/R$ is an element of $\mathcal{M}$.

One says that the quotient Y of X is $\mathcal{M}$ -effective if the canonical morphism $X \rightarrow Y$ is an element of $\mathcal{M}$.

III.IV.3.4.3

The following consequences result from this definition: [N.D.E-IV-15]

Proposition 3.4.3.1. (i) An $\mathcal{M}$ -effective equivalence relation is of type $\mathcal{M}$ and universally effective.

(ii) An $\mathcal{M}$ -effective quotient is universally effective (cf. 3.3.3).

(iii) The maps $R \rightarrow X/R$ and $p \rightarrow R(p)$ realize a one-to-one correspondence between $\mathcal{M}$ -effective equivalence relations in X and $\mathcal{M}$ -effective quotients of X .

(iv) $\{M_i\}$ -effective is equivalent to universally effective.

III.IV.3.4.3.1

Let us prove point (i). Since R is $\mathcal{M}$ -effective, one has a cartesian square

$$\begin{array}{ccc}
 R & \xrightarrow{p_2} & X \\
 \downarrow p_1 & & \downarrow p \\
 X & \xrightarrow{p} & X/R,
 \end{array}$$

original page 194

and $p \in (M)$. Then, by 3.4.1 (a), p_1 and p_2 belong to $\mathcal{M}$, hence R is of type $\mathcal{M}$.

Set $Y = X/R$ and let $Y' \rightarrow Y$ be an arbitrary morphism. By 3.4.1 (a), the fiber products $X' = X \times_Y Y'$ and $R' = R \times_Y Y'$ exist and the morphisms $X' \rightarrow Y'$ and $p'_i : R' \rightarrow X'$ belong to $\mathcal{M}$. Finally, since $R = X \times_Y X$, one obtains, by associativity of the fiber product:

$$R' = X \times_Y X \times_Y Y' = X' \times_{Y'} X'.$$

This shows that R' is $\mathcal{M}$ -effective; hence in particular, R is universally effective. This proves (i), and also (iv). Points (ii) and (iii) follow from this, taking account of Definition 3.3.2.

<!-- original page 183 -->

****3.4.4.**** Let H be an S -group whose structural morphism is an element of (M) . Then if H acts freely on the S -object X , it defines an equivalence relation of type (M) . Indeed, by (a) the fiber product $H \times_S X$ exists and $\text{pr}_2 : H \times_S X \rightarrow X$ is an element of (M) . One says that the action of H is (M) -effective if the equivalence relation defined in X by this action is (M) -effective.

****Proposition 3.4.5 ((M)-effectivity and base change).**** Let R be an (M) -effective equivalence relation in X over S . Set $Y = X/R$. Let $S' \rightarrow S$ be a change of base such that $Y' = Y \times_S S'$ exists. Then $X' = X \times_S S'$ exists, $R' = R \times_S S'$ is an (M) -effective equivalence relation in X' over S' and $X'/R' \simeq (X/R)'$.

<!-- label: III.IV.3.4.5 -->

Indeed, the canonical morphisms $X \rightarrow Y$ and $R \rightarrow Y$ are elements of (M) , hence by (a') X' and R' are representable. By associativity of the product, R' is the equivalence relation defined in X' by the canonical morphism $X' \rightarrow Y'$ which is an element of (M) , whence the conclusion.

****Proposition 3.4.6 ((M)-effectivity and cartesian products).**** Let R (resp. R') be an (M) -effective equivalence relation in X (resp. X') over S . If $(X/R) \times_S (X'/R')$ exists, then $X \times_S X'$ exists, $R \times_S R'$ is an (M) -effective equivalence relation in $X \times_S X'$ over S and*

``text
 $(X \times_S X') / (R \times_S R') \simeq (X/R) \times_S (X'/R').$
 ``

<!-- label: III.IV.3.4.6 -->

Set $Y = X/R$, $Y' = X'/R'$. By (a'), the fiber product $X \times_S X'$ exists and the canonical morphism

``text
 $q : X \times_S X' \rightarrow Y \times_S Y'$
 ``

is an element of (M) . Now the formula

``text
 $(X \times_S X') \times_{\{(Y \times_S Y')\}} (X \times_S X') = (X \times_Y X) \times_S (X' \times_{Y'} X')$
 ``

<!-- original page 184 -->

(all products without subscript are taken over S) shows that $R \times_S R'$ is the equivalence relation defined by q in $X \times_S X'$, which completes the proof.

****3.4.7.**** [N.D.E-IV-16] Suppose that C has a final object e and let $f : G \rightarrow G'$ be a morphism of C -groups, such that $f \in (M)$. Then, by 3.4.1 (a), the kernel $\text{Ker}(f)$ is representable by $e \times_{G'} G$, and the morphism $\text{Ker}(f) \rightarrow e$ belongs to (M) .

On the other hand, the equivalence relation defined by f is the same as that defined by the action of $\text{Ker}(f)$ (say, on the right) on G , i.e., it is the image of the morphism $G \times \text{Ker}(f) \rightarrow G \times G$, defined set-theoretically by $(g, h) \mapsto (g, gh)$. Consequently, one deduces from 3.3.2.1 the following corollary:

****Corollary 3.4.7.1.**** Suppose that C has a final object e and let $f : G \rightarrow G'$ be a morphism of C -groups, such that $f \in (M)$. Then the action of $\text{Ker}(f)$ on G is (M) -effective and G' is the quotient $G/\text{Ker}(f)$.

<!-- label: III.IV.3.4.7.1 -->

3.5. Construction of quotients by descent

It frequently happens that one does not know how to construct a quotient directly, but that one does know how to do so after a suitable change of base. The present number gives a criterion useful in this situation.

We have seen in §2.1 the definition of a descent datum on an object X' over S' relative to a morphism $S' \rightarrow S$.

****Definition 3.5.1.**** *One says that a descent datum on X' relative to $S' \rightarrow S$ is* effective *if X' equipped with this descent datum is isomorphic to the inverse image on S' of an object X over S , equipped with its canonical descent datum.*

<!-- label: III.IV.3.5.1 -->

If $S' \rightarrow S$ is a descent morphism (2.2), then the X of the definition is unique up to unique isomorphism. To say that $S' \rightarrow S$ is an effective descent morphism (2.2), is to say that it is a descent morphism and that every descent datum relative to this morphism is effective.

Consider now an equivalence relation R in an object X over S . Let X' (resp. X'' , resp. X''') be the inverse images of X on S' , $S'' = S' \times_{S'} S'$ and $S''' = S' \times_{S'} S' \times_{S'} S'$ and let R' , R'' , R''' be the equivalence relations deduced from R by inverse image. Suppose that the equivalence relation R' in X' is (M) -effective, and consider the quotient $Y' = X'/R'$, which is an object over S' . Its two inverse images on S'' are isomorphic to X''/R'' by 3.4.5. The S' -object Y' is therefore endowed with a canonical gluing datum. Using likewise the uniqueness of X'''/R''' , one sees that this is even a descent datum. (Remark: it has been implicitly supposed in this proof that all the fiber products written existed, which is the case in particular if $S' \rightarrow S$ is squarable, for example a descent morphism).

<!-- original page 185 -->

****Proposition 3.5.2.**** *Let R be an equivalence relation in the object X over S . Let $S' \rightarrow S$ be a universal effective epimorphism. Suppose that every S -morphism whose inverse image on S' is in (M) is itself in (M) . The following conditions are equivalent:*

*(i) R is (M) -effective in X ;

<!-- original page 196 -->

(ii) R' is (M) -effective in X' and the canonical descent datum on X'/R' is effective.

If this is so, the "descended" object of X'/R' is canonically isomorphic to X/R .

<!-- label: III.IV.3.5.2 -->

The fact that (i) entails (ii) is none other than the translation, in the language of descent, of 3.4.4. If one shows the converse, the last assertion of the proposition will be a consequence of the fact that a universal effective epimorphism is a descent morphism (2.3), hence that the "descended object" is unique (up to unique isomorphism).

So let us prove (ii) $\Rightarrow$ (i). Let Y' be the quotient X'/R' and Y the descended object. As the canonical morphism $\rho' : X' \rightarrow X'/R' = Y'$ is by construction compatible with the descent data (its inverse images on S'' coincide with the canonical morphism $X'' \rightarrow X''/R''$), it comes by inverse image on S' from an S -morphism $\rho : X \rightarrow Y$. Since ρ' is an element of (M) , it follows from the hypothesis made on the morphism $S' \rightarrow S$ that ρ is also an element of (M) . As ρ' is compatible with the equivalence relation R' , ρ is compatible with R , again because a universal effective epimorphism is a descent morphism. One thus has a morphism

```
```text
R → X ×_Y X.
```
```

To prove that R is (M) -effective and that Y is isomorphic to X/R , it suffices to prove that this morphism is an isomorphism. Now it becomes one by extension of the base from S to S' , since R' is effective; it is therefore an isomorphism for the same reason as before (2.4).

<!-- original page 186 -->

Note that the hypothesis of the text is satisfied if one takes for (M) the family $\{M_{\{0\}}\}$ of universal effective epimorphisms and if C has fiber products (1.10). One deduces the

****Corollary 3.5.3.**** *Suppose that C has fiber products (over S would suffice). Let R be an equivalence relation in X over S and $S' \rightarrow S$ a universal effective epimorphism. The following conditions are equivalent:*

*(i) R is universally effective in X ;

(ii) R is universally effective in X and the canonical descent datum on X'/R is effective.

If this is so, the "descended" object of X'/R is canonically isomorphic to X/R .

<!-- label: III.IV.3.5.3 -->

4. Topologies and sheaves

The notion of sieve, and the presentation of the notion of topology (4.2.1) adopted here (more intrinsic and in many respects more convenient than the one by covering families of [MA]), are due to J. Giraud [AS].

4.1. Sieves

Definition 4.1.1. *One calls a sieve s of the category $\mathcal{C}$ a subfunctor s of the final functor $e : \mathcal{C}^{\text{circ}} \rightarrow (\text{Ens})$.*

<!-- label: III.IV.4.1.1 -->

<!-- original page 197 -->

To every sieve s of $\mathcal{C}$ one associates the set $E(s)$ of objects X of $\mathcal{C}$ such that $s(X) \neq \emptyset$, that is, such that the structural morphism $X \rightarrow e$ factors through s . One thus has the equivalences

```
```text
(+) $X \in E(s) \iff s(X) = e(X) = \{\emptyset\}.$
 $X \notin E(s) \iff s(X) = \emptyset.$
```
```

<!-- original page 187 -->

The set $E = E(s)$ enjoys the following property:

```
```text
(++) If $X \in E$ and if $\text{Hom}(Y, X) \neq \emptyset$, then $Y \in E.$
```
```

(Note that if one equips the set $\text{Ob } \mathcal{C}$ with its natural preorder structure (Y dominating X if there exists an arrow from Y into X), the sets E satisfying (++) are the subsets of $\text{Ob } \mathcal{C}$ that contain every dominator [N.D.E-IV-17] of one of their elements.)

Conversely, if E is a subset of $\text{Ob } \mathcal{C}$ enjoying property (++) , then E is written in a unique way in the form $E(s)$ and s is defined by the formulas (+). There is therefore a one-to-one correspondence between sieves of $\mathcal{C}$ and subsets of $\text{Ob } \mathcal{C}$ satisfying condition (++) . By abuse of language, we shall sometimes say that the set $E(s)$ is a sieve of $\mathcal{C}$.

[N.D.E-IV-18] Let s and s' be two sieves of $\mathcal{C}$; since they are two subfunctors of the final functor e , it amounts to the same to say that s dominates s' (for the relation of domination in $\text{Ob } \hat{\mathcal{C}}$), or that s is a subfunctor of s' , or yet that $E(s) \subset E(s')$; one then says that s is *finer* than s' . One sees that this gives an order structure on the set of sieves of $\mathcal{C}$. Furthermore, one has $E(s) \cap E(s') = E(s \times s')$ and therefore the set of sieves of $\mathcal{C}$ is filtered for the order relation "being finer".

Every subset E of $\text{Ob } \hat{\mathcal{C}}$, for example a subset of $\text{Ob } \mathcal{C}$, defines a sieve $s(E)$: the set of $X \in \text{Ob } \mathcal{C}$ such that $s(X) \neq \emptyset$ for at least one $s \in E$ satisfies condition (++) and defines the sought sieve.

This sieve can also be defined as the image of the family of morphisms $\{s \rightarrow e, s \in E\}$ in the sense of the following definition:

Definition 4.1.2. *Let $\{f_i\} \rightarrow F$ be a family of morphisms of $\hat{\mathcal{C}}$ with the same target F . One calls image of this family the subfunctor of F defined by*

```
```text
 $S \mapsto \bigcup_i \text{Im } f_i(S) \subset F(S).$
```
```

<!-- label: III.IV.4.1.2 -->

Proposition 4.1.3. The formation of the image commutes with base extension: in the preceding notation, denote by I the image of the family $\{F_i\}$ to F ; for every

original page 198 -->

morphism G to F of $\hat{C}$, the image of the family of morphisms $\{F_i\} \times_F G$ to G is the subfunctor $I \times_F G$ of G .

label: III.IV.4.1.3 -->

Definition 4.1.4.0. [N.D.E-IV-19] Let C be a sieve of C . If E is a subset of $\text{Ob } C$ such that $C(E) = C$, one says that E is a base of C . Every sieve C has a base, for example the set $E(C)$.

label: III.IV.4.1.4.0 -->

We propose to describe the set $\text{Hom}(C, F)$, where C is a sieve of C and F an object of $\hat{C}$, using a base $\{S_i\}$ of C . For each pair (i, j) , one has a diagram in $\hat{C}$:

$$\begin{array}{ccc} S_i \times S_j & & S_i \\ \downarrow & & \downarrow \\ S_j & \xrightarrow{e} & e, \end{array}$$

whence a diagram of sets

$$\Gamma(F) = \text{Hom}(e, F) \xrightarrow{\sigma} \prod_i \text{Hom}(S_i, F) \xrightarrow{\tau_1, \tau_2} \prod_{\{i,j\}} \text{Hom}(S_i \times S_j, F)$$

such that $\tau_1 \sigma = \tau_2 \sigma$. One thus has a morphism

$$\text{Hom}(e, F) \rightarrow \text{Ker}(\prod_i \text{Hom}(S_i, F) \xrightarrow{\tau_{\{i,j\}}} \prod_{\{i,j\}} \text{Hom}(S_i \times S_j, F)).$$

One verifies immediately:

Proposition 4.1.4. One has an isomorphism, functorial in F ,

$$\text{Hom}(C, F) \cong \text{Ker}(\prod_i \text{Hom}(S_i, F) \xrightarrow{\tau_{\{i,j\}}} \prod_{\{i,j\}} \text{Hom}(S_i \times S_j, F)),$$

such that the diagram

$$\begin{array}{ccc} \text{Hom}(e, F) & \rightarrow & \text{Ker}(\prod_i \text{Hom}(S_i, F) \xrightarrow{\tau_{\{i,j\}}} \prod_{\{i,j\}} \text{Hom}(S_i \times S_j, F)) \\ & \uparrow \cong & \\ \text{Hom}(e, F) & \rightarrow & \text{Hom}(C, F), \end{array}$$

where the last line is induced by the canonical morphism C to e , is commutative.

label: III.IV.4.1.4 -->

Corollary 4.1.5. Suppose that the fiber products $S_i \times S_j$ are representable, for example

original page 199 -->

that the S_i are squarable. One then has, for every F in $\text{Ob } \hat{C}$, an isomorphism

text

$\text{Hom}(C, F) \subseteq \text{Ker}(\prod_i F(S_i) \rightarrow \prod_{\{i,j\}} F(S_i \times S_j)).$

<!-- label: III.IV.4.1.5 -->

Remark 4.1.6. Let $\mathcal{R}$ be a sieve of $\mathcal{C}$; denote by $\bar{\mathcal{R}}$ the full subcategory of $\mathcal{C}$ whose set of objects is $E(\mathcal{R})$ and by

$i_{\mathcal{R}} : \bar{\mathcal{R}} \rightarrow \mathcal{C}$

the inclusion functor. One has an isomorphism, functorial in $F \in \text{Ob } \hat{\mathcal{C}}$,

$\text{Hom}(\mathcal{R}, F) \cong \Gamma(F \circ i_{\mathcal{R}})$

such that the diagram

$$\begin{array}{ccc} \text{Hom}(\mathcal{R}, F) & \rightarrow & \text{Hom}(\mathcal{R}, F) \\ \uparrow & & \uparrow \\ \Gamma(\mathcal{R}) & \rightarrow & \Gamma(F \circ i_{\mathcal{R}}), \end{array}$$

where the second line is induced by the functor $i_{\mathcal{R}}$, is commutative.

<!-- label: III.IV.4.1.6 -->

Definition 4.1.7. Let $\mathcal{C}$ be a category. One calls a sieve of the object S of $\mathcal{C}$ a sieve of the category $\mathcal{C}/S$.

<!-- label: III.IV.4.1.7 -->

A sieve of S is therefore a sub- $\hat{\mathcal{C}}$ -object of $\mathcal{C}/S$. To it corresponds canonically a subset of $\text{Ob } \mathcal{C}/S$ containing the source of every arrow whose target it contains. By abuse of language, such a set will also be called a sieve of S .

4.2. Topologies: definitions

Definition 4.2.1. Let $\mathcal{C}$ be a category. One calls a topology on $\mathcal{C}$ the datum, for each S of $\mathcal{C}$, of a set $J(S)$ of sieves of S , called covering sieves or refinements of S ,

<!-- original page 190 -->

the datum satisfying the following axioms:

(T 1) For every refinement $\mathcal{R}$ of S and every morphism $T \rightarrow S$, the sieve $\mathcal{R} \times_{\{S\}} T$ of T is covering ("stability under base change").

(T 2) If $\mathcal{R}, \mathcal{C}$ are two sieves of S , if $\mathcal{R}$ is covering, and if for every $T \in \text{Ob } \mathcal{C}$ and every morphism $T \rightarrow \mathcal{R}$, the sieve $\mathcal{C} \times_{\{S\}} T$ of T is covering, then $\mathcal{C}$ is a refinement of $\mathcal{R}$. [N.D.E-IV-20]

(T 3) If $\mathcal{C} \supseteq \mathcal{R}$ are two sieves of S and if $\mathcal{R}$ is covering, then $\mathcal{C}$ is covering.

(T 4) For every S , S is a refinement of S .

<!-- label: III.IV.4.2.1 -->

One can reformulate these axioms in the following way. Suppose given a topology $S \mapsto J(S)$ on $\mathcal{C}$ and, for every object F of $\hat{\mathcal{C}}$, denote by $J(F)$ the set of subfunctors $\mathcal{R}$ of F such that for every morphism $T \rightarrow F$ of $\hat{\mathcal{C}}$ where T is representable, $\mathcal{R} \times_{\{F\}} T$, which is a sieve of T , is covering. By virtue of (T 1), this notation is compatible with the preceding one. One will also say that $\mathcal{R} \in J(F)$ is a refinement of F . One verifies immediately that the preceding axioms entail the following properties:

(T' 0) If $F \in \mathcal{C}$ and $G \in \mathcal{C}$ are two objects of $\mathcal{C}$, and if for every $S \in \mathcal{C}$ and every morphism $S \rightarrow F$, $G \times_{F,S} S \in \mathcal{C}$, then $G \in \mathcal{C}$.

(T' 1) If $G \in \mathcal{C}$, and if $H \rightarrow F$ is a morphism of $\mathcal{C}$, then $G \times_{F,H} H \in \mathcal{C}$.

(T' 2) If $F \in \mathcal{C}$ and $G \in \mathcal{C}$ are two objects of $\mathcal{C}$, if $G \in \mathcal{C}$ and $H \in \mathcal{C}$, then $H \in \mathcal{C}$.

(T' 3) If $F \in \mathcal{C}$ and $G \in \mathcal{C}$ are two objects of $\mathcal{C}$ and if $H \in \mathcal{C}$, then $G \in \mathcal{C}$.

(T' 4) For every $F \in \mathcal{C}$, $F \in \mathcal{C}$.

<!-- original page 191 -->

Conversely, if one gives oneself, for every $F \in \mathcal{C}$, a set $\mathcal{J}(F)$ of subobjects of F satisfying the properties (T' 0) through (T' 4), the map $S \mapsto \mathcal{J}(S)$ defines a topology on $\mathcal{C}$ and the two preceding constructions are inverse to each other.

From (T' 1), (T' 2) and (T' 3) [N.D.E-IV-21] results the following property:

(T' 5) If G and H are two subobjects of F and if $G, H \in \mathcal{C}$, then $G \cap H \in \mathcal{C}$.

The set $\mathcal{J}(F)$, ordered by the relation $\supseteq$, is therefore filtered; this remark will be useful later.

4.2.2. One says that the topology defined by $\mathcal{J}$ is *finer* than the topology defined by $\mathcal{J}'$ if for every $S \in \mathcal{C}$, $\mathcal{J}(S) \supseteq \mathcal{J}'(S)$ (it amounts to the same to say that for every $F \in \mathcal{C}$, $\mathcal{J}(F) \supseteq \mathcal{J}'(F)$).

Every set of topologies on $\mathcal{C}$ has a greatest lower bound: let I be an indexing set, and for each $i \in I$, let $\mathcal{J}_i$ be a topology on $\mathcal{C}$. Set $\mathcal{J}(S) = \bigcap_{i \in I} \mathcal{J}_i(S)$; it is immediate that one has thus defined a topology on $\mathcal{C}$, and that this is indeed the greatest lower bound of the given set.

In particular, let us give ourselves, for each $S \in \mathcal{C}$, a set $\mathcal{E}(S)$ of sieves of S . One calls the *topology* generated by these sets the least fine topology for which the elements of $\mathcal{E}(S)$ are refinements of S for every S .

Definition 4.2.3. Let $\{F_i \rightarrow F\}$ be a family of morphisms of $\mathcal{C}$. Let $G \subset F$ be the image (4.1.2) of this family. The family is said to be *covering* if $G \in \mathcal{C}$. A morphism is said to be *covering* if the family reduced to this morphism is covering.

<!-- label: III.IV.4.2.3 -->

This definition applies in particular to an inclusion: a sieve $\mathcal{C}$ of S is covering if and only if the canonical morphism $\mathcal{C} \rightarrow S$ is covering.

<!-- original page 192 -->

The axioms (T' 0) through (T' 5) entail for covering families the following properties:

(C 0) Let $\{F_i \rightarrow F\}$ be a family of morphisms of $\mathcal{C}$. If for every representable base change $S \rightarrow F$, the family $\{F_i \times_F S \rightarrow S\}$ is covering, then so is the initial family.

(C 1) For every covering family $\{F_i \rightarrow F\}$ and every morphism $G \rightarrow F$, the family $\{F_i \times_F G \rightarrow G\}$ is covering ("stability under base change").

(C 2) If $\{F_i \rightarrow F\}$ is a covering family and if, for each i , $\{F_{ij} \rightarrow F_i\}$ is a covering family, then the composite family $\{F_{ij} \rightarrow F\}$ is covering ("stability under composition").

(C 3) If $\{G_j \rightarrow F\}$ is a covering family, and if $\{F_i \rightarrow F\}$ is a family of morphisms with target F such that for each j there exists an i such that $G_j \rightarrow F$ factors through $F_i \rightarrow F$, then $\{F_i \rightarrow F\}$ is covering ("saturation").

(C 4) Every family reduced to an isomorphism is covering.

Note that (C 2) and (C 3) also entail:

(C 5) If $\{F_i \rightarrow F\}$ is a family of morphisms with target F such that there exists a covering family

$\{G_j\}$ to F such that for every j the family $\{F_i \times F G_j\}$ to $G_j\}$ is covering, then the family $\{F_i\}$ to F is covering ("a locally covering family is covering").

4.2.4. Conversely, let $\mathcal{C}$ be a category having fiber products and let us give ourselves, for each $S \in \text{Ob } \mathcal{C}$, a set of families of morphisms of $\mathcal{C}$ with target S , said to be *covering families*, the datum satisfying axioms (C 1) through (C 4) (hence also (C 5) which is a consequence). For every $S \in \text{Ob } \mathcal{C}$, let $J(S)$ be the set

<!-- original page 193 -->

of sieves of S having a covering base (or, what amounts to the same by (C 3), all of whose bases are covering). Then $S \mapsto J(S)$ defines a topology on $\mathcal{C}$. The two preceding constructions are inverse to each other.

In fact, in applications, it is impractical to consider all covering families, since one sometimes has fairly simple descriptions of a "sufficient" number of such families. This leads to posing the following definitions.

Definition 4.2.5.0. [N.D.E-IV-22] Let $\mathcal{C}$ be a category. Suppose given, for each $S \in \text{Ob } \mathcal{C}$, a set $P(S)$ of families of morphisms of $\mathcal{C}$ with target S . One calls the topology generated by P the *least fine topology* for which the given families are covering.*

<!-- label: III.IV.4.2.5.0 -->

Definition 4.2.5. Let $\mathcal{C}$ be a category. One calls a *pretopology* on $\mathcal{C}$ the datum for each $S \in \text{Ob } \mathcal{C}$ of a set $R(S)$ of families of morphisms $\{S_i\}$ to S with target S , said to be *covering* for the pretopology under consideration, *satisfying the following axioms*.*

(P 1) For every family $\{S_i\}$ to S in $R(S)$ and every morphism $T \rightarrow S$, the fiber products $S_i \times_S T$ exist and $\{S_i \times_S T\}$ to T is in $R(T)$.*

<!-- original page 202 -->

(P 2) If $\{S_i\}$ to S is in $R(S)$ and if for each i , $\{T_{ij}\}$ to S_i is in $R(S_i)$, then the composite family $\{T_{ij}\}$ to S belongs to $R(S)$.*

(P 3) Every family reduced to an isomorphism is covering.*

<!-- label: III.IV.4.2.5 -->

Proposition 4.2.6. For every S , let $J(S)$ be the set of sieves of S covering for the topology generated by the pretopology R . Let $J_{\{R\}}(S)$ be the part of $J(S)$ formed by the sieves defined by the families of $R(S)$. Then $J_{\{R\}}(S)$ is cofinal in $J(S)$: every refinement of S contains a sieve defined by a family of $R(S)$.*

<!-- label: III.IV.4.2.6 -->

<!-- original page 194 -->

For every S , let $J'(S)$ be the set of sieves of S containing a sieve of $J_{\{R\}}(S)$. One evidently has $J'(S) \subset J(S)$. To show that $J(S) = J'(S)$, it suffices to show that the $J'(S)$ make a topology on $\mathcal{C}$, that is, that they satisfy axioms (T 1) through (T 4). Now (T 1), (T 3), (T 4) are evidently satisfied. It remains to verify (T 2). [N.D.E-IV-23]

So let U be an element of $J'(S)$ and $\mathcal{C}$ a sieve of S ; one supposes that for every $T \rightarrow U$, the sieve $\mathcal{C} \times_{\{T\}} T$ is in $J'(T)$ and one must prove that $\mathcal{C} \in J'(S)$. By definition of J' , U contains a refinement U' defined by a family $\{S_i\}$ to S in $R(S)$. Since one has verified (T 3), it suffices to prove that $U' \cap \mathcal{C} \in J'(S)$, so one may suppose that $U = U'$. By hypothesis, for every i , $\mathcal{C} \times_{\{S_i\}} S_i \in J'(S_i)$; there therefore exists, for each i , a covering family $\{T_{ij}\}$ to S_i in $R(S_i)$ such that $T_{ij} \rightarrow S_i$ factors through $\mathcal{C} \times_{\{S_i\}} S_i \rightarrow S_i$. The morphism $T_{ij} \rightarrow S$ therefore factors through $\mathcal{C} \rightarrow S$, which shows that $\mathcal{C}$ contains the sieve defined by the composite family $\{T_{ij}\}$ to S , and one has finished by (P 2).

The axioms (P 1) through (P 3) are those of [MA]. Given the practical interest of pretopologies, we shall interpret each important result with the aid of a pretopology defining the given topology.

Remark 4.2.7. One can introduce a somewhat more general notion: one gives, for each S , a set of covering families satisfying (P 1), (P 3) and Proposition 4.2.6. This presents itself in particular when the given families satisfy (P 1), (P 3) and (C 5). The reader may consult [D].*

<!-- label: III.IV.4.2.7 -->

Definition 4.2.8. Let C be equipped with a topology, and let S be an object of C . Let $P(S)$ be a relation involving an argument $S' \in \text{Ob } C/S$. Suppose that $\text{Hom}(S', S) \neq \emptyset$ entails $P(S') \Rightarrow P(S)$. One says that P is true* locally on S *for the topology under consideration, if the following equivalent conditions are satisfied:*

(i) The set of $S' \rightarrow S$ such that $P(S')$ is true is a refinement of S .*

(ii) There exists a refinement of S such that $P(S')$ is true for every S' of this refinement.*

<!-- original page 195 -->

(iii) (If the given topology is defined by a pretopology). There exists a covering family for this pretopology such that $P(S')$ is true for every S' of this family.*

<!-- label: III.IV.4.2.8 -->

Example 4.2.9. Let $f : X \rightarrow Y$ be an S -morphism. One will say that f is* locally an isomorphism *if there exists a covering family $\{S_i \rightarrow S\}$ such that for every i , $f|_{S_i} : S_i \rightarrow S$ is*

<!-- original page 203 -->

an isomorphism. It amounts to the same to require that there exist a refinement R of S such that for every $T \rightarrow R$, $X(T) \rightarrow Y(T)$ is an isomorphism.*

<!-- label: III.IV.4.2.9 -->

One will see in the sequel many other examples of "local" language.

4.3. Presheaves, sheaves, sheaf associated to a presheaf

Definition 4.3.1. Let C be a category. One calls a* presheaf of sets *on C any contravariant functor from C into the category of sets. The category $\hat{C} = \text{Hom}(C^{\text{op}}, \text{Ens})$ is called the* category of presheaves *on C . If C is equipped with a topology, one says that the presheaf P is* separated *(resp. is a sheaf*) if for every $S \in \text{Ob } C$ and every $R \in J(S)$, the canonical map*

text

$$P(S) = \text{Hom}(S, P) \rightarrow \text{Hom}(R, P)$$

is injective (resp. bijective). One calls* category of sheaves, *and denotes by $\tilde{C}$, the full subcategory of $\hat{C}$ whose objects are the sheaves.*[N.D.E-IV-24]

<!-- label: III.IV.4.3.1 -->

Proposition 4.3.2. Let P be a separated presheaf (resp. a sheaf). For every functor $H \in \text{Ob } \hat{C}$ and every $R \in J(H)$, the canonical map*

text

$$\text{Hom}(H, P) \rightarrow \text{Hom}(R, P)$$

is injective (resp. bijective).*

<!-- label: III.IV.4.3.2 -->

Indeed, let P be a separated presheaf, H a presheaf, $R \in J(H)$, and $u, v : H \rightarrow P$ such that $uj = vj$. For every $f : S \rightarrow H$, $S \in \text{Ob } C$, $R|_S$ is a refinement of S and $\sum_j j_S = \sum_j j_S$:

<!-- original page 196 -->

text

$$R \times_H S \rightarrow S$$

```

      if_R      if
      R  -j-→  H  ⇒_{u, v} P.
    ...

```

Since P is separated, one deduces $uf = vf$. This being true for every representable S , one has $u = v$.

Suppose now that P is a sheaf. Let $g : R \rightarrow P$; let us show that it factors through H . For every $f : S \rightarrow H$, $S \in \text{Ob } C$, $g \circ f_R : R \times_S S \rightarrow P$ factors

<!-- original page 204 -->

in a unique way through S , hence defines a morphism $h : S \rightarrow P$, which is evidently functorial in f , by uniqueness:

```

    ``text
    R ×_H S -f_R→ R -g→ P
      |j_S      |j      ^h
      S      -f→  H.
    ...

```

One has thus defined for every S a map from $H(S)$ into $P(S)$ functorial in S , hence a morphism from H into P that answers the required conditions.

Corollary 4.3.2.1. [N.D.E-IV-25] Let R, F be two sheaves. If R is a refinement of F , then $R = F$.

<!-- label: III.IV.4.3.2.1 -->

Indeed, suppose that R is a refinement of F and denote by j the inclusion $R \hookrightarrow F$. By 4.3.2, one has $\text{Hom}(F, R) = \text{End}(R)$, hence there exists $\pi : F \rightarrow R$ such that $\pi \circ j = \text{id}_R$. One has likewise $\text{Hom}(R, F) = \text{Hom}(R, F)$, and the equality $j \circ \pi \circ j = j$ entails $j \circ \pi = \text{id}_F$, hence j is an isomorphism.

Proposition 4.3.3 ([AS], 1.3). Let C be a category. Let P be a presheaf on C ; for every $S \in \text{Ob } C$, denote by $J(S)$ the set of sieves R of S such that for every $T \rightarrow S$, the map

```

    ``text
    (+)  Hom(T, P) → Hom(R ×_S T, P)
    ...

```

is injective (resp. bijective). Then the $J(S)$ define a topology on C , i.e. satisfy axioms (T 1) through (T 4).

<!-- label: III.IV.4.3.3 -->

Corollary 4.3.4. Let, for every $S \in \text{Ob } C$, $K(S)$ be a family of sieves satisfying (T 1). Let P be a presheaf on C . For it to be separated (resp. a sheaf) for the topology generated by the $K(S)$, it is necessary and sufficient that for every $S \in \text{Ob } C$ and every $R \in K(S)$, the canonical map

```

    ``text
    (+)  Hom(S, P) → Hom(R, P)
    ...

```

is injective (resp. bijective).

<!-- label: III.IV.4.3.4 -->

<!-- original page 197 -->

Corollary 4.3.5. Let, for each $S \in \text{Ob } C$, $R(S)$ be a set of families of morphisms of C with target S , satisfying (P 1) (for example defining a pretopology). Let P be a presheaf on C . For P to be separated (resp. a sheaf) for the topology generated by R , it is necessary and sufficient that for every $S \in \text{Ob } C$ and every family $\{S_i \rightarrow S\} \in R(S)$, the map

```

    P(S) → ∏_{i} P(S_i)

```

```

*be injective, (resp. the diagram*

```text

$$P(S) \rightarrow \prod_i P(S_i) \rightrightarrows \prod_{i,j} P(S_i \times_S S_j)$$

```

*be exact).*

<!-- label: III.IV.4.3.5 -->

**Definition 4.3.6.** *Let  $\mathcal{C}$  be a category. One calls the canonical topology on  $\mathcal{C}$  the finest topology for which all representable functors are sheaves.*

<!-- label: III.IV.4.3.6 -->

**Corollary 4.3.7.** *For a sieve  $R$  of  $S$  to be a refinement for the canonical topology, it is necessary and sufficient that for every morphism  $T \rightarrow S$  of  $\mathcal{C}$  and every  $X \in \text{Ob } \mathcal{C}$ , the canonical map*

<!-- label: III.IV.4.3.7 -->

**Definition 4.3.8.** *A sieve covering for the canonical topology will be called a universal effective epimorphic sieve.*

<!-- label: III.IV.4.3.8 -->

**Corollary 4.3.9.** *A universal effective epimorphic family defines a universal effective epimorphic sieve. Conversely, every squarable family defining a universal effective epimorphic sieve is universal effective epimorphic.*

<!-- label: III.IV.4.3.9 -->

Let us return to the case where  $\mathcal{C}$  is equipped with an arbitrary topology and pass to the construction of the sheaf associated to a presheaf  $P$ . Let  $S$  be an object of  $\mathcal{C}$ . If  $R \supseteq R'$  are

<!-- original page 198 -->

two refinements of  $S$ , one has a diagram

```text
Hom(S, P) → Hom(R, P)
 ↘
 Hom(R', P).
```

The ordered set  $J(S)$  is filtered, as has already been remarked. Since  $S$  is an element of  $J(S)$ , one has an evident morphism

```text
Hom(S, P) → \lim_{\leftarrow} \{R \in J(S)\} Hom(R, P).
```

<!-- original page 206 -->

**Definition 4.3.10.0.** [N.D.E-IV-26] *One sets  $\check{H}^0(S, P) = \varinjlim_{R \in J(S)} \text{Hom}(R, P)$ . One verifies that  $\check{H}^0(S, P)$  depends functorially on  $S$ , hence defines a functor  $\text{LP}$  by*

```text
(++) Hom(S, LP) = \check{H}^0(S, P) = \varinjlim_{R \in J(S)} Hom(R, P).
```

```

<!-- label: III.IV.4.3.10.0 -->

One has by construction morphisms

```

```text
□_P : P → LP
z_R : Hom(R, P) → Hom(S, LP).
```

```

Lemma 4.3.10. (i) For every refinement R of S and every $u : R \rightarrow P$, the diagram

```

$
P \xrightarrow{\ell_P} LP
\uparrow u \quad \uparrow z_R(u)
R \xrightarrow{i_R} S
$

```

is commutative.

(ii) For every morphism $v : S \rightarrow LP$, there exists a refinement R of S and a morphism $u : R \rightarrow P$ with $v = z_R(u)$.

<!-- original page 199 -->

(iii) Let Q be a functor and $u, v : Q \rightarrow P$ such that $\ell_P u = \ell_P v$. Then the kernel of the pair (u, v) is a refinement of Q .

(iv) Let $u : R \rightarrow P$ and $u' : R' \rightarrow P$; for $z_R(u) = z_{R'}(u')$, it is necessary and sufficient that there exist a refinement $R'' \subset R \cap R'$ of S such that u and u' coincide on R'' .

<!-- label: III.IV.4.3.10 -->

Proof. (i): One must verify that $z_R(u) i_R = \ell_P u$. For this, it suffices to verify that the composites of these two morphisms with every morphism $g : T \rightarrow R$, where T is representable, are equal. Now consider $f = i_R g$ and the fiber product $R' = R \times_S T$: [N.D.E-IV-27]

```

```text
P □_P → LP
↑u ↑z_R(u)
R □_R → S
↑p ↑f
R' →→ T (via i_R, g)
```

```

By definition of ℓ_P , $\ell_P u g = z_R(u) f$ (this is the particular case of what one is trying to prove in which i_R is an isomorphism), and now $z_R(u) f = z_R(u) i_R g$.

(ii) and (iv) merely translate the definition of $\text{Hom}(S, LP)$ as a direct limit.

(iii): If K denotes the kernel of the pair (u, v) , then for each morphism $f : S \rightarrow Q$ where S is representable, $K \times_Q S$ is a subfunctor of the kernel of the pair of arrows $uf, vf : S \rightarrow P$. One is therefore reduced, by $(T' \rightarrow 0)$, to proving the assertion in the case where $Q = S$ is representable. But in this case, it follows from (ii) and (iv) that K contains a refinement of S hence is a refinement of S .

One verifies finally that $\square_P$ defines a functor

<!-- original page 200 -->

```

$
L : \hat{C} \rightarrow \hat{C}
$

```

and $\square_P$ a morphism of functors

$\ell : \text{Id}_{\hat{C}} \rightarrow L$.
 ℓ

Let us now state the essential result:

Proposition 4.3.11. (i) If $\mathcal{P}$ is any presheaf, LP is separated and $\ell_P : \mathcal{P} \rightarrow \text{LP}$ is covering (4.2.3).

(ii) If $\mathcal{P}$ is a sheaf, $\mathcal{P} \rightarrow \text{LP}$ is an isomorphism.

(iii) For every presheaf $\mathcal{P}$ and every separated presheaf (resp. sheaf) $\mathcal{F}$, the map

$\text{Hom}(\square_P, \mathcal{F}) : \text{Hom}(\text{LP}, \mathcal{F}) \rightarrow \text{Hom}(\mathcal{P}, \mathcal{F})$

is injective (resp. bijective).

(iv) If $\mathcal{P}$ is separated, $\ell_P : \mathcal{P} \rightarrow \text{LP}$ is a covering monomorphism (hence $\mathcal{P}$ is a refinement of LP), and LP is a sheaf.

Proof. (i) First, $\mathcal{P} \rightarrow \text{LP}$ is covering; indeed, for every morphism $v : S \rightarrow \text{LP}$, there exists, by 4.3.10 (i) and (ii), a refinement $\mathcal{R}$ of $\mathcal{S}$ such that one has a commutative diagram

$$\begin{array}{ccc}
 \mathcal{P} & \xrightarrow{\ell_P} & \text{LP} \\
 \uparrow v' & & \uparrow v \\
 \mathcal{P} \times_{\text{LP}} S & \xleftarrow{\quad} & S \\
 \uparrow & & \uparrow i_R \\
 \mathcal{R} & &
 \end{array}$$

hence $\mathcal{P} \times_{\text{LP}} S \rightarrow S$ is covering. It follows, by (C 0), that $\mathcal{P} \rightarrow \text{LP}$ is covering.

If on the other hand two morphisms $v_1, v_2 : S \rightarrow \text{LP}$ induce the same morphism on a refinement $\mathcal{R}$ of $\mathcal{S}$, let us show that they are equal. There exist refinements $\mathcal{R}_i$, $i = 1, 2$, and morphisms $u_i : \mathcal{R}_i \rightarrow \mathcal{P}$ such that $z_{\mathcal{R}_i}(u_i) = v_i$. Taking $\mathcal{R}$ small enough, one may suppose $\mathcal{R}_1 = \mathcal{R}_2 = \mathcal{R}$. It then follows from the commutative diagram of 4.3.10

original page 201

(i) that $\ell_P u_1 = \ell_P u_2$. By loc. cit. (iii), u_1 and u_2 therefore coincide on a refinement of $\mathcal{R}$, hence a refinement of $\mathcal{S}$, which entails that $z_{\mathcal{R}}(u_1) = z_{\mathcal{R}}(u_2)$, by loc. cit. (iv).

(ii) is clear, for if $\mathcal{P}$ is a sheaf, $\text{Hom}(S, \mathcal{P}) \rightarrow \text{Hom}(R, \mathcal{P})$ is already an isomorphism for every refinement $\mathcal{R}$ of $\mathcal{S}$.

(iii) Let u and v be two morphisms $\text{LP} \rightarrow \mathcal{F}$ such that $\ell_P u = \ell_P v$. To show that $u = v$, it suffices to see that $u_f = v_f$ for every $f : S \rightarrow \text{LP}$ where $\mathcal{S}$ is representable. Now there exists a refinement $\mathcal{R}$ of $\mathcal{S}$ and a morphism $g : \mathcal{R} \rightarrow \mathcal{P}$ with $f = z_{\mathcal{R}}(g)$. Then u_f and v_f coincide on $\mathcal{R}$ with $\ell_P g = \ell_P g$, hence coincide on $\mathcal{R}$. If $\mathcal{F}$ is separated, one therefore has $u_f = v_f$. Suppose now that $\mathcal{F}$ is a sheaf; one then has the commutative diagram

$$\begin{array}{ccc}
 \mathcal{P} & \xrightarrow{\ell_P} & \text{LP} \\
 \downarrow & & \downarrow \\
 \mathcal{F} & \rightarrow & \text{LF}
 \end{array}$$

which shows that $\text{Hom}(\ell_P, \mathcal{F})$ is surjective.

(iv) Let us show that if $\mathcal{P}$ is separated, $\mathcal{P} \rightarrow \text{LP}$ is a monomorphism. For this, it suffices to see that for every pair of morphisms $u, v : S \rightarrow \mathcal{P}$ (where $\mathcal{S}$ is representable) such that $\ell_P u = \ell_P v$ one has $u = v$. Now

loc. cit. (iii) shows that $\mathcal{S}$ and $\mathcal{V}$ coincide on a refinement of $\mathcal{S}$, hence coincide because $\mathcal{P}$ is separated. This shows that $\mathcal{P} \rightarrow \mathcal{LP}$ is a monomorphism; as it is covering by (i), one obtains that $\mathcal{P}$ is a refinement of $\mathcal{LP}$.

Let us finally show that $\mathcal{LP}$ is a sheaf. As we already know by (i) that it is a separated presheaf, it suffices to see that for every $\mathcal{S} \in \mathbf{Ob} \mathcal{C}$, every refinement $\mathcal{R}$ of $\mathcal{S}$ and every morphism $h : \mathcal{R} \rightarrow \mathcal{LP}$, there exists a morphism $\mathcal{S} \rightarrow \mathcal{LP}$ with $\mathcal{S} \rightarrow \mathcal{R} = h$. Now $\mathcal{R}' = \mathcal{P} \times_{\mathcal{LP}} \mathcal{R}$ is a refinement of $\mathcal{R}$, since $\mathcal{P}$ is a refinement of $\mathcal{LP}$, hence $\mathcal{R}'$ is

<!-- original page 202 -->

a refinement of $\mathcal{S}$. Set $\mathcal{U} = \mathcal{Z}_{\mathcal{R}'}(h)$:

```

$$\begin{array}{ccc} \mathcal{P} & \xrightarrow{\quad} & \mathcal{LP} \\ \uparrow h' & & \uparrow \mathcal{U} \text{ (via } h) \\ \mathcal{R}' & \xrightarrow{\quad} & \mathcal{R} \xrightarrow{\quad} \mathcal{S}. \end{array}$$

```

One has $\mathcal{S} \rightarrow \mathcal{R}' = \mathcal{U} \rightarrow \mathcal{P} \rightarrow \mathcal{LP}$, whence $\mathcal{S} \rightarrow \mathcal{R}' = \mathcal{U} \rightarrow \mathcal{P} \rightarrow \mathcal{LP}$. Since $\mathcal{R}'$ is a refinement of $\mathcal{R}$ and since $\mathcal{LP}$ is separated, 4.3.2 shows that $\mathcal{S} \rightarrow \mathcal{R}' = \mathcal{U} \rightarrow \mathcal{P} \rightarrow \mathcal{LP}$.

Corollary 4.3.12. [N.D.E-IV-28] Let $\mathcal{F}$ be a sheaf and $\mathcal{R}$ a sub- $\hat{\mathcal{C}}$ -object of $\mathcal{F}$. Then $\mathcal{R}$ is a separated presheaf, $\mathcal{S} \rightarrow \mathcal{R}$ is a covering monomorphism, and one has a commutative diagram*

```

$$\begin{array}{ccc} \mathcal{R} & \xrightarrow{\quad} & \mathcal{F} \\ \downarrow & & \downarrow j \\ \mathcal{S} & \xrightarrow{\quad} & \mathcal{F} \\ \uparrow \mathcal{R} & & \uparrow \mathcal{R} \end{array}$$

```

Consequently, $\mathcal{R}$ is a refinement of $\mathcal{F}$ if and only if j is an isomorphism.

<!-- label: III.IV.4.3.12 -->

We have already noted that $\mathcal{R}$ is separated and that j is a monomorphism, cf. N.D.E. (24) and (26). By 4.3.11 (iv), $\mathcal{S} \rightarrow \mathcal{R}$ is a covering monomorphism. Therefore, if j is an isomorphism, $\mathcal{R}$ is a refinement of $\mathcal{F}$. Conversely, if $\mathcal{S} \rightarrow \mathcal{R}$ is covering, so is j , hence it is an isomorphism by 4.3.2.1.

Remark 4.3.13. If $J'(S)$ is a cofinal subset of $J(S)$, one has*

```

$$\mathrm{Hom}(S, \mathcal{LP}) = \varinjlim_{\mathcal{R} \in J'(S)} \mathrm{Hom}(\mathcal{R}, \mathcal{P}).$$

```

In particular, let $\mathcal{S} \in \mathcal{R}(S)$ be a pretopology generating the given topology. The functor $\mathcal{L}$ can be described using the covering families that are elements of $\mathcal{R}(S)$. Making the formula above explicit, one recovers the construction of [MA].

<!-- label: III.IV.4.3.13 -->

Denote by $\mathcal{I}$ the inclusion functor $\mathcal{S} \rightarrow \hat{\mathcal{C}}$. From Proposition 4.3.11 results the following theorem:

Theorem 4.3.14. There exists a unique functor $\mathcal{A} : \hat{\mathcal{C}} \rightarrow \mathcal{S}$ such that the following diagram is commutative*

```

$$\begin{array}{ccc} \hat{\mathcal{C}} & \xrightarrow{\quad} & \hat{\mathcal{C}} \\ \downarrow \mathcal{A} & & \downarrow \mathcal{L} \\ \mathcal{S} & \xrightarrow{\quad} & \hat{\mathcal{C}}, \end{array}$$

```

<!-- original page 210 -->

*i.e., for every presheaf $\mathcal{P}$, $\mathcal{L}(\mathcal{L}(\mathcal{P}))$ is a sheaf. The functors $\mathcal{I}$ and $\mathcal{A}$ are adjoint to one another: for every

presheaf $\mathcal{P}$ and every sheaf $\mathcal{F}$ one has an isomorphism, functorial in $\mathcal{P}$ and $\mathcal{F}$,

```

```text
Hom_C(P, i(F)) = Hom_C(a(P), F),
```

```

<!-- original page 203 -->

that is,

```

```text
Hom(P, F) = Hom(a(P), F).
```

```

<!-- label: III.IV.4.3.14 -->

Definition 4.3.15. *The sheaf $\mathcal{a}(\mathcal{P})$ is said to be associated to the presheaf $\mathcal{P}$.*

<!-- label: III.IV.4.3.15 -->

Remark 4.3.16. *As the functor $\mathcal{L}$ is constructed using inverse limits and filtered direct limits, it commutes with finite inverse limits.*^[N.D.E-IV-29]

Moreover, if one identifies $\mathcal{L}(\mathcal{P} \times \mathcal{P})$ with $\mathcal{L}\mathcal{P} \times \mathcal{L}\mathcal{P}$, the morphism $\ell_{\mathcal{P} \times \mathcal{P}}$ is identified with $\ell_{\mathcal{P}} \times \ell_{\mathcal{P}}$. It follows for example that if $\mathcal{P}$ is a presheaf of groups, $\mathcal{L}\mathcal{P}$ is also canonically equipped with a structure of presheaf of groups and the canonical morphism $\mathcal{P} \rightarrow \mathcal{L}\mathcal{P}$ is a morphism of groups. The same holds for the functor $\mathcal{a}$, which shows that if $\mathcal{P}$ is a presheaf of groups and $\mathcal{F}$ a sheaf of groups, one has an isomorphism*

```

```text
Hom_{C-gr}(P, i(F)) = Hom_{C-gr}(a(P), F).
```

```

See [D] for more details.

<!-- label: III.IV.4.3.16 -->

4.3.17. If $\mathcal{V}$ is any category, one calls a *presheaf* on $\mathcal{C}$ with values in $\mathcal{V}$ a contravariant functor from $\mathcal{C}$ into $\mathcal{V}$. To define sheaves with values in $\mathcal{V}$, we must first recall the definition of the inverse limit of a functor. If $\mathcal{R}$ and $\mathcal{V}$ are two categories, and

```

F : R^{circ} -> V

```

a contravariant functor from $\mathcal{R}$ to $\mathcal{V}$, one denotes by $\varprojlim F$ the object of $\hat{\mathcal{V}}$ defined as follows:

```

```text
lim F(X) = Hom_V(X, lim F) = lim_{U in Ob R} Hom_V(F(U), X) = Hom(c_X, F),
```

```

<!-- original page 204 -->

where X is a variable object of $\mathcal{V}$, where c_X denotes the contravariant functor from $\mathcal{R}$ to $\mathcal{V}$ that sends each object of $\mathcal{R}$ to X and each arrow of $\mathcal{R}$ to id_X , and where the last Hom is taken in the category $\text{Hom}(\mathcal{R}^{\text{circ}}, \mathcal{V})$. If $\mathcal{R}$ has a final object $e_{\mathcal{R}}$, one has $\varprojlim F = F(e_{\mathcal{R}})$. If $\mathcal{V}$ is the category of sets, the functor $\varprojlim$ is identified with the functor Γ .

If S is an object of $\mathcal{C}$ and $\mathcal{R}$ a sieve of S , denote by $\bar{\mathcal{R}}$ the full subcategory of $\mathcal{C}/S$ whose set of objects is $E(\mathcal{R})$ and $i_{\mathcal{R}} : \bar{\mathcal{R}} \rightarrow \mathcal{C}/S$ the canonical functor. If $\mathcal{P}$ is a presheaf on $\mathcal{C}$ with values in $\mathcal{V}$, it defines by restriction a functor $\mathcal{P}_{\mathcal{R}} : (\mathcal{C}/S)^{\text{circ}} \rightarrow \mathcal{V}$. The functor $i_{\mathcal{R}}$ induces a morphism of $\hat{\mathcal{V}}$:

```

```text
P(S) = P_S(S) = lim P_S -> lim(P_S o i_R).
```

```

<!-- original page 211 -->

One denotes by $\varinjlim P_S$ the object $\varinjlim (P_S \circ i_R)$ of $\hat{V}$. By virtue of 4.1.6, Definition 4.3.1 generalizes to the

Definition 4.3.18. The presheaf P on C with values in V is said to be separated (resp. a sheaf), if for every $S \in \text{Ob } C$ and every $R \in J(S)$, the canonical morphism of $\hat{V}$

$$P(S) \longrightarrow \varinjlim P$$

is a monomorphism (resp. an isomorphism).

<!-- label: III.IV.4.3.18 -->

In the case where V is the category $(Gr.)$ of groups (or any other category of sets equipped with algebraic structures defined by finite inverse limits), one can see (cf. [D]) that there is equivalence between the following notions: a presheaf on C with values in $(Gr.)$ whose underlying presheaf of sets is a sheaf, and a group in the category of sheaves of sets. Taking account of these identifications, we shall always consider sheaves with values in a category of sets equipped with algebraic structures defined by finite inverse limits

<!-- original page 205 -->

as sheaves of sets, equipped in the category $\tilde{C}$ with the corresponding algebraic structure.

4.4. Exactness properties of the category of sheaves

Theorem 4.4.1. (i) Arbitrary inverse limits exist in $\tilde{C}$; they are computed in $\hat{C}$, i.e. the inclusion functor $i : \tilde{C} \rightarrow \hat{C}$ commutes with inverse limits: if (X_α) is an inverse system of sheaves, the presheaf

$$\lim_{\leftarrow} i(X_\alpha) : S \mapsto \lim_{\leftarrow} X_\alpha(S)$$

is a sheaf and one has $i(\lim_{\leftarrow} X_\alpha) = \lim_{\leftarrow} i(X_\alpha)$.

(ii) Arbitrary direct limits exist in $\tilde{C}$: if (X_α) is a direct system of sheaves, one has

$$\lim_{\rightarrow} X_\alpha = a(\lim_{\rightarrow} i(X_\alpha))$$

where $\lim_{\rightarrow} i(X_\alpha)$ is the presheaf direct limit of the $i(X_\alpha)$:

$$\lim_{\rightarrow} i(X_\alpha) : S \mapsto \lim_{\rightarrow} X_\alpha(S).$$

(iii) The functor $a : \hat{C} \rightarrow \tilde{C}$ commutes with arbitrary direct limits and with finite inverse limits.

<!-- label: III.IV.4.4.1 -->

Assertions (i) and (ii) follow formally from the adjunction formula (4.3.14), and [N.D.E-IV-30] the first assertion of (iii) follows from (ii). Finally, the second assertion of (iii) has already been pointed out in 4.3.16.

Scholie 4.4.2. This theorem allows one to use the following method to prove in $\tilde{C}$ an assertion bearing simultaneously on arbitrary direct limits and finite inverse limits (for example: "every epimorphism is universally effective", cf. below). One begins by proving the corresponding assertion in the category of sets, then one extends it "argument by argument" to the category

<!-- original page 206 -->

of presheaves. Next, one uses the preceding theorem to pass from the category of presheaves to the category of sheaves. One will see in the sequel many examples of this method (4.4.3, 4.4.6, 4.4.9, etc.).

<!-- label: III.IV.4.4.2 -->

<!-- original page 212 -->

Let us finally remark that the assertions relative to the category of presheaves are formally corollaries of the assertions relative to the category of sheaves. It suffices in fact to take as topology the least fine topology ("chaotic"), that is, the topology defined by $J(S) = \{S\}$ for every $S \in \mathcal{O}b \mathcal{C}$; every functor is indeed a sheaf for this topology.

Proposition 4.4.3. *Let $\mathcal{F} = \{F_i \rightarrow F\}$ be a family of morphisms of sheaves. The following conditions are equivalent:*

(i) $\mathcal{F}$ is an epimorphic family.*

(ii) $\mathcal{F}$ is a universal effective epimorphic family (1.13).*

(iii) $\mathcal{F}$ is covering (4.2.3).*

(iv) The sheaf image of $\mathcal{F}$ (that is, the sheaf associated to the presheaf image of $\mathcal{F}$ (4.1.2)) is $\mathcal{F}$.*

<!-- label: III.IV.4.4.3 -->

The equivalence of (iii) and (iv) follows from 4.3.12. The other equivalences will follow from the following lemmas.

Lemma 4.4.4. *Let $f : X \rightarrow Y$ be a monomorphism of sheaves which is an epimorphism. Then f is an isomorphism.*

<!-- label: III.IV.4.4.4 -->

The lemma is first clear in the category of sets. Let us prove it next in the category of presheaves. Consider the presheaf

```

```text
V : S → Y(S) ∪X(S) Y(S);
```

```

<!-- original page 207 -->

it is the amalgamated sum of Y and Y under X in the category of presheaves. [N.D.E-IV-31] Denote by i_1 and i_2 the two "coordinate" morphisms $Y \rightarrow V$. If $X \rightarrow Y$ is an epimorphism in the category of presheaves, then $i_1 = i_2$. In this case, for each S , the map $X(S) \rightarrow Y(S)$ is surjective; as it is also injective, it is a bijection, and therefore $X \rightarrow Y$ is an isomorphism.

Let us place ourselves finally in the category $\tilde{\mathcal{C}}$ of sheaves. By 4.4.1 (ii), the amalgamated sum in $\tilde{\mathcal{C}}$ of the sheaves Y and Y under X is the sheaf Z associated to the presheaf V . Consider the diagram of morphisms:

```

```text
X →f Y →i1, i2 V →τ Z = a(V).
```

```

One has $i_1 f = i_2 f$, whence $\tau i_1 f = \tau i_2 f$, and therefore $\tau i_1 = \tau i_2$, since f is an epimorphism in $\tilde{\mathcal{C}}$. By point (iii) of the lemma below, the presheaf V is separated, hence τ is a monomorphism (4.3.11 (iv)). Therefore $i_1 = i_2$, and we have seen above that this

<!-- original page 213 -->

entails that $f : X \rightarrow Y$ is an isomorphism. This proves Lemma 4.4.4, once one has verified that V is separated.

[N.D.E-IV-32] Let $R_{\emptyset}$ be the presheaf that to every $S \in \mathcal{O}b \mathcal{C}$ associates the empty set; it is an initial object of $\tilde{\mathcal{C}}$.

Lemma 4.4.5. (i) Suppose that $R_{\emptyset} \notin J(S)$, for every $S \in \mathcal{O}b \mathcal{C}$. If (X_i) is a family of separated presheaves, the direct sum presheaf $\coprod_i X_i$ is separated. [N.D.E-IV-33]

(ii) Consider an equivalence relation in the category of presheaves:

```
```text
 $X \approx_{\{u, v\}} Y$
```
```

and let $\pi : Y \rightarrow Z$ be the quotient. If X is a sheaf and Y separated, then Z is separated.

(iii) Consider an amalgamated sum in the category of presheaves, where u and u' are monomorphisms:

```
```text

$$\begin{array}{ccc} X & \xrightarrow{u} & Y \\ u' \downarrow & & \downarrow \\ Y' & \rightarrow & V. \end{array}$$

```
```

If Y and Y' are separated, and X a sheaf, then V is separated.

<!-- label: III.IV.4.4.5 -->

(i) Set $X = \coprod_i X_i$. Let $S \in \mathcal{C}$ and $\tau : R \rightarrow S$ a refinement of S , and let x_1, x_2 be two elements of $X(S)$ such that $x_1 \circ \tau = x_2 \circ \tau$; there exist indices i, j such that $x_1 \in X_i(S)$ and $x_2 \in X_j(S)$. Since $R \neq \emptyset$, there exists a morphism $\phi : T \rightarrow R$, with $T \in \mathcal{C}$. Then, $x_1 \circ \tau \circ \phi = x_2 \circ \tau \circ \phi$, and since $X(T)$ is the disjoint union of the $X_k(T)$, this entails $i = j$. Then, since X_i is separated and a subobject of X , the map $X_i(S) \rightarrow X_i(R) \rightarrow X(R)$ is injective, and therefore $x_1 = x_2$. This proves that X is separated.

Let us prove (iii). Consider the morphisms $i : Y \rightarrow V$ and $j : Y' \rightarrow V$, and let K be the kernel of:

```
```text
 $Y \times Y' \rightrightarrows V,$
```
```

where $p = i \circ \text{pr}_1$ and $q = j \circ \text{pr}_2$.

Let $S \in \mathcal{C}$. Since u and u' are monomorphisms, one can identify $X(S)$ with its image in $Y(S)$ (resp. $Y'(S)$); denote by $Z(S)$ (resp. $Z'(S)$) the complement. Then

<!-- original page 214 -->

$V(S)$ is identified with the disjoint union of $Z(S)$, $Z'(S)$ and $X(S)$, and one easily sees that the maps $i(S) : Y(S) \rightarrow V(S)$ and $j(S) : Y'(S) \rightarrow V(S)$ are injective, and that the map

```
```text
 $(u \times u')(S) : X(S) \rightarrow K(S)$
```
```

is bijective. Consequently, i and j are monomorphisms, and $u \times u' : X \rightarrow K$ is an isomorphism.

Set $U = Y \coprod Y'$, and let $\tau : R \rightarrow S$ be a refinement of S ; one has a commutative diagram:

```
$$
\begin{array}{ccc}
U(S) & \xrightarrow{U(\tau)} & U(R) \\
\downarrow & & \downarrow \\
V(S) & \xrightarrow{V(\tau)} & V(R).
\end{array}
$$
```

Let $v_1, v_2 \in V(S)$ whose images in $V(R)$ coincide. By the definition of V , v_1, v_2 lift to elements y_1, y_2 of $U(S)$; denote by z_1, z_2 their images in $U(R)$. Then z_1, z_2 have the same image in $V(R)$.

Since $i : Y \rightarrow V$ and $j : Y' \rightarrow V$ are monomorphisms, the maps $Y(R) \rightarrow V(R)$ and $Y'(R) \rightarrow V(R)$ are injective. Therefore, since Y and Y' are separated, if y_1 and y_2 both belong to $Y(S)$ or to $Y'(S)$, then $y_1 = y_2$. Otherwise, one may suppose that $y_1 \in Y(S)$ and $y_2 \in Y'(S)$, whence $z_1 \in Y(R)$ and

$z_2 \in Y(R)$. But then, since $i \circ z_1 = j \circ z_2$, the morphism $z_1 \boxtimes z_2 : R \rightarrow Y \times Y$ factors through $K = X$. Moreover, since $X(R) = X(S)$ (because X is a sheaf), there exists $x \in X(S)$ such that $u(x) \circ \tau = z_1 = y_1 \circ \tau$ and $u'(x) \circ \tau = z_2 = y_2 \circ \tau$, whence, since Y and Y' are separated, $u(x) = y_1$ and $u'(x) = y_2$, and therefore $v_1 = v_2$. This proves that V is separated.

Let us prove (ii). Let us first remark that the morphism of presheaves

$$X \rightarrowtail u \boxtimes v : K,$$

where K denotes the kernel of the pair of morphisms $w \circ pr_i : Y \times Y \rightarrow Z$, is an isomorphism. Indeed, for every $T \in \text{Ob } C$, $X(T)$ is an equivalence relation in $Y(T)$, so that the diagram

$$\begin{array}{ccc} X(T) & \xrightarrow{u \boxtimes v} & Y(T) \times Y(T) \\ & & \searrow \scriptstyle w \circ pr_1, w \circ pr_2 \\ & & Z(T) \end{array}$$

is exact in the category of sets.

Let now $S \in \text{Ob } C$ and $g_1, g_2 : S \rightarrow Z$ be two morphisms that coincide on a refinement $\tau : R \hookrightarrow S$ of S . Since $S \in \text{Ob } C$, one has $Z(S) = Y(S)/X(S)$,

<!-- original page 208 -->

by construction of Z , and therefore there exist morphisms $f_1, f_2 : S \rightarrow Y$ such that $w f_i = g_i$.

Then, $w f_1 \circ \tau = w f_2 \circ \tau$ and therefore, by what precedes, there exists a morphism $\phi : R \rightarrow X$ such that $u \phi = f_1 \circ \tau$ and $v \phi = f_2 \circ \tau$. Since X is a sheaf, there exists $\psi : S \rightarrow X$ such that $\psi \circ \tau = \phi$, and therefore one has in $Y(R)$ the equalities:

$$u \psi \tau = f_1 \tau, \quad v \psi \tau = f_2 \tau.$$

<!-- original page 215 -->

Since $Y(S) \rightarrow Y(R)$ is injective (Y being separated), this entails $u \psi = f_1$ and $v \psi = f_2$, whence it follows that $g_1 = g_2$. This proves that Z is separated.

Lemma 4.4.6. (N.D.E-IV-34) (i) Let $\{F_i \rightarrowtail F\}$ be a family of morphisms of presheaves, and let $G \subset F$ be the presheaf image. Then the following diagram in $\hat{C}$ is exact:

$$\coprod_i F_i \times_G \coprod_j F_j \rightrightarrows \coprod_i F_i \rightarrow G$$

i.e., for every presheaf H , the following diagram of sets is exact:

$$(*) \quad \text{Hom}(G, H) \rightarrow \coprod_i \text{Hom}(F_i, H) \rightrightarrows \coprod_{i,j} \text{Hom}(F_i \times_G F_j, H).$$

(ii) Every covering family of morphisms of sheaves is universally effective epimorphic.

<!-- label: III.IV.4.4.6 -->

(i) Let H be a presheaf. The map f which to a morphism $\phi : G \rightarrow H$ associates the family of morphisms $\phi \circ f_i : F_i \rightarrow H$ is injective, since for every $S \in \text{Ob } C$, $\phi(S)$ is determined by the $(\phi \circ f_i)(S)$, since the family $f_i(S) : F_i(S) \rightarrow G(S)$ is surjective. It is clear that the image of f is contained in $\text{Ker}(p, q)$. Conversely, let $\phi_i : F_i \rightarrow H$ be a family of morphisms such that, for every i, j , the diagram below is commutative:

$$\begin{array}{ccc} & & \\ & & \\ & & \end{array}$$

$$\begin{array}{ccc} F_i \times_G F_j & \rightarrow & F_j \\ \downarrow & & \downarrow \varphi_j \\ F_i & \xrightarrow{\varphi_i} & H. \end{array}$$

Then, for every S , the map $\coprod_i F_i(S) \rightarrow H(S)$ factors uniquely as a map $\varphi(S) : G(S) \rightarrow H(S)$, and this defines a morphism $\varphi : G \rightarrow H$ such that $f^*(\varphi) = (\varphi_i)$. This proves the exactness of the sequence $(*)$, and point (i).

Let us prove (ii). Since the notion of covering family is stable under base extension, it suffices to show that every covering family is effective epimorphic. So let $\{F_i \rightarrow F\}$ be a covering family of morphisms of sheaves, and let G be the presheaf image of this family. Since the family is covering, so is the monomorphism $G \hookrightarrow F$, hence, by 4.3.12, one has $a(G) = F$.

On the other hand, since $G \hookrightarrow F$ is a monomorphism, the fiber products $F_i \times_G F_j$ and $F_i \times_F F_j$ are the same. Hence, by (i), the following diagram of sets is exact, for every presheaf H :

$$(*) \quad \text{Hom}(G, H) \rightarrow \prod_i \text{Hom}(F_i, H) \rightrightarrows \prod_{i,j} \text{Hom}(F_i \times_F F_j, H).$$

If moreover H is a sheaf, one has

$$\text{Hom}(G, H) = \text{Hom}(a(G), H) = \text{Hom}(F, H),$$

<!-- original page 216 -->

and then $(*)$ shows that $\{F_i \rightarrow F\}$ is indeed an effective epimorphic family in the category $\mathcal{C}$ of sheaves.

Lemma 4.4.7. Every family of morphisms of sheaves $\{F_i \rightarrow F\}$ factors as a covering family $\{F_i \rightarrow G\}$ and a monomorphism $G \rightarrow F$.

<!-- label: III.IV.4.4.7 -->

It suffices in fact to take for G the sheaf image of the given family.

<!-- original page 209 -->

Proof of Proposition 4.4.3: one has seen in 4.4.6 that (iii) $\Rightarrow$ (ii), and one evidently has (ii) $\Rightarrow$ (i). Let finally $\{F_i \rightarrow F\}$ be an epimorphic family; by Lemma 4.4.7, it factors as a covering family followed by a monomorphism. But the latter, being dominated [N.D.E-IV-35] by an epimorphic family, is an epimorphism, hence an isomorphism by 4.4.4.

Remark 4.4.8. [N.D.E-IV-36] As the presheaf image of the family $\{F_i\}$ is separated, the construction of the associated sheaf shows that the conditions of Proposition 4.4.3 are also equivalent to the following:

(v) For every $S \in \mathcal{C}$, every $f \in F(S)$ is locally in the image of $\{F_i\}$, that is:

(vi) For every $S \in \mathcal{C}$ and every $f \in F(S)$, the set of $S' \rightarrow S$ such that the image of f in $F(S')$ is in the image of one of the $\{F_i\}(S')$ is a refinement of $\{S\}$.

(vii) (If the topology is defined by a pretopology $\mathcal{R}$). For every $S \in \mathcal{C}$ and every $f \in F(S)$, there exists a family $\{S_j \rightarrow S\} \in \mathcal{R}(S)$ such that for every j the image f_j of f in $F(S_j)$ is in the image of one of the $\{F_i\}(S_j)$.

<!-- label: III.IV.4.4.8 -->

Remark 4.4.8.bis. If the sheaf F is representable, the preceding conditions are also equivalent to:

(viii) The set of $T \rightarrow F$ ($T \in \mathcal{C}$), such that there exist an i and a commutative diagram

$$\begin{array}{ccc} & & \\ F_i & \rightarrow & F \end{array}$$

↑ ↗
T
...

is a refinement of $\mathcal{F}$.

<!-- label: III.IV.4.4.8.bis -->

<!-- original page 210 -->

Indeed, if (viii) is satisfied, the presheaf image of the $\mathcal{F}_1$ is dominated by [N.D.E-IV-37] a refinement of $\mathcal{F}$, which entails that the family is covering. Conversely, one applies (vi) to id_F in $F(F)$.

This condition is expressed in pictorial language in the following way: *locally on $\mathcal{F}$, there exists an $\mathcal{F}_i$ such that $\mathcal{F}_i \rightarrow \mathcal{F}$ has a section*. In particular, a morphism

<!-- original page 217 -->

$\mathcal{G} \rightarrow \mathcal{F}$, where $\mathcal{G}$ is a sheaf and $\mathcal{F}$ a representable sheaf, will be covering if and only if it has *locally (on $\mathcal{F}$) a section*.

[N.D.E-IV-38] The following lemmas will be useful in VI_B, 8.1 and 8.2.

Lemma 4.4.8.1. *Let $\mathcal{Q} \subset \mathcal{P}$ be presheaves of groups on $\mathcal{C}$, $\mathcal{Q}$ being normal in $\mathcal{P}$. Suppose that $\mathcal{P}$ is separated, and that $\mathcal{Q}$ is a sheaf. Then the presheaf of groups $\mathcal{P}/\mathcal{Q}$ is separated. Consequently, one has*

```text  
a(P/Q) = L(P/Q) =  $\lim_{\rightarrow \{R \in J(S)\}} (P/Q)(R)$ .  
```

<!-- label: III.IV.4.4.8.1 -->

It suffices to show the first assertion, since the second follows from it, by 4.3.11 (iv) and (ii). Let $\mathcal{S} \in \text{Ob } \mathcal{C}$ and $\mathcal{R}$ a sieve of $\mathcal{S}$, and let $\gamma \in \mathcal{P}(\mathcal{S})/\mathcal{Q}(\mathcal{S})$ whose image in $(\mathcal{P}/\mathcal{Q})(\mathcal{R})$ is the identity. One must show that $\gamma = 1$. Now, by hypothesis, the morphism $\mathcal{P}(\mathcal{S}) \rightarrow \mathcal{P}(\mathcal{R})$ (resp. $\mathcal{Q}(\mathcal{S}) \rightarrow \mathcal{Q}(\mathcal{R})$) is injective (resp. an isomorphism), and in the commutative diagram below, the top row is exact:

$$\begin{array}{ccccccc} \mathcal{S} & & & & & & \\ 1 \rightarrow \mathcal{Q}(\mathcal{S}) \rightarrow \mathcal{P}(\mathcal{S}) \rightarrow \mathcal{P}(\mathcal{S})/\mathcal{Q}(\mathcal{S}) \rightarrow 1 & & & & & & \\ & \searrow \downarrow \text{wr} & & \searrow \downarrow & & & \\ 1 \rightarrow \mathcal{Q}(\mathcal{R}) \rightarrow \mathcal{P}(\mathcal{R}) \rightarrow (\mathcal{P}/\mathcal{Q})(\mathcal{R}) & & & & & & \\ \mathcal{S} & & & & & & \end{array}$$

The result will follow from this, if one shows that the bottom row is exact. Let $f : \mathcal{R} \rightarrow \mathcal{P}$ whose image in $(\mathcal{P}/\mathcal{Q})(\mathcal{R})$ is the identity, and let $\phi : \mathcal{T} \rightarrow \mathcal{R}$ with $\mathcal{T} \in \text{Ob } \mathcal{C}$. Then $f \circ \phi$ is the identity of $(\mathcal{P}/\mathcal{Q})(\mathcal{T}) = \mathcal{P}(\mathcal{T})/\mathcal{Q}(\mathcal{T})$, i.e. $f \circ \phi \in \mathcal{Q}(\mathcal{T})$. Therefore, $\phi \mapsto f \circ \phi$ is a functorial map $\mathcal{R}(\mathcal{T}) \rightarrow \mathcal{Q}(\mathcal{T})$, hence defines a morphism of functors $\pi : \mathcal{R} \rightarrow \mathcal{Q}$ such that $\pi(\text{id}_{\mathcal{R}}) = f$, whence $f \in \mathcal{Q}(\mathcal{R})$. This proves the exactness of the bottom row, and the lemma is proved.

Lemma 4.4.8.2. *Let $\mathcal{H} \subset \mathcal{G}$ be presheaves of groups on $\mathcal{C}$.*

(i) If $\mathcal{H}$ is normal in $\mathcal{G}$, then $\mathcal{L}(\mathcal{H})$ is normal in $\mathcal{L}(\mathcal{G})$.*

(ii) If $\mathcal{H}$ is central in $\mathcal{G}$, then $\mathcal{L}(\mathcal{H})$ is central in $\mathcal{L}(\mathcal{G})$.*

<!-- label: III.IV.4.4.8.2 -->

Let $\mathcal{S} \in \text{Ob } \mathcal{C}$; it must be shown (cf. I 2.3.6) that $\mathcal{L}(\mathcal{H})(\mathcal{S})$ is normal (resp. central) in $\mathcal{L}(\mathcal{G})(\mathcal{S})$. Let $h \in \mathcal{L}(\mathcal{H})(\mathcal{S})$ and $g \in \mathcal{L}(\mathcal{G})(\mathcal{S})$; there exist a sieve $\mathcal{R}$ of $\mathcal{S}$ and elements $h' \in \mathcal{H}(\mathcal{R})$, $g' \in \mathcal{G}(\mathcal{R})$, such that $h = z_{\mathcal{R}}(h')$ and $g = z_{\mathcal{R}}(g')$ (notation of 4.3.10). Since $z_{\mathcal{R}}$ is a morphism of groups, one has $g h g^{-1} h^{-1} = z_{\mathcal{R}}(g' h' g'^{-1} h'^{-1})$.

In case (i), one has $g' h' g'^{-1} h'^{-1} \in \mathcal{H}(\mathcal{R})$, whence $g h g^{-1} h^{-1} \in \mathcal{L}(\mathcal{H})(\mathcal{S})$; in case (ii), $g' h' g'^{-1} h'^{-1} = 1$ and therefore $g h g^{-1} h^{-1} = 1$.

<!-- original page 218 -->

****Proposition 4.4.9.**** *Every equivalence relation in $\mathcal{C}$ is universally effective (3.3.3): let $\mathcal{R}$ be a $\mathcal{C}$ -equivalence relation in the sheaf $\mathcal{X}$; then the sheaf associated to the separated presheaf*

```
```text
i(X)/i(R) : S → X(S)/R(S)
```
```

is a universal effective quotient of $\mathcal{X}$ by $\mathcal{R}$.

<!-- label: III.IV.4.4.9 -->

Let $\mathcal{X}/\mathcal{R}$ be the sheaf quotient of $\mathcal{X}$ by $\mathcal{R}$, which exists by 4.4.1 (ii): $\mathcal{X}/\mathcal{R} = a(i(X)/i(R))$. We must show that $\mathcal{X} \rightarrow \mathcal{X}/\mathcal{R}$ is a universal effective epimorphism, and that the morphism $f : \mathcal{R} \rightarrow \mathcal{X} \times_{\mathcal{X}/\mathcal{R}} \mathcal{X}$ is an isomorphism. The first assertion has already been proved (4.4.3). As for f , it comes by application of the functor a from the morphism $i(\mathcal{R}) \rightarrow i(\mathcal{X}) \times_{i(\mathcal{X}/\mathcal{R})} i(\mathcal{X})$ or, since $i(\mathcal{X})/i(\mathcal{R})$ is separated (4.4.5 (ii)) so that $i(\mathcal{X})/i(\mathcal{R}) \rightarrow i(\mathcal{X}/\mathcal{R})$ is a monomorphism, from the canonical morphism $i(\mathcal{R}) \rightarrow i(\mathcal{X}) \times_{i(\mathcal{X})/i(\mathcal{R})} i(\mathcal{X})$.

One is therefore reduced to proving the same assertion in the category of presheaves. But $i(\mathcal{X})/i(\mathcal{R})$ is the presheaf $S \rightarrow X(S)/R(S)$ and one is reduced to proving the analogous assertion in the category of sets, where it is immediate.

****Proposition 4.4.10.**** *Under the conditions of 4.4.9, let $\mathcal{Y}$ be a subsheaf of $\mathcal{X}$. Denote by $\mathcal{R}_Y$ the equivalence relation induced in $\mathcal{Y}$ by $\mathcal{R}$. Then the canonical morphism (3.1.6)*

<!-- original page 211 -->

```
$$
Y/R_Y \rightarrow X/R
$$
```

is a monomorphism: it identifies Y/R_Y with a subsheaf of $\mathcal{X}/\mathcal{R}$, which is the sheaf image *of the composite morphism*

```
$$
Y \rightarrow X \rightarrow X/R.
$$
```

<!-- label: III.IV.4.4.10 -->

The morphism of presheaves

```
$$
i(Y)/i(R_Y) = i(Y)/i(R)_{i(Y)} \rightarrow i(X)/i(R)
$$
```

is a monomorphism. Since the functor a is left exact (4.3.16), it transforms monomorphisms into monomorphisms, and therefore

```
$$
Y/R_Y \rightarrow X/R
$$
```

is a monomorphism. The last assertion follows from the commutative diagram

```
$$
Y \rightarrow X
\downarrow \quad \downarrow
Y/R_Y \rightarrow X/R,
$$
```

and the fact that $Y \rightarrow Y/R_Y$ is covering.

By virtue of this proposition, we shall always identify Y/R_Y with a subsheaf of $\mathcal{X}/\mathcal{R}$.

<!-- original page 219 -->

****Proposition 4.4.11.**** *Let $\mathcal{R}$ be a $\sim_C$ -equivalence relation in the sheaf $\mathcal{X}$. For every subsheaf $\mathcal{Y}$ of $\mathcal{X}$ stable under $\mathcal{R}$, denote by $\mathcal{Y}'$ the quotient $\mathcal{Y}/\mathcal{R}_Y$ considered as a subsheaf of $\mathcal{X}' = \mathcal{X}/\mathcal{R}$. Then $\mathcal{Y} = \mathcal{Y}' \times_{\mathcal{X}'} \mathcal{X}$, and the maps $\mathcal{Y} \rightarrow \mathcal{Y}/\mathcal{R}_Y$ and $\mathcal{Y}' \times_{\mathcal{X}'} \mathcal{X} \rightarrow \mathcal{X}$ realize a bijective correspondence between the set of subsheaves $\mathcal{Y}$ of $\mathcal{X}$ stable under $\mathcal{R}$ and the set of subsheaves $\mathcal{Y}'$ of $\mathcal{X}'$.*

<!-- label: III.IV.4.4.11 -->

If $\mathcal{Y}'$ is a subsheaf of $\mathcal{X}'$, then $\mathcal{Y}' \times_{\mathcal{X}'} \mathcal{X}$ is a subsheaf of $\mathcal{X}$ stable

<!-- original page 212 -->

under $\mathcal{R}$. [N.D.E-IV-39] If $\mathcal{Y}'$ is obtained by passage to the quotient from a subsheaf $\mathcal{Y}$ of $\mathcal{X}$, then $\mathcal{Y}$ is a subobject of $\mathcal{Y}' \times_{\mathcal{X}'} \mathcal{X}$. It therefore suffices to show that if one has two subsheaves $\mathcal{Y}$ and $\mathcal{Y}_{\{1\}}$ of $\mathcal{X}$, stable under $\mathcal{R}$, $\mathcal{Y}_{\{1\}}$ containing $\mathcal{Y}$, and if the quotients $\mathcal{Y}/\mathcal{R}_Y$ and $\mathcal{Y}_{\{1\}}/\mathcal{R}_{Y_{\{1\}}}$ are identical, then $\mathcal{Y} = \mathcal{Y}_{\{1\}}$. One is evidently reduced to proving the same assertion in the case where $\mathcal{Y}_{\{1\}} = \mathcal{X}$. Denoting then by $\mathcal{P}$ (resp. $\mathcal{Q}$) the presheaf $i(X)/i(R)$ (resp. $i(Y)/i(R_Y)$), the diagram

$$\begin{array}{ccc} \mathcal{X} & \rightarrow & \mathcal{P} \\ \uparrow & & \uparrow \\ \mathcal{Y} & \rightarrow & \mathcal{Q} \end{array}$$

is cartesian. Since one has a commutative diagram

$$\begin{array}{ccc} \mathcal{P} & \rightarrow & a(\mathcal{P}) \\ \uparrow & & \uparrow \\ \mathcal{Q} & \rightarrow & a(\mathcal{Q}), \end{array}$$

and since $\mathcal{Q} \hookrightarrow a(\mathcal{Q})$ is covering (4.3.11), the monomorphism $\mathcal{Q} \hookrightarrow \mathcal{P}$ is covering, hence $\mathcal{Q}$ is a refinement of $\mathcal{P}$. By base change, $\mathcal{Y}$ is a refinement of $\mathcal{X}$. Since $\mathcal{X}$ and $\mathcal{Y}$ are sheaves, this entails (4.3.12) $\mathcal{Y} = \mathcal{X}$.

****4.4.12.**** In particular, if $\mathcal{Y}$ is a subsheaf of $\mathcal{X}$, and if $\mathcal{Y}' = \mathcal{Y}/\mathcal{R}_Y$, then the preceding correspondence defines a subsheaf $\mathcal{Y}'$ of $\mathcal{X}'$, stable under $\mathcal{R}$, containing $\mathcal{Y}$ and minimum for these properties, which one calls the **saturation** of $\mathcal{Y}$ for the equivalence relation $\mathcal{R}$.

Footnotes (chunk-A)

4.5. The case of a topology coarser than the canonical topology

By 4.3.6 and 4.3.8, the following conditions are equivalent for a topology $\mathcal{T}$ on $\mathcal{C}$:

(i) $\mathcal{T}$ is coarser than the canonical topology of $\mathcal{C}$.

<!-- original page 219 -->

(ii) Every representable presheaf is a sheaf for $\mathcal{T}$.

(iii) Every covering sieve for $\mathcal{T}$ is universal effective epimorphic.

If $\mathcal{T}$ is defined by a pretopology $\mathcal{S} \mapsto R(\mathcal{S})$, these conditions are further equivalent to

(iv) Every family belonging to $R(\mathcal{S})$ is universal effective epimorphic.

In the case where these conditions are satisfied, the canonical functor $\mathcal{C} \rightarrow \hat{\mathcal{C}}$ factors through a functor $j_{\mathcal{C}} = j : \mathcal{C} \rightarrow \tilde{\mathcal{C}}$ (we shall also write $j(\mathcal{S}) = \tilde{\mathcal{S}}$ [N.D.E-IV-40]).

****Proposition 4.5.1.**** *The functor $j : \mathcal{C} \rightarrow \tilde{\mathcal{C}}$ is fully faithful and commutes with arbitrary inverse limits. It is in particular left exact and therefore preserves the algebraic structures defined by finite inverse limits.*

<!-- label: III.IV.4.5.1 -->

This follows at once from consideration of the commutative diagram

```

```text
 C
 / \
 j (canonical)
 / \
 C~ i → Ĉ
 ...

```

and from 4.4.1 (i).

Before exhibiting other properties of the functor  $j$ , we need to define the topology induced on a category  $\mathcal{C}/\mathcal{S}$ . No longer assuming the given topology necessarily coarser than the canonical one, this is done as follows: if  $\mathcal{C}$  is a sieve of  $\mathcal{T}$  in  $\mathcal{C}$  and one has a morphism  $\mathcal{T} \rightarrow \mathcal{S}$ , then  $\mathcal{C}$  defines naturally a sieve of  $\mathcal{T}$  in  $\mathcal{C}/\mathcal{S}$ , denoted  $J(\mathcal{T})$  (since the definition of a sieve of  $\mathcal{T}$  depends only on the category  $\mathcal{C}/\mathcal{T} = (\mathcal{C}/\mathcal{S})/\mathcal{T}$ ). If, for example,  $\mathcal{C}$  is defined by the family  $\{T_i \rightarrow T\}$ , then its image in  $\mathcal{C}/\mathcal{S}$  is defined by the same family considered as a family of morphisms of  $\mathcal{C}/\mathcal{S}$ . This being said, the map  $\mathcal{T} \mapsto J(\mathcal{T})$  defines a topology on  $\mathcal{C}/\mathcal{S}$  called the *topology induced* by the given topology. With the definitions of [AS], 2.3, it is the coarsest of the topologies on  $\mathcal{C}/\mathcal{S}$  for which the canonical functor

```

$$
i_{\mathcal{S}} : \mathcal{C}/\mathcal{S} \rightarrow \mathcal{C}
$$

```

<!-- original page 214 -->

is a comorphism [N.D.E-IV-41]. One will note that the identifications

```

```text
(C/S)/T = C/T
```

```

respect the topologies by definition.

**Proposition 4.5.2.** Let  $\mathcal{S}$  be a representable sheaf on  $\mathcal{C}$  and  $F \rightarrow \mathcal{S}$  a morphism of  $\hat{\mathcal{C}}$ . In order for  $\mathcal{S}' \mapsto \operatorname{Hom}_{\mathcal{S}}(\mathcal{S}', F)$  to be a separated presheaf (resp. a sheaf) on  $\mathcal{C}/\mathcal{S}$ , it is necessary and sufficient that  $F$  be a separated presheaf (resp. a sheaf) on  $\mathcal{C}$ .

<!-- label: III.IV.4.5.2 -->

For every functor  $P$ , one has (I 1.4.1)

```

```text
Hom(P, F) = \bigsqcup_{f \in \operatorname{Hom}(P, \mathcal{S})} \operatorname{Hom}_f(P, F).
```

```

[N.D.E-IV-42]

<!-- original page 221 -->

Let  $\mathcal{S}' \in \operatorname{Ob} \mathcal{C}$  and  $\eta : \mathcal{C}' \rightarrow \mathcal{S}'$  a covering sieve. As  $\mathcal{S}$  is a sheaf, the map  $f \mapsto f \circ \eta$  establishes a bijection  $\operatorname{Hom}_{\mathcal{S}}(\mathcal{S}', \mathcal{S}) \xrightarrow{\sim} \operatorname{Hom}(\mathcal{C}', \mathcal{S})$ . Consequently, the map

```

```text
Hom_{\hat{\mathcal{C}}}(\mathcal{S}', F) \rightarrow \operatorname{Hom}_{\hat{\mathcal{C}}}(\mathcal{C}', F)
```

```

decomposes as a "disjoint union" of the maps

```

```text
Hom_f(\mathcal{S}', F) \rightarrow \operatorname{Hom}_{\{f \circ \eta\}}(\mathcal{C}', F).
```

```

The proposition follows.

**Corollary 4.5.3.** \*The topology induced on  $\mathcal{C}/\mathcal{S}$  by a topology on  $\mathcal{C}$  coarser than the canonical topology of  $\mathcal{C}$ , is coarser than the canonical topology of  $\mathcal{C}/\mathcal{S}$ .\*

<!-- label: III.IV.4.5.3 -->

**Corollary 4.5.4.** \*Suppose the given topology on  $\mathcal{C}$  is coarser than the canonical topology. For every  $\mathcal{S} \in \mathbf{Ob} \mathcal{C}$ , one has an equivalence of categories\*

$$\mathcal{S} \backslash \tilde{\mathcal{C}} / \tilde{\mathcal{S}} \xrightarrow{\sim} \tilde{\mathcal{C}} / \mathcal{S}.$$

\*The following diagrams are commutative up to isomorphism (all unlabelled arrows being equivalences):\*

```

```text
      C/S  --(j_C)/S--> C~/S~ --(i_C)/S~--> C~/S --(a_C)/S--> C~/S~

 C~/S~ C~/S / T~
 \ /
 \ /
 C~/T~ -> C~/T
...

```

<!-- original page 215 -->

The commutativity of the first two squares results from the definition of the equivalence  $\mathcal{S} \backslash \tilde{\mathcal{C}} / \tilde{\mathcal{S}} \rightarrow \tilde{\mathcal{C}} / \mathcal{S}$ . To prove the commutativity of the last, one must see that the following square is commutative:

```

```text
      L'
     / 
    C~/S --> C~/S
    |       |
    |       |
    C~/S --L''--> C~/S ,
...

```

where L' is the restriction of the functor L_C to $\mathcal{S} \backslash \hat{\mathcal{C}} / \hat{\mathcal{S}}$ and L'' the functor $L_{C/S}$; this is easily seen by going back to the definition of the functors L (given after 4.3.9). As for the second diagram, this is none other than the restriction to the sheaf categories of the corresponding diagram on the categories of presheaves (Exposé I, n° 1), which is commutative.

Scholie 4.5.5. *The various assertions of this number show that, in the case where the given topology is coarser than the canonical topology, one may identify $\mathcal{C}$ with a full subcategory of $\mathcal{S} \backslash \tilde{\mathcal{C}} / \tilde{\mathcal{S}}$, itself a full subcategory of $\hat{\mathcal{C}}$, and that under this identification one may indulge in the usual abuses of language regarding $\mathcal{C} \rightarrow \hat{\mathcal{C}}$, justified by the commutativities above. Let us explicitly remark that the first diagram of 4.5.4 shows that one may use the functor a without special precaution.*

<!-- label: III.IV.4.5.5 -->

<!-- original page 216 -->

We shall see in the next number that the identification of $\mathcal{C}$ with a full subcategory of $\tilde{\mathcal{C}}$ (contrary to what was the case for $\hat{\mathcal{C}}$) commutes with the formation of certain direct limits, and we shall then say how to use this fact.

From now on, and unless explicitly stated otherwise, we shall assume the given topology coarser than the canonical topology and we shall systematically make the identifications described above.

Proposition 4.5.6. *Let $\mathcal{F}$ and $\mathcal{G}$ be two sheaves over $\mathcal{S}$ and $f : \mathcal{F} \rightarrow \mathcal{G}$ an $\mathcal{S}$ -morphism. The following conditions on f are equivalent:*

<!-- label: III.IV.4.5.6 -->

(i) f is a monomorphism (resp. an epimorphism, resp. an isomorphism) in $\tilde{\mathcal{C}}$.*

(ii) f is a monomorphism (resp. an epimorphism, resp. an isomorphism) in $\tilde{\mathcal{C}}/\mathcal{S} = \tilde{\mathcal{C}}/\mathcal{S}$.*

For monomorphism and isomorphism, this is evident (it is a question of presheaves). For epimorphism, it follows from the description of epimorphisms as covering morphisms (4.4.3) and from the fact that, by definition of the induced topology, these are the same in $\tilde{\mathcal{C}}$ and $\tilde{\mathcal{C}}/\mathcal{S}$.

Proposition 4.5.7. *Let $f : \mathcal{F} \rightarrow \mathcal{G}$ be a morphism of sheaves. The following conditions are equivalent:*

<!-- label: III.IV.4.5.7 -->

(i) f is a monomorphism (resp. an epimorphism, resp. an isomorphism).*

<!-- original page 217 -->

(ii) For each $\mathcal{S} \in \mathcal{O}_b \mathcal{C}$, $f_{\mathcal{S}} : \mathcal{F}_{\mathcal{S}} \rightarrow \mathcal{G}_{\mathcal{S}}$ is locally a monomorphism (resp. an epimorphism, resp. an isomorphism), that is:*

(iii) For each $\mathcal{S} \in \mathcal{O}_b \mathcal{C}$, the set of $\mathcal{T} \rightarrow \mathcal{S}$ such that $f_{\mathcal{T}} : \mathcal{F}_{\mathcal{T}} \rightarrow \mathcal{G}_{\mathcal{T}}$ is a monomorphism (resp. an epimorphism, resp. an isomorphism) is a refinement of $\mathcal{S}$.*

If the given topology is defined by a pretopology $\mathcal{R}$, these conditions are further equivalent to the following:

(iv) For each $\mathcal{S} \in \mathcal{O}_b \mathcal{C}$, there exists a covering family $\{S_i \rightarrow \mathcal{S} \mid i \in I\}$ such that for every i , $f_{S_i} : \mathcal{F}_{S_i} \rightarrow \mathcal{G}_{S_i}$ is a monomorphism (resp. an epimorphism, resp. an isomorphism).*

If the category $\mathcal{C}$ has a final object e , one may content oneself with taking $\mathcal{S} = e$ in conditions (ii), (iii), and (iv).

One obviously has (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (iv). To prove the equivalence of (i) and (ii) as well as the supplement concerning the final object, one must show that (ii) $\Rightarrow$ (i) and that the notions in question are stable under base extension. Let us first prove this last point. For monomorphism and isomorphism, this is evident (it is a question of presheaves). For epimorphism, it follows from the fact that every epimorphism of sheaves is universal (4.4.3).

Let us finally show that (ii) entails (i). Suppose first that $f_{\mathcal{S}} : \mathcal{F}_{\mathcal{S}} \rightarrow \mathcal{G}_{\mathcal{S}}$ is locally a monomorphism (resp. an isomorphism). There then exists a covering sieve $\mathcal{C}$ of $\mathcal{S}$ such that for every $\mathcal{T} \rightarrow \mathcal{C}$, $f_{\mathcal{T}}$ is a monomorphism (resp. an isomorphism). As an inverse limit of monomorphisms (resp. isomorphisms) is one, $\operatorname{Hom}_{\mathcal{C}}(\mathcal{C}, f)$ will be a monomorphism (resp. an isomorphism) (cf. 4.1.4). The commutative diagram

```

```text
 Hom(C, f)
Hom(C, F) -----> Hom(C, G)
 ↑ ↑
 □ □
 f(S)
... F(S) -----> G(S)
```

```

<!-- original page 218 -->

then shows that $f(S)$ is injective (resp. bijective). Suppose finally that $f : \mathcal{F} \rightarrow \mathcal{G}$ is locally an epimorphism and let $\mathcal{H} \subset \mathcal{G}$ be its image. For each $\mathcal{S} \rightarrow \mathcal{G}$, $\mathcal{H} \times_{\mathcal{G}} \mathcal{S}$ is the image of

$f : F \rightarrow S$. To show that f is an epimorphism, one must show that H is a refinement of G , that is, that $H \times_S S$ is a refinement of G for each S . But since this is so after every base change $T \rightarrow S$ of a refinement of G (since $f \times_S S$ is locally covering), $H \times_S S$ is indeed a refinement of G (Axiom (T 2)).

Corollary 4.5.8. *Let F and G be two sheaves over S and $f : F \rightarrow G$ an S -morphism. In order for f to be a monomorphism, resp. an epimorphism, resp. an isomorphism, it is necessary and sufficient that it be so locally on S .*

<!-- label: III.IV.4.5.8 -->

Remark 4.5.9. *The proof of the proposition shows that it remains valid, for the part concerning monomorphisms (resp. isomorphisms), when one only assumes that F is a separated presheaf (resp. a sheaf) and G an arbitrary presheaf (resp. a separated presheaf).*

<!-- label: III.IV.4.5.9 -->

Let us provisionally return to the case of an arbitrary topology and lay down a definition.

Definition 4.5.10. *Let $G \rightarrow F$ be a morphism of $\mathcal{C}$. We say that G is a relative sheaf above F if for every F -functor H and every refinement R of H , the canonical map*

<!-- label: III.IV.4.5.10 -->

```
```text
(+) Hom_F(H, G) → Hom_F(R, G)
```
```

is bijective.

<!-- original page 224 -->

Proposition 4.5.2 immediately generalizes:

Proposition 4.5.11. *If F is a sheaf, G is a relative sheaf above F if and only if it is a sheaf.*

<!-- label: III.IV.4.5.11 -->

Lemma 4.5.12. *In the situation $X \rightarrow T \rightarrow S$ (where X, T, S are three objects of $\mathcal{C}$), if X is a relative sheaf above T , then $U = \prod_{T/S} X$ is a relative sheaf above S .*

<!-- label: III.IV.4.5.12 -->

<!-- original page 219 -->

Indeed, one has for every S -functor Y

```
```text
Hom_S(Y, U) = Hom_T(T ×_S Y, X).
```
```

If C is a sieve of Y , then $T \times_S C$ is a sieve of $T \times_S Y$; one concludes at once.

Corollary 4.5.13. *The presheaves $\operatorname{Hom}_{T/S}(X, Y)$, $\operatorname{Isom}_S(X, Y)$, etc., are sheaves when the arguments appearing in them are also.*

<!-- label: III.IV.4.5.13 -->

Indeed, all these presheaves are constructed by means of fibered products and presheaves $\prod_{T/S} X$ (I 1.7 and II 1). It therefore suffices to verify the result for a presheaf $\prod_{T/S} X$; in this case, the assertion follows from 4.5.11 and 4.5.12.

4.6. Description of the quotient of a sheaf by an equivalence relation

Recall that we are assuming the topology $\mathcal{T}$ given to be coarser than the canonical topology.

Proposition 4.6.1. Let $R \rightarrowtail X$ (with morphisms p_1, p_2) be a $\sim_C$ -equivalence relation in the sheaf $\mathcal{X}$. Let $\mathcal{F} \in \mathbf{Ob} \hat{\mathcal{C}}$ be defined as follows: for each $\mathcal{S}$ of $\mathcal{C}$,

`<!-- label: III.IV.4.6.1 -->`

```
``text
 $\mathcal{F}(\mathcal{S}) = \{ \text{sub-}\mathcal{S}\text{-sheaves } \mathcal{Z} \text{ of } \mathcal{X}_{\mathcal{S}} \text{ stable under } R \times S [^{\text{N.D.E-IV-43}}, \text{ whose quotient by } R_{\mathcal{Z}} \text{ is } S, \\ \text{i.e. such that the diagram } R_{\mathcal{Z}} \Rightarrow \mathcal{Z} \rightarrow S \text{ is exact} \}.$ 
``
```

Then for every sheaf $\mathcal{Y}$, $\operatorname{Hom}(Y, \mathcal{F})$ is identified with the set:

```
``text
{ sub- $\mathcal{Y}$ -sheaves of  $X \times Y$  stable under  $R \times Y$  and whose quotient is  $Y$  }.
``
```

In particular the sub-sheaf $\mathcal{R}$ of $X \times X$ corresponds to an element p of $\operatorname{Hom}(X, \mathcal{F})$ and the diagram

```
``text
 $R \Rightarrow X \xrightarrow{p} \mathcal{F}$ 
``
```

is exact, hence identifies $\mathcal{F}$ with the sheaf-quotient X/R .

`<!-- original page 220 -->`

Indeed, set $\mathcal{Q} = X/R$. For every sheaf $\mathcal{Y}$ and every morphism $f \in \operatorname{Hom}(Y, \mathcal{Q})$ corresponding to a section $s : Y \rightarrowtail \mathcal{Q} \times Y$, consider the diagram

```
``text
 $R \times Y \Rightarrow X \times Y \longrightarrow \mathcal{Q} \times Y$ 
(*)
       $\begin{array}{ccc} & \uparrow & \uparrow \\ & \mathcal{Z} & \mathcal{Y} \\ & \downarrow & \downarrow \\ & \mathcal{Z} & \mathcal{Y} \end{array} \quad s$ 
``
```

`<!-- original page 225 -->`

where the square is cartesian. It is immediate by 4.4.11 that $\mathcal{Z}$ is a sub- $\mathcal{Y}$ -sheaf of $X \times Y$, stable under $R \times Y$, whose quotient is $\mathcal{Y}$, and that, conversely, every $\mathcal{Z}$ of this type comes from a unique section of $\mathcal{Q} \times Y$ over $\mathcal{Y}$. Taking first $\mathcal{Y}$ representable, one extracts an isomorphism $\mathcal{Q} \simeq \mathcal{F}$. Taking next $\mathcal{Y}$ arbitrary, one extracts the announced form of $\operatorname{Hom}(Y, \mathcal{F})$. Considering finally the canonical morphism $X \rightarrowtail \mathcal{Q}$, one sees at once that it corresponds to the sub- X -sheaf $\mathcal{R}$ of $X \times X$, which completes the proof.

Corollary 4.6.2. Let $\mathcal{G}$ be an arbitrary subfunctor of $\mathcal{F}$ such that $\operatorname{Hom}(X, \mathcal{G}) \subset \operatorname{Hom}(X, \mathcal{F})$ contains $\mathcal{R}$. Then the canonical morphism $p : X \rightarrowtail \mathcal{F}$ factors through $\mathcal{G}$.

`<!-- label: III.IV.4.6.2 -->`

Since p is covering (4.4.9 and 4.4.3), it follows that $\mathcal{G}$ is a refinement of $\mathcal{F}$. In particular, every sub-sheaf $\mathcal{G}$ of $\mathcal{F}$ satisfying the preceding condition is equal to $\mathcal{F}$ (4.3.12).

4.6.3. We are now going to interest ourselves in the case where X and R are representable. Let us first introduce some terminology. Besides the conditions (a) to (d) introduced in 3.4.1, we shall use other conditions on a family (M) of morphisms of $\mathcal{C}$, which we state below, recalling the conditions (a) to (c) already given, for completeness.

`<!-- label: III.IV.4.6.3 -->`

(a) (M) is stable under base extension.

(b) The composite of two elements of $\mathcal{M}$ is in $\mathcal{M}$.

(c) Every isomorphism is an element of $\mathcal{M}$.

(d_T) Every element of $\mathcal{M}$ is covering. [N.D.E-IV-44]

(e_T) Let $f : X \rightarrow Y$ be a morphism of $\mathcal{C}$. If there exists a refinement R of f such that for every $Y' \rightarrow R$, $X \times_{Y'} Y \rightarrow Y'$ is an element of $\mathcal{M}$, then f is an element of $\mathcal{M}$.

<!-- original page 221 -->

Recall that (a) and (b) entail

(a') The cartesian product of two elements of $\mathcal{M}$ is an element of $\mathcal{M}$.

On the other hand, (a) and (d_T) entail by 4.3.9:

(d') Every element of $\mathcal{M}$ is a universal effective epimorphism.

4.6.4. The preceding conditions are verified by the family of covering morphisms, denoted $\mathcal{M}_T$, when $\mathcal{C}$ has fibered products. Indeed (cf. 4.2.3), (a) follows from (C 1), (b) from (C 2), (c) from (C 4), (d_T) from the definition, (e_T) from (C 5). The results we shall establish for a family satisfying these conditions will apply in particular to the family $\mathcal{M}_T$. In particular, one may take for T the canonical topology and for $\mathcal{M}$ the family of universal effective epimorphisms.

Lemma 4.6.5. Let $\mathcal{M}$ be a family of morphisms satisfying the properties (a) to (e_T) above. Let R be a $\mathcal{C}$ -equivalence relation in X in $\text{Ob } \mathcal{C}$, of type $\mathcal{M}$. Let $\tilde{X}$ be the sheaf defined by X , $\tilde{R}$ the $\mathcal{C}$ -equivalence relation in $\tilde{X}$ defined by R and $\tilde{X}/\tilde{R}$ the sheaf-quotient. In order for R to be $\mathcal{M}$ -effective, it is necessary and sufficient that $\tilde{X}/\tilde{R}$ be representable. If this is so, $\tilde{X}/\tilde{R}$ is represented by the quotient X/R .

<!-- label: III.IV.4.6.5 -->

Suppose first that R is $\mathcal{M}$ -effective and denote $Y = X/R$. The canonical morphism $p : X \rightarrow Y$ is an element of $\mathcal{M}$, hence covering by (d_T). The corresponding morphism

$\tilde{p} : \tilde{X} \rightarrow \tilde{X}/\tilde{R}$

is therefore a universal effective epimorphism of $\mathcal{C}$ (4.4.3), hence identifies $\tilde{X}/\tilde{R}$ with the quotient of $\tilde{X}$ by the equivalence relation R' defined in $\tilde{X}$ by $\tilde{p}$. As the canonical functor $\mathcal{C} \rightarrow \mathcal{C}$ commutes with fibered products, R' is none other than $\tilde{R}$, since R is the equivalence relation defined by p .

<!-- original page 222 -->

Conversely, suppose $\tilde{X}/\tilde{R}$ representable by an object Y of $\mathcal{C}$. Let $p : X \rightarrow Y$ be the morphism deduced from the canonical morphism $\tilde{X} \rightarrow \tilde{X}/\tilde{R}$; it is a covering morphism by 4.4.3. It is clear as before that R is the equivalence relation defined by p . It only remains to show that $p \in \mathcal{M}$. Now the cartesian square

```

$$\begin{array}{ccc}
 X & \times_Y & X \\
 \downarrow & & \downarrow \\
 X & \xrightarrow{p} & Y
 \end{array}$$

```

shows that p becomes p_2 , which is an element of $\mathcal{M}$, after base change by the covering morphism p . One concludes by (e_T).

Corollary 4.6.5.1. [N.D.E-IV-45] Let $\mathcal{M}$ satisfy the properties (a) to (e_T) above and let $f : G \rightarrow G'$ be a morphism of $\mathcal{C}$ -groups, such that $f \in \mathcal{M}$. Suppose $\text{Ker}(f)$ representable (which is the case if $\mathcal{C}$ has a final

object $\mathcal{S}$). Then the equivalence relation in $\mathcal{G}$ defined by $H = \text{Ker}(f)$ is (M) -effective and $\mathcal{G}'$ represents the sheaf-quotient $\tilde{\mathcal{G}}/\tilde{\mathcal{H}}$ for the topology $\mathcal{T}$.*

<!-- label: III.IV.4.6.5.1 -->

This follows from 4.6.5 and 3.4.7.1.

We are now in a position to state the main result of this number.

Theorem 4.6.6. *Let (M) be a family of morphisms verifying the axioms (a) to (e_T) of 4.6.3. Let $\mathcal{R}$ be a $\mathcal{C}$ -equivalence relation of type (M) (cf. 3.4.3) in the object $\mathcal{X}$ of $\mathcal{C}$. Consider the functor $F \in \text{Ob } \hat{\mathcal{C}}$ defined as follows:*

<!-- label: III.IV.4.6.6 -->

```
```text
F(S) = { sub-S-sheaves Z of X_S stable under R × S whose quotient by R_Z is S }.
```
```

Let F_0 be the subfunctor of F defined as follows: $F_0(S)$ consists of the $Z \in F(S)$ that are representable, that is:

```
```text
F_0(S) = { sub-C/S-objects Z of X_S stable under R × S, such that
 R_Z is (M)-effective and has quotient S (i.e. such that
 Z → S belongs to (M) and R_Z = Z ×_S Z) }.
```
```

Then:

<!-- original page 227 -->

(i) The morphism $\mathcal{p} \in \text{Hom}(X, F) = F(X)$ defined by the sub-object $\mathcal{R}$ of $X \times X$ identifies F with the sheaf-quotient of X by $\mathcal{R}$.*

(ii) The following conditions are equivalent:*

- *a) $\mathcal{F}$ is representable.*
- *b) F_0 is representable.*
- *c) $\mathcal{R}$ is (M) -effective.*

<!-- original page 223 -->

Under these conditions, $\mathcal{F} = F_0 = X/\mathcal{R}$.

(iii) Let (N) be a family of morphisms stable under base change, such that for every covering family $\{S_i \rightarrow S\}$ and every family $\{T_i \rightarrow S_i\}$ of morphisms of (N) , every descent datum on the T_i relative to $\{S_i \rightarrow S\}$ is effective. Suppose X squarable (cf. 1.6.0) and the morphism $\mathcal{R} \rightarrow X \times X$ an element of (N) . Then $F_0 = F$.*

Proof. (i) has already been proved (4.6.1).

(ii) We have seen the equivalence of a) and c) as well as the equality $\mathcal{F} = X/\mathcal{R}$. It remains to prove that b) or c) implies $F_0 = F$. Let us first remark, as is moreover affirmed in the statement, that F_0 is indeed a subfunctor of F ; for every $S \in \text{Ob } \mathcal{C}$ and every $Z \in F_0(S)$, the morphism $Z \rightarrow S$ is squarable, hence $Z \times_{S'} S'$ is an element of $F_0(S')$ for every $S' \rightarrow S$. As $\mathcal{R} \in F(X)$ belongs to $F_0(X)$, 4.6.2 shows that b) implies $F_0 = F$.

Now suppose c) verified and let Q be an object of $\mathcal{C}$ representing $X/\mathcal{R}$. Then the morphism $X \rightarrow Q$ is an element of (M) and, for every $S \in \text{Ob } \mathcal{C}$ and every $Z \in F(S)$, the diagram (*) of 4.6.1 shows that $Z = S \times_{Q \times S} X \times_S S$ is representable, and $Z \rightarrow S$ belongs to (M) , hence $Z \in F_0(S)$.

(iii) Let $f \in \text{Hom}(S, F)$ correspond to $Z \in F(S)$. We must show that f factors through F_0 , that is, that Z is representable. This is clear first if f factors through X , by virtue of:

****Lemma 4.6.7.**** *Let $x_{\{0\}}$ in $X(S)$. The image of $x_{\{0\}}$ in $F(S)$ corresponds to the sub-sheaf Z of X_S defined by the two cartesian squares*

<!-- label: III.IV.4.6.7 -->

$$\begin{array}{ccccc} & & \text{id}_{X_S} \times x_{\{0\}} & & \\ & & \longrightarrow & & \\ X_S & \xrightarrow{\quad} & X_S \times_S X_S & \longrightarrow & X \times X \\ \uparrow & & \uparrow & & \uparrow \\ Z & \longrightarrow & R_S & \longrightarrow & R \end{array}$$

<!-- original page 224 -->

This lemma follows at once from the description of the morphism $X \rightarrow F$.

Let us return to the proof of the theorem. If f factors through X , then Z is representable and, as $R \rightarrow X \times X$ is an element of (N) , the same holds for $Z \rightarrow X_S$.

In general, f does not necessarily factor through X ; but since $X \rightarrow F$ is covering (4.4.3), there exists by 4.4.8 (vii) a covering family $\{S_i \rightarrow S\}$ and for each i a morphism $S_i \rightarrow X$ making commutative the diagram

$$\begin{array}{ccc} X & \longrightarrow & F \\ \uparrow & & \uparrow \\ S_i & \longrightarrow & S \end{array} \quad \begin{array}{c} f \\ \\ \end{array}$$

<!-- original page 228 -->

By what precedes, the morphism $f_i : S_i \rightarrow F$ defined by the preceding diagram belongs to $\text{Hom}(S_i, F_{\{0\}})$ and corresponds to the sub-sheaf $Z \times_{S_i} S_i$ of X_{S_i} . The morphism $Z \times_{S_i} S_i \rightarrow X_{S_i}$ is an element of (N) and the family $\{X_{S_i}\} \rightarrow X_S$ covering. It therefore only remains to establish:

****Proposition 4.6.8.**** *Let $\{S_i \rightarrow S\}$ be a covering family and Z a sheaf above S . Suppose that for each i , the S_i -functor $Z \times_{S_i} S_i$ is representable by an object T_i . Then the family of T_i is equipped with a canonical descent datum relative to $S_i \rightarrow S$. In order for Z to be representable, it is necessary and sufficient that this datum be effective; if this is so, the "descended" object represents Z .*

<!-- label: III.IV.4.6.8 -->

Let us first remark that by 4.4.3, $\{S_i \rightarrow S\}$ is a universal effective epimorphic family in $\mathcal{C}$, hence a descent family in $\mathcal{C}$ (2.3). If Z is representable by the object T , then $T \times_S S_i$ (considered as a sheaf) is isomorphic to $Z \times_{S_i} S_i$, hence the descent datum on the T_i is effective and the (unique) descended object is isomorphic to Z . Conversely, suppose that the canonical descent datum on the T_i is effective and let T be the descended object. Since the family $\{S_i \rightarrow S\}$ is a descent family in $\mathcal{C}$, there exists an S -morphism $T \rightarrow Z$ which by base extension to each S_i recovers the canonical morphism $T_i \rightarrow Z \times_{S_i} S_i$. This morphism is locally an isomorphism; as T and Z are sheaves, it follows from 4.5.8 that it is an isomorphism.

<!-- original page 225 -->

****Corollary 4.6.9.**** *Let R be an (M) -effective equivalence relation in X . For every sheaf F , the map*

<!-- label: III.IV.4.6.9 -->

$$\text{Hom}(X/R, F) \rightarrow \text{Hom}(X, F)$$

identifies the first set with the part of the second consisting of the morphisms compatible with R .

****Corollary 4.6.10.**** *Let $\mathcal{T}$ be a topology coarser than $\mathcal{T}_S$, for which the morphisms of $\mathcal{M}$ are covering. Under the conditions of 4.6.6 (iii), $\mathcal{X}/\mathcal{R}$ is also the sheaf-quotient of $\mathcal{X}$ by $\mathcal{R}$ in every intermediate topology between $\mathcal{T}$ and the canonical topology.*

<!-- label: III.IV.4.6.10 -->

****Remark 4.6.11.**** *If in the statement of 4.6.6 (iii), one furthermore assumes that, under the hypotheses of the text, if one denotes $\mathcal{T}_S$ the descended object, the morphism $\mathcal{T} \rightarrow \mathcal{S}$ is an element of $\mathcal{N}$, then the inclusion morphisms $\mathcal{Z} \hookrightarrow \mathcal{X}_{\mathcal{S}}$ are also elements of $\mathcal{N}$, as follows at once from the construction of $\mathcal{Z}$ by descent.*

<!-- label: III.IV.4.6.11 -->

****Remark 4.6.12.**** *The implications $c) \Rightarrow b) \Rightarrow a)$ and $c) \Rightarrow [F_0 = F = \mathcal{X}/\mathcal{R}]$ have been established without recourse to the "if" part of Lemma 4.6.5, which is the only place where condition (e_T) is used. They therefore remain valid if $\mathcal{M}$ satisfies only conditions (a) to (d_T) . An example of such a family $\mathcal{M}$ is that of squarable covering morphisms (compare with 4.6.4). In the case of the canonical topology, these are none other than the universal effective epimorphisms. One therefore has:*

<!-- label: III.IV.4.6.12 -->

<!-- original page 226 -->

<!-- original page 229 -->

****Corollary 4.6.13.**** *Let $\mathcal{R}$ be a universal effective equivalence relation in $\mathcal{X}$. Then the object $\mathcal{X}/\mathcal{R}$ of $\mathcal{C}$ is the sheaf-quotient of $\mathcal{X}$ by $\mathcal{R}$ for the canonical topology. It represents the following functor: $(\mathcal{X}/\mathcal{R})(\mathcal{S})$ is the set of sub- $\mathcal{C}/\mathcal{S}$ -objects $\mathcal{Z}$ of $\mathcal{X}_{\mathcal{S}}$ stable under $\mathcal{R} \times \mathcal{S}$ and such that the induced equivalence relation is universal effective and has $\mathcal{S}$ as quotient.*

<!-- label: III.IV.4.6.13 -->

Similarly, for an arbitrary topology:

****Corollary 4.6.14.**** *Let $\mathcal{M}$ be the family of squarable covering morphisms. If $\mathcal{R}$ is an $\mathcal{M}$ -effective equivalence relation in $\mathcal{X}$, then the object $\mathcal{X}/\mathcal{R}$ of $\mathcal{C}$ is the sheaf-quotient of $\mathcal{X}$ by $\mathcal{R}$ and represents the functor F_0 of 4.6.6.*

<!-- label: III.IV.4.6.14 -->

****Scholie 4.6.15.**** *We can now bring the following precisions to 4.5.5.* Whereas in questions involving exclusively inverse limits (fibered products, algebraic structures, etc.), one may, by the results of Exposé I and 4.5.5, identify $\mathcal{C}$ indifferently with a full subcategory of $\tilde{\mathcal{C}}$ or of $\mathcal{C}$, it is not the same in those that mix inverse and direct limits. In all questions involving both inverse and direct limits, in particular passages to the quotient (example: group structure on the quotient of a group by an invariant subgroup), we shall consider the given category as embedded in the category of sheaves; thus if $\mathcal{R}$ is a $\mathcal{C}$ -equivalence relation in the object $\mathcal{X}$ of $\mathcal{C}$, $\mathcal{X}/\mathcal{R}$ will denote the sheaf-quotient of $\mathcal{X}$ by $\mathcal{R}$ (previously denoted $j(X)/j(\mathcal{R})$), hence in the case where this sheaf is representable, the object it represents. The preceding results show that in the most important cases, a quotient in $\mathcal{C}$ will also be a quotient in the category of sheaves; in any case, we forbid ourselves the use of the notation $\mathcal{X}/\mathcal{R}$ for a quotient in $\mathcal{C}$ that does not coincide with the quotient in $\tilde{\mathcal{C}}$ (for example one that is not universal), thus modifying the definitions of n° 3.

<!-- label: III.IV.4.6.15 -->

<!-- original page 227 -->

To study a problem of the type above, one therefore places oneself first in the category of sheaves, where all the usual results are valid (cf. n° 4.4), then one specializes the results obtained to the original category, using the results of the present number and, when one has them, descent effectivity criteria. We shall see examples of this method in the following numbers.

4.7. Use of effectivity criteria: isomorphism theorem

In this number, we give an example of the use of effectivity criteria. The data of departure are a topology $\mathcal{T}$ on $\mathcal{C}$ (always coarser than the canonical topology), a family $\mathcal{M}$ of morphisms of $\mathcal{C}$ verifying the axioms (a) to (e_T) of 4.6.3, and a family $\mathcal{N}$ of morphisms of $\mathcal{C}$ liable to verify the following axioms:

(a) $\mathcal{N}$ is stable under base extension.

(f_T) "the morphisms of $\mathcal{N}$ descend by the given topology"; that is: for every $S \in \mathcal{C}$, every covering family $\{S_i \rightarrow S\}$ and every family $\{T_i \rightarrow S_i\}$ of morphisms of $\mathcal{N}$, every descent datum on the T_i relative to $\{S_i \rightarrow S\}$ is effective, and if one denotes T the descended object, the morphism $T \rightarrow S$ is an element of $\mathcal{N}$.

<!-- original page 230 -->

Since every element of $\mathcal{M}$ is covering (condition 4.6.3 (d_T)), (f_T) entails the following axiom: [N.D.E-IV-46]

(f_M) If $Y \rightarrow X$ is an element of $\mathcal{N}$ and $X \rightarrow X_1$ an element of $\mathcal{M}$, every descent datum on Y relative to $X \rightarrow X_1$ is effective; if one denotes Y_1 the descended object, $Y_1 \rightarrow X_1$ is an element of $\mathcal{N}$.

Let us at once signal an example of this situation, which will be treated later: $\mathcal{C}$ is the category of schemes, T the faithfully flat quasi-compact topology; $\mathcal{M}$ the family of faithfully flat quasi-compact morphisms, $\mathcal{N}$ the family of closed immersions, or that of quasi-compact immersions. [N.D.E-IV-47]

Let us recall the principal result of 4.6.6 (taking into account 4.6.11):

Proposition 4.7.1. *If X is a squarable object of $\mathcal{C}$, R an equivalence relation of type $\mathcal{M}$ in X , such that $R \rightarrow X \times X$ is an element of $\mathcal{N}$, with $\mathcal{N}$ verifying (a) and (f_T), then the sheaf-quotient X/R is defined by*

<!-- label: III.IV.4.7.1 -->

<!-- original page 228 -->

``text
(X/R)(S) = { sub-S-objects Z of X_S , stable under $R \times S$, such that $Z \rightarrow X_S$
belongs to $\mathcal{N}$, $Z \rightarrow S$ is covering (or an element of $\mathcal{M}$),
and $R_Z \approx Z \times_S Z$ }.
...

Moreover, one has:

Proposition 4.7.2. *Let $X \in \mathcal{C}$ and R an $\mathcal{M}$ -effective equivalence relation in X . Let $\mathcal{N}$ be a family of morphisms verifying (a) and (f_M).*

<!-- label: III.IV.4.7.2 -->

<!-- original page 229 -->

For every sub-object Y of X , stable under R and such that $Y \rightarrow X$ belongs to $\mathcal{N}$, the equivalence relation induced in Y by R is $\mathcal{M}$ -effective and the quotient $Y/R_Y = Y'$ is a sub-object of $X' = X/R$ such that $Y' \rightarrow X'$ belongs to $\mathcal{N}$.

The map $Y \mapsto Y'$ is a bijection between the set of sub-objects Y of X , stable under R , such that $Y \rightarrow X$ belongs to $\mathcal{N}$, and the set of sub-objects Y' of X' such that $Y' \rightarrow X'$ belongs to $\mathcal{N}$. The inverse map is $Y' \mapsto Y' \times_{X'} X$.

Proof. As R is $\mathcal{M}$ -effective, the morphism $X \rightarrow X'$ belongs to $\mathcal{M}$. Let Y' be a sub-object of X' such that the canonical morphism $Y' \rightarrow X'$ belongs to $\mathcal{N}$. Then, the sub-object $Y = Y' \times_{X'} X$ of X is stable under R , and the morphism $Y \rightarrow X$ (resp. $Y \rightarrow Y'$) belongs to $\mathcal{N}$ (resp. $\mathcal{M}$) since $\mathcal{N}$ and $\mathcal{M}$ are stable under base change. Let R_Y denote the equivalence relation induced in Y by R . By 4.4.11, the sheaf quotient Y/R_Y is represented by Y' and therefore, by 4.6.5, R_Y is $\mathcal{M}$ -effective.

Conversely, let us show that every sub-object Y of X , stable under R , such that the structural morphism $Y \rightarrow X$ belongs to $\mathcal{N}$, is obtained in this way. Indeed, if Y is stable under R , its two images in $R = X \times_{X'} X$ are identical and Y is equipped with a descent datum relative to $X \rightarrow X'$; the desired result follows, since the family $\mathcal{N}$ verifies the axiom (f_M).

<!-- original page 231 -->

****Corollary 4.7.3.**** *Let X in $\mathcal{O}b\ C$ and R an (M) -effective equivalence relation in X ; assume moreover that $R \times X$ belongs to (N) , where (N) verifies (a) and (f_T). Then, for every Y as in 4.7.2, $R \times Y$ also belongs to (N) and therefore, by 4.7.1, one has:

<!-- label: III.IV.4.7.3 -->

```

```text
(Y/R_Y)(S) = { sub-S-objects Z of Y_S, stable under R_Y × S, such that Z → Y_S
 belongs to (N) (then Z → X_S also belongs to it), Z → S is covering,
 and R_Z ≈ Z ×_S Z }.
...

```

## ## 5. Passage to the quotient and algebraic structures

<!-- label: III.IV.5 -->

### ### 5.1. Principal homogeneous bundles

**\*\*Definition 5.1.0.\*\***[<sup>N.D.E-IV-48</sup>] \*We recall (III 0.1) that an object  $X$  with (right) operator group  $H$  is said to be formally principal homogeneous [<sup>N.D.E-IV-49</sup>] under  $H$  if the canonical morphism (of functors)

<!-- label: III.IV.5.1.0 -->

```

```text
X × H → X × X
...

```

defined by $(x, h) \mapsto (x, xh)$ is an isomorphism. It amounts to the same thing to say (cf. loc. cit.) that for every S in $\mathcal{O}b\ C$, $X(S)$ is formally principal homogeneous under $H(S)$, that is, empty or principal homogeneous under $H(S)$. In particular, if H is made to operate on itself by (right) translations, H becomes formally principal homogeneous under itself.

<!-- original page 230 -->

****Definition 5.1.1.**** *The object X with operator group H is said to be trivial if it is isomorphic (as object with operator group H) to H on which H operates by translations.*

<!-- label: III.IV.5.1.1 -->

****Proposition 5.1.2.**** *Let X be formally principal homogeneous under H . One has an isomorphism*

<!-- label: III.IV.5.1.2 -->

```

$$
\Gamma(X) \xrightarrow{\sim} \text{Isom}_{\{H\text{-obj.}\}}(H, X)
$$

```

of principal homogeneous sets under $\Gamma(H)$.

To every section x of X one associates the morphism from H to X defined setwise by $h \mapsto xh$. The stated assertion is immediate, by reduction to the set-theoretic case.

****Corollary 5.1.3.**** *One has an isomorphism of objects with operators H *

<!-- label: III.IV.5.1.3 -->

```

$$
X \xrightarrow{\sim} \text{Isom}_{\{H\text{-obj.}\}}(H, X).
$$

```

****Corollary 5.1.4.**** *In order for an object with operator group to be trivial, it is necessary and sufficient that it be formally principal homogeneous and possess a section.*

<!-- label: III.IV.5.1.4 -->

<!-- original page 232 -->

Definition 5.1.5. *Let $\mathcal{C}$ be a category equipped with a topology. We say that the $\mathcal{S}$ -object X with $\mathcal{S}$ -operator group H is a principal homogeneous bundle under H if it is locally trivial, that is, if the following equivalent conditions are satisfied: [N.D.E-IV-50]*

<!-- label: III.IV.5.1.5 -->

(i) The set of $T \rightarrow S$ such that (the functor) $X \times_S T$ is trivial under $H \times_S T$ is a refinement of $\mathcal{S}$.

<!-- original page 231 -->

(ii) There exists a covering family (for a pretopology defining the given topology) $\{S_i \rightarrow S\}$ such that for each i , the S_i -functor $X \times_S S_i$ with S_i -functor-group of operators $H \times_S S_i$ is trivial (= has a section over S_i).

Proposition 5.1.6. *Let $\mathcal{C}$ be a category equipped with a topology $\mathcal{T}$. Let (M) be a family of morphisms of $\mathcal{C}$ verifying the axioms (a) to (e_T) of 4.6.3. Let H be an $\mathcal{S}$ -group such that the structural morphism $H \rightarrow S$ is an element of (M) and P an $\mathcal{S}$ -object with $\mathcal{S}$ -operator group H . The following conditions are equivalent:*

<!-- label: III.IV.5.1.6 -->

(i) P is a principal homogeneous bundle under H (Definition 5.1.5).

(ii) P is formally principal homogeneous under H and the structural morphism $P \rightarrow S$ is an element of (M) .

(iii) There exists a morphism $S' \rightarrow S$ element of (M) such that by base extension from $\mathcal{S}$ to $\mathcal{S}'$, P becomes trivial, that is, $P \times_S S'$ is trivial under $H \times_S S'$.

(iv) H operates freely on P , in an (M) -effective manner, and the quotient P/H is isomorphic to $\mathcal{S}$.

Let us first remark that (ii) and (iv) are equivalent, taking into account that, in either case, $P \rightarrow S$ is an element of (M) , hence squarable, which ensures the representability of the fibered products $H \times_S P$ and $P \times_S P$. It is clear that (ii) entails (iii), as one can take P itself as S' , the hypothesis that P is formally principal homogeneous entailing that $P \times_S P$ is trivial under $H \times_S P$ (5.1.4), since it has a section (the diagonal section). It is clear that (iii) entails (i), since $\{S' \rightarrow S\}$ is a covering family, by axiom (d_T). It therefore remains to show that (i) entails (ii). The morphism of sheaves $P \times_S H \rightarrow P \times_S P$ is locally an isomorphism, hence an isomorphism (4.5.8); P is therefore formally principal homogeneous. The structural morphism $P \rightarrow S$ is locally isomorphic to the structural morphism $H \rightarrow S$ which is an element of (M) . It is therefore itself an element of (M) by (e_T).

<!-- original page 232 -->

The equivalence between (i) and (iv) generalizes:

Proposition 5.1.7. *Under the same hypotheses on $\mathcal{C}$ and (M) , let H be an $\mathcal{S}$ -group and X an $\mathcal{S}$ -object on which H operates (on the right). Suppose the structural morphism $H \rightarrow S$ is an element of (M) . The following conditions are equivalent:*

<!-- label: III.IV.5.1.7 -->

(i) H operates freely on X and in an (M) -effective manner.

(ii) There exists an $\mathcal{S}$ -morphism $p : X \rightarrow Y$ compatible with the equivalence relation defined in X by the action of H and such that the operation of $H \times_S Y$ on X above Y thus deduced makes X a principal homogeneous bundle under H_Y above Y .

*Under these conditions p identifies Y with the quotient X/H .

<!-- original page 233 -->

If $p : X \rightarrow Y$ is a morphism compatible with the action of H , then the operation of $H \times_S Y$ on X above Y thus deduced defines in X the same equivalence relation as the action of H , by virtue of the formula

```
```text
H_Y \times_Y X \cong H \times_S X.
```

The proposition follows from this remark and from the equivalence (iv)  $\Leftrightarrow$  (i) above.

**Corollary 5.1.7.1.** <sup>[N.D.E-IV-51]</sup> Let  $\mathcal{C}$  be a category having a final object, stable under fibered products, and equipped with a topology  $\mathcal{T}$  coarser than the canonical topology. Let  $f : G \rightarrow H$  be a morphism of  $\mathcal{C}$ -groups, and  $K = \text{Ker}(f)$ . Assume  $f$  covering for the topology  $\mathcal{T}$ .

<!-- label: III.IV.5.1.7.1 -->

Then  $H/K$  represents the sheaf quotient  $G/K$ , and  $f$  is a  $K_H$ -torsor. (N.B. One will also say that: " $G$  is a  $K$ -torsor above  $H$ ".)

Indeed, as  $f$  is covering, it is a universal effective epimorphism (4.4.3), hence by 3.3.3.1,  $H$  is the quotient of  $G$  by the equivalence relation  $R(f) = G \times_{\mathcal{C}}^H G$ . On the other hand, the morphism  $G \times K \rightarrow G \times_{\mathcal{C}}^H G$ ,  $(g, k) \mapsto (g, gk)$  is an isomorphism of objects with operator group  $K_G = G \times_{\mathcal{C}}^H K_H$  (its inverse being given by  $(g, g') \mapsto (g, g^{-1}g')$ ). Hence, on the one hand,  $R(f)$  is the equivalence relation defined by  $K$ ; on the other hand, since the morphism  $f : G \rightarrow H$  is covering,  $f$  is a  $K_H$ -torsor, by 5.1.6 (ii) (or directly by definition 5.1.5 (ii)).

We can now make Theorem 4.6.6 more precise in the case of passage to the quotient by an operator group:

**Proposition 5.1.8.** Under the hypotheses of 5.1.7, let  $F_0$  denote the functor over  $\mathcal{S}$  defined as follows: for each  $S \rightarrow \mathcal{S}$ ,  $F_0(S)$  is the set of representable sub- $\mathcal{S}$ -functors  $Z$  of  $X \times_{\mathcal{S}} S$ , stable under  $H \times_{\mathcal{S}} S$  and being principal homogeneous bundles under this  $S$ -group for the induced action (3.2.2).

<!-- label: III.IV.5.1.8 -->

(i) The following conditions are equivalent:

<!-- original page 233 -->

- \*a) The operation of  $H$  on  $X$  is  $(M)$ -effective and free. <sup>[N.D.E-IV-52]</sup>
- \*b)  $F_0$  is representable.

Under these conditions, one has  $F_0 = X/H$ .

(ii) Let  $(N)$  be a family of morphisms, stable under base change, such that for every covering family  $\{S'_i \rightarrow S\}$  and every family  $\{T_i \rightarrow S'_i\}$  of morphisms of  $(N)$ , every descent datum on the  $T_i$  relative to  $\{S'_i \rightarrow S\}$  is effective. Assume the morphism  $X \times_{\mathcal{S}} H \rightarrow X \times_{\mathcal{S}} X$  is an element of  $(N)$  and  $X$  squarable. Then the element  $p$  of  $\text{Hom}(X, F_0)$  corresponding to the sub-object  $X \times_{\mathcal{S}} H$  of  $X \times_{\mathcal{S}} X$  identifies  $F_0$  with the sheaf-quotient  $X/H$ .

<!-- original page 234 -->

### 5.2. Group structures and passage to the quotient

In this number we interest ourselves in the algebraic structures one can place on the quotient  $G/H$  of a group by a subgroup. We shall first place ourselves in the category of sheaves on  $\mathcal{C}$  for an arbitrary topology. By taking the canonical topology and using 4.5.12, we shall obtain results for the universal effective passage to the quotient in  $\mathcal{C}$ .

**Proposition 5.2.1.** Let  $u : H \rightarrow G$  be a monomorphism of sheaves of groups. There exists on the sheaf-quotient  $G/H$  a unique structure of object with operator group  $G$  such that the canonical morphism

<!-- label: III.IV.5.2.1 -->

```

G
p : G \longrightarrow G/H
G
```

is a morphism of objects with operator group  $G$ . This structure is functorial with respect to the pair  $(G, H)$ : if one has a commutative diagram

```

```text
H  →  G
|      |
↓      ↓ f
H' →  G' ,
```

```

\*the morphism  $f : G/H \rightarrow G'/H'$  (3.2.3) is compatible with the morphism  $ff$  on the operator groups.\*

Indeed, the sheaf  $\mathcal{G}/H$  is the sheaf associated with the presheaf

```

$$
i(G)/i(H) : S \rightarrow G(S)/H(S);
$$

```

as the functor  $a$  is left exact, it transforms objects with operator groups into objects with operator group. As the presheaf  $i(G)/i(H)$  is equipped with a structure of object with operator groups  $i(G)$ , then  $\mathcal{G}/H = a(i(G)/i(H))$  is equipped with a structure of object with operators  $a(i(G)) = G$ . This structure obviously enjoys all the stated properties.

**Corollary 5.2.2.** \*Let  $u : H \rightarrow G$  be a monomorphism of  $\mathcal{C}$ -groups. Suppose that the operation of  $H$  on  $G$  is universal effective. There exists on the object-quotient  $G/H$  in  $\text{Ob } \mathcal{C}$  a unique structure of object with operator group  $G$  such that  $p : G \rightarrow G/H$  is a morphism of objects with operators. This structure is functorial in the pair  $(H, G)$  (with  $H$  operating in a universal effective manner in  $G$ ), in the preceding sense.\*

<!-- label: III.IV.5.2.2 -->

**Proposition 5.2.3.** \*Let  $u : H \rightarrow G$  be a monomorphism of sheaves of groups identifying  $H$  with an invariant sub-sheaf of groups of  $G$ . There exists on the sheaf-quotient  $G/H$  a unique structure of sheaf of groups such that the canonical morphism  $p : G \rightarrow G/H$  is a morphism of groups. This structure is functorial in the pair  $(H, G)$  (with  $H$  invariant).\*

<!-- label: III.IV.5.2.3 -->

The proof is similar to that of 5.2.1.

**Corollary 5.2.4.** \*Let  $u : H \rightarrow G$  be a monomorphism of  $\mathcal{C}$ -groups identifying  $H$  with an invariant subgroup of  $G$ . Suppose that the action of  $H$  on  $G$  is universal effective. There exists on the object-quotient  $G/H$  in  $\text{Ob } \mathcal{C}$  a unique group structure\*

<!-- label: III.IV.5.2.4 -->

<!-- original page 235 -->

\*such that the canonical morphism  $G \rightarrow G/H$  is a morphism of groups. This structure is functorial with respect to the pair  $(H, G)$  ( $H$  invariant,  $H$  operating in a universal effective manner).\*

One can characterize the group structure of  $G/H$  in a more telling manner:

**Proposition 5.2.5.** \*Under the conditions of 5.2.4, let  $K$  be a  $\mathcal{C}$ -group and  $f : G \rightarrow K$  a morphism. The following conditions are equivalent:\*

<!-- label: III.IV.5.2.5 -->

(i)  $ff$  is a morphism of groups compatible with the equivalence relation defined by  $H$ .\*

(ii)  $ff$  is a morphism of groups inducing the trivial morphism  $H \rightarrow K$ .\*

(iii)  $ff$  factors as a morphism of groups  $G/H \rightarrow K$ .\*

\*In particular, one has an isomorphism, functorial in the group  $K$ \*

```

```text
Hom_{C-gr.}(G/H, K) \cong \{f \in Hom_{C-gr.}(G, K) \mid f \circ u = e\}.

```

...

The equivalence of (i) and (ii) is proved set-theoretically. One obviously has (iii) $\Rightarrow$ (ii). The equivalence of (iii) and (ii) follows from the formula

```
```text
Hom(G/H, K) = Hom(i(G)/i(H), K)
```
```

and from the definition of the group structure of G/H .

Remark 5.2.6. In the preceding situation, if the kernel of f is exactly H , the morphism $G/H \rightarrow K$ that factors f is a monomorphism. This follows at once from 3.3.4.*

<!-- label: III.IV.5.2.6 -->

In the case of sheaves of groups, one can make 4.4.11 more precise by means of the

Proposition 5.2.7. Let G be a sheaf of groups, H an invariant sub-sheaf of groups. For every sub-sheaf of groups K of G containing H , let K' be the quotient group K/H considered as a subgroup of $G' = G/H$.*

<!-- label: III.IV.5.2.7 -->

<!-- original page 236 -->

One has $K = K' \times_{G'} G$, and the maps $K \rightarrow K/H$ and $K' \rightarrow K' \times_{G'} G$ realize a bijection between the set of sub-sheaves of groups of G containing H and the set of sub-sheaves of groups of G' . In this correspondence, the invariant sub-sheaves of groups of G and of G' correspond.*

The first part follows easily from 4.4.11 and 3.2.4. It remains to see that K is invariant in G if and only if K' is invariant in G' . If K is invariant in G , then the presheaf $i(K)/i(H)$ is invariant in $i(G)/i(H)$. The same holds for the associated sheaves, by virtue of the usual argument. If conversely K' is invariant in G' , then the fibered product $K \times_{G'} G$ is invariant in G , as one sees immediately.

If now L is an arbitrary sub-sheaf of groups of G , let $\bar{L}$ be the saturation of L for the equivalence relation defined by H ; we shall also write $\bar{L} = L \cdot H$.

Proposition 5.2.8. Under the preceding conditions, $L \cdot H$ is a sub-sheaf of groups of G containing H and the image of L in G/H is identified with*

<!-- label: III.IV.5.2.8 -->

```
```text
(L · H)/H = L/(H ∩ L).
```
```

Indeed, let L' denote the sheaf image of L in G/H . It is a sub-sheaf of groups of G/H corresponding to $L \cdot H$ in the correspondence of the preceding proposition. As the morphism $L \rightarrow L'$ is covering, hence a universal effective epimorphism of sheaves, it follows from 4.4.9 that L' is identified with the quotient of L by the kernel of $L \rightarrow L'$ which is obviously none other than $H \cap L$.

Let us finally consider the following situation: we have a sheaf of groups G , a sub-sheaf of groups K and a sub-sheaf of groups H of K , invariant in K . Let us first define a (right) operation of the sheaf of groups $H \backslash K$ ($= K/H$) on G/H . The group K operates by right translations on G . As H is invariant in K , this operation is compatible with the equivalence relation defined by the action of H and therefore defines an operation of K on G/H , that is, a morphism from the opposite group K^{op} to K into $\text{Aut}(G/H)$. As the latter is a sheaf (4.5.13) and this morphism is trivial on H , it factors through K/H and defines the sought operation. As the right and left operations of G on itself commute, the operations of G and K/H on G/H commute.

<!-- original page 237 -->

Proposition 5.2.9. Under the preceding conditions, K/H operates freely (on the right) on G/H and one has a canonical isomorphism of sheaves with operator group G .*

<!-- label: III.IV.5.2.9 -->

\$\$
 $(G/H)/(K/H) \simeq G/K.$
 \$\$

When K is invariant in G , in which case K/H is invariant in G/H (5.2.7), this isomorphism respects the group structures of the two sides.

One has an isomorphism of presheaves

\$\$
 $(i(G)/i(H)) / (i(K)/i(H)) \xrightarrow{\sim} i(G)/i(K),$
 \$\$

which respects the structures of objects with operator group $i(G)$. The announced result is obtained by applying the functor i to this relation.

Corollary 5.2.10. *Let G be a C -group, K a sub- C -group of G , H an invariant sub- C -group of K . Let (M) be a family of morphisms of C verifying the axioms (a) to (e_T) . Suppose the operation of H on G (resp. K) on the right is (M) -effective. Then K/H operates in a natural manner freely on the right on G/H ; this operation commutes with that of G . The following conditions are equivalent:*

<!-- label: III.IV.5.2.10 -->

<!-- original page 238 -->

(i) The operation of K on G is (M) -effective.*

(ii) The operation of K/H on G/H is (M) -effective.*

Under these conditions, one has an isomorphism of objects $[^N.D.E-IV-53]$ with operator group G :

\$\$
 $(G/H)/(K/H) \simeq G/K.$
 \$\$

5.3. Use of effectivity criteria: Noether's theorem $[^N.D.E-IV-54]$

Let C , T and (M) be as usual. Let (N) be a family of morphisms verifying the axioms (a) and (f_M) of 4.7. Putting together 5.2.7 and 4.7.2, one obtains:

Proposition 5.3.1. *Let G be a C -group. Let H be a sub- C -group of G , invariant and operating in an (M) -effective manner in G .*

<!-- label: III.IV.5.3.1 -->

For every sub- C -group K of G containing H and such that the morphism $K \rightarrow G$ belongs to (N) , H operates in K in an (M) -effective manner and the quotient $K/H = K'$ is a sub- C -group of $G/H = G'$ such that the morphism $K' \rightarrow G'$ belongs to (N) .

The map $K \mapsto K'$ is a bijection between the set of sub- C -groups K of G , containing H and such that $K \rightarrow G$ belongs to (N) , and the set of sub- C -groups K' of G' such that $K' \rightarrow G'$ belongs to (N) . The inverse map is $K' \mapsto K \times_{G'} G$. In this correspondence, the invariant subgroups of G and G' correspond.

Corollary 5.3.2. *If $H \rightarrow G$ is an element of (N) , then C has a final object e and the unit section $e \rightarrow G/H$ is an element of (N) . $[^N.D.E-IV-55]$ *

<!-- label: III.IV.5.3.2 -->

6. Topologies in the category of schemes

<!-- label: III.IV.6 -->

<!-- original page 239 -->

6.1. The Zariski topology

This is the topology generated by the following pretopology: a family of morphisms $\{S_i \rightarrow S\}$ is covering if each morphism is an open immersion and the union of the images of the S_i is all of S . It is denoted (Zar).

Definition 6.1.1. A sheaf for the Zariski topology is also called a functor of local nature: it is a contravariant functor from (Sch) to (Ens) such that for every scheme S and every covering of S by opens S_i , one has an exact diagram:

<!-- label: III.IV.6.1.1 -->

```

```text
F(S) → ∏_i F(S_i) ⇒ ∏_{i,j} F(S_i ∩ S_j).
```

```

In particular, a functor of local nature transforms direct sums into products. As every representable functor is a sheaf, this topology is coarser than the canonical topology.

From the terminological point of view, whenever we say "local", "locally", without precision, it will be with reference to the Zariski topology, hence in the usual sense.

6.2. A procedure for constructing topologies

Proposition 6.2.1. Let $\mathcal{C}$ be a category, $\mathcal{C}'$ a full subcategory, $\mathcal{P}$ a set of families of morphisms of $\mathcal{C}$ with the same target, stable under base change and under composition (i.e. verifying the axioms (P 1) and (P 2) of 4.2.5), $\mathcal{P}'$ a set of families of morphisms of $\mathcal{C}'$ containing the families reduced to an identity isomorphism. Equip $\mathcal{C}$ with the topology generated by $\mathcal{P}$ and $\mathcal{P}'$ (cf. 4.2.5.0) and suppose the three conditions below are verified:

<!-- label: III.IV.6.2.1 -->

(a) If $\{S_i \rightarrow S\} \in \mathcal{P}'$ (hence $S_i, S \in \text{Ob } \mathcal{C}'$) and if $T \rightarrow S$ is a morphism of $\mathcal{C}'$, then the fibered products $S_i \times_S T$ (in $\mathcal{C}$) exist and the family $\{S_i \times_S T \rightarrow T\}$ belongs to $\mathcal{P}'$ (hence $S_i \times_S T \in \text{Ob } \mathcal{C}'$). (Remark: this condition entails that $\mathcal{P}'$ is stable under base change in $\mathcal{C}'$, but is not equivalent to it, since it further supposes that the inclusion functor from $\mathcal{C}'$ to $\mathcal{C}$ commutes with certain fibered products).

<!-- original page 240 -->

(b) For every $S \in \text{Ob } \mathcal{C}$, there exists $\{S_i \rightarrow S\} \in \mathcal{P}$ with $S_i \in \text{Ob } \mathcal{C}'$ for each i .

(c) In the following situation:

```

```text
 S_{ijk}
 |
 (P')
 ↓
S_i ← (P) S_{ij}
 (P')
 ↓
 S ,
...
```

```

where $S, S_i, S_{ij}, S_{ijk} \in \text{Ob } \mathcal{C}'$; $\{S_i \rightarrow S\} \in \mathcal{P}'$; $\{S_{ij} \rightarrow S_i\} \in \mathcal{P}$ for each i ; $\{S_{ijk} \rightarrow S_{ij}\} \in \mathcal{P}'$ for each ij , there exists a family $\{T_n \rightarrow S\} \in \mathcal{P}'$ and for each n a multi-index (ijk) and a commutative diagram

```

```text
 S_{ijk} ← T_n
 / \
 S
...
```

```

Then, in order for a sieve R of $S \in \mathcal{C}$ to be covering, it is necessary and sufficient that there exist a composite family

```

```text
R ← S_{ij}
 | (P')
 ↓
S ← S_i
 (P)
...

```

\*where  $S_{ij}, S_{ij} \in \mathcal{C}$ ,  $S_{ij} \rightarrow S \in \mathcal{P}$ ,  $S_{ij} \rightarrow S_{ij} \in \mathcal{P}$  for each  $i$ , and the morphisms  $S_{ij} \rightarrow S$  so obtained factor through  $R$  (in other words, the sieve generated by this composite family is contained in  $R$ ).

<!-- original page 239 -->

\*Proof.\* As the families elements of  $\mathcal{P}$  and of  $\mathcal{P}'$  are covering, a family composed of such families will be also  $(\mathcal{C})$ , hence a sieve of the indicated form will be covering, since it contains a covering sieve.

<!-- original page 241 -->

Conversely, it suffices to see that the sieves of this form do indeed form a topology, i.e. it suffices to verify the axioms (T 1) to (T 4) of 4.2.1.

\*Axiom (T 4).\* Let  $S \in \mathcal{C}$ . There exists by (b) a family  $S_{ij} \rightarrow S \in \mathcal{P}$  with  $S_{ij} \in \mathcal{C}$ . The families  $S_{ij} \rightarrow S_{ij}$  are elements of  $\mathcal{P}'$  by hypothesis. The sieve  $S$  of  $S$  is therefore of the desired form:

```

```text
S_i → S
| (P') id id_S
| (P)
↓
S_i → S
...

```

Axiom (T 3). Evident.

Axiom (T 2). Let R be a sieve of S of the desired form and let C be a sieve of S such that, for every $T \in \mathcal{C}$ and every morphism $T \rightarrow S$ factoring through R , the sieve $C \times_S T$ of T is of the desired form. Then, as $S_{ij} \rightarrow S$ factors through R , the sieve $C_{ij} = C \times_S S_{ij}$ of S_{ij} :

```

```text
S_{ij} ← C_{ij}
| (P')
S_i
| (P)
↓
S ← C
↑
R
...

```

is of the desired form; hence, for each  $ij$ , one has a diagram of the form:

```

```text
S_{ijkl}
| (P')
↓
S_{ijk}
| (P)
↓

```

$S_{ij} \longleftarrow C_{ij}$.

One has therefore proved that there exists a composite family

```
```text
 $S_{ijkl} \xrightarrow{(P')} S_{ijk} \xrightarrow{(P)} S_{ij} \xrightarrow{(P')} S_i \xrightarrow{(P)} S$
```
```

<!-- original page 240 -->

belonging to $\mathcal{P} \circ P' \circ P \circ P'$, factoring through $\mathcal{C}$, and where all objects other than S are in $\mathcal{C}$. Applying condition (c) to each family $\{S_{ijkl} \rightarrow S_{ijk}\}$, one deduces that for each i there exists a family $\{T_{in} \rightarrow S_{ij} \mid i \in P'\}$, such that $T_{in} \rightarrow S$ factors through one of the S_{ijkl} , hence through $\mathcal{C}$:

<!-- original page 242 -->

```
```text
 $T_{in} \xrightarrow{(P')} S_{ijkl}$
 |
 v
 $S_i \xrightarrow{(P)}$
 |
 v
 $S \longleftarrow C$
```
```

The sieve $\mathcal{C}$ of S is therefore of the desired form, which completes the verification.

Axiom (T 1). Let $\mathcal{R}$ be a sieve of S of the given form and let $T \rightarrow S$ be a morphism of $\mathcal{C}$. Let us show that the sieve $\mathcal{R} \times_S T$ of T is of the desired form.

```
```text
 $S_{ij} \xleftarrow{(P')} U_{ikj}$
 |
 v
 $S_i \xleftarrow{(P)} T_i \xleftarrow{(P)} U_{ik}$
 | |
 v v
 $R \rightarrow S \xleftarrow{(P)} T \xleftarrow{(P)}$
```
```

Let $T_i = S_i \times_S T$. The family $\{T_i \rightarrow T\}$ belongs to $\mathcal{P}$ (by (P 1)). Applying (b), one constructs $\{U_{ik} \rightarrow T_i \mid i \in P\}$, with the $U_{ik} \in \text{Ob } \mathcal{C}$. By hypothesis (condition (P 2) on $\mathcal{P}$), one has $\{U_{ik} \rightarrow T\} \in P$. By (a), $U_{ik} \times_{S_i} S_{ij} = U_{ikj}$ is an object of $\mathcal{C}$ and for each ik , $\{U_{ikj} \rightarrow U_{ik}\} \in P'$. Then, the commutative diagram below

```
```text
 $R \xleftarrow{(P')} U_{ikj}$
 |
 v
 $U_{ik} \xleftarrow{(P)}$
 |
 v
 $S \xleftarrow{(P)} T \xleftarrow{(P)}$
```
```

shows that the morphisms $U_{ikj} \rightarrow T$ factor through the sieve $\mathcal{R} \times_S T$ of T , which is therefore of the desired form, which completes the proof.

****Corollary 6.2.2.**** *If $S \in \text{Ob } \mathcal{C}$ and if $\mathcal{R}$ is a sieve of S , $\mathcal{R}$ is covering if and only if there exists a family $\{T_i \rightarrow S\} \in P'$, factoring through $\mathcal{R}$.*

<!-- label: III.IV.6.2.2 -->

<!-- original page 243 -->

Indeed, such a sieve is covering. On the other hand, it suffices to apply (c) by taking the family $\{S_i \rightarrow S\}$ reduced to the identity isomorphism of S to deduce from the proposition that a covering sieve is of the indicated form.

Corollary 6.2.3. *In order for a presheaf F on $\mathcal{C}$ to be separated (resp. a sheaf), it is necessary and sufficient that the morphism*

<!-- label: III.IV.6.2.3 -->

$$F(S) \rightarrow \prod_i F(S_i)$$

be injective (resp. that the diagram

$$F(S) \rightarrow \prod_i F(S_i) \rightrightarrows \prod_{i,j} F(S_i \times_S S_j)$$

be exact) in the two following cases:

(i) $\{S_i \rightarrow S\} \in \mathcal{P}$,

(ii) $S, S_i \in \mathcal{C}$; $\{S_i \rightarrow S\} \in \mathcal{P}'$.

Indeed, the conditions are necessary, since the families in question are covering. If $\mathcal{C}$ is the sieve of S image of a family of morphisms $\{S_{ij} \rightarrow^{(P')} S_i \rightarrow^{(P)} S\}$, a straightforward diagram chase shows that the conditions of the corollary entail that $\operatorname{Hom}(S, F) \rightarrow \prod_i \operatorname{Hom}(S_i, F)$ is injective (resp. bijective). But every refinement $\mathcal{R}$ of $\mathcal{S}$ contains a sieve $\mathcal{C}$ of the above type and one has a commutative diagram

$$\begin{array}{ccc} \operatorname{Hom}(S, F) & \xrightarrow{f} & \operatorname{Hom}(R, F) \\ & \searrow g & \nearrow h \\ & \operatorname{Hom}(C, F) & \end{array}$$

One knows that g is injective, hence so is f . Therefore F is separated. But $\mathcal{R}$ is a refinement of $\mathcal{C}$, hence h is also injective. If g is bijective, then f is also, hence F is a sheaf.

<!-- original page 244 -->

Remark 6.2.4. *The preceding corollary does not follow from 4.3.5, because $\mathcal{P}'$ is not stable under base extension.*

<!-- label: III.IV.6.2.4 -->

Remark 6.2.5. *Condition (c) is verified in particular in the case where*

<!-- label: III.IV.6.2.5 -->

(i) $\mathcal{P}'$ is stable under composition.*

(ii) If $\{S_j \rightarrow S\}$ is a family of morphisms of $\mathcal{C}$, element of $\mathcal{P}$, there exists a subfamily element of $\mathcal{P}'$.

6.3. Application to the category of schemes

One takes for $\mathcal{C}$ the category of schemes, for $\mathcal{C}'$ the full subcategory formed by affine schemes, for $\mathcal{P}$ the set of surjective families of open immersions. One will consider several sets $\mathcal{P}'$:

$\mathcal{P}'_{\{1\}}$: finite surjective families, composed of flat morphisms.

<!-- original page 242 -->

$\mathcal{P}'_{\{2\}}$: finite surjective families, composed of flat morphisms of finite presentation and quasi-finite. [N.D.E-IV-57]

$\mathcal{P}'_{\{3\}}$: finite surjective families, composed of étale morphisms.

$\mathcal{P}'_{\{4\}}$: finite surjective families, composed of étale and finite morphisms.

For each of these sets $\mathcal{P}'_{\{i\}}$, except $\mathcal{P}'_{\{4\}}$, the conditions of Proposition 6.2.1 are verified ((c) thanks to 6.2.5, since an affine scheme being quasi-compact, every family of morphisms of $\mathcal{C}$, element of $\mathcal{P}$, contains a finite subfamily that is also in $\mathcal{P}$, hence in $\mathcal{P}'_{\{i\}}$ for $i = 1, 2, 3$). The topology $\mathcal{T}_{\{i\}}$ generated by $\mathcal{P}$ and $\mathcal{P}'_{\{i\}}$ is denoted and called in the following way:

<!-- original page 245 -->

```
```text
T_1 = (fpqc) = faithfully flat quasi-compact topology.
T_2 = (fppf) = faithfully flat (locally) of finite presentation topology.
T_3 = (ét) = étale topology.
T_4 = (étf) = étale finite topology.
```
```

As $\mathcal{P}'_{\{1\}} \supset \mathcal{P}'_{\{2\}} \supset \mathcal{P}'_{\{3\}} \supset \mathcal{P}'_{\{4\}}$, one has

```
```text
(fpqc) ≥ (fppf) ≥ (ét) ≥ (étf) ≥ (Zar).
```
```

Proposition 6.3.1. (i) In order for the sieve $\mathcal{R}$ of $\mathcal{S}$ to be covering for $\mathcal{T}_{\{i\}}$, $1 \leq i \leq 3$, it is necessary and sufficient that there exist a covering $\mathcal{S}_{\{p\}}$ of $\mathcal{S}$ by affine opens and for each p a family $\mathcal{S}_{\{pq\}} \rightarrow \mathcal{S}_{\{p\}}$ element of $\mathcal{P}'_{\{i\}}$, the $\mathcal{S}_{\{pq\}}$ being affine, such that each morphism $\mathcal{S}_{\{pq\}} \rightarrow \mathcal{S}$ factors through $\mathcal{R}$. [N.D.E-IV-58]

<!-- label: III.IV.6.3.1 -->

(ii) In order for a presheaf $\mathcal{F}$ on (Sch) to be a sheaf for (fpqc) (resp. (fppf), (ét), (étf)), it is necessary and sufficient that*

- *a) $\mathcal{F}$ be a sheaf for (Zar), i.e. a functor of local nature.*
- *b) For every faithfully flat (resp. faithfully flat of finite presentation and quasi-finite, resp. surjective étale, resp. surjective étale finite) morphism $T \rightarrow S$, where T and S are affine, one has an exact diagram:*

```
```text
F(S) → F(T) ⇒ F(T ×S T).
```
```

(iii) The topologies $\mathcal{T}_{\{i\}}$, $i = 1, 2, 3, 4$, are coarser than the canonical topology.*

<!-- original page 246 -->

(iv) Every surjective family formed of flat and open morphisms (resp. flat and locally of finite presentation, resp. étale, resp. étale and finite) is covering for (fpqc) (resp. (fppf), resp. (ét), resp. (étf)).*

(v) Every finite surjective family formed of flat and quasi-compact morphisms is covering for (fpqc). In particular, every faithfully flat and quasi-compact morphism is covering for (fpqc).*

Proof. (i) follows from 6.2.1, (ii) from 6.2.3, taking into account the fact that a sheaf for the Zariski topology transforms direct sums into products. Every representable functor being a sheaf for (Zar) and verifying condition (b) of (ii) by SGA 1, VIII 5.3, $\mathcal{T}_1$ is coarser than the canonical topology, which proves (iii).

Let us prove (iv). Let $\mathcal{S}_{\{i\}} \rightarrow \mathcal{S}$ be a family of morphisms as in the statement. Considering a covering of $\mathcal{S}$ by affine opens, one reduces immediately to the case where $\mathcal{S}$ is affine. [N.D.E-IV-59]

Let us first treat the case where the morphisms $S_{\{i\}} \rightarrow S$ are flat and open (resp. étale). Let $S_{\{ij\}}$ be a covering of $S_{\{i\}}$ by affine opens. As the morphisms in question are open, the images $T_{\{ij\}}$ of the $S_{\{ij\}}$ form an open covering of $S_{\{i\}}$. As $S_{\{i\}}$ is affine, hence quasi-compact, it is covered by a finite number of opens $T_{\{ij\}}$, for (i, j) running through a finite set F . Then $S' = \bigsqcup_{F} S_{\{ij\}}$ is affine, and the morphism $S' \rightarrow S$ belongs to $\mathcal{P}'_{\{1\}}$, resp. $\mathcal{P}'_{\{3\}}$, hence is covering. As it factors through the given family, the latter is covering.

In the case (étf), each $S_{\{i\}}$ is finite over S hence is affine; in the preceding argument, one can then take the covering $\{S_{\{i\}}\}$ of $S_{\{i\}}$, and one obtains that $S' \rightarrow S$ belongs to $\mathcal{P}'_{\{4\}}$.

Let us now consider the case where the morphisms $f_{\{i\}} : S_{\{i\}} \rightarrow S$ are flat and locally of finite presentation. For every $s \in S$, there exists, by (the proof of) EGA IV_4, 17.16.2, an affine subscheme $X(s)$ of a certain $S_{\{i\}}$, such that $s \in f_{\{i\}}(X(s))$ and that the morphism $g_{\{i\}} : X(s) \rightarrow S$, restriction of $f_{\{i\}}$, is flat, of finite presentation, and quasi-finite. Then, $g_{\{i\}}(X(s))$ is an open neighborhood $U(s)$ of s (EGA IV_2, 2.4.6), and, S being affine, it is covered by a finite number of such opens $U(s_{\{j\}})$, $j = 1, \dots, n$. Consequently, $X' = \bigsqcup_{\{j\}} X(s_{\{j\}})$ is affine, and the morphism $X' \rightarrow S$ is surjective, flat, of finite presentation, and quasi-finite, hence belongs to $\mathcal{P}'_{\{2\}}$. [N.D.E-IV-60] This completes the proof of (iv).

Let us prove (v). Let $\{S_{\{i\}} \rightarrow S\}$ be a finite faithfully flat and quasi-compact family. Let $T_{\{j\}}$ be a covering of S by affine opens. The $S_{\{ij\}} = T_{\{j\}} \times_S S_{\{i\}}$ are quasi-compact and therefore have finite affine open coverings $T_{\{ijk\}}$. Each morphism $T_{\{ijk\}} \rightarrow T_{\{j\}}$ is flat, and the family $\{T_{\{ijk\}} \rightarrow T_{\{j\}}\}$ is finite and surjective, hence covering for $T_{\{j\}}$. The family $\{T_{\{ijk\}} \rightarrow S\}$ is therefore also, by composition. It factors through the given family which is therefore also:

<!-- original page 247 -->

```

```text
S_i ← S_{ij} ← T_{ijk}
 /
S_ ← T_j ←
```

```

Corollary 6.3.2. Let $\{M_{\{i\}}\}$ be the following family of morphisms:

<!-- label: III.IV.6.3.2 -->

- (M_1) : faithfully flat and quasi-compact morphisms.
- (M_2) : faithfully flat morphisms locally of finite presentation.
- (M_3) : surjective étale morphisms.
- (M_4) : surjective étale finite morphisms. [N.D.E-IV-61]

The family $\{M_{\{i\}}\}$ verifies the axioms (a), (b), (c), $(d_{\{T_i\}})$ and $(e_{\{T_i\}})$ of 4.6.3.

Indeed, for (a), (b), (c), it is classical (EGA and SGA 1, passim). [N.D.E-IV-62] By 6.3.1, (iv) and (v), $\{M_{\{i\}}\}$ verifies $(d_{\{T_i\}})$. It remains to see that $\{M_{\{i\}}\}$ verifies $(e_{\{T_i\}})$; for this, it suffices to see that $\{M_{\{i\}}\}$ verifies $(e_{\{T_1\}})$, which entails the others. This follows from SGA 1, VIII (nos 4 and 5).

Corollary 6.3.3. If X is a scheme and R an equivalence relation in X of type $\{M_{\{i\}}\}$, R is $\{M_{\{i\}}\}$ -effective if and only if the sheaf-quotient of X by R for $T_{\{i\}}$ is representable and in this case it is represented by the quotient X/R .

<!-- label: III.IV.6.3.3 -->

Indeed, this is 4.6.5.

<!-- original page 248 -->

6.4. Effectivity conditions

We now seek families $\{N\}$ of morphisms verifying axiom (f_T) of 4.7. Let us first remark that $(f_{\{T_1\}})$ entails $(f_{\{T_i\}})$, so that we may restrict ourselves to the case of the topology (fpqc).

Lemma 6.4.1. The following families of morphisms verify axiom $(f_{\{T_1\}})$ of 4.7, that is, "descend by (fpqc)":

<!-- label: III.IV.6.4.1 -->

- (N) : open immersions.*
- (N') : closed immersions.*
- (N'') : quasi-compact immersions.*

By virtue of 6.3.1 (ii), it suffices to verify that the given families descend by the Zariski topology and by a faithfully flat quasi-compact morphism. The first assertion is clear; let us verify the second. For (N) , this is SGA 1, VIII 4.4; for (N') , this is loc. cit., 1.9. For (N'') one argues as in loc. cit., 5.5, using the two preceding results.

<!-- original page 245 -->

Corollary 6.4.2. *The same result holds for quasi-compact open immersions.*

<!-- label: III.IV.6.4.2 -->

These results allow one to apply to the present situation the general results of 4.7.1, 4.7.2, 5.1.8, 5.3.1, etc. Let us state one as an example, the first.

Corollary 6.4.3. $(= 4.7.1 + 4.6.10).$ *Let X be a scheme and R an equivalence relation in X . Suppose that $R \rightarrow X$ is faithfully flat and quasi-compact and that $R \rightarrow X \times X$ is a closed immersion (resp. open, resp. quasi-compact, resp. quasi-compact open). Then the sheaf-quotient X/R is the same for the topology (fpqc) and for the canonical topology, and for each scheme S , one has*

<!-- label: III.IV.6.4.3 -->

<!-- original page 249 -->

```
```text
(X/R)(S) = { closed (resp. open, resp. retrocompact[^N.D.E-IV-63], resp. open retrocompact)
 subschemes Z of X_S , stable under $R \times S$, such that $Z \rightarrow S$ is
 faithfully flat quasi-compact and the diagram $R_Z \rightarrow Z \rightarrow S$ is exact }.
```
```

6.5. Principal homogeneous bundles

Let us simply indicate the terminology:

```
```text
topology principal homogeneous bundles
(fpqc) " " " (tout court)
(ét) " " " quasi-isotrivial
(étf) " " " locally isotrivial
(Zar) " " " locally trivial.
```
```

6.6. Other topologies

One sometimes uses other topologies on the category of schemes. Let us indicate one: the *global étale finite* topology (étfg), generated by the pretopology whose covering families are the surjective families formed of étale finite morphisms. It is not finer than the Zariski topology. The corresponding principal homogeneous bundles are called "isotrivial".

6.7. Homogeneous spaces [N.D.E-IV-65]

Let G be an S -group scheme, X an S -scheme with (left) operator group G , and

```

```text
Φ : G ×_S X → X ×_S X
```

```

the morphism of S -schemes defined setwise by $(g, x) \mapsto (gx, x)$. Let us recall (cf. 5.1.0 and III.0.1) that one says that X is a *formally principal homogeneous space* under G if the following equivalent conditions are satisfied:

- (i) for every $T \rightarrow S$, the set $X(T)$ is empty or principal homogeneous under $G(T)$,
- (ii) Φ is an isomorphism of S -functors,
- (iii) Φ is an isomorphism of S -schemes.

(The equivalence (i) $\Leftrightarrow$ (ii) is clear, and one has (ii) $\Leftrightarrow$ (iii) since $\mathcal{C} = (\text{Sch}/S)$ is a full subcategory of $\hat{\mathcal{C}}$.)

The definition of formally homogeneous space (not necessarily principal homogeneous) is obtained by requiring that Φ be an epimorphism in the category of sheaves for an appropriate topology $\mathcal{T}$. Indeed, the condition that Φ be an epimorphism of S -functors amounts to the requirement that, for every $T \rightarrow S$, the set $X(T)$ be empty or homogeneous (not necessarily principal homogeneous) under $G(T)$, but this condition is too restrictive, as the following simple example shows. Let $S = \operatorname{Spec} R$, $G = G_{\{m, R\}}$ and $X = G_{\{m, R\}}$ on which G acts via $t \cdot x = t^2 x$. Then the morphism Φ is étale, finite, and surjective, hence an epimorphism in the category of sheaves for the topology (étf) (a fortiori, an epimorphism of S -schemes); on the other hand, the points 1 and -1 of $X(R)$ are not conjugate by an element of $G(R)$, so that the morphism $G(R) \times X(R) \rightarrow X(R) \times X(R)$ is not surjective. [N.D.E-IV-66] One is therefore led to lay down the following definition:

`<!-- original page 247 -->`

Definition 6.7.1. Let G be an S -group, X an S -scheme with operator group G , and $\mathcal{T}$ a topology on (Sch/S) , coarser than the canonical topology. We say that X is a *formally homogeneous space* under G (relative to the topology $\mathcal{T}$) if the following equivalent conditions are satisfied:

`<!-- label: III.IV.6.7.1 -->`

(i) the morphism $\Phi : G \times_{\mathcal{T}} X \rightarrow X \times_{\mathcal{T}} X$ is an epimorphism in the category of sheaves for the topology $\mathcal{T}$,

(ii) for every $T \rightarrow S$, and $x, y \in X(T)$, there exists a morphism $T' \rightarrow T$ covering for the topology $\mathcal{T}$, and $g \in G(T')$, such that $y_{T'} = g \cdot x_{T'}$.

Remark 6.7.2. Condition (i) implies, in particular, that Φ is a universal effective epimorphism in (Sch/S) (cf. 4.4.3). This entails, as one easily sees, that Φ is surjective (cf. 1.3, N.D.E. (3)).

`<!-- label: III.IV.6.7.2 -->`

Proposition and Definition 6.7.3. [N.D.E-IV-67] Let G be an S -group, X an S -scheme with operator group G , and $\mathcal{T}$ a topology on (Sch/S) , coarser than the canonical topology. The following conditions are equivalent:

`<!-- label: III.IV.6.7.3 -->`

(i) X verifies the two hypotheses below:

- (1) the morphism $\Phi : G \times_{\mathcal{T}} X \rightarrow X \times_{\mathcal{T}} X$ is covering, i.e. X is a G -formally homogeneous

space,*

- *(2) the morphism $X \rightarrow S$ is also covering, i.e. locally for the topology $\mathcal{T}$, it has a section (cf. RefIV.4.4.8bis.bis).*

(ii) "Locally on S for the topology $\mathcal{T}$ ", X is isomorphic, as a scheme with operator group G , to the sheaf quotient (for $\mathcal{T}$) of G by a sub-group-scheme H , i.e. there exists a covering family $\{S_i \rightarrow S\}$ such that each $X \times_{S_i} S_i$ represents the sheaf quotient of $G \times_{S_i} S_i$ by a certain sub-group-scheme H_i .

Under these conditions, one says that X is a G -homogeneous space (relative to the topology $\mathcal{T}$).*

Proof. Suppose (ii) is verified. Set $G_i = G \times_{S_i} S_i$ and $X_i = X \times_{S_i} S_i$. Then, X_i has a section over S_i , namely the composite of the unit section $\epsilon_i : S_i \rightarrow G_i$ and the projection $\pi_i : G_i \rightarrow X_i = G_i/H_i$. Hence $X \rightarrow S$ is covering.

<!-- original page 248 -->

On the other hand, π_i is covering, hence $\pi_i \times \pi_i$ is also (cf. 4.2.3 (C 1) and (C 2)), and one has a commutative diagram:

$$\begin{array}{ccc} G_i \times_{S_i} X_i & \xrightarrow{\Phi_i} & G_i \times_{S_i} X_i \\ \uparrow \text{id} \times \pi_i & & \uparrow \pi_i \times \pi_i \\ G_i \times_{S_i} G_i & \xrightarrow[\sim]{\Psi_i} & G_i \times_{S_i} G_i \end{array}$$

where Φ_i is deduced from Φ by the base change $S_i \rightarrow S$ and Ψ_i is the isomorphism defined setwise by $(g, g') \mapsto (gg', g)$. Then $(\pi_i \times \pi_i) \circ \Psi_i$ is covering, hence Φ_i is also (4.2.3 (C 3)). This shows that Φ is "locally covering", hence is covering (4.2.3 (C 5)). This proves that (ii) $\Rightarrow$ (i).

Conversely, suppose (i) is verified, and suppose moreover that the structural morphism $X \rightarrow S$ has a section σ . By EGA I, 5.3.13, σ is an immersion. Let us define $H = G \times_X S$ by the diagram below, in which the two squares are cartesian:

$$\begin{array}{ccccc} H & \longrightarrow & G & \xrightarrow{\text{id}_G \boxtimes \sigma} & G \times_S X \\ \downarrow \sigma & & \downarrow \pi & & \downarrow \Phi \\ S & \longrightarrow & X & \xrightarrow{\text{id}_X \boxtimes \sigma} & X \times_S X \end{array}$$

where π , $\text{id}_G \boxtimes \sigma$ and $\text{id}_X \boxtimes \sigma$ denote the morphisms defined setwise, for $T \rightarrow S$ and $g \in G(T)$, $x \in X(T)$, by:

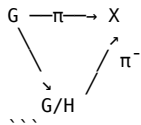

$$\pi(g) = g \cdot \sigma_T, \quad (\text{id}_G \boxtimes \sigma)(g) = (g, \sigma_T), \quad (\text{id}_X \boxtimes \sigma)(x) = (x, \sigma_T).$$

Then, π is covering, and H is a sub-group-scheme of G , representing the stabilizer $\text{Stab}_G(\sigma)$ of σ (cf. I, 2.3.3), i.e., for every $T \rightarrow S$, one has:

$$H(T) = \{ g \in G(T) \mid g \cdot \sigma_T = \sigma_T \}.$$

Let us denote G/H the presheaf $T \mapsto G(T)/H(T)$, and $a(G/H)$ the associated sheaf, for the topology $\mathcal{T}$. By what precedes, one obtains a commutative diagram of morphisms of presheaves with operator group G :

```text

where  $\bar{\pi}$  is a monomorphism. As  $\pi$  is covering,  $\bar{\pi}$  is also and therefore, by 4.3.12,  $\bar{\pi}$  induces an isomorphism  $a(G/H) \xrightarrow{\sim} X$ . One has therefore proved that: if  $X$  is a  $G$ -homogeneous space such that  $X \rightarrow S$  admits a section  $\sigma$ , then  $X$  represents the sheaf quotient  $G/H$ , where  $H = G \times_X S$  is the stabilizer of  $\sigma$ .

In the general case, there exists by hypothesis a covering family  $\{S_i \rightarrow S\}$  such that each morphism  $X_i = X \times_S S_i \rightarrow S_i$  has a section  $\sigma_i$ . Set  $G_i = G \times_S S_i$ ; then the morphism  $\Phi_i : G_i \times_{S_i} X_i \rightarrow X_i \times_{S_i} X_i$  deduced from  $\Phi$  by the base change  $S_i \rightarrow S$  is again covering. Hence, by what precedes,  $X_i \cong G_i/H_i$ , where  $H_i$  is the stabilizer in  $G_i$  of  $\sigma_i$ . This completes the proof of the implication (i)  $\Rightarrow$  (ii).

[^IV-0-1]: This text develops the substance of two oral expositions of A. Grothendieck, completing the latter on several important points which had been passed over in silence or scarcely touched on.

[^N.D.E-IV-0]: N.D.E.: Version of 13/10/2024.

[^IV-1-1]: N.D.E.: that is, if  $u$  is right-cancellable.

[^N.D.E-IV-2]: N.D.E.: This implies, in particular, that  $u$  be an epimorphism.

[^N.D.E-IV-3]: N.D.E.: For example, if  $\mathcal{C} = (\text{Sch})$  is the category of schemes, one sees easily that every universal epimorphism is surjective. Let  $\mathcal{T} = \coprod_{p \text{ prime}} \operatorname{Spec}(F_p)$  and  $\mathcal{S} = \operatorname{Spec}(\mathbb{Z})$ ; then the morphism  $u : \mathcal{T} \rightarrow \mathcal{S}$  is an epimorphism that is not universal. On the other hand, one sees that  $\mathcal{T} \times_{\mathcal{S}} \mathcal{T}$  is identified with  $\mathcal{T}$ , so that the two projections  $\mathcal{T} \times_{\mathcal{S}} \mathcal{T} \rightrightarrows \mathcal{T}$  coincide; since  $\operatorname{id}_{\mathcal{T}}$  does not descend to a morphism  $\mathcal{S} \rightarrow \mathcal{T}$ , this shows that  $u$  is not an effective epimorphism.

[^N.D.E-IV-4]: N.D.E.: The numbering 1.4.0 has been added for later references.

[^N.D.E-IV-5]: N.D.E.: The numbering 1.6.0 has been added for later references.

[^N.D.E-IV-6]: N.D.E.: This is the following argument, communicated by M. Demazure. Let  $f, g : T' \rightarrow T$ , and let  $\phi : T' \rightarrow T \times_{\mathcal{S}} T$  be the morphism with components  $f$  and  $g$ , whence  $p_1 \circ \phi = f$  and  $p_2 \circ \phi = g$ . Then  $F(\phi) : F(T \times_{\mathcal{S}} T) \rightarrow F(T)$  satisfies  $F(\phi) \circ F(p_1) = F(f)$  and

$\phi \circ F(p_2) = F(g)$ . Now, for every  $x \in \check{H}^0(T/S, F)$ , one has  $F(p_1)(x) = F(p_2)(x)$ . Hence, applying  $\phi$  to both sides, one obtains  $F(f)(x) = F(g)(x)$ , which shows that  $f$  and  $g$  induce the same morphism.

[^N.D.E-IV-7]: N.D.E.: One will note that a monomorphism which is an epimorphism is not necessarily an isomorphism. For example, in  $\mathcal{C} = (\text{Sch})$ , the morphism  $\text{Spec}(F_p) \amalg \text{Spec}(Z[1/p]) \rightarrow \text{Spec}(Z)$  is a monomorphism and a surjective epimorphism, but is not an isomorphism.

[^N.D.E-IV-8]: N.D.E.: for example, one has identified, on the one hand,  $\text{pr}_{2,1}(X'_{-1}) = \text{pr}_{3,1}(X'_{-1})$  and, on the other hand,  $\text{pr}_{2,1}(X'_{-2}) = \text{pr}_{3,2}(X'_{-2})$ .

[^N.D.E-IV-9]: N.D.E.: applied to  $f : S' \times_T S' \rightarrow S \times_T S = Y$ .

[^N.D.E-IV-10]: N.D.E.: The condition is evidently necessary. Conversely, if for every  $S \in \mathcal{C}$ ,  $R(S)$  is the graph of an equivalence relation, then this equivalence relation extends to  $R(F)$  for every  $F \in \hat{\mathcal{C}}$ , by declaring that two morphisms  $\phi, \psi : F \rightarrow R$  are equivalent if, for every  $S \in \mathcal{C}$  and  $x \in F(S)$ ,  $\phi(x)$  and  $\psi(x)$  are equivalent in  $X(S)$ .

[^N.D.E-IV-11]: N.D.E.: Let us illustrate this by giving an outline of the sequel of this Exposé. Let  $G$  be a  $\mathcal{C}$ -group,  $H$  a sub- $\mathcal{C}$ -group,  $R$  the equivalence relation in  $G$  defined by  $G \times H \rightarrow G \times G$ ,  $(g, h) \mapsto (g, gh)$  (cf. 3.2). The functor  $Q$  defined by  $Q(S) = G(S)/H(S)$  is a quotient in  $\hat{\mathcal{C}}$  (according to 4.4.9 applied to the least fine topology, cf. 4.4.2), but it is not in general the quotient that one wishes. For example, for  $\mathcal{C} = (\text{Sch})$ , one has an exact sequence of (affine) group schemes:

$$1 \rightarrow \mu_2 \rightarrow G_m \xrightarrow{p} G_m \rightarrow 1$$

which identifies  $G_m$  with the quotient  $G_m/\mu_2$ . Moreover, since  $p$  is a finite and locally free morphism, then  $G_m$  is the sheaf-quotient of  $G_m$  by  $\mu_2$  in the larger category of sheaves for the (fppf) topology, cf. 4.6.6 (ii) and 6.3.2. By contrast, the quotient  $Q$  in  $\hat{\mathcal{C}}$  is not isomorphic to  $G_m$  since, for example,  $Q(Z) = \{1\}$  while  $G_m(Z) = \mathbb{Z}$ . Hence  $Q$  is not an (fppf) sheaf, and *a fortiori*  $Q$  is not representable.

[^N.D.E-IV-12]: N.D.E.: Note that, even for a  $\hat{\mathcal{C}}$ -equivalence relation in  $X$ , one is interested in the existence of a quotient in  $\mathcal{C}$ .

[^N.D.E-IV-13]: N.D.E.: "in  $\mathcal{C}$ " has been added.

[^N.D.E-IV-14]: N.D.E.: The numbering 3.3.2.1 (resp. 3.3.3.1) has been added for later references. On the other hand, Remark 3.3.3.2 has been added.

[^N.D.E-IV-15]: N.D.E.: The numbering 3.4.3.1 has been added for later references, and the proof of point (i) has been detailed.

[^N.D.E-IV-16]: N.D.E.: This paragraph has been added.

[^N.D.E-IV-17]: N.D.E.: Here, "dominator" is taken in the sense of the preorder relation mentioned above, i.e.,  $Y$  dominates  $X$  if there exists an arrow  $Y \rightarrow X$ . On the other hand, if  $X, Y$  are two subobjects of an object  $Z$ , one says (cf. 2.4) that  $Y$  contains  $X$  if  $X \subset Y$ . To avoid any ambiguity between these two terminologies, "majorant" has been replaced in the sequel by "dominating" in the first case, and by "containing", in the second.

[^N.D.E-IV-18]: N.D.E.: The sentence that follows has been detailed.

[^N.D.E-IV-19]: N.D.E.: The numbering 4.1.4.0 has been added in order to highlight this definition.

[^N.D.E-IV-20]: N.D.E.: that is: if  $\mathcal{C}$  is covering "locally with respect to the covering sieve  $R$ ", then  $\mathcal{C}$  is covering.

[^N.D.E-IV-21]: N.D.E.:  $(T' 1)$  and  $(T' 2)$  suffice:  $G \cap H = G \times_{\{F\}} H$  belongs to  $J(H)$ , by  $(T' 1)$ , hence to  $J(F)$ , by  $(T' 2)$ .

[^N.D.E-IV-22]: N.D.E.: This definition has been placed here (placed in the original after 4.2.5), since it will be used in 6.2.1 in a slightly more general setting than that of 4.2.5.

[^N.D.E-IV-23]: N.D.E.: in what follows, typographical errors of the original have been corrected.

[^N.D.E-IV-24]: N.D.E.: One will note that if  $Q$  is a subpresheaf of a separated presheaf  $P$ , then  $Q$  is separated. Indeed, for every sieve  $R$  of  $S$ , the composite map  $Q(S) \rightarrowtail P(S) \rightarrowtail P(R)$  is injective and factors through  $Q(S) \rightarrowtail Q(R)$ .

[^N.D.E-IV-25]: N.D.E.: This corollary has been added.

[^N.D.E-IV-26]: N.D.E.: The numbering 4.3.10.0 has been added for later references. On the other hand, it follows from the definition that if  $Q \rightarrowtail P$  is a monomorphism, the same holds for  $LP \rightarrowtail LQ$ ; hence  $L$  "preserves monomorphisms" (see also 4.3.16 for a more general result:  $L$  "commutes with finite inverse limits").

[^N.D.E-IV-27]: N.D.E.: Denote by  $p$  the projection  $R' \rightarrowtail R$ . Since  $i_{R'}$  is a monomorphism, one has  $p = g \circ i_{R'}$ . Let  $g'$  be the section of  $i_{R'}$  defined by  $g$ ; then  $p \circ g' = g$  and therefore  $p \circ g' \circ i_{R'} = g \circ i_{R'} = p$ ; this entails  $g' \circ i_{R'} = \text{id}_{R'}$  and therefore  $i_{R'} : R' \rightarrowtail T$  is an isomorphism, with inverse  $g'$ .

[^N.D.E-IV-28]: N.D.E.: The statement of the corollary and its proof have been detailed.

[^N.D.E-IV-29]: N.D.E.: In particular, if  $K$  is the kernel of a pair of morphisms of presheaves  $u, v : Q \rightrightarrows P$ , then  $LK$  is the kernel of  $Lu, Lv : LQ \rightrightarrows LP$  (this will be used in 4.4.5).

[^N.D.E-IV-30]: N.D.E.: The original has been modified here.

[^N.D.E-IV-31]: N.D.E.: The continuation of the proof has been slightly modified.

[^N.D.E-IV-32]: N.D.E.: Point (i) of Lemma 4.4.5 has been corrected, and the proof of the three points detailed.

[^N.D.E-IV-33]: N.D.E.: In general, the direct sum of two sheaves  $F, G$  is not a sheaf. Indeed, let  $S_1, S_2 \in \text{Ob } C$ ; suppose that the direct sum  $S = S_1 \coprod S_2$  exists in  $C$  and that the fiber product  $S_1 \times_S S_2$  is an initial object  $\emptyset$  of  $C$  (cf. I, 1.8). Let  $R$  be the sieve of  $S$  with base  $\{S_1, S_2\}$ ; then  $(F \coprod G)(R)$  is the disjoint union of  $F(S) \coprod G(S)$  and of  $F(S_i) \times G(S_j)$  for  $i \neq j$ , hence  $F \coprod G$  is not a sheaf in general. On the other hand, if  $C$  is the category with a single object  $S$  and  $\text{id}_S$  as sole morphism, equipped with the topology defined by  $J(S) = \{\emptyset, S\}$ , then the only separated presheaves are  $R_{\emptyset}$  and  $X = h_S$  (which is a sheaf), and  $X \coprod X$  is not separated.

[^N.D.E-IV-34]: N.D.E.: The statement of the lemma and its proof have been detailed.

[^N.D.E-IV-35]: N.D.E.: Recall (cf. N.D.E. (17)) that one says that a morphism  $g : G \rightarrowtail H$  is *\*dominated\** by a family of morphisms  $F_i \rightarrowtail H$  if this family factors through  $g$ .

[^N.D.E-IV-36]: N.D.E.: In order to be in accord with later references, the numbering of the original, which contained two nos. 4.4.7, has been corrected.

[^N.D.E-IV-37]: N.D.E.: "contains" has been replaced by: "is dominated by", cf. N.D.E. (17).

[^N.D.E-IV-38]: N.D.E.: Lemmas 4.4.8.1 and 4.4.8.2 have been added.

[^N.D.E-IV-39]: N.D.E.: and one has  $(Y' \times_{X'} X)/R = Y'$ .

[^N.D.E-IV-40]: N.D.E.: and we shall also write  $h_S = \hat{S}$ , cf. the first commutative diagram of 4.5.4.

[^N.D.E-IV-41]: N.D.E.: i.e., such that for every object  $T \rightarrowtail S$  of  $C/S$ , every covering sieve  $R$  of  $i_S(T \rightarrowtail S) = T$ , considered as a sieve of  $(T \rightarrowtail S) \in \text{Ob } C/S$ , is covering.

[^N.D.E-IV-42]: N.D.E.: We have expanded the original in what follows.

[^N.D.E-IV-44]: N.D.E.: Recall that  $T$  denotes the given topology on  $C$ , coarser than the canonical topology.

[^N.D.E-IV-45]: N.D.E.: We have added this corollary.

[^N.D.E-IV-46]: N.D.E.: We have placed the axiom  $(f_M)$  here (which figured before Proposition 4.7.2).

[^N.D.E-IV-47]: N.D.E.: cf. § 6.4, see also VI\_A, 5.3.1.

[^N.D.E-IV-48]: N.D.E.: We have introduced the numbering 5.1.0, to refer to it later.

[^N.D.E-IV-49]: N.D.E.: One also says "pseudo-torsor", cf. EGA IV\_4, 16.5.15. On the other hand, the more general notion of formally homogeneous object (not necessarily principal homogeneous), is defined in the addendum 6.7.1 at the end of this Exposé.

[^N.D.E-IV-50]: N.D.E.: In this case, one also says that  $\mathcal{X}$  is an  $\mathcal{H}$ -torsor.

[^N.D.E-IV-51]: N.D.E.: We have added this particular case as a corollary, which will be used several times in the following Exposés.

[^N.D.E-IV-52]: N.D.E.: We have added "and free".

[^N.D.E-IV-53]: N.D.E.: of  $\mathcal{C}$ .

[^N.D.E-IV-54]: N.D.E.: In fact, the isomorphisms established in 5.2.8 to 5.2.10 would deserve to be called "Noether isomorphism theorems".

[^N.D.E-IV-55]: N.D.E.: This follows from the proposition applied to  $\mathcal{K} = \mathcal{H}$ .

[^N.D.E-IV-56]: N.D.E.: We have corrected the original here.

[^N.D.E-IV-57]: N.D.E.: Let  $\mathcal{P}'_{\{2\}}$  denote the set of finite surjective families, composed of flat morphisms of  $\mathcal{C}$  of finite presentation. According to Proposition 6.3.1 below, the topology  $\tau_{\{2\}}$  generated by  $\mathcal{P}$  and  $\mathcal{P}'_{\{2\}}$  coincides with the topology generated by  $\mathcal{P}$  and  $\mathcal{P}'_{\{2\}}$ . This follows from the results of EGA IV\_4, § 17.16 on quasi-sections; see the proof of 6.3.1. Let us cite here the following particular case of EGA IV\_4, 17.16.2: let  $\mathcal{S}$  be affine and  $f : X \rightarrow \mathcal{S}$  a surjective flat morphism locally of finite presentation; then there exists a morphism  $\mathcal{S}' \rightarrow \mathcal{S}$  faithfully flat, of finite presentation, quasi-finite, with  $\mathcal{S}'$  affine, and an  $\mathcal{S}'$ -morphism  $\mathcal{S}' \rightarrow X$ .

[^N.D.E-IV-58]: N.D.E.: By hypothesis, each family  $\{S_{\{pq\}} \rightarrow S\}_{p \in P'_{\{i\}}}$  is finite, hence  $\mathcal{S}'_{\{p\}} = \bigsqcup_{q \in P'_{\{i\}}} S_{\{pq\}}$  is affine and the family can therefore be replaced by the morphism  $\mathcal{S}'_{\{p\}} \rightarrow S_{\{p\}}$ , which still belongs to  $\mathcal{P}'_{\{i\}}$ .

[^N.D.E-IV-59]: N.D.E.: We have simplified what follows, taking advantage of the fact that  $\mathcal{S}$  is henceforth assumed affine.

[^N.D.E-IV-60]: N.D.E.: This shows that, if one denotes  $\mathcal{P}'_{\{2\}}$  the set of finite surjective families of morphisms of  $\mathcal{C}$  of finite presentation, the topology generated by  $\mathcal{P}$  and  $\mathcal{P}'_{\{2\}}$  equals  $\tau_{\{2\}}$ . On the other hand, with the notations at the start of the proof of (iv), if one takes a covering of  $\mathcal{S}_{\{i\}}$  by affine opens, of finite presentation over  $\mathcal{S}$ , one obtains that  $\mathcal{S}' \rightarrow \mathcal{S}$  belongs to  $\mathcal{P}'_{\{2\}}$ .

[^N.D.E-IV-61]: N.D.E.: We have corrected the original by adding the surjectivity hypothesis for  $(M_3)$  and  $(M_4)$ , which is automatically satisfied in the other cases.

[^N.D.E-IV-62]: N.D.E.: cf. EGA I, 6.6.4 for "quasi-compact", EGA II, 6.1.5 for "finite", EGA IV\_1, 1.6.2 for "locally of finite presentation", EGA IV\_2, 2.2.13 for "faithfully flat", and EGA IV\_4, 17.3.3 for "étale".

[^N.D.E-IV-65]: N.D.E.: We have added the numbers that follow.

[^N.D.E-IV-66]: N.D.E.: Evidently, this difficulty arises from the fact that if  $\mathcal{C}$  is a full subcategory of  $\hat{\mathcal{C}}$  containing  $\mathcal{C}$ , for example, the category  $\tilde{\mathcal{C}}_{\{T\}}$  of sheaves on  $\mathcal{C}$  for a topology  $T$  coarser than the canonical topology, and if  $f : X \rightarrow Y$  is a morphism in  $\mathcal{C}$ , then the implications:

$$\begin{array}{l} \text{''text} \\ f \text{ epimorphism of } \hat{\mathcal{C}} \Rightarrow f \text{ epimorphism of } \mathcal{C}' \Rightarrow f \text{ epimorphism of } \mathcal{C} \\ \text{''''} \end{array}$$

are in general strict.

[^N.D.E-IV-67]: N.D.E.: cf. [Ray70], Def. VI.1.1.

[^N.D.E-IV-68]: N.D.E.: We have added this reference.

[^N.D.E-IV-43]: N.D.E.:  $\mathcal{R} \times \mathcal{S}$  denotes the equivalence relation in  $\mathcal{X} \times \mathcal{S}$  defined by  $\mathcal{R} \times S_{\{\text{diagonal}\}} \subset X \times X \times S \times S$ , and  $\mathcal{R}_Z$  is the equivalence relation it induces in

$\mathcal{Z}$  (cf. 3.1.6).

[^N.D.E-IV-63]: N.D.E.: Recall that a subscheme  $\mathcal{Z}$  of a scheme  $T$  is said to be *retrocompact* if the immersion  $\mathcal{Z} \hookrightarrow T$  is quasi-compact, cf. EGA 0\_III, 9.1.1.

[^N.D.E-IV-64]: N.D.E.: Recall (cf. 4.4.2) that the chaotic topology is the coarsest topology, defined by  $\mathcal{J}(S) = \{S\}$  for every  $S \in \text{Ob } \mathcal{C}$ .

# Exposé V. Construction of quotient schemes

<!-- label: III.V -->

\*by P. Gabriel\*

<!-- original page 251 -->

The aim of this Exposé is to prove the theorems stated in TDTE III.[^N.D.E-V-1] If  $X$  and  $T$  are two objects of a category  $\mathcal{C}$ , we write  $X(T)$  instead of  $\text{Hom}_{\mathcal{C}}(T, X)$ . Similarly, if  $\phi : Y \rightarrow X$  is an arrow (resp. an object  $T$ ) of  $\mathcal{C}$ , then  $\phi(T)$  denotes the map  $g \mapsto \phi \circ g$  from  $Y(T)$  to  $X(T)$ :

```

```text
      T
     /\
    g  \phi \circ g
   /\   \
  Y - \phi -> X,
...

```

and $T(\phi)$ denotes the map $g \mapsto g \circ \phi$ from $T(X)$ to $T(Y)$:

```

```text
 Y - \phi -> X
 \ /\
 g \circ \phi \circ g
 \ /\
 T.
...

```

Finally, if  $\mathcal{P}$  is a scheme, we write  $\mathcal{P}$  for the underlying set of  $\mathcal{P}$ .

Exceptionally, in the present Exposé we do not follow the convention stated in IV 4.6.15 on the notation for quotients (loc. cit., top of page 227 of the original), since we wish to give here a construction of quotients which also applies to "pre-equivalence relations" [^N.D.E-V-2] that are not equivalence relations.

<!-- original page 252 -->

## 1.  $\mathcal{C}$ -groupoids

<!-- label: III.V.1 -->

**a)** Let  $\mathcal{C}$  be a category in which products and fiber products exist. Recall first that a diagram

```

```text
      d1      p
     X1 => X0 -> Y
      d0
...

```

in $\mathcal{C}$ is said to be *exact* if $d_0 = p \circ d_1$ and if, for every $T \in \mathcal{C}$, $T(p)$ is a bijection of $T(Y)$ onto the subset of $T(X_0)$ consisting of arrows $f : X_0 \rightarrow T$ such that $f \circ d_0 = f \circ d_1$. One also says that (Y, p) is the *cokernel* of (d_0, d_1) and writes

```
```text
(Y, p) = Coker(d0, d1).
```
```

****b)**** Let, for example, $\mathcal{C}$ be the category (Esp.An) of ringed spaces. In this case, there always exists a cokernel (Y, p) , which can be described as follows: the underlying topological space of Y is obtained from X_0 by identifying the points $d_0(x)$ and $d_1(x)$ and endowing Y with the quotient topology. The canonical map $\pi : X_0 \rightarrow Y$ together with d_0, d_1 then induces a double arrow of sheaves of rings on Y :

```
```text
 d0
 π-*(00) ⇒ π-*(d0* 01) = π-*(d1* 01),
 d1
```
```

where 0_i is the structure sheaf of X_i . We choose for the sheaf of rings on Y the subsheaf of $\pi_{-1}(0_0)$ whose sections s satisfy $\delta_0(s) = \delta_1(s)$. The arrow p is defined in the evident way.

Let $(X_1 \rightrightarrows X_0)$ be a diagram (with arrows d_0, d_1) in (Esp.An) and let (Y, p) be its cokernel. We say that an open set U of X_0 is *saturated* if $d_0^{-1}(U) = d_1^{-1}(U)$, which is equivalent to saying that $U = p^{-1}(p(U))$. In this case, since Y is endowed with the quotient topology, $p(U)$ is an open subset of Y .

Lemma 1.1. Let U be a saturated open set of X_0 and $V = p(U)$. If we denote by U_1 the open set $d_0^{-1}(U) = d_1^{-1}(U)$ of X_1 , and by $\tilde{d}_0, \tilde{d}_1$, and $\tilde{p}$ the restrictions of d_0, d_1 to U_1 , and of p to U , then $(V, \tilde{p})$ is a cokernel in (Esp.An) of $(\tilde{d}_0, \tilde{d}_1)$.

<!-- label: III.V.1.1 -->

```
```text
 d1 p~
 U1 ⇒ U → V.
 d0
```
```

The verification is straightforward.

Lemma 1.2. Let $(X_1 \rightrightarrows X_0)$ be a diagram in (Sch) (with arrows d_0, d_1) and let (Y, p) be its cokernel in (Esp.An) .

<!-- label: III.V.1.2 -->

(i) If Y is a scheme and p a morphism of schemes, then (Y, p) is a cokernel of (d_0, d_1) in (Sch) .

(ii) Suppose that every point of X_0 possesses a saturated open neighborhood U such that, denoting by $\tilde{d}_0$ and $\tilde{d}_1$ the restrictions of d_0 and d_1 to $d_0^{-1}(U) = d_1^{-1}(U)$, and by (Q, q) the cokernel of $(\tilde{d}_0, \tilde{d}_1)$ in (Esp.An) , the space Q is a scheme and q a morphism of schemes. Then (Y, p) is a cokernel of (d_0, d_1) in (Sch) .

(i) is proved in § 4.c); since the proof is short, let us repeat it here. Let $f : X_0 \rightarrow Z$ be a morphism of schemes such that $f \circ d_0 = f \circ d_1$. By hypothesis, there is a unique morphism of ringed spaces $r : Y \rightarrow Z$ such that $f = r \circ p$. It remains to show that, for every $y \in Y$, the homomorphism $0_{\{r(y)\}} \rightarrow 0_{\{y\}}$ induced by r is local. This follows from the fact that p is surjective, so that y is of the form $p(x)$, and from the fact that the homomorphism $0_{\{f(x)\}} \rightarrow 0_{\{x\}}$ induced by f is local.

(ii) follows from (i) and the preceding lemma.

<!-- original page 253 -->

****c)**** In this Exposé we study the existence of $\text{Coker}(d_0, d_1)$ when the double arrow (d_0, d_1) is inserted in a richer context; more precisely, let $X_2 = X_1 \times_{(d_1, d_0)} X_1$ denote the fiber product of the diagram

```

$X_1
      X_1
```

$$\begin{array}{ccc} & \downarrow d_{\{1\}} & \\ (\ast) & X_{\{0\}} & \\ & \uparrow d_{\{0\}} & \\ & X_{\{1\}}, & \end{array}$$

and let $d'_{\{0\}}$ and $d'_{\{2\}}$ be the two canonical projections of $X_{\{2\}}$ onto $X_{\{1\}}$; one then has by definition a Cartesian square

$$\begin{array}{ccc} & d'_{\{0\}} & \\ X_2 & \longrightarrow & X_1 \\ d'_{\{2\}} \downarrow & & \downarrow d_{\{1\}} \\ X_1 & \longrightarrow & X_0 \\ & d_{\{0\}} & \end{array}$$

$(\emptyset)$

Moreover, let us give ourselves a third arrow $d'_{\{1\}} : X_{\{2\}} \rightarrow X_{\{1\}}$; we say that $(d_{\{0\}}, d_{\{1\}} : X_1 \rightrightarrows X_0, d'_{\{1\}})$ is a C^* -groupoid if for every object T of C , $X_{\{1\}}(T)$ is the set of arrows of a groupoid $X \backslash \ast(T)$ whose set of objects is $X_{\{0\}}(T)$, with source map $d_{\{1\}}(T)$, target map $d_{\{0\}}(T)$, and composition map $d'_{\{1\}}(T)$ (one identifies, as usual, $(X_{\{1\}} \times_{d_{\{1\}}, d_{\{0\}}} X_{\{1\}})(T)$ with $X_{\{1\}}(T) \times_{d_{\{1\}}(T), d_{\{0\}}(T)} X_{\{1\}}(T)$; we also recall that a groupoid is a category in which every arrow is invertible).[^{N.D.E-V-5}]

If ϕ is an arrow of the groupoid $X \backslash \ast(T)$, the map $f \mapsto \phi \circ f$ is a bijection from the set of arrows f whose target coincides with the source of ϕ onto the set of arrows having the same target as ϕ . One sees easily that this fact can be translated by saying that the square

$$\begin{array}{ccc} & d'_{\{1\}} & \\ X_2 & \longrightarrow & X_1 \\ d'_{\{0\}} \downarrow & & \downarrow d_{\{0\}} \\ X_1 & \longrightarrow & X_0 \\ & d_{\{0\}} & \end{array}$$

(1)

is Cartesian.

Similarly, the map $g \mapsto g \circ \phi$ is a bijection from the set of arrows g of $X \backslash \ast(T)$ having source equal to the target of ϕ onto the set of arrows having the same source as ϕ . This fact can again be translated by saying that the square

$$\begin{array}{ccc} & d'_{\{1\}} & \\ X_2 & \longrightarrow & X_1 \\ d'_{\{2\}} \downarrow & & \downarrow d_{\{1\}} \\ X_1 & \longrightarrow & X_0 \\ & d_{\{1\}} & \end{array}$$

(2)

is Cartesian.

<!-- original page 254 -->

On the other hand, let $s : X_{\{0\}} \rightarrow X_{\{1\}}$ be the unique arrow of C such that, for every T , $s(T) : X_{\{0\}}(T) \rightarrow X_{\{1\}}(T)$ associates to every object of $X \backslash \ast(T)$ the identity arrow of that object.[^{N.D.E-V-6}]
The arrow s satisfies the equalities

```

```text
(3) d1 s = idX0,
(3 bis) d0 s = idX0.
```

```

Finally, the associativity of the composition maps $d'_1(T)$ translates into the commutativity of the diagram

```

```text
 d'1 × X1
X1 ×_{d1, d0} X1 ×_{d1, d0} X1 → X1 ×_{d1, d0} X1
 | |
 ↓ ↓ d'1
X1 ×_{d1, d0} X1 →_{d'1} X1.
(4)
```

```

Conversely, the conditions (1), (2), and (4) together with the existence of an arrow s satisfying (3) imply that $(X_1 \rightrightarrows X_0, d'_1)$ is a $\mathcal{C}$ -groupoid. The condition (3) is harmless; it merely ensures that the map $d_{\{1\}}(T) : X_{\{1\}}(T) \rightarrow X_{\{0\}}(T)$ is surjective for every $T \in \mathcal{C}$. In what follows we shall mostly make use of the Cartesian squares (0), (1) and (2), which we summarize in the diagram

```

```text
 d'1 d0
X2 → X1 → X0
 | |
d'2 ↓ ↓ d1
 X1 → X0
 d0
(0,1,2)
```

```

In this diagram the two left-hand squares (i.e. the squares (0) and (2)) are Cartesian; the first row is exact, and $X_{\{2\}}$ is identified with the fiber product $X_{\{1\}} \times_{d_{\{0\}}} X_{\{1\}}$.

We use associativity only indirectly, for instance to ensure the existence of an arrow s satisfying (3) and (3 bis), or else to ensure the existence of an arrow

```

```text
(†) σ : X1 → X1 such that d0 σ = d1 and d1 σ = d0
```

```

(one chooses σ so that $\sigma(T) : X_{\{1\}}(T) \rightarrow X_{\{1\}}(T)$ sends every arrow of $X_{\text{ast}}(T)$ to its inverse).^[N.D.E-V-7]

By abuse of language, we shall sometimes call a $\mathcal{C}$ -groupoid a diagram

```

```text
 d'0, d'1, d'2 d0, d1
X2 ≅ X1 ≅ X0
```

```

such that (0), (1) and (2) are Cartesian, (4) is commutative, and there exists s satisfying (3). The object $X_{\{2\}}$ will therefore be allowed to be "a" fiber product of $(*)$ without being "the" fiber product of $(*)$.^[N.D.E-V-8]

****Terminology.**** Instead of $\mathcal{C}$ -groupoid X_{ast} , we shall also speak of the *groupoid* X_{ast} with base $X_{\{0\}}^*$, or of the *pre-equivalence relation* X_{ast} in $X_{\{0\}}^*$.

<!-- original page 255 -->

2. Examples of $\mathcal{C}$ -groupoids

<!-- label: III.V.2 -->

****a)**** Let X be an object of $\mathcal{C}$ and G a $\mathcal{C}$ -group acting on the left on X . We denote by $d_0 : G \times X \rightarrow X$ the arrow defining the action of G on X , by $d_1 : G \times X \rightarrow X$ the projection of the product onto the second factor, by $\mu : G \times G \rightarrow G$ the arrow defining the $\mathcal{C}$ -group structure of G , and finally by $\text{pr}_{2,3}$ the projection of $G \times G \times X = G \times (G \times X)$ onto the second factor. Then

```

```text
 G × G × X pr_{2,3} d_1
 ↘ ↗ ↘ ↗
 μ × X d_0
 ↘ ↗
 G × d_0
...

```

<!-- original page 256 -->

is a  $\mathcal{C}$ -groupoid.

**\*\*b)\*\*** Let  $d_0, d_1 : X_1 \rightarrow X_0$  be an \*equivalence pair\*, i.e., if  $d_0 \boxtimes d_1 : X_1 \rightarrow X_0 \times X_0$  is the arrow with components  $d_0$  and  $d_1$ , we suppose that  $(d_0 \boxtimes d_1)(T)$  is, for every object  $T$  of  $\mathcal{C}$ , a bijection of  $X_1(T)$  onto the graph of an equivalence relation on  $X_0(T)$ . The set  $X_1(T)$  therefore identifies with the set of pairs  $(x, y)$  of elements of  $X_0(T)$  such that  $x \sim y$ ; similarly, the set  $X_2(T) = (X_1 \times_{d_1} d_0) \times_{X_1}(T)$  identifies with the set of triples  $(x, y, z)$  of elements of  $X_0(T)$  such that  $x \sim y$  and  $y \sim z$ . There is therefore one and only one arrow  $d'_1 : X_2 \rightarrow X_1$  making the squares (1) and (2) commute:  $d'_1(T)$  must send  $(x, y, z) \in X_2(T)$  to  $(x, z) \in X_1(T)$ . For this choice of  $d'_1$ ,  $(d_0, d_1 : X_1 \rightarrow X_0, d'_1)$  is a  $\mathcal{C}$ -groupoid.

Conversely, consider a  $\mathcal{C}$ -groupoid  $X$  such that  $d_0 \boxtimes d_1 : X_1 \rightarrow X_0 \times X_0$  is a monomorphism. Then  $(d_0, d_1)$  is an equivalence pair and  $X$  can be reconstructed from  $(d_0, d_1)$  as explained a few lines above. [N.D.E-V-9]

**\*\*c)\*\*** If  $p : X \rightarrow Y$  is any arrow of  $\mathcal{C}$  and if  $\text{pr}_1$  and  $\text{pr}_2$  are the two projections of  $X \times_{\{p, p\}} X$  onto  $X$ , then  $(\text{pr}_1, \text{pr}_2) : X \times_{\{p, p\}} X \rightarrow X$  is an equivalence pair. One says that  $p$  is an \*effective epimorphism\* if the diagram

```

```text
      pr_1      p
      ↘      ↗
      X ×_{p, p} X  ⇒ X  → Y
      pr_2
...

```

is exact, that is, if $(Y, p) = \text{Coker}(\text{pr}_1, \text{pr}_2)$.

Let, for example, S be a Noetherian scheme and let $\mathcal{C}$ be the category of schemes finite over S . Let us show that an epimorphism in $\mathcal{C}$ is not necessarily effective: take S equal to $\text{Spec } k[T^3, T^5]$, where k is a commutative field, Y equal to S , and X equal to $\text{Spec } k[T]$. If i is the inclusion of $B = k[T^3, T^5]$ into $A = k[T]$, take p equal to $\text{Spec } i$. In this case $X \times_{\{p, p\}} X$ identifies with $\text{Spec } (A \otimes_B A)$ and $\text{Coker}(\text{pr}_1, \text{pr}_2)$ with $\text{Spec } B'$, where B' is the subring of A consisting of a such that $a \otimes_B 1 = 1 \otimes_B a$. Now

<!-- original page 257 -->

```

```text
T^7 ⊗_B 1 = (T^2 T^5) ⊗_B 1 = T^2 ⊗_B T^5 = T^2 ⊗_B (T^3 T^2) = T^5 ⊗_B T^2 = 1 ⊗_B T^7.
...

```

So  $T^7$  belongs to  $B'$ , does not belong to  $B$ , and  $\text{Spec } B'$  is distinct from  $\text{Spec } B$ , which yields the counterexample. [N.D.E-V-10]

### ## 3. Some sorites on $\mathcal{C}$ -groupoids

<!-- label: III.V.3 -->

Here, in no particular order, are some remarks used in what follows:

**\*\*a)\*\*** Let

```

```text
      d'₀, d'₁, d'₂      d₀, d₁
X₂ ⇌ X₁ ⇌ X₀
...

```

be a $\mathcal{C}$ -groupoid and $f_{\{0\}} : Y_{\{0\}} \rightarrow X_{\{0\}}$ an arrow of $\mathcal{C}$. We shall define a $\mathcal{C}$ -groupoid with base $Y_{\{0\}}$

```

```text
 e'₀, e'₁, e'₂ e₀, e₁
Y₂ ⇌ Y₁ ⇌ Y₀
...

```

which we shall call *induced by  $X$  and  $f_{\{0\}}$* . One also says that  $Y$  is the *inverse image of  $X$*  under the base change  $f_{\{0\}}$ .

We choose for  $Y_{\{1\}}$  the fiber product of the diagram

```

```text
      f₁
Y₁  →  X₁
  ↓      ↓ d₀ ∘ d₁
Y₀ × Y₀ → X₀ × X₀,
      f₀ × f₀
...

```

and for $e_{\{0\}}$ and $e_{\{1\}}$ the arrows obtained by composing the canonical arrow $Y_{\{1\}} \rightarrow Y_{\{0\}} \times Y_{\{0\}}$ with the first and second projections of $Y_{\{0\}} \times Y_{\{0\}}$. The morphism $Y_{\{1\}} \rightarrow Y_{\{0\}} \times Y_{\{0\}}$ is then $e_{\{0\}} \boxtimes e_{\{1\}}$, and one has $f_{\{0\}} \circ e_{\{i\}} = d_{\{i\}} \circ f_{\{1\}}$ for $i = 0, 1$, where we have written $f_{\{1\}}$ for the projection of $Y_{\{1\}}$ onto $X_{\{1\}}$.

<!-- original page 258 -->

We set $Y_{\{2\}} = Y_{\{1\}} \times_{\{e_{\{0\}}, e_{\{1\}}\}} Y_{\{1\}}$, cf. 1.c). One can say that the pair $(e_{\{0\}}, e_{\{1\}})$ is defined in such a way that, for every $T \in \mathcal{C}$ and every pair (y, x) of elements of $Y_{\{0\}}(T)$, there is a certain one-to-one correspondence $\psi \mapsto \{y\} \psi_x$ between the arrows ψ of $X(T)$ with source $f_{\{0\}}(x)$ and target $f_{\{0\}}(y)$ and the arrows $\{y\} \psi_x$ of $Y(T)$ with source x and target y . One therefore determines $e_{\{1\}} : Y_{\{2\}} \rightarrow Y_{\{1\}}$ by defining, for every $T \in \mathcal{C}$, the composition of arrows of $Y(T)$ by the formula

```

```text
... _Z ψ_Y ∘ _Y φ_X = _Z (ψ ∘ φ)_X.
...

```

It is clear that this definition makes each  $Y(T)$  into a groupoid.

**\*\*b)\*\*** Knowing the  $\mathcal{C}$ -groupoid  $X$  and the base change  $f_{\{0\}} : Y_{\{0\}} \rightarrow X_{\{0\}}$ , one can reconstruct the pair  $(e_0, e_1) : Y_1 \rightrightarrows Y_0$  in another way: [N.D.E-V-11] construct  $Y_{\{0\}} \times_{X_{\{0\}}} X_{\{1\}}$ ,  $\text{spr}_{\{1\}}$  and  $\text{spr}_{\{2\}}$  so that the square

```

```text
      pr₂
Y₀ ×_{X₀} X₁  →  X₁
  ↓ pr₁      ↓ d₀
Y₀  →  X₀
      f₀
...

```

is Cartesian. One then verifies without difficulty, by reduction to the set-theoretic case, that one has the Cartesian square

```

```text
...

```

$$\begin{array}{ccc}
 Y_1 & \xrightarrow{e_0 \boxtimes f_1} & Y_0 \times_{\{X_0\}} X_1 \\
 e_1 \downarrow & & \downarrow d_1 \circ \text{pr}_2 \\
 Y_0 & \xrightarrow{f_0} & X_0,
 \end{array}$$

...

where  $f_1$  denotes the canonical projection of  $Y_1 = (Y_0 \times Y_0) \times_{(X_0 \times X_0)} X_1$  onto  $X_1$ .

<!-- original page 259 -->

**c)** We shall give two examples of inverse images of a  $\mathcal{C}$ -groupoid. Take  $Y_0$  equal to  $X_1$ ,  $f_0$  equal to  $d_0$ . For every object  $T$  of  $\mathcal{C}$ ,  $Y_1(T)$  then identifies with the set of diagrams of the form

$$\begin{array}{ccc}
 & \varphi & \\
 b & \longrightarrow & d \\
 \uparrow & & \uparrow \\
 f & & g \\
 \downarrow & & \downarrow \\
 a & & c
 \end{array}$$

...

of  $X \ast(T)$ . The source of such a diagram is the arrow  $f$ , the target is the arrow  $g$ . These diagrams compose in the evident way.

Now put  $Y'_0 = X_1$ ,  $f'_0 = d_1$  (we add the primes [N.D.E-V-12] to avoid any confusion with the preceding example). In this case,  $Y'_1(T)$  identifies, for every  $T \in \mathcal{C}$ , with the set of diagrams of the form

$$\begin{array}{ccc}
 b & & d \\
 \uparrow & & \uparrow \\
 f & & g \\
 \downarrow & \psi & \downarrow \\
 a & \longrightarrow & c
 \end{array}$$

...

of the groupoid  $X \ast(T)$ . The source of such a diagram is  $f$ , the target is  $g$ ; the composition of these diagrams is evident.

This being so, it is clear that the identity map of  $Y_0(T)$  and the map

$$\begin{array}{ccc}
 b & \xrightarrow{\varphi} & d \\
 \uparrow & & \uparrow \\
 f & & g \\
 \downarrow & & \downarrow \\
 a & & c
 \end{array}
 \mapsto
 \begin{array}{ccc}
 b & & d \\
 \uparrow & & \uparrow \\
 f & & g \\
 \downarrow & g^{-1}\varphi f & \downarrow \\
 a & \longrightarrow & c
 \end{array}$$

...

from  $Y_1(T)$  to  $Y'_1(T)$  define an isomorphism of the groupoid  $X \ast(T)$  onto  $Y' \ast(T)$ . Moreover, this isomorphism depends functorially on  $T$ , so that the  $\mathcal{C}$ -groupoids  $Y \ast$  and  $Y' \ast$  are isomorphic. [N.D.E-V-13]

<!-- original page 260 -->

**d)**

**Proposition 3.1.** We keep the notations of a) and assume that  $f_0$  is an effective and universal epimorphism. Then  $\text{Coker}(d_0, d_1)$  exists if and only if  $\text{Coker}(e_0, e_1)$  exists. [N.D.E-V-14] Moreover, in that case,  $f_0$  induces an isomorphism

<!-- label: III.V.3.1 -->

```
```text
Coker(d0, d1) ≅ Coker(e0, e1).
```
```

Let us first recall that an epimorphism  $f_{\{0\}} : Y_{\{0\}} \rightarrow X_{\{0\}}$  is said to be *universal* if, for every Cartesian square

```
```text
Y'  →  Y0
f' ↓    ↓ f0
X'  →  X0,
```
```

$f'$  is an epimorphism. This being so, let us denote by  $C(d_{\{0\}}, d_{\{1\}})$  the covariant functor from  $C$  to sets which associates to every  $T \in C$  the kernel of the pair  $(T(d_0), T(d_1)) : T(X_0) \rightrightarrows T(X_1)$ . We define  $C(e_{\{0\}}, e_{\{1\}})$  similarly. For every  $T \in C$ , one therefore has a commutative diagram

```
```text
C(d0, d1)(T) → T(X0) ≅ T(X1)
      |           | T(d0)           |
T(f) ↓           ↓ T(f0)           ↓ T(f1)
C(e0, e1)(T) → T(Y0) ≅ T(Y1),
      |           | T(e0)           |
```
```

where  $T(f)$  is the injection induced by the injection  $T(f_{\{0\}})$ . If we show that  $T(f)$  is a surjection for every  $T$ , we shall have a functorial isomorphism  $f : C(d_{\{0\}}, d_{\{1\}}) \xrightarrow{\sim} C(e_{\{0\}}, e_{\{1\}})$ , so that the representability of one of these functors will be equivalent to that of the other; this will prove our proposition.

To prove the surjectivity of  $T(f)$ , consider the diagram

```
```text
      Y1 → X1
      ↑   |
Δ ↗ e0 | e1   d0 | d1
      ↓   |
Y0 ×X0 Y0 → Y0 → X0,
      pr1   pr2   f0
```
```

<!-- original page 261 -->

where  $\Delta$  is the section of  $Y_{\{1\}} \rightarrow Y_{\{0\}} \times Y_{\{0\}}$  defined by the morphism  $\Delta \circ f_{\{0\}} \circ pr_{\{1\}} : Y_{\{0\}} \times Y_{\{0\}} \rightarrow X_{\{1\}}$ , with  $\Delta : X_{\{0\}} \rightarrow X_{\{1\}}$  the arrow satisfying equalities (3) and (3 bis) of section 1.

If the arrow  $g : Y_{\{0\}} \rightarrow T$  is such that  $g \circ e_{\{0\}} = g \circ e_{\{1\}}$ , then  $g \circ e_{\{0\}} \circ \Delta = g \circ e_{\{1\}} \circ \Delta$ , so  $g \circ pr_{\{1\}} = g \circ pr_{\{2\}}$ . Since  $f_{\{0\}}$  is an effective epimorphism,  $g$  factors through  $f_{\{0\}}$  and an arrow  $h : X_{\{0\}} \rightarrow T$ , that is to say  $g = T(f_{\{0\}})(h)$ . It remains to show that  $h$  belongs to  $C(d_{\{0\}}, d_{\{1\}})(T)$ , i.e. satisfies  $h \circ d_{\{0\}} = h \circ d_{\{1\}}$ ; now one has

```
```text
h d0 f1 = h f0 e0 = g e0 = g e1 = h f0 e1 = h d1 f1,
```
```

whence the desired equality, since  $f_{\{1\}}$  is an epimorphism (because  $f_{\{0\}}$  is a universal epimorphism).

**\*\*e)\*\*** Consider now a scheme  $S$  and choose  $C$  equal to  $(\text{Sch}/S)$ . The data of a  $C$ -groupoid

```
```text
      d'₀, d'₁, d'₂      d₀, d₁
X₂ ⇌ X₁ ⇌ X₀
```
```

allows one to define an equivalence relation on the set  $X_{\{0\}}$  underlying the scheme  $X_{\{0\}}$ : if  $x, y \in X_{\{0\}}$ , one writes  $x \sim y$  when there exists  $z \in X_{\{1\}}$  such that  $x = d_{\{1\}} z$  and  $y = d_{\{0\}} z$ . The reflexivity and symmetry of this relation are evident; [N.D.E-V-15] let us prove transitivity: if  $x \sim y$  and  $y \sim z$ , there exist  $u, v \in X_{\{1\}}$  with  $x = d_{\{1\}} u$ ,  $y = d_{\{0\}} u$ ,  $y = d_{\{1\}} v$ ,  $z = d_{\{0\}} v$ . It follows that  $(v, u)$  belongs to the set-theoretic fiber product  $X_{\{1\}} \times_{d_{\{1\}}, d_{\{0\}}} X_{\{1\}}$ . Since the canonical map

<!-- original page 262 -->

```
```text
X₁ ×_{d₁, d₀} X₁ → X₁ ×_{d₁, d₀} X₁
```
```

from the set underlying the fiber product into the fiber product of the underlying sets is surjective,  $(v, u)$  is the image of some  $w \in X_{\{2\}}$ . One then has  $x = d_{\{1\}} d'_{\{1\}} w$  and  $z = d_{\{0\}} d'_{\{1\}} w$ , whence  $x \sim z$ .

**\*\*f)\*\*** We keep the notations of a) and b),  $C$  still being  $(\text{Sch}/S)$ . If  $x, y$  are points of  $Y_{\{0\}}$ , we shall see that one has  $x \sim y$  if and only if  $f_{\{0\}}(x) \sim f_{\{0\}}(y)$  (the inverse image of the equivalence relation defined by a groupoid is the equivalence relation defined by the inverse image of the groupoid).

Indeed, suppose  $x \sim y$ . There exists therefore  $z \in Y_{\{1\}}$  such that  $x = e_{\{1\}}(z)$  and  $y = e_{\{0\}}(z)$ . Since  $f_{\{0\}} \circ e_{\{i\}} = d_{\{i\}} \circ f_{\{1\}}$  for  $i = 0, 1$ , one then has  $f_{\{0\}}(x) = d_{\{1\}} f_{\{1\}}(z)$  and  $f_{\{0\}}(y) = d_{\{0\}} f_{\{1\}}(z)$ , whence  $f_{\{0\}}(x) \sim f_{\{0\}}(y)$ .

Conversely, suppose  $f_{\{0\}}(x) \sim f_{\{0\}}(y)$  and let  $z \in X_{\{1\}}$  be such that  $f_{\{0\}}(y) = d_{\{1\}}(z)$  and  $f_{\{0\}}(x) = d_{\{0\}}(z)$ . Using the construction and notations of b), there is then a point  $t$  of  $Y_{\{0\}} \times_{X_{\{0\}}} X_{\{1\}}$  such that  $\text{pr}_{\{1\}}(t) = x$  and  $\text{pr}_{\{2\}}(t) = z$ . Similarly, since  $f_{\{0\}}(y) = d_{\{1\}} \text{pr}_{\{2\}}(t)$ , there is  $s \in Y_{\{1\}}$  such that  $y = e_{\{1\}}(s)$  and  $(e_{\{0\}} \boxtimes f_{\{1\}})(s) = t$ . One then has  $e_{\{0\}}(s) = \text{pr}_{\{1\}}(e_{\{0\}} \boxtimes f_{\{1\}})(s) = \text{pr}_{\{1\}}(t) = x$ . Whence  $x \sim y$ .

<!-- original page 261 -->

**## 4. Passage to the quotient by a finite and flat groupoid (proof of a particular case)**

<!-- label: III.V.4 -->

**\*Theorem 4.1.\*** \*Consider a  $(\text{Sch}/S)$ -groupoid\*

<!-- label: III.V.4.1 -->

```
```text
      d'₀, d'₁, d'₂      d₀, d₁
X₂ ⇌ X₁ ⇌ X₀.
```
```

\*Suppose the following conditions are satisfied:\*[N.D.E-V-16]

<!-- original page 263 -->

\*a)  $d_{\{1\}}$  is finite locally free;\*

\*b) for every  $x \in X_{\{0\}}$ , the set  $d_{\{0\}} d^{-1}_{\{1\}}(x)$  is contained in an affine open of  $X_{\{0\}}$ .\*[N.D.E-V-17]

\*Then:\*

(i) There exists a cokernel  $(Y, p)$  of  $(d_{\{0\}}, d_{\{1\}})$  in  $(\text{Sch}/S)$ ; moreover, such a  $(Y, p)$  is a cokernel of  $(d_{\{0\}}, d_{\{1\}})$  in the category of all ringed spaces.\*

\*(ii)  $\mathcal{P}$  is integral and open, and  $\mathcal{Y}$  is affine if  $X_0$  is affine.\*<sup>[N.D.E-V-18]</sup>

\*(iii) The morphism  $X_1 \rightarrow X_0 \times_{\mathcal{Y}} X_0$  with components  $d_0$  and  $d_1$  is surjective.\*

\*(iv) If  $(d_0, d_1)$  is an equivalence pair, then  $X_1 \rightarrow X_0 \times_{\mathcal{Y}} X_0$  is an isomorphism\*<sup>[N.D.E-V-19]</sup> and  $\mathcal{P} : X_0 \rightarrow \mathcal{Y}$  is finite locally free.\*<sup>[N.D.E-V-20]</sup> Moreover,  $(Y, \mathcal{P})$  is a cokernel of  $(d_0, d_1)$  in the category of sheaves for the (fppf) topology and, for every base change  $\mathcal{Y}' \rightarrow \mathcal{Y}$ ,  $\mathcal{Y}'$  is the cokernel of the groupoid  $X \times_{\mathcal{Y}} \mathcal{Y}'$  obtained from  $X$  by the base change  $X_0 \times_{\mathcal{Y}} \mathcal{Y}' \rightarrow X_0$ .\*

In particular, for every base change  $\mathcal{S}' \rightarrow \mathcal{S}$ ,  $\mathcal{Y}' = \mathcal{Y} \times_{\mathcal{S}} \mathcal{S}'$  is the cokernel of the  $\mathcal{S}'$ -groupoid  $X' \times_{\mathcal{S}} X \times_{\mathcal{S}} \mathcal{S}'$ . So, in this case, "the formation of the quotient commutes with base change".\*

It evidently follows from (i) that the topological space underlying  $\mathcal{Y}$  is the quotient of the topological space underlying  $X_0$  by the equivalence relation defined by the  $(\text{Sch}/\mathcal{S})$ -groupoid  $X \times_{\mathcal{S}} X$ .

We shall first prove this theorem when  $X_0$  is affine and  $d_1$  is locally free of constant rank  $n$ . We shall see next how to reduce to this particular case.

<!-- original page 262 -->

In the case in which we have placed ourselves,  $X_0$ ,  $X_1$  and  $X_2$  are affine. We can therefore suppose that

```

```text
X_i = Spec A_i,    d_j = Spec δ_j,    d'_k = Spec δ'_k,
```

```

the  $A_i$  being commutative rings and the  $\delta_j$ ,  $\delta'_k$  ring homomorphisms. One can then replace the diagram (0, 1, 2) by the following

```

```text
              δ'_1
      A_2 = A_1 = A_0
              δ'_0      δ_0
(0,1,2)*  δ'_2      δ_1
              δ_1
      A_1 = A_0,
              δ_0
```

```

where the two left-hand squares are cocartesian.

Let  $\mathcal{B}$  denote the subring of  $A_0$  consisting of those  $a \in A_0$  such that  $\delta_0(a) = \delta_1(a)$ .

<!-- original page 264 -->

\*\*a)\*\* Let us show that  $A_0$  is integral over  $\mathcal{B}$ . If  $a$  belongs to  $A_0$ , let

```

```text
P_{δ_1}(T, δ_0(a)) = T^n - σ_1 T^{n-1} + ... + (-1)^n σ_n
```

```

be the characteristic polynomial of  $\delta_0(a)$  when  $A_1$  is regarded as an algebra over  $A_0$  via the homomorphism  $\delta_1$  (cf. Bourbaki, Alg. VIII, § 12 and Alg. comm. II, § 5, exercise 9). Since the left-hand squares of  $(0,1,2)$  are cocartesian, one has

```

```text
δ_0(P_{δ_1}(T, δ_0(a))) = P_{δ'_2}(T, δ'_0 δ_0(a))
```

```

and

```

```text
δ_1(P_{δ_1}(T, δ_0(a))) = P_{δ'_2}(T, δ'_1 δ_0(a)).
```

```

...

Since  $\delta_0' \delta_0 = \delta_1' \delta_0$ , one has

$$\delta_0(P_{\delta_1}(T, \delta_0(a))) = \delta_1(P_{\delta_1}(T, \delta_0(a))),$$

that is,  $\delta_0(\sigma_i) = \delta_1(\sigma_i)$  for every  $i$ . Hamilton–Cayley moreover tells us that

$$\delta_0(a)^n - \delta_1(\sigma_1) \delta_0(a)^{n-1} + \dots + (-1)^n \delta_1(\sigma_n) = 0.$$

Since  $\delta_1(\sigma_i) = \delta_0(\sigma_i)$ , one also has

$$\delta_0(a)^n - \delta_0(\sigma_1) \delta_0(a)^{n-1} + \dots + (-1)^n \delta_0(\sigma_n) = 0,$$

whence

$$a^n - \sigma_1 a^{n-1} + \dots + (-1)^n \sigma_n = 0,$$

<!-- original page 265 -->

since there exists a homomorphism  $\tau : A_1 \rightarrow A_0$  such that  $\tau \delta_0 = \text{id}_{A_0}$ , hence  $\delta_0$  is injective. It follows that  $A_0$  is integral over  $B$ .

**\*\*b)\*\*** Consider now two prime ideals  $\mathfrak{x}$  and  $\mathfrak{y}$  of  $A_0$ . We shall show that the equality  $\mathfrak{x} \cap B = \mathfrak{y} \cap B$  entails the existence of a prime ideal  $\mathfrak{z}$  of  $A_1$  such that  $\mathfrak{x} = \mathfrak{d}(z)$  and  $\mathfrak{y} = \mathfrak{d}_1(z)$ .

Indeed, if the assertion were not true,  $\mathfrak{x}$  would be distinct from  $\delta^{-1}_0(t)$  for every prime ideal  $\mathfrak{t}$  of  $A_1$  such that  $\delta^{-1}_0(t) = \mathfrak{y}$ . For such a  $\mathfrak{t}$  one would have  $\delta^{-1}_0(t) \cap B = \delta^{-1}_1(t) \cap B = \mathfrak{y} \cap B = \mathfrak{x} \cap B$ , whence by Cohen–Seidenberg (cf. Bourbaki, Alg. comm. V, § 2, cor. 1 of prop. 1)  $\mathfrak{x}$  would be contained in no  $\delta^{-1}_0(t)$ . [N.D.E-V-21] Now there are at most  $n$  prime ideals  $\mathfrak{t}$  of  $A_1$  such that  $\delta^{-1}_1(t) = \mathfrak{y}$  (cf. loc. cit., prop. 3), so, by the "Prime Avoidance Lemma" (loc. cit., II, § 1, prop. 3), there would exist  $\mathfrak{a} \in \mathfrak{x}$  belonging to no  $\delta^{-1}_0(t)$ . Consequently,  $\delta_0(a)$  would belong to none of these ideals  $\mathfrak{t}$ , and so, by the lemma below, the norm  $N_{\delta_1}(\delta_0(a))$  would not belong to  $\mathfrak{y}$  (one computes this norm by regarding  $A_1$  as an algebra over  $A_0$  via the homomorphism  $\delta_1$ ; one has  $N_{\delta_1}(\delta_0(a)) = \sigma_n$  with the notations of a)). But, since  $(-1)^{n-1} \sigma_n = a^n + \sum_{i=1}^{n-1} (-1)^i \sigma_i a^{n-i}$ , this norm belongs to  $B \cap \mathfrak{x} = B \cap \mathfrak{y}$ , whence the contradiction.

**\*\*Lemma 4.1.1.\*\*** \*Let  $A \rightarrow A'$  be a morphism of commutative rings making  $A'$  into a projective  $A$ -module of rank  $n$ . Let  $\mathfrak{p} \in \text{Spec}(A)$ ,  $q_1, \dots, q_r$  the elements of  $\text{Spec}(A')$  above  $\mathfrak{p}$ , and  $\mathfrak{a} \in A'$ . Then  $\mathfrak{a}$  belongs to  $\mathfrak{q}_1 \cup \dots \cup \mathfrak{q}_r$  if and only if its norm  $N(a)$  belongs to  $\mathfrak{p}$ .\*

<!-- label: III.V.4.1.1 -->

Indeed, replacing  $A$  and  $A'$  by the localizations  $A_{\mathfrak{p}}$  and  $A'_{\mathfrak{p}}$ , we reduce to the case where  $(A, \mathfrak{p})$  is local and  $A'$  is semilocal, with  $\text{Spec}(A') = \{q_1, \dots, q_r\}$ . In this case,  $A'$  is a free  $A$ -module of rank  $n$  (cf. Bourbaki, Alg. comm. II, § 3.2, cor. 2 of prop. 5), and  $N(a)$  is the determinant of the endomorphism  $\ell_a : a' \mapsto a a'$  of  $A'$ , so one has the equivalences

$$N(a) \notin \mathfrak{p} \iff N(a) \text{ invertible} \iff a \text{ invertible} \iff a \notin \mathfrak{q}_1 \cup \dots \cup \mathfrak{q}_r.$$

**\*\*c)\*\*** Proof of (i):

Set  $Y = \text{Spec } B$  and  $\mathfrak{p} = \text{Spec } i$ , where  $i$  is the inclusion of  $B$  into  $A_0$ . By a), the morphism  $\mathfrak{p} : X_0 \rightarrow Y$  is surjective. Let us first show that  $(Y, \mathfrak{p})$  is a cokernel of  $(d_0, d_1)$  in the

category of all ringed spaces: it follows indeed from b) that the set underlying  $\operatorname{Spec} B$  is obtained from the set underlying  $X_0$  by identifying the points  $x$  and  $y$  such that there exists  $z \in X_1$  with  $d_1 z = y$ ,  $d_0 z = x$ . Moreover, since  $S$  is integral,  $p = \operatorname{operatorname{Spec}} i$  is closed, so  $Y$  is endowed with the quotient topology of that of  $X_0$ . It follows that  $p$  is open. Indeed, let  $U$  be any open of  $X_0$ ; since  $d_1$  is surjective and finite locally free, hence faithfully flat and of finite presentation, and therefore open, the saturation  $U = d_1(d_0^{-1}(U))$  of  $U$  for the equivalence relation defined by  $X \ast$  is open. Then  $p(U) = p(U)$  is open, since  $Y$  is endowed with the quotient topology.

It follows finally from the choice of  $B$  and from the fact that  $p$ ,  $d_0$  and  $d_1$  are affine that the canonical sequence of sheaves of rings

`<!-- original page 266 -->`

```

``text
 0_Y \longrightarrow p_*(0_{X_0}) \rightrightarrows p_*(d_{0*}(0_{X_1})) = p_*(d_{1*}(0_{X_1}))
 \qquad \qquad \qquad p_*(\delta_0)
...

```

is exact.

It remains to show that  $(Y, p)$  is also the cokernel of  $(d_0, d_1)$  in the category of schemes (more generally, in the category of ringed spaces in local rings). Let then  $q : X_0 \rightarrow Z$  be a morphism of schemes such that  $d_0 = q d_1$ . By what precedes, there is a unique morphism of ringed spaces  $r : Y \rightarrow Z$  such that  $q = r p$ . It remains to show that, for every  $y \in Y$ , the homomorphism  $\mathcal{O}_{r(y)} \rightarrow \mathcal{O}_y$  induced by  $r$  is local. This follows from the fact that  $p$  is surjective, so that  $y$  is of the form  $p(x)$ , and from the fact that the homomorphism  $\mathcal{O}_{q(x)} \rightarrow \mathcal{O}_x$  induced by  $q$  is local.

**d)** Proof of (ii): Follows from a) and c).

**e)** Proof of (iii):

Recall that one denotes by  $P$  the set underlying a scheme  $P$ , and by  $d : P \rightarrow Q$  the map induced by a morphism  $d : P \rightarrow Q$ .

**Lemma 4.1.2.** [N.D.E-V-22] \*Let  $(A, m)$  be a local ring,  $k$  its residue field, and  $K$  an extension of the field  $k$ . Then there exists a local and flat  $A$ -algebra  $B$  such that  $B/mB$  is  $k$ -isomorphic to  $K$ ; moreover, one can choose  $B$  finite and free over  $A$  if  $K$  is of finite degree over  $k$ .\*

`<!-- label: III.V.4.1.2 -->`

This is proved in EGA 0\_III, 10.3.1, where it is moreover shown that one can choose  $B$  Noetherian if  $A$  is. For the reader's convenience, let us indicate the proof.

Put  $A' = A[T]$ , where  $T$  is an indeterminate. If  $K = k(T)$ , let  $p = m A'$  and  $B = A'_p$ . Then  $B/mB \cong k[T]_{(0)} = k(T)$ , and  $B$  is flat over  $A'$ , which is a free  $A$ -module, so  $B$  is flat over  $A$ .

If  $K = k(t) = k[t]$ , where  $t$  is algebraic over  $k$ , set  $B = A'/(F)$ , where  $F \in A'$  is a monic polynomial whose image in  $k[t]$  is the minimal polynomial  $f$  of  $t$  over  $k$ . Then  $B$  is a free  $A$ -module of finite rank  $\deg(F) = \deg(f)$ . In particular,  $B$  is integral over  $A$ , hence every maximal ideal of  $B$  contains  $m$ . Since  $B/mB \cong k[t]/(f) \cong K$ , it follows that  $B$  is local, with maximal ideal  $mB$ . This already shows that if  $[K : k] < \infty$ , one can choose  $B$  finite and free over  $A$ .

In the general case, let  $(t_i)_{i \in I}$  be a system of generators of  $K$  over  $k$ , and endow  $I$  with a well-ordering (i.e., a total order  $\leq$  such that every non-empty subset of  $I$  has a least element). For every  $i \in I$ , let  $k_{\leq i}$  (resp.  $k_{< i}$ ) denote the subfield of  $K$  generated by the  $t_j$  for  $j \leq i$  (resp.  $j < i$ ). Adding one element if necessary, we may suppose that  $I$  has a greatest element  $\xi$ , so that  $K = k_{\xi}$ . Consider the subset  $J$  of  $I$  consisting of indices  $i$  such that there exists an inductive system  $(A_j)_{j \leq i}$  of local and flat  $A$ -algebras such that  $A_j/m A_j \cong k_{\leq j}$  and  $A_j$  is flat over  $A_{\leq \ell}$  for every  $\ell < j$ . Suppose  $I - J$  non-empty; let  $i$  be its least element and let  $A' = \varinjlim_{j < i} A_j$ . Since tensor product commutes with direct limits,  $A'$  is flat over  $A$  and over each  $A_j$  for  $j < i$ , and one has  $A'/m A' \cong A' \otimes_A A_{\leq i} / (m A_{\leq i}) \cong k_{\leq i}$ . Moreover,  $A'$  is local, with maximal ideal  $m A'$ . Indeed, if  $x = f_{\leq j}(x_{\leq j})$  is non-invertible, then  $x_{\leq j}$  is not invertible, hence belongs to the maximal ideal  $m A_{\leq j}$  of  $A_{\leq j}$ , whence  $x \in m A'$ . It then follows from the monogenic case treated above that there exists a local and flat  $A$ -algebra  $A_i$  such that  $A_i/m A_i \cong k_{\leq i}(t_i) = k_{\leq i}$ ; then  $A_i$  is flat over

each  $A_{\{j\}}$  for  $j < i$ , and so  $i \in J$ , contrary to hypothesis. This contradiction shows that  $J = I$ , and so  $A_{\{i\}}$  answers the question. Lemma 4.1.2 is proved.

<!-- original page 265 -->

Let us now prove 4.1 (iii). Recall that one denotes by  $P$  the set underlying a scheme  $P$ , and by  $d : P \rightarrow Q$  the map induced by a morphism  $d : P \rightarrow Q$ . One can then translate b) by saying that the map

```
```text
    d_0 \otimes d_1 : X_0 \rightarrow X_0 \times_Y X_0
```
```

with components  $d_0$  and  $d_1$  is surjective; now this map factors as follows

```
```text
    X_0 \xrightarrow{d_0 \otimes d_1} X_0 \times X_0 \xrightarrow{q} X_0 \times_Y X_0,
    (set-theoretic Y-product)
```
```

$q$  being the canonical map; the image of  $d_0 \boxtimes d_1$  therefore contains all points  $v$  of  $X_0 \times_Y X_0$  such that  $\{v\} = q^{-1}(q(v))$ . This last condition [N.D.E-V-23] will be realized in particular if  $v$  is rational over  $Y$ , that is to say, if the residue field  $\kappa(v)$  of  $v$  identifies with the residue field  $\kappa(w)$  of the image  $w$  of  $v$  in  $Y$ .

<!-- original page 267 -->

If  $v \in X_0 \times_Y X_0$  is not rational over  $Y$ , let  $w$  again be the image of  $v$  in  $Y$ . By lemma 4.1.2, there exists a local ring  $C$  of radical  $\mathfrak{m}$  and a local and flat homomorphism  $f : O_w \rightarrow C$  such that  $C/\mathfrak{m}$  is isomorphic to  $\kappa(v)$  as a  $\kappa(w)$ -algebra. If one sets  $Y' = \operatorname{Spec} C$  and if  $\pi : Y' \rightarrow Y$  is the morphism induced by  $f$ , it is clear that the canonical projection of  $(X_0 \times_Y X_0) \times_{Y'} Y'$  to  $X_0 \times_Y X_0$  sends to  $v$  a point  $v'$  of  $(X_0 \times_Y X_0) \times_{Y'} Y'$  which is rational over  $Y'$ . Since

```
```text
    (X_0 \times_Y X_0) \times_{Y'} Y' \cong (X_0 \times_{Y'} Y') \times_{Y'} (X_0 \times_Y Y'),
```
```

and since the hypotheses of theorem 4.1 and the previous results, in particular point b), remain valid after the base change  $\pi : Y' \rightarrow Y$ , then  $v'$  is the image of an element  $u' \in X_0 \times_Y Y'$  by the morphism deduced from  $d_0 \boxtimes d_1$  by base change. If  $u$  is the image of  $u'$  in  $X_0 \times_Y Y$ , one indeed has  $v = (d_0 \boxtimes d_1)(u)$ .

**\*\*f)\*\* Proof of (iv): [N.D.E-V-24]**

**\*Lemma 4.1.3.\*** *If a monomorphism of schemes  $f : T \rightarrow Z$  is a finite morphism, it is a closed immersion.\**

<!-- label: III.V.4.1.3 -->

Indeed, covering  $Z$  by affine opens  $Z_i$  and replacing  $f$  by the induced morphisms  $f^{-1}(Z_i) \rightarrow Z_i$ , we reduce ( $f$  being finite, hence affine) to the case where  $Z = \operatorname{Spec} B$  and  $T = \operatorname{Spec} A$ . Since  $f$  is a monomorphism, the diagonal morphism  $T \rightarrow T \times_Z T$  is an isomorphism (EGA I, 5.3.8), i.e.,  $A \otimes_B A \rightarrow A$  is an isomorphism. Consequently, for every maximal ideal  $\mathfrak{m}$  of  $B$ , one has an isomorphism

```
```text
    (A/\mathfrak{m}A) \otimes_k (A/\mathfrak{m}A) \cong (A/\mathfrak{m}A),
```
```

<!-- original page 266 -->

where we have set  $k = B/\mathfrak{m}$ . Since  $A$  is finite over  $B$ ,  $A/\mathfrak{m}A$  is a  $k$ -vector space of finite dimension  $d$ , and the above isomorphism entails  $d = 0$  or  $1$ , so that the morphism  $k \rightarrow A/\mathfrak{m}A$  is surjective. Hence, by Nakayama's lemma ( $A$  being finite over  $B$ ), the morphism  $B_{\mathfrak{m}} \rightarrow A_{\mathfrak{m}}$  is surjective. It follows that the morphism of  $B$ -modules  $B \rightarrow A$  is surjective (since its cokernel  $C$  satisfies  $C_{\mathfrak{m}} = 0$  for every  $\mathfrak{m}$ , so is zero). This proves the lemma.

Let us now prove (iv). By hypothesis,  $X_{\{0\}} = \operatorname{Spec} A_{\{0\}}$ ,  $X_{\{1\}} = \operatorname{Spec} A_{\{1\}}$ , and, for  $i = 0, 1$ , the morphism  $\delta_{\{i\}} : A_{\{0\}} \rightarrow A_{\{1\}}$  makes  $A_{\{1\}}$  a finitely generated  $A_{\{0\}}$ -module; thus, a fortiori, the morphism  $A_{\{0\}} \otimes_B A_{\{0\}} \rightarrow A_{\{1\}}$  is finite.

One assumes in addition that  $d = d_{\{0\}} \boxtimes d_{\{1\}} : X_{\{1\}} \rightarrow X_{\{0\}} \times_Y X_{\{0\}}$  is a monomorphism; hence, by the preceding lemma, the morphism  $A_{\{0\}} \otimes_B A_{\{0\}} \rightarrow A_{\{1\}}$  is surjective.

We shall show that it is an isomorphism (we shall prove along the way that  $p : X_{\{0\}} \rightarrow Y$  is finite and locally free). It suffices to show that, for every prime ideal  $\mathfrak{p}$  of  $B$ , the homomorphism  $(A_{\{0\}})_{\mathfrak{p}} \otimes_{(B)_{\mathfrak{p}}} (A_{\{0\}})_{\mathfrak{p}} \rightarrow (A_{\{1\}})_{\mathfrak{p}}$  with components  $\delta_{\{0\}\mathfrak{p}}$  and  $\delta_{\{1\}\mathfrak{p}}$  is bijective. In other words, one may suppose  $B$  local. It then follows from b) that  $(A_{\{0\}})_{\mathfrak{p}}$  is semilocal; indeed, if  $\mathfrak{m}$  is a maximal ideal of  $(A_{\{0\}})_{\mathfrak{p}}$ , the other maximal ideals are of the form  $\delta_{\{0\}\mathfrak{p}}^{-1}(\mathfrak{m})$ , where  $\mathfrak{m}$  runs over the prime ideals of  $A_{\{1\}}$  such that  $\delta_{\{0\}\mathfrak{p}}^{-1}(\mathfrak{m}) = \mathfrak{m}$ ; the assertion follows from the fact that there are at most  $n = [A_{\{1\}} : A_{\{0\}}]$  such prime ideals  $\mathfrak{m}$ . Possibly performing a faithfully flat base change, [N.D.E-V-25] one can also suppose that the residue field of  $B$  is infinite, so that one can use the following lemma:

**Lemma 4.2.** \*Let  $B$  be a local ring with infinite residue field,  $A$  a semilocal ring, and  $i : B \rightarrow A$  a homomorphism sending the maximal ideal  $\mathfrak{m}$  of  $B$  into the radical  $\mathfrak{r}$  of  $A$ . Let  $M$  be a free  $A$ -module of rank  $n$  and  $N$  a  $B$ -submodule of  $M$  that generates  $M$  as an  $A$ -module. Then  $N$  contains a basis of  $M$  over  $A$ .\*

<!-- label: III.V.4.2 -->

<!-- original page 268 -->

Recall indeed that a sequence  $m_1, \dots, m_n$  of elements of  $M$  is an  $A$ -basis of  $M$  if and only if the canonical images of  $m_1, \dots, m_n$  in  $M/rM$  form a basis of  $M/rM$  over  $A/r$ . One can therefore replace  $M$  by  $M/rM$ ,  $N$  by  $N/(N \cap rM)$ ,  $A$  by  $A/r$  and  $B$  by  $B/r$ . In this case the lemma is easy (if  $A$  is a product of fields  $K_1 \times \dots \times K_r$ , one can identify  $M$  with the module  $K_1^n \times \dots \times K_r^n$ ; if  $x_j$  is then an element of  $N$  whose  $j$ -th component in  $K_1^n \times \dots \times K_r^n$  is non-zero, show that a certain linear combination  $x$  of the  $x_j$  with coefficients in  $B$  has all components non-zero; then replace  $M$  by  $M/Ax$  and proceed by induction on  $n$ ).

We apply the preceding lemma in the following situation:  $B = B$ ,  $A = A_{\{0\}}$ ,  $i$  is the inclusion of  $B$  in  $A_{\{0\}}$ ,  $M = A_{\{1\}}$  regarded as an  $A_{\{0\}}$ -module via the homomorphism  $\delta_{\{1\}}$ ,  $N = \delta_{\{0\}}(A_{\{0\}})$ . Indeed, since  $d_{\{0\}} \boxtimes d_{\{1\}} : X_{\{1\}} \rightarrow X_{\{0\}} \times_Y X_{\{0\}}$  is a closed immersion, the homomorphism  $A_{\{0\}} \otimes_B A_{\{0\}} \rightarrow A_{\{1\}}$  with components  $\delta_{\{0\}}$  and  $\delta_{\{1\}}$  is surjective; this means precisely that  $\delta_{\{0\}}(A_{\{0\}})$  generates the  $A_{\{0\}}$ -module  $A_{\{1\}}$ .

Let then  $a_1, \dots, a_n$  be elements of  $A_{\{0\}}$  such that  $\delta_{\{0\}}(a_1), \dots, \delta_{\{0\}}(a_n)$  form a basis of  $A_{\{1\}}$  over  $A_{\{0\}}$ . If we show that  $a_1, \dots, a_n$  is a basis of  $A_{\{0\}}$  over  $B$ , it will follow that the homomorphism  $A_{\{0\}} \otimes_B A_{\{0\}} \rightarrow A_{\{1\}}$  sends the basis  $(1 \otimes a_i)_{1 \leq i \leq n}$  to the basis  $(\delta_{\{0\}}(a_i))_{1 \leq i \leq n}$ , hence is bijective. Consequently, if  $\epsilon : \mathbb{Z}^n \rightarrow A_{\{0\}}$  is the morphism of abelian groups sending the natural basis of  $\mathbb{Z}^n$  to  $a_1, \dots, a_n$ , it suffices to prove that the map  $B \otimes_{\mathbb{Z}} \mathbb{Z}^n \rightarrow A_{\{0\}}$  with components  $i$  and  $\epsilon$  is bijective.

<!-- original page 269 -->

Now the diagram  $(0, 1, 2)_{\text{ast}}$  considered at the beginning of this proof induces the following commutative diagram:

$$\begin{array}{ccc} & \delta'_{\{1\}} & \delta_0 \\ A_2 \simeq A_1 & \simeq A_0 & \\ & \delta'_{\{0\}} & \\ u_2 \downarrow & u_1 \downarrow \cong & u_0 \downarrow \\ & \delta_1 \otimes \mathbb{Z}^n & i \otimes \mathbb{Z}^n \\ A_1 \otimes_{\mathbb{Z}} \mathbb{Z}^n \simeq A_0 \otimes_{\mathbb{Z}} \mathbb{Z}^n \simeq B \otimes_{\mathbb{Z}} \mathbb{Z}^n, & & \\ & \delta_0 \otimes \mathbb{Z}^n & \end{array}$$

where  $u_{\{0\}}$ ,  $u_{\{1\}}$  and  $u_{\{2\}}$  have respectively as components  $i$  and  $\epsilon$ ,  $\delta_{\{1\}}$  and  $\delta_{\{0\}} \epsilon$ ,  $\delta'_{\{2\}}$  and  $\delta'_{\{0\}} \delta_{\{0\}} \epsilon$ . We know that  $u_{\{1\}}$  is an isomorphism. Since the two left-hand squares of  $(0, 1, 2)_{\text{ast}}$  are cocartesian,  $u_{\{2\}}$  is bijective. But the two horizontal rows of

our diagram are exact, so  $u_0$  is bijective. [N.D.E-V-26] This shows that  $A_0$  is a  $B$ -module locally free of rank  $n$ , and, by the previous reductions, this entails that  $\delta_0 \otimes \delta_1 : A_0 \otimes B \rightarrow A_1$  is an isomorphism. This completes the proof of theorem 4.1 in the particular case considered ( $X_0$  affine and  $d_1$  locally free of constant rank  $n$ ).

## 5. Passage to the quotient by a finite and flat groupoid (general case)

<!-- label: III.V.5 -->

**\*\*a\*\*** Let  $U^{(n)}$  be the largest open subset of  $X_0$  above which  $d_1$  is finite locally free of rank  $n$ . One knows that  $X_0$  is the direct sum of the  $U^{(n)}$ . It follows on the other hand from the two Cartesian squares

```

```text
      d'_0
      X_2  →  X_1
      |      |
d'_2 ↓      ↓ d_1
      X_1  →  X_0
      d_0

and

      d'_1
      X_2  →  X_1
      |      |
d'_2 ↓      ↓ d_1
      X_1  →  X_0
      d_1
```

```

that the inverse images of  $U^{(n)}$  under  $d_0$  and  $d_1$  both coincide with the largest open subset of  $X_1$  above which  $d'_2$  is locally free of rank  $n$ ; [N.D.E-V-27] one therefore has  $d^{-1}_1(U^{(n)}) = d^{-1}_1(U^{(n)})$ , so that the groupoid  $X_{\text{ast}}$  is the direct sum of the groupoids  $X_{\text{ast}}^{(n)}$  induced by  $X_{\text{ast}}$  on the open-and-closed subsets  $U^{(n)}$ . Consequently, as one sees easily, it suffices to prove theorem 4.1 for each of the  $X_{\text{ast}}^{(n)}$ : one is reduced to the case where  $d_1$  is finite locally free of rank  $n$ .

**\*\*b\*\*** We are now in a position to prove our theorem in the general case.

<!-- original page 270 -->

By a) one may suppose  $d_1$  locally free of rank  $n$ . Let then  $(Y, p)$  be a cokernel of  $(d_0, d_1)$  in the category of all ringed spaces. The argument at the end of paragraph 4.c) shows that to prove 4.1 (i) it suffices to prove that  $Y$  is a scheme and  $p : X_0 \rightarrow Y$  a morphism of schemes. By lemma 1.2, the question is local on  $Y$ : let  $y \in Y$  and let  $x \in X_0$  with  $p(x) = y$ ; if  $x$  possesses a saturated affine open neighborhood  $U$ , then  $p(U)$  will be an affine open of  $Y$  by § 4, and  $p|_U$  will be a morphism of schemes. It therefore suffices to prove that every  $x \in X_0$  possesses a saturated affine open neighborhood  $U$ . Here is how one proceeds (the proof is taken from SGA 1, VIII, cor. 7.6).

```

```text
      d_1(d_0^{-1}(x)) ⊂ U = (V_f)' ⊂ V_f ⊂ V' ⊂ V ⊂ X_0

      ↑           ↑           ↑

               of V
               ↑           ↑
               largest      largest
               saturated     saturated
               open in V_f  open in V
```

```

By condition b) of 4.1, there exists an affine open  $V$  of  $X_0$  containing  $d_1(d^{-1}_0(x))$ ; [N.D.E-V-28] if  $F = X_0 - V$ , then  $d_1(d^{-1}_0(F))$  is closed since  $d_1$  is integral, and  $V' = X_0 - d_1(d^{-1}_0(F))$  is the largest saturated open contained in  $V$ . Since  $V'$  is a neighborhood of the finite set  $d_1(d^{-1}_0(x))$ , there exists a section  $f$  of the structure sheaf of  $V$  vanishing on  $V - V'$  and such that  $d_1(d^{-1}_0(x))$  is contained in the open  $V_f$  of  $V$  consisting of points where  $f$  does not vanish. We shall show that the largest saturated open  $(V_f)'$  of  $V_f$  is affine, and therefore answers the question.

Indeed, let  $Z(f) = V' - V_f$ . Then  $d^{-1}_0(Z(f))$  is the set of points of  $d^{-1}_0(V') = d^{-1}_1(V')$  where the image  $d_{\text{ast}}(f)$  of  $f$  under the map induced by  $d_0$  vanishes. On the other hand, since  $d_1$  induces a locally free morphism of rank  $n$  from  $d^{-1}_0(V') = d^{-1}_1(V')$  onto  $V'$ , [N.D.E-V-29] then, by lemma 4.1.1,  $d_1(d^{-1}_0(Z(f)))$  is the set of points where the norm  $N$  of  $d_{\text{ast}}(f)$  for the morphism  $d_1$

vanishes. It follows that  $(V_{\{f\}})' = V' - d_{\{1\}}(d^{-1}_{\{1\}}(Z(f)))$  is the set of points of  $V_{\{f\}}$  where  $N$  does not vanish; consequently,  $(V_{\{f\}})'$  is affine.

<!-- original page 271 -->

This proves 4.1 (i); assertions (ii), (iii), and the first part of (iv) are then clear. Let us finally show the consequences indicated at the end of point (iv) (cf. [Ray67a], th. 1 (iii)).

By hypothesis, the groupoid  $X_{\text{ast}}$  comes from an equivalence relation  $i : R \rightarrow X_{\{0\}} \times X_{\{0\}}$  ( $i$  being therefore an immersion, cf. N.D.E. 19), and one has established that  $R$  is effective (cf. Exp. IV, 3.3.2) and that  $p : X_{\{0\}} \rightarrow Y = X_{\{0\}}/R$  is a surjective and finite locally free morphism, hence in particular faithfully flat and of finite presentation.

Consequently, denoting by  $(M)$  the family of faithfully flat morphisms locally of finite presentation,  $R$  is  $(M)$ -effective. Therefore, by Exp. IV, 6.3.3,  $(Y, p)$  represents the quotient sheaf of  $X_{\{0\}}$  by  $R$  for the (fppf) topology, and the assertions concerning base change follow from IV, 3.4.3.1.

**Remark 5.1.** [N.D.E-V-30] We keep the hypotheses and notations of 4.1, and suppose in addition that  $S$  is locally Noetherian and  $\pi : X_{\{0\}} \rightarrow S$  is quasi-projective. Let us then show that  $\pi : Y \rightarrow S$  is quasi-projective.\*

<!-- label: III.V.5.1 -->

The above hypotheses imply that  $Y \rightarrow S$  is of finite type, see the proof of 6.1 (ii). Let  $A$  be an invertible  $\mathcal{O}_{X_{\{0\}}}$ -module that is ample for  $\pi$ . By EGA II, 6.1.12,  $p_{\text{ast}}(A)$  is an invertible  $p_{\text{ast}}(\mathcal{O}_{X_{\{0\}}})$ -module. There therefore exists a covering  $(V_i)_{i \in I}$  of  $Y$  by affine opens such that  $A$  is trivial above each of the saturated affine opens  $U_i = p^{-1}(V_i)$ .

For each index  $i$ , write  $A_{i,0} = \mathcal{O}_{X_{\{0\}}}(U_i)$ ,  $A_{i,1}$  the ring of the affine open  $d^{-1}_{\{1\}}(U_i) = d^{-1}_{\{1\}}(U_i)$  of  $X_{\{1\}}$ ,  $\delta_{i,0}$  (resp.  $\delta_{i,1}$ ) the morphism  $A_{i,0} \rightarrow A_{i,1}$  induced by  $d_{\{0\}}$  (resp.  $d_{\{1\}}$ ), and  $B_i = \mathcal{O}_Y(V_i) = \{b \in A_{i,0} \mid \delta_{i,0}(b) = \delta_{i,1}(b)\}$ .

Following EGA II, § 6.5, consider the invertible  $\mathcal{O}_{X_{\{0\}}}$ -module  $N_{\{d_{\{1\}}(d^{\text{ast}}_{\{0\}}(A))\}}$ , the norm relative to the finite locally free morphism  $d_{\{1\}} : X_{\{1\}} \rightarrow X_{\{0\}}$  of the invertible  $\mathcal{O}_{X_{\{1\}}}$ -module  $d^{\text{ast}}_{\{0\}}(A)$ . If  $A$  is given, relative to the covering  $(U_i)_{i \in I}$ , by transition functions  $c_{ij} \in \mathcal{O}_{X_{\{0\}}}(U_i \cap U_j)^{\times}$ , then  $N_{\{d_{\{1\}}(d^{\text{ast}}_{\{0\}}(A))\}}$  is given by the transition functions  $N_{\{d_{\{1\}}(\delta_{i,0}(c_{ij}))\}} \in \mathcal{O}_{X_{\{0\}}}(U_i \cap U_j)^{\times}$ ; since, by paragraph 4.a), these elements belong to  $\mathcal{O}_Y(V_i \cap V_j)^{\times}$ , they define an invertible  $\mathcal{O}_Y$ -module  $L$ , such that  $p^{\text{ast}}(L) = N_{\{d_{\{1\}}(d^{\text{ast}}_{\{0\}}(A))\}}$ . Moreover, note that for every  $n \in \mathbb{N}^{\text{ast}}$ , one has  $p^{\text{ast}}(L^{\wedge n}) = N_{\{d_{\{1\}}(d^{\text{ast}}_{\{0\}}(A^{\wedge n}))\}}$ , cf. loc. cit., (6.5.2.1).

Let us show that  $L$  is ample for the morphism  $\pi : Y \rightarrow S$ . For this, replacing  $S$  by an affine open, we may suppose  $S$  affine. Let then  $y \in Y$ ,  $x \in X_{\{0\}}$  with  $p(x) = y$ ,  $V$  an affine open of  $Y$  containing  $y$ , and  $U = p^{-1}(V)$ . Since  $A$  is  $\pi$ -ample, there exists  $n \in \mathbb{N}^{\text{ast}}$  and a section  $s \in \Gamma(X_{\{0\}}, A^{\wedge n})$  such that the open  $(X_{\{0\}})_s$  satisfies  $x \in (X_{\{0\}})_s \subset U$ . With the preceding notations,  $s$  is given by sections  $a_i \in A_{i,0} = \mathcal{O}_{X_{\{0\}}}(U_i)$  such that  $a_i = c_{ij} a_j$  on  $U_i \cap U_j$ , and  $(X_{\{0\}})_s$  is the union of the opens  $U'_i = \{p \in \text{Spec}(A_{i,0}) \mid a_i \notin p\}$ .

For each index  $i$ , put  $N(a_i) = N_{\{\delta_{i,1}(\delta_{i,0}(a_i))\}} \in B_i$ . By 4.1 (i) and lemma 4.1.1, one has:

```
``text
... p(U'_i) = p d_1(d_0^{-1}(U'_i)) = p d_1(\{q \in \text{Spec}(A_{i,1}) \mid \delta_{i,0}(a_i) \notin q\})
...
```

and  
 $\delta_{i,1}(\{q \in \text{Spec}(A_{i,1}) \mid \delta_{i,0}(a_i) \notin q\}) = \{p \in \text{Spec}(A_{i,0}) \mid N_{\{\delta_{i,1}(\delta_{i,0}(a_i))\}} \notin p\}$ ,  
whence

```
``text
... p(U'_i) = \{p \in \text{Spec}(B_i) \mid N(a_i) \notin p\}.
```

It follows that  $p((X_{\{0\}})_s)$  equals  $Y_{\{N(s)\}}$ , where we have written  $N(s)$  for the section of  $L^{\wedge n}$  over  $Y$

defined by the sections  $N(a_{\{i\}}) \in O_Y(V_{\{i\}})$ . One thus has

```
```text
(*)    $y \in p((X_0)_s) = Y_{\{N(s)\}} \subset p(U) = V.$ 
```
```

This shows that  $\mathcal{L}$  is ample for  $\pi : Y \rightarrow S$ , which finishes showing that  $\pi : Y \rightarrow S$  is quasi-projective.

<!-- original page 270 -->

## 6. Passage to the quotient when a quasi-section exists

<!-- label: III.V.6 -->

We shall now prove a lemma of technical character which will be useful in the proof of the two theorems we have in view. Let  $S$  be a scheme and

```
```text
       $d'_0, d'_1, d'_2 \quad d_0, d_1$ 
 $X_2 \rightrightarrows X_1 \rightrightarrows X_0$ 
```
```

a  $(Sch/S)$ -groupoid. We shall call a \*quasi-section\* of the groupoid  $X$  any subscheme  $U$  of  $X_{\{0\}}$  such that (1) and (2) hold:

(1) The restriction  $v$  of  $d_{\{1\}}$  to  $d_{\{1\}}^{-1}(U)$  is a finite, locally free, and surjective morphism from  $d_{\{1\}}^{-1}(U)$  onto  $X_{\{0\}}$ .

(2) Every subset  $E$  of  $U$  consisting of points pairwise equivalent for the equivalence relation defined by  $X$  ( $\S$  3.e)) is contained in an affine open of  $U$ . [N.D.E-V-31]

If  $U$  is a quasi-section of  $X$ , the  $(Sch/S)$ -groupoid

```
```text
       $u'_0, u'_1, u'_2 \quad u_0, u_1$ 
 $U_2 \rightrightarrows U_1 \rightrightarrows U$ 
```
```

<!-- original page 272 -->

induced by  $X$  and the inclusion of  $U$  into  $X_{\{0\}}$  (cf.  $\S$  3.a)) satisfies the hypotheses of theorem 4.1. Set indeed  $V = d_{\{1\}}^{-1}(U)$  and let  $u$  and  $v$  be the morphisms with source  $V$  induced respectively by  $d_{\{0\}}$  and  $d_{\{1\}}$ :

```
```text
 $X_0 \xleftarrow{v} V \xrightarrow{u} U.$ 
```
```

By paragraph 3.b), one has a Cartesian square

```
```text
       $U_1 \longrightarrow V$ 
 $u_1 \downarrow \quad \quad \downarrow v$ 
 $U \xrightarrow{\text{inclusion}} X_0,$ 
```
```

so  $u_{\{1\}}$  is surjective and finite locally free by (1). With (2), condition (1) therefore ensures that the groupoid  $U$  satisfies the hypotheses of theorem 4.1. In particular  $\text{Coker}(u_{\{0\}}, u_{\{1\}})$  exists in  $(Sch/S)$ . Moreover,  $d_{\{0\}}$  has a section, so that  $u$  is a universal effective epimorphism (cf. III 1.12); it follows, by proposition 3.1, that  $\text{Coker}(u_{\{0\}}, u_{\{1\}})$  coincides with the cokernel  $\text{Coker}(v_{\{0\}}, v_{\{1\}})$  of the groupoid  $V$ :

```
```text
```

$$V'_0, V'_1, V'_2 \quad V_0, V_1$$

$$V_2 \ni V_1 \ni V,$$

inverse image of U under the base change $u : V \rightarrow U$, that is also the inverse image of X under the base change:

$$V \xrightarrow{\text{inclusion}} X_1 \xrightarrow{d_0} X_0.$$

By paragraph 3.c), V is isomorphic to the groupoid V' , the inverse image of X under the base change:

$$v : V \xrightarrow{\text{inclusion}} X_1 \xrightarrow{d_1} X_0,$$

and so V' admits a cokernel in (Sch/S) . Now, being flat, surjective and finite, $v : V \rightarrow X_0$ is faithfully flat and quasi-compact, hence a universal effective epimorphism by III 6.3.2. Consequently, by proposition 3.1, the groupoid X admits a cokernel $\text{Coker}(d_0, d_1)$ in (Sch/S) . We have thus proved the first assertion of point (i) of the following lemma: [N.D.E-V-32]

<!-- original page 273 -->

Lemma 6.1. Suppose that the (Sch/S) -groupoid X possesses a quasi-section. Then:

<!-- label: III.V.6.1 -->

(i) There exists a cokernel (Y, p) of (d_0, d_1) in (Sch/S) ; moreover, such a (Y, p) is a cokernel of (d_0, d_1) in the category of all ringed spaces.

(i') p is surjective, and is open (resp. universally closed) if d_0 is.

(ii) Suppose S locally Noetherian and X_0 locally of finite type (resp. of finite type) over S . Then p and $Y \rightarrow S$ are locally of finite presentation (resp. of finite presentation).

(iii) The morphism $X_1 \rightarrow X_0 \times_{X_0} X_1$ with components d_0 and d_1 is surjective.

(iv) If (d_0, d_1) is an equivalence pair, then $X_1 \rightarrow X_0 \times_{X_0} X_1$ is an isomorphism. Moreover, if $d_0 : X_1 \rightarrow X_0$ is flat, p is faithfully flat.

Before proving the second assertion of (i), we shall demonstrate (i'), (ii) and (iii).

a) Proof of (i') and (ii):

We have just seen that (Y, p) identifies with $\text{Coker}(v_0, v_1)$ and $\text{Coker}(u_0, u_1)$. Let then q and r be the canonical epimorphisms from U and V into Y :

$$\begin{array}{ccccc} & & V & \xrightarrow{u} & U \\ & \swarrow v & & & \searrow u \\ X_0 & & & & \\ & \searrow r & & & \swarrow q \\ & & Y & & \end{array}$$

By hypothesis, v is surjective and finite locally free, hence open. On the other hand, if $d_0 : X_1 \rightarrow X_0$ is open (resp. universally closed), then u , which is obtained from it by base change, is also.

<!-- original page 274 -->

Since, by theorem 4.1, q is surjective, integral, and open, it follows that r is surjective, and open (resp. universally closed) if d_0 is. The same therefore holds for p , since v is surjective. This proves (i').

Suppose now S locally Noetherian and X_0 locally of finite type over S , so that X_0 is locally Noetherian.

Let us show that Y is locally of finite presentation over S . Let $S' = \operatorname{Spec} R$ be an affine open of S , $Y' = \operatorname{Spec} B$ an affine open of Y projecting into S' , and $U' = \operatorname{Spec} A$ the inverse image of Y' in U . Since R is Noetherian, it suffices to show that B is a finitely generated R -algebra; but, by paragraphs 4 and 5, B is contained in A , which is a finitely generated R -algebra; the assertion therefore follows from the fact that R is Noetherian and A is integral over B .

Finally, since $X_{\{0\}} \rightarrow S$ is locally of finite type, so is p (EGA I, 6.6.6), hence p is locally of finite presentation since Y is locally Noetherian.

It remains to show the last assertion of (ii). Suppose in addition $X_{\{0\}}$ of finite type over S . Then, since p is surjective, Y is also quasi-compact over S , hence of finite type over S . Since S is locally Noetherian, then $X_{\{0\}} \rightarrow S$ and $Y \rightarrow S$ are of finite presentation, and so $p : X_{\{0\}} \rightarrow Y$ is also (EGA IV_1, 1.6.2 (v)).

****b)** Proof of (iii):**

Since the groupoid $V \rightrightarrows V$ with base V is isomorphic both to the inverse image of $U \rightrightarrows U$ under the base change u and to the inverse image of $X \rightrightarrows X$ under the base change v , one has a double Cartesian square

$$\begin{array}{ccccc} X_1 & \xleftarrow{d_1} & V_1 & \xrightarrow{v_1} & U_1 \\ \downarrow d_0 & & \downarrow v_0 & & \downarrow u_0 \\ X_0 & \xleftarrow{v \times v} & V & \xrightarrow{u \times u} & U \end{array}$$

Since $u_0 \times u_1$ is surjective, so is $v_0 \times v_1$. Since $v \times v$ is surjective, so is the composite morphism $V_1 \rightarrow X_{\{0\}} \times_Y X_{\{0\}}$, and therefore so is $d_0 \times d_1$.

<!-- original page 275 -->

****c)** Proof of (i):**

It remains to prove that (Y, p) is a cokernel of (d_0, d_1) in the category of all ringed spaces. We first show that Y is obtained from $X_{\{0\}}$ by identifying the points x and y such that there exists $z \in X_{\{1\}}$ with $d_0(z) = x$ and $d_1(z) = y$. Indeed, p is surjective and one has $p \circ d_0 = p \circ d_1$; moreover, if $p(x) = p(y)$, there is a point z of $X_{\{0\}} \times_Y X_{\{0\}}$ whose first projection is x and second projection is y . If z is a point of $X_{\{1\}}$ such that $(d_0 \times d_1)(z) = z$, one indeed has $d_0(z) = x$ and $d_1(z) = y$.

On the other hand, if W is a saturated open of $X_{\{0\}}$, then $W \cap U$ is a saturated open of U ; by 4.1, $q(W \cap U)$ is an open of Y . Since $q(W \cap U)$ is none other than $p(W)$, one sees that Y is endowed with the quotient topology of that of $X_{\{0\}}$.

It remains to show that the canonical sequence of sheaves of rings

$$0_Y \rightarrow p_*(0_{X_0}) \rightrightarrows p_* d_{0*}(0_{X_1}) = p_* d_{1*}(0_{X_1})$$

is exact.

Let then Y' be an open of Y and put $U' = q^{-1}(Y')$, $X'_{\{0\}} = p^{-1}(Y')$, etc. [N.D.E-V-33] Then U' is an open of U saturated for the equivalence relation defined by the groupoid $U \rightrightarrows U$, and it follows from lemmas 1.1 and 1.2 that Y' is the cokernel, in (Sch/S) and in $(\operatorname{Esp}/\operatorname{An})$, of the groupoid induced by $U \rightrightarrows U$. Similarly, $X'_{\{0\}}$ is an open of $X_{\{0\}}$ saturated for the equivalence relation defined by $X \rightrightarrows X$, and one has the following commutative diagram, where the two squares are Cartesian:

$$\begin{array}{ccc} X'_0 & \xleftarrow{d_1^{-1}} & V' = d_0^{-1}(U') \xrightarrow{d_0^{-1}} U' \\ \downarrow & & \downarrow \end{array}$$

$$\begin{array}{ccc} \downarrow & & \downarrow \\ X_0 & \xleftarrow[d_1]{V = d_0^{-1}(U)} & U' \\ \downarrow & & \downarrow \\ & & d_0 \end{array}$$

Then $\tilde{d}_1$ is surjective, and finite locally free. On the other hand, let $x \in U'$. Since U is a quasi-section, the set $E := d_0^{-1}(x) \cap U$ is finite and contained in an affine open W of U . Then $E' = E \cap U'$ is a finite set, contained in the quasi-affine open $W \cap U'$. Consequently, there exists an affine open W' of $W \cap U'$ containing E' . This shows that U' is a quasi-section of the groupoid $X \backslash \text{ast}$ induced by $X \backslash \text{ast}$ on X_0 . The first assertion of (i), applied to $X \backslash \text{ast}$ and U' , then shows that Y' is the cokernel in (Sch/S) of $\tilde{X} \backslash \text{ast}$.

In particular, for every S -scheme T , one has the exact sequence

$$\begin{array}{ccc} & T(p|_{X'_0}) & T(d_1|_{X'_1}) \\ T(Y') & \longrightarrow T(X'_0) \rightrightarrows T(X'_1) & \\ & & T(d_0|_{X'_1}) \end{array}$$

<!-- original page 276 -->

Now, if T is the "affine line" $G_{a,S}$ (I 4.3), this sequence identifies with the sequence

$$\begin{array}{ccc} & \delta_1 & \\ \Gamma(Y', 0_Y) \rightarrow \Gamma(p^{-1}(Y'), 0_{X_0}) & \rightrightarrows \Gamma(d_0^{-1} p^{-1}(Y'), 0_{X_1}) = \Gamma(d_1^{-1} p^{-1}(Y'), 0_{X_1}) & \\ & \delta_0 & \end{array}$$

which is therefore exact for every open Y' . This completes the proof of 6.1 (i).

****d)**** Proof of (iv):

If (d_0, d_1) is an equivalence pair, the same holds for (u_0, u_1) . It follows that $u_0 \boxtimes u_1 : U_1 \rightarrow U \times_{U_0} U$ is an isomorphism (theorem 4.1), hence so is $v_0 \boxtimes v_1$ (confer the Cartesian squares of b)); since $v \times v$ is faithfully flat and quasi-compact, $d_0 \boxtimes d_1$ is an isomorphism (SGA 1, VIII 5.4).

Moreover, if d_0 is flat, so is u_0 . Now q is flat, by theorem 4.1, so r also is. Since v is faithfully flat, then p is flat, and therefore faithfully flat since surjective.

7. Quotient by a proper and flat groupoid

<!-- label: III.V.7 -->

****Theorem 7.1.****[^{N.D.E-V-34}] *Let S be a locally Noetherian scheme and**

<!-- label: III.V.7.1 -->

$$\begin{array}{ccc} & d'_0, d'_1, d'_2 & d_0, d_1 \\ X_2 \rightrightarrows X_1 \rightrightarrows X_0 & & \end{array}$$

*a (Sch/S) -groupoid such that d_1 is proper and flat, X_0 is quasi-projective over S , [^{N.D.E-V-35}] *and the morphism $d : X_1 \rightarrow X_0 \times_{X_0} X_1$ with components d_0 and d_1 is quasi-finite. Then:*

*(i) There exists a cokernel (Y, p) of (d_0, d_1) in (Sch/S) ; moreover, such a (Y, p) is a cokernel of (d_0, d_1) in the category of all ringed spaces.**

<!-- original page 277 -->

*(ii) p is surjective, open, proper, of finite presentation, and $Y \rightarrow S$ is of finite presentation and separated.**[^{N.D.E-V-36}]

(iii) The morphism $X_{\{1\}} \rightarrow X_{\{0\}} \times_{Y'} X_{\{0\}}$ with components $d_{\{0\}}$ and $d_{\{1\}}$ is surjective.

(iv) If $(d_{\{0\}}, d_{\{1\}})$ is an equivalence pair, then $X_{\{1\}} \rightarrow X_{\{0\}} \times_{Y'} X_{\{0\}}$ is an isomorphism and p is faithfully flat.[^{N.D.E-V-37}] Moreover, (Y, p) is a cokernel of $(d_{\{0\}}, d_{\{1\}})$ in the category of sheaves for the (fppf) topology and, for every base change $Y' \rightarrow Y$, Y' is the cokernel of the groupoid $X \rightrightarrows Y'$ obtained from $X \rightrightarrows Y$ by the base change $X_{\{0\}} \times_{Y'} Y' \rightarrow X_{\{0\}}$.*

In particular, for every base change $S' \rightarrow S$, $Y' = Y \times_S S'$ is the cokernel of the S' -groupoid $X' \rightrightarrows S'$. So, in this case, "the formation of the quotient commutes with base change".

Let (Y, p) be the cokernel of $(d_{\{0\}}, d_{\{1\}})$ in the category of all ringed spaces. Lemma 1.2 shows that, to prove (i), it suffices to show that every point z of $X_{\{0\}}$ possesses a saturated open neighborhood U_z such that, denoting by $\tilde{d}_{\{0\}}$ and $\tilde{d}_{\{1\}}$ the restrictions of $d_{\{0\}}$ and $d_{\{1\}}$ to $\tilde{d}_{\{1\}}^{-1}(U_z) = \tilde{d}_{\{0\}}^{-1}(U_z)$, and by (Q, q) the cokernel of $(\tilde{d}_{\{0\}}, \tilde{d}_{\{1\}})$ in (Esp, An) , Q is a scheme and q a morphism of schemes.

By lemma 6.1 (i), it therefore suffices to show that every point z of $X_{\{0\}}$ possesses a saturated open neighborhood U_z such that the groupoid induced on U_z by $X \rightrightarrows S$ possesses a quasi-section. One can even suppose that z is closed in its fiber over S (we shall say that z is "closed relative to S ").[^{N.D.E-V-38}] The existence of U_z then follows from the lemmas below:

<!-- original page 275 -->

Lemma 7.2. *Let T be an affine Noetherian scheme, X, Y , and Z T -schemes of finite type, with X quasi-projective over T , and*

```

```text
 Y --u--> X
 | |
 v |
 Z ->->-> T
```

```

a diagram in (Sch/T) . Let z be a point of $v(Y)$ that is closed relative to T and such that v is flat at the points of $v^{-1}(z)$. Then there exists a closed subscheme F of X such that $u(u^{-1}(F) \cap v^{-1}(z))$ is finite and non-empty, and such that the restriction of v to $u^{-1}(F)$ is flat at the points of $v^{-1}(z)$.

Let $T = \text{Spec } A$. One may suppose X of the form $\text{Proj } S$, where S is the symmetric algebra of a finitely generated A -module E .

If $u(v^{-1}(z))$ is finite, one can choose F equal to X . Otherwise, we denote by $y_1, \dots, y_n$

<!-- original page 278 -->

the points of the fiber $v^{-1}(z)$ associated with the structure sheaf $\mathcal{O}_{v^{-1}(z)}$ of $v^{-1}(z)$ (the y_i are such that, if $\mathcal{O}_i$ denotes the local ring of $v^{-1}(z)$ at y_i , the maximal ideal of $\mathcal{O}_i$ consists of zero divisors). If t is the image of z in T , $u(v^{-1}(z))$ is an infinite constructible subset of the fiber of t in X . There therefore exists a point x closed in this fiber, belonging to $u(v^{-1}(z))$ and distinct from $u(y_1), \dots, u(y_n)$. Then $X - \{x\}$ is an open neighborhood of $u(y_1), \dots, u(y_n)$, hence contains an open neighborhood of the form $D_+(f)$, where f is a homogeneous element of degree d of S (the notations are those of EGA II, § 2.3).

Consequently, the closed subscheme $X_{\{1\}} = V_+(f)$ defined by f contains x and avoids the points $u(y_1), \dots, u(y_n)$. It follows of course that the inverse image $Y_{\{1\}} = u^{-1}(V_+(f))$ of this subscheme is distinct from Y and meets $v^{-1}(z)$. We shall further show that the restriction $v_{\{1\}}$ of v to $Y_{\{1\}}$ is flat at the points of $v^{-1}(z)$; if $u(v_{\{1\}}^{-1}(z))$ is finite, we shall therefore only need to choose F equal to $X_{\{1\}}$; otherwise, we shall repeat the argument we have just developed, replacing Y by $Y_{\{1\}}$, v by $v_{\{1\}}$, u by the morphism $u_{\{1\}}$ induced on $Y_{\{1\}}$ by u ; in this way we shall obtain a decreasing sequence $X, X_{\{1\}}, \dots$ of closed subschemes of X ; since such a sequence terminates, $u(u^{-1}(X_{\{n\}}) \cap v^{-1}(z))$ will be finite and non-empty for some n , and one will choose F equal to $X_{\{n\}}$.

It remains then to show that $\mathcal{O}_{Y_1}$ is flat at the points of $\mathcal{O}_{Y_1}^{-1}(z)$; let y be a point of Y_1 above z , $\mathcal{O}_y$ the local ring of y in Y , $\bar{\mathcal{O}}_y$ the local ring of y in $\mathcal{O}_{Y_1}^{-1}(z)$, $\mathcal{O}_{v(y)}$ the local ring of $v(y)$ in Z . If $g \in S_1$ is such that $\mathcal{O}_{D_+}(g)$ is a neighborhood of $u(y)$ in X , let ϕ be the image of f/g^{d_1} in $\mathcal{O}_y$ and $\bar{\phi}$ the image of f/g^{d_1} in $\bar{\mathcal{O}}_y$. It then follows from the construction of ϕ that $\bar{\phi}$ is not a zero divisor in $\bar{\mathcal{O}}_y$; since

<!-- original page 276 -->

$\mathcal{O}_y$ is flat over $\mathcal{O}_z$, ϕ is not a zero divisor in $\mathcal{O}_y$ and $\mathcal{O}_y/\mathcal{O}_y \phi$ is flat over $\mathcal{O}_z$ (SGA 1, IV 5.7). But $\mathcal{O}_y/\mathcal{O}_y \phi$ is precisely the local ring of y in Y_1 .

<!-- original page 279 -->

Lemma 7.3. We keep the notations and hypotheses of 7.1. Every point z of X_0 closed relative to S therefore possesses a saturated open neighborhood U_z such that the groupoid induced by $X \times_S U_z$ on U_z possesses a quasi-section.*

<!-- label: III.V.7.3 -->

The statement being local on S , one may suppose S affine Noetherian and apply the previous lemma to the diagram

$$\begin{array}{ccc} & X_1 & \xrightarrow{d_0} X_0 \\ d_1 \downarrow & & \downarrow \\ & X_0 & \xrightarrow{\quad} S \end{array}$$

of $(S/\mathcal{O}_S)$. Let then F be a closed subscheme of X_0 such that $d_0(d_0^{-1}(F) \cap d_0^{-1}(z))$ is finite and non-empty, and such that the restriction of d_1 to $d_0^{-1}(F)$ is flat at the points of $d_0^{-1}(z)$. [N.D.E-V-39]

Denote by F_1 and F_2 the inverse images of F under d_0 and under $d_0 \circ d_1^{-1} = d_0 \circ d_1^{-1}$, and denote by $\tilde{d}_0$, $\tilde{d}_1$, etc., the morphisms induced by d_0 , d_1 , etc. One thus has a commutative diagram

$$\begin{array}{ccccc} & & d_1^{-1} & & \\ F_2 & \xrightarrow{\quad} & F_1 & \xrightarrow{\quad} & F \\ & & d_0^{-1} & & \\ d_2^{-1} \downarrow & & \downarrow d_1 & & \downarrow \\ X_1 & \xrightarrow{\quad} & X_0 & \xrightarrow{\quad} & S, \\ & & d_1 & & q \\ & & d_0 & & \end{array} \quad \begin{array}{c} \tilde{d}_0 \\ \square \quad q \\ \square \\ \downarrow \end{array}$$

where the two left-hand squares are Cartesian and the first row is exact (confer (0,1,2), § 1), and where q and $\tilde{q}$ denote the structure morphisms.

Let us first show that there are only finitely many points of F_1 above z . [N.D.E-V-39] Indeed, let s be the image of z in S ; since F is of finite type over S , the fiber $\tilde{q}^{-1}(s)$ is a Noetherian scheme. On the other hand, since $\tilde{d}_0$ is proper, $\tilde{d}_0(\tilde{d}_0^{-1}(z))$ is a closed subscheme of $\tilde{q}^{-1}(s)$, consisting of finitely many points. Consequently (cf. EGA I, 6.2.2), the points of this set are closed in $\tilde{q}^{-1}(s)$, and also (since F is closed in X_0) in the fiber $\tilde{q}^{-1}(s)$ of s in X_0 . Let y be one of these points; since the fiber $\tilde{q}^{-1}(s)$ is of finite type over $\kappa(s)$, it contains affine open neighborhoods $\text{Spec } B$ and $\text{Spec } C$ of y and z , respectively, where B and C are finitely generated $\kappa(s)$ -algebras. Then y and z correspond to maximal ideals $\mathfrak{p} \subset B$ and $\mathfrak{q} \subset C$, the fields $B/\mathfrak{p}$ and $C/\mathfrak{q}$ are of finite degree over $\kappa(s)$, and so $(B/\mathfrak{p}) \otimes_{\kappa(s)} (C/\mathfrak{q})$ is a $\kappa(s)$ -algebra of finite dimension, whose maximal ideals correspond exactly to the points of $X_0 \times_S X_0$ whose second (resp. first) projection is z (resp. y). There are therefore only finitely many points u of $X_0 \times_S X_0$ whose

<!-- original page 280 -->

second projection is z and whose first projection belongs to $\tilde{d}_0(\tilde{d}^{-1}_1(z))$. Finally, since $X_1 \rightarrow X_0 \times_S X_0$ has finite fibers, such a point u comes from finitely many points of X_1 , whence the desired assertion.

The morphism $\tilde{d}_1$ is therefore quasi-finite and flat at the points of F_1 above z . Since $\tilde{d}_1$ is of finite type, it follows from SGA 1, IV 6.10 and EGA III, 4.4.10, [N.D.E-V-40] that the set Φ of points of F_1 where $\tilde{d}_1$ is not simultaneously flat and quasi-finite is closed in F_1 , hence in X_1 (since F_1 is closed in X_1). Since d_1 is proper, $\tilde{d}_1(\Phi)$ is closed, and does not contain z by what precedes. Put $W = \tilde{d}_1(F_1) - \tilde{d}_1(\Phi)$. Then the restriction of $\tilde{d}_1$ to $\tilde{d}_1^{-1}(W)$ is [N.D.E-V-41] of finite presentation (in view of the Noetherian hypotheses), flat, proper and quasi-finite, hence finite, locally free, and open, by EGA III, 4.4.2, and EGA IV 2, 2.1.12 and 2.4.6. Consequently, $\tilde{d}_1(F_1)$ is a neighborhood of z , and W is the largest open of X_0 contained in $\tilde{d}_1(F_1)$ above which $\tilde{d}_1$ is simultaneously flat and quasi-finite.

We shall see in lemma 7.4 that the inverse images of Φ by $\tilde{d}'_1$ and $\tilde{d}'_0$ both identify with the set of points of F_2 where $\tilde{d}'_2$ is not simultaneously flat and quasi-finite. It follows that $d^{-1}_0(W) = \tilde{d}'_2(F_2) - \tilde{d}'_2(\tilde{d}'_0(\Phi))$ coincides with $d^{-1}_1(W) = \tilde{d}'_2(F_2) - \tilde{d}'_2(\tilde{d}'_1(\Phi))$, that is, W is saturated. Consequently, setting $W_1 = \tilde{d}_1^{-1}(W)$, the equality $d^{-1}_0(W) = d^{-1}_1(W)$ entails $\tilde{d}_2^{-1} \tilde{d}_1^{-1}(W) = \tilde{d}_2^{-1} \tilde{d}_0^{-1}(W)$, that is, $\tilde{d}^{-1}_0(W_1) = \tilde{d}^{-1}_1(W_1)$. Since $\tilde{d}_0$ is faithfully flat and quasi-compact (because d_0 is, like d_1 , surjective, proper and flat), and the square

```

```text
 d~'_1
 F_2 ----> F_1
 | |
d~'_0 | | d~'_0
 v v
 F_1 ----> F
 d~'_0
```

```

is Cartesian, it follows that W_1 is of the form $\tilde{d}_0^{-1}(U)$, where U is an open of F

<!-- original page 281 -->

(SGA 1, VIII 4.4). This open U of F is a quasi-section for the groupoid with base W induced by $X \rightrightarrows$. One can therefore choose U_z equal to W .

It remains for us therefore to state lemma 7.4, whose proof is classical:

Lemma 7.4. *Consider a Cartesian square of schemes*

<!-- label: III.V.7.4 -->

```

```text
 F_2 --v--> F_1
 | |
d' | | d
 v v
 X_1 --u--> X_0
```

```

and let x be a point of F_2 .

(i) If u is flat, d' is flat at x if and only if d is flat at $v(x)$.*

(ii) If d is locally of finite type, d' is quasi-finite at x if and only if d is quasi-finite at $v(x)$. [N.D.E-V-42]

We have thus proved that there exists a covering of X_0 by saturated opens W such that the groupoid $X \rightrightarrows$ induced by $X \rightrightarrows$ on W possesses a quasi-section. [N.D.E-V-43]

By lemma 6.1 and the reductions stated after theorem 7.1, this implies assertions (i) and (iii) of theorem 7.1, and the fact that p is surjective and open, and that p and $Y \rightarrow S$ are locally of finite presentation. Moreover, since $X_{\{0\}} \rightarrow S$ is quasi-projective, hence separated and of finite type, then p is separated, and the proof of point (ii) of lemma 6.1 shows that p and $Y \rightarrow S$ are of finite presentation.

To show that p is proper, it remains therefore to show that it is universally closed. As the assertion is local on Y , one may place oneself on a saturated open W such that the groupoid $W \ast$ induced by $X \ast$ on W possesses a quasi-section U (since $X_{\{0\}}$ is covered by such opens). Taking up the notations of 6.a), one has a commutative diagram

$$\begin{array}{ccccc} & & \text{``text} & & \\ & & W \xleftarrow{v} V \xrightarrow{u} U & & \\ & \searrow & & \swarrow & \\ & r & & q & \\ & \searrow & & \swarrow & \\ & & Z, & & \\ & & \text{``} & & \end{array}$$

where Z is an open of Y , all the arrows are surjective, and q is integral. Moreover, by hypothesis, $d_{\{0\}} : X_{\{1\}} \rightarrow X_{\{0\}}$ is proper, so u , obtained from it by base change, is also. Consequently, r is universally closed, and so is p , since v is surjective.

Finally, p being surjective and universally closed, and $X_{\{0\}}$ quasi-projective hence separated, the diagonal $\Delta_{Y/S}(Y)$ is closed in $Y \times_S Y$, being the image under $p \times p$ of the diagonal $\Delta_{X_{\{0\}}/S}(X_{\{0\}})$. So Y is separated over S . This completes the proof of 7.1 (ii).

The assertions to prove in 7.1 (iv) are local on Y ; since $X_{\{0\}}$ is covered by the saturated opens $U_{\{z\}}$, it suffices to verify these assertions by replacing X and Y by $U_{\{z\}}$ and $V = p(U_{\{z\}})$. As one has already seen at the beginning of the proof of 7.1, it follows from lemmas 1.1, 1.2, and 6.1 (i), that $(V_{\{z\}}, p|_{U_{\{z\}}})$ is the cokernel in (Sch) and in (Esp.An) of the groupoid induced by $X \ast$ on $U_{\{z\}}$. Now the hypothesis that

<!-- original page 282 -->

$d = (d_{\{0\}}, d_{\{1\}})$ is a monomorphism is preserved by the base change $U_{\{z\}} \rightarrow X_{\{0\}}$. Consequently, the first two assertions of 7.1 (iv) follow from 6.1 (iv).

Let us finally show the consequences indicated at the end of point (iv) (cf. [Ray67a], th. 1 (iii)). By hypothesis, the groupoid $X \ast$ comes from an equivalence relation $R \rightarrow X_{\{0\}} \times X_{\{0\}}$, and one has established that R is effective (cf. Exp. IV, 3.3.2) and that $p : X_{\{0\}} \rightarrow Y = X_{\{0\}}/R$ is faithfully flat and of finite presentation. Consequently, denoting by (M) the family of faithfully flat morphisms locally of finite presentation, R is (M) -effective. Therefore, by Exp. IV, 6.3.3, (Y, p) represents the quotient sheaf of $X_{\{0\}}$ by R for the (fppf) topology, and the assertions concerning base change follow from IV, 3.4.3.1.

8. Passage to the quotient by a flat, not necessarily proper, groupoid

<!-- label: III.V.8 -->

Theorem 8.1. [N.D.E-V-44] *Let S be a Noetherian scheme and**

<!-- label: III.V.8.1 -->

$$\begin{array}{ccccccc} & & d'_{\{0\}}, d'_{\{1\}}, d'_{\{2\}} & & d_{\{0\}}, d_{\{1\}} & & \\ X_2 \ni X_1 \ni X_0 & & & & & & \end{array}$$

a (Sch/S) -groupoid such that $d_{\{1\}}$ is flat and of finite type, $X_{\{0\}}$ is of finite type over S , and the morphism $X_{\{1\}} \rightarrow X_{\{0\}} \times_S X_{\{0\}}$ with components $d_{\{0\}}$ and $d_{\{1\}}$ is quasi-finite.

<!-- original page 282 -->

*There then exists an open W of $X_{\{0\}}$ which is dense, saturated, and satisfies the following properties:

(i) If $W_2 \ni W_1 \ni W$ (with arrows $w'_{\{i\}}, w_{\{j\}}$) is the groupoid induced by $X \ast$ on W , then $(w_{\{0\}}, w_{\{1\}})$ admits a cokernel (V, p) in (Sch/S) ; moreover, (V, p) is a cokernel of $(w_{\{0\}}, w_{\{1\}})$ in the category of all

ringed spaces.*

(ii) ρ is surjective and open.

(ii') ρ and $V \rightarrow S$ are of finite presentation.

(iii) The morphism $W_1 \rightarrow W \times_{\{V\}} W$ with components w_0 and w_1 is surjective.

(iv) If (d_0, d_1) is an equivalence pair, $W_1 \rightarrow W \times_{\{V\}} W$ is an isomorphism and ρ is faithfully flat.

<!-- original page 280 -->

We shall show that one can choose W in such a way that the (Sch/S) -groupoid W_{ast} induced by X_{ast} possesses a quasi-section (confer § 7). Theorem 8.1 will then follow from lemma 6.1.

Suppose provisionally that, for every point $z \in X_0$ closed relative to S (confer § 7), there exists a saturated open W_z which possesses a quasi-section and meets all the irreducible components of X_0 passing through z . Then the exterior $X_0 - W_z$ of W_z in X_0 is saturated (since the saturation $d_1(d^{-1}_0(X_0 - W_z))$ of this exterior is open and does not meet W_z). If this exterior is non-empty, one can choose in it a point z' closed relative to S and associate to z' an open $W_{z'}$ as above; one may moreover suppose $W_{z'}$ contained in $X_0 - W_z$; then W_z and $W_{z'}$ are disjoint and the groupoid induced by X_{ast} on $W_z \cup W_{z'}$ possesses a quasi-section. The process must stop, because X_0 has only finitely many irreducible components. It therefore remains to construct W_z .

For this, one may suppose S affine; in this case, let y be a point of X_1

<!-- original page 283 -->

such that $d_1(y) = z$, X an affine open of X_0 containing $d_0(y)$, Y the inverse image of X in X_1 under d_0 , and finally $u : Y \rightarrow X$ and $v : Y \rightarrow X_0$ the morphisms induced by d_0 and d_1 . Since X is affine, hence quasi-projective, one can apply lemma 7.2: there is therefore a closed subscheme F of X_0 such that $d^{-1}_0(F) \cap d^{-1}_1(z)$ is non-empty, $d_0(d^{-1}_0(F) \cap d^{-1}_1(z))$ is finite, and the restriction of d_1 to $d^{-1}_0(F)$ is flat at the points of $v^{-1}(z)$. This allows us to take up the notations of lemma 7.3, denoting by F_1 and F_2 the inverse images of F in X_1 and X_2 , etc.

```

``text

```

One then shows as in 7.3 that $\tilde{d}_1$ is quasi-finite at the points of $\tilde{d}^{-1}_1(z)$, so that it is natural to consider the open F'_1 of F_1 consisting of points where $\tilde{d}_1$ is simultaneously flat and quasi-finite. By 7.4, the two inverse images of F'_1 under $\tilde{d}'_1$ and $\tilde{d}'_0$ consist of the points of F_2 where $\tilde{d}'_2$ is flat and quasi-finite, so these two inverse images coincide, and F'_1 is of the form $\tilde{d}^{-1}_0(F')$, where F' is an open of F .

(SGA 1, VIII 4.4). Possibly replacing F by F' , one may therefore suppose that $\tilde{d}_1$ is quasi-finite and flat. In this case, we denote by W_z the largest open of $\tilde{d}_1(F_1)$ above which $\tilde{d}_1$ is finite and flat.

This open W_z does not necessarily contain z , but it contains the generic points of the irreducible components of X_0 passing through z . [N.D.E-V-45] Since d_0 (resp. d_1) is faithfully flat and of finite presentation (hence open), it then follows from SGA 1, VIII 5.7, that $d^{-1}_0(W_z)$ and $d^{-1}_1(W_z)$ both coincide with the largest open of $\tilde{d}'_2(F_2)$ above which $\tilde{d}'_2$ is finite and flat. One sees consequently as in 7.3 that the two inverse images of $\tilde{d}^{-1}_1(W_z)$ under $\tilde{d}'_0$ and $\tilde{d}'_1$ coincide, so that $\tilde{d}^{-1}_1(W_z)$ is of the form $\tilde{d}^{-1}_0(U)$ where U is an open of F which is a quasi-section for the groupoid induced by X_{ast} on W_z .

9. Elimination of the Noetherian hypotheses in theorem 7.1

<!-- label: III.V.9 -->

<!-- original page 284 -->

****a)**** We take up the notations and hypotheses of lemma 6.1 and let $\pi : S' \rightarrow S$ be an arbitrary base change. Denote by $f' : X' \rightarrow Y'$ the morphism of S' -schemes deduced by extension via π of the base from a morphism $f : X \rightarrow Y$. With this convention, $p' : X'_{\{0\}} \rightarrow Y'$ is surjective, as is the morphism $X'_{\{1\}} \rightarrow X'_{\{0\}} \times_{Y'} X'_{\{0\}}$ with components $d'_{\{0\}}$ and $d'_{\{1\}}$. The set underlying Y' therefore identifies with the quotient of the set underlying $X'_{\{0\}}$ by the equivalence relation defined in $X'_{\{0\}}$ by the S' -groupoid $X'_{\ast}$. Moreover, $q' : U' \rightarrow Y'$ is integral and surjective, so that the topology of Y' is the quotient topology of that of U' , hence also of that of $X'_{\{0\}}$ (confer the proof in § 6.c).

On the other hand, it is clear that U' is a quasi-section of the S' -groupoid $X'_{\ast}$, to which one can therefore apply lemma 6.1. In particular, $X'_{\ast}$ possesses a cokernel $(Y_{\{1\}}, p_{\{1\}})$ and the topological space underlying $Y_{\{1\}}$ is obtained from the topological space underlying $X'_{\{0\}}$ by identifying the points equivalent under the relation defined by $X'_{\ast}$. It follows that the canonical morphism $Y_{\{1\}} \rightarrow Y'$ is a homeomorphism; I claim that $Y_{\{1\}} \rightarrow Y'$ is even a universal homeomorphism: indeed, if S'' is above S' , let $Y_{\{2\}}$ be the cokernel of $(d_{\{0\}} \times_{S'} S'', d_{\{1\}} \times_{S'} S'')$. By what precedes, applied to the base changes $S'' \rightarrow S'$ and $S' \rightarrow S$,

```
```text
... Y_2 → Y_1 ×_{S'} S'' and Y_2 → Y ×_S S'' = Y' ×_{S'} S''
```

are homeomorphisms, so the same holds for  $Y_{\{1\}} \times_{S'} S'' \rightarrow Y' \times_{S'} S''$ .

**\*\*b)\*\*** Analogous remarks evidently apply to the case where the groupoid  $X_{\ast}$  "locally" possesses quasi-sections (confer the proof of theorem 7.1). [N.D.E-V-46] For example, one has the following theorem:

<!-- original page 285 -->

**\*Theorem 9.0.\*** Let  $S$  be an arbitrary scheme and  $X_2 \rightrightarrows X_1 \rightrightarrows X_0$  a  $(\text{Sch}/S)$ -groupoid (with arrows  $d_{\{i\}}$  and  $d_{\{j\}}$ ) such that:  $X_{\{0\}}$  is of finite presentation and quasi-projective over  $S$ ,  $d_{\{1\}}$  is of finite presentation, proper and flat, the morphism  $d_{\{0\}} \times_{X_{\{0\}}} d_{\{1\}} : X_{\{1\}} \rightarrow X_{\{0\}} \times_{X_{\{0\}}} X_{\{0\}}$  is quasi-finite. Then:

<!-- label: III.V.9.0 -->

(1) Every point  $x$  of  $X_{\{0\}}$  has an open neighborhood  $W$  that is saturated and such that the groupoid induced by  $X_{\ast}$  on  $W$  possesses a quasi-section.\*

(2) Let  $(Y, p)$  be the cokernel of  $(d_{\{0\}}, d_{\{1\}})$  in the category of all ringed spaces. Then  $Y$  is a scheme,  $p$  is a morphism of schemes, and  $(Y, p)$  is a cokernel of  $(d_{\{0\}}, d_{\{1\}})$  in  $(\text{Sch}/S)$ .\*

(3)  $p$  is surjective, open and universally closed.\*

(4) The morphism  $d : X_{\{1\}} \rightarrow X_{\{0\}} \times_{X_{\{0\}}} X_{\{0\}}$  with components  $d_{\{0\}}$  and  $d_{\{1\}}$  is surjective.\*

(5) If  $(d_{\{0\}}, d_{\{1\}})$  is an equivalence pair, then:\*

(a)  $d : X_{\{1\}} \rightarrow X_{\{0\}} \times_{X_{\{0\}}} X_{\{0\}}$  is an isomorphism and  $p$  is faithfully flat.\*

(b)  $p$  and  $Y \rightarrow S$  are of finite presentation, and  $(Y, p)$  is a cokernel of  $(d_{\{0\}}, d_{\{1\}})$  in the category of sheaves for the (fppf) topology.\*

**\*Proof.\*** For (1), the question is local on  $S$ , so one may suppose  $S = \text{Spec } B$  affine. There then exists a ring  $A$  of finite type over  $\mathbb{Z}$ , a morphism  $S \rightarrow T = \text{Spec } A$  and a  $(\text{Sch}/T)$ -groupoid  $Z_{\ast}$  such that  $X_{\ast}$  identifies with  $Z_{\ast} \times_{T \times_S T} S$  (cf. EGA IV<sub>3</sub>, 8.8.3, applied to  $S_{\{0\}} = \text{Spec } \mathbb{Z}$  and  $S_{\{i\}} = \text{Spec } A_{\{i\}}$ , with the  $A_{\{i\}}$  running over the finitely generated  $\mathbb{Z}$ -subalgebras of  $B$ ). Moreover, one may suppose that  $Z_{\ast}$  satisfies the hypotheses of theorem 7.1 (cf. EGA IV<sub>3</sub>, 8.10.5). Consequently,  $Z_{\ast}$  "locally" possesses quasi-sections.

The same therefore holds for  $X_{\ast}$ , by a), and assertions (2), (3), (4) and (5) (a) follow from 6.1, as in the proof of 7.1.

**\*\*c)\*\*** Let us show that  $\mathcal{Y} \rightarrow \mathcal{S}$  is of finite presentation. [N.D.E-V-47] By hypothesis,  $(d^{\wedge}(X_{\ast})_0, d^{\wedge}(X_{\ast})_1)$  is an equivalence pair, that is,  $d^{\wedge}(X_{\ast}) : X_1 \rightarrow X_0 \times_{\mathcal{S}} X_1$  is a monomorphism. By EGA IV\_3, 8.10.5, one may suppose, possibly enlarging  $\mathcal{A}$ , that  $d^{\wedge}(Z_{\ast}) : Z_1 \rightarrow Z_0 \times_{\mathcal{T}} Z_1$  is a monomorphism. Since  $\mathcal{T} = \operatorname{Spec} \mathcal{A}$ , with  $\mathcal{A}$  Noetherian, it then follows from theorem 7.1 that the groupoid  $Z_{\ast}$  possesses a cokernel  $(Q, q)$  in  $(\operatorname{Sch}/\mathcal{T})$ , that  $q$  and  $Q \rightarrow \mathcal{T}$  are of finite presentation, and moreover that  $q : Z_0 \rightarrow Q$  is faithfully flat and that  $d^{\wedge}(Z_{\ast})$  induces an isomorphism  $Z_1 \xrightarrow{\sim} Z_0 \times_Q Z_0$ . Put  $Q_{\mathcal{S}} = Q \times_{\mathcal{T}} \mathcal{S}$ .

Since  $X_i \rightarrow Z_i \times_{\mathcal{T}} \mathcal{S}$ , one therefore obtains an isomorphism:

```

```text
... d^{\wedge}\{Z_{\ast}\} \times_{\mathcal{T}} \mathcal{S} : X_1 \rightarrow X_0 \times_{Q_{\mathcal{S}}} X_0.
...

```

Denote its inverse by ϕ , and let π be the canonical morphism

```

```text
... X_0 \times_{\mathcal{Y}} X_0 \rightarrow X_0 \times_{Q_{\mathcal{S}}} X_0.
...

```

<!-- original page 283 -->

Then  $\phi \circ \pi$  is the inverse of  $d_0 \times d_1 : X_1 \rightarrow X_0 \times_{\mathcal{Y}} X_0$ . It follows that the equivalence relation defined by  $X_{\ast}$ , that is, the monomorphism

```

```text
... X_1 \xrightarrow{d_0 \times d_1} X_0 \times_{\mathcal{Y}} X_0 \xrightarrow{\phi \circ \pi} X_0 \times_{Q_{\mathcal{S}}} X_0,
...

```

identifies with the equivalence relation $R(q_{\mathcal{S}})$ defined by the morphism $q_{\mathcal{S}} : X_0 \rightarrow Q_{\mathcal{S}}$. Since the latter is faithfully flat and of finite presentation, hence a universal effective epimorphism, $R(q_{\mathcal{S}})$ has quotient $Q_{\mathcal{S}}$ (cf. IV 3.3.2). Consequently, $\mathcal{Y} \rightarrow Q \times_{\mathcal{T}} \mathcal{S}$, so $\mathcal{Y} \rightarrow \mathcal{S}$ and $\mathcal{p}$ are of finite presentation. Moreover, by IV 6.3.3, $(\mathcal{Y}, \mathcal{p})$ is also a cokernel of (d_0, d_1) in the category of sheaves for the (fppf) topology.

****Proposition 9.1.**** *Consider morphisms of schemes*

<!-- label: III.V.9.1 -->

```

```text
... X_0 \xrightarrow{\mathcal{p}} \mathcal{Y} \xrightarrow{\mathcal{q}} \mathcal{S}
...

```

\*such that  $\mathcal{q}$  is of finite type (resp. of finite presentation) and  $\mathcal{p}$  is faithfully flat of finite presentation. Then  $\mathcal{q}$  is of finite type (resp. of finite presentation) [V-9-1].\*

Since  $\mathcal{p}$  is surjective and  $\mathcal{q}$  quasi-compact,  $\mathcal{q}$  is quasi-compact. So one may suppose  $\mathcal{S}$ ,  $\mathcal{Y}$  and  $X_0$  affine, with rings  $\mathcal{A}$ ,  $\mathcal{B}$ ,  $\mathcal{C}$ . One has  $\mathcal{B} = \varinjlim \mathcal{B}_i$ , where the  $\mathcal{B}_i$  run over the finitely generated  $\mathcal{A}$ -subalgebras of  $\mathcal{B}$ . Since  $\mathcal{C}$  is of finite presentation over  $\mathcal{B}$ , there exists an index  $i_0$ , a  $\mathcal{B}_{i_0}$ -algebra of finite presentation  $\mathcal{C}_{i_0}$ , and an isomorphism  $\mathcal{C} \simeq \mathcal{C}_{i_0} \otimes_{\mathcal{B}_{i_0}} \mathcal{B}$ ; if we put  $\mathcal{C}_i = \mathcal{C}_{i_0} \otimes_{\mathcal{B}_{i_0}} \mathcal{B}_i$  for  $i \geq i_0$ , we therefore have  $\mathcal{C} \simeq \mathcal{C}_{i_0} \otimes_{\mathcal{B}_{i_0}} \mathcal{B}$ .

```

```text
...
      B  \longrightarrow C
      \uparrow           \uparrow
      B_i \longrightarrow C_i
      \uparrow
      A
...

```

Since $\mathcal{C}$ is faithfully flat over $\mathcal{B}$, one extracts from EGA IV_3, 11.2.6 and 8.10.5 (vi) the existence of an $i_1 \geq i_0$ such that $\mathcal{C}_{i_1}$ is faithfully flat over $\mathcal{B}_{i_1}$; consequently $\mathcal{C}_{i_1}$ is faithfully flat over $\mathcal{B}_i$ for $i \geq i_1$. For $i \geq i_1$, the canonical map $\mathcal{C}_{i_1} \rightarrow \mathcal{C}$ is then injective, since deduced from $\mathcal{B}_i \rightarrow \mathcal{B}$ by faithfully flat extension of the base.

<!-- original page 286 -->

If C_S is of finite type over A_S , it follows that there exists an index $j \geq i_1$ such that $C_{\{j\}} = C_S$, whence $B_{\{j\}} = B_S$, since $C_{\{j\}}$ is faithfully flat over $B_{\{j\}}$. Consequently, B_S is of finite type over A_S .

Suppose now C_S of finite presentation over A_S . By what precedes, B_S is of finite type over A_S , hence of the form $\bar{B}/I_S$ where $\bar{B}$ is a polynomial algebra over A_S in a finite number of indeterminates, and I_S an ideal of $\bar{B}$. Then I_S is the union of its finitely generated subideals $I_{\{\alpha\}}$; whence the equality $B = \varinjlim B_{\{\alpha\}}$ with $B_{\{\alpha\}} = \bar{B}/I_{\{\alpha\}}$. Proceeding as above, there exists an index α_0 , a $B_{\{\alpha_0\}}$ -algebra of finite presentation $C_{\{\alpha_0\}}$, and an isomorphism $C_S \simeq C_{\{\alpha_0\}} \otimes_{B_{\{\alpha_0\}}} B_S$. For $\alpha \geq \alpha_0$, one again sets $C_{\{\alpha\}} = C_{\{\alpha_0\}} \otimes_{B_{\{\alpha_0\}}} B_{\{\alpha\}}$ so that one has $C_S \simeq C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} B_S$ for $\alpha \geq \alpha_0$. Again by EGA IV₃, 11.2.6 and 8.10.5 (vi), one concludes as above that $C_{\{\alpha\}}$ is faithfully flat over $B_{\{\alpha\}}$ for α large enough. In this case, the kernel of the map $C_{\{\alpha\}} \rightarrow C_S$ (resp. $C_{\{\alpha\}} \rightarrow C_{\{\beta\}}$ for $\beta \geq \alpha$) identifies with $C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} (I/I_{\{\alpha\}})$ (resp. with $C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} (I_{\{\beta\}}/I_{\{\alpha\}})$).

Since $C_{\{\alpha\}}$ and C_S are of finite presentation over A_S and $C_{\{\alpha\}} \rightarrow C_S$ is surjective, $C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} (I/I_{\{\alpha\}})$ is a finitely generated ideal [N.D.E-V-48] and is the union of the ideals $C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} (I_{\{\beta\}}/I_{\{\alpha\}})$. One therefore has $C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} (I_{\{\beta\}}/I_{\{\alpha\}}) = C_{\{\alpha\}} \otimes_{B_{\{\alpha\}}} B_{\{\beta\}} (I/I_{\{\alpha\}})$ for β large enough, whence also $I_{\{\beta\}} = I_S$ (since $C_{\{\alpha\}}$ is faithfully flat over $B_{\{\alpha\}}$); so B_S is of finite presentation over A_S .

10. Complement: quotients by a group scheme

<!-- label: III.V.10 -->

The following §§ 10.2–10.4, written following indications of M. Raynaud, aim to apply the preceding theorems to the case of an action of a group scheme. For the reader's convenience, we have begun by reproducing, in § 10.1, statements 2.1 to 2.3 of Exp. XVI.

10.1. Representability theorems for quotients.

<!-- label: III.V.10.1 -->

"Recall" first the following result:

Theorem 10.1.1. *Let S be a scheme, X and Y two S -schemes, $f : X \rightarrow Y$ an S -morphism. Suppose that one is in one of the following two cases:*

<!-- label: III.V.10.1.1 -->

α) The morphism f is locally of finite presentation.

β) The scheme S is locally Noetherian and X is locally of finite type over S .

Then the following conditions are equivalent:

*(i) There exists an S -scheme X' and a factorization of f :

```

```text
 f : X → X' → Y,
```

```

where f' is a faithfully flat S -morphism locally of finite presentation and f'' is a monomorphism.

*(ii) The (first) projection:

```

```text
 p_1 : X ×_Y X → X
```

```

is a flat morphism.

Moreover, if the preceding conditions are realized, (X', f') is a quotient of X by the equivalence relation defined by f (for the (fppf) topology), so that the factorization $f = f' \circ f$ of i is unique up to isomorphism.

The case Y locally Noetherian, X of finite type over Y , is treated in [Mur65], cor. 2 of th. 2. We shall see that one can reduce to this case.

Let us first make a few remarks:

<!-- original page 285 -->

****a)**** The implication (i) $\Rightarrow$ (ii) is trivial. Indeed, the first projection

```text  
p'\_1 : X \times\_{X'} X \rightarrow X  
```

factors through $X \times_Y X$:

```text  
p'\_1 : X \times\_{X'} X \xrightarrow{u} X \times\_Y X \xrightarrow{p\_1} X.  
```

The morphism u is an isomorphism, since f' is a monomorphism, and p'_1 is flat, since f is flat, so p_1 is flat.

****b)**** The assertions of 10.1.1 are local on Y (hence local on S); they are also local on X , as follows easily from the fact that a flat morphism locally of finite presentation is open (EGA IV_3, 11.3.1).

****c)**** Under the hypotheses of 10.1.1 α), in view of what precedes, we are reduced to the case where X and Y are affine and f of finite presentation. Possibly replacing S by Y , one may suppose X and Y of finite presentation over S . One then reduces to the case S Noetherian thanks to EGA IV_3, 11.2.6.

****d)**** Under the hypotheses of 10.1.1 β), one may suppose S , X , Y affine, S Noetherian and X of finite type over S . Consider Y as filtered inverse limit of affine schemes $Y_{\{i\}}$ of finite type over S . The schemes $X \times_{Y_{\{i\}}} Y$ form a filtered decreasing family of closed subschemes of $X \times_S Y$, whose inverse limit is $X \times_Y Y$. Since $X \times_S Y$ is Noetherian, one has $X \times_{Y_{\{i\}}} Y = X \times_Y Y$ for i large enough, so that $f_{\{i\}} : X \rightarrow Y_{\{i\}}$ satisfies the hypotheses of 10.1.1 ii) if f does. Since the equivalence relation defined by f on X coincides with that defined by $f_{\{i\}}$, it is clear that it suffices to prove ii) $\Rightarrow$ i) for $f_{\{i\}}$, which reduces us to the case where Y is of finite type over S .

Application to group schemes. Let S be a scheme, G an S -group scheme locally of finite presentation over S , acting (on the left) on an S -scheme X . If $X \rightarrow S$ possesses a section ξ , recall that the stabilizer $\text{Stab}_G(\xi)$ is representable by a subgroup scheme of G (cf. I, 2.3.3).

****Theorem 10.1.2.**** *Let S be a scheme, G an S -group scheme locally of finite presentation over S , acting on an S -scheme X .*

<!-- label: III.V.10.1.2 -->

One assumes that $X \rightarrow S$ possesses a section ξ , such that the stabilizer H of ξ in G is flat over S . If one of the following hypotheses is satisfied:

a) X is locally of finite type over S ,

b) S is locally Noetherian,

then the quotient (fppf) sheaf G/H is representable by an S -scheme, locally of finite presentation over S , and the S -morphism:

```text  
f : G \rightarrow X, \quad g \mapsto g \cdot \xi  
```

Definition 10.2.1. We denote by $F \subset G \times_S X$ the stabilizer of the diagonal section, i.e. the X -scheme defined by the Cartesian product

`<!-- label: III.V.10.2.1 -->`

$$\begin{array}{ccc} F & \longrightarrow & X \\ | & & | \Delta \\ G \times_S X & \xrightarrow{(d_0, d_1)} & X \times_S X. \end{array}$$

Then F is an X -subgroup scheme of $G \times_S X$. Since $G \times_S X$ is of finite type over S Noetherian, hence Noetherian, F is of finite type over S and over X (EGA I, 6.3.5 and 6.3.6). Moreover, if $X \rightarrow S$ is separated, F is a closed X -subgroup scheme of $G \times_S X$.

Recall that one says that G acts freely on X if the morphism

$$G \times_S X \xrightarrow{(d_0, d_1)} X \times_S X$$

is a monomorphism (cf. Exp. III, 3.2.1). This amounts to saying that F is the trivial group scheme with base X .

10.3. Case where F is quasi-finite over X .

`<!-- label: III.V.10.3 -->`

Since F is of finite type over X , it is quasi-finite over X if and only if the fixators of the geometric points of X are finite.

Theorem 10.3.1. [N.D.E-V-49] Under the hypotheses of 10.2, suppose that F is quasi-finite over X . Then there exists an open U of X , dense and G -saturated, satisfying the following properties:

`<!-- label: III.V.10.3.1 -->`

(i) In (Sch/S) , the cokernel $V = G \backslash U$ exists; moreover, the scheme V is a quotient in the category of ringed spaces.

(ii) $\rho_p : U \rightarrow V$ is surjective, open, and of finite presentation.

(iii) V is of finite presentation over S .

(iv) The morphism $G \times_S U \rightarrow U \times_S V$, $(g, x) \mapsto (gx, x)$, is surjective.

(v) Suppose in addition that G acts freely on X . Then $U \rightarrow V$ is a (left) G -torsor locally trivial for the (fppf) topology. In particular, $U \rightarrow V$ is faithfully flat. [N.D.E-V-50]

Proof. It is assumed that the morphism $G \times_S X \rightarrow X \times_S X$, $(g, x) \mapsto (gx, x)$, is quasi-finite. Theorem 8.1 therefore applies to the groupoid defined by (X, G) . Thus there exists a dense saturated open $U \subset X$ such that the quotient $G \backslash U$ exists; it satisfies properties (i), (ii), (iii).

`<!-- original page 288 -->`

To establish (iv), recall that G acts freely on X if and only if (d_0, d_1) is an equivalence pair (III 3.2.1). In this case, theorem 8.1 (iv) shows that the morphism $G \times_S U \rightarrow U \times_S V$ is an isomorphism and that ρ_p is faithfully flat and of finite presentation. Thus U is a G -torsor with base V , locally trivial for the (fppf) topology.

10.4. Case where F is flat over X .

`<!-- label: III.V.10.4 -->`

We denote

```

```text
d = (d0, d1) : G ×S X → X ×S X
```

```

the morphism $d(g, x) = (gx, x)$. Recall that the sheaf-theoretic graph $\tilde{\Gamma}$ of the equivalence relation associated with (X, G) is the (fppf) $\mathcal{G}$ -subsheaf of $X \times_S X$ image of (d_0, d_1) . It is the (fppf) sheaf associated to the graph functor:

```

```text
T ↦ Γ(T) = {(x0, x1) ∈ X(T) × X(T) | x0 ∈ G(T) x1}.
```

```

Set $G_X = G \times_S X$. For every $\mathcal{G}$ -scheme T , one has a surjective map

```

```text
G_X(T) → Γ(T), (g, x) ↦ (gx, x),
```

```

which induces a bijective map

```

$$\phi(T) : G_X(T)/F(T) \xrightarrow{\sim} \tilde{\Gamma}(T);$$

```

indeed, if $(g, x), (g', x') \in G_X(T)$ satisfy $(gx, x) = (g'x', x')$, then $x' = x$ and $g^{-1}g'x = x$, so $(g^{-1}g'x, x) \in F(T)$ and (g, x) and (g', x) have the same image in $G_X(T)/F_X(T)$.

By definition (cf. IV, 4.4.1 (ii) or proof of 5.2.1), the quotient sheaf G_X/F is the (fppf) sheaf associated to the presheaf

```

$$T \mapsto G_X(T)/F(T) \cong \tilde{\Gamma}(T).$$

```

One therefore has an isomorphism of sheaves $\phi : G_X/F \rightarrow \tilde{\Gamma}$.

Theorem 10.4.1. ^[N.D.E-V-51] Under the hypotheses of 10.2, one has:

III.V.10.4.1

- a) $\tilde{\Gamma}$ is representable if and only if $\mathcal{G}$ is flat over X .
- b) Suppose $\mathcal{G}$ flat over X . Then the morphisms induced by d_1 and d_0 :

```

```text
G_X/F ⇒ X
 d0 ↗ d1
```

```

are faithfully flat and of finite presentation.

original page 289

Proof of a): Suppose the (fppf) sheaf G_X/F representable by an $\mathcal{G}$ -scheme Y . Then, by IV 6.3.3, $\phi : G_X/F \rightarrow Y$ is faithfully flat and locally of finite presentation, and the second square of the diagram below is Cartesian:

```

```text
F → F ×_X G_X → G_X
| | p
↓ ↓
X →_e_X G_X → Y,
```

```

the first square being obtained by base change along the unit section $e_X : X \rightarrow G_X$. Since p is faithfully flat and locally of finite presentation, so is $F \rightarrow X$.

Conversely, suppose F flat over X . Put $X_2 = X \times_S X$. The morphism $d : G_X \rightarrow X_2$ allows one to form the fiber product:

$$\begin{array}{ccc} G_X \times_{X_2} G_X & \longrightarrow & G_X \\ \downarrow & & \downarrow \\ G_X & \longrightarrow & X_2. \end{array}$$

Then the morphism $G_X \times_{X_2} G_X \rightarrow X_2$ is an $F \times_X X_2$ -torsor over X_2 , and is therefore flat and of finite type (since F is). By theorem 10.1.1, the morphism d factors uniquely:

$$G_X \xrightarrow{\psi} Y \xrightarrow{\tau} X \times_S X,$$

where ψ is faithfully flat (of finite type) and τ is a monomorphism of schemes.

Consequently, the morphism of sheaves $\psi : G_X \rightarrow Y$ is therefore F -invariant, and there comes a morphism of sheaves $\bar{\psi} : G_X/F \rightarrow Y$. Moreover, since ψ is faithfully flat (of finite type), the monomorphism of sheaves τ factors through the sheaf image of d , that is $\tilde{\Gamma}$. The isomorphism of sheaves $G_X/F \cong \tilde{\Gamma}$ therefore factors through the monomorphism $Y \rightarrow \tilde{\Gamma}$. One concludes that Y represents G_X/F .

Proof of b): Suppose F flat over X . Then, by a) and its proof, G_X/F is representable, and the morphism $p : G_X \rightarrow G_X/F$ is faithfully flat and of finite presentation. On the other hand, the morphisms $d_i : G_X \rightarrow X$ ($i = 0, 1$) are faithfully flat and of finite presentation by hypothesis. Since $d_i = \bar{d}_i \circ p$, it follows from EGA IV_2, 2.2.13 (iii) and EGA IV_3, 11.3.16, that $\bar{d}_i$ is faithfully flat and of finite presentation.

****Theorem 10.4.2.**** [N.D.E-V-52] Under the hypotheses of 10.2, suppose F flat over X . Then there exists a dense saturated open U of X such that the (fppf) quotient $V = G \backslash U$ is an S -scheme of finite type and $U \rightarrow V$ is faithfully flat and of finite presentation.*

<!-- label: III.V.10.4.2 -->

<!-- original page 290 -->

Proof. Theorem 10.4.1 shows that $G_X/F \cong \tilde{\Gamma}$ is representable. Then the (fppf) sheaf $G \backslash X$ identifies with the quotient sheaf of

$$G_X/F \quad \rightrightarrows \quad \begin{array}{c} d_1 \\ X. \\ d_0 \end{array}$$

By what precedes, $\bar{d}_i : G_X/F \rightarrow X$ is faithfully flat and of finite presentation ($i = 0, 1$), and the morphism

$$G_X/F \rightrightarrows \Gamma \rightarrow X \times_S X$$

is a monomorphism, that is, $(\bar{d}_0, \bar{d}_1)$ is an equivalence pair. Consequently, theorem 8.1 applies. There therefore exists an open U of X , dense and saturated, such that the (fppf) quotient $V = G \backslash U$ is an S -scheme of finite type, and $U \rightarrow V$ is faithfully flat and of finite presentation.

Taking into account the generic flatness theorem (EGA IV_2, 6.9.3), one obtains the

Corollary 10.4.3. Under the hypotheses of 10.2, suppose X reduced. Then there exists a dense saturated open U

of $\$X$ such that the (fppf) quotient $\$G\backslash U$ is an $\$S$ -scheme of finite type and $\$U \rightarrow G\backslash U$ is faithfully flat and of finite presentation.*

[^N.D.E-V-1]: N.D.E.: namely, theorems 5.1, 5.3, 6.1, 6.2 and 7.2 of TDTE III. The first two (resp. the next two) correspond to theorem 4.1 (resp. theorems 7.1 and 8.1) of this Exposé. Theorem 7.2 of TDTE III is proved in Exp. VI_A, 3.2 and 3.3.

[^N.D.E-V-2]: N.D.E.: that is, groupoids with base XS , cf. the terminology at the end of section 1. When CS is the category of schemes, the quotient $\mathfrak{p} : X \rightarrowtail Y$ of a groupoid $X \rightrightarrows Y$ with base XS exists under certain hypotheses (cf. 4.1, 6.1, 7.1); if, moreover, $X \rightrightarrows Y$ is an equivalence relation, then $\mathfrak{p}$ is, under the same hypotheses, faithfully flat and quasi-compact, hence a universal epimorphism, cf. loc. cit.

[^N.D.E-V-3]: N.D.E.: Lemmas 1.1 and 1.2 have been added; they are used several times in sections 5 to 9.

[^N.D.E-V-4]: N.D.E.: This is not the case in the category of schemes. Take, for example, $S = \operatorname{Spec}(C)$, $X_{\{0\}} = A^2_S = \operatorname{Spec}(C[x_1, x_2])$, let $d_{\{1\}} : G_{\{m, S\}} \times_S A^2_S \rightarrow A^2_S$ be the action of $G_{\{m, S\}}$ by homotheties on A^2_S , let $d_{\{0\}}$ be the projection onto the second factor, and $U = A^2_S - \{m\}$, where m is the point $(0, 0)$. Then projective space P^1_S is the cokernel of $(\tilde{d}_{\{0\}}, \tilde{d}_{\{1\}})$ in $(\operatorname{Esp. An})$ and in (Sch) , and the cokernel Y of $(d_{\{0\}}, d_{\{1\}})$ in $(\operatorname{Esp. An})$ is the union of P^1_S and the point $y_{\{0\}} = \{p(m)\}$; the only open set containing $y_{\{0\}}$ is Y , and one has $\Gamma(Y, \mathcal{O}_Y) = C$. If $f : A^2_S \rightarrow T$ is a morphism of S -schemes such that $f d_{\{0\}} = f d_{\{1\}}$ and if $V = \operatorname{Spec}(A)$ is an affine open of T containing the point $t_{\{0\}} = f(y_{\{0\}})$, then $f^{-1}(V) = A^2_S$ and the ring morphism $A \rightarrow C[x_1, x_2]$ factors through C ; this shows that $\bar{S} = \operatorname{Spec}(C)$ is the cokernel of $(d_{\{0\}}, d_{\{1\}})$ in the category (Sch/S) .

[^N.D.E-V-5]: N.D.E.: Hence, in this case, $X_{\{2\}}(T)$ is the set of pairs $(f_{\{2\}}, f_{\{1\}})$ of composable arrows, that is, such that $d_{\{0\}}(f_{\{1\}}) = d_{\{1\}}(f_{\{2\}})$, and $d'_{\{0\}}$, $d'_{\{1\}}$, $d'_{\{2\}}$ send $(f_{\{2\}}, f_{\{1\}})$ to $f_{\{2\}}$, $f_{\{2\}} \circ f_{\{1\}}$, $f_{\{1\}}$ respectively.

[^N.D.E-V-6]: N.D.E.: $T \mapsto s(T)$ defines an element of $\operatorname{Hom}(h_{X_{\{0\}}}, h_{X_{\{1\}}})$, and the latter equals $\operatorname{Hom}(X_{\{0\}}, X_{\{1\}})$ by the Yoneda lemma.

[^N.D.E-V-7]: N.D.E.: It follows from the Yoneda lemma that σ is an involutive automorphism of $X_{\{1\}}$; this will be used, for example, in 3.e) and in theorem 4.1.

[^N.D.E-V-8]: N.D.E.: see example 2.a) below.

[^N.D.E-V-9]: N.D.E.: In particular, if GS is a CS -group acting on the left on an object XS of CS and if $X \rightrightarrows Y$ is

the $\mathcal{C}$ -groupoid defined in a), then $(d_{\{0\}}, d_{\{1\}})$ is an equivalence pair if and only if G acts freely on X , cf. Exp. III, 3.2.1.

[^N.D.E-V-10]: N.D.E.: The same argument applies for $B = k[T^{\{3\}}, T^{\{4\}}]$ and $T^{\{5\}} \otimes_{\{B\}} 1$; more generally, for $B = k[T^{\{n\}}, T^{\{n+r\}}]$ and the element $T^{\{n+2r\}} \otimes_{\{B\}} 1$, provided that n does not divide $2r$.

[^N.D.E-V-11]: N.D.E.: this second viewpoint will be used in 3.f) and in the proof of 6.1.

[^N.D.E-V-12]: N.D.E.: "accents" in the original.

[^N.D.E-V-13]: N.D.E.: This will play a crucial role in the proof of lemma 6.1.

[^N.D.E-V-14]: N.D.E.: The original has been modified to make explicit the isomorphism below.

[^N.D.E-V-15]: N.D.E.: Reflexivity follows from the existence of $s : X_{\{0\}} \rightarrow X_{\{1\}}$ which is a section of both $d_{\{0\}}$ and $d_{\{1\}}$; symmetry follows from the existence of the involution σ of $X_{\{1\}}$ which "exchanges $d_{\{0\}}$ and $d_{\{1\}}$ ", that is, satisfies $d_{\{0\}} \circ \sigma = d_{\{1\}}$ and $d_{\{1\}} \circ \sigma = d_{\{0\}}$, cf. § 1, (3), (3 bis) and (†).

[^N.D.E-V-16]: N.D.E.: Since $d_{\{0\}} = d_{\{1\}} \circ \sigma$, where σ is an involutive automorphism of $X_{\{1\}}$, these two conditions are symmetric in $d_{\{1\}}$ and $d_{\{0\}}$; moreover, one has $d_{\{0\}} \circ d_{\{1\}}^{-1}(x) = d_{\{1\}} \circ d_{\{0\}}^{-1}(x)$.

[^N.D.E-V-17]: N.D.E.: One cannot omit hypothesis b). Indeed, H. Hironaka has given an example of an action of the finite group $G = \mathbb{Z}/2\mathbb{Z}$ on a proper $\mathcal{C}$ -variety $X_{\{0\}}$ such that the quotient $X_{\{0\}}/G$ is an algebraic space which is not a scheme ([Hi62], see also [Mum65], Chap. 4, § 3).

[^N.D.E-V-18]: N.D.E.: We have added that p is open, by taking up the analogous proof given in 6.1.

[^N.D.E-V-19]: N.D.E.: Note that, in this case, $X_{\{1\}} \rightarrow X_{\{0\}} \times_{\{X_{\{0\}}\}} X_{\{0\}}$ is therefore an immersion (EGA I, 5.3.10); see also VI_B, 9.2.1. On the other hand, for the existence of the quotient (in the category of schemes or that of algebraic spaces) under the weaker hypothesis that $d_{\{0\}}$ and $d_{\{1\}}$ are finite (but not necessarily flat), see [An73], § 1.1, [Fe03], [Ko08]...

[^N.D.E-V-20]: N.D.E.: We have made explicit the consequences which follow; see [Ray67a], th. 1 (iii) and the proof given further on, at the end of section 5.

[^N.D.E-V-21]: N.D.E.: We have expanded on the original in what follows; in particular, we have added lemma 4.1.1, taken from [DG70], III, § 2.4, Lemma 4.3.

[^N.D.E-V-22]: N.D.E.: We have inserted this lemma, which is used several times in this Exposé and in subsequent Exposés (VI_A, VI_B). It appeared as Lemma VI_B, 4.5.1 in the original 1965 edition of SGAD.

[^N.D.E-V-23]: N.D.E.: Note the permutation of pages in Lecture Notes 151; the real order is 265-266-268-269-267-270-271.

[^N.D.E-V-24]: N.D.E.: We have added the following lemma, taken from [DG70], I, § 5, Prop. 1.5 (see also the proof of EGA IV_3, 8.11.5), used implicitly in the original, and explicitly in [DG70], III, § 2, 4.6. It is moreover useful in th. 7.1 further on.

[^N.D.E-V-25]: N.D.E.: cf. Lemma 4.1.2.

[^N.D.E-V-26]: N.D.E.: We have added what follows.

[^N.D.E-V-27]: N.D.E.: indeed, since $d_{\{0\}}$ (resp. $d_{\{1\}}$) is surjective, flat and finite, hence faithfully flat and affine, then $d_{\{2\}}$ is of rank n above a neighborhood of a point x of $X_{\{1\}}$ if and only if $d_{\{1\}}$ is of rank n above a neighborhood of $d_{\{0\}}(x)$ (resp. $d_{\{1\}}(x)$).

[^N.D.E-V-28]: N.D.E.: one has $d_{\{1\}} \circ d_{\{1\}}^{-1}(x) = d_{\{0\}} \circ d_{\{1\}}^{-1}(x)$, cf. N.D.E. 16 in theorem 4.1.

[^N.D.E-V-29]: N.D.E.: We have added the reference to lemma 4.1.1, cf. [DG70], III, § 5.2, p. 313.

[^N.D.E-V-30]: N.D.E.: We have added this paragraph.

[^N.D.E-V-31]: N.D.E.: If $x, y \in E$, there exists $z \in X_{\{1\}}$ such that $d_{\{1\}}(z) = x$ and $d_{\{0\}}(z) = y$, that is, z belongs to the set $v^{-1}(x)$, which is finite by (1). Hence E is contained in the finite set

$d_{\{0\}}(v^{-1}(x)) = d_{\{0\}} d^{-1}_{\{1\}}(x) \cap U$.

[^N.D.E-V-32]: N.D.E.: We have slightly modified what follows; in particular, in lemma 6.1, the additional hypothesis that $d_{\{0\}}$ be flat has been moved to (iv), and (ii) has been separated into (i') + (ii), and the second assertion of (i') added.

[^N.D.E-V-33]: N.D.E.: We have expanded what follows, in particular the fact that U is a quasi-section of the groupoid induced on $X'_{\{0\}}$.

[^N.D.E-V-34]: N.D.E.: Let us mention here the article of S. Keel and S. Mori ([KM97]), where the following theorem is established. Let X be an algebraic space of finite type over a locally Noetherian base S , and $j : R \rightarrow X \times_S X$ a flat groupoid whose stabilizer $j^{-1}(\Delta_X)$ is finite over X ; there then exists an algebraic space which is a geometric quotient of X by R and a uniform categorical quotient; moreover, if j is separated, this quotient is separated. In particular, if a flat S -group scheme G acts properly on X , with finite stabilizer (i.e., the morphism $G \times_S X \rightarrow X \times_S X$, $(g, x) \mapsto (x, g \cdot x)$, is proper and the stabilizer of the diagonal is finite over X), then there exists a geometric quotient $X \rightarrow X/G$. In the case of a reductive S -group scheme G , this is a result of J. Kollár ([Ko97]).

[^N.D.E-V-35]: N.D.E.: This hypothesis on $X_{\{0\}}$ is necessary, cf. N.D.E. 17 in Th. 4.1.

[^N.D.E-V-36]: N.D.E.: In TDTE III, Th. 6.1, it is indicated that $Y \rightarrow S$ is quasi-projective if S is Noetherian. The editors have not seen how to deduce this from the local existence of quasi-sections.

[^N.D.E-V-37]: N.D.E.: We have made explicit the consequences which follow; see [Ray67a], th. 1 (iii) and the end of the proof of the theorem. Let us also mention that another proof of th. 7.1 in the case of an equivalence relation, based on the existence of Hilbert schemes, is given in [AK80], Th. 2.9, see also [BLR90], § 8.2, Th. 12; it is moreover shown there, in this case, that $Y \rightarrow S$ is quasi-projective.

[^N.D.E-V-38]: N.D.E.: Indeed, if one has constructed such an open neighborhood U_z for every point z closed relative to S , then the union of these U_z covers $X_{\{0\}}$, since each fiber over S of the closed complement is a Noetherian scheme without closed points, hence empty.

[^N.D.E-V-39]: N.D.E.: We have added details, and made explicit the role of the hypothesis that $d_{\{0\}}$ and $d_{\{1\}}$ are proper in theorem 7.1. (One can compare with the statement and proof of theorem 8.1, where this properness hypothesis is omitted.)

[^N.D.E-V-40]: N.D.E.: If $f : X \rightarrow Y$ is a morphism locally of finite type, the set of x in X isolated in their fiber $f^{-1}(f(x))$ is open in X : in EGA III, 4.4.10, this is deduced, for Y locally Noetherian, from Zariski's "Main Theorem"; on the other hand, for arbitrary Y , this follows from Chevalley's semi-continuity theorem (EGA IV_3, 13.1.3 and 13.1.4). Consequently, f is quasi-finite at x if and only if f is of finite type at x and x is isolated in $f^{-1}(f(x))$; this will be used further on, cf. N.D.E. 42.

[^N.D.E-V-41]: N.D.E.: We have expanded on the original in what follows.

[^N.D.E-V-42]: N.D.E.: The conditions are sufficient, by base change (cf. EGA II, 6.2.4 (iii) and EGA IV_2, 2.1.4). Conversely, put $y = d'(x)$ and $z = u(y) = d(v(x))$, and suppose d flat at x and u (hence also v) flat. Then $0_{\{v(x)\}} \rightarrow 0_{\{x\}}$ is faithfully flat, as is $0_{\{z\}} \rightarrow 0_{\{y\}} \rightarrow 0_{\{x\}}$. Consequently, $0_{\{z\}} \rightarrow 0_{\{v(x)\}}$ is faithfully flat (cf. EGA IV_2, 2.2.11 (iv)). Finally, suppose d locally of finite type and d' quasi-finite at x . Then $v(x)$ is isolated in its fiber $d^{-1}(z)$, since x is in its fiber $d'^{-1}(y) = d^{-1}(z) \otimes_{\kappa(z)} \kappa(y)$. Hence, by Chevalley's semi-continuity theorem, there exists an open neighborhood of $v(x)$ every point of which is isolated in its fiber (EGA IV_3, 13.1.3 and 13.1.4), so that d is quasi-finite at $v(x)$.

[^N.D.E-V-43]: N.D.E.: We have modified the sequel, taking advantage of the additions made in lemma 6.1.

[^N.D.E-V-44]: N.D.E.: There exists a largest open W of $X_{\{0\}}$ satisfying the conclusions of the theorem. Indeed, let W be an open as in the theorem and $W^{\sharp}$ a dense saturated open contained in W . Since p is open, $V^{\sharp} = p(W^{\sharp})$ is an open of V , and $W^{\sharp} = p^{-1}(V^{\sharp})$, since $W^{\sharp}$ is saturated. By lemma 1.1, $V^{\sharp}$ is a cokernel for the groupoid induced on $W^{\sharp}$. Thus one can glue along their intersection $W^{\sharp}$ two opens W and W' satisfying the conclusions of the theorem, and the conditions (i), (ii), (iii), (iv), as well as the fact that p and $V \rightarrow S$ are locally of finite presentation, are preserved. The conclusion (ii') follows, as in the proof of 6.1 (ii), from the hypothesis that $X_{\{0\}}$ is of finite type over S Noetherian. Moreover, lemmas 1.1 and 1.2 also show that the union of all saturated opens U of $X_{\{0\}}$ such that the open $p(U)$ of Y is a scheme and $p|_U : U \rightarrow p(U)$ is a morphism of schemes is the largest saturated open Ω of $X_{\{0\}}$ satisfying condition (i) of 8.1. Theorem 8.1 shows that Ω contains

a dense open U , but it is not immediate that Ω satisfies properties (ii) to (iv). On this subject, the reader may consult [Ray67a], [Ray67b], and Appendix I of [An73], which give more precise results, and study the question of the representability of the quotient S -sheaf (fppf) $\tilde{X}/R$ (where one has denoted by R the groupoid X_{ast} with base $X = X_{\{0\}}$), all this under weaker hypotheses (S an arbitrary scheme, X a scheme locally of finite type over S , and R an S -groupoid with base X such that $d_{\{0\}}$ (and therefore $d_{\{1\}}$) is flat and of finite presentation). Let us mention in particular the following results. If $\tilde{X}/R$ is representable by an S -scheme Y , then Y is also the cokernel in the category (Esp. An) . The converse is in general false (cf. example 0.4 of [Mum65], Chap. 0, § 3, cited in [Ray67a], Rem. 1), but is true if $d = (d_{\{0\}}, d_{\{1\}})$ is an immersion. Under this hypothesis, the morphism $p : \Omega \rightarrow Z := \Omega/R_{\Omega}$ is faithfully flat and of finite presentation; if moreover S is locally Noetherian, then a point x of codimension 1 in X belongs to Ω if and only if the graph of the groupoid induced on $\text{Spec}(O_{X,x})$ is closed. For all this, see [Ray67a], Prop. 1, [Ray67b], Prop. 1 and Theorems 2, 1 and 4, and [An73], Theorems 5 and 6 pages 66–67, and Prop. 3.3.1 page 49. (See also, in the case of an action of an algebraic group on an algebraically closed field k , the article [DR81].)

[^N.D.E-V-45]: N.D.E.: Indeed, let η be such a generic point. The hypotheses imply that $O_{X_{\{0\}}, \eta}$ is an Artinian local ring, and $O_{F_{\{1\}}, \eta}$ a finitely generated $O_{X_{\{0\}}, \eta}$ -module. Therefore, by SGA 1, VIII 6.5, there exists an open neighborhood of η above which $\tilde{d}_{\{1\}}$ is finite.

[^N.D.E-V-46]: N.D.E.: We have expanded what follows, to highlight theorem 9.0 below.

[^N.D.E-V-47]: N.D.E.: The original states that this follows from proposition 9.1 below. We were not able to reconstruct that argument. The proof that follows was indicated to us by O. Gabber.

[^V-9-1]: Cf. EGA IV₄, 17.7.5 for a more general result.

[^N.D.E-V-48]: N.D.E.: cf. EGA IV₁, 1.4.4.

[^N.D.E-V-49]: N.D.E.: Here too, there exists a largest open U of X satisfying the conclusions of the theorem, cf. N.D.E. 44.

[^N.D.E-V-50]: N.D.E.: If one assumes in addition that G is a reductive S -group scheme and that the (free) action of G on X is linearizable, then it is known that $G \backslash X$ is representable and that $X \rightarrow G \backslash X$ is a (left) G -torsor. This follows from results of Raynaud and Seshadri and is found in the article [CTS79] (proposition 6.11).

[^N.D.E-V-51]: N.D.E.: This is point (2) of theorem 3 of [Ray67b]. In this Note another proof of th. 10.1.1 is sketched.

[^N.D.E-V-52]: N.D.E.: Here too, there exists a largest open U of X satisfying the conclusions of the theorem; moreover, a point x in X of codimension 1 in X belongs to U if and only if the morphism $(G_X/F) \times_X \text{Spec}(O_{X,x}) \rightarrow \text{Spec}(O_{X,x}) \times_S \text{Spec}(O_{X,x})$ is a closed immersion, cf. N.D.E. 44.

Exposé VI_A. Generalities on algebraic groups

<!-- label: III.VI_A -->

by P. Gabriel

> [^N.D.E-VI_A-0] Version of 13/10/2024.

Throughout this entire chapter, A will denote an Artinian local ring with residue field k . A group scheme G over $\text{Spec}(A)$ will be called simply an A -group. This A -group is said to be *locally of finite type* if the underlying scheme is locally of finite type over A ; it is said to be *algebraic* if the underlying scheme is of finite type over A .

<!-- original page 287 -->

0. Preliminary remarks

<!-- label: III.VI_A.0 -->

0.1.

Let us first consider a group scheme G over an arbitrary scheme S . We call *multiplication* the structural morphism $\mu : G \times_S G \rightarrow G$, and *inversion* the morphism $c : G \rightarrow G$ defined by the equalities $c(T)(x) = x^{-1}$ (with T a scheme over S and x an element of $G(T)$). If U and V are subsets of the underlying set of G , we write $U \cdot V$ for the image under the multiplication morphism of the part of $G \times_S G$ consisting of points whose first projection lies in U and second projection in V . Likewise, the notations U^{-1} and $c(U)$ are equivalent.

Let pr_1 denote the projection of $G \times_S G$ onto the first factor and $\sigma : G \times_S G \rightarrow G \times_S G$ the morphism with components pr_1 and μ . For every S -scheme T , $\sigma(T)$ is the map $(x, y) \mapsto (x, xy)$; it follows that σ is an automorphism. The composition of this automorphism with the projection pr_2 of $G \times_S G$ onto the second factor is the multiplication morphism. When G is flat over S , pr_2 and hence μ are flat morphisms; when G is smooth over S , pr_2 and hence μ are smooth morphisms, etc.

<!-- original page 288 -->

0.2.

We assume from now on that S is the spectrum of an Artinian local ring A with residue field k . We denote by $(\text{Sch}/k)_{\text{red}}$ the category of reduced schemes over k . For every scheme X over A , the reduced scheme X_{red} is an object of $(\text{Sch}/k)_{\text{red}}$, and the functor $X \mapsto X_{\text{red}}$ is right adjoint to the inclusion of $(\text{Sch}/k)_{\text{red}}$ into (Sch/A) . It follows that, for every A -group G , G_{red} is a group in the category $(\text{Sch}/k)_{\text{red}}$, [N.D.E-VI A-1] i.e., for every reduced k -scheme T , $G_{\text{red}}(T)$ is equipped with a group structure, functorial in T . One should beware that G_{red} is not necessarily a k -group, since the "multiplication" is only a morphism from $(G_{\text{red}} \times_k G_{\text{red}})_{\text{red}}$ into G_{red} . [N.D.E-VI A-2]

<!-- original page 294 -->

[N.D.E-VI A-3] However, if k is a perfect field, the inclusion of $(\text{Sch}/k)_{\text{red}}$ into (Sch/k) commutes with products, so that groups in the category $(\text{Sch}/k)_{\text{red}}$ are identified with group schemes over k whose underlying scheme is reduced. In this case, if G is a k -group, G_{red} is a group subscheme of G ; this subgroup is not in general normal in G .

For example, if k is a field of characteristic 3, the constant group $(\mathbb{Z}/2\mathbb{Z})_k$ acts non-trivially on the diagonalizable group $D_k(\mathbb{Z}/3\mathbb{Z})$ (cf. Exp. I, 4.1 and 4.4); if G denotes the semidirect product of $D_k(\mathbb{Z}/3\mathbb{Z})$ by $(\mathbb{Z}/2\mathbb{Z})_k$ defined by this action, G_{red} is identified with $(\mathbb{Z}/2\mathbb{Z})_k$ and is not normal in G . [N.D.E-VI A-4]

Let k be an arbitrary field, $k^{\text{p}^{\infty}}$ its perfect closure, and H a group in the category $(\text{Sch}/k)_{\text{red}}$. Then $H \otimes_k k^{\text{p}^{\infty}}$ is a group scheme over the perfect field $k^{\text{p}^{\infty}}$. Since $H \otimes_k k^{\text{p}^{\infty}}$ and $H \otimes_k k^{\text{p}^{\infty}}$ have the same underlying topological space, one sees that the groups of $(\text{Sch}/k)_{\text{red}}$ share with k -groups certain topological properties invariant under extension of the base field: for example, it will follow from 0.3 and the remarks just made that every group of $(\text{Sch}/k)_{\text{red}}$ is separated.

<!-- original page 289 -->

We shall encounter groups of $(\text{Sch}/k)_{\text{red}}$ in what follows whenever we deal with a non-empty, locally closed subset U of an A -group G such that $U \cdot U = U$ and $U^{-1} = U$: indeed, the reduced subscheme of G defined by U is then a group of $(\text{Sch}/k)_{\text{red}}$.

0.3.

An A -group G is always separated, since the unit section $e : \text{Spec } A \rightarrow G$ is a closed immersion. Indeed, let x be the unique point of $\text{Spec } A$ and η the structural morphism $G \rightarrow \text{Spec } A$. Since $\eta \circ e = \text{id}_{\text{Spec } A}$, for every affine open $U = \text{Spec } B$ of G containing $e(x)$, the morphism $B \rightarrow A$ has a section, and so is surjective. It follows that e is a closed immersion. [N.D.E-VI A-5] Now the diagonal of $G \times_S A$ is identified with the functor from $(\text{Sch}/A)^{\circ}$ with values in (Ens) that associates to every scheme S over A the inverse image of the unit element of $G(S)$ under the map $\phi(S) : (x, y) \mapsto x \cdot y^{-1}$ from $G(S) \times G(S)$ to $G(S)$. We therefore have the cartesian square below, so that the diagonal morphism, being obtained from a closed immersion by base change, is itself a closed immersion:

```

```text
 φ
G × S G → G
 ↓ ↑
diagonal unit section
 G Spec A.
```

```

<!-- original page 295 -->

0.4.

[^N.D.E-VI_A-6] Let G be an A -scheme. We shall say that a point g of G is *strictly rational over* A if there exists an A -morphism $s : \operatorname{Spec} A \rightarrow G$ sending the unique point of $\operatorname{Spec} A$ to g , i.e. if the morphism $A \rightarrow \mathcal{O}_{G,g}$ admits a retraction. Note that one then has $\kappa(g) = k$, and so g is a closed point of G (if B is the ring of an affine open neighborhood of g and $\mathfrak{p}$ the prime ideal of B corresponding to g , then $B/\mathfrak{p} \subset k$ is a finite A -algebra, hence an integral Artinian ring, hence a field).

<!-- original page 290 -->

Suppose henceforth that G is an A -group; then such a section $s : \operatorname{Spec} A \rightarrow G$ defines an automorphism r_s of the scheme G over A , which we call *right translation by* s : for every morphism $\pi : S \rightarrow \operatorname{Spec} A$, $r_s(\pi)$ is the automorphism of $G(S)$ defined by $x \mapsto x \cdot G(\pi)(s)$, for every $x \in G(S)$. Similarly, we write ℓ_s for the *left translation by* s , i.e. the automorphism of G defined by the equalities $\ell_s(\pi)(x) = G(\pi)(s) \cdot x$, for every $x \in G(S)$.

Since $G \otimes_A k$ and G have the same underlying topological space G , since $G \otimes_A k$ is a k -group, and since $s \otimes_A k$ depends only on g and not on s , one sees that the automorphisms of G induced by r_s and ℓ_s (or by $r_s \otimes_A k$ and $\ell_s \otimes_A k$) depend only on g and not on s ; when P is a subset of G , we may therefore write $r_g(P)$ or $P \cdot g$ (resp. $\ell_g(P)$ or $g \cdot P$) instead of $r_s(P)$ (resp. $\ell_s(P)$), in agreement with 0.1.

Remark 0.4.1. *If g is a strictly rational point of G and if $A \rightarrow A'$ is a morphism of Artinian local rings, then $G' = G \otimes_A A'$ has a unique point g' above g , and g' is strictly rational over A' ; moreover, if one writes P' for the inverse image of P in G' , then $P' \cdot g'$ is the inverse image of $P \cdot g$ (cf. EGA I, 3.4.8).*

<!-- label: III.VI_A.0.4.1 -->

Proposition 0.5. [^N.D.E-VI_A-7] *Let G be an A -group and U, V two dense open subsets of G . Then $U \cdot V$ (i.e. the image of $U \times_A V$ under multiplication) is equal to the whole underlying space of G .*

<!-- label: III.VI_A.0.5 -->

Proof. *Since G and $G \otimes_A k$ have the same underlying space, we may, possibly replacing A by k and G by $G \otimes_A k$, assume that $A = k$. Let $g \in G$. Set $K = \kappa(g)$; then left translation ℓ_g is an automorphism of G_K . Since the projection $G_K \rightarrow G$ is open, U_K and V_K are dense open subsets of G_K , as is the image of V_K under λ_g . There exists therefore $v \in V_K$ such that $u = \ell_g(v)$ belongs to U_K . Let L be an extension of K containing $\kappa(v)$ (and so $\kappa(u)$), and let g_L and v_L be the L -points of G_L deduced from g and v . Then $g_L \cdot v_L = u$ is a point of G_L above u , and so $g_L = u \cdot v^{-1}_L$ lies above $U \cdot V$, whence $g \in U \cdot V$, which proves the proposition.

<!-- original page 296 -->

Corollary 0.5.1. [^N.D.E-VI_A-8] *If G is an irreducible A -group, then G is quasi-compact.*

<!-- label: III.VI_A.0.5.1 -->

Proof. *Let U be a non-empty affine open subset of G ; then U is dense in G , so by 0.5 the morphism $\mu : U \times_A U \rightarrow G$ is surjective, and therefore G is quasi-compact since $U \times_A U$ is.

Corollary 0.5.2. [^N.D.E-VI_A-9] *Let G be an A -group scheme, and H a group subscheme of G over A . Then H is closed.*

<!-- label: III.VI_A.0.5.2 -->

Proof. Let k^* be the perfect closure of the residue field k of A . Since the underlying topological spaces of G and H are unchanged under the base change $A \rightarrow k \rightarrow k^*$, we may suppose that $A = k$ is a perfect field. We may then suppose that G and H are reduced, hence geometrically reduced.

Let $\bar{H}$ be the closure of H ; then $\mu^{-1}(H^-)$ is a closed subset of $G \times G$ containing $H \times H$. Since the morphism $H \rightarrow \operatorname{Spec} k$ (resp. $\bar{H} \rightarrow \operatorname{Spec} k$) is universally open, and since H is dense in $\bar{H}$, then $H \times H$ is dense in $H \times \bar{H}$ and $H \times H$ is dense in $\bar{H} \times \bar{H}$, so $H \times H$ is dense in $\bar{H} \times \bar{H}$. Therefore $\mu(H^- \times H^-) \subset H^-$, and so, since $\bar{H} \times \bar{H}$ is reduced, μ induces a morphism $\mu' : H^- \times H^- \rightarrow H^-$.

Let then $g \in \bar{H}$, and set $K = \kappa(g)$. Since the projection $\bar{H}_{\{K\}} \rightarrow \bar{H}$ is open, H_K and $\ell_{\{g\}}(H_K)$ are two dense open subsets of $\bar{H}_{\{K\}}$, so there exist $u, v \in H_K$ such that $\ell(g)(v) = u$. One concludes, as in the proof of 0.5, that g belongs to $H \cdot H = H$, whence $\bar{H} = H$.

1. Local properties of an A -group locally of finite type

<!-- label: III.VI_A.1 -->

<!-- original page 292 -->

We shall first see that, if G is locally of finite type and flat over A , one can "make strictly rational any closed point of G " by means of a finite, flat extension of the base.

1.1.

Unless explicit mention is made to the contrary, we assume from now on that G is an A -group locally of finite type. When A is a field k , we shall obtain in Exposé VII_B very precise results on the local rings of G . [N.D.E-VI_A-10] We content ourselves here with a few elementary results:

****Proposition 1.1.1.**** *Let x be a point of an A -group G locally of finite type and flat over A . Then the local ring $\mathcal{O}_{G,x}$ is Cohen–Macaulay, and there exists a system $a_1, \dots, a_n$ of parameters of $\mathcal{O}_{G,x}$ such that $\mathcal{O}_{G,x}/(a_1, \dots, a_n)$ is a finite and flat (hence finite and free) A -module.*

<!-- label: III.VI_A.1.1.1 -->

We first assume A equal to its residue field k ; it then suffices to prove that $\mathcal{O}_{G,x}$ is Cohen–Macaulay and one may limit oneself to the case where x is a closed point (cf. EGA 0_IV, 16.5.13). By Lemma 1.1.2 below, G contains a closed point y such that $\mathcal{O}_{G,y}$ is Cohen–Macaulay. By SGA 1, I § 9, this amounts to saying that, for every finite extension K of the base field k and every point $\bar{y}$ of $\bar{G} = G \times_k K$ above y , $\mathcal{O}_{\bar{G},\bar{y}}$ is Cohen–Macaulay. If the extension K has been chosen large enough – i.e. if K contains a normal extension of k containing the residue fields $\kappa(y)$ and $\kappa(x)$ – then $\bar{y}$ is (strictly) rational over K , as is every point $\bar{x}$ of $\bar{G}$ above x . [N.D.E-VI_A-11] Since the automorphism $r_{\bar{x}} \circ (r_{\bar{y}})^{-1}$ sends $\bar{y}$ to $\bar{x}$, it follows that $\mathcal{O}_{\bar{G},\bar{y}}$, and hence $\mathcal{O}_{G,x}$ (SGA 1, I § 9), are Cohen–Macaulay.

<!-- original page 293 -->

When A is again assumed arbitrary, the preceding argument applies to G_A , so that $\mathcal{O}_{G_A,x}$ is Cohen–Macaulay. If $a_1, \dots, a_n$ is a sequence of elements of $\mathcal{O}_{G,x}$ whose image in $\mathcal{O}_{G_A,x}$ is a system of parameters, it follows from SGA 1, IV 5.7 or from EGA 0_IV, 15.1.16, that $a_1, \dots, a_n$ is an $\mathcal{O}_{G,x}$ -regular sequence and that $\mathcal{O}_{G,x}/(a_1, \dots, a_n)$ is finite and flat (hence finite and free) over A .

****Lemma 1.1.2.**** *Every non-empty scheme X , locally of finite type over an Artinian ring A , contains a closed point x whose local ring is Cohen–Macaulay.*

<!-- label: III.VI_A.1.1.2 -->

We may of course assume X affine with algebra B , and argue by induction on $\dim X$ (the assertion is clear if X is discrete, since all local rings are then Artinian). Since B is of finite type over A , if $\dim B > 0$, B contains an element a that is non-invertible and not a zero-divisor. [N.D.E-VI_A-12] The closed subscheme $X' = \operatorname{Spec} B/(a)$ of X is then of dimension strictly less than $\dim X$, and by induction contains a closed point x such that $\mathcal{O}_{X',x}$ is Cohen–Macaulay. Since $\mathcal{O}_{X',x} = \mathcal{O}_{X,x}/(a)$ and a is non-invertible and

not a zero-divisor in $\mathcal{O}_{X,x}$, then $\mathcal{O}_{X,x}$ is Cohen–Macaulay (see also EGA IV₂, 6.11.3).

****Proposition 1.2.**** *Let A be an Artinian local ring, G an A -group locally of finite type and flat over A , and x a closed point of G . There exists an A -algebra A' that is local, finite and free over A , such that every point of $G \times_A A'$ above x is strictly rational over A' .*

<!-- label: III.VI_A.1.2 -->

<!-- original page 294 -->

[^N.D.E-VI_A-13] Indeed, let k_1 be a normal extension of finite degree of k containing the residue field $\kappa(x)$ of x . By Lemma V 4.1.2, there exists an A -algebra A_1 that is local, finite and free over A , with residue field k_1 . In this case (cf. N.D.E. (11)) all the points $g_1, \dots, g_n$ of $G \times_A A_1$ above $x \in G$ have k_1 as residue field (i.e. $g_1, \dots, g_n$ are rational over A_1 in the sense of Exp. V, § 4.e)).

Let then $B_1, \dots, B_n$ be the local rings of $g_1, \dots, g_n$. By 1.1.1, $B_1, \dots, B_n$ have quotients $B'_1, \dots, B'_n$ that are Artinian and finite and free over A_1 . Set $A' = B'_1 \times_{A_1} \dots \times_{A_1} B'_n$. Then A' is local, finite and free over A_1 and, for each $i = 1, \dots, n$, we have surjective homomorphisms

```
```text
B_i \otimes_{A_1} A' \twoheadrightarrow B'_i \otimes_{A_1} A' \twoheadrightarrow A',
```

the second induced by the multiplication map  $B'_i \times_{A_1} B'_i \twoheadrightarrow B'_i$ . Consequently,  $A'$  answers the question.

### 1.3.

Let  $e$  denote the unit element (or origin) of  $G$ , i.e. the image of the unique point of  $\operatorname{Spec} A$  by the unit section  $\operatorname{Spec} A \rightarrow G$ . By definition itself,  $e$  is strictly rational over  $A$ .

**\*\*Proposition 1.3.1.\*\*** [^N.D.E-VI\_A-14] \*Let  $G$  be a group locally of finite type and flat over an Artinian ring  $A$ , and  $K$  (resp.  $\bar{k}$ ) the perfect closure (resp. an algebraic closure) of the residue field  $k$  of  $A$ .\*

\*(1) For every closed point  $x$  of  $\bar{G} = G \times_k \bar{k}$ , the local rings  $\mathcal{O}_{\bar{G}, \bar{e}}$  and  $\mathcal{O}_{\bar{G}, x}$  are isomorphic. In particular, the tangent spaces  $T_e G$  and  $T_x G$  have the same dimension.\*

\*(2) The following assertions are equivalent:\*

\*(i)  $G \times_A K$  is reduced.\* \*(i bis)  $\mathcal{O}_{G, e} \times_A K$  is reduced.\* \*(ii)  $G$  is smooth over  $A$ .\* \*(ii bis)  $G$  is smooth over  $A$  at the origin.\*

<!-- label: III.VI\_A.1.3.1 -->

**\*Proof.\*** (1) Let  $x$  be a closed point of  $\bar{G}$ ; there is exactly one  $\bar{k}$ -morphism  $s : \operatorname{Spec} \bar{k} \rightarrow \bar{G}$  whose image is  $x$ ; right translation  $r_s$  then induces an isomorphism from  $\mathcal{O}_{\bar{G}, \bar{e}} = \mathcal{O}_{G, e} \times_k \bar{k}$  onto  $\mathcal{O}_{\bar{G}, x}$ , whence assertion (1).

<!-- original page 295 -->

Let us prove assertion (2). By SGA 1, II.2.1, one reduces immediately to the case where  $A$  is a field ( $A = k$ ). The implications (i)  $\Rightarrow$  (i bis), (ii)  $\Rightarrow$  (ii bis), (ii)  $\Rightarrow$  (i) and (ii bis)  $\Rightarrow$  (i bis) are obvious, so it suffices to prove that (i bis) implies (ii).

Now, it follows from (i bis) that  $\mathcal{O}_{G, e} \times_k \bar{k}$  is reduced. Hence, by (1),  $\mathcal{O}_{\bar{G}, x}$  is reduced for every closed point  $x$  of  $\bar{G}$ , so that  $\bar{G}$  is reduced. Then, since  $\bar{G}$  is locally of finite type over  $\bar{k}$ , there exists at least one closed point  $y$  such that  $\mathcal{O}_{\bar{G}, y}$  is regular. Since, by (1), the local rings of the closed points of  $\bar{G}$  are all isomorphic to  $\mathcal{O}_{\bar{G}, \bar{e}}$ , one sees that all these local rings are regular, so that  $\bar{G}$  is smooth over  $\bar{k}$ , and hence  $G$  is smooth over  $k$ .

[^N.D.E-VI\_A-15] One may now give the examples below, signalled by M. Raynaud, of group schemes  $G$  over a non-perfect field  $k$  such that  $G_{\text{red}}$  is not a group scheme over  $k$ .

**\*\*Examples 1.3.2.\*\*** \*Let  $k$  be a non-perfect field of characteristic  $p > 0$ ,  $t \in k - k^{\{p\}}$ ,  $\bar{k}$  an algebraic closure of  $k$ , and  $\alpha \in \bar{k}$  such that  $\alpha^p = t$ .\*

<!-- label: III.VI\_A.1.3.2 -->

(1) Consider the additive group  $G_{\{a,k\}} = \operatorname{Spec} k[X]$ , and let  $G$  be the group subscheme, finite over  $k$ , defined by the additive polynomial  $X^{p^2} - tX^p$ . Then\*

```
```text
G_red = Spec k[X]/X(X^{p-1}) - t)
```

is étale at the origin. If it were a group scheme over k , it would be smooth (by 1.3.1); but G_{red} is not geometrically reduced, so it is not a group scheme over k .*

(2) Consider $G^4_{\{a,k\}} = \operatorname{Spec} k[X, Y, U, V]$ and let G be the group subscheme defined by the ideal I generated by the additive polynomials $P = X^p - tY^p$ and $Q = U^p - tV^p$. Then G is of dimension 2 and irreducible, since $(G_{\bar{k}})_{\text{red}} \cong \operatorname{Spec} \bar{k}[Y, V]$ is.*

Let $A = k[X, Y, U, V]$ and $\mathfrak{m}$ its augmentation ideal. Denote by x, y, u, v the images of dX, dY, dU, dV in $\Omega^1_{A/k} \otimes_A (A/\mathfrak{m})$, viewed as linear forms on the tangent space $k^4 = T_{\{0\}} G^4_{\{a,k\}}$. Let us show that the subspace $E = T_{\{0\}} G_{\text{red}}$ equals k^4 . Otherwise, there would exist a linear form $f = ax + by + a'u + b'v$, with $a, b, a', b' \in k$ not all zero, vanishing on E . Recall that the formation of $\Omega^1_{A/k}$ (and hence of tangent spaces) commutes with base change (cf. EGA IV_4, 16.4.5), and identify f with its image in $(\bar{k}^4)^*$. Since $(G_{\bar{k}})_{\text{red}} \subset (G_{\text{red}})_{\bar{k}}$, then f vanishes on the subspace $T_{\{0\}} (G_{\bar{k}})_{\text{red}}$ of $\bar{k}^4$, which is defined by the equations $g_{\{1\}} = x - \alpha y$ and $g_{\{2\}} = u - \alpha v$, and so $f = \lambda g_{\{1\}} + \mu g_{\{2\}}$, with $\lambda, \mu \in k$. Now $\lambda g_{\{1\}} + \mu g_{\{2\}}$ belongs to k^4 only if $\lambda = \mu = 0$! This contradiction shows that $E = k^4$, and so $T_{\{0\}} (G_{\text{red}})_{\bar{k}} = \bar{k}^4$.

On the other hand, $R = XV - YU$ belongs to $\sqrt{I}$, since $R^p = (X^p - tY^p)V^p - Y^p(U^p - tV^p)$. Consequently, the tangent space F at the point $(\alpha, 1, \alpha, 1)$ of $(G_{\text{red}})_{\bar{k}}$ is contained in the hyperplane H of $\bar{k}^4$ with equation $\alpha dv + dX - dU - \alpha dY = 0$, hence is of dimension ≤ 3 . [^N.D.E-VI_A-16] Therefore, by point (1) of 1.3.1, G_{red} is not a group scheme over k .

2. Connected components of an A -group locally of finite type

<!-- label: III.VI_A.2 -->

<!-- original page 296 -->

2.1.

Let us first consider an arbitrary A -group G , and let G' be the connected component of the origin e of G . This connected component is evidently closed, so that we may identify it with the reduced closed subscheme of G having G' as underlying space. [^N.D.E-VI_A-17]

****Proposition 2.1.1.**** *For every extension K of the residue field k of A , $G' \otimes_A K$ has as underlying space the connected component of the origin in the K -group $G \otimes_A K$ (i.e. G' is geometrically connected).*

<!-- label: III.VI_A.2.1.1 -->

Indeed, let $(G \otimes_A K)'$ be the connected component of the origin in $G \otimes_A K$. Since the image of $(G \otimes_A K)'$ in G is connected and contains the unit element of G , this image is contained in G' , so that $(G \otimes_A K)'$ is contained in the inverse image

<!-- original page 300 -->

$G' \otimes_A K$ of G' in $G \otimes_A K$. The proposition therefore follows from the connectedness of $G' \otimes_A K$, which is proved in Lemma 2.1.2.

****Lemma 2.1.2.**** *Let X and Y be two connected schemes over a field k . If X contains a rational point, then $X \times_k Y$ is connected.*

<!-- label: III.VI_A.2.1.2 -->

We give below a direct proof of this result from EGA IV₂ (4.5.8 and 4.5.14).

Suppose first Y non-empty, connected and affine, with algebra B . In this case, $X \times_k Y$ is the spectrum of the quasi-coherent $\mathcal{O}_X$ -algebra $\mathcal{B} = \mathcal{O}_X \otimes_k B$. We want to show that every subset U of $X \times_k Y$ that is open, closed, and non-empty coincides with $X \times_k Y$. Now U is affine over X and its affine $\mathcal{O}_X$ -algebra is a direct factor of $\mathcal{B}$. It therefore follows from Lemma 2.1.3 below that the image of U in X is open and closed,

<!-- original page 297 -->

i.e. coincides with all of X . This image contains in particular a rational point x of X , so that U meets the inverse image of x in $X \times_k Y$. Since this inverse image is isomorphic to Y , hence connected, U contains this inverse image. The same would hold for the complement of U in $X \times_k Y$ if U were distinct from $X \times_k Y$, which would be absurd.

If Y is now an arbitrary k -scheme, what precedes shows that the fibers of the canonical projection $X \times_k Y \rightarrow Y$ are connected. If x is a rational point of X , these fibers all meet the subscheme $\{x\} \times_k Y$, which is itself connected, whence the proposition.

Lemma 2.1.3. Let X be a scheme and $\mathcal{A}$ a quasi-coherent $\mathcal{O}_X$ -algebra which is locally $\mathcal{O}_X$ -finite. Then the image of $\text{Spec } \mathcal{A}$ in X is then open and closed.

<!-- label: III.VI_A.2.1.3 -->

Let V be this image. It is clear that V is contained in the support of $\mathcal{A}$. Conversely, if x belongs to the support of $\mathcal{A}$, then $\mathcal{A}_x$ is non-zero and is a free $\mathcal{O}_{X,x}$ -module, since by Kaplansky every projective module over a local ring is free. Consequently the fiber of $\text{Spec } \mathcal{A}$ at x , which is affine with algebra $\mathcal{A}_x \otimes_{\mathcal{O}_{X,x}} k(x)$, is non-empty. One thus sees that the image of $\text{Spec } \mathcal{A}$ coincides with the support of $\mathcal{A}$.

If s is the unit section of $\mathcal{A}$, the equality $s_x = 0$ implies that s , and hence $\mathcal{A}$, are

<!-- original page 298 -->

zero in a neighborhood of x . So the support of $\mathcal{A}$ is closed. On the other hand, one may assume that $\mathcal{A}$ is a direct factor of the direct sum L of a family $\mathcal{O}^{\alpha}_X$ of copies of $\mathcal{O}_X$. For every β , write ϕ_β for the restriction to $\mathcal{A}$ of the canonical projection of $L = \bigoplus_{\alpha} \mathcal{O}^{\alpha}_X$ onto $\mathcal{O}^{\beta}_X$. For $x \in X$, denote by $\mathcal{A}^{(*)}_x$ the dual module $\text{Hom}_{\mathcal{O}_{X,x}}(\mathcal{A}_x, \mathcal{O}_{X,x})$. Since $\mathcal{A}_x$ is a direct factor of L_x , the restriction map

```

text
Hom_{\mathcal{O}_{X,x}}(L_x, \mathcal{O}_{X,x}) \rightarrow Hom_{\mathcal{O}_{X,x}}(\mathcal{A}_x, \mathcal{O}_{X,x}) = \mathcal{A}^{(*)}_x

```

<!-- original page 299 -->

is surjective. If $\mathcal{A}_x \neq 0$ then, since $\mathcal{A}_x$ is free and non-zero, there exist $a \in \mathcal{A}_x$ and a linear form $\phi \in \mathcal{A}^{(*)}_x$ such that $\phi(a) = 1$. There exists therefore a family ξ^{α} of elements of $\mathcal{O}_{X,x}$ such that, for every $u \in \mathcal{A}_x$, one has $\phi(u) = \sum_{\alpha} \xi^{\alpha} \phi^{\alpha}(u)$ (this sum being finite since $\phi^{\alpha}(u) = 0$ except for finitely many α). Applying this to $u = a$, one obtains that there exist $\alpha_1, \dots, \alpha_n$ such that

```

text
1 = \phi(a) = \xi^{\alpha_1} \phi^{\alpha_1}(a) + \dots + \xi^{\alpha_n} \phi^{\alpha_n}(a).

```

There exists then an open neighborhood U of x such that a and the ξ^{α_i} come from sections $\tilde{a} \in \mathcal{A}(U)$ and $\tilde{\xi}^{\alpha_i} \in \mathcal{O}_X(U)$, and the equality $\sum_i \tilde{\xi}^{\alpha_i} \phi^{\alpha_i}(\tilde{a}) = 1$ on U shows that $\tilde{a}(y) \neq 0$ for every $y \in U$. ("The support of a projective module is open.")

2.2.

The notations being still those of 2.1, it is clear that G' is a reduced k -scheme. Lemma 2.1.2 shows that $G' \times_k G'$ is connected, so that $(G' \times_k G')_{\text{red}}$ is the reduced subscheme of $G \times_A G$ having as underlying space the connected component of the origin. In particular, the multiplication morphism $\mu : G \times_A G \rightarrow G'$ induces a morphism $\mu' : (G' \times_k G')_{\text{red}} \rightarrow G'$ that makes G' a group in $(\text{Sch}/k)_{\text{red}}$.

2.2.bis.

[^N.D.E-VI_A-20] One recalls (cf. Exp. V) that, if S is a scheme, one writes S for the underlying topological space of S . Now one defines a sub- A -functor G^0 of G by setting, for every A -scheme S ,

```
```text
G^0(S) = {u ∈ G(S) | u(S) ⊂ G'}.
```
```

Let $\sigma : G \rightarrow G'$ be the inversion morphism; since $\sigma(G') = G'$, we have $\sigma \circ u \in G^0(S)$ for every $u \in G^0(S)$. On the other hand, if $u, v \in G^0(S)$, then $u \boxtimes v$ sends S into the subspace of $G \times_A G$ consisting of points whose two projections belong to G' ; this subspace is identified with the underlying space of $G' \times_A G'$, which is connected by Lemma 2.1.2. Consequently, $\mu \circ (u \boxtimes v)$ sends S into G' . This shows that G^0 is a sub- A -functor in groups of G .

If the connected component of e is open in G , then the subfunctor G^0 is representable by the subscheme induced by G on this open set, which is therefore a group subscheme of G ; we shall also write G^0 for it. In this case, with the notations of 2.1, one has $G' = (G^0)_{\text{red}}$ and the topological spaces G' and G^0 coincide. [^N.D.E-VI_A-21]

2.3.

In accordance with our conventions of 1.1, we again assume from now on that G is locally of finite type over A . Then G is locally noetherian, hence locally connected, [^N.D.E-VI_A-22] hence: every connected component of G is open.

We then write G^0 for the subscheme induced by G on the connected component G' of the unit element. By 2.2.bis, G^0 is a group subscheme of G , which we shall call the *neutral component* of G ;

<!-- original page 300 -->

for every A -scheme S we therefore have:

```
```text
G^0(S) = {u ∈ G(S) | u(S) ⊂ G^0 = G'}.
```
```

Let G^{α} be an arbitrary connected component of G and $\nu^{\alpha} : G^{\alpha} \times_A G^0 \rightarrow G$ the morphism defined by the equalities

```
$$
\nu^{\alpha}(S)(g, \gamma) = g\gamma g^{-1},
$$
```

for every $S \in (\text{Sch}/A)$, $g \in G^{\alpha}(S)$, $\gamma \in G^0(S)$.

If e is the origin of G , the restriction of ν^{α} to $G^{\alpha} \times_A \{e\}$ is the trivial morphism; since $G^{\alpha} \times_A G^0$ is connected by 2.1.2, one sees that ν^{α} factors through G^0 . Therefore, for every A -scheme S , $G^0(S)$ is a normal subgroup of $G(S)$. We have thus obtained the following proposition: [^N.D.E-VI_A-23]

****Proposition 2.3.1.**** *Let G be an A -group locally of finite type. Then the neutral component G^0 is an open normal group subscheme of G .*

<!-- label: III.VI_A.2.3.1 -->

****Proposition 2.4.**** *Let G be an A -group locally of finite type.*

(i) G^0 is irreducible, and $G^0 \otimes_A k$ is geometrically irreducible over k .

*(ii) $G^{\{0\}}$ is quasi-compact, hence of finite type over A .

<!-- label: III.VI_A.2.4 -->

[^N.D.E-VI_A-24] *Proof.* (i) Since $G^{\{0\}}$ and $G^{\{0\}} \otimes_A k$ have the same underlying topological space, it suffices to show the second assertion. Let $\bar{k}$ be an algebraic closure of k . By 2.2, $(G \otimes_A \bar{k})_{\text{red}}$ is a $\bar{k}$ -group locally of finite type and reduced, hence smooth over $\bar{k}$ (1.3.1). A fortiori the local rings of $(G \otimes_A \bar{k})_{\text{red}}$ are integral domains, so, [^N.D.E-VI_A-25] since $G \otimes_A \bar{k}$ is locally noetherian, the connected components of $G \otimes_A \bar{k}$ are irreducible (cf. EGA I, 6.1.10). In particular, the connected component $G^{\{0\}} \otimes_A \bar{k}$ (cf. 2.1.1) is irreducible.

(ii) Let us now show that $G^{\{0\}}$ is of finite type over A . Since $G^{\{0\}}$ is locally of finite type over A , it suffices to prove that $G^{\{0\}}$ is quasi-compact. As $G^{\{0\}}$ is irreducible, this follows from 0.5.1.

<!-- original page 301 -->

Corollary 2.4.1. Every connected component of G is irreducible, [^N.D.E-VI_A-26] of finite type over A , [^N.D.E-VI_A-27] and of the same dimension as $G^{\{0\}}$.

<!-- label: III.VI_A.2.4.1 -->

One may indeed assume A equal to its residue field k . Let then C be a connected component of G , x a closed point of C , $\kappa(x)$ the residue field of x , and k' a normal extension of k containing $\kappa(x)$ and of finite degree over k . The canonical projection $\pi : C \otimes_k k' \rightarrow C$ is open and closed; [^N.D.E-VI_A-28] consequently, if C' is a connected component of $C \otimes_k k'$, the projection $C' \rightarrow C$ is surjective, so C' contains a point $y \in \pi^{-1}(x)$, and such a point is rational over k' (cf. the proof of 1.2), so that C' is the image by translation r_y of $G^{\{0\}} \otimes_k k'$. Now $G^{\{0\}} \otimes_k k'$ is of finite type over k' by 2.4, and $\pi^{-1}(x)$ is finite (of cardinality $\leq [k' : k]$), so $C \otimes_k k'$ is of finite type over k' , and hence C is of finite type over k .

On the other hand, since $G^{\{0\}} \otimes_k k'$ is irreducible by 2.4, the same holds for C' , [^N.D.E-VI_A-29] and hence also for C , since the projection $C' \rightarrow C$ is surjective.

Finally, we have seen above that $C \otimes_k k'$ is a disjoint union of finitely many translates of $G^{\{0\}} \otimes_k k'$. Since dimension is invariant under extension of the base field (cf. EGA IV_2, 4.1.4), it follows that C has the same dimension as $G^{\{0\}}$. (Moreover, by EGA IV_2, 5.2.1, one has $\dim_g G = \dim G^{\{0\}}$ for every point $g \in G$.)

2.5.

This paragraph has been added. The results that follow appear in Exp. VI_B, but could (or should) have figured in VI_A, and it is useful to have them available from now on, in order to make precise Theorem 3.2 below.

Lemma 2.5.1. Let $(A, \mathfrak{m})$ be an Artinian local ring, and $k = A/\mathfrak{m}$ its residue field.

(i) If X is an A -scheme such that $X \otimes_A k$ is locally of finite type (resp. of finite type) over k , then the same holds for X over A .

(ii) Let $u : X \rightarrow Y$ be a morphism of A -schemes. If $u \otimes_A k$ is an immersion (resp. a closed immersion), then so is u .

<!-- label: III.VI_A.2.5.1 -->

Proof. (i) Suppose $X \otimes_A k$ locally of finite type over k . Let $U = \operatorname{Spec} B$ be an affine open of X . By hypothesis, there exist elements $x_1, \dots, x_n$ of B whose images generate $B/\mathfrak{m}B$ as a k -algebra, and it follows from the "nilpotent Nakayama lemma" that the x_i generate B as an A -algebra. This proves that X is locally of finite type over A . If, in addition, $X \otimes_A k$ is quasi-compact, then so is X (which has the same underlying topological space), and hence X is of finite type over A . This proves (i).

Let us prove (ii). Suppose $u \otimes_A k$ is an immersion (resp. a closed immersion). Then u is a homeomorphism of X onto a locally closed (resp. closed) part of Y , and for every $x \in X$, the ring morphism $\phi_x : \mathcal{O}_{Y,u(x)} \rightarrow \mathcal{O}_{X,x}$ is such that $\phi_x \otimes_A k$ is surjective. By the nilpotent Nakayama lemma, it follows that ϕ_x is surjective, so u is an immersion (resp. a closed immersion).

Proposition 2.5.2. Let A be an Artinian local ring with residue field k , and let $u : G \rightarrow H$ be a

quasi-compact morphism between A -group schemes locally of finite type.*

(a) The set $u(G)$ is closed in H , and its connected components are irreducible and all of the same dimension.

(b) One has $\dim G = \dim u(G) + \dim \text{Ker}(u)$.

(c) If u is a monomorphism, it is a closed immersion.

<!-- label: III.VI_A.2.5.2 -->

Proof. By the preceding lemma, it suffices to prove the proposition in the case where $A = k$. Moreover, since the properties under consideration are stable by

<!-- original page 304 -->

(fpqc) descent, and since dimension is invariant under extension of the base field, one may assume k algebraically closed.

Let us prove (a). Denote by C the reduced subscheme of H whose underlying topological space is $u(G)$. Since $u(G)$ is stable under the inversion morphism of H , so is C . On the other hand, $u : G \rightarrow C$ is quasi-compact and dominant, so by EGA IV_2, 2.3.7 the same holds for $u \times_{\text{id}_G} \text{id}_H$ and $\text{id}_H \times_{\text{id}_G} u$, and hence for their composition $u \times_{\text{id}_G} u : G \times_{\text{id}_G} G \rightarrow C \times_{\text{id}_G} C$. Consequently, the multiplication of H sends $C \times_{\text{id}_G} C$ into C , and so C is a group subscheme of H .

So, replacing H by C , we reduce to the case where u is dominant. Then $G(k)$ is dense in H , hence meets every connected component of H , and hence acts transitively on the set of these connected components. It therefore suffices to show that $u(G)$ contains H^0 . Replacing G by $u^{-1}(H^0)$, we may suppose $H = H^0$; in this case, by 2.4, H is irreducible and of finite type over k , hence noetherian. On the other hand, u is locally of finite type (cf. EGA I, 6.6.6) and quasi-compact, hence of finite type. Consequently, by Chevalley's constructibility theorem (cf. EGA IV_1, 1.8.5), $u(G)$ is a constructible (and dense) part of $H = u(G)$, hence contains a dense open U of H (cf. EGA 0_III, 9.2.2). Then, by 0.5, one has $H = U \cdot U \subset u(G)$, whence $u(G) = H$. Taking 2.4.1 into account, this proves assertion (a).

Let us prove (b). Recall first that the functor $\text{Ker}(u)$ (cf. I, 2.3.6.1) is representable by $u^{-1}(e)$, where e denotes the unit element of H . Since u is of finite type, $\text{Ker}(u)$ is of finite type over k . On the other hand, replacing H by the reduced closed subscheme $u(G)$, we may assume u surjective. Denote by u^0 the restriction of u to G^0 . Since G and $\text{Ker}(u)$ are equidimensional, and since $\text{Ker}(u)^0 \subset \text{Ker}(u^0)$, we reduce to the case where G , and hence also H , are irreducible.

Then, by EGA IV_3, 9.2.6.2 and 10.6.1 (ii), the set of $y \in H$ such that $\dim u^{-1}(y) = \dim G - \dim H$ contains a non-empty open set V . Since u is surjective, $U = u^{-1}(V)$ is then a non-empty open subset of G , hence contains a closed point x of G , since G is a Jacobson scheme (cf. EGA IV_3, 10.4.8). Then right translation r_x is an isomorphism of $\text{Ker}(u)$ onto $u^{-1}(u(x))$, whence:

```text  
dim Ker(u) = dim u^{-1}(u(x)) = dim G - dim H.  
```

Let us prove (c), following [DG70], I, § 3.4. (Another proof is given in Exp. VI_B, 1.4.2.) Assume u a monomorphism. If C is a connected component of G , there exists a closed point $x \in G$ such that $C = r_x(G^0)$, and if one denotes by u_C (resp. u^0) the restriction of u to C (resp. to G^0), one has $u_C = r_{u(x)} \circ u^0 \circ r^{-1}_x$, so it suffices to show that u^0 is a closed immersion. We may therefore suppose $G = G^0$, so that G is irreducible and of finite type over k .

Let ξ be the generic point of G ; then $0_{\{G, \xi\}}$ is an Artinian local ring; denote by $\mathfrak{m}$ its maximal ideal. On the other hand, let $h = u(\xi)$, $\mathfrak{n}$ the maximal ideal of $0_{\{H, h\}}$, and $A = 0_{\{G, \xi\}}/\mathfrak{m}$, $0_{\{G, \xi\}}$. Since u is a monomorphism, so is the morphism $u_h : \text{Spec}(A) \rightarrow \text{Spec}(\kappa(h))$ obtained by base change, so the multiplication morphism $A \otimes_{\kappa(h)} A \rightarrow A$ is an isomorphism (cf. EGA I, 5.3.8), whence $A = \kappa(h)$. By Nakayama's lemma (since $0_{\{G, \xi\}}$ is contained in $\mathfrak{m}$, hence nilpotent), it follows that the morphism $0_{\{H, h\}} \rightarrow 0_{\{G, \xi\}}$ is surjective.

<!-- original page 305 -->

Let then V be an affine open of H containing h , U a non-empty affine open of G contained in $u^{-1}(V)$,

$\phi : 0_{\{H\}}(V) \rightarrow 0_{\{G\}}(U)$ the morphism of k -algebras induced by u , $\mathfrak{p}$ the prime ideal of $0_{\{G\}}(U)$ corresponding to ξ , and $\mathfrak{q} = \phi^{-1}(\mathfrak{p})$. Since G is of finite type over k , $0_{\{G\}}(U)$ is generated as a k -algebra by a finite number of elements $a_1, \dots, a_n$. By what precedes, there exist elements $b_1, \dots, b_n$ and s in $0_{\{H\}}(V)$ such that $s \notin \mathfrak{q}$ and such that one has in $0_{\{G\}}(U)$ the equalities $a_i/1 = \phi(b_i)/\phi(s)$. There exist therefore elements $t_1, \dots, t_n$ of $0_{\{G\}}(U) - \mathfrak{p}$ such that $t_i(a_i \phi(s) - \phi(b_i)) = 0$. Then, setting $t = t_1 \cdots t_n \phi(s) \in 0_{\{G\}}(U) - \mathfrak{p}$, the equalities $a_i/1 = \phi(b_i)/\phi(s)$ already hold in $0_{\{G\}}(U)_t$ and, since $t \in 0_{\{G\}}(U) = k[a_1, \dots, a_n]$, there exists $b \in 0_{\{H\}}(V)$ such that $t/1 = \phi(b)/\phi(s)^r$, for some $r \in \mathbb{N}$. Consequently, ϕ induces a surjection of $0_{\{H\}}(V)_{\{sb\}}$ onto $0_{\{G\}}(U)_t$, and so u is a local immersion at the point ξ .

The open subset W of G consisting of the points at which u is a local immersion is therefore non-empty. Since G is a Jacobson scheme, W contains a closed point y , and to show $W = G$, it suffices to show that every closed point of G belongs to W . Now every closed point x is the image of y by translation $r_x \circ r^{-1}_y$, hence belongs to W , whence $W = G$. This proves that u is a local immersion.

Since G is irreducible, it follows that u is an immersion. Indeed, for every $x \in G$, let U_x and V_x be open subsets of G and H such that $x \in U_x$ and such that u induces a closed immersion of U_x into V_x . Since U_x is dense in G , $u(U_x)$ is dense in $u(G) \cap V_x$, and since $u(U_x)$ is closed in V_x , one has $u(U_x) = V_x$. Moreover, since u is injective, one has $U_x = u^{-1}(V_x)$, and it follows that u induces a closed immersion of G into the open subscheme of H covered by the V_x . So $u : G \rightarrow H$ is an immersion. But we have already seen that $u(G)$ is closed in H , hence u is a closed immersion.

Lemma 2.5.3. [N.D.E-VI_A-30] *Let A be an Artinian local ring, k its residue field, G a flat A -group, X an A -scheme equipped with a left action $\mu : G \times A \rightarrow X$ of G and with a section $s_0 : \text{Spec } A \rightarrow X$. (This is the case, for instance, if G' is a second A -group and one is given an A -group morphism $G \rightarrow G'$.)*

Let ϕ be the morphism $\mu \circ (\text{id}_G \times s_0)$ from $G = G \times \{A\}$ to X . If ϕ is flat at a point g of G , then ϕ is flat.

<!-- label: III.VI_A.2.5.3 -->

Proof. Since G is flat over A , the flatness-by-fibers criterion (EGA IV_3, 11.3.10.2) shows that it suffices to show that $\phi \otimes_A k$ is flat; hence we may suppose $A = k$. In this case, the datum of s_0 is equivalent to that of a k -point $x_0 \in X(k)$, and ϕ is the morphism $h \mapsto h \cdot x_0$.

Let then $h \in G$; let us show that ϕ is flat at the point h . Let K be an extension of k containing a copy of $\kappa(g)$ and of $\kappa(h)$; one has a cartesian square

$$\begin{array}{ccc} G_K & \xrightarrow{\phi_K} & X_K \\ \downarrow & & \downarrow \\ G & \xrightarrow{\phi} & X \end{array}$$

<!-- original page 306 -->

in which the two vertical arrows are faithfully flat. So, by V 7.4 (i), ϕ_K is flat at every point $g' \in G_K$ above g , and to show that ϕ is flat at h , it suffices to show that ϕ_K is flat at a point h' above h . We are thus reduced to the case where g and h are rational. Let then $u = h \cdot g^{-1}$ and ℓ_u (resp. μ_u) the left translation of G (resp. of X) defined by u ; since $\phi \circ \ell_u = \mu_u \circ \phi$, one obtains a commutative square

$$\begin{array}{ccc} 0_{\{G,h\}} & \xrightarrow{\sim} & 0_{\{G,g\}} \\ \uparrow & & \uparrow \\ 0_{\{X, hx_0\}} & \xrightarrow{\sim} & 0_{\{X, gx_0\}} \end{array}$$

in which the horizontal arrows are isomorphisms. Since the morphism $0_{\{X, g_{X,0}\}} \rightarrow 0_{\{G,g\}}$ is flat, the morphism $0_{\{X, h_{X,0}\}} \rightarrow 0_{\{G,h\}}$ is also flat.

Proposition 2.5.4. *Let A be an Artinian local ring, k its residue field, G an A -group locally of finite type, $X \neq \emptyset$ an A -scheme locally of finite type equipped with a left action of G . Assume that the morphism $\phi : G \times_A X \rightarrow X$ defined set-theoretically by $(g, x) \mapsto (gx, x)$ is surjective. Then:

(i) The connected components of X are of finite type, irreducible, and all of the same dimension.*

(ii) More precisely, let $\bar{k}$ be an algebraic closure of k and x a closed point of $X \otimes_A \bar{k}$; its stabilizer F is a closed group subscheme of $G \otimes_A \bar{k}$, and the dimension of the irreducible components of X is $\dim G - \dim F$.*

<!-- label: III.VI_A.2.5.4 -->

Taking Lemma 2.5.1 into account, we may suppose $A = k$. Suppose first k algebraically closed. Then G_{red} is a k -group locally of finite type, and hence, replacing G by G_{red} and X by X_{red} , we may suppose G and X reduced.

Since $G \times_k X$ is locally of finite type over k , ϕ is locally of finite type (cf. EGA I, 6.6.6 (v)), hence locally of finite presentation since $X \times_k X$ is locally noetherian. Let x be a rational point of X ; then the morphism $\phi_x : G \rightarrow X$ obtained from ϕ by base change is surjective and locally of finite presentation. If η is a maximal point of X , then $0_{\{X,\eta\}}$ is a field (since X is reduced), so ϕ_x is flat at every point of G above η . So, by Lemma 2.5.3, ϕ_x is flat. Consequently, $\phi_x : G \rightarrow X$ is faithfully flat and locally of finite presentation, hence open (cf. EGA IV_2, 2.4.6). Since G^0 is open in G , irreducible and quasi-compact (by 2.4), each orbit $G^0 \cdot x = \phi_x(G^0)$, for x running through the rational points of X , is an open subset of X , irreducible and quasi-compact, hence of finite type over k (since X is locally of finite type over k).

Since every non-empty open subset of X contains a rational point, it follows that X is covered by these open sets. Moreover, two such open sets are either disjoint or equal. Indeed, if $\phi_x(G^0) \cap \phi_y(G^0) \neq \emptyset$ is non-empty, it contains a rational point z , and there exist therefore two rational points $g, h \in G^0$ such that $gx = z = hy$, whence $x = g^{-1}z$ and $y = h^{-1}z$, and so $\phi_x(G^0) = \phi_z(G^0) = \phi_y(G^0)$. It follows that the orbits $\phi_x(G^0)$ are also closed, and so are at once the connected components and the irreducible components of X .

<!-- original page 307 -->

Finally, let x, y be two rational points of X . Since ϕ_x is surjective, there exists a rational point $g \in G$ such that $y = gx$, and since G^0 is a normal subgroup of G , the orbit $G^0 \cdot y$ is the image of $G^0 \cdot x$ under translation ℓ_g of X , so that $G^0 \cdot y$ and $G^0 \cdot x$ have the same dimension.

Moreover, by I, 2.3.3.1, the stabilizer of x is represented by the closed subscheme F of G defined by the cartesian square below:

$$\begin{array}{ccc} F & \longrightarrow & G \\ \downarrow & & \downarrow \phi_x \\ \text{Spec } k & \longrightarrow & X. \end{array}$$

Then F is a k -group locally of finite type, $F \cap G^0$ is a k -group of finite type containing F^0 , and by 2.4.1, F and $F \cap G^0$ are equidimensional, of the same dimension as F^0 . Let $C = \phi_x(G^0)$ be the irreducible component of X containing x . Proceeding as in the proof of point (b) of 2.5.2, one obtains that $\dim C = \dim G^0 - \dim F^0 = \dim G - \dim F$.

In the general case (i.e. for k an arbitrary field), let $\bar{k}$ be an algebraic closure of k . Let C be a connected component of X and C' a connected component of $C \otimes_k \bar{k}$; then C' is a connected component of $X' = X \otimes_k \bar{k}$. The morphism $\pi : X' \rightarrow X$ is open (cf. EGA IV_2, 2.4.10), and since it is integral, it is also closed; consequently $\pi(C') = C$. Since C' is irreducible and quasi-compact, C is irreducible and quasi-compact, hence of finite type over k (since X is locally of finite type over k).

Finally, since dimension is invariant under extension of the base field (cf. EGA IV_2, 4.1.4), $\dim C = \dim C'$, and since all the irreducible components of X' have the same dimension, the same holds for those of X .

2.6. Complements.

This paragraph has been added, drawn from [Per75] II, §§ 1–2, with complements due to O. Gabber.[^N.D.E-VI_A-31] This shows that the preceding results are valid for any group scheme G over a field k . (This will be used in sections 5, 6 and 7 of Exp. VI_B.)

We fix a field k . Let us begin with the following lemma (loc. cit., II 2.1.1), which does not appear explicitly in EGA IV_2, § 4.4 (although it can perhaps be read between the lines at the beginning of loc. cit., § 4.4.1).

Lemma 2.6.0. *Let X be an irreducible k -scheme, K an extension of k , X' an irreducible component of X_K . The projection $X' \rightarrow X$ is surjective.*

<!-- label: III.VI_A.2.6.0 -->

Indeed, let B be a transcendence basis of K over k and $L = k(B) \subset K$. By EGA IV_2, 4.3.2 and 4.4.1, X_L is irreducible and X' dominates X_L . The morphism $X' \rightarrow X_L$ is therefore integral and dominant, hence surjective. Since $X_L \rightarrow X$ is surjective (loc. cit., 4.4.1), so is $X' \rightarrow X$.

<!-- original page 308 -->

For the rest of 2.6, we fix a k -group scheme G and an action $\mu : G \times X \rightarrow X$ of G on a k -scheme X satisfying the following condition:

(*) the morphism $\Phi : G \times X \rightarrow X \times X$, $(g, x) \mapsto (gx, x)$ is surjective

(this is the case in particular for G acting on itself by left translations). We shall then say, for short: "Let X be a G -scheme satisfying (*)". Finally, we write k' for the perfect closure of k .

Proposition 2.6.1. *Let X be a G -scheme satisfying $(\star)$.*

(i) X is geometrically pointwise irreducible over k , i.e. for every extension K of k , each $x \in X_K$ belongs to a unique irreducible component of X_K .

(ii) Each local ring of $(X_{k'})_{\text{red}}$ is normal.

(iii) Let η be a maximal point of $(X_{k'})_{\text{red}}$, $C = \{\eta\}^{\text{cl}}$, and L the algebraic closure of k in $k(\eta)$. Then C is an L -scheme, and is geometrically irreducible over L (i.e. $C \otimes_L K$ is irreducible for every extension K of L).

(iv) In particular, if x is a rational point of X , then the irreducible component of X containing x is geometrically irreducible over k .

<!-- label: III.VI_A.2.6.1 -->

Proof. (i) Since hypothesis $(\star)$ is preserved by every base change $k \rightarrow K$, it suffices to show that each $x \in X$ belongs to a unique irreducible component of X . Since the morphism $\text{Spec}(k') \rightarrow \text{Spec}(k)$ is a universal homeomorphism, we may moreover assume k perfect. We may then assume G and X reduced. Let η be a maximal point of X and z an arbitrary point of $Z = \{\eta\}^{\text{cl}}$. Since X is reduced, the local ring $\mathcal{O}_{X,\eta}$ equals $k(\eta)$, and since k is perfect, for every extension K of k , $k(\eta) \otimes_k K$ is normal (cf. EGA IV_2, 6.14.2), so every point of X_K above η is normal.

Since Φ is surjective, there exists a point γ of $G \times X$ such that $\Phi(\gamma)$ has projections z and η . Let $K = k(\gamma)$; there exist then rational points g and η' of G_K and X_K such that η' lies above η and $z' = g \eta'$ lies above z . By what precedes, η' is a normal point of X_K , hence so is z' . Since $\pi : X_K \rightarrow X$ is flat, it follows that $z = \pi(z')$ is a normal point of X (cf. EGA IV_2, 2.1.13). This proves (ii) and (i).

The first assertion of (iii) then follows from (ii). Then, since L is algebraically closed in $k(\eta)$, C is

geometrically irreducible over L , by EGA IV₂, 4.5.9.

Finally, if X has a rational point x , it follows from (iii) that $L = k$, and so X is geometrically irreducible over k . This can also be seen directly as follows (cf. [Per75], II 2.1): let C be the irreducible component of X containing x and let K be an extension of k ; X_K has a unique point e_K above e , and, by (i), e_K belongs to a unique irreducible component C' of X_K ; on the other hand, by 2.6.0, every irreducible component of X_K contains e_K , hence equals C' .

Notation. Let us write provisionally $C^{\{0\}}$ for the reduced closed subscheme of G whose underlying space is the unique irreducible component of G containing the unit element e .

<!-- original page 309 -->

Corollary 2.6.2. $C^{\{0\}}$ is geometrically irreducible over k and is set-theoretically stable under the group law, i.e. $(C^{\{0\}}_{\{k'\}})_{\text{red}}$ is a subgroup of $(G_{\{k'\}})_{\text{red}}$. Consequently, $C^{\{0\}}$ is quasi-compact.*

<!-- label: III.VI_A.2.6.2 -->

Indeed, by 2.6.1, $C^{\{0\}}$ is geometrically irreducible over k , so $C^{\{0\}} \times C^{\{0\}}$ is irreducible, so $\nu(C^{\{0\}} \times C^{\{0\}}) \subset C^{\{0\}}$, where ν denotes the morphism $(g, h) \mapsto gh^{-1}$. Since $\text{Spec } k' \rightarrow \text{Spec } k$ is a universal homeomorphism, the same conclusion holds for $C^{\{0\}}_{\{k'\}}$, and then for $H = (C^{\{0\}}_{\{k'\}})_{\text{red}}$, and so, since $H \times_{\{k'\}} H$ is reduced, ν induces a morphism $H \times_{\{k'\}} H \rightarrow H$, i.e. H is a subgroup of $(G_{\{k'\}})_{\text{red}}$. Consequently, by 0.5.1, H (and hence also $C^{\{0\}}$) is quasi-compact.

Recollection 2.6.3. Let Y be a scheme. Recall (EGA 0_III, 9.1.1) that a subset E of Y is said to be retrocompact if the inclusion $E \hookrightarrow Y$ is quasi-compact, and that, by EGA IV₁, 1.9.5 (v) and 1.10.1, if U is a retrocompact open subset of Y , then the closure $\overline{U}$ of U is the union of the closures $\overline{\{y\}}$ of the points $y \in U$, and of course it is enough to take y running through the maximal points of U , i.e. the maximal points of Y contained in U .*

<!-- label: III.VI_A.2.6.3 -->

Consequently, if Y is quasi-separated and if η is a maximal point of Y , then the intersection of the closed neighborhoods of η equals $\{\eta\}$: indeed, if $y \in Y - \{\eta\}$, then y is contained in an affine open V not containing η ; since Y is quasi-separated, V is retrocompact, so $\overline{V}$ is the union of the $\overline{\{x_i\}}$, for x_i running through the maximal points of Y belonging to V , and hence $\eta \notin \overline{V}$, i.e. $Y - V$ is a closed neighborhood of η not containing y .*

Proposition 2.6.4. Let X be a G -scheme satisfying $(\star)$ and let U be an open subset of X .*

(i) $C^{\{0\}} U$ is an open subset of X , equal to the union of the irreducible components of X whose generic point belongs to U .*

(i') Consequently, if X is irreducible, it is quasi-compact.*

(ii) If moreover U is retrocompact in X , then $C^{\{0\}} U$ equals $\overline{U}$, hence is an open-and-closed subset of X .*

<!-- label: III.VI_A.2.6.4 -->

Proof. (i) First, $C^{\{0\}} U$ is open, since it is the union, for $g \in C^{\{0\}}$, of the projections of the open sets $g \cdot U_{\kappa(g)} \subset X_{\kappa(g)}$, and each projection $X_{\kappa(g)} \rightarrow X$ is open.

To prove the second assertion of (i), we may replace k by k' (since $\text{Spec } k' \rightarrow \text{Spec } k$ is a universal homeomorphism), and so assume k perfect. We may then assume G and X reduced, hence geometrically reduced.

Let η be a maximal point of X contained in U and let Z be its closure. Consider the morphism $\mu: C^0 \times Z \rightarrow X$. Since $C^{\{0\}}$ is geometrically irreducible, $C^{\{0\}} \times Z$ is irreducible; write γ for its generic point. Since μ sends the point γ to η (where γ denotes the unit section of $C^{\{0\}}$) to η , then γ is sent to a generization of η , hence to η . So μ sends the underlying space of $C^{\{0\}} \times Z$ into Z , and so, since $C^{\{0\}} \times Z$ is reduced, μ factors through Z .

Let now $z \in Z$. Set $K = \kappa(z)$. Then the morphism $\mu_z: G_K \rightarrow X_K$, $h \mapsto h \cdot z$ is surjective; let α be a maximal point of X_K ; the local ring $\mathcal{O}_{X_K, \alpha}$ is

<!-- original page 310 -->

a field, since X_K is reduced, so μ_z is flat at every point of G_K above α , so μ_z is flat, by Lemma 2.5.3.

On the other hand, μ_z sends the generic point ω of C_K to a point t in Z_K . Let β be a maximal point of Z_K such that $t \in \{\beta\}$; since μ_z is flat, there exists a generization ξ of ω such that $\mu_z(\xi) = \beta$, and since ω is a maximal point of G_K , one necessarily has $\xi = \omega$, and so $\mu_z(\omega) = \beta$, which lies above η (since $Z_K \rightarrow \mathbb{A}^1_K$ is flat).

Set $L = \kappa(\omega)$ and let ω_L and z_L be the L -points deduced from ω and z ; then $\omega_L \cdot z_L = \beta$ is a point of Z_L above β , and so $z_L = \omega_L^{-1}$ $\cdot \beta$ in $C_K \cdot U$, whence $z \in C_K \cdot U$. This proves (i).

Since C_K is quasi-compact, by 2.6.2, point (i') follows from this: if X is irreducible and if U is a non-empty affine open, then X equals $C_K \cdot U$, i.e. is the image of the morphism $C_K \times U \rightarrow X$, hence is quasi-compact. Finally, if U is retrocompact in X , then (cf. 2.6.3) U is the union of the $\{\eta\}$ for η running through the maximal points of X contained in U , hence equals $C_K \cdot U$. This proves (ii).

One then obtains the following result ([Per75] II Th. 2.4, see also [Per76], Prop. 4.1.1):

Theorem 2.6.5. *Let k be a field, G a k -group scheme.*

(i) There exists a unique group subscheme G^0 of G , called the neutral component of G , such that:

(a) The underlying space of G^0 is the irreducible component of the unit element. (b) $G^0 \rightarrow G$ is a flat closed immersion, i.e. $0_{G,g} = 0_{G^0,g}$ for every $g \in G^0$.

(ii) Moreover, G^0 is quasi-compact, geometrically irreducible, and is a characteristic subgroup of G .

(iii) If G is connected, then $G = G^0$.

<!-- label: III.VI_A.2.6.5 -->

Proof. (i) Recall first that G is separated (0.3), hence a fortiori quasi-separated. Let U be an affine open of G containing the generic point ω of C_K . By 2.6.3 and 2.6.4, $U = C_K \cdot U$ is at once open and closed, and $C_K = \{\omega\}$ is set-theoretically the intersection of these open-and-closed parts.

For U running through the affine opens containing ω , one obtains a projective system of G -schemes $U = C_K \cdot U$, whose transition morphisms are affine (since they are closed immersions). One may therefore form the projective limit G^0 (cf. EGA IV₃, 8.2.2), i.e. for every affine open V of G , $G^0 \cap V$ is the spectrum of the algebra

$$\lim_{\substack{\longrightarrow \\ U \subset V \\ G \in U}} 0_G(V \cap U) = 0_G(V) / \sum U(V),$$

where $I_U(V)$ denotes the kernel of $0_G(V) \rightarrow 0_{G^0}(V \cap U)$. It follows that G^0 has C_K as underlying space, and that $G^0 \rightarrow G$ is a closed immersion. Moreover, for every $g \in G^0$, $0_{G^0,g}$ is the inductive limit, for V running through the affine opens of G containing g , of the k -algebras $0_{G^0}(V \cap G^0) = \varprojlim_U 0_G(V \cap U)$, and this double inductive limit is

<!-- original page 311 -->

identified with

$$\lim_{\substack{\longrightarrow \\ U \subset V \\ G \in U}} \lim_{\longrightarrow} 0_G(V) = 0_{G,g}$$

i.e. one has $0_{G^0,g} = 0_{G,g}$ (see also EGA IV₂, 5.13.3 (ii)). So $i : G^0 \rightarrow G$ is a flat closed immersion.

Conversely, this condition implies that $i^*(0_{G'}) = 0_{G'^{\{0\}}}$, and so $G'^{\{0\}}$ is uniquely determined by conditions (a) and (b). This proves (i).

The first two assertions of (ii) follow from 2.6.2. Finally, let S be a k -scheme and ϕ an automorphism of the S -group G_S . For every $s \in S$, ϕ_s sends $G^{\{0\}}_{\kappa(s)}$ into itself, so $\phi(G^{\{0\}}_S) \subset G^{\{0\}}_S$. Moreover, the closed immersion $i_S : G^{\{0\}}_S \hookrightarrow G_S$ deduced from i by base change is flat, so one has $0_{G_S}, \phi(z) = 0_{G^{\{0\}}_S}, \phi(z)$ for every $z \in G^{\{0\}}_S$, and so $\phi \circ i_S$ factors through $G^{\{0\}}_S$. This proves that $G^{\{0\}}$ is a characteristic subgroup of G , whence (ii). Finally, (iii) is a particular case of point (i) of the following proposition. [N.D.E-VI_A-32]

Proposition 2.6.6. *Let k be a field, G a k -group acting on a k -scheme X in such a way that the morphism $G \times X \rightarrow X \times X$, $(g, x) \mapsto (gx, x)$ is surjective. Suppose X quasi-separated. Then:*

(i) Every connected component C of X is irreducible.*

(ii) Let η be the generic point of C and L the algebraic closure of k in $\kappa(\eta)$. Then C is an L -scheme, geometrically irreducible over L , and the morphism*

text
 $G^0_L \times_L C \rightarrow C \times_L C$
 $\downarrow$

is surjective.*

(iii) In particular, if C contains a rational point x , then C is geometrically irreducible over k and the morphism $\phi : G^{\{0\}} \rightarrow C$, $g \mapsto gx$ is surjective.*

<!-- label: III.VI_A.2.6.6 -->

Proof. (i) Let C be a connected component of X , Y an irreducible component of X contained in C , η the generic point of Y , and U an affine open of X containing η . Since X is quasi-separated, U is retrocompact in X , so by 2.6.4, $U^{\{0\}} = G^{\{0\}} U$ is an open-and-closed part of X meeting C , hence containing C . Now, by 2.6.3, the intersection of the $U^{\{0\}}$, for U running through a fundamental system of affine open neighborhoods of η , equals $\{\eta\}^{\{0\}}$. It follows that $C = \{\eta\}^{\{0\}}$. This proves (i).

The first assertion of (ii) (and also of (iii)) follows from 2.6.1. Let us start by showing the second assertion of (iii). Denote by ω (resp. η) the generic point of $G^{\{0\}}$ (resp. C). Let $z \in C$ and $K = \kappa(z)$. Since $G^{\{0\}}$ (resp. C) is geometrically irreducible over k , $G^{\{0\}}_K$ (resp. C_K) is irreducible; let ξ (resp. β) denote its generic point. We saw in the proof of 2.6.4 that the morphism $\mu_z : G_K \rightarrow C_K$, $h \mapsto h \cdot z$ sends ξ to β , and similarly one has $\phi(\omega) = \eta$.

<!-- original page 312 -->

Let $L = \kappa(\xi)$ and let ξ_L, z_L be the L -points deduced from ξ and z ; then $\xi_L \cdot z_L = \beta$ is a point of C_L above $\beta \in C_K$, hence also above $\eta \in C$. Consider the cartesian square:

text

$$\begin{array}{ccc} G^0_L & \xrightarrow{\phi_L} & C_L \\ \downarrow \pi_{G^0} & \phi & \downarrow \pi_C \\ G^0 & \longrightarrow & C \end{array}$$

since $\phi^{-1}_L(\pi^{-1}_{G^0}(\omega)) = \pi^{-1}_L(C)(\eta)$ (cf. EGA I, 3.4.8), there exists $g \in G^{\{0\}}_L$ such that $\phi_L(g) = \beta$. One therefore has $z_L = \xi^{-1}_L \cdot \phi_L(g) = \phi_L(\xi^{-1}_L g)$, whence $\phi(\pi^{-1}_{G^0}(\xi^{-1}_L g)) = \pi_C(z_L) = z$. This proves that ϕ is surjective.

Now let us prove the second assertion of (ii). It suffices to show that, for every $z \in C$, the morphism $\mu_z : G^0_L \otimes_L \kappa(z) \rightarrow C \otimes_L \kappa(z)$ is surjective, but this follows from (iii), since z is a rational point of $C \otimes_L \kappa(z)$.

****Remark 2.6.7.**** *Under the hypotheses of 2.6.6, if $C(k) = \emptyset$, the morphism $G^{\times k} \times_C C \rightarrow C \times_C C$ is not necessarily surjective. For example, for $k = \mathbb{R}$ and $G = \{ \pm 1 \}$, the G -torsor $X = \operatorname{Spec} \mathbb{R}[X]/(X^2 + 1)$ is connected, but the morphism $G^{\times 0} \times_{\mathbb{R}} X \rightarrow X \times_{\mathbb{R}} X$ is not surjective. (But one has $L = \mathbb{C}$ and the morphism $G^{\times 0} \times_{\mathbb{R}} X \rightarrow X \times_{\mathbb{C}} X$ is an isomorphism.)*

<!-- label: III.VI_A.2.6.7 -->

3. Construction of quotients $F \backslash G$ (for G, F of finite type)

<!-- label: III.VI_A.3 -->

<!-- original page 302 -->

3.1.

Let A be an Artinian local ring and $u : F \rightarrow G$ a homomorphism of A -groups. If $\mu : F \times_A F \rightarrow F$ and $\nu : G \times_A G \rightarrow G$ denote the multiplication morphisms and λ the composite morphism

$$\begin{array}{c} \text{``text} \\ F \times_A G \xrightarrow{u \times G} G \times_A G \xrightarrow{\nu} G, \\ \text{``} \end{array}$$

we recall that the *left quotient* $F \backslash G$ of G by F is the cokernel of the (Sch/A) -groupoid $G_{\{ \}$ described below:

$$\begin{array}{ccc} & F \times \lambda & \\ & \longrightarrow & \\ F \times_A F \times_A G & \xrightarrow{\mu \times G} & F \times_A G \xrightarrow{\lambda} G \\ & \longrightarrow & \text{pr}_2 \\ & \text{pr}_{\{2,3\}} & \end{array}$$

...

(pr_2 and $\text{pr}_{\{2,3\}}$ are the projections of $F \times_{\{ \}} G$ and $F \times_{\{ \}} (F \times_{\{ \}} G)$ onto the second factors). We shall say that $G_{\{ \}}$ is the *groupoid* with base G defined by* u (cf. Exp. V, § 2.a; as in Exposé V, we do not follow in this Exposé the convention of IV, 4.6.15).

Since the unique A -morphism $F \rightarrow \operatorname{Spec} A$ is universally open (EGA IV₂, 2.4.9), pr_2 is an open morphism; the same therefore holds for λ , which is the composition of pr_2 and the automorphism σ of $F \times_{\{ \}} G$ defined by the formulas: $\sigma(S)(x, y) = (x, u(S)(x) \cdot y)$, where S is a variable A -scheme, and x and y belong to $F(S)$ and $G(S)$. One sees in the same way that pr_2 and λ are flat when F is flat over A .

<!-- original page 303 -->

Let us also note, to conclude these preliminaries, that every A -morphism $s : \operatorname{Spec} A \rightarrow G$ defines an automorphism of the groupoid $G_{\{ \}}$ which induces on G , $F \times_{\{ \}} G$ and $F \times_{\{ \}} F \times_{\{ \}} G$ the automorphisms r_s , $\text{id}_F \times_{\{ \}} r_s$ and $\text{id}_F \times_{\{ \}} \text{id}_F \times_{\{ \}} r_s$ respectively. We shall again write r_s for this automorphism of $G_{\{ \}}$, and we shall say that r_s is the *right translation* defined by* s (cf. 0.4).

3.2. Theorem.

****Theorem 3.2.**** *Let F and G be flat groups locally of finite type over an Artinian local ring A . Let $u : F \rightarrow G$ be a quasi-compact A -group homomorphism with kernel finite over A . Then:*[^{N.D.E-VI_A-33}]

(i) The left quotient $F \backslash G$ of G by F exists in (Sch/A) , and the sequence*

$$\begin{array}{ccc} \text{``text} \\ F \times_A G \xrightarrow{\lambda} G \xrightarrow{\text{pr}_2} F \backslash G \\ \text{``} \end{array}$$

...

is exact in the category of all ringed spaces.

(ii) The canonical morphism $p : G \rightarrow F \backslash G$ is surjective and open, and $F \backslash G$ is a direct sum of schemes of finite type over A .

(ii') More precisely, $X = F \backslash G$ is equipped with a right action of G such that $p(e) \cdot g = p(g)$ for every $g \in G$; consequently, the connected components of X are of finite type over A , irreducible, and all of dimension $\dim G - \dim F$.

(iii) The canonical morphism $F \times_A G \rightarrow G \times_{F \backslash G} G$ is surjective.

(iv) If u is a monomorphism, [N.D.E-VI_A-34] then:

(a) $F \times_A G \xrightarrow{(\lambda, pr_2)} G \times_{F \backslash G} G$ is an isomorphism, and $G \rightarrow F \backslash G$ is faithfully flat and locally of finite presentation. *(a') $F \backslash G$ represents the (fppf) quotient sheaf $F \backslash G$, and $G \rightarrow F \backslash G$ is a locally trivial F -torsor for the (fppf) topology.* *(b) $F \backslash G$ is flat over A , and is smooth over A if G is so.*

(c) $u : F \rightarrow G$ is a closed immersion, and $F \backslash G$ is separated. *(d) If, in addition, F is a normal subgroup of G , there exists on $F \backslash G$ one and only one A -group structure such that $p : G \rightarrow F \backslash G$ is a morphism of A -groups.*

<!-- label: III.VI_A.3.2 -->

In the proof of this theorem, A will denote an A -algebra that is local, finite and free over A . If R is a relation involving A , we shall say that " $R(A)$ is true when A is large enough" if there exists an A -algebra A_1 that is local, finite and free over A such that the relation $R(A)$ is satisfied for each A -algebra A that is local, finite and free over A_1 .

<!-- original page 304 -->

We shall first prove the theorem when F and G are of finite type over A .

3.2.1.

Suppose for a moment that every point of G has an open saturated neighborhood W such that the groupoid induced by $G_{\{*\}}$ on W possesses a quasi-section (cf. V § 6). Then, by V 6.1, one has assertions (i), (ii), (iii) and (iv)(a), and $F \backslash G$ is of finite type over k . Moreover, under the hypothesis of (iv), since $G \rightarrow F \backslash G$ is faithfully flat and locally of finite presentation, assertion (b) follows from EGA IV, 2.2.14 and 17.7.7. On the other hand, assertion (iv)(a') follows from (iv)(a), by Exp. IV, 3.4.3.1, 5.2.2 and 5.1.6. Finally, (iv)(c) will be proved in 3.2.5, and (ii') and (iv)(d) will be proved in section 5.

Let us now prove the following assertion:

``text
(†) every finite subset of $F \backslash G$ is then contained in an affine open.
``

[N.D.E-VI_A-35]

If u is a quasi-section of the groupoid induced by $G_{\{*\}}$ on a saturated open W of G , then $u \otimes_A A$ is a quasi-section of the (Sch/A) -groupoid induced by $G_{\{*\}} \otimes_A A$ on $W \otimes_A A$. Moreover, if $u_{\{*\}}$ is the (Sch/A) -groupoid induced by $G_{\{*\}}$ on u , then $u_{\{*\}} \otimes_A A$ is identified with the (Sch/A) -groupoid induced by $G_{\{*\}} \otimes_A A$ on $u \otimes_A A$. [N.D.E-VI_A-36]

It follows from the proofs of Exposé V that the construction of the quotient $X = F \backslash G$ commutes with the extension $A \rightarrow A'$ of the base of the type considered here. [N.D.E-VI_A-37]

Let then $x_1, \dots, x_n$ be points of $X = F \backslash G$, which we may assume closed, [N.D.E-VI_A-38] and $g_1, \dots, g_n$ closed points of G projecting onto $x_1, \dots, x_n$. Let V be an everywhere dense affine open of X , [N.D.E-VI_A-39] and let u be the inverse image of V in G . By 1.2, there exists an A -algebra A' that is local, finite and free over A , such that the points $g'_1, \dots, g'_p$ of $G' = G \otimes_A A'$ above $g_1, \dots, g_n$ are strictly rational over A' . [N.D.E-VI_A-40] Since the morphisms $G' \rightarrow G$ and $G \rightarrow X$ are open, $u' = u \otimes_A A'$ is dense in G' , so the open set $\bigcap_{i=1}^p (U')^{-1} \cdot g'_i$ is non-empty, hence contains a closed point x . So, by 1.2 (and 0.4.1), one may suppose, by possibly enlarging A' , that x is strictly rational over A' . Then, since $x \in (U')^{-1} \cdot g'_i$, one has $g'_i \in U' \cdot x$.

Denote by V' the inverse image of V in $X' = X \otimes_{\mathbb{A}} \mathbb{A}'$; this is an affine open of X' , and is also the image of U under the projection $G' \rightarrow X'$. Since right translation r_x is an automorphism of the groupoid $G_* \otimes_{\mathbb{A}} \mathbb{A}'$, it induces an automorphism, again denoted r_x , of the quotient X' . Consequently, the image $V' \cdot x = r_x(V')$ of $U \cdot x$ in X' is

<!-- original page 305 -->

an affine open of X' containing the images $x'_1, \dots, x'_p$ of $g_1, \dots, g_p$.

Consider now the equivalence relation on $X' = X \otimes_{\mathbb{A}} \mathbb{A}'$ defined by the projection $X \otimes_{\mathbb{A}} \mathbb{A}' \rightarrow X$:

```

```text
 d_1
 |
X \otimes_{\mathbb{A}} \mathbb{A}' \otimes_{\mathbb{A}} \mathbb{A}' \xrightarrow{\quad} X \otimes_{\mathbb{A}} \mathbb{A}' \rightarrow X,
 |
 d_0
...

```

where  $d_0$  and  $d_1$  are induced by the two canonical injections of  $\mathbb{A}'$  into  $\mathbb{A}' \otimes_{\mathbb{A}} \mathbb{A}'$ . Since  $\mathbb{A}'$  is a finite, free  $\mathbb{A}$ -algebra, say of rank  $n$ , then  $d_0$  and  $d_1$  are finite and locally free of rank  $n$ ; consequently, one may apply the reasoning of Exp. V, 5.b (drawn from the proof of SGA 1, VIII.7.6). One thus obtains that  $x'_1, \dots, x'_p$  are contained in an affine saturated open  $W'$  contained in the affine open  $V' \cdot x$ . The image of  $W'$  in  $X$  then contains  $x_1, \dots, x_n$  and is an affine open of  $X$ , by V, 4.1 (ii).

### 3.2.2.

For every  $\mathbb{A}$ -algebra  $\mathbb{A}'$  that is local, finite and free over  $\mathbb{A}$ , let us now write  $U(\mathbb{A}')$  for the set of points of  $G \otimes_{\mathbb{A}} \mathbb{A}'$  having an open saturated neighborhood  $W$  such that the groupoid induced by  $G_* \otimes_{\mathbb{A}} \mathbb{A}'$  on  $W$  has a quasi-section. It is clear that  $U(\mathbb{A}')$  is saturated for the action of  $G(\operatorname{Spec} \mathbb{A}')$  on  $G \otimes_{\mathbb{A}} \mathbb{A}'$ . We shall see that, when  $\mathbb{A}'$  is large enough,  $U(\mathbb{A}')$  is equal to  $G \otimes_{\mathbb{A}} \mathbb{A}'$ .

By Theorem V 8.1,  $U(\mathbb{A}')$  is non-empty, hence contains a closed point  $y$ . The proof then proceeds by induction on  $\dim(G - U(\mathbb{A}'))$ . Let  $g_1, \dots, g_n$  be closed points belonging to the various irreducible components of  $G - U(\mathbb{A}')$ . By 1.2, there exists  $\mathbb{A}'$  local, finite and free over  $\mathbb{A}$ , such that the points  $g'_1, \dots, g'_p$  (resp.  $x = x_1, \dots, x_r$ ) of  $G' = G \otimes_{\mathbb{A}} \mathbb{A}'$  projecting onto  $g_1, \dots, g_n$  (resp. onto  $y$ ) are strictly rational over  $\mathbb{A}'$ . Then  $U(\mathbb{A}')$  contains  $(U(\mathbb{A}) \otimes_{\mathbb{A}} \mathbb{A}') \cdot x^{-1} g'_i$  for every  $i$ ; so  $U(\mathbb{A}')$  contains

<!-- original page 306 -->

$g'_1, \dots, g'_p$ , and one has

```

```text
dim(G' - U(A')) < dim(G - U(A)).
...

```

The induction hypothesis then implies the existence of an algebra $\mathbb{A}''$ local, finite and free over $\mathbb{A}'$ such that one has $U(\mathbb{A}'') = G' \otimes_{\mathbb{A}'} \mathbb{A}'' = G \otimes_{\mathbb{A}} \mathbb{A}''$.

3.2.3.

We are now in a position to prove the existence of $F \backslash G$ when F and G are of finite type over $\mathbb{A}$. Let $\mathbb{A}'$ be large enough over $\mathbb{A}$ so that $U(\mathbb{A}')$ coincides with $G \otimes_{\mathbb{A}} \mathbb{A}'$ (cf. 3.2.2). We shall set $\mathbb{A}'' = \mathbb{A}' \otimes_{\mathbb{A}} \mathbb{A}'$ and, for every $\mathbb{A}$ -scheme X , we shall denote by X' and X'' the fibered products $X \otimes_{\mathbb{A}} \mathbb{A}'$ and $X \otimes_{\mathbb{A}} \mathbb{A}''$. By 3.2.1 and 3.2.2, the quotients $F' \backslash G'$ and $F'' \backslash G''$ exist, and one has the following commutative diagram, in which the first two lines and columns are exact:

```

```text
 pr''_2 p''
F' \otimes_{\mathbb{A}'} G'' \xrightarrow{\lambda''} G'' \longrightarrow F'' \setminus G''
 | | |
 w_1 w_2 v_1 v_2 u_1 u_2

```

$$\begin{array}{ccccc}
 (*) & F' \times_{A'} G' & \xrightarrow[\lambda']{pr'_2} & G' & \xrightarrow{p'} & F' \setminus G' \\
 & h & & g & & \\
 & F \times_A G & \xrightarrow[\lambda]{pr_2} & G & & . \\
 & \dots & & & & 
 \end{array}$$

In this diagram,  $pr'_2$  and  $\lambda'$  (resp.  $pr'_2$  and  $\lambda$ ) are obtained from  $pr_2$  and  $\lambda$  by obvious base changes; the morphisms  $g$  and  $h$  are induced by the canonical injection  $A \rightarrow A'$ . One denotes by  $p'$  and  $p''$  the canonical morphisms; the morphisms  $v_1, v_2$  and  $w_1, w_2$  are induced by the two canonical injections of  $A'$  into  $A''$ . Finally, since the construction of the quotient  $F' \setminus G'$  commutes with the two base changes

<!-- original page 307 -->

$f_1, f_2 : \operatorname{Spec} A' \rightarrow \operatorname{Spec} A'$ , one has, writing  $\pi' : F' \setminus G' \rightarrow \operatorname{Spec} A'$  for the structural morphism, canonical isomorphisms, for  $i = 1, 2$ :

```text

$$\tau_i : F' \setminus G' \rightarrow (F' \setminus G') \times_{\pi', f_i} \operatorname{Spec} A',$$

and the morphism u_i is the composite of τ_i and the projection $(F' \setminus G') \times_{\pi', f_i} \operatorname{Spec} A' \rightarrow F' \setminus G'$.

Now, when one has a diagram of type $(\ast)$ with the first two rows and columns exact, one verifies easily that $\operatorname{Coker}(pr_2, \lambda)$ exists if and only if $\operatorname{Coker}(u_1, u_2)$ exists, and these two cokernels are identified. The existence of $F \setminus G$ will therefore follow from that of $\operatorname{Coker}(u_1, u_2)$.

Now it follows from the compatibility of the formation of $F \setminus G$ with the base extensions considered here (cf. N.D.E. (37) in 3.2.1, and 4.6 below) that the composite morphism

```text

$$(F' \setminus G') \times_{\pi', f_1} \operatorname{Spec} A' \xrightarrow{\tau_1^{-1}} F' \setminus G' \xrightarrow{\tau_2} (F' \setminus G') \times_{\pi', f_2} \operatorname{Spec} A'$$

is a descent datum on  $F' \setminus G'$  relative to  $f : \operatorname{Spec} A' \rightarrow \operatorname{Spec} A$ . By 3.2.1 (†) and SGA 1, VIII 7.6, this descent datum is effective, that is,  $\operatorname{Coker}(u_1, u_2)$  exists (one could also use directly Theorem 4.1 of Exp. V).

### 3.2.4.

To complete the proof of assertions (i), (ii), (iii) and (iv)(a) of 3.2 in the case where  $F$  and  $G$  are of finite type over  $A$ , it remains to study the quotient  $F \setminus G$ . By V 6.1, assertions (ii), (iii) and (iv)(a) "become true" after the base change  $f : \operatorname{Spec} A' \rightarrow \operatorname{Spec} A$ ; by EGA IV\_2, 2.6.1, 2.6.2 and 2.7.1, these assertions were therefore true before the base change. Finally, to prove the second assertion of (i), i.e. that  $F \setminus G$  is the cokernel of  $(pr_2, \lambda)$  in the category of all ringed spaces, one need only refer to V § 6.c).

<!-- original page 313 -->

### 3.2.5.

[^N.D.E-VI\_A-41] Let us now prove assertion (iv)(c) of 3.2, by reproducing the proof of VI\_B, 9.2.1. Write  $X = F \setminus G$ , and  $d$  for the morphism  $F \times_A G \rightarrow G \times_A G$  with components  $\lambda$  and  $pr_2$ .

Since  $u$  is a closed immersion by 2.5.2, and since  $d = \sigma \circ (u \times \operatorname{id}_G)$ , where  $\sigma$  is the automorphism of  $G \times_A G$  defined by  $\sigma(x, y) = (xy, y)$ ,  $d$  is a closed immersion. On the other hand, by (iv)(a), one has the cartesian square

```text

$$\begin{array}{ccc}
 F \times_A G & \xrightarrow{d} & G \times_A G \\
 \downarrow & & \downarrow p \times p \\
 X & \xrightarrow{\Delta_X} & X \times_A X
 \end{array}$$

and p , hence also $p \times p$, is faithfully flat and locally of finite presentation. So, by (fppf) descent, since d is a closed immersion, the same holds for Δ_X , i.e. X is separated.

3.3.

[^N.D.E-VI_A-42] In Theorem 3.2, the hypothesis that G be flat can be removed when $u : F \rightarrow G$ is a monomorphism. This generalization is mentioned in Remark 9.3 b) of Exp. VI_B, and also in [Ray67a], Example a) i), p. 82. The proof, found in Theorem 4 of [An73], follows from Theorem 3.2 and from the following theorem of Grothendieck (mentioned in [Ray67a], Th. 1 ii) and proved in [DG70], § III.2, 7.1). If X is a scheme and R an equivalence relation in X , we shall write $\tilde{X}/R$ for the (fppf) quotient sheaf of X by R (cf. IV 4.4.9).

Theorem 3.3.1 (Grothendieck). *Let A be a ring, X an A -scheme, and $d_{\{0\}}, d_{\{1\}} : R \rightarrow X$ an A -equivalence relation in X , such that $d_{\{i\}}$ is faithfully flat, of finite presentation. Let X_0 be a saturated closed subscheme of X , defined by a nilpotent ideal, and let R_0 be the equivalence relation induced by R on X_0 . Then, if the (fppf) quotient sheaf $\tilde{X}_{\{0\}}/R_{\{0\}}$ is representable by an A -scheme, so is $\tilde{X}/R$.*

<!-- label: III.VI_A.3.3.1 -->

For the proof, we refer to [DG70], § III.2, 7.1. Let us now return to the case where A is an Artinian local ring. Let $u : F \rightarrow G$ be a quasi-compact morphism between A -groups locally of finite type, and suppose further that u is a monomorphism. Then, by 2.5.2, u is a closed immersion.

One may now state the following variant of Theorem 3.2.

Theorem 3.3.2. *Let A be an Artinian local ring, G an A -group locally of finite type, F a closed subgroup of G , flat over A .[^N.D.E-VI_A-43] *Then:*

(i) The (fppf) quotient sheaf $\tilde{F} \backslash G$ is representable by an A -scheme $F \backslash G$ that is separated and locally of finite type; moreover, the sequence*

$$\begin{array}{ccccc}
 & & // & & p \\
 F \times_A G & \longrightarrow & G & \longrightarrow & F \backslash G
 \end{array}$$

<!-- original page 318 -->

is exact in the category of all ringed spaces.

(ii) $F \times_{\{A\}} G \rightarrowtail G \times_{F \backslash G} G$ is an isomorphism, and $p : G \rightarrow F \backslash G$ is faithfully flat and locally of finite presentation, so that p is a locally trivial F -torsor for the (fppf) topology.*

(iii) If G is flat (resp. of finite type, resp. smooth) over A , then so is $F \backslash G$.*

(iv) $X = F \backslash G$ is equipped with a right action of G , such that $p(e) \cdot g = p(g)$ for every $g \in G$; consequently, the connected components of X are of finite type over A , irreducible, and all of dimension $\dim G - \dim F$.*

(v) If, in addition, F is a normal subgroup of G , there exists on $F \backslash G$ one and only one A -group structure such that $p : G \rightarrow F \backslash G$ is a morphism of A -groups.*

<!-- label: III.VI_A.3.3.2 -->

Assertions (i) and (ii) follow from 3.2 and 3.3.1, and since $G \rightarrow F \backslash G$ is faithfully flat and locally of finite presentation, assertion (iii) follows from EGA IV, 2.2.14, 2.7.1 and 17.7.7. We shall prove assertions (iv) and (v) in section 5. Let us note immediately the following corollary.

****Corollary 3.3.3.**** *Let A be an Artinian local ring, G an A -group locally of finite type, H a closed subgroup of G , flat over A . Write ρ for the morphism $G \rightarrow G/H$ and λ (resp. ρ_1) for the morphism $G \times H \rightarrow G$ defined by $\lambda(g, h) = gh$ (resp. the projection $G \times H \rightarrow G$). Then, for every open subset U of G/H , one has*

```
```text
O(U) = {φ ∈ O(p-1(U)) | φ ∘ λ = φ ∘ ρ1}
```

i.e.  $O(U)$  is the set of  $\phi \in O(p^{-1}(U))$  such that  $\phi(gh) = \phi(g)$  for every  $A$ -scheme  $S$  and  $g \in G(S)$ ,  $h \in H(S)$ .\*

<!-- label: III.VI\_A.3.3.3 -->

Indeed, since  $\rho : G \rightarrow G/H$  is faithfully flat and locally of finite presentation, hence covering for the (fppf) topology, this follows from IV, 3.3.3.2.

## 4. Construction of quotients  $F \backslash G$  (general case)

<!-- label: III.VI\_A.4 -->

<!-- original page 308 -->

We now assume the hypotheses of Theorem 3.2 to be satisfied,  $F$  and  $G$  not necessarily being of finite type over  $A$ .

### 4.1.

Let us first consider a connected component  $G^\alpha$  of  $G$  and show that the saturation  $S(G^\alpha)$  [N.D.E-VI A-44] of  $G^\alpha$  for the equivalence relation defined by the groupoid  $G^*$  is an open-and-closed subset of  $G$  (in other words, is the union of certain connected components of  $G$ ).

This saturation is the image of  $F \times_A G^\alpha$  under  $\lambda$ , hence is open in  $G$  (cf. § 3.1). If  $k$  is the residue field of  $A$  and  $\bar{k}$  an algebraic closure of  $k$ , it remains to show that the image of  $(F \times_A G^\alpha) \times_A \bar{k}$  by  $\lambda \times \text{id}$  is closed in  $G \times_A \bar{k}$ , or equivalently, by SGA 1, VIII.4.4, that the image of  $(F \times_A G^\alpha) \times_A \bar{k}$  by  $\lambda \times \text{id}$  is closed. Since  $G^\alpha \times_A \bar{k}$  is the union of a finite number of connected components of  $G \times_A \bar{k}$ , we are reduced to the case where  $A$  is an algebraically closed field, which we shall assume. In this case,  $S(G^\alpha)$  is the union of the images of  $G^\alpha$  under the left translations  $\ell_u(x)$ , where

<!-- original page 319 -->

$x$  runs through the closed points of  $F$ ; the assertion follows therefore from the fact that these images are connected components of  $G$ .

### 4.2.

Let us in particular take  $G^\alpha$  to be the connected component  $G^0$  of the origin of  $G$ . Then  $S(G^0)$  obviously contains the image of  $F$  under  $\rho$ , which is none other than the equivalence class of the origin. On the other hand, if  $F^\beta$  is a connected component of  $F$ ,  $F^\beta \times_A G^0$  is connected (2.1.2), so that the image of  $F^\beta \times_A G^0$  by  $\lambda$  is contained in the connected component of  $\rho(F^\beta)$  in  $G$ . In other words,  $S(G^0)$  is the union of the connected components which meet the image of  $F$ .

One will also note that the open subscheme of  $G$  having  $S(G^0)$  as underlying space is a subgroup of  $G$  (which we still denote  $S(G^0)$ ):

<!-- original page 309 -->

indeed, the inversion morphism of  $G$  preserves the image of  $F$  and permutes the connected components of  $G$  meeting this image; it therefore suffices to show that  $\nu : G \times_A G \rightarrow G$  sends  $S(G^0) \times_A S(G^0)$  into  $S(G^0)$ , and for this one may suppose that  $A$  is an algebraically closed field (with the notations of 4.1,  $S(G^0) \times_A \bar{k}$  is indeed identified with the saturation of  $(G \times_A \bar{k})^0$  by the equivalence relation defined by the homomorphism  $\nu \times \text{id}$ ); if  $G^\gamma$  and  $G^\delta$  are then connected components of  $S(G^0)$ ,  $G^\gamma \times_A G^\delta$  is connected and its image under  $\nu$  meets the

image of  $F$ ; consequently,  $u(G^{\gamma} \times_A G^{\delta})$  is contained in a connected component of  $G$  meeting  $u(F)$ .

### 4.3.

It follows from what precedes that the groupoid  $G_*$  with base  $G$  defined by  $u$  is the direct sum of the groupoids  $S(G^{\alpha})_*$  induced by  $G_*$  on the various open-and-closed parts of  $G$  of the form  $S(G^{\alpha})$ . The cokernel of  $G_*$  is therefore the direct sum of the cokernels of these groupoids  $S(G^{\alpha})_*$ , which one is led to study separately.

Let us first consider the groupoid  $S(G^0)_*$  induced by  $G_*$  on  $S(G^0)$ . It is clear that  $S(G^0)_*$  is the groupoid with base  $S(G^0)$  defined by the homomorphism from  $F$  into  $S(G^0)$  induced by  $u$  (§ 3.1). The cokernel whose existence we wish to prove is therefore identified with  $S(G^0)$ . Consider on the other hand the groupoid

```

```text
      \begin{array}{ccccc}
      & \xrightarrow{\varphi'_2} & & & \\
      & \varphi'_1 & \xrightarrow{\quad} & \varphi_1 & \\
G^0_2 & \xrightarrow{\quad} & G^0_1 & \xrightarrow{\quad} & G^0_0 = G^0 \\
      & & & \varphi_0 & \\
      & \varphi'_0 & & & 
      \end{array}
```

```

induced by  $S(G^0)_*$  on  $G^0$ . If one refers to the construction explicit in V § 3.b), the object then denoted  $Y_0 \times_{X_0} X_1$  is none other than

<!-- original page 310 -->

$F \times_A G^0$ , so that  $G^0_1$  is the inverse image of  $G^0$  under the morphism  $F \times_A G^0 \rightarrow S(G^0)$  induced by  $\lambda$ .

I claim that this inverse image is  $F^0 \times_A G^0$ , where  $F^0$  denotes the inverse image of  $G^0$  under  $u$ . Indeed, if  $F^{\beta}$  is a connected component of  $F^0$ ,  $F^{\beta} \times_A G^0$  is connected (2.1.2) and  $\lambda(F^{\beta} \times_A G^0)$  is contained in  $G^0$ ; conversely, if  $F^{\beta}$  is a connected component of  $F$  not contained in  $F^0$ , the image of  $F^{\beta} \times_A G^0$  is again connected and contains  $u(F^{\beta})$ ; if  $u(F^{\beta})$  is not contained in  $G^0$ ,  $\lambda(F^{\beta} \times_A G^0)$  does not meet  $G^0$ .

It follows from what precedes that the groupoid  $G^0_*$  induced by  $G_*$  on  $G^0$  is the groupoid with base  $G^0$  defined by the homomorphism  $F^0 \rightarrow G^0$  induced by  $u$ . Since  $G^0$ , and hence  $F^0$ , are of finite type over  $A$ , then, by paragraph 4,  $G^0_*$  has a cokernel which is none other than  $F^0 \backslash G^0$ .

I now claim that  $F^0 \backslash G^0$  is identified with  $S(G^0)$ . Indeed, the proof is analogous to that of the first part of assertion (i) of Lemma V § 6.1; consider the diagram:

```

```text
      \begin{array}{ccc}
      & \xleftarrow{v} & \\
S(G^0) & \xleftarrow{\quad} & F \times_A G^0 \xrightarrow{\quad} G^0, \quad \text{pr}_2 \\
      & & 
      \end{array}
```

```

where  $v$  is the morphism induced by  $\lambda$ . Since  $\text{pr}_2$  has a section,  $\text{pr}_2$  is a universal effective epimorphism, so that  $F^0 \backslash G^0$  coincides with  $\text{Coker}(v_0, v_1)$ , where

```

```text
      \begin{array}{ccccc}
      & \xrightarrow{v'_2} & & & \\
      & v'_1 & \xrightarrow{\quad} & v_1 & \\
V_2 & \xrightarrow{\quad} & V_1 & \xrightarrow{\quad} & V = F \times_A G^0 \\
      & & & v_0 & \\
      & v'_0 & & & 
      \end{array}
```

```

<!-- original page 311 -->

is the inverse image by  $\text{pr}_2$  of the groupoid  $G^{\{0\}}_*$  (cf. V § 3.a), that is, also the inverse image of  $S(G^{\{0\}}_*)$  by the composite morphism

$$\begin{array}{c} \text{``text} \\ F \times_A G^0 \xrightarrow{\text{inclusion}} F \times_A S(G^0) \xrightarrow{\text{pr}_2} S(G^0). \end{array}$$

Similarly, since  $v$  is faithfully flat and quasi-compact,  $F \backslash S(G^{\{0\}})$  coincides with the cokernel of the inverse image of  $S(G^{\{0\}}_*)$  by the base change  $v$ . Now this inverse image is isomorphic to  $V_*$  by Exp. V, § 3.c; it follows that the canonical inclusion of  $G^{\{0\}}_*$  into  $S(G^{\{0\}}_*)$  induces an isomorphism of  $F^{\{0\}} \backslash G^{\{0\}}$  onto  $F \backslash S(G^{\{0\}})$ .

We finally note that: the construction of  $F \backslash S(G^{\{0\}})$  commutes with finite locally free base changes, because the same holds for  $F^{\{0\}} \backslash G^{\{0\}}$  (cf. N.D.E. (37) and 4.6 below).

### 4.4.

It remains to construct the cokernel of the groupoid  $S(G^{\{\alpha\}}_*)$  when  $G^{\{\alpha\}}$  is an arbitrary connected component of  $G$ . If  $A'$  is a large enough local, finite, free  $A$ -algebra (cf. 3.2),  $G^{\{\alpha\}} \otimes_{A'} A'$  is the union of a finite number of connected components  $C_1, \dots, C_n$  of  $G \otimes_{A'} A'$ , all of which have a strictly rational point. For every  $i$ , there exists therefore a right translation  $r_i$  of  $G \otimes_{A'} A'$  sending  $G^{\{0\}} \otimes_{A'} A'$  onto  $C_i$ ; this translation induces an isomorphism of the groupoid  $S(G^{\{0\}}_*) \otimes_{A'} A'$  onto  $S(C_i)_*$ , so that the groupoid induced by  $G_* \otimes_{A'} A'$  on the saturation of  $C_i$  has a cokernel.

Since  $S(G^{\{\alpha\}}_*) \otimes_{A'} A'$  is the direct sum of some of the  $S(C_i)_*$ , then  $S(G^{\{\alpha\}}_*) \otimes_{A'} A'$  has a cokernel; this cokernel is the direct sum of a certain number of copies of  $(F^0 \otimes_A A') \backslash (G^0 \otimes_A A')$ , so that every finite subset of this cokernel is contained in an affine open; moreover, the construction of this cokernel commutes with finite locally free extensions

<!-- original page 312 -->

of the base (cf. N.D.E. (37) and 4.6 below). One thus sees, as in 3.2.3, that this cokernel is of the form  $Y \otimes_{A'} A'$ , where  $Y$  is a cokernel of  $S(G^{\{\alpha\}}_*)$ .

### 4.5.

We have therefore constructed  $F \backslash G$  and shown that it is a direct sum of schemes of finite type over  $A$ . The other assertions of Theorem 3.2 reduce directly to assertions concerning the groupoids  $S(G^{\{\alpha\}}_*)$ . As in V § 6, the second assertion of (i) follows from the first and from (ii) and (iii), so it suffices to prove (ii), (iii) and (iv)(a). Since  $A'$  is a local, finite, free  $A$ -algebra, the morphism  $A \rightarrow A'$  is faithfully flat and of finite presentation, so, by SGA 1, VIII (3.1, 4.6, 5.4), it suffices to verify the corresponding assertions in the case of the groupoid  $S(G^{\{\alpha\}}_*) \otimes_{A'} A'$ . Now the latter is isomorphic to the direct sum of a finite number of copies of  $S(G^{\{0\}}_*) \otimes_{A'} A'$  (cf. 4.4), so that one is reduced to the groupoid  $S(G^{\{0\}}_*)$ .

For this last one continues to mimic the proof established in V § 6, as one began to do in 4.3.

### 4.6.

Let us add to conclude this paragraph some remarks concerning Lemma 6.1 and § 9.a of Exposé V: with the hypotheses and notations of V § 9.a, we seek a condition under which the construction of the cokernel of the  $(\text{Sch}/S)$ -groupoid  $X_*$  commutes with an extension  $\pi : S' \rightarrow S$  of the base. Since the cokernels of  $X_*$  and  $X'_*$  are identified with the cokernels of the groupoids  $U_*$  and  $U'_*$  induced by  $X_*$  and  $X'_*$  on the quasi-sections  $U$  and  $U'$ , one is reduced to the case of a  $(\text{Sch}/S)$ -groupoid satisfying the hypotheses of Theorem V 4.1.

[^N.D.E-VI\_A-45] If one denotes by  $Y$  the cokernel of  $U_*$ ,  $Y' = Y \otimes_S S'$ , and  $Y'_1$  the cokernel of  $U'_*$ , one saw in V § 9.a that the canonical morphism  $Y_1 \rightarrow Y'$  is a homeomorphism (and even a universal homeomorphism); one may therefore identify  $Y'_1$  and  $Y'$  as topological spaces. If  $\rho : U \rightarrow Y$  is the canonical morphism and if  $\rho' : U' \rightarrow Y'$  is obtained from it by base change, we then want the sequence of  $\mathcal{O}_{Y'}$ -modules

$$\begin{array}{c} \text{``text} \\ (*) \quad \mathcal{O}_{Y'} \xrightarrow{\rho'_*(\mathcal{O}_{U'})} \longrightarrow \rho'_*(\mathcal{O}_{U'_1}) = \rho'_*(\mathcal{O}_{U'}) \end{array}$$

...

<!-- label: eq:III.VI\_A.4.6-star -->

to be exact.[^N.D.E-VI\_A-46] Since we are under the hypotheses of V 4.1,  $u_0$  and  $u_1$  are finite and locally free; and, by V.4.1 (ii),  $p$  is integral. Then,  $p$  and  $p \circ u_i$  are affine, hence separated and quasi-compact.

<!-- original page 313 -->

Consequently, if  $S$  is flat over  $S$ , it follows from EGA III\_1, 1.4.15 (taking into account the correction Err\_III 25 in EGA III\_2) that the sequence  $(\ast)$  is identified with the inverse image of the sequence

```text

$$(**) \quad 0_Y \longrightarrow \xrightarrow{p_*(0_U)} p_* u_{1*}(0_{U_1}) = p_* u_{0*}(0_{U_1}),$$

```

<!-- label: eq:III.VI\_A.4.6-doublestar -->

which is an exact sequence.[^N.D.E-VI\_A-47] An analogous argument applies when the groupoid  $X_*$  has "locally" quasi-sections (cf. the proof of Theorem V 7.1). One thus obtains the:

**Proposition 4.6.1.** \*The construction of the cokernel of  $X_*$  commutes with flat extensions of the base when  $X_*$  has locally quasi-sections.\*

<!-- label: III.VI\_A.4.6.1 -->

### 4.7.

Let us now consider the case of the groupoid  $G_*$  of Theorem 3.2 when one provisionally assumes  $F$  and  $G$  of finite type over  $A$ .

By 3.2.2, there exists an  $A$ -algebra  $A'$  local, finite and free over  $A$  such that the groupoid  $G_* \otimes_{A'} A'$  has "locally" quasi-sections. For every extension  $T \rightarrow \operatorname{Spec} A$  of the base, the sequence

```text

$$(F' \backslash G') \times_{\operatorname{Spec} A} T \xrightarrow{\quad} (F' \backslash G') \times_{\operatorname{Spec} A} T \longrightarrow (F \backslash G) \times_{\operatorname{Spec} A} T$$

```

deduced from the diagram  $(\ast)$  of 3.2.3 is exact. If one supposes in addition  $T$  flat over  $\operatorname{Spec} A$ , then  $(F' \backslash G') \times_{\operatorname{Spec} A} T$  and  $(F' \backslash G') \times_{\operatorname{Spec} A} T$  are identified respectively, by 4.6, with the cokernels of the groupoids

```text

$$(G_* \otimes_{A'} A') \times_{\operatorname{Spec} A} T \quad \text{and} \quad (G_* \otimes_{A'} A') \times_{\operatorname{Spec} A} T.$$

```

The diagram deduced from 3.2.3  $(\ast)$  by the base change  $T \rightarrow \operatorname{Spec} A$  then shows that  $(F \backslash G) \times_{\operatorname{Spec} A} T$  is identified with the cokernel of  $G_* \times_{\operatorname{Spec} A} T$ . An analogous argument is valid in the general case (i.e. when  $G$  and  $F$  are locally of finite type over  $A$ ). One therefore obtains:[^N.D.E-VI\_A-48]

**Proposition 4.7.1.** \*Under the hypotheses of Theorem 3.2, for every flat  $A$ -scheme  $T$ ,  $(F \backslash G) \times_{\operatorname{Spec} A} T$  is identified with the left quotient of  $G \times_{\operatorname{Spec} A} T$  by  $F \times_{\operatorname{Spec} A} T$ .\*

<!-- label: III.VI\_A.4.7.1 -->

## 5. Connections with Exposé IV and consequences

<!-- label: III.VI\_A.5 -->

<!-- original page 314 -->

### 5.1.

[^N.D.E-VI\_A-49] We resume the notations of § 3 and the hypotheses of Theorem 3.2; one then has the following commutative diagram

$$\begin{array}{ccc} & & F \times v \\ F \times_A G \times_A G & \longrightarrow & F \times_A G \\ \text{pr}_2 \times G & \lambda \times G & \text{pr}_2 \quad \lambda \\ & v & \\ G \times_A G & \longrightarrow & G \\ p \times G & & p \\ & \rho & \\ (F \backslash G) \times_A G & \rightarrow \rightarrow \rightarrow \rightarrow \rightarrow & F \backslash G, \end{array}$$

which satisfies the equalities  $\text{pr}_2 \circ (F \times \nu) = \nu \circ (\text{pr}_2 \times G)$  and  $\lambda \circ (F \times \nu) = \nu \circ (\lambda \times G)$ . Moreover, since  $G$  is assumed flat over  $A$ , the left vertical sequence is exact by 4.7, so that  $\nu$  induces a morphism of  $A$ -schemes:

$$\rho : (F \backslash G) \times_A G \rightarrow F \backslash G.$$

This morphism  $\rho$  makes  $G$  act on the right on  $F \backslash G$ , as one verifies immediately; moreover, the canonical morphism  $G \rightarrow F \backslash G$  commutes with the right actions of  $G$  on  $G$  and on  $F \backslash G$ .

[^N.D.E-VI\_A-50] This proves the first assertion of point (ii') of 3.2. By 2.5.4, one then obtains that the connected components of  $X = F \backslash G$  are of finite type, irreducible, and all of the same dimension. To evaluate this dimension, one may suppose  $A = k$  and  $k$  algebraically closed. By I, 2.3.3.1, the stabilizer of the  $k$ -point  $p(e)$  is represented by the fiber  $H = p^{-1}(p(e))$ , and since  $F \backslash G$  is the quotient of  $G$  by  $F$  in the category of ringed spaces, this fiber has  $u(F)$  as underlying space, and since  $\text{Ker}(u)$  is finite, one therefore has  $\dim H = \dim u(F) = \dim F$ . By 2.5.4 (ii), one obtains therefore that  $\dim X = \dim G - \dim F$ . This proves point (ii') of Theorem 3.2 (and hence also point (iv) of 3.3.2).

### 5.2.

When the homomorphism of  $A$ -groups  $u : F \rightarrow G$  is a monomorphism, one can recover 5.1 by using the results of Exposé IV. Indeed, the canonical morphism  $p : G \rightarrow F \backslash G$  is faithfully flat and open by 3.2; it is therefore covering for the (fpqc) topology (IV 6.3.1), and one may apply corollaries IV.5.2.2 and IV.5.2.4.

<!-- original page 315 -->

In particular, if we assume, in addition to the hypotheses of 3.2, that  $u$  is the inclusion in  $G$  of a normal subgroup  $F$ , there exists on  $F \backslash G$  one and only one  $A$ -group structure such that the canonical morphism  $p : G \rightarrow F \backslash G$  is a homomorphism of  $A$ -groups.[^N.D.E-VI\_A-51] This proves point (v) of 3.3.2.

### 5.3.

We shall now review some statements from Exposé IV.

#### 5.3.1.

Statements IV 5.2.7 and IV 5.3.1 translate as follows. Let  $F$  and  $G$  be two groups locally of finite type and flat over  $A$ ,  $F$  being a closed normal subgroup of  $G$ . The maps  $H \mapsto F \backslash H$  and  $H' \mapsto H' \times_{(F \backslash G)} G$  define a bijective correspondence between flat  $A$ -subgroups of  $G$  containing  $F$  and flat  $A$ -subgroups of  $F \backslash G$ . In this bijection, closed (resp. normal) subgroups of  $G$  containing  $F$  correspond to closed (resp. normal) subgroups of  $F \backslash G$ .[^N.D.E-VI\_A-52]

#### 5.3.2.

Proposition IV 5.2.9 implies the following result. Let  $F$ ,  $H$  and  $G$  be groups locally of finite type and flat over

$A$ ; assume  $F \subset H \subset G$ , with  $F$  closed in  $G$  and normal in  $H$ . Under these conditions,  $F \backslash H$  acts freely on the left on  $F \backslash G$ , the quotient scheme  $(F \backslash H) \backslash (F \backslash G)$  exists, and there is a canonical isomorphism of schemes with operator group  $G$ :

$$(F \backslash H) \backslash (F \backslash G) = H \backslash G.$$

### 5.3.3.

From IV 5.2.8, finally, follows the assertion below. Let  $F$ ,  $H$  and  $G$  be groups locally of finite type and flat over  $A$ ; assume that  $F$  is contained in, closed and normal

<!-- original page 316 -->

in  $G$ , that  $H$  is contained in  $G$ , and that  $F \cap H$  is flat over  $A$ . Let  $F \times_{\tau_A} H$  denote the  $A$ -group having the product  $F \times_{\tau_A} H$  as underlying scheme, with multiplication defined by the morphism  $((x, h), (y, h')) \mapsto (xhy^{-1}, hh')$ ; similarly, let  $u : H \cap F \rightarrow F \times_{\tau_A} H$  be the monomorphism  $x \mapsto (x^{-1}, x)$ , and let  $F \cdot H$  be the quotient  $(F \cap H) \backslash (F \times_{\tau_A} H)$ . Under these conditions, there is a canonical isomorphism

$$F \backslash (F \cdot H) = (F \cap H) \backslash H.$$

### 5.4.

[^N.D.E-VI\_A-53] Let  $u : G \rightarrow H$  be a quasi-compact morphism between  $A$ -groups locally of finite type, such that the kernel  $N$  of  $u$  is flat over  $A$ . In this case, by 3.3.2 and 5.2, the quotient  $A$ -group  $C = N \backslash G$  exists and the morphism  $p : G \rightarrow C$  is faithfully flat and locally of finite presentation. On the other hand, by IV 5.2.6,  $u$  induces a monomorphism  $v : C \rightarrow H$ , which is quasi-compact (because  $u$  is, and  $G \rightarrow C$  is surjective; cf. EGA IV\_1, 1.1.3), hence is a closed immersion by 2.5.2. We have therefore obtained the following proposition:

**Proposition 5.4.1.** \*Let  $u : G \rightarrow H$  be a quasi-compact morphism between  $A$ -groups locally of finite type, such that  $N = \text{Ker } u$  is flat over  $A$ . Then one has the factorization:\*

$$\begin{array}{ccc} G & \xrightarrow{u} & H \\ \downarrow p & \nearrow i & \uparrow \\ & N \backslash G & \end{array}$$

\*where  $p$  is faithfully flat, locally of finite presentation, and  $i$  a closed immersion.\*

<!-- label: III.VI\_A.5.4.1 -->

Suppose in addition  $G$  flat over  $A$ . Then, by 3.3.2,  $C = N \backslash G$  is flat over  $A$ , and so the quotient  $X = C \backslash H$  exists in  $(\text{Sch}/A)$  and represents the (fppf) quotient sheaf  $\tilde{C} \backslash H$ , and  $q : H \rightarrow X$  is a  $C$ -torsor. Consequently, writing  $e : \text{operatorname{Spec}} A \rightarrow G$  for the unit section of  $G$ ,  $v$  induces an isomorphism of (fppf) sheaves between  $\tilde{C}$  and the fibered product of  $q$  and of  $q \circ e : \text{operatorname{Spec}} A \rightarrow X$ , which is represented by a closed subscheme of  $H$ . Consequently,  $v$  is an isomorphism of  $C$  onto a closed group subscheme  $K$  of  $G$  (equal to the stabilizer of the  $A$ -point  $q \circ e$  of  $X$ ). (This gives another proof of the fact that every quasi-compact monomorphism  $v : C \rightarrow H$  between  $A$ -groups locally of finite type is a closed immersion, cf. 2.5.2 and VI\_B 1.4.2.)

Suppose in addition that  $C$  is a normal subgroup of  $H$ ; in this case, the  $A$ -group  $\bar{H} = C \backslash H$  is the cokernel in the category of  $A$ -groups of the morphism  $u : G \rightarrow H$ , and  $K$  is the kernel of the morphism  $H \rightarrow \bar{H}$ . When  $G$  and  $H$  are abelian  $A$ -groups,  $K$  is the image of  $u$  in the category of abelian  $A$ -groups, while  $C = (\text{Ker } u) \backslash G$  is the coimage of  $u$ . Taking into account the isomorphism  $C \xrightarrow{\sim} K$  just established, one obtains:[^N.D.E-VI\_A-54]

**Theorem 5.4.2.** Let  $k$  be a field. The category of commutative algebraic  $k$ -groups is abelian.\*

<!-- label: III.VI\_A.5.4.2 -->

Indeed, when  $k$  is a field,  $\text{Ker}(u)$  is flat over  $k$  whatever  $u$ .

[^N.D.E-VI\_A-55] Let us note that the full subcategory of affine commutative algebraic  $k$ -groups is *thick*. Indeed, consider an exact sequence of commutative algebraic  $k$ -groups:

```

```text
1  →  N  →  G  →  G/N  →  1.
```

```

If  $G$  is affine, it is clear that  $N$  is so, and  $G/N$  is also so by a theorem of Chevalley, cf. VI\_B, 11.17. Conversely, if  $N$  and  $G/N$  are affine, then so is  $G$ , by VI\_B, 9.2 (viii). One therefore obtains:

**Corollary 5.4.3.** Let  $k$  be a field. The category of commutative affine algebraic  $k$ -groups is abelian.\*

<!-- label: III.VI\_A.5.4.3 -->

Let us further point out that the category of all commutative affine  $k$ -groups (not necessarily of finite type) is abelian; this is deduced from VI\_B, 11.17 and 11.18.2 (cf. [DG70], § III.3, 7.4), see also VII\_B, 2.4.2 for a proof using formal groups.

<!-- original page 317 -->

### 5.5.

Let  $G$  be a group locally of finite type and flat over an Artinian local ring  $A$ . We know (2.3) that the connected component of the origin  $G^{\{0\}}$  is a normal open group subscheme of  $G$ , hence also flat over  $A$ . Then, by 3.2 and 5.2,  $G^{\{0\}} \backslash G$  is an  $A$ -group scheme, flat over  $A$ . Moreover, since each connected component  $G^{\{\alpha\}}$  of  $G$  is saturated for the equivalence relation defined by  $G^{\{0\}}$ , then  $G^{\{0\}} \backslash G$  is the direct sum of the  $G^{\{0\}} \backslash G^{\{\alpha\}}$  (cf. 4.3). In particular, the connected component of the origin in  $G^{\{0\}} \backslash G$  is none other than  $G^{\{0\}} \backslash G^{\{0\}} \cong \text{operatorname{Spec}} A$ , and so  $G^{\{0\}} \backslash G \rightarrow \text{operatorname{Spec}} A$  is a local isomorphism at the origin. Consequently,  $G^{\{0\}} \backslash G$  is étale over  $\text{operatorname{Spec}} A$ , by VI\_B, 1.3.[^N.D.E-VI\_A-56] One therefore obtains the following proposition (for point (ii), one refers to [DG70], § II.5, 1.7–1.10):

**Proposition 5.5.1.** Let  $A$  be an Artinian local ring and  $G$  an  $A$ -group locally of finite type and flat.\*

(i)  $G^{\{0\}} \backslash G$  is an étale  $A$ -group.\*

(ii) Consequently, if  $A = k$  is an algebraically closed field,  $G^{\{0\}} \backslash G$  is a constant  $k$ -group, acting in a simply transitive way on the set of connected components of  $G$ ; hence if  $G$  is algebraic,  $G^{\{0\}} \backslash G$  is finite.\*

<!-- label: III.VI\_A.5.5.1 -->

### 5.6.

Let  $k$  be a perfect field and  $G$  a  $k$ -group locally of finite type. We have seen (0.2) that  $G_{\text{red}}$  is then a group subscheme of  $G$ . Moreover, the equivalence class of the origin of  $G$  under the left action of  $G_{\text{red}}$  on  $G$  is the whole underlying space of  $G$ . So, by Theorem 3.2, one obtains:

**Proposition 5.6.1.** Let  $k$  be a perfect field and  $G$  a  $k$ -group locally of finite type. Then the  $k$ -scheme  $G_{\text{red}} \backslash G$  is the spectrum of a finite, local  $k$ -algebra with residue field  $k$ .\*

<!-- label: III.VI\_A.5.6.1 -->

[^N.D.E-VI\_A-57] Indeed, by 3.2,  $G_{\text{red}} \backslash G$  has a single point, with residue field  $k$ , and is a  $k$ -scheme of finite type; it is therefore the spectrum of a local  $k$ -algebra of finite dimension (cf. EGA I, 6.4.4).

**Proposition 5.6.2.** Let  $u : F \rightarrow G$  be a morphism between groups locally of finite type over a perfect field  $k$ . The following assertions are equivalent:\*

(i)  $u$  is flat.\*

\*(ii)  $u^{\{0\}} : F^{\{0\}} \rightarrow G^{\{0\}}$  is dominant and the morphism  $v : F_{\text{red}} \rightarrow G_{\text{red}}$  induced by  $u$  is flat.\*

<!-- label: III.VI\_A.5.6.2 -->

<!-- original page 318 -->

[^N.D.E-VI\_A-58] Indeed, consider the following commutative diagram:

$$\begin{array}{ccc} & & p \\ F & \longrightarrow & F_{\text{red}} \\ u & & v \\ G & \xrightarrow{q} & G_{\text{red}} \end{array}$$

where  $p$  and  $q$  denote the canonical projections. By 3.2 (iv),  $p$  and  $q$  are faithfully flat; consequently, if  $u$  is flat, then  $q \circ u = v \circ p$  is flat, hence so is  $v$ .

Conversely, suppose  $v$  flat and  $u^{\{0\}}$  dominant. Since  $u^{\{0\}}$  is quasi-compact ( $F^{\{0\}}$  being of finite type over  $k$  by 2.4, hence noetherian), it sends the generic point  $\xi$  of  $F^{\{0\}}$  to the generic point  $\eta$  of  $G^{\{0\}}$ . Let  $R$  be the finite local  $k$ -algebra of which  $G_{\text{red}}$  is the spectrum, and  $\mathfrak{m}$  its maximal ideal. One has local morphisms of local rings:  $R \rightarrow \mathcal{O}_{G, \eta} \rightarrow \mathcal{O}_{F, \xi}$ . Note that one has a cartesian square:

$$\begin{array}{ccc} & & q \\ G_{\text{red}} & \longrightarrow & G \\ & & \downarrow \\ \text{Spec}(R/\mathfrak{m}) & \longrightarrow & \text{Spec}(R) \end{array}$$

and so  $\mathcal{O}_{G, \eta} / \mathfrak{m} \mathcal{O}_{G, \eta} \cong \mathcal{O}_{G_{\text{red}}, \eta} = k(\eta)$ , so that  $\mathcal{O}_{F, \xi} / \mathfrak{m} \mathcal{O}_{F, \xi}$  is flat over  $\mathcal{O}_{G, \eta} / \mathfrak{m} \mathcal{O}_{G, \eta}$ .

On the other hand, since  $q$  and  $v \circ p$  are flat,  $G$  and  $F$  are flat over  $R$ . Consequently, by the local flatness criterion (cf. EGA IV\_3, 11.3.10.2),  $\mathcal{O}_{F, \xi}$  is flat over  $\mathcal{O}_{G, \eta}$ , i.e.  $u$  is flat at the point  $\xi$ . So, by 2.5.3,  $u$  is flat.

## 6. Complements on  $k$ -groups not necessarily of finite type

<!-- label: III.VI\_A.6 -->

[^N.D.E-VI\_A-59] Let us further point out the following results, which will be useful in the addendum VI\_B, § 12. We fix a base field  $k$ .

**Lemma 6.1.** \*Let  $G$  be a  $k$ -group. For every  $x \in G$ , there exists a point  $u \in G \times G$  such that  $\mu(u) = x$  and that the two projections  $p_1(u)$  and  $p_2(u)$  are maximal points of  $G$ .\*

<!-- label: III.VI\_A.6.1 -->

<!-- original page 327 -->

**Proof.** Set  $K = k(x)$ . Since the projection  $G \rightarrow G$  sends maximal points to maximal points, one is reduced to the case where  $x$  is rational. Then left translation  $\lambda_x$  (resp. right translation  $\rho_x$ ) gives us a morphism  $G \rightarrow G \times G$ ,  $g \mapsto (\lambda_x(g), g)$  (resp.  $g \mapsto (g, \rho_x(g))$ ) which induces an isomorphism of  $G$  onto  $\mu^{-1}(x)$ , inverse of  $p_2$  (resp.  $p_1$ ). So, if  $u$  is a maximal point of  $\mu^{-1}(x)$ , then  $p_1(u)$  and  $p_2(u)$  are maximal points of  $G$ , and so  $u$  is suitable.

**Corollary 6.2.** \*Let  $f : G \rightarrow H$  be a quasi-compact, dominant morphism of  $k$ -groups.\*

\*(i)  $f$  is surjective.\*

\*(ii) If  $H$  is reduced,  $f$  is faithfully flat.\*

<!-- label: III.VI\_A.6.2 -->

**\*Proof.\*** Write  $\mu_H$  (resp.  $\mu_G$ ) for the multiplication of  $H$  (resp.  $G$ ). Let  $h \in H$ . By 6.1, there exists  $u \in H \times H$  such that  $\mu_H(u) = h$  and that  $\alpha = p_1(u)$  and  $\beta = p_2(u)$  are maximal points of  $H$ . Since  $f$  is quasi-compact and dominant,  $f^{-1}(\alpha)$  and  $f^{-1}(\beta)$  are non-empty (cf. EGA IV<sub>1</sub>, 1.1.5), and so there exists  $v \in G \times G$  such that  $(f \times f)(v) = u$  (cf. EGA I, 3.5.2). Then  $g = \mu_G(v)$  satisfies  $f(g) = h$ . This shows that  $f$  is surjective.

Suppose in addition  $H$  reduced. Then  $\mathcal{O}_{H, \alpha}$  is a field, and we have seen above that  $f^{-1}(\alpha) \neq \emptyset$ , so  $f$  is flat at every point  $x$  of  $f^{-1}(\alpha)$ , so  $f$  is flat by Lemma 2.5.3.

**\*\*Recollection 6.3.\*\*** Recall (cf. EGA IV<sub>3</sub>, 11.10.1) that a morphism of schemes  $f : X \rightarrow Y$  is said to be schematically dominant if it satisfies the following condition: for every open  $U$  of  $Y$ , if  $Z$  is a closed subscheme of  $U$  such that the morphism  $f^{-1}(U) \rightarrow U$  factors through  $Z$ , then  $Z = U$ . When  $f$  is quasi-compact and quasi-separated, this is equivalent to saying that the closed image of  $X$  by  $f$  is  $Y$  (cf. loc. cit., 11.10.3 (iv) and EGA I, 9.5.8).

<!-- label: III.VI\_A.6.3 -->

**\*\*Proposition 6.4.\*\*** Let  $f : H \rightarrow G$  be a quasi-compact morphism of  $k$ -groups. Then the closed image of  $f$  is a group subscheme  $H'$  of  $G$ , and  $f$  factors as:

```

```text
      f
H  ----> G
 \      ^
  f'     i
   \    /
    H'
```

```

where  $f'$  is schematically dominant, quasi-compact and surjective.

<!-- label: III.VI\_A.6.4 -->

**\*Proof.\*** Since  $H$  is separated (0.3),  $f$  is quasi-compact and separated, so  $f_*(\mathcal{O}_H)$  is a quasi-coherent  $\mathcal{O}_G$ -module, and the closed image  $H'$  of  $f$  exists and is the closed subscheme of  $G$  defined by the quasi-coherent ideal  $\mathcal{I} = \text{Ker}(\mathcal{O}_G \rightarrow f_*(\mathcal{O}_H))$  (cf. EGA I, § 9.5).

<!-- original page 328 -->

Write  $c_G$  and  $\mu_G$  (resp.  $c_H$  and  $\mu_H$ ) for the inversion and multiplication morphisms of  $G$  (resp.  $H$ ). Then  $c_G \circ f = f \circ c_H$  factors through the closed subscheme  $c_G(H')$ , whence  $H' \subset c_G(H')$  and so  $H' = c_G(H')$  (since  $c_G^2 = \text{id}_G$ ). Similarly, since  $f \circ \pi_H = \pi_G \circ (f \times f)$  factors through  $H'$ , then  $f \times f$  factors through the closed subscheme  $\pi_G^{-1}(H')$  of  $G \times G$ . On the other hand, since the formation of the closed image commutes with flat base changes (EGA III 1.4.15 and IV<sub>1</sub> 1.7.21), the closed image of  $f \times \text{id}_H$  (resp.  $\text{id}_H \times f$ ) is  $H' \times H$  (resp.  $H \times H'$ ). So, by "transitivity of closed images" (EGA I, 9.5.5), the closed image of  $f \times f$  is  $H' \times H'$ , which is therefore contained in  $\pi_G^{-1}(H')$ , i.e. the restriction of  $\pi_G$  to  $H' \times H'$  factors through  $H'$ . This shows that  $H'$  is a closed group subscheme of  $G$ . Write  $i$  for the inclusion  $H' \hookrightarrow G$ .

Then  $f$  equals  $i \circ f'$ , where  $f' : H \rightarrow H'$  is schematically dominant and quasi-compact (since  $f$  is quasi-compact and  $i$  is separated). So, by 6.2,  $f'$  is surjective. This proves 6.4.

One can now state the following theorem ([Per75], V 3.1 & 3.2, see also [Per76], 0.0 & 0.1).

**\*\*Theorem 6.5 (D. Perrin).\*\*** Let  $G$  be a quasi-compact  $k$ -group. Then

(i)  $G$  is the projective limit of a filtered system  $(G_i)$  of  $k$ -groups of finite type (whose transition morphisms  $u_{ij} : G_j \rightarrow G_i$  are affine for  $i$  large enough), and the morphisms  $G \rightarrow G_i$  are faithfully flat (and affine for  $i$  large enough).

(ii) Let  $H$  be a closed  $k$ -subgroup of  $G$ . Then the (fpqc) quotient sheaf  $\tilde{G}/H$  is a  $k$ -scheme in the

following two cases:\*

\*(1) The immersion  $H \rightarrow G$  is of finite presentation; in this case,  $G/H$  is of finite type over  $k$ .\*(2)  $H$  is normal in  $G$ .\*

<!-- label: III.VI\_A.6.5 -->

For the proof of this theorem (which rests on several intermediate theorems), we refer to [Per75]. For the reader's convenience, let us however prove the two corollaries below, cf. [Per75] V 3.3 to 3.4 or [Per76] 4.2.3 to 4.2.5.

**Corollary 6.6.** \*Let  $f : G \rightarrow H$  be a quasi-compact morphism of  $k$ -groups.\*

\*(i) If  $f$  is schematically dominant, it is faithfully flat.\*

\*(ii) This is the case, in particular, if  $H$  is affine and the morphism  $f^{\text{natural}} : O(H) \rightarrow O(G)$  is injective.\*

<!-- label: III.VI\_A.6.6 -->

**Proof.** Suppose  $f$  is schematically dominant. Then, by 6.2 (i),  $f$  is surjective, so, by 2.5.3, it suffices to show that  $f$  is flat at the unit element of  $G$ . Since  $0_{\{H,e\}} = 0_{\{H^{\{0\}},e\}}$  (cf. 2.6.5), one may replace  $H$  by  $H^{\{0\}}$ , and hence assume  $H$  irreducible. Then  $H$  is quasi-compact (loc. cit.), and since  $f$  is quasi-compact, so is  $G$ . By 6.5 (i),  $H = \varinjlim H_i$ , where each  $H_i$  is an algebraic  $k$ -group. Denote by  $N_i$  the kernel of  $G \rightarrow H_i$ ; this is a closed normal  $k$ -subgroup of  $G$ . Moreover, since the unit section  $\{e\} \rightarrow H_i$  is of finite presentation, the immersion  $N_i \rightarrow G$  is

<!-- original page 329 -->

also so; so, by 6.5 (ii), the (fpqc) quotient  $G/N_i$  is an algebraic  $k$ -group. One has then a commutative diagram

$$\begin{array}{ccc} & f & \\ G & \longrightarrow & H \\ q_i & & p_i \\ & f_i & \\ G/N_i & \longrightarrow & H_i \end{array}$$

where  $f$  is schematically dominant,  $p_i, q_i$  are faithfully flat (hence schematically dominant). Then  $f_i \circ q_i = p_i \circ f$  is schematically dominant, and so  $f_i$  is also so. On the other hand,  $f_i$  is a monomorphism, hence a closed immersion, since  $G/N_i$  and  $H_i$  are algebraic (2.5.2). It follows that  $f_i$  is an isomorphism, and so  $G \rightarrow H_i$  is faithfully flat. Then, by [BAC] I § 2.7, Prop. 9, the morphism  $G \rightarrow H$  is flat; on the other hand, it is surjective by 6.2 (i), so it is faithfully flat. This proves point (i); and point (ii) follows, since if  $H$  is affine and  $f^{\text{natural}}$  injective, then the closed image of  $f$  equals  $H$ , so  $f$  is schematically dominant (cf. 6.4).

**Corollary 6.7.** \*Let  $u : G \rightarrow H$  be a morphism of  $k$ -groups and  $N = \text{Ker}(u)$ . Suppose  $u$  quasi-compact.\*

\*(i) The (fpqc) quotient sheaf  $\tilde{G}/N$  is represented by a  $k$ -group scheme  $G/N$ , and  $u$  factors as:\*

$$\begin{array}{ccc} G & \xrightarrow{u} & H \\ \downarrow p & & \uparrow i \\ & G/N & \end{array}$$

\*where  $p$  is faithfully flat and  $i$  a closed immersion.\*

\*(ii) In particular, if  $u$  is a monomorphism,  $u$  is a closed immersion, and if  $u$  is schematically dominant,  $u$  is faithfully flat.\*

<!-- label: III.VI\_A.6.7 -->

\*Proof.\* (i) By 6.4 and 6.6, the closed image  $G'$  of  $u$  is a closed group subscheme of  $G$ , and  $p : G \rightarrow G'$  is faithfully flat and quasi-compact. One evidently has  $\text{Ker}(p) = \text{Ker}(u) = N$ , and so by Exp. IV, 3.3.2.1 and 5.1.7,  $G'$  represents the (fpqc) quotient sheaf  $\tilde{G}/N$ .

(ii) The second assertion is contained in 6.6; let us show the first. If  $u$  is a monomorphism, so is  $p$ ; then  $p$  is at once a monomorphism and an effective epimorphism, hence an isomorphism (cf. IV, 1.14). This proves 6.7.

Let us finally point out the following corollaries (cf. [Per76], 4.2.6 to 4.2.8).

**Corollary 6.8.** The category of commutative quasi-compact  $k$ -group schemes is abelian.

<!-- label: III.VI\_A.6.8 -->

Taking 6.7 into account, the proof is analogous to that of 5.4.2.

**Corollary 6.9.** If  $\text{char}(k) = 0$ , every  $k$ -group scheme  $G$  is geometrically reduced.

<!-- label: III.VI\_A.6.9 -->

<!-- original page 330 -->

Indeed, if  $g \in G$  and if  $K$  is an algebraic closure of  $k$ , one has  $0_{G,e} \otimes_{\mathbb{Z}} K \simeq 0_{G(K)}, g_{(K)}$ , so it suffices to show that  $0_{G,e} = 0_{G^{\{0\}}, e}$  is geometrically reduced. One is thus reduced to the case where  $G$  is connected, hence quasi-compact (2.6.5). Then the result follows from 6.5 and from Cartier's theorem for algebraic groups (cf. VI\_B, 1.6.1 or [DG70] § II.6, Th. 1.1).

**Corollary 6.10.** Let  $G$  be a quasi-compact  $k$ -group. Assume  $k$  algebraically closed.

(i) Let  $f : G \rightarrow H$  be a faithfully flat morphism of  $k$ -groups. Then the induced map  $G(k) \rightarrow H(k)$  is surjective.

(ii) The set of rational points is dense in  $G$ .

<!-- label: III.VI\_A.6.10 -->

For the proof, we refer to [Per75], V 3.7 & 3.9.

[^N.D.E-VI\_A-0]: N.D.E.: Version of 13/10/2024.

[^N.D.E-VI\_A-1]: N.D.E.: The sentences that follow have been added.

[^N.D.E-VI\_A-2]: N.D.E.: For examples of group schemes  $G$  over a non-perfect field  $k$  such that  $G_{\text{red}}$  is not a group scheme over  $k$ , see 1.3.2 below.

[^N.D.E-VI\_A-3]: N.D.E.: We have slightly modified what follows of 0.2, as well as 0.3.

[^N.D.E-VI\_A-4]: N.D.E.: To have an analogous example with  $G$  connected, one may consider, for  $\text{char}(k) = p > 0$ , the semidirect product of  $\alpha_{p,k}$  and  $G_{m,k}$ .

[^N.D.E-VI\_A-5]: N.D.E.: This argument is valid for every local ring  $A$  of dimension zero, and shows that if  $S$  is a discrete scheme, every  $S$ -group is separated, cf. VI\_B, 5.2; on the other hand (cf. VI\_B, 5.6.4), if  $S$  contains a closed point  $s$  that is not isolated, the  $S$ -scheme  $G$  obtained by gluing two copies of  $S$  along the open subset  $S - \{s\}$  is not separated over  $S$ , but is equipped with an  $S$ -group structure.

[^N.D.E-VI\_A-6]: N.D.E.: We have detailed the original in what follows, in particular we have added Remark 0.4.1.

[^N.D.E-VI\_A-7]: N.D.E.: The original stated this result under the hypothesis that  $G$  is locally of finite type over  $A$ . Since it is useful to have it available in the general case, and since the proof is essentially the same, we have stated and proved the result in the general case. This will be used several times in what follows.

[^N.D.E-VI\_A-8]: N.D.E.: We have inserted this corollary here, cf. 2.4 and 2.6.2 below.

[^N.D.E-VI\_A-9]: N.D.E.: We have added this corollary, used implicitly in VIII, 6.7; see also VI\_B 6.2.5.

[^N.D.E-VI\_A-10]: N.D.E.: For example, they are always complete intersections, cf. VII\_B, 5.5.1. Moreover, if  $\text{char}(k) = 0$  then  $G$  is smooth (VI\_B, 1.6.1; see also VII\_B, 3.3.1).

[^N.D.E-VI\_A-11]: N.D.E.: Indeed, the hypothesis on  $K$  entails that, for every extension  $L$  of  $K$ , every  $k$ -morphism  $\kappa(x) \rightarrow L$  (resp.  $\kappa(y) \rightarrow L$ ) factors through  $K$ ; consequently, all points of  $G \times_k K$  above  $x$  or  $y$  have  $K$  as residue field, i.e. are (strictly) rational over  $K$ .

[^N.D.E-VI\_A-12]: N.D.E.: Indeed,  $B$  is a noetherian Jacobson ring (cf. [BAC], V § 3.4). If every non-invertible element is a zero-divisor, then every prime ideal is an associated prime ideal of  $B$ , so in particular  $B$  has only a finite number of maximal ideals  $\mathfrak{m}_1, \dots, \mathfrak{m}_n$ . Since  $B$  is a Jacobson ring, the intersection of the  $\mathfrak{m}_i$  is the nilradical of  $B$ , and it follows that each  $\mathfrak{m}_i$  is a minimal prime ideal of  $B$ , so that  $\dim B = 0$ .

[^N.D.E-VI\_A-13]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VI\_A-14]: N.D.E.: We have added point (1), useful in the examples 1.3.2 that follow.

[^N.D.E-VI\_A-15]: N.D.E.: We have added the sentence that follows and the examples 1.3.2.

[^N.D.E-VI\_A-16]: N.D.E.: In fact one sees without difficulty that  $\sqrt{I}$  is generated by  $P, Q, R$  at every point  $\neq \emptyset$ , so  $F = H$ .

[^N.D.E-VI\_A-17]: N.D.E.: We shall see below (2.2) that  $G'$  is a group in the category  $(\text{Sch}/k)_{\text{red}}$ .

[^N.D.E-VI\_A-18]: N.D.E.: We have added the word "locally". Moreover, the reference to Kaplansky is: \*Projective modules\*, Ann. of Maths. \*\*68\* (1958), 372–377; see also [BAC], § II.3, Ex. 3.

[^N.D.E-VI\_A-19]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VI\_A-20]: N.D.E.: We have added this paragraph, in order to make the link with VI\_B, § 3.

[^N.D.E-VI\_A-21]: N.D.E.: In this Exposé, the notation  $G^{\{0\}}$  is reserved for the case where the connected component of  $e$  is open; in VI\_B, § 3, this connected component will be denoted  $G^{\{0\}}$  in all cases. This is a slightly abusive notation, but one that is compatible with what precedes when the connected component is the underlying topological space of an open group subscheme  $G^{\{0\}}$  of  $G$ .

[^N.D.E-VI\_A-22]: N.D.E.: Indeed, in a noetherian space, the connected components are finite in number, hence each one is open; see also EGA I, 6.1.9.

[^N.D.E-VI\_A-23]: N.D.E.: We have added the numbering 2.3.1 to make this statement explicit. Note moreover that  $G^{\{0\}}$  is even a characteristic subgroup of  $G$ , cf. 2.6.5 (ii).

[^N.D.E-VI\_A-24]: N.D.E.: In the statement, we have replaced " $G^{\{0\}}$  is geometrically irreducible" by " $G^{\{0\}} \times_A k$  is geometrically irreducible over  $k$ ", and we have detailed the proof.

[^N.D.E-VI\_A-25]: N.D.E.: We have detailed the original by adding the reference to EGA I, 6.1.10.

[^N.D.E-VI\_A-26]: N.D.E.: One should beware that a non-neutral connected component is not in general geometrically connected. For example, if  $k = \mathbb{R}$ , the group  $\mu_{\{3, \mathbb{R}\}}$ , represented by  $\mathbb{R}[X]/(X^3 - 1)$ , has two connected components:  $\{e\} = \text{Spec } \mathbb{R}$  and  $C = \text{Spec } \mathbb{R}[X]/(X^2 + X + 1)$ , and  $C \times_{\mathbb{R}} \mathbb{C}$  has two components.

[^N.D.E-VI\_A-27]: N.D.E.: We have added the assertion that follows, cf. VI\_B, 1.5.

[^N.D.E-VI\_A-28]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VI\_A-29]: N.D.E.: We have simplified the original here.

[^N.D.E-VI\_A-30]: N.D.E.: We make no finiteness hypotheses in this statement; this will be useful later (cf. 6.2 and VI\_B, § 12).

[^N.D.E-VI\_A-31]: N.D.E.: These results were communicated to us by O. Gabber, in particular 2.6.6, which plays an important role in section 5 of VI\_B.

[^N.D.E-VI\_A-32]: N.D.E.: This proposition (as well as the preceding results) was communicated to us by O. Gabber; it will be used to correct the proof of Theorem 5.3 of VI\_B.

[^N.D.E-VI\_A-33]: N.D.E.: We have added (ii') and detailed point (iv), taking into account the additions made in 2.5.2, 2.5.4, and in Exp. V, 6.1.

[^N.D.E-VI\_A-34]: N.D.E.: In this case, the hypothesis that  $G$  is flat may be removed, cf. subsection 3.3.

[^N.D.E-VI\_A-35]: N.D.E.: Let us point out here that if  $A = k$  is a field, then every quasi-compact open of  $F \backslash G$  is quasi-projective (a result due to Chow for smooth algebraic groups), cf. [Ray70], VI 2.6. By contrast, over the Artinian local ring  $A = \mathbb{C}[\epsilon]/(\epsilon^2)$ , there exist abelian  $A$ -schemes  $G$  that are not projective (loc. cit., XII 4.2).

[^N.D.E-VI\_A-36]: N.D.E.: What precedes is valid for every base change  $A \rightarrow A'$ .

[^N.D.E-VI\_A-37]: N.D.E.: This is detailed in 4.6 below: it is a matter of seeing that the formation of the direct image by the morphisms  $p$ ,  $\lambda$  and  $\mathrm{pr}_2$  commutes with flat base changes  $A \rightarrow A'$ . Since  $F$  and  $G$  are of finite type over the Artinian ring  $A$ , the morphisms  $f$  in question are all quasi-compact and quasi-separated, and the equality  $f_*(\mathcal{O}_X) \otimes_{A'} \mathcal{O}_{X'} = f'_*(\mathcal{O}_{X'})$  (with obvious notations) follows from EGA IV\_1, 1.7.21.

[^N.D.E-VI\_A-38]: N.D.E.: Indeed, let  $y_1, \dots, y_n$  be arbitrary points of  $X$ ; since  $X$  is of finite type over  $A$ , each  $y_i$  has in its closure a closed point  $x_i$ , and every open subset containing  $x_i$  contains  $y_i$ .

[^N.D.E-VI\_A-39]: N.D.E.: Such an open exists, since  $X$  is of finite type over  $k$ :  $X$  has a finite number of irreducible components  $C_1, \dots, C_p$ , and it suffices to take, for each  $i$ , a non-empty affine open contained in  $C_i - \bigcup_{j \neq i} C_j$ . (Here one knows moreover, by (ii'), that the  $C_i$  are disjoint...)

[^N.D.E-VI\_A-40]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VI\_A-41]: N.D.E.: We have added this paragraph.

[^N.D.E-VI\_A-42]: N.D.E.: We have added this subsection.

[^N.D.E-VI\_A-43]: N.D.E.: For an example where  $F$  is not flat and  $\tilde{F} \backslash G$  not representable, see [DG70], § III.3, n° 3.3.

[^N.D.E-VI\_A-44]: N.D.E.: We have written  $S(G^{\alpha})$  instead of  $\bar{G}^{\alpha}$  for the saturation of  $G^{\alpha}$ .

[^N.D.E-VI\_A-45]: N.D.E.: We have added the sentence that follows.

[^N.D.E-VI\_A-46]: N.D.E.: In what follows, we have modified the original; the supplementary hypotheses made on  $X_*$  were superfluous.

[^N.D.E-VI\_A-47]: N.D.E.: We have added on the one hand the following sentence and, on the other hand, the numbering 4.6.1 below, to make the stated result explicit.

[^N.D.E-VI\_A-48]: N.D.E.: We have added the numbering 4.7.1 below to make the stated result explicit.

[^N.D.E-VI\_A-49]: N.D.E.: We have changed the title of this section (called "Compléments" in the original).

[^N.D.E-VI\_A-50]: N.D.E.: We have added what follows.

[^N.D.E-VI\_A-51]: N.D.E.: We have added the sentence that follows.

[^N.D.E-VI\_A-52]: N.D.E.: In addition to the aforementioned statements of Exp. IV, one uses the fact that, since  $G \rightarrow F \backslash G$  is faithfully flat, an  $A$ -subgroup  $H$  of  $G$  is flat over  $A$  if and only if  $F \backslash H$  is.

[^N.D.E-VI\_A-53]: N.D.E.: We have detailed the original in what follows; in particular, we have added Proposition 5.4.1.

[^N.D.E-VI\_A-54]: N.D.E.: We have added the number 5.4.2 to this theorem.

[^N.D.E-VI\_A-55]: N.D.E.: We have added what follows.

[^N.D.E-VI\_A-56]: N.D.E.: We have detailed the original in what precedes and have added Proposition 5.5.1 to make this result explicit.

[^N.D.E-VI\_A-57]: N.D.E.: We have added the numbering 5.6.1, as well as the proof that follows.

[^N.D.E-VI\_A-58]: N.D.E.: We have detailed the proof of (ii)  $\Rightarrow$  (i), and have simplified the diagram below.

[^N.D.E-VI\_A-59]: N.D.E.: We have added the results that follow, taken from [Per75]. Note that Lemma 6.1 can be expressed, in Weil's language, by saying that "every point of  $G$  is the product of two generic points".

[^N.D.E-VI\_A-60]: N.D.E.: Additional references cited in this Exposé.

# Exposé VI\_B. Generalities on group schemes

<!-- label: III.VI\_B -->

\*by J.-E. Bertin\*

> [^N.D.E-VI\_B-0] Version of 13/10/2024.

<!-- original page 319 -->

This Exposé, which corresponds to no oral lecture of the seminar, is intended to bring together a number of technical results, commonly used, concerning group schemes.[^VI\_B-0-1]

## 1. Morphisms of groups locally of finite type over a field

<!-- label: III.VI\_B.1 -->

### 1.1.

Let  $A$  be an Artinian local ring,  $G$  and  $H$  two  $A$ -groups[^N.D.E-VI\_B-2], and  $u : G \rightarrow H$  a morphism of  $A$ -groups. Then  $u$  induces a morphism of groups  $u(A) : G(A) \rightarrow H(A)$ .[^N.D.E-VI\_B-3] Since  $H(A)$  acts on  $H$  by right translation,  $u(A)$  defines, by restriction, an action of  $G(A)$  on  $H$ . This action is compatible with the morphism  $u$  and with the action of  $G(A)$  on  $G$  defined by right translation. Since  $G(A)$  acts transitively on the strictly rational points of  $G$  (see (VI\_A, 0.4) for the definition), one sees that these points "all behave in the same way with respect to  $u$ "; from this spring the following properties.

**\*\*Proposition 1.2.\*\*** \*Let  $u : G \rightarrow H$  be a quasi-compact morphism between  $A$ -groups locally of finite type over  $A$ . Then the set  $u(G)$  is closed in  $H$  and one has  $\dim G = \dim u(G) + \dim \text{Ker } u$ .\*[^N.D.E-VI\_B-4]

<!-- label: III.VI\_B.1.2 -->

<!-- original page 320 -->

Since  $u$  commutes with the inversion morphisms of  $G$  and  $H$ , the image  $u(G)$  is invariant under the inversion morphism of  $H$ ; the same is therefore true of its closure  $u(G)^{-}$  in  $H$ . On the other hand, let  $L$  denote the set of points of  $H \times_A H$  whose two projections both lie in  $u(G)$ ; it is clear that  $L$  is the image of the morphism  $u \times u : G \times_A G \rightarrow H \times_A H$ . Hence the multiplication morphism of  $H$  sends  $L$  into  $u(G)$ , in other words  $u(G) \cdot u(G) = u(G)$ . On the other hand, Lemma 1.2.1 below shows that  $L^{-}$ , the closure of  $L$  in  $H \times_A H$ , is the set of points of  $H \times_A H$  whose two projections lie in  $u(G)^{-}$ ; hence  $u(G)^{-} \cdot u(G)^{-} = u(G)^{-}$ , so that the reduced subscheme of  $H$  whose underlying space is  $u(G)^{-}$  is naturally equipped with a group structure in the category  $(\text{Sch}/k)_{\text{red}}$ , where  $k$  is the residue field of  $A$  (cf. (VI\_A, 0.2)).

Let us prove the first assertion of 1.2. Replacing  $A$  by the algebraic closure of its residue field  $k$ , we may assume that  $A$  is an algebraically closed field  $k$  (cf. EGA IV<sub>2</sub>, 2.3.12). Replacing  $u$  by  $u_{\text{red}} : G_{\text{red}} \rightarrow H_{\text{red}}$ , we may assume  $G$  and  $H$  reduced; in this case, as we have just seen,  $u(G)$  is the underlying space of a reduced group subscheme of  $G$ ; we may therefore assume  $u$  dominant. Then  $G(k)$  acts transitively on the set of connected components of  $H$ , and it suffices to show that  $u(G) \cap H^{\{0\}}$  is closed: we are reduced to the case where  $H$  is connected, hence irreducible and of finite type (VI\_A, 2.4). Then  $u$  is of finite type, since it is quasi-compact and locally of

finite type; since  $H$  is noetherian,  $u(G)$  is constructible (EGA IV<sub>1</sub>, 1.8.5), so it contains an open subset  $V$  of  $H$  (EGA 0\_III, 9.2.2), and then, by (VI\_A, 0.5), we have  $H = V \cdot V \subset u(G) \cdot u(G) = u(G)$ .

Let us prove the second assertion. Recall first that the functor  $\text{Ker } u$  (cf. I, 2.3.6.1) is representable by  $u^{-1}(e)$ , where  $e$  denotes the unit element of  $H$ . When  $u$  is locally of finite type,  $\text{Ker } u$  is therefore locally of finite type over  $A$ . We reduce as before, this time using EGA IV<sub>2</sub>, 4.1.4, to the case where  $A$  is an algebraically closed field  $k$ .

<!-- original page 321 -->

We may further assume  $G$  and  $H$  irreducible and of finite type and  $u$  dominant: indeed,  $k$  being algebraically closed, it is clear that the connected components of  $G$ , on the set of which  $G(k)$  acts transitively, all have the same dimension, and that if  $u^0$  denotes the restriction of  $u$  to  $G^0$ , then  $(\text{Ker } u)^0 \subset \text{Ker } u^0$ , and  $\dim \text{Ker } u^0 = \dim \text{Ker } u$ . One sees likewise that  $u$  is then of finite type over  $k$ . If  $\eta$  denotes the generic point of  $H$ , one has  $\dim u^{-1}(\eta) = \dim G - \dim H$  (EGA IV<sub>3</sub>, 10.6.1 (ii)). By EGA IV<sub>3</sub>, 9.2.3 and 9.2.6, the set of  $y \in H$  such that  $\dim u^{-1}(y) = \dim u^{-1}(\eta)$  contains a non-empty open subset  $V$ . Since  $u$  is dominant,  $U = u^{-1}(V)$  is then a non-empty open subset of  $G$  and contains a closed point  $x$  of  $G$ , since  $G$  is a Jacobson scheme (EGA IV<sub>3</sub>, 10.4.7). Then right translation  $r_x$  is an isomorphism of  $\text{Ker } u$  onto  $u^{-1}(u(x))$ , so that:

```
```text
dim Ker u = dim u^{-1}(u(x)) = dim u^{-1}(\eta) = dim G - dim H.
```
```

**\*Lemma 1.2.1.\*** \*Let  $f : X \rightarrow X$  and  $g : Y \rightarrow Y$  be two quasi-compact, dominant morphisms of schemes over an Artinian local ring  $A$ . Then  $f \times_A g : X \times_A Y \rightarrow X \times_A Y$  is dominant (and quasi-compact).\*

<!-- label: III.VI\_B.1.2.1 -->

Indeed, one has  $f \times_A g = (\text{id}_X \times_A g) \circ (f \times_A \text{id}_Y)$ . It therefore suffices to show that  $f \times_A \text{id}_Y$  and  $\text{id}_X \times_A g$  are dominant. For this one may replace  $A$  by its residue field  $k$ . In this case,  $X$  and  $Y$  are flat over  $A = k$ , and since  $f \times_A \text{id}_Y$  (resp.  $\text{id}_X \times_A g$ ) is deduced from  $f$  (resp.  $g$ ) by the flat base change  $Y \rightarrow A$  (resp.  $X \rightarrow A$ ), it is dominant (and quasi-compact), by EGA IV<sub>2</sub>, 2.3.7.

<!-- original page 333 -->

**\*Counterexample 1.2.2.\*** \*Let  $k$  be a field of characteristic 0,  $G$  the constant  $k$ -group  $\mathbb{Z}$ , and  $H$  the additive  $k$ -group  $G_{a,k}$ . Let  $u : G \rightarrow H$  be a morphism of  $k$ -groups. If  $u \neq 0$ , then  $u(G)$  is not closed in  $H$ .\*

<!-- label: III.VI\_B.1.2.2 -->

**\*Proposition 1.3.\*** [^N.D.E-VI\_B-5] \*Let  $A$  be an Artinian local ring,  $k$  its residue field,  $G$  an  $A$ -group locally of finite type and flat,  $u : G \rightarrow H$  a morphism of  $A$ -groups. The following assertions are equivalent:\*

\*(i)  $u$  is flat (resp. quasi-finite, resp. unramified, resp. smooth, resp. étale) at some point of  $G$ .\*[^N.D.E-VI\_B-6]

\*(ii)  $u$  is flat (resp. quasi-finite, resp. unramified, resp. smooth, resp. étale).\*

<!-- label: III.VI\_B.1.3 -->

**\*Proof.\*** It suffices to show that (i) implies (ii). First, we have the following lemma.

**\*Lemma 1.3.0.\*** \*Let  $A \rightarrow B \rightarrow C$  be morphisms of commutative rings and let  $n$  be a nilpotent ideal of  $A$ . Suppose that  $C/nC$  is a  $(B/nB)$ -algebra of finite type.\*

\*(i) Then  $C$  is a  $B$ -algebra of finite type.\*

\*(ii) Moreover, if  $C$  is flat over  $A$  and if  $C/nC$  is a  $(B/nB)$ -algebra of finite presentation, then  $C$  is a  $B$ -algebra of finite presentation.\*

<!-- label: III.VI\_B.1.3.0 -->

Indeed, let  $x_1, \dots, x_n$  be elements of  $C$  whose images generate  $C/nC$  as a  $(B/n)$ -algebra. By the nilpotent Nakayama lemma, the  $x_i$  generate  $C$  as a  $B$ -algebra. This proves (i). Let  $\phi$  be the resulting

surjective morphism  $B[X_1, \dots, X_n] \rightarrow C$ , and let  $I = \ker(\phi)$ .

Suppose now that  $C$  is flat over  $A$  and that  $C/nC$  is of finite presentation over  $B/nB$ . Then, on the one hand,  $I/nI$  is identified with the kernel of  $\bar{\phi} = \phi \otimes_A (A/n)$ . On the other hand, by EGA IV<sub>1</sub>, 1.4.4, the kernel of  $\bar{\phi}$  is an ideal of finite type. Let then  $P_1, \dots, P_s$  be elements of  $I$  whose images generate  $I/nI$  as an ideal; by the nilpotent Nakayama lemma, they generate  $I$ . This proves (ii).

Let us return to the proof of 1.3. Let  $x$  be an arbitrary point of  $G$ . Since  $G$  is flat over  $A$ , the fiber-wise flatness criterion in the form of EGA IV<sub>3</sub>, 11.3.10.2, shows that  $u$  is flat at  $x$  if  $u \otimes_A k$  is. Likewise, by the preceding lemma, one sees that  $u$  is of finite type (resp. of finite presentation) at  $x$  if  $u \otimes_A k$  is. Since the other properties are then verified on fibers (cf. EGA IV<sub>4</sub>, 17.4.1, 17.5.1, and 17.6.1, for unramified, smooth, and étale), we are reduced to the case  $A = k$ .

<!-- original page 334 -->

Let now  $x$  be a point of  $G$  where one of the conditions of 1.3 (i) holds. Since the properties under consideration are preserved by (fpqc) descent (cf. EGA IV, 2.5.1, 2.7.1, and 17.7.1), one reduces, by replacing  $k$  by an algebraic closure of  $k(x)$ , to the case where  $k$  is algebraically closed and  $x \in G(k)$ .

Since  $G$  is a Jacobson scheme (cf. EGA IV<sub>3</sub>, 10.4.7) and since the set  $W$  of points of  $G$  where  $u$  is flat (resp. quasi-finite, unramified, smooth, or étale) is stable under generization [N.D.E-VI\_B-7] (resp. open), it suffices to show that every point  $y \in G(k)$  belongs to  $W$ . Now, for such a point  $y$ , the translation  $r_y \circ r^{-1}_x$  sends  $x$  to  $y$ , hence  $u$  has the desired property at  $y$ , i.e.  $y \in W$ . ■

**Corollary 1.3.1.** \*Let  $A$  be an Artinian local ring,  $k$  its residue field,  $G$  a flat  $A$ -group. The following assertions are equivalent: [N.D.E-VI\_B-8]

(i)  $G$  is locally quasi-finite (resp. unramified, resp. smooth, resp. étale) over  $A$  at some point.\*

(ii)  $G$  is locally quasi-finite (resp. unramified, resp. smooth, resp. étale) over  $A$ .\*

<!-- label: III.VI\_B.1.3.1 -->

[N.D.E-VI\_B-9] \*Proof.\* Indeed, if  $G$  satisfies one of the conditions of (i) at a point  $x$ , there exists an open neighborhood  $U$  of  $x$  which is of finite type over  $A$ . Consequently, it suffices to apply 1.3 in the case where  $H$  is the unit  $A$ -group, taking into account the following lemma. ■

**Lemma 1.3.1.1.** \*Let  $A$  be an Artinian local ring and  $G$  an  $A$ -group. If there exists a non-empty open subset of  $G$  of finite type over  $A$ , then  $G$  is locally of finite type over  $A$ .\*

<!-- label: III.VI\_B.1.3.1.1 -->

By Lemma 1.3.0, we may assume  $A$  equal to its residue field  $k$ . Moreover, by (fpqc) descent, we may assume  $k$  algebraically closed (cf. EGA IV<sub>2</sub>, 2.7.1). Let  $V$  be the open subset of  $G$  formed by the points where  $G$  is of finite type over  $k$ ; by hypothesis,  $V \neq \emptyset$ . Since  $G$  is a Jacobson scheme,  $V$  contains a closed point  $x$  and, to show that  $V = G$ , it suffices to show that every closed point  $y$  of  $G$  belongs to  $V$ . Now, for such a point  $y$ , the translation  $r_y \circ r^{-1}_x$  sends  $x$  to  $y$ , whence  $y \in V$ . ■

**Corollary 1.3.2.** \*Let  $A$  be an Artinian local ring,  $u : G \rightarrow H$  a morphism between  $A$ -groups locally of finite type. The following assertions are equivalent:\*

(i)  $u$  is universally open,\*

(ii)  $u$  is open,\*

(iii)  $u$  is open at some point of  $G$ ,\*

(iv) the morphism  $u^{\{0\}} : G^{\{0\}} \rightarrow H^{\{0\}}$  deduced from  $u$  is dominant,\*

(iv')  $u^{\{0\}}$  is surjective,\*

(v) there exists a connected component  $C$  of  $G$  such that, if  $D$  denotes the connected component of  $H$  containing  $u(C)$ , the morphism  $u' : C \rightarrow D$  deduced from  $u$  is dominant.\*

<!-- label: III.VI\_B.1.3.2 -->

\*Proof.\* The implications (i)  $\Rightarrow$  (ii)  $\Rightarrow$  (iii) and (iv')  $\Rightarrow$  (iv)  $\Rightarrow$  (v) are clear. Since  $G^{\{0\}}$  is of finite type over  $A$  (VI\_A, 2.4), and hence noetherian,  $u^{\{0\}}$  is quasi-compact, so  $u^{\{0\}}(G^{\{0\}})$  is closed in  $H^{\{0\}}$  by 1.2; hence (iv)  $\Rightarrow$  (iv'). On the other hand, since  $G^{\{0\}}$  (resp.  $C$ ) is open in  $G$  (VI\_A, 2.3) and  $H^{\{0\}}$  (resp.  $D$ ) is irreducible (VI\_A, 2.4.1), one sees that (ii) implies (iv) (resp. (iii) implies (v)). It remains to show that (v) implies (i).

<!-- original page 324 -->

The open subset  $C$  (resp.  $D$ ) of  $G$  (resp.  $H$ ) will be endowed with its induced scheme structure, and  $u$  will denote the morphism  $C \rightarrow D$  deduced from  $u$ . Let  $k$  be the residue field of  $A$ . [N.D.E-VI\_B-10] Since the base change  $\operatorname{Spec} k \rightarrow \operatorname{Spec} A$  is a universal homeomorphism, we may assume  $A = k$ . By hypothesis,  $u$  is dominant and, since  $C$  is of finite type over  $k$  (VI\_A, 2.4.1) and hence noetherian,  $u$  is quasi-compact. By EGA IV<sub>2</sub>, 2.3.7,  $u^{\{0\}}$  is again quasi-compact and dominant, where  $\bar{k}$  denotes an algebraic closure of  $k$ . Then, since  $C^{\{0\}}$  is a union of connected components of  $G^{\{0\}}$ , the morphism  $u^{\{0\}} : G^{\{0\}} \rightarrow H^{\{0\}}$  satisfies assertion (v). We are thus reduced to the case where  $A = k$  is an algebraically closed field, taking into account EGA IV<sub>2</sub>, 2.6.4.

In this case, we may further replace  $u$  by  $u_{\text{red}}$ , and we are reduced to the case where  $H$  is reduced. Let then  $\xi$  (resp.  $\eta$ ) be the generic point of  $C$  (resp.  $D$ ). Since  $u$  is quasi-compact and dominant,  $u'(\xi) = \eta$  (cf. EGA IV<sub>1</sub>, 1.1.5). On the other hand, since  $H$  is reduced, the local ring  $\mathcal{O}_{H,\eta}$  is a field, hence  $u$  is flat at the point  $\xi$ . [N.D.E-VI\_B-11] Hence, by 1.3,  $u$  is flat; moreover, since  $u$  is locally of finite type and  $H$  is locally noetherian,  $u$  is locally of finite presentation. Therefore, by EGA IV<sub>2</sub>, 2.4.6,  $u$  is universally open. ■

**\*Proposition 1.4.\*** \*Let  $A$  be an Artinian local ring, and  $u : G \rightarrow H$  a quasi-compact morphism between  $A$ -groups locally of finite type. The following assertions are equivalent:\*

- \*(i)  $u$  is proper,\*
- \*(ii) there exists  $h \in H$  such that the fiber  $u^{-1}(h)$  is non-empty and proper over  $\kappa(h)$ ,\*
- \*(iii)  $\operatorname{Ker} u$  is proper over  $A$ .\*

<!-- label: III.VI\_B.1.4 -->

\*Proof.\* It is clear that (i) implies (iii), and that (iii) implies (ii). On the other hand, it follows from the hypotheses that  $u$  is of finite type and, since  $G$  is separated (VI\_A, 0.3), so is  $u$  (EGA I, 5.5.1). It therefore remains to show that assertion (ii) implies that  $u$  is universally closed, so that we may assume  $A$  equal to its residue field  $k$ . [N.D.E-VI\_B-12] Let  $k'$  be an algebraic closure of  $\kappa(h)$ ,  $u' : G' \rightarrow H'$  the morphism deduced from  $u$  by base change, and  $h'$  a point of  $H'$  above  $h$ ; then the fiber  $u'^{-1}(h') = u^{-1}(h) \times_{\kappa(h)} k'$  is non-empty and proper, and it suffices to show that  $u$  is proper (EGA IV<sub>2</sub>, 2.6.4). We may therefore assume that  $k$  is algebraically closed and  $h \in H(k)$ . ■

<!-- original page 336 -->

We have seen (1.2) that  $u(G)$  is then the underlying set of a closed reduced group subscheme of  $H$ ; since every closed immersion is proper (EGA II, 5.4.2), we may assume that  $u$  is surjective and that  $H$  is reduced. Since  $u$  is surjective, the group  $G(k)$  acts transitively on the set of closed points of  $H$ ; whatever the closed point  $y$  of  $H$ ,  $u^{-1}(y)$  is therefore proper over  $\kappa(y)$ . By EGA IV<sub>3</sub>, 9.6.1, the set of  $y \in H$  such that  $u^{-1}(y)$  is not proper over  $\kappa(y)$  is locally constructible; since it contains no closed point, it is empty (cf. EGA IV<sub>3</sub>, 10.3.1 and 10.4.7).

[N.D.E-VI\_B-13] Consider now the generic point  $\eta$  of  $H^{\{0\}}$ ; by what precedes, the fiber  $u^{-1}(\eta) = G^{\{0\}}$  is proper over  $\kappa(\eta)$ . On the other hand, since  $H$  is reduced,  $\kappa(\eta)$  equals  $\mathcal{O}_{H,\eta}$ . Since  $\mathcal{O}_{H,\eta}$  is the direct limit of the rings  $\mathcal{O}_H(V)$ , as  $V$  runs through the non-empty open subsets of  $H^{\{0\}}$ , it follows from EGA IV<sub>3</sub>, 8.1.2 a) and 8.10.5 (xii), that there exists a non-empty open subset  $V$  of  $H^{\{0\}}$  such that the restriction of  $u$  over  $V$  is proper. It is then clear that the  $g \cdot V$ , for  $g \in G(k)$ , form an open cover of  $H$  such that, for every  $g \in G(k)$ , the restriction of  $u$  over the open  $g \cdot V$  is proper; one deduces that  $u$  is proper (cf. EGA II, 5.4.1). ■

**\*Corollary 1.4.1.\*** \*Let  $A$  be an Artinian local ring, and  $u : G \rightarrow H$  a morphism between  $A$ -groups locally of finite type. The following assertions are equivalent:\*

- \*(i)  $u$  is locally quasi-finite,\*

\*(ii)  $u$  is quasi-finite at some point,\*

\*(iii)  $\text{Ker } u$  is discrete,\*

\*(iv) the restriction of  $u$  to each connected component of  $G$  is finite.\*

\*If in addition  $u$  is quasi-compact, these assertions are equivalent to the following:\*

\*(v)  $u$  is finite.\*

<!-- label: III.VI\_B.1.4.1 -->

\*Proof.\* It is clear that (iv) implies (iii), that (iii) implies (ii) (EGA I, 6.4.4), and that, in the case where  $u$  is quasi-compact, assertions (iv) and (v) are equivalent. We have already seen in 1.3 that (i) and (ii) are equivalent.

Let us show finally that (i) implies (iv). Let  $C$  be a connected component of  $G$ ; since  $C$  is of finite type over  $A$  (VI\_A, 2.4.1) and  $G$  and  $H$  are separated (VI\_A, 0.2), by EGA I, 5.5.1 and 6.3.4, the restriction  $u|_C$  of  $u$  to  $C$  is separated and of finite type. [N.D.E-VI\_B-14] Since the fibers of  $u|_C$  are discrete, it follows that  $u|_C$  is quasi-finite (cf. EGA II, 6.2.2). Since every quasi-finite proper morphism is finite (cf. EGA III<sub>1</sub>, 4.4.2), it therefore suffices to show that  $u|_C$  is universally closed.

For this, we may assume that  $A$  is equal to its residue field  $k$ . Then, by (fpqc) descent (cf. EGA IV<sub>2</sub>, 2.6.4), it suffices to show that  $u|_{C \otimes_k \bar{k}}$  is universally closed, where  $\bar{k}$  denotes an algebraic closure of  $k$ . Moreover, since  $C$  is of finite type over  $k$ ,  $C \otimes_k \bar{k}$  is the sum of finitely many connected components  $C'_1, \dots, C'_n$  of  $G \otimes_k \bar{k}$ , and it suffices to show the assertion for each  $C'_i$ . One is thus reduced to the case where  $k$  is algebraically closed.

<!-- original page 337 -->

Let then  $g$  be a closed point of  $C$ . If  $u|_{G^g} : G^g \rightarrow H^g$  is the restriction of  $u$  to  $G^g$ , one has  $u|_{G^g} = r_{u(g)} \circ u|_{G^g} \circ r_{-1}^{-1}|_{G^g}$ , where  $r_g$  denotes right translation by  $g$ . Therefore, to show that  $u|_C$  is proper, it suffices to show that  $u|_{G^g}$  is. By hypothesis,  $u$  is locally quasi-finite, so the fiber  $\text{Ker } u$  is discrete (and non-empty); we have seen that  $u|_{G^g}$  is of finite type, so the fiber  $\text{Ker } u|_{G^g}$  is finite (cf. EGA II, 6.2.2), hence proper and non-empty. Therefore  $u|_{G^g}$  is proper by 1.4. ■

**\*\*Corollary 1.4.2.\*\*** \*Let  $A$  be an Artinian local ring, and  $u : G \rightarrow H$  a quasi-compact morphism between  $A$ -groups locally of finite type. The following assertions are equivalent: [N.D.E-VI\_B-15]

\*(i)  $u$  is a closed immersion,\*

\*(ii)  $u$  is a monomorphism,\*

\*(iii)  $\text{Ker } u$  is trivial, i.e. isomorphic to the unit  $k$ -group.\*

\*In particular, every group subscheme [N.D.E-VI\_B-16] of  $H$  is closed.\*

<!-- label: III.VI\_B.1.4.2 -->

\*Proof.\* It is clear that (i) implies (ii), and if one considers the functors represented respectively by  $G$  and  $H$ , it is immediate that conditions (ii) and (iii) are equivalent. Finally, if  $\text{Ker } u$  is the unit  $k$ -group,  $\text{Ker } u$  is a proper non-empty fiber, so  $u$  is a proper monomorphism by 1.4, of finite presentation since  $H$  is locally noetherian (EGA IV<sub>1</sub>, 1.6.1), and hence a closed immersion (EGA IV<sub>3</sub>, 8.11.5).

The last assertion follows from the fact that, since  $H$  is locally noetherian, every immersion  $G \rightarrow H$  is quasi-compact (EGA I, 6.6.4). ■

**\*\*Counterexample 1.4.3.\*\*** \*Let  $k$  be a field of characteristic 0,  $G$  the constant  $k$ -group  $\mathbb{Z}$ , and  $H$  the  $k$ -group  $G_{a,k}$ . Let  $u : G \rightarrow H$  be a morphism of  $k$ -groups. If  $u \neq 0$ , then  $\text{Ker } u = 0$ , but  $u$  is not a closed immersion (cf. 1.2.2).\*

<!-- label: III.VI\_B.1.4.3 -->

We shall use later the two following results, which should have appeared in Exposé VI\_A:

**\*\*Lemma 1.5.\*\*** \*Let  $k$  be a field and  $G$  a  $k$ -group locally of finite type. Then:

(i) All irreducible components of  $G$  have the same dimension.

(ii) For every  $g \in G$ , one has  $\dim_g G = \dim G$ .

!-- label: III.VI\_B.1.5 -->

!-- original page 338 -->

[^N.D.E-VI\_B-17] Assertion (i) has already been proved in (VI\_A, 2.4.1), and assertion (ii) follows from it. Indeed, let  $g$  be a point of  $G$  and  $U$  the connected component of  $G$  containing  $g$ . By definition (EGA 0\_IV, 14.1.2),  $\dim_g U$  is the infimum of the integers  $\dim U$ , as  $U$  runs through the open neighborhoods of  $g$ ; one therefore has  $\dim_g U = \dim U_0$  for some  $U_0$ , which one may assume contained in  $U$  (since  $\dim U_0 \leq \dim U$  if  $U_0 \subset U$ ). Then, since  $U$  is irreducible and of finite type over  $k$  (VI\_A, 2.4.1), one has  $\dim U_0 = \dim U = \dim G = \dim U_0$ , where  $U_0$  is the generic point of  $U$ , by EGA IV<sub>2</sub>, 5.2.1. Hence  $\dim_g U = \dim U = \dim G$ . ■

**\*\*Proposition 1.6.\*\*** [^N.D.E-VI\_B-18] \*Let  $S$  be a scheme of characteristic zero and  $G$  an  $S$ -group scheme, locally of finite presentation over  $S$  at every point of the unit section  $\epsilon(S)$ . For  $G$  to be smooth over  $S$  at every point of the unit section, it is necessary and sufficient that the  $\mathcal{O}_S$ -module  $\omega_{G/S} = \epsilon^*(\Omega_{G/S})$  (called the conormal module to the unit section of  $G$ ) be locally free.\*

!-- label: III.VI\_B.1.6 -->

Recall that a scheme  $S$  is said to be of characteristic zero if for every closed point  $x$  of  $S$ , the field  $k(x)$  has characteristic zero.

Recall also (II 4.11) that, if  $\pi$  denotes the structural morphism  $G \rightarrow S$ , one has  $\Omega_{G/S}^1 = \pi^*(\Omega_{G/S})$ , so that it comes to the same thing to say that the  $\mathcal{O}_S$ -module  $\omega_{G/S}$  is locally free, or that the  $\mathcal{O}_G$ -module  $\Omega_{G/S}^1$  is locally free.

If there exists an open neighborhood  $U$  of  $\epsilon(S)$  which is smooth over  $S$ , then, by EGA IV<sub>4</sub>, 17.2.3,  $\omega_{G/S}^1|_U$  is locally free of finite type, as well as  $\omega_{G/S} = \epsilon^*(\Omega_{G/S}^1|_U)$ .

Conversely, if  $\omega_{G/S}$  is locally free, the same holds for  $\Omega_{G/S}^1 = \pi^*(\omega_{G/S})$ . Since  $S$  is of characteristic 0, the Jacobian criterion (EGA IV<sub>4</sub>, 16.12.2) therefore implies that  $G$  is differentially smooth over  $S$ . Then it follows from EGA IV<sub>4</sub>, 17.12.5, that  $G$  is smooth over  $S$  at every point of the unit section. ■

**\*\*Corollary 1.6.1 (Cartier).\*\*** \*Given a field  $k$  of characteristic zero, every  $k$ -group locally of finite type over  $k$  is smooth over  $k$ .\*

!-- label: III.VI\_B.1.6.1 -->

Indeed, it is then clear that the  $k$ -module  $\omega_{G/k}$  is locally free, so, by 1.6,  $G$  is smooth over  $k$  at the unit point  $e$ , and hence smooth over  $k$  by 1.3.1. ■

**## 2. "Open properties" of groups and group morphisms locally of finite presentation**

!-- label: III.VI\_B.2 -->

### 2.0.

In all that follows,  $S$  will denote an arbitrary scheme; an  $S$ -group scheme will be called an  $S$ -group. Given an  $S$ -group  $G$ , we shall denote by  $\epsilon$  the unit section, by  $c : G \rightarrow G$  the inversion morphism, and by  $\mu$  the multiplication morphism  $G \times_S G \rightarrow G$ . For every  $S$ -scheme  $X$ , we shall denote by  $\pi$  or  $\pi_X$  the structural morphism  $X \rightarrow S$ .

!-- original page 329 -->

Given a property  $P(u)$  of a morphism of  $S$ -schemes  $u : X \rightarrow Y$ , we shall say that  $P(u)$  is *stable under base change* if, whenever  $u$  satisfies  $P(u)$ , so does the morphism  $u_{(Y')}$ , for any  $S$ -morphism  $Y' \rightarrow Y$ . We say that  $P(u)$  is *local in nature* for the topology  $\mathcal{T}$  (cf. Exp. IV, §§ 4 and 6) if  $P(u)$  satisfies the following two conditions:

a)  $P(u)$  is stable under base change,

b) whenever there exists a covering family of  $S$ -morphisms  $Y_i \rightarrow Y$  for the topology  $T$  such that each morphism  $u_i: Y_i \rightarrow Y$  satisfies  $P(u)$ , then  $u$  satisfies  $P(u)$ .

**Proposition 2.1.** \*Let  $P(u)$  be a property of a morphism of  $S$ -schemes, local in nature for the (fpqc) topology. Let  $u: G \rightarrow H$  be a morphism of  $S$ -groups. Assume  $G$  flat and universally open over  $S$ .\*

\*Let  $W$  be the largest open subset of  $H$  above which  $u$  satisfies the property  $P(u)$ , and let  $V = u^{-1}(W)$ . Then  $U = \pi_G(V)$  is open in  $S$  and  $V$  is an open group subscheme of  $G_U$ .\*

<!-- label: III.VI\_B.2.1 -->

The existence of a largest open subset  $W$  of  $H$  above which  $u$  satisfies  $P(u)$  follows from the fact that  $P(u)$  is local in nature for the Zariski topology. Since  $\pi_G$  is universally open,  $\pi_G(V)$  is an open subset  $U$  of  $S$ . It suffices to show that  $V$  is a group subscheme of  $G_U$ . We may therefore assume  $U = S$ .

<!-- original page 330 -->

Set then  $G' = G \times_S V$ ,  $H' = H \times_S V$ ,  $V' = V \times_S V$ ,  $W' = W \times_S V$ , and  $u' = u_{(V)}$ ; let  $W'_1$  be the largest open subset of  $H'$  above which  $u'$  satisfies  $P(u)$ ; since  $V$  is flat and universally open over  $S$ , so is  $H'$  over  $H$ , and Lemma 2.1.1 below shows that  $W'_1 = W'$ . Now consider the automorphism of  $V$ -schemes  $a$  (resp.  $b$ ) of  $G'$  (resp.  $H'$ ), namely right translation by the inverse of the diagonal section  $\delta$  (resp. by the inverse of  $u(\delta)$ ), defined by

```text  
a(g, v) = (g · v⁻¹, v), (resp. b(h, v) = (h · u(v⁻¹), v)),
```

for any morphism  $T \rightarrow S$ ,  $g \in G(T)$ ,  $v \in V(T)$ , and  $h \in H(T)$ . It is clear that  $u' \circ a = b \circ u'$ , which shows that  $W'$  is stable under  $b$ , hence  $V$  is stable under  $a$ , so that  $V$  is a group subscheme of  $G$ . ■

**Lemma 2.1.1.** \*Let  $P(u)$  be a property of an  $S$ -morphism  $u$ , local in nature for the (fpqc) topology. Consider a cartesian square of morphisms of  $S$ -schemes:\*

```text  
 f'
X' → Y'
↓ ↓ g
X → Y,
 f
```

\*where  $g$  is flat and open. Let  $W$  (resp.  $W'_1$ ) be the largest open subset of  $Y$  (resp.  $Y'$ ) above which  $f$  (resp.  $f' = f_{(Y')}$ ) satisfies  $P(u)$ . Then  $W'_1 = W \times_Y Y'$ .\*

<!-- label: III.VI\_B.2.1.1 -->

Set  $W' = W \times_Y Y'$ ; since  $P(u)$  is stable under base change, one has  $W' \subset W'_1$ . Since  $g$  is open,  $W_1 = g(W'_1)$  is an open subset of  $Y$ . Set  $V_1 = f'^{-1}(W_1)$  and  $V'_1 = V_1 \times_{Y'} W'_1$ ; it is clear that  $V'_1 = f'^{-1}(W'_1)$ . Since  $g$  is flat and open, the morphism  $W'_1 \rightarrow W_1 = g(W'_1)$  deduced from  $g$  is faithfully flat and open, hence covering for the (fpqc) topology (cf. IV 6.3.1 (iv)). Since the morphism  $V'_1 \rightarrow W'_1$  deduced from  $f'$  satisfies  $P(u)$ , the same holds for the morphism  $V_1 \rightarrow W_1$  deduced from  $f$ ; hence  $W_1 \subset W$ , and  $W'_1 \subset g^{-1}(W_1) \subset g^{-1}(W) = W'$ ; therefore  $W' = W'_1$ . ■

**Remark 2.1.2.** \*A great many properties of a morphism are local in nature for the (fpqc) topology; let us mention the properties of being flat, (universally) open, (locally) of finite type, of finite presentation, quasi-finite (cf. EGA IV<sub>2</sub>, 2.5.1, 2.6.1 and 2.7.1), smooth, étale, unramified (EGA IV<sub>4</sub>, 17.7.3).\*

\*The proof of 2.1 in fact uses only base changes by flat morphisms; the proposition therefore applies to a property satisfying condition b) of 2.0 relative to the (fpqc) topology, and stable under base change by flat morphisms (for example, that of being quasi-compact and dominant).\*

<!-- original page 331 -->

\*Of course, one can state an analogous proposition concerning properties local in nature for a topology  $\mathcal{T}$  finer than the Zariski topology, the condition to verify on  $G$  being then that  $\pi_G$  be universally open and covering for the topology  $\mathcal{T}$ .\*

\*In particular, if  $G$  is flat and locally of finite presentation over  $S$ , one has an analogous statement for properties stable under base change by flat morphisms locally of finite presentation, satisfying condition b) of 2.0 relative to the (fpqc) topology (e.g., the properties of being regular, reduced, Cohen-Macaulay, etc. (EGA IV<sub>2</sub>, 6.8)).\*

<!-- label: III.VI\_B.2.1.2 -->

**\*\*Proposition 2.2.\*\*** \*Let  $G$  and  $H$  be two  $S$ -groups and  $u : G \rightarrow H$  a morphism of  $S$ -groups.  
Then:\*(N.D.E-VI\_B-19)

\*(i) Suppose  $G$  or  $H$  flat over  $S$ , and  $G$  or  $H$  locally of finite presentation over  $S$ , and let  $V$  be the largest open subset of  $G$  such that the restriction of  $u$  to  $V$  is flat and locally of finite presentation (resp. smooth, resp. étale). Then  $U = \pi_V(V)$  is open in  $S$ , and  $V$  is an open group subscheme of  $G|_U$ .\*

\*(ii) Suppose  $G$  or  $H$  universally open over  $S$ , and let  $V$  be the largest open subset of  $G$  such that the restriction of  $u$  to  $V$  is universally open. Then  $U = \pi_V(V)$  is open in  $S$ , and  $V$  is an open group subscheme of  $G|_U$ .\*

<!-- label: III.VI\_B.2.2 -->

**\*Proof.\*** We first show (i). Let us show that the restriction  $\pi_V$  of  $\pi_G$  to  $V$  is flat and locally of finite presentation.

a) If  $\pi_G$  is flat (resp. locally of finite presentation), so is  $\pi_V$ .

b) If  $\pi_H$  is flat (resp. locally of finite presentation), so is  $\pi_V$ , as the composition of the restriction of  $u$  to  $V$  and  $\pi_H$ .

So in the four cases envisaged in the statement,  $\pi_V$  is flat and locally of finite presentation, hence universally open (EGA IV<sub>2</sub>, 2.4.6). Set  $U = \pi_V(V)$ ;  $U$  is therefore open in  $S$ . It then suffices to show that  $V$  is an open group subscheme of  $G|_U$ ; we may therefore assume  $U = S$ .

Set then  $G' = G \times_S V$ ,  $H' = H \times_S V$ ,  $V' = V \times_S V$  and  $u' = u_{(V)}$ . Then, since  $V$  is flat and locally of finite presentation over  $S$ , so is  $H'$  over  $H$ . By EGA IV<sub>4</sub>, 17.7.4,  $V'$  is then the largest open subset of  $G'$  such that the restriction of  $u'$  to  $V'$  is flat and locally of finite presentation (resp. smooth, resp. étale). With the automorphisms  $a$  and  $b$  defined as in the proof of 2.1, it is then clear that  $V'$  is stable under  $a$ , hence  $V$  is a group subscheme of  $G$ .

Let us show (ii). The restriction  $\pi_V$  of  $\pi_G$  to  $V$  is a universally open morphism, either because so is  $\pi_G$ , or as the composition of the restriction of  $u$  to  $V$  and  $\pi_H$  in the case where  $\pi_H$  is universally open. Set  $U = \pi_V(V)$ ;  $U$  is then open in  $S$ . It suffices to show that  $V$  is an open group subscheme of  $G|_U$ . We may therefore assume  $U = S$ .

Set as before  $G' = G \times_S V$ ,  $H' = H \times_S V$ ,  $V' = V \times_S V$  and  $u' = u_{(V)}$ . Then  $\pi_V : V \rightarrow S$  is surjective and universally open, the same is true of  $G' \rightarrow G$ , so that  $V'$  is the largest open subset of  $G'$  such that the restriction of  $u'$  to  $V'$  is universally open, by virtue of (EGA IV<sub>3</sub>, 14.3.4 (i) and (ii)). With the automorphisms  $a$  and  $b$  defined as before, it is then clear that  $V'$  is stable under  $a$ , hence  $V$  is a group subscheme of  $G$ . ■

<!-- original page 333 -->

**\*\*Corollary 2.3.\*\*** \*Let  $G$  be an  $S$ -group and  $V$  the largest open subset of  $G$  which is flat and locally of finite presentation (resp. smooth, étale, universally open) over  $S$ . Then  $U = \pi_V(V)$  is open in  $S$ , and  $V$  is an open group subscheme of  $G|_U$ .\*

<!-- label: III.VI\_B.2.3 -->

It suffices to apply 2.2 in the case where  $H$  is the unit  $S$ -group and  $u$  is the unique morphism of  $S$ -groups  $G \rightarrow H$ , since then  $\pi_H$  is an isomorphism and  $\pi_G = \pi_H \circ u$ . ■

**\*\*Corollary 2.4.\*\*** \*Let  $G$  be an  $S$ -group; if there exists a neighborhood  $X$  of the unit section having one (or several) of the following properties:\*

\* $X$  is flat and locally of finite presentation (resp. smooth, étale, universally open) over  $S$ ,\*

\*then there exists an open group subscheme of  $G$  having the same properties.\*

<!-- label: III.VI\_B.2.4 -->

It suffices to apply 2.3, remarking that here, with the notations of 2.2, one has  $\epsilon(S) \subset V$ , hence  $U = S$ . ■

**\*\*Proposition 2.5.\*\*** [N.D.E-VI-B-20] \*Let  $u : G \rightarrow H$  be a morphism of  $S$ -groups.\*

\*(i) Suppose that  $G$  (resp.  $H$ ) is of finite presentation and flat (resp. of finite type) over  $S$  at the points of its unit section. Then the sets:

$U_{\text{flat}} \subset U_{\text{smooth}} \subset U_{\text{acute}}^t$ ,  
 $S$

\*formed of the points  $s \in S$  such that  $u_s$  is flat (resp. smooth, étale), are open in  $S$ .\*

\*If moreover  $G$  (resp.  $H$ ) is locally of finite presentation and flat (resp. locally of finite type) over  $S$ , then the set  $V_{\text{flat}}$  (resp.  $V_{\text{smooth}}$ ,  $V_{\text{acute}}^t$ ) of points of  $G$  where  $u$  is flat (resp. smooth, resp. étale) is the inverse image under  $\pi_G$  of  $U_{\text{flat}}$  (resp.  $U_{\text{smooth}}$ ,  $U_{\text{acute}}^t$ ).\*

\*(ii) Suppose that, for every  $s \in S$ ,  $G_s$  is locally of finite type over  $\kappa(s)$  (a condition satisfied if  $G$  is of finite type over  $S$  at the points of the unit section (1.3.1.1)), and that  $u$  is locally of finite type (resp. locally of finite presentation) at the points of the unit section of  $G$ . Then the sets:

$U_{\text{q.f.}} \subset U_{\text{n.r.}}$   
 $S$

\*formed of the  $s \in S$  such that  $u_s$  is locally quasi-finite (resp. unramified) are open in  $S$ .\*

\*If moreover  $u$  is locally of finite type (resp. locally of finite presentation), then the set  $V_{\text{q.f.}}$  (resp.  $V_{\text{n.r.}}$ ) of points of  $G$  where  $u$  is quasi-finite (resp. unramified) is the inverse image under  $\pi_G$  of  $U_{\text{q.f.}}$  (resp.  $U_{\text{n.r.}}$ ).\*

<!-- label: III.VI\_B.2.5 -->

**\*Proof.\*** Let us show (i). First note (1.3.1.1) that, for every  $s \in S$ ,  $G_s$  is locally of finite type over  $\kappa(s)$ . Let  $Y$  be the open subset of  $H$  formed by the points where  $\pi_H$  is of finite type, and let  $X_1$  be the open subset of  $u^{-1}(Y)$  formed by the points where  $\pi_G$  is of finite presentation. By EGA IV<sub>3</sub>, 11.3.1, the set  $X$  of points of  $X_1$  where  $\pi_G$  is of finite presentation and flat is open in  $X_1$ , hence in  $G$ .

Let  $u_X : X \rightarrow Y$  be the morphism deduced from  $u$ . Since  $Y$  (resp.  $X$ ) contains the unit section of  $H$  (resp.  $G$ ), the restriction  $\pi_X$  of  $\pi_G$  to  $X$  is surjective, and the morphism  $S \rightarrow X$  deduced from  $\epsilon_G$  is an  $S$ -section of  $X$ .

Consider the sets  $W_{\text{flat}} \subset W_{\text{smooth}} \subset W_{\text{acute}}^t$ , formed by the points of  $X$  where  $u_X$  is flat (resp. smooth, resp. étale). It is clear that  $W_{\text{smooth}}$  and  $W_{\text{acute}}^t$  are open in  $X$ , cf. N.D.E. (6). On the other hand, since  $\pi_Y$  is locally of finite type and  $\pi_X = \pi_Y \circ u_X$  is locally of finite presentation, by EGA IV<sub>1</sub>, 1.4.3 (v),  $u_X$  is locally of finite presentation. Consequently, the flat locus  $W_X$  of  $u_X$  is open in  $X$  (EGA IV<sub>3</sub>, 11.3.1).

Let  $x \in X$  and set  $s = \pi_X(x)$ ; then by EGA IV<sub>2</sub>, 11.3.10 (combined with EGA IV<sub>4</sub>, 17.5.1, resp. 17.6.1),  $x$  belongs to  $W_{\text{flat}}$  (resp.  $W_{\text{smooth}}$ ,  $W_{\text{acute}}^t$ ) if and only if  $u_s$  is flat (resp. smooth, étale) at the point  $x$ , or, what comes to the same by 1.3, if and only if  $u_s$  is flat (resp. smooth, étale).

Consequently, for " $\flat$  = flat, smooth or étale", one has  $U_{\text{flat}} = \epsilon^{-1}_G(W_{\text{flat}})$  and  $W_{\text{flat}} = \pi^{-1}_X(U_{\text{flat}})$ . Since  $W_{\text{flat}}$  is open in  $X$ , hence in  $G$ , the first equality shows that

$U_{\text{flat}}$  is open in  $S$ .

<!-- original page 335 -->

The second assertion of (i) follows from what has just been seen, since then  $Y = H$ ,  $X = G$ , and  $V_{\text{flat}} = W_{\text{flat}} = \pi^{-1}_G(U_{\text{flat}})$ .

Let us show assertion (ii). Let  $V_{\text{t.f.}} \supset V_{\text{q.f.}}$  be the open subsets of  $G$  formed by the points at which  $u$  is of finite type (resp. quasi-finite). Set  $X = V_{\text{t.f.}}$  and denote by  $u_X$  the restriction of  $u$  to  $X$ . By hypothesis,  $X$  contains  $\epsilon(S)$ . Let  $x \in X$  and set  $s = \pi_X(x)$ .

If  $u$  is quasi-finite at  $x$ , then, by base change,  $u_s$  is quasi-finite at  $x$ , and so, since  $G_s$  is assumed locally of finite type,  $u_s$  is locally quasi-finite by 1.3.1.

Conversely, if  $u_s$  is locally quasi-finite, then  $u^{-1}_X(u_X(x)) \subset u^{-1}_s(u_s(x))$  is a finite set. Since  $u_X : X \rightarrow H$  is locally of finite type, it follows from Chevalley's semicontinuity theorem (EGA IV<sub>3</sub>, 13.1.3) that there exists an open neighborhood  $W$  of  $x$  in  $X$  such that the fiber  $u^{-1}_X(u_X(x'))$  is discrete for every  $x' \in W$ . Hence, by EGA II, 6.2.2 (and EGA III<sub>2</sub>, Err\_III 20),  $u_X$  is quasi-finite at  $x$ .

Consequently, one has  $U_{\text{t.f.}} = \epsilon^{-1}_G(V_{\text{t.f.}})$  and  $V_{\text{t.f.}} = \pi^{-1}_X(U_{\text{t.f.}})$ , and the first equality shows that  $U_{\text{t.f.}}$  is open in  $S$ .

If moreover  $G$  is locally of finite type over  $S$ , then  $X = G$ , and so  $V_{\text{t.f.}}$  is the inverse image under  $\pi_G$  of  $U_{\text{t.f.}}$ . This proves the first half of (ii).

Consider now the open subsets  $V_{\text{p.f.}} \supset V_{\text{r.}}$ , formed by the points where  $u$  is of finite presentation (resp. unramified), and suppose that  $Z = V_{\text{p.f.}}$  contains the unit section of  $G$ . Let  $z \in Z$ ; set  $s = \pi_Z(z)$  and  $h = u_Z(z)$ .

If  $u$  is unramified at  $z$ , then, by base change,  $u_s$  is unramified at  $z$ , and so, since  $G_s$  is assumed locally of finite type,  $u_s$  is unramified by 1.3.1.

Conversely, if  $u_s$  is unramified at the point  $z$ , then the fiber  $u^{-1}_s(u_s(h)) = u^{-1}(h)$  is unramified over  $\kappa(h)$  at the point  $z$ . Since  $Z$  is an open subset of  $G$ , the fiber  $u^{-1}_Z(u_s(h)) = u^{-1}_s(u_s(h)) \cap Z$  is unramified over  $\kappa(h)$  at the point  $z$ . Since  $u_Z$  is locally of finite presentation, this entails, by EGA IV<sub>4</sub>, 17.4.1, that  $u_Z$  is unramified at the point  $z$ .

One therefore has  $U_{\text{r.}} = \epsilon^{-1}_G(V_{\text{r.}})$  and  $V_{\text{r.}} = \pi^{-1}_Z(U_{\text{r.}})$ , and the first equality shows that  $U_{\text{r.}}$  is open in  $S$ .

If moreover  $G$  is locally of finite presentation over  $S$ , then  $Z = G$ , and so  $V_{\text{r.}}$  is the inverse image under  $\pi_G$  of  $U_{\text{r.}}$ . This completes the proof of assertion (ii). ■

**\*\*Corollary 2.6.\*\*** \*Let  $u : G \rightarrow H$  be a morphism of  $S$ -groups which is a radicial morphism (which is the case if  $u$  is a monomorphism (EGA I, 3.5.4)). Suppose  $G$  (resp.  $H$ ) locally of finite presentation and flat (resp. locally of finite type) over  $S$ . Then the set  $U$  of  $s \in S$  such that  $u_s$  is an open immersion is open in  $S$ , and the restriction of  $u$  over  $U$  is an open immersion.\*

<!-- label: III.VI\_B.2.6 -->

By 2.5 (i), the set  $U'$  of points  $s \in S$  such that  $u_s$  is étale is open in  $S$ . Since  $u$  is radicial, so is  $u_s$ , for every  $s \in S$ , hence by EGA IV<sub>4</sub>, 17.9.1, one has  $U = U'$ , which shows that  $U$  is open. Finally, by 2.5 (i), the restriction of  $u$  over  $U$  is étale; since  $u$  is radicial, this restriction is an open immersion (EGA IV<sub>4</sub>, 17.9.1). ■

**\*\*Proposition 2.7.\*\*** \*Let  $G$  be an  $S$ -group. The following conditions are equivalent:\*

\*(i)  $G$  is unramified over  $S$  at the points of the unit section,\*

\*(ii) the unit section is an open immersion,\*

\*(iii)  $G$  is of finite presentation over  $S$  at the points of the unit section, and for every  $s \in S$ ,  $G_s$  is unramified over  $\kappa(s)$ .\*

\*If, moreover, one assumes  $G$  locally of finite presentation over  $S$ , then each of the three preceding conditions is

equivalent to the following:\*

\*(iv)  $G_S$  is unramified over  $S_S$ .\*

<!-- label: III.VI\_B.2.7 -->

The equivalence of assertions (i) and (ii) follows from the more general Lemma 2.7.1 below. Note (1.3.1.1) that either of conditions (i) or (iii) implies that, for every  $s \in S$ ,  $G_s$  is locally of finite type over  $\kappa(s)$ . Then (EGA IV<sub>4</sub>, 17.4.1), assertion (i) is equivalent to the fact that, for every  $s \in S$ ,  $G_s$  is unramified over  $\kappa(s)$  at the point  $e_s$ , unit of  $G_s$ , or again (1.3.1), to the fact that  $G_s$  is unramified over  $\kappa(s)$ , so assertions (i) and (iii) are equivalent. Finally, if  $G_S$  is locally of finite presentation over  $S$ , assertions (iii) and (iv) are equivalent (EGA IV<sub>4</sub>, 17.4.1). ■

**Lemma 2.7.1.** \*Let  $G_S$  be an  $S_S$ -scheme equipped with a section  $\epsilon_S$ . In order that  $G_S$  be unramified over  $S_S$  at the points of this section, it is necessary and sufficient that  $\epsilon_S$  be an open immersion.\*

<!-- label: III.VI\_B.2.7.1 -->

The condition is necessary, by EGA IV<sub>4</sub>, 17.4.1 a)  $\Rightarrow$  b'). Conversely, if  $\epsilon_S$  is an open immersion, then the restriction to  $\epsilon_S(S)$  of the structural morphism  $G \rightarrow S$  is an isomorphism, hence  $G_S$  is unramified over  $S_S$  at the points of  $\epsilon_S(S)$ . ■

**Corollary 2.8.** \*Let  $u : G \rightarrow H$  be a morphism of  $S_S$ -groups. Suppose that, for every  $s \in S$ ,  $G_s$  is locally of finite type over  $\kappa(s)$ .\*[^N.D.E-VI\_B-21]

\*a) If  $u_S$  is locally of finite type, the following conditions are equivalent:\*

\*(i)  $u_S$  is locally quasi-finite,\*

\*(ii) for every  $s \in S$ ,  $u_s : G_s \rightarrow H_s$  is locally quasi-finite,\*

\*(iii)  $\text{Ker } u$  is locally quasi-finite over  $S_S$ ,\*

\*(iv) the fibers of  $\text{Ker } u$  are discrete.\*

\*b) If  $u_S$  is locally of finite presentation, the following conditions are equivalent:\*

\*(v)  $u_S$  is unramified,\*

\*(vi) for every  $s \in S$ ,  $u_s : G_s \rightarrow H_s$  is unramified,\*

\*(vii)  $\text{Ker } u$  is unramified,\*

\*(viii) the unit section  $S \rightarrow \text{Ker } u_S$  is an open immersion.\*

<!-- label: III.VI\_B.2.8 -->

The equivalences (i)  $\Leftrightarrow$  (ii) and (v)  $\Leftrightarrow$  (vi) follow from 2.5 (ii), and Reminder 2.8.1 below shows that (i)  $\Rightarrow$  (iii) and (v)  $\Rightarrow$  (vii).

<!-- original page 345 -->

For every  $s \in S$ , denote by  $e_s$  the unit element of  $H_s$ . Then (iii) (resp. (vii)) implies that, for every  $s \in S$ ,

```text  
(Ker u)_s = Ker u_s = u_s⁻¹(e_s)
```

is locally quasi-finite (resp. unramified) over  $\kappa(s) = \kappa(e_s)$ , hence  $u_s$  is quasi-finite (resp. unramified) at the unit point of  $G_s$ , hence, by 1.3,  $u_s$  is locally quasi-finite (resp. unramified). So (iii)  $\Rightarrow$  (ii) and (vii)  $\Rightarrow$  (vi). Finally, (ii)  $\Leftrightarrow$  (iv) by 1.4.1, and (vii)  $\Leftrightarrow$  (viii) by 2.7. ■

**Reminder 2.8.1.** \*Recall (cf. I 2.3.6.1) that, given a morphism  $u : G \rightarrow H$  of  $S_S$ -groups, the kernel of  $u$ , denoted  $\text{Ker } u$ , is the group subfunctor of  $G_S$  defined by setting, for any morphism  $f : T \rightarrow S$ ,

```

```text
(Ker u)(T) = {a ∈ G(T) | u ◦ a = ε_H ◦ f}.
```

```

\*By loc. cit. (or EGA I, 4.4.1), this functor is representable by the  $S$ -group  $G \times_{\epsilon_H} S = u^{-1}(\epsilon_H(S))$ , simply denoted  $\text{Ker } u$ . In particular, the structural morphism  $\text{Ker } u \rightarrow S$  is deduced from  $u$  by base change.\*

**Lemma 2.9.** \*Let  $\pi : X \rightarrow S$  be a morphism admitting an  $S$ -section  $\epsilon$ .\*

(i) If  $\pi$  is injective, it is integral.\*[VI\_B-2-9-i]

(ii) If  $\pi$  is locally of finite type, and if, for every  $s \in S$ ,  $\pi_s$  is an isomorphism, then  $\pi$  is an isomorphism.\*[VI\_B-2-9-ii]

```

<!-- label: III.VI_B.2.9 -->

```

Let us first note that, by Lemma 2.9.1 below,  $\pi$ , being a homeomorphism, is an affine morphism.

If  $\pi$  is injective,  $\epsilon$  is surjective. Since  $\epsilon$  is a surjective immersion,  $\epsilon(S)$  is isomorphic to the closed subscheme of  $X$  defined by a nil-ideal  $I$  of  $\mathcal{O}_X$ . Since  $\epsilon$  is an  $S$ -section of the morphism  $\pi$ , one has a direct sum decomposition  $\mathcal{O}_X = \mathcal{O}_S \oplus I$  of  $\mathcal{O}_S$ -modules. Since  $I$  is a nil-ideal of  $\mathcal{O}_X$ ,  $I$  is evidently integral over  $\mathcal{O}_S$ , hence  $\mathcal{O}_X$  is integral over  $\mathcal{O}_S$ , and  $\pi$  is integral.

Suppose now that  $\pi$  is locally of finite type. Since  $\pi \circ \epsilon = \text{id}_S$ ,  $\epsilon$  is locally of finite presentation (cf. EGA IV<sub>1</sub>, 1.4.3 (v)), hence  $I$  is an ideal of finite type of  $\mathcal{O}_X$  (EGA IV<sub>1</sub>, 1.4.1). For every  $s \in S$ , one has  $\mathcal{O}_{X_s} = \mathcal{O}_s \oplus I \otimes_{\mathcal{O}_S} \mathcal{O}_s$ . By hypothesis,  $\epsilon_s$  is an isomorphism, hence  $I \otimes_{\mathcal{O}_S} \mathcal{O}_s = 0$  for every  $s \in S$ , hence a fortiori  $I \otimes_{\mathcal{O}_S} \mathcal{O}_X = 0$  for every  $x \in X$ , which implies, by Nakayama's lemma, that  $I = 0$ , hence  $\pi$  is an isomorphism. ■

**Lemma 2.9.1.** \*Let  $f : X \rightarrow Y$  be a morphism of schemes which is a homeomorphism; then  $f$  is an affine morphism.\*[VI\_B-2-9-1]

```

<!-- label: III.VI_B.2.9.1 -->

```

It suffices to show that every point  $y \in Y$  has an open neighborhood  $W$  such that the restriction of  $f$  over  $W$  is an affine morphism. So let  $y \in Y$ , and let  $V$  be an affine open neighborhood of  $y$  in  $Y$ . Let  $V' = f^{-1}(V)$ . Then  $V'$  is an open neighborhood of  $x = f^{-1}(y)$  in  $X$ . There exists an open affine neighborhood  $W'$  of  $x$  in  $X$  contained in  $V'$ . Set then  $W = f(W')$ . Then  $W$  is an open neighborhood of  $y$  in  $Y$  contained in the affine scheme  $V$ , hence  $W$  is separated. Since  $W$  is an affine scheme, the restriction of  $f$  over  $W$  is then an affine morphism (EGA II, 1.2.3). ■

**Corollary 2.10.** \*Let  $G$  be an  $S$ -group locally of finite type. Suppose that, for every  $s \in S$ ,  $G_s$  is the unit  $\mathcal{K}(s)$ -group; then  $G$  is the unit  $S$ -group.\*

```

<!-- label: III.VI_B.2.10 -->

```

More generally:

**Corollary 2.11.** \*Let  $f : X \rightarrow Y$  be an  $S$ -morphism locally of finite type. In order that  $f$  be a monomorphism, it is necessary and sufficient that  $f_s$  be a monomorphism for every  $s \in S$ .\*

```

<!-- label: III.VI_B.2.11 -->

```

It is clear that the condition is necessary; let us show that it is sufficient. If, for every  $s \in S$ ,  $f_s$  is a monomorphism, then a fortiori for every  $y \in Y$ ,  $f_y$  is a monomorphism; we may therefore assume  $Y = S$ .

By EGA I, 5.3.8, to show that  $f$  is a monomorphism, it suffices to show that  $\Delta_f : X \rightarrow X \times_S X$  is an isomorphism, or, what comes to the same, that the first projection  $p : X \times_S X \rightarrow X$  is an isomorphism. But, if  $f_s$  is a monomorphism, it likewise follows from EGA I, 5.3.8 that the first projection  $X_s \times_{\mathcal{K}(s)} X_s \rightarrow X_s$  (which is identified with  $p_s$ ) is an isomorphism. Now  $p$  has the

$S$ -section  $\Delta_f$ , hence Lemma 2.9 affirms that if for every  $s \in S$ ,  $p_s$  is an isomorphism, then so is  $p$ . ■

**Corollary 2.12.** Let  $G$  be an  $S$ -scheme having an  $S$ -section  $\epsilon$  and such that the structural morphism  $\pi : G \rightarrow S$  is closed. Let  $s \in S$  be such that  $\pi$  is of finite presentation at the point  $\epsilon(s)$  and that  $\epsilon_s : \operatorname{Spec}(\kappa(s)) \rightarrow G_s$  is an isomorphism (or, what comes to the same, that  $\pi_s : G_s \rightarrow \operatorname{Spec} \kappa(s)$  is an isomorphism). Then there exists an open neighborhood  $U$  of  $s$  in  $S$  such that  $\epsilon|_U : U \rightarrow G \times_S U$  is an isomorphism.\*

<!-- label: III.VI\_B.2.12 -->

Let  $V$  be the set of points of  $G$  where  $\pi$  is unramified; it is known that  $V$  is open (cf. N.D.E. (6)) and contains  $\epsilon(s)$ . Hence  $W = \epsilon^{-1}(V)$  is an open subset of  $S$  containing  $s$ , such that for every  $t \in W$ ,  $\pi$  is unramified at  $\epsilon(t)$ . Since  $\pi$  is closed, so is  $\pi|_W$ , hence we may assume  $W = S$ .

Then, by 2.7.1,  $X = G - \epsilon(S)$  is a closed subset of  $G$  not meeting  $G_s$ , hence, since  $\pi$  is closed,  $F = \pi(X)$  is a closed subset of  $S$  not containing  $s$ ; set  $U = S - F$ ; then  $U$  is an open subset of  $S$  such that  $\epsilon|_U$  is an isomorphism of  $U$  onto  $G|_U$ . ■

## 3. Neutral component of a group locally of finite presentation

<!-- label: III.VI\_B.3 -->

### 3.0.

Given a part  $A$  (resp.  $B$ ) of an  $S$ -scheme  $X$  (resp.  $Y$ ), by abuse of notation,  $A \times_S B$  will denote the part of  $X \times_S Y$  formed by the points whose first projection lies in  $A$  and second in  $B$ .

<!-- original page 347 -->

Given a part  $A$  of an  $S$ -group  $G$ , we shall say that  $A$  is *\*stable* under the group law of  $G$  if  $c(A) \subset A$  and  $\mu(A \times_S A) \subset A$ .

**Definition 3.1.** Let  $G$  be an  $S$ -functor in groups satisfying the following condition:\*

``text  
(+) for every  $s \in S$ , the functor  $G_s = G \otimes_S \kappa(s)$  is representable.

\*One then denotes by  $G^{\{0\}}_s$  the connected component of the unit element of the  $\kappa(s)$ -group  $G_s$ . [N.D.E-VI\_B-22] One defines a sub- $S$ -functor in groups of  $G$ , called the *\*neutral component* of  $G$ , denoted  $G^{\{0\}}$ , by setting, for every morphism  $T \rightarrow S$ :

``text  
 $G^{\{0\}}(T) = \{u \in G(T) \mid \forall s \in S, u_s(T_s) \in G^{\{0\}}_s\}.$

\*One has thus defined the functor  $G \mapsto G^{\{0\}}$  from  $(\operatorname{Sch}/S)\text{-gr.}$  to  $(\operatorname{Sch}/S)\text{-gr.}$ \*

<!-- label: III.VI\_B.3.1 -->

**Remark 3.2.** (i) Let  $G$  be an  $S$ -functor in groups satisfying condition (+); then  $\operatorname{Lie}(G^{\{0\}}/S) = \operatorname{Lie}(G/S)$ , by virtue of Exposé II. [N.D.E-VI\_B-23] Indeed, for every  $S$ -scheme  $T$ , denote by  $I_T$  the  $T$ -scheme of dual numbers over  $T$  and by  $\tau : T \rightarrow I_T$  the zero section (cf. II, 2.1). By definition, one has\*

``text  
 $\operatorname{Lie}(G/S)(T) = \{u \in G(I_T) \mid u \circ \tau = e\},$

\*where  $e : T \rightarrow G$  denotes the composition of  $T \rightarrow S$  and the unit section  $S \rightarrow G$ , and likewise\*

``text  
 $\operatorname{Lie}(G^{\{0\}}/S)(T) = \{u \in G^{\{0\}}(I_T) \mid u \circ \tau = e\}$   
 $= \{u \in G(I_T) \mid u \circ \tau = e \text{ and } u_s((I_T)_s) \in G^{\{0\}}_s, \forall s \in S\}.$

\*Now, for every  $s \in S$ ,  $T_s$  and  $(I_{T_s})_s = I_{T_s}$  have the same underlying set, hence if  $u \in \text{Lie}(G/S)(T)$ , one has  $u_s(I_{T_s}) = e_s$ , where  $e_s$  denotes the unit point of  $G_s$ , whence  $u \in \text{Lie}(G^{\{0\}}/S)(T)$ . So the inclusion  $\text{Lie}(G^{\{0\}}/S)(T) \subset \text{Lie}(G/S)(T)$  is an equality for every  $T$ , whence  $\text{Lie}(G^{\{0\}}/S) = \text{Lie}(G/S)$ .\*

(ii) Let  $G$  and  $G'$  be two  $S$ -functors in groups satisfying (+); then:

a) if  $G \subset G'$ , then  $G^{\{0\}} \subset G'^{\{0\}}$ ,

b) if  $G \subset G'$  and  $G'^{\{0\}} \subset G$ , then  $G^{\{0\}} = G'^{\{0\}}$ ,

c) if for every  $s \in S$ ,  $G_s$  is locally of finite type over  $\kappa(s)$ , then  $G^{\{0\}}$  satisfies property (+), by (VI\_A, 2.3), and one has  $(G^{\{0\}})^{\{0\}} = G^{\{0\}}$ .\*

<!-- label: III.VI\_B.3.2 -->

**Proposition 3.3.** \*Let  $G$  be an  $S$ -functor in groups satisfying condition (+) and let  $S'$  be an  $S$ -scheme. Then  $(G \times_{S'} S')^{\{0\}} = G^{\{0\}} \times_{S'} S'$ ; in other words, the functor  $G \mapsto G^{\{0\}}$  commutes with base change, i.e. the following diagram is commutative:

```

```text
(Sch/S)-gr.  ——— G ↦ G^0 ———> (Sch/S)-gr.
      |                               |
      v                               v
(Sch/S')-gr. —————> (Sch/S')-gr.
```

```

<!-- label: III.VI\_B.3.3 -->

<!-- original page 342 -->

It suffices indeed to check that, for every  $s' \in S'$  with image  $s$  in  $S$ ,  $((G \times_{S'} S') \times_{\kappa(s')} \kappa(s'))^{\{0\}} = (G_s \times_{\kappa(s)} \kappa(s'))^{\{0\}}$  equals  $G_s^{\{0\}} \times_{\kappa(s)} \kappa(s')$ ; this follows from (VI\_A, 2.1.2). Note, for later use in 4.2, that we have not used the group structure of  $G_s$ , only the fact that  $G_s^{\{0\}}$  has a rational point, namely  $\epsilon(s)$ , hence is geometrically connected (see also EGA IV<sub>2</sub>, 4.5.14). ■

**Special case 3.4.** \*Let  $G$  be an  $S$ -group scheme; denote by  $G^{\{0\}}$  the subset of  $G$  equal to the union of the  $G_s^{\{0\}}$  as  $s$  runs through  $S$ . Then  $G^{\{0\}}$  is a part of  $G$  stable under the group law of  $G$  (cf. 3.0), and for any morphism  $S' \rightarrow S$  one has:

```

```text
G^0(S') = {u ∈ G(S') | u(S') ⊂ G^0}.
```

```

When  $G^{\{0\}}$  is an open part of  $G$ , it is clear that  $G^{\{0\}}$  is representable by the subscheme of  $G$  induced on the open  $G^{\{0\}}$ .\*

<!-- label: III.VI\_B.3.4 -->

**Proposition 3.5.** \*Let  $S$  be a quasi-compact and quasi-separated scheme, and  $G$  an  $S$ -group with fibers locally of finite type. Then there exists a quasi-compact open subset  $U$  of  $G$  containing  $G^{\{0\}}$ .\*

<!-- label: III.VI\_B.3.5 -->

The unit section  $\epsilon$  being an immersion,  $\epsilon(S)$  is a quasi-compact subspace of  $G$ , so there exists a quasi-compact open subset  $V$  of  $G$  containing  $\epsilon(S)$ . Since  $S$  is quasi-separated and  $V$  quasi-compact,  $V$  is quasi-compact over  $S$  (EGA IV<sub>1</sub>, 1.2.4), so  $V \times_S V$  is quasi-compact over  $S$ , hence quasi-compact. Then  $V \cdot V = \mu(V \times_S V)$  is quasi-compact. Set  $V_s = V \cap G_s$  and  $V_s^{\{0\}} = V \cap G_s^{\{0\}}$ . Then  $V_s^{\{0\}}$  is an open subset of  $G_s^{\{0\}}$ , dense in  $G_s^{\{0\}}$  since  $G_s^{\{0\}}$  is irreducible (VI\_A, 2.4), so  $V_s^{\{0\}} \cdot V_s^{\{0\}} = G_s^{\{0\}}$  (VI\_A, 0.5), which shows that  $V_s \cdot V_s \supset G_s^{\{0\}}$ , hence  $V \cdot V \supset G^{\{0\}}$ . Finally, since  $V \cdot V$  is quasi-compact, there exists a quasi-compact open subset  $U$  of  $G$  containing  $V \cdot V$  and a fortiori  $G^{\{0\}}$ . ■

**\*\*Corollary 3.6.\*\*** \*Let  $G$  be an  $S$ -group with fibers locally of finite type and connected. Then  $G$  is quasi-compact over  $S$ .\*

<!-- label: III.VI\_B.3.6 -->

<!-- original page 343 -->

Our assertion being local on  $S$  (EGA I, 6.6.1), one reduces to the case where  $S$  is affine. By 3.5, there then exists a quasi-compact open  $U$  of  $G$  containing  $G^\circ = G$ , hence  $G$  is quasi-compact, hence quasi-compact over the affine scheme  $S$  (EGA I, 6.6.4 (v)). ■

**\*\*Proposition 3.7.\*\*** [<sup>N.D.E-VI\_B-24</sup>] \*Let  $G$  be an  $S$ -group locally of finite presentation. Then:\*

\*(i)  $G^\circ$  is ind-constructible in  $G$ .\*

\*(ii) If moreover  $G$  is quasi-separated over  $S$ , and  $S$  quasi-compact and quasi-separated, then  $G^\circ$  is constructible.\*

\*(iii) Consequently, if  $G$  is quasi-separated over  $S$ ,  $G^\circ$  is locally constructible.\*

<!-- label: III.VI\_B.3.7 -->

**\*Proof.\*** Let us first show the first assertion. Since  $\pi : G \rightarrow S$  is locally of finite presentation, given  $s \in S$ , there exists an open subset  $U$  of  $G$  containing  $\pi^{-1}(s)$  and an open subset  $V$  of  $S$  containing  $s$  such that  $\pi(U) \subset V$  and such that the morphism  $\pi' : U \rightarrow V$  deduced from  $\pi$  is of finite presentation. Then  $T = \pi^{-1}(U)$  is an open subset of  $G$  and if we let  $W = \pi'^{-1}(T)$  and  $\pi'' = \pi'|_W$ , then  $\pi'' : W \rightarrow T$  is of finite presentation, and admits as section the morphism  $\pi''^{-1} : T \rightarrow W$  deduced from  $\pi^{-1}$ .

For every  $t \in T$ , since  $G^\circ_t$  is irreducible (VI\_A, 2.4),  $W \cap G^\circ_t$  is dense in  $G^\circ_t$ , hence irreducible, hence connected: it is therefore the connected component of  $\pi'^{-1}(t)$  containing  $\pi''^{-1}(t)$ . It then follows from EGA IV<sub>3</sub>, 9.7.12 that the union  $W^\circ$  of the  $W \cap G^\circ_t$ , for  $t \in T$ , is locally constructible in  $W$ . On the other hand, it follows from (VI\_A, 0.5) that  $G^\circ \cap \pi'^{-1}(T) = W^\circ \cap \pi'^{-1}(T)$ , i.e.  $G^\circ \cap \pi'^{-1}(T)$  is the image of  $W^\circ \times_T W^\circ$  under the morphism  $\mu : W \times_T W \rightarrow \pi^{-1}(T)$  deduced from  $\mu$ . [<sup>N.D.E-VI\_B-25</sup>] Since  $W \times_T W$  (resp.  $\pi'^{-1}(T)$ ) is of finite presentation (resp. locally of finite presentation) over  $T$ ,  $\mu$  is locally of finite presentation and quasi-separated, by EGA IV<sub>1</sub>, 1.4.3 and 1.2.2; if moreover  $\pi'^{-1}(T)$  is quasi-separated over  $T$ , then  $\mu$  is quasi-compact (loc. cit. 1.2.4), hence of finite presentation. Since  $W^\circ \times_T W^\circ$  is locally constructible in  $W \times_T W$  (since  $W^\circ$  is in  $W$ ), it follows from Chevalley's constructibility theorem (loc. cit., 1.8.4 and 1.9.5 (viii)) that  $G^\circ \cap \pi'^{-1}(T)$  is ind-constructible in  $\pi'^{-1}(T)$ , and is locally constructible in  $\pi'^{-1}(T)$  if  $G$  (and hence  $\pi'^{-1}(T)$ ) is quasi-separated over  $T$ . This proves assertions (i) and (iii).

<!-- original page 344 -->

Suppose now  $G$  quasi-separated over  $S$ , and  $S$  quasi-compact and quasi-separated. Then, by 3.5, there exists a quasi-compact open  $U$  of  $G$  containing  $G^\circ$ . Since  $G$  is quasi-separated over  $S$ ,  $G$  is quasi-separated, so the open  $U$  is retrocompact (EGA IV<sub>1</sub>, 1.2.7), and it suffices to show that  $G^\circ$  is constructible in  $U$  (EGA 0\_III, 9.1.8). Moreover,  $U$  being quasi-compact, hence quasi-compact over  $S$  (EGA IV<sub>1</sub>, 1.2.4), and quasi-separated over  $S$ , the restriction of  $\pi$  to  $U$  is of finite presentation, so by EGA IV<sub>3</sub>, 9.7.12,  $G^\circ$  is locally constructible in  $U$ , hence constructible in  $U$ , since  $U$  is quasi-compact and quasi-separated (EGA IV<sub>1</sub>, 1.8.1). This proves (ii), and it follows that for every quasi-compact and quasi-separated open  $T$  of  $S$  (e.g., for every affine open of  $S$ ),  $G^\circ \cap \pi'^{-1}(T)$  is constructible. ■

**\*\*Corollary 3.8.\*\*** \*Let  $S_0$  be a quasi-compact and quasi-separated scheme,  $I$  a filtered increasing preordered set,  $(A_i)_{i \in I}$  a direct system of commutative quasi-coherent  $S_0[S_i]$ -algebras,  $A = \varinjlim A_i$  (direct limit),  $S_i = \operatorname{Spec} A_i$  for  $i \in I$ , and  $S = \operatorname{Spec} A$  (cf. EGA II, 1.3.1).\*

\*Let  $G$  be an  $S_0$ -group scheme locally of finite presentation. Then the canonical map  $\varinjlim G(S_i) \rightarrow G(S)$  is bijective.\*

<!-- label: III.VI\_B.3.8 -->

Since  $G$  is locally of finite presentation over  $S_0$ , the canonical map  $\varinjlim G(S_i) \rightarrow G(S)$  is bijective, by EGA IV<sub>2</sub>, 8.14.2 c). It follows immediately that the canonical map  $\varinjlim G(S_i) \rightarrow G(S)$  is injective. Let us show that it is surjective. Let  $g \in G(S)$ . There exists  $i \in I$  such that  $g$  factors through

$g_{\{i\}} \in G(S_{\{i\}})$  via  $S \rightarrow S_{\{i\}}$ ; by hypothesis,  $g_{\{-1\}}(G^{\{0\}}) = S$ . But, by 3.7,  $G^{\{0\}}$  is ind-constructible in  $G$ , so  $g_{\{-1\}}(G^{\{0\}})$  is ind-constructible in  $S_{\{i\}}$ . It then follows from EGA IV<sub>2</sub>, 8.3.4, that there exists an index  $j \geq i$  such that  $g_{\{-1\}}(G^{\{0\}}) = S_{\{j\}}$ , where  $g_{\{j\}}$  is the map deduced from  $g_{\{i\}}$  by the base change  $S_{\{j\}} \rightarrow S_{\{i\}}$ . This shows that  $g_{\{j\}} \in G^{\{0\}}(S_{\{j\}})$ , hence that  $g$  comes from an element of  $\varinjlim G^{\{0\}}(S_{\{i\}})$ . ■

**Proposition 3.9.** \*Let  $G$  be an  $S$ -group locally of finite presentation. Suppose that  $G^{\{0\}}$  is representable; then the canonical morphism  $\iota : G^{\{0\}} \rightarrow G$  is an open immersion; moreover,  $G^{\{0\}}$  is quasi-compact over  $S$ .\*

<!-- label: III.VI\_B.3.9 -->

Since  $G^{\{0\}}$  is a subfunctor of the functor  $G$ , the morphism  $\iota$  is a monomorphism, hence radicial. By the definition of the functor  $G^{\{0\}}$ , one verifies immediately from the definition (EGA IV<sub>4</sub>, 17.1.1) that  $\iota$  is a formally étale morphism (noting that  $G^{\{0\}}$  is the image of  $\iota$  in  $G$ ). Finally, it follows from the characterization (EGA IV<sub>3</sub>, 8.14.2 c)) of  $S$ -schemes locally of finite presentation via the functor they represent, and from 3.8, that, since  $G$  is locally of finite presentation over  $S$ , so is  $G^{\{0\}}$ . Hence  $\iota$  is locally of finite presentation (cf. EGA IV<sub>1</sub>, 1.4.3); it is therefore a radicial étale morphism; hence an open immersion (EGA IV<sub>4</sub>, 17.9.1).

Finally, the last assertion follows from 3.6. ■

**Theorem 3.10.** \*Let  $G$  be an  $S$ -group. The following conditions are equivalent:\*

(i)  $G$  is smooth over  $S$  at the points of the unit section.\*

(ii)  $G$  is flat and locally of finite presentation over  $S$  at the points of the unit section, and for every  $s \in S$ ,  $G_s$  is smooth over  $k(s)$ .\*

(iii) There exists an open group subscheme  $G'$  of  $G$ , smooth over  $S$ .\*

(iv)  $G^{\{0\}}$  is representable by an open subscheme of  $G$ , smooth over  $S$ .\*

<!-- label: III.VI\_B.3.10 -->

<!-- original page 351 -->

It is clear that (iv)  $\Rightarrow$  (iii)  $\Rightarrow$  (i) and, by 1.3.1 and 2.4, (i) implies (ii) and (iii). Moreover, (ii)  $\Rightarrow$  (i) by EGA IV<sub>4</sub>, 17.5.1.

Let us show finally that (iii) implies (iv). Lemma 3.10.1 below shows that  $G'$  contains  $G^{\{0\}}$ , and that  $G'^{\{0\}} = G^{\{0\}}$ . It therefore suffices to show that  $G^{\{0\}}$  is open in  $G$ , since we have already seen (3.4) that  $G^{\{0\}}$  will then be representable by the smooth group subscheme induced by  $G'$  on the open  $G'^{\{0\}} = G^{\{0\}}$ . We may therefore assume  $G' = G$ .

To show that  $G^{\{0\}}$  is open, it suffices to show that every  $s \in S$  has a neighborhood  $T$  in  $S$  such that  $G^{\{0\}} \cap \pi^{-1}(T)$  is open in  $\pi^{-1}(T)$ . Let  $s \in S$ . Since  $G = G'$ ,  $\pi$  is locally of finite presentation, so one can construct, as in the proof of 3.7, an open subset  $T$  of  $S$  containing  $s$ , and an open subset  $W$  of  $G$  containing  $\pi^{-1}(s)$ , such that the morphism  $\pi : W \rightarrow T$  deduced from  $\pi$  is of finite presentation and admits as section the morphism  $\pi^{-1} : T \rightarrow W$  deduced from  $\pi$ . For every  $t \in T$ ,  $W \cap G^{\{0\}}_t$  is then the connected component of  $\pi^{-1}(t)$  containing  $\pi^{-1}(t)$ . Since  $\pi$  is smooth, so is  $\pi^{-1}$ , which is therefore smooth and of finite presentation. Then, by EGA IV<sub>3</sub>, 15.6.5, the union  $W^{\{0\}}$  of the  $W \cap G^{\{0\}}_t$  for  $t \in T$  is open in  $W$ .

On the other hand, by (VI\_A, 0.5), one has  $W^{\{0\}} \cdot W^{\{0\}} = G^{\{0\}} \cap \pi^{-1}(T)$ , and one must show that this is open in  $\pi^{-1}(T)$ . We may therefore now assume  $T = S$ ; it remains to show that  $W^{\{0\}} \cdot W^{\{0\}}$  is open in  $G$ . Since  $\pi$  is universally open, so is  $\mu$  (VI\_A, 0.1). Hence, since  $W^{\{0\}}$  is open in  $G$ , so is  $W^{\{0\}} \cdot W^{\{0\}} = \mu(W^{\{0\}} \times_S W^{\{0\}})$ .

This result will be improved in 4.4. ■

**Lemma 3.10.1.** \*Let  $G$  be an  $S$ -group with fibers locally of finite type. Then every open group subscheme  $H$  of  $G$  contains  $G^{\{0\}}$ , and satisfies  $G^{\{0\}} = H^{\{0\}}$ .\*

<!-- label: III.VI\_B.3.10.1 -->

Let  $s \in S$ ; set  $G'_s = H_s \cap G^{\{0\}}_s$ ; then  $G'_s$  is an open subset of  $G^{\{0\}}_s$ , which is dense in

$G^{\{0\}}_s$  since  $G^{\{0\}}_s$  is irreducible (VI\_A, 2.4), hence  $G^{\{0\}}_s \cdot G^{\{0\}}_s = G^{\{0\}}_s$  (VI\_A, 0.5), which shows that  $G^{\{0\}}_s = G^{\{0\}}_s \cdot G^{\{0\}}_s \subset H_s \cdot H_s = H_s$ . One thus has  $G^{\{0\}}_s = H^{\{0\}}_s$  for every  $s$ , whence  $G^{\{0\}} \subset H$  and  $G^{\{0\}} = H^{\{0\}}$ . ■

**Proposition 3.11.** \*Let  $u : G \rightarrow H$  be a morphism between  $S$ -groups locally of finite presentation. If  $u$  is flat, the map  $u^{\{0\}} : G^{\{0\}} \rightarrow H^{\{0\}}$  deduced from  $u$  is surjective; the converse is true if  $G$  is flat over  $S$  and  $H$  has reduced fibers.\*<sup>[N.D.E-VI\_B-26]</sup>

<!-- label: III.VI\_B.3.11 -->

<sup>[N.D.E-VI\_B-27]</sup> Suppose  $u$  flat; then for every  $s \in S$ ,  $u_s$  is flat and locally of finite presentation, hence open (EGA IV<sub>2</sub>, 2.4.6), so the morphism  $u^{\{0\}}_s : G^{\{0\}}_s \rightarrow H^{\{0\}}_s$  is surjective by 1.3.2. Hence the map  $u^{\{0\}} : G^{\{0\}} \rightarrow H^{\{0\}}$  is surjective.

Conversely, suppose the map  $u^{\{0\}} : G^{\{0\}} \rightarrow H^{\{0\}}$  is surjective,  $G$  flat over  $S$  and  $H$  with reduced fibers. Then, for every  $s \in S$ , the morphism  $u^{\{0\}}_s : G^{\{0\}}_s \rightarrow H^{\{0\}}_s$  is surjective, hence flat at every point above the generic point  $\eta$  of  $H^{\{0\}}_s$  (since  $0_{H^{\{0\}}_s}$ ,  $\eta$  is a field), hence  $u_s$  is flat by 1.3. Hence  $u$  is flat, by the fiber-wise flatness criterion (EGA IV<sub>3</sub>, 11.3.11). ■

## 4. Dimension of fibers of groups locally of finite presentation

<!-- label: III.VI\_B.4 -->

**Proposition 4.1.** \*Let  $G$  be an  $S$ -scheme locally of finite type, equipped with an  $S$ -section  $\epsilon$ , and such that for every  $s \in S$ , one has  $\dim G_s = \dim_{\epsilon(s)} G_s$  (which is the case if  $G$  is an  $S$ -group (1.5)).\*

(i) The function  $s \mapsto \dim G_s$  is upper semicontinuous on  $S$ .\*

(ii) If, moreover,  $G$  is locally of finite presentation over  $S$ , this function is locally constructible.\*

<!-- label: III.VI\_B.4.1 -->

Let  $\pi : G \rightarrow S$  be the structural morphism. Chevalley's semicontinuity theorem (EGA IV<sub>3</sub>, 13.1.3) asserts that the function  $x \mapsto \dim_x \pi^{-1}(\pi(x))$  is upper semicontinuous on  $G$ . Now, for every  $s \in S$ , one has

```
```text
dim G_s = dim π-1(s) = dim{ε(s)} π-1(π(ε(s)));
```
```

and since the function  $s \mapsto \dim_{\epsilon(s)} G_s$  is continuous on  $S$ , the composite function  $s \mapsto \dim G_s$  is upper semicontinuous on  $S$ .

<!-- original page 348 -->

Suppose  $G$  locally of finite presentation over  $S$ . To show that the function  $s \mapsto \dim G_s$  is locally constructible, one sees, reasoning as above, that it suffices to show that the function  $x \mapsto \dim_x \pi^{-1}(\pi(x))$  is locally constructible on  $G$ , which follows from EGA IV<sub>3</sub>, 9.9.1. ■

**Proposition 4.2.** \*Let  $\pi : G \rightarrow S$  be an  $S$ -scheme locally of finite presentation, equipped with an  $S$ -section  $\epsilon$  and satisfying the following two conditions (which are satisfied if  $G$  is an  $S$ -group, by 1.5 and (VI\_A, 2.4.1)):

a) For every  $s \in S$  and every  $x \in G_s$ , one has  $\dim G_s = \dim_x G_s$  (or, what comes to the same (1.5), for every  $s \in S$ , all irreducible components of  $G_s$  have the same dimension).\*

b) For every  $s \in S$ , if one denotes by  $G^{\{0\}}_s$  the connected component of  $G_s$  containing  $\epsilon(s)$ ,  $G^{\{0\}}_s$  is geometrically irreducible.\*

\*Let  $s \in S$ . The following conditions are equivalent:\*

(i)  $G$  is universally open over  $S$  at the points of  $G^{\{0\}}_s$ .\*

(i bis)  $G$  is universally open over  $S$  at every point of a neighborhood of  $\epsilon(s)$  in  $G^{\{0\}}_s$ .\*<sup>[N.D.E-VI\_B-28]</sup>

\*(ii) The function  $t \mapsto \dim G_t$  is constant in a neighborhood of  $s$  in  $S$ .

\*(iii)  $G^0$  is "universally open over  $S$  at the points of  $G^0_{\{s\}}$ ", i.e., given  $S' \rightarrow S$ ,  $s' \in S'_{\{s\}}$ ,  $g \in G^0_{\{s'\}}$  and  $V$  an open neighborhood of  $g$  in  $G' = G_{(S')}$ , then  $\pi(V \cap G'^0)$  is an open neighborhood of  $s$  in  $S$ . [N.D.E-VI\_B-29]

<!-- label: III.VI\_B.4.2 -->

\*Proof.\* Clearly (i)  $\Rightarrow$  (i bis). By EGA IV<sub>3</sub>, 14.3.3.1 (ii), the set of points of  $G^0_{\{s\}}$  where  $\pi_G$  is universally open is closed in  $G^0_{\{s\}}$ . Hence, since  $G^0_{\{s\}}$  is irreducible, one has (i bis)  $\Rightarrow$  (i).

Let us show that (i) implies (ii). Let  $T$  be the set of  $t \in S$  such that  $\dim G_t = \dim G_s$ . By 4.1,  $T$  is locally constructible, hence, by EGA IV<sub>1</sub>, 1.10.1, to show that  $T$  is a neighborhood of  $s$ , it suffices to show that every generalization  $s'$  of  $s$  belongs to  $T$ .

<!-- original page 349 -->

Let  $x$  be the generic point of  $G^0_{\{s\}}$  and  $U$  an open subset of  $G$  containing  $x$ . Since  $\pi_G$  is universally open at  $x$ , by EGA IV<sub>3</sub>, 14.3.13, for every generalization  $s'$  of  $s$ , one has  $\dim(U \cap G_{\{s'\}}) \geq \dim_x(U \cap G_{\{s\}})$ . Taking hypothesis a) into account, this entails  $\dim G_{\{s'\}} \geq \dim G_{\{s\}}$ . Since the function  $s \mapsto \dim G_s$  is upper semicontinuous by 4.1, one also has  $\dim G_{\{s'\}} \leq \dim G_{\{s\}}$ , whence  $s' \in T$ . This proves that (i)  $\Rightarrow$  (ii).

It is clear that (iii)  $\Rightarrow$  (i); let us show that (ii)  $\Rightarrow$  (iii). Since the dimension of fibers is unchanged by extension of the base field, and the formation of  $G^0$  commutes with base change (cf. the proof of 3.3), one may assume  $S' = S$  and  $s' = s$ . Moreover, since every open  $V$  of  $G$  meeting  $G^0_{\{s\}}$  contains the generic point  $\eta$  of  $G^0_{\{s\}}$ , one may assume  $g = \eta$ .

One may further assume  $S$  affine. Let  $U$  be an affine open neighborhood of  $\pi^{-1}(s)$ ; it is then of finite presentation over  $S$ . Replacing  $S$  by  $\pi^{-1}(U)$  and then  $U$  by  $U \cap \pi^{-1}(S)$ , we reduce to the case where  $\pi : U \rightarrow S$  is of finite presentation and admits  $\pi : S \rightarrow U$  as section. Then, by EGA IV<sub>3</sub>, 9.7.12,  $G^0 \cap U$  is constructible in  $U$ . Then, replacing  $V$  by an affine open contained in  $V \cap U$ , we obtain that  $G^0 \cap V$  is constructible in  $V$ . Since  $\pi : V \rightarrow S$  is of finite presentation,  $\pi(G^0 \cap V)$  is locally constructible in  $S$ , by Chevalley's constructibility theorem (cf. EGA IV<sub>1</sub>, 1.8.4).

Hence, by loc. cit., 1.10.1, to show that  $\pi(G^0 \cap V)$  is an open neighborhood of  $s$ , it suffices to show that for every generalization  $t$  of  $s$ , there exists a generalization  $\xi$  of  $\eta$  belonging to  $G^0$  (and hence to  $G^0 \cap V$ ). Now the generic point  $\xi$  of  $G^0_{\{t\}}$  is a generalization of  $\eta$ . Indeed,  $\pi(s)$  belongs to the closure  $X$  of  $\{\xi\}$  in  $G$ , so by Chevalley's semicontinuity theorem (cf. EGA IV<sub>3</sub>, 13.1.3), one has  $\dim_{\pi(s)} X_{\{s\}} \geq \dim_{\xi} X_{\{t\}}$ ; on the other hand, hypothesis (ii) entails that  $\dim_{\xi} G^0_{\{t\}} = \dim_{\pi(s)} G_{\{s\}}$ . It follows that one of the irreducible components of  $X_{\{s\}}$  containing  $\pi(s)$  equals  $G^0_{\{s\}}$ , whence  $\eta \in \{\xi\}$ . This proves that (ii)  $\Rightarrow$  (iii), which proves the proposition. ■

[N.D.E-VI\_B-30] One can also prove the implication (ii)  $\Rightarrow$  (i) as follows. Since  $\pi$  is locally of finite presentation, there exists an open subset  $U$  of  $G$  containing  $\pi^{-1}(s)$  and an open subset  $V$  of  $S$  containing  $s$  such that  $\pi(U) \subset V$  and such that the morphism  $\pi' : U \rightarrow V$  deduced from  $\pi$  is of finite presentation. Set then  $T = \pi^{-1}(U)$  and  $W = \pi'^{-1}(T) = U \cap \pi^{-1}(T)$ . Then the morphism  $\pi'' : W \rightarrow T$  deduced from  $\pi'$  is of finite presentation and admits as section the morphism  $\pi'' : T \rightarrow W$  deduced from  $\pi$ . Moreover, for every  $t \in T$ ,  $G^0_{\{t\}}$  being irreducible,  $W \cap G^0_{\{t\}}$  is dense in  $G^0_{\{t\}}$ , hence irreducible, hence connected: so it is the connected component of  $\pi'^{-1}(t)$  containing  $\pi''(t)$ .

<!-- original page 354 -->

Since  $W \cap G^0_{\{t\}}$  is a dense open subset of  $G^0_{\{t\}}$ , one has, by 1.5 and EGA IV<sub>2</sub>, 5.2.1,  $\dim(W \cap G^0_{\{t\}}) = \dim G^0_{\{t\}} = \dim G_t$ , so the function  $t \mapsto \dim W \cap G^0_{\{t\}}$  is constant in a neighborhood of  $s$  in  $T$ . Let us show finally that, for every  $t \in T$ ,  $W \cap G^0_{\{t\}}$  is geometrically irreducible. Let  $K$  be an extension of  $k(t)$ ; then  $(W \cap G^0_{\{t\}}) \otimes_{k(t)} K = (W \otimes_{k(t)} K) \cap (G^0_{\{t\}} \otimes_{k(t)} K)$  is a non-empty open subset of  $G^0_{\{t\}} \otimes_{k(t)} K$ , hence is irreducible since  $G^0_{\{t\}} \otimes_{k(t)} K$  is.

We are then in the conditions of application of EGA IV<sub>3</sub>, 15.6.6 (ii), which asserts that  $\pi''$  (hence  $\pi$ ) is

universally open at the points of  $W \cap G^{\{0\}}_S$ . But, by EGA IV<sub>3</sub>, 14.3.3.1 (ii), the subset of  $G_S$  formed by the points where  $\pi$  is universally open is closed in  $G_S$ ; since it contains  $W \cap G^{\{0\}}_S$ , it therefore contains its closure  $G^{\{0\}}_S$ . ■

<!-- original page 350 -->

**Corollary 4.3.** Let  $G$  be a flat  $S$ -group locally of finite presentation. Then the function  $s \mapsto \dim G_s$  is locally constant on  $S$ .

<!-- label: III.VI\_B.4.3 -->

This follows immediately from 4.2, since every flat morphism locally of finite presentation is universally open (EGA IV<sub>2</sub>, 2.4.6). ■

**Corollary 4.4.** Let  $G$  be an  $S$ -group locally of finite presentation over  $S$  at the points of the unit section. Consider the conditions:

(i)  $G$  is smooth over  $S$  at the points of the unit section (cf. 3.10).

(ii) For every  $s \in S$ ,  $G_s$  is smooth over  $\kappa(s)$ , and the function  $s \mapsto \dim G_s$  is locally constant on  $S$ .

(iii) For every  $s \in S$ ,  $G_s$  is smooth over  $\kappa(s)$ , and there exists a neighborhood  $V$  of the unit section such that  $\pi|_V : V \rightarrow S$  is universally open.

(iv) For every  $s \in S$ ,  $G^{\{0\}}_s$  is smooth over  $\kappa(s)$ , and  $G^{\{0\}}$  is representable by an open group subscheme of  $G$ , universally open over  $S$ .

Then one has the following implications: (i)  $\Rightarrow$  (ii)  $\Leftrightarrow$  (iii)  $\Leftrightarrow$  (iv).

If one further assumes  $S$  reduced, then conditions (i) to (iv) are equivalent, and imply that  $G^{\{0\}}$  is smooth over  $S$ . [N.D.E-VI\_B-31]

<!-- label: III.VI\_B.4.4 -->

**Proof.** Let us show that (i) implies (ii). For every  $x \in G$ , one has  $\dim_x \pi^{-1}(\pi(x)) = \dim \pi^{-1}(\pi(x))$ , by 1.5. Consequently, by EGA IV<sub>4</sub>, 17.10.2, the function

text  

$$x \mapsto \dim_x \pi^{-1}(\pi(x)) = \dim \pi^{-1}(\pi(x))$$

is continuous in a neighborhood of the unit section; so the function  $s \mapsto \dim G_s$  is continuous on  $S$ , hence locally constant on  $S$ . Moreover, for every  $s \in S$ ,  $G_s$  is smooth over  $\kappa(s)$  by 1.3.1.

<!-- original page 355 -->

Let us show that (ii) implies (iv). It suffices to show that  $G^{\{0\}}$  is open in  $G$ , for then, by 3.4,  $G^{\{0\}}$  will be representable by the group subscheme induced on  $G^{\{0\}}$ , and the properties of  $G^{\{0\}}$  cited in the statement will follow from 2.4 and 4.2. Given  $s \in S$ , construct as in the proof of 3.10,  $W_s$ ,  $T_s$ ,  $\pi'_s$ ,  $\epsilon'_s$ , and  $W^{\{0\}}_s$ . Then, by EGA IV<sub>3</sub>, 15.6.7,  $W^{\{0\}}_s$  is open in  $W_s$ . On the other hand, under hypothesis 4.4 (ii), it follows from 4.2 that  $\pi$  is universally open at every point of  $W^{\{0\}}_s$ , hence (VI\_A, 0.1)  $\mu$  is universally open at every point of  $W^{\{0\}}_s \times_S W^{\{0\}}_s$ , which shows that  $W^{\{0\}} \cdot W^{\{0\}}$  is open, and one concludes as in the proof of Theorem 3.10.

It is clear that (iv)  $\Rightarrow$  (iii), and (iii)  $\Rightarrow$  (ii) follows from 4.2 applied to  $V$ .

Finally, suppose (ii)–(iv) hold and let us show that  $G^{\{0\}}$  is smooth over  $S$  if  $S$  is reduced. [N.D.E-VI\_B-32] For this, one may assume  $G = G^{\{0\}}$ . Then  $G$  is of finite presentation over  $S$  by virtue of 5.5 below. Thus,  $\pi|_G$  is of finite presentation, with geometrically integral fibers, of locally constant dimension on  $S$ . Then, by EGA IV<sub>3</sub>, 15.6.7, the morphism  $G \times_S S_{\text{red}} \rightarrow S_{\text{red}}$  deduced from  $\pi|_G$  is flat, hence  $\pi|_G$  is flat if  $S$  is reduced. In this case,  $G = G^{\{0\}}$  is smooth over  $S$ , by Theorem 3.10. ■

## 5. Separation of groups and homogeneous spaces

<!-- label: III.VI\_B.5 -->

**Proposition 5.1.** \*In order that an  $S$ -group  $G$  be separated, it is necessary and sufficient that the unit section of  $G$  be a closed immersion.\*

<!-- label: III.VI\_B.5.1 -->

The condition is necessary (EGA I, 5.4.6); it is sufficient by virtue of the following cartesian diagram (cf. (VI\_A, 0.3)):

$$\begin{array}{ccc} G \times_S G & \xrightarrow{\mu \circ (\text{id}_G \times c)} & G \\ \downarrow \Delta_{\{G/S\}} & & \uparrow \varepsilon \\ G & \xrightarrow{\pi} & S. \end{array}$$

**Proposition 5.2.** \*If  $S$  is discrete, every  $S$ -group is separated.\*

<!-- label: III.VI\_B.5.2 -->

Indeed,  $S$  is then equal to  $\coprod_{s \in S} \text{Spec } \mathcal{O}_{\{S,s\}}$ , and by EGA I, 5.5.5, it suffices to show that for every  $s \in S$ ,  $G \times_{\text{Spec } \mathcal{O}_{\{S,s\}}} \text{Spec } \mathcal{O}_{\{S,s\}}$  is separated, which follows from (VI\_A, 0.3), since  $\mathcal{O}_{\{S,s\}}$  is a local ring of dimension 0. [N.D.E-VI\_B-33]

<!-- original page 352 -->

**Theorem 5.3.** \*Let  $S$  be a scheme,  $G$  an  $S$ -group scheme locally of finite presentation over  $S$  and universally open over  $S$  in a neighborhood of the unit section,  $X$  an  $S$ -scheme on which  $G$  acts in such a way that the morphism:

$$\Phi : G \times_S X \rightarrow X \times_S X, \quad (g, x) \mapsto (gx, x)$$

is surjective. Suppose moreover that, for every  $s \in S$ :

(i) there exists an open subscheme  $U$  of  $X$ , separated over  $S$ , such that  $U_{\{s\}}$  is dense in  $X_{\{s\}}$ ,

(ii) the fiber  $X_{\{s\}}$  is locally of finite type over  $\kappa(s)$ . [N.D.E-VI\_B-34]

Then  $X$  is separated over  $S$ .

<!-- label: III.VI\_B.5.3 -->

**Corollary 5.4.** \*Let  $S$ ,  $G$ ,  $X$  be as in the preliminary hypotheses of 5.3. Suppose moreover that  $X$  has fibers locally of finite type and connected. Then:

(i)  $X$  is separated over  $S$ .

(ii) If there exists an open subset  $V$  of  $X$ , quasi-compact over  $S$  and meeting every non-empty fiber  $X_{\{s\}}$ , [N.D.E-VI\_B-35] then  $X$  is quasi-compact over  $S$ .

<!-- label: III.VI\_B.5.4 -->

**Proof.** (i) Indeed, let  $s \in S$  be such that  $X_{\{s\}} \neq \emptyset$ . Since the morphism  $\Phi_{\{s\}} : G_{\{s\}} \times_{\kappa(s)} X_{\{s\}} \rightarrow X_{\{s\}} \times_{\kappa(s)} X_{\{s\}}$  deduced from  $\Phi$  by base change is surjective, and  $X_{\{s\}}$  is connected,  $X_{\{s\}}$  is irreducible by (VI\_A, 2.5.4). Hence, if  $U$  is an affine open of  $X$  such that  $U_{\{s\}}$  is non-empty,  $U_{\{s\}}$  is dense in  $X_{\{s\}}$ , and the theorem applies.

To prove (ii), one may assume  $S$  affine. Then  $V$  is quasi-compact and, by 3.5, there exists a quasi-compact open  $U$  of  $G$  containing  $G^{\{0\}}$ . Let  $s \in S$  be such that  $X_{\{s\}} \neq \emptyset$ . Then  $X_{\{s\}}$  is irreducible (VI\_A, 2.6.6)

and so, since  $U_s$  contains  $G^{\{0\}}_s$ , the morphism  $U_s \times_{\kappa(s)} V_s \rightarrow X_s$ ,  $(g, x) \mapsto gx$ , is surjective (VI\_A, 2.6.4). Consequently, the morphism  $U \times_S V \rightarrow X$  is surjective, and so  $X$  is quasi-compact (since  $U$  and  $V$  are); as we assumed  $S$  affine, hence separated, it follows that  $X$  is quasi-compact over  $S$  (cf. EGA I, 6.6.4 (v)). ■

**Remark 5.4.1.** [N.D.E-VI\_B-36] We shall see in the course of the proof that the conclusion of Theorem 5.3 holds if one makes only the hypothesis: (i') there exists an open subscheme  $U$  of  $X$ , separated over  $S$ , such that  $U_s$  is dense in every irreducible component of  $X_s$ . (The latter is a consequence of (i) if  $X_s$  has locally a finite number of irreducible components, which is the case under hypothesis (ii).) On the other hand, we shall see later that 5.4 is also valid under the hypothesis that each fiber  $X_s$  is quasi-separated and connected.\*

<!-- label: III.VI\_B.5.4.1 -->

**Theorem 5.3A (Raynaud).** Let  $G$  be an  $S$ -group locally of finite presentation, universally open over  $S$ , and with connected fibers. Then  $G$  is separated over  $S$ . More generally, any  $S$ -scheme  $X$  locally of finite presentation over  $S$ , equipped with an action of  $G$  such that the morphism  $\phi : G \times_S X \rightarrow X \times_S X$ ,  $(g, x) \mapsto (gx, x)$  is surjective, is separated over  $S$ .\*

<!-- label: III.VI\_B.5.3.A -->

<!-- original page 357 -->

**Corollary 5.5.** Let  $S$  be a scheme,  $G$  an  $S$ -group scheme, locally of finite presentation, with connected fibers, and universally open over  $S$ . Then  $G$  is separated and of finite presentation over  $S$ . [N.D.E-VI\_B-37]

<!-- label: III.VI\_B.5.5 -->

Indeed, by 3.6 and 5.4,  $G$  is quasi-compact and separated over  $S$ , and since  $G$  is locally of finite presentation over  $S$ , it is therefore of finite presentation over  $S$ . ■

### 5.6. Proof of Theorem 5.3.

Before establishing 5.3, let us prove a few lemmas.

**Lemma 5.6.0.** [N.D.E-VI\_B-38] (i) Let  $A \subset B$  be integral rings, with  $B$  integral over  $A$ , and let  $q \in \operatorname{Spec}(B)$  be such that  $A$  is unibranch at the point  $p = q \cap A$ . Then the morphism  $\pi : \operatorname{Spec}(B) \rightarrow \operatorname{Spec}(A)$  is open at the point  $q$ .\*

(ii) Let  $X, Y$  be two irreducible preschemes,  $f : X \rightarrow Y$  a dominant morphism,  $x$  a point of  $X$  such that  $f$  is quasi-finite at  $x$  and  $y = f(x)$  is a unibranch point of  $Y$ . Then  $f$  is open at the point  $x$ . In particular, if  $Y = \operatorname{Spec}(O_{Y,y})$  is a local prescheme with closed point  $y$ , then  $f(U) = Y$  for every neighborhood  $U$  of  $x$ .\*

<!-- label: III.VI\_B.5.6.0 -->

**Proof.** (i) Let  $K$  (resp.  $L$ ) be the fraction field of  $A$  (resp.  $B$ ),  $A'$  the normalization of  $A$ , and  $B'$  the subring of  $L$  generated by  $A'$  and  $B$ . Then  $B'$  is integral over  $A'$ . Set  $Y = \operatorname{Spec}(A)$ ,  $X = \operatorname{Spec}(B)$ ,  $Y' = \operatorname{Spec}(A')$ ,  $X' = \operatorname{Spec}(B')$ , so that one has a commutative diagram

$$\begin{array}{ccc} X' & \xrightarrow{\pi'} & Y' \\ \downarrow & & \downarrow \varphi \\ X & \xrightarrow{\pi} & Y \end{array}$$

in which all morphisms are integral and surjective.

Since  $A$  is unibranch at  $p$ ,  $Y'$  has a unique point  $p'$  above  $p$ ; consequently, if  $U$  is an open neighborhood of  $p'$  in  $Y'$ , then  $\phi(Y' - U)$  is a closed subset not containing  $p$ , so that the complementary open is contained in  $\phi(U)$ . This shows that  $\phi : Y' \rightarrow Y$  is open at  $p'$ , and so it suffices to show that  $\pi$  is open. We are thus reduced to the case where  $A = A'$  is normal.

Let  $N$  be a quasi-Galois extension of  $K$  containing  $L$ , let  $\tilde{X} = \operatorname{Spec}(\tilde{B})$ , where  $\tilde{B}$  is the integral closure of  $B$  in  $N$ , and let  $\Gamma = \operatorname{Aut}(N/K)$ . Since  $\tilde{X} \rightarrow X$  is surjective, it suffices to show that  $\tilde{\pi} : \tilde{X} \rightarrow Y$  is open. Let  $U$  be an open of  $\tilde{X}$  and  $U' = \bigcup_{g \in \Gamma} gU$ . Since  $\Gamma$  acts transitively on the fibers of  $\tilde{X} \rightarrow Y$  (cf. [BAC], Chap. V, § 2.3, Prop. 6),  $\tilde{\pi}(U)$  equals  $\tilde{\pi}(U')$ , and the latter equals the complementary open of the closed  $\tilde{\pi}(\tilde{X} - U')$ . This proves (i).

<!-- original page 358 -->

(ii) One may assume  $Y$  and  $X$  reduced. By Zariski's "Main Theorem" (cf. EGA IV<sub>3</sub>, 8.12.9), there exist affine open neighborhoods  $U$  of  $x$ , and  $V = \operatorname{Spec}(A)$  of  $y$ , such that  $f(U) \subset V$ , and a factorization:

$$\begin{array}{ccc} & j & \\ U & \xrightarrow{\quad} & V' \\ \downarrow f & & \downarrow u \\ & & V, \end{array}$$

where  $j$  is an open immersion and  $u$  is finite. Replacing  $V'$  by the closure of  $j(U)$ , one may assume  $V'$  irreducible, hence  $V' = \operatorname{Spec}(B)$ , where  $B$  is an integral  $A$ -algebra, finite over  $A$ . Moreover, since  $f$  is dominant, so is  $u$ , so that the morphism  $A \rightarrow B$  is injective. Since, by hypothesis,  $A$  is unibranch at the point  $y$ , it follows from (i) that  $u$  is open at the point  $j(x)$ , and hence  $f = u \circ j$  is open at the point  $x$ . This proves the first assertion of (ii). The second follows, since if  $Y$  is a local prescheme with closed point  $y$ , every open containing  $y$  equals  $Y$ . (In the case where  $Y = \operatorname{Spec}(0_{\{Y,y\}})$ , one may also use, instead of EGA IV<sub>3</sub>, 8.12.9, the local form of Zariski's Main Theorem, which one finds, e.g., in [Pes66], or [Ray70b], Ch. IV, Th. 1.) ■

**\*Lemma 5.6.1.0.\*** [N.D.E-VI\_B-39] \*Let  $f : X \rightarrow S$  be a morphism locally of finite presentation,  $s \in S$ , and  $x \in X_s$ . Let  $n = \dim_x(X_s)$  and let  $q$  be the structural morphism  $A^n_S \rightarrow S$ .\*

\*Suppose given a morphism  $u : X \rightarrow A^n_S$  quasi-finite such that  $f = q \circ u$ , and suppose  $f$  universally open at the generic point  $z$  of an irreducible component  $z_x$  of  $X_s$ , containing  $x$  and of dimension  $n$ . Then  $u$  is universally open at the point  $x \in X_s$ .\*

<!-- label: III.VI\_B.5.6.1.0 -->

Let us note first that: (†) the hypotheses are preserved by any base change  $\pi : S' \rightarrow S$  covering  $s$  (i.e., such that  $\pi^{-1}(s) \neq \emptyset$ ). Indeed, let  $S' \rightarrow S$  be such a morphism, let

$$\begin{array}{ccc} & u' & \\ X' & \xrightarrow{\quad} & A^n_{S'} \\ \downarrow f' & & \downarrow q' \\ & & S' \end{array}$$

be the diagram obtained by base change, and let  $s'$  be a point of  $S'$  above  $s$  and  $x'$  a point of  $X'_s$  above  $x$ . Since  $X'_s = X_s \otimes_{\kappa(s)} \kappa(s')$ , by lifting of generalizations and invariance of dimension under field extension (EGA IV<sub>2</sub>, 2.3.4 (i) and 4.1.4),  $x'$  is contained in an irreducible component  $z'_x$  of  $X'_s$  whose generic point  $z'$  lies above  $z$ , and one has  $n \leq \dim z' \leq \dim_x X'_s \leq n$ , whence  $\dim z' = n = \dim_x X'_s$ . Since  $f$  is universally open at  $x$ ,  $f'$  is universally open at  $x'$ .

Set  $Y = A^n_S$ . By EGA IV<sub>3</sub>, 14.3.3.1 (i), to prove that  $u$  is universally open at  $x$ , it suffices to prove that, for every integer  $r \geq 0$  and every point  $x'$  of

<!-- original page 359 -->

$X' = X[T_1, \dots, T_r]$  above  $x$ , the morphism  $u' : X' \rightarrow Y' = A^n_{S'}[T_1, \dots, T_r]$  is open at the point  $x'$ . Now, with  $S' = S[T_1, \dots, T_r]$  and  $q'$  the projection  $Y' \cong A^n_{S'} \rightarrow S'$ , one is in the situation obtained by the base change  $S' \rightarrow S$ . So, by what precedes, one is reduced to showing that  $u$  is open at

the point  $x$ .

Set  $y = u(x)$ . Since  $u$  is locally of finite presentation (since  $f$  and  $q$  are, cf. EGA IV<sub>1</sub>, 1.4.3), then by EGA IV<sub>1</sub>, 1.10.3, it suffices to show that  $u(\operatorname{Spec} 0_{\{X,x\}}) = \operatorname{Spec}(0_{\{Y,y\}})$ . For this, one may assume  $S$  affine and integral. Let then  $\pi : S' \rightarrow S$  be its normalization; denote by  $u' : X' \rightarrow Y'$  the morphism deduced from  $u$  by base change. Since the morphism  $\pi_{Y'} : Y' \rightarrow Y$  is integral and surjective, one has

$$\operatorname{Spec}(0_{\{Y,y\}}) = \bigcup_{y'} \pi_{Y'}(\operatorname{Spec}(0_{\{Y',y'\}})),$$

the union being taken over all points of  $Y'$  above  $y$ ; it therefore suffices to show that, for each such  $y'$ , and every  $x' \in X'_{\{y'\}}$  above  $x$ , one has  $u'(\operatorname{Spec} 0_{\{X',x'\}}) = \operatorname{Spec}(0_{\{Y',y'\}})$ . As the hypotheses are preserved by the base change  $\pi : S' \rightarrow S$ , one is thus reduced to the case of  $S'$ , i.e., one may assume  $S$  integral and normal.

Now, the hypotheses on  $f$  imply, by EGA IV<sub>3</sub>, 14.3.13, that there exists an irreducible component  $Z$  of  $X$  containing  $z$  (and hence  $x$ ), dominating  $S$  and such that

$$\dim_z(Z) = n = \dim(Z_{\eta}),$$

where  $\eta$  is the generic point of  $S$ . Let  $\xi$  be the generic point of  $Z$ . Since  $u$ , and hence also  $u_{\eta} : Z_{\eta} \rightarrow A^n_{\eta}$ , is quasi-finite, the closure in  $A^n_{\eta}$  of the point  $u_{\eta}(\xi) = u(\xi)$  is of dimension  $n$ , hence  $u(\xi)$  is the generic point of  $A^n_{\eta}$ , which is also the generic point of  $Y = A^n_S$ . Consequently, denoting by  $g$  the restriction of  $u$  to  $Z$ , the morphism  $g : Z \rightarrow Y$  is quasi-finite and dominant. Since  $Y$  is normal, it follows from Lemma 5.6.0 that  $g$  is open, so that  $u$  is open at every point of  $Z$ , in particular at the point  $x$ . Consequently,  $u(\operatorname{Spec} 0_{\{X,x\}}) = \operatorname{Spec}(0_{\{Y,y\}})$ , and this completes the proof of Lemma 5.6.1.0. ■

The following lemma advantageously replaces EGA IV<sub>3</sub>, 14.5.10, [N.D.E-VI-B-40] in that it is independent of noetherian hypotheses.

**Lemma 5.6.1.** \*Let  $S$  be a scheme,  $f : X \rightarrow S$  an  $S$ -scheme locally of finite presentation,  $s$  a point of  $S$ ,  $x$  a closed point of  $X_s$ . Suppose that  $f$  is universally open at the generic point  $z$  of an irreducible component  $Z$  of  $X_s$ , containing  $x$  and such that  $\dim_x(X_s) = \dim z$ . Then there exists a commutative diagram:\*

$$\begin{array}{ccc} X & \xrightarrow{f} & S \\ \uparrow h & \searrow \varphi & \uparrow w \\ S'' & \xrightarrow{\pi} & S' \end{array}$$

\*where  $S'$  is an affine scheme,  $w$  an étale morphism,  $\pi$  a finite surjective morphism, of finite presentation, and  $\pi^{-1}(s')$  is formed of a single point  $s''$ , such that  $h(s'') = x$  and  $\pi(s'') = \pi(x)$ .\* [N.D.E-VI-B-41]

<!-- label: III.VI\_B.5.6.1 -->

<!-- original page 360 -->

**Proof.** First, one may assume  $S = \operatorname{Spec} A$  and  $X = \operatorname{Spec} B$ , where  $B$  is an  $A$ -algebra of finite presentation. Let  $p$  and  $q$  be the prime ideals of  $A$  and  $B$  corresponding to  $s$  and  $x$ , respectively, so that  $p = A \cap q$ . Set  $n = \dim_x X_s$ , and let  $t_1, \dots, t_n$  be elements of  $B$  whose images in  $0_{\{X_s, x\}} = B_q / p B_q$  form a system of parameters. Then  $0_{\{X_s, x\}} / (t_1, \dots, t_n)$  is of finite dimension over  $\kappa(x)$  and hence also over  $\kappa(s)$ , since  $x$  is a closed point of the  $\kappa(s)$ -algebraic scheme  $X_s$ . Consequently, the  $S$ -morphism

$$u : X \rightarrow A^n_S = \operatorname{Spec}(A[T_1, \dots, T_n]),$$

...

defined by  $T_i \mapsto t_i$ , is of finite presentation,  $x$  is isolated in its fiber  $u^{-1}(u(x))$ , and one has  $u(x) = \tau_0(s)$ , where  $\tau_0 : S \rightarrow A^{(n)}_S$  denotes the "zero section" of  $A^{(n)}_S \rightarrow S$ , corresponding to the morphism of  $A$ -algebras  $A[T_1, \dots, T_n] \rightarrow A$  that sends each  $T_i$  to 0. Since the set of points of  $X$  that are isolated in their fiber above  $A^{(n)}_S$  is open (EGA IV<sub>3</sub>, 13.1.4), one may assume, shrinking  $X$ , that  $u$  is quasi-finite and that  $u^{-1}(u(x)) = \{x\}$ . By Lemma 5.6.1.0,  $u$  is universally open at the point  $x$ .

Let  $B_0 = B/(t_1, \dots, t_n)$  and let  $X_0 = X \times_{A^{(n)}_S} \tau_0(S) = \operatorname{Spec} B_0$  and  $u_0 : X_0 \rightarrow S$  be the morphism deduced from  $u$  by the base change  $\tau_0 : S \rightarrow A^{(n)}_S$ . Then  $u_0$  is quasi-finite and of finite presentation, universally open at the point  $x$ , and  $x$  is the unique point of  $X_0$  above  $s$ .

Let  $A'$  be the henselization of the local ring  $A_p = 0_{(S,s)}$ , and let  $S' = \operatorname{Spec}(A')$ ,  $B'_0 = B_0 \otimes_A A'$ , and  $X'_0 = X_0 \times_S S' = \operatorname{Spec}(B'_0)$ . Then the closed point  $s'$  of  $S'$  is the unique point of  $S'$  above  $s$ , one has  $\kappa(s') = \kappa(s)$ , and  $X'_0$  has a unique point  $x'$  above  $s'$ ; one has  $\kappa(x') = \kappa(x)$  and  $x'$  is also the unique point of  $X'_0$  above  $s'$  and above  $x$ . Since  $A'$  is henselian, by EGA IV<sub>4</sub>, 18.5.11,  $X'_0$  is the disjoint sum of two open and closed parts:

...text  
 (\*)  $X'_0 = V \sqcup W$ , where  $V = \operatorname{Spec}(0_{(X'_0, x')})$ ;  
 ...

and the local ring  $0_{(X'_0, x')}$  is finite and of finite presentation over  $A'$ . The restriction  $\pi$  of  $u'_0$  to  $V$  is therefore finite and of finite presentation. Moreover, since  $u'_0 : X'_0 \rightarrow S'$  is open at  $x'$ , one has  $u'_0(V) = \operatorname{Spec}(0_{(S', s)}) = S'$ , so that  $\pi$  is surjective.

This proves the desired result when  $S = S'$ . In the general case,  $A$  is a filtered direct limit of subalgebras  $A_i$  étale over  $A$ , and such that  $S_i = \operatorname{Spec}(A_i)$  has a unique point  $s_i$  above  $s$  (and  $\kappa(s_i) = \kappa(s)$ ). Then  $B'_0 = \varinjlim B_i$ , where  $B_i = B_0 \otimes_A A_i$ . Set  $X_i = \operatorname{Spec}(B_i) = \bar{X}_0 \times_S S_i$  and  $C = 0_{(\bar{X}_0, x')}$ . By (\*) above, one has  $C \cong B'_0 / f B'_0$ , for some idempotent  $f \in B'_0$ , and there exist an index  $i$  and  $f_i \in B_i$  such that  $f$  is the image of  $f_i$  in  $B'_0$ . Set  $C_i = B_i / f_i B_i$  and  $V_i = \operatorname{Spec}(C_i)$ .

<!-- original page 361 -->

Then  $C = C_i \otimes_{A_i} A$ , whence  $V = V_i \times_{S_i} S$ , and  $C_i$  is an  $A_i$ -algebra of finite presentation (since the same is true of  $B_i$ ). Consequently, the morphisms:

...text  

$$\begin{array}{ccc} X'_0 & \xrightarrow{u'_0} & S' \\ \uparrow h' & & \uparrow \pi \\ V & \xrightarrow{\quad} & \end{array}$$
  
 ...

come, by the base change  $S' \rightarrow S_i$ , from morphisms of finite presentation:

...text  

$$\begin{array}{ccc} X_i & \xrightarrow{u_i} & S_i \\ \uparrow h_i & & \uparrow \pi_i \\ V_i & \xrightarrow{\quad} & \end{array}$$
  
 ...

For every  $j \geq i$ , let  $V_j = V_i \times_{S_i} S_j$  and let  $\pi_j : V_j \rightarrow S_j$  be the morphism (of finite presentation) deduced from  $\pi_i$  by base change. Since  $\pi : V \rightarrow S$  is finite and surjective, by EGA IV<sub>2</sub>, 8.10.5, there exists an index  $j$  such that  $\pi_j : V_j \rightarrow S_j$  is finite and surjective. Then  $w : S_j \rightarrow S$  is étale affine,  $S_j$  has a unique point  $s_j$  above  $s$ , and  $V_j$  has a unique point  $x_j$  above  $s_j$  (since  $x$  is the unique point of  $V = V_j \times_{S_j} S$  above  $s$ ):

...text

$$\begin{array}{ccccc}
X_j & \longrightarrow & X_0 & \longrightarrow & X \\
\uparrow u_j & & \uparrow u_0 & & \uparrow u \\
h_j & & f & & f \\
V_j & \longrightarrow & S_j & \longrightarrow & S \xrightarrow{\tau_0} A^n_S. \\
\pi_j & & w & & 
\end{array}$$

Hence  $x_{\{j\}}$  is the unique point of  $V_{\{j\}}$  above  $s$ , its image under the morphism  $V_{\{j\}} \rightarrow X_{\{j\}} \rightarrow X$  is  $x$ , and one has  $\kappa(x_{\{j\}}) = \kappa(x)$ . ■

<!-- original page 354 -->

*\*(iii) Suppose  $G = H^0$ , where  $H$  is a  $k$ -group scheme locally of finite type, acting on a non-empty  $k$ -scheme  $X$  in such a way that the morphism  $H \times X \rightarrow X \times X$ ,  $(h, x) \mapsto (hx, x)$  is surjective. Let  $U$  be an open of  $X$ . Then:\**

*\*(a)  $G \cdot U$  is an open of  $X$ , equal to the union of the irreducible components of  $X$  whose generic point belongs to  $U$ .\**

*\*(b) Suppose  $U$  dense in every irreducible component of  $X$ . Then, for every finite subset  $A$  of  $X$ , there exists a closed point  $g \in G$  such that  $g \cdot A' \subset U_{\kappa(g)}$ , where  $A'$  is the inverse image of  $A$  in  $X_{\kappa(g)}$ . In particular, the morphism  $G \times U \rightarrow X$  is surjective.\**

<!-- label: III.VI\_B.5.6.2.0 -->

*\*Proof.\* (i) Let  $\bar{k}$  be a separable closure of  $k$  and let  $L$  be an extension of  $k$  containing a copy of  $\bar{k}$  and of  $K$ . Denote by  $\pi_L$  (resp.  $\phi$ ) the projection  $G_L \rightarrow G$  (resp.  $G_L \rightarrow G_K$ ). Since, for every  $g \in G$ ,  $\phi$  sends the maximal points of  $\pi_L^{-1}(g)$  surjectively onto those of  $\pi^{-1}(g)$ , one sees that  $U = \{g \in G \mid W_L \text{ contains every maximal point of } \pi_L^{-1}(g)\}$ . So, replacing  $K$  by  $L$ , we reduce to the case where  $K$  contains  $\bar{k}$ .*

Since the projection  $p : G_K \rightarrow G_{\bar{k}}$  is surjective and open,  $V = p(W)$  is a dense open of  $G_{\bar{k}}$ , and since  $p^{-1}(g) = \text{operatorname{Spec}}(\kappa(g) \otimes_{\bar{k}} K)$  is irreducible for every  $g \in G_{\bar{k}}$  (cf. EGA IV<sub>2</sub>, 4.3.3), then for every  $g \in V$ , the generic point of  $p^{-1}(g)$  belongs to  $W$ . On the other hand, let  $\Gamma = \text{operatorname{Gal}}(\bar{k}/k)$ ; since the projection  $q : G_{\bar{k}} \rightarrow G$  is surjective and  $\Gamma$  acts transitively on the fibers of  $q$ , then  $U = q(V')$ , where  $V'$  is the intersection of the  $\Gamma$ -conjugates of  $V$ .

<!-- original page 362 -->

Now, let  $Z$  be the closed  $G_{\bar{k}} - V$ , with its reduced closed subscheme structure. Since  $G_{\bar{k}}$ , and

hence  $Z$ , is of finite presentation over  $\bar{k}$ ,  $Z$  comes by base change from a reduced closed subscheme  $Z_1$  of  $G \times_k k_1$ , for some finite Galois extension  $k_1$  of  $k$ , so the  $\Gamma$ -conjugates of  $Z$  are finite in number, so that their union is again a rare closed  $F$  of  $G_{\bar{k}}$ , and  $V' = G_{\bar{k}} - F$  is a dense open of  $G_{\bar{k}}$ . Hence, since the projection  $q : G_{\bar{k}} \rightarrow G$  is surjective and open,  $U = q(V')$  is a dense open of  $G$ . Moreover, for every closed point  $g$  of  $G$ , the fiber  $\pi^{-1}(g)$  is formed of finitely many closed points of  $G_K$ , so if  $g \in U$  then  $\pi^{-1}(g) \subset W$ . This proves (i), and (ii) follows from it.

On the other hand, (iii)(a) has been proved in (VI\_A, 2.6.4). Finally, if  $U$  is dense in every irreducible component of  $X$ , then  $X = G \cdot U$ , hence for every  $x \in X$ ,  $\mu_{x^{-1}}(U_{\kappa(x)})$  is a non-empty open of  $G_{\kappa(x)}$ , and then (iii)(b) follows from (ii). ■

**Corollary 5.6.2.** \*Let  $S, G, X$  be as in the preliminary hypotheses of 5.3, and let  $U$  be an open of  $X$ ,  $s \in S$ , and  $A$  a finite part of  $X_s$ . Suppose  $U_s$  dense in  $X_s$  and  $X_s$  locally of finite type over  $\kappa(s)$ . \*<sup>[N.D.E-VI\_B-43]</sup>

\*Then there exists a morphism  $f : S' \rightarrow S$ , composed of a finite surjective morphism  $S' \rightarrow S$  and an étale morphism  $S' \rightarrow S$ , and a morphism  $h : S' \rightarrow G$ , such that the inverse image  $A'$  of  $A$  in  $X \times_S S'$  (i.e. in  $X_s \times_{\operatorname{Spec} \kappa(s)} S'_s$ ) is contained in  $\ell^{-1}_h(U_{S'})$ , where  $\ell_h$  denotes the translation of  $X_{S'} = X \times_S S'$  defined by the element  $h \in G(S')$ . \*

<!-- label: III.VI\_B.5.6.2 -->

**Proof.** \* Since  $X_s$  is locally of finite type over  $\kappa(s)$ , the connected components of  $X_s$  are open, and irreducible (cf. (VI\_A, 2.5.4)), so  $U_s$  is dense in every irreducible component of  $X_s$ .

Hence, by Lemma 5.6.2.0, there exists a closed point  $g \in G^0_s$  such that  $g \cdot a' \in U_s \times_{\kappa(s)} \kappa(g)$  for every  $a' \in X_{\kappa(g)}$  above a point of  $A$ .

<!-- original page 355 -->

By Lemma 5.6.1, there exists a morphism  $f : S' \rightarrow S$ , composed of a finite surjective morphism  $S' \rightarrow S$  and an étale morphism  $S' \rightarrow S$ , and a morphism  $h : S' \rightarrow G$ , such that  $f^{-1}(s)$  is formed of a single point  $s_0$ , and such that  $h(s_0) = g$  and  $\kappa(s_0) = \kappa(g)$ . Then, denoting by  $A'$  the inverse image of  $A$  in  $X_s \times_{\operatorname{Spec} \kappa(s)} S'_s$ ,  $S'_s = X_s \times_{\kappa(s)} \kappa(s_0) = X_s \times_{\kappa(s)} \kappa(g)$ , the translation  $\ell_h$  of  $X_{S'}$  sends  $A'$  into  $U_s \times_{\kappa(s)} \kappa(s_0)$ . ■

**Lemma 5.6.3.** \*Let  $X$  be an  $S$ -scheme. The following conditions are equivalent: \*

(i)  $X$  is separated over  $S$ . \*

(ii) For every  $S$ -scheme  $T$ , every section  $\sigma : T \rightarrow X_T$  is a closed immersion. \*

(iii) For every reduced  $S$ -scheme  $T$ , two  $S$ -morphisms  $f_1$  and  $f_2 : T \rightarrow X$  that coincide on a dense open  $U$  of  $T$  are equal. \*

(iv) For every  $s \in S$  and every pair of points  $x_1, x_2$  of  $X_s$ , there exists a morphism  $\phi : S' \rightarrow S$  and an open subscheme  $V$  of  $X_{S'}$ , separated over  $S'$ , such that: \*

a)  $S' \rightarrow S$  is open,  $S' \rightarrow S$  closed surjective, and  $\phi^{-1}(s) \neq \emptyset$ . \*

b) The inverse image of  $\{x_1, x_2\}$  in  $X_{S'}$  is contained in  $V$ . \*

(iv') For every  $s \in S$ , every pair of points  $x_1, x_2 \in X_s$  is contained in an open  $V$  of  $X$ , separated over  $S$ . \*<sup>[N.D.E-VI\_B-44]</sup>

<!-- label: III.VI\_B.5.6.3 -->

**Proof.** \* The implication (ii)  $\Rightarrow$  (i) is clear (take  $T = X$  and  $\sigma$  the diagonal section), as is (i)  $\Rightarrow$  (iv')  $\Rightarrow$  (iv). On the other hand, one has (i)  $\Rightarrow$  (ii) by EGA I, 5.4.6.

(iii)  $\Rightarrow$  (ii). Let  $\sigma : T \rightarrow X_T$  be a section of  $\rho : X_T \rightarrow T$ . By EGA I, 5.3.13,  $\sigma$  is an immersion, i.e. an isomorphism of  $T$  onto a locally closed subscheme  $E$  of  $X_T$ . To show that  $E$  is closed, one may assume  $T$  and  $E$  reduced. Let  $\tilde{E}$  be the reduced closed subscheme of  $X_T$  having the closure of  $E$  as underlying space, so that  $E$  is a dense open subscheme of  $\tilde{E}$ . Then the immersion  $i : \bar{E} \hookrightarrow X_T$  and  $\sigma \circ \rho^{-1} \circ i$  coincide on  $E$ , hence on  $\tilde{E}$  by hypothesis (iii). Hence every point of  $\tilde{E}$  belongs to

$\sigma(T) = E$ , whence  $E = \bar{E}$ .

<!-- original page 364 -->

(i)  $\Rightarrow$  (iii). Suppose  $X$  separated over  $S$  and let  $T$  be a reduced  $S$ -scheme,  $f_1, f_2$  two  $S$ -morphisms  $T \rightarrow X$  that coincide on a dense open  $U$  of  $T$ , and  $g$  the morphism  $T \rightarrow X \times_S X$  with components  $f_1$  and  $f_2$ . Since  $D = \Delta_{X/S}(X)$  is closed, its inverse image under  $g$  is a closed subset of  $T$  containing  $U$ , hence equal to  $T$ , and since  $T$  is reduced,  $g$  factors through  $D$  (cf. EGA I, 5.2.2); consequently  $f_1 = p_1 \circ g = p_2 \circ g = f_2$ .

(iv)  $\Rightarrow$  (iii). Let  $T$  be a reduced  $S$ -scheme and  $f_1, f_2$  two  $S$ -morphisms  $T \rightarrow X$  that coincide on a dense open  $U$ . Since  $T$  is reduced, to see that  $f_1 = f_2$ , it suffices to see that  $f_1 = f_2$  set-theoretically. Indeed, suppose this established, and let  $t \in T$ ,  $V$  an affine open of  $X$  containing  $f_1(t) = f_2(t)$ , and  $W$  the open neighborhood of  $t$  equal to the inverse image of  $V$  under the continuous map underlying  $f_1$  and  $f_2$ ; then the morphisms  $f_i|_W : W \rightarrow V$  coincide on the dense open  $U \cap W$  of  $W$ . Since  $V$  is separated and  $W$  reduced, this entails that  $f_1|_W = f_2|_W$ , whence  $f_1 = f_2$ .

Let then  $t \in T$  and  $s$  its image in  $S$ ; let us show that the points  $x_1 = f_1(t)$  and  $x_2 = f_2(t)$  of  $X_s$  are equal. Let  $\phi : S' \rightarrow S$  and  $V$  an open of  $X \times_S S'$  as in (iv); set  $T' = T \times_S S'$  and  $T'' = T \times_S S'$  and denote by  $g : T' \rightarrow T$  and  $f_i'' : T' \rightarrow X_{S'}$  ( $i = 1, 2$ ) the morphisms obtained by base change.

Since  $U$  is dense in  $T$  and  $T' \rightarrow T$  is open, the inverse image  $U'$  of  $U$  in  $T'$  is dense in  $T'$ . Let  $U''$  be the inverse image of  $U'$  in  $T''$  and let  $F$  be the reduced subscheme of  $T''$  having  $U''$  as underlying space. Since  $T'' \rightarrow T'$  is surjective and closed, the image of  $F$  contains  $U'$  and is closed, hence equals  $T'$ . Consequently,  $F \cap g^{-1}(t)$  contains a point  $u$ .

For  $i = 1, 2$ , denote by  $h_i$  the restriction to  $F$  of  $f_i''$ . Then  $h_i(u)$  is a point of  $X_{S'}$  above  $f_i(t) = x_i$ , hence belongs to  $V$ , since  $V$  contains the inverse image of  $\{x_1, x_2\}$  in  $X_{S'}$ .

Then  $W = h^{-1}_1(V) \cap h^{-1}_2(V)$  is an open of  $F$ , containing  $u$ , and the  $S'$ -morphisms  $h_i|_W : W \rightarrow V$  coincide on the dense open  $U'' \cap W$  of  $W$ . Since  $V$  is separated over  $S'$ , one has  $h_1|_W = h_2|_W$ , whence  $h_1(u) = h_2(u)$ , and hence  $f_1(t) = f_2(t)$ . This proves (iv)  $\Rightarrow$  (iii). ■

Theorem 5.3 then follows from 5.6.2 and the implication (iv)  $\Rightarrow$  (i) of 5.6.3. ■

**Counterexample 5.6.4.** Not every  $S$ -group  $G$  is separated. Let  $S$  be a scheme having a non-isolated closed point  $s$ ; let  $G$  be the scheme obtained by glueing two copies of  $S$  along the open  $S - \{s\}$ ; one sees easily that  $G$  is not separated over  $S$ , and that it is equipped with a natural structure of  $S$ -group, all of whose fibers are trivial, except the fiber  $G_s$  which is isomorphic to the two-element group  $\mathbb{Z}/2\mathbb{Z}$ . [N.D.E-VI\_B-45]

<!-- label: III.VI\_B.5.6.4 -->

**Theorem 5.7.** [N.D.E-VI\_B-46] Let  $S$  be a scheme,  $G$  an  $S$ -group locally of finite presentation over  $S$  such that the function  $s \mapsto \dim G_s$  is locally constant on  $S$ ,  $X$  an  $S$ -scheme on which  $G$  acts, and  $U$  an open of  $X$ , separated over  $S$ . Then  $G \cdot U$  is an open of  $X$ , separated over  $S$ .

<!-- label: III.VI\_B.5.7 -->

<!-- original page 365 -->

**Proof.** Denote by  $\mu : G \times_S X \rightarrow X$  the action of  $G$  on  $X$ ; it is the composition of the automorphism  $(g, x) \mapsto (g, gx)$  of  $G \times_S X$  and the projection onto  $X$ . Since  $G \times_S U$  is an open of  $G \times_S X$ , by 4.2 (iii),  $V = G \cdot U$  is open in  $X$ .

Then, proceeding as in the proof of 5.6.2, one deduces from the implication (iv)  $\Rightarrow$  (i) of 5.6.3 that  $V$  is separated over  $S$ . ■

**Corollary 5.7.1.** Let  $S$  and  $G$  be as in 5.7, and let  $\sigma, \tau$  be two  $S$ -sections of  $G$  (i.e.  $\sigma, \tau \in G(S)$ ). Then the coincidence subscheme  $S(\sigma, \tau) \subset S$  of  $\sigma$  and  $\tau$  (i.e. the inverse image of the diagonal of  $G \times_S G$  under the morphism  $(\sigma, \tau)$ ) is closed.

<!-- label: III.VI\_B.5.7.1 -->

Indeed, for every  $s \in S$ , let  $U$  be an affine open of  $G$  containing  $\epsilon(s)$ ; then  $V = \epsilon^{-1}(U)$  is

an open neighborhood of  $s$  in  $S$ , and since  $G^0 U$  is separated,  $S(\sigma, \tau) \cap V$  is closed in  $V$ . ■

**Remark 5.7.2.** \*Gabber points out to us that one can show that if  $S$  is henselian local, with closed point  $s$ , then the intersection of the opens  $G^0 U$ , where  $U$  runs through the affine open neighborhoods of  $\epsilon(s)$ , is an open group subscheme of  $G$ , separated over  $S$ .\*

<!-- label: III.VI\_B.5.7.2 -->

### 5.8. Complements.

[^N.D.E-VI\_B-47] Let us begin by recalling Proposition (VI\_A, 2.6.6):

**Proposition 5.8.1.** \*Let  $k$  be a field,  $G$  a  $k$ -group locally of finite type acting on a  $k$ -scheme  $X$  in such a way that the morphism  $G \times X \rightarrow X \times X$ ,  $(g, x) \mapsto (gx, x)$  is surjective. Suppose  $X$  quasi-separated. Then the connected components of  $X$  are irreducible.\*

<!-- label: III.VI\_B.5.8.1 -->

**Corollary 5.8.2.** \*Let  $S$ ,  $G$ ,  $X$  be as in the preliminary hypotheses of 5.3. Suppose moreover that every fiber  $X_s$  is quasi-separated and connected. Then  $X$  is separated and quasi-compact over  $S$ .\*

<!-- label: III.VI\_B.5.8.2 -->

Indeed, by the preceding proposition, each fiber  $X_s$  is irreducible, and the rest of the proof is identical to that of 5.4. ■

**Example 5.8.3.** \*Fix an algebraically closed field  $k$ . Recall first that every "locally Boolean" topological space  $X$  (i.e. having a basis of compact open subsets), equipped with the sheaf of locally constant functions with values in  $k$ , is a  $k$ -scheme (cf. [DG70], I § 1, 2.12). One then says that  $X$  is a locally Boolean  $k$ -scheme.

\*Note moreover that every topological space  $E$  admitting a basis of separated opens (and likewise every scheme  $X$ ) admits a dense separated open. Indeed, since every increasing union of separated opens is a separated open (for a scheme  $X$  this follows from 5.6.3), there exists such an open  $U$  which is maximal. But then  $U$  is dense, for if there existed a non-empty open  $V$  such that  $U \cap V = \emptyset$ , then  $V$  would contain a non-empty separated open  $W$ , and  $U \cup W$  would still be separated, contradicting the maximality of  $U$ .\*

\*Now, let  $C$  be the Cantor space, viewed as the underlying space of the group  $(\mathbb{Z}/2\mathbb{Z})^{\mathbb{N}}$  equipped with the product topology. For every point  $p$  of  $C$ , let  $C(p)$  be another copy of  $C$ , and let  $X$  be the space obtained by glueing each  $C(p)$  to  $C$  along  $C - \{p\}$ ; then  $X$  is a non-separated locally Boolean  $k$ -scheme, and  $C$  is a dense open of  $X$ .\*

\*Let  $G$  be the group of automorphisms of the  $k$ -scheme  $X$  (i.e., of homeomorphisms of  $X$ ). Then  $G$  acts transitively on  $X$ . Indeed,  $X$  is the union of  $C$  and, for each point  $p$  in  $C$ , of a second point  $p'$ , which can be characterized as the unique point  $x$  of  $X - \{p\}$  such that  $(C - \{p\}) \cup \{x\}$  is separated. It follows that every automorphism  $\phi$  of  $C$  extends to an automorphism  $\phi_X$  of  $X$  such that  $\phi_X(p') = \phi(p)$  for every  $p$ . On the other hand, the map  $\theta_p : X \rightarrow X$  that exchanges  $p$  and  $p'$  and fixes the other points is an automorphism of  $X$ . Finally, the group of automorphisms of  $C$  acts transitively on  $C$ : for example, using the group structure of  $C$ , it suffices to consider translations.\*

\*Hence the discrete  $k$ -group  $G$  (hence locally of finite type) acts on the  $k$ -scheme  $X$  in such a way that the morphism  $G \times X \rightarrow X \times X$ ,  $(g, x) \mapsto (gx, x)$  is surjective, but  $X$  is not separated (although  $C$  is a dense separated open).\*

<!-- label: III.VI\_B.5.8.3 -->

**Example 5.8.4.** \*We retain the notations of the preceding example. Using the description of  $C$  as the set of sequences  $(u_n)_{n \in \mathbb{N}}$  of elements of  $\mathbb{Z}/2\mathbb{Z}$ , one sees that  $C$  minus a point  $p$  is homeomorphic to a countable disjoint union of copies of  $C$ . Indeed, using e.g. the group structure of  $C$ , one reduces by translation to the case where  $p$  is the element  $0$ , i.e. the zero sequence; then  $C - \{0\}$  is the disjoint union of the subspaces  $C_i = \{(u_n)_{n \in \mathbb{N}} \mid u_i = 1 \text{ and } u_j = 0 \text{ for } j < i\}$ , for  $i \in \mathbb{N}$ , each homeomorphic to  $C$ . For every non-empty finite subset  $F$  of  $C$ , one deduces, by induction on  $|F|$ , that  $C - F$  is homeomorphic to a countable disjoint union of copies of  $C$ , hence to  $C$  minus a point.\*

\*For each  $F$  of cardinality 2, let  $C(F)$  be another copy of  $C$ , denote by  $q_F$  the point  $0$  of  $C(F)$ , and choose a homeomorphism  $\phi_F : C(F) - \{q_F\} \xrightarrow{\sim} C - F$ ; let then  $X'$  be the space obtained by glueing

each  $C(F)$  to  $C$  by means of  $\phi_F$ . Then  $X'$  is a non-separated locally Boolean  $k$ -scheme. Moreover, it follows from the construction that every locally constant function  $f : X' \rightarrow k$  is constant. Indeed, if  $x, y \in C$  and  $F = \{x, y\}$ , every neighborhood of  $q_F$  meets every neighborhood of  $x$  or  $y$ , so if  $f : X \rightarrow k$  is locally constant, one has  $f(x) = f(q_F) = f(y)$ , and if  $F' = \{z, t\}$  with  $z, t \in C$ , one likewise has  $f(q_{F'}) = f(z) = f(q_{\{z, x\}}) = f(x)$ . Consequently,  $X'$  is connected.\*

\*Moreover, every point  $x \in X'$  has a pointed neighborhood homeomorphic to  $(C, 0)$ . More precisely, fix for each  $F$  a homeomorphism of pointed topological spaces  $h_F : (C, 0) \xrightarrow{\sim} (C(F), q_F)$ , and denote by  $T$  the group of translations of  $C$ . Then, if  $x = q_F$  one has the homeomorphism  $q_F$ , and if  $x \in C$ , the translation  $t_x \in T$  is a homeomorphism  $(C, 0) \xrightarrow{\sim} (C, x)$  (and it is the unique element of  $T$  having this property).\*

<!-- original page 367 -->

\*Denote by  $L$  the free group generated by the  $h_F$  and let  $G = T * L$  be the "free product" (= coproduct) of  $T$  and  $L$ . For every  $h \in \{h_F\}_{|F|=2} \cup T$ , let  $\sigma(h)$  be the generator of  $G$  corresponding to  $h$  and let  $S(h)$  (resp.  $B(h)$ ) be the source (resp. target) of  $h$ . It is convenient to also set  $\sigma(h^{-1}_F) = \sigma(h_F)^{-1}$  and  $S(h^{-1}_F) = B(h_F)$  (resp.  $B(h^{-1}_F) = S(h_F)$ ), and to denote by  $E$  the set formed by  $T$ , and the  $h_F$  and  $h^{-1}_F$ .\*

\*On the product space  $P = G \times X'$  (where  $G$  is endowed with the discrete topology), consider the equivalence relation generated by the relations:\*

```
``text
(gσ(h), x) ~ (g, h(x)) when x ∈ S(h)
``
```

\*for every  $h \in E$ , and let  $Z$  be the quotient space. Then  $Z$  is obtained from the disjoint union  $\coprod_{g \in G} \{g\} \times X'$  by glueing of opens, and hence, for every open  $U$  of  $P$ , its saturate  $\tilde{U}$  is open (cf. [BTop], I § 5.1, Example 2). Explicitly, since every open of  $P$  is the union of its intersections with the "slices"  $\{g\} \times X'$ , it suffices to consider an open of the form  $\{1\} \times W$ , where  $W$  is an open of  $X'$ . In this case, the saturate is the union of  $\{1\} \times W$ , and of\*

```
``text
{σ(h1) × h1-1(W ∩ B(h1)), {σ(h1) σ(h2)} × h2-1(h1-1(W ∩ B(h1)) ∩ B(h2)),
``
```

\*etc., for all finite sequences  $h_1, \dots, h_n$  of elements of  $E$ , hence is open. Therefore the projection  $\pi : P \rightarrow Z$  is open.\*

\*Note moreover that the word  $\sigma(h_1) \cdots \sigma(h_n)$  is a reduced word of  $G$ , except if one of the  $h_i$  is the neutral element of  $T$  or if two consecutive  $h_i$  belong to  $T$ , or if  $(h_i, h_{i+1})$  equals  $(h_F, h^{-1}_F)$  or  $(h^{-1}_F, h_F)$ . So, if  $x \in X'$  and if an element  $\beta = (\sigma(h_1) \cdots \sigma(h_n), h^{-1}_n \cdots h^{-1}_1(x))$  belongs to  $\{1\} \times X'$ , then one may assume that each  $h_i$  is a translation  $t_i$ , and in this case the equality  $\sigma(t_1) \cdots \sigma(t_n) = 1$  entails that  $t_1 \cdots t_n = 1$ , and hence  $\beta = (1, x)$ . Since the equivalence relation is compatible with the action of  $G$  (acting on  $P = G \times X'$  by left translations on the first factor), one deduces that for every  $g \in G$ , the restriction of  $\pi$  to  $\{g\} \times X'$  is injective.\*

\*Let then  $z \in Z$  be arbitrary and let  $(g, x) \in P$  be a representative of  $z$ . By what precedes,  $U = \pi(\{g\} \times X')$  is an open neighborhood of  $z$ , and the continuous map  $\{g\} \times X' \rightarrow U$  induced by  $\pi$  is open and bijective, hence a homeomorphism. This shows that  $Z$  is locally isomorphic to  $X'$  (hence also to  $C$ ), and is therefore still a locally Boolean  $k$ -scheme.\*

\*Finally,  $G$  acts transitively on  $Z$ . Indeed, since every  $z \in Z$  is  $G$ -conjugate to an element of the form  $\pi((1, x))$ , it suffices to see that every element  $(1, x) \in P$  is equivalent to an element  $(\sigma(h), 0)$ ; now if  $x \in C$  one may take for  $h$  the translation  $t_x$ , and if  $x = q_F$  one may take  $h = h_F$ . Hence  $Z$  is a locally Boolean  $k$ -scheme equipped with a transitive action of the discrete group  $G$ , but  $Z$  is not separated.\*

## 6. Subfunctors and group subschemes[^VI\_B-6-1]

<!-- label: III.VI\_B.6 -->

**\*\*Definition 6.1.\*\*** (i) Let  $G$  be an  $S$ -functor (i.e., a functor from  $(\text{Sch}/S)^{\text{op}}$  into  $(\text{Ens})^{\text{op}}$ ),  $G$  an  $S$ -functor in groups,  $u$  and  $v$  two  $S$ -morphisms from  $G$  to  $G$ . The transporter of  $u$  into  $v$ , denoted  $\text{Transp}(u, v)$ , is the sub- $S$ -functor of  $G$  defined as follows:

```

```text
Transp(u, v)(S') = {g ∈ G(S') | (int g) ∘ u_{S'} = v_{S'}}
                  = {g ∈ G(S') | g_{S'} u_{S'}(x) g_{S'}^{-1} = v_{S'}(x), ∀ x ∈ X(S'), S' → S}.
```

```

In particular,  $\text{Transp}(u, u)$  is a sub- $S$ -functor in groups of  $G$ ; it is called the centralizer of  $u$  and is denoted  $\text{Centr}(u)$ .

(ii) Let  $G$  be an  $S$ -functor in groups,  $X$  and  $Y$  two sub- $S$ -functors of  $G$ . The transporter of  $X$  into  $Y$  (resp. the strict transporter of  $X$  into  $Y$ ), denoted  $\text{Transp}_G(X, Y)$  (resp.  $\text{Transpstr}_G(X, Y)$ ), is the sub- $S$ -functor of  $G$  defined as follows:

```

```text
Transp_G(X, Y)(S') = {g ∈ G(S') | (int g)(X_{S'}) ⊂ Y_{S'}}
                  = {g ∈ G(S') | g_{S'} X(S') g_{S'}^{-1} ⊂ Y(S'), ∀ S' → S}

Transpstr_G(X, Y)(S') = {g ∈ G(S') | (int g)(X_{S'}) = Y_{S'}}
                  = {g ∈ G(S') | g_{S'} X(S') g_{S'}^{-1} = Y(S'), ∀ S' → S}.
```

```

Note that one has

```

```text
Transpstr_G(X, Y) = Transp_G(X, Y) ∩ c(Transp_G(Y, X)),
```

```

where  $c$  denotes the inversion morphism of  $G$ . [N.D.E-VI\_B-49]

(iii) Let  $G$  be an  $S$ -functor in groups,  $H$  a sub- $S$ -functor of  $G$ ,  $i$  the canonical  $S$ -morphism  $H \rightarrow G$ ; the centralizer and normalizer of  $H$  in  $G$  are the following sub- $S$ -functors in groups of  $G$ :

```

```text
Centr_G H = Centr(i) = Transp(i, i),    Norm_G H = Transpstr_G(H, H).
```

```

Finally, the center of  $G$  is the  $S$ -functor in groups  $\text{Centr}(\text{id}_G) = \text{Centr}_G G$ ; it will be denoted  $\text{Centr } G$ .

<!-- label: III.VI\_B.6.1 -->

**\*\*Remark 6.1.1.\*\*** [N.D.E-VI\_B-50] It follows from the definitions that the functors  $\text{Transp}(u, v)$  and  $\text{Transp}_G(X, Y)$  (and hence also  $\text{Transpstr}_G(X, Y)$ ) commute with base change: for every  $S' \rightarrow S$ , if  $G', X', Y', u', v'$  are deduced from  $G, X, Y, u, v$  by base change, then

```

```text
Transp(u, v)_{S'} = Transp(u', v')    and    Transp(X, Y)_{S'} = Transp(X', Y').
```

```

<!-- label: III.VI\_B.6.1.1 -->

<!-- original page 369 -->

**\*\*Proposition 6.2.\*\*** [N.D.E-VI\_B-51] Let  $G$  be an  $S$ -group. For a subfunctor  $T$  of the functor  $G$ , consider the following property:

```

```text
(+f) for every  $s \in S$ ,  $T_s$  is representable by a closed subscheme of  $G_s$ .
```

```

Let  $u, w : X \rightarrow G$  and  $v : Y \rightarrow G$  be morphisms of  $S$ -schemes. Then:

(i)  $\text{Transp}(u, w)$  and  $\text{Centr}(u) = \text{Transp}(u, u)$  satisfy condition (+f).

\*(ii)  $\text{Transp}_{\{G\}}(u(X), v(Y))$  and  $\text{Norm}_{\{G\}} v(Y)$  satisfy condition  $(+f)$  if, for every  $s \in S$ ,  $v_{\{s\}}$  is a closed immersion.\*

\*(iii)  $\text{Transpstr}_{\{G\}}(X, Y)$  satisfies condition  $(+f)$  if, for every  $s \in S$ ,  $u_{\{s\}}$  and  $v_{\{s\}}$  are closed immersions.\*

<!-- label: III.VI\_B.6.2 -->

This follows from Remark 6.1.1 and from Corollary 6.2.5 below.[^N.D.E-VI\_B-52]

**Definition 6.2.1.** \*Let  $f : X \rightarrow S$  be a morphism of schemes. One says that  $f$  is essentially free, or that  $X$  is essentially free over  $S$ , if one can find a covering of  $S$  by affine open sets  $S_i$ , for every  $i$  an  $S_i$ -scheme  $S'_i$  affine and faithfully flat over  $S_i$ , and a covering  $(X'_{ij})_{j \in J_i}$  of  $X'_i = X \times_S S'_i$  by affine open sets  $X'_{ij}$ , such that for every  $(i, j)$ , the ring of  $X'_{ij}$  is a projective[^N.D.E-VI\_B-53] module over the ring of  $S'_i$ .\*

<!-- label: III.VI\_B.6.2.1 -->

**Proposition 6.2.2.** \*a) If  $X$  is essentially free over  $S$ , it is flat over  $S$ ; the converse is true if  $S$  is Artinian.\*

\*b) If  $S$  is the spectrum of a field, every  $S$ -scheme is essentially free over  $S$ .\*

\*c) If  $X$  is essentially free over  $S$ , then  $X' = X \times_S S'$  is essentially free over  $S'$ , for every  $S' \rightarrow S$ . The converse is true if  $S' \rightarrow S$  is faithfully flat and quasi-compact.\*

<!-- label: III.VI\_B.6.2.2 -->

<!-- original page 370 -->

The proof is immediate; for the converse in a) one uses the fact that a flat module over an Artinian local ring is free.[^N.D.E-VI\_B-54]

The introduction of Definition 6.2.1 is justified by the following theorem.

**Theorem 6.2.3.** \*Let  $S$  be a scheme,  $Z$  an essentially free  $S$ -scheme,  $Y$  a closed subscheme of  $Z$ . Consider the functor  $F = \prod_{Z/S} Y/Z : (\text{Sch})^{\circ}_{/S} \rightarrow (\text{Ens})$  defined by the following condition:  $F(S') = \emptyset$  when  $Y_{\{S'\}} \neq Z_{\{S'\}}$ , and  $F(S')$  is reduced to a single element otherwise.[^N.D.E-VI\_B-55]

\*(i) This functor is representable by a closed subscheme  $T$  of  $S$ .\*

\*(ii) If moreover  $Y \rightarrow Z$  is of finite presentation, then so is  $T \rightarrow S$ .\*

<!-- label: III.VI\_B.6.2.3 -->

Let us first note that the functor under consideration is a sheaf for the (fpqc) topology: since  $F(S') = \emptyset$  or  $\{\text{pt}\}$  for every  $S'$ , this reduces to verifying that if  $(S_i)$  is an open covering of  $S$  (resp.  $S' \rightarrow S$  a faithfully flat and quasi-compact morphism), and if each  $Y_{\{S_i\}} \rightarrow Z_{\{S_i\}}$  (resp.  $Y_{\{S'\}} \rightarrow Z_{\{S'\}}$ ) is an isomorphism, then so is  $Y \rightarrow Z$ ; this is clear (resp. follows from SGA 1, VIII 5.4 or EGA IV<sub>2</sub>, 2.7.1).

Moreover, by SGA 1, VIII 1.9, faithfully flat and quasi-compact morphisms are of effective descent for the fibered category of closed-immersion arrows. This allows us, with the notations of 6.2.1, to limit ourselves to the case where  $S = S'_i$ .

Let then  $(Z_j)$  be a covering of  $Z$  by affine open sets such that  $\mathcal{O}_Z(Z_j)$  is a projective module over  $A = \mathcal{O}_S(S)$ , and let  $Y_j = Y \cap Z_j$  and  $F_j : (\text{Sch})^{\circ}_{/S} \rightarrow (\text{Ens})$  be the functor defined in terms of  $(Z_j, Y_j)$  as  $F$  is in terms of  $(Z, Y)$ . It is a subfunctor of the final functor, and one obviously has  $F = \bigcap_j F_j$ , which reduces us to proving that each  $F_j$  is representable by a closed subscheme  $T_j$  of  $S$  (for then  $F$  will be representable by the closed subscheme  $T$  intersection of the  $T_j$ ). We may therefore also suppose  $Z$  affine,  $Z = \text{Spec}(B)$ , where  $B$  is a projective  $A$ -module. Let  $L$  be a free  $A$ -module with basis  $(e_{\lambda})_{\lambda \in \Lambda}$ , of which  $B$  is a direct factor as an  $A$ -module, and let  $\phi_{\lambda} : L \rightarrow A$  be the "coordinate" forms relative to this basis. Let  $E$  be a generating set of the ideal  $J$  of  $B$  defining the subscheme  $Y$  of  $Z$ , and let  $I$  be the ideal in  $A$  generated by the coordinates  $\phi_{\lambda}(x)$ , for  $x \in E$ . For every  $A$ -algebra  $C$ , one sees then that the morphism

$\phi : C \rightarrow (B/J) \otimes_A C$  is an isomorphism if and only if the image of  $x \otimes 1$  in  $L \otimes_A C$  is zero for every  $x \in E$ , which amounts to saying that the kernel of  $\phi$  contains the ideal  $I$ . This shows that  $T = V(I) = \operatorname{Spec}(A/I)$  satisfies the desired condition, which proves (i).

Moreover, if  $Y \rightarrow Z$  is of finite presentation, one may take  $E$  finite, and then  $I$  is a finitely generated ideal of  $A$ , i.e. the closed immersion  $T \rightarrow S$  is of finite presentation.

<!-- original page 371 -->

**Examples 6.2.4.** Let us give important examples of functors which reduce to functors  $\prod_{Z/S} Y/Z$  of the type considered in 6.2.3 and for which it is useful to have representability criteria in what follows. We denote by  $S$  a scheme, and by  $X, Y, Z$ , etc., schemes over  $S$ .

a) Suppose given an  $S$ -morphism

```

$$(x) \quad q : X \rightarrow \operatorname{Hom}_S(Y, Z),$$

```

( $x$  acts on  $Y$ , with values in  $Z$ ), i.e. a morphism

```

$$(xx) \quad r : X \times_S Y \rightarrow Z.$$

```

Consider a subscheme  $Z'$  of  $Z$ , whence a monomorphism

```

$$\operatorname{Hom}_S(Y, Z') \rightarrow \operatorname{Hom}_S(Y, Z)$$

```

which makes the first functor a subfunctor of the second; let  $X'$  be the inverse image of this subfunctor under the morphism  $q$ . This is the subfunctor of  $X$  such that  $X'(T)$  is the set of  $x \in X(T)$  such that  $q(x) : Y_{\{T\}} \rightarrow Z_{\{T\}}$  factors through  $Z'_{\{T\}}$ . This functor  $X'$  can be described as follows: set  $P = X \times_S Y$ , let  $P'$  be the inverse image of  $Z'$  under  $r : P \rightarrow Z$ ; then one has an obvious isomorphism

```

$$(xxx) \quad X' = \coprod_{P/X} P'/P.$$

```

One thus obtains: if  $Y$  is essentially free over  $S$  and  $Z'$  closed in  $Z$ , the subfunctor  $X'$  of  $X$  is representable by a closed subscheme of  $X$ .<sup>[^N.D.E-VI\_B-56]</sup> If moreover  $Z' \rightarrow Z$  is of finite presentation, then so is  $X' \rightarrow X$ .

b) Suppose given two ways of letting  $X$  act on  $Y$  with values in  $Z$ , i.e. two morphisms

```

$$q_1, q_2 : X \rightarrow \operatorname{Hom}_S(Y, Z),$$

```

and set  $X' = \operatorname{Ker}(q_1, q_2)$ : this is the subfunctor of  $X$  such that  $X'(T)$  is the set of  $x \in X(T)$  such that the two morphisms  $q_1(x), q_2(x) : Y_{\{T\}} \rightarrow Z_{\{T\}}$  are equal. Now the data of  $q_1, q_2$  is equivalent to the data of a morphism

```

$$q : X \rightarrow \operatorname{Hom}_S(Y, Z \times_S Z),$$

```

or equivalently of a morphism  $r : X \times_S Y \rightarrow Z \times_S Z$ ; set then  $U = Z \times_S Z$ , let  $U'$  be the diagonal subscheme of  $Z \times_S Z$ . Then  $X'$  is nothing but the inverse image of the subfunctor  $\operatorname{Hom}_S(Y, U')$  of  $\operatorname{Hom}_S(Y, U)$  under  $q$ , hence can be put in the form  $(xxx)$ , with  $P = X \times_S Y$ , and  $P' =$  inverse image of the diagonal under  $r$ , i.e. kernel of  $r_1, r_2 : X \times_S Y \rightarrow Z$ . One is therefore in the conditions of (a).

One sees consequently that: if  $Y$  is essentially free over  $S$  and  $Z$  separated over  $S$ , then the subfunctor  $X'$  of

$X$  is representable by a closed subscheme of  $X$ .<sup>[N.D.E-VI\_B-56]</sup> If moreover  $Z \rightarrow S$  is locally of finite type, then  $X' \rightarrow X$  is of finite presentation.\*

<!-- original page 372 -->

\*c) Suppose given a morphism\*

```text  
 $q : X \rightarrow \mathrm{Hom}_S(Y, Y),$

i.e. " X acts on Y ". Let X' be the "kernel" of this morphism, i.e. the subfunctor X' of X such that $X'(T)$ is the set of $x \in X(T)$ such that $q(x) : Y_{\{T\}} \rightarrow Y_{\{T\}}$ is the identity. This functor falls under b), as one sees by introducing a second homomorphism*

```text  
 $q' : X \rightarrow \mathrm{Hom}_S(Y, Y)$

"by letting  $X$  act trivially on  $Y$ ". Hence: if  $Y$  is essentially free and separated over  $S$ , the subfunctor  $X'$  of  $X$  kernel of  $q$  is representable by a closed subscheme of  $X$ .<sup>[N.D.E-VI\_B-56]</sup> If moreover  $Y \rightarrow S$  is locally of finite type, then  $X' \rightarrow X$  is of finite presentation.\*

\*d) Under the conditions of c), consider the subfunctor  $Y'$  of  $Y$  "of the invariants under  $X$ ", so that  $Y'(T)$  is the set of  $y \in Y(T)$  such that the corresponding morphism  $q(y) : X_{\{T\}} \rightarrow Y_{\{T\}}$  is "the constant  $T$ -morphism with value  $y$ ". Introducing  $q'$  as in c), and the homomorphisms corresponding to  $q$  and  $q'$ .\*

```text  
 $q, q' : Y \Rightarrow \mathrm{Hom}_S(X, Y),$

one sees that Y' is precisely $\mathrm{Ker}(q, q')$, and hence falls again under b) (with the roles of X, Y reversed and $Z = Y$).*

Consequently, if X is essentially free over S and Y separated over S , then the subfunctor Y' of Y of the invariants under X is representable by a closed subscheme of Y .^[N.D.E-VI_B-56] If moreover $Y \rightarrow S$ is locally of finite type, then $Y' \rightarrow Y$ is of finite presentation.*

e) Constructions of the type made explicit in the preceding examples are particularly frequent in group theory. Thus, when G is an S -group scheme acting on the S -scheme X .

G
 $q : G \rightarrow \mathrm{Aut}_S(X),$
 G

the kernel of q ("the subgroup of G acting trivially") is a closed subscheme of G provided X is essentially free and separated over S (example c)), and the subobject X^G of invariants is a closed subscheme of X , provided G is essentially free over S and X separated over S (example d)).*

Let Y, Z be subschemes of X ; consider the subfunctor $\mathrm{Transp}_G(Y, Z)$ of G ("transporter of Y into Z "), whose points with values in a T over S are those $g \in G(T)$ such that the corresponding automorphism of X_T satisfies $g(Y_{\{T\}}) \subset Z_{\{T\}}$, i.e. induces a morphism $Y_{\{T\}} \rightarrow X_{\{T\}}$ factoring through $Y_{\{T\}} \rightarrow Z_{\{T\}}$. Hence: if Y is essentially free over S , and Z closed in X , then $\mathrm{Transp}_G(Y, Z)$ is a closed subscheme of G (example a)).*

One may also consider the strict transporter of Y into Z ,^[N.D.E-VI_B-57] whose points with values in a T over S are those $g \in G(T)$ such that $g(Y_{\{T\}}) = Z_{\{T\}}$, which is nothing but $\mathrm{Transp}_G(Y, Z) \cap \sigma(\mathrm{Transp}_G(Z, Y))$, where σ is the inversion morphism of G . Consequently,*

<!-- original page 373 -->

if Y and Z are essentially free over S and closed in X , the strict transporter of Y into Z is a closed subscheme of G .*

An important case is the one where $X = G$, with G acting on itself by inner automorphisms. If H is a subscheme of

G , the strict transporter of H into H is also called the $*$ normalizer of H in G , and denoted $\text{Norm}_G(H)$. Hence: if H is a closed group subscheme of G , essentially free over S , then $\text{Norm}_G(H)$ is representable by a closed group subscheme of G .

Let finally Z be a subscheme of G ; then its centralizer $\text{Centr}_G(Z)$ in G is the subfunctor in groups of G defined by the procedure of d), when one considers that " Z acts on G " by the operations induced by those of G ; hence if Z is essentially free over S and G is separated over S , $\text{Centr}_G(Z)$ is a closed group subscheme of G . In particular, if G is essentially free and separated over S , then the center C of G , which is none other than $\text{Centr}_G(G)$, is a closed group subscheme of G .

<!-- label: III.VI_B.6.2.4 -->

When S is the spectrum of a field, 6.2.2 b) shows that in examples a) to e) above, the "essentially free" conditions are automatically satisfied; only the separation conditions remain. Recalling that a group scheme over a field is necessarily separated (VI_A, 0.3), one finds for example:

Corollary 6.2.5. Let G be a group scheme over a field k and let Y, Y' be two subschemes of G . Then:

(i) The centralizer of Y in G is a closed group subscheme of G ; in particular, this is the case for the center $\text{Centr}_G(G)$ of G .

(i') More generally, if $u, v : X \rightarrow G$ are morphisms of schemes, $\text{Transp}_G(u, v)$ is representable by a closed subscheme of G .

(ii) If Y is closed, the transporter $\text{Transp}_G(Y', Y)$ is a closed subscheme of G . If Y' is also closed, the same conclusion holds for $\text{Transpstr}_G(Y', Y)$.

(iii) For every group subscheme H of G , $\text{Norm}_G(H)$ is a closed group subscheme of G .

<!-- label: III.VI_B.6.2.5 -->

Corollary 6.2.6. Let k be a field, G a connected algebraic k -group. Then $\text{Centr}_G(G)$ is representable by a closed group subscheme Z of G , and G/Z is an affine algebraic k -group.

<!-- label: III.VI_B.6.2.6 -->

Proof. The first assertion is of course contained in 6.2.5 (i), but we shall see that it also follows from the proof of the second assertion. Indeed, G acts by the adjoint representation on the finite-dimensional k -vector spaces $V_n = \mathcal{O}_{G,e}/\mathfrak{m}^{n+1}_e$ (where $\mathfrak{m}_e$ is the maximal ideal of $\mathcal{O}_{G,e}$); let K_n denote the kernel of the morphism $\rho_n : G \rightarrow \text{GL}(V_n)$. By VI_A, 5.4.1, ρ_n induces a closed immersion $G/K_n \hookrightarrow \text{GL}(V_n)$, hence each G/K_n is affine. Since G is noetherian, the intersection K of the K_n equals one of the K_n , so G/K is affine.

<!-- original page 374 -->

On the other hand, letting Z denote the center of G , it is clear that $Z \subset K$. Let us show that $Z = K$. Let $\hat{\mathcal{O}}_{G,e}$ denote the completion of $\mathcal{O}_{G,e}$ for the $\mathfrak{m}_e$ -adic topology and $\hat{S}$ its spectrum (resp. $S = \text{Spec } \mathcal{O}_{G,e}$). Since $\hat{S} \rightarrow S$ is faithfully flat and since the two morphisms

$$\begin{array}{l} \text{``text} \\ K \times_k S \rightarrow S, \quad (g, x) \mapsto gxg^{-1} \quad \text{resp.} \quad (g, x) \mapsto x \end{array}$$

coincide after base change $\hat{S} \rightarrow S$, they coincide, i.e. K acts trivially on $\mathcal{O}_{G,e}$. Now, by 6.2.4 e), the subobject G^K of invariants of G under K (which is none other than $\text{Centr}_G(K)$) is a closed subscheme of G , hence defined by a quasi-coherent ideal $\mathcal{I}$ of $\mathcal{O}_G$. As G^K majorizes $S = \text{Spec } \mathcal{O}_{G,e}$ and $\mathcal{I}$ is of finite type (since G is noetherian), there exists an open neighborhood U of e such that $\mathcal{I}|_U = 0$. Then the subgroup $G^K = \text{Centr}_G(K)$ contains U , hence also $U \cdot U$, which equals G since G is irreducible (VI_A 0.5). Hence $\text{Centr}_G(K) = G$, whence $K \subset Z$ and therefore $Z = K$. ■

Remark 6.3. Let k be an algebraically closed field, G a k -group and H a group subscheme of G ; assume G and H are of finite type over k and reduced. Then $\text{Norm}_G(H)$ (resp. $\text{Centr}_G(H)$) is representable by a group subscheme of G , whose associated reduced subscheme is none other than the normalizer (resp. the centralizer) of H in

G in the sense of the* Bible.

<!-- label: III.VI_B.6.3 -->

Proposition 6.4. *Let G be an S -group and $u : X \rightarrow G$ a monomorphism of S -schemes. Set $T = \text{Transp}_{\{G\}}(X, X)$. The following conditions are equivalent:*

(i) T is a sub- S -functor in groups of G .*

(ii) $T = \text{Transpstr}_{\{G\}}(X, X) = \text{Norm}_{\{G\}} X$.*

These conditions are satisfied in each of the two following cases:*

a) X is of finite presentation over S .*

b) T is representable by a scheme of finite presentation over S .*

<!-- label: III.VI_B.6.4 -->

The equivalence of conditions (i) and (ii) follows from the fact that, whatever the morphism $S' \rightarrow S$, whatever $t, t' \in T(S')$, one has $tt' \in T(S')$, and from the fact that $\text{Transpstr}_{\{G\}}(X, X) = T \cap c(T)$ (cf. 6.1 (ii)).

Let us place ourselves in case a). Let $t \in T(S)$; then $\text{int}(t)$ is a monomorphism of X into X , hence an S -automorphism of X (EGA IV₄, 17.9.6), so that t belongs to $\text{Transpstr}_{\{G\}}(X, X)$, whence a).

In case b), it is clear that $\mu(T \times_S T) \subset T$, and the assertion follows from the following lemma.

Lemma 6.4.2. [N.D.E-VI_B-60] *Let G be an S -scheme of finite presentation, equipped with an associative law (in the sense of EGA 0_III 8.2.5). Suppose that for every S -scheme S' and every $g \in G(S')$, right and left translations by g in the set $G(S')$ are injective, and that $G(S) \neq \emptyset$. Then G is an S -group.*

<!-- label: III.VI_B.6.4.2 -->

<!-- original page 375 -->

It suffices to show that, whatever the S -scheme S' , the set $G(S')$ is a group; now from the hypothesis it follows at once that right and left translations by every element $g \in G(S')$ in $G_{\{S'\}}$ are S -monomorphisms of $G_{\{S'\}}$ into $G_{\{S'\}}$. They are therefore S -automorphisms, since G is of finite presentation over S (EGA IV₄, 17.9.6), so that right and left translations by g in the set $G(S')$ are bijective, and one is reduced to the following lemma.

Lemma 6.4.3. *Let G be a non-empty set equipped with an associative law such that right and left translations are bijective. Then G is a group.*

<!-- label: III.VI_B.6.4.3 -->

The proof is left to the reader.

Definition 6.5. *Let G be an S -group, H an S -functor, and $u : H \rightarrow G$ a monomorphism.*

(i) The* connected centralizer of H in G , *denoted $\text{Centr}^{\{0\}}_{\{G\}} H$, is the neutral component of the functor $\text{Centr}_{\{G\}} H$ (cf. 3.1 and 6.1 (iii)).*

(i') For every morphism $u : X \rightarrow G$, one defines similarly the functor $\text{Centr}^{\{0\}}(u)$ (cf. 6.2 (iv)).*

(ii) When for every $s \in S$, u_s is a closed immersion, the* connected normalizer of H in G *, denoted $\text{Norm}^{\{0\}}_{\{G\}} H$, is the neutral component of the functor $\text{Norm}_{\{G\}} H$.*

N.B. By 1.4.2, the hypothesis in (ii) is satisfied when H is an S -group scheme, G and H are locally of finite type over S , and u is a quasi-compact morphism of S -groups.*

<!-- label: III.VI_B.6.5 -->

Proposition 6.5.1. *Let G be an S -group locally of finite presentation and quasi-separated over S , H a smooth S -group with connected fibers, and $u : H \rightarrow G$ a monomorphism. Let N be the normalizer of H in G (cf. 6.1). According to 6.5.5 below, N is representable by a closed group subscheme of G , of finite presentation over

\$G\$. This being so, the following conditions are equivalent:*

(i) The canonical morphism $H \rightarrow N$ is an open immersion.

(ii) $H^0 = H$ (cf. 3.10).

(iii) For every $s \in S$, one has $H_s = (N_s)^0$.

<!-- label: III.VI_B.6.5.1 -->

Condition (i) entails (ii) by Lemma 3.10.1, since $H^0 = H$. On the other hand, it is clear that (ii) entails (iii), since $H_s = (H^0)_s = (N_s)^0$.

Let us show finally that (iii) entails (i). Since $H_s = (N^0)_s$ for every $s \in S$, then $H_s \rightarrow N_s$ is an open immersion. Moreover, H and N are locally of finite presentation over S , and H is flat over S , hence (EGA IV₄, 17.9.5), $H \rightarrow N$ is an open immersion. ■

[^N.D.E-VI_B-61] For the reader's convenience, we have included below the results 6.8 to 6.11 of Exp. XI.

<!-- original page 376 -->

Theorem 6.5.2. *Let X be a smooth scheme over S , with geometrically irreducible fibers.*[^N.D.E-VI_B-62]

(i) For every closed subscheme Y of X , the functor $\prod_{X/S} Y/X$ is representable by a closed subscheme T of S .

(ii) Moreover, if $Y \rightarrow X$ is of finite presentation, then so is $T \rightarrow S$.

<!-- label: III.VI_B.6.5.2 -->

Since $f : X \rightarrow S$ is faithfully flat locally of finite presentation, it is covering for the (fpqc) topology. On the other hand, since $T = \prod_{X/S} Y/X$ is obviously a subsheaf of S for the (fpqc) topology, it follows that the question of representability of T by a closed subscheme of S is local in nature on S for the (fpqc) topology, [^N.D.E-VI_B-63] and the same is true of the question of deciding whether T is of finite presentation over S (cf. EGA IV₂, 2.7.1). Up to making the base change $S' \rightarrow S$, with $S' = X$, one is reduced to the case where X admits a section ϵ over S . One may moreover suppose S affine and a fortiori quasi-compact. One then has:

Corollary 6.5.3. *Under the conditions of 6.5.2, suppose that S is quasi-compact, that $X \rightarrow S$ admits a section ϵ , and that $Y \rightarrow X$ is of finite presentation. Then there exists an integer $n \geq 0$ such that one has*

``text
$$\prod_{X/S} Y/X = \bigcap_{n \geq 0} Y_n/X_n,$$

where X_n is the n -th infinitesimal neighborhood of the immersion $\epsilon : S \rightarrow X$, and $Y_n = Y \cap X_n$.

<!-- label: III.VI_B.6.5.3 -->

When Y is of finite presentation over X , this corollary implies 6.5.2: indeed, X being smooth over S , X_n is finite and locally free over S , hence a fortiori "essentially free" over S (cf. 6.2.1), so $\prod_{X_n/S} Y_n/X_n$ is representable by a closed subscheme T of S , of finite presentation over S , by 6.2.3.

Let us first prove 6.5.3 (and hence 6.5.2) when S is noetherian. Let $T_n = \prod_{X_n/S} Y_n/X_n$; then the T_n form a decreasing sequence of closed subschemes of S , and S being noetherian, this sequence is stationary. Let $R = \bigcap_{n \geq 0} \prod_{X_n/S} Y_n/X_n$ be their common value for large n ; one has obviously $T \subset R$, and it suffices to establish that $R \subset T$. Up to making the base change $R \rightarrow S$, one is reduced to the case where $R = S$, i.e. $Y_n = X_n$ for every n , i.e. $Y \supset X_n$ for every n , and one must then prove that $T = S$, i.e. $Y = X$.

Now $Y \supset X_n$ for every n implies (thanks to the fact that X is locally noetherian) that Y is, in a neighborhood of every point of $\epsilon(S)$, an induced open subscheme of X ; [^N.D.E-VI_B-64] hence there exists an induced open U of X , containing $\epsilon(S)$, such that $U \subset Y$. By virtue of EGA IV₃, 11.10.10, the fibers

of X/S being integral, U is schematically dense in X , hence (Y being a closed subscheme majorizing U) one has $Y = X$. This proves 6.5.3 hence 6.5.2 when S is noetherian.

<!-- original page 377 -->

The general case proceeds by reduction to the preceding case. For every $s \in S$, there exists an affine open neighborhood U_s of s and an affine open neighborhood V_s of $\epsilon(s)$ such that $f(V_s) \subset U_s$. Then $f(V_s)$ is an open neighborhood of s contained in U_s , and if S'_s is an affine open neighborhood of s contained in $\epsilon^{-1}(V_s) \cap f^{-1}(U_s)$, then X'_s and S'_s are affine opens of X resp. S , and X'_s/S'_s admits a section. Because of the local nature of 6.5.2 and 6.5.3 we may suppose $S = S'_s$. Then X'_s is an affine open of X containing $\epsilon(s)$. As each fiber $X_{\{s\}}$ is supposed irreducible, $X'_{\{s\}}$ is schematically dense in $X_{\{s\}}$, hence, by EGA IV₃, 11.10.10, X'_s is schematically dense in X , and similarly, for every base change $S_{\{1\}} \rightarrow S$, $X' \times_S S_{\{1\}}$ is schematically dense in $X \times_S S_{\{1\}}$.

It follows that $\prod_{X/S} Y/X = \prod_{X'/S} Y'/X'$, where $Y' = Y \cap X'$. This reduces us to the case where $X = X'$, so one may suppose S and X affine. Moreover, if $X = \operatorname{Spec}(B)$ and if J is the ideal of B defining Y , then J is a direct limit of its finitely generated sub-ideals, hence Y is the intersection of closed subschemes $Y_{\{i\}}$ of X which are of finite presentation over X , and consequently $\prod_{X/S} Y/X = \bigcap_{\{i\}} \prod_{X/S} Y_{\{i\}}/X$, which reduces us, to prove 6.5.2, to the case where Y is of finite presentation over X , with S and X affine.

But then X and Y over S come by base change $S \rightarrow S_0$ from an analogous situation X_0 and Y_0 over S_0 , with S_0 noetherian, which reduces us to the case where S is noetherian, already treated. This completes the proof of 6.5.2 and 6.5.3. ■

Corollary 6.5.4. *Let X be a smooth S -group scheme of finite presentation with connected fibers, Y a group scheme of finite presentation over S , $i : Y \rightarrow X$ a monomorphism of S -group schemes.*

(i) Then $\prod_{X/S} Y/X$ is representable by a closed subscheme of finite presentation of S .*

(ii) If moreover S is quasi-compact, one has for large enough n :*

```text  
 $\prod_{X/S} Y/X = \prod_{X_n/S} Y_n/X_n$ ,

\*where  $X_n$  denotes the  $n$ -th infinitesimal neighborhood of the unit section  $\epsilon : S \rightarrow X$ , and  $Y_n = Y \cap X_n$ .\*

<!-- label: III.VI\_B.6.5.4 -->

The proof is essentially that of 6.5.3. [N.D.E-VI\_B-65] On the one hand,  $i$  is locally of finite presentation (cf. EGA IV<sub>1</sub>, 1.4.3). On the other hand, the unit sections of  $Y$  and of  $X$  induce bijective immersions  $S \rightarrow Y_n$  and  $S \rightarrow X_n$ , hence isomorphisms of  $S_{\text{red}}$  with  $(Y_n)_{\text{red}}$  and  $(X_n)_{\text{red}}$ . Consequently,  $i_n$  is quasi-compact hence of finite type, and one has a commutative diagram:

```text  

$$\begin{array}{ccc} (Y_n)_{\text{red}} & \xrightarrow{\tau} & Y_n \\ & \searrow \sigma & \downarrow i_n \\ & & X_n \end{array}$$

<!-- original page 378 -->

where σ, τ are closed immersions and τ is surjective. Since i_n is separated (being a monomorphism), it follows that i_n is proper (cf. EGA II, 5.4.3). Hence i_n is a proper monomorphism of finite presentation, hence a closed immersion (cf. EGA IV₃, 8.11.5). Consequently, by virtue of 6.2.3 already used, $\prod_{X_n/S} Y_n/X_n$ is representable by a closed subscheme T_n of S of finite presentation over S , and it remains therefore to prove the last assertion of 6.5.4 in the case where one supposes moreover S affine.

One reduces immediately again to the case where S is noetherian, and one is reduced to proving that one has $R = T$ (with the notations of the proof of 6.5.3), or, again, that $Y \supset X_n$ for every n implies $Y = X$. Now the

hypothesis implies that $\pi_i : Y \rightarrow X$ is étale at the points of the unit section of Y over S , hence Y is smooth over S at the points of the unit section, whence it follows that the open U of points of Y at which Y is smooth over S is an induced open subgroup of Y (cf. 2.3). Then $\tau : U \rightarrow X$ is an étale monomorphism by virtue of 2.5, hence an open immersion; since the fibers of X are connected and every open subgroup of an algebraic group is also closed, it follows that τ is a surjective open immersion, i.e. an isomorphism. Hence $U = X$ and a fortiori $Y = X$, which completes the proof of 6.5.4. ■

Proceeding as in 6.2.4 e), one concludes from 6.5.4:

Corollary 6.5.5. *Let G be an S -group scheme locally of finite type and quasi-separated over S , H a smooth group scheme of finite presentation over S with connected fibers, $\pi : H \rightarrow G$ a monomorphism of S -groups. Then:

a) $\text{Centr}_G(H)$ and $\text{Norm}_G(H)$ are representable by closed subschemes of G , of finite presentation over G .

a') Similarly, for every monomorphism $j : K \rightarrow G$ of finite presentation of S -group schemes, $\text{Transp}_G(H, K)$ is representable by a closed subscheme of G , of finite presentation over G .

b) If G is quasi-compact, there exists an integer $n \geq 0$ such that (if H_n denotes the n -th infinitesimal neighborhood of the unit section of H) one has:

```

```text
Centr_G(H) = Centr_G(H_n) Norm_G(H) = Norm_G(H_n)
Transp_G(H, K) = Transp_G(H_n, K) = Transp_G(H_n, K_n).
```

```

<!-- label: III.VI_B.6.5.5 -->

Proof. [N.D.E-VI_B-66] Let us first note that the hypothesis on G entails that the monomorphism $H \rightarrow G$ is of finite presentation (EGA IV₁, 1.2.4 and 1.4.3), as is the diagonal immersion $\Delta_{G/S} : G \rightarrow G \times_S G$ (loc. cit. 1.4.3.1). The case of $\text{Norm}_G(H)$ therefore reduces to that of the transporter, by taking $H = K$. Taking 6.2.4 e) into account, we shall apply 6.5.4 to the group scheme $X = H \times G = H \times_S G$ over the base scheme G , and to the following group subscheme Y .

In the case of $\text{Transp}_G(H, K)$, we take for Y the inverse image of K under the morphism of G -groups $H \times_S G \rightarrow G \times_S G$, $(h, g) \mapsto (ghg^{-1}, g)$. In the case of

<!-- original page 379 -->

$\text{Centr}_G(H)$, we take for Y the inverse image of the diagonal subgroup $\Delta_{G/S}(G)_G$ of $(G \times_S G)_G$ under the morphism of G -groups:

```

```text
H x_S G -> G x_S G x_S G, (h, g) -> (h, ghg^-1, g).
```

```

■

Definition 6.6. *Let G be an S -functor in groups, H a sub- S -functor in groups; one says that H is invariant (resp. central, resp. χ -characteristic) in G if $\text{Norm}_G(H) = G$ (resp. if $\text{Centr}_G(H) = G$, resp. if, whatever the S -scheme T and the automorphism α of $\text{Aut}_{T\text{-gr}}(G_T)$, one has $\alpha(H_T) \subset H_T$), in other words, if, whatever the S -scheme T , the subgroup $H(T)$ of $G(T)$ is invariant in $G(T)$ (resp. central in $G(T)$, resp. invariant under every automorphism of G_T).

N.B. If H is central (resp. characteristic), then it is invariant.

<!-- label: III.VI_B.6.6 -->

Remark 6.7. *Let G and H be two S -groups and $\pi : H \rightarrow G$ a monomorphism. For H to be invariant (resp. central) in G , it is necessary and sufficient that the morphism

```

```text
(\pi \circ c \circ pr_2, \pi \circ (u \times id_G)) : H x_S G -> G
```

```

(defined by $(h, g) \mapsto g^{-1} h g$ whatever $g \in G(S)$ and $h \in H(S)$) factor through π (resp. equal

$u \circ \text{pr}_1$), and for H to be characteristic in G , it is necessary and sufficient that for every S -scheme T and every T -automorphism of groups a of G_T , $a \circ u(T)$ factor through $u(T)$.

<!-- label: III.VI_B.6.7 -->

Example 6.8. Let G be an S -functor in groups. Then $\text{Centr } G$ is characteristic and central. If, for every $s \in S$, G_s is representable, then G^0 is characteristic. This follows from the definitions and from 3.3.

<!-- label: III.VI_B.6.8 -->

6.9.

[^N.D.E-VI_B-67] In [RG71], I 3.3.3, the authors introduce the geometric notion of pure S -scheme, which is local on S for the étale topology; we refer to loc. cit. for the precise definition. Let us simply point out the following:

a) (loc. cit., Th. 3.3.5) If B is a flat A -algebra of finite presentation, then B is a projective A -module if and only if $\text{operatorname{Spec}}(B)$ is pure over $\text{operatorname{Spec}}(A)$.

b) Consequently, if $X \rightarrow S$ is locally of finite presentation, flat and pure, then X is essentially free over S .

c) (loc. cit., 3.3.4 (iii)) If $X \rightarrow S$ is locally of finite type, flat, with geometrically irreducible fibers and without embedded components, then X is pure over S .

Since every group scheme locally of finite type over a field is Cohen-Macaulay (cf. VI_A, 1.1.1), hence without embedded components, one obtains in particular:

d) Every S -group scheme G locally of finite presentation, flat, and with connected fibers is pure over S , hence essentially free over S .

One may then take up again all the statements of 6.2.4 e) taking into account results (b) and (d) above.

<!-- original page 380 -->

7. Generated subgroups; commutator group

<!-- label: III.VI_B.7 -->

In this number, k denotes a fixed field.

Proposition 7.1. Let G be a k -group, $(X_i)_{i \in I}$ a family of geometrically reduced k -schemes;[^N.D.E-VI_B-68] for every $i \in I$, let $f_i : X_i \rightarrow G$ be a k -morphism.

(i) There exists a smallest closed group sub- k -scheme of G majorizing each of the f_i , denoted $\Gamma_G((f_i)_{i \in I})$. It is a geometrically reduced k -scheme, hence smooth in the case where G is supposed locally of finite type over k (1.3.1).

(ii) Set $X = \coprod_{i \in I} X_i$, and let $f : X \rightarrow G$ be the morphism whose restriction to X_i is f_i , for every $i \in I$. Set $X^1 = X \sqcup X$, let $f^1 : X^1 \rightarrow G$ be the morphism whose restrictions to X are respectively f and $c \circ f$. For every $n > 1$, set

```text  
 $X^n = X^1 \times_k X^{n-1}$       and       $f^n = \mu \circ (f^1 \times_k f^{n-1}) : X^n \rightarrow G$ .  
 ```

Then $\Gamma_G((f_i)_{i \in I})$ is the reduced subscheme of G whose underlying space is the closure of the union of the $f^n(X^n)$, for $n \geq 1$.

(iii) For every k -scheme S , $\Gamma_G((f_i)_{i \in I})_S$ is the smallest closed group subscheme of G_S majorizing each of the $f_{i,S} : X_{i,S} \rightarrow G_{i,S}$.

(iii') Moreover, $\Gamma_G((f_i)_{i \in I})_S$ is the smallest group subscheme of G_S majorizing each of the $f_{i,S}$.[^N.D.E-VI_B-69]

<!-- label: III.VI_B.7.1 -->

Let us first note that, to prove (i), (iii) and (iii'), by defining $\mathcal{G}$ and $\mathcal{H}$ as in (ii), one is reduced to the case where $\mathcal{I}$ is reduced to a single element.

Let $\mathcal{H}$ be the reduced subscheme of $\mathcal{G}$ with underlying set $\bigcup_{f \in X} f^{-1}(X)$. Then the family of morphisms $f : X \rightarrow \mathcal{H}$ is schematically dominant (cf. EGA IV₃, 11.10.4), hence every closed subscheme of $\mathcal{G}$ which majorizes the $f^{-1}(X)$ also majorizes $\mathcal{H}$. Moreover, by loc. cit., 11.10.7, $\mathcal{H}$ is geometrically reduced. Hence to show (i) and (ii), it suffices to show that $\mathcal{H}$ is a group subscheme of $\mathcal{G}$, i.e. that the restriction of $\mathcal{G}$ to $\mathcal{H}$ and the restriction of μ to $\mathcal{H} \times \mathcal{H}$ factor through the injection $\mathcal{H} \rightarrow \mathcal{G}$.

Since $\mathcal{H}$ is geometrically reduced, $\mathcal{H} \times \mathcal{H}$ is reduced, and it suffices to verify that $\mathcal{C}(\mathcal{H}) \subset \mathcal{H}$ and that $\mu(\mathcal{H} \times \mathcal{H}) \subset \mathcal{H}$ (set-theoretically). But by EGA IV₃, 11.10.6, the union of the $f^{-1}(\mathcal{H}) \times (X \times \mathcal{H})$ is schematically dense in $\mathcal{H} \times \mathcal{H}$. Similarly, for every $n \in \mathbb{N}$, the union of the $f^{-1}(\mathcal{H}) \times (X \times \mathcal{H}) \times \dots \times (X \times \mathcal{H})$, for $m \in \mathbb{N}$, is schematically dense in $X \times \mathcal{H} \times \dots \times \mathcal{H}$. Hence it suffices to show that $\mu(f^{-1}(\mathcal{H}) \times (X \times \mathcal{H})) \subset \mathcal{H}$ and that $\mathcal{C}(f^{-1}(\mathcal{H})) \subset \mathcal{H}$. Now

``text
 $\mu(f^{-1}(\mathcal{H}) \times (X \times \mathcal{H})) = \mu((f \times \text{id})(X \times \mathcal{H})) = f^{-1}(\mu(X \times \mathcal{H})) = f^{-1}(\mathcal{H}) \subset \mathcal{H}$;

and, since $\mathcal{C}(f^{-1}(\mathcal{H})) \subset f^{-1}(\mathcal{H}) \subset \mathcal{H}$, one has, whatever $n \in \mathbb{N}$, $\mathcal{C}(f^{-1}(\mathcal{H})) \subset f^{-1}(\mathcal{H}) \subset \mathcal{H}$. This proves (i) and (ii).

<!-- original page 381 -->

Let us now show (iii). Let $\mathcal{G}$ be a closed group subscheme of $\mathcal{G}$ majorizing $f^{-1}(S)$; we must show that $\mathcal{G}$ majorizes $\mathcal{H}$, or, what amounts to the same, that $\mathcal{H} = \mathcal{H} \times \mathcal{G}$. Set $\mathcal{H}' = \mathcal{H} \times \mathcal{G}$. Since $\mathcal{G}$ majorizes $f^{-1}(S)$, the same is true of $\mathcal{H}'$. Now (EGA IV₃, 11.10.6), since the family of $f : X \rightarrow \mathcal{H}$ is schematically dominant, the same is true of the family of $f : X \rightarrow \mathcal{H}'$, so that $\mathcal{H}'$, which majorizes each of the $f^{-1}(S)$, is equal to $\mathcal{H}$ by EGA IV₃, 11.10.1 c). This proves (iii).

Let us show finally that $\mathcal{H}$ is the smallest group subscheme (not necessarily closed) of $\mathcal{G}$ majorizing $f^{-1}(S)$.

Let $\mathcal{G}$ be a group subscheme of $\mathcal{G}$ majorizing $f^{-1}(S)$. It must likewise be shown that, if one sets $\mathcal{H}' = \mathcal{H} \times \mathcal{G}$, then $\mathcal{H}' = \mathcal{H}$. It suffices for this to show that $\mathcal{H}'$ is closed in $\mathcal{H}$ and to apply (iii). It suffices therefore to show that $\mathcal{H}$ and $\mathcal{H}'$ have the same underlying set, a fortiori it suffices to show that, for every $s \in S$, $\mathcal{H}_s = \mathcal{H}'_s$.

``text
 $\mathcal{H}'_s := \mathcal{H}_s \times \mathcal{G}_s = \mathcal{H}_s \times \mathcal{G}_s = \mathcal{H}_s$.

Now, by VI_A, 0.5.2, the group sub- $\kappa(s)$ -scheme $\mathcal{G}'_s$ is closed in $\mathcal{G}_s$. Hence $\mathcal{H}'_s$ is closed in $\mathcal{H}_s$, and then the preceding reasoning, applied to $\mathcal{H}'_s$, to $\mathcal{H}_s$ and to the $f^{-1}(S)$, shows that $\mathcal{H}'_s = \mathcal{H}_s$. ■

****Corollary 7.1.1.**** [^N.D.E-VI_B-70] *Let $\mathcal{G}$ be a κ -group locally of finite type and let A, B be two sub- κ -groups of $\mathcal{G}$, smooth and of finite type, and i_A (resp. i_B) the inclusion of A (resp. B) into $\mathcal{G}$. Assume that B normalizes A . Then $A \cdot B = \Gamma_G(i_A, i_B)$.*

<!-- label: III.VI_B.7.1.1 -->

Indeed, let $H = A \rtimes B$ be the semidirect product of A and B (cf. I, 2.3.5); it is a smooth κ -group of finite type. Then the group morphism $u : H \rightarrow \mathcal{G}$, $(a, b) \mapsto ab$, is quasi-compact, hence, by 1.2, $u(H) = A \cdot B$ is a closed reduced subscheme of $\mathcal{G}$, which is a group in the category $(\text{Sch}/\kappa)_{\text{red}}$. Now, by EGA IV₃, 11.10.7, $A \cdot B = u(H)$ is geometrically reduced (since H is), so it is a closed subgroup of $\mathcal{G}$. Since obviously $A \cdot B \subset \Gamma_G(i_A, i_B)$, the corollary follows. ■

****Definitions and remarks 7.2.**** [^N.D.E-VI_B-71] *(i) Given a κ -group $\mathcal{G}$, a family $(X_i)_{i \in I}$ of geometrically reduced κ -schemes, and for each $i \in I$ a κ -morphism $f_i : X_i \rightarrow \mathcal{G}$, one calls* closed group subscheme of $\mathcal{G}$ generated by the family $(f_i)_{i \in I}$, and we shall denote in this number $\Gamma_G((f_i)_{i \in I})$, the smallest closed group subscheme of $\mathcal{G}$ majorizing each of the f_i . If $\mathcal{G}$ is a

subscheme of G , geometrically reduced over k , and if f is the immersion $X \hookrightarrow G$, one writes $\Gamma_G(X)$ instead of $\Gamma_G(f)$.

(i') With the notations of 7.1 (ii), we shall sometimes set $\Gamma'_G(f) = \bigcup_{n \geq 1} f^n(X^n)$. Note that $\Gamma'_G(f)$ is a subset of G stable for the group law (in the sense of 3.0).

(ii) It is clear that if X_1 and X_2 are two geometrically reduced k -schemes and $f_1 : X_1 \rightarrow G$ and $f_2 : X_2 \rightarrow G$ two k -morphisms such that the sets $f_1(X_1)$ and $f_2(X_2)$ are equal, then $\Gamma_G(f_1) = \Gamma_G(f_2)$.

<!-- original page 382 -->

(iii) Let E be a subset of G such that the reduced subscheme E of G is geometrically reduced. One calls closed group subscheme of G generated by E , denoted $\Gamma_G(E)$, the group subscheme $\Gamma_G(i)$, where i is the injection of the reduced subscheme E of G into G .

(iv) Since every group subscheme of G is closed, by VI_A, 0.5.2, [N.D.E-VI_B-72] one will speak of "generated group subscheme" instead of "generated closed group subscheme".

(v) Let X be a geometrically reduced k -scheme and $f : X \rightarrow G$ a k -morphism. Suppose that $f(X)$ contains the unit element e of G . Set $X'^1 = X \times_k X$ and $f'^1 = \mu \circ (f^{-1} \times_k f^{-1})$, and for $n > 1$,

text
 $X'^n = X'^1 \times_k X'^{n-1}$ and $f'^n = \mu \circ (f'^1 \times_k f'^{n-1})$.
 ``

Then $\Gamma_G(f)$ is the reduced subscheme of G whose underlying space is the closure of the union of the $f'^n(X'^n)$, for $n \geq 1$.

Indeed, recalling the notation of 7.1 (ii): $X^1 = X \sqcup X$ and $X^n = X^1 \times_k X^{n-1}$, for $n \geq 2$, one has the following inclusions, where the first follows from the hypothesis $e \in f(X)$:

text
 $f^n(X^n) \subset f'^n(X'^n) \subset f^{2n}(X^{2n})$, for every $n \geq 1$.
 ``

This shows moreover that, for there to exist an integer n such that $f'^n(X'^n) = \Gamma_G(f)$, it is necessary and sufficient that there exist an integer m such that $f'^m(X'^m) = \Gamma_G(f)$.

From Remark 7.2 (v) one deduces the

<!-- label: III.VI_B.7.2 -->

Corollary 7.2.1. Let X be a geometrically reduced and geometrically connected k -scheme, and $f : X \rightarrow G$ a k -morphism such that $f(X)$ contains the neutral element of G . Then the k -group $\Gamma_G(f)$ is connected, hence irreducible.

<!-- label: III.VI_B.7.2.1 -->

Indeed, each of the X'^n is then connected, hence the union of the $f'^n(X'^n)$ (which all contain the neutral element) is connected, and the same is true of its closure $\Gamma_G(f)$. Hence $\Gamma_G(f)$ is irreducible, by VI_A, 2.4 (when G , hence also $\Gamma_G(f)$, is locally of finite type over k) and 2.6.5 (iii) (in the general case). ■

Definition 7.2.2. Let G be a k -group.

a) Let A and B be two geometrically reduced group sub- k -schemes of G . The commutator group subscheme of A and B in G , denoted $(A, B)_G$ or simply (A, B) , is the closed group subscheme of G generated by the morphism $\nu : A \times_k B \rightarrow G$ defined by: $(a, b) \mapsto aba^{-1}b^{-1}$, for every k -scheme S and $a \in A(S)$, $b \in B(S)$.

b) Suppose G geometrically reduced over k . The derived group of G , denoted $D(G)$, [N.D.E-VI_B-73] is the group (G, G) .

N.B. For G to be commutative, it is necessary and sufficient that $D(G)$ be the unit k -group.

<!-- label: III.VI_B.7.2.2 -->

<!-- original page 383 -->

****Reminders 7.3.0.**** [^{N.D.E-VI_B-74}] *Recall that if $\phi : Y \rightarrow Z$ is a morphism of S -schemes, the image presheaf $\phi(Y)$ is the S -functor which to every S' over S associates the subset $\phi(Y(S'))$ of $Z(S')$. Note that if T is a subscheme of Z and if the inclusion of presheaves $\phi(Y) \hookrightarrow Z$ factors through T , i.e. if $\phi \circ h \in T(S')$ for every S -morphism $h : S' \rightarrow Y$, then set-theoretically $\phi(Y) \subset T$ (take $h = \text{id}_Y$), and the converse is true if Y is reduced, since in this case ϕ factors through T .*

Recall also that, by 6.2, if H is a closed group sub- k -scheme of G , then $\text{Centr}\{G\} H$ and $\text{Norm}\{G\} H$ are representable by closed group sub- k -schemes of G .

<!-- label: III.VI_B.7.3.0 -->

****Corollary 7.3.**** *Let G be a k -group, X a geometrically reduced k -scheme, $f : X \rightarrow G$ a k -morphism.*

(i) Let S be a k -scheme and u an endomorphism of the S -group G_S .

(a) If one has $u(f(S)(X_S)) \subset \Gamma_G(f)_S$ (set-theoretically), then the morphism $u : \Gamma_G(f)_S \rightarrow G_S$ factors through $\Gamma_G(f)_S$.

(b) If u is an automorphism of the S -group G_S and if one has $u(f(S)(X_S)) = f(S)(X_S)$ (set-theoretically), then u induces an automorphism of $\Gamma_G(f)_S$. In particular, if an element $g \in G(S)$ satisfies $\text{int}(g)(f(S)(X_S)) = f(S)(X_S)$ (set-theoretically), then $g \in \text{Norm}\{G\}(\Gamma_G(f)_S)(S)$.

(c) If $u \circ f_S = f_S$, then the restriction of u to the subgroup $\Gamma_G(f)_S$ of G_S is the identity. In particular, if an element $g \in G(S)$ satisfies $\text{int}(g)(f_S) = f_S$, then $g \in \text{Centr}\{G_S\}(\Gamma_G(f)_S)(S)$.

(ii) Let H be a group subscheme of G ; then H centralizes (resp. normalizes) $\Gamma_G(f)$ if and only if, for every $S \rightarrow \text{operatorname{Spec}} k$ and $h \in H(S)$, one has $\text{int}(h) \circ f_S = f_S$ (resp. $\text{int}(h)(f_S(X_S)) \subset \Gamma_G(f)_S$), i.e. if for every $S' \rightarrow S$ and $x \in X(S')$, the elements $h_{S'} \circ f(x)$ of $G(S')$ commute (resp. $h_{S'} \circ f(x) \in \Gamma_G(f)(S')$).

(iii) In particular, let Y be a second geometrically reduced k -scheme and $\phi : Y \rightarrow G$ a k -morphism. Suppose that, whatever the k -scheme S' , for every $x \in X(S')$ and $y \in Y(S')$, the elements $\phi(y)$ and $f(x)$ of $G(S')$ commute (resp. $\text{int}(\phi(y))(f(x)) \in \Gamma_G(f)(S')$).

Then $\Gamma_G(\phi)$ is a sub- k -group of $\text{Centr}\{G\} \Gamma_G(f)$, resp. $\text{Norm}\{G\} \Gamma_G(f)$.

(iv) If g is a k -point of G , then the k -group $\Gamma_G(\{g\})$ is commutative.

(v) Let A and B be two group subschemes of G geometrically reduced over k . If A and B are invariant (resp. characteristic), so is (A, B) .

<!-- label: III.VI_B.7.3 -->

Proof. (i) Let us prove (a). Set $\Gamma_S = \Gamma_G(f)_S$. Then $u^{-1}(\Gamma_S)$ is a closed group sub- S -scheme of G_S , hence, by 7.1 (iii), it suffices to show that f_S factors through $u^{-1}(\Gamma_S)$. Now, since $u(f_S(X_S)) \subset \Gamma_S$ and since X_S is reduced, $u \circ f_S$ factors through Γ_S , hence f_S factors through $u^{-1}(\Gamma_S)$. This proves (a).

<!-- original page 384 -->

Then the first assertion of (b) is a consequence of (a), applied to u and u^{-1} (and in fact it suffices to assume that $u(f_S(X_S)) \subset \Gamma_S$ and $u^{-1}(f_S(X_S)) \subset \Gamma_S$), and the second assertion is the particular case where $u = \text{int}(g)$.

Let us prove (c). Consider the morphism of S -groups $G_S \rightarrow G_S \times_S G_S$, $g \mapsto (u(g), g)$ and let H be the inverse image of the diagonal; it is a group subscheme of G_S . Since G is separated over k (VI_A 0.3), G_S is separated over S , hence H is closed in G_S . As, by hypothesis, H majorizes f_S , it contains $\Gamma_G(f)_S$, by 7.1 (iii). This proves the first assertion of (c), and the second is the particular case where

$\$u = \text{int}(g)\$.$

Let us prove (ii). Set $\Gamma = \Gamma_{\{G\}}(f)\$$ and let $\$i\$$ denote the inclusion $\Gamma \hookrightarrow G\$$. Then $\$H\$$ is contained in $\$N = \text{Norm}_{\{G\}}(\Gamma)\$$ if and only if, for every $\$k\$$ -scheme $\$S\$$ and $\$h \in H(S)\$,$ one has $\text{int}(h)(\Gamma_{\{S\}}) \subset \Gamma_{\{S\}}\$$ (this condition applied to $\$h\$$ and $\$h^{-1}\$$ entailing that $\text{int}(h)(\Gamma_{\{S\}}) = \Gamma_{\{S\}}\$$); and by (i)(a) this is the case if and only if $\text{int}(h)(f_{\{S\}}(X_{\{S\}})) \subset \Gamma_{\{S\}}\$$.

Similarly, $\$H\$$ is contained in $\$C = \text{Centr}_{\{G\}}(\Gamma)\$$ if and only if, for every $\$k\$$ -scheme $\$S\$$ and $\$h \in H(S)\$,$ one has $\text{int}(h) \circ i_{\{S\}} = i_{\{S\}}\$$, and by (i)(c) this is the case if and only if $\text{int}(h)(f_{\{S\}}) = f_{\{S\}}\$$. This proves (ii).

Let us prove (iii). Taking (ii) into account, the hypothesis entails that $\phi\$$ factors through $\$C\$$ (resp. $\$N\$$); since the latter is a closed subgroup of $\$G\$$, by 6.2, it therefore contains $\Gamma_{\{G\}}(f)\$,$ by 7.1 (i).

Assertion (iv) follows from (iii), when one takes for $\$f\$$ and $\phi\$$ the closed immersion $\text{operatorname{Spec}} k \hookrightarrow G\$$ defined by $\$g\$$: in this case, for every $\$k\$$ -scheme $\$S\$$, $\$X(S)\$$ and $\$Y(S)\$$ have only one point, which is sent by $\$f\$$ (resp. $\phi\$$) to $\$g\$$.

Let us finally show (v). Let $\nu\$$ be the morphism $\$G \times G \rightarrow G\$$, $\$(g, h) \mapsto gh^{-1}\$$ and let $\nu'\$$ be its restriction to $\$A \times B\$$; by definition (7.2.2), $\$(A, B) = \Gamma_{\{G\}}(\nu')\$$. Let $\$S\$$ be a $\$k\$$ -scheme, and $\$u\$$ an inner automorphism (resp. an automorphism of $\$S\$$ -group) of $\Gamma_{\{S\}}\$$. One has $\$u \circ \nu_{\{S\}} = \nu_{\{S\}} \circ \text{circ}(u \times \text{id})\$$. On the other hand, the hypothesis entails that $\$u\$$ induces an automorphism $\$u_{\{1\}}\$$ of $\Gamma_{\{S\}}(A_{\{S\}})$ (resp. $\$u_{\{2\}}\$$ of $\Gamma_{\{S\}}(B_{\{S\}})$), hence

```
```text
u(v'_S(A_S x_S B_S)) = v'_S(u_1(A_S) x_S u_2(B_S)) = v'_S(A_S x_S B_S).
```

Hence, by (i)(b),  $\$u\$$  induces an automorphism of  $\$(A, B)_{\{S\}}\$$ . This proves (v). ■

**\*\*Proposition 7.4.\*\*** \*Let  $\$G\$$  be a  $\$k\$$ -group locally of finite type,  $\$X\$$  a  $\$k\$$ -scheme of finite type, geometrically reduced and geometrically connected, and  $\$f : X \rightarrow G\$$  a  $\$k\$$ -morphism such that  $\$f(X)\$$  contains the neutral element  $\$e\$$  of  $\$G\$$ . Then, with the notations of 7.1 (ii), there exists an integer  $\$N\$$  such that one has (set-theoretically):\*

```
$$
f^{N}(X^{N}) = \Gamma_{\{G\}}(f).
$$
```

<!-- label: III.VI\_B.7.4 -->

By 7.1 (iii) and EGA IV<sub>2</sub>, 2.6.1, we may suppose  $\$k\$$  algebraically closed. By Corollary 7.2.1, we may suppose  $\$G = G^{\{0\}}\$$ ; finally, it suffices to show that there exists an integer  $\$N\$$  such that one has  $\$f'^{N}(X'^{N}) = \Gamma_{\{G\}}(f)\$,$  with the notations of 7.2 (v).

**\*First case.\*** Suppose  $\$X\$$  irreducible. Then the  $\$f'^{n}(X'^{n})\$$  form an increasing sequence of irreducible closed sets in the space  $\$G\$$ , which is noetherian, since  $\$G = G^{\{0\}}\$$  is

<!-- original page 385 -->

of finite type over  $\$k\$$  (VI\_A 2.4). Hence this sequence is stationary, and there exists an integer  $\$m\$$  such that  $\$f'^{m}(X'^{m}) = \Gamma_{\{G\}}(f)\$$ .

Moreover, since  $\$X\$$  and  $\$G\$$  are of finite type over  $\$k\$$ , the morphisms  $\$f'^{n}\$$  are of finite type over  $\$k\$$ . Consequently,  $\$f'^{m}(X'^{m})\$$  is constructible in  $\$G\$$  (EGA IV<sub>1</sub>, 1.8.5), hence contains an open  $\$U\$$  of its closure  $\Gamma_{\{G\}}(f)\$$  (EGA 0\_IV, 9.2.3). Then, by VI\_A 0.5, one has:

```
```text
Γ_G(f) ⊂ U · U ⊂ f'^{2m}(X'^{2m}) ⊂ Γ_G(f),
```

whence $\$f'^{2m}(X'^{2m}) = \Gamma_{\{G\}}(f)\$$.

Second case. Suppose $\$X\$$ has exactly two irreducible components $\$A_1\$$ and $\$A_2\$$. Then, since $\$X\$$ is connected and $\$k\$$ algebraically closed, there exists $\$a \in (A_1 \cap A_2)(k)\$$. Hence the four irreducible parts

$A_{\{i\}} \times_{\{k\}} A_{\{j\}}$ ($i, j = 1, 2$) cover $X \times_{\{k\}} X$, and the image of each of them under the morphism $f'^{\{1\}} = \mu \circ (f \times_{\{k\}} (c \circ f))$ contains e . If $f'^{\{1\}}_{\{ij\}}$ denotes the restriction of $f'^{\{1\}}$ to the reduced subscheme $A_{\{i\}} \times_{\{k\}} A_{\{j\}}$, set

```

```text
Y = (A_1 \times_k A_1) \times_k (A_1 \times_k A_2) \times_k (A_2 \times_k A_2) \times_k (A_2 \times_k A_1) and
g = \mu \circ (\mu \circ (f'^{-1}_{11} \times_k f'^{-1}_{12})) \times_k \mu \circ (f'^{-1}_{22} \times_k f'^{-1}_{21})).
```

```

Then Y is irreducible, reduced and of finite type, hence we just saw that there exists an integer m such that $g'^{\{m\}}(Y'^{\{m\}}) = \Gamma_{\{G\}}(g)$. Now, for every $n \geq 1$, one has $f'^{\{n\}}(X'^{\{n\}}) \subset g'^{\{n\}}(Y'^{\{n\}}) \subset f'^{\{4n\}}(X'^{\{4n\}})$, whence $\Gamma_{\{G\}}(f) = \Gamma_{\{G\}}(g)$ and $f'^{\{4m\}}(X'^{\{4m\}}) = \Gamma_{\{G\}}(f)$.

General case. Let us argue by induction on the number of irreducible components of X (this number is finite since X , being of finite type over k , is noetherian). Suppose the proposition proved in the case where X has at most $r - 1$ irreducible components, and suppose it has r , namely $A_1, \dots, A_r$. Then e belongs to the image of one of the $A_{\{i\}}$; suppose for example that $e \in f(A_1)$. Set then $Y = \Gamma_{\{G\}}(f_{\{r\}})$, where $f_{\{r\}}$ denotes the restriction of f to the reduced subscheme $X_{\{r\}} = A_1 \cup \dots \cup A_{\{r-1\}}$ (we suppose the numbering of the $A_{\{i\}}$ chosen so that this scheme is connected, which is always possible). Then Y is a subgroup of G , closed, reduced and irreducible, by Corollary 7.2.1.

Set $Z = f(A_r)$, and let $T = Y \cup Z$, equipped with the closed reduced subscheme structure, and i the injection of T into G . It is clear (7.2 (ii)) that $\Gamma_{\{G\}}(i) = \Gamma_{\{G\}}(f)$ and that T is connected (because since X is connected, $A_1 \cup \dots \cup A_{\{r-1\}}$ and A_r have in common a point a , and Y and Z have in common the point $f(a)$). Moreover, $e \in T$, and T has at most two irreducible components, since Y and Z are irreducible. By the induction hypothesis, there exists an integer m such that one has $f'^{\{m\}}_{\{r\}}(X'^{\{m\}}_{\{r\}}) = \Gamma_{\{G\}}(f_{\{r\}}) = Y$. Since $X = X_{\{r\}} \cup A_r$ and since $Z = f(A_r)$ is contained in $f'^{\{m\}}(X'^{\{m\}})$ (since $e \in f(A_1)$), one therefore has:

```

```text
f(X) \subset Y \cup Z \subset f'^{\{m\}}(X'^{\{m\}}).
```

```

On the other hand, since T has at most two irreducible components, one has already seen that there exists an integer p such that $i'^{\{p\}}(T'^{\{p\}}) = \Gamma_{\{G\}}(i) = \Gamma_{\{G\}}(f)$. Now, $T \subset f'^{\{m\}}(X'^{\{m\}})$, hence $f'^{\{mp\}}(X'^{\{mp\}}) = \Gamma_{\{G\}}(f)$, and one shows, as in the first case, that this last equality entails $f'^{\{2mp\}}(X'^{\{2mp\}}) = \Gamma_{\{G\}}(f)$. ■

<!-- original page 386 -->

****Lemma 7.5.**** *Let S be a scheme, G an S -group scheme, X an S -prescheme, $f : X \rightarrow G$ an S -morphism. Suppose that X and G are locally of finite presentation over S , and that for every $s \in S$ and every maximal point g of G_s , there exists a point x of X such that $f(x) = g$ and f is flat at x . Then the morphism $\mu \circ (f \times_S f) : X \times_S X \rightarrow G$ is covering for the (fppf) topology.*

<!-- label: III.VI_B.7.5 -->

[^N.D.E-VI_B-75] By EGA IV₃, 11.3.1, the set V of points of X at which f is flat is open and $f|_V$ is an open morphism, hence $U = f(V)$ is an open of G ; moreover, by the hypothesis, $U \cap G_s$ is dense in G_s , for every $s \in S$. Denote by ϕ the restriction to $V \times_S V$ of $\mu \circ (f \times_S f)$.

It suffices to show that ϕ is covering for the (fppf) topology, and for this it suffices to show that ϕ is faithfully flat and of finite presentation (cf. IV, 6.3.1 (iv)). Now ϕ is equal to the composite $V \times_S V \rightarrow U \times_S U \rightarrow G$, where the first morphism is faithfully flat and locally of finite presentation, since $f|_V$ is. It therefore suffices to prove that the same is true of the restriction of μ to $U \times_S U$.

Now, $G \rightarrow S$ being locally of finite presentation and flat, the same is true of $\mu : G \times_S G \rightarrow G$ (which is isomorphic to the morphism deduced from $G \rightarrow S$ by the base change $G \rightarrow S$, cf. VI_A 0.1), hence also of the induced morphism $U \times_S U \rightarrow G$. To prove that the latter is surjective, it suffices to look fiber by fiber, where it follows from VI_A 0.5, since $U \cap G_s$ is a dense open of G_s , for every $s \in S$. ■

****Remark 7.6.0.**** [^N.D.E-VI_B-76] *Let S be a scheme, H an S -group, and $f : X \rightarrow H$ a morphism of S -schemes. The sub-presheaf in groups of H generated by the image of f , denoted $\langle \text{Im } f \rangle$, is the sub- S -functor

in groups of $\mathbb{H}$ which to every S -scheme S' associates the subgroup of $H(S')$ generated by $f(X(S'))$. Since each element of this subgroup can be written as a finite product $f(x_1)^{\epsilon_1} \cdots f(x_n)^{\epsilon_n}$, with $n \in \mathbb{N}$, $x_i \in X(S')$ and $\epsilon_i = \pm 1$, one sees therefore that if one sets $X^{\infty} = X \sqcup X$ and defines the morphisms $f^n : X^n \rightarrow H$ as in 7.1, then $\langle \text{Im } f \rangle$ is nothing but the image presheaf of the morphism*

$$f^{\infty} : X^{\infty} \rightarrow H,$$

where $X^{\infty} = \coprod_{n \geq 1} X^n$ and $f^{\infty} : X^{\infty} \rightarrow H$ is the S -morphism whose restriction to each X^n is f^n .

<!-- label: III.VI_B.7.6.0 -->

Proposition 7.6. [N.D.E-VI_B-77] *Let S be a scheme, X a flat S -scheme locally of finite presentation over S , H an S -group, locally of finite presentation over S and with reduced fibers, $f : X \rightarrow H$ a morphism of S -schemes, and $f^{\infty} : X^{\infty} \rightarrow H$ the S -morphism introduced above. The following conditions are equivalent:*

(i) H represents the (fppf) S -sheaf associated with the presheaf $\langle \text{Im } f \rangle$.*

(ii) f^{∞} is covering for the (fppf) topology.*

<!-- original page 387 -->

(iii) f^{∞} is surjective, i.e. $H = \bigcup_{n \geq 1} f^n(X^n)$.*

If moreover H is quasi-compact, these conditions are also equivalent to the following:*

(iv) There exists an integer n such that $f^n : X^n \rightarrow H$ is covering for the (fppf) topology (and a fortiori surjective).*

This applies in particular in the case where X is a k -scheme locally of finite type and geometrically reduced, G a k -group locally of finite type, $\phi : X \rightarrow G$ a morphism of k -schemes, $H = \Gamma_G(\phi)$, and $f : X \rightarrow H$ the morphism induced by ϕ .*

<!-- label: III.VI_B.7.6 -->

Proof. The sheaf considered in (i) is the image sheaf of X^{∞} by f^{∞} , hence, by IV 4.4.3, to say that H represents this sheaf is equivalent to saying that f^{∞} is covering, and this implies that f^{∞} is surjective. Conversely, suppose f^{∞} surjective and let us show that it is then covering for the (fppf) topology.

Let $s \in S$, η a maximal point of the fiber H_s , and $x \in X^{\infty}_s$ such that $f^{\infty}(x) = \eta$ (such an x exists, since f^{∞} is surjective). Since the fiber H_s is reduced, $\mathcal{O}_{H_s, \eta}$ is a field, hence f^{∞}_s is flat at the point x . Since X^{∞} and H are locally of finite presentation over S , and X^{∞} flat over S , it follows from the fibrewise flatness criterion (EGA IV₃, 11.3.10) that f^{∞} is flat at the point x . Hence, by Lemma 7.5, the morphism

$$\mu \circ (f^{\infty} \times f^{\infty}) : X^{\infty} \times_S X^{\infty} \rightarrow H$$

is covering for the (fppf) topology. Now, since $X^n \times_S X^m$ is canonically isomorphic to X^{n+m} , and that, under this isomorphism, $\mu \circ (f^n \times f^m)$ corresponds to f^{n+m} , it is clear that $\mu \circ (f^{\infty} \times f^{\infty})$ factors through f^{∞} , so that f^{∞} is covering for the (fppf) topology. This proves that (iii) $\Rightarrow$ (ii), whence the equivalence of conditions (i), (ii) and (iii).

Note moreover that, since the morphisms $X \rightarrow S$ and $H \rightarrow S$ are locally of finite presentation, the same is true of $f : X \rightarrow H$ (cf. EGA IV₁, 1.4.3 (v)), and as $\mu : H \times_S H \rightarrow H$ is also of finite presentation (cf. VI_A, 0.1), it follows that each $f^n : X^n \rightarrow H$ is so. Hence, by EGA IV₁, 1.9.5 (viii), the $f^n(X^n)$ are ind-constructible parts of H .

Suppose moreover H quasi-compact (then S is also, since $H \rightarrow S$ is surjective). Then, by EGA IV₁, 1.9.9, one

concludes that there exists p such that $f^p(X^p) = H$. As before, one then deduces, from the fact that the fibers of H are reduced and from Lemma 7.5, that the morphism $\mu \circ (f^p \times_S f^p) : X^p \times_S X^p \rightarrow H$ is covering for the (fppf) topology; since this morphism equals $f^{2p} : X^{2p} \rightarrow H$, this concludes the proof of 7.6. ■

Remark 7.6.1. Obviously, the equivalent conditions of 7.6 imply that the sheaf F considered is representable. The converse is false in general: [N.D.E-VI_B-78] for example, if k is of characteristic 0, let $G = G_{a,k}$ and let $f : \operatorname{Spec} k \rightarrow G$ be the morphism given by the point 1 of $G(k)$; then F is represented by the constant k -group $\mathbb{Z}_k$, while $\Gamma_G(f) = G$, hence the monomorphism $\mathbb{Z}_k \hookrightarrow G$ is not surjective.*

Let us place ourselves, for simplicity, under the hypotheses of the particular case of 7.6, and suppose F representable. Then, by EGA IV₃, 8.14.2, F is locally*

<!-- original page 388 -->

of finite presentation over k , hence the question is whether the dominant monomorphism $F \rightarrow \Gamma_G(f)$ is an isomorphism, or equivalently, a closed immersion. This will be the case, by virtue of 1.4.2, if F is quasi-compact, and, by VI_A, 0.5.1, this will be verified if F is connected, hence, in particular (7.2.1), if X is connected and if $f(X)$ contains the unit element of G .*

<!-- label: III.VI_B.7.6.1 -->

Lemma 7.7. Let k be an algebraically closed field, G a k -group locally of finite type, X a geometrically reduced and locally of finite type k -scheme, $f : X \rightarrow G$ a k -morphism and H a group subscheme of G such that $H \subset f(X)$. Set*

text
 $\Gamma'_n = \bigcup_{i=1}^n f^n(X^n), \quad \Gamma'_0 = \Gamma' \cap G(k), \quad H_0 = H(k)$

and assume H_0 is of finite index in Γ'_0 . Then there exists an integer m such that $f^m(X^m) = \Gamma'_m$ (cf. 7.6), and Γ'_m is the union of finitely many translates of H .*

<!-- label: III.VI_B.7.7 -->

For every $n \geq 1$, $f^n(X^n)$ is an ind-constructible part of G (EGA IV₁, 1.9.5 (viii)), the same is therefore true of Γ'_n , so that, since G is a Jacobson scheme, Γ'_0 is dense in Γ' . By hypothesis, there exists a finite sequence $a_1, \dots, a_r$ of points of Γ'_0 such that $\Gamma'_0 = a_1 H_0 \cup \dots \cup a_r H_0$, whence

text
 $\Gamma'_m = \Gamma' = \Gamma'_0 = a_1 H_0 \cup \dots \cup a_r H_0 = a_1 H_0 \cup \dots \cup a_r H_0 = a_1 H \cup \dots \cup a_r H,$

the last equality resulting from the fact that translation by a_i is a homeomorphism of G onto G . One has therefore $\Gamma'_m = a_1 H \cup \dots \cup a_r H$. On the other hand, it is clear that there exists an integer p such that each of the a_i ($1 \leq i \leq r$) belongs to $f^p(X^p)$. Finally, since $H \subset f(X)$, one has, for every i : $a_i H \subset f^{p+1}(X^{p+1})$, so that $f^{p+1}(X^{p+1}) = \Gamma'_m$. ■

Proposition 7.8. Let G be a k -group locally of finite type, A and B two geometrically reduced group sub- k -schemes (hence smooth at the generic points of their irreducible components, hence smooth by 1.3) of G . Suppose one of the following conditions a) or b) is satisfied:*

a) A and B are invariant and of finite type over k .*

b) A is connected and B is of finite type over k .*

Then (A, B) is of finite type over k , and represents the sheaf associated for the (fppf) topology (or (fpqc)) with the presheaf in groups of commutators of A and B in G . Moreover, [N.D.E-VI_B-79] the k -groups (A, B^0) and (A^0, B) are connected, and one has*

text
 $(A, B)^0 = (A, B^0) \cdot (A^0, B).$

...

<!-- label: III.VI_B.7.8 -->

Proof. By 7.6, to show that (A, B) is the desired associated sheaf, it suffices to show that there exists an integer n such that $\nu^n((A \times_k B)^n) = (A, B)$ (notations of 7.2.2). To show this, as well as to show the two other assertions, we may suppose

<!-- original page 389 -->

k algebraically closed. Indeed, let $\bar{k}$ be an algebraic closure of k . By 7.1 (iii) and VI_A 2.4, one has, with obvious notations:

```
```text
(A, B)_{k^-} = (A_{k^-}, B_{k^-}), ((A, B)^\circ)_{k^-} = (A_{k^-}, B_{k^-})^\circ, (A, B^\circ)_{k^-} = (A_{k^-}, B^\circ_{k^-}), etc.
```
```

Consequently, if one shows that $(A_{\bar{k}}, B_{\bar{k}})$ is of finite type over $\bar{k}$ (resp. that $(A_{\bar{k}}, B^{\circ}_{\bar{k}})$ and $(A^{\circ}_{\bar{k}}, B_{\bar{k}})$ are connected, and that the morphism $(A_{\bar{k}}, B^{\circ}_{\bar{k}}) \times_{(A_{\bar{k}}, B_{\bar{k}})} (A^{\circ}_{\bar{k}}, B_{\bar{k}}) \rightarrow (A_{\bar{k}}, B_{\bar{k}})$ is surjective), then the analogous assertions will be true over k , by EGA IV₂, 2.7.1 and 2.6.1.

Let then $B_1, \dots, B_p$ be the connected components of B other than the neutral component B° (these are finite in number since B is supposed of finite type over k , hence noetherian), and in case (a), let similarly $A_1, \dots, A_q$ be those of A . (In case (b), one will consider only $A^{\circ} = A$). Let ν_{ij} be the restriction of ν to $A_i \times_k B_j$. Then each of the A_i and B_j is irreducible (VI_A 2.4.1), so the same is true of $A^{\circ} \times_k B_j$ and $A_i \times_k B^{\circ}$. Since the neutral element of G belongs to A° and B° , it belongs to $\nu_{0j}(A^{\circ} \times_k B_j)$ and to $\nu_{i0}(A_i \times_k B^{\circ})$. Then each of the $\Gamma_G(\nu_{0j})$ and $\Gamma_G(\nu_{i0})$ is connected (7.2.1). Similarly, if u_{0j} (resp. u_{i0}) denotes the injection of $\Gamma_G(\nu_{0j})$ (resp. $\Gamma_G(\nu_{i0})$) into G , then

```
```text
(A^\circ, B) = \Gamma_G((u_{0j})_{j=0}^p) and (A, B^\circ) = \Gamma_G((u_{i0})_{i=0}^q)
```
```

are connected. Moreover, one easily deduces from 7.4 and the preceding constructions that there exists an index r such that (A°, B) and (A, B°) are included in $\nu^r((A \times_k B)^r)$. In case b), one has $(A, B) = (A^{\circ}, B)$, and we are done.

Let us now place ourselves in case (a). [N.D.E-VI_B-80] We already know that (A°, B) and (A, B°) are smooth and connected sub- k -groups of G , hence of finite type (cf. VI_A, 2.4). On the other hand, since A° is a characteristic subgroup of A (cf. VI_A, 2.6.5), it is an invariant subgroup of G and hence, by 7.3 (v), (A°, B) is an invariant subgroup of G , and similarly for (A, B°) . Hence, by 7.1.1, the subgroup H of G generated by (A, B°) and (A°, B) is none other than $(A, B^{\circ}) \cdot (A^{\circ}, B)$. In particular, one has therefore $H \subset \nu^{2r}((A \times_k B)^{2r})$.

Given a part X of G stable for the group law (cf. 3.0), we shall denote by X_0 the group of k -points of G belonging to X . Set $\Gamma' = \bigcup_{q \geq 1} \nu^q((A \times_k B)^q)$. Then, by Proposition 7.9 below, one has:

```
```text
(A^\circ, B)_0 = (A^\circ_0, B_0), (A, B^\circ)_0 = (A_0, B^\circ_0) and \Gamma'_0 = (A_0, B_0),
```
```

so that $H_0 = (A^{\circ}_0, B_0) \cdot (A_0, B^{\circ}_0)$ is of finite index in Γ'_0 (Bible, Exp. 3, Appendix) since A°_0 and B°_0 are invariant, and A°_0 (resp. B°_0) is of finite index in A_0 (resp. B_0). We are then in the conditions of Lemma 7.7: since $H \subset \nu^{2r}((A \times_k B)^{2r})$, there exists an integer m such that $\nu^{2rm}((A \times_k B)^{2rm}) = (A, B)$, and there exists a finite sequence $a_1, \dots, a_n$ of k -points of G such that: $(A, B) = a_1 H \cup \dots \cup a_n H$. Then, since H is of finite type over k , each of the $a_i H$ is quasi-compact, hence their union (A, B) is quasi-compact, hence of finite type over k . Since H is irreducible, the same is true of each of the $a_i H$, and since $e \in H$, it is clear that $H = (A, B)^{\circ}$. ■

<!-- original page 390 -->

****Proposition 7.9.**** *Let k be an algebraically closed field, G a k -group locally of finite type.*

(i) Let A and B be two ind-constructible parts of G . Denote by A_0 the set of rational points of G belonging to A . Then $(A \cdot B)_0 = A_0 \cdot B_0$, the second product being taken in the group $G(k)$.*

(ii) Let X be a geometrically reduced and locally of finite type k -scheme, and $f : X \rightarrow G$ a k -morphism. Set $\Gamma'_G(f) = \bigcup_{n \geq 1} f^n(X^n)$. Then $\Gamma'_G(f)_0$ is the subgroup of $G(k)$ generated by $f(X)_0$.*

(iii) In particular, let A and B be two smooth group subschemes of G ; set $\Gamma'_G = \bigcup_{n \geq 1} \nu^n(A \times_k B)^n$ (notations of 7.2.2). Then Γ'_G is the group of commutators of $A(k)$ and $B(k)$ in $G(k)$.*

<!-- label: III.VI_B.7.9 -->

Let us prove (i). It is clear that $A_0 \cdot B_0 \subset (A \cdot B)_0$. Conversely, let $z \in (A \cdot B)_0$. Then $\mu^{-1}(z)$ is a closed subset of $G \times_k G$, and $A \times_k B$ (cf. 3.0) is an ind-constructible part of $G \times_k G$, so that $\mu^{-1}(z) \cap (A \times_k B)$ is a non-empty ind-constructible part of $G \times_k G$; by EGA IV₃, 10.4.8, it therefore contains a rational point of $G \times_k G$, whose projections x and y are rational points of G such that $x \in A$, $y \in B$ and $x \cdot y = z$, so that $(A \cdot B)_0 = A_0 \cdot B_0$.

To prove (ii), note that, f^n being locally of finite type, $f^n(X^n)$ is an ind-constructible part of G (EGA IV₄, 1.9.5 (viii)). Assertion (i) then allows one to show by induction that, if one sets $A = f(X)_0$, one has: $f^n(X^n)_0 = (A \cup A^{-1})^n$, and consequently,

```
```text
Γ'_G(f)_0 = ⋃_{n ≥ 1} f^n(X^n)_0 = ⋃_{n ≥ 1} (A ∪ A-1)n,
```

which is the subgroup of  $G(k)$  generated by  $A = f(X)_0$ .

Finally, (iii) follows from (ii) and the definitions. ■

**\*\*Corollary 7.10.\*\*** \*Under the conditions of 7.8, if  $k$  is algebraically closed, then  $(A, B)(k)$  is the commutator subgroup of  $A(k)$  and  $B(k)$  in  $G(k)$ .\*

<!-- label: III.VI\_B.7.10 -->

Indeed, it suffices to apply 7.9 (iii), 7.8 and 7.6.

**## 8. Solvable or nilpotent group schemes**

<!-- label: III.VI\_B.8 -->

**### 8.1.**

Let  $\mathcal{C}$  be a category equipped with a topology  $T$  (cf. IV § 4). For every presheaf  $P$  on  $\mathcal{C}$ , we denote by  $P^\flat$  the associated sheaf.

Let  $G$  be a presheaf in groups on  $\mathcal{C}$ ,  $A$  and  $B$  two sub-presheaves in groups of  $G$ , and let  $\text{Comm}(A, B)$  be the presheaf in groups of commutators of  $A$  and  $B$  in  $G$ ; i.e., for every  $S \in \text{Ob } \mathcal{C}$ ,  $\text{Comm}(A, B)(S)$  is the subgroup of  $G(S)$  generated by the commutators  $a b a^{-1} b^{-1}$ , with  $a \in A(S)$  and  $b \in B(S)$ . We write

```
```text
Comm_T(A, B) = Comm(A, B)^\flat.
```

In the proof of 8.2, we shall need the following results.[^N.D.E-VI_B-81]

****Lemma 8.1.1.**** *Let $A \subset G$ be sheaves in groups, with A invariant in G .*

(i) $\text{Comm}_T(G, A)$ is the smallest invariant sub-sheaf in groups C of G such that the sheaf $(A/C)^\flat$, associated with the quotient presheaf A/C , is central in $(G/C)^\flat$.*

(ii) In particular, $\text{Comm}_T(G, G)$ is the smallest invariant sub-sheaf in groups C of G such that the quotient sheaf $(G/C)^{\flat}$ is commutative.

<!-- label: III.VI_B.8.1.1 -->

Obviously, (ii) is the particular case $A = G$ of (i), so it suffices to show (i). Let C be a sub-sheaf in groups of A , invariant in G , and such that the quotient sheaf $(A/C)^{\flat}$ is central in $(G/C)^{\flat}$. By Lemma IV 4.4.8.1, the presheaves A/C and G/C are separated, hence, by IV 4.3.11, all the morphisms in the diagram below are monomorphisms:

$$\begin{array}{ccc} A/C & \longrightarrow & G/C \\ \downarrow & & \downarrow \\ (A/C)^{\flat} & \twoheadrightarrow & (G/C)^{\flat} \end{array}$$

Since $(A/C)^{\flat}$ is central in $(G/C)^{\flat}$, then A/C is central in G/C , whence $\text{Comm}(G, A) \subset C$, and hence C contains $\text{Comm}_T(G, A)$, by IV 4.3.12.

Conversely, $\text{Comm}(G, A)$ is a sub-presheaf in groups of A , invariant in G , and separated (cf. IV 4.3.1, N.D.E. (24)), hence, by IV 4.4.8.2 (i) and IV 4.3.11, $C = \text{Comm}_T(G, A)$ is a sub-sheaf in groups of A , invariant in G and containing $\text{Comm}(G, A)$. Consequently, the presheaf A/C is central in G/C and hence, by IV 4.4.8.2 (ii), $(A/C)^{\flat}$ is central in $(G/C)^{\flat}$. This proves Lemma 8.1.1. ■

Lemma 8.1.2. *Let G be a sheaf in groups, A, B two sub-presheaves in groups of G .*

(i) The morphism $\tau : \text{Comm}(A, B) \rightarrow \text{Comm}(A^{\flat}, B^{\flat})$ is a covering monomorphism.

(ii) Consequently, one has an isomorphism

$$\text{Comm}_T(A, B) \cong \text{Comm}_T(A^{\flat}, B^{\flat}).$$

<!-- label: III.VI_B.8.1.2 -->

Proof. (i) As A (resp. B) is a sub-presheaf of G , then $A^{\flat}$ (resp. $B^{\flat}$) is a sub-presheaf of G containing A (resp. B), and it follows that τ is a monomorphism.

Let us show that τ is covering. Let $S \in \text{Ob } \mathcal{C}$ and $g \in \text{Comm}(A^{\flat}, B^{\flat})(S)$. Then, there exists an integer $n \geq 1$ and, for $i = 1, \dots, n$, elements $a'_i \in A^{\flat}(S)$, $b'_i \in B^{\flat}(S)$, and $\epsilon_i \in \pi_1$, such that

$$g = (a'_1, b'_1)^{\epsilon_1} \cdots (a'_n, b'_n)^{\epsilon_n},$$

<!-- original page 392 -->

where (a, b) denotes the commutator $aba^{-1}b^{-1}$, and there exists a refinement R of S such that $a'_i \in A(R)$ and $b'_i \in B(R)$ for every i . Then g is the composite morphism

$$R \xrightarrow{\tau} (a'_1, \dots, b'_n) \rightarrow (A \times B)^n \xrightarrow{\Phi(\epsilon_1, \dots, \epsilon_n)} \text{Comm}(A, B),$$

where $\Phi = \Phi_{\epsilon_1, \dots, \epsilon_n}$ is the morphism defined set-theoretically by:

$$\Phi(a_1, b_1, \dots, a_n, b_n) = (a_1, b_1)^{\epsilon_1} \cdots (a_n, b_n)^{\epsilon_n},$$

for every $T \in \text{Ob } \mathcal{C}$ and $a_i \in A(T)$, $b_i \in B(T)$. This shows that $g \in \text{Comm}(A, B)(R)$ and it follows, as in the proof of IV 4.3.11 (i), that $\text{Comm}(A, B) \rightarrow \text{Comm}(A^{\flat}, B^{\flat})$ is covering.

As $\text{Comm}(A^{\{\flat\}}, B^{\{\flat\}}) \rightarrow \text{Comm}(A^{\{\flat\}}, B^{\{\flat\}})^{\{\flat\}}$ is also a covering monomorphism (IV 4.3.11 (iv)), the same is true of $\text{Comm}(A, B) \rightarrow \text{Comm}(A^{\{\flat\}}, B^{\{\flat\}})^{\{\flat\}}$, hence, by IV 4.3.12, one obtains an isomorphism:

```
```text
Comm(A, B)^b ≅ Comm(A^b, B^b)^b.
```
```

This proves Lemma 8.1.2. ■

Proposition 8.2. *Let $\mathcal{C}$ be a category, $\mathcal{T}$ a topology on $\mathcal{C}$, $\mathcal{G}$ a sheaf in groups on $\mathcal{C}$, n an integer ≥ 0 . The following conditions are equivalent:*

(i) If one sets $K_{\{0\}} = \mathcal{G}$, and for $p \geq 1$, $K_{\{p\}} = \text{Comm}(K_{\{p-1\}}, K_{\{p-1\}})$ (resp. $K_{\{p\}} = \text{Comm}(\mathcal{G}, K_{\{p-1\}})$), then $K_{\{n\}}$ is the unit presheaf in groups.*

(ii) If one sets $K'_{\{0\}} = \mathcal{G}$, and for $p \geq 1$, $K'_{\{p\}} = \text{Comm}_{\mathcal{T}}(K'_{\{p-1\}}, K'_{\{p-1\}})$ (resp. $K'_{\{p\}} = \text{Comm}_{\mathcal{T}}(\mathcal{G}, K'_{\{p-1\}})$), then $K'_{\{n\}}$ is the unit sheaf in groups.*

(iii) There exists a sequence $\mathcal{G} = H_{\{0\}} \supset H_{\{1\}} \supset \cdots \supset H_{\{n\}}$ of invariant sub-sheaves of $\mathcal{G}$, such that, whatever i , the quotient sheaf $H_{\{i\}}/H_{\{i+1\}}$ is commutative (resp. central in $\mathcal{G}/H_{\{i+1\}}$), and $H_{\{n\}}$ is the unit sheaf.*

<!-- label: III.VI_B.8.2 -->

It is clear that $K_{\{n\}} \subset K'_{\{n\}}$; consequently (ii) entails (i). Let us show that (i) entails (ii). One has $K'_{\{1\}} = \text{Comm}_{\mathcal{T}}(\mathcal{G}, \mathcal{G}) = K^{\{\flat\}}_{\{1\}}$, and one deduces by induction from Lemma 8.1.2 that $K'_{\{p\}} = K^{\{\flat\}}_{\{p\}}$ for every p . Consequently, if $K_{\{n\}}$ is the unit presheaf, then $K'_{\{n\}} = K^{\{\flat\}}_{\{n\}}$ is the unit sheaf.

Finally, conditions (ii) and (iii) are equivalent by Lemma 8.1.1. ■

Definition 8.2.1. *When these conditions are satisfied, the sheaf $\mathcal{G}$ is said to be solvable of class n (resp. nilpotent of class n). When there exists an integer n such that these conditions are satisfied, one says that $\mathcal{G}$ is solvable (resp. nilpotent).*

Note that, by condition (i), this does not depend on the topology $\mathcal{T}$.

<!-- label: III.VI_B.8.2.1 -->

Proposition 8.3. *Let k be a field, S a non-empty k -scheme, Ω an algebraically closed extension of k , $\mathcal{G}$ a smooth k -group of finite type. The following conditions are equivalent:*

(i) $\mathcal{G}$ is solvable of class n (resp. nilpotent of class n).*

(ii) $\mathcal{G} \times_k S$ is solvable of class n (resp. nilpotent of class n).*

(iii) The group $\mathcal{G}(\Omega)$ is solvable of class n (resp. nilpotent of class n).*

<!-- original page 393 -->

(iv) If one sets $K_{\{0\}} = \mathcal{G}$ and considers, for $p \geq 1$, the k -groups $K_{\{p\}} = (K_{\{p-1\}}, K_{\{p-1\}})$ (resp. $K_{\{p\}} = (\mathcal{G}, K_{\{p-1\}})$) (cf. 7.2.2), then $K_{\{n\}}$ is the unit k -group.*

<!-- label: III.VI_B.8.3 -->

The equivalence of conditions (i) and (ii) follows from Proposition 8.2, given that the formation of the presheaf in groups of commutators commutes with base change (IV 4.1.3).

The equivalence of (i) and (iv) follows from the fact that, by 7.8, the k -group $K_{\{p\}} = (K_{\{p-1\}}, K_{\{p-1\}})$ (resp. $K_{\{p\}} = (\mathcal{G}, K_{\{p-1\}})$) represents the sheaf $\text{Comm}_{\mathcal{T}}(K_{\{p-1\}}, K_{\{p-1\}})$ (resp. $\text{Comm}_{\mathcal{T}}(\mathcal{G}, K_{\{p-1\}})$), where $\mathcal{T}$ is the (fppf) (or (fpqc)) topology.

To show that conditions (iii) and (iv) are equivalent, one may suppose $k = \Omega$, and then the equivalence of conditions (iii) and (iv) follows from 7.10. ■

****Proposition 8.4.**** *Let G_S be an S_S -group of finite presentation, such that for every $s \in S$, G_s is smooth over $\kappa(s)$. Let T be the set of $s \in S$ such that G_s is solvable (resp. nilpotent).*

***(i)** Then T is locally constructible in S .*

***(ii)** If one moreover assumes G_S flat and separated over S (i.e. when G_S is smooth, quasi-compact and separated over S), then T is closed in S .*

<!-- label: III.VI_B.8.4 -->

Proof. It is clear that one may suppose S affine with ring A . There exists then, by 10.1 and 10.10 b), [VI_B -8-1] a noetherian subring A' of A and an A' -group of finite type G' such that $G' \otimes_{A'} A$ is isomorphic to G_S . By EGA IV₃, 11.2.6 and 8.10.5, [N.D.E-VI_B -82] if G_S is flat and separated over S , one may suppose G' flat and separated over $S' = \operatorname{Spec} A'$. [N.D.E-VI_B -83] As G_S is of finite presentation over S , then (EGA IV₃, 9.7.7) the set of $s \in S$ such that G_s is geometrically reduced (or, equivalently, smooth over $\kappa(s)$) is locally constructible. Hence, by EGA IV₃, 9.3.3, one may suppose that, for every $s' \in S'$, $G'_{s'}$ is smooth over $\kappa(s')$. On the other hand, if $s \in S$ denotes the image of s' in S , one has: $G'_{s'} \otimes_{\kappa(s')} \kappa(s) \simeq G_s$. Hence, by 8.3, for G_s to be solvable (resp. nilpotent), it is necessary and sufficient that the same be true of $G'_{s'}$. We are therefore reduced to the case where S is a noetherian affine scheme.

Let us show then that T is constructible. By applying the criterion (EGA 0_III, 9.2.3), one sees, reasoning as before, that one is reduced to showing that, in the case where S is noetherian and integral, either T or $S - T$ contains a non-empty open of S .

Suppose then S integral and noetherian, with generic point η . Set, whatever $s \in S$, $K^{\{0\}}_s = G_s$, and $K^{\{p\}}_s = (K^{\{p-1\}}_s, K^{\{p-1\}}_s)$ (resp. $K^{\{p\}}_s = (G, K^{\{p-1\}}_s)$). Let us first show that the sequence of closed subschemes $K^{\{p\}}_{\eta}$ is stationary. It follows from 7.3 (v) that each of the $K^{\{p\}}_{\eta}$ is invariant, hence the sequence of $K^{\{p\}}_{\eta}$ is decreasing; this sequence is then stationary since G_{η} is noetherian; there exists therefore an integer n such that, for every $p \geq n$, one has: $K^{\{p\}}_{\eta} = K^{\{n\}}_{\eta}$.

On the other hand, by 10.12.1 and 10.13, there exists a non-empty open S' of S and

<!-- original page 394 -->

an S' -group of finite presentation D such that for every $s \in S'$, one has $D_s = K^{\{n\}}_s$ and $(D_s, D_s) = D_s$ (resp. $(G_s, D_s) = D_s$). We may suppose $S' = S$. Then, whatever $s \in S$, and whatever $p \geq n$, one has $D_s = K^{\{p\}}_s$, so that G_s is solvable (resp. nilpotent) if and only if D_s is isomorphic to the unit $\kappa(s)$ -group.

But by EGA IV₃, 9.6.1 (xi), the set of $s \in S$ such that the structural morphism $D_s \rightarrow \operatorname{Spec} \kappa(s)$ is an isomorphism is constructible, [N.D.E-VI_B -84] hence is either rare or contains a non-empty open of S . We have therefore obtained that T is locally constructible.

Let us show that if, moreover, G_S is flat and separated over S , then T is closed. Since T is locally constructible, for T to be closed, it is necessary and sufficient that T be stable under specialization (cf. EGA IV₁, 1.10.1).

Let then $s \in S$ and s' a specialization of s in S . Since one has reduced to the case where S is noetherian, then, by EGA II, 7.1.9, there exists a discrete valuation ring A and a morphism $\operatorname{Spec}(A) \rightarrow S$ such that s (resp. s') is the image of the generic point α (resp. of the closed point a) of $\operatorname{Spec}(A)$. It suffices then to show that if one sets $G' = G \otimes_S A$, and if G'_{α} is solvable (resp. nilpotent), then so is G'_a . Note that, since G_S is flat and separated over S , G'_{α} is flat and separated over A , so we are reduced to the case where S is the spectrum of a discrete valuation ring A .

Then, since G'_{α} is supposed solvable (resp. nilpotent), there exists an integer q such that $K^{\{q\}}_{\alpha}$ (with the notations introduced above) is isomorphic to the unit $\kappa(\alpha)$ -group. For every n , let $\bar{K}^{\{n\}}_{\alpha}$ denote the schematic closure (in the sense of EGA IV₂, 2.8.5) of $K^{\{n\}}_{\alpha}$ in G_S . Let us show, by induction on p , that $(\bar{K}^{\{p\}}_{\alpha})_a \subset K^{\{p\}}_a$. Note first that, since G_S is flat over A , then G'_{α} is equal to $G_S^{\sim}$ (EGA IV₂, 2.8.5), so $(\bar{K}^{\{0\}}_{\alpha})_a = K^{\{0\}}_a$.

Let $p \geq 0$. Suppose we have established that $K^{\{p\}}_a \subset (\bar{K}^{\{p\}}_{\alpha})_a$, and denote by $\nu_a, \nu_{\alpha}, \nu, \bar{\nu}_a$ the following morphisms, defined as in 7.2.2:

```

```text
 solvable case
v_a : K^p_a x_{\kappa(a)} K^p_a \to G_a, resp.
v_\alpha : K^p_\alpha x_{\kappa(\alpha)} K^p_\alpha \to G_\alpha, resp.
v^- : K^p_\alpha x_A K^p_\alpha \to G, resp.
v^-_a : (K^p_\alpha)_a x_{\kappa(a)} (K^p_\alpha)_a \to G_a, resp.

 nilpotent case
G_a x_{\kappa(a)} K^p_a \to G_a,
G_\alpha x_{\kappa(\alpha)} K^p_\alpha \to G_\alpha,
G x_A K^p_\alpha \to G,
G_a x_{\kappa(a)} (K^p_\alpha)_a \to G_a.

```

Since  $\bar{K}^{\{p+1\}}_{\alpha}$  factors through  $K^{\{p+1\}}_{\alpha}$ , then  $\bar{K}^{\{p+1\}}_{\alpha}$  factors through  $\bar{K}^{\{p+1\}}_{\alpha}$ , which is obviously a group subscheme of  $G$ , hence  $\bar{K}^{\{p+1\}}_{\alpha}$  contains  $\Gamma_{\alpha}$ . By 7.1 (iii), one has  $\Gamma_{\alpha} = \Gamma_{\alpha}(\bar{K}^{\{p+1\}}_{\alpha})$ ; and, by the induction hypothesis,

```

```text
K^p_a x_{\kappa(a)} K^p_a \subset (K^p_\alpha)_a x_{\kappa(a)} (K^p_\alpha)_a      resp.      G_a x_{\kappa(a)} K^p_a \subset G_a x_{\kappa(a)} (K^p_\alpha)_a,

```

so that $\bar{K}^{\{p+1\}}_{\alpha} = \Gamma_{\alpha}(\bar{K}^{\{p+1\}}_{\alpha}) \subset \Gamma_{\alpha}(\bar{K}^{\{p+1\}}_{\alpha}) = \Gamma_{\alpha}(\bar{K}^{\{p+1\}}_{\alpha}) \subset \bar{K}^{\{p+1\}}_{\alpha}$.

<!-- original page 395 -->

But since $\bar{K}^{\{q\}}_{\alpha}$ is isomorphic to the unit $\kappa(\alpha)$ -group, and the unit A -group is flat over A and is isomorphic to a closed subscheme of G (since G is separated over A , cf. 5.1), it follows from EGA IV₂, 2.8.5 that the schematic closure $\bar{K}^{\{q\}}_{\alpha}$ is isomorphic to the unit A -group. As we just saw that $\bar{K}^{\{q\}}_{\alpha} \subset \bar{K}^{\{q\}}_{\alpha}$, this entails that $\bar{K}^{\{q\}}_{\alpha}$ is isomorphic to the unit $\kappa(\alpha)$ -group, so that G_{α} is solvable (resp. nilpotent). ■

9. Quotient sheaves

<!-- label: III.VI_B.9 -->

The present number is limited essentially to a reminder, in the particular case of homogeneous spaces of groups, of well-known general facts about passage to the quotient by flat equivalence relations (cf. Exp. IV).

Definition 9.1. *Given a monomorphism $u : G' \rightarrow G$ of S -groups, one denotes by G/G' (resp. $G \backslash G'$), and calls *right (resp. left) quotient sheaf of G by G' , the sheaf (for the (fpqc) topology) quotient of G by the equivalence relation defined by the monomorphism:

```

```text
G x_S G' \rightrightarrows G x_S G (resp. G' x_S G \rightrightarrows G x_S G),

```

\*where  $\delta$  (resp.  $\gamma$ ) denotes the automorphism of  $G \times_S G$  defined by  $(g, h) \mapsto (g, gh)$  (resp.  $(h, g) \mapsto (hg, g)$ ) for  $g, h \in G(T)$ .

<!-- label: III.VI\_B.9.1 -->

**Proposition 9.2.** \*Let  $u : G' \rightarrow G$  be a monomorphism of  $S$ -groups. Suppose that  $G/G'$  is representable by an  $S$ -scheme  $G''$ . Then:

(i) The canonical morphism  $p : G \rightarrow G''$  is covering for the (fpqc) topology.

(ii) If one sets  $\epsilon = p \circ u$  (this morphism is called the unit section of  $G''$ ), the following diagrams are cartesian:

```

```text
G x_S G' \rightrightarrows G x_S G      G' \rightrightarrows G
|      |      |      |      |      |      |      |
pr_1   |      p     p     p     p     p     p
|      |      |      |      |      |      |
G \rightrightarrows G''      S \xrightarrow{\epsilon} G''.

```

*In particular, u is an immersion.

(iii) There exists on G' a unique structure of S -scheme with left operator group G , such that p is a morphism of S -schemes with operator group G .

(iv) If one moreover supposes G' invariant in G , there exists on G' a unique structure of S -group such that p is a morphism of S -groups.

(v) Let S_0 be an S -scheme; set $G_{\{0\}} = G \times_S S_0$, and $G'_{\{0\}} = G' \times_S S_0$; then $G_{\{0\}}/G'_{\{0\}}$ is representable by $G'_{\{0\}} = G' \times_S S_0$.[^N.D.E-VI_B-85]

(vi) Let P be a property for an S -morphism. Suppose P stable under base change; then if $p : G \rightarrow G'$ satisfies P , the same is true of the structural morphism $\pi' : G' \rightarrow S$.

<!-- original page 396 -->

(vii) Let P be a property for an S -morphism. Suppose P is local in nature for the (fpqc) topology (cf. 2.0 and 2.1.2). Then, for the morphism $p : G \rightarrow G'$ to satisfy P , it is necessary and sufficient that the same be true of $\pi' : G' \rightarrow S$.

(viii) Let P be a property for an S -morphism; suppose P is local in nature for the (fpqc) topology, and stable under composition; then, if the structural morphisms $G' \rightarrow S$ and $G' \rightarrow S$ satisfy P , the same is true of the structural morphism $G \rightarrow S$.

(ix) Suppose G reduced; then G' is reduced.

(x) For G' to be separated over S , it is necessary and sufficient that u (or, equivalently, ϵ) be a closed immersion.

(xi) For G to be flat over S , it is necessary and sufficient that p be a flat morphism (or, equivalently, faithfully flat).

In this case, for G' to be flat over S , it is necessary and sufficient that G be flat over S .

(xii) For G to be flat and locally of finite presentation over S , it is necessary and sufficient that $p : G \rightarrow G'$ be faithfully flat and locally of finite presentation.

In this case, for G' to be locally of finite presentation (resp. locally of finite type, of finite type, smooth, étale, unramified, locally quasi-finite, quasi-finite) over S , it suffices that the same be true of G over S (and the condition is also necessary in the first two cases, cf. (viii)).

(xiii) Suppose G flat and of finite presentation over S .

a) Then p is of finite presentation and faithfully flat;

b) moreover, for G to be of finite presentation over S , it is necessary and sufficient that the same be true of G' .

<!-- label: III.VI_B.9.2 -->

Recall that the equivalence relation under consideration is universally effective (IV 4.4.9). Then assertions (i), (iii), (iv), (v) and the first assertion of (ii) follow from IV 4.4.3, 5.2.2, 5.2.4, 3.4.5 and 3.3.2 (iii). The second assertion of (ii) follows from the first, as the following cartesian diagram shows, since $(G \times_S G') \times_S S$ is isomorphic to G :

$$\begin{array}{ccccc} \text{``text} & & & & \\ G' \rightarrow ((\epsilon \circ \pi'), \text{id}_{\{G'\}}) & \rightarrow & G \times_S G' & \xrightarrow{-\mu} & (G \times_S S) \rightarrow G \\ \downarrow & & \downarrow \text{pr}_1 & & \downarrow p \\ \pi' & & & & p \\ \downarrow & & \downarrow & & \downarrow \\ S & \xrightarrow{\epsilon} & G & \xrightarrow{p} & G'' \end{array}$$

Finally, it is clear that ϵ is an S -section of G' , hence an immersion (EGA I, 5.3.13); by the preceding cartesian diagram, the same is true of u , which completes the proof of (ii). Moreover, (vi) is an immediate

consequence of the second cartesian diagram of (ii).

Let us show (vii). By (i), $\mathcal{P}$ is covering for the (fpqc) topology; hence, by (ii), to show that $\mathcal{P}$ satisfies $\mathcal{P}$, it suffices to show that the first projection $\text{pr}_1 : G \times_S G' \rightarrow G$ satisfies $\mathcal{P}$, which follows from the fact that $\mathcal{P}$ is stable under base change, since pr_1 comes from π by base change.

<!-- original page 397 -->

It is clear that (viii) follows from (vii), since $\pi = \pi' \circ p$, where $\pi' : G' \rightarrow S$ denotes the structural morphism.

Let us show (ix). By (i), $\mathcal{P}$ is an epimorphism; since G is reduced, $\mathcal{P}$ factors through the immersion $G'_{\text{red}} \rightarrow G'$, which is therefore also an epimorphism, hence an isomorphism (IV 4.4.4).

Let us show (x). If G' is separated over S , then ϵ is a closed immersion, by EGA I, 5.4.6. On the other hand, one saw in (ii) that ϵ is a closed immersion if and only if u is. Finally, if u is a closed immersion, then so is $\Delta \circ \text{id}_G \circ \text{id}_G : G \times_S G' \rightarrow G \times_S G$; hence, by Lemma 9.2.1 below, G' is separated over S .

Assertion (xi) follows from (vii) and from EGA IV₂, 2.2.13.

Assertion (xii) follows from (vii), from EGA IV₄, 17.7.5 and 17.7.7, and from the fact that, $\mathcal{P}$ being universally open, whatever $S \in S$, if the underlying space of G_S is discrete, the same is true of the underlying space of G'_S .

Finally, assertion (xiii) follows from (vii), (viii), and from EGA IV₄, 17.7.5. ■

Lemma 9.2.1. *Let X be an S -scheme and R an equivalence relation defined on X by the monomorphism $v : R \rightarrow X \times_S X$. Suppose R effective. Then:*

(i) v is an immersion, and is a closed immersion if $Y = X/R$ is separated.*

(ii) Suppose moreover that Y represents the (fpqc) quotient sheaf of X by R [N.D.E-VI_B-86] and that v is a closed immersion. Then $Y = X/R$ is separated over S .*

<!-- label: III.VI_B.9.2.1 -->

Recall (IV Def. 3.3.2) that the hypothesis " R effective" means that there exists a morphism of S -schemes $p : X \rightarrow Y$ such that the natural morphism $R \rightarrow X \times_S Y$ is an isomorphism. From this one deduces (EGA I, 5.3.5) the following cartesian diagram:

$$\begin{array}{ccc} \text{``text} & & \\ R & \xrightarrow{v} & X \times_S X \\ \downarrow & & \downarrow p \times p \\ Y & \xrightarrow{\Delta_{Y/S}} & Y \times_S Y. \\ \text{``} & & \end{array}$$

Then, since $\Delta_{Y/S}$ is an immersion (EGA I, 5.3.9), the same is true of v . Similarly, if Y is separated over S , $\Delta_{Y/S}$ is a closed immersion, hence so is v .

Conversely, suppose that v is a closed immersion and that Y represents the (fpqc) quotient sheaf of X by R . Then $\mathcal{P}$ is covering for the (fpqc) topology (IV 4.4.3), and hence $\mathcal{P} \times \mathcal{P}$ is too (by base change, $\mathcal{P} \times \text{id}_X$ and $\text{id}_Y \times \mathcal{P}$ are covering, hence so is their composite $\mathcal{P} \times \mathcal{P}$). Hence, by (fpqc) descent (cf. EGA IV₂, 2.7.1), $\Delta_{Y/S}$ is a closed immersion, i.e. Y is separated over S . ■

Remark 9.2.2. *Under the general hypotheses of 9.2, if one assumes G flat and locally of finite presentation over S , then $\mathcal{P}$ is covering for the (fppf) topology, [N.D.E-VI_B-87] by 9.2 (vii), hence assertions (vii) and (viii) of 9.2 can be extended to properties $\mathcal{P}$ local in nature for the (fppf) topology.*

<!-- label: III.VI_B.9.2.2 -->

<!-- original page 398 -->

****Remark 9.3.**** *a) The question of whether a quotient G/G' is representable or not is often delicate; in this seminar we demonstrate the representability of certain particular quotients.*

In general, in order to assert that the quotient G/G' is representable, it is not sufficient to suppose G and G' of finite presentation over S and G' flat over S . Indeed, suppose moreover G smooth with connected fibers. In this case, if G/G' is a scheme, it is separated, by Corollary 5.4, and hence $G' \hookrightarrow G$ is a closed immersion, by 9.2 (x); consequently, if G' is not closed in G , then G/G' is not representable.

To obtain such a counterexample, one may take for S the spectrum of a discrete valuation ring, and set $G = G_{(m,S)}$. Consider moreover an integer $n > 1$, invertible on S ; then $\mu_n = \text{Ker}(G \rightarrow G)$ is a closed subgroup of G étale over S (N.D.E-VI_B-88) (cf. VII_A). Let G' be the open subgroup of μ_n obtained by removing from μ_n the closed part of the closed fiber of μ_n complementary to the origin. Then G' is not closed in G , hence G/G' is not representable. (One can also fabricate such examples where G' is smooth with connected fibers.)

b) It is not excluded that G/G' be representable on the other hand, when G and G' are of finite presentation over S , and G' is flat over S and closed in G . (VI_B-9-1) (N.D.E-VI_B-89) Under these hypotheses, it is known that G/G' is representable in the following particular cases:

1° – S is the spectrum of an Artinian ring (cf. VI_A 3.2 and 3.3.2).*

2° – G' is proper over S and G quasi-projective over S (cf. V 7.1).*

3° – S is locally noetherian of dimension 1 (cf. [An73], Th. 4.C).*

<!-- label: III.VI_B.9.3 -->

10. Passage to the inverse limit in group schemes and in schemes with operator group

<!-- label: III.VI_B.10 -->

10.0.

Let us recall the essential result of EGA IV₃, § 8.8. Suppose given the following situation: S_0 a quasi-compact and quasi-separated scheme, I a filtered increasing preordered set, $(A_i)_{i \in I}$ an inductive system of quasi-coherent commutative S_0 -algebras, $A = \varinjlim A_i$, $S_i = \text{Spec } A_i$ for $i \in I$, and $S = \text{Spec } A$; (N.D.E-VI_B-90) then the category of S -schemes of finite presentation is determined up to equivalence by the data of the categories of S_i -schemes of finite presentation, of the functors between these categories $\rho_{ji} : X_i \mapsto X_i \times_{S_i} S_j$ for $i \leq j$, and the transitivity isomorphisms $\rho_{kj} \circ \rho_{ji} \xrightarrow{\sim} \rho_{ki}$.

Let us be precise. Given $j \in I$, and an S_j -scheme of finite presentation X_j , we shall set, for every $i \in I$ such that $i \leq j$, $X_i = X_j \times_{S_j} S_i$, and $X = X_j \times_{S_j} S$. Then (EGA IV₃, 8.8.2):

(i) Given $j \in I$, and two S_j -schemes of finite presentation X_j and Y_j , the canonical map $\varprojlim_{i \leq j} \text{Hom}_{S_i}(X_i, Y_i) \rightarrow \text{Hom}_S(X, Y)$ is bijective.

(ii) For every S -scheme of finite presentation X , there exists an index $j \in I$, an S_j -scheme of finite presentation X_j and an S -isomorphism $X \xrightarrow{\sim} X_j \times_{S_j} S$.

<!-- original page 386 -->

One concludes (EGA IV₃, 8.8.3) that, whenever one has a diagram $\mathcal{D}$ involving a finite number of objects and arrows of the category of S -schemes of finite presentation, one can find an index $i \in I$ and a diagram $\mathcal{D}_i$ in the category of S_i -schemes of finite presentation, such that the diagram $\mathcal{D}$ comes up to isomorphism from the diagram $\mathcal{D}_i$ by base change $S \rightarrow S_i$. One can even find i and $\mathcal{D}_i$ such that every cartesian square of $\mathcal{D}$ comes from a cartesian square of $\mathcal{D}_i$.

10.1.

Moreover, a great number of common properties for a morphism, stable under base change, possess the following property:

> Let $u : X \rightarrow Y$ be an S -morphism between S -schemes of finite presentation; it comes by base change from an

> $S_{\{j\}}$ -morphism $u_{\{j\}} : X_{\{j\}} \rightarrow Y_{\{j\}}$ between $S_{\{j\}}$ -schemes of finite presentation, by 10.0; then, for u to
> have property P , it is necessary and sufficient that there exist $i \geqslant j$ such that
> $u_{\{i\}} = u_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}}$ has property P .

This is so in the case where P is one of the following properties for a morphism: being separated, surjective, radical, affine, quasi-affine, finite, quasi-finite, proper, projective, quasi-projective, an isomorphism, a monomorphism, an immersion, an open immersion, a closed immersion (EGA IV₃, 8.10.5), flat (EGA IV₃, 11.2.6), smooth, unramified or étale (EGA IV₄, 17.7.8). [N.D.E-VI-B-91]

Note that this is also the case where P is the property of being covering for the (fppf) topology; indeed, given two S -schemes of finite presentation X and Y , and an S -morphism $u : X \rightarrow Y$, it follows from IV, 6.3.1 (i) [N.D.E-VI-B-92] that, for u to be covering for the (fppf) topology, it is necessary and sufficient that there exist an S -scheme Z and an S -morphism $v : Z \rightarrow Y$ faithfully flat and of finite presentation which factors through u .

The aim of this section 10 is to give variants of this kind of results for the category of S -groups of finite presentation, that of S -schemes with operator group, and for certain properties for monomorphisms of groups (being invariant, central with representable quotient sheaf, etc.).

The two preliminary results of this type are the following. (In nos. 10.2 to 10.9 below, we keep the notations introduced in 10.0.)

<!-- original page 400 -->

Lemma 10.2. *Let $G_{\{j\}}$ and $H_{\{j\}}$ be two $S_{\{j\}}$ -groups of finite presentation; set, for every $i \geqslant j$, $G_{\{i\}} = G_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}}$, $G = G_{\{j\}} \times_{S_{\{j\}}} S$, and define similarly $H_{\{i\}}$ and H . Then the canonical map below is bijective:*

```

```text
lim_{i \geq j} Hom_{S_i-gr.}(G_i, H_i) \rightarrow Hom_{S-gr.}(G, H).
```

```

<!-- label: III.VI_B.10.2 -->

Lemma 10.3. *Let G be an S -group of finite presentation; then there exist $j \in I$, an $S_{\{j\}}$ -group of finite presentation $G_{\{j\}}$, and an isomorphism of S -groups $G \cong G_{\{j\}} \times_{S_{\{j\}}} S$.*

<!-- label: III.VI_B.10.3 -->

Assertions 10.2 and 10.3 are easy consequences of 10.0 and 10.1, taking into account the interpretation [N.D.E-VI-B-93] of the structure of S -group given in EGA 0_III, 8.2.5 and 8.2.6.

Lemma 10.4. *Let $u : G \rightarrow H$ be a morphism of S -groups between S -groups of finite presentation. By 10.3 and 10.2, u comes by base change from a morphism $u_{\{j\}} : G_{\{j\}} \rightarrow H_{\{j\}}$ between $S_{\{j\}}$ -groups of finite presentation. Then, for u to be a central monomorphism (resp. an invariant monomorphism), it is necessary and sufficient that there exist $i \geqslant j$ such that $u_{\{i\}} = u_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}}$ has the same property.*

<!-- label: III.VI_B.10.4 -->

This is an immediate consequence of 10.0 and 10.1, taking into account the characterization given in 6.7 of central or invariant monomorphisms of groups.

Corollary 10.5. *Let $G_{\{j\}}$ be an $S_{\{j\}}$ -group of finite presentation. For $G_{\{j\}} \times_{S_{\{j\}}} S$ to be commutative, it is necessary and sufficient that there exist $i \geqslant j$ such that $G_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}}$ is so.*

<!-- label: III.VI_B.10.5 -->

Indeed, it amounts to the same to say that an S -group is commutative, or that, considered as a group subscheme of itself, it is central.

Proposition 10.6. *Let $G_{\{j\}}$ be an $S_{\{j\}}$ -group of finite presentation, $G'_{\{j\}}$ a group subscheme of $G_{\{j\}}$ flat and of finite presentation over $S_{\{j\}}$. For $(G_{\{j\}} \times_{S_{\{j\}}} S)/(G'_{\{j\}} \times_{S_{\{j\}}} S)$ to be representable for the (fpqc) topology, it is necessary and sufficient that there exist $i \geqslant j$ such that $(G_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}})/(G'_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}})$ is so.*

<!-- label: III.VI_B.10.6 -->

This is a consequence of the following more general lemma.

Lemma 10.7. *Let $X_{\{j\}}$ be an $S_{\{j\}}$ -scheme of finite presentation, and $R_{\{j\}}$ an equivalence relation on $X_{\{j\}}$ flat and of finite presentation.*^[N.D.E-VI_B-94] *For the quotient sheaf $(X_{\{j\}} \times_{S_{\{j\}}} S)/(R_{\{j\}} \times_{S_{\{j\}}} S)$ for the topology $T = (fppf)$ or $(fpqc)$ to be representable, it is necessary and sufficient that there exist $i \geq j$, such that the quotient sheaf $(X_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}})/(R_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}})$ for the topology T is so.*

<!-- label: III.VI_B.10.7 -->

Taking into account the statements of EGA IV₂, 8.8.2, 8.8.3, 8.10.5 and 11.2.6 recalled in 10.0, this lemma is a consequence of the following result.

<!-- original page 401 -->

Lemma 10.8. *Let T be the $(fppf)$ or $(fpqc)$ topology; let X be an S -scheme of finite presentation (resp. locally of finite presentation), R an equivalence relation on X defined by a monomorphism $v : R \rightarrow X \times_S X$ such that $\text{pr}_1 \circ v$ is flat and of finite presentation (resp. flat and locally of finite presentation). Then the following conditions are equivalent:*

(i) The quotient sheaf X/R for the topology T is representable.*

(ii) There exist an S -scheme of finite presentation (resp. locally of finite presentation) Y and a faithfully flat morphism $p : X \rightarrow Y$ such that the diagram*

```

``text
(D)  R  --pr_1 o v--> X
      |               |
      pr_2 o v         p
      |               |
      X  --p--> Y
...

```

is cartesian.

<!-- label: III.VI_B.10.8 -->

Let us note first that, by IV, 3.3.2 and 4.4.3, for the sheaf X/R for the topology T to be representable by Y , it is necessary and sufficient that the diagram (D) be cartesian and that p be covering for the topology T .

Let us show that (i) entails (ii). Hypothesis (i) implies that the diagram (D) is cartesian, hence that $\text{pr}_1 \circ v$ is deduced from p by base change by p , and that p is covering for the $(fpqc)$ topology. Hence, by $(fpqc)$ descent (EGA IV₂, 2.7.1), since $\text{pr}_1 \circ v$ is faithfully flat and (locally) of finite presentation, so is p . Then, by EGA IV₄, 17.7.5, since X is (locally) of finite presentation over S , so is Y .

Let us show that (ii) entails (i). It suffices to show that p is covering for the $(fppf)$ topology; now p is faithfully flat by hypothesis, and is locally of finite presentation since X and Y are locally of finite presentation over S (EGA IV₁, 1.4.3 (v)). ■

Lemma 10.9. *Let $G_{\{j\}}$ be an $S_{\{j\}}$ -group of finite presentation, and $G = G_{\{j\}} \times_{S_{\{j\}}} S$. For $G^{\{0\}}$ to be representable, it is necessary and sufficient that there exist $i \geq j$ such that $G_{\{i\}}^{\{0\}} = (G_{\{j\}} \times_{S_{\{j\}}} S_{\{i\}})^{\{0\}}$ is so.*

<!-- label: III.VI_B.10.9 -->

The condition is sufficient, since the functor $G \mapsto G^{\{0\}}$ commutes with base change, by 3.3.

Conversely, suppose $G^{\{0\}}$ representable. Then, by 3.9, $G^{\{0\}}$ is open in G and quasi-compact over S , hence of finite presentation over S , since G is. Then, by 10.3 and 10.1, there exist $i \geq j$ and an open group subscheme $H_{\{i\}}$ of $G_{\{i\}}$ such that $H_{\{i\}} \times_{S_{\{i\}}} S = G^{\{0\}}$. The structural morphism $G^{\{0\}} \rightarrow S$ is connected, i.e. has geometrically connected fibers (VI_A 2.1.1), hence, by EGA IV₃, 9.3.3 and 9.7.7, up to increasing

η , one may suppose that the structural morphism $H_i \rightarrow S$ is connected. Then, by 3.10.1, the underlying space of H_i is none other than $(G_i)^{\{0\}}$, and hence H_i represents $(G_i)^{\{0\}}$. ■

10.10.

Let us recall two very useful particular cases of the situation stated in 10.0 (cf. EGA IV₃, 8.1.2 a) and c)):

<!-- original page 402 -->

a) Given a point x of a scheme X , one sets $S_{\{0\}} = \operatorname{Spec} \mathbb{Z}$ and considers the filtered decreasing projective system $(S_i)_{i \in \mathbb{N}}$ of affine open neighborhoods of x ; then $S = \operatorname{Spec} \mathcal{O}_{X,x}$. In particular, if x is the generic point of an integral scheme X , one finds $S = \operatorname{Spec} \kappa(x)$.

b) One sets $S_{\{0\}} = \operatorname{Spec} \mathbb{Z}$, and considers the family $(A_i)_{i \in \mathbb{N}}$ preordered by inclusion of the finitely generated sub- $\mathbb{Z}$ -algebras of the ring of an affine scheme S . Given that the A_i are noetherian rings, this allows in many cases to pass from the noetherian case to the general case.

We are now going to give two results concerning the particular case considered in a). [N.D.E-VI_B-95]

****Proposition 10.11.**** [N.D.E-VI_B-96] *Let S be an integral scheme with generic point η , G (resp. Y, Z) an S -group (resp. S -schemes) of finite presentation, $u, v, i : Y \rightarrow G$ and $j : Z \rightarrow G$ morphisms of S -schemes. Suppose that $i_{\eta} : Y_{\eta} \rightarrow G_{\eta}$ and $j_{\eta} : Z_{\eta} \rightarrow G_{\eta}$ are closed immersions.*

*Then, there exists a non-empty open S' of S such that the morphisms $i' : Y' \rightarrow G'$ and $j' : Z' \rightarrow G'$ obtained by base change are closed immersions, and such that the functors:

```

```text
Transp(u', v'), Transp_{G'}(i'(Y'), j'(Z')) and Transpstr_{G'}(i'(Y'), j'(Z'))
```

```

resp.

```

```text
Centr(u') and Norm_{G'} i'(Y')
```

```

are representable by closed sub- S' -schemes (resp. sub- S' -groups) of G' , of finite presentation over S' .

<!-- label: III.VI_B.10.11 -->

We shall apply the results of 10.1, first in the situation of 10.10 a), then in that of 10.10 b). Since $G_{\eta}, Y_{\eta}, Z_{\eta}$ are flat over the field $\kappa(\eta)$, G_{η} is separated over $\kappa(\eta)$ (VI_A 0.3), and i_{η}, j_{η} are closed immersions, then, by 10.1, there exists an affine open $S' = \operatorname{Spec} (A')$ of S , a noetherian subring A of A' , A -schemes G_A, Y_A, Z_A , flat and of finite presentation over A , and morphisms $u_A, v_A, i_A : Y_A \rightarrow G_A$ and $j_A : Z_A \rightarrow G_A$, such that G_A is an A -group, separated over A , i_A and j_A are closed immersions, and $G \times_S S' = G_A \otimes_A A'$, etc. As the functors considered for S' are deduced by base change from the analogous functors for $\operatorname{Spec} (A)$, it suffices to establish the result for the latter.

By EGA IV₂, 6.9.2, up to replacing A by a localization $A_{\{f\}}$ (and hence S' by the affine open $S'_{\{f\}}$), one may suppose that G_A, Y_A, Z_A are essentially free over A (in the sense of 6.2.1). [N.D.E-VI_B-97] It follows then from 6.2.4 b) and e) that, under the hypotheses of the statement, the functors considered are representable by closed sub- A -schemes of G_A (hence of finite presentation over A , since A is noetherian and G_A of finite presentation

<!-- original page 403 -->

over A), and these are sub- A -groups of G_A in the case of $\operatorname{Centr}(u_A)$ and of $\operatorname{Norm}_{G_A} i_A(Y_A)$. ■

****Corollary 10.11.1.**** *Let S be an integral scheme with generic point η , G, H, K S -groups of finite presentation, $i : H \rightarrow G$ and $j : K \rightarrow G$ two quasi-compact monomorphisms of S -groups. Then, there exists a non-empty open S' of S such that the morphisms $i' : H' \rightarrow G'$ and $j' : K' \rightarrow G'$ obtained by base change are closed immersions, and such that the functors:

```text  
 $\text{Transp}_{\{G'\}}(H', K')$       and       $\text{Transpstr}_{\{G'\}}(H', K')$       (resp.  $\text{Centr}_{\{G'\}} H'$       and       $\text{Norm}_{\{G'\}} H'$ )  
 ```

are representable by closed sub- S' -schemes (resp. sub- S' -groups) of G' , of finite presentation over S' .

<!-- label: III.VI_B.10.11.1 -->

This follows from the preceding proposition since, by 1.4.2, the hypotheses entail that i_{η} and j_{η} are closed immersions.

Proposition 10.12. *Let S be an integral scheme, G an S -group of finite presentation, A and B two group subschemes of G , of finite presentation over S and with smooth generic fiber. Suppose moreover satisfied one of the following conditions:

a) A has connected generic fiber,*

b) A and B are invariant in G .*

Then, there exists a non-empty open S' of S and a closed group subscheme D' of $G' = G|_{S'}$, of finite presentation over S' , with smooth fibers, which represents the (fppf) sheaf associated with the presheaf in groups of commutators of $A' = A|_{S'}$ and $B' = B|_{S'}$ in G' , and D' has connected fibers in case (a), and is invariant in G' in case (b).*

In particular, for every $s \in S'$, one has $D'_s = (A_s, B_s)$ with the notations of 7.2.2.*

<!-- label: III.VI_B.10.12 -->

Let η be the generic point of S ; set $H_{\eta} = (A_{\eta}, B_{\eta})$. Since A_{η} and B_{η} are smooth, then, by 7.8 in case (a), and 7.3 (v) in case (b), H_{η} is connected (resp. invariant in G_{η}).

We are in the situation of 10.0 corresponding to 10.10 (a); hence, by 10.3 and 10.1, there exists a non-empty open S' of S and a sub- S' -group scheme D' of finite presentation and closed in G' , such that $D'_{\eta} = D' \otimes_{S'} \kappa(\eta)$ equals H_{η} . Moreover, by EGA IV₃, 9.7.7 and 9.3.3, one may suppose that D' has geometrically reduced fibers. In case (a), one may suppose, by EGA IV₃, 9.7.7 and 9.3.3 again, that D' has connected fibers, hence geometrically connected (cf. VI_A, 2.1.1). In case (b), one may suppose, by 10.4, that D' is invariant in G' .

Moreover, we have seen, in the course of the proof of 7.8, that there exists an integer n such that $\nu^n_{\eta}((A_{\eta} \otimes \kappa(\eta) B_{\eta})^n) = D'_{\eta}$, where ν^n_{η} and ν^n_{η} are defined as in 7.2.2 (a) and 7.1 (ii). We may define by the same formulas the morphisms

```text  
 $\nu' : A' \times_{S'} B' \rightarrow G' \quad \text{and} \quad \nu'^n : (A' \times_{S'} B')^n \rightarrow G',$   
 ```

and one has $\nu'^n \otimes_{S'} \kappa(\eta) = \nu^n_{\eta}$.

<!-- original page 404 -->

Consequently, by 10.1, one may choose S' such that the morphism ν'^n is flat and factors through D' , and such that the morphism $\nu'^n : (A' \otimes_{S'} B')^n \rightarrow D'$ thus obtained is surjective. Then, by 7.5, the morphism [N.D.E-VI_B-98]

```text  
 $\nu'^{2n} = \mu \circ (\nu'^n \times_{S'} \nu'^n) : (A' \times_{S'} B')^{2n} \rightarrow D',$   
 ```

is covering for the (fppf) topology. Hence, by 7.6, D' represents the (fppf) sheaf associated with the presheaf of commutators of A' and B' in G' .

Moreover, ν'^n induces, for every $s \in S'$, a surjective morphism $\nu'^n_s : (A_s \otimes_{\kappa(s)} B_s)^n \rightarrow D'_s$. [N.D.E-VI_B-99] Then D'_s is a closed subgroup of G_s containing $\nu^n_s(A_s \otimes_{\kappa(s)} B_s)$, hence also (A_s, B_s) . As ν'^n_s is surjective, D'_s equals (A_s, B_s) and represents, by 7.6, the (fppf) sheaf of commutators of A_s and

B_s in G_s . ■

Corollary 10.12.1. [N.D.E-VI_B-100] Let S be an integral scheme, with generic point η , and G an S -group of finite presentation with smooth fibers. Set $K^{\{0\}}_{\eta} = G_{\eta}$ and $K^{\{p\}}_{\eta} = (K^{\{p-1\}}_{\eta})$ (resp. $K^{\{p\}}_{\eta} = (G, K^{\{p-1\}}_{\eta})$) for every $p \in \mathbb{N}$. Fix $n \in \mathbb{N}$. Then there exists a non-empty open S' of S and a group subscheme D_S invariant in $G|_{S'}$, of finite presentation and with smooth fibers, such that $D_s = K^{\{n\}}_s$ for every $s \in S'$.

<!-- label: III.VI_B.10.12.1 -->

This follows from 10.12, by induction on n .

Corollary 10.13. Let S be an integral scheme with generic point η , G an S -group, H an invariant sub- S -group scheme in G ; suppose G and H of finite presentation over S and with smooth generic fiber. [N.D.E-VI_B-101]

If one has $(H_{\eta}, H_{\eta}) = H_{\eta}$ (resp. $(G_{\eta}, H_{\eta}) = H_{\eta}$), then there exists a non-empty open S' of S such that for every $s \in S'$, one has $(H_s, H_s) = H_s$ (resp. $(G_s, H_s) = H_s$).

<!-- label: III.VI_B.10.13 -->

Indeed, by the proof of 10.12, there exists a non-empty open S' of S and a sub- S' -group scheme D_S of $G|_{S'}$, of finite presentation and with smooth fibers, such that $D_s = (H_s, H_s)$ (resp. $D_s = (G_s, H_s)$) for every $s \in S'$. On the other hand, since $D_{\eta} = H_{\eta}$ and since D_S and H_S are of finite presentation over S' , then, by EGA IV₃, 8.8.2.5, there exists a non-empty open S'' of S' such that $D|_{S''} = H|_{S''}$. For every $s \in S''$, one has therefore $H_s = D_s = (H_s, H_s)$ (resp. $H_s = D_s = (G_s, H_s)$). ■

10.14.

Statements 10.2 and 10.3 concerning the category of S -groups of finite presentation extend to the category of pairs formed by an S -group of finite presentation and an S -scheme of finite presentation with operator group G . To be precise, in the situation recalled at the start of 10.0:

(i) Let $j \in I$ and G_j and G'_j two S_j -groups of finite presentation, H_j (resp. H'_j) an S_j -scheme of finite presentation with operator group G_j (resp. G'_j). Set, for $i \in I$, $i \geq j$, $G_i = G_j \times_{S_j} S_i$ and $G = G_j \times_{S_j} S$, and define similarly G'_i , G' , H_i , H , H'_i .

<!-- original page 405 -->

and H . Denote by $\text{Dihom}_{S\text{-gr.}}((G, H), (G', H'))$ the set of di-morphisms of S -groups and S -schemes with operator group of the pair (G, H) into the pair (G', H') . Then the canonical map

$$\lim_{\leftarrow} \text{Dihom}_{S\text{-gr.}}((G_i, H_i), (G'_i, H'_i)) \rightarrow \text{Dihom}_{S\text{-gr.}}((G, H), (G', H'))$$

is bijective.

(ii) Let G be an S -group of finite presentation and H an S -scheme of finite presentation with operator group G ; there then exists an index $j \in I$, an S_j -group of finite presentation G_j , an S_j -scheme of finite presentation H_j with operator group G_j and a di-isomorphism of S_j -groups and S_j -schemes with operator groups from $(G_j \times_{S_j} S, H_j \times_{S_j} S)$ onto (G, H) .

<!-- label: III.VI_B.10.14 -->

Definition 10.15. [N.D.E-VI_B-102] Let $\mathcal{T}$ be a topology on (Sch/S) , less fine than the canonical topology. Given an S -group scheme G and an S -scheme X with operator group G , one says that X is a* formally homogeneous space under G *(relative to the topology $\mathcal{T}$) if the morphism $\Phi : G \times_S X \rightarrow X \times_S X$, defined by $(g, x) \mapsto (gx, x)$ for every $S' \rightarrow S$ and $g \in G(S')$, $x \in X(S')$, is an epimorphism in the category of sheaves for the topology $\mathcal{T}$, which amounts to saying that Φ is covering for the topology $\mathcal{T}$ (cf. IV 4.4.3).

One says that X is a* homogeneous space *if it is formally homogeneous and if moreover the morphism $X \rightarrow S$ is also

covering for the topology $\mathcal{T}$.

*In particular, one says that X is a formally principal homogeneous space under G if Φ is an isomorphism, and that X is a principal homogeneous bundle (or G -torsor) if Φ is an isomorphism and if moreover the morphism $X \rightarrow S$ is covering for the topology $\mathcal{T}$ (cf. IV 5.1.5 and 5.1.6 (ii)).

<!-- label: III.VI_B.10.15 -->

Proposition 10.16. We place ourselves in the situation considered at the beginning of 10.0. Let $j \in I$, G_j an S_j -group and X_j an S_j -scheme with operator group G_j . Suppose G_j and X_j of finite presentation over S_j .

For $X = X_j \times_{S_j} S$ to be a homogeneous space (resp. a principal homogeneous bundle) under $G = G_j \times_{S_j} S$ for the (fppf) topology, it is necessary and sufficient that there exist an index $i \geq j$ such that $X_i = X_j \times_{S_j} S_i$ is a homogeneous space (resp. a principal homogeneous bundle) under $G_i = G_j \times_{S_j} S_i$.

<!-- label: III.VI_B.10.16 -->

Taking into account 10.14 and EGA IV₃, 8.8.2, 8.8.3 and 8.10.5, the statement follows from the property concerning covering morphisms for the (fppf) topology recalled in 10.1.[^N.D.E-VI_B-103]

11. Affine group schemes

<!-- label: III.VI_B.11 -->

11.0. Reminders.

[^N.D.E-VI_B-C-104] Let $q : X \rightarrow S$ be a quasi-compact and quasi-separated morphism of schemes (cf. EGA IV₁, 1.1 & 1.2), and let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$ -module. Recall that $q_*(\mathcal{F})$ is a quasi-coherent $\mathcal{O}_S$ -module (EGA I, 9.2.1). Moreover, by EGA III, 1.4.15 (completed by EGA IV₁, 1.7.21), one has point (c) below, and the proof of loc. cit. also gives points (a) and (b):

(a) If $\mathcal{F}$ is a filtered inductive limit of quasi-coherent submodules $\mathcal{F}_{\alpha}$, then $q_*(\mathcal{F}) = \varinjlim_{\alpha} q_*(\mathcal{F}_{\alpha})$.

(b) If $\mathcal{E}$ is a flat $\mathcal{O}_S$ -module, the canonical morphism $\mathcal{E} \otimes_{\mathcal{O}_S} q_*(\mathcal{O}_X) \rightarrow q_*(\mathcal{E})$ is an isomorphism.

(c) Let $p : S' \rightarrow S$ be a flat morphism, $q' : X' \rightarrow S'$ the morphism deduced from q by base change, and $\mathcal{F}'$ the inverse image of $\mathcal{F}$ on X' . Then the canonical morphism $p_* q'_*(\mathcal{F}') \rightarrow q_*(\mathcal{F})$ is an isomorphism.

Indeed, let $U = \operatorname{Spec}(A)$ be an arbitrary affine open of S . By hypothesis, $q^{-1}(U)$ is the union of affine opens $V_i = \operatorname{Spec}(B_i)$, for $i = 1, \dots, n$, and each intersection $V_i \cap V_j$ is the union of finitely many affine opens $W_{ijk} = \operatorname{Spec}(C_{ijk})$. Then $\Gamma(U, q_*(\mathcal{F})) = \Gamma(q^{-1}(U), \mathcal{F})$ is the kernel of the morphism

$$\bigoplus_{i=1}^n \Gamma(V_i, \mathcal{F}) \rightarrow \bigoplus_{i,j,k} \Gamma(W_{ijk}, \mathcal{F}).$$

Point (a) follows, since each of the terms above commutes with filtered inductive limits (since the V_i and W_{ijk} are affine, hence quasi-compact). Let us prove (b): $\mathcal{E} = \Gamma(U, \mathcal{E})$ is a flat A -module, and $\Gamma(U, q_*(\mathcal{E}))$ is the kernel $K(\mathcal{E})$ of the morphism

$$\bigoplus_{i=1}^n B_i \otimes_A \mathcal{E} \rightarrow \bigoplus_{i,j,k} C_{ijk} \otimes_A \mathcal{E}$$

and since $\mathcal{E}$ is flat over A , this kernel is identified with $K(A) \otimes_A \mathcal{E} = \mathcal{O}_X(q^{-1}(U)) \otimes_A \mathcal{E}$. Finally, if U' is an arbitrary affine open of S' above U , then $A' = \mathcal{O}(U')$ is a flat A -algebra, and one obtains as above that $\Gamma(q'^{-1}(U'), \mathcal{F}') \xrightarrow{\sim} \Gamma(q^{-1}(U), \mathcal{F})$.

Notation. Let S be a scheme, X an S -scheme, $f : X \rightarrow S$ the structural morphism; we set $\mathcal{A}(X) = f_*(\mathcal{O}_X)$.

****Lemma 11.1.**** *Let X and Y be two S -schemes quasi-compact and quasi-separated over S , $f : X \rightarrow S$ and $g : Y \rightarrow S$ the structural morphisms. Then the canonical homomorphism*

$$\varphi : \mathcal{O}(X) \otimes_{\mathcal{O}_S} \mathcal{O}(Y) \rightarrow \mathcal{O}(X \times_S Y)$$

is an isomorphism in each of the following cases: [N.D.E-VI_B-C-105]

a) f and g are affine,

b) g (or f) is flat and affine,

c) g is flat and $f_*(\mathcal{O}_X)$ is a flat $\mathcal{O}_S$ -module.

!-- label: III.VI_B.11.1 -->

We shall assume, in case (b), that it is g which is flat and affine. Set then $S' = \operatorname{Spec} \mathcal{A}(X)$, $Y' = Y \times_S S'$, $g' = g \times_S S'$, and denote by v the morphism $S' \rightarrow S$:

$$\begin{array}{ccc} Y' & \xrightarrow{\quad} & Y \\ g' \downarrow & & \downarrow g \\ \operatorname{Spec} \mathcal{A}(X) = S' & \xrightarrow{\quad v \quad} & S \end{array}$$

In cases (a) and (b), g is affine and so, by EGA II, 1.5.2, one has:

$$(1) \quad g'_*(\mathcal{O}_{Y'}) = v_* g_*(\mathcal{O}_Y) = \mathcal{O}(Y) \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}.$$

One has the same equality in case (c), by 11.0 (c), since S' is flat over S and g is quasi-compact and quasi-separated.

On the other hand (EGA II 1.2.7), $f : X \rightarrow S$ factors through v by means of a morphism $p : X \rightarrow S'$, and one has $p_*(\mathcal{O}_X) = \mathcal{O}_{S'}$ and $X \times_S Y = X \times_{S'} Y'$. Since f is quasi-separated, so is p (EGA IV₁, 1.2.2), and since f is quasi-compact and v is quasi-separated, p is also quasi-compact (EGA IV₁, 1.2.4). Consider then the cartesian square:

$$\begin{array}{ccc} X \times_S Y & \xrightarrow{p'} & Y' \\ p \downarrow & & \downarrow g' \\ X & \xrightarrow{\quad p \quad} & S' \end{array}$$

In cases (b) and (c), Y is flat over S , hence Y' is flat over S' ; applying 11.0 (c) again, one obtains:

$$(2) \quad p'_*(\mathcal{O}_{X \times_S Y}) = g'_* p_*(\mathcal{O}_X) = g'_*(\mathcal{O}_{S'}) = \mathcal{O}_{Y'},$$

and one has the same equality in case (a), since in this case p and p' are isomorphisms.

Finally, v being affine, one has, by EGA II, 1.4.7, $v_*(F \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}) = F \otimes_{\mathcal{O}_S} \mathcal{A}(X)$ for every quasi-coherent $\mathcal{O}_S$ -module F . Combined with (2) and (1), this gives:

```

```text

$$\square(X \times_S Y) = v_* \, g'_* \, p'_* (0_{X \times_S Y}) = v_* \, g'_* (0_{Y'}) = v_* (\square(Y) \otimes_{0_S} 0_{S'}) = \square(Y) \otimes_{0_S} \square(X).$$

```

■

**Corollary 11.2.** \*The functor  $X \mapsto \operatorname{Spec} \mathcal{A}(X)$ , from the full subcategory of  $(\operatorname{Sch}/S)$  formed of  $S$ -schemes  $X$  flat, quasi-compact and quasi-separated over  $S$ , and such that  $\mathcal{A}(X)$  is a flat  $0_S$ -module, into that of  $S$ -schemes flat and affine over  $S$ , commutes with finite products, hence transforms  $S$ -groups into  $S$ -groups.\*

<!-- label: III.VI\_B.11.2 -->

**Definition 11.3.** \*Given an  $S$ -group  $G$  flat, quasi-compact and quasi-separated over  $S$ , such that  $\mathcal{A}(G)$  is flat over  $0_S$ , [^N.D.E-VI\_B-C-106] we shall denote by  $G_{\text{af}}$ , and call the\* affine envelope \*of  $G$ , the  $S$ -group  $G_{\text{af}} = \operatorname{Spec} \mathcal{A}(G)$ .\*

<!-- label: III.VI\_B.11.3 -->

**Proposition 11.3.1.** [^N.D.E-VI\_B-C-107] \*The canonical morphism  $\tau_G : G \rightarrow G_{\text{af}}$  is a morphism of  $S$ -groups. Moreover, it satisfies the following universal property:\*

(i) For every morphism of  $S$ -schemes  $\phi : G \rightarrow H$ , where  $H$  is affine over  $S$ , there exists a unique morphism of  $S$ -schemes  $\phi' : G_{\text{af}} \rightarrow H$  such that  $\phi = \phi' \circ \tau_G$ .\*

(ii) If moreover  $H$  is an  $S$ -group and if  $\phi$  is a morphism of  $S$ -groups, then so is  $\phi'$ .\*

<!-- label: III.VI\_B.11.3.1 -->

### 11.4.

[^N.D.E-VI\_B-C-108] Let  $E$  and  $F$  be two quasi-coherent  $0_S$ -modules. Consider the  $S$ -functor  $\operatorname{Hom}_{0_S}(W(E), W(F))$  (cf. I, 3.1.4), i.e. for every  $S$ -scheme  $f : X \rightarrow S$ ,

```

```text

$$\operatorname{Hom}_{0_S}(W(E), W(F))(X) = \operatorname{Hom}_{0_X}(W(E)_X, W(F)_X).$$

```

Moreover, by I, 4.6.2, one has $W(E)_X = W(f^*(E))$ (and similarly for F) and

```

```text

$$\operatorname{Hom}_{0_X}(W(f^*(E)), W(f^*(F))) = \operatorname{Hom}_{0_X}(f^*(E), f^*(F)).$$

```

One thus obtains (using the adjunction formula for the last equality):

```

```text

$$(\dagger) \quad \operatorname{Hom}_{0_S}(W(E), W(F))(X) = \operatorname{Hom}_{0_X}(f^*(E), f^*(F)) = \operatorname{Hom}_{0_S}(E, f_* f^*(F)).$$

```

Proposition 11.5. *Let X be an S -scheme quasi-compact and quasi-separated over S , $f : X \rightarrow S$ the structural morphism, E and F two quasi-coherent 0_S -modules. Suppose one of the two following conditions holds:*

a) f is affine,*

b) E is flat over 0_S .*

Then the canonical morphism $E \otimes_{0_S} \mathcal{A}(X) \rightarrow f_ f^*(E)$ is an isomorphism, and one therefore has*

```

```text

$$\operatorname{Hom}_{0_S}(W(E'), W(E))(X) = \operatorname{Hom}_{0_S}(E', E \otimes_{0_S} \square(X)).$$

```

<!-- label: III.VI\_B.11.5 -->

Indeed, the second assertion follows from 11.4 and the first; this latter follows from EGA II, 1.4.7 in case (a), and from 11.0 (b) in case (b).<sup>[^N.D.E-VI\_B-C-109]</sup> ■

### 11.6.

[^N.D.E-VI\_B-C-110] Let  $G$  be an  $S$ -group and  $E$  a quasi-coherent  $\mathcal{O}_S$ -module. To give  $E$  a  $G$ - $\mathcal{O}_S$ -module structure (i.e. an  $\mathcal{O}_S$ -linear action of  $G$  on  $W(E)$ , cf. I 4.7.1) is equivalent to giving a morphism of  $S$ -functors in monoids  $\rho : G \rightarrow \operatorname{End}_{\mathcal{O}_S}(W(E))$  (indeed, such a  $\rho$  necessarily sends  $G$  into  $\operatorname{Aut}_{\mathcal{O}_S}(W(E))$ ).

Now, by 11.4, giving a morphism of  $S$ -functors  $\rho : G \rightarrow \operatorname{End}_{\mathcal{O}_S}(W(E))$  is equivalent to giving an element  $\theta$  of  $\operatorname{Hom}_{\mathcal{O}_G}(f^*(E), f^*(E))$ , which corresponds by adjunction to an element  $\delta$  of  $\operatorname{Hom}_{\mathcal{O}_S}(E, f_* f^*(E))$ , where one has denoted by  $f$  the projection  $G \rightarrow S$ .

Let  $m : G \times_S G \rightarrow G$  be the multiplication,  $\delta_G$  the morphism  $\mathcal{O}_G \rightarrow m_*(\mathcal{O}_{G \times_S G})$ , and  $\phi$  the projection  $G \times_S G \rightarrow S$  (which equals  $f \circ \pi$ ). It is convenient to denote by  $\boxtimes$  the "external" tensor product; one thus obtains a morphism

```

$$\operatorname{id}_E \boxtimes \delta_G : f^*(E) = E \otimes_{\mathcal{O}_S} \mathcal{O}_G \rightarrow E \otimes_{\mathcal{O}_S} m_*(\mathcal{O}_{G \times_S G})$$

```

and by abuse of notation, we shall denote again by  $\operatorname{id}_E \boxtimes \delta_G$  the composite of the preceding morphism with the canonical morphism  $E \boxtimes_{\mathcal{O}_S} m_*(\mathcal{O}_{G \times_S G}) \rightarrow m_* f^*(E) = m_* \phi^*(E)$ .

On the other hand, designate by  $h : G \rightarrow S$  a second copy of  $f : G \rightarrow S$  and consider the following commutative diagram, where  $p, q$  denote the two projections:

```

$$\begin{array}{ccccc} G \times_S G & & \xrightarrow{q} & G & \\ & \searrow p & & \downarrow \phi & \\ & G & \xrightarrow{f} & S & \end{array}$$

```

Denoting again by  $\delta$  the morphism  $E \rightarrow h_* h^*(E)$ , one obtains the morphism

```

$$\delta \boxtimes \operatorname{id}_{\mathcal{O}_G} : f^*(E) = E \otimes_{\mathcal{O}_S} \mathcal{O}_G \rightarrow h_* h^*(E) \otimes_{\mathcal{O}_S} \mathcal{O}_G = f_* h_* h^*(E)$$

```

and by abuse we shall denote again by  $\delta \boxtimes \operatorname{id}_{\mathcal{O}_G}$  the composite of this morphism with the canonical morphism  $f_* h_* h^*(E) \rightarrow p_* \phi^*(E)$ .

Then the condition that  $\rho$  be compatible with the multiplication is equivalent to saying that, for every open  $U$  of  $S$ , the diagram below is commutative:

```

$$\begin{array}{ccc} \Gamma(U, E) & \xrightarrow{\delta} & \Gamma(U \times_S G, E \otimes_{\mathcal{O}_S} \mathcal{O}_G) \\ \delta \downarrow & & \downarrow \operatorname{id}_E \boxtimes \delta_G \\ \Gamma(U \times_S G, E \otimes_{\mathcal{O}_S} \mathcal{O}_G) & \xrightarrow{\delta \boxtimes \operatorname{id}_{\mathcal{O}_G}} & \Gamma(U \times_S G \times_S G, E \otimes_{\mathcal{O}_S} \mathcal{O}_G \otimes_{\mathcal{O}_S} \mathcal{O}_G). \end{array}$$

```

(1)

Moreover, the unit section  $\epsilon : S \rightarrow G$  induces a morphism  $u$  from  $\mathcal{O}_G$  to  $\epsilon_* \epsilon^*(\mathcal{O}_G) = \epsilon_*(\mathcal{O}_S)$ , and the condition that  $\rho$  preserves the unit elements is

equivalent to the commutativity of the diagram:

```

```text
      δ
      |
Γ(U, E) -----> Γ(U ×S G, E ⊗0_S 0_G)
      |           |
      ≈           ↙ id_E ⊗ u
      |           |
      ↓           ↘
      Γ(U ×S S, E ⊗0_S 0_S).
...

```

(2)

One thus sees that giving E a G - 0_S -module structure is equivalent to giving a morphism of 0_S -modules $\delta : E \rightarrow f_* f^*(E)$ satisfying conditions (1) and (2) above, and in this case the morphism $\theta : f^*(E) \rightarrow f^*(E)$, deduced from δ by adjunction, is an isomorphism (since it corresponds to the isomorphism $G \times_S W(E) \xrightarrow{\sim} G \times_S W(E)$ defined set-theoretically by $(g, x) \mapsto (g, gx)$; see also I, 6.5.4).

Suppose now that G is flat, quasi-compact and quasi-separated over S , and that $\mathcal{A}(G)$ is a flat 0_S -module; then, by 11.1 (c), the canonical morphism $\mathcal{A}(G) \otimes_{0_S} \mathcal{A}(G) \rightarrow \mathcal{A}(G \times_S G)$ is an isomorphism, and the morphism $\delta_G : \mathcal{A}(G) \rightarrow \mathcal{A}(G) \otimes_{0_S} \mathcal{A}(G)$ will be denoted by Δ .

If moreover $E \otimes_{0_S} \mathcal{A}(G) = f_* f^*(E)$ (which is the case, by 11.5, if $G \rightarrow S$ is affine, or if E is flat over 0_S), one obtains that conditions (1) and (2) are equivalent to the conditions below, which express that $\delta : E \rightarrow E \otimes_{0_S} \mathcal{A}(G)$ makes E a right $\mathcal{A}(G)$ -comodule (cf. I 4.7.2):

(CM 1) Setting $A = \mathcal{A}(G)$, the diagram below is commutative:

```

```text
 δ
 |
E -----> E ⊗ A
 | |
 ↓ ↓ id_E ⊗ Δ
 E ⊗ A -----> E ⊗ A ⊗ A.
...

```

(CM 2) Denoting by  $\eta : A \rightarrow 0_S$  the morphism  $\mathcal{A}(\epsilon)$ , the diagram below is commutative:

```

```text
      δ
      |
E -----> E ⊗ A
      |           |
      ≈           ↙ id_E ⊗ η
      |           |
      ↓           ↘
      E ⊗ 0_S.
...

```

Remark 11.6.A. Recall that one denotes by $V(E)$ the vector fibration on S representing the functor $V(E)$, i.e. for every $S' \rightarrow S$, $V(E)(S') = \operatorname{Hom}_{0_{S'}}(E_{S'}, 0_{S'})$. As one has, by I, 4.6.2, an anti-isomorphism of S -functors in monoids $\operatorname{End}_{0_S}(W(E)) \simeq \operatorname{End}_{0_S}(V(E))$, one sees that if E is a left G - 0_S -module, one has a right action $\mu : V(E) \times_S G \rightarrow V(E)$ of G on $V(E)$, defined set-theoretically by $(\phi g)(x) = \phi(gx)$, for every $g \in G(S')$, $x \in \Gamma(S', E_{S'})$ and $\phi \in \operatorname{Hom}_{0_{S'}}(E_{S'}, 0_{S'})$. One thus obtains commutative diagrams:

<!-- label: III.VI_B.11.6.A -->

```

```text
 μ × id_G
V(E) ×S G ×S G -----> V(E) ×S G
 | | |
 ↓ ↓ ↓ μ
 μ μ μ

 μ
 |
V(E) -----> V(E) ×S G
 | |
 ≈ ↑ id × ε
 ↓ |
 μ μ

```

$$\begin{array}{ccc} V(E) \times_S G & \longrightarrow & V(E) \\ \downarrow & & \downarrow \\ V(E) \times_S S & & V(E) \times_S S \end{array}$$

When  $G$  is flat, quasi-compact and quasi-separated over  $S$ , when  $\mathcal{A}(G)$  is a flat  $\mathcal{O}_S$ -module, and when one of the conditions of 11.5 is satisfied, one recovers similarly the conditions (CM 1) and (CM 2).

Consequently, we have obtained:

**Proposition 11.6.1.** *Let  $G$  be an  $S$ -group flat, quasi-compact and quasi-separated over  $S$ , such that  $\mathcal{A}(G)$  is a flat  $\mathcal{O}_S$ -module, and let  $E$  be a quasi-coherent  $\mathcal{O}_S$ -module.*

(i) It amounts to the same to give an  $\mathcal{A}(G)$ -comodule structure  $\delta : E \rightarrow E \otimes_S \mathcal{A}(G)$  or a  $G$ - $\mathcal{O}_S$ -module structure on  $E$  (i.e. an  $\mathcal{O}_S$ -linear action of  $G$  on  $E$ ). By composition with the morphism of  $S$ -groups  $G \rightarrow G_{\text{af}}$ , this defines a  $G$ - $\mathcal{O}_S$ -module structure on  $E$ .

(ii) If moreover  $E$  is flat, every  $\mathcal{O}_S$ -linear action of  $G$  on  $E$  factors through  $G_{\text{af}}$  and corresponds to a unique  $\mathcal{A}(G)$ -comodule structure on  $E$ .

*III.VI.B.11.6.1*

**Lemma 11.7.** *Let  $G$  be an  $S$ -group flat, quasi-compact and quasi-separated over  $S$ , such that  $\mathcal{A}(G)$  is a flat  $\mathcal{O}_S$ -module. Let  $E$  be a quasi-coherent  $\mathcal{O}_S$ -module,  $\delta : E \rightarrow E \otimes_S \mathcal{A}$  an  $\mathcal{A}$ -comodule structure, and  $\rho : G \rightarrow \text{Aut}_{\mathcal{O}_S}(W(E))$  the action of  $G$  on  $E$  associated with it.*

Let  $E_0$  be a quasi-coherent  $\mathcal{O}_S$ -submodule of  $E$  such that the restriction  $\delta_0$  of  $\delta$  to  $E_0$  factors through  $E_0 \otimes_S \mathcal{A}$ , i.e. such that one has a commutative diagram:

$$\begin{array}{ccc} E_0 & \xrightarrow{\delta_0} & E \\ \downarrow & & \downarrow \delta \\ E_0 \otimes_S \mathcal{A} & \xrightarrow{\quad} & E \otimes_S \mathcal{A} \end{array}$$

(N.B. The morphism  $E_0 \otimes_S \mathcal{A} \rightarrow E \otimes_S \mathcal{A}$  is injective, since  $\mathcal{A}$  is flat over  $\mathcal{O}_S$ .)

Then  $\delta_0$  makes  $E_0$  an  $\mathcal{A}(G)$ -comodule, hence defines an action  $\rho_0$  of  $G$  on  $E_0$  (which one will call the induced action on  $E_0$  by  $\rho$ , and one will say that  $E_0$  is stable under  $\rho$ ).

*III.VI.B.11.7*

This follows immediately from the definitions and from 11.6. One will remark, however, that in general the canonical map  $W(E_0) \rightarrow W(E)$  is not a monomorphism. ■

**Remark 11.7.bis.** [N.D.E-VI.B-C-111] Let  $G$  be a flat  $S$ -group and  $E$  a quasi-coherent  $G$ - $\mathcal{O}_S$ -module. Denote by  $f$  the morphism  $G \rightarrow S$  and by  $\delta$  the morphism  $E \rightarrow f_* f^*(E)$  defined in 11.6. Let  $E_0$  be a quasi-coherent  $\mathcal{O}_S$ -submodule of  $E$ ; since  $f$  is flat,  $f_* f^*(E_0)$  is an  $\mathcal{O}_S$ -submodule of  $f_* f^*(E)$ , and similarly for  $\phi = f \times f$ . Consequently, if the restriction  $\delta_0$  of  $\delta$  to  $E_0$  factors through  $f_* f^*(E_0)$ , then it makes  $E_0$  a  $G$ - $\mathcal{O}_S$ -module. In this case, one says that  $E_0$  is a  $G$ -stable submodule of  $E$ .

*III.VI.B.11.7.bis*

**Definition 11.8.0.** [N.D.E-VI.B-C-112] Let  $S$  be a scheme. An  $\mathcal{O}_S$ -coalgebra is an  $\mathcal{O}_S$ -module  $C$  endowed with two morphisms of  $\mathcal{O}_S$ -modules  $\Delta : C \rightarrow C \otimes C$  and  $\epsilon : C \rightarrow \mathcal{O}_S$ , satisfying the following two axioms (cf. I 4.2):

(C0 1)  $\Delta$  is co-associative: the following diagram is commutative

$$\begin{array}{ccc} C & \otimes & C \\ \Delta \downarrow & & \downarrow \Delta \\ C \otimes C & \otimes & C \end{array}$$

$$\begin{array}{ccc}
 \Delta & & \text{id} \otimes \Delta \\
 & \searrow & \searrow \\
 C & & C \otimes C \otimes C \\
 & \swarrow & \swarrow \\
 \Delta & & \Delta \otimes \text{id} \\
 & \searrow & \searrow \\
 & C \otimes C & 
 \end{array}$$

\*(C0 2):  $\epsilon$  is a counit, i.e. the two following composites are the identity\*

```

```text
      Δ      id ⊗ ε      ~
C  →  C ⊗ C  →  C ⊗ 0_S  →  C,
      Δ      ε ⊗ id      ~
C  →  C ⊗ C  →  0_S ⊗ C  →  C.
```

```

\*A (right)  $C$ -comodule is an  $0_S$ -module  $E$  endowed with a morphism of  $0_S$ -modules  $\mu : E \rightarrow E \otimes C$  satisfying the axioms (CM 1) and (CM 2) of 11.6.\*

\*One says that  $C$  (resp.  $E$ ) is a quasi-coherent coalgebra \*(resp. a quasi-coherent comodule\*) if it is a quasi-coherent  $0_S$ -module.\*

\*Let  $A$  be a commutative ring and  $C$  an  $A$ -coalgebra; then  $C^{\vee} = \operatorname{Hom}_A(C, A)$  is an  $A$ -algebra. We shall denote by  $\text{ev}$  the natural evaluation map  $C \otimes C^{\vee} \rightarrow A$ .\*

<!-- label: III.VI\_B.11.8.0 -->

**Lemma 11.8.** \*Let  $C$  be an  $A$ -coalgebra,  $V$  a  $C$ -comodule,  $M$  an  $A$ -submodule of  $V$ . Suppose that  $C$  is a projective  $A$ -module. [^N.D.E-VI\_B-C-113] Let  $c(M)$  be the image of the morphism of  $A$ -modules\*

```

```text
      μ ⊗ id      id ⊗ ev
θ :  M ⊗_A C^V  →  V ⊗_A C ⊗_A C^V  →  V.
```

```

\*Then  $c(M)$  is the smallest subcomodule of  $V$  containing  $M$ , and is a finitely generated  $A$ -module if  $M$  is. One will say that  $c(M)$  is the subcomodule generated by  $M$ .\*

\*Moreover, for every morphism of rings  $A \rightarrow A'$ , if one denotes by  $M'$  the image of  $M \otimes_A A'$  in  $V' = V \otimes_A A'$ , then  $c(M')$  is the image of  $c(M) \otimes_A A'$  in  $V'$ , hence: "the formation of  $c(M)$  commutes with base change".\*

<!-- label: III.VI\_B.11.8 -->

First,  $M \subset c(M)$  by (CM 2), and if  $N$  is a subcomodule of  $V$  containing  $M$ , one has  $\mu(M) \subset N \otimes C$  and therefore  $c(M) \subset N$ .

By hypothesis,  $C$  is a direct factor of a free  $A$ -module  $L$ , with basis  $(e_i)_{i \in I}$ . Denote by  $\phi_i$  the restriction to  $C$  of the linear form  $e^*_i$ , defined by  $e^*_i(e_j) = \delta_{ij}$ . Let  $x \in M$ . One can write:

```

```text
(1)  μ(x) = ∑_{i ∈ J} x_i ⊗ e_i,
```

```

where  $x_i \in V$  and  $J$  is a finite subset of  $I$ . Then  $x_i = \theta(x \otimes \phi_i)$  belongs to  $c(Ax)$ , and one therefore has  $c(Ax) = \sum_{i \in J} Ax_i$ . Since  $C$  is a direct factor of  $L$ , say  $L = C \oplus R$ , whence  $V \otimes L = (V \otimes C) \oplus (V \otimes R)$ , one obtains that

```

```text
(c(Ax) ⊗ L) ∩ (V ⊗ C) = c(Ax) ⊗ C.
```

```

Consequently,  $\mu(x)$  can also be written in the form

```
```text
(2)       $\mu(x) = \sum_{j \in J} x_j \otimes b_j,$ 
```
```

with  $b_j \in C$ . One can write  $\Delta(b_j) = \sum_{i \in I} b_{ij} \otimes e_i$ , with  $b_{ij} \in C$ . Then, applying  $\mu \otimes \text{id}$  to (1) (resp.  $\text{id} \otimes \Delta$  to (2)) and using the axiom (CM 1), one obtains, for every  $i \in J$ :

```
```text
 $\mu(x_i) = \sum_{j \in J} x_j \otimes b_{ij} \in c(Ax) \otimes C.$ 
```
```

This shows that  $c(M)$  is a subcomodule of  $V$ , and is therefore the smallest subcomodule of  $V$  containing  $M$ .

It is clear that  $c(M)$  is a finitely generated  $A$ -module if  $M$  is: if  $M = Ax_1 + \dots + Ax_n$  and  $\mu(x_k) = \sum_i x_{ik} \otimes e_i$ , then  $c(M)$  is generated by the  $x_{ik}$ , for  $k = 1, \dots, n$  and  $i$  running through a finite subset of  $I$ .

Finally, let  $A \rightarrow A'$  be a morphism of rings and let  $M'$  be the image of  $M \otimes A'$  in  $V' = V \otimes A'$ . Then  $c(M')$  (resp. the image of  $c(M) \otimes A'$  in  $V'$ ) is the image of the morphism  $\theta'$  below (resp. of the composite  $\theta' \circ \tau$ ):

```
```text

$$M \otimes A' \otimes C^v \xrightarrow{\tau} M \otimes \text{Hom}_A(C, A') \xrightarrow{\theta'} V'.$$

```
```

Now, these two morphisms have the same image. Indeed, let  $\psi \in \text{Hom}_A(C, A')$  and  $x \in M$ . Set  $\mu(x) = \sum_{i \in J} x_i \otimes e_i$ . Then

```
```text
 $\theta'(x \otimes \psi) = \sum_{i \in J} \psi(e_i) x_i$ 
```
```

is the image by  $\theta' \circ \tau$  of the element  $\sum_{i \in J} x \otimes \psi(e_i) \otimes \phi_i$  of  $M \otimes A' \otimes C^{\vee}$ . This proves the lemma. ■

Moreover, one has the following proposition:

**Proposition 11.8.bis.** [N.D.E-VI\_B-C-114] \*Let  $A$  be a noetherian ring,  $C$  an  $A$ -coalgebra flat over  $A$ ,  $V$  a  $C$ -comodule, and  $M$  a finitely generated  $A$ -submodule of  $V$ . Then there exists a subcomodule  $W$  of  $V$ , finitely generated over  $A$ , containing  $M$ .\*

<!-- label: III.VI\_B.11.8.bis -->

Indeed, since  $M$  is finitely generated, so is  $\Delta_V(M)$ , hence there exists a finitely generated  $A$ -submodule  $M'$  of  $V$  such that  $\Delta_V(M) \subset M' \otimes_A C$ . Let  $\pi$  be the projection  $V \rightarrow V/M'$  and  $\Delta_V^- = (\pi \otimes \text{id}_C) \Delta_V$ , and let

```
```text
 $W = \{x \in V \mid \Delta_V^-(x) \in M' \otimes_A C\} = \text{Ker } \Delta_V^-;$ 
```
```

this is an  $A$ -submodule of  $V$  containing  $M$  and contained in  $M'$  (since  $x = (\text{id}_V \otimes \epsilon) \Delta_V(x)$ ), hence finitely generated over  $A$ . Moreover,  $(\Delta_V^- \otimes \text{id}_C) \Delta_V = (\pi \otimes \Delta_C) \Delta_V$  vanishes on  $W$ , i.e.  $\Delta_V(W)$  is contained in the kernel  $K$  of  $(\Delta_V^- \otimes \text{id}_C)$ . But since  $C$  is flat over  $A$ , one has  $K = W \otimes C$ , hence  $W$  is a subcomodule of  $V$ . ■

**Lemma 11.8.1.** [N.D.E-VI\_B-C-115] \*Let  $C$  be an  $A$ -coalgebra,  $V$  a  $C$ -comodule,  $M$  an  $A$ -submodule of  $V$ , and  $f : A \rightarrow A'$  a faithfully flat morphism of rings. Suppose that  $C' = C \otimes A'$  is a projective  $A'$ -module.\*

(i) Then there exists a smallest subcomodule  $t(M)$  of  $V$  containing  $M$ , and  $t(M)$  is a finitely generated  $A$ -module if  $M$  is. Moreover, "the formation of  $t(M)$  commutes with base change".\*

(ii) More precisely,  $C$  is a projective  $A$ -module, and one has  $t(M) = c(M)$ .\*

<!-- label: III.VI\_B.11.8.1 -->

\*Proof.\* (ii) By [RG71] (see Proposition 11.8.2 below),  $C$  is a projective  $A$ -module. One can therefore apply Lemma 11.8:  $c(M)$  is the smallest subcomodule of  $V$  containing  $M$ , it is a finitely generated  $A$ -module if  $M$  is, and its formation commutes with base change.

To avoid an anachronism ([RG71] being subsequent to SGA 3), let us sketch a direct proof of point (i). Since  $A \rightarrow A'$  is flat,  $M' = M \otimes A'$  is an  $A'$ -submodule of  $V' = V \otimes A'$ , and, since  $C'$  is a projective  $A'$ -module,  $c(M')$  is the smallest subcomodule of  $V'$  containing  $M'$ . Denote by  $V' \otimes A'$  and  $A' \otimes V'$  the two  $A' \otimes A'$ -comodule structures on  $V' = V \otimes A'$  ( $A' \otimes A'$ ) obtained by the two base changes  $A' \rightarrow A' \otimes A'$ ,  $a \mapsto a \otimes 1$  and  $a \mapsto 1 \otimes a$ . The  $A'$ -comodule  $V'$  is equipped with an isomorphism of  $A' \otimes A'$ -comodules  $\phi : V' \otimes A' \xrightarrow{\sim} A' \otimes V'$ ,  $(x \otimes a) \mapsto b \otimes (x \otimes a)$ , which is a descent datum, i.e. which satisfies  $\phi_{31} = \phi_{32} \circ \phi_{21}$ .

Since  $M' = M \otimes A'$ ,  $\phi$  sends  $M' \otimes A'$  onto  $A' \otimes M'$ , and therefore  $c(M' \otimes A')$  onto  $c(A' \otimes M')$ . Since the formation of  $c(M')$  commutes with base change, one has  $c(M' \otimes A') = c(M') \otimes A'$  and  $c(A' \otimes M') = A' \otimes c(M')$ . One therefore has

```
```text
φ(c(M') ⊗ A') = A' ⊗ c(M')
```

and it follows that ϕ equips $c(M')$ with a descent datum. By (fpqc) descent, there exists a unique subcomodule $t(M)$ of V such that $c(M') = t(M) \otimes A'$, and $t(M)$ contains M since $t(M) \otimes A'$ contains M' . Moreover, if N is a subcomodule of V containing M , then N contains $t(M)$, since $N \otimes A'$ contains $c(M') = t(M) \otimes A'$. Hence $t(M)$ is the smallest subcomodule of V containing M .

Finally, let $A \rightarrow B$ be a morphism of rings. Let $B' = B \otimes A'$ and let M_B (resp. $M_{B'}$) be the image of $M \otimes B$ in $V_B = V \otimes B$ (resp. of $M' \otimes_{A'} B'$ in $V \otimes B'$); then $M_B \otimes_{B'} B' = M_{B'}$. On the one hand, the preceding construction, applied to C_B and to the morphism $B \rightarrow B'$, gives:

```
```text
c(M_B ⊗_{B'} B') = t(M_B) ⊗_{B'} B' = t(M_B) ⊗ A'.
```

On the other hand, since the formation of  $c(M')$  commutes with base change,  $c(M_{B'})$  is the image in  $V \otimes_{A'} B' = V \otimes B \otimes A'$  of

```
```text
c(M') ⊗_{A'} B' = t(M) ⊗ B ⊗ A'.
```

It follows that $t(M_{B'})$ is the image in V_B of $t(M) \otimes B$. ■

****Proposition 11.8.2 (Gruson–Raynaud).**** *Let $f : A \rightarrow A'$ be a faithfully flat morphism; then f "descends projectivity", i.e. if M' is an A' -module and if $M \otimes_{A'} A'$ is a projective A' -module, then M is a projective A -module.*

<!-- label: III.VI_B.11.8.2 -->

Indeed, by [RG71] II 2.5.1, f "descends the Mittag-Leffler condition", and therefore, by loc. cit. II 3.1.3, f descends projectivity. [^N.D.E-VI_B-C-116] ■

****Proposition 11.9.**** [^N.D.E-VI_B-C-117] *Let C be an 0S -coalgebra, E a C -comodule, F an 0S -submodule of E , all quasi-coherent. Suppose given a covering of S by affine opens $U_{\alpha} = \operatorname{Spec} A_{\alpha}$, and for each α , a faithfully flat morphism of rings $A_{\alpha} \rightarrow A'_{\alpha}$ such that $\Gamma(U_{\alpha}, C) \otimes_{A_{\alpha}} A'_{\alpha} \otimes_{A'_{\alpha}} A'_{\alpha}$ is a projective A'_{α} -module. [^VI_B-C-11-9]*

Then there exists a smallest quasi-coherent subcomodule $t(F)$ of E containing F , and $t(F)$ is a finitely generated 0S -module if F is. Moreover, for every base change $S' \rightarrow S$, if one denotes by F' the image of $F \otimes {}^0S$ in $E' = E \otimes {}^0S'$, then $t(F')$ is the image of $t(F) \otimes {}^0S$ in E' , i.e. "the formation of $t(F)$ commutes with base change".

<!-- label: III.VI_B.11.9 -->

Proof. For each U_{α} , the $\mathcal{O}_{U_{\alpha}}$ -module $\mathcal{T}_{\alpha}$ associated with the $\mathcal{A}_{\alpha}$ -module $\mathcal{T}_{\alpha} = t(\Gamma(U_{\alpha}, F))$ is, by 11.8.1 (i), the smallest quasi-coherent subcomodule of $\mathcal{E}|_{U_{\alpha}}$ containing $\mathcal{F}|_{U_{\alpha}}$, and is a finitely generated $\mathcal{O}_{U_{\alpha}}$ -module if $\mathcal{F}|_{U_{\alpha}}$ is.

For all α, β , set $\mathcal{U}_{\alpha\beta} = \mathcal{U}_{\alpha} \cap \mathcal{U}_{\beta}$. Since the construction of $t(M)$ commutes with base change, one has, for all α, β , canonical isomorphisms of $\mathcal{O}_{\mathcal{U}_{\alpha\beta}}$ -modules

$$\varphi_{\alpha\beta} : \mathcal{O}_{\beta} \otimes_{\mathcal{A}_{\beta}} \mathcal{O}_{\mathcal{U}_{\alpha\beta}} \rightarrow \mathcal{O}_{\alpha} \otimes_{\mathcal{A}_{\alpha}} \mathcal{O}_{\mathcal{U}_{\alpha\beta}}$$

which satisfy the cocycle condition $\varphi'_{\alpha\gamma} = \varphi'_{\alpha\beta} \circ \varphi'_{\beta\gamma}$, where $\varphi'_{\alpha\gamma}$ (resp. $\varphi'_{\alpha\beta}$) denotes the restriction of $\varphi_{\alpha\gamma}$ (resp. $\varphi_{\alpha\beta}$) to $\mathcal{U}_{\alpha} \cap \mathcal{U}_{\beta} \cap \mathcal{U}_{\gamma}$.

Consequently, the $\mathcal{T}_{\alpha}$ glue together into a quasi-coherent subcomodule $t(F)$ of $\mathcal{E}$ containing $\mathcal{F}$. We leave to the reader the task of verifying that $t(F)$ is the smallest quasi-coherent subcomodule of $\mathcal{E}$ containing $\mathcal{F}$, and that its formation commutes with base change. ■

Definition 11.9.1 [N.D.E-VI-B-C-118] *Let S be a scheme and P a quasi-coherent $\mathcal{O}_S$ -module. The following conditions are equivalent:*

- *(i) For every affine open U of S , $\Gamma(U, P)$ is a projective $\mathcal{O}_S(U)$ -module.*
- *(ii) There exists a covering $\{U_{\alpha}\}$ of S by affine opens such that each $\Gamma(U_{\alpha}, P)$ is a projective $\mathcal{O}_S(U_{\alpha})$ -module.*
- *(iii) There exists a covering $\{U_{\alpha}\}$ of S by affine opens, and faithfully flat morphisms of rings $\mathcal{A}_{\alpha} = \mathcal{O}_S(U_{\alpha}) \rightarrow \mathcal{A}'_{\alpha}$, such that, for each α , $\Gamma(U_{\alpha}, P) \otimes_{\mathcal{A}_{\alpha}} \mathcal{A}'_{\alpha}$ is a projective $\mathcal{A}'_{\alpha}$ -module.*

<!-- label: III.VI_B.11.9.1 -->

Indeed, it is clear that (i) $\Rightarrow$ (ii) $\Rightarrow$ (iii). Conversely, if (iii) is satisfied, 11.8.2 implies that each $\Gamma(U_{\alpha}, P)$ is a projective $\mathcal{O}_S(U_{\alpha})$ -module, whence (ii). Finally, suppose (ii) satisfied and let $V = \operatorname{Spec} A$ be an arbitrary affine open; it is covered by finitely many affine opens $V_1, \dots, V_n$, where each $V_i = \operatorname{Spec} A_i$ is contained in at least one U_{α} , so that $\Gamma(V_i, P)$ is a projective $\mathcal{A}_i$ -module. Let $\mathcal{A}' = A_1 \times \dots \times A_n$; then $\mathcal{A} \rightarrow \mathcal{A}'$ is faithfully flat and $\Gamma(V, P) \otimes_{\mathcal{A}} \mathcal{A}'$ is a projective $\mathcal{A}'$ -module. Hence, by 11.8.2, $\Gamma(V, P)$ is a projective $\mathcal{A}$ -module.

When these equivalent conditions are satisfied, one says that P is a *locally projective* $\mathcal{O}_S$ -module.

Corollary 11.10 *Let S be a quasi-compact and quasi-separated scheme, G an S -group, and ρ a linear action of G on a quasi-coherent $\mathcal{O}_S$ -module $\mathcal{E}$. Suppose that:*

(i) G satisfies one of the following conditions:

- *a) G is affine and flat over S ,
- *b) G is flat, quasi-compact and quasi-separated over S , and $\mathcal{E}$ is flat;

(ii) $\mathcal{A}(G)$ is a locally projective $\mathcal{O}_S$ -module.

Then $\mathcal{E}$ is an inductive limit of a filtered increasing family of quasi-coherent finitely generated $\mathcal{O}_S$ -submodules of $\mathcal{E}$, stable under G .

<!-- label: III.VI_B.11.10 -->

By hypothesis (i) and 11.6.1, $\mathcal{E}$ is equipped with an $\mathcal{A}(G)$ -comodule structure. On the other hand, since S is quasi-compact and quasi-separated, $\mathcal{E}$ is the inductive limit of its finitely generated quasi-coherent submodules (EGA I, 9.4.9 and EGA IV₁, 1.7.7). Consequently, the corollary follows from Proposition 11.9, applied to the coalgebra

$\mathcal{A}(G)$. ■

Moreover, one has the following proposition:

Proposition 11.10.bis. [N.D.E-VI_B-C-119] Let S be a noetherian scheme, G an S -group flat, quasi-compact and quasi-separated over S , E a quasi-coherent G -module, M a coherent G -submodule of E . Then M is contained in a coherent G -submodule stable under G .

Proof. Denote by f the morphism $G \rightarrow S$ and by τ the adjunction morphism $E \rightarrow f_* f^*(E)$. By 11.6, the G -module structure on E is given by an automorphism θ of the G -module $f^*(E)$, such that the morphism $\delta = \theta \circ \tau$ satisfies conditions (1) and (2) of 11.6. (The situation considered in [Th87] is more general, in that the author considers a G -scheme X and a G -equivariant X -module E (cf. Exp. I, Section 6); here $X = S$ equipped with the trivial action of G .)

Since S is noetherian, E is the filtered inductive limit of its coherent submodules F_α (cf. EGA I, 9.4.9). Then $f^*(E)$ is the filtered inductive limit of the $f^*(F_\alpha)$, which are submodules of $f^*(E)$ since f is flat. Since, moreover, f is quasi-compact and quasi-separated, by 11.0, the G -module $f_* f^*(E)$ is quasi-coherent and is the filtered inductive limit of the quasi-coherent submodules $f_* f^*(F_\alpha)$. Consequently, E is the filtered inductive limit of the quasi-coherent G -submodules E_α , where E_α denotes the inverse image by δ of $f_* f^*(F_\alpha)$, i.e. the kernel of the composite morphism

$$\delta_\alpha : E \xrightarrow{\quad} f_* f^*(E) \xrightarrow{\quad} f_* f^*(E/F_\alpha).$$

Since M is coherent and S noetherian, every increasing sequence of submodules of M is stationary, so M is contained in some E_α . Let us show that each E_α is coherent and G -stable.

Let u be the morphism $f^*(E) \rightarrow \epsilon_*(E)$ corresponding by adjunction to the identity morphism from E to $f_* f^*(E)$; then the composite morphism

$$E \xrightarrow{\quad} f_* f^*(E) \xrightarrow{\quad} f_* \epsilon_*(E) = E$$

is the identity (cf. 11.6 (2)). Since one has a commutative diagram:

$$\begin{array}{ccccc} E_\alpha & \xrightarrow{\delta} & f_* f^*(F_\alpha) & \xrightarrow{\quad} & f_* f^*(u) \\ i_\alpha \downarrow & & & & \downarrow j_\alpha \\ E & \xrightarrow{\tau} & f_* f^*(E) & \xrightarrow{\quad} & E, \end{array}$$

where i_α (resp. j_α) denotes the inclusion of E_α (resp. $f_* f^*(F_\alpha)$) into E , one deduces that i_α factors through j_α , i.e. E_α is a submodule of $f_* f^*(F_\alpha)$, hence is coherent.

Let us finally show that E_α is G -stable (cf. 11.7.bis). Designate by $h : G \rightarrow S$ a second copy of $f : G \rightarrow S$ and consider the following commutative diagram:

$$\begin{array}{ccc} G \times_S G & \xrightarrow{q} & G \\ p \searrow & & \downarrow \varphi \\ & G & \xrightarrow{f} S. \end{array}$$

Then the exact sequence

$$\begin{array}{c} \text{\texttt{``text}} \\ 0 \longrightarrow E_\alpha \longrightarrow E \longrightarrow h_* h^*(E/F_\alpha) \\ \text{\texttt{````}} \end{array}$$

gives, since f is flat, the exact sequence

$$\begin{array}{c} \text{\texttt{``text}} \\ (\dagger) \quad 0 \longrightarrow f_* f^*(E_\alpha) \longrightarrow f_* f^*(E) \xrightarrow{f_* f^*(\delta_\alpha)} f_* f^*(h_* h^*(E/F_\alpha)). \\ \text{\texttt{````}} \end{array}$$

Moreover, since h is quasi-compact and quasi-separated, and f flat, the canonical morphism

$$\begin{array}{c} \text{\texttt{``text}} \\ f_* h_* h^*(E/F_\alpha) \rightarrow p_* q^* h^*(E/F_\alpha) = p_* \varphi^*(E/F_\alpha) \\ \text{\texttt{````}} \end{array}$$

is an isomorphism, so that the right-hand term in $(\dagger)$ is $\phi_* \phi^*(E/F_\alpha)$. Resuming the notations of 11.6 and denoting by π_α the projection $E \rightarrow E/F_\alpha$, one obtains the commutative diagram below, whose bottom line is exact:

$$\begin{array}{ccccc} \text{\texttt{``text}} & & & & \\ E_\alpha & \xrightarrow{\quad \quad \quad} & f_* f^*(E) & & \\ \delta \downarrow & & \downarrow f_*(f^*(\pi) \boxtimes \delta_G) & & \\ f_* f^*(E_\alpha) & \longrightarrow & f_* f^*(E) \xrightarrow{f_* f^*(\delta_\alpha)} & \varphi_* \varphi^*(E/F_\alpha) & \end{array}$$

and since $f_*(f^*(\pi) \boxtimes \delta_G) \circ \delta_\alpha$ vanishes on E_α , it follows that δ sends E_α into $f_*(f^*(E/F_\alpha))$, i.e. that E_α is G -stable. The proposition is proved. ■

Remark 11.10.1. [N.D.E-VI_B-C-120] In 11.8, it does not suffice to assume that C be a flat A -module, even if A is a principal ring. Indeed, one has the following counterexamples, which were pointed out (independently) to us by O. Gabber and J.-P. Serre.

<!-- label: III.VI_B.11.10.1 -->

(a) Let $(A, \mathfrak{m})$ be a discrete valuation ring, K its field of fractions, and G the "extension by zero" A -group of the K -group $(\mathbb{Z}/2\mathbb{Z})_K$. Then the constant group $(\mathbb{Z}/2\mathbb{Z})_A$, and hence also its subgroup G , acts on the free A -module V with basis v_1, v_2 by exchanging v_1 and v_2 . Then Av_1 is not a sub- G -module of V , but it is the intersection of the sub- G -modules $Av_1 + \mathfrak{m}^n v_2$, for $n \in \mathbb{N}$. Hence there does not exist a smallest sub- G -module of V containing v_1 .

(b) Let A be an integral ring, distinct from its field of fractions K , and let G be the flat affine A -group corresponding to the Hopf algebra

$$\begin{array}{c} \text{\texttt{``text}} \\ \Gamma(G) = \{P \in K[T] \mid P(0) \in A\}, \\ \text{\texttt{````}} \end{array}$$

the comultiplication, resp. the counit and the antipode, being defined by $\Delta(T) = T \otimes 1 + 1 \otimes T$, resp. $\epsilon(T) = 0$ and $\tau(T) = -T$. (N.B. One thus has $G \otimes_A K = G_{a,K}$.)

Let V be the free A -module $Av_1 \oplus Av_2$ and u the endomorphism of V defined by $u(v_1) = v_2$, $u(v_2) = 0$, so that $u^2 = 0$. Then V is equipped with an $\mathcal{A}(G)$ -comodule structure, defined by

$$\begin{array}{c} \text{\texttt{``text}} \\ \mu(m) = 1 \otimes m + T \otimes u(m). \\ \text{\texttt{````}} \end{array}$$

The sub- G -modules of V containing v_1 are exactly the sub- A -modules of the form $Av_1 \oplus Iv_2$, for I a non-zero ideal of A ; their intersection is Av_1 , which is not a sub- G -module. Hence there does not exist a smallest sub- G -module of V containing v_1 . (Note moreover that $C = A \oplus K \cdot T$ is a sub-coalgebra of $\mathcal{A}(G)$, flat over A , and that the coaction $\mu : V \rightarrow V \otimes \mathcal{A}(G)$ factors through $V \otimes C$, so one also obtains a counterexample for the "very simple" coalgebra C .)

Finally, note that the two preceding examples are particular cases of the following construction. Let A be an integral ring, distinct from its field of fractions K , let B be an A -Hopf algebra, free over A . Denote by $\epsilon : B \rightarrow A$ the augmentation of B and $I = \ker(\epsilon)$ the augmentation ideal. Since $B = A \cdot 1 \oplus I$, one easily sees that $B' = \{b \in B \mid \epsilon(b) = 1\}$ is a sub-Hopf algebra of B . If V is a B -comodule, free with basis $(v_1, \dots, v_n)$ as A -module, and if $\mu_V(v_1) \neq v_1 \otimes 1$, then Av_1 is not a subcomodule of V but it is the intersection of the subcomodules $Av_1 + I \cdot v_1$, for I running through the non-zero ideals of A . Hence there does not exist a smallest subcomodule of V containing v_1 .

Proposition 11.11. Let G be an algebraic group over the field k . The following conditions are equivalent:

- (i) G is affine.
- (ii) G is quasi-affine.
- (iii) G acts faithfully on a quasi-affine k -scheme X .
- (iv) G acts linearly and faithfully on a k -vector space (not necessarily of finite dimension).
- (v) G is isomorphic to a closed subgroup of a group $GL(n)_k$.

`<!-- label: III.VI_B.11.11 -->`

Proof. One has (i) $\Rightarrow$ (ii) trivially, and (ii) $\Rightarrow$ (iii), since G acts faithfully on itself by translations.

Suppose that G acts faithfully on the right on a quasi-affine k -scheme X . [N.D.E-VI_B-C-121] Since X is quasi-affine, it is separated and quasi-compact. [N.D.E-VI_B-C-122] Similarly, G is separated (VI_A 0.3) and quasi-compact (since of finite type over k). Hence, by 11.1 (c), one has canonical isomorphisms:

```

```text
0(X × G) = 0(X) ⊗ 0(G) and 0(X × G × G) = 0(X) ⊗ 0(G) ⊗ 0(G).
```

```

One deduces that the morphism $\mu : 0(X) \rightarrow 0(X) \otimes 0(G)$ induced by the morphism $X \times G \rightarrow X$ equips $0(X)$ with a right $0(G)$ -comodule structure, i.e. G acts linearly on the left on the k -algebra $0(X)$. Consequently, G also acts on the right on the affine envelope $X_{\text{af}} = \operatorname{Spec} 0(X)$ of X , and the canonical morphism $X \rightarrow X_{\text{af}}$ is G -equivariant.

Moreover, X being quasi-affine, $X \rightarrow X_{\text{af}}$ is an open immersion (EGA II, 5.1.2), hence a fortiori G acts faithfully on X_{af} . One thus obtains that the linear (left) action of G on the k -algebra $0(X) = 0(X_{\text{af}})$ is faithful. This proves the implication (iii) $\Rightarrow$ (iv).

Suppose now that G acts faithfully on a k -vector space V . Then, by virtue of 11.10, V is the inductive limit of finite-dimensional vector subspaces V_i , stable under the action of G . If K_i is the kernel of the induced action of G on V_i , i.e. of the morphism $G \rightarrow \operatorname{Aut}(V_i)$, then K_i is a closed subscheme of G , and the hypothesis that G acts faithfully is expressed by the fact that the intersection of the K_i is the unit subgroup of G . Since G is noetherian, it follows that one of the K_i is already reduced to the unit group, hence that $G \rightarrow \operatorname{Aut}(V_i)$ is a monomorphism. It is therefore a closed immersion by virtue of 1.4.2, which proves that (iv) $\Rightarrow$ (v). Since (v) $\Rightarrow$ (i) trivially, this proves 11.11. ■

Remark 11.11.1. One can generalize 11.11 as follows. Let S be a regular locally noetherian scheme of dimension ≤ 1 , and G a group scheme flat, quasi-compact and quasi-separated over S . (In this case, $\mathcal{A}(G)$ is a torsion-free $\mathcal{O}_S$ -module, hence flat.)

`<!-- label: III.VI_B.11.11.1 -->`

(a) One then has the equivalence of the following conditions: [N.D.E-VI_B-C-123]

- (i) G is affine over S .

(ii) G is quasi-affine over S .

(iii) G acts faithfully on a quasi-affine and flat S -scheme.

(iv) G acts linearly and faithfully on a flat quasi-coherent $\mathcal{O}_S$ -module.

(b) If moreover G is of finite type over S and S noetherian, these conditions imply that G is isomorphic to a closed subgroup of an $\operatorname{Aut}(E)$, where E is a finitely generated locally free $\mathcal{O}_S$ -module. [N.D.E-VI_B-C-124]

Lemma 11.12. Let k be a field, G an affine k -group. Set $A = \mathcal{A}(G)$. Given $x \in A$, there exists a finitely generated k -subalgebra B of A such that $x \in B$, that $\Delta(B) \subset B \otimes_k B$, and $u(B) \subset B$, where u denotes the involution of A corresponding to the inversion morphism of G . [N.D.E-VI_B-C-125]

<!-- label: III.VI_B.11.12 -->

One can suppose $x \neq 0$; then $\Delta(x) \neq 0$ since $(\varepsilon \otimes \operatorname{id}) \Delta(x) = x$, where ε denotes the augmentation (counit) of A . Write

text
(1) $\Delta(x) = \sum_{j=1}^n e_j \otimes a_j$ with n minimal,

in which case the e_j (resp. a_j) are linearly independent. Complete $(e_1, \dots, e_n)$ into a basis $(e_i)_{i \in I}$ of A and set, for $j \in J = \{1, \dots, n\}$,

text
 $\Delta(e_j) = \sum_{i \in I} e_i \otimes b_{ij}$.

Applying $\Delta \otimes \operatorname{id}$ and $\operatorname{id} \otimes \Delta$ to (1), one obtains from the axiom (CO 1) of 11.8.0 (see also (HA 1) in I 4.2) the equalities:

text
 $\sum_{j \in J} e_j \otimes \Delta(a_j) = \sum_{\square \in J} \Delta(e_{\square}) \otimes a_{\square} = \sum_{i \in I} e_i \otimes (\sum_{\square \in J} b_{i\square} \otimes a_{\square})$.

Since the e_i are linearly independent, it follows that

text
(2) $\forall j \in J, \quad \Delta(a_j) = \sum_{\square \in J} b_{j\square} \otimes a_{\square}$.

Let then B be the finitely generated k -subalgebra of A generated by the b_{ij} and the $u(b_{ij})$, for $i, j \in J$. It is clear that $u(B) = B$.

Applying $\Delta \otimes \operatorname{id}$ and $\operatorname{id} \otimes \Delta$ to (2), one obtains further from (CO 1) the equalities:

text
 $\sum_{\square \in J} \Delta(b_{j\square}) \otimes a_{\square} = \sum_{i \in J} b_{ji} \otimes \Delta(a_i) = \sum_{i, \square \in J} b_{ji} \otimes b_{i\square} \otimes a_{\square}$,

and since the a_{ℓ} are linearly independent, one deduces that

text
(3) $\forall j, \square \in J, \quad \Delta(b_{j\square}) = \sum_{i \in J} b_{ji} \otimes b_{i\square}$.

Since $\Delta \circ u = (u \times u) \circ v \circ \Delta$, where $v(a \otimes b) = b \otimes a$, one therefore also has

text
(4) $\forall j, \square \in J, \quad \Delta(u(b_{j\square})) = \sum_{i \in J} u(b_{i\square}) \otimes u(b_{ji})$.

Since Δ is an algebra homomorphism, one deduces from (3) and (4) that $\Delta(B) \subset B \otimes_k B$. Finally, the axiom (C0 2) of 11.8.0 (see also (HA 2) in I, 4.2) shows that $a_{\{j\}} = \sum_{i \in I} \epsilon(a_{\{j\}}) b_{\{ij\}}$ and that $x = \sum_{j \in J} \epsilon(e_{\{j\}}) a_{\{j\}}$, so that $x \in B$. ■

****Proposition 11.13.**** *Let k be a field and G an affine k -group with algebra A . Then G is a projective limit of an increasing filtered system of finitely generated affine k -groups, whose transition morphisms are faithfully flat.*

<!-- label: III.VI_B.11.13 -->

If B and B' are two finitely generated subalgebras of A stable under Δ and u , then so is the subalgebra generated by B and B' . Hence, by Lemma 11.12, A is the inductive limit of a filtered increasing family $(B_{\{i\}})_{i \in I}$ of finitely generated subalgebras stable under Δ and u . Then each $B_{\{i\}}$, equipped with the restriction of u and the morphism $B_{\{i\}} \rightarrow B_{\{i\}} \otimes_k B_{\{i\}}$ deduced from Δ , is a Hopf algebra, hence by I 4.2 it is the algebra of an affine k -group $G_{\{i\}}$, of finite type over k . Finally, since $A = \varinjlim B_{\{i\}}$, one has $G = \varinjlim G_{\{i\}}$ (cf. EGA IV₃ 8.2.3). The transition morphisms are faithfully flat by the following lemma:

****Lemma 11.14.**** *Let k be a field, $u : G \rightarrow H$ a morphism between finitely generated affine k -groups, and $u^{\natural} : B \rightarrow A^{[N.D.E-VI_B-C-126]}$ the corresponding morphism of k -algebras. For u to be faithfully flat, it is necessary and sufficient that $u^{\natural}$ be injective.*

<!-- label: III.VI_B.11.14 -->

The condition is obviously necessary (cf. EGA 0_I 6.6.1). Let us show it is sufficient. Set $N = \text{Ker } u$. Then, by VI_A, 3.3.2 and 5.4.1, G/N is a finitely generated k -group and u factors as $G \twoheadrightarrow G/N \twoheadrightarrow H$, where p is faithfully flat and v is a closed immersion. Hence, since H is an affine scheme, G/N is an affine scheme and the morphism $v^{\natural} : B \rightarrow O(G/N)$ is surjective (cf. EGA I 4.2.3). Now, since $u^{\natural}$ is assumed injective, and since $u^{\natural} = p^{\natural} \circ v^{\natural}$, then $v^{\natural}$ is also injective: it is therefore an isomorphism, as is v , and since p is faithfully flat, so is u . ■

****Definition 11.15.**** [N.D.E-VI_B-C-127] *Let k be a field, G a quasi-compact k -group and V a k -vector space equipped with a k -linear action of G , hence with an $\mathcal{A}(G)$ -comodule structure $\delta : V \rightarrow V \otimes \mathcal{A}(G)$, by 11.6.1. Let $v \in V$ be non-zero. The following conditions are equivalent:*

(i) There exists $\lambda \in \mathcal{A}(G)$ (necessarily unique) such that $\delta(v) = v \otimes \lambda$.*

(ii) For every k -algebra R and every $g \in G(R)$, one has $g \cdot v \in Rv$ (i.e. there exists $f \in R$, necessarily unique, such that one has in $V \otimes R$ the equality $g \cdot v = v \otimes f$).*

<!-- label: III.VI_B.11.15 -->

Indeed, it is clear that (i) $\Rightarrow$ (ii). Conversely, if (ii) is satisfied and one applies it to $R = \mathcal{A}(G)$ and $g = \text{id}_{\mathcal{A}(G)}$, one obtains that there exists a unique $\lambda \in \mathcal{A}(G)$ such that $\delta(v) = v \otimes \lambda$.

If v satisfies these conditions, one says that v is a *semi-invariant vector* under G , and that λ is the *weight* of v ; one will also say that " v is a semi-invariant of weight λ ".

Denote by Δ the comultiplication of $\mathcal{A}(G)$; then the equality

$$v \otimes \lambda \otimes \lambda = (\delta \otimes \text{id})(\delta(v)) = (\text{id} \otimes \Delta)(\delta(v)) = v \otimes \Delta(\lambda)$$

implies that $\Delta(\lambda) = \lambda \otimes \lambda$. Consequently, λ defines a morphism of Hopf algebras

$$\square(G_{\{m,k\}}) = k[T, T^{-1}] \rightarrow \square(G), \quad T \mapsto \lambda,$$

and hence a morphism of k -groups $\lambda : G \rightarrow G_{\{m,k\}}$, i.e. λ is a *character* of G , called the *character associated with the semi-invariant vector v* .

****Lemma 11.16.0.**** [N.D.E-VI_B-C-128] *Let k be a field, H an affine k -group, V an H -module of dimension n

and U a vector subspace of V of dimension d . Consider the line $D = \bigwedge^d U \subset \bigwedge^d V$. For U to be stable under H , it is necessary and sufficient that D be so.*

<!-- label: III.VI_B.11.16.0 -->

Necessity being clear, let us prove sufficiency. One may suppose $d < n$. Let $(e_1, \dots, e_d)$ be a basis of U , complete it into a basis $(e_1, \dots, e_n)$ of V . For every k -algebra R , $V_R = V \otimes R$ is a free R -module and one has

```
```text
U_R = {v ∈ V_R | v ∧ (e_1 ∧ ... ∧ e_d) = 0}
```

(since for  $i > d$  the  $e_i \wedge e_1 \wedge \dots \wedge e_d$  are linearly independent in  $\bigwedge^{d+1} V_R$ ). Since  $H(R)$  acts on  $\bigwedge^{\bullet} V_R$  by

```
```text
h(x_1 ∧ ... ∧ x_s) = h(x_1) ∧ ... ∧ h(x_s),
```

it follows that if $H(R)$ stabilizes $D_R = R e_1 \wedge \dots \wedge e_d$, it also stabilizes U_R . ■

Theorem 11.16 (Chevalley). *Let k be a field, G an algebraic affine k -group, H a closed group subscheme of G . [N.D.E-VI_B-C-129] Then there exist a finite-dimensional G -module V and a line D in V such that $H = \text{Norm}_G(D)$, i.e. such that for every k -algebra R ,

```
```text
H(R) = {g ∈ G(R) | g(D_R) = D_R}.
```

\*In other words, there exist finitely many elements  $a_1, \dots, a_n \in \mathcal{A}(G)$ , which are semi-invariant, all of the same weight  $\lambda$ , for the "right" action of  $H$  (i.e.  $a_i(gh) = \lambda(h) a_i(g)$ , for every  $k$ -algebra  $R$  and  $g \in G(R)$ ,  $h \in H(R)$ ), such that  $H$  be the largest closed group subscheme of  $G$  under which the  $a_i$  are semi-invariant.\*

<!-- label: III.VI\_B.11.16 -->

Denote by  $\Delta$  (resp.  $\epsilon$ ) the comultiplication (resp. the augmentation) of  $A = \mathcal{A}(G)$ . Then  $H = \text{operatorname{Spec}}(A/I)$ , for some ideal  $I$  of  $A$ , contained in  $\text{Ker } \epsilon$  and such that  $\Delta(I) \subset I \otimes A + A \otimes I$ . Let  $B = A/I$  and  $\pi$  the projection  $A \rightarrow B$ . Consider the left action of  $H$  on  $A$  given by  $(h\phi)(g) = \phi(gh)$ ; the corresponding  $B$ -comodule structure is given by:

```
```text
Δ⁻ : A → A ⊗ A —id_A ⊗ π→ A ⊗ B.
```

Then I is a sub- H -module of A , since $\Delta^{-}(I) \subset I \otimes B$.

On the other hand, A is a finitely generated k -algebra, hence noetherian, hence I admits a finite system of generators $(x_1, \dots, x_r)$. By 11.8, the x_i are contained in a sub- G -module V of finite dimension over k . Then $W = V \cap I$ is an H -module of finite dimension, whose dimension we denote by d . Since V contains all the x_i , W generates the ideal I .

Set $E = \bigwedge^d V$, let $(w_1, \dots, w_d)$ be a basis of W , and let $B = (e_0, \dots, e_n)$ be a basis of E containing the vector $e_0 = w_1 \wedge \dots \wedge w_d$. The action of G on V canonically determines an action of G on E , hence an A -comodule structure $\rho : E \rightarrow E \otimes A$. For $j = 0, \dots, n$, set $\rho(e_j) = \sum_{i=1}^n e_i \otimes b_{ij}$; one has seen in the proof of 11.12 that

```
```text
(*) Δ(b_{ij}) = \sum_{\square=0}^n b_{i\square} \otimes b_{\square j}.
```

Set  $a_i = b_{i0}$ , i.e. if  $(e^*_0, \dots, e^*_n)$  is the dual basis of  $B$ , the  $a_i$  are the "matrix coefficients"  $g \mapsto e^*_i(g e_0)$ . On the other hand, the action of  $H$  on  $E$  corresponds to:

```

```text

$$\rho^- : E \longrightarrow E \otimes A \xrightarrow{\text{id}_E \otimes \pi} E \otimes B.$$

```

```

Since  $W$  is stable under  $H$ ,  $e_0$  is semi-invariant under  $H$ , hence  $\bar{\rho}(e_0) = e_0 \otimes \pi(a_0)$  and  $a_i = b_{i0}$  belongs to  $I$  for  $i = 1, \dots, n$ . Substituting this into (\*), one obtains  $\Delta(a_i) = a_i \otimes \pi(a_0)$  for  $i = 0, \dots, n$ , i.e. the  $a_i$  are semi-invariant under  $H$  with weight  $\pi(a_0)$ . (Moreover, possibly by replacing  $E$  by the sub- $G$ -module generated by  $e_0$  (cf. 11.8), one may assume that the  $a_i$  are linearly independent.)

Conversely, let  $H' = \text{operatorname{Spec}} B'$ , where  $B' = A/I'$ , be a closed group subscheme of  $G$  under which each of the  $a_i$  is semi-invariant, with weight  $\lambda_i \in B'$  (this is the case, in particular, if  $e_0$  is invariant under  $H'$  with weight  $\lambda$ ). Let us show that  $H' = H$ . Denote by  $\pi'$  the projection  $A \rightarrow B'$ ; the hypothesis implies that

```

```text

$$a_i \otimes \lambda_i = (\text{id}_A \otimes \pi') \Delta(b_{i0}) = \sum_{j=0}^n b_{ij} \otimes \pi'(a_j),$$

```

```

whence  $\lambda_i = \pi'(a_0)$  and  $a_{\ell} \in I'$  for  $\ell = 1, \dots, n$ , and hence  $e_0$  is semi-invariant under  $H'$ . By Lemma 11.16.0, this implies that  $W$  is stable under  $H'$ . Since the ideal  $I$  is generated by  $W$ , it is also stable under  $H'$ , and therefore

```

```text

$$\Delta(I) \subset I \otimes A + A \otimes I'.$$

```

```

Since  $I \subset \text{Ker } \epsilon$  and  $(\epsilon \otimes \text{id}_A) \circ \Delta = \text{id}_A$ , it follows that  $I \subset I'$ , whence  $H' \subset H$ . ■

**Lemma 11.17.0.** [N.D.E-VI\_B-C-130] \*Let  $k$  be an algebraically closed field,  $G$  a reduced algebraic affine  $k$ -group,  $V$  a finite-dimensional  $G$ -module over  $k$ , and  $v \in V$ . Let  $E$  be the vector subspace of  $V$  generated by the vectors  $gv$ , for  $g \in G(k)$ . Then  $E$  is the smallest sub- $G$ -module of  $V$  containing  $v$ , and hence the morphism  $G \times E \rightarrow V$ ,  $(g, x) \mapsto gx$ , factors through  $E$ .\*

```

<!-- label: III.VI_B.11.17.0 -->

```

**Proof.** By 11.8, we know that there exists a smallest sub- $G$ -module  $U$  of  $V$  containing  $v$ : if  $\mu : V \rightarrow V \otimes \mathcal{A}(G)$  denotes the comodule structure and if one writes  $\mu(v) = \sum_{i=1}^n v_i \otimes a_i$  with the  $a_i$  linearly independent, one has  $U = \text{Vect}(v_1, \dots, v_n)$ . It is clear that  $U$  contains  $E$ , and that the morphism  $G \times U \rightarrow V$  factors through  $U$ .

Conversely, the inverse image of  $E$  by the morphism  $\mu_v : g \mapsto gv$  is a closed subset of  $G$  which contains the rational points; now these are dense in  $G$ , since  $G$  is of finite type over  $k$  (cf. EGA IV<sub>3</sub>, 10.4.8), hence  $\mu_v^{-1}(v)(E) = G$  and so, since  $G$  is reduced,  $\mu_v$  factors through  $E$ , whence  $E = U$ . ■

**Theorem 11.17 (Chevalley).** \*Let  $k$  be a field,  $G$  an affine  $k$ -group (not necessarily of finite type), and  $N$  a closed group subscheme of  $G$  invariant in  $G$ ; then the (fpqc) sheaf quotient  $G/N$  is representable by an affine  $k$ -group.\* [N.D.E-VI\_B-C-131]

```

<!-- label: III.VI_B.11.17 -->

```

Suppose first  $G$  of finite type. By VI\_A 3.2 and 5.2, the (fpqc) sheaf quotient  $G/N$  is representable by a  $k$ -group  $Q$ ; it therefore remains to show that  $Q$  is affine. The proof is done in several stages; suppose first  $k$  algebraically closed. [N.D.E-VI\_B-C-132]

(a) Suppose moreover  $G$  reduced and connected, and  $N$  reduced. By 11.16, there exist a  $G$ -module  $V$ , of finite dimension over  $k$ , and a line  $D = k e_0$  such that  $\text{Norm}_G(D) = N$ ; in particular  $N$  acts on  $D$  via a character  $\chi : N \rightarrow G_m(k)$ .

Fix  $h \in N(k)$ . For every  $g \in G(k)$ , one has  $hg e_0 = g(g^{-1} h g) e_0 = \chi(g^{-1} h g) g e_0$ , hence  $\chi(g^{-1} h g)$  is an eigenvalue of  $h$ . Hence the continuous map  $\phi : G(k) \rightarrow k$ ,  $g \mapsto \chi(g^{-1} h g)$ , takes only finitely many values, and since  $G(k)$  is irreducible (since dense in  $G$ ), one therefore has  $\phi(g) = \phi(e) = \chi(h)$  for every  $g \in G(k)$ , and so

```

```text

$$\chi(g^{-1} h g) = \chi(h), \quad \forall g \in G(k), h \in N(k).$$

```

Let E be the vector subspace of V generated by the vectors $e_{\{0\}}$, for $g \in G(k)$; by Lemma 11.17.0, this is the sub- G -module of V generated by $e_{\{0\}}$.

By what precedes, the two morphisms $N \times E \rightarrow E$, $(h, x) \mapsto hx$ and $(h, x) \mapsto \chi(h)x$, coincide on the set of rational points $(N \times E)(k) = N(k) \times E(k)$, which is dense in $N \times E$. Since $N \times E$ is reduced (and E separated), these two morphisms are therefore equal, so N acts on E by homotheties. Consequently, N is contained in the kernel K of the morphism $\rho : G \rightarrow \mathrm{GL}(\mathrm{End}_k(E))$, defined by $\rho(g)(u) = gu g^{-1}$, for every $g \in G(R)$ and $u \in \mathrm{End}_R(E \otimes R)$ (R a k -algebra). On the other hand, if $g \in K(R)$ then $g(e_{\{0\}}) = R e_{\{0\}}$, whence $g \in N(R)$. This shows that $N = K$. Then, by VI_A 5.4.1, the morphism $G/N \rightarrow \mathrm{GL}(\mathrm{End}_k(E))$ is a closed immersion, and hence G/N is affine.

(b) Suppose now G and N reduced, G not necessarily connected. Set $N' = N \cap G^{\{0\}}$; then $G^{\{0\}}/N'$ is affine by (a). On the other hand, $NG^{\{0\}}$ is an invariant subgroup of G and $G/NG^{\{0\}}$, being a quotient of the finite constant group $G/G^{\{0\}}$ (cf. VI_A, 5.5.1), is likewise a finite constant group. Hence G/N is the direct sum of the fibers of the morphism $G/N \rightarrow G/NG^{\{0\}}$, all isomorphic to $NG^{\{0\}}/N$, hence to $G^{\{0\}}/N'$, by VI_A, 5.3.3. Hence G/N is affine.

(c) Suppose G reduced, and N arbitrary. The morphism $G \times N \rightarrow N$, $(g, h) \mapsto ghg^{-1}$, induces a morphism $(G \times N)_{\mathrm{red}} \rightarrow N_{\mathrm{red}}$; now, since G is reduced and k algebraically closed, one has $(G \times N)_{\mathrm{red}} = G \times N_{\mathrm{red}}$, hence N_{red} is an invariant subgroup of G . (N.B. this fails when G is not reduced, cf. VI_A, 0.2.)

Hence, by (a), $G' = G/N_{\mathrm{red}}$ is affine. On the other hand, by VI_A 5.6.1, $N' = N/N_{\mathrm{red}}$ is a finite k -group, hence by Theorem 4.1 of Exp. V, the quotient $G/N = G'/N'$ is affine.

(d) For arbitrary G and N , the equivalence relation deduced from $G \times N \rightarrow G$ by the base change $G_{\mathrm{red}} \rightarrow G$ is:

```

```text

$$G_{\mathrm{red}} \times N' \rightarrow G_{\mathrm{red}}, \quad \text{where} \quad N' = N \cap G_{\mathrm{red}}.$$

```

Since the underlying spaces are the same (and since the quotient is the quotient ringed space), the morphism  $G_{\mathrm{red}}/N' \rightarrow G/N$  is a homeomorphism. Since  $G_{\mathrm{red}}/N'$  is reduced (since  $p : G_{\mathrm{red}} \rightarrow G_{\mathrm{red}}/N'$  is faithfully flat), it follows that  $(G/N)_{\mathrm{red}}$  is identified with  $G_{\mathrm{red}}/N'$ , which is affine by (c). Since  $G/N$  is of finite type over  $k$  (cf. VI\_A, 3.3.2), this implies, by EGA I, 5.1.10, that  $G/N$  is affine.

Finally, for arbitrary  $k$ , let  $\bar{k}$  be an algebraic closure of  $k$ . Then, by 9.2 (v),  $(G \times_{\bar{k}} \bar{k})/(N \times_{\bar{k}} \bar{k})$  is isomorphic to  $(G/N) \times_{\bar{k}} \bar{k}$ , hence since the former is affine, so is the latter, and so  $G/N$  is also affine, by (fpqc) descent (cf. EGA IV<sub>2</sub>, 2.7.1). This proves 11.17 when  $G$  is of finite type. To extend this to the general case, we shall need the following lemma. [N.D.E-VI\_B-C-133]

**\*Lemma 11.17.1.\*** \*Let  $(C_i \rightarrow A_i)_{i \in I}$  be a filtered inductive system of ring morphisms, all faithfully flat. Then  $A = \varinjlim A_i$  is faithfully flat over  $C = \varinjlim C_i$ .\*

<!-- label: III.VI\_B.11.17.1 -->

**\*Proof.\*** By [BAC] § I.3, Prop. 9, for a morphism of rings  $B \rightarrow B'$  to be faithfully flat, it is necessary and sufficient that it be injective and that  $B'/B$  be a flat  $B$ -module. Since each  $C_i \rightarrow A_i$  is faithfully flat, one therefore has exact sequences

```

```text

$$0 \rightarrow C_i \rightarrow A_i \rightarrow A_i / C_i \rightarrow 0$$

```

and A_i / C_i is a flat C_i -module, hence $(A_i / C_i) \otimes_{C_i} C$ is a flat C -module. Since inductive limits are exact and commute with the tensor product, one obtains an exact sequence

```

```text

$$0 \rightarrow C \rightarrow A \rightarrow A/C \rightarrow 0$$

```

as well as an isomorphism

```
```text
lim ((A_i / C_i) \otimes_{C_i} C) = (A/C) \otimes_C C = A/C,
```

from which one deduces that A/C is a flat C -module. Hence A is faithfully flat over C . ■

Let us now return to the proof of 11.17 in the general case, i.e. when G is not assumed to be of finite type. Set $\mathcal{A}(G) = A$ and $\mathcal{A}(N) = B = A/J$. By 11.13, A is the inductive limit of a filtered increasing family $(A_i)_{i \in I}$ of finitely generated sub-Hopf algebras, hence G is the projective limit of the algebraic affine k -groups $G_i = \operatorname{Spec}(A_i)$. Denote by Δ (resp. τ) the comultiplication (resp. the antipode) of A , and $\Delta_2 = (\Delta \otimes \operatorname{id}_A) \circ \Delta$.

For every i , $B_i = A_i / (J \cap A_i)$ is a quotient Hopf algebra of A_i , hence $N_i = \operatorname{Spec}(B_i)$ is a closed subgroup of G_i . Moreover, since N is invariant in G , the morphism $G \times N \rightarrow G$ defined by $(g, n) \mapsto g n g^{-1}$ factors through N , and this is equivalent to saying that the couple (A, J) satisfies the following property:

```
```text
(m_{13}) \circ (\Delta \otimes \tau) \circ \Delta_2(J) \subset A \otimes_k J
```

where  $m_{13}$  denotes the map  $a_1 \otimes a_2 \otimes a_3 \mapsto a_1 a_3 \otimes a_2$ . It follows that  $(A_i, J \cap A_i)$  satisfies the analogous property, hence that  $N_i$  is invariant in  $G_i$ . On the other hand, one has  $\varprojlim B_i = B$  and hence  $\varprojlim N_i = N$ .

By what we have seen previously, each (fpqc) sheaf quotient  $G_i / N_i$  is representable by an affine  $k$ -group  $Q_i = \operatorname{Spec}(C_i)$ . Set  $C = \varprojlim C_i$ . One thus has a filtered projective system of affine  $k$ -groups  $Q_i$ ; its projective limit  $Q = \varprojlim Q_i$  is the  $k$ -group  $\operatorname{Spec}(C)$  (cf. EGA IV<sub>3</sub>, 8.2.3). One then has an exact sequence of  $k$ -groups:

```
```text
1 \longrightarrow N \longrightarrow G \longrightarrow Q.
```

Let us show that Q represents the (fpqc) sheaf quotient of G by N ; for this, it suffices to verify that the morphism $G \rightarrow Q$ is covering for the (fpqc) topology (cf. IV, 3.3.2.1 and 5.1.7.1). Now, each of the morphisms $G_i \rightarrow Q_i$ is faithfully flat (cf. 9.2 (xi)), in other words A_i is faithfully flat over C_i ; since $A = \varprojlim A_i$ and $C = \varprojlim C_i$, it follows from Lemma 11.17.1 that A is faithfully flat over C , so that $G \rightarrow Q$ is a faithfully flat morphism. Since this morphism is affine, it is quasi-compact, hence covering for the (fpqc) topology. This completes the proof of Theorem 11.17. ■

11.18. Complements.

[^N.D.E-VI_B-C-134] Moreover, one deduces from 11.17 (and from its proof) the following results, taken from [DG70], III § 3.7. Let k be a field. We begin with the following lemma (cf. [An73], 2.3.3.2), which will be useful later (cf. 12.10).

Lemma 11.18.1. *Let $u : G \rightarrow G'$ be a morphism of k -groups, $N = \operatorname{Ker}(u)$. Suppose G' affine and G of finite type.*

(i) The morphism $\tau : G/N \rightarrow G'$ is a closed immersion. In particular, G/N is affine.*

(ii) If moreover the morphism $u^{\operatorname{natural}} : 0(G') \rightarrow 0(G)$ is injective, then τ is an isomorphism. (And hence G' is of finite type and u is faithfully flat.)*

<!-- label: III.VI_B.11.18.1 -->

Indeed, we know (11.13) that G is the projective limit of a filtered system of algebraic affine k -groups G'_i . Denote by u_i the composite morphism $G \rightarrow G' \rightarrow G'_i$ and by N_i its kernel. Then the N_i form a filtered decreasing system of closed subgroups of G , whose intersection is N . Since G is noetherian, there exists an index i such that $N = N_i$. Since G and G'_i are of finite type, by VI_A, 3.2 and 5.4.1, the quotient G/N is a finitely generated k -group and u_i is the composite of the projection $p : G \rightarrow G/N$, which is faithfully

flat, and a closed immersion $\tau_i : G/N \hookrightarrow G_i$.

Consider then the following commutative diagram:

$$\begin{array}{ccc} & & u \\ & & \nearrow \\ G & \xrightarrow{\quad} & G' \\ p \downarrow & \tau_i \nearrow & \searrow q_i \\ G/N & \xrightarrow{\quad} & G_i. \end{array}$$

Since $q_i \circ \tau_i = \tau_i$ is a closed immersion and q_i is separated (G' being separated, cf. VI_A, 0.3), then τ_i is a closed immersion (cf. EGA I, 5.4.4). It follows that G/N is affine, and that the morphism $\tau^{\text{natural}} : 0(G') \rightarrow 0(G/N)$ is surjective, whence (i).

If moreover $\tau^{\text{natural}} : 0(G') \rightarrow 0(G)$ is injective, so is τ^{natural} , hence τ^{natural} is an isomorphism, hence so is τ (since G' and G/N are affine). This proves (ii). ■

Theorem 11.18.2. *Let G and G' be two affine k -groups, with algebras A and A' , and let $u : G \rightarrow G'$ be a morphism of k -groups, $N = \text{Ker}(u)$, and $\phi : A' \rightarrow A$ the morphism induced by u .*

(i) If ϕ is injective, then u is faithfully flat and identifies G' with G/N .*

(ii) One has $G/N = \text{Spec}(B)$, where $B = \phi(A')$, and hence u is the composite of the faithfully flat morphism $G \rightarrow G/N$, corresponding to the inclusion $B \hookrightarrow A$, and of the closed immersion $G/N \hookrightarrow G'$, which corresponds to the surjection $A' \rightarrow B$. Moreover, N is defined in G by the ideal AB_+ , where B_+ denotes the augmentation ideal of B .*

(iii) In particular, if u is a monomorphism, it is a closed immersion.*

<!-- label: III.VI_B.11.18.2 -->

Proof. (i) Suppose ϕ injective and identify A' with a sub-Hopf algebra of A . By 11.13, A is the filtered union of finitely generated sub-Hopf algebras $A_i = 0(G_i)$; denote $G'_i = \text{Spec}(A_i)$, where $A'_i = A' \cap A_i$, and N_i the kernel of the morphism $G_i \rightarrow G'_i$ induced by the inclusion $A'_i \hookrightarrow A_i$. By the preceding lemma, one has $G_i / N_i \cong G'_i$ and one therefore obtains, for every i , an exact sequence

$$1 \longrightarrow N_i \longrightarrow G_i \xrightarrow{p_i} G'_i \longrightarrow 1$$

where p_i is faithfully flat. Since $G = \varinjlim G_i$ and $G' = \varinjlim G'_i$, one therefore obtains an exact sequence

$$1 \longrightarrow N \longrightarrow G \xrightarrow{p} G/N$$

where one has set $N = \varinjlim N_i$. Moreover, by Lemma 11.17.1, p is faithfully flat (and affine), hence G' represents the (fpqc) sheaf quotient of G by N . This proves (i).

In the general case, $B = \phi(A')$ is a sub-Hopf algebra of A ; denote by H the k -group $\text{Spec}(B)$ and N' the kernel of the morphism $G \rightarrow H$ induced by the inclusion $B \hookrightarrow A$. By (i), H is identified with G/N' , and u is therefore the composite of the projection $G \rightarrow G/N'$ and the closed immersion $G/N' \hookrightarrow G'$ induced by the surjection $A' \rightarrow B$. It follows that $N' = N$. Moreover, by 9.2 (ii), one has a cartesian square:

$$\begin{array}{ccc} & & \\ N & \longrightarrow & G \end{array}$$

$$\begin{array}{ccc} & \downarrow & \downarrow p \\ & \varepsilon & \downarrow \\ \mathrm{Spec}(k) & \longrightarrow & G' \end{array}$$

where ε is the unit section of G' , which corresponds to the augmentation morphism $B \rightarrow k$. It follows that N is defined in G by the ideal AB_+ . This proves (ii), and (iii) follows. ■

Remark 11.18.3. Let G be an affine k -group and N a normal k -subgroup. Since the morphism $p : G \rightarrow G/N$ is faithfully flat and quasi-compact, by IV 3.3.3.2, $O(G/N)$ is the subalgebra of $O(G)$ formed of functions ϕ which are right N -invariant, i.e. which satisfy $\phi(gh) = \phi(g)$, for every k -scheme S and $g \in G(S)$, $h \in N(S)$. Denoting by J the ideal of $A = O(G)$ which defines N , this is equivalent to saying that $\Delta(\phi) - \phi \otimes 1 \in O(G) \otimes J$, where Δ is the comultiplication of A .

<!-- label: III.VI_B.11.18.3 -->

The preceding theorem can then be reformulated in terms of Hopf algebras as follows.

Corollary 11.18.4. Let k be a field, A a commutative k -Hopf algebra, $G = \mathrm{Spec}(A)$.

(i) If B is a sub-Hopf algebra of A , then A is faithfully flat over B .

(ii) The map $N \mapsto O(G/N)$ is a bijection between the set of normal subgroups of G and that of sub-Hopf algebras of A ; the inverse map is given by $B \mapsto \mathrm{Spec}(A/AB_+)$. Moreover, if J is the ideal of A defining N , one has*

$$O(G/N) = \{x \in A \mid \Delta(x) - x \otimes 1 \in A \otimes J\}.$$

<!-- label: III.VI_B.11.18.4 -->

Remarks 11.18.5. (a) A consequence of the preceding theorem is that the category of commutative affine k -groups is abelian. For this, as well as for other results on affine k -groups, we refer to [DG70], § III.3, 7.4 to 7.8.

(b) Let us finally point out that M. Takeuchi has given another proof of results 11.17 to 11.18.4, cf. [Ta72], § 5; he moreover strengthened 11.18.4 (i) above by showing that A is even a projective B -module, cf. [Ta79], Th. 5 (see also [MW94], Th. 3.6).

<!-- label: III.VI_B.11.18.5 -->

12. Complements on G_{af} and the "anti-affine" groups

<!-- label: III.VI_B.12 -->

[^N.D.E-VI_B-C-135] We begin with the following lemma, which extends 11.18.1 to the case where G is not assumed to be of finite type.[^N.D.E-VI_B-C-136]

Lemma 12.1. Let k be a field, $u : G \rightarrow H$ a monomorphism of k -groups, with H affine. Suppose u quasi-compact. Then u is a closed immersion.*

<!-- label: III.VI_B.12.1 -->

Proof. By (fpqc) descent, one may suppose k algebraically closed. By VI_A, 6.4, the closed image I of u is a closed group subscheme of H , hence still affine. Hence, replacing H by I , one may suppose u schematically dominant. Since k is algebraically closed, $H' = H_{\mathrm{red}}$ is a group subscheme of H ; set $G' = G \times_{\mathrm{red}} H'$; then the morphism $u' : G' \rightarrow H'$ deduced from u by base change is a quasi-compact monomorphism, and is dominant (the underlying continuous map being the same for u and u'). Hence, by VI_A, 6.2, u' is faithfully flat; it is therefore a quasi-compact faithfully flat monomorphism, hence an isomorphism (cf. IV 1.14).

Hence $u : G \rightarrow H$ is a homeomorphism, so it is affine by 2.9.1. Hence G is affine, and so u is a closed immersion by 11.18.2 (iii). ■

Theorem 12.2. Let G be an algebraic k -group. Denote by ρ the canonical morphism $G \rightarrow G_{\mathrm{af}}$ and N its kernel.*

(i) The canonical morphism $G/N \rightarrow G_{\text{af}}$ is an isomorphism, and hence G_{af} is an algebraic affine group, and ρ is faithfully flat.

(ii) One has a canonical isomorphism $(G/N)_{\text{af}} = G_{\text{af}}$.

(iii) N is a characteristic subgroup of G .

(iv) $0(N) = k$.

(v) N is smooth, connected, and commutative.

<!-- label: III.VI_B.12.2 -->

Proof. Point (i) is a particular case of 11.18.1, and point (ii) follows from the universal properties of G_{af} and $(G/N)_{\text{af}}$.

Let us prove (iii). For an arbitrary k -scheme $\pi : S \rightarrow \operatorname{Spec} k$, consider the cartesian square:

$$\begin{array}{ccc} G_S & \longrightarrow & G \\ q \downarrow & & \downarrow p \\ S & \xrightarrow{\pi} & \operatorname{Spec} k. \end{array}$$

Since p is quasi-compact and separated and π flat, by EGA III 1.4.15 and EGA IV₁ 1.7.21, one has $q_*(0_{G_S}) = \pi_*(0(G)) = \pi_*(0(G_{\text{af}}))$, and hence, by EGA II, 1.5.2, one has $(G_S)_{\text{af}} = (G_{\text{af}})_S$. Hence N_S , being the kernel of the canonical morphism $G_S \rightarrow (G_S)_{\text{af}}$, is invariant under every automorphism of G_S , i.e. N is a characteristic subgroup of G .

To prove (iv), set $N' = \operatorname{Ker}(N \rightarrow N_{\text{af}})$; by (ii), this is an invariant subgroup of G . Since N is algebraic (being a closed subgroup of G), by (i), $N/N' \cong N_{\text{af}}$; moreover, by VI_A, 3.2 and 5.3.2, one has an isomorphism of k -groups

$$(G/N') / N_{\text{af}} \cong (G/N') / (N/N') \cong G/N.$$

Since N_{af} is affine, the projection $G/N' \rightarrow G/N$ is also affine, by 9.2 (vii), and since $G/N = G_{\text{af}}$ is affine, so is G/N' . Hence, by the universal property of G_{af} , the projection $p' : G \rightarrow G/N'$ factors through $G_{\text{af}} = G/N$, whence $N \subset N'$ and hence $N = N'$. Hence N_{af} is the trivial group, whence $0(N) = k$.

Finally, assertion (v) follows from the following lemma. ■

Lemma 12.3. Let k be a field and N an algebraic k -group such that $0(N) = k$. Then N is smooth, connected, and commutative.

<!-- label: III.VI_B.12.3 -->

Indeed, one may suppose k algebraically closed. Then $H = N^{\{0\}}$ is a k -subgroup of N , and the quotient k -scheme $X = N/H$ is finite (hence affine) over k , by VI_A, 5.5.1 and 5.6.1. Moreover, since $p : N \rightarrow X$ is faithfully flat, one has $0(X) \subset 0(N) = k$. It follows that $N = N^{\{0\}}$, hence N is smooth (VI_A 1.3.1) and connected.

Let then Z be the center of N . By 6.2.6, N/Z is affine, and one obtains as above that $0(N/Z) = k$, whence $N = Z$. This proves 12.3 and completes the proof of 12.2. ■

Let us also state, without proof, the following theorem. (Recall that an *abelian variety* over a field k is a proper, smooth, and connected k -group scheme.)

Theorem 12.4 (Chevalley). Let k be a perfect field and G an algebraic, smooth and connected k -group. Then there exists an affine, smooth and connected k -subgroup L , invariant in G , such that the quotient G/L is an abelian variety. Moreover, L is unique and its formation commutes with extension of the base field.

<!-- label: III.VI_B.12.4 -->

Remarks 12.5. (1) This theorem was announced in 1953 by C. Chevalley, who published his proof in 1960 ([Ch60]). Meanwhile, other proofs were obtained, independently, by I. Barsotti and M. Rosenlicht ([Ba55, Ro56]); see [Se99] for historical comments.

(2) A modern version (i.e. in the language of schemes) of Chevalley's proof has been given by B. Conrad ([Co02]). (Note that in loc. cit., "algebraic group" means smooth and connected k -group scheme.)

(3) On the other hand, a modern version of Rosenlicht's proof has been given by Ngô B.-C. in a course at Orsay in 2005-2006.

(4) If one drops the hypothesis that k is perfect, there still exists a smallest invariant connected affine subgroup L (not necessarily smooth) such that G/L is an abelian variety ([BLR], § 9.2, Thm. 1).

(5) One may also drop the hypothesis that G is smooth over k : indeed, by VII_A, 8.3, there exists an integer $n \geq 1$ such that the quotient $G' = G/(F^{n-1}G)$ is smooth; then G' contains a subgroup L' as in (4) above, and the inverse image of L' in G still has the same properties. Hence, for every connected algebraic group G over a field k , there exists an exact sequence

$$1 \longrightarrow H \longrightarrow G \longrightarrow A \longrightarrow 1$$

where H is an affine k -group and A a k -abelian variety. Moreover, by [Per76], Cor. 4.2.9, one has such an exact sequence for every connected k -group G (not necessarily algebraic).

(6) Let k be an algebraically closed field and G the semi-direct product of an elliptic curve E by the constant k -group $\mathbb{G}_m$, for the action defined by $(-1) \cdot x = -x$; in this case, if L is a closed invariant subgroup of G such that G/L is connected, then $L = G$.

<!-- label: III.VI_B.12.5 -->

Remark 12.6. One will say, following [Br09], that a k -group N is *anti-affine* if $H^0(N) = k$. By 12.3 and 12.4, if k is perfect, every anti-affine algebraic k -group is an extension of an abelian variety by a smooth, connected, commutative affine algebraic k -group. For the precise structure of anti-affine algebraic groups over a perfect field, and various consequences, see the recent articles of M. Brion and C. & F. Sancho de Salas ([Br09, SS09]).

<!-- label: III.VI_B.12.6 -->

To conclude this section, we shall prove two results due to M. Raynaud, the first being Remark 11.11.1, the second Proposition 2.1 of Exp. XVII, Appendix III. We shall need the following lemma, [N.D.E-VI_B-C-137] which improves (for a complete discrete valuation ring R) the flatness criteria given in [BAC], § III.5.

Lemma 12.7. Let R be a discrete valuation ring, K its field of fractions, π a uniformizer. Let A be a flat R -algebra and M an A -module flat over R . Suppose that:

- (i) $M/\pi M$ is a flat module over $\bar{A} = A/\pi A$,
- (ii) $M \otimes_R K$ is a flat module over $A \otimes_R K$.

Then M is a flat A -module.

<!-- label: III.VI_B.12.7 -->

Proof. By the flatness criterion in the nilpotent case (cf. [BAC], III § 5.2, Th. 1), $M/\pi^n M$ is a flat module over $A/\pi^n A$, for every $n \in \mathbb{N}$. It then follows from [RG71], II Lemma 1.4.2.1, that M is a flat A -module. For the reader's convenience, let us briefly indicate the proof. Set $s = \pi^n$ and $P = M/sM$. Since P is flat over A/sA and the latter is of projective dimension 1 over A , it follows from the spectral sequence of composite functors that P is of Tor-dimension ≤ 1 over A . Now, since M is R -flat hence without π -torsion, $M_{(K)} / M$ is the inductive limit of the A -modules $\pi^{-n} M / M \cap \pi^{-n} M$, and hence $M_{(K)} / M$ is also of Tor-dimension ≤ 1 . Since one has the exact sequence $0 \rightarrow M \rightarrow M_{(K)} \rightarrow M_{(K)} / M \rightarrow 0$ and by hypothesis $M_{(K)}$ is flat over $A_{(K)}$ hence over A , it follows that M is flat.

For completeness, let us also indicate the following simpler proof, pointed out by O. Gabber. Let I be a finitely generated ideal of A ; one must show that the morphism $u : M \otimes_A I \rightarrow M$ is injective. By hypothesis (ii), $u \otimes_{\mathcal{R}} K$ is injective, hence $\ker(u)$ is an $\mathcal{R}$ -module of π -torsion. It therefore suffices to show that the π -torsion part of $M \otimes_A I$ is zero; now this is a quotient of $\mathrm{Tor}_1^A(M, I/\pi I)$, as one sees by tensoring with M the exact sequence:

$$0 \longrightarrow I \xrightarrow{\pi} I \longrightarrow I/\pi I \longrightarrow 0.$$

On the other hand, M being without π -torsion (since flat over $\mathcal{R}$), one obtains that $\mathrm{Tor}_i^A(M, \bar{A}) = 0$ for every $i \geq 1$. Consequently, if $(P_{\bullet})$ is a projective resolution of the A -module M , then $(P_{\bullet} \otimes_A \bar{A})$ is a projective resolution of the $\bar{A}$ -module $\bar{M} = M/\pi M$, and hence for every $\bar{A}$ -module N , one has $\mathrm{Tor}_i^A(M, N) = \mathrm{Tor}_i^{\bar{A}}(\bar{M}, N)$, and this is zero for $i \geq 1$ since $\bar{M}$ is flat over $\bar{A}$. One thus has $\mathrm{Tor}_1^A(M, I/\pi I) = 0$, which proves the lemma. ■

Remark 12.8. Let S be a regular locally noetherian scheme of dimension 1, and X a flat, quasi-separated and quasi-compact S -scheme. Then $\mathcal{A}(X)$ is a flat $\mathcal{O}_S$ -module. Indeed, one may suppose S local; denote by s its closed point, i_s the inclusion $X_s \hookrightarrow X$, and π a uniformizer of $\mathcal{R} = \mathcal{O}(S)$; since X is flat over S , one has an exact sequence of sheaves

$$0 \longrightarrow \mathcal{O}_X \xrightarrow{\pi} \mathcal{O}_X \longrightarrow i_{*}(\mathcal{O}_{X_s}) \rightarrow 0$$

and so, by taking global sections, one obtains that $\mathcal{A}(X)$ is an $\mathcal{R}$ -module without π -torsion, hence flat. [N.D.E-VI_B-C-138] One obtains moreover that the morphism from $\mathcal{A}((X_{\mathrm{af}})_s) = \mathcal{A}(X)/\pi \mathcal{A}(X)$ to $\mathcal{A}(X_s)$, induced by the morphism $X \rightarrow X_{\mathrm{af}}$, is injective.

<!-- label: III.VI_B.12.8 -->

One can now prove the following proposition (cf. Remark 11.11.1).

Proposition 12.9. *Let S be a regular locally noetherian scheme of dimension ≤ 1 , G an S -group scheme flat, quasi-separated and quasi-compact over S . Then the following conditions are equivalent:*

- *(i) G is affine over S .*
- *(ii) G is quasi-affine over S .*
- *(iii) G acts faithfully on a quasi-affine and flat S -scheme X .*
- *(iv) G acts linearly and faithfully on a quasi-coherent module E flat over S .*
- *(v) The morphism $\rho : G \rightarrow G_{\mathrm{af}}$ is a monomorphism.*

<!-- label: III.VI_B.12.9 -->

Proof. The implication (i) $\Rightarrow$ (ii) is evident, as is (ii) $\Rightarrow$ (iii) (take $X = G$).

Suppose (iii) holds. Since $\mathcal{A}(G)$ and $\mathcal{A}(X)$ are flat $\mathcal{O}_S$ -modules, one obtains, proceeding as in 11.11, that G acts (on the right) faithfully on X_{af} and hence acts (on the left) linearly and faithfully on the flat quasi-coherent $\mathcal{O}_S$ -module $\mathcal{A}(X)$.

Moreover, if (iv) holds, by 11.6.1 (ii), the monomorphism $G \rightarrow \mathrm{Aut}_{\mathcal{O}_S}(E)$ factors through G_{af} , hence $G \rightarrow G_{\mathrm{af}}$ is a monomorphism.

Finally, suppose (v) holds and let us show that $\rho : G \rightarrow G_{\mathrm{af}}$ is an isomorphism. Replacing S by one of its connected components, one may suppose S irreducible, with generic point η . Since the formation of G_{af} commutes with flat base changes, one has $(G_{\mathrm{af}})_{\eta} = (G_{\eta})_{\mathrm{af}}$, and therefore the morphism $G_{\eta} \rightarrow (G_{\eta})_{\mathrm{af}}$ is a monomorphism, hence a closed immersion by 12.1, hence an isomorphism since $0((G_{\eta})_{\mathrm{af}}) = 0(G_{\eta})$. If $S = \mathrm{Spec}(\kappa(\eta))$ we are done; one may therefore suppose

$\dim S = 1$.

Let then s be a closed point of S ; let us show that $G_s \rightarrow (G_{\text{af}})_s$ is an isomorphism and that ρ is flat at every point of G_s . For this, one may suppose S local, with closed point s . The morphism $\rho_s : G_s \rightarrow (G_{\text{af}})_s$ obtained by base change is a monomorphism, hence a closed immersion by 12.1, hence the morphism $0((G_{\text{af}})_s) \rightarrow 0(G_s)$, induced by ρ_s , is surjective. Now, by the preceding remark, it is also injective, hence it is an isomorphism. (In particular, ρ is therefore surjective.)

It then follows from Lemma 12.7 that $\rho : G \rightarrow G_{\text{af}}$ is faithfully flat. Since G is quasi-compact over S and G_{af} separated over S , ρ is also quasi-compact (cf. EGA I, 6.6.4). Consequently, ρ is a faithfully flat quasi-compact monomorphism, hence an isomorphism. This proves the proposition. ■

Finally, let us prove Prop. 2.1 of Exp. XVII, Appendix III; taking into account [Per76], Cor. 4.2.5, we have substituted in the hypotheses "quasi-compact and quasi-separated" for "of finite type" (if one assumes G of finite type, one can use 12.1 instead of loc. cit.).

****Proposition 12.10.**** *Let S be a regular locally noetherian scheme of dimension ≤ 1 , G an S -group scheme flat, quasi-compact and quasi-separated.*

(i) The canonical morphism $\rho : G \rightarrow G_{\text{af}}$ is faithfully flat and quasi-compact. Consequently, G_{af} represents the (fpqc) sheaf quotient of G by $N = \text{Ker}(\rho)$.*

(ii) If moreover G is of finite type over S , then ρ is of finite presentation and G_{af} represents the (fppf) sheaf quotient of G by N and is of finite type over S .*

(iii) Suppose moreover G_{η} affine for every maximal point η of S . Then N is an étale S -group, and is the unit group if G is separated over S .*

<!-- label: III.VI_B.12.10 -->

Proof. First, since G_{af} is affine, hence separated over S , ρ is quasi-compact (cf. EGA I, 6.6.4) and the kernel $N = \text{Ker}(\rho)$ is a closed subgroup of G . Moreover, replacing S by one of its connected components, one may suppose S irreducible, with generic point η .

Let us remark that, to prove (i) and (ii), it suffices to show that ρ is faithfully flat, because then, by Exp. IV, 5.1.7.1, G_{af} represents the (fpqc) sheaf quotient of G by N , and if moreover G is of finite type over S , hence of finite presentation (S being locally noetherian), then, by 9.2 (xiii), ρ is of finite presentation (as is $G_{\text{af}} \rightarrow S$) and hence ρ is covering for the (fppf) topology.

One may therefore suppose $S = \text{Spec}(R)$, where R is a discrete valuation ring (if $\dim S = 1$) or else the field $\kappa(\eta)$ (if $\dim S = 0$). Denote by s the closed point of S . Since the formation of G_{af} commutes with flat base changes, the canonical morphism $G_{\eta} \rightarrow (G_{\eta})_{\text{af}}$ is identified with the morphism $\rho_{\eta} : G_{\eta} \rightarrow (G_{\text{af}})_{\eta}$, and since $0((G_{\text{af}})_{\eta}) = 0((G_{\eta})_{\text{af}}) = 0(G_{\eta})$, then ρ_{η} is faithfully flat by [Per76], 4.2.5 (see also the addition VI_A, 6.6). If $\dim S = 1$, one similarly obtains that ρ_s is faithfully flat, since the morphism $0((G_{\text{af}})_s) \rightarrow 0(G_s)$ is injective, by Remark 12.8. Hence, by Lemma 12.7, ρ is faithfully flat. This proves (i) and (ii). In particular, N is flat over S .

Suppose now G_{η} affine. Since ρ_{η} coincides with the canonical morphism $G_{\eta} \rightarrow (G_{\eta})_{\text{af}}$, its kernel N_{η} is the unit group. Let us show that N is étale over S . Since N is flat over S , it remains to see that N_s is étale over $\kappa(s)$, for every point $s \neq \eta$ of S . There is nothing to prove if $S = \text{Spec}(\kappa(\eta))$, so one may suppose $S = \text{Spec}(R)$, where R is a discrete valuation ring. Let s be the closed point of S , K the field of fractions of R , and π a uniformizer. Let $x \in N_s$ and U_x an affine open neighborhood of x in N ; since N is flat over S , $U_x \cap N_{\eta}$ is non-empty, hence equal to $\{\epsilon(\eta)\}$, where $\epsilon(\eta)$ denotes the unit section. Hence $A = 0(U_x)$ is a flat R -algebra, such that $A_K = K$ and $\pi^{-1} \notin A$ (since π belongs to the maximal ideal of $0_{U,x}$). It follows that $A = R$, and hence the projection $U_x \rightarrow S$ is an isomorphism. This proves that N is étale over S ; if moreover G is separated over S , then the inverse isomorphism $S \rightarrow U_x$ equals the unit section (since they coincide on the dense open subset $\{\eta\}$ of $S = \text{Spec}(R)$), hence N is the unit group. The proposition is proved. ■

One obtains in particular the following corollary, two other proofs of which are found in [An73], Prop. 2.3.1 and [PY06], Prop. 3.1.

****Corollary 12.10.1.**** *Let R be a discrete valuation ring, K its field of fractions, G an R -group scheme separated, flat and of finite type over R . If G_K is affine, then G is affine.*

<!-- label: III.VI_B.12.10.1 -->

Remarks 12.10.2. (a) On the one hand, O. Gabber has pointed out to us examples where G is a flat group of finite type over a discrete valuation ring, whose generic fiber is an abelian variety, and where the kernel N of $G \rightarrow G_{\text{af}}$ is not smooth.

(b) On the other hand, let us point out that M. Raynaud has given an example, for S the affine plane of dimension 2 over a field k , of a smooth and quasi-affine S -group scheme, with affine and connected fibers, which is not affine over S , cf. [Ray70a], § VII.3, p. 116.

13. Flat affine groups over a regular base of dimension ≤ 2

<!-- label: III.VI_B.13 -->

[^N.D.E-VI_B-D-139] Let us begin by remarking that the well-known argument which shows that every affine algebraic group over a field k is linear, as well as Lemma 11.12, extend to the case of a group scheme G , affine, flat, and of finite type over a base scheme S which is noetherian, regular, of dimension ≤ 2 . For S of dimension ≤ 1 , this proves point (b) of Remark 11.11.1. The extension to the case $\dim S = 2$ rests on the following lemma, which was communicated to us by O. Gabber.

Lemma 13.1. *Let S be a normal noetherian scheme, $\mathcal{A}$ a flat quasi-coherent $\mathcal{O}_S$ -module, $\mathcal{F}$ a quasi-coherent $\mathcal{O}_S$ -submodule of finite type of $\mathcal{A}$, $\mathcal{F}^{**}$ its bidual, and $\mathcal{U}$ the flatness locus of $\mathcal{F}$, i.e. the set of points $s \in S$ such that $\mathcal{F}_s$ is a flat $\mathcal{O}_{S,s}$ -module.*

(i) $\mathcal{U}$ is an open subset of S and $\mathcal{F}^{**} = j_* j^*(\mathcal{F})$, where j denotes the inclusion $\mathcal{U} \hookrightarrow X$.

(ii) The canonical morphism $j_* j^*(\mathcal{F}) \otimes_{\mathcal{O}_S} \mathcal{A} \rightarrow j_* j^*(\mathcal{F}) \otimes_{\mathcal{O}_S} \mathcal{A}$ is an isomorphism, for every quasi-coherent $\mathcal{O}_U$ -module $\mathcal{E}$.

(iii) In particular, $\mathcal{V} = j_{\ast} j^{\ast}(\mathcal{F})$ is a submodule of $\mathcal{A} = j_{\ast} j^{\ast}(\mathcal{A})$, and the canonical morphism $\mathcal{V} \otimes_{\mathcal{O}_S} \mathcal{A} \rightarrow j_{\ast} j^{\ast}(\mathcal{F}) \otimes_{\mathcal{O}_S} \mathcal{A}$ is an isomorphism.

<!-- label: III.VI_B.13.1 -->

Proof. Replacing S by one of its connected components, we may suppose S integral. By EGA IV₂, 2.1.12, the flatness locus of $\mathcal{F}$, i.e. the set of points s in S such that $\mathcal{F}_s$ is a flat $\mathcal{O}_{S,s}$ -module, is an open subset U of S ; denote by j the inclusion $U \hookrightarrow S$. Since $\mathcal{A}_s$ is flat, hence torsion-free, so is $\mathcal{F}_s$,

<!-- original page 436 -->

so U contains every point of codimension ≤ 1 . Consequently, by [BAC], VII, § 4.2, cor. of th. 1, one has $\mathcal{F}^{\ast} = j_{\ast} j^{\ast}(\mathcal{F})$, and one therefore obtains a monomorphism $\mathcal{F}^{\ast} \rightarrow j_{\ast} j^{\ast}(\mathcal{A})$.

The proof of (ii) is analogous to that of EGA III, 1.4.15, recalled in 11.0. On the other hand, since S is normal, the morphism $\mathcal{O}_S \rightarrow j_{\ast} j^{\ast}(\mathcal{O}_S)$ is an isomorphism (cf. EGA IV₂, 5.8.6 and 5.10.5). By (ii) applied to $\mathcal{E} = \mathcal{O}_U$, one therefore has $\mathcal{A} = j_{\ast} j^{\ast}(\mathcal{A})$. Finally, since $j^{\ast}(\mathcal{F} \otimes_{\mathcal{O}_S} \mathcal{A}) = j^{\ast}(\mathcal{F}) \otimes_{\mathcal{O}_U} j^{\ast}(\mathcal{A})$, the final assertion of (iii) follows from (ii) applied to $\mathcal{E} = j^{\ast}(\mathcal{F})$. The lemma is proved. ■

Furthermore, recall that a finitely generated R -module M is said to be *reflexive* if the canonical morphism from M to its bidual $M^{\ast\ast}$ is an isomorphism. When R is a noetherian regular ring of dimension ≤ 2 , this entails that M is projective. Indeed, for every finitely generated R -module N , consider a resolution $L_1 \rightarrow L_0 \rightarrow N \rightarrow 0$, where L_0 and L_1 are finitely generated free R -modules; then one has an exact sequence

$$\begin{array}{l} \text{``text} \\ 0 \rightarrow N^{\ast} \rightarrow L_0^{\ast} \rightarrow L_1^{\ast} \rightarrow 0 \rightarrow 0, \\ \text{``} \end{array}$$

where Q denotes the cokernel of $L_0^{\ast} \rightarrow L_1^{\ast}$, and since R is of homological dimension ≤ 2 (cf. [BAC], X § 4.2, cor. 1 of th. 1), it follows that $N^{\ast}$ is projective.

Proposition 13.2. *Let S be a noetherian regular scheme of dimension ≤ 2 , G an affine flat S -group, $\mathcal{A}(G)$ its affine algebra.*

(i) If G is of finite type over S , it is isomorphic to a closed subgroup of $H = \operatorname{Aut}_{\mathcal{O}_S}(\mathcal{V})$, for some $\mathcal{O}_S$ -module $\mathcal{V}$ locally free of finite rank. If moreover S is affine, one may take $\mathcal{V} = \mathcal{O}^{\oplus d}$ for some d , whence $H = GL_{d,S}$.*

(ii) $\mathcal{A}(G)$ is a filtered inductive limit of flat $\mathcal{O}_S$ -sub-Hopf-algebras of finite type.*

<!-- label: III.VI_B.13.2 -->

Proof. Let $\mathcal{B}$ be a finitely generated $\mathcal{O}_S$ -subalgebra of $\mathcal{A}(G)$. Since every coherent module on an open of S extends to a coherent module on S (cf. EGA I, 9.4.5), there exists a coherent $\mathcal{O}_S$ -submodule $\mathcal{M}$ of $\mathcal{B}$ which generates $\mathcal{B}$ as an $\mathcal{O}_S$ -algebra (loc. cit., 9.6.5). By 11.10.bis, $\mathcal{M}$ is contained in a coherent G -stable $\mathcal{O}_S$ -submodule $\mathcal{F}$. (N.B. Since G is here affine over S , the proof of loc. cit. is written more simply: one may there replace $f_{\ast} f^{\ast}(\mathcal{E})$ by $\mathcal{E} \otimes_{\mathcal{O}_S} \mathcal{A}(G)$, etc.)

Let j be the inclusion $U \hookrightarrow S$, where U denotes the flatness locus of $\mathcal{F}$. By Lemma 13.1 and the remarks following it, $\mathcal{V} = j_{\ast} j^{\ast}(\mathcal{F})$ is a locally free $\mathcal{O}_S$ -submodule of $\mathcal{A}(G)$, and since the canonical morphism

$$\begin{array}{l} \text{``text} \\ \mathcal{V} \otimes \mathcal{V}(G) \rightarrow j_{\ast} j^{\ast}(\mathcal{V} \otimes \mathcal{V}(G)) \\ \text{``} \end{array}$$

is an isomorphism, $\mathcal{V}$ is a G -submodule of $\mathcal{A}(G)$. The action of G on $\mathcal{V}$ then induces a morphism of affine S -groups $\rho_{\mathcal{V}} : G \rightarrow H = \operatorname{Aut}_{\mathcal{O}_S}(\mathcal{V})$ and hence a morphism of $\mathcal{O}_S$ -Hopf algebras $\phi_{\mathcal{V}} : \mathcal{A}(H) \rightarrow \mathcal{A}(G)$. Denote by

$\mathcal{A}_{\mathcal{V}}$ the image of $\phi_{\mathcal{V}}$; this is the affine algebra of a closed subgroup $G_{\mathcal{V}}$ of H , which is the closed image of $\rho_{\mathcal{V}}$. Let us show that $\mathcal{A}_{\mathcal{V}}$ contains $\mathcal{B}$.

The question being local on S , one may suppose $S = \operatorname{Spec}(R)$ and $V = \Gamma(S, \mathcal{V})$ is a free R -module with basis $v_1, \dots, v_n$; in this case $H \simeq GL_n(R)$ and $\mathcal{A}(H)$ is generated as an R -algebra by the "matrix coefficients" c_{ij} and the element d^{-1} , where

<!-- original page 437 -->

d denotes the determinant. Let Δ (resp. ϵ) be the comultiplication (resp. the augmentation) of $\mathcal{A}$. For $j = 1, \dots, n$, write $\Delta(v_j) = \sum_{i=1}^n v_i \otimes a_{ij}$; then $a_{ij} = \phi(c_{ij})$ belongs to $\operatorname{Im}(\phi)$. On the other hand, since V is an R -submodule of $\mathcal{A}$, one can use the identity $(\epsilon \otimes \operatorname{id}_{\mathcal{A}}) \circ \Delta = \operatorname{id}_{\mathcal{A}}$, which entails that $v_j = \sum_i \epsilon(v_i) a_{ij}$ belongs to $\operatorname{Im}(\phi)$. Since V contains a system of generators of $\mathcal{B} = \Gamma(S, \mathcal{B})$, it follows that $\mathcal{B} \subset \operatorname{Im}(\phi)$.

If G is of finite type over S , one may take $\mathcal{B} = \mathcal{A}(G)$ and ϕ is then surjective, so the morphism of S -groups $G \rightarrow H = \operatorname{Aut}_{\{0\}}(\mathcal{V})$ is a closed immersion.

If moreover S is affine, there exists a locally free $\mathcal{O}_S$ -module $\mathcal{V}'$ of finite rank such that $\mathcal{V} \oplus \mathcal{V}' = \mathcal{O}_S^d$ as $\mathcal{O}_S$ -modules. Regarding $\mathcal{V}'$ as a trivial G -module, one may replace $\mathcal{V}$ by $\mathcal{O}_S^d$, and one thus obtains that G is a closed subgroup of $GL_{\{d\}}(S)$.

Finally, let us return to the case of an arbitrary flat affine S -group G . By EGA I, 9.4.9, $\mathcal{A}(G)$ is the union of its coherent $\mathcal{O}_S$ -submodules $\mathcal{M}$, hence also of the $\mathcal{O}_S$ -sub-Hopf-algebras $\mathcal{A}_{\mathcal{V}}$ as above, whence (ii). ■

Example 13.3. Let R be a discrete valuation ring, with uniformizer π and field of fractions K . Consider the filtered projective system of R -groups:

```

text
... → G_{a,R} →^{×π} G_{a,R} →^{×π} G_{a,R}

```

(corresponding to the inductive system $R[X_0] \rightarrow R[X_1] \rightarrow R[X_2] \rightarrow \dots$, where the transition morphisms are given by $X_n = \pi X_{n+1}$). Its projective limit G is a flat affine R -group scheme, not of finite type, whose special fiber is trivial and whose generic fiber is $G_{a,K}$; the affine R -algebra $\mathcal{A}(G)$ is the subring of $K[X]$ formed of polynomials whose constant coefficient belongs to R . (N.B. We have already encountered this example in Remark 11.10.1.) Note that G represents the functor which to every R -algebra B associates the set of sequences $(x_n)_n$ in $\mathbb{N}$ of elements of B such that $x_n = \pi x_{n+1}$ for every n . (In particular, each x_n is indefinitely π -divisible.)

<!-- label: III.VI_B.13.3 -->

Now let S be a noetherian scheme such that every coherent $\mathcal{O}_S$ -module is the quotient of a locally free $\mathcal{O}_S$ -module of finite type; this is the case, for example, if S is a separated noetherian regular scheme, cf. SGA 6, Exp. II, 2.1.1 and 2.2.7. (One can show that every noetherian regular scheme of dimension ≤ 1 also has this property; on the other hand, it fails when S is the affine plane over a field k with the origin doubled, cf. loc. cit., 2.2.7.2.)

Definition 13.4. Let G be a flat affine S -group. Following R. W. Thomason ([Th87], 2.1), we say that the pair (G, S) possesses the equivariant resolution property*, or satisfies (RE), if for every coherent $\mathcal{O}_S$ -module $\mathcal{F}$, there exists a locally free $\mathcal{O}_S$ -module $\mathcal{E}$ of finite rank and a G -equivariant epimorphism $\mathcal{E} \rightarrow \mathcal{F}$.

<!-- label: III.VI_B.13.4 -->

In loc. cit., Th. 3.1, Thomason proves the result below, under the hypothesis that G is essentially free over S (cf. the remark further on). Gabber pointed out to us the simpler proof below, which does not use this hypothesis.

Proposition 13.5. Let S be a noetherian scheme and G an S -group affine, flat, and of finite type, with affine algebra $\mathcal{A}(G)$. Suppose that (G, S) satisfies (RE). Then:

<!-- original page 438 -->

(i) G is isomorphic to a closed subgroup of $H = \operatorname{Aut}_{\{0\}}(\mathcal{V})$, for some 0_S -module $\mathcal{V}$ locally free of finite rank.

(ii) If moreover S is affine, one may take $\mathcal{V} = 0^{\oplus d}_{\{S\}}$ for some d , whence $H = \operatorname{GL}_{\{d,S\}}$.

<!-- label: III.VI_B.13.5 -->

The proof is analogous to that of 13.2. As in loc. cit., there exists a coherent G -stable 0_S -submodule $\mathcal{F}$ which generates $\mathcal{A} = \mathcal{A}(G)$ as an 0_S -algebra. Replacing S by one of its connected components, we may suppose S connected. By hypothesis (RE), there exists a locally free G - 0_S -module $\mathcal{E}$ of rank n , and an epimorphism of $\mathcal{A}$ -comodules $\pi : \mathcal{E} \rightarrow \mathcal{F}$. Set $H = \operatorname{Aut}_{\{0\}}(\mathcal{E})$; this is an S -group scheme, locally isomorphic to $\operatorname{GL}_{\{n,S\}}$. The action of G on $\mathcal{E}$ induces a morphism of affine S -groups $\rho : G \rightarrow H$, corresponding to a morphism of 0_S -Hopf algebras $\phi : \mathcal{A}(H) \rightarrow \mathcal{A}(G)$. Let us show that ρ is a closed immersion.

The question being local on S , one may suppose $S = \operatorname{Spec}(R)$ and $V = \Gamma(S, \mathcal{E})$ is a free R -module with basis $v_1, \dots, v_n$; in this case $H \simeq \operatorname{GL}_{\{n,R\}}$ and $B = \Gamma(S, \mathcal{A}(H))$ is generated as an R -algebra by the "matrix coefficients" c_{ij} and the element d^{-1} , where d denotes the determinant. Let Δ (resp. ϵ) be the comultiplication (resp. the augmentation) of $A = \Gamma(S, \mathcal{A}(G))$, let $\mu : V \rightarrow V \otimes_R A$ be the A -comodule structure on V , and let $F = \Gamma(S, \mathcal{F})$. For $j = 1, \dots, n$, write

$$\mu(v_j) = \sum_{i=1}^n v_i \otimes a_{ij}$$

then $\phi(c_{ij}) = a_{ij}$. On the other hand, since $\pi : V \rightarrow F$ is a morphism of A -comodules, one has

$$\sum_{i=1}^n \pi(v_i) \otimes a_{ij} = (\pi \otimes_R \operatorname{id}_A)(\mu(v_j)) = \Delta(\pi(v_j))$$

and therefore

$$\pi(v_j) = (\epsilon \otimes_R \operatorname{id}_A) \Delta(\pi(v_j)) = \sum_{i=1}^n (\epsilon \pi(v_i)) a_{ij} = \phi(\sum_{i=1}^n (\epsilon \pi(v_i)) c_{ij}).$$

Hence $\phi(B)$ contains $\pi(V) = F$, which generates A as an R -algebra, and hence ϕ is surjective. This shows that ρ is a closed immersion, whence assertion (i).

If moreover S is affine, there exists a locally free 0_S -module $\mathcal{V}$ of finite rank such that $\mathcal{V} \oplus \mathcal{V}' = 0^{\oplus d}_{\{S\}}$ as 0_S -modules. Regarding $\mathcal{V}'$ as a trivial G -module, one may replace $\mathcal{V}$ by $0^{\oplus d}_{\{S\}}$, and one thus obtains that G is a closed subgroup of $\operatorname{GL}_{\{d,S\}}$. The proposition is proved. ■

Remarks 13.6. (a) For the sake of completeness, let us briefly sketch Thomason's argument ([Th87], Th. 3.1), keeping the preceding notation. The G -equivariant epimorphism $\pi : \mathcal{E} \rightarrow \mathcal{F}$ induces a closed immersion $\tau : G \rightarrow V(\mathcal{E})$ such that $\tau(g) = \tau(g) \cdot g$ (N.B.: G acts on the right on $V(\mathcal{E})$), and one has an isomorphism $H \simeq \operatorname{Aut}_{\{0\}}(V(\mathcal{E}))^{\otimes}$, which is compatible with the actions of G on the left on $\mathcal{E}$ and on the right on $V(\mathcal{E})$. Now let N be the strict transporter $\operatorname{Transp}^{\{H\}}(\tau(G), \tau(G))$; when G is essentially free over S , it follows from 6.2.4 e) that N is a closed subgroup scheme of H , hence affine over S . Moreover, ρ factors through a

<!-- original page 439 -->

morphism of S -groups $\rho' : G \rightarrow N$. On the other hand, for every $S' \rightarrow S$ and $h \in N(S')$, set $\pi(h) = \tau(1) \cdot h$ (where 1 is the unit element of $G(S')$); this defines a morphism of S -schemes $\pi : N \rightarrow \tau(G)$, which is a retraction of ρ' (when one identifies G with $\tau(G)$). Since N is separated over S , it follows that ρ' is a closed immersion.

(b) It seems that the proof of [Th87], Th. 3.1 requires the hypothesis that G be essentially free over S , which does not appear in loc. cit. (the author invoking in its place the fact that H is essentially free). This hypothesis is however satisfied when G is reductive (cf. Exp. XXII 5.7.8), and so is satisfied in all the cases considered in loc. cit., Cor. 3.2. In particular, Thomason proves in loc. cit., 2.5, that if S is separated noetherian regular of

dimension ≤ 2 , and if G is affine, of finite presentation, and such that $\mathcal{A}(G)$ is a locally projective 0_S -module, then (G, S) satisfies (RE); by 13.5, this gives 13.2 under a slightly more restrictive hypothesis.

<!-- label: III.VI_B.13.6 -->

To conclude, let us point out that the proof of [Th87], 2.5, may be slightly simplified, as follows. (For brevity, we place ourselves in the situation where $S = \operatorname{Spec}(R)$ is affine.)

Proposition 13.7. *Let R be a noetherian regular ring of dimension ≤ 2 , C an R -coalgebra, projective as an R -module, and F a C -comodule, of finite type over R . Then F is the quotient of a C -comodule V , projective of finite type over R .*

<!-- label: III.VI_B.13.7 -->

Proof. Replacing $\operatorname{Spec}(R)$ by one of its connected components, one may suppose R integral, with field of fractions K . Denote by Δ (resp. ϵ) the comultiplication (resp. the augmentation) of C and by $\rho : F \rightarrow F \otimes C$ the comodule structure on F . Let $\pi : W \rightarrow F$ be a surjective morphism, where W is a free R -module of finite rank. We endow $W \otimes C$ with the comodule structure defined by $\operatorname{id}_W \otimes \Delta$, and similarly for $F \otimes C$. Then $\rho : F \rightarrow F \otimes C$ is a morphism of C -comodules, which admits $\operatorname{id}_F \otimes \epsilon$ as a section.

Let W' be the C -comodule defined by the cartesian square below:

$$\begin{array}{ccc} W' & \xrightarrow{\quad} & F \\ \downarrow \pi \otimes \operatorname{id}_C & & \downarrow \rho \\ W \otimes C & \xrightarrow{\quad} & F \otimes C \end{array}$$

i.e. W' is identified with the kernel of the morphism $W \otimes C \rightarrow (F \otimes C)/\rho(F)$, and the projection $\pi' : W' \rightarrow F$, given by $x \mapsto (\pi \otimes \epsilon)(x)$, is surjective. Since F is a finitely generated R -module, there exists a subcomodule V' of W' , finitely generated over R , such that $\pi'(V') = F$. Since $W \otimes C$ is R -torsion-free, so is V' ; hence, replacing F by V' , one may assume at the outset that F is torsion-free.

Applying the preceding construction to this new F , one obtains V' as above. Consider then the subcomodule V , kernel of the morphism

$$W \otimes C \rightarrow E = (W \otimes C \otimes K) / (V' \otimes K).$$

Then V contains V' , and $Q = (W \otimes C)/V$ is an R -submodule of the K -vector space E ; set $Q' = E/Q$. Since $W \otimes C$ and E are flat R -modules, one obtains that,

<!-- original page 440 -->

for every R -module N ,

$$\operatorname{Tor}_1^R(V, N) \cong \operatorname{Tor}_2^R(Q, N) \cong \operatorname{Tor}_3^R(Q', N)$$

and since R is regular of dimension ≤ 2 , the right-hand term is zero. This shows that V is a flat R -module. Let us finally show that V is a finitely generated R -module. Set $M = W \otimes C$; it follows from the definition that V/V' is isomorphic to the R -torsion submodule $(M/V')_{\operatorname{tors}}$ of M/V' .

Since M is a projective R -module, there exists a projective R -module P such that $M \oplus P$ is a free R -module L . Then $(M/V')_{\operatorname{tors}} \subseteq (L/V')_{\operatorname{tors}}$. On the other hand, since V' is of finite type, there exists a direct factor $L' \subseteq L$ such that $V' \subseteq L'$, and one therefore also has $(L/V')_{\operatorname{tors}} \subseteq (L'/V')_{\operatorname{tors}}$, and the latter is of finite type since (L'/V') is. Consequently, V is a flat R -module of finite type, hence projective of finite type (R being noetherian). Proposition 13.7 is proved. ■

```

[^VI_B-0-1]: This Exposé has been seriously reworked since its mimeographed edition; in particular, §§ 10 and 11 have been entirely rewritten.[^N.D.E-VI_B-1]

[^N.D.E-VI_B-2]: Recall the convention adopted at the beginning of 'VI_A': an \$A\$-group is an \$A\$-group scheme (and such a scheme is separated, cf. (VI_A, 0.3)).

[^N.D.E-VI_B-3]: We have replaced "homomorphism" by "morphism".

[^N.D.E-VI_B-4]: This statement also appears in (VI_A, 2.5.2).

[^N.D.E-VI_B-5]: In the original, 1.3, 1.3.1, and 1.3.1.1 are stated for \$A\$ a field. For completeness, we have treated the case of an Artinian local ring; to do so, we have added Lemma 1.3.0.

[^N.D.E-VI_B-6]: Recall that a morphism of schemes \$f : X \to Y\$ is said to be *of finite type* (resp. *of finite presentation*, resp. *quasi-finite*) *at \$x\$* if there exist affine opens \$V\$ containing \$f(x)\$ and \$U\$ containing \$x\$ such that \$f(U) \subset V\$ and \$f^{-1}(f(x))\$ is an \$f^{-1}(f(x))\$-algebra of finite type (resp. of finite presentation, resp. and moreover the fiber \$f^{-1}(f(x))\$ is finite for all \$x' \in U\$; see also N.D.E. (40) of Exp. V). One says that \$f\$ is *locally quasi-finite* (resp. *of finite type*, *of finite presentation*) if it has this property at every point \$x\$. On the other hand, one says that \$f\$ is *smooth* (resp. *unramified*, resp. *étale*) *at \$x\$* if there exists an open neighborhood \$U\$ of \$x\$ such that the morphism \$f|_U : U \to Y\$ is smooth (resp. unramified, resp. étale). In view of these definitions, it is clear that the set of points where \$f\$ is of finite presentation, resp. of finite type, quasi-finite, smooth, unramified, étale, is open in \$X\$. Moreover, since the flat locus of a

morphism locally of finite presentation is open (EGA IV₃, 11.3.1), the set of points of X where f is of finite presentation and flat is also open in X . All of this will be used repeatedly in what follows.

[^N.D.E-VI_B-7]: The original stated that W_{flat} is open, which does not seem a priori obvious...

[^N.D.E-VI_B-8]: Note that it does not suffice to assume that G is flat over A at one point: for instance, suppose $A \not\cong k$, let H be the constant A -group $(\mathbb{Z}/2\mathbb{Z})_A$ and G the closed A -subgroup of H whose non-neutral component is reduced; then the structural morphism $G \rightarrow \operatorname{Spec} A$ is a local isomorphism at the unit point e , but is not flat at the point $g \neq e$.

[^N.D.E-VI_B-9]: We have added the following sentence, and simplified the proof of Lemma 1.3.1.1, by invoking EGA IV, 2.7.1 instead of loc. cit., 17.7.5.

[^N.D.E-VI_B-10]: We have expanded the original in what follows.

[^N.D.E-VI_B-11]: The original invoked the generic flatness theorem (EGA IV₂, 6.9.1), which is not necessary here.

[^N.D.E-VI_B-12]: We have added the following sentence.

[^N.D.E-VI_B-13]: We have expanded the original in what follows.

[^N.D.E-VI_B-14]: We have expanded the original in what follows.

[^N.D.E-VI_B-15]: The hypothesis that G and H are locally of finite type may be removed, since according to [Per76, 4.2.4]: every quasi-compact monomorphism $u : G \rightarrow H$ between group schemes over a field k is a closed immersion; see also [DG70, III.3.7.2 b)] for the case where G and H are affine (in which case every morphism $G \rightarrow H$ is affine (EGA II, 1.6.2 (v)), hence quasi-compact).

[^N.D.E-VI_B-16]: In this particular case, see also (VI_A, 0.5.2), valid without finiteness hypotheses.

[^N.D.E-VI_B-17]: The implication (ii) $\Rightarrow$ (i) is a general fact (cf. EGA 0_IV, 14.1.6), and (i) $\Rightarrow$ (ii) follows from the fact that if X is an irreducible scheme of finite type over a field, one has $\dim X = \dim U$ for every non-empty open subset U of X ; the essential point here is therefore to establish assertion (i), which has already been done in addition to (VI_A, 2.4.1). We have modified the statement and proof of the lemma accordingly.

[^N.D.E-VI_B-18]: In the statement, we have replaced "along the unit section" by "at every point of the unit section"; on the other hand, at the end of the proof, we have made explicit the results of EGA IV₄ cited in reference.

[^N.D.E-VI_B-19]: In case (i), the open subset V is formed by all the points of G at which u is smooth, resp. étale, resp. of finite presentation and flat, cf. N.D.E. (6). On the other hand, in case (ii), V is the largest open subset contained in the set E of points of G at which u is universally open, but E is not necessarily open, as shown by the following example (EGA IV₃, 14.1.3 (i)): let k be a field, $H = S = \operatorname{Spec} A$ with $A = k[x]$, and G the S -group $\operatorname{Spec} A[y]/(xy)$; then E equals the unit section of G , which is not open.

[^N.D.E-VI_B-20]: We have expanded the statement and the proof, and in (i) we have weakened the hypothesis on H by replacing "of finite presentation" by "of finite type".

[^N.D.E-VI_B-21]: We have modified the presentation, separating the assertions relative to the "quasi-finite" case from those relative to the "unramified" case.

[^VI_B-2-9-i]: This is also a particular case of EGA IV₄, 18.12.11, since π is evidently a universal homeomorphism.

[^VI_B-2-9-ii]: This is also an immediate consequence of EGA IV₄, 18.12.6.

[^VI_B-2-9-1]: Cf. EGA IV₄, 18.12.7.1 for a slightly more general result, provable by the same proof.

[^N.D.E-VI_B-22]: This is a slightly abusive notation, but one which is compatible with the notations of (VI_A, 2.3) when this connected component is the underlying topological space of an open group subscheme $G^{\{0\}}$ of G , cf. (VI_A, 2.2.bis).

[^N.D.E-VI_B-23]: We have added what follows.

[^N.D.E-VI_B-24]: Recall the following definitions and results (cf. EGA 0_III, § 9.1 and EGA IV₁, §§ 1.8 and 1.9). Let X be a topological space. (i) An open U of X is called **retrocompact** if the inclusion $U \hookrightarrow X$

is quasi-compact, i.e. if $U \cap V$ is quasi-compact for every quasi-compact open $V \subset X$. (ii) A part C of X is called **constructible** if it is a finite union of parts of the form $U - V$, where U and V are retrocompact opens in X . (iii) A part L of X is called **locally constructible** if for every $x \in X$ there exists an open neighborhood U of x in X such that $L \cap U$ is constructible in U . (N.B. If X is quasi-compact and quasi-separated, L is then constructible.) (iv) A part I of X is called **ind-constructible** if for every $x \in X$, there exists an open neighborhood U of x in X such that $I \cap U$ is a union of parts locally constructible in U . Let now $f : X \rightarrow Y$ be a morphism of schemes. By Chevalley's constructibility theorem (cf. EGA IV₁, 1.8.4 and 1.9.5 (viii)), if f is of finite presentation (resp. locally of finite presentation), then the image under f of any locally constructible part is locally constructible (resp. ind-constructible).

[^N.D.E-VI_B-25]: We have expanded the original in what follows.

[^N.D.E-VI_B-26]: Compare with (VI_A, 5.6).

[^N.D.E-VI_B-27]: We have shortened the original, referring here to 1.3.2. We have also simplified the argument below by removing a reference to the generic flatness theorem (EGA IV₂, 6.9.1), which is not necessary here.

[^N.D.E-VI_B-28]: One finds in the original: "at the points of ϵ "; it is not sufficient to assume that G is universally open over S at ϵ , as shown by the example given in N.D.E. (19). We have corrected the proof accordingly.

[^N.D.E-VI_B-29]: We have added condition (iii), pointed out by O. Gabber; it will be useful later (5.7).

[^N.D.E-VI_B-30]: The preceding has been communicated to us by O. Gabber; we have also preserved the proof of the implication (ii) $\Rightarrow$ (i) given in the original.

[^N.D.E-VI_B-31]: One cannot do without the hypothesis that S is reduced here: if k is a field, $S = \operatorname{Spec} A$, where $A = k[\delta]$ with $\delta^2 = 0$, and G the closed subgroup $\operatorname{Spec} A[X]/(\delta X)$ of $G_{a,S}$ (which to every A -algebra R associates the subgroup of $r \in R$ such that $\delta r = 0$), then G is an S -group satisfying (ii)–(iv), but is not flat, hence not smooth, over S .

[^N.D.E-VI_B-32]: We have expanded the original in what follows.

[^N.D.E-VI_B-33]: We have replaced "Artinian" by "of dimension 0" (and mentioned this generalization in (VI_A, 0.3)).

[^N.D.E-VI_B-34]: We have corrected the original by assuming G universally open over S in a neighborhood of the unit section and by adding hypothesis (ii); see below for examples, due to O. Gabber, showing that statements 5.3 and 5.4 of the original are false without additional hypotheses. On the other hand, we note that Thm. 5.3 is a reworked version of Thm. 5.3A below, which appears in the 1965 edition of SGAD, and is due to M. Raynaud, cf. the Notes (*) in Exp. X, 8.5 and 8.8.

[^N.D.E-VI_B-35]: Without this hypothesis, one has the following counterexample, pointed out by O. Gabber: let $G = S$ be a local scheme with closed point s , such that $S^* = S - \{s\}$ is not quasi-compact, and X the disjoint union of $\{s\}$ and S^* .

[^N.D.E-VI_B-36]: We have added this remark, cf. N.D.E. (34).

[^N.D.E-VI_B-37]: Let us point out here the following result ([Ray70a], VI 2.5): if S is normal, G smooth with connected fibers, and if X is a (fppf) homogeneous G -space (i.e. the morphisms $X \rightarrow S$ and $G \times_S X \rightarrow X \times_S X$ are covering for the (fppf) topology), locally of finite type over S , then X is locally quasi-projective over S . In particular, G is quasi-projective over S . See also N.D.E. (35) in VI_A.

[^N.D.E-VI_B-38]: We have added this lemma, communicated by O. Gabber, which improves EGA IV₃, 14.4.1.2 and corrects the proof of loc. cit., 14.4.1.3 without modifying its hypotheses (compare with the erratum (Err_IV, 38) in EGA IV₄).

[^N.D.E-VI_B-39]: We have made this lemma explicit, used in the proof of Lemma 5.6.1.

[^N.D.E-VI_B-40]: We have corrected the original, which indicated 19.5.10.

[^N.D.E-VI_B-41]: Consequently, h induces a section σ of $X \times_S S' \rightarrow S'$ such that $\sigma(s')$ lies above x ; compare with EGA IV₃, 14.5.10.

[^N.D.E-VI_B-42]: We have added this lemma, communicated by O. Gabber. It allows us to simplify the proof of 5.6.2, and

to prove Theorem 5.3, as well as 5.4, in a more general form, see 5.7 and 5.8 below.

[^N.D.E-VI_B-43]: We have added the hypothesis on $X_{\{s\}}$ and simplified (and corrected) the proof, taking into account the addition 5.6.2.0. Moreover, the proof shows that the conclusion is valid if one assumes only that $U_{\{s\}}$ is dense in every irreducible component of $X_{\{s\}}$.

[^N.D.E-VI_B-44]: We have simplified the formulation of condition (iv) and added condition (iv'). On the other hand, we have added the proof of the implication (i) $\Rightarrow$ (iii), used in the proof of (iv) $\Rightarrow$ (iii). Note moreover that if $T = \operatorname{Spec} k[\epsilon, x]/(\epsilon^2, \epsilon x)$ (k a field), $X = T_{\text{red}} = \operatorname{Spec} k[x]$, then the morphisms $\phi_{\lambda} : T \rightarrow X$ defined by $x \mapsto x + \lambda \epsilon$ ($\lambda \in k$) coincide on the dense open $\operatorname{Spec} B_{\{x\}}$ but are not equal.

[^N.D.E-VI_B-45]: We have reproduced this example in (VI_A, 0.3), N.D.E. (5).

[^N.D.E-VI_B-46]: On the one hand, we have suppressed the corollary 5.6.5, which was a repetition of 5.5. On the other hand, the original stated as Remark 5.7 the corollary 5.7.1 below, referring for the proof to 4.7, a number which does not exist in Lect. Notes 151 (but which appeared in the 1965 edition of SGAD, whose nos. 4.5 and 4.6 became 5.6.1 and 5.6.2); we have added Theorem 5.7, communicated by O. Gabber, which makes precise the aforementioned statement in SGAD.

[^N.D.E-VI_B-47]: We have added this paragraph of complements and counterexamples, all communicated by O. Gabber.

[^VI_B-6-1]: On the same theme, see also the results of XI 6, whose natural place would be in the present Exposé VI_B. There one finds in particular representability criteria for certain subfunctors-in-groups of a given group scheme. [^N.D.E-VI_B-48]

[^N.D.E-VI_B-49]: If $u : X \rightarrow G$ and $v : Y \rightarrow G$ are two arbitrary morphisms of S -functors, let $u(X)$ be the image-functor of u , defined by $u(X)(S') = u(S')(X(S')) \subset G(S')$; this is a subfunctor of G , as is the image-functor $v(Y)$. One may then consider the transporter of the image of u into the image of v , $\operatorname{Transp}_G(u(X), v(Y))$. We see thus that, in definition (ii), it is not necessary to restrict to subfunctors, i.e. to the case where u and v are monomorphisms. This restriction sometimes imposed in the original repetitions in the hypotheses, such as: "Let $u, v : X \rightarrow G$ be morphisms of S -functors, $w : H \rightarrow G$ and $w' : K \rightarrow G$ monomorphisms, then $\operatorname{Transp}(u, v)$, $\operatorname{Centr}_G(w) = \operatorname{Centr}_G H$ and $\operatorname{Transp}_G(H, K)$ verify...", which can be avoided by considering $\operatorname{Transp}_G(u(X), v(Y))$. We have made such modifications in 6.2 and, later, in 10.11.

[^N.D.E-VI_B-50]: We have added this remark, used implicitly in Proposition 6.2.

[^N.D.E-VI_B-51]: We have modified the statement, as indicated in N.D.E. (49).

[^N.D.E-VI_B-52]: The original referred to the results of Exp. VIII, § 6. For the reader's convenience, we have reproduced these results (with the exception of VIII, 6.3 and 6.8) in nos. 6.2.1 to 6.2.5 below. Moreover, this was suggested by A. Grothendieck in a Note at the beginning of VIII.6: "The present number is independent of the theory of diagonalizable groups; its natural place would be in VI_B."

[^N.D.E-VI_B-53]: On the one hand, we have replaced the word "free" by "projective", as indicated in VIII, Remark 6.8. On the other hand, the notion of essentially free S -scheme is intimately related to the geometric notion of flat and pure S -scheme, introduced and studied by M. Raynaud and L. Gruson ([RG71]); cf. the addition 6.9 below.

[^N.D.E-VI_B-54]: Indeed, let $(A, \mathfrak{m})$ be an Artinian local ring, k its residue field, M an arbitrary A -module, $(x_i)_{i \in I}$ elements of M whose images form a basis of $M/\mathfrak{m}M$ over k . Let F be the free A -module with basis $(e_i)_{i \in I}$, and $\phi : F \rightarrow M$ the A -morphism defined by $\phi(e_i) = x_i$. Then $Q = \operatorname{Coker} \phi$ satisfies $Q = \mathfrak{m}Q$, hence, since $\mathfrak{m}$ is nilpotent, $Q = 0$. Suppose moreover M flat over A ; then $K = \operatorname{Ker} \phi$ satisfies $K \otimes_A k = 0$, i.e. $K = \mathfrak{m}K$, hence $K = 0$.

[^N.D.E-VI_B-55]: cf. Exp. II § 1, where this functor is denoted $\prod_{Z/S} Y$; for every $S' \rightarrow S$, $F(S') = \Gamma(Y_{S'}/Z_{S'})$, which here equals $\{id_{Z_{S'}}\}$ if $Y_{S'} = Z_{S'}$, and is empty otherwise. On the other hand, we have added assertion (ii), used in the proof of 6.5.3.

[^N.D.E-VI_B-56]: We have added the sentence that follows.

[^N.D.E-VI_B-57]: denoted $\operatorname{Transpstr}_G(Y, Z)$.

[^N.D.E-VI_B-58]: Indeed, over a field k , every group subscheme of G is closed, cf. VI_A, 0.5.2. Moreover, 6.2.5

concludes the insertion of the results drawn from VIII § 6.

[^N.D.E-VI_B-59]: We have inserted here this corollary (cf. Exp. XII, 6.1), which will be useful later. Moreover, in 6.3 we return to the original text of VI_B.

[^N.D.E-VI_B-60]: We have kept the numbering of the original: there is no n° 6.4.1.

[^N.D.E-VI_B-61]: We have inserted here nos. 6.5.2 to 6.5.5, drawn from Exp. XI, 6.8 to 6.11. This was moreover suggested by A. Grothendieck in a Note at the beginning of XI 6: "The present number does not use the results of nos. 3, 4, 5 (of XI); its natural place would be in VI_B."

[^N.D.E-VI_B-62]: On the one hand, we have corrected the original, by replacing "connected" with "irreducible" (cf. the proof). On the other hand, by [RG71] I, 3.3.4 (iii) and 4.1.1, it suffices to assume that X_S is flat over S_S , with geometrically irreducible fibers and without embedded components.

[^N.D.E-VI_B-63]: See for example the addition 1.7 in Exp. VIII.

[^N.D.E-VI_B-64]: see, for example, the proof of 6.2.6.

[^N.D.E-VI_B-65]: We have detailed the original in what follows, adding references to EGA IV.

[^N.D.E-VI_B-66]: We have detailed what follows. Moreover, this concludes the insertion of XI, 6.8 to 6.11, i.e. we return in 6.6 below to the original text of VI_B.

[^N.D.E-VI_B-67]: We have added this subsection.

[^N.D.E-VI_B-68]: We have replaced, here and in the sequel, the little-used terminology "separable" by the usual terminology "geometrically reduced", cf. EGA IV₂, 4.6.2.

[^N.D.E-VI_B-69]: The original stated (iii') under the additional hypothesis that G_S be locally of finite type over k_S , but this can be omitted, by VI_A, 0.5.2.

[^N.D.E-VI_B-70]: We have added this corollary, to point out this particular case of 7.1.

[^N.D.E-VI_B-71]: We have placed in (i') the point (viii) of the original, and we have highlighted points (vi) and (vii) in the form of Corollary 7.2.1 and Definition 7.2.2 below.

[^N.D.E-VI_B-72]: We have suppressed here the hypothesis that G_S be locally of finite type over k_S .

[^N.D.E-VI_B-73]: We have changed the notation $\operatorname{Der}(G)$ of the original, in order to avoid any risk of confusion with a space of derivations.

[^N.D.E-VI_B-74]: We have added these reminders, and modified accordingly, and detailed, the statement of 7.3.

[^N.D.E-VI_B-75]: We have detailed the original in what follows.

[^N.D.E-VI_B-76]: We have added this definition, which in the original was contained in the statement of Proposition 7.6.

[^N.D.E-VI_B-77]: The original stated this result under the hypotheses of the particular case, but the more general form was used implicitly in the proof of 10.12; we have rewritten the statement accordingly.

[^N.D.E-VI_B-78]: We have detailed the original in what follows.

[^N.D.E-VI_B-79]: We have made the following precise and, in the proof, detailed the reduction to the case where k_S is algebraically closed.

[^N.D.E-VI_B-80]: We have detailed the original in what follows, taking into account the addition 7.1.1.

[^N.D.E-VI_B-81]: These results are mentioned without proof in the original; we have highlighted them in the form of Lemmas 8.1.1 and 8.1.2, and detailed the proofs.

[^VI_B-8-1]: We shall make use in the course of this proof of results established in number 10, which do not depend, any more than number 9, on the present n° 8.

[^N.D.E-VI_B-82]: We have corrected 10.8.5 to 8.10.5.

[^N.D.E-VI_B-83]: We have detailed what follows.

[^N.D.E-VI_B-84]: Taking into account the fact that S is supposed affine, hence quasi-compact and quasi-separated (cf. EGA 0_III, 9.1.12).

[^N.D.E-VI_B-85]: i.e., the quotient is universal, cf. Exp. IV § 3.

[^N.D.E-VI_B-86]: As pointed out by O. Gabber, this is used in the proof and must be inserted in the hypotheses.

[^N.D.E-VI_B-87]: We have corrected (fpqc) to (fppf).

[^N.D.E-VI_B-88]: see VII_A, 8.4 or VIII, 2.1.

[^VI_B-9-1]: This is too optimistic, as M. Raynaud shows in his thesis (loc. cit. X 14).

[^N.D.E-VI_B-89]: The remark (*) refers to the counterexample X.14 in [Ray70a]. The base there is regular local of dimension 2.

[^N.D.E-VI_B-90]: Note that S , being affine over S_0 , is therefore quasi-compact and quasi-separated, cf. N.D.E. (92) below.

[^N.D.E-VI_B-91]: We have added the word "flat", and corrected 17.7.6 to 17.7.8.

[^N.D.E-VI_B-92]: and from the fact that Y , being of finite presentation over S , is quasi-compact.

[^N.D.E-VI_B-93]: in terms of commutative diagrams of S -morphisms.

[^N.D.E-VI_B-94]: i.e., such that the composite $R_j \hookrightarrow X_j \otimes_{S_j} X_j \rightarrow_{pr_1} X_j$ is flat and of finite presentation.

[^N.D.E-VI_B-95]: Note that the proof uses also case b).

[^N.D.E-VI_B-96]: We have simplified the statement, and treated separately, in Corollary 10.11.1, the case of subgroups.

[^N.D.E-VI_B-97]: Indeed, G_A being flat and of finite presentation over A , it is covered by affine opens $G_1, \dots, G_n$ such that each $\mathcal{O}(G_i)$ is a flat and finitely presented A -algebra; then, by EGA IV₂, 6.9.2, there exists $f_i \in A$ such that $\mathcal{O}(G_i)_{f_i}$ is a free module over A_{f_i} ; one may then replace $\operatorname{Spec}(A)$ by the affine open $D(f)$, where $f = f_1 \cdots f_n$, and one does the same for Y_A and Z_A .

[^N.D.E-VI_B-98]: We have corrected $n+1$ to $2n$ below.

[^N.D.E-VI_B-99]: We have detailed the original in what follows.

[^N.D.E-VI_B-100]: We have added this corollary, used in the proof of 8.4.

[^N.D.E-VI_B-101]: The original assumed G, H of finite presentation and H with smooth fibers; we have modified the hypothesis in order to be able to apply 10.12. We have also detailed the proof.

[^N.D.E-VI_B-102]: (Added by editors; see source.)

[^N.D.E-VI_B-103]: (End of section 10.)

[^N.D.E-VI_B-C-104]: We have added this reminders paragraph.

[^N.D.E-VI_B-C-105]: Note that if k is a field and if X is an infinite sum of copies of $S = \operatorname{Spec} k$ (so that X is not quasi-compact), then $\mathcal{A}(X) = k^X$ and the canonical morphism $k^X \otimes k^X \rightarrow k^{X \times X}$ is not surjective.

[^N.D.E-VI_B-C-106]: Note that if S is a regular locally noetherian scheme of dimension ≤ 2 , and X is a flat, quasi-compact and quasi-separated S -scheme, then $\mathcal{A}(X)$ is a flat S_0 -module, cf. [Ray70a], VII 3.2.

[^N.D.E-VI_B-C-107]: We have added this proposition; see also the additional paragraph 12 below for a study of the

morphism $G \rightarrow G_{\text{af}}$ and its kernel.

[^N.D.E-VI_B-C-108]: In 11.4–11.6, we have considered $\operatorname{Hom}_{\{0\}}(W(E), W(F))$ instead of $\operatorname{Hom}_{\{0\}}(V(F), V(E))$ (cf. I, 4.6.3) and simplified the original by taking into account the addition 11.0 (b).

[^N.D.E-VI_B-C-109]: We have simplified the original, which used the isomorphism $\operatorname{Hom}_{\{0\}}(W(E), W(E')) \simeq \operatorname{Hom}_{\{0\}}(V(E'), V(E))$ then the inclusion of the right-hand side into $\operatorname{Hom}_S(V(E), V(E')) = \operatorname{Hom}_{\{0\}}(E', f_* f^*(\operatorname{Sym}(E)))$ and applied EGA III, 4.1.15 to $V(E) = \operatorname{Spec}(\operatorname{Sym}(E))$ to deduce 11.0 (b).

[^N.D.E-VI_B-C-110]: We have expanded 11.6, and highlighted the results obtained in the form of Proposition 11.6.1.

[^N.D.E-VI_B-C-111]: We have added this remark, which generalizes 11.7 and will be useful in 11.10.bis.

[^N.D.E-VI_B-C-112]: Since the statements 11.8 and 11.9 bear solely on the notion of comodule over a coalgebra, we have introduced Definition 11.8.0 and reformulated 11.8 and 11.9 accordingly.

[^N.D.E-VI_B-C-113]: In the original, it is assumed that C is a free A -module; the generalization to the case where C is a projective A -module, pointed out by J.-P. Serre, was mentioned in Remark 11.10.1. We have included this generalization here and in 11.9, and expanded the proofs accordingly.

[^N.D.E-VI_B-C-114]: We have added this proposition, taken from [Se68], § 1.5, Prop. 2.

[^N.D.E-VI_B-C-115]: We have added this lemma, which is used in the proof of 11.9.

[^N.D.E-VI_B-C-116]: Let us point out in passing that assertion II 2.5.2 of loc. cit., more general than II 2.5.1, is corrected in the article [Gr73] (this does not affect the case of faithfully flat morphisms).

[^N.D.E-VI_B-C-117]: As pointed out in N.D.E. (112), we have rewritten the statement for an 0_S -coalgebra C (rather than for an S -group G satisfying the hypotheses indicated in Corollary 11.10). Moreover, we have spelled out the proof (the original indicated: "($\Leftarrow$) the proposition is a consequence of Lemma 11.8.>").

[^VI_B-C-11-9]: This is the case, for example, when $C = \mathcal{A}(G)$, where G is a reductive S -group, as we shall see in Exp. XXII 5.7.8.

[^N.D.E-VI_B-C-118]: We have added this definition, taken from [RG71], bottom of p. 82. Thus, in Proposition 11.9, the hypothesis is that the coalgebra C is a locally projective 0_S -module, and we have used this terminology in Corollary 11.10.

[^N.D.E-VI_B-C-119]: We have added this proposition, which is a particular case of [Th87], 1.4–1.5. The author makes reference there to an argument of Deligne (cf. [Kn71], III Th. 1.1); one may also note the similarity with the argument of Serre ([Se68], Prop. 2) recalled in 11.8.bis.

[^N.D.E-VI_B-C-120]: The first part of the original Remark 11.10.1 has been incorporated into 11.8 and 11.9 (by replacing "free" by "projective"); the counterexamples below correct the second part.

[^N.D.E-VI_B-C-121]: We have expanded the original in what follows; on the other hand, we have chosen to have G act on the right on X in order to obtain a left linear action of G on $0(X)$.

[^N.D.E-VI_B-C-122]: Recall that a k -scheme X is said to be quasi-affine if it is isomorphic to a quasi-compact open of an affine k -scheme (EGA II, 5.1.1).

[^N.D.E-VI_B-C-123]: The equivalence of these conditions is proved in the additional section 12.

[^N.D.E-VI_B-C-124]: This is proved, with various generalizations, in the additional section 13.

[^N.D.E-VI_B-C-125]: On the one hand, this is generalized in Section 13 to the case where G is affine and flat over a regular base of dimension ≤ 2 . On the other hand, in what follows we have spelled out and corrected the original.

[^N.D.E-VI_B-C-126]: We have denoted by u^{natural} (instead of u^{circ}) the morphism $B \rightarrow A$ corresponding to $u : \operatorname{Spec}(A) \rightarrow \operatorname{Spec}(B)$.

[^N.D.E-VI_B-C-127]: We have added the hypothesis that G be quasi-compact and spelled out the equivalence of

conditions (i) and (ii).

[^N.D.E-VI_B-C-128]: We have added this lemma, taken from [DG70], § II.2, 3.5.

[^N.D.E-VI_B-C-129]: On the one hand, we recall that every group subscheme of G is closed (1.4.2). On the other hand, we have stated the result in the usual form: " H is the stabilizer of a line in a representation of G ", while keeping the original formulation in terms of a sequence $a_1, \dots, a_n$ of semi-invariants in $\mathcal{A}(G)$.

[^N.D.E-VI_B-C-130]: We have added this lemma, taken from the proof of thm. 5.6 of [DG70], § III.3 (by abuse of notation, we designate by the same letter E a k -vector space and the k -scheme in modules $W(E) = \operatorname{Spec} S(E^{\ast})$).

[^N.D.E-VI_B-C-131]: For another proof of this theorem, not using the results of VI_A, see [Ta72], Th. 5.2 (see also Remark 11.18.5).

[^N.D.E-VI_B-C-132]: In what follows, we have spelled out the original (and corrected the erroneous assertion $(G/N)_{\text{red}} = G_{\text{red}} / N_{\text{red}}$), relying on [DG70], § III.3, 5.6.

[^N.D.E-VI_B-C-133]: We have added this lemma, taken from [DG70], § III.3, 7.1.

[^N.D.E-VI_B-C-134]: We have added this subsection.

[^N.D.E-VI_B-C-135]: We have added this section.

[^N.D.E-VI_B-C-136]: This lemma was communicated to us by M. Raynaud; it will be used in the proof of Proposition 12.9.

[^N.D.E-VI_B-C-137]: This is a version improved by O. Gabber of a statement communicated by M. Raynaud.

[^N.D.E-VI_B-C-138]: This is true, more generally, if S is regular locally noetherian of dimension ≤ 2 , cf. [Ray70a], VII 3.2.

[^N.D.E-VI_B-D-139]: This section has been added.

[^N.D.E-VI_B-D-140]: Additional references cited in this Exposé.

[^N.D.E-VI_B-1]: And also § 5, cf. N.D.E. (34) and (46).

[^N.D.E-VI_B-48]: We have inserted these results in what follows (nos. 6.5.2 to 6.5.5).

<!-- SOURCE: 07A-etude-infinitesimale-operateurs-differentiels.md -->

Exposé VII_A. Infinitesimal study: differential operators and restricted p -Lie algebras

<!-- label: III.VII_A -->

by P. Gabriel

<!-- original page 412 -->

In Exposé II we restricted ourselves to the study of first-order differential invariants and did not address certain phenomena specific to characteristic $p > 0$ or to characteristic 0. Our object in part A of this Exposé is to fill in this gap.

Moreover, the infinitesimal study of arbitrary order of a group scheme is related to that of the associated formal group; the object of the second part of this Exposé is to present the first definitions and properties concerning formal groups.

A) Differential operators and restricted p -Lie algebras[^VII_A-A-1]

1. Differential operators

<!-- label: III.VII_A.1 -->

In this section, as well as in sections 2 and 3, S denotes a fixed scheme and the products considered are cartesian products in the category of S -schemes. [N.D.E-VII_A-1] If X is an S -scheme, we write $p_{X/S}$, p_X or simply p for the structural morphism of X into S .

1.1.

<!-- label: III.VII_A.1.1 -->

Let $u : Y \rightarrow X$ be a morphism of S -schemes and endow the direct image $u_* (O_Y)$ of the structure sheaf of Y with the O_X -module structure induced by u . The sheaf $\mathcal{H} = \operatorname{Hom}_{O_X}(u^* (O_Y), u_* (O_Y))$ of $u^* (O_Y)$ -modules homomorphisms <!-- original page 413 --> from $u^* (O_Y)$ into $u_* (O_Y)$ is therefore naturally equipped with a structure of O_X -bimodule: if U is an open of X , f and g sections of O_X and $\mathcal{H}$ on U , then fd and df are respectively the morphisms $g \mapsto f d(g)$ and $g \mapsto d(fg)$ from $u^* (O_Y)$ into $u_* (O_Y)$. We shall henceforth write $(ad f)(d)$ in place of $fd - df$.

Definition 1.1.1. An S -deviation of order n is by definition a pair $D = (u, d)$ consisting of a morphism of S -schemes $u : Y \rightarrow X$ and a morphism of $u^* (O_Y)$ -modules $d : O_X \rightarrow u_* (O_Y)$ such that, for every open U of X and every sequence of $n + 1$ sections $f_0, \dots, f_n$ in $O_X(U)$, one has in $\operatorname{Hom}_{O_X}(u^* (O_Y), u_* (O_Y))|_U$ the equality:

<!-- label: III.VII_A.1.1.1 -->

```
```text
(*_n) (ad f_0)(ad f_1) ... (ad f_n)(d) = 0.
```

[N.D.E-VII\_A-2]

In this case, we shall also say that  $d$  is an  $S$ -deviation of  $u$  of order  $n$ . In particular, an  $S$ -deviation of  $u$  of order  $0$  is a morphism of  $O_X$ -modules from  $O_X$  into  $u_* (O_Y)$ , i.e., an element of  $\Gamma(Y, O_Y)$ .

**Definition 1.1.2.** A morphism of  $u^* (O_Y)$ -modules  $d : O_X \rightarrow u_* (O_Y)$  is an  $S$ -deviation of  $u$  if, for every point  $y$  of  $Y$ , there exist an open neighborhood  $U$  of  $u(y)$  in  $X$  and an open neighborhood  $V$  of  $y$  in  $Y$  satisfying the following conditions:

a)  $u(V) \subset U$ ;

b) if  $v : V \rightarrow U$  is the morphism induced by  $u$ , there is an integer  $n$  such that the morphism  $O_U \rightarrow v_* (O_V)$  induced by  $d$  is an  $S$ -deviation of  $v$  of order  $n$ . [N.D.E-VII\_A-3]

<!-- label: III.VII\_A.1.1.2 -->

If  $d$  is an  $S$ -deviation of  $u$ , we also say that the pair  $D = (u, d)$  is an  $S$ -deviation and it will happen that we write  $Y \rightarrowtail D X$  or  $Y \rightarrowtail_d X$  (over  $u$ ).

When  $d$  is the algebra homomorphism  $u^* (O_Y) \rightarrow u_* (O_Y)$  corresponding to the morphism  $u : Y \rightarrow X$ , we shall also write  $u$  in place of  $D$ .

**Remarks 1.1.3.** [N.D.E-VII\_A-4] Let  $D \acute{e}v(u)$  (resp.  $D \acute{e}v_{\leq n}(u)$ ) be the set of  $S$ -deviations of  $u$  (resp.  $S$ -deviations of  $u$  of order  $\leq n$ ). It is equipped with a natural structure of  $O_Y(Y)$ -module: if  $\lambda \in O_Y(Y)$ ,  $\lambda d$  is the deviation sending  $f$  to  $\lambda d(f)$ , for every section  $f$  of  $O_X$  on an open  $U$ .

<!-- label: III.VII\_A.1.1.3 -->

For every open  $V$  of  $Y$ , set  $\mathcal{D} \acute{e}v(u)(V) = D \acute{e}v(u|_V)$ , i.e.,  $\mathcal{D} \acute{e}v(u)(V)$  is the set of

```
```text
d_V \in \operatorname{Hom}_{O_X}(u^* (O_Y), u_* (O_Y)) \simeq \operatorname{Hom}_{O_X}(u^* (O_Y), u_* (O_Y))
= \operatorname{Hom}_{O_X}(u^* (O_Y), u_* (O_Y))
```

<!-- original page 444 -->

such that, for every open U of X , the map $d_{\{V\}}(U) : \mathcal{O}_{\{X\}}(U) \rightarrow \mathcal{O}_{\{Y\}}(U) \cap V$ satisfies $(\ast_n)$. This defines a presheaf of $\mathcal{O}_Y$ -modules on Y , and one sees easily that it is a sheaf (more precisely, a subsheaf of $\operatorname{Hom}_{\mathcal{P}^{-1}(\mathcal{V})}(\mathcal{O}_S)(U) \cap \mathcal{O}_X, \mathcal{O}_Y$).

1.2.

<!-- label: III.VII_A.1.2 -->

Consider now two $\mathcal{S}$ -deviations $D = (u, d)$ and $E = (v, e)$:

```
```text
Z $\xrightarrow{v,e}$ Y $\xrightarrow{u,d}$ X.
```
```

When U ranges over the opens of X , the composed maps

```
```text
 $\Gamma(U, \mathcal{O}_X) \xrightarrow{d} \Gamma(\mathcal{O}_Y^{-1} U, \mathcal{O}_Y) \xrightarrow{e} \Gamma(\mathcal{O}_Y^{-1} U, \mathcal{O}_Z)$
```
```

define an $\mathcal{S}$ -deviation of $\mathcal{O}_Y$ which we shall denote d_e ; <!-- original page 414 --> when d is of order $\leq m$ and e of order $\leq n$, d_e is of order $\leq m + n$. We shall also write

```
```text
(t)
 $D \circ E = (uv, de)$
```
```

[^N.D.E-VII_A-5]

and we shall say that $D \circ E$ or d_e is the *composed $\mathcal{S}$ -deviation*. When $d = u^{\circ}$ (i.e., $D = u$ with the convention of 1.1), one also says that d_e is the *image* of E by u .

The map $(D, E) \mapsto D \circ E$ we have just defined will henceforth allow us to speak of the *category of $\mathcal{S}$ -deviations*, whose objects are the $\mathcal{S}$ -schemes and whose morphisms are the $\mathcal{S}$ -deviations. [^N.D.E-VII_A-6]

Definition 1.2.0. [^N.D.E-VII_A-7] Let $w : Z \rightarrow X$ be an $\mathcal{S}$ -morphism. An $\mathcal{S}$ -derivation of w , or $\mathcal{S}$ -derivation of $\mathcal{O}_X$ into $w_{\ast}(\mathcal{O}_Z)$, is a morphism of $\mathcal{P}^{-1}(\mathcal{O}_S)$ -modules $d : \mathcal{O}_X \rightarrow w_{\ast}(\mathcal{O}_Z)$ such that, for every open U of X and $f, g \in \mathcal{O}_X(U)$,

<!-- label: III.VII_A.1.2.0 -->

```
```text
 $d(fg) = w^{\sharp}(f) d(g) + w^{\sharp}(g) d(f).$
```
```

Then d is a deviation of w of order ≤ 1 which vanishes on the unit section of $\mathcal{O}_X$. We denote by $D_{\operatorname{er}_S}(w)$ the set of $\mathcal{S}$ -derivations of w ; it is an $\mathcal{O}(Z)$ -module.

With the notations of 1.2, take $\mathcal{Y}$ equal to $\operatorname{Spec} \mathcal{O}_Z[t]$, where $t^2 = 0$, and v equal to the zero section $\tau : Z \rightarrow \mathcal{Y}$, defined by the morphism of $\mathcal{O}_Z$ -algebras $\mathcal{O}_Z[t] \rightarrow \mathcal{O}_Y$ sending t to 0 , and take e equal to the morphism of $\mathcal{O}_Z$ -modules $\sigma : \mathcal{O}_Z[t] \rightarrow \mathcal{O}_Z$ defined by $\sigma(1) = 0$ and $\sigma(t) = 1$, [^N.D.E-VII_A-8] which it is convenient to denote σ_t .

If $u : \mathcal{Y} \rightarrow X$ is a morphism satisfying $w = u \circ \tau$, then $\sigma \circ u^{\circ}$ is an $\mathcal{S}$ -derivation of $\mathcal{O}_X$ into $w_{\ast}(\mathcal{O}_Z)$. Conversely, to every $\mathcal{S}$ -derivation d we associate the morphism $u : \mathcal{Y} \rightarrow X$ such that $u = w$ on the underlying spaces, and

```
```text
 $u^{\sharp}(f) = w^{\sharp}(f) + d(f) t,$
```
```

<!-- original page 446 -->

for every section f of $\mathcal{O}_X$ on an open U . One thus obtains:

SGA 3 existing English translation – plaintext render from existing Markdown – page 422

...

If one sets $D = (u, d)$ and $E = (v, e)$, we shall also write $D \times E = (u \times v, d \times e)$.

1.3.

<!-- label: III.VII_A.1.3 -->

[^N.D.E-VII_A-10] Let $u : Y \rightarrow X$ be a morphism of S -schemes. Recall that the adjunction isomorphism

```
```text
Hom_{p_X^{-1}(O_S)}(O_X, u_*(O_Y)) \cong Hom_{p_Y^{-1}(O_S)}(u^{-1}(O_X), O_Y)
```

associates with every morphism of  $p_X^{-1}(O_S)$ -modules  $d : O_X \rightarrow u_*(O_Y)$  the morphism  $d' = \epsilon \circ u^{-1}(d)$ , where  $\epsilon$  is the canonical morphism  $u^{-1}u_*(O_Y) \rightarrow O_Y$ .

Let us write  $J_u$  (resp.  $I_u$ ) for the kernel of the algebra homomorphism  $u^{\natural} : O_X \rightarrow u_*(O_Y)$  (resp.  $u^{\natural} : u^{-1}(O_X) \rightarrow O_Y$ ), and let  $d : O_X \rightarrow u_*(O_Y)$  be a morphism of  $p_X^{-1}(O_S)$ -modules. If  $U$  is an open of  $X$  and  $f_0, \dots, f_n, g \in O_X(U)$ , one sees easily by induction on  $n$  that the condition  $(\ast_n)$  is equivalent to the following equality (cf. EGA IV<sub>4</sub>, 16.8.8.2):

<!-- label: III.VII\_A.1.3.1 -->

```
```text
(**_n) \quad \theta = \sum_{I \subset \llbracket 0, n \rrbracket} (-1)^{|I|} u^{\natural}(f_{\llbracket 0, n \rrbracket} - I) d(f_I g),
```

where f_I denotes the product of the f_i , for $i \in I$. It follows that if d satisfies $(\ast_n)$, then d vanishes on the ideal J^{n+1}_u .

Suppose now Y equal to S ; then $u : S \rightarrow X$ is a section of $p : X \rightarrow S$, hence is an immersion (cf. EGA I, 5.3.13). Then, on the one hand, $\epsilon : u^{-1}u_*(O_S) \rightarrow O_S$ is an isomorphism, so that $u^{-1}(J_u) = I_u$. On the other hand, one has an isomorphism:

```
$$
(\star) \quad u^{-1}(O_X) \simeq O_S \oplus I_u.
$$
```

Suppose that d vanishes on J^{n+1}_u . Then $d' = \epsilon \circ u^{-1}(d)$ vanishes on I^{n+1}_u and hence d' satisfies the analogues $(\ast'_{n+1})$ and $(\ast'_n)$ of $(\ast_n)$ and $(\ast'_n)$, when $f_0, \dots, f_n \in I_u(u^{-1}(U))$. Moreover, since $(\text{ad } a)(\phi) = 0$ for every $a \in O_S(u^{-1}(U))$ and every morphism of $O_{u^{-1}(U)}$ -modules $\phi : u^{-1}(O_U) \rightarrow u^{-1}(O_U)$, one deduces from $(\star)$ that d satisfies the analogue $(\ast'_n)$ of $(\ast_n)$. It follows that d satisfies $(\ast_n)$. Consequently, one has obtained:

Lemma. *If $u : S \rightarrow X$ is a section of $p : X \rightarrow S$, then d is an S -deviation of u of order $\leq n$ if and only if d' vanishes on I^{n+1}_u .*

This interpretation may be generalized as follows. Let $u : Y \rightarrow X$ be an arbitrary S -morphism and Γ_u the graph of u , i.e., the morphism $Y \rightarrow Y \times X$ with components id_Y and u . For every S -deviation d of u of order $\leq n$, one obtains by composition

```
```text
Y \xrightarrow{\text{diag.}} Y \times Y \xrightarrow{d} Y \times X \text{ (over } u_Y)
```

a  $S$ -deviation of  $\Gamma_u$  of order  $\leq n$  which we shall denote  $\Gamma_d$  (the graph of  $d$ ).

Conversely, to every  $S$ -deviation  $e$  of  $\Gamma_u$  one associates the composed  $S$ -deviation  $e_X = \text{pr}_2^* \circ e$ :

```
```text
Y \xrightarrow{e} Y \times X \xrightarrow{\text{pr}_2} X \text{ (over } \Gamma_u).
```

One sees at once that $(\Gamma_d)_X = d$, and the equality $(\Gamma_e)_X = e$ follows from the fact that e is 0_Y -linear. [N.D.E-VII_A-11] One thus obtains an isomorphism of $0_Y(Y)$ -modules:

```
```text
{ S-deviations of u of order n } ≅ { Y-deviations of Γ_u of order n }
 d ↦ Γ_d.
```
```

Moreover, one sees easily that d is an S -derivation of u if and only if (Γ_d) is a Y -derivation of (Γ_u) .

<!-- original page 416 -->

Let us call I_u the kernel of the algebra homomorphism $(\Gamma_u)^{-1}(0_{Y \times X}) \rightarrow 0_Y$ corresponding to (Γ_u) . Taking into account the preceding lemma, one has obtained:

Proposition. *Let $u : Y \rightarrow X$ be an S -morphism and $(\Gamma_u) : Y \rightarrow Y \times X$ its graph. The S -deviations of u of order $\leq n$ are identified with the Y -deviations of (Γ_u) of order $\leq n$, which are in bijection with*

```
```text
Hom_{0_Y}((\Gamma_u)^{-1}(0_{Y \times X}) / I_{\Gamma_u}^{n+1}, 0_Y).
```
```

1.3.1.

<!-- label: III.VII_A.1.3.1 -->

[N.D.E-VII_A-12] Let us return to the case where $u : S \rightarrow X$ is a section of $p : X \rightarrow S$. Then the homomorphism $\phi : u^{-1}(0_X) \rightarrow 0_S$ admits a section, which we shall denote simply $g \mapsto g \cdot 1$, so that, with the notations of 1.3, one has an isomorphism of 0_S -modules:

```

$$(\star) \quad u^{-1}(0_X) \simeq 0_S \oplus I_u,
$$
```

and for every section f of $u^{-1}(0_X)$, $f - \phi(f) \cdot 1$ is a section of I_u .

Let d be an S -deviation of u of order ≤ 1 , and d' the 0_S -morphism $u^{-1}(0_X) \rightarrow 0_S$ corresponding to d . If a, b are sections of $u^{-1}(0_X)$, one has:

```
```text
0 = d'((a - \phi(a) \cdot 1)(b - \phi(b) \cdot 1)) = d'(ab) - \phi(a) d'(b) - \phi(b) d'(a) + \phi(ab) d'(1).
```
```

Consequently, one sees that d is an S -derivation of u (cf. 1.2.1 and N.D.E. (2)) if and only if $d'(1) = 0$. One thus obtains:

<!-- original page 449 -->

Lemma. *The S -derivations of u are exactly the S -deviations of u of order ≤ 1 which vanish on the unit section of 0_X ; they correspond to the $0_S(S)$ -module*

```

$$(\operatorname{Hom}_{0_S}(I_u / I_u^2, 0_S)),
$$
```

and one has an isomorphism of $0_S(S)$ -modules $D_{\leq 1}(u) \simeq 0_S(S) \oplus D_{\leq 1}(u)$.

Returning to the general case, one deduces, with the notations of 1.3,

Corollary. *Let $u : Y \rightarrow X$ be an S -morphism and $(\Gamma_u) : Y \rightarrow Y \times X$ its graph. One has a canonical isomorphism of $0_Y(Y)$ -modules*

```

```text
Dér_S(u) = Dér_Y(Γ_u) = Hom_{O_Y}(I_{Γ_u} / I_{Γ_u}^2, O_Y).
```

```

Definition 1.4.

```

<!-- label: III.VII_A.1.4 -->

```

Let X be an S -scheme. We call S -differential operator (resp. S -differential operator of order $\leq n$) on X any S -deviation (resp. any S -deviation of order $\leq n$) of the identity morphism of X .

According to 1.1, an S -differential operator of order $\leq n$ is therefore an endomorphism of $\mathcal{P}^{-1}(O_S)$ -module of O_X which satisfies the equalities $(\ast_n)$ of 1.1. We shall denote by $\text{Dif}_n^{X/S}$ the $\Gamma(O_S)$ -module $[\wedge^{n,D.E-VII_A-13}]$ formed by the S -differential operators of order $\leq n$, and by $\text{Dif}_n^{X/S}$ that formed by all the S -differential operators.

As we saw in 1.2, one can compose S -deviations of id_X , which equips $\text{Dif}_n^{X/S}$ with a structure of $\Gamma(O_S)$ -algebra; we shall say that this is the $\ast$ -algebra of differential operators of X / S .

Similarly, for every open V of X , set $\mathcal{D}_n^{X/S}(V) = \text{Dif}_n^{V/S} = \mathcal{D}_n^{V/S}(\text{id}_V)$; according to 1.1.3, this defines a sheaf of O_X -modules, called the $\ast$ -sheaf of S -differential operators on X . $[\wedge^{n,D.E-VII_A-14}]$

1.4.1.

```

<!-- label: III.VII_A.1.4.1 -->

```

As we saw in 1.3, one can interpret the differential operators of X / S by means of the graph of the identity morphism of X , i.e., of the diagonal morphism $\Delta = \Delta_{X/S}$ of X into $X \times X$. Let us translate into the present context the statements of 1.3.

Endow $O_{X \times X}$ with the $\mathcal{P}^{-1}(O_X)$ -algebra structure defined by $\mathcal{P}^{-1}$, so that $\Delta^{-1}(O_{X \times X})$ is equipped with a structure of algebra over $O_X = \Delta^{-1} \mathcal{P}^{-1}(O_X)$. Let $I_{X/S}$ be the kernel of the homomorphism

```

```text
Δ^{-1}(O_{X \times X}) \longrightarrow O_X
```

```

adjoint to the homomorphism $O_{X \times X} \rightarrow \Delta_*(O_X)$, and let $\mathcal{P}_m^{X/S}$ be the O_X -algebra

```

```text
Δ^{-1}(O_{X \times X}) / I_{X/S}^{m+1}.
```

```

If V is an affine open of S and U an affine open of X above V , and if one sets

```

<!-- original page 417 --> `k = Γ(V, O_S)` and `A = Γ(U, O_X)`, one has therefore:

```

```

```text
Γ(U, P_m^{X/S}) = (A \otimes_k A) / I^{m+1},
```

```

```

<!-- original page 450 -->

```

where I is the ideal generated by the elements $a \otimes 1 - 1 \otimes a$, for $a \in A$. This being so, one has according to 1.3 an isomorphism of $O_X(X)$ -modules:

```

```text
j_X : \text{Dif}_m^{X/S} \longrightarrow \text{Hom}_{O_X}(\mathcal{P}_m^{X/S}, O_X)
```

```

which one can define as follows: if d belongs to $\text{Dif}_m^{X/S}$ and if c is a section of $\mathcal{P}_m^{X/S}$ on U of the form $a \otimes b + I^{m+1}$, one has $j_X(d)(c) = a \cdot d(b)$. $[\wedge^{n,D.E-VII_A-15}]$

1.4.2.

<!-- label: III.VII_A.1.4.2 -->

Let d be a differential operator and u a section of X over S . We call *value of d at u* the composed S -deviation

```
```text
S → X → X (over id_X).
```
```

According to 1.3 and 1.4.1, if d is a differential operator of order $\leq m$, then du (resp. d) is canonically associated with a morphism of 0_S -modules $d' : u^{-1}(0_X) / I^{m+1}_u \rightarrow 0_S$ (resp. a morphism of 0_X -modules $d'' : P^m_{X/S} \rightarrow 0_X$).

It is clear that one can construct d' from d'' as follows: the square

```
```text
 X = S ×_X X u × X X × X
 | | |
 p u pr_1
 | | |
 v v v
 S X X
```
```

is cartesian, which allows us to identify X with $S \times_X (X \times X)$, u with $S \times_X \Delta$, hence $u^*(P^m_{X/S})$ with $u^{-1}(0_X) / I^{m+1}_u$. One thus identifies $u^*(d')$ with a morphism $u^{-1}(0_X) / I^{m+1}_u \rightarrow 0_S$, which is none other than d' .

1.5.

<!-- label: III.VII_A.1.5 -->

<!-- original page 418 -->

Set as usual $I_S = \operatorname{Spec} 0_S[T] / (T^2)$. Let $\tau : S \rightarrow I_S$ be the zero section and σ the canonical deviation of τ which we defined in 1.2.0, i.e. the homomorphism of 0_S -modules which vanishes on the unit section of $0_S[T]/(T^2)$ and which sends the class t of T modulo T^2 to the unit section of 0_S .

Let X be an S -scheme. To every I_S -automorphism u of $I_S \times X$ inducing the identity on X there is associated by composition a differential operator D_u of X :

```
```text
X = S × X → I_S × X → I_S × X → pr_2 → X.
```
```

According to II, 3.14, the map $u \mapsto D_u$ is an isomorphism of the $\Gamma(0_S)$ -Lie algebra

```
```text
Lie(Aut X) := Lie(Aut X)(S)
```
```

onto the $\Gamma(0_S)$ -Lie algebra of $p^{-1}(0_S)$ -derivations of 0_X . The inverse isomorphism associates with every derivation D the automorphism of $I_S \times X$ corresponding to the automorphism $a + bt \mapsto a + (Da + b)t$ of $0_X[T]/(T^2)$.

2. Invariant differential operators on group schemes

<!-- label: III.VII_A.2 -->

2.1.

<!-- label: III.VII_A.2.1 -->

<!-- original page 419 -->

Let G be an S -group scheme; we denote by ϵ or $\epsilon_G : S \rightarrow G$ the unit section of G .

Definition. Let $U(G)$ be the $\Gamma(S)$ -module of S -deviations of ϵ_G (or S -deviations of the origin) (cf. 1.1).

If d and e are two elements of $U(G)$, $d \times e$ is an S -deviation of $\epsilon \times \epsilon : S \times S \rightarrow S \times G \times G$. The image of $d \times e$ by the multiplication morphism $m : G \times G \rightarrow G$ (cf. 1.2) will be called the product of d and e and will be denoted $d \cdot e$.

The $\Gamma(S)$ -module $U(G)$ is thus equipped with a structure of associative $\Gamma(S)$ -algebra having ϵ_G as unit element (1.1). We shall say that $U(G)$ is the infinitesimal algebra of G . [N.D.E-VII_A-16]

When T ranges over the schemes above S , the infinitesimal algebra $U(G_T)$ of the T -group $G \times T$ obviously varies contravariantly in T , so that we may speak of the infinitesimal algebra functor.

When T ranges over the opens of S , one therefore obtains a presheaf $T \mapsto U(G_T)$ of $\mathcal{O}_S$ -algebras; moreover, according to 1.1.3, this is a sheaf. We shall denote it $\mathcal{U}(G)$ and we shall call it the sheaf of infinitesimal algebras of G .

The algebra $U(G)$ is also a covariant functor in G . Indeed, if $u : G \rightarrow H$ is a homomorphism of S -groups and d an S -deviation of ϵ_G , the image of d by u is an element $U(u)(d) = u_*d$ of $U(H)$. The map $U(u) : U(G) \rightarrow U(H)$ thus defined is obviously a homomorphism of $\Gamma(S)$ -algebras. One defines similarly a homomorphism $\mathcal{U}(u)$ from $\mathcal{U}(G)$ to $\mathcal{U}(H)$.

2.2.

<!-- label: III.VII_A.2.2 -->

Let d be an element of $U(G)$, i.e., an S -deviation of the origin of G . Consider the S -deviation $d \times \epsilon$ of $\epsilon \times \epsilon : S \times S \rightarrow S \times G \times G$ obtained from d by base change (1.2.2); the image of $d \times \epsilon$ by the multiplication morphism $m : G \times G \rightarrow G$ is an S -deviation of $\epsilon \circ m : S \rightarrow G$, i.e., an element of $\text{Dif}_G(S)$, which we shall denote d_G .

The map $d \mapsto d_G$ is obviously $\Gamma(S)$ -linear and the "commutative" diagram below shows that one has $(e \cdot d)_G = d_G \cdot e_G$. [N.D.E-VII_A-17] <!-- original page 420 -->

$$\begin{array}{ccccc}
 & & m \times G & & \\
 G \times G \times G & \xrightarrow{\quad} & G \times G & & \\
 \begin{array}{c} \Delta \\ \downarrow \\ G \times d \times G \\ \downarrow \\ \epsilon \times G \times G \end{array} & & \begin{array}{c} \Delta \\ \downarrow \\ G \times m \end{array} & & \\
 \\
 \begin{array}{ccccc}
 G \times G & & G \times G & & m \\
 \begin{array}{c} \Delta \\ \downarrow \\ e \times G \\ \downarrow \\ \epsilon \times G \end{array} & \xrightarrow{\quad} & \begin{array}{c} \Delta \\ \downarrow \\ d \times G \\ \downarrow \\ \epsilon \times G \end{array} & & \\
 \uparrow & & \uparrow & & \\
 G & \xrightarrow{e_G} & G & \xrightarrow{d_G} & G
 \end{array}
 \end{array}$$

(over id_G everywhere).

The commutativity of the two bottom triangles follows from the definition of d_G and e_G ; on the other hand, the composed S -deviation of $\epsilon \times \epsilon : S \times S \rightarrow S \times G \times G$ is $(e \times d) \times \epsilon$ (cf. 1.2.2), its image by $m \times \epsilon$ is $(e \cdot d) \times \epsilon$, and the image of the latter by m is therefore equal to $(e \cdot d)_G$.

One thus obtains an anti-homomorphism $U(G) \rightarrow \text{Dif}_G(S)$ of $\Gamma(S)$ -algebras, called *right translation*. [N.D.E-VII_A-18]

If $\mathcal{D}_G$ denotes the sheaf of S -differential operators on G (cf. 1.4) and p the structural morphism $G \rightarrow S$, one defines similarly a "right translation": $\mathcal{U}(G) \rightarrow p_* \mathcal{D}_G$.

2.3.

<!-- label: III.VII_A.2.3 -->

We shall now characterize the differential operators of G over S of the form d_G . Let $g : S \rightarrow G$ be a section of the structural morphism of G and $g_{\circ}$ the right translation of G by g , i.e., the composed morphism:

```

$$g_{\circ} : G \cong G \times S \xrightarrow{G \times g} G \times G \xrightarrow{m} G.$$

```

For every differential operator D of G over S , the composition $g^{*-1}_{\circ} D g_{\circ}$ (cf. 1.2) is again an S -deviation of id_G , i.e., an element of $\text{Dif}_{X/S}$; we shall denote:

```

$$D^g = g^{*-1}_{\circ} D g_{\circ}.$$

```

We shall say that D is *right-invariant* if, for every base change $t : T \rightarrow S$ and every section $g : T \rightarrow G \times_S T$, one has $(D_T)^g = D_T$.

Lemma. For every differential operator D of G over S , the following assertions are equivalent (where m is the multiplication morphism of G):

<!-- original page 421 -->

(i) D is right-invariant.

(ii) The two following deviations of m are equal: $D m = m(D \times G)$.

(ii) $\Rightarrow$ (i): since the condition (ii) is stable under base change, it suffices to show that (ii) entails the equality $D^g = D$ for every section $g : S \rightarrow G$. Let h be the morphism $G \times g : G \times_S S \rightarrow G \times_S G$, so that $m \circ h$ is the right translation $g_{\circ}$. The equality $D^g = D$ is equivalent to the equality $g_{\circ} \circ D = D \circ g_{\circ}$, and this follows from the commutative diagram:

```

$$\begin{array}{ccccc} & m & & h & \\ G & \xleftarrow{\quad} & G \times G & \xleftarrow{\quad} & G \\ D, \text{id}_G & & D \times G, \text{id}_{G \times G} & & D, \text{id}_G \\ & m & & h & \\ G & \xleftarrow{\quad} & G \times G & \xleftarrow{\quad} & G. \end{array}$$

```

(i) $\Rightarrow$ (ii): take indeed for $t : T \rightarrow S$ the structural morphism $p : G \rightarrow S$, for section $g : T \rightarrow G \times_S T$ the diagonal morphism $\Delta : G \rightarrow G \times G$. The right translation

```

$$\Delta_{G \times G} : G \times G \rightarrow G \times G$$

```

is then the morphism from $G \times G$ into $G \times G$ with components m and pr_2 . The equality $(D_G)^{\Delta} = D_G$ is then equivalent to the commutativity of the first square of the following diagram:

```

$$\begin{array}{ccccc} G \times G & \xrightarrow{\Delta_{G \times G}} & G \times G & \xrightarrow{\text{pr}_1} & G \\ D_G, \text{id}_{G \times G} & & D_G, \text{id}_{G \times G} & & D, \text{id}_G \\ G \times G & \xrightarrow{\Delta_{G \times G}} & G \times G & \xrightarrow{\text{pr}_1} & G. \end{array}$$

```

The equality (ii) thus follows from the fact that $m = pr_1 \circ \Delta_{G \times G}$.

<!-- original page 422 -->

Consider for example an element d of the infinitesimal algebra $U(G)$. The squares of the diagram

```

```text
 G × G ← S × $\begin{matrix} d \times G \times G \\ \epsilon \times G \times G \end{matrix}$ → G × G × G $\xrightarrow{m \times G}$ G × G

 m S × m G × m m

 G ← S × G $\xrightarrow{\begin{matrix} d \times G \\ \epsilon \times G \end{matrix}}$ G × G $\xrightarrow{m}$ G
...

```

are then commutative. Since one has

```

```text
m ∘ (d × G) = d_G    and    (m × G) ∘ (d × G × G) = d_G × G,
...

```

one also has $d_G \circ m = m \circ (d_G \times G)$. Therefore: *for every S -deviation d of the origin, d_G is a right-invariant differential operator*.

2.4. Theorem.

<!-- label: III.VII_A.2.4 -->

(i) The map $d \mapsto d_G$ is an anti-isomorphism [N.D.E-VII_A-19] of the infinitesimal algebra $U(G)$ onto the subalgebra $\text{Dif}^{\wedge}\{G/S\}$ of $\text{Dif}\{G/S\}$ formed by the right-invariant differential operators.*

(ii) Similarly, the map $d \mapsto \{ \}_G d$ is an isomorphism of $U(G)$ onto the subalgebra of $\text{Dif}\{G/S\}$ formed by the left-invariant differential operators.*

Let in fact D be an arbitrary differential operator of G over S and let us denote by D_0 its value at the origin, i.e., the composed deviation $S \xrightarrow{\epsilon} G \xrightarrow{D} G$ (over id_G). The right-invariant differential operator $(D_0)_G$ is then obtained by composition:

```

```text
G ≈ S × G $\xrightarrow{\epsilon \times G}$ G × G $\xrightarrow{D \times G}$ G × G $\xrightarrow{m}$ G (over $\text{id}_{G \times G}$).
...

```

If  $D$  is right-invariant, one has  $Dm = m(D \times G)$ , whence

```

```text
D = D m(ε × G) = m(D × G)(ε × G) = (D_0)_G.
...

```

In particular, the map $d \mapsto d_G$ is surjective.

Conversely, let d be an S -deviation of the origin. One then has a commutative square

```

```text
 G × G ← $\begin{matrix} d \times G \\ G \end{matrix}$
 Δ Δ
 G × ε | | ε
 d
 G × S ≈ G ← S
...

```

<!-- original page 423 -->

whence it follows that  $d = m(G \times \epsilon) d = m(d \times G) \epsilon = (d_G)_0$ . *A fortiori*, the map  $d \mapsto d_G$  is injective. This proves the theorem.

When  $S$  varies, Theorem 2.4 obviously implies that the right translation  $\mathcal{U}(G) \rightarrow p_*(\mathcal{D}_{G/S})$  is an anti-isomorphism of  $\mathcal{O}_S$ -algebras of  $\mathcal{U}(G)$  onto the sheaf of  $\mathcal{O}_S$ -algebras  $p_*(\mathcal{D}_{G/S})^G$ , which to every open  $U$  of  $S$  associates  $\mathcal{D}_{G_U}^G(G_U / U)$ .

### 2.4.1. Remark.

<!-- label: III.VII\_A.2.4.1 -->

Consider the commutative diagram

```

```text
      G      ←      G × G
      Δ      η
      p      ε      p
      ↓      ↓      ↓
      S      ←      G,
...

```

where η denotes the morphism $(x, y) \mapsto yx^{-1}$. [N.D.E-VII_A-20] The latter induces morphisms

```

```text
η' : η^{-1}(0_G) → 0_{G × G} and Δ^{-1}(η') : p^{-1} ε^{-1}(0_G) → Δ^{-1}(0_{G × G}).
```

```

For every integer $n \geq 1$, set $p^n_{G/S} = \epsilon^{-1}(0_G) / I^{n+1}_{\epsilon}$ (cf. 1.3 and 1.4 for the notations). [N.D.E-VII_A-21] Since the square formed by the morphisms ϵ , η , Δ and p is cartesian, $\Delta^{-1}(\eta')$ induces an isomorphism of $\mathcal{O}_G$ -modules:

```

$$
p^*(p^n_{G/S}) \xrightarrow{\sim} P^n_{G/S}.
$$

```

The differential operators of G over S of order $\leq n$ therefore correspond bijectively to the morphisms of $\mathcal{O}_G$ -modules $p^*(p^n_{G/S}) \rightarrow 0_G$, i.e., to the morphisms <!-- original page 424 --> of $\mathcal{O}_S$ -modules

```

$$
p^n_{G/S} \rightarrow p_*(0_G).
$$

```

In this bijection, the right-invariant differential operators correspond to the composed arrows

```

```text
p^n_{G/S} → 0_S → p_*(0_G).
```

```

One thus recovers the isomorphism of Theorem 2.4.

2.5.

<!-- label: III.VII_A.2.5 -->

[N.D.E-VII_A-22] Let $\text{Lie}(G)$ be the Lie algebra of G ; [N.D.E-VII_A-23] we shall define a morphism of $\Gamma(\mathcal{O}_S)$ -Lie algebras $\alpha : \text{Lie}(G) \rightarrow \mathcal{U}(G)$.

Let $s : S \rightarrow I_S$ be the zero section of $I_S \rightarrow S$ and σ the deviation of s defined in 1.2.0. Recall (cf. II, 4.1) that $\text{Lie}(G)$ is the set of morphisms $x : I_S \rightarrow G$ such that $x \circ s = \epsilon_G$. Then the composition

```

```text

$$S \xrightarrow{\sigma} I_S \xrightarrow{x} G \text{ (over } s)$$

```

```

is an $\mathbb{K}$ -deviation of $\mathfrak{g}$, i.e., an element of $U(\mathfrak{g})$; with the notations of 1.2 (†), it is denoted σ_x . Moreover, according to 1.2.1, the map $\alpha : x \mapsto \sigma_x$ is an isomorphism of $0_S(S)$ -modules from $\text{Lie}(\mathfrak{g})$ onto the submodule $\mathfrak{d}(\mathfrak{g})$ of $U(\mathfrak{g})$ formed by the $\mathbb{K}$ -derivations of $\mathfrak{g}$. We shall see that α is a morphism of Lie algebras. [N.D.E-VII-A-24] Let

```

$$\rho' : U(\mathfrak{g}) \rightarrow \text{Dif}_{G/S}$$

```

be the algebra morphism which to an $\mathbb{K}$ -deviation d of $\mathfrak{g}$ associates the left-invariant differential operator $d \in \text{Dif}_{G/S}$, cf. 2.2, N.D.E. (17).

Let $\rho : G \rightarrow \text{Aut}_S(G)$ be the homomorphism of group functors which to an $\mathbb{K}$ -morphism $g : T \rightarrow G$ associates the right translation of G_T by g , i.e. the morphism:

```

```text

$$G_T \cong T \times_T G_T \xrightarrow{g} G_T \times_T G_T \xrightarrow{m} G_T.$$

```

```

Recall also (cf. 1.5 and II, 3.14) that $\text{Lie}(\text{Aut } G) = \text{Lie}(\text{Aut}_S(G)/S)$ is identified with the infinitesimal automorphisms of G , i.e., with the automorphisms of $I_S \times G$ inducing the identity on G .

<!-- original page 456 -->

Since ρ is a monomorphism, the same holds for the morphism $\text{Lie}(\rho) : \text{Lie}(G/S) \rightarrow \text{Lie}(\text{Aut}_S(G)/S)$ (see, for example, Exp. II, N.D.E. (50)), hence $\text{Lie}(\rho) : \text{Lie}(G) \rightarrow \text{Lie}(\text{Aut } G)$ is injective.

On the other hand, according to 1.5, the map β which to every infinitesimal automorphism u of G associates the differential operator D_u of G :

```

```text

$$G \cong S \times G \xrightarrow{\sigma} I_S \times G \xrightarrow{u} I_S \times G \xrightarrow{\text{pr}_2} G$$

```

```

is an isomorphism of $\text{Lie}(\text{Aut } G)$ onto the Lie subalgebra of $\text{Dif}_{G/S}$ formed by the $\mathfrak{p}^{-1}(0_S)$ -derivations of 0_G .

For every $x \in \text{Lie}(G)$, one has the commutative square below which determines the image of x by $\text{Lie}(\rho)$:

```

```text

$$\begin{array}{ccc} I_S \times G & \xrightarrow{\text{Lie}(\rho)(x)} & I_S \times G \\ x \times G & & \text{pr}_2 \\ G \times G & \xrightarrow{m} & G. \end{array}$$

```

```

<!-- original page 425 -->

Taking this diagram into account, the image of $\text{Lie}(\rho)(x)$ by β is the composed deviation

```

```text

$$G \cong S \times G \xrightarrow{\sigma} I_S \times G \xrightarrow{x} G \times G \xrightarrow{m} G \text{ (over } s \times G)$$

```

```

which, according to 2.2 N.D.E. (17), is none other than $\sigma_x(\sigma_x) = \rho'(\alpha(x))$. One thus obtains a commutative diagram:

```

```text

$$\text{Lie}(\rho)$$

```

$$\begin{array}{ccc}
 \mathrm{Lie}(G) & \xrightarrow{\quad} & \mathrm{Lie}(\mathrm{Aut} \, G) \\
 \alpha \downarrow & \rho' & \downarrow \beta \\
 \mathrm{U}(G) & \xrightarrow{\quad} & \mathrm{Dif}_{\{G/S\}}
 \end{array}$$

where  $\mathrm{Lie}(\rho)$ ,  $\beta$  and  $\rho'$  are morphisms of Lie algebras. Since  $\rho'$  is injective, it follows that  $\alpha$  is also a morphism of Lie algebras. Consequently, one has obtained:

**Proposition.**  $\alpha$  is an isomorphism of  $0_S(S)$ -Lie algebras, from  $\mathrm{Lie}(G)$  into the Lie algebra of  $S$ -derivations of  $\epsilon_G$ , itself isomorphic via  $\mathrm{Lie}(\rho)$  to the Lie algebra of  $S$ -derivations of  $G$  invariant under left translation. [N.D.E-VII\_A-25]

### 3. Coalgebras and Cartier duality

<!-- label: III.VII\_A.3 -->

### 3.1.

<!-- label: III.VII\_A.3.1 -->

<!-- original page 426 -->

Let  $S$  be a scheme (or, more generally, a ringed space). An  $0_S$ -coalgebra [N.D.E-VII\_A-26] is a pair  $(\square, \Delta_\square)$  consisting of an  $0_S$ -module  $\mathcal{U}$  and a morphism of  $0_S$ -modules  $\Delta_\square : \square \rightarrow \square \otimes_{0_S} \square$  (called the *diagonal morphism* or *comultiplication*) such that:

(i)  $\sigma \circ \Delta_\square = \Delta_\square$ , where  $\sigma(a \otimes b) = b \otimes a$ .

(ii) The square

$$\begin{array}{ccc}
 \square & \xrightarrow{\Delta_\square} & \square \otimes_{0_S} \square \\
 \Delta_\square \downarrow & & \downarrow \mathrm{id}_\square \otimes \Delta_\square \\
 \square \otimes_{0_S} \square & \xrightarrow{\Delta_\square \otimes \mathrm{id}_\square} & \square \otimes_{0_S} \square \otimes_{0_S} \square
 \end{array}$$

is commutative.

(iii) There exists a morphism of  $0_S$ -modules  $\epsilon_{\mathcal{U}} : \mathcal{U} \rightarrow 0_S$ , called the *augmentation*, such that the composed morphisms

$$\begin{aligned}
 \square &\xrightarrow{\Delta_\square} \square \otimes_{0_S} \square \xrightarrow{\mathrm{id}_\square \otimes \epsilon_\square} \square \otimes_{0_S} 0_S = \square \\
 \square &\xrightarrow{\Delta_\square} \square \otimes_{0_S} \square \xrightarrow{\epsilon_\square \otimes \mathrm{id}_\square} 0_S \otimes_{0_S} \square = \square
 \end{aligned}$$

are the identity morphism of  $\mathcal{U}$ .

If  $\epsilon_{\mathcal{U}}$  and  $\epsilon'_{\mathcal{U}}$  are two augmentations, one has  $\epsilon_\square = (\epsilon_\square \otimes \epsilon'_\square) \circ \Delta_\square = \epsilon'_\square$ ; the augmentation is therefore uniquely determined by (iii).

If  $(\square, \Delta_\square)$  and  $(\square, \Delta'_\square)$  are two  $0_S$ -coalgebras, a *morphism* from the first into the second is a morphism of  $0_S$ -modules  $f : \mathcal{U} \rightarrow \mathcal{V}$  such that the diagrams

$$\begin{array}{ccc}
 \square & \xrightarrow{f} & \square \\
 | & & | \\
 \square & \xrightarrow{f} & \square
 \end{array}$$

$$\begin{array}{ccc}
 \Delta_{\square} & \Delta_{\square} & \text{and} \\
 \downarrow & \downarrow & \\
 \epsilon_{\square} & \epsilon_{\square} & \\
 \downarrow & \downarrow & \\
 \square \otimes \square & \rightarrow \square \otimes \square & \quad \quad \quad \square \otimes \square \rightarrow 0_S
 \end{array}$$

are commutative. Morphisms of coalgebras compose like morphisms of  $0_S$ -modules, so that we shall be able to speak of the \*category of  $0_S$ -coalgebras\*.

<!-- original page 427 -->

### 3.1.0.

<!-- label: III.VII\_A.3.1.0 -->

[^N.D.E-VII\_A-27] This category has finite products: the final object is the  $0_S$ -module  $0_S$ , the comultiplication being the identity; the product of two coalgebras  $(\square, \Delta_{\square})$  and  $(\square, \Delta_{\square})$  is the tensor product  $\square \otimes \square$ , the comultiplication being the composed morphism

$$\square \otimes \square \xrightarrow{\Delta_{\square} \otimes \Delta_{\square}} \square \otimes \square \otimes \square \otimes \square \xrightarrow{\text{id}_{\square} \otimes \sigma \otimes \text{id}_{\square}} \square \otimes \square \otimes \square \otimes \square$$

where  $\sigma(a \otimes b) = b \otimes a$ ; the canonical projections of  $\square \otimes \square$  onto the factors  $\square$  and  $\square$  are the morphisms  $\text{id}_{\square} \otimes \epsilon_{\square}$  and  $\epsilon_{\square} \otimes \text{id}_{\square}$  and the "diagonal morphism"  $\square \rightarrow \square \otimes \square$  (corresponding to the pair of morphisms  $(\text{id}_{\square}, \text{id}_{\square})$ ) is none other than the comultiplication  $\Delta_{\square}$ .

### 3.1.1.

<!-- label: III.VII\_A.3.1.1 -->

Let  $\square$  be a commutative  $0_S$ -algebra, locally free and of finite type as an  $0_S$ -module. If we set

$$\square^* = \text{Hom}_{0_S\text{-Mod.}}(\square, 0_S),$$

the canonical morphism  $\phi$  from  $\square^* \otimes \square^*$  into  $\square^*$  is invertible. If  $m : \square \otimes \square \rightarrow \square$  is the morphism defining the multiplication of  $\square$ , one obtains by composition a diagonal morphism

$$\Delta_{\square^*} : \square^* \otimes \square^* \xrightarrow{m^*} (\square \otimes \square)^* \xrightarrow{\phi^{-1}} \square^* \otimes \square^*.$$

This diagonal morphism obviously makes  $\square^*$  an  $0_S$ -coalgebra whose augmentation is the

<!-- original page 428 --> transpose morphism of the morphism  $0_S \rightarrow \square$  defined by the unit section of  $\square$ . Moreover,

it is clear that:

\*The functor  $\square \mapsto \square^*$  is an anti-equivalence of the category of  $0_S$ -algebras which are locally free and of finite type as  $0_S$ -modules, onto the category of  $0_S$ -coalgebras locally free and of finite type as  $0_S$ -modules.\*

### 3.1.2.

<!-- label: III.VII\_A.3.1.2 -->

To every  $0_S$ -coalgebra  $\square$  is canonically associated an  $\square$ -functor

$$\text{Spec}^* \square : (\text{Sch}/S)^{\circ} \rightarrow (\text{Ens}).$$

...

Note indeed that, for every  $S$ -scheme  $q : T \rightarrow S$ ,  $q^*(\mathcal{U} \otimes_{\mathcal{O}_S} \mathcal{U})$  is identified with  $q^*(\mathcal{U}) \otimes_{\mathcal{O}_T} q^*(\mathcal{U})$ , so that  $q^*(\Delta_{\mathcal{U}})$  makes  $\mathcal{U}_T = q^*(\mathcal{U})$  into an  $\mathcal{O}_T$ -coalgebra; we can therefore set by definition and with an obvious abuse of notation: [^N.D.E-VII\_A-29]

text  
 $(\mathrm{Spec}^* \mathcal{U})(T) = \{ x \in \Gamma(T, \mathcal{U}_T) \mid \varepsilon_{\mathcal{U}_T}(x) = 1 \text{ and } \Delta_{\mathcal{U}_T}(x) = x \otimes x \}.$

<!-- original page 458 -->

The sections  $x$  of  $\mathcal{U}_T$  obviously correspond to the morphisms of  $\mathcal{O}_T$ -modules  $\xi : \mathcal{O}_T \rightarrow \mathcal{U}_T$ ; the conditions  $\varepsilon(x) = 1$  and  $\Delta(x) = x \otimes x$  simply express that  $\xi$  is a morphism of coalgebras. One therefore also has:

text  
 $(\mathrm{Spec}^* \mathcal{U})(T) = \mathrm{Hom}_{\mathcal{O}_T\text{-coalg.}}(\mathcal{O}_T, \mathcal{U}_T).$

In particular, one has the following proposition: [^N.D.E-VII\_A-30]

**Proposition 3.1.2.1.** \*Let  $A$  be a commutative  $\mathcal{O}_S$ -algebra which is locally free of finite type as an  $\mathcal{O}_S$ -module. Then the  $S$ -functor  $\mathrm{Spec}^* \mathcal{A}$  is represented by  $\mathrm{Spec} A$ .\*

<!-- label: III.VII\_A.3.1.2.1 -->

Indeed, for every  $S$ -scheme  $T$ , one has canonical isomorphisms:

text  
 $(\mathrm{Spec}^* \mathcal{A})(T) = \mathrm{Hom}_{\mathcal{O}_T\text{-coalg.}}(\mathcal{O}_T, \mathcal{A}_T) \simeq \mathrm{Hom}_{\mathcal{O}_T\text{-alg.}}(\mathcal{U}_T, \mathcal{A}_T) \simeq (\mathrm{Spec} \mathcal{A})(T).$

### 3.2.

<!-- label: III.VII\_A.3.2 -->

An  $\mathcal{O}_S$ -coalgebra in groups (i.e., a group in the category of  $\mathcal{O}_S$ -coalgebras) consists of the data of an  $\mathcal{O}_S$ -coalgebra  $(\mathcal{U}, \Delta_{\mathcal{U}})$  and three morphisms of  $\mathcal{O}_S$ -coalgebras  $m_{\mathcal{U}} : \mathcal{U} \otimes \mathcal{U} \rightarrow \mathcal{U}$ ,  $\eta_{\mathcal{U}} : \mathcal{O}_S \rightarrow \mathcal{U}$  and  $c_{\mathcal{U}} : \mathcal{U} \rightarrow \mathcal{U}$  satisfying the conditions (ii)\*, (iii)\* and (vi) below; on the other hand, the fact that  $m_{\mathcal{U}}$  is a morphism of coalgebras translates into the commutativity of diagrams (iv) and (v)

<!-- original page 429 --> below:

text

$$\begin{array}{ccc}
 & & m_{\mathcal{U}} \\
 & \mathcal{U} \otimes \mathcal{U} & \longrightarrow \mathcal{U} \\
 & \Delta_{\mathcal{U}} \otimes \Delta_{\mathcal{U}} & \\
 & \downarrow & \\
 \text{(iv)} & \mathcal{U} \otimes \mathcal{U} \otimes \mathcal{U} & \xrightarrow{\Delta_{\mathcal{U}}} \mathcal{U} \\
 & \text{id}_{\mathcal{U}} \otimes c \otimes \text{id}_{\mathcal{U}} & \\
 & \mathcal{U} \otimes \mathcal{U} \otimes \mathcal{U} & \xrightarrow{m_{\mathcal{U}} \otimes m_{\mathcal{U}}} \mathcal{U} \otimes \mathcal{U}
 \end{array}$$

...

text

$$\begin{array}{ccc}
 & & m_{\mathcal{U}} \\
 & \mathcal{U} \otimes \mathcal{U} & \longrightarrow \mathcal{U}
 \end{array}$$

$$(v) \quad \begin{array}{c} \epsilon_{\square} \otimes \epsilon_{\square} \\ \diagdown \quad \diagup \\ 0_S \end{array} \quad \begin{array}{c} \epsilon_{\square} \\ \diagup \end{array}$$

...

(ii)\* The square

$$\begin{array}{ccc} \square \otimes \square \otimes \square & \xrightarrow{\text{id}_{\square} \otimes m_{\square}} & \square \otimes \square \\ m_{\square} \otimes \text{id}_{\square} & & m_{\square} \\ \square \otimes \square & \xrightarrow{m_{\square}} & \square \end{array}$$

...

is commutative.

(iii)\* The two compositions below equal the identity morphism of  $\mathcal{U}$ :

$$\begin{aligned} \square &= \square \otimes 0_S \xrightarrow{\text{id}_{\square} \otimes \eta_{\square}} \square \otimes \square \xrightarrow{m_{\square}} \square \\ \square &= 0_S \otimes \square \xrightarrow{\eta_{\square} \otimes \text{id}_{\square}} \square \otimes \square \xrightarrow{m_{\square}} \square. \end{aligned}$$

(vi) The composed morphism below is equal to  $\eta_{\mathcal{U}} \circ \epsilon_{\mathcal{U}}$ :

<!-- original page 430 -->

$$\square \xrightarrow{\Delta_{\square}} \square \otimes \square \xrightarrow{c_{\square} \otimes \text{id}_{\square}} \square \otimes \square \xrightarrow{m_{\square}} \square.$$

### 3.2.1.

<!-- label: III.VII\_A.3.2.1 -->

The morphisms  $\eta_{\mathcal{U}}$  and  $c_{\mathcal{U}}$  are uniquely determined by  $m_{\mathcal{U}}$ . On the other hand, conditions (ii)\* and (iii)\* simply express that  $m_{\mathcal{U}}$  makes  $\mathcal{U}$  an  $0_S$ -algebra having as unit section the image by  $\eta_{\mathcal{U}}$  of the unit section of  $0_S$ . Condition (iv) also expresses that the diagonal morphism  $\Delta_{\square}$  is compatible with multiplication; and indeed,  $\Delta_{\square} : \square \rightarrow \square \otimes \square$  must be a homomorphism of group coalgebras, which also entails the commutativity of the triangle

$$(v)^* \quad \begin{array}{ccc} & 0_S & \\ \eta_{\square} \diagup & & \diagdown \eta_{\square} \otimes \eta_{\square} \\ \square & \xrightarrow{\Delta_{\square}} & \square \otimes \square \end{array}$$

...

On the other hand, as in every category, the \*antipode\*  $c_{\mathcal{U}}$  is an isomorphism of  $\mathcal{U}$  onto the "opposite" group object; [N.D.E-VII\_A-31] in particular,  $c_{\mathcal{U}}$  induces an algebra isomorphism of  $\mathcal{U}$  onto the opposite algebra  $\mathcal{U}^{\text{op}}$ .

### 3.2.2.

<!-- label: III.VII\_A.3.2.2 -->

Since the functor  $\mathcal{U} \mapsto \text{Spec}^*(\mathcal{U})$  commutes with finite products, it transforms

a group coalgebra into a group  $S$ -functor; and indeed, for every  $S$ -scheme  $T$ , the elements  $x \in \Gamma(T, \mathcal{U}_T)$  belonging to  $(\operatorname{Spec}^{\wedge{*}} \mathcal{U})(T)$  form a group under the multiplication of the algebra  $\Gamma(T, \mathcal{U}_T)$ ; the inverse of  $x$  is none other than  $c_{\mathcal{U}}(x)$ . According to 3.1.2.1, one has:

**Scholium 3.2.2.1.** [N.D.E-VII\_A-32] Let  $\mathcal{U}$  be an  $0_S$ -coalgebra in groups, finite and locally free as an  $0_S$ -module. Then the group  $S$ -functor  $\operatorname{Spec}^{\wedge{*}} \mathcal{U}$  is represented by the  $S$ -group, finite and locally free,  $\operatorname{Spec} \mathcal{U}^{\wedge{*}}$ .

<!-- label: III.VII\_A.3.2.2.1 -->

**Remark 3.2.2.2.** Let  $\mathcal{L}$  be an  $0_S$ -Lie algebra and  $\mathcal{U}(\mathcal{L})$  the enveloping algebra of  $\mathcal{L}$ , i.e., the sheaf on  $S$  associated with the presheaf which to every open  $V$  assigns the enveloping algebra  $U(\Gamma(V, \mathcal{L}))$  of the Lie algebra  $\Gamma(V, \mathcal{L})$ .

<!-- label: III.VII\_A.3.2.2.2 -->

Every homomorphism from  $\mathcal{L}$  into the Lie algebra underlying an associative  $0_S$ -algebra factors in one and only one way through the canonical morphism <!-- original page 431 --> from  $\mathcal{L}$  into  $\mathcal{U}(\mathcal{L})$ ; moreover, this universal property entails, besides the functoriality of  $\mathcal{U}(\mathcal{L})$  in  $\mathcal{L}$ , that the enveloping algebra of a product of Lie algebras is identified with the tensor product of the enveloping algebras.

In particular, the diagonal morphism  $\delta : \mathcal{L} \rightarrow \mathcal{L} \times \mathcal{L}$  induces an algebra homomorphism  $\Delta : \Gamma(\square) \rightarrow \Gamma(\square \times \square) \simeq \Gamma(\square) \otimes \Gamma(\square)$ . The zero morphism  $\mathcal{L} \rightarrow 0$  induces a homomorphism  $\epsilon : \mathcal{U}(\mathcal{L}) \rightarrow \mathcal{U}(0) \simeq 0_S$ . The isomorphism  $x \mapsto -x$  of  $\mathcal{L}$  onto the opposite Lie algebra  $\mathcal{L}^{\circ}$  induces an anti-isomorphism  $c$  of the algebra  $\mathcal{U}(\mathcal{L})$ . One then verifies easily that the multiplication  $m$  of the algebra  $\mathcal{U}(\mathcal{L})$  makes  $(\Gamma(\square), \Delta)$  an  $0_S$ -coalgebra in groups with  $\epsilon$  as augmentation and  $c$  as antipode. [N.D.E-VII\_A-33]

### 3.2.3.

<!-- label: III.VII\_A.3.2.3 -->

[N.D.E-VII\_A-34] Let  $\mathcal{U}$  be an  $0_S$ -coalgebra in groups. We shall see that the group  $S$ -functor  $G = \operatorname{Spec}^{\wedge{*}} \mathcal{U}$  is *very good*, in the sense of II, 4.6 and 4.10.

Let  $M$  be a free  $0_S$ -module of rank  $r$ , and let  $T \rightarrow S$  be an  $S$ -scheme. Since  $\Gamma(T, M) = \operatorname{Spec}(0_T \oplus M_T)$ , so that  $\pi : \Gamma(T, M) \rightarrow T$  is affine, one has

$$\pi^*(\Gamma(T, M)) = \Gamma(T, 0_T) \oplus \pi^*(0_T \oplus M_T) = \Gamma(T, 0_T) \oplus M_T,$$

and so

$$(1) \quad \Gamma(T, \Gamma(T, M)) \simeq \Gamma(T, \Gamma(T, 0_T) \oplus \Gamma(T, M_T)).$$

Let  $(d_1, \dots, d_r)$  be a basis of  $M$ . Then an element  $u_0 + \sum_i u_i d_i$  of  $\Gamma(T, M)$  belongs to  $G(T)$  if and only if one has:

$$1 = \epsilon(u_0 + \sum_i u_i d_i) = \epsilon(u_0) + \sum_i \epsilon(u_i) d_i,$$

and

$$(u_0 + \sum_i u_i d_i) \otimes (u_0 + \sum_i u_i d_i) = \Delta(u_0 + \sum_i u_i d_i) = \Delta(u_0) + \sum_i \Delta(u_i) d_i,$$

that is to say:

```

```text
(2) {  $\varepsilon(u_0) = 1, \Delta u_0 = u_0 \otimes u_0, \quad (\text{i.e. } u_0 \in G(T))$ 
      {  $\varepsilon(u_i) = 0, \Delta(u_i) = u_i \otimes u_0 + u_0 \otimes u_i, \quad \text{for } i = 1, \dots, r.$ 
...

```

Moreover, the morphism $G(I_{\{T\}}(M)) \rightarrow G(T)$ corresponding to the zero section of $I_{\{T\}}(M) \rightarrow T$ is given by $u_0 + \sum_i u_i d_i \mapsto u_0$. From this, combined with (1) and (2), one deduces that, if N is a second free 0_S -module of finite rank, the diagram of sets

```

```text
 G(I_T(M \otimes N)) \longrightarrow G(I_T(N))
 \downarrow \qquad \qquad \downarrow
 G(I_T(M)) \qquad \longrightarrow G(T)
...

```

is cartesian, i.e.  $G$  satisfies condition (E) of II, 3.5.

<!-- original page 462 -->

Let us denote by  $\text{Prim } \Gamma(T, \mathcal{U}_T)$  the sub- $0(T)$ -module of  $\Gamma(T, \mathcal{U}_T)$  formed by the \*primitive elements\*, i.e., the elements  $u$  which satisfy (with the abuse of notation signaled in 3.1.2):

```

```text
 $\Delta u = u \otimes 1 + 1 \otimes u, \quad \varepsilon(u) = 0.$ 
...

```

[^N.D.E-VII_A-35]

Since $(\text{Lie } G)(T)$ is the set of elements $u_0 + u d \in G(I_{\{T\}})$ above the unit element $u_0 = 1$ of $G(T)$, one obtains an isomorphism of $0(T)$ -modules, functorial in T : [^N.D.E-VII_A-36]

```

```text
 $(\text{Lie } G)(T) \simeq \text{Prim } \Gamma(T, \square_T).$
...

```

On the other hand, one deduces from (1) that

```

```text
 $\text{Prim } \Gamma(I_T(M), \square_{I_T(M)}) \simeq \text{Prim } \Gamma(T, \square_T) \otimes_{0(T)} 0(I_T(M)),$ 
...

```

and it follows that the natural morphism of $0(I_{\{T\}}(M))$ -modules:

```

```text
 $(\text{Lie } G)(T) \otimes_{0(T)} 0(I_T(M)) \rightarrow (\text{Lie } G)(I_T(M))$
...

```

is an isomorphism, i.e.  $\text{Lie } G$  is a \*good  $0_S$ -module\* (cf. II, Déf. 4.4).

So  $G$  is a good group  $S$ -functor (cf. II, Déf. 4.6), and according to II, 4.7.2,  $\text{Lie } G$  is equipped with an  $0_S$ -bilinear "Lie bracket" satisfying the Jacobi identity. It remains to show that  $G$  is very good, i.e., that the "bracket" on  $(\text{Lie } G)(T)$  satisfies  $[u, u] = 0$  for every  $u \in (\text{Lie } G)(T)$  (cf. II, 4.10).

Let  $u, v$  be two elements of  $(\text{Lie } G)(T)$ , i.e., two primitive elements of  $\Gamma(T, \mathcal{U}_T)$ . Set  $I = \text{operatorname{Spec}} 0_S[d]/(d^2)$  and  $I' = \text{operatorname{Spec}} 0_S[d']/(d'^2)$ . Since the composition law of  $G(I \times I')$  is induced by the multiplication of the algebra  $\mathcal{U}_{I \times I'}$ , one has in  $G(I \times I')$  the equality:

```

```text
 $(1 + ud)(1 + vd')(1 + ud)^{-1}(1 + vd')^{-1} = (1 + ud)(1 + vd')(1 - ud)(1 - vd')$ 
 $\qquad \qquad \qquad = 1 + (uv - vu) dd'$ 
...

```

<!-- original page 432 -->

According to the description of the bracket $[u, v]$ given before Prop. 4.8 of Exp. II, one obtains that

```
```text
[u, v] = uv - vu,
```
```

where the right-hand term is the commutator of u and v in the algebra $\Gamma(T, \mathcal{U}_T)$, whence $[u, u] = 0$. One has thus obtained the following proposition: [N.D.E-VII_A-37]

Proposition. *Let $\mathcal{U}$ be an 0S -coalgebra in groups. The group S -functor $G = \operatorname{Spec}^* \mathcal{U}$ is very good, and one has an isomorphism $\operatorname{Lie} G \simeq \operatorname{Prim} \mathcal{W}(\mathcal{U})$ of 0S -Lie algebras, where $\operatorname{Prim} \mathcal{W}(\mathcal{U})$ denotes the functor which to every T to S associates the ${}^0(T)$ -Lie algebra formed by the primitive elements of $\mathcal{W}(\mathcal{U})(T) = \Gamma(T, \mathcal{U}_T)$.*

3.3.

<!-- label: III.VII_A.3.3 -->

Suppose finally that $\mathcal{U}$ is a commutative group coalgebra, i.e., the triangle

```
```text
 σ
 |
 □ ⊗ □ -----> □ ⊗ □
 | |
 m_□ m_□
 | |
 □ □
(i)*
```
```

is commutative, or in other words that $m_{\mathcal{U}}$ makes $\mathcal{U}$ a commutative 0S -algebra. Conditions (i), (ii), (iii), (iv), (v), (vi), (i)*, (ii)*, (iii)* and (v)* then also signify that $\mathcal{U}$ is a cogroup in the category of commutative 0S -algebras. Therefore, if moreover $\mathcal{U}$ is a quasi-coherent 0S -module, then the affine S -scheme $\operatorname{Spec}^* \mathcal{U}$ is a commutative S -group scheme.

In this case, since the diagonal morphism Δ' of ${}^0_S[T, T^{-1}]$ sends T to $T \otimes T$, the morphisms of S -groups from $\operatorname{Spec}^* \mathcal{U}$ into $\mathbb{G}_m(S)$ (I 4.3.2) correspond bijectively to the morphisms of unital 0S -algebras

```
```text
φ : {}^0_S[T, T^{-1}] → {}^0_S
```
```

such that $(\phi \otimes \phi) \circ \Delta' = \Delta_{\phi} \circ \phi$ (in this case, $\epsilon_{\mathcal{U}} \circ \phi$ is the neutral element of $\mathbb{G}_m(S)$, i.e., the augmentation ϵ). Such a morphism ϕ is determined by the image $\phi(T)$, which must be an invertible element x of $\mathcal{U}$ satisfying $\Delta_{\phi} x = x \otimes x$ and $\epsilon_{\mathcal{U}}(x) = \epsilon(T) = 1$. One therefore has:

```
```text
Hom_{S-gr.}(\operatorname{Spec} \square, \square_{\{m, S\}}) = (\operatorname{Spec}^* \square)(S)
```
```

and since this formula remains valid after any base change, this gives: <!-- original page 433 -->

```
```text
\operatorname{Spec}^* \square \simeq \operatorname{Hom}_{S-gr.}(\operatorname{Spec} \square, \square_{\{m, S\}}).
```
```

One has therefore obtained the

Proposition 3.3.0. *If $\mathcal{U}$ is an 0S -coalgebra in commutative groups, quasi-coherent as an 0S -module, then the affine S -scheme $G = \operatorname{Spec}^* \mathcal{U}$ is a commutative S -group scheme, and one has an

isomorphism of group S -functors*

<!-- label: III.VII_A.3.3.0 -->

```
```text
Spec^* \cong Hom_{S-gr.}(G, \Gamma_m(S)).
```
```

If one supposes moreover that $\mathcal{U}$ is a locally free 0_S -module of finite type, then, according to 3.1.2.1, the group S -functor $\operatorname{Spec}^* \mathcal{U}$ is represented by $\operatorname{Spec} \mathcal{U}^*$. One thus obtains the

Proposition 3.3.1 (Cartier duality). *The functor**

<!-- label: III.VII_A.3.3.1 -->

```
```text
\Gamma(G) \mapsto \Gamma(G)^* = Hom_{0_S-Mod.}(\Gamma(G), 0_S)
```
```

induces a duality $(\ast)$ of the category of commutative, finite and locally free S -group schemes; it associates with G the S -group $\operatorname{Hom}_{S-gr.}(G, \mathbb{G}_m(S))^$.

4. "Frobeniusseries"

<!-- label: III.VII_A.4 -->

<!-- original page 434 -->

Let p be a fixed prime number and $(\operatorname{Sch}/\mathbb{F}_p)$ the category of schemes of characteristic p , i.e., of schemes above the prime field $\mathbb{F}_p$. Following the general conventions of this Seminar, we identify $(\operatorname{Sch}/\mathbb{F}_p)$ with a subcategory of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$ by means of the functor h of I 1.1. We likewise take advantage of the isomorphism from $\operatorname{Hom}(h(X), F)$ onto $F(X)$ defined in I 1.1 to identify these two sets whenever X is an $\mathbb{F}_p$ -scheme and F an object of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$.

Notations 4.0. [^N.D.E-VII_A-39] If T is an $\mathbb{F}_p$ -scheme, a T -functor is a morphism $q : F \rightarrow T$ of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$ having T as target; for every T -scheme $r : X \rightarrow T$, the set of T -morphisms $X \rightarrow F$, i.e., of $\mathbb{F}_p$ -morphisms $s : X \rightarrow F$ such that $q \circ s = r$, will then be denoted $q(r)$, $q(X/T)$, $F(r)$ or $F(X/T)$ (or even $F(X)$ when no confusion will be possible with $\operatorname{Hom}(h(X), F)$).

<!-- label: III.VII_A.4.0 -->

4.1.

<!-- label: III.VII_A.4.1 -->

For every scheme S of characteristic p , we denote by $\operatorname{fr}(S)$, or simply fr , the endomorphism of S which induces the identity on the underlying topological space of S and which associates x^p with a section x of 0_S on an open U .

Then the map $\operatorname{fr} : S \rightarrow S$ is an endomorphism of the identity functor of $(\operatorname{Sch}/\mathbb{F}_p)$, [^N.D.E-VII_A-40] which implies the following results. Let E be an $\mathbb{F}_p$ -functor, i.e., an object of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$; the map which to every $\mathbb{F}_p$ -scheme S associates the endomorphism $E(\operatorname{fr}(S))$ of $E(S)$ is a functorial endomorphism of E which we shall denote $\operatorname{fr}(E)$ or fr ; this notation is compatible with the identification of $(\operatorname{Sch}/\mathbb{F}_p)$ with a subcategory of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$. Moreover, the map $E \rightarrow \operatorname{fr}(E)$ is an endomorphism of the identity functor of $(\operatorname{Sch}/\mathbb{F}_p)^{\wedge}$ (which we shall again denote fr). [^N.D.E-VII_A-41]

For every $\mathbb{F}_p$ -scheme S and every S -functor $q : X \rightarrow S$, we denote by $X^{(p/S)}$ or $X^{(p)}$ the inverse image of X by the base change $\operatorname{fr}(S)$:

```
```text
 pr_X
X^{(p/S)} -----> X
 | |
 | q
```
```

$$\begin{array}{ccc} \blacktriangledown & & \blacktriangledown \\ S & \xrightarrow{\text{fr}(S)} & S. \end{array}$$

<!-- original page 465 -->

The commutative square

```

```text

$$\begin{array}{ccc} X & \xrightarrow{\text{fr}(X)} & X \\ q \downarrow & & \downarrow q \\ S & \xrightarrow{\text{fr}(S)} & S \end{array}$$

```

induces an  $S$ -morphism, denoted  $\text{Fr}(X/S)$  (or simply  $\text{fr}$ ), from  $X$  into  $X^{(p/S)}$  such that  $\text{fr}(X) = \text{pr}_X \circ \text{Fr}(X/S)$ :

```

```text

$$\begin{array}{ccccc} X & & & & \\ & \searrow \text{Fr}(X/S) & & & \\ & X^{(p/S)} & \xrightarrow{\text{pr}_X} & X & \\ & \downarrow q^{(p/S)} & & \downarrow q & \\ q \downarrow & S & \xrightarrow{\text{fr}(S)} & S & \end{array}$$

```

We shall say that $\text{Fr}(X/S)$ is the *Frobenius morphism* of X relative to S ; it is clear that the map $\text{Fr} : X \mapsto \text{Fr}(X/S)$ is a functorial homomorphism.

[^N.D.E-VII_A-42] Let $r : T \rightarrow S$ be an S -scheme. For every $\phi \in X(r) = \text{Hom}_S(T, X)$ (cf. 4.0), one has a commutative diagram:

```

```text

$$\begin{array}{ccccc} X & \xrightarrow{\text{Fr}(X/S)} & X^{(p/S)} & \xrightarrow{\text{pr}_X} & X \\ & \searrow \phi & \downarrow q^{(p/S)} & & \downarrow q \\ r \downarrow & T & \xrightarrow{\text{fr}(S)} & S & \end{array}$$

```

According to the definition of  $X^{(p/S)}$  as fibered product,  $\text{pr}_X$  induces a bijection:

```

```text

$$X^{(p/S)}(r) = \text{Hom}_S(T, X^{(p/S)}) \cong \text{Hom}_S(T, X) = X(\text{fr}(S) \circ r).$$

```

On the other hand, $r \circ \text{fr}(T) = \text{fr}(S) \circ r$, since fr is an endomorphism of the identity functor. It follows that the map $\text{Fr}(X/S)(r) : X(r) \rightarrow X^{(p/S)}(r)$ can be characterized by the commutativity of the following square:

```

```text

$$\begin{array}{ccc} X(r) & \xrightarrow{\text{Fr}(X/S)(r)} & X^{(p/S)}(r) \\ \text{(†)} \quad X(\text{fr}(T)) & & \square \end{array}$$

```

```
... X(r ∘ fr(T)) X(fr(S) ∘ r).
```

<!-- original page 466 -->

For example, if  $X$  is the subscheme of  $S$  defined by a quasi-coherent ideal  $\mathcal{I}$ , then  $X^{(p)}$  is the subscheme of  $S$  defined by the ideal  $\mathcal{I}^{(p)}$  generated by the  $p$ -th powers of the sections of  $\mathcal{I}$ ; moreover,  $\mathrm{Fr}(X/S)$  is then the canonical immersion of  $\mathrm{Spec}(0_X / \mathcal{I})$  into  $\mathrm{Spec}(0 / \mathcal{I}^{(p)})$ .

### 4.1.1.

<!-- label: III.VII\_A.4.1.1 -->

[^N.D.E-VII\_A-43] Let  $t : T \rightarrow S$  be a base change and  $X_T = X \times_{q, t} T$ . Consider the inverse image of  $X_T$  by  $\mathrm{fr}(T)$ :

```
```text
      (X_T)^{(p/T)}  →  X_T  →  X
                    |
                    q
      fr(T)         t
      T  →  T  →  S.
...```
```

<!-- original page 436 -->

Since $t \circ \mathrm{fr}(T) = \mathrm{fr}(S) \circ t$, then $(X_T)^{(p/T)}$ is identified with the inverse image of $X^{(p/S)}$ by t ; in other words, one has a canonical isomorphism:

```
$$
X^{(p/T)}_T \xrightarrow{\sim} (X^{(p/S)})_T.
$$
```

It is clear that, in this identification, $\mathrm{Fr}(X_T / T)$ is identified with the inverse image $\mathrm{Fr}(X/S)_T$ of $\mathrm{Fr}(X/S)$.

4.1.1.1.

<!-- label: III.VII_A.4.1.1.1 -->

In particular, if S is the spectrum of the prime field $\mathbb{F}_p$, $X^{(p/S)}$ is equal to X and $\mathrm{Fr}(X/S)$ to $\mathrm{fr}(X)$. Consequently, $(X_T)^{(p/T)}$ is identified with X_T and $\mathrm{Fr}(X_T / T)$ with $\mathrm{fr}(X)_T$.

For example, if E is a set and E_T the constant T -scheme of type E , one has $E^{(p/T)}_T \simeq E_T$ and $\mathrm{Fr}(E_T / T) \simeq \mathrm{id}_{E_T}$.

4.1.2.

<!-- label: III.VII_A.4.1.2 -->

The functor $X \mapsto X^{(p/S)}$ obviously commutes with products; it therefore transforms an S -group G into an S -group $G^{(p/S)}$; moreover, since Fr is a functorial homomorphism, then

```
$$
\mathrm{Fr}(G/S) : G \rightarrow G^{(p/S)}
$$
```

is a homomorphism of S -groups. We shall denote $\mathrm{Fr} G$ its kernel.

If $r : T \rightarrow S$ is a scheme above S , it follows from the diagram (t) of 4.1 that the value of $\mathrm{Fr} G$ at r is the kernel of the homomorphism

```
```text
G(fr(T)) : G(r) → G(r ∘ fr(T)).
...```
```

Now, when  $T$  is the scheme  $\mathbb{A}_R^1$  of dual numbers over an  $S$ -scheme  $R$ ,  $\mathrm{Fr}(I_R)$  factors as follows:

```

$$\begin{array}{c} \text{I}_R \\ \text{---} \end{array} \text{can.} \rightarrow R \xrightarrow{\mathrm{Fr}(R)} R \xrightarrow{s} \mathbb{A}_R^1,$$

```

where  $s$  is the zero section. It follows that  $\mathrm{Fr}(G)(I_R)$  contains the kernel  $\mathrm{Lie}(G/S)(R)$  of the morphism  $G(s) : G(I_R) \rightarrow G(R)$ , and that one therefore has:  $\mathrm{Lie}(G/S) = \mathrm{Lie}(\mathrm{Fr} G / S)$ .

### 4.1.3.

<!-- label: III.VII\_A.4.1.3 -->

<!-- original page 437 -->

More generally, for every  $S$ -functor  $X$ , we define the  $S$ -functor  $X^{\{p^n\}}$  by recursion on  $n$  by means of the formulas:

```

$$\begin{array}{c} \text{X}^{\{p\}} \\ \text{---} \end{array} = X^{\{p/S\}} \quad \text{and} \quad X^{\{p^n\}} = (X^{\{p^{n-1}\}})^{\{p\}}.$$

```

Similarly,  $\mathrm{Fr}^n(X/S)$  or  $\mathrm{Fr}^n$  denote the composed functorial homomorphism

```

$$\begin{array}{c} X \\ \text{---} \end{array} \xrightarrow{\mathrm{Fr}(X/S)} X^{\{p\}} \xrightarrow{\mathrm{Fr}(X^{\{p\}}/S)} X^{\{p^2\}} \longrightarrow \cdots \longrightarrow X^{\{p^{n-1}\}} \xrightarrow{\mathrm{Fr}(X^{\{p^{n-1}\}}/S)} X^{\{p^n\}}.$$

```

One will note that, according to 4.1.1,  $\mathrm{Fr}(X^{\{p\}}/S)$  coincides with  $\mathrm{Fr}(X/S)^{\{p\}}$ , i.e., the following diagram is commutative:

```

$$\begin{array}{ccc} X^{\{p\}} & \longrightarrow & X \\ \mathrm{Fr}(X^{\{p\}}/S) & & \mathrm{Fr}(X/S) \\ X^{\{p^2\}} & \longrightarrow & X^{\{p\}}. \end{array}$$

```

If  $G$  is a group  $S$ -functor,  $G^{\{p^n\}}$  is also one and  $\mathrm{Fr}^n(G/S)$  is a homomorphism of group  $S$ -functors.

**Definition.** We shall denote by  $\mathrm{Fr}^n G$  the kernel of  $\mathrm{Fr}^n(G/S)$  and we shall say that  $G$  is of height  $\leq n$  if  $\mathrm{Fr}^n(G/S)$  is zero, i.e., if  $\mathrm{Fr}^n G = G$ .

**Lemma.** The group subfunctor  $\mathrm{Fr}^n G$  of  $G$  is characteristic, i.e., for every  $S$ -scheme  $T$ , every endomorphism  $\phi$  of the group  $T$ -functor  $G_T$  induces an endomorphism of  $(\mathrm{Fr}^n G)_T$ .

Indeed, since the construction of  $G^{\{p^n\}}$  and of  $\mathrm{Fr}^n(G/S)$  commutes with base changes according to 4.1.1, one may suppose  $T = S$ ; in this case, the assertion follows from the fact that  $\mathrm{Fr}^n(G/S)$  is a functorial homomorphism.

### 4.1.4. Examples.

<!-- label: III.VII\_A.4.1.4 -->

a) Consider first an "abstract" abelian group  $M$  and the diagonalizable group  $G = D_S(M)$  of type  $M$  (I 4.4): for every  $S$ -scheme  $T$ ,  $G(T)$  is therefore the abelian group  $\mathrm{Hom}_{\mathrm{Ab}}(M, \Gamma(T, \mathcal{O}_T)^{\times})$ . Since  $G$  is the inverse image of the diagonalizable group  $D(M)$  over  $\mathbb{F}_p$ ,  $G^{\{p\}}$  is identified with  $G$  and  $\mathrm{Fr}(G/S)(T)$  is identified with the endomorphism  $x \mapsto x^p$  of  $G(T)$  (4.1.1). In particular, when  $M$  is equal to  $\mathbb{Z}$ , one has  $D_S(M) = \mathbb{G}_m$ , so that:

$\mathrm{Fr} \mathbb{G}_m$  is the  $S$ -group  $\mu_p$  which to every  $S$ -scheme  $T$  associates the group of  $p$ -th roots of unity in  $\Gamma(T, \mathcal{O}_T^{\times})$ .

b) Consider now a scheme  $S$  of characteristic  $p$  and a sheaf of modules  $\mathcal{E}$  on  $S$ . According to I 4.6.2,

one has a canonical isomorphism

$$\mathcal{W}(\mathcal{E}^{(p)}) \simeq \mathcal{W}(\mathcal{E}^{(p)}),$$

where  $\mathcal{E}^{(p)}$  is the inverse image of  $\mathcal{E}$  by  $\text{fr}(S)$ . For every  $S$ -scheme  $\pi : T \rightarrow S$ , the map  $\text{Fr}(\mathcal{W}(\mathcal{E}))(\pi)$  is determined, according to 4.1 (†), by the commutative triangle

$$\begin{array}{ccc} \Gamma(T, \pi^* \text{fr}(S)^* \square) & \xrightarrow{\text{can.}} & \Gamma(T, \text{fr}(T)^* \pi^* \square) \\ & \searrow \text{Fr}(\square(\square)/S)(\pi) & \nearrow f' \\ & \Gamma(T, \pi^* \square), & \end{array}$$

where  $f'$  is the map induced by  $\text{fr}(T)$ .

In particular, if  $\mathcal{E}$  is equal to  $0_S$ ,  $\mathcal{W}(\mathcal{E})$  is identified with the additive group  $\mathbb{G}_a(S)$ . In this case, one has  $\mathcal{E}^{(p)} = 0_S$  and the Frobenius morphism  $\text{Fr}(\mathbb{G}_a(S)/S)$  sends  $x \in \Gamma(T, 0_T)$  to  $x^p$ . So:

>  $\text{Fr}(\mathbb{G}_a(S))$  is the  $S$ -group  $\alpha_{p,S}$  which to every  $S$ -scheme  $T$  associates the group:  
>  $\{x \in \Gamma(T, 0_T) \mid x^p = 0\}$ .

c) One would see similarly that, for every quasi-coherent  $0_S$ -algebra  $\mathcal{A}$ ,  $\text{Spec}(\mathcal{A})^{(p)}$  is identified with the spectrum  $\text{Spec}(\mathcal{A}^{(p)})$  of the inverse image of  $\mathcal{A}$  by  $\text{fr}(S)$ . If  $\pi$  denotes the endomorphism  $x \mapsto x^p$  of the sheaf of rings  $0_S$ , one has therefore

$$\mathcal{A}^{(p)} = \mathcal{A} \otimes_{\pi} 0_S \quad [\text{N.D.E-VII}_A\text{-44}]$$

and  $\text{Fr}(\text{Spec}(\mathcal{A})/S)$  is induced by the morphism of  $0_S$ -algebras  $\mathcal{A} \otimes_{\pi} 0_S \rightarrow \mathcal{A}$  defined by  $a \otimes_{\pi} x \mapsto a^p x$ .

For every quasi-coherent  $0_S$ -module  $\mathcal{E}$ , finally, one has canonical isomorphisms

$$\square(\square)^{(p)} = \square(\square^{(p)}) \quad \text{and} \quad \square(\square)^{(p)} = \square(\square^{(p)}),$$

where  $\mathcal{S}(\mathcal{E})$  denotes the symmetric algebra of the  $0_S$ -module  $\mathcal{E}$ .

<!-- original page 439 -->

d) Let  $\mathcal{U}$  be an  $0_S$ -coalgebra (3.1) and  $T$  a scheme of characteristic  $p$ . If  $\mathcal{U}^{(p/S)}$  or  $\mathcal{U}^{(p)}$  denote the inverse image of the coalgebra  $\mathcal{U}$  by  $\text{fr}(S)$ , one has as in b) a canonical isomorphism:

$$(\text{Spec}^* \square)^{(p)} = \text{Spec}^* \square^{(p)}.$$

If  $\mathcal{U}$  is a coalgebra in groups, the value of  $\text{Fr}(\text{Spec}^* \mathcal{U})$ , i.e., of the kernel of the Frobenius morphism  $\text{Spec}^* \mathcal{U} \rightarrow \text{Spec}^* \mathcal{U}^{(p)}$ , for an  $S$ -scheme  $T$  is therefore the set of elements  $\gamma$  of

$$(\text{Spec}^* \square)(T) = \{x \in \Gamma(T, \square_T) \mid \varepsilon_{\square_T}(x) = 1, \Delta_{\square_T} x = x \otimes x\}$$

such that the image in  $\Gamma(T, \mathcal{U}_T \otimes_{\mathcal{O}(T)} \mathcal{O}_T)$  of the element  $\gamma \otimes_{\mathcal{O}(T)} 1$  of  $\Gamma(T, \mathcal{U}_T \otimes_{\mathcal{O}(T)} \mathcal{O}(T))$  is equal to  $1$ .

### 4.2.

<!-- label: III.VII\_A.4.2 -->

<!-- original page 440 -->

[^N.D.E-VII\_A-45] We shall now occupy ourselves with a construction close to the preceding one: let  $S$  be a scheme of characteristic  $p$ ,  $X$  an  $S$ -scheme and  $X^{[p]}$  the product in the category  $(\text{Sch}/S)$  of  $p$  copies of  $X$ .

We then denote by  $U_{[p]}(X)$  the open subscheme of  $X^{[p]}$  which is the union of the products  $U_{[p]}^{(i)}$ , when  $U$  ranges over the affine opens of  $X$ . A point  $x$  of  $X^{[p]}$  therefore belongs to  $U_{[p]}(X)$  if and only if the projections  $\text{pr}_i x$  of  $x$  onto the factors of  $X^{[p]}$  belong to a common affine open of  $X$ . For example, if every finite part of  $X$  is contained in an affine open, one has  $U_{[p]}(X) = X^{[p]}$ .

The symmetric group  $\mathfrak{S}_p$  of order  $p$  operates on  $X^{[p]}$  by permutation of factors and leaves stable the open  $U_{[p]}(X)$ . We shall call the  $p$ -fold symmetric product of  $X$  and we shall denote  $\Sigma^p X$  the quotient of  $X^{[p]}$  by  $\mathfrak{S}_p$  in the category of ringed spaces. Let  $q(X)$ , or simply  $q$ , be the canonical projection  $X^{[p]} \rightarrow \Sigma^p X$ .

Then  $q$  maps  $U_{[p]}(X)$  onto an open  $V_{[p]}(X)$  of the symmetric product, which one may describe as follows (cf. V 4.1). The structure sheaf of  $\Sigma^p X$  induces on  $V_{[p]}(X)$  a scheme structure; the morphism  $q'(X) : U_{[p]}(X) \rightarrow V_{[p]}(X)$  induced by  $q(X)$  is affine and even integral; when  $U$  ranges over the affine opens of  $X$  which project into an affine open  $V$  of  $S$  varying, the  $\Sigma^p U$  form an affine covering of  $V_{[p]}(X)$ ; if  $R \subset \mathcal{O}_U$  denotes the affine algebra of  $V$  and  $A$  that of  $U$ ,  $\Sigma^p U$  has as affine algebra the subalgebra  $\Sigma^p A$  of  $\bigotimes^p R$  formed by the symmetric tensors.

Consider now the diagonal morphism  $\delta$  of  $X$  into  $U_{[p]}(X)$ . If  $V = \text{Spec } R$  is an affine open of  $S$  and  $U = \text{Spec } A$  an affine open of  $X$  above  $V$ , the restriction of  $\delta$  to  $U$  is defined by the algebra morphism

```

```text
η : Ⓜ^p_R A → A,    a_1 ⊗ ⋯ ⊗ a_p ↦ a_1 a_2 ⋯ a_p.
```

```

One therefore has, if  $N$  is the symmetrization operator:

```

```text
η(N(a_1 ⊗ ⋯ ⊗ a_p)) = η(∑_{σ ∈ Ⓜ_p} a_{σ(1)} ⊗ ⋯ ⊗ a_{σ(p)}) = p! a_1 ⋯ a_p = 0.
```

```

In other words,  $\eta$  vanishes on the subspace  $N(\bigotimes^p R)A$  of  $\Sigma^p A$  formed by the symmetrized tensors. Moreover, if  $f$  is a symmetric tensor, one has obviously  $N(fa) = fN(a)$ , which shows that  $N(\bigotimes^p R)A$  is an ideal of  $\Sigma^p A$ . We shall henceforth denote

```

```text
U^{[p/S]} = Spec(∑^p A / N(Ⓜ^p_R A));
```

```

it is a closed subscheme of  $\Sigma^p(U) = V_{[p]}(U)$ . The union of the  $U^{[p/S]}$ , when  $U$  ranges over the affine opens of  $X$  which project into a varying affine open  $V$  of  $S$ , is a closed subscheme of  $V_{[p]}(X)$ , denoted  $X^{[p/S]}$ .

Moreover, if  $i(X)$  denotes the inclusion of  $X^{[p/S]}$  into  $V_{[p]}(X)$ , we have just seen that  $q'(X) \circ \delta$  factors through  $X^{[p/S]}$ , whence a morphism  $f^{[p]}(X/S) : X \rightarrow X^{[p/S]} : [^N.D.E-VII_A-46]$

<!-- original page 470 -->

```

```text
X^{[p_S]} ⊃ U_p(X) ←^{δ(X)} X
```

```

$$\begin{array}{ccc} q(X) & & q'(X) & & F^{\{p\}}(X/S) \\ & & & \swarrow i(X) & \\ \Sigma^p(X) & \supset & V_p(X) & \longleftarrow & X^{\{p/S\}}. \end{array}$$

It is clear that  $X^{\{p/S\}}$  is functorial in  $X$  and that the map  $F^{\{p\}} : X \mapsto F^{\{p\}}(X/S)$  is a functorial homomorphism.

### 4.2.1.

<!-- label: III.VII\_A.4.2.1 -->

The schemes  $X^{\{p/S\}}$  and  $X^{\{p/S\}}$  are obviously related: let  $V$  be an affine open of  $S$  with affine ring  $R$  and  $U$  an affine open of  $X$  above  $V$ ; let  $A$  be the affine algebra of  $U$ . If  $\pi$  denotes the endomorphism  $x \mapsto x^p$  of  $R$ , then  $U^{\{p/S\}}$  has  $A \otimes_{\pi} R$  as affine algebra. One verifies moreover that the map

$$a \otimes_{\pi} \lambda \mapsto (\lambda a \otimes \cdots \otimes a \mod N(\bigotimes^p_R A))$$

defines a morphism of  $R$ -algebras from  $A \otimes_{\pi} R$  into  $\Sigma^p A / N(\bigotimes^p_R A)$ , and the latter induces a morphism  $\phi(U) : U^{\{p/S\}} \rightarrow U^{\{p/S\}}$  such that  $\phi(U) \circ F^{\{p\}}(U/S) = \text{Fr}(U/S)$ .

"Gluing the pieces", one then obtains a commutative triangle

$$\begin{array}{ccc} & X & \\ F^{\{p\}}(X/S) & & \text{Fr}(X/S) \\ & \searrow & \swarrow \\ X^{\{p/S\}} & \xrightarrow{\phi(X)} & X^{\{p/S\}}. \end{array}$$

For example, if  $X$  is the subscheme of  $S$  defined by a quasi-coherent ideal  $\mathcal{I}$ ,  $F^{\{p\}}(X/S)$  is identified with the identity morphism of  $X$ , so that  $\phi(X)$  is the canonical immersion of  $\text{Spec}(0_S / \mathcal{I})$  into  $\text{Spec}(0_S / \mathcal{I}^{\{p\}})$ . One thus sees that  $\phi(X)$  is not an isomorphism in general.

However, when  $M$  is a free  $R$ -module, it is clear that the map

$$M \otimes_{\pi} R \rightarrow \Sigma^p M / N(\bigotimes^p_R M), \quad m \otimes_{\pi} \lambda \mapsto (\lambda m \otimes \cdots \otimes m \mod N(\bigotimes^p_R M))$$

is bijective; this map therefore remains bijective when  $M$  is  $R$ -flat, because every flat module is a filtered direct limit of free modules (Lazard[VII\_A-4-1] [N.D.E-VII\_A-47]). It follows that

$\phi(X) : X^{\{p/S\}} \rightarrow X^{\{p/S\}}$  is an isomorphism if  $X$  is a flat  $S$ -scheme.

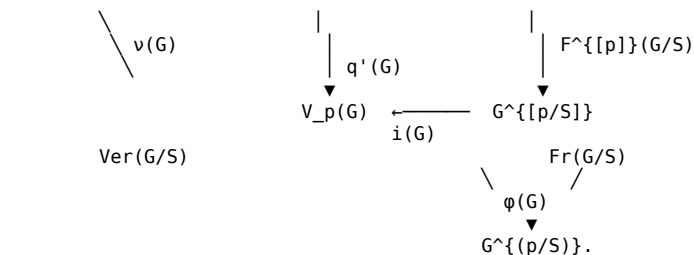

### 4.3.

<!-- label: III.VII\_A.4.3 -->

<!-- original page 471 -->

Consider finally an  $S$ -group scheme  $G$  in abelian groups. Then the composed morphism  $\mu(G) : U_p(G) \rightarrow G$ , which is defined by the multiplication, factors through  $V_p(G)$ , i.e., there exists a morphism  $\nu(G) : V_p(G) \rightarrow G$  such that  $\nu(G) \circ q'(G) = \mu(G)$ , so that one has the following commutative diagram:

$$\begin{array}{ccccc} & & \mu(G) & & \delta(G) \\ G & \longleftarrow & U_p(G) & \longleftarrow & G \end{array}$$

<!-- original page 442 -->

When  $G$  is  $S$ -flat,  $\phi(G)$  is an isomorphism and one can define a morphism (called the *Verschiebung*)

$Ver(G/S) : G^{(p/S)} \rightarrow G$

by means of the formula  $Ver(G/S) = \nu(G) \circ i(G) \circ \phi(G)^{-1}$ . When  $G$  ranges over  $S$ -flat group schemes in abelian groups, the map  $Ver : G \mapsto Ver(G/S)$  is obviously a functorial homomorphism; consequently,  $Ver(G/S)$  is a group homomorphism. For every  $S$ -scheme  $T$  finally, the composed map

$G(T) \xrightarrow{\delta(G)(T)} U_p(G)(T) \xrightarrow{\mu(G)(T)} G(T)$

sends  $x \in G(T)$  to  $p \cdot x$ . We may write  $p \cdot id_G$  instead of  $\mu(G) \circ \delta(G)$ , thus obtaining the classical formula:

$Ver(G/S) \circ Fr(G/S) = p \cdot id_G$ .

**Examples 4.3.1.**

<!-- label: III.VII\_A.4.3.1 -->

(a) When  $G$  is a constant  $S$ -scheme in abelian groups, we know that  $Fr(G/S)$  is identified with the identity morphism of  $G$  (cf. 4.1.1.1). One therefore has  $Ver(G/S) = p \cdot id_G$ .

(b) When  $G$  is the diagonalizable  $S$ -group of type  $M$ ,  $Fr(G/S)$  is equal to  $p \cdot id_G$  according to 4.1.4 (a); one then sees easily that  $Ver(G/S)$  is the identity morphism of  $G$ .

(c) When  $\mathcal{E}$  is a flat  $0_S$ -module and  $G$  is the  $S$ -group  $\mathcal{V}(\mathcal{E})$ , the morphism  $Ver(G/S)$  is zero, as is  $p \cdot id_G$ . One will see in Exposé VII\_B that a commutative algebraic group  $G$  over a field  $k$  is "unipotent" if and only if the composed homomorphism

$G^{(p^n)} \rightarrow Ver(G^{(p^{n-1})}/S) \rightarrow G^{(p^{n-1})} \rightarrow \dots \rightarrow G^{(p)} \rightarrow Ver(G/S) \rightarrow G$

<!-- original page 443 -->

is zero for some  $n$  (one has set  $G^{(p^n)} = (G^{(p^{n-1})})^{(p)}$ , cf. 4.1.3). [N.D.E-VII\_A-48]

**4.3.2.**

<!-- label: III.VII\_A.4.3.2 -->

Since the map  $Ver : G \mapsto Ver(G/S)$  is a functorial homomorphism when  $G$  ranges over  $S$ -flat group schemes in commutative groups, the square

```

```text
      Ver(G/S)
G^{{p}}  ----->  G
      Fr(G/S)^{{p}}          Fr(G/S)

      Ver(G^{{p}}/S)
G^{{p^2}} ----->  G^{{p}}
...

```

is commutative, where $\text{Fr}(G/S)^{\{p\}}$ denotes the inverse image of $\text{Fr}(G/S)$ by the base change $\text{fr}(S)$. According to 4.1.1, one has $\text{Fr}(G/S)^{\{p\}} = \text{Fr}(G^{\{p\}}/S)$, so, according to 4.3 $(\ast)$ applied to $G^{\{p\}}$, one obtains:

```

```text
(**) Fr(G/S) \circ Ver(G/S) = Ver(G^{{p}}/S) \circ Fr(G^{{p}}/S) = p \cdot \text{id}_{G^{{p}}}.
```

```

4.3.3.

<!-- label: III.VII_A.4.3.3 -->

<!-- original page 444 -->

Suppose finally that G is a commutative, finite and locally free S -group; let $\mathcal{A}$ be the 0_S -affine algebra of G and π the endomorphism of the sheaf of rings 0_S which sends a section x of 0_S to x^p . [N.D.E-VII_A-49] We denote by $\Sigma^p \mathcal{A}$ the subalgebra of $\bigotimes^p_{0_S} \mathcal{A}$ formed by the sections invariant under the action of the symmetric group, by $\iota(\mathcal{A})$ the inclusion of $\Sigma^p \mathcal{A}$ into the tensor product. Let $\Delta_p(\square) : \square \rightarrow \square^p_{0_S}$ be the morphism obtained by iterating the diagonal morphism of the coalgebra $\mathcal{A}$ (it corresponds to the morphism of multiplication $U_p(G) = G^{\{p\}} \rightarrow G$); according to the beginning of paragraph 4.3, $\Delta_p(\square)$ factors through $\Sigma^p \mathcal{A}$, i.e., it induces a morphism

```

```text
a(\square) : \square \rightarrow \Sigma^p \square
```

```

such that $\iota(\square) \circ a(\square) = \Delta_p(\square)$.

On the other hand, let $S^p(\mathcal{A})$ be the degree- p component of the symmetric algebra of $\mathcal{A}$ and $q(\mathcal{A}) : \bigotimes^p_{0_S} \mathcal{A} \rightarrow S^p(\mathcal{A})$ the canonical projection. The multiplication $m_p(\mathcal{A}) : \bigotimes^p_{0_S} \mathcal{A} \rightarrow \mathcal{A}$ factors through $S^p(\mathcal{A})$, i.e., it induces a map

```

$$
b(\mathcal{A}) : S^p(\mathcal{A}) \longrightarrow \mathcal{A}
$$

```

such that $b(\mathcal{A}) \circ q(\mathcal{A}) = m_p(\mathcal{A})$.

Since $\Sigma^p \mathcal{A}$ is the affine algebra of $V_p(\mathcal{A})$, then, according to the beginning of 4.3 again, the composed morphism $\iota(G) \circ \phi(G)^{-1}$ induces an algebra homomorphism

```

```text
r(\square) : \Sigma^p \square \rightarrow \square \otimes_{0_S}
```

```

this homomorphism vanishes on the sections of the form

```

```text
\sum_{\sigma \in \square_p} a_{\sigma(1)} \otimes \cdots \otimes a_{\sigma(p)}
```

```

<!-- original page 473 -->

and sends $a \otimes \cdots \otimes a$ to $a \otimes_{\pi} 1$. Similarly, $j(\mathcal{A})$ is the morphism of

term equals

```
```text

$$\sum_{\tau} \sum_{r=0}^{p-1} \sum_{i_1 < \dots < i_r} (-1)^s a_{\tau(i_1)} a_{\tau(i_2)} \dots a_{\tau(i_r)} a_p a_{\tau(j_s)} \dots a_{\tau(j_1)}$$

```

where  $\tau$  ranges over the permutations of  $p - 1$  letters,  $i_1, \dots, i_r$  the strictly increasing sequences of integers of the interval  $[1, p - 1]$  and where  $j_1, \dots, j_s$  denotes the strictly increasing sequence whose values are the integers of  $[1, p - 1]$  different from  $i_1, \dots, i_r$ . For a fixed value of  $r$ , the sum of the terms  $(-1)^s a_{\tau(i_1)} \dots a_{\tau(i_r)} a_p a_{\tau(j_s)} \dots a_{\tau(j_1)}$  obviously equals

```
```text

$$(-1)^s (p-1 \text{ choose } s) \sum_p a_{\rho(1)} \dots a_{\rho(r)} a_p a_{\rho(r+1)} \dots a_{\rho(p-1)}$$

```

<!-- original page 446 -->

where ρ ranges over the permutations of $p - 1$ letters. Now $(-1)^s (p-1 \text{ choose } s) = 1$ in $\mathbb{F}_p$, since in $\mathbb{F}_p[x]$ (x an indeterminate) one has:
 $(x - 1)^p = x^p - 1 = (x - 1)(x^{p-1} + \dots + 1)$ and therefore
 $(x - 1)^{p-1} = x^{p-1} + \dots + 1$. This proves $(\ast)$.

On the other hand, if x_0 and x_1 are two elements of A , one has

```
```text

$$(x_0 + x_1)^p = x_0^p + x_1^p + \sum x_{z(1)} x_{z(2)} \dots x_{z(p)},$$

```

where  $z$  ranges over the non-constant maps from  $[1, p]$  into  $\{0, 1\}$ . One deduces

```
```text

$$(x_0 + x_1)^p = x_0^p + x_1^p + \sum_{0 < r < p} \frac{1}{r!(p-r)!} N(x_0, \dots, x_0, x_1, \dots, x_1)$$

```

(with r factors x_0 and $p-r$ factors x_1). [N.D.E-VII_A-52] Now, according to $(\ast)$, one has:

```
```text

$$N(x_0, \dots, x_0, x_1, \dots, x_1) = r! (p - 1 - r)! \sum_t [x_{t(1)} x_{t(2)} \dots x_{t(p-1)}, x_1] \dots$$

```

(with  $r$  factors  $x_0$  and  $p-r$  factors  $x_1$ ), where  $t$  ranges over the maps  $[1, p-1] \rightarrow \{0, 1\}$  taking the value  $0$  exactly  $r$  times. From this one deduces Jacobson's second formula:

```
```text
(ii) 
$$(x_0 + x_1)^p = x_0^p + x_1^p - \sum_{0 < r < p} \sum_t \frac{1}{r} [x_{t(1)} x_{t(2)} \dots x_{t(p-1)}, x_1] \dots$$

```

where t ranges over the maps $[1, p-1] \rightarrow \{0, 1\}$ taking the value 0 exactly r times.

5.2.

<!-- label: III.VII_A.5.2 -->

Let now $\mathfrak{g}$ be an R -Lie algebra. One says that a map $x \mapsto x^{(p)}$ from $\mathfrak{g}$ into $\mathfrak{g}$ makes $\mathfrak{g}$ a *restricted p -Lie algebra* over R if the following conditions are satisfied:

(0) $(\lambda x)^{(p)} = \lambda x^{(p)}$, for $\lambda \in R$, $x \in \mathfrak{g}$

(i) $\text{ad } x^{(p)} = (\text{ad } x)^p$, for $x \in \mathfrak{g}$

```
(ii)

$$x^{(p)} + x^{(1)} = x^{(p)}_0 + x^{(p)}_1 - \sum_{0 < r < p} \sum_t \frac{1}{r} [x_{t(1)} x_{t(2)} \dots x_{t(p-1)}, x_1]$$

```

<!-- original page 447 -->

where x ranges over the maps $[1, p-1] \rightarrow \{0, 1\}$ taking the value 0 exactly r times ($x_0, x_1 \in \mathfrak{g}$). The map $x \mapsto x^{(p)}$ will then be called the "symbolic p -th power".

For example, if A is an associative R -algebra, we saw in 5.1 that one obtains a p -Lie algebra, which we shall denote A_{Lie} , by taking the R -module underlying A and setting, for $x, y \in A$,

```
```text
[x, y] = xy - yx and x^{(p)} = x^p.
```
```

We shall say that A_{Lie} is the p -Lie algebra underlying A .

In what follows we shall consider mostly sub- p -Lie algebras of p -algebras of the form A_{Lie} ; here is an example: let S be a scheme of characteristic $p > 0$ and X an S -scheme. Recall that a derivation of X over S is an endomorphism D of the sheaf of abelian groups $\mathcal{O}_X$ such that

```
```text
D(λ · s) = λ · D(s) and D(st) = (Ds) t + s (Dt)
```
```

when λ and s, t range over the sections of $\mathcal{O}_S$ and of $\mathcal{O}_X$ on opens such that the formulas make sense. Leibniz's formula

```
```text
D^n(st) = \sum_{i=0}^n (n choose i) (D^i s) (D^{n-i} t)
```
```

shows that D^p is again a derivation of X over S , taking into account the equality $\binom{p}{i} \equiv 0 \pmod p$ for $i \neq 0, p$. It follows that:

> The algebra $\mathcal{D}_r(X/S)$ of derivations of X over S is a sub- p -Lie algebra of the
> $\Gamma(S, \mathcal{O}_S)$ -algebra of differential operators of X over S .

5.2.1.

<!-- label: III.VII_A.5.2.1 -->

If $\mathfrak{g}$ and $\mathfrak{h}$ are two p -Lie algebras, a *homomorphism* $h : \mathfrak{g} \rightarrow \mathfrak{h}$ is an R -linear map from $\mathfrak{g}$ into $\mathfrak{h}$ such that $h([x, y]) = [h(x), h(y)]$ and $h(x^{(p)}) = h(x)^{(p)}$ if $x, y \in \mathfrak{g}$. The composition of two homomorphisms is again a homomorphism, so that we may speak of the *category of p -Lie algebras* over R .

If (X, R) is a ringed space, we shall say that an R -module $\mathfrak{g}$ is equipped with a structure of p -Lie algebra over R if, for every open U , $\Gamma(U, \mathfrak{g})$ is equipped with a structure of p -Lie algebra over $\Gamma(U, R)$ <!-- original page 448 --> and if the restrictions are homomorphisms.

5.3.

<!-- label: III.VII_A.5.3 -->

We are now interested in the left adjoint functor to the functor $A \mapsto A_{\text{Lie}}$ of 5.2. Let $\mathfrak{g}$ be a p -Lie algebra over the ring R of characteristic p , $U(\mathfrak{g})$ the enveloping algebra of the Lie algebra underlying $\mathfrak{g}$ (cf. [Blie], I § 2.1) and $i_{\mathfrak{g}}$ (or simply i) the canonical map $\mathfrak{g} \rightarrow U(\mathfrak{g})$.

Let A be a unital associative R -algebra. One knows that, for every Lie algebra homomorphism $\phi : \mathfrak{g} \rightarrow A_{\text{Lie}}$ there exists a unique homomorphism of unital R -algebras $\psi : U(\mathfrak{g}) \rightarrow A$ such that $\psi \circ i = \phi$. Moreover, ϕ is a p -Lie algebra homomorphism if and only if ψ vanishes on the elements $i(x)^p - i(x^{(p)})$, when x ranges over $\mathfrak{g}$.

Definition. One denotes by $U_{\mathfrak{g}}(\mathfrak{g})$ or simply $U_{\mathfrak{g}}$ the quotient of $U(\mathfrak{g})$ by the two-sided ideal generated by the elements $i(x)^p - i(x^{(p)})$, and $j_{\mathfrak{g}}$ (or simply j) the map $\mathfrak{g} \rightarrow U_{\mathfrak{g}}$ composed of $i : \mathfrak{g} \rightarrow U(\mathfrak{g})$ and the

canonical map $U(\mathfrak{g}) \rightarrow U_p(\mathfrak{g})$. One says that $U_p(\mathfrak{g})$ is the* restricted enveloping algebra *of $\mathfrak{g}$.*

According to what precedes, one has the

Proposition. *For every unital associative R -algebra and every p -Lie algebra morphism $\phi : \mathfrak{g} \rightarrow A_{\text{Lie}}$, there exists a unique homomorphism of unital algebras $\psi : U_p(\mathfrak{g}) \rightarrow A$ such that $\psi \circ j = \phi$. In other words, the functor $\mathfrak{g} \mapsto U_p(\mathfrak{g})$ is left adjoint to the forgetful functor $A \mapsto A_{\text{Lie}}$.*

5.3.1.

<!-- label: III.VII_A.5.3.1 -->

With the notations of 5.3, set now $\beta(x) = i(x)^p - i(x^{(p)})$. For every element y of $\mathfrak{g}$, one has, according to 5.1 (i) and 5.2 (i):

```

```text
β(x) i(y) = i(y) β(x) + [β(x), i(y)]
 = i(y) β(x) + (ad i(x))^p i(y) - i((ad x)^p y)
 = i(y) β(x),
```

```

<!-- original page 449 -->

so $\beta(x)$ belongs to the center of $U(\mathfrak{g})$; in particular, the left ideal generated by the elements $\beta(x)$ is already two-sided.

On the other hand, it is clear that $\beta(\lambda x) = \lambda^p \beta(x)$, for $\lambda \in R$, and it follows from 5.1 (ii) and 5.2 (ii) that, for $x, y \in \mathfrak{g}$,

```

```text
β(x + y) = β(x) + β(y).
```

```

In particular, if (x_α) is a family of generators of the R -module $\mathfrak{g}$, the left ideal generated by the elements $\beta(x_\alpha)$ is already generated by the $\beta(x_\alpha)$.

5.3.2. Proposition.

<!-- label: III.VII_A.5.3.2 -->

[^N.D.E-VII_A-53] *Let $\mathfrak{g}$ be an R -Lie algebra whose underlying R -module is free with basis (x_α) . Then the structures of p -Lie algebra on $\mathfrak{g}$ correspond bijectively to the families (y_α) of $\mathfrak{g}$ such that $\text{ad } y_\alpha = (\text{ad } x_\alpha)^p$.*

Indeed, if $\mathfrak{g}$ is equipped with a structure of p -Lie algebra $x \mapsto x^{(p)}$, then according to 5.2 (i) and (0), (ii), the $y_\alpha = x_\alpha^{(p)}$ satisfy $\text{ad } y_\alpha = (\text{ad } x_\alpha)^p$, and determine the p -Lie algebra structure.

Let us prove the converse. Since $\mathfrak{g}$ is a free R -module, the canonical map $i : \mathfrak{g} \rightarrow U(\mathfrak{g})$ is injective, according to the Poincaré–Birkhoff–Witt theorem (cf. [BLie], I § 2.7), so one can identify $\mathfrak{g}$ with an R -submodule of $U(\mathfrak{g})$. Suppose that (y_α) is a family of elements of $\mathfrak{g}$ such that $\text{ad } y_\alpha = (\text{ad } x_\alpha)^p$. Let π be the map $r \mapsto r^{(p)}$ from R into R , and let $\mathfrak{g} \otimes_{\pi} R$ be the R -Lie algebra obtained by extension of scalars $\pi : R \rightarrow R$.[^N.D.E-VII_A-54]

There then exists an R -linear map γ from $\mathfrak{g} \otimes_{\pi} R$ into $U(\mathfrak{g})$ which sends $x_\alpha \otimes 1$ to $x_\alpha^{(p)} - y_\alpha$; moreover, since one has, for every $x \in \mathfrak{g}$,

```

```text
(ad x_α^p)(x) = (ad x_α)^p(x) = (ad y_α)(x),
```

```

γ maps $\mathfrak{g} \otimes_{\pi} R$ into the center of $U(\mathfrak{g})$. Set, for every $x \in \mathfrak{g}$:

```

```text

$$x^{\{p\}} = x^p - \gamma(x \otimes_{\pi} 1).$$

```

```

Then, for every α , one has $x^{\{p\}}_{\alpha} = y_{\alpha}$. If $x = \sum \lambda_{\alpha} x_{\alpha}$, one deduces from 5.1 (ii) (by induction on the number of indices α such that $\lambda_{\alpha} \neq 0$), that

```

<!-- original page 477 -->

```

```

```text

$$x^p - \sum_{\alpha} \lambda_{\alpha} x_{\alpha}^p \in \mathfrak{g};$$

```

```

denoting this element by z , one then has $x^{\{p\}} = \sum \lambda_{\alpha} x_{\alpha}^p + z$ and therefore $x^{\{p\}} \in \mathfrak{g}$.

It is clear that the map $x \mapsto x^{\{p\}}$ satisfies $(\lambda x)^{\{p\}} = \lambda x^{\{p\}}$. Moreover, since $\gamma(x \otimes_{\pi} 1)$ is central, then $\text{ad } x^{\{p\}} = \text{ad } x^p$ and therefore, according to Jacobson's first formula (5.1 (i)), one has

```

```text

$$\text{ad } x^{\{p\}} = (\text{ad } x)^p.$$

```

```

Finally, according to Jacobson's second formula (5.1 (ii)), the map $x \mapsto x^{\{p\}}$ satisfies condition (ii) of 5.2. It therefore makes $\mathfrak{g}$ a p -Lie algebra. This proves the proposition.

5.3.3. Proposition.

```

<!-- label: III.VII_A.5.3.3 -->

```

Let $\mathfrak{g}$ be a p -Lie algebra over R whose underlying module is free with basis (x_{α}) . Then the map $j : \mathfrak{g} \rightarrow U_p(\mathfrak{g})$ is injective and, if one sets $z_{\alpha} = j(x_{\alpha})$, then $U_p(\mathfrak{g})$ has as basis the monomials

```

```text

$$\prod_{\alpha} z_{\alpha}^{n_{\alpha}} \quad \text{where} \quad 0 \leq n_{\alpha} < p,$$

```

```

(the n_{α} are assumed to be zero except for a finite number of them; one assumes the basis to be totally ordered and the products to be performed in increasing order).

Indeed, identify $\mathfrak{g}$ with a submodule of the enveloping algebra $U(\mathfrak{g})$ by means of the canonical map i . For every family $n = (n_{\alpha})$ of natural integers, zero except for a finite number of them, set

```

```text

$$|n| = \sum_{\alpha} n_{\alpha} \quad \text{and} \quad x^n = \prod_{\alpha} x_{\alpha}^{n_{\alpha}}.$$

```

```

```

<!-- original page 450 -->

```

Writing $n_{\alpha} = m_{\alpha} + p \ell_{\alpha}$, with $0 \leq m_{\alpha} < p$, set also

```

```text

$$T_n = \prod_{\alpha} x_{\alpha}^{m_{\alpha}} \beta(x_{\alpha})^{\ell_{\alpha}}$$

```

```

where $\beta(x) = x^p - x^{\{p\}}$ is the map $\mathfrak{g} \rightarrow U(\mathfrak{g})$ defined in 5.3.1.

For every $r \in \mathbb{N}$, denote by U_r the sub- R -module of $U(\mathfrak{g})$ generated by the x^n such that $|n| \leq r$. Since the graded ring $\bigoplus_r U_r / U_{r-1}$ is commutative (cf. [BLie], I § 2.6), one sees that, for every n :

```

```text

```

$T_n = \prod_{\alpha} x_{\alpha}^{n_{\alpha}} \in U_{\{|n| - 1\}}.$

For every  $s \in \mathbb{N}$ , the  $x^{(n)}$  such that  $|n| = s$  form, according to the Poincaré–Birkhoff–Witt theorem (loc. cit., § 2.7), a basis of  $U_{\{s\}} / U_{\{s-1\}}$ , and therefore the same holds for the  $T_{\{n\}}$  such that  $|n| = s$ .

Therefore, when  $s = |n|$  varies, the  $T_{\{n\}}$  form a basis of  $U(\mathfrak{g})$ . Now the kernel  $J$  of the canonical map  $U(\mathfrak{g}) \rightarrow U_{\{p\}}(\mathfrak{g})$  is the left ideal of  $U(\mathfrak{g})$  generated by the central elements  $\beta(x_{\alpha})$  (5.3.1). Consequently, the  $T_{\{n\}}$  such that  $\ell_{\alpha} \neq 0$  original page 478 --> form a basis of  $J$ , and the  $T_{\{n\}}$  such that  $n_{\alpha} < p$  for every  $\alpha$ , form a basis of  $U_{\{p\}}(\mathfrak{g}) = U(\mathfrak{g}) / J$ .

### 5.3.3 bis.

<!-- label: III.VII\_A.5.3.3-bis -->

Let  $\mathfrak{g}$  be a  $\mathfrak{p}$ -Lie algebra over  $R$  and  $f : R \rightarrow R'$  an extension of the base ring. I claim that there exists on the  $R'$ -module  $R' \otimes_R \mathfrak{g}$  a  $\mathfrak{p}$ -Lie algebra structure and only one such that

```
```text
(*)      [ $\lambda \otimes x, \mu \otimes y$ ] =  $\lambda\mu \otimes [x, y]$       and       $(\lambda \otimes x)^{(p)} = \lambda^p \otimes x^{(p)}.$ 
```
```

It will follow, in particular, that the functor  $\mathfrak{g} \mapsto R' \otimes_R \mathfrak{g}$  is left adjoint to the functor "restriction of scalars from  $R'$  to  $R$ ".

The uniqueness of the  $\mathfrak{p}$ -Lie algebra structure defined by  $(\ast)$  being clear, let us prove existence. When  $\mathfrak{g}$  is free with basis  $(x_{\alpha})$  there exists, according to 5.3.2, one and only one  $\mathfrak{p}$ -Lie algebra structure on the Lie algebra  $R' \otimes_R \mathfrak{g}$  such that

```
$$
(1 \otimes x_{\alpha})^{(p)} = 1 \otimes x^{(p)}_{\alpha};
$$
```

this structure is the one we seek.

When  $\mathfrak{g}$  is an arbitrary  $\mathfrak{p}$ -Lie algebra, there exists a  $\mathfrak{p}$ -Lie algebra  $L_0$  free (as an  $R$ -module) and a surjective homomorphism  $q_0 : L_0 \rightarrow \mathfrak{g}$ ; it suffices for example to take for  $L_0$  the  $\mathfrak{p}$ -Lie algebra  $R \otimes_{\mathbb{F}} \mathfrak{F}$ , where  $\mathbb{F}$  denotes the prime field original page 451 --> of characteristic  $\mathfrak{p}$ , and for  $q_0$  the homomorphism  $\lambda \otimes x \mapsto \lambda x$  ( $\mathfrak{g}$  is free over  $\mathbb{F}$ ). The kernel of  $q_0$  is then a  $\mathfrak{p}$ -ideal of  $L_0$ , i.e., an ideal of the Lie algebra  $L_0$  which is stable under the endomorphism  $x \mapsto x^{(p)}$ ; there is therefore also a  $\mathfrak{p}$ -Lie algebra  $L_1$  free (as an  $R$ -module) and a homomorphism  $q_1 : L_1 \rightarrow L_0$  whose image is  $\ker q_0$ , whence the exact sequence:

```
```text
L_1  $\xrightarrow{q_1}$  L_0  $\xrightarrow{q_0}$   $\square \rightarrow 0.$ 
```
```

One deduces from this an exact sequence of  $R'$ -Lie algebras

```
```text
R'  $\otimes_R$  L_1  $\rightarrow$  R'  $\otimes_R$  L_0  $\rightarrow$  R'  $\otimes_R$   $\square \rightarrow 0.$ 
```
```

Since  $R' \otimes_R q_1$  is manifestly a homomorphism of  $\mathfrak{p}$ -Lie algebras, the kernel of  $R' \otimes_R q_0$  is a  $\mathfrak{p}$ -ideal, so that the symbolic  $\mathfrak{p}$ -th power operation of  $R' \otimes_R L_0$  induces by passage to the quotient a map from  $R' \otimes_R \mathfrak{g}$  into  $R' \otimes_R \mathfrak{g}$  (use formula (ii) of 5.2); this last one equips  $R' \otimes_R \mathfrak{g}$  with the  $\mathfrak{p}$ -Lie algebra structure sought.

### 5.3.4.

<!-- label: III.VII\_A.5.3.4 -->

The canonical map  $j_{\mathfrak{g}} : \mathfrak{g} \rightarrow U_{\{p\}}(\mathfrak{g})$  induces, for every extension  $R \rightarrow R'$  of the base ring, a homomorphism

```

```text

$$R' \otimes_R j_{\square} : R' \otimes_R \square \rightarrow R' \otimes_R U_p(\square),$$

```

whence a homomorphism

```

```text

$$h : U_p(R' \otimes_R \square) \rightarrow R' \otimes_R U_p(\square)$$

```

such that  $h \circ j_{R' \otimes \mathfrak{g}} = R' \otimes j_{\mathfrak{g}}$ . It obviously follows from the universal properties of  $R' \otimes \mathfrak{g}$  and the restricted enveloping algebra that  $h$  is an isomorphism, which will allow us to identify  $U_p(R' \otimes \mathfrak{g})$  with  $R' \otimes U_p(\mathfrak{g})$ .

In particular, if  $r$  is an element of  $R$  and if  $R'_r$  is the localized ring  $R_r$ , one sees that  $\mathfrak{g}_r = R_r \otimes \mathfrak{g}$  is equipped canonically with a structure of  $p$ -Lie algebra over  $R_r$ , <!-- original page 452 --> so that the sheaf  $\tilde{\mathfrak{g}}$  on  $\operatorname{Spec} R$  is a quasi-coherent  $p$ -Lie algebra on  $\operatorname{Spec} R$ . Moreover, the restricted enveloping algebra  $U_{\{R_r\}_p}(\mathfrak{g}_r)$  is identified with  $U_{\{R\}_p}(\mathfrak{g})_r$ , so that the sheaf associated with the presheaf  $V \mapsto U_p(\Gamma(V, \tilde{\mathfrak{g}}))$  is quasi-coherent.

**Definition.** More generally, if  $S$  is a scheme of characteristic  $p$  and  $\mathcal{G}$  a quasi-coherent  $p$ -Lie algebra on  $S$ , the sheaf associated with the presheaf  $V \mapsto U_p(\Gamma(V, \mathcal{G}))$  is quasi-coherent; it will be denoted  $U_p(\mathcal{G})$  and called the restricted enveloping algebra of  $\mathcal{G}$ . If  $V$  is affine,  $U_p(\Gamma(V, \mathcal{G}))$  is identified with  $\Gamma(V, U_p(\mathcal{G}))$ .

### 5.4.

<!-- label: III.VII\_A.5.4 -->

The universal character of  $U_p(\mathfrak{g})$  entails that  $U_p(\mathfrak{g})$  is functorial in  $\mathfrak{g}$ : every homomorphism of  $p$ -Lie algebras  $\phi : \mathfrak{g} \rightarrow \mathfrak{h}$  induces a homomorphism of unital algebras  $U_p(\phi)$  and only one such that  $j_{\mathfrak{h}} \circ \phi = U_p(\phi) \circ j_{\mathfrak{g}}$ . Here are some examples:

a) If  $\mathfrak{h} = 0$ ,  $U_p(\mathfrak{h})$  is identified with the base ring and  $U_p(\phi)$  is an algebra homomorphism  $\epsilon_{\mathfrak{g}} : U_p(\mathfrak{g}) \rightarrow R$  called the *augmentation*.

b) Now take for  $\mathfrak{h}$  the algebra  $\mathfrak{g}^{\circ}$  opposite to  $\mathfrak{g}$ , i.e.,  $\mathfrak{g}^{\circ}$  has the same underlying module as  $\mathfrak{g}$ , the same symbolic  $p$ -th power, the bracket of two elements in  $\mathfrak{g}^{\circ}$  being the opposite of the bracket in  $\mathfrak{g}$ . It is clear that we can identify  $U_p(\mathfrak{g}^{\circ})$  with the algebra opposite to  $U_p(\mathfrak{g})$ . Moreover, the isomorphism  $x \mapsto -x$  of  $\mathfrak{g}$  onto  $\mathfrak{g}^{\circ}$  induces an isomorphism  $c_{\mathfrak{g}}$  of  $U_p(\mathfrak{g})$  onto  $U_p(\mathfrak{g}^{\circ}) \simeq U_p(\mathfrak{g})^{\circ}$ . One says that  $c_{\mathfrak{g}}$  is the *antipode* of  $U_p(\mathfrak{g})$ .

c) Let finally  $\mathfrak{f}$  and  $\mathfrak{g}$  be two  $p$ -Lie algebras and  $\mathfrak{h}$  the  $p$ -Lie algebra product  $\mathfrak{f} \times \mathfrak{g}$  which has as underlying  $R$ -module the direct product  $\mathfrak{f} \times \mathfrak{g}$ , the bracket and the symbolic  $p$ -th power being defined by the formulas

```

```text

$$[(x, y), (x', y')] = ([x, x'], [y, y']) \quad \text{and} \quad (x, y)^{(p)} = (x^{(p)}, y^{(p)}).$$

```

If $h_1 : \mathfrak{f} \rightarrow \mathfrak{k}$ and $h_2 : \mathfrak{g} \rightarrow \mathfrak{k}$ are two p -Lie algebra homomorphisms <!-- original page 453 --> such that $[h_1(x), h_2(y)] = 0$ for every x of $\mathfrak{f}$ and every y of $\mathfrak{g}$, the map $h_1 + h_2 : (x, y) \mapsto h_1(x) + h_2(y)$ is a p -Lie algebra homomorphism; conversely, every homomorphism from $\mathfrak{f} \times \mathfrak{g}$ into $\mathfrak{k}$ is of this type, which allows us to characterize $\mathfrak{f} \times \mathfrak{g}$ as the solution of a universal problem. For example, the maps

```

```text

$$h_1 : x \mapsto i_{\square}(x) \otimes 1 \quad \text{and} \quad h_2 : y \mapsto 1 \otimes i_{\square}(y)$$

```

induce a homomorphism  $h_1 + h_2$  from  $\mathfrak{f} \times \mathfrak{g}$  into the  $\mathfrak{p}$ -Lie algebra underlying  $U_p(\mathfrak{f}) \otimes U_p(\mathfrak{g})$ . It follows from the universal characters of  $\mathfrak{f} \times \mathfrak{g}$  and of the restricted enveloping algebras that  $h_1 + h_2$  extends to an isomorphism:

```
```text
φ : U_p(□ × □) → U_p(□) ⊗ U_p(□).
```

Definition. If $\mathfrak{f} = \mathfrak{g}$, the diagonal map $\delta : x \mapsto (x, x)$ of $\mathfrak{g}$ into $\mathfrak{g} \times \mathfrak{g}$ induces a homomorphism of $U_p(\mathfrak{g})$ into $U_p(\mathfrak{g} \times \mathfrak{g})$. We shall denote by $\Delta_\square$ the composition of this homomorphism with the isomorphism $\phi : U_p(\mathfrak{g} \times \mathfrak{g}) \xrightarrow{\sim} U_p(\mathfrak{g}) \otimes U_p(\mathfrak{g})$. *^[N.D.E-VII_A-55]

One then sees easily that $\Delta_\square$ and the multiplication of the algebra $U_p(\mathfrak{g})$ make $U_p(\mathfrak{g})$ an $\mathfrak{R}$ -coalgebra in groups (cf. 3.2) which has $\epsilon_\square$ as augmentation and $c_\square$ as antipode.

5.5.

<!-- label: III.VII_A.5.5 -->

^[N.D.E-VII_A-56] Let now S be a scheme of characteristic $\mathfrak{p}$. First, if $\mathcal{U}$ is an 0_S -coalgebra in groups and G the group S -functor $\operatorname{Spec}^* \mathcal{U}$, we saw (3.2.3) that, for every $T \rightarrow S$, $(\operatorname{Lie} G)(T)$ is the Lie subalgebra of $\Gamma(T, \mathcal{U}_T)$ formed by the primitive elements. Now, if x is such an element, one has $\Delta(x^p) = x^p \otimes 1 + 1 \otimes x^p$ (since $\binom{p}{i} = 0 \pmod{\mathfrak{p}}$ for $0 < i < \mathfrak{p}$), i.e. x^p is again a primitive element. It follows, according to 5.1 and 5.2, that the map $x \mapsto x^p$ equips $(\operatorname{Lie} G)(T)$ with a structure of $0(T)$ - $\mathfrak{p}$ -Lie algebra.

Let now $\mathcal{L}$ be an 0_S - $\mathfrak{p}$ -Lie algebra, quasi-coherent on 0_S . When V ranges over the opens of S , the structures of group coalgebras previously defined on the sets $U_p(\Gamma(V, \mathcal{L}))$ induce on the associated sheaf, i.e., on the restricted enveloping algebra $\mathcal{U}_p(\mathcal{L})$, a structure of 0_S -coalgebra in groups. Moreover, <!-- original page 480 --> for every S -scheme T , one has an isomorphism $\mathcal{U}_p(\mathcal{U}_T) \xrightarrow{\sim} \mathcal{U}_p(\mathcal{L}_T)$.

Denote by $\operatorname{Prim} \mathcal{U}_p(\mathcal{L})$ the subpresheaf of $\mathcal{U}_p(\mathcal{L})$ associating with every open V the set of primitive elements of $\mathcal{U}_p(\mathcal{L})(V)$; one sees easily that this is a sheaf. When V ranges over the opens of S , the composed maps

```
```text
Γ(V, □) → Prim U_p(Γ(V, □)) → Prim □_p(□)
```

define a morphism  $\mathcal{L} \rightarrow \operatorname{Prim} \mathcal{U}_p(\mathcal{L})$ , which we shall again denote by  $j$  or  $j_{\mathcal{L}}$ , and this defines further a morphism of  $0_S$ - $\mathfrak{p}$ -Lie algebras  $\mathcal{W}(\mathcal{L}) \rightarrow \operatorname{Prim} \mathcal{W}(\mathcal{U}_p(\mathcal{L}))$  (cf. 3.2.3).

**Proposition 5.5.1.** Let  $\mathcal{L}$  be an  $0_S$ - $\mathfrak{p}$ -Lie algebra, locally free as an  $0_S$ -module. Then  $j_{\mathcal{L}}$  induces an isomorphism of  $0_S$ - $\mathfrak{p}$ -Lie algebras.\*

<!-- label: III.VII\_A.5.5.1 -->

```
$$
\mathcal{W}(\mathcal{L}) \xrightarrow{\sim} \operatorname{Prim} \mathcal{W}(\mathcal{U}_p(\mathcal{L})).
$$
```

**Proof.** Let  $T$  be an  $S$ -scheme; taking into account the identification  $\mathcal{U}_p(\mathcal{L}_T) = \mathcal{U}_p(\mathcal{L})_T$ , the task is to show that the map  $\Gamma(T, \mathcal{L}_T) \rightarrow \operatorname{Prim} \Gamma(T, \mathcal{U}_p(\mathcal{L}_T))$  is bijective. Replacing  $S$  by  $T$ , one is reduced to the case where  $T = S$ , and it then suffices to show that the morphism of sheaves  $j_{\mathcal{L}} : \mathcal{L} \rightarrow \operatorname{Prim} \mathcal{U}_p(\mathcal{L})$  is an isomorphism. This question being local on  $S$ , we may suppose that  $S$  is affine with ring  $\mathfrak{R}$  and that  $\mathcal{L}$  is the sheaf associated with an  $\mathfrak{R}$ - $\mathfrak{p}$ -Lie algebra  $L$  with basis  $(x_\alpha)$ . As in 5.3.3, denote by  $z_\alpha$  the image of  $x_\alpha$  in  $U = U_p(L)$  and, for every family  $n = (n_\alpha)$  of integers between  $0$  and  $\mathfrak{p} - 1$ , zero except for a finite number of them,

denote  $z^{\{n\}}$  the product

$$\prod_{\alpha} z^{\{n_{\alpha}\}}_{\alpha} / n_{\alpha}!$$

<!-- original page 481 -->

(one supposes the basis  $(x_{\alpha})$  totally ordered and the products performed in increasing order).

Since  $\Delta(z_{\alpha}) = z_{\alpha} \otimes 1 + 1 \otimes z_{\alpha}$ , one sees easily that

$$\Delta(z^{\{n\}}) = \sum_r z^{\{(n-r)\}} \otimes z^{\{r\}}$$

the sum being taken over the (finite!) set of  $r$  such that  $0 \leq r_{\alpha} \leq n_{\alpha}$  for every  $\alpha$ . Since the  $z^{\{n\}}$  (resp. the  $z^{\{n\}} \otimes z^{\{m\}}$ ) form a basis of  $U$  (resp. of  $U \otimes U$ ), one deduces that an element  $u$  of  $U$  satisfies  $\Delta(u) = u \otimes 1 + 1 \otimes u$  if and only if  $u$  is a linear combination of the  $z_{\alpha}$ . This proves 5.5.1.

**Remark 5.5.2.** Recall (cf. 3.2.2 and 3.2.3), that the group  $S$ -functor  $G = \operatorname{Spec}^* \mathcal{U}_{\{p\}}(\mathcal{L})$  is very good and that  $\operatorname{Lie}(G) = \operatorname{Prim} \mathcal{W}_{\{p\}}(\mathcal{L})$ . The preceding proposition therefore signifies that  $j_{\mathcal{L}}$  induces an isomorphism  $\mathcal{W}_{\mathcal{L}} \xrightarrow{\sim} \operatorname{Lie}(G)$ .

<!-- label: III.VII\_A.5.5.2 -->

If one supposes moreover that  $\mathcal{L}$  is a locally free  $0_S$ -module of finite rank, then  $\mathcal{U}_{\{p\}}(\mathcal{L})$  is finite locally free over  $0_S$ , according to 5.3.3, so  $\operatorname{Spec}^* \mathcal{U}_{\{p\}}(\mathcal{L})$  is represented by the  $S$ -group  $\mathcal{G}_{\{p\}}(\mathcal{L}) = \operatorname{Spec} \mathcal{U}_{\{p\}}(\mathcal{L})^*$  (cf. 3.2.2.1), and one obtains the following more precise proposition:

**Proposition 5.5.3.** Let  $\mathcal{L}$  be an  $0_S$ - $p$ -Lie algebra, locally free of finite rank as an  $0_S$ -module, let  $\mathcal{A} = \mathcal{U}_{\{p\}}(\mathcal{L})^*$  and let  $G = \mathcal{G}_{\{p\}}(\mathcal{L})$  be the affine  $S$ -group  $\operatorname{Spec} \mathcal{A}$ .

<!-- label: III.VII\_A.5.5.3 -->

(i)  $j_{\mathcal{L}}$  induces an isomorphism  $\mathcal{W}_{\mathcal{L}} \xrightarrow{\sim} \operatorname{Lie}(G)$  of  $0_S$ - $p$ -Lie algebras.

(ii) Let  $\mathcal{I}$  be the augmentation ideal of  $\mathcal{A}$  and  $\omega_G = \mathcal{I} / \mathcal{I}^2$  (cf. II, 4.11.4). Then  $\omega_G$  is identified with  $\mathcal{L}^* = \operatorname{Hom}_{0_S}(\mathcal{L}, 0_S)$ , hence is a locally free  $0_S$ -module of finite rank (and one has  $\omega_G^* = \mathcal{L}$ ).

**Proof.** (i) following from 5.5.2, let us prove (ii). Denote by  $\eta_{\mathcal{U}}$  and  $\epsilon_{\mathcal{U}}$  the unit section and the augmentation of  $\mathcal{U} = \mathcal{U}_{\{p\}}(\mathcal{L})$ , by  $\eta_{\mathcal{A}}$  and  $\epsilon_{\mathcal{A}}$  those of  $\mathcal{A}$ , and  $\mathcal{J} = \operatorname{Ker} \epsilon_{\mathcal{U}}$ . Then one has:

(1) 
$$\mathcal{U} = \eta_{\mathcal{U}}(0_S) \oplus \mathcal{J}.$$

Let  $\delta$  be the morphism defined by the diagram below, where  $\tau$  and  $\pi$  denote the inclusion and the projection deduced from the decomposition (1):

$$\begin{array}{ccc} \square & \xrightarrow{\delta} & \square \otimes \square \\ \tau \downarrow & & \uparrow \pi \\ \square & \xrightarrow{\Delta} & \square \otimes \square \end{array}$$

$$\begin{array}{l} \text{``text} \\ (*) \\ \text{````} \end{array} \quad 0 \longrightarrow \square^* \longrightarrow j_{\square} \square \xrightarrow{\delta} \square \otimes \square.$$

```

``text
(**) 0 ← □ ←tj_□ □ ←tδ □ ⊗ □.
````

```

$$\eta_{\mathcal{A}}(0_S) \oplus \mathcal{I}$$
$$\begin{array}{ccccc} \text{``text} & & & & m' \\ & \leftarrow & & \otimes & \\ \tau \downarrow & & & & \downarrow \pi \\ & \leftarrow & m_- & \otimes & \\ \text{``} & & & & \end{array}$$

> $\mathrm{Lie}(G/S)(S)$ is a sub- $\mathfrak{p}$ -Lie algebra of the infinitesimal algebra $\mathcal{U}(G)$.

6.1.1.

<!-- label: III.VII_A.6.1.1 -->

Let $\phi : G \rightarrow H$ be a homomorphism of S -group schemes. It is clear that the homomorphisms $\mathrm{Lie}(\phi/S)(S)$ and $\mathcal{U}(\phi)$ are compatible with the identifications of $\mathrm{Lie}(G/S)(S)$ and $\mathrm{Lie}(H/S)(S)$ with sub- $\mathfrak{p}$ -Lie algebras of $\mathcal{U}(G)$ and $\mathcal{U}(H)$. Since $\mathcal{U}(\phi)$ is an algebra homomorphism, one sees therefore that $\mathrm{Lie}(\phi/S)(S)$ is a homomorphism of $\mathfrak{p}$ -Lie algebras.

Similarly, if $s : T \rightarrow S$ is a base change, the map from $\mathrm{Lie}(G/S)(S)$ into $\mathrm{Lie}(G/S)(T)$, which is induced by s , is a homomorphism of $\mathfrak{p}$ -Lie algebras. One can translate this by saying that the functor $\mathrm{Lie}(G/S)$ is equipped with a structure of $'0_S'$ - $\mathfrak{p}$ -Lie algebra. In particular, when T ranges over the opens of S , one sees that

<!-- original page 455 --> the sheaf $\mathrm{Lie}(G/S)$ is equipped with a structure of $'0_S'$ - $\mathfrak{p}$ -Lie algebra.

6.2.

<!-- label: III.VII_A.6.2 -->

Following an idea of Demazure, we shall now generalize what precedes to certain group S -functors not necessarily representable. For this, we shall first give another definition of the symbolic $\mathfrak{p}$ -th power in the Lie algebra of an S -group scheme G .

Let D be a derivation of G at the origin; [N.D.E-VII_A-58] according to 1.2.1, D is the composition of the S -derivation $\delta = (\tau, \partial_t)$ of the zero section $\tau : S \rightarrow I_S$, and a morphism $x : I_S \rightarrow G$ such that $x \circ \tau = \epsilon$ (i.e. $x \in \mathrm{Lie}(G/S)(S)$). According to the definition we gave in 2.1, D^p is the following composed deviation:

```text  
 $S \simeq S \times S \times \cdots \times S \xrightarrow{\delta} I_S \times \cdots \times I_S \xrightarrow{x} G \times \cdots \times G \xrightarrow{m^{(p)}} G$   
 ```

($\mathfrak{p}$ copies), where $m^{(p)}$ is the morphism induced by the multiplication $m : G \times G \rightarrow G$. Since $I_S \times \cdots \times I_S$ is affine over S and has as affine algebra $B = 0_S[d_1, \dots, d_p] / (d_1^2, \dots, d_p^2)$, the deviation $\delta \times \cdots \times \delta$ is defined by the morphism of $'0_S'$ -modules

$\phi : B \rightarrow 0_S$
 ϕ

which sends to $'1'$ the monomial $d_1 d_2 \cdots d_p$, and to $'0'$ the other monomials $d_{i_1} \cdots d_{i_r}$, for $0 \leq r < p$. On the other hand, if pr_i denotes the projection of I^p_S onto the i -th factor and if x_i is the image in $G(I^p_S)$ of x by pr_i , then the composed morphism $m^{(p)} \circ (x \times \cdots \times x)$ is none other than the product $x_1 x_2 \cdots x_p$. Consequently, D^p is also the following composed deviation:

```text  
 $S \xrightarrow{\delta} I_S \times \cdots \times I_S \xrightarrow{x_1 x_2 \cdots x_p} G$   
 ```

This description allows us to re-prove that D^p is a derivation of G at the origin. <!-- original page 456 --> Indeed, since G is a very good group (II 4.11), the images $G(\mathrm{pr}_1)(x)$ and $G(\mathrm{pr}_2)(x)$ of x in $G(I_S \times I_S)$ commute with each other. It follows that the elements x_i of $G(I^p_S)$ commute pairwise and therefore, for every permutation γ of the factors of I^p_S , one has $(x_1 \cdots x_p) \circ \gamma = x_1 \cdots x_p$; it follows that $x_1 \cdots x_p$ factors through the canonical projection of I^p_S into the symmetric product $\Sigma^p I_S$ (cf. 4.2).

The symmetric product $\Sigma^p I_S$ has as affine algebra the subalgebra A of B which has as basis over $'0_S'$ the elementary symmetric functions $\sigma_0 = 1, \sigma_1, \dots, \sigma_p$ of $d_1, \dots, d_p$. Denote by κ the inclusion $A \hookrightarrow B$ and π the morphism of $'0_S'$ -algebras $A \rightarrow 0_S[t]/(t^2)$ which annihilates $\sigma_1, \dots, \sigma_{p-1}$ and sends σ_p to t ; then one has

```
```text
```

$$\begin{array}{ccc} S & \xrightarrow{\delta} \times \cdots \times \delta \rightarrow & I_S^{\wedge p} \xrightarrow{\text{can.}} x_1 \cdots x_p \rightarrow G \\ & & \downarrow \delta \\ I_S & \xrightarrow{i} & \Sigma^p I_S \xrightarrow{y} G \end{array}$$

which shows that  $D^{\{p\}}$  is of the form  $y \circ \delta$ , so is indeed a derivation of  $G$  at the origin.

### 6.3.

```
<!-- label: III.VII A.6.3 -->
```

Let  $\mathfrak{S}_p$  be the symmetric group of order  $p$  and  $I^p_{\mathfrak{S}} \times \mathfrak{S}_p$  the direct sum of a family of copies of  $I^p_{\mathfrak{S}}$  indexed by  $\mathfrak{S}_p$ . We denote by  $\pi_i : I^p_{\mathfrak{S}} \times \mathfrak{S}_p \rightarrow I^p_{\mathfrak{S}}$  the canonical projection and

```
```text
```

$$\mu : I_{S^p} \times \mathbb{A}_p \rightarrow I_{S^p}$$

the morphism defining the action of $\mathfrak{S}_{\{p\}}$ on $I^{\{p\}}_{\{S\}}$ (i.e., if τ is an element of $\mathfrak{S}_{\{p\}}$, the restriction of μ to $I^{\{p\}}_{\{S\}} \times \tau$ has $\text{pr}_{\{\tau(j)\}}$ as j -th component). This being so, we lay down the following definition:

<!-- original page 457 -->

Definition. A functor $X : (\text{Sch}/S)^{\circ} \rightarrow (\text{Ens})$ satisfies condition (F) if:

a) $\$X\$$ transforms finite direct sums into direct products,

*b) for every S -scheme T , the following sequence is exact:

```
```text
```

$$X(T \times \Sigma^p I_S) \rightarrow X(T \times I_S^{\wedge p}) \rightrightarrows X(T \times I_S^{\wedge p} \times \square_p),$$

(the two parallel arrows being  $X(\text{id } T \times \pi)$  and  $X(\text{id } T \times \mu)$ ).

Every  $\mathcal{S}$ -scheme satisfies (F); if  $\mathcal{F}$  is an  $\mathcal{O}_S$ -module,  $\mathcal{W}(\mathcal{F})$  satisfies (F); every projective limit of functors satisfying (F) also satisfies (F); if  $\mathcal{Y}$  satisfies (F) and if  $\mathcal{X}$  is an arbitrary  $\mathcal{S}$ -functor,  $\operatorname{Hom}\{ \mathcal{S} \}(X, \mathcal{Y})$  satisfies (F).

Let  $X$  be a very good group (II 4.10) satisfying condition (F). Denoting by  $x : I_{\{S\}} \rightarrow X$  a morphism which extends the unit section of  $X$  and resuming the notations of 6.2, one sees as above that  $x_{\{1\}} \cdots x_{\{p\}} : I^{\{p\}}_{\{S\}} \rightarrow X$  factors through  $\Sigma^p I_{\{S\}}$ :

```
```text
```

$$\begin{array}{c}
 I_S^p \xrightarrow{-x_1 \cdots x_p} X \\
 \text{can.} \quad \searrow \quad \swarrow \\
 \Sigma^p I_S
 \end{array}$$

and defines by composition a morphism

```
```text
```

$$x^{\{p\}} : I_S \xrightarrow{i} \Sigma^p I_S \xrightarrow{\Sigma^p(x)} X$$

which we shall call the *symbolic  $p$ -th power* of  $x$ .

<!-- original page 485 -->

The endomorphism  $x \mapsto x^{(p)}$  of  $\mathrm{Lie}(G/S)(S)$  is obviously compatible with base changes and is functorial in  $G$ . It would be interesting to know for which  $G$  this endomorphism makes  $\mathrm{Lie}(G/S)(S)$  a  $p$ -Lie algebra.

### 6.4.

<!-- label: III.VII\_A.6.4 -->

<!-- original page 458 -->

The last definition of the symbolic  $p$ -th power, which we have just given, is particularly well-suited to computation. Here are some examples:

#### 6.4.1.

<!-- label: III.VII\_A.6.4.1 -->

Let  $M$  be an "abstract" abelian group and  $D_{\{S\}}(M)$  the diagonalizable  $S$ -group of type  $M$  (I 4.4.2). For every  $S$ -scheme  $T$ , one has therefore

$$D_{\{S\}}(M)(T) = \operatorname{Hom}_{\{Ab\}}(M, O(T)^{\wedge \infty}).$$

Let  $x$  be an element of  $\mathrm{Lie}(D_{\{S\}}(M)/S)(S)$ , i.e., a homomorphism of abelian groups

$$M \xrightarrow{x} \Gamma(S, O_S + d O_S)^{\wedge \infty}$$

of the form  $m \mapsto 1 + d \xi(m)$ , where  $\xi \in \operatorname{Hom}_{\{Ab\}}(M, O(S))$ . With the notations of 6.2 and 6.3, the product  $x_{\{1\}} \cdot \cdots \cdot x_{\{p\}}$  associates with an element  $m$  of  $M$  the expression

$$(1 + d_1 \xi(m)) \cdots (1 + d_p \xi(m))$$

i.e.  $1 + \sigma_1 \xi(m) + \sigma_2 \xi(m)^2 + \cdots + \sigma_p \xi(m)^p$ .

This expression indeed belongs to  $O(S)[d]/(d^2)$  by annihilating  $\sigma_1, \dots, \sigma_{p-1}$  and sending  $\sigma_p$  to  $d$ , one sees that  $x^{(p)}$  is the following homomorphism from  $M$  into  $\Gamma(S, O_S + d O_S)^{\wedge \infty}$ :

$$m \mapsto 1 + d \xi(m)^p.$$

In summary, if one identifies  $\mathrm{Lie}(D_{\{S\}}(M)/S)(S)$  with  $\operatorname{Hom}_{\{Ab\}}(M, O(S))$  as in II 5.1, the symbolic  $p$ -th power associates with  $\xi$  the homomorphism  $\xi^{(p)} : m \mapsto \xi(m)^p$ .

#### 6.4.2.

<!-- label: III.VII\_A.6.4.2 -->

<!-- original page 459 -->

Let  $\mathcal{F}$  be an  $O_S$ -module and  $G$  the group  $S$ -functor in abelian groups  $\mathcal{W}(\mathcal{F})$  (cf. I, 4.6). Let  $y$  be an element of  $\mathcal{W}(\mathcal{F})(S) = \Gamma(S, \mathcal{F})$  and  $y'$  its image in  $\mathcal{W}(\mathcal{F})(I_S)$  by  $\mathcal{W}(\mathcal{F})(I_S) \rightarrow \mathcal{W}(\mathcal{F})(S)$ .

One knows (cf. II, 4.4.2 and 4.5.1) that the map  $y \mapsto d y'$  is an isomorphism of  $O(S)$ -modules from

$\mathcal{W}(\mathcal{F})(S)$  onto  $\mathrm{Lie}(\mathcal{W}(\mathcal{F})/S)(S)$ . If one sets  $x = dy$ , the quantity  $x_i$  of 6.2 is none other than  $d_i y'$ , where  $y'$  denotes the canonical image of  $y$ 's [N.D.E-VII\_A-59] in  $\mathcal{W}(\mathcal{F})(I^p_S)$ . Consequently, the product  $x_1 \cdots x_p$  is equal here to

```

```text
x_1 + ... + x_p = (d_1 + ... + d_p) y' = σ_1 y'
```

```

and belongs to  $\mathcal{W}(\mathcal{F})(\Sigma^p I_S)$ . Since the homomorphism  $0(\Sigma^p I_S) \rightarrow 0(I_S)$ , which defines the morphism  $\sigma_1$  of 6.1, annihilates  $\sigma_1$ , one sees that  $x^{(p)}$  is zero. Therefore:

> For every  $0_S$ -module  $\mathcal{F}$ , the operation  $x \mapsto x^{(p)}$  in  $\mathrm{Lie} \mathcal{W}(\mathcal{F})$  is zero.

### 6.4.3.

<!-- label: III.VII\_A.6.4.3 -->

Let  $X$  be an  $S$ -scheme,  $G$  the group  $S$ -functor  $\mathrm{Aut}_S X$  and  $D$  an  $S$ -derivation of the structure sheaf  $0_X$ . According to 1.5,  $D$  can be identified with an  $I_S$ -automorphism  $x$  of  $X_{I_S}$ , inducing the identity on  $X$ , which one can describe as follows. If  $f$  is a section of  $0_S[d]/(d^2)$  of the form  $a + bd$ , set  $D_{I_S} f = D a + (D b) d$ ; in other words,  $D_{I_S}$  is deduced from  $D$  by the base change  $I_S \rightarrow S$ ; then the automorphism in question of  $X_{I_S}$  is associated with the endomorphism  $f \mapsto f + (D_{I_S} f) d = a + (D(a) + b) d$  of  $0_S[d]/(d^2)$ .

Similarly, let  $D_{I^p_S}$  be the differential operator of  $X_{I^p_S}$  deduced from  $D$  by the base change  $I^p_S \rightarrow S$ . With the notations of 6.2, the automorphism  $x_i$  of  $X_{I^p_S}$  is then associated with the endomorphism  $f \mapsto f + (D_{I^p_S} f) d_i$  of  $0_S[d_1, \dots, d_p]/(d_1^2, \dots, d_p^2)$ . The product  $x_1 \cdots x_p$  is therefore associated with the endomorphism

```

```text
(1 + d_1 D_{I_S^p})(1 + d_2 D_{I_S^p}) ... (1 + d_p D_{I_S^p})
```

```

<!-- original page 460 -->

i.e.,  $1 + \sigma_1 D_{I^p_S} + \sigma_2 D_{I^p_S}^2 + \cdots + \sigma_p D_{I^p_S}^p$ .

The coefficient of  $\sigma_p$  is  $D_{I^p_S}^p$ , which means that the Lie algebra isomorphism

```

```text
Dér_S(0_X) ≅ Lie(Aut_S X),    D ↦ x
```

```

(cf. 1.5), is also an isomorphism of  $p$ -Lie algebras.

### 6.4.4.

<!-- label: III.VII\_A.6.4.4 -->

Using the same method, one sees that, for every  $0_S$ -module  $\mathcal{F}$ , the Lie algebra isomorphism

```

```text
Lie(Aut_{0_S-mod.} ( ) / S)(S) ≅ (End_{0_S-mod.} ( ))(S).
```

```

(cf. II 4.8) is also an isomorphism of  $p$ -Lie algebras.

### 6.4.5.

<!-- label: III.VII\_A.6.4.5 -->

[N.D.E-VII\_A-60] Let  $\mathcal{U}$  be an  $0_S$ -coalgebra in groups and  $G$  the group  $S$ -functor  $\mathrm{Spec}^* \mathcal{U}$ ; suppose that  $G$  is representable. In this case, for every  $T \rightarrow S$ , one has defined in 5.5 and 6.1.1 two structures of  $p$ -Lie algebra on  $L(T) = \mathrm{Lie}(G)(T)$ . Since one has a commutative diagram

```

```text
      L(T)  ----->  Γ(T, U_T)
      |               ^
      | α             | ψ
      |               |
      v             U(L(T))
      U(G_T)  <----- φ
      ...

```

where $U(L(T))$ is the enveloping algebra of $L(T)$ and ϕ , ψ the algebra morphisms induced by α , τ , one sees that the two p -Lie algebra structures coincide: if one identifies $x \in L(T)$ with its image in $U(G_T)$ (resp. $\Gamma(T, U_T)$), then $x^{(p)}$ is the image of the element $x^{(p)}$ of $U(L(T))$ by ϕ (resp. ψ).

7. Radicial groups of height 1

<!-- label: III.VII_A.7 -->

<!-- original page 461 -->

[^N.D.E-VII_A-61] Let S be a scheme of characteristic $p > 0$. We shall say that an $'0_S$ -algebra $\mathcal{A}$ (resp. an $'0_S$ - p -Lie algebra $\mathcal{L}$) is *finite locally free* if the $'0_S$ -module underlying $\mathcal{A}$ (resp. $\mathcal{L}$) is locally free and of finite type. If $\mathcal{L}$ is a finite locally free $'0_S$ - p -Lie algebra, we know (cf. 5.5.2) that the group S -functor $\operatorname{Spec}^* \mathcal{U}_p(\mathcal{L})$ is represented by an S -group scheme $\mathfrak{G}_p(\mathcal{L})$, finite and locally free. We shall see that this S -group scheme is the solution of a universal problem (7.2) and we shall characterize the S -group schemes of the form $\mathfrak{G}_p(\mathcal{L})$ (7.4).

Definition 7.0.

<!-- label: III.VII_A.7.0 -->

[^N.D.E-VII_A-62] *Let $H = \operatorname{Spec} \mathcal{A}$ be a finite locally free S -group scheme. We say that H is *infinitesimal* if the unit section $\epsilon_H : S \rightarrow H$ is a homeomorphism, which is equivalent to saying that the augmentation ideal of $\mathcal{A}$ is locally nilpotent.*

7.1.

<!-- label: III.VII_A.7.1 -->

[^N.D.E-VII_A-63] Let $\mathcal{L}$ be a finite locally free $'0_S$ - p -Lie algebra and let $\mathfrak{G}_p(\mathcal{L})$ be the affine S -group $\operatorname{Spec} \mathcal{U}_p(\mathcal{L})$. According to 5.5, one knows that $\mathcal{L}$ is identified with $\operatorname{Lie} \mathfrak{G}_p(\mathcal{L})$.

Consider now a very good group S -functor G satisfying condition (F) of 6.3 and let $\phi : \mathfrak{G}_p(\mathcal{L}) \rightarrow G$ be a morphism of group S -functors. According to 6.3, the morphism of $'0_S$ -Lie algebras $\operatorname{Lie} \phi : \operatorname{Lie} \mathfrak{G}_p(\mathcal{L}) \rightarrow \operatorname{Lie} G$ is compatible with the symbolic p -th power. If we denote by $\operatorname{Hom}_p(\mathcal{L}, \operatorname{Lie} G)$ the set of $'0_S$ -Lie algebra morphisms which are compatible with the symbolic p -th power, one therefore has a map <!-- original page 462 -->

```

```text
Lie : Hom_{S-Gr.}(\mathfrak{G}_p(\mathcal{L}), G) \rightarrow Hom_p(\mathcal{L}, \operatorname{Lie} G), \quad \phi \mapsto \operatorname{Lie} \phi.
```

```

7.2. Theorem.

<!-- label: III.VII_A.7.2 -->

If $\mathcal{L}$ is a finite locally free $'0_S$ - p -Lie algebra, the map

```

```text
Hom_{S-gr.}(\mathfrak{G}_p(\mathcal{L}), G) \rightarrow Hom_p(\mathcal{L}, \operatorname{Lie} G)
```

```

...

is bijective in each of the following cases:

(i) G is an S -group scheme;

(ii) G is of the form $\operatorname{Aut}_S(X)$, where X is an S -scheme;

(iii) G is of one of the forms $\mathcal{W}(\mathcal{F})$ or $\operatorname{Aut}_{0_S\text{-mod}}(\mathcal{W}(\mathcal{F}))$, where $\mathcal{F}$ denotes a quasi-coherent 0_S -module.

The proof of the theorem rests on the following lemma:

Lemma. *If $\mathcal{L}$ is a finite locally free 0_S - p -Lie algebra, the S -group $G = \mathcal{W}(\mathcal{L})$ is annihilated by the Frobenius morphism $\operatorname{Fr} : G \rightarrow G^{(p)}$. In particular, G is infinitesimal.*

[^N.D.E-VII_A-64] Let in fact $\mathcal{U}$ be the restricted enveloping algebra of $\mathcal{L}$, $\mathcal{A} = \mathcal{U}^*$ the affine algebra of G , and $\mathcal{I} = \operatorname{Ker} \epsilon_{\mathcal{A}}$ the augmentation ideal of $\mathcal{A}$. One has

$$(1) \quad \mathcal{A} = \mathcal{I} \oplus \eta_{\mathcal{A}}(0_S),$$

where $\eta_{\mathcal{A}}$ denotes the unit section of $\mathcal{A}$, and since $\epsilon_{\mathcal{A}}$ (resp. $\eta_{\mathcal{A}}$) is the transpose of $\epsilon_{\mathcal{U}}$ (resp. $\eta_{\mathcal{U}}$), this decomposition corresponds by duality to the decomposition

$$(2) \quad \mathcal{U} = \mathcal{J} \oplus \eta_{\mathcal{U}}(0_S),$$

where $\mathcal{J}$ is the augmentation ideal of $\mathcal{U}$; one therefore has $\mathcal{J} = \mathcal{I}^*$.

Let π denote the endomorphism $x \mapsto x^p$ of 0_S . We must show that the morphism $\operatorname{Fr} : G \rightarrow G^{(p)}$ factors through the unit section of $G^{(p)}$, which is equivalent to saying (cf. 4.1.4 (c)) that the morphism $\Phi : a \otimes_{\pi} x \mapsto a^p x$ from $\mathcal{I} \otimes_{\pi} 0_S$ into $\mathcal{A}$ is zero. Since $\mathcal{A}$ is finite locally free over 0_S , it suffices to see that the transposed morphism Φ^t is zero.

Now Φ is none other than the following composition

$$\tau_{\pi} : \mathcal{I} \otimes_{\pi} 0_S \rightarrow \mathcal{I} \otimes_{\pi} 0_S \xrightarrow{j} S^p \rightarrow \mathcal{A} \xrightarrow{b} \mathcal{A},$$

where τ is deduced from the inclusion $\mathcal{I} \hookrightarrow \mathcal{A}$, and $b(\mathcal{A})$ and $j(\mathcal{A})$ are defined as in 4.3.3 (i.e. $b(\mathcal{A})$ is induced by the multiplication of $\mathcal{A}$ and $j(\mathcal{A})$ sends $a \otimes_{\pi} 1$ to the image of $a \otimes \cdots \otimes a$ in $S^p \otimes \mathcal{A}$). Since the 0_S -dual module of $S^p \otimes \mathcal{A}$ is none other than the submodule $\Sigma^p \mathcal{U}$ of $\bigotimes^p \mathcal{U}$ formed by the sections invariant under the action of the symmetric group of order p , one sees that Φ^t is the following composed morphism:

<!-- original page 463 -->

$$\rho : \mathcal{A} \rightarrow S^p \rightarrow \mathcal{I} \otimes_{\pi} 0_S \rightarrow \mathcal{I} \otimes_{\pi} 0_S,$$

where ρ is deduced from the projection $\mathcal{U} \rightarrow \mathcal{J}$ of kernel $\eta_{\mathcal{U}}(0_S)$, $\rho(\mathcal{U})$ is induced by the comultiplication of $\mathcal{U}$ and $\rho(\mathcal{U})$ vanishes on the symmetrized tensors and sends a section $x \otimes \cdots \otimes x$ to $x \otimes_{\pi} 1$ (confer 4.3.3).

It is clear that $\Phi^t \circ \eta_{\mathcal{U}} = 0$ and therefore, according to (2), it remains to see that Φ^t annihilates the augmentation ideal $\mathcal{J}$. Since Φ^t is an algebra morphism and since the

ideal $\mathcal{J}$ is generated by $\mathcal{L}$ (identified with its image in $\mathcal{U}$), it suffices to see that $\Phi(x) = 0$ for every section x of $\mathcal{L}$. Now $a(\mathcal{U})(x) = (p-1)! a(\mathcal{U})(x)$ is the symmetrization of $x \otimes 1 \otimes \dots \otimes 1$, so its image by $r(\mathcal{U})$ is zero. This proves the first assertion of the lemma.

The second follows. Indeed, since every local section of $\mathcal{I}$ has p -th power zero and since $\mathcal{I}$ is an 0_S -module of finite type, $\mathcal{I}$ is locally nilpotent (explicitly, if V is an affine open of S such that $\mathcal{I} = \Gamma(V, \mathcal{I})$ is generated by r elements, then $\mathcal{I}^{r(p-1)+1} = 0$), whence $G_{\text{red}} = S_{\text{red}}$ and therefore the unit section $\epsilon_G : S \rightarrow G$ is a homeomorphism.

7.2.1.

<!-- label: III.VII_A.7.2.1 -->

[^N.D.E-VII_A-65] We shall first prove assertion (ii) of Theorem 7.2. Let $\pi : X \rightarrow S$ be an S -scheme. Consider first an arbitrary infinitesimal S -group H . The <!-- original page 489 --> morphisms ϕ from H into $\text{Aut}(X)$ correspond bijectively to left actions $\mu : H \times X \rightarrow X$ of H on X . For such an action, if ϵ is the unit section of H , the composed morphism

```

```text

$$X \simeq S \times X \xrightarrow{\epsilon \times \text{id}} H \times X \xrightarrow{\mu} X$$

```

```

must be the identity. Since $(H \times X)_{\text{red}}$ is identified with X_{red} , one sees that μ must induce the identity on the associated reduced schemes. In particular, μ induces an action of H on each open of X , and one therefore obtains, for every open U of X , affine over S , a morphism of unital associative algebras:

```

$$\mathcal{A}(U) \xrightarrow{\quad} \mathcal{A}(H) \otimes \mathcal{A}(U)$$

```

making $\mathcal{A}(U)$ an $\mathcal{A}(H)$ -comodule on the left, in such a way that the restriction maps $\mathcal{A}(U) \rightarrow \mathcal{A}(U')$, for $U' \subset U$, are comodule morphisms. Conversely, every datum of this type comes from a unique left action $\mu : H \times X \rightarrow X$. On the other hand, one has the following lemma:

Lemma. *Let $X = \text{Spec } \mathcal{C}$ be an affine S -scheme, $H = \text{Spec } \mathcal{A}$ an infinitesimal S -group,*

<!-- original page 464 -->

and $\mathcal{U} = \mathcal{A}^ = \text{Hom}(\mathcal{A}, 0_S)$. The left actions of H on X correspond bijectively to the representations of the algebra $\mathcal{U}$ in the 0_S -module $\mathcal{C}$ such that one has:*

```

```text
(a) $u(1_\square) = \epsilon(u) \cdot 1_\square$
(b) $u(xy) = \sum_i v_i(x) w_i(y)$ if $\Delta u = \sum_i v_i \otimes w_i$.
```

```

(In the formulas above, u denotes an arbitrary section of $\mathcal{U}$ on an affine open V of S , x and y sections of $\mathcal{C}$ on V ; one denotes by $1_{\mathcal{C}}$ the unit section of $\mathcal{C}$, by ϵ and Δ the augmentation and the diagonal morphism of $\mathcal{U}$.)

Indeed, a left action μ of H on X is defined by a morphism of unital associative algebras:

```

```text

$$\lambda : \square \rightarrow \square \otimes \square$$

```

```

making $\mathcal{C}$ an $\mathcal{A}$ -comodule on the left. We shall denote by α the composed morphism

```

```text

$$\square \otimes_{0_S} \square \rightarrow \square \otimes \lambda \rightarrow \square \otimes_{0_S} \square \otimes_{0_S} \square \rightarrow \gamma \otimes \square \rightarrow 0_S \otimes_{0_S} \square \simeq \square$$

```

```

where γ is the "contraction" of $\mathcal{A}^{\otimes} \otimes_{\mathcal{S}} \mathcal{A}$ into $\mathcal{O}_S$. Since $\mathcal{A}$ is finite locally free over $\mathcal{O}_S$, one knows that the map $\lambda \mapsto (\gamma \otimes \mathcal{C})(\mathcal{U} \otimes \lambda)$ is a bijection from $\operatorname{Hom}_{\mathcal{S}}(\mathcal{C}, \mathcal{A} \otimes \mathcal{C})$ onto $\operatorname{Hom}_{\mathcal{S}}(\mathcal{U} \otimes \mathcal{C}, \mathcal{C})$. Moreover, one sees easily that the condition that λ define a structure of $\mathcal{A}$ -comodule on the left (resp. be a morphism of unital associative algebras) is equivalent, by duality, to the condition that α be a representation of $\mathcal{U}$ in $\mathcal{C}$ (resp. that α satisfy conditions (a) and (b)). This proves the lemma.

Moreover, it is clear that, for every representation of $\mathcal{U}$ in the $\mathcal{O}_S$ -module $\mathcal{C}$, the sections s of $\mathcal{U}$ which satisfy conditions (a) and (b) of the lemma form a subalgebra of $\mathcal{U}$.

In the particular case $H = \mathcal{G}_p(\mathcal{L})$ of interest to us, these conditions will therefore be satisfied for all sections s of $\mathcal{U} = \mathcal{U}_p(\mathcal{L})$, if they are true for the original page 490 --> sections s of $\mathcal{L}$ (by identifying $\mathcal{L}$ with its image in $\mathcal{U}_p(\mathcal{L})$). Now, if s is a section of $\mathcal{L}$, conditions (a) and (b) simply mean that $u(1_{\mathcal{C}}) = 0$ and that $u(xy) = u(x)y + x u(y)$, i.e. that $\alpha(u)$ is an $\mathcal{O}_S$ -derivation of $\mathcal{C} = \mathcal{A}(X)$. Assertion (ii)

original page 465 --> of 7.2 follows. Indeed, every morphism φ from $\square_p = \square_p(\square)$ into $\operatorname{Aut} X$ defines a

homomorphism of $\mathfrak{p}$ -Lie algebras $\operatorname{Lie} \varphi$ from $\mathcal{L} = \operatorname{Lie} \mathcal{G}_p$ into $\pi_*(\mathcal{D}_{\mathcal{O}_S/\mathcal{O}_X})$, and conversely every datum of this type comes, according to what precedes, from a unique action $\mu : \mathcal{G} \times X \rightarrow X$.

7.2.2.

label: III.VII_A.7.2.2 -->

Let us now show how assertion (i) of Theorem 7.2 follows from (ii). Let G be an S -group scheme. If T is an S -scheme and x an element of $G(T)$, we denote by ℓ^T_x (resp. r^T_x) the left translation (resp. right translation) of G_T defined by x . The maps $\ell^T : x \mapsto \ell^T_x$ therefore determine a homomorphism ℓ from G into $\operatorname{Aut} G$. On the other hand, let f be a T -automorphism of G_T ; one then defines f^x as being equal to $(r^T_x)^{-1} \circ f \circ r^T_x$, i.e. for every $T' \rightarrow T$ and $g \in G(T')$, $(f^x)^{(g)}(g) = f(gx)x^{-1}$. In this way G acts on the left on the group S -functor $\operatorname{Aut} G$, hence also on the functors $T \mapsto \operatorname{Hom}_{T\text{-Gr.}}(\mathcal{G}_p(\mathcal{L}_T), \operatorname{Aut} G_T)$ and $T \mapsto \operatorname{Hom}_p(\square_T, \operatorname{Lie}(\operatorname{Aut} G_T / T))$. On the other hand, the morphism $\ell^T : G_T \rightarrow \operatorname{Aut} G_T$ identifies G_T with the group of automorphisms of the T -scheme G_T commuting with right translations, and the derived morphism $\operatorname{Lie}(\ell^T)$ identifies $\operatorname{Lie} G_T$ with the $\mathfrak{p}$ -Lie algebra of $\mathcal{O}_T$ -derivations of $\mathcal{O}_{G_T}$ commuting with right translations (cf. II, 4.11.1); they therefore induce commutative squares

$$\begin{array}{ccc} \operatorname{Hom}_{T\text{-Gr.}}(\square_p(\square_T), G_T) & \xrightarrow{\operatorname{Lie}} & \operatorname{Hom}_p(\square_T, \operatorname{Lie}(G_T / T)) \\ \square^T \downarrow & & \downarrow \operatorname{Lie} \square^T \\ \operatorname{Hom}_{T\text{-Gr.}}(\square_p(\square_T), \operatorname{Aut} G_T) & \xrightarrow{\operatorname{Lie}} & \operatorname{Hom}_p(\square_T, \operatorname{Lie}(\operatorname{Aut} G_T / T)). \end{array}$$

The images of the two vertical arrows are the subfunctors formed by the invariants under the action of the S -group G . Since the bottom horizontal arrow is invertible according to 7.2.1 and is compatible with the action of G , the top horizontal arrow is also invertible. This proves 7.2 (i).

7.2.3.

label: III.VII_A.7.2.3 -->

original page 466 -->

Consider now the case where $G = \operatorname{Aut}_{\mathcal{S}\text{-mod.}}(\mathcal{W}(\mathcal{F}))$. [N.D.E-VII_A-66] Set $\mathcal{U} = \mathcal{U}_p(\mathcal{L})$, $\mathcal{A} = \mathcal{U}^{\otimes}$ and $H = \mathcal{G}_p(\mathcal{L}) = \operatorname{Spec} \mathcal{A}$. Since H is affine over S then, according to VI_B 11.6.1, a morphism of S -groups from H into $\operatorname{Aut}_{\mathcal{S}\text{-mod.}}(\mathcal{W}(\mathcal{F}))$ is the

same thing as a structure of $\mathcal{A}$ -comodule on the right

```
```text
μ : □ → □ ⊗ □.
```

Moreover, since  $\mathcal{A}$  is finite locally free over  $0_S$ , this is equivalent to the datum of a representation

```
$$
\alpha : \mathcal{U} \longrightarrow \operatorname{End}_{0_S}(\mathcal{F})
$$
```

of  $\mathcal{U}$  in  $\mathcal{F}$ . Finally, according to the universal property of  $\mathcal{U} = \mathcal{U}_{\{p\}}(\mathcal{L})$ , to give such a morphism  $\alpha$  is equivalent to giving its restriction  $\rho$  to  $\mathcal{L}$  (identified with its image in  $\mathcal{U}$ ), which is a  $\mathfrak{p}$ -Lie algebra morphism from  $\mathcal{L}$  into  $\operatorname{End}_{0_S}(\mathcal{F})$ .

[^N.D.E-VII\_A-67] Finally, consider the case where  $G = \mathcal{W}(\mathcal{F})$ , keeping the preceding notations. First, to give a morphism of  $S$ -functors  $\phi : H \rightarrow \mathcal{W}(\mathcal{F})$  is equivalent to giving an element  $\theta$  of  $\Gamma(H, \mathcal{F} \otimes 0_H)$ , and since  $H$  is finite locally free over  $S$ , one has:

```
```text
Γ(H, □ ⊗ 0_H) = Γ(S, □ ⊗ □) = Hom_{0_S}(□, □).
```

The condition that ϕ be a group morphism then translates into the fact that θ , considered as morphism of 0_S -modules $\mathcal{U} \rightarrow \mathcal{F}$, vanishes on $\mathcal{L}_1$ and on $\mathcal{J}^2 / \mathcal{J}$, where $\mathcal{J}$ is the augmentation ideal of $\mathcal{U}$, whence

```
```text
(1) Hom_{S-gr.}(H, □(□)) = Hom_{0_S}(□ / □^2, □).
```

On the other hand, consider the quasi-coherent sheaf  $[\mathcal{L}, \mathcal{L}]$ , image of the morphism  $\mathcal{L} \otimes \mathcal{L} \rightarrow \mathcal{L}$ ,  $x \otimes y \mapsto [x, y]$ ; for every affine open  $V$  of  $S$ , one has  $[\mathcal{L}, \mathcal{L}](V) = [\mathcal{L}(V), \mathcal{L}(V)]$ . Then one has an exact sequence

```
```text
(†) 0 → [□, □] → □ → □ / □^2 → 0,
```

where π is the composition of the inclusion $\mathcal{L} \hookrightarrow \mathcal{J}$ and the projection $\mathcal{J} \rightarrow \mathcal{J} / \mathcal{J}^2$.

Indeed, the question being local on S , we may suppose that S is affine with ring R and that $\mathcal{L} = \mathcal{L}(S)$ is free with basis $(x_1, \dots, x_r)$. Identifying $\mathcal{L}$ with its image in $\mathcal{U} = U_{\{p\}}(\mathcal{L})$, let K be the sub- R -module of $\mathcal{U}$ direct sum of $[L, L]$ and the submodule with basis the monomials $x_1 \cdots x_r$ such that $n_1 + \cdots + n_r \geq 2$; one then verifies that K is a two-sided ideal of $\mathcal{U}$. Since K is contained in $\mathcal{J}^2$ (where $\mathcal{J}$ is the augmentation ideal of $\mathcal{U}$) and contains all the products $x_i x_j$ (which generate $\mathcal{J}^2$), one deduces that $K = \mathcal{J}^2$, whence $\mathcal{J}^2 \cap \mathcal{L} = [L, L]$ and one has the exact sequence $(†)$.

On the other hand, one knows from 6.4.2 that $\operatorname{Lie} \mathcal{W}(\mathcal{F})$ is none other than $\mathcal{W}(\mathcal{F})$, the Lie bracket and the symbolic $\mathfrak{p}$ -th power being zero. From this and from what precedes one deduces that

```
```text
(2) Hom_p(□, □) = Hom_{0_S}(□ / [□, □], □) = Hom_{0_S}(□ / □^2, □)
```

and this, combined with (1), completes the proof of Theorem 7.2.

### 7.3. Lemma.

<!-- label: III.VII\_A.7.3 -->

\*If  $\mathcal{L}$  is a finite locally free  $\mathcal{O}_S$ - $\mathfrak{p}$ -Lie algebra, the morphism  $j_{\mathcal{L}} : \mathcal{L} \rightarrow \mathrm{Lie} \mathfrak{g}_p(\mathcal{L})$  of 5.5 is invertible.\*

<!-- original page 467 -->

[^N.D.E-VII\_A-68] For the proof, see 5.5.1.

### 7.4.

<!-- label: III.VII\_A.7.4 -->

To end this section, we shall give a characterization of the  $\mathfrak{g}$ -group schemes of the form  $\mathfrak{g}_p(\mathcal{L})$ , where  $\mathcal{L}$  is a finite locally free  $\mathcal{O}_S$ - $\mathfrak{p}$ -Lie algebra.

Let  $G$  be an  $\mathfrak{g}$ -group scheme,  $\epsilon_G$  the unit section and  $\mathcal{I}'$  the kernel of the morphism  $\epsilon_G^{-1}(\mathcal{O}_G) \rightarrow \mathcal{O}_S$  corresponding to  $\epsilon_G$ . The image of  $\mathrm{Lie}(G/S)(S)$  in  $\mathcal{U}(G)$  is identified, according to 2.5 and 1.3.1, with the morphisms of  $\mathcal{O}_S$ -modules from  $\epsilon_G^{-1}(\mathcal{O}_G)$  into  $\mathcal{O}_S$  which vanish on the unit section of  $\epsilon_G^{-1}(\mathcal{O}_G)$  and on  $\mathcal{I}'^2$ . One thus recovers the canonical isomorphism of  $\mathrm{Lie}(G/S)(S)$  onto  $\mathrm{Hom}_{\mathcal{O}_S}(\mathcal{I}' / \mathcal{I}'^2, \mathcal{O}_S)$  of II, 3.3 and 4.11.4.[^N.D.E-VII\_A-69] We shall set  $\omega_{G/S} = \mathcal{I}' / \mathcal{I}'^2$  as in loc. cit., so that the sheaf  $\mathrm{Lie}(G/S)$  is identified with  $\omega_{G/S}^* = \mathrm{Hom}_{\mathcal{O}_S}(\omega_{G/S}, \mathcal{O}_S)$ .[^N.D.E-VII\_A-70] Moreover, if  $G = \mathfrak{g}_p(\mathcal{L})$ , where  $\mathcal{L}$  is a finite locally free  $\mathcal{O}_S$ - $\mathfrak{p}$ -Lie algebra, one saw in 5.5.3 that  $\omega_{G/S} = \mathcal{L}^*$ .

**Theorem.** \*If  $G$  is a group scheme over a scheme  $S$  of characteristic  $p > 0$ , the following assertions are equivalent:\*

(i) There exists a finite locally free  $\mathcal{O}_S$ - $\mathfrak{p}$ -Lie algebra  $\mathcal{L}$  such that  $G \simeq \mathfrak{g}_p(\mathcal{L})$ .\*

(i') The  $\mathcal{O}_S$ - $\mathfrak{p}$ -Lie algebra  $\mathrm{Lie}(G)$  is finite locally free and  $G \simeq \mathfrak{g}_p(\mathrm{Lie}(G))$ .\*

(ii)  $G$  is affine over  $S$ ,  $\omega_{G/S}$  is a locally free  $\mathcal{O}_S$ -module of finite type and the affine algebra of  $G$  is locally isomorphic to the quotient of the symmetric algebra  $S_{\mathcal{O}_S}(\omega_{G/S})$  by the ideal generated by the  $\mathfrak{p}$ -th powers of the sections of  $\omega_{G/S}$ .\*

(iii)  $G$  is locally of finite presentation over  $S$ , of height  $\leq 1$ , and  $\omega_{G/S}$  is locally free.\*

(iii')  $G$  is locally of finite type over  $S$ , of height  $\leq 1$ , and  $\omega_{G/S}$  is locally free.\*

(iv)  $G$  is locally of finite presentation and flat over  $S$ , of height  $\leq 1$ .[^N.D.E-VII\_A-71]

### 7.4.1.

<!-- label: III.VII\_A.7.4.1 -->

<!-- original page 468 -->

The equivalence (i)  $\Leftrightarrow$  (i') follows from 5.5.3 (i), the implications (ii)  $\Rightarrow$  (iii)  $\Rightarrow$  (iii') are clear, and one has (i)  $\Rightarrow$  (iv) since  $\mathfrak{g}_p(\mathcal{L})$  is finite locally free and of height  $\leq 1$ , according to 5.5.2 and Lemma 7.2. Let us show that (i) entails (ii). Denote by  $\mathcal{I}$  the augmentation ideal of  $\mathcal{U} = \mathcal{U}_{\mathcal{O}_S}(\mathcal{L})^*$ . One has already seen in 5.5.3 (ii) that  $\omega_{G/S} = \mathcal{I} / \mathcal{I}^2$  is identified with  $\mathcal{L}^*$ , hence is finite locally free.

Now suppose  $S$  affine. There is then a section  $\sigma : \omega_{G/S} \rightarrow \mathcal{I}$  of the projection  $\mathcal{I} \rightarrow \mathcal{I} / \mathcal{I}^2$ ; it induces an algebra morphism  $\sigma' : S_{\mathcal{O}_S}(\omega_{G/S}) \rightarrow \mathcal{U}$  and, according to Lemma 7.2,  $\sigma'$  factors into a morphism

```text  
 $\varphi : S_{\mathcal{O}_S}(\omega_{G/S}) / K \rightarrow \square,$

where K denotes the ideal generated by the $\mathfrak{p}$ -th powers of sections of $\omega_{G/S}$. If one filters $\mathcal{U}$

(resp. $S_{0\{S\}}(\omega_{G/S}) / K$) by the powers of $\mathcal{I}$ (resp. of the ideal generated by $\omega_{G/S}$), it is clear that ϕ induces an epimorphism of the associated graded modules. So ϕ is an epimorphism of locally free $\mathcal{O}_S$ -modules of the same rank (cf. 5.3.3); so ϕ is an isomorphism. This proves that (i) $\Rightarrow$ (ii).

7.4.2.

<!-- label: III.VII_A.7.4.2 -->

Suppose now G of height ≤ 1 and locally of finite presentation <!-- original page 469 --> over S . [N.D.E-VII_A-72] Since the Frobenius morphism $\text{Fr} : G \rightarrow G^{(p)}$ is integral and factors through the unit section of $G^{(p)}$, then G is integral (hence affine) over S . Let then $\mathcal{A} = \mathcal{A}(G)$; since G is supposed locally of finite presentation over S , it follows that G is finite and of finite presentation over S , hence $\mathcal{A}(G)$ is an $\mathcal{O}_S$ -module of finite presentation (cf. EGA IV₁, 1.4.7). Let $\mathcal{I}$ be the augmentation ideal of $\mathcal{A}$; since $\mathcal{A} = \eta_{\mathcal{A}}(\mathcal{O}_S) \oplus \mathcal{I}$ (where $\eta_{\mathcal{A}}$ is the unit section of $\mathcal{A}$), $\mathcal{I}$ is an $\mathcal{O}_S$ -module of finite presentation, and so is $\omega_G = \mathcal{I} / \mathcal{I}^2$. When one supposes G of height ≤ 1 and locally of finite type over S , one obtains similarly that $\mathcal{A}(G)$, $\mathcal{I}$ and $\omega_G = \mathcal{I} / \mathcal{I}^2$ are $\mathcal{O}_S$ -modules of finite type.

So, under hypothesis (iii'), one obtains that $\omega_{G/S}$ is finite locally free over $\mathcal{O}_S$, as is $\mathcal{L} = \text{Lie}(G/S) = \omega_{G/S}^*$. Let then $\mathcal{B} = \mathcal{U}_p(\mathcal{L})^*$ and $\mathcal{H} = \mathcal{G}_p(\mathcal{L}) = \text{Spec } \mathcal{B}$. According to Theorem 7.2, the identity map of $\mathcal{L}$ corresponds to a group morphism from $\mathcal{H} = \mathcal{G}_p(\mathcal{L})$ to G , hence to a morphism of $\mathcal{O}_S$ -algebras $\theta : \mathcal{A} \rightarrow \mathcal{B}$. The task is to show that θ , which induces by definition an isomorphism of $\omega_{G/S}$ onto $\omega_{\mathcal{H}/S}$, is an isomorphism.

For this, one may restrict to the case where S is affine. There is then a section τ of the projection $\mathcal{I} \rightarrow \omega_{G/S}$; it induces an algebra morphism $\tau' : S_{0\{S\}}(\omega_{G/S}) \rightarrow \mathcal{A}$ and since every local section of $\mathcal{I}$ has p -th power zero (since $\text{Fr} : G \rightarrow G^{(p)}$ factors through the unit section of $G^{(p)}$), τ' induces a morphism of $\mathcal{O}_S$ -algebras ψ which fits in the commutative diagram below:

```text

$$\begin{array}{ccc} S_{0\{S\}}(\omega_{G/S}) / K & \xrightarrow{\psi} & \mathcal{A} \\ \searrow \phi & & \downarrow \theta \\ & & \mathcal{B} \end{array}$$

...

where  $K$  is the ideal generated by the  $p$ -th powers of sections of  $\omega_{G/S}$ . On the one hand, one shows as in 7.4.1 that  $\psi$  is an epimorphism of  $\mathcal{O}_S$ -modules. On the other hand, we saw in 7.4.1 that  $\phi = \theta \circ \psi$  is an isomorphism. The same therefore holds for  $\theta$ . This proves that (iii')  $\Rightarrow$  (i).

### 7.4.3.

<!-- label: III.VII\_A.7.4.3 -->

[N.D.E-VII\_A-73] Let us finally show that (iv) entails (iii). It suffices to show that  $\omega_{G/S}$  is locally free, so one may suppose  $S$  affine with ring  $R$ . As remarked at the beginning of 7.4.2, hypothesis (iv) then entails that  $\mathcal{G} = \text{Spec } \mathcal{A}$ , for an  $R$ -algebra  $\mathcal{A}$  which is an  $R$ -module of finite presentation, as is  $\omega_{\mathcal{A}} = \mathcal{I} / \mathcal{I}^2$  (where  $\mathcal{I}$  is the augmentation ideal of  $\mathcal{A}$ ). Since one supposes moreover that  $G$  is flat over  $S$ , then  $\mathcal{A}$  is a finite locally free  $R$ -module (cf. [BAC] II, § 5.2, Th. 1 and cor. 2) and, according to loc. cit., to show that  $\omega_{\mathcal{A}}$  is locally free of finite rank, it suffices to show that  $(\omega_{\mathcal{A}})_{\mathcal{M}} = \mathcal{I}_{\mathcal{M}} / \mathcal{I}_{\mathcal{M}}^2$  is flat for every maximal ideal  $\mathcal{M}$  of  $R$ . So one may suppose  $R$  local <!-- original page 494 --> and  $\mathcal{A}$  free of rank  $n + 1$ , hence  $\mathcal{I}$  free of rank  $n$ . Let  $\mathcal{M}$  be the maximal ideal of  $R$  and  $\mathfrak{m} = \mathcal{M} / \mathcal{M}^2$ .

Denote by  $\mathcal{I}_k$  the augmentation ideal of  $\mathcal{A}_k$  and  $r$  the dimension of  $\omega_{\mathcal{G}_k} / k = \mathcal{I}_k / \mathcal{I}_k^2$ . Let  $(e_1, \dots, e_n)$  be a basis of  $\mathcal{I}_k$  such that  $(e_{r+1}, \dots, e_n)$  is a basis of  $\mathcal{I}_k^2$ , and let  $x_1, \dots, x_n$  be elements of  $\mathcal{I}$  lifting the  $e_i$ . According to Nakayama's lemma,  $(x_1, \dots, x_n)$  is a basis of  $\mathcal{I}$  over  $R$ . Let  $\mathcal{N}$  be the sub- $R$ -module of  $\mathcal{I}$  with basis  $(x_1, \dots, x_r)$  and let  $\mathcal{B}$  be the quotient of the symmetric algebra of  $\mathcal{N}$  by the ideal generated by the elements  $x^p$ , for  $x \in \mathcal{N}$ . Since every element of  $\mathcal{I}$  has  $p$ -th power zero, one obtains a morphism of  $R$ -algebras

$\psi : B \rightarrow A.$

According to 7.4.2,  $\psi \otimes k$  is an isomorphism. It follows that  $\text{Coker } \psi = 0$  and that, denoting  $K = \text{Ker } \psi$ , the morphism  $\tau : K \otimes k \rightarrow B \otimes k$  is zero. But since  $\psi$  is surjective and  $A$  is flat over  $R$ , then  $\tau$  is also injective, whence  $K \otimes k = 0$ . On the other hand, since  $A$  is an  $R$ -module of finite presentation,  $K$  is an  $R$ -module of finite type (cf. [BAC] I, § 2.8, Lemma 9), whence  $K = 0$  by Nakayama. So  $\psi$  is an isomorphism of  $R$ -algebras, and since  $\psi^{-1}(I)$  contains the augmentation ideal  $J$  of  $B$ , it follows that  $\psi^{-1}(I) = J$ , and therefore  $\psi^{-1}$  induces an isomorphism of  $R$ -modules from  $I / I^2$  onto  $J / J^2 = N$ . This proves that  $\omega_{G/S}$  is finite locally free, whence the implication (iv)  $\Rightarrow$  (iii). This completes the proof of Theorem 7.4.

### Remark 7.5.

<!-- label: III.VII\_A.7.5 -->

<sup>[N.D.E-VII\_A-74]</sup> It obviously follows from Theorems 7.2 and 7.4 that the functors  $G \mapsto \text{Lie}(G)$  and  $\mathcal{L} \mapsto \mathfrak{G}_{\mathcal{L}}$  induce equivalences, quasi-inverses of each other, between the category of  $S$ -groups locally of finite presentation and flat, of height  $\leq 1$ , and the full subcategory of that of  $0_S$ - $p$ -Lie algebras formed by the finite locally free  $0_S$ - $p$ -Lie algebras.

## 8. The case of a base field

<!-- label: III.VII\_A.8 -->

<!-- original page 470 -->

### 8.1.

<!-- label: III.VII\_A.8.1 -->

Let us now summarize the results obtained in the case where  $S$  is the spectrum of a field  $k$  of characteristic  $p > 0$ . Let us then say that a  $k$ -group scheme is *\*algebraic\** if the underlying scheme is of finite type over  $k$ . In this case, according to Theorem 7.2, one obtains:<sup>[N.D.E-VII\_A-75]</sup>

#### Theorem 8.1.1.

<!-- label: III.VII\_A.8.1.1 -->

\*The functor  $\mathfrak{G}_{\mathcal{L}}$ , which to every  $p$ -Lie algebra  $\mathcal{L}$  of finite dimension over  $k$  associates the  $k$ -group  $\mathfrak{G}_{\mathcal{L}}$ , is left adjoint to the functor which to every algebraic  $k$ -group  $G$  associates  $\text{Lie}(G)$ .\*

Combining this with Theorem 7.4, one obtains:

#### Theorem 8.1.2.

<!-- label: III.VII\_A.8.1.2 -->

\*The functors  $\mathfrak{G}_{\mathcal{L}} : \mathcal{L} \mapsto \mathfrak{G}_{\mathcal{L}}$  and  $G \mapsto \text{Lie}(G)$  induce equivalences, quasi-inverses of each other, between the category of  $p$ -Lie algebras of finite dimension over  $k$ , and that of algebraic  $k$ -groups of height  $\leq 1$ .\*

Then, since  $\mathfrak{G}_{\mathcal{L}}$  is a left adjoint functor, it commutes with inductive limits,<sup>[N.D.E-VII\_A-76]</sup> hence in particular with the formation of cokernels. On the other hand, if one has two morphisms  $\phi : G \rightarrow H$  and  $\phi' : G' \rightarrow H$  between algebraic  $k$ -groups of height  $\leq 1$ , then the fibered product  $G \times_H G'$  is again an algebraic  $k$ -group of height  $\leq 1$  (since the morphism  $f : G \rightarrow G_{\mathcal{L}}$  commutes with fibered products). So the inclusion of the category of algebraic  $k$ -groups of height  $\leq 1$  into that of all algebraic  $k$ -groups commutes with fibered products, hence in particular with the formation of kernels. From this one deduces the:

#### Corollary 8.1.3.

<!-- label: III.VII\_A.8.1.3 -->

\*The functor  $\mathfrak{G}_{\{p\}}$  is exact, in the following sense. If  $\pi : \mathcal{L}_{\{1\}} \rightarrow \mathcal{L}_{\{2\}}$  is a surjective morphism between  $p$ -Lie algebras of finite dimension over  $k$  and if  $i$  is the inclusion of  $\mathcal{L}_{\{0\}} = \text{Ker } \pi$  in  $\mathcal{L}_{\{1\}}$ , one has an exact sequence of algebraic  $k$ -groups:\*

```
```text
1 → G_p(0) → G_p(i) → G_p(1) → G_p(π) → G_p(2) → 1.
```

[^N.D.E-VII_A-77]

Indeed, according to what precedes, $\mathfrak{G}_{\{p\}}(i)$ induces an isomorphism of $\mathfrak{G}_{\{p\}}(\mathcal{L}_{\{0\}})$ onto $\text{Ker}(\mathfrak{G}_{\{p\}}(\pi))$ (this kernel being the same in the category of all algebraic k -groups H or in that of H of height ≤ 1), and $\mathfrak{G}_{\{p\}}(\pi) : \mathfrak{G}_{\{p\}}(\mathcal{L}_{\{1\}}) \rightarrow \mathfrak{G}_{\{p\}}(\mathcal{L}_{\{2\}})$ identifies $\mathfrak{G}_{\{p\}}(\mathcal{L}_{\{2\}})$ with the quotient of $\mathfrak{G}_{\{p\}}(\mathcal{L}_{\{1\}})$ by $\mathfrak{G}_{\{p\}}(\mathcal{L}_{\{0\}})$ in the category of algebraic k -groups.

Remark 8.1.4.

<!-- label: III.VII_A.8.1.4 -->

[^N.D.E-VII_A-78] Let $\phi : G \rightarrow H$ be a morphism of k -groups and $K = \text{Ker}(\phi)$. Suppose ϕ covering for the (fpqc) topology (this will be the case, in particular, if ϕ is covering for a less fine topology, for example the (fppf) topology). Then, on the one hand, ϕ is a K -torsor above H (cf. IV 5.1.7.1). On the other hand, (cf. IV 6.3.1) there exists a covering of H by affine opens S_i , and for each i an affine faithfully flat morphism $T_i \rightarrow S_i$ factoring through ϕ . Then $G \times_H T_i$ is T_i -isomorphic to $K \times T_i$, hence faithfully flat over T_i , and therefore, by (fpqc) descent, $G \times_H S_i \rightarrow S_i$ is faithfully flat, so that ϕ is faithfully flat.

Conversely, if ϕ is faithfully flat and quasi-compact (resp. and locally of finite presentation), it is covering for the (fpqc) topology (resp. (fppf)), cf. IV 6.3.1. Recall finally that a morphism of sheaves is covering if and only if it is an epimorphism, cf. IV 4.4.3. One therefore obtains, in particular, that a quasi-compact morphism of k -groups is faithfully flat if and only if it is an epimorphism of (fpqc) sheaves.

8.2. Proposition.

<!-- label: III.VII_A.8.2 -->

*Consider an exact sequence[^N.D.E-VII_A-79] of algebraic groups over a field k of characteristic $p > 0$ *

```
```text
1 → G' → G → G'' → 1
```

<!-- original page 496 -->

\*and the following assertions:\*

\*(i) The morphism  $\pi$  is smooth.\*

\*(ii)  $G'$  is smooth.\*

\*(iii) For every integer  $n > 0$ , the following sequence, induced by  $\tau$  and  $\pi$ , is exact:\*

<!-- original page 471 -->

```
```text
1 → Fr^n G' → Fr^n G → Fr^n G'' → 1.
```

(iv) The morphism $\text{Fr } \pi : \text{Fr } G \rightarrow \text{Fr } G''$ is an epimorphism of (fppf) sheaves.

(v) The morphism $\text{Lie}(\pi) : \text{Lie}(G) \rightarrow \text{Lie}(G'')$ is surjective.

Then one has the implications (i) $\Leftrightarrow$ (ii) $\Rightarrow$ (iii) $\Rightarrow$ (iv) $\Leftrightarrow$ (v) and all the assertions are equivalent when G is smooth over k .

Indeed, (i) is equivalent to (ii) according to VI_B 9.2 (vii), and it is clear that (iii) implies (iv). On the other hand, the equivalence of (iv) and (v) follows from 8.1.3.

The implication (ii) $\Rightarrow$ (iii) follows from the diagram:

$$\begin{array}{ccccccc} 1 & \rightarrow & G' & \xrightarrow{\tau} & G & \xrightarrow{\pi} & G'' \rightarrow 1 \\ & & \text{Fr}^n(G'/k) & & \text{Fr}^n(G/k) & & \text{Fr}^n(G''/k) \\ \dots & & 1 \rightarrow G'^{\wedge\{p^n\}} & \xrightarrow{\tau^{\wedge\{p^n\}}} & G^{\wedge\{p^n\}} & \xrightarrow{\pi^{\wedge\{p^n\}}} & G''^{\wedge\{p^n\}} \rightarrow 1 \end{array}$$

whose two rows are exact: since $\text{Fr}^n(G'/k)$ is an epimorphism of (fppf) sheaves according to Corollary 8.3.1 below, π induces an epimorphism of $\text{Fr}^n(G)$ onto $\text{Fr}^n(G'')$ (generalize the snake lemma to sheaves of groups not necessarily commutative).

Similarly, when G is smooth over k , $\text{Fr}(G/k)$ is an epimorphism, so if moreover π is an epimorphism, the same snake lemma applied to the diagram above for $n = 1$ shows that $\text{Fr}(G'/k)$ is an epimorphism, so G' is smooth over k , according to 8.3.1 below.

8.3. Proposition.

<!-- label: III.VII_A.8.3 -->

If G is a group locally of finite type [N.D.E-VII_A-80] *over a field k of characteristic $p > 0$, there exists an integer n_0 such that $G / (\text{Fr}^n G)$ is smooth over k for $n \geq n_0$.*

<!-- original page 472 -->

Since the construction of $G / (\text{Fr}^n G)$ commutes with extension of the base field (4.1.1 and VI_A, 3.3.2), we may suppose k perfect. In this case, G_{red} is a k -group locally of finite type (cf. VI_A 0.2) and one has the following commutative and exact diagram, where one has denoted by H the k -scheme $G_{\text{red}} \setminus G$:

$$\begin{array}{ccccccc} & & 1 & \longrightarrow & G_{\text{red}} & \longrightarrow & G \longrightarrow H \\ & & \text{Fr}^n(G_{\text{red}}/k) & & \text{Fr}^n(G/k) & & \text{Fr}^n(H/k) \\ & & 1 & \longrightarrow & G^{\wedge\{p^n\}}_{\text{red}} & \longrightarrow & G^{\wedge\{p^n\}} \longrightarrow H^{\wedge\{p^n\}}. \end{array}$$

Now H is the spectrum of a finite local k -algebra with residue field k (cf. VI_A, 5.6.1). Consequently, there exists an integer n_0 such that, for every $n \geq n_0$, $\text{Fr}^n(H/k)$ factors through the "unit" section of $H^{\wedge\{p^n\}}$. It follows that, for $n \geq n_0$, $\text{Fr}^n(G/k)$ factors through $G^{\wedge\{p^n\}}_{\text{red}}$ and therefore, according to VI_A, 5.4.1, one has a commutative diagram

$$\begin{array}{ccc} G & \xrightarrow{\text{Fr}^n(G/k)} & G^{\wedge\{p^n\}}_{\text{red}} \\ \pi \swarrow & & \uparrow i \\ G / (\text{Fr}^n G) & & \end{array}$$

where i is a closed immersion (and π is the canonical projection). Since moreover i induces a homeomorphism of the underlying topological spaces, it is therefore an isomorphism. Since k is perfect, $G^{\wedge\{p^n\}}_{\text{red}}$ is smooth over k (VI_A, 1.3.1), and therefore $G / (\text{Fr}^n G)$ is smooth over k , for every $n \geq n_0$.

8.3.1. Corollary.

<!-- label: III.VII_A.8.3.1 -->

*Let G be a group locally of finite type over a field k of characteristic $p > 0$ and let n be an integer ≥ 1 . *The following conditions are equivalent:*

(i) G is smooth over k .

(ii) $\mathrm{Fr}^n(G/k) : G \rightarrow G^{(p^n)}$ is an epimorphism of (fppf) sheaves.

(iii) $\mathrm{Fr}^n(G/k) : G \rightarrow G^{(p^n)}$ is faithfully flat.

First, since G is locally of finite type over k , $\mathrm{Fr}^n(G/k)$ is of finite presentation, so the equivalence of (ii) and (iii) follows from 8.1.4. Suppose G smooth over k , hence G reduced. Then, since $\mathrm{Fr}^n(G/k)$ is surjective, it is faithfully flat (cf. VI_A, 6.2 or VI_B, 1.3).

Conversely, suppose $\mathrm{Fr}^n(G/k)$ faithfully flat. Since $\mathrm{Fr}^n(G^{(p^n)}/k)$ is deduced from $\mathrm{Fr}^n(G/k)$ by base change (cf. 4.1.3), it is therefore also faithfully flat, as is the composition:

```

```text
Fr^{2n}(G/k) : G → G^{(p^n)} → G^{(p^{2n})}.
```

```

One thus obtains that, for every $m \in \mathbb{N}$, $\mathrm{Fr}^m(G/k) : G \rightarrow G^{(p^m)}$ is faithfully flat, hence induces an isomorphism $G / (\mathrm{Fr}^m(G) \setminus \mathrm{Fr}^m(G)) \simeq G^{(p^m)}$ (cf. VI_A, 5.4.1). Now, according to Proposition 8.3, $G^{(p^m)}$ is smooth over k for m large, so G is also, by (fpqc) descent (cf. EGA IV₄, 17.7.1).

8.4.

<!-- label: III.VII_A.8.4 -->

<!-- original page 498 -->

In the two statements which end this Exposé, we return to the case of a field k of arbitrary characteristic.

When k is of characteristic 0 (resp. $p > 0$), let n be an integer ≥ 1 (resp. an integer ≥ 1 and coprime to p); in both cases, we say simply that n is *coprime to the characteristic of k *. Moreover, if G is a group scheme over k , we denote by $n_G : G \rightarrow G$ the morphism of k -schemes <!-- original page 473 --> which sends an element x of $G(T)$ to x^n in $G(T)$, when T is a k -scheme.

Proposition. *Let G be an algebraic group over a field k and n an integer coprime to the characteristic of k . Then $n_G : G \rightarrow G$ is an étale morphism.*

[^N.D.E-VII_A-82] According to VI_B 1.3, it suffices to show that n_G is étale at the origin. Let A be the local ring of G at the origin and $\mathfrak{I}$ the maximal ideal of A . According to II 3.9.4, the map $\mathrm{Lie}(n_G) : \mathrm{Lie}(G) \rightarrow \mathrm{Lie}(G)$, which is induced by n_G , is the homothety of ratio n . It is therefore an isomorphism, as is the endomorphism induced by n_G on $\mathfrak{I} / \mathfrak{I}^2 = \mathrm{Lie}(G)^*$. If k is of characteristic 0, G is smooth over k (VI_B 1.6.1, see also VII_B 3.3.1), so the canonical morphism $S(\mathfrak{I} / \mathfrak{I}^2) \rightarrow \mathrm{gr}_{\mathfrak{I}}(A)$ is an isomorphism, where $\mathrm{gr}_{\mathfrak{I}}(A)$ denotes the graded module associated with the $\mathfrak{I}$ -adic filtration. It follows that n_G induces an automorphism of $\mathrm{gr}_{\mathfrak{I}}(A)$, hence also of the completion $\hat{A}$ of A , hence n_G is étale at the origin (cf. EGA IV₄, 17.6.3).

If the characteristic is $p > 0$ and if G is of height ≤ 1 , then A is isomorphic to the quotient of the symmetric algebra of $\omega_{G/k} = \mathfrak{I} / \mathfrak{I}^2$ by the ideal generated by the p -th powers of the elements of $\omega_{G/k}$ (cf. 7.4); one may then apply the "same" reasoning as in characteristic 0, and one obtains that n_G induces an automorphism of A .

If G is of height $\leq r$ and if we suppose our assertion proved for groups of height $\leq r - 1$, denote by B , A and A' the affine algebras of $\mathrm{Fr} G$, G and $G' = \mathrm{Fr} G \setminus G$, and n_B , n_A and $n_{A'}$ the endomorphisms of B , A and A' which are induced by $n_{\mathrm{Fr} G}$, n_G and $n_{G'}$.[^N.D.E-VII_A-83] Let $\mathfrak{I}' = \mathfrak{I} \cap A'$ be the maximal ideal of A' , since one has a cartesian square

```

```text
Fr G → G
```

```

... $e \longrightarrow G'$

one has $B = A / I' A$. Observe that $\pi_{n\{A\}}$ (resp. $\pi_{n\{B\}}$) is none other than the endomorphism induced by $\pi_{n\{A\}}$ on A' (resp. on B). According to VI_A 3.2, A is a faithfully flat A' -module, and since A' is an Artinian local ring (G being an algebraic k -group of height $\leq r - 1$), it follows that A is a free A' -module. Since the restriction of $\pi_{n\{A\}}$ to A' is $\pi_{n\{A\}}$, which is an isomorphism according to the inductive hypothesis, it follows from Nakayama's lemma that $\pi_{n\{A\}}$ will be an automorphism if the endomorphism it induces on $A / I' A$ is one.

<!-- original page 499 --> Now this endomorphism is none other than $\pi_{n\{B\}}$, which is an automorphism since $\pi_{n\{B\}}$ is of height $\leq r - 1$. So $\pi_{n\{A\}}$ is an automorphism.

Finally, when G is an arbitrary algebraic group over a field of characteristic $p > 0$, what precedes shows that $\pi_{n\{G\}}$ induces automorphisms of the k -schemes $\text{Fr}^r G$; these schemes are affine over k and have as algebras the quotients of the local algebra A by the ideal $I^{\{p^r\}}$ generated by the p^r -th powers of the elements of I . Since <!-- original page 474 --> $\pi_{n\{G\}}$ defines automorphisms of the algebras $A / I^{\{p^r\}}$, one sees by passage to the projective limit that $\pi_{n\{G\}}$ induces an automorphism of $\hat{A}$, hence $\pi_{n\{G\}}$ is étale at the origin (EGA IV₄, 17.6.3).

8.5. Proposition.

<!-- label: III.VII_A.8.5 -->

Let G be a finite algebraic group, of rank n over the field k . Then $\pi_{n\{G\}} : G \rightarrow G$ is the zero morphism of G .

Let us point out at once the following corollary, obtained by combining 8.4 and 8.5: [N.D.E-VII_A-84]

Corollary 8.5.1.

<!-- label: III.VII_A.8.5.1 -->

Let G be a finite algebraic group, of rank n over the field k . If n is coprime to the characteristic of k , then G is étale over k .

Let us now prove 8.5. Let H be a normal subgroup of G of rank m over k . Denote by $\lambda : H \times G \rightarrow G$ the morphism induced by the multiplication of G . Then, with the notations of VI_A 3.2, one has a cartesian square:

```

```text
 H x G --λ--> G
 pr_2 π

 G --> H \ G.
...

```

Since  $\pi : G \rightarrow H \setminus G$  is faithfully flat, quasi-compact (VI\_A 3.2), and since  $\text{pr}_2$  is locally free of rank  $m$ , it follows from EGA IV<sub>2</sub>, 2.5.2, that  $G \rightarrow H \setminus G$  is locally free of rank  $m$ . Denoting  $r = \text{rg}_k(H \setminus G)$ , one therefore has  $n = \text{rg}_k(G) = r + m$ .

On the other hand, one has an exact sequence of "abstract" groups

```

```text
1 → H(T) → G(T) → (H \ G)(T)
...

```

for every k -scheme T ; it is therefore clear that $\pi_{n\{G\}}$ is zero if $\pi_{m\{H\}}$ and $\pi_{r\{H \setminus G\}}$ are. If one takes for H the neutral component G_0 of G , then $G_0 \setminus G$ is étale (cf. VI_A 5.5.1), so that one may suppose G étale over k or else infinitesimal (cf. 7.0).

If G is étale, one reduces, by extension of the base field, to the case where k is algebraically closed. In this case, G is a constant group (cf. I 4.1), and the statement is classical.

If G is infinitesimal and non-zero, k is necessarily of characteristic $p > 0$ (cf. VI_B 1.6.1 or VII_B 3.3.1); the

subgroups $\mathfrak{F}_n G$ then form a composition series of G , whose quotients are of height $\leqslant 1$.

<!-- original page 475 -->

This reduces us to the case where G is of height $\leqslant 1$. Let then A (resp. L) be the affine algebra (resp. the Lie algebra) of G and $U = U_p(L)$. According to 7.4, one has $G = \mathfrak{mathfrak{G}}_p(L)$ whence $A = U^{[*]}$; so if $\dim_k L = r$, the rank of $\mathfrak{G}$ over k is p^r (cf. 5.3.3). We shall therefore study the morphism $\mathfrak{p}_G : G \rightarrow G$ defined by raising to the p -th power; it induces an endomorphism $\mathfrak{p}_A$ of A and, by duality, an endomorphism $\mathfrak{p}_U$ of U .

Let I be the augmentation ideal of A ; we shall show that $\mathfrak{p}_A(I) \subset I^p$. Supposing this established, one will therefore have $\mathfrak{p}_A(I) \subset I^{p^r}$. On the other hand, one knows that $I^{r(p-1)+1} = 0$ (since I is generated by r elements of p -th power zero). Since $p^r > r(p-1)$, it follows that $\mathfrak{p}_A(I) = 0$, so $\mathfrak{p}_G$ is the zero morphism. It therefore remains to show the assertion:

$$\mathfrak{p}_A(I) \subset I^p.$$

For every integer $s \geqslant 1$, we shall denote $\mathfrak{m}_{s-1}^A : A^{\otimes s} \rightarrow A$ (resp. $\Delta_{U^{s-1}} : U \rightarrow U^{\otimes s}$) the map induced by the multiplication $\mathfrak{m}_A$ of A (resp. the comultiplication Δ_U of U). Then $\mathfrak{p}_A$ is equal to the following composition:

$$A \xrightarrow{\Delta_{A^{p-1}}} A^{\otimes p} \xrightarrow{\mathfrak{m}_A^{p-1}} A,$$

and since the transpose of $\mathfrak{m}_A$ (resp. Δ_U) is Δ_U (resp. $\mathfrak{m}_U$), the endomorphism $\mathfrak{p}_U = \mathfrak{p}_A^t$ of U is the following composition:

$$U \xrightarrow{\Delta_U^{p-1}} U^{\otimes p} \xrightarrow{\mathfrak{m}_U^{p-1}} U.$$

[N.D.E-VII_A-85] Let J be the augmentation ideal of U ; one has $U = k_1 \oplus J$ and one will denote by π the projection $U \rightarrow J$ of kernel k_1 . For every integer $s \geqslant 1$, denote $(I^s)^{\perp}$ the orthogonal of I^s in $A^* = U$, i.e., $(I^s)^{\perp}$ is the set of $u \in U$ such that the composition below is zero:

$$I^{\otimes s} \xrightarrow{\mathfrak{m}_A^{s-1}} I \xrightarrow{u} k.$$

Since the transpose of $\mathfrak{m}_A$ is Δ_U , one sees that $(I^s)^{\perp}$ is the vector subspace P_{s-1} formed by the $u \in U$ such that $\Delta_U^{s-1}(u)$ vanishes on $I^{\otimes s}$, i.e., denoting by Δ_U^{s-1} the composition of Δ_U^{s-1} and the projection $\pi^{\otimes s} : U^{\otimes s} \rightarrow J^{\otimes s}$, one obtains that

$$(I^s)^{\perp} = P_{s-1} = \text{Ker } \Delta_U^{s-1}$$

(see also VII B, 1.3.6). So, to prove assertion $(\ast)$, one must show that the transpose map $\mathfrak{p}_U = \mathfrak{p}_A^t$ sends P_{p-1} into $(I^p)^{\perp} = k_1$. Since $\mathfrak{p}_U(1_U) = 1_U$, it suffices to show the assertion below, where P_{p-1}^+ denotes $J \cap P_{p-1}$:

$$\mathfrak{p}_U(P_{p-1}^+) = 0.$$

On the other hand, one shows easily, by induction on s , that P_{s-1}^+ is the vector subspace of U generated by the products $x_1 \cdots x_t$, with $1 \leqslant t \leqslant s-1$ and $x_i \in L$ (cf. VII_B <!-- original page 501 --> 4.3). Now, if $x_1, x_2, \dots, x_t$ are elements of L , one has:

$$\mathfrak{p}_U(x_1 x_2 \cdots x_t) = \mathfrak{m}_U^{p-1}(\prod_{j=1}^t \sum_{i=1}^p x_i^p \otimes 1 \otimes \cdots \otimes x_j \otimes \cdots \otimes 1) \quad (x_j \text{ in position } i)$$

It is clear that the expression $\prod_j \sum_i 1 \otimes \cdots \otimes x_j \otimes \cdots \otimes 1$ is a sum of p^t terms $x_{\{h\}}$ indexed by the maps h from $\{1, \dots, t\}$ into $\{1, \dots, p\}$. [N.D.E-VII_A-86] Such a map h defines an ordered partition $p_{\{h\}}$ of $\{1, \dots, t\}$ into at most p parts. Indeed, denote $i_{\{1\}} < \cdots < i_{\{r\}}$ the elements of the image of h and, for $s = 1, \dots, r$, set $I_{\{s\}} = h^{-1}(i_{\{s\}})$ and $x_{\{I_{\{s\}}\}} = \prod_{j \in I_{\{s\}}} x_j$, the product being taken in increasing order. Then h corresponds to the p -tensor

$$1 \otimes \cdots \otimes x_{\{I_{\{1\}}\}} \otimes \cdots \otimes x_{\{I_{\{r\}}\}} \otimes \cdots \otimes 1$$

(where each $x_{\{I_{\{s\}}\}}$ is in position $i_{\{s\}}$), and its image by m^p_U is the product:

$$x_{\{I_{\{1\}}\}} \otimes \cdots \otimes x_{\{I_{\{r\}}\}}$$

which depends only on the ordered partition $p = \{I_{\{1\}}, \dots, I_{\{r\}}\}$, and which one will denote x_p . For p fixed, x_p is obtained for all choices of $i_{\{1\}} < \cdots < i_{\{r\}}$ in $\{1, \dots, p\}$, and one therefore obtains the equality

$$p_U(x_1 x_2 \cdots x_t) = \sum_p (p \text{ choose } n(p)) x_p,$$

where p ranges over the set of ordered partitions of $\{1, \dots, t\}$ into at most p parts, and where $n(p)$ denotes the number of parts of p . (One has $1 \leq n(p) \leq \min(t, p)$.)

When $t < p$, all the terms $(p \text{ choose } n(p))$ are therefore zero, so that $p_U(x_1 \cdots x_t) = 0$.

<!-- original page 476 --> So p_U vanishes on P^{+}_{p-1} , which proves assertion $(\ast)$, and hence $(\ast)$, and completes the proof of 8.5.

Corollary 8.5.2.

<!-- label: III.VII_A.8.5.2 -->

[N.D.E-VII_A-87] *Let S be a reduced scheme and G a finite locally free S -group of rank n . Then $n_G : G \rightarrow G$ is the zero morphism of G .*

Indeed, let S' be the sum of the $\operatorname{Spec} \mathcal{O}_{\{S, \eta\}}$, for η ranging over the maximal points of S . Since S is reduced, the morphism $S' \rightarrow S$ is schematically dominant, and the same holds for the morphism $f : G_{\{S'\}} \rightarrow G$, since G is finite locally free over S (cf. EGA IV₃, 11.10.5). Since $G \rightarrow S$ is affine, hence separated, the locus of coincidence of n_G and the zero morphism is a closed subscheme of G , and it majorizes f according to 8.5, hence equals G , i.e. n_G is the zero morphism.

Remark 8.5.3.

<!-- label: III.VII_A.8.5.3 -->

Let us also point out that, according to a theorem of P. Deligne (see [T070], p. 4), if G is a commutative finite locally free S -group of rank n over an arbitrary base S , then $n_G = 0$.

[^VII_A-A-1]: Part A of the present Expos   had not been treated seriously in the oral seminars.

[^N.D.E-VII_A-1]: In particular, if X and Y are two S -schemes, $X \times_S Y$ is denoted simply $X \times Y$. Moreover, let us point out that for the content of sections 1 and 2, one may also consult [DG70], § II.4, nos 5–6; see also [Ja03], § I.7.

[^N.D.E-VII_A-2]: One sees easily that this is equivalent to saying that, for every $x \in X$ and $f_0, \dots, f_n \in \mathcal{O}_{X,x}$, one has $(\text{ad } f_0)(\text{ad } f_1) \cdots (\text{ad } f_n)(d_x)(g) = 0$. On the other hand, recall that the adjunction isomorphism

```text  
    : Hom\_{p\_X^{-1}(O\_S)}(O\_X, u\_\*(O\_Y))    Hom\_{p\_Y^{-1}(O\_S)}(u^{-1}(O\_X), O\_Y)  
 ```

associates with every morphism of $p^{-1}_X(X)(O_S)$ -modules $d : O_X \rightarrow u_*(O_Y)$ the morphism $d' = \epsilon \circ u^{-1}(d)$, where ϵ is the canonical morphism $u^{-1}u_*(O_Y) \rightarrow O_Y$. Conversely, for every $p^{-1}_Y(Y)(O_S)$ -morphism $d' : u^{-1}(O_X) \rightarrow O_Y$, one has $\theta^{-1}(d') = u_*(d') \circ \eta$, where η is the canonical morphism $X \rightarrow u_*u^{-1}(O_X)$. It follows that d satisfies $(\text{ad } f_n)$ if and only if d' satisfies:

```text  
 (\*'\_n) (ad f\_0) ... (ad f\_n)(d')(g) = 0  
 ```

for every open V of Y and $f_0, \dots, f_n, g \in u^{-1}(O_X)(V)$.

[^N.D.E-VII_A-3]: If X and u are quasi-compact, every S -deviation of u is therefore of order $\leq n$, for some integer n .

[^N.D.E-VII_A-4]: These remarks have been added, as they will be useful in 1.3, 1.4 and 2.1.

[^N.D.E-VII_A-5]: One will note that with this notation, `de` denotes the composition " d followed by e ".

[^N.D.E-VII_A-6]: Often, one considers only the S -deviations of the morphism id_X , which form the algebra of S -differential operators of X , cf. 1.4 below. However, the more general framework of S -deviations provides a convenient "functorial" language for proving statements such as: "if G is an S -group, the algebra of S -differential operators on G invariant under left translation is isomorphic to the algebra of S -deviations of

the unit section $\epsilon : S \rightarrow G$, cf. 2.1 and 2.4 below."

[^N.D.E-VII_A-7]: This paragraph has been expanded, with the number 1.2.0 (resp. 1.2.1) being assigned to this definition (resp. to the lemma which follows).

[^N.D.E-VII_A-8]: The following has been added, i.e. the notation ∂_t has been introduced.

[^N.D.E-VII_A-9]: Explicitly, if V is an affine open of S and U (resp. U') an affine open of X (resp. T) above V , so that $0_X \times T \rightarrow (U \times U') = 0_X(U) \otimes_{0_S(V)} 0_T(U')$, then $d_T(U \times U')$ is the composition:

$$0_X(U) \otimes_{0_S(V)} 0_T(U') \xrightarrow{d(U) \otimes \text{id}} 0_Y(u^{-1} U) \otimes_{0_S(V)} 0_T(U') \longrightarrow 0_{Y \times T}(u^{-1} U \times U').$$

The author left to the reader the verification that d_T is well-defined, and the editors do the same.

[^N.D.E-VII_A-10]: This paragraph has been expanded with respect to the original; see also N.D.E. (2) in 1.1.1.

[^N.D.E-VII_A-11]: If λ, f are local sections of 0_Y and 0_X , one has $(\Gamma_{e_X})(\lambda \otimes f) = \lambda \otimes e(\bar{1} \otimes g)$, and this equals $e(\lambda \otimes g)$ since e is 0_Y -linear.

[^N.D.E-VII_A-12]: This paragraph has been added.

[^N.D.E-VII_A-13]: In this Exposé, the ring $\Gamma(S, 0_S) = 0_S(S)$ is denoted $\Gamma(0_S)$.

[^N.D.E-VII_A-14]: We have modified the original here, which mentioned the sheaf $U \mapsto \text{Dif}_X(U) / U$, where U ranges over the opens of S ; this is the direct image of $\mathcal{D}_{X/S}$ by the morphism $p_X : X \rightarrow S$.

[^N.D.E-VII_A-15]: Via this isomorphism, the X -derivations of $\Delta_{X/S}$ correspond, according to 1.3.1, to the S -derivations of id_X , i.e., to the $p_X^{-1}(0_S)$ -derivations of 0_X .

[^N.D.E-VII_A-16]: One now says "the algebra of distributions" (at the origin) of G , cf. [DG70], § II.4, 6.1 and [Ja03], I 7.7.

[^N.D.E-VII_A-17]: We have corrected the original, replacing in the diagram $d \times G \times G$ by $G \times d \times G$, so that the composition on the left side of the triangle is $(e \times d) \times G$, and so that the map $d \mapsto d_G$ is an anti-isomorphism of $U(G)$ onto the right-invariant differential operators (cf. 2.3, 2.4 below); on the other hand, by defining $\{ \}_G d$ as the image under m of $G \times d$, one would obtain similarly an isomorphism of $U(G)$ onto the left-invariant differential operators (cf. [DG70], § II.4, Th. 6.5). We have corrected 2.4 and 2.5 accordingly.

[^N.D.E-VII_A-18]: It would be preferable to call this a *left action*. Indeed, let for example d be an S -derivation of the origin; according to 1.2.1, d is the composition of the S -derivation $(\tau, \partial_t) : S \rightarrow I_S$ and a morphism $x : I_S \rightarrow G$ such that $x \circ \tau = \epsilon$ (i.e. $x \in \text{Lie}(G/S)(S)$), and then d_G is the derivation of 0_G which sends a local section ϕ to the section $g \mapsto \partial_t \phi(xg)$. Moreover, with this terminology, one could say: "the left action commutes with right translations".

[^N.D.E-VII_A-19]: We have corrected "isomorphism" to "anti-isomorphism", and added assertion (ii), cf. N.D.E. (17).

[^N.D.E-VII_A-20]: i.e., G acts on itself on the left by right translations.

[^N.D.E-VII_A-21]: In what follows, we have corrected the original, which referred to the square formed by the morphisms p, p, ϵ , and p_{r1} , instead of $\epsilon, \epsilon, \Delta$ and p .

[^N.D.E-VII_A-22]: In this paragraph, we have modified the order, beginning by defining the map $\alpha : \text{Lie}(G) \rightarrow U(G)$, and we have corrected the original as indicated in N.D.E. (17).

[^N.D.E-VII_A-23]: In this Exposé, if G (resp. X) is an S -group scheme (resp. an S -scheme), the "Lie algebra" $\text{Lie}(G)$ (resp. $\text{Lie}(\text{Aut}(X))$) denotes, with the notations of Exposé II, $\text{Lie}(G/S)(S)$ (resp. $\text{Lie}(\text{Aut}_S(X/S)(S))$; it is a $\Gamma(0_S)$ -Lie algebra, according to II, 4.11 and 3.14.

[^N.D.E-VII_A-24]: See also II, 4.11.

[^N.D.E-VII_A-25]: There are examples of Lie algebras $\mathfrak{g}$ over a ring A , such that the map $\mathfrak{g} \rightarrow U(\mathfrak{g})$ is not injective, cf. [BLie], § I.2, Ex. 9. The above result shows (since α factors through $\text{Lie}(G) \rightarrow U(\text{Lie}(G)) \rightarrow U(G)$) that this cannot happen for "algebraic" Lie algebras, i.e., of the form $\text{Lie}(G)$, where G is an A -group scheme.

[^N.D.E-VII_A-26]: One also says "cogebra", cf. [BAlg], III § 11.1. On the other hand, one will note that in this Exposé (as well as in VII_B), we place ourselves in the category of cocommutative coalgebras (i.e., those satisfying condition (i)), which is crucial for defining the product and the notion of group coalgebra (cf. 3.1.0 and 3.2).

[^N.D.E-VII_A-27]: We have added the numbering 3.1.0, for later references.

[^N.D.E-VII_A-28]: The following has been added. Let us also recall that, to show that $U \otimes V$ is indeed the product of U and V in the category of cocommutative 0_S -cogbras, one verifies that if one has an arbitrary 0_S -cogebra E and morphisms of cogbras $f : E \rightarrow U$ and $g : E \rightarrow V$, then every morphism of cogbras $\phi : E \rightarrow U \otimes V$ such that $\text{pr}_U \circ \phi = f$ and $\text{pr}_V \circ \phi = g$ is necessarily equal to $(f \otimes g) \circ \Delta$, and this is a morphism of cogbras if and only if it equals $(g \otimes f) \circ \Delta$.

[^N.D.E-VII_A-29]: For every $x \otimes y \in \Gamma(T, U_T) \otimes_{0(T)} \Gamma(T, U_T)$, its image in $\Gamma(T, U_T) \otimes_{0_T} U_T$ is again denoted $x \otimes y$.

[^N.D.E-VII_A-30]: We have added the numbering 3.1.2.1, for later references. Note moreover that the $\text{Spec}^* U$ is a sheaf for the Zariski topology (and even for the (fpqc) topology if U is a quasi-coherent 0_S -module).

[^N.D.E-VII_A-31]: i.e. endowed with the multiplication $m'_U = m_U \circ \sigma$.

[^N.D.E-VII_A-32]: We have added this scholium, implicit in the original.

[^N.D.E-VII_A-33]: The group $\text{Spec}^* U(\mathcal{L})$ is not representable in general, but one will see later (5.5) that if S is a scheme of characteristic p , if $\mathcal{L}$ is finite locally free over 0_S and if $U_p(\mathcal{L})$ is its restricted enveloping algebra (cf. 5.3), then $\text{Spec}^* U_p(\mathcal{L})$ is represented by a finite and locally free S -group.

[^N.D.E-VII_A-34]: We have expanded this paragraph.

[^N.D.E-VII_A-35]: Note that the second condition is a consequence of the first, since the first entails that $u = (\text{id} \otimes \varepsilon) \Delta(u) = u + \varepsilon(u)$, whence $\varepsilon(u) = 0$.

[^N.D.E-VII_A-36]: The structure of 0_S -module on $\text{Lie } G$ is defined in II, Prop. 3.6.

[^N.D.E-VII_A-37]: We have added this proposition, which summarizes the preceding discussion.

[^N.D.E-VII_A-39]: We have added the numbering 4.0, for later references.

[^N.D.E-VII_A-40]: i.e. for every morphism of $\mathbb{F}_p$ -schemes $f : Y \rightarrow X$, the diagram below is commutative:

```

```text
 f
 Y ----> X
fr(Y) fr(X)
 f
 Y ----> X.
```

```

[^N.D.E-VII_A-41]: One says that $\text{fr}(X)$ is the "absolute" Frobenius morphism of X , to distinguish it from the "relative" Frobenius morphism $\text{Fr}(X/S)$ introduced below.

[^N.D.E-VII_A-42]: We have expanded the original in what follows.

[^N.D.E-VII_A-43]: We have expanded the original in what follows.

[^N.D.E-VII_A-45]: For the content of nos 4.2 and 4.3, one may also consult [DG70], § IV.3, nos 4–6.

[^N.D.E-VII_A-46]: In the original, this morphism (resp. the relative Frobenius morphism) was denoted F' (resp. F).

[^VII_A-4-1]: D. Lazard, C. R. Acad. Sc. Paris 258, 1964, p. 6313–6316.

[^N.D.E-VII_A-47]: See also: D. Lazard, Bull. Soc. Math. France 97 (1969), 81–128, or: [BAlg], X § 1.6, Th. 1.

[^N.D.E-VII_A-48]: Since this does not appear explicitly in VII_B, one refers to [DG70], § IV.3, Prop. 4.11.

[^N.D.E-VII_A-49]: We have modified the order, by first introducing the objects appearing in the diagram that follows.

[^N.D.E-VII_A-50]: See also [DG70], § IV.3, 4.9.

[^N.D.E-VII_A-51]: cf. P. Cartier, Exemples d'hyperalgèbres, Sémin. Sophus Lie 1955/56, Exp. 3 (accessible on the Numdam site: <http://www.numdam.org>).

[^N.D.E-VII_A-52]: We have inserted the explanation that follows, taken from [DG70], § II.7, 3.2.

[^N.D.E-VII_A-53]: In this paragraph, we have modified the order, first stating the result, then detailing the proof.

[^N.D.E-VII_A-54]: i.e., $x \cdot \pi^1 = x \cdot \pi^{r^p}$ and $r \cdot (x \cdot \pi^1) = x \cdot \pi^1 \cdot r$, for $x \in \mathfrak{g}$, $r \in R$.

[^N.D.E-VII_A-55]: i.e. $\Delta_\square(x) = x \otimes 1 + 1 \otimes x$ for every $x \in \mathfrak{g}$; in particular, the comultiplication $\Delta_\square$ is indeed cocommutative ...

[^N.D.E-VII_A-56]: We have transformed § 5.4.1 of the original into this § 5.5: on the one hand, Proposition 5.5.1 combines the results of Section 5 and Proposition 3.2.3 and contains Lemma 7.3 of the original; on the other hand, the proof of 5.5.3 (ii) takes up, in expanded form, that of the implication (i) $\Rightarrow$ (ii) in Theorem 7.4 below.

[^N.D.E-VII_A-57]: One can also show directly (without the intermediary of $\mathrm{Dif}(G/S)$) that the Lie algebra of derivations of G at the origin (isomorphic to $\mathrm{Lie}(G/S)(S)$ according to 2.5) is stable under raising to the p -th power in $U(G)$: this is done in 6.2 below.

[^N.D.E-VII_A-58]: We have expanded the original in what follows.

[^N.D.E-VII_A-59]: We have corrected xx to y' .

[^N.D.E-VII_A-60]: We have added the numbering 6.4.5, and expanded the original.

[^N.D.E-VII_A-61]: For the results of this section, one may also consult [DG70], § II.7, nos 3-4.

[^N.D.E-VII_A-62]: We have added this definition (cf. [DG70], § II.4, 7.1), which will be used in 7.2.1.

[^N.D.E-VII_A-63]: We have simplified the original, taking into account the additions made in 5.5.

[^N.D.E-VII_A-64]: We have expanded the original in what follows. For another proof, see [DG70], § II.7, 3.9.

[^N.D.E-VII_A-65]: We have expanded the original in what follows.

[^N.D.E-VII_A-66]: In what follows, we have expanded (and simplified) the original, taking into account VI_B, 11.6.1.

[^N.D.E-VII_A-67]: We have added the following. (The original indicated "the case of $\mathcal{W}(\mathcal{F})$ is analogous").

[^N.D.E-VII_A-68]: In order not to modify the numbering, the statement 7.3 has been preserved, although it has been included, with its proof, in 5.5.1.

[^N.D.E-VII_A-69]: If G is affine over S and if $\mathcal{I}$ denotes the augmentation ideal of $\mathcal{A}(G)$, then $\mathcal{I}' / \mathcal{I}^2$ is identified with $\epsilon^*_{\mathcal{I}}(\mathcal{I} / \mathcal{I}^2)$, cf. loc. cit.

[^N.D.E-VII_A-70]: We have added the following sentence.

[^N.D.E-VII_A-71]: We have added, on the one hand, assertion (i'), implicit in the original, and on the other hand, assertions (iii') and (iv), pointed out by O. Gabber; assertion (iv) takes up a footnote of the original, which

indicated: "The condition on $\omega_{G/S}$ is in fact useless, as one sees easily by reducing to the case where S is local with residue field k , and applying the theorem to the case of the group G_k ". As pointed out by Gabber, this is inaccurate without a flatness hypothesis: if A is an Artinian local ring of characteristic $p > 0$ and J a proper non-zero ideal of A , let H be the subgroup $\operatorname{Spec} A[x] / (x^p, Jx)$ of $\alpha_p(A)$ (i.e. for every A -algebra R , $H(R) = \{x \in R \mid x^p = 0 \text{ and } Jx = 0\}$), then H is not flat over A so is not of the form $\mathcal{G}_p(\mathcal{L})$, where $\mathcal{L}$ is a free p -Lie algebra of finite rank over A .

[^N.D.E-VII_A-72]: We have expanded (and simplified) the original in what follows.

[^N.D.E-VII_A-73]: We have added this paragraph to prove that (iv) $\Rightarrow$ (iii), cf. N.D.E. (71).

[^N.D.E-VII_A-74]: We have added this remark.

[^N.D.E-VII_A-75]: We have added the numbering 8.1.1 to 8.1.3, to highlight the results stated there.

[^N.D.E-VII_A-76]: We have expanded what follows, as well as the proof of the corollary below.

[^N.D.E-VII_A-77]: Moreover, according to VI_A, 3.2, $\mathcal{G}_p(\mathcal{L}_2)$ represents the (fppf) sheaf quotient of $\mathcal{G}_p(\mathcal{L}_1)$ by $\mathcal{G}_p(\mathcal{L}_0)$.

[^N.D.E-VII_A-78]: We have added this remark, pointed out by O. Gabber, which will be useful in 8.3.1.

[^N.D.E-VII_A-79]: i.e. π is faithfully flat and ι is an isomorphism of G' onto $\operatorname{Ker} \pi$, so that G' represents the (fppf) sheaf quotient of G by G' , cf. VI_A, 3.2 and 5.2.

[^N.D.E-VII_A-80]: We have replaced "algebraic" by "locally of finite type".

[^N.D.E-VII_A-81]: We have made explicit the equivalence between (ii) and (iii) and we have expanded the proof.

[^N.D.E-VII_A-82]: We have changed in the statement "étale at the origin" to "étale", and we have added the following sentence.

[^N.D.E-VII_A-83]: We have expanded the original in what follows.

[^N.D.E-VII_A-84]: We have added this corollary, indicated implicitly in the original by: "(confer 8.4)". For another proof of the corollary, not using 8.5, see for example [T070], Lemma 5.

[^N.D.E-VII_A-85]: We have expanded the original in the paragraph that follows.

[^N.D.E-VII_A-86]: We have expanded the original in what follows, replacing the notion of preorder by the equivalent notion of ordered partition.

[^N.D.E-VII_A-87]: We have added this corollary, signaled in Exp. VIII, Remark 7.3.1.

[^N.D.E-VII_A-44]: $\mathcal{A} \otimes_{\pi} 0_S$ denotes the 0_S -algebra obtained by extension of scalars $\pi : 0_S \rightarrow 0_S$, i.e., one has: $a \otimes_{\pi} 1 = a \otimes_{\pi} x^p$, and $x \cdot (a \otimes_{\pi} 1) = a \otimes_{\pi} x$.

<!-- SOURCE: 07B-etude-infinitesimale-groupes-formels.md -->

Exposé VII_B. Infinitesimal study: formal groups

<!-- label: III.VII_B -->

by P. Gabriel

B) Formal groups

<!-- original page 477 -->

[^N.D.E-VII_B-0]

The study of formal groups is usually of extreme simplicity. If this does not appear clearly in the pages that follow,

the responsibility lies with an arithmetician who claims to know formal groups over "something other than fields".^[^N.D.E-VII_B-1] We have therefore unrolled, for formal groups "locally free over inverse limits of artinian rings", the generalities one ordinarily states for formal groups defined over a field. For a more detailed study of the latter, we refer the reader to the 1964/65 algebraic geometry seminar of Heidelberg–Strasbourg.^[^N.D.E-VII_B-2]

0. Reminders on pseudocompact rings and modules

<!-- label: III.VII_B.0 -->

This paragraph contains a few technical preliminaries; we recall and complete in it some results from [CA] (*Des catégories abéliennes*, Bull. Soc. Math. France 90, 1962).

0.1.

<!-- label: III.VII_B.0.1 -->

A **left pseudocompact ring** is a topological ring with unit element, separated and complete, which possesses a basis of neighborhoods of 0 consisting of left ideals $\mathcal{I}$ of finite colength (i.e. $\text{length}_A(A/\mathcal{I}) < +\infty$). We shall assume here that A is commutative, <!-- original page 478 --> so that there is no need to distinguish "between left and right".

In particular, the quotients $A/\mathcal{I}$ are artinian rings and A is identified with the topological inverse limit of these rings, each endowed with the discrete topology.

A complete noetherian local ring $(A, \mathfrak{m})$ is obviously pseudocompact.^[^N.D.E-VII_B-3]

0.1.1.

<!-- label: III.VII_B.0.1.1 -->

Every closed ideal $\mathcal{I}$ of A is the intersection of the open ideals containing it.^[^N.D.E-VII_B-4] Every closed maximal ideal is therefore open. Moreover, if $\mathcal{I}$ is an open ideal of A , the maximal ideals of $A/\mathcal{I}$ are in bijective correspondence with the maximal ideals $\mathfrak{m}$ of A containing $\mathcal{I}$; these are therefore both open and closed. Consequently, every closed maximal ideal is an open (and hence closed) maximal ideal; the converse being evident. We denote by $\mathcal{U}(A)$ the set of these ideals.

If $\mathcal{I}$ is an open ideal of A and if $\mathfrak{m} \in \mathcal{U}(A)$, the localization $(A/\mathcal{I})_{\mathfrak{m}}$ is therefore a local ring if $\mathfrak{m}$ contains $\mathcal{I}$ and zero otherwise. Since the ring $A/\mathcal{I}$ is artinian, it is a direct product of finitely many local rings, which one can write

```
```text
A/𝐼 = ∏_{𝐼 ∈ Y(A)} (A/𝐼)_{𝐼}.
```

From this one deduces "canonical" isomorphisms

```
```text
A ≅ lim_{←} (A/𝐼) = lim_{←} ∏_{𝐼 ∈ Y(A)} (A/𝐼)_{𝐼} = ∏_{𝐼 ∈ Y(A)} lim_{←} (A/𝐼)_{𝐼} = ∏_{𝐼 ∈ Y(A)} A_{𝐼},
```

where one has set

```
$$
A_{\mathfrak{m}} = \varprojlim_{\mathcal{I} \in Y(A)} (A/\mathcal{I})_{\mathfrak{m}}.
$$
```

This local component $A_{\mathfrak{m}}$ is a filtered inverse limit of artinian local rings, endowed with the discrete topology; it is therefore a local ring which is pseudocompact for the inverse-limit topology.^[^N.D.E-VII_B-5]

<!-- original page 479 -->

0.1.2.

<!-- label: III.VII_B.0.1.2 -->

Let $r(A)$ be the intersection of the open maximal ideals of A , that is, the cartesian product of the ideals $\mathfrak{A}_{\mathfrak{m}}$ when one identifies A with $\prod \mathfrak{A}_{\mathfrak{m}}$. For every open ideal $\mathcal{I}$ of A , the image of $r(A)$ in $A/\mathcal{I}$ is contained in the radical of $A/\mathcal{I}$. Some power of this image is therefore zero, so that $r(A)^n$ is contained in $\mathcal{I}$ when n is large enough. The sequence of $r(A)^n$ therefore tends to 0 .

The same holds for the sequence of x^n , when x belongs to $r(A)$. In other words, every element of $r(A)$ is topologically nilpotent and the converse is clear. It follows that the sequence with general term $1 + x + \dots + x^n$ is convergent and converges to $1/(1 - x)$ when $x \in r(A)$. This shows that $r(A)$ is the Jacobson radical of A , i.e., the intersection of all maximal ideals of A (cf. Bourbaki, *Algèbre*, Chap. 8, § 6, th. 1). [N.D.E-VII_B-6]

Remarks. [N.D.E-VII_B-7] a) If $\mathfrak{p}$ is an open prime ideal of A , then since $A/\mathfrak{p}$ is artinian, $\mathfrak{p}$ is a maximal ideal. Consequently, $\mathcal{U}(A)$ equals the set of open prime ideals of A .

b) Each $\mathfrak{A}_{\mathfrak{m}}$ is an ideal of definition of $A_{\mathfrak{m}}$, i.e. an open ideal I such that the sequence of I^n tends to 0 (cf. EGA 0_I, 7.1.2). Consequently, $\operatorname{Spec}(A_{\mathfrak{m}} / \mathfrak{A}_{\mathfrak{m}})$, endowed with the topological ring $A_{\mathfrak{m}}$, is an affine formal scheme in the sense of (EGA I, 10.1.2).

c) The topological ring A is *admissible* in the sense of (EGA 0_I, 7.1.2) if and only if $r(A)$ is open (hence an ideal of definition), and this is the case if and only if $\mathcal{U}(A)$ is finite. In this case, the affine formal scheme $\operatorname{Spf}(A) = \operatorname{Spec}(A / r(A))$ (cf. EGA I, 10.1.2) has $\mathcal{U}(A)$, endowed with the discrete topology, as underlying space, and its structure sheaf has as ring of sections on a subset E of $\mathcal{U}(A)$ the product $\prod_{\mathfrak{m} \in E} \mathfrak{A}_{\mathfrak{m}}$.

d) Let A be an arbitrary pseudocompact ring. In 1.1 below, the space $\mathcal{U}(A)$ is endowed with the discrete topology and with the sheaf of rings whose ring of sections on any subset E is $\prod_{\mathfrak{m} \in E} \mathfrak{A}_{\mathfrak{m}}$. By b), every point then admits an open neighborhood which is an affine formal scheme, so this defines a formal scheme (EGA I, 10.4.2), which we shall denote $\operatorname{Spf}(A)$. (For this formal scheme to be affine, it must be quasi-compact, hence $\mathcal{U}(A)$ must be finite; in this case, $\operatorname{Spf}(A)$ coincides with the definition of (EGA I, 10.1.2)).

0.1.3.

<!-- label: III.VII_B.0.1.3 -->

If A and B are two pseudocompact rings, a *homomorphism* from A to B is, by definition, a continuous map compatible with addition, multiplication, and the unit elements. Such a homomorphism sends a topologically nilpotent element of A to a topologically nilpotent element of B ; it therefore maps the radical $r(A)$ of A into the radical $r(B)$ of B .

0.2.

<!-- label: III.VII_B.0.2 -->

Let A be a (commutative) pseudocompact ring. A *pseudocompact A -module* M is a topological A -module, separated and complete, which possesses a basis of neighborhoods of 0 consisting of submodules M' such that M/M' is of finite length over A .

If M and N are two pseudocompact A -modules, a *morphism* from M to N is by definition a continuous A -linear map. We shall denote by $\operatorname{Hom}_{\mathcal{C}}(M, N)$ the group of these morphisms.

<!-- original page 480 -->

Proposition 0.2.B. [N.D.E-VII_B-8] (i) The pseudocompact A -modules form an abelian category, which we shall denote $\operatorname{PC}(A)$. (In particular, for every morphism $f : M \rightarrow N$, $\operatorname{Im}(f)$ is a complete submodule, hence closed in N).

(ii) The pseudocompact A -modules of finite length (whose topology is therefore discrete) form a system of cogenerators of $\operatorname{PC}(A)$.

(iii) Infinite products and filtered inverse limits are exact, i.e., $\operatorname{PC}(A)$ satisfies axiom (AB5*). [N.D.E-VII_B-9]

<!-- label: III.VII_B.0.2.B -->

For the convenience of the reader, let us briefly indicate the steps of the proof. First, one has the following lemma ([CA] § IV.3, Lemma 1; for the proof, see [BEns], III, § 7.4, th. 1 and example 2):

Lemma 0.2.C. Let B be a ring, I a filtered ordered set, (M_i) and (N_i) two inverse systems of left B -modules indexed by I . Let (s_i) be a morphism of inverse systems $(M_i) \rightarrow (N_i)$, such that s_i is surjective with artinian kernel for every i . Then the map

$$\lim_{\leftarrow} s_i : \lim_{\leftarrow} M_i \rightarrow \lim_{\leftarrow} N_i$$

is surjective.

Proof. (label: III.VII_B.0.2.C -->)

Corollary 0.2.D. ([CA] § IV.3, Prop. 10 & 11). Let M be a pseudocompact A -module.

(i) Let K be a closed submodule of M . Then M/K , endowed with the quotient topology, is a pseudocompact A -module.

(ii) Let (M_i) be a filtered decreasing family of closed submodules of M .

(a) The canonical map $M \rightarrow \lim_{\leftarrow} M/M_i$ is surjective and has kernel $\bigcap_i M_i$.

(b) For every closed submodule N of M , one has $N + \bigcap_i M_i = \bigcap_i (N + M_i)$.

Proof. (label: III.VII_B.0.2.D -->)

Proof. Let (L_j) be the filtered decreasing family of open submodules of M . We endow M/K with the quotient topology, i.e. a basis of neighborhoods of 0 is formed by the open submodules $(K + L_j)/K$. Since K is closed, it equals the intersection of the $K + L_j$, so the map

$$\tau : M/K \rightarrow \lim_{\leftarrow} M/(K + L_j)$$

is injective. It is also open, the right-hand side being the inverse limit of the discrete modules $M/(K + L_j)$. Moreover, for each j , the map $t_j : M/L_j \rightarrow M/(K + L_j)$ is surjective with artinian kernel, so by the preceding lemma, the map t in the commutative diagram below is surjective:

$$\begin{array}{ccc} M & \xrightarrow{p} & \lim_{\leftarrow} M/L_j \\ \downarrow \tau & & \downarrow t \\ M/K & \xrightarrow{p} & \lim_{\leftarrow} M/(K + L_j). \end{array}$$

Since p is an isomorphism because M is complete, it follows that τ is surjective, hence is an isomorphism. This proves (i).

Proof. (original page 507 -->)

Let us prove (ii)(a). By what precedes, one has for every i an isomorphism $M/M_i \xrightarrow{\sim} \lim_{\leftarrow} M/(M_i + L_j)$, and so the two horizontal arrows in the commutative diagram below are isomorphisms:

$$\begin{array}{ccc} M & \xrightarrow{p} & \lim_{\leftarrow} M/L_j \\ \downarrow g & & \downarrow s \\ \lim_{\leftarrow} M/M_i & \xrightarrow{p} & \lim_{\leftarrow} M/(M_i + L_j). \end{array}$$

Moreover, for each j , the family of submodules $(M_i + L_j)/L_j$ admits a smallest element, since M/L_j is

artinian, so the morphism $s_{\{j\}} : M/L_{\{j\}} \rightarrow \varprojlim_i M/(L_{\{j\}} + M_{\{i\}})$ is surjective; therefore, by the preceding lemma, s is surjective. It follows that g is surjective. Finally, the kernel of g is the inverse limit of the $M_{\{i\}}$, i.e. their intersection. This proves part (a).

Let us deduce part (b) from it. Since N is a closed submodule (hence separated and complete), it is a pseudocompact module for the topology induced by that of M . Therefore, by (a), the morphisms f and g in the commutative exact diagram below are surjective:

$$\begin{array}{ccccccc} 0 & \rightarrow & N & \xrightarrow{f} & M & \xrightarrow{g} & M/N \rightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \rightarrow & \varprojlim_i N/(N \cap M_{\{i\}}) & \rightarrow & \varprojlim_i M/M_{\{i\}} & \rightarrow & \varprojlim_i M/(N + M_{\{i\}}). \end{array}$$

Then, by the "snake lemma", the sequence $0 \rightarrow \text{Ker } f \rightarrow \text{Ker } g \rightarrow \text{Ker } h \rightarrow 0$ is exact, and the equality $N + \bigcap_i M_{\{i\}} = \bigcap_i (N + M_{\{i\}})$ follows.

We can now prove Proposition 0.2.B. Let $f : M \rightarrow N$ be a morphism of pseudocompact A -modules. Then $K = \text{Ker}(f)$ is a closed submodule of M , hence separated and complete, so K is a pseudocompact module for the topology induced by that of M . By 0.2.D (i), M/K endowed with the quotient topology is pseudocompact.

Let us show that the continuous bijective morphism $M/K \rightarrow \text{Im}(f)$ is bicontinuous. Identifying M/K with $\text{Im}(f)$, it suffices to show that the quotient topology Q is finer than the topology T induced by that of N . Let $(L_{\{j\}})$ (resp. $(N_{\{i\}})$) be the filtered decreasing family of open submodules of M (resp. N) and set $N'_{\{i\}} = N_{\{i\}} \cap \text{Im}(f)$. Let $P = (K + L_{\{j\}})/K$ be a submodule of M/K open for Q . Since $M/(K + L_{\{j\}})$ is artinian, the family $N'_{\{i\}} + P$ has a smallest element $N'_{\{i_0\}} + P$. Since the $N'_{\{i\}}$ are open, hence closed, for T and hence also for Q , it follows from 0.2.D (ii) (b) that

$$N'_{\{i_0\}} + P = \bigcap_i (N'_{\{i\}} + P) = P + \bigcap_i N'_{\{i\}} = P,$$

whence $N'_{\{i_0\}} \subset P$. This shows that P is open for T , and $M/K \rightarrow \text{Im}(f)$ is therefore an isomorphism of pseudocompact modules.

In particular, $\text{Im}(f)$ is complete for T , hence closed in N . Then, by 0.2.D (i) again, $\text{Coker}(f)$ endowed with the quotient topology is pseudocompact. This proves that $\text{PC}(A)$ is an abelian category.

On the other hand, arbitrary inverse limits exist in $\text{PC}(A)$: if $(M_{\{i\}})$ is an inverse system of pseudocompact modules, the inverse limit of the $M_{\{i\}}$ has as underlying module the inverse limit of the underlying modules, with the inverse-limit topology. Moreover, if one has a family of exact sequences in $\text{PC}(A)$:

$$0 \rightarrow K_{\{i\}} \rightarrow M_{\{i\}} \rightarrow Q_{\{i\}} \rightarrow 0,$$

<!-- original page 508 -->

then the sequence $0 \rightarrow \prod_i K_{\{i\}} \rightarrow \prod_i M_{\{i\}} \rightarrow \prod_i Q_{\{i\}} \rightarrow 0$ is exact. Point (iii) of 0.2.B follows, since in any abelian category where arbitrary products exist, conditions (a) and (b) of 0.2.D are equivalent and equivalent to the exactness of filtered inverse limits (cf. [Mi65], III 1.2–1.9 or [Po73], Chap. 2, Th. 8.6).

Finally, every pseudocompact module M is a submodule of the product $\prod_L M/L$, where L ranges over the open submodules of M , so the objects of finite length form a system of cogenerators of $\text{PC}(A)$. (Moreover, every object of length n is isomorphic to a quotient A^n / L , where L is an open submodule of A^n of colength n ; these quotients therefore form a set of cogenerators.) This completes the proof of 0.2.B.

[^N.D.E-VII_B-10] Let (Ab) be the category of abelian groups and $\text{LF}(A)$ the full subcategory of $\text{PC}(A)$ formed by the objects of finite length. For every object M of $\text{PC}(A)$, denote by h^M_c the functor:

$$\text{LF}(A) \rightarrow (\text{Ab}), \quad N \mapsto \text{Hom}_c(M, N).$$

By [CA], § II.4, th. 1, Lemma 4 and Cor. 1, one has the following results.[^N.D.E-VII_B-11]

Proposition 0.2.E. *The functor $M \mapsto h^M_c$ is an anti-equivalence of $PC(A)$ onto the category $\text{Lex}(LF(A), (Ab))$ of left-exact functors $LF(A) \rightarrow (Ab)$.*

<!-- label: III.VII_B.0.2.E -->

Corollary 0.2.F. *(i) An object P of $PC(A)$ is projective if and only if the functor h^P_c is exact (i.e., if and only if the functor $\text{Hom}_c(P, -)$ is exact on $LF(A)$).*

*(ii) Let (M_i) be a filtered inverse system[^N.D.E-VII_B-12] of objects of $PC(A)$. For every object N of $LF(A)$, one has a functorial isomorphism in N :

```text  
Hom\_c(lim M\_i, N) = colim Hom\_c(M\_i, N).  
```

(iii) Every filtered inverse limit and every product[^N.D.E-VII_B-12] of projective objects of $PC(A)$ is a projective object of $PC(A)$.

<!-- label: III.VII_B.0.2.F -->

Finally, one deduces from 0.2.F the

Corollary 0.2.G. *Let $(M_i)_{i \in I}$ be a family of objects of $PC(A)$. Then $\prod_{i \in I} M_i$ is projective if and only if each M_i is.*

<!-- label: III.VII_B.0.2.G -->

<!-- original page 509 -->

Indeed, for every $N \in \text{Ob } LF(A)$, one has
 $\text{Hom}_c(\prod_{i \in I} M_i, N) \cong \bigoplus_{i \in I} \text{Hom}_c(M_i, N)$.

0.2.1.

<!-- label: III.VII_B.0.2.1 -->

Each local component $A_{\mathfrak{m}}$ of A is a direct factor of A , hence a projective object of $PC(A)$ (A is manifestly projective). Moreover, $A_{\mathfrak{m}}$ has $S_{\mathfrak{m}} = A_{\mathfrak{m}} / \mathfrak{m} A_{\mathfrak{m}}$ as its unique simple quotient, hence is indecomposable. On the other hand, every simple object of $PC(A)$ is isomorphic to a unique $S_{\mathfrak{m}}$. By [CA], IV § 3, Cor. 1 of th. 3,[^N.D.E-VII_B-13] one therefore has:

Proposition. *(i) Every projective object of $PC(A)$ is a direct product of indecomposable projective objects, uniquely determined (up to isomorphism).*

(ii) Every indecomposable projective object is isomorphic to a unique $A_{\mathfrak{m}}$ ($\mathfrak{m} \in \text{Upsilon}(A)$).

Definition. *A pseudocompact A -module M is said to be topologically free if it is isomorphic to the product of a family (A_i) of copies of A .*

In this case, a family (m_i) of elements of M is called a pseudobasis of M if the A -linear maps from A_i into M sending the unit element of A_i to m_i extend to an isomorphism of $\prod A_i$ onto M .

0.2.2.

<!-- label: III.VII_B.0.2.2 -->

[^N.D.E-VII_B-14] If M is a pseudocompact A -module, we shall denote by M^+ the A -module (without topology) $\text{Hom}_c(M, A)$.

Conversely, if N is an A -module, we denote by $N^+ = \text{Hom}_c(A, N)$ its dual, endowed with the topology of pointwise convergence, i.e., a basis of neighborhoods of 0 in N^+ is formed by the following

submodules, where $x \in N$ and $\mathcal{I}$ is an open ideal of A :

```
```text
V(x, I) = {f ∈ N* | f(x) ∈ I}.
```

This makes  $N^*$  a pseudocompact  $A$ -module. Indeed, one sees first that if  $N = A$ , then  $N^* = A$ , endowed with its topology of pseudocompact ring, and if  $N$  is a free module  $A^{(I)}$ , then  $N^*$  is the product  $A^I$ , endowed with the product topology. On the other hand, for every morphism  $\phi : N_1 \rightarrow N_2$ , the transposed morphism  $\phi^t : N_2^* \rightarrow N_1^*$  is continuous, since the inverse image under  $\phi^t$  of a submodule  $V(x_1, \mathcal{I})$  of  $N_1^*$  is nothing but the submodule  $V(\phi(x_1), \mathcal{I})$  of  $N_2^*$ . Then, for arbitrary  $N$ , taking a presentation

```
```text
A^{(J)} \xrightarrow{\phi} A^{(I)} \rightarrow N \rightarrow 0,
```

one sees that N^* is the kernel of the continuous morphism $\phi^t : A^I \rightarrow A^J$, so N^* is pseudocompact.

When A is artinian (in which case one can take $\mathcal{I} = 0$ above), one deduces from 0.2.F:

<!-- original page 481 -->

Proposition. When A is artinian, the functors

```
```text
P ↦ P^+ and Q ↦ Q^*,
```

where  $P$  (resp.  $Q$ ) is a projective object of  $\text{PC}(A)$  (resp. a projective  $A$ -module), establish an anti-equivalence between the category of projective pseudocompact  $A$ -modules and that of projective  $A$ -modules. [N.D.E-VII\_B-15]

In particular, when  $A$  is a field  $k$ ,  $P \mapsto P^+$  is an anti-equivalence between the category of all pseudocompact  $k$ -modules (one also speaks of *linearly compact*  $k$ -vector spaces) and that of  $k$ -vector spaces. [N.D.E-VII\_B-16]

### 0.3.

<!-- label: III.VII\_B.0.3 -->

[N.D.E-VII\_B-17] Let  $L$  and  $M$  be two pseudocompact  $A$ -modules. The functor

```
```text
LF(A) → (Ab),      N ↦ Bil_c(L × M, N),
```

where $\text{Bil}_c(L \times M, N)$ denotes the abelian group of continuous A -bilinear maps from $L \times M$ into N , is left exact.

By 0.2.E, there therefore exists a pseudocompact A -module $L \hat{\otimes}_A M$, unique up to unique isomorphism, which represents this functor, i.e. such that one has a functorial isomorphism, for every object N of $\text{LF}(A)$:

```
```text
Hom_c(L \hat{\otimes}_A M, N) \cong Bil_c(L × M, N).
```

<!-- original page 482 -->

Moreover,  $L \hat{\otimes}_A M$  is identified with the inverse limit  $P$  of the (discrete)  $A$ -modules  $(L/L') \otimes_A (M/M')$ , where  $L'$  and  $M'$  range respectively over the open submodules of  $L$  and  $M$ .

Indeed, let  $\phi : L \times M \rightarrow N$  be a continuous bilinear map of  $L \times M$  into an  $A$ -module (discrete) of finite length  $N$ . By Lemma 0.3.1 below, there exist open submodules  $L'$  and  $M'$  of  $L$  and  $M$  such that  $\phi(L' \times M') = \{0\}$ . This means that the map  $\bar{\phi} : L \otimes_A M \rightarrow N$ , which is induced by  $\phi$ , is of the form  $\bar{\phi} = p \circ \phi$ , where  $p$  is the canonical projection of  $L \otimes_A M$  onto

$(L/L') \otimes_A (M/M')$ . If one denotes by  $\hat{\phi}$  the composite:

```
```text
P → (L/L') ⊗_A (M/M') → N,
```

one sees that the map $\phi \mapsto \hat{\phi}$ is a functorial bijection of $\text{Bil}_c(L \times M, N)$ onto $\text{Hom}_c(P, N)$, whence $P \simeq L \otimes_A M$.

The pseudocompact module $L \otimes_A M$ is therefore the separated completion of $L \otimes_A M$ for the linear topology defined by the kernels of the canonical projections of $L \otimes_A M$ onto $(L/L') \otimes_A (M/M')$, and it will be called the *completed tensor product* of L and M .

If x and y belong to L and M , the image of $x \otimes y$ in $L \otimes_A M$ will be denoted $x \otimes y$.

0.3.1.

<!-- label: III.VII_B.0.3.1 -->

Lemma 0.3.1. Let L , M and N be pseudocompact A -modules, N of finite length. If $\phi : L \times M \rightarrow N$ is a continuous A -bilinear map, there exist open submodules L' and M' of L and M such that $\phi(L' \times M') = \{0\}$.

<!-- label: III.VII_B.0.3.1.statement -->

Indeed, $\phi^{-1}(0)$ is an open neighborhood of $(0, 0)$, hence contains an open of the form $L_1 \times M_1$, where L_1 and M_1 are open submodules of L and M . Since L/L_1 is of finite length, there exist elements $x_1, \dots, x_r$ of L such that $L_1 + Ax_1 + \dots + Ax_r = L$. If $M' \subset M_1$ is "small enough", one also has $\phi(x_i, M') = 0$ for every i , because the map $y \mapsto \phi(x_i, y)$ is continuous; from this one deduces $\phi(L, M') = \{0\}$; likewise, $\phi(L', M) = \{0\}$ if L' is small enough.

Corollary 0.3.1.1. Let M be a pseudocompact A -module.

(i) For every open submodule M' , there exists an open ideal $\mathcal{I}$ of A such that $\mathcal{I} M \subset M'$.

(ii) Consequently, $M \simeq \varprojlim \mathcal{I} M / \mathcal{I} M$, where $\mathcal{I}$ ranges over the filtered inverse system of open ideals of A and each $\mathcal{I} M / \mathcal{I} M$ is endowed with the quotient topology (which makes it a pseudocompact module, cf. 0.2.D).

<!-- label: III.VII_B.0.3.1.1 -->

Indeed, consider the map $\phi : A \times M \rightarrow M/M'$, $(a, m) \mapsto am + M'$; by 0.3.1 there exists an open ideal $\mathcal{I}$ of A such that $\mathcal{I} M \subset M'$, and since M' is also closed, it contains also $\mathcal{I} M$. Since the intersection of the open submodules of M is zero, one therefore has $\bigcap \mathcal{I} M = (0)$. On the other hand, by 0.2.D, the map $\phi : M \rightarrow \varprojlim \mathcal{I} M / \mathcal{I} M$ is surjective; by (the proof of) 0.2.B, ϕ therefore induces an isomorphism $M / \text{Ker}(\phi) \xrightarrow{\sim} \varprojlim \mathcal{I} M / \mathcal{I} M$, but we have just seen that $\text{Ker}(\phi) = \bigcap \mathcal{I} M$ is zero.

Remark 0.3.1.2. The completed tensor product satisfies the usual associativity condition: if L , M , P are pseudocompact A -modules, one has a canonical isomorphism

```
```text
(L ⊗ M) ⊗ P ≅ L ⊗ (M ⊗ P);
```

indeed, these two objects represent the functor that associates to every object  $N$  of  $\text{LF}(A)$  the abelian group of continuous  $A$ -trilinear maps from  $L \times M \times P$  into  $N$ .

<!-- label: III.VII\_B.0.3.1.2 -->

### 0.3.2.

<!-- label: III.VII\_B.0.3.2 -->

Let  $L' \xrightarrow{f} L \xrightarrow{g} L''$  be an exact sequence and  $M$  an object of  $\mathcal{P}C(A)$ . It is clear that for every object  $N$  of  $\mathcal{L}F(A)$ , the induced sequences:

```

```text
0 → Bil_c(L' × M, N) → Bil_c(L × M, N) → Bil_c(L' × M, N)

0 → Hom_c(L' ⊗_A M, N) → Hom_c(L ⊗_A M, N) → Hom_c(L' ⊗_A M, N)
```

```

<!-- original page 483 -->

are exact. By 0.2.E, this is equivalent to saying that the sequence

```

```text
(*)      L' ⊗_A M →f ⊗ M→ L ⊗_A M →g ⊗ M→ L'' ⊗_A M → 0
```

```

is exact. Hence:

**Corollary.** For every pseudocompact  $A$ -module  $M$ , the functor  $-\hat{\otimes}_A M$  is right exact.\*

In particular, take for  $L$  the ring  $A$ , for  $f$  the inclusion of a closed ideal  $\mathfrak{a}$  in  $A$ , and for  $g$  the canonical projection of  $A$  onto  $A/\mathfrak{a}$ . One can then identify  $\hat{\otimes}_A M$  with  $M$  by means of the map  $x \hat{\otimes}_A m \mapsto xm$ . Since the image of  $\mathfrak{a} \hat{\otimes}_A M$  is closed in  $M$  (cf. 0.2.B) and the image of  $\mathfrak{a} \hat{\otimes}_A M$  is everywhere dense in  $\mathfrak{a} \hat{\otimes}_A M$ , the image of  $f \hat{\otimes}_A M$  is nothing but the closure  $\bar{\mathfrak{a} \hat{\otimes}_A M}$  of  $\mathfrak{a} \hat{\otimes}_A M$  in  $M$ . The exact sequence (\*) therefore yields the isomorphism:

```

```text
(A/\mathfrak{a}) ⊗_A M ≅ M / \mathfrak{a} M.
```

```

### 0.3.3.

<!-- label: III.VII\_B.0.3.3 -->

**Lemma 0.3.3 (Nakayama's Lemma).** Let  $A$  be a pseudocompact ring,  $M$  a pseudocompact  $A$ -module, and  $\mathfrak{a}$  an ideal of  $A$  contained in the radical  $\mathfrak{r}(A)$ . The equality  $\bar{\mathfrak{a}M} = M$  then implies  $M = 0$ .\*

<!-- label: III.VII\_B.0.3.3 -->

Indeed, suppose  $\bar{\mathfrak{a}M} = M$ . [N.D.E-VII\_B-20] Let  $M'$  be an open submodule of  $M$  and  $M' = M/M'$ . Since  $M'$  is discrete,  $\mathfrak{a}M'$  is closed in  $M'$ , hence equal to  $\bar{\mathfrak{a}M'}$ . By 0.3.2, the canonical map of  $M/\mathfrak{a}M$  to  $M'/\mathfrak{a}M'$  is surjective, so one has  $\mathfrak{a}M' = \bar{\mathfrak{a}M'}$ . Since  $M'$  is a finitely generated  $A$ -module and  $\mathfrak{a} \subset \mathfrak{r}(A)$ , this implies  $M' = 0$  by the usual Nakayama's Lemma. Consequently, every open submodule  $M'$  of  $M$  equals  $M$ , and so  $M$  is zero. [N.D.E-VII\_B-21]

### 0.3.4.

<!-- label: III.VII\_B.0.3.4 -->

From Nakayama's Lemma one draws the usual consequences:

**Corollary.** Let  $\mathfrak{a}$  be a closed ideal contained in  $\mathfrak{r}(A)$  and  $f : M \rightarrow N$  a morphism of pseudocompact  $A$ -modules.\*

(i)  $f$  is surjective if the induced map  $f' : M/\mathfrak{a}M \rightarrow N/\mathfrak{a}N$  is.\* [N.D.E-VII\_B-22]

(ii) If  $N$  is projective,  $f$  is invertible if  $f'$  is.\*

<!-- original page 484 -->

Indeed, (i) follows from Lemma 0.3.3 applied to  $\text{Coker } f$ . For (ii), suppose  $f$  is invertible. Then by (i),  $f$  is surjective, hence has a section; one then applies 0.3.3 to  $\text{Ker } f$ .

When  $A$  is local with maximal ideal  $\mathfrak{m}$ , one can also deduce from 0.3.3 the following exchange theorem:

**Theorem.** Let  $A$  be a local pseudocompact ring,  $\mathfrak{m}$  its maximal ideal,  $M$  a topologically free  $A$ -module with pseudobasis  $(m_i)_{i \in I}$  (0.2.1), and  $N$  a (closed) direct factor of  $M$ . There exists a pseudobasis of  $M$  formed of elements of  $N$  and of certain  $m_{i_j}$ .

Indeed, this is clear when  $A$  is a field (one then uses the duality of 0.2.2 and applies the usual exchange theorem); consequently,  $N/\mathfrak{m}N$  [N.D.E-VII\_B-23] has as a supplement a topologically free module over  $A/\mathfrak{m}$  with pseudobasis  $(\bar{m}_i)_{i \in J}$ , where  $\bar{m}_i$  is the image of  $m_i$  in  $M/\mathfrak{m}M$  and  $J$  is a subset of  $I$ . If  $P$  denotes the direct product  $\prod_{i \in J} A m_i$ , the canonical map of  $N \oplus P$  to  $M$  is "bijective modulo  $\mathfrak{m}$ "; it is therefore bijective by what precedes (for another proof see [CA], § IV.2, Prop. 8).

### 0.3.5.

<!-- label: III.VII\_B.0.3.5 -->

<!-- original page 485 -->

Consider now three pseudocompact  $A$ -modules  $L$ ,  $M$  and  $N$ , where  $N$  is of finite length. Endowing the  $A$ -module  $\text{Hom}_c(M, N)$  with the discrete topology, every element  $\psi$  of  $\text{Hom}_c(L, \text{Hom}_c(M, N))$  defines a continuous bilinear map  $\psi : (l, m) \mapsto \psi(l)(m)$  from  $L \times M$  to  $N$ . One thus obtains a natural isomorphism

```

(1) Hom_c(L, Hom_c(M, N)) ≅ Hom_c(L ⊗_A M, N),

```

hence another characterization of  $\text{Hom}_c(L \hat{\otimes}_A M, N)$ , which we shall use when  $M$  is the inverse limit of a filtered inverse system of pseudocompact  $A$ -modules  $M_i$ . Then, by (1) and 0.2.F (ii), one has natural isomorphisms:

```

(2) Hom_c(L ⊗_A lim M_i, N) ≅ Hom_c(L, Hom_c(lim M_i, N))
 ≅ Hom_c(L, colim Hom_c(M_i, N)).

```

Moreover, since the module  $\text{colim } \text{Hom}_c(M_i, N)$  is discrete, every continuous map with source  $L$  factors through a finite-length quotient of  $L$ . Consequently, the natural map below is an isomorphism:

```

(3) colim Hom_c(L, Hom_c(M_i, N)) → Hom_c(L, colim Hom_c(M_i, N)).

```

Finally, by (1) and 0.2.F (ii) again, one has natural isomorphisms:

```

(4) colim Hom_c(L, Hom_c(M_i, N)) ≅ colim Hom_c(L ⊗_A M_i, N)
 ≅ Hom_c(lim (L ⊗_A M_i), N).

```

Combining isomorphisms (2), (3), (4), one obtains:

**Proposition.** Let  $(M_i)$  be a filtered inverse system of objects of  $\text{PC}(A)$ , and let  $L$  (resp.  $N$ ) be an object of  $\text{PC}(A)$  (resp.  $\text{LF}(A)$ ). One has a functorial isomorphism in  $N$ :

```

Hom_c(L ⊗_A lim M_i, N) ≅ Hom_c(lim (L ⊗_A M_i), N),

```

and hence an isomorphism:

```

```text

$$L \otimes^A \lim M_i \approx \lim (L \otimes^A M_i).$$

```

```

\*The completed tensor product therefore commutes with filtered inverse limits.\*[<sup>N.D.E-VII\_B-24</sup>]

#### 0.3.6.

<!-- label: III.VII\_B.0.3.6 -->

In particular,[<sup>N.D.E-VII\_B-25</sup>] the completed tensor product commutes with infinite products. For example, since the ring  $A$  is the product of its local components  $A_{\mathfrak{m}}$  (0.1.1), every pseudocompact  $A$ -module  $M$  ( $\hat{A} \otimes M \approx M$ ) is identified with the product of the modules  $M_{\mathfrak{m}} = A_{\mathfrak{m}} \hat{\otimes} M$  (the local components of  $M$ ).

<!-- original page 514 -->

Likewise, let  $M$  and  $N$  be two pseudocompact  $A$ -modules. Recall (cf. 0.2.2) that  $M^{\wedge}$  denotes  $\operatorname{Hom}_c(M, A)$ . Consider the map

```

```text

$$\varphi : M^{\wedge} \otimes_A N^{\wedge} \rightarrow (M \otimes_A N)^{\wedge}$$

```

```

which associates to an element  $f \otimes g$  of  $M^{\wedge} \otimes_A N^{\wedge}$  the map  $m \mapsto f(m)g$  from  $M \hat{\otimes}_A N$  to  $A$ . This map  $\varphi$  is bijective when  $M$  is isomorphic to  $A$ .

**Corollary.** \*When  $A$  is artinian,  $\varphi$  is an isomorphism whenever  $M$  is topologically free (or more generally projective).\*

Indeed, for  $N$  fixed, the functor  $M \mapsto (M \otimes_A N)^{\wedge}$  (resp.  $M \mapsto M^{\wedge} \otimes_A N^{\wedge}$ ) transforms every direct product into a direct sum, by what precedes and 0.2.F.

**Remark 0.3.6.A.**[<sup>N.D.E-VII\_B-26</sup>] \*Using 0.2.F in a similar way, one also obtains the following result: Let  $A$  be an artinian ring,  $M, Q$  objects of  $\operatorname{PC}(A)$ , and  $N$  an object of  $\operatorname{LF}(A)$ . Suppose  $Q$  projective; then one has natural isomorphisms:\*

```

```text

$$\operatorname{Hom}_c(M, Q) \cong \operatorname{Hom}_A(Q^{\wedge}, M^{\wedge}) \quad \text{and} \quad Q^{\wedge} \otimes_A N \cong \operatorname{Hom}_c(Q, N).$$

```

```

<!-- label: III.VII\_B.0.3.6.A -->

#### 0.3.7.

<!-- label: III.VII\_B.0.3.7 -->

For every  $\mathfrak{m} \in \operatorname{Upsilon}(A)$ , the functor  $M \mapsto A_{\mathfrak{m}} \hat{\otimes}_A M$  is evidently exact. <!-- original page 486 --> Since every projective pseudocompact  $A$ -module  $P$  is a product of modules of the form  $A_{\mathfrak{m}}$ , it follows that the functor  $M \mapsto P \hat{\otimes}_A M$  is exact when  $P$  is projective. The converse is true:

**Proposition.** \*Let  $A$  be a pseudocompact ring,  $P$  a pseudocompact  $A$ -module. The following conditions are equivalent:\*

- \*(i)  $P$  is a projective object of  $\operatorname{PC}(A)$ .\*
- \*(ii) Each local component  $P_{\mathfrak{m}}$  is a topologically free  $A_{\mathfrak{m}}$ -module.\*
- \*(iii) The functor  $M \mapsto P \hat{\otimes}_A M$  is exact.\*

Indeed, the equivalence of (i) and (ii) follows from 0.2.F (iii) and 0.2.1, and we have just seen that (ii)  $\Rightarrow$  (iii). Suppose the functor  $M \mapsto P \hat{\otimes}_A M$  is exact. Since  $P \hat{\otimes}_A M$  is the product of its local components:

```

```text

$$(P \otimes_A M)_{\square} \cong P_{\square} \otimes_{A_{\square}} M_{\square},$$

```

```

one is reduced to the case where the ring  $A$  is local. We then prove that  $P$  is topologically free.

Let  $\mathfrak{m}$  be the maximal ideal of  $A$ ; then  $P / \bar{\mathfrak{m}} P$  is a linearly compact vector space over  $A/\mathfrak{m}$ , hence a product of copies of  $A/\mathfrak{m}$  (cf. 0.2.2). There is therefore a family  $(A_i)_{i \in I}$  of copies of  $A$  and an isomorphism  $\phi : \prod_{i \in I} (A_i / \mathfrak{m} A_i) \xrightarrow{\sim} P / \bar{\mathfrak{m}} P$ . Since  $\prod_{i \in I} A_i$  is projective, there is a commutative square

```

```text

$$\begin{array}{ccc} \prod A_i & \xrightarrow{\psi} & P \\ \downarrow p & & \downarrow q \\ \prod (A_i / \mathfrak{m}) & \xrightarrow{\phi} & P / \bar{\mathfrak{m}} P, \end{array}$$

```

```

<!-- original page 515 -->

where  $p$  and  $q$  denote the canonical projections. Applying Nakayama's Lemma to  $\text{Coker } \psi$  and noting that  $(A/\mathfrak{m}) \hat{\otimes}_A \psi$  is nothing but  $\phi$ , one sees that  $\psi$  is surjective. [^N.D.E-VII\_B-27]

Setting then  $B = \prod_{i \in I} A_i$  and  $N = \text{Ker } \psi$ , one has the following commutative and exact diagram:

```

```text

$$\begin{array}{ccccccc} \prod \otimes_A N & \longrightarrow & \prod \otimes_A B & \longrightarrow & \prod \otimes_A P & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ A \otimes_A N & \longrightarrow & A \otimes_A B & \xrightarrow{\psi} & A \otimes_A P & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ (A/\mathfrak{m}) \otimes_A N & \longrightarrow & (A/\mathfrak{m}) \otimes_A B & \xrightarrow{\phi} & (A/\mathfrak{m}) \otimes_A P & \longrightarrow & 0. \end{array}$$

```

```

The "snake lemma" applied to the first two rows then shows that, in the bottom row, the morphism  $(A/\mathfrak{m}) \hat{\otimes}_A N \rightarrow (A/\mathfrak{m}) \hat{\otimes}_A B$  is a monomorphism. But then, since  $\phi$  is an isomorphism,  $(A/\mathfrak{m}) \hat{\otimes}_A N$  is zero; whence  $N = 0$  (0.3.3) and  $\psi$  is an isomorphism. [^N.D.E-VII\_B-28]

<!-- original page 487 -->

### 0.3.8.

<!-- label: III.VII\_B.0.3.8 -->

**Corollary 0.3.8.** \*Let  $A$  be a complete noetherian local ring and  $P$  a pseudocompact  $A$ -module. Then  $P$  is topologically free if and only if  $P$  is flat over  $A$ .\*

Indeed, the canonical map of  $M \otimes_A P$  into  $M \hat{\otimes}_A P$  is bijective when  $M$  equals  $A$ , hence also when  $M$  is noetherian (take a finite presentation of  $M$  and use the right exactness of the tensor product and of the completed tensor product).

Now  $P$  is flat if and only if the functor  $M \mapsto M \otimes_A P$  is exact when  $M$  ranges over the noetherian modules. Likewise, we saw in the proof of Proposition 0.3.7 that  $P$  is topologically free if the sequence

```

```text

$$0 \rightarrow \prod \otimes_A P \rightarrow A \otimes_A P \rightarrow (A/\mathfrak{m}) \otimes_A P \rightarrow 0$$

```

```

<!-- original page 488 -->

is exact. So  $P$  is topologically free if and only if the functor  $M \mapsto M \hat{\otimes}_A P$  is exact when  $M$  ranges over the noetherian modules. The corollary therefore follows from the equality  $M \otimes_A P = M \hat{\otimes}_A P$  established above.

### 0.4.

<!-- label: III.VII\_B.0.4 -->

Let  $k$  be a pseudocompact ring; a *topological  $k$ -algebra* is a (commutative) topological ring  $A$ , equipped with a morphism of topological rings  $k \rightarrow A$ . One says that  $A$  is a *profinite  $k$ -algebra* if the underlying topological  $k$ -module is pseudocompact.

In this case, let  $\mathcal{L}$  be an open  $k$ -submodule of  $A$ . The composite map

```

```text
φ : A × A →mult→ A →can→ A/ℒ
```

```

is continuous, hence by Lemma 0.3.1, there exists an open  $k$ -submodule  $\mathfrak{m}$  of  $A$  such that  $\phi(A \times \mathfrak{m}) = 0$ . This means that  $\mathcal{L}$  contains the open ideal  $\mathfrak{m}$  and implies that  $A$  is a pseudocompact ring.

Likewise, let  $M$  be a topological  $A$ -module whose underlying  $k$ -module is pseudocompact. If  $M'$  is an open  $k$ -submodule of  $M$ , Lemma 0.3.1 applied to the map

```

```text
A × M →mult→ M →can→ M/M'
```

```

shows that  $M'$  contains an open  $A$ -submodule, so that  $M$  is also a pseudocompact  $A$ -module. [N.D.E-VII\_B-29]  
Conversely:

**Lemma.** *Let  $A$  be a profinite  $k$ -algebra and  $M$  a pseudocompact  $A$ -module. Then the  $k$ -module  $M|_k$  obtained by restriction of scalars is pseudocompact.*

Indeed, every pseudocompact  $A$ -module of finite length is isomorphic to a quotient  $A^n / L$  (where  $L$  is an open submodule of  $A^n$ ), hence is a pseudocompact  $k$ -module. Since  $M|_k$  is an inverse limit of such modules, it is a pseudocompact  $k$ -module.

#### 0.4.1.

<!-- label: III.VII\_B.0.4.1 -->

If  $A$  and  $B$  are two profinite  $k$ -algebras, a *morphism* from  $A$  to  $B$  is, by definition, a continuous homomorphism of  $k$ -algebras. We shall denote by  $\mathcal{A}p/k$  the category of profinite  $k$ -algebras.

It evidently possesses inverse limits: the algebra underlying an inverse limit is the inverse limit of the underlying algebras; the topology is that of the inverse limit. <!-- original page 489 -->

It also possesses finite direct limits [N.D.E-VII\_B-30]: for example, if  $f : A \rightarrow B$  and  $g : A \rightarrow C$  are two morphisms of profinite  $k$ -algebras, the amalgamated sum of  $B$  and  $C$  over  $A$  has  $B \hat{\otimes}_A C$  as underlying topological  $A$ -module (by 0.4,  $f$  and  $g$  endow  $B$  and  $C$  with pseudocompact  $A$ -module structures); the multiplication of  $B \hat{\otimes}_A C$  is obviously such that  $(b \hat{\otimes} c)(b' \hat{\otimes} c') = (bb') \hat{\otimes} (cc')$  if  $b, b' \in B$  and  $c, c' \in C$ .

### 0.4.2.

<!-- label: III.VII\_B.0.4.2 -->

**Definition 0.4.2.** *A profinite  $k$ -algebra  $C$  is said to be of finite length if the underlying  $k$ -module is of finite length (hence discrete); we denote by  $\mathcal{A}f/k$  the full subcategory of  $\mathcal{A}p/k$  formed by  $k$ -algebras of finite length.* [N.D.E-VII\_B-31]

<!-- label: III.VII\_B.0.4.2 -->

For every profinite  $k$ -algebra  $A$ , we denote by  $h_A$  the functor:

```

```text

```

$\text{Alf}/k \rightarrow (\text{Sets}), \quad C \mapsto \text{Hom}_{\{\text{Alp}/k\}}(A, C).$

It is clear that $h_{\{A\}}$ is a left-exact functor [N.D.E-VII_B-32]. Moreover, the canonical projections $A \twoheadrightarrow A/\mathcal{I}$ (where $\mathcal{I}$ ranges over the open ideals of A) induce, for every object C of Alf/k , a canonical isomorphism

```text  
 $\text{colim}_{\square} \text{Hom}_{\{\text{Alf}/k\}}(A/\square, C) \cong \text{Hom}_{\{\text{Alp}/k\}}(A, C),$   
 ```

functorial in C . This means that $h_{\{A\}}$ is the direct limit of the representable functors $h_{\{A/\mathcal{I}\}}$, i.e.,

\$\$
 (\ast) \quad h_{\{A\}} \simeq \text{colim}_{\{\mathcal{I}\}} h_{\{A/\mathcal{I}\}}.
 \$\$

If B is another profinite k -algebra, the general properties of the bifunctor Hom and the isomorphism $\text{Hom}(h_{\{C\}}, h_{\{B\}}) = h_{\{B\}}(C)$ for C of finite length give isomorphisms:

```text  
 $\text{Hom}_{\{\text{Alp}/k\}}(B, A) = \lim \text{Hom}_{\{\text{Alp}/k\}}(B, A/\square)$   
 $= \lim \text{Hom}(h_{\{A/\square\}}, h_{\{B\}})$   
 $= \text{Hom}(\text{colim}_{\square} h_{\{A/\square\}}, h_{\{B\}});$   
 ```

combined with (*), this shows that the contravariant functor $A \mapsto h_{\{A\}}$ is fully faithful. In fact:

<!-- original page 490 -->

Proposition. The functor $A \mapsto h_{\{A\}}$ is an anti-equivalence of Alp/k onto the category of left-exact functors from Alf/k to (Sets) .

Indeed, by what precedes, it suffices to show that every left-exact functor $F : \text{Alf}/k \rightarrow (\text{Sets})$ is isomorphic to a functor of the type $h_{\{A\}}$; for this, one can construct A as follows (cf. TDTE II, § 3).

Since F is left-exact, for every k -algebra of finite length C and every element ξ of $F(C)$, there is a smallest subalgebra C' of C such that ξ belongs to the image of $F(C')$ in $F(C)$. If one has $C' = C$, one says that the pair (C, ξ) is *minimal*.

The minimal pairs form a category if one takes for morphisms from (C, ξ) to (D, η) the homomorphisms ϕ from C to D such that $(F\phi)(\xi) = \eta$; it is clear that such a ϕ is a surjection and that the category of minimal pairs is "left filtered". Moreover, one can restrict to pairs (C, ξ) such that C belongs to a set containing k -algebras of finite length of each isomorphism type [N.D.E-VII_B-33]. Hence, the functor $(C, \xi) \mapsto C$, with source category that of minimal pairs and target category that of profinite k -algebras, possesses an inverse limit; one takes for A this inverse limit.

Corollary. The category Alp/k possesses infinite direct limits.

Indeed, the category of left-exact functors from Alf/k to (Sets) possesses inverse limits, which are defined "argument by argument", i.e., if (F_i) is an inverse system of such functors, one has, for every object C of Alf/k :

```text  
 $(\lim F_i)(C) = \lim F_i(C).$   
 ```

[N.D.E-VII_B-34]

0.5.

<!-- label: III.VII_B.0.5 -->

[N.D.E-VII_B-35] Let $\phi : k \rightarrow \ell$ be a homomorphism of pseudocompact rings (cf. 0.1.3). One can generalize the construction of 0.3 as follows.

<!-- original page 491 -->

****Definition 0.5.A.**** For every object M of $PC(k)$ (resp. N of $PC(\ell)$), we shall denote by $M \hat{\otimes}_k N$ the separated completion of $M \otimes_k N$ for the linear topology defined by the kernels of the projections:*

```text  
 $M \otimes_k \square \rightarrow (M/M') \otimes_k (N/N'),$

\*where  $M'$  (resp.  $N'$ ) is an open submodule of  $M$  (resp. of  $N$ ). Then  $M \hat{\otimes}_k N$  is a pseudocompact  $\ell$ -module. If  $m \in M$  and  $x \in N$ , we shall denote by  $m \hat{\otimes}_k x$  the canonical image of  $m \otimes_k x$  in  $M \hat{\otimes}_k N$ .\*

<!-- label: III.VII\_B.0.5.A -->

\*This applies in particular when  $N = \ell$ , in which case we shall say that  $M \hat{\otimes}_k \ell$  is the pseudocompact  $\ell$ -module deduced from  $M$  by the base change  $k \rightarrow \ell$ .\*

**\*\*Remarks 0.5.B.\*\*** (i) When one considers such a base change,  $\ell$  will not in general be a profinite  $k$ -algebra: a typical example is the case where  $k$  is a field and  $\ell$  is an arbitrary extension  $K$  of  $k$ .\*

(ii) However, if the  $k$ -module underlying  $N$  is pseudocompact (for example if  $\ell$  is a profinite  $k$ -algebra) then, by 0.4, every open  $k$ -submodule of  $N$  contains an open  $\ell$ -submodule of  $N$ ; consequently,  $M \hat{\otimes}_k N$  coincides in this case with the completed tensor product (cf. 0.3) of the pseudocompact  $k$ -modules  $M$  and  $N$ , and the notation therefore does not present any ambiguity.\*

<!-- label: III.VII\_B.0.5.B -->

The  $k$ -module  $N|_k$  obtained by restriction of scalars is in any case a topological  $k$ -module, i.e. the map  $k \times N \rightarrow N$ ,  $(t, n) \mapsto \phi(t)n$  is continuous. We denote by  $\text{Hom}_c(M, N|_k)$  the abelian group of continuous  $k$ -module homomorphisms of  $M$  into  $N|_k$ .

**\*\*Proposition 0.5.C.\*\*** For every  $M \in \text{Ob } PC(k)$  and  $N \in \text{Ob } PC(\ell)$ , one has a functorial isomorphism\*

```text  
 $\text{Hom}_{PC(\ell)}(M \otimes_k \square, N) \simeq \text{Hom}_c(M, N|_k).$

<!-- label: III.VII_B.0.5.C -->

[^N.D.E-VII_B-36]

Indeed, let ϕ be a continuous homomorphism $M \rightarrow N|_k$; then the map $\phi' : M \times \ell \rightarrow N$, $(m, \lambda) \mapsto \lambda \phi(m)$ is continuous and "bilinear" (i.e., k -linear in the first factor and ℓ -linear in the second). If N' is an open ℓ -submodule of N , one shows as in Lemma 0.3.1 that there exist an open submodule M' of M and an open ideal ℓ' of ℓ such that $\phi'(M' \times \ell')$ and $\phi'(M \times \ell')$ are contained in N' . It follows that ϕ induces a continuous homomorphism of ℓ -modules $\Phi : M \hat{\otimes}_k \ell \rightarrow N$, such that $\Phi(m \hat{\otimes}_k \lambda) = \lambda \phi(m)$, for every $m \in M$ and $\lambda \in \ell$.

Conversely, to every morphism $f : M \hat{\otimes}_k \ell \rightarrow N$ one associates the morphism $f' : m \mapsto f(m \hat{\otimes}_k 1)$ from M to $N|_k$.

One then obtains, as in 0.3.2, 0.3.5, and 0.3.1.2, the:

****Corollary 0.5.D.**** The functor $PC(k) \rightarrow PC(\ell)$, $M \mapsto M \hat{\otimes}_k \ell$ is right exact and commutes with filtered inverse limits, i.e., if (M_i) is a filtered inverse system of objects of $PC(k)$, one has a canonical isomorphism:*

```text  
 $(\varprojlim M_i) \otimes_k \ell \simeq \varprojlim (M_i \otimes_k \ell).$

\*Moreover, if  $M, N$  are pseudocompact  $k$ -modules, one has a canonical isomorphism:

```
```text
(M ⊗k N) ⊗k Λ = (M ⊗k Λ) ⊗k (N ⊗k Λ).
```

<!-- label: III.VII_B.0.5.D -->

Definition 0.5.E. *Finally, if A is a profinite k -algebra, there is on $A \hat{\otimes}_k \ell$ one and only one structure of profinite ℓ -algebra such that, if $a, b \in A$ and $\lambda \in \ell$,

```
```text
(a ⊗k λ)(b ⊗k μ) = (ab) ⊗k (λμ).
```

\*One says that  $A \hat{\otimes}_k \ell$  is the profinite  $\ell$ -algebra deduced from  $A$  by the extension of scalars (or "base change")  $k \rightarrow \ell$ .

<!-- label: III.VII\_B.0.5.E -->

## 1. Formal varieties over a pseudocompact ring

<!-- label: III.VII\_B.1 -->

<!-- original page 492 -->

### 1.1.

<!-- label: III.VII\_B.1.1 -->

One can associate to every pseudocompact ring  $A$  a formal scheme (EGA I, 10.4.2) by proceeding as follows: the underlying topological space is the set  $\Upsilon(A)$  of open (hence maximal) prime ideals of  $A$ , endowed with the discrete topology; the structure sheaf has the cartesian product  $\prod_{\mathfrak{m} \in E} A_{\mathfrak{m}}$  as space of sections on a subset  $E$  of  $\Upsilon(A)$ . The formal scheme thus obtained is denoted  $\mathrm{Spf}(A)$  (the *formal spectrum* of  $A$ ). [N.D.E-VII\_B-37]

If  $A$  and  $B$  are two pseudocompact rings, a morphism from  $\mathrm{Spf}(B)$  to  $\mathrm{Spf}(A)$  consists of the datum of a map  $f$  from  $\Upsilon(B)$  to  $\Upsilon(A)$  and of a family of continuous homomorphisms  $f^{\mathbb{N}}_y : A_{f(y)} \rightarrow B_y$ , for  $y \in \Upsilon(B)$ . Such a morphism induces a continuous homomorphism  $f^{\mathbb{N}}$  from  $A = \prod_{x \in \Upsilon(A)} A_x$  to  $B = \prod_{y \in \Upsilon(B)} B_y$ . The converse is true:

<!-- original page 520 -->

**Proposition.** \*The contravariant functor  $A \mapsto \mathrm{Spf}(A)$  is fully faithful.\*

Indeed, if  $\phi : A \rightarrow B$  is a continuous algebra homomorphism, the inverse image  $\phi^{-1}(\mathfrak{m})$  of an open maximal ideal of  $B$  is an open prime ideal of  $A$ , hence maximal in  $A$ . One thus obtains a map  $\mathfrak{m} \mapsto \phi^{-1}(\mathfrak{m})$  from  $\Upsilon(B)$  to  $\Upsilon(A)$ , and  $\phi$  induces a continuous homomorphism  $A_{\phi^{-1}(\mathfrak{m})} \rightarrow B_{\mathfrak{m}}$ . So  $\phi$  induces a morphism of formal schemes  $\mathrm{Spf}(\phi) : \mathrm{Spf}(B) \rightarrow \mathrm{Spf}(A)$ . One verifies easily that  $\mathrm{Spf}(\phi)^{\mathbb{N}} = \phi$ , and that  $\mathrm{Spf}(f^{\mathbb{N}}) = f$  for every morphism  $f : \mathrm{Spf}(B) \rightarrow \mathrm{Spf}(A)$ , whence the proposition.

Although we shall here speak only of formal schemes of the form  $\mathrm{Spf}(A)$ , we shall use the language of formal schemes rather than that of pseudocompact rings, in order to base our assertions on a geometric intuition.

### 1.2.

<!-- label: III.VII\_B.1.2 -->

Let  $k$  be a pseudocompact ring.

<!-- original page 493 -->

**Definition 1.2.A.** [N.D.E-VII\_B-38] \*We shall call a formal variety over  $k$  any formal scheme  $X$  over  $\mathrm{Spf}(k)$  which is isomorphic to a formal  $k$ -scheme  $\mathrm{Spf}(A)$  for some profinite  $k$ -algebra  $A$ . The algebra  $A$  is then

isomorphic to the affine algebra of  $X$ , that is, to the algebra of sections of the structure sheaf  $\mathcal{O}_X$  of  $X$ .

We denote by  $\mathcal{Vaf}/k$  the full subcategory of the category of formal schemes over  $\mathrm{Spf}(k)$  whose objects are the formal  $k$ -varieties. [N.D.E-VII\_B-39]

<!-- label: III.VII\_B.1.2.A -->

By 1.1, the functor  $\mathcal{A} \mapsto \mathrm{Spf}(\mathcal{A})$  is an anti-equivalence of  $\mathcal{Alp}/k$  (0.4.1) onto  $\mathcal{Vaf}/k$ . So, by the corollary of 0.4.2:

**Proposition 1.2.B.** The category  $\mathcal{Vaf}/k$  possesses inverse and direct limits. [N.D.E-VII\_B-40]

<!-- label: III.VII\_B.1.2.B -->

For example, let  $X \in \mathcal{Vaf}/k$  and  $f : Y \rightarrow X$  and  $g : Z \rightarrow X$  be two formal  $k$ -varieties over  $X$  and let  $\mathcal{A}$ ,  $\mathcal{B}$ ,  $\mathcal{C}$  be the affine algebras of  $X$ ,  $Y$ ,  $Z$ ; by 0.4.1, the affine algebra of the fiber product  $Y \times_X Z$  is identified with  $\mathcal{B} \hat{\otimes}_{\mathcal{A}} \mathcal{C}$ , [N.D.E-VII\_B-41] so that the inclusion of  $\mathcal{Vaf}/k$  in the category of all formal  $k$ -schemes commutes with finite inverse limits (cf. EGA I, 10.7).

The direct limits of formal  $k$ -varieties correspond to inverse limits of their affine algebras.

**Example 1.2.C (Cokernels).** Let, for example,  $d, e : X \rightarrow Y$  be a double arrow of  $\mathcal{Vaf}/k$ ; the affine algebra of  $\mathrm{Coker}(d, e)$  is isomorphic to the kernel of the homomorphisms induced on the affine algebras of  $X$  and  $Y$ , but one can also give the following construction of  $\mathrm{Coker}(d, e)$ : the topological space underlying  $\mathrm{Coker}(d, e)$  is the cokernel of the underlying spaces; [N.D.E-VII\_B-42] if  $p$  is the canonical projection of the set underlying  $Y$  onto the cokernel and if  $z$  belongs to the cokernel, the local algebra of  $\mathrm{Coker}(d, e)$  at  $z$  is the kernel of the double arrow

$$d^{\natural}, e^{\natural} : \{p(y) = z\} \cap \mathcal{O}_Y \rightarrow \{p(x) = z\} \cap \mathcal{O}_X,$$

where one has set  $q = p \circ d = p \circ e$  and where  $d^{\natural}$  and  $e^{\natural}$  are induced by the homomorphisms  $d^{\natural}_x$  and  $e^{\natural}_x$  (notations of 1.1).

<!-- original page 494 -->

**Definition 1.2.D.** If  $\phi : k \rightarrow \ell$  is a homomorphism of pseudocompact rings and  $X$  is a formal  $k$ -variety with affine algebra  $\mathcal{A}$ , the formal scheme  $X \times_{\mathrm{Spf}(k)} \mathrm{Spf}(\ell)$ , obtained by base change, is a formal  $\ell$ -variety, which we shall also denote  $X \hat{\otimes}_k \ell$  and which has as affine algebra the completed tensor product  $\mathcal{A} \hat{\otimes}_k \ell$  (cf. 0.5 and EGA I, § 10).

<!-- label: III.VII\_B.1.2.D -->

**Remark 1.2.E.** Since every formal variety over  $k$  decomposes into formal varieties over the local components of  $k$ , we shall assume in some proofs that  $k$  is a local pseudocompact ring.

<!-- label: III.VII\_B.1.2.E -->

We now give some examples while fixing our terminology.

### 1.2.1.

<!-- label: III.VII\_B.1.2.1 -->

A  $k$ -functor will be, by definition, a covariant functor from  $\mathcal{Alf}/k$  to  $(\mathrm{Sets})$ . By 1.1 and 0.4.2, one can identify  $\mathcal{Vaf}/k \simeq (\mathcal{Alp}/k)^{\circ}$  with a full subcategory of the category of  $k$ -functors, by associating to every formal  $k$ -variety  $X$  the functor:

$$\mathcal{Alf}/k \rightarrow (\mathrm{Sets}), \quad C \mapsto X(C) = \mathrm{Hom}_{\mathcal{Vaf}/k}(\mathrm{Spf}(C), X).$$

We shall encounter later  $k$ -functors  $F$  that associate to every object  $C$  of  $\mathcal{Alf}/k$  a module  $F(C)$  over  $C$  and to every morphism  $\phi : C \rightarrow D$  of  $\mathcal{Alf}/k$  a  $k$ -linear map  $F(\phi) : F(C) \rightarrow F(D)$  such that, if  $x \in F(C)$  and

$\lambda$  in  $C$ :

```
```text
F( $\varphi$ )( $\lambda$  x) =  $\varphi(\lambda)$  F( $\varphi$ )(x).
```

By Exposé I, 3.1, such an F is equipped with a structure of A_k -module, if one denotes by A_k the k -functor in rings that associates to every object C of $\mathcal{A}/k$ the ring underlying C .

<!-- original page 495 -->

Definitions. (i) An A_k -module F will be said to be *admissible* if every morphism $\varphi : C \rightarrow D$ of $\mathcal{A}/k$ induces a bijection of $D \otimes_k F(C)$ onto $F(D)$. [N.D.E-VII_B-43]

(ii) One says that F is *flat* if it is admissible and if, for every object C of $\mathcal{A}/k$, $F(C)$ is a flat C -module. [N.D.E-VII_B-44]

For example, if M is a k -module (not necessarily pseudocompact), we shall denote (as in Exposé I, 4.6.1) by $W(M)$ the A_k -module $C \mapsto C \otimes_k M$; then $W(M)$ is flat when M is flat over k .

Moreover, the functor $M \mapsto W(M)$ has as right adjoint the functor that associates to every A_k -module F the k -module $\varinjlim_{\mathcal{A}} F(k/\mathfrak{a})$, where $\mathfrak{a}$ ranges over the open ideals of k .

1.2.2.

<!-- label: III.VII_B.1.2.2 -->

In what follows, an A_k -module will always be denoted by a boldface letter such as $\mathbf{F}$; when k is artinian, we shall then write simply F instead of $\mathbf{F}(k)$. In this case, it goes without saying that the functor $\mathbf{F} \mapsto F$ induces an equivalence of the category of flat A_k -modules onto that of flat k -modules! The terminology we have adopted has therefore only the goal of allowing us to reason "as if k were always artinian".

In accordance with Exposé I § 3.1, we shall use analogous conventions for other algebraic structures: thus, an A_k -algebra (resp. an A_k -coalgebra, resp. an A_k -Lie algebra, resp. an A_k - $\mathfrak{p}$ -Lie algebra) will consist of the datum of an A_k -module $\mathbf{M}$ and, for every object C of $\mathcal{A}/k$, of a structure of C -algebra (resp. C -coalgebra, resp. C -Lie algebra, resp. C - $\mathfrak{p}$ -Lie algebra) on $\mathbf{M}(C)$; one assumes moreover that, for every morphism $\varphi : C \rightarrow D$ of $\mathcal{A}/k$, the map from $D \otimes_k \mathbf{M}(C)$ to $\mathbf{M}(D)$ induced by $\mathbf{M}(\varphi)$ is a homomorphism of D -algebras (resp. D -coalgebras, etc.).

Note finally that, if $\mathbf{F}$ and $\mathbf{G}$ are two A_k -modules, $\mathbf{F} \otimes_k \mathbf{G}$ will denote the A_k -module $C \mapsto \mathbf{F}(C) \otimes_k \mathbf{G}(C)$.

1.2.3.

<!-- label: III.VII_B.1.2.3 -->

[N.D.E-VII_B-45] We begin with the following lemma.

<!-- original page 523 -->

Lemma 1.2.3.A. Let $k \rightarrow K$ be a morphism of pseudocompact rings, B a pseudocompact K -module, and M a (topology-free) projective k -module. One has a canonical isomorphism of pseudocompact K -modules

```
```text
(2) $\theta : \text{Hom}_k(M, k) \otimes_k B \rightarrow \text{Hom}_k(M, B)$.
```

<!-- label: III.VII\_B.1.2.3.A -->

Here,  $M^* = \text{Hom}_k(M, k)$  is endowed with the topology defined in 0.2.2, which makes it a pseudocompact  $k$ -module, and the topology of  $\text{Hom}_k(M, B)$  is defined analogously: a basis of neighborhoods of  $\theta$  is formed by the following  $K$ -submodules, where  $x$  in  $M$  and  $B'$  is an open  $K$ -submodule of  $B$ :

```
```text
```

$\hat{\Gamma}(X, B') = \{f \in \text{Hom}_k(M, B) \mid f(x) \in B'\}.$

Finally, $M^* \hat{\otimes}_k B$ is the pseudocompact k -module deduced from M^* by base change, cf. 0.5.A.

This being so, θ is evidently an isomorphism when $M = k$; moreover, both sides of (2), considered as functors in M , transform direct sums into products (in particular, commute with finite direct sums). One thus obtains that (2) is an isomorphism when M is a free k -module, and then when M is projective.

<!-- original page 496 -->

Definition 1.2.3.B. Let N be a pseudocompact k -module. We denote by $V^f_k(N)$ or $N^{\wedge^+}$ [N.D.E-VII_B-46] the 0_k -module that associates to every $C \in \text{Ob } \text{Alf}/k$ the C -module $(C \otimes_k N)^+$ dual of $C \hat{\otimes}_k N$ (0.2.2), i.e. the C -module*

text
 $\text{Hom}_C(C \otimes_k N, C) \simeq \text{Hom}_C(N, C|_k),$

where $C|_k$ denotes the k -module C obtained by restriction of scalars. This 0_k -module $V^f_k(N)$ will be called the dual of N .*

<!-- label: III.VII_B.1.2.3.B -->

If $k_{\mathfrak{m}}$ is a local component of k , then for every object C of Alf/k ,

text
 $\text{Hom}_C(k_{\square}, C|_k) = C_{\square} = C \otimes_k k_{\square}$

is a projective C -module, and moreover one has $D \otimes_{\{C\}} C_{\mathfrak{m}} = D_{\mathfrak{m}}$ for every morphism $C \rightarrow D$ of Alf/k ; so $V^f_k(k_{\mathfrak{m}})$ is a flat 0_k -module (cf. 1.2.1). Since every projective pseudocompact k -module is a product of modules $k_{\mathfrak{m}}$ (cf. Prop. 0.2.1), one deduces from Corollary 0.2.F the:

Corollary 1.2.3.C. $V^f_k(N)$ is a flat 0_k -module when N is a projective pseudocompact k -module.*

<!-- label: III.VII_B.1.2.3.C -->

Definition 1.2.3.D. Conversely, if M^* is an admissible 0_k -module (cf. 1.2.1), [N.D.E-VII_B-47] we call dual of M^* and denote by $\Gamma^*(M^*)$ the pseudocompact k -module defined as follows. As $\mathcal{I}$ ranges over the open ideals of k , we endow each $k_{\mathcal{I}}$ -module*

$M^*(k_{\mathcal{I}})^* = \text{Hom}_k(k_{\mathcal{I}}/M^*(k_{\mathcal{I}}), k_{\mathcal{I}})$

with the topology described in 0.2.2, which makes it a pseudocompact k -module. Since $M^*(k_{\mathcal{I}}) \subseteq M^*(k_{\mathcal{I}'}) \otimes (k_{\mathcal{I}}/k_{\mathcal{I}'})$ for $\mathcal{I} \subseteq \mathcal{I}'$, one has transition morphisms:*

text
 $\text{Hom}_k(k_{\mathcal{I}'}/M^*(k_{\mathcal{I}'}), k_{\mathcal{I}'}) \rightarrow \text{Hom}_k(k_{\mathcal{I}'}/M^*(k_{\mathcal{I}'}), k_{\mathcal{I}}) = \text{Hom}_k(k_{\mathcal{I}}/M^*(k_{\mathcal{I}}), k_{\mathcal{I}}),$

and by definition $\Gamma^*(M^*)$ is the inverse limit of this filtered inverse system of pseudocompact k -modules.*

<!-- label: III.VII_B.1.2.3.D -->

<!-- original page 524 -->

From now on, suppose moreover that M^* is a flat 0_k -module (cf. 1.2.1); then each $M^*(k_{\mathcal{I}'})$ is a projective $k_{\mathcal{I}'}$ -module, so the transition morphisms above are surjective, and hence so are the projections $\Gamma^*(M^*) \rightarrow M^*(k_{\mathcal{I}})^*$, since in $\text{PC}(k)$ filtered inverse limits are exact.

If $\tau : k \rightarrow K$ is a morphism of pseudocompact rings, we shall denote by $M \otimes_k K$ or simply M_K the 0_K -functor defined as follows. If C is a k -algebra of finite length, then the kernel of $k \rightarrow C$ is an open ideal $\mathcal{I}$, and one sets $M_K(C) = M(k/\mathcal{I}) \otimes_k C$; one then has $M_K(C) = M(k/\mathcal{I}') \otimes_k C$ for every open ideal $\mathcal{I}'$ contained in $\mathcal{I}$. One then defines $\Gamma^*(M)_K$ as the inverse limit, for $\mathcal{I}$ ranging over the open ideals of k , of the pseudocompact K -modules:

```

```text
Hom_K(I)(M_K(K/I), K/I) = Hom_{k/I}(M(k/I), K/I),
```

```

where in the right-hand term $\mathcal{I}$ is any open ideal of k such that $\tau(\mathcal{I}) \subset I$. Moreover, by 1.2.3.A, the right-hand side is identified with $M(k/\mathcal{I})^* \hat{\otimes}_k (K/I)$. Since the projections $\Gamma^*(M) \rightarrow M(k/\mathcal{I})^*$ are surjective, one sees that the inverse limit of $M(k/\mathcal{I})^* \hat{\otimes}_k (K/I)$ is nothing but the pseudocompact K -module $\Gamma^*(M) \hat{\otimes}_k K$ (cf. 0.5.A). One has thus obtained that, for every flat 0_k -module M , the formation of $\Gamma^*(M)$ commutes with extension of the base, i.e. one has

```

```text
(*) Γ^*_K(M ⊗_k K) = Γ^*(M) ⊗_k K.
```

```

Proposition 1.2.3.E. (i) The functors $N \mapsto V^*_k(N)$ and $M \mapsto \Gamma^*(M)_K$ define an anti-equivalence between the category of projective pseudocompact k -modules and that of flat 0_k -modules. [N.D.E-VII_B-48]

(ii) Moreover, if $k \rightarrow K$ is a morphism of pseudocompact rings, then the previous anti-equivalence "commutes with base change" in the following sense: if $N \simeq \Gamma^*(M)$, then $N \hat{\otimes}_k K \simeq \Gamma^*(M)_K$.

<!-- label: III.VII_B.1.2.3.E -->

Proof. On the one hand, one has a natural transformation $\phi_N : N \rightarrow \Gamma^*(V^*_k(N))$. Since the functor $\Gamma^* \circ V^*_k$ commutes with products, by 0.3.5 and 0.2.F, it suffices to verify that ϕ_N is an isomorphism when N is a local component $k_{\mathfrak{m}}$ of k . In this case, for every open ideal $\mathcal{I}$ of k contained in $\mathfrak{m}$, the natural morphism

```

```text
(k/I) → Hom_{k/I}(Hom_c(k/I ⊗ k/I, k/I), k/I)
```

```

is an isomorphism, whence the result.

<!-- original page 525 -->

On the other hand, let M be a flat 0_k -module. Let us show that $\Gamma^*(M) = \varprojlim M(k/\mathcal{I})^*$ is a projective object of $\text{PC}(k)$. Let $N \rightarrow N'$ be a surjective morphism between objects of $\text{LF}(k)$. By 0.2.F (i) and (ii), it suffices to show that the natural map

```

```text
colim Hom_c(M(k/I)^*, N) → colim Hom_c(M(k/I)^*, N')
```

```

is surjective. But this is clear, because N and N' are $k_{\mathcal{I}_0}$ -modules for some open ideal $\mathcal{I}_0$; so if $\mathcal{I} \subset \mathcal{I}_0$, every morphism $M(k/\mathcal{I})^* \rightarrow N'$ lifts to a morphism $M(k/\mathcal{I})^* \rightarrow N$, since $M(k/\mathcal{I})^*$ is a projective object of $\text{PC}(k/\mathcal{I})$.

One has a morphism $\psi : M \rightarrow V^*_k(\Gamma^*(M)_K)$ of functors from Alg/k to (Sets) . Let B be an object of Alg/k ; let us show that

```

```text
(1) ψ(B) : M(B) → V^*_k(Γ^*(M)_K(B)) = Hom_c(lim_I M(k/I)^* ⊗_k B, B)
```

```

is a bijection (in the equality above, we have used the fact that $\hat{} \otimes B$ commutes with filtered inverse limits). Let $\mathcal{I}_0$ be an open ideal of k contained in the kernel of $k \rightarrow B$. By Lemma 1.2.3.A, for every $\mathcal{I} \subset \mathcal{I}_0$, one has a canonical isomorphism of pseudocompact B -modules:

```

```text
***M**($k/\mathcal{I}$) $^{\otimes k} \cong \text{Hom}_{k/\mathcal{I}}(M(k/\mathcal{I}), B)$
```

```

and, since $M(B) = M(k/\mathcal{I}) \otimes_{k/\mathcal{I}} B$, the right-hand side equals $\text{Hom}_B(M(k/\mathcal{I}), B)$. So the inverse system in (1) is constant for $\mathcal{I} \subset \mathcal{I}_0$, and (1) reduces to the canonical morphism

```

```text
***M**(B) $\rightarrow \text{Hom}_C(\text{Hom}_B(M(B), B), B)$,
```

```

which is an isomorphism by 0.2.2, since B is artinian and $M(B)$ a projective B -module. This proves point (i) of the proposition, and point (ii) follows from the isomorphism (*) established above.

Remark 1.2.3.F. Let us return to the statement of the proposition, and suppose moreover that N is a topologically free pseudocompact k -module. In this case, one can choose "coherently" bases for the C -modules $V_k(N)(C)$.

<!-- label: III.VII_B.1.2.3.F -->

Indeed, let $\{n_i\}$ be a pseudobasis of N (0.2.1) and $n^{\{C\}}_i$ the canonical image of n_i in $C \hat{\otimes}_k N$, for $C \in \text{Alf}/k$. If one defines the element $\delta^{\{C\}}_i$ of $(C \hat{\otimes}_k N)^+$ by the equalities $\delta^{\{C\}}_i(n^{\{C\}}_i) = 1$ and $\delta^{\{C\}}_i(n^{\{C\}}_j) = 0$ for $i \neq j$, the family $\{\delta^{\{C\}}_i\}$ is a basis of $V^{\{C\}}_k(N)(C)$; moreover, for every morphism $\phi : C \rightarrow D$ of Alf/k , $V^{\{C\}}_k(N)(\phi)$ sends $\delta^{\{C\}}_i$ to $\delta^{\{D\}}_i$.

1.2.4.

<!-- label: III.VII_B.1.2.4 -->

[^N.D.E-VII_B-49] For every pseudocompact k -module E , let $\hat{S}_{\{k\}}(E)$ be the *completed symmetric algebra* of E , defined as follows. Let $T_{\{k\}}(E)$ be the direct sum of the pseudocompact k -modules:

```

```text
 $\otimes^{\wedge n}_k E = E \otimes^{\wedge k} \cdots \otimes^{\wedge k} E \quad (n \geq 0; \text{ if } n = 0, \otimes^{\wedge 0}_k E = k);$
```

```

one makes $T_{\{k\}}(E)$ into a graded k -algebra by defining the multiplication in the usual way; <!-- original page 497 --> let $S_{\{k\}}(E)$ be the quotient of $T_{\{k\}}(E)$ by the homogeneous ideal whose n -th component is the closed k -submodule of $\hat{\otimes}^n_{\{k\}} E$ generated by the elements:

```

```text
 $x_1 \otimes^{\wedge} \cdots \otimes^{\wedge} x_i \otimes^{\wedge} x_{i+1} \otimes^{\wedge} \cdots \otimes^{\wedge} x_n - x_1 \otimes^{\wedge} \cdots \otimes^{\wedge} x_{i+1} \otimes^{\wedge} x_i \otimes^{\wedge} \cdots \otimes^{\wedge} x_n.$
```

```

If one denotes by $S^{\wedge n}_{\{k\}}(E)$ this quotient, $S_{\{k\}}(E)$ is obviously a graded k -algebra with n -th component $S^{\wedge n}_{\{k\}}(E)$.

One endows $S_{\{k\}}(E)$ with the linear topology defined by the set $\mathcal{U}$ of ideals $\mathcal{I}$ such that $S_{\{k\}}(E)/\mathcal{I}$ is a k -module of finite length and that $S^{\wedge n}_{\{k\}}(E) \cap \mathcal{I}$ is an open submodule of $S^{\wedge n}_{\{k\}}(E)$ for every n . Then the profinite algebra $\hat{S}_{\{k\}}(E)$ is the separated completion of $S_{\{k\}}(E)$ for this topology. [^N.D.E-VII_B-50]

We denote by $V^{\{f\}}_{\{k\}}(E)$ the formal k -variety $\text{Spf}(\hat{S}_{\{k\}}(E))$. It represents the k -functor $V^{\{f\}}_{\{k\}}(E)$, i.e., for every object C of Alf/k , one has a canonical isomorphism:

```

```text
 $V^{\{f\}}_k(E)(C) = \text{Hom}_C(E, C|_k) \cong \text{Hom}_{\{\text{Alf}/k\}}(\hat{S}_k(E), C) = \text{Hom}_{\{\text{Vaf}/k\}}(\text{Spf}(C), V^{\{f\}}_k(E)).$
```

```

In all the sequel, we identify $V^{\{f\}}_{\{k\}}(E)$ with the k -functor $V^{\{f\}}_{\{k\}}(E)$.

1.2.5.

<!-- label: III.VII_B.1.2.5 -->

By 1.2.4, the zero morphism from E to k is associated with a morphism of profinite algebras $\pi : \hat{S}_{\{k\}}(E) \rightarrow k$; this morphism π induces the zero map on $S^{\{n\}}_{\{k\}}(E)$ for $n \geq 1$ and defines a section of the structure morphism $V^{\{f\}}_{\{k\}}(E) \rightarrow \mathrm{Spf}(k)$.

We shall denote by $V^{\{f,0\}}_{\{k\}}(E)$ the formal variety which has as points the images of the points of $\mathrm{Spf}(k)$ under the section π and which has the same local algebras as $V^{\{f\}}_{\{k\}}(E)$ at these points. [N.D.E-VII_B-51]

Then, the affine algebra of $V^{\{f,0\}}_{\{k\}}(E)$ is the separated completion of $S_{\{k\}}(E)$ for the topology defined by the ideals $\mathcal{I}_n$ in $\mathcal{U}$ (cf. 1.2.4) that contain $S^{\{n\}}_{\{k\}}(E)$ for n large enough. One deduces that it is the infinite product:

```text  
k[[E]] = k × E × S^2\_k(E) × S^3\_k(E) × ...  
```

On the other hand, let C be an object of $\mathcal{A}/k$, u an element of $V^{\{f\}}_{\{k\}}(C) = \mathrm{Hom}_{\mathcal{C}}(E, C)$, and $\phi : \hat{S}_{\{k\}}(E) \rightarrow C$ the corresponding morphism of profinite k -algebras. Then $\mathrm{Ker}(\phi)$ is an open ideal (i.e. ϕ belongs to $V^{\{f,0\}}_{\{k\}}(C)$) if and only if $\mathrm{Ker}(\phi)$ contains $S^{\{n\}}_{\{k\}}(E)$ for n large enough, i.e., if and only if u is contained in the radical $\mathcal{R}(C)$ of C . Therefore: for every object C of $\mathcal{A}/k$, one has canonical isomorphisms:

<!-- original page 498 -->

```text  
 $V^{\{f,0\}}_{\{k\}}(C) = \mathrm{Hom}_{\mathcal{A}/k}(k[[E]], C) = \mathrm{Hom}_{\mathcal{C}}(E, \mathcal{R}(C)).$   
```

1.2.6.

<!-- label: III.VII_B.1.2.6 -->

A formal k -variety V is said to be of finite length if its affine algebra is. Likewise, if S is a scheme, an S -scheme X is said to be of finite length if X is finite over S and if the direct image of $\mathcal{O}_X$ on S is an $\mathcal{O}_S$ -module of finite length. [N.D.E-VII_B-52] So, to give an S -scheme of finite length X is "the same thing" as to give a finite set $\{s_1, \dots, s_n\}$ of closed points of S , and at each of these points, an $\mathcal{O}_{S, s_i}$ -algebra of finite length.

One sees therefore that the S -schemes of finite length identify with the formal varieties of finite length over the formal scheme $\hat{S}$ that follows. The topological space underlying $\hat{S}$ is the set of closed points of S endowed with the discrete topology; if s is such a closed point, the structure sheaf $\mathcal{O}_{\hat{S}}$ has as stalk $\mathcal{O}_{\hat{S}, s}$ at s the separated completion $\hat{\mathcal{O}}_{S, s}$ of $\mathcal{O}_{S, s}$ for the linear topology defined by the ideals of finite colength; one therefore has $\hat{\mathcal{O}}_{\hat{S}} = \mathrm{Spf} \mathcal{A}(\hat{S})$, where $\mathcal{A}(\hat{S})$ is the product of the $\hat{\mathcal{O}}_{S, s}$, for s ranging over the closed points of S , endowed with the product topology.

Definition. If X is an S -scheme, we denote by $\hat{X}/\hat{S}$ the formal variety over $k = \mathcal{A}(\hat{S})$ defined as follows. The underlying topological space is formed by the points $x \in X$ such that $[\kappa(x) : \kappa(s)] < \infty$, where s is the image of x in S ; the local ring $\hat{\mathcal{O}}_{\hat{X}/\hat{S}, x}$ is the separated completion of $\mathcal{O}_{X, x}$ for the linear topology defined by the ideals $\mathcal{I}_i$ of $\mathcal{O}_{X, x}$ such that $\mathcal{O}_{X, x}/\mathcal{I}_i$ is of finite length as an $\mathcal{O}_{S, s}$ -module (N.B. since $[\kappa(x) : \kappa(s)] < \infty$, this is equivalent to saying that $\mathcal{O}_{X, x}/\mathcal{I}_i$ is of finite length as an $\mathcal{O}_{X, x}$ -module).*

Let $\mathcal{V}_{\mathrm{ell}}/\hat{S}$ be the category of formal varieties of finite length over $\hat{S}$ (identified with that of S -schemes of finite length). By 1.1 and 1.2.1, the category $\mathcal{V}_{\mathrm{ell}}/\hat{S}$ of formal varieties over $\hat{S}$ is equivalent to that of left-exact contravariant functors from $\mathcal{V}_{\mathrm{ell}}/\hat{S}$ to (Sets) . In particular, for every S -scheme X , the functor $T \mapsto \mathrm{Hom}_{\mathcal{C}}(\hat{S}(T), X)$, from $\mathcal{V}_{\mathrm{ell}}/\hat{S}$ to (Sets) , is such a left-exact functor, hence corresponds to a formal variety over $\hat{S}$. The latter is nothing but $\hat{X}/\hat{S}$: [N.D.E-VII_B-53]

****Proposition.**** *For every S -scheme X , the functors*

```
```text
Hom_{Vaf/S}(-, X^{\wedge}) and Hom_{(Sch/S)}(-, X)
```

\*have the same restriction to  $Vaf \setminus \ell f / \hat{S}$ . One thus obtains a functor  $X \mapsto \hat{X} / \hat{S}$  from  $(Sch/S)$  to  $Vaf / \hat{S}$  which commutes with finite inverse limits.\*

<!-- original page 528 -->

Indeed, one sees easily that the formal variety  $\hat{X} / \hat{S}$  has the required property, and that the correspondence  $X \mapsto \hat{X} / \hat{S}$  is functorial. Let us prove the second assertion.

Set  $S^* = (Sch/S)$  and  $V^* = Vaf / \hat{S}$ , and write  $\hat{X}$  instead of  $\hat{X} / \hat{S}$ . We know (1.2.B) that  $V^*$  possesses arbitrary inverse limits. Let  $(X_i)_{i \in I}$  be an inverse system in  $S^*$  and suppose that  $X = \varprojlim X_i$  exists in  $S^*$  (which is the case if  $I$  is finite). Since the functor that associates to every object  $Y$  of  $S^*$  (resp.  $V$  of  $V^*$ ) the functor  $h^Y = \operatorname{Hom}_{S^*}(-, Y)$  (resp.  $h^V = \operatorname{Hom}_{V^*}(-, V)$ ) commutes with inverse limits, one has, for every  $S$ -scheme  $T$  of finite length, functorial isomorphisms:

```
```text
Hom_{S^*}(T, X) = \lim Hom_{S^*}(T, X_i) = \lim Hom_{V^*}(T, X_i^{\wedge}) = Hom_{V^*}(T, \lim X_i^{\wedge}).
```

Consequently, the functor $X \mapsto \hat{X} / \hat{S}$ commutes with inverse limits when they exist in (Sch/S) ; in particular, it commutes with finite inverse limits.

1.3.

<!-- label: III.VII_B.1.3 -->

<!-- original page 499 -->

****Proposition 1.3.**** *Let $f : X \rightarrow Y$ be a morphism of formal varieties over k , A and B the affine algebras of X and Y , $g : B \rightarrow A$ the morphism induced by f . Then f is a monomorphism of Vaf/k if and only if g is a surjection.*

<!-- label: III.VII_B.1.3 -->

[^N.D.E-VII_B-54] By 1.1, $A \mapsto \operatorname{Spf}(A)$ is an anti-equivalence of Alp/k onto Vaf/k , so f is a monomorphism if and only if g is an epimorphism, and this is the case if g is surjective.

Conversely, suppose that g is an epimorphism and let us show that it is surjective. For every $\frac{n}{\epsilon} \in \operatorname{Upsilon}(B)$, set $A_{\frac{n}{\epsilon}} = A \hat{\otimes}_B B_{\frac{n}{\epsilon}}$; by 0.4, A is a pseudocompact B -module, hence is the product of the $A_{\frac{n}{\epsilon}}$ (cf. 0.3.6). Then g is the product of the morphisms $g_{\frac{n}{\epsilon}} : B_{\frac{n}{\epsilon}} \rightarrow A_{\frac{n}{\epsilon}}$ deduced from g by base change. These are still epimorphisms, which reduces us to proving the result when B is local with maximal ideal $\frac{n}{\epsilon}$. Set $K = B / \frac{n}{\epsilon}$.

By Nakayama's Lemma 0.3.3, it suffices to show that the morphism $g \hat{\otimes}_B K$ is surjective; it is deduced from g by base change, so is an epimorphism of Alp/K . One can therefore assume that $B = K$ is a field. Now f is a monomorphism if and only if the diagonal morphism $X \rightarrow X \times_Y X$ is an isomorphism, that is, if the homomorphism $x \hat{\otimes}_K x' \mapsto x x'$ is an isomorphism of $A \hat{\otimes}_K A$ onto A . Since K is a field, this implies $A = K$.

****Remark.****[^N.D.E-VII_B-55] *It follows from the proposition that every monomorphism $f : X \rightarrow Y$ of formal varieties is an isomorphism of X onto a (necessarily closed!) formal subvariety of Y .*

1.3.1.

<!-- label: III.VII_B.1.3.1 -->

The preceding proposition implies in particular that every monomorphism $f : X \rightarrow Y$ of Vaf/k is effective (cf. IV

1.3).[^{N.D.E-VII_B-56}] It is not the same for epimorphisms, as one easily sees by slightly modifying the counterexample of Exposé V, § 2.c);[^{N.D.E-VII_B-57}] this is why we shall consider a sympathetic class of effective epimorphisms.

<!-- original page 529 -->

Lemma.[^{N.D.E-VII_B-58}] *Let $f : X \rightarrow Y$ be a morphism of formal k -varieties and let A , B be the affine algebras of X , Y and $f^{\mathbb{N}} : B \rightarrow A$ the morphism induced by f . The following conditions are equivalent:*

(i) For every $x \in X$, the homomorphism $f^{\mathbb{N}}_{\{x\}} : 0_{\{Y, f(x)\}} \rightarrow 0_{\{X, x\}}$ makes $0_{\{X, x\}}$ a topologically free pseudocompact $0_{\{Y, f(x)\}}$ -module.*

(ii) For every $y \in Y$, the local component $A_{\{y\}} = \prod_{f(x)=y} 0_{\{X, x\}}$ is a topologically free pseudocompact $B_{\{y\}}$ -module.*

(iii) $f^{\mathbb{N}} : B \rightarrow A$ makes A a projective pseudocompact B -module.*

(iv) The functor $PC(B) \rightarrow PC(A)$, $M \mapsto M \hat{\otimes}_B A$, is exact.*

If these conditions are satisfied, one says that f is topologically flat.

The implications (i) $\Rightarrow$ (ii) $\Leftrightarrow$ (iii) $\Leftrightarrow$ (iv) follow from 0.2.F (iii) and 0.3.7. Conversely, assume (ii) holds and let $x \in X$ and $y = f(x)$. Since $0_{\{X, x\}}$ is a direct factor of $A_{\{y\}}$, it is a projective pseudocompact $B_{\{y\}}$ -module, hence topologically free by 0.2.1 (since $B_{\{y\}}$ is local).

On the other hand, a morphism $f : X \rightarrow Y$ of formal k -varieties is said to be *surjective* if it induces a surjection of the underlying sets.

<!-- original page 500 -->

Proposition. *Let $f : X \rightarrow Y$ be a surjective and topologically flat morphism of formal k -varieties. Then f is an effective epimorphism (cf. IV 1.3).*

Indeed, let A , B be the affine algebras of X , Y and $g : B \rightarrow A$ the morphism induced by f . We must show that Y is identified with the cokernel of $X \times_Y X \rightarrow X$, i.e., that for every $\frac{n}{m} \in \mathbb{N} \setminus \{0\}$, $\frac{n}{m}$ is identified with the subring of $A_{\frac{n}{m}} = A \hat{\otimes}_B B_{\frac{n}{m}}$ formed by the a such that $a \hat{\otimes} 1 = 1 \hat{\otimes} a$.

We can therefore assume B local, with maximal ideal $\frac{n}{m}$. Our hypothesis then means that g makes A a topologically free and nonzero B -module. By Nakayama's Lemma 0.3.3, $A / \frac{n}{m} A$ is not zero, so the morphism $g' : B / \frac{n}{m} B \rightarrow A / \frac{n}{m} A$ deduced from g is injective. By Lemma 1.3.2 below, B is a direct factor of A as a B -module, say $A = B \oplus A'$; it follows that B is identified with the part of A formed by the a such that $a \hat{\otimes} 1_B = 1 \hat{\otimes} a$.

1.3.2.

<!-- label: III.VII_B.1.3.2 -->

Lemma 1.3.2. *Let B be a local pseudocompact ring, $\frac{n}{m}$ its maximal ideal, M and N two projective pseudocompact B -modules, and g a morphism $M \rightarrow N$. If $(B / \frac{n}{m}) \hat{\otimes}_B g$ is injective, g is an isomorphism of M onto a direct factor of N .*

<!-- label: III.VII_B.1.3.2 -->

Indeed, suppose $g' = (B / \frac{n}{m}) \hat{\otimes}_B g$ is injective. Since $B / \frac{n}{m}$ is a field, g' then has a retraction r' . Let p and q be the canonical projections of M and N onto $M / \frac{n}{m} M$ and $N / \frac{n}{m} N$; since N is projective, there exists a morphism $r : N \rightarrow M$ such that $p \circ r = r' \circ q$; consequently, r' is deduced from r by passage to the quotient. Then, since $r' \circ g'$ is an isomorphism, so is $r \circ g$, by 0.3.4 (since M is projective). Let s be the inverse isomorphism of $r \circ g$; then $s \circ r$ is a retraction of g .

1.3.3.

<!-- label: III.VII_B.1.3.3 -->

Proposition 1.3.3. Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$ be morphisms of formal k -varieties.

(i) If f and g are topologically flat, so is $g \circ f$.

(ii) If f and $g \circ f$ are topologically flat and if f is surjective, g is topologically flat.

(iii) If f is topologically flat, so is $f|_{Y'}$ for every base change $Y' \rightarrow Y$.

label: III.VII_B.1.3.3 -->

original page 501 -->

Assertions (i) and (iii) are clear. To prove (ii), let A, B, C be the affine algebras of X, Y, Z , and $f' : B \rightarrow A$ and $g' : C \rightarrow B$ the morphisms induced by f and g . Since $g \circ f$ is topologically flat, $f' \circ g'$ makes A a projective pseudocompact C -module; likewise, f' makes A a projective pseudocompact B -module that is also faithful. As P ranges over the pseudocompact C -modules and N over the pseudocompact B -modules, the functors $P \mapsto P \hat{\otimes}_C A$ and $N \mapsto N \hat{\otimes}_B A$ are therefore exact; since the second is moreover faithful, the functor $P \mapsto P \hat{\otimes}_C B$ is exact; by 0.3.7, B is therefore a projective pseudocompact C -module.

1.3.4.

label: III.VII_B.1.3.4 -->

Proposition 1.3.4. Let S be a scheme, Y a locally noetherian S -scheme, and $f : X \rightarrow Y$ an S -morphism locally of finite type and faithfully flat, so that f is an effective epimorphism, i.e., the sequence below is exact (cf. IV 6.3.1 (iv) and IV 1.3):

text
(*) $X \times_Y X \rightarrow X \rightarrow Y$.

Then the morphism of formal $\hat{S}$ -varieties $\hat{f} : \hat{X} \rightarrow \hat{Y}$ (cf. 1.2.6) is surjective and topologically flat, and the sequence below, deduced from (*), is exact:

text
(*) $\hat{X} \times_{\hat{Y}} \hat{X} \rightarrow \hat{X} \rightarrow \hat{Y}$.

label: III.VII_B.1.3.4 -->

Indeed, let y be a point of Y with projection s on S and such that $\kappa(y)$ is a finite extension of the residue field $\kappa(s)$ of s . Since f is surjective and locally of finite type, $f^{-1}(y)$ is non-empty and locally of finite type over $\kappa(y)$; the closed points of $f^{-1}(y)$ are then the points of $\hat{X}/\hat{S}$ projecting onto y . This shows that $\hat{f}$ is surjective.

original page 531 -->

[N.D.E-VII_B-59] Let x be a closed point of $f^{-1}(y)$. Since Y is locally noetherian and f locally of finite type, the local ring $\mathcal{O}_{Y, y}$ (resp. $\mathcal{O}_{X, x}$) is noetherian, so the powers of the maximal ideal are of finite colength, so that the local ring of $\hat{Y}/\hat{S}$ at y (resp. of $\hat{X}/\hat{S}$ at x) is the completion $\hat{\mathcal{O}}_{Y, y}$ of $\mathcal{O}_{Y, y}$ (resp. $\hat{\mathcal{O}}_{X, x}$ of $\mathcal{O}_{X, x}$) for the $\mathfrak{m}$ -adic topology. Then, since f is flat, $\hat{\mathcal{O}}_{X, x}$ is flat over $\hat{\mathcal{O}}_{Y, y}$, by (SGA 1, IV 5.8). Hence, by 0.3.8, $\hat{\mathcal{O}}_{X, x}$ is a topologically free $\hat{\mathcal{O}}_{Y, y}$ -module. This shows that $\hat{f}$ is topologically flat.

So, by Proposition 1.3.1, $\hat{f}$ is an effective epimorphism, i.e., the sequence below (where one has written $\hat{X}$ instead of $\hat{X}/\hat{S}$) is exact:

text
 $\hat{X} \times_{\hat{Y}} \hat{X} \rightarrow \hat{X} \rightarrow \hat{Y}$.

Moreover, by 1.2.6, one has a natural isomorphism (which in particular commutes with the projections on $\hat{X}$):

text

$$X^{\wedge} \times_Y X = X^{\wedge} \times_{\tilde{Y}} X^{\wedge}.$$

Consequently, the sequence $\mathcal{H}^{\ast}$ is exact.

1.3.5.

<!-- label: III.VII_B.1.3.5 -->

Let k be a pseudocompact ring. A formal variety X over k is said to be *topologically flat* if its affine algebra A is a projective pseudocompact k -module, i.e., if the structure morphism $X \rightarrow \mathrm{Spf}(k)$ is topologically flat.

[^N.D.E-VII_B-60] Let us first note that 0.2.2 and 0.3.6 imply the following result (analogous to VII_A, 3.1.1).

Lemma 1.3.5.A. Suppose k artinian. The functors $A \mapsto A^{\dagger} = \mathrm{Hom}_c(A, k)$ and $C \mapsto C^{\dagger} = \mathrm{Hom}_c(C, k)$ define an anti-equivalence between the category of topologically flat profinite k -algebras, and that of flat k -coalgebras.

<!-- label: III.VII_B.1.3.5.A -->

Indeed, if A is a topologically flat profinite k -algebra, then by 0.3.6, one has an isomorphism of k -modules:

$$A^{\dagger} \otimes_k A^{\dagger} \cong (A \otimes A)^{\dagger},$$

so that the multiplication $A \hat{\otimes} A \rightarrow A$ induces by duality a k -coalgebra structure on $A^{\dagger}$. The rest then follows from Proposition 0.2.2.

Let us return to the case of an arbitrary pseudocompact ring k .

Definition 1.3.5.B. To every formal k -variety X whose affine ring A is a projective pseudocompact k -module, one associates a flat 0_k -coalgebra $H(X)$, defined as follows.

<!-- label: III.VII_B.1.3.5.B -->

Denote by $H(X)$ the 0_k -module $V^f_k(A)$, “dual of A ”; it is a flat 0_k -module, since the pseudocompact k -module underlying A is projective (cf. 1.2.3.C). Moreover, by 0.3.6, one has:

<!-- original page 503 -->

$$V_k^f(A \otimes A) \cong V_k^f(A) \otimes V_k^f(A),$$

and so the multiplication of A induces by transposition a diagonal morphism:

$$H(X) = V_k^f(A) \rightarrow V_k^f(A \otimes A) = H(X) \otimes H(X),$$

which makes $H(X)$ a flat 0_k -coalgebra. We shall say that $H(X)$ is the *coalgebra of X over 0_k* .

Definition 1.3.5.C. Conversely, to every 0_k -coalgebra C one can associate a k -functor (cf. 1.2.1) $\mathrm{Spf}^*(C)$, defined as follows. For every object B of Alg/k , one sets (with the notations of VII_A 3.1):

$$(1) \quad \mathrm{Spf}^*(C)(B) = \mathrm{Hom}_{\{B\text{-} \mathrm{coalg.}\}}(B, C(B)) \\ = \{x \in C(B) \mid \varepsilon_{C(B)}(x) = 1 \text{ and } \Delta_{C(B)}(x) = x \otimes x\}.$$

<!-- label: III.VII_B.1.3.5.C -->

[^N.D.E-VII_B-61] Assume moreover that the 0_k -module underlying C is admissible (cf. 1.2.1), and set

```

```text
(2) $A = \Gamma^*(C) = \varprojlim C(k/\square)^*.$
```

```

Then the algebra structures on each $C(k/\mathcal{l})^*$ endow A with a structure of profinite k -algebra. For every object B of $\mathcal{A}/k$, one has:

```

```text
(3) $\mathrm{Hom}_{\mathcal{V}/k}(\mathrm{Spf}(B), \mathrm{Spf}(A)) = \mathrm{Hom}_{\mathcal{A}/k}(A, B) = \mathrm{Hom}_{\mathcal{A}/B}(A \otimes B, B).$
```

```

Assume finally that C is a flat 0_k -module. Then, by 1.2.3.E, $A = \Gamma^*(C)$ is a projective pseudocompact k -module. Moreover, we saw in the proof of *loc. cit.* that, if $\mathcal{l}_0$ is an open ideal of k contained in the kernel of $k \rightarrow B$, one has isomorphisms

```

```text
(4) $A \otimes B = \varprojlim C(k/\square)^* \otimes_k B \simeq \mathrm{Hom}_{\mathcal{A}/\mathcal{l}_0}(C(k/\mathcal{l}_0), B) \simeq \mathrm{Hom}_B(C(B), B),$
```

```

and we shall denote by $C(B)^*$ the right-hand term. Finally, by Lemma 1.3.5.A applied to the artinian ring B , one has a natural isomorphism

```

```text
(5) $\mathrm{Hom}_{\mathcal{B}\text{-coalg.}}(B, C(B)) \simeq \mathrm{Hom}_{\mathcal{A}/B}(C(B)^*, B).$
```

```

Then, combining (1), (5), (4), (3) and (2), one obtains, when C is a flat 0_k -coalgebra, an isomorphism of functors:

```

```text
(*) $\mathrm{Spf}^*(C) \simeq \mathrm{Spf}(A) = \mathrm{Spf}(\Gamma^*(C)).$
```

```

Consequently, if one denotes by $\mathcal{A}(X)$ the affine algebra of a formal k -variety X , one obtains, taking 1.2.3.E into account:

Proposition 1.3.5.D. (i) The functors $X \mapsto H(X) = \bigvee_k \mathcal{A}(X)_k$ and $C \mapsto \mathrm{Spf}^*(C) = \mathrm{Spf}(\Gamma^*(C))$ define an equivalence between the category of topologically flat formal k -varieties and that of flat 0_k -coalgebras.*

(ii) Moreover, this equivalence "commutes with base change": if $k \rightarrow K$ is a morphism of pseudocompact rings, then $X \hat{\otimes}_k K$ corresponds to $H(X) \otimes_k K$.*

<!-- label: III.VII_B.1.3.5.D -->

1.3.6.

<!-- label: III.VII_B.1.3.6 -->

<!-- original page 533 -->

In the rest of this Exposé, we shall several times define a topologically flat formal k -variety X by exhibiting the coalgebra $H(X)$. We shall then need to interpret by means of $H(X)$ certain geometric properties of X . We give here an example of this situation: suppose given a section σ of the structure morphism $X \rightarrow \mathrm{Spf}(k)$ and ask ourselves under what condition σ induces an isomorphism on the underlying topological spaces. [N.D.E-VII_B-62]

To begin, suppose k artinian. Let (H, Δ, ϵ) be a flat k -coalgebra, $H^+ = \mathrm{Ker}(\epsilon)$ and $A = H^+$ the profinite k -algebra dual to H . Suppose given a morphism of k -coalgebras $k \rightarrow H$, i.e., an element ϕ of H such that $\epsilon(\phi) = 1$ and $\Delta(\phi) = \phi \otimes \phi$. On the one hand, ϕ defines a continuous algebra morphism $\Phi : A \rightarrow k$, and hence a section $\sigma : \mathrm{Spf}(k) \rightarrow \mathrm{Spf}(A)$ of the projection $\mathrm{Spf}(A) \rightarrow \mathrm{Spf}(k)$.

<!-- original page 504 -->

On the other hand, one defines k -submodules of H by setting $H_{\{0\}} = k \cdot \phi$ and, for $n \geq 1$,

```
```text
H_n = {x ∈ H | Δ(x) - x ⊗ ϕ ∈ H_{n-1} ⊗ H^+};
```

this is also valid for  $n = 0$  if one sets  $H_{\{-1\}} = (0)$ . One sees, by induction on  $n$ , that  $H_{\{n-1\}} \subset H_{\{n\}}$ . We say that  $H_{\{0\}} \subset H_{\{1\}} \subset \dots$  is the *filtration* of  $H$  defined by  $\phi$ .

**Remark.** Since  $\Delta(H_{\{n\}}) \subset H_{\{n\}} \otimes H_{\{0\}} \oplus H_{\{n-1\}} \otimes H^+$ , one has  $\Delta(H_{\{n\}}) \subset H_{\{n\}} \otimes H$ . Since  $\Delta$  is cocommutative (i.e.  $\sigma \circ \Delta = \Delta$ , where  $\sigma(a \otimes b) = b \otimes a$ ), one also has  $\Delta(H_{\{n\}}) \subset H \otimes H_{\{n\}}$ . When  $H/H_{\{n\}}$  is flat over  $k$ , it follows that  $H_{\{n\}}$  is a sub-coalgebra of  $H$  (see also 1.3.6.A (iii) below). But in general,  $\Delta : H_{\{n\}} \rightarrow H_{\{n\}} \otimes H$  does not factor through  $H_{\{n\}} \otimes H_{\{n\}}$ . [N.D.E-VII-B-63]

**Lemma 1.3.6.A.** Let  $k$  be an artinian ring,  $H$  a flat  $k$ -coalgebra,  $A = H^*$  the dual profinite  $k$ -algebra,  $\phi$  an element of  $H$  such that  $\epsilon(\phi) = 1$  and  $\Delta(\phi) = \phi \otimes \phi$ . Let  $\Phi : A \rightarrow k$  be the continuous algebra morphism,  $\sigma : \text{Spf}(k) \rightarrow \text{Spf}(A)$  the section of  $\text{Spf}(A) \rightarrow \text{Spf}(k)$ , and  $(H_{\{n\}})$  the filtration of  $H$  defined by  $\phi$ . Set  $I = \text{Ker } \Phi$ .

(i) For every  $n \geq 1$ ,  $H_{\{n-1\}}$  is the orthogonal in  $H$  of the closure  $\bar{I}^{\{n\}}$  of  $I^{\{n\}}$ .

(ii) Consequently,  $\sigma$  induces a bijection of the underlying sets if and only if  $H = \bigcup_{\{n\}} H_{\{n\}}$ . [N.D.E-VII-B-64]

(iii) If moreover each  $H/H_{\{n\}}$  is flat over  $k$ , then for every  $n \geq 0$ ,

```
```text
(*) Δ(H_n) ⊂ ∑_{i=0}^n H_i ⊗ H_{n-i};
```

in particular, each $H_{\{n\}}$ is then a sub-coalgebra of H .

<!-- label: III.VII_B.1.3.6.A -->

Proof. Note that, for every $x \in H$, the map $A \rightarrow k$, $f \mapsto f(x)$ is continuous, so if $I^{\{n\}}$ is annihilated by x , so is its closure $\bar{I}^{\{n\}}$. We set then, for every $n \geq 1$,

```
```text
(I^n)^⊥ = {x ∈ H | f(x) = 0, for every f ∈ I^n}.
```

Suppose that  $\sigma : \mathfrak{m} \rightarrow \Phi^{-1}(\mathfrak{m})$  is a bijection of  $\text{Spf}(k)$  onto  $\text{Spf}(A)$ . Since  $I$  is contained in the intersection of the  $\Phi^{-1}(\mathfrak{m})$ , it follows from 0.1.2 that the sequence of ideals  $(\bar{I}^{\{n\}})$  tends to  $0$ . Let then  $x \in H$ ; since  $J(x) = \{f \in A \mid f(x) = 0\}$  is an open and closed  $k$ -submodule of  $A$ , it contains  $\bar{I}^{\{n\}}$  for  $n$  large enough; in other words,  $x \in (I^{\{n\}})^{\perp}$  for  $n$  large enough.

Conversely, suppose that  $H = \bigcup_{\{n\}} (I^{\{n\}})^{\perp}$ . Let  $\mathfrak{p}$  be an open prime ideal of  $A$ ; by the definition of the topology of  $A$  (0.2.2),  $\mathfrak{p}$  contains an open  $k$ -submodule of the form

```
```text
V(x_1, ..., x_s) = {f ∈ A | f(x_1) = ... = f(x_s) = 0}.
```

By hypothesis, there exists an integer n such that $x_1, \dots, x_s \in (I^{\{n\}})^{\perp}$, and so $\bar{I}^{\{n\}} \subset \mathfrak{p}$. Moreover, since k is artinian, $\text{Spf}(k)$ is a finite set $\{\mathfrak{m}_1, \dots, \mathfrak{m}_r\}$ and there exists an integer $t \geq 1$ such that $(\prod_{\{i\}} \mathfrak{m}_i)^t = 0$, whence

```
$$
\prod_{\{i\}} \Phi^{-1}(\mathfrak{m}_i)^t \subset I.
$$
```

So $\mathfrak{p}$ contains the product of the $\Phi^{-1}(\mathfrak{m}_i)^t$; since $\mathfrak{p}$ is prime, it

follows that $\mathfrak{p}$ contains, hence equals, one of the $\Phi^{-1}(\mathfrak{m}_i)$. One has thus shown that:

```
```text
σ is a bijection H = ⋃n (I^n)^⊥.
```

[^N.D.E-VII\_B-65]

<!-- original page 535 -->

On the other hand, one has  $H = k[\phi] \oplus H^+$ ; denote by  $\pi$  the projection  $H \rightarrow H^+$  of kernel  $k[\phi]$ . For every  $n \geq 0$ , let  $\Delta^n$  be the "iterated" comultiplication  $H \rightarrow H^{\otimes(n+1)}$ ,  $\bar{\Delta}^n$  the composite of  $\Delta^n$  with the projection  $\pi^{\otimes(n+1)} : H^{\otimes(n+1)} \rightarrow (H^+)^{\otimes(n+1)}$ , and

```
```text
H'_n = Ker(Δ^n) = {x ∈ H | Δ^n(x) ∈ ⋃_{i=0}^n H^{\otimes(n-i)} ⊗ H_0 ⊗ H^{\otimes i}}.
```

(One sets $\bar{\Delta}^0 = \text{id}_H$, whence $H'_0 = H_0$.) One sees easily, by induction on n , that

```
$(\text{last}) \quad H_n \subset H'_n \subset (I^{(n+1)})^{\perp}.$
$`
```

Up to this point, one has not used the hypothesis that H is flat over k . Suppose now H flat, hence projective over k , so that $A^+ = H^+$ by 0.2.2, and let us show that $H_n = (I^{(n+1)})^{\perp}$. This is clear for $n = 0$. Assume it verified for $n < r$. Then H_{r-1} is the kernel of the morphism $H \rightarrow (I^r)^+$, and so, since H^+ is flat, the morphism

```
```text
(H/H_{r-1}) ⊗ H^+ → (I^r)^+ ⊗ H^+
```

is injective. On the other hand, the hypothesis implies that  $I$  is a projective pseudocompact  $k$ -module (since a direct factor of  $A = H^*$ ), whence, by 0.3.6,

```
```text
(I^r ⊗ I)^+ = (I^r)^+ ⊗ I^+ = (I^r)^+ ⊗ H^+.
```

Then the exact sequence

```
```text
I^r ⊗ I → A → A/I^{r+1} → 0
```

<!-- original page 505 -->

gives by duality the exact sequence:

```
```text
(1) (I^r)^+ ⊗ H^+ ← H ← (A/I^{r+1})^+ ← 0,
```

where δ is obtained by composing Δ_H with the projection:

```
```text
(2) H ⊗ H → H ⊗ H^+ → (H/H_{r-1}) ⊗ H^+ ← (I^r)^+ ⊗ H^+.
```

Now, for every  $u \in H$ , the projection of  $\Delta(u)$  onto  $H \otimes H^+$  is  $\Delta(u) - u \otimes \phi$ . Then (1) and (2) show that if  $u$  belongs to  $(A/I^{r+1})^+ = (I^{r+1})^{\perp}$ , then  $\Delta(u) - u \otimes \phi$  belongs to the kernel of the map  $H \otimes H^+ \rightarrow (H/H_{r-1}) \otimes H^+$ , that is, to  $H_{r-1} \otimes H^+$ , so  $u \in H_r$ . This completes the proof of points (i) and (ii), and also shows that  $H_n = \text{Ker}(\bar{\Delta}^n)$ .

Let us prove (iii). For every  $i \geqslant 0$ , set  $H^+_i = H_i \cap H^+$ . Let  $n \geqslant 1$ . For every  $x \in H^+_n$ ,  $\bar{x} = x - \epsilon(x) \phi$  belongs to  $H^+_n$  and one has:

$$\Delta(x) = \epsilon(x) \phi \otimes \phi + x \otimes \phi + \phi \otimes x + \Delta^-(x).$$

So it suffices to show that:

$$\Delta^-(H^+_n) \subset \sum_{i=1}^{n-1} H^+_i \otimes H^+_{n-i}.$$

For every  $i = 0, \dots, n-1$ ,  $\bar{\Delta}^n$  factors as:

$$\begin{array}{ccc} H^+ & \xrightarrow{\Delta^-} & H^+ \otimes H^+ \xrightarrow{\Delta^{-i} \otimes \Delta^{-(n-i-1)}} (H^+)^{\otimes(i+1)} \otimes (H^+)^{\otimes(n-i)} \\ & \downarrow & \uparrow g \\ & H^+/H^+_i \otimes H^+/H^+_{n-i-1} \xrightarrow{f} & H^+ \otimes (H^+)^{\otimes(n-i)} / H^+_i. \end{array}$$

Moreover, since  $H^+/H^+_i$  and  $(H^+)^{\otimes(n-i)}$  are flat, the maps  $f$  and  $g$  above are injective. It follows that  $\bar{\Delta}(H^+_n)$  is contained in  $H^+_i \otimes H^+ + H^+ \otimes H^+_{n-i-1}$ , for every  $i = 0, \dots, n-1$ . Point (iii) then follows from the lemma below, applied to  $M = H^+$  and  $E_i = H^+_{i-1}$ .

**Lemma 1.3.6.B.** Let  $k$  be a ring,  $E_0 = E_{\{0\}} \subset E_{\{1\}} \subset \dots \subset E_{\{n\}} \subset M$   $k$ -modules. Suppose  $M/E_i$  flat for every  $i$ . Then one has the equality:

$$\bigcap_{i=0}^n (E_i \otimes M + M \otimes E_i) = \sum_{i=1}^n E_i \otimes E_{n-i+1}.$$

<!-- label: III.VII\_B.1.3.6.B -->

<!-- original page 536 -->

Denote by  $K$  (resp.  $S$ ) the left-hand (resp. right-hand) term. One easily sees that  $S \subset K$ ; let us show the converse. For  $i = 0, \dots, n$ , set  $K_i = K \cap (E_i \otimes M)$ . For every  $i = 1, \dots, n$ , since  $M/E_{n-i+1}$  and  $E_i/E_{i-1}$  are flat, the map  $\tau_i$  below is injective, and the composite map:

$$(E_i/E_{i-1}) \otimes M \rightarrow (E_i/E_{i-1}) \otimes (M/E_{n-i+1}) \xrightarrow{\tau_i} (M/E_{i-1}) \otimes (M/E_{n-i+1})$$

has kernel  $(E_i/E_{i-1}) \otimes E_{n-i+1}$ . Since the image of  $K_i$  in  $(E_i \otimes M)/(E_{i-1} \otimes M)$  is contained in, and contains, this kernel, one deduces that

$$K_i = K_{i-1} + E_i \otimes E_{n-i+1},$$

whence the lemma.

[^N.D.E-VII\_B-66] To finish this paragraph, let us return to an arbitrary pseudocompact ring  $k$ . Let  $(H^+, \Delta, \epsilon)$  be a flat  $0_k$ -coalgebra,  $H^+ = \text{Ker}(\epsilon)$ ,  $A = \Gamma^*(H^+)$  the dual profinite  $k$ -algebra,  $X = \text{Spf}(A)$ , so that  $H^+ = H^+(X)$  (cf. 1.3.5). Suppose given a morphism of  $0_k$ -coalgebras  $\phi : 0_k \rightarrow H^+$ ; it defines a continuous morphism of  $k$ -algebras  $A \rightarrow k$ , and hence a section  $\sigma$  of the structure morphism  $X \rightarrow \text{Spf}(k)$ .

For every object  $B$  of  $\text{Alf}/k$ , denote  $H^+_0(B) = \phi(B) = B \phi_B$ , where  $\phi_B$  is the element  $\phi(1_B)$  of  $H^+(B)$ , and one defines sub- $0_k$ -modules  $H^+_n$  of  $H^+$ , by setting, for  $n \geqslant 1$ ,

```

```text
**H**n(B) = {u ∈ **H**n(B) | Δ(u) - u ⊗ φB ∈ **H**n-1(B) ⊗ **H**+n(B)}.
```

```

One thus obtains a filtration  $**H**_{\{0\}} \subset **H**_{\{1\}} \subset \dots$  of  $**H**_n(X)$ . By what precedes, one has:

**Proposition.** In order for  $\sigma$  to induce an isomorphism on the underlying topological spaces, it is necessary and sufficient that  $**H**_n(X)$  be the union of the  $**H**_{\{n\}}$ .

### 1.4. Theorem.

<!-- label: III.VII\_B.1.4 -->

**Theorem 1.4.** Let  $k$  be a pseudocompact ring and  $d_{\{0\}}, d_{\{1\}} : X_{\{1\}} \rightarrow X$  an equivalence couple in  $\mathcal{V}_{af}$  (cf. Exp. V, § 2.b) such that  $d_{\{1\}}$  is topologically flat.

(i) The canonical projection of  $X$  onto  $X/X_{\{1\}}$  ( $= \text{Coker}(d_{\{0\}}, d_{\{1\}})$ ) is surjective and topologically flat, and the morphism  $X_{\{1\}} \rightarrow X \times_{X/X_{\{1\}}} X$  with components  $d_{\{0\}}$  and  $d_{\{1\}}$  is an isomorphism.

(ii) If  $X$  is topologically flat over  $k$ , then so is  $X/X_{\{1\}}$ .

<!-- label: III.VII\_B.1.4.thm -->

Let us first note that (ii) follows from (i), by 1.3.3 (ii). The proof of (i) occupies paragraphs 1.4.1, 1.4.2 and 1.4.3.

### 1.4.1.

<!-- label: III.VII\_B.1.4.1 -->

Let us first show that one may reduce to the case where  $X$  has a single point. Since we are dealing with an equivalence couple, one sees as in Exp. V, § 3.e), that one defines <!-- original page 506 --> an equivalence relation on the underlying set of  $X$  by declaring two points  $x, y$  to be equivalent if there exists a point  $z$  of  $X_{\{1\}}$  such that  $d_{\{0\}}(z) = y$  and  $d_{\{1\}}(z) = x$ . One may evidently suppose without loss of generality that  $X$  contains a single equivalence class for this relation, in other words that  $X/X_{\{1\}}$  has a single point (see the construction of  $X/X_{\{1\}}$  given in 1.2).

In this case, let  $x$  be an arbitrary point of  $X$  and  $U$  the formal variety which has  $x$  as its only point and the same local ring as  $X$  at  $x$ . One sees then as in Exp. V, § 6, that the equivalence relation induced by  $(d_{\{0\}}, d_{\{1\}})$  on  $U$  again satisfies the hypotheses of the theorem and that it suffices to give the proof for the latter equivalence relation ( $U$  is a "quasi-section").

Let us briefly recall the principle of the proof given in Exp. V, § 6. Set  $V = d_{\{0\}}^{-1}(U) = U \times_{\{d_{\{0\}}\}} X_{\{1\}}$ , where  $i$  is the inclusion of  $U$  in  $X$ ; let  $u$  and  $v$  be the morphisms with source  $V$  induced respectively by  $d_{\{0\}}$  and  $d_{\{1\}}$ :

```

```text
      V      u
X  -----> U.
      v
```

```

It is clear that  $u$  and  $v$  are topologically flat and that  $u$  is surjective; since  $X$  contains a single equivalence class,  $v$  is surjective. If  $(v_{\{0\}}, v_{\{1\}})$  is the inverse image of the equivalence couple  $(d_{\{0\}}, d_{\{1\}})$  under  $v$  (cf. V, 3.a)), it follows from V, 3.c) and 3.d) that  $X/X_{\{1\}}$  and the quotient of  $U$  by the equivalence relation induced by  $(d_{\{0\}}, d_{\{1\}})$  are both identified with  $\text{Coker}(v_{\{0\}}, v_{\{1\}})$ . One sees then, as in the proof of V, 6.1, that if the conclusion of Theorem 1.4 is verified for  $U$ , it is also verified for  $X$ .

### 1.4.2.

<!-- label: III.VII\_B.1.4.2 -->

We are thus reduced to the case where  $X$  has a single point. [N.D.E-VII\_B-67] Consider then the following commutative diagram (cf. V, § 1, (0,1,2)):

```

```text
      d'1
X2  ----- X1  -----> X
      d'0

d'2      d1
X1  ----- X  -----> X/X1
      d0
```

```

where  $X_{\{2\}}$  is the fiber product  $X_{\{1\}} \times_{d_{\{1\}}, d_{\{0\}}} X_{\{1\}}$ , and where  $d'_{\{0\}}$ ,  $d'_{\{1\}}$  and  $d'_{\{2\}}$  are respectively <!-- original page 507 --> the morphisms " $(x, y, z) \mapsto (x, y)$ ", " $(x, y, z) \mapsto (x, z)$ ", and " $(x, y, z) \mapsto (y, z)$ ".<sup>[N.D.E-VII\_B-68]</sup>

If  $B$ ,  $A$ ,  $A_{\{1\}}$  and  $A_{\{2\}}$  denote respectively the affine algebras of  $X/X_{\{1\}}$ ,  $X$ ,  $X_{\{1\}}$  and  $X_{\{2\}}$ , the preceding diagram induces a commutative diagram:

```

```text
      j1      i0
A2  <----- A1  <----- A
      j0

j2      i1      i
A1  <----- A  <----- B
      i1      i0
```

```

in which the two rows are exact and the squares determined by  $(i_{\{0\}}, j_{\{0\}})$  and  $(i_{\{1\}}, j_{\{1\}})$  are cocartesian. Since the morphism  $X_{\{1\}} \rightarrow X \times X$  with components  $d_{\{0\}}$  and  $d_{\{1\}}$  is a monomorphism by hypothesis, the morphism  $A \otimes_k A \rightarrow A_1$  with components  $i_{\{0\}}$  and  $i_{\{1\}}$  is surjective, by Proposition 1.3.

This means that  $i_{\{1\}}$  makes  $A_{\{1\}}$  into a pseudocompact  $A$ -module (assumed topologically free), generated by  $i_{\{0\}}(A)$ . Since  $A$  is local, Lemma 1.4.3 below yields the existence of a topologically free  $k$ -module  $V$  and a morphism of pseudocompact  $k$ -modules  $f : V \rightarrow A$  such that the morphism

```

```text
α1 : A ⊗_k V → A1,    a ⊗ v ↦ i1(a) · i0(f(v))
```

```

<!-- original page 508 --> is invertible. Let  $\alpha : B \otimes_k V \rightarrow A$  and  $\alpha_2 : A_1 \otimes_k V \rightarrow A_2$  be the morphisms:

```

```text
b ⊗ v ↦ i(b) · f(v)    and    a1 ⊗ v ↦ j2(a1) · j0 i0(f(v)).
```

```

In the following commutative diagram, the two rows are therefore exact and the two left-hand squares are cocartesian. Since  $\alpha_{\{1\}}$  is invertible, the same holds for  $\alpha_{\{2\}}$ , hence for  $\alpha$ .

```

```text
      j1      i0
A2  <----- A1  <----- A
      j0

α2      α1      α
A1 ⊗_k V  <----- A ⊗_k V  <----- B ⊗_k V.
      i1 ⊗ V      i ⊗ V
      i0 ⊗ V
```

```

This shows on the one hand that  $A$  is topologically free over  $B$ , with pseudobasis  $f(V)$  (cf. 0.2.1), and that one

obtains a pseudobasis of  $A_1$  over  $A$  (where  $A_1$  is considered as an  $A$ -module via  $i_1$ ) by taking the image under  $i_0$  of  $f(V)$ ; this entails that the morphism  $A \otimes_B A \rightarrow A_1$  with components  $i_1$  and  $i_0$  is invertible:

```
```text
A ⊗_B A ≅ A ⊗_B B ⊗_k V ≅ A ⊗_k V ≅ A_1.
```
```

This proves Theorem 1.4, modulo Lemma 1.4.3 which follows.

### 1.4.3. Lemma.

<!-- label: III.VII\_B.1.4.3 -->

**Lemma 1.4.3.** Let  $k$  be a pseudocompact ring,  $A$  a local profinite  $k$ -algebra,  $A_1$  a topologically free  $A$ -module and  $i_0 : M \rightarrow A_1$  a morphism of pseudocompact  $k$ -modules. Suppose that the map

```
```text
A ⊗_k M → A_1,    a ⊗ m ↦ a · i_0(m)
```
```

is surjective. Then there exist a topologically free  $k$ -module  $V$  and a morphism of pseudocompact  $k$ -modules  $f : V \rightarrow M$  such that the map

```
```text
A ⊗_k V → A_1,    a ⊗ v ↦ a · i_0(f(v))
```
```

is bijective.

Since every pseudocompact  $k$ -module is the quotient of a topologically free  $k$ -module (cf. N.D.E. (27)), one may suppose without loss of generality that  $M$  is <!-- original page 509 --> topologically free; so let us take for  $M$  the direct product of a family  $(M_i)_{i \in I}$  of copies of  $k$ . In this case,  $A \otimes_k M$  is none other than the product  $\prod_{i \in I} A \otimes_k M_i$ . Since the map  $a \otimes m \mapsto a \cdot i_0(m)$  is surjective and  $A_1$  is projective, the kernel of this map is a direct factor of  $A \otimes_k M$ ; since  $A$  is local, it follows from the exchange theorem (0.3.4) that this kernel has as supplement a partial product  $\prod_{i \in J} A \otimes_k M_i$ , where  $J$  denotes some subset of  $I$ . One may therefore take  $V = \prod_{i \in J} M_i$ .

### 1.5.

<!-- label: III.VII\_B.1.5 -->

Let  $k$  be a pseudocompact ring.

**Definition 1.5.** We shall say that a family of morphisms  $f_i : X_i \rightarrow X$  of  $Vaf_k$  is a topologically flat surjective family if the morphism  $\coprod_i X_i \rightarrow X$  induced by the  $f_i$  is surjective and topologically flat; this means that each  $f_i$  is topologically flat and that every point of  $X$  belongs to the image of at least one of the  $X_i$ .

<!-- label: III.VII\_B.1.5.def -->

It follows from 1.3.3 that the topologically flat surjective families define a pretopology on  $Vaf_k$  (IV 4.2.5); the corresponding topology will be called the *flat topology* on  $Vaf_k$ .

By IV, 4.3.5, a functor  $F : (Vaf_k)^{\text{circ}} \rightarrow (\text{Ens})$  is a sheaf for the flat topology if and only if  $F$  transforms every direct sum into a direct product and the sequence

```
```text
          F(f)                F(pr_1)
F(Y)  -----> F(X)  -----> F(X ×_Y X)
                      F(pr_2)
```
```

is exact for every topologically flat surjective morphism  $f : X \rightarrow Y$ .

By IV, 4.5, Proposition 1.3.1 implies that the flat topology is <!-- original page 510 --> less fine than the canonical topology, i.e., for every object  $X$  of  $\mathcal{V}_{\text{f}}/k$ , the functor  $h_X : T \mapsto \operatorname{Hom}_{\mathcal{V}_{\text{f}}/k}(T, X)$  is a sheaf for the flat topology. (In what follows, one will identify, as usual (cf. Exp. I),  $X$  with  $h_X$ .)

By IV, 4.6.5, one may reformulate Theorem 1.4 as follows.

**Theorem 1.5.** *Let  $k$  be a pseudocompact ring,  $d_0, d_1 : X_1 \rightarrow X$  an equivalence couple in  $\mathcal{V}_{\text{f}}/k$ , and  $X/X_1$  the formal quotient variety (i.e.,  $\operatorname{Coker}(d_0, d_1)$ , cf. 1.2). If  $d_1$  is topologically flat, then  $X/X_1$  represents the quotient sheaf for the flat topology.*

<!-- label: III.VII\_B.1.5.thm -->

### 1.6.

<!-- label: III.VII\_B.1.6 -->

To complete these generalities on formal varieties, it remains to define briefly the étale formal varieties over  $k$ . [N.D.E-VII\_B-70]

**Recollections 1.6.A.** (i) Let us first recall (cf. EGA IV, 19.10.2) that a topological  $k$ -algebra  $A$  is said to be *formally étale* over  $k$  (for the topologies given on  $k$  and  $A$ , resp. for the discrete topologies) if, for every discrete topological  $k$ -algebra  $C$  (not necessarily artinian), and every nilpotent ideal  $J$  of  $C$ , every continuous morphism  $A \rightarrow C/J$  lifts in a unique way to a continuous morphism  $A \rightarrow C$  ( $A$  being endowed with the given topology, resp. with the discrete topology). One sees at once that this property is preserved by base change, i.e., for every morphism  $k \rightarrow k'$  of pseudocompact rings,  $A \otimes_k k'$  is then formally étale over  $k'$ . On the other hand, one sees easily that it suffices to verify the lifting condition for every ideal  $J$  of square zero, cf. EGA IV, 17.1.2 (ii). One says that  $A$  is *étale* over  $k$  if it is formally étale over  $k$  for the discrete topologies, and if moreover  $A$  is a  $k$ -algebra of finite presentation (cf. EGA IV, 17.3.2 (ii)). In what follows,  $k$  being a pseudocompact ring and  $A$  a profinite  $k$ -algebra, one will use "formally étale" in the sense of the given topologies (unless otherwise stated).

<!-- label: III.VII\_B.1.6.A -->

(ii) Recall also that if  $F \in k[T]$  is a monic polynomial of degree  $d \geq 1$ , separable (i.e., such that the ideal generated by  $F$  and its derivative polynomial  $F'$  is  $k[T]$ ), then the  $k$ -algebra  $B = k[T]/(F)$  (which is free of rank  $d$  over  $k$ , and endowed with the product topology) is formally étale over  $k$ . Indeed, let  $C$  be a discrete  $k$ -algebra (so that the kernel of  $k \rightarrow C$  is an open ideal  $I$  of  $k$ ),  $J$  an ideal of  $C$  of square zero, and  $\phi : B \rightarrow C/J$  a continuous morphism of  $k$ -algebras. Note that,  $B$  being a  $k$ -module free of finite rank,  $IB$  is an open ideal of  $B$ , hence every lifting  $\phi : B \rightarrow C$  of  $\phi$  is automatically continuous. Let  $t$  be the image of  $T$  in  $B$  and  $u_0$  an arbitrary lifting of  $\phi(t)$  in  $C$ ; then  $F(u_0) \in J$  (since  $\phi(t)$  is a root of  $F$ ); on the other hand there exist  $G, H \in k[T]$  such that  $GF + HF' = 1$ , hence  $H(u_0)F'(u_0) = 1 - G(u_0)F(u_0)$ , and the right-hand term is invertible, since  $F(u_0)$  is of square zero, hence  $F'(u_0)$  is invertible. Let us seek  $h \in J$  such that  $x = u_0 + h$  be a root of  $F$ ; this amounts to  $0 = F(u) = F(u_0) + F'(u_0)h$ , and as  $F'(u_0)$  is invertible, this has the unique solution  $h = -F'(u_0)^{-1} F(u_0) \in J$ . Of course, the same proof (without making continuity hypotheses on the morphisms  $k \rightarrow C$ ,  $\phi$  and  $\phi$ ) shows that  $B$  is also an étale  $k$ -algebra.

(iii) Recall finally that if  $A$  is a finite product  $A_1 \times \dots \times A_n$ , then  $A$  is formally étale over  $k$  if and only if the  $A_i$  are. [N.D.E-VII\_B-71] Indeed, it suffices to see this for  $n = 2$ , in which case let  $e = 1_{A_1}$  be the idempotent such that  $A_1 = Ae$  and  $A_2 = A(1 - e)$ , and suppose given a continuous morphism  $A \rightarrow C/J$ , where  $J$  is an ideal of square zero. Since the polynomial  $F = X^2 - X$  is separable (one has  $F' = 2X - 1$  and  $(F')^2 - 4F = 1$ ), the idempotent  $\phi(e)$  of  $C/J$  lifts in a unique way to an idempotent  $f$  of  $C$ , whence  $C = Cf \oplus C(1 - f)$ , and then to give a lifting of  $\phi$  amounts to giving two morphisms  $\phi_1 : A_1 \rightarrow Cf$  and  $\phi_2 : A_2 \rightarrow C(1 - f)$ , lifting the restrictions of  $\phi$  to  $A_1$  and  $A_2$ . The same argument shows that if  $e$  is an idempotent of  $k$  such that  $A = Ae$ , then  $A$  is formally étale over  $k$  if and only if it is so over the localization  $k_e$  (which is identified with  $k_e$ ).

Let now  $X$  be a  $k$ -formal variety and  $A$  its affine algebra. If  $x$  is a point of  $X$  (i.e., a maximal open ideal  $\mathfrak{m}$  of  $A$ ), with image  $s$  in  $\operatorname{Spf}(k)$ , one will denote by  $k_{\mathfrak{m}}$  or  $k_s$  the local component of  $k$  corresponding to  $s$ .

**Definition 1.6.B.** The following conditions are equivalent:

(a)  $A$  is formally étale over  $k$ .

\*(b) For every  $\mathfrak{m} \in \text{Upsilon}(A)$ ,  $A_{\mathfrak{m}}$  is formally étale over  $k$  (or over  $k_{\mathfrak{m}}$ ).

\*(c) For every open ideal  $\mathfrak{l}$  of  $k$ ,  $A_{\mathfrak{k}}(k/\mathfrak{l}) = A/\mathfrak{l}$  is formally étale over  $k/\mathfrak{l}$ .

\*(d) For every  $\mathfrak{m} \in \text{Upsilon}(A)$  and every open ideal  $\mathfrak{l}$  of  $k_{\mathfrak{m}}$ ,  $A_{\mathfrak{m}}/A_{\mathfrak{m}}\mathfrak{l}$  is formally étale over  $k_{\mathfrak{m}}/\mathfrak{l}$ .

<!-- label: III.VII\_B.1.6.B -->

We shall say that  $X$  is *étale over  $k$*  if it satisfies these conditions, and one denotes by  $\text{Vaf}^{\text{ét}}_k$  the full subcategory of  $\text{Vaf}_k$  formed by the formal varieties étale over  $k$ . [N.D.E-VII\_B-72]

Note that if  $\phi : A \rightarrow C/J$  is a continuous morphism of  $k$ -algebras, where  $C$  is a discrete  $k$ -algebra and  $J$  an ideal of square zero, then  $I = \text{Ker}(\phi)$  is an open ideal of  $A$ , hence  $A/I$  is artinian, hence  $I$  is contained in only a finite number of maximal open ideals  $\mathfrak{m}_1, \dots, \mathfrak{m}_r$ , hence contains the product of the components  $A_{\mathfrak{m}_i}$  for  $\mathfrak{m} \neq \mathfrak{m}_i$ , which equals  $A(1 - e)$  where  $e$  denotes the idempotent of  $A$  such that  $Ae = \prod_{i=1}^r A_{\mathfrak{m}_i}$ . Thus  $\phi(e) = 1_{C/J}$  and it amounts to the same to give a continuous lifting of  $\phi$  or of the morphism from  $Ae \simeq A/(1 - e)$  to  $C/J$ , induced by  $\phi$ .

On the other hand, one knows (cf. N.D.E. (24)) that  $A \simeq \varprojlim_{\mathfrak{l}} A/\mathfrak{l}$ . Taking these remarks and the preceding recollections into account, one easily obtains the equivalence of the indicated conditions.

**Definitions 1.6.C.** Set  $\kappa(k) = \prod_{s \in \text{Spf}(k)} \kappa(s)$ , endowed with the product topology, i.e., the formal variety  $\text{Spf}(\kappa(k))$  is the direct sum of the  $\text{Spec} \kappa(s)$ , for  $s \in \text{Spf}(k)$ . On the other hand, one denotes by  $S_{\kappa(k)}$  the scheme direct sum of the  $\text{Spec} \kappa(s)$ , for  $s \in \text{Spf}(k)$ .

<!-- label: III.VII\_B.1.6.C -->

For every formal variety  $X$  over  $k$ , one denotes by  $X_{\kappa} = X \times_{\kappa(k)}$  the formal variety over  $\kappa(k)$  obtained by base change, i.e.,  $X_{\kappa}$  has the same points as  $X$  and for every  $x \in X$ , of projection  $s$  on  $\text{Spf}(k)$ , one has  $0_{X_{\kappa}, x} = 0_{X, x} \times_{\kappa(s)}$ . This base change functor  $\text{Vaf}_k \rightarrow \text{Vaf}_{\kappa(k)}$  sends  $\text{Vaf}^{\text{ét}}_k$  into  $\text{Vaf}^{\text{ét}}_{\kappa(k)}$  (cf. 1.6.A (i)).

One then has (cf. SGA 1, I 6.2):

**Lemma 1.6.D.** For every  $Y \in \text{Ob } \text{Vaf}^{\text{ét}}_k$  and  $X \in \text{Ob } \text{Vaf}_{\kappa(k)}$ , the canonical map

text  
 $\text{Hom}_{\text{Vaf}_k}(X, Y) \rightarrow \text{Hom}_{\text{Vaf}_{\kappa(k)}}(X_{\kappa}, Y_{\kappa})$

is bijective. In particular, the functor  $\text{Vaf}^{\text{ét}}_k \rightarrow \text{Vaf}^{\text{ét}}_{\kappa(k)}$  is fully faithful (and one will see below that it is an equivalence).

<!-- label: III.VII\_B.1.6.D -->

Indeed, let  $A$  (resp.  $B$ ) be the affine algebra of  $X$  (resp.  $Y$ ) and  $\mathfrak{r}$  the radical of  $k$ , and suppose given a morphism  $B_{\kappa(k)} \rightarrow A_{\kappa(k)}$  or, what amounts to the same, a morphism  $\phi : B \rightarrow A/\mathfrak{r}A$ .

For every open ideal  $\mathfrak{l}$  of  $k$ , there exists  $n \in \mathbb{N}$  such that  $\mathfrak{r}^n \subset \mathfrak{l}$ , whence  $(\mathfrak{r}A)^n \subset \mathfrak{l}A \subset \mathfrak{l}A$ , and since the multiplication map  $\mathfrak{m}^{n-1} : A^n \rightarrow A$  is continuous, one also has  $(\mathfrak{r}A)^n \subset \mathfrak{l}A$ , i.e.,  $\mathfrak{r}A/\mathfrak{l}A$  is a nilpotent ideal of  $A/\mathfrak{l}A$ . Consequently,  $\phi$  lifts in a unique way to a morphism  $\phi_{\mathfrak{l}} : B \rightarrow A/\mathfrak{l}A$ . By uniqueness, these morphisms form a projective system, hence give a continuous morphism  $\Phi : B \rightarrow \varprojlim_{\mathfrak{l}} A/\mathfrak{l}A = A$ . Moreover,  $\Phi$  is unique since if  $\Phi'$  is a second lifting of  $\phi$ , then  $\Phi'$  and  $\Phi$  coincide modulo  $\mathfrak{l}A$  for every  $\mathfrak{l}$ , hence are equal.

**Proposition 1.6.E.** (a) Let  $X$  be a formal variety over  $k$  and  $A$  its affine algebra. The following conditions are equivalent:

(i)  $X$  is étale over  $k$ .

(ii)  $X$  is topologically flat over  $k$  and the diagonal morphism  $\Delta : X \rightarrow X \times X$  is a local isomorphism, i.e.,  $\Delta_X$  induces an isomorphism  $0_{X \times X, \Delta(x)} \times 0_{X, x}$  for every point  $x$  of  $X$ .

\*(iii) For every  $x \in X$ , of projection  $\pi_x$  on  $\mathrm{Spf}(k)$ ,  $0_{\{X, x\}}$  is isomorphic to  $k_{\{s\}}[T]/(F)$ , where  $F \in k_{\{s\}}[T]$  is a monic separable polynomial (cf. 1.6.A (ii)).\*

\*(iv)  $X$  is topologically flat over  $k$ , and, for every point  $x \in X$ , of projection  $\pi_x$  on  $\mathrm{Spf}(k)$ ,  $0_{\{X, x\}} \subset k(s)$  is a finite separable extension of  $kappa(s)$ .\*

\*(v) For every open ideal  $I$  of  $k$ , each local component of  $A \otimes_k (k/I)$  is a finite étale algebra over the artinian ring  $k/I$ .\*

\*(b)  $Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k$  is identified with the category of étale schemes over  $S_{\{kappa(k)\}}$  (cf. 1.6.C), and the functor  $X \mapsto X_{\{kappa\}}$  induces an equivalence of categories  $Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k \xrightarrow{\sim} Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k$  (cf. SGA 1, I 6.1).\*

<!-- label: III.VII.B.1.6.E -->

\*Proof.\* (a) Let  $I$  denote the kernel of the multiplication morphism  $m : A \otimes_k A \rightarrow A$ . Suppose  $X$  étale over  $k$ , i.e.,  $A$  formally étale over  $k$ . Then, by EGA 0<sub>IV</sub>, 20.7.4, the Hausdorff completion of  $I/I^2$ , for the quotient topology of that of  $I$ , is zero, i.e., one has  $I = I^2$ . Now, for every  $x \in X$ ,  $I$  is contained in the maximal ideal  $m_{\{X, x\}}$  of  $A \otimes_k k$ , hence the localization  $I_{m_{\{X, x\}}}$  is contained in the maximal ideal of  $0_{\{X, x\}} \otimes_k k$ , and so, by Nakayama's lemma 0.3, one has  $I_{m_{\{X, x\}}} = 0$ , and hence  $\Delta : X \rightarrow X \times X$  is a local isomorphism.

Suppose now that  $\Delta$  is a local isomorphism and that  $k$  is a field  $kappa$ , and let us show that each  $0_{\{X, x\}}$  is a finite-dimensional étale  $kappa$ -algebra. Replacing  $X$  by  $\mathrm{Spf}(0_{\{X, x\}})$ , one may suppose that  $A = 0_{\{X, x\}}$  is local. One proceeds then as in the proof of EGA IV<sub>4</sub>, 17.4.1, (b)  $\Rightarrow$  (d'). Let  $K$  be a finite normal extension of  $kappa$  containing the residue field  $kappa(x)$ , and let  $B = A \otimes_k K = A \otimes_k K$  (since  $[K : kappa] < \infty$ , then  $\otimes_k K$  and  $\otimes_k K$  coincide) and  $X_K = \mathrm{Spf}(B) = X \otimes_k K$ . Then  $\Delta_K : X_K \rightarrow X_K \otimes_k K$  is again a local isomorphism, so for every  $y \in X_K$ , the multiplication  $B_y \otimes_k B_y \rightarrow B_y$  induces an isomorphism  $(B_y \otimes_k B_y)_{m_{\{X_K, y\}}} \otimes_k B_y$ . Now, since the residue field of  $B_y$  is  $K$  (cf. for example VI<sub>A</sub>, 1.1.1, N.D.E. (11)),  $C = B_y \otimes_k B_y$  is already a local ring (indeed,  $n = m_y \otimes_k B_y + B_y \otimes_k m_y$  consists of topologically nilpotent elements, hence is contained in the radical of  $C$ , and  $C/n = K \otimes_k K = K$  is a field), hence one obtains that the multiplication morphism  $B_y \otimes_k B_y \rightarrow B_y$  is an isomorphism. Taking a pseudobasis of  $B_y$  over  $K$  containing the unit element  $1$ , one deduces that  $B_y = K$ . Since moreover  $B$  is finite over  $A$ ,  $X_K$  is a finite set, hence  $B = A \otimes_k K$  is the product of a finite number of copies of  $K$ , and this entails that  $A$  is a finite étale  $kappa$ -algebra.

One thus obtains that, if  $kappa$  is a field, every profinite  $kappa$ -algebra  $A$  étale over  $kappa$  is the product of finite separable extensions  $K_i$  of  $kappa$ , endowed with the product topology, hence the formal variety  $\mathrm{Spf}(A)$  is the direct sum of the  $\mathrm{Spf}(K_i) = \mathrm{operatorname{Spec}}(K_i)$ , and one deduces that  $Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k$  is identified with the category of étale  $kappa$ -schemes.

What precedes shows the implication (ii)  $\Rightarrow$  (iv) (since  $0_{\{X, x\}} \otimes_{k(s)} k$  is formally étale over  $kappa(s)$ ), and entails point (b) of 1.6.E. Indeed, let  $k$  be again an arbitrary pseudocompact ring. By what precedes,  $Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k$  is identified with the category of étale schemes over  $S_{\{kappa(k)\}}$ . Let us show that  $X \mapsto X_{\{kappa\}}$  induces an equivalence  $Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k \xrightarrow{\sim} Vaf^{\acute{e}}_{\{X, x\}} \otimes_{k(s)} k$ . Taking 1.6.D into account, it suffices to show that for every  $\pi_x$  on  $\mathrm{Spf}(k)$  and every finite separable extension  $K$  of  $kappa(s)$ , there exists an étale  $k_{\{s\}}$ -algebra  $A$  such that  $A \otimes_{k(s)} K = K$ . Let  $\xi$  be a primitive element of the extension  $K/kappa(s)$ ,  $n$  its degree, and  $F \in k_{\{s\}}[T]$  a monic polynomial of degree  $n$  whose image  $\bar{F}$  in  $kappa(s)[T]$  is the minimal polynomial of  $\xi$ . Since  $\bar{F}$  is invertible in  $kappa(s)[T]/(\bar{F})$ , it follows from Nakayama's lemma that  $F$  is invertible in  $k_{\{s\}}[T]/(F)$ , hence  $F$  is a separable polynomial and hence, by 1.6.A (ii),  $A = k_{\{s\}}[T]/(F)$  is an étale  $k_{\{s\}}$ -algebra such that  $A \otimes_{k(s)} K = K$ . One thus obtains that every local profinite étale  $k_{\{s\}}$ -algebra is free of finite rank over  $k_{\{s\}}$  (hence a fortiori topologically free over  $k$ ), and hence every profinite étale  $k$ -algebra is topologically free over  $k$ .

On the other hand, condition (v) implies condition (d) of 1.6.B, hence implies (i). One has thus obtained that (i), (iii) and (v) are equivalent, and imply (ii), which implies (iv). Finally, let  $A$  be a profinite  $k$ -algebra satisfying (iv); let us show that  $A$  is formally étale over  $k$ . For this, one may suppose  $A$  and  $k$  local; denote by  $kappa$  the residue field of  $k$ . By hypothesis,  $K = A \otimes_k k$  is a finite separable extension of  $kappa$ , say of degree  $n$ . By what we have seen above (and taking Lemma 1.6.D into account), there exists then a  $k$ -algebra  $B$  free of rank  $n$ , formally étale over  $k$ , and a continuous morphism  $\phi : B \rightarrow A$  such that  $\phi \otimes_k k$  is an isomorphism. Since  $A$  is topologically flat over  $k$ , this entails that  $\mathrm{Coker}(\phi) \otimes_k k = 0$  and also  $\mathrm{Ker}(\phi) \otimes_k k = 0$ ; by Nakayama's lemma 0.3, one therefore has  $\mathrm{Coker}(\phi) = 0 = \mathrm{Ker}(\phi)$ , hence  $\phi$  is an isomorphism (cf. the proof of 0.2.B). This completes the proof of 1.6.E.

Let  $X$  be a formal variety over  $k$ . For every  $x \in X$ , of projection  $\pi_x$  on  $\mathrm{Spf}(k)$ , the residue field  $kappa(x)$

is a finite extension of  $k$  and one denotes by  $k_e(x)$  the separable closure of  $k$  in  $k(x)$ .

**Proposition 1.6.F.** (i) The inclusion of  $V_{\text{af}}^{\text{et}}(k)$  in  $V_{\text{af}}(k)$  has a left adjoint  $X \mapsto X_e$ : the variety  $X_e$  has the same points as  $X$ , and for every  $x \in X$ , of projection  $\pi_x$  on  $\text{Spf}(k)$ , let  $\xi_x$  be a primitive element of  $k_e(x)$ ,  $n_x$  its degree,  $u_x$  an arbitrary lifting of  $\xi_x$  in  $\mathbb{Z}[X, x]$ , and  $f_x \in k[T]$  monic of degree  $n_x$  annihilating  $u_x$ ; one sets  $\mathbb{Z}[X_e, x] = k[T]/(f_x)$ . Then for every  $Y \in \text{Ob } V_{\text{af}}^{\text{et}}(k)$ , the canonical maps below are bijective:

$$\begin{array}{ccc} \text{Hom}_{V_{\text{af}}(k)}(X, Y) & \xrightarrow{\quad} & \text{Hom}_{V_{\text{af}}/k(k)}(X_k, Y_k) \\ & \uparrow & \\ \text{Hom}_{V_{\text{af}}(k)}(X_e, Y) & \xrightarrow{\quad} & \text{Hom}_{V_{\text{af}}/k(k)}((X_e)_k, Y_k), \end{array}$$

the vertical arrow being induced by the inclusions  $k_e(x) \hookrightarrow k(x)$  for every  $x \in X$ . This defines, in particular, a morphism  $\pi : X \rightarrow X_e$ , and every morphism of  $k$ -formal varieties  $\phi : X \rightarrow Y$ , with  $Y$  étale over  $k$ , factors uniquely through  $\pi$ .

(ii) The functor  $X \mapsto X_e$  commutes with finite products.

*III.VII\_B.1.6.F*

Indeed, (i) follows from 1.6.E (b) and 1.6.D. Let us prove (ii). Taking the equivalence of categories 1.6.E (b) into account, one may suppose that  $k$  is a field. In this case, one sees easily that if  $X$  is a semi-local  $k$ -formal variety, i.e., one whose affine algebra  $A_X$  is semi-local, then the affine algebra of  $X_e$  is the largest subalgebra of  $A_X$  which is étale over  $k$ ; let us denote it by  $A_{X_e}$ . One thus reduces to seeing that if  $K, L$  are two finite-degree extensions of  $k$ , then the inclusion  $K_e \cap L_e \subset (K \cap L)_e$  is an equality. Let  $p$  be the characteristic exponent of  $k$  (i.e.,  $p = 1$  if  $\text{char}(k) = 0$  and  $p = \text{char}(k)$  otherwise), then for every  $x \in K \cap L$ , there exists  $n \in \mathbb{N}$  such that  $x^{p^n} \in K_e \cap L_e$ , hence every subalgebra  $B$  of  $K \cap L$  is radical over  $K_e \cap L_e$ , and it follows that  $K_e \cap L_e = (K \cap L)_e$ .

Note, keeping the preceding notations, that  $\mathbb{Z}[X_e, x]$  is not necessarily a subalgebra of  $\mathbb{Z}[X, x]$ , but this is the case when  $X$  is topologically flat over  $k$ , by the following proposition.

**1.6.1.**

*III.VII\_B.1.6.1*

Let  $Y$  be an étale  $k$ -formal variety and  $f : X \rightarrow Y$  a morphism of  $V_{\text{af}}(k)$ . Then one has the cartesian square below, where  $\Gamma_f$  is the graph morphism  $X \rightarrow X \times Y$ , with components  $\text{id}_X$  and  $f$ ,

$$\begin{array}{ccc} X & \xrightarrow{\Gamma_f} & X \times Y \\ f & & f \boxtimes \text{id}_Y \\ Y & \xrightarrow{\Delta_Y} & Y \times Y. \end{array}$$

It follows that  $\Gamma_f$  is a local isomorphism, hence that  $f = \text{pr}_Y \circ \Gamma_f$  is topologically flat if  $\text{pr}_Y$  is, for example if  $X$  is topologically flat over  $k$ .

Conversely, since  $Y \rightarrow k$  is topologically flat,  $X \rightarrow k$  will be as well if  $f$  is so (cf. 1.3.3). Taking in particular  $f$  to be the canonical morphism  $\pi : X \rightarrow X_e$  of 1.6, one obtains:

**Proposition 1.6.1.** Let  $X$  be a formal variety over  $k$ . The morphism  $X \rightarrow X_e$  is topologically flat if and only if  $X$  is topologically flat over  $k$ .

*III.VII\_B.1.6.1.prop*

**Remark 1.6.2.** [N.D.E-VII\_B-74] When  $k$  is a perfect field, the functor  $X \mapsto X_e$  is also right adjoint to

the inclusion  $V_{\text{af}}^{\{\acute{e}\}} \hookrightarrow V_{\text{af}}^{\{k\}}$ . Indeed, in this case one has  $0_{\{X_{\{e\}}, x\}} = \kappa(x)$  for every  $x \in X$ , and the canonical projections  $0_{\{X, x\}} \rightarrow \kappa(x)$  define a morphism  $s : X_{\{e\}} \rightarrow X$ , which is a section of  $p : X \rightarrow X_{\{e\}}$ . For every morphism  $f : X \rightarrow Y$  the diagrams below are commutative:

$$\begin{array}{ccc} 0_{\{Y, f(x)\}} \rightarrow 0_{\{X, x\}} & & \\ & \begin{array}{ccc} & f & \\ X & \longrightarrow & Y \\ \uparrow & & \uparrow \\ s_X & & s_Y \\ & f_e & \\ X_e & \longrightarrow & Y_e \end{array} & \\ \kappa(f(x)) \longrightarrow \kappa(x) & & \end{array}$$

hence  $s$  is functorial in  $X$ , and it follows that  $X \mapsto X_{\{e\}}$  is right adjoint to the inclusion  $V_{\text{af}}^{\{\acute{e}\}} \hookrightarrow V_{\text{af}}^{\{k\}}$ . Hence, being a right adjoint,  $X \mapsto X_{\{e\}}$  commutes with inverse limits when they exist in  $V_{\text{af}}^{\{\acute{e}\}} \hookrightarrow V_{\text{af}}^{\{k\}}$ , [N.D.E-VII\_B-75] hence in particular with finite products. (This can also be verified directly: for every  $k$ -formal variety  $X$ , of affine algebra  $A$ ,  $X_{\{e\}}$  has as affine algebra the quotient of  $A$  by its radical  $r(A)$ , and since  $k$  is perfect, the quotient of  $0_{\{X, x\}} \times 0_{\{Y, y\}}$  by its radical is the algebra  $\kappa(x) \times \kappa(y)$ , since the latter is semi-simple.)

<!-- label: III.VII\_B.1.6.2 -->

## ## 2. Generalities on formal groups

<!-- label: III.VII\_B.2 -->

<!-- original page 512 -->

### ### 2.1.

<!-- label: III.VII\_B.2.1 -->

Let  $k$  be a pseudocompact ring and  $G$  a  $k$ -formal group, that is, a group of the category  $V_{\text{af}}^{\{k\}}$  of formal varieties over  $k$ . Let  $A$  be the affine algebra of  $G$ . The composition law of  $G$  evidently defines a diagonal morphism, that is, a homomorphism of profinite  $k$ -algebras  $\Delta_A : A \rightarrow A \times_k A$ ; this homomorphism satisfies the following conditions:

(i) the diagram

$$\begin{array}{ccc} & \Delta_A & \\ A & \longrightarrow & A \times_k A \\ \Delta_A & & \Delta_A \times \text{id}_A \\ & \text{id}_A \times \Delta_A & \\ A \times_k A & \longrightarrow & A \times_k A \times_k A \end{array}$$

is commutative.

(ii) there exists an augmentation (necessarily unique), that is, a homomorphism of profinite  $k$ -algebras  $\epsilon_{\{A\}} : A \rightarrow k$  such that the composite maps

$$\begin{array}{ccc} A & \xrightarrow{\Delta_A} & A \times_k A \xrightarrow{\epsilon_A \times \text{id}_A} k \times_k A \simeq A \\ \text{and } A & \xrightarrow{\Delta_A} & A \times_k A \xrightarrow{\text{id}_A \times \epsilon_A} A \times_k k \simeq A \end{array}$$

are the identity maps of  $A$ .

(iii) there exists an antipodism (necessarily unique), that is, a homomorphism of profinite  $k$ -algebras

$\eta_A : A \rightarrow A$  such that the composite map

```

```text
      Δ_A      c_A ∘ id_A      m_A
A  →  A ⊗_k A  →  A ⊗_k A  →  A
```

```

is equal to  $\eta_A \circ \epsilon_A$ , where  $m_A$  denotes the linear map sending  $a \otimes b$  to  $ab$  and  $\eta_A$  the map  $\lambda \mapsto \lambda \cdot 1_A$  from  $k$  into  $A$ .

<!-- original page 513 -->

Conversely, the data of  $(\Delta_A, \epsilon_A, c_A)$  satisfying (i)–(iii) endows  $G$  with a structure of  $k$ -formal group. [N.D.E-VII\_B-76] Explicitly, for every profinite  $k$ -algebra  $B$ , the set  $\operatorname{Hom}_{\mathcal{C}}(A, B)$  of continuous morphisms of  $k$ -modules  $\phi : A \rightarrow B$  is endowed with a group structure, functorial in  $B$ , defined by

```

```text
φ ∘ φ' = m_B ∘ (φ ⊗ φ') ∘ Δ_A,
```

```

the neutral element being  $\eta_B \circ \epsilon_A$  (where  $m_B$  is the multiplication of  $B$  and  $\eta_B$  the map  $\lambda \mapsto \lambda \cdot 1_B$  from  $k$  into  $B$ ), and  $\phi \circ c_A$  being the inverse of  $\phi$ ; and the set  $\operatorname{Hom}_{\mathcal{A}/k}(A, B)$  of continuous morphisms of  $k$ -algebras  $A \rightarrow B$  is a subgroup of it (since the algebra  $B$  is commutative).

**Definition 2.1.** A morphism of  $k$ -formal groups  $\theta : K \rightarrow G$  is, by definition, a morphism of  $k$ -formal varieties which respects the group structures. If  $B$  (resp.  $A$ ) is the affine algebra of  $K$  (resp.  $G$ ) and if  $f : A \rightarrow B$  is the morphism corresponding to  $\theta$ , this amounts to saying that  $f$  is compatible with the comultiplications, i.e.,

```

```text
(f ⊗ f) ∘ Δ_A = Δ_B ∘ f
```

```

(the conditions  $\epsilon_B \circ f = \epsilon_A$  and  $c_B \circ f = f \circ c_A$  being then automatically satisfied). One will denote by  $\operatorname{Grf}_k$  the category of  $k$ -formal groups.

<!-- label: III.VII\_B.2.1.def -->

**Notations.** In what follows, we shall call augmentation ideal of  $A$  the ideal  $I_A = \operatorname{Ker}(\epsilon_A)$ , and we shall denote by  $\omega_k$  the pseudocompact  $k$ -module  $I_A/I_A^2$ , that is, the quotient of  $I_A$  by the closed ideal generated by the products  $xy$ , for  $x, y \in I_A$ .

### 2.2.

<!-- label: III.VII\_B.2.2 -->

Let  $H$  be a group of the category of coalgebras over  $k$ , i.e., for every object  $C$  of  $\mathcal{A}/k$ ,  $H(C)$  is endowed with a structure of  $k$ -coalgebra in groups (cf. VII\_A 3.2; following Manin, we shall say *bialgebra* [N.D.E-VII\_B-77] instead of *coalgebra in groups*); moreover, if  $\phi : C \rightarrow D$  is a morphism of  $\mathcal{A}/k$ , the map  $D \otimes_C H(C) \rightarrow H(D)$  is a homomorphism of  $D$ -bialgebras.

**Definition 2.2.** We shall summarize the above properties by saying that  $H$  is a *bialgebra* over  $k$ .

<!-- label: III.VII\_B.2.2.def -->

It is clear that the functor  $H \mapsto \operatorname{Spf}(H)$  of 1.3.5 commutes with finite products. It therefore transforms a bialgebra over  $k$  into a  $k$ -group functor, that is, a (covariant) functor from  $\mathcal{A}/k$  to the category of groups.

And indeed, for every  $k$ -algebra  $C$  of finite length, the elements of

```

```text
Spf(H)(C) = Spf(H(C)) = {x ∈ H(C) | ε(x) = 1 and Δ(x) = x ⊗ x}
```

```

form a group for the multiplication of the algebra  $H(C)$  (cf. VII\_A 3.2.2). Note moreover that the condition  $\Delta(x) = x \otimes x$  entails the equality  $\epsilon(x) = \epsilon(x)^2$ , hence also  $\epsilon(x) = 1$  if  $C$  is local and  $x \neq 0$ . [N.D.E-VII\_B-78]

### 2.2.1.

<!-- label: III.VII\_B.2.2.1 -->

A bialgebra  $H$  over  $k$  is said to be *flat* if the underlying module is flat (cf. 1.2.1). [N.D.E-VII\_B-79]

<!-- original page 514 --> If  $H$  is flat then, by 1.3.5,  $A = \Gamma(H)$  is a topologically flat profinite  $k$ -algebra, and  $\mathrm{Spf}^*(H)$  is isomorphic, as a functor from  $(\mathrm{Alg}_k)^{\mathrm{c}} = \mathrm{Vaf}_k$  to  $(\mathrm{Ens})$ , to the functor

```
``text
... \mathrm{Spf}(A) : C \mapsto \mathrm{Hom}_{\mathrm{Vaf}_k}(\mathrm{Spf}(C), \mathrm{Spf}(A)).
```

The group structure of  $\mathrm{Spf}^*(H)$  thus endows  $\mathcal{G}(H) = \mathrm{Spf}(A)$  with a structure of formal group, which is described explicitly as follows.

For every object  $C$  of  $\mathrm{Alg}_k$ , since the  $C$ -module underlying  $H(C)$  is projective, one deduces from Lemma 1.2.3.A, by induction on  $n$ , natural isomorphisms:

```
``text
... H(C)^{\square(n+1)} \simeq \mathrm{Hom}_C(H(C), (H(C)^{\square n}))
 \simeq \mathrm{Hom}_C(H(C), (H(C)^{\square n})^*) \simeq (H(C)^{\square(n+1)})^*.
```

One deduces from this (for  $n = 1, 2$ ) that the  $C$ -algebra structure of  $H(C)$  endows  $H(C)^*$  with a diagonal map satisfying conditions 2.1 (i)–(iii), all of this functorially in  $C$ .

Consequently,  $A = \Gamma(H) = \varprojlim H(k/l)$  is endowed with a structure of cogroup in  $\mathrm{Alg}_k$ , which defines on  $\mathcal{G}(H)$  the announced formal group structure.

Conversely, let  $G$  be a topologically flat  $k$ -formal group, of affine algebra  $A$ , and denote by  $H(G)$  the  $k$ -coalgebra  $V_{kf}(A)$  (cf. 1.2.3). The diagonal morphism  $\Delta_A : A \rightarrow A \square_k A$  then induces, for every  $k$ -algebra  $C$  of finite length, a  $C$ -linear map

```
``text
... V_{kf}(A)(C) \otimes_C V_{kf}(A)(C) \rightarrow V_{kf}(A)(C)
```

which makes the coalgebra  $V_{kf}(A)(C)$  into a  $C$ -bialgebra. One says that  $H(G)$  is the *covariant bialgebra* of the formal group  $G$ . [N.D.E-VII\_B-80] Therefore, by Proposition 1.3.5.D:

**Proposition 2.2.1.** (i) The functors  $G \mapsto H(G)$  and  $H \mapsto \mathcal{G}(H)$  define an equivalence between the category of topologically flat  $k$ -formal groups and that of flat  $k$ -bialgebras. [N.D.E-VII\_B-81]

(ii) This equivalence "commutes with base change": if  $k \rightarrow K$  is a morphism of pseudocompact rings, then  $H(G \square_k K) = H(G) \square_k K$  and  $\mathcal{G}(H \square_k K) = \mathcal{G}(H) \square_k K$ .

<!-- label: III.VII\_B.2.2.1.prop -->

When  $k$  is an artinian ring and  $G$  a topologically flat  $k$ -formal group, the functor  $H(G)$  is evidently determined by its value  $H(G) = H(G)(k)$  at  $k$ . One will also say that  $H(G)$  is the (covariant) *bialgebra* of  $G$ . [N.D.E-VII\_B-82] Consequently, denoting by  $H_k$  the category of  $k$ -Hopf algebras and  $H^{\mathrm{cocom}}_{\mathrm{flat}/k}$  the full subcategory formed by  $k$ -Hopf algebras flat over  $k$  and cocommutative, one obtains:

**Corollary 2.2.1.** Let  $k$  be an artinian ring.

(i) The functors  $G \mapsto H(G)$  and  $H \mapsto \mathcal{G}(H) = \mathrm{Spf}^* H(G)$  define an equivalence between the category of topologically flat  $k$ -formal groups and  $H^{\mathrm{cocom}}_{\mathrm{flat}/k}$ .

(ii) This equivalence "commutes with base change": if  $k \rightarrow K$  is a morphism of artinian rings, then  $H(G \square_k K) = H(G) \square_k K$  and  $\mathcal{G}(H \square_k K) = \mathcal{G}(H) \square_k K$ .

<!-- label: III.VII\_B.2.2.1.cor -->

On the other hand, let us denote  $\mathcal{H}^{\text{com}}_{\text{flat}/k}$  the full subcategory of  $\mathcal{H}_k$  formed by the  $k$ -Hopf algebras flat over  $k$  and commutative, and recall that the functor  $K \mapsto 0(K)$  is an anti-equivalence of the category of affine  $k$ -group schemes onto  $\mathcal{H}^{\text{com}}_{\text{flat}/k}$ .

### 2.2.2.

<!-- label: III.VII\_B.2.2.2 -->

<!-- original page 515 -->

Let us suppose for simplicity that  $k$  is artinian and let  $G$  be a topologically flat  $k$ -formal group. [N.D.E-VII\_B-83] Then  $G$  is commutative if and only if its affine algebra  $\mathcal{A}(G)$  has a cocommutative multiplication, which is equivalent to saying that the bialgebra  $H(G)$  has a commutative multiplication. In this case,  $H(G)$  is a commutative and cocommutative Hopf algebra, flat over  $k$ ; if one sets  $D'(G) = \operatorname{Spec} H(G)$ , then  $D'(G)$  is a commutative  $k$ -group scheme, affine and flat over  $k$ . Conversely, if  $T$  is such a  $k$ -group scheme, its affine algebra  $0(T)$  is a commutative group in the category of cocommutative  $k$ -coalgebras flat over  $k$  and hence, by 1.3.5.C, one obtains a topologically flat  $k$ -formal group  $D(T)$  by setting:

```
```text
... D(T) = Spf* 0(T) = Spf(□),    where □ = 0(T)*.
```

As, by 1.3.5.D, one has canonical isomorphisms $G = \operatorname{Spf}^* H(G)$ and $H(D(T)) = 0(T)$, one obtains canonical isomorphisms:

```
```text
... D(D'(G)) = Spf* 0(D'(G)) = Spf* H(G) = G,
... D'(D(T)) = Spec H(D(T)) = Spec 0(T) = T.
```

Moreover, denoting by  $k\text{-Gr.}$  the category of  $k$ -group schemes, one has, by Corollary 2.2.1, functorial isomorphisms:

```
```text
... Hom_{Grf/k}(G, D(T)) = Hom_{H_k}(H(G), 0(T)) = Hom_{k-Gr.}(T, D'(G)),
```

One thus obtains:

Proposition (Cartier duality) 2.2.2. *Let k be an artinian ring.*

(i) The functors $G \mapsto D'(G) = \operatorname{Spec} H(G)$ and $T \mapsto D(T) = \operatorname{Spf}^* 0(T)$ induce an anti-equivalence between the category $\mathcal{FC}_k$ of commutative topologically flat k -formal groups and the category $\mathcal{AC}_k$ of commutative k -group schemes, affine and flat, i.e., G and $D'(G)$ (resp. T and $D(T)$) are related by the equalities: [N.D.E-VII_B-84]

```
```text
... H(G) = 0(D'(G)) and 0(T) = H(D(T)).
```

(ii) This anti-equivalence "commutes with base change": if  $k \rightarrow K$  is a morphism of artinian rings, then  $D'(G \otimes_k K) = D'(G) \otimes_k K$  and  $D(T \otimes_k K) = D(T) \otimes_k K$ .

(iii) In particular, if  $k$  is a field, one obtains an anti-equivalence between the category of commutative  $k$ -formal groups and that of commutative affine  $k$ -group schemes, which commutes with extension of the base field.

<!-- label: III.VII\_B.2.2.2.prop -->

### 2.3.

<!-- label: III.VII\_B.2.3 -->

Let us now consider an arbitrary  $k$ -formal group  $G$ , of affine algebra  $A$ . Let us still denote by

$H(G)$  the  $\mathcal{O}_k$ -module  $V_{kf}(A)$  dual to  $A$  and let  $\varphi_G$  denote the functorial homomorphism

```
```text
...  $\phi_G : H(G) \otimes_k H(G) \rightarrow H(G \times G)$ 
```

induced by the natural map (0.3.6), for every object C of $\mathcal{A}_{f/k}$:

```
```text
... $(A \otimes_k C)^\dagger \otimes_C (A \otimes_k C)^\dagger \rightarrow ((A \otimes_k C) \otimes_C (A \otimes_k C))^\dagger.$
```

If  $m : G \times G \rightarrow G$  is the multiplication of  $G$ , the composite map

```
```text
... 
$$H(G) \otimes_k H(G) \xrightarrow{\phi_G} H(G \times G) \xrightarrow{H(m)} H(G)$$

```

makes $H(G)$ into an algebra over $\mathcal{O}_k$; for every $C \in \mathcal{A}_{f/k}$, the unit element of $H(G)(C) = (A \otimes_k C)^\dagger$ is the augmentation of $A \otimes_k C$ (cf. 2.1). [N.D.E-VII_B-86] If G is not topologically flat over k , φ_G is not necessarily an isomorphism, and hence the morphism $\delta_G : H(G) \rightarrow H(G \times G)$ induced by the diagonal morphism " $x \mapsto (x, x)$ " from G into $G \times G$ does not necessarily factor through $H(G) \otimes_k H(G)$, i.e., $H(G)$ is not necessarily an $\mathcal{O}_k$ -bialgebra.

For this reason we shall simply say, in the general case, that $H(G)$ is the <!-- original page 516 --> "covariant algebra" of the formal group G .

Of course, when G is topologically flat over k , φ_G is an isomorphism, and one recovers the structure of $\mathcal{O}_k$ -bialgebra on $H(G)$ defined in 2.2.1.

2.3.1. Proposition.

<!-- label: III.VII_B.2.3.1 -->

Proposition 2.3.1. *Let K and G be two k -formal groups, of affine algebras B and A . Assume K topologically flat over k . Then there exists a canonical bijection from $\operatorname{Hom}_{\operatorname{Grf}/k}(K, G)$ onto the set of homomorphisms of unital $\mathcal{O}_k$ -algebras $h : H(K) \rightarrow H(G)$ such that the diagram*

```
```text
...
$$\begin{array}{ccc} H(K) \otimes_k H(K) & \xrightarrow{h \otimes h} & H(G) \otimes_k H(G) \\ \uparrow & & \searrow \phi_G \\ (*) \quad \Delta_{H(K)} & & H(G \times G) \\ & & \nearrow \delta_G \\ H(K) & \xrightarrow{h} & H(G) \end{array}$$

```

\*is commutative.\*

Since  $K$  is topologically flat,  $H(K)$  is endowed with a structure of bialgebra (cf. 2.2) and  $\Delta_{H(K)}$  is its diagonal morphism; in other words, with the notations of 2.3, one has  $\Delta_{H(K)} = \phi_K^{-1} \circ \delta_K$ . When  $G$  is also topologically flat over  $k$ , our proposition follows from the equivalence of categories established in 2.2.1.

<!-- original page 517 -->

In the general case, one may suppose  $k$  artinian and argue on the algebras  $H(K) = B^\dagger$  and  $H(G) = A^\dagger$ . Let  $\operatorname{Hom}_{\operatorname{Grf}/k}(A, B)$  be the set of continuous  $k$ -linear maps from  $A$  into  $B$  and  $\operatorname{Hom}_k(B^\dagger, A^\dagger)$  the set of  $k$ -linear maps from  $B^\dagger$  into  $A^\dagger$ .

By 0.3.6.A, one knows that if  $M, P$  are pseudocompact  $k$ -modules and  $P$  is projective, the canonical map

$$\text{Hom}_c(M, P) \rightarrow \text{Hom}_k(P^\dagger, M^\dagger), \quad f \mapsto {}^t f$$

(where  ${}^t f$  denotes the transpose of  $f$ ) is bijective. (One will apply this to  $M = A \square A$  and  $P = B$ , or  $M = A$  and  $P = B \square B$ .)

Let  $f \in \text{Hom}_c(A, B)$ . Consider the diagrams below, where the squares (0) are commutative, and where the two unnamed vertical arrows are  ${}^t(f \square f)$ .

$$\begin{array}{ccccc} & m_A & & \Delta_A & \\ A \square A & \longrightarrow & A & \longrightarrow & A \square A \\ f \square f & (1) & f & (2) & f \square f \\ & m_B & & \Delta_B & \\ B \square B & \longrightarrow & B & \longrightarrow & B \square B \end{array}$$

$$\begin{array}{ccccccc} A^\dagger \otimes A^\dagger & \rightarrow & (A \square A)^\dagger & \xleftarrow{{}^t m_A = \delta_G} & A^\dagger & \xrightarrow{{}^t \Delta_A = \phi_G} & (A \square A)^\dagger \xleftarrow{{}^t} A^\dagger \otimes A^\dagger \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ {}^t f \otimes {}^t f & (0) & & (1') & {}^t f & (2') & {}^t f \otimes {}^t f \\ B^\dagger \otimes B^\dagger & \rightarrow & (B \square B)^\dagger & \xleftarrow{{}^t m_B = \delta_K} & B^\dagger & \xrightarrow{{}^t \Delta_B = \phi_K} & (B \square B)^\dagger \xleftarrow{{}^t} B^\dagger \otimes B^\dagger \end{array}$$

If  $f : A \rightarrow B$  corresponds to a morphism of formal groups  $K \rightarrow G$ , then squares (1) and (2) are commutative, and  $\epsilon_B \circ f = \epsilon_A$ ; consequently, squares (1') and (2') are commutative and  ${}^t f$  sends the unit of  $B^\dagger = H(K)$  to that of  $A^\dagger = H(G)$ , i.e.,  ${}^t f$  is a morphism of unital  $k$ -algebras  $H(K) \rightarrow H(G)$  such that the diagram  $(\ast)$  of the proposition is commutative.

Conversely, if  ${}^t f$  satisfies these conditions, then  $\epsilon_B \circ f = \epsilon_A$  and the squares (1') and (2') are commutative. Since, for  $M = A \square A$  and  $P = B$  (resp.  $M = A$  and  $P = B \square B$ ), the map  $g \mapsto g^\dagger$  is injective, one deduces that squares (1) and (2) are commutative, hence  $f$  is compatible with the multiplications and the diagonal morphisms of  $A$  and  $B$ . It remains to see that  $f(1_A) = 1_B$ . But it follows from what precedes that  $\epsilon_B \circ f(1) = 1$ ,  $\Delta_B \circ f(1) = f(1) \square f(1)$  and  $f(1) \cdot f(1) = f(1)$ . The first two conditions entail, by 2.1 (iii), that  $f(1)$  admits  $\epsilon_B$  as inverse in  $B$ ; consequently  $f(1) \cdot f(1) = f(1)$  entails  $f(1) = 1$ . So  $f : A \rightarrow B$  is a morphism of  $A/k$ , compatible with the comultiplications of  $A$  and  $B$ .

### 2.3.2.

<!-- label: III.VII\_B.2.3.2 -->

<!-- original page 518 -->

Let us suppose now, for simplicity, that the ring  $k$  is artinian. When  $G$  is topologically flat over  $k$ , the algebra  $H(G) = H(G)(k)$  may be characterized by a universal property (due to Cartier). Recall (cf. 1.2.1) that if  $U$  is a  $k$ -module, one denotes by  $W(U)$  the functor which to every  $k$ -algebra  $C$  of finite length associates the  $C$ -module  $U \otimes_k C$ . [^N.D.E-VII\_B-88] If  $U$  is a  $k$ -algebra (associative, with unit element), so is  $U \otimes_k C$ ; we shall denote by  $W(U) \times C$  the  $k$ -group functor which to every  $C$  in  $\text{Ob } \text{Alf}_k$  associates the multiplicative group of the invertible elements of the algebra  $U \otimes_k C$ :

$$W(U) \times (C) = (U \otimes_k C)^\times.$$

Moreover, let us identify  $G$  with the  $k$ -group functor  $C \mapsto \text{Hom}_{\text{Vaf}/k}(\text{Spf}(C), G)$  and denote by  $\text{Hom}_{\text{k-Gr.}}(G, W(U) \times C)$  the set of homomorphisms of  $k$ -group functors from  $G$  into  $W(U) \times C$ .

One has the

**\*\*Proposition 2.3.2.\*\*** \*Let  $k$  be an artinian ring. For every formal group  $G$  topologically flat over  $k$  and for every  $k$ -algebra  $U$ , there is a canonical isomorphism\*

```
```text
... Hom_{k-Gr.}(G, W(U) \times) \cong Hom_{k-Alg.}(H(G), U).
```

<!-- label: III.VII_B.2.3.2.prop -->

Let us denote by A the affine algebra of G ; by hypothesis it is a projective object of $\text{PC}(k)$, and $H(G) = A^+$. For every object P of $\text{PC}(k)$, let us denote by $U \otimes_k P$ the projective limit of the k -modules $U \otimes_k (P/N)$, where N ranges over the open submodules of P . One has linear maps

```
```text
... U \otimes_k (P/N) \rightarrow Hom_k((P/N)^*, U)
```

sending  $u \otimes x$  to the  $k$ -linear map  $f \mapsto f(x)u$ , and forming a filtered projective system. One obtains therefore, by passage to the projective limit, a morphism

```
```text
(1) U \otimes_k P \xrightarrow{\psi_P} Hom_k(P^*, U) .
```

<!-- original page 519 -->

When $P = k$, ψ_k is evidently an isomorphism; moreover, the two sides of (1), considered as functors in P , commute with infinite products (every product being a filtered projective limit of finite products). One obtains therefore that (1) is an isomorphism when P is a product of copies of k , then when P is a projective object of $\text{PC}(k)$ (the two sides of (1) commuting with finite direct sums).

Let us now denote by $\text{Hom}_F(G, W(U))$ the set of morphisms of k -functors from G into $W(U)$. Since $G = \text{Spf}(A) = \lim \text{Spf}(A/I)$, where I ranges over the open ideals of A , one has canonical isomorphisms

```
```text
... Hom_F(G, W(U)) = \lim Hom_F(\text{Spf}(A/I), W(U)) = \lim U \otimes_k (A/I) = U \otimes_k A.
```

By what precedes, one obtains therefore a canonical isomorphism:

```
```text
(2) Hom_F(G, W(U)) = U \otimes_k A \xrightarrow{\psi_A} Hom_k(H(G), U).
```

For every k -algebra C of finite length, the multiplication makes $U \otimes_k C$ into a monoid with unit, and every morphism of monoids with unit $G(C) \rightarrow U \otimes_k C$ is necessarily a morphism of groups $G(C) \rightarrow (U \otimes_k C)^\times$. Consequently, one obtains that $\text{Hom}_{k-Gr.}(G, W(U)^\times)$ is the part of $\text{Hom}_F(G, W(U))$ formed by the morphisms of k -functors into monoids with unit element.

It remains to see that these morphisms correspond to the k -linear maps from $H(G)$ into U which preserve multiplication and the unit elements. [N.D.E-VII_B-89] To simplify the writing, $H(G) = A^+$ will be denoted H and one will write $\square$ instead of $\otimes_k$. Let Δ_A, m_A and ϵ_A (resp. Δ_H, m_H and ϵ_H) denote the comultiplication, multiplication and augmentation of A (resp. H). Let $\theta \in \text{Hom}_F(G, W(U))$, denote by γ its image in $U \otimes A$ and $\phi : H \rightarrow U$ the associated k -linear map. Then θ sends the unit section $s \in G(k)$ onto an element su of U , and since s corresponds to the augmentation $\epsilon : A \rightarrow k$, which is the unit element 1_H of H , one sees that $\theta(s) = 1_U$ if and only if $\phi(1_H) = 1_U$.

Moreover, the morphism $\theta \circ m_G : G \times G \rightarrow W(U)$ corresponds to the element $(\text{id}_U \otimes \Delta_A)(\gamma)$, and this corresponds, by duality, to the map $\phi \circ m_H : H \times H \rightarrow U$.

On the other hand, the morphism $\theta \circ \text{pr}_1 : G \times G \rightarrow W(U)$ corresponds to the element $\gamma \otimes 1_A$ of

```

``text
   $(U \sqcup A \sqcup A) \times (U \sqcup A \sqcup A), \quad (u \sqcup a_1 \sqcup a_2, u' \sqcup a_3 \sqcup a_4) \mapsto uu' \sqcup a_1a_3 \sqcup a_2a_4$ 

```

$$(U \otimes U) \otimes A^{\otimes 2} \otimes A^{\otimes 2} \xrightarrow{m_U \otimes m_A \otimes m_A} U \otimes A \otimes A.$$
$$\begin{array}{ccc}
H \otimes H & \xrightarrow{\beta} & U \\
\uparrow & & \uparrow \\
\text{id}_H \circ \sigma_{\{23\}} \circ \text{id}_H & & m_U \\
\\
H \otimes H \otimes H \otimes H & & U \otimes U \\
\\
(\text{id}_H \otimes \varepsilon_H) \otimes (\varepsilon_H \otimes \text{id}_H) & \varphi \otimes \varphi & \\
\\
H \otimes H & \xrightarrow{\quad} & .
\end{array}$$

```
### 2.4.
```

```
<!-- label: III.VII B.2.4 -->
```

$$\lambda : G \times H \xrightarrow{\text{id}_G \times u} G \times G \xrightarrow{\mu} G.$$
$$\begin{array}{ccc} & & \text{pr}_1 \\ & & \longrightarrow \\ G \times H & & G \\ & & \longrightarrow \\ & & \lambda \end{array}$$

SGA 3 existing English translation – plaintext render from existing Markdown – page 524

Let $O(G)$ and $O(H)$ be the affine algebras of G and H , $\Delta : O(G) \rightarrow O(G) \otimes_k O(G)$ the diagonal morphism of $O(G)$, and I the kernel of the morphism $u^{\text{natural}} : O(G) \rightarrow O(H)$. (One knows, by Proposition 1.3, that u^{natural} induces an isomorphism $O(G)/I \xrightarrow{\sim} O(H)$.) Then the affine algebra $O(G/H)$ of G/H is the kernel of the couple of morphisms:

$$\begin{array}{ccc} & \tau_1 & \\ & \xrightarrow{\quad} & \\ O(G) & & O(G) \otimes_k O(H), \\ & \xrightarrow{\quad} & \\ & (\text{id} \otimes u^{\natural})\Delta & \end{array}$$

where $\tau_1(x) = x \otimes 1$, i.e.,

$$O(G/H) = \{x \in O(G) \mid \Delta(x) - x \otimes 1 \in O(G) \otimes I\}.$$

If, moreover, H is topologically flat over k , then pr_1 is topologically flat and one deduces from Theorem 1.4 the following theorem.

Theorem 2.4. *Let $u : H \rightarrow G$ be a monomorphism of k -formal groups. Assume H topologically flat over k . Then the projection $p : G \rightarrow G/H$ is surjective and topologically flat, one has an isomorphism*

$$(*) \quad G \times H \rightarrow G \times_{G/H} G$$

and G/H represents the quotient-sheaf for the flat topology.

Consequently, G/H is endowed with a canonical structure of object with group of operators G , such that $p : G \rightarrow G/H$ is a morphism of objects with operators. If moreover u identifies H with an invariant subgroup of G , then G/H is endowed with a canonical structure of k -formal group, such that $p : G \rightarrow G/H$ is a morphism of k -formal groups, and H is the kernel of p .*

<!-- label: III.VII_B.2.4.thm -->

Indeed, the first assertion follows from 1.4; the other two from IV, Corollaries 5.2.2 and 5.2.4.

Corollary 2.4. [N.D.E-VII_B-91] *Let G be a k -formal group, H a formal subgroup of G , A (resp. A/J , B) the affine algebra of G (resp. H , G/H), I_A the augmentation ideal of A , and $I_B = B \cap I_A$. Assume H topologically flat over k . Then J equals I_B , the closed ideal generated by I_B .*

<!-- label: III.VII_B.2.4.cor -->

Indeed, the projection $B \rightarrow B/I_B$ corresponds to the "unit section" $\text{se} : \text{Spf}(k) \rightarrow G/H$ of G/H . By $(\ast)$, H is identified with the fiber product $\text{Spf}(k) \times_{G/H} G$, and hence its affine algebra A/J is identified with $(B/I_B) \cap_B A = A/I_B$.

2.4.A.

<!-- label: III.VII_B.2.4.A -->

Let G, Q be topologically flat k -formal groups; assume that there exist homomorphisms $\sigma : Q \rightarrow G$ and $\pi : G \rightarrow Q$ such that $\pi \circ \sigma = \text{id}_Q$. In particular, σ is a monomorphism, so Q is a formal subgroup of G (cf. Remark 1.3). Let $N = \text{Ker}(\pi)$ and σ' the inclusion $N \hookrightarrow G$. Then G is the semi-direct product of N by Q (cf. I, 2.3.8), i.e., for every $B \in \text{Ob } \mathcal{A}_{\text{f-}}^k$, identifying $N(B)$ and $Q(B)$ with their images in $G(B)$ via σ' and σ , $N(B)$ is an invariant subgroup of $G(B)$ and the map

$$(1) \quad \mu : N(B) \times Q(B) \rightarrow G(B), \quad (x, q) \mapsto xq$$

is bijective. Then the morphism of k -formal varieties

```
```text
(2) $\theta : G(B) \rightarrow N(B), \quad g \mapsto g \cdot \sigma(g^{-1})$
```
```

is a retraction of σ , the inverse of μ is the map

```
$$
(3)    $g \mapsto (\theta(g), \pi(g))$ 
$$
```

and $\theta \circ \sigma' : N \rightarrow G/Q$ is an isomorphism of k -formal varieties. In particular, N is topologically flat over k , by 1.4 (ii). Denote by α (resp. β) the map from $Q \times N$ (resp. $G \times N = N \times Q \times N$) to N defined setwise by $\alpha(q, y) = yq^{-1}$ (resp. $\beta(x, q, y) = x \alpha(q, y)$). Then one has the following commutative diagram:

```
```text
 id × θ θ × id
G × G → G × N → N × N
m_G β m_N

 θ
G → N.
```
```

This may be expressed as follows in terms of the affine algebras A , A_0 and A' of G , Q and N (cf. 5.1.3 below). Let $\rho' : A \rightarrow A'$, $\rho : A \rightarrow A_0$ and $\tau : A_0 \rightarrow A$ be the homomorphisms of k -bialgebras corresponding to σ , σ' and π , and let $I = \text{Ker}(\rho)$. Then, by the preceding Corollary, A' is identified with $A/A\tau(I_0)$, where I_0 denotes the augmentation ideal of A_0 .

On the other hand, let B be the affine algebra of G/Q ; it is the kernel of the couple of morphisms

```
```text
 τ_1
 ↓
A → A ⊗_k A_0,
 ↓
 (id ⊗ ρ)Δ_A
```
```

i.e., $B = \{x \in A \mid \Delta_A(x) - x \otimes 1 \in A \otimes I\}$. Denote by γ the continuous morphism of k -algebras $\theta^{\mathbb{N}} : A' \rightarrow A$; it is a section of ρ and an isomorphism of profinite k -algebras from A' onto B . On the other hand, $\tau = \pi^{\mathbb{N}}$ identifies A_0 with a sub-bialgebra of A , which is none other than the affine algebra of the quotient $N \backslash G$. One deduces from (1) and (3) that one has an isomorphism of profinite k -algebras

```
```text
(*) $A' \otimes_k A_0 \cong A, \quad a' \otimes a_0 \mapsto \gamma(a') \tau(a_0),$
```
```

whose inverse is the map $a \mapsto (\rho' \otimes \rho)\Delta_A(a)$.

Finally, let us identify A' with its image in A via γ , so that the projection $A \rightarrow A'$ is then $\gamma \circ \rho$. Denoting by $\Delta_{A'}$ the comultiplication of A' , one deduces from (4) that $\Delta_{A'}(A') \subset A \otimes A'$ and that the following diagram is commutative:

```
```text
 Δ_A
A' → A ⊗ A'
 γρ' ⊗ id

 Δ_{A'}
A' → A' ⊗ A'
```
```

...

(one also has therefore $\gamma \circ \rho' \circ c_{\{A\}} = c_{\{A'\}}$, where $c_{\{A\}}$ (resp. $c_{\{A'\}}$) is the antipode of A (resp. A')). On the other hand, denoting by $m_{\{A\}}$ the multiplication of A , one deduces from (2) that, for every $a \in A$,

```
```text
... \gamma'(a) = (m_A \circ (id \otimes \tau_p c_A) \circ \Delta_A)(a).
```

### 2.4.B.

<!-- label: III.VII\_B.2.4.B -->

Let us suppose, for simplicity,  $k$  artinian. Then what precedes is expressed more simply in terms of the covariant bialgebras of  $G, Q, N$ . Indeed, since  $G = N \times Q$  as  $k$ -formal varieties, then  $H(G) = H(N) \otimes_k H(Q)$  as  $k$ -coalgebras. Moreover, since the multiplication of  $G$  is given by

```
```text
... (x, q) \cdot (x', q') = (x \alpha(q, x'), qq'), \quad \text{where } \alpha(q, x') = qx'q^{-1},
```

the multiplication of $H(G)$ is given as follows: for every $x \in H(N), q \in H(Q)$,

```
```text
... (x \otimes q) \cdot (x' \otimes q') = x \varphi(q, x') \otimes qq',
```

where  $\varphi : H(Q) \otimes_k H(N) \rightarrow H(N)$  is the morphism of  $k$ -coalgebras induced by  $\alpha$ . Since  $\alpha$  is the composite morphism below (where  $\delta_{\{G\}}$  (resp.  $m_{\{G\}}$ ) is the diagonal morphism (resp. multiplication) of  $G$ ,  $c_{\{Q\}}$  the inversion morphism of  $Q$ , and  $\nu(q \otimes q' \otimes x) = q \otimes x \otimes q'$ ):

```
```text
... \begin{array}{c} \text{v} \circ (\delta_G \times \text{id}) \\ Q \times N \longrightarrow Q \times N \times Q \xrightarrow{\text{id} \times \text{id} \times c_Q} Q \times N \times Q \xrightarrow{m_G} G, \end{array}
```

one obtains, denoting still by $c_{\{Q\}}$ the antipode of $H(Q)$, that

```
```text
(*) \quad \varphi(q \otimes x') = \sum_i q_i x' c_Q(q'_i) \quad \text{if } \Delta_{\{H(Q)\}}(q) = \sum_i q_i \otimes q'_i.
```

In particular, if  $M$  is an abstract group and if  $H(Q)$  is the group algebra  $kM$  (i.e.,  $Q = \text{Spf } kM$  is the constant  $k$ -formal group  $M_{\{k\}}$ ), then for every  $\gamma \in M$  and  $x' \in H(N)$  one has  $\varphi(\gamma \otimes x') = \gamma x' \gamma^{-1}$ , and this defines an action of  $M$  on  $H(N)$  by Hopf algebra automorphisms.

### 2.4.1. Proposition.

<!-- label: III.VII\_B.2.4.1 -->

**Proposition 2.4.1.** \*Let  $f : G \rightarrow K$  be a morphism of  $k$ -formal groups. If  $H = \text{Ker}(f)$  is topologically flat over  $k$ , the homomorphism  $f' : G/H \rightarrow K$  <!-- original page 521 --> induced by  $f$  is a monomorphism.\*

<!-- label: III.VII\_B.2.4.1.prop -->

This is a consequence of the results of Exposé IV;[N.D.E-VII\_B-93] we nonetheless give a direct proof. Let  $T$  be a formal variety of finite length over  $k$  and  $t \in (G/H)(T)$  such that  $f' \circ t$  is the unit element of  $K(T)$ . We must show that  $t$  is the unit element of  $(G/H)(T)$ . Denote by  $p$  the projection  $G \rightarrow G/H$  and by  $X$  the fiber product  $T \times_{G/H} G$ .

By 2.4,  $p$  is surjective and topologically flat, hence so is the morphism  $\text{pr}_1 : X \rightarrow T$ , hence  $\text{pr}_1$  is an epimorphism by Proposition 1.3.1, hence it suffices to show that  $t \circ \text{pr}_1$  is the unit element of  $(G/H)(X)$ . Denote by  $\text{pr}_2$  the projection  $X \rightarrow G$ ; one has  $t \circ \text{pr}_1 = p \circ \text{pr}_2$ , whence the equality

$\pi_1 = f' \circ t \circ \pi_{\{1\}} = f' \circ p \circ \pi_{\{2\}} = f \circ \pi_{\{2\}}$ . Then the exact sequence

```

```text
      f
1  →  H  →  G  →  K
...

```

shows that $\pi_{\{2\}}$ factors through H , hence $p \circ \pi_{\{2\}}$ is the zero morphism. Since $p \circ \pi_{\{2\}} = t \circ \pi_{\{1\}}$, this proves the proposition.

One deduces from the proposition the following corollary. Let $A(G)$, $A(K)$ and $A(G/H)$ denote the affine algebras of G , K and G/H ; one has seen (2.4) that p induces an injection of $A(G/H)$ into $A(G)$. Moreover, by Proposition 1.3, since $f' : G/H \rightarrow K$ is a monomorphism, the morphism $A(K) \rightarrow A(G/H)$ is surjective, whence:

Corollary 2.4.1. *Let $f : G \rightarrow K$ be a morphism of k -formal groups and $H = \text{Ker}(f)$. If H is topologically flat over k , then $A(G/H)$ is the image of $A(K)$ in $A(G)$.*

<!-- label: III.VII_B.2.4.1.cor -->

2.4.2.

<!-- label: III.VII_B.2.4.2 -->

Let us keep the preceding notations and assume H and G topologically flat over k . Then G is topologically flat over k and over G/H , hence, by 1.3.3, G/H is topologically flat over k . Consequently, by 2.4, the canonical projection q from K onto $\text{Coker}(f')$ is topologically flat and f' is an isomorphism from G/H onto $\text{Ker}(q)$. It is clear on the other hand that one has $\text{Coker}(f) = \text{Coker}(f')$. Hence, under the hypothesis that G and $H = \text{Ker}(f)$ are topologically flat over k , one has obtained an isomorphism between $\text{Ker}(q)$, the image of f , and $G/\text{Ker}(f)$, the coimage of f . This entails the theorem below.

Theorem 2.4.2. *Let k be a field. The commutative k -formal groups form an abelian category.*

<!-- original page 522 -->

<!-- label: III.VII_B.2.4.2.thm -->

Corollary 2.4.2. *Let k be a field. The commutative affine k -group schemes form an abelian category.*^[N.D.E-VII_B-94]

<!-- label: III.VII_B.2.4.2.cor -->

This follows from the theorem and the equivalence of categories 2.2.2.

2.5.

<!-- label: III.VII_B.2.5 -->

A k -formal group is said to be *étale* if the underlying formal variety is étale (cf. 1.6); these formal groups have a very simple structure. Indeed, suppose k local; let κ be the residue field of k , κ_s a separable closure of κ , and Γ the topological Galois group of κ_s over κ . Let us call a Γ -set the datum of a set E and a continuous operation of Γ on E (i.e., the isotropy group of every element x in E is an open subgroup of Γ).

For every k -formal variety X , one sets:

```

```text
X(κ_s) = lim X(□),
 ↗
 □
...

```

where  $\ell$  ranges over the finite extensions of  $\kappa$  contained in  $\kappa_s$ .<sup>[N.D.E-VII\_B-95]</sup> Then  $\Gamma$  operates continuously on each  $X(\ell)$ , hence also on  $X(\kappa_s)$ . Moreover, let  $X_\kappa = X \square_\kappa \kappa$  (cf. 1.6.C); for every  $\ell$  one has  $X(\ell) = X_{\kappa}(\ell)$ , whence  $X(\kappa_s) = X_{\kappa}(\kappa_s)$ .

Suppose now  $X$  étale over  $k$ ; then  $X_{\kappa}$  is the  $\kappa$ -formal variety direct sum of the

$\operatorname{Spec} \kappa(x)$ , for  $x \in X$ , and if one denotes by  $X'_{\kappa}$  the  $\kappa$ -scheme direct sum of the  $\operatorname{Spec} \kappa(x)$ , one sees that  $X'_{\kappa}(\kappa_s)$  is none other than  $X'_{\kappa}(\kappa_s) = \operatorname{Hom}_{(\operatorname{Sch}/\kappa)}(\operatorname{Spec} \kappa_s, X'_{\kappa})$ .

Let us denote  $\mathcal{C} = (\operatorname{Sch}_{\kappa})_{\kappa}$  the full subcategory of  $(\operatorname{Sch}_{\kappa})$  formed by the étale  $\kappa$ -schemes. One knows that the functor  $X' \mapsto X'(\kappa_s)$  is an equivalence of  $\mathcal{C}$  onto the category  $\Gamma$  of  $\Gamma$ -sets (cf. SGA 1, V §§ 7–8 or [DG70], § I.4 6.4); it therefore induces an equivalence between the category of  $\mathcal{C}$ -groups and that of  $\Gamma$ -groups; now one sees at once that a  $\mathcal{C}$ -group is the same thing as an abstract group  $G$  endowed with a continuous operation of  $\Gamma$  by group automorphisms (one will then say that  $G$  is a  $\Gamma$ -group).

Taking into account the equivalences  $\operatorname{Vaf}^{\text{ét}}/\kappa \simeq \operatorname{Vaf}^{\text{ét}}/\kappa \simeq (\operatorname{Sch}^{\text{ét}}/\kappa)$  of 1.6.E, one therefore obtains:

**Proposition 2.5.** \*Let  $\kappa$  be a local pseudocompact ring,  $\kappa$  its residue field,  $\kappa_s$  a separable closure of  $\kappa$ , and  $\Gamma = \operatorname{Gal}(\kappa_s/\kappa)$ .\*

(i) The functor  $X \mapsto X(\kappa_s)$  is an equivalence of the category of étale  $\kappa$ -formal varieties onto that of  $\Gamma$ -sets.\*

(ii) It induces an equivalence of the category of étale  $\kappa$ -formal groups onto that of  $\Gamma$ -groups.\*

<!-- label: III.VII\_B.2.5.prop -->

**Remark 2.5.A.** [N.D.E-VII\_B-96] Let  $\kappa$  be a field,  $\kappa_s$  a separable closure of  $\kappa$ ,  $G$  an étale  $\kappa$ -formal group and  $M$  the abstract group  $G(k_s)$ . Let us denote by  $X$  a set of representatives of the orbits of  $\Gamma = \operatorname{Gal}(\kappa_s/\kappa)$  in  $M$ , and for every  $x \in X$  let  $\Gamma_x$  be its stabilizer, which is a subgroup of  $\Gamma$  of finite index, and  $L_x = k^{\Gamma_x}$ , which is an extension of  $\kappa$  of degree  $[\Gamma : \Gamma_x]$  (see, for example, [BALg], V § 10.10). Then, by the equivalence of categories above, the affine algebra  $\mathcal{A}(G)$  of  $G$  is the product of the  $L_x$ , endowed with the product topology, and hence the  $L_x$  are precisely the simple quotients  $\mathcal{A}(G)/\mathfrak{m}_x$ , where  $\mathfrak{m}_x$  is a maximal open ideal of  $\mathcal{A}(G)$ . Since these correspond by duality to the subcoalgebras of  $H(G)$ , one obtains that  $H(G)$  is pointed (i.e.,  $\dim_k(C) = 1$  for every simple subcoalgebra  $C$ ) if and only if  $L_x = \kappa$  for every  $x$ , and in this case  $\mathcal{A}(G)$  is the topological algebra  $k^M$ , hence  $H(G)$  is the group algebra  $kM$ , and one has

text  
 $M = \{x \in H(G) \mid \varepsilon(x) = 1 \text{ and } \Delta(x) = x \otimes x\} = G(k).$   
 ...

<!-- label: III.VII\_B.2.5.A -->

### 2.5.1.

<!-- label: III.VII\_B.2.5.1 -->

Let us now suppose  $\kappa$  an arbitrary pseudocompact ring. Since the functor <!-- original page 523 -->  $X \mapsto X_e$  of 1.6.F commutes with finite products, it transforms every formal group  $G$  into an étale formal group  $G_e$ , and since the morphism  $\rho : X \rightarrow X_e$  of loc. cit. is functorial in  $X$ , then  $\rho : G \rightarrow G_e$  is in this case a morphism of formal groups.

Consider the kernel  $\operatorname{Ker}(\rho)$ ; [N.D.E-VII\_B-97] it is the fiber product of the diagram:

text  

$$\begin{array}{ccc} & G & \\ & \rho & \\ \varepsilon & & \\ \operatorname{Spf}(\kappa) & \longrightarrow & G_e \end{array}$$
  
 ...

where  $\varepsilon$  is the unit section of  $G_e$ . Since  $\rho$  induces a bijection on the underlying sets, one deduces (cf. 1.2, N.D.E. (41)) that  $\operatorname{Ker}(\rho)$  has as underlying set the image of  $\operatorname{Spf}(\kappa)$  under  $\varepsilon$  and that for every point  $s$  of  $\operatorname{Spf}(\kappa)$ , the local algebra of  $\operatorname{Ker}(\rho)$  at the point  $\varepsilon(s)$  is  $0_{\{G, \varepsilon(s)\}} \cap 0_{\{G_e, \varepsilon(s)\}} \cap \kappa_s$ . Moreover, at each point  $\varepsilon(s)$ , the residue field of  $0_{\{G, \varepsilon(s)\}}$  is  $\kappa(s)$ , and hence  $0_{\{G_e, \varepsilon(s)\}} \cap \kappa_s = \kappa(s)$ , whence  $0_{\{\operatorname{Ker}(\rho), \varepsilon(s)\}} = 0_{\{G, \varepsilon(s)\}}$ . For these reasons we shall say that  $\operatorname{Ker}(\rho)$  is the \*infinitesimal neighborhood of the origin\* of  $G$  and we shall write  $\operatorname{Ker}(\rho) = G^0$ , thereby

obtaining an exact sequence:

$$\begin{array}{c} \text{``text} \\ 1 \longrightarrow G^\circ \xrightarrow{\text{incl.}} G \xrightarrow{p} G_e. \\ \text{...} \end{array}$$

In what follows, we shall say that  $G$  is *infinitesimal* if  $G = G^{\{0\}}$ .<sup>[^N.D.E-VII\_B-98]</sup> This is equivalent to saying that for every  $s \in \text{Spf}(k)$ , or also for every continuous morphism  $k \rightarrow \kappa$ , where  $\kappa$  is a field endowed with the discrete topology, the unit element is the unique element of  $G(\kappa(s))$  resp. of  $G(\kappa)$ .

Suppose furthermore that  $G$  is topologically flat over  $k$ .<sup>[^N.D.E-VII\_B-99]</sup> Then, by 1.6.1, the morphism  $p : G \rightarrow G_e$  is topologically flat, and since it is bijective, it is therefore an effective epimorphism by Proposition 1.3.1. Consequently,  $G_e$  is identified with the quotient  $G/G^{\{0\}}$ . One has therefore obtained:

**Corollary 2.5.1.** *Let  $G$  be a formal group topologically flat over  $k$ . Then  $G_e$  is identified with the quotient  $G/G^{\{0\}}$ ; i.e., one has an exact sequence of formal groups:*

$$\begin{array}{c} \text{``text} \\ 1 \longrightarrow G^\circ \xrightarrow{\text{incl.}} G \xrightarrow{p} G_e \longrightarrow 1. \\ \text{...} \end{array}$$

<!-- label: III.VII\_B.2.5.1.cor -->

### 2.5.2.

<!-- label: III.VII\_B.2.5.2 -->

Suppose  $k$  is a perfect field. In this case, one has seen (cf. 1.6.2) that the morphism  $p : X \mapsto X_e$  admits a section  $s : X_e \rightarrow X$  which depends functorially <!-- original page 524 --> on  $X$ ; this section is therefore a morphism of formal groups when  $X$  is a formal group. One obtains thus:

**Proposition 2.5.2.** *When  $k$  is a perfect field, every  $k$ -formal group  $G$  is canonically isomorphic to the semi-direct product of an infinitesimal group  $G^{\{0\}}$  and an étale group  $G_e$  operating on  $G^{\{0\}}$ .*<sup>[^N.D.E-VII\_B-100]</sup>

If, moreover,  $G$  is commutative, then  $G$  is the product of  $G^{\{0\}}$  and of  $G_e$ . By 2.2.2, this canonical decomposition of commutative  $k$ -formal groups corresponds to an analogous decomposition of affine commutative  $k$ -group schemes; see paragraph 2.5.3 below.\*

<!-- label: III.VII\_B.2.5.2.prop -->

**Remark 2.5.2.A.**<sup>[^N.D.E-VII\_B-101]</sup> The exact sequence  $1 \rightarrow G^{\{0\}} \rightarrow G \rightarrow G_e \rightarrow 1$  is not necessarily split when  $k$  is not perfect: let us give the following example, taken from [DG70], § III.6, 8.6. Let  $k$  be a non-perfect field of characteristic  $p > 0$ . Let  $L_\lambda \subset k[x, y]$ , let  $L_\lambda$  be the abelian  $p$ -Lie algebra with basis  $(x, y)$ , the *symbolic  $p$ -th power* (cf. VII\_A, 5.2) being given by  $x^{(p)} = x$  and  $y^{(p)} = \lambda x$ , let  $U_p(L_\lambda) = k[x, y]/(x^{(p)} - x, y^{(p)} - \lambda x)$  be the restricted enveloping algebra of  $L_\lambda$  (cf. VII\_A, 5.3), and let  $G_\lambda$  be the commutative  $k$ -formal group with affine algebra  $U_p(L_\lambda)$ . Then  $G_\lambda$  is a non-split extension of the étale constant  $k$ -group  $(\mathbb{Z}/p\mathbb{Z})/p\mathbb{Z}$  by the infinitesimal  $k$ -group  $\alpha_{p,k} = \text{Spf } k[x]/(x^{(p)} - x)$ , i.e., one has a non-split exact sequence of commutative  $k$ -formal groups:<sup>[^N.D.E-VII\_B-102]</sup>

$$\begin{array}{c} \text{``text} \\ 0 \longrightarrow \alpha_{p,k} \longrightarrow G_\lambda \longrightarrow (\mathbb{Z}/p\mathbb{Z})_k \longrightarrow 0. \\ \text{...} \end{array}$$

It corresponds by duality to a non-split exact sequence of commutative  $k$ -algebraic groups:

$$\begin{array}{c} \text{``text} \\ 0 \longrightarrow \mu_{p,k} \longrightarrow D'(G_\lambda) \longrightarrow \alpha_{p,k} \longrightarrow 0, \\ \text{...} \end{array}$$

where  $\mu_{p,k} = \text{operatorname{Spec}} k[t]/(t^{(p)} - 1)$  (and one obtains thus all extensions of  $\alpha_{p,k}$  by  $\mu_{p,k}$ , cf. [DG70], § III.6, 8.6).

<!-- label: III.VII\_B.2.5.2.A -->

### 2.5.3.

<!-- label: III.VII\_B.2.5.3 -->

Let  $k$  be a field.

**Definition 2.5.3.A.** One says that a commutative  $k$ -group scheme is unipotent if it is isomorphic to  $H(G)$ , where  $G$  is an infinitesimal commutative  $k$ -formal group. [N.D.E-VII\_B-104]

<!-- label: III.VII\_B.2.5.3.A -->

On the other hand, following Exp. IX, Definition 1.1, one says that a  $k$ -group scheme  $H$  is of multiplicative type if there exists a scheme  $S$ , faithfully flat and quasi-compact over  $k$ , such that  $H_S$  is a diagonalizable  $S$ -group, i.e., is isomorphic to  $D_{\{S\}}(M)$  for some "abstract" abelian group  $M$ . [N.D.E-VII\_B-105] By (fpqc) descent, this implies that  $H$  is affine and commutative. On the other hand, since one may replace  $S$  by the residue field of one of its points, one sees that  $H$  is of multiplicative type if and only if there exists an extension  $K$  of  $k$  such that  $H_K$  is a diagonalizable  $K$ -group.

**Proposition 2.5.3.B.** Let  $T$  be an affine commutative  $k$ -group scheme and let  $k_{\{s\}}$  be a separable closure of  $k$ .

(i) For  $T$  to be of multiplicative type, it is necessary and sufficient that its dual  $D(T)$  be an étale commutative  $k$ -formal group.

(ii) Consequently,  $T$  is of multiplicative type if and only if  $T_{\square_k k_s}$  is diagonalizable.

<!-- label: III.VII\_B.2.5.3.B -->

**Proof.** Let  $A$  denote the affine algebra of  $D(T)$  and  $A_{\{0\}}$  its local component at the neutral element; then  $D(T)$  is étale over  $k$  if and only if  $A_{\{0\}} = k$ . If  $K$  is an extension of  $k$ , then the algebra  $A_{\square_k K}$  is local (since it is a projective limit of local artinian rings), so it coincides with the local component  $(A_{\square_k K})_{\circ}$ ; moreover, since the formation of  $D(T)$  commutes with base change (cf. 2.2.2), one also has  $A_{\square_k K} \simeq D(T_K)$ .

Suppose  $T$  of multiplicative type; then there exists an extension  $K$  of  $k$  such that  $D(T)_{\square_k K}$  is isomorphic, as a  $K$ -Hopf algebra, to the group algebra  $KM$ , for some abelian group  $M$ . Then  $A_{\square_k K}$  is isomorphic to the algebra  $K^{M^*}$ , endowed with the product topology, hence one has  $K = (A_{\square_k K})_{\circ} = A_{\square_k K}$  and this entails that  $A_{\{0\}} = k$ , so  $D(T)$  is étale.

Conversely, suppose  $D(T)$  étale. Then  $D(T)_{\square_k k_s} = D(T_{k_s})$  is a  $k_s$ -constant group  $M_s$ , so its covariant bigèbre is the group algebra  $k_s^{M_s}$  (cf. Remark 2.5.A), so  $D(T)_{\square_k k_s} = k_s^{M_s}$ , which proves that  $T$  is of multiplicative type, and split by the extension  $k \rightarrow k_s$ . The proposition follows.

By 2.2.2, 2.5.1, and 2.5, one obtains:

**Corollary 2.5.3.C.** Let  $k$  be a field and  $G$  an affine commutative  $k$ -group scheme.

(i)  $G$  contains a subgroup of multiplicative type  $G_{\{m\}}$  such that  $G/G_{\{m\}}$  is unipotent.

(ii) When  $k$  is perfect, there exists furthermore a canonical retraction of  $G$  onto  $G_{\{m\}}$ , so that  $G$  is the product of a unipotent group and a group of multiplicative type.

(iii) [N.D.E-VII\_B-106] Let  $k_{\{s\}}$  be a separable closure of  $k$  and  $\Gamma = \text{Gal}(k_{\{s\}}/k)$ . The category of  $k$ -group schemes of multiplicative type is anti-equivalent to the category of continuous  $\Gamma$ -modules.

<!-- label: III.VII\_B.2.5.3.C -->

### 2.6.

<!-- label: III.VII\_B.2.6 -->

We shall now study infinitesimal formal groups, to which the following paragraphs are devoted. In this study, Lie algebras play a primordial role.

Suppose first that the base ring  $k$  is artinian and let  $G$  be a formal group over  $k$ . One can give three different interpretations of the Lie algebra of  $G$ , all of which we shall use:

a) Let  $D$  be the algebra  $k[d]/(d^2)$  of dual numbers over  $k$  and  $\delta$  the homomorphism  $\delta : D \rightarrow G$  from  $D$  to  $G$  which annihilates  $d$ . For every formal group  $G$  over  $k$ ,  $\text{Lie}(G)$  is the kernel of  $G(\delta)$ , so that by definition one has an exact sequence of groups

$$1 \longrightarrow \text{Lie}(G) \longrightarrow G(D) \xrightarrow{G(\delta)} G(k) \longrightarrow 1.$$

b) Let  $A$  be the affine algebra of  $G$  and  $I_A = \text{Ker } \epsilon_A$  its augmentation ideal. The group  $G(D)$  has as elements the morphisms of profinite  $k$ -algebras  $f : A \rightarrow D$ . The condition  $G(\delta)(f) = 1$  is equivalent to  $\delta \circ f = \epsilon_A$ . Since  $x - \epsilon_A(x) \cdot 1 \in I_A$  for every  $x \in A$ , this is equivalent to  $f(I_A) \subset k \cdot d$ , hence  $\text{Ker}(f)$  contains  $I_A^2$  and therefore also  $\bar{I}_A^2$  (the closure), so  $f$  induces a continuous linear map  $f' : I_A / I_A^2 \rightarrow \omega_{G/k}$  such that, for every  $x \in A$ , one has the equality

$$f(x) = \epsilon_A(x) \cdot 1_D + f'(x) \cdot d,$$

where  $\bar{x}$  designates the image of  $x - \epsilon_A(x) \cdot 1$  in  $I_A / I_A^2$ . One sees then that the map  $f \mapsto f'$  defines a bijection of  $\text{Lie}(G)$  onto the topological dual  $\omega_{G/k}^*$  of  $\omega_{G/k}$  (cf. 0.2.2).

This bijection respects the group structures. Indeed, let  $f$  and  $g$  be two elements of  $\text{Lie}(G)$ ; their product  $f \cdot g$  is the composite map  $h \circ \Delta_A$ , where  $h : A \rightarrow D$  is such that  $h(b \cdot b') = f(b) \cdot g(b')$ . Now if  $a \in I_A$  one has, by 2.1 (ii),  $\Delta_A(a) = a \cdot 1 + 1 \cdot a \in I_A \cdot I_A$ , whence  $(f \cdot g)(a) = f(a) + g(a)$  (cf. also II 3.10).

In what follows, we identify  $\text{Lie}(G)$  with  $\omega_{G/k}^*$  by means of the bijection  $f \mapsto f'$  described above. The group  $\text{Lie}(G)$  is thus endowed with a structure of  $k$ -module.

<!-- original page 526 -->

c) Let  $A^*$  and  $D^*$  be the  $k$ -modules dual to  $A$  and  $D$ ,  $\{1_D^*, d^*\}$  the dual basis of the basis  $\{1_D, d\}$  of  $D$  over  $k$  (one has  $1_D^* = \delta^*$ ). Since  $D$  is free of finite rank over  $k$ , the canonical map

$$\text{Hom}_k(A, D) \rightarrow \text{Hom}_k(D^*, A^*), \quad f \mapsto {}^t f$$

is bijective. On the other hand,  $f$  is determined by the values  $f(1_D^*)$  and  $f(d^*) = x$ .

The condition  $G(\delta)(f) = 1$  is equivalent to the equality  $f(1_D^*) = \epsilon_A$ . One sees easily on the other hand that  $f$  is compatible with multiplication if and only if one has (cf. 2.3):

$$\delta \circ \delta \circ \delta(x) = \delta_G(x) \cdot \delta_G(y) = \phi_G(x \otimes 1 + 1 \otimes x)(y \otimes 1 + 1 \otimes y).$$

Finally, it is clear that a continuous linear map  $f : A \rightarrow D$  which is compatible with multiplication and such that  $\delta \circ f = \epsilon_A$  sends the unit element of  $A$  to that of  $D$ . [N.D.E-VII\_B-107] The map  $f \mapsto x$  thus permits us to identify  $\text{Lie}(G)$  with the set of "primitive elements" of  $H(G)$  (i.e., the  $x \in H(G)$  satisfying relation  $\delta(x) = x$ ). If  $x$  and  $y$  are two such elements, one has

$$\delta_G(xy) = \delta_G(x) \cdot \delta_G(y) = \phi_G(x \otimes 1 + 1 \otimes x)(y \otimes 1 + 1 \otimes y) = \phi_G(xy \otimes 1 + x \otimes y + y \otimes x + 1 \otimes xy),$$

whence  $\delta_G(xy - yx) = \phi_G((xy - yx) \otimes 1 + 1 \otimes (xy - yx))$ .

This shows that the  $k$ -module  $\text{Lie}(G)$  is identified with a Lie subalgebra of  $H(G)$ : we shall say that  $\text{Lie}(G)$  is the

\*Lie algebra\* of  $G$ . [N.D.E-VII\_B-108]

### 2.6.1.

<!-- label: III.VII\_B.2.6.1 -->

<!-- original page 527 -->

When  $k$  is an arbitrary pseudocompact ring and  $G$  a formal group over  $k$ , we call  $*\mathfrak{g}_k$ -Lie algebra of  $G$  the functor  $\text{Lie}(G)$  which associates to every object  $C$  of  $\mathcal{A}_k$  the  $C$ -Lie algebra of the  $C$ -formal group  $G_C = G \times_k C$ . [N.D.E-VII\_B-109] set  $A = A \times_k C$ , since  $I_A$  is a direct factor of  $A$ , then  $I_{A'} = I_A \times_k C$  equals  $I_A \times_k C = I_A \times_k A$ , and since  $\omega_{G/k} = I_A \times_k A$  and similarly  $\omega_{G'/C} = I_{A'} \times_k A$ , one obtains that  $\omega_{G'/C} = \omega_{G/k} \times_k A$  and hence

```text  
Lie(G)(C) = Hom_c($\omega_{G/k} \times_k A$, C) i.e. Lie(G) = $V_{kf}(\omega_{G/k})$
```

(with the notations of 1.2.3.B). Therefore, by Proposition 1.2.3.E,  $\text{Lie}(G)$  is flat over  $\mathfrak{g}_k$  if and only if  $\omega_{G/k}$  is a projective pseudocompact  $k$ -module.

### 2.6.2.

<!-- label: III.VII\_B.2.6.2 -->

Conversely, every Lie algebra  $L$  over  $\mathfrak{g}_k$  defines a  $k$ -group functor. Indeed, let us denote by  $U(L)$  the functor which associates to every object  $C$  of  $\mathcal{A}_k$  the enveloping algebra  $U(L(C))$  of the  $C$ -Lie algebra  $L(C)$ . By VII\_A, 3.2.2,  $U(L)$  is a bialgebra over  $\mathfrak{g}_k$  and therefore determines, by 2.2, a  $k$ -group functor  $\text{Spf}^* U(L)$  which we shall henceforth denote  $\mathcal{G}(L)$ . Thus,  $\mathcal{G}(L)(C)$  is the group of elements  $z \in U(L(C))$  of augmentation 1 and such that  $\Delta_{U(L(C))}(z) = z \otimes z$ .

Moreover, when  $L$  is flat over  $\mathfrak{g}_k$ , one has the following proposition.

**Proposition 2.6.2.** [N.D.E-VII\_B-110] *Let  $L$  be a flat  $\mathfrak{g}_k$ -Lie algebra.*

*(i)  $\mathcal{G}(L)$  is a formal group topologically flat over  $k$ , having  $U(L)$  as  $\mathfrak{g}_k$ -bialgebra.*

*(ii)  $\mathcal{G}(L)$  is infinitesimal.*

*(iii) For every object  $C$  of  $\mathcal{A}_k$ ,  $\text{Lie}(\mathcal{G}(L))(C)$  is identified with the set*

```text  
Prim $U(L(C)) = \{x \in U(L(C)) \mid \varepsilon(x) = 0 \text{ and } \Delta(x) = x \otimes 1 + 1 \otimes x\}$
```

*of primitive elements of  $U(L(C))$ . In particular, one has a natural morphism of  $\mathfrak{g}_k$ -Lie algebras  $\tau_L : L \rightarrow \text{Lie}(\mathcal{G}(L))$ .*

<!-- label: III.VII\_B.2.6.2.prop -->

Indeed, the hypothesis that  $L$  be flat over  $\mathfrak{g}_k$  means that for every morphism  $C \rightarrow D$  of  $\mathcal{A}_k$ , one has  $L(D) = L(C) \otimes_C D$ , and that for each local component  $C'$  of  $C$ ,  $L(C')$  is a free  $C'$ -module. The first condition entails that  $U(L(D)) = U(L(C)) \otimes_C D$  (by the universal property of the tensor product and that of the functor  $L \mapsto U(L)$ ), and the second condition entails, by the Poincaré-Birkhoff-Witt theorem (cf. Bourbaki, *Groupes et algèbres de Lie*, I 2.7), that  $U(L(C'))$  is a free  $C'$ -module. Therefore the bialgebra  $U(L)$  is flat over  $\mathfrak{g}_k$ .

To prove (ii) and (iii), one may suppose  $k$  artinian. Set then  $L = L(k)$ ,  $U = U(L)$ ,  $U_0 = k \cdot 1_U$  and let  $U^+ = U \setminus U_0$  be the two-sided ideal of  $U$  generated by the image of  $L$ . Set in addition, for every  $n \geq 1$ ,

```text  
 $U_n = \{u \in U \mid \Delta_U(u) - u \otimes 1 \in U_{n-1} \otimes U^+\}$.
```

By 1.3.6, it suffices to show that  $U$  is the union of the  $U_n$ . Now, if one identifies  $L$  with its

<!-- original page 528 --> canonical image in  $U$ ,  $L$  is evidently contained in  $U_1$ . If  $x_1, \dots, x_n$  are elements of  $L$ , one has  $\Delta_U(x_1 \cdots x_n) = (x_1 \otimes 1 + 1 \otimes x_1) \cdots (x_n \otimes 1 + 1 \otimes x_n)$ , which shows, by induction on  $n$ , that the product  $x_1 \cdots x_n$  belongs to  $U_n$ , hence that  $U = \cup_n U_n$ . This proves (ii).

On the other hand, let  $D = k[d]/(d^2)$  be the algebra of dual numbers over  $k$ . By hypothesis one has  $L(D) \simeq L \otimes D$ , whence  $U(L(D)) \simeq U \otimes D$ , by the universal properties of the tensor product and of the enveloping algebra. It follows that  $\text{Lie}(\mathcal{G}(L))(k)$  is identified with the set of elements  $z = 1 + xd$  of  $U \oplus U$  (where  $x \in U$ ) such that  $\epsilon(z) = 1$  and  $\Delta(z) = z \otimes z$ , which is equivalent to  $\epsilon(x) = 0$  and  $\Delta(x) = x \otimes 1 + 1 \otimes x$ , i.e., to  $x \in \text{Prim } U$ . In particular, the map  $\tau_L : x \mapsto 1 + dx$  is a morphism of  $0$ -Lie algebras, from  $L$  to  $\text{Lie}(\mathcal{G}(L))$ .

### 2.6.3.

<!-- label: III.VII\_B.2.6.3 -->

If  $L$  is a Lie algebra flat over  $0$ , the formal group  $\mathcal{G}(L)$  may be characterized by a universal property. [N.D.E-VII\_B-111] Indeed, every morphism  $\phi$  from  $\mathcal{G}(L)$  into a formal group  $G$  induces a morphism  $\text{Lie}(\phi) : \text{Lie}(\mathcal{G}(L)) \rightarrow \text{Lie}(G)$ ; composing it with the morphism  $\tau_L : L \rightarrow \text{Lie}(\mathcal{G}(L))$  (cf. 2.6.2), one obtains a morphism  $\phi' : L \rightarrow \text{Lie}(G)$ , and one has:

**Proposition 2.6.3.** \*If  $G$  is a  $k$ -formal group and  $L$  a flat  $0$ -Lie algebra, the map  $\phi \mapsto \phi'$  defined above is a bijection\*

```
``text
Hom_{Grf/k}(\mathcal{G}(L), G) \cong Hom_{Lie}(L, \text{Lie}(G))
``
```

\*where the right-hand term designates the set of morphisms of  $0$ -Lie algebras from  $L$  to  $\text{Lie}(G)$ .\*

<!-- label: III.VII\_B.2.6.3.prop -->

One reduces at once to the case where  $k$  is artinian. Set  $L = L(k)$ . By 2.3.1,  $\text{Hom}_{\text{Grf/k}}(\mathcal{G}(L), G)$  is in bijection with the set of unital algebra morphisms  $\phi : U(L) \rightarrow H(G)$  such that the following diagram is commutative:

```
``text
 h
U(L) ----> H(G)
 ^ / \
 | | \delta_G
 | | \
\Delta_{U(L)} H(G \times G)
 / \
 / \phi_G
 h \otimes h
U(L) \otimes U(L) \longrightarrow H(G) \otimes H(G)
``
```

<!-- original page 529 -->

Now  $\phi$  is determined by its restriction to  $L$ , which is a morphism of Lie algebras from  $L$  to the Lie algebra underlying  $H(G)$ , and the commutativity of the diagram means that  $\phi$  sends  $L$  into the part of  $H(G)$  formed by the  $x$  such that  $\delta_G(x) = \varphi_G(x \otimes 1 + 1 \otimes x)$ , which is none other than  $\text{Lie}(G)$ , cf. 2.6 c).

### 2.7.

<!-- label: III.VII\_B.2.7 -->

We end these generalities with a statement which goes back to S. Lie and which will serve us in paragraph 5.1. A *formal monoid* over  $k$  is by definition a couple  $(M, m)$  consisting of a formal variety  $M$  and a morphism  $m : M \times M \rightarrow M$  such that  $m(C)$  makes  $M(C)$  into a monoid for every object  $C$  of  $\text{Alg}_k$ . [N.D.E-VII\_B-112] In particular, the "unit section", which associates to every object  $C$  the unit element of  $M(C)$ , defines <!-- original page 565 --> a section  $\epsilon_M$  of the canonical projection  $M \rightarrow \text{Spf}(k)$ . We shall say that the formal monoid  $M$  is *infinitesimal* if  $\epsilon_M$  induces a bijection of the underlying sets.

**\*\*Proposition 2.7.\*\*** Every topologically flat infinitesimal  $k$ -formal monoid  $M$  is a  $k$ -formal group. <sup>[N.D.E-VII\_B-113]</sup>

<!-- label: III.VII\_B.2.7.prop -->

We must show that  $M(C)$  is a group for every object  $C$  of  $\mathcal{A}lf_k$ . One reduces immediately to the case where  $k$  is artinian. Let then  $U = H(M)$  be the coalgebra of  $M$  (1.3.5); the multiplication  $m : M \times M \rightarrow M$  induces a morphism of coalgebras  $m_U : U \otimes U \rightarrow U$ , which makes  $U$  into an associative algebra over  $k$ ; this algebra has as unit element the image of the unit element of  $k$  by the map from  $k$  into  $U$  <!-- original page 530 --> induced by the unit section  $\epsilon_M$  of  $M$ . Similarly, the projection  $M \rightarrow \mathrm{Spf}(k)$  induces a homomorphism  $\epsilon_U$  from  $U$  to  $k$ ; we shall denote  $U^+ = \ker \epsilon_U$ .

We must show that there exists an antipodism, that is, a morphism of coalgebras  $c_U : U \rightarrow U$  such that, for every  $u \in U$ ,

``text  
 (\*)  $(m_U \circ (c_U \otimes \mathrm{id}_U) \circ \Delta_U)(x) = \epsilon_U(u) \cdot 1_U$ .  
 ```

Let (U_n) be the filtration of U defined in 1.3.6, set $U^+_n = U^+ \cap U_n$. Since M is infinitesimal, U^+_n is the union of the submodules U^+_n . ^[N.D.E-VII_B-114] One sets $c_{\{0\}}(1) = 1$ and $c_{\{1\}}(x) = -x$ if $x \in U^+_1$, i.e., if x is a primitive element. Suppose $c_{\{n-1\}} : U_{n-1} \rightarrow U$ constructed so as to satisfy $(\ast)$ for every $x \in U_{n-1}$, and let $x \in U^+_n$. By the proof of Lemma 1.3.6.A, one has $\Delta_U(x) - x \otimes 1 \in U_{n-1} \otimes U^+$ (this is where the hypothesis that U be flat over k intervenes), so one may write $\Delta_U(x) = x \otimes 1 + \sum_i y_i \otimes z_i$, with $y_i \in U_{n-1}$; one then sets $c_{\{n\}}(x) = -\sum_i c_{\{n-1\}}(y_i) z_i$. One obtains thus a k -linear map $c : U \rightarrow U$, which is the left inverse of id_U for the monoid law on $\mathrm{End}_k(U)$, defined by $f \cdot g = m_U \circ (f \otimes g) \circ \Delta_U$ (the unit element being the map $\epsilon : u \mapsto \epsilon(u) \cdot 1_U$). It follows that c is uniquely determined, and is also the right inverse of id_U , i.e., one also has $m_U \circ (c_U \otimes \mathrm{id}_U) \circ \Delta_U = \eta$ (without supposing U cocommutative).

2.8. Unipotent group schemes over a field.

<!-- label: III.VII_B.2.8 -->

Let k be a field. "Recall" that a k -group scheme G is said to be *unipotent* if it satisfies the following two conditions (cf. [DG70], § IV.2, Prop. 2.5):

(a) G is affine.

(b) Every simple $O(G)$ -comodule is trivial, i.e., if $\rho : V \rightarrow V \otimes_k O(G)$ is an $O(G)$ -comodule structure on a k -vector space $V \neq 0$, and if there exists no nonzero subspace $W \neq V$ such that $\rho(W) \subset W \otimes_k O(G)$, then V is one-dimensional and $\rho(v) = v \otimes 1$ for every $v \in V$.

By loc. cit., when G is of finite type over k , this is equivalent to the definition given in Exp. XVII, § 1, namely that G possesses a finite composition series whose successive quotients are isomorphic to k -subgroups of $\mathrm{Mat}_{a,k}$.

Now, for every affine k -group scheme G , the comultiplication of $O(G)$ endows the pseudocompact k -module $A = O(G)^*$ with a structure of profinite k -algebra, not necessarily commutative, the unit element 1_A being the augmentation $\epsilon : O(G) \rightarrow k$. On the other hand, let $I = \{f \in A \mid f(1_{O(G)}) = 0\}$; this is a two-sided ideal of A , and one has $A = k \cdot 1_A \oplus I$, cf. 1.3.6.

Let V be a subspace of A of finite codimension, consider the continuous k -bilinear map $\varphi : A \times A \rightarrow A/V$, $(a, b) \mapsto ab + V$; by Lemma 0.3.1, there exist two subspaces L_1, L_2 of finite codimension in A such that V contains $L_1 L_2$ and $L_1 L_2 \subset V$; then $L = L_1 \cap L_2$ is a subspace of A of finite codimension, and V contains the two-sided ideal L^2 , which is of finite codimension. This shows that the two-sided ideals of finite codimension form a basis of neighborhoods of 0 . One deduces that an $O(G)$ -comodule "is the same thing" as a continuous A -module, i.e., an A -module V such that the map $A \times V \rightarrow V$ is continuous, V being endowed with the discrete topology. Such a module is evidently the union of submodules V_i of finite dimension over k , each of which is a module over a k -algebra quotient A_i of A , of finite dimension over k . It follows that if M is a simple continuous module, it is of finite dimension over k , and is a faithful simple module over the finite-dimensional k -algebra $A/\mathrm{Ann}(M)$; the latter is therefore a finite-dimensional simple k -algebra, i.e., $\mathrm{Ann}(M)$ is a maximal open ideal of A . Conversely, let P be an open prime ideal ^[N.D.E-VII_B-116] of A ; then A/P is a finite-dimensional k -algebra in which the ideal (0) is prime, hence it is a finite-dimensional simple

k -algebra, so there exists, up to isomorphism, a unique simple continuous A -module whose annihilator is P . It follows that the map $M \mapsto \text{Ann}(M)$ defines a bijection between the isomorphism classes of simple continuous A -modules and the open prime ideals of A . In particular, the A -module A/I , which is one-dimensional over k , is called the "trivial module"; it corresponds to the one-dimensional $0(G)$ -comodule V which is trivial, i.e., such that $\rho(v) = v \otimes 1_{0(G)}$ for every $v \in V$. One thus obtains the following proposition:

Proposition 2.8.1. Let k be a field, G an affine k -group scheme and $A = 0(G)$.

(i) Then G is unipotent if and only if I is the unique open prime ideal of A . [N.D.E-VII_B-117]

(ii) In particular, if G is commutative, so that $0(G) = H(D(G))$, where $D(G) = \text{Spf}(A)$ designates the Cartier dual of G , then G is unipotent if and only if $D(G)$ is infinitesimal.

<!-- label: III.VII_B.2.8.1 -->

2.9. Pointed cocommutative Hopf algebras over a field.

<!-- label: III.VII_B.2.9 -->

Let k be a field, C a k -coalgebra, A the algebra C^* endowed with the structure of profinite k -algebra (not necessarily commutative) described in 2.8; by 0.2.2, one has $C = A^\dagger = \text{Hom}_c(A, k)$. One deduces that the map $D \mapsto D^\perp = \{f \in A \mid f(D) = 0\}$ is a bijection from the set of subcoalgebras of C onto that of closed two-sided ideals (in the sequel, one will simply say "ideals") of A ; the inverse bijection being given by $I \mapsto I^\perp = \{x \in C \mid x(I) = 0\}$. Since every maximal closed ideal is a maximal open ideal (cf. 0.2.1), every subcoalgebra therefore contains a simple subcoalgebra, necessarily of finite dimension.

Recall that a subcoalgebra D of C is called *irreducible* if it contains only one simple subcoalgebra S_0 , which is equivalent to saying that $m_0 = S_0^\perp$ is the unique maximal open ideal containing $D^\perp$, i.e., $D^\perp + m = A$ for every maximal open ideal $m \neq m_0$. This is in particular the case if $D = S_0$. Then the sum Σ_0 of all the irreducible subcoalgebras C_i containing S_0 is evidently a subcoalgebra, and it is irreducible because, for every $m \neq m_0$, one has, by 0.2.D:

```
```text
... m + n_i C_{i1} = n_i (m + C_{i1}) = A.
```

One says that  $\Sigma_0$  is the *irreducible component* of  $C$  corresponding to  $C_0$ .

Moreover, one says that  $C$  is *pointed* if every simple  $k$ -subcoalgebra of  $C$  is one-dimensional; this is equivalent to saying that for every maximal open ideal  $m$  of  $A$ , one has  $A/m = k$ . Recall also that  $C$  is said to be *connected* if it is irreducible and pointed. (Let us note in passing that if  $C$  is a bialgebra, it is connected if and only if it is irreducible, since  $k \subset C$  is a simple subcoalgebra.)

Suppose henceforth that  $C$  is cocommutative. Then  $A$  is commutative and is therefore the product of its local components  $A_m$ , for  $m \in \text{Upsilon}(A)$  (cf. 0.1.1); denote by  $S_m$  the simple subcoalgebra  $m^\perp \simeq (A/m)^*$  and by  $\Sigma_m$  its irreducible component. One may describe  $\Sigma_m$  as follows. Denote by  $J_m$  the kernel of the projection  $A \rightarrow A_m$ ; it is contained in  $m$  and is the smallest closed ideal  $I$  of  $m$  such that  $I + m' = A$  for every  $m' \neq m$ . Indeed, if  $I$  has this property, then  $I$  contains  $A_{m'}$  for every  $m' \neq m$ , so contains  $J_m$ . Since  $A = J_m \oplus A_m$ , it follows that  $\Sigma_m = J_m^\perp$  is identified with  $A_{m^\dagger}$ . One can now prove the:

**Proposition 2.9.1.** Let  $k$  be a field.

(i) Let  $G$  be a  $k$ -formal group such that all the residue fields of  $G$  equal  $k$ . Then  $G_e$  is the constant  $k$ -group  $M_k$ , where  $M = G(k) = \{x \in H(G) \mid \varepsilon(x) = 1 \text{ and } \Delta(x) = x \otimes x\}$ , and  $H(G)$  is the semi-direct product of  $H(G_e)$  by  $kM$  (cf. 2.4.B).

(ii) Equivalently: let  $H$  be a cocommutative pointed  $k$ -Hopf algebra. Then  $H$  is the semi-direct product of the irreducible component  $H_0$  of the unit element  $1_H$  by  $kM$ , where  $M = \{x \in H \mid \varepsilon(x) = 1 \text{ and } \Delta(x) = x \otimes x\}$ .

<!-- label: III.VII\_B.2.9.1 -->

Let us prove (i). Since all the residue fields of  $G$  equal  $k$ , the projection  $\pi : G \rightarrow G_e$  admits the section  $s : G_e \rightarrow G$  defined by  $0_{G,g} \rightarrow \kappa(g) = k$ , for every  $g \in G$ ; moreover, for every  $g, h \in G$ ,  $0_{G,g} \square_k 0_{G,h}$  is local with residue field  $k$ , and one therefore obtains that  $s \times s$  is a section of the

projection  $\pi : G \rightarrow (G \times G)_e = G_e \times G_e$ . Since  $\pi$  is a group morphism, it follows that  $\pi \circ m_G \circ (s \times s) = m_{G_e} = \pi \circ s \circ \pi \circ m_{G_e}$ , and since  $\pi$  is an epimorphism this entails that  $s$  is a group morphism. One obtains therefore that  $G = G^0 \rtimes G_e$ , and hence  $H(G)$  is the semi-direct product of  $H(G^0)$  by  $H(G_e)$ . Moreover, since all the residue fields of  $G$  equal  $k$ , then  $H(G_e)$  is the group algebra  $kM$ , where  $M = G_e(k)$  (cf. 2.5.A). Finally, since  $G^0$  is infinitesimal, the morphism  $G(k) \rightarrow G_e(k)$  is injective; it is therefore bijective (since it admits a section), so  $M = G(k)$ . Point (i) follows.

To prove (ii), it remains only to see that  $H_0$  equals  $H(G^0)$ . Now the unit element  $1_H$  of  $H$  is none other than the augmentation  $\epsilon : A \rightarrow k$ , which is the unit section of  $G(k)$ , so the local component of  $\mathcal{H}(G)$  corresponding to  $H_0$  is none other than  $\mathcal{H}(G^0)$  and therefore, by what was seen above, one has  $H_0 = \Gamma(G^0)^\dagger = H(G^0)$ . This proves the proposition.

**Remarks 2.9.2.** (a) The proposition above, contained implicitly in 2.5.2, has been obtained independently by B. Kostant (cf. [Sw69], Preface). Combined with Cartier's Theorem 3.3 below (cf. [Ca62], § 12, Th. 3), also obtained by Kostant (cf. [Sw69], loc. cit.), this result is often called the "Cartier–Gabriel–Kostant theorem".

(b) In the form (ii), 2.9.1 has been extended by R. G. Heyneman and M. E. Sweedler to the case where one assumes that  $H$  is pointed and a direct sum of its irreducible components (but not necessarily cocommutative), cf. [HS69], Th. 3.5.8.

<!-- label: III.VII\_B.2.9.2 -->

## 3. Phenomena specific to characteristic 0

<!-- label: III.VII\_B.3 -->

<!-- original page 531 -->

Throughout Section 3, we assume that the pseudocompact ring  $k$  contains the field of rational numbers  $\mathbb{Q}$ .

### 3.1. Lemma.

<!-- label: III.VII\_B.3.1 -->

**Lemma 3.1.** Let  $C$  be a commutative unital  $\mathbb{Q}$ -algebra,  $L$  a Lie algebra over  $C$  whose underlying  $C$ -module is free. Then the canonical map  $L \rightarrow U(L)$  is an isomorphism of  $L$  onto the set of primitive elements of  $U(L)$ .

<!-- label: III.VII\_B.3.1.lem -->

Indeed, let us identify  $L$  with its canonical image in  $U(L)$ ; let  $I$  be a totally ordered set and  $(x_i)_{i \in I}$  a basis of  $L$  indexed by  $I$ ; let us denote by  $\mathbb{N}^{(I)}$  the set of <!-- original page 569 --> families  $n = (n_i)_{i \in I}$  of natural integers such that  $n_i$  is zero except perhaps for a finite number of indices  $i_1 < i_2 < \dots < i_s$  (these indices depend on  $n$ ); set finally

$$x^n = x_{i_1}^{n_{i_1}} x_{i_2}^{n_{i_2}} \cdots x_{i_s}^{n_{i_s}} \quad \text{and} \quad n! = (n_{i_1}!)(n_{i_2}!) \cdots (n_{i_s}!).$$

One knows then that the  $x^n$  form a basis of  $U(L)$  (Poincaré–Birkhoff–Witt theorem) and one sees easily that one has

$$(*) \quad \Delta_{U(L)}(x^n) = \sum_{m \leq n} \frac{x^m}{m!} \otimes \frac{x^{n-m}}{(n-m)!},$$

the sum being extended over all elements  $m$  of  $\mathbb{N}^{(I)}$  such that  $0 \leq m \leq n$  (i.e., such that  $0 \leq m_i \leq n_i$  for every  $i$ ). It evidently follows that one has  $\Delta_{U(L)}(u) = u \otimes 1 + 1 \otimes u$  if and only if  $u$  is a linear combination of the  $x_i$ .

### 3.2.

<!-- label: III.VII\_B.3.2 -->

Suppose now  $\mathcal{C}$  artinian, of radical  $\mathfrak{r}$ . For every  $\mathcal{C}$ -algebra  $\mathcal{U}$  (original page 532 --> (associative, unital), the ideal  $\mathfrak{r}\mathcal{U}$  therefore consists of nilpotent elements; if  $x$  belongs to  $\mathfrak{r}\mathcal{U}$ , we shall set

$$\exp_{\mathcal{U}} x = 1 + x + \frac{x^2}{2!} + \dots$$

[^N.D.E-VII\_B-119]

One thus obtains a bijection of  $\mathfrak{r}\mathcal{U}$  onto  $1 + \mathfrak{r}\mathcal{U}$ ; the inverse bijection sends an element  $1 + y$  of  $1 + \mathfrak{r}\mathcal{U}$  to

$$\log_{\mathcal{U}}(1 + y) = y - \frac{y^2}{2} + \frac{y^3}{3} - \dots$$

Moreover, it is clear that the map  $\exp_{\mathcal{U}}$  is functorial in  $\mathcal{U}$ .[^N.D.E-VII\_B-120]

The ring  $\mathcal{C}$  still being artinian, suppose  $\mathcal{U}$  endowed with a structure of bialgebra over  $\mathcal{C}$  (cf. 2.2). For every primitive element  $x$  of  $\mathfrak{r}\mathcal{U}$  (cf. VII\_A 3.2.3), one has then

$$\begin{aligned} \Delta_{\mathcal{U}}(\exp_{\mathcal{U}} x) &= \exp_{\mathcal{U} \otimes \mathcal{U}}(\Delta_{\mathcal{U}}(x)) \\ &= \exp_{\mathcal{U} \otimes \mathcal{U}}(x \otimes 1 + 1 \otimes x) \\ &= \exp_{\mathcal{U} \otimes \mathcal{U}}(x \otimes 1) \cdot \exp_{\mathcal{U} \otimes \mathcal{U}}(1 \otimes x) \\ &= ((\exp_{\mathcal{U}} x) \otimes 1) \cdot (1 \otimes (\exp_{\mathcal{U}} x)) \\ &= (\exp_{\mathcal{U}} x) \otimes (\exp_{\mathcal{U}} x). \end{aligned}$$

One thus sees that the bijection  $\exp_{\mathcal{U}}$  transforms a primitive element of  $\mathfrak{r}\mathcal{U}$  into an element  $z$  of  $1 + \mathfrak{r}\mathcal{U}$  such that  $\Delta_{\mathcal{U}}(z) = z \otimes z$ . Conversely, if  $z$  satisfies these conditions then, setting  $x = \log_{\mathcal{U}}(z)$ , the preceding computation shows that  $\exp_{\mathcal{U} \otimes \mathcal{U}}(x \otimes 1 + 1 \otimes x)$  equals  $z \otimes z = \Delta_{\mathcal{U}}(\exp_{\mathcal{U}} x) = \exp_{\mathcal{U} \otimes \mathcal{U}}(\Delta_{\mathcal{U}}(x))$ , whence  $x \otimes 1 + 1 \otimes x = \Delta_{\mathcal{U}}(x)$ .[^N.D.E-VII\_B-121] Let us moreover note that if  $z \in 1 + \mathfrak{r}\mathcal{U}$  satisfies  $\Delta_{\mathcal{U}}(z) = z \otimes z$ , then  $\epsilon_{\mathcal{U}}(z)^2 = \epsilon_{\mathcal{U}}(z)$ , and since  $\epsilon_{\mathcal{U}}(z)$  is invertible (since  $z$  is,  $\mathfrak{r}$  being nilpotent), it follows that  $\epsilon_{\mathcal{U}}(z) = 1$ .

Consider in particular a Lie algebra  $\mathcal{L}$  flat over  $\mathcal{C}$ , take for  $\mathcal{U}$  the enveloping algebra  $U(\mathcal{L})$  of  $\mathcal{L}$  over  $\mathcal{C}$ , and identify  $\mathcal{L}$  with its canonical image in  $\mathcal{U}$ . By Lemma 3.1,  $\mathcal{L}$  is therefore the set of primitive elements of  $\mathcal{U}$  (indeed  $\mathcal{L}$  is a product of free modules over the local components of  $\mathcal{C}$ ). Consider then (original page 533 --> the  $\mathcal{C}$ -formal group  $\mathcal{G}(\mathcal{L}) = \mathrm{Spf}^* U(\mathcal{L})$ , which has  $\mathcal{U} = U(\mathcal{L})$  as covariant bialgebra (cf. 2.6.2). Let  $\mathfrak{m}$  be a maximal ideal of  $\mathcal{C}$  and  $\bar{\mathcal{C}} = \mathcal{C}/\mathfrak{m}$ . Since  $\mathcal{G}(\mathcal{L})$  is infinitesimal (loc. cit.), the unit element of  $\bar{\mathcal{U}} = U \otimes_{\mathcal{C}} \bar{\mathcal{C}}$  is the only element  $z$  of  $\bar{\mathcal{U}}$  such that[^N.D.E-VII\_B-122]  $\epsilon_{\bar{\mathcal{U}}}(z) = 1$  and  $\Delta_{\bar{\mathcal{U}}}(z) = z \otimes z$ . It follows that the elements  $z$  of  $\mathcal{U}$  such that  $\epsilon_{\mathcal{U}}(z) = 1$  and  $\Delta_{\mathcal{U}}(z) = z \otimes z$  necessarily belong to  $1 + \mathfrak{r}\mathcal{U}$ .

Finally, since  $\mathcal{L} \cap \mathfrak{r}\mathcal{U}$  is identified with  $\mathfrak{r}\mathcal{L} = \mathcal{L} \otimes_{\mathcal{C}} \mathfrak{r}$ , one sees finally that:  $\exp_{\mathcal{U}}$  defines a bijection of  $\mathcal{L} \otimes_{\mathcal{C}} \mathfrak{r}$  onto the group  $\mathcal{G}(\mathcal{L})(\bar{\mathcal{C}})$ . We summarize:

**Proposition 3.2.** \*Let  $\mathcal{K}$  be a pseudocompact ring containing  $\mathbb{Q}$  and  $\mathcal{L}$  a flat  $\mathcal{O}_{\mathcal{K}}$ -Lie algebra.\*

(i) For every object  $\mathcal{C}$  of  $\mathcal{A}\mathrm{lf}_{/\mathcal{K}}$ , denote by  $\mathfrak{r}(\mathcal{C})$  its radical; then the map\*

$$\exp_{\mathcal{U}(\mathcal{L}(\mathcal{C}))} : \mathcal{L}(\mathcal{C}) \otimes_{\mathcal{C}} \mathfrak{r}(\mathcal{C}) \rightarrow \mathcal{G}(\mathcal{L})(\mathcal{C})$$

\*is bijective and functorial in  $\mathcal{C}$  and  $\mathcal{L}$ .\*

(ii) The natural morphism  $\mathcal{L} \rightarrow \mathrm{Lie}(\mathcal{G}(\mathcal{L}))$  (cf. 2.6.2) is an isomorphism of  $\mathcal{O}_{\mathcal{K}}$ -Lie algebras.[^N.D.E-VII\_B-123]

### 3.3.

<!-- label: III.VII\_B.3.3 -->

If  $G$  is a  $k$ -formal group of affine algebra  $A$ , recall that one denotes by  $I_A$  the augmentation ideal of  $A$  and by  $\omega_{G/k}$  the pseudocompact  $k$ -module  $I_A / I_A^2 \approx I_A \square_A k$ .

**Theorem 3.3 (Cartier).** *Let  $k$  be a pseudocompact ring [N.D.E-VII\_B-125] containing  $\mathbb{Q}$  and  $G$  a  $k$ -formal group. The following assertions are equivalent:*

(i) There exists a flat  $\mathbb{Q}_k$ -Lie algebra  $L$  such that  $G$  is isomorphic to  $\mathcal{G}(L)$  (and in this case  $L = \text{Lie}(G)$  by 3.2).\*

(ii) There exists a projective pseudocompact  $k$ -module  $\omega$  such that the formal variety underlying  $G$  is isomorphic to the formal variety  $V^{\{f,0\}}_k(\omega)$  (cf. 1.2.5) of affine algebra  $k[[\omega]]$  (and in this case  $\omega \simeq \omega_{G/k}$ ).

(iii)  $G$  is infinitesimal and  $\omega_{G/k}$  is a projective pseudocompact  $k$ -module.\*

(iv)  $G$  is infinitesimal and topologically flat over  $k$ .\*

<!-- label: III.VII\_B.3.3.thm -->

(i)  $\Rightarrow$  (ii):\* Let  $\omega = \Gamma^*(L)$  be the pseudocompact  $k$ -module dual to  $L$  (cf. 1.2.3.D). For every object  $C$  of  $\mathcal{A}^{\{f,0\}}_k$ , we must exhibit an isomorphism from  $V^{\{f,0\}}_k(\omega)(C)$  onto  $\mathcal{G}(L)(C)$  which is functorial in  $C$ . By 1.2.5,  $V^{\{f,0\}}_k(\omega)(C)$  is identified with the set  $\text{Hom}_c(\omega, r(C))$  of continuous  $k$ -linear maps from  $\omega$  into the radical of  $C$ . This set is naturally isomorphic to the set  $\text{Hom}_c(\omega \square_k C, r(C))$  of continuous  $k$ -linear maps from  $\omega \square_k C$  into  $r(C)$ ; finally, since  $\omega \square_k C$  is a projective pseudocompact  $k$ -module, the canonical map

text  
 $(\omega \square_k C) \dagger \otimes_C r(C) \rightarrow \text{Hom}_c(\omega \square_k C, r(C))$

is bijective (cf. 0.3.6.A). Since, by 1.2.3.E,  $L(C)$  is identified with  $V_k(\Gamma^*(L))(C) = (\omega \square_k C) \dagger$ , one obtains that  $V^{\{f,0\}}_k(\omega)(C)$  is canonically isomorphic to  $L(C) \otimes_C r(C)$ , which is canonically isomorphic to  $\mathcal{G}(L)(C)$  by Proposition 3.2. This proves  $\leftarrow$  original page 536  $\rightarrow$  implication (i)  $\Rightarrow$  (ii).

(ii)  $\Rightarrow$  (iii):\* Let  $\omega$  be a projective object of  $\mathcal{P}\mathcal{C}(k)$  and  $h$  an isomorphism from  $k[[\omega]]$  onto the affine algebra  $A$  of  $G$ . Composing  $h$  with the augmentation  $\epsilon_A : A \rightarrow k$ , one obtains a homomorphism  $\epsilon_A \circ h : k[[\omega]] \rightarrow k$ , which is determined by its restriction  $\lambda$  to  $\omega$ ; the latter sends  $\omega$  into the radical of  $k$ . Therefore, the map  $x \mapsto x - \lambda(x)$ , from  $\omega$  into the radical of  $k[[\omega]]$ , extends by the universal property of  $k[[\omega]]$  (cf. 1.2.5) to an endomorphism  $\ell_\lambda$  of  $k[[\omega]]$ . The equalities  $\ell_\lambda \circ \lambda \circ h = \lambda \circ h$  show that  $\ell_\lambda$  is an automorphism of  $k[[\omega]]$ . Consequently,  $h \circ \ell_\lambda$  is, like  $h$ , an isomorphism from  $k[[\omega]]$  onto  $A$ , and moreover  $\epsilon_A \circ h \circ \ell_\lambda$  sends  $\omega$  to  $0$ . Replacing  $h$  by  $h \circ \ell_\lambda$  if necessary, one may therefore suppose that  $\epsilon_A \circ h$  vanishes on the closed ideal  $I$  of  $k[[\omega]]$  generated by  $\omega$ . In this case,  $h$  induces an isomorphism from  $I/I^2$  onto  $I_A/I_A^2$ ; since  $I/I^2 \simeq \omega$ , it follows that  $\omega_{G/k} = I_A/I_A^2$  is isomorphic to  $\omega$ , hence projective. It is clear on the other hand that  $V^{\{f,0\}}_k(\omega)$  is infinitesimal, as is  $G$ .

(iii)  $\Rightarrow$  (i):\* Suppose that  $G$  is infinitesimal and that  $\omega_{G/k}$  is projective. Let  $L$  be the  $\mathbb{Q}_k$ -Lie

algebra of  $\mathcal{G}$ ; the underlying  $\mathcal{O}_k$ -module is  $V_{\mathcal{G}}(\omega_{\mathcal{G}/k})$ , by 2.6.1. Consequently,  $\mathcal{L}$  is flat over  $\mathcal{O}_k$ , and  $\Gamma(L) \simeq \omega_{\mathcal{G}/k}$ , by Proposition 1.2.3.E. Hence, by the proof of (i)  $\Rightarrow$  (ii), the affine algebra of the  $\mathcal{G}$ -formal group  $\mathcal{M}_{\mathcal{G}}(L)$  is identified with  $k[[\omega_{\mathcal{G}/k}]]$ . On the other hand, by 2.6.3, the identity morphism of  $\mathcal{L}$  is canonically associated with a morphism of formal groups  $\mathcal{M}_{\mathcal{G}}(L) \rightarrow \mathcal{G}$ , hence with a continuous morphism of  $\mathcal{G}$ -algebras

```
```text
... \varphi : A \rightarrow k[[\omega_{\mathcal{G}/k}]].
```

Let $\mathcal{I}$ be the closed ideal of $k[[\omega_{\mathcal{G}/k}]]$ generated by $\omega_{\mathcal{G}/k}$; let us filter $k[[\omega_{\mathcal{G}/k}]]$ (resp. $\mathcal{A}$) by the closures of the ideals $\mathcal{I}^n$ (resp. $\mathcal{I}^n_{\mathcal{A}}$). We have to show that φ , which by definition induces the identity on $\omega_{\mathcal{G}/k} = \mathcal{I}_{\mathcal{A}}/\mathcal{I}^2_{\mathcal{A}} = \mathcal{I}/\mathcal{I}^2$, is an isomorphism.

<!-- original page 537 -->

Since $\omega_{\mathcal{G}/k}$ is a projective object of $\text{PC}(k)$, there exists a section τ of the canonical projection $\mathcal{I}_{\mathcal{A}} \rightarrow \omega_{\mathcal{G}/k}$. By the universal property of $k[[\omega_{\mathcal{G}/k}]]$ (cf. 1.2.5), τ defines a continuous morphism of algebras

```
```text
... \psi : k[[\omega_{\mathcal{G}/k}]] \rightarrow \mathcal{A}
```

and  $\varphi \circ \psi$  induces the identity map on  $\omega_{\mathcal{G}/k}$ , hence also on the associated graded of  $k[[\omega_{\mathcal{G}/k}]]$ . It follows that  $\varphi \circ \psi$  is an isomorphism, by [CA], § V.7, Lemma 1. [N.D.E-VII\_B-126]

Moreover,  $\psi$  induces an isomorphism from  $\mathcal{I}/\mathcal{I}^2$  onto  $\mathcal{I}_{\mathcal{A}}/\mathcal{I}^2_{\mathcal{A}}$ , hence a surjection of the associated gradings of  $k[[\omega_{\mathcal{G}/k}]]$  and  $\mathcal{A}$ . On the other hand, since  $\mathcal{G}$  is radicial,  $\mathcal{I}_{\mathcal{A}}$  is contained in the radical of  $\mathcal{A}$ , so that the intersection of the  $\mathcal{I}^n_{\mathcal{A}}$  is zero. Therefore, by loc. cit.,  $\psi$  is surjective. Then, since  $\varphi \circ \psi$  is an isomorphism and  $\psi$  a surjection,  $\psi$  and  $\varphi$  are isomorphisms. This proves (iii)  $\Rightarrow$  (i).

Let us note finally that it is clear that (i) or (ii) entail (iv), so that it remains to prove the implication (iv)  $\Rightarrow$  (ii). For this, one may suppose  $k$  local, with residue field  $k_0$ . Set then  $\mathcal{G}_0 = \mathcal{G} \square_k k_0$ ,  $\omega_{\mathcal{G}} = \omega_{\mathcal{G}/k}$ ,  $\omega_0 = \omega \square_k k_0$ , etc. [N.D.E-VII\_B-127] Since  $k_0$  is a field, the pseudocompact  $k_0$ -module  $\omega_{\mathcal{G}_0}$  has a pseudobasis  $(y_{\lambda})_{\lambda \in \Lambda}$ ; denoting  $\omega_{\mathcal{G}}$  the topologically free  $k$ -module product of copies  $k_{\lambda}$  of  $k$ , for  $\lambda \in \Lambda$ , and lifting each  $y_{\lambda}$  to an element  $x_{\lambda}$  of  $\omega_{\mathcal{G}}$ , one obtains a continuous  $k$ -linear map  $f : \omega_{\mathcal{G}} \rightarrow \omega_{\mathcal{G}_0}$  such that  $f_0 = f \square_k k_0$  is invertible. [N.D.E-VII\_B-128] Since  $\omega_{\mathcal{G}}$  is a projective pseudocompact  $k$ -module,  $f$  lifts to a continuous  $k$ -linear map  $g : \omega_{\mathcal{G}} \rightarrow \mathcal{I}_{\mathcal{A}}$  such that  $\varphi \circ g = f$ , where  $\varphi$  is the projection  $\mathcal{I}_{\mathcal{A}} \rightarrow \omega_{\mathcal{G}}$ . By the universal property of  $k[[\omega_{\mathcal{G}}]]$  (cf. 1.2.5),  $g$  induces a morphism of topological algebras  $\varphi : k[[\omega_{\mathcal{G}}]] \rightarrow \mathcal{A}$ .

<!-- original page 538 -->

Now  $\omega \square_k k_0$  is identified with  $\omega \square_k k_0 = \omega_{\mathcal{G}_0/k_0}$  and hence  $k[[\omega]] \square_k k_0$  is identified with  $k_0[[\omega_{\mathcal{G}_0/k_0}]]$ . Since hypotheses (iii) are satisfied for  $k_0$  and  $\mathcal{G}_0$ , the proof of (iii)  $\Rightarrow$  (i) shows that  $\varphi_0 = \varphi \square_k k_0$  is invertible. Since, on the other hand,  $k[[\omega_{\mathcal{G}}]]$  and  $\mathcal{A}$  are projective pseudocompact  $k$ -modules,  $\varphi$  is invertible by 0.3.4. (In particular, denoting  $\mathcal{I}$  the augmentation ideal of  $k[[\omega_{\mathcal{G}}]]$ ,  $\varphi$  induces an isomorphism from  $\omega_{\mathcal{G}} = \mathcal{I}/\mathcal{I}^2$  onto  $\mathcal{I}_{\mathcal{A}}/\mathcal{I}^2_{\mathcal{A}} = \omega_{\mathcal{G}}$ .)

### 3.3.1.

<!-- label: III.VII\_B.3.3.1 -->

**\*Corollary 3.3.1.\*** \*Let  $S$  be a locally noetherian scheme over  $\mathbb{Q}$  and  $\mathcal{G}$  an  $S$ -group scheme that is flat and locally of finite type. [N.D.E-VII\_B-C-11] If  $\omega_{\mathcal{G}/S}$  is a locally free  $\mathcal{O}_S$ -module,  $\mathcal{G}$  is smooth over  $S$  at every point of the unit section.\*

<!-- label: III.VII\_B.3.3.1 -->

Indeed, let  $x$  be a point of the unit section,  $s$  its image in  $S$ ,  $\mathcal{O}_x$  and  $\mathcal{O}_s$  the local algebras of  $x$  and  $s$ . [N.D.E-VII\_B-C-12] Since, by hypothesis,  $\mathcal{O}_s$  and  $\mathcal{O}_x$  are noetherian local rings, the  $m$ -adic topology on each of these rings coincides with the "pseudocompact" topology defined by the ideals of finite codimension.

Denote then by  $\hat{O}_x$  and  $\hat{O}_S$  the completions for this topology. By (EGA IV<sub>4</sub>, 17.5.3),  $\mathcal{G}$  is smooth over  $S$  at the point  $x$  if and only if  $\hat{O}_x$  is formally smooth over  $\hat{O}_S$ ; these two algebras being endowed with the  $\mathfrak{m}$ -adic topology; it therefore suffices to show this latter property. Now  $\hat{O}_x$  and  $\hat{O}_S$  are the local rings of  $x$  and  $S$  in the formal varieties  $\hat{G}/\hat{S}$  and  $\hat{S}$  defined in 1.2.6. Set  $k = \hat{O}_S$  and  $H = \mathrm{Spf}(\hat{O}_x)$ ; then  $H$  is a  $k$ -formal variety that is infinitesimal and, since the formation of  $\hat{G}/\hat{S}$  commutes with products (loc. cit.),  $H$  is an infinitesimal  $k$ -formal group. Denote by  $I$  the augmentation ideal of  $\hat{O}_x$ . By hypothesis,  $\omega_{G/S, x} = I/I^2$  is a locally free  $\hat{O}_x$ -module of finite rank  $n$ . Since  $\hat{O}_x$  is noetherian, it follows that  $\omega_{H/k}$ , which is the completion of  $\omega_{G/S, x}$ , is identified with  $\omega_{G/S} \otimes_{\hat{O}_S} \hat{O}_x$ , hence is a topologically free  $k$ -module of rank  $n$ . Hence, by the implication (iv)  $\Rightarrow$  (ii) of 3.3,  $\hat{O}_x$  is isomorphic to  $k[[\omega_{H/k}]]$ , i.e., to a formal power series algebra  $k[[t_1, \dots, t_n]]$ . Finally, this last is formally smooth over  $k$ , by (EGA 0-IV, 19.3.3). This proves the corollary.

We thus recover a result obtained otherwise for group schemes locally of finite presentation over an arbitrary scheme  $S$ , cf. VI<sub>B</sub>, 1.6.

### 3.3.2.

<!-- label: III.VII\_B.3.3.2 -->

<!-- original page 574 -->

**Corollary 3.3.2.** Let  $k$  be a field of characteristic 0. The functor  $L \mapsto G^*(L)$  is an equivalence from the category of  $k$ -Lie algebras onto that of infinitesimal  $k$ -formal groups. [N.D.E-VII\_B-C-13]

<!-- label: III.VII\_B.3.3.2 -->

<!-- original page 574, marginal 539 -->

Indeed, when  $\mathcal{G}$  runs through the infinitesimal  $k$ -formal groups, the functor  $G \mapsto G^*(\mathrm{Lie} G)$  is isomorphic, by Theorem 3.3, to the identity functor of the category of infinitesimal  $k$ -groups. Likewise, by 3.2 (ii), the functor  $L \mapsto \mathrm{Lie}(G^*(L)) = \mathrm{Prim}(U(L))$  is isomorphic to the identity functor of the category of  $k$ -Lie algebras.

### 3.3.3.

<!-- label: III.VII\_B.3.3.3 -->

Suppose still that  $k$  is a field of characteristic 0. Let  $\bar{k}$  be an algebraic closure of  $k$  and  $\Gamma$  the topological Galois group of  $\bar{k}$  over  $k$ .

For every  $k$ -formal group  $G$ , we denote by  $\mathrm{Aut}_k^*(G)$  the  $k$ -group functor that associates to every commutative  $k$ -algebra  $C$  of finite dimension the group of automorphisms of the  $C$ -formal group  $G \otimes_{\hat{O}_x} C$ . [N.D.E-VII\_B-C-14] Since  $G$  is topologically flat over  $k$  (since  $k$  is a field), i.e., its affine algebra  $A = A^*(G)$  is topologically flat over  $k$ , or, equivalently, its covariant bialgebra  $H = H^*(G)$  is flat over  $k$ , this  $k$ -functor is a  $k$ -formal group. Indeed, since  $\mathrm{Aut}_k^*(G)$  is identified with the fibered product of the following diagram (cf. Exp. I, 1.7.3):

$$\begin{array}{ccc} & & \mathrm{Aut}_k^*(G) \times \mathrm{Aut}_k^*(G) \\ & & \downarrow \\ \mathrm{Spf}(k) & \rightarrow & \mathrm{Aut}_k^*(G) \times \mathrm{Aut}_k^*(G) \end{array}$$

where the vertical (resp. horizontal) arrow is given by  $(\phi, \psi) \mapsto (\phi \circ \psi, \psi \circ \phi)$  (resp. is the unit section), it suffices to check that the  $k$ -functor  $\mathrm{Aut}_k^*(G)$  is represented by an element of  $V_{\mathrm{af}}/k$ , that is (cf. 1.1 and 0.4.2), that it is left exact, i.e., commutes with fibered products of  $k$ -algebras. Now to give an element of  $\mathrm{Aut}_k^*(G)$  is equivalent to giving, say, a morphism of  $k$ -algebras  $\phi : H \rightarrow H \otimes_k C$  that also respects the coalgebra structure, i.e., such that the well-known diagrams are commutative; since  $H$  is flat over  $k$ , the functor  $H \otimes_k -$  commutes with fibered products of  $k$ -algebras, and one deduces that the  $k$ -functor  $\mathrm{Aut}_k^*(G)$  is left exact, so we can treat it as a  $k$ -formal group.

<!-- original page 575 -->

If  $L$  is a  $k$ -Lie algebra and  $G$  the formal group  $G^*(L)$ , Theorem 3.3 shows that  $\mathrm{Aut}_k^*(G)$

is isomorphic to the  $k$ -group functor  $\text{Aut}_k(L)$  which associates to a finite-dimensional  $k$ -algebra  $C$  the group of automorphisms of the  $C$ -Lie algebra  $C \otimes_k L$ .

If  $G$  is an arbitrary  $k$ -formal group, we saw in 2.5.2 that  $G$  decomposes canonically into a semi-direct product of an étale formal group  $G_e$  and an infinitesimal formal group  $G^0$ . This semi-direct product is determined by the data of  $L = \text{Lie}(G) = \text{Lie}(G^0)$ , of the  $\Gamma$ -group  $M = G_e(\bar{k}) = G(\bar{k})$ , and of a morphism of  $k$ -formal groups

```

$$\phi : G_e \rightarrow \text{Aut}_k(G^0) \simeq \text{Aut}_k(L).$$

```

Such a morphism sends  $G_e$  into the "étale part"  $\text{Aut}_k(L)_e$  of  $\text{Aut}_k(L)$ , cf. 2.5.1. It is therefore determined by the data of a morphism of  $\Gamma$ -groups:

```

$$\phi = \phi(k^-) : M \rightarrow (\text{Aut}_k(L)(k^-) = \text{Aut}_k(k^-)(L \otimes_k k^-).$$

```

<!-- original page 575, marginal 540 -->

If we let  $\Gamma$  act on  $L \otimes_k \bar{k}$  by the formula  $\gamma(\ell \otimes t) = \ell \otimes \gamma(t)$ , then  $\phi$  makes  $M$  act on  $L \otimes_k \bar{k}$  by automorphisms of  $\bar{k}$ -Lie algebra in such a way that one has  $\phi(\gamma(m)) = \gamma(\phi(m))$ , i.e.:

```

$$\gamma(m)(\ell \otimes t) = \gamma(m(\ell \otimes \gamma^{-1}(t)))$$

```

for every  $m \in M$ ,  $\gamma \in \Gamma$  and  $\ell \otimes t \in L \otimes_k \bar{k}$ . We express this last condition by saying that  $M$  acts on  $L \otimes_k \bar{k}$  compatibly with  $\Gamma$ .

One can summarize the situation by means of a "highbrow" statement: let us call  $\Gamma$ -Lie algebra over  $k$  the data of a triple  $(L, M, \phi)$  formed by a  $k$ -Lie algebra  $L$ , a  $\Gamma$ -group  $M$ , and an action  $\phi$  of  $M$  on  $L \otimes_k \bar{k}$  that is "compatible with the action of  $\Gamma$  on  $M$  and on  $L \otimes_k \bar{k}$ ".

If  $(L, M, \phi)$  and  $(L', M', \phi')$  are two such  $\Gamma$ -Lie algebras, a morphism of the first into the second is a pair  $(f, \theta)$  formed by a morphism  $f : L \rightarrow L'$  of  $k$ -Lie algebras and a morphism  $\theta : M \rightarrow M'$  of  $\Gamma$ -groups such that

```

$$(f \otimes 1)(m \cdot x) = \theta(m) \cdot (f \otimes 1)(x)$$

```

for every  $x \in L \otimes_k \bar{k}$  and  $m \in M$ . One then obtains:

**Theorem.** Let  $k$  be a field of characteristic 0. Then the functor that associates to  $G$  the triple  $(\text{Lie}(G), G(\bar{k}), \Phi(\bar{k}))$  is an equivalence of the category of  $k$ -formal groups onto that of  $\Gamma$ -Lie algebras. [N.D.E-VII\_B-C-15]

## 4. Phenomena specific to characteristic  $p > 0$

<!-- label: III.VII\_B.4 -->

<!-- original page 575, marginal 541 -->

Throughout Section 4, we denote by  $p$  a prime number, by  $k$  a pseudocompact ring of characteristic  $p$ , and by  $\pi$  the continuous endomorphism  $x \mapsto x^p$  of  $k$ .

### 4.1.

<!-- label: III.VII\_B.4.1 -->

<!-- original page 576 -->

Let  $X$  be a  $k$ -formal variety with affine algebra  $A$ ; one denotes by  $X^{(p/k)}$  or  $X^{(p)}$  the  $k$ -formal variety  $X \hat{\otimes}_{\pi} k$  obtained by the base change  $\pi : k \rightarrow k$  (cf. 1.2.D); it has as affine algebra the completed tensor product  $A \hat{\otimes}_{\pi} k$ . Then, the continuous morphism  $A \hat{\otimes}_{\pi} k \rightarrow A$  which sends  $a \hat{\otimes}_{\pi} \lambda$  onto  $a^p \lambda$  induces a morphism of  $k$ -formal varieties

$$\mathrm{Fr}(X/k) : X \rightarrow X^{(p/k)}.$$

In what follows, we shall say that  $\mathrm{Fr}(X/k)$  is the \*Frobenius morphism of  $X$  relative to  $k$  and we shall often write 'Fr' instead of  $\mathrm{Fr}(X/k)$ .

### 4.1.1.

<!-- label: III.VII\_B.4.1.1 -->

[^N.D.E-VII\_B-C-16] Consider now a scheme  $S$  over the prime field  $\mathbb{F}_p$  and an  $S$ -scheme  $\eta : X \rightarrow S$ ; let  $\mathrm{fr}(S)$  be the "absolute" Frobenius morphism of  $S$  (it induces the identity on the underlying topological space and sends every section  $f$  of the structure sheaf onto  $f^p$ ; cf. VII\_A 4.1) and let  $X^{(p)}$  be the  $S$ -scheme  $X \times_{\mathrm{fr}(S)} S$  (VII\_A, loc. cit.), i.e., the structure morphism  $X^{(p)} \rightarrow S$  is  $\mathrm{fr}(S) \circ \eta$ .

Let  $\hat{S}$  be the formal scheme whose underlying topological space is the set of closed points of  $S$ , endowed with the discrete topology, the local ring  $\hat{S}_s$  at such a closed point  $s$  being the separated completion  $\hat{S}_s$  of  $S_s$  for the linear topology defined by the ideals of finite colength (cf. 1.2.6); its affine algebra  $k = \hat{A}$  is therefore the product of the  $\hat{S}_s$ , as  $s$  runs through the closed points of  $S$ . Recall (loc. cit.) that one denotes by  $\hat{X}/\hat{S}$  the  $k$ -formal variety formed by the points  $x \in X$  such that  $[\kappa(x) : \kappa(s)] < \infty$ , where  $\kappa(s)$  is the image of  $s$  in  $S$ , the local ring  $\hat{S}_s$  being the separated completion  $\hat{S}_s$  of  $S_s$  for the linear topology defined by the ideals  $I$  such that  $S_x/I$  is of finite length as  $S_x$ -module (and therefore also as  $S_s$ -module). One can therefore form, by base change, the  $k$ -formal variety  $(\hat{X}/\hat{S})^{(p)} = (\hat{X}/\hat{S}) \hat{\otimes}_{\pi} k$ .

One can also consider the  $k$ -formal variety  $\hat{X}^{(p)}/\hat{S}$ : the underlying set is formed by the  $x \in X^{(p)}$  such that, denoting by  $\kappa(s)$  the image of  $s$  in  $S$ , the morphism

$$\kappa(s) \rightarrow \kappa(s) \rightarrow \kappa(s)$$

makes  $\kappa(x)$  an extension of finite degree of  $\kappa(s)$ ; in this case, the same holds for  $\eta^{\sharp} : \kappa(s) \rightarrow \kappa(x)$ , i.e.,  $x$  is a point of  $\hat{X}/\hat{S}$ , and one then has

$$\hat{X}^{(p)}/\hat{S}_s = \hat{X}_s \otimes_{\pi} \hat{S}_s = \hat{X}^{(p)}_s, x$$

<!-- original page 576, marginal 542 -->

(the second equality since  $X \mapsto \hat{X}/\hat{S}$  commutes with products, cf. 1.2.6). One therefore sees that:  $\hat{X}^{(p)}/\hat{S}$  is identified with a formal subvariety of  $(\hat{X}/\hat{S})^{(p)}$ . Moreover, equality holds if and only if for every closed point  $s$  of  $S$ ,  $\kappa(s)$  is of finite degree over  $\kappa(s)^p$ , which is the case for example if  $S$  is a scheme locally of finite type over a field  $k$  such that  $[\kappa : \kappa^p] < \infty$ .

### 4.1.2.

<!-- label: III.VII\_B.4.1.2 -->

<!-- original page 577 -->

Let  $G$  be a  $k$ -formal group. Since the functor  $X \mapsto X^{(p)} = X \hat{\otimes}_{\pi} k$  commutes with finite products, it transforms a  $k$ -formal group into a  $k$ -formal group. Moreover, since  $\mathrm{Fr}(X/k)$  is functorial in  $X$ , the morphism

$$\mathrm{Fr} : G \rightarrow G^{(p)}$$

is a homomorphism of  $k$ -formal groups. If one sets  $G^{\{p^{n+1}\}} = (G^{\{p^n\}})^{(p)}$ , the same holds for the composite morphism

```
```text
Fr^n = Fr^n(G/k) : G → G^{(p)} → G^{(p^2)} → ... → G^{(p^n)}.
```
```

Denote by  $A$  the affine algebra of  $G$  and by  $I_A$  its augmentation ideal.

**Definitions.** (a) The kernel of  $Fr^n$  will be denoted  $Fr_n G$ . It follows directly from the definitions that  $Fr_n G$  is infinitesimal and has as affine algebra the quotient  $A / I^{\{p^n\}}_A$ , where  $I^{\{p^n\}}_A$  denotes the closed ideal of  $A$  generated by the  $p^n$ -th powers of the elements of  $I_A$ .

(b) One says that  $G$  is of height  $\leq n$  if  $I^{\{p^n\}}_A = 0$ , that is to say if one has  $Fr_n G = G$ .

### 4.2.

<!-- label: III.VII\_B.4.2 -->

<!-- original page 577, marginal 543 -->

It is clear that the Lie algebra  $Lie(G)$  of a  $k$ -formal group  $G$  is a  $p$ -Lie subalgebra of the algebra  $H^*(G)$  (cf. 2.3). Indeed, one reduces immediately to the case where  $k$  is artinian; in this case,  $Lie(G)$  is the part of  $H^*(G)$  formed by the elements  $x$  such that  $\phi_G(x \otimes 1 + 1 \otimes x) = \Delta_G(x)$  with the notations of 2.3 and 2.6 (c). One then has

```
```text
φ_G(x^p ⊗ 1 + 1 ⊗ x^p) = φ_G((x ⊗ 1 + 1 ⊗ x)^p)
                        = (φ_G(x ⊗ 1 + 1 ⊗ x))^p = Δ_G(x)^p = Δ_G(x^p).
```
```

### 4.2.1.

<!-- label: III.VII\_B.4.2.1 -->

Conversely, every  $p$ -Lie algebra  $L$  over  $k$  defines a  $k$ -group functor. Denote indeed by  $U_p(L)$  the functor that associates to every object  $C$  of  $\mathcal{A}/k$  the restricted enveloping algebra  $U_p(L(C))$  of the  $p$ -Lie algebra  $L(C)$  over  $C$  (VII\_A 5.3). By VII\_A 5.4,  $U_p(L)$  is an  $k$ -bialgebra and therefore determines, by 2.2, a  $k$ -group functor  $Sp^*(U_p(L))$  that we shall henceforth denote  $G^*(L)$ .

Thus,  $G^*(L)(C)$  is the group of elements  $z \in U_p(L(C))$  of augmentation 1 and such that  $\Delta_{U_p(L(C))}(z) = z \otimes z$ .

### 4.2.2.

<!-- label: III.VII\_B.4.2.2 -->

Suppose  $L$  is a  $p$ -Lie algebra that is flat over  $k$ . Then, taking account of VII\_A 5.3.3, one shows as in point (i) of Proposition 2.6.2 that  $U_p(L)$  is flat over  $k$ ; hence  $G^*(L)$  is a topologically flat  $k$ -formal group which has  $U_p(L)$  as covariant  $k$ -bialgebra.

[^N.D.E-VII\_B-C-17] By the proof of 2.6.2 (iii), for every  $k$ -algebra  $C$  of finite length,  $Lie(G^*(L)(C))$  is the set of primitive elements of  $U_p(L)(C) = U_p(L(C))$  (see also VII\_A 3.2.3); moreover, by VII\_A 5.5.3, the canonical morphism  $L \rightarrow U_p(L)$  induces an isomorphism of  $p$ -Lie algebras

```
```text
τ_{p, L} : L → Lie(G^*_p(L))
```
```

(compare with 3.1 in characteristic 0).

The formal group  $G^*(L)$  can be characterized by a universal property. Indeed, every morphism  $h$  of  $G^*(L)$  into a formal group  $G$  induces a morphism  $Lie(h) : Lie(G^*_p(L)) \rightarrow Lie(G)$ . Composing this with the isomorphism  $\tau_{p, L}$ , one obtains a morphism  $h' : L \rightarrow Lie(G)$ .

<!-- original page 577, marginal 544 -->

**Proposition.** If  $k$  is a pseudocompact ring of characteristic  $p > 0$ ,  $G$  a  $k$ -formal group, and  $L$  a  $p$ -Lie algebra that is flat over  $k$ , the map  $h$  defined above is a bijection

$$\text{Hom}_{\text{Grf}/k}(G, G) \cong \text{Hom}_{\text{p-Lie}}(L, \text{Lie}(G))$$

where the right-hand term denotes the set of morphisms of  $p$ -Lie algebras from  $L$  into  $\text{Lie}(G)$ .

[^N.D.E-VII\_B-C-18] One reduces indeed immediately to the case where  $k$  is artinian. Set  $L = L(k)$ . By 2.3.1,  $\text{Hom}_{\text{Grf}/k}(G, G)$  is in bijection with the set of morphisms of unitary algebras  $h : U_p(L) \rightarrow H(G)$  such that the following diagram is commutative:

$$\begin{array}{ccccc} U_p(L) & \xrightarrow{h} & H(G) & \xrightarrow{\delta_G} & H(G \times G) \\ \downarrow & & & & \uparrow \\ \Delta_{U_p(L)} & & & & \phi_G \\ \downarrow & & & & \downarrow \\ U_p(L) \otimes U_p(L) & \xrightarrow{h \otimes h} & H(G) \otimes H(G) & & \end{array}$$

Now  $h$  is determined by its restriction to  $L$ , which is a morphism of  $p$ -Lie algebras from  $L$  into the  $p$ -Lie algebra underlying  $H(G)$ , and the commutativity of the diagram means that  $h$  sends  $L$  into the part of  $H(G)$  formed by the  $x$  such that  $\delta_G(x) = \phi_G(x \otimes 1 + 1 \otimes x)$ , which is none other than  $\text{Lie}(G)$ , cf. 2.6 (c).

### 4.3.

<!-- label: III.VII\_B.4.3 -->

We now propose to study in greater detail the  $k$ -formal group  $G_p(L)$  when  $L$  is a  $p$ -Lie algebra that is flat over  $k$ .

<!-- original page 577, marginal 545 -->

For this, we first consider a ring  $C$  of characteristic  $p$  and a  $p$ -Lie algebra  $L$  over  $C$  whose underlying module is free with basis  $\{x_i\}_{i \in I}$ . Denote moreover by  $P$  the set of families  $n = (n_i)_{i \in I}$  of natural integers such that  $0 \leq n_i < p$  and that the  $n_i$  are zero except possibly a finite number of them. If we endow  $P$  with a total order and if we call  $i_1, i_2, \dots, i_r$  ( $i_1 < i_2 < \dots < i_r$ ) the indices  $i$  such that  $n_i \neq 0$ , we can therefore set  $|n| = n_{i_1} + \dots + n_{i_r}$  and

$$x^n = x_{i_1}^{n_{i_1}} \cdot x_{i_2}^{n_{i_2}} \cdot \dots \cdot x_{i_r}^{n_{i_r}}, \quad n! = (n_{i_1}!) \cdot \dots \cdot (n_{i_r}!).$$

It is known that the monomials  $x^n/n!$  form a basis of  $U_p(L)$  (VII\_A 5.3.3) and it is clear that one has

$$(*) \quad \Delta(x^n/n!) = \sum_{m \leq n} (x^m/m!) \otimes (x^{n-m}/(n-m)!)$$

<!-- original page 578 -->

the sum being extended to all  $m \in P$  such that  $m \leq n$  (i.e.,  $m_i \leq n_i$  for all  $i \in I$ ).

Formula  $(*)$  allows an easy determination of the natural filtration of  $U_p(L)$  (cf. 1.3.6). Set  $U = U_p(L)$ , let  $U^+$  be the two-sided ideal generated by  $L$ , and let  $U_0 = C \cdot 1_U$ . As in 1.3.6, one defines a filtration of  $U$  (by  $C$ -subcoalgebras) by setting, for  $n \geq 1$ :

$$U_n = \{u \in U \mid \Delta_U(u) - u \otimes 1 \in U_{n-1} \otimes U^+\}.$$

Formula  $(\ast)$  then entails that  $U_n$  is the free  $C$ -module having as basis the monomials  $x^m$  such that  $|m| \leq n$ .

### 4.3.1.

<!-- label: III.VII\_B.4.3.1 -->

<!-- original page 578, marginal 546 -->

With the notations of 4.3, let us determine the elements  $\xi$  of  $U = U_p(L)$  such that  $\epsilon_U(\xi) = 1$  and  $\Delta_U(\xi) = \xi \otimes \xi$ . Every element  $\xi$  of  $U$  is written  $\xi = \sum_{n \in P} \xi_n (x^n/n!)$ , with  $\xi_n \in C$ . The condition  $\epsilon_U(\xi) = 1$  entails the equality  $\xi_0 = 1$ , where  $0$  denotes the element of  $P$  all of whose components are zero. The condition  $\Delta_{U_p(L)}(\xi) = \xi \otimes \xi$  entails:

$$\sum_{m+n=q} \xi_m (x^m/m!) \otimes \xi_n (x^n/n!) = \sum_{q \in P} \xi_q \xi_r (x^q/q!) \otimes (x^r/r!)$$

that is to say,

$$\xi_{q+r} = \xi_q \xi_r \quad \text{if } q_i + r_i < p, \quad \text{and} \quad \xi_q \xi_r = 0 \quad \text{otherwise.}$$

If one denotes by  $\xi_i$  the value of  $\xi_n$  when  $n_i = 1$  and  $n_j = 0$  for  $j \neq i$ , these conditions mean that one has

$$\xi_n = \prod_i \xi_i^{n_i} \quad \text{if } n \in P, \quad \text{and} \quad \xi_i^p = 0 \quad \forall i \in I.$$

One deduces from this:

**Proposition.** Let  $k$  be a local pseudocompact ring [N.D.E-VII\_B-C-19] of characteristic  $p > 0$ ,  $L$  a  $p$ -Lie algebra that is flat over  $k$ ,  $C$  an object of  $\text{Alg}/k$ , and  $\{^p\sqrt{0_C}\}$  the ideal of  $C$  formed by the elements  $x$  such that  $x^p = 0$ . There exists a bijection "functorial in  $C$ ":

$$L(C) \otimes_C {}^p\sqrt{0_C} \rightarrow {}^*G^*_p(L)(C).$$

<!-- label: III.VII\_B.4.3.1 -->

<!-- original page 578, marginal 547 -->

By Remark 1.2.3.F, one can indeed choose a basis  $\{x_i\}_{i \in I}$  of  $L(C)$  over  $C$  in such a way that, for every morphism  $\phi : C \rightarrow D$  of  $\text{Alg}/k$ ,  $L(\phi)$  sends  $\{x_i\}$  onto  $\{d_i\}$ . By what precedes, the map

$$\sum_i (\wedge x_i) \otimes \xi_i \mapsto \sum_{n \in P} (\prod_i \xi_i^{n_i}) \cdot ((\wedge x)^n / n!)$$

is a functorial bijection from  $L(C) \otimes_C \{^p\sqrt{0_C}\}$  onto  ${}^*G^*_p(L)(C)$ .

### 4.3.2.

<!-- label: III.VII\_B.4.3.2 -->

<!-- original page 579 -->

"There is no Campbell–Hausdorff formula in characteristic  $p > 0$ ". Let us explain ourselves: the functorial isomorphism of 4.3.1 depends on the choice of the bases  $\{x_i\}_{i \in I}$ . Unlike what happens in 3.2 (case of characteristic 0), there is no, in general, bijection from  $L(C) \otimes_C \{^p\sqrt{0_C}\}$  onto  ${}^*G^*_p(L)(C)$

that is "functorial both in  $C$  and in  $L$ ". The argument that follows shows for example that such an isomorphism does not exist when  $k$  is a field containing the  $(p^2 - 1)$ -th roots of unity.

Choose  $L$  indeed in such a way that, for every  $C \in \text{Alg}/k$ ,  $L(C)$  is the abelian  $p$ -Lie algebra over  $C$  generated by an element  $x$  subject to the relation  $x^{(p^2)} = 0$ . One has therefore

```

```text

$$L(C) = Cx \otimes Cx^{(p)}, \quad U_p(L(C)) \cong k[x]/(x^{(p^2)}).$$

```

```

We shall show that the only functorial morphism

```

```text

$$\chi_C : L(C) \otimes_C {}^pV_{0,C} \rightarrow U_p(L(C))$$

```

```

that is compatible with the endomorphisms of  $L$  and that sends  $L(C) \otimes {}^pV_{0,C} \rightarrow U_p(L(C))$  into  $G_p(L(C))$  is the constant morphism of value  $1$ .

<!-- original page 579, marginal 548 -->

Indeed, let  $\psi_C$  be the bijection from  $L(C) \otimes {}^pV_{0,C} \rightarrow U_p(L(C))$  onto  $G_p(L(C)) = \text{Prim}(U_p(L(C)))$  given by 4.3.1, i.e.,

```

```text

$$x \otimes a + x^{(p)} \otimes b \mapsto \sum_{0 \leq i, j < p} a^i b^j x^{(i+pj)}.$$

```

```

Composing  $\chi_C$  with  $\psi_C^{-1}$ , one obtains a functorial morphism (in  $C$ ):

```

```text

$$\theta_C : L(C) \otimes_C {}^pV_{0,C} \rightarrow L(C) \otimes_C {}^pV_{0,C}$$

$$x \otimes a + x^{(p)} \otimes b \mapsto x \otimes P(a, b) + x^{(p)} \otimes Q(a, b).$$

```

```

Functoriality in  $C$  implies that  $P(a, b)$  and  $Q(a, b)$  are the values at  $(a, b)$  of two polynomials  $P, Q \in k[X, Y]$  that one can assume of degree  $< p$  in  $X$  as well as in  $Y$ . [N.D.E-VII\_B-C-20] Let  $\alpha$  be an element of  $k$  and  $\ell_\alpha$  the  $p$ -Lie algebra endomorphism of  $L$  that sends  $x$  onto  $\alpha x$  (and therefore  $x^{(p)}$  onto  $\alpha^p x^{(p)}$ ). Then  $U_p(\ell_\alpha)$  is the algebra endomorphism that sends  $x$  onto  $\alpha x$  (and therefore each  $x^{(i)}$  onto  $\alpha^i x^{(i)}$ , for  $i < p^2$ ), and one sees easily that the square below

```

```text

$$\begin{array}{ccc} L(C) \otimes_C {}^pV_{0,C} & \xrightarrow{\psi_C} & U_p(L(C)) \\ \downarrow \theta_C & & \downarrow \\ \ell_\alpha(C) \otimes_C {}^pV_{0,C} & \xrightarrow{\psi_C} & U_p(\ell_\alpha(C)) \end{array}$$

```

```

is commutative. The hypothesis  $\chi_C \circ (\ell_\alpha(C) \otimes \text{id}) = U_p(\ell_\alpha(C)) \circ \chi_C$  then entails the equalities:

```

```text

$$P(\alpha a, \alpha^p b) = \alpha P(a, b) \quad \text{and} \quad Q(\alpha a, \alpha^p b) = \alpha^p Q(a, b).$$

```

```

Writing  $P = \sum_{i, j < p} \lambda_{ij} X^i Y^j$  and  $Q = \sum_{i, j < p} \mu_{ij} X^i Y^j$ , and taking for  $C$  the algebra  $k[X, Y]/(X^p, Y^p)$ , one deduces that if  $\lambda_{ij} \neq 0$  (resp.  $\mu_{ij} \neq 0$ ) then  $\alpha^{i+j-1+pj} = 1$

<!-- original page 580 -->

(resp.  $\alpha^{i+j+p(j-1)} = 1$ ). Hence, taking for  $\alpha$  a primitive root of unity of order  $p^2 - 1$ , one deduces that  $P = \lambda X$  and  $Q = \mu Y$ , with  $\lambda, \mu \in k$ . Consequently, one has:

```

```text
χ_C(x ⊗ a + x^{(p)} ⊗ b) = ∑_{0 ≤ i, j < p} (λ a)^i (μ b)^j x^{i + pj}.
```

```

[^N.D.E-VII\_B-C-20] Finally, consider the endomorphism  $f$  of  $L$  that sends  $x$  onto  $x + x^{(p)}$ ; taking  $C = k[a]/(a^3)$  and comparing the coefficients of  $x^{(p)}$  and  $x^{(p+1)}$  in  $(\chi_C \circ f)(x \otimes a)$  and in  $(U_{(f)}(C) \circ \chi_C)(x \otimes a)$ , one obtains that  $\lambda = \mu$  and  $\lambda^2 a^2 = 0$ , whence  $\lambda = \mu = 0$ .

### 4.4.

<!-- label: III.VII\_B.4.4 -->

<!-- original page 580, marginal 549 -->

**Theorem 4.4.** \*Let  $k$  be a pseudocompact ring of characteristic  $p > 0$  and  $G$  a  $k$ -formal group. The following assertions are equivalent:\*

<!-- label: III.VII\_B.4.4 -->

(i) There exists a  $p$ -Lie algebra  $L$  that is flat over  $0_{(k)}$  such that  $G$  is isomorphic to  $G_{(L)}$  (and in this case  $L = \text{Lie}(G)$  by 4.2.2).\*

(ii) There exists a projective pseudocompact  $k$ -module  $\omega$  such that the affine algebra of  $G$  is isomorphic to the quotient of  $k[[\omega]]$  by the closed ideal generated by the  $x^{(p)}$ , for  $x \in \omega$  (and in this case  $\omega \simeq \omega_{(G/k)}$ ).

(iii)  $G$  is of height  $\leq 1$  and  $\omega_{(G/k)}$  is a projective pseudocompact  $k$ -module.\*

(iv)  $G$  is of height  $\leq 1$  and is topologically flat over  $k$ .\*

(i)  $\Rightarrow$  (ii): Let  $\omega = \Gamma_{(L)}$  (cf. 1.2.3.D) and  $A$  the quotient of  $k[[\omega]]$  by the closed ideal generated by the  $x^{(p)}$ , for  $x \in \omega$ . Every continuous morphism  $h : A \rightarrow C$ , where  $C$  is an object of  $\mathcal{A}_f/k$ , is determined by its restriction  $h'$  to  $\omega$ ; this restriction  $h'$  sends  $\omega$  into  $\{x^{(p)} \mid x \in \omega\}$ . One thus obtains a canonical bijection from  $\text{Hom}_{\mathcal{A}_f/k}(A, C)$  onto the set  $\text{Hom}_{\mathcal{A}_f/k}(\omega, \{x^{(p)} \mid x \in \omega\})$  of continuous  $k$ -linear maps from  $\omega$  into  $\{x^{(p)} \mid x \in \omega\}$ . This last set is canonically isomorphic to  $L(C) \otimes_{(C)} \{x^{(p)} \mid x \in \omega\}$  (see the proof of 3.3). The implication (i)  $\Rightarrow$  (ii) thus follows from the functorial bijection  $L(C) \otimes_{(C)} \{x^{(p)} \mid x \in \omega\} \xrightarrow{\sim} G_{(L)}(C)$  established in 4.3.1.

For the other implications, consult the proofs of Theorems 3.3 and VII\_A 7.4.1, which are analogous.

**Remark 4.4.A.** [^N.D.E-VII\_B-C-21] \*Let  $G$  be an infinitesimal  $k$ -formal group, with affine algebra  $A$ , such that  $\omega_{(G/k)} = I_{(A)} / I_{(A)}^2$  is a projective pseudocompact  $k$ -module. Then there exists a section  $\tau : \omega_{(G/k)} \rightarrow I_{(A)}$  of the projection  $I_{(A)} \rightarrow \omega_{(G/k)}$ , and  $\tau$  induces a continuous morphism of algebras  $\psi : k[[\omega_{(G/k)}]] \rightarrow A$  that is surjective, cf. the proof of the implication (iii)  $\Rightarrow$  (i) in 3.3.\*

#### 4.4.1.

<!-- label: III.VII\_B.4.4.1 -->

**Corollary 4.4.1.** \*If  $k$  is a field of characteristic  $p > 0$ , the functor  $L \mapsto G_{(L)}$  is an equivalence of the category of  $p$ -Lie algebras over  $k$  onto that of  $k$ -formal groups of height  $\leq 1$ .\*

<!-- label: III.VII\_B.4.4.1 -->

<!-- original page 580, marginal 550 -->

Indeed, when  $G$  runs through the formal groups of height  $\leq 1$ , the functor  $G \mapsto G_{(L)}$  is isomorphic to the identity functor by Theorem 4.4; likewise, we saw in 4.2.2 that the functor  $L \mapsto \text{Lie } G_{(L)}$  is isomorphic to the identity functor (see also VII\_A, 5.5.3). [^N.D.E-VII\_B-C-22]

#### 4.4.2.

<!-- label: III.VII\_B.4.4.2 -->

<!-- original page 581 -->

Take still  $k$  to be a field of characteristic  $p$ . Let  $G$  be an infinitesimal  $k$ -formal group, with affine algebra  $A$ . Since  $G$  is infinitesimal, every open ideal of  $A$  contains  $I^{(p^n)}_A$  for  $n$  large enough, hence  $G$  is the inverse limit of the affine algebras  $A / I^{(p^n)}_A$  of the groups  $\mathrm{Fr}_n G$  (cf. 4.1.2). Every infinitesimal  $k$ -formal group is therefore a direct limit of  $k$ -formal groups of finite height.

Suppose  $G$  is of height  $\leq n$  and write  $H = G / \mathrm{Fr}_n G$ . [^N.D.E-VII\_B-C-23] By 2.4 and 2.4.1,  $\mathrm{Fr} : G \rightarrow G^{(p)}$  factorizes through an epimorphism  $\pi : G \rightarrow H$  followed by a monomorphism  $i : H \rightarrow G^{(p)}$ . One has then the following commutative diagram:

```

```text
G  --π--> H --Fr^{n-1}--> H^{(p^{n-1})}
|               |
Fr              i^{(p^{n-1})}
|               |
G^{(p)} --Fr^{n-1}--> G^{(p^n)}
```

```

and since the functor  $X \mapsto X^{(p)}$  commutes with fibered products,  $i^{(p^{n-1})}$  is still a monomorphism. Since  $\mathrm{Fr}^{(n)}(G/k)$  is zero and  $\pi$  is an epimorphism, then  $\mathrm{Fr}^{(n-1)}(G^{(p)}/k) \circ i = i^{(p^{n-1})} \circ \mathrm{Fr}^{(n-1)}(H/k)$  is zero, and hence,  $i^{(p^{n-1})}$  being a monomorphism,  $\mathrm{Fr}^{(n-1)}(H/k)$  is zero, so  $H$  is of height  $\leq n - 1$ . One therefore sees that: \*every  $k$ -formal group of finite height possesses a composition series whose quotients are of height  $\leq 1$ , hence can be described by  $p$ -Lie algebras over  $k$ .

Finally, the affine algebra  $A$  of  $G$  is a quotient of  $k[[\omega_{G/k}]]$ , cf. 4.4.A; hence if  $\omega_{G/k}$  is of finite dimension over  $k$ , then all the algebras  $A / I^{(p^n)}_A$  are  $k$ -vector spaces of finite dimension. One therefore sees that: \*every infinitesimal formal group  $G$  over a field of characteristic  $p > 0$ , such that  $\omega_{G/k}$  is of finite dimension over  $k$ , is a direct limit of finite formal groups (i.e., of finite length, cf. 1.2.6)\*.

## 5. Homogeneous spaces of infinitesimal formal groups over a field

<!-- label: III.VII\_B.5 -->

### 5.0.

<!-- label: III.VII\_B.5.0 -->

<!-- original page 581, marginal 551 -->

[^N.D.E-VII\_B-C-24] Assume, for simplicity, that  $k$  is a field. Let  $G$  be a  $k$ -formal group with affine algebra  $A = **A^{**}(\bar{G})$ . Let  $A^{+}$  be the augmentation ideal of  $A$ ; for every  $a \in A$  we shall denote by  $\bar{a} = a - \epsilon_{A}(a) 1_A$  its projection onto  $A^{+}$ . Let  $F$  be a formal subgroup

<!-- original page 582 -->

of  $G$ , defined by the closed ideal  $J$  of  $A$ , and let  $\pi$  (resp.  $\bar{\pi}$ ) be the projection  $A \rightarrow A/J$  (resp. the composition of the projections  $A \rightarrow A^{+} \rightarrow A^{+}/J$ ). Note that, for every  $a \in A$ , the projection of  $\Delta_A(a)$  onto  $A \hat{\otimes} A^{+}$  is  $\Delta_A(a) - a \hat{\otimes} 1$ .

By Theorem 2.4, one can form the quotient  $k$ -formal variety  $X = G/F$ , its affine algebra  $B$  is

```

```text
                                     τ₁
B = Ker( A → A ⊗^k_k (A/J) )
      (id_A ⊗ π) Δ_A

      = { a ∈ A | (id_A ⊗ π) Δ_A(a) = a ⊗ π(1) }

      = Ker( (id_A ⊗ π̄) Δ_A ).
```

```

It is also the subalgebra of  $A$  formed by the elements  $\phi$  such that, for every  $C \in \text{Ob } \mathcal{A}/k$  and  $g \in G(C)$ ,  $h \in F(C)$ , one has  $\phi(gh) = \phi(g)$ . For every  $g, g' \in G(C)$  and  $h \in F(C)$ , one has  $\phi(g g' h) = \phi(g g')$ , hence  $\Delta(\phi)$  belongs to the kernel of  $\text{id}_A \otimes \pi$  (  $\text{id}_A \otimes \pi \circ \Delta$  ), which equals  $A \otimes \pi(B)$  since  $A$  is topologically flat over  $k$ . One has therefore  $\Delta(A)(B) \subset A \otimes \pi(B)$ , i.e., the closed subalgebra  $B$  is also a left coideal.

On the other hand,  $B$  determines  $F$  since, by Corollary 2.4.1, one has  $J = A^{B^+}$ , i.e.,  $J$  is the closed ideal generated by  $B^{+} = B \cap A^{+}$ . One thus obtains an injective map  $Q$  from the set  $F$  of formal subgroups of  $G$  into the set  $B$  of closed subalgebras  $B$  of  $A$  that are left coideals. The question then arises of determining the image of this map, and Proposition 5.1 below shows that  $Q$  is bijective when  $G$  is infinitesimal. In fact, this is true for every  $k$ -formal group  $G$ .

Indeed, recall (cf. 2.2.1) that the functor  $G \mapsto H(G)$  is an equivalence between the category of  $k$ -formal groups and that of cocommutative  $k$ -Hopf algebras; if  $F$  is a formal subgroup of  $G$ , defined by the closed ideal  $J$  of  $A$ , then the Hopf subalgebra  $H(F)$  of  $H = H(G)$  is the orthogonal of  $J$  for the duality between  $A = H^*$  and  $H = A^+$  (cf. 0.2.2). On the other hand, if  $B$  is a closed subalgebra of  $A$  that is also a left coideal, then its orthogonal  $I = B^\perp$  is a coideal of  $H$  (i.e.,  $\Delta_H(I) \subset I \otimes H + H \otimes I$  and  $\epsilon_H(I) = 0$ ) and a left ideal. Denote by  $H^*$  (resp.  $H^*$ ) the set of Hopf subalgebras (resp. left ideals that are coideals) of  $H$ . For every  $I \in H^*$ , one will denote by  $\pi_I$  (resp.  $\bar{\pi}_I$ ) the projection  $H \rightarrow H/I$  (resp. the composition of the projections  $H \rightarrow H^+ \rightarrow H^+/I$ ), where  $H^+$  is the augmentation ideal of  $H$ .

Let  $K$  be a Hopf subalgebra of  $H$  and  $K^+ = K \cap H^+$ . If  $F$  is the formal subgroup corresponding to  $K$ , then  $J = K^\perp$  and  $A^+/J$  is identified with the dual of  $K^+$ , and since  $B = Q(F)$  is the kernel of the map

$$A \xrightarrow{\Delta} A \otimes_k A \xrightarrow{\text{id} \otimes \pi} A \otimes_k (A^+/J)$$

one obtains that  $Q$  corresponds by duality to the map  $\Phi$  which to  $K$  associates the image of

$$H \xleftarrow{m_H} H \otimes_k H \xleftarrow{\text{id} \otimes \text{can.}} H \otimes_k K^+$$

i.e., the left ideal  $H K^+$ , which is also a coideal. One sees similarly that the map which to  $B \in B$  associates  $A B^+$  corresponds by duality to the map  $\Psi$  which to every  $I \in H^*$

<!-- original page 584 -->

associates the kernel of  $(\text{id} \otimes \pi) \circ \Delta$ , i.e., one has

$$\Psi(I) = \{ x \in H \mid (\text{id} \otimes \pi) \Delta_H(x) = x \otimes \pi(1) \}.$$

One then has the following theorem:

**Theorem 5.0.1.** \*Let  $k$  be a field and  $H$  a cocommutative Hopf algebra. Then the maps  $\Phi$  and  $\Psi$  above are inverse bijections between the set of Hopf subalgebras of  $H$  and that of left ideals that are coideals.\*

<!-- label: III.VII.B.5.0.1 -->

This theorem was first proved by K. Newman, cf. [Ne75], Th. 4.1 (where the word "cocommutative" was forgotten). Its proof uses "the Cartier–Gabriel–Kostant theorem" (cf. 2.9) to reduce to the case where  $H$  is connected, then the existence in that case of a "Sweedler basis" (cf. [Sw67], Th. 3), a result dual to the Dieudonné–Cartier theorem 5.2.2 below. Another proof, shorter, was given by H. J. Schneider [Sch90], Th. 4.15. A generalization was then obtained by A. Masuoka when one assumes only that the coradical  $H_0$  of  $H$  (i.e., the sum of the simple subcoalgebras) is commutative [Ma91], Th. 1.3 (3).

Let us point out finally that for a commutative  $k$ -Hopf algebra, corresponding therefore to an affine  $k$ -group scheme  $G$ , one cannot expect an analogue of 5.0.1 without additional hypotheses, since for a  $k$ -subgroup  $F$  of  $G$ , the quotient  $G/F$  is not necessarily affine. But M. Takeuchi established in [Tak72], Th. 4.3 (resp. [Tak79], Th. 3), an

analogous bijection between the set of  $k$ -subgroups  $F$  of  $G$  which are invariant (resp. such that  $G/F$  is affine), and that of subalgebras  $B$  of  $0(G)$  such that  $\Delta(B) \subset A \otimes B$  and which are stable under the antipode (resp. and such that  $B \rightarrow A$  is faithfully flat).

### 5.1.

<!-- label: III.VII\_B.5.1 -->

Let  $k$  be a pseudocompact ring. [N.D.E-VII\_B-C-25] Let  $G$  be a topologically flat infinitesimal  $k$ -formal group,  $A$  its affine algebra,  $B$  a closed subalgebra of  $A$ ,  $X = \mathrm{Spf}(B)$ , and  $r : G \rightarrow X$  the epimorphism induced by the inclusion of  $B$  into  $A$ . One proposes to see under what condition  $r$  makes  $X$  the right quotient of  $G$  by a subgroup  $H$  (cf. 2.4). [N.D.E-VII\_B-C-26]

**Proposition.** \*Let  $G$  be a topologically flat infinitesimal  $k$ -formal group,  $A$  its affine algebra,  $I_A$  the augmentation ideal of  $A$ ,  $B$  a closed subalgebra of  $A$ , and  $J_B = A \cap I_B$ , where  $I_B = B \cap I_A$ . Assume that  $A$  is topologically flat over  $k$ , as well as  $J_B^n / J_B^{n+1}$  for every  $n \geq 0$ . Then the following two assertions are equivalent:\*

(i) For every  $x \in B$ ,  $\Delta_A(x) - x \otimes 1$  belongs to  $A \otimes_k J_B$ .

<!-- original page 584 -->

(ii) The sequence below (where  $\tau_1(a) = a \otimes 1$  and  $\pi$  is the projection  $A \rightarrow A/J_B$ ) is exact:\*

```text

$$(*) \quad B \rightarrow A \xrightarrow{\tau_1} A \otimes_k (A/J_B) \xrightarrow{(\pi \otimes \mathrm{id}_A) \Delta_A} A \otimes_k J_B$$

that is, B is the set of all $x \in A$ such that $\Delta_A(x) - x \otimes 1$ belongs to $A \otimes_k J_B$.

In this case, $H = \mathrm{Spf}(A/J_B)$ is a formal subgroup of G , and the sequence below (where λ is the restriction to $G \times H$ of the multiplication of G) is exact:

```text

$$(**) \quad G \times H \xrightarrow{\lambda} G \rightarrow \mathrm{Spf}(B)$$

\*that is,  $\mathrm{Spf}(B)$  is isomorphic to  $G/H$ .\*

Set  $\bar{A} = A/J_B$  and  $H = \mathrm{Spf}(\bar{A})$ ; then  $H$  is a formal subvariety of  $G$ . Since  $J_B \subset I_A$ , the augmentation  $\epsilon_A$  induces a continuous morphism of  $k$ -algebras  $\bar{\epsilon} : \bar{A} \rightarrow k$ .

If (i) is satisfied, then  $\Delta_A(I_B) \subset J_B \otimes 1 + A \otimes J_B$ , and hence  $\Delta_A$  induces by passage to the quotient a diagonal morphism  $\bar{\Delta} : \bar{A} \rightarrow \bar{A}$ . Then  $\bar{\Delta}$  and  $\bar{\epsilon}$  endow  $H$  with a structure of formal submonoid of  $G$ . Since  $G$  is infinitesimal, so is  $H$ ; hence, by Proposition 2.7,  $H$  is a formal subgroup of  $G$ . It then follows from the definition of  $G/H$  (cf. 2.4) that (ii) entails the last assertion of the proposition.

On the other hand, it is clear that (ii) implies (i). The proof of the converse occupies paragraphs 5.1.1 to 5.1.5.

#### 5.1.1.

<!-- label: III.VII\_B.5.1.1 -->

<!-- original page 584, marginal 552 -->

Let us first consider the following category  $\mathcal{C}$ : an object of  $\mathcal{C}$  is a pair  $(A, J)$  formed by a profinite  $k$ -algebra  $A$  and a closed ideal  $J$  of  $A$ ; a morphism  $\psi : (A, J) \rightarrow (A', J')$  of  $\mathcal{C}$  is a continuous homomorphism of  $k$ -algebras  $A \rightarrow A'$  that sends  $J$  into  $J'$ . If one associates to  $(A, J)$  the pair

$(\mathrm{Spf}(A/J), \mathrm{Spf}(A))$ , one obtains evidently an anti-equivalence of  ${}^{**}C^{**}$  onto the category of pairs  $(Z, Y)$  formed by a  $k$ -formal variety  $Y$  and a formal subvariety  $Z$ , a morphism  $\phi : (Z, Y) \rightarrow (Z', Y')$  being a morphism of  $k$ -formal varieties  $Y \rightarrow Y'$  that sends  $Z$  into  $Z'$ .

A *cogroup structure* on an object  $(A, J)$  of  ${}^{**}C^{**}$  consists of the data of a structure of formal group on  $\mathrm{Spf}(A)$  such that the following conditions are realized (notations of 2.1):

- (1)  $\Delta_A(J) \subset J \hat{\otimes}_k A + A \hat{\otimes}_k J$ ;
- (2)  $\epsilon_A(J) = 0$ ;
- (3)  $c_A(J) \subset J$ .

These conditions also mean that  $H = \mathrm{Spf}(A/J)$  is a formal subgroup of  $G = \mathrm{Spf}(A)$ .<sup>[N.D.E-VII\_B-C-27]</sup>

<!-- original page 585 -->

Suppose moreover that  $A$  is local, i.e., that  $\mathrm{Spf}(A)$  is an infinitesimal formal group. Then, if  $J \neq A$ , conditions (2) and (3) are consequences of (1). Indeed, if  $J$  is a closed ideal distinct from  $A$ , it is contained in the augmentation ideal  $I_A$ , hence (2) is verified, and  $M = \mathrm{Spf}(A/J)$  is a formal submonoid of  $G$ . Since  $G$  is infinitesimal, it follows from 2.7 that  $M$  is a formal subgroup of  $G$ , i.e., condition (3) is verified.

### 5.1.2.

<!-- label: III.VII\_B.5.1.2 -->

<!-- original page 585, marginal 553 -->

Denote by  $\mathcal{A}lpg/k$  the category of *graded profinite  $k$ -algebras*: an object of this category consists of the data of a sequence  $A_0, A_1, \dots, A_n, \dots$  of pseudocompact  $k$ -modules and of a profinite algebra structure on the product  $\prod_{n \geq 0} A_n$  such that one has  $A_n \cdot A_m \subset A_{m+n}$  ( $A_n$  being identified with a part of  $\prod_{i \geq 0} A_i$  by means of the canonical injection); a morphism  $\psi : (A_n) \rightarrow (B_n)$  is a sequence of continuous linear maps  $\psi_n : A_n \rightarrow B_n$  such that one has  $\psi_{m+n}(a \cdot a') = \psi_m(a) \cdot \psi_n(a')$  if  $a \in A_m$  and  $a' \in A_n$ .

**Definitions.** It is clear that two graded profinite  $k$ -algebras  $(A_n)$  and  $(B_n)$  have a coproduct<sup>[N.D.E-VII\_B-C-28]</sup> in  $\mathcal{A}lpg/k$ , which has as  $n$ -th component the product  $\prod_{i=0}^n A_i \hat{\otimes}_k B_{n-i}$  of the pseudocompact  $k$ -modules  $A_i \hat{\otimes}_k B_{n-i}$ . This coproduct will be denoted  $(A_n) \hat{\otimes}_k (B_n)$ .

Then, a cogroup structure on an object  $(A_n)$  of  $\mathcal{A}lpg/k$  is the data of continuous  $k$ -linear maps  $\Delta_n : A_n \rightarrow \prod_{i=0}^n A_i \hat{\otimes}_k A_{n-i}$  and  $\epsilon : A_0 \rightarrow k$ , which induce on  $\prod_{n \geq 0} A_n$  (setting  $\epsilon(A_i) = 0$  for  $i \geq 1$ ) a cogroup structure in  $\mathcal{A}lpg/k$ .

Finally, for every object  $(A, J)$  of  ${}^{**}C^{**}$ , one denotes by  $Gr_{\{J\}}(A)$  the graded profinite algebra associated with the filtration of  $A$  by the closures  $J^n$  of the powers of  $J$ ; one has therefore  $Gr_{\{J\}}(A)_n = J^n/J^{n+1}$  and the multiplication of  $Gr_{\{J\}}(A)$  is induced by that of  $A$ .

**Lemma.**<sup>[N.D.E-VII\_B-C-29]</sup> Let  $U, V$  be two pseudocompact  $k$ -modules, with  $U$  topologically flat, and let  $U = U_0 \supset U_1 \supset \dots$  and  $V = V_0 \supset V_1 \supset \dots$  be two decreasing sequences of closed  $k$ -submodules. Filter the completed tensor product  $W = U \hat{\otimes}_k V$  by means of the closed submodules\*

$$W_n = U_n \otimes_k V_0 + U_{n-1} \otimes_k V_1 + \dots + U_0 \otimes_k V_n.$$

Suppose that each  $U_i/U_{i+1}$  is topologically flat over  $k$  (so that  $U/U_n$  and hence  $U_n$  are also so, for every  $n$ ). Then, for every  $n$ , one has an isomorphism\*

$$W_n / W_{n+1} \cong \bigoplus_{i+j=n} (U_i/U_{i+1}) \otimes_k (V_j/V_{j+1}).$$

<!-- original page 585, marginal 554 -->

\*Proof.\* Set  $W_{i,j} = U_i \hat{\otimes} V_j$  and  $\bar{W}_{i,j} = (U_i/U_{i+1}) \hat{\otimes}_k (V_j/V_{j+1})$ , for every  $i, j \geq 0$ . Let us show by induction on  $n$  that the natural map

```

```text
π_n : W_n → ⋂_{i+j=n} W_{i,j}
```

```

is surjective and that the inclusion  $W_{n+1} \subset \text{Ker}(\pi_n)$  is an equality. For  $n = 0$ , the projection

```

```text
π_0 : U_0 ⊗_k V_0 → (U_0/U_1) ⊗_k (V_0/V_1)
```

```

is surjective and, since  $U_0/U_1$  and hence  $U_1$  are topologically flat over  $k$ , one sees that  $\text{Ker}(\pi_0) = U_0 \hat{\otimes}_k V_1 + U_1 \hat{\otimes}_k V_0$  and that, moreover,  $U_0 \hat{\otimes}_k V_1 \cap U_1 \hat{\otimes}_k V_0 = U_1 \hat{\otimes}_k V_1$ .

Suppose then  $n > 0$  and the result established for  $n - 1$ . Set  $M_0 = U_0 \hat{\otimes}_k V_n$  and  $S_0 = \sum_{i=1}^n U_i \hat{\otimes}_k V_{n-i}$ . One has  $S_0 \subset U_1 \hat{\otimes}_k V_0$  and hence, by what precedes applied to  $U_0 \supset V_n$  instead of  $V_0 \supset V_1$ , one has

```

```text
M_0 ∩ S_0 ⊂ U_0 ⊗_k V_n ∩ U_1 ⊗_k V = U_1 ⊗_k V_n
```

```

from which one deduces that  $M_0 \cap S_0 = U_1 \hat{\otimes}_k V_n$ . Since  $W_n = M_0 + S_0$ , one obtains a commutative diagram with exact rows, where one has set  $U'_i = U_{i+1}$  and  $W'_{i, n-1-i} = W_{i+1, n-1-i}$  for  $i = 0, \dots, n - 1$ :

```

```text
0 → S_0 → W_n → (U_0/U_1) ⊗_k V_n → 0
      |π'_{n-1}      |π_n              |p
      ↓            ↓                ↓
0 → ⋂_{i=0}^{n-1} W'_{i, n-1-i} → ⋂_{i=0}^n W_{i, n-1} → W_{0, n} → 0.
```

```

Then  $p$  is surjective, with kernel  $(U_0/U_1) \hat{\otimes}_k V_{n+1}$ . Moreover, by the induction hypothesis applied to the sequence  $(U'_i)$ ,  $\pi'_{n-1}$  is surjective, with kernel equal to  $W'_n = \sum_{i=1}^n W_{i, n+1-i}$ . It follows that  $\pi_n$  is surjective, and that the inclusion  $W_{n+1} \subset \text{Ker}(\pi_n)$  is an equality. This proves the lemma.

Let us return to an object  $(A, J)$  of  $\mathbf{C}^*$  and note that, by 0.2.G, the hypothesis that each  $J^n/J^{n+1}$  is topologically flat over  $k$  is equivalent to saying that  $\text{Gr}_J(A)$  is topologically flat over  $k$ .

**Corollary.** \*Let  $\mathbf{P}$  be the full subcategory of  $\mathbf{C}^*$  formed by the objects  $(A, J)$  such that  $A$  and  $\text{Gr}_J(A)$  are topologically flat over  $k$ . Then the functor  $\text{Alpg}/k \rightarrow \mathbf{P}$ ,  $(A, J) \mapsto \text{Gr}_J(A)$ , commutes with finite coproducts, hence transforms a cogroup of  $\mathbf{P}$  into a cogroup of  $\text{Alpg}/k$ .\*

\*In particular, if  $k$  is a field then, for every cogroup  $(A, J)$  of  $\mathbf{C}^*$ ,  $\text{Gr}_J(A)$  is a cogroup of  $\text{Alpg}/k$ .\* [N.D.E-VII\_B-C-30]

### 5.1.3.

<!-- label: III.VII\_B.5.1.3 -->

<!-- original page 587 -->

Identify every profinite  $k$ -algebra  $\Gamma$  with the graded profinite  $k$ -algebra  $(\Gamma_n)_{n \geq 0}$  such that  $\Gamma_0 = \Gamma$  and  $\Gamma_n = 0$  if  $n > 0$ . In particular, if  $(A_n)_{n \geq 0}$  is a graded profinite  $k$ -algebra, we shall consider  $A_0$  indifferently as a profinite  $k$ -algebra or as a graded profinite  $k$ -algebra. We shall then denote by  $\rho : (A_n) \rightarrow A_0$  the morphism of  $\text{Alpg}/k$  such that  $\rho_0 = \text{id}_{A_0}$  and  $\rho_n = 0$  if  $n > 0$ . Similarly,  $\tau : A_0 \rightarrow (A_n)$  will denote the section of  $\rho$  such that  $\tau_0 = \text{id}_{A_0}$  and  $\tau_n = 0$  if  $n > 0$ .

Every cogroup structure on  $(A_n)_{n \in \mathbb{N}}$  induces a cogroup structure on  $A_0$  such that  $\rho$  and  $\tau$  are homomorphisms of cogroups. In this case, denote by  $I_0$  the augmentation ideal of  $A_0$  and set  $A'_n = A_n / I_0 A_n$  for every  $n \geq 0$  (so that  $A'_0 = k$ ).

Then,  $(A'_n)_{n \in \mathbb{N}}$  is a cogroup in  $\mathcal{A}lpg/k$  (note that, since  $A_0 = I_0 \oplus k \cdot 1$ , then  $I_0 \hat{\otimes} A_n \simeq I_0 A_n$  is a direct factor of  $A_n$ , for every  $n$ ). Since  $\tau$  is a section of  $\rho$ , then, by 2.4.A, the cogroup  $(A_n)_{n \in \mathbb{N}}$  is the "semi-direct coproduct" of  $A_0$  and of the cogroup  $(A'_n)_{n \in \mathbb{N}}$ . More precisely,  $(A'_n)_{n \in \mathbb{N}}$  is isomorphic, as an object of  $\mathcal{A}lpg/k$ , to the kernel of the pair:

$$\begin{array}{ccc} & \tau_1 & \\ (A_n) \Rightarrow (A_n) \otimes_k A_0 & & \\ & (\text{id} \otimes \rho) \Delta & \end{array}$$

(where  $\Delta : (A_n) \rightarrow (A_n) \hat{\otimes} (A_n)$  is the comultiplication of  $(A_n)$  and  $\tau_1(x) = x \hat{\otimes} 1$ ), and, identifying  $A'_n$  with its image in  $A_n$ , the map

$$(A'_n \otimes_k A_0) \rightarrow (A_n), \quad a'_n \otimes a_0 \mapsto a'_n a_0$$

is an isomorphism in  $\mathcal{A}lpg/k$ . (N.B. This is not an isomorphism of cogroups, but  $\Delta(A') \subset A \hat{\otimes} A$  and  $(\gamma_{\rho} \hat{\otimes} \text{id}) \circ \Delta|_{A'} = \Delta$ , where  $\Delta$  is the comultiplication of  $A$  and  $\gamma_{\rho}$  the projection  $A \rightarrow A'$ , cf. 2.4.A.)

### 5.1.4.

<!-- label: III.VII\_B.5.1.4 -->

<!-- original page 587, marginal 555 -->

Let  $(A, J)$  be an object of  $C$  and  $(A_n) = Gr_J(A)$  the object of  $\mathcal{A}lpg/k$  associated, i.e.,  $A_n = J^n/J^{n+1}$  for every  $n \geq 0$ . It is clear that the algebra  $A^* = \prod_{n \geq 0} A_n$  is generated by  $A_0$  and  $A_1$ , that is to say that, for  $n \geq 1$ , the map

$$(1) \quad A_1 \otimes_{A_0} A_1 \otimes_{A_0} \dots \otimes_{A_0} A_1 \rightarrow A_n$$

defined by multiplication is surjective.

Suppose moreover that  $(A, J)$  is a cogroup of  $C$  and that  $A$  and the quotients  $J^n/J^{n+1}$  are flat over  $k$ . Then, by Corollary 5.1.2,  $Gr_J(A)$  is a cogroup of  $\mathcal{A}lpg/k$ . Therefore, by 5.1.3, if one sets

$$(2) \quad A'_n = \{ x \in J^n/J^{n+1} \mid \Delta(x) - x \otimes 1 \in \bigoplus_{i=1}^n (J^{n-i}/J^{n-i+1}) \otimes (J^i/J^{i+1}) \},$$

then the map  $(A'_n \hat{\otimes} A_0) \rightarrow (A_n)$ ,  $a'_n \hat{\otimes} a_0 \mapsto a'_n a_0$ , is an isomorphism in  $\mathcal{A}lpg/k$ . [N.D.E-VII\_B-C-31]

<!-- original page 588 -->

Denoting by  $I_0$  the augmentation ideal of  $A_0$ , one deduces from (1) and the commutative diagram below, where  $A'_1 \hat{\otimes}^n A_0$  denotes  $A'_1 \hat{\otimes} A_0 \hat{\otimes} \dots \hat{\otimes} A_0$  ( $n$  factors):

$$\begin{array}{ccccc} A_1 \otimes_{A_0} \dots \otimes_{A_0} A_1 & & A'_1 \otimes^{\wedge n} \otimes_k A_0 & & (A'_1 \otimes^{\wedge n} \otimes_k I_0) \otimes A'_1 \otimes^{\wedge n} \\ \downarrow m & & \downarrow m' \otimes \text{id} & & \downarrow m' \otimes \text{id} \otimes m' \\ A_n & \square & A'_n \otimes_k A_0 & \square & (A'_n \otimes_k I_0) \otimes A'_n \end{array}$$

```

```text
(3)      m' : A'_1 \otimes^k \cdots \otimes^k A'_1 \rightarrow A'_n
```

```

[^N.D.E-VII\_B-C-32] Let us now return to the hypothesis (i) of Proposition 5.1: let  $G$  be a topologically flat infinitesimal  $k$ -formal group,  $A$  its affine algebra,  $I_A$  the augmentation ideal of  $A$ ,  $B$  a closed subalgebra of  $A$ , and  $J = A \setminus B$ , where  $I_B = B \cap I_A$ . Denote by  $H$  the formal subgroup  $\mathrm{Spf}(A/J)$  and  $\pi$  the projection  $A \rightarrow A/J$ . Suppose that  $A/J^n$  is topologically flat over  $k$ , for every  $n \geq 1$ , and that  $B$  is contained in the kernel  $\tilde{B}$  of the pair:

```

``text
 τ1
A ⇒ A ⊗^k (A/J).
 (idA ⊗^k π) ΔA
``

```

```

```text
**B** =  $\prod_{n \in \mathbb{N}} B_n \subset \text{**B~**} = \prod_{n \in \mathbb{N}} B_n^~$ 

```

On the other hand, $\$J\$$ (resp. $\$J^{\{2\}}\$$) is the image in $\$A\$$ of $\$I_{\{B\}} \hat{\otimes}_{\{k\}} A\$$ (resp. of $\$I^{\{2\}}_{\{B\}} \hat{\otimes}_{\{k\}} A\$$). Consequently, the map

$$(I_B/I_B^2) \otimes_k A \rightarrow J/J^2 = A_1 \simeq A'_1 \otimes_k A_0$$

is surjective, and it factors through $(\mathbb{A}_k^1/I^2) \hat{\otimes}_k A_0$. Since $A_0 = k \oplus I_0$, one deduces from the commutative and exact diagram:

$$\begin{array}{ccc} \text{``text} & & \\ (I_B/I_{B^2}) \otimes^k A_0 & \cong & ((I_B/I_{B^2}) \otimes^k I_0) \oplus (I_B/I_{B^2}) \\ \downarrow & & \downarrow \\ J/J^2 & \cong & (A'_1 \otimes^k I_0) \oplus A'_1 \\ \downarrow & & \downarrow \\ 0 & & 0 \\ \text{````} & & \end{array}$$

SGA 3 existing English translation – plaintext render from existing Markdown – page 556

Finally, since the formal group G is infinitesimal, one has $\mathfrak{I}^n(A) = \mathfrak{I}_n(A)$ and hence the ideals $\mathfrak{I}^n_{\tilde{B}}$ tend to $\mathfrak{I}_0$ (cf. 0.1.2); a fortiori, the ideals $\mathfrak{J}^n$ tend to $\mathfrak{I}_0$, and hence the induced filtrations on $\tilde{B}$ and B are separated. Moreover, since B is a closed subalgebra of A , it is complete for the topology defined by the ideals $B \cap \mathfrak{J}^n$. Consequently, it follows from [CA], § V.7, Lemma 1 (see also 5.1.5 below) that $B = \tilde{B}$. This completes the proof of Proposition 5.1.

One has moreover the following supplement. For every n , $\mathfrak{J}^n = A \cap \mathfrak{I}^n_{\tilde{B}}$ is the image in A of $A \hat{\otimes}_{\tilde{B}} \mathfrak{I}^n_{\tilde{B}}$ and also of $A \hat{\otimes}_{\tilde{B}} (B \cap \mathfrak{J}^n)$. Now, by hypothesis, the affine algebra A/J of the formal subgroup H is topologically flat over k . Hence, by Theorem 2.4, the morphism $G = \mathrm{Spf}(A) \rightarrow \mathrm{Spf}(B) = G/H$ is surjective and topologically flat; one has therefore

$$A \hat{\otimes}_{\tilde{B}} \mathfrak{I}^n_{\tilde{B}} = \mathfrak{J}^n = A \hat{\otimes}_{\tilde{B}} (B \cap \mathfrak{J}^n),$$

and this entails that $\mathfrak{I}^n_{\tilde{B}} = B \cap \mathfrak{J}^n$ for every n . This also follows from the fact that the maps

$$\mathfrak{I}^n_{\tilde{B}} / \mathfrak{I}^{n+1}_{\tilde{B}} \rightarrow A'/\mathfrak{I}^n = (B \cap \mathfrak{J}^n) / (B \cap \mathfrak{J}^{n+1})$$

are surjective, and from 5.1.5 (ii) below, applied to $B'_n = \mathfrak{I}^n_{\tilde{B}}$ and $B_n = B \cap \mathfrak{J}^n$.

5.1.5.

<!-- label: III.VII_B.5.1.5 -->

Lemma 5.1.5. (N.D.E-VII_B-C-34) (i) Let M and N be two abelian groups filtered by decreasing sequences of subgroups $(M_n)_{n \in \mathbb{Z}}$ and $(N_n)_{n \in \mathbb{Z}}$. Suppose that the union of the M_n (resp. N_n) equals M (resp. N), that the intersection of the M_n (resp. N_n) is zero, and that M is complete for the topology defined by the M_n . Let $f : M \rightarrow N$ be a morphism of filtered groups.*

<!-- label: III.VII_B.5.1.5 -->

<!-- original page 590 -->

a) If f induces a surjection of the associated graded modules, then f is a surjection and N is complete for the topology defined by the N_n .

b) If f induces an injection of the associated graded modules, then f is an injection.

(ii) Let B be an abelian group, $B = B'_0 \supset B'_1 \supset \dots$ and $B = B'_0 \supset B_1 \supset \dots$ two separated filtrations of B by subgroups such that $B'_n \subset B_n$ for every n . Suppose B is complete for the topology defined by the filtration (B'_n) .*

If the map $B'_i/B'_{i+1} \rightarrow B_i/B_{i+1}$ is surjective for every i , then $B'_n = B_n$ for every n .*

Indeed, (i) is Lemma 1 of [CA], § V.7 (see also [BAC], III, § 2.8), and (ii) follows from it by taking $M = B'_n \supset B'_{n+1} \supset \dots$ and $N = B_n \supset B_{n+1} \supset \dots$.

5.2.

<!-- label: III.VII_B.5.2 -->

In all the rest of Section 5, k denotes a perfect field of characteristic $p > 0$.

We set $\bar{N} = \mathbb{N} \cup \{\infty\}$. If B is a profinite k -algebra and $r \in \bar{N}$, we denote by $(x^{(p^r)})_{x \in \mathfrak{I}(B)}$ the closed ideal of B generated by the elements $x^{(p^r)}$, where x runs through the radical $\mathfrak{I}(B)$ of B . If $r = \infty$, we use the same notation, with the convention that $(x^{(p^\infty)})_{x \in \mathfrak{I}(B)}$ is the zero ideal. In both cases, $B_{(r)}$ denotes the quotient $B / (x^{(p^r)})_{x \in \mathfrak{I}(B)}$.

We say that B is of height $\leq r$ if $(x^{(p^r)})_{x \in \mathfrak{I}(B)}$ is the zero ideal; if this holds and r is finite, we say that B is of finite height*.

Consider in particular the case where B is of the form $k[[\omega]]$, ω being a pseudocompact k -vector space (cf. 1.2.5). [N.D.E-VII_B-C-35] We then say that B is a *formal power series algebra* and that B_r is a *truncated formal power series algebra* ($r \in \bar{\mathbb{N}}$); we therefore agree to say that $B = B_{\infty}$ is also "truncated". If $B = k[[\omega]]$, we also write $((x^{p^r}))_{x \in \omega}$ instead of $((x^{p^r}))_{x \in \mathfrak{f}(B)}$.

<!-- original page 590, marginal 557 -->

Notations. Let ω be a pseudocompact k -vector space filtered by an increasing sequence of closed vector subspaces

text
 $0 = \omega_0 \subset \omega_1 \subset \omega_2 \subset \omega_3 \subset \dots$

(a) The closed ideal of $k[[\omega]]$ generated by the elements x^{p^r} , where r runs through $\mathbb{N}$ and x runs through ω_r , will be denoted $((x^{p^r}))_{r \in \omega_r}$.

(b) On the other hand, we shall denote by ω^r the filtered pseudocompact vector space such that

text
 $\omega^r_i = \omega_i \quad \text{if } i < r \quad \text{and} \quad \omega^r_i = \omega \quad \text{if } i \geq r.$

Theorem (Dieudonné–Cartier). Let $H \rightarrow G$ be a monomorphism of infinitesimal formal groups over a perfect field k of characteristic $p > 0$. Let B be the affine algebra of the homogeneous space G/H and suppose one of the following three conditions verified: [N.D.E-VII_B-C-36]

<!-- label: III.VII_B.5.2 -->

<!-- original page 591 -->

(i) B is of finite height (this is the case in particular if G is of finite height).

(ii) B is a complete noetherian local ring.

(iii) B is a reduced ring.

Then B is isomorphic to the completed tensor product of a finite family of truncated formal power series algebras.

<!-- original page 591, marginal 558 -->

The proof of this theorem occupies paragraphs 5.2.1 to 5.2.5.

5.2.1.

<!-- label: III.VII_B.5.2.1 -->

Let A be the affine algebra of G , I_A its augmentation ideal, and $I = B \cap I_A$. By 2.4, one has $H = \text{Spf}(A/I)$ and $B = \{x \in A \mid \Delta(x) - 1 \in \hat{\otimes} x \in A \hat{\otimes} A/I\}$. Set $\omega = I/I^2$. One denotes by I_r the closed sub-ideal of I formed by the x such that $x^{p^r} = 0$, and by ω_r the canonical image of I_r in ω . We shall prove:

Proposition. If there exists a continuous section $\sigma : \omega \rightarrow I$ of the projection $I \rightarrow I/I^2$, such that $\sigma(\omega_r) \subset I_r$ for every r , then B is isomorphic to $k[[\omega]] / ((x^{p^r}))_{x \in \omega_r}$.

<!-- label: III.VII_B.5.2.1 -->

Such a section indeed extends into a continuous morphism $k[[\omega]] \rightarrow B$, which factors through $B' = k[[\omega]] / ((x^{p^r}))_{x \in \omega_r}$. We prove from 5.2.2 to 5.2.5 that the morphism

text
 $\varphi : B' = k[[\omega]] / ((x^{p^r}))_{x \in \omega_r} \rightarrow B$

thus obtained is an isomorphism.

5.2.1.A.

<!-- label: III.VII_B.5.2.1.A -->

[^N.D.E-VII_B-C-37] For each $r \in \mathbb{N}$, set $\bar{I}_r = I^2 + I_r$, so that $\bar{I}_r/I^2 \simeq \omega_r$; one then has a commutative diagram with exact rows:

$$\begin{array}{ccccccc} 0 & \longrightarrow & \bar{I}_{r-1} & \longrightarrow & \bar{I}_r & \longrightarrow & \bar{I}_r/\bar{I}_{r-1} \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \omega_{r-1} & \longrightarrow & \omega_r & \longrightarrow & \omega_r/\omega_{r-1} \longrightarrow 0 \end{array}$$

and since k is a field, the rows are split: one can complete a pseudobasis B_{r-1} of $\bar{I}_{r-1}$ into a pseudobasis $B_{r-1} \cup B'_r$ of $\bar{I}_r$, and then the closed subspace S_r with pseudobasis B'_r is a supplement of $\bar{I}_{r-1}$ in $\bar{I}_r$, and the projection $\pi : I \rightarrow \omega$ induces an isomorphism of S_r onto a supplement ω'_r of ω_{r-1} in ω_r . Denote by I_{∞} the closed ideal $\bigcup_r \bar{I}_r$; it admits similarly a supplement S_{∞} in I , and π induces an isomorphism of I_{∞}/I^2 (resp. of S_{∞}) onto the closure ω_{∞} of the union of the ω_r (resp. onto a supplement ω'_{∞} of ω_{∞} in ω). Denote by η the isomorphism $S_{\infty}/I^2 \xrightarrow{\sim} \omega'_{\infty}$. One then obtains continuous linear maps:

$$\begin{array}{c} \text{``text} \\ I^2 \times S_{\infty} \times \bigoplus_r S_r \xrightarrow{\varphi} I \\ \quad \quad \quad \downarrow \\ \quad \quad \quad \eta \times \theta \\ \quad \quad \quad \downarrow \\ \quad \quad \quad \omega = \omega'_{\infty} \times \omega_{\infty} \\ \dots \end{array}$$

<!-- original page 592, marginal 559 -->

where $\bigoplus_r S_r$ is the direct sum of the S_r in $PC(k)$, i.e., $(\bigoplus_r S_r)^{\wedge^*}$ (cf. N.D.E. (16) of 0.2.2) and where $\theta : \bigoplus_r S_r \rightarrow \omega_{\infty}$ is induced by the maps $S_r \rightarrow \omega'_r \hookrightarrow \omega_{\infty}$. One therefore sees that a sufficient condition (but not necessary, see below) to obtain a section $\sigma : \omega \rightarrow I$ as desired is that θ be an isomorphism. By duality (cf. 0.2.2), this amounts to saying that the linear map $\omega_{\infty}^{\wedge} \rightarrow \bigoplus_r S_r^{\wedge}$ is bijective.

5.2.1.B.

<!-- label: III.VII_B.5.2.1.B -->

Denote, as before, $\omega_{\infty} = \bigcup_n \omega_n$. A second case in which a section $\sigma : \omega \rightarrow I$ as desired exists is the case where ω_{∞} possesses a pseudobasis B_{∞} that is a union of pseudobases of the ω_n/ω_{n-1} , for $n \in \mathbb{N}$ (one can then complete it by a pseudobasis B'_{∞} of $\omega_{\infty}/\omega_{\infty}$ to obtain a pseudobasis of ω compatible with the filtration). Setting $V = \omega_{\infty}^{\wedge}$ and denoting by V_n the orthogonal in V of ω_n , this amounts to saying that, in the category of "ordinary" k -vector spaces, the decreasing separated filtration

$$\text{``text} \\ V = V_0 \supset V_1 \supset V_2 \supset \dots$$

is split, i.e., that V is the direct sum, for $n \in \mathbb{N}$, of subspaces F_n such that $F_n \simeq V_n/V_{n+1}$. This is not necessarily the case: for example, if V is the space $S = k^{\mathbb{N}}$ of sequences of elements of k and S_n the subspace of sequences (u_i) such that $u_i = 0$ for $i < n$, so that $\dim S_n/S_{n+1} = 1$, then S is not isomorphic to the direct sum of the S_n/S_{n+1} since S is not of countable dimension (on the other hand, S is here the product of the S_n/S_{n+1} , cf. 5.2.1.A). It is however the case if V is of countable dimension. [^N.D.E-VII_B-C-38] Indeed, let $(e_n)_{n \in \mathbb{N}}$ be a basis of V ; we shall construct by induction on n an increasing function $g : \mathbb{N} \rightarrow \mathbb{N}$ and subspaces F_i , for $i = 0, \dots, g(n)$, such that $F_i \simeq V_i/V_{i+1}$ and that $F_{\leq g(n)} = \bigoplus_{i=0}^{g(n)} F_i$ is a supplement of $V_{g(n)+1}$ containing $e_0, \dots, e_n$;

one will then have $V = \bigoplus_{i \geq 0} F_i$. Let $n + 1 \in \mathbb{N}$; we may assume the assertion established for n (the assertion being vacuous for $n = -1$). If $e_{n+1} \in F_{\leq g(n)}$, set $g(n + 1) = g(n)$; otherwise write $e_{n+1} = f + x$ with $f \in F_{\leq g(n)}$ and $x \in V_{g(n)+1}$ nonzero. Let j be the smallest integer such that $x \in V_j - V_{j+1}$; for $i = g(n) + 1, \dots, j$, choose a supplement F_i of V_{i+1} in V_i , so that $e_{n+1} \in F_j$; one then sets $g(n + 1) = j$.

5.2.1.C.

<!-- label: III.VII_B.5.2.1.C -->

[^N.D.E-VII_B-C-39] In particular, the two preceding conditions (5.2.1.A and B) are verified when the filtration of ω is stationary, i.e., when there exists an integer n_0 such that $\omega_n = \omega_{n_0}$ for $n \geq n_0$. In this case, one obtains an isomorphism of $k[[\omega]] / ((x^p))_{x \in \omega_r}$ onto the completed tensor product:

```text  
(  $k[[\omega_1]] / ((x^p))_{x \in \omega_1}$  )  $\otimes$  (  $k[[\omega'_2]] / ((x^p))_{x \in \omega'_2}$  )  $\otimes \dots \otimes$  (  $k[[\omega'_{n_0}]] / ((x^p))_{x \in \omega'_{n_0}}$  )  $\otimes$   $k[[\omega'_\infty]]$

where  $\omega'_n$  (resp.  $\omega'_{\infty}$ ) is a supplement of  $\omega_{n-1}$  in  $\omega_n$  (resp. of  $\omega_{\infty} = \omega_{n_0}$  in  $\omega$ ). The filtration of  $\omega$  is obviously stationary in case (i), i.e., if  $\omega_r = \omega$  for  $r$  large enough, and in case (ii), i.e., if  $\omega$  is of finite dimension, and also in case (iii), i.e., if  $I_r = 0$  for every  $r$  (and in this case  $B$  will be isomorphic to the formal power series algebra

<!-- original page 593 -->

$k[[\omega]]$ ). The remarks above therefore imply our theorem, modulo points 5.2.2–5.2.5 below.

#### 5.2.2.

<!-- label: III.VII\_B.5.2.2 -->

<!-- original page 593, marginal 559 -->

Suppose first that  $B$  is of height  $\leq 1$ , that is to say that  $x^p = 0$  if  $x \in I$ . By 5.1.4, the graded ring  $Gr_I(B)$  associated with  $B$  for the filtration  $I \supset I^2 \supset I^3 \supset \dots$  is endowed with a cogroup structure in the category  $Alpg/k$ , i.e., the profinite algebra  $C = \prod_{n \geq 0} Gr_I(B)_n$  is the affine algebra of a  $k$ -formal group  $N$ . It is clear that one has  $\omega_{N/k} = I/I^2$  and that  $N$  is infinitesimal of height  $\leq 1$ . By 4.4, the identity map of  $\omega_{N/k}$  therefore induces an isomorphism of  $B' = k[[\omega_{N/k}]] / ((x^p))_{x \in \omega_{N/k}}$  onto  $C$ . This implies in particular that the map  $\phi$  of 5.2.1 induces an isomorphism of the associated graded rings of  $B'$  and  $B$  when one filters  $B'$  and  $B$  by the powers of the augmentation ideal. Hence  $\phi$  is an isomorphism, by [CA], § V.7, Lemma 1 (see also 5.1.5).

#### 5.2.3.

<!-- label: III.VII\_B.5.2.3 -->

Suppose now  $B$  of finite height  $\leq r$ . Let  $\pi$  be the isomorphism  $x \mapsto x^p$  of  $k$  onto  $k$ . The linear map of  $B \hat{\otimes}_{\pi} k$  into  $B$  which sends  $b \hat{\otimes}_{\pi} x$  onto  $b^{1/p} x = (b x^{1/p})^{1/p}$  has a closed image which is none other than the closed subalgebra  $B^{\{p\}} = \{ b^{1/p} \mid b \in B \}$  of  $B$ . Set  $J = B^{\{p\}} \cap I = B^{\{p\}} \cap I_A$ .

[^N.D.E-VII\_B-C-40] Denote by  $G_1$  the kernel of the Frobenius morphism  $Fr : G \rightarrow G^{(p)}$  and by  $H G_1$  the formal subgroup of  $G$  inverse image of the formal subgroup  $H^{(p)}$  of  $G^{(p)}$ . Then  $H G_1$  is defined by the closed ideal generated by the  $p$ -th powers of elements of  $AI$ , which equals  $AJ$ . On the other hand, since the formation of  $G/H$  commutes with base change (since  $G/H$  represents the sheaf-quotient for the flat topology, cf. 2.4), then  $(G/H)^{(p)} = G^{(p)}/H^{(p)}$ , and one therefore has commutative diagrams:

```text  
 $G \xrightarrow{Fr} G^{(p)}$ $A \xleftarrow{a \otimes 1} a^p \xrightarrow{\quad} A \xleftarrow{\pi} k$
 $\downarrow$ $\uparrow$
 $G/H \xrightarrow{Fr} G^{(p)}/H^{(p)}$ $B \xleftarrow{b \otimes 1} b^p \xrightarrow{\quad} B \xleftarrow{\pi} k$
```

from which one deduces that  $B^{\{p\}}$  is the affine algebra of the quotient  $G/H \ G_{\{1\}}$ .<sup>[N.D.E-VII\_B-C-41]</sup> Denote provisionally by  $C$  the affine algebra of the quotient  $H \ G_{\{1\}} / H$ . Since the formation of  $G/H$  commutes with base change, one has a cartesian square:

$$\begin{array}{ccc} H \ G_{\{1\}} & \xrightarrow{\quad} & G \\ \downarrow & & \downarrow \\ H \ G_{\{1\}}/H & \xrightarrow{\quad} & G/H \end{array}$$

whence an isomorphism  $A \ \hat{\otimes}_{B^{\{p\}}} C \simeq A/AJ = A \ \hat{\otimes}_{B^{\{p\}}} (B/BJ)$ , and since  $A$  is topologically free over  $B$  (by 2.4, since  $A$  and  $B$  are local), it follows that the natural morphism  $B/BJ \rightarrow C$  is an isomorphism, hence  $B/BJ$  is the affine algebra of  $H \ G_{\{1\}} / H$ ,<sup>[N.D.E-VII\_B-C-41]</sup> and of course  $B/BJ = B_{\{1\}}$  is of height  $\leq 1$  since  $J = ((x^{\{p\}}))_{x \in \mathfrak{m}_{\mathfrak{H}}(B)}$ .

<!-- original page 594 -->

Let  $B' = k[[\omega]] / ((x^{\{p^r\}}))_{x \in \omega_r}$ ,  $\phi : B' \rightarrow B$  the morphism introduced in 5.2.1,  $B'^{\{p\}}$  the subalgebra  $\{x^{\{p\}} \mid x \in B'\}$ , and  $J'$  the augmentation ideal of  $B'^{\{p\}}$ . Then, one has a commutative diagram:

$$\begin{array}{ccc} B' & \xrightarrow{\phi} & B \\ \downarrow & & \downarrow \\ B'_1 = B'/B'_1 J' & \rightarrow & B_1 = B/BJ \end{array}$$

and, by 5.2.2,  $\phi_1$  is an isomorphism.

<!-- original page 594, marginal 560 -->

On the other hand, by 2.4,  $A$  is topologically flat over  $B = A(G/H)$  and over  $B^{\{p\}} = A(G/H \ G_{\{1\}})$ ; hence, by 1.3.3,  $B$  is topologically flat over  $B^{\{p\}}$ . Moreover, by 5.2.4 below, the morphism  $B'^{\{p\}} \rightarrow B^{\{p\}}$  induced by  $\phi$  is an isomorphism. One can then apply 0.3.4 to the pseudocompact ring  $B'^{\{p\}} = B^{\{p\}}$  and to the pseudocompact  $B^{\{p\}}$ -modules  $M = B'$ ,  $N = B$ : by what precedes,  $\phi_1 = \phi \ \hat{\otimes}_{B^{\{p\}}} k$  is an isomorphism, and it follows that  $\phi$  is an isomorphism. This proves 5.2 when  $B$  is of finite height, modulo point 5.2.4 below.

### 5.2.4.

<!-- label: III.VII\_B.5.2.4 -->

For every pseudocompact vector space  $V$  over  $k$ , we denote by  ${}^{\wedge\pi} V$  the space  $V \ \hat{\otimes}_{\pi} k$  deduced from  $V$  by the extension  $x \mapsto x^{\{p\}}$  of the field of scalars.<sup>[N.D.E-VII\_B-C-42]</sup> One then has a commutative diagram with exact rows

$$\begin{array}{ccccccc} {}^{\wedge\pi} I^2 & \xrightarrow{\alpha} & {}^{\wedge\pi} I & \xrightarrow{\beta} & {}^{\wedge\pi} \omega & \rightarrow & 0 \\ \downarrow u & & \downarrow v & & \downarrow w & & \\ 0 & \rightarrow & J^2 & \xrightarrow{\gamma} & J & \xrightarrow{\delta} & \omega^- \rightarrow 0 \end{array}$$

where one has set  $\bar{\omega} = J/J^2$  and where the maps  $u, v, w$  are induced by the linear map  $x \ \hat{\otimes}_{\pi} a \mapsto x^{\{p\}}$  as from  ${}^{\wedge\pi} B$  into  $B^{\{p\}}$ . Since  $u$  and  $v$  are surjections,  $w$  is a surjection and has as kernel the image  ${}^{\wedge\pi} \omega_1$  of  ${}^{\wedge\pi} I_1 = \text{Ker}(v)$ .

Then, setting  $J_n = \{x \in J \mid x^{\{p^n\}} = 0\}$  and  $\bar{\omega}_n = \delta(I_n)$ , one has  $J_n = v({}^{\wedge\pi} I_{n+1})$  and  $\bar{\omega}_n = w({}^{\wedge\pi} \omega_{n+1})$ , for every  $n \geq 0$ . The section  ${}^{\wedge\pi} \sigma : {}^{\wedge\pi} \omega \rightarrow {}^{\wedge\pi} I$ , which is induced by the section  $\sigma$  of 5.2.1, therefore defines by passage to the quotient a section  $\tau : \bar{\omega} \rightarrow J$  that is compatible with the filtrations of  $J$  and  $\bar{\omega}$ . Since  $B^{\{p\}}$  is of height  $\leq r - 1$ , this section induces, by induction hypothesis, an isomorphism

$$\psi : B' = k[[\omega^-]] / ((x^{\{p^n\}}))_{x \in \omega^-} \rightarrow B^{\{p\}}.$$

Now  $B'$  is identified with  $B'^{(p)}$  and  $\psi$  with the morphism  $B'^{(p)} \rightarrow B^{(p)}$  induced by  $\phi$ , hence our

<!-- original page 595, marginal 561 -->

theorem is proved when  $B$  is of finite height.

**Remark 5.2.4.A.** [N.D.E-VII\_B-C-43] Suppose  $B$  of height  $\leq r + 1$  (with  $r \in \mathbb{N}$ ). Then  $I_{r+1} = I$  and one has an isomorphism

<!-- label: III.VII\_B.5.2.4.A -->

text  
 (1)  $B = (k[[S_1]]/(x_1^p))_{x_1 \in S_1} \otimes_k \cdots \otimes_k (k[[S_r]]/(x_r^{p^r}))_{x_r \in S_r} \otimes_k (k[[S_{r+1}]]/(x_{r+1}^{p^{r+1}}))_{x_{r+1} \in S_{r+1}}$

where each  $S_n$  is a supplement of  $I^2 + I_{n-1}$  in  $I^2 + I_n$ . Then  $\omega = I/I^2$  is identified with  $\prod_{i=1}^{r+1} S_i$ , and one sees easily that, for  $n = 1, \dots, r + 1$ , the image  $\omega_n$  of  $I_n$  in  $\omega$  is identified with  $\prod_{i=1}^n S_i$ .

This has the following consequence. Let  $B_r = B/\check{J}_r$ , where  $\check{J}_r = ((x^{p^r}))_{x \in \mathfrak{m}}$ , and let  $\mathfrak{m} = I/\check{J}_r$  be the augmentation ideal of  $B_r$ ; since  $\check{J}_r \subset I^2$ , then  $\omega(r) = \mathfrak{m}/\mathfrak{m}^2$  is identified with  $\omega$ . For  $n = 1, \dots, r$ , denote by  $\omega(r)_n$  the image in  $\omega(r)$  of  $\mathfrak{m}^n$ ; it is also the image in  $\omega$  of  $\{x \in I \mid x^{p^n} \in \check{J}_r\}$ , hence  $\omega(r)_n$  contains  $\omega_n$ . On the other hand, it follows from isomorphism (1) that one has  $\check{J}_r = ((x^{p^r})_{x_{r+1}})_{x_{r+1} \in S_{r+1}}$ , whence

text  
 (2)  $B_r = (k[[S_1]]/(x_1^p))_{x_1 \in S_1} \otimes_k \cdots \otimes_k (k[[S_r]]/(x_r^{p^r}))_{x_r \in S_r} \otimes_k (k[[S_{r+1}]]/(x_{r+1}^{p^r}))_{x_{r+1} \in S_{r+1}}$

and therefore, by what precedes,  $\omega(r)_n$  is identified with  $\prod_{i=1}^n S_i$  for  $n = 1, \dots, r - 1$ . One thus obtains that the inclusion  $\omega_n \subset \omega(r)_n$  is an equality, for  $n = 1, \dots, r - 1$ .

### 5.2.5.

<!-- label: III.VII\_B.5.2.5 -->

It remains to consider the case where  $B$  is of infinite height, and where the projection  $I \rightarrow \omega$  possesses a section  $\sigma$  compatible with the filtrations of  $\omega$  and  $I$ . Consider the morphism

text  
 $\phi: B' = k[[\omega]] / ((x^{p^n}))_{x \in \omega_n} \rightarrow B$

induced by  $\sigma$ ; it suffices to show that for every  $r \in \mathbb{N}$ , the map  $\phi_r: B'_r \rightarrow B_r$  induced by  $\phi$  is invertible. [N.D.E-VII\_B-C-44]

For every  $r \in \mathbb{N}$ , denote by  $G_r$  the kernel of the iterated Frobenius morphism  $G \rightarrow G^{(p^r)}$  and by  $H_r$  the formal subgroup of  $G$  inverse image of the formal subgroup  $H^{(p^r)}$  of  $G^{(p^r)}$ , so that  $H_r$  is defined by the closed ideal generated by the  $p^r$ -th powers of elements of  $A$ , which equals  $\check{J}_r$ , where  $\check{J}_r = \{x^{p^r} \mid x \in I\}$ . One obtains then, exactly as in 5.2.3, that  $B_r = B/\check{J}_r$  is the affine algebra of  $H_r/H$  (and is of course of height  $\leq r$ ).

Denote by  $\mathfrak{m}(r) = I/\check{J}_r$  the augmentation ideal of  $B_r$ ; the canonical projection of  $B$  onto  $B_r$  obviously induces an isomorphism of  $\omega = I/I^2$  onto  $\omega(r) = \mathfrak{m}(r)/\mathfrak{m}(r)^2$ , which allows us to identify these two spaces. Let  $\omega(r)_n$  be the image in  $\omega(r)$  of the closed ideal  $\mathfrak{m}(r)_n = \{y \in \mathfrak{m}(r) \mid y^{p^n} = 0\}$ ; it is also the image in  $\omega$  of the closed ideal

<!-- original page 596 -->

$I(r)_n = \{x \in I \mid x^{p^n} \in \check{J}_r\}$ . [N.D.E-VII\_B-C-45] It is clear that  $\omega_n(r) = \omega$  if

$\geq$  let us show that  $\omega_n(r) = \omega_n$  if  $n < r$ . For every  $r, n$ , the sequence below is exact:

$$0 \rightarrow I(r)_n \cap I^2 \rightarrow I(r)_n \rightarrow \omega(r)_n \rightarrow 0.$$

Moreover, for  $n$  fixed, one has  $\bigcap_r I(r)_n = I_n$ , since  $\bigcap_r B_{\check{J}} = 0$ . Since in  $\text{PC}(k)$  filtered inverse limits are exact (cf. 0.2), it follows that, for every  $n$ , one has

$$(\ast) \quad \omega_n = \bigcap_r \omega(r)_n.$$

On the other hand, by Remark 5.2.4.A, one has  $\omega(r)_n = \omega(r+1)_n$  if  $n < r$ . Combined with  $(\ast)$ , this entails that  $\omega(r)_n = \omega_n$  if  $n < r$ .

<!-- original page 596, marginal 562 -->

Consequently, the vector space  $\omega$  filtered by the subspaces  $\omega(r)_n$  is none other than  $\omega$  (Notations 5.2). A fortiori, the map  $\sigma$  composed of  $\sigma : \omega \rightarrow I$  and of the projection  $I \rightarrow \mathfrak{m}(r)$  is compatible with the filtrations  $\omega(r)_n$  and  $\mathfrak{m}(r)_n$  of  $\omega$  and  $\mathfrak{m}(r)$ . Since  $k[[\omega]] / ((x^{p^n}))_x \in \omega_n$  is none other than  $B'_r$  and  $\phi_r : B'_r \rightarrow B_r$  is the morphism induced by  $\sigma$ , the result already established for algebras of finite height shows that  $\phi_r$  is an isomorphism.

### 5.2.6.

<!-- label: III.VII\_B.5.2.6 -->

**Definition 5.2.6.** [N.D.E-VII\_B-C-46] Let  $(A_\lambda)_{\lambda \in \Lambda}$  be a family of profinite  $k$ -algebras, each endowed with an augmentation  $\epsilon_\lambda : A_\lambda \rightarrow k$  (this is the case in particular if each  $A_\lambda$  is local with residue field  $k$ ). One defines then the infinite completed tensor product

$$A^\wedge = \otimes^c_{\lambda \in \Lambda} A_\lambda$$

as the inverse limit in  $\text{Alp}/k$  of the  $A^\wedge_F = \hat{\otimes}_{\lambda \in F} A_\lambda$ , for  $F$  running through the finite subsets of  $\Lambda$ , the transition morphisms  $A^\wedge_{F'} \rightarrow A^\wedge_F$ , for  $F' = F \cup \{\lambda\}$ , being  $\text{id} \hat{\otimes} \epsilon_\lambda$ .

<!-- label: III.VII\_B.5.2.6 -->

In particular, if  $\Lambda = \mathbb{N}^*$  and if one denotes by  $X_n$  the  $k$ -formal variety  $\text{Spf}(A_n)$ , then  $\text{Spf}(A^\wedge)$  represents the functor that to every  $C \in \text{Alf}/k$  associates the set of "finite" sequences of elements of  $\prod_{n \geq 1} X_n(C)$ , i.e., sequences

$$(x_1, x_2, \dots) \in \prod_{n \geq 1} X_n(C)$$

such that  $x_n = \epsilon_n$  for  $n$  large enough, where  $\epsilon_n$  denotes, by abuse of notation, the composite of  $\epsilon_n : A_n \rightarrow k$  and of the structure morphism  $k \rightarrow C$ . (If moreover each  $A_n$  is a quotient of an algebra  $k[[\omega'_n]]$ , one can denote by  $\theta$  the unique morphism  $A^\wedge \rightarrow C$  that vanishes on  $\omega'_n$ , and one therefore obtains the set of sequences such that " $x_n = 0$ " for  $n$  large enough.)

### 5.3.

<!-- label: III.VII\_B.5.3 -->

**Remarks.** (a) Let us call **stationary** every profinite  $k$ -algebra that is the completed tensor product of a family of truncated formal power series algebras. [N.D.E-VII\_B-C-47]

<!-- original page 597 -->

If  $G$  is an infinitesimal  $k$ -formal group and  $B$  the affine algebra of a homogeneous space of  $G$ , it follows from Theorem 5.2 that the algebra  $B / ((x^{p^r}))_{x \in \mathfrak{r}(B)}$  is stationary for every integer  $r \in \mathbb{N}$ . This implies in particular that  $B$  is an inverse limit of stationary algebras. [N.D.E-VII\_B-C-48]

(b) I do not know if, with the notations of 5.2.1, one can choose  $A$  and  $B$  in such a way that there exists no section  $\sigma : \Omega \rightarrow I$  compatible with the filtrations. [N.D.E-VII\_B-C-49] One will however note that one can have for  $\Omega$  any pseudocompact vector space filtered by an increasing sequence of closed subspaces. Indeed, if  $\Omega_1 \subset \Omega_2 \subset \dots \subset \Omega$  is such a filtered space, one can define in the algebra  $B = A = k[[\Omega]] / ((x^{p^r}))_{x \in \Omega_r}$  a diagonal morphism  $\Delta_A : A \rightarrow A \hat{\otimes}_k A$  satisfying conditions (i), (ii), (iii) of 2.1; it suffices to set  $\Delta_A(y) = y \hat{\otimes} 1 + 1 \hat{\otimes} y$  when  $y$  is the image in  $A$  of an element of  $\Omega$ .

### 5.4.

<!-- label: III.VII\_B.5.4 -->

<!-- original page 597, marginal 563 -->

**Corollary 5.4.** Let  $G$  be an algebraic group over a perfect field  $k$  of characteristic  $p > 0$ ,  $H$  an algebraic subgroup of  $G$ ,  $e$  the image of the neutral element of  $G$  in  $G/H$ , and  $A$  the local algebra of  $G/H$  at  $e$ . Then  $\hat{A}$  is isomorphic to an algebra of the form

text  
 $k[[X_1, \dots, X_r, \dots, X_s]] / (X_1^{p^{n_1}}, \dots, X_r^{p^{n_r}}).$

<!-- label: III.VII\_B.5.4 -->

Indeed, consider the infinitesimal formal groups  $\hat{G} = \mathrm{Spf}(\hat{O}_{G,e})$  and  $\hat{H} = \mathrm{Spf}(\hat{O}_{H,e})$ ; by 1.3.4, the completion  $\hat{A}$  of  $A = O_{G/H,e}$  is isomorphic to  $\hat{A} = \hat{O}_{\hat{G}/\hat{H}}$ , and the corollary therefore follows from Theorem 5.2 (ii). [N.D.E-VII\_B-C-50]

### 5.5. Complements.

<!-- label: III.VII\_B.5.5 -->

[N.D.E-VII\_B-C-51] Recall the following definitions. On the one hand, one says that a noetherian local ring  $A$  is a *complete intersection* if the completion  $\hat{A}$  is a quotient of a complete regular noetherian local ring  $B$  by an ideal  $I$  generated by a regular sequence of elements of  $B$  (cf. EGA IV<sub>4</sub>, 19.3.1). On the other hand, let  $\tau : Y \rightarrow X$  be a closed immersion of schemes. If  $y \in Y$ , one says that  $\tau$  is a *regular immersion at the point  $y$*  if the kernel of  $\mathcal{O}_{X,y} \rightarrow \mathcal{O}_{Y,y}$  is generated by a regular sequence; if moreover  $X$  is locally noetherian and if  $\tau$  is a regular immersion at every point, one says that  $\tau$  is a *regular immersion* (cf. loc. cit., Prop. 16.9.10 and Déf. 16.9.2).

<!-- original page 599 -->

**Corollary 5.5.1.** If  $G$  is an algebraic group over a field  $k$ , the local ring  $\mathcal{O}_{G,e}$  is a complete intersection.

<!-- label: III.VII\_B.5.5.1 -->

Indeed, by EGA IV<sub>4</sub>, 19.3.4, one can assume  $k$  algebraically closed. If  $\mathrm{car}(k) = 0$ , we already know that  $G$  is smooth (cf. 3.3.1 or VI\_B, 1.6.1) and hence  $\mathcal{O}_{G,e}$  is a  $k$ -algebra of formal power series, by EGA IV<sub>4</sub>, 17.5.3 (d'). If  $\mathrm{car}(k) = p > 0$ , it follows from 5.4, applied to  $H = \{e\}$ , that  $\mathcal{O}_{G,e}$  is a complete intersection.

**Remarks 5.5.2.** Let  $k$  be a field,  $G$  a smooth  $k$ -algebraic group, and  $H$  a closed subgroup of  $G$ .

<!-- label: III.VII\_B.5.5.2 -->

a) We saw in Exp. III, 4.15, that the immersion  $H \rightarrow G$  is regular; this can also be deduced from 5.4, as follows. As in loc. cit., one can assume  $k$  algebraically closed, and it suffices to show that the kernel  $I$  of  $\mathcal{O}_{G,e} \rightarrow \mathcal{O}_{H,e}$  is generated by a regular sequence. Set  $A = \mathcal{O}_{G,e}$ ,  $\hat{G} = \mathrm{Spf}(\hat{A})$  and  $\hat{H} = \mathrm{Spf}(\hat{O}_{H,e})$ . Since  $A$  is noetherian, one has an exact sequence

```

```text

$$0 \rightarrow I \otimes_A \hat{A} \rightarrow \hat{A} \xrightarrow{\pi} **A**(\hat{H}) \rightarrow 0$$

```

```

and  $\hat{A}$  is faithfully flat over  $A$ . Hence, by EGA IV<sub>4</sub>, 16.9.10 (ii) and 19.1.5 (ii), it suffices to show that the kernel  $\hat{H} = I \otimes_A \hat{A}$  of  $\pi$  is generated by a regular sequence of elements of  $\hat{A}$ .

Now, since  $G$  is smooth,  $\hat{A}$  is reduced; by 5.4, the subalgebra  $B = **A**(\hat{G}/\hat{H})$  is therefore isomorphic to a formal power series algebra  $k[[x_1, \dots, x_n]]$ , and hence the unit section of  $\hat{G}/\hat{H}$  is defined in  $B$  by the regular sequence  $(x_1, \dots, x_n)$ . Since  $\hat{A}$  is noetherian, the ideal  $J$  of  $\hat{A}$  generated by  $x_1, \dots, x_n$  is closed, hence equal to  $\hat{I}$ , by Corollary 1.4. Moreover, since  $\hat{A}$  is topologically flat, hence flat over  $B$  (cf. 0.3.8), then  $(x_1, \dots, x_n)$  is a regular sequence in  $\hat{A}$ , by EGA IV<sub>4</sub>, 19.1.5 (ii).

\*b) One can also deduce from 5.2 (ii) the following more precise result.\* Suppose  $k$  perfect. By 5.2 (ii) applied to the algebra  $C = **A**(\hat{H})$ , there exists a basis  $(y_1, \dots, y_{r+s})$  of  $\omega_H$  and integers  $1 \leq n_1 \leq \dots \leq n_{r+s}$  such that  $**A**(\hat{H})$  is isomorphic to the quotient of  $k[[y_1, \dots, y_{r+s}]]$  by the ideal generated by the  $y^{p^{n_i}}_i$  for  $i = 1, \dots, r+s$ . Lift the  $y_i$  to elements  $x_i$  of  $\omega_G$  and complete  $(x_1, \dots, x_{r+s})$  into a basis  $(x_1, \dots, x_n)$  of  $\omega_G$ . Since  $**A**(\hat{G})$  is reduced, the morphism  $k[[x_1, \dots, x_n]] \rightarrow **A**(\hat{G})$  is an isomorphism, by 5.2 (iii). One thus obtains: "there exists a "system of coordinates"  $(x_1, \dots, x_n)$  of  $G$  (i.e., an isomorphism  $**A**(\hat{G}) \cong k[[x_1, \dots, x_n]]$ ) such that  $H$  is defined by the equations  $x^{p^{n_i}}_i = 0$  for  $i = 1, \dots, r+s$  and  $x_i = 0$  for  $i > r+s$ " (Dieudonné's theorem", compare with [Di55], § 19, Th. 6 and [Di73], II § 3.2, Prop. 3 and what precedes it).

| cogroupe                                   | cogroup                                 | Object of $\mathbf{C}^*$ with compatible formal group structure on $\mathrm{Spf}(A)$ ; cf. 5.1.1.                                |
| coproduit (au lieu de "somme directe")     | coproduct                               | Per N.D.E. in 5.1.2; replacing the original "somme directe".                                                                     |
| produit semi-direct (de cogroupes)         | semi-direct coproduct                   | Per 5.1.3; structural decomposition of graded cogroups.                                                                          |
| complété formel $\hat{G}_H$ le long de $H$ | formal completion $\hat{G}_H$ along $H$ | Per N.D.E. in 5.1.2.                                                                                                             |
| algèbre de séries formelles tronquée       | truncated formal power series algebra   | Per 5.2; $B_r = k[[w]]/(x^{p^r})$ .                                                                                              |
| espace vectoriel pseudocompact             | pseudocompact vector space              | Replaces the source's "linearly compact" per N.D.E. 5.2; for consistency.                                                        |
| pseudobase                                 | pseudobasis                             | Basis in $\mathrm{PC}(k)$ ; standard chunk-A usage retained.                                                                     |
| stationnaire (algèbre)                     | stationary (algebra)                    | Per 5.3; N.D.E. flags that "stable" would be preferable.                                                                         |

| intersection complète | complete intersection | Per 5.5.1, EGA IV<sub>4</sub> 19.3.1. |  
 | immersion régulière | regular immersion | Per 5.5; cf. EGA IV<sub>4</sub> 16.9.10. |  
 | « théorème de Dieudonné » | "Dieudonné's theorem" | Per 5.5.2 b); compare with [Di55] § 19. |  
 |  $\hat{p}v_0C$  |  $\hat{p}v_0C$  | Ideal of  $\hat{p}$ -nilpotent elements; per 4.3.1. |  
 |  $((x^{\hat{p}r}))_{\{x \in r(B)\}}$  |  $((x^{\hat{p}r}))_{\{x \in \square(B)\}}$  | Closed ideal generated by  $\hat{p}^r$ -th powers of radical elements; per 5.2. |  
 |  $\text{Alpg}/k$  |  $\text{Alpg}/k$  | Category of graded profinite  $k$ -algebras; per 5.1.2. |  
 |  $\text{Fr}_n G$  |  $\text{Fr}_n G$  | Kernel of iterated Frobenius; per 4.1.2 (a). |  
 | « hauteur infinie » | infinite height | Per 5.2.5. |  
 | catégorie  $^{**}C^{**}$  (algèbre profinie + idéal fermé) | category  $^{**}C^{**}$  (profinite algebra + closed ideal) | Per 5.1.1. |  
 |  $HG_1$  |  $HG_1$  | Inverse image of  $H^{\{p\}}$  under Frobenius; per 5.2.3. |  
 -->

[^N.D.E-VII\_B-0]: N.D.E.: Version of 13/10/2024.

[^N.D.E-VII\_B-1]: N.D.E.: The interest of formal groups over a complete noetherian local ring appears, for example, in the work of Lubin and Tate (cf. [LT65]). The study of formal groups over an arbitrary base, and questions of lifting and deformation, in particular for Barsotti–Tate groups ("p-divisible groups"), has given rise to an abundant literature; cf. for example [LT66, Ta67, Gr74, Me72, La75, Fo77, Il85, Br00]. In particular, the results of the present Exposé are largely taken up again in Chapter I of [Fo77].

[^N.D.E-VII\_B-2]: N.D.E.: The editors have found only such a seminar dated 1965/66, entitled "Linear algebraic groups", in which the notion of formal group does not appear; see instead [De72].

[^N.D.E-VII\_B-3]: N.D.E.: (when endowed with the  $\mathfrak{m}$ -adic topology).

[^N.D.E-VII\_B-4]: N.D.E.: Indeed, if  $x \notin I$ , there exists an open ideal  $\mathcal{I}$  such that  $(x + \mathcal{I}) \cap I = \emptyset$ , and then  $I + \mathcal{I}$  is an open ideal not containing  $x$ . On the other hand, in what follows, we have made explicit the fact that every "closed maximal" ideal is maximal and open.

[^N.D.E-VII\_B-5]: N.D.E.: We note that  $A_{\mathfrak{m}}$  is the localization of  $A$  at the maximal ideal  $\mathfrak{m}$ . Indeed, the unit element  $e_{\mathfrak{m}}$  of  $A_{\mathfrak{m}}$  is an idempotent of  $A$  not belonging to  $\mathfrak{m}$ , and since  $A = A_{\mathfrak{m}} \times B$ , where  $B = A(1 - e_{\mathfrak{m}})$ , then  $A_{\mathfrak{m}}$  is identified with the localization  $A_{e_{\mathfrak{m}}}$  and thus also with the localization  $S^{-1}A$ , where  $S = A - \mathfrak{m}$ . On the other hand, since  $e_{\mathfrak{m}}(1 - e_{\mathfrak{m}}) = 0$ , then  $\mathfrak{m}$  contains  $1 - e_{\mathfrak{m}}$  and hence also  $B$ , and so  $A_{\mathfrak{m}}$  is identified with  $A_{\mathfrak{m}} \times B$ .

[^N.D.E-VII\_B-6]: N.D.E.: Indeed, let  $x \in r(A)$ ; if  $\mathfrak{m}$  is a maximal ideal not containing  $x$ , there exists  $y \in A$  such that  $1 - xy \in \mathfrak{m}$ , and since  $xy \in r(A)$ ,  $1 - xy$  is invertible, whence a contradiction. We note the following consequence: if  $\text{Upsilon}(A)$  is a finite set  $\{\mathfrak{m}_1, \dots, \mathfrak{m}_r\}$ , the  $\mathfrak{m}_i$  are all the maximal ideals of  $A$ .

[^N.D.E-VII\_B-7]: N.D.E.: We have added these remarks, in order to be able to compare the definition of the formal spectrum  $\text{Spf}(A)$  given in 1.1 with those of (EGA I, 10.1.2) and (EGA I, 10.4.2).

[^N.D.E-VII\_B-8]: N.D.E.: We have brought out the results of this paragraph in the proposition that follows, and have indicated below the steps of the proof; cf. [CA], § IV.3 or [DG70], § V.2.

[^N.D.E-VII\_B-9]: N.D.E.: cf. [Gr57], I § 1.5 and Prop. 1.8; one may also consult, for example, [Po73], § 2.8 or [We95], Append. A.4.

[^N.D.E-VII\_B-10]: N.D.E.: We have inserted into this paragraph Proposition 0.2.E and Corollary 0.2.F, which will be useful in 0.2.2. (In the original, these results appeared in 0.3.)

[^N.D.E-VII\_B-11]: N.D.E.: Indeed,  $\text{PC}(A)$  has a set of artinian cogenerators, filtered inverse limits in it are exact, and  $\text{LF}(A)$  is the subcategory of artinian objects. The dual category  $\text{PC}(A)^{\circ}$  therefore has a set of noetherian generators, and filtered direct limits in it are exact. By the proof of [CA] § II.4, th. 1, the functor  $\text{Hom}_{\text{PC}(A)}(M, -)$  is an anti-equivalence of  $\text{PC}(A)$  with  $\text{Lex}(\text{LF}(A), (\text{Ab}))$ . Likewise, Lemma 4 and Cor. 1 of \*loc. cit.\* state results "dual" to those of Corollary 0.2.F. For a "direct" proof, see [DG70], § V.2, th. 3.1, Lemma 3.5, Cor. 3.3 & 3.4.

[^N.D.E-VII\_B-12]: N.D.E.: As every infinite product is a filtered inverse limit of finite products, every additive functor that commutes with filtered inverse limits also commutes with infinite products.

[^N.D.E-VII\_B-13]: N.D.E.: This refers to the "dual" statements established in \*loc. cit.\*, § 2, Th. 2 and § 1, Prop. 2; for a "direct" proof, see [DG70], V, § 2, Th. 4.5 and Example 4.6 b).

[^N.D.E-VII\_B-14]: N.D.E.: We have detailed the results of this paragraph, which play an important role in what follows (cf. 1.2.3, 1.3.5, 2.2.1, etc.).

[^N.D.E-VII\_B-15]: N.D.E.: Recall on the other hand that, over an artinian ring, a module is projective if and only if it is flat; see for example (VI\_B, N.D.E. (54)) or 0.3.7 below.

[^N.D.E-VII\_B-16]: N.D.E.: One will note that the direct sum in  $\mathcal{P}(k)$  of a family  $(V_i)_{i \in I}$  of linearly compact  $k$ -vector spaces is  $(\prod_{i \in I} V_i)^*$ .

[^N.D.E-VII\_B-17]: N.D.E.: We have modified this paragraph, taking into account the additions made in 0.2.

[^N.D.E-VII\_B-18]: N.D.E.: We have added this corollary.

[^N.D.E-VII\_B-19]: N.D.E.: We have added this remark.

[^N.D.E-VII\_B-20]: N.D.E.: Up to replacing  $\mathfrak{a}$  by its closure, one can assume  $\mathfrak{a}$  closed.

[^N.D.E-VII\_B-21]: N.D.E.: since equal to the inverse limit of the  $M/M' = 0$ .

[^N.D.E-VII\_B-22]: N.D.E.: Consequently, every pseudocompact  $A$ -module is a quotient of a topologically free  $A$ -module (one first reduces to the case where  $A$  is local), cf. the proof of 0.3.7.

[^N.D.E-VII\_B-23]: N.D.E.: We have corrected  $N/\mathfrak{m}$   $N$  to  $N / \overline{\mathfrak{m}}$   $N$ , and likewise for  $M/\mathfrak{m}$   $M$  below.

[^N.D.E-VII\_B-24]: N.D.E.: One thus recovers 0.3.1.1:  
 $L = L \hat{\otimes}_A A = L \hat{\otimes}_A \varinjlim \mathcal{L} (A/\mathcal{L}) \simeq \varinjlim \mathcal{L} L/\mathcal{L}$ ,  
 where  $\mathcal{L}$  ranges over the open ideals of  $A$ .

[^N.D.E-VII\_B-25]: N.D.E.: cf. N.D.E. (12).

[^N.D.E-VII\_B-26]: N.D.E.: We have added this remark, which will be useful in 2.3.1.

[^N.D.E-VII\_B-27]: N.D.E.: This shows the result announced in N.D.E. (22): every pseudocompact  $A$ -module  $M$  is a quotient of a topologically free  $A$ -module. (Since products are exact in  $\mathcal{P}(A)$ , one reduces to the case where  $A$  is local, treated above.)

[^N.D.E-VII\_B-28]: N.D.E.: A fully analogous proof, using "nilpotent Nakayama's Lemma", shows that if  $A$  is artinian and  $P$  is a flat  $A$ -module, then each local component of  $P$  is a free  $A$ -module (cf. [BAC], II § 3.2, cor. 2 of prop. 5).

[^N.D.E-VII\_B-29]: N.D.E.: We have added the following lemma, cf. N.D.E. (36) in Proposition 0.5.

[^N.D.E-VII\_B-30]: N.D.E.: We will see in 0.4.2 that it possesses arbitrary direct limits.

[^N.D.E-VII\_B-31]: N.D.E.: Caution:  $k$  is an object of  $\mathcal{A}/k$  only if  $k$  is artinian, cf. 1.2.2 below.

[^N.D.E-VII\_B-32]: N.D.E.: i.e., which commutes with finite inverse limits.

[^N.D.E-VII\_B-33]: N.D.E.: Indeed, every discrete  $k$ -module of length  $n$  is isomorphic to  $k^n / L$ , where  $L$  is an open submodule of  $k^n$  of colength  $n$ . One can then consider the set of (isomorphism classes of) profinite  $k$ -algebra structures on each such module.

[^N.D.E-VII\_B-34]: N.D.E.: If  $(A_i)_{i \in I}$  is a direct system in  $\mathcal{A}/k$ , its direct limit in  $\mathcal{A}/k$  is the separated completion of the  $k$ -algebra  $B$ , direct limit of the underlying  $k$ -algebras, for the topology defined by the ideals  $I$  such that  $I \cap A_i$  is an open ideal of  $A_i$  for every  $i$ , and  $\text{length}_k(B/I) < \infty$ . Note that if, for example,  $K/k$  is an algebraic extension of fields, of infinite degree, and if  $(k_i)$  denotes the filtered direct system of subextensions of finite degree, then the direct limit of the system  $(k_i)$  in  $\mathcal{A}/k$  is the zero ring!

[^N.D.E-VII\_B-35]: N.D.E.: We have detailed this paragraph.

[^N.D.E-VII\_B-36]: N.D.E.: Consequently, if  $\ell$  is a profinite  $k$ -algebra, the functor  $M \mapsto M \hat{\otimes}_\ell k$  is left adjoint to the restriction-of-scalars functor.

[^N.D.E-VII\_B-37]: N.D.E.: cf. Remarks 0.1.2.

[^N.D.E-VII\_B-38]: N.D.E.: We have added the numbering 1.2.A to 1.2.E, for later references.

[^N.D.E-VII\_B-39]: N.D.E.: We note that, by the definition of morphisms (1.1), every  $X \in \text{Ob } \mathcal{V}/k$  is the direct sum in  $\mathcal{V}/k$  of the pointwise formal varieties  $\text{Spf}(0_{X,x})$ , for  $x \in X$ .

[^N.D.E-VII\_B-40]: N.D.E.: In particular, cokernels exist in  $\mathcal{V}/k$ , see below. We note moreover that a filtered inverse limit in  $\mathcal{V}/k$ , all of whose transition morphisms are surjective, can be empty, cf. N.D.E. (34).

[^N.D.E-VII\_B-41]: N.D.E.: We note that  $\bigoplus_{x \in X} Z_x$  is the direct sum, for  $x \in X$ , of the formal varieties  $B_x \hat{\otimes}_{0_{X,x}} C_x$ , where  $B_x$  is the product of the  $0_{Y,y}$  for  $y \in Y$  such that  $f(y) = x$ , and  $C_x$  is defined analogously. This will be used in 2.5.1.

[^N.D.E-VII\_B-42]: N.D.E.: i.e., the quotient set of  $Y$  by the identifications  $d(x) = e(x)$ , for every  $x \in X$ , endowed with the quotient topology, which is here the discrete topology.

[^N.D.E-VII\_B-43]: N.D.E.: We have introduced this terminology, cf. N.D.E. (47) in 1.2.3.

[^N.D.E-VII\_B-44]: N.D.E.: and hence projective, since  $C$  is artinian.

[^N.D.E-VII\_B-45]: N.D.E.: We have added the lemma that follows and have introduced the numbering 1.2.3.A to 1.2.3.F, for later references.

[^N.D.E-VII\_B-46]: N.D.E.: In fact, we shall not use this second notation, see N.D.E. (47).

[^N.D.E-VII\_B-47]: N.D.E.: The editors do not understand the following definition if  $M^*$  is not assumed admissible, whence the addition of this hypothesis. On the other hand, we have written  $\Gamma^*(M^*)$  instead of  $M^{**\wedge}$ , in order to avoid confusions between  $M^*$ , the dual module of the functor  $M^*$ , and  $M^{**\wedge}$ , the dual functor of the module  $N$ , cf. N.D.E. (46). Finally, we have detailed the construction of  $\Gamma^*(M^*)$ .

[^N.D.E-VII\_B-48]: N.D.E.: We have added point (ii) below, as well as the proof that follows. The original stated: "If  $M^*$  is a flat  $0_k$ -module, it is clear that  $M^*$  is nothing other than the dual of  $M^{**\wedge}$ , so the functors  $N \mapsto M^{**\wedge}$  and  $M^* \mapsto M^{**\wedge}$  define an anti-equivalence..."

[^N.D.E-VII\_B-49]: N.D.E.: In this paragraph, we have modified the order, by first defining  $\hat{S}_k(E)$  and then stating that  $V^f_k(E)$  represents  $\hat{S}_k(E)$ .

[^N.D.E-VII\_B-50]: N.D.E.: For example, let  $k$  be a field,  $E$  a pseudocompact  $k$ -vector space,  $V = \text{Hom}_c(E, k)$ ; one has  $E \simeq V^*$  (cf. 0.2.2). For every finite-dimensional subspace  $W$  of  $V$ , let  $F(W)$  be the set of closed points of the  $k$ -scheme  $V(W) = \text{Spec } S_k(W^*)$ . Denote by  $F(V)$  the direct limit of the  $F(W)$ . Then  $\hat{S}_k(E)$  is the product, for  $x \in F(V)$ , of the pseudocompact  $k$ -algebras  $\hat{S}_k(E)_x = \varinjlim_W \hat{0}_{\{W, x\}}$ , where  $W$  ranges over the finite-dimensional subspaces of  $V$  such that  $x \in F(W)$ , and  $\hat{0}_{\{W, x\}}$  denotes the separated completion of the local ring  $0_{V(W), x}$  for the topology defined by the ideals of finite codimension (which here coincides with the  $\mathfrak{m}$ -adic topology). If  $k$  is algebraically closed and  $(v_i)_{i \in I}$  a basis of  $V$ , so that  $E$  possesses a pseudobasis  $(e_i)_{i \in I}$ , then each local component  $\hat{S}_k(E)_x$  is isomorphic to the ring of formal series  $k[[e_i, i \in I]]$ , endowed with the topology defined by the ideals of finite codimension.

[^N.D.E-VII\_B-51]: N.D.E.: We have detailed the rest of this paragraph.

[^N.D.E-VII\_B-52]: N.D.E.: We have added the following sentence.

[^N.D.E-VII\_B-53]: N.D.E.: We have amplified the following proposition by inserting in it the fact that the functor  $X \mapsto \hat{X}/\hat{S}$  commutes with finite inverse limits (in the original, this appeared in the proof of 1.3.4 – the proof given here is more direct than the original). Moreover, this result will be useful in Section 2 and in 3.3.1.

[^N.D.E-VII\_B-54]: N.D.E.: We have detailed the beginning of the proof.

[^N.D.E-VII\_B-55]: N.D.E.: We have added this remark.

[^N.D.E-VII\_B-56]: N.D.E.: i.e., in the opposite category  $\mathcal{A}^{\text{op}} = \mathcal{A}^{\text{op}}/k$ , the morphism  $g : B \rightarrow A$  corresponding to  $f$  is an effective epimorphism. This is the case, because  $g$  is surjective, hence induces (cf. the proof of 0.2.B) an isomorphism of profinite  $k$ -algebras  $B/I \xrightarrow{\sim} A$ , where  $I = \text{Ker } g$ . Consequently, every morphism  $\phi : B \rightarrow C$  of  $\mathcal{A}^{\text{op}}/k$  that is zero on  $I$  descends to a morphism  $\bar{\phi} : A \rightarrow C$  such that  $\phi = \bar{\phi} \circ g$ .

[^N.D.E-VII\_B-57]: N.D.E.: i.e., let  $k$  be a field,  $X = \text{Spf}(k[[T]])$  and  $Y = \text{Spf}(B)$ , where  $B$  is the  $k$ -subalgebra of  $A = k[[T]]$  generated topologically by  $T^3$  and  $T^4$  (i.e.,  $B$  is formed by the formal series  $\sum_{n \geq 0} a_n T^n$  such that  $a_n = 0$  for  $n = 1, 2, 5$ ). Then  $X \rightarrow Y$  is an epimorphism that is not effective; indeed, the cokernel of  $X \times_Y X \rightarrow X$  is  $\text{Spf}(B')$ , where  $B'$  is the subalgebra of  $A$  formed by the  $a$  such that  $a \cdot \hat{1} = 1 \cdot \hat{1} \cdot a$ , and  $B'$  contains  $T^5$ .

[^N.D.E-VII\_B-58]: N.D.E.: We have added this lemma, which explains the terminology "topologically flat".

[^N.D.E-VII\_B-59]: N.D.E.: We have detailed what follows; then we have taken advantage of the addition made in 1.2.6.

[^N.D.E-VII\_B-60]: N.D.E.: We have added the following lemma, used implicitly in the original; on the other hand, we have introduced the numbering 1.3.5.A to 1.3.5.D, for later references.

[^N.D.E-VII\_B-61]: N.D.E.: We have detailed what follows.

[^N.D.E-VII\_B-62]: N.D.E.: In Lemma 1.3.6.A that follows, we have detailed the proof of points (i) and (ii), and have added point (iii).

[^N.D.E-VII\_B-63]: N.D.E.: For example, let  $k_0$  be a field,  $k = k_0[[T]]/(T^n)$ , where  $n \geq 4$ ,  $H = k \oplus kx$ , with  $\epsilon(x) = 0$  and  $\Delta(x) = x \otimes \phi + \phi \otimes x + t \cdot x \otimes x$ , where  $t$  is the image of  $T$  in  $k$ . Then  $H_i = k \oplus t^{n-i}x$  for  $i = 0, \dots, n$ , but for  $2 \leq i \leq n-2$ ,  $\Delta(t^{n-i}x)$  does not belong to the image of  $H_i \otimes H_i$  in  $H \otimes H$ .

[^N.D.E-VII\_B-64]: N.D.E.: In this case, one says that the coalgebra  $H$  is *\*connected\**, cf. the addition 2.9.

[^N.D.E-VII\_B-65]: N.D.E.: This also holds without assuming  $H$  cocommutative ( $k$  remaining a commutative artinian ring): in this case, a basis of neighborhoods of  $0$  in  $A = H^*$  is given by the two-sided ideals  $J$  such that  $A/J$  is of finite length over  $k$ , and the preceding proof shows that  $H = \bigcup_n (I^n)^\perp$  if and only if the  $\phi^{-1}(\frac{m}{n})$  are the only open prime ideals of  $A$ .

[^N.D.E-VII\_B-66]: The following has been added; the original was limited to the case where  $k$  is artinian.

[^N.D.E-VII\_B-67]: One may therefore suppose  $k$  local.

[^N.D.E-VII\_B-68]: cf. Exp. V, § 2.b).

[^N.D.E-VII\_B-70]: The original continued thus: "A formal variety  $X$  over  $k$  is said to be étale if the diagonal morphism  $\Delta_X : X \rightarrow X \times X$  is a local isomorphism, that is, if  $\Delta_X$  induces an isomorphism of  $\mathcal{O}_{X \times X, \Delta_X(x)}$  onto  $\mathcal{O}_{X, x}$  for every point  $x$  of  $X$ . One sees easily with the aid of SGA I that this formulation is equivalent to the following two: the formal variety  $X$  is topologically flat, and, for every point  $x$  in  $X$ , of projection  $s$  in  $\text{Spf}(k)$ ,  $\mathcal{O}_{X, x} \otimes_k k(s)$  is a finite separable extension of the residue field  $k(s)$  of  $s$ ; or also, if  $A$  denotes the affine algebra of  $X$ , the local components (0.1) of  $\bigoplus_k (k/l)$  are finite étale algebras over  $k/l$ , for every open ideal  $l$  of  $k$ ." In what follows, we have rectified the omission of the flatness hypothesis in the first condition above, and detailed the equivalence of the said conditions.

[^N.D.E-VII\_B-71]: Let us point out in passing that the proof given in EGA 0\_{IV}, 19.3.5 (v) is erroneous.

[^N.D.E-VII\_B-72]: Note that  $\mathcal{V}^{\text{acute}}_t$  is stable under finite inverse limits.

[^N.D.E-VII\_B-74]: We have inserted this remark here, which in the original appeared in 2.5.2.

[^N.D.E-VII\_B-75]: This is the case for finite inverse limits.

[^N.D.E-VII\_B-76]: One will also say that  $A$  is a *\*cogroup\** in the category of profinite  $k$ -algebras. On the other hand, we have detailed what follows; in particular, we have made explicit what a morphism of formal groups  $K \rightarrow G$  is, cf. Proposition 2.3.1.

[^N.D.E-VII\_B-77]: One also says *\*bigèbre\** (cf. [BA]g, III § 11.4); recall (cf. VII\_A, 3.1, N.D.E. (26)) that all the "bialgebras" considered here are assumed cocommutative and equipped with an antipode, i.e., they are in fact cocommutative Hopf algebras.

[^N.D.E-VII\_B-78]: Since  $\Delta(x) = x \otimes x$  one has  $x = \epsilon(x)x$ , hence  $\epsilon(x) = 0$  can occur only if  $x = 0$ .

[^N.D.E-VII\_B-79]: We have detailed the original in what follows.

[^N.D.E-VII\_B-80]: We have added the adjective "covariant" to make it visible that the functor  $G \mapsto H(G)$  is covariant; this terminology is used in [Di73], I § 2.14.

[^N.D.E-VII\_B-81]: Recall that in this Exposé, "bialgebra" means "cocommutative Hopf algebra".

[^N.D.E-VII\_B-82]: We have introduced here the notation  $H^{\text{cocom}}_{\text{flat}/k}$ , which will be useful below.

[^N.D.E-VII\_B-83]: We have detailed the original in what follows, in order to introduce the notations  $D'(G)$  and  $D(K)$ , cf. [Ca62], § 14.

[^N.D.E-VII\_B-84]: If one denotes by  $\mathcal{FC}^f_k$  (resp.  $\mathcal{AC}^f_k$ ) the full subcategory of  $\mathcal{FC}_k$  (resp.  $\mathcal{AC}_k$ ) formed by the objects  $G$  (resp.  $T$ ) such that  $H(G)$  (resp.  $0(T)$ ) is a finite  $k$ -module (and hence finite locally free), then  $\mathcal{FC}^f_k$  and  $\mathcal{AC}^f_k$  both have the same objects as the category  $\mathcal{C}$  of commutative and cocommutative Hopf  $k$ -algebras, finite and flat over  $k$ , the correspondence  $G \mapsto H(G)$  (resp.  $T \mapsto 0(T)$ ) being covariant (resp. contravariant), and one thus recovers the "Cartier duality" of the category  $\mathcal{AC}_k$ , already seen in VII\_A, 3.3.1.

[^N.D.E-VII\_B-85]: That is, not necessarily topologically flat over  $k$ .

[^N.D.E-VII\_B-86]: We have modified the order of the sentences in what follows.

[^N.D.E-VII\_B-88]: We have added the preceding sentence, and in what follows we have denoted  $W(U) \times$  instead of  $U_m$ . Recall on the other hand (cf. 1.2.1) that one calls " $k$ -functor" a covariant functor  $\text{Alf}_{/k} \rightarrow (\text{Ens})$ .

[^N.D.E-VII\_B-89]: The original indicated: "(this) follows from the functorial character of  $\psi_A$ ". We have detailed this in what follows.

[^N.D.E-VII\_B-90]: We have detailed the original in what follows.

[^N.D.E-VII\_B-91]: We have made this corollary explicit, since it is used, for example, in 5.2.1/5.2.3.

[^N.D.E-VII\_B-93]: cf. IV, 5.2.6.

[^N.D.E-VII\_B-94]: See also the remarks following VI\_A, 5.4.3.

[^N.D.E-VII\_B-95]: Note that if  $[\kappa_s] : \kappa = \infty$ ,  $\kappa_s$  is not a profinite  $\kappa$ -algebra, so the preceding notation is an abuse of notation. On the other hand, we have detailed the original in what follows.

[^N.D.E-VII\_B-96]: We have added this remark.

[^N.D.E-VII\_B-97]: We have detailed the original in what follows.

[^N.D.E-VII\_B-98]: We have added the following sentence.

[^N.D.E-VII\_B-99]: We have detailed what follows.

[^N.D.E-VII\_B-100]: The same argument shows also that, for an arbitrary field  $k$ , if all the residue fields of  $G$  equal  $k$ , then  $G_e$  is the constant  $k$ -group  $(M)_k$ , where  $M = G(k) = \text{Spf}^* H(G)$ , and  $H(G)$  is the semi-direct product of  $H(G^{\{0\}})$  by the group algebra  $kM$ , cf. the addition 2.9 further below.

[^N.D.E-VII\_B-101]: We have added this remark.

[^N.D.E-VII\_B-102]:  $\alpha_{p,k}$ ,  $(\mathbb{Z}/p\mathbb{Z})_k$  and  $G_{\lambda}$  are also  $k$ -algebraic groups, finite and flat over  $k$ , cf. N.D.E. (84) in 2.2.2.

[^N.D.E-VII\_B-104]: This coincides with the "usual" notion of unipotent  $k$ -group scheme, cf. the addition 2.8 at the end of Section 2.

[^N.D.E-VII\_B-105]: The original indicated: "let us say that a commutative  $k$ -group scheme is of multiplicative type if it is isomorphic to  $\operatorname{Spec} H(G)$ , where  $G$  is an étale commutative  $k$ -formal group." We have given here the "usual" definition, drawn from Exp. IX, 1.1, and we have shown its equivalence with the preceding condition; see also [DG70], § IV.1, Th. 2.2.

[^N.D.E-VII\_B-106]: We have added point (iii), a consequence of Proposition 2.5.

[^N.D.E-VII\_B-107]: Indeed,  $\delta \circ f = \epsilon_A$  entails  $f(1) = 1 + \lambda d$ , with  $\lambda \in k$ , and then  $f(1) = f(1)^2 = 1 + 2\lambda d$  gives  $\lambda = 0$ .

[^N.D.E-VII\_B-108]: Comparing with VII\_A 2.5, one sees that if  $K$  is a  $k$ -group scheme of finite type and if  $G$  is the formal completion of  $K$  at the origin (i.e.,  $\mathcal{A}(G)$  is the completion of the local ring  $\mathcal{O}_{K,e}$  for the  $m$ -adic topology, where  $m$  is the kernel of the augmentation  $\epsilon : \mathcal{O}_{K,e} \rightarrow k$ ), then  $H(G)$  is identified with the algebra of distributions  $U(K)$ , and  $\operatorname{Lie}(G)$  with  $\operatorname{Lie}(K)$ . (The condition that  $K$  be of finite type over  $k$  is used to ensure that  $m/m^2$  is a  $k$ -module of finite length, hence discrete, so that its topological dual coincides with its ordinary dual.) In particular, when  $G$  is a finite  $k$ -formal group (i.e., such that  $\mathcal{A}(G)$  is a finite  $k$ -module), in which case  $G$  may also be considered as the  $k$ -group scheme  $\operatorname{Spec} \mathcal{A}(G)$ , the two definitions of  $\operatorname{Lie}(G)$  coincide.

[^N.D.E-VII\_B-109]: We have detailed the original in what follows.

[^N.D.E-VII\_B-110]: We have highlighted points (i) and (ii), and added point (iii), which will be useful in 2.6.3 and 3.3.2.

[^N.D.E-VII\_B-111]: We have modified what follows, taking advantage of the addition made in 2.6.2.

[^N.D.E-VII\_B-112]: Here and in what follows, we have written "monoid" instead of "monoid with unit element" (recall that a monoid is by definition a set endowed with an associative composition law and possessing a unit element).

[^N.D.E-VII\_B-113]: By the equivalence of categories 1.3.5.D, a monoid in the category of topologically flat  $k$ -formal varieties "is the same thing" as a monoid in the category of cocommutative flat  $\mathcal{O}_k$ -coalgebras, i.e., a cocommutative  $\mathcal{O}_k$ -bialgebra (in the usual sense, i.e., not necessarily equipped with an antipode). Moreover, by 1.3.6, the hypothesis that  $M$  be infinitesimal is equivalent to saying that the corresponding bialgebra is connected. So, if  $k$  is an artinian ring, the proposition is equivalent to saying that: every cocommutative connected  $k$ -bialgebra, flat over  $k$ , is a  $k$ -Hopf algebra, i.e., possesses an antipode (and the cocommutativity hypothesis is in fact superfluous, cf. the proof).

[^N.D.E-VII\_B-114]: The original continued thus: "one shows then easily, by induction on  $n$ , that there exists one and only one linear map  $c_n : U_n \rightarrow U_n$  such that the composite map  $m_U \circ (c_n \otimes \operatorname{id}_U) \circ \Delta_U : U_n \rightarrow U$  be zero"; we have detailed the proof, which rests on that of Lemma 1.3.6.A.

[^N.D.E-VII\_B-116]: Recall that a two-sided ideal  $P$  of a ring  $A$  is called *prime* if in  $A/P$  the product of two nonzero two-sided ideals is nonzero.

[^N.D.E-VII\_B-117]: This is also equivalent to saying that  $k \cdot 1_{\mathcal{O}(G)}$  is the unique simple  $k$ -subcoalgebra of  $\mathcal{O}(G)$ ; see for example [Ab80], 3.1.4. Let us point out in passing a misprint in loc. cit., p. 130, line 4:  $M \simeq C^*/\operatorname{ann} M$  is to be replaced by  $C^*/\operatorname{ann} M \simeq \operatorname{End}_k(M)$ .

[^N.D.E-VII\_B-119]: If  $x, x' \in rU$  commute, one has therefore  $\exp_U(x + x') = (\exp_U x)(\exp_U x')$ .

[^N.D.E-VII\_B-120]: That is, for every morphism  $\phi : U \rightarrow V$  of  $C$ -algebras, one has  $\phi(\exp_U(x)) = \exp_V(\phi(x))$ .

[^N.D.E-VII\_B-121]: We have detailed what precedes and added the following sentence.

[^N.D.E-VII\_B-122]: We have added the condition  $\epsilon_U(z) = 1$ , omitted in the original.

[^N.D.E-VII\_B-123]: We have added point (ii), an immediate consequence of 3.1.

[^N.D.E-VII\_B-124]: We have corrected the formula given, which was erroneous, and added the reference [BLie].

[^N.D.E-VII\_B-125]: We have removed the hypothesis that  $k$  be local (the proof reduces to this case).

[^N.D.E-VII\_B-126]: cf. 5.1.5 further below; see also [BAC], III, § 2.8, Th. 1 and corollaries. On the other hand, we

have detailed the original in what follows.

[^N.D.E-VII\_B-127]: We have detailed the original in what follows.

[^N.D.E-VII\_B-128]: We do not know a priori that  $\Omega$  is a projective pseudocompact  $k$ -module, but this will follow from what follows: compare with the proof of (iv)  $\Rightarrow$  (iii) in VII\_A, 7.4.

[^N.D.E-VII\_B-C-11]: N.D.E.: We have added the flatness hypothesis, omitted in the original.

[^N.D.E-VII\_B-C-12]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VII\_B-C-13]: N.D.E.: Since, by 2.7, 2.2.1 and 1.3.6, an infinitesimal  $k$ -formal group  $G$  is "the same thing" as a connected cocommutative  $k$ -bialgebra  $H$  (cf. 2.9), this statement is equivalent to the theorem below, obtained independently by Kostant (cf. 2.9.2). This theorem had been obtained earlier by J. W. Milnor and J. C. Moore ([MM65]), under the additional hypothesis that  $H$  is generated as an algebra by its primitive elements (although published in 1965, this text had circulated before 1960, cf. the review [Ja65]), so that it is often called the "Cartier–Kostant–Milnor–Moore theorem".

**\*\*Theorem (Cartier–Kostant–Milnor–Moore).\*\*** \*Let  $k$  be a field of characteristic 0. The functors  $L \mapsto U(L)$  and  $H \mapsto \text{Prim}(H)$  define an equivalence between the category of  $k$ -Lie algebras and that of connected cocommutative  $k$ -bialgebras.\*

On the other hand, if  $k$  is an artinian ring containing  $\mathbb{Q}$ , then 3.2 (ii) and 3.3 (combined with 2.7, 2.2.1 and 1.3.6) similarly show that the functor  $L \mapsto G(L)$  (resp.  $L \mapsto U(L)$ ) is an equivalence of the category of flat  $k$ -Lie algebras onto that of infinitesimal  $k$ -formal groups topologically flat (resp. onto that of connected cocommutative  $k$ -bialgebras that are flat).

[^N.D.E-VII\_B-C-14]: N.D.E.: The original stated: "This  $k$ -functor is manifestly left exact ( $H$  is topologically flat over  $k$ )". We have detailed this in what follows.

[^N.D.E-VII\_B-C-15]: N.D.E.: In particular, when  $\bar{k} = k$ , one thus recovers the "Cartier–Gabriel–Kostant theorem" mentioned in 2.9.2.

[^N.D.E-VII\_B-C-16]: N.D.E.: We have corrected the original, which gave the inclusion  $\widehat{X}/\widehat{S}^{(p)} \subset \widehat{X}^{(p)}/\widehat{S}$  instead of the opposite inclusion. Let us point out moreover that this paragraph is not used in the sequel.

[^N.D.E-VII\_B-C-17]: N.D.E.: We have detailed what follows.

[^N.D.E-VII\_B-C-18]: N.D.E.: The proof is identical to that of 2.6.3.

[^N.D.E-VII\_B-C-19]: N.D.E.: We have added the hypothesis that  $k$  be local, so that every topologically flat pseudocompact  $k$ -module be topologically free; cf. the proof.

[^N.D.E-VII\_B-C-20]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VII\_B-C-21]: N.D.E.: We have added this remark, used in 4.4.2.

[^N.D.E-VII\_B-C-22]: N.D.E.: If  $k$  is an artinian ring of characteristic  $p > 0$ , the same proof gives an equivalence between the category of  $p$ -Lie algebras that are flat over  $k$  and that of  $k$ -formal groups of height  $\leqslant 1$ , topologically flat over  $k$ .

[^N.D.E-VII\_B-C-23]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VII\_B-C-24]: N.D.E.: We have added subsection 5.0, in order to express in the language of cocommutative Hopf algebras the proposition 5.1 that follows, and to cite the results obtained since in this direction.

[^N.D.E-VII\_B-C-25]: N.D.E.: In the original, it is supposed in 5.1 that  $k$  is a field. In fact, this hypothesis can be replaced by flatness hypotheses; we have modified accordingly nos. 5.1 to 5.1.5.

[^N.D.E-VII\_B-C-26]: N.D.E.: We have replaced "left" by "right" and have modified the statement of Proposition 5.1, in order to bring out more clearly, on the one hand, the equivalent conditions (i), (ii), and, on the other hand, the conclusion  $\text{Spf}(B) \simeq G/H$ .

[^N.D.E-VII\_B-C-27]: N.D.E.: Note that if  $(A', J')$  is a second cogroup of  $C$ , corresponding to a pair

$\mathcal{H}' \subset \mathcal{G}$  of  $k$ -formal groups, then to give a morphism of cogroups  $(A', J') \rightarrow (A, J)$  amounts to giving a morphism of  $k$ -formal groups  $G \rightarrow G'$  that sends  $\mathcal{H}$  into  $\mathcal{H}'$ .

[^N.D.E-VII\_B-C-28]: N.D.E.: We have replaced "direct sum" by "coproduct".

[^N.D.E-VII\_B-C-29]: N.D.E.: In the original, the lemma is stated when  $k$  is a field, the proof in this case being left to the reader.

[^N.D.E-VII\_B-C-30]: N.D.E.: To a pair  $\mathcal{H} \subset \mathcal{G}$  of  $k$ -formal groups, one therefore associates the "formal completion  $\hat{\mathcal{G}}_{\mathcal{H}}$  of  $\mathcal{G}$  along  $\mathcal{H}$ ", which is a  $k$ -formal group; moreover, one shall see in 5.1.3–5.1.4 that the inclusion  $\sigma : \mathcal{H} \hookrightarrow \hat{\mathcal{G}}_{\mathcal{H}}$  admits a retraction  $\pi : \hat{\mathcal{G}}_{\mathcal{H}} \rightarrow \mathcal{H}$  and that the  $k$ -formal group  $N = \text{Ker}(\pi)$  is identified, as a formal variety, with the completion of the homogeneous space  $G/H$  along the unit section. This will be useful in 5.2.2.

[^N.D.E-VII\_B-C-31]: N.D.E.: Let  $G, H$  and  $\hat{\mathcal{G}}_{\mathcal{H}}$  be the  $k$ -formal groups corresponding to  $A, A_0 = A/J$  and  $\text{Gr}_J(A)$ ; then  $\tau : A_0 \hookrightarrow \text{Gr}_J(A)$  corresponds to a retraction  $\pi : \hat{\mathcal{G}}_{\mathcal{H}} \rightarrow \mathcal{H}$  of the inclusion  $\mathcal{H} \hookrightarrow \hat{\mathcal{G}}_{\mathcal{H}}$ , and what precedes means that  $\hat{\mathcal{G}}_{\mathcal{H}}$  is the semi-direct product of  $N = \text{Ker}(\pi)$  by  $\mathcal{H}$ .

[^N.D.E-VII\_B-C-32]: N.D.E.: We have detailed the original in what follows, and we have put at the end the "supplement"  $I^{\{n\}}_B = B \cap J^{\{n\}}$  (which is not necessary to establish Proposition 5.1).

[^N.D.E-VII\_B-C-33]: N.D.E.: With the notations of N.D.E. [^N.D.E-VII\_B-C-31], this entails that the formal completion of  $G/H$  along the unit section (which has  $\prod_n B_n$  as affine algebra) is isomorphic, as a formal variety, to the  $k$ -formal group  $N$ .

[^N.D.E-VII\_B-C-34]: N.D.E.: The original stated only point (ii); for the reader's convenience, we have stated in (i) Lemma 1 of [CA], § V.7.

[^N.D.E-VII\_B-C-35]: N.D.E.: In the original, the author uses "linearly compact vector space", which is equivalent to "pseudocompact vector space" (cf. [BAC], § III.2, Exercises 15 a), 19 a), and 20 d)). We have preferred to keep the terminology "pseudocompact" used so far.

[^N.D.E-VII\_B-C-36]: N.D.E.: On the one hand, we have replaced  $\mathcal{H} \backslash G$  by  $G/H$ , and likewise in the proof; on the other hand, we have added condition (iii).

[^N.D.E-VII\_B-C-37]: N.D.E.: We have added paragraphs 5.2.1.A and 5.2.1.B.

[^N.D.E-VII\_B-C-38]: N.D.E.: This paragraph is the fruit of discussions with J.-M. Fontaine and E. Bouscaren; in particular Bouscaren indicated to us the proof that follows.

[^N.D.E-VII\_B-C-39]: N.D.E.: We return here to the original, which we have shortened taking account of the preceding additions.

[^N.D.E-VII\_B-C-40]: N.D.E.: We have added what follows.

[^N.D.E-VII\_B-C-41]: N.D.E.: As indicated in the original, this also follows from Proposition 5.1, but we have preferred to indicate the argument above, which does not use the implication (i)  $\Rightarrow$  (ii) of loc. cit.

[^N.D.E-VII\_B-C-42]: N.D.E.: Since  $k$  is perfect, one can identify  $\mathbb{F}_p^{\{p\}} V$  with the abelian group  $V$  on which  $k$  acts by  $\lambda \cdot v = \lambda^{1/p} v$ .

[^N.D.E-VII\_B-C-43]: N.D.E.: We have added this remark, used in 5.2.5.

[^N.D.E-VII\_B-C-44]: N.D.E.: Indeed,  $B'$  (resp.  $B$ ) is the inverse limit of the  $B'_r$  (resp.  $B_r$ ). On the other hand, we have modified the original in what follows, taking account of the addition made in 5.2.3.

[^N.D.E-VII\_B-C-45]: N.D.E.: We have detailed the original in what follows.

[^N.D.E-VII\_B-C-46]: N.D.E.: We have added this number, in order to define the infinite tensor products used in 5.3 (a).

[^N.D.E-VII\_B-C-47]: N.D.E.: The author no doubt had in mind a tensor product  $**A** = \hat{\otimes}_{\{c\}_n \in \mathbb{N}^{\{*\}}} k[[\omega'_{\{n\}}]] / ((x^{p^{\{n\}}}))_{x \in \omega'_{\{n\}}}$ , where the  $\omega'_{\{n\}}$  are arbitrary pseudocompact  $k$ -vector spaces. In this case, one sees without difficulty that  $\omega = \omega_{**A**/k}$  is identified with the product of the  $\omega'_{\{n\}}$ , and the filtration

$\omega_n$  is given by  $\omega_n = \prod_{i=1}^n \omega_i$ , i.e., one is in case 5.2.1.B. For this reason, it would be preferable to name these algebras *stable* (rather than "stationary"), cf. [Di73], II § 2.9, p. 75. If for example  $\dim \omega_n = 1$  for every  $n \in \mathbb{N}$ , then  $A$  represents the functor that to every  $C \in \mathbf{Alg}/k$  associates the set of sequences  $(x_n)_{n \in \mathbb{N}}$  of elements of  $C$  such that  $x^{p^n}_n = 0$ , and  $x_n = 0$  for  $n$  large enough. Let us note finally that this case (i.e., the case where  $\omega = \prod_{n \in \mathbb{N}} \omega_n$ ) corresponds to the case studied, in the dual situation of connected cocommutative Hopf algebras, by M. E. Sweedler, cf. [Sw67], Th. 3.

[^N.D.E-VII\_B-C-48]: N.D.E.: But such an inverse limit is not necessarily a stable profinite  $k$ -algebra (in the sense of the previous N.D.E.). For example, let  $S$  be the "ordinary"  $k$ -vector space of sequences  $(u_1, u_2, \dots)$  of elements of  $k$  and let  $\omega = S^*$ ; then  $\omega$  is the direct sum in  $\mathbf{PC}(k)$  of copies  $k_n$  of  $k$ , for  $n \in \mathbb{N}$ , i.e., one is in case 5.2.1.A. If one denotes by  $x_n$  the element of  $\omega$  defined by  $x_n(u) = u_n$ , for every sequence  $u = (u_i)_i \in \mathbb{N}$ , then the  $k$ -algebra  $A = k[[\omega]] / ((x^{p^n}_n)_n)_{n \in \mathbb{N}}$  is such that  $\omega_{A/k} = \omega$  and  $\omega_n = \prod_{i=1}^n k x_i$ , but is not stable:  $\mathrm{Spf}(A)$  represents the functor that to every  $C \in \mathbf{Alg}/k$  associates the set of "infinite" sequences  $(x_n)_{n \in \mathbb{N}}$  of elements of  $C$  such that  $x^{p^n}_n = 0$  for every  $n \in \mathbb{N}$ .

[^N.D.E-VII\_B-C-49]: N.D.E.: The editors do not know either, outside the cases considered in 5.2.1.A and B.

[^N.D.E-VII\_B-C-50]: N.D.E.: See also [DG70], § III.3, Th. 6.1.

[^N.D.E-VII\_B-C-51]: N.D.E.: We have added this subsection, in order to give some consequences of 5.4, mentioned in Exposés III and VI\_A.

[^N.D.E-VII\_B-C-52]: N.D.E.: We have added to this reference, which appeared in the original, the references which follow.

# Exposé VIII. Diagonalizable groups

<!-- label: III.VIII -->

\*by A. Grothendieck\*

> Version 1.1 of 8 November 2009: additions in 1.2, 1.4, 1.7, 3.1, 3.4, 4.5.1, 6.4, 6.8 – 1.5.1 and section 7 to be > revised.[^VIII-0-0]

## 1. Biduality

<!-- original page 1 -->

Let  $C$  be a category, which we identify, as is usual, with a full subcategory of  $\hat{C} = \operatorname{Hom}(C^{\circ}, \mathbf{Ens})$  (cf. Exp. I). Let  $I$  be a commutative group functor, i.e. an object of  $\hat{C}$  endowed with a commutative group structure (cf. I, 2.1).[^N.D.E-VIII-1] For every  $X \in \operatorname{Ob}(\hat{C})$ , the object  $\operatorname{Hom}(X, I)$  carries a commutative group structure induced by that of  $I$ . For every group  $G$  in  $\hat{C}$ , let

$$D(G) = \operatorname{Hom}_{\mathbf{gr}}(G, I)$$

be the subobject of  $\operatorname{Hom}(G, I)$  defined, for every  $S \in \operatorname{Ob}(C)$ , by

$$D(G)(S) = \operatorname{Hom}_{\mathbf{S-gr.}}(G_S, I_S),$$

<!-- label: eq:III.VIII.1.0-star -->

where  $G_S = G \times S$  and  $I_S = I \times S$  are considered as  $S$ -groups, i.e. groups in  $\hat{C}/S$ . Then  $D(G)$  is a  $\hat{C}$ -subgroup of  $\operatorname{Hom}(G, I)$ . In this way one obtains a contravariant functor  $D$  from the category of  $\hat{C}$ -groups to the category of commutative  $\hat{C}$ -groups.

The right-hand side of  $(*)$  can also be interpreted as the subset of  $\text{Hom}(G \times S, I)$  consisting of morphisms  $G \times S \rightarrow I$  which are "multiplicative with respect to the first argument  $G$ ". Moreover, the preceding formulas remain valid more generally when  $S$  is an arbitrary object of  $\mathcal{C}$ , not necessarily coming from  $C$ .

If we now take for  $S$  a group in  $\mathcal{C}$ , which we shall denote  $G'$ , then in the left-hand side  $\text{Hom}(G', D(G))$  of  $(*)$  we can single out the subset  $\text{Hom}_{\text{gr}}(G', D(G))$  consisting of morphisms that respect the group structures of  $G'$  and  $D(G)$ .

<!-- original page 2 -->

It then corresponds to the subset of  $\text{Hom}(G \times G', I)$  consisting of morphisms that are multiplicative with respect to the first and with respect to the second argument – which one may call *bilinear* morphisms from  $G \times G'$  to  $I$ , or *pairings* of  $G$  and  $G'$  with values in  $I$ . One thus finds

```

$$\text{Hom}_{\text{gr}}(G', D(G)) \cong \text{Hom}_{\text{bil}}(G \times G', I),$$

```

<!-- label: eq:III.VIII.1.0-doublestar -->

which is an isomorphism functorial in the pair  $(G, G')$ . Since the right-hand side is symmetric in  $G$  and  $G'$ , one deduces a functorial bijection

```

$$\text{Hom}_{\text{gr}}(G', D(G)) \cong \text{Hom}_{\text{gr}}(G, D(G')).$$

```

<!-- label: eq:III.VIII.1.0-triplestar -->

In other words, "it amounts to the same thing" to give a group homomorphism  $G' \rightarrow D(G)$  or a group homomorphism  $G \rightarrow D(G')$ , both reducing in effect to the datum of a pairing  $G \times G' \rightarrow I$ .

Applying this to the case  $G' = D(G)$  and to the identity homomorphism  $G' \rightarrow D(G)$ , one finds a canonical homomorphism

```

$$G \rightarrow D(D(G)).$$

```

<!-- label: eq:III.VIII.1.0-quadstar -->

**Definition 1.0.** [N.D.E-VIII-2] We say that  $G$  is *reflexive* (relative to  $I$ ) if the preceding homomorphism is an isomorphism. We note that this implies that  $G$  is commutative.

<!-- label: III.VIII.1.0 -->

One thus sees that:

**Proposition 1.0.1.** The functor  $D$  induces an anti-equivalence of the category of reflexive  $\mathcal{C}$ -groups with itself.

<!-- label: III.VIII.1.0.1 -->

In particular, if  $G, H$  are two reflexive groups,  $D$  induces an isomorphism

```

$$\text{Hom}_{\text{gr}}(G, H) \cong \text{Hom}_{\text{gr}}(D(H), D(G))$$

```

(it even suffices that  $H$  be reflexive, as one sees from formula  $(**)$ ).

<!-- original page 3 -->

**Definition 1.0.2.** As usual, we shall then say that a  $C$ -group  $G$  is *reflexive* if it is reflexive as a  $\mathcal{C}$ -group (without worrying whether  $D(G)$  is representable or not).

<!-- label: III.VIII.1.0.2 -->

One thus obtains, by  $D$ , an anti-equivalence of the category of reflexive  $C$ -groups  $G$  such that  $D(G)$  is representable, with itself.

**Remark 1.0.3.** \*To conclude these generalities, let us point out that the formation of duals  $D(G)$  commutes with base extension, which therefore transforms reflexive groups into reflexive groups.\*

<!-- label: III.VIII.1.0.3 -->

We shall be interested henceforth in the case where  $C = (\text{Sch})/S$ , the category of preschemes over  $S$ , and  $I = G_{\{m,S\}}$ , the "multiplicative group over  $S$ " (cf. Exp. I). For every ordinary group  $M$ , we consider the  $S$ -group  ${}_M S$ . One sees at once that for every prescheme in groups  $J$  over  $S$ , there is a canonical isomorphism (functorial in  $M$  and  $J$ , and compatible with base extension):

```
```text
Hom_{S-gr.}(M_S, J) = Hom_{gr.}(M, J(S)).
```

Applying this to $J = I = G_{\{m,S\}}$ and to a variable S' over S , one finds a functorial isomorphism:

```
$$
(1.0.4) \quad D(M_{\{S\}})(S') \xrightarrow{\sim} \operatorname{Hom}_{\{gr.\}}(M, G_{\{m\}}(S')).
$$
```

<!-- label: eq:III.VIII.1.0.4 -->

One thus recovers the functor already considered in I, 4.4, also denoted $D_{\{S\}}(M)$, which is representable for M commutative, since

```
```text
D_{\{S\}}(M) = D(M_S) = \operatorname{Spec} 0_S(M),
```

where  $0_{\{S\}}(M)$  denotes the algebra of the group  $M$  with coefficients in  ${}_0 S$ . (Let us note moreover, in the general case, that  $D(M)$  does not change if one replaces  $M$  by its abelianization, so that no information is lost by assuming  $M$  commutative.)

**Definition 1.1.** \*A prescheme in groups  $G$  over  $S$  is said to be diagonalizable if it is isomorphic to a scheme of the form  $D_{\{S\}}(M) = D(M_{\{S\}}) = \operatorname{Hom}_{\{S-gr.\}}(M_{\{S\}}, G_{\{m\}})$  for some suitable commutative group  $M$ .\*

<!-- label: III.VIII.1.1 -->

<!-- original page 4 -->

We say that  $G$  is locally diagonalizable if every point of  $S$  admits an open neighborhood  $U$  such that  $G|_U$  is diagonalizable.\*

**Theorem 1.2.** \*Let  $\Gamma$  be a constant commutative group scheme over  $S$ , i.e. isomorphic to a group scheme of the form  ${}_M S$ , where  $M$  is an ordinary commutative group. Then  $\Gamma$  is reflexive, i.e. the canonical homomorphism\*

<!-- label: III.VIII.1.2 -->

```
$$
\Gamma \rightarrow D(D(\Gamma))
$$
```

is an isomorphism.\*<sup>[N.D.E-VIII-3]</sup> \*The diagonalizable group  $D(M_{\{S\}})$  is therefore also reflexive.\*

Taking the definitions into account, this follows from the following statement (which one will apply to a prescheme  $S'$  over  $S$ ):

**Corollary 1.3.** \*Let  $G = D(M_{\{S\}})$ . Then every homomorphism of  $S$ -groups\*

<!-- label: III.VIII.1.3 -->

\$\$  
 $u : G \rightarrow G_{\{m,S\}}$   
 \$\$

\*is defined by a uniquely determined section of  $\mathcal{M}_S$  over  $S$ , i.e. by a uniquely determined locally constant map from  $S$  to  $M$ .\*

\*Proof.\* Since by definition

\$\$  
 $G_{\{m,S\}} = GL(1)_S = \text{Aut}_{\{0_S\}\text{-mod.}}(\mathcal{O}_S),$   
 \$\$

one sees that giving a group homomorphism  $G \rightarrow G_{\{m,S\}}$  is equivalent to giving on  $\mathcal{O}_S$  a structure of  $G$ - $\mathcal{O}_S$ -module compatible with the natural  $\mathcal{O}_S$ -module structure on  $\mathcal{O}_S$  (cf. I, 4.7). By I, 4.7.3, this also amounts to giving an  $M$ -grading on  $\mathcal{O}_S$ , i.e. a decomposition of  $\mathcal{O}_S$  as a direct sum of modules  $\mathcal{L}_m$  ( $m \in M$ ).

<!-- original page 5 -->

Now it is well known that a direct factor of a locally free module of finite type is locally free of finite type; therefore each  $\mathcal{L}_m$  is, in a neighborhood of each point of  $S$ , either zero or free of rank 1, and in the latter case identical to  $\mathcal{O}_S$  in that neighborhood. Let  $S_m$  be the open subset of  $S$  consisting of the points where this second alternative occurs. Expressing that  $\mathcal{O}_S$  is the direct sum of the  $\mathcal{L}_m$ , one sees that the union of the  $S_m$  is  $S$ , and that the  $S_m$  are pairwise disjoint. Hence giving a group homomorphism  $G \rightarrow G_{\{m,S\}}$  is equivalent to giving a decomposition of  $S$  as a union of pairwise disjoint open subsets  $S_m$  ( $m \in M$ ), i.e. to giving a locally constant map from  $S$  to  $M$ . This establishes 1.3, hence 1.2.

**Corollary 1.4.** \*A diagonalizable group is reflexive; the same therefore holds for a locally diagonalizable group. If  $M$ ,  $N$  are two ordinary commutative groups, the natural homomorphism\*

<!-- label: III.VIII.1.4 -->

```text  
 $\text{Hom}_{\{S\text{-gr.}\}}(M_S, N_S) \rightarrow \text{Hom}_{\{S\text{-gr.}\}}(D(N_S), D(M_S))$
 ```

\*is bijective.\*

[<sup>N.D.E-VIII-4</sup>] The preceding isomorphism being compatible with base extension, one deduces an isomorphism of  $S$ -functors in groups:

```text  
 (1) $\text{Hom}_{\{S\text{-gr.}\}}(M_S, N_S) \cong \text{Hom}_{\{S\text{-gr.}\}}(D(N_S), D(M_S)).$
 ```

<!-- label: eq:III.VIII.1.4.1 -->

For every  $S$ -prescheme  $T$ , one has

```text  
 $\text{Hom}_{\{S\text{-gr.}\}}(M_S, N_S)(T) = \text{Hom}_{\text{gr.}}(M, \Gamma(N_T/T)),$
 ```

and, by I 1.8,  $\Gamma(N_T/T)$  is the abelian group of locally constant maps  $T \rightarrow N$ . On the other hand, let  $\text{Hom}_{\{S\text{-gr.}\}}(M, N)_S$  be the constant  $S$ -group associated with the ordinary abelian group  $\text{Hom}_{\{S\text{-gr.}\}}(M, N)$ . One has an evident homomorphism of  $S$ -functors in commutative groups:

```text  
 (2) $\text{Hom}_{\text{gr.}}(M, N)_S \rightarrow \text{Hom}_{\{S\text{-gr.}\}}(M_S, N_S),$
 ```

<!-- label: eq:III.VIII.1.4.2 -->

which is always a monomorphism. Moreover, it is an isomorphism if  $M$  is of finite type.[<sup>N.D.E-VIII-5</sup>]

From the foregoing one deduces point (a) of the following corollary; point (b) follows from it by the descent results "recalled" in 1.7.[^N.D.E-VIII-6]

<!-- original page 6 -->

**Corollary 1.5.** \*a) Let  $M, N$  be two ordinary commutative groups, with  $M$  of finite type. Then one has an isomorphism\*

<!-- label: III.VIII.1.5 -->

$$\text{Hom}_{\text{gr.}}(M, N)_S \cong \text{Hom}_{\{S\text{-gr.}\}}(D(N_S), D(M_S));$$

\*consequently  $\text{Hom}_{\{S\text{-gr.}\}}(D(N_S), D(M_S))_S$  is representable.\*

\*b) More generally, if  $G, H$  are locally diagonalizable, with  $H$  of finite type, then  $\text{Hom}_{\{S\text{-gr.}\}}(G, H)_S$  is representable.\*

[^N.D.E-VIII-7] From 1.5 one concludes:

**Corollary 1.6.** \*Under the conditions of 1.5, if  $S$  is connected, one has\*

<!-- label: III.VIII.1.6 -->

$$\text{Hom}_{\{S\text{-gr.}\}}(D_S(N), D_S(M)) \cong \text{Hom}_{\text{gr.}}(M, N)$$

\*and\*

$$\text{Isom}_{\{S\text{-gr.}\}}(D_S(N), D_S(M)) \cong \text{Isom}_{\text{gr.}}(M, N).$$

### 1.7. Descent of representability

<!-- label: III.VIII.1.7 -->

[^N.D.E-VIII-8] In this paragraph we "recall" some descent results that will be used frequently in what follows.

**Scholium 1.7.1.** \*Let  $S$  be a prescheme and  $X, Y, T$   $S$ -preschemes. If  $\{T_i\}$  is an open covering of  $T$ , and if we set  $T_{ij} = T_i \cap T_j = T_i \times_T T_j$ , then, since giving a morphism of  $T$ -preschemes  $X \rightarrow Y$  is local on  $T$ , one has an exact sequence of sets:\*

<!-- label: III.VIII.1.7.1 -->

$$(1) \quad \text{Hom}_T(X, Y) \rightarrow \prod_i \text{Hom}_{T_i}(X_{T_i}, Y_{T_i}) \rightrightarrows \prod_{i,j} \text{Hom}_{T_{ij}}(X_{T_{ij}}, Y_{T_{ij}})$$

<!-- label: eq:III.VIII.1.7.1 -->

\*i.e.  $\text{Hom}_{\{S\}}(X, Y)$  is a local  $S$ -functor, that is, a sheaf on  $(\text{Sch})/S$  endowed with the Zariski topology.\*

\*More generally, by IV 4.5.13,  $\text{Hom}_{\{S\}}(X, Y)$  is a sheaf on  $(\text{Sch})/S$  for every topology coarser than the canonical topology – for example, for the (fpqc) topology.\*

\*If  $G, H$  are  $S$ -preschemes in groups, one deduces that the subfunctor  $\text{Hom}_{\{S\text{-gr.}\}}(X, Y)$  is a sheaf for the (fpqc) topology (hence a fortiori a local functor).\*

**Lemma 1.7.2.** [^N.D.E-VIII-9] \*Let  $F$  be a local  $S$ -functor.\*

<!-- label: III.VIII.1.7.2 -->

\*(i) Suppose there exists an open covering  $\{S_i\}$  of  $S$  such that the restriction  $F_i = F|_{S_i}$  of  $F$  to each  $S_i$  is representable by an  $S_i$ -prescheme  $X_i$ . Then  $F$  is representable by an  $S$ -prescheme  $X$ .\*

\*(ii) Suppose  $F$  is an (fpqc) sheaf and that there exists a faithfully flat quasi-compact morphism  $S' \rightarrow S$  such that the restriction  $F' = F|_{S'}$  of  $F$  to  $S'$  is representable by an  $S'$ -prescheme  $X'$ . Then  $X'$  is endowed with a descent datum (cf. IV 2.1) relative to  $S' \rightarrow S$ .\*

\*If moreover this descent datum is effective (which is the case if  $X'$  is affine over  $S'$ ), then  $F$  is representable by an  $S$ -prescheme  $X$ .\*

<!-- original page 7 -->

\*Proof.\* (i) It follows from the hypothesis that  $X_i|_{S_j} = X_j|_{S_i}$  and  $X_j|_{S_i} = X_i|_{S_j}$  both represent the restriction of  $F$  to  $S_{ij} = S_i \times S_j$ , hence, by the Yoneda lemma, there is a unique isomorphism of  $S_{ij}$ -preschemes

```
```text
c_{ji} : X_i \times_{S_j} S_j \rightarrow X_j \times_{S_i} S_i;
```

one then has isomorphisms of preschemes over $S_{ijk} = S_i \times S_j \times S_k$:

```
```text
 c_{ji} \times id_{S_k} c_{kj} \times id_{S_i}
X_i \times_{S_j} S_j \times_{S_k} S_k \longrightarrow X_j \times_{S_i} S_i \times_{S_k} S_k \cong X_j \times_{S_k} S_k \times_{S_i} S_i \longrightarrow X_k \times_{S_j} S_j \times_{S_i} S_i

 c_{ki} \times id_{S_j}
X_i \times_{S_k} S_k \times_{S_j} S_j \longrightarrow X_k \times_{S_i} S_i \times_{S_j} S_j
```

and since all these objects represent the restriction of  $F$  to  $S_{ijk}$ , this diagram is commutative, i.e. the  $c_{ji}$  satisfy the usual cocycle relation  $c_{kj} \circ c_{ji} = c_{ki}$ .

It follows that the  $X_i$  glue together into an  $S$ -prescheme  $X$  such that  $X|_{S_i} = X_i$  for every  $i$ . For every  $Y$  over  $S_i$ , one therefore has

```
```text
(*)   F(Y) = F_i(Y) = Hom_{S_i}(Y, X \times_{S_j} S_j) = Hom_{S_i}(Y, X) = h_X(Y).
```

Then, for $Y \rightarrow S$ arbitrary, the $Y_i = Y|_{S_i}$ form an open covering of Y ; set $Y_{ij} = Y_i|_{S_j} = Y|_{S_{ij}}$. Since F (resp. h_X) is a local functor by hypothesis (resp. because the Zariski topology is coarser than the canonical topology), $F(Y_i)$ and $h_X(Y_i)$ both identify, in view of $(*)$, with the kernel of the double arrow:

```
```text
\prod_i F(Y_i) \rightrightarrows \prod_{i,j} F(Y_{ij})

\prod_i h_X(Y_i) \rightrightarrows \prod_{i,j} h_X(Y_{ij}).
```

This proves (i).

(ii) It follows from the hypothesis that  $F'_1 = F'|_{S'_1} = F'|_{S' \times_{S'} S'_1}$  (where  $S'_1 = S' \times_{S'} S'$  is considered as  $S'$ -prescheme via the first projection) is represented by  $X'_1 = X'|_{S'_1} = X'|_{S' \times_{S'} S'_1}$ ; similarly,  $F'_2 = F'|_{S'_2} = F'|_{S' \times_{S'} S'_2}$  is represented by  $X'_2 = X'|_{S'_2} = X'|_{S' \times_{S'} S'_2}$ . Now  $F'_1 = F'|_{S'_1} = F'|_{S' \times_{S'} S'_1} = F'_2$ , hence there exists a (unique)  $S'$ -isomorphism  $\sigma : X'_1 \rightarrow X'_2$ . Then, denoting by  $q_i$  (resp.  $p_{ij}$ ) the projection of  $S' \times_{S'} S' \times_{S'} S'$  onto the  $i$ -th factor (resp. onto the factors  $i$  and  $j$ ),  $X'_i = X'|_{S'_i} = X'|_{S' \times_{S'} S'_i}$  (where  $S'_i = S' \times_{S'} S'$  considered as  $S'$ -prescheme via  $q_i$ ), and  $p^*_{ij}(c) : X'_i \rightarrow X'_j$  the isomorphism of  $S'$ -preschemes deduced from  $\sigma$  by base change, one obtains a diagram of isomorphisms of  $S'$ -preschemes:

```

```text
      p_{21}^{*(c)}
      |
X''_1 ----> X''_2
      |      |
p_{31}^{*(c)} \  p_{32}^{*(c)}
      |      |
      X''_3  ↓
...

```

<!-- original page 8 -->

and since all these objects represent the restriction of $\mathcal{F}$ to S'' , this diagram is commutative, i.e. the usual cocycle relation $p^*_{32}(c) \circ p^*_{21}(c) = p^*_{31}(c)$ holds, i.e. c is a descent datum on X' relative to $S' \rightarrow S$ (cf. IV 2.1).

Suppose moreover that this descent datum is effective, i.e. that there exists an S -prescheme X such that $X' \simeq X \times_S S'$ (by SGA 1, VIII 2.1, this is the case if X' is affine over $S'^{\wedge \text{N.D.E-VIII-10}}$). Then, for every $Y \rightarrow S'$, one has

```

```text
(**) F(Y) = F'(Y) = Hom_{S'}(Y, X \times_S S') = Hom_S(Y, X) = h_X(Y).
```

```

Then, for $Y \rightarrow S$ arbitrary, set $Y' = Y \times_S S'$ and $Y'' = Y' \times_{S'} Y' \simeq Y \times_S S'$. Then $Y' \rightarrow Y$, like $S' \rightarrow S$, is faithfully flat and quasi-compact, hence an $\mathcal{M}$ -effective epimorphism (where $\mathcal{M}$ = family of faithfully flat quasi-compact morphisms), i.e. the equivalence relation

```

```text
Y' \times_Y Y' \Rightarrow Y'
```

```

is $\mathcal{M}$ -effective and has quotient Y . Since $\mathcal{F}$ (resp. h_X) is an (fpqc) sheaf by hypothesis (resp. because the (fpqc) topology is coarser than the canonical topology), $\mathcal{F}(Y)$ and $h_X(Y)$ both identify, in view of $(**)$, with the kernel of the double arrow

```

```text
F(Y') \Rightarrow F(Y' \times_Y Y')
h_X(Y') \Rightarrow h_X(Y' \times_Y Y').
```

```

This proves (ii).

Corollary 1.7.3. *Let $\mathcal{F}$ be an (fpqc) sheaf on $(\text{Sch})/S$. Suppose there exists an open covering (S_i) of S and, for each i , a faithfully flat quasi-compact morphism $S'_i \rightarrow S_i$ such that the restriction $\mathcal{F}'_i = \mathcal{F}|_{S'_i}$ is representable by an S'_i -prescheme X'_i affine over S'_i . Then $\mathcal{F}$ is representable by an S -prescheme X affine over S (such that $X \times_S S'_i = X'_i$ for every i).

<!-- label: III.VIII.1.7.3 -->

*If moreover each $X'_i \rightarrow S'_i$ is a closed immersion (resp. a finite étale morphism), the same holds for $X \rightarrow S$.

The first assertion follows from 1.7.2. For the second, it suffices to verify that each morphism $X \times_S S_i \rightarrow S_i$ is a closed immersion (resp. finite and étale), which follows from EGA IV₂, 2.7.1 (resp. and IV₄, 17.7.3).

Remark 1.7.4. *Assertion 1.5 (b) follows, as announced, from 1.7.1 and 1.7.2 (i).

<!-- label: III.VIII.1.7.4 -->

2. Schematic properties of diagonalizable groups

They are summarized in the following.

<!-- original page 8 -->

****Proposition 2.1.**** *Let S be a non-empty prescheme, M an ordinary commutative group, $G = D(M_S)$ the diagonalizable S -group defined by M . Then:*

<!-- label: III.VIII.2.1 -->

*a) G is faithfully flat over S , and affine over S (a fortiori quasi-compact over S).

*b) M of finite type $\Leftrightarrow G$ of finite type over $S \Leftrightarrow G$ of finite presentation over S .

*c) M finite $\Leftrightarrow G$ finite over $S \Leftrightarrow G$ of finite type over S and annihilated by an integer $n > 0$. Then $\deg(G/S) = \text{Card}(M)$.

*c') M a torsion group $\Leftrightarrow G$ integral over S .

*d) $M = 0 \Leftrightarrow G = \text{unit } S\text{-group}$.

*e) M of finite type, and the order of its torsion subgroup is prime to the residue characteristics of $S \Leftrightarrow G$ is smooth over S .

The verification of (a) to (d) is trivial, and is left to the reader. Let us prove (e). If G is smooth over S , it is locally of finite presentation over S , hence of finite presentation over S since it is affine over S , hence M is of finite type. So we may already assume M of finite type, hence G of finite presentation over S . Then [N.D.E-VIII-11] G is smooth over S if and only if its geometric fibers are, which reduces us to the case where S is the spectrum of an algebraically closed field k . Writing $M = T \times L$, with T the torsion subgroup and L free, $L \simeq \mathbb{Z}^r$, one has $D(M) = D(T) \times D(L)$, where $D(L) \simeq G^r_m$ is smooth over k . So $G = D(M)$ is smooth over k if and only if $D(T)$ is, which means, since $D(T)$ is finite over k of degree equal to the order n of T , that $D(T)(k)$ has n elements. Now T is isomorphic to a sum of groups $\mathbb{Z}/n_i\mathbb{Z}$, n_i being the product of the n_i , so $D(T)$ is the product of the $D(\mathbb{Z}/n_i\mathbb{Z}) = \mu_{n_i}$ (group scheme of n_i -th roots of unity), hence

```text  
card(D(T)(k)) =  $\prod_i \text{card } \mu_{n_i}(k)$ ,  
```

where $\mu_{n_i}(k) = (\text{number of } n_i\text{-th roots of unity in } k) \leq n_i$, equality being attained if and only if n_i is prime to the characteristic p of k . Hence one has $\text{card}(D(T)(k)) = n$ (where $n = \prod_i n_i$) if and only if all the n_i are prime to p , i.e. if and only if n is prime to p . QED.

3. Exactness properties of the functor D_S

****Theorem 3.1.**** *Let S be a prescheme, and*

<!-- label: III.VIII.3.1 -->

```text  
 $0 \rightarrow M' \rightarrow M \rightarrow M'' \rightarrow 0$   
```

<!-- original page 8 -->

*an exact sequence of ordinary commutative groups. Consider the sequence of transposed homomorphisms:

```text  
 $0 \rightarrow D_S(M'') \rightarrow D_S(M) \rightarrow D_S(M') \rightarrow 0$ .  
```

(i) v^t induces an isomorphism of $D_S(M'')$ with the kernel of u^t , and u^t is faithfully flat and quasi-compact.

(ii) [N.D.E-VIII-12] $D_S(M')$ represents the (fpqc) quotient sheaf $D_S(M)/D_S(M'')$.

<!-- original page 9 -->

Let $\mathcal{M}$ denote the family of faithfully flat quasi-compact morphisms. First, (ii) follows from (i) (cf. IV, 4.6.5.1). Indeed, the equivalence relation in $\mathcal{D}_{\{S\}}(M)$ defined by $u^{\{t\}}$ is the same as that defined by the subgroup $\text{Ker}(u^{\{t\}}) = \mathcal{D}_{\{S\}}(M')$; since $u^{\{t\}} \in \mathcal{M}$, this equivalence relation is $\mathcal{M}$ -effective (cf. IV, 3.3.2.1), and therefore $\mathcal{D}_{\{S\}}(M')$ represents the quotient sheaf for the (fpqc) topology (cf. IV, 4.6.5).

The first assertion of (i) is a trivial consequence of the definition of the functors $\mathcal{D}_{\{S\}}(-)$; more generally, for any exact sequence

$$\mathcal{M}' \rightarrow \mathcal{M} \rightarrow \mathcal{M}'' \rightarrow 0$$

(without zero on the left), one will have a transposed exact sequence:

$$0 \rightarrow \mathcal{D}_{\{S\}}(\mathcal{M}'') \rightarrow \mathcal{D}_{\{S\}}(\mathcal{M}) \rightarrow \mathcal{D}_{\{S\}}(\mathcal{M}').$$

(This is valid more generally in the context of the beginning of §1.) On the other hand, since $\mathcal{D}_{\{S\}}(M)$ and $\mathcal{D}_{\{S\}}(M')$ are affine over $\mathcal{S}$, $u^{\{t\}}$ is necessarily an affine morphism, a fortiori quasi-compact (whatever the homomorphism $u : M' \rightarrow M$). The second assertion of (i) will therefore follow from point (a) of the following:

Corollary 3.2. Let $\mathcal{S}$ be a non-empty prescheme, $u : M' \rightarrow M$ a homomorphism of ordinary commutative groups, $u^{\{t\}} : G \rightarrow G'$ the transposed homomorphism. Then:

--- label: III.VIII.3.2 ---

a) For u to be a monomorphism, it is necessary and sufficient that $u^{\{t\}}$ be faithfully flat.

b) For u to be an epimorphism, it is necessary and sufficient that $u^{\{t\}}$ be a monomorphism (and then $u^{\{t\}}$ is even a closed immersion).

To prove (a), one notes that if u is a monomorphism, then $\mathcal{D}_{\{S\}}(M)$ is a module over $\mathcal{D}_{\{S\}}(M')$ admitting a non-empty basis (namely, the system of sections defined by any system of representatives of $\mathcal{M}$ modulo M'), a fortiori it is faithfully flat. Conversely, if this is the case, then $u^{\{t\}} : \mathcal{D}_{\{S\}}(M') \rightarrow \mathcal{D}_{\{S\}}(M)$ is injective, which (for $\mathcal{S} \neq \emptyset$) implies that $u : M' \rightarrow M$ is injective.

To prove (b), one notes that if u is an epimorphism, then $\mathcal{D}_{\{S\}}(M') \rightarrow \mathcal{D}_{\{S\}}(M)$ is surjective, hence $u^{\{t\}}$ is a closed immersion and a fortiori a monomorphism. Conversely, if this is the case, then $\text{Ker } u^{\{t\}} = \text{unit group}$; now setting $M'' = \text{Coker } u$, we have seen that $\text{Ker } u^{\{t\}} \subseteq \mathcal{D}_{\{S\}}(M'')$, hence by 2.1 (d) one has $M'' = 0$, hence u is an epimorphism.

One concludes from 3.1 in the usual way:

Corollary 3.3. Let $\mathcal{M}' \rightarrow \mathcal{M} \rightarrow \mathcal{M}''$ be an exact sequence of ordinary commutative groups; consider the transposed sequence

--- label: III.VIII.3.3 ---

$$G'' \rightarrow G' \rightarrow G$$

Then $v^{\{t\}}$ induces a faithfully flat quasi-compact morphism from G'' to $\text{Ker } u^{\{t\}}$, and the latter is a diagonalizable group isomorphic to $\mathcal{D}_{\{S\}}(v(M)) = \mathcal{D}_{\{S\}}(\text{Coker } u)$.

--- original page 10 ---

Corollary 3.4. Let $\mathcal{S}$ be a prescheme, $u : G \rightarrow H$ a homomorphism of $\mathcal{S}$ -preschemes in locally diagonalizable groups, with H of finite type over $\mathcal{S}$. Set $G' = \text{Ker } u$. Then:

--- label: III.VIII.3.4 ---

a) G' is locally diagonalizable; it is of finite type over $\mathcal{S}$ if G is.

b) The quotient G/G' "exists"; more precisely, the equivalence relation defined by G' in G is M -effective (where M = set of faithfully flat quasi-compact morphisms, cf. IV, 3.4). Moreover, G/G' is locally diagonalizable, of finite type over S .

c) The homomorphism $u : G \rightarrow H$ factors uniquely as

```

```text
G -v-> G/G' -w-> H,
```

```

where v is the canonical homomorphism (so v is faithfully flat and quasi-compact). Moreover w is a closed immersion, and a fortiori a monomorphism.

Finally, the quotient $H' = H/\text{Im } w = \text{Coker } w = \text{Coker } u$ exists; more precisely, the equivalence relation defined by G/G' in H is M -effective, and H' is of finite type over S .

The first assertion of (c) is a consequence of (b), by definition of the quotient G/G' (cf. IV, 3.2.3). [N.D.E-VIII-13] Let us show that the (fpqc) quotient sheaf $\tilde{G}/\tilde{G}'$ is representable. This may be verified locally on S , as may all the other assertions; we may therefore suppose G and H diagonalizable, of the form $D_{\{S\}}(M)$ and $D_{\{S\}}(N)$.

Since H is of finite type over S , N is of finite type by 2.1 (b), hence by 1.5 u is defined by a homomorphism $u_0 : N \rightarrow M$. Then, in virtue of 3.1 and 3.2, G' is isomorphic to $D_{\{S\}}(\text{Coker } u_0)$ and $\tilde{G}/\tilde{G}'$ is representable by $D_{\{S\}}(\text{Im } u_0)$; moreover, considering the exact sequence

```

```text
0 -> Ker u_0 -> N -w_0-> Im u_0 -> 0,
```

```

one obtains that w is a closed immersion, and that the quotient $H' = H/\text{Im } w$ is $D_{\{S\}}(\text{Ker } u_0)$; the latter is of finite type over S since N , and hence $\text{Ker } u_0$, is of finite type.

Remarks. The existence-of-quotients result 3.4 will be substantially generalized in §5.

On the other hand, one will note that in the present § and the preceding one, the hypothesis $S \neq \emptyset$ was used only to ensure the validity of certain converses, enabling one to deduce from certain hypotheses on diagonalizable S -groups properties of the corresponding ordinary groups. The "direct"-sense results are valid without restriction on S , and the proofs given here apply in the general case.

Corollary 3.5. *Let G be a diagonalizable group prescheme over S , and let n be an integer $\neq 0$. Then the subgroup $\{ \}_{nG}$ of G , kernel of the homomorphism $n \cdot \text{id}_G : G \rightarrow G$, is integral over S , and finite over S if G is of finite type over S .*

<!-- label: III.VIII.3.5 -->

<!-- original page 11 -->

Indeed, if $G = D_{\{S\}}(M)$, then $\{ \}_{nG} = D_{\{S\}}(M/nM)$ by 3.1, and one concludes by 2.1 (b), (c), (c').

4. Torsors under a diagonalizable group

Let S be a prescheme, and $G = D_{\{S\}}(M)$ a diagonalizable group over S . We propose to determine the G -torsors (or principal homogeneous G -bundles) on S , in the sense of the "faithfully flat quasi-compact topology" (cf. Exp. IV, 5.1). Recall that a prescheme P over S with operator group G is called a *torsor* or *principal homogeneous* if every point of S admits an open neighborhood U and a faithfully flat quasi-compact morphism $S' \rightarrow U$ such that $P' = P \times_{\{S\}} S'$ is, as a bundle with operators, isomorphic to $G' = G \times_{\{S\}} S'$ (acting on itself by right translations). Since G is affine over S , it follows from SGA 1, VIII 5.6 that P is necessarily affine over S . Note also that since G is itself faithfully flat and quasi-compact over S , P is principal homogeneous under G if and only if it is "formally principal homogeneous", and if moreover it is faithfully flat and quasi-compact over S (cf. IV, 5.1.6).

Recall on the other hand (Exp. I, 4.7.3) that giving an S -prescheme P affine over S with operator group $G = D_{\{S\}}(M)$ amounts to giving a quasi-coherent commutative M -graded algebra on S , i.e. a quasi-coherent algebra $\mathcal{A}$ on S endowed with a direct sum decomposition (as a module):

```

```text
 $\Omega = \Omega_{\{m \in M\}} \Omega_m,$

```

with

```

```text
 $\Omega_m \cdot \Omega_{\{m'\}} \subseteq \Omega_{\{m+m'\}} \quad \text{for } m, m' \in M.$ 

```

This said, the answer to the problem posed above is given by:

****Proposition 4.1.**** *For the prescheme P with operator group $G = D_{\{S\}}(M)$, defined by the M -graded algebra $\mathcal{A}$, to be a principal homogeneous bundle under G , it is necessary and sufficient that $\mathcal{A}$ satisfy the following conditions:*

<!-- label: III.VIII.4.1 -->

a) For every $m \in M$, $\mathcal{A}_m$ is an invertible module on S .

b) For $m, m' \in M$, the homomorphism

```

```text
 $\Omega_m \otimes_{0_S} \Omega_{\{m'\}} \rightarrow \Omega_{\{m+m'\}}$

```

\*induced by the multiplication in  $\mathcal{A}$ , is an isomorphism.\*

<!-- original page 12 -->

The necessity of the conditions is immediate by descent, since they are satisfied in the case where  $P$  is the trivial principal homogeneous bundle, i.e.  $\mathcal{A} = 0_{\{S\}}(M)$ . For the sufficiency, one notes that (a) already implies that  $P$  is faithfully flat over  $S$ , it is in any case quasi-compact over  $S$  (being affine over  $S$ ), so it remains to verify that it is formally principal homogeneous under  $G$ , i.e. that the well-known homomorphism

```

```text
 $P \times_S G \rightarrow P \times_S P$ 

```

is an isomorphism. Now on affine algebras, this homomorphism is given explicitly as the homomorphism

```

```text
 $\Omega \otimes \Omega \rightarrow \Omega(M) = \Omega \otimes 0_S(M)$

```

which in bidegree  $(m, n)$  (where  $m, n \in M$ ) is given by

```

```text
 $x_m \otimes y_n \mapsto x_m y_n \otimes e_n.$ 

```

From the standpoint of degrees, this homomorphism is compatible with the homomorphism $M \times M \rightarrow M \times M$ given by

```

```text
 $(m, n) \mapsto (m + n, n),$

```

which is an isomorphism. This shows that (b) expresses precisely (independently of (a)) that  $P$  is formally principal homogeneous, and establishes 4.1.

Note also that one obtains, by faithfully flat descent:

**\*\*Corollary 4.2.\*\*** \*The conditions of 4.1 imply that the homomorphism\*

<!-- label: III.VIII.4.2 -->

$O_S \rightarrow \mathcal{A}_0$

is an isomorphism.

If for example  $M = \mathbb{Z}$ , then under the conditions of 4.1 one sees that  $\mathcal{A}$  is essentially known when one knows  $\mathcal{A}_1 = \mathcal{L}$ , namely

$\mathcal{A} \cong \bigoplus_{n \in \mathbb{Z}} \mathcal{A}^{\otimes n}$

(isomorphism of graded algebras). One thereby recovers the well-known result:

**Corollary 4.3.** There is an equivalence between the category of principal homogeneous bundles  $P$  on  $S$  with group  $G_{m,S}$ , and the category of invertible modules  $\mathcal{L}$  on  $S$  (taking as morphisms, for the definition of each category, the isomorphisms of the structures in play). One obtains two quasi-inverse functors by associating with each  $P$  the degree-1 component of its  $\mathbb{Z}$ -graded affine algebra, and with each  $\mathcal{L}$  the spectrum of the  $\mathbb{Z}$ -graded algebra  $\bigoplus_{n \in \mathbb{Z}} \mathcal{L}^{\otimes n}$ .

<!-- label: III.VIII.4.3 -->

In particular:

**Corollary 4.4.** The group of classes of principal homogeneous bundles on  $S$  with group  $G_{m,S}$  is isomorphic to the group  $\mathrm{Pic}(S)$  of classes of invertible modules on  $S$ , i.e. to  $H^1(S, \mathcal{O}_S^\times)$ .

<!-- label: III.VIII.4.4 -->

Taking into account that  $G_{m,S}$  is the scheme of automorphisms of the module  $\mathcal{O}_S$ , one sees that 4.4 is equivalent to the following statement, which is one of the variants of Hilbert's "Theorem 90":

**Corollary 4.5.** Every principal homogeneous bundle on  $S$  with group  $G_m$  is locally trivial (in the sense of the Zariski topology).

<!-- label: III.VIII.4.5 -->

**Remark 4.5.1.** One will note that the preceding statement is no longer true in general for a group such as  $\mu_n$ , or for a "twisted form" of  $G_m$ ; for example, the unique twisted form of  $G_m$  over the field  $\mathbb{R}$  of reals gives a group of  $\mathbb{Z}/2\mathbb{Z}$ -cohomology equal to  $\mathbb{Z}/2\mathbb{Z}$ .

<!-- label: III.VIII.4.5.1 -->

<!-- original page 13 -->

[^N.D.E-VIII-14] Indeed, let  $S^1$  be the kernel of the norm morphism  $N : \prod_{\mathbb{C}/\mathbb{R}} G_{m,\mathbb{C}} \rightarrow G_{m,\mathbb{R}}$ ; this is a  $\mathbb{C}/\mathbb{R}$ -twisted form of  $G_{m,\mathbb{R}}$ . The equation  $N(z) = -1$  in  $\prod_{\mathbb{C}/\mathbb{R}} G_{m,\mathbb{C}}$  defines an  $S^1$ -torsor  $X$  over  $\mathrm{Spec}(\mathbb{R})$ , locally trivial for the étale topology, but not trivial since  $X(\mathbb{R}) = \emptyset$ . Let us show that  $H^1_{\acute{e}t}(\mathbb{R}, S^1) \cong \mathbb{Z}/2\mathbb{Z}$ . One has an exact sequence of smooth commutative  $\mathbb{R}$ -group schemes:

$1 \rightarrow S^1 \rightarrow \prod_{\mathbb{C}/\mathbb{R}} G_{m,\mathbb{C}} \rightarrow G_{m,\mathbb{R}} \rightarrow 1$

which gives rise to a long exact sequence of étale cohomology (or of Galois cohomology):

$0 \rightarrow S^1(\mathbb{R}) \rightarrow \mathbb{C}^\times \rightarrow \mathbb{R}^\times \rightarrow H^1_{\acute{e}t}(\mathbb{R}, S^1) \rightarrow H^1_{\acute{e}t}(\mathbb{R}, \prod_{\mathbb{C}/\mathbb{R}} G_{m,\mathbb{C}}) \rightarrow \dots$

Now (see for example XXIV, 8.4),  

$$H^1_{\acute{e}t}(\mathbb{R}, \prod_{\mathbb{C}/\mathbb{R}} G_{m,\mathbb{C}}) \simeq H^1_{\acute{e}t}(\mathbb{C}, G_{m,\mathbb{C}}),$$
and the latter is zero by 4.5 (or, here, because  $\mathbb{C}$  is algebraically closed). One thus obtains an isomorphism  $H^1_{\acute{e}t}(\mathbb{R}, S^1) \simeq \mathbb{R}^{\times}/N(\mathbb{C}^{\times}) \simeq \{\pm 1\}$ .

We shall need in the following § the following result:

**Proposition 4.6.** \*Under the conditions of 4.1, conditions (a) and (b) are equivalent to the following conditions:\*

<!-- label: III.VIII.4.6 -->

\*a')  $\mathcal{A}_S \rightarrow \mathcal{A}_0$  is an isomorphism.\*

\*b') For every  $M$  in  $\mathcal{M}$  (it suffices: in a system of generators of  $\mathcal{M}$ ), one has\*

$$\mathcal{A}_M \cdot \mathcal{A}_{-M} = \mathcal{A}_0.$$

The necessity being evident, taking 4.2 into account, [N.D.E-VIII-15] we shall reduce to proving:

**Corollary 4.7.** \*Let  $A = \bigoplus_{n \in \mathbb{Z}} A_n$  be a  $\mathbb{Z}$ -graded ring such that\*

<!-- label: III.VIII.4.7 -->

$$A_1 \cdot A_{-1} = A_0.$$

\*Then the  $A_n$  are invertible  $A_0$ -modules, and for  $n, n' \in \mathbb{Z}$ , the homomorphism\*

$$A_n \otimes_{A_0} A_{n'} \rightarrow A_{n+n'}$$

\*induced by the multiplication in  $A$ , is an isomorphism.\*

By hypothesis, there exist  $f_i \in A_1$ ,  $g_i \in A_{-1}$ , such that

$$(*) \quad \sum_i f_i g_i = 1.$$

As the conclusion to be established is local on  $\operatorname{Spec}(A_0)$ , [N.D.E-VIII-16] and as, by  $(*)$ ,  $\operatorname{Spec}(A_0)$  is covered by the affine opens  $D(f_i g_i)$ , one is reduced to the case where there exists an element  $f \in A_1$  invertible in  $A$ . Then for every  $n \in \mathbb{Z}$ ,  $f^n$  is an element of  $A_n$  invertible in  $A$ , hence defines an isomorphism  $h \mapsto f^n h$  from  $A_0$  onto  $A_n$ . Moreover,

<!-- original page 14 -->

this shows that one obtains an isomorphism  $A_0[t, t^{-1}] \rightarrow A$  of graded  $A_0$ -algebras by sending  $t$  to  $f$ , which completes the proof of 4.7.

Then, under the conditions of 4.6, 4.7 already implies that the  $\mathcal{A}_m$  ( $m \in \mathcal{M}$ ) are invertible. To prove condition 4.1 (b), one may therefore suppose that  $\mathcal{A}_m$  and  $\mathcal{A}_{m'}$  admit bases  $f_m$  and  $f_{m'}$ , having inverses  $f_{-1}^m \in \Gamma(\mathcal{A}_{-m})$  and  $f_{-1}^{m'} \in \Gamma(\mathcal{A}_{-m'})$ . Then the product by  $f_{-1}^m f_{-1}^{m'} \in \Gamma(\mathcal{A}_{-m-m'})$  defines a homomorphism  $\mathcal{A}_{m+m'} \rightarrow \mathcal{A}_0$ , sending the image of  $f_m \otimes f_{m'}$  to the section  $1$  of  $\mathcal{O}_S$ . In the diagram

$$\begin{array}{ccc} & & w \\ & \xrightarrow{\quad} & \\ \nearrow & & \searrow \end{array}$$

$\pi_m \otimes \pi_{m'} \rightarrow \pi_{m+m'} \rightarrow \pi_0 \cong 0_S$

$w_*$  and  $v_*$  are therefore epimorphisms of invertible sheaves, hence isomorphisms, hence  $u_*$  is an isomorphism. QED.

## 5. Quotient of an affine scheme by a diagonalizable group acting freely

<!-- original page 15 -->

[^N.D.E-VIII-17] We denote by  $\mathcal{M}$  the set of faithfully flat quasi-compact morphisms, and we recall that torsors are considered in the sense of the (fpqc) topology.

**Theorem 5.1.** *Let  $S$  be a prescheme,  $M$  an ordinary commutative group,  $G = D_{\{S\}}(M)$  the diagonalizable group over  $S$  defined by it,  $P$  an  $S$ -prescheme affine over  $S$  on which  $G$  acts freely on the right.*

<!-- label: III.VIII.5.1 -->

Then the equivalence relation defined by  $G$  in  $P$  is  $M$ -effective (cf. IV, 3.4), i.e. the quotient  $X = P/G$  exists and  $P$  is a torsor over  $X$  with group  $G_X = D_X(M)$ . Moreover,  $P/G$  is affine over  $S$ ; more precisely, if  $P$  is defined by the  $M$ -graded algebra  $\mathcal{A}$ , then  $P/G$  is isomorphic to  $\operatorname{Spec}(\mathcal{A}_0)$ , where  $\mathcal{A}_0 = \mathcal{A}^G$  is the degree-0 component of  $\mathcal{A}$ .

**Proof.** Set  $X = \operatorname{Spec}(\mathcal{A}_0)$ . Then one has a natural morphism  $P \rightarrow X$ , deduced from  $\mathcal{A}_0 \rightarrow \mathcal{A}$ , which is invariant under the action of  $G$ . In this way,  $P$  becomes an  $X$ -prescheme, affine over  $X$ , with operator group  $G_X = D_X(M)$ , and the hypothesis that  $G$  acts freely on  $P/S$  implies that  $G_X$  acts freely on  $P/X$ . Everything reduces to showing that  $P$  is a principal homogeneous bundle under  $G_X$ , using the fact that  $\mathcal{B}_0 = 0_X$ , where  $\mathcal{B}$  is the  $M$ -graded algebra on  $X$  defining  $P/X$ . We may then suppose  $X = S$  and  $S$  affine, so  $P$  is affine, given by an  $M$ -graded ring  $A$  whose homogeneous part of degree  $m$  will be denoted  $A_m$ , so that  $S = \operatorname{Spec}(A_0)$ . Taking 4.6 into account, it remains to verify that one has:

text  
 (\*)  $A_m \cdot A_{-m} = A_0$  for every  $m \in M$ .  
 text

One observes moreover by a direct computation that (\*) is equivalent to saying that  $P \times_S G \rightarrow P \times_S P$  is a closed immersion, and not only a monomorphism (under the hypothesis that  $G$  acts freely), i.e. that the homomorphism on affine rings

<!-- original page 16 -->

text  
 $\theta : A \otimes_{A_0} A \rightarrow A(M)$   
 text

is surjective[^N.D.E-VIII-18]. This gives 5.1 when one supposes that the equivalence relation defined by  $G$  in  $P$  is closed. We shall, however, show that this hypothesis is already a consequence of the fact that  $G$  acts freely (which is moreover implicitly contained in Theorem 5.1, since  $G \times_S P$  must be isomorphic to  $P \times_X P$ , which is closed in  $P \times_S P$  since  $X$  is affine over  $S$  hence separated over  $S$ ).

Let  $R = P \times_S G$ . The hypothesis that  $G$  acts freely, i.e. that  $R \rightarrow P \times_S P$  is a monomorphism, can be written as saying that the diagonal morphism

text  
 $R \rightarrow R \times_{(P \times_S P)} R = R_0$   
 text

is an isomorphism. One has  $R = \operatorname{Spec}(A(M))$  and

$R_0 = \operatorname{Spec}(A(M \times M)/K)$   
 $R_0$

[^N.D.E-VIII-19] where  $K$  is the ideal generated by the elements of the form

```

```text
x_m(e_{m,0} - e_{0,m}),    with m ∈ M, x_m ∈ A_m;
```

```

let  $\phi : A(M \times M) \rightarrow A(M)$  be the surjective ring homomorphism defined by

```

```text
x e_{m,n} ↦ x e_{m+n}    (m, n ∈ M, x ∈ A)
```

```

(where the  $e_m$ , resp.  $e_{m,n} = e_m \otimes e_n$ , are the elements of the canonical basis of  $A(M)$ , resp.  $A(M \times M)$ ). Then the diagonal morphism  $R \rightarrow R_0$  corresponds to the homomorphism

```

```text
φ⁻ : A(M × M)/K → A(M)
```

```

obtained by passing to the quotient by  $K$ . Now the kernel of  $\phi$  is the ideal  $K'$  generated by the

```

$$
d_m = e_{m,0} - e_{0,m}.
$$

```

One has  $K \subseteq K'$ , and the hypothesis that  $G$  acts freely on  $P$ , i.e. that  $\bar{\phi}$  is an isomorphism, is equivalent to the equality  $K' = K$ , which is expressed by the relations

```

```text
(**)  d_m ∈ K = ∑_p A(M × M) A_p d_p,    for every m ∈ M.
```

```

Using the natural tri-grading of  $A(M \times M)$ , and the fact that the first degree of  $d_m$  is zero, this means that one can write  $d_m$  as a sum of elements of the form

```

```text
f e_{r,s} (e_{p,0} - e_{0,p})    with f ∈ A_{-p} · A_p,
```

```

and using the fact that the total degree of  $d_m$  is  $m$ , one can restrict to terms such that

```

```text
r + s + p = m.
```

```

<!-- original page 16 -->

Hence one must have, for every  $m \in M$ , an expression:

```

```text
(***)  { d_m = e_{m,0} - e_{0,m} = ∑_{r,s} λ_{r,s} (e_{m-s,s} - e_{r,m-r})
        with λ_{r,s} ∈ J_p = A_p · A_{-p} ⊆ A_0, p = m - (r + s).
```

```

One must conclude the relation  $(*)$ , i.e. the relations

```

```text
(***)  J_n = A_0    for every n ∈ M.
```

```

Now for this, it suffices to establish the same relation modulo every maximal ideal of  $A_0$ . As the hypotheses made are invariant under such a reduction, one may already suppose that  $A_0$  is a field.

**Lemma 5.2.** \*Under the preceding conditions (with  $A_0$  a field), if  $M \neq \emptyset$ , there exists a  $p \in M - \{0\}$  such that  $J_p = A_0$ .\*

<!-- label: III.VIII.5.2 -->

Indeed, if this were not so, the sum in the right-hand side of  $(***)$  would be zero for every  $m \in M$ , which is absurd.

<!-- original page 18 -->

**Corollary 5.3.** Under the preceding conditions, but without supposing any longer that  $A_0$  is a field, there exist finitely many elements  $p_i \in M - \{0\}$  such that  $\sum_i J_{p_i} = A_0$ .

<!-- label: III.VIII.5.3 -->

Indeed, one applies the result 5.2 to the situations deduced from  $A/A_0$  by reduction modulo the maximal ideals of  $A_0$ . [N.D.E-VIII-20]

**Corollary 5.4.** Suppose again that  $A_0$  is a field. Then for every subgroup  $N$  of  $M$  such that  $N \neq M$ , there exists a  $p \in M - N$  such that  $J_p = A_0$ .

<!-- label: III.VIII.5.4 -->

Indeed, let  $M' = M/N$ , and consider the  $M'$ -graded ring  $A'$ , whose underlying ring is  $A$ , and whose grading is given by

$$A'_{m'} = \bigoplus_{m \in h^{-1}(m')} A_m,$$

where  $h : M \rightarrow M' = M/N$  is the canonical homomorphism. Geometrically, this construction amounts to considering the subgroup  $G' = D_{\{S\}}(M')$  of  $G$ , and the structure on  $P$  of scheme with operator group  $G'$  induced by the action of  $G$ . It is then evident that  $G'$  acts freely on  $P'$ , i.e. the pair  $(M', A')$  satisfies the hypotheses of 5.3. One thus obtains

$$1 = \sum_i f_i g_i \quad \text{with } f_i \in A'_{m'_i}, g_i \in A'_{-m'_i} \text{ and } m'_i \in M' - \{0\},$$

whence at once the conclusion 5.4 by taking the components of the right-hand side along  $A_0$ , and using that  $A_0$  is a field.

Let us now note that

$$J_p \cdot J_q \subseteq J_{p+q} \quad \text{and } J_p = J_{-p},$$

<!-- original page 17 -->

so if  $N$  denotes the set of  $m \in M$  such that  $J_m = A_0$ , one sees that  $N$  is a subgroup of  $M$ . Using 5.4 one sees that it is equal to  $M$ . This completes the proof of Theorem 5.1.

As we have pointed out in the course of the proof, Theorem 5.1 implies:

**Corollary 5.5.** Under the conditions of 5.1, the graph morphism

<!-- label: III.VIII.5.5 -->

$$P \times_S G \rightarrow P \times_S P$$

is a closed immersion.

One concludes at once:

**Corollary 5.6.** Let  $\sigma$  be a section of  $P$  over  $S$ . Then the morphism  $g \mapsto \sigma \cdot g$  from  $G$  to  $P$  defined by  $\sigma$  is a closed immersion.

<!-- label: III.VIII.5.6 -->

**\*\*Corollary 5.7.\*\*** \*Let  $G, H$  be two  $S$ -groups, with  $G$  diagonalizable,  $H$  affine over  $S$ , and let  $u : G \rightarrow H$  be a homomorphism of  $S$ -groups that is a monomorphism. Then  $u$  is a closed immersion,  $H/G = X$  exists and  $H$  is a principal homogeneous bundle over  $X$  with group  $G_X$ ; finally,  $X$  is affine over  $S$ .\*

<!-- label: III.VIII.5.7 -->

**\*\*Corollary 5.8.\*\*** \*Under the conditions of 5.1, if  $P$  is of finite type (resp. of finite presentation) over  $S$ , the same holds for  $X = P/G$ .\*

<!-- label: III.VIII.5.8 -->

Indeed, it follows from the hypothesis that the fibers of  $G_X$  are of finite type, hence  $G_X$  is of finite presentation over  $X$  by 2.1 (b), hence  $P$  being a torsor under  $G_X$  is of finite presentation over  $X$  [N.D.E-VIII-21]. Since it is also faithfully flat over  $X$ , our conclusion then follows from Exp. V, Prop. 9.1.

## 6. Essentially free morphisms, and representability of certain functors of the form  $\prod_{Y/S} Z/Y$  [VIII-6-star]

<!-- original page 20 -->

**\*\*Definition 6.1.\*\*** \*Let  $f : X \rightarrow S$  be a morphism of preschemes. We say that  $f$  is essentially free, or also that  $X$  is essentially free over  $S$ , if one can find a covering of  $S$  by affine opens  $U_i$ , for each  $i$  an  $U_i$ -prescheme  $S'_i$  affine and faithfully flat over  $U_i$ , and a covering  $(X'_{ij})_j$  of  $X'_{U_i} = X \times_S S'_i$  by affine opens  $X'_{ij}$ , such that for every  $(i, j)$ , the ring of  $X'_{ij}$  is a free module over the ring of  $S'_i$ .\* [N.D.E-VIII-22]

<!-- label: III.VIII.6.1 -->

**\*\*Proposition 6.2.\*\*** \*a) If  $X$  is essentially free over  $S$ , it is flat over  $S$ , the converse being true if  $S$  is Artinian.\*

<!-- label: III.VIII.6.2 -->

\*b) If  $S$  is the spectrum of a field, every  $S$ -prescheme is essentially free over  $S$ .\*

\*c) If  $X$  is essentially free over  $S$ , and if  $S' \rightarrow S$  is a base change morphism, then  $X' = X \times_S S'$  is essentially free over  $S'$ . The converse is true if  $S' \rightarrow S$  is faithfully flat and quasi-compact.\*

The proof is immediate, using for the converse in (a) the fact that a flat module over an Artinian local ring is free. [N.D.E-VIII-23]

**\*\*Proposition 6.3.\*\*** \*Let  $H$  be an  $S$ -prescheme in groups that is diagonalizable (more generally, that becomes diagonalizable by suitable faithfully flat quasi-compact extension of every affine open of  $S$ , i.e.  $H$  is "of multiplicative type", cf. IX 1.1). Then  $H$  is essentially free over  $S$ .\*

<!-- label: III.VIII.6.3 -->

Indeed, if  $H$  is diagonalizable, it is affine over  $S$  and defined by an algebra which is a free  $0_S$ -module.

<!-- original page 21 -->

The introduction of Definition 6.1 is justified by the following:

**\*\*Theorem 6.4.\*\*** \*Let  $S$  be a prescheme,  $Z$  an essentially free  $S$ -prescheme,  $Y$  a closed subprescheme of  $Z$ . Consider the following functor\* [N.D.E-VIII-24]

<!-- label: III.VIII.6.4 -->

```
```text
F = [ [Z/S] Y/Z : (Sch)o/S → (Ens),
F(S') = Γ(Y_{S'}/Z_{S'}) = { ∅ if Z_{S'} ≠ Y_{S'};
{id_{Z_{S'}}} if Z_{S'} = Y_{S'}.
```
```

\*This functor is representable by a closed subscheme of  $S$ .\*<sup>[N.D.E-VIII-25]</sup>

<sup>[N.D.E-VIII-26]</sup> Let us first note that  $F$  is a sheaf for the (fpqc) topology: since  $F(S') = \emptyset$  or  $\{\text{pt}\}$  for every  $S'$ , this reduces to verifying that if  $\{S_i\}$  is an open covering of  $S$  (resp.  $S' \rightarrow S$  a faithfully flat quasi-compact morphism), and if each  $F(S_i) \rightarrow F(S_i \times_S S')$  (resp. if  $F(S') \rightarrow F(S)$ ) is an isomorphism, the same holds for  $F \rightarrow Z$ ; now this is clear (resp. follows from SGA 1, VIII 5.4 or EGA IV<sub>2</sub>, 2.7.1).

Moreover, by SGA 1, VIII 2.1 and 5.5, faithfully flat quasi-compact morphisms are of effective descent for the fibered category of closed immersion arrows. This allows us to restrict ourselves, with the notation of 6.1, to the case where  $S = S'_i$ .

Let  $\{Z_j\}$  be a covering of  $Z$  by affine opens such that  $\mathcal{O}(Z_j)$  is a free module over  $A = \mathcal{O}(S)$ , and let  $Y_j = Y \times_S Z_j$  and  $F_j : (\text{Sch})^{\text{loc}}/S \rightarrow (\text{Ens})$  be the functor defined in terms of  $\{Z_j\}, \{Y_j\}$  as  $F$  in terms of  $(Z, Y)$ . It is a subfunctor of the final functor, and one evidently has  $F = \bigcap_j F_j$ , which reduces us to

<!-- original page 19 -->

proving that each  $F_j$  is representable by a closed subscheme  $T_j$  of  $S$  (for then  $F$  will be representable by the closed subscheme  $T$  intersection of the  $T_j$ ). One may therefore suppose  $Z$  also affine,  $Z = \text{Spec}(B)$ , where  $B$  is a free  $A$ -module. Let  $J$  be a subset of  $B$  defining the subscheme  $Y$  of  $Z$ , and let  $K$  be the ideal in  $A$  generated by the  $u_i(J) \subseteq A$ , where the  $u_i : B \rightarrow A$  are the coordinate forms with respect to the chosen basis. One observes at once that  $T = V(K) = \text{Spec}(A/K)$  satisfies the desired condition, which completes the proof.

**Examples 6.5.** Let us give some important examples of functors that reduce to functors  $\prod_{Z/S} Y/Z$  of the type envisaged in 6.4 and for which it is useful in the sequel to have criteria of representability. We denote by  $S$  a prescheme, by  $X, Y, Z$ , etc., preschemes over  $S$ .

<!-- label: III.VIII.6.5 -->

a) Suppose given an  $S$ -morphism

```

```text
(*)   q : X → Hom_S(Y, Z),
```

```

( $X$  acts on  $Y$  with values in  $Z$ ), i.e. a morphism

```

```text
(**)   r : X ×_S Y → Z.
```

```

Consider a subscheme  $Z'$  of  $Z$ , whence a monomorphism

<!-- original page 22 -->

```

```text
Hom_S(Y, Z') → Hom_S(Y, Z)
```

```

which makes the first functor a subfunctor of the second; let  $X'$  be the inverse image of this subfunctor by  $(*)$ , that is the subfunctor of  $X$  such that  $X'(T)$  is the set of  $x \in X(T)$  such that  $q(x) : Y_T \rightarrow Z_T$  factors through  $Z'_T$ . This functor  $X'$  can be described as follows: set  $P = X \times_S Y$ , let  $P'$  be the inverse image of  $Z'$  by  $r : P \rightarrow Z$ ; then one has an evident isomorphism

```

$$
(***) X' \cong \prod_{P/X} P'/P.
$$

```

One thus obtains: \*if  $Y$  is essentially free over  $S$  and  $Z'$  closed in  $Z$ , the subfunctor  $X'$  of  $X$  is representable by a closed subscheme of  $X$ .\*

b) Suppose given two ways of making  $X$  act on  $Y$  with values in  $Z$ , i.e. two morphisms

```

```text
q_1, q_2 : X → Hom_S(Y, Z),
```

```

and set  $X' = \text{Ker}(q_1, q_2)$ : this is the subfunctor of  $X$  such that  $X'(T)$  is the set of  $x \in X(T)$  such that the two morphisms  $q_1(x), q_2(x) : Y_T \rightarrow Z_T$  are equal. Now giving  $q_1, q_2$  is equivalent to giving a morphism

```

```text
q : X → Hom_S(Y, Z ×_S Z),
```

```

or, again, a morphism  $r : X \times_S Y \rightarrow Z$ ; setting  $U = Z \times_S Z$ , let  $U'$  be the diagonal subscheme of  $Z \times_S Z$ ; then  $X'$  is none other than the inverse image of the subfunctor  $\text{Hom}_S(Y, U') \rightarrow \text{Hom}_S(Y, U)$  by  $q$ , hence can be put in the form  $(***)$ , with  $P = X \times_S Y$  and  $P' = \text{inverse image of the diagonal by } r$ , i.e. kernel of

<!-- original page 23 -->

```

```text
X ×_S Y → Z.
```

```

One is thus in the conditions of (a). One sees consequently that: \*if  $Y$  is essentially free over  $S$  and  $Z$  separated over  $S$ , the subfunctor  $X'$  of  $X$  is representable by a closed subscheme of  $X^*$ .

c) Suppose given a morphism

```

```text
q : X → Hom_S(Y, Y),
```

```

i.e. " $X$  acts on  $Y$ ". Let  $X'$  be the "kernel" of this morphism, i.e. the subfunctor  $X'$  of  $X$  such that  $X'(T)$  is the set of  $x \in X(T)$  such that  $q(x) : Y_T \rightarrow Y_T$  is the identity. This functor is amenable to (b), as one sees by introducing a second homomorphism

```

```text
q' : X → Hom_S(Y, Y)
```

```

<!-- original page 20 -->

"by making  $X$  act trivially on  $Y$ ". Hence: \*if  $Y$  is essentially free over  $S$  and separated over  $S$ , the kernel subfunctor of  $q$  is representable by a closed subscheme of  $X^*$ .

d) Under the conditions of (c), consider the subfunctor  $Y'$  of  $Y$  "of invariants under  $X$ ", so  $Y'(T)$  is the set of  $y \in Y(T)$  such that the corresponding morphism  $q(y) : X_T \rightarrow Y_T$  is "the  $T$ -constant morphism with value  $y$ ". Introducing  $q'$  as in (c), and the homomorphisms corresponding to  $q$  and  $q'$ :

```

```text
q, q' : Y → Hom_S(X, Y),
```

```

one sees that  $Y'$  is precisely  $\text{Ker}(q, q')$ , and is therefore amenable again to (b) (with the roles of  $X$ ,  $Y$  reversed and  $Z = Y$ ).

Consequently, \*if  $X$  is essentially free over  $S$ ,  $Y$  separated over  $S$ , then the subfunctor  $Y'$  of  $Y$  of invariants under  $X$  is representable by a closed subscheme of  $Y^*$ .

<!-- original page 24 -->

e) Constructions of the type explained in the preceding examples are especially frequent in group theory. Thus, when  $G$  is an  $S$ -prescheme in groups acting on the  $S$ -prescheme  $X$ :

$q : G \rightarrow \text{operatorname{Aut}}_S(X),$   
 $q : G \rightarrow \text{operatorname{Aut}}_S(X),$

the kernel of  $q$  ("the subgroup of  $G$  acting trivially") is a closed subscheme of  $G$  provided that  $X$  is essentially free and separated over  $S$  (example (c)), and the subobject  $X^G$  of invariants is a closed subscheme of  $X$ , provided that  $G$  is essentially free over  $S$  and  $X$  separated over  $S$  [N.D.E-VIII-27] (example (d)).

Let  $Y, Z$  be subschemes of  $X$ ; consider the subfunctor  $\text{Transp}_G(Y, Z)$  of  $G$  ("transporter of  $Y$  into  $Z$ ") whose points with values in a  $T$  over  $S$  are the  $g \in G(T)$  such that the corresponding automorphism of  $X_T$  satisfies  $g(Y_T) \subseteq Z_T$  i.e. induces a morphism  $Y_T \rightarrow Z_T$  factoring through  $Y_T \rightarrow Z_T$ . Hence: \*if  $Y$  is essentially free over  $S$ , and  $Z$  closed in  $X$ , then  $\text{Transp}_G(Y, Z)$  is a closed subscheme of  $G$ \* (example (a)).

One may also consider the strict transporter of  $Y$  into  $Z$ , [N.D.E-VIII-28] whose points with values in a  $T$  over  $S$  are the  $g \in G(T)$  such that  $g(Y_T) = Z_T$ , which is nothing but  $\text{Transp}_G(Y, Z) \cap \sigma(\text{Transp}_G(Z, Y))$ , where  $\sigma$  is the symmetry of  $G$ . Consequently, if  $Y$  and  $Z$  are essentially free over  $S$  and closed in  $X$ , the strict transporter of  $Y$  into  $Z$  is a closed subscheme of  $G$ .

An important case is that where  $X = G$ , with  $G$  acting on itself by inner automorphisms. If  $H$  is a subscheme of  $G$ , the strict transporter of  $H$  into  $H$  is also called the \*normalizer of  $H$  in  $G$ \*, and denoted  $\text{Norm}_G(H)$ . Hence: \*if  $H$  is a closed subscheme of  $G$  in groups, essentially free over  $S$ , then  $\text{Norm}_G(H)$  is representable by a closed subscheme of  $G$  in groups.\*

Let finally  $Z$  be a subscheme of  $G$ ; then its \*centralizer\*  $\text{Centr}_G(Z)$  in  $G$  is the subfunctor of  $G$  in groups defined by the procedure of (d), considering " $Z$  acts on  $G$ " via the action induced by that of  $G$ ; hence \*if  $Z$  is essentially free over  $S$  and  $G$  separated over  $S$ ,  $\text{Centr}_G(Z)$  is a closed subscheme of  $G$  in groups\*.

<!-- original page 25 -->

In particular, if  $G$  is essentially free and separated over  $S$ , then \*the center  $C$  of  $G$ , which is none other than  $\text{Centr}_G(G)$ , is a closed subscheme of  $G$  in groups\*.

When  $S$  is the spectrum of a field, 6.3 (b) shows that in examples (a) to (e) above, the conditions "essentially free" are automatically satisfied; only separation conditions remain. Recalling that a prescheme in groups over a field is necessarily separated, one finds for example:

**Corollary 6.7.** [N.D.E-VIII-29] \*Let  $G$  be a prescheme in groups over a field  $k$ . Then:\*

<!-- label: III.VIII.6.7 -->

\*For every subscheme  $Z$  of  $G$ , the centralizer of  $Z$  in  $G$  is a closed subscheme of  $G$  in groups; this is in particular the case for the center  $\text{Centr}_G(G)$  of  $G$ .\*

\*More generally, if  $u, v : X \rightarrow G$  are morphisms of preschemes,  $\text{Transp}_G(u, v)$  is representable by a closed subscheme of  $G$ .\*

\*For two subschemes  $Y, Z$  of  $G$ , with  $Z$  closed,  $\text{Transp}_G(Y, Z)$  is a closed subscheme of  $G$ . If  $Y$  is also closed, the same conclusion holds for  $\text{Transp}_G(Y, Z)$ .\*

\*For every subscheme in groups [N.D.E-VIII-30]  $H$  of  $G$ , the normalizer  $\text{Norm}_G(H)$  is a closed subscheme of  $G$  in groups.\*

**Remark 6.8.** [N.D.E-VIII-31] \*Let  $A$  be a commutative ring,  $M$  an  $A$ -module,  $M^{\vee} = \text{operatorname{Hom}}_A(M, A)$ ; endow the  $A$ -module  $\text{operatorname{End}}_A(M)$  with the topology of pointwise convergence (discrete), i.e. a basis of neighborhoods of  $0$  is formed by the following  $A$ -submodules, where  $n \in \mathbb{N}$  and  $m_1, \dots, m_n \in M$ :

<!-- label: III.VIII.6.8 -->

$$K(m_1, \dots, m_n) = \{ u \in \text{End}_A(M) \mid u(m_i) = 0 \text{ for } i = 1, \dots, n \}.$$

\*We say that  $M$  is a \*quasi-free  $A$ -module\* if the image of the canonical morphism

$\Theta : M \otimes_{\{A\}} M^{\vee} \rightarrow \operatorname{End}_{\{A\}}(M)$  contains  $\operatorname{id}_M$  in its closure, i.e. if the following condition holds:

```

``text
(*) { for all $m_1, \dots, m_n \in M$, there exist $x_1, \dots, x_r \in M$ and $f_1, \dots, f_r \in M^{\vee}$
 { such that $m_i = \sum_{s=1}^r x_s \otimes f_s(m_i) = \sum_{s=1}^r f_s(m_i) x_s$ for $i = 1, \dots, n$.

```

(In this case,  $\Theta$  is dense in  $\operatorname{End}_{\{A\}}(M)$ , since for every  $u \in \operatorname{End}_{\{A\}}(M)$  one has

```

``text

$$u(m_i) = \sum_{s=1}^r f_s(m_i) u(x_s) = \sum_{s=1}^r u(x_s) \otimes f_s(m_i).$$

```

Let us note first that this property is stable under base change. Indeed, let  $\phi : A \rightarrow A'$  be a morphism of rings,  $M' = M \otimes_{\{A\}} A'$ , and  $m'_1, \dots, m'_n \in M'$ . Then  $m'_i = \sum_j m_{ij} \otimes b_{ij}$  ( $m_{ij} \in M$ ,  $b_{ij} \in A'$ ); by hypothesis, there exist  $x_1, \dots, x_r \in M$  and  $f_1, \dots, f_r \in \operatorname{Hom}_{\{A\}}(M, A)$  such that  $m_{ij} = \sum_s x_s f_s(m_{ij})$  for all  $i, j$ . Denote by  $\phi \circ f_s$  the image of  $f_s$  in  $\operatorname{Hom}_{\{A'\}}(M, A')$ ; then for every  $i = 1, \dots, n$  one has:

```

``text

$$\left(\sum_s x_s \otimes \phi \circ f_s \right)(m'_i) = \sum_{s,j} x_s \otimes \phi(f_s(m_{ij})) b_{ij} = \sum_j \left(\sum_s x_s f_s(m_{ij}) \right) \otimes b_{ij} = m'_i,$$

```

!-- original page 22 -->

which proves that  $M'$  is quasi-free over  $A'$ .

Let us also note that every projective  $A$ -module  $P$  is quasi-free (there exist  $A$ -morphisms  $A^{(I)} \rightarrow P \rightarrow A^{(I)}$  such that  $\pi \circ \tau = \operatorname{id}_P$ ); denote by  $(e_i)$  the canonical basis of  $A^{(I)}$  and  $f_i$  the linear form  $e_i^*$ ; if  $m_1, \dots, m_n \in P$ , there exists a finite subset  $J$  of  $I$  such that  $m_k = \sum_{i \in J} f_i(m_k) \pi(e_i)$  for  $k = 1, \dots, n$ .

Then, Theorem 6.4 remains valid if in the statement of Definition 6.1 the word "free" is replaced by "projective" or, more generally, by "quasi-free". Indeed, proceeding as in the proof of 6.4, one is reduced to proving:

**Lemma 6.8.1.** Let  $M$  be a quasi-free  $A$ -module,  $N$  a submodule,  $F$  the covariant functor  $(A\text{-algebras}) \rightarrow (\text{Ens})$  such that  $F(B) = \{\text{pt}\}$  if  $M_B = (M/N)_B$ , and  $F(B) = \emptyset$  otherwise. Then there exists an ideal  $K$  of  $A$  such that  $F(B) = \{\text{pt}\}$  if and only if the morphism  $A \rightarrow B$  factors through  $A/K$ , i.e. one has a functorial isomorphism in  $B$ :

!-- label: III.VIII.6.8.1 -->

```

$$
F(B) \simeq \operatorname{Hom}_{\{A\text{-alg.}\}}(A/K, B).
$$

```

**Proof.** Let  $(n_j)$  be a system of generators of  $N$ , and let  $F_j$  be the subfunctor of the final functor  $e$  ( $e(B) = \{\text{pt}\}$  for every  $B$ ) corresponding to the submodule  $A_{n_j}$ . One has  $F(B) = \{\text{pt}\}$  if and only if the image of each  $n_j$  in  $M_B$  is zero, hence  $F$  is the intersection of the functors  $F_j$ . This reduces us to the case where  $N$  is generated by one element  $n$ .

Let  $\phi : A \rightarrow B$  be an  $A$ -algebra; if the image  $n \otimes 1$  of  $n$  in  $M_B$  is zero, then for every  $f \in M^{\vee} = \operatorname{Hom}_{\{A\}}(M, A)$  one has  $0 = f(n \otimes 1) = \phi(f(n))$ . On the other hand, since  $M$  is quasi-free, there exist  $x_1, \dots, x_r \in M$  and  $f_1, \dots, f_r \in M^{\vee}$  such that  $n = \sum_s f_s(n) x_s$ , whence  $n \otimes 1 = \sum_s x_s \otimes \phi(f_s(n))$ . It follows that  $n \otimes 1 = 0$  if and only if  $\phi$  factors through  $A/K$ , where  $K$  is the ideal generated by the  $f_s(n)$  for  $s = 1, \dots, r$ . This proves the lemma.

**7. Appendix. On monomorphisms of preschemes in groups**

The result proved in the present § is unnecessary for the sequel of the seminar, except for X 8.8 and XV and XVI. It rests in an essential way on the existence theorem for quotient groups of Exposé VI.A.<sup>[N.D.E-VIII-32]</sup>

<!-- original page 26 -->

Corollary 5.7 leads one to ask under what conditions one can assert that a monomorphism  $u : G \rightarrow H$  of  $S$ -groups is an immersion, or even a closed immersion.

We have seen in VI\_B 1.4.2 that this is the case if  $S$  is the spectrum of a field, provided that  $G$  is of finite type over  $k$  and  $H$  is locally of finite type over  $k$ . One easily concludes that the same result remains valid if one only supposes  $S$  Artinian. [N.D.E-VIII-33]

On the other hand, it is easy to give examples of bijective monomorphisms that are not immersions, with  $S$  being for example the affine line over a field, or the spectrum of a discrete valuation ring. One will take for example  $H = (\mathbb{A}^1_S / 2\mathbb{A}^1_S)_{(S)}$ ,  $G = G_1 \times_S G_2$ , where  $G_1$  is the open subgroup of  $H$ , the complement of the closed point  $x$  distinct from  $0$  of the fiber  $H_s \simeq \mathbb{A}^1_S / 2\mathbb{A}^1_S$  (where  $s$  denotes a fixed closed point of  $S$ ), and  $G_2$  is the closed subscheme of  $H$  that is the sum of the subscheme reduced to the unit section, and the closed reduced subscheme defined by the closed point  $x$ . One easily verifies that  $G_2$  is indeed stable under the multiplication of  $H$ , hence is a group scheme. The immersions  $G_i \rightarrow H$  ( $i = 1, 2$ ) then define a homomorphism of  $S$ -groups  $G = G_1 \times G_2 \rightarrow H$ , which is obviously a bijective monomorphism (and moreover a local immersion), but is not an immersion. (One observes that  $G$  and  $H$  are reduced,  $G$  having three disjoint irreducible components, while  $H$  has only two irreducible components.) One will note that  $G_1 \rightarrow H$  also gives an example of an open subgroup  $G$  of  $H$  which is not closed (contrary to what occurs for algebraic groups over a field). The theory of the degeneration of elliptic curves provides further examples of this latter phenomenon, with moreover  $H$  smooth over  $S$  of relative dimension  $1$ , and  $G$  with connected fibers.

It is possible [VIII-7-star] on the other hand that, as soon as one assumes  $G$  flat over  $S$ , and (say)  $G$  and  $H$  of finite presentation over  $S$ , a monomorphism  $u : G \rightarrow H$  of  $S$ -groups is automatically an immersion. We shall prove a result of this nature, under supplementary hypotheses.

Let us note first that one may assume  $S$  affine, and (thanks to the finite presentation hypothesis on  $G$  and  $H$ , which allows one to reduce to the case of the spectrum of a ring of finite type over  $\mathbb{A}^1_S$  [N.D.E-VIII-34])  $S$  Noetherian. Then  $G$  and  $H$  are Noetherian. To say that  $u : G \rightarrow H$  is a closed immersion (resp. an immersion) then amounts to saying that  $u$  is a monomorphism (which is true by hypothesis) and that  $u$  is proper (resp. and that  $u$  is

<!-- original page 27 -->

proper at every point of  $u(G)$  [N.D.E-VIII-35]. The valuative criterion of properness assures us that it suffices to verify that for every base change  $S' \rightarrow S$ , with  $S'$  the spectrum of a discrete valuation ring, complete if one wishes, the morphism  $u' : G' \rightarrow H'$  has the same properness property. (The case of local properness was forgotten in EGA II 7.3, and will appear as an erratum in EGA IV [VIII-7-starstar].) This therefore reduces us to the case where  $S$  itself is the spectrum of a complete discrete valuation ring — subject to the supplementary hypotheses on  $G$ ,  $H$ ,  $u$  that we are led to formulate being stable under base change.

Let then  $s$  (resp.  $s_0$ ) be the closed point (resp. the generic point) of  $S$ . Then the homomorphisms induced on the fibers

``text  
 $u_s : G_s \rightarrow H_s$     and     $u_{s_0} : G_{s_0} \rightarrow H_{s_0}$

are closed immersions, since these are monomorphisms of group schemes of finite type over fields (VI\_B 1.4.2). We may therefore identify  $G_{s_0}$  with a closed subscheme of  $H_{s_0}$ . Now we have the following result:

**\*Lemma 7.1.\*** \*Let  $S$  be the spectrum of a discrete valuation ring,  $s_0$  its generic point,  $H$  an  $S$ -prescheme,  $L_0$  a closed subscheme of the generic fiber  $H_{s_0}$ , so that  $L_0$  is also a subscheme of  $H$ .\*

<!-- label: III.VIII.7.1 -->

\*Then the schematic closure  $\bar{L}_0$  in  $H$  (i.e. the smallest closed subscheme of  $H$  majorizing  $L_0$ , cf. EGA I 9.5) exists and is also the unique closed subscheme of  $H$ , flat over  $S$ , whose generic fiber is  $L_0$ . Moreover, the formation of  $\bar{L}_0$  is functorial with respect to a variable couple  $(H, L_0)$ , and commutes with the formation of cartesian products over  $S$ .\*

<!-- original page 28 -->

\*In particular, if  $H$  is an  $S$ -group and  $L_0$  is a subgroup of  $H_{s_0}$ , then  $\bar{L}_0$  is a subgroup of  $H$ .\*

The proof is immediate and left to the reader[<sup>VIII-7-starstarstar</sup>]. Applying this to the situation  $H$ ,  $G_{\{s_0\}}$ , one sees that the monomorphism  $u : G \rightarrow H$  factors as  $G \rightarrow L \rightarrow H$ , where  $L$  is a subgroup of  $H$  that is a closed subscheme, flat over  $S$ , and where  $G \rightarrow L$  induces an isomorphism on the generic fibers. Then  $u : G \rightarrow H$  is an immersion (resp. a closed immersion) if and only if  $u' : G \rightarrow L$  is. This therefore reduces us to the case where  $H$  is flat over  $S$  and  $u_{\{s_0\}} : G_{\{s_0\}} \rightarrow H_{\{s_0\}}$  is an isomorphism (subject to the supplementary hypotheses we may have to formulate on  $G$ ,  $H$ ,  $u$  being respected when  $H$  is replaced by a closed subscheme in groups). As then  $H$  is the schematic closure of  $H_{\{s_0\}}$ , if  $u$  is an immersion, then  $u(G)$  will be a subscheme [N.D.E-VIII-36] of  $H$  majorizing  $H_{\{s_0\}}$ , hence its schematic closure will also be  $H$ , and consequently  $u(G)$  will be an open subscheme of  $H$ . Hence, we shall in fact have to prove that  $u$  is an open immersion (resp. an isomorphism, if we want to establish that  $u$  is a closed immersion). Since  $G$  and  $H$  are flat

<!-- original page 29 -->

over  $S$ , it amounts to the same thing to say that the morphisms induced on the fibers are open immersions, resp. isomorphisms (cf. SGA 1, I 5.7), and since this is already the case for  $u_{\{s_0\}}$ , one is reduced to proving that  $u_{\{s\}}$  is an open immersion, resp. an isomorphism.

Let us note first that, since  $G$  and  $H$  are flat over  $S$ , the dimension of their fibers remains constant (VI\_B 4.3). Since  $G$  and  $H$  have the same generic fiber, it follows that this dimension is the same for  $G$  and  $H$ , hence  $u_{\{s\}} : G_{\{s\}} \rightarrow H_{\{s\}}$  is a monomorphism of algebraic groups of the same dimension. One concludes easily that  $G_{\{s\}}$  is open in  $H_{\{s\}}$ , and in fact is set-theoretically a union of connected components of  $H_{\{s\}}$  (one is reduced to the case where the base field is algebraically closed, and  $G$  and  $H$  reduced, hence smooth over  $k$ , where it is immediate...). Hence  $H_{\{s\}} - G_{\{s\}}$  is closed in  $H_{\{s\}}$ , hence in  $H$ , hence its complement  $H_0$  in  $H$  is open, and is obviously an open stable under the group law of  $H$ . Hence, up to replacing  $H$  by  $H_0$ , one may, in order to prove that  $u$  is an immersion, reduce (with the usual proviso) to the case where, in addition to the preceding hypotheses, one assumes  $u$  bijective, i.e.  $u_{\{s\}} : G_{\{s\}} \rightarrow H_{\{s\}}$  bijective. One is therefore in any case reduced to proving that  $u$  or again  $u_{\{s\}}$  is an isomorphism, possibly under the hypothesis of bijectivity.

Suppose therefore first that  $u$  is bijective. If  $H_{\{s\}}$  is reduced, one can evidently conclude that  $u_{\{s\}}$  is an isomorphism, since  $G_{\{s\}}$  identifies with a closed subscheme of  $H_{\{s\}}$  having the same underlying set. In particular, if  $k = \kappa(s)$  is of characteristic zero, every algebraic group over  $k$  is reduced by Cartier (cf. VI\_B, 1.6.1, or VII\_B, 3.3.1, or EGA IV<sub>4</sub>, 16.12.2 and 17.12.5), and one has thus obtained:

**\*\*Proposition 7.2.\*\*** \*Let  $u : G \rightarrow H$  be a homomorphism of preschemes in groups of finite presentation over  $S$ . Suppose that  $u$  is a monomorphism,  $G$  flat over  $S$ , and the residue fields of  $S$  of characteristic zero. Then  $u$  is an immersion.\*

<!-- label: III.VIII.7.2 -->

When  $\kappa(s)$  is of characteristic  $p > 0$ , we shall restrict to the case where  $G$  is commutative. Then (with the reductions made)  $H$  is also commutative, since it is the schematic closure of  $H_{\{s_0\}}$  which is isomorphic to  $G_{\{s_0\}}$ , hence commutative. For every integer  $n \geq 0$ , we set  $S_n = \operatorname{Spec}(V/m^{n+1})$  (where  $V$  is the valuation ring defining  $S$  and  $m$  its maximal ideal),  $G_n = G \times_S S_n$ ,  $H_n = H \times_S S_n$ . For every integer  $m > 0$ , we also introduce the subgroups  $\{G_n\}$  and  $\{H_n\}$  of  $G$  and  $H$ , kernels of the  $m$ -th power. One defines similarly  $\{G_n\} = (\{G_n\})_n$ , which one denotes simply  $G_n$ , and likewise for  $H$ .

By virtue of VI\_A 3.2, one can form the quotients  $Q_n = H_n/G_n$ . Then  $Q_n$  is a commutative group scheme over  $S_n$ , flat over  $S_n$ , and  $H_n \rightarrow Q_n$  is a faithfully flat morphism with kernel  $G_n$ . Since the formation of quotients commutes with base extension [N.D.E-VIII-37], one has

```
```text
Q_n = Q_m \times_{S_m} S_n    for m \leq n,
```

in particular the fiber $Q_n \times_{S_n} S_0$ is none other than $Q_0 = H_0/G_0$. Since H_0 has the same

<!-- original page 30 -->

underlying set as H_0 , then Q_0 is set-theoretically reduced to a single point: it is a purely infinitesimal group. Consequently, each Q_n is finite and flat over S_n . Hence Q_n is defined by an algebra C_n over $V_n = V/m^{n+1}$ which is a free module of finite type over this ring, and for $m \geq n$ one has $C_n = C_m \otimes_{V_m} V_n$, an isomorphism also respecting the diagonal map. One thus obtains a free module of finite type $C = \varprojlim C_n$ over $V = \varprojlim V_n$, and the diagonal maps of the C_n define a diagonal map of

$\mathbb{C}$, so that $Q = \operatorname{Spec}(C)$ becomes a group scheme finite and flat over $\mathbb{S}$, such that

```
```text
Q x_S S_n = Q_n
```

for every  $n$ .

**Lemma 7.3.** [N.D.E-VIII-38] \*Let  $K$  be a field,  $Q$  a finite group scheme over  $K$ , of degree  $n$ . Then the  $n$ -th power morphism in  $Q$  is zero.\*

<!-- label: III.VIII.7.3 -->

Cf. VII\_A 8.5.

**Remark 7.3.1.** \*Statement 7.3 retains a sense for a group scheme  $Q/S$  finite and locally free over  $\mathbb{S}$ ,  $\mathbb{S}$  being an arbitrary base prescheme. It would be interesting to find a proof in this general case.\*

<!-- label: III.VIII.7.3.1 -->

One will note that 7.3 (i.e. VII\_A, 8.5) proves in any case that the envisaged statement is true if  $\mathbb{S}$  is reduced, as one sees by applying 7.3 to the fibers of  $Q$  at the maximal points (i.e. generic points of the irreducible components) of  $\mathbb{S}$ . [N.D.E-VIII-39]

In particular, under the conditions of the preceding proof, where  $\mathbb{S}$  is the spectrum of a discrete valuation ring and  $Q$  is commutative, one finds that  $n \cdot \operatorname{id}_Q = 0$ . Moreover, here  $n$  is a power  $p^{\nu}$  of the residue characteristic, and one finds:

**Corollary 7.4.** \*With  $Q$  and the  $Q_n$  as above, and their common degree being  $p^{\nu}$ , one will have  $p^{\nu} \cdot \operatorname{id}_Q = 0$  and consequently  $p^{\nu} \cdot \operatorname{id}_{Q_n} = 0$  for every  $n$ .\*

<!-- label: III.VIII.7.4 -->

<!-- original page 31 -->

**Corollary 7.5.** \*Suppose moreover that  $G_0$  is smooth over  $k$ , and the homomorphism  $p \cdot \operatorname{id}_{G_0}$  flat (which amounts to saying, in virtue of the structure of algebraic groups over an algebraically closed field  $\bar{k}$ , that  $G_{\bar{k}}$  contains no subgroup isomorphic to the additive group). Then for every  $\nu \geq \nu_0$  and  $n > 0$ , the group  $p^{\nu} H_n$  is flat over  $S_n$ .\*

<!-- label: III.VIII.7.5 -->

Indeed, it follows from  $p^{\nu} \cdot \operatorname{id}_{Q_n} = 0$  that  $p^{\nu} \cdot \operatorname{id}_{H_n}$  factors through  $G_n$ , so that one has a commutative diagram:

```
```text
      p^nu · id_{H_n}
      ────────────────────→ H_n
      /      \
     v_n      u_n
    /          |
   u_n         |
    \          |
     \      p^nu · id_{G_n}
      ────────────────────→ G_n
...
```
```

I claim that  $v_n$  is flat. Indeed, since  $H_n$  and  $G_n$  are flat over  $S_n$ , one is reduced to verifying that  $v_n$  is flat (SGA 1, IV 5.9), so one may assume that  $n = 0$ , whence  $S_n = \operatorname{Spec}(k)$ . Since  $p \cdot \operatorname{id}_{G_0}$  is flat, and hence  $p^{\nu} \cdot \operatorname{id}_{G_0}$  is flat, its image is an open induced subgroup  $G'_0$  of  $G_0$ , and since  $u_0 : G_0 \rightarrow H_0$  is surjective, it follows that  $v_n$  takes its values in  $G'_0$ , hence may be considered as a homomorphism into  $G'_0$ . Since its composition with  $u_0$  is an epimorphism, it is itself an epimorphism, hence a flat homomorphism into  $G'_0$ , hence a flat homomorphism into  $G_0$ . Hence  $v_n$  is flat, hence  $\operatorname{Ker} v_n = p^{\nu} H$  is flat over  $\mathbb{S}$ . QED.

**Remark.** We have not explicitly used the fact that  $G_0$  is smooth over  $k$ ; but it is easy to see that this is a consequence of the fact that  $p \cdot \operatorname{id}_G$  is flat – this is why we made this condition explicit in the hypothesis of

Corollary 7.5.

**Lemma 7.6.** \*Let  $\varphi : G \rightarrow H$  be a surjective monomorphism of commutative algebraic groups over a field  $k$  of characteristic  $p > 0$ ; consider the (purely infinitesimal) group  $Q = H/G$ . Then there exists an integer  $\nu_1$  such that for  $\nu \geq \nu_1$ , the sequence\*

<!-- label: III.VIII.7.6 -->

$$0 \rightarrow {}_{p^\nu}G \rightarrow {}_{p^\nu}H \rightarrow Q \rightarrow 0$$

is exact.\*

It suffices to ensure exactness at  $Q$ , and for this to ensure that the homomorphism

$$(*) \quad 0_{Q,e} \rightarrow 0_{{}_{p^\nu}H, e}$$

of local rings at the neutral elements is injective (N.B. recall that  $Q$  is set-theoretically reduced to the element  $e$ ). Now one has a natural homomorphism

$$(**) \quad 0_{{}_{p^\nu}H, e} \rightarrow 0_{H,e}/m_{{}_{p^\nu}H},$$

where  $m$  is the augmentation ideal (i.e. the maximal ideal) of  $0_{H,e}$ , as one sees by noting that  $p^\nu \cdot \text{id}_H$  vanishes on the kernel of "the iterated Frobenius homomorphism"  $F^\nu$ ; the composite of the homomorphisms  $(*)$  and  $(**)$  is also equal to the natural composite

$$(***) \quad 0_{Q,e} \rightarrow 0_{H,e} \rightarrow 0_{H,e}/m_{{}_{p^\nu}H}.$$

<!-- original page 32 -->

Now  $0_{Q,e} \rightarrow 0_{H,e}$  is injective, since  $H \rightarrow Q$  is an epimorphism hence is flat; on the other hand  $0_{Q,e}$  is Artinian, and finally the intersection in  $0_{H,e}$  of the  $m_{{}_{p^\nu}H}$  is reduced to  $0$ , hence so is the intersection of their traces on  $0_{Q,e}$ . Consequently one of these traces is reduced to  $0$ , which proves that  $(***)$  is injective, and a fortiori  $(*)$  is injective.

**Lemma 7.7.** \*Under the conditions of 7.5 there exists a  $\nu_1$  such that, for  $\nu \geq \nu_1$  and every  $n$ , the sequence of  $S_n$ -groups\*

<!-- label: III.VIII.7.7 -->

$$0 \rightarrow {}_{p^\nu}G_n \rightarrow {}_{p^\nu}H_n \rightarrow Q_n \rightarrow 0$$

is exact (more precisely,  $w_n$  is faithfully flat and its kernel is  ${}_{p^\nu}G_n$ ).\*

One takes  $\nu_1$  as in 7.6 applied to  $\varphi : G \rightarrow H$ , and  $\nu_1 \geq \nu_0$  (where  $p^{\nu_0}$  is rank  $Q$ ). It only remains to verify that  $w_n$  is faithfully flat. Now by virtue of 7.5,  ${}_{p^\nu}H$  is flat over  $S_n$ , and since  $Q_n$  is too, one is reduced to verifying that  $w_0 : {}_{p^\nu}H_0 \rightarrow Q_0$  is faithfully flat, i.e. is an epimorphism, which is true by the choice of  $\nu_1$ .

**Corollary 7.8.** \*Suppose moreover  $H$  separated over  $S$ , more generally that  ${}_{p^\nu}H$  is separated over  $S$  for every  $\nu$ , and that  ${}_{p^\nu}G$  is finite over  $S$  for every  $\nu$ . Then the group schemes  ${}_{p^\nu}G$  and  ${}_{p^\nu}H$  are finite and flat over  $S$  for  $\nu \geq \nu_1$ , and one has an exact sequence\*

<!-- label: III.VIII.7.8 -->

text

$\theta \rightarrow \pi_{\{p^\nu\}} G \rightarrow \pi_{\{p^\nu\}} H \xrightarrow{-w} Q \rightarrow 0.$

Since  $\pi_u : G \rightarrow H$  is surjective, so is the induced morphism  $\pi_{\{p^\nu\}} G \rightarrow \pi_{\{p^\nu\}} H$ , and since the first member is finite over  $S$  and the second separated over  $S$ , it follows that the second member is finite over  $S$ . To then verify that  $\pi_{\{p^\nu\}} G$  and  $\pi_{\{p^\nu\}} H$  are also flat over  $S$ , it suffices to verify that this is the case for  $\pi_{\{p^\nu\}} G_n$  and  $\pi_{\{p^\nu\}} H_n$  for every  $n$ , which is contained in 7.5. Finally, the exact sequence of 7.8 comes from the exact sequences 7.7 for variable  $n$ .

<!-- original page 34 -->

Taking the generic fibers in the exact sequence 7.8 and recalling that  $\pi_{\{s_0\}} : G_{\{s_0\}} \rightarrow H_{\{s_0\}}$  is an isomorphism, one finds  $\pi_{\{s_0\}} = \text{unit group}$ , whence (since  $Q$  is flat over  $S$ )  $Q = \text{unit group}$ , whence  $\pi_{\{s_0\}} = \text{unit group}$ , hence  $\pi_{\{s\}} : G_{\{s\}} \rightarrow H_{\{s\}}$  is an isomorphism. Hence:

**Proposition 7.9.** \*Let  $\pi_u : G \rightarrow H$  be a homomorphism of preschemes in groups of finite presentation over the prescheme  $S$ . Suppose:

<!-- label: III.VIII.7.9 -->

a)  $\pi_u$  is a monomorphism.

b)  $G$  is flat over  $S$ .

c) For every  $s \in S$  such that  $\kappa(s)$  is of residue characteristic  $p > 0$ , one wants the following conditions to be satisfied for the homomorphism  $\pi'_s : G'_s \rightarrow H'_s$  of preschemes in groups over  $S' = \operatorname{Spec}(O_{S,s})$  deduced from  $\pi_u : G \rightarrow H$  by the base change  $S' \rightarrow S$ :

–  $G'_s$  is commutative,

– the special fiber  $G'_0 = G_{\{s\}}$  is smooth over  $\kappa(s)$ ,

– for every integer  $\nu > 0$ ,  $\pi_{\{p^\nu\}} G'_s$  is finite over  $S'$  and  $\pi_{\{p^\nu\}} H'_s$  is separated over  $S'$ .

Under these conditions,  $\pi_u$  is an immersion.

It suffices to remark that, in (c), the condition that  $\pi_{\{pG'\}}'_0$  be finite over  $S'$  implies that  $\pi_{\{pG'\}}'_0$  is finite over  $\kappa(s)$ , which already implies that  $G'_0 \otimes_{\kappa(s)} \overline{\kappa(s)}$  contains no subgroup isomorphic to the additive group, so that one is under the hypotheses of 7.5.

<!-- original page 29 -->

**Remark 7.10.** \*Examples of M. Raynaud (XVI 1.1 (a) and (b)) show that in (c) one cannot drop either the hypothesis that the  $\pi_{\{p^\nu\}} G'_s$  are finite over  $S'$  or the hypothesis that the  $\pi_{\{p^\nu\}} H'_s$  are separated over  $S'$ .

<!-- label: III.VIII.7.10 -->
