Elements of Algebraic Geometry

(Éléments de géométrie algébrique)

Chapters 0–IV

English translation

Translated from the French transcription of the original publication in the *Publications mathématiques de l'IHÉS* 4, 8, 11, 17, 20, 24, 28 and 32 (1960–1967), `https://github.com/KokunoYumeto/ega-fr`. The translation is AI-translated: by Claude Opus 5.5 (Anthropic) for the Introduction, Chapter 0, §§1–11 and 14, Chapter I, Chapter II with its errata, Chapter III, §§1 and 3, and Chapter IV: its introduction, §§1, 16, 17 and 20, and the bibliography and indexes that close its first part; by OpenAI Codex models (GPT-6 Astra, GPT-5.6 Sol) for the other sections.

The rights in the original work remain with its rights holders. Anything in this edition that the publisher holds rights to is dedicated to the public domain under CC0 1.0. Rights holders who object to the availability of this material can open an issue at `https://github.com/KokunoYumeto/ega-en/issues`; the material will be taken down.

Contents

Introduction **17**

Chapter 0. Preliminaries **23**
§1 Rings of fractions 23
1.0 Rings and algebras 23
1.1 Radical of an ideal. Nilradical and radical of a ring 24
1.2 Modules and rings of fractions 24
1.3 Functorial properties 26
1.4 Change of multiplicative subset 27
1.5 Change of ring 29
1.6 Identification of the module M_f with an inductive limit 31
1.7 Support of a module 32
§2 Irreducible spaces. Noetherian spaces 33
2.1 Irreducible spaces 33
2.2 Noetherian spaces 34
§3 Supplement on sheaves 35
3.1 Sheaves with values in a category 35
3.2 Presheaves on a basis of open subsets 37
3.3 Gluing sheaves 39
3.4 Direct images of presheaves 40
3.5 Inverse images of presheaves 42
3.6 Simple sheaves and locally simple sheaves 44
3.7 Inverse images of presheaves of groups or of rings 45
3.8 Sheaves of pseudo-discrete spaces 46
§4 Ringed spaces 47
4.1 Ringed spaces, $\mathcal{A}$-modules, $\mathcal{A}$-algebras 47
4.2 Direct image of an $\mathcal{A}$-module 50
4.3 Inverse image of a $\mathcal{B}$-module 51
4.4 Relations between direct images and inverse images 53
§5 Quasi-coherent sheaves and coherent sheaves 55
5.1 Quasi-coherent sheaves 55
5.2 Sheaves of finite type 56
5.3 Coherent sheaves 57
5.4 Locally free sheaves 59
5.5 Sheaves on a ringed space in local rings 63
§6 Flatness 65
6.1 Flat modules 65
6.2 Change of rings 66
6.3 Localization of flatness 66
6.4 Faithfully flat modules 67

6.5 Restriction of scalars . . . 68
6.6 Faithfully flat rings . . . 69
6.7 Flat morphisms of ringed spaces . . . 69
§7 Adic rings . . . 70
7.1 Admissible rings . . . 70
7.2 Adic rings and projective limits . . . 73
7.3 Noetherian preadic rings . . . 76
7.4 Quasi-finite modules over local rings . . . 78
7.5 Rings of restricted formal power series . . . 79
7.6 Complete rings of fractions . . . 81
7.7 Completed tensor products . . . 85
7.8 Topologies on modules of homomorphisms . . . 86
§8 Representable functors . . . 87
8.1 Representable functors . . . 87
8.2 Algebraic structures in categories . . . 91
§9 Constructible sets . . . 93
9.1 Constructible sets . . . 93
9.2 Constructible sets in Noetherian spaces . . . 95
9.3 Constructible functions . . . 97
§10 Supplement on flat modules . . . 98
10.1 Relations between flat modules and free modules . . . 98
10.2 Local flatness criteria . . . 99
10.3 Existence of flat extensions of local rings . . . 101
§11 Supplement on homological algebra . . . 103
11.1 Review of spectral sequences . . . 103
11.2 The spectral sequence of a filtered complex . . . 107
11.3 The spectral sequences of a bicomplex . . . 109
11.4 Hypercohomology of a functor with respect to a complex $K^\bullet$ . . . 112
11.5 Passage to the inductive limit in hypercohomology . . . 115
11.6 Hyperhomology of a functor with respect to a complex $K_\bullet$ . . . 119
11.7 Hyperhomology of a functor with respect to a bicomplex $K_{\bullet\bullet}$ . . . 121
11.8 Supplement on the cohomology of simplicial complexes . . . 123
11.9 A lemma on complexes of finite type . . . 127
11.10 Euler–Poincaré characteristic of a complex of modules of finite length 129
§12 Supplement on sheaf cohomology . . . 130
12.1 Cohomology of sheaves of modules on ringed spaces . . . 130
12.2 Higher direct images . . . 137
12.3 Supplements on the Ext functors of sheaves . . . 140
12.4 Hypercohomology of the direct image functor . . . 143
§13 Projective limits in homological algebra . . . 145
13.1 The Mittag-Leffler condition . . . 145
13.2 The Mittag-Leffler condition for abelian groups . . . 147
13.3 Application: cohomology of a projective limit of sheaves . . . 150
13.4 Mittag-Leffler condition and graded objects associated with projective systems . . . 152
13.5 Projective limits of spectral sequences of filtered complexes . . . 154
13.6 Spectral sequence of a functor relative to an object equipped with a finite filtration . . . 157
13.7 Derived functors of a projective limit of arguments . . . 159
§14 Combinatorial dimension of a topological space . . . 165

14.1 Combinatorial dimension of a topological space 165
14.2 Codimension of a closed subset 168
14.3 The chain condition 170
§15 M-regular sequences and $\mathscr{F}$-regular sequences 172
15.1 M-regular sequences and M-quasi-regular sequences 172
15.2 $\mathscr{F}$-regular sequences 179
§16 Dimension and depth of Noetherian local rings 181
16.1 Dimension of a ring 181
16.2 Dimension of a semi-local Noetherian ring 184
16.3 Systems of parameters in a Noetherian local ring 187
16.4 Depth and codepth 190
16.5 Cohen-Macaulay modules 194
§17 Regular rings 198
17.1 Definition of regular rings 198
17.2 Reminders on projective and injective dimension of modules 201
17.3 Cohomological theory of regular rings 205
§18 Supplement on extensions of algebras 209
18.1 Inverse images of augmented rings 210
18.2 Extensions of a ring by a bimodule 212
18.3 The group of classes of A-extensions 217
18.4 Extensions of algebras 221
18.5 Case of topological rings 223
§19 Formally smooth algebras and Cohen rings 225
19.0 Introduction 225
19.1 Formal epimorphisms and monomorphisms 227
19.2 Formally projective modules 234
19.3 Formally smooth algebras 235
19.4 First criteria for formal smoothness 241
19.5 Formal smoothness and associated graded rings 245
19.6 The case of algebras over a field 256
19.7 The case of local homomorphisms; existence and uniqueness theorems 260
19.8 Cohen algebras and Cohen rings; application to the structure of complete local rings 265
19.9 Relatively formally smooth algebras 269
19.10 Formally unramified algebras and formally étale algebras 271
§20 Derivations and differentials 272
20.1 Derivations and algebra extensions 272
20.2 Functorial properties of derivations 274
20.3 Continuous derivations in topological rings 276
20.4 Principal parts and differentials 278
20.5 Fundamental functorial properties of $\Omega^1_{B/A}$ 282
20.6 Modules of imperfection and characteristic homomorphisms 290
20.7 Generalizations to topological rings 300
§21 Differentials in rings of characteristic p 307
21.1 Systems of p-generators and p-bases 307
21.2 p-bases and formal smoothness 310
21.3 p-bases and modules of imperfection 313
21.4 The case of field extensions 315
21.5 Application: criteria for separability 317
21.6 Admissible fields for an extension 319

21.7 Cartier's equality . . . 322
21.8 Criteria for admissibility . . . 324
21.9 Completed modules of differentials in formal power series rings . . 328
§22 Differential criteria for smoothness and regularity . . . 334
22.1 Lifting of formal smoothness . . . 335
22.2 Differential characterization of local algebras formally smooth over a field . . . 337
22.3 Application to relations between certain local rings and their completions . . . 342
22.4 Preliminary results on finite extensions of local rings whose maximal ideal has square zero . . . 344
22.5 Geometrically regular algebras and formally smooth algebras . . . 351
22.6 Zariski's Jacobian criterion . . . 355
22.7 Nagata's Jacobian criterion . . . 359
§23 Japanese rings . . . 363
23.1 Japanese rings . . . 363
23.2 Integral closure of a local Noetherian integral ring . . . 366

Chapter I. The language of schemes 371
§1 Affine schemes . . . 371
1.1 The prime spectrum of a ring . . . 371
1.2 Functorial properties of the prime spectra of rings . . . 374
1.3 Sheaf associated with a module . . . 375
1.4 Quasi-coherent sheaves on a prime spectrum. . . . 381
1.5 Coherent sheaves on a prime spectrum. . . . 383
1.6 Functorial properties of quasi-coherent sheaves on a prime spectrum. 384
1.7 Characterization of morphisms of affine schemes. . . . 386
§2 Preschemes and morphisms of preschemes . . . 387
2.1 Definition of preschemes. . . . 387
2.2 Morphisms of preschemes. . . . 388
2.3 Gluing of preschemes . . . 390
2.4 Local schemes . . . 391
2.5 Preschemes over a prescheme . . . 393
§3 Product of preschemes . . . 394
3.1 Sum of preschemes. . . . 394
3.2 Product of preschemes. . . . 394
3.3 Formal properties of the product; change of base prescheme. . . . 397
3.4 Points of a prescheme with values in a prescheme; geometric points 400
3.5 Surjections and injections . . . 403
3.6 Fibres. . . . 406
3.7 Application: reduction of a prescheme mod. $\mathfrak{J}^1$ . . . 407
§4 Subpreschemes and immersion morphisms . . . 408
4.1 Subpreschemes. . . . 408
4.2 Immersion morphisms . . . 410
4.3 Product of immersions. . . . 412
4.4 Inverse image of a sub-prescheme. . . . 413
4.5 Local immersions and local isomorphisms. . . . 414
§5 Reduced preschemes; separation condition . . . 415
5.1 Reduced preschemes. . . . 415
5.2 Existence of a sub-prescheme with a given underlying space. . . . 419

5.3 Diagonal; graph of a morphism. . . . 419
5.4 Separated morphisms and preschemes. . . . 423
5.5 Criteria for separatedness. . . . 424
§6 Finiteness conditions 428
6.1 Noetherian and locally Noetherian preschemes. . . . 428
6.2 Artinian preschemes. . . . 431
6.3 Morphisms of finite type. . . . 431
6.4 Algebraic preschemes. . . . 434
6.5 Local determination of a morphism 437
6.6 Quasi-compact morphisms and morphisms locally of finite type . . 439
§7 Rational maps 442
7.1 Rational maps and rational functions 442
7.2 Domain of definition of a rational map 445
7.3 Sheaf of rational functions 448
7.4 Torsion sheaves and torsion-free sheaves 449
§8 Chevalley schemes 450
8.1 Related local rings 450
8.2 Local rings of an integral scheme 452
8.3 Chevalley schemes 454
§9 Supplement on quasi-coherent sheaves 455
9.1 Tensor product of quasi-coherent sheaves. . . . 455
9.2 Direct image of a quasi-coherent sheaf. . . . 458
9.3 Extension of sections of quasi-coherent sheaves. . . . 459
9.4 Extension of quasi-coherent sheaves. . . . 460
9.5 Closed image of a prescheme. Closure of a sub-prescheme. . . . 463
9.6 Quasi-coherent sheaves of algebras; change of the structural sheaf. 466
§10 Formal schemes 467
10.1 Affine formal schemes. . . . 467
10.2 Morphisms of affine formal schemes. . . . 469
10.3 Ideals of definition of an affine formal scheme. . . . 470
10.4 Formal preschemes and morphisms of formal preschemes. . . . 472
10.5 Ideals of definition of formal preschemes. . . . 473
10.6 Formal preschemes as inductive limits of preschemes. . . . 475
10.7 Product of formal preschemes. . . . 479
10.8 Formal completion of a prescheme along a closed subset. . . . 480
10.9 Extension of a morphism to the completions. . . . 484
10.10 Application to coherent sheaves on affine formal schemes. . . . 487
10.11 Coherent sheaves on formal preschemes. . . . 489
10.12 Adic morphisms of formal preschemes. . . . 491
10.13 Morphisms of finite type. . . . 493
10.14 Closed sub-preschemes of formal preschemes. . . . 495
10.15 Separated formal preschemes. . . . 497
Bibliography 500

Chapter II. Elementary global study of some classes of morphisms 503
§1 Affine morphisms 503
1.1 S-preschemes and $\mathcal{O}_S$-algebras 503
1.2 Preschemes affine over a prescheme 504
1.3 Prescheme affine over S associated to an $\mathcal{O}_S$-algebra 505
1.4 Quasi-coherent sheaves on a prescheme affine over S 507

1.5 Change of the base prescheme . . . 509
1.6 Affine morphisms . . . 511
1.7 Vector bundle associated to a sheaf of modules . . . 511
§2 Homogeneous prime spectra . . . 516
2.1 Generalities on graded rings and modules. . . . 516
2.2 Rings of fractions of a graded ring. . . . 520
2.3 Homogeneous prime spectrum of a graded ring. . . . 521
2.4 The scheme structure on Proj(S). . . . 525
2.5 Sheaf associated to a graded module. . . . 527
2.6 Graded S-module associated to a sheaf on Proj(S). . . . 533
2.7 Finiteness conditions. . . . 535
2.8 Functorial behaviour. . . . 538
2.9 Closed subschemes of a scheme Proj(S). . . . 543
§3 Homogeneous spectrum of a sheaf of graded algebras . . . 545
3.1 Homogeneous spectrum of a quasi-coherent graded $\mathcal{O}_Y$-algebra. . . . 545
3.2 Sheaf on Proj($\mathcal{S}$) associated to a graded $\mathcal{S}$-module. . . . 550
3.3 Graded $\mathcal{S}$-module associated to a sheaf on Proj($\mathcal{S}$). . . . 552
3.4 Finiteness conditions. . . . 554
3.5 Functorial behaviour. . . . 557
3.6 Closed sub-preschemes of a prescheme Proj($\mathcal{S}$). . . . 560
3.7 Morphisms from a prescheme to a homogeneous spectrum. . . . 561
3.8 Criteria for immersion into a homogeneous spectrum. . . . 564
§4 Projective bundles. Ample sheaves . . . 566
4.1 Definition of projective bundles. . . . 566
4.2 Morphisms from a prescheme to a projective bundle. . . . 568
4.3 The Segre morphism. . . . 571
4.4 Immersions into projective bundles. Very ample sheaves . . . 574
4.5 Ample sheaves . . . 578
4.6 Relatively ample sheaves . . . 584
§5 Quasi-affine morphisms; quasi-projective morphisms. Proper morphisms; projective morphisms . . . 589
5.1 Quasi-affine morphisms. . . . 589
5.2 Serre's criterion. . . . 592
5.3 Quasi-projective morphisms. . . . 594
5.4 Proper morphisms and universally closed morphisms. . . . 595
5.5 Projective morphisms. . . . 598
5.6 Chow's lemma. . . . 601
§6 Integral morphisms and finite morphisms . . . 604
6.1 Preschemes integral over another. . . . 604
6.2 Quasi-finite morphisms. . . . 608
6.3 Integral closure of a prescheme. . . . 610
6.4 Determinant of an endomorphism of an $\mathcal{O}_X$-module. . . . 614
6.5 Norm of an invertible sheaf. . . . 618
6.6 Application: ampleness criteria. . . . 622
6.7 Chevalley's theorem. . . . 627
§7 Valuative criteria . . . 630
7.1 Review of valuation rings. . . . 630
7.2 Valuative criterion for separatedness . . . 632
7.3 Valuative criterion for properness . . . 634
7.4 Algebraic curves and function fields of dimension one . . . 638

§8 Blow-up schemes; projecting cones; projective closure 642
8.1 Blow-up preschemes 642
8.2 Preliminary results on localization in graded rings 646
8.3 Projecting cones 651
8.4 Projective closure of a vector bundle 656
8.5 Functorial behaviour 658
8.6 A canonical isomorphism for punctured cones 660
8.7 Blow-up of projecting cones 662
8.8 Ample sheaves and contractions 666
8.9 Grauert's ampleness criterion: statement 670
8.10 Grauert's ampleness criterion: proof 672
8.11 Uniqueness of contractions 677
8.12 Quasi-coherent sheaves on projecting cones 679
8.13 Projective closures of sub-sheaves and of closed subschemes 683
8.14 Supplement on the sheaves associated to graded $\mathcal{S}$-modules 685
Bibliography (continued) 691
Errata and Addenda (List 1) 692

Chapter III. Cohomological study of coherent sheaves 699
§1 Cohomology of affine schemes 699
1.1 Review of the exterior algebra complex 699
1.2 Čech cohomology of an open covering 702
1.3 Cohomology of an affine scheme 704
1.4 Application to the cohomology of arbitrary preschemes 705
§2 Cohomological study of projective morphisms 711
2.1 Explicit calculations of certain cohomology groups 711
2.2 The fundamental theorem of projective morphisms 715
2.3 Application to graded sheaves of algebras and modules 720
2.4 A generalisation of the fundamental theorem 726
2.5 Euler–Poincaré characteristic and the Hilbert polynomial 729
2.6 Application: ampleness criteria 733
§3 The finiteness theorem for proper morphisms 738
3.1 The dévissage lemma 738
3.2 The finiteness theorem: the case of ordinary schemes 740
3.3 Generalization of the finiteness theorem (ordinary schemes) 742
3.4 The finiteness theorem: the case of formal schemes 742
§4 The fundamental theorem of proper morphisms. Applications 746
4.1 The fundamental theorem 746
4.2 Particular cases and variants 754
4.3 Zariski's connectedness theorem 756
4.4 Zariski's "main theorem" 761
4.5 Completions of modules of homomorphisms 765
4.6 Relations between formal morphisms and ordinary morphisms . . . 767
4.7 An ampleness criterion 773
4.8 Finite morphisms of formal preschemes 775
§5 An existence theorem for coherent algebraic sheaves 779
5.1 Statement of the theorem 779
5.2 Proof of the existence theorem: the projective and quasi-projective case 781
5.3 Proof of the existence theorem: the general case 785

5.4 Application: comparison between morphisms of ordinary preschemes and morphisms of formal preschemes. Algebraizable formal preschemes . . . 787
5.5 A decomposition of certain preschemes . . . 791
§6 Local and global Tor functors; Künneth formula . . . 799
6.1 Introduction . . . 799
6.2 Hypercohomology of complexes of modules on a prescheme . . . 801
6.3 Hypertor of two complexes of modules . . . 804
6.4 Local hypertor functors of complexes of quasi-coherent modules: the affine scheme case . . . 810
6.5 Local hypertor functors of complexes of quasi-coherent modules: the general case . . . 812
6.6 Global hypertor functors of complexes of quasi-coherent modules and Künneth spectral sequences: the affine-base case . . . 817
6.7 Global hypertor functors of complexes of quasi-coherent modules and Künneth spectral sequences: the general case . . . 824
6.8 The associativity spectral sequences of global hypertor . . . 834
6.9 The base change spectral sequences of global hypertor . . . 836
6.10 Local structure of certain cohomological functors . . . 844
§7 Base change for homological functors of sheaves of modules . . . 848
7.1 Functors of A-modules . . . 848
7.2 Characterisation of the tensor product functor . . . 851
7.3 Exactness criteria for homological functors of modules . . . 856
7.4 Exactness criteria for the functors $H_\bullet(P_\bullet \otimes_A M)$ . . . 862
7.5 The case of Noetherian local rings . . . 867
7.6 Descent of exactness properties. Semicontinuity theorem and Grauert's exactness criterion . . . 870
7.7 Application to proper morphisms: I. The exchange property . . . 877
7.8 Application to proper morphisms: II. Cohomological flatness criteria 885
7.9 Application to proper morphisms: III. Invariance of the Euler–Poincaré characteristic and the Hilbert polynomial . . . 889

Chapter IV. Local study of schemes and morphisms of schemes 905
§1 Relative finiteness conditions. Constructible sets in preschemes . . . 907
1.1 Quasi-compact morphisms . . . 907
1.2 Quasi-separated morphisms . . . 909
1.3 Morphisms locally of finite type . . . 911
1.4 Morphisms locally of finite presentation . . . 913
1.5 Morphisms of finite type . . . 916
1.6 Morphisms of finite presentation . . . 917
1.7 Improvements of earlier results . . . 919
1.8 Morphisms of finite presentation and constructible sets . . . 920
1.9 Pro-constructible and ind-constructible sets . . . 924
1.10 Application to open morphisms . . . 931
Bibliography (continued) . . . 934
Index of notation . . . 935
Terminological index . . . 937
Table of contents . . . 941
§2 Base change and flatness . . . 943
2.1 Flat Modules on preschemes . . . 943

2.2 Faithfully flat Modules on preschemes . . . 947
2.3 Topological properties of flat morphisms . . . 952
2.4 Universally open morphisms and flat morphisms . . . 957
2.5 Permanence of properties of Modules by faithfully flat descent . . 960
2.6 Permanence of set-theoretic and topological properties of morphisms by faithfully flat descent . . . 967
2.7 Permanence of various properties of morphisms under faithfully flat descent . . . 970
2.8 Preschemes over a regular base of dimension 1; closure of a closed subprescheme of the generic fibre . . . 975
§3 Associated prime cycles and primary decompositions . . . 977
3.1 Associated prime cycles of a module . . . 978
3.2 Irredundant decompositions . . . 981
3.3 Relations with flatness . . . 985
3.4 Properties of the sheaves $\mathscr{F}/t\mathscr{F}$ . . . 987
§4 Change of base field for algebraic preschemes . . . 994
4.1 Dimension of algebraic preschemes . . . 994
4.2 Associated prime cycles on algebraic preschemes . . . 998
4.3 Reminders on tensor products of fields . . . 1002
4.4 Irreducible preschemes and connected preschemes over an algebraically closed field . . . 1004
4.5 Geometrically irreducible and geometrically connected preschemes 1006
4.6 Geometrically reduced algebraic preschemes . . . 1014
4.7 Multiplicities in the primary decomposition on an algebraic prescheme . . . 1022
4.8 Fields of definition . . . 1027
4.9 Fields of definition of subsets of a prescheme . . . 1031
§5 Dimension, depth, and regularity in locally Noetherian preschemes . . . 1033
5.1 Dimension of preschemes . . . 1033
5.2 Dimension of an algebraic prescheme . . . 1037
5.3 Dimension of the support of a module and Hilbert polynomial . . 1040
5.4 Dimension of the image of a morphism . . . 1041
5.5 Dimension formula for a morphism of finite type . . . 1043
5.6 Dimension formula and universally catenary rings . . . 1047
5.7 Depth and property (S_k) . . . 1053
5.8 Regular preschemes and property (R_k). Serre's normality criterion 1058
5.9 Z-pure and Z-closed modules . . . 1060
5.10 Property (S_2) and Z-closure . . . 1065
5.11 Coherence criteria for the modules $\mathscr{H}^0_{X/Z}(\mathscr{F})$ . . . 1075
5.12 Relations between the properties of a Noetherian local ring A and of a quotient ring A/tA . . . 1080
5.13 Properties preserved under passage to a direct limit . . . 1086
§6 Flat morphisms of locally Noetherian preschemes . . . 1092

Introduction

To Oscar Zariski and André Weil.

This memoir, and the numerous others which are to follow it, are intended to form [I | 5]
a treatise on the foundations of Algebraic Geometry. In principle they presuppose no particular knowledge of this discipline, and it has even turned out that such knowledge, despite its obvious advantages, could sometimes (through the overly exclusive habit of the birational point of view which it implies) be harmful to one who wishes to become familiar with the point of view and the techniques presented here. On the other hand, we shall assume that the reader has a good knowledge of the following subjects:

a) *Commutative Algebra*, as presented for example in the volumes of the *Éléments* of N. Bourbaki now in preparation (and, until these volumes appear, in Samuel-Zariski [13] and Samuel [11], [12]).

b) *Homological Algebra*, for which we refer to Cartan-Eilenberg [2] (cited as (M)) and Godement [4] (cited as (G)), as well as to the recent article of A. Grothendieck [6] (cited as (T)).

c) *Sheaf Theory*, where our principal references will be (G) and (T); this last theory provides the indispensable language for interpreting the essential notions of Commutative Algebra in "geometric" terms, and for "globalizing" them.

d) Finally, it will be useful for the reader to have a certain familiarity with the *functorial language*, which will be used constantly in this Treatise, and for which the reader may consult (M), (G) and above all (T); the principles of this language and the principal results of the general theory of functors will be presented in more detail in a work being prepared by the authors of this Treatise.

* * *

This Introduction is not the place to give a more or less summary description of the point of view of "schemes" in Algebraic Geometry, nor the long list of reasons which have made its adoption necessary, and in particular the systematic acceptance of nilpotent elements in the local rings of the "varieties" that we consider (which necessarily relegates the notion of rational map to the background, in favour of that of regular map or "morphism"). The present Treatise aims precisely at developing the language of "schemes" systematically, and will, we hope, demonstrate its necessity. Although it would be easy to do so, we
shall not attempt here either to give an "intuitive" introduction to the notions developed [I | 6]
in Chapter One. The reader who would like a preliminary overview of the material of this Treatise may refer to the address given by A. Grothendieck at the International Congress of Mathematicians in Edinburgh in 1958 [7], and to the exposé [8] by the same author. The work [14] (cited as (FAC)) of J.-P. Serre may also be regarded as an exposition intermediate between the classical point of view and the point of view of schemes in Algebraic Geometry, and as such, reading it may be an excellent preparation for reading our *Éléments*.

* * *

For information, we give below the general plan envisaged for this Treatise, which is moreover subject to later modifications, especially as regards the last chapters:

Chapter One. — The language of schemes.
— **II**. — Elementary global study of some classes of morphisms.
— **III**. — Cohomology of coherent algebraic sheaves. Applications.
— **IV**. — Local study of morphisms.
— **V**. — Elementary procedures for constructing schemes.
— **VI**. — Descent technique. General method for constructing schemes.
— **VII**. — Group schemes, principal fibre spaces.
— **VIII**. — Differential study of fibre spaces.
— **IX**. — The fundamental group.
— **X**. — Residues and duality.
— **XI**. — Intersection theories, Chern classes, Riemann-Roch theorem.
— **XII**. — Abelian schemes and Picard schemes.
— **XIII**. — Weil cohomology.

In principle, all the chapters are regarded as open, and supplementary paragraphs may always be added to them later; such paragraphs will appear in separate fascicles, in order to lessen the drawbacks of the mode of publication adopted. When such a paragraph is planned or in preparation at the time a chapter is published, it will be mentioned in the summary of that chapter, even if, owing to certain orders of urgency, its actual publication should come appreciably later. For the convenience of the reader, we give in a "Chapter 0" various supplements on Commutative Algebra, on Homological Algebra and on Sheaf Theory, used in the course of the chapters of this Treatise, which are more or less well known, but for which it has not been possible to give convenient references. The reader is advised to refer to Chapter 0 only in the course of reading the Treatise proper, and to the extent that the results to which we refer are not
[I | 7] sufficiently familiar to the reader. We believe, moreover, that in this way the reading of this Treatise may be a good method for the beginner to become familiar with Commutative Algebra and Homological Algebra, the study of which, when it is not accompanied by tangible applications, is judged tedious, even depressing, by a fairly large number of people.

* * *

It is beyond our competence to give in this Introduction a historical survey, even a summary one, of the notions and results presented. The text will contain only the references judged particularly useful for its understanding, and we shall indicate the origin only of the most important results. Formally at least, the subjects treated in our work are fairly new, which will explain the scarcity of references to the Fathers of Algebraic Geometry of the nineteenth century and of the beginning of the twentieth century, whose works we know only by hearsay. It is appropriate, however, to say a few words here about the works which have most directly influenced the authors and contributed to the development of the point of view of schemes. First and foremost we must cite the fundamental work (FAC) of J.-P. Serre, which has served as an introduction to Algebraic Geometry for more than one young adept (among them one of the authors of the present Treatise), put off by the aridity of A. Weil's classic *Foundations* [18]. That

work was the first to show that the "Zariski topology" of an "abstract" algebraic variety lends itself perfectly to certain techniques of Algebraic Topology, and in particular to the construction of a cohomology theory. Moreover, the definition of an algebraic variety given there is the one which lends itself most naturally to the extension of this notion that we develop here[2]. Serre had moreover observed himself that the cohomology theory of affine algebraic varieties carries over without difficulty when the affine algebras over a field are replaced by arbitrary commutative rings. In essence, therefore, Chapters I and II of this Treatise and the first two paragraphs of Chapter III can be viewed as easy transpositions, to this enlarged framework, of the principal results of (FAC) and of a later article by the same author [15]. We have also profited greatly from the *Séminaire de Géométrie algébrique* of C. Chevalley [1]; in particular, the systematic use of the "constructible sets" introduced by him has proved very useful in the theory of schemes (cf. Chapter IV). From him, too, we have taken the study of morphisms from the point of view of dimension (Chapter IV), which carries over without notable change to the framework of schemes. It should be noted, furthermore, that the notion of "schemes of local rings", introduced by Chevalley, lends itself naturally to an extension of Algebraic Geometry (not having, however, all the flexibility and generality that we intend to give it here); for the relations between this notion and our theory, see Chapter One, § 8. Such an extension has been developed by M. Nagata in a series of memoirs [9] containing numerous special results concerning Algebraic Geometry over Dedekind rings[3]. [I | 8]

* * *

Finally, it goes without saying that a book on Algebraic Geometry, and above all a book dealing with foundations, is necessarily influenced, if only through intermediaries, by mathematicians such as O. Zariski and A. Weil. In particular, the *Theory of holomorphic functions* of Zariski [20], suitably made more flexible by means of cohomological methods and completed by an existence theorem (Chapter III, §§ 4 and 5), is (together with the descent technique presented in Chapter VI) one of the principal tools used in this Treatise, and seems to us one of the most powerful available in Algebraic Geometry.

The general technique into which it fits can be sketched as follows (a typical example of it will be provided in Chapter IX, in the study of the fundamental group). One has a proper morphism (Chapter II) $f : X \to Y$ from one algebraic variety to another (more generally, from one scheme to another), which one wishes to study in a neighbourhood of a point $y \in Y$, with a view to solving a problem P relative to a neighbourhood of y. One proceeds in successive steps:

1° One may suppose Y affine, so that X becomes a scheme defined over the affine ring A of Y, and one may even replace A by the local ring of y. This reduction is always easy in practice (Chapter V) and brings us back to the case where A is a *local* ring.

[2] As J.-P. Serre has pointed out to us, it should be noted that the idea of defining the structure of a variety through a sheaf of rings goes back to H. Cartan, who made it the starting point of his theory of analytic spaces. Naturally, in "Analytic Geometry" just as in Algebraic Geometry, nilpotent elements ought to be given full rights of citizenship in the local rings of analytic spaces. This extension of the definition of H. Cartan and J.-P. Serre has recently been taken up by H. Grauert [5], and there is reason to hope that a systematic exposition of Analytic Geometry in this general framework will soon see the light of day. It is moreover evident that the notions and techniques developed in this Treatise retain a meaning in Analytic Geometry, although one must expect more considerable technical difficulties in the latter theory. One may foresee that Algebraic Geometry, through the simplicity of its methods, will be able to serve as a kind of formal model for future developments in the theory of analytic spaces.

[3] Among the works which come close to our point of view in Algebraic Geometry, let us mention the important work of E. Kähler [22], and a recent Note of Chow and Igusa [3], who take up, within the framework of the Nagata-Chevalley theory, certain results of (FAC) and also give a Künneth formula.

2° One studies the problem under consideration when A is an *Artinian* local ring. In order for it to retain a genuine meaning when A is not assumed to be integral, it is sometimes necessary to reformulate the problem P, and it turns out that one often thereby obtains a better understanding of the problem, which at this stage is of an "infinitesimal" nature.

3° The theory of formal schemes (Chapter III, §§ 3, 4 and 5) makes it possible to pass from the case of an Artinian ring to the case of a *complete local ring*.

4° Finally, if A is an arbitrary local ring, the consideration of "multivalued sections" over suitable schemes over X, approximating a given "formal" section (Chapter IV), will often make it possible to pass from a result known for the scheme

[I | 9] deduced from X by extension of scalars to the completion of A, to an analogous result for a fairly simple (for example unramified) finite extension of A.

This sketch shows the importance of the systematic study of schemes defined over an Artinian ring A. Serre's point of view in his formulation of local class field theory, and recent work of Greenberg, seem to suggest that such a study could be undertaken by functorially attaching to such a scheme X a scheme X' over the residue field k of A (assumed perfect), of dimension equal (in favourable cases) to $n \dim X$, where n is the length of A.

As for the influence of A. Weil, suffice it to say that it is the necessity of developing the tools needed to formulate, with all the desired generality, the definition of "Weil cohomology", and to undertake the proof[4] of all the formal properties needed to establish his celebrated conjectures in Diophantine Geometry [19], that has been one of the principal motivations for the writing of the present Treatise, on the same footing as the desire to find the natural framework for the usual notions and methods of Algebraic Geometry, and to give the authors the opportunity of understanding the said notions and techniques.

* * *

To conclude, we think it useful to warn readers that, just like the authors themselves, they will no doubt have some difficulty before becoming accustomed to the language of schemes, and before convincing themselves that the usual constructions suggested by geometric intuition can be transcribed, in essentially only one reasonable way, into this language. As in many parts of modern Mathematics, the initial intuition moves further and further away, in appearance, from the language suited to expressing it with all the desired precision and generality. In the present case, the psychological difficulty stems from the necessity of transferring to the objects of a category already rather different from the category of sets (namely the category of preschemes, or the category of preschemes over a given prescheme) notions which are familiar for sets: Cartesian products, laws of group, of ring, of module, fibre bundles, principal homogeneous fibre bundles, etc. It will no doubt be difficult for the mathematician, in the future, to shirk this new effort of abstraction, perhaps rather slight, all things considered, in comparison with the one made by our fathers in familiarizing themselves with Set Theory.

* * *

[4] To avoid any misunderstanding, let us make clear that this task has barely been undertaken at the time this Introduction is being written, and has therefore not yet led to the proof of the Weil conjectures.

References will be given according to the decimal system; for example, in III, 4.9.3, the numeral III indicates the chapter, the numeral 4 the paragraph, and the numeral 9 the section of the paragraph. Within the same chapter, mention of the chapter will be omitted.

Chapter 0. Preliminaries

§1 Rings of fractions

1.0 Rings and algebras

(1.0.1) Every ring considered in this Treatise has a *unit element*; every module over such a ring is assumed to be *unital*; ring homomorphisms will always be assumed to *map the unit element to the unit element*; unless expressly stated otherwise, a subring of a ring A will be assumed to *contain the unit element of* A. We shall consider mainly *commutative* rings, and when we speak of a ring without further qualification, it will be understood that a commutative ring is meant. If A is a not necessarily commutative ring, by an A-module we shall always mean a *left* module, unless expressly stated otherwise. [0_{I} | 11]

(1.0.2) Let A, B be two not necessarily commutative rings, and $\varphi : A \to B$ a homomorphism. Every left (resp. right) B-module M can be endowed with a left (resp. right) A-module structure by setting $a.m = \varphi(a).m$ (resp. $m.a = m.\varphi(a)$); when it is necessary to distinguish between the A-module and B-module structures on M, we shall denote by $M_{[\varphi]}$ the left (resp. right) A-module thus defined. If L is an A-module, a homomorphism $u : L \to M_{[\varphi]}$ is therefore a homomorphism of commutative groups such that $u(a.x) = \varphi(a).u(x)$ for $a \in A$, $x \in L$; we shall also say that it is a *φ-homomorphism* $L \to M$, and that the pair (φ, u) (or, by abuse of language, u) is a *di-homomorphism* from (A, L) to (B, M). The pairs (A, L) consisting of a ring A and an A-module L therefore form a *category* whose morphisms are the di-homomorphisms.

(1.0.3) Under the hypotheses of (1.0.2), if $\mathfrak{J}$ is a left (resp. right) ideal of A, we shall denote by $B\mathfrak{J}$ (resp. $\mathfrak{J}B$) the left (resp. right) ideal $B\varphi(\mathfrak{J})$ (resp. $\varphi(\mathfrak{J})B$) of B generated by $\varphi(\mathfrak{J})$; it is also the image of the canonical homomorphism $B \otimes_A \mathfrak{J} \to B$ (resp. $\mathfrak{J} \otimes_A B \to B$) of left (resp. right) B-modules.

(1.0.4) If A is a (commutative) ring and B a not necessarily commutative ring, giving an *A-algebra* structure on B is equivalent to giving a ring homomorphism $\varphi : A \to B$ such that $\varphi(A)$ is contained in the centre of B. For every ideal $\mathfrak{J}$ of A, $\mathfrak{J}B = B\mathfrak{J}$ is then a two-sided ideal of B, and for every B-module M, $\mathfrak{J}M$ is then a B-module equal to $(B\mathfrak{J})M$.

(1.0.5) We shall not go back over the notions of *module of finite type* and of (commutative) *algebra of finite type*; to say that an A-module M is of finite type means that there exists
an exact sequence $A^p \to M \to 0$. An A-module M is said to admit a *finite presentation* [0_{I} | 12]
if it is isomorphic to the cokernel of a homomorphism $A^p \to A^q$, in other words if there exists an exact sequence $A^p \to A^q \to M \to 0$. Note that over a *Noetherian* ring A, every A-module of finite type admits a finite presentation.

Recall that an A-algebra B is said to be *integral over* A if every element of B is a root in B of a monic polynomial with coefficients in A; it amounts to the same to say that every element of B is contained in a subalgebra of B which is an A-*module of finite type*. When this is so, and B is commutative, the subalgebra of B generated by a finite subset of B is an A-module of finite type; for the commutative algebra B to be integral and of finite type over A, it is therefore necessary and sufficient that B be an A-module of finite type; one then also says that B is a *finite integral* A-algebra (or simply a *finite* one, if no confusion results). Observe that in these definitions the homomorphism $A \to B$ defining the A-algebra structure is not assumed to be injective.

(1.0.6) An *integral* ring is a ring in which the product of a finite family of elements $\neq 0$ is $\neq 0$; it amounts to the same to say that in such a ring one has $0 \neq 1$ and the product of two elements $\neq 0$ is nonzero. A *prime* ideal of a ring A is an ideal $\mathfrak{p}$ such that $A/\mathfrak{p}$ is integral; this therefore implies $\mathfrak{p} \neq A$. For a ring A to have at least one prime ideal, it is necessary and sufficient that $A \neq \{0\}$.

(1.0.7) A *local* ring is a ring A in which there exists only one maximal ideal, which is then the complement of the set of invertible elements and contains all the ideals $\neq A$. If A and B are two local rings, and $\mathfrak{m}$ and $\mathfrak{n}$ their respective maximal ideals, a homomorphism $\varphi : A \to B$ is said to be *local* if $\varphi(\mathfrak{m}) \subset \mathfrak{n}$ (or, what amounts to the same, if $\varphi^{-1}(\mathfrak{n}) = \mathfrak{m}$). By passage to the quotients, such a homomorphism then defines a monomorphism of the residue field $A/\mathfrak{m}$ into the residue field $B/\mathfrak{n}$. The composite of two local homomorphisms is a local homomorphism.

1.1 Radical of an ideal. Nilradical and radical of a ring

(1.1.1) Let $\mathfrak{a}$ be an ideal of a ring A; the *radical* of $\mathfrak{a}$, denoted $\mathfrak{r}(\mathfrak{a})$, is the set of $x \in A$ such that $x^n \in \mathfrak{a}$ for at least one integer $n > 0$; it is an ideal containing $\mathfrak{a}$. We have $\mathfrak{r}(\mathfrak{r}(\mathfrak{a})) = \mathfrak{r}(\mathfrak{a})$; the relation $\mathfrak{a} \subset \mathfrak{b}$ implies $\mathfrak{r}(\mathfrak{a}) \subset \mathfrak{r}(\mathfrak{b})$; the radical of a finite intersection of ideals is the intersection of their radicals. If φ is a homomorphism from a ring A' to A, we have $\mathfrak{r}(\varphi^{-1}(\mathfrak{a})) = \varphi^{-1}(\mathfrak{r}(\mathfrak{a}))$ for every ideal $\mathfrak{a} \subset A$. An ideal is the radical of an ideal if and only if it is an intersection of prime ideals. The radical of an ideal $\mathfrak{a}$ is the intersection of the prime ideals which are *minimal* among those containing $\mathfrak{a}$; if A is Noetherian, these minimal prime ideals are finite in number.

The radical of the ideal (0) is also called the *nilradical* of A; it is the set $\mathfrak{N}$ of nilpotent elements of A. The ring A is said to be *reduced* if $\mathfrak{N} = (0)$; for every ring A, the quotient $A/\mathfrak{N}$ of A by its nilradical is a reduced ring.

(1.1.2) Recall that the *radical* $\mathfrak{R}(A)$ of a (not necessarily commutative) ring A is the intersection of the maximal left ideals of A (and also the intersection of the maximal right ideals). The radical of $A/\mathfrak{R}(A)$ is (0).

1.2 Modules and rings of fractions

[0_I | 13] **(1.2.1)** A subset S of a ring A is said to be *multiplicative* if $1 \in S$ and the product of two elements of S is in S. The examples which will be the most important in what follows are: 1° the set S_f of the powers f^n ($n \geq 0$) of an element $f \in A$; 2° the complement $A - \mathfrak{p}$ of a *prime* ideal $\mathfrak{p}$ of A.

(1.2.2) Let S be a multiplicative subset of a ring A, and M an A-module; in the set $M \times S$, the relation between pairs (m_1, s_1), (m_2, s_2):

$$\text{“there exists } s \in S \text{ such that } s(s_1 m_2 - s_2 m_1) = 0\text{”}$$

is an equivalence relation. We denote by $S^{-1}M$ the quotient set of $M \times S$ by this relation, and by m/s the canonical image in $S^{-1}M$ of the pair (m, s); the map $i_M^S : m \mapsto m/1$ (also denoted i^S) is called the *canonical map* from M to $S^{-1}M$. This map is in general neither injective nor surjective; its kernel is the set of $m \in M$ for which there exists an $s \in S$ such that $sm = 0$.

On $S^{-1}M$ one defines an additive group law by taking

$$(m_1/s_1) + (m_2/s_2) = (s_2 m_1 + s_1 m_2)/(s_1 s_2)$$

(one checks that this is indeed independent of the expressions of the elements of $S^{-1}M$ considered). On $S^{-1}A$ one further defines a multiplicative law by taking $(a_1/s_1)(a_2/s_2) = (a_1 a_2)/(s_1 s_2)$, and finally an external law on $S^{-1}M$, having $S^{-1}A$ as set of operators, by setting $(a/s)(m/s') = (am)/(ss')$. One checks in this way that $S^{-1}A$ is endowed with a ring structure (called the *ring of fractions of A with denominators in S*) and $S^{-1}M$ with an $S^{-1}A$-module structure (called the *module of fractions of M with denominators in S*); for every $s \in S$, $s/1$ is invertible in $S^{-1}A$, its inverse being $1/s$. The canonical map i_A^S (resp. i_M^S) is a ring homomorphism (resp. a homomorphism of A-modules, $S^{-1}M$ being regarded as an A-module by means of the homomorphism $i_A^S : A \to S^{-1}A$).

(1.2.3) If $S_f = \{f^n\}_{n \geq 0}$ for some $f \in A$, we write A_f and M_f instead of $S_f^{-1}A$ and $S_f^{-1}M$; when A_f is regarded as an algebra over A, we may write $A_f = A[1/f]$. A_f is isomorphic to the quotient algebra $A[T]/(fT - 1)A[T]$. When $f = 1$, A_f and M_f are canonically identified with A and M; if f is nilpotent, A_f and M_f are reduced to 0.

When $S = A - \mathfrak{p}$, where $\mathfrak{p}$ is a prime ideal of A, we write $A_\mathfrak{p}$ and $M_\mathfrak{p}$ instead of $S^{-1}A$ and $S^{-1}M$; $A_\mathfrak{p}$ is a *local ring* whose maximal ideal $\mathfrak{q}$ is generated by $i_A^S(\mathfrak{p})$, and we have $(i_A^S)^{-1}(\mathfrak{q}) = \mathfrak{p}$; by passage to the quotients, i_A^S gives a monomorphism of the integral ring $A/\mathfrak{p}$ into the field $A_\mathfrak{p}/\mathfrak{q}$, which is identified with the field of fractions of $A/\mathfrak{p}$.

(1.2.4) The ring of fractions $S^{-1}A$ and the canonical homomorphism i_A^S are a solution of a *universal mapping problem*: every homomorphism u from A to a ring B such that $u(S)$ consists of elements *invertible* in B factorizes in a unique way as

$$u : A \xrightarrow{i_A^S} S^{-1}A \xrightarrow{u^*} B$$

where u^* is a ring homomorphism. Under the same hypotheses, let M be an A-module, N a B-module, and $v : M \to N$ a homomorphism of A-modules (for the B-module structure on N defined by $u : A \to B$); then v factorizes in a unique way as [0_I | 14]

$$v : M \xrightarrow{i_M^S} S^{-1}M \xrightarrow{v^*} N$$

where v^* is a homomorphism of $S^{-1}A$-modules (for the $S^{-1}A$-module structure on N defined by u^*).

(1.2.5) One defines a canonical isomorphism $S^{-1}A \otimes_A M \xrightarrow{\sim} S^{-1}M$ of $S^{-1}A$-modules by mapping the element $(a/s) \otimes m$ to the element $(am)/s$, the inverse isomorphism mapping m/s to $(1/s) \otimes m$.

(1.2.6) For every ideal $\mathfrak{a}'$ of $S^{-1}A$, $\mathfrak{a} = (i_A^S)^{-1}(\mathfrak{a}')$ is an ideal of A, and $\mathfrak{a}'$ is the ideal of $S^{-1}A$ generated by $i_A^S(\mathfrak{a})$, which is identified with $S^{-1}\mathfrak{a}$ (1.3.2). The map $\mathfrak{p}' \mapsto (i_A^S)^{-1}(\mathfrak{p}')$ is an isomorphism, for the order structures, of the set of *prime* ideals of $S^{-1}A$ onto the set of prime ideals $\mathfrak{p}$ of A such that $\mathfrak{p} \cap S = \varnothing$. Moreover, the local rings $A_\mathfrak{p}$ and $(S^{-1}A)_{S^{-1}\mathfrak{p}}$ are then canonically (1.5.1) isomorphic.

(1.2.7) When A is an *integral* ring, whose field of fractions we denote by K, the canonical map $i_A^S : A \to S^{-1}A$ is injective for every multiplicative subset S not containing 0, and $S^{-1}A$ is then canonically identified with a subring of K containing A. In particular, for every prime ideal $\mathfrak{p}$ of A, $A_\mathfrak{p}$ is a local ring containing A, with maximal ideal $\mathfrak{p}A_\mathfrak{p}$, and we have $\mathfrak{p}A_\mathfrak{p} \cap A = \mathfrak{p}$.

(1.2.8) If A is a *reduced* ring (1.1.1), so is $S^{-1}A$: indeed, if $(x/s)^n = 0$ for $x \in A$, $s \in S$, this means that there exists $s' \in S$ such that $s'x^n = 0$, whence $(s'x)^n = 0$, which by hypothesis implies $s'x = 0$, hence $x/s = 0$.

1.3 Functorial properties

(1.3.1) Let M, N be two A-modules, and u an A-homomorphism $M \to N$. If S is a multiplicative subset of A, one defines an $S^{-1}A$-homomorphism $S^{-1}M \to S^{-1}N$, denoted $S^{-1}u$, by setting $(S^{-1}u)(m/s) = u(m)/s$; if $S^{-1}M$ and $S^{-1}N$ are canonically identified with $S^{-1}A \otimes_A M$ and $S^{-1}A \otimes_A N$ (1.2.5), $S^{-1}u$ is identified with $1 \otimes u$. If P is a third A-module and v an A-homomorphism $N \to P$, we have $S^{-1}(v \circ u) = (S^{-1}v) \circ (S^{-1}u)$; in other words, $S^{-1}M$ is a *covariant functor in* M, from the category of A-modules to that of $S^{-1}A$-modules (A and S being fixed).

(1.3.2) The functor $S^{-1}M$ is *exact*; in other words, if the sequence

$$M \xrightarrow{u} N \xrightarrow{v} P$$

is exact, so is the sequence

$$S^{-1}M \xrightarrow{S^{-1}u} S^{-1}N \xrightarrow{S^{-1}v} S^{-1}P.$$

In particular, if $u : M \to N$ is injective (resp. surjective), so is $S^{-1}u$;
[0_I | 15] if N and P are two submodules of M, $S^{-1}N$ and $S^{-1}P$ are canonically identified with submodules of $S^{-1}M$, and we have

$$S^{-1}(N + P) = S^{-1}N + S^{-1}P \quad \text{and} \quad S^{-1}(N \cap P) = (S^{-1}N) \cap (S^{-1}P).$$

(1.3.3) Let $(M_\alpha, \varphi_{\beta\alpha})$ be an inductive system of A-modules; then $(S^{-1}M_\alpha, S^{-1}\varphi_{\beta\alpha})$ is an inductive system of $S^{-1}A$-modules. Expressing the $S^{-1}M_\alpha$ and $S^{-1}\varphi_{\beta\alpha}$ as tensor products (1.2.5 and 1.3.1), it follows from the fact that the operations of tensor product and of inductive limit commute that there is a canonical isomorphism

$$S^{-1}\varinjlim M_\alpha \xrightarrow{\sim} \varinjlim S^{-1}M_\alpha,$$

which one also expresses by saying that the functor $S^{-1}M$ (in M) *commutes with inductive limits.*

(1.3.4) Let M, N be two A-modules; there exists a canonical *functorial* isomorphism (in M and N)

$$(S^{-1}M) \otimes_{S^{-1}A} (S^{-1}N) \xrightarrow{\sim} S^{-1}(M \otimes_A N)$$

which maps $(m/s) \otimes (n/t)$ to $(m \otimes n)/st$.

(1.3.5) Similarly, there is a *functorial* homomorphism (in M and N)

$$S^{-1}\operatorname{Hom}_A(M,N) \longrightarrow \operatorname{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N)$$

which maps u/s to the homomorphism $m/t \mapsto u(m)/st$. When M has a *finite presentation*, the preceding homomorphism is an *isomorphism*: this is immediate when M is of the form A^r, and one passes from there to the general case by starting from the exact sequence $A^p \to A^q \to M \to 0$ and using the exactness of the functor $S^{-1}M$ and the left exactness of the functor $\operatorname{Hom}_A(M,N)$ in M. Note that this case always occurs when A is *Noetherian* and the A-module M is *of finite type*.

1.4 Change of multiplicative subset

(1.4.1) Let S, T be two multiplicative subsets of a ring A such that $S \subset T$; there exists a canonical homomorphism $\rho_A^{T,S}$ (or simply $\rho^{T,S}$) from $S^{-1}A$ to $T^{-1}A$, which maps the element denoted a/s of $S^{-1}A$ to the element denoted a/s in $T^{-1}A$; we have

$$i_A^T = \rho_A^{T,S} \circ i_A^S.$$

For every A-module M, there likewise exists an $S^{-1}A$-linear map from $S^{-1}M$ to $T^{-1}M$ (the latter being regarded as an $S^{-1}A$-module by means of the homomorphism $\rho_A^{T,S}$), which maps the element m/s of $S^{-1}M$ to the element m/s of $T^{-1}M$; this map is denoted $\rho_M^{T,S}$, or simply $\rho^{T,S}$, and we again have

$$i_M^T = \rho_M^{T,S} \circ i_M^S;$$

under the canonical identification (1.2.5), $\rho_M^{T,S}$ is identified with $\rho_A^{T,S} \otimes 1$. The homomorphism $\rho_M^{T,S}$ is a *functorial morphism* (or natural transformation) from the functor $S^{-1}M$ to the functor $T^{-1}M$; in other words, the diagram

$$\begin{array}{ccc} S^{-1}M & \xrightarrow{S^{-1}u} & S^{-1}N \\ {\scriptstyle \rho_M^{T,S}}\downarrow & & \downarrow{\scriptstyle \rho_N^{T,S}} \\ T^{-1}M & \xrightarrow{T^{-1}u} & T^{-1}N \end{array}$$

is commutative for every homomorphism $u : M \to N$; note moreover that $T^{-1}u$ is entirely determined by $S^{-1}u$, since for $m \in M$ and $t \in T$ we have [0_{I} | 16]

$$(T^{-1}u)(m/t) = (t/1)^{-1}\rho^{T,S}((S^{-1}u)(m/1)).$$

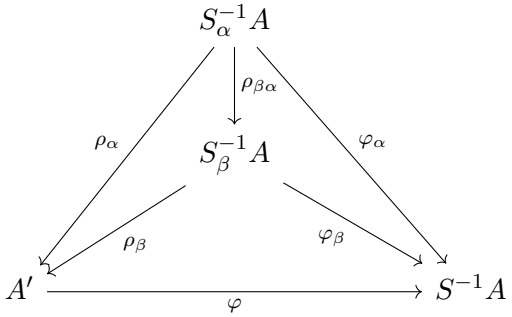
(1.4.2) With the same notation, for two A-modules M, N, the diagrams (cf. (1.3.4) and (1.3.5))

$$\begin{array}{ccc} (S^{-1}M) \otimes_{S^{-1}A} (S^{-1}N) & \xrightarrow{\sim} & S^{-1}(M \otimes_A N) \\ \downarrow & & \downarrow \\ (T^{-1}M) \otimes_{T^{-1}A} (T^{-1}N) & \xrightarrow{\sim} & T^{-1}(M \otimes_A N) \end{array}$$

$$\begin{array}{ccc} S^{-1}\operatorname{Hom}_A(M,N) & \longrightarrow & \operatorname{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N) \\ \downarrow & & \downarrow \\ T^{-1}\operatorname{Hom}_A(M,N) & \longrightarrow & \operatorname{Hom}_{T^{-1}A}(T^{-1}M, T^{-1}N) \end{array}$$

are commutative.

(1.4.3) There is an important case in which the homomorphism $\rho^{T,S}$ is *bijective*, namely when every element of T is a divisor of an element of S; one then identifies the modules $S^{-1}M$ and $T^{-1}M$ by means of $\rho^{T,S}$. We say that S is *saturated* if every divisor in A of an element of S is in S; by replacing S by the set T of all divisors of the elements of S (a set which is multiplicative and saturated), one sees that one can always, if one wishes, restrict oneself to considering modules of fractions $S^{-1}M$ where S is saturated.



(1.4.4) If S, T, U are three multiplicative subsets of A such that $S \subset T \subset U$, we have

$$\rho^{U,S} = \rho^{U,T} \circ \rho^{T,S}.$$

(1.4.5) Consider an *increasing filtered family* (S_α) of multiplicative subsets of A (we write $\alpha \leq \beta$ for $S_\alpha \subset S_\beta$), and let S be the multiplicative subset $\bigcup_\alpha S_\alpha$; set

$$\rho_{\beta\alpha} = \rho_A^{S_\beta, S_\alpha} \quad \text{for } \alpha \leq \beta;$$

by (1.4.4), the homomorphisms $\rho_{\beta\alpha}$ define a ring A', the *inductive limit* of the inductive system of rings $(S_\alpha^{-1}A, \rho_{\beta\alpha})$. Let ρ_α be the canonical map $S_\alpha^{-1}A \to A'$, and set $\varphi_\alpha = \rho_A^{S,S_\alpha}$; since $\varphi_\alpha = \varphi_\beta \circ \rho_{\beta\alpha}$ for $\alpha \leq \beta$ by (1.4.4), one can define in a unique way a homomorphism $\varphi : A' \to S^{-1}A$ such that the diagram

is commutative. In fact, φ is an *isomorphism*: indeed, it is immediate from the construction that φ is surjective. On the other hand, if $\rho_\alpha(a/s_\alpha) \in A'$ is such that $\varphi(\rho_\alpha(a/s_\alpha)) = 0$, this means that $a/s_\alpha = 0$ in $S^{-1}A$, that is, that there exists $s \in S$ such that $sa = 0$; but there is a $\beta \geq \alpha$ such that $s \in S_\beta$, and consequently, since $\rho_\alpha(a/s_\alpha) = \rho_\beta(sa/ss_\alpha) = 0$, we see that φ is injective. The case of an A-module M is treated in the same way, and we have thus defined canonical isomorphisms

$$\varinjlim S_\alpha^{-1}A \xrightarrow{\sim} (\varinjlim S_\alpha)^{-1}A, \qquad \varinjlim S_\alpha^{-1}M \xrightarrow{\sim} (\varinjlim S_\alpha)^{-1}M,$$

the second being *functorial in* M.

[0_I | 17] **(1.4.6)** Let S_1, S_2 be two multiplicative subsets of A; then S_1S_2 is also a multiplicative subset of A. Denote by S_2' the canonical image of S_2 in the ring $S_1^{-1}A$, which is a multiplicative subset of that ring. For every A-module M, there then exists a functorial isomorphism

$$S_2'^{-1}(S_1^{-1}M) \xrightarrow{\sim} (S_1S_2)^{-1}M$$

which maps $(m/s_1)/(s_2/1)$ to the element $m/(s_1s_2)$.

1.5 Change of ring

(1.5.1) Let A, A' be two rings, φ a homomorphism $A' \to A$, and S (resp. S') a multiplicative subset of A (resp. A') such that $\varphi(S') \subset S$; the composite homomorphism

$$A' \xrightarrow{\varphi} A \longrightarrow S^{-1}A$$

factorizes as

$$A' \longrightarrow S'^{-1}A' \xrightarrow{\varphi^{S'}} S^{-1}A$$

by (1.2.4); we have $\varphi^{S'}(a'/s') = \varphi(a')/\varphi(s')$. If $A = \varphi(A')$ and $S = \varphi(S')$, $\varphi^{S'}$ is *surjective*. If $A' = A$ and φ is the identity, $\varphi^{S'}$ is none other than the homomorphism $\rho_A^{S,S'}$ defined in (1.4.1).

(1.5.2) Under the hypotheses of (1.5.1), let M be an A-module. There exists a canonical functorial homomorphism

$$\sigma : S'^{-1}(M_{[\varphi]}) \longrightarrow (S^{-1}M)_{[\varphi^{S'}]}$$

of $S'^{-1}A'$-modules, which maps every element m/s' of $S'^{-1}(M_{[\varphi]})$ to the element $m/\varphi(s')$ of $(S^{-1}M)_{[\varphi^{S'}]}$; indeed, one checks immediately that this definition does not depend on the expression m/s' of the element considered. When $S = \varphi(S')$, the homomorphism σ is *bijective*. When $A' = A$ and φ is the identity, σ is none other than the homomorphism $\rho_M^{S,S'}$ defined in (1.4.1).

When in particular one takes $M = A$, the homomorphism φ defines an A'-algebra structure on A; $S'^{-1}(A_{[\varphi]})$ is then endowed with a ring structure, for which it is identified with $(\varphi(S'))^{-1}A$, and the homomorphism

$$\sigma : S'^{-1}(A_{[\varphi]}) \longrightarrow S^{-1}A$$

is a homomorphism of $S'^{-1}A'$-algebras.

(1.5.3) Let M and N be two A-modules; by composing the homomorphisms defined in (1.3.4) and (1.5.2), one obtains a homomorphism

$$(S^{-1}M \otimes_{S^{-1}A} S^{-1}N)_{[\varphi^{S'}]} \longleftarrow S'^{-1}((M \otimes_A N)_{[\varphi]})$$

which is an isomorphism when $\varphi(S') = S$. Similarly, by composing the homomorphisms (1.3.5) and (1.5.2), one obtains a homomorphism

$$S'^{-1}((\mathrm{Hom}_A(M,N))_{[\varphi]}) \longrightarrow (\mathrm{Hom}_{S^{-1}A}(S^{-1}M, S^{-1}N))_{[\varphi^{S'}]}$$

which is an isomorphism when $\varphi(S') = S$ and M admits a finite presentation.

(1.5.4) Now consider an A'-module N', and form the tensor product $N' \otimes_{A'} A_{[\varphi]}$, which can be regarded as an A-module by setting

$$a.(n' \otimes b) = n' \otimes (ab).$$

There exists a functorial isomorphism of $S^{-1}A$-modules

$$\tau : (S'^{-1}N') \otimes_{S'^{-1}A'} (S^{-1}A)_{[\varphi^{S'}]} \xrightarrow{\sim} S^{-1}(N' \otimes_{A'} A_{[\varphi]})$$

[0$_{\mathrm{I}}$ | 18] which maps the element $(n'/s') \otimes (a/s)$ to the element $(n' \otimes a)/(\varphi(s')s)$; indeed, one checks separately that when n'/s' (resp. a/s) is replaced by another expression of the same element, $(n' \otimes a)/(\varphi(s')s)$ does not change; on the other hand, one can define an inverse homomorphism of τ by mapping $(n' \otimes a)/s$ to the element $(n'/1) \otimes (a/s)$: one uses the fact that $S^{-1}(N' \otimes_{A'} A_{[\varphi]})$ is canonically isomorphic to $(N' \otimes_{A'} A_{[\varphi]}) \otimes_A S^{-1}A$ (1.2.5), hence also to $N' \otimes_{A'} (S^{-1}A)_{[\psi]}$, where ψ denotes the composite homomorphism $a' \mapsto \varphi(a')/1$ from A' to $S^{-1}A$.

(1.5.5) If M' and N' are two A'-modules, by composing the isomorphisms (1.3.4) and (1.5.4) one obtains an isomorphism

$$S'^{-1}M' \otimes_{S'^{-1}A'} S'^{-1}N' \otimes_{S'^{-1}A'} S^{-1}A \xrightarrow{\sim} S^{-1}(M' \otimes_{A'} N' \otimes_{A'} A).$$

Similarly, if M' admits a finite presentation, one has, by (1.3.5) and (1.5.4), an isomorphism

$$\mathrm{Hom}_{S'^{-1}A'}(S'^{-1}M', S'^{-1}N') \otimes_{S'^{-1}A'} S^{-1}A \xrightarrow{\sim} S^{-1}(\mathrm{Hom}_{A'}(M', N') \otimes_{A'} A).$$

(1.5.6) Under the hypotheses of (1.5.1), let T (resp. T') be a second multiplicative subset of A (resp. A') such that $S \subset T$ (resp. $S' \subset T'$) and $\varphi(T') \subset T$. Then the diagram

$$\begin{array}{ccc} S'^{-1}A' & \xrightarrow{\varphi^{S'}} & S^{-1}A \\ {\scriptstyle \rho^{T',S'}}\downarrow & & \downarrow{\scriptstyle \rho^{T,S}} \\ T'^{-1}A' & \xrightarrow[\varphi^{T'}]{} & T^{-1}A \end{array}$$

is commutative. If M is an A-module, the diagram

$$\begin{array}{ccc} S'^{-1}(M_{[\varphi]}) & \xrightarrow{\sigma} & (S^{-1}M)_{[\varphi^{S'}]} \\ {\scriptstyle \rho^{T',S'}}\downarrow & & \downarrow{\scriptstyle \rho^{T,S}} \\ T'^{-1}(M_{[\varphi]}) & \xrightarrow[\sigma]{} & (T^{-1}M)_{[\varphi^{T'}]} \end{array}$$

is commutative. Finally, if N' is an A'-module, the diagram

$$\begin{array}{ccc} (S'^{-1}N') \otimes_{S'^{-1}A'} (S^{-1}A)_{[\varphi^{S'}]} & \xrightarrow[\sim]{\tau} & S^{-1}(N' \otimes_{A'} A_{[\varphi]}) \\ \downarrow & & \downarrow{\scriptstyle \rho^{T,S}} \\ (T'^{-1}N') \otimes_{T'^{-1}A'} (T^{-1}A)_{[\varphi^{T'}]} & \xrightarrow[\tau]{\sim} & T^{-1}(N' \otimes_{A'} A_{[\varphi]}) \end{array}$$

is commutative, the left vertical arrow being obtained by applying $\rho_{N'}^{T',S'}$ to $S'^{-1}N'$ and $\rho_A^{T,S}$ to $S^{-1}A$.

[0$_{\mathrm{I}}$ | 19] **(1.5.7)** Let A'' be a third ring, $\varphi' : A'' \to A'$ a ring homomorphism, and S'' a multiplicative subset of A'' such that $\varphi'(S'') \subset S'$. Set $\varphi'' = \varphi \circ \varphi'$; then we have

$$\varphi''^{S''} = \varphi^{S'} \circ \varphi'^{S''}.$$

Let M be an A-module; obviously $M_{[\varphi'']} = (M_{[\varphi]})_{[\varphi']}$; if σ' and σ'' are the homomorphisms defined from φ' and φ'' as σ is defined in (1.5.2) from φ, we have the transitivity formula

$$\sigma'' = \sigma \circ \sigma'.$$

Finally, let N'' be an A''-module; the A-module $N'' \otimes_{A''} A_{[\varphi'']}$ is canonically identified with

$$(N'' \otimes_{A''} A'_{[\varphi']}) \otimes_{A'} A_{[\varphi]},$$

and similarly, the $S^{-1}A$-module

$$(S''^{-1}N'') \otimes_{S''^{-1}A''} (S^{-1}A)_{[\varphi''S'']}$$

is canonically identified with

$$\big((S''^{-1}N'') \otimes_{S''^{-1}A''} (S'^{-1}A')_{[\varphi'S'']}\big) \otimes_{S'^{-1}A'} (S^{-1}A)_{[\varphi^{S'}]}.$$

With these identifications, if τ' and τ'' are the isomorphisms defined from φ' and φ'' as τ is defined in (1.5.4) from φ, we have the transitivity formula

$$\tau'' = \tau \circ (\tau' \otimes 1).$$

(1.5.8) Let A be a subring of a ring B; for every *minimal* prime ideal $\mathfrak{p}$ of A, there exists a minimal prime ideal $\mathfrak{q}$ of B such that $\mathfrak{p} = A \cap \mathfrak{q}$. Indeed, $A_\mathfrak{p}$ is a subring of $B_\mathfrak{p}$ (1.3.2) and has only one prime ideal $\mathfrak{p}'$ (1.2.6); since $B_\mathfrak{p}$ is not reduced to 0, it has at least one prime ideal $\mathfrak{q}'$, and we necessarily have $\mathfrak{q}' \cap A_\mathfrak{p} = \mathfrak{p}'$; the prime ideal $\mathfrak{q}_1$ of B which is the inverse image of $\mathfrak{q}'$ is therefore such that $\mathfrak{q}_1 \cap A = \mathfrak{p}$, and *a fortiori* we have $\mathfrak{q} \cap A = \mathfrak{p}$ for every minimal prime ideal $\mathfrak{q}$ of B contained in $\mathfrak{q}_1$.

1.6 Identification of the module M_f with an inductive limit

(1.6.1) Let M be an A-module and f an element of A. Consider a sequence (M_n) of A-modules, all identical to M, and for every pair of integers $m \leq n$, let φ_{nm} be the homomorphism $z \mapsto f^{n-m}z$ from M_m to M_n; it is immediate that $((M_n), (\varphi_{nm}))$ is an *inductive system* of A-modules; let $N = \varinjlim M_n$ be the inductive limit of this system. We shall define a canonical *functorial* A-isomorphism of N onto M_f. To this end, note that for every n, $\theta_n : z \mapsto z/f^n$ is an A-homomorphism from $M = M_n$ to M_f, and it follows from the definitions that $\theta_n \circ \varphi_{nm} = \theta_m$ for $m \leq n$. There therefore exists an A-homomorphism $\theta : N \to M_f$ such that, if φ_n denotes the canonical homomorphism $M_n \to N$, we have $\theta_n = \theta \circ \varphi_n$ for every n. Since by hypothesis every element of M_f is of the form z/f^n for at least one n, it is clear that θ is surjective. On the other hand, if $\theta(\varphi_n(z)) = 0$, in other words $z/f^n = 0$, there exists an integer $k > 0$ such that $f^k z = 0$, hence $\varphi_{n+k,n}(z) = 0$, which implies $\varphi_n(z) = 0$. We can therefore identify M_f and $\varinjlim M_n$ by means of θ.

(1.6.2) Let us now write $M_{f,n}$, φ^f_{nm} and φ^f_n instead of M_n, φ_{nm} and φ_n. Let g be a second element of A. Since f^n divides $f^n g^n$, we have a functorial homomorphism

$$\rho_{fg,f} : M_f \longrightarrow M_{fg} \qquad \text{(1.4.1 and 1.4.3)};$$

[0I | 20] if M_f and M_{fg} are identified with $\varinjlim M_{f,n}$ and $\varinjlim M_{fg,n}$ respectively, $\rho_{fg,f}$ is identified with the *inductive limit* of the maps $\rho^n_{fg,f} : M_{f,n} \to M_{fg,n}$ defined by $\rho^n_{fg,f}(z) = g^n z$. Indeed, this follows immediately from the commutativity of the diagram

$$\begin{array}{ccc} M_{f,n} & \xrightarrow{\rho^n_{fg,f}} & M_{fg,n} \\ \downarrow{\scriptstyle \varphi^f_n} & & \downarrow{\scriptstyle \varphi^{fg}_n} \\ M_f & \xrightarrow{\rho_{fg,f}} & M_{fg}. \end{array}$$

1.7 Support of a module

(1.7.1) Given an A-module M, the *support* of M, denoted $\mathrm{Supp}(M)$, is the set of prime ideals $\mathfrak{p}$ of A such that $M_\mathfrak{p} \neq 0$. For $M = 0$, it is necessary and sufficient that $\mathrm{Supp}(M) = \varnothing$, for if $M_\mathfrak{p} = 0$ for every $\mathfrak{p}$, the annihilator of an element $x \in M$ cannot be contained in any prime ideal of A, and is therefore the whole of A.

(1.7.2) If $0 \to N \to M \to P \to 0$ is an exact sequence of A-modules, we have

$$\mathrm{Supp}(M) = \mathrm{Supp}(N) \cup \mathrm{Supp}(P)$$

since for every prime ideal $\mathfrak{p}$ of A the sequence $0 \to N_\mathfrak{p} \to M_\mathfrak{p} \to P_\mathfrak{p} \to 0$ is exact (1.3.2), and for $M_\mathfrak{p} = 0$ it is necessary and sufficient that $N_\mathfrak{p} = P_\mathfrak{p} = 0$.

(1.7.3) If M is the sum of a family (M_λ) of submodules, $M_\mathfrak{p}$ is the sum of the $(M_\lambda)_\mathfrak{p}$ for every prime ideal $\mathfrak{p}$ of A (1.3.3 and 1.3.2), hence

$$\mathrm{Supp}(M) = \bigcup_\lambda \mathrm{Supp}(M_\lambda).$$

(1.7.4) If M is an A-module *of finite type*, $\mathrm{Supp}(M)$ is the set of prime ideals *containing the annihilator of* M. Indeed, if M is monogenic and generated by x, to say that $M_\mathfrak{p} = 0$ means that there exists $s \notin \mathfrak{p}$ such that $s.x = 0$, that is, that $\mathfrak{p}$ does not contain the annihilator of x. If now M has a finite system $(x_i)_{1 \leq i \leq n}$ of generators and $\mathfrak{a}_i$ is the annihilator of x_i, it follows from (1.7.3) that $\mathrm{Supp}(M)$ is the set of the $\mathfrak{p}$ containing one of the $\mathfrak{a}_i$, or, what amounts to the same, the set of the $\mathfrak{p}$ containing $\mathfrak{a} = \bigcap_i \mathfrak{a}_i$, which is the annihilator of M.

(1.7.5) If M and N are two A-modules *of finite type*, we have

$$\mathrm{Supp}(M \otimes_A N) = \mathrm{Supp}(M) \cap \mathrm{Supp}(N).$$

We must show that if $\mathfrak{p}$ is a prime ideal of A, the condition $M_\mathfrak{p} \otimes_{A_\mathfrak{p}} N_\mathfrak{p} \neq 0$ is equivalent to "$M_\mathfrak{p} \neq 0$ and $N_\mathfrak{p} \neq 0$" (taking (1.3.4) into account). In other words, we must show that if P, Q are two modules of finite type over a *local* ring B, not reduced to 0, then $P \otimes_B Q \neq 0$. Let $\mathfrak{m}$ be the maximal ideal of B. By Nakayama's lemma, the vector spaces $P/\mathfrak{m}P$ and $Q/\mathfrak{m}Q$ are not reduced to 0, hence neither is their tensor product

$$(P/\mathfrak{m}P) \otimes_{B/\mathfrak{m}} (Q/\mathfrak{m}Q) = (P \otimes_B Q) \otimes_B (B/\mathfrak{m}),$$

whence the conclusion.

In particular, if M is an A-module of finite type and $\mathfrak{a}$ an ideal of A, $\mathrm{Supp}(M/\mathfrak{a}M)$ is the set of prime ideals containing both $\mathfrak{a}$ and the annihilator $\mathfrak{n}$ of M (1.7.4), in other words the set of prime ideals containing $\mathfrak{a} + \mathfrak{n}$.

§2 Irreducible spaces. Noetherian spaces [0I | 21]

2.1 Irreducible spaces

(2.1.1) A topological space X is said to be *irreducible* if it is non-empty and is not the union of two closed subspaces distinct from X. It amounts to the same to say that $X \neq \varnothing$ and that the intersection of two (and hence of finitely many) non-empty open subsets of X is non-empty, or that every non-empty open subset is everywhere dense, or that every closed subset $\neq X$ is *nowhere dense*, or finally that every open subset of X is *connected*.

(2.1.2) For a subspace Y of a topological space X to be irreducible, it is necessary and sufficient that its closure $\overline{Y}$ be irreducible. In particular, every subspace which is the closure $\overline{\{x\}}$ of a subspace reduced to one point is irreducible; we shall express the relation $y \in \overline{\{x\}}$ (equivalent to $\overline{\{y\}} \subset \overline{\{x\}}$) by saying that y is a *specialization of* x or that x is a *generization of* y. When there exists in an irreducible space X a point x such that $X = \overline{\{x\}}$, we shall say that x is a *generic point* of X. Every non-empty open subset of X then contains x, and every subspace containing x has x as a generic point.

(2.1.3) Recall that a *Kolmogorov space* is a topological space X satisfying the separation axiom:

(T_0) If $x \neq y$ are any two points of X, there exists an open set containing one of the points x, y and not the other.

If an irreducible Kolmogorov space has a generic point, it has *only one*, since a non-empty open set contains every generic point.

Recall that a topological space X is said to be *quasi-compact* if from every open covering of X one can extract a finite covering of X (or, what amounts to the same, if every decreasing filtered family of non-empty closed sets has a non-empty intersection). If X is a quasi-compact space, every non-empty closed subset A of X contains a *minimal* non-empty closed set M, since the set of non-empty closed subsets of A is inductive for the relation $\supset$; if moreover X is a Kolmogorov space, M is necessarily reduced to a single point (or, as one says by abuse of language, is a *closed point*).

(2.1.4) In an irreducible space X, every non-empty open subspace U is irreducible, and if X has a generic point x, x is also a generic point of U.

Let (U_α) be a covering (with non-empty index set) of a topological space X, consisting of non-empty open sets; for X to be irreducible, it is necessary and sufficient that U_α be irreducible for every α, and that $U_\alpha \cap U_\beta \neq \varnothing$ for all α, β. The condition is obviously necessary; to see that it is sufficient, it suffices to prove that if V is a non-empty open subset of X, $V \cap U_\alpha$ is non-empty for every α, for then $V \cap U_\alpha$ is dense in U_α for every α, and consequently V is dense in X. Now, there is at least one index γ such that $V \cap U_\gamma \neq \varnothing$, so $V \cap U_\gamma$ is dense in U_γ, and since, for every α, $U_\alpha \cap U_\gamma \neq \varnothing$, we also have $V \cap U_\alpha \cap U_\gamma \neq \varnothing$.

(2.1.5) Let X be an irreducible space and f a continuous map from X to a topological space Y. Then $f(X)$ is irreducible, and if x is a generic point of X, $f(x)$ is a generic point of $f(X)$ and consequently also of $\overline{f(X)}$. In particular, if moreover Y is irreducible and has only one generic point y, then for $f(X)$ to be everywhere dense it is necessary and sufficient that $f(x) = y$. [0I | 22]

(2.1.6) Every irreducible subspace of a topological space X is contained in a *maximal* irreducible subspace, which is necessarily closed. The maximal irreducible subspaces

of X are called the *irreducible components* of X. If Z_1, Z_2 are two distinct irreducible components of the space X, $Z_1 \cap Z_2$ is a *nowhere dense* closed set in each of the subspaces Z_1, Z_2; in particular, if an irreducible component of X has a generic point (2.1.2), such a point cannot belong to any other irreducible component. If X has only a *finite* number of irreducible components Z_i $(1 \leq i \leq n)$, and if, for each i, we set

$$U_i = Z_i \cap \complement\Big(\bigcup_{j \neq i} Z_j\Big),$$

then the U_i are open, irreducible and pairwise disjoint, and their union is dense in X.

Let U be an open subset of a topological space X. If Z is an irreducible subset of X meeting U, $Z \cap U$ is open and dense in Z, hence irreducible; conversely, for every irreducible closed subset Y of U, the closure $\overline{Y}$ of Y in X is irreducible and $\overline{Y} \cap U = Y$. One concludes that there is a *bijective correspondence* between the irreducible components of U and the irreducible components of X which meet U.

(2.1.7) If a topological space X is the union of a *finite* number of irreducible closed subspaces Y_i, the irreducible components of X are the maximal elements of the set of the Y_i, for if Z is an irreducible closed subset of X, Z is the union of the $Z \cap Y_i$, from which one deduces at once that Z must be contained in one of the Y_i. Let Y be a subspace of a topological space X, and suppose that Y has only a finite number of irreducible components Y_i $(1 \leq i \leq n)$; then the closures $\overline{Y_i}$ in X are the irreducible components of $\overline{Y}$.

(2.1.8) Let Y be an irreducible space having only one generic point y. Let X be a topological space and f a continuous map from X to Y. Then, for every irreducible component Z of X meeting $f^{-1}(y)$, $f(Z)$ is dense in Y. The converse is not necessarily true; however, if Z has a generic point z and $f(Z)$ is dense in Y, we necessarily have $f(z) = y$ (2.1.5); moreover, $Z \cap f^{-1}(y)$ is then the closure of $\{z\}$ in $f^{-1}(y)$ and is therefore irreducible, and since every irreducible subset of $f^{-1}(y)$ containing z is necessarily contained in Z (2.1.6), z is a generic point of $Z \cap f^{-1}(y)$. Since every irreducible component of $f^{-1}(y)$ is contained in an irreducible component of X, we see that if every irreducible component Z of X meeting $f^{-1}(y)$ has a generic point, then there is a *bijective correspondence* between the set of these components and the set of irreducible components $Z \cap f^{-1}(y)$ of $f^{-1}(y)$, the generic points of Z being identical with those of $Z \cap f^{-1}(y)$.

[0I | 23]

2.2 Noetherian spaces

(2.2.1) A topological space X is said to be *Noetherian* if the set of open subsets of X satisfies the *maximal* condition, or, what amounts to the same, if the set of closed subsets of X satisfies the *minimal* condition. We say that X is *locally Noetherian* if every $x \in X$ has a neighbourhood which is a Noetherian subspace.

(2.2.2) Let E be an ordered set satisfying the *minimal* condition, and let P be a property of the elements of E subject to the following condition: if $a \in E$ is such that $P(x)$ is true for every $x < a$, then $P(a)$ is true. Under these conditions, $P(x)$ *is true for every* $x \in E$ ("principle of Noetherian induction"). Indeed, let F be the set of $x \in E$ for which $P(x)$ is false; if F were non-empty, it would have a minimal element a, and since $P(x)$ is then true for every $x < a$, $P(a)$ would also be true, which is a contradiction.

We shall apply this principle in particular when E is a *set of closed subsets of a Noetherian space.*

(2.2.3) Every subspace of a Noetherian space is Noetherian. Conversely, every topological space which is a finite union of Noetherian subspaces is Noetherian.

(2.2.4) Every Noetherian space is quasi-compact; conversely, every topological space in which every open subset is quasi-compact is Noetherian.

(2.2.5) A Noetherian space has only a *finite* number of irreducible components, as one sees by Noetherian induction.

§3 Supplement on sheaves

3.1 Sheaves with values in a category

(3.1.1) Let $\mathbf{K}$ be a category, $(A_\alpha)_{\alpha\in I}$, $(A_{\alpha\beta})_{(\alpha,\beta)\in I\times I}$ two families of objects of $\mathbf{K}$ such that $A_{\beta\alpha} = A_{\alpha\beta}$, and $(\rho_{\alpha\beta})_{(\alpha,\beta)\in I\times I}$ a family of morphisms $\rho_{\alpha\beta} : A_\alpha \to A_{\alpha\beta}$. We shall say that a pair consisting of an object A of $\mathbf{K}$ and a family of morphisms $\rho_\alpha : A \to A_\alpha$ is a *solution of the universal problem* defined by the families (A_α), $(A_{\alpha\beta})$ and $(\rho_{\alpha\beta})$ if, for every object B of $\mathbf{K}$, the map which sends every $f \in \mathrm{Hom}(B, A)$ to the family $(\rho_\alpha \circ f) \in \prod_\alpha \mathrm{Hom}(B, A_\alpha)$ is a *bijection* of $\mathrm{Hom}(B, A)$ onto the set of the (f_α) such that $\rho_{\alpha\beta} \circ f_\alpha = \rho_{\beta\alpha} \circ f_\beta$ for every pair of indices (α, β). One sees at once that if such a solution exists, it is unique up to isomorphism.

(3.1.2) We shall not recall the definition of a *presheaf* $U \to \mathcal{F}(U)$ on a topological space X with values in a category $\mathbf{K}$ (G, I, 1.9); we shall say that such a presheaf is a *sheaf with values in* $\mathbf{K}$ if it satisfies the following axiom:

(F) *For every covering (U_α) of an open subset U of X by open subsets U_α contained in U, if we denote by ρ_α (resp. $\rho_{\alpha\beta}$) the restriction morphism*

$$\mathcal{F}(U) \to \mathcal{F}(U_\alpha) \qquad (\text{resp. } \mathcal{F}(U_\alpha) \to \mathcal{F}(U_\alpha \cap U_\beta)),$$

the pair consisting of $\mathcal{F}(U)$ and the family (ρ_α) is a solution of the universal problem for [0$_\mathrm{I}$ | 24]
$(\mathcal{F}(U_\alpha))$, $(\mathcal{F}(U_\alpha \cap U_\beta))$ and $(\rho_{\alpha\beta})$ (3.1.1)[5].

It amounts to the same to say that, for every object T of $\mathbf{K}$, the family $U \to \mathrm{Hom}(T, \mathcal{F}(U))$ is a *sheaf of sets*.

(3.1.3) Suppose that $\mathbf{K}$ is the category defined by a "species of structure with morphisms" Σ, the objects of $\mathbf{K}$ thus being the sets endowed with structures of species Σ and the morphisms those of Σ. Suppose moreover that the category $\mathbf{K}$ satisfies the following condition:

(E) If $(A, (\rho_\alpha))$ is a solution of a universal mapping problem *in the category* $\mathbf{K}$ for families (A_α), $(A_{\alpha\beta})$, $(\rho_{\alpha\beta})$, then it is also a solution of the universal mapping problem for the same families *in the category of sets* (that is, when A, the A_α and the $A_{\alpha\beta}$ are regarded as sets, and the ρ_α and $\rho_{\alpha\beta}$ as maps)[6].

Under these conditions, condition (F) implies that, regarded as a presheaf *of sets*, $U \to \mathcal{F}(U)$ is a *sheaf*. Moreover, for a map $u : T \to \mathcal{F}(U)$ to be a morphism of $\mathbf{K}$, it is necessary and sufficient, by (F), that each map $\rho_\alpha \circ u$ be a morphism $T \to \mathcal{F}(U_\alpha)$, which

[5] This is a special case of the general notion of (non-filtered) *projective limit* (*see* (T, I, 1.8) and the book in preparation announced in the Introduction).

[6] One can prove that this also means that the canonical functor $\mathbf{K} \to (\mathrm{Ens})$ *commutes with projective limits* (not necessarily filtered).

means that the structure of species Σ on $\mathcal{F}(U)$ is the *initial structure* for the morphisms ρ_α. Conversely, suppose that a presheaf $U \to \mathcal{F}(U)$ on X with values in $\mathbf{K}$ is a *sheaf of sets* and satisfies the preceding condition; it is then clear that it satisfies (F), and hence is a *sheaf with values in* $\mathbf{K}$.

(3.1.4) When Σ is the species of structure of group or of ring, the fact that the presheaf $U \to \mathcal{F}(U)$ with values in $\mathbf{K}$ is a *sheaf of sets* implies *ipso facto* that it is a *sheaf with values in* $\mathbf{K}$ (in other words, a sheaf of groups or of rings in the sense of (G))[7]. But this is no longer the case when, for example, $\mathbf{K}$ is the category of *topological rings* (with continuous homomorphisms as morphisms): a sheaf with values in $\mathbf{K}$ is a sheaf of rings $U \to \mathcal{F}(U)$ such that, for every open subset U and every covering of U by open subsets $U_\alpha \subset U$, the topology of the ring $\mathcal{F}(U)$ is the *coarsest* making the homomorphisms $\mathcal{F}(U) \to \mathcal{F}(U_\alpha)$ continuous. In this case we shall say that $U \to \mathcal{F}(U)$, regarded as a sheaf of rings (without topology), *underlies* the sheaf of topological rings $U \to \mathcal{F}(U)$. The morphisms $u_V : \mathcal{F}(V) \to \mathcal{G}(V)$ (V an arbitrary open subset of X) of sheaves of topological rings are therefore homomorphisms of the underlying sheaves of rings such that u_V is *continuous* for every open subset $V \subset X$; to distinguish them from arbitrary homomorphisms of the underlying sheaves of rings, we shall call them *continuous* homomorphisms of sheaves of topological rings. There are analogous definitions and conventions for sheaves of topological spaces or of topological groups.

[0_I | 25] **(3.1.5)** It is clear that for every category $\mathbf{K}$, if $\mathcal{F}$ is a presheaf (resp. a sheaf) on X with values in $\mathbf{K}$ and U an open subset of X, the $\mathcal{F}(V)$ for the open subsets $V \subset U$ constitute a presheaf (resp. a sheaf) with values in $\mathbf{K}$, which is called the presheaf (resp. sheaf) *induced* by $\mathcal{F}$ on U and which is denoted $\mathcal{F}|U$.

For every morphism $u : \mathcal{F} \to \mathcal{G}$ of presheaves on X with values in $\mathbf{K}$, we shall denote by $u|U$ the morphism $\mathcal{F}|U \to \mathcal{G}|U$ formed by the u_V for $V \subset U$.

(3.1.6) Suppose now that the category $\mathbf{K}$ admits *inductive limits* (T, 1.8); then, for every presheaf (and in particular every sheaf) $\mathcal{F}$ on X with values in $\mathbf{K}$ and every $x \in X$, one can define the *stalk* $\mathcal{F}_x$ as the object of $\mathbf{K}$ which is the inductive limit of the $\mathcal{F}(U)$ over the set, filtered (for $\supset$), of open neighbourhoods U of x in X, with respect to the morphisms $\rho_U^V : \mathcal{F}(V) \to \mathcal{F}(U)$. If $u : \mathcal{F} \to \mathcal{G}$ is a morphism of presheaves with values in $\mathbf{K}$, one defines, for every $x \in X$, the morphism $u_x : \mathcal{F}_x \to \mathcal{G}_x$ as the inductive limit of the $u_U : \mathcal{F}(U) \to \mathcal{G}(U)$ over the set of open neighbourhoods of x; one thus defines $\mathcal{F}_x$ as a covariant functor in $\mathcal{F}$, with values in $\mathbf{K}$, for every $x \in X$.

When $\mathbf{K}$ is moreover defined by a species of structure with morphisms Σ, the elements of $\mathcal{F}(U)$ are also called the *sections over* U of a *sheaf* $\mathcal{F}$ with values in $\mathbf{K}$, and one then writes $\Gamma(U, \mathcal{F})$ instead of $\mathcal{F}(U)$; for $s \in \Gamma(U, \mathcal{F})$ and V an open subset contained in U, one writes $s|V$ instead of $\rho_V^U(s)$; for every $x \in U$, the canonical image of s in $\mathcal{F}_x$ is the *germ* of s at the point x, denoted s_x (*we shall never use the notation* $s(x)$ *in this sense*, this notation being reserved for another notion relating to the particular sheaves which will be considered in this Treatise (5.5.1)).

If then $u : \mathcal{F} \to \mathcal{G}$ is a morphism of sheaves with values in $\mathbf{K}$, we shall write $u(s)$ instead of $u_V(s)$ for every $s \in \Gamma(V, \mathcal{F})$.

If $\mathcal{F}$ is a sheaf of commutative groups, or of rings, or of modules, the set of $x \in X$ such that $\mathcal{F}_x \neq \{0\}$ is called the *support* of $\mathcal{F}$, denoted $\mathrm{Supp}(\mathcal{F})$; this set is not necessarily closed in X.

[7] This is because in the category $\mathbf{K}$, every morphism which is a *bijection* (as a map of sets) is an *isomorphism*. This is no longer true when $\mathbf{K}$ is, for example, the category of topological spaces.

When **K** is defined by a species of structure with morphisms, *we shall systematically refrain from bringing in the point of view of "étalé spaces"* as regards sheaves with values in **K**; in other words, we shall never regard a sheaf as a topological space (nor even as the set which is the union of its stalks), and neither shall we regard a morphism $u : \mathcal{F} \to \mathcal{G}$ of such sheaves on X as a continuous map of topological spaces.

3.2 Presheaves on a basis of open subsets

(3.2.1) In what follows we shall restrict ourselves to categories **K** admitting *projective limits* (generalized ones, that is, corresponding to preordered sets which are not necessarily filtered, cf. (T, 1.8)). Let X be a topological space and $\mathfrak{B}$ a basis of open subsets for the topology of X. We shall call a *presheaf on* $\mathfrak{B}$ *with values in* **K** a family of objects $\mathcal{F}(U) \in \mathbf{K}$, attached to each $U \in \mathfrak{B}$, together with a family of morphisms $\rho_U^V : \mathcal{F}(V) \to \mathcal{F}(U)$ defined for every pair (U, V) of elements of $\mathfrak{B}$ such that $U \subset V$, subject to the conditions $\rho_U^U =$ identity and $\rho_U^W = \rho_U^V \circ \rho_V^W$ if U, V, W in $\mathfrak{B}$ are such that $U \subset V \subset W$. One can associate with it a *presheaf with values in* **K**: $U \to \mathcal{F}'(U)$ in the ordinary sense, by taking, for every open subset U, [0_I | 26]

$$\mathcal{F}'(U) = \varprojlim_{V \subset U} \mathcal{F}(V),$$

where V runs through the ordered set (for $\subset$, *not filtered in general*) of the sets $V \in \mathfrak{B}$ such that $V \subset U$; for the $\mathcal{F}(V)$ form a projective system for the ρ_V^W ($V \subset W \subset U$, $V \in \mathfrak{B}$, $W \in \mathfrak{B}$). Indeed, if U, U' are two open subsets of X such that $U \subset U'$, one defines ${\rho'}_U^{U'}$ as the projective limit (for $V \subset U$) of the canonical morphisms $\mathcal{F}'(U') \to \mathcal{F}(V)$, in other words the unique morphism $\mathcal{F}'(U') \to \mathcal{F}'(U)$ which, composed with the canonical morphisms $\mathcal{F}'(U) \to \mathcal{F}(V)$, gives the canonical morphisms $\mathcal{F}'(U') \to \mathcal{F}(V)$; the verification of the transitivity of ${\rho'}_U^{U'}$ is then immediate. Moreover, if $U \in \mathfrak{B}$, the canonical morphism $\mathcal{F}'(U) \to \mathcal{F}(U)$ is an isomorphism, which allows us to identify these two objects[8].

(3.2.2) For the presheaf $\mathcal{F}'$ thus defined to be a *sheaf*, it is necessary and sufficient that the presheaf $\mathcal{F}$ on $\mathfrak{B}$ satisfy the condition:

(F_0) *For every covering* (U_α) *of* $U \in \mathfrak{B}$ *by sets* $U_\alpha \in \mathfrak{B}$ *contained in* U*, and for every object* $T \in \mathbf{K}$*, the map which sends every* $f \in \mathrm{Hom}(T, \mathcal{F}(U))$ *to the family*

$$(\rho_{U_\alpha}^U \circ f) \in \prod_\alpha \mathrm{Hom}(T, \mathcal{F}(U_\alpha))$$

is a bijection of $\mathrm{Hom}(T, \mathcal{F}(U))$ *onto the set of the* (f_α) *such that* $\rho_V^{U_\alpha} \circ f_\alpha = \rho_V^{U_\beta} \circ f_\beta$ *for every pair of indices* (α, β) *and every* $V \in \mathfrak{B}$ *such that* $V \subset U_\alpha \cap U_\beta$[9].

[8] If X is a *Noetherian* space, one can still define $\mathcal{F}'(U)$ and show that it is a presheaf (in the ordinary sense) when one assumes only that **K** admits projective limits for *finite* projective systems. Indeed, if U is an arbitrary open subset of X, there is a *finite* covering (V_i) of U consisting of sets of $\mathfrak{B}$; for every pair (i, j) of indices, let (V_{ijk}) be a finite covering of $V_i \cap V_j$ consisting of sets of $\mathfrak{B}$. Let I be the set consisting of the i and of the triples (i, j, k), ordered by the relations $i > (i, j, k)$, $j > (i, j, k)$ only; one then takes for $\mathcal{F}'(U)$ the projective limit of the system of the $\mathcal{F}(V_i)$ and $\mathcal{F}(V_{ijk})$; one easily checks that this does not depend on the coverings (V_i) and (V_{ijk}) and that $U \to \mathcal{F}'(U)$ is a presheaf.

[9] This also means that the pair consisting of $\mathcal{F}(U)$ and the $\rho_\alpha = \rho_{U_\alpha}^U$ is a *solution of the universal problem* defined (3.1.1) by the data $A_\alpha = \mathcal{F}(U_\alpha)$, $A_{\alpha\beta} = \prod \mathcal{F}(V)$ (for the $V \in \mathfrak{B}$ such that $V \subset U_\alpha \cap U_\beta$) and $\rho_{\alpha\beta} = (\rho''_V) : \mathcal{F}(U_\alpha) \to \prod \mathcal{F}(V)$ defined by the condition that for $V \in \mathfrak{B}$, $V' \in \mathfrak{B}$, $W \in \mathfrak{B}$, $V \cup V' \subset U_\alpha \cap U_\beta$, $W \subset V \cap V'$, $\rho_W^V \circ \rho''_V = \rho_W^{V'} \circ \rho''_{V'}$.

The condition is obviously necessary. To show that it is sufficient, let us first consider a second basis $\mathfrak{B}'$ of the topology of X, *contained in* $\mathfrak{B}$, and show that if $\mathcal{F}''$ denotes the presheaf deduced from the subfamily $(\mathcal{F}(V))_{V\in\mathfrak{B}'}$, then $\mathcal{F}''$ is *canonically isomorphic* to $\mathcal{F}'$. Indeed, first of all, the projective limit (for $V \in \mathfrak{B}'$, $V \subset U$) of the canonical morphisms $\mathcal{F}'(U) \to \mathcal{F}(V)$ is a morphism $\mathcal{F}'(U) \to \mathcal{F}''(U)$ for every open subset U. If $U \in \mathfrak{B}$, this morphism is an isomorphism, since by hypothesis the canonical morphisms $\mathcal{F}''(U) \to \mathcal{F}(V)$ for $V \in \mathfrak{B}'$, $V \subset U$, factorize as

$$\mathcal{F}''(U) \to \mathcal{F}(U) \to \mathcal{F}(V),$$

and it is immediate that the composites of the morphisms $\mathcal{F}(U) \to \mathcal{F}''(U)$ and $\mathcal{F}''(U) \to \mathcal{F}(U)$ thus defined are the identities. This being so, for every open subset U, the morphisms $\mathcal{F}''(U) \to \mathcal{F}''(W) = \mathcal{F}(W)$ for $W \in \mathfrak{B}$ and $W \subset U$ satisfy the conditions characterizing the projective limit of the $\mathcal{F}(W)$ ($W \in \mathfrak{B}$, $W \subset U$), which proves our assertion, taking into account the uniqueness of a projective limit up to isomorphism.

That said, let U be an arbitrary open subset of X, (U_α) a covering of U by open subsets contained in U, and let $\mathfrak{B}'$ be the subfamily of $\mathfrak{B}$ consisting of the sets
[0_{I} | 27] of $\mathfrak{B}$ contained in at least one U_α; it is clear that $\mathfrak{B}'$ is again a basis of the topology of U, so $\mathcal{F}'(U)$ (resp. $\mathcal{F}''(U_\alpha)$) is the projective limit of the $\mathcal{F}(V)$ for $V \in \mathfrak{B}'$ and $V \subset U$ (resp. $V \subset U_\alpha$); axiom (F) is then verified at once by the definition of the projective limit.

When (F_0) is satisfied, we shall say, by abuse of language, that the presheaf $\mathcal{F}$ on the basis $\mathfrak{B}$ is a *sheaf*.

(3.2.3) Let $\mathcal{F}$, $\mathcal{G}$ be two presheaves on the basis $\mathfrak{B}$ with values in $\mathbf{K}$; a *morphism* $u : \mathcal{F} \to \mathcal{G}$ is defined as a family $(u_V)_{V\in\mathfrak{B}}$ of morphisms $u_V : \mathcal{F}(V) \to \mathcal{G}(V)$ satisfying the usual compatibility conditions with the restriction morphisms ρ_V^W. With the notation of (3.2.1), one deduces from it a morphism $u' : \mathcal{F}' \to \mathcal{G}'$ of the corresponding (ordinary) presheaves by taking for u'_U the projective limit of the u_V for $V \in \mathfrak{B}$ and $V \subset U$; the verification of the compatibility conditions with ${\rho'_U}^{U'}$ follows from the functorial character of the projective limit.

(3.2.4) If the category $\mathbf{K}$ admits inductive limits, and if $\mathcal{F}$ is a presheaf on the basis $\mathfrak{B}$ with values in $\mathbf{K}$, then for every $x \in X$ the neighbourhoods of x belonging to $\mathfrak{B}$ form a cofinal set (for $\supset$) in the set of neighbourhoods of x; hence, if $\mathcal{F}'$ is the (ordinary) presheaf corresponding to $\mathcal{F}$, the stalk $\mathcal{F}'_x$ is equal to

$$\varinjlim_{\mathfrak{B}} \mathcal{F}(V)$$

over the set of the $V \in \mathfrak{B}$ containing x. If $u : \mathcal{F} \to \mathcal{G}$ is a morphism of presheaves on $\mathfrak{B}$ with values in $\mathbf{K}$, and $u' : \mathcal{F}' \to \mathcal{G}'$ the corresponding morphism of ordinary presheaves, u'_x is likewise the inductive limit of the morphisms $u_V : \mathcal{F}(V) \to \mathcal{G}(V)$ for $V \in \mathfrak{B}$, $x \in V$.

(3.2.5) Let us return to the general conditions of (3.2.1). If $\mathcal{F}$ is an ordinary *sheaf* with values in $\mathbf{K}$, and $\mathcal{F}_1$ the sheaf *on* $\mathfrak{B}$ obtained by restricting $\mathcal{F}$ to $\mathfrak{B}$, then the ordinary sheaf $\mathcal{F}'_1$ obtained from $\mathcal{F}_1$ by the procedure of (3.2.1) is canonically isomorphic to $\mathcal{F}$, by condition (F) and the uniqueness properties of the projective limit. We shall usually identify $\mathcal{F}$ and $\mathcal{F}'_1$.

If $\mathcal{G}$ is a second (ordinary) sheaf on X with values in $\mathbf{K}$, and $u : \mathcal{F} \to \mathcal{G}$ a morphism, the preceding remark shows that the data of the $u_V : \mathcal{F}(V) \to \mathcal{G}(V)$ *for the* $V \in \mathfrak{B}$ *only* completely determine u; conversely, the u_V being given for $V \in \mathfrak{B}$, it suffices to verify

the commutativity diagram with the restriction morphisms ρ_V^W for $V \in \mathfrak{B}$, $W \in \mathfrak{B}$ and $V \subset W$ in order that there exist one and only one morphism u' from $\mathcal{F}$ to $\mathcal{G}$ such that $u'_V = u_V$ for every $V \in \mathfrak{B}$ (3.2.3).

(3.2.6) Suppose again that $\mathbf{K}$ admits projective limits. Then the category of *sheaves on X with values in $\mathbf{K}$* also admits *projective limits*; indeed, if $(\mathcal{F}_\lambda)$ is a projective system of sheaves on X with values in $\mathbf{K}$, the

$$\mathcal{F}(U) = \varprojlim_\lambda \mathcal{F}_\lambda(U)$$

define a presheaf with values in $\mathbf{K}$, and the verification of axiom (F) follows from the transitivity of projective limits; the fact that $\mathcal{F}$ is then the projective limit of the $\mathcal{F}_\lambda$ is immediate.

When $\mathbf{K}$ is the category of sets, for every projective system $(\mathcal{H}_\lambda)$ such that $\mathcal{H}_\lambda$ is a *subsheaf* of $\mathcal{F}_\lambda$ for every λ, $\varprojlim_\lambda \mathcal{H}_\lambda$ is canonically identified with a *subsheaf* of $\varprojlim_\lambda \mathcal{F}_\lambda$. If $\mathbf{K}$ is the category of commutative groups, the covariant functor $\varprojlim_\lambda \mathcal{F}_\lambda$ is *additive and left exact*. [0I | 28]

3.3 Gluing sheaves

(3.3.1) Suppose again that the category $\mathbf{K}$ admits (generalized) projective limits. Let X be a topological space, $\mathfrak{U} = (U_\lambda)_{\lambda \in L}$ an open covering of X, and for each $\lambda \in L$, let $\mathcal{F}_\lambda$ be a sheaf on U_λ with values in $\mathbf{K}$; for every pair of indices (λ, μ), suppose given an *isomorphism*

$$\theta_{\lambda\mu} : \mathcal{F}_\mu|(U_\lambda \cap U_\mu) \xrightarrow{\sim} \mathcal{F}_\lambda|(U_\lambda \cap U_\mu);$$

moreover, suppose that for every triple (λ, μ, ν), denoting by $\theta'_{\lambda\mu}$, $\theta'_{\mu\nu}$, $\theta'_{\lambda\nu}$ the restrictions of $\theta_{\lambda\mu}$, $\theta_{\mu\nu}$, $\theta_{\lambda\nu}$ to $U_\lambda \cap U_\mu \cap U_\nu$, we have

$$\theta'_{\lambda\nu} = \theta'_{\lambda\mu} \circ \theta'_{\mu\nu}$$

(*gluing condition for the $\theta_{\lambda\mu}$*). Then there exist a sheaf $\mathcal{F}$ on X with values in $\mathbf{K}$ and, for each λ, an isomorphism

$$\eta_\lambda : \mathcal{F}|U_\lambda \xrightarrow{\sim} \mathcal{F}_\lambda$$

such that, for every pair (λ, μ), denoting by η'_λ and η'_μ the restrictions of η_λ and η_μ to $U_\lambda \cap U_\mu$, we have

$$\theta_{\lambda\mu} = \eta'_\lambda \circ {\eta'_\mu}^{-1};$$

moreover, $\mathcal{F}$ and the η_λ are determined up to unique isomorphism by these conditions. Indeed, the uniqueness follows at once from (3.2.5). To establish the existence of $\mathcal{F}$, denote by $\mathfrak{B}$ the basis of open subsets formed by the open subsets contained in at least one U_λ, and for every $U \in \mathfrak{B}$ choose (by means of Hilbert's τ function) one of the $\mathcal{F}_\lambda(U)$ for one of the λ such that $U \subset U_\lambda$; if this object is denoted by $\mathcal{F}(U)$, the ρ_U^V for $U \subset V$, $U \in \mathfrak{B}$, $V \in \mathfrak{B}$ are defined in the obvious way (by means of the $\theta_{\lambda\mu}$), and the transitivity condition is a consequence of the gluing condition; moreover, the verification of (F_0) is immediate, so the presheaf on $\mathfrak{B}$ thus defined is indeed a sheaf, and from it one deduces by the general procedure (3.2.1) an (ordinary) sheaf, again denoted $\mathcal{F}$, which answers the question. We say that $\mathcal{F}$ is obtained by *gluing the $\mathcal{F}_\lambda$ by means of the $\theta_{\lambda\mu}$*, and we shall usually identify $\mathcal{F}_\lambda$ and $\mathcal{F}|U_\lambda$ by means of η_λ.

It is clear that every sheaf $\mathcal{F}$ on X with values in $\mathbf{K}$ can be regarded as obtained by gluing the sheaves $\mathcal{F}_\lambda = \mathcal{F}|U_\lambda$ (where (U_λ) is an arbitrary open covering of X) by means of the isomorphisms $\theta_{\lambda\mu}$ reduced to the identity.

(3.3.2) With the same notation, let $\mathcal{G}_\lambda$ be a second sheaf on U_λ (for every $\lambda \in L$) with values in $\mathbf{K}$, and suppose given, for every pair (λ, μ), an isomorphism

$$\omega_{\lambda\mu} : \mathcal{G}_\mu|(U_\lambda \cap U_\mu) \xrightarrow{\sim} \mathcal{G}_\lambda|(U_\lambda \cap U_\mu),$$

these isomorphisms satisfying the gluing condition. Finally, suppose given, for every λ, a morphism $u_\lambda : \mathcal{F}_\lambda \to \mathcal{G}_\lambda$, and suppose that the diagrams

$$\begin{array}{ccc} \mathcal{F}_\mu|(U_\lambda \cap U_\mu) & \xrightarrow{u_\mu} & \mathcal{G}_\mu|(U_\lambda \cap U_\mu) \\ \downarrow & & \downarrow \\ \mathcal{F}_\lambda|(U_\lambda \cap U_\mu) & \xrightarrow[u_\lambda]{} & \mathcal{G}_\lambda|(U_\lambda \cap U_\mu) \end{array} \tag{3.3.2.1}$$

are commutative. Then, if $\mathcal{G}$ is obtained by gluing the $\mathcal{G}_\lambda$ by means of the $\omega_{\lambda\mu}$, there exists one and only one morphism $u : \mathcal{F} \to \mathcal{G}$ such that the diagrams

[0I | 29]

$$\begin{array}{ccc} \mathcal{F}|U_\lambda & \xrightarrow{u|U_\lambda} & \mathcal{G}|U_\lambda \\ \downarrow & & \downarrow \\ \mathcal{F}_\lambda & \xrightarrow[u_\lambda]{} & \mathcal{G}_\lambda \end{array}$$

are commutative; this follows at once from (3.2.3). The correspondence between the family (u_λ) and u is a functorial bijection of the subset of $\prod_\lambda \mathrm{Hom}(\mathcal{F}_\lambda, \mathcal{G}_\lambda)$ satisfying the conditions (3.3.2.1) onto $\mathrm{Hom}(\mathcal{F}, \mathcal{G})$.

(3.3.3) With the notation of (3.3.1), let V be an open subset of X; it is immediate that the restrictions of the $\theta_{\lambda\mu}$ to $V \cap U_\lambda \cap U_\mu$ satisfy the gluing condition for the induced sheaves $\mathcal{F}_\lambda|(V \cap U_\lambda)$, and that the sheaf on V obtained by gluing the latter is canonically identified with $\mathcal{F}|V$.

3.4 Direct images of presheaves

(3.4.1) Let X, Y be two topological spaces and $\psi : X \to Y$ a continuous map. Let $\mathcal{F}$ be a presheaf on X with values in a category $\mathbf{K}$; for every open subset $U \subset Y$, let

$$\mathcal{G}(U) = \mathcal{F}(\psi^{-1}(U)),$$

and if U, V are two open subsets of Y such that $U \subset V$, let ρ_U^V be the morphism

$$\mathcal{F}(\psi^{-1}(V)) \to \mathcal{F}(\psi^{-1}(U));$$

it is immediate that the $\mathcal{G}(U)$ and the ρ_U^V define a *presheaf* on Y with values in $\mathbf{K}$, which is called the *direct image of* $\mathcal{F}$ *by* ψ and which is denoted $\psi_*(\mathcal{F})$. If $\mathcal{F}$ is a sheaf, one verifies at once axiom (F) for the presheaf $\mathcal{G}(U)$, so $\psi_*(\mathcal{F})$ is a sheaf.

(3.4.2) Let $\mathcal{F}_1$, $\mathcal{F}_2$ be two presheaves on X with values in $\mathbf{K}$, and let $u : \mathcal{F}_1 \to \mathcal{F}_2$ be a morphism. As U runs through the set of open subsets of Y, the family of morphisms

$$u_{\psi^{-1}(U)} : \mathcal{F}_1(\psi^{-1}(U)) \to \mathcal{F}_2(\psi^{-1}(U))$$

satisfies the compatibility conditions with the restriction morphisms, and consequently defines a morphism

$$\psi_*(u) : \psi_*(\mathcal{F}_1) \to \psi_*(\mathcal{F}_2).$$

If $v : \mathcal{F}_2 \to \mathcal{F}_3$ is a morphism from $\mathcal{F}_2$ to a third presheaf on X with values in $\mathbf{K}$, we have

$$\psi_*(v \circ u) = \psi_*(v) \circ \psi_*(u);$$

in other words, $\psi_*(\mathcal{F})$ is a *covariant functor* in $\mathcal{F}$, from the category of presheaves (resp. sheaves) on X with values in $\mathbf{K}$ to that of presheaves (resp. sheaves) on Y with values in $\mathbf{K}$.

(3.4.3) Let Z be a third topological space, $\psi' : Y \to Z$ a continuous map, and let $\psi'' = \psi' \circ \psi$. It is clear that we have

$$\psi''_*(\mathcal{F}) = \psi'_*(\psi_*(\mathcal{F}))$$

for every presheaf $\mathcal{F}$ on X with values in $\mathbf{K}$; moreover, for every morphism $u : \mathcal{F} \to \mathcal{G}$ of such presheaves, we have

$$\psi''_*(u) = \psi'_*(\psi_*(u)).$$

In other words, ψ''_* is the *composite* of the functors ψ'_* and ψ_*, which can be written

$$(\psi' \circ \psi)_* = \psi'_* \circ \psi_*.$$

Moreover, for every open subset U of Y, the image by the restriction $\psi|\psi^{-1}(U)$ of the induced presheaf $\mathcal{F}|\psi^{-1}(U)$ is none other than the induced presheaf $\psi_*(\mathcal{F})|U$.

(3.4.4) Suppose that the category $\mathbf{K}$ admits inductive limits, and let $\mathcal{F}$ be a presheaf on X with values in $\mathbf{K}$; for every $x \in X$, the morphisms

$$\Gamma(\psi^{-1}(U), \mathcal{F}) \to \mathcal{F}_x$$

(U an open neighbourhood of $\psi(x)$ in Y) form an inductive system, which by passage to the limit gives a morphism [0_{I} | 30]

$$\psi_x : (\psi_*(\mathcal{F}))_{\psi(x)} \to \mathcal{F}_x$$

of stalks; in general, this morphism is *neither injective nor surjective*. It is functorial; indeed, if $u : \mathcal{F}_1 \to \mathcal{F}_2$ is a morphism of presheaves on X with values in $\mathbf{K}$, the diagram

$$\begin{array}{ccc} (\psi_*(\mathcal{F}_1))_{\psi(x)} & \xrightarrow{\psi_x} & (\mathcal{F}_1)_x \\ \downarrow{\scriptstyle (\psi_*(u))_{\psi(x)}} & & \downarrow{\scriptstyle u_x} \\ (\psi_*(\mathcal{F}_2))_{\psi(x)} & \xrightarrow[\psi_x]{} & (\mathcal{F}_2)_x \end{array}$$

is commutative. If Z is a third topological space, $\psi' : Y \to Z$ a continuous map, and $\psi'' = \psi' \circ \psi$, we have

$$\psi''_x = \psi_x \circ \psi'_{\psi(x)}$$

for $x \in X$.

(3.4.5) Under the hypotheses of (3.4.4), suppose moreover that ψ is a *homeomorphism* of X onto the subspace $\psi(X)$ of Y. Then, for every $x \in X$, ψ_x is an *isomorphism*. This applies in particular to the canonical injection j of a subset X of Y into Y.

(3.4.6) Suppose that **K** is the category of groups, or of rings, etc. If $\mathcal{F}$ is a sheaf on X with values in **K**, with support S, and if $y \notin \overline{\psi(S)}$, it follows from the definition of $\psi_*(\mathcal{F})$ that

$$(\psi_*(\mathcal{F}))_y = \{0\},$$

in other words, the support of $\psi_*(\mathcal{F})$ is contained in $\overline{\psi(S)}$; but it is not necessarily contained in $\psi(S)$. Under the same hypotheses, if j is the canonical injection of a subset X of Y into Y, the sheaf $j_*(\mathcal{F})$ induces $\mathcal{F}$ on X; if moreover X is *closed* in Y, $j_*(\mathcal{F})$ is the sheaf on Y which induces $\mathcal{F}$ on X and 0 on $Y - X$ (G, II, 2.9.2), but in general it is distinct from the latter when X is assumed locally closed but not closed.

3.5 Inverse images of presheaves

(3.5.1) Under the hypotheses of (3.4.1), if $\mathcal{F}$ (resp. $\mathcal{G}$) is a presheaf on X (resp. Y) with values in **K**, every morphism $u : \mathcal{G} \to \psi_*(\mathcal{F})$ of presheaves on Y is also called a *ψ-morphism* from $\mathcal{G}$ to $\mathcal{F}$, and is also written $\mathcal{G} \to \mathcal{F}$. We also denote by $\mathrm{Hom}_\psi(\mathcal{G}, \mathcal{F})$ the set $\mathrm{Hom}_Y(\mathcal{G}, \psi_*(\mathcal{F}))$ of the ψ-morphisms from $\mathcal{G}$ to $\mathcal{F}$.

For every pair (U, V), where U is an open subset of X and V an open subset of Y such that $\psi(U) \subset V$, one has a morphism $u_{U,V} : \mathcal{G}(V) \to \mathcal{F}(U)$ obtained by composing the restriction morphism $\mathcal{F}(\psi^{-1}(V)) \to \mathcal{F}(U)$ and the morphism $u_V : \mathcal{G}(V) \to \psi_*(\mathcal{F})(V) = \mathcal{F}(\psi^{-1}(V))$; it is immediate that these morphisms make commutative the diagrams

$$\begin{array}{ccc} \mathcal{G}(V) & \xrightarrow{u_{U,V}} & \mathcal{F}(U) \\ \downarrow & & \downarrow \\ \mathcal{G}(V') & \xrightarrow[u_{U',V'}]{} & \mathcal{F}(U') \end{array} \qquad (3.5.1.1)$$

for $U' \subset U$, $V' \subset V$, $\psi(U') \subset V'$. Conversely, a family $(u_{U,V})$ of morphisms making the diagrams (3.5.1.1) commutative defines a ψ-morphism u, since it suffices to take

$$u_V = u_{\psi^{-1}(V),V}.$$

[0I | 31] If the category **K** admits (generalized) projective limits, and if $\mathfrak{B}$, $\mathfrak{B}'$ are bases of the topologies of X and Y respectively, then to define a ψ-morphism u of *sheaves*, one may restrict oneself to giving the $u_{U,V}$ for $U \in \mathfrak{B}$, $V \in \mathfrak{B}'$ and $\psi(U) \subset V$, satisfying the compatibility conditions (3.5.1.1) for U, U' in $\mathfrak{B}$ and V, V' in $\mathfrak{B}'$; indeed, it suffices to define u_W, for every open subset $W \subset Y$, as the projective limit of the $u_{U,V}$ for $V \in \mathfrak{B}'$ and $V \subset W$, $U \in \mathfrak{B}$ and $\psi(U) \subset V$.

When the category **K** admits inductive limits, one has, for every $x \in X$, a morphism

$$\mathcal{G}(V) \to \mathcal{F}(\psi^{-1}(V)) \to \mathcal{F}_x$$

for every open neighbourhood V of $\psi(x)$ in Y, and these morphisms form an inductive system which by passage to the limit gives a morphism

$$\mathcal{G}_{\psi(x)} \to \mathcal{F}_x.$$

(3.5.2) Under the hypotheses of (3.4.3), let $\mathcal{F}$, $\mathcal{G}$, $\mathcal{H}$ be presheaves with values in **K** on X, Y, Z respectively, and let $u : \mathcal{G} \to \psi_*(\mathcal{F})$, $v : \mathcal{H} \to \psi'_*(\mathcal{G})$ be a ψ-morphism and a ψ'-morphism respectively. One deduces from them a ψ''-morphism

$$w : \mathcal{H} \xrightarrow{v} \psi'_*(\mathcal{G}) \xrightarrow{\psi'_*(u)} \psi'_*(\psi_*(\mathcal{F})) = \psi''_*(\mathcal{F}),$$

which is called, by definition, the *composite* of u and v. One can therefore regard the pairs $(X, \mathcal{F})$ consisting of a topological space X and a presheaf $\mathcal{F}$ on X (with values in $\mathbf{K}$) as forming a *category*, the morphisms being the pairs $(\psi, \theta) : (X, \mathcal{F}) \to (Y, \mathcal{G})$ consisting of a continuous map $\psi : X \to Y$ and a ψ-morphism $\theta : \mathcal{G} \to \mathcal{F}$.

(3.5.3) Let $\psi : X \to Y$ be a continuous map and $\mathcal{G}$ a *presheaf* on Y with values in $\mathbf{K}$. We shall call an *inverse image of* $\mathcal{G}$ *by* ψ a pair $(\mathcal{G}', \rho)$, where $\mathcal{G}'$ is a *sheaf* on X with values in $\mathbf{K}$ and $\rho : \mathcal{G} \to \mathcal{G}'$ a ψ-morphism (in other words a homomorphism $\mathcal{G} \to \psi_*(\mathcal{G}')$) such that, for every *sheaf* $\mathcal{F}$ on X with values in $\mathbf{K}$, the map

$$\mathrm{Hom}_X(\mathcal{G}', \mathcal{F}) \longrightarrow \mathrm{Hom}_\psi(\mathcal{G}, \mathcal{F}) = \mathrm{Hom}_Y(\mathcal{G}, \psi_*(\mathcal{F})) \tag{3.5.3.1}$$

sending v to $\psi_*(v) \circ \rho$ is a *bijection*; this map, being functorial in $\mathcal{F}$, will then define an isomorphism of functors in $\mathcal{F}$. Since the pair $(\mathcal{G}', \rho)$ is a solution of a universal problem, we know that it is *determined up to unique isomorphism* when it exists. We shall then write $\mathcal{G}' = \psi^*(\mathcal{G})$, $\rho = \rho_{\mathcal{G}}$, and, by abuse of language, we shall say that $\psi^*(\mathcal{G})$ is *the inverse image sheaf* of $\mathcal{G}$ by ψ, it being understood that $\psi^*(\mathcal{G})$ is regarded as equipped with the *canonical* ψ-morphism $\rho_{\mathcal{G}} : \mathcal{G} \to \psi^*(\mathcal{G})$, that is, with the *canonical homomorphism* of presheaves on Y:

$$\rho_{\mathcal{G}} : \mathcal{G} \to \psi_*(\psi^*(\mathcal{G})). \tag{3.5.3.2}$$

For every homomorphism $v : \psi^*(\mathcal{G}) \to \mathcal{F}$ (where $\mathcal{F}$ is a sheaf on X with values in $\mathbf{K}$), we shall set $v^b = \psi_*(v) \circ \rho_{\mathcal{G}} : \mathcal{G} \to \psi_*(\mathcal{F})$. By definition, *every* morphism of presheaves $u : \mathcal{G} \to \psi_*(\mathcal{F})$ is of the form v^b for one and only one v, which we shall denote by $u^\sharp$. In other words, every morphism $u : \mathcal{G} \to \psi_*(\mathcal{F})$ of presheaves factorizes uniquely as

$$u : \mathcal{G} \xrightarrow{\rho_{\mathcal{G}}} \psi_*(\psi^*(\mathcal{G})) \xrightarrow{\psi_*(u^\sharp)} \psi_*(\mathcal{F}). \tag{3.5.3.3}$$

(3.5.4) Suppose now that the category $\mathbf{K}$ is such[10] that *every* presheaf $\mathcal{G}$ on Y with values in $\mathbf{K}$ admits an inverse image by ψ, which we shall denote by $\psi^*(\mathcal{G})$. [0_{I} | 32]

We shall see that one can define $\psi^*(\mathcal{G})$ as a *covariant functor* in $\mathcal{G}$, from the category of presheaves on Y with values in $\mathbf{K}$ to that of sheaves on X with values in $\mathbf{K}$, in such a way that the isomorphism $v \to v^b$ is an *isomorphism of bifunctors*

$$\mathrm{Hom}_X(\psi^*(\mathcal{G}), \mathcal{F}) \xrightarrow{\sim} \mathrm{Hom}_Y(\mathcal{G}, \psi_*(\mathcal{F})) \tag{3.5.4.1}$$

in $\mathcal{G}$ and $\mathcal{F}$.

Indeed, for every morphism $w : \mathcal{G}_1 \to \mathcal{G}_2$ of presheaves on Y with values in $\mathbf{K}$, consider the composite morphism

$$\mathcal{G}_1 \xrightarrow{w} \mathcal{G}_2 \xrightarrow{\rho_{\mathcal{G}_2}} \psi_*(\psi^*(\mathcal{G}_2)) \ ;$$

there corresponds to it a morphism $(\rho_{\mathcal{G}_2} \circ w)^\sharp : \psi^*(\mathcal{G}_1) \to \psi^*(\mathcal{G}_2)$, which we shall denote by $\psi^*(w)$. We therefore have, by (3.5.3.3),

$$\psi_*(\psi^*(w)) \circ \rho_{\mathcal{G}_1} = \rho_{\mathcal{G}_2} \circ w. \tag{3.5.4.2}$$

For every morphism $u : \mathcal{G}_2 \to \psi_*(\mathcal{F})$, where $\mathcal{F}$ is a sheaf on X with values in $\mathbf{K}$, we have, by (3.5.3.3), (3.5.4.2) and the definition of v^b,

$$(u^\sharp \circ \psi^*(w))^b = \psi_*(u^\sharp) \circ \psi_*(\psi^*(w)) \circ \rho_{\mathcal{G}_1} = \psi_*(u^\sharp) \circ \rho_{\mathcal{G}_2} \circ w = u \circ w$$

[10] In the book cited in the Introduction, we shall give very general conditions on the category $\mathbf{K}$ ensuring the existence of inverse images of presheaves with values in $\mathbf{K}$.

or again

$$(u \circ w)^\sharp = u^\sharp \circ \psi^*(w). \tag{3.5.4.3}$$

If in particular we take for u a morphism

$$\mathcal{G}_2 \xrightarrow{w'} \mathcal{G}_3 \xrightarrow{\rho_{\mathcal{G}_3}} \psi_*(\psi^*(\mathcal{G}_3)),$$

we obtain

$$\psi^*(w' \circ w) = (\rho_{\mathcal{G}_3} \circ w' \circ w)^\sharp = (\rho_{\mathcal{G}_3} \circ w')^\sharp \circ \psi^*(w) = \psi^*(w') \circ \psi^*(w),$$

whence our assertion.

Finally, for every sheaf $\mathcal{F}$ on X with values in $\mathbf{K}$, let $i_{\mathcal{F}}$ be the identity morphism of $\psi_*(\mathcal{F})$ and denote by

$$\sigma_{\mathcal{F}} : \psi^*(\psi_*(\mathcal{F})) \to \mathcal{F}$$

the morphism $(i_{\mathcal{F}})^\sharp$; formula (3.5.4.3) gives in particular the factorization

$$u^\sharp : \psi^*(\mathcal{G}) \xrightarrow{\psi^*(u)} \psi^*(\psi_*(\mathcal{F})) \xrightarrow{\sigma_{\mathcal{F}}} \mathcal{F} \tag{3.5.4.4}$$

for every morphism $u : \mathcal{G} \to \psi_*(\mathcal{F})$. We shall say that the morphism $\sigma_{\mathcal{F}}$ is *canonical*.

(3.5.5) Let $\psi' : Y \to Z$ be a continuous map, and suppose that every presheaf $\mathcal{H}$ on Z with values in $\mathbf{K}$ admits an inverse image $\psi'^*(\mathcal{H})$ by ψ'. Then (with the hypotheses of (3.5.4)) every presheaf $\mathcal{H}$ on Z with values in $\mathbf{K}$ admits an inverse image by $\psi'' = \psi' \circ \psi$, and there is a canonical functorial isomorphism

$$\psi''^*(\mathcal{H}) \xrightarrow{\sim} \psi^*(\psi'^*(\mathcal{H})) \tag{3.5.5.1}$$

[0$_{\mathrm{I}}$ | 33] This indeed follows at once from the definitions, taking into account that $\psi''_* = \psi'_* \circ \psi_*$. Moreover, if $u : \mathcal{G} \to \psi_*(\mathcal{F})$ is a ψ-morphism, $v : \mathcal{H} \to \psi'_*(\mathcal{G})$ a ψ'-morphism, and $w = \psi'_*(u) \circ v$ their composite (3.5.2), one sees at once that $w^\sharp$ is the composite morphism

$$w^\sharp : \psi^*(\psi'^*(\mathcal{H})) \xrightarrow{\psi^*(v^\sharp)} \psi^*(\mathcal{G}) \xrightarrow{u^\sharp} \mathcal{F}.$$

(3.5.6) Take in particular for ψ the identity map $1_X : X \to X$. Then, if the inverse image by ψ of a presheaf $\mathcal{F}$ on X with values in $\mathbf{K}$ exists, this inverse image is called the *sheaf associated with the presheaf* $\mathcal{F}$. Every morphism $u : \mathcal{F} \to \mathcal{F}'$ from $\mathcal{F}$ to a *sheaf* $\mathcal{F}'$ with values in $\mathbf{K}$ therefore factorizes uniquely as

$$\mathcal{F} \xrightarrow{\rho_{\mathcal{F}}} 1_X^*(\mathcal{F}) \xrightarrow{u^\sharp} \mathcal{F}'.$$

3.6 Simple sheaves and locally simple sheaves

(3.6.1) We shall say that a *presheaf* $\mathcal{F}$ on X with values in $\mathbf{K}$ is *constant* if the canonical morphisms $\mathcal{F}(X) \to \mathcal{F}(U)$ are *isomorphisms* for every non-empty open set $U \subset X$; note that $\mathcal{F}$ is not necessarily a sheaf. A *sheaf* is said to be *simple* if it is associated (3.5.6) to a constant presheaf. A sheaf $\mathcal{F}$ is said to be *locally simple* if every $x \in X$ has an open neighbourhood U such that $\mathcal{F}|U$ is simple.

(3.6.2) Suppose that X is *irreducible* (2.1.1); then the following properties are equivalent:

a) *$\mathcal{F}$ is a constant presheaf on X;*

b) *$\mathcal{F}$ is a simple sheaf on X;*

c) *$\mathcal{F}$ is a locally simple sheaf on X.*

Indeed, let $\mathcal{F}$ be a constant presheaf on X; if U, V are two non-empty open sets in X, then $U \cap V$ is non-empty, so, since $\mathcal{F}(X) \to \mathcal{F}(U) \to \mathcal{F}(U \cap V)$ and $\mathcal{F}(X) \to \mathcal{F}(U)$ are isomorphisms, so is $\mathcal{F}(U) \to \mathcal{F}(U \cap V)$, and likewise $\mathcal{F}(V) \to \mathcal{F}(U \cap V)$ is an isomorphism. One concludes at once that axiom (F) of (3.1.2) is indeed satisfied, that $\mathcal{F}$ is isomorphic to its associated sheaf, and consequently that a) implies b).

Now let (U_α) be an open covering of X by non-empty open sets, and let $\mathcal{F}$ be a sheaf on X such that $\mathcal{F}|U_\alpha$ is simple for every α; since U_α is irreducible, $\mathcal{F}|U_\alpha$ is a constant presheaf by the foregoing. Since $U_\alpha \cap U_\beta$ is not empty, $\mathcal{F}(U_\alpha) \to \mathcal{F}(U_\alpha \cap U_\beta)$ and $\mathcal{F}(U_\beta) \to \mathcal{F}(U_\alpha \cap U_\beta)$ are isomorphisms, from which one deduces a canonical isomorphism $\theta_{\alpha\beta} : \mathcal{F}(U_\alpha) \to \mathcal{F}(U_\beta)$ for every pair of indices. But then, if one applies condition (F) for $U = X$, one sees that for every index α_0, $\mathcal{F}(U_{\alpha_0})$ and the $\theta_{\alpha_0\alpha}$ form a solution of the universal problem, which (by uniqueness) implies that $\mathcal{F}(X) \to \mathcal{F}(U_{\alpha_0})$ is an isomorphism, and therefore proves that c) implies a).

3.7 Inverse images of presheaves of groups or of rings

(3.7.1) We shall show that when **K** is taken to be the category of sets, the inverse image under ψ of every presheaf $\mathcal{G}$ with values in **K** *always exists* (the notation and hypotheses on X, Y, ψ being those of (3.5.3)). Indeed, for every open set $U \subset X$, define $\mathcal{G}'(U)$ as follows: an element s' of $\mathcal{G}'(U)$ is a family $(s'_x)_{x \in U}$, where $s'_x \in \mathcal{G}_{\psi(x)}$ for every $x \in U$, and where, for every $x \in U$, the following condition is satisfied: there exist an open neighbourhood V of $\psi(x)$ in Y, a neighbourhood $W \subset \psi^{-1}(V) \cap U$ of x and an element $s \in \mathcal{G}(V)$ such that $s'_z = s_{\psi(z)}$ for every $z \in W$. One verifies immediately that $U \mapsto \mathcal{G}'(U)$ does satisfy the axioms of *sheaves*. [0_I | 34]

Now let $\mathcal{F}$ be a sheaf of sets on X, and let $u : \mathcal{G} \to \psi_*(\mathcal{F})$, $v : \mathcal{G}' \to \mathcal{F}$ be morphisms. One defines $u^\sharp$ and $v^\flat$ as follows: if s' is a section of $\mathcal{G}'$ over a neighbourhood U of $x \in X$, and if V is an open neighbourhood of $\psi(x)$ and $s \in \mathcal{G}(V)$ is such that $s'_z = s_{\psi(z)}$ for z in a neighbourhood of x contained in $\psi^{-1}(V) \cap U$, one takes $u^\sharp_x(s'_x) = u_{\psi(x)}(s_{\psi(x)})$. Likewise, if $s \in \mathcal{G}(V)$ (V open in Y), $v^\flat(s)$ is the section of $\mathcal{F}$ over $\psi^{-1}(V)$ that is the image under v of the section s' of $\mathcal{G}'$ such that $s'_x = s_{\psi(x)}$ for every $x \in \psi^{-1}(V)$. Moreover, the canonical homomorphism (3.5.3) $\rho : \mathcal{G} \to \psi_*(\psi^*(\mathcal{G}))$ is defined as follows: for every open set $V \subset Y$ and every section $s \in \Gamma(V, \mathcal{G})$, $\rho(s)$ is the section $(s_{\psi(x)})_{x \in \psi^{-1}(V)}$ of $\psi^*(\mathcal{G})$ over $\psi^{-1}(V)$. The verification of the relations $(u^\sharp)^\flat = u$, $(v^\flat)^\sharp = v$ and $v^\flat = \psi_*(v) \circ \rho$ is immediate, and proves our assertion.

One verifies that, if $w : \mathcal{G}_1 \to \mathcal{G}_2$ is a homomorphism of presheaves of sets on Y, then $\psi^*(w)$ is given explicitly as follows: if $s' = (s'_x)_{x \in U}$ is a section of $\psi^*(\mathcal{G}_1)$ over an open set U of X, $(\psi^*(w))(s')$ is the family $(w_{\psi(x)}(s'_x))_{x \in U}$. Finally, it is immediate that for every open set V of Y, the inverse image of $\mathcal{G}|V$ under the restriction of ψ to $\psi^{-1}(V)$ is identical to the induced sheaf $\psi^*(\mathcal{G})|\psi^{-1}(V)$.

When ψ is the identity 1_X, one recovers the definition of a sheaf of sets associated to a presheaf (G, II, 1.2). The preceding considerations apply without change when **K** is the category of groups or of rings (not necessarily commutative).

When X is an arbitrary subset of a topological space Y, and j is the canonical injection $X \to Y$, then for every sheaf $\mathcal{G}$ on Y with values in a category **K**, the inverse

image $j^*(\mathcal{G})$ (when it exists) is called the sheaf *induced* on X by $\mathcal{G}$; for sheaves of sets (or of groups, or of rings) one recovers the usual definition (G, II, 1.5).

(3.7.2) Keeping the notation and hypotheses of (3.5.3), suppose that $\mathcal{G}$ is a *sheaf* of groups (resp. of rings) on Y. The definition of the sections of $\psi^*(\mathcal{G})$ (3.7.1) shows (taking (3.4.4) into account) that the homomorphism of stalks $\psi_x \circ \rho_{\psi(x)} : \mathcal{G}_{\psi(x)} \to (\psi^*(\mathcal{G}))_x$ is an *isomorphism functorial in* $\mathcal{G}$, which allows one to identify these two stalks; with this identification, $u_x^\sharp$ is identical to the homomorphism defined in (3.5.1), and in particular one has $\mathrm{Supp}(\psi^*(\mathcal{G})) = \psi^{-1}(\mathrm{Supp}(\mathcal{G}))$.

An immediate consequence of this result is that *the functor* $\psi^*(\mathcal{G})$ *is exact in* $\mathcal{G}$ in the abelian category of sheaves of commutative groups.

3.8 Sheaves of pseudo-discrete spaces

[0_I | 35] **(3.8.1)** Let X be a topological space whose topology has a base $\mathfrak{B}$ consisting of *quasi-compact* open sets. Let $\mathcal{F}$ be a *sheaf of sets* on X; if each of the $\mathcal{F}(U)$ is endowed with the *discrete* topology, $U \mapsto \mathcal{F}(U)$ is a *presheaf of topological spaces*. We shall see that there exists a *sheaf of topological spaces* $\mathcal{F}'$ *associated to* $\mathcal{F}$ (3.5.6) such that $\Gamma(U, \mathcal{F}')$ is the discrete space $\mathcal{F}(U)$ for every *quasi-compact* open set U. For this it will suffice to show that the presheaf $U \mapsto \mathcal{F}(U)$ of discrete topological spaces *on* $\mathfrak{B}$ satisfies condition (F_0) of (3.2.2), and more generally that if U is a quasi-compact open set and (U_α) is a covering of U by sets of $\mathfrak{B}$, the coarsest topology $\mathcal{T}$ on $\Gamma(U, \mathcal{F})$ making the maps $\Gamma(U, \mathcal{F}) \to \Gamma(U_\alpha, \mathcal{F})$ continuous is the *discrete* topology. Now, there exist finitely many indices α_i such that $U = \bigcup_i U_{\alpha_i}$. Let $s \in \Gamma(U, \mathcal{F})$ and let s_i be its image in $\Gamma(U_{\alpha_i}, \mathcal{F})$; the intersection of the inverse images of the sets $\{s_i\}$ is by definition a neighbourhood of s for $\mathcal{T}$; but since $\mathcal{F}$ is a sheaf of sets and the U_{α_i} cover U, this intersection reduces to s, whence our assertion.

Note that if U is a non-quasi-compact open set of X, the topological space $\Gamma(U, \mathcal{F}')$ still has $\Gamma(U, \mathcal{F})$ as its underlying set, but its topology is not discrete in general: it is the coarsest topology making the maps $\Gamma(U, \mathcal{F}) \to \Gamma(V, \mathcal{F})$ continuous, for $V \in \mathfrak{B}$ and $V \subset U$ (the $\Gamma(V, \mathcal{F})$ being discrete).

The preceding considerations apply without modification to sheaves of groups or of rings (not necessarily commutative), and associate with them sheaves of *topological groups* or of *topological rings*, respectively. For brevity, we shall say that the sheaf $\mathcal{F}'$ is the sheaf of *pseudo-discrete spaces* (resp. *groups*, *rings*) associated to the sheaf of sets (resp. groups, rings) $\mathcal{F}$.

(3.8.2) Let $\mathcal{F}$, $\mathcal{G}$ be two sheaves of sets (resp. groups, rings) on X, and $u : \mathcal{F} \to \mathcal{G}$ a homomorphism. Then u is also a *continuous* homomorphism $\mathcal{F}' \to \mathcal{G}'$, where $\mathcal{F}'$ and $\mathcal{G}'$ denote the pseudo-discrete sheaves associated to $\mathcal{F}$ and $\mathcal{G}$; indeed, this follows from (3.2.5).

(3.8.3) Let $\mathcal{F}$ be a sheaf of sets, $\mathcal{H}$ a sub-sheaf of $\mathcal{F}$, and $\mathcal{F}'$ and $\mathcal{H}'$ the pseudo-discrete sheaves associated to $\mathcal{F}$ and $\mathcal{H}$ respectively. Then, for every open set $U \subset X$, $\Gamma(U, \mathcal{H}')$ is *closed* in $\Gamma(U, \mathcal{F}')$: indeed, it is the intersection of the inverse images of the $\Gamma(V, \mathcal{H})$ (for $V \in \mathfrak{B}$, $V \subset U$) under the continuous maps $\Gamma(U, \mathcal{F}) \to \Gamma(V, \mathcal{F})$, and $\Gamma(V, \mathcal{H})$ is closed in the discrete space $\Gamma(V, \mathcal{F})$.

§4 Ringed spaces

4.1 Ringed spaces, $\mathcal{A}$-modules, $\mathcal{A}$-algebras

(4.1.1) A *ringed space* (resp. *topologically ringed space*) is a pair $(X, \mathcal{A})$ consisting of a topological space X and a sheaf of rings (not necessarily commutative) (resp. a sheaf of topological rings) $\mathcal{A}$ on X; one says that X is the topological space *underlying* the ringed space $(X, \mathcal{A})$, and $\mathcal{A}$ its *structure sheaf*. The latter is denoted by $\mathcal{O}_X$, and its stalk at a point $x \in X$ is denoted by $\mathcal{O}_{X,x}$, or simply $\mathcal{O}_x$ when no confusion results. [0_I | 36]

We shall denote by 1 or e the *unit section* of $\mathcal{O}_X$ over X (the unit element of $\Gamma(X, \mathcal{O}_X)$).

Since in this Treatise we shall mostly have to consider sheaves of *commutative* rings, it will be understood, when we speak of a ringed space $(X, \mathcal{A})$ without further specification, that $\mathcal{A}$ is a sheaf of commutative rings.

Ringed spaces whose structure sheaf is not necessarily commutative (resp. topologically ringed spaces) form a *category* when one defines a *morphism* $(X, \mathcal{A}) \to (Y, \mathcal{B})$ as a pair $(\psi, \theta) = \Psi$ consisting of a continuous map $\psi : X \to Y$ and a *ψ-morphism* $\theta : \mathcal{B} \to \mathcal{A}$ (3.5.1) of sheaves of rings (resp. of sheaves of topological rings); the *composite* of a second morphism $\Psi' = (\psi', \theta') : (Y, \mathcal{B}) \to (Z, \mathcal{C})$ and Ψ, denoted by $\Psi'' = \Psi' \circ \Psi$, is the morphism (ψ'', θ''), where $\psi'' = \psi' \circ \psi$ and θ'' is the composite of θ and θ' (equal to $\psi'_*(\theta) \circ \theta'$, cf. 3.5.2). For ringed spaces, recall that one then has $\theta''^\sharp = \theta^\sharp \circ \psi^*(\theta'^\sharp)$ (3.5.5); hence, if $\theta'^\sharp$ and $\theta^\sharp$ are *injective* (resp. *surjective*) homomorphisms, so is $\theta''^\sharp$, in view of the fact that $\psi_x \circ \rho_{\psi(x)}$ is an isomorphism for every $x \in X$ (3.7.2). Using the foregoing, one verifies at once that when ψ is an *injective* continuous map and $\theta^\sharp$ a *surjective* homomorphism of sheaves of rings, the morphism (ψ, θ) is a *monomorphism* (T, 1.1) in the category of ringed spaces.

By abuse of language, we shall often replace ψ by Ψ in the notation, for example writing $\Psi^{-1}(U)$ instead of $\psi^{-1}(U)$ for a subset U of Y, when this is not likely to cause confusion.

(4.1.2) For every subset M of X, the pair $(M, \mathcal{A}|M)$ is evidently a ringed space, said to be *induced* on M by the ringed space $(X, \mathcal{A})$ (and also called the *restriction* of $(X, \mathcal{A})$ to M). If j is the canonical injection $M \to X$ and ω the identity map of $\mathcal{A}|M$, then (j, ω^b) is a monomorphism $(M, \mathcal{A}|M) \to (X, \mathcal{A})$ of ringed spaces, called the *canonical injection*. The composite of a morphism $\Psi : (X, \mathcal{A}) \to (Y, \mathcal{B})$ and this injection is called the *restriction* of Ψ to M.

(4.1.3) We shall not return to the definition of $\mathcal{A}$-modules, or algebraic sheaves, on a ringed space $(X, \mathcal{A})$ (G, II, 2.2); when $\mathcal{A}$ is a sheaf of not necessarily commutative rings, by $\mathcal{A}$-module one must always understand "left $\mathcal{A}$-module" unless the contrary is expressly stated. The sub-$\mathcal{A}$-modules of $\mathcal{A}$ will be called sheaves of (left, right or two-sided) ideals in $\mathcal{A}$, or $\mathcal{A}$-Ideals.

When $\mathcal{A}$ is a sheaf of commutative rings and, in the definition of $\mathcal{A}$-modules, one replaces the module structure everywhere by that of algebra, one obtains the definition of an $\mathcal{A}$-algebra on X. It amounts to the same to say that a (not necessarily commutative) $\mathcal{A}$-algebra is an $\mathcal{A}$-module $\mathcal{C}$ endowed with a homomorphism of $\mathcal{A}$-modules $\varphi : \mathcal{C} \otimes_{\mathcal{A}} \mathcal{C} \to \mathcal{C}$

[0$_{\mathrm{I}}$ | 37] and a section e over X such that: 1° the diagram

$$\begin{array}{ccc} \mathcal{C}\otimes_{\mathcal{A}}\mathcal{C}\otimes_{\mathcal{A}}\mathcal{C} & \xrightarrow{\varphi\otimes 1} & \mathcal{C}\otimes_{\mathcal{A}}\mathcal{C} \\ {\scriptstyle 1\otimes\varphi}\downarrow & & \downarrow{\scriptstyle \varphi} \\ \mathcal{C}\otimes_{\mathcal{A}}\mathcal{C} & \xrightarrow[\varphi]{} & \mathcal{C} \end{array}$$

is commutative; 2° for every open set $U \subset X$ and every section $s \in \Gamma(U, \mathcal{C})$, one has $\varphi((e|U)\otimes s) = \varphi(s\otimes(e|U)) = s$. To say that $\mathcal{C}$ is a commutative $\mathcal{A}$-algebra amounts, moreover, to saying that the diagram

$$\begin{array}{ccc} \mathcal{C}\otimes_{\mathcal{A}}\mathcal{C} & \xrightarrow{\sigma} & \mathcal{C}\otimes_{\mathcal{A}}\mathcal{C} \\ & {\scriptstyle\varphi}\searrow \quad \swarrow{\scriptstyle\varphi} & \\ & \mathcal{C} & \end{array}$$

is commutative, where σ denotes the canonical symmetry of the tensor product $\mathcal{C}\otimes_{\mathcal{A}}\mathcal{C}$.

Homomorphisms of $\mathcal{A}$-algebras are also defined like the homomorphisms of $\mathcal{A}$-modules in (G, II, 2.2), but naturally they no longer form an abelian group.

If $\mathcal{M}$ is a sub-$\mathcal{A}$-module of an $\mathcal{A}$-algebra $\mathcal{C}$, the sub-$\mathcal{A}$-algebra of $\mathcal{C}$ generated by $\mathcal{M}$ is the sum of the images of the homomorphisms $\bigotimes^n \mathcal{M} \to \mathcal{C}$ (for $n \geqslant 0$). It is also the sheaf associated to the presheaf of algebras $U \mapsto \mathcal{B}(U)$, where $\mathcal{B}(U)$ is the subalgebra of $\Gamma(U, \mathcal{C})$ generated by the submodule $\Gamma(U, \mathcal{M})$.

(4.1.4) A sheaf of rings $\mathcal{A}$ on a topological space X is said to be *reduced at a point* x of X if the stalk $\mathcal{A}_x$ is a *reduced* ring (1.1.1); $\mathcal{A}$ is said to be *reduced* if it is reduced at every point of X. Recall that a ring A is said to be *regular* if each of the local rings $A_{\mathfrak{p}}$ (where $\mathfrak{p}$ ranges over the set of prime ideals of A) is a regular local ring; we shall say that a sheaf of rings $\mathcal{A}$ on X is *regular at a point* x (resp. *regular*) if the stalk $\mathcal{A}_x$ is a regular ring (resp. if $\mathcal{A}$ is regular at every point). Finally, we shall say that a sheaf of rings $\mathcal{A}$ on X is *normal at a point* x (resp. *normal*) if its stalk $\mathcal{A}_x$ is an integral and integrally closed ring (resp. if $\mathcal{A}$ is normal at every point). We shall say that a ringed space $(X, \mathcal{A})$ has one of the preceding properties if the sheaf of rings $\mathcal{A}$ has that property.

A sheaf of *graded* rings $\mathcal{A}$ is by definition a sheaf of rings that is the direct sum (G, II, 2.7) of a family $(\mathcal{A}_n)_{n\in\mathbf{Z}}$ of sheaves of abelian groups satisfying the conditions $\mathcal{A}_m\mathcal{A}_n \subset \mathcal{A}_{m+n}$; a *graded* $\mathcal{A}$*-module* is an $\mathcal{A}$-module $\mathcal{F}$ that is the direct sum of a family $(\mathcal{F}_n)_{n\in\mathbf{Z}}$ of sheaves of abelian groups, satisfying the conditions $\mathcal{A}_m\mathcal{F}_n \subset \mathcal{F}_{m+n}$. Moreover, it amounts to the same to say that $(\mathcal{A}_m)_x(\mathcal{A}_n)_x \subset (\mathcal{A}_{m+n})_x$ (resp. $(\mathcal{A}_m)_x(\mathcal{F}_n)_x \subset (\mathcal{F}_{m+n})_x$) at every point x.

(4.1.5) Given a (not necessarily commutative) ringed space $(X, \mathcal{A})$, we shall not recall here the definitions of the bifunctors $\mathcal{F}\otimes_{\mathcal{A}}\mathcal{G}$, $\mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G})$ and $\mathrm{Hom}_{\mathcal{A}}(\mathcal{F}, \mathcal{G})$ (G, II, 2.8 and 2.2) on the categories of left or right $\mathcal{A}$-modules (as the case may be), with values in the category of sheaves of abelian groups (or more
[0$_{\mathrm{I}}$ | 38] generally of $\mathcal{C}$-modules, if $\mathcal{C}$ is the centre of $\mathcal{A}$). The stalk $(\mathcal{F}\otimes_{\mathcal{A}}\mathcal{G})_x$ at every point $x \in X$ is canonically identified with $\mathcal{F}_x \otimes_{\mathcal{A}_x} \mathcal{G}_x$, and one defines a canonical functorial homomorphism

$$(\mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G}))_x \longrightarrow \mathrm{Hom}_{\mathcal{A}_x}(\mathcal{F}_x, \mathcal{G}_x)$$

which, in general, is neither injective nor surjective. The bifunctors considered above are additive and, in particular, commute with finite direct sums; $\mathcal{F}\otimes_{\mathcal{A}}\mathcal{G}$ is right exact in $\mathcal{F}$

and in $\mathcal{G}$, commutes with inductive limits, and $\mathcal{A} \otimes_{\mathcal{A}} \mathcal{G}$ (resp. $\mathcal{F} \otimes_{\mathcal{A}} \mathcal{A}$) is canonically identified with $\mathcal{G}$ (resp. $\mathcal{F}$). The functors $\mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G})$ and $\mathrm{Hom}_{\mathcal{A}}(\mathcal{F}, \mathcal{G})$ are *left exact* in $\mathcal{F}$ and $\mathcal{G}$; more precisely, if there is an exact sequence of the form $0 \to \mathcal{G}' \to \mathcal{G} \to \mathcal{G}''$, the sequence

$$0 \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G}') \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G}) \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G}'')$$

is exact, and if there is an exact sequence of the form $\mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$, the sequence

$$0 \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}'', \mathcal{G}) \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G}) \longrightarrow \mathcal{H}om_{\mathcal{A}}(\mathcal{F}', \mathcal{G})$$

is exact, with analogous properties for the functor Hom. Moreover, $\mathcal{H}om_{\mathcal{A}}(\mathcal{A}, \mathcal{G})$ is canonically identified with $\mathcal{G}$; finally, for every open set $U \subset X$, one has

$$\Gamma\big(U, \mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{G})\big) = \mathrm{Hom}_{\mathcal{A}|U}(\mathcal{F}|U, \mathcal{G}|U).$$

For every left (resp. right) $\mathcal{A}$-module $\mathcal{F}$, the right (resp. left) $\mathcal{A}$-module $\mathcal{H}om_{\mathcal{A}}(\mathcal{F}, \mathcal{A})$ is called the *dual of* $\mathcal{F}$ and is denoted by $\check{\mathcal{F}}$.

Finally, if $\mathcal{A}$ is a sheaf of commutative rings and $\mathcal{F}$ an $\mathcal{A}$-module, then $U \mapsto \bigwedge^p \Gamma(U, \mathcal{F})$ is a presheaf whose associated sheaf is an $\mathcal{A}$-module, which is denoted by $\bigwedge^p \mathcal{F}$ and called the *p-th exterior power of* $\mathcal{F}$; one easily verifies that the canonical map from the presheaf $U \mapsto \bigwedge^p \Gamma(U, \mathcal{F})$ to the associated sheaf $\bigwedge^p \mathcal{F}$ is *injective*, and that for every $x \in X$ one has $(\bigwedge^p \mathcal{F})_x = \bigwedge^p (\mathcal{F}_x)$. It is clear that $\bigwedge^p \mathcal{F}$ is a covariant functor in $\mathcal{F}$.

(4.1.6) Suppose that $\mathcal{A}$ is a sheaf of not necessarily commutative rings, $\mathcal{J}$ a sheaf of left ideals of $\mathcal{A}$, and $\mathcal{F}$ a left $\mathcal{A}$-module; one then denotes by $\mathcal{J}\mathcal{F}$ the sub-$\mathcal{A}$-module of $\mathcal{F}$ that is the image of $\mathcal{J} \otimes_{\mathbf{Z}} \mathcal{F}$ (where $\mathbf{Z}$ is the sheaf associated to the constant presheaf $U \to \mathbf{Z}$) under the canonical map $\mathcal{J} \otimes_{\mathbf{Z}} \mathcal{F} \to \mathcal{F}$; it is clear that for every $x \in X$ one has $(\mathcal{J}\mathcal{F})_x = \mathcal{J}_x \mathcal{F}_x$. When $\mathcal{A}$ is commutative, $\mathcal{J}\mathcal{F}$ is also the image of the canonical map $\mathcal{J} \otimes_{\mathcal{A}} \mathcal{F} \to \mathcal{F}$. It is immediate that $\mathcal{J}\mathcal{F}$ is also the $\mathcal{A}$-module associated to the presheaf $U \to \Gamma(U, \mathcal{J})\Gamma(U, \mathcal{F})$. If $\mathcal{J}_1$, $\mathcal{J}_2$ are two sheaves of left ideals of $\mathcal{A}$, one has $\mathcal{J}_1(\mathcal{J}_2\mathcal{F}) = (\mathcal{J}_1\mathcal{J}_2)\mathcal{F}$.

(4.1.7) Let $(X_\lambda, \mathcal{A}_\lambda)_{\lambda \in L}$ be a family of ringed spaces; for every pair (λ, μ), suppose given an open subset $V_{\lambda\mu}$ of X_λ and an isomorphism of ringed spaces

$$\varphi_{\lambda\mu} : (V_{\mu\lambda}, \mathcal{A}_\mu | V_{\mu\lambda}) \xrightarrow{\sim} (V_{\lambda\mu}, \mathcal{A}_\lambda | V_{\lambda\mu}),$$

with $V_{\lambda\lambda} = X_\lambda$, $\varphi_{\lambda\lambda}$ being the identity. Suppose moreover that, for every triple (λ, μ, ν), if $\varphi'_{\mu\lambda}$ denotes the restriction of $\varphi_{\mu\lambda}$ to $V_{\lambda\mu} \cap V_{\lambda\nu}$, then $\varphi'_{\mu\lambda}$ is an isomorphism of

$$(V_{\lambda\mu} \cap V_{\lambda\nu}, \mathcal{A}_\lambda | (V_{\lambda\mu} \cap V_{\lambda\nu}))$$

onto

$$(V_{\mu\nu} \cap V_{\mu\lambda}, \mathcal{A}_\mu | (V_{\mu\nu} \cap V_{\mu\lambda}))$$

and that $\varphi'_{\lambda\nu} = \varphi'_{\lambda\mu} \circ \varphi'_{\mu\nu}$ (*gluing condition* for the $\varphi_{\lambda\mu}$). One can then first consider the topological space obtained by gluing (by means of the $\varphi_{\lambda\mu}$) the X_λ
along the $V_{\lambda\mu}$; if X_λ is identified with the corresponding open subset X'_λ of X, the [0$_{\mathrm{I}}$ | 39]
hypotheses imply that the three sets $V_{\lambda\mu} \cap V_{\lambda\nu}$, $V_{\mu\nu} \cap V_{\mu\lambda}$, $V_{\nu\lambda} \cap V_{\nu\mu}$ are identified with $X'_\lambda \cap X'_\mu \cap X'_\nu$. One can then transport to X'_λ the ringed space structure of X_λ, and if $\mathcal{A}'_\lambda$ is the sheaf of rings transported from $\mathcal{A}_\lambda$, the $\mathcal{A}'_\lambda$ satisfy the gluing condition (3.3.1) and therefore define a sheaf of rings $\mathcal{A}$ on X; $(X, \mathcal{A})$ is called the ringed space obtained by *gluing the* $(X_\lambda, \mathcal{A}_\lambda)$ *along the* $V_{\lambda\mu}$, by means of the $\varphi_{\lambda\mu}$.

4.2 Direct image of an $\mathcal{A}$-module

(4.2.1) Let $(X, \mathcal{A})$, $(Y, \mathcal{B})$ be two ringed spaces, and $\Psi = (\psi, \theta)$ a morphism $(X, \mathcal{A}) \to (Y, \mathcal{B})$; thus $\psi_*(\mathcal{A})$ is a sheaf of rings on Y, and θ a homomorphism $\mathcal{B} \to \psi_*(\mathcal{A})$ of sheaves of rings. Now let $\mathcal{F}$ be an $\mathcal{A}$-module; its direct image $\psi_*(\mathcal{F})$ is a sheaf of abelian groups on Y. Moreover, for every open set $U \subset Y$,

$$\Gamma(U, \psi_*(\mathcal{F})) = \Gamma(\psi^{-1}(U), \mathcal{F})$$

is endowed with a module structure over the ring $\Gamma(U, \psi_*(\mathcal{A})) = \Gamma(\psi^{-1}(U), \mathcal{A})$; the bilinear maps defining these structures, being compatible with the restriction operations, define on $\psi_*(\mathcal{F})$ a structure of $\psi_*(\mathcal{A})$-module. The homomorphism $\theta : \mathcal{B} \to \psi_*(\mathcal{A})$ then also makes it possible to define on $\psi_*(\mathcal{F})$ a structure of $\mathcal{B}$-module; we shall say that this $\mathcal{B}$-module is the *direct image of $\mathcal{F}$ under the morphism* Ψ, and we shall denote it by $\Psi_*(\mathcal{F})$. If $\mathcal{F}_1$, $\mathcal{F}_2$ are two $\mathcal{A}$-modules on X and u is an $\mathcal{A}$-homomorphism $\mathcal{F}_1 \to \mathcal{F}_2$, it is immediate (by considering the sections over the open sets of Y) that $\psi_*(u)$ is a $\psi_*(\mathcal{A})$-homomorphism $\psi_*(\mathcal{F}_1) \to \psi_*(\mathcal{F}_2)$, and *a fortiori* a $\mathcal{B}$-homomorphism $\Psi_*(\mathcal{F}_1) \to \Psi_*(\mathcal{F}_2)$; as a $\mathcal{B}$-homomorphism, we shall denote it by $\Psi_*(u)$. We thus see that Ψ_* is a *covariant functor* from the category of $\mathcal{A}$-modules to that of $\mathcal{B}$-modules. Moreover, it is immediate that this functor is *left exact* (G, II, 2.12).

On $\psi_*(\mathcal{A})$, the $\mathcal{B}$-module structure and the structure of sheaf of rings define a structure of $\mathcal{B}$-algebra; this $\mathcal{B}$-algebra will be denoted by $\Psi_*(\mathcal{A})$.

(4.2.2) Let $\mathcal{M}$, $\mathcal{N}$ be two $\mathcal{A}$-modules. For every open set U of Y, there is a canonical map

$$\Gamma(\psi^{-1}(U), \mathcal{M}) \times \Gamma(\psi^{-1}(U), \mathcal{N}) \longrightarrow \Gamma(\psi^{-1}(U), \mathcal{M} \otimes_{\mathcal{A}} \mathcal{N})$$

which is bilinear over the ring $\Gamma(\psi^{-1}(U), \mathcal{A}) = \Gamma(U, \psi_*(\mathcal{A}))$, and *a fortiori* over $\Gamma(U, \mathcal{B})$; it therefore defines a homomorphism

$$\Gamma(U, \Psi_*(\mathcal{M})) \otimes_{\Gamma(U,\mathcal{B})} \Gamma(U, \Psi_*(\mathcal{N})) \longrightarrow \Gamma(U, \Psi_*(\mathcal{M} \otimes_{\mathcal{A}} \mathcal{N}))$$

and since one verifies at once that these homomorphisms are compatible with the restriction operations, they give a canonical functorial homomorphism of $\mathcal{B}$-modules

$$\Psi_*(\mathcal{M}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{N}) \longrightarrow \Psi_*(\mathcal{M} \otimes_{\mathcal{A}} \mathcal{N}). \tag{4.2.2.1}$$

[0_{I} | 40] which will in general be neither injective nor surjective. If $\mathcal{P}$ is a third $\mathcal{A}$-module, one verifies at once that the diagram

$$\begin{array}{ccc} \Psi_*(\mathcal{M}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{N}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{P}) & \longrightarrow & \Psi_*(\mathcal{M} \otimes_{\mathcal{A}} \mathcal{N}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{P}) \\ \downarrow & & \downarrow \\ \Psi_*(\mathcal{M}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{N} \otimes_{\mathcal{A}} \mathcal{P}) & \longrightarrow & \Psi_*(\mathcal{M} \otimes_{\mathcal{A}} \mathcal{N} \otimes_{\mathcal{A}} \mathcal{P}) \end{array} \tag{4.2.2.2}$$

is commutative.

(4.2.3) Let $\mathcal{M}$, $\mathcal{N}$ be two $\mathcal{A}$-modules. For every open set $U \subset Y$, one has by definition

$$\Gamma(\psi^{-1}(U), \mathcal{H}om_{\mathcal{A}}(\mathcal{M}, \mathcal{N})) = \mathrm{Hom}_{\mathcal{A}|V}(\mathcal{M}|V, \mathcal{N}|V),$$

where, to lighten the notation, we have set $V = \psi^{-1}(U)$; the map $u \to \Psi_*(u)$ is a homomorphism

$$\mathrm{Hom}_{\mathcal{A}|V}(\mathcal{M}|V, \mathcal{N}|V) \longrightarrow \mathrm{Hom}_{\mathcal{B}|U}(\Psi_*(\mathcal{M})|U, \Psi_*(\mathcal{N})|U)$$

for the $\Gamma(U, \mathcal{B})$-module structures; these homomorphisms, being compatible with the restriction operations, therefore define a canonical functorial homomorphism of $\mathcal{B}$-modules

$$\Psi_*(\mathcal{H}om_{\mathcal{A}}(\mathcal{M}, \mathcal{N})) \longrightarrow \mathcal{H}om_{\mathcal{B}}(\Psi_*(\mathcal{M}), \Psi_*(\mathcal{N})). \tag{4.2.3.1}$$

(4.2.4) If $\mathcal{C}$ is an $\mathcal{A}$-algebra, the composite homomorphism

$$\Psi_*(\mathcal{C}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{C}) \longrightarrow \Psi_*(\mathcal{C} \otimes_{\mathcal{A}} \mathcal{C}) \longrightarrow \Psi_*(\mathcal{C})$$

defines on $\Psi_*(\mathcal{C})$ a structure of $\mathcal{B}$-algebra, as follows from (4.2.2.2). One sees likewise that if $\mathcal{M}$ is a $\mathcal{C}$-module, $\Psi_*(\mathcal{M})$ is canonically endowed with a structure of $\Psi_*(\mathcal{C})$-module.

(4.2.5) Consider in particular the case where X is a *closed* subspace of Y and ψ is the canonical injection $j : X \to Y$. If $\mathcal{B}' = \mathcal{B}|X = j^*(\mathcal{B})$ is the restriction of the sheaf of rings $\mathcal{B}$ to X, an $\mathcal{A}$-module $\mathcal{M}$ can be regarded as a $\mathcal{B}'$-module by means of the homomorphism $\theta^\sharp : \mathcal{B}' \to \mathcal{A}$; $\Psi_*(\mathcal{M})$ is then the $\mathcal{B}$-module that induces $\mathcal{M}$ on X and 0 elsewhere. If $\mathcal{N}$ is a second $\mathcal{A}$-module, $\Psi_*(\mathcal{M}) \otimes_{\mathcal{B}} \Psi_*(\mathcal{N})$ is therefore identified with $\Psi_*(\mathcal{M} \otimes_{\mathcal{B}'} \mathcal{N})$, and $\mathcal{H}om_{\mathcal{B}}(\Psi_*(\mathcal{M}), \Psi_*(\mathcal{N}))$ with $\Psi_*(\mathcal{H}om_{\mathcal{B}'}(\mathcal{M}, \mathcal{N}))$.

(4.2.6) Let $(Z, \mathcal{C})$ be a third ringed space, and $\Psi' = (\psi', \theta')$ a morphism $(Y, \mathcal{B}) \to (Z, \mathcal{C})$; if Ψ'' is the composite morphism $\Psi' \circ \Psi$, it is clear that $\Psi''_* = \Psi'_* \circ \Psi_*$.

4.3 Inverse image of a $\mathcal{B}$-module [0I | 41]

(4.3.1) The hypotheses and notation being those of (4.2.1), let $\mathcal{G}$ be a $\mathcal{B}$-module and $\psi^*(\mathcal{G})$ its inverse image (3.7.1), which is thus a sheaf of abelian groups on X. The definition of the sections of $\psi^*(\mathcal{G})$ and of $\psi^*(\mathcal{B})$ (3.7.1) shows that $\psi^*(\mathcal{G})$ is canonically endowed with a structure of $\psi^*(\mathcal{B})$-module. On the other hand, the homomorphism $\theta^\sharp : \psi^*(\mathcal{B}) \to \mathcal{A}$ endows $\mathcal{A}$ with a structure of $\psi^*(\mathcal{B})$-module, which we shall denote by $\mathcal{A}_{[\theta]}$ when confusion must be avoided; the tensor product $\psi^*(\mathcal{G}) \otimes_{\psi^*(\mathcal{B})} \mathcal{A}_{[\theta]}$ is then endowed with a structure of $\mathcal{A}$-module. We shall say that this $\mathcal{A}$-module is the inverse image of $\mathcal{G}$ under the morphism Ψ, and we shall denote it by $\Psi^*(\mathcal{G})$. If $\mathcal{G}_1$, $\mathcal{G}_2$ are two $\mathcal{B}$-modules on Y and v is a $\mathcal{B}$-homomorphism $\mathcal{G}_1 \to \mathcal{G}_2$, then $\psi^*(v)$, as one verifies at once, is a $\psi^*(\mathcal{B})$-homomorphism from $\psi^*(\mathcal{G}_1)$ to $\psi^*(\mathcal{G}_2)$; consequently $\psi^*(v) \otimes 1$ is an $\mathcal{A}$-homomorphism $\Psi^*(\mathcal{G}_1) \to \Psi^*(\mathcal{G}_2)$, which we shall denote by $\Psi^*(v)$. We have thus defined Ψ^* as a *covariant functor* from the category of $\mathcal{B}$-modules to that of $\mathcal{A}$-modules. Here this functor (unlike ψ^*) is no longer exact in general, but only *right exact*, since tensoring with $\mathcal{A}$ is a right exact functor on the category of $\psi^*(\mathcal{B})$-modules.

For every $x \in X$, one has

$$(\Psi^*(\mathcal{G}))_x = \mathcal{G}_{\psi(x)} \otimes_{\mathcal{B}_{\psi(x)}} \mathcal{A}_x,$$

by virtue of (3.7.2). The support of $\Psi^*(\mathcal{G})$ is therefore contained in $\psi^{-1}(\operatorname{Supp} \mathcal{G})$.

(4.3.2) Let $(\mathcal{G}_\lambda)$ be an inductive system of $\mathcal{B}$-modules, and let $\mathcal{G} = \varinjlim \mathcal{G}_\lambda$ be its inductive limit. The canonical homomorphisms $\mathcal{G}_\lambda \to \mathcal{G}$ define $\psi^*(\mathcal{B})$-homomorphisms $\psi^*(\mathcal{G}_\lambda) \to \psi^*(\mathcal{G})$, which give a canonical homomorphism

$$\varinjlim \psi^*(\mathcal{G}_\lambda) \longrightarrow \psi^*(\mathcal{G}).$$

Since the stalk at a point of an inductive limit of sheaves is the inductive limit of the stalks at that point (G, II, 1.11), the preceding canonical homomorphism is *bijective*

(3.7.2). Moreover, the tensor product commutes with inductive limits of sheaves, and one therefore has a *canonical functorial isomorphism*

$$\varinjlim \Psi^*(\mathcal{G}_\lambda) \xrightarrow{\sim} \Psi^*(\varinjlim \mathcal{G}_\lambda)$$

of $\mathcal{A}$-modules.

On the other hand, for a finite direct sum $\bigoplus_i \mathcal{G}_i$ of $\mathcal{B}$-modules, it is clear that

$$\psi^*(\bigoplus_i \mathcal{G}_i) = \bigoplus_i \psi^*(\mathcal{G}_i) \ ;$$

hence, by tensor product with $\mathcal{A}_{[\theta]}$,

$$\Psi^*(\bigoplus_i \mathcal{G}_i) = \bigoplus_i \Psi^*(\mathcal{G}_i). \tag{4.3.2.1}$$

Passing to the inductive limit, one deduces from this, by virtue of the foregoing, that the preceding equality still holds for an *arbitrary* direct sum.

(4.3.3) Let $\mathcal{G}_1$, $\mathcal{G}_2$ be two $\mathcal{B}$-modules; from the definition of inverse images of sheaves of abelian groups (3.7.1), one immediately deduces a canonical homomorphism

$$\psi^*(\mathcal{G}_1) \otimes_{\psi^*(\mathcal{B})} \psi^*(\mathcal{G}_2) \longrightarrow \psi^*(\mathcal{G}_1 \otimes_{\mathcal{B}} \mathcal{G}_2)$$

of $\psi^*(\mathcal{B})$-modules, and since the stalk at a point of a tensor product of sheaves is the tensor product of the stalks at that point (G, II, 2.8), one deduces from (3.7.2) that the preceding homomorphism is in fact an *isomorphism*. By tensor product with $\mathcal{A}$, one deduces from it a *canonical functorial isomorphism*

$$\Psi^*(\mathcal{G}_1) \otimes_{\mathcal{A}} \Psi^*(\mathcal{G}_2) \xrightarrow{\sim} \Psi^*(\mathcal{G}_1 \otimes_{\mathcal{B}} \mathcal{G}_2). \tag{4.3.3.1}$$

(4.3.4) Let $\mathcal{C}$ be a $\mathcal{B}$-algebra; giving the Algebra structure on $\mathcal{C}$ amounts to giving a $\mathcal{B}$-homomorphism

$$\mathcal{C} \otimes_{\mathcal{B}} \mathcal{C} \longrightarrow \mathcal{C}$$

satisfying the conditions of associativity and commutativity (conditions that are verified on each stalk); the preceding isomorphism makes it possible to transport this homomorphism into a homomorphism of $\mathcal{A}$-modules

$$\Psi^*(\mathcal{C}) \otimes_{\mathcal{A}} \Psi^*(\mathcal{C}) \longrightarrow \Psi^*(\mathcal{C})$$

satisfying the same conditions, so that $\Psi^*(\mathcal{C})$ is thereby endowed with a structure of $\mathcal{A}$-algebra. In particular, it follows at once from the definitions that the $\mathcal{A}$-algebra $\Psi^*(\mathcal{B})$ is equal to $\mathcal{A}$ (up to a canonical isomorphism).

[0_{I} | 42] Likewise, if $\mathcal{M}$ is a $\mathcal{C}$-module, giving this Module structure amounts to giving a $\mathcal{B}$-homomorphism $\mathcal{C} \otimes_{\mathcal{B}} \mathcal{M} \to \mathcal{M}$ satisfying the associativity condition; whence, by transport, a structure of $\Psi^*(\mathcal{C})$-module on $\Psi^*(\mathcal{M})$.

(4.3.5) Let $\mathcal{J}$ be a sheaf of ideals of $\mathcal{B}$; since the functor ψ^* is exact, the $\psi^*(\mathcal{B})$-module $\psi^*(\mathcal{J})$ is canonically identified with a sheaf of ideals of $\psi^*(\mathcal{B})$; the canonical injection $\psi^*(\mathcal{J}) \to \psi^*(\mathcal{B})$ then gives a homomorphism of $\mathcal{A}$-modules

$$\Psi^*(\mathcal{J}) = \psi^*(\mathcal{J}) \otimes_{\psi^*(\mathcal{B})} \mathcal{A}_{[\theta]} \longrightarrow \mathcal{A} \ ;$$

we shall denote by $\Psi^*(\mathcal{J})\mathcal{A}$, or by $\mathcal{J}\mathcal{A}$ if no confusion is to be feared, the image of $\Psi^*(\mathcal{J})$ under this homomorphism. Thus, by definition,

$$\mathcal{J}\mathcal{A} = \theta^\sharp(\psi^*(\mathcal{J}))\mathcal{A}$$

and in particular, for every $x \in X$,

$$(\mathcal{J}\mathcal{A})_x = \theta_x^\sharp(\mathcal{J}_{\psi(x)})\mathcal{A}_x,$$

taking into account the canonical identification of the stalks of $\psi^*(\mathcal{J})$ with those of $\mathcal{J}$ (3.7.2). If $\mathcal{J}_1$, $\mathcal{J}_2$ are two ideals of $\mathcal{B}$, one has

$$(\mathcal{J}_1\mathcal{J}_2)\mathcal{A} = \mathcal{J}_1(\mathcal{J}_2\mathcal{A}) = (\mathcal{J}_1\mathcal{A})(\mathcal{J}_2\mathcal{A}).$$

If $\mathcal{F}$ is an $\mathcal{A}$-module, we shall set $\mathcal{J}\mathcal{F} = (\mathcal{J}\mathcal{A})\mathcal{F}$.

(4.3.6) Let $(Z, \mathcal{C})$ be a third ringed space, and $\Psi' = (\psi', \theta')$ a morphism $(Y, \mathcal{B}) \to (Z, \mathcal{C})$; if Ψ'' is the composite morphism $\Psi' \circ \Psi$, it follows from the definition (4.3.1) and from (4.3.3.1) that $\Psi''^* = \Psi^* \circ \Psi'^*$.

4.4 Relations between direct images and inverse images

(4.4.1) The hypotheses and notation being those of (4.2.1), let $\mathcal{G}$ be a $\mathcal{B}$-module. By definition, a homomorphism $u : \mathcal{G} \to \Psi_*(\mathcal{F})$ of $\mathcal{B}$-modules is also called a *Ψ-morphism from $\mathcal{G}$ to $\mathcal{F}$*, or simply a *homomorphism from $\mathcal{G}$ to $\mathcal{F}$*, and one writes it $u : \mathcal{G} \to \mathcal{F}$ when no confusion results. Giving such a homomorphism amounts to giving, for every pair (U, V), where U is an open set of X and V an open set of Y such that $\psi(U) \subset V$, a *homomorphism*

$$u_{U,V} : \Gamma(V, \mathcal{G}) \longrightarrow \Gamma(U, \mathcal{F})$$

of $\Gamma(V, \mathcal{B})$-modules, $\Gamma(U, \mathcal{F})$ being regarded as a $\Gamma(V, \mathcal{B})$-module by means of the ring homomorphism $\theta_{U,V} : \Gamma(V, \mathcal{B}) \to \Gamma(U, \mathcal{A})$; the $u_{U,V}$ must moreover make the diagrams (3.5.1.1) commutative. Furthermore, to define u it suffices to give the $u_{U,V}$ when U (resp. V) ranges over a base $\mathfrak{B}$ (resp. $\mathfrak{B}'$) of the topology of X (resp. Y), and to verify the commutativity of (3.5.1.1) for these restrictions.

(4.4.2) Under the hypotheses of (4.2.1) and (4.2.6), let $\mathcal{H}$ be a $\mathcal{C}$-module and $v : \mathcal{H} \to \Psi'_*(\mathcal{G})$ a Ψ'-morphism; then

$$w : \mathcal{H} \xrightarrow{v} \Psi'_*(\mathcal{G}) \xrightarrow{\Psi'_*(u)} \Psi'_*(\Psi_*(\mathcal{F}))$$

is a Ψ''-morphism, which is called the *composite of u and v*.

(4.4.3) We shall now see that one can define a canonical *isomorphism* of *bifunctors* in $\mathcal{F}$ and $\mathcal{G}$

$$\mathrm{Hom}_{\mathcal{A}}(\Psi^*(\mathcal{G}), \mathcal{F}) \xrightarrow{\sim} \mathrm{Hom}_{\mathcal{B}}(\mathcal{G}, \Psi_*(\mathcal{F})) \tag{4.4.3.1}$$

which we shall denote by $v \mapsto v_\theta^\flat$ (or simply $v \mapsto v^\flat$ if no confusion is possible); we shall denote the inverse isomorphism by $u \mapsto u_\theta^\sharp$, or $u \mapsto u^\sharp$. This definition is as follows: composing $v : \Psi^*(\mathcal{G}) \to \mathcal{F}$ with the canonical map $\psi^*(\mathcal{G}) \to \Psi^*(\mathcal{G})$, one obtains a homomorphism of sheaves of groups $v' : \psi^*(\mathcal{G}) \to \mathcal{F}$, which is also a homomorphism of $\psi^*(\mathcal{B})$-modules. From it one deduces (3.7.1) a homomorphism $v'^\flat : \mathcal{G} \to \psi_*(\mathcal{F}) = \Psi_*(\mathcal{F})$, which is also a homomorphism of $\mathcal{B}$-modules, as one verifies without difficulty; one takes [0_I | 43]

$v_\theta^\flat = v'^\flat$. Likewise, from $u : \mathcal{G} \to \Psi_*(\mathcal{F})$, which is a homomorphism of $\mathcal{B}$-modules, one deduces (3.7.1) a homomorphism $u^\sharp : \psi^*(\mathcal{G}) \to \mathcal{F}$ of $\psi^*(\mathcal{B})$-modules, whence, by tensoring with $\mathcal{A}$, a homomorphism of $\mathcal{A}$-modules $\Psi^*(\mathcal{G}) \to \mathcal{F}$, which we shall denote by $u_\theta^\sharp$. It is immediate to verify that $(u_\theta^\sharp)_\theta^\flat = u$ and $(v_\theta^\flat)_\theta^\sharp = v$, as well as the functoriality in $\mathcal{F}$ of the isomorphism $v \mapsto v_\theta^\flat$. The functoriality in $\mathcal{G}$ of $u \mapsto u_\theta^\sharp$ then follows formally as in (3.5.4) (an argument which would also prove the functoriality of Ψ^* established directly in (4.3.1)).

If one takes for v the identity homomorphism of $\Psi^*(\mathcal{G})$, then $v_\theta^\flat$ is a homomorphism

$$\rho_{\mathcal{G}} : \mathcal{G} \longrightarrow \Psi_*(\Psi^*(\mathcal{G})) \; ; \tag{4.4.3.2}$$

if one takes for u the identity homomorphism of $\Psi_*(\mathcal{F})$, then $u_\theta^\sharp$ is a homomorphism

$$\sigma_{\mathcal{F}} : \Psi^*(\Psi_*(\mathcal{F})) \longrightarrow \mathcal{F} \; ; \tag{4.4.3.3}$$

these homomorphisms will be called *canonical*. They are in general neither injective nor surjective. There are canonical factorizations analogous to (3.5.3.3) and (3.5.4.4).

Note that if s is a section of $\mathcal{G}$ over an open set V of Y, $\rho_{\mathcal{G}}(s)$ is the section $s' \otimes 1$ of $\Psi^*(\mathcal{G})$ over $\psi^{-1}(V)$, where s' is such that $s'_x = s_{\psi(x)}$ for every $x \in \psi^{-1}(V)$. Note also that if $u : \mathcal{G} \to \psi_*(\mathcal{F})$ is a homomorphism, it defines for every $x \in X$ a homomorphism $u_x : \mathcal{G}_{\psi(x)} \to \mathcal{F}_x$ on the stalks, obtained by composing $(u^\sharp)_x : (\Psi^*(\mathcal{G}))_x \to \mathcal{F}_x$ with the canonical homomorphism $s_x \mapsto s_x \otimes 1$ from $\mathcal{G}_{\psi(x)}$ to $(\Psi^*(\mathcal{G}))_x = \mathcal{G}_{\psi(x)} \otimes_{\mathcal{B}_{\psi(x)}} \mathcal{A}_x$. The homomorphism u_x is also obtained by passage to the inductive limit from the homomorphisms

$$\Gamma(V, \mathcal{G}) \xrightarrow{u} \Gamma(\psi^{-1}(V), \mathcal{F}) \longrightarrow \mathcal{F}_x,$$

where V ranges over the neighbourhoods of $\psi(x)$.

(4.4.4) Let $\mathcal{F}_1$, $\mathcal{F}_2$ be $\mathcal{A}$-modules, $\mathcal{G}_1$, $\mathcal{G}_2$ $\mathcal{B}$-modules, and u_i $(i = 1, 2)$ a homomorphism from $\mathcal{G}_i$ to $\mathcal{F}_i$. We shall denote by $u_1 \otimes u_2$ the homomorphism

$$u : \mathcal{G}_1 \otimes_{\mathcal{B}} \mathcal{G}_2 \longrightarrow \mathcal{F}_1 \otimes_{\mathcal{A}} \mathcal{F}_2$$

such that $u^\sharp = (u_1)^\sharp \otimes (u_2)^\sharp$ (taking (4.3.3.1) into account); one verifies that u is also the composite

$$\mathcal{G}_1 \otimes_{\mathcal{B}} \mathcal{G}_2 \longrightarrow \Psi_*(\mathcal{F}_1) \otimes_{\mathcal{B}} \Psi_*(\mathcal{F}_2) \longrightarrow \Psi_*(\mathcal{F}_1 \otimes_{\mathcal{A}} \mathcal{F}_2),$$

where the first arrow is the ordinary tensor product $u_1 \otimes_{\mathcal{B}} u_2$ and the second the canonical homomorphism (4.2.2.1).

(4.4.5) Let $(\mathcal{G}_\lambda)_{\lambda \in L}$ be an inductive system of $\mathcal{B}$-modules, and, for every $\lambda \in L$, let u_λ be a homomorphism $\mathcal{G}_\lambda \to \Psi_*(\mathcal{F})$, these forming an inductive system; set $\mathcal{G} = \varinjlim \mathcal{G}_\lambda$ and $u = \varinjlim u_\lambda$; then the $(u_\lambda)^\sharp$ form an inductive system of homomorphisms $\Psi^*(\mathcal{G}_\lambda) \to \mathcal{F}$, and the inductive limit of this system is none other than $u^\sharp$.

(4.4.6) Let $\mathcal{M}$, $\mathcal{N}$ be two $\mathcal{B}$-modules, V an open set of Y, and $U = \psi^{-1}(V)$; the map $v \mapsto \Psi^*(v)$ is a homomorphism

$$\mathrm{Hom}_{\mathcal{B}|V}(\mathcal{M}|V, \mathcal{N}|V) \longrightarrow \mathrm{Hom}_{\mathcal{A}|U}(\Psi^*(\mathcal{M})|U, \Psi^*(\mathcal{N})|U)$$

for the $\Gamma(V, \mathcal{B})$-module structures ($\mathrm{Hom}_{\mathcal{A}|U}(\Psi^*(\mathcal{M})|U, \Psi^*(\mathcal{N})|U)$ is naturally endowed with a structure of $\Gamma(U, \psi^*(\mathcal{B}))$-module, and by means of the canonical homomorphism (3.7.2) $\Gamma(V, \mathcal{B}) \to \Gamma(U, \psi^*(\mathcal{B}))$, it is therefore also a $\Gamma(V, \mathcal{B})$-module). [0_{I} | 44]

One sees at once that these homomorphisms are compatible with restrictions, and consequently define a canonical functorial homomorphism

$$\gamma : \mathcal{H}om_{\mathcal{B}}(\mathcal{M},\mathcal{N}) \longrightarrow \Psi_*(\mathcal{H}om_{\mathcal{A}}(\Psi^*(\mathcal{M}),\Psi^*(\mathcal{N}))) \ ;$$

consequently, there also corresponds to this homomorphism the homomorphism

$$\gamma^\sharp : \Psi^*(\mathcal{H}om_{\mathcal{B}}(\mathcal{M},\mathcal{N})) \longrightarrow \mathcal{H}om_{\mathcal{A}}(\Psi^*(\mathcal{M}),\Psi^*(\mathcal{N}))$$

and these canonical homomorphisms are functorial in $\mathcal{M}$ and $\mathcal{N}$.

(4.4.7) Suppose that $\mathcal{F}$ (resp. $\mathcal{G}$) is an $\mathcal{A}$-algebra (resp. a $\mathcal{B}$-algebra). If $u : \mathcal{G} \to \Psi_*(\mathcal{F})$ is a homomorphism of $\mathcal{B}$-algebras, then $u^\sharp$ is a homomorphism $\Psi^*(\mathcal{G}) \to \mathcal{F}$ of $\mathcal{A}$-algebras; this follows from the commutativity of the diagram

$$\begin{array}{ccc} \mathcal{G} \otimes_{\mathcal{B}} \mathcal{G} & \longrightarrow & \mathcal{G} \\ \downarrow & & \downarrow u \\ \Psi_*(\mathcal{F} \otimes_{\mathcal{A}} \mathcal{F}) & \longrightarrow & \Psi_*(\mathcal{F}) \end{array}$$

and from (4.4.4). Likewise, if $v : \Psi^*(\mathcal{G}) \to \mathcal{F}$ is a homomorphism of $\mathcal{A}$-algebras, then $v^\flat : \mathcal{G} \to \Psi_*(\mathcal{F})$ is a homomorphism of $\mathcal{B}$-algebras.

(4.4.8) Let $(Z,\mathcal{C})$ be a third ringed space, $\Psi' = (\psi',\theta')$ a morphism $(Y,\mathcal{B}) \to (Z,\mathcal{C})$, and $\Psi'' : (X,\mathcal{A}) \to (Z,\mathcal{C})$ the composite morphism $\Psi' \circ \Psi$. Let $\mathcal{H}$ be a $\mathcal{C}$-module and v' a homomorphism from $\mathcal{H}$ to $\mathcal{G}$; the composite $v'' = v \circ v'$ is by definition the homomorphism from $\mathcal{H}$ to $\mathcal{F}$ defined by

$$\mathcal{H} \xrightarrow{v'} \Psi'_*(\mathcal{G}) \xrightarrow{\Psi'_*(v)} \Psi'_*(\Psi_*(\mathcal{F})) \ ;$$

one verifies that $v''^\sharp$ is the homomorphism

$$\Psi^*(\Psi'^*(\mathcal{H})) \xrightarrow{\Psi^*(v'^\sharp)} \Psi^*(\mathcal{G}) \xrightarrow{v^\sharp} \mathcal{F}.$$

§5 Quasi-coherent sheaves and coherent sheaves

5.1 Quasi-coherent sheaves

(5.1.1) Let $(X,\mathcal{O}_X)$ be a ringed space and $\mathcal{F}$ an $\mathcal{O}_X$-module. Giving a homomorphism $u : \mathcal{O}_X \to \mathcal{F}$ of $\mathcal{O}_X$-modules is equivalent to giving the section $s = u(1) \in \Gamma(X,\mathcal{F})$. Indeed, when s is given, for every section $t \in \Gamma(U,\mathcal{O}_X)$ one necessarily has $u(t) = t \cdot (s|U)$; we say that u is *defined by the section* s. If now I is an arbitrary index set, consider the direct sum sheaf $\mathcal{O}_X^{(I)}$, and for every $i \in I$, let h_i be the canonical injection of the i-th factor into $\mathcal{O}_X^{(I)}$; we know that $u \mapsto (u \circ h_i)$ is an isomorphism of $\mathrm{Hom}_{\mathcal{O}_X}(\mathcal{O}_X^{(I)},\mathcal{F})$ onto the product $\left(\mathrm{Hom}_{\mathcal{O}_X}(\mathcal{O}_X,\mathcal{F})\right)^I$. There is therefore a canonical one-to-one correspondence between the homomorphisms $u : \mathcal{O}_X^{(I)} \to \mathcal{F}$ and the *families of sections* $(s_i)_{i\in I}$ *of* $\mathcal{F}$ *over* X. The homomorphism u corresponding to (s_i) maps an element $(a_i) \in (\Gamma(U,\mathcal{O}_X))^{(I)}$ to $\sum_{i\in I} a_i \cdot (s_i|U)$.

We say that $\mathcal{F}$ is *generated by the family* (s_i) if the homomorphism $\mathcal{O}_X^{(I)} \to \mathcal{F}$ defined by this family is *surjective* (in other words, if, for every $x \in X$, $\mathcal{F}_x$ is an $\mathcal{O}_x$-module [0I | 45]

generated by the $(s_i)_x$). We say that $\mathcal{F}$ is *generated by its sections over* X if it is generated by the family of all these sections (or by a subfamily); in other words, if there exists a surjective homomorphism $\mathcal{O}_X^{(I)} \to \mathcal{F}$ for a suitable I.

Note that an $\mathcal{O}_X$-module $\mathcal{F}$ can be such that there exists a point $x_0 \in X$ for which $\mathcal{F}|U$ is not generated by its sections over U, *for every open neighbourhood* U *of* x_0: it suffices to take $X = \mathbb{R}$, for $\mathcal{O}_X$ the simple sheaf $\mathbb{Z}$, for $\mathcal{F}$ the algebraic sub-sheaf of $\mathcal{O}_X$ such that $\mathcal{F}_0 = \{0\}$, $\mathcal{F}_x = \mathbb{Z}$ for $x \neq 0$, and finally $x_0 = 0$: the only section of $\mathcal{F}|U$ over U is 0 for a neighbourhood U of 0.

(5.1.2) Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathcal{F}$ is an $\mathcal{O}_X$-module generated by its sections over X, then the canonical homomorphism $f^*(f_*(\mathcal{F})) \to \mathcal{F}$ (4.4.3.3) is *surjective*: indeed, with the notation of (5.1.1), $s_i \otimes 1$ is a section of $f^*(f_*(\mathcal{F}))$ over X, and its image in $\mathcal{F}$ is s_i. The example of (5.1.1), where f is the identity, shows that the converse of this proposition is false in general.

(5.1.3) An $\mathcal{O}_X$-module $\mathcal{F}$ is said to be *quasi-coherent* if, for every $x \in X$, there is an open neighbourhood U of x such that $\mathcal{F}|U$ is isomorphic to the *cokernel* of a homomorphism of the form $\mathcal{O}_X^{(I)}|U \to \mathcal{O}_X^{(J)}|U$, where I and J are arbitrary index sets. It is clear that $\mathcal{O}_X$ itself is a quasi-coherent $\mathcal{O}_X$-module, and that every direct sum of quasi-coherent $\mathcal{O}_X$-modules is a quasi-coherent $\mathcal{O}_X$-module. An $\mathcal{O}_X$-algebra $\mathcal{A}$ is said to be *quasi-coherent* if it is so as an $\mathcal{O}_X$-module.

(5.1.4) Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathcal{G}$ is a quasi-coherent $\mathcal{O}_Y$-module, then $f^*(\mathcal{G})$ is a quasi-coherent $\mathcal{O}_X$-module. Indeed, for every $x \in X$, there is an open neighbourhood V of $f(x)$ in Y such that $\mathcal{G}|V$ is the cokernel of a homomorphism $\mathcal{O}_Y^{(I)}|V \to \mathcal{O}_Y^{(J)}|V$. If $U = f^{-1}(V)$ and f_U is the restriction of f to U, one has $f^*(\mathcal{G})|U = f_U^*(\mathcal{G}|V)$; since f_U^* is right exact and commutes with direct sums, $f_U^*(\mathcal{G}|V)$ is the cokernel of a homomorphism $\mathcal{O}_X^{(I)}|U \to \mathcal{O}_X^{(J)}|U$.

5.2 Sheaves of finite type

(5.2.1) An $\mathcal{O}_X$-module $\mathcal{F}$ is said to be *of finite type* if, for every $x \in X$, there exists an open neighbourhood U of x such that $\mathcal{F}|U$ is generated by a *finite* family of sections over U, or equivalently is isomorphic to a quotient sheaf of a sheaf of the form $(\mathcal{O}_X|U)^p$ with p finite. Every quotient sheaf of a sheaf of finite type is of finite type, as is every finite direct sum and every finite tensor product of sheaves of finite type. An $\mathcal{O}_X$-module of finite type is not necessarily quasi-coherent, as can be seen for the $\mathcal{O}_X$-module $\mathcal{O}_X/\mathcal{F}$, where $\mathcal{F}$ is the example of (5.1.1). If $\mathcal{F}$ is of finite type, then $\mathcal{F}_x$ is an $\mathcal{O}_x$-module of finite type for every $x \in X$, but the example (5.1.1) shows that this necessary condition is not in general sufficient.

(5.2.2) Let $\mathcal{F}$ be an $\mathcal{O}_X$-module *of finite type*. If s_i $(1 \leq i \leq n)$ are sections of $\mathcal{F}$ over an open neighbourhood U of a point $x \in X$ and if the $(s_i)_x$ generate $\mathcal{F}_x$, there exists an open neighbourhood $V \subset U$ of x such that the $(s_i)_y$ generate $\mathcal{F}_y$ for every $y \in V$ (FAC, I, 2, 12, prop. 1). In particular, one concludes that the support of $\mathcal{F}$ is *closed*.

[0I | 46] Likewise, if $u : \mathcal{F} \to \mathcal{G}$ is a homomorphism such that $u_x = 0$, then there exists a neighbourhood U of x such that $u_y = 0$ for every $y \in U$.

(5.2.3) Suppose X *quasi-compact*, and let $\mathcal{F}$, $\mathcal{G}$ be two $\mathcal{O}_X$-modules such that $\mathcal{G}$ is *of finite type*, and $u : \mathcal{F} \to \mathcal{G}$ a *surjective* homomorphism. Suppose moreover that $\mathcal{F}$ is the

inductive limit of an inductive system $(\mathcal{F}_\lambda)$ of $\mathcal{O}_X$-modules. Then there exists an index μ such that the homomorphism $\mathcal{F}_\mu \to \mathcal{G}$ is *surjective*. Indeed, for every $x \in X$, there exists a finite system of sections s_i of $\mathcal{G}$ over an open neighbourhood $U(x)$ of x such that the $(s_i)_y$ generate $\mathcal{G}_y$ for every $y \in U(x)$; there is therefore an open neighbourhood $V(x) \subset U(x)$ of x and n sections t_i of $\mathcal{F}$ over $V(x)$ such that $s_i|V(x) = u(t_i)$ for every i; one can moreover suppose that the t_i are the canonical images of sections of one and the same sheaf $\mathcal{F}_{\lambda(x)}$ over $V(x)$. Now cover X with finitely many neighbourhoods $V(x_k)$, and let μ be an index greater than all the $\lambda(x_k)$; it is clear that this index answers the question.

Still supposing X quasi-compact, let $\mathcal{F}$ be an $\mathcal{O}_X$-module of finite type generated by its sections over X (5.1.1); then $\mathcal{F}$ is generated by a *finite* subfamily of these sections: indeed, it suffices to cover X by finitely many open neighbourhoods U_k such that, for each k, there are finitely many sections s_{ik} of $\mathcal{F}$ over X whose restrictions to U_k generate $\mathcal{F}|U_k$; it is clear that the s_{ik} then generate $\mathcal{F}$.

(5.2.4) Let $f : X \to Y$ be a morphism of ringed spaces. If $\mathcal{G}$ is an $\mathcal{O}_Y$-module of finite type, then $f^*(\mathcal{G})$ is an $\mathcal{O}_X$-module of finite type. Indeed, for every $x \in X$, there are an open neighbourhood V of $f(x)$ in Y and a surjective homomorphism $v : \mathcal{O}_Y^p|V \to \mathcal{G}|V$. If $U = f^{-1}(V)$ and f_U is the restriction of f to U, one has $f^*(\mathcal{G})|U = f_U^*(\mathcal{G}|V)$; since f_U^* is right exact (4.3.1) and commutes with direct sums (4.3.2), $f_U^*(v)$ is a surjective homomorphism $\mathcal{O}_X^p|U \to f^*(\mathcal{G})|U$.

(5.2.5) An $\mathcal{O}_X$-module $\mathcal{F}$ is said to *admit a finite presentation* if, for every $x \in X$, there exists an open neighbourhood U of x such that $\mathcal{F}|U$ is isomorphic to a *cokernel of an $(\mathcal{O}_X|U)$-homomorphism $\mathcal{O}_X^p|U \to \mathcal{O}_X^q|U$*, p and q being two integers > 0. Such an $\mathcal{O}_X$-module is thus of finite type and quasi-coherent. If $f : X \to Y$ is a morphism of ringed spaces and $\mathcal{G}$ is an $\mathcal{O}_Y$-module admitting a finite presentation, then $f^*(\mathcal{G})$ admits a finite presentation, as the argument of (5.1.4) shows.

(5.2.6) Let $\mathcal{F}$ be an $\mathcal{O}_X$-module admitting a finite presentation (5.2.5); then, for every $\mathcal{O}_X$-module $\mathcal{H}$, the canonical functorial homomorphism

$$\big(\mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{H})\big)_x \longrightarrow \mathrm{Hom}_{\mathcal{O}_x}(\mathcal{F}_x, \mathcal{H}_x)$$

is *bijective* (T, 4.1.1).

(5.2.7) Let $\mathcal{F}$, $\mathcal{G}$ be two $\mathcal{O}_X$-modules having a finite presentation. If, for some $x \in X$, $\mathcal{F}_x$ and $\mathcal{G}_x$ are *isomorphic* $\mathcal{O}_x$-modules, then there exists an open neighbourhood U of x such that $\mathcal{F}|U$ and $\mathcal{G}|U$ are *isomorphic*. Indeed, if $\varphi : \mathcal{F}_x \to \mathcal{G}_x$ and $\psi : \mathcal{G}_x \to \mathcal{F}_x$ are two mutually inverse isomorphisms, there exist, by (5.2.6), an open neighbourhood V of x and a section u (resp. v) of $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})$ (resp. $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{G}, \mathcal{F})$) over V such that $u_x = \varphi$ (resp. $v_x = \psi$). Since $(u \circ v)_x$ and $(v \circ u)_x$ are the identity automorphisms, there exists an open neighbourhood $U \subset V$ of x such that $(u \circ v)|U$ and $(v \circ u)|U$ are the identity automorphisms, whence the proposition. [0_{I} | 47]

5.3 Coherent sheaves

(5.3.1) An $\mathcal{O}_X$-module $\mathcal{F}$ is said to be *coherent* if it satisfies the following two conditions:

a) $\mathcal{F}$ is of finite type.

b) For every open set $U \subset X$, every integer $n > 0$, and every homomorphism $u : \mathcal{O}_X^n|U \to \mathcal{F}|U$, the kernel of u is of finite type.

Note that these two conditions are of a *local* nature.

For most of the proofs of the properties of coherent sheaves recalled in what follows, cf. (FAC), I, 2.

(5.3.2) Every coherent $\mathcal{O}_X$-module admits a finite presentation (5.2.5); the converse is not necessarily true, since $\mathcal{O}_X$ itself is not necessarily a coherent $\mathcal{O}_X$-module.

Every sub-$\mathcal{O}_X$-module *of finite type* of a coherent $\mathcal{O}_X$-module is coherent; every *finite* direct sum of coherent $\mathcal{O}_X$-modules is a coherent $\mathcal{O}_X$-module.

(5.3.3) If $0 \to \mathcal{F} \to \mathcal{G} \to \mathcal{H} \to 0$ is an exact sequence of $\mathcal{O}_X$-modules and two of these $\mathcal{O}_X$-modules are coherent, then so is the third.

(5.3.4) If $\mathcal{F}$ and $\mathcal{G}$ are two coherent $\mathcal{O}_X$-modules and $u : \mathcal{F} \to \mathcal{G}$ is a homomorphism, then $\mathrm{Im}(u)$, $\mathrm{Ker}(u)$ and $\mathrm{Coker}(u)$ are coherent $\mathcal{O}_X$-modules. In particular, if $\mathcal{F}$ and $\mathcal{G}$ are coherent sub-$\mathcal{O}_X$-modules of a coherent $\mathcal{O}_X$-module, then $\mathcal{F}+\mathcal{G}$ and $\mathcal{F}\cap\mathcal{G}$ are coherent.

(5.3.5) If $\mathcal{F}$ and $\mathcal{G}$ are two coherent $\mathcal{O}_X$-modules, so are $\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G}$ and $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})$.

(5.3.6) Let $\mathcal{F}$ be a coherent $\mathcal{O}_X$-module and $\mathcal{J}$ a coherent sheaf of ideals of $\mathcal{O}_X$. Then the $\mathcal{O}_X$-module $\mathcal{J}\mathcal{F}$ is coherent, as the image of $\mathcal{J} \otimes_{\mathcal{O}_X} \mathcal{F}$ under the canonical homomorphism $\mathcal{J} \otimes_{\mathcal{O}_X} \mathcal{F} \to \mathcal{F}$ (5.3.4 and 5.3.5).

(5.3.7) An $\mathcal{O}_X$-algebra $\mathcal{A}$ is said to be *coherent* if $\mathcal{A}$ is a coherent $\mathcal{O}_X$-module. In particular, $\mathcal{O}_X$ is a *coherent sheaf of rings* if and only if, for every open set $U \subset X$ and every homomorphism of the form $u : \mathcal{O}_X^p|U \to \mathcal{O}_X|U$, the kernel of u is an $(\mathcal{O}_X|U)$-module of finite type.

If $\mathcal{O}_X$ is a coherent sheaf of rings, every $\mathcal{O}_X$-module $\mathcal{F}$ admitting a finite presentation (5.2.5) is coherent, by virtue of (5.3.4).

The *annihilator* of an $\mathcal{O}_X$-module $\mathcal{F}$ is the kernel $\mathcal{J}$ of the canonical homomorphism $\mathcal{O}_X \to \mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{F})$ which assigns to every section $s \in \Gamma(U, \mathcal{O}_X)$ the multiplication by s in $\mathrm{Hom}(\mathcal{F}|U, \mathcal{F}|U)$; if $\mathcal{O}_X$ is coherent and $\mathcal{F}$ is a coherent $\mathcal{O}_X$-module, then $\mathcal{J}$ is coherent (5.3.4 and 5.3.5) and, for every $x \in X$, $\mathcal{J}_x$ is the annihilator of $\mathcal{F}_x$ (5.2.6).

[0I | 48] **(5.3.8)** Suppose $\mathcal{O}_X$ coherent; let $\mathcal{F}$ be a coherent $\mathcal{O}_X$-module, x a point of X, and M a submodule of finite type of $\mathcal{F}_x$; then there exist an open neighbourhood U of x and a coherent sub-$(\mathcal{O}_X|U)$-module $\mathcal{G}$ of $\mathcal{F}|U$ such that $\mathcal{G}_x = M$ (T, 4.1, lemma 1).

This result, together with the properties of the sub-$\mathcal{O}_X$-modules of a coherent $\mathcal{O}_X$-module, imposes necessary conditions on the rings $\mathcal{O}_x$ for $\mathcal{O}_X$ to be coherent. For example (5.3.4), the intersection of two ideals of finite type of $\mathcal{O}_x$ must again be an ideal of finite type.

(5.3.9) Suppose $\mathcal{O}_X$ coherent, and let M be an $\mathcal{O}_x$-module admitting a finite presentation, hence isomorphic to a cokernel of a homomorphism $\varphi : \mathcal{O}_x^p \to \mathcal{O}_x^q$; then there exist an open neighbourhood U of x and a coherent $(\mathcal{O}_X|U)$-module $\mathcal{F}$ such that $\mathcal{F}_x$ is isomorphic to M. Indeed, by virtue of (5.2.6), there exists a section u of $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X^p, \mathcal{O}_X^q)$ over an open neighbourhood U of x such that $u_x = \varphi$; the cokernel $\mathcal{F}$ of the homomorphism $u : \mathcal{O}_X^p|U \to \mathcal{O}_X^q|U$ answers the question (5.3.4).

(5.3.10) Suppose $\mathcal{O}_X$ coherent, and let $\mathcal{J}$ be a coherent sheaf of ideals in $\mathcal{O}_X$. For an $(\mathcal{O}_X/\mathcal{J})$-module $\mathcal{F}$ to be coherent, it is necessary and sufficient that it be coherent as an $\mathcal{O}_X$-module. In particular, $\mathcal{O}_X/\mathcal{J}$ is a coherent sheaf of rings.

(5.3.11) Let $f : X \to Y$ be a morphism of ringed spaces, and suppose $\mathcal{O}_X$ coherent; then, for every coherent $\mathcal{O}_Y$-module $\mathcal{G}$, $f^*(\mathcal{G})$ is a coherent $\mathcal{O}_X$-module. Indeed, with the notation of (5.2.4), one can suppose that $\mathcal{G}|V$ is the cokernel of a homomorphism $v : \mathcal{O}_Y^q|V \to \mathcal{O}_Y^p|V$; since f_U^* is right exact, $f^*(\mathcal{G})|U = f_U^*(\mathcal{G}|V)$ is the cokernel of the homomorphism $f_U^*(v) : \mathcal{O}_X^q|U \to \mathcal{O}_X^p|U$, whence our assertion.

(5.3.12) Let Y be a closed subset of X, $j : Y \to X$ the canonical injection, $\mathcal{O}_Y$ a sheaf of rings on Y, and set $\mathcal{O}_X = j_*(\mathcal{O}_Y)$. For an $\mathcal{O}_Y$-module $\mathcal{G}$ to be of finite type (resp. quasi-coherent, coherent), it is necessary and sufficient that $j_*(\mathcal{G})$ be an $\mathcal{O}_X$-module of finite type (resp. quasi-coherent, coherent).

5.4 Locally free sheaves

(5.4.1) Let X be a ringed space. An $\mathcal{O}_X$-module $\mathcal{F}$ is said to be *locally free* if, for every $x \in X$, there exists an open neighbourhood U of x such that $\mathcal{F}|U$ is isomorphic to an $(\mathcal{O}_X|U)$-module of the form $\mathcal{O}_X^{(I)}|U$, where I may depend on U. If I is finite for every U, $\mathcal{F}$ is said to be *of finite rank*; if for every U, I has the same finite number n of elements, $\mathcal{F}$ is said to be *of rank n*. A locally free $\mathcal{O}_X$-module of rank 1 is also called *invertible* (cf. (5.4.3)). If $\mathcal{F}$ is a locally free $\mathcal{O}_X$-module of finite rank, then for every $x \in X$, $\mathcal{F}_x$ is a free $\mathcal{O}_x$-module of finite rank $n(x)$, and there exists a neighbourhood U of x such that $\mathcal{F}|U$ is of rank $n(x)$; if X is connected, $n(x)$ is therefore *constant*.

It is clear that every locally free sheaf is quasi-coherent, and if $\mathcal{O}_X$ is a coherent sheaf of rings, every locally free $\mathcal{O}_X$-module of finite rank is coherent.

If $\mathcal{L}$ is locally free, $\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{F}$ is an *exact* functor in $\mathcal{F}$ on the category of $\mathcal{O}_X$-modules.

We shall mostly have to consider locally free $\mathcal{O}_X$-modules of finite rank,
and when we speak of locally free sheaves without further specification, it will be understood that they are of *finite rank*. [0_{I} | 49]

(5.4.2) If $\mathcal{L}$, $\mathcal{F}$ are two $\mathcal{O}_X$-modules, there is a canonical functorial homomorphism

$$\check{\mathcal{L}} \otimes_{\mathcal{O}_X} \mathcal{F} = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}, \mathcal{O}_X) \otimes_{\mathcal{O}_X} \mathcal{F} \longrightarrow \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}, \mathcal{F}) \tag{5.4.2.1}$$

defined as follows: for every open set U, to every pair (u, t), where

$$u \in \Gamma\big(U, \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}, \mathcal{O}_X)\big) = \mathrm{Hom}(\mathcal{L}|U, \mathcal{O}_X|U) \quad \text{and} \quad t \in \Gamma(U, \mathcal{F}),$$

one assigns the element of $\mathrm{Hom}(\mathcal{L}|U, \mathcal{F}|U)$ which, for every $x \in U$, assigns to $s_x \in \mathcal{L}_x$ the element $u_x(s_x)t_x$ of $\mathcal{F}_x$. If $\mathcal{L}$ is *locally free of finite rank*, this homomorphism is *bijective*; indeed, the property being local, one may restrict oneself to the case where $\mathcal{L} = \mathcal{O}_X^n$; since, for every $\mathcal{O}_X$-module $\mathcal{G}$, $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X^n, \mathcal{G})$ is canonically isomorphic to $\mathcal{G}^n$, one is reduced to the case $\mathcal{L} = \mathcal{O}_X$, which is immediate.

(5.4.3) If $\mathcal{L}$ is invertible, so is its dual $\check{\mathcal{L}} = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}, \mathcal{O}_X)$, since one is immediately reduced (the question being local) to the case $\mathcal{L} = \mathcal{O}_X$. Moreover, there is a canonical isomorphism

$$\mathcal{H}om_{\mathcal{O}_X}(\mathcal{L}, \mathcal{O}_X) \otimes_{\mathcal{O}_X} \mathcal{L} \xrightarrow{\sim} \mathcal{O}_X \tag{5.4.3.1}$$

indeed, by (5.4.2), it suffices to define a canonical isomorphism $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{L},\mathcal{L}) \xrightarrow{\sim} \mathcal{O}_X$. Now, for *every* $\mathcal{O}_X$-module $\mathcal{F}$, there is a canonical homomorphism $\mathcal{O}_X \longrightarrow \mathcal{H}om_{\mathcal{O}_X}(\mathcal{F},\mathcal{F})$ (5.3.7). It remains to prove that if $\mathcal{F}=\mathcal{L}$ is invertible, this homomorphism is bijective, and since the question is local, one is reduced to the case $\mathcal{L}=\mathcal{O}_X$, which is immediate.

In view of the foregoing, we set $\mathcal{L}^{-1} = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{L},\mathcal{O}_X)$ and say that $\mathcal{L}^{-1}$ is the *inverse* of $\mathcal{L}$. The terminology "invertible sheaf" can be justified as follows when X is reduced to a point and $\mathcal{O}_X$ is a *local* ring A with maximal ideal $\mathfrak{m}$; if M and M' are two A-modules (M being of finite type) such that $M\otimes_A M'$ is isomorphic to A, then, since $(A/\mathfrak{m})\otimes_A(M\otimes_A M')$ is identified with $(M/\mathfrak{m}M)\otimes_{A/\mathfrak{m}}(M'/\mathfrak{m}M')$, this last tensor product of vector spaces over the field $A/\mathfrak{m}$ is isomorphic to $A/\mathfrak{m}$, which requires $M/\mathfrak{m}M$ and $M'/\mathfrak{m}M'$ to be of dimension 1. For every element $z\in M$ not belonging to $\mathfrak{m}M$, one therefore has $M=Az+\mathfrak{m}M$, which implies $M=Az$ by Nakayama's lemma, M being of finite type. Moreover, since the annihilator of z annihilates $M\otimes_A M'$, which is isomorphic to A, this annihilator is $\{0\}$, and M is consequently *isomorphic to* A. In the general case, this shows that if $\mathcal{L}$ is an $\mathcal{O}_X$-module of finite type such that there exists an $\mathcal{O}_X$-module $\mathcal{F}$ for which $\mathcal{L}\otimes_{\mathcal{O}_X}\mathcal{F}$ is isomorphic to $\mathcal{O}_X$, and if moreover the rings $\mathcal{O}_x$ are local rings, then $\mathcal{L}_x$ is an $\mathcal{O}_x$-module isomorphic to $\mathcal{O}_x$ for every $x\in X$. If $\mathcal{O}_X$ and $\mathcal{L}$ are assumed to be *coherent*, one therefore concludes that $\mathcal{L}$ is invertible, by virtue of (5.2.7).

(5.4.4) If $\mathcal{L}$ and $\mathcal{L}'$ are two invertible $\mathcal{O}_X$-modules, so is $\mathcal{L}\otimes_{\mathcal{O}_X}\mathcal{L}'$, since, the question being local, one may suppose that $\mathcal{L}=\mathcal{O}_X$, and the result is then trivial. For every integer $n\geq 1$, one denotes by $\mathcal{L}^{\otimes n}$ the tensor product of n sheaves
[0I | 50] identical to $\mathcal{L}$; by convention one sets $\mathcal{L}^{\otimes 0}=\mathcal{O}_X$ and, for $n\geq 1$, $\mathcal{L}^{\otimes(-n)}=(\mathcal{L}^{-1})^{\otimes n}$. With this notation, there then exists a *canonical functorial isomorphism*

$$\mathcal{L}^{\otimes m}\otimes_{\mathcal{O}_X}\mathcal{L}^{\otimes n}\xrightarrow{\sim}\mathcal{L}^{\otimes(n+m)} \tag{5.4.4.1}$$

for all rational integers m,n: indeed, by virtue of the definitions, one is immediately reduced to the case where $m=-1$, $n=1$, and the isomorphism in question was then defined in (5.4.3).

(5.4.5) Let $f: Y\to X$ be a morphism of ringed spaces. If $\mathcal{L}$ is a locally free (resp. invertible) $\mathcal{O}_X$-module, then $f^*(\mathcal{L})$ is a locally free (resp. invertible) $\mathcal{O}_Y$-module: this follows at once from the facts that the inverse images of two locally isomorphic $\mathcal{O}_X$-modules are locally isomorphic, that f^* commutes with finite direct sums, and that $f^*(\mathcal{O}_X)=\mathcal{O}_Y$ (4.3.4). Moreover, we know that there is a canonical functorial homomorphism

$$f^*(\check{\mathcal{L}})\longrightarrow(f^*\check{(}\mathcal{L}))$$

(4.4.6), and when $\mathcal{L}$ is locally free, this homomorphism is *bijective*: indeed, one is again reduced to the case where $\mathcal{L}=\mathcal{O}_X$, which is trivial. One concludes that if $\mathcal{L}$ is invertible, $f^*(\mathcal{L}^{\otimes n})$ is canonically identified with $(f^*(\mathcal{L}))^{\otimes n}$ for every rational integer n.

(5.4.6) Let $\mathcal{L}$ be an invertible $\mathcal{O}_X$-module; one denotes by $\Gamma_*(X,\mathcal{L})$, or simply $\Gamma_*(\mathcal{L})$, the abelian group that is the direct sum $\bigoplus_{n\in\mathbb{Z}}\Gamma(X,\mathcal{L}^{\otimes n})$; it is endowed with a structure of *graded ring* by assigning to the pair (s_n,s_m), where $s_n\in\Gamma(X,\mathcal{L}^{\otimes n})$, $s_m\in\Gamma(X,\mathcal{L}^{\otimes m})$, the section of $\mathcal{L}^{\otimes(n+m)}$ over X that corresponds canonically (5.4.4.1) to the section $s_n\otimes s_m$ of $\mathcal{L}^{\otimes n}\otimes_{\mathcal{O}_X}\mathcal{L}^{\otimes m}$; the associativity of this multiplication is verified immediately. It is clear that $\Gamma_*(X,\mathcal{L})$ is a covariant functor in $\mathcal{L}$, with values in the category of graded rings.

If now $\mathcal{F}$ is an arbitrary $\mathcal{O}_X$-module, one sets

$$\Gamma_*(\mathcal{L},\mathcal{F})=\bigoplus_{n\in\mathbb{Z}}\Gamma(X,\mathcal{F}\otimes_{\mathcal{O}_X}\mathcal{L}^{\otimes n}).$$

This abelian group is endowed with a structure of *graded module* over the graded ring $\Gamma_*(\mathcal{L})$ as follows: to the pair (s_n, u_m), where $s_n \in \Gamma(X, \mathcal{L}^{\otimes n})$ and $u_m \in \Gamma(X, \mathcal{F}\otimes_{\mathcal{O}_X}\mathcal{L}^{\otimes m})$, one assigns the section of $\mathcal{F}\otimes_{\mathcal{O}_X}\mathcal{L}^{\otimes(m+n)}$ that corresponds canonically (5.4.4.1) to $s_n\otimes u_m$; the verification of the module axioms is immediate. For fixed X and $\mathcal{L}$, $\Gamma_*(\mathcal{L}, \mathcal{F})$ is a covariant functor in $\mathcal{F}$ with values in the category of graded $\Gamma_*(\mathcal{L})$-modules; for fixed X and $\mathcal{F}$, it is a covariant functor in $\mathcal{L}$ with values in the category of abelian groups.

If $f : Y \to X$ is a morphism of ringed spaces, the canonical homomorphism (4.4.3.2)

$$\rho : \mathcal{L}^{\otimes n} \longrightarrow f_*(f^*(\mathcal{L}^{\otimes n}))$$

defines a homomorphism of abelian groups

$$\Gamma(X, \mathcal{L}^{\otimes n}) \longrightarrow \Gamma(Y, f^*(\mathcal{L}^{\otimes n})),$$

and since $f^*(\mathcal{L}^{\otimes n}) = (f^*(\mathcal{L}))^{\otimes n}$, it follows from the definitions of the canonical homomorphisms (4.4.3.2) and (5.4.4.1) that the preceding homomorphisms define a *functorial homomorphism of graded rings* $\Gamma_*(\mathcal{L}) \to \Gamma_*(f^*(\mathcal{L}))$. The same canonical homomorphism (4.4.3) likewise defines a homomorphism of abelian groups

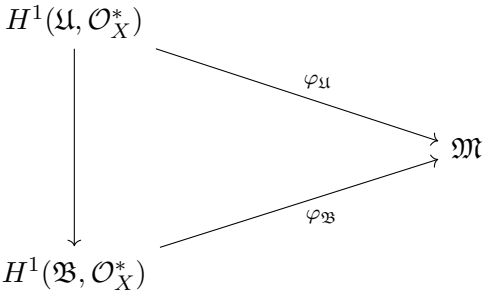
$$\Gamma(X, \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}^{\otimes n}) \longrightarrow \Gamma(Y, f^*(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}^{\otimes n})),$$

and since

$$f^*(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{L}^{\otimes n}) = f^*(\mathcal{F}) \otimes_{\mathcal{O}_Y} (f^*(\mathcal{L}))^{\otimes n} \tag{4.3.3.1}$$

these homomorphisms (for variable n) define a *di-homomorphism of graded modules* [0I | 51]

$$\Gamma_*(\mathcal{L}, \mathcal{F}) \longrightarrow \Gamma_*(f^*(\mathcal{L}), f^*(\mathcal{F})).$$



(5.4.7) One can show that there exists a *set* $\mathfrak{M}$ (also denoted $\mathfrak{M}(X)$) of invertible $\mathcal{O}_X$-modules such that every invertible $\mathcal{O}_X$-module is isomorphic to one and only one element of $\mathfrak{M}$[11]; one defines on $\mathfrak{M}$ a law of composition by assigning to two elements $\mathcal{L}$, $\mathcal{L}'$ of $\mathfrak{M}$ the unique element of $\mathfrak{M}$ isomorphic to $\mathcal{L}\otimes_{\mathcal{O}_X}\mathcal{L}'$. With this law of composition, $\mathfrak{M}$ is a *group isomorphic to the cohomology group* $H^1(X, \mathcal{O}_X^*)$, where $\mathcal{O}_X^*$ is the sub-sheaf of $\mathcal{O}_X$ such that $\Gamma(U, \mathcal{O}_X^*)$ is the group of invertible elements of the ring $\Gamma(U, \mathcal{O}_X)$ for every open set $U \subset X$ (so $\mathcal{O}_X^*$ is a sheaf of *multiplicative* abelian groups).

To see this, note that for every open set $U \subset X$, the group of sections $\Gamma(U, \mathcal{O}_X^*)$ is canonically identified with the *group of automorphisms* of the $(\mathcal{O}_X|U)$-module $\mathcal{O}_X|U$, the identification assigning to a section ε of $\mathcal{O}_X^*$ over U the automorphism u of $\mathcal{O}_X|U$ such that $u_x(s_x) = \varepsilon_x s_x$ for every $x \in U$ and every $s_x \in \mathcal{O}_x$. Now let $\mathfrak{U} = (U_\lambda)$ be an open covering of X; giving, for every pair of indices (λ, μ), an automorphism $\theta_{\lambda\mu}$ of $\mathcal{O}_X|(U_\lambda \cap U_\mu)$ amounts to giving a 1-*cochain* of the covering $\mathfrak{U}$ with values in $\mathcal{O}_X^*$, and to say that the $\theta_{\lambda\mu}$ satisfy the gluing condition (3.3.1) means that the corresponding cochain is a *cocycle*. Likewise, giving, for every λ, an automorphism ω_λ of $\mathcal{O}_X|U_\lambda$ amounts to giving a 0-cochain of the covering $\mathfrak{U}$ with values in $\mathcal{O}_X^*$, and its *coboundary* corresponds to the family of automorphisms $(\omega_\lambda|U_\lambda \cap U_\mu) \circ (\omega_\mu|U_\lambda \cap U_\mu)^{-1}$.

To every 1-cocycle of $\mathfrak{U}$ with values in $\mathcal{O}_X^*$ one can assign the element of $\mathfrak{M}$ isomorphic to the invertible $\mathcal{O}_X$-module obtained by gluing by means of the family of automorphisms $(\theta_{\lambda\mu})$ corresponding to this cocycle, and to two cohomologous cocycles there correspond two equal elements of $\mathfrak{M}$ (3.3.2); in other words, one has thus defined a map $\varphi_{\mathfrak{U}}$:

[11] See the book in preparation cited in the Introduction.

$H^1(\mathfrak{U}, \mathcal{O}_X^*) \to \mathfrak{M}$. Moreover, if $\mathfrak{B}$ is a second open covering of X, finer than $\mathfrak{U}$, the diagram

where the vertical arrow is the canonical homomorphism (G, II, 5.7), is commutative, as follows from (3.3.3). By passage to the inductive limit, one therefore indeed obtains a map $H^1(X, \mathcal{O}_X^*) \to \mathfrak{M}$, the Čech cohomology group $\check{H}^1(X, \mathcal{O}_X^*)$ being identified, as is well known, with the first cohomology group $H^1(X, \mathcal{O}_X^*)$ (G, II, 5.9, cor. of th. 5.9.1). This map is *surjective*: indeed, by definition, for every invertible $\mathcal{O}_X$-module $\mathcal{L}$, there is an open covering (U_λ) of X such that $\mathcal{L}$ is obtained by gluing the sheaves $\mathcal{O}_X|U_\lambda$ (3.3.1). It is also *injective*, for it suffices to prove this for the maps $H^1(\mathfrak{U}, \mathcal{O}_X^*) \to \mathfrak{M}$, and this then follows from (3.3.2). It remains to show that

[0_I | 52] the bijection thus defined is a group homomorphism. Now, given two invertible $\mathcal{O}_X$-modules $\mathcal{L}$, $\mathcal{L}'$, there is an open covering (U_λ) such that $\mathcal{L}|U_\lambda$ and $\mathcal{L}'|U_\lambda$ are isomorphic to $\mathcal{O}_X|U_\lambda$ for every λ; there is therefore, for each index λ, an element a_λ (resp. a'_λ) of $\Gamma(U_\lambda, \mathcal{L})$ (resp. $\Gamma(U_\lambda, \mathcal{L}')$) such that the elements of $\Gamma(U_\lambda, \mathcal{L})$ (resp. $\Gamma(U_\lambda, \mathcal{L}')$) are the $s_\lambda \cdot a_\lambda$ (resp. $s_\lambda \cdot a'_\lambda$), where s_λ ranges over $\Gamma(U_\lambda, \mathcal{O}_X)$. The corresponding cocycles $(\varepsilon_{\lambda\mu})$, $(\varepsilon'_{\lambda\mu})$ are such that $s_\lambda \cdot a_\lambda = s_\mu \cdot a_\mu$ (resp. $s_\lambda \cdot a'_\lambda = s_\mu \cdot a'_\mu$) over $U_\lambda \cap U_\mu$ is equivalent to $s_\lambda = \varepsilon_{\lambda\mu} s_\mu$ (resp. $s_\lambda = \varepsilon'_{\lambda\mu} s_\mu$) over $U_\lambda \cap U_\mu$. Since the sections of $\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{L}'$ over U_λ are the finite sums of the $s_\lambda s'_\lambda \cdot (a_\lambda \otimes a'_\lambda)$, where s_λ and s'_λ range over $\Gamma(U_\lambda, \mathcal{O}_X)$, it is clear that the cocycle $(\varepsilon_{\lambda\mu}\varepsilon'_{\lambda\mu})$ corresponds to $\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{L}'$, which completes the proof[12].

(5.4.8) Let $f = (\psi, \omega)$ be a morphism $Y \to X$ of ringed spaces. The functor f^*, restricted to the category of invertible $\mathcal{O}_X$-modules, defines a map (again denoted by f^*, by abuse of language) from the set $\mathfrak{M}(X)$ to the set $\mathfrak{M}(Y)$. On the other hand, there is a canonical homomorphism (T, 3.2.2)

$$H^1(X, \mathcal{O}_X^*) \longrightarrow H^1(Y, \mathcal{O}_Y^*). \tag{5.4.8.1}$$

When $\mathfrak{M}(X)$ and $H^1(X, \mathcal{O}_X^*)$ (resp. $\mathfrak{M}(Y)$ and $H^1(Y, \mathcal{O}_Y^*)$) are canonically identified (5.4.7), the homomorphism (5.4.8.1) *is identified with the map* f^*. Indeed, if $\mathcal{L}$ comes from a cocycle $(\varepsilon_{\lambda\mu})$ corresponding to an open covering (U_λ) of X, it suffices to show that $f^*(\mathcal{L})$ comes from a cocycle whose cohomology class is the image under (5.4.8.1) of that of $(\varepsilon_{\lambda\mu})$. Now, if $\theta_{\lambda\mu}$ is the automorphism of $\mathcal{O}_X|(U_\lambda \cap U_\mu)$ corresponding to $\varepsilon_{\lambda\mu}$, it is clear that $f^*(\mathcal{L})$ is obtained by gluing the $\mathcal{O}_Y|\psi^{-1}(U_\lambda)$ by means of the automorphisms $f^*(\theta_{\lambda\mu})$, and it therefore suffices to verify that the latter correspond to the cocycle $(\omega^\#(\varepsilon_{\lambda\mu}))$, which follows at once from the definitions (we have identified $\varepsilon_{\lambda\mu}$ with its canonical image under ρ (3.7.2), a section of $\psi^*(\mathcal{O}_X^*)$ over $\psi^{-1}(U_\lambda \cap U_\mu)$).

(5.4.9) Let $\mathcal{E}$, $\mathcal{F}$ be two $\mathcal{O}_X$-modules, $\mathcal{F}$ being assumed *locally free*, and let $\mathcal{G}$ be an $\mathcal{O}_X$-module that is an *extension of* $\mathcal{F}$ *by* $\mathcal{E}$, in other words such that there exists an exact sequence

$$0 \longrightarrow \mathcal{E} \xrightarrow{i} \mathcal{G} \xrightarrow{p} \mathcal{F} \longrightarrow 0.$$

[12] For a general form of this result, see the book cited in the footnote on p. 51.

Then, for every $x \in X$, there exists an open neighbourhood U of x such that $\mathcal{G}|U$ is isomorphic to the *direct sum* $\mathcal{E}|U \oplus \mathcal{F}|U$. Indeed, one may restrict oneself to the case where $\mathcal{F} = \mathcal{O}_X^n$; let e_i $(1 \leq i \leq n)$ be the canonical sections (5.5.5) of $\mathcal{O}_X^n$; there then exist an open neighbourhood U of x and n sections s_i of $\mathcal{G}$ over U such that $p(s_i|U) = e_i|U$ for $1 \leq i \leq n$. That being so, let f be the homomorphism $\mathcal{F}|U \to \mathcal{G}|U$ defined by the sections $s_i|U$ (5.1.1). It is immediate that for every open set $V \subset U$ and every section $s \in \Gamma(V, \mathcal{G})$ one has $s - f(p(s)) \in \Gamma(V, \mathcal{E})$, whence our assertion.

(5.4.10) Let $f : X \to Y$ be a morphism of ringed spaces, $\mathcal{F}$ an $\mathcal{O}_X$-module, and $\mathcal{L}$ a locally free $\mathcal{O}_Y$-module of finite rank. There then exists a canonical isomorphism

$$f_*(\mathcal{F}) \otimes_{\mathcal{O}_Y} \mathcal{L} \xrightarrow{\sim} f_*(\mathcal{F} \otimes_{\mathcal{O}_X} f^*(\mathcal{L})). \tag{5.4.10.1}$$

Indeed, for every $\mathcal{O}_Y$-module $\mathcal{L}$, there is a canonical homomorphism [0_{I} | 53]

$$f_*(\mathcal{F}) \otimes_{\mathcal{O}_Y} \mathcal{L} \xrightarrow{1\otimes\rho} f_*(\mathcal{F}) \otimes_{\mathcal{O}_Y} f_*(f^*(\mathcal{L})) \xrightarrow{\alpha} f_*(\mathcal{F} \otimes_{\mathcal{O}_X} f^*(\mathcal{L})),$$

where ρ is the homomorphism (4.4.3.2) and α the homomorphism (4.2.2.1). To show that this homomorphism is bijective when $\mathcal{L}$ is locally free, it suffices, the question being local on Y, to consider the case where $\mathcal{L} = \mathcal{O}_Y^n$; moreover, since f_* and f^* commute with finite direct sums, one may suppose $n = 1$, and in this case the proposition follows at once from the definitions and from the relation $f^*(\mathcal{O}_Y) = \mathcal{O}_X$.

5.5 Sheaves on a ringed space in local rings

(5.5.1) We shall say that a ringed space $(X, \mathcal{O}_X)$ is a *ringed space in local rings* if, for every $x \in X$, $\mathcal{O}_x$ is a local ring; these ringed spaces will be by far the most frequent of those considered in this work. We shall then denote by $\mathfrak{m}_x$ the *maximal ideal* of $\mathcal{O}_x$, and by $k(x)$ the *residue field* $\mathcal{O}_x/\mathfrak{m}_x$; for every $\mathcal{O}_X$-module $\mathcal{F}$, every open set U of X, every point $x \in U$ and every section $f \in \Gamma(U, \mathcal{F})$, we shall denote by $f(x)$ the *class* of the germ $f_x \in \mathcal{F}_x \pmod{\mathfrak{m}_x\mathcal{F}_x}$, and we shall say that it is the *value* of f at the point x. The relation $f(x) = 0$ thus means that $f_x \in \mathfrak{m}_x\mathcal{F}_x$; when it holds, we shall say (by abuse of language) that f *vanishes at* x. Care must be taken not to confuse this relation with $f_x = 0$.

(5.5.2) Let X be a ringed space in local rings, $\mathcal{L}$ an invertible $\mathcal{O}_X$-module, and f a section of $\mathcal{L}$ over X. Then the following three properties at a point $x \in X$ are *equivalent*:

a) *f_x is a generator of $\mathcal{L}_x$;*

b) *$f_x \notin \mathfrak{m}_x\mathcal{L}_x$* (in other words, $f(x) \neq 0$);

c) *There exists a section g of $\mathcal{L}^{-1}$ over an open neighbourhood V of x such that the canonical image of $f \otimes g$ in $\Gamma(V, \mathcal{O}_X)$ (5.4.3) is the unit section.*

Indeed, the question being local, one may restrict oneself to the case where $\mathcal{L} = \mathcal{O}_X$; the equivalence of *a*) and *b*) is then obvious, and it is clear that *c*) implies *b*). On the other hand, if $f_x \notin \mathfrak{m}_x$, then f_x is invertible in $\mathcal{O}_x$, say $f_x g_x = 1_x$. By the definition of germs of sections, this means that there exist a neighbourhood V of x and a section g of $\mathcal{O}_X$ over V such that $fg = 1$ in V, whence *c*).

It follows at once from condition *c*) that the set X_f of the x satisfying the equivalent conditions *a*), *b*), *c*) is *open* in X; following the terminology introduced in (5.5.1), it is the set of the x at which f *does not vanish*.

(5.5.3) Under the hypotheses of (5.5.2), let $\mathcal{L}'$ be a second invertible $\mathcal{O}_X$-module; then, if $f \in \Gamma(X, \mathcal{L})$ and $g \in \Gamma(X, \mathcal{L}')$, one has

$$X_f \cap X_g = X_{f \otimes g}.$$

Indeed, one is immediately reduced to the case where $\mathcal{L} = \mathcal{L}' = \mathcal{O}_X$ (the question being local); since $f \otimes g$ is then canonically identified with the product fg, the proposition is obvious.

[0_{I} | 54] **(5.5.4)** Let $\mathcal{F}$ be a locally free $\mathcal{O}_X$-module of rank n; it is immediate that $\bigwedge^p \mathcal{F}$ is a locally free $\mathcal{O}_X$-module of rank $\binom{n}{p}$ if $p \leq n$, and reduced to 0 if $p > n$, since the question is local and one is reduced to the case where $\mathcal{F} = \mathcal{O}_X^n$; moreover, for every $x \in X$,

$$(\bigwedge^p \mathcal{F})_x / \mathfrak{m}_x (\bigwedge^p \mathcal{F})_x$$

is a vector space of dimension $\binom{n}{p}$ over $k(x)$, which is canonically identified with

$$\bigwedge^p (\mathcal{F}_x / \mathfrak{m}_x \mathcal{F}_x).$$

Let $s_1, \ldots, s_p$ be sections of $\mathcal{F}$ over an open set U of X, and let $s = s_1 \wedge \cdots \wedge s_p$, which is a section of $\bigwedge^p \mathcal{F}$ over U (4.1.5); one has $s(x) = s_1(x) \wedge \cdots \wedge s_p(x)$, and consequently, to say that $s_1(x), \ldots, s_p(x)$ are *linearly dependent* means that $s(x) = 0$. One concludes that *the set of $x \in U$ such that $s_1(x), \ldots, s_p(x)$ are linearly independent is open in X*: indeed, it suffices, reducing to the case where $\mathcal{F} = \mathcal{O}_X^n$, to apply (5.5.2) to the section that is the image of s under one of the projections of $\bigwedge^p \mathcal{F} = \mathcal{O}_X^{\binom{n}{p}}$ onto the $\binom{n}{p}$ factors.

In particular, if $s_1, \ldots, s_n$ are n sections of $\mathcal{F}$ over U such that $s_1(x), \ldots, s_n(x)$ are linearly independent at every point $x \in U$, the homomorphism $u : \mathcal{O}_X^n | U \to \mathcal{F}|U$ defined by the s_i (5.1.1) is an *isomorphism*: indeed, one may restrict oneself to the case where $\mathcal{F} = \mathcal{O}_X^n$ and where $\bigwedge^n \mathcal{F}$ and $\mathcal{O}_X$ are canonically identified; $s = s_1 \wedge \cdots \wedge s_n$ is then an *invertible* section of $\mathcal{O}_X$ over U, and one defines an inverse homomorphism of u by means of Cramer's formulas.

(5.5.5) Let $\mathcal{E}$, $\mathcal{F}$ be two locally free $\mathcal{O}_X$-modules (of finite rank), and let $u : \mathcal{E} \to \mathcal{F}$ be a homomorphism. For there to exist a neighbourhood U of $x \in X$ such that $u|U$ is *injective* and $\mathcal{F}|U$ is *the direct sum of $u(\mathcal{E})|U$ and a locally free sub-$(\mathcal{O}_X|U)$-module $\mathcal{G}$*, it is necessary and sufficient that $u_x : \mathcal{E}_x \to \mathcal{F}_x$ give, by passage to the quotients, an *injective* homomorphism of vector spaces

$$\mathcal{E}_x / \mathfrak{m}_x \mathcal{E}_x \longrightarrow \mathcal{F}_x / \mathfrak{m}_x \mathcal{F}_x.$$

The condition is indeed *necessary*, since $\mathcal{F}_x$ is then the direct sum of the free $\mathcal{O}_x$-modules $u_x(\mathcal{E}_x)$ and $\mathcal{G}_x$, so that $\mathcal{F}_x / \mathfrak{m}_x \mathcal{F}_x$ is the direct sum of $u_x(\mathcal{E}_x) / \mathfrak{m}_x u_x(\mathcal{E}_x)$ and $\mathcal{G}_x / \mathfrak{m}_x \mathcal{G}_x$. The condition is *sufficient*, for one may restrict oneself to the case where $\mathcal{E} = \mathcal{O}_X^m$; let $s_1, \ldots, s_m$ be the images under u of the sections e_i of $\mathcal{O}_X^m$ such that $(e_i)_y$ is equal to the i-th element of the canonical basis of $\mathcal{O}_y^m$ for every $y \in X$ (*canonical sections of* $\mathcal{O}_X^m$); by hypothesis $s_1(x), \ldots, s_m(x)$ are linearly independent, so, if $\mathcal{F}$ is of rank n, there exist $n - m$ sections $s_{m+1}, \ldots, s_n$ of $\mathcal{F}$ over a neighbourhood V of x such that the $s_i(x)$ $(1 \leq i \leq n)$ form a basis of $\mathcal{F}_x / \mathfrak{m}_x \mathcal{F}_x$. There then exists (5.5.4) a neighbourhood $U \subset V$ of x such that the $s_i(y)$ $(1 \leq i \leq n)$ form a basis of $\mathcal{F}_y / \mathfrak{m}_y \mathcal{F}_y$ for every $y \in U$, and one concludes (5.5.4) that there is an isomorphism of $\mathcal{F}|U$ onto $\mathcal{O}_X^n|U$ mapping the $s_i|U$ $(1 \leq i \leq m)$ to the $e_i|U$, which completes the proof.

§6 Flatness

(6.0) The notion of flatness is due to J.-P. Serre [16]; in what follows, we omit the proofs of the results that are presented in the *Algèbre commutative* of N. Bourbaki, to which we refer the reader. We assume all rings to be commutative.[13]
If M, N are two A-modules and M' (resp. N') is a submodule of M (resp. N), we shall denote by $\mathrm{Im}(M' \otimes_A N')$ the submodule of $M \otimes_A N$ that is the image of the canonical map $M' \otimes_A N' \to M \otimes_A N$. [0$_\mathrm{I}$ | 55]

6.1 Flat modules

(6.1.1) Let M be an A-module. The following properties are equivalent:

a) The functor $M \otimes_A N$ in N is exact in the category of A-modules;

b) $\mathrm{Tor}_i^A(M, N) = 0$ for every $i > 0$ and every A-module N;

c) $\mathrm{Tor}_1^A(M, N) = 0$ for every A-module N.

When M satisfies these conditions, M is said to be a *flat A-module*. It is clear that every free A-module is flat.

For M to be a flat A-module, it suffices that for every ideal $\mathfrak{J}$ of A *of finite type*, the canonical map $M \otimes_A \mathfrak{J} \to M \otimes_A A = M$ be *injective*.

(6.1.2) Every inductive limit of flat A-modules is a flat A-module. For a direct sum $\bigoplus_{\lambda \in L} M_\lambda$ of A-modules to be a flat A-module, it is necessary and sufficient that each of the A-modules M_λ be flat. In particular, every projective A-module is flat.

Let

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

be an exact sequence of A-modules such that M'' is *flat*. Then, for every A-module N, the sequence

$$0 \longrightarrow M' \otimes N \longrightarrow M \otimes N \longrightarrow M'' \otimes N \longrightarrow 0$$

is exact. Moreover, for M to be flat, it is then necessary and sufficient that M' be so (but it can happen that M and M' are flat without $M'' = M/M'$ being so).

(6.1.3) Let M be a flat A-module and N an arbitrary A-module; for any two submodules N', N'' of N, we then have

$$\mathrm{Im}(M \otimes (N' + N'')) = \mathrm{Im}(M \otimes N') + \mathrm{Im}(M \otimes N''),$$

$$\mathrm{Im}(M \otimes (N' \cap N'')) = \mathrm{Im}(M \otimes N') \cap \mathrm{Im}(M \otimes N'')$$

(images taken in $M \otimes N$).

(6.1.4) Let M, N be two A-modules, M' (resp. N') a submodule of M (resp. N), and suppose that one of the modules M/M', N/N' is flat. Then we have

$$\mathrm{Im}(M' \otimes N') = \mathrm{Im}(M' \otimes N) \cap \mathrm{Im}(M \otimes N')$$

(images in $M \otimes N$). In particular, if $\mathfrak{J}$ is an ideal of A and if M/M' is flat, we have $\mathfrak{J}M' = M' \cap \mathfrak{J}M$.

[13] See the cited exposition by N. Bourbaki for the generalization of most of the results to the noncommutative case.

6.2 Change of rings

When an additive group M is endowed with several module structures relative to rings A, B, ..., instead of saying that M is flat as an A-module, B-module, ..., we shall sometimes also say that M is *A-flat*, *B-flat*, ...

(6.2.1) Let A and B be two rings, M an A-module, N an (A, B)-bimodule. If M is flat and N is B-flat, then $M \otimes_A N$ is B-flat. In particular, if M and N are two flat A-modules, $M \otimes_A N$ is a flat A-module. If B is an A-algebra and M is a flat A-module, the B-module $M_{(B)} = M \otimes_A B$ is flat. Finally, if B is an A-algebra that is flat as an A-module, and if N is a flat B-module, then N is also A-flat.

[0I | 56]

(6.2.2) Let A be a ring and B an A-algebra that is flat as an A-module. Let M, N be two A-modules such that M admits a finite presentation; then the canonical homomorphism

$$\mathrm{Hom}_A(M, N) \otimes_A B \longrightarrow \mathrm{Hom}_B(M \otimes_A B, N \otimes_A B) \tag{6.2.2.1}$$

(which sends $u \otimes b$ to the homomorphism $m \otimes b' \longmapsto u(m) \otimes b'b$) is an isomorphism.

(6.2.3) Let $(A_\lambda, \varphi_{\mu\lambda})$ be a filtered inductive system of rings, and let $A = \varinjlim A_\lambda$. On the other hand, for each λ, let M_λ be an A_λ-module, and for $\lambda \leq \mu$ let $\theta_{\mu\lambda} : M_\lambda \to M_\mu$ be a $\varphi_{\mu\lambda}$-homomorphism, such that $(M_\lambda, \theta_{\mu\lambda})$ is an inductive system; $M = \varinjlim M_\lambda$ is then an A-module. That being so, if for every λ, M_λ is a *flat* A_λ-module, then M is a *flat* A-module. Indeed, let $\mathfrak{J}$ be an ideal *of finite type* of A; by the definition of the inductive limit, there exist an index λ and an ideal $\mathfrak{J}_\lambda$ of A_λ such that $\mathfrak{J} = \mathfrak{J}_\lambda A$. If we set $\mathfrak{J}'_\mu = \mathfrak{J}_\lambda A_\mu$ for $\mu \geq \lambda$, we also have $\mathfrak{J} = \varinjlim \mathfrak{J}'_\mu$ (where μ runs through the indices $\geq \lambda$), whence (the functor $\varinjlim$ being exact and commuting with the tensor product)

$$M \otimes_A \mathfrak{J} = \varinjlim(M_\mu \otimes_{A_\mu} \mathfrak{J}'_\mu) = \varinjlim \mathfrak{J}'_\mu M_\mu = \mathfrak{J}M.$$

6.3 Localization of flatness

(6.3.1) If A is a ring and S a multiplicative subset of A, $S^{-1}A$ is a *flat* A-module. Indeed, for every A-module N, $N \otimes_A S^{-1}A$ is identified with $S^{-1}N$ (1.2.5), and we know (1.3.2) that $S^{-1}N$ is an exact functor in N.

If now M is a flat A-module, $S^{-1}M = M \otimes_A S^{-1}A$ is a flat $S^{-1}A$-module (6.2.1), and hence is also A-flat by virtue of the preceding and of (6.2.1). In particular, if P is an $S^{-1}A$-module, it can be considered as an A-module isomorphic to $S^{-1}P$; for P to be A-flat, it is necessary and sufficient that it be $S^{-1}A$-flat.

(6.3.2) Let A be a ring, B an A-algebra, and T a multiplicative subset of B. If P is a B-module that is A-flat, $T^{-1}P$ is A-flat. Indeed, for every A-module N, we have

$$(T^{-1}P) \otimes_A N = (T^{-1}B \otimes_B P) \otimes_A N = T^{-1}B \otimes_B (P \otimes_A N) = T^{-1}(P \otimes_A N)\ ;$$

now, $T^{-1}(P \otimes_A N)$ is an exact functor in N, being the composite of the two exact functors $P \otimes_A N$ (in N) and $T^{-1}Q$ (in Q). If S is a multiplicative subset of A whose image in B is *contained in* T, $T^{-1}P$ is equal to $S^{-1}(T^{-1}P)$, and hence is also $S^{-1}A$-flat by virtue of (6.3.1).

(6.3.3) Let $\varphi : A \to B$ be a ring homomorphism and M a B-module. The following properties are equivalent:

a) M is a flat A-module.

b) For every maximal ideal $\mathfrak{n}$ of B, $M_{\mathfrak{n}}$ is a flat A-module.

c) For every maximal ideal $\mathfrak{n}$ of B, setting $\mathfrak{m} = \varphi^{-1}(\mathfrak{n})$, $M_{\mathfrak{n}}$ is a flat $A_{\mathfrak{m}}$-module.

Indeed, since $M_{\mathfrak{n}} = (M_{\mathfrak{n}})_{\mathfrak{m}}$, the equivalence of *b*) and *c*) follows from (6.3.1), and the fact that *a*) implies *b*) is a special case of (6.3.2). It remains to see that *b*) implies *a*), that [0_{I} | 57] is, that for every injective homomorphism $u : N' \to N$ of A-modules, the homomorphism $v = 1 \otimes u : M \otimes_A N' \to M \otimes_A N$ is injective. Now, v is also a homomorphism of B-modules, and we know that for it to be injective, it suffices that for every maximal ideal $\mathfrak{n}$ of B,

$$v_{\mathfrak{n}} : (M \otimes_A N')_{\mathfrak{n}} \longrightarrow (M \otimes_A N)_{\mathfrak{n}}$$

be injective. But since

$$(M \otimes_A N)_{\mathfrak{n}} = B_{\mathfrak{n}} \otimes_B (M \otimes_A N) = M_{\mathfrak{n}} \otimes_A N,$$

$v_{\mathfrak{n}}$ is none other than the homomorphism

$$1 \otimes u : M_{\mathfrak{n}} \otimes_A N' \longrightarrow M_{\mathfrak{n}} \otimes_A N,$$

which is injective since $M_{\mathfrak{n}}$ is A-flat.

In particular (taking $B = A$), for an A-module M to be flat, it is necessary and sufficient that $M_{\mathfrak{m}}$ be $A_{\mathfrak{m}}$-flat for every maximal ideal $\mathfrak{m}$ of A.

(6.3.4) Let M be an A-module; if M is flat and if $f \in A$ is not a divisor of 0 in A, then f annihilates no element $\neq 0$ of M, because the homomorphism $m \mapsto f \cdot m$ can be written $1 \otimes u$, where u is the multiplication $a \mapsto f \cdot a$ in A and M is identified with $M \otimes_A A$; if u is injective, the same therefore holds for $1 \otimes u$, since M is flat. In particular, if A is *integral*, M is *torsion-free*.

Conversely, suppose A integral and M torsion-free, and suppose that for every maximal ideal $\mathfrak{m}$ of A, $A_{\mathfrak{m}}$ is a *discrete valuation ring*; then M is A-flat. Indeed, it suffices (6.3.3) to prove that $M_{\mathfrak{m}}$ is $A_{\mathfrak{m}}$-flat, and we can therefore assume that A is already a discrete valuation ring. But since M is the inductive limit of its submodules of finite type, and these are torsion-free, we can moreover restrict ourselves to the case where M is of finite type (6.1.2). In this case the proposition follows from the fact that M is a free A-module.

In particular, if A is an *integral* ring and $\varphi : A \to B$ a ring homomorphism making B an A-module that is *flat* and $\neq \{0\}$, then φ is necessarily *injective*. Conversely, if B is integral, A a subring of B, and if for every maximal ideal $\mathfrak{m}$ of A, $A_{\mathfrak{m}}$ is a discrete valuation ring, then B is A-flat.

6.4 Faithfully flat modules

(6.4.1) For an A-module M, the following four properties are equivalent:

a) For a sequence $N' \to N \to N''$ of A-modules to be exact, it is necessary and sufficient that the sequence $M \otimes N' \to M \otimes N \to M \otimes N''$ be exact;

b) M is flat and for every A-module N, the relation $M \otimes N = 0$ implies $N = 0$;

c) M is flat and for every homomorphism $v : N \to N'$ of A-modules, the relation $1_M \otimes v = 0$ implies $v = 0$, 1_M being the identity automorphism of M;

d) M is flat and for every maximal ideal $\mathfrak{m}$ of A, $\mathfrak{m}M \neq M$.

When M satisfies these conditions, M is said to be a *faithfully flat* A-module; M is then necessarily a *faithful* module. Moreover, if $u : N \to N'$ is a homomorphism of A-modules, for u to be injective (resp. surjective, bijective), it is necessary and sufficient that $1 \otimes u : M \otimes N \to M \otimes N'$ be so.

[0I | 58] **(6.4.2)** A free module $\neq \{0\}$ is faithfully flat; the same holds for the direct sum of a flat module and a faithfully flat module. If S is a multiplicative subset of A, $S^{-1}A$ is a faithfully flat A-module only if S consists of invertible elements (hence $S^{-1}A = A$).

(6.4.3) Let

$$0 \longrightarrow M' \longrightarrow M \longrightarrow M'' \longrightarrow 0$$

be an exact sequence of A-modules; if M' and M'' are flat, and if one of them is faithfully flat, then M is faithfully flat.

(6.4.4) Let A and B be two rings, M an A-module, N an (A, B)-bimodule. If M is faithfully flat and N is a faithfully flat B-module, then $M \otimes_A N$ is a faithfully flat B-module. In particular, if M and N are two faithfully flat A-modules, the same holds for $M \otimes_A N$. If B is an A-algebra and M is a faithfully flat A-module, the B-module $M_{(B)}$ is faithfully flat.

(6.4.5) If M is a faithfully flat A-module and S is a multiplicative subset of A, $S^{-1}M$ is a faithfully flat $S^{-1}A$-module, since $S^{-1}M = M \otimes_A (S^{-1}A)$ (6.4.4). Conversely, if for every maximal ideal $\mathfrak{m}$ of A, $M_{\mathfrak{m}}$ is a faithfully flat $A_{\mathfrak{m}}$-module, then M is a faithfully flat A-module, because M is A-flat (6.3.3), and we have

$$M_{\mathfrak{m}}/\mathfrak{m}M_{\mathfrak{m}} = (M \otimes_A A_{\mathfrak{m}}) \otimes_{A_{\mathfrak{m}}} (A_{\mathfrak{m}}/\mathfrak{m}A_{\mathfrak{m}}) = M \otimes_A (A/\mathfrak{m}) = M/\mathfrak{m}M,$$

so the hypothesis implies that $M/\mathfrak{m}M \neq 0$ for every maximal ideal $\mathfrak{m}$ of A, which proves our assertion (6.4.1).

6.5 Restriction of scalars

(6.5.1) Let A be a ring and $\varphi : A \to B$ a ring homomorphism making B an A-algebra. Suppose there exists a B-module N that is a *faithfully flat* A-module. Then, for every A-module M, the homomorphism $x \mapsto 1 \otimes x$ from M to $B \otimes_A M = M_{(B)}$ is *injective*. In particular, φ is injective; for every ideal $\mathfrak{a}$ of A, we have $\varphi^{-1}(\mathfrak{a}B) = \mathfrak{a}$; for every maximal (resp. prime) ideal $\mathfrak{m}$ of A, there exists a maximal (resp. prime) ideal $\mathfrak{n}$ of B such that $\varphi^{-1}(\mathfrak{n}) = \mathfrak{m}$.

(6.5.2) When the condition of (6.5.1) is satisfied, we identify A with a subring of B by means of φ, and more generally, for every A-module M, we identify M with a sub-A-module of $M_{(B)}$. Note that if B is then *Noetherian*, so is A, because the map $\mathfrak{a} \mapsto \mathfrak{a}B$ is an increasing injection of the set of ideals of A into the set of ideals of B; the existence of an infinite strictly increasing sequence of ideals of A would therefore imply the existence of an analogous sequence of ideals of B.

6.6 Faithfully flat rings

(6.6.1) Let $\varphi : A \to B$ be a ring homomorphism making B an A-algebra. The following five properties are equivalent:

a) B is a faithfully flat A-module (in other words, $M_{(B)}$ is an exact and faithful functor in M).

b) The homomorphism φ is injective and the A-module $B/\varphi(A)$ is flat.

c) The A-module B is flat (in other words, the functor $M_{(B)}$ is exact), and for every A-module M, the homomorphism $x \mapsto 1 \otimes x$ from M to $M_{(B)}$ is injective. [0_I | 59]

d) The A-module B is flat and for every ideal $\mathfrak{a}$ of A, we have $\varphi^{-1}(\mathfrak{a}B) = \mathfrak{a}$.

e) The A-module B is flat and for every maximal ideal $\mathfrak{m}$ of A, there exists a maximal ideal $\mathfrak{n}$ of B such that $\varphi^{-1}(\mathfrak{n}) = \mathfrak{m}$.

When these conditions hold, we identify A with a subring of B.

(6.6.2) Let A be a local ring, $\mathfrak{m}$ its maximal ideal, and B an A-algebra such that $\mathfrak{m}B \neq B$ (which is the case for example when B is a local ring and $A \to B$ a local homomorphism). If B is a flat A-module, B is a faithfully flat A-module. Indeed, since $\mathfrak{m}B \neq B$, there is a maximal ideal $\mathfrak{n}$ of B containing $\mathfrak{m}B$; since $\varphi^{-1}(\mathfrak{n}) \cap A$ contains $\mathfrak{m}$ and does not contain 1, we have $\varphi^{-1}(\mathfrak{n}) = \mathfrak{m}$ and criterion *e*) of (6.6.1) applies. Under the stated conditions, we thus see that if B is Noetherian, so is A (6.5.2).

(6.6.3) Let B be an A-algebra that is a faithfully flat A-module. For every A-module M and every sub-A-module M' of M, we have (identifying M with a sub-A-module of $M_{(B)}$) $M' = M \cap M'_{(B)}$. For M to be a flat (resp. faithfully flat) A-module, it is necessary and sufficient that $M_{(B)}$ be a flat (resp. faithfully flat) B-module.

(6.6.4) Let B be an A-algebra and N a faithfully flat B-module. For B to be a flat (resp. faithfully flat) A-module, it is necessary and sufficient that N be so.

In particular, let C be a B-algebra; if the ring C is faithfully flat over B and B is faithfully flat over A, then C is faithfully flat over A; if C is faithfully flat over B and over A, then B is faithfully flat over A.

6.7 Flat morphisms of ringed spaces

(6.7.1) Let $f : X \to Y$ be a morphism of ringed spaces, and let $\mathcal{F}$ be an $\mathcal{O}_X$-module. We say that $\mathcal{F}$ is f-flat (or Y-flat when no confusion about f is to be feared) at a point $x \in X$ if $\mathcal{F}_x$ is a flat $\mathcal{O}_{f(x)}$-module; we say that $\mathcal{F}$ is f-flat over $y \in Y$ if $\mathcal{F}$ is f-flat at all the points $x \in f^{-1}(y)$; we say that $\mathcal{F}$ is f-flat if $\mathcal{F}$ is f-flat at all the points of X. We say that the morphism f is flat at $x \in X$ (resp. flat over $y \in Y$, resp. flat) if $\mathcal{O}_X$ is f-flat at x (resp. f-flat over y, resp. f-flat).

(6.7.2) With the notation of (6.7.1), if $\mathcal{F}$ is f-flat at x, then for every open neighbourhood U of $y = f(x)$, the functor $(f^*(\mathcal{G}) \otimes_{\mathcal{O}_X} \mathcal{F})_x$ in $\mathcal{G}$ is exact in the category of $(\mathcal{O}_Y|U)$-modules; indeed, this stalk is canonically identified with $\mathcal{G}_y \otimes_{\mathcal{O}_y} \mathcal{F}_x$, and our assertion follows from the definition. In particular, if f is a flat morphism, the functor f^* is exact in the category of $\mathcal{O}_Y$-modules.

(6.7.3) Conversely, suppose the sheaf of rings $\mathcal{O}_Y$ is coherent, and suppose that for every open neighbourhood U of y, the functor $(f^*(\mathcal{G}) \otimes_{\mathcal{O}_X} \mathcal{F})_x$ is exact in $\mathcal{G}$ in the category of coherent $(\mathcal{O}_Y|U)$-modules. Then $\mathcal{F}$ is f-flat at x. Indeed, it suffices to prove that for every ideal of finite type $\mathfrak{J}$ of $\mathcal{O}_y$, the canonical homomorphism $\mathfrak{J} \otimes_{\mathcal{O}_y} \mathcal{F}_x \to \mathcal{F}_x$ is injective (6.1.1). Now, we know (5.3.8) that there then exist an open
[0_I | 60] neighbourhood U of y and a coherent sheaf of ideals $\mathcal{J}$ of $\mathcal{O}_Y|U$ such that $\mathcal{J}_y = \mathfrak{J}$, whence the conclusion.

(6.7.4) The results of (6.1) on flat modules translate immediately into propositions on sheaves that are f-flat at a point:

If $0 \to \mathcal{F}' \to \mathcal{F} \to \mathcal{F}'' \to 0$ is an exact sequence of $\mathcal{O}_X$-modules and if $\mathcal{F}''$ is f-flat at the point $x \in X$, then, for every open neighbourhood U of $y = f(x)$ and every $(\mathcal{O}_Y|U)$-module $\mathcal{G}$, the sequence

$$0 \longrightarrow (f^*(\mathcal{G}) \otimes_{\mathcal{O}_X} \mathcal{F}')_x \longrightarrow (f^*(\mathcal{G}) \otimes_{\mathcal{O}_X} \mathcal{F})_x \longrightarrow (f^*(\mathcal{G}) \otimes_{\mathcal{O}_X} \mathcal{F}'')_x \longrightarrow 0$$

is exact. For $\mathcal{F}$ to be f-flat at x, it is then necessary and sufficient that $\mathcal{F}'$ be so. There are analogous statements for the corresponding notions of an $\mathcal{O}_X$-module f-flat over $y \in Y$, or of an f-flat $\mathcal{O}_X$-module.

(6.7.5) Let $f : X \to Y$, $g : Y \to Z$ be two morphisms of ringed spaces; let $x \in X$, $y = f(x)$, and let $\mathcal{F}$ be an $\mathcal{O}_X$-module. If $\mathcal{F}$ is f-flat at the point x and if the morphism g is flat at the point y, then $\mathcal{F}$ is $(g \circ f)$-flat at x (6.2.1). In particular, if f and g are flat morphisms, $g \circ f$ is flat.

(6.7.6) Let X, Y be two ringed spaces and $f : X \to Y$ a flat morphism. Then the canonical homomorphism of bifunctors (4.4.6)

$$f^*(\mathcal{H}om_{\mathcal{O}_Y}(\mathcal{F}, \mathcal{G})) \longrightarrow \mathcal{H}om_{\mathcal{O}_X}(f^*(\mathcal{F}), f^*(\mathcal{G})) \tag{6.7.6.1}$$

is an isomorphism when $\mathcal{F}$ admits a finite presentation (5.2.5).

Indeed, the question being local, we can assume that there exists an exact sequence $\mathcal{O}_Y^m \to \mathcal{O}_Y^n \to \mathcal{F} \to 0$. Now, both sides of (6.7.6.1) are left exact functors in $\mathcal{F}$ by virtue of the hypothesis on f; we are then reduced to proving the proposition when $\mathcal{F} = \mathcal{O}_Y$, a case in which it is trivial.

(6.7.8) A morphism $f : X \to Y$ of ringed spaces is said to be faithfully flat if f is surjective and if, for every $x \in X$, $\mathcal{O}_x$ is a faithfully flat $\mathcal{O}_{f(x)}$-module. When X and Y are locally ringed spaces (5.5.1), this amounts to saying that the morphism f is surjective and flat (6.6.2). When f is faithfully flat, f^* is an exact and faithful functor in the category of $\mathcal{O}_Y$-modules (6.6.1, *a*)), and for an $\mathcal{O}_Y$-module $\mathcal{G}$ to be Y-flat, it is necessary and sufficient that $f^*(\mathcal{G})$ be so (6.6.3).

§7 Adic rings

7.1 Admissible rings

(7.1.1) Recall that in a topological ring A (not necessarily separated), an element x is said to be topologically nilpotent if 0 is a limit of the sequence $(x^n)_{n\geq 0}$. A topological ring A is said to be linearly topologized if there exists a fundamental system of neighbourhoods of 0 in A consisting of ideals (necessarily open).

(7.1.2) Definition. In a linearly topologized ring A, an ideal $\mathfrak{J}$ is said to be an ideal of definition if $\mathfrak{J}$ is open and if, for every neighbourhood V of 0, there exists an integer $n > 0$ such
that $\mathfrak{J}^n \subset V$ (which is expressed, by abuse of language, by saying that the sequence $(\mathfrak{J}^n)$ [0$_{\text{I}}$ | 61]
tends to 0). A linearly topologized ring A is said to be preadmissible if there exists in A an ideal of definition; A is said to be admissible if it is preadmissible and if moreover it is separated and complete.

It is clear that if $\mathfrak{J}$ is an ideal of definition and $\mathfrak{L}$ an open ideal of A, then $\mathfrak{J} \cap \mathfrak{L}$ is again an ideal of definition; the ideals of definition of a preadmissible ring A therefore form a fundamental system of neighbourhoods of 0.

(7.1.3) Lemma. *Let A be a linearly topologized ring.*

(i) *For $x \in A$ to be topologically nilpotent, it is necessary and sufficient that for every open ideal $\mathfrak{J}$ of A, the canonical image of x in $A/\mathfrak{J}$ be nilpotent. The set $\mathfrak{T}$ of topologically nilpotent elements of A is an ideal.*

(ii) *Suppose moreover that A is preadmissible, and let $\mathfrak{J}$ be an ideal of definition of A. For $x \in A$ to be topologically nilpotent, it is necessary and sufficient that its canonical image in $A/\mathfrak{J}$ be nilpotent; the ideal $\mathfrak{T}$ is the inverse image of the nilradical of $A/\mathfrak{J}$ and is therefore open.*

(i) follows immediately from the definitions. To prove (ii), it suffices to note that for every neighbourhood V of 0 in A, there exists $n > 0$ such that $\mathfrak{J}^n \subset V$; if $x \in A$ is such that $x^m \in \mathfrak{J}$, we have $x^{mq} \in V$ for $q \geq n$, so x is topologically nilpotent.

(7.1.4) Proposition. *Let A be a preadmissible ring and $\mathfrak{J}$ an ideal of definition of A.*

(i) *For an ideal $\mathfrak{J}'$ of A to be contained in an ideal of definition, it is necessary and sufficient that there exist an integer $n > 0$ such that $\mathfrak{J}'^n \subset \mathfrak{J}$.*

(ii) *For an $x \in A$ to be contained in an ideal of definition, it is necessary and sufficient that it be topologically nilpotent.*

(i) If $\mathfrak{J}'^n \subset \mathfrak{J}$, then for every open neighbourhood V of 0 in A, there exists m such that $\mathfrak{J}^m \subset V$, hence $\mathfrak{J}'^{mn} \subset V$.

(ii) The condition is obviously necessary; it is sufficient, because if it is satisfied, there exists n such that $x^n \in \mathfrak{J}$, so $\mathfrak{J}' = \mathfrak{J} + Ax$ is an ideal of definition, since it is open and $\mathfrak{J}'^n \subset \mathfrak{J}$.

(7.1.5) Corollary. *In a preadmissible ring A, an open prime ideal contains all the ideals of definition.*

(7.1.6) Corollary. *The notation and hypotheses being those of (7.1.4), the following properties of an ideal $\mathfrak{J}_0$ of A are equivalent:*

a) $\mathfrak{J}_0$ is the largest ideal of definition of A;

b) $\mathfrak{J}_0$ is a maximal ideal of definition;

c) $\mathfrak{J}_0$ is an ideal of definition such that the ring $A/\mathfrak{J}_0$ is reduced.

For there to exist an ideal $\mathfrak{J}_0$ having these properties, it is necessary and sufficient that the nilradical of $A/\mathfrak{J}$ be nilpotent; $\mathfrak{J}_0$ is then equal to the ideal $\mathfrak{T}$ of topologically nilpotent elements of A.

It is clear that *a*) implies *b*), and *b*) implies *c*) by virtue of (7.1.4, (ii)) and (7.1.3, (ii)); for the same reason, *c*) implies *a*). The last assertion follows from (7.1.4, (i)) and (7.1.3, (ii)).

When $\mathfrak{T}/\mathfrak{J}$, the nilradical of $A/\mathfrak{J}$, is nilpotent, we denote by A_{red} the (reduced) quotient ring $A/\mathfrak{T}$.

[0_{I} | 62] **(7.1.7) Corollary.** *A Noetherian preadmissible ring has a largest ideal of definition.*

(7.1.8) Corollary. *If a preadmissible ring A is such that, for one ideal of definition $\mathfrak{J}$, the powers $\mathfrak{J}^n$ $(n > 0)$ form a fundamental system of neighbourhoods of 0, then the same holds for the powers $\mathfrak{J}'^n$ of every ideal of definition $\mathfrak{J}'$ of A.*

(7.1.9) Definition. A preadmissible ring A is said to be preadic if there exists an ideal of definition $\mathfrak{J}$ of A such that the $\mathfrak{J}^n$ form a fundamental system of neighbourhoods of 0 in A (or, what amounts to the same, such that the $\mathfrak{J}^n$ are open). An adic ring is a separated and complete preadic ring.

If $\mathfrak{J}$ is an ideal of definition of a preadic (resp. adic) ring A, we also say that A is a $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) ring, and that its topology is the $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) topology. More generally, if M is an A-module, the topology on M having as a fundamental system of neighbourhoods of 0 the submodules $\mathfrak{J}^n M$ is called the $\mathfrak{J}$-*preadic* (resp. $\mathfrak{J}$-*adic*) topology. By virtue of (7.1.8), these topologies are independent of the choice of the ideal of definition $\mathfrak{J}$.

(7.1.10) Proposition. *Let A be an admissible ring and $\mathfrak{J}$ an ideal of definition of A. Then $\mathfrak{J}$ is contained in the radical of A.*

This statement is equivalent to any one of the following corollaries:

(7.1.11) Corollary. *For every $x \in \mathfrak{J}$, $1 + x$ is invertible in A.*

(7.1.12) Corollary. *For $f \in A$ to be invertible in A, it is necessary and sufficient that its canonical image in $A/\mathfrak{J}$ be invertible in $A/\mathfrak{J}$.*

(7.1.13) Corollary. *For every A-module M of finite type, the relation $M = \mathfrak{J}M$ (equivalent to $M \otimes_A (A/\mathfrak{J}) = 0$) implies $M = 0$.*

(7.1.14) Corollary. *Let $u : M \to N$ be a homomorphism of A-modules, N being of finite type; for u to be surjective, it is necessary and sufficient that $u \otimes 1 : M \otimes_A (A/\mathfrak{J}) \to N \otimes_A (A/\mathfrak{J})$ be so.*

Indeed, the equivalence of (7.1.10) and (7.1.11) follows from Bourbaki, *Alg.*, chap. VIII, §6, n° 3, th. 1, and that of (7.1.10) and (7.1.13) from *loc. cit.*, th. 2; the fact that (7.1.10) implies (7.1.14) follows from *loc. cit.*, cor. 4 of prop. 6; on the other hand, (7.1.14) implies (7.1.13) by applying it to the zero homomorphism. Finally, (7.1.10) implies that if f is invertible in $A/\mathfrak{J}$, f is not contained in any maximal ideal of A, so f is invertible in A; in other words, (7.1.10) implies (7.1.12); and conversely, (7.1.12) implies (7.1.11).

Everything therefore comes down to proving (7.1.11). Now, since A is separated and complete and the sequence $(\mathfrak{J}^n)$ tends to 0, it is immediate that the series $\sum_{n=0}^{\infty}(-1)^n x^n$ is convergent in A and that, if y is its sum, we have $y(1 + x) = 1$.

7.2 Adic rings and projective limits

(7.2.1) Every projective limit of discrete rings is obviously a linearly topologized, separated and complete ring. Conversely, let A be a linearly topologized ring, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open neighbourhoods of 0 in A consisting of ideals. The canonical maps $\varphi_\lambda : A \to A/\mathfrak{J}_\lambda$ form a projective system of continuous maps and therefore define a continuous map $\varphi : A \to \varprojlim A/\mathfrak{J}_\lambda$; if A is separated, φ is a topological isomorphism of A onto an everywhere dense subring of $\varprojlim A/\mathfrak{J}_\lambda$; if, moreover, A is complete, φ is a topological isomorphism of A onto $\varprojlim A/\mathfrak{J}_\lambda$. [$0_I$ | 63]

(7.2.2) Lemma. *For a linearly topologized ring to be admissible, it is necessary and sufficient that it be isomorphic to a projective limit $A = \varprojlim A_\lambda$, where $(A_\lambda, u_{\lambda\mu})$ is a projective system of discrete rings having as index set a filtered ordered set L (for $\leq$) which has a smallest element, denoted 0, and satisfies the following conditions: 1° the $u_\lambda : A \to A_\lambda$ are surjective; 2° the kernel $\mathfrak{J}_\lambda$ of $u_{0\lambda} : A_\lambda \to A_0$ is nilpotent. When this is so, the kernel $\mathfrak{J}$ of $u_0 : A \to A_0$ is equal to $\varprojlim \mathfrak{J}_\lambda$.*

The necessity of the condition follows from (7.2.1), by taking for $(\mathfrak{J}_\lambda)$ a fundamental system of neighbourhoods of 0 consisting of ideals of definition contained in one of them, $\mathfrak{J}_0$, and applying (7.1.4, (i)). The converse follows from the definition of a projective limit and from (7.1.2), and the last assertion is immediate.

(7.2.3) Let A be an admissible topological ring and $\mathfrak{J}$ an ideal of A contained in an ideal of definition (in other words (7.1.4) such that $(\mathfrak{J}^n)$ tends to 0); we can consider on A the ring topology having as a fundamental system of neighbourhoods of 0 the powers $\mathfrak{J}^n$ $(n > 0)$; we shall again call it the $\mathfrak{J}$-*preadic* topology. The hypothesis that A is admissible implies that $\bigcap_n \mathfrak{J}^n = 0$, so the $\mathfrak{J}$-preadic topology on A is separated; let $\widehat{A} = \varprojlim A/\mathfrak{J}^n$ be the completion of A for this topology (where the $A/\mathfrak{J}^n$ are endowed with the discrete topology), and denote by u the ring homomorphism $A \to \widehat{A}$ (not necessarily continuous) that is the projective limit of the sequence of homomorphisms $u_n : A \to A/\mathfrak{J}^n$. On the other hand, the $\mathfrak{J}$-preadic topology on A is finer than the given topology $\mathcal{T}$ on A; since A is separated and complete for $\mathcal{T}$, we can extend by continuity the identity map from A (endowed with the $\mathfrak{J}$-preadic topology) to A endowed with $\mathcal{T}$; this gives a continuous map $v : \widehat{A} \to A$.

(7.2.4) Proposition. *If A is an admissible ring and $\mathfrak{J}$ is contained in an ideal of definition of A, then A is separated and complete for the $\mathfrak{J}$-preadic topology.*

Indeed, with the notation of (7.2.3), it is immediate that $v \circ u$ is the identity map of A. On the other hand, $u_n \circ v : \widehat{A} \to A/\mathfrak{J}^n$ is the extension by continuity (for the $\mathfrak{J}$-preadic topology on A and the discrete topology on $A/\mathfrak{J}^n$) of the canonical map u_n; in other words, it is the canonical map of $\widehat{A} = \varprojlim_k A/\mathfrak{J}^k$ onto $A/\mathfrak{J}^n$; $u \circ v$ is therefore the projective limit of this sequence of maps, that is, by definition, the identity map of $\widehat{A}$; this proves the proposition.

(7.2.5) Corollary. *Under the hypotheses of (7.2.3), the following conditions are equivalent:*

a) The homomorphism u is continuous;

b) The homomorphism v is bicontinuous; [0_I | 64]

c) A is a $\mathfrak{J}$-adic ring.

(7.2.6) Corollary. *Let A be an admissible ring and $\mathfrak{J}$ an ideal of definition of A. For A to be Noetherian, it is necessary and sufficient that $A/\mathfrak{J}$ be Noetherian and that $\mathfrak{J}/\mathfrak{J}^2$ be an $(A/\mathfrak{J})$-module of finite type.*

These conditions are obviously necessary. Conversely, suppose they are satisfied; since by virtue of (7.2.4) A is complete for the $\mathfrak{J}$-preadic topology, for it to be Noetherian it is necessary and sufficient that the associated graded ring $\mathrm{grad}(A)$ (for the filtration by the $\mathfrak{J}^n$) be so ([I], p. 18-07, th. 4). Now let $a_1, \ldots, a_n$ be elements of $\mathfrak{J}$ whose classes modulo $\mathfrak{J}^2$ are generators of $\mathfrak{J}/\mathfrak{J}^2$ as an $A/\mathfrak{J}$-module. It is immediate by induction that the classes modulo $\mathfrak{J}^{m+1}$ of the monomials of total degree m in the a_i $(1 \leq i \leq n)$ form a system of generators of the $(A/\mathfrak{J})$-module $\mathfrak{J}^m/\mathfrak{J}^{m+1}$. We conclude that $\mathrm{grad}(A)$ is a ring isomorphic to a quotient of $(A/\mathfrak{J})[T_1, \ldots, T_n]$ (T_i indeterminates), which completes the proof.

(7.2.7) Proposition. *Let (A_i, u_{ij}) be a projective system ($i \in \mathbf{N}$) of discrete rings, and for every integer i, let $\mathfrak{J}_i$ be the kernel in A_i of the homomorphism $u_{0i} : A_i \to A_0$. Suppose that:*

a) For $i \leq j$, u_{ij} is surjective and its kernel is $\mathfrak{J}_j^{i+1}$ (so A_i is isomorphic to $A_j/\mathfrak{J}_j^{i+1}$).

b) $\mathfrak{J}_1/\mathfrak{J}_1^2$ $(= \mathfrak{J}_1)$ is a module of finite type over $A_0 = A_1/\mathfrak{J}_1$.

Let $A = \varprojlim_i A_i$, and for every integer $n \geq 0$, let u_n be the canonical homomorphism $A \to A_n$ and $\mathfrak{J}^{(n+1)} \subset A$ its kernel. Under these conditions:

(i) A is an adic ring, having as an ideal of definition $\mathfrak{J} = \mathfrak{J}^{(1)}$.

(ii) We have $\mathfrak{J}^{(n)} = \mathfrak{J}^n$ for every $n \geq 1$.

(iii) $\mathfrak{J}/\mathfrak{J}^2$ is isomorphic to $\mathfrak{J}_1 = \mathfrak{J}_1/\mathfrak{J}_1^2$, and is consequently a module of finite type over $A_0 = A/\mathfrak{J}$.

The hypothesis that the u_{ij} are surjective implies that u_n is surjective; moreover, hypothesis *a*) implies that $\mathfrak{J}_j^{j+1} = 0$, so A is an admissible ring (7.2.2); by definition, the $\mathfrak{J}^{(n)}$ form a fundamental system of neighbourhoods of 0 in A, so (ii) implies (i). Moreover, we have $\mathfrak{J} = \varprojlim_i \mathfrak{J}_i$ and the maps $\mathfrak{J} \to \mathfrak{J}_i$ are surjective, so (ii) implies (iii), and we are reduced to proving (ii). By definition, $\mathfrak{J}^{(n)}$ consists of the elements $(x_k)_{k\geq 0}$ of A such that $x_k = 0$ for $k < n$, hence $\mathfrak{J}^{(n)}\mathfrak{J}^{(m)} \subset \mathfrak{J}^{(n+m)}$; in other words, the $\mathfrak{J}^{(n)}$ constitute a *filtration* of A. On the other hand, $\mathfrak{J}^{(n)}/\mathfrak{J}^{(n+1)}$ is isomorphic to the projection of $\mathfrak{J}^{(n)}$ onto A_n; since $\mathfrak{J}^{(n)} = \varprojlim_{i>n} \mathfrak{J}_i^n$, this projection is none other than $\mathfrak{J}_n^n$, which is a module over $A_0 = A_n/\mathfrak{J}_n$. Now let $a_j = (a_{jk})_{k\geq 0}$ be r elements of $\mathfrak{J} = \mathfrak{J}^{(1)}$ such that $a_{11}, \ldots, a_{r1}$ form a system of generators of $\mathfrak{J}_1$ over A_0; we shall see that the set S_n of monomials of total degree n in the a_j generates the ideal $\mathfrak{J}^{(n)}$ of A. Since $\mathfrak{J}_i^{i+1} = 0$, it is first of all clear that $S_n \subset \mathfrak{J}^{(n)}$; since A is complete for the filtration $(\mathfrak{J}^{(m)})$, it suffices to prove that the set $\overline{S}_n$ of the classes modulo $\mathfrak{J}^{(n+1)}$ of the elements of S_n generates the graded module $\mathrm{grad}(\mathfrak{J}^{(n)})$ over the graded ring $\mathrm{grad}(A)$ for the preceding filtration ([I], p. 18-06, lemma); by virtue of the definition of multiplication in $\mathrm{grad}(A)$,

[0_I | 65] it will suffice to prove that for every m, $\overline{S}_m$ is a system of generators of the A_0-module $\mathfrak{J}^{(m)}/\mathfrak{J}^{(m+1)}$, or again that $\mathfrak{J}_m^m$ is generated by the monomials of degree m in the a_{jm} $(1 \leq j \leq r)$. For this, it remains to show that $\mathfrak{J}_m$ is (as an A_m-module) generated by the monomials of degree $\leq m$ with respect to the a_{jm}; the proposition being obvious by definition for $m = 1$, let us argue by induction on m, and let $\mathfrak{J}'_m$ be the sub-A_m-module of $\mathfrak{J}_m$ generated by these monomials. The relation $\mathfrak{J}_{m-1} = \mathfrak{J}_m/\mathfrak{J}_m^m$ and the induction

hypothesis prove that $\mathfrak{J}_m = \mathfrak{J}'_m + \mathfrak{J}_m^m$, whence, since $\mathfrak{J}_m^{m+1} = 0$, we obtain $\mathfrak{J}_m^m = {\mathfrak{J}'_m}^m$, and finally $\mathfrak{J}_m = \mathfrak{J}'_m$.

(7.2.8) Corollary. *Under the conditions of (7.2.7), for A to be Noetherian, it is necessary and sufficient that A_0 be so.*

This follows at once from (7.2.6).

(7.2.9) Proposition. *Suppose the hypotheses of (7.2.7) are satisfied: for every integer i, let M_i be an A_i-module, and, for $i \leq j$, let $v_{ij} : M_j \to M_i$ be a u_{ij}-homomorphism, such that (M_i, v_{ij}) is a projective system. Suppose moreover that M_0 is an A_0-module of finite type, that v_{ij} is surjective and that its kernel is $\mathfrak{J}_j^{i+1} M_j$. Then $M = \varprojlim M_i$ is an A-module of finite type, and the kernel of the surjective u_n-homomorphism $v_n : M \to M_n$ is $\mathfrak{J}^{n+1}M$ (so that M_n is identified with $M/\mathfrak{J}^{n+1}M = M \otimes_A (A/\mathfrak{J}^{n+1})$).*

Let $z_h = (z_{hk})_{k\geq 0}$ be a system of s elements of M such that the z_{h0} $(1 \leq h \leq s)$ form a system of generators of M_0; we shall show that the z_h generate the A-module M. The A-module M is separated and complete for the filtration formed by the $M^{(n)}$, where $M^{(n)}$ is the set of the $y = (y_k)_{k\geq 0}$ in M such that $y_k = 0$ for $k < n$; it is clear that we have $\mathfrak{J}^{(n)}M \subset M^{(n)}$ and that $M^{(n)}/M^{(n+1)} = \mathfrak{J}_n^n M_n$. We are therefore reduced to showing that the classes of the z_h modulo $M^{(1)}$ generate the graded module $\mathrm{grad}(M)$ (for the preceding filtration) over the graded ring $\mathrm{grad}(A)$ ([I], p. 18-06, lemma); for this, one easily verifies that it again suffices to prove that the z_{hn} $(1 \leq h \leq s)$ generate the A_n-module M_n. We again argue by induction on n, the proposition being obvious by definition for $n = 0$; the relation $M_{n-1} = M_n/\mathfrak{J}_n^n M_n$ and the induction hypothesis show that if M'_n is the submodule of M_n generated by the z_{hn}, we have $M_n = M'_n + \mathfrak{J}_n^n M_n$, and since $\mathfrak{J}_n$ is nilpotent, this implies $M_n = M'_n$. The same argument of passing to the associated graded modules shows that the canonical map from $\mathfrak{J}^{(n)}M$ to $M^{(n)}$ is surjective (hence bijective), in other words that $\mathfrak{J}^{(n)}M = \mathfrak{J}^n M$ is the kernel of $M \to M_{n-1}$.

(7.2.10) Corollary. *Let (N_i, w_{ij}) be a second projective system of A_i-modules satisfying the conditions of (7.2.9), and let $N = \varprojlim N_i$. There is a one-to-one correspondence between the projective systems (h_i) of A_i-homomorphisms $h_i : M_i \to N_i$ and the homomorphisms of A-modules $h : M \to N$ (which are necessarily continuous for the $\mathfrak{J}$-adic topologies).*

It is clear that if $h : M \to N$ is an A-homomorphism, we have $h(\mathfrak{J}^n M) \subset \mathfrak{J}^n N$, whence the continuity of h; by passage to quotients, there therefore corresponds to h a projective system of A_i-homomorphisms $h_i : M_i \to N_i$, of which h is the projective limit, whence the corollary.

(7.2.11) Remark. Let A be an adic ring having an ideal of definition $\mathfrak{J}$ such that $\mathfrak{J}/\mathfrak{J}^2$ is an $(A/\mathfrak{J})$-module of finite type; it is clear that the $A_i = A/\mathfrak{J}^{i+1}$ satisfy the conditions of (7.2.7); since A is the projective limit of the A_i, we see that Proposition (7.2.7) gives the description of *all* the adic rings of the type considered (and in particular of all the *Noetherian adic* rings). [0_{I} | 66]

(7.2.12) Example. Let B be a ring and $\mathfrak{J}$ an ideal of B such that $\mathfrak{J}/\mathfrak{J}^2$ is a module of finite type over $B/\mathfrak{J}$ (or over B, which amounts to the same); set $A = \varprojlim_n B/\mathfrak{J}^{n+1}$; A is the separated completion of B endowed with the $\mathfrak{J}$-preadic topology. If $A_n = B/\mathfrak{J}^{n+1}$, it is immediate that the A_n satisfy the conditions of (7.2.7); hence A is an adic ring, and if $\overline{\mathfrak{J}}$ is the closure in A of the canonical image of $\mathfrak{J}$, then $\overline{\mathfrak{J}}$ is an ideal of definition of A, $\overline{\mathfrak{J}^n}$ is the closure of the canonical image of $\mathfrak{J}^n$, $A/\overline{\mathfrak{J}^n}$ is identified with $B/\mathfrak{J}^n$, and $\overline{\mathfrak{J}}/\overline{\mathfrak{J}^2}$ is isomorphic to $\mathfrak{J}/\mathfrak{J}^2$ as an $(A/\overline{\mathfrak{J}})$-module. Likewise, if N is such that $N/\mathfrak{J}N$ is a B-module

of finite type, and if we set $M_i = N/\mathfrak{J}^{i+1}N$, then $M = \varprojlim M_i$ is an A-module of finite type, isomorphic to the separated completion of N for the $\mathfrak{J}$-preadic topology, $\overline{\mathfrak{J}^n}M$ is identified with the closure of the canonical image of $\mathfrak{J}^nN$, and $M/\overline{\mathfrak{J}^n}M$ with $N/\mathfrak{J}^nN$.

7.3 Noetherian preadic rings

(7.3.1) Let A be a ring, $\mathfrak{J}$ an ideal of A, and M an A-module; we shall denote by $\widehat{A} = \varprojlim_n A/\mathfrak{J}^n$ (resp. $\widehat{M} = \varprojlim_n M/\mathfrak{J}^nM$) the separated completion of A (resp. M) for the $\mathfrak{J}$-preadic topology. Let

$$M' \xrightarrow{u} M \xrightarrow{v} M'' \to 0$$

be an exact sequence of A-modules; since $M/\mathfrak{J}^nM = M \otimes_A (A/\mathfrak{J}^n)$, the sequence

$$M'/\mathfrak{J}^nM' \xrightarrow{u_n} M/\mathfrak{J}^nM \xrightarrow{v_n} M''/\mathfrak{J}^nM'' \to 0$$

is exact for every n. Moreover, since $v(\mathfrak{J}^nM) = \mathfrak{J}^nv(M) = \mathfrak{J}^nM''$, $\widehat{v} = \varprojlim v_n$ is surjective (Bourbaki, *Top. gén.*, chap. IX, 2nd ed., p. 60, cor. 2). On the other hand, if $z = (z_k)$ is an element of the kernel of $\widehat{v}$, then for every integer k there exists a $z'_k \in M'/\mathfrak{J}^kM'$ such that $u_k(z'_k) = z_k$; we conclude that there exists $z' = (z'_n) \in \widehat{M'}$ such that the first k components of $\widehat{u}(z')$ coincide with those of z; in other words, the image under $\widehat{u}$ of $\widehat{M'}$ is *dense* in the kernel of $\widehat{v}$.

If A is assumed *Noetherian*, so is $\widehat{A}$, by virtue of (7.2.12), since $\mathfrak{J}/\mathfrak{J}^2$ is then an A-module of finite type. Moreover:

(7.3.2) Krull's theorem. *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A, M an A-module of finite type, and M' a submodule of M; then the topology induced on M' by the $\mathfrak{J}$-preadic topology of M is identical to the $\mathfrak{J}$-preadic topology of M'.*

This follows at once from the

(7.3.2.1) Artin–Rees lemma. *Under the hypotheses of (7.3.2), there exists an integer p such that, for $n \geq p$, we have*

$$M' \cap \mathfrak{J}^nM = \mathfrak{J}^{n-p}(M' \cap \mathfrak{J}^pM).$$

For the proof, see ([I], p. 2-04).

[0_I | 67] **(7.3.3) Corollary.** *Under the hypotheses of (7.3.2), the canonical map $M \otimes_A \widehat{A} \to \widehat{M}$ is bijective, and the functor $M \otimes_A \widehat{A}$ is exact in M in the category of A-modules of finite type; consequently, the $\mathfrak{J}$-adic separated completion $\widehat{A}$ is a flat A-module (6.1.1).*

Let us first note that in the category of A-modules of finite type, $\widehat{M}$ is an *exact* functor in M. Indeed, let

$$0 \to M' \xrightarrow{u} M \xrightarrow{v} M'' \to 0$$

be an exact sequence; we already know that $\widehat{v} : \widehat{M} \to \widehat{M''}$ is surjective (7.3.1); on the other hand, if i is the canonical homomorphism $M \to \widehat{M}$, it follows from Krull's theorem that the closure in $\widehat{M}$ of $i(u(M'))$ is identified with the separated completion of M' for the $\mathfrak{J}$-preadic topology; hence $\widehat{u}$ is injective, and by virtue of (7.3.1) the image of $\widehat{u}$ is equal to the kernel of $\widehat{v}$.

That being so, the canonical map $M \otimes_A \widehat{A} \to \widehat{M}$ is obtained by passing to the projective limit over the maps

$$M \otimes_A \widehat{A} \to M \otimes_A (A/\mathfrak{J}^n) = M/\mathfrak{J}^nM.$$

It is clear that this map is bijective when M is of the form A^p. If M is an A-module of finite type, we have an exact sequence $A^p \to A^q \to M \to 0$, whence, by virtue of the *right* exactness of the functors $M \otimes_A \widehat{A}$ and $\widehat{M}$ (in M) in the category of A-modules of finite type, the commutative diagram

$$\begin{array}{ccccccc} A^p \otimes_A \widehat{A} & \longrightarrow & A^q \otimes_A \widehat{A} & \longrightarrow & M \otimes_A \widehat{A} & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ \widehat{A}^p & \longrightarrow & \widehat{A}^q & \longrightarrow & \widehat{M} & \longrightarrow & 0 \end{array}$$

where the two rows are exact and the first two vertical arrows are isomorphisms; the conclusion follows at once.

(7.3.4) Corollary. *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A, and M, N two A-modules of finite type; we have canonical functorial isomorphisms*

$$(M \otimes_A N)^\wedge \xrightarrow{\sim} \widehat{M} \otimes_{\widehat{A}} \widehat{N}, \qquad \big(\mathrm{Hom}_A(M,N)\big)^\wedge \xrightarrow{\sim} \mathrm{Hom}_{\widehat{A}}(\widehat{M},\widehat{N}).$$

This follows from (7.3.3), (6.2.1) and (6.2.2).

(7.3.5) Corollary. *Let A be a Noetherian ring and $\mathfrak{J}$ an ideal of A. The following conditions are equivalent:*

a) *$\mathfrak{J}$ is contained in the radical of A.*

b) *$\widehat{A}$ is a faithfully flat A-module (6.4.1).*

c) *Every A-module of finite type is separated for the $\mathfrak{J}$-preadic topology.*

d) *Every submodule of an A-module of finite type is closed for the $\mathfrak{J}$-preadic topology.*

Since $\widehat{A}$ is a flat A-module, conditions *b*) and *c*) are equivalent, because *b*) amounts to saying that if M is an A-module of finite type, the canonical map $M \to \widehat{M} = M \otimes_A \widehat{A}$ is injective (6.6.1, *c*)). It is immediate that *c*) implies *d*), because if N is a submodule of an A-module M of finite type, M/N is separated for the $\mathfrak{J}$-preadic topology, so N is closed in M. Let us show that *d*) implies *a*): if $\mathfrak{m}$ is a maximal ideal of A, $\mathfrak{m}$ is closed in A for the $\mathfrak{J}$-preadic topology, so

$$\mathfrak{m} = \bigcap_{p \geq 0} (\mathfrak{m} + \mathfrak{J}^p),$$

and since $\mathfrak{m} + \mathfrak{J}^p$ is necessarily equal to A or to $\mathfrak{m}$, we have $\mathfrak{m} + \mathfrak{J}^p = \mathfrak{m}$ for p sufficiently large, whence $\mathfrak{J}^p \subset \mathfrak{m}$ and $\mathfrak{J} \subset \mathfrak{m}$ since $\mathfrak{m}$ is prime. Finally, *a*) implies *b*): indeed, let P [0I | 68] be the closure of $\{0\}$ in an A-module M of finite type, for the $\mathfrak{J}$-preadic topology; by virtue of Krull's theorem (7.3.2), the topology induced on P by the $\mathfrak{J}$-preadic topology of M is the $\mathfrak{J}$-preadic topology of P, so $\mathfrak{J}P = P$; since P is of finite type, it follows from Nakayama's lemma that $P = 0$ ($\mathfrak{J}$ being contained in the radical of A).

Note that the conditions of (7.3.5) are satisfied when A is a *Noetherian local ring* and $\mathfrak{J} \neq A$ is an arbitrary ideal of A.

(7.3.6) Corollary. *If A is a Noetherian $\mathfrak{J}$-adic ring, every A-module of finite type is separated and complete for the $\mathfrak{J}$-preadic topology.*

Since we then have $\widehat{A} = A$, this follows at once from (7.3.3).

We conclude that Proposition (7.2.9) gives the description of *all* the modules of finite type over a Noetherian adic ring.

(7.3.7) Corollary. *Under the hypotheses of (7.3.2), the kernel of the canonical map* $M \to \widehat{M} = M \otimes_A \widehat{A}$ *is the set of* $x \in M$ *annihilated by an element of* $1 + \mathfrak{J}$.

Indeed, for $x \in M$ to belong to this kernel, it is necessary and sufficient that the separated completion of the submodule Ax reduce to 0 (by (7.3.2)), in other words that $x \in \mathfrak{J}x$.

7.4 Quasi-finite modules over local rings

(7.4.1) Definition. Given a local ring A with maximal ideal $\mathfrak{m}$, an A-module M is said to be quasi-finite (over A) if $M/\mathfrak{m}M$ is of finite rank over the residue field $k = A/\mathfrak{m}$.

When A is Noetherian, the separated completion $\widehat{M}$ of M for the $\mathfrak{m}$-preadic topology is then an $\widehat{A}$-*module of finite type*; indeed, since $\mathfrak{m}/\mathfrak{m}^2$ is then an A-module of finite type, this follows from (7.2.12) and from the hypothesis on $M/\mathfrak{m}M$.

In particular, if we suppose moreover that A is *complete* and M *separated* for the $\mathfrak{m}$-preadic topology (in other words, $\bigcap_n \mathfrak{m}^n M = 0$), then M itself is an A-*module of finite type*: indeed, $\widehat{M}$ is then an A-module of finite type, and since M is identified with a submodule of $\widehat{M}$, M is also of finite type (and moreover identical to its completion by virtue of (7.3.6)).

(7.4.2) Proposition. *Let* A, B *be two local rings,* $\mathfrak{m}$, $\mathfrak{n}$ *their maximal ideals, and suppose* B *Noetherian. Let* $\varphi : A \to B$ *be a local homomorphism and* M *a* B*-module of finite type. If* M *is a quasi-finite* A*-module, the* $\mathfrak{m}$*-preadic and* $\mathfrak{n}$*-preadic topologies on* M *are identical, hence separated.*

Let us observe that by hypothesis $M/\mathfrak{m}M$ is of *finite length* as an A-module, hence also *a fortiori* as a B-module. We conclude that $\mathfrak{n}$ is the *only prime ideal* of B containing the annihilator of $M/\mathfrak{m}M$: indeed, we immediately reduce, by virtue of (I.7.4) and (I.7.2), to the case where $M/\mathfrak{m}M$ is *simple*, hence necessarily isomorphic to $B/\mathfrak{n}$, and our assertion is obvious in this last case. On the other hand, since M is a B-module of finite type, the prime ideals that contain the annihilator of $M/\mathfrak{m}M$ are those that contain $\mathfrak{m}B + \mathfrak{b}$, where $\mathfrak{b}$ denotes the annihilator of the B-module M (I.7.5). Since B is Noetherian, we conclude ([III], p. 127, cor. 4) that $\mathfrak{m}B + \mathfrak{b}$ is an ideal
[0_{I} | 69] of definition of B, in other words that there exists $k > 0$ such that $\mathfrak{n}^k \subset \mathfrak{m}B + \mathfrak{b} \subset \mathfrak{n}$; consequently, for every $h > 0$

$$\mathfrak{n}^{hk} M \subset (\mathfrak{m}B + \mathfrak{b})^h M = \mathfrak{m}^h M \subset \mathfrak{n}^h M,$$

which proves that the $\mathfrak{m}$-preadic and $\mathfrak{n}$-preadic topologies on M are the same; the second is moreover separated by virtue of (7.3.5).

(7.4.3) Corollary. *Under the hypotheses of (7.4.2), if moreover* A *is Noetherian and complete for the* $\mathfrak{m}$*-preadic topology,* M *is an* A*-module of finite type.*

Indeed, M is then separated for the $\mathfrak{m}$-preadic topology, and our assertion follows from the remark made in (7.4.1).

(7.4.4) The most important case of application of (7.4.2) is the one where B itself is a *quasi-finite* A*-module*, which amounts to saying that $B/\mathfrak{m}B$ is an *algebra of finite rank over* $k = A/\mathfrak{m}$; this condition can moreover be decomposed into the conjunction of the following two, by virtue of what precedes:

(i) $\mathfrak{m}B$ *is an ideal of definition of* B;

(ii) $B/\mathfrak{n}$ *is an extension of finite rank of the field* $A/\mathfrak{m}$.

When this is so, every B-module of finite type is obviously a quasi-finite A-module.

(7.4.5) Corollary. *Under the hypotheses of (7.4.2), if* $\mathfrak{b}$ *is the annihilator of the* B*-module* M*,* $B/\mathfrak{b}$ *is a quasi-finite* A*-module.*

Suppose $M \neq 0$ (otherwise the corollary is obvious). We can consider M as a module over the Noetherian local ring $B/\mathfrak{b}$; its annihilator then being reduced to 0, the proof of (7.4.2) shows that $\mathfrak{m}(B/\mathfrak{b})$ is an ideal of definition of $B/\mathfrak{b}$. Furthermore, $M/\mathfrak{n}M$ is a vector space of finite rank over $A/\mathfrak{m}$, being a quotient of $M/\mathfrak{m}M$, which is by hypothesis of finite rank over $A/\mathfrak{m}$; since $M \neq 0$, we have $M \neq \mathfrak{n}M$ by virtue of Nakayama's lemma; since $M/\mathfrak{n}M$ is a vector space $\neq 0$ over $B/\mathfrak{n}$, the fact that it is of finite rank over $A/\mathfrak{m}$ implies that $B/\mathfrak{n}$ is also of finite rank over $A/\mathfrak{m}$; the conclusion therefore follows from (7.4.4) applied to the ring $B/\mathfrak{b}$.

7.5 Rings of restricted formal power series

(7.5.1) Let A be a topological ring that is linearly topologized, separated and complete; let $(\mathfrak{J}_\lambda)$ be a fundamental system of neighbourhoods of 0 in A consisting of (open) ideals, so that A is canonically identified with $\varprojlim A/\mathfrak{J}_\lambda$ (7.2.1). For every λ, let $B_\lambda = (A/\mathfrak{J}_\lambda)[T_1, \ldots, T_r]$, where the T_i are indeterminates; it is clear that the B_λ form a projective system of discrete rings. We shall set $\varprojlim B_\lambda = A\{T_1, \ldots, T_r\}$, and we shall see that this topological ring is independent of the fundamental system of ideals $(\mathfrak{J}_\lambda)$ considered. More precisely, let A' be the subring of the ring of formal power series $A[\![T_1, \ldots, T_r]\!]$ consisting of the formal power series $\sum_\alpha c_\alpha T^\alpha$ (with $\alpha = (\alpha_1, \ldots, \alpha_r) \in \mathbf{N}^r$) such that $\lim_\alpha c_\alpha = 0$ (along the filter of complements of finite subsets of $\mathbf{N}^r$); we shall say that these series are the *restricted* formal power series in the T_i, with coefficients in A.

For every neighbourhood V of 0 in A, let V' be the set of $x = \sum_\alpha c_\alpha T^\alpha \in A'$ such that $c_\alpha \in V$ for every α. One verifies at once that the V' form a fundamental system of neighbourhoods of 0 defining on A' a *separated* ring topology; we shall define canonically a *topological isomorphism* of the ring $A\{T_1, \ldots, T_r\}$ onto A'. For every $\alpha \in \mathbf{N}^r$ and every λ, let $\varphi_{\lambda,\alpha}$ be the map from $(A/\mathfrak{J}_\lambda)[T_1, \ldots, T_r]$ to $A/\mathfrak{J}_\lambda$ which assigns to every polynomial of the first ring the coefficient of T^α in this polynomial. It is clear that the $\varphi_{\lambda,\alpha}$ form a projective system of homomorphisms of $(A/\mathfrak{J}_\lambda)$-modules, whose projective limit is a continuous homomorphism $\varphi_\alpha : A\{T_1, \ldots, T_r\} \to A$; we shall see that, for every $y \in A\{T_1, \ldots, T_r\}$, the formal power series $\sum_\alpha \varphi_\alpha(y) T^\alpha$ is *restricted*. Indeed, if y_λ is the component of y in B_λ, and if we denote by H_λ the finite set of the $\alpha \in \mathbf{N}^r$ for which the coefficients of the polynomial y_λ are not zero, we have $\varphi_{\mu,\alpha}(y_\mu) \in \mathfrak{J}_\lambda$ for $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ and $\alpha \notin H_\lambda$, and, by passage to the limit, $\varphi_\alpha(y) \in \mathfrak{J}_\lambda$ for $\alpha \notin H_\lambda$. We therefore define a ring homomorphism $\varphi : A\{T_1, \ldots, T_r\} \to A'$ by setting $\varphi(y) = \sum_\alpha \varphi_\alpha(y) T^\alpha$, and it is immediate that φ is continuous. Conversely, if θ_λ is the canonical homomorphism $A \to A/\mathfrak{J}_\lambda$, then for every element $z = \sum_\alpha c_\alpha T^\alpha \in A'$ and every λ, there is only a finite number of indices α such that $\theta_\lambda(c_\alpha) \neq 0$, and consequently $\psi_\lambda(z) = \sum_\alpha \theta_\lambda(c_\alpha) T^\alpha$ belongs to B_λ; the ψ_λ are continuous and form a projective system of homomorphisms whose projective limit is a continuous homomorphism $\psi : A' \to A\{T_1, \ldots, T_r\}$; finally, it remains to verify that $\varphi \circ \psi$ and $\psi \circ \varphi$ are the identity automorphisms, which is immediate. [0I | 70]

(7.5.2) We shall identify $A\{T_1,\dots,T_r\}$ with the ring A' of restricted formal power series by means of the isomorphisms defined in (7.5.1). The canonical isomorphisms

$$((A/\mathfrak{J}_\lambda)[T_1,\dots,T_r])[T_{r+1},\dots,T_s] \xrightarrow{\sim} (A/\mathfrak{J}_\lambda)[T_1,\dots,T_s]$$

define, by passage to the projective limit, a canonical isomorphism

$$(A\{T_1,\dots,T_r\})\{T_{r+1},\dots,T_s\} \xrightarrow{\sim} A\{T_1,\dots,T_s\}$$

(7.5.3) For every continuous homomorphism $u : A \to B$ from A to a linearly topologized ring B that is separated and complete, and every system $(b_1,\dots,b_r)$ of r elements of B, there exists *one and only one continuous homomorphism* $\overline{u} : A\{T_1,\dots,T_r\} \to B$ such that $\overline{u}(a) = u(a)$ for every $a \in A$ and $\overline{u}(T_j) = b_j$ for $1 \leq j \leq r$. Indeed, it suffices to take

$$\overline{u}\Big(\sum_\alpha c_\alpha T^\alpha\Big) = \sum_\alpha u(c_\alpha) b_1^{\alpha_1}\cdots b_r^{\alpha_r} \ ;$$

the verifications of the fact that the family $(u(c_\alpha)b_1^{\alpha_1}\cdots b_r^{\alpha_r})$ is summable in B and of the continuity of $\overline{u}$ are immediate and are left to the reader. Note that this property (for arbitrary B and b_j) *characterizes* the topological ring $A\{T_1,\dots,T_r\}$ up to unique isomorphism.

(7.5.4) Proposition.

(i) If A is an admissible ring, so is $A' = A\{T_1,\dots,T_r\}$.

(ii) Let A be an adic ring and $\mathfrak{J}$ an ideal of definition of A such that $\mathfrak{J}/\mathfrak{J}^2$ is of finite type

[0$_I$ / 71] *over $A/\mathfrak{J}$. If we set $\mathfrak{J}' = \mathfrak{J}A'$, then A' is a $\mathfrak{J}'$-adic ring, and $\mathfrak{J}'/\mathfrak{J}'^2$ is of finite type over $A'/\mathfrak{J}'$. If, moreover, A is Noetherian, so is A'.*

(i) If $\mathfrak{J}$ is an ideal of A and $\mathfrak{J}'$ the ideal of A' consisting of the $\sum_\alpha c_\alpha T^\alpha$ such that $c_\alpha \in \mathfrak{J}$ for every α, then $(\mathfrak{J}')^n \subset (\mathfrak{J}^n)'$; if $\mathfrak{J}$ is an ideal of definition of A, $\mathfrak{J}'$ is therefore an ideal of definition of A'.

(ii) Set $A_i = A/\mathfrak{J}^{i+1}$, and for $i \leq j$, let u_{ij} be the canonical homomorphism $A/\mathfrak{J}^{j+1} \to A/\mathfrak{J}^{i+1}$; set $A'_i = A_i[T_1,\dots,T_r]$, and let u'_{ij} be the homomorphism $A'_j \to A'_i$ $(i \leq j)$ obtained by applying u_{ij} to the coefficients of the polynomials of A'_j. Let us show that the projective system (A'_i, u'_{ij}) satisfies the conditions of (7.2.7); since $\mathfrak{J}'$ is the kernel of $A' \to A'_0$, this will prove the first assertion of (ii). Now, it is clear that the u'_{ij} are surjective; the kernel $\mathfrak{J}'_i$ of u'_{0i} is the set of polynomials of $A_i[T_1,\dots,T_r]$ whose coefficients lie in $\mathfrak{J}/\mathfrak{J}^{i+1}$; in particular, $\mathfrak{J}'_1$ is the set of polynomials of $A_1[T_1,\dots,T_r]$ whose coefficients lie in $\mathfrak{J}/\mathfrak{J}^2$. Since $\mathfrak{J}/\mathfrak{J}^2$ is of finite type over $A_1 = A/\mathfrak{J}^2$, we see already that $\mathfrak{J}'_1/\mathfrak{J}'^2_1$ is a module of finite type over A'_1 (or, what amounts to the same, over $A'_0 = A'_1/\mathfrak{J}'_1$). Let us show that the kernel of u'_{ij} is $\mathfrak{J}'^{i+1}_j$. It is obvious that $\mathfrak{J}'^{i+1}_j$ is contained in this kernel. On the other hand, let $a_1,\dots,a_m$ be elements of $\mathfrak{J}$ whose classes modulo $\mathfrak{J}^2$ generate $\mathfrak{J}/\mathfrak{J}^2$; one verifies immediately that the classes modulo $\mathfrak{J}^{j+1}$ of the monomials of degree $\leq j$ in the a_k $(1 \leq k \leq m)$ generate $\mathfrak{J}/\mathfrak{J}^{j+1}$, and the classes of the monomials of degree $> i$ and $\leq j$ therefore generate $\mathfrak{J}^{i+1}/\mathfrak{J}^{j+1}$; a monomial in the T_k having such an element as coefficient is therefore a product of $i+1$ elements of $\mathfrak{J}'_j$, which establishes our assertion. Finally, if A is Noetherian, so is $A'/\mathfrak{J}' = (A/\mathfrak{J})[T_1,\dots,T_r]$, hence A' is Noetherian (7.2.8).

(7.5.5) Proposition. *Let A be a Noetherian $\mathfrak{J}$-adic ring, B an admissible topological ring, and $\varphi : A \to B$ a continuous homomorphism making B an A-algebra. The following conditions are equivalent:*

a) B is Noetherian and $\mathfrak{J}B$-adic, and $B/\mathfrak{J}B$ is an algebra of finite type over $A/\mathfrak{J}$.

b) B is topologically A-isomorphic to $\varprojlim B_n$, where $B_n = B_m/\mathfrak{J}^{n+1}B_m$ for $m \geq n$, and B_1 is an algebra of finite type over $A_1 = A/\mathfrak{J}^2$.

c) B is topologically A-isomorphic to a quotient of an algebra of the form $A\{T_1, \ldots, T_r\}$ by an ideal (necessarily closed by virtue of (7.3.6) and (7.5.4 (ii))).

Since A is Noetherian, so is $A' = A\{T_1, \ldots, T_r\}$ (7.5.4), hence c) implies that B is Noetherian; since $\mathfrak{J}' = \mathfrak{J}A'$ is an open neighbourhood of 0 in A' such that the $\mathfrak{J}'^n$ form a fundamental system of neighbourhoods of 0, the images $\mathfrak{J}^n B$ of the $\mathfrak{J}'^n$ form a fundamental system of neighbourhoods of 0 in B, and since we know that B is separated and complete, B is a $\mathfrak{J}B$-adic ring. Finally, $B/\mathfrak{J}B$ is an algebra (over $A/\mathfrak{J}$) that is a quotient of $A'/\mathfrak{J}A' = (A/\mathfrak{J})[T_1, \ldots, T_r]$, hence is of finite type, which completes the proof that c) implies a).

If B is $\mathfrak{J}B$-adic and Noetherian, B is isomorphic to $\varprojlim B_n$, where $B_n = B/\mathfrak{J}^{n+1}B$ (7.2.11), and $\mathfrak{J}B/\mathfrak{J}^2B$ is a module of finite type over $B/\mathfrak{J}B$. Let $(a_j)_{1\leq j\leq s}$ be a system of generators of the $(B/\mathfrak{J}B)$-module $\mathfrak{J}B/\mathfrak{J}^2B$, and $(c_i)_{1\leq i\leq r}$ a system of elements of $B/\mathfrak{J}^2B$ whose classes
modulo $\mathfrak{J}B/\mathfrak{J}^2B$ form a system of generators of the $(A/\mathfrak{J})$-algebra $B/\mathfrak{J}B$; one sees at [0_{I} | 72]
once that the c_i, a_j form a system of generators of the $(A/\mathfrak{J}^2)$-algebra $B/\mathfrak{J}^2B$, hence a) implies b).

It remains to prove that b) implies c). The hypothesis implies that B_1 is a Noetherian ring, and since $B_1 = B_2/\mathfrak{J}^2B_2$, we have $\mathfrak{J}^2B_1 = 0$, so $\mathfrak{J}B_1 = \mathfrak{J}B_1/\mathfrak{J}^2B_1$ is a B_0-module of finite type. The conditions of (7.2.7) are therefore satisfied by the projective system (B_n), and B is a $\mathfrak{J}B$-adic ring. Let $(c_i)_{1\leq i\leq r}$ be a finite system of elements of B whose classes modulo $\mathfrak{J}B$ generate the $(A/\mathfrak{J})$-algebra $B/\mathfrak{J}B$, and whose linear combinations with coefficients in $\mathfrak{J}$ are such that their classes modulo $\mathfrak{J}^2B$ generate the B_0-module $\mathfrak{J}B/\mathfrak{J}^2B$. There exists a continuous A-homomorphism u from $A' = A\{T_1, \ldots, T_r\}$ to B which reduces to φ on A and is such that $u(T_i) = c_i$ for $1 \leq i \leq r$ (7.5.3); if we prove that u is *surjective*, c) will be established, for from $u(A') = B$ we shall deduce $u(\mathfrak{J}^n A') = \mathfrak{J}^n B$; in other words, u will be a strict morphism of topological rings, and B will therefore be isomorphic to a quotient of A' by a closed ideal. Now, since B is complete for the $\mathfrak{J}B$-adic topology, it suffices ([I], p. 18-07) to show that the homomorphism $\mathrm{grad}(A') \to \mathrm{grad}(B)$ deduced canonically from u for the $\mathfrak{J}$-adic filtrations on A' and B is surjective. But by definition, the homomorphisms $A'/\mathfrak{J}A' \to B/\mathfrak{J}B$ and $\mathfrak{J}A'/\mathfrak{J}^2A' \to \mathfrak{J}B/\mathfrak{J}^2B$ deduced from u are surjective; by induction on n, one deduces at once that the same holds for $\mathfrak{J}A'/\mathfrak{J}^nA' \to \mathfrak{J}B/\mathfrak{J}^nB$, and *a fortiori* for $\mathfrak{J}^nA'/\mathfrak{J}^{n+1}A' \to \mathfrak{J}^nB/\mathfrak{J}^{n+1}B$, which completes the proof.

7.6 Complete rings of fractions

(7.6.1) Let A be a linearly topologized ring, $(\mathfrak{J}_\lambda)$ a fundamental system of neighbourhoods of 0 in A consisting of ideals, and S a multiplicative subset of A. Let u_λ be the canonical homomorphism $A \to A_\lambda = A/\mathfrak{J}_\lambda$, and for $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$, let $u_{\lambda\mu}$ be the canonical homomorphism $A_\mu \to A_\lambda$. Set $S_\lambda = u_\lambda(S)$, so that $u_{\lambda\mu}(S_\mu) = S_\lambda$. The $u_{\lambda\mu}$ canonically

give surjective homomorphisms $S_\mu^{-1}A_\mu \to S_\lambda^{-1}A_\lambda$, for which these rings form a projective system; denote by $A\{S^{-1}\}$ the projective limit of this system. This definition does not depend on the fundamental system of neighbourhoods $(\mathfrak{J}_\lambda)$ chosen; indeed:

(7.6.2) Proposition. *The ring $A\{S^{-1}\}$ is topologically isomorphic to the separated completion of the ring $S^{-1}A$ for the topology of which a fundamental system of neighbourhoods of 0 is formed by the $S^{-1}\mathfrak{J}_\lambda$.*

Indeed, if v_λ is the canonical homomorphism $S^{-1}A \to S_\lambda^{-1}A_\lambda$ deduced from u_λ, the kernel of v_λ is $S^{-1}\mathfrak{J}_\lambda$ and v_λ is surjective, whence the proposition (7.2.1).

(7.6.3) Corollary. *If S' is the canonical image of S in the separated completion $\widehat{A}$ of A, then $A\{S^{-1}\}$ is canonically identified with $\widehat{A}\{S'^{-1}\}$.*

Note that even if A is separated and complete, the same is not true of $S^{-1}A$ for the topology defined by the $S^{-1}\mathfrak{J}_\lambda$, as one sees for example by taking for S the set of the f^n $(n \geq 0)$, where f is topologically nilpotent and not nilpotent: indeed, $S^{-1}A$ does not reduce to 0, and on the other hand, for every λ there exists n such that $f^n \in \mathfrak{J}_\lambda$, hence $1 = f^n/f^n \in S^{-1}\mathfrak{J}_\lambda$ and $S^{-1}\mathfrak{J}_\lambda = S^{-1}A$.

[0_{I} | 73] **(7.6.4) Corollary.** *If, in A, 0 is not adherent to S, the ring $A\{S^{-1}\}$ does not reduce to 0.*

Indeed, 0 is not adherent to $\{1\}$ in the ring $S^{-1}A$; otherwise, we would have $1 \in S^{-1}\mathfrak{J}_\lambda$ for every open ideal $\mathfrak{J}_\lambda$ of A, and it would follow that $\mathfrak{J}_\lambda \cap S \neq \varnothing$ for every λ, contrary to the hypothesis.

(7.6.5) We shall say that $A\{S^{-1}\}$ is the *complete ring of fractions* of A with denominators in S. With the preceding notation, it is clear that the inverse image of $S^{-1}\mathfrak{J}_\lambda$ in A contains $\mathfrak{J}_\lambda$, so the canonical map $A \to S^{-1}A$ is continuous, and if it is composed with the canonical map $S^{-1}A \to A\{S^{-1}\}$, one obtains a continuous canonical homomorphism $A \to A\{S^{-1}\}$, the projective limit of the homomorphisms $A \to S_\lambda^{-1}A_\lambda$.

(7.6.6) The pair formed by $A\{S^{-1}\}$ and the canonical map $A \to A\{S^{-1}\}$ is characterized by the following *universal property*: every continuous homomorphism u from A to a linearly topologized ring B that is separated and complete, such that $u(S)$ consists of elements invertible in B, factors in one and only one way as $A \to A\{S^{-1}\} \xrightarrow{u'} B$, where u' is continuous. Indeed, u factors in one and only one way as $A \to S^{-1}A \xrightarrow{v'} B$; since for every open ideal $\mathfrak{K}$ of B, $u^{-1}(\mathfrak{K})$ contains some $\mathfrak{J}_\lambda$, $v'^{-1}(\mathfrak{K})$ necessarily contains $S^{-1}\mathfrak{J}_\lambda$, so v' is continuous; since B is separated and complete, v' factors in one and only one way as $S^{-1}A \to A\{S^{-1}\} \xrightarrow{u'} B$, where u' is continuous; whence our assertion.

(7.6.7) Let B be a second linearly topologized ring, T a multiplicative subset of B, and $\varphi : A \to B$ a continuous homomorphism such that $\varphi(S) \subset T$. By what precedes, the continuous homomorphism $A \xrightarrow{\varphi} B \to B\{T^{-1}\}$ factors uniquely as $A \to A\{S^{-1}\} \xrightarrow{\varphi'} B\{T^{-1}\}$, where φ' is continuous. In particular, if $B = A$ and φ is the identity, we see that for $S \subset T$ we have a continuous homomorphism $\rho^{T,S} : A\{S^{-1}\} \to A\{T^{-1}\}$ obtained by passing to the separated completion from $S^{-1}A \to T^{-1}A$; if U is a third multiplicative subset of A such that $S \subset T \subset U$, we have $\rho^{U,S} = \rho^{U,T} \circ \rho^{T,S}$.

(7.6.8) Let S_1, S_2 be two multiplicative subsets of A, and let S_2' be the canonical image of S_2 in $A\{S_1^{-1}\}$; we then have a canonical topological isomorphism $A\{(S_1S_2)^{-1}\} \xrightarrow{\sim} A\{S_1^{-1}\}\{S_2'^{-1}\}$, as one sees by starting from the canonical isomorphism $(S_1S_2)^{-1}A \xrightarrow{\sim} S_2''^{-1}(S_1^{-1}A)$ (where S_2'' is the canonical image of S_2 in $S_1^{-1}A$), which is bicontinuous.

(7.6.9) Let $\mathfrak{a}$ be an *open* ideal of A; we may assume that $\mathfrak{J}_\lambda \subset \mathfrak{a}$ for every λ, and consequently $S^{-1}\mathfrak{J}_\lambda \subset S^{-1}\mathfrak{a}$ in the ring $S^{-1}A$; in other words, $S^{-1}\mathfrak{a}$ is an *open* ideal of $S^{-1}A$; we shall denote by $\mathfrak{a}\{S^{-1}\}$ its separated completion, equal to $\varprojlim(S^{-1}\mathfrak{a}/S^{-1}\mathfrak{J}_\lambda)$, which is an *open* ideal of $A\{S^{-1}\}$, isomorphic to the closure of the canonical image of $S^{-1}\mathfrak{a}$. Moreover, *the discrete ring* $A\{S^{-1}\}/\mathfrak{a}\{S^{-1}\}$ *is canonically isomorphic to* $S^{-1}A/S^{-1}\mathfrak{a} = S^{-1}(A/\mathfrak{a})$. Conversely, if $\mathfrak{a}'$ is an open ideal of $A\{S^{-1}\}$, $\mathfrak{a}'$ contains an ideal of the form $\mathfrak{J}_\lambda\{S^{-1}\}$, hence is the inverse image of an ideal of $S^{-1}A/S^{-1}\mathfrak{J}_\lambda$, which is necessarily (1.2.6) of the form $S^{-1}\mathfrak{a}$, where $\mathfrak{a} \supset \mathfrak{J}_\lambda$. We conclude that we have $\mathfrak{a}' = \mathfrak{a}\{S^{-1}\}$. In particular (1.2.6):

(7.6.10) Proposition. *The map* $\mathfrak{p} \mapsto \mathfrak{p}\{S^{-1}\}$ *is an increasing bijection of the set of open prime ideals* $\mathfrak{p}$ *of* A *such that* $\mathfrak{p} \cap S = \varnothing$ *onto the set of open prime ideals of* $A\{S^{-1}\}$*; moreover, the field of fractions of* $A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ *is canonically isomorphic to that of* $A/\mathfrak{p}$. [0I / 74]

(7.6.11) Proposition.

(i) *If* A *is an admissible ring, so is* $A' = A\{S^{-1}\}$*, and for every ideal of definition* $\mathfrak{J}$ *of* A*,* $\mathfrak{J}' = \mathfrak{J}\{S^{-1}\}$ *is an ideal of definition of* A'.

(ii) *Let* A *be an adic ring and* $\mathfrak{J}$ *an ideal of definition of* A *such that* $\mathfrak{J}/\mathfrak{J}^2$ *is of finite type over* $A/\mathfrak{J}$*; then* A' *is a* $\mathfrak{J}'$*-adic ring and* $\mathfrak{J}'/\mathfrak{J}'^2$ *is of finite type over* $A'/\mathfrak{J}'$*. If moreover* A *is Noetherian, so is* A'.

(i) If $\mathfrak{J}$ is an ideal of definition in A, it is clear that $S^{-1}\mathfrak{J}$ is an ideal of definition in the topological ring $S^{-1}A$, since we have $(S^{-1}\mathfrak{J})^n = S^{-1}\mathfrak{J}^n$. Let A'' be the separated ring associated with $S^{-1}A$, and $\mathfrak{J}''$ the image of $S^{-1}\mathfrak{J}$ in A''; the image of $S^{-1}\mathfrak{J}^n$ is $\mathfrak{J}''^n$, so $\mathfrak{J}''^n$ tends to 0 in A''; since $\mathfrak{J}'$ is the closure of $\mathfrak{J}''$ in A', $\mathfrak{J}'^n$ is contained in the closure of $\mathfrak{J}''^n$, and therefore tends to 0 in A'.

(ii) Set $A_i = A/\mathfrak{J}^{i+1}$, and for $i \leq j$, let u_{ij} be the canonical homomorphism $A/\mathfrak{J}^{j+1} \to A/\mathfrak{J}^{i+1}$; let S_i be the canonical image of S in A_i, and set $A'_i = S_i^{-1}A_i$; finally, let $u'_{ij} : A'_j \to A'_i$ be the homomorphism deduced canonically from u_{ij}. Let us show that the projective system (A'_i, u'_{ij}) satisfies the conditions of Proposition (7.2.7): it is clear that the u'_{ij} are surjective; on the other hand, the kernel of u'_{ij} is $S_j^{-1}(\mathfrak{J}^{i+1}/\mathfrak{J}^{j+1})$ (1.3.2), equal to $\mathfrak{J}'^{i+1}_j$, where $\mathfrak{J}'_j = S_j^{-1}(\mathfrak{J}/\mathfrak{J}^{j+1})$; finally, $\mathfrak{J}'_1/\mathfrak{J}'^2_1 = S_1^{-1}(\mathfrak{J}/\mathfrak{J}^2)$, and since $\mathfrak{J}/\mathfrak{J}^2$ is of finite type over $A/\mathfrak{J}^2$, $\mathfrak{J}'_1/\mathfrak{J}'^2_1$ is of finite type over A'_1. Finally, if A is Noetherian, so is $A'_0 = S_0^{-1}(A/\mathfrak{J})$, which, by Corollary (7.2.8), completes the proof of Proposition (7.6.11).

(7.6.12) Corollary. *Under the hypotheses of (7.6.11, (ii)), we have* $(\mathfrak{J}\{S^{-1}\})^n = \mathfrak{J}^n\{S^{-1}\}$.

This follows indeed from (7.2.7) and from the proof of (7.6.11).

(7.6.13) Proposition. *Let* A *be a Noetherian adic ring and* S *a multiplicative subset of* A*; then* $A\{S^{-1}\}$ *is a flat* A*-module.*

Indeed, if $\mathfrak{J}$ is an ideal of definition of A, $A\{S^{-1}\}$ is the separated completion of the Noetherian ring $S^{-1}A$ endowed with the $S^{-1}\mathfrak{J}$-preadic topology; consequently (7.3.3) $A\{S^{-1}\}$ is a flat $S^{-1}A$-module; since $S^{-1}A$ is a flat A-module (6.3.1), the proposition follows from the transitivity of flatness (6.2.1).

(7.6.14) Corollary. *Under the hypotheses of (7.6.13), let $S' \subset S$ be a second multiplicative subset of A; then $A\{S^{-1}\}$ is a flat $A\{S'^{-1}\}$-module.*

Indeed (7.6.8), $A\{S^{-1}\}$ is canonically identified with $A\{S'^{-1}\}\{S_0^{-1}\}$, where S_0 is the canonical image of S in $A\{S'^{-1}\}$, and $A\{S'^{-1}\}$ is Noetherian (7.6.11).

(7.6.15) For every element f of a linearly topologized ring A, we shall denote by $A_{\{f\}}$ the complete ring of fractions $A\{S_f^{-1}\}$, where S_f is the multiplicative set of the f^n ($n \geq 0$); for every open ideal $\mathfrak{a}$ of A, we shall write $\mathfrak{a}_{\{f\}}$ instead of $\mathfrak{a}\{S_f^{-1}\}$. If g is a second element of A, we have a continuous canonical homomorphism $A_{\{f\}} \to A_{\{fg\}}$ (7.6.7). When f runs through a multiplicative subset S of A, the $A_{\{f\}}$ therefore form a filtered inductive system of rings for the preceding homomorphisms; we shall set $A_{\{S\}} = \varinjlim_{f\in S} A_{\{f\}}$. For every $f \in S$, we have a homomorphism $A_{\{f\}} \to A\{S^{-1}\}$ (7.6.7), and
[0_I | 75] these homomorphisms form an inductive system; by passage to the inductive limit, they therefore define a canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$.

(7.6.16) Proposition. *If A is a Noetherian ring, $A\{S^{-1}\}$ is a flat module over $A_{\{S\}}$.*

Indeed (7.6.14), $A\{S^{-1}\}$ is flat over each of the rings $A_{\{f\}}$ for $f \in S$, and the conclusion follows from (6.2.3).

(7.6.17) Proposition. *Let $\mathfrak{p}$ be an open prime ideal in an admissible ring A, and let $S = A - \mathfrak{p}$. Then the rings $A\{S^{-1}\}$ and $A_{\{S\}}$ are local rings, the canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local, and the residue fields of $A_{\{S\}}$ and $A\{S^{-1}\}$ are canonically isomorphic to the field of fractions of $A/\mathfrak{p}$.*

Indeed, let $\mathfrak{J} \subset \mathfrak{p}$ be an ideal of definition of A; we have $S^{-1}\mathfrak{J} \subset S^{-1}\mathfrak{p} = \mathfrak{p}A_{\mathfrak{p}}$, so $A_{\mathfrak{p}}/S^{-1}\mathfrak{J}$ is a local ring; we conclude from (7.1.12), (7.6.9) and (7.6.11, (i)) that $A\{S^{-1}\}$ is a local ring. Set $\mathfrak{m} = \varinjlim_{f\in S} \mathfrak{p}_{\{f\}}$, which is an ideal of $A_{\{S\}}$; we shall see that every element of $A_{\{S\}}$ not belonging to $\mathfrak{m}$ is invertible. Indeed, such an element is the image in $A_{\{S\}}$ of an element $z \in A_{\{f\}}$ not belonging to $\mathfrak{p}_{\{f\}}$, for some $f \in S$; its canonical image z_0 in $A_{\{f\}}/\mathfrak{J}_{\{f\}} = S_f^{-1}(A/\mathfrak{J})$ therefore does not belong to $S_f^{-1}(\mathfrak{p}/\mathfrak{J})$ (7.6.9), which means that $z_0 = \overline{x}/\overline{f}^k$, where $x \notin \mathfrak{p}$ and $\overline{x}, \overline{f}$ are the classes of x, f modulo $\mathfrak{J}$. Since $x \in S$, we have $g = xf \in S$, and in $S_g^{-1}A$, $y_0 = x^{k+1}/g^k$, the canonical image of $x/f^k \in S_f^{-1}A$, has an inverse $x^{k-1}f^{2k}/g^k$. This implies *a fortiori* that the image of y_0 in $S_g^{-1}A/S_g^{-1}\mathfrak{J}$ is invertible, hence (7.6.9 and 7.1.12) the canonical image y of z in $A_{\{g\}}$ is invertible; the image of z in $A_{\{S\}}$ (equal to that of y) is consequently invertible. We therefore see that $A_{\{S\}}$ is a local ring with maximal ideal $\mathfrak{m}$; moreover, the image of $\mathfrak{p}_{\{f\}}$ in $A\{S^{-1}\}$ is contained in the maximal ideal $\mathfrak{p}\{S^{-1}\}$ of this ring; *a fortiori*, the image of $\mathfrak{m}$ in $A\{S^{-1}\}$ is contained in $\mathfrak{p}\{S^{-1}\}$, so the canonical homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local. Finally, since every element of $A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ is the image of an element of a ring $S_f^{-1}A$ for a suitable $f \in S$, the homomorphism $A_{\{S\}} \to A\{S^{-1}\}/\mathfrak{p}\{S^{-1}\}$ is surjective, and therefore gives, by passage to quotients, an isomorphism of the residue fields.

(7.6.18) Corollary. *Under the hypotheses of (7.6.17), if we suppose moreover that A is a Noetherian adic ring, the local rings $A\{S^{-1}\}$ and $A_{\{S\}}$ are Noetherian, and $A\{S^{-1}\}$ is a faithfully flat $A_{\{S\}}$-module.*

We already know (7.6.11, (ii)) that $A\{S^{-1}\}$ is Noetherian and $A_{\{S\}}$-flat (7.6.16); since the homomorphism $A_{\{S\}} \to A\{S^{-1}\}$ is local, we conclude that $A\{S^{-1}\}$ is a faithfully flat $A_{\{S\}}$-module (6.6.2), and consequently that $A_{\{S\}}$ is Noetherian (6.5.2).

7.7 Completed tensor products

(7.7.1) Let A be a linearly topologized ring and M, N two linearly topologized A-modules. Let $\mathfrak{J}$, V, W be open neighbourhoods of 0 in A, M, N respectively, which are A-modules and are such that $\mathfrak{J}M \subset V$, $\mathfrak{J}N \subset W$, so that M/V and N/W can be considered as $(A/\mathfrak{J})$-modules. When $\mathfrak{J}$, V, W run through the systems of open neighbourhoods satisfying the preceding conditions, it is immediate that the modules $(M/V) \otimes_{A/\mathfrak{J}} (N/W)$ form a projective system of modules
over the projective system of rings $A/\mathfrak{J}$; by passage to the projective limit, one therefore [0_I | 76]
deduces from them a module over the separated completion $\widehat{A}$ of A, which is called the *completed tensor product* of M and N and is denoted $(M \otimes_A N)^\wedge$. If one notes that M/V is canonically isomorphic to $\widehat{M}/\overline{V}$, where $\widehat{M}$ is the separated completion of M and $\overline{V}$ the closure in $\widehat{M}$ of the image of V, one sees that the completed tensor product $(M \otimes_A N)^\wedge$ is canonically identified with $(\widehat{M} \otimes_{\widehat{A}} \widehat{N})^\wedge$, which is also denoted $\widehat{M}\widehat{\otimes}_{\widehat{A}}\widehat{N}$.

(7.7.2)
With the preceding notation, the tensor products $(M/V) \otimes_A (N/W)$ and $(M/V) \otimes_{A/\mathfrak{J}} (N/W)$ are canonically identified; they are therefore also identified with $(M \otimes_A N)/(\mathrm{Im}(V \otimes_A N) + \mathrm{Im}(M \otimes_A W))$. We conclude that $(M \otimes_A N)^\wedge$ is *the separated completion of the A-module $M \otimes_A N$, endowed with the topology for which the submodules*

$$\mathrm{Im}(V \otimes_A N) + \mathrm{Im}(M \otimes_A W)$$

form a fundamental system of neighbourhoods of 0 (V and W running through the set of open submodules of M and N respectively); we shall say for short that this topology is the *tensor product* of the given topologies on M and N.

(7.7.3) Let M', N' be two linearly topologized A-modules and $u : M \to M'$, $v : N \to N'$ two continuous homomorphisms; it is immediate that $u \otimes v$ is continuous for the tensor product topologies on $M \otimes_A N$ and $M' \otimes_A N'$ respectively; by passage to the separated completion, one deduces from it a continuous homomorphism $(M \otimes_A N)^\wedge \to (M' \otimes_A N')^\wedge$, which we shall denote by $u\widehat{\otimes}v$; $(M \otimes_A N)^\wedge$ is therefore a *bifunctor* in M and N on the category of linearly topologized A-modules.

(7.7.4) One defines in the same way the completed tensor product of an arbitrary finite number of linearly topologized A-modules; it is immediate that this product has the usual properties of associativity and commutativity.

(7.7.5) If B, C are two linearly topologized topological A-algebras, the tensor product topology on $B \otimes_A C$ has as a fundamental system of neighbourhoods of 0 the *ideals* $\mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ of the algebra $B \otimes_A C$, $\mathfrak{K}$ (resp. $\mathfrak{L}$) running through the set of open ideals of B (resp. C). Consequently, $(B \otimes_A C)^\wedge$ is endowed with a structure of *topological $\widehat{A}$-algebra*, the projective limit of the projective system of $(A/\mathfrak{J})$-algebras $(B/\mathfrak{K}) \otimes_{A/\mathfrak{J}} (C/\mathfrak{L})$ ($\mathfrak{J}$ an open ideal of A such that $\mathfrak{J}.B \subset \mathfrak{K}$, $\mathfrak{J}.C \subset \mathfrak{L}$; such ideals always exist). This algebra is called the *completed tensor product* of the algebras B and C.

(7.7.6) The homomorphisms of A-algebras $b \mapsto b \otimes 1$, $c \mapsto 1 \otimes c$ from B and C to $B \otimes_A C$ are continuous when the latter algebra is endowed with the tensor product topology; by composition with the canonical homomorphism from $B \otimes_A C$ to its separated completion, they therefore give *canonical homomorphisms* $\rho : B \to (B \otimes_A C)^\wedge$, $\sigma : C \to (B \otimes_A C)^\wedge$. The algebra $(B \otimes_A C)^\wedge$ and the homomorphisms ρ and σ moreover have the *following*

universal property: for every linearly topologized, separated and complete A-algebra D, and every pair of continuous A-homomorphisms $u : B \to D$, $v : C \to D$, there exists one and only one continuous A-homomorphism $w : (B \otimes_A C)^\wedge \to D$ such that $u = w \circ \rho$ and $v = w \circ \sigma$. Indeed, there already exists a unique A-homomorphism $w_0 : B \otimes_A C \to D$ such that $u(b) = w_0(b \otimes 1)$ and $v(c) = w_0(1 \otimes c)$, and everything comes down to proving that w_0 is continuous, because it will then give a continuous
[0_I | 77] homomorphism w by passage to the separated completion. Now, if $\mathfrak{M}$ is an open ideal of D, there exist by hypothesis open ideals $\mathfrak{K} \subset B$, $\mathfrak{L} \subset C$ such that $u(\mathfrak{K}) \subset \mathfrak{M}$, $v(\mathfrak{L}) \subset \mathfrak{M}$; the image under w_0 of $\mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ is again contained in $\mathfrak{M}$, whence our assertion.

(7.7.7) Proposition. *If B and C are two preadmissible A-algebras, $(B \otimes_A C)^\wedge$ is admissible, and if $\mathfrak{K}$ (resp. $\mathfrak{L}$) is an ideal of definition of B (resp. C), the closure in $(B \otimes_A C)^\wedge$ of the canonical image of $\mathfrak{H} = \mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$ is an ideal of definition.*

It suffices to show that $\mathfrak{H}^n$ tends to 0 for the tensor product topology, which follows immediately from the inclusion

$$\mathfrak{H}^{2n} \subset \mathrm{Im}(\mathfrak{K}^n \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L}^n).$$

(7.7.8) Proposition. *Let A be a preadic ring, $\mathfrak{J}$ an ideal of definition of A, and M an A-module* of finite type*, endowed with the $\mathfrak{J}$-preadic topology. For every adic and Noetherian topological A-algebra B, $B \otimes_A M$ is identified with the completed tensor product $(B \otimes_A M)^\wedge$.*

If $\mathfrak{K}$ is an ideal of definition of B, there exists by hypothesis an integer m such that $\mathfrak{J}^m B \subset \mathfrak{K}$, hence $\mathrm{Im}(B \otimes_A \mathfrak{J}^{nm} M) = \mathrm{Im}(\mathfrak{J}^{nm} B \otimes_A M) \subset \mathrm{Im}(\mathfrak{K}^n B \otimes_A M) = \mathfrak{K}^n (B \otimes_A M)$; we conclude that on $B \otimes_A M$, the tensor product of the topologies of B and of M is the $\mathfrak{K}$-preadic topology. Since $B \otimes_A M$ is a B-module of finite type, the proposition follows at once from (7.3.6).

7.8 Topologies on modules of homomorphisms

(7.8.1) Let A be a Noetherian $\mathfrak{J}$-adic ring, and M and N two A-modules of finite type, endowed with the $\mathfrak{J}$-preadic topology; we know (7.3.6) that they are separated and complete; moreover, every A-homomorphism $M \to N$ is automatically continuous, and the A-module $\mathrm{Hom}_A(M, N)$ is of finite type. For every integer $i \geq 0$, set $A_i = A/\mathfrak{J}^{i+1}$, $M_i = M/\mathfrak{J}^{i+1}M$, $N_i = N/\mathfrak{J}^{i+1}N$; for $i \leq j$, every homomorphism $u_j : M_j \to N_j$ maps $\mathfrak{J}^{i+1}M_j$ into $\mathfrak{J}^{i+1}N_j$, and hence gives, by passage to quotients, a homomorphism $u_i : M_i \to N_i$, which defines a canonical homomorphism $\mathrm{Hom}_{A_j}(M_j, N_j) \to \mathrm{Hom}_{A_i}(M_i, N_i)$; moreover, the $\mathrm{Hom}_{A_i}(M_i, N_i)$ constitute a *projective system* for these homomorphisms, and it follows from (7.2.10) that there is a canonical isomorphism

$$\varphi : \mathrm{Hom}_A(M, N) \longrightarrow \varprojlim_i \mathrm{Hom}_{A_i}(M_i, N_i).$$

Moreover:

(7.8.2) Proposition. *If M and N are modules of finite type over a Noetherian $\mathfrak{J}$-adic ring A, the submodules $\mathrm{Hom}_A(M, \mathfrak{J}^{i+1}N)$ form a fundamental system of neighbourhoods of 0 in $\mathrm{Hom}_A(M, N)$ for the $\mathfrak{J}$-adic topology, and the canonical homomorphism*

$$\varphi : \mathrm{Hom}_A(M, N) \longrightarrow \varprojlim_i \mathrm{Hom}_{A_i}(M_i, N_i)$$

is a topological isomorphism.

Indeed, we can consider M as a quotient of a free A-module L of finite type, and consequently identify $\mathrm{Hom}_A(M,N)$ with a submodule of $\mathrm{Hom}_A(L,N)$; under this identification, $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$ is the intersection of $\mathrm{Hom}_A(M,N)$ and $\mathrm{Hom}_A(L,\mathfrak{J}^{i+1}N)$; since the topology induced on $\mathrm{Hom}_A(M,N)$ by the $\mathfrak{J}$-adic topology of $\mathrm{Hom}_A(L,N)$ is the $\mathfrak{J}$-adic topology (7.3.2), we are reduced to proving the first assertion for $M = L = A^m$; but then $\mathrm{Hom}_A(L,N) = N^m$, $\mathrm{Hom}_A(L,\mathfrak{J}^{i+1}N) = (\mathfrak{J}^{i+1}N)^m = \mathfrak{J}^{i+1}N^m$, and the result is obvious. To establish the second assertion, note that the image of $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$ in $\mathrm{Hom}_{A_j}(M_j,N_j)$ is zero for $j \leq i$, so φ is continuous; conversely, the inverse image in $\mathrm{Hom}_A(M,N)$ of the 0 of $\mathrm{Hom}_{A_i}(M_i,N_i)$ is $\mathrm{Hom}_A(M,\mathfrak{J}^{i+1}N)$, so φ is bicontinuous. [0I | 78]

If we suppose only that A is a Noetherian $\mathfrak{J}$-preadic ring, and M and N two A-modules of finite type that are separated for the $\mathfrak{J}$-preadic topology, the preceding proof shows that the first assertion of (7.8.2) remains valid, and that φ is a topological isomorphism of $\mathrm{Hom}_A(M,N)$ onto a submodule of $\varprojlim_i \mathrm{Hom}_{A_i}(M_i,N_i)$.

(7.8.3) Proposition. *Under the hypotheses of (7.8.2), the set of injective (resp. surjective, bijective) homomorphisms from M to N is an open subset of* $\mathrm{Hom}_A(M,N)$.

Indeed, by virtue of (7.3.5) and (7.1.14), for u to be surjective, it is necessary and sufficient that the corresponding homomorphism $u_0 : M/\mathfrak{J}M \to N/\mathfrak{J}N$ be so, and the set of surjective homomorphisms from M to N is therefore the inverse image under the continuous map $\mathrm{Hom}_A(M,N) \to \mathrm{Hom}_{A_0}(M_0,N_0)$ of a subset of a discrete space. Let us now show that the set of injective homomorphisms is open; let v be such a homomorphism, and set $M' = v(M)$; by the Artin–Rees lemma (7.3.2.1), there exists an integer $k \geq 0$ such that $M' \cap \mathfrak{J}^{m+k}N \subset \mathfrak{J}^m M'$ for every $m > 0$; we shall see that for $w \in \mathfrak{J}^{k+1}\mathrm{Hom}_A(M,N)$, $u = v + w$ is injective, which will complete the proof. Indeed, let $x \in M$ be such that $u(x) = 0$; let us prove that for every $i \geq 0$ the relation $x \in \mathfrak{J}^i M$ implies $x \in \mathfrak{J}^{i+1}M$; it will indeed follow that

$$x \in \bigcap_{i\geq 0} \mathfrak{J}^i M = (0).$$

Indeed, we then have $w(x) \in \mathfrak{J}^{i+k+1}N$, and moreover $w(x) = -v(x) \in M'$, hence $v(x) \in M' \cap \mathfrak{J}^{i+k+1}N \subset \mathfrak{J}^{i+1}M'$, and since v is an isomorphism of M onto M', $x \in \mathfrak{J}^{i+1}M$; Q.E.D.

(To be continued.)

§8 Representable functors

8.1 Representable functors

(8.1.1) We denote by Ens the category of sets. Let C be a category; for two objects X, Y of C, we set $h_X(Y) = \mathrm{Hom}(Y,X)$; for every morphism $u : Y \to Y'$ in C, we denote by $h_X(u)$ the map $v \mapsto vu$ from $\mathrm{Hom}(Y',X)$ to $\mathrm{Hom}(Y,X)$. It is immediate that with these definitions, $h_X : C \to \mathrm{Ens}$ is a *contravariant functor*, that is, an object of the category, denoted $\mathrm{Hom}(C^0,\mathrm{Ens})$, of covariant functors from the category C^0, dual to the category C, to the category Ens (T, 1.7, d) and [29]).

(8.1.2) Now let $w : X \to X'$ be a morphism in C; for every $Y \in C$ and every $v \in \mathrm{Hom}(Y,X) = h_X(Y)$, we have $wv \in \mathrm{Hom}(Y,X') = h_{X'}(Y)$; denote by $h_w(Y)$ the map

$v \mapsto wv$ from $h_X(Y)$ to $h_{X'}(Y)$. It is immediate that for every morphism $u : Y \to Y'$ in C, the diagram

$$\begin{array}{ccc} h_X(Y') & \xrightarrow{h_X(u)} & h_X(Y) \\ {\scriptstyle h_w(Y')}\downarrow & & \downarrow{\scriptstyle h_w(Y)} \\ h_{X'}(Y') & \xrightarrow[h_{X'}(u)]{} & h_{X'}(Y) \end{array}$$

is commutative; in other words, h_w is a *functorial morphism* $h_X \to h_{X'}$ (T, 1.2), or again a morphism in the category $\mathrm{Hom}(C^0, \mathrm{Ens})$ (T, 1.7, d)). The definitions of h_X and of h_w therefore constitute the definition of a *canonical covariant functor*

$$h : C \to \mathrm{Hom}(C^0, \mathrm{Ens}), \qquad X \mapsto h_X. \tag{8.1.2.1}$$

(8.1.3) Let X be an object of C and F a contravariant functor from C to Ens (an object of $\mathrm{Hom}(C^0, \mathrm{Ens})$). Let $g : h_X \to F$ be a *functorial morphism*: for every $Y \in C$, [0III | 6] $g(Y)$ is then a map $h_X(Y) \to F(Y)$ such that for every morphism $u : Y \to Y'$ in C, the diagram

$$\begin{array}{ccc} h_X(Y') & \xrightarrow{h_X(u)} & h_X(Y) \\ {\scriptstyle g(Y')}\downarrow & & \downarrow{\scriptstyle g(Y)} \\ F(Y') & \xrightarrow[F(u)]{} & F(Y) \end{array} \tag{8.1.3.1}$$

is commutative. In particular, we have a map $g(X) : h_X(X) = \mathrm{Hom}(X, X) \to F(X)$, whence an element

$$\alpha(g) = (g(X))(1_X) \in F(X) \tag{8.1.3.2}$$

and consequently a canonical map

$$\alpha : \mathrm{Hom}(h_X, F) \to F(X). \tag{8.1.3.3}$$

Conversely, consider an element $\xi \in F(X)$; for every morphism $v : Y \to X$ in C, $F(v)$ is a map $F(X) \to F(Y)$; consider the map

$$v \mapsto (F(v))(\xi) \tag{8.1.3.4}$$

from $h_X(Y)$ to $F(Y)$; if we denote this map by $(\beta(\xi))(Y)$, then

$$\beta(\xi) : h_X \to F \tag{8.1.3.5}$$

is a *functorial morphism*, since for every morphism $u : Y \to Y'$ in C we have $(F(vu))(\xi) = (F(u) \circ F(v))(\xi)$, which verifies the commutativity of (8.1.3.1) for $g = \beta(\xi)$. We have thus defined a canonical map

$$\beta : F(X) \to \mathrm{Hom}(h_X, F). \tag{8.1.3.6}$$

(8.1.4) Proposition. *The maps α and β are bijections inverse to each other.*

Let us compute $\alpha(\beta(\xi))$ for $\xi \in F(X)$; for every $Y \in C$, $(\beta(\xi))(Y)$ is the map $g_1(Y) : v \mapsto (F(v))(\xi)$ from $h_X(Y)$ to $F(Y)$. We therefore have

$$\alpha(\beta(\xi)) = (g_1(X))(1_X) = (F(1_X))(\xi) = 1_{F(X)}(\xi) = \xi.$$

Let us now compute $\beta(\alpha(g))$ for $g \in \mathrm{Hom}(h_X, F)$; for every $Y \in C$, $(\beta(\alpha(g)))(Y)$ is the map $v \mapsto (F(v))((g(X))(1_X))$; by virtue of the commutativity of (8.1.3.1), this map is none other than $v \mapsto (g(Y))((h_X(v))(1_X)) = (g(Y))(v)$ by definition of $h_X(v)$; in other words, it is equal to $g(Y)$, which proves the proposition.

(8.1.5) Recall that a *subcategory* C' of a category C is defined by the condition that its objects are objects of C, and that if X', Y' are two objects of C', the set $\mathrm{Hom}_{C'}(X', Y')$ of morphisms $X' \to Y'$ *in* C' is a subset of the set $\mathrm{Hom}_C(X', Y')$ of morphisms $X' \to Y'$ *in* C, the canonical map of "composition of morphisms"

$$\mathrm{Hom}_{C'}(X', Y') \times \mathrm{Hom}_{C'}(Y', Z') \to \mathrm{Hom}_{C'}(X', Z')$$

being the restriction of the canonical map [0_{III} | 7]

$$\mathrm{Hom}_C(X', Y') \times \mathrm{Hom}_C(Y', Z') \to \mathrm{Hom}_C(X', Z').$$

We say that C' is a *full subcategory* of C if $\mathrm{Hom}_{C'}(X', Y') = \mathrm{Hom}_C(X', Y')$ for every pair of objects of C'. The subcategory C'' of C consisting of the objects of C isomorphic to objects of C' is then again a full subcategory of C, *equivalent* (T, 1.2) to C', as is easily verified.

A covariant functor $F : C_1 \to C_2$ is said to be *fully faithful* if, for every pair of objects X_1, Y_1 of C_1, the map $u \mapsto F(u)$ from $\mathrm{Hom}(X_1, Y_1)$ to $\mathrm{Hom}(F(X_1), F(Y_1))$ is *bijective*; this implies that the subcategory $F(C_1)$ of C_2 is *full*. Moreover, if two objects X_1, X_1' have the same image X_2, there exists a unique isomorphism $u : X_1 \to X_1'$ such that $F(u) = 1_{X_2}$. For every object X_2 of $F(C_1)$, let then $G(X_2)$ be one of the objects X_1 of C_1 such that $F(X_1) = X_2$ (G being defined by means of the axiom of choice); for every morphism $v : X_2 \to Y_2$ in $F(C_1)$, $G(v)$ will be the unique morphism $u : G(X_2) \to G(Y_2)$ such that $F(u) = v$; G is then a *functor* from $F(C_1)$ to C_1; FG is the identity functor on $F(C_1)$, and the foregoing shows that there exists an isomorphism of functors $\varphi : 1_{C_1} \to GF$ such that F, G, φ and the identity $1_{F(C_1)} \to FG$ define an *equivalence* of the category C_1 with the full subcategory $F(C_1)$ of C_2 (T, 1.2).

(8.1.6) Let us apply Proposition (8.1.4) to the case where the functor F is $h_{X'}$, X' being an arbitrary object of C; the map $\beta : \mathrm{Hom}(X, X') \to \mathrm{Hom}(h_X, h_{X'})$ is here none other than the map $w \mapsto h_w$ defined in (8.1.2); this map being *bijective*, we see, with the terminology of (8.1.5), that:

(8.1.7) Proposition. *The canonical functor* $h : C \to \mathrm{Hom}(C^0, \mathrm{Ens})$ *is fully faithful.*

(8.1.8) Let F be a contravariant functor from C to Ens; we say that F is *representable* if there exists an object $X \in C$ such that F is *isomorphic* to h_X; it follows from (8.1.7) that the data of an $X \in C$ and of an isomorphism of functors $g : h_X \to F$ determine X up to a unique isomorphism. Proposition (8.1.7) also means that h defines an *equivalence* of C with the full subcategory of $\mathrm{Hom}(C^0, \mathrm{Ens})$ consisting of the *representable contravariant functors*. It follows moreover from (8.1.4) that giving a functorial morphism $g : h_X \to F$ is equivalent to giving an element $\xi \in F(X)$; saying that g is an *isomorphism* is equivalent, for ξ, to the following condition: *for every object* Y *of* C, *the map* $v \mapsto (F(v))(\xi)$ *from* $\mathrm{Hom}(Y, X)$ *to* $F(Y)$ *is bijective*. When ξ satisfies this condition, we will say that the pair (X, ξ) *represents* the representable functor F. By abuse of language, we will also say that the object $X \in C$ represents F if there exists $\xi \in F(X)$ such that (X, ξ) represents F, in other words if h_X is isomorphic to F.

Let F, F' be two representable contravariant functors from C to Ens, and $h_X \to F$ and $h_{X'} \to F'$ two isomorphisms of functors. Then it follows from (8.1.6) that there

is a canonical bijective correspondence between $\mathrm{Hom}(X, X')$ and the set $\mathrm{Hom}(F, F')$ of functorial morphisms $F \to F'$.

(8.1.9) *Examples. I: projective limits.* The notion of representable contravariant functor covers in particular the notion "dual" to the usual notion of "solution of a universal problem". More generally, we will see that the notion of *projective limit* is a particular case of that of representable functor. Recall that in a category C, a *projective system* is defined by giving a preordered set I, a family $(A_\alpha)_{\alpha\in I}$ of objects of C, and, for every pair of indices (α, β) such that $\alpha \leq \beta$, a morphism $u_{\alpha\beta} : A_\beta \to A_\alpha$. A *projective limit* of this system in C consists of an object B of C (denoted $\varprojlim A_\alpha$) and, for each $\alpha \in I$, a morphism $u_\alpha : B \to A_\alpha$, such that: 1° $u_\alpha = u_{\alpha\beta}u_\beta$ for $\alpha \leq \beta$; 2° For every object X of C and every family $(v_\alpha)_{\alpha\in I}$ of morphisms $v_\alpha : X \to A_\alpha$ such that $v_\alpha = u_{\alpha\beta}v_\beta$ for $\alpha \leq \beta$, there exists a unique morphism $v : X \to B$ (denoted $\varprojlim v_\alpha$) such that $v_\alpha = u_\alpha v$ for every $\alpha \in I$ (T, 1.8). This is interpreted as follows: the $u_{\alpha\beta}$ canonically define maps

[0_{III} | 8]

$$\overline{u}_{\alpha\beta} : \mathrm{Hom}(X, A_\beta) \to \mathrm{Hom}(X, A_\alpha)$$

which define a *projective system* of sets $(\mathrm{Hom}(X, A_\alpha), \overline{u}_{\alpha\beta})$, and (v_α) is by definition an element of the set $\varprojlim_\alpha \mathrm{Hom}(X, A_\alpha)$; it is clear that $X \mapsto \varprojlim_\alpha \mathrm{Hom}(X, A_\alpha)$ is a *contravariant functor* from C to Ens, and the existence of the projective limit B amounts to saying that $(v_\alpha) \mapsto \varprojlim v_\alpha$ is an *isomorphism* of functors in X

$$\varprojlim_\alpha \mathrm{Hom}(X, A_\alpha) \xrightarrow{\sim} \mathrm{Hom}(X, B) \tag{8.1.9.1}$$

in other words, that the functor $X \mapsto \varprojlim_\alpha \mathrm{Hom}(X, A_\alpha)$ is *representable*.

(8.1.10) *Examples. II: Final object.* Let C be a category and $\{a\}$ a set consisting of a single element. Consider the contravariant functor $F : C \to \mathrm{Ens}$ which assigns to every object X of C the set $\{a\}$, and to every morphism $X \to X'$ in C the unique map $\{a\} \to \{a\}$. To say that this functor is *representable* means that there exists an object $e \in C$ such that for every $Y \in C$, $\mathrm{Hom}(Y, e) = h_e(Y)$ *consists of a single element*; we say that e is a *final object* of C, and it is clear that two final objects of C are isomorphic (which makes it possible to define, in general with the help of the axiom of choice, a final object of C, which is then denoted e_C). For example, in the category Ens, the final objects are the sets consisting of a single element; in the category of *augmented algebras* over a field K (where the morphisms are the algebra homomorphisms compatible with the augmentations), K is a final object; in the category of *S-preschemes* (I, 2.5.1), S is a final object.

(8.1.11) For two objects X, Y of a category C, set $h'_X(Y) = \mathrm{Hom}(X, Y)$, and for every morphism $u : Y \to Y'$, let $h'_X(u)$ be the map $v \mapsto uv$ from $\mathrm{Hom}(X, Y)$ to $\mathrm{Hom}(X, Y')$; h'_X is then a *covariant functor* $C \to \mathrm{Ens}$, from which we deduce, as in (8.1.2), the definition of a canonical covariant functor $h' : C^0 \to \mathrm{Hom}(C, \mathrm{Ens})$; a *covariant functor* F from C to Ens, in other words an object of $\mathrm{Hom}(C, \mathrm{Ens})$, is then said to be *representable* if there exists an object $X \in C$ (necessarily unique up to unique isomorphism) such that F is *isomorphic to* h'_X; we leave it to the reader to develop the considerations "dual" to the preceding ones for this notion, which this time covers that of *inductive limit*, and in particular the usual notion of "solution of a universal problem".

8.2 Algebraic structures in categories

(8.2.1) Given two contravariant functors F, F' from C to Ens, recall that for every object $Y \in C$ we set $(F \times F')(Y) = F(Y) \times F'(Y)$, and for every morphism $u : Y \to Y'$ in C we set $(F \times F')(u) = F(u) \times F'(u)$, which is the map $(t, t') \mapsto ((F(u))(t), (F'(u))(t'))$ from $F(Y') \times F'(Y')$ to $F(Y) \times F'(Y)$; $F \times F' : C \to \text{Ens}$ is therefore a *contravariant functor* (which, moreover, is none other than the *product* of the objects F, F' in the category $\text{Hom}(C^0, \text{Ens})$). Given an object $X \in C$, we will call an *internal composition law on* X a functorial morphism [0_{III} | 9]

$$\gamma_X : h_X \times h_X \to h_X. \tag{8.2.1.1}$$

In other words (T, 1.2), for every object $Y \in C$, $\gamma_X(Y)$ is a map $h_X(Y) \times h_X(Y) \to h_X(Y)$ (hence by definition an *internal composition law* on the set $h_X(Y)$) subject to the condition that, for every morphism $u : Y \to Y'$ in C, the diagram

$$\begin{array}{ccc} h_X(Y') \times h_X(Y') & \xrightarrow{h_X(u) \times h_X(u)} & h_X(Y) \times h_X(Y) \\ \Big\downarrow{\scriptstyle \gamma_X(Y')} & & \Big\downarrow{\scriptstyle \gamma_X(Y)} \\ h_X(Y') & \xrightarrow[h_X(u)]{} & h_X(Y) \end{array}$$

is commutative; this means that for the composition laws $\gamma_X(Y)$ and $\gamma_X(Y')$, $h_X(u)$ is a *homomorphism* from $h_X(Y')$ to $h_X(Y)$.

In the same way, given two objects Z, X of C, we call an *external composition law on X, having Z as domain of operators*, a functorial morphism

$$\omega_{X,Z} : h_Z \times h_X \to h_X. \tag{8.2.1.2}$$

We see as above that for every $Y \in C$, $\omega_{X,Z}(Y)$ is an external composition law on $h_X(Y)$, having $h_Z(Y)$ as domain of operators, and such that for every morphism $u : Y \to Y'$, $h_X(u)$ and $h_Z(u)$ form a *di-homomorphism* from $(h_Z(Y'), h_X(Y'))$ to $(h_Z(Y), h_X(Y))$.

(8.2.2) Let X' be a second object of C, and suppose given on X' an internal composition law $\gamma_{X'}$; we will say that a morphism $w : X \to X'$ in C is a *homomorphism* for these composition laws if for every $Y \in C$, $h_w(Y) : h_X(Y) \to h_{X'}(Y)$ is a homomorphism for the composition laws $\gamma_X(Y)$ and $\gamma_{X'}(Y)$. If X'' is a third object of C equipped with an internal composition law $\gamma_{X''}$, and $w' : X' \to X''$ a morphism in C which is a homomorphism for $\gamma_{X'}$ and $\gamma_{X''}$, it is clear that the morphism $w'w : X \to X''$ is a homomorphism for the composition laws γ_X and $\gamma_{X''}$. An isomorphism $w : X \xrightarrow{\sim} X'$ in C is called an *isomorphism for the composition laws γ_X and $\gamma_{X'}$* if w is a homomorphism for these composition laws and if its inverse morphism w^{-1} is a homomorphism for the composition laws $\gamma_{X'}$ and γ_X. [0_{III} | 10]

The *di-homomorphisms* for pairs of objects of C equipped with external composition laws are defined in the same way.

(8.2.3) When an internal composition law γ_X on an object $X \in C$ is such that $\gamma_X(Y)$ is a *group law* on $h_X(Y)$ for *every* $Y \in C$, we say that X, equipped with this law, is a *C-group* or a *group object in C*. The *C-rings*, *C-modules*, etc. are defined in the same way.

(8.2.4) Suppose that the *product* $X \times X$ of an object $X \in C$ with itself exists in C; by definition, we then have $h_{X\times X} = h_X \times h_X$ up to canonical isomorphism, since this is a particular case of projective limit (8.1.9); an internal composition law on X can therefore be regarded as a functorial morphism $\gamma_X : h_{X\times X} \to h_X$, and therefore canonically determines (8.1.6) an element $c_X \in \mathrm{Hom}(X \times X, X)$ such that $h_{c_X} = \gamma_X$; in this case, giving an internal composition law on X is therefore equivalent to giving a morphism $X \times X \to X$; when C is the category Ens, we recover the classical notion of internal composition law on a set. There is an analogous result for an external composition law when the product $Z \times X$ exists in C.

(8.2.5) With the preceding notation, suppose moreover that $X \times X \times X$ exists in C; the characterization of the product as an object representing a functor (8.1.9) implies the existence of canonical isomorphisms

$$(X \times X) \times X \xrightarrow{\sim} X \times X \times X \xrightarrow{\sim} X \times (X \times X)\ ;$$

if we canonically identify $X \times X \times X$ with $(X \times X) \times X$, the map $\gamma_X(Y) \times 1_{h_X(Y)}$ is identified with $h_{c_X\times 1_X}(Y)$ for every $Y \in C$. Consequently it is equivalent to say that for every $Y \in C$ the internal law $\gamma_X(Y)$ is *associative*, or that the diagram of maps

$$\begin{array}{ccc} h_X(Y) \times h_X(Y) \times h_X(Y) & \xrightarrow{\gamma_X(Y)\times 1} & h_X(Y) \times h_X(Y) \\ \Big\downarrow{\scriptstyle 1\times\gamma_X(Y)} & & \Big\downarrow{\scriptstyle \gamma_X(Y)} \\ h_X(Y) \times h_X(Y) & \xrightarrow[\gamma_X(Y)]{} & h_X(Y) \end{array}$$

[0_{III} | 11] is commutative, or that the diagram of morphisms

$$\begin{array}{ccc} X \times X \times X & \xrightarrow{c_X\times 1_X} & X \times X \\ \Big\downarrow{\scriptstyle 1_X\times c_X} & & \Big\downarrow{\scriptstyle c_X} \\ X \times X & \xrightarrow[c_X]{} & X \end{array}$$

is commutative.

(8.2.6) Under the hypotheses of (8.2.5), if we want to express that for every $Y \in C$ the internal law $\gamma_X(Y)$ is a *group law*, we must on the one hand express that it is associative, and on the other that there exists a map $\alpha_X(Y) : h_X(Y) \to h_X(Y)$ having the properties of the *inverse* in a group; since, for every morphism $u : Y \to Y'$ in C, we have seen that $h_X(u)$ must be a group homomorphism $h_X(Y') \to h_X(Y)$, we see first that $\alpha_X : h_X \to h_X$ must be a *functorial morphism*. On the other hand, we can express the characteristic properties of the inverse $s \mapsto s^{-1}$ in a group G without bringing in the neutral element: it suffices to write that the two composite maps

$$(s,t) \mapsto (s, s^{-1}, t) \mapsto (s, s^{-1}t) \mapsto s(s^{-1}t),$$

$$(s,t) \mapsto (s, s^{-1}, t) \mapsto (s, ts^{-1}) \mapsto (ts^{-1})s$$

are equal to the second projection $(s,t) \mapsto t$ from $G \times G$ to G. By virtue of (8.1.3), we have $\alpha_X = h_{a_X}$, where $a_X \in \mathrm{Hom}(X,X)$; the first of the preceding conditions then expresses that the composite morphism

$$X \times X \xrightarrow{(1_X, a_X)\times 1_X} X \times X \times X \xrightarrow{1_X \times c_X} X \times X \xrightarrow{c_X} X$$

is the second projection $X \times X \to X$ in C, and the second condition is expressed in the same way.

(8.2.7) Suppose now that there exists in C a *final object* e (8.1.10). Suppose still that $\gamma_X(Y)$ is a group law on $h_X(Y)$ for every $Y \in C$, and denote by $\eta_X(Y)$ the neutral element of $\gamma_X(Y)$. Since, for every morphism $u : Y \to Y'$ in C, $h_X(u)$ is a group homomorphism, we have $\eta_X(Y) = (h_X(u))(\eta_X(Y'))$; taking in particular $Y' = e$, in which case u is the unique element ε of $\mathrm{Hom}(Y,e)$, we see that the element $\eta_X(e)$ completely determines $\eta_X(Y)$ for every $Y \in C$. Set $e_X = \eta_X(X)$, the neutral element of the group $h_X(X) = \mathrm{Hom}(X,X)$; the commutativity of the diagram

$$\begin{array}{ccc} h_X(e) & \xrightarrow{h_X(\varepsilon)} & h_X(Y) \\ {\scriptstyle h_{e_X}(e)}\downarrow & & \downarrow{\scriptstyle h_{e_X}(Y)} \\ h_X(e) & \xrightarrow[h_X(\varepsilon)]{} & h_X(Y) \end{array}$$

(cf. 8.1.2) shows that, in the set $h_X(Y)$, the map $h_{e_X}(Y)$ is none other than $s \mapsto \eta_X(Y)$, [0III | 12] which transforms every element into the neutral element. One then verifies that the fact that $\eta_X(Y)$ is the neutral element of $\gamma_X(Y)$ for every $Y \in C$ is equivalent to saying that the composite morphism

$$X \xrightarrow{(1_X, 1_X)} X \times X \xrightarrow{1_X \times e_X} X \times X \xrightarrow{c_X} X,$$

and the analogous one in which 1_X and e_X are interchanged, are both *equal* to 1_X.

(8.2.8) One could of course easily multiply the examples of algebraic structures in categories. The example of groups has been treated in some detail, but in what follows we will generally leave it to the reader to develop analogous considerations in the examples of algebraic structures that we will encounter.

§9 Constructible sets

9.1 Constructible sets

(9.1.1) Definition. We say that a continuous map $f : X \to Y$ is *quasi-compact* if for every quasi-compact open subset U of Y, $f^{-1}(U)$ is quasi-compact. We say that a subset Z of a topological space X is *retrocompact in* X if the canonical injection $Z \to X$ is quasi-compact, in other words if for every quasi-compact open subset U of X, $U \cap Z$ is quasi-compact.

A *closed* subset of X is retrocompact in X, but a quasi-compact subset of X is not necessarily retrocompact in X. If X is quasi-compact, every open subset retrocompact in X is quasi-compact. It is clear that every *finite* union of sets retrocompact in X is retrocompact in X, every finite union of quasi-compact sets being quasi-compact. Every

finite intersection of open subsets retrocompact in X is an open subset retrocompact in X. In a *locally Noetherian* space X, every quasi-compact set is a Noetherian subspace, and consequently *every subset* of X is retrocompact in X.

(9.1.2) Definition. Given a topological space X, we say that a subset of X is *constructible* if it belongs to the smallest set $\mathfrak{F}$ of subsets of X containing all the retrocompact open subsets of X and stable under finite intersection and passage to the complement (which implies that $\mathfrak{F}$ is also stable under finite union).

(9.1.3) Proposition. *For a subset of X to be constructible, it is necessary and sufficient that it be a finite union of sets of the form $U \cap \complement V$, where U and V are open subsets retrocompact in X.*

It is clear that the condition is sufficient. To see that it is necessary, consider the set $\mathfrak{G}$ of finite unions of sets of the form $U \cap \complement V$, where U and V are open and retrocompact in X; it suffices to see that the complement of every set of $\mathfrak{G}$ belongs to $\mathfrak{G}$. So let $Z = \bigcup_{i\in I}(U_i \cap \complement V_i)$, where I is finite and U_i and V_i are open and retrocompact in X; we have $\complement Z = \bigcap_{i\in I}(V_i \cup \complement U_i)$, so $\complement Z$ is a finite union of sets which are intersections of some
[0_{III} | 13] of the V_i and some of the $\complement U_i$, hence of the form $V \cap \complement U$, where U is a union of some of the U_i and V an intersection of some of the V_i; but we remarked above that finite unions and intersections of open subsets retrocompact in X are open subsets retrocompact in X, whence the conclusion.

(9.1.4) Corollary. *Every constructible subset of X is retrocompact in X.*

It suffices to show that if U and V are open and retrocompact in X, then $U \cap \complement V$ is retrocompact in X; now, if W is open and quasi-compact in X, $W \cap U \cap \complement V$ is closed in the quasi-compact space $W \cap U$, hence is quasi-compact.

In particular:

(9.1.5) Corollary. *For an open subset U of X to be constructible, it is necessary and sufficient that it be retrocompact in X. For a closed subset F of X to be constructible, it is necessary and sufficient that the open subset $\complement F$ be retrocompact.*

(9.1.6) An important case is that in which every quasi-compact open subset of X is retrocompact, in other words, in which the intersection of two quasi-compact open subsets of X is quasi-compact (cf. I, 5.5.6). When X itself is quasi-compact, this means that the open subsets retrocompact in X are identical with the quasi-compact open subsets of X, and the constructible subsets of X with the finite unions of sets of the form $U \cap \complement V$, where U and V are open and quasi-compact.

(9.1.7) Corollary. *For a subset of a Noetherian space X to be constructible, it is necessary and sufficient that it be a finite union of locally closed subsets of X.*

(9.1.8) Proposition. *Let X be a topological space and U an open subset of X.*

(i) If T is a constructible subset of X, $T \cap U$ is a constructible subset of U.

(ii) Suppose moreover that U is retrocompact in X. For a subset Z of U to be constructible in X, it is necessary and sufficient that it be constructible in U.

(i) Using (9.1.3), we are reduced to showing that if T is open and retrocompact in X, then $T \cap U$ is open and retrocompact in U, in other words, that for every quasi-compact open subset $W \subset U$, $T \cap U \cap W = T \cap W$ is quasi-compact, which follows immediately from the hypothesis.

(ii) The condition being necessary by virtue of (i), it remains to prove that it is sufficient. Taking into account (9.1.3), it suffices to consider the case where Z is open and retrocompact *in* U, since it will then follow that $U \setminus Z$ is constructible in X, and if Z, Z' are two open subsets retrocompact *in* U, $Z \cap (U \setminus Z')$ will indeed be constructible in X. Now, if W is open and quasi-compact in X and Z is open and retrocompact in U, we have $Z \cap W = Z \cap (W \cap U)$, and by hypothesis $W \cap U$ is open and quasi-compact in U; hence $W \cap Z$ is indeed quasi-compact, and consequently Z is open and retrocompact in X, and *a fortiori* constructible in X.

(9.1.9) Corollary. *Let X be a topological space and $(U_i)_{i\in I}$ a finite covering of X consisting of open sets retrocompact in X. For a subset Z of X to be constructible in X, it is necessary and sufficient that for every $i \in I$, $Z \cap U_i$ be constructible in U_i.*

(9.1.10) Suppose in particular that X is quasi-compact and that every point of X has [0_{III} | 14] a fundamental system of open neighbourhoods retrocompact in X (and *a fortiori* quasi-compact); then the condition for a subset Z of X to be constructible in X is of a *local* nature, in other words, it is necessary and sufficient that for every $x \in X$ there exist an open neighbourhood V of x such that $V \cap Z$ is constructible in V. Indeed, if this condition is satisfied, there exists for every $x \in X$ an open neighbourhood V of x *retrocompact in* X and such that $V \cap Z$ is constructible in V, by virtue of the hypothesis on X and of (9.1.8, (i)); it then suffices to cover X by finitely many of these neighbourhoods and to apply (9.1.9).

(9.1.11) Definition. Let X be a topological space. We say that a subset T of X is *locally constructible in* X if, for every $x \in X$, there exists an open neighbourhood V of x such that $T \cap V$ is constructible in V.

It follows immediately from (9.1.8, (i)) that if V is such that $V \cap T$ is constructible in V, then for every open subset $W \subset V$, $W \cap T$ is constructible in W. If T is locally constructible in X, then, for every open subset U of X, $T \cap U$ is locally constructible in U, as follows from the preceding remark. This same remark shows that the set of subsets locally constructible in X is stable under finite union and finite intersection; it is clear, on the other hand, that it is also stable under passage to complements.

(9.1.12) Proposition. *Let X be a topological space. Every set constructible in X is locally constructible in X. The converse is true if X is quasi-compact and its topology has a basis consisting of sets retrocompact in X.*

The first assertion follows from the definition (9.1.11), and the second from (9.1.10).

(9.1.13) Corollary. *Let X be a topological space whose topology has a basis consisting of sets retrocompact in X. Then every subset T locally constructible in X is retrocompact in X.*

Indeed, let U be a quasi-compact open set in X; $T \cap U$ is locally constructible in U, hence constructible in U by virtue of (9.1.12), and consequently quasi-compact by virtue of (9.1.4).

9.2 Constructible sets in Noetherian spaces

(9.2.1) We have seen (9.1.7) that in a Noetherian space X, the subsets constructible in X are the *finite unions of locally closed subsets of X*.

The inverse image of a set constructible in X under a continuous map from a Noetherian space X' to X is constructible in X'. If Y is a constructible subset of a Noetherian

space X, the subsets of Y which are constructible as subspaces of Y are identical with those which are constructible as subspaces of X.

(9.2.2) Proposition. *Let X be an irreducible Noetherian space and E a constructible subset of X. For E to be everywhere dense in X, it is necessary and sufficient that E contain a non-empty open subset of X.*

[0III | 15] The condition is evidently sufficient, every non-empty open set being dense in X. Conversely, let $E = \bigcup_{i=1}^{n}(U_i \cap F_i)$ be a constructible subset of X, the U_i being non-empty open sets and the F_i closed sets in X; we therefore have $\overline{E} \subset \bigcup_i F_i$. Consequently, if $\overline{E} = X$, X is equal to one of the F_i, hence $E \supset U_i$, which completes the proof.

When X has a generic point x (0I, 2.1.2), the condition of (9.2.2) is equivalent to the relation $x \in E$.

(9.2.3) Proposition. *Let X be a Noetherian space. For a subset E of X to be constructible, it is necessary and sufficient that, for every irreducible closed subset Y of X, $E \cap Y$ be rare in Y or contain a non-empty open subset of Y.*

The necessity of the condition comes from the fact that $E \cap Y$ must be a constructible subset of Y, and from (9.2.2), since a non-dense subset of Y is necessarily rare in the irreducible space Y (0I, 2.1.1). To prove that the condition is sufficient, let us apply the principle of Noetherian induction (0I, 2.2.2) to the set $\mathfrak{F}$ of closed subsets Y of X such that $Y \cap E$ is constructible (relative to Y or relative to X, which amounts to the same thing): we may therefore suppose that for every closed subset $Y \neq X$ of X, $E \cap Y$ is constructible. Suppose first that X is not irreducible, and let X_i $(1 \leq i \leq m)$ be its irreducible components, which are necessarily finite in number (0I, 2.2.5); by hypothesis, the $E \cap X_i$ are constructible, hence so is their union E. Suppose next that X is irreducible; then, by hypothesis, either E is rare, so that $\overline{E} \neq X$ and $E = E \cap \overline{E}$ is constructible; or E contains a non-empty open subset U of X, and is therefore the union of U and $E \cap (X \setminus U)$; but $X \setminus U$ is a closed set distinct from X, so $E \cap (X \setminus U)$ is constructible; E itself is consequently constructible, which completes the proof.

(9.2.4) Corollary. *Let X be a Noetherian space and (E_α) an increasing filtered family of constructible subsets of X, such that:*

1° *X is the union of the family (E_α).*

2° *Every irreducible closed subset of X is contained in the closure of one of the E_α.*

Then there exists an index α such that $X = E_\alpha$.

When every irreducible closed subset of X has a generic point, hypothesis 2° can be omitted.

Let us apply the principle of Noetherian induction (0I, 2.2.2) to the set $\mathfrak{M}$ of closed subsets of X contained in at least one of the E_α; we may therefore suppose that every closed subset $Y \neq X$ of X is contained in one of the E_α. The proposition is evident if X is not irreducible, since each of the irreducible components X_i of X $(1 \leq i \leq m)$ is contained in some E_{α_i}, and there exists an E_α containing all the E_{α_i}. So suppose X irreducible. By hypothesis, there exists β such that $X = \overline{E_\beta}$, hence (9.2.2) E_β contains a non-empty open subset U of X. But then the closed set $X \setminus U$ is contained in some E_γ, and it suffices to take E_α containing E_β and E_γ. When every irreducible closed subset
[0III | 16] Y of X has a generic point y, there exists α such that $y \in E_\alpha$, hence $Y = \overline{\{y\}} \subset \overline{E_\alpha}$, and condition 2° is a consequence of 1°.

(9.2.5) Proposition. *Let X be a Noetherian space, x a point of X, and E a constructible subset of X. For E to be a neighbourhood of x, it is necessary and sufficient*

that for every irreducible closed subset Y of X containing x, $E \cap Y$ be dense in Y (if there exists a generic point y of Y, this also means (9.2.2) that $y \in E$).

The condition is evidently necessary; let us prove that it is sufficient. Applying the principle of Noetherian induction to the set $\mathfrak{M}$ of closed subsets Y of X containing x and such that $E \cap Y$ is a neighbourhood of x in Y, we may suppose that every closed subset $Y \neq X$ of X containing x belongs to $\mathfrak{M}$. If X is not irreducible, each of the irreducible components X_i of X containing x is distinct from X, so $E \cap X_i$ is a neighbourhood of x relative to X_i; consequently, E is a neighbourhood of x in the union of the irreducible components of X containing x, and since this union is a neighbourhood of x in X, the same is true of E. If X is irreducible, E is dense in X by hypothesis, and therefore contains a non-empty open subset U of X (9.2.2); the proposition is then evident if $x \in U$; otherwise, x is by hypothesis interior to $E \cap (X \setminus U)$ relative to $X \setminus U$, so the closure in X of $X \setminus E$ does not contain x, and the complement of this closure is a neighbourhood of x contained in E, which completes the proof.

(9.2.6) Corollary. *Let X be a Noetherian space and E a subset of X. For E to be an open set in X, it is necessary and sufficient that for every irreducible closed subset Y of X meeting E, $E \cap Y$ contain a non-empty open subset of Y.*

The condition is evidently necessary; conversely, if it is satisfied, it implies that E is constructible by virtue of (9.2.3). Moreover, (9.2.5) shows that E is then a neighbourhood of each of its points, whence the conclusion.

9.3 Constructible functions

(9.3.1) Definition. Let h be a map from a topological space X to a set T. We say that h is *constructible* if $h^{-1}(t)$ is constructible for every $t \in T$, and empty except for finitely many values of t; for every subset S of T, $h^{-1}(S)$ is then constructible. We say that h is *locally constructible* if every $x \in X$ has an open neighbourhood V such that $h|V$ is constructible.

Every constructible function is locally constructible; the converse is true when X is quasi-compact and has a basis consisting of open sets retrocompact in X (in particular when X is Noetherian).

(9.3.2) Proposition. *Let h be a map from a Noetherian space X to a set T. For h to be constructible, it is necessary and sufficient that for every irreducible closed subset Y of X there exist a non-empty subset U of Y, open relative to Y, on which h is constant.*

The condition is necessary: indeed, by hypothesis, h takes on Y only finitely many values t_i, and each of the sets $h^{-1}(t_i) \cap Y$ is constructible in Y (9.2.1); since they cannot all be rare subsets of the space Y, at least one of them contains a non-empty open set (9.2.3).

To see that the condition is sufficient, let us apply the principle of Noetherian induction to the set $\mathfrak{M}$ of closed subsets Y of X such that the restriction $h|Y$ is constructible; we may therefore suppose that for every closed subset $Y \neq X$ of X, $h|Y$ is constructible. If X is not irreducible, the restriction of h to each of the irreducible components X_i of X (finite in number) is therefore constructible, and it then follows immediately from the definition (9.3.1) that h is constructible. If X is irreducible, there exists by hypothesis a non-empty open subset U of X on which h is constant; on the other hand, the restriction of h to $X \setminus U$ is constructible by hypothesis, and it follows immediately that h is constructible. [0_{III} | 17]

(9.3.3) Corollary. *Let X be a Noetherian space in which every irreducible closed subset has a generic point. If h is a map from X to a set T such that, for every $t \in T$, $h^{-1}(t)$ is constructible, then h is constructible.*

Indeed, if Y is a irreducible closed subset of X and y its generic point, $Y \cap h^{-1}(h(y))$ is constructible and contains y, so (9.2.2) this set contains a non-empty open subset of Y, and it suffices to apply (9.3.2).

(9.3.4) Proposition. *Let X be a Noetherian space in which every irreducible closed subset has a generic point, and h a constructible map from X to an ordered set. For h to be upper semi-continuous in X, it is necessary and sufficient that for every $x \in X$ and every generization (0_{I}, 2.1.2) x' of x, we have $h(x') \leq h(x)$.*

The function h takes only finitely many values; saying that it is upper semi-continuous therefore means that for every $x \in X$, the set E of $y \in X$ such that $h(y) \leq h(x)$ is a neighbourhood of x. By hypothesis, E is a constructible subset of X; on the other hand, saying that a irreducible closed subset Y of X contains x means that its generic point y is a generization of x; the conclusion then follows from (9.2.5).

§10 Supplement on flat modules

For the proofs of the properties stated without proof in n^{os} (10.1) and (10.2), we refer the reader to Bourbaki, *Alg. comm.*, chap. II and III.

10.1 Relations between flat modules and free modules

(10.1.1) Let A be a ring, $\mathfrak{J}$ an ideal of A, and M an A-module; for every integer $p \geq 0$, we have a canonical homomorphism of $(A/\mathfrak{J})$-modules

$$\varphi_p : (M/\mathfrak{J}M) \otimes_{A/\mathfrak{J}} (\mathfrak{J}^p/\mathfrak{J}^{p+1}) \longrightarrow \mathfrak{J}^p M/\mathfrak{J}^{p+1}M \tag{10.1.1.1}$$

which is evidently *surjective*. We denote by $\mathrm{gr}(A) = \bigoplus_{p\geq 0} \mathfrak{J}^p/\mathfrak{J}^{p+1}$ the graded ring associated to A filtered by the $\mathfrak{J}^p$, and by $\mathrm{gr}(M) = \bigoplus_{p\geq 0} \mathfrak{J}^p M/\mathfrak{J}^{p+1}M$ the graded $\mathrm{gr}(A)$-module associated to M filtered by the $\mathfrak{J}^p M$; we thus have $\mathrm{gr}_p(A) = \mathfrak{J}^p/\mathfrak{J}^{p+1}$, $\mathrm{gr}_p(M) = \mathfrak{J}^p M/\mathfrak{J}^{p+1}M$; the φ_p define a *surjective* homomorphism of graded $\mathrm{gr}(A)$-modules

$$\varphi : \mathrm{gr}_0(M) \otimes_{\mathrm{gr}_0(A)} \mathrm{gr}(A) \longrightarrow \mathrm{gr}(M). \tag{10.1.1.2}$$

[0_{III} | 18] **(10.1.2)** Suppose that one of the following hypotheses holds:

(i) $\mathfrak{J}$ is nilpotent;

(ii) A is Noetherian, $\mathfrak{J}$ is contained in the radical of A, and M is of finite type.

Then the following properties are equivalent:

a) M is a free A-module.

b) $M/\mathfrak{J}M = M \otimes_A (A/\mathfrak{J})$ is a free $(A/\mathfrak{J})$-module, and $\mathrm{Tor}_1^A(M, A/\mathfrak{J}) = 0$.

c) $M/\mathfrak{J}M$ is a free $(A/\mathfrak{J})$-module and the canonical homomorphism (10.1.1.2) is injective (hence bijective).

(10.1.3) Suppose that $A/\mathfrak{J}$ is a *field* (in other words that $\mathfrak{J}$ is maximal), and that one of the hypotheses (i), (ii) of (10.1.2) holds. Then the following properties are equivalent:

a) M is a free A-module.

b) M is a projective A-module.

c) M is a flat A-module.

d) $\mathrm{Tor}_1^A(M, A/\mathfrak{J}) = 0$.

e) The canonical homomorphism (10.1.1.2) is bijective.

This result will apply in particular in the following two cases:

(i) M is an *arbitrary* module over a local ring A whose maximal ideal $\mathfrak{J}$ is *nilpotent* (for example an Artinian local ring).

(ii) M is a module *of finite type* over a *Noetherian* local ring.

10.2 Local flatness criteria

(10.2.1) The hypotheses and notation being those of (10.1.1), consider the following conditions:

a) M is a flat A-module.

b) $M/\mathfrak{J}M$ is a flat $(A/\mathfrak{J})$-module and $\mathrm{Tor}_1^A(M, A/\mathfrak{J}) = 0$.

c) $M/\mathfrak{J}M$ is a flat $(A/\mathfrak{J})$-module and the canonical homomorphism (10.1.1.2) is bijective.

d) For every $n \geq 1$, $M/\mathfrak{J}^n M$ is a flat $(A/\mathfrak{J}^n)$-module.

We then have the implications

$$a \Rightarrow b \Rightarrow c \Rightarrow d$$

and if $\mathfrak{J}$ is *nilpotent*, the four conditions *a*), *b*), *c*), *d*) are *equivalent*. The same holds if A is Noetherian and moreover M is *ideally separated*, that is, if for every ideal $\mathfrak{a}$ of A, the A-module $\mathfrak{a} \otimes_A M$ is *separated* for the $\mathfrak{J}$-preadic topology.

(10.2.2) Let A be a Noetherian ring, B a commutative Noetherian A-algebra, $\mathfrak{J}$ an ideal of A such that $\mathfrak{J}B$ is contained in the radical of B, and M a B-module of finite type. Then, when M is considered as an A-module, the conditions *a*), *b*), *c*), *d*) of (10.2.1) are equivalent.

This result applies above all when A and B are Noetherian *local* rings and the homomorphism $A \to B$ is a *local* homomorphism. More particularly, if $\mathfrak{J}$ is then the *maximal* ideal of A, we can, in conditions *b*) and *c*), drop the hypothesis that $M/\mathfrak{J}M$ is flat, which is automatically satisfied, and condition *d*) means that the modules $M/\mathfrak{J}^n M$ are *free* over the $A/\mathfrak{J}^n$.

(10.2.3) The hypotheses on A, B, $\mathfrak{J}$, M being those formulated at the beginning of (10.2.2), let $\widehat{A}$ be the separated completion of A for the $\mathfrak{J}$-preadic topology, and $\widehat{M}$ the separated completion of M for the $\mathfrak{J}B$-preadic topology. Then, for M to be a flat A-module, it is necessary and sufficient that $\widehat{M}$ be a flat $\widehat{A}$-module. [0_{III} | 19]

(10.2.4) Let $\rho : A \to B$ be a local homomorphism of Noetherian local rings, k the residue field of A, and M, N two B-modules of finite type, N being assumed to be A-*flat*. Let $u : M \to N$ be a B-homomorphism. Then the following conditions are equivalent:

a) u is injective and $\mathrm{Coker}(u)$ is a flat A-module.

b) $u \otimes 1 : M \otimes_A k \to N \otimes_A k$ is injective.

(10.2.5) Let $\rho : A \to B$, $\sigma : B \to C$ be local homomorphisms of Noetherian local rings, k the residue field of A, and M a C-module of finite type. Suppose that B is a *flat* A-module. Then the following conditions are equivalent:

a) M is a flat B-module.

b) M is a flat A-module, and $M \otimes_A k$ is a flat $(B \otimes_A k)$-module.

(10.2.6) Proposition. *Let A, B be two Noetherian local rings, $\rho : A \to B$ a local homomorphism, $\mathfrak{J}$ an ideal of B contained in the maximal ideal, and M a B-module of finite type. Suppose that for every $n \geq 0$, $M_n = M/\mathfrak{J}^{n+1}M$ is a flat A-module. Then M is a flat A-module.*

We must prove that for every injective homomorphism $u : N' \to N$ of A-modules of finite type, $v = 1 \otimes u : M \otimes_A N' \to M \otimes_A N$ is injective. Now, $M \otimes_A N'$ and $M \otimes_A N$ are B-modules of finite type, hence separated for the $\mathfrak{J}$-preadic topology (0_{I}, 7.3.5); it therefore suffices to prove that the homomorphism $\widehat{v} : \widehat{(M \otimes_A N')} \to \widehat{(M \otimes_A N)}$ of the separated completions is injective. Now, we have $\widehat{v} = \varprojlim v_n$, where v_n is the homomorphism $1 \otimes u : M_n \otimes_A N' \to M_n \otimes_A N$; since by hypothesis M_n is A-flat, v_n is injective for every n, hence so is $\widehat{v}$, the functor $\varprojlim$ being left exact.

(10.2.7) Corollary. *Let A be a Noetherian ring, B a Noetherian local ring, $\rho : A \to B$ a homomorphism, f an element of the maximal ideal of B, and M a B-module of finite type. Suppose that the homothety $f_M : x \mapsto fx$ of M is injective and that M/fM is a flat A-module. Then M is a flat A-module.*

Set $M_i = f^i M$ for $i \geq 0$; since f_M is injective, M_i/M_{i+1} is isomorphic to M/fM, hence A-flat for every $i \geq 0$; from the exact sequence

$$0 \longrightarrow M_i/M_{i+1} \longrightarrow M/M_{i+1} \longrightarrow M/M_i \longrightarrow 0$$

we deduce by induction on i that M/M_i is A-*flat* for every $i \geq 0$ (0_{I}, 6.1.2); we can therefore apply (10.2.6). We can also argue directly as follows: for every A-module N of finite type, $M \otimes_A N$ is a B-module of finite type; since f belongs to the radical $\mathfrak{n}$ of B,
[0_{III} | 20] the (f)-adic topology on $M \otimes_A N$ is finer than the $\mathfrak{n}$-adic topology, and we know that the latter is *separated* (0_{I}, 7.3.5). Moreover, since M/M_i is A-flat, we have

$$f^i(M \otimes_A N) = \mathrm{Im}(M_i \otimes_A N \to M \otimes_A N) = \mathrm{Ker}(M \otimes_A N \to (M/M_i) \otimes_A N)$$

(0_{I}, 6.1.2). Now let N be an A-module of finite type, N' a submodule of N, and $j : N' \to N$ the canonical injection; in the commutative diagram

$$\begin{array}{ccc} M \otimes_A N' & \longrightarrow & (M/M_i) \otimes_A N' \\ {\scriptstyle 1_M \otimes j}\downarrow & & \downarrow{\scriptstyle 1_{M/M_i} \otimes j} \\ M \otimes_A N & \longrightarrow & (M/M_i) \otimes_A N \end{array}$$

$1_{M/M_i} \otimes j$ is injective since M/M_i is A-flat; we conclude that

$$\mathrm{Ker}(M \otimes_A N' \to M \otimes_A N) \subset \mathrm{Ker}(M \otimes_A N' \to (M/M_i) \otimes_A N')$$

whatever i may be; since the intersection of the right-hand sides reduces to 0, as we saw above, the same holds for the left-hand side, and consequently M is A-flat.

(10.2.8) Proposition. *Let A be a reduced Noetherian ring and M an A-module of finite type. Suppose that for every A-algebra B which is a discrete valuation ring, $M \otimes_A B$ is a flat B-module (hence free (10.1.3)). Then M is a flat A-module.*

We know that for M to be flat, it is necessary and sufficient that for every maximal ideal $\mathfrak{m}$ of A, $M_{\mathfrak{m}}$ be a flat $A_{\mathfrak{m}}$-module (0_{I}, 6.3.3); we may therefore restrict to the case where A is *local* (0_{I}, 1.2.8). Let then $\mathfrak{m}$ be the maximal ideal of A, $\mathfrak{p}_i$ $(1 \leq i \leq r)$ its minimal prime ideals, and k the residue field $A/\mathfrak{m}$. We know (II, 7.1.7) that for each i there exists a discrete valuation ring B_i having the same field of fractions K_i as the integral ring $A/\mathfrak{p}_i$, and dominating the latter. Set $M_i = M \otimes_A B_i$. By hypothesis, M_i is free over B_i, so, denoting by k_i the residue field of B_i, we have

$$\mathrm{rg}_{k_i}(M_i \otimes_{B_i} k_i) = \mathrm{rg}_{K_i}(M_i \otimes_{B_i} K_i). \tag{10.2.8.1}$$

But it is clear that the composite homomorphism $A \to A/\mathfrak{p}_i \to B_i$ is local, so k_i is an extension of k, and we have $M_i \otimes_{B_i} k_i = M \otimes_A k_i = (M \otimes_A k) \otimes_k k_i$, and on the other hand $M_i \otimes_{B_i} K_i = M \otimes_A K_i$. Equality (10.2.8.1) therefore implies

$$\mathrm{rg}_k(M \otimes_A k) = \mathrm{rg}_{K_i}(M \otimes_A K_i) \qquad \text{for } 1 \leq i \leq r$$

and since A is reduced, we know that this condition implies that M is a *free* A-module (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 2, prop. 7).

10.3 Existence of flat extensions of local rings

(10.3.1) Proposition. *Let A be a Noetherian local ring, $\mathfrak{J}$ its maximal ideal, and $k = A/\mathfrak{J}$ its residue field. Let K be an extension of the field k. There exists a local homomorphism from A to a Noetherian local ring B such that $B/\mathfrak{J}B$ is k-isomorphic to K and B is a flat A-module.*

We will prove this proposition in several steps.

(10.3.1.1) Suppose first that $K = k(T)$, where T is an indeterminate. In the polynomial ring $A' = A[T]$, consider the prime ideal $\mathfrak{J}' = \mathfrak{J}A'$ consisting of the polynomials having their coefficients in the ideal $\mathfrak{J}$; it is clear that $A'/\mathfrak{J}'$ is canonically isomorphic to $k[T]$. Let us show that the ring of fractions $B = A'_{\mathfrak{J}'}$ answers the question; it is evidently a Noetherian local ring with maximal ideal $\mathfrak{L} = \mathfrak{J}B$. Moreover, $B/\mathfrak{L} = (A'/\mathfrak{J}')_{\mathfrak{J}'} = (k[T])_{\mathfrak{J}'}$ is none other than the field of fractions K of $k[T]$. Finally, B is a flat A'-module and A' a free A-module, hence B is a flat A-module (0_{I}, 6.2.1). [0_{III} | 21]

(10.3.1.2) Suppose next that $K = k(t) = k[t]$, where t is algebraic over k; let $f \in k[T]$ be the minimal polynomial of t; there exists a monic polynomial $F \in A[T]$ whose canonical image in $k[T]$ is f. Again set $A' = A[T]$, and let $\mathfrak{J}'$ be the ideal $\mathfrak{J}A' + (F)$ in A'. We will see that the quotient ring $B = A'/(F)$ answers the question this time. First of all, it is clear that B is a *free* A-module, hence flat. The ring $A'/\mathfrak{J}'$ is isomorphic to

$$(A'/\mathfrak{J}A')/((\mathfrak{J}A' + (F))/\mathfrak{J}A') = k[T]/(f) = K\ ;$$

the image $\mathfrak{L}$ of $\mathfrak{J}'$ in B is therefore maximal, and we evidently have $\mathfrak{L} = \mathfrak{J}B$. Finally, B is a semi-local ring, since it is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9), and its maximal ideals correspond bijectively to those of $B/\mathfrak{J}B$ ([13], vol. I, p. 259); what precedes therefore proves that B is a local ring.

(10.3.1.3) Lemma. *Let $(A_\lambda, f_{\mu\lambda})$ be a filtered inductive system of local rings such that the $f_{\mu\lambda}$ are local homomorphisms; let $\mathfrak{m}_\lambda$ be the maximal ideal of A_λ, and let $K_\lambda = A_\lambda/\mathfrak{m}_\lambda$. Then $A' = \varinjlim A_\lambda$ is a local ring of which $\mathfrak{m}' = \varinjlim \mathfrak{m}_\lambda$ is the maximal ideal and $K = \varinjlim K_\lambda$ the residue field. Moreover, if $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$ for $\lambda < \mu$, we have $\mathfrak{m}' = \mathfrak{m}_\lambda A'$ for every λ. If, in addition, for $\lambda < \mu$, A_μ is a flat A_λ-module, and if all the A_λ are Noetherian, then A' is Noetherian and is a flat A_λ-module for every λ.*

Since $f_{\mu\lambda}(\mathfrak{m}_\lambda) \subset \mathfrak{m}_\mu$ for $\lambda < \mu$ by hypothesis, the $\mathfrak{m}_\lambda$ form an inductive system, and its limit $\mathfrak{m}'$ is evidently an ideal of A'. Moreover, if $x' \notin \mathfrak{m}'$, there exists λ such that $x' = f_\lambda(x_\lambda)$ for some $x_\lambda \in A_\lambda$ ($f_\lambda : A_\lambda \to A'$ denoting the canonical homomorphism); since $x' \notin \mathfrak{m}'$, we necessarily have $x_\lambda \notin \mathfrak{m}_\lambda$, so x_λ has an inverse y_λ in A_λ, and $y' = f_\lambda(y_\lambda)$ is the inverse of x' in A', which proves that A' is a local ring with maximal ideal $\mathfrak{m}'$; the assertion concerning K follows immediately from the fact that $\varinjlim$ is an exact functor. The hypothesis $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$ means that the canonical map $\mathfrak{m}_\lambda \otimes_{A_\lambda} A_\mu \to \mathfrak{m}_\mu$ is surjective; the relation $\mathfrak{m}' = \mathfrak{m}_\lambda A'$ therefore again follows from the exactness of the functor $\varinjlim$ and from the fact that it commutes with the tensor product.

Suppose now that for $\lambda < \mu$ we have $\mathfrak{m}_\mu = \mathfrak{m}_\lambda A_\mu$ and that A_μ is a flat A_λ-module. Then A' is a flat A_λ-module for every λ, by virtue of (0_I, 6.2.3); since A' and A_λ are local rings and $\mathfrak{m}' = \mathfrak{m}_\lambda A'$, A' is even a *faithfully flat* A_λ-module (0_I, 6.6.2). Finally, suppose in addition that the A_λ are *Noetherian*; the $\mathfrak{m}_\lambda$-preadic topologies are then separated (0_I, 7.3.5); let us show that it follows first of all that on A' the $\mathfrak{m}'$-adic topology is *separated*. Indeed, if $x' \in A'$ belongs to all the $\mathfrak{m}'^n$ ($n > 0$), it is the image of some $x_\mu \in A_\mu$ for a certain index μ, and since the inverse image in A_μ of $\mathfrak{m}'^n = \mathfrak{m}_\mu^n A'$ is $\mathfrak{m}_\mu^n$ (0_I, 6.6.1), x_μ belongs to all the $\mathfrak{m}_\mu^n$, hence $x_\mu = 0$ by hypothesis, and consequently $x' = 0$. Let us denote by $\widehat{A}'$ the completion of A' for the $\mathfrak{m}'$-adic topology; what precedes shows that we have $A' \subset \widehat{A}'$. We will show that $\widehat{A}'$ is *Noetherian* and A_λ*-flat* for every λ; it will
[0_III | 22] follow that $\widehat{A}'$ is A'-flat (0_I, 6.2.3), and since $\mathfrak{m}'\widehat{A}' \neq \widehat{A}'$, $\widehat{A}'$ is a faithfully flat A'-module (0_I, 6.6.2), whence we will finally conclude that A' is *Noetherian* (0_I, 6.5.2), which will complete the proof of the lemma.

We have $\widehat{A}' = \varprojlim_n A'/\mathfrak{m}'^n$; because A' is A_λ-flat, we have

$$\mathfrak{m}'^n/\mathfrak{m}'^{n+1} = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{A_\lambda} A' = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{K_\lambda} (K_\lambda \otimes_{A_\lambda} A') = (\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}) \otimes_{K_\lambda} K\ ;$$

since $\mathfrak{m}_\lambda^n/\mathfrak{m}_\lambda^{n+1}$ is a K_λ-vector space of finite dimension, $\mathfrak{m}'^n/\mathfrak{m}'^{n+1}$ is a K-vector space of finite dimension for every $n \geq 0$. It therefore follows from (0_I, 7.2.12) and (0_I, 7.2.8) that $\widehat{A}'$ is Noetherian. We know moreover that the maximal ideal of $\widehat{A}'$ is $\mathfrak{m}'\widehat{A}'$ and that $\widehat{A}'/\mathfrak{m}'^n\widehat{A}'$ is isomorphic to $A'/\mathfrak{m}'^n$; since $A'/\mathfrak{m}'^n = (A_\lambda/\mathfrak{m}_\lambda^n) \otimes_{A_\lambda} A'$, $A'/\mathfrak{m}'^n$ is a flat $(A_\lambda/\mathfrak{m}_\lambda^n)$-module ($0_\mathrm{I}$, 6.2.1); the criterion (10.2.2) is therefore applicable to the Noetherian A_λ-algebra $\widehat{A}'$, and shows that $\widehat{A}'$ is A_λ-flat. Q.E.D.

(10.3.1.4) Let us now tackle the general case. There exist an ordinal γ and, for every ordinal $\lambda \leq \gamma$, a subfield k_λ of K containing k, such that: 1° For every $\lambda < \gamma$, $k_{\lambda+1}$ is an extension of k_λ generated by a single element; 2° For every ordinal μ without a predecessor, $k_\mu = \bigcup_{\lambda<\mu} k_\lambda$; 3° $K = k_\gamma$. Indeed, it suffices to consider a bijection $\xi \mapsto t_\xi$ of the set of ordinals $\xi \leq \beta$ (for a suitable β) onto K, to define k_λ by transfinite induction (for $\lambda \leq \beta$) as the union of the k_μ for $\mu < \lambda$ if λ has no predecessor, and, if $\lambda = \nu + 1$,

as $k_\nu(t_\xi)$, where ξ is the smallest ordinal such that $t_\xi \notin k_\nu$; γ is then by definition the smallest ordinal $\leq \beta$ such that $k_\gamma = K$.

That being so, we will define, by transfinite induction, a family of Noetherian local rings A_λ for $\lambda \leq \gamma$, and local homomorphisms $f_{\mu\lambda} : A_\lambda \to A_\mu$ for $\lambda \leq \mu$, satisfying the following conditions:

(i) $(A_\lambda, f_{\mu\lambda})$ is an inductive system and $A_0 = A$.

(ii) For every λ, we have a k-isomorphism $A_\lambda/\mathfrak{J}A_\lambda \xrightarrow{\sim} k_\lambda$.

(iii) For $\lambda \leq \mu$, A_μ is a flat A_λ-module.

Suppose then that the A_λ and the $f_{\mu\lambda}$ have been defined for $\lambda < \mu < \xi$, and suppose first that $\xi = \zeta + 1$, so that $k_\xi = k_\zeta(t)$. If t is transcendental over k_ζ, we define A_ξ, following the procedure of (10.3.1.1), to be equal to $(A_\zeta[t])_{\mathfrak{J}A_\zeta[t]}$; $f_{\xi\zeta}$ is the canonical map, and for $\lambda < \zeta$ we take $f_{\xi\lambda} = f_{\xi\zeta} \circ f_{\zeta\lambda}$; the verification of conditions (i) to (iii) is then immediate, in view of what was proved in (10.3.1.1). Next suppose t algebraic, and let h be its minimal polynomial in $k_\zeta[T]$ and H a monic polynomial in $A_\zeta[T]$ whose image in $k_\zeta[T]$ is h; we then take A_ξ equal to $A_\zeta[T]/(H)$, the $f_{\xi\lambda}$ being defined as before; the verification of conditions (i) to (iii) then follows from what was seen in (10.3.1.2).

Now suppose that ξ has no predecessor; we then take for A_ξ the inductive limit of the inductive system of local rings $(A_\lambda, f_{\mu\lambda})$ for $\lambda < \xi$; $f_{\xi\lambda}$ is defined as the canonical map for $\lambda < \xi$. The fact that A_ξ is local and Noetherian, that the $f_{\xi\lambda}$ are local homomorphisms, and conditions (i) to (iii) for $\lambda \leq \xi$ then follow from the induction hypothesis and from Lemma (10.3.1.3). Once this construction is made, it is clear that the ring $B = A_\gamma$ satisfies the statement of (10.3.1). [0_{III} | 23]

Note that, by virtue of (10.2.1, *c*)), we have a canonical isomorphism

$$\mathrm{gr}(A) \otimes_k K \xrightarrow{\sim} \mathrm{gr}(B). \tag{10.3.1.5}$$

On the other hand, we can replace B by its $\mathfrak{J}B$-adic completion $\widehat{B}$ without changing the conclusions of (10.3.1), since $\widehat{B}$ is a flat B-module (0_{I}, 7.3.3), hence a flat A-module (0_{I}, 6.2.1).

We have moreover proved the

(10.3.2) Corollary. *If K is an extension of finite degree, we may assume that B is a finite A-algebra.*

§11 Supplement on homological algebra

11.1 Review of spectral sequences

(11.1.1) In what follows we will use a notion of spectral sequence more general than the one defined in (T, 2.4); keeping the notation of (T, 2.4), we will call a *spectral sequence* in an abelian category $\mathcal{C}$ a system E consisting of the following elements:

(a) A family (E_r^{pq}) of objects of $\mathcal{C}$ defined for $p \in \mathbb{Z}$, $q \in \mathbb{Z}$ and $r \geq 2$.

(b) A family of morphisms $d_r^{pq} : E_r^{pq} \to E_r^{p+r,q-r+1}$ such that $d_r^{p+r,q-r+1} d_r^{pq} = 0$. We set $Z_{r+1}(E_r^{pq}) = \mathrm{Ker}(d_r^{pq})$, $B_{r+1}(E_r^{pq}) = \mathrm{Im}(d_r^{p-r,q+r-1})$, so that

$$B_{r+1}(E_r^{pq}) \subset Z_{r+1}(E_r^{pq}) \subset E_r^{pq}.$$

(c) A family of isomorphisms $\alpha_r^{pq} : Z_{r+1}(E_r^{pq})/B_{r+1}(E_r^{pq}) \xrightarrow{\sim} E_{r+1}^{pq}$.

We then define for $k \geq r+1$, by induction on k, the subobjects $B_k(E_r^{pq})$ and $Z_k(E_r^{pq})$ as the inverse images, under the canonical morphism $E_r^{pq} \to E_r^{pq}/B_{r+1}(E_r^{pq})$, of the subobjects of this quotient identified by α_r^{pq} with the subobjects $B_k(E_{r+1}^{pq})$ and $Z_k(E_{r+1}^{pq})$ respectively. It is clear that we then have, up to isomorphism,

$$Z_k(E_r^{pq})/B_k(E_r^{pq}) = E_k^{pq} \qquad \text{for } k \geq r+1, \tag{11.1.1.1}$$

and, if we further set $B_r(E_r^{pq}) = 0$ and $Z_r(E_r^{pq}) = E_r^{pq}$, we have the inclusion relations

$$0 = B_r(E_r^{pq}) \subset B_{r+1}(E_r^{pq}) \subset B_{r+2}(E_r^{pq}) \subset \cdots \subset Z_{r+2}(E_r^{pq}) \subset Z_{r+1}(E_r^{pq}) \subset Z_r(E_r^{pq}) = E_r^{pq}. \tag{11.1.1.2}$$

The other elements of the data of E are then:

(d) Two subobjects $B_\infty(E_2^{pq})$ and $Z_\infty(E_2^{pq})$ of E_2^{pq} such that $B_\infty(E_2^{pq}) \subset Z_\infty(E_2^{pq})$ and, for every $k \geq 2$,

$$B_k(E_2^{pq}) \subset B_\infty(E_2^{pq}) \qquad \text{and} \qquad Z_\infty(E_2^{pq}) \subset Z_k(E_2^{pq}).$$

We set

$$E_\infty^{pq} = Z_\infty(E_2^{pq})/B_\infty(E_2^{pq}). \tag{11.1.1.3}$$

(e) A family (E^n) of objects of $\mathcal{C}$, each of which is equipped with a *decreasing filtration* $(F^p(E^n))_{p\in\mathbb{Z}}$. As usual we denote by $\mathrm{gr}(E^n)$ the graded object associated to the filtered object E^n, the direct sum of the $\mathrm{gr}_p(E^n) = F^p(E^n)/F^{p+1}(E^n)$. [0III | 24]

(f) For every pair $(p,q) \in \mathbb{Z}\times\mathbb{Z}$, an isomorphism $\beta^{pq} : E_\infty^{pq} \xrightarrow{\sim} \mathrm{gr}_p(E^{p+q})$.

The family (E^n), without the filtrations, is called *the abutment* of the spectral sequence E.

Suppose that the category $\mathcal{C}$ admits infinite direct sums, or that for every $r \geq 2$ and every $n \in \mathbb{Z}$, there are only finitely many pairs (p,q) such that $p+q = n$ and $E_r^{pq} \neq 0$ (it suffices that this be so for $r = 2$). Then the

$$E_r^{(n)} = \sum_{p+q=n} E_r^{pq}$$

are defined, and, denoting by $d_r^{(n)}$ the morphism $E_r^{(n)} \to E_r^{(n+1)}$ whose restriction to E_r^{pq} is d_r^{pq} for each pair (p,q) such that $p+q = n$, we have $d_r^{(n+1)} \circ d_r^{(n)} = 0$, in other words $(E_r^{(n)})_{n\in\mathbb{Z}}$ is a *complex* $E_r^{(\bullet)}$ in $\mathcal{C}$, with differential of degree $+1$, and it follows from c) that $\mathrm{H}^n(E_r^{(\bullet)})$ is isomorphic to $E_{r+1}^{(n)}$ for every $r \geq 2$.

(11.1.2) A *morphism* $u : E \to E'$ from a spectral sequence E to a spectral sequence $E' = (E_r'^{pq}, E'^n)$ consists of systems of morphisms $u_r^{pq} : E_r^{pq} \to E_r'^{pq}$, $u^n : E^n \to E'^n$, the u^n being compatible with the filtrations of E^n and E'^n, and the diagrams

$$\begin{array}{ccc} E_r^{pq} & \xrightarrow{d_r^{pq}} & E_r^{p+r,q-r+1} \\ {\scriptstyle u_r^{pq}}\downarrow & & \downarrow{\scriptstyle u_r^{p+r,q-r+1}} \\ E_r'^{pq} & \xrightarrow[d_r'^{pq}]{} & E_r'^{p+r,q-r+1} \end{array}$$

being commutative; moreover, by passing to quotients, u_r^{pq} gives a morphism

$$\overline{u}_r^{pq} : Z_{r+1}(E_r^{pq})/B_{r+1}(E_r^{pq}) \longrightarrow Z_{r+1}(E_r'^{pq})/B_{r+1}(E_r'^{pq})$$

and we must have $\alpha_r'^{pq} \circ \overline{u}_r^{pq} = u_{r+1}^{pq} \circ \alpha_r^{pq}$; finally, we must have $u_2^{pq}(B_\infty(E_2^{pq})) \subset B_\infty(E_2'^{pq})$, $u_2^{pq}(Z_\infty(E_2^{pq})) \subset Z_\infty(E_2'^{pq})$; by passing to quotients, u_2^{pq} then gives a morphism $u_\infty^{pq} : E_\infty^{pq} \to E_\infty'^{pq}$, and the diagram

$$\begin{array}{ccc} E_\infty^{pq} & \xrightarrow{u_\infty^{pq}} & E_\infty'^{pq} \\ \downarrow{\scriptstyle \beta^{pq}} & & \downarrow{\scriptstyle \beta'^{pq}} \\ \mathrm{gr}_p(E^{p+q}) & \xrightarrow[\mathrm{gr}_p(u^{p+q})]{} & \mathrm{gr}_p(E'^{p+q}) \end{array}$$

must be commutative.

The preceding definitions show, by induction on r, that if the u_2^{pq} are *isomorphisms*, then so are the u_r^{pq} for $r \geq 2$; *if we know moreover that* $u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq})$ and $u_2^{pq}(Z_\infty(E_2^{pq})) = Z_\infty(E_2'^{pq})$ *and that the* u^n *are isomorphisms*, then we can conclude that u is an *isomorphism*.

(11.1.3) Recall that if $(F^p(X))_{p\in\mathbb{Z}}$ is a (decreasing) filtration of an object $X \in \mathcal{C}$, we say that this filtration is *separated* if $\inf(F^p(X)) = 0$, *discrete* if there exists a p such that $F^p(X) = 0$, *exhaustive* (or *co-separated*) if $\sup(F^p(X)) = X$, and *co-discrete* if there exists p such that $F^p(X) = X$. [0_{III} | 25]

We will say that a spectral sequence $E = (E_r^{pq}, E^n)$ is *weakly convergent* if we have

$$B_\infty(E_2^{pq}) = \sup_k(B_k(E_2^{pq})), \qquad Z_\infty(E_2^{pq}) = \inf_k(Z_k(E_2^{pq}))$$

(in other words the objects $B_\infty(E_2^{pq})$ and $Z_\infty(E_2^{pq})$ are determined by the data a) to c) of the spectral sequence E). We will say that the spectral sequence E is *regular* if it is weakly convergent and if moreover:

1° For every pair (p, q), the decreasing sequence $(Z_k(E_2^{pq}))_{k\geq 2}$ is *stationary*; the hypothesis that E is weakly convergent then implies $Z_\infty(E_2^{pq}) = Z_k(E_2^{pq})$ for k sufficiently large (depending on p and q).

2° For every n, the filtration $(F^p(E^n))_{p\in\mathbb{Z}}$ of E^n is *discrete* and *exhaustive*.

We say that the spectral sequence E is *coregular* if it is weakly convergent and if moreover:

3° For every pair (p, q), the increasing sequence $(B_k(E_2^{pq}))_{k\geq 2}$ is *stationary*, which implies $B_\infty(E_2^{pq}) = B_k(E_2^{pq})$, and consequently $E_\infty^{pq} = \inf E_k^{pq}$.

4° For every n, the filtration of E^n is *co-discrete*.

Finally, we say that E is *biregular* if it is both regular and coregular, in other words if the following conditions hold:

(a) For every pair (p, q), the sequences $(B_k(E_2^{pq}))_{k\geq 2}$ and $(Z_k(E_2^{pq}))_{k\geq 2}$ are *stationary* and we have $B_\infty(E_2^{pq}) = B_k(E_2^{pq})$ and $Z_\infty(E_2^{pq}) = Z_k(E_2^{pq})$ for k sufficiently large (which implies $E_\infty^{pq} = E_k^{pq}$).

(b) For every n, the filtration $(F^p(E^n))_{p\in\mathbb{Z}}$ is *discrete* and *co-discrete* (which is also expressed by saying that it is *finite*).

The spectral sequences defined in (T, 2.4) are thus the biregular spectral sequences.

(11.1.4) Suppose that in the category $\mathcal{C}$ filtered inductive limits exist and that the functor $\varinjlim$ is *exact* (which amounts to saying that axiom AB 5) of (T, 1.5) holds (cf. T, 1.8)). The condition that the filtration $(F^p(X))_{p\in\mathbb{Z}}$ of an object $X \in \mathcal{C}$ be exhaustive can then also be written $\varinjlim_{p\to-\infty} F^p(X) = X$. If a spectral sequence E is weakly convergent, we have $B_\infty(E_2^{pq}) = \varinjlim_{k\to\infty} B_k(E_2^{pq})$; if moreover $u : E \to E'$ is a morphism from E to a weakly convergent spectral sequence E' of $\mathcal{C}$, we have $u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq})$ because of the exactness of $\varinjlim$. Moreover:

(11.1.5) Proposition. *Let $\mathcal{C}$ be an abelian category in which filtered inductive limits are exact, E, E' two regular spectral sequences of $\mathcal{C}$, and $u : E \to E'$ a morphism of spectral sequences. If the u_2^{pq} are isomorphisms, then so is u.*

Proof. We already know (11.1.2) that the u_r^{pq} are isomorphisms and that

$$u_2^{pq}(B_\infty(E_2^{pq})) = B_\infty(E_2'^{pq}) ;$$

[0_{III} | 26] the hypothesis that E and E' are regular also implies $u_2^{pq}(Z_\infty(E_2^{pq})) = Z_\infty(E_2'^{pq})$, and since u_2^{pq} is an isomorphism, so is u_∞^{pq}; we therefore conclude that $\mathrm{gr}_p(u^{p+q})$ is also an isomorphism. But since the filtrations of the E^n and of the E'^n are discrete and exhaustive, this implies that the u^n are also isomorphisms (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, th. 1). □

(11.1.6) It follows from (11.1.1.2) and from the definition (11.1.1.3) that if, in a spectral sequence E, we have $E_r^{pq} = 0$, then $E_k^{pq} = 0$ for $k \geq r$ and $E_\infty^{pq} = 0$. We say that a spectral sequence is *degenerate* if there exist an integer $r \geq 2$ and, for every integer $n \in \mathbb{Z}$, an integer $q(n)$ such that $E_r^{n-q,q} = 0$ for every $q \neq q(n)$. We first deduce from the preceding remark that we also have $E_k^{n-q,q} = 0$ for $k \geq r$ (including $k = \infty$) and $q \neq q(n)$. Moreover, the definition of E_{r+1}^{pq} shows that we have $E_{r+1}^{n-q(n),q(n)} = E_r^{n-q(n),q(n)}$; if E is weakly convergent, we therefore also have $E_\infty^{n-q(n),q(n)} = E_r^{n-q(n),q(n)}$; in other words, for every $n \in \mathbb{Z}$, $\mathrm{gr}_p(E^n) = 0$ for $p \neq n - q(n)$ and $\mathrm{gr}_{n-q(n)}(E^n) = E_r^{n-q(n),q(n)}$. If moreover the filtration of E^n is discrete and exhaustive, the sequence E is regular and we have $E^n = E_r^{n-q(n),q(n)}$ up to isomorphism.

(11.1.7) Suppose that in the category $\mathcal{C}$ filtered inductive limits exist and are exact, and let $(E_\lambda, u_{\mu\lambda})$ be an inductive system (over a filtered index set) of spectral sequences of $\mathcal{C}$. Then the *inductive limit* of this inductive system exists in the additive category of spectral sequences of objects of $\mathcal{C}$: to see this, it suffices to define E_r^{pq}, d_r^{pq}, α_r^{pq}, $B_\infty(E_2^{pq})$, $Z_\infty(E_2^{pq})$, E^n, $F^p(E^n)$ and β^{pq} as the respective inductive limits of $E_{r,\lambda}^{pq}$, $d_{r,\lambda}^{pq}$, $\alpha_{r,\lambda}^{pq}$, $B_\infty(E_{2,\lambda}^{pq})$, $Z_\infty(E_{2,\lambda}^{pq})$, E_λ^n, $F^p(E_\lambda^n)$ and β_λ^{pq}; the verification of the conditions of (11.1.1) follows from the exactness of the functor $\varinjlim$ in $\mathcal{C}$.

(11.1.8) Remark. Suppose that the category $\mathcal{C}$ is the category of A-modules over a *Noetherian* ring A (resp. over a ring A). Then the definitions of (11.1.1) show that if, for a given r, the E_r^{pq} are A-modules *of finite type* (resp. of *finite length*), then so are all the modules E_s^{pq} for $s \geq r$, as well as the E_∞^{pq}. If moreover the filtration of the abutment (E^n) is discrete and co-discrete for every n, we conclude that each of the E^n is also an A-module *of finite type* (resp. of *finite length*).

(11.1.9) We will have to consider conditions ensuring that a spectral sequence E is biregular in a "uniform" way in $p+q=n$. We will then use the following lemma:

(11.1.10) Lemma. *Let (E_r^{pq}) be a family of objects of $\mathcal{C}$ related by the data a), b), c) of (11.1.1). For a fixed integer n, the following properties are equivalent:*

(a) There exists an integer $r(n)$ such that for $r \geq r(n)$, $p+q=n$ or $p+q=n-1$, the morphisms d_r^{pq} are all zero.

(b) There exists an integer $r(n)$ such that for $p+q=n$ or $p+q=n+1$, we have $B_r(E_2^{pq}) = B_s(E_2^{pq})$ for $s \geq r \geq r(n)$.

(c) There exists an integer $r(n)$ such that for $p+q=n$ or $p+q=n-1$, we have $Z_r(E_2^{pq}) = Z_s(E_2^{pq})$ for $s \geq r \geq r(n)$.

(d) There exists an integer $r(n)$ such that for $p+q=n$, we have $B_r(E_2^{pq}) = B_s(E_2^{pq})$ and $Z_r(E_2^{pq}) = Z_s(E_2^{pq})$ for $s \geq r \geq r(n)$.

Proof. Indeed, by conditions a), b), c) of (11.1.1), saying that $Z_{r+1}(E_2^{pq}) = Z_r(E_2^{pq})$ is equivalent to saying that $d_r^{pq} = 0$, and saying that $B_r(E_2^{p+r,q-r+1}) = B_{r+1}(E_2^{p+r,q-r+1})$ is also equivalent to saying that $d_r^{pq} = 0$; the lemma follows immediately from this remark. □ [0_{III} | 27]

11.2 The spectral sequence of a filtered complex

(11.2.1) Given an abelian category $\mathcal{C}$, we adopt the convention of denoting by notations such as $K^\bullet$ the *complexes* $(K^i)_{i\in\mathbb{Z}}$ of objects of $\mathcal{C}$ in which the differential is of degree $+1$, and by notations such as $K_\bullet$ the complexes $(K_i)_{i\in\mathbb{Z}}$ of objects of $\mathcal{C}$ in which the differential is of degree -1. To every complex $K^\bullet = (K^i)$ whose differential d is of degree $+1$, we can associate a complex $K'_\bullet = (K'_i)$ by setting $K'_i = K^{-i}$, the differential $K'_i \to K'_{i-1}$ being the operator $d : K^{-i} \to K^{-i+1}$; and *vice versa*, which will allow us, depending on the circumstances, to consider one or the other type of complex and to translate every result for one of the types into results for the other. Likewise we will denote by notations such as $K^{\bullet\bullet} = (K^{ij})$ (resp. $K_{\bullet\bullet} = (K_{ij})$) *bicomplexes* of objects of $\mathcal{C}$ in which *both* differentials are of degree $+1$ (resp. -1); again we pass from one type to the other by changing the signs of the indices, and we have analogous notations and remarks for arbitrary multicomplexes. The notation $K^\bullet$ or $K_\bullet$ will also be used for *graded objects* of $\mathcal{C}$, of type $\mathbb{Z}$, which are not necessarily complexes (or which can be regarded as such for zero differentials); for example, we will write $\mathrm{H}^\bullet(K^\bullet) = (\mathrm{H}^i(K^\bullet))_{i\in\mathbb{Z}}$ for the *cohomology* of a complex $K^\bullet$ whose differential is of degree $+1$, and $\mathrm{H}_\bullet(K_\bullet) = (\mathrm{H}_i(K_\bullet))_{i\in\mathbb{Z}}$ for the *homology* of a complex $K_\bullet$ whose differential is of degree -1; when we pass from $K^\bullet$ to $K'_\bullet$ by the operation described above, we have $\mathrm{H}_i(K'_\bullet) = \mathrm{H}^{-i}(K^\bullet)$.

Recall in this connection that for a complex $K^\bullet$ (resp. $K_\bullet$), we will in general write $Z^i(K^\bullet) = \mathrm{Ker}(K^i \to K^{i+1})$ ("object of cocycles") and $B^i(K^\bullet) = \mathrm{Im}(K^{i-1} \to K^i)$ ("object of coboundaries") (resp. $Z_i(K_\bullet) = \mathrm{Ker}(K_i \to K_{i-1})$ ("object of cycles") and $B_i(K_\bullet) = \mathrm{Im}(K_{i+1} \to K_i)$ ("object of boundaries")), so that $\mathrm{H}^i(K^\bullet) = Z^i(K^\bullet)/B^i(K^\bullet)$ (resp. $\mathrm{H}_i(K_\bullet) = Z_i(K_\bullet)/B_i(K_\bullet)$).

If $K^\bullet = (K^i)$ (resp. $K_\bullet = (K_i)$) is a complex in $\mathcal{C}$, and $T : \mathcal{C} \to \mathcal{C}'$ a functor from $\mathcal{C}$ to an abelian category $\mathcal{C}'$, we denote by $T(K^\bullet)$ (resp. $T(K_\bullet)$) the complex $(T(K^i))$ (resp. $(T(K_i))$) in $\mathcal{C}'$.

We do not return to the definition of ∂-functors (T, 2.1), except to point out that we will also say ∂-functor instead of ∂^*-functor when the morphism ∂ decreases the degree

by one unit, the context having to make this point precise each time if there can be any doubt.

Finally, we will say that a *graded object* $(A_i)_{i\in\mathbb{Z}}$ of $\mathcal{C}$ is *bounded below* (resp. *above*) if there exists i_0 such that $A_i = 0$ for $i < i_0$ (resp. $i > i_0$).

(11.2.2) Let $K^\bullet$ be a complex of $\mathcal{C}$ whose differential d is of degree $+1$, and suppose it [0_{III} | 28] equipped with a *filtration* $F(K^\bullet) = (F^p(K^\bullet))_{p\in\mathbb{Z}}$ consisting of graded subobjects of $K^\bullet$, in other words $F^p(K^\bullet) = (K^i \cap F^p(K^\bullet))_{i\in\mathbb{Z}}$; moreover, we suppose that $d(F^p(K^\bullet)) \subset F^p(K^\bullet)$ for every $p \in \mathbb{Z}$. Let us then recall briefly how a spectral sequence $E(K^\bullet)$ is defined *functorially* from $K^\bullet$ (M, XV, 4 and G, I, 4.3). For $r \geq 2$, the canonical morphism $F^p(K^\bullet)/F^{p+r}(K^\bullet) \to F^p(K^\bullet)/F^{p+1}(K^\bullet)$ defines a morphism in cohomology

$$\mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+r}(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)).$$

We denote by $Z_r^{pq}(K^\bullet)$ the image of this morphism. Likewise, from the exact sequence

$$0 \to F^p(K^\bullet)/F^{p+1}(K^\bullet) \to F^{p-r+1}(K^\bullet)/F^{p+1}(K^\bullet) \to F^{p-r+1}(K^\bullet)/F^p(K^\bullet) \to 0$$

we deduce, by the cohomology exact sequence, a morphism

$$\mathrm{H}^{p+q-1}(F^{p-r+1}(K^\bullet)/F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet))$$

and we denote by $B_r^{pq}(K^\bullet)$ the image of this morphism; one shows that $B_r^{pq}(K^\bullet) \subset Z_r^{pq}(K^\bullet)$ and we take $E_r^{pq}(K^\bullet) = Z_r^{pq}(K^\bullet)/B_r^{pq}(K^\bullet)$; we will not spell out the definition of the d_r^{pq}, nor of the α_r^{pq}.

Note here that all the $Z_r^{pq}(K^\bullet)$ and $B_r^{pq}(K^\bullet)$, for fixed p, q, are subobjects of the same object $\mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet))$, which is denoted $Z_1^{pq}(K^\bullet)$; we set $B_1^{pq}(K^\bullet) = 0$, so that the preceding definitions for $Z_r^{pq}(K^\bullet)$ and $B_r^{pq}(K^\bullet)$ also apply for $r = 1$; we further set $E_1^{pq}(K^\bullet) = Z_1^{pq}(K^\bullet)$. We further define the d_1^{pq} and α_1^{pq} so that the conditions of (11.1.1) are satisfied for $r = 1$. On the other hand, we define the subobjects $Z_\infty^{pq}(K^\bullet)$, the image of the morphism

$$\mathrm{H}^{p+q}(F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)) = E_1^{pq}(K^\bullet)$$

and $B_\infty^{pq}(K^\bullet)$, the image of the morphism

$$\mathrm{H}^{p+q-1}(K^\bullet/F^p(K^\bullet)) \longrightarrow \mathrm{H}^{p+q}(F^p(K^\bullet)/F^{p+1}(K^\bullet)) = E_1^{pq}(K^\bullet)$$

deduced as above from a cohomology exact sequence. We take for $Z_\infty(E_2^{pq}(K^\bullet))$ and $B_\infty(E_2^{pq}(K^\bullet))$ the canonical images in $E_2^{pq}(K^\bullet)$ of $Z_\infty^{pq}(K^\bullet)$ and $B_\infty^{pq}(K^\bullet)$.

Finally, we denote by $F^p(\mathrm{H}^n(K^\bullet))$ the image in $\mathrm{H}^n(K^\bullet)$ of the morphism $\mathrm{H}^n(F^p(K^\bullet)) \to \mathrm{H}^n(K^\bullet)$ arising from the canonical injection $F^p(K^\bullet) \to K^\bullet$; by the cohomology exact sequence, it is also the kernel of the morphism $\mathrm{H}^n(K^\bullet) \to \mathrm{H}^n(K^\bullet/F^p(K^\bullet))$. We thus define a filtration on $E^n(K^\bullet) = \mathrm{H}^n(K^\bullet)$; we will not give here the definition of the isomorphisms β^{pq} either.

(11.2.3) The *functorial* character of $E(K^\bullet)$ is to be understood in the following way: given two *filtered* complexes $K^\bullet$, $K'^\bullet$ of $\mathcal{C}$, and a morphism of complexes $u : K^\bullet \to K'^\bullet$ *compatible with the filtrations*, we deduce from it in an evident way the morphisms u_r^{pq} (for $r \geq 1$) and u^n, and one shows that these morphisms are compatible with the d_r^{pq}, α_r^{pq} and β^{pq} in the sense of (11.1.2), and hence indeed define a morphism $E(u) : E(K^\bullet) \to E(K'^\bullet)$ of spectral sequences. Moreover, one shows that if u and v are morphisms $K^\bullet \to K'^\bullet$ of the preceding type that are *homotopic of order* $\leq k$, then $u_r^{pq} = v_r^{pq}$ for $r > k$ and $u^n = v^n$ for every n (M, XV, 3.1).

(11.2.4) Suppose that in $\mathcal{C}$ filtered inductive limits are exact. Then, if the filtration $(F^p(K^\bullet))$ of $K^\bullet$ is *exhaustive*, so is the filtration $(F^p(\mathrm{H}^n(K^\bullet)))$ for every n, since by hypothesis we have $K^\bullet = \varinjlim_{p\to-\infty} F^p(K^\bullet)$ and the hypothesis on $\mathcal{C}$ implies that cohomology commutes with inductive limits. Moreover, for the same reason, we have $B_\infty(E_2^{pq}(K^\bullet)) = \sup_k B_k(E_2^{pq}(K^\bullet))$. We say that the filtration $(F^p(K^\bullet))$ of $K^\bullet$ is *regular* if for every n there exists an integer $u(n)$ such that $\mathrm{H}^n(F^p(K^\bullet)) = 0$ for $p > u(n)$. This is the case in particular when the filtration of $K^\bullet$ is *discrete*. When the filtration of $K^\bullet$ is regular and exhaustive, and filtered inductive limits in $\mathcal{C}$ are exact, one shows (M, XV, 4) that the spectral sequence $E(K^\bullet)$ is *regular*. [0_{III} | 29]

11.3 The spectral sequences of a bicomplex

(11.3.1) As regards the conventions concerning bicomplexes, we follow those of (T, 2.4) rather than those of (M), the two differentials d', d'' (of degree $+1$) of such a bicomplex $K^{\bullet\bullet} = (K^{ij})$ being therefore assumed to *commute*. Suppose that one of the following two conditions holds:

1° Infinite direct sums exist in $\mathcal{C}$.

2° For every $n \in \mathbb{Z}$, there are only a *finite* number of pairs (p, q) such that $p + q = n$ and $K^{pq} \neq 0$.

Then the bicomplex $K^{\bullet\bullet}$ defines a (simple) complex $(K'^n)_{n\in\mathbb{Z}}$, with $K'^n = \sum_{i+j=n} K^{ij}$, the differential d (of degree $+1$) of this complex being given by $dx = d'x + (-1)^i d''x$ for $x \in K^{ij}$. When we speak in what follows of the (simple) complex *defined by a bicomplex* $K^{\bullet\bullet}$, it will always be understood that one of the preceding conditions is satisfied. We will adopt analogous conventions for multicomplexes.

We denote by $K^{i,\bullet}$ (resp. $K^{\bullet,j}$) the simple complex $(K^{ij})_{j\in\mathbb{Z}}$ (resp. $(K^{ij})_{i\in\mathbb{Z}}$), and by $Z^p_{\mathrm{II}}(K^{i,\bullet})$, $B^p_{\mathrm{II}}(K^{i,\bullet})$, $\mathrm{H}^p_{\mathrm{II}}(K^{i,\bullet})$ (resp. $Z^p_{\mathrm{I}}(K^{\bullet,j})$, $B^p_{\mathrm{I}}(K^{\bullet,j})$, $\mathrm{H}^p_{\mathrm{I}}(K^{\bullet,j})$) its p-th objects of cocycles, of coboundaries and of cohomology respectively; the differential $d' : K^{i,\bullet} \to K^{i+1,\bullet}$ is a morphism of complexes, which therefore gives an operator on the cocycles, the coboundaries and the cohomology,

$$\begin{aligned} d' &: Z^p_{\mathrm{II}}(K^{i,\bullet}) \longrightarrow Z^p_{\mathrm{II}}(K^{i+1,\bullet}), \\ d' &: B^p_{\mathrm{II}}(K^{i,\bullet}) \longrightarrow B^p_{\mathrm{II}}(K^{i+1,\bullet}), \\ d' &: \mathrm{H}^p_{\mathrm{II}}(K^{i,\bullet}) \longrightarrow \mathrm{H}^p_{\mathrm{II}}(K^{i+1,\bullet}), \end{aligned}$$

and it is clear that for these operators, $(Z^p_{\mathrm{II}}(K^{i,\bullet}))_{i\in\mathbb{Z}}$, $(B^p_{\mathrm{II}}(K^{i,\bullet}))_{i\in\mathbb{Z}}$ and $(\mathrm{H}^p_{\mathrm{II}}(K^{i,\bullet}))_{i\in\mathbb{Z}}$ are complexes; we will denote the complex $(\mathrm{H}^p_{\mathrm{II}}(K^{i,\bullet}))_{i\in\mathbb{Z}}$ by $\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet})$, and its q-th objects of cocycles, of coboundaries and of cohomology by $Z^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$, $B^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$ and $\mathrm{H}^q_{\mathrm{I}}(\mathrm{H}^p_{\mathrm{II}}(K^{\bullet\bullet}))$. We define similarly the complexes $\mathrm{H}^p_{\mathrm{I}}(K^{\bullet\bullet})$ and their cohomology objects $\mathrm{H}^q_{\mathrm{II}}(\mathrm{H}^p_{\mathrm{I}}(K^{\bullet\bullet}))$. Recall on the other hand that $\mathrm{H}^n(K^{\bullet\bullet})$ denotes the n-th cohomology object of the (simple) complex defined by $K^{\bullet\bullet}$.

(11.3.2) On the complex defined by a bicomplex $K^{\bullet\bullet}$, we can consider two canonical filtrations $(F^p_{\mathrm{I}}(K^{\bullet\bullet}))$ and $(F^p_{\mathrm{II}}(K^{\bullet\bullet}))$ given by

$$F^p_{\mathrm{I}}(K^{\bullet\bullet}) = \left(\sum_{\substack{i+j=n \\ i\geq p}} K^{ij}\right)_{n\in\mathbb{Z}}, \qquad F^p_{\mathrm{II}}(K^{\bullet\bullet}) = \left(\sum_{\substack{i+j=n \\ j\geq p}} K^{ij}\right)_{n\in\mathbb{Z}}. \tag{11.3.2.1}$$

[0_{III} | 30] which, by definition, are indeed graded subobjects of the (simple) complex defined by $K^{\bullet\bullet}$, and therefore make this complex a filtered complex; moreover, it is clear that these filtrations are exhaustive and separated.

To each of these filtrations there corresponds a spectral sequence (11.2.2); we will denote by ${}'E(K^{\bullet\bullet})$ and ${}''E(K^{\bullet\bullet})$ the spectral sequences corresponding to $(F_{\text{I}}^p(K^{\bullet\bullet}))$ and $(F_{\text{II}}^p(K^{\bullet\bullet}))$ respectively, called the *spectral sequences of the bicomplex* $K^{\bullet\bullet}$, both having as abutment the cohomology $(\text{H}^n(K^{\bullet\bullet}))$. One shows moreover (M, XV, 6) that we have

$$ {}'E_2^{pq}(K^{\bullet\bullet}) = \text{H}_{\text{I}}^p(\text{H}_{\text{II}}^q(K^{\bullet\bullet})), \qquad {}''E_2^{pq}(K^{\bullet\bullet}) = \text{H}_{\text{II}}^q(\text{H}_{\text{I}}^p(K^{\bullet\bullet})). \tag{11.3.2.2} $$

Every morphism $u : K^{\bullet\bullet} \to K'^{\bullet\bullet}$ of bicomplexes is *ipso facto* compatible with the filtrations of the same type of $K^{\bullet\bullet}$ and $K'^{\bullet\bullet}$, and hence defines a morphism for each of the two spectral sequences; moreover, two *homotopic* morphisms define a homotopy *of order* ≤ 1 of the corresponding filtered (simple) complexes, and hence the *same* morphism for each of the two spectral sequences (M, XV, 6.1).

(11.3.3) Proposition. *Let $K^{\bullet\bullet} = (K^{ij})$ be a bicomplex in an abelian category $\mathcal{C}$.*

(i) If there exist i_0 and j_0 such that $K^{ij} = 0$ for $i < i_0$ or $j < j_0$ (resp. $i > i_0$ or $j > j_0$), the two spectral sequences ${}'E(K^{\bullet\bullet})$ and ${}''E(K^{\bullet\bullet})$ are biregular.

(ii) If there exist i_0 and i_1 such that $K^{ij} = 0$ for $i < i_0$ or $i > i_1$ (resp. if there exist j_0 and j_1 such that $K^{ij} = 0$ for $j < j_0$ or $j > j_1$), the two spectral sequences ${}'E(K^{\bullet\bullet})$ and ${}''E(K^{\bullet\bullet})$ are biregular.

Suppose moreover that in $\mathcal{C}$ filtered inductive limits exist and are exact. Then:

(iii) If there exists i_0 such that $K^{ij} = 0$ for $i > i_0$ (resp. if there exists j_0 such that $K^{ij} = 0$ for $j < j_0$), the sequence ${}'E(K^{\bullet\bullet})$ is regular.

(iv) If there exists i_0 such that $K^{ij} = 0$ for $i < i_0$ (resp. if there exists j_0 such that $K^{ij} = 0$ for $j > j_0$), the sequence ${}''E(K^{\bullet\bullet})$ is regular.

Proof. The proposition follows immediately from the definitions (11.1.3) and from (11.2.4), as well as from the following observations concerning the filtration F_{I} (and the analogous observations deduced from them for F_{II} by exchanging the roles of the two indices in $K^{\bullet\bullet}$):

1° If there exists i_0 such that $K^{ij} = 0$ for $i > i_0$, the filtration $F_{\text{I}}(K^{\bullet\bullet})$ is discrete.

2° If there exists i_0 such that $K^{ij} = 0$ for $i < i_0$, the filtration $F_{\text{I}}(K^{\bullet\bullet})$ is codiscrete. We deduce immediately that the same holds for the corresponding filtration $F_{\text{I}}(\text{H}^n(K^{\bullet\bullet}))$ for every n; moreover, the definition of B_r^{pq} corresponding to the filtration $F_{\text{I}}(K^{\bullet\bullet})$ (11.2.2) shows that for every pair (p, q), the sequence $(B_r^{pq})_{r\geq 2}$ is stationary.

3° If there exists j_0 such that $K^{ij} = 0$ for $j < j_0$, we have

$$ F_{\text{I}}^{p+r}(K^{\bullet\bullet}) \cap \left(\sum_{i+j=n} K^{ij} \right) = 0 $$

as soon as $p + r + j_0 > n$, hence $Z_r^{pq} = Z_\infty(E_2^{pq})$ for $r > q - j_0 + 1$; on the other hand, $\text{H}^n(F_{\text{I}}^p(K^{\bullet\bullet})) = 0$ for $p > n - j_0 + 1$.

4° If there exists j_0 such that $K^{ij} = 0$ for $j > j_0$, we have

$$F_{\mathrm{I}}^{p-r+1}(K^{\bullet\bullet}) \cap \left(\sum_{i+j=n} K^{ij} \right) = \sum_{i+j=n} K^{ij}.$$

as soon as $p - r + 1 + j_0 < n$, hence $B_r^{pq} = B_\infty(E_2^{pq})$ for $r > j_0 - q + 1$; on the other hand, $\mathrm{H}^n(F_{\mathrm{I}}^p(K^{\bullet\bullet})) = \mathrm{H}^n(K^{\bullet\bullet})$ for $p + j_0 < n - 1$. [0_{III} | 31]

□

(11.3.4) Suppose that the bicomplex $K^{\bullet\bullet} = (K^{ij})$ is such that $K^{ij} = 0$ for $i < 0$ or $j < 0$. We know that we can then define, for every $p \in \mathbb{Z}$, a canonical "edge homomorphism"

$$'E_2^{p0}(K^{\bullet\bullet}) \longrightarrow \mathrm{H}^p(K^{\bullet\bullet}) \tag{11.3.4.1}$$

(M, XV, 6). Let us recall briefly that this is due, on the one hand, to the fact that in the spectral sequence $'E(K^{\bullet\bullet})$ we have $Z_r^{p0} = Z_{\mathrm{I}}^p(Z_{\mathrm{II}}^0(K^{\bullet\bullet}))$ for $2 \leq r \leq +\infty$, and on the other hand to the fact that $\mathrm{H}^p(F_{\mathrm{I}}^{p+1}(K^{\bullet\bullet})) = 0$, so that the isomorphism $\beta^{p0} :' E_\infty^{p0} \xrightarrow{\sim} \mathrm{H}^p(F_{\mathrm{I}}^p)/\mathrm{H}^p(F_{\mathrm{I}}^{p+1})$ gives a homomorphism $'E_\infty^{p0} \to \mathrm{H}^p(F_{\mathrm{I}}^p(K^{\bullet\bullet})) \to \mathrm{H}^p(K^{\bullet\bullet})$; the equality of all the Z_r^{p0} then makes it possible to define canonical homomorphisms $'E_r^{p0} \to' E_s^{p0}$ for $r \leq s$, and in particular a homomorphism $'E_2^{p0} \to' E_\infty^{p0}$, whence by composition the edge homomorphism $'E_2^{p0} \to \mathrm{H}^p(K^{\bullet\bullet})$; moreover, one verifies immediately that, to the class mod. B_2^{p0} of an element $z \in Z_{\mathrm{II}}^0(K^{\bullet\bullet}) \subset K^{p0}$ such that $d'z = 0$, the edge homomorphism thus defined assigns in $'E_\infty^{p0}$ the class of z mod. B_∞^{p0}, and then to the latter the cohomology class of z in $\mathrm{H}^p(K^{\bullet\bullet})$. We thus see finally that *the edge homomorphism (11.3.4.1) arises, by passing to cohomology, from the canonical injection* $Z_{\mathrm{II}}^0(K^{\bullet\bullet}) \to K^{\bullet\bullet}$ (where $K^{\bullet\bullet}$ is considered as a simple complex). In the same way we naturally interpret the edge homomorphism

$$''E_2^{p0}(K^{\bullet\bullet}) \longrightarrow \mathrm{H}^p(K^{\bullet\bullet}) \tag{11.3.4.2}$$

as arising from the canonical injection $Z_{\mathrm{I}}^0(K^{\bullet\bullet}) \to K^{\bullet\bullet}$.

(11.3.5) Now let $K_{\bullet\bullet} = (K_{ij})$ be a bicomplex of $\mathcal{C}$ whose two differentials are of degree -1. We will then write $K_{i,\bullet}$ (resp. $K_{\bullet,j}$) for the simple complex $(K_{ij})_{j\in\mathbb{Z}}$ (resp. $(K_{ij})_{i\in\mathbb{Z}}$), $\mathrm{H}_p^{\mathrm{II}}(K_{i,\bullet})$ (resp. $\mathrm{H}_p^{\mathrm{I}}(K_{\bullet,j})$) for its p-th homology object, $\mathrm{H}_p^{\mathrm{II}}(K_{\bullet\bullet})$ (resp. $\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet})$) for the complex $(\mathrm{H}_p^{\mathrm{II}}(K_{i,\bullet}))_{i\in\mathbb{Z}}$ (resp. $(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet,j}))_{j\in\mathbb{Z}}$), and $\mathrm{H}_q^{\mathrm{I}}(\mathrm{H}_p^{\mathrm{II}}(K_{\bullet\bullet}))$ (resp. $\mathrm{H}_q^{\mathrm{II}}(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet}))$) for its q-th homology object; analogous notation for the objects of cycles and objects of boundaries; finally, $\mathrm{H}_n(K_{\bullet\bullet})$ will denote (when it exists) the n-th homology object of the simple complex (with differential of degree -1) defined by $K_{\bullet\bullet}$.

Let $K'^{\bullet\bullet} = (K'^{ij})$, with $K'^{ij} = K_{-i,-j}$, be the bicomplex with differentials of degree $+1$ associated to $K_{\bullet\bullet}$; by definition, the *spectral sequences* of $K_{\bullet\bullet}$ are those of $K'^{\bullet\bullet}$, which are written $'E(K_{\bullet\bullet})$ and $''E(K_{\bullet\bullet})$, where however the notation is changed by setting

$$'E_{pq}^r(K_{\bullet\bullet}) =' E_r^{-p,-q}(K'^{\bullet\bullet}), \qquad ''E_{pq}^r(K_{\bullet\bullet}) ='' E_r^{-p,-q}(K'^{\bullet\bullet})$$

for $2 \leq r \leq \infty$. With this notation, we have

$$'E_{pq}^2(K_{\bullet\bullet}) = \mathrm{H}_p^{\mathrm{I}}(\mathrm{H}_q^{\mathrm{II}}(K_{\bullet\bullet})), \qquad ''E_{pq}^2(K_{\bullet\bullet}) = \mathrm{H}_q^{\mathrm{II}}(\mathrm{H}_p^{\mathrm{I}}(K_{\bullet\bullet})).$$

To avoid sign errors, it will in general be preferable, for the relations between these spectral sequences and their abutment, to go back to the complex $K'^{\bullet\bullet}$. Let us note, however, the criteria corresponding to (11.3.3):

(11.3.6) The spectral sequences $'E(K_{\bullet\bullet})$ and $''E(K_{\bullet\bullet})$ are *biregular* in the following cases:

[0$_{\text{III}}$ | 32]

(a) There exist i_0 and j_0 such that $K_{ij} = 0$ for $i > i_0$ or for $j > j_0$ (resp. for $i < i_0$ or for $j < j_0$).

(b) There exist i_0 and i_1 such that $K_{ij} = 0$ for $i < i_0$ and $i > i_1$.

(c) There exist j_0 and j_1 such that $K_{ij} = 0$ for $j < j_0$ and $j > j_1$.

The sequence $'E(K_{\bullet\bullet})$ is regular if there exists i_0 such that $K_{ij} = 0$ for $i < i_0$, or if there exists j_0 such that $K_{ij} = 0$ for $j > j_0$.

The sequence $''E(K_{\bullet\bullet})$ is regular if there exists i_0 such that $K_{ij} = 0$ for $i > i_0$, or if there exists j_0 such that $K_{ij} = 0$ for $j < j_0$.

11.4 Hypercohomology of a functor with respect to a complex $K^\bullet$

(11.4.1) Let $\mathcal{C}$ be an abelian category; recall that a *right* (or *cohomological*) *resolution* of an object A of $\mathcal{C}$ is a complex of objects of $\mathcal{C}$, whose differential is of degree $+1$,

$$0 \longrightarrow L^0 \longrightarrow L^1 \longrightarrow L^2 \longrightarrow \cdots$$

equipped with a morphism $\varepsilon : A \to L^0$ called the *augmentation* of the resolution (and which can be regarded as a morphism of complexes

$$\begin{array}{ccccccccc} 0 & \longrightarrow & A & \longrightarrow & 0 & \longrightarrow & 0 & \longrightarrow & \cdots) \\ & & \downarrow{\scriptstyle \varepsilon} & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & L^0 & \longrightarrow & L^1 & \longrightarrow & L^2 & \longrightarrow & \cdots \end{array}$$

such that the sequence

$$0 \longrightarrow A \xrightarrow{\varepsilon} L^0 \longrightarrow L^1 \longrightarrow \cdots$$

is exact; likewise a *left* (or *homological*) *resolution* of A is a complex $0 \leftarrow L_0 \leftarrow L_1 \leftarrow \cdots$ of objects of $\mathcal{C}$ whose differential is of degree -1, equipped with an augmentation $\varepsilon : L_0 \to A$, such that the sequence

$$0 \longleftarrow A \xleftarrow{\varepsilon} L_0 \longleftarrow L_1 \longleftarrow \cdots$$

is exact.

When a right resolution $(L^i)_{i\geq 0}$ of an object A is such that $L^i = 0$ for $i \geq n+1$, we say that this resolution is of *length* $\leq n$. A left resolution of length $\leq n$ is defined similarly. A resolution that is of length $\leq n$ for some integer n is said to be *finite*.

A resolution of A is said to be *projective* (resp. *injective*) if the objects of $\mathcal{C}$ other than A of which it is composed are *projective* (resp. *injective*). When $\mathcal{C}$ is the category of modules (left modules, for example) over a ring, we will likewise say that a resolution of A is *flat* (resp. *free*) when the modules other than A of which it is composed are *flat* (resp. *free*).

(11.4.2) Let $K^\bullet = (K^i)_{i\in\mathbb{Z}}$ be a complex of objects of $\mathcal{C}$ whose differential is of degree $+1$.

We call a *right Cartan–Eilenberg resolution* of $K^\bullet$ the pair consisting of a bicomplex $L^{\bullet\bullet} = (L^{ij})$ with differentials of degree $+1$, with $L^{ij} = 0$ for $j < 0$, and of a morphism of
[0$_{\text{III}}$ | 33] simple complexes $\varepsilon : K^\bullet \to L^{\bullet,0}$, such that the following conditions are satisfied:

(i) For each index i, the sequences

$$0 \longrightarrow K^i \xrightarrow{\varepsilon} L^{i0} \longrightarrow L^{i1} \longrightarrow \cdots$$
$$0 \longrightarrow \mathrm{B}^i(K^\bullet) \xrightarrow{\varepsilon} \mathrm{B}_{\mathrm{I}}^i(L^{\bullet,0}) \longrightarrow \mathrm{B}_{\mathrm{I}}^i(L^{\bullet,1}) \longrightarrow \cdots$$
$$0 \longrightarrow \mathrm{Z}^i(K^\bullet) \xrightarrow{\varepsilon} \mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,0}) \longrightarrow \mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,1}) \longrightarrow \cdots$$
$$0 \longrightarrow \mathrm{H}^i(K^\bullet) \xrightarrow{\varepsilon} \mathrm{H}_{\mathrm{I}}^i(L^{\bullet,0}) \longrightarrow \mathrm{H}_{\mathrm{I}}^i(L^{\bullet,1}) \longrightarrow \cdots$$

are exact; in other words $(L^{i,\bullet})$, $(\mathrm{B}_{\mathrm{I}}^i(L^{\bullet,\bullet}))$, $(\mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,\bullet}))$ and $(\mathrm{H}_{\mathrm{I}}^i(L^{\bullet,\bullet}))$ are *resolutions* of K^i, $\mathrm{B}^i(K^\bullet)$, $\mathrm{Z}^i(K^\bullet)$ and $\mathrm{H}^i(K^\bullet)$ respectively.

(ii) For each j, the simple complex $L^{\bullet,j}$ is *split*, in other words, the exact sequences

$$0 \longrightarrow \mathrm{B}_{\mathrm{I}}^i(L^{\bullet,j}) \longrightarrow \mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,j}) \longrightarrow \mathrm{H}_{\mathrm{I}}^i(L^{\bullet,j}) \longrightarrow 0 \tag{11.4.2.1}$$
$$0 \longrightarrow \mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,j}) \longrightarrow L^{ij} \longrightarrow \mathrm{B}_{\mathrm{I}}^{i+1}(L^{\bullet,j}) \longrightarrow 0 \tag{11.4.2.2}$$

are split.

One proves (M, XVII, 1.2) that if every object of $\mathcal{C}$ is a subobject of an injective object, every complex $K^\bullet$ of $\mathcal{C}$ admits an *injective* Cartan–Eilenberg resolution, that is, one consisting of injective objects L^{ij} (condition (ii) above then implies that the $\mathrm{B}_{\mathrm{I}}^i(L^{\bullet,j})$, $\mathrm{Z}_{\mathrm{I}}^i(L^{\bullet,j})$ and $\mathrm{H}_{\mathrm{I}}^i(L^{\bullet,j})$ are also injective objects). Moreover, for every morphism $f : K^\bullet \to K'^\bullet$ of complexes of $\mathcal{C}$, every Cartan–Eilenberg resolution $L^{\bullet\bullet}$ of $K^\bullet$ and every injective Cartan–Eilenberg resolution $L'^{\bullet\bullet}$ of $K'^\bullet$, there exists a morphism of bicomplexes $F : L^{\bullet\bullet} \to L'^{\bullet\bullet}$ compatible with f and the augmentations, and if f and g are two homotopic morphisms from $K^\bullet$ to $K'^\bullet$, the corresponding morphisms from $L^{\bullet\bullet}$ to $L'^{\bullet\bullet}$ are homotopic (*loc. cit.*).

When $K^\bullet$ is *bounded below* (resp. *above*), we can take $L^{\bullet\bullet}$ such that $L^{ij} = 0$ for $i < i_0$ (resp. $i > i_0$) if $K^i = 0$ for $i < i_0$ (resp. $i > i_0$) (M, XVII, 1.3).

Suppose on the other hand that there exists an integer n such that every object of $\mathcal{C}$ admits an *injective resolution of length* $\leq n$; then we may suppose that $L^{ij} = 0$ for $j > n$ (M, XVII, 1.4).

(11.4.3) Now let T be a *covariant additive functor* from $\mathcal{C}$ to an abelian category $\mathcal{C}'$. Given a complex $K^\bullet$ of $\mathcal{C}$ and an injective Cartan–Eilenberg resolution $L^{\bullet\bullet}$ of $K^\bullet$, suppose that the (simple) complex defined by the bicomplex $T(L^{\bullet\bullet})$ exists (cf. 11.3.1); then the two spectral sequences ${}'E(T(L^{\bullet\bullet}))$ and ${}''E(T(L^{\bullet\bullet}))$ of this bicomplex are called the *hypercohomology spectral sequences of* T *with respect to the complex* $K^\bullet$; by virtue of (11.4.2) and (11.3.2), they indeed depend only on $K^\bullet$ and not on the injective Cartan–Eilenberg resolution $L^{\bullet\bullet}$ chosen; moreover, they depend *functorially* on $K^\bullet$. They have the same abutment $\mathrm{H}^\bullet(T(L^{\bullet\bullet}))$, also called the *hypercohomology of* T *with respect to* $K^\bullet$, and denoted $\mathrm{R}^\bullet T(K^\bullet)$. One shows that the E_2 terms of the two preceding spectral sequences are given by

$${}'E_2^{pq} = \mathrm{H}^p(\mathrm{R}^q T(K^\bullet)) \tag{11.4.3.1}$$
$${}''E_2^{pq} = \mathrm{R}^p T(\mathrm{H}^q(K^\bullet)) \tag{11.4.3.2}$$

$\mathrm{R}^p T$ denoting as usual the p-th *derived functor* of T for $p \in \mathbb{Z}$; $\mathrm{R}^q T(K^\bullet)$ denotes the complex $(\mathrm{R}^q T(K^i))_{i\in\mathbb{Z}}$. [$0_{\mathrm{III}}$ | 34]

Unless expressly stated otherwise, we will henceforth suppose that every object of $\mathcal{C}$ is a subobject of an injective object of $\mathcal{C}$, so that injective Cartan–Eilenberg resolutions exist for every complex of $\mathcal{C}$. Since $L^{ij} = 0$ for $j < 0$, the criteria of (11.3.3) show that *both* hypercohomology spectral sequences of T with respect to $K^\bullet$ exist and are *biregular* in each of the following two cases:

1° $K^\bullet$ is bounded below;

2° Every object of $\mathcal{C}$ admits an injective resolution of length at most equal to an integer n (independent of the object under consideration).

Indeed, in the first case we may suppose (11.4.2) that there exists i_0 such that $L^{ij} = 0$ for $i < i_0$, and in the second that there exists j_1 such that $L^{ij} = 0$ for $j > j_1$; in each of the two cases it is moreover clear that for given n there are only finitely many pairs (i, j) such that $L^{ij} \neq 0$ and $i + j = n$, which establishes our assertions.

When we suppose that in $\mathcal{C}'$ filtered inductive limits exist and are exact (which implies in particular the existence in $\mathcal{C}'$ of infinite direct sums), then the complex defined by the bicomplex $T(L^{\bullet\bullet})$ exists, and the criterion (11.3.3) shows that the sequence ${}'E(T(L^{\bullet\bullet}))$ is always *regular*.

When $K^\bullet$ is a complex all of whose terms K^i are zero except a single one K^{i_0}, $\mathrm{R}^n T(K^\bullet)$ is isomorphic to $\mathrm{R}^{n-i_0}T(K^{i_0})$, as follows immediately from the definitions by taking a Cartan–Eilenberg resolution $L^{\bullet\bullet}$ such that $L^{ij} = 0$ for $i \neq i_0$.

If $K^\bullet$ and $K'^\bullet$ are two complexes of $\mathcal{C}$, and f, g two *homotopic* morphisms from $K^\bullet$ to $K'^\bullet$, then the morphisms $\mathrm{R}^\bullet T(K^\bullet) \to \mathrm{R}^\bullet T(K'^\bullet)$ deduced from f and g are identical, and the same holds for the morphisms of the cohomology spectral sequences.

(11.4.5) Proposition. *Suppose that in $\mathcal{C}'$ filtered inductive limits exist and are exact. If $\mathrm{R}^n T(K^i) = 0$ for every $n > 0$ and every $i \in \mathbb{Z}$, we have functorial isomorphisms*

$$\mathrm{R}^i T(K^\bullet) \xrightarrow{\sim} \mathrm{H}^i(T(K^\bullet)) \qquad (i \in \mathbb{Z}). \tag{11.4.5.1}$$

Proof. Indeed, the only nonzero E_2 terms of the first spectral sequence (11.4.3.1) are then ${}'E_2^{p0} = \mathrm{H}^p(T(K^\bullet))$; in other words, this sequence is *degenerate*; since it is regular (11.4.4), the conclusion follows from (11.1.6). □

(11.4.6) Now consider, for example, a *covariant bifunctor* $(M, N) \mapsto T(M, N)$ from $\mathcal{C} \times \mathcal{C}'$ to $\mathcal{C}''$, $\mathcal{C}$, $\mathcal{C}'$, $\mathcal{C}''$ being three abelian categories; we suppose, for simplicity, that T is additive in each of its arguments, and moreover that every object of $\mathcal{C}$ and every object of $\mathcal{C}'$ is a subobject of an injective object, and that filtered inductive limits exist in $\mathcal{C}''$ and are exact. We then define the *hypercohomology of T with respect to two complexes* $K^\bullet$, $K'^\bullet$ of $\mathcal{C}$ and $\mathcal{C}'$ respectively, with differentials of degree $+1$, by taking for $K^\bullet$ (resp. $K'^\bullet$) an injective Cartan–Eilenberg resolution $L^{\bullet\bullet}$ (resp. $L'^{\bullet\bullet}$); then $T(L^{\bullet\bullet}, L'^{\bullet\bullet})$ is a quadricomplex of $\mathcal{C}''$, which we regard as a *bicomplex* of $\mathcal{C}''$ by taking as degrees of $T(L^{ij}, L'^{hk})$ the integers $i + h$ and $j + k$. The *hypercohomology of T with respect to $K^\bullet$ and $K'^\bullet$* is by definition the cohomology $\mathrm{H}^\bullet(T(L^{\bullet\bullet}, L'^{\bullet\bullet}))$ of this bicomplex (in other words, that of the associated simple complex), denoted $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet)$; it is the abutment
[0_{III} | 35] of two spectral sequences whose E_2 terms are given by

$${}'E_2^{pq} = \mathrm{H}^p(\mathrm{R}^q T(K^\bullet, K'^\bullet)) \tag{11.4.6.1}$$

$${}''E_2^{pq} = \sum_{q'+q''=q} \mathrm{R}^p T(\mathrm{H}^{q'}(K^\bullet), \mathrm{H}^{q''}(K'^\bullet)) \tag{11.4.6.2}$$

(cf. M, XVII, 2).

Here $\mathrm{R}^q T(K^\bullet, K'^\bullet)$ is the bicomplex $(\mathrm{R}^q T(K^i, K'^j))_{(i,j)\in\mathbb{Z}\times\mathbb{Z}}$ and the right-hand side of (11.4.6.1) is its cohomology when it is regarded as a simple complex.

Moreover, the first spectral sequence is always regular, and the two spectral sequences are biregular when there exists n such that every object of $\mathcal{C}$ and every object of $\mathcal{C}'$ admits

an injective resolution of length $\leq n$, or when $K^\bullet$ and $K'^\bullet$ are bounded below; in the latter case, we can moreover omit the hypothesis that inductive limits exist in $\mathcal{C}''$.

If $K_1^\bullet$, $K_1'^\bullet$ are two other complexes of $\mathcal{C}$ and $\mathcal{C}'$ respectively, f, g two homotopic morphisms from $K^\bullet$ to $K_1^\bullet$, and f', g' two homotopic morphisms from $K'^\bullet$ to $K_1'^\bullet$, then the morphisms $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \to \mathrm{R}^\bullet T(K_1^\bullet, K_1'^\bullet)$ deduced from f and f' on the one hand, and from g and g' on the other, are identical, and the same holds for the morphisms of the hypercohomology spectral sequences.

This generalizes easily to an arbitrary covariant additive multifunctor.

(11.4.7) Proposition. *Suppose that for every injective object I of $\mathcal{C}$ (resp. I' of $\mathcal{C}'$), $A' \mapsto T(I, A')$ (resp. $A \mapsto T(A, I')$) is an exact functor. Then, with the notation of (11.4.6), we have canonical isomorphisms*

$$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, K'^\bullet)) \xrightarrow{\sim} \mathrm{H}^\bullet(T(K^\bullet, L'^{\bullet\bullet})) \tag{11.4.7.1}$$

where the last two terms are the cohomology of the simple complexes defined by the tricomplexes $T(L^{\bullet\bullet}, K'^\bullet)$ and $T(K^\bullet, L'^{\bullet\bullet})$ respectively.

Proof. Let us define, for example, the first of these isomorphisms. The quadricomplex $T(L^{\bullet\bullet}, L'^{\bullet\bullet})$ can be regarded as a *bicomplex* by taking as degrees of $T(L^{ij}, L'^{hk})$ the numbers $i + j + h$ and k. Since for each h, $L'^{h,\bullet}$ is a *resolution* of K'^h, we have for this bicomplex, by virtue of the hypothesis on T, $\mathrm{H}_{\mathrm{II}}^q(T(L^{\bullet\bullet}, L'^{\bullet\bullet})) = 0$ for $q \neq 0$ and $\mathrm{H}_{\mathrm{II}}^0(T(L^{\bullet\bullet}, L'^{\bullet\bullet})) = T(L^{\bullet\bullet}, K'^\bullet)$; the first spectral sequence of this bicomplex is therefore *degenerate*; since $L'^{hk} = 0$ for $k < 0$, this sequence is moreover regular (11.3.3), and the conclusion therefore follows from (11.1.6). □

We have analogous results for a covariant multifunctor in an arbitrary number n of arguments: in the computation of hypercohomology, it is not necessary to replace *all* the complexes by a Cartan–Eilenberg resolution, but only $n-1$ of them, provided that, when we fix any $n-1$ arguments by giving them *injective* objects as values, the covariant functor in the remaining argument is *exact*.

11.5 Passage to the inductive limit in hypercohomology

(11.5.1) Lemma. *Let $K^\bullet = (K^i)_{i\in\mathbb{Z}}$ be a complex of $\mathcal{C}$, and for every integer $r \in \mathbb{Z}$, let $K_{(r)}^\bullet$ be the complex such that $K_{(r)}^i = 0$ for $i < r$ and $K_{(r)}^i = K^i$ for $i \geq r$. Let T be a covariant additive functor from $\mathcal{C}$ to $\mathcal{C}'$ commuting with inductive limits (we suppose that filtered inductive limits exist and are exact in $\mathcal{C}$ and $\mathcal{C}'$). Then $\mathrm{R}^\bullet T(K^\bullet)$ is isomorphic to the inductive limit* [0_{III} / 36]

$$\varinjlim_{r\to-\infty} \mathrm{R}^\bullet T(K_{(r)}^\bullet)$$

as r tends to $-\infty$.

The construction of an injective Cartan–Eilenberg resolution of $K^\bullet$ is carried out by choosing arbitrarily, for each i, an injective resolution $(X_{\mathrm{B}}^{ij})_{j\geq 0}$ of $\mathrm{B}^i(K^\bullet)$ and an injective resolution $(X_{\mathrm{H}}^{ij})_{j\geq 0}$ of $\mathrm{H}^i(K^\bullet)$; this done, the method of construction shows that the injective resolution $(L^{ij})_{j\geq 0}$ of K^i and the differentials $L^{i,j} \to L^{i+1,j}$ *depend only on the resolutions* $(X_{\mathrm{B}}^{i,\bullet})$, $(X_{\mathrm{H}}^{i,\bullet})$ and $(X_{\mathrm{B}}^{i+1,\bullet})$ (M, XVII, 1.2). Now, it is clear that we have $\mathrm{B}^i(K_{(r)}^\bullet) = \mathrm{B}^i(K^\bullet)$ and $\mathrm{H}^i(K_{(r)}^\bullet) = \mathrm{H}^i(K^\bullet)$ for $i \geq r+1$. On the other hand, for each r we have a canonical injection $\varphi_{r-1,r}^\bullet : K_{(r)}^\bullet \to K_{(r-1)}^\bullet$, $\varphi_{r-1,r}^i$ being the identity for $i \neq r-1$. The preceding remark shows that, if $L^{\bullet\bullet} = (L^{ij})$ is an injective

Cartan–Eilenberg resolution of $K^\bullet$, we can for each r define an injective Cartan–Eilenberg resolution $L^{\bullet\bullet}_{(r)} = (L^{ij}_{(r)})$ of $K^\bullet_{(r)}$ such that $L^{ij}_{(r)} = 0$ for $i < r$ and $L^{ij}_{(r)} = L^{ij}$ for $i \geq r+1$. On the other hand, we can define a morphism of bicomplexes $\Phi^{\bullet\bullet}_{r-1,r} : L^{\bullet\bullet}_{(r)} \to L^{\bullet\bullet}_{(r-1)}$ corresponding to $\varphi^\bullet_{r-1,r}$, and the method of definition of this morphism (*loc. cit.*) again shows that it can be constructed so that $\Phi^{ij}_{r-1,r}$ is the identity for $i \neq r$ and $i \neq r-1$. We have thus defined an inductive system $(L^{\bullet\bullet}_{(r)})$ of bicomplexes of $\mathcal{C}$, of which $L^{\bullet\bullet}$ is evidently the inductive limit as r tends to $-\infty$; since direct sums and inductive limits commute, the simple complex associated to $L^{\bullet\bullet}$ is also the inductive limit of the simple complex associated to $L^{\bullet\bullet}_{(r)}$. Since T commutes with inductive limits by hypothesis, and so does cohomology (because of the exactness of the functor $\varinjlim$), we indeed have

$$\mathrm{H}^\bullet(T(L^{\bullet\bullet})) = \varinjlim \mathrm{H}^\bullet(T(L^{\bullet\bullet}_{(r)}))$$

up to isomorphism.

Lemma (11.5.1) makes it possible to extend to arbitrary complexes $K^\bullet$, by passage to the inductive limit, properties valid for complexes *bounded below*. As a first example, we will prove:

(11.5.2) Proposition. *Under the hypotheses of (11.5.1) concerning $\mathcal{C}$, $\mathcal{C}'$ and T, $\mathrm{R}^\bullet T(K^\bullet)$ is a cohomological functor in the abelian category of complexes of $\mathcal{C}$.*

Proof. Let us show that we can reduce to the case of complexes bounded below: if we have an exact sequence

$$0 \longrightarrow K'^\bullet \longrightarrow K^\bullet \longrightarrow K''^\bullet \longrightarrow 0$$

of complexes, we evidently deduce from it for each r an exact sequence

$$0 \longrightarrow K'^\bullet_{(r)} \longrightarrow K^\bullet_{(r)} \longrightarrow K''^\bullet_{(r)} \longrightarrow 0,$$

whence, by hypothesis, an exact sequence

$$\cdots \longrightarrow \mathrm{R}^n T(K'^\bullet_{(r)}) \longrightarrow \mathrm{R}^n T(K^\bullet_{(r)}) \longrightarrow \mathrm{R}^n T(K''^\bullet_{(r)}) \xrightarrow{\partial} \mathrm{R}^{n+1} T(K'^\bullet_{(r)}) \longrightarrow \cdots$$

these exact sequences forming an inductive system; Lemma (11.5.1) and the exactness of the functor $\varinjlim$ prove that we have an exact sequence

$$\cdots \longrightarrow \mathrm{R}^n T(K'^\bullet) \longrightarrow \mathrm{R}^n T(K^\bullet) \longrightarrow \mathrm{R}^n T(K''^\bullet) \xrightarrow{\partial} \mathrm{R}^{n+1} T(K'^\bullet) \longrightarrow \cdots$$

□

To treat the case of complexes bounded below, we may restrict to those such that $K^i = 0$ for $i < 0$; they evidently form an abelian category $\mathcal{K}$.

(11.5.2.1) Lemma. *In $\mathcal{K}$, let $\mathfrak{J}$ be the set of complexes $Q^\bullet = (Q^i)_{i\geq 0}$ having the following properties:* [0_{III} / 37]

1° *Every Q^i is an injective object of $\mathcal{C}$;*

2° *For every $i \geq 0$, we have $\mathrm{Z}^i(Q^\bullet) = \mathrm{B}^i(Q^\bullet)$, and $\mathrm{Z}^i(Q^\bullet)$ is a direct factor of Q^i.*

Then:

(i) Every $Q^\bullet \in \mathfrak{J}$ is an injective object of $\mathcal{K}$.

(ii) Every object of $\mathcal{K}$ is isomorphic to a subcomplex of a complex belonging to $\mathfrak{J}$.

Proof. (i) Let $A^\bullet = (A^i)$ be an object of $\mathcal{K}$, $A'^\bullet = (A'^i)$ a subobject of $A^\bullet$, and $Q^\bullet = (Q^i)$ an object of $\mathfrak{J}$, and suppose given a morphism $f = (f^i) : A'^\bullet \to Q^\bullet$, which we have to extend to a morphism $g = (g^i) : A^\bullet \to Q^\bullet$. We will use the language of the category of modules for simplicity (cf. [27]).

Let us identify Q^i with $\mathrm{B}^i(Q^\bullet) \oplus \mathrm{B}^{i+1}(Q^\bullet)$; let us proceed by induction on i, and suppose therefore that the g^j have been defined for $j < i$, compatible with the differentials $d^j : A^j \to A^{j+1}$ and $d'^j : Q^j \to Q^{j+1}$ for $j < i-1$, and moreover such that:

1° $g^{i-1}(\mathrm{Z}^{i-1}(A^\bullet)) \subset \mathrm{Z}^{i-1}(Q^\bullet)$;

2° If we set $C^j = (d^j)^{-1}(A'^{j+1})$ for every j, then $d'^{i-1} \circ g^{i-1}$ coincides with $f^i \circ d^{i-1}$ on C^{i-1}.

The morphism $f^i : A'^i \to Q^i$ gives, by composition with the projections, two morphisms $f'^i : A'^i \to \mathrm{B}^i(Q^\bullet)$ and $f''^i : A'^i \to \mathrm{B}^{i+1}(Q^\bullet)$. Since $d'^{i-1} \circ g^{i-1}$ maps A^{i-1} into $\mathrm{B}^i(Q^\bullet)$ and vanishes on $\mathrm{Z}^{i-1}(A^\bullet)$, it defines a morphism $h^i : \mathrm{B}^i(A^\bullet) \to \mathrm{B}^i(Q^\bullet)$, and since $d'^{i-1} \circ g^{i-1}$ coincides with $f^i \circ d^{i-1}$ on C^{i-1}, h^i coincides with f'^i on $\mathrm{B}^i(A^\bullet) \cap A'^i$. Since $\mathrm{B}^i(Q^\bullet)$, being a direct factor of Q^i, is injective, there is a morphism $g'^i : A^i \to \mathrm{B}^i(Q^\bullet)$ which coincides with h^i on $\mathrm{B}^i(A^\bullet)$ and with f'^i on A'^i. Consider on the other hand the morphism $f'^{i+1} \circ d^i : C^i \to \mathrm{B}^{i+1}(Q^\bullet)$, which vanishes on $\mathrm{Z}^i(A^\bullet)$; since $\mathrm{B}^{i+1}(Q^\bullet)$ is injective, there is a morphism $g''^i : A^i \to \mathrm{B}^{i+1}(Q^\bullet)$ which coincides with $f'^{i+1} \circ d^i$ on C^i and with 0 on $\mathrm{Z}^i(A^\bullet)$. It then suffices to take $g^i = g'^i + g''^i$ in order to be able to continue the induction.

(ii) To embed $A^\bullet = (A^i)$ in a complex belonging to $\mathfrak{J}$, we take for each $i \geq 1$ an injective object Q'^i of $\mathcal{C}$ such that there exists an injection $f'^i : A^i \to Q'^i$. Then set

$$Q^i = 0 \quad (i < 0), \qquad Q^0 = Q'^1, \qquad Q^i = Q'^i \oplus Q'^{i+1} \quad (i \geq 1),$$

with the evident differential. Set $f^i = f'^i + (f'^{i+1} \circ d^i)$ for every i (with $f'^i = 0$ for $i \leq 0$); it is immediate that f^i is injective for every i, and that the f^i are compatible with the differentials. □

(11.5.2.2) Corollary. *Every object $K^\bullet$ of $\mathcal{K}$ admits a right resolution consisting of objects of $\mathfrak{J}$. If $L^{\bullet\bullet}$ is such a resolution, then for every resolution $L'^{\bullet\bullet}$ of $K^\bullet$ consisting of objects of $\mathcal{K}$, there is a morphism of bicomplexes $F : L'^{\bullet\bullet} \to L^{\bullet\bullet}$ compatible with the augmentations, and any two such morphisms F, F' are homotopic.*

Proof. This is nothing other than (M, V, 1.1 a)) applied to the abelian category $\mathcal{K}$. □

(11.5.2.3) These preliminaries having been established, consider an injective Cartan–Eilenberg resolution $L'^{\bullet\bullet}$ of $K^\bullet$ and a resolution $L^{\bullet\bullet}$ of $K^\bullet$ consisting of objects of $\mathfrak{J}$, and let us show that we have an isomorphism

$$\mathrm{H}^\bullet(T(L'^{\bullet\bullet})) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet})).$$

Indeed, we deduce from (11.5.2.2) a morphism of bicomplexes $T(L'^{\bullet\bullet}) \to T(L^{\bullet\bullet})$, and consequently a morphism ${}'E(T(L'^{\bullet\bullet})) \to {}'E(T(L^{\bullet\bullet}))$ of the first spectral sequences of these bicomplexes. Since, by virtue of (11.3.3), these spectral sequences are regular, it suffices (11.1.5) to see that the preceding morphism is an isomorphism for the E_2 terms, or again that $\mathrm{H}^q_{\mathrm{II}}(T(L^{i,\bullet}))$ is equal to $\mathrm{R}^qT(K^i)$; since $L^{i,\bullet}$ is a right resolution of K^i, we are reduced to proving the

[0III | 38] **(11.5.2.4) Lemma.** *If $L^\bullet = (L^i)_{i\in\mathbb{Z}}$ is a right resolution of an object A of $\mathcal{C}$ such that $\mathrm{R}^n T(L^i) = 0$ for every $i \in \mathbb{Z}$ and every $n > 0$, then we have $\mathrm{H}^\bullet T(L^\bullet) = \mathrm{R}^\bullet T(A)$.*

Proof. This is a particular case of (T, 2.5.2). □

(11.5.2.5) The proof of (11.5.2) is now completed immediately, since $L'^{\bullet\bullet}$ is an injective resolution of $K^\bullet$ in the abelian category $\mathcal{K}$; in other words, $K^\bullet \mapsto \mathrm{H}^\bullet(T(L'^{\bullet\bullet}))$ is nothing other than the right derived cohomological functor of T in the category $\mathcal{K}$ (T, 2.3).

(11.5.3) Proposition. *Under the hypotheses of (11.5.1) concerning $\mathcal{C}$, $\mathcal{C}'$ and T, let $L^{\bullet\bullet} = (L^{ij})$ be a bicomplex such that $L^{ij} = 0$ for $j < 0$ and such that, for every i, $L^{i,\bullet}$ is a resolution of K^i; suppose finally that $\mathrm{R}^n T(L^{ij}) = 0$ for every pair (i, j) and every $n > 0$. Then there exists a functorial isomorphism*

$$\mathrm{R}^\bullet T(K^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet})). \tag{11.5.3.1}$$

Proof. Let $L^{\bullet\bullet}_{(r)} = (L^{ij}_{(r)})$ be the bicomplex such that $L^{ij}_{(r)} = 0$ for $i < r$ and $L^{ij}_{(r)} = L^{ij}$ for $i \geq r$; it is immediate that $L^{\bullet\bullet}$ is the inductive limit of $L^{\bullet\bullet}_{(r)}$ as r tends to $-\infty$; by virtue of the hypothesis on T and of (11.5.1), it therefore suffices to prove the proposition when $K^\bullet$ is bounded below, for example $K^i = 0$ for $i < 0$, and $L^{ij} = 0$ for $i < 0$. Let then $L'^{\bullet\bullet} = (L'^{ij})$ be a right resolution of $K^\bullet$ consisting of objects of $\mathfrak{J}$ (11.5.2.2); there is a morphism of bicomplexes $L^{\bullet\bullet} \to L'^{\bullet\bullet}$ compatible with the augmentations, whence a morphism ${}'E(T(L^{\bullet\bullet})) \to {}'E(T(L'^{\bullet\bullet}))$ for the first spectral sequences; Lemma (11.5.2.4) shows, as in (11.5.2.3), that this morphism is an *isomorphism*, whence the conclusion. □

(11.5.4) Remark. The preceding arguments prove that the conclusions of (11.5.2) and (11.5.3) are valid in the category of complexes $K^\bullet$ bounded below, *without supposing that T commutes with filtered inductive limits*. Moreover, when we consider only the category $\mathcal{K}$ of complexes $K^\bullet$ such that $K^i = 0$ for $i < 0$, the characterization of $\mathrm{R}^\bullet T(K^\bullet)$ as the system of *right derived functors* of T in $\mathcal{K}$ shows that this cohomological functor is *universal* (T, 2.3).

Another case in which (11.5.2) is valid without making any additional hypothesis on T is the case where there exists an integer $m > 0$ such that every object of $\mathcal{C}$ admits an injective resolution of length $\leq m$. Indeed, in the proof of (11.5.1), all the injective resolutions of objects of $\mathcal{C}$ that occur can be taken of length $\leq m$, from which it follows immediately that the terms of total degree n of the bicomplex $T(L^{\bullet\bullet}_{(r)})$ are equal to those of $T(L^{\bullet\bullet})$ and finite in number, as soon as $-r$ is sufficiently large, which implies that for every n, $\mathrm{H}^n(T(L^{\bullet\bullet})) = \mathrm{H}^n(T(L^{\bullet\bullet}_{(r)}))$ as soon as $-r$ is sufficiently large. With the notation of (11.5.2), we therefore also have $\mathrm{R}^n T(K^\bullet_{(r)}) = \mathrm{R}^n T(K^\bullet)$ for $-r$ sufficiently large (depending on n), and likewise for $K'^\bullet$ and $K''^\bullet$, whence the conclusion. In the same way, (11.5.3) is valid without any additional condition on T when $\mathcal{C}$ satisfies the preceding hypothesis and the resolutions $L^{i,\bullet}$ are assumed to be of length $\leq m$.

(11.5.5) The result of (11.5.2) generalizes to covariant multifunctors. Consider for
[0III | 39] example the situation of (11.4.6), where we suppose that in $\mathcal{C}$, $\mathcal{C}'$ and $\mathcal{C}''$ filtered inductive limits exist and are exact, and that T commutes with inductive limits. Then $\mathrm{R}^\bullet T(K^\bullet, K'^\bullet)$ is a cohomological bifunctor in each of the complexes $K^\bullet$, $K'^\bullet$; to see this, we reduce as in (11.5.2) to the case where $K^\bullet$ and $K'^\bullet$ are bounded below; then, taking for $K^\bullet$ and $K'^\bullet$ injective resolutions of the type described in (11.5.2.2), we are reduced to the general property proved in (M, V, 4.1).

(11.5.6) Likewise, the results of (11.4.7) and (11.5.3) generalize as follows. Suppose (under the hypotheses of (11.5.5)) that we have two bicomplexes $L^{\bullet\bullet} = (L^{ij})$, $L'^{\bullet\bullet} = (L'^{ij})$ such that $L^{ij} = 0$ and $L'^{ij} = 0$ for $j < 0$, that for every i, $L^{i,\bullet}$ is a resolution of K^i and $L'^{i,\bullet}$ a resolution of K'^i, and finally that $\mathrm{R}^n T(L^{ij}, L'^{hk}) = 0$ for $n > 0$ and for every system of indices (i, j, h, k). Then we have an isomorphism, functorial in $K^\bullet$ and $K'^\bullet$,

$$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, L'^{\bullet\bullet})). \tag{11.5.6.1}$$

This is established as in (11.5.3) by reducing to the case where $K^\bullet$ and $K'^\bullet$ are bounded below.

Suppose moreover that for every pair (i, j) and every pair (h, k), the functors $A \mapsto T(A, L'^{hk})$ and $A' \mapsto T(L^{ij}, A')$ are exact on $\mathcal{C}$ and $\mathcal{C}'$ respectively. Then we also have functorial isomorphisms

$$\mathrm{R}^\bullet T(K^\bullet, K'^\bullet) \xrightarrow{\sim} \mathrm{H}^\bullet(T(L^{\bullet\bullet}, K'^\bullet)) \xrightarrow{\sim} \mathrm{H}^\bullet(T(K^\bullet, L'^{\bullet\bullet})). \tag{11.5.6.2}$$

The proof is similar to that of (11.4.7).

(11.5.7) Note further that the results of (11.5.5) and (11.5.6) are valid without supposing that T commutes with inductive limits, provided that we restrict to complexes $K^\bullet$, $K'^\bullet$ bounded below, or that we suppose that every object of $\mathcal{C}$ (resp. $\mathcal{C}'$) admits an injective resolution of bounded length and that in (11.5.6) the bicomplexes $L^{\bullet\bullet}$ and $L'^{\bullet\bullet}$ have their second degree bounded above.

11.6 Hyperhomology of a functor with respect to a complex $K_\bullet$

(11.6.1) Let $\mathcal{C}$ be an abelian category and $K_\bullet = (K_i)_{i\in\mathbb{Z}}$ a complex of objects of $\mathcal{C}$ whose differential is of degree -1. A *left Cartan–Eilenberg resolution* of $K_\bullet$ consists of a bicomplex $L_{\bullet\bullet} = (L_{ij})$ with differentials of degree -1, with $L_{ij} = 0$ for $j < 0$, and of a morphism of simple complexes $\varepsilon : L_{\bullet,0} \to K_\bullet$, such that the conditions obtained from those of (11.4.2) by "reversing the arrows" are satisfied. If every object of $\mathcal{C}$ is a quotient of a projective object, every complex $K_\bullet$ of $\mathcal{C}$ admits a *projective* Cartan–Eilenberg resolution, that is, one consisting of projective objects L_{ij}, with functorial properties similar to those of (11.4.2). Moreover, if $K_\bullet$ is bounded below (resp. above), we may suppose that $L_{ij} = 0$ for $i < i_0$ (resp. $i > i_0$) if $K_i = 0$ for $i < i_0$ (resp. $i > i_0$). If every object of $\mathcal{C}$ admits a projective resolution of length $\leq n$, we may suppose that $L_{ij} = 0$ for $j > n$.

(11.6.2) Suppose that T is a covariant additive functor from $\mathcal{C}$ to an abelian category $\mathcal{C}'$. The definition of *the hyperhomology* $L_\bullet T(K_\bullet)$ and of the *hyperhomology spectral sequences* of T with respect to a complex $K_\bullet$ of $\mathcal{C}$ (when they exist) is again obtained from (11.4.3) by "reversing the arrows", the E_2 terms of the two spectral sequences thus obtained being [0_{III} | 40]

$$'E^2_{pq} = H_p(L_q T(K_\bullet)) \tag{11.6.2.1}$$

$$''E^2_{pq} = L_p T(H_q(K_\bullet)), \tag{11.6.2.2}$$

where $L_p T$ denotes the p-th left derived functor of T for $p \geq 0$, and 0 for $p < 0$, and $L_q T(K_\bullet)$ the complex $(L_q T(K_i))_{i\in\mathbb{Z}}$.

The properties of hyperhomology are not all deduced by simple "reversal of the arrows" from those of hypercohomology (unless additional hypotheses of the type (AB 5*) of (T, 1.5) are made on the category $\mathcal{C}'$), because of the regularity conditions of the two

preceding spectral sequences, to which the criteria of (11.3.4) must this time be applied. These criteria show that when we suppose that in $\mathcal{C}'$ filtered inductive limits exist and are exact, then the complex defined by the bicomplex $T(L_{\bullet\bullet})$ exists, and the second spectral sequence ${}''E(T(L_{\bullet\bullet}))$ is this time regular. If we suppose either that $K_\bullet$ is bounded below, or that there exists an integer n such that every object of $\mathcal{C}$ admits a projective resolution of length $\leq n$, then the two hyperhomology spectral sequences exist (without any hypothesis on $\mathcal{C}'$) and are biregular.

(11.6.3) Proposition. *Let $\mathcal{C}$, $\mathcal{C}'$ be two abelian categories and T a covariant additive functor from $\mathcal{C}$ to $\mathcal{C}'$. Then:*

(i) The hyperhomology $L_\bullet T(K_\bullet)$ is a homological functor in the abelian category of complexes of $\mathcal{C}$ bounded below.

(ii) Let $K_\bullet$ be a complex of $\mathcal{C}$ bounded below. If $L_n T(K_i) = 0$ for every $n > 0$ and every $i \in \mathbb{Z}$, we have functorial isomorphisms

$$L_i T(K_\bullet) \simeq H_i(T(K_\bullet)) \qquad (i \in \mathbb{Z}). \tag{11.6.3.1}$$

(iii) Let $K_\bullet$ be a complex of $\mathcal{C}$ bounded below. Let $L_{\bullet\bullet} = (L_{ij})$ be a bicomplex such that $L_{ij} = 0$ for $j < 0$ and such that, for every i, $L_{i,\bullet}$ is a resolution of K_i; suppose finally that $L_n T(L_{ij}) = 0$ for every pair (i, j) and every $n > 0$. Then there exists a functorial isomorphism

$$L_\bullet T(K_\bullet) \simeq H_\bullet(T(L_{\bullet\bullet})). \tag{11.6.3.2}$$

The proofs are carried out like those of (11.5.2), (11.4.5) and (11.5.3) in the case of complexes bounded below. We leave the details of these arguments to the reader.

(11.6.4) We have entirely analogous results for covariant multifunctors that are additive in each of the arguments. For example, for a bifunctor T, we have the two hyperhomology
[0_{III} | 41] spectral sequences with E_2 terms given by

$${}'E^2_{pq} = H_p(L_q T(K_\bullet, K'_\bullet)) \tag{11.6.4.1}$$

$${}''E^2_{pq} = \sum_{q'+q''=q} L_p T(H_{q'}(K_\bullet), H_{q''}(K'_\bullet)). \tag{11.6.4.2}$$

Here again it is the second spectral sequence that is regular, the two sequences being biregular when complexes $K_\bullet$, $K'_\bullet$ bounded below are concerned, or when the objects of the abelian categories under consideration have projective resolutions of fixed length.

Moreover:

(11.6.5) Proposition. *Let $\mathcal{C}$, $\mathcal{C}'$, $\mathcal{C}''$ be three abelian categories and T a covariant biadditive bifunctor from $\mathcal{C} \times \mathcal{C}'$ to $\mathcal{C}''$.*

(i) $L_\bullet T(K_\bullet, K'_\bullet)$ is a homological bifunctor in each of the complexes $K_\bullet$, $K'_\bullet$ bounded below (consisting respectively of objects of $\mathcal{C}$ and of objects of $\mathcal{C}'$).

(ii) Suppose $K_\bullet$ and $K'_\bullet$ bounded below. Let $L_{\bullet\bullet} = (L_{ij})$, $L'_{\bullet\bullet} = (L'_{ij})$ be two bicomplexes such that $L_{ij} = 0$ and $L'_{ij} = 0$ for $j < 0$, such that for every i, $L_{i,\bullet}$ is a resolution of K_i and $L'_{i,\bullet}$ a resolution of K'_i, and finally such that $L_n T(L_{ij}, L'_{hk}) = 0$ for $n > 0$ and every system (i, j, h, k). Then we have a functorial isomorphism

$$L_\bullet T(K_\bullet, K'_\bullet) \simeq H_\bullet(T(L_{\bullet\bullet}, L'_{\bullet\bullet})). \tag{11.6.5.1}$$

(iii) Suppose moreover that for every pair (i,j) and every pair (h,k), the functors

$$A \longmapsto T(A, L'_{hk}), \qquad A' \longmapsto T(L_{ij}, A')$$

are exact on $\mathcal{C}$ and $\mathcal{C}'$ respectively. Then we have functorial isomorphisms

$$L_\bullet T(K_\bullet, K'_\bullet) \simeq H_\bullet(T(L_{\bullet\bullet}, K'_\bullet)) \simeq H_\bullet(T(K_\bullet, L'_{\bullet\bullet})). \tag{11.6.5.2}$$

The proofs are analogous to those of (11.5.5) and (11.5.6).

11.7 Hyperhomology of a functor with respect to a bicomplex $K_{\bullet\bullet}$

(11.7.1) Let $\mathcal{C}$ be an abelian category in which every object is a quotient of a projective object. Consider a bicomplex $K_{\bullet\bullet} = (K_{ij})$ formed of objects of $\mathcal{C}$, both of whose degrees are bounded below; we may always restrict to the case where $K_{ij} = 0$ for $i < 0$ or $j < 0$, and this is what we will do from now on. We can regard $K_{\bullet\bullet}$ as a (simple) complex formed of objects $K_{i,\bullet} = (K_{ij})_{j\geq 0}$ of the abelian category $\mathcal{K}$ of complexes of objects of $\mathcal{C}$ in positive degrees. It follows from Lemma (11.5.2.1) (or rather from the "dual" lemma obtained by "reversing the arrows") and from (M, V, 2.2) that $K_{\bullet\bullet}$ admits a *projective Cartan–Eilenberg resolution* in the category $\mathcal{K}$; such a resolution is a tricomplex $M_{\bullet\bullet\bullet} = (M_{ijk})$ of $\mathcal{C}$, with all degrees ≥ 0, formed of projective objects, such that for every i, $M_{i,\bullet\bullet}$, $\mathrm{B}^{\mathrm{I}}_i(M_{\bullet\bullet\bullet})$, $\mathrm{Z}^{\mathrm{I}}_i(M_{\bullet\bullet\bullet})$, $H^{\mathrm{I}}_i(M_{\bullet\bullet\bullet})$ constitute projective resolutions of $K_{i,\bullet}$, $\mathrm{B}^{\mathrm{I}}_i(K_{\bullet\bullet})$, $\mathrm{Z}^{\mathrm{I}}_i(K_{\bullet\bullet})$, $H^{\mathrm{I}}_i(K_{\bullet\bullet})$ respectively in the category $\mathcal{K}$; in particular, for every pair (i,j), $M_{ij,\bullet}$ is a projective resolution of K_{ij} in $\mathcal{C}$.

(11.7.2) Proposition. *Let T be an additive covariant functor from $\mathcal{C}$ to an abelian category $\mathcal{C}'$. With the notation of (11.7.1),* the homology $H_\bullet(T(M_{\bullet\bullet\bullet}))$ of the simple complex associated to the tricomplex $T(M_{\bullet\bullet\bullet})$ is canonically isomorphic to the hyperhomology $L_\bullet T(K_{\bullet\bullet})$ of the simple complex associated to $K_{\bullet\bullet}$ (11.6.2), and is the common abutment of six biregular spectral sequences denoted ${}^{(t)}E$ (with $t = a, b, a', b', c$ or d), whose E_2 terms are given by the formulas [0_{III} | 42]

$$\begin{aligned}
{}^{(a)}E^2_{pq} &= L_pT(H_q(K_{\bullet\bullet})), \quad & {}^{(b)}E^2_{pq} &= H_p(L^{\mathrm{II}}_qT(K_{\bullet\bullet})),\\
{}^{(a')}E^2_{pq} &= L_pT(H^{\mathrm{I}}_q(K_{\bullet\bullet})), \quad & {}^{(b')}E^2_{pq} &= H_p(L_qT(K_{\bullet\bullet})),\\
{}^{(c)}E^2_{pq} &= L_pT(H^{\mathrm{II}}_q(K_{\bullet\bullet})), \quad & {}^{(d)}E^2_{pq} &= H_p(L^{\mathrm{I}}_qT(K_{\bullet\bullet})).
\end{aligned}$$

Recall that we use the notation $F(A_\bullet)$ to denote the complex of the objects $F(A_i)$, for every complex $A_\bullet = (A_i)$; for example, $L^{\mathrm{II}}_qT(K_{\bullet\bullet})$ denotes the complex $(L^{\mathrm{II}}_qT(K_{i,\bullet}))_{i\geq 0}$, where $L^{\mathrm{II}}_qT(K_{i,\bullet})$ is the hyperhomology of index q of the functor T with respect to the simple complex $K_{i,\bullet}$.

Proof. Denote by $L_\bullet$ the simple complex associated to $K_{\bullet\bullet}$, so that

$$L_i = \bigoplus_{r+s=i} K_{rs},$$

and set

$$N_{ij} = \bigoplus_{r+s=i} M_{rsj};$$

it is clear that for each i, $N_{i,\bullet}$ is a projective resolution of L_i in $\mathcal{C}$; it therefore follows from (11.6.3) and (11.6.4) that we have a functorial isomorphism

$$L_\bullet T(L_\bullet) \simeq H_\bullet(T(N_{\bullet\bullet}));$$

since the simple complex associated to the bicomplex $T(N_{\bullet\bullet})$ is also associated to the tricomplex $T(M_{\bullet\bullet\bullet})$, this proves the first assertion of the statement.

Moreover, $L_\bullet T(L_\bullet)$ is the abutment of the two hyperhomology spectral sequences (11.6.2) of T relative to the simple complex $L_\bullet$, which are none other than the sequences ${}^{(b')}E$ and ${}^{(a)}E$ respectively.

Let us now regard $M_{\bullet\bullet\bullet}$ as a bicomplex $U_{\bullet\bullet}$ with

$$U_{ij} = \bigoplus_{r+s=j} M_{irs};$$

$H_\bullet(T(M_{\bullet\bullet\bullet}))$ is again the abutment of the two spectral sequences of the bicomplex $T(U_{\bullet\bullet})$. Now, for every i, $M_{i,\bullet\bullet}$ is a bicomplex satisfying the conditions of (11.6.3) relative to the simple complex $K_{i,\bullet}$; hence $H_q^{\mathrm{II}}(T(U_{i,\bullet})) = L_q^{\mathrm{II}}T(K_{i,\bullet})$, and the first spectral sequence of $T(U_{\bullet\bullet})$ is none other than ${}^{(b)}E$. On the other hand, for every r, $M_{\bullet,r,\bullet}$ is a Cartan–Eilenberg resolution of the simple complex $K_{\bullet,r}$, the computation made in (M, XV, 2) shows that

$$H_q^{\mathrm{I}}(T(M_{\bullet,rs})) = T(H_q^{\mathrm{I}}(M_{\bullet,rs})),$$

whence

$$H_q^{\mathrm{I}}(T(U_{\bullet,j})) = \bigoplus_{r+s=j} T(H_q^{\mathrm{I}}(M_{\bullet,rs}));$$

in other words, the simple complex $H_q^{\mathrm{I}}(T(U_{\bullet\bullet}))$ is none other than the simple complex associated to the bicomplex $T(H_q^{\mathrm{I}}(M_{\bullet\bullet\bullet}))$. Now, for every q, $H_q^{\mathrm{I}}(M_{\bullet\bullet\bullet})$ is a projective resolution of the simple complex $H_q^{\mathrm{I}}(K_{\bullet\bullet})$ in the category $\mathcal{K}$; applying (11.6.3), we see that we have

$$H_p^{\mathrm{II}}(T(H_q^{\mathrm{I}}(M_{\bullet\bullet\bullet}))) = L_pT(H_q^{\mathrm{I}}(K_{\bullet\bullet})),$$

and we thus obtain the sequence ${}^{(a')}E$. Finally, the sequences ${}^{(c)}E$ and ${}^{(d)}E$ are obtained by interchanging the roles of the indices i and j in the definition of the tricomplex $M_{\bullet\bullet\bullet}$ and applying the preceding arguments to this new tricomplex. □

We say that $L_\bullet T(K_{\bullet\bullet})$ is *the hyperhomology* of T relative to the bicomplex $K_{\bullet\bullet}$.

(11.7.3) *Remarks.*

(i) It follows from (11.6.3) that $L_\bullet T(K_{\bullet\bullet})$ is a homological functor on the category of bicomplexes $K_{\bullet\bullet}$ of $\mathcal{C}$ bounded below in each of their degrees. [0_{III} | 43]

(ii) Let $M_{\bullet\bullet\bullet}$ be a tricomplex of $\mathcal{C}$ such that for each pair (r,s), $M_{rs,\bullet}$ is a resolution of K_{rs} and $L_nT(M_{ijk}) = 0$ for all triples (i,j,k) and every $n > 0$. Then we have an isomorphism

$$L_\bullet T(K_{\bullet\bullet}) \simeq H_\bullet(T(M_{\bullet\bullet\bullet}));$$

indeed, with the notation of the proof of (11.7.2), $N_{i,\bullet}$ is a resolution of L_i such that $L_nT(N_{ij}) = 0$ for $n > 0$ and every pair (i,j), and it suffices to apply (11.6.3, (iii)).

(iii) The results of (11.7.2) generalize immediately to covariant multifunctors; for example, let $\mathcal{C}'$ be a second abelian category in which every object is a quotient of a projective object, $K'_{\bullet\bullet}$ a bicomplex of $\mathcal{C}'$ both of whose degrees are bounded below, and T an additive covariant bifunctor from $\mathcal{C} \times \mathcal{C}'$ to an abelian category $\mathcal{C}''$. If $L_\bullet$ and $L'_\bullet$ are the simple complexes associated to $K_{\bullet\bullet}$ and $K'_{\bullet\bullet}$ respectively, we define the hyperhomology of T with respect to the two bicomplexes $K_{\bullet\bullet}$, $K'_{\bullet\bullet}$ as the hyperhomology $L_\bullet T(L_\bullet, L'_\bullet)$; applying (11.6.4) and (11.6.5), we have, just as in (11.7.2), six spectral sequences abutting to this hyperhomology, which we leave to the reader to write down.

11.8 Supplement on the cohomology of simplicial complexes

(11.8.1) Let A be a finite set and $\Sigma(A)$ the set of finite sequences $\sigma = (\alpha_0, \dots, \alpha_h)$ of elements of A ("simplices" of A); we set $|\sigma| = \{\alpha_0, \dots, \alpha_h\}$; recall that the complex of chains $\mathrm{C}_\bullet(A)$ is the graded free abelian group generated by the elements of $\Sigma(A)$, $(\alpha_0, \dots, \alpha_h)$ being of degree h, with a differential defined by

$$d(\alpha_0, \dots, \alpha_h) = \sum_{j=0}^{h} (-1)^j (\alpha_0, \dots, \widehat{\alpha_j}, \dots, \alpha_h).$$

The subgroup $\mathrm{D}_\bullet(A)$ of $\mathrm{C}_\bullet(A)$ generated by the chains $\sigma = (\alpha_0, \dots, \alpha_h)$ for which two of the α_i are equal, and by the chains $\pi(\sigma) - \varepsilon_\pi \sigma$, where, for every permutation π,

$$\pi(\sigma) = (\alpha_{\pi(0)}, \dots, \alpha_{\pi(h)})$$

and ε_π is the signature of π, is a subcomplex of $\mathrm{C}_\bullet(A)$ whose elements are called *degenerate chains*; we set $\mathrm{L}_\bullet(A) = \mathrm{C}_\bullet(A)/\mathrm{D}_\bullet(A)$, and we have a natural homomorphism of complexes

$$p : \mathrm{C}_\bullet(A) \longrightarrow \mathrm{L}_\bullet(A).$$

On the other hand, we define a homomorphism of complexes

$$j : \mathrm{L}_\bullet(A) \longrightarrow \mathrm{C}_\bullet(A)$$

in the following way: we totally order A; to the class mod. $\mathrm{D}_\bullet(A)$ of a simplex $\sigma = (\alpha_0, \dots, \alpha_h)$ we assign 0 if two of the α_i are equal, and $\varepsilon_\pi(\beta_0, \dots, \beta_h)$ otherwise, where $(\beta_0, \dots, \beta_h) = \pi(\sigma)$ is the sequence of the α_i arranged in increasing order. It is clear that $p \circ j$ is the identity of $\mathrm{L}_\bullet(A)$.

(11.8.2) Let B be a second finite set; if d', d'' are the differentials of $\mathrm{C}_\bullet(A)$ and $\mathrm{C}_\bullet(B)$, the tensor product complex $\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)$ can be regarded as the free abelian group generated by the elements of $\Sigma(A) \times \Sigma(B)$, with the differential

$$d(\sigma, \tau) = (d'\sigma, \tau) + (-1)^{h+1}(\sigma, d''\tau) \quad \text{if } \deg \sigma = h.$$

The natural homomorphisms $\mathrm{C}_\bullet(A) \to \mathrm{L}_\bullet(A)$, $\mathrm{C}_\bullet(B) \to \mathrm{L}_\bullet(B)$ define a homomorphism

$$p : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{L}_\bullet(A) \otimes \mathrm{L}_\bullet(B),$$

the latter tensor product being isomorphic to

$$\frac{\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)}{\mathrm{C}_\bullet(A) \otimes \mathrm{D}_\bullet(B) + \mathrm{D}_\bullet(A) \otimes \mathrm{C}_\bullet(B)}.$$

Similarly, by means of the homomorphisms $\mathrm{L}_\bullet(A) \to \mathrm{C}_\bullet(A)$ and $\mathrm{L}_\bullet(B) \to \mathrm{C}_\bullet(B)$ defined in (11.8.1) (by means of total orders on A and B), we define a homomorphism

$$j : \mathrm{L}_\bullet(A) \otimes \mathrm{L}_\bullet(B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)$$

such that $p \circ j$ is the identity.

With this notation: [0_{III} | 44]

(11.8.3) Proposition. There exists a homotopy

$$h : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B),$$

such that $h(\sigma, \tau)$ is a linear combination of pairs of simplices (σ_i, τ_i) with $|\sigma_i| \subset |\sigma|$, $|\tau_i| \subset |\tau|$, and such that, for $f = j \circ p$, we have

$$f - 1 = h \circ d + d \circ h. \tag{11.8.3.1}$$

Proof. It suffices to define h on each pair (σ, τ) of simplices, arguing by induction on the sum of the degrees of σ and τ, since we can take $h = 0$ when this sum is 0. Let

$$\omega = f(\sigma, \tau) - (\sigma, \tau) - h(d(\sigma, \tau));$$

by virtue of the induction hypothesis and the definition of d, we have

$$\omega \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|).$$

We have

$$d\omega = f(d(\sigma, \tau)) - d(\sigma, \tau) - d(h(d(\sigma, \tau))) = h(d(d(\sigma, \tau))) = 0$$

by virtue of (11.8.3.1) and the induction hypothesis. Now, we have $H_q(\mathrm{C}_\bullet(A)) = 0$ for $q > 0$ (G, I, 3.7.4), hence also

$$H_q(\mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B)) = 0 \quad (q > 0),$$

by virtue of the Künneth formula (G, I, 5.5.2). Applying this remark with A replaced by $|\sigma|$ and B by $|\tau|$, we see that there exists an element

$$\omega' \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|)$$

such that $\omega = d\omega'$; taking $h(\sigma, \tau) = \omega'$, we verify (11.8.3.1) for the pair (σ, τ) and the induction can be continued. □

(11.8.4) The notation being that of (11.8.2), we will write $(\sigma, \tau) \leq (\sigma', \tau')$ if $|\sigma| \subset |\sigma'|$ and $|\tau| \subset |\tau'|$. A *coefficient system* Γ on $\Sigma(A) \times \Sigma(B)$ consists of a family $(\Gamma_{\sigma,\tau})$ of abelian groups, where $\Gamma_{\sigma,\tau}$ depends only on the sets $|\sigma|$ and $|\tau|$, and a family of homomorphisms

$$\Gamma_{\sigma,\tau} \longrightarrow \Gamma_{\sigma',\tau'} \quad \text{for } (\sigma, \tau) \leq (\sigma', \tau'),$$

forming an inductive system for this preorder relation. We then define a complex of cochains $\mathrm{C}^\bullet(A, B; \Gamma)$ as the set of families $\lambda = (\lambda(\sigma, \tau))$, where (σ, τ) ranges over $\Sigma(A) \times \Sigma(B)$, with $\lambda(\sigma, \tau) \in \Gamma_{\sigma,\tau}$ for every pair (σ, τ). The differential is given as follows: if

$$d(\sigma, \tau) = \sum_i \pm(\sigma_i, \tau_i),$$

we have $|\sigma_i| \subset |\sigma|$, $|\tau_i| \subset |\tau|$ for every i, and we take

$$d\lambda(\sigma, \tau) = \sum_i \pm\lambda_i(\sigma_i, \tau_i),$$

where $\lambda_i(\sigma_i, \tau_i)$ denotes the canonical image of $\lambda(\sigma_i, \tau_i)$ in $\Gamma_{\sigma,\tau}$.

We will say that a cochain $\lambda \in \mathrm{C}^\bullet(A, B; \Gamma)$ is *bi-alternating* if $\lambda(\sigma, \tau) = 0$ whenever one of the two simplices σ, τ has two equal terms, and if we have

$$\lambda(\pi(\sigma), \tau) = \varepsilon_\pi \lambda(\sigma, \tau), \qquad \lambda(\sigma, \pi'(\tau)) = \varepsilon_{\pi'} \lambda(\sigma, \tau)$$

for arbitrary permutations π, π' of the indices. It is clear that these cochains generate a subcomplex $\mathrm{L}^\bullet(A, B; \Gamma)$ of $\mathrm{C}^\bullet(A, B; \Gamma)$.

(11.8.5) Proposition. The canonical injection

$$\mathrm{L}^\bullet(A, B; \Gamma) \longrightarrow \mathrm{C}^\bullet(A, B; \Gamma)$$

defines an isomorphism on the cohomology of these two complexes.

Proof. Note that if p and j have the meaning defined in (11.8.2), the maps

$$'p : \lambda \longmapsto \lambda \circ p, \qquad 'j : \lambda \longmapsto \lambda \circ j$$

are defined on $\mathrm{L}^\bullet(A, B; \Gamma)$ and $\mathrm{C}^\bullet(A, B; \Gamma)$ respectively, the first being none other than the canonical injection. Since $'j \circ 'p$ is the identity, it suffices to prove that $'p \circ 'j$ is homotopic to the identity; now, by (11.8.3), $'h : \lambda \mapsto \lambda \circ h$ is defined on $\mathrm{C}^\bullet(A, B; \Gamma)$, and we can therefore transpose the identity (11.8.3.1), which gives the desired result. □

(11.8.6) Proposition (11.8.5) reduces the computation of the cohomology of $\mathrm{L}^\bullet(A, B; \Gamma)$ [0_{III} | 45] to that of the cohomology of $\mathrm{C}^\bullet(A, B; \Gamma)$. Recall on the other hand that the latter is, by virtue of the Eilenberg–Zilber theorem (G, I, 3.10.2), canonically isomorphic to the cohomology of the complex of cochains defined as follows: we form the complex of chains $\mathrm{P}_\bullet(A, B)$, consisting of the linear combinations of the $(\sigma, \tau) \in \Sigma(A) \times \Sigma(B)$ such that σ and τ have the same degree; the differential of this complex is given by

$$d(\sigma, \tau) = \sum_{j,k} (-1)^{j+k} (\sigma_j, \tau_k)$$

if

$$d\sigma = \sum_j (-1)^j \sigma_j, \qquad d\tau = \sum_k (-1)^k \tau_k;$$

we then have two canonical homomorphisms of complexes

$$f : \mathrm{P}_\bullet(A, B) \longrightarrow \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B), \qquad g : \mathrm{C}_\bullet(A) \otimes \mathrm{C}_\bullet(B) \longrightarrow \mathrm{P}_\bullet(A, B),$$

and it is proved (*loc. cit.*) that there are homotopies h, h' such that

$$f \circ g - 1 = d \circ h + h \circ d, \qquad g \circ f - 1 = d \circ h' + h' \circ d.$$

Moreover, we have

$$f(\sigma, \tau) \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|), \qquad g(\sigma, \tau) \in \mathrm{P}_\bullet(|\sigma|, |\tau|)$$

and the homotopies h, h' can be chosen such that

$$h(\sigma, \tau) \in \mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|), \qquad h'(\sigma, \tau) \in \mathrm{P}_\bullet(|\sigma|, |\tau|).$$

This point comes from the fact that the definition of $h(\sigma, \tau)$ and $h'(\sigma, \tau)$ can be made by induction on the sum of the degrees of σ and τ, and from the fact that

$$H_q(\mathrm{C}_\bullet(|\sigma|) \otimes \mathrm{C}_\bullet(|\tau|)) \quad \text{and} \quad H_q(\mathrm{P}_\bullet(|\sigma|, |\tau|))$$

are zero for $q > 0$ (*loc. cit.*); we then argue as in (11.8.3) and the conclusion follows.

We then define $\mathrm{P}^\bullet(A, B; \Gamma)$ as the set of families $\lambda = (\lambda(\sigma, \tau))$ where (σ, τ) ranges over the pairs whose terms have the same degree, with $\lambda(\sigma, \tau) \in \Gamma_{\sigma,\tau}$, and since we have

$$d\sigma = \sum_j (-1)^j \sigma_j, \qquad d\tau = \sum_k (-1)^k \tau_k,$$

$$d\lambda(\sigma, \tau) = \sum_{j,k} (-1)^{j+k} \lambda(\sigma_j, \tau_k)$$

is defined and gives the differential of the complex $\mathrm{P}^\bullet(A, B; \Gamma)$. This being so, the maps

$$'f : \lambda \mapsto \lambda \circ f, \quad 'g : \lambda \mapsto \lambda \circ g, \quad 'h : \lambda \mapsto \lambda \circ h, \quad 'h' : \lambda \mapsto \lambda \circ h'$$

are all defined by virtue of the preceding remarks; ${}'f \circ {}'g$ and ${}'g \circ {}'f$ are therefore homotopic to the identity, whence the desired isomorphism between the cohomology of $\mathrm{C}^\bullet(A, B; \Gamma)$ and that of $\mathrm{P}^\bullet(A, B; \Gamma)$.

(11.8.7) *Remark.* The same reasoning as in (11.8.3), but applied to $\mathrm{C}_\bullet(A)$ and $\mathrm{L}_\bullet(A)$, shows that if j and p are defined as in (11.8.1), $f = j \circ p$ again satisfies a relation (11.8.3.1), with $|h(\sigma)| \subset |\sigma|$, from which we deduce, as in (11.8.5), an isomorphism of the cohomology of $\mathrm{L}^\bullet(A; \Gamma)$ onto that of $\mathrm{C}^\bullet(A; \Gamma)$, these two complexes being defined in the obvious way. This is the result whose proof is sketched in (G, I, 3.8.1).

(11.8.8) Let us now return to the notation and hypotheses of (11.8.2), and consider a complex $\Gamma^\bullet = (\Gamma^k)$ of coefficient systems on $\Sigma(A) \times \Sigma(B)$: for each (σ, τ), the $\Gamma^k_{\sigma,\tau}$ thus form a complex of abelian groups ($k \in \mathbb{Z}$), and we have the commutative diagrams

$$\begin{array}{ccc} \Gamma^k_{\sigma,\tau} & \longrightarrow & \Gamma^{k+1}_{\sigma,\tau} \\ \downarrow & & \downarrow \\ \Gamma^k_{\sigma',\tau'} & \longrightarrow & \Gamma^{k+1}_{\sigma',\tau'} \end{array}$$

[0_{III} | 46] for $(\sigma, \tau) \leq (\sigma', \tau')$. Then one verifies immediately that

$$\mathrm{C}^\bullet(A, B; \Gamma^\bullet) = \left(\mathrm{C}^h(A, B; \Gamma^k)\right)_{(h,k) \in \mathbb{Z} \times \mathbb{Z}}$$

is a bicomplex of abelian groups, and

$$\mathrm{L}^\bullet(A, B; \Gamma^\bullet) = \left(\mathrm{L}^h(A, B; \Gamma^k)\right)$$

is a subbicomplex of it.

(11.8.9) Proposition. The canonical injection

$$\mathrm{L}^\bullet(A, B; \Gamma^\bullet) \longrightarrow \mathrm{C}^\bullet(A, B; \Gamma^\bullet)$$

defines an isomorphism on the cohomology of these two bicomplexes.

Proof. Set $\mathrm{C}^{\bullet\bullet} = \mathrm{C}^\bullet(A, B; \Gamma^\bullet)$ and $\mathrm{L}^{\bullet\bullet} = \mathrm{L}^\bullet(A, B; \Gamma^\bullet)$ for simplicity, and note that since $\mathrm{C}^{hk} = \mathrm{L}^{hk} = 0$ for $h < 0$, the second spectral sequences of these bicomplexes are regular (11.3.3); the homomorphism $\mathrm{L}^{\bullet\bullet} \to \mathrm{C}^{\bullet\bullet}$ therefore gives a morphism of spectral sequences

$$''E(\mathrm{L}^{\bullet\bullet}) \longrightarrow ''E(\mathrm{C}^{\bullet\bullet})$$

which, for the E_2 terms, reduces to

$$H^p_{\mathrm{II}}(H^q_{\mathrm{I}}(\mathrm{L}^{\bullet\bullet})) \longrightarrow H^p_{\mathrm{II}}(H^q_{\mathrm{I}}(\mathrm{C}^{\bullet\bullet})). \tag{11.8.9.1}$$

But for every $k \in \mathbb{Z}$, it follows from (11.8.5) that the homomorphism $H^q_{\mathrm{I}}(\mathrm{L}^{\bullet,k}) \to H^q_{\mathrm{I}}(\mathrm{C}^{\bullet,k})$ is bijective; the conclusion therefore follows from (11.1.5). □

(11.8.10) Similarly, with the notation of (11.8.6), we have canonical homomorphisms of bicomplexes

$$\mathrm{C}^\bullet(A, B; \Gamma^\bullet) \longrightarrow \mathrm{P}^\bullet(A, B; \Gamma^\bullet)$$

(with the obvious notation), and the same reasoning as in (11.8.9), based this time on (11.8.6), shows that this homomorphism again gives an isomorphism in cohomology.

11.9 A lemma on complexes of finite type

(11.9.1) Proposition. *Let $\mathcal{C}$ be an abelian category, and K' and K'' subsets of the set of objects of $\mathcal{C}$ such that $K'' \subset K'$ and satisfying the following conditions:*

(i) For every object $A' \in K'$ and every epimorphism $u : A \to A'$ in $\mathcal{C}$, there exist an object $B \in K''$ and a morphism $v : B \to A$ such that $u \circ v$ is an epimorphism.

(ii) For every pair of objects $A \in K'$, $B \in K'$ and every epimorphism $u : A \to B$, $\mathrm{Ker}(u)$ belongs to K'.

(iii) The product of two objects of K'' belongs to K''.

Let $P_\bullet = (P_i)_{i\in\mathbb{Z}}$ be a complex in $\mathcal{C}$ such that $H_i(P_\bullet) \in K'$ for every i and such that there exists d with $H_i(P_\bullet) = 0$ for $i < d$. Then there exist a complex $Q_\bullet = (Q_i)_{i\in\mathbb{Z}}$ in $\mathcal{C}$ such that $Q_i \in K''$ for every i and $Q_i = 0$ for $i < d$, and a morphism $u : Q_\bullet \to P_\bullet$ of complexes such that the corresponding morphism $H_\bullet(Q_\bullet) \to H_\bullet(P_\bullet)$ is an isomorphism.

Proof. Let us first prove the following consequence of property (i):

(i bis) Let $u : C \to B$ be an epimorphism in $\mathcal{C}$, A an object of K', and $v : A \to B$ a morphism in $\mathcal{C}$; then there exist an object $D \in K''$, an epimorphism $u' : D \to A$ and a morphism $v' : D \to C$ such that the diagram

$$\begin{array}{ccc} D & \xrightarrow{u'} & A \\ {\scriptstyle v'}\downarrow & & \downarrow{\scriptstyle v} \\ C & \xrightarrow[u]{} & B \end{array} \qquad (11.9.1.1)$$

is commutative.

Indeed, consider the fibre product $C \times_B A$ in $\mathcal{C}$ and the canonical projections $p : C \times_B A \to C$, $q : C \times_B A \to A$, which make the diagram [0_{III} | 47]

$$\begin{array}{ccc} C \times_B A & \xrightarrow{q} & A \\ {\scriptstyle p}\downarrow & & \downarrow{\scriptstyle v} \\ C & \xrightarrow[u]{} & B \end{array} \qquad (11.9.1.2)$$

commutative. We know ([27], p. 1-12) that the cokernel of q is the quotient of A by $v^{-1}(u(C))$; since u is an epimorphism, $u(C) = B$ and $v^{-1}(u(C)) = A$, so q is an epimorphism; it then suffices to apply (i) to the epimorphism $q : C \times_B A \to A$: there exist an object $D \in K''$ and a morphism $w : D \to C \times_B A$ such that $q \circ w$ is an epimorphism; we take $u' = q \circ w$, $v' = p \circ w$.

This being so, to prove the proposition, we proceed by induction. Suppose that, for some $i \geq d - 1$, the objects Q_j, the morphisms $d_j : Q_j \to Q_{j-1}$ and the morphisms $u_j : Q_j \to P_j$ have been constructed for $j \leq i$, in such a way that $Q_j = 0$ for $j < d$, $d_{j-1} \circ d_j = 0$ and $d_j \circ u_j = u_{j-1} \circ d_j$ for $j \leq i$; moreover, we suppose that the following conditions are satisfied:

(I_i) We have $Q_j \in K''$ for $j \leq i$ and $B_j(Q_\bullet) \in K'$ for $j < i$.

(II_i) For $j < i$, the homomorphism $H_j(Q_\bullet) \to H_j(P_\bullet)$ deduced from the family $(u_k)_{k\leq i}$ is an isomorphism.

(III$_i$) The composite morphism

$$v_i : Z_i(Q_\bullet) \longrightarrow Z_i(P_\bullet) \longrightarrow H_i(P_\bullet)$$

(where the left arrow is the restriction of u_i and the right arrow the canonical morphism) is an epimorphism.

Note that, by (ii), $Z_i(Q_\bullet)$, the kernel of the epimorphism $Q_i \to B_{i-1}(Q_\bullet)$, belongs to K' by virtue of hypothesis (I$_i$). We further deduce from (ii) that $N_i = \mathrm{Ker}(v_i)$ also belongs to K', taking into account hypothesis (III$_i$). By virtue of (i bis), there exist a $Q'_{i+1} \in K''$, an epimorphism $d'_{i+1} : Q'_{i+1} \to N_i$ and a morphism $u'_{i+1} : Q'_{i+1} \to P_{i+1}$ such that the diagram

$$\begin{array}{ccc} Q'_{i+1} & \xrightarrow{d'_{i+1}} & N_i \\ {\scriptstyle u'_{i+1}}\downarrow & & \downarrow{\scriptstyle u_i} \\ P_{i+1} & \xrightarrow[d_{i+1}]{} & B_i(P_\bullet) \end{array} \tag{11.9.1.3}$$

is commutative.

Since the canonical morphism $Z_{i+1}(P_\bullet) \to H_{i+1}(P_\bullet)$ is an epimorphism and $H_{i+1}(P_\bullet) \in K'$ by hypothesis, it follows from (i) that there exist an object $Q''_{i+1} \in K''$ and a morphism $u''_{i+1} : Q''_{i+1} \to Z_{i+1}(P_\bullet)$ such that the composite $Q''_{i+1} \to Z_{i+1}(P_\bullet) \to H_{i+1}(P_\bullet)$ is an epimorphism. If we take $d''_{i+1} : Q''_{i+1} \to N_i$ equal to 0, the diagram

$$\begin{array}{ccc} Q''_{i+1} & \xrightarrow{d''_{i+1}} & N_i \\ {\scriptstyle u''_{i+1}}\downarrow & & \downarrow{\scriptstyle u_i} \\ Z_{i+1}(P_\bullet) & \xrightarrow[d_{i+1}]{} & P_i \end{array} \tag{11.9.1.4}$$

[0_{III} | 48] is commutative, the lower horizontal arrow being 0. Then take

$$Q_{i+1} = Q'_{i+1} \times Q''_{i+1}, \qquad d_{i+1} = d'_{i+1} + d''_{i+1}, \qquad u_{i+1} = u'_{i+1} + u''_{i+1}.$$

Since $d_{i+1}(Q_{i+1}) = d'_{i+1}(Q'_{i+1}) = N_i \subset Z_i(Q_\bullet)$, we have $d_i \circ d_{i+1} = 0$ and, with the usual notation, $B_i(Q_\bullet) = N_i$, which verifies (I$_{i+1}$). The commutativity of the diagrams (11.9.1.3) and (11.9.1.4) shows that $d_{i+1} \circ u_{i+1} = u_i \circ d_{i+1}$. By definition of N_i, the morphism

$$H_i(Q_\bullet) = Z_i(Q_\bullet)/N_i \longrightarrow H_i(P_\bullet)$$

deduced from the system of the u_k ($k \leq i+1$) is the morphism deduced from v_i by passage to the quotients, so it is an isomorphism since v_i is an epimorphism, whence (II$_{i+1}$). Finally, we have $Q''_{i+1} \subset Z_{i+1}(Q_\bullet)$ by definition; the choice of u''_{i+1} shows that the morphism

$$v_{i+1} : Z_{i+1}(Q_\bullet) \longrightarrow Z_{i+1}(P_\bullet) \longrightarrow H_{i+1}(P_\bullet)$$

is an epimorphism, since its restriction to Q''_{i+1} already is, whence (III$_{i+1}$). The induction can therefore be continued, and the proposition is proved. □

(11.9.2) Corollary. *Let A be a Noetherian ring (not necessarily commutative) and $P_\bullet = (P_i)_{i\in\mathbb{Z}}$ a complex of right A-modules. Suppose that the $H_i(P_\bullet)$ are A-modules of finite type and that there exists d such that $H_i(P_\bullet) = 0$ for $i < d$. Then there exist a complex $Q_\bullet = (Q_i)_{i\in\mathbb{Z}}$ formed of free right A-modules of finite rank, such that $Q_i = 0$ for $i < d$, and a homomorphism $u : Q_\bullet \to P_\bullet$ of complexes such that the homomorphism $H_\bullet(Q_\bullet) \to H_\bullet(P_\bullet)$ corresponding to u is bijective.*

Proof. We apply (11.9.1), taking for $\mathcal{C}$ the category of right A-modules, and for K' (resp. K'') the set of A-modules of finite type (resp. the set of free A-modules of finite rank); the verification of conditions (i), (ii) and (iii) of (11.9.1) is immediate, taking into account the hypothesis that A is Noetherian. □

(11.9.3) *Remarks.*

(i) Under the conditions of (11.9.2), suppose moreover that the P_i are flat right A-modules. Then, for every left A-module M, the homomorphism of complexes

$$u \otimes 1 : Q_\bullet \otimes_A M \longrightarrow P_\bullet \otimes_A M$$

again defines an isomorphism $H_\bullet(Q_\bullet \otimes_A M) \simeq H_\bullet(P_\bullet \otimes_A M)$ of the homology, as we will see in Chapter III.

(ii) The conclusion of (11.9.2) is no longer necessarily true when A is not assumed Noetherian; indeed, applying it to a complex reduced to 0 except for a single term, we would conclude that every right A-module of finite type admits a resolution by free modules of finite type, which is not true in general (cf. Bourbaki, *Alg. comm.*, chap. I, § 2, exerc. 6).

However, instead of assuming A Noetherian, we can assume only that the $H_i(P_\bullet)$ have a finite ∞-presentation (cf. Chapter IV).

11.10 Euler–Poincaré characteristic of a complex of modules of finite length

(11.10.1) Let A be a ring (not necessarily commutative) and

$$M^\bullet : 0 \longrightarrow M^0 \longrightarrow M^1 \longrightarrow \cdots \longrightarrow M^n \longrightarrow 0 \tag{11.10.1.1}$$

a complex of left A-modules of finite length. We call the *Euler–Poincaré characteristic* of this complex the number [0_{III} | 49]

$$\chi(M^\bullet) = \sum_{i=0}^{n} (-1)^i \operatorname{long}(M^i). \tag{11.10.1.2}$$

(11.10.2) Proposition. For every finite complex $M^\bullet$ of left A-modules of finite length, we have

$$\chi(M^\bullet) = \chi(H^\bullet(M^\bullet))$$

($H^\bullet(M^\bullet)$ being regarded as a complex with the trivial differential). In particular, if the sequence (11.10.1.1) is exact, we have $\chi(M^\bullet) = 0$.

Proof. For brevity, set $B^i = B^i(M^\bullet)$, $Z^i = Z^i(M^\bullet)$, $H^i = H^i(M^\bullet) = Z^i/B^i$; the B^i, Z^i, H^i are of finite length. From the exact sequences

$$0 \longrightarrow B^i \longrightarrow Z^i \longrightarrow H^i \longrightarrow 0, \qquad 0 \longrightarrow Z^i \longrightarrow M^i \longrightarrow B^{i+1} \longrightarrow 0$$

we obtain the relations

$$\operatorname{long}(Z^i) = \operatorname{long}(H^i) + \operatorname{long}(B^i), \qquad \operatorname{long}(M^i) = \operatorname{long}(Z^i) + \operatorname{long}(B^{i+1}),$$

whence

$$\log(M^i) - \log(H^i) = \log(B^{i+1}) + \log(B^i).$$

Multiplying this relation by $(-1)^i$ and summing the relations obtained for $0 \leq i \leq n$, noting that $B^0 = B^{n+1} = 0$, we obtain the desired equality. □

(11.10.3) Corollary. *Let $E = (E_r^{pq})$ be a spectral sequence in the category of modules over a ring A. Suppose that the E_2^{pq} are A-modules of finite length and that there are only finitely many pairs (p, q) such that $E_2^{pq} \neq 0$. Then the Euler–Poincaré characteristics $\chi(E_r^\bullet)$ of all the complexes $E_r^\bullet = (E_r^{(n)})_{n\in\mathbb{Z}}$ (11.1.1) are all equal. If, moreover, the sequence E is weakly convergent and if we set*

$$E_\infty^{(n)} = \bigoplus_{p+q=n} E_\infty^{pq} \quad (n \in \mathbb{Z}),$$

we also have $\chi(E_\infty^\bullet) = \chi(E_2^\bullet)$, $E_\infty^\bullet = (E_\infty^{(n)})_{n\in\mathbb{Z}}$ being regarded as a complex with trivial differential.

Proof. Note first that if $E_2^{pq} = 0$, then $E_r^{pq} = 0$ for $2 \leq r < +\infty$, so all the complexes $E_r^\bullet$ are finite and formed of A-modules of finite length; the relation $\chi(E_r^\bullet) = \chi(E_{r+1}^\bullet)$ for every finite r therefore follows from (11.10.2) and from the isomorphism between $H^\bullet(E_r^\bullet)$ and $E_{r+1}^\bullet$ (as complexes with trivial differential). The hypothesis that the E_r^{pq} are of finite length implies that for every pair (p, q), the sequences $(B_k(E_2^{pq}))_{k\geq 2}$ and $(Z_k(E_2^{pq}))_{k\geq 2}$ are stationary; the hypothesis that E is weakly convergent and that $E_2^{pq} = 0$ except for finitely many pairs (p, q) therefore implies that there exists an integer $r \geq 2$ such that $E_\infty^{pq} = E_r^{pq}$ for every pair (p, q); whence the assertion concerning $\chi(E_\infty^\bullet)$. □

§12 Supplement on sheaf cohomology

12.1 Cohomology of sheaves of modules on ringed spaces

[0_{III} | 49] **(12.1.1)** Let $(X, \mathscr{O}_X)$ be a ringed space. Recall that, for every $\mathscr{O}_X$-Module $\mathscr{F}$, one defines the cohomology $\mathrm{H}^\bullet(X, \mathscr{F})$, which is a universal cohomological functor (T, 2.2) from the category $\mathbf{C}(X)$ of $\mathscr{O}_X$-Modules to the category of abelian groups; it is the derived functor of the left exact functor

$$\mathscr{F} \longmapsto \Gamma(X, \mathscr{F}).$$

[0_{III} | 50] The functor $\mathrm{H}^\bullet(X, \mathscr{F})$ is isomorphic to the restriction to the category $\mathbf{C}(X)$ of the cohomological functor defined in the same way on the category of sheaves of abelian groups on X (G, II, 7.2.1).

(12.1.2) Set $A = \Gamma(X, \mathscr{O}_X)$. Since every element of A defines an endomorphism of the abelian group $\Gamma(X, \mathscr{F})$, it defines by functoriality an endomorphism of the δ-functor $\mathrm{H}^\bullet(X, \mathscr{F})$. These endomorphisms endow each $\mathrm{H}^p(X, \mathscr{F})$ with an A-module structure, and the boundary operator ∂ is A-linear. Moreover, for any two nonnegative integers p, q and any two $\mathscr{O}_X$-Modules $\mathscr{F}, \mathscr{G}$, there is a homomorphism of A-modules, called the *cup product*,

$$\mathrm{H}^p(X, \mathscr{F}) \otimes_A \mathrm{H}^q(X, \mathscr{G}) \longrightarrow \mathrm{H}^{p+q}(X, \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}) \tag{12.1.2.1}$$

(G, II, 6.6). These homomorphisms make the direct sum S of the $\mathrm{H}^p(X, \mathscr{O}_X)$, for $p \geq 0$, an anticommutative graded A-algebra, and the direct sum of the $\mathrm{H}^p(X, \mathscr{F})$ a graded S-module.

For every open covering $\mathfrak{U}$ of X, we shall always denote by $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F})$ (contrary to (G, II, 5.1)) the complex of alternating cochains of the nerve of $\mathfrak{U}$ with values in the coefficient system $\Gamma(U_\alpha, \mathscr{F})$. It is clear that $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F})$ is a graded A-module, so that the cohomology groups $\check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F})$ of this complex are endowed with an A-module structure. Moreover, the canonical maps

$$\check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \longrightarrow \mathrm{H}^p(X, \mathscr{F})$$

(G, II, 5.4) are A-linear.

(12.1.3) Let $(X', \mathscr{O}_{X'})$ be a second ringed space, and let $f = (\psi, \theta)$ be a morphism from X' to X. Set $A' = \Gamma(X', \mathscr{O}_{X'})$; the ψ-morphism θ canonically defines a ring homomorphism $A \to A'$. Let $\mathscr{F}$ be an $\mathscr{O}_X$-Module and $\mathscr{F}'$ an $\mathscr{O}_{X'}$-Module. For every f-morphism $u : \mathscr{F} \to \mathscr{F}'$ (0_I, 4.4.1), we shall see that one can define, for every $p \geq 0$, a di-homomorphism

$$u_p : \mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X', \mathscr{F}'). \tag{12.1.3.1}$$

Indeed, since ψ^* is exact in the category of sheaves of abelian groups on X, the functor

$$\mathscr{F} \longmapsto \mathrm{H}^\bullet(X', \psi^*(\mathscr{F}))$$

is a δ-functor on that category, and it is known that there is a canonical homomorphism of δ-functors

$$\mathrm{H}^\bullet(X, \mathscr{F}) \longrightarrow \mathrm{H}^\bullet(X', \psi^*(\mathscr{F})) \tag{12.1.3.2}$$

uniquely determined by the condition that, in degree 0, it reduces to the canonical homomorphism

$$\Gamma(X, \mathscr{F}) \longrightarrow \Gamma(X', \psi^*(\mathscr{F}))$$

(T, 3.2.2). Moreover, every element of A determines an endomorphism μ of $\Gamma(X, \mathscr{F})$ and an endomorphism μ' of $\Gamma(X', \psi^*(\mathscr{F}))$ such that the diagram

$$\begin{array}{ccc} \Gamma(X, \mathscr{F}) & \longrightarrow & \Gamma(X', \psi^*(\mathscr{F})) \\ {\scriptstyle\mu}\downarrow & & \downarrow{\scriptstyle\mu'} \\ \Gamma(X, \mathscr{F}) & \longrightarrow & \Gamma(X', \psi^*(\mathscr{F})) \end{array} \tag{12.1.3.3}$$

is commutative. By the uniqueness property for extending morphisms of universal cohomological functors (T, 2.2), one obtains unique extensions of μ and μ' to cohomology which make the diagrams analogous to (12.1.3.3) commutative. Thus (12.1.3.2) is a homomorphism of A-modules. [0_III | 51]

Now note that

$$f^*(\mathscr{F}) = \psi^*(\mathscr{F}) \otimes_{\psi^*(\mathscr{O}_X)} \mathscr{O}_{X'},$$

and hence that there is a canonical di-homomorphism

$$\psi^*(\mathscr{F}) \longrightarrow f^*(\mathscr{F})$$

from the $\psi^*(\mathscr{O}_X)$-Module $\psi^*(\mathscr{F})$ to the $\mathscr{O}_{X'}$-Module $f^*(\mathscr{F})$. By functoriality, one therefore obtains a functorial di-homomorphism

$$\mathrm{H}^p(X', \psi^*(\mathscr{F})) \longrightarrow \mathrm{H}^p(X', f^*(\mathscr{F})), \tag{12.1.3.4}$$

the corresponding rings being A and A'. Composing this di-homomorphism with (12.1.3.2), one obtains a canonical di-homomorphism, functorial in $\mathscr{F}$,

$$\theta_p : \mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X', f^*(\mathscr{F})). \tag{12.1.3.5}$$

Finally, by functoriality, the homomorphism $u^\sharp : f^*(\mathscr{F}) \to \mathscr{F}'$ gives a homomorphism of A'-modules

$$\mathrm{H}^p(X', f^*(\mathscr{F})) \longrightarrow \mathrm{H}^p(X', \mathscr{F}'),$$

which, composed with (12.1.3.5), gives (12.1.3.1).

Let $f' = (\psi', \theta') : X'' \to X'$ be a second morphism of ringed spaces, and let $f'' = f \circ f'$ be the composite morphism. Taking account of the compatibility of the functor ψ'^* with tensor products (0_I, 4.3.3), one immediately checks that the composite of the di-homomorphism

$$\mathrm{H}^p(X', f^*(\mathscr{F})) \longrightarrow \mathrm{H}^p(X'', f'^*(f^*(\mathscr{F})))$$

with (12.1.3.5) is the corresponding di-homomorphism

$$\mathrm{H}^p(X, \mathscr{F}) \longrightarrow \mathrm{H}^p(X'', f''^*(\mathscr{F})).$$

(12.1.4) A direct definition of the homomorphism (12.1.3.2) can be given as follows. Take an injective resolution $\mathscr{L}^\bullet = (\mathscr{L}^i)$ of $\mathscr{F}$ consisting of sheaves of abelian groups on X. Since the functor ψ^* is exact, $\psi^*(\mathscr{L}^\bullet)$ is a resolution of $\psi^*(\mathscr{F})$ consisting of sheaves on X'. If $\mathscr{L}'^\bullet = (\mathscr{L}'^i)$ is an injective resolution of $\psi^*(\mathscr{F})$ in the category of sheaves of abelian groups on X', there is a morphism

$$\psi^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet$$

of complexes of sheaves of abelian groups, compatible with the augmentations (M, V, 1.1.a), and determined up to homotopy. One thereby obtains homomorphisms

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X', \psi^*(\mathscr{L}^\bullet)) \longrightarrow \Gamma(X', \mathscr{L}'^\bullet)$$

of complexes of abelian groups. Their composite, on passing to cohomology, gives a morphism of δ-functors

$$\mathrm{H}^\bullet(X, \mathscr{F}) \longrightarrow \mathrm{H}^\bullet(X', \psi^*(\mathscr{F}));$$

since it coincides with (12.1.3.2) in degree 0, it is identical to it (T, 2.2).

Now consider an open covering $\mathfrak{U} = (U_\alpha)$ of X, and let $\mathfrak{U}' = (f^{-1}(U_\alpha))$ be its inverse-image open covering of X'. For every open subset V of X, the canonical homomorphisms

$$\Gamma(V, \mathscr{F}) \longrightarrow \Gamma(f^{-1}(V), f^*(\mathscr{F}))$$

immediately define (cf. G, II, 5.1) a homomorphism of complexes

$$\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}) \longrightarrow \check{\mathrm{C}}^\bullet(\mathfrak{U}', f^*(\mathscr{F})),$$

and hence canonical homomorphisms

$$\theta_p : \check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) \longrightarrow \check{\mathrm{H}}^p(\mathfrak{U}', f^*(\mathscr{F})). \tag{12.1.4.1}$$

[0_III | 52] Moreover, there are commutative diagrams

$$\begin{array}{ccc} \check{\mathrm{H}}^p(\mathfrak{U}, \mathscr{F}) & \xrightarrow{\theta_p} & \check{\mathrm{H}}^p(\mathfrak{U}', f^*(\mathscr{F})) \\ \downarrow & & \downarrow \\ \mathrm{H}^p(X, \mathscr{F}) & \xrightarrow[\theta_p]{} & \mathrm{H}^p(X', f^*(\mathscr{F})), \end{array} \tag{12.1.4.2}$$

where the vertical arrows are the canonical homomorphisms of (G, II, 5.2). To prove the commutativity of (12.1.4.2), consider the complex of sheaves of alternating cochains of $\mathscr{F}$ relative to $\mathfrak{U}$, $\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})$, for which

$$\Gamma\big(X,\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})\big)=\check{\mathrm{C}}^\bullet(\mathfrak{U},\mathscr{F})$$

(G, II, 5.2). The canonical homomorphisms

$$\Gamma(V,\mathscr{F})\longrightarrow\Gamma(f^{-1}(V),\psi^*(\mathscr{F}))$$

then define a ψ-morphism

$$\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})\longrightarrow\mathscr{C}^\bullet(\mathfrak{U}',\psi^*(\mathscr{F})),$$

and, with the notation above, there is a commutative diagram

$$\begin{array}{ccccc}
\Gamma\big(X,\mathscr{C}^\bullet(\mathfrak{U},\mathscr{F})\big) & \longrightarrow & \Gamma\big(X',\mathscr{C}^\bullet(\mathfrak{U}',\psi^*(\mathscr{F}))\big) & & \\
\downarrow & & \downarrow & & \\
\Gamma(X,\mathscr{L}^\bullet) & \longrightarrow & \Gamma(X',\psi^*(\mathscr{L}^\bullet)) & \longrightarrow & \Gamma(X',\mathscr{L}'^\bullet).
\end{array}$$

Passing to cohomology gives commutative diagrams

$$\begin{array}{ccc}
\check{\mathrm{H}}^p(\mathfrak{U},\mathscr{F}) & \longrightarrow & \check{\mathrm{H}}^p(\mathfrak{U}',\psi^*(\mathscr{F})) \\
\downarrow & & \downarrow \\
\mathrm{H}^p(X,\mathscr{F}) & \longrightarrow & \mathrm{H}^p(X',\psi^*(\mathscr{F})),
\end{array}$$

where the vertical arrows are the canonical homomorphisms of (G, II, 5.2). It remains only to combine these diagrams with the commutative diagrams

$$\begin{array}{ccc}
\check{\mathrm{H}}^p(\mathfrak{U}',\psi^*(\mathscr{F})) & \longrightarrow & \check{\mathrm{H}}^p(\mathfrak{U}',f^*(\mathscr{F})) \\
\downarrow & & \downarrow \\
\mathrm{H}^p(X',\psi^*(\mathscr{F})) & \longrightarrow & \mathrm{H}^p(X',f^*(\mathscr{F})),
\end{array}$$

which arise from the homomorphism $\psi^*(\mathscr{F})\to f^*(\mathscr{F})$ and the functoriality of the canonical homomorphisms of (G, II, 5.2), to obtain the commutativity of (12.1.4.2). [$0_{\mathrm{III}}\,|\,53$]

Note that if $A=\Gamma(X,\mathscr{O}_X)$ and $A'=\Gamma(X',\mathscr{O}_{X'})$, then (12.1.4.1) is a di-homomorphism of modules corresponding to the rings A and A'. There is a transitivity property for (12.1.4.1) with respect to a composite of two morphisms, analogous to that of (12.1.3.5). Finally, in the preceding definitions, instead of an injective resolution $\mathscr{L}^\bullet$ of $\mathscr{F}$, one could equally well have started with a resolution such that

$$\mathrm{H}^p(X,\mathscr{L}^i)=0\qquad\text{for every } i \text{ and every } p>0$$

(G, II, 4.7.1).

(12.1.5) Let $\mathscr{F},\mathscr{G},\mathscr{H}$ be three $\mathscr{O}_X$-Modules, and consider an $\mathscr{O}_X$-homomorphism

$$u:\mathscr{F}\otimes_{\mathscr{O}_X}\mathscr{G}\longrightarrow\mathscr{H},$$

which gives, in cohomology, the homomorphisms

$$\mathrm{H}^p(X,\mathscr{F})\otimes_A\mathrm{H}^q(X,\mathscr{G})\longrightarrow\mathrm{H}^{p+q}(X,\mathscr{H})\qquad(12.1.5.1)$$

deduced from the cup product (12.1.2.1). We show that, under the hypotheses and with the notation of (12.1.3), the diagrams

$$\begin{array}{ccc} \mathrm{H}^p(X,\mathscr{F})\otimes_A \mathrm{H}^q(X,\mathscr{G}) & \longrightarrow & \mathrm{H}^{p+q}(X,\mathscr{H}) \\ \downarrow & & \downarrow \\ \mathrm{H}^p(X',f^*(\mathscr{F}))\otimes_{A'} \mathrm{H}^q(X',f^*(\mathscr{G})) & \to & \mathrm{H}^{p+q}(X',f^*(\mathscr{H})) \end{array} \tag{12.1.5.2}$$

are commutative, where the vertical arrows come from the canonical homomorphisms (12.1.3.5).

Recall for this purpose that (12.1.5.1) can be obtained from the canonical resolutions (G, II, 4.3) $\mathscr{L}^\bullet, \mathscr{M}^\bullet, \mathscr{N}^\bullet$ of $\mathscr{F},\mathscr{G},\mathscr{H}$ respectively, which consist of $\mathscr{O}_X$-Modules, and from the linear map

$$\mathscr{L}^\bullet \otimes_{\mathscr{O}_X} \mathscr{M}^\bullet \longrightarrow \mathscr{N}^\bullet$$

of complexes of $\mathscr{O}_X$-Modules corresponding to u. This map provides a homomorphism of complexes of A-modules

$$\Gamma(X,\mathscr{L}^\bullet)\otimes_A \Gamma(X,\mathscr{M}^\bullet) \longrightarrow \Gamma(X,\mathscr{N}^\bullet),$$

and hence, on passing to cohomology, homomorphisms

$$\mathrm{H}^p\big(\Gamma(X,\mathscr{L}^\bullet)\big)\otimes_A \mathrm{H}^q\big(\Gamma(X,\mathscr{M}^\bullet)\big) \longrightarrow \mathrm{H}^{p+q}\big(\Gamma(X,\mathscr{N}^\bullet)\big)$$

(G, II, 6.6). There is clearly a commutative diagram

$$\begin{array}{ccc} \Gamma(X,\mathscr{L}^\bullet)\otimes_A \Gamma(X,\mathscr{M}^\bullet) & \longrightarrow & \Gamma(X,\mathscr{N}^\bullet) \\ \downarrow & & \downarrow \\ \Gamma(X',\psi^*(\mathscr{L}^\bullet))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))} \Gamma(X',\psi^*(\mathscr{M}^\bullet)) & \to & \Gamma(X',\psi^*(\mathscr{N}^\bullet)). \end{array} \tag{12.1.5.3}$$

[0_{III} | 54] Passing to cohomology gives commutative diagrams

$$\begin{array}{ccc} \mathrm{H}^p(X,\mathscr{F})\otimes_A \mathrm{H}^q(X,\mathscr{G}) & \longrightarrow & \mathrm{H}^{p+q}(X,\mathscr{H}) \\ \downarrow & & \downarrow \\ \mathrm{H}^p\big(\Gamma(X',\psi^*(\mathscr{L}^\bullet))\big)\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))} \mathrm{H}^q\big(\Gamma(X',\psi^*(\mathscr{M}^\bullet))\big) & \to & \mathrm{H}^{p+q}\big(\Gamma(X',\psi^*(\mathscr{N}^\bullet))\big). \end{array} \tag{12.1.5.4}$$

But since $\psi^*(\mathscr{L}^\bullet)$, $\psi^*(\mathscr{M}^\bullet)$, and $\psi^*(\mathscr{N}^\bullet)$ are resolutions of $\psi^*(\mathscr{F})$, $\psi^*(\mathscr{G})$, and $\psi^*(\mathscr{H})$ respectively, there is a commutative diagram (G, II, 6.6.1)

$$\begin{array}{ccc} \mathrm{H}^p\big(\Gamma(X',\psi^*(\mathscr{L}^\bullet))\big)\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))} \mathrm{H}^q\big(\Gamma(X',\psi^*(\mathscr{M}^\bullet))\big) & \to & \mathrm{H}^{p+q}\big(\Gamma(X',\psi^*(\mathscr{N}^\bullet))\big) \\ \downarrow & & \downarrow \\ \mathrm{H}^p(X',\psi^*(\mathscr{F}))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))} \mathrm{H}^q(X',\psi^*(\mathscr{G})) & \longrightarrow & \mathrm{H}^{p+q}(X',\psi^*(\mathscr{H})). \end{array} \tag{12.1.5.5}$$

Finally, by functoriality, there is a commutative diagram

$$\begin{array}{ccc} \mathrm{H}^p(X',\psi^*(\mathscr{F}))\otimes_{\Gamma(X',\psi^*(\mathscr{O}_X))} \mathrm{H}^q(X',\psi^*(\mathscr{G})) & \to & \mathrm{H}^{p+q}(X',\psi^*(\mathscr{H})) \\ \downarrow & & \downarrow \\ \mathrm{H}^p(X',f^*(\mathscr{F}))\otimes_{A'} \mathrm{H}^q(X',f^*(\mathscr{G})) & \longrightarrow & \mathrm{H}^{p+q}(X',f^*(\mathscr{H})). \end{array} \tag{12.1.5.6}$$

Combining the three diagrams (12.1.5.4), (12.1.5.5), and (12.1.5.6) yields the desired commutative diagram (12.1.5.2).

(12.1.6) Remark. With the notation of (12.1.3), suppose that there is a commutative diagram [$0_{\mathrm{III}}\,|\,55$]

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathscr{F} & \xrightarrow{r} & \mathscr{G} & \xrightarrow{s} & \mathscr{H} & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle u} & & \downarrow{\scriptstyle v} & & \downarrow{\scriptstyle w} & & \\ 0 & \longrightarrow & \mathscr{F}' & \xrightarrow[r']{} & \mathscr{G}' & \xrightarrow[s']{} & \mathscr{H}' & \longrightarrow & 0, \end{array} \tag{12.1.6.1}$$

where r, s are homomorphisms of $\mathscr{O}_X$-Modules, r', s' are homomorphisms of $\mathscr{O}_{X'}$-Modules, u, v, w are f-morphisms, and the rows are exact. It follows that the diagram

$$\begin{array}{ccccccccc} \cdots \to \mathrm{H}^p(X,\mathscr{F}) & \longrightarrow & \mathrm{H}^p(X,\mathscr{G}) & \longrightarrow & \mathrm{H}^p(X,\mathscr{H}) & \xrightarrow{\partial} & \mathrm{H}^{p+1}(X,\mathscr{F}) & \to \cdots \\ \downarrow{\scriptstyle u_p} & & \downarrow{\scriptstyle v_p} & & \downarrow{\scriptstyle w_p} & & \downarrow{\scriptstyle u_{p+1}} & \\ \cdots \to \mathrm{H}^p(X',\mathscr{F}') & \to & \mathrm{H}^p(X',\mathscr{G}') & \to & \mathrm{H}^p(X',\mathscr{H}') & \xrightarrow[\partial]{} & \mathrm{H}^{p+1}(X',\mathscr{F}') & \to \cdots \end{array} \tag{12.1.6.2}$$

is commutative. Indeed, (12.1.6.1) factors as

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathscr{F} & \longrightarrow & \mathscr{G} & \longrightarrow & \mathscr{H} & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \psi^*(\mathscr{F}) & \longrightarrow & \psi^*(\mathscr{G}) & \longrightarrow & \psi^*(\mathscr{H}) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathscr{F}' & \longrightarrow & \mathscr{G}' & \longrightarrow & \mathscr{H}' & \longrightarrow & 0, \end{array}$$

where the middle row is exact (0_{I}, 3.7.2). It is then enough to use the fact that (12.1.3.2) is a homomorphism of δ-functors and that the $\mathrm{H}^p(X',\mathscr{F}')$ form a δ-functor in $\mathscr{F}'$.

(12.1.7) With the hypotheses and notation of (12.1.3), consider now the case

$$\mathscr{F} = f_*(\mathscr{F}') = \psi_*(\mathscr{F}').$$

We shall see that the di-homomorphism defined in (12.1.3),

$$\mathrm{H}^p(X, f_*(\mathscr{F}')) \longrightarrow \mathrm{H}^p(X',\mathscr{F}'), \tag{12.1.7.1}$$

can be obtained (up to an automorphism of $\mathrm{H}^p(X',\mathscr{F}')$) as an edge homomorphism of a spectral sequence for the composite functor

$$\mathscr{F}' \rightsquigarrow \Gamma(X, \psi_*(\mathscr{F}'))$$

(T, 2.4). The description of (12.1.7.1) given in (12.1.4) shows here that this homomorphism can be obtained as follows. Take injective resolutions $\mathscr{L}^\bullet$ and $\mathscr{L}'^\bullet$ of $\psi_*(\mathscr{F}')$ and $\mathscr{F}'$, respectively, and then a homomorphism of complexes

$$v : \psi^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet$$

"above" the canonical homomorphism $\psi^*(\psi_*(\mathscr{F}')) \to \mathscr{F}'$. We next note that [$0_{\mathrm{III}}\,|\,56$]

$$\Gamma(X', \mathscr{L}'^\bullet) = \Gamma(X, \psi_*(\mathscr{L}'^\bullet))$$

and that the composite homomorphism

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X', \psi^*(\mathscr{L}^\bullet)) \xrightarrow{\Gamma(v)} \Gamma(X', \mathscr{L}'^\bullet)$$

is none other than

$$\Gamma(v^\flat) : \Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X, \psi_*(\mathscr{L}'^\bullet)) \tag{12.1.7.2}$$

(0_{I}, 3.7.1); and (12.1.7.1) is obtained by passing to cohomology in (12.1.7.2).

On the other hand, the spectral sequences for the composite functor

$$\mathscr{F}' \rightsquigarrow \Gamma(X, \psi_*(\mathscr{F}'))$$

are obtained by taking an injective Cartan–Eilenberg resolution

$$\mathscr{M}^{\bullet\bullet} = (\mathscr{M}^{ij})$$

of the complex $\psi_*(\mathscr{L}'^\bullet)$ in the category of sheaves of abelian groups on X. The spectral sequences in question are those of the bicomplex $\Gamma(X, \mathscr{M}^{\bullet\bullet})$; they are biregular, since $\mathscr{M}^{ij} = 0$ for $i < 0$ or $j < 0$. Now the first spectral sequence of this bicomplex degenerates, since the sheaves $\psi_*(\mathscr{L}'^i)$ are flasque (G, II, 3.1.1), and therefore

$$\mathrm{H}^q_{\mathrm{II}}(\Gamma(X, \mathscr{M}^{i,\bullet})) = \mathrm{H}^q(\psi_*(\mathscr{L}'^i)) = 0 \qquad (q > 0)$$

(G, II, 4.4.3). Consequently, there are bijective edge homomorphisms (11.1.6)

$${}'E_2^{i0} = \mathrm{H}^i\Big(\mathrm{H}^0_{\mathrm{II}}(\Gamma(X, \mathscr{M}^{\bullet\bullet}))\Big) \longrightarrow \mathrm{H}^i(\Gamma(X, \mathscr{M}^{\bullet\bullet})), \tag{12.1.7.3}$$

and we know (11.3.4) that this homomorphism comes, on passing to cohomology, from the augmentation

$$\Gamma(X, \psi_*(\mathscr{L}'^\bullet)) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}), \tag{12.1.7.4}$$

which itself comes from the augmentation

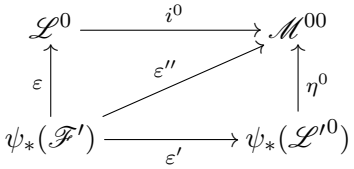
$$\eta : \psi_*(\mathscr{L}'^\bullet) \longrightarrow \mathscr{M}^{\bullet\bullet}.$$

For the second spectral sequence, on the other hand, there are edge homomorphisms

$${}''E_2^{i0} = \mathrm{H}^i\Big(\mathrm{H}^0_{\mathrm{I}}(\Gamma(X, \mathscr{M}^{\bullet\bullet}))\Big) \longrightarrow \mathrm{H}^i(\Gamma(X, \mathscr{M}^{\bullet\bullet})), \tag{12.1.7.5}$$

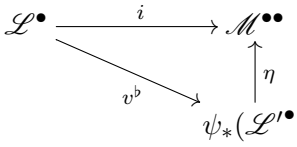
which come (11.3.4), on passing to cohomology, from the homomorphism of complexes

$$Z^0_{\mathrm{I}}(\Gamma(X, \mathscr{M}^{\bullet\bullet})) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}).$$



Since ψ_* is left exact, the sequence

$$0 \longrightarrow \psi_*(\mathscr{F}') \longrightarrow \psi_*(\mathscr{L}'^0) \longrightarrow \psi_*(\mathscr{L}'^1)$$



is exact. By the definition of a Cartan–Eilenberg resolution (11.4.2), we may therefore take

$$B^0_{\mathrm{I}}(\mathscr{M}^{\bullet\bullet}) = 0, \qquad Z^0_{\mathrm{I}}(\mathscr{M}^{\bullet\bullet}) = \mathscr{L}^\bullet.$$

Since the diagram

is commutative, the injection of complexes $i : \mathscr{L}^\bullet \to \mathscr{M}^{\bullet\bullet}$ is compatible with the augmentations ε and ε''. Thus there are two homomorphisms of complexes from $\mathscr{L}^\bullet$ to $\mathscr{M}^{\bullet\bullet}$,

compatible with the augmentations ε and ε''. Since $\mathscr{L}^\bullet$ is an injective resolution and $\mathscr{M}^{\bullet\bullet}$ consists of injective sheaves, it follows from (M, V, 1.1(a)) that these two homomorphisms are homotopic. The same is therefore true of the two corresponding homomorphisms [0_{III} | 57]

$$\Gamma(X, \mathscr{L}^\bullet) \longrightarrow \Gamma(X, \mathscr{M}^{\bullet\bullet}),$$

and, on passing to cohomology, they consequently give the same homomorphism. In other words, we have shown that the edge homomorphism (12.1.7.5), written

$$\mathrm{H}^p(X, \psi_*(\mathscr{F}')) \longrightarrow \mathrm{H}^p\big(\Gamma(X, \mathscr{M}^{\bullet\bullet})\big),$$

is the composite of (12.1.7.1) and (12.1.7.3), the latter being written

$$\mathrm{H}^p(X', \mathscr{F}') \longrightarrow \mathrm{H}^p\big(\Gamma(X, \mathscr{M}^{\bullet\bullet})\big)$$

and having been seen to be an isomorphism. This proves the assertion.

12.2 Higher direct images

(12.2.1) Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be two ringed spaces, and let $f = (\psi, \theta)$ be a morphism from X to Y. It defines the direct image functor

$$f_* : \mathbf{C}(X) \longrightarrow \mathbf{C}(Y),$$

which is moreover identical to the restriction to $\mathbf{C}(X)$ of the functor ψ_* defined on the category of sheaves of abelian groups on X. The latter functor is additive and left exact; and since every sheaf of abelian groups on X is isomorphic to a subsheaf of an injective sheaf of abelian groups, one defines the right derived functors

$$\mathscr{F} \longmapsto \mathrm{R}^p\psi_*(\mathscr{F})$$

of ψ_*. The $\mathrm{R}^p\psi_*(\mathscr{F})$ are sheaves of abelian groups on Y, and the $\mathrm{R}^p\psi_*$ form a universal cohomological functor (T, 2.3).

Moreover, $\mathrm{R}^p\psi_*(\mathscr{F})$ is the sheaf associated with the presheaf

$$V \longmapsto \mathrm{H}^p(f^{-1}(V), \mathscr{F})$$

(T, 3.7.2). Suppose now that $\mathscr{F}$ is an $\mathscr{O}_X$-module. Then $\mathrm{H}^p(f^{-1}(V), \mathscr{F})$ is naturally endowed with the structure of a $\Gamma(f^{-1}(V), \mathscr{O}_X)$-module, hence with that of a $\Gamma(V, \psi_*(\mathscr{O}_X))$-module; the homomorphism

$$\theta : \mathscr{O}_Y \longrightarrow \psi_*(\mathscr{O}_X)$$

then endows it with the structure of a $\Gamma(V, \mathscr{O}_Y)$-module. For the structures so defined, restriction from an open subset V to an open subset $V' \subset V$ defines a di-homomorphism. This therefore defines on every $\mathrm{R}^p\psi_*(\mathscr{F})$ the structure of an $\mathscr{O}_Y$-module. We denote this $\mathscr{O}_Y$-module by $\mathrm{R}^p f_*(\mathscr{F})$; thus $\mathrm{R}^p f_*$ is defined as an additive functor from $\mathbf{C}(X)$ to $\mathbf{C}(Y)$.

Moreover, the $\mathrm{R}^p f_*$ form a δ-functor. Indeed, if

$$0 \longrightarrow \mathscr{F}' \longrightarrow \mathscr{F} \longrightarrow \mathscr{F}'' \longrightarrow 0$$

is an exact sequence of $\mathscr{O}_X$-modules, the preceding description of the $\mathrm{R}^p\psi_*$ and of the $\mathscr{O}_Y$-module structure on $\mathrm{R}^p\psi_*(\mathscr{F})$ immediately shows that the boundary homomorphism

$$\partial : \mathrm{R}^p\psi_*(\mathscr{F}'') \longrightarrow \mathrm{R}^{p+1}\psi_*(\mathscr{F}')$$

is an $\mathscr{O}_Y$-module homomorphism. Finally, the $\mathrm{R}^p f_*$ are identified with the right derived functors of f_*. Every $\mathscr{O}_X$-module admits an injective resolution by $\mathscr{O}_X$-modules, and such a resolution consists of flasque sheaves of abelian groups (G, II, 7.1); it can therefore be used to compute the $\mathrm{R}^p\psi_*(\mathscr{F})$, since $\mathrm{R}^n\psi_*(\mathscr{G}) = 0$ for $n \geq 1$ and every flasque sheaf $\mathscr{G}$ (T, 2.4.1, Remark 3, and the corollary of Proposition 3.3.2). It follows that the $\mathrm{R}^p f_*$ form a universal cohomological functor from $\mathbf{C}(X)$ to $\mathbf{C}(Y)$ (T, 2.3).

(12.2.2) Let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_X$-modules. With the notation of (12.2.1), for every open subset V of Y there is the cup-product homomorphism (12.1.2.1)

$$\mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(f^{-1}(V),\mathscr{O}_X)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}) \longrightarrow \mathrm{H}^{p+q}\big(f^{-1}(V), \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}\big).$$

[0_{III} | 58] It follows immediately from the definition of the cup product (G, II, 6.6) that these homomorphisms commute with restriction from V to an open subspace V' of V. On the other hand, θ gives a ring homomorphism

$$\Gamma(V, \mathscr{O}_Y) \longrightarrow \Gamma(V, \psi_*(\mathscr{O}_X)) = \Gamma(f^{-1}(V), \mathscr{O}_X),$$

and hence a canonical homomorphism of tensor products

$$\mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(V,\mathscr{O}_Y)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}) \longrightarrow \mathrm{H}^p(f^{-1}(V), \mathscr{F}) \otimes_{\Gamma(f^{-1}(V),\mathscr{O}_X)} \mathrm{H}^q(f^{-1}(V), \mathscr{G}),$$

which is likewise compatible with restriction from V to V'. By composition, one thus obtains a homomorphism of $\Gamma(V, \mathscr{O}_Y)$-modules. For the sheaves associated with the presheaves in question, it defines a canonical homomorphism, functorial in $\mathscr{F}$ and $\mathscr{G}$,

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathrm{R}^q f_*(\mathscr{G}) \longrightarrow \mathrm{R}^{p+q} f_*(\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}). \tag{12.2.2.1}$$

For $p = q = 0$, this homomorphism reduces to (0_{I}, 4.2.2.1).

(12.2.3) Proposition. *For every $\mathscr{O}_X$-module $\mathscr{F}$ and every locally free $\mathscr{O}_Y$-module $\mathscr{L}$ of finite rank, there are canonical functorial isomorphisms*

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} \mathscr{L} \xrightarrow{\sim} \mathrm{R}^p f_*(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})). \tag{12.2.3.1}$$

Proof. The homomorphism (12.2.3.1) is obtained by composing the following particular case of (12.2.2.1),

$$\mathrm{R}^p f_*(\mathscr{F}) \otimes_{\mathscr{O}_Y} f_*(f^*(\mathscr{L})) \longrightarrow \mathrm{R}^p f_*(\mathscr{F} \otimes_{\mathscr{O}_X} f^*(\mathscr{L})), \tag{12.2.3.2}$$

with the homomorphism from the first member of (12.2.3.1) to that of (12.2.3.2) induced by the canonical homomorphism (0_{I}, 4.4.3.2). To verify that (12.2.3.1) is an isomorphism when $\mathscr{L}$ is locally free, one may immediately reduce to the case $\mathscr{L} = \mathscr{O}_Y$, since the question is local on Y and the functors in question are additive in $\mathscr{L}$. In that case, in view of the definition of (12.2.2.1), the proposition reduces to verifying that the corresponding homomorphism of presheaves is bijective; this follows immediately from $f^*(\mathscr{O}_Y) = \mathscr{O}_X$. □

(12.2.4) Let $(Z, \mathscr{O}_Z)$ be a third ringed space, and let $g : Y \to Z$ be a morphism of ringed spaces. We know (G, II, 7.1 and 3.1.1) that, for every injective $\mathscr{O}_X$-module $\mathscr{G}$, $f_*(\mathscr{G})$ is a flasque sheaf of abelian groups. Consequently, by (12.2.1),

$$\mathrm{R}^p g_*(f_*(\mathscr{G})) = 0 \qquad (p > 0).$$

It follows (T, 2.4.1) that the Leray spectral sequence for composite functors applies to the composite $g_* \circ f_*$. There is a biregular spectral sequence whose abutment is the functor $\mathrm{R}^\bullet h_*$, where $h = g \circ f$, and whose E_2-term is

$$E_2^{pq} = \mathrm{R}^p g_*(\mathrm{R}^q f_*(\mathscr{F})). \tag{12.2.4.1}$$

(12.2.5) Under the conditions of (12.2.4), we shall directly define canonical homomorphisms of $\mathscr{O}_Z$-modules

$$\mathrm{R}^n g_*(f_*(\mathscr{F})) \longrightarrow \mathrm{R}^n h_*(\mathscr{F}) \tag{12.2.5.1}$$

and

$$\mathrm{R}^n h_*(\mathscr{F}) \longrightarrow g_*(\mathrm{R}^n f_*(\mathscr{F})), \tag{12.2.5.2}$$

which may be identified with the "edge homomorphisms" of the Leray spectral sequence [0_{III} | 59] (cf. (12.1.7)). It is enough to work with the presheaves with which the higher direct image sheaves are associated (12.2.1). For this purpose, let W be any open subset of Z, and consider its inverse image $g^{-1}(W)$ in Y. There is a canonical di-homomorphism

$$\mathrm{H}^n(g^{-1}(W), f_*(\mathscr{F})) \longrightarrow \mathrm{H}^n(f^{-1}(g^{-1}(W)), f^*(f_*(\mathscr{F}))), \tag{12.2.5.3}$$

the corresponding rings being $\Gamma(g^{-1}(W), \mathscr{O}_Y)$ and $\Gamma(h^{-1}(W), \mathscr{O}_X)$. On the other hand, the canonical homomorphism (0_{I}, 4.4.3.3) gives, by functoriality, canonical homomorphisms

$$\mathrm{H}^n(h^{-1}(W), f^*(f_*(\mathscr{F}))) \longrightarrow \mathrm{H}^n(h^{-1}(W), \mathscr{F}), \tag{12.2.5.4}$$

which are homomorphisms of $\Gamma(h^{-1}(W), \mathscr{O}_X)$-modules. Taking into account the ring homomorphism

$$\Gamma(W, \mathscr{O}_Z) \longrightarrow \Gamma(g^{-1}(W), \mathscr{O}_Y),$$

we see that composing (12.2.5.3) with (12.2.5.4) gives a homomorphism of presheaves and hence the homomorphism of sheaves (12.2.5.1).

The definition of (12.2.5.2) is still simpler. By definition, $\mathrm{R}^n h_*(\mathscr{F})$ is associated with the presheaf

$$W \longmapsto \mathrm{H}^n(f^{-1}(g^{-1}(W)), \mathscr{F}),$$

while $\mathrm{R}^n f_*(\mathscr{F})$ is associated with the presheaf

$$V \longmapsto \mathrm{H}^n(f^{-1}(V), \mathscr{F}).$$

There is therefore a canonical homomorphism

$$\mathrm{H}^n(f^{-1}(g^{-1}(W)), \mathscr{F}) \longrightarrow \Gamma(g^{-1}(W), \mathrm{R}^n f_*(\mathscr{F})),$$

and it is immediate that these homomorphisms define a homomorphism of presheaves, which in turn defines (12.2.5.2).

(12.2.6) Under the hypotheses of (12.2.4), let $\mathscr{F}$, $\mathscr{G}$, and $\mathscr{K}$ be three $\mathscr{O}_X$-modules, and let

$$u : \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G} \longrightarrow \mathscr{K}$$

be an $\mathscr{O}_X$-homomorphism. Then the following diagrams are commutative:

$$\begin{array}{ccc} \mathrm{R}^p g_*(f_*(\mathscr{F})) \otimes_{\mathscr{O}_Z} \mathrm{R}^q g_*(f_*(\mathscr{G})) & \to & \mathrm{R}^{p+q} g_*(f_*(\mathscr{K})) \\ \downarrow & & \downarrow \\ \mathrm{R}^p h_*(\mathscr{F}) \otimes_{\mathscr{O}_Z} \mathrm{R}^q h_*(\mathscr{G}) & \longrightarrow & \mathrm{R}^{p+q} h_*(\mathscr{K}), \end{array} \tag{12.2.6.1}$$

and

$$\begin{array}{ccc} \mathrm{R}^p h_*(\mathscr{F}) \otimes_{\mathscr{O}_Z} \mathrm{R}^q h_*(\mathscr{G}) & \longrightarrow & \mathrm{R}^{p+q} h_*(\mathscr{K}) \\ \downarrow & & \downarrow \\ g_*(\mathrm{R}^p f_*(\mathscr{F})) \otimes_{\mathscr{O}_Z} g_*(\mathrm{R}^q f_*(\mathscr{G})) & \to & g_*(\mathrm{R}^{p+q} f_*(\mathscr{K})). \end{array} \tag{12.2.6.2}$$

[0_{III} | 60] Here the horizontal arrows come from (12.2.2.1) (the last one combined with (0_{I}, 4.2.2.1)), and the vertical arrows from (12.2.5.1) and (12.2.5.2), respectively.

Indeed, it is enough to verify the assertion for the corresponding homomorphisms of presheaves. Returning to the definitions in (12.2.2) and (12.2.5), one is immediately reduced, for (12.2.6.1), to the commutative diagrams (12.1.5.2); the verification is still simpler for (12.2.6.2).

12.3 Supplements on the Ext functors of sheaves

(12.3.1) Let $(X, \mathscr{O}_X)$ be a ringed space. We shall not recall the definition and principal properties of the bifunctors

$$\mathrm{Ext}^p_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G}), \qquad \mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G}),$$

the first taking values in the category of $\Gamma(X, \mathscr{O}_X)$-modules and the second in the category of $\mathscr{O}_X$-modules, nor the biregular spectral sequence $E(\mathscr{F}, \mathscr{G})$ relating them (T, 4.2 and G, II, 7.3).

(12.3.2) Just as in (M, XIV, 1), one defines the notion of an *extension* of an $\mathscr{O}_X$-module $\mathscr{F}$ by an $\mathscr{O}_X$-module $\mathscr{G}$ and the composition law on classes of equivalent extensions: the arguments used for modules plainly carry over to an arbitrary abelian category. The second proof of (M, XIV, 1.1), which uses only the existence of embeddings into injective objects, is therefore still valid in the category of $\mathscr{O}_X$-modules. It shows that

$$\mathrm{Ext}^1_{\mathscr{O}_X}(X; \mathscr{F}, \mathscr{G})$$

is canonically identified with the abelian group of classes of extensions of $\mathscr{F}$ by $\mathscr{G}$.

(12.3.3) Proposition. *Let $(X, \mathscr{O}_X)$ be a ringed space whose sheaf of rings $\mathscr{O}_X$ is coherent. Then, for every pair of coherent $\mathscr{O}_X$-modules $\mathscr{F}$ and $\mathscr{G}$ and every $p \geq 0$,*

$$\mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$$

is a coherent $\mathscr{O}_X$-module.

Proof. The $\mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$ form a contravariant cohomological functor in $\mathscr{F}$. Since $\mathscr{F}$ is coherent, for every p and every point $x \in X$ there are an open neighbourhood U of x in X and an exact sequence of $(\mathscr{O}_X|U)$-modules

$$0 \longrightarrow \mathscr{R} \longrightarrow \mathscr{L}_{p-1} \longrightarrow \cdots \longrightarrow \mathscr{L}_0 \longrightarrow \mathscr{F}|U \longrightarrow 0,$$

where each $\mathscr{L}_i$ $(0 \leq i \leq p-1)$ is isomorphic to $\mathscr{O}_X^{n_i}|U$, and $\mathscr{R}$ is coherent. This follows by induction on p from (0_{I}, 5.3.2) and (0_{I}, 5.3.4), since $\mathscr{O}_X$ is coherent.

For $p \geq 1$, moreover,

$$\mathscr{E}xt^p_{\mathscr{O}_X|U}(\mathscr{L}|U, \mathscr{G}|U) = 0$$

for every $\mathscr{O}_X$-module $\mathscr{L}$ for which $\mathscr{L}|U$ is isomorphic to $\mathscr{O}_X^n|U$ (T, 4.2.3). The argument of (M, V, 7.2) therefore applies to the contravariant cohomological functor

$$\mathscr{F} \longmapsto \mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{F}|U, \mathscr{G}|U)$$

and gives an exact sequence

$$\begin{aligned}\mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{L}_{p-1}, \mathscr{G}|U) &\longrightarrow \mathscr{H}om_{\mathscr{O}_X|U}(\mathscr{R}, \mathscr{G}|U)\\ &\longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X|U}(\mathscr{F}|U, \mathscr{G}|U) \longrightarrow 0.\end{aligned}$$

The first two terms are coherent $(\mathscr{O}_X|U)$-modules (0_{I}, 5.3.5); hence so is the third (0_{I}, 5.3.4). □

(12.3.4) Proposition. *Let $f : X \to Y$ be a flat morphism of ringed spaces, and let $\mathscr{F}$ and $\mathscr{G}$ be two $\mathscr{O}_Y$-modules.* [0_{III} | 61]

(i) *There is a homomorphism of cohomological bifunctors*

$$f^*(\mathscr{E}xt^\bullet_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})) \longrightarrow \mathscr{E}xt^\bullet_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G})), \tag{12.3.4.1}$$

which in degree 0 reduces to the canonical homomorphism (0_I, 4.4.6).

(ii) *There is a canonical morphism of spectral sequences*

$$E(\mathscr{F}, \mathscr{G}) \longrightarrow E(f^*(\mathscr{F}), f^*(\mathscr{G})), \tag{12.3.4.2}$$

whose map on E_2-terms is given by the homomorphisms

$$\mathrm{H}^p(Y, \mathscr{E}xt^q_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})) \longrightarrow \mathrm{H}^p(X, \mathscr{E}xt^q_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G}))), \tag{12.3.4.3}$$

deduced from (12.3.4.1) and (12.1.3.1).

Proof. (i) Since f^* is exact on the category of $\mathscr{O}_Y$-modules (0_{I}, 6.7.2), the functors

$$\mathscr{G} \longmapsto f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})), \qquad \mathscr{G} \longmapsto \mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{G}))$$

are left exact. The canonical homomorphism (0_{I}, 4.4.6) therefore canonically induces a homomorphism between their derived functors.

To compute these derived functors, take an injective resolution $\mathscr{L}^\bullet = (\mathscr{L}^i)$ of $\mathscr{G}$. One then has homomorphisms

$$\mathscr{H}^p(f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{L}^\bullet))) \longrightarrow \mathscr{H}^p(\mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}), f^*(\mathscr{L}^\bullet)))$$

between the cohomology sheaves of complexes. By the exactness of f^*, the first member is

$$f^*(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F}, \mathscr{G})).$$

The exactness of f^* also implies that $f^*(\mathscr{L}^\bullet)$ is a resolution of $f^*(\mathscr{G})$. If $\mathscr{L}'^\bullet = (\mathscr{L}'^i)$ is an injective resolution of $f^*(\mathscr{G})$ in the category of $\mathscr{O}_X$-modules, there is a homomorphism of complexes

$$f^*(\mathscr{L}^\bullet) \longrightarrow \mathscr{L}'^\bullet,$$

determined up to homotopy, and hence a well-defined homomorphism on cohomology. Its composite with the preceding homomorphism is (12.3.4.1).

(ii) With the preceding notation, there is a homomorphism of complexes of $\mathscr{O}_X$-modules

$$f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet)) \longrightarrow \mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}),\mathscr{L}'^\bullet).$$

Let $\mathscr{M}^{\bullet\bullet}$ be a Cartan–Eilenberg injective resolution of $\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet)$ in the category of $\mathscr{O}_Y$-modules. Since f^* is exact, $f^*(\mathscr{M}^{\bullet\bullet})$ is a Cartan–Eilenberg resolution of $f^*(\mathscr{H}om_{\mathscr{O}_Y}(\mathscr{F},\mathscr{L}^\bullet))$. If $\mathscr{M}'^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\mathscr{H}om_{\mathscr{O}_X}(f^*(\mathscr{F}),\mathscr{L}'^\bullet)$, there is (11.4.2) a homomorphism, determined up to homotopy,

$$f^*(\mathscr{M}^{\bullet\bullet}) \longrightarrow \mathscr{M}'^{\bullet\bullet},$$

compatible with the preceding homomorphism; in other words, there is an f-morphism $\mathscr{M}^{\bullet\bullet} \to \mathscr{M}'^{\bullet\bullet}$ of bicomplexes of sheaves. It induces a di-homomorphism

$$\Gamma(Y,\mathscr{M}^{\bullet\bullet}) \longrightarrow \Gamma(X,\mathscr{M}'^{\bullet\bullet})$$

of bicomplexes of modules, determined up to homotopy, and therefore a well-defined morphism of spectral sequences (11.3.2). This is precisely the desired morphism (12.3.4.2), and the description (12.3.4.3) follows immediately from the definitions. □

(12.3.5) Proposition. *Under the hypotheses of (12.3.4), suppose in addition that the sheaf of rings $\mathscr{O}_Y$ is coherent. Then, for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$, the canonical homomorphisms (12.3.4.1) are bijective.*

Proof. Since the question is local on Y, we may suppose that there is an exact sequence [0_{III} | 62]

$$0 \longrightarrow \mathscr{R} \longrightarrow \mathscr{O}_Y^n \longrightarrow \mathscr{F} \longrightarrow 0.$$

Then $\mathscr{R}$ is also a coherent $\mathscr{O}_Y$-module (0_{I}, 5.3.4). To prove that the homomorphisms

$$f^*(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})) \longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X}(f^*(\mathscr{F}),f^*(\mathscr{G}))$$

are bijective, we argue by induction on p. For $p=0$, the assertion is (0_{I}, 6.7.6.1). There is a commutative diagram with exact rows

$$\begin{array}{ccccccc}
f^*\left(\mathscr{E}xt^{p-1}_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G})\right) & \to & f^*\left(\mathscr{E}xt^{p-1}_{\mathscr{O}_Y}(\mathscr{R},\mathscr{G})\right) & \xrightarrow{\partial} & f^*\left(\mathscr{E}xt^{p}_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})\right) & \to & f^*\left(\mathscr{E}xt^{p}_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G})\right) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathscr{E}xt^{p-1}_{\mathscr{O}_X}(\mathscr{O}_X^n,f^*(\mathscr{G})) & \to & \mathscr{E}xt^{p-1}_{\mathscr{O}_X}(f^*(\mathscr{R}),f^*(\mathscr{G})) & \xrightarrow{\partial} & \mathscr{E}xt^{p}_{\mathscr{O}_X}(f^*(\mathscr{F}),f^*(\mathscr{G})) & \to & \mathscr{E}xt^{p}_{\mathscr{O}_X}(\mathscr{O}_X^n,f^*(\mathscr{G})).
\end{array}$$

Here we have used $f^*(\mathscr{O}_Y)=\mathscr{O}_X$; since f^* is exact, both rows are exact. Moreover,

$$\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{O}_Y^n,\mathscr{G})=0, \qquad \mathscr{E}xt^p_{\mathscr{O}_X}(\mathscr{O}_X^n,f^*(\mathscr{G}))=0 \qquad (p>0)$$

(T, 4.2.3). By the induction hypothesis, the first two vertical arrows in the preceding diagram are isomorphisms, while the right-hand terms are zero. It follows that

$$f^*(\mathscr{E}xt^p_{\mathscr{O}_Y}(\mathscr{F},\mathscr{G})) \longrightarrow \mathscr{E}xt^p_{\mathscr{O}_X}(f^*(\mathscr{F}),f^*(\mathscr{G}))$$

is an isomorphism. □

12.4 Hypercohomology of the direct image functor

(12.4.1) Let $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ be two ringed spaces, and let $f : X \longrightarrow Y$ be a morphism of ringed spaces. One can form the hypercohomology of f_* with respect to an arbitrary complex of $\mathscr{O}_X$-modules $\mathscr{K}^\bullet = (\mathscr{K}^i)_{i\in\mathbf{Z}}$ (11.4.4), since filtered inductive limits exist and are exact in the abelian category of $\mathscr{O}_Y$-modules (T, 3.1.1). The $\mathscr{O}_Y$-modules of hypercohomology $\mathrm{R}^p f_*(\mathscr{K}^\bullet)$ will also be denoted $\mathscr{H}^p(f, \mathscr{K}^\bullet)$, or simply $\mathscr{H}^p_f(\mathscr{K}^\bullet)$. Recall that $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$ is the cohomology of the bicomplex of $\mathscr{O}_Y$-modules $f_*(\mathscr{L}^{\bullet\bullet})$, where $\mathscr{L}^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet$ in the category of $\mathscr{O}_X$-modules. It is the abutment of two spectral sequences whose E_2-terms are given by

$$'E_2^{pq} = \mathscr{H}^p\big(\mathscr{H}^q(f, \mathscr{K}^\bullet)\big) \tag{12.4.1.1}$$

and

$$''E_2^{pq} = \mathscr{H}^p\big(f, \mathscr{H}^q(\mathscr{K}^\bullet)\big) \quad (= \mathrm{R}^p f_*(\mathscr{H}^q(\mathscr{K}^\bullet))). \tag{12.4.1.2}$$

In these formulas we have adopted the general notation $T(A^\bullet)$ for the transform of a complex by a functor (11.2.1), and, for an $\mathscr{O}_X$-module $\mathscr{F}$, we write $\mathscr{H}^p(f, \mathscr{F})$ in place of $\mathrm{R}^p f_*(\mathscr{F})$. Recall also that the first spectral sequence is always regular. Both spectral sequences are biregular when $\mathscr{K}^\bullet$ is bounded below, or when there is an integer m such that every $\mathscr{O}_X$-module admits a flasque resolution of length $\leq m$ (11.4.4). [0_{III} | 63]

(12.4.2) We shall similarly denote by $\mathbf{H}^\bullet(X, \mathscr{K}^\bullet)$ the hypercohomology of the functor Γ with respect to a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules. Thus the $\mathbf{H}^p(X, \mathscr{K}^\bullet)$ are $\Gamma(X, \mathscr{O}_X)$-modules. Moreover, $\mathbf{H}^\bullet(X, \mathscr{K}^\bullet)$ may be regarded as a special case of $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$, where f is a morphism from $(X, \mathscr{O}_X)$ to a ringed space consisting of one point equipped with the ring $\Gamma(X, \mathscr{O}_X)$.

For every open subset V of X, we shall write $\mathbf{H}^\bullet(V, \mathscr{K}^\bullet)$ in place of $\mathbf{H}^\bullet(V, \mathscr{K}^\bullet|V)$.

(12.4.3) Proposition. *For every integer $p \in \mathbf{Z}$, the $\mathscr{O}_Y$-module $\mathscr{H}^p(f, \mathscr{K}^\bullet)$ is canonically isomorphic to the sheaf associated with the presheaf*

$$U \longmapsto \mathbf{H}^p\big(f^{-1}(U), \mathscr{K}^\bullet\big)$$

on Y.

Proof. With the notation of (12.4.1), the cohomology sheaf $\mathscr{H}^p(f_*(\mathscr{L}^{\bullet\bullet}))$ is associated with the presheaf

$$U \longmapsto \mathrm{H}^p\big(\Gamma(U, f_*(\mathscr{L}^{\bullet\bullet}))\big) = \mathrm{H}^p\big(\Gamma(f^{-1}(U), \mathscr{L}^{\bullet\bullet})\big).$$

But it is clear that $\mathscr{L}^{\bullet\bullet}|f^{-1}(U)$ is a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet|f^{-1}(U)$ (T, 3.1.3). Consequently,

$$\mathrm{H}^p\big(\Gamma(f^{-1}(U), \mathscr{L}^{\bullet\bullet})\big) = \mathbf{H}^p\big(f^{-1}(U), \mathscr{K}^\bullet\big)$$

by definition. □

(12.4.4) Proposition. *The hypercohomology $\mathscr{H}^\bullet(f, \mathscr{K}^\bullet)$ is a cohomological functor of $\mathscr{K}^\bullet$ in each of the following cases:*

a) *$\mathscr{K}^\bullet$ varies in the category of bounded below complexes;*

b) *there is an integer m such that every $\mathscr{O}_X$-module admits a flasque resolution of length $\leq m$;*

c) *X is a Noetherian space.*

Proof. Cases a) and b) are special cases of (11.5.4). Case c), on the other hand, follows from (11.5.2), since in this case the functor f_* commutes with inductive limits (G, II, 3.10.1). □

(12.4.5) Let $\mathfrak{U} = (U_\alpha)$ now be an open covering of X. For every complex of *presheaves* $\mathscr{K}^\bullet = (\mathscr{K}^j)$ on X, consider the bicomplex $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ whose component of bidegree (i, j) is $\check{\mathrm{C}}^i(\mathfrak{U}, \mathscr{K}^j)$, the group of alternating i-cochains of the nerve of $\mathfrak{U}$ with values in $\mathscr{K}^j$ (G, II, 5.1). We call the cohomology of this bicomplex the *hypercohomology of the covering $\mathfrak{U}$ with coefficients in $\mathscr{K}^\bullet$*, and denote it by

$$\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet) = \mathrm{H}^\bullet\big(\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)\big).$$

The Leray spectral sequence of a covering (T, 3.8.1 and G, II, 5.9.1) generalizes to hypercohomology as follows.

(12.4.6) Proposition. *Let $\mathscr{K}^\bullet = (\mathscr{K}^i)$ be a complex of $\mathscr{O}_X$-modules. There is a regular spectral functor of $\mathscr{K}^\bullet$ with abutment $\mathbf{H}^\bullet(X, \mathscr{K}^\bullet)$ and E_2-term*

$$E_2^{pq} = \check{\mathrm{H}}^p(\mathfrak{U}, h^q(\mathscr{K}^\bullet)), \tag{12.4.6.1}$$

where $h^q(\mathscr{K}^\bullet)$ denotes the presheaf complex

$$V \longmapsto \mathrm{H}^q(V, \mathscr{K}^\bullet)$$

on X. This spectral sequence is biregular if $\mathscr{K}^\bullet$ is bounded below.

Proof. Let $\mathscr{L}^{\bullet\bullet}$ be a Cartan–Eilenberg injective resolution of $\mathscr{K}^\bullet$, and consider the tricomplex

$$\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet}) = \big(\check{\mathrm{C}}^i(\mathfrak{U}, \mathscr{L}^{jk})\big).$$

First regard this tricomplex as a bicomplex in the degrees i and $j + k$. Since i takes only nonnegative values, the second spectral sequence of this bicomplex is regular (11.3.3) and degenerate, because

$$\check{\mathrm{H}}^q(\mathfrak{U}, \mathscr{L}^{jk}) = 0 \qquad (q > 0),$$

[0_{III} | 64] the $\mathscr{O}_X$-modules $\mathscr{L}^{jk}$ being flasque sheaves (G, II, 5.2.3). It follows that there is a canonical isomorphism

$$\mathrm{H}^n\big(\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})\big) \xrightarrow{\sim} \mathrm{H}^n\big(\Gamma(X, \mathscr{L}^{\bullet\bullet})\big)$$

(11.1.6), by virtue of (G, II, 5.2.2), and therefore, by definition (12.4.2), an isomorphism

$$\mathrm{H}^n\big(\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})\big) \xrightarrow{\sim} \mathbf{H}^n(X, \mathscr{K}^\bullet).$$

Now regard $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{L}^{\bullet\bullet})$ as a bicomplex in the degrees $i + j$ and k. Since k takes only nonnegative values, the first spectral sequence of this bicomplex is always regular. It is biregular if $\mathscr{L}^{jk} = 0$ for $j < j_0$, that is, when $\mathscr{K}^\bullet$ is bounded below (11.3.3). This is the desired spectral sequence. Indeed, for every j, $\mathscr{L}^{j,\bullet}$ is an injective resolution of $\mathscr{K}^j$; consequently, as i varies,

$$\mathrm{H}^q\big(\check{\mathrm{C}}^i(\mathfrak{U}, \mathscr{L}^{j,\bullet})\big)$$

is precisely the cochain complex $\check{\mathrm{C}}^i(\mathfrak{U}, h^q(\mathscr{K}^j))$. This proves the proposition. □

(12.4.7) Corollary. *If, for every simplex σ of the nerve of $\mathfrak{U}$ and every integer i, one has*

$$\mathrm{H}^q(U_\sigma, \mathscr{K}^i) = 0 \qquad (q > 0),$$

then there is a canonical isomorphism

$$\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet) \xrightarrow{\sim} \mathbf{H}^\bullet(X, \mathscr{K}^\bullet). \tag{12.4.7.1}$$

Proof. The hypothesis implies that $\check{\mathrm{C}}^\bullet(\mathfrak{U}, h^q(\mathscr{K}^j)) = 0$ for $q > 0$, and hence that $E_2^{pq} = 0$ for $q > 0$. Since the spectral sequence (12.4.6.1) is degenerate and regular, the conclusion follows from the definition (12.4.5) of $\mathbf{H}^\bullet(\mathfrak{U}, \mathscr{K}^\bullet)$ and from (11.1.6). □

(12.4.8) Let $(X', \mathscr{O}_{X'})$ be a second ringed space, and let $f = (\psi, \theta)$ be a morphism from X' to X. By the same method as in (12.1.3) and (12.1.4), one defines a di-homomorphism for the hypercohomology of a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules:

$$\mathbf{H}^p(X, \mathscr{K}^\bullet) \longrightarrow \mathbf{H}^p(X', f^*(\mathscr{K}^\bullet)). \tag{12.4.8.1}$$

Starting with a Cartan–Eilenberg injective resolution $\mathscr{L}^{\bullet\bullet}$ of $\mathscr{K}^\bullet$, observe that, since ψ^* is exact, $\psi^*(\mathscr{L}^{\bullet\bullet})$ is a Cartan–Eilenberg resolution of $\psi^*(\mathscr{K}^\bullet)$ in the category of $\psi^*(\mathscr{O}_X)$-modules. There is therefore a morphism

$$\psi^*(\mathscr{L}^{\bullet\bullet}) \longrightarrow \mathscr{L}'^{\bullet\bullet},$$

where $\mathscr{L}'^{\bullet\bullet}$ is a Cartan–Eilenberg injective resolution of $\psi^*(\mathscr{K}^\bullet)$. It induces a morphism in cohomology

$$\mathbf{H}^\bullet(X, \mathscr{K}^\bullet) \longrightarrow \mathbf{H}^\bullet(X', \psi^*(\mathscr{K}^\bullet)).$$

Composing it with the morphism induced by functoriality from $\psi^*(\mathscr{K}^\bullet) \longrightarrow f^*(\mathscr{K}^\bullet)$ gives the desired morphism (12.4.8.1).

Starting with (12.4.8.1) and (12.4.3), and arguing as in (12.2.5), one can then define, for two morphisms of ringed spaces

$$f : X \longrightarrow Y, \qquad g : Y \longrightarrow Z,$$

with $h = g \circ f$, homomorphisms for the hypercohomology of a complex $\mathscr{K}^\bullet$ of $\mathscr{O}_X$-modules:

$$\mathscr{H}^n(g, f_*(\mathscr{K}^\bullet)) \longrightarrow \mathscr{H}^n(h, \mathscr{K}^\bullet), \tag{12.4.8.2}$$

and

$$\mathscr{H}^n(h, \mathscr{K}^\bullet) \longrightarrow g_*(\mathscr{H}^n(f, \mathscr{K}^\bullet)). \tag{12.4.8.3}$$

We leave the details of the definitions to the reader.

§13 Projective limits in homological algebra

13.1 The Mittag-Leffler condition

(13.1.1) Let $\mathbf{C}$ be an abelian category in which infinite products exist (axiom AB 3* of T, 1.5). Then the infimum of a family of subobjects of an object of $\mathbf{C}$ exists, and every projective system of objects of $\mathbf{C}$ has a projective limit; the latter is a left exact functor

[0_{III} | 65] of the projective system in question (T, 1.8). Let $(A_\alpha, f_{\alpha\beta})$ be a projective system of objects of **C** whose index set I is filtered to the right. Put

$$A = \varprojlim A_\alpha,$$

and, for each $\alpha \in \mathrm{I}$, let $f_\alpha : A \longrightarrow A_\alpha$ be the canonical morphism. For every $\alpha \in \mathrm{I}$, the subobjects $f_{\alpha\beta}(A_\beta)$, for $\alpha \leq \beta$, form a decreasing filtered family of subobjects of A_α. The subobject

$$A'_\alpha = \inf_{\beta \geq \alpha} f_{\alpha\beta}(A_\beta)$$

is called the subobject of *universal images* in A_α. It is clear that

$$f_\alpha(A) \subset A'_\alpha, \qquad f_{\alpha\beta}(A'_\beta) \subset A'_\alpha \quad (\alpha \leq \beta).$$

Thus $(A'_\alpha, f_{\alpha\beta}|A'_\beta)$ is a projective system and

$$A = \varprojlim A'_\alpha.$$

(13.1.2) For a projective system $(A_\alpha, f_{\alpha\beta})$ in **C**, the following is called the *Mittag-Leffler condition*:

(ML) *For every index α, there is a $\beta \geq \alpha$ such that, for every $\gamma \geq \beta$,*

$$f_{\alpha\gamma}(A_\gamma) = f_{\alpha\beta}(A_\beta).$$

It is clear that condition (ML) holds if all the $f_{\alpha\beta}$ are epimorphisms. Conversely, suppose that (ML) holds, and for each $\alpha \in \mathrm{I}$ let A'_α be the subobject of universal images in A_α. Then, for $\alpha \leq \beta$, the restriction of $f_{\alpha\beta}$ to A'_β is an *epimorphism*

$$A'_\beta \longrightarrow A'_\alpha.$$

Indeed, choose $\gamma \geq \beta$ such that

$$f_{\beta\delta}(A_\delta) = f_{\beta\gamma}(A_\gamma) \qquad (\delta \geq \gamma).$$

Then $A'_\beta = f_{\beta\gamma}(A_\gamma)$, and therefore

$$f_{\alpha\beta}(A'_\beta) = f_{\alpha\gamma}(A_\gamma), \qquad A'_\alpha = f_{\alpha\gamma}(A_\gamma) = f_{\alpha\beta}(A'_\beta).$$

Condition (ML) also holds when the objects A_α are *Artinian* in **C**, that is, when every family of subobjects of A_α has a minimal member. Indeed, a minimal member of the decreasing filtered family $\big(f_{\alpha\beta}(A_\beta)\big)$ of subobjects of A_α is necessarily the smallest of those subobjects.

(13.1.3) *Remark* (13.1.3). Condition (ML) can also be formulated when **C** is, for example, the category of sets. One can again define the subset of universal images in A_α, and the observations made in (13.1.1) and (13.1.2) remain valid.

13.2 The Mittag-Leffler condition for abelian groups

(13.2.1) Proposition. *Let*

$$0 \longrightarrow A_\alpha \xrightarrow{u_\alpha} B_\alpha \xrightarrow{v_\alpha} C_\alpha \longrightarrow 0$$

be an exact sequence of projective systems of abelian groups, relative to the same filtered index set I.

(i) *If* (B_α) *satisfies* (ML)*, then so does* (C_α).

(ii) *If* (A_α) *and* (C_α) *satisfy* (ML)*, then so does* (B_α).

Proof. Let $(f_{\alpha\beta})$, $(g_{\alpha\beta})$, and $(h_{\alpha\beta})$ be the systems of homomorphisms defining (A_α), (B_α), and (C_α), respectively.

(i) Suppose that

$$g_{\alpha\beta}(B_\beta) = g_{\alpha\lambda}(B_\lambda) \qquad (\lambda \geq \beta).$$

Since v_β and v_λ are surjective,

$$h_{\alpha\beta}(C_\beta) = v_\alpha(g_{\alpha\beta}(B_\beta)) = v_\alpha(g_{\alpha\lambda}(B_\lambda)) = h_{\alpha\lambda}(C_\lambda)$$

for $\lambda \geq \beta$.

(ii) Let $\alpha \in \mathrm{I}$. Choose $\beta \geq \alpha$ such that

$$f_{\alpha\beta}(A_\beta) = f_{\alpha\lambda}(A_\lambda) \qquad (\lambda \geq \beta),$$

and then choose $\gamma \geq \beta$ such that

$$h_{\beta\gamma}(C_\gamma) = h_{\beta\lambda}(C_\lambda) \qquad (\lambda \geq \gamma).$$

Let $y_\alpha \in g_{\alpha\gamma}(B_\gamma)$, write $y_\alpha = g_{\alpha\gamma}(y_\gamma)$ with $y_\gamma \in B_\gamma$, and put $y_\beta = g_{\beta\gamma}(y_\gamma)$. Then

$$v_\beta(y_\beta) = h_{\beta\gamma}(v_\gamma(y_\gamma)).$$

For every $\lambda \geq \gamma$, there is, by hypothesis, a $y_\lambda \in B_\lambda$ such that

$$h_{\beta\gamma}(v_\gamma(y_\gamma)) = h_{\beta\lambda}(v_\lambda(y_\lambda)).$$

Hence $v_\beta(y_\beta - g_{\beta\lambda}(y_\lambda)) = 0$, and therefore there is an $x_\beta \in A_\beta$ such that [0_{III} | 66]

$$y_\beta = g_{\beta\lambda}(y_\lambda) + u_\beta(x_\beta).$$

It follows that

$$y_\alpha = g_{\alpha\lambda}(y_\lambda) + u_\alpha(f_{\alpha\beta}(x_\beta)).$$

Since $\lambda \geq \beta$, there is an $x_\lambda \in A_\lambda$ such that

$$f_{\alpha\beta}(x_\beta) = f_{\alpha\lambda}(x_\lambda).$$

Consequently,

$$y_\alpha = g_{\alpha\lambda}(y_\lambda + u_\lambda(x_\lambda)) \in g_{\alpha\lambda}(B_\lambda),$$

which proves the assertion. □

(13.2.2) Proposition. *Let* I *be a filtered ordered set having a countable cofinal subset, and let*

$$0 \longrightarrow A_\alpha \xrightarrow{u_\alpha} B_\alpha \xrightarrow{v_\alpha} C_\alpha \longrightarrow 0$$

be an exact sequence of projective systems of abelian groups indexed by I. *If* (A_α) *satisfies* (ML), *then the sequence*

$$0 \longrightarrow \varprojlim A_\alpha \longrightarrow \varprojlim B_\alpha \longrightarrow \varprojlim C_\alpha \longrightarrow 0$$

is exact.

Proof. It remains only to prove that the homomorphism

$$v = \varprojlim v_\alpha : \varprojlim B_\alpha \longrightarrow \varprojlim C_\alpha$$

is surjective. Let $z = (z_\alpha) \in \varprojlim C_\alpha$, and put

$$E_\alpha = v_\alpha^{-1}(z_\alpha).$$

The E_α plainly form a projective system of nonempty sets under the restrictions of the homomorphisms $g_{\alpha\beta} : B_\beta \longrightarrow B_\alpha$.

We show that this projective system satisfies (ML). Identifying A_α with a subgroup of B_α by means of u_α, choose, for every $\alpha \in \mathrm{I}$, an index $\beta \geq \alpha$ such that

$$g_{\alpha\beta}(A_\beta) = g_{\alpha\lambda}(A_\lambda) \qquad (\lambda \geq \beta).$$

We claim that also

$$g_{\alpha\beta}(E_\beta) = g_{\alpha\lambda}(E_\lambda) \qquad (\lambda \geq \beta).$$

Indeed, take $y_\lambda \in E_\lambda$ and set

$$y_\beta = g_{\beta\lambda}(y_\lambda), \qquad y_\alpha = g_{\alpha\lambda}(y_\lambda).$$

Let $y'_\alpha = g_{\alpha\beta}(y'_\beta)$ for some $y'_\beta \in E_\beta$. Then $y'_\beta - y_\beta = x_\beta \in A_\beta$, and by hypothesis there is an $x_\lambda \in A_\lambda$ such that

$$g_{\alpha\beta}(x_\beta) = g_{\alpha\lambda}(x_\lambda).$$

Thus

$$y'_\alpha = g_{\alpha\beta}(y_\beta) + g_{\alpha\beta}(x_\beta) = g_{\alpha\lambda}(y_\lambda + x_\lambda) \in g_{\alpha\lambda}(E_\lambda),$$

which proves the claim.

It is known (Bourbaki, *Top. gén.*, chap. II, §3, th. 1) that, under the hypotheses imposed on I, a projective system of nonempty sets satisfying (ML) has a nonempty projective limit. There is therefore a point $y = (y_\alpha) \in \varprojlim E_\alpha$. Since $v_\alpha(y_\alpha) = z_\alpha$ for every α, one has $z = v(y)$. □

(13.2.3) Proposition. *Under the hypotheses on* I *of (13.2.2), let* $(\mathrm{K}_\alpha^\bullet)_{\alpha\in\mathrm{I}}$ *be a projective system of complexes of abelian groups*

$$\mathrm{K}_\alpha^\bullet = (\mathrm{K}_\alpha^n)_{n\in\mathbf{Z}},$$

whose differentials have degree $+1$. *For every* n, *there is a canonical functorial homomorphism*

$$h_n : \mathrm{H}^n(\varprojlim \mathrm{K}_\alpha^\bullet) \longrightarrow \varprojlim \mathrm{H}^n(\mathrm{K}_\alpha^\bullet). \tag{13.2.3.1}$$

If, for every degree n, *the projective system of abelian groups* $(\mathrm{K}_\alpha^n)_{\alpha\in\mathrm{I}}$ *satisfies* (ML), *then every* h_n *is surjective. If, in addition, the projective system* $(\mathrm{H}^{n-1}(\mathrm{K}_\alpha^\bullet))_{\alpha\in\mathrm{I}}$ *satisfies* (ML), *then* h_n *is bijective.*

Proof. Put

$$\mathrm{K}^n = \varprojlim \mathrm{K}_\alpha^n \qquad (n \in \mathbf{Z}).$$

The homomorphisms h_n are defined by the commutative diagrams

$$\begin{array}{ccccccccc} \cdots & \longrightarrow & \mathrm{K}^{n-1} & \longrightarrow & \mathrm{K}^n & \longrightarrow & \mathrm{K}^{n+1} & \longrightarrow & \cdots \\ & & \downarrow & & \downarrow & & \downarrow & & \\ \cdots & \longrightarrow & \mathrm{K}_\alpha^{n-1} & \longrightarrow & \mathrm{K}_\alpha^n & \longrightarrow & \mathrm{K}_\alpha^{n+1} & \longrightarrow & \cdots, \end{array}$$

the differentials in $\mathrm{K}^\bullet$ being the projective limits of the corresponding differentials in the $\mathrm{K}_\alpha^\bullet$. Consider the exact sequences [$0_{\mathrm{III}}\,|\,67$]

$$(*_n) \qquad 0 \longrightarrow \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow \mathrm{Z}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow \mathrm{H}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow 0$$

and

$$(**_n) \qquad 0 \longrightarrow \mathrm{Z}^{n-1}(\mathrm{K}_\alpha^\bullet) \longrightarrow \mathrm{K}_\alpha^{n-1} \longrightarrow \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow 0.$$

The hypothesis and Proposition (13.2.1) (i) show that the projective system $(\mathrm{B}^n(\mathrm{K}_\alpha^\bullet))_{\alpha\in\mathrm{I}}$ satisfies (ML) for every n. It follows from (13.2.2) that

$$(***_n) \qquad 0 \longrightarrow \varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow \varprojlim_\alpha \mathrm{Z}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow \varprojlim_\alpha \mathrm{H}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow 0$$

is exact. Now $\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet)$ identifies with a subgroup of K^n containing $\mathrm{B}^n(\mathrm{K}^\bullet)$, while $\varprojlim_\alpha \mathrm{Z}^n(\mathrm{K}_\alpha^\bullet)$ identifies with a subgroup of $\mathrm{Z}^n(\mathrm{K}^\bullet)$. Consequently, h_n is surjective.

Suppose now, in addition, that $(\mathrm{H}^{n-1}(\mathrm{K}_\alpha^\bullet))_{\alpha\in\mathrm{I}}$ satisfies (ML). The exact sequences $(*_{n-1})$ and Proposition (13.2.1) (ii) show that $(\mathrm{Z}^{n-1}(\mathrm{K}_\alpha^\bullet))_{\alpha\in\mathrm{I}}$ satisfies (ML). Applying (13.2.2) to the exact sequences $(**_n)$ gives an exact sequence

$$0 \longrightarrow \varprojlim_\alpha \mathrm{Z}^{n-1}(\mathrm{K}_\alpha^\bullet) \longrightarrow \mathrm{K}^{n-1} \xrightarrow{u} \varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow 0.$$

Since $\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \supset \mathrm{B}^n(\mathrm{K}^\bullet)$ and the composite of u with the injection

$$\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) \longrightarrow \mathrm{K}^n$$

is the differential $\mathrm{K}^{n-1} \longrightarrow \mathrm{K}^n$, the surjectivity of u implies

$$\varprojlim_\alpha \mathrm{B}^n(\mathrm{K}_\alpha^\bullet) = \mathrm{B}^n(\mathrm{K}^\bullet).$$

Thus h_n is injective. □

(13.2.4) *Remarks* (13.2.4).

(i) The argument of (13.2.2) (cf. Bourbaki, *loc. cit.*) shows that the conclusion of that proposition remains valid if one assumes only that the A_α can be equipped with structures of complete metrizable spaces in which translations are homeomorphisms, that the maps $f_{\alpha\beta} : A_\beta \longrightarrow A_\alpha$ defining the projective system are uniformly continuous for the metrics in question, and that (A_α) satisfies the condition

(ML') *For every index α, there is a $\beta \geq \alpha$ such that, for every $\gamma \geq \beta$, $f_{\alpha\gamma}(A_\gamma)$ is dense in $f_{\alpha\beta}(A_\beta)$.*

This gives an analogous supplement to (13.2.3). Suppose that $\mathrm{K}_\alpha^n = 0$ for $n < 0$ and every α; that $(\mathrm{K}_\alpha^n)_{\alpha\in\mathrm{I}}$ satisfies (ML) for $n \geq 0$; and that $A_\alpha = \mathrm{H}^0(\mathrm{K}_\alpha^\bullet)$ can be equipped with metric-space structures having the properties just stated. Then the conclusions of (13.2.3) are unchanged for $n \geq 2$, and h_1 is moreover *bijective*. Indeed, the argument of (13.2.2) also shows that $(\mathrm{B}^1(\mathrm{K}_\alpha^\bullet))_{\alpha\in\mathrm{I}}$ satisfies (ML), that the sequence $(***_1)$ is exact, and finally that

$$\varprojlim_\alpha \mathrm{B}^1(\mathrm{K}_\alpha^\bullet) = \mathrm{B}^1(\mathrm{K}^\bullet).$$

This proves, among other things, the assertions of (T, 3.10.2).

(ii) One can introduce the right derived functors $\varprojlim^{(n)}$ of the functor $\varprojlim$, and obtain more complete statements than those above [28].

13.3 Application: cohomology of a projective limit of sheaves

[0_{III} / 68] **(13.3.1) Proposition.** *Let X be a topological space, let $(\mathscr{F}_k)_{k\in\mathbf{N}}$ be a projective system of sheaves of abelian groups on X, and put $\mathscr{F} = \varprojlim_k \mathscr{F}_k$. Suppose that the following conditions hold:*

(i) *There is a basis $\mathfrak{B}$ for the topology of X such that, for every $U \in \mathfrak{B}$ and every $i \geq 0$, the projective system $(\mathrm{H}^i(U, \mathscr{F}_k))_{k\in\mathbf{N}}$ satisfies (ML).*

(ii) *For every $x \in X$ and every $i > 0$, one has*

$$\varinjlim_U (\varprojlim_k \mathrm{H}^i(U, \mathscr{F}_k)) = 0,$$

where U ranges over the neighbourhoods of x belonging to $\mathfrak{B}$.

(iii) *The homomorphisms $u_{hk} : \mathscr{F}_k \longrightarrow \mathscr{F}_h$ $(h \leq k)$ defining the projective system $(\mathscr{F}_k)$ are surjective.*

Under these conditions, for every $i > 0$, the canonical homomorphism

$$h_i : \mathrm{H}^i(X, \mathscr{F}) \longrightarrow \varprojlim_k \mathrm{H}^i(X, \mathscr{F}_k)$$

is surjective. If, moreover, for a given value of i the projective system $(\mathrm{H}^{i-1}(X, \mathscr{F}_k))_{k\in\mathbf{N}}$ satisfies (ML), then h_i is bijective.

Proof. a) We first suppose that the $\mathscr{F}_k$, as well as the kernels $\mathscr{N}_{hk}$ of the u_{hk}, are flasque; we shall then show that condition (iii) in the statement implies $\mathrm{H}^i(X, \mathscr{F}) = 0$ for $i > 0$. It suffices to prove that, for every open subset U of X and every covering $\mathfrak{U}$ of U by open subsets of U, one has

$$\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}) = 0 \qquad (i > 0).$$

Indeed, it then follows first that, for Čech cohomology, $\check{\mathrm{H}}^i(U, \mathscr{F}) = 0$ for every $i > 0$, and hence, by (G, II, 5.9.2) applied to the set of all open subsets of X, that $\mathrm{H}^i(X, \mathscr{F}) = 0$ for every $i > 0$.

Since the $\mathscr{F}_k$ are flasque, one has $\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k) = 0$ for every $i > 0$ (G, II, 5.2.3). For each k, consider the complex $\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k)$ of alternating cochains on the nerve of the covering

$\mathfrak{U}$ (G, II, 5.1); these complexes plainly form a projective system of complexes of abelian groups. Let us show that all the maps

$$\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k) \longrightarrow \check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_h) \qquad (h \leq k)$$

are surjective. By definition, it is enough to show that, for every open subset V of X, the map $\Gamma(V, \mathscr{F}_k) \longrightarrow \Gamma(V, \mathscr{F}_h)$ is surjective. But the sequence

$$0 \longrightarrow \mathscr{N}_{hk} \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{F}_h \longrightarrow 0$$

is exact by hypothesis and therefore gives the exact cohomology sequence

$$\Gamma(V, \mathscr{F}_k) \longrightarrow \Gamma(V, \mathscr{F}_h) \longrightarrow \mathrm{H}^1(V, \mathscr{N}_{hk}) = 0,$$

since $\mathscr{N}_{hk}$ is flasque.

The projective system $(\check{\mathrm{C}}^\bullet(\mathfrak{U}, \mathscr{F}_k))_{k\in\mathbf{N}}$ therefore satisfies (ML), and the same is true of $(\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k))_{k\in\mathbf{N}}$ for every $i \geq 0$: for $i > 0$ this is trivial, while for $i = 0$ it follows from what precedes, since $\check{\mathrm{H}}^0(\mathfrak{U}, \mathscr{F}_k) = \Gamma(U, \mathscr{F}_k)$ (G, II, 5.2.2). We may therefore apply (13.2.3), which gives

$$\check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}) = \varprojlim_k \check{\mathrm{H}}^i(\mathfrak{U}, \mathscr{F}_k) = 0 \qquad (i > 0).$$

b) We now pass to the general case. For each $k \in \mathbf{N}$, consider the *canonical resolution*

$$\mathscr{C}^\bullet(X, \mathscr{F}_k) = \big(\mathscr{C}^i(X, \mathscr{F}_k)\big)_{i\geq 0}$$

of $\mathscr{F}_k$ by flasque sheaves (G, II, 4.3). For every $i \geq 0$, it is clear that $(\mathscr{C}^i(X, \mathscr{F}_k))_{k\in\mathbf{N}}$ is a projective system of flasque sheaves; let us show that it satisfies the conditions of part *a)*. Indeed, if $\mathscr{N}_{hk}$ denotes the kernel of u_{hk} for $h \leq k$, then the sequence [0_{III} | 69]

$$0 \longrightarrow \mathscr{N}_{hk} \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{F}_h \longrightarrow 0$$

is exact by (iii), and our assertion follows from the exactness of the functor $\mathscr{A} \longmapsto \mathscr{C}^i(X, \mathscr{A})$ (G, II, 4.3).

Put

$$\mathscr{G}^i = \varprojlim_k \mathscr{C}^i(X, \mathscr{F}_k).$$

By part *a)*, one has $\mathrm{H}^j(X, \mathscr{G}^i) = 0$ for $j > 0$ and $i \geq 0$. We shall show that $\mathscr{G}^\bullet = (\mathscr{G}^i)_{i\geq 0}$ is a resolution of the sheaf $\mathscr{F}$. Since $\mathrm{H}^j(X, \mathscr{G}^i) = 0$ for $j > 0$, the cohomology $\mathrm{H}^\bullet(X, \mathscr{F})$ will then be equal to $\mathrm{H}^\bullet(\Gamma(X, \mathscr{G}^\bullet))$ (G, II, 4.7.1).

Taking the projective limit of the exact sequences

$$0 \longrightarrow \mathscr{F}_k \longrightarrow \mathscr{C}^0(X, \mathscr{F}_k) \longrightarrow \mathscr{C}^1(X, \mathscr{F}_k) \longrightarrow \cdots$$

plainly gives a complex of sheaves of abelian groups

$$0 \longrightarrow \mathscr{F} \longrightarrow \mathscr{G}^0 \longrightarrow \mathscr{G}^1 \longrightarrow \cdots .$$

To prove our assertion, it remains to establish that $\mathscr{H}^i(\mathscr{G}^\bullet) = 0$ for $i > 0$. This sheaf is generated by the presheaf

$$U \longmapsto \mathrm{H}^i\big(\Gamma(U, \mathscr{G}^\bullet)\big)$$

(G, II, 4.1). Now the complex $\Gamma(U, \mathscr{G}^\bullet)$ is the projective limit of the projective system of complexes of abelian groups

$$\big(\Gamma(U, \mathscr{C}^\bullet(X, \mathscr{F}_k))\big)_{k\in\mathbf{N}}$$

(0_{I}, 3.2.6). We saw in part *a)* that, for every $i \geq 0$, the maps

$$\Gamma(U, \mathscr{C}^i(X, \mathscr{F}_k)) \longrightarrow \Gamma(U, \mathscr{C}^i(X, \mathscr{F}_h)) \qquad (h \leq k)$$

are surjective. On the other hand,

$$\mathrm{H}^i(U, \mathscr{F}_k) = \mathrm{H}^i(\Gamma(U, \mathscr{C}^\bullet(X, \mathscr{F}_k))),$$

since the canonical resolution $\mathscr{C}^\bullet(U, \mathscr{F}_k|U)$ is induced on U by $\mathscr{C}^\bullet(X, \mathscr{F}_k)$. By hypothesis (i), for every $U \in \mathfrak{B}$ we may apply (13.2.3) to this projective system of complexes, and hence

$$\mathrm{H}^i(\Gamma(U, \mathscr{G}^\bullet)) = \varprojlim_k \mathrm{H}^i(U, \mathscr{F}_k) \qquad (i \geq 0).$$

Hypothesis (ii) then shows, by definition, that the sheaves $\mathscr{H}^i(\mathscr{G}^\bullet)$ vanish for $i > 0$.

Thus, for every $i \geq 0$,

$$\mathrm{H}^i(X, \mathscr{F}) = \mathrm{H}^i(\Gamma(X, \mathscr{G}^\bullet)), \qquad \Gamma(X, \mathscr{G}^\bullet) = \varprojlim_k \Gamma(X, \mathscr{C}^\bullet(X, \mathscr{F}_k)).$$

We have just observed that all the maps

$$\Gamma(X, \mathscr{C}^i(X, \mathscr{F}_k)) \longrightarrow \Gamma(X, \mathscr{C}^i(X, \mathscr{F}_h)) \qquad (h \leq k)$$

are surjective; the conclusion therefore follows once more from (13.2.3). □

(13.3.2) *Remarks* (13.3.2).

(i) The statement of (13.3.1) is of interest only for $i > 0$, since, for $i = 0$, h_i is always an isomorphism without any hypothesis (0_{I}, 3.2.6).

(ii) Conditions (i) and (ii) of (13.3.1) are satisfied, in particular, if $\mathrm{H}^i(U, \mathscr{F}_k) = 0$ for every k, every $i > 0$, and every $U \in \mathfrak{B}$, and if, for $U \in \mathfrak{B}$, the maps

$$\Gamma(U, \mathscr{F}_k) \longrightarrow \Gamma(U, \mathscr{F}_h)$$

are surjective. This is the most frequent case in which (13.3.1) is applied.

13.4 Mittag-Leffler condition and graded objects associated with projective systems

(13.4.1) Let $\mathbf{A} = (A_k, u_{kh})_{k \in \mathbf{Z}}$ be a projective system in an abelian category $\mathbf{C}$. We say that it is *bounded below* if there is a k_0 such that $A_k = 0$ for $k < k_0$. On each A_k we define a *filtration* $(\mathrm{F}^p(A_k))_{p \in \mathbf{Z}}$ by

$$\mathrm{F}^p(A_k) = \begin{cases} \mathrm{Ker}(A_k \longrightarrow A_{p-1}) & \text{for } p \leq k+1, \\ 0 & \text{for } p \geq k+1. \end{cases} \tag{13.4.1.1}$$

[0_{III} | 70] By hypothesis, $\mathrm{F}^{k_0}(A_k) = A_k$ and $\mathrm{F}^{k+1}(A_k) = 0$; in other words, the filtration under consideration is finite ((11.1.3)). The graded objects associated with this filtration are therefore

$$\mathrm{gr}^p(A_k) = \mathrm{Ker}(A_k \longrightarrow A_{p-1}) / \mathrm{Ker}(A_k \longrightarrow A_p).$$

Consequently, $\mathrm{gr}^p(A_k)$ is isomorphic to the image under $A_k \longrightarrow A_p$ of $\mathrm{Ker}(A_k \longrightarrow A_{p-1})$. By the transitivity of the morphisms defining a projective system, one therefore has

$$\mathrm{gr}^p(A_k) = \mathrm{Ker}(A_p \longrightarrow A_{p-1}) \cap \mathrm{Im}(A_k \longrightarrow A_p). \tag{13.4.1.2}$$

But (13.4.1.1) gives $\mathrm{Ker}(A_p \longrightarrow A_{p-1}) = \mathrm{gr}^p(A_p)$, and hence

$$\mathrm{gr}^p(A_k) = \mathrm{gr}^p(A_p) \cap \mathrm{Im}(A_k \longrightarrow A_p). \tag{13.4.1.3}$$

The preceding definitions also show that, for $k \leq h$,

$$u_{kh}(\mathrm{F}^p(A_h)) \subset \mathrm{F}^p(A_k),$$

and consequently, for every $p \in \mathbf{Z}$, the $\mathrm{gr}^p(u_{kh})$ define a projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$.

(13.4.2) We say that the projective system $\mathbf{A}$ is *essentially constant* if the morphisms $A_{k+1} \longrightarrow A_k$ are isomorphisms for all sufficiently large k. We say that $\mathbf{A}$ is *strict* if the morphisms $A_i \longrightarrow A_j$ $(j \leq i)$ are epimorphisms.

When $\mathbf{A}$ is strict, it follows from (13.4.1.3) that, for $p \leq k \leq h$, the canonical morphism

$$\mathrm{gr}^p(A_h) \longrightarrow \mathrm{gr}^p(A_k)$$

is an isomorphism; in other words, the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant. The sequence of objects $\mathrm{gr}^p(A_p)$, identified for every p with $\varprojlim_k \mathrm{gr}^p(A_k)$, is then denoted $\mathrm{gr}^\bullet(\mathbf{A})$ and is called the *graded object associated with the strict projective system* $\mathbf{A} = (A_k)$.

Suppose now that the bounded-below projective system $\mathbf{A}$ satisfies (ML). By (13.1.2), the projective system $\mathbf{A}' = (A'_k)$ of "universal image" objects is strict; it is also bounded below. The graded object $\mathrm{gr}^\bullet(\mathbf{A}')$ associated with $\mathbf{A}'$ is then likewise called the graded object *associated with* $\mathbf{A}$ and is denoted $\mathrm{gr}^\bullet(\mathbf{A})$.

(13.4.3) Proposition. *Let $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ be a bounded-below projective system in an abelian category $\mathbf{C}$. The following conditions are equivalent:*

a) $\mathbf{A}$ *satisfies (ML).*

b) *For every $p \in \mathbf{Z}$, the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant.*

Moreover, when these conditions hold, there is, for every $p \in \mathbf{Z}$, a canonical isomorphism

$$\mathrm{gr}^p(\mathbf{A}) \xrightarrow{\sim} \varprojlim_k \mathrm{gr}^p(A_k). \tag{13.4.3.1}$$

Proof. It follows at once from (13.4.1.2) that *a)* implies *b)*. The same formula, applied to the projective system $\mathbf{A}'$ in the notation of (13.4.2), gives (13.4.3.1) by definition.

For $k \leq h$, put

$$A_{kh} = \mathrm{Im}(A_h \longrightarrow A_k).$$

If $k \leq h \leq j$, then $A_{kj} \subset A_{kh} \subset A_k$. Equip A_{kh} with the filtration induced by $(\mathrm{F}^p(A_k))$. The transitivity of the morphisms defining $\mathbf{A}$ shows immediately that this is also the quotient filtration of $(\mathrm{F}^p(A_h))$; consequently,

$$\mathrm{gr}^p(A_{kh}) = \mathrm{Im}(\mathrm{gr}^p(A_h) \longrightarrow \mathrm{gr}^p(A_k)). \tag{13.4.3.2}$$

[0_{III} | 71] Suppose now that *b)* holds. For every $p \in \mathbf{Z}$ and every $k \geq p$, there is an integer $\mathrm{L}(p,k)$ such that the right-hand side of (13.4.3.2) is constant for $h \geq \mathrm{L}(p,k)$. Since $\mathrm{gr}^p(A_k) = 0$ for $p < k_0$, for fixed k only finitely many of the integers $\mathrm{L}(p,k)$ need be nonzero as p ranges over the integers $\leq k$. Let $\mathrm{L}(k) = m$ be the largest of these integers. For every $h \geq m$, one has $A_{kh} \subset A_{km}$, and, by the definition of m, the canonical injection $A_{kh} \longrightarrow A_{km}$ induces an isomorphism

$$\mathrm{gr}^\bullet(A_{kh}) \xrightarrow{\sim} \mathrm{gr}^\bullet(A_{km}).$$

Since the filtrations are finite, this injection is itself bijective (Bourbaki, *Alg. comm.*, chap. III, §2, n° 8, th. 1). This proves that **A** satisfies (ML). □

(13.4.4) Suppose that the projective limit $A = \varprojlim_k A_k$ exists in **C**. In the definitions of (13.4.1), one may then replace A_k by A, and the filtration thereby defined on A still satisfies

$$\mathrm{gr}^p(A) = \mathrm{gr}^p(A_p) \cap \mathrm{Im}(A \longrightarrow A_p). \tag{13.4.4.1}$$

(13.4.5) Corollary. *Suppose that* **C** *is the category of abelian groups. If the projective system* **A** *satisfies (ML) and* $A = \varprojlim_k A_k$*, then for every* $p \in \mathbf{Z}$ *there is a canonical isomorphism*

$$\mathrm{gr}^p(A) \xrightarrow{\sim} \varprojlim_k \mathrm{gr}^p(A_k). \tag{13.4.5.1}$$

Proof. Indeed,

$$\mathrm{Im}(A_k \longrightarrow A_p) = \mathrm{Im}(A \longrightarrow A_p)$$

for all sufficiently large k (Bourbaki, *Top. gén.*, chap. II, 3e éd., §3, n° 5, th. 1), and the conclusion follows from (13.4.1.3) and (13.4.4.1). □

13.5 Projective limits of spectral sequences of filtered complexes

(13.5.1) Let **C** be an abelian category and let $X^\bullet$ be a complex of objects of **C** equipped with a filtration $(\mathrm{F}^p(X^\bullet))_{p\in\mathbf{Z}}$ such that $\mathrm{F}^{p_0}(X^\bullet) = X^\bullet$ for some index p_0. For every $k \in \mathbf{Z}$, consider the complex

$$X_k^\bullet = X^\bullet/\mathrm{F}^{k+1}(X^\bullet);$$

it is canonically equipped with the filtration consisting of

$$\mathrm{F}^p(X_k^\bullet) = \mathrm{F}^p(X^\bullet)/\mathrm{F}^{k+1}(X^\bullet) \quad \text{for } p \leq k,$$

and $\mathrm{F}^p(X_k^\bullet) = 0$ for $p \geq k+1$. Moreover, there are canonical morphisms $X_{k+1}^\bullet \longrightarrow X_k^\bullet$, which make $\mathbf{X}^\bullet = (X_k^\bullet)_{k\in\mathbf{Z}}$ a *projective system of filtered complexes of objects of* **C**. We note that this projective system is *strict* and that $X_k^\bullet = 0$ for $k < p_0$.

(13.5.2) More generally, consider a bounded-below strict projective system $\mathbf{X}^\bullet = (X_k^\bullet)_{k\in\mathbf{Z}}$ of complexes of objects of **C**, and equip each $X_k^\bullet$ with the filtration defined in (13.4.1) (applied in the abelian category of bounded-below complexes of objects of **C**). The morphisms $X_k^\bullet \longrightarrow X_p^\bullet$ $(p \leq k)$ then become morphisms of *filtered* complexes with finite filtrations. The functoriality of the spectral sequences of filtered complexes ((11.2.3)) shows that the transition morphisms of $\mathbf{X}^\bullet$ induce morphisms making

$$\mathrm{E}(\mathbf{X}^\bullet) = \left(\mathrm{E}(X_k^\bullet)\right)_{k\in\mathbf{Z}}$$

a *projective system of spectral sequences.*

(13.5.3) Lemma. *Suppose that the projective system* $\mathbf{X}^\bullet = (X_k^\bullet)_{k\in\mathbf{Z}}$ *of filtered complexes is obtained as in (13.5.2). Then:*

a) *For* $r \geq p - p_0$*, one has*

$$\mathrm{B}_r^{pq}(X_k^\bullet) = \mathrm{B}_\infty^{pq}(X_k^\bullet)$$

for every $k \in \mathbf{Z}$*.*

b) *For* $k+1 \leq p+r$*, one has*

$$\mathrm{Z}_r^{pq}(X_k^\bullet) = \mathrm{Z}_\infty^{pq}(X_k^\bullet).$$

c) *For* $k+1 \geq p+r$*, the morphisms*

$$\mathrm{Z}_r^{pq}(X_h^\bullet) \longrightarrow \mathrm{Z}_r^{pq}(X_k^\bullet) \quad \textit{and} \quad \mathrm{B}_r^{pq}(X_h^\bullet) \longrightarrow \mathrm{B}_r^{pq}(X_k^\bullet)$$

are isomorphisms for every $h \geq k$*.*

These three properties follow immediately from the definitions in (11.2.2), taking into account that $\mathrm{F}^{p-r+1}(X_k^\bullet) = X_k^\bullet$ when $p - r < p_0$. [0_{III} | 72]

(13.5.4) Suppose that the hypotheses of (13.5.3) hold. Then, for fixed p, q, and r (with r finite), the projective systems

$$\big(\mathrm{Z}_r^{pq}(X_k^\bullet)\big)_{k\in\mathbf{Z}}, \qquad \big(\mathrm{B}_r^{pq}(X_k^\bullet)\big)_{k\in\mathbf{Z}}, \qquad \big(\mathrm{E}_r^{pq}(X_k^\bullet)\big)_{k\in\mathbf{Z}}$$

are *essentially constant*; their respective projective limits will be denoted by $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$, $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$, and

$$\mathrm{E}_r^{pq}(\mathbf{X}^\bullet) = \mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)/\mathrm{B}_r^{pq}(\mathbf{X}^\bullet).$$

The objects $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$ and $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$ identify canonically with subobjects of $\mathrm{E}_1^{pq}(\mathbf{X}^\bullet)$. The definition of the d_r^{pq} (M, XV, 1) shows that these morphisms, taken relative to the $X_k^\bullet$, are also essentially constant, and hence define morphisms

$$d_r^{pq} : \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \longrightarrow \mathrm{E}_r^{p+r,q-r+1}(\mathbf{X}^\bullet) \tag{13.5.4.1}$$

such that $d_r^{p+r,q-r+1} \circ d_r^{pq} = 0$. Moreover, there are canonical isomorphisms from $\mathrm{Ker}(d_r^{pq})$ onto

$$\mathrm{Z}_{r+1}^{pq}(\mathbf{X}^\bullet)/\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$$

and from $\mathrm{Im}(d_r^{pq})$ onto

$$\mathrm{B}_{r+1}^{p+r,q-r+1}(\mathbf{X}^\bullet)/\mathrm{B}_r^{p+r,q-r+1}(\mathbf{X}^\bullet).$$

(13.5.5) Lemma. *Under the hypotheses of (13.5.3), for* $s \geq r > p - p_0$ *there is a canonical monomorphism*

$$i : \mathrm{E}_s^{pq}(\mathbf{X}^\bullet) \longrightarrow \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \tag{13.5.5.1}$$

and a canonical isomorphism

$$j_r : \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \xrightarrow{\sim} \mathrm{E}_\infty^{pq}(X_{p+r-1}^\bullet) \tag{13.5.5.2}$$

such that the diagram

$$\begin{array}{ccc} \mathrm{E}_s^{pq}(\mathbf{X}^\bullet) & \xrightarrow{j_s} & \mathrm{E}_\infty^{pq}(X^\bullet_{p+s-1}) \\ {\scriptstyle i}\downarrow & & \downarrow \\ \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) & \xrightarrow{j_r} & \mathrm{E}_\infty^{pq}(X^\bullet_{p+r-1}) \end{array} \tag{13.5.5.3}$$

is commutative, where the right vertical arrow is induced by the morphism $X^\bullet_{p+s-1} \longrightarrow X^\bullet_{p+r-1}$.

Proof. The existence of i follows from

$$\mathrm{B}_r^{pq}(X_k^\bullet) = \mathrm{B}_\infty^{pq}(X_k^\bullet) \qquad (r > p - p_0)$$

((13.5.3), a)). For $k + 1 \leq p + r$, one has

$$\mathrm{Z}_r^{pq}(X_k^\bullet) = \mathrm{Z}_\infty^{pq}(X_k^\bullet)$$

((13.5.3), b)); in particular,

$$\mathrm{Z}_r^{pq}(X^\bullet_{p+r-1}) = \mathrm{Z}_\infty^{pq}(X^\bullet_{p+r-1}).$$

On the other hand, $\mathrm{Z}_r^{pq}(X^\bullet_{p+r-1})$ and $\mathrm{B}_r^{pq}(X^\bullet_{p+r-1})$ identify canonically with $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$ and $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$ by (13.5.3), c). This proves the existence of j_r and the commutativity of (13.5.5.3). □

(13.5.6) Corollary. *Under the hypotheses of (13.5.3), if one of the projective limits*

$$\varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet), \qquad \varprojlim_k \mathrm{E}_\infty^{pq}(X_k^\bullet)$$

exists, then so does the other, and there is a canonical isomorphism

$$j_\infty : \varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet) \xrightarrow{\sim} \varprojlim_k \mathrm{E}_\infty^{pq}(X_k^\bullet). \tag{13.5.6.1}$$

Moreover, the projective system $(\mathrm{E}_r^{pq}(\mathbf{X}^\bullet))_{r\in\mathbf{Z}}$ *is essentially constant ((13.4.2)) if and only if the projective system* $(\mathrm{E}_\infty^{pq}(X_k^\bullet))_{k\in\mathbf{Z}}$ *is essentially constant.*

(13.5.7) We denote by $\mathrm{B}_\infty^{pq}(\mathbf{X}^\bullet)$ and $\mathrm{Z}_\infty^{pq}(\mathbf{X}^\bullet)$ the subobjects of $\mathrm{E}_1^{pq}(\mathbf{X}^\bullet)$ equal respectively to $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$ for $r > p - p_0$ and to $\inf_r \mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$, when the latter exists. Thus

$$\varprojlim_r \mathrm{E}_r^{pq}(\mathbf{X}^\bullet)$$

[0_{III} | 73] identifies canonically with

$$\mathrm{E}_\infty^{pq}(\mathbf{X}^\bullet) = \mathrm{Z}_\infty^{pq}(\mathbf{X}^\bullet)/\mathrm{B}_\infty^{pq}(\mathbf{X}^\bullet).$$

We note that the objects $\mathrm{Z}_r^{pq}(\mathbf{X}^\bullet)$, $\mathrm{B}_r^{pq}(\mathbf{X}^\bullet)$, $\mathrm{E}_r^{pq}(\mathbf{X}^\bullet)$ $(1 \leq r \leq +\infty)$, and the morphisms d_r^{pq} depend *functorially* on the projective system $\mathbf{X}^\bullet$, subject to the restrictions in (13.5.5), and the morphisms defined in (13.5.5) and (13.5.6) are functorial.

13.6 Spectral sequence of a functor relative to an object equipped with a finite filtration

(13.6.1) Let $\mathbf{C}$ and $\mathbf{C}'$ be two abelian categories, and let $\mathrm{T} : \mathbf{C} \longrightarrow \mathbf{C}'$ be an additive covariant functor. Suppose that every object of $\mathbf{C}$ is isomorphic to a subobject of an injective object, so that the right derived functors $\mathrm{R}^p\mathrm{T}$ ($p \geq 0$) exist.

(13.6.2) Lemma. *Let A be an object of $\mathbf{C}$ equipped with a finite filtration $(\mathrm{F}^i(A))_{i\in\mathbf{Z}}$. There exists an injective resolution $X^\bullet = (X^j)_{j\geq 0}$ of A, equipped with a finite filtration $(\mathrm{F}^i(X^\bullet))_{i\in\mathbf{Z}}$, such that*

$$\mathrm{F}^i(A) = A \quad \textit{(respectively, } \mathrm{F}^i(A) = 0\textit{)}$$

implies

$$\mathrm{F}^i(X^\bullet) = X^\bullet \quad \textit{(respectively, } \mathrm{F}^i(X^\bullet) = 0\textit{)},$$

and such that, for every $i \in \mathbf{Z}$, $\mathrm{F}^i(X^\bullet)$ is an injective resolution of $\mathrm{F}^i(A)$.

Proof. Let p (respectively, $q > p$) be the largest index such that $\mathrm{F}^p(A) = A$ (respectively, the smallest index such that $\mathrm{F}^q(A) = 0$). We argue by induction on $q - p$, the lemma being immediate when $q - p = 1$. Suppose that an injective resolution $X''^\bullet$ of $A/\mathrm{F}^{q-1}(A)$ having the required properties has been constructed. Consider the exact sequence

$$0 \longrightarrow \mathrm{F}^{q-1}(A) \longrightarrow A \longrightarrow A/\mathrm{F}^{q-1}(A) \longrightarrow 0,$$

take an injective resolution $X'^\bullet$ of $\mathrm{F}^{q-1}(A)$, and then choose an injective resolution $X^\bullet$ of A so as to obtain an exact sequence

$$0 \longrightarrow X'^\bullet \longrightarrow X^\bullet \longrightarrow X''^\bullet \longrightarrow 0$$

compatible with the preceding sequence (M, V, 2.2). It is clear that $X^\bullet$ has the required properties. □

(13.6.3) Corollary. *Let B be a second object of $\mathbf{C}$, equipped with a finite filtration $(\mathrm{F}^i(B))_{i\in\mathbf{Z}}$, let s be an integer, and let $u : A \longrightarrow B$ be a morphism such that*

$$u(\mathrm{F}^i(A)) \subset \mathrm{F}^{i+s}(B)$$

for every $i \in \mathbf{Z}$. If $Y^\bullet = (Y^j)_{j\geq 0}$ is an injective resolution of B equipped with a filtration $(\mathrm{F}^i(Y^\bullet))_{i\in\mathbf{Z}}$ having the properties stated in (13.6.2), then there exists a morphism $v : X^\bullet \longrightarrow Y^\bullet$, compatible with u, such that

$$v(\mathrm{F}^i(X^\bullet)) \subset \mathrm{F}^{i+s}(Y^\bullet)$$

for every $i \in \mathbf{Z}$. Moreover, any two such morphisms v and v' are homotopic.

This follows immediately, by induction on $q - p$, from the preceding construction and from (M, V, 2.3).

(13.6.4) Under the hypotheses of (13.6.2), consider the complex $\mathrm{T}(X^\bullet)$ in $\mathbf{C}'$. It is filtered by the complexes $\mathrm{T}(\mathrm{F}^i(X^\bullet))$, since $\mathrm{F}^i(X^\bullet)$ is a direct summand of $X^\bullet$. It follows from (13.6.3) that the *spectral sequence* of this filtered complex depends, up to isomorphism, only on the filtered object A. Its abutment is the cohomology $\mathrm{R}^\bullet\mathrm{T}(A)$, equipped with the filtration

$$\begin{aligned} \mathrm{F}^p(\mathrm{R}^n\mathrm{T}(A)) &= \mathrm{Im}\big(\mathrm{R}^n\mathrm{T}(\mathrm{F}^p(A)) \longrightarrow \mathrm{R}^n\mathrm{T}(A)\big) \\ &= \mathrm{Ker}\big(\mathrm{R}^n\mathrm{T}(A) \longrightarrow \mathrm{R}^n\mathrm{T}(A/\mathrm{F}^p(A))\big), \end{aligned} \tag{13.6.4.1}$$

by (11.2.2), and its E_1-term is

$$E_1^{pq} = R^{p+q}T(\mathrm{gr}^p(A)), \tag{13.6.4.2}$$

where, as usual, $\mathrm{gr}^p(A) = F^p(A)/F^{p+1}(A)$. It is clear from (11.2.2) that the filtration of
[0_{III} | 74] the abutment is finite and that, for fixed p and q, the sequences

$$B_r^{pq}(A) = B_r^{pq}(T(X^\bullet)) \quad \text{and} \quad Z_r^{pq}(A) = Z_r^{pq}(T(X^\bullet))$$

are stationary. The preceding spectral sequence is therefore *biregular* ((11.1.3)). We denote it by $E(A) = (E_r^{pq}(A))$ and call it the *spectral sequence of the functor* T *relative to the filtered object* A.

(13.6.5) Now suppose that the hypotheses of (13.6.3) hold, and retain its notation. Since $F^i(X^\bullet)$ (respectively, $F^i(Y^\bullet)$) is a direct summand of $X^\bullet$ (respectively, $Y^\bullet$), one has

$$(Tv)(T(F^i(X^\bullet))) \subset T(F^{i+s}(Y^\bullet))$$

for every $i \in \mathbf{Z}$. The definitions in (11.2.2) then show that, for $1 \leq r \leq +\infty$, Tv defines morphisms

$$B_r^{pq}(T(X^\bullet)) \longrightarrow B_r^{p+s,q-s}(T(Y^\bullet))$$

and

$$Z_r^{pq}(T(X^\bullet)) \longrightarrow Z_r^{p+s,q-s}(T(Y^\bullet)),$$

and hence a morphism

$$w_r : E_r^{pq}(A) \longrightarrow E_r^{p+s,q-s}(B).$$

Similarly, on the abutments one has morphisms

$$u_n : R^nT(A) \longrightarrow R^nT(B)$$

such that

$$u_n(F^p(R^nT(A))) \subset F^{p+s}(R^nT(B)).$$

The definition of the d_r^{pq} (M, XV, 1) also shows that the diagrams

$$\begin{array}{ccc} E_r^{pq}(A) & \xrightarrow{d_r^{pq}} & E_r^{p+r,q-r+1}(A) \\ \downarrow{\scriptstyle w_r} & & \downarrow{\scriptstyle w_r} \\ E_r^{p+s,q-s}(B) & \xrightarrow[d_r^{p+s,q-s}]{} & E_r^{p+r+s,q-r-s+1}(B) \end{array}$$

are commutative. It follows that there is an analogous commutative diagram for the isomorphisms α_r^{pq}, which we leave to the reader to make explicit. Finally (*loc. cit.*), one also has commutative diagrams on the abutments:

$$\begin{array}{ccc} E_\infty^{pq}(A) & \xrightarrow{\beta^{pq}} & \mathrm{gr}^p(R^{p+q}T(A)) \\ \downarrow{\scriptstyle w_\infty} & & \downarrow{\scriptstyle u_{p+q}} \\ E_\infty^{p+s,q-s}(B) & \xrightarrow[\beta^{p+s,q}]{} & \mathrm{gr}_s^{p+s}(R^{p+q}T(B)). \end{array}$$

(13.6.6) Suppose in particular that there is a ring S, equipped with a *filtration* $(F^i(S))_{i\in\mathbf{Z}}$, and a ring homomorphism

$$h : S \longrightarrow \mathrm{Hom}_{\mathbf{C}}(A, A) \tag{13.6.6.1}$$

such that, for every $t \in \mathrm{F}^i(S)$, [0_{III} | 75]

$$h_t(\mathrm{F}^j(A)) \subset \mathrm{F}^{i+j}(A)$$

for every pair i, j. For brevity, we then say that A is equipped with the structure of a *filtered S–$\mathbf{C}$-module* over the filtered ring S.

Passing to the associated graded objects, every h_t, for $t \in \mathrm{F}^i(S)$, defines a graded endomorphism $\overline{h}_t$ of $\mathrm{gr}^\bullet(A)$, homogeneous of degree i. Moreover, this endomorphism depends only on the class of t in $\mathrm{gr}^i(S)$, and one thereby obtains a homomorphism of *graded rings*

$$\overline{h} : \mathrm{gr}^\bullet(S) \longrightarrow \mathrm{Hom}^\bullet_{\mathbf{C}}(\mathrm{gr}^\bullet(A), \mathrm{gr}^\bullet(A)),$$

where the right-hand side is the ring of graded endomorphisms of $\mathrm{gr}^\bullet(A)$. We say that $\mathrm{gr}^\bullet(A)$ is equipped with the structure of a *graded* $\mathrm{gr}^\bullet(S)$–$\mathbf{C}$-*module*.

It follows from (13.6.5) that, for $1 \leq r \leq +\infty$, every $\overline{t} \in \mathrm{gr}^i(S)$ canonically defines, on the bigraded objects

$$(\mathrm{B}_r^{pq}(A))_{(p,q)\in\mathbf{Z}\times\mathbf{Z}}, \qquad (\mathrm{Z}_r^{pq}(A))_{(p,q)\in\mathbf{Z}\times\mathbf{Z}},$$

and

$$\mathrm{E}_r(A) = (\mathrm{E}_r^{pq}(A))_{(p,q)\in\mathbf{Z}\times\mathbf{Z}},$$

bigraded endomorphisms of degree $(i, -i)$. On $\mathrm{E}_r(A)$, for finite r, this endomorphism commutes with the bigraded endomorphism defined by the d_r^{pq}. These endomorphisms satisfy the usual associativity and distributivity conditions with respect to addition in $\mathrm{gr}^\bullet(S)$ and in the bigraded objects in question. For brevity, we say that the latter are *bigraded* $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-*modules*; it is immediate that the α_r^{pq} define an isomorphism for this type of structure.

For every integer n, let $\mathrm{B}_r^{(n)}(A)$ (respectively, $\mathrm{Z}_r^{(n)}(A)$ and $\mathrm{E}_r^{(n)}(A)$) denote the graded subobject of $\mathrm{B}_r^{\bullet,\bullet}(A)$ (respectively, $\mathrm{Z}_r^{\bullet,\bullet}(A)$ and $\mathrm{E}_r^{\bullet,\bullet}(A)$) consisting of the terms for which $p + q = n$ ($1 \leq r \leq +\infty$). It is immediate that these are *graded* $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-*modules*.

Finally, every $\overline{t} \in \mathrm{gr}^i(S)$ defines, for every n, a graded endomorphism of degree i on the graded object $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A))$, which thereby acquires the structure of a graded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-module. For $p + q = n$, the β^{pq} define an isomorphism

$$\mathrm{E}^{(n)}(A) \xrightarrow{\sim} \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A))$$

for this type of structure.

We note that, when $\mathbf{C}'$ is the category of abelian groups, the structures of an S–$\mathbf{C}'$-module (respectively, of a graded or bigraded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-module) are simply the usual structures of an S-module (respectively, a graded or bigraded $\mathrm{gr}^\bullet(S)$-module).

13.7 Derived functors of a projective limit of arguments

(13.7.1) Let $\mathbf{C}$ and $\mathbf{C}'$ be two abelian categories, and suppose that every object of $\mathbf{C}$ is isomorphic to a subobject of an injective object. Let

$$\mathrm{T} : \mathbf{C} \longrightarrow \mathbf{C}'$$

be an additive covariant functor. Consider a strict projective system $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ in $\mathbf{C}$, bounded below; more precisely, suppose that $A_k = 0$ for $k < k_0$. To this system we

canonically associate, on each A_k, the filtration $(\mathrm{F}^p(A_k))_{p\in\mathbf{Z}}$ given by (13.4.1.1). Since the projective system is strict, the canonical morphisms

$$\mathrm{F}^i(A_h)/\mathrm{F}^j(A_h) \longrightarrow \mathrm{F}^i(A_k)/\mathrm{F}^j(A_k) \qquad (h \geq k) \tag{13.7.1.1}$$

are isomorphisms for $i \leq j \leq k+1$. Recall also that $\mathrm{F}^{k_0}(A_k) = A_k$ and $\mathrm{F}^{k+1}(A_k) = 0$ for every k.

(13.7.2) For each k, construct an injective resolution $\mathrm{X}_k^\bullet = (\mathrm{X}_k^j)_{j\geq 0}$ of A_k having the properties of (13.6.2). The canonical morphisms $A_{k+1} \longrightarrow A_k$ allow us, by (13.6.3), to define for each k a morphism of complexes

$$\mathrm{X}_{k+1}^\bullet \longrightarrow \mathrm{X}_k^\bullet$$

compatible with the filtrations and making $\mathbf{X}^\bullet = (\mathrm{X}_k^\bullet)_{k\in\mathbf{Z}}$ a projective system of com-
[0_{III} | 76] plexes. We may moreover suppose that this projective system is strict. Indeed, by (13.7.1.1),

$$A_k \simeq A_{k+1}/\mathrm{F}^{k+1}(A_{k+1}).$$

Thus, in constructing $\mathrm{X}_{k+1}^\bullet$, we may take the injective resolution of $A_{k+1}/\mathrm{F}^{k+1}(A_{k+1})$ to be *equal* to $\mathrm{X}_k^\bullet$. It then follows from (M, V, 2.3) that the morphism of complexes $\mathrm{X}_{k+1}^\bullet \longrightarrow \mathrm{X}_k^\bullet$ may be constructed so that, on passing to quotients, it induces an isomorphism

$$\mathrm{X}_{k+1}^\bullet/\mathrm{F}^{k+1}(\mathrm{X}_{k+1}^\bullet) \xrightarrow{\sim} \mathrm{X}_k^\bullet$$

respecting the filtrations; this is precisely the condition of (13.5.1).

(13.7.3) By construction, the projective system $\mathrm{T}(\mathbf{X}^\bullet)$ of complexes $\mathrm{T}(\mathrm{X}_k^\bullet)$ satisfies the hypotheses of (13.5.3). The results of (13.5.4), (13.5.5), and (13.5.6) therefore apply to the spectral sequences

$$\mathrm{E}(\mathrm{T}(\mathrm{X}_k^\bullet)) = \mathrm{E}(A_k).$$

For $1 \leq r \leq +\infty$, we write $\mathrm{E}_r^{pq}(\mathbf{A})$ in place of $\mathrm{E}_r^{pq}(\mathrm{T}(\mathbf{X}^\bullet))$ (cf. (13.5.7) when $r = +\infty$), and use the same convention for the analogous notation. In particular,

$$\mathrm{E}_1^{pq}(\mathbf{A}) = \mathrm{R}^{p+q}\mathrm{T}\big(\mathrm{gr}^p(\mathbf{A})\big), \tag{13.7.3.1}$$

by (13.6.4.2) and the fact that the projective system $(\mathrm{gr}^p(A_k))_{k\in\mathbf{Z}}$ is essentially constant. These results, together with (13.4.3), give the following proposition, first proved by Shih Weishu by a different method (unpublished).

(13.7.4) Proposition. (Shih). *Let n be an integer. The following two conditions are equivalent:*

a) *For every pair (p, q) such that $p + q = n$, the projective system $(\mathrm{E}_r^{pq}(\mathbf{A}))_{r\geq 2}$ is essentially constant.*

b) *The projective system*

$$\mathrm{R}^n\mathrm{T}(\mathbf{A}) = \big(\mathrm{R}^n\mathrm{T}(A_k)\big)_{k\in\mathbf{Z}}$$

satisfies (ML).

Moreover, when these conditions hold, there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{R}^n\mathrm{T}(\mathbf{A})\big) \xrightarrow{\sim} \mathrm{E}_\infty^{p,n-p}(\mathbf{A}) \qquad (p \in \mathbf{Z}). \tag{13.7.4.1}$$

Proof. By (13.5.6), condition a) says precisely that, for $p+q=n$, the projective system $(\mathrm{E}_\infty^{pq}(A_k))_{k\in\mathbf{Z}}$ is essentially constant. On the other hand, $\mathrm{gr}^p(\mathrm{R}^n\mathrm{T}(A_k))$ is canonically isomorphic to $\mathrm{E}_\infty^{p,n-p}(A_k)$. It follows from (13.4.3) that a) and b) are equivalent, and (13.7.4.1) is just (13.5.6.1) in the case under consideration. □

(13.7.5) Corollary. *Let $\mathscr{F}=(\mathscr{F}_k)_{k\in\mathbf{N}}$ be a projective system of sheaves of abelian groups satisfying conditions* (i), (ii), *and* (iii) *of (13.3.1), and put $\mathscr{F}=\varprojlim_k \mathscr{F}_k$. Suppose that, for the functor $\mathscr{G}\longmapsto\Gamma(X,\mathscr{G})$, the projective system $(\mathrm{E}_r^{pq}(\mathscr{F}))_r$ is essentially constant whenever $p+q=n$ or $p+q=n+1$. On $\mathrm{H}^{n+1}(X,\mathscr{F})$, consider the filtration*

$$\mathrm{F}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F})\big)=\mathrm{Ker}\big(\mathrm{H}^{n+1}(X,\mathscr{F})\longrightarrow\mathrm{H}^{n+1}(X,\mathscr{F}_{p-1})\big).$$

Then there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F})\big)\xrightarrow{\sim}\mathrm{E}_\infty^{p,n-p+1}(\mathscr{F})\qquad(p\in\mathbf{Z}).\tag{13.7.5.1}$$

Proof. Apply (13.7.4) with $\mathbf{C}$ the category of sheaves of abelian groups on X, $\mathbf{C}'$ the category of abelian groups, and $\mathrm{T}=\Gamma$. It gives, for every $p\in\mathbf{Z}$, a canonical isomorphism [$0_{\mathrm{III}}\,|\,77$]

$$\mathrm{gr}^p\big(\mathrm{R}^{n+1}\Gamma(\mathscr{F})\big)\xrightarrow{\sim}\mathrm{E}_\infty^{p,n-p+1}(\mathscr{F}).$$

Moreover, by (13.7.4), the projective system $(\mathrm{H}^n(X,\mathscr{F}_k))_{k\in\mathbf{Z}}$ satisfies (ML); hence (13.3.1) gives a canonical isomorphism

$$\mathrm{H}^{n+1}(X,\mathscr{F})\xrightarrow{\sim}\varprojlim_k\mathrm{H}^{n+1}(X,\mathscr{F}_k).$$

Since the projective system $\mathrm{R}^{n+1}\Gamma(\mathscr{F})$ satisfies (ML) by (13.7.4), there is a canonical isomorphism

$$\mathrm{gr}^p\big(\mathrm{R}^{n+1}\Gamma(\mathscr{F})\big)\xrightarrow{\sim}\varprojlim_k\mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F}_k)\big)$$

by (13.4.3), and a canonical isomorphism

$$\varprojlim_k\mathrm{gr}^p\big(\mathrm{H}^{n+1}(X,\mathscr{F}_k)\big)\xrightarrow{\sim}\mathrm{gr}^p\left(\varprojlim_k\mathrm{H}^{n+1}(X,\mathscr{F}_k)\right)$$

by (13.4.5). It remains only to check that the preceding isomorphism is compatible with the filtrations on its two sides. This follows immediately from the definitions and, for every p, from the commutativity of

$$\begin{array}{ccc}\mathrm{H}^{n+1}(X,\mathscr{F})&\xrightarrow{\sim}&\varprojlim_k\mathrm{H}^{n+1}(X,\mathscr{F}_k)\\&\searrow&\downarrow\\&&\mathrm{H}^{n+1}(X,\mathscr{F}_{p-1}).\end{array}$$

□

(13.7.6) Let S be a ring equipped with a filtration $(\mathrm{F}^i(S))_{i\in\mathbf{Z}}$ such that $\mathrm{F}^0(S)=S$ (and hence $\mathrm{gr}^i(S)=0$ for $i<0$). Suppose that each A_k, with the filtration defined in (13.7.1), is a filtered S–$\mathbf{C}$-module in the sense of (13.6.6), and that the morphisms $A_h\longrightarrow A_k$ for $k\leq h$ are morphisms of filtered S–$\mathbf{C}$-modules. For brevity, we then say that $\mathbf{A}$ is a *projective system of filtered S–$\mathbf{C}$-modules.*

It is immediate that, for $k \leq h$ and $1 \leq r \leq +\infty$, the morphisms

$$\mathrm{B}_r^{pq}(A_h) \longrightarrow \mathrm{B}_r^{pq}(A_k), \qquad \mathrm{Z}_r^{pq}(A_h) \longrightarrow \mathrm{Z}_r^{pq}(A_k)$$

are morphisms of bigraded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-modules ((13.6.5)), and that, for finite r, the families

$$(\mathrm{Z}_r^{pq}(\mathbf{A})), \qquad (\mathrm{B}_r^{pq}(\mathbf{A})), \qquad (\mathrm{E}_r^{pq}(\mathbf{A}))$$

are bigraded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-modules, the first two being submodules of $(\mathrm{E}_1^{pq}(\mathbf{A}))$. We again write $\mathrm{Z}_r^{(n)}(\mathbf{A})$, $\mathrm{B}_r^{(n)}(\mathbf{A})$, and $\mathrm{E}_r^{(n)}(\mathbf{A})$ for the respective graded subobjects obtained by retaining only the terms with $p+q=n$; these are graded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-modules.

When the projective system $(\mathrm{E}_r^{pq}(\mathbf{A}))_r$ is essentially constant, $\mathrm{E}_\infty^{pq}(\mathbf{A})$ is likewise a bigraded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-module, and each $\mathrm{E}_\infty^{(n)}(\mathbf{A})$ is a graded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-module. Moreover, for each k, the isomorphisms

$$\beta^{p,n-p} : \mathrm{E}_\infty^{p,n-p}(A_k) \xrightarrow{\sim} \mathrm{gr}^p(\mathrm{R}^n\mathrm{T}(A_k))$$

form an isomorphism of graded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-modules from $\mathrm{E}_\infty^{(n)}(A_k)$ onto $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k))$. Under the preceding hypotheses, the isomorphism

$$\beta^{p,n-p} : \mathrm{E}_\infty^{(n)}(\mathbf{A}) \xrightarrow{\sim} \varprojlim_k \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k))$$

therefore also respects these structures. The same is plainly true of the canonical isomorphism

$$\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \xrightarrow{\sim} \varprojlim_k \mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(A_k));$$

consequently, the isomorphisms (13.7.4.1) form an isomorphism of graded $\mathrm{gr}^\bullet(S)$–$\mathbf{C}'$-modules.

(13.7.7) Proposition. *Let S be a Noetherian $\mathfrak{J}$-adic ring. Suppose that $\mathbf{C}$ is an abelian category in which every object is isomorphic to a subobject of an injective object, and let T be an additive covariant functor from $\mathbf{C}$ to the category of abelian groups.* [0_{III} / 78] *Let $\mathbf{A} = (A_k)_{k\in\mathbf{Z}}$ be a strict projective system of filtered S–$\mathbf{C}$-modules, for the $\mathfrak{J}$-adic filtration on S, bounded below. For a fixed integer n, suppose that the following condition holds:*

(F_n) The graded $\mathrm{gr}^\bullet(S)$-module

$$\mathrm{E}_1^{(m)}(\mathbf{A}) = (\mathrm{R}^m\mathrm{T}(\mathrm{gr}^p(\mathbf{A})))_{p\in\mathbf{Z}}$$

of (13.7.3.1) is of finite type for $m = n$ and $m = n+1$.

Then:

(i) *The projective systems $(\mathrm{R}^n\mathrm{T}(A_k))_{k\in\mathbf{Z}}$ and $(\mathrm{R}^{n+1}\mathrm{T}(A_k))_{k\in\mathbf{Z}}$ satisfy* (ML).

(ii) *If*

$$\mathrm{R}'^n\mathrm{T}(\mathbf{A}) = \varprojlim_k \mathrm{R}^n\mathrm{T}(A_k),$$

then $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ is an S-module of finite type.

(iii) *The filtration on* $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ *defined by*

$$\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) = \mathrm{Ker}(\mathrm{R}'^n\mathrm{T}(\mathbf{A}) \longrightarrow \mathrm{R}^n\mathrm{T}(A_{p-1})) \qquad (p \in \mathbf{Z})$$

is $\mathfrak{J}$*-good; that is,*

$$\mathfrak{J}\,\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) \subset \mathrm{F}^{p+1}(\mathrm{R}'^n\mathrm{T}(\mathbf{A}))$$

for every p*, with equality for all sufficiently large* p*. In particular, the topology on* $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ *defined by this filtration is the* $\mathfrak{J}$*-adic topology.*

(iv) *The projective system* $(\mathrm{E}_r^{pq}(\mathbf{A}))_r$ *is essentially constant whenever* $p+q=n$ *or* $p+q=n+1$*. Thus* $\mathrm{E}_\infty^{pq}(\mathbf{A})$ *is defined ((13.5.7)), and the isomorphisms*

$$\mathrm{gr}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) \xrightarrow{\sim} \mathrm{E}_\infty^{p,n-p}(\mathbf{A}) \qquad (p \in \mathbf{Z}) \tag{13.7.7.1}$$

form an isomorphism of graded $\mathrm{gr}^\bullet(S)$*-modules.*

Proof. In view of (13.7.7.1), and taking account of the isomorphisms (13.7.4.1), we shall by abuse of notation also write $\mathrm{R}^n\mathrm{T}(\mathbf{A})$ for the projective limit $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ of the projective system $(\mathrm{R}^n\mathrm{T}(A_k))$.

The graded ring $\mathrm{gr}^\bullet(S)$ is Noetherian (Bourbaki, *Alg. comm.*, chap. III, §2, n° 9, cor. 5 of th. 2). Hence the increasing sequence of graded $\mathrm{gr}^\bullet(S)$-submodules $\mathrm{B}_r^{(m)}(\mathbf{A})$ of $\mathrm{E}_1^{(m)}(\mathbf{A})$ is stationary for $m=n$ and $m=n+1$. Condition (b) of (11.1.10) is therefore satisfied. It follows that condition (a) of (13.7.4) holds for n and for $n+1$, proving (i).

Furthermore, the isomorphisms (13.7.4.1), together with the remarks of (13.7.6), show that $\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A}))$ is a graded $\mathrm{gr}^\bullet(S)$-module isomorphic to

$$\mathrm{E}_\infty^{(n)}(\mathbf{A}) = \mathrm{Z}_\infty^{(n)}(\mathbf{A})/\mathrm{B}_\infty^{(n)}(\mathbf{A}).$$

Since $\mathrm{Z}_\infty^{(n)}(\mathbf{A})$ is a submodule of $\mathrm{E}_1^{(n)}(\mathbf{A})$, it is of finite type, and so is $\mathrm{E}_\infty^{(n)}(\mathbf{A})$. Finally, for the filtration $(\mathrm{F}^p(\mathrm{R}'^n\mathrm{T}(\mathbf{A})))$, it follows from (13.4.5) that

$$\mathrm{gr}^\bullet(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \quad \text{and} \quad \mathrm{gr}^\bullet(\mathrm{R}'^n\mathrm{T}(\mathbf{A}))$$

are isomorphic graded $\mathrm{gr}^\bullet(S)$-modules. This proves (iv). Assertions (ii) and (iii) will follow from these results and the following lemma. □

(13.7.7.2) Lemma. *Let* S *be a Noetherian* $\mathfrak{J}$*-adic ring, and let* M *be an* S*-module equipped with a codiscrete filtration* $(\mathrm{F}^p(M))_{p\in\mathbf{Z}}$ *such that*

$$\mathfrak{J}\mathrm{F}^p(M) \subset \mathrm{F}^{p+1}(M).$$

Thus M *is a filtered module over* S *endowed with its* $\mathfrak{J}$*-adic filtration. Suppose moreover that* M *is separated for the topology defined by* $(\mathrm{F}^p(M))$*. Then the following conditions are equivalent:*

a) M *is an* S*-module of finite type and* $(\mathrm{F}^p(M))$ *is a* $\mathfrak{J}$*-good filtration.*

b) $\mathrm{gr}^\bullet(M)$ *is a* $\mathrm{gr}^\bullet(S)$*-module of finite type.*

c) *The* $\mathrm{gr}^p(M)$ *are* S*-modules of finite type and, for all sufficiently large* p*, the canonical homomorphisms*

$$\mathfrak{J} \otimes_S \mathrm{gr}^p(M) \longrightarrow \mathrm{gr}^{p+1}(M) \tag{13.7.7.3}$$

[0_{III} / 79] *are surjective. They are induced by* $\mathfrak{J} \otimes_S \mathrm{F}^p(M) \longrightarrow \mathrm{F}^{p+1}(M)$*, taking account of the fact that the image of the composite homomorphism*

$$\mathfrak{J} \otimes_S \mathrm{F}^{p+1}(M) \longrightarrow \mathfrak{J} \otimes_S \mathrm{F}^p(M) \longrightarrow \mathrm{F}^{p+1}(M)$$

is $\mathfrak{J}\mathrm{F}^{p+1}(M) \subset \mathrm{F}^{p+2}(M)$.

For the proof, see Bourbaki, Alg. comm.*, chap. III, §3, n° 1, prop. 3.*

(13.7.7.4) To apply the lemma (13.7.7.2), it remains to observe that the topology on $\mathrm{R}'^n\mathrm{T}(\mathbf{A})$ defined by the filtration under consideration makes it a separated and complete S-module: this is the projective-limit topology of the discrete groups $\mathrm{R}^n\mathrm{T}(A_k)$. On the other hand, if $A_k = 0$ for $k < k_0$, then also $\mathrm{R}^n\mathrm{T}(A_k) = 0$ for $k < k_0$; hence

$$\mathrm{F}^{k_0}(\mathrm{R}'^n\mathrm{T}(\mathbf{A})) = \mathrm{R}'^n\mathrm{T}(\mathbf{A}).$$

Thus all the hypotheses of the lemma are indeed satisfied.

(13.7.8) Corollary. *If hypothesis* (F_n) *holds, then for every* $f \in S$ *there is a canonical isomorphism*

$$\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f \xrightarrow{\sim} \mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_{\{f\}}. \tag{13.7.8.1}$$

Proof. Indeed, $\mathrm{R}^n\mathrm{T}(\mathbf{A})$ is an S-module of finite type, and $S_{\{f\}}$ is a Noetherian adic S-algebra ($(0_{\mathrm{I}}, 7.6.11)$), namely the separated completion of S_f for the $\mathfrak{J}$-preadic topology ($(0_{\mathrm{I}}, 7.6.2)$). It follows from $(0_{\mathrm{I}}, 7.7.8)$ and $(0_{\mathrm{I}}, 7.7.1)$ that

$$\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_{\{f\}}$$

is isomorphic to the separated completion of $\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_f$ for the $\mathfrak{J}$-preadic topology. A fundamental system of neighbourhoods of zero for this topology is

$$(\mathfrak{J}^p\mathrm{R}^n\mathrm{T}(\mathbf{A})) \otimes_S S_f;$$

the groups

$$\mathrm{F}^p(\mathrm{R}^n\mathrm{T}(\mathbf{A})) \otimes_S S_f$$

therefore also form such a system. The latter group is the kernel of the canonical map

$$(\mathrm{R}^n\mathrm{T}(\mathbf{A}))_f \longrightarrow (\mathrm{R}^n\mathrm{T}(A_{p-1}))_f.$$

Consequently, the separated group associated with $\mathrm{R}^n\mathrm{T}(\mathbf{A}) \otimes_S S_f$ identifies with a subgroup G of

$$\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f.$$

But the projective system $((\mathrm{R}^n\mathrm{T}(A_k))_f)_k$ plainly satisfies (ML), and the image of $(\mathrm{R}^n\mathrm{T}(\mathbf{A}))_f$ in each $(\mathrm{R}^n\mathrm{T}(A_k))_f$ equals the common image of the $(\mathrm{R}^n\mathrm{T}(A_h))_f$ for all sufficiently large $h \geq k$. It follows at once that G is *everywhere dense* in $\varprojlim_k (\mathrm{R}^n\mathrm{T}(A_k))_f$. Since the latter group is separated and complete, the corollary is proved. □

§ 23. Japanese rings.

Almost all of the preceding sections are devoted to the exposition of notions of Commutative Algebra that will be used in the course of Chapter IV. Although a good part of these notions already appears in several works ([1], [12], [13], [17], [30]), we thought that it would be more convenient for the reader to have a continuous and more or less self-contained exposition of them. Together with §§ 5, 6 and 7 of Chapter IV (where the language of schemes is used), these sections constitute, within our Treatise, a small special Treatise, more or less independent of Chapters I to III, which aims to present in a coherent form the properties of rings that "behave well" with respect to operations such as completion or integral closure, by systematically relating these properties to a few general concepts[15].

§14 Combinatorial dimension of a topological space

14.1 Combinatorial dimension of a topological space

(14.1.1) Let I be an ordered set; a *chain* of elements of I is by definition a strictly increasing finite sequence $i_0 < i_1 < \cdots < i_n$ of elements of I ($n \geq 0$); by definition the *length* of this chain is n. If X is a topological space, the set of its *irreducible closed* subsets is ordered by inclusion, whence the notion of a *chain* of irreducible closed subsets of X. [$0_{\text{IV-1}}$ | 6]

(14.1.2) Definition. Let X be a topological space. We call *combinatorial dimension of X* (or simply *dimension of X* if no confusion can arise), and denote by $\dim_c(X)$, or simply $\dim(X)$, the supremum of the lengths of the chains of irreducible closed subsets of X. For every $x \in X$, we call *combinatorial dimension of X at x* (or simply *dimension of X at x*), and denote by $\dim_x(X)$, the number $\inf_U(\dim(U))$, where U runs through the set of open neighbourhoods of x in X.

[14] Recall that the symbol 0_N (resp. Err_N) refers to the part of Chapter 0 (resp. the list of Errata) attached to Chapter N.

[15] Most of the properties in question are due to Chevalley, Zariski, Nagata and Serre. The method followed here was first set out by A. Grothendieck in a course at Harvard University in the autumn of 1961.

It follows from this definition that we have

$$\dim(\varnothing) = -\infty$$

(the supremum in $\overline{\mathbb{R}}$ of the empty subset being $-\infty$). If (X_α) is the family of irreducible components of X, we have

$$\dim(X) = \sup_\alpha \dim(X_\alpha) \tag{14.1.2.1}$$

since every chain of irreducible closed subsets of X is by definition contained in an irreducible component of X, and conversely these components are closed in X, so every irreducible closed subset of an X_α is an irreducible closed subset of X.

(14.1.3) Definition. We say that a topological space X is *equidimensional* if all its irreducible components have the same dimension (then equal to $\dim(X)$ by (14.1.2.1)).

(14.1.4) Proposition.

(i) *For every subset Y of a topological space X, we have* $\dim(Y) \leq \dim(X)$.

(ii) *If a topological space X is a finite union of closed subsets X_i, we have* $\dim(X) = \sup_i \dim(X_i)$.

Proof. For every irreducible closed subset Z of Y, the closure $\overline{Z}$ of Z in X is irreducible (0_{I}, 2.1.2) and $\overline{Z} \cap Y = Z$, whence (i). On the other hand, if $X = \bigcup_{i=1}^n X_i$, where the X_i are closed, every irreducible closed subset of X is contained in one of the X_i (0_{I}, 2.1.1), and consequently every chain of irreducible closed subsets of X is contained in one of the X_i; whence (ii). □

We deduce from (14.1.4, (i)) that for every $x \in X$ we can also write

$$\dim_x(X) = \lim_U \dim(U) \tag{14.1.4.1}$$

the limit being taken along the decreasing filtered set of open neighbourhoods of x in X.

[$0_{\text{IV-1}}$ | 7] **(14.1.5) Corollary.** *Let X be a topological space, x a point of X, U a neighbourhood of x, and Y_i ($1 \leq i \leq n$) closed subsets of U such that $x \in Y_i$ for every i and U is the union of the Y_i. Then we have*

$$\dim_x(X) = \sup_i\big(\dim_x(Y_i)\big). \tag{14.1.5.1}$$

Proof. It follows from (14.1.4, (ii)) that we have $\dim_x(X) = \inf_V(\sup_i(\dim(Y_i \cap V)))$ when V runs through the set of open neighbourhoods of x contained in U; likewise we have $\dim_x(Y_i) = \inf_V(\dim(Y_i \cap V))$ for every i. The corollary is therefore evident if

$$\sup_i\big(\dim_x(Y_i)\big) = +\infty\ ;$$

otherwise, there is an open neighbourhood $V_0 \subset U$ of x such that $\dim(Y_i \cap V) = \dim_x(Y_i)$ for $1 \leq i \leq n$ and for every $V \subset V_0$, whence the conclusion. □

(14.1.6) Proposition. *For every topological space X, we have* $\dim(X) = \sup_{x \in X} \dim_x(X)$.

Proof. It follows from the definition (14.1.2) and from Proposition (14.1.4) that $\dim_x(X) \leq \dim(X)$ for every $x \in X$. On the other hand, let $Z_0 \subset Z_1 \subset \cdots \subset Z_n$ be a chain of irreducible closed subsets of X, and let $x \in Z_0$; for every open subset $U \subset X$ containing x, $U \cap Z_i$ is irreducible (0_{I}, 2.1.6) and closed in U, and since we have $\overline{U \cap Z_i} = Z_i$ in X, the $U \cap Z_i$ are pairwise distinct; therefore we have $\dim(U) \geq n$, which completes the proof. □

(14.1.7) Corollary. *If (X_α) is an open covering of X, or a locally finite closed covering of X, we have* $\dim(X) = \sup_\alpha(\dim(X_\alpha))$.

Proof. If X_α is a neighbourhood of $x \in X$, we have $\dim_x(X) \leq \dim(X_\alpha)$, whence the first assertion. On the other hand, if the X_α are closed and if U is a neighbourhood of $x \in X$ that meets only finitely many of the sets X_α, we have

$$\dim_x(X) \leq \dim(U) = \sup_\alpha\big(\dim(U \cap X_\alpha)\big) \leq \sup_\alpha\big(\dim(X_\alpha)\big)$$

by (14.1.4), whence the second assertion. □

(14.1.8) Corollary. *Let X be a Noetherian Kolmogorov space (0_{I}, 2.1.3), and let F be the set of closed points of X. Then* $\dim(X) = \sup_{x \in F} \dim_x(X)$.

Proof. With the notation of the proof of (14.1.6), it suffices to remark that there exists a closed point in Z_0 (0_{I}, 2.1.3). □

(14.1.9) Proposition. *Let X be a non-empty Noetherian Kolmogorov space. For* $\dim(X) = 0$, *it is necessary and sufficient that X be finite and discrete.*

Proof. If a space X is separated (and *a fortiori* if X is a discrete space), the only irreducible closed sets of X consist of a single point, so $\dim(X) = 0$. Conversely, suppose that X is a Noetherian Kolmogorov space such that $\dim(X) = 0$; since every irreducible component of X contains a closed point (0_{I}, 2.1.3), it must reduce to that point. Since X has only finitely many irreducible components, it is finite and discrete. □

(14.1.10) Corollary. *Let X be a Noetherian Kolmogorov space. For a point $x \in X$ to be isolated, it is necessary and sufficient that* $\dim_x(X) = 0$.

Proof. The condition is evidently necessary (without any hypothesis on X). It is sufficient, since it implies that $\dim(U) = 0$ for an open neighbourhood U of x, and since U is a Noetherian Kolmogorov space, U is finite and discrete. □ [$0_{\mathrm{IV\text{-}1}}$ | 8]

(14.1.11) Proposition. *The function $x \mapsto \dim_x(X)$ is upper semi-continuous on X.*

Proof. It is clear that this function is upper semi-continuous at every point where it takes the value $+\infty$. So suppose $\dim_x(X) = n < +\infty$; then formula (14.1.4.1) shows that there exists an open neighbourhood U_0 of x such that $\dim(U) = n$ for every open neighbourhood $U \subset U_0$ of x. This being so, for every $y \in U_0$ and every open neighbourhood $V \subset U_0$ of y, we have $\dim(V) \leq \dim(U_0) = n$ (14.1.4); we therefore deduce from (14.1.4.1) that $\dim_y(X) \leq n$. □

(14.1.12) Remark. If X, Y are two topological spaces and $f : X \to Y$ is a continuous map, we can have $\dim(f(X)) > \dim(X)$; an example is obtained by taking for X a discrete space with 2 elements a, b, and for Y the set $\{a, b\}$ endowed with the topology for which the closed sets are $\varnothing$, $\{a\}$ and $\{a, b\}$; if $f : X \to Y$ is the identity map, we have $\dim(Y) = 1$ and $\dim(X) = 0$. Note that Y is the spectrum of a discrete valuation ring A, of which a is the unique closed point and b the generic point; if K and k are the field of fractions and the residue field of A, then X is the spectrum of the ring $k \times K$ and f is the continuous map corresponding to the homomorphism $(\varphi, \psi) : A \to k \times K$, where $\varphi : A \to k$ and $\psi : A \to K$ are the canonical homomorphisms (cf. IV, 5.4.3).

14.2 Codimension of a closed subset

(14.2.1) Definition. Given an irreducible closed subset Y of a topological space X, we call *combinatorial codimension* (or simply *codimension*) of Y in X, and denote by $\operatorname{codim}(Y, X)$, the supremum of the lengths of the chains of irreducible closed subsets of X of which Y is the smallest element. If Y is an arbitrary closed subset of X, we call *codimension of Y in X*, and again denote by $\operatorname{codim}(Y, X)$, the infimum of the codimensions in X of the irreducible components of Y. We say that X is *equicodimensional* if all the minimal irreducible closed subsets of X have the same codimension in X.

It follows from this definition that $\operatorname{codim}(\varnothing, X) = +\infty$, the infimum of the empty subset of $\overline{\mathbb{R}}$ being $+\infty$. If Y is closed in X and if (X_α) (resp. (Y_β)) is the family of irreducible components of X (resp. Y), every Y_β is contained in some X_α, and more generally every chain of irreducible closed subsets of X of which Y_β is the smallest element consists of subsets of some X_α; we therefore have

$$\operatorname{codim}(Y, X) = \inf_\beta \left(\sup_\alpha \big(\operatorname{codim}(Y_\beta, X_\alpha)\big) \right) \tag{14.2.1.1}$$

where for each β, α runs through the set of indices such that $Y_\beta \subset X_\alpha$.

(14.2.2) Proposition. *Let X be a topological space.*

(i) *If Φ is the set of irreducible closed subsets of X, we have*

$$\dim(X) = \sup_{Y \in \Phi} \big(\operatorname{codim}(Y, X)\big). \tag{14.2.2.1}$$

[$0_{IV\text{-}1}$ / 9]

(ii) *For every non-empty closed subset Y of X, we have*

$$\dim(Y) + \operatorname{codim}(Y, X) \leq \dim(X). \tag{14.2.2.2}$$

(iii) *If Y, Z, T are three closed subsets of X such that $Y \subset Z \subset T$, we have*

$$\operatorname{codim}(Y, Z) + \operatorname{codim}(Z, T) \leq \operatorname{codim}(Y, T). \tag{14.2.2.3}$$

(iv) *For a closed subset Y of X to satisfy $\operatorname{codim}(Y, X) = 0$, it is necessary and sufficient that Y contain an irreducible component of X.*

Proof. Assertions (i) and (iv) are immediate consequences of the definition (14.2.1). To prove (ii), we may restrict to the case where Y is irreducible, and then the formula follows from the definitions (14.1.1) and (14.2.1). Finally, to prove (iii), we may, by virtue of the definition (14.2.1), first restrict to the case where Y is irreducible; then $\operatorname{codim}(Y, Z) = \sup_\alpha(\operatorname{codim}(Y, Z_\alpha))$ for the irreducible components Z_α of Z containing Y; it is clear that $\operatorname{codim}(Y, T) \geq \operatorname{codim}(Y, Z)$, so the inequality is true if $\operatorname{codim}(Y, Z) = +\infty$; otherwise, there exists an α such that $\operatorname{codim}(Y, Z) = \operatorname{codim}(Y, Z_\alpha)$, and by virtue of (14.2.1) we may restrict to the case where Z too is irreducible; but then the inequality (14.2.2.3) is an evident consequence of the definition (14.2.1). □

(14.2.3) Proposition. *Let X be a topological space and Y a closed subset of X. For every open subset U of X, we have*

$$\operatorname{codim}(Y \cap U, U) \geq \operatorname{codim}(Y, X). \tag{14.2.3.1}$$

Moreover, for the two sides of (14.2.3.1) to be equal, it is necessary and sufficient that, if (Y_α) is the family of irreducible components of Y meeting U, we have $\operatorname{codim}(Y, X) = \inf_\alpha(\operatorname{codim}(Y_\alpha, X))$.

Proof. We know (0_{I}, 2.1.6) that $Z \mapsto \overline{Z}$ is a bijection from the set of irreducible closed subsets of U onto the set of irreducible closed subsets of X meeting U, and in particular maps the irreducible components of $Y \cap U$ to the irreducible components of Y meeting U; if Y_α is one of the latter, we therefore have $\operatorname{codim}(Y_\alpha, X) = \operatorname{codim}(Y_\alpha \cap U, U)$, and the proposition then follows from the definition (14.2.1). □

(14.2.4) Definition. Let X be a topological space, Y a closed subset of X, and x a point of X. We call *codimension of Y in X at the point x*, and denote by $\operatorname{codim}_x(Y, X)$, the number $\sup_U(\operatorname{codim}(Y \cap U, U))$, where U runs through the set of open neighbourhoods of x in X.

By virtue of (14.2.3), we can also write

$$\operatorname{codim}_x(Y, X) = \lim_U\big(\operatorname{codim}(Y \cap U, U)\big) \tag{14.2.4.1}$$

the limit being taken along the decreasing filtered set of open neighbourhoods of x in X. Note that we have

$$\operatorname{codim}_x(Y, X) = +\infty \quad \text{if} \quad x \in X - Y.$$

(14.2.5) Proposition. *If $(Y_i)_{1 \leq i \leq n}$ is a finite family of closed subsets of a topological space X, and Y is the union of this family, we have* [$0_{\mathrm{IV\text{-}1}}$ | 10]

$$\operatorname{codim}(Y, X) = \inf_i\big(\operatorname{codim}(Y_i, X)\big). \tag{14.2.5.1}$$

Proof. Indeed, every irreducible component of one of the Y_i is contained in an irreducible component of Y, and conversely every irreducible component of Y is also an irreducible component of one of the Y_i (0_{I}, 2.1.1); the conclusion therefore follows from the definition (14.2.1) and from the inequality (14.2.2.3). □

(14.2.6) Corollary. *Let X be a topological space and Y a locally Noetherian closed subspace of X.*

(i) *For every $x \in X$, there exist only finitely many irreducible components Y_i ($1 \leq i \leq n$) of Y containing x, and we have* $\operatorname{codim}_x(Y, X) = \inf_i(\operatorname{codim}(Y_i, X))$.

(ii) *The function $x \mapsto \operatorname{codim}_x(Y, X)$ is lower semi-continuous on X.*

Proof. Indeed, by hypothesis there is an open neighbourhood U_0 of x in X such that $Y \cap U_0$ is Noetherian, and therefore has only finitely many irreducible components, which are the traces on U_0 of irreducible components of Y; *a fortiori* there are only finitely many irreducible components Y_i ($1 \leq i \leq n$) of Y containing x, and, replacing U_0 by an open neighbourhood $U \subset U_0$ of x meeting none of the Y_j that do not contain x, we may suppose that the $Y_i \cap U$ are the irreducible components of $Y \cap U$; for every open neighbourhood $V \subset U$ of x in X, the $Y_i \cap V$ are then the irreducible components of $Y \cap V$, and (14.2.3) then shows that $\operatorname{codim}(Y_i, X) = \operatorname{codim}(Y_i \cap V, V)$, which proves (i). Moreover, for every $x' \in U$, the irreducible components of Y containing x' are among the Y_i, so $\operatorname{codim}_{x'}(Y, X) \geq \operatorname{codim}_x(Y, X)$, which proves (ii). □

14.3 The chain condition

(14.3.1) In a topological space X, we will say that a chain $Z_0 \subset Z_1 \subset \cdots \subset Z_n$ of irreducible closed subsets is *saturated* if there exists no irreducible closed subset Z' distinct from the Z_i and such that $Z_k \subset Z' \subset Z_{k+1}$ for some index k.

(14.3.2) Proposition. *Let X be a topological space such that, for any two irreducible closed subsets Y, Z of X with $Y \subset Z$, we have* $\operatorname{codim}(Y, Z) < +\infty$. *The following two conditions are equivalent:*

(a) *Two saturated chains of irreducible closed subsets of X having the same endpoints have the same length.*

(b) *If Y, Z, T are three irreducible closed subsets of X such that $Y \subset Z \subset T$, we have*

$$\operatorname{codim}(Y, T) = \operatorname{codim}(Y, Z) + \operatorname{codim}(Z, T). \tag{14.3.2.1}$$

Proof. It is immediate that a) implies b). Conversely, suppose that b) holds, and let us prove that if two saturated chains with the same endpoints have lengths m and $n \leq m$, we necessarily have $m = n$. We argue by induction on n, the proposition being evident for
[0IV-1 | 11] $n = 1$. So suppose $n > 1$, $n < m$, and let $Z_0 \subset Z_1 \subset \cdots \subset Z_n$ be a saturated chain such that there exists another saturated chain with endpoints Z_0, Z_n and of length m. Since $\operatorname{codim}(Z_0, Z_n) \geq m > n$ and $\operatorname{codim}(Z_0, Z_1) = 1$, it follows from b) that $\operatorname{codim}(Z_1, Z_n) = \operatorname{codim}(Z_0, Z_n) - 1 > n - 1$, which contradicts the induction hypothesis. □

When the conditions of (14.3.2) are satisfied, we say that X satisfies the *chain condition*, or also that it is a *catenary space*. Every closed subspace of a catenary space is clearly catenary.

(14.3.3) Proposition. *Let X be a Noetherian Kolmogorov space of finite dimension. The following conditions are equivalent:*

(a) *Any two maximal chains of irreducible closed subsets of X have the same length.*

(b) *X is equidimensional, equicodimensional and catenary.*

(c) *X is equidimensional, and for any two irreducible closed subsets Y, Z of X such that $Y \subset Z$, we have*

$$\dim(Z) = \dim(Y) + \operatorname{codim}(Y, Z). \tag{14.3.3.1}$$

(d) *X is equicodimensional, and for any two irreducible closed subsets Y, Z of X such that $Y \subset Z$, we have*

$$\operatorname{codim}(Y, X) = \operatorname{codim}(Y, Z) + \operatorname{codim}(Z, X). \tag{14.3.3.2}$$

Proof. The hypotheses on X imply that the endpoints of a maximal chain of irreducible closed subsets of X are necessarily a closed point and an irreducible component of X (0_{I}, 2.1.3); moreover, every saturated chain with endpoints Y, Z (with $Y \subset Z$) is contained in a maximal chain whose elements other than those of the given chain are either contained in Y or contain Z. These remarks immediately establish the equivalence of a) and b), and also prove that if a) holds, we have, for every irreducible closed subset Y of X,

$$\dim(Y) + \operatorname{codim}(Y, X) = \dim(X)\ ; \tag{14.3.3.3}$$

since (14.3.2.1) holds, we immediately deduce (14.3.3.1) and (14.3.3.2) from (14.3.3.3). Conversely, (14.3.3.1) implies (14.3.2.1), so (14.3.3.1) implies the chain condition by virtue of (14.3.2); moreover, by applying (14.3.3.1) to the case where Y is reduced to a closed point x of X and Z to an irreducible component of X, we obtain $\operatorname{codim}(\{x\}, X) = \dim(Z)$; we conclude that c) implies b). Likewise, (14.3.3.2) implies (14.3.2.1), hence the chain condition; moreover, with the same choice of Y and Z as above, (14.3.3.2) again implies $\operatorname{codim}(\{x\}, X) = \dim(Z)$, so (every irreducible component of X containing a closed point by virtue of (0_{I}, 2.1.3)) d) implies b). □

We say that a Noetherian Kolmogorov space is *biequidimensional* if it is of *finite dimension* and satisfies the equivalent conditions of (14.3.3).

(14.3.4) Corollary. *Let X be a biequidimensional Noetherian Kolmogorov space; then, for every closed point x of X and every irreducible component Z of X, we have*

$$\dim(X) = \dim(Z) = \operatorname{codim}(\{x\}, X) = \dim_x(X). \tag{14.3.4.1}$$

Proof. The last equality follows from the fact that if $Y_0 = \{x\} \subset Y_1 \subset \cdots \subset Y_m$ is a maximal chain of irreducible closed subsets of X and U is an open neighbourhood of x, the $U \cap Y_i$ are pairwise distinct irreducible closed subsets of U (since $\overline{U \cap Y_i} = Y_i$), whence $\dim(U) = \dim(X)$ by virtue of (14.1.4). □ [$0_{\text{IV-1}}$ | 12]

(14.3.5) Corollary. *Let X be a Noetherian Kolmogorov space; if X is biequidimensional, so is every union of irreducible components of X and every irreducible closed subset of X. Moreover, for every closed subset Y of X, we then have*

$$\dim(Y) + \operatorname{codim}(Y, X) = \dim(X). \tag{14.3.5.1}$$

Proof. Since every chain of irreducible closed subsets of X is contained in an irreducible component of X, the first assertion follows immediately from (14.3.3). Moreover, if X' is an irreducible closed subset of X, X' trivially satisfies the conditions (14.3.3, c)), whence the second assertion.

Finally, to prove (14.3.5.1), let us remark that we saw in the proof of (14.3.3) that this relation holds when Y is irreducible; if Y_i $(1 \leq i \leq m)$ are the irreducible components of Y, the one among the Y_i for which $\dim(Y_i)$ is largest is also the one for which $\operatorname{codim}(Y_i, X)$ is smallest; therefore (14.3.5.1) follows from the definitions of $\dim(Y)$ and of $\operatorname{codim}(Y, X)$. □

(14.3.6) Remark. The reader will notice that the proof of (14.3.2) applies to an arbitrary ordered set, the fact that we are dealing with irreducible closed subsets of a topological space playing no role in that proof. The same holds for the proof of (14.3.3) in an ordered set E such that for every $x \in E$ there exists a $z \leq x$ that is *minimal* in E, and in which the length of chains of elements of E is bounded.

§15 M-regular sequences and $\mathscr{F}$-regular sequences

15.1 M-regular sequences and M-quasi-regular sequences

[$0_{\text{IV-1}}$ | 12] **(15.1.1)** Let A be a ring, N an A-module; in what follows, we will write $N[T_1, \ldots, T_n]$, for short, for the graded A-module $N \otimes_A A[T_1, \ldots, T_n]$ (T_i indeterminates), where N is graded by the trivial graduation and $A[T_1, \ldots, T_n]$ by the total degree.

Let M be an A-module, f_i $(1 \leq i \leq n)$ elements of A, $\mathfrak{J} = \sum_{i=1}^n f_i A$ the ideal of A generated by the f_i, and let us equip M with the $\mathfrak{J}$-preadic filtration; we then define a *surjective graded homomorphism of graded A-modules*, of degree 0,

$$\varphi : (\operatorname{gr}_0(M))[T_1, \ldots, T_n] \to \operatorname{gr}_\bullet(M) \tag{15.1.1.1}$$

[$0_{\text{IV-1}}$ | 13] in the following way: if $\xi \in \operatorname{gr}_0(M)$ is the class mod $\mathfrak{J}M$ of an element $x \in M$, to the pair formed by ξ and a homogeneous polynomial $P[T_1, \ldots, T_n]$ of degree k, we associate the class mod $\mathfrak{J}^{k+1}M$ of $P(f_1, \ldots, f_n)x$; it is immediate that this class depends only on ξ and on P, and if S_k is the set of homogeneous polynomials of degree k in $A[T_1, \ldots, T_n]$, we have thus defined an A-linear map

$$\varphi_k : \operatorname{gr}_0(M) \otimes_A S_k \to \operatorname{gr}_k(M),$$

which is surjective by definition of $\mathfrak{J}^k M$.

We will say in what follows that an element $f \in A$ is *not a zero divisor in an A-module M* if the homothety $f_M : x \mapsto fx$ of M is injective.

(15.1.2) Lemma. *Let M be an A-module, f an element of A, and let us equip M with the (fA)-preadic filtration. If f is not a zero divisor in M, the canonical homomorphism defined in (15.1.1):*

$$\varphi : (M/fM)[T] \to \operatorname{gr}_\bullet(M) \tag{15.1.2.1}$$

is bijective. The converse is true if M is separated for the (fA)-preadic topology.

Proof. We have here $\operatorname{gr}_k(M) = f^k M / f^{k+1} M$; to say that φ is injective means that for all $x \in M$ and all k, the relation $f^k x \in f^{k+1} M$ implies $x \in fM$; it is clear that this is indeed the case if f is not a zero divisor in M. Conversely, note that the homothety $f_M : x \mapsto fx$

defines, by passing to quotients, homomorphisms $\mathrm{gr}_k(M) \to \mathrm{gr}_{k+1}(M)$, hence a graded homomorphism g of degree 1 of $\mathrm{gr}_\bullet(M)$ into itself; and to say that φ is injective also means that g is injective. If we further suppose the filtration of M separated, it follows that f_M is injective (Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 1 of th. 1). □

(15.1.3) Corollary. *Let A be a Noetherian ring, M a finitely generated A-module. For f to be not a zero divisor in M, it is necessary and sufficient that φ be bijective.*

Proof. We need only show that the condition is sufficient; to prove that f_M is injective, it suffices to show that for every prime ideal $\mathfrak{p}$ of A, the homothety of ratio $f' = f/1 \in A' = A_\mathfrak{p}$ in the $A_\mathfrak{p}$-module $M_\mathfrak{p} = M'$ is injective (Bourbaki, *Alg. comm.*, chap. II, § 3, no. 4, th. 1). Now $f'^k M'/f'^{k+1}M' = (f^k M/f^{k+1}M) \otimes_A A'$, and it is immediate that the canonical homomorphism $\varphi' : (M'/f'M')[T] \to \mathrm{gr}_\bullet(M')$ is equal to $\varphi \otimes 1_{A'}$; if φ is injective, so is φ' (**0**$_\mathbf{I}$, 1.3.2). We are thus reduced to the case where A is a Noetherian *local* ring, whose maximal ideal we denote by $\mathfrak{m}$. If $f \notin \mathfrak{m}$, then f is invertible and there is nothing to prove. If $f \in \mathfrak{m}$, we know that M is separated for the (fA)-preadic topology (**0**$_\mathbf{I}$, 7.3.5), and it suffices therefore to apply (15.1.2). □

(15.1.4) Definition. Let A be a ring, M an A-module. We say that an element $f \in A$ is *M-regular* (resp. *M-quasi-regular*) if f is not a zero divisor in M (resp. if the homomorphism (15.1.2.1) is bijective).

We have thus just shown that every M-regular element is M-quasi-regular, and that the converse is true if A is Noetherian and M a finitely generated A-module. When M is no longer assumed to be finitely generated, the converse can fail: for example, if A is a principal ideal domain that is not a field, K its field of fractions, and M the A-module K/A, we have $fM = M$ for all $f \neq 0$ in A, hence both sides of (15.1.2.1) reduce to 0, but f is then a zero divisor in M.

(15.1.5) Suppose now that M is equipped with a *filtration* (M_k) such that $M_0 = M$, [0$_{\text{IV-1}}$ | 14] and denote by $\mathrm{gr}_\bullet(M) = \bigoplus_{k\geq 0} M_k/M_{k+1}$ the associated graded A-module. The notations being those of (15.1.1), set, for all $k \geq 0$,

$$M'_k = M_k + \mathfrak{J}M_{k-1} + \cdots + \mathfrak{J}^{k-1}M_1 + \mathfrak{J}^k M_0. \tag{15.1.5.1}$$

It is clear that (M'_k) is a filtration on M. When $M_k = \mathfrak{Q}^k M$, where $\mathfrak{Q}$ is an ideal of A, the filtration (M'_k) is none other than the $(\mathfrak{J}+\mathfrak{Q})$-preadic filtration. We will again write $(\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J}))[T_1, \ldots, T_n]$ for the graded tensor product of graded A-modules (**II**, 2.1.2) $(\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J})) \otimes_A A[T_1, \ldots, T_n]$. We define a *surjective graded homomorphism of graded A-modules*, of degree 0,

$$\psi : (\mathrm{gr}_\bullet(M) \otimes_A (A/\mathfrak{J}))[T_1, \ldots, T_n] \to \mathrm{gr}'_\bullet(M) \tag{15.1.5.2}$$

in the following way: if $\alpha \in A/\mathfrak{J}$ is the class of an element $a \in A$, $\xi \in M_k/M_{k+1}$ the class of an element $x \in M_k$, and $P[T_1, \ldots, T_n]$ a homogeneous polynomial of degree h, we associate to the triplet (α, ξ, P) the class mod M'_{k+h+1} of $P(f_1, \ldots, f_n)ax$; one verifies immediately that this element depends only on ξ, α, and P, and this defines the surjective graded homomorphism (15.1.5.2), by virtue of the definition (15.1.5.1). One recovers the homomorphism (15.1.1.1) by considering the filtration on M such that $M_1 = 0$.

(15.1.6) Lemma. *We keep the notations of (15.1.5) and suppose $n = 1$, setting $f = f_1$. If f is $\mathrm{gr}_\bullet(M)$-regular, the homomorphism (15.1.5.2) is bijective.*

Proof. Let Q_k (resp. Q'_k) be the sub-A-module of elements of degree k in the first (resp. second) member of (15.1.5.2). We equip Q_k with the filtration

$$(Q_k)_i = \sum_{j\leq k-i} (\mathrm{gr}_{k-j}(M)\otimes_A (A/fA))T^j \tag{15.1.6.1}$$

so that $(Q_k)_0 = Q_k$ and $(Q_k)_{k+1} = 0$, and for this filtration, one has

$$\mathrm{gr}_i(Q_k) = (\mathrm{gr}_i(M)\otimes_A (A/fA))T^{k-i}.$$

We equip Q'_k with the filtration formed by $\psi((Q_k)_i) = (Q'_k)_i$. As these filtrations are *finite*, it suffices to prove that the homomorphisms $\psi_{ki} : \mathrm{gr}_i(Q_k) \to \mathrm{gr}_i(Q'_k)$ induced by ψ_k are injective (Bourbaki, *Alg. comm.*, chap. III, § 3, no. 8, cor. 1 of th. 1). Now $\mathrm{gr}_i(Q_k) = ((M_i/M_{i+1})\otimes_A (A/fA))T^{k-i}$; on the other hand, $(Q'_k)_{i+1}$ is the image of

$$M_k + fM_{k-1} + \cdots + f^{k-i-1}M_{i+1}$$

[$0_{\text{IV-1}}$ | 15] in M'_k/M'_{k+1}. We are thus led to write that, for $x \in M_i$, the relation

$$f^{k-i}x \in M_k + fM_{k-1} + \cdots + f^{k-i-1}M_{i+1} + M'_{k+1} \tag{15.1.6.2}$$

implies $x \in fM_i + M_{i+1}$. Now, the second member of (15.1.6.2) is contained in $M_{i+1} + M'_{k+1}$, and by virtue of (15.1.5.1), M'_{k+1} is contained in $M_{i+1} + f^{k+1-i}M$. The hypothesis on f implies that f is not a zero divisor in M/M_h for all h (Bourbaki, *loc. cit.*). The relation $f^{k-i}x \in f^{k+1-i}M + M_{i+1}$ thus implies (reasoning by induction) $x \in fM_i + M_{i+1}$. □

(15.1.7) Definition. Let $(f_i)_{1\leq i\leq n}$ be a sequence of elements of A. We say that it is *M-regular* if, for $1 \leq i \leq n$, f_i is $(M/(\sum_{1\leq j\leq i-1} f_jM))$-regular. We say that the sequence (f_i) is *M-quasi-regular* if the canonical homomorphism φ defined in (15.1.1.1) is bijective.

When $M = A$, we say simply "regular sequence" and "quasi-regular sequence".

(15.1.8) Proposition. *The notations being those of (15.1.5), suppose that the sequence $(f_i)_{1\leq i\leq n}$ is $\mathrm{gr}_\bullet(M)$-regular. Then the canonical homomorphism (15.1.5.2) is bijective.*

Proof. The proposition is none other than (15.1.6) for $n = 1$; let us reason by induction on n. Set $\mathfrak{J}'' = \sum_{i=1}^{n-1} f_iA$, so that $\mathfrak{J} = \mathfrak{J}'' + f_nA$, and let

$$M''_k = M_k + \mathfrak{J}''M_{k-1} + \cdots + \mathfrak{J}''^{k-1}M_1 + \mathfrak{J}''^kM_0;$$

one can then write

$$M'_k = M''_k + f_nM''_{k-1} + \cdots + f_n^{k-1}M''_1 + f_n^kM''_0.$$

Let us write $\mathrm{gr}''_\bullet(M)$ for the graded A-module associated to M filtered by the filtration (M''_k). One can write, up to canonical isomorphisms,

$$(\mathrm{gr}_\bullet(M)\otimes(A/\mathfrak{J}))\otimes_A A[T_1,\ldots,T_n] = (\mathrm{gr}_\bullet(M)\otimes(A/\mathfrak{J}''))[T_1,\ldots,T_{n-1}]\otimes(A/f_nA)\otimes_A A[T_n]$$

and by (15.1.5.2), ψ factorizes as

$$(\mathrm{gr}''_\bullet(M)\otimes_A (A/f_nA))[T_n] \to \mathrm{gr}'_\bullet(M) \tag{15.1.8.1}$$

and

$$((\mathrm{gr}_\bullet(M)\otimes(A/\mathfrak{J}''))[T_1,\ldots,T_{n-1}])\otimes(A/f_nA)\otimes_A A[T_n] \xrightarrow{\psi'\otimes 1} \mathrm{gr}''_\bullet(M)\otimes(A/f_nA)\otimes_A A[T_n]$$

where ψ' is the map (15.1.5.2) in which one replaces n by $n-1$, $\mathfrak{J}$ by $\mathfrak{J}''$, and $\mathrm{gr}'_\bullet(M)$ by $\mathrm{gr}''_\bullet(M)$. The induction hypothesis implies that ψ' is bijective, and it remains to see, by applying (15.1.6), that it suffices to show that f_n is $\mathrm{gr}''_\bullet(M)$-regular. But $\mathrm{gr}''_\bullet(M)$ identifies with $(\mathrm{gr}_\bullet(M)\otimes(A/\mathfrak{J}''))[T_1,\dots,T_{n-1}]$; by hypothesis, the homothety of ratio f_n in $\mathrm{gr}_\bullet(M)\otimes(A/\mathfrak{J}'')$ is injective; since $A[T_1,\dots,T_{n-1}]$ is a free A-module, it follows that f_n is $\mathrm{gr}''_\bullet(M)$-regular. □

(15.1.9) Proposition. *Let M be an A-module, $(f_i)_{1\leq i\leq n}$ a sequence of elements of A. If the sequence (f_i) is M-regular, it is M-quasi-regular. The converse is true when one supposes in addition that the A-modules M, M/f_1M, …, $M/(\sum_{1\leq i\leq n-1} f_iM)$ are separated for the $\mathfrak{J}$-preadic topology.*

Proof. The first assertion follows from (15.1.8), taking $M_1=0$, and then the homomorphism (15.1.5.2) reduces to (15.1.1.1). Conversely, suppose that the homomorphism φ of (15.1.1.1) is bijective. Note that if we set

$$\mathfrak{J}''=\sum_{i=1}^{n-1} f_iA,$$

and denote by $\mathrm{gr}''_\bullet(M)$ the graded A-module associated to M filtered by the $\mathfrak{J}''$-preadic filtration, φ factorizes as [$0_{\text{IV-1}}$ | 16]

$$(\mathrm{gr}''_\bullet(M)\otimes(A/f_nA))[T_n]\to \mathrm{gr}_\bullet(M) \tag{15.1.9.1}$$

and $\varphi'\otimes 1$, where φ' is the canonical homomorphism

$$(\mathrm{gr}''_0(M))[T_1,\dots,T_{n-1}]\to \mathrm{gr}''_\bullet(M).$$

As these two homomorphisms are surjective, they are both bijective if φ is supposed bijective, hence φ' is necessarily injective, and thus bijective since it is surjective. One can then reason by induction on n (the case $n=1$ follows from (15.1.2)), since on M, M/f_1M, …, $M/(\sum_{j=1}^{n-2} f_jM)$ the $\mathfrak{J}''$-preadic topology is finer than the $\mathfrak{J}$-preadic topology, and is thus separated. One sees therefore that the sequence $(f_i)_{1\leq i\leq n-1}$ is M-regular. On the other hand, let us show that if $y\in M/\mathfrak{J}''M$ is such that $f_n^k y\in f_n^{k+1}(M/\mathfrak{J}''M)$, then $y\in f_n(M/\mathfrak{J}''M)$. Indeed, if x is a representative of y, let us show that $f_n^k x\in\mathfrak{J}^{k+1}M$; our assertion will then follow from the fact that (15.1.9.1) is injective. The hypothesis implies $f_n^k x\in f_n^{k+1}M+\mathfrak{J}''M\subset\mathfrak{J}M$, whence, since φ is injective, $f_n^{k-1}x\in\mathfrak{J}^kM$; by induction, one thus obtains $x\in\mathfrak{J}M$, and finally $f_n^k x\in\mathfrak{J}^{k+1}M$. We finish the reasoning as in (15.1.2): on $M/\mathfrak{J}''M$, the $\mathfrak{J}$-preadic filtration is identical to the (f_nA)-preadic filtration, which is separated by hypothesis, and one concludes that the homothety of ratio f_n in $M/\mathfrak{J}''M$ is injective, which finishes showing that the sequence $(f_i)_{1\leq i\leq n}$ is M-regular. □

(15.1.10) Corollary. *With the notations of (15.1.9), suppose that for every finitely generated A-module N, $M\otimes_A N$ is separated for the $\mathfrak{J}$-preadic topology. Then, for the sequence (f_i) to be M-regular, it is necessary and sufficient that it be M-quasi-regular.*

One will note that the hypothesis of (15.1.10) implies that, if the sequence $(f_i)_{1\leq i\leq n}$ is M-regular, so is the sequence $(f_{\sigma(i)})$ for every permutation σ of the interval $[1,n]$.

(15.1.11) Corollary. *Let A be a Noetherian ring, M a finitely generated A-module, $(f_i)_{1\leq i\leq n}$ a finite sequence of elements contained in the radical of A. Then, for the sequence (f_i) to be M-regular, it is necessary and sufficient that it be M-quasi-regular.*

Proof. This is a particular case of (15.1.10), since every finitely generated A-module is then separated for the $\mathfrak{J}$-preadic topology (**0**$_{\mathbf{I}}$, 7.3.5). □

(15.1.12) Remarks.

(i) When A is a Noetherian local ring, M a finitely generated A-module, and when the f_i are contained in the maximal ideal of A, the notion of M-regular sequence was introduced by J.-P. Serre under the name of *M-suite* [17].

(ii) Even if A is Noetherian and $M = A$, a sequence (f, g) of two elements of A that is quasi-regular is not necessarily regular. For example, the sequence $(0, 1)$ is quasi-regular, since then $\mathfrak{J} = fA + gA = A$, hence $\mathrm{gr}_\bullet(A) = 0$; but if $A \neq 0$ it is not regular, since 0 is not A-regular. One will note however that in this case the sequence $(1, 0)$ is regular, since 1 is not a zero divisor in A, and since $A/A = 0$, 0 is not a zero divisor in this module (cf. (15.1.1)).

[$0_{\text{IV-1}}$ | 17]

(iii) In (15.1.6), one cannot in general replace the hypothesis that f is $\mathrm{gr}_\bullet(M)$-regular by the hypothesis that it is $\mathrm{gr}_\bullet(M)$-quasi-regular. To see this, let us take the example (15.1.4) where A is a principal ideal domain with field of fractions $K \neq A$, and let us take $M = K$, the filtration (M_k) of M being defined by $M_0 = M = K$, $M_1 = A$, $M_k = 0$ for $k \geq 2$, whence $\mathrm{gr}_0(M) = K/A$, $\mathrm{gr}_1(M) = A$, $\mathrm{gr}_k(M) = 0$ for $k \geq 2$. If $f \neq 0$ in A, one sees that f is not $\mathrm{gr}_\bullet(M)$-regular, but since $f^k \mathrm{gr}_\bullet(M)/f^{k+1}\mathrm{gr}_\bullet(M) = f^kA/f^{k+1}A$, it is immediate that the homomorphism (15.1.2.1) (where M is replaced by $\mathrm{gr}_\bullet(M)$) is injective, hence f is $\mathrm{gr}_\bullet(M)$-quasi-regular. But with the notations of (15.1.6), one then has $M'_k = K$ for all $k \geq 0$, hence $\mathrm{gr}'_\bullet(M) = 0$, while the first member of (15.1.5.2) is not reduced to 0.

(15.1.13) Proposition. *Let A be a ring, M, N two A-modules, $(f_i)_{1\leq i\leq n}$ a sequence of elements of A. If the sequence (f_i) is M-regular and if N is a flat A-module, then the sequence (f_i) is $(M\otimes_A N)$-regular. The converse is true if N is a faithfully flat A-module.*

Proof. Indeed (without any hypothesis on N), $(M\otimes_A N)/(\sum_{j=1}^{i-1} f_j(M\otimes_A N))$ is isomorphic to $(M/(\sum_{j=1}^{i-1} f_jM))\otimes_A N$; it suffices then to apply (**0**$_{\mathbf{I}}$, 6.1.1) and (**0**$_{\mathbf{I}}$, 6.4.1) to the homothety of ratio f_i in $M/(\sum_{j=1}^{i-1} f_jM)$. □

(15.1.14) Corollary. *Let A be a ring, M an A-module, $(f_i)_{1\leq i\leq n}$ a finite sequence of elements of A. Let $\rho : A \to B$ be a ring homomorphism, $M' = M_{(B)} = M \otimes_A B$, $f'_i = \rho(f_i)$ for $1 \leq i \leq n$. If B is a flat A-module and if the sequence (f_i) is M-regular, then the sequence (f'_i) is M'-regular; the converse is true if B is a faithfully flat A-module.*

Proof. Indeed, $M'/(\sum_{j=1}^{i-1} f'_jM')$ identifies with $(M/(\sum_{j=1}^{i-1} f_jM))\otimes_A B$, and the homothety of ratio f'_i in the B-module $M'/(\sum_{j=1}^{i-1} f'_jM')$ is identified with the homothety of ratio f_i in the A-module $(M/(\sum_{j=1}^{i-1} f_jM))\otimes_A B$; the assertion thus follows from (15.1.13). □

(15.1.15) Proposition. *Let A be a ring, B a commutative A-algebra, $(f_i)_{1\leq i\leq n}$ a finite sequence of elements of B, M a B-module. Suppose that the sequence (f_i) is M-regular and that each of the A-modules $M/(\sum_{j=1}^{i-1} f_jM)$ $(1 \leq i \leq n+1)$ is flat. Then, for every ring homomorphism $\rho : A \to A'$, setting $B' = B \otimes_A A'$, $M' = M \otimes_A A'$, and $f'_i = f_i \otimes 1$ $(1 \leq i \leq n)$, the sequence (f'_i) is M'-regular and the A'-modules $M'/(\sum_{j=1}^{i-1} f'_jM')$ $(1 \leq i \leq n+1)$ are flat.*

Proof. Consider the exact sequence (by hypothesis)

$$0 \to M \xrightarrow{f_1} M \to M/f_1M \to 0$$

(the arrow $M \xrightarrow{f_1} M$ being the homothety of ratio f_1 in M). The hypothesis that M/f_1M is A-flat implies that the sequence

$$0 \to M \otimes_A A' \xrightarrow{f_1 \otimes 1} M \otimes_A A' \to (M/f_1M) \otimes_A A' \to 0$$

is exact (**0**$_{\mathbf{I}}$, 6.1.2). This shows that the homothety of ratio f'_1 in M' is injective. [0$_{\text{IV-1}}$ | 18]

Set then, for $1 \leq i \leq n-1$, $M_i = M/(\sum_{j=1}^{i} f_jM)$, $M'_i = M'/(\sum_{j=1}^{i} f'_jM')$; we have $M'_i = M_i \otimes_A A'$, $M_i/f_{i+1}M_i = M_{i+1}$, $M'_i/f'_{i+1}M'_i = M'_{i+1}$; it suffices to replace M and f_1 by M_i and f_{i+1} to conclude that the homothety of ratio f'_{i+1} in M'_i is injective, by reason of the flatness of $M_i/f_{i+1}M_i$. The last assertion follows from (**0**$_{\mathbf{I}}$, 6.2.1). □

(15.1.16) Proposition. *Let A, B be two Noetherian local rings, k the residue field of A, $\varphi : A \to B$ a local homomorphism, M a finitely generated B-module. Let $(f_i)_{1\leq i\leq n}$ be a sequence of elements of the maximal ideal of B, and for each i, let g_i be the image of f_i in $B \otimes_A k$. The following conditions are equivalent:*

a) The sequence (f_i) is M-regular and the quotients $M_i = M/(\sum_{j=1}^{i} f_jM)$ are flat A-modules for $1 \leq i \leq n$.

b) The sequence (f_i) is M-regular and the A-module M_n is flat.

c) The A-module M is flat and the sequence $(g_i)_{1\leq i\leq n}$ is $(M \otimes_A k)$-regular.

d) The A-module M is flat, and for every ring homomorphism $\rho : A \to A'$, if we set $B' = B \otimes_A A'$, $M' = M \otimes_A A'$, $f'_i = f_i \otimes 1$ $(1 \leq i \leq n)$, the sequence (f'_i) is M'-regular.

Proof. It is clear that a) implies b); to show that b) implies d), it suffices, by virtue of (15.1.15), to show that b) implies that the M_i are flat A-modules for $0 \leq i \leq n-1$ (setting $M_0 = M$). As $M_{i+1} = M_i/f_{i+1}M_i$, we are reduced, by descending induction, to proving that if h is an element of the maximal ideal of B such that the homothety of ratio h in M is injective and M/hM is a flat A-module, then M is a flat A-module; but this is none other than (**0**$_{\mathbf{III}}$, 10.2.7). It is clear that c) is a particular case of d) obtained by taking $A' = k$. It thus remains to prove that c) implies a). As M is a flat A-module and a finitely generated B-module, it follows from c) and from (**0**$_{\mathbf{III}}$, 10.2.4) that the homothety of ratio f_1 in M is injective and that its cokernel $M/f_1M = M_1$ is a flat A-module. Let us reason by induction on i and suppose shown that M_i is a flat A-module; as the homothety of ratio g_{i+1} in $M_i \otimes_A k$ is injective by hypothesis, it follows again from (**0**$_{\mathbf{III}}$, 10.2.4) that the homothety of ratio f_{i+1} in M_i is injective and that $M_i/f_{i+1}M_i = M_{i+1}$ is a flat A-module, which finishes the proof. One will note that the proof that c) implies a) does not use the fact that the f_i belong to the maximal ideal of B. □

(15.1.17) Corollary. *The hypotheses on A and B being those of (15.1.16), let M be a finitely generated B-module, flat over A, R a sub-B-module of M such that $N = M/R$ is a flat A-module. Let $(f_i)_{1\leq i\leq n}$ be a sequence of elements of the maximal ideal of B having the following properties:*

(i) $f_i M \subset R$ *for* $1 \leq i \leq n$.

(ii) If g_i *is the image of* f_i *in* $B \otimes_A k$, *the sequence* $(g_i)_{1 \leq i \leq n}$ *is* $(M \otimes_A k)$*-regular.*

(iii) The sum of the sub-$(B \otimes_A k)$*-modules* $g_i(M \otimes_A k)$ *of* $M \otimes_A k$ *is the image of* $R \otimes_A k$ *in* $M \otimes_A k$ *(equal to the kernel of the canonical homomorphism* $M \otimes_A k \to N \otimes_A k$*).*

Then the sequence (f_i) *is* M*-regular and* $R = \sum_{i=1}^{n} f_i M$.

Proof. As N is a flat A-module, it follows from the exactness of the sequence $0 \to R \to M \to N \to 0$ that the sequence $0 \to R \otimes_A k \to M \otimes_A k \to N \otimes_A k \to 0$ is exact ($\mathbf{0_I}$, 6.1.2); we thus have $R \otimes_A k = \sum g_i(M \otimes_A k)$. As M is a finitely generated B-module and B is Noetherian, R is also a finitely generated B-module, whence $R = \sum f_i M$ by Nakayama's lemma, since the f_i belong to the maximal ideal of B. □

[0IV-1 | 19]

(15.1.18) Lemma. *Let* A *be a ring,* M *an* A*-module equipped with a separated and exhaustive filtration* $(M_k)_{k \geq 0}$, *and let* $f \in A$ *be a* $\mathrm{gr}_\bullet(M)$*-regular element. Then:*

(i) f *is* M*-regular.*

(ii) For all k, *one has* $M_k \cap fM = fM_k$, *and the canonical image* M'_k *of* M_k *in* $M' = M/fM$ *is thus canonically isomorphic to* M_k/fM_k.

(iii) The sequence

$$0 \to M_{k+1}/fM_{k+1} \to M_k/fM_k \to \mathrm{gr}_k(M)/f \cdot \mathrm{gr}_k(M) \to 0$$

is exact, and if one equips M' *with the quotient filtration* (M'_k), $\mathrm{gr}_\bullet(M')$ *is thus canonically isomorphic to* $\mathrm{gr}_\bullet(M)/f \cdot \mathrm{gr}_\bullet(M)$.

Proof. Assertion (i) follows from the hypothesis on f and from Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 1 of th. 1. As $\mathrm{gr}_\bullet(M/M_k)$ is a direct factor of $\mathrm{gr}_\bullet(M)$, f is $\mathrm{gr}_\bullet(M/M_k)$-regular for every k, hence (M/M_k)-regular by (i), which establishes (ii). To prove (iii), it suffices to see that the map $M_{k+1}/fM_{k+1} \to M_k/fM_k$ is injective: now, if $x \in M_{k+1}$ is such that $x \in fM_k$, it follows from (ii) that $x \in fM_{k+1}$, which finishes proving the lemma. □

(15.1.19) Proposition. *Let* A *be a ring,* M *an* A*-module equipped with a filtration* $(M_k)_{k \geq 0}$ *such that* $M_0 = M$, $(f_i)_{1 \leq i \leq n}$ *a* $\mathrm{gr}_\bullet(M)$*-regular sequence of elements of* A. *Suppose in addition that, for* $0 \leq i \leq n-1$, *the quotient filtration of* (M_k) *on* $M/(\sum_{j \leq i} f_j M)$ *is separated. Then the sequence* (f_i) *is* M*-regular, and if one sets* $M' = M/(\sum_{i \leq n} f_i M)$ *and equips* M' *with the quotient filtration of* (M_k), $\mathrm{gr}_\bullet(M')$ *is canonically isomorphic to* $\mathrm{gr}_\bullet(M)/(\sum_{i \leq n} f_i \,\mathrm{gr}_\bullet(M))$.

Proof. For $n = 1$, the proposition follows from the lemma (15.1.18). Let us reason by induction on n, setting $N = M/(\sum_{i \leq n-1} f_i M)$ and denoting by (N_k) the quotient filtration of (M_k) on N, which is separated by hypothesis; moreover, $\mathrm{gr}_\bullet(N)$ is isomorphic to

$$\mathrm{gr}_\bullet(M)/\Big(\sum_{i \leq n-1} f_i \,\mathrm{gr}_\bullet(M)\Big).$$

By hypothesis, f_n is thus $\mathrm{gr}_\bullet(N)$-regular, and it follows from the lemma (15.1.18) applied to N that f_n is N-regular and $\mathrm{gr}_\bullet(M')$ is isomorphic to $\mathrm{gr}_\bullet(N)/f_n \,\mathrm{gr}_\bullet(N)$, which proves the proposition. □

The proposition (15.1.19) will apply in particular for filtrations satisfying one or the other of the following hypotheses:

1° The filtration (M_k) is finite and separated (since this implies $M_k = 0$ for k large enough);

2° A is a Noetherian ring, $\mathfrak{J}$ an ideal contained in the radical of A, M a finitely generated A-module, and (M_k) the $\mathfrak{J}$-preadic filtration (**0**$_{\mathbf{I}}$, 7.3.5).

(15.1.20) Corollary. *Let A be a ring, M an A-module, $(f_i)_{1\leq i\leq n}$ an M-regular sequence of elements of A. Then, for any integers $\nu_i \geq 1$, the sequence $(f_i^{\nu_i})$ is M-regular, and $M/(\sum_{i\leq n} f_i^{\nu_i} M)$ has a composition series whose quotients are isomorphic to $M/(\sum_{i\leq n} f_i M)$.* [0$_{IV\text{-}1}$ / 20]

Proof. Let us reason by induction on n; for $n = 1$ the assertions are immediate since $f^j M/f^{j+1}M$ is isomorphic to M/fM, the homothety of ratio f in M being injective by hypothesis. Set then $N = M/(\sum_{i\leq n-1} f_i^{\nu_i} M)$; by the induction hypothesis, N admits a finite filtration (N_k) for which $\mathrm{gr}_k(N)$ are isomorphic to $M/(\sum_{i\leq n-1} f_i M)$; by hypothesis f_n is thus $\mathrm{gr}_\bullet(N)$-regular; it follows by (15.1.19) that f_n is N-regular. Applying the case $n = 1$ proved at the start, one concludes that $f_n^{\nu_n}$ is N-regular and that $N/f_n^{\nu_n}N$ admits a composition series whose quotients are isomorphic to N/f_nN; but for the filtration of N/f_nN given by the quotient filtration of (N_k), $\mathrm{gr}_k(N/f_nN)$ is isomorphic to $\mathrm{gr}_k(N)/f_n\,\mathrm{gr}_k(N)$ by (15.1.19) for all k, hence to $M/(\sum_{i\leq n} f_i M)$, which proves the corollary. □

(15.1.21) Proposition. *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, M a finitely generated B-module, $(f_i)_{1\leq i\leq n}$ an A-regular sequence of elements of the maximal ideal of A. The following properties are equivalent:*

a) M is a flat A-module.

b) If $\mathfrak{J}$ is the ideal $\sum_{i\leq n} f_i A$, $M/\mathfrak{J}M$ is a flat $A/\mathfrak{J}$-module and the sequence (f_i) is M-regular.

Proof. The fact that a) implies b) follows from (15.1.13) and from (**0**$_{\mathbf{III}}$, 10.2.2). Conversely, if the sequence (f_i) is M-regular, it is M-quasi-regular (15.1.9), hence the homomorphism (15.1.1.1) is bijective. But as the sequence $(f_i)_{1\leq i\leq n}$ is also supposed A-regular, it is A-quasi-regular (15.1.9), and the corresponding canonical homomorphism $(A/\mathfrak{J})[T_1, \ldots, T_n] \to \mathrm{gr}_\bullet(A)$ is bijective. One concludes that the canonical morphism (**0**$_{\mathbf{III}}$, 10.1.1.2)

$$\mathrm{gr}_0(M) \otimes_{A/\mathfrak{J}} \mathrm{gr}_\bullet(A) \to \mathrm{gr}_\bullet(M)$$

is bijective. The conclusion then follows from (**0**$_{\mathbf{III}}$, 10.2.2), the f_i being in the maximal ideal of A and the homomorphism φ being local. □

15.2 $\mathscr{F}$-regular sequences

(15.2.1) Let X be a ringed space, $\mathscr{F}$ an $\mathscr{O}_X$-Module, f_i $(1 \leq i \leq n)$ a sequence of sections of $\mathscr{O}_X$ over X, $\mathscr{J}$ the Ideal of $\mathscr{O}_X$ generated by the f_i (image of $\mathscr{O}_X^n$ by the homomorphism $\mathscr{O}_X^n \to \mathscr{O}_X$ defined canonically by the f_i (**0**$_{\mathbf{I}}$, 5.1.1)). The sub-$\mathscr{O}_X$-Modules $\mathscr{J}^k\mathscr{F}$ define a *filtration* on $\mathscr{F}$, and one sets further $\mathrm{gr}_k(\mathscr{F}) = \mathscr{J}^k\mathscr{F}/\mathscr{J}^{k+1}\mathscr{F}$;

if S_k is the set of homogeneous polynomials of total degree k in the ring $\mathbf{Z}[T_1, \ldots, T_n]$, S_k can be considered as a simple sheaf on X, and one defines as in (15.1.1) a canonical homomorphism

$$\varphi_k : \mathrm{gr}_0(\mathscr{F}) \otimes_{\mathbf{Z}} S_k \to \mathrm{gr}_k(\mathscr{F}) \tag{15.2.1.1}$$

[$0_{\text{IV-1}}$ | 21] in the following way: for every open set U of X (or of a base of the topology of X), one considers the homomorphism (15.1.1.1)

$$\varphi_{k,U} : (\mathrm{gr}_0(\Gamma(U, \mathscr{F}))) \otimes_{\mathbf{Z}} S_k \to \mathrm{gr}_k(\Gamma(U, \mathscr{F}))$$

defined by the n sections $f_i|U \in \Gamma(U, \mathscr{O}_X)$, the $\Gamma(U, \mathscr{O}_X)$-module $\Gamma(U, \mathscr{F})$ being filtered by the submodules $(\Gamma(U, \mathscr{J}))^k \Gamma(U, \mathscr{F})$. The $\mathscr{O}_X$-Module $\mathrm{gr}_k(\mathscr{F})$ being associated to the presheaf $U \mapsto \mathrm{gr}_k(\Gamma(U, \mathscr{F}))$ for all k, the $\varphi_{k,U}$ define the homomorphism of $\mathscr{O}_X$-Modules (15.2.1.1). By virtue of the exactness properties of inductive limits of modules and their commutation with tensor products, it follows from the above that for all $x \in X$, the homomorphism $(\varphi_k)_x$ of the stalks of the two members of (15.2.1.1) at the point x identifies with the homomorphism of (15.1.1)

$$\mathrm{gr}_0(\mathscr{F}_x) \otimes_{\mathbf{Z}} S_k \to \mathrm{gr}_k(\mathscr{F}_x) \tag{15.2.1.2}$$

defined by the sequence $((f_i)_x)_{1 \leq i \leq n}$ of elements of $\mathscr{O}_x$.

(15.2.2) The notations being those of (15.2.1), we say that the sequence $(f_i)_{1 \leq i \leq n}$ is *$\mathscr{F}$-regular* if, denoting by $f_j\mathscr{F}$ the sub-$\mathscr{O}_X$-Module of $\mathscr{F}$ that is the image of the endomorphism of $\mathscr{F}$ defined by f_j, the endomorphism of $\mathscr{F}/(\sum_{j=1}^{i-1} f_j\mathscr{F})$ defined by f_i is *injective* for $1 \leq i \leq n$; we say that the sequence (f_i) is *$\mathscr{F}$-quasi-regular* if the homomorphisms (15.2.1.1) are injective. It follows from these definitions and the remarks of (15.2.1) that for the sequence (f_i) to be $\mathscr{F}$-regular (resp. $\mathscr{F}$-quasi-regular), it is necessary and sufficient that, for all $x \in X$, the sequence $((f_i)_x)_{1 \leq i \leq n}$ be $\mathscr{F}_x$-regular (resp. $\mathscr{F}_x$-quasi-regular). Every $\mathscr{F}$-regular sequence is thus $\mathscr{F}$-quasi-regular (15.1.9); the converse is true if $\mathscr{F}$ is an $\mathscr{O}_X$-Module *of finite type*, if the $\mathscr{O}_x$ are *Noetherian* rings for all $x \in X$, and if moreover the $(f_i)_x$ belong to the *radical* of $\mathscr{O}_x$ for all $x \in X$ (15.1.11).

If $X = \mathrm{Spec}(A)$ is an affine scheme, and $\mathscr{F} = \widetilde{M}$, it follows from (**I**, 1.3) that for the sequence (f_i) to be $\mathscr{F}$-regular (resp. $\mathscr{F}$-quasi-regular), it is necessary and sufficient that it be M-regular (resp. M-quasi-regular).

When $\mathscr{F} = \mathscr{O}_X$, one omits the mention of $\mathscr{F}$ in the preceding definitions.

(15.2.3) Remark. When $X = \mathrm{Spec}(A)$ and $\mathfrak{J} = \sum_{i=1}^n f_i A$, the sequence (f_j) is quasi-regular for *every* A-module M in every open set U not meeting $V(\mathfrak{J})$, since for every point $x \in U$, $\mathfrak{J}_x = \mathscr{O}_x$ and the two members of (15.2.1.2) are zero. The notion of $\widetilde{M}$-regular sequence is thus of interest only in a neighbourhood of the points of $V(\mathfrak{J})$.

(15.2.4) Proposition. *Let X be a ringed space, $\mathscr{F}$ a coherent $\mathscr{O}_X$-Module, x a point of X, $(f_i)_{1 \leq i \leq n}$ a sequence of elements of $\Gamma(X, \mathscr{O}_X)$. If the sequence $((f_i)_x)_{1 \leq i \leq n}$ is $\mathscr{F}_x$-regular, there exists an open neighbourhood U of x such that the sequence $(f_i|U)_{1 \leq i \leq n}$ is $(\mathscr{F}|U)$-regular.*

Proof. Indeed, for $1 \leq i \leq n$, the $\mathscr{O}_X$-Module $\mathscr{F}/(\sum_{j=1}^{i-1} f_j\mathscr{F})$ is coherent (**0**$_{\mathbf{I}}$, 5.3.4), hence so is the kernel of the endomorphism of this $\mathscr{O}_X$-Module defined by f_i (**0**$_{\mathbf{I}}$, 5.3.4); as the stalk of this kernel at the point x is zero, the same holds for its restriction to a neighbourhood of x (**0**$_{\mathbf{I}}$, 5.2.2). □

(15.2.5) Proposition. *Let $u = (\psi, \theta) : X \to Y$ be a flat morphism of ringed spaces (**0**$_{\mathbf{I}}$, 6.7.1); let $\mathscr{F}$ be an $\mathscr{O}_Y$-Module, $\mathscr{G} = u^*(\mathscr{F})$, $(f_i)_{1\leq i\leq n}$ a sequence of elements of $\Gamma(Y, \mathscr{O}_Y)$, $(g_i)_{1\leq i\leq n}$ the sequence of their images $g_i = \theta(f_i) \in \Gamma(Y, u_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X)$. If the sequence (f_i) is $\mathscr{F}$-regular, the sequence (g_i) is $\mathscr{G}$-regular. The converse is true if u is a faithfully flat morphism (**0**$_{\mathbf{I}}$, 6.7.8).* [0$_{IV\text{-}1}$ | 22]

Proof. Let x be a point of X, $y = u(x) = \psi(x)$; we have

$$\mathscr{G}_x = \psi_x^*(\mathscr{F}_y) \otimes_{\psi_x^*(\mathscr{O}_y)} \mathscr{O}_x, \qquad \text{and} \qquad (g_i)_x = \theta_x^{\#}(\psi_x^*((f_i)_y));$$

as $\theta_x^{\#} : \psi_x^*(\mathscr{O}_y) \to \mathscr{O}_x$ makes $\mathscr{O}_x$ a flat $\psi_x^*(\mathscr{O}_y)$-module, and since the functor ψ^* is exact, the first assertion follows from the corresponding assertion of (15.1.14); the same holds for the second, taking into account the fact that u being faithfully flat means that ψ is surjective and that $\theta_x^{\#}$ makes $\mathscr{O}_x$ a faithfully flat $\psi_x^*(\mathscr{O}_y)$-module. □

§16 Dimension and depth of Noetherian local rings

16.1 Dimension of a ring

(16.1.1) We call the *dimension* (or *Krull dimension*) of a ring A and denote by $\dim \mathrm{A}$ the (combinatorial) dimension of its spectrum Spec(A) (14.2.1); as the irreducible closed subsets of Spec(A) are the V($\mathfrak{p}$), where $\mathfrak{p}$ is a prime ideal of A (Bourbaki, *Alg. comm.*, chap. II, § 4, n° 3, cor. 1 of prop. 14), it amounts to saying that dim(A) is *the upper bound of the lengths of chains* (14.1.1)

$$\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_n$$

of *prime ideals* of A. If $\mathrm{A} \neq 0$, we have $\dim \mathrm{A} \geq 0$. A nonzero Artinian ring (in particular a field) is of dimension 0 (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 7); a Dedekind ring that is not a field (in particular $\mathbf{Z}$ or a polynomial ring $k[\mathrm{T}]$ over a field k) is of dimension 1 (Bourbaki, *Alg. comm.*, chap. VII, § 2). A Noetherian ring is not necessarily of finite dimension [30]. If $(\mathfrak{p}_\alpha)$ is the family of minimal prime ideals of A, we have (14.1.2.1)

$$\dim(\mathrm{A}) = \sup_\alpha(\dim(\mathrm{A}/\mathfrak{p}_\alpha)). \tag{16.1.1.1}$$

(16.1.2) For every ideal $\mathfrak{a}$ of A, the prime ideals of $\mathrm{A}/\mathfrak{a}$ correspond bijectively to the prime ideals of A containing $\mathfrak{a}$, hence

$$\dim(\mathrm{A}/\mathfrak{a}) \leq \dim(\mathrm{A}). \tag{16.1.2.1}$$

If in addition $\mathfrak{a}$ *is not contained in any minimal prime ideal* $\mathfrak{p}_\alpha$ of A, every chain of prime ideals of A containing $\mathfrak{a}$ can be completed by one of the $\mathfrak{p}_\alpha$, hence

$$1 + \dim(\mathrm{A}/\mathfrak{a}) \leq \dim(\mathrm{A}). \tag{16.1.2.2}$$

(16.1.3) If S is a multiplicative subset of A, the prime ideals of $\mathrm{S}^{-1}\mathrm{A}$ correspond bijectively to the prime ideals of A not meeting S, hence [0$_{\text{IV-1}}$ | 23]

$$\dim(\mathrm{S}^{-1}\mathrm{A}) \leq \dim(\mathrm{A}). \tag{16.1.3.1}$$

For every prime ideal $\mathfrak{p}$ of A, we have, by definition (14.2.1)

$$\dim(\mathrm{A}_{\mathfrak{p}}) = \operatorname{codim}(\mathrm{V}(\mathfrak{p}), \operatorname{Spec}(\mathrm{A})). \tag{16.1.3.2}$$

This number is also called the *height* of the prime ideal $\mathfrak{p}$ and denoted $\operatorname{ht}(\mathfrak{p})$. More generally, for every ideal $\mathfrak{a}$ of A, we call the *height* of $\mathfrak{a}$ the number

$$\operatorname{ht}(\mathfrak{a}) = \operatorname{codim}(\mathrm{V}(\mathfrak{a}), \operatorname{Spec}(\mathrm{A})). \tag{16.1.3.3}$$

If $(\mathfrak{p}_\lambda)$ is the family of minimal prime ideals among those containing $\mathfrak{a}$, we have then (14.2.1)

$$\operatorname{ht}(\mathfrak{a}) = \inf_{\lambda}(\operatorname{ht}(\mathfrak{p}_\lambda)). \tag{16.1.3.4}$$

We evidently have

$$\dim(\mathrm{A}) = \sup_{\mathfrak{m}}(\dim(\mathrm{A}_{\mathfrak{m}})) \tag{16.1.3.5}$$

where $\mathfrak{m}$ ranges over the set of maximal ideals of A.

(16.1.4) For every prime ideal $\mathfrak{p}$ of A, we have (14.2.2.2)

$$\dim(\mathrm{A}_{\mathfrak{p}}) + \dim(\mathrm{A}/\mathfrak{p}) \leq \dim \mathrm{A}. \tag{16.1.4.1}$$

We say that A is *catenary* (resp. *equidimensional*, *equicodimensional*, *biequidimensional*) when $\operatorname{Spec}(\mathrm{A})$ is catenary (resp. equidimensional, equicodimensional, biequidimensional). When A is Noetherian and biequidimensional, the two members of (16.1.4.1) are equal for every prime ideal $\mathfrak{p}$ of A (14.3.5).

For every ideal $\mathfrak{a}$ of A, the prime ideals of $\mathrm{A}/\mathfrak{a}$ correspond bijectively to the prime ideals of A containing $\mathfrak{a}$, hence, *if* A *is catenary, so is* $\mathrm{A}/\mathfrak{a}$. Similarly, for every multiplicative subset S of A, the prime ideals of $\mathrm{S}^{-1}\mathrm{A}$ correspond bijectively to the prime ideals of A not meeting S, hence *if* A *is catenary, so is* $\mathrm{S}^{-1}\mathrm{A}$.

Furthermore, as the prime ideals of A contained in a prime ideal $\mathfrak{p}$ correspond bijectively to the prime ideals of $\mathrm{A}_{\mathfrak{p}}$, for A to be catenary it is necessary and sufficient that $\mathrm{A}_{\mathfrak{p}}$ be so for every $\mathfrak{p}$. To say that A is catenary means ((14.3.2) and (16.1.3.2)) that for every pair of prime ideals $\mathfrak{p}$, $\mathfrak{q}$ of A such that $\mathfrak{q} \subset \mathfrak{p}$, we have

$$\dim(\mathrm{A}_{\mathfrak{q}}) + \dim(\mathrm{A}_{\mathfrak{p}}/\mathfrak{q}\mathrm{A}_{\mathfrak{p}}) = \dim(\mathrm{A}_{\mathfrak{p}}). \tag{16.1.4.2}$$

If A is biequidimensional, it is the same for $\mathrm{A}_{\mathfrak{p}}$ for every prime ideal $\mathfrak{p}$ of A.

(16.1.5) Proposition. *Let* $\rho : \mathrm{A} \to \mathrm{B}$ *be a ring homomorphism making* B *an integral* A*-algebra. Then* $\dim(\mathrm{B}) \leq \dim(\mathrm{A})$*; if in addition* ρ *is injective, we have* $\dim(\mathrm{B}) = \dim(\mathrm{A})$.

Proof. If $\mathfrak{n}$ is the kernel of ρ, $\rho(\mathrm{A})$ is isomorphic to $\mathrm{A}/\mathfrak{n}$, hence $\dim \rho(\mathrm{A}) \leq \dim(\mathrm{A})$ by (16.1.2.1), and since B is integral over $\rho(\mathrm{A})$, one can reduce to proving the second assertion. If $\mathfrak{p}'_0 \subset \mathfrak{p}'_1 \subset \ldots \subset \mathfrak{p}'_n$ is a chain of prime ideals of B, the $\mathfrak{p}'_i \cap \mathrm{A}$ are then distinct prime ideals in A (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, cor. 1 of prop. 1), hence they form a chain of prime ideals. Conversely, for every chain $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_m$ of prime ideals of A, we know that for each i there exists a prime ideal $\mathfrak{p}'_i$ of B such that $\mathfrak{p}'_i \cap \mathrm{A} = \mathfrak{p}_i$ and $\mathfrak{p}'_i \subset \mathfrak{p}'_{i+1}$ for $0 \leq i \leq m-1$ (*loc. cit.*, cor. 2 of th. 1). Hence the conclusion. □

[0IV-1 | 24]

(16.1.6) Proposition. *Let* B *be an integral ring,* A *a local subring of* B*,* $\mathfrak{m}$ *its maximal ideal. Suppose that* A *is integrally closed and that* B *is integral over* A*; then, for every maximal ideal* $\mathfrak{n}$ *of* B*, we have* $\dim(\mathrm{B}_{\mathfrak{n}}) = \dim(\mathrm{A})$.

Proof. The first part of the reasoning of (16.1.5) shows that $\dim(B_{\mathfrak{n}}) \leq \dim(A)$. Conversely, consider a chain of prime ideals $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_k = \mathfrak{m}$ of A; we know that $\mathfrak{n} \cap A = \mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, prop. 1) and by virtue of the hypotheses made, one can apply the second theorem of Cohen-Seidenberg (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 4, th. 3), which proves the existence of a chain of prime ideals $\mathfrak{p}'_0 \subset \mathfrak{p}'_1 \subset \ldots \subset \mathfrak{p}'_k = \mathfrak{n}$ of B such that $\mathfrak{p}'_i \cap A = \mathfrak{p}_i$ for each i; from this one deduces immediately $\dim(B_{\mathfrak{n}}) \geq \dim(A)$, whence the proposition. □

(16.1.7) Let M be an A-module; we call the *dimension* of M and denote by $\dim_A(M)$ or $\dim(M)$ the dimension of the ring $A/\operatorname{Ann}(M)$ (isomorphic to the ring of homotheties A_M of M). We thus have $\dim(M^k) = \dim(M)$ for every $k > 0$. If M is *of finite type*, the prime ideals of A containing Ann(M) are exactly those belonging to Supp(M) (**0**$_{\mathrm{I}}$, 1.7.4) and the latter is closed in Spec(A), hence we then have

$$\dim(M) = \dim(\operatorname{Supp}(M)) \leq \dim(A). \tag{16.1.7.1}$$

If M, N are two A-modules such that $N \subset M$, we have

$$\dim(N) \leq \dim(M), \qquad \dim(M/N) \leq \dim(M). \tag{16.1.7.2}$$

If S is a multiplicative subset of A and if M is of finite type, we have

$$\dim_{S^{-1}A}(S^{-1}M) \leq \dim_A(M). \tag{16.1.7.3}$$

Furthermore, every maximal chain of prime ideals containing Ann(M) terminates at a maximal ideal $\mathfrak{m}$, hence its length is equal to the length of the chain of corresponding prime ideals of $A_{\mathfrak{m}}$ (which contain $(\operatorname{Ann}(M))_{\mathfrak{m}}$); from this remark and from (16.1.7.3), one obtains

$$\dim_A(M) = \sup_{\mathfrak{m}}(\dim_{A_{\mathfrak{m}}}(M_{\mathfrak{m}})) \tag{16.1.7.4}$$

where $\mathfrak{m}$ ranges over the set of maximal ideals of A. We say that M is *catenary* (resp. *equidimensional*, *equicodimensional*, *biequidimensional*) when $A/\operatorname{Ann}(M)$ is.

(16.1.8) Proposition. *Let* A *be a ring,* M *an* A*-module of finite type,* $\mathfrak{p}$ *a prime ideal of* A*. We have*

$$\dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}) + \dim_A(M/\mathfrak{p}M) \leq \dim_A(M). \tag{16.1.8.1}$$

Proof. We have $\operatorname{Ann}(M_{\mathfrak{p}}) = (\operatorname{Ann}(M))_{\mathfrak{p}}$, hence the prime ideals of $A_{\mathfrak{p}}$ containing $\operatorname{Ann}(M_{\mathfrak{p}})$ correspond bijectively to the prime ideals of A containing Ann(M) and contained in $\mathfrak{p}$. [0$_{\text{IV-1}}$ | 25]
On the other hand, if $\operatorname{Ann}(M) = \mathfrak{n}$, $V(\operatorname{Ann}(M/\mathfrak{p}M)) = V(\mathfrak{p} + \mathfrak{n})$ (**0**$_{\mathrm{I}}$, 1.7.5), hence the prime ideals of A containing $\operatorname{Ann}(M/\mathfrak{p}M)$ contain $\mathfrak{p} + \mathfrak{n}$; whence the conclusion. We note in addition that

$$\dim_{A/\mathfrak{p}}(M/\mathfrak{p}M) = \dim_A(M/\mathfrak{p}M). \tag{16.1.8.2}$$

□

(16.1.9) Proposition. *Let* A *be a Noetherian ring,* $\rho : A \to B$ *a ring homomorphism,* M *a* B*-module such that* $M_{[\rho]}$ *is an* A*-module of finite type. Then*

$$\dim_A(M_{[\rho]}) = \dim_B(M). \tag{16.1.9.1}$$

Proof. Indeed, the ring B_M of homotheties of the B-module M is a subring of the A-module $C = \mathrm{End}_A(M_{[\rho]})$, and C is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 1, lemma 2), hence it is the same for B_M; moreover the ring A_M of homotheties of the A-module $M_{[\rho]}$ is a subring of B_M, canonical image of A in C, hence B_M is finite over A_M; the conclusion then follows from (16.1.5). □

(16.1.10) Let A be a Noetherian ring; if M is an A-module of *finite length*, we know (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 7 and cor. 1 of prop. 7) that Supp(M) is a finite discrete set, hence $\dim(M) = 0$ if $M \neq 0$; conversely, if M is an A-module of finite type such that $\dim(M) = 0$, every point of Supp(M) is closed, in other words it is a maximal ideal of A, hence (*loc. cit.*, prop. 7) M is of finite length.

16.2 Dimension of a semi-local Noetherian ring[16]

(16.2.1) Let A be a *semi-local Noetherian* ring, $\mathfrak{r}$ its radical; recall that an *ideal of definition* $\mathfrak{q}$ of A is an ideal such that $\mathfrak{q} \subset \mathfrak{r}$ and $\mathfrak{q}$ contains a power of $\mathfrak{r}$, or equivalently, that the only prime ideals containing $\mathfrak{q}$ are *maximal*, or that $A/\mathfrak{q}$ is an Artinian ring. Let M be an A-module of finite type; for every integer $n > 0$, $M/\mathfrak{q}^n M$ is an A-module of *finite length*, equal to $\sum_{i=0}^{n-1} \mathrm{long}(\mathrm{gr}_i(M))$, where $\mathrm{gr}_\bullet(M)$ is the $(A/\mathfrak{q})$-graded module associated to M equipped with the $\mathfrak{q}$-preadic filtration. Recall that there exists a *polynomial* $Q(n)$ with rational coefficients such that $\mathrm{long}(\mathrm{gr}_n(M)) = Q(n)$ for n sufficiently large (**III**, 2.5.4); from this one deduces immediately that there exists a polynomial $P_\mathfrak{q}(M, n)$ in n, with rational coefficients, such that $\mathrm{long}(M/\mathfrak{q}^n M) = P_\mathfrak{q}(M, n)$ *for n sufficiently large*; it is clear that this polynomial is unique and that its leading coefficient is > 0 if $M \neq 0$; we call it the *Hilbert–Samuel polynomial* of M for the $\mathfrak{q}$-preadic filtration.

[$0_{\text{IV-1}}$ | 26] **(16.2.2.1) Lemma.** *Let (M_n) be a $\mathfrak{q}$-good filtration of* M *(Bourbaki,* Alg. comm.*, chap. III, § 3, n° 1); then* $\mathrm{long}(M/M_n)$ *is equal, for n sufficiently large, to a polynomial in n whose degree and leading coefficient are the same as those of* $P_\mathfrak{q}(M, n)$.

Proof. Indeed, there exists n_0 such that $M_{n+1} = \mathfrak{q}M_n$ for $n \geq n_0$, whence the inclusions $\mathfrak{q}^{n+n_0}M \subset M_{n+n_0} = \mathfrak{q}^n M_{n_0} \subset \mathfrak{q}^n M \subset M_n$ for n sufficiently large, which implies

$$P_\mathfrak{q}(M, n + n_0) \geq \mathrm{long}(M/M_{n+n_0}) \geq P_\mathfrak{q}(M, n) \geq \mathrm{long}(M/M_n)$$

hence the conclusion. □

If $\mathfrak{q}'$ is a second ideal of definition, one has $\mathfrak{q}' \supset \mathfrak{q}^m$ for some integer m, hence $P_{\mathfrak{q}'}(M, n) \leq P_\mathfrak{q}(M, mn)$; the *degree* of $P_\mathfrak{q}(M, n)$ therefore *does not depend on the ideal of definition* $\mathfrak{q}$; we denote it $d(M)$.

(16.2.2.2) Lemma. *Let $0 \to M' \to M \to M'' \to 0$ be a short exact sequence of* A*-modules of finite type. Then the polynomial* $P_\mathfrak{q}(M, n) - P_\mathfrak{q}(M', n) - P_\mathfrak{q}(M'', n)$ *has degree* $\leq d(M') - 1 \leq d(M) - 1$.

Proof. Indeed, the filtration of the $M'_n = M' \cap \mathfrak{q}^n M$ is $\mathfrak{q}$-good (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 1, prop. 1); as $\mathrm{long}(M/\mathfrak{q}^n M) = \mathrm{long}(M''/\mathfrak{q}^n M'') + \mathrm{long}(M'/M'_n)$, the lemma follows immediately from (16.2.2.1) applied to M'. □

[16] This section reproduces the lecture given by Serre in a course at the Collège de France in 1958.

(16.2.3) Theorem. (Krull-Chevalley-Samuel). *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* $M \neq 0$ *an* A*-module of finite type,* $d(M)$ *the degree of the Hilbert–Samuel polynomial of* M *(for any ideal of definition of* A*); let* $s(M)$ *denote the lower bound of the number of elements* $x_1, \ldots, x_n$ *of* $\mathfrak{r}$ *such that* $M/(x_1M + \ldots + x_nM)$ *is of finite length. Then*

$$d(M) = s(M) = \dim(M).$$

(16.2.3.1) Lemma. *For every* $x \in \mathfrak{r}$*, let* ${}_xM$ *be the submodule of* M *of elements annihilated by* x*. Then:*

(i) $s(M) \leq s(M/xM) + 1$.

(ii) *Let* $\mathfrak{p}_i$ *be the prime ideals belonging to* $\mathrm{Supp}(M)$ *and such that*

$$\dim(A/\mathfrak{p}_i) = \dim(M) \quad (1 \leq i \leq m).$$

If $x \notin \mathfrak{p}_i$ *for every* i*, we have* $\dim(M/xM) \leq \dim(M) - 1$.

(iii) *If* $\mathfrak{q}$ *is an ideal of definition of* A*, the polynomial*

$$P_{\mathfrak{q}}({}_xM, n) - P_{\mathfrak{q}}(M/xM, n)$$

has degree $\leq d(M) - 1$.

Proof. The assertion (i) is trivial, since if $(x_i)_{1 \leq i \leq m}$ is such that for the module $N = M/xM$, $N/(x_1N + \ldots + x_mN)$ is of finite length, this amounts to saying that $M/(xM + x_1M + \ldots + x_mM)$ is isomorphic to this module.

For (ii), note that, if $\mathfrak{a}$ denotes the annihilator of M, the prime ideals containing the annihilator of M/xM are those containing $\mathfrak{a} + Ax$ (**0**$_{\mathrm{I}}$, 1.7.5); none of the $\mathfrak{p}_i$ can therefore contain $\mathfrak{a} + Ax$ and by definition of $\dim(M)$ (16.1.7) every chain of prime ideals containing $\mathfrak{a} + Ax$ has therefore length $\leq \dim(M) - 1$.

Finally, to prove (iii), note that one has two short exact sequences [$0_{\mathrm{IV\text{-}1}}$ | 27]

$$0 \to {}_xM \to M \xrightarrow{x} xM \to 0, \qquad 0 \to xM \to M \to M/xM \to 0$$

and the assertion follows immediately from the lemma (16.2.2.2). □

The proof of (16.2.3) proceeds in three steps:

(16.2.3.2) $\dim(M) \leq d(M)$.

We argue by induction on $d(M)$, the case $d(M) = 0$ being trivial. Suppose thus $d(M) \geq 1$, and let $\mathfrak{p}_0 \in \mathrm{Supp}(M)$ such that $\dim(A/\mathfrak{p}_0) = \dim(M)$. This implies that $\mathfrak{p}_0$ is a *minimal* element of $\mathrm{Supp}(M)$, hence is associated to M (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2) and M therefore contains a submodule N isomorphic to $A/\mathfrak{p}_0$ (*loc. cit.*, § 1, n° 1); as $d(M) \geq d(N)$ by (16.2.2.2), it suffices to prove that $\dim(N) \leq d(N)$. Let then $\mathfrak{p}_0 \subset \mathfrak{p}_1 \subset \ldots \subset \mathfrak{p}_n$ be a chain of distinct prime ideals in A, and let us show that $n \leq d(N)$. This is evident if $n = 0$. Otherwise, there exists $x \in \mathfrak{p}_1 \cap \mathfrak{r}$ such that $x \notin \mathfrak{p}_0$, for the relation $\mathfrak{p}_0 \supset \mathfrak{p}_1 \cap \mathfrak{r}$ would imply $\mathfrak{p}_0 \supset \mathfrak{r}$ since $\mathfrak{p}_0$ does not contain $\mathfrak{p}_1$, hence $\mathfrak{p}_0$ would be maximal, which is absurd. We have $\mathfrak{p}_i \in \mathrm{Supp}(N/xN)$, for $i \geq 1$, hence $n-1 \leq \dim(N/xN)$ (16.1.7). As ${}_xN = 0$ by the choice of x, we have $d(N/xN) \leq d(N)-1$ by (16.2.3.1), (iii). The induction hypothesis then implies $d(N/xN) = \dim(N/xN) \geq n - 1$, hence $n - 1 \leq d(N) - 1$.

(16.2.3.3) $d(\mathrm{M}) \leq s(\mathrm{M})$.

Let indeed $(x_i)_{1\leq i\leq n}$ be a family of elements of $\mathfrak{r}$ such that, if we set $\mathfrak{a} = x_1\mathrm{A} + \ldots + x_n\mathrm{A}$, $\mathrm{M}/\mathfrak{a}\mathrm{M}$ is of finite length. The ideals associated to $\mathrm{M}/\mathfrak{a}\mathrm{M}$ are then maximal (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 7) and since these are the only prime ideals containing $\mathfrak{q} = \mathfrak{a} + (\mathfrak{r} \cap \mathrm{Ann}(\mathrm{M}))$, $\mathrm{A}/\mathfrak{q}$ is Artinian (*loc. cit.*, prop. 9) and $\mathfrak{q}$ is an ideal of definition of A. But as $\mathfrak{q}^m\mathrm{M}/\mathfrak{q}^{m+1}\mathrm{M} = \mathfrak{a}^m\mathrm{M}/\mathfrak{a}^{m+1}\mathrm{M}$, and if M is generated by r elements z_j, $\mathfrak{a}^m\mathrm{M}/\mathfrak{a}^{m+1}\mathrm{M}$ is an $(\mathrm{A}/\mathfrak{q})$-module generated by the canonical images of $x_1^{\nu_1}x_2^{\nu_2}\cdots x_n^{\nu_n}z_j$ where $\sum_i \nu_i = m$, hence by $r\binom{m+n-1}{n-1}$ elements; its length is therefore $\leq ar\binom{m+n-1}{n-1}$, where a is a constant, and one deduces immediately that the degree of $\mathrm{P}_{\mathfrak{q}}(\mathrm{M}, n)$ is $\leq n$; whence $d(\mathrm{M}) \leq s(\mathrm{M})$.

(16.2.3.4) $s(\mathrm{M}) \leq \dim(\mathrm{M})$.

Let us note first that $n = \dim(\mathrm{M})$ is finite by (16.2.3.2). We argue by induction on n; the proposition is evident for $n = 0$, since M is then of finite length (16.1.10). Suppose $n \geq 1$, and let $\mathfrak{p}_i$ $(1 \leq i \leq m)$ be the prime ideals of $\mathrm{Supp}(\mathrm{M})$ such that $\dim(\mathrm{A}/\mathfrak{p}_i) = n$; the definition of the $\mathfrak{p}_i$ shows that they are minimal elements of $\mathrm{Supp}(\mathrm{M})$, hence finite in number (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2). As $n \geq 1$, the $\mathfrak{p}_i$ are not maximal, and there therefore exists $x \in \mathfrak{r}$ such that $x \notin \mathfrak{p}_i$ for every i (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2). By virtue of (16.2.3.1), we have $s(\mathrm{M}) \leq s(\mathrm{M}/x\mathrm{M}) + 1$ and $\dim(\mathrm{M}) \geq \dim(\mathrm{M}/x\mathrm{M}) + 1$; the induction hypothesis gives the conclusion.

(16.2.4) Corollary. *Under the hypotheses of (16.2.3), we have*

$$\dim_{\widehat{\mathrm{A}}}(\widehat{\mathrm{M}}) = \dim_{\mathrm{A}}(\mathrm{M}). \tag{16.2.4.1}$$

Proof. Indeed, $\mathrm{M}/\mathfrak{r}^n\mathrm{M}$ and $\widehat{\mathrm{M}}/\mathfrak{r}^n\widehat{\mathrm{M}}$ are isomorphic, hence $d(\widehat{\mathrm{M}}) = d(\mathrm{M})$. □

[$0_{\text{IV-1}}$ | 28]

(16.2.5) Corollary. *The dimension of a semi-local Noetherian ring* A *is finite and equal to the minimum number of elements of the radical of* A *generating an ideal of definition.*

Proof. This is the equality $s(\mathrm{M}) = \dim(\mathrm{M})$ for $\mathrm{M} = \mathrm{A}$. □

In particular:

(16.2.6) Corollary. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field; we have*

$$\dim(\mathrm{A}) \leq \mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2). \tag{16.2.6.1}$$

Proof. Indeed, we know that if the x_i $(1 \leq i \leq n)$ are elements of $\mathfrak{m}$ whose classes mod. $\mathfrak{m}^2$ form a basis of the k-vector space $\mathfrak{m}/\mathfrak{m}^2$, the x_i generate $\mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 2, cor. 2 of prop. 4). □

(16.2.7) Proposition. *Let* k *be a field,* B *a graded* k*-algebra of finite type generated by its elements of degree* 1 *and such that* $\mathrm{B}_0 = k$*; let* E *be a graded* B*-module of finite type, such that* (**III**, 2.5.4) *for* n *sufficiently large,* $\mathrm{rg}_k(\mathrm{E}_n) = r(n)$ *is of the form* $\Phi(n) - \Phi(n-1)$*, where* Φ *is a polynomial in* n *of degree* d*. Then there exist* d *homogeneous elements of degree* ≥ 1 *in* B*,* $t_1, \ldots, t_d$*, forming a family* $(t_i)_{1\leq i\leq d}$ *such that* $\mathrm{E}/(\sum_i t_i\mathrm{E})$ *is of finite rank over* k*.*

Proof. Let $\mathfrak{q}$ be the maximal ideal $\bigoplus_{n\geq 1} B_n$ of B, and, for every n, let E'_n be the sub-B-module $\bigoplus_{h\geq n+1} E_h$ of E. Every element of $B - \mathfrak{q}$ determines an injective homothety in the Artinian B-module E/E'_n, and this homothety is thus bijective (Bourbaki, *Alg.*, chap. VIII, § 2, n° 2, lemma 3), which implies that $(E/E'_n)_\mathfrak{q}$ identifies with E/E'_n; as the residue field of $B_\mathfrak{q}$ is k, one deduces from the hypothesis that $\log_{B_\mathfrak{q}}((E/E'_n)_\mathfrak{q})$ is a polynomial in n of degree d. Moreover, E is a B-module of finite type and B is generated over k by its homogeneous elements of degree 1, hence the filtration (E'_n) is $\mathfrak{q}$-good (Bourbaki, *Alg. comm.*, chap. III, § 1, n° 3, lemma 1), hence the filtration $((E'_n)_\mathfrak{q})$ on $E_\mathfrak{q}$ is $\mathfrak{q}B_\mathfrak{q}$-good. Since $B_\mathfrak{q}$ is a local Noetherian ring, one concludes from (16.2.3) and (16.2.2.1) that $\dim(E_\mathfrak{q}) = d$. We argue by induction on d, the assertion being evident if $d = 0$. Suppose $d \geq 1$, and observe that the minimal prime ideals $\mathfrak{p}_i$ $(1 \leq i \leq r)$ in Ass(E) are *graded* (Bourbaki, *Alg. comm.*, chap. IV, § 3, n° 1, prop. 1), and that $\mathfrak{q}$ is distinct from the union of the $\mathfrak{p}_i$ since $d \geq 1$; there is therefore a *homogeneous* element $t_1 \in \mathfrak{q}$ not belonging to any of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. III, § 1, n° 4, prop. 8). As the prime ideals $(\mathfrak{p}_i)_\mathfrak{q}$ are the minimal elements of $\mathrm{Ass}(E_\mathfrak{q})$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 2, prop. 5), we have $\dim(E_\mathfrak{q}/t_1E_\mathfrak{q}) = d - 1$ (16.3.4). It suffices then to apply the induction hypothesis to the graded B-module E/t_1E to obtain the conclusion. □

16.3 Systems of parameters in a Noetherian local ring

(16.3.1) Proposition. *Let* A *be a Noetherian ring,* $\mathfrak{p}$ *a prime ideal of* A*, and* n *an integer. The following conditions are equivalent:*

a) $\mathrm{ht}(\mathfrak{p}) = \dim(A_\mathfrak{p}) \leq n$*;*

b) There exist n *elements* x_i *of* A $(1 \leq i \leq n)$ *such that* $\mathfrak{p}$ *is minimal in the set of prime ideals containing the ideal* $\mathfrak{a}$ *generated by the* x_i *(in other words,* $V(\mathfrak{p})$ *is an irreducible component of* $V(\mathfrak{a})$*).*

Proof. Condition b) implies that $\mathfrak{a}A_\mathfrak{p}$ is an ideal of definition of $A_\mathfrak{p}$, whence a) by virtue of (16.2.5). Conversely, if a) holds, there exists an ideal of definition $\mathfrak{b}$ of $A_\mathfrak{p}$ generated by n elements x_i/s, with $s \in A - \mathfrak{p}$. By virtue of the one-to-one correspondence between prime ideals of $A_\mathfrak{p}$ and prime ideals of A contained in $\mathfrak{p}$, the ideal $\mathfrak{a}$ of A generated by the x_i satisfies b). □

For $n = 1$, one obtains the special case: [$0_{\text{IV-1}}$ | 29]

(16.3.2) Corollary. ("Hauptidealsatz"). *For a prime ideal in a Noetherian ring to be of height* ≤ 1*, it is necessary and sufficient that it be minimal in the set of prime ideals containing a suitable principal ideal.*

(16.3.3) Corollary. (Artin-Tate). *Let* A *be an integral Noetherian ring. The following conditions are equivalent:*

a) A *is a semi-local ring of dimension* ≤ 1*.*

b) There exists $f \neq 0$ *in* A *such that* A_f *is a field.*

Proof. The condition *a*) is equivalent to saying that A has only finitely many prime ideals $\mathfrak{m}_i \neq 0$, and that these ideals are all maximal (0 being a prime ideal). As the product of the $\mathfrak{m}_i$ is not zero, since A is integral, an element $f \neq 0$ of this product belongs to

every maximal ideal, hence (0) is the only prime ideal of the integral ring A_f, in other words A_f is a field. (One notes that this part of the argument does not use the fact that A is Noetherian.) Let us now prove that *b*) implies *a*); the hypothesis *b*) means that every prime ideal $\mathfrak{p} \neq 0$ of A contains f. Let $\mathfrak{p}_i$ $(1 \leq i \leq n)$ be the minimal prime ideals among those containing f (which are finite in number since A/fA is Noetherian); it suffices to prove that the $\mathfrak{p}_i$ are *maximal* ideals, for then every nonzero prime ideal necessarily contains one of the $\mathfrak{p}_i$ and is therefore equal to it. Suppose then that there exists a maximal ideal $\mathfrak{m}$ containing one of the $\mathfrak{p}_i$ and distinct from the $\mathfrak{p}_i$; $\mathfrak{m}$ is therefore not contained in the union of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2), in other words there exists $g \in \mathfrak{m}$ not belonging to any of the $\mathfrak{p}_i$. Let $\mathfrak{q}$ be a minimal prime ideal among those containing g; it follows from the "Hauptidealsatz" (16.3.2) that $\mathfrak{q}$ is of height 1, hence $\neq 0$; it therefore contains by assumption f, hence also one of the $\mathfrak{p}_i$, and as g does not belong to any of the $\mathfrak{p}_i$, $\mathfrak{q}$ is distinct from the $\mathfrak{p}_i$; it would thus be of height ≥ 2, which is a contradiction. □

(16.3.4) Proposition. *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* M *an* A*-module of finite type,* $\mathfrak{p}_i$ *the elements of* Supp(M) *such that* $\dim(A/\mathfrak{p}_i) = \dim(M)$. *Then the* $\mathfrak{p}_i$ *are minimal elements of* Ass(M)*, and* $\dim(M/\mathfrak{p}_i M) = \dim(M)$. *For every* $x \in \mathfrak{r}$*, we have*

$$\dim(M/xM) \geq \dim(M) - 1. \tag{16.3.4.1}$$

Furthermore, for the two members of (16.3.4.1) to be equal, it is necessary and sufficient that x *not belong to any of the* $\mathfrak{p}_i$.

Proof. The first assertion is immediate, since the $\mathfrak{p}_i$ are by definition the minimal elements of Supp(M) (16.1.6), and they are also the minimal elements of Ass(M) (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2). Furthermore, $\mathrm{Supp}(M/\mathfrak{p}_i M)$ is the set of prime ideals of A containing $\mathfrak{p}_i$ ($\mathbf{0}_{\mathrm{I}}$, 1.7.5), hence $\dim(M/\mathfrak{p}_i M) = \dim(A/\mathfrak{p}_i) = \dim(M)$.

Set $N = M/xM$. If $x_1, \ldots, x_n$ are elements of $\mathfrak{r}$ such that $M/(xM + x_1M + \ldots + x_nM)$ is of finite length, we have $s(M) \leq n+1$, hence $\dim(M) \leq n+1$ by (16.2.3), and as one can choose them so that $n = s(N) = \dim(N)$, we get (16.3.4.1).

The fact that the two members of (16.3.4.1) are equal when x does not belong to any
[$0_{\text{IV-1}}$ | 30] of the $\mathfrak{p}_i$ follows from (16.3.4.1) and (16.2.3.1). Conversely, if $\dim(M/xM) = \dim(M) - 1$, none of the $\mathfrak{p}_i$ can belong to $\mathrm{Supp}(M/xM)$, and the prime ideals in the support of the latter are those containing $\mathrm{Ann}(M) + Ax$; since the $\mathfrak{p}_i$ contain Ann(M), they cannot contain x. □

(16.3.5) Corollary. *With the notations of (16.3.4), for every ideal* $\mathfrak{a} \subset \mathfrak{p}_i$*, we have* $\dim(M/\mathfrak{a}M) = \dim(M)$ *and if one sets* $N = M/\mathfrak{a}M$*, the relation* $\dim(M/xM) = \dim(M) - 1$ *implies* $\dim(N/xN) = \dim(N) - 1$.

Proof. Indeed, Supp(N) is the set of prime ideals containing $\mathfrak{a} + \mathrm{Ann}(M)$, hence $\mathfrak{p}_i$ belongs to Supp(N) and $\dim(N) \leq \dim(M) = \dim(A/\mathfrak{p}_i)$, hence $\dim(A/\mathfrak{p}_i) = \dim(N)$; furthermore the prime ideals $\mathfrak{q} \in \mathrm{Supp}(N)$ such that $\dim(A/\mathfrak{q}) = \dim(N)$ are certain of the $\mathfrak{p}_j$; if x does not belong to any of the $\mathfrak{p}_j$, we have then $\dim(N/xN) = \dim(N) - 1$ by virtue of (16.3.4). □

(16.3.6) Definition. Let A be a semi-local Noetherian ring, $\mathfrak{r}$ its radical, M an A-module of finite type, and set $n = \dim(M)$. A *system of parameters* for M is any family $(x_i)_{1 \leq i \leq n}$ of n elements of $\mathfrak{r}$ such that $M/(x_1M + \ldots + x_nM)$ is of *finite length*.

We have seen (16.2.3) that such systems always exist. We have seen in the course of the proof of (16.2.3.3) that if $\mathfrak{J} = \sum_{i=1}^{n} x_i \mathrm{A}$ is such that $\mathrm{M}/\mathfrak{J}\mathrm{M}$ is of finite length, $\mathfrak{q} = \mathfrak{J} + \mathrm{Ann}(\mathrm{M})$ is an *ideal of definition* of A, and conversely, if this is so, $\mathrm{M}/\mathfrak{J}\mathrm{M}$ is a module of finite type over the Artinian ring $\mathrm{A}/\mathfrak{q}$, hence is of finite length. It amounts to the same to say that $(x_i)_{1\leq i\leq n}$ is a system of parameters *for* M or *for* $\mathrm{A}/\mathrm{Ann}(\mathrm{M})$ (or equivalently that their images in $\mathrm{A}/\mathrm{Ann}(\mathrm{M})$ form a system of parameters for this ring). If $(x_i)_{1\leq i\leq n}$ is a system of parameters for M, so is (x_i^k) for every integer $k \geq 1$, since one can reduce, by the preceding, to the case $\mathrm{M} = \mathrm{A}$, and if $\mathfrak{J}$ is an ideal of definition of A, $\sum_i x_i^k \mathrm{A}$ contains $\mathfrak{J}^{kn}$, hence is also an ideal of definition.

(16.3.7) Proposition. *Let* A *be a semi-local Noetherian ring,* $\mathfrak{r}$ *its radical,* $x_1, \ldots, x_k$ *elements of* $\mathfrak{r}$*,* M *an* A*-module of finite type. Then*

$$\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})) \geq \dim(\mathrm{M}) - k. \tag{16.3.7.1}$$

Furthermore, for the two members of (16.3.7.1) to be equal, it is necessary and sufficient that there exist elements x_i $(k+1 \leq i \leq n = \dim(\mathrm{M}))$ *of* $\mathfrak{r}$ *such that* $(x_i)_{1\leq i\leq n}$ *is a system of parameters for* M*.*

Proof. The inequality (16.3.7.1) follows from (16.3.4.1) by induction on k. If the two members of (16.3.7.1) are equal, and if $x_{k+1}, \ldots, x_n$ is a system of parameters for $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})$, it is clear that $\mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M} + x_{k+1}\mathrm{M} + \ldots + x_n\mathrm{M})$ is of finite length, hence $(x_i)_{1\leq i\leq n}$ is a system of parameters for M; conversely, if there exist x_i $(k+1 \leq i \leq n)$ having this property and if one sets $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_k\mathrm{M})$, it is clear that $\mathrm{N}/(x_{k+1}\mathrm{N} + \ldots + x_n\mathrm{N})$ is of finite length, hence $\dim(\mathrm{N}) \leq n - k$, and the two members are equal by virtue of (16.3.7.1). □

(16.3.8) Proposition. *Let* A *be a semi-local Noetherian ring,* $\mathrm{X} = \mathrm{Spec}(\mathrm{A})$ *its spectrum,* $\mathfrak{a}$ *an ideal of* A *distinct from* A *such that* $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{X}) = r > 0$*. Then there exist* r *elements* $x_1, \ldots, x_r$ *of* $\mathfrak{a}$*, forming part of a system of parameters of* A*, such that* [$0_{\text{IV-1}}$ | 31]

$$\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x_1 + \ldots + \mathrm{A}x_r)) = 0.$$

Proof. Let $\mathfrak{p}_i$ $(1 \leq i \leq m)$ be the minimal prime ideals of the ring A, $\mathfrak{q}_j$ $(1 \leq j \leq n)$ the minimal prime ideals among those containing $\mathfrak{a}$; we have (14.2.1) $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{X}) = \inf_j(\dim(\mathrm{A}_{\mathfrak{q}_j}))$ (16.1.3.2). The hypothesis $r > 0$ implies that $\mathfrak{a}$ is not contained in any of the $\mathfrak{p}_i$; hence there exists $x \in \mathfrak{a}$ not belonging to any of the $\mathfrak{p}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2). One has as above $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x)) = \inf_j(\dim((\mathrm{A}/\mathrm{A}x)_{\mathfrak{q}_j/\mathrm{A}x})) = \inf_j(\dim(\mathrm{A}_{\mathfrak{q}_j}/\mathrm{A}_{\mathfrak{q}_j}x))$; but as $x/1$ is not in any of the minimal prime ideals of $\mathrm{A}_{\mathfrak{q}_j}$, $\dim(\mathrm{A}_{\mathfrak{q}_j}/\mathrm{A}_{\mathfrak{q}_j}x) = \dim(\mathrm{A}_{\mathfrak{q}_j}) - 1$ (16.3.4), whence $\mathrm{codim}(\mathrm{V}(\mathfrak{a}), \mathrm{V}(\mathrm{A}x)) = r - 1$. For the same reason, $\dim(\mathrm{A}/\mathrm{A}x) = \dim(\mathrm{A}) - 1$. We argue by induction on r; if $r > 1$, there exist $r - 1$ elements x_i' $(2 \leq i \leq r)$ of $\mathrm{A}' = \mathrm{A}/\mathrm{A}x$, forming part of a system of parameters of A' and such that $\mathrm{codim}(\mathrm{V}(\mathfrak{a}/\mathrm{A}x), \mathrm{V}(\mathrm{A}'x_2' + \ldots + \mathrm{A}'x_r')) = 0$. Let $(x_i')_{r+1\leq i\leq s}$ be a family of elements of A' such that $(x_i')_{2\leq i\leq s}$ is a system of parameters of A'; for every i such that $2 \leq i \leq s$, let x_i be a representative of the class x_i' in A, with $x_i \in \mathfrak{a}$ for $2 \leq i \leq r$. It is immediate that $\mathrm{A}/(\mathrm{A}x + \mathrm{A}x_2 + \ldots + \mathrm{A}x_s)$ is of finite length, and as $\dim(\mathrm{A}) = s$, we see that $x_1 = x$ and the x_i for $i \geq 2$ satisfy the conditions of the statement. □

(16.3.9) Proposition. *Let* A, B *be two local Noetherian rings,* $\mathfrak{m}$ *the maximal ideal of* A*,* k *its residue field,* $\varphi : \mathrm{A} \to \mathrm{B}$ *a local homomorphism.*

(i) *We have*

$$\dim(\mathrm{B}) \leq \dim(\mathrm{A}) + \dim(\mathrm{B} \otimes_{\mathrm{A}} k). \tag{16.3.9.1}$$

(ii) *Let* $\mathrm{M} \neq 0$ *be an* A*-module of finite type,* $\mathrm{N} \neq 0$ *a* B*-module of finite type. We have*

$$\dim_{\mathrm{B}}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N}) \leq \dim_{\mathrm{A}}(\mathrm{M}) + \dim_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N} \otimes_{\mathrm{A}} k). \tag{16.3.9.2}$$

Proof. Let m be the dimension of A, $(s_i)_{1\leq i\leq m}$ a system of parameters of A (16.3.6), so that $\mathfrak{a} = \sum_i s_i\mathrm{A}$, $\mathrm{A}/\mathfrak{a}$ is an A-module of finite length. Then the Artinian ring $\mathrm{A}/\mathfrak{a}$ has nilpotent maximal ideal $\mathfrak{m}/\mathfrak{a}$; the ideal $\mathfrak{m}\mathrm{B}/\mathfrak{a}\mathrm{B}$ of $\mathrm{B}/\mathfrak{a}\mathrm{B}$, image of $(\mathfrak{m}/\mathfrak{a}) \otimes_{\mathrm{A}} \mathrm{B}$, is therefore also nilpotent, and hence $\dim(\mathrm{B}/\mathfrak{a}\mathrm{B}) = \dim(\mathrm{B}/\mathfrak{m}\mathrm{B})$ (the spectra of these two rings having the same underlying space). On the other hand $\mathrm{B}/\mathfrak{a}\mathrm{B} = \mathrm{B}/(s_1\mathrm{B}+\ldots+s_m\mathrm{B})$, and the images of the s_i in B belong to the maximal ideal of B. Hence by (16.3.7), we have

$$\dim(\mathrm{B}) \leq m + \dim(\mathrm{B} \otimes_{\mathrm{A}} k)$$

which is (16.3.9.1).

[$0_{\text{IV-1}}$ | 32] To prove (16.3.9.2), note that if $\mathfrak{r}$ (resp. $\mathfrak{s}$) is the annihilator of M (resp. N) in A (resp. B), we have $\dim_{\mathrm{A}}(\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{r})$, $\dim_{\mathrm{B}}(\mathrm{N}) = \dim(\mathrm{B}/\mathfrak{s})$ by definition (16.1.7); on the other hand, $\mathrm{Supp}(\mathrm{M} \otimes_{\mathrm{A}} \mathrm{N})$ is a closed subset of $\mathrm{Spec}(\mathrm{B})$ that identifies (**I**, 9.1.13) to $\mathrm{Supp}(\mathrm{M}) \times_{\mathrm{Spec}(\mathrm{A})} \mathrm{Supp}(\mathrm{N}) = \mathrm{Spec}((\mathrm{B}/\mathfrak{s}) \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{r})) = \mathrm{Spec}(\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B}))$. As $\mathrm{N} \otimes_{\mathrm{A}} k$ is a B-module of finite type, we have $\dim_{\mathrm{B}\otimes_{\mathrm{A}}k}(\mathrm{N} \otimes_{\mathrm{A}} k) = \dim_{\mathrm{B}}(\mathrm{N} \otimes_{\mathrm{A}} k)$ (16.1.9), and $\mathrm{Supp}(\mathrm{N} \otimes_{\mathrm{A}} k)$ is equal to $\mathrm{Spec}(\mathrm{B}/(\mathfrak{s} + \mathfrak{m}\mathrm{B}))$ by the same reasoning as above. Applying (16.3.9.1) to $\mathrm{A}/\mathfrak{r}$ and to $\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B})$, we get

$$\dim(\mathrm{B}/(\mathfrak{s} + \mathfrak{r}\mathrm{B})) \leq \dim(\mathrm{A}/\mathfrak{r}) + \dim(\mathrm{B}/(\mathfrak{s} + \mathfrak{m}\mathrm{B}))$$

which is nothing other than (16.3.9.2). □

(16.3.10) Corollary. *Under the hypotheses of (16.3.9), if* $\mathfrak{m}\mathrm{B}$ *is an ideal of definition of* B*, we have* $\dim(\mathrm{B}) \leq \dim(\mathrm{A})$*; if in addition* A *is integral and* $\dim(\mathrm{A}) = \dim(\mathrm{B})$*,* φ *is injective.*

Proof. The first assertion follows from (16.3.9) since then $\dim(\mathrm{B}/\mathfrak{m}\mathrm{B}) = 0$. One can moreover replace A by $\varphi(\mathrm{A})$, hence $\dim(\mathrm{B}) \leq \dim(\varphi(\mathrm{A}))$; if $\mathfrak{a} = \mathrm{Ker}(\varphi) \neq 0$, and if A is integral, we have $\dim(\varphi(\mathrm{A})) = \dim(\mathrm{A}/\mathfrak{a}) < \dim(\mathrm{A})$ (16.1.2.2), hence one can have $\dim(\mathrm{A}) = \dim(\mathrm{B})$ only if $\mathfrak{a} = 0$. □

16.4 Depth and codepth[17]

(16.4.1) Proposition. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type. Then every* M*-regular sequence* $(x_i)_{1\leq i\leq r}$ *(15.1.7) formed of elements of* $\mathfrak{m}$*, is part of a system of parameters for* M*.*

[17] In the third part of Chapter III, we develop the notion of depth from the cohomological point of view and in a more general framework.

Proof. We argue by induction on r; consider the A-module

$$\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_{r-1}\mathrm{M});$$

by the induction hypothesis $x_1, \ldots, x_{r-1}$ form part of a system of parameters for M, hence $\dim(\mathrm{N}) = \dim(\mathrm{M}) - (r-1)$ (16.3.7). As by hypothesis the homothety of ratio x_r in N is injective, x_r does not belong to any of the prime ideals associated to N, hence (16.3.4) $\dim(\mathrm{N}/x_r\mathrm{N}) = \dim(\mathrm{N}) - 1$, which can also be written

$$\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})) = \dim(\mathrm{M}) - r;$$

the conclusion then follows from (16.3.7). □

For an M-regular sequence formed of elements of $\mathfrak{m}$, $\mathrm{M} \neq 0$, there are at most $\dim(\mathrm{M})$ elements.

(16.4.2) Lemma. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module. For an* M*-regular sequence* $(x_i)_{1\leq i\leq n}$ *of elements of* $\mathfrak{m}$ *to be maximal, it is necessary and sufficient that* $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})) \neq 0$.

Proof. To say that (x_i) is maximal means that, for no $x \in \mathfrak{m}$, the homothety of ratio x in $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})$ is injective, or equivalently that $\mathfrak{m}$ is contained in the union of the prime ideals associated to N (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2), hence equal to one of them, since it is a maximal ideal (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2); in other words, there is an element $z \in \mathrm{N}$ whose annihilator is $\mathfrak{m}$, and hence the submodule $\mathrm{A}z$ of N is isomorphic to $\mathrm{A}/\mathfrak{m} = k$; whence the lemma. □ [$0_{\text{IV-1}}$ | 33]

(16.4.3) Lemma. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module,* $(x_i)_{1\leq i\leq n}$ *an* M*-regular sequence of elements of* $\mathfrak{m}$*. Then the* A*-modules* $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M}))$ *and* $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M})$ *are isomorphic, and for* $n \geq 1$*, they are also isomorphic to* $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M}/x_1\mathrm{M})$.

Proof. We argue by induction on n, the proposition being evident for $n = 0$. Set $\mathrm{N} = \mathrm{M}/x_1\mathrm{M}$; the sequence $(x_i)_{2\leq i\leq n}$ is N-regular, hence

$$\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_n\mathrm{M})) = \mathrm{Hom}_{\mathrm{A}}(k, \mathrm{N}/(x_2\mathrm{N} + \ldots + x_n\mathrm{N}))$$

is isomorphic to $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{N})$ by the induction hypothesis. Consider then the short exact sequence $0 \to \mathrm{M} \xrightarrow{x_1} \mathrm{M} \to \mathrm{M}/x_1\mathrm{M} = \mathrm{N} \to 0$; one deduces the exact sequence of Ext

$$\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M}) \to \mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{N}) \to \mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M}) \xrightarrow{x_1} \mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M}). \qquad (16.4.3.1)$$

By the induction hypothesis, $\mathrm{Ext}^{n-1}_{\mathrm{A}}(k, \mathrm{M})$ is isomorphic to $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{M}/(x_1\mathrm{M} + \ldots + x_{n-1}\mathrm{M}))$, which is zero since $(x_i)_{1\leq i\leq n-1}$ is not a maximal M-regular sequence (16.4.2). On the other hand, as $x_1 \in \mathfrak{m}$, the homothety of ratio x_1 in the A-module $\mathrm{Hom}_{\mathrm{A}}(k, \mathrm{T})$ is zero for every A-module T, hence it is the same for every A-module $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{T})$; the assertions of the lemma then follow immediately from the exact sequence (16.4.3.1). □

(16.4.4) Corollary. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* $k = \mathrm{A}/\mathfrak{m}$ *its residue field,* M *an* A*-module of finite type* $\neq 0$*. All maximal* M*-regular sequences of elements of* $\mathfrak{m}$ *have the same number of elements, which is the smallest integer* n *such that* $\mathrm{Ext}^n_{\mathrm{A}}(k, \mathrm{M}) \neq 0$.

(16.4.5) Definition. Let A be a local Noetherian ring, $\mathfrak{m}$ its maximal ideal, M an A-module of finite type. We call the upper bound of the numbers of elements in M-regular sequences formed of elements of $\mathfrak{m}$ the *depth* of M, and denote it $\operatorname{prof}_{\mathrm{A}}\mathrm{M}$ or $\operatorname{prof}(\mathrm{M})$. We thus have $\operatorname{prof}(\mathrm{M}) = +\infty$ if and only if $\mathrm{M} = 0$, and, by (16.4.1),

$$\operatorname{prof}(\mathrm{M}) \leq \dim(\mathrm{M}) \quad \text{if} \quad \mathrm{M} \neq 0. \tag{16.4.5.1}$$

We evidently have $\operatorname{prof}(\mathrm{M}^k) = \operatorname{prof}(\mathrm{M})$ for every $k > 0$.

(16.4.6) Proposition. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type.*

(i) *For* $\operatorname{prof}(\mathrm{M}) = 0$*, it is necessary and sufficient that* $\mathfrak{m} \in \operatorname{Ass}(\mathrm{M})$ *(or equivalently that there exists a submodule of* M *isomorphic to the residue field* $k = \mathrm{A}/\mathfrak{m}$ *of* A*).*

(ii) *For every* M*-regular element* x *belonging to the maximal ideal of* A*, we have*

$$\operatorname{prof}(\mathrm{M}/x\mathrm{M}) = \operatorname{prof}(\mathrm{M}) - 1. \tag{16.4.6.1}$$

(iii) *If* $\mathrm{M} \neq 0$*, we have*

$$\operatorname{prof}(\mathrm{M}) \leq \inf_{\mathfrak{p} \in \operatorname{Ass}(\mathrm{M})} \dim(\mathrm{A}/\mathfrak{p}) \leq \dim(\mathrm{M}). \tag{16.4.6.2}$$

[$0_{\text{IV-1}}$ / 34]

(iv) *We have* $\operatorname{prof}_{\mathrm{A}}(\mathrm{M}) = \operatorname{prof}_{\widehat{\mathrm{A}}}(\widehat{\mathrm{M}})$.

Proof. (i) To say $\operatorname{prof}(\mathrm{M}) = 0$ means that there is no $x \in \mathfrak{m}$ such that the homothety of ratio x in M is injective, that is, every $x \in \mathfrak{m}$ belongs to a prime ideal associated to M (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2); but $\mathfrak{m}$ cannot be the union of prime ideals associated to M unless it is equal to one of them (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2).

(ii) If $(x_i)_{1 \leq i \leq m}$ is a $(\mathrm{M}/x\mathrm{M})$-regular sequence of elements of $\mathfrak{m}$, the sequence formed of x and the x_i is M-regular, and it follows from the definition that it is maximal when the first sequence is; whence the conclusion.

(iii) We argue by induction on $n = \operatorname{prof}(\mathrm{M})$, the assertion being evident for $n = 0$. We use the following lemma: □

(16.4.6.3) Lemma. *Let* A *be a Noetherian ring,* M *an* A*-module of finite type,* $t \in \mathrm{A}$ *an* M*-regular element. Then, for every* $\mathfrak{p} \in \operatorname{Ass}(\mathrm{M})$*, every* minimal *prime ideal among those containing* $\mathfrak{p} + \mathrm{A}t$ *belongs to* $\operatorname{Ass}(\mathrm{M}/t\mathrm{M})$.

Proof of the lemma. We know that there exists a short exact sequence

$$0 \to \mathrm{M}' \to \mathrm{M} \to \mathrm{M}'' \to 0$$

such that $\operatorname{Ass}(\mathrm{M}') = \{\mathfrak{p}\}$, $\operatorname{Ass}(\mathrm{M}'') = \operatorname{Ass}(\mathrm{M}) - \{\mathfrak{p}\}$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, prop. 4); as t is M-regular, it is also M'-regular and M''-regular (*loc. cit.*, § 1, n° 1, cor. 2 of prop. 2). One deduces that the sequence

$$0 \to \mathrm{M}'/t\mathrm{M}' \to \mathrm{M}/t\mathrm{M} \to \mathrm{M}''/t\mathrm{M}'' \to 0$$

is exact (15.1.18). Consequently, $\mathrm{Ass}(M'/tM') \subset \mathrm{Ass}(M/tM)$. But the prime ideals of A containing $\mathfrak{p}$ are the points of $\mathrm{Supp}(M')$ (*loc. cit.*, § 1, n° 3, prop. 7), hence the prime ideals containing $\mathfrak{p} + At$ are the points of the support of $M'/tM' = M' \otimes_A (A/tA)$ (**0**$_I$, 1.7.5); a minimal element of the set of these prime ideals belongs then to $\mathrm{Ass}(M'/tM')$ (Bourbaki, *loc. cit.*, § 1, n° 3, cor. 1 of prop. 7), and *a fortiori* to $\mathrm{Ass}(M/tM)$. □

Continuation of the proof of (16.4.6). This lemma established, we return to the proof of (iii). Let $x \in \mathfrak{m}$ be an M-regular element, so that $\mathrm{prof}(M/xM) = n - 1$ by (ii); for every $\mathfrak{p} \in \mathrm{Ass}(M)$, it follows from the lemma that there is a prime ideal $\mathfrak{p}'$ associated to M/xM and containing $\mathfrak{p} + xA$; but as x is M-regular, we have $x \notin \mathfrak{p}$, whence $\mathfrak{p}' \neq \mathfrak{p}$ and hence $\dim(A/\mathfrak{p}') \leq \dim(A/\mathfrak{p}) - 1$. The induction hypothesis shows that $n - 1 \leq \dim(A/\mathfrak{p}')$; one concludes that $n \leq \dim(A/\mathfrak{p})$ for every $\mathfrak{p} \in \mathrm{Ass}(M)$.

(iv) One can restrict to the case $M \neq 0$. Recall that $\widehat{M} = M \otimes_A \widehat{A}$ up to canonical isomorphism (**0**$_I$, 7.3.3); as $\widehat{A}$ is a flat A-module, there are canonical isomorphisms $\mathrm{Ext}^i_A(k, M) \otimes_A \widehat{A} \xrightarrow{\sim} \mathrm{Ext}^i_{\widehat{A}}(k, M \otimes_A \widehat{A})$ since $k = k \otimes_A \widehat{A}$ up to canonical isomorphism (**0**$_{III}$, 12.3.5). The assertion (iv) then follows from (16.4.4) and the fact that $\widehat{A}$ is a faithfully flat A-module (**0**$_I$, 7.3.5). □

(16.4.6.4) One notes that if $\mathfrak{p}$ is a prime ideal of A, one can *also* have $\mathrm{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) < \mathrm{prof}_A(M)$ and $\mathrm{prof}_{A_\mathfrak{p}}(M_\mathfrak{p}) > \mathrm{prof}_A(M)$; for an example of the first case, it suffices to take [0$_{IV\text{-}1}$ | 35]
A a local integral ring of dimension ≥ 1; we have $\mathrm{prof}(A) \geq 1$ but $\mathrm{prof}(K) = 0$ for the field of fractions K of A. For an example of the second case, consider a Noetherian integral local ring A_0 of dimension ≥ 2, with maximal ideal $\mathfrak{m}_0$ and residue field $k = A_0/\mathfrak{m}_0$; let $A = A_0 \oplus \mathfrak{J}$ be the trivial extension of A_0 by the A_0-module k (so that the multiplication in A is given by $(x, z)(x', z') = (xx', xz' + x'z)$). It is clear that $\mathfrak{J}$ is the nilradical of A and $A/\mathfrak{J}$ is isomorphic to A_0, so that every prime ideal $\mathfrak{p}$ of A is of the form $\mathfrak{p}_0 \oplus \mathfrak{J}$, where $\mathfrak{p}_0$ is a prime ideal of A_0; in particular $\mathfrak{m} = \mathfrak{m}_0 \oplus \mathfrak{J}$ is the only maximal ideal of A. As every element of $\mathfrak{m}_0$ annihilates $\mathfrak{J}$, we have $\mathrm{prof}(A) = \mathrm{prof}(A_\mathfrak{m}) = 0$; on the contrary, if $\mathfrak{p}_0 \neq \mathfrak{m}_0$, the elements of $\mathfrak{J}$ are annihilated by those of $\mathfrak{m}_0 - \mathfrak{p}_0$, hence $A_\mathfrak{p}$ is canonically isomorphic to $(A_0)_{\mathfrak{p}_0}$, and as A_0 is integral, $\mathrm{prof}((A_0)_{\mathfrak{p}_0}) \geq 1$ if $\mathfrak{p}_0 \neq 0$.

(16.4.7) Corollary. *For a local Noetherian reduced ring* A *to be of depth* 0*, it is necessary and sufficient that* A *be a field.*

Proof. Indeed, as the intersection of the minimal prime ideals of A is 0, A has no embedded associated prime ideals; by (16.4.6), (i), if $\mathrm{prof}(A) = 0$, the maximal ideal $\mathfrak{m}$ of A is also a minimal prime ideal, hence it is the only prime ideal of A, and as A is reduced, $\mathfrak{m} = 0$. □

(16.4.8) Proposition. *Let* A, B *be two local Noetherian rings,* $\rho : A \to B$ *a local homomorphism,* M *a* B*-module such that* $M_{[\rho]}$ *is an* A*-module of finite type. Then*

$$\mathrm{prof}_A(M_{[\rho]}) = \mathrm{prof}_B(M). \tag{16.4.8.1}$$

Proof. One can restrict to the case $M \neq 0$; suppose $\mathrm{prof}_A(M_{[\rho]}) = n$. If $(x_i)_{1 \leq i \leq n}$ is a $(M_{[\rho]})$-regular maximal sequence formed of elements of the maximal ideal of A, the $\rho(x_i)$ constitute an M-regular sequence formed of elements of the maximal ideal of B, and we have then, setting $N = M/(\rho(x_1)M + \ldots + \rho(x_n)M)$, $\mathrm{prof}_B(N) = \mathrm{prof}_B(M) - n$ (16.4.6), (ii); similarly $N_{[\rho]} = M_{[\rho]}/(x_1 M_{[\rho]} + \ldots + x_n M_{[\rho]})$ and $\mathrm{prof}_A(N_{[\rho]}) = 0$; one is thus reduced to proving the proposition when $n = 0$. Let k be the residue field of A; since k is a

quotient of A, the A-module $P = \mathrm{Hom}_A(k, M_{[\rho]})$ is a submodule of $\mathrm{Hom}_A(A, M_{[\rho]}) = M_{[\rho]}$, and the hypothesis implies that $P \neq 0$ (16.4.6), (i); furthermore, P is an A-module of finite type (since $M_{[\rho]}$ is an A-module of finite type), hence a finite-dimensional k-vector space, annihilated by the maximal ideal of A, and finally an A-module of *finite length*. Moreover, P is also a submodule of the B-module M, and since it is of finite length as an A-module, it is *a fortiori* of finite length as a B-module. As it is $\neq 0$, it contains a simple sub-B-module, that is to say one isomorphic to the residue field of B; one concludes then by (16.4.6), (i) that $\mathrm{prof}_B(M) = 0$. □

(16.4.9) Definition. Let A be a local Noetherian ring, M an A-module of finite type. If $M \neq 0$, we call the *codepth* of M and denote $\mathrm{coprof}_A(M)$ or $\mathrm{coprof}(M)$, the finite integer $\dim_A(M) - \mathrm{prof}_A(M) \geq 0$ (16.4.5.1). If $M = 0$, we set $\mathrm{coprof}(M) = 0$. We evidently have $\mathrm{coprof}(M^k) = \mathrm{coprof}(M)$ for every $k > 0$.

(16.4.10) Proposition. *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type.* *[0IV-1 / 36]*

(i) *For every* M*-regular element x belonging to the maximal ideal of* A*, we have* $\mathrm{coprof}(M/xM) = \mathrm{coprof}(M)$.

(ii) *We have* $\mathrm{coprof}_A(M) = \mathrm{coprof}_{\widehat{A}}(\widehat{M})$.

Proof. Indeed, (i) follows from (16.3.4) and (16.4.6), (ii), and (ii) from (16.2.4) and (16.4.6), (iv). □

We shall show later (**IV**, 6.11.5) that for every prime ideal $\mathfrak{p}$ of A, we have $\mathrm{coprof}_{A_\mathfrak{p}}(M_\mathfrak{p}) \leq \mathrm{coprof}_A(M)$.

(16.4.11) Proposition. *Under the hypotheses of (16.4.8), we have*

$$\mathrm{coprof}_A(M_{[\rho]}) = \mathrm{coprof}_B(M). \tag{16.4.11.1}$$

Proof. This follows from (16.1.9) and (16.4.8). □

16.5 Cohen-Macaulay modules

(16.5.1) Definition. Let A be a local Noetherian ring. An A-module of finite type M is called a *Cohen-Macaulay module* if $\mathrm{coprof}(M) = 0$, that is, if $M = 0$ or $\dim(M) = \mathrm{prof}(M)$. We say that A is a *Cohen-Macaulay ring* if the A-module A is a Cohen-Macaulay module.

An A-module of finite length is a Cohen-Macaulay module since it is of dimension 0 (16.1.10). A local reduced ring of dimension 1 is a Cohen-Macaulay ring, since then its maximal ideal $\mathfrak{m}$ cannot be associated to A (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, prop. 10), hence $\mathrm{prof}(A) = 1$ by virtue of (16.4.6), (i). If A is an *integral local integrally closed* ring of dimension ≥ 2, we have $\mathrm{prof}(A) \geq 2$: indeed, if $x \neq 0$ is an element of $\mathfrak{m}$, we know (Bourbaki, *Alg. comm.*, chap. VII, § 1, n° 4, prop. 8) that the prime ideals associated to A/xA are of height 1, hence distinct from $\mathfrak{m}$ and their union is therefore distinct from $\mathfrak{m}$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2); there thus exist (x, y) sequences that are A-regular and formed of elements of $\mathfrak{m}$, whence our

assertion. One concludes that an integral local integrally closed ring of dimension 2 is a Cohen-Macaulay ring.

(16.5.2) Proposition. *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. For* M *to be a Cohen-Macaulay module, it is necessary and sufficient that* $\widehat{\mathrm{M}}$ *be a* $\widehat{\mathrm{A}}$*-module of Cohen-Macaulay.*

Proof. This follows immediately from (16.4.10), (ii). □

(16.5.3) Proposition. *Under the hypotheses of (16.4.8), for* M *to be a Cohen-Macaulay* B*-module, it is necessary and sufficient that* $\mathrm{M}_{[\rho]}$ *be a Cohen-Macaulay* A*-module.*

Proof. This follows from (16.4.11). □

(16.5.4) Proposition. *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type* $\neq 0$*. If* M *is a Cohen-Macaulay module, we have* $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M})$ *for every prime ideal* $\mathfrak{p} \in \mathrm{Ass}(\mathrm{M})$*; in particular no prime ideal associated to* M *is embedded.*

Proof. This follows immediately from the inequalities (16.4.6.2). □

One can also say that M (or Supp(M)) is *equidimensional* (16.1.7).

(16.5.5) Proposition. *Let* A *be a local Noetherian ring,* $\mathfrak{m}$ *its maximal ideal,* M *an* A*-module of finite type* $\neq 0$*, x an element of* $\mathfrak{m}$*. Suppose that* M *is a Cohen-Macaulay module; then the following conditions are equivalent:* [$0_{\text{IV-1}}$ | 37]

a) x is M*-regular;*

b) $\dim(\mathrm{M}/x\mathrm{M}) = \dim(\mathrm{M}) - 1$*;*

c) x does not belong to any minimal *element of* Supp(M)*.*

Furthermore, $\mathrm{M}/x\mathrm{M}$ *is then a Cohen-Macaulay module.*

Proof. We have seen (16.5.4) that all the $\mathfrak{p}$ in Ass(M) are minimal in Supp(M) and such that $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M})$; the equivalence of a) and c) then follows from Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2; the equivalence of b) and c) follows from (16.3.4). The fact that $\mathrm{M}/x\mathrm{M}$ is a Cohen-Macaulay module follows finally from (16.4.10), (i). □

(16.5.6) Corollary. *Under the hypotheses of (16.5.5), let* $(x_i)_{1\leq i\leq r}$ *be a sequence of elements of* $\mathfrak{m}$*. The following conditions are equivalent:*

a) The sequence (x_i) *is* M*-regular.*

b) $\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})) = \dim(\mathrm{M}) - r$*.*

c) The x_i *form part of a system of parameters for* M*.*

Furthermore, when these conditions are satisfied, $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})$ *is a Cohen-Macaulay module, hence for every prime ideal* $\mathfrak{p} \in \mathrm{Ass}(\mathrm{N})$*, we have* $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{M}) - r$*.*

Proof. We already know that b) and c) are equivalent (16.3.6) and that a) implies c) (16.4.1) without any hypothesis on M. To see that c) implies a), and to prove the last assertion of the statement, we argue by induction on r, the assertion being trivial for $r = 0$. Since x_1 forms part of a system of parameters, $\dim(\mathrm{M}/x_1\mathrm{M}) = \dim(\mathrm{M}) - 1$ (16.3.6), hence x_1 is M-regular and $\mathrm{M}/x_1\mathrm{M}$ is Cohen-Macaulay by (16.5.5). Since the sequence $(x_i)_{2\leq i\leq r}$ forms part of a system of parameters for $\mathrm{P} = \mathrm{M}/x_1\mathrm{M}$, the induction hypothesis shows that $(x_i)_{2\leq i\leq r}$ is a P-regular sequence and that $\mathrm{P}/(x_2\mathrm{P}+\ldots+x_r\mathrm{P}) = \mathrm{N}$ is a Cohen-Macaulay module; furthermore $(x_i)_{1\leq i\leq r}$ is M-regular. □

(16.5.7) Remark. It follows from (16.5.6) that there is an identity between *systems of parameters* for M and the maximal M-regular sequences of elements of $\mathfrak{m}$ when M is a Cohen-Macaulay module. Conversely, it follows from (16.4.1) that if there is any M-regular sequence that is a system of parameters for M, then M is a Cohen-Macaulay module. The last property stated in (16.5.6) also *characterizes* Cohen-Macaulay modules:

(16.5.8) Proposition. *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. Suppose that for every sequence* $(x_i)_{1\leq i\leq r}$ *of elements of* A *forming part of a system of parameters for* M*, and for every prime ideal* $\mathfrak{p}$ *associated to* $\mathrm{N} = \mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})$*, we have* $\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{N})$*. Then* M *is a Cohen-Macaulay module.*

Proof. Let $(y_i)_{1\leq i\leq n}$ be a system of parameters for M; it suffices to show that the sequence (y_i) is M-regular. We argue by induction on $n = \dim(\mathrm{M})$, the proposition being trivial for $n = 0$. By hypothesis (applied with $r = 0$) the prime ideals $\mathfrak{p}_j$ associated to M are all such
[$0_{\text{IV-1}}$ | 38] that $\dim(\mathrm{A}/\mathfrak{p}_j) = \dim(\mathrm{M})$; as y_1 forms part of a system of parameters for M, it follows from (16.3.7) and (16.3.4) that y_1 does not belong to any of the $\mathfrak{p}_j$, hence is M-regular. If we set $\mathrm{P} = \mathrm{M}/y_1\mathrm{M}$, then $(y_i)_{2\leq i\leq n}$ is a system of parameters for P, and it is immediate that P satisfies the hypothesis of the statement; applying the induction hypothesis, one sees that $(y_i)_{2\leq i\leq n}$ is a P-regular sequence, which proves the proposition. □

(16.5.9) Proposition. *Let* A *be a local Noetherian ring,* M *an* A*-module of finite type. Suppose that* M *is a Cohen-Macaulay module. Let* $\mathfrak{p} \in \mathrm{Supp}(\mathrm{M})$*, and set* $r = \dim(\mathrm{M}) - \dim(\mathrm{M}/\mathfrak{p}\mathrm{M})$*. Then there exists an* M*-regular sequence* $(x_i)_{1\leq i\leq r}$*, formed of elements of* $\mathfrak{p}$*; for every such sequence, we have*

$$\dim(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M})) = \dim(\mathrm{M}/\mathfrak{p}\mathrm{M}) = \dim(\mathrm{A}/\mathfrak{p}),$$

and $\mathfrak{p}$ *is a* minimal *element of* $\mathrm{Ass}(\mathrm{M}/(x_1\mathrm{M} + \ldots + x_r\mathrm{M}))$.

Proof. Let us first prove the existence of the x_i; there is nothing to prove for $r = 0$. For $r > 0$, we proceed by induction. As for every prime ideal $\mathfrak{q}_i$ associated to M we have $\dim(\mathrm{A}/\mathfrak{q}_i) = \dim(\mathrm{M})$ (16.5.4), the hypothesis $\dim(\mathrm{M}/\mathfrak{p}\mathrm{M}) < \dim(\mathrm{M})$ implies that $\mathfrak{p}$ cannot be contained in any of the $\mathfrak{q}_i$, the latter being the minimal prime ideals among those containing $\mathrm{Ann}(\mathrm{M})$ (16.1.2.2) and (16.1.7); one concludes that $\mathfrak{p}$ is not contained in the union of the $\mathfrak{q}_i$ (Bourbaki, *Alg. comm.*, chap. II, § 1, n° 1, prop. 2), and hence there exists $x_1 \in \mathfrak{p}$ that is M-regular (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 1, cor. 2 of prop. 2). It follows from (16.5.5) that $\mathrm{N} = \mathrm{M}/x_1\mathrm{M}$ is a Cohen-Macaulay module, of dimension $\dim(\mathrm{M}) - 1$; as $x_1 \in \mathfrak{p}$, moreover $\mathrm{N}/\mathfrak{p}\mathrm{N} = \mathrm{M}/\mathfrak{p}\mathrm{M}$, whence $\dim(\mathrm{N}) - \dim(\mathrm{N}/\mathfrak{p}\mathrm{N}) = r - 1$; one can therefore apply the induction hypothesis to N, and if $(x_i)_{2\leq i\leq r}$ is an N-regular sequence formed of elements of $\mathfrak{p}$, it is clear that $(x_i)_{1\leq i\leq r}$ is an M-regular sequence formed of elements of $\mathfrak{p}$.

Now if one sets $P = M/(x_1M + \ldots + x_rM)$, we have $P/\mathfrak{p}P = M/\mathfrak{p}M$ since the x_i are in $\mathfrak{p}$, and $\dim(P) = \dim(P/\mathfrak{p}P)$ by (16.5.6). But since P is a Cohen-Macaulay module, we also have $\dim(P) = \dim(A/\mathfrak{p}')$ for every $\mathfrak{p}' \in \mathrm{Ass}(P)$ (16.5.4). As $\mathfrak{p} \in \mathrm{Supp}(P)$ (**0**$_{\mathrm{I}}$, 1.7.5), $\mathfrak{p}$ contains some $\mathfrak{p}' \in \mathrm{Ass}(P)$ (Bourbaki, *Alg. comm.*, chap. IV, § 1, n° 4, th. 2), and as $\dim(P) = \dim(P/\mathfrak{p}P) \leq \dim(A/\mathfrak{p}) \leq \dim(A/\mathfrak{p}') = \dim(P)$, one necessarily has $\mathfrak{p} = \mathfrak{p}'$ (16.1.2.2), which completes the proof. □

(16.5.10) Corollary. *Under the same hypotheses as in (16.5.9):*

(i) $M_{\mathfrak{p}}$ *is an* $A_{\mathfrak{p}}$*-module of Cohen-Macaulay.*

(ii) *We have*

$$\dim(M) = \dim_A(M/\mathfrak{p}M) + \dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}). \tag{16.5.10.1}$$

Proof. With the notations of (16.5.9), let x'_i be the canonical images of the x_i in $A_{\mathfrak{p}}$ $(1 \leq i \leq r)$; as the x'_i belong to the maximal ideal of $A_{\mathfrak{p}}$ and form a $M_{\mathfrak{p}}$-regular sequence by flatness (15.1.14), we have

$$\mathrm{prof}_{A_{\mathfrak{p}}}(M_{\mathfrak{p}}) \geq r = \dim(M) - \dim(M/\mathfrak{p}M) \geq \dim_{A_{\mathfrak{p}}}(M_{\mathfrak{p}})$$

(by virtue of (16.1.8.1)). But taking into account (16.4.5.1), the three terms of this inequality are necessarily equal, whence the corollary. □

(16.5.11) Corollary. *Let* A *be a local Noetherian ring; suppose that there exists a* [$0_{\text{IV-1}}$ | 39] *Cohen-Macaulay* A*-module of finite type* M *with support* Spec(A)*. Then, for every prime ideal* $\mathfrak{p}$ *of* A*, we have*

$$\dim(A) = \dim(A/\mathfrak{p}) + \dim(A_{\mathfrak{p}}). \tag{16.5.11.1}$$

Proof. Indeed, $\mathrm{Supp}(M/\mathfrak{p}M) = \mathrm{Spec}(A/\mathfrak{p})$ (**0**$_{\mathrm{I}}$, 1.7.5) and $\mathrm{Supp}(M_{\mathfrak{p}}) = \mathrm{Spec}(A_{\mathfrak{p}})$; the relation (16.5.11.1) is thus a special case of (16.5.10.1). □

(16.5.12) Corollary. *Every quotient ring of a local Noetherian ring* A *satisfying the conditions of (16.5.11) (in particular every quotient ring of a local Cohen-Macaulay ring) is* catenary*.*

Proof. It suffices evidently to prove that A itself is catenary, that is to say for two prime ideals $\mathfrak{p} \subset \mathfrak{q}$ of A, we have (16.1.4.2)

$$\dim(A_{\mathfrak{q}}) = \dim(A_{\mathfrak{q}}/\mathfrak{p}A_{\mathfrak{q}}) + \dim(A_{\mathfrak{p}}).$$

But, by virtue of (16.5.10), (i) $A_{\mathfrak{q}}$ satisfies the same hypotheses as A, and the preceding relation is then none other than (16.5.11.1) applied to $A_{\mathfrak{q}}$ and to the prime ideal $\mathfrak{p}A_{\mathfrak{q}}$ of $A_{\mathfrak{q}}$. □

(16.5.13) Let A be a Noetherian ring, M an A-module of finite type. We say that M is a *Cohen-Macaulay* A*-module* if, for every prime ideal $\mathfrak{p}$ of A, $M_{\mathfrak{p}}$ is an $A_{\mathfrak{p}}$-module of Cohen-Macaulay; by virtue of (16.5.10) this definition coincides with (16.5.1) when A is *local*. We say that A is a *Cohen-Macaulay ring* if all the $A_{\mathfrak{p}}$ are. It is clear that if M (resp. A) is a Cohen-Macaulay A-module (resp. a Cohen-Macaulay ring), $S^{-1}M$ is a Cohen-Macaulay $S^{-1}A$-module (resp. $S^{-1}A$ is a Cohen-Macaulay ring) for every multiplicative subset S of A.

§17 Regular rings

17.1 Definition of regular rings

[$0_{\text{IV-1}}$ | 39] **(17.1.1) Proposition.** *Let A be a Noetherian local ring of dimension n, $\mathfrak{m}$ its maximal ideal, $k = A/\mathfrak{m}$ its residue field. The following conditions are equivalent:*

a) *The canonical surjective homomorphism of graded k-modules (15.1.1)*

$$\varphi : \mathbf{S}_k^*(\mathfrak{m}/\mathfrak{m}^2) \to \mathrm{gr}_{\mathfrak{m}}^*(A)$$

(where the second term is the graded k-module associated to A equipped with the $\mathfrak{m}$-preadic filtration) is bijective.

b) *We have $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2) = n$.*

c) *The ideal $\mathfrak{m}$ admits a system of generators of n elements.*

d) *The ideal $\mathfrak{m}$ admits a system of generators that is an A-regular sequence.*

Proof. By Nakayama's lemma, $\mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2)$ is the smallest number of elements of a system of generators of $\mathfrak{m}$, so b) and c) are equivalent. On the other hand, if $(x_i)_{1\leq i\leq r}$ is a system of generators of $\mathfrak{m}$ whose classes $\overline{x}_i$ mod. $\mathfrak{m}^2$ form a basis of the k-vector space $\mathfrak{m}/\mathfrak{m}^2$,
[$0_{\text{IV-1}}$ | 40] $\mathbf{S}^*(\mathfrak{m}/\mathfrak{m}^2)$ is isomorphic to the polynomial ring $k[\mathrm{T}_1, \ldots, \mathrm{T}_r]$; taking into account that every A-module of finite type is separated for the $\mathfrak{m}$-preadic filtration (0_{I}, 7.3.5), it follows from (15.1.9) that conditions a) and d) are equivalent; moreover, since every A-regular sequence of elements of $\mathfrak{m}$ has at most n elements (16.4.1), we see that d) implies c). It remains to prove that c) implies a).

Let us set, for brevity, $\mathrm{S} = \mathbf{S}^*(\mathfrak{m}/\mathfrak{m}^2) = k[\mathrm{T}_1, \ldots, \mathrm{T}_n]$, $\mathrm{G} = \mathrm{gr}_{\mathfrak{m}}^*(A)$, and consider the exact sequence $0 \to \mathfrak{J} \to \mathrm{S} \xrightarrow{\varphi} \mathrm{G} \to 0$, where the kernel $\mathfrak{J}$ of φ is thus a graded ideal of S. For every integer $s > 0$, we thus have

$$\binom{s+n-1}{n-1} = \mathrm{long}(\mathrm{S}_s) = \mathrm{long}(\mathrm{G}_s) + \mathrm{long}(\mathfrak{J}_s). \tag{17.1.1.1}$$

Suppose $\mathfrak{J} \neq 0$, so that there exists a homogeneous element $u \in \mathfrak{J}$ of degree $h > 0$; $\mathfrak{J}_s$ contains $u\mathrm{S}_{s-h}$ for $s \geq h$, and since $u \neq 0$ and S is integral, $u\mathrm{S}_{s-h}$ is isomorphic to S_{s-h} as a k-vector space; we would thus have $\mathrm{long}(\mathfrak{J}_s) \geq \mathrm{long}(\mathrm{S}_{s-h}) = \binom{s-h+n-1}{n-1}$, whence for $s \geq h$,

$$\mathrm{long}(\mathrm{G}_s) \leq \binom{s+n-1}{n-1} - \binom{s-h+n-1}{n-1}. \tag{17.1.1.2}$$

But the second term of (17.1.1.2) is a polynomial in s of degree $\leq n-2$; since $\mathrm{G}_s = \mathfrak{m}^s/\mathfrak{m}^{s+1}$, and for s sufficiently large, $\mathrm{long}(\mathrm{G}_s)$ is a polynomial in s of degree exactly equal to $n-1$ whose leading coefficient is > 0 (16.2.1), which contradicts the inequality (17.1.1.2). □

(17.1.2) Definition. We say that a Noetherian local ring that satisfies the equivalent conditions of (17.1.1) is *regular*.

(17.1.3) Corollary. *A regular local ring is integral, integrally closed, and a Cohen-Macaulay ring.*

Proof. The last assertion follows from (17.1.1)[d)]; on the other hand, if A is regular, $\mathrm{gr}^*_{\mathfrak{m}}(A)$ is integral and completely integrally closed, being isomorphic to $k[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; we conclude that A also possesses these two properties (Bourbaki, *Alg. comm.*, chap. III, §2, n° 3, cor. of prop. 1 and chap. V, §1, n° 5, prop. 15). □

(17.1.4) Example.

(i) A regular local ring of dimension 0, being integral by (17.1.3), is necessarily a *field*, and conversely.

(ii) For a Noetherian local ring of dimension 1 to be regular, it is necessary and sufficient that it be a *discrete valuation ring*: indeed, to say that a Noetherian local ring of dimension 1 is regular means that its maximal ideal is *principal*, and the conclusion follows from Bourbaki, *Alg. comm.*, chap. VI, §3, n° 6, prop. 9.

(iii) Let k be a field; the formal power series ring $A = k[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is a *regular ring of dimension n*; indeed, it is clear that the T_i $(1 \leq i \leq n)$ generate the maximal ideal $\mathfrak{m}$ of A and form an A-regular sequence, since $A/(\mathrm{T}_1 A + \cdots + \mathrm{T}_i A)$ is isomorphic to $k[[\mathrm{T}_{i+1}, \ldots, \mathrm{T}_n]]$.

(17.1.5) Proposition. *For a Noetherian local ring A to be regular, it is necessary and sufficient that its completion $\widehat{A}$ be regular.*

Proof. Indeed, the maximal ideal of $\widehat{A}$ is $\mathfrak{m}\widehat{A}$ and we know that $\mathfrak{m}^h/\mathfrak{m}^{h+1}$ and $(\mathfrak{m}\widehat{A})^h/(\mathfrak{m}\widehat{A})^{h+1}$ are isomorphic k-vector spaces; condition a) of (17.1.1) is thus the same for A and $\widehat{A}$. □ [0IV-1 | 41]

(17.1.6) Definition. Given a Noetherian local ring A, with maximal ideal $\mathfrak{m}$, we call a *regular system of parameters* of A a system of parameters for A (16.3.5) that generates $\mathfrak{m}$.

The existence of such a system is equivalent to the fact that A is regular (17.1.1); if $(x_i)_{1 \leq i \leq n}$ is a regular system of parameters, it is a minimal system of generators of $\mathfrak{m}$, whose classes mod. $\mathfrak{m}^2$ form a basis of $\mathfrak{m}/\mathfrak{m}^2$ over k; by virtue of (17.1.1)[a)] and (15.1.9), (x_i) is a maximal A-regular sequence (whence the terminology).

One should note however that, in a regular ring, a system of parameters for A that is also an A-regular sequence is *not* necessarily a regular system of parameters, as shown by the example of k-th powers of a regular system of parameters (15.1.20).

(17.1.7) Proposition. *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, $k = A/\mathfrak{m}$ its residue field, $(x_i)_{1 \leq i \leq r}$ a sequence of elements of $\mathfrak{m}$, $\mathfrak{J}$ the ideal $x_1 A + \cdots + x_r A$. The following conditions are equivalent:*

a) *A is regular and the x_i are part of a regular system of parameters of A.*

a') *A is regular and the classes $\overline{x}_i$ of the x_i mod. $\mathfrak{m}^2$ are linearly independent over k.*

b) *The x_i are part of a system of parameters for A and $A/\mathfrak{J}$ is a regular ring.*

Moreover, when these conditions are satisfied, $\mathfrak{J}$ is a prime ideal.

Proof. The last assertion follows trivially from the fact that $A/\mathfrak{J}$, being regular, is integral (17.1.3). Set $n = \dim(A)$. The equivalence of a) and a') is immediate; indeed, the classes mod. $\mathfrak{m}^2$ of the elements of a regular system of parameters form a basis of $\mathfrak{m}/\mathfrak{m}^2$ over k, and conversely, if the $\overline{x}_i$ $(1 \leq i \leq r)$ are linearly independent over k, one can find $n-r$ elements $x_i \in \mathfrak{m}$ $(r+1 \leq i \leq n)$ such that the $\overline{x}_i$ $(1 \leq i \leq n)$ form a basis of $\mathfrak{m}/\mathfrak{m}^2$, so $(x_i)_{1\leq i\leq n}$ is a regular system of parameters. To see that a) implies b), note that since the x_i are part of a system of parameters of A, we have $\dim(A/\mathfrak{J}) = n-r$ (16.3.6); let $\mathfrak{n} = \mathfrak{m}/\mathfrak{J}$ be the ideal of $A/\mathfrak{J}$. We have an exact sequence

$$0 \to (\mathfrak{m}^2+\mathfrak{J})/\mathfrak{m}^2 \to \mathfrak{m}/\mathfrak{m}^2 \to \mathfrak{n}/\mathfrak{n}^2 \to 0 \tag{17.1.7.1}$$

since $\mathfrak{n}^2 = (\mathfrak{m}^2+\mathfrak{J})/\mathfrak{J}$; hypothesis a) implies that $\operatorname{rg}_k((\mathfrak{m}^2+\mathfrak{J})/\mathfrak{m}^2) = r$, so $\operatorname{rg}_k(\mathfrak{n}/\mathfrak{n}^2) = n-r = \dim(A/\mathfrak{J})$, which proves b) by virtue of (17.1.1)[b)].

Conversely, to prove that b) implies a), note that the fact that the x_i are part of a system of parameters implies $\dim(A/\mathfrak{J}) = n-r$ (16.3.6); the hypothesis that $A/\mathfrak{J}$ is regular implies on the other hand $\operatorname{rg}_k(\mathfrak{n}/\mathfrak{n}^2) = n-r$ (17.1.1); moreover we evidently have $\operatorname{rg}_k((\mathfrak{m}^2+\mathfrak{J})/\mathfrak{m}^2) \leq r$, so from (17.1.7.1) we obtain $\operatorname{rg}_k(\mathfrak{m}/\mathfrak{m}^2) \leq r+(n-r) = n$; thus A is regular by (16.2.6) and (17.1.1). Furthermore the relation $\operatorname{rg}_k(\mathfrak{m}/\mathfrak{m}^2) = n$ then implies $\operatorname{rg}_k((\mathfrak{m}^2+\mathfrak{J})/\mathfrak{m}^2) = r$, and consequently the $\overline{x}_i$ are linearly independent over k. □

[$0_{\text{IV-1}}$ | 42] **(17.1.8) Corollary.** *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, t an element of $\mathfrak{m}$. The following conditions are equivalent:*

a) *A/tA is regular and t is a non-zero-divisor in A.*

b) *A is regular and $t \notin \mathfrak{m}^2$.*

Proof. This is the special case $r = 1$ of (17.1.7) (taking into account that an element of $\mathfrak{m}$ that is a non-zero-divisor is part of a system of parameters (16.4.1)). □

(17.1.9) Corollary. *Let A be a regular local ring, $\mathfrak{m}$ its maximal ideal, $\mathfrak{J}$ an ideal of A contained in $\mathfrak{m}$. The following conditions are equivalent:*

a) *The ring $A/\mathfrak{J}$ is regular.*

b) *$\mathfrak{J}$ is generated by a sequence $(x_i)_{1\leq i\leq r}$ forming part of a regular system of parameters of A.*

Proof. We have already seen (17.1.7) that b) implies a). Conversely, suppose that $A/\mathfrak{J}$ is regular (which implies that $\mathfrak{J}$ is prime) and let $n = \dim(A)$, $n-r = \dim(A/\mathfrak{J})$; with the notation of (17.1.7), the exact sequence (17.1.7.1) gives $\operatorname{rg}_k((\mathfrak{m}^2+\mathfrak{J})/\mathfrak{m}^2) = r$, so there exists a sequence $(x_i)_{1\leq i\leq r}$ of elements of $\mathfrak{J}$ forming part of a regular system of parameters of A. Set $\mathfrak{J}' = x_1A + \cdots + x_rA$; it follows from (17.1.7) that $\mathfrak{J}'$ is a prime ideal of A and that $A/\mathfrak{J}'$ is regular and of dimension $n-r$; but since $A/\mathfrak{J} = (A/\mathfrak{J}')/(\mathfrak{J}/\mathfrak{J}')$ and $\mathfrak{J}/\mathfrak{J}'$ is prime in the integral ring $A/\mathfrak{J}'$, the dimensions of $A/\mathfrak{J}$ and $A/\mathfrak{J}'$ can only be equal if $\mathfrak{J} = \mathfrak{J}'$ (16.1.2.2). □

17.2 Reminders on projective and injective dimension of modules

(17.2.1) Let A be a ring, M an A-module. Recall (M, VI, 2) that we call *projective dimension* (resp. *injective dimension*) of M and denote $\dim.\,\mathrm{proj}(M)$ or $\dim.\,\mathrm{proj}_A(M)$ (resp. $\dim.\,\mathrm{inj}(M)$ or $\dim.\,\mathrm{inj}_A(M)$) the smallest n (integer or equal to $+\infty$) such that there exists a left projective resolution (resp. a right injective resolution) of M of length n. It is equivalent (loc. cit.) to say that n is the smallest number such that for every A-module N, we have $\mathrm{Ext}^i_A(M,N)=0$ (resp. $\mathrm{Ext}^i_A(N,M)=0$) for all $i>n$, or only for $i=n+1$. For every direct factor M' of M, we thus have $\dim.\,\mathrm{proj}(M')\leq\dim.\,\mathrm{proj}(M)$ since $\mathrm{Ext}^i_A(M',N)$ is a direct factor of $\mathrm{Ext}^i_A(M,N)$; similarly $\dim.\,\mathrm{inj}(M')\leq\dim.\,\mathrm{inj}(M)$. A condition equivalent to $\dim.\,\mathrm{proj}(M)=n$ (resp. $\dim.\,\mathrm{inj}(M)=n$) is that n is the smallest number such that, for every exact sequence

$$0\to \mathrm{R}\to \mathrm{P}_{n-1}\to\cdots\to \mathrm{P}_0\to M\to 0$$

(resp. $0\to M\to \mathrm{Q}_0\to\cdots\to \mathrm{Q}_{n-1}\to \mathrm{C}\to 0$), where all the P_i for $0\leq i<n$ are projective (resp. all the Q_i for $0\leq i<n$ are injective), R is projective (resp. C is injective).

(17.2.2) Remark.

(i) To say that M is a projective (resp. injective) A-module is therefore equivalent to saying that $\dim.\,\mathrm{proj}(M)=0$ (resp. $\dim.\,\mathrm{inj}(M)=0$).

(ii) Let T be a covariant additive functor from the category of A-modules to an abelian category. It follows immediately from the definitions of (17.2.1) and those of derived functors that if $\dim.\,\mathrm{proj}(M)\leq n$ (resp. $\dim.\,\mathrm{inj}(M)\leq n$), we have $\mathrm{L}^i\mathrm{T}(M)=0$ (resp. $\mathrm{R}^i\mathrm{T}(M)=0$) for all $i>n$. [$0_{\text{IV-1}}$ | 43]

(iii) If we suppose A Noetherian and M of finite type, the last interpretation of the projective dimension given in (17.2.1) shows that if $\dim.\,\mathrm{proj}(M)=n$, M admits a left resolution of length n formed of projective modules *of finite type*. If moreover A is a Noetherian *local* ring, M admits a resolution of length n by *free* modules of finite type, a projective module of finite type then being free (Bourbaki, *Alg. comm.*, chap. II, §3, n° 2, cor. 2 of prop. 5).

(17.2.3) Lemma. *Let A be a ring, M an A-module. For $\dim.\,\mathrm{inj}(M)\leq n$, it is necessary and sufficient that for every monogenic A-module N, we have $\mathrm{Ext}^{n+1}_A(N,M)=0$.*

Proof. With the notation of (17.2.1), it suffices to prove that C is injective; for every A-module N, $\mathrm{Ext}^{n+1}_A(N,M)$ is isomorphic to $\mathrm{Ext}^1_A(N,\mathrm{C})$ (M, V, 7), so we have $\mathrm{Ext}^1_A(N,\mathrm{C})=0$ for every module N of the form $A/\mathfrak{J}$, where $\mathfrak{J}$ is any ideal of A. The exact sequence of Ext then shows that the canonical homomorphism $\mathrm{Hom}(A,\mathrm{C})\to\mathrm{Hom}(\mathfrak{J},\mathrm{C})$ is surjective for every ideal $\mathfrak{J}$ of A, which implies that C is an injective A-module (M, I, 3.2). □

(17.2.4) Lemma. *Let A be a Noetherian local ring, M an A-module of finite type. For $\dim.\,\mathrm{proj}(M)\leq n$, it is necessary and sufficient that for every monogenic A-module N, we have $\mathrm{Ext}^{n+1}_A(M,N)=0$.*

Proof. We know in fact (M, VI, 2.5) that the condition $\dim.\,\mathrm{proj}(M) \leq n$ is equivalent to $\mathrm{Ext}_A^{n+1}(M,N) = 0$ for every A-module N of finite type; to see that the condition of the statement is also sufficient, we argue by induction on the number m of generators of N: there is a submodule N_1 of N generated by $m-1$ elements and such that $\mathrm{N}_2 = N/\mathrm{N}_1$ is monogenic; from the exact sequence $0 \to \mathrm{N}_1 \to N \to \mathrm{N}_2 \to 0$, we then deduce the exact sequence $\mathrm{Ext}_A^{n+1}(M,\mathrm{N}_1) \to \mathrm{Ext}_A^{n+1}(M,N) \to \mathrm{Ext}_A^{n+1}(M,\mathrm{N}_2)$ and the induction hypothesis shows that the condition of the statement indeed implies $\mathrm{Ext}_A^{n+1}(M,N) = 0$. □

(17.2.5) Corollary. *Let A be a Noetherian ring, M an A-module. We have*

$$\dim.\,\mathrm{inj}_A(M) = \sup_{\mathfrak{m}} \big(\dim.\,\mathrm{inj}_{A_\mathfrak{m}}(M_\mathfrak{m})\big) \tag{17.2.5.1}$$

and if M is of finite type

$$\dim.\,\mathrm{proj}_A(M) = \sup_{\mathfrak{m}} \big(\dim.\,\mathrm{proj}_{A_\mathfrak{m}}(M_\mathfrak{m})\big) \tag{17.2.5.2}$$

where $\mathfrak{m}$ ranges over the set of prime ideals (or the set of maximal ideals) of A.

Proof. Indeed, if N is an A-module of finite type (thus of finite presentation), we have, for every [$0_{\text{IV-1}}$ | 44] multiplicative subset S of A and for all $i \geq 0$

$$S^{-1}\,\mathrm{Ext}_A^i(N,M) = \mathrm{Ext}_{S^{-1}A}^i(S^{-1}N, S^{-1}M)$$

by flatness, considering a free resolution of N and using the fact that the preceding relation is true for $i = 0$ (Bourbaki, *Alg. comm.*, chap. II, §2, n° 7, prop. 19). In particular $\mathrm{Ext}_{A_\mathfrak{m}}^i(A_\mathfrak{m}/\mathfrak{J}A_\mathfrak{m}, M_\mathfrak{m}) = (\mathrm{Ext}_A^i(A/\mathfrak{J},M))_\mathfrak{m}$ for every prime ideal $\mathfrak{m}$ and every ideal $\mathfrak{J}$ of A; taking into account (17.2.3) and the fact that every ideal of $A_\mathfrak{m}$ is of the form $\mathfrak{J}A_\mathfrak{m}$ for a suitable ideal $\mathfrak{J}$ of A, we deduce formula (17.2.5.1) from what precedes and from Bourbaki, *Alg. comm.*, chap. II, §3, n° 3, th. 1. We proceed similarly for (17.2.5.2) using this time (17.2.4) and interchanging the roles of M and N. □

For Noetherian rings and modules of finite type, the study of projective or injective dimension is thus reduced by (17.2.5) to the case of local rings. We then have the

(17.2.6) Lemma. *Let A be a Noetherian local ring, k its residue field, M an A-module of finite type. For $\dim.\,\mathrm{proj}(M) \leq n$, it is necessary and sufficient that $\mathrm{Tor}_i^A(M,k) = 0$ for $i > n$, and it suffices that $\mathrm{Tor}_{n+1}^A(M,k) = 0$.*

Proof. The necessity is a special case of the remark (17.2.2)[(ii)], applied to the covariant functor $M \mapsto k \otimes_A M$. To prove the sufficiency, it suffices, with the notation of (17.2.1), to establish that R is projective when the P_i are assumed of finite type; now $\mathrm{Tor}_{n+1}^A(M,k)$ is isomorphic to $\mathrm{Tor}_1^A(\mathrm{R},k)$ (M, V, 7); and we know that, since R is of finite type, the condition $\mathrm{Tor}_1^A(\mathrm{R},k) = 0$ implies that R is free (Bourbaki, *Alg. comm.*, chap. II, §3, n° 2, cor. 2 of prop. 5). □

(17.2.7) Corollary. *Under the hypotheses of (17.2.6), let x be an M-regular element of A belonging to the maximal ideal of A; then we have*

$$\dim.\,\mathrm{proj}(M/xM) = \dim.\,\mathrm{proj}(M) + 1. \tag{17.2.7.1}$$

Proof. Indeed, from the exact sequence $0 \to M \xrightarrow{x} M \to M/xM \to 0$ defined by multiplication by x in M, we deduce by the exact sequence of Tor:

$$\mathrm{Tor}_i^A(M,k) \xrightarrow{x} \mathrm{Tor}_i^A(M/xM,k) \to \mathrm{Tor}_{i-1}^A(M,k) \xrightarrow{x} \mathrm{Tor}_{i-1}^A(M,k)$$

for all $i \geq 1$. Now, for every A-module N, the homothety of ratio x in $M \otimes_A N$ arises equally well from the homothety of ratio x in M as from the homothety of ratio x in N; we conclude immediately, since the homothety of ratio x in k is zero by definition, that for every i, the homomorphism $\mathrm{Tor}_i^A(M,k) \xrightarrow{x} \mathrm{Tor}_i^A(M,k)$ is zero; in other words, we have the exact sequence

$$0 \to \mathrm{Tor}_i^A(M,k) \to \mathrm{Tor}_i^A(M/xM,k) \to \mathrm{Tor}_{i-1}^A(M,k) \to 0.$$

If $\dim.\mathrm{proj}(M) = n$, we have $\mathrm{Tor}_n^A(M,k) \neq 0$ and $\mathrm{Tor}_{n+1}^A(M,k) = \mathrm{Tor}_{n+2}^A(M,k) = 0$ by (17.2.6). It thus follows from what precedes that $\mathrm{Tor}_{n+1}^A(M/xM,k) \neq 0$ and $\mathrm{Tor}_{n+2}^A(M/xM,k) = 0$, so $\dim.\mathrm{proj}(M/xM) = n+1$ by (17.2.6). □

(17.2.8) Proposition. (M. Auslander) *Let A be a ring. The following conditions are equivalent:*

a) *Every A-module is of projective dimension $\leq n$.*

a') *Every A-module of finite type is of projective dimension $\leq n$.*

b) *Every A-module is of injective dimension $\leq n$.*

c) *For every pair of A-modules M, N we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*

c') *For every pair of A-modules M, N such that M is of finite type (or only monogenic), we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*

Proof. This follows immediately from (17.2.1) and (17.2.3). □

The smallest number n (integer or $+\infty$) for which the equivalent conditions of (17.2.8) are satisfied is called the *global cohomological dimension* (or simply *cohomological dimension*) of A and denoted $\dim.\mathrm{coh}(A)$. [$0_{\text{IV-1}}$ | 45]

(17.2.9) Proposition. *Let A be a Noetherian ring. The following conditions are equivalent:*

a) $\dim.\mathrm{coh}(A) \leq n$.

b) *Every A-module of finite type is of injective dimension $\leq n$.*

c) *For every pair of A-modules of finite type, M, N, we have $\mathrm{Ext}_A^{n+1}(M,N) = 0$.*

Proof. This follows immediately from the definition and from (17.2.4). □

(17.2.10) Corollary. *If A is a Noetherian ring, we have*

$$\dim.\mathrm{coh}(A) = \sup_{\mathfrak{m}} \left(\dim.\mathrm{coh}(A_{\mathfrak{m}})\right) \tag{17.2.10.1}$$

where $\mathfrak{m}$ ranges over the spectrum of A (or the set of maximal ideals of A).

Proof. This follows immediately from (17.2.9) and (17.2.5). □

(17.2.11) Proposition. *Let A be a Noetherian local ring, k its residue field. For* $\dim.\operatorname{coh}(A) \leq n$, *it is necessary that* $\operatorname{Tor}_i^A(k,k) = 0$ *for* $i > n$, *and it suffices that* $\operatorname{Tor}_{n+1}^A(k,k) = 0$.

Proof. Taking into account (17.2.6), it suffices to prove that the relations $\dim.\operatorname{coh}(A) \leq n$ and $\dim.\operatorname{proj}_A(k) \leq n$ are equivalent. It is clear that the first implies the second by definition. Conversely, if $\dim.\operatorname{proj}_A(k) \leq n$, we have $\operatorname{Tor}_i^A(M,k) = 0$ for $i > n$ and for every A-module M by (17.2.2)[(ii)]; thus $\dim.\operatorname{proj}(M) \leq n$, which proves the proposition by (17.2.8). □

(17.2.12) Corollary. *Let A be a Noetherian ring. For* $\dim.\operatorname{coh}(A) \leq n$, *it is necessary that, for every maximal ideal $\mathfrak{m}$ of A, we have* $\operatorname{Tor}_i^{A_{\mathfrak{m}}}(A/\mathfrak{m}, A/\mathfrak{m}) = 0$ *for* $i > n$, *and it suffices that these relations be satisfied for* $i = n+1$.

Proof. This follows immediately from (17.2.11) and (17.2.10). □

(17.2.13) Proposition. *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism making B a flat A-module. Then we have*

$$\dim.\operatorname{coh}(A) \leq \dim.\operatorname{coh}(B). \tag{17.2.13.1}$$

Proof. Suppose that $\dim.\operatorname{coh}(B) = n$ is finite; it suffices to prove that for every pair (M,N) of A-modules of finite type, we have $\operatorname{Tor}_i^A(M,N) = 0$ for $i > n$ (17.2.11). Since B is a faithfully flat A-module (0_{I}, 6.6.2), it amounts to the same (0_{I}, 6.4.1) to show that

$$\operatorname{Tor}_i^A(M,N) \otimes_A B = 0. \tag{17.2.13.2}$$

[$0_{\text{IV-1}}$ | 46] Now, if $\mathrm{L}_\bullet = (\mathrm{L}_j)$ is a right resolution of M by free A-modules, it follows from the fact that B is a flat A-module that $\mathrm{L}_\bullet \otimes_A B = (\mathrm{L}_j \otimes_A B)$ is a right resolution of the B-module $M \otimes_A B$ by free B-modules; moreover, we have $(\mathrm{L}_j \otimes_A B) \otimes_B (N \otimes_A B) = (\mathrm{L}_j \otimes_A N) \otimes_A B$, whence we conclude immediately that the first term of (17.2.13.2) is equal to $\operatorname{Tor}_i^B(M \otimes_A B, N \otimes_A B)$; the hypothesis on B implies that this B-module is zero for $i > n$ (17.2.2)[(ii)], whence the conclusion. □

(17.2.14) Let $(X, \mathscr{O}_X)$ be a ringed space, $\mathscr{F}$ an $\mathscr{O}_X$-Module; we call the *pointwise projective dimension* (resp. *injective dimension*) of $\mathscr{F}$ and denote $\dim.\operatorname{proj}(\mathscr{F})$ (resp. $\dim.\operatorname{inj}(\mathscr{F})$) the number $\sup_{x\in X}(\dim.\operatorname{proj}(\mathscr{F}_x))$ (resp. $\sup_{x\in X}(\dim.\operatorname{inj}(\mathscr{F}_x))$). We call the *pointwise cohomological dimension* of X and denote $\dim.\operatorname{coh}(X)$ the number $\sup_{x\in X}(\dim.\operatorname{coh}(\mathscr{O}_x))$. It follows from (17.2.5) and (17.2.10) that when A is a Noetherian ring, M an A-module of finite type and $X = \operatorname{Spec}(A)$, we have $\dim.\operatorname{proj}(\widetilde{M}) = \dim.\operatorname{proj}(M)$, $\dim.\operatorname{inj}(\widetilde{M}) = \dim.\operatorname{inj}(M)$ and $\dim.\operatorname{coh}(X) = \dim.\operatorname{coh}(A)$. We call the *projective dimension* (resp. *injective dimension*) of $\mathscr{F}$ at a point $x \in X$ the projective (resp. injective) dimension of $\mathscr{F}_x$, and the *cohomological dimension of X at a point x* the cohomological dimension of $\mathscr{O}_x$.

(17.2.15) Proposition. *Let X, Y be two ringed spaces in Noetherian local rings, $f : X \to Y$ a flat morphism. If* $\dim.\operatorname{coh}(X) \leq n$, *then Y is of cohomological dimension $\leq n$ at every point of $f(X)$.*

Proof. This follows immediately from (17.2.13). □

17.3 Cohomological theory of regular rings

(17.3.1) Theorem. (Hilbert-Serre) *Let A be a Noetherian local ring. For A to be of finite cohomological dimension, it is necessary and sufficient that A be regular; we then have*

$$\dim.\,\mathrm{coh}(A) = \dim(A). \tag{17.3.1.1}$$

Proof. Suppose A regular; let $\mathfrak{m}$ be its maximal ideal, $\mathbf{x} = (x_i)_{1\leq i\leq n}$ a regular system of parameters of A (17.1.6); consider the Koszul complex $\mathrm{K}_\bullet(\mathbf{x})$ (**III**, 1.1.1), which is formed of free A-modules, with $\mathrm{K}_i(\mathbf{x}) = 0$ for $i > n$; since (x_i) is a regular sequence, we have $\mathrm{H}_i(\mathrm{K}_\bullet(\mathbf{x})) = 0$ for $i > 0$ (**III**, 1.1.4 and 1.1.3.3) and $\mathrm{H}_0(\mathrm{K}_\bullet(\mathbf{x})) = A/(x_1A + \cdots + x_nA) = A/\mathfrak{m} = k$; the $\mathrm{K}_i(\mathbf{x})$ thus form a free resolution of k of length n. Now, the fact that the x_i belong to $\mathfrak{m}$ immediately implies that in the complex $\mathrm{K}_\bullet(\mathbf{x}, k) = \mathrm{K}_\bullet(\mathbf{x})\otimes_A k$, the boundary operator is zero in all dimensions, so that we have, by definition, $\mathrm{Tor}_i^A(k,k) = \bigwedge^i(k^n)$; the equality (17.3.1.1) thus follows immediately from (17.2.11) (this result is essentially the "syzygy theorem" of Hilbert).

Let us now show that if A is a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, and if $\dim.\,\mathrm{proj}_A(\mathfrak{m})$ is *finite*, then A is regular, which will finish proving (17.3.1). We proceed by induction on $n = \mathrm{rg}_k(\mathfrak{m}/\mathfrak{m}^2)$. For $n = 0$, we have $\mathfrak{m} = 0$ and the assertion is trivial. □

(17.3.1.2) Lemma. (Nagata) *If every element of $\mathfrak{m} - \mathfrak{m}^2$ is a zero divisor in A, there exists $c \neq 0$ in A such that $c\mathfrak{m} = 0$ (in other words $\mathfrak{m} \in \mathrm{Ass}(A)$).*

Proof. We may restrict to the case $\mathfrak{m} \neq 0$, hence $\mathfrak{m} \neq \mathfrak{m}^2$. The hypothesis implies that $\mathfrak{m} - \mathfrak{m}^2$ is contained in the union of the ideals $\mathfrak{p}_i$ of $\mathrm{Ass}(A)$ (Bourbaki, *Alg. comm.*, chap. IV, §1, n° 1, cor. 3 of prop. 2); thus $\mathfrak{m}$ is contained in the union of $\mathfrak{m}^2$ and the $\mathfrak{p}_i$, hence in one of the $\mathfrak{p}_i$, since $\mathfrak{m} \not\subset \mathfrak{m}^2$ (Bourbaki, *Alg. comm.*, chap. II, §1, n° 1, prop. 2); $\mathfrak{m}$ being maximal, this proves the lemma. [$0_{\text{IV-1}}$ | 47] □

(17.3.1.3) Lemma. *If $a \in \mathfrak{m} - \mathfrak{m}^2$, $\mathfrak{m}/Aa$ is isomorphic to a direct factor of $\mathfrak{m}/a\mathfrak{m}$.*

Proof. There exists a minimal system of generators of $\mathfrak{m}$ containing a (whose images in $\mathfrak{m}/\mathfrak{m}^2$ form a basis of this k-vector space); let $\mathfrak{b}$ be the ideal generated by the elements of this system other than a. Since the relation $xa \in \mathfrak{b}$ implies $x \in \mathfrak{m}$ (considering the image of xa in $\mathfrak{m}/\mathfrak{m}^2$), we have $\mathfrak{b} \cap Aa \subset a\mathfrak{m}$ whence a homomorphism $\mathfrak{b}/(\mathfrak{b} \cap Aa) \to \mathfrak{m}/a\mathfrak{m}$ deduced from the injection $\mathfrak{b} \to \mathfrak{m}$ by passing to quotients, and which is injective. Moreover, $\mathfrak{b} + Aa = \mathfrak{m}$, and the composite homomorphism

$$\mathfrak{m}/Aa = (\mathfrak{b} + Aa)/Aa \xrightarrow{\sim} \mathfrak{b}/(\mathfrak{b} \cap Aa) \to \mathfrak{m}/a\mathfrak{m} \to \mathfrak{m}/Aa$$

is the identity; whence the lemma. □

(17.3.1.4) Lemma. *Let A be a Noetherian local ring, $\mathfrak{m}$ its maximal ideal, E an A-module of finite type and of finite projective dimension. If $a \in \mathfrak{m}$ is A-regular and E-regular, then E/aE is an (A/aA)-module of finite projective dimension, at most equal to $\dim.\,\mathrm{proj}_A(E)$.*

Proof. We argue by induction on $h = \dim.\,\mathrm{proj}_A(E)$, the case $h = 0$ being trivial since then E is a projective A-module, hence E/aE is a projective (A/aA)-module. There exists an exact sequence

$$0 \to N \to L \to E \to 0$$

where L is free and $\dim.\,\mathrm{proj}_A(N) = h-1$ (17.2.2)[(iii)], N being of finite type. Moreover, the sequence

$$0 \to N/aN \to L/aL \to E/aE \to 0$$

[$0_{\text{IV-1}}$ | 48] is exact (15.1.18). Since a is A-regular, it is also N-regular since L is free; the induction hypothesis implies that N/aN is an (A/aA)-module of projective dimension $\leq h-1$, and since L/aL is a free (A/aA)-module, E/aE is an (A/aA)-module of projective dimension $\leq h$. □

Let us now examine two cases:

I. — Suppose first that every element of $\mathfrak{m} - \mathfrak{m}^2$ is a zero divisor in A, in which case (17.3.1.2) there exists $c \neq 0$ in A such that $c\mathfrak{m} = 0$. Let us show then that $\mathfrak{m} = 0$. If this were not the case, note first that $\mathfrak{m}$ could not be a projective A-module, since it would be free (Bourbaki, *Alg. comm.*, chap. II, §3, n° 2, cor. 2 of prop. 5), which contradicts the relation $c\mathfrak{m} = 0$. We would thus have $n = \dim.\,\mathrm{coh}(A) \geq 1$. Since $\mathfrak{m} \in \mathrm{Ass}(A)$, there would exist an exact sequence of A-homomorphisms

$$0 \to k \to A \to E \to 0.$$

But this is absurd, since, in view of the relation $n \geq 1$, the exact sequence of Tor would give the exact sequence $0 \to \mathrm{Tor}^A_{n+1}(E,k) \to \mathrm{Tor}^A_n(k,k) \to 0$; but we have $\mathrm{Tor}^A_{n+1}(E,k) = 0$ (17.2.2)[(ii)] and $\mathrm{Tor}^A_n(k,k) \neq 0$ (17.2.11) and we have reached a contradiction.

II. — We can thus restrict to the case where there exists $a \in \mathfrak{m} - \mathfrak{m}^2$ that is A-regular, and consequently also $\mathfrak{m}$-regular. Consider the ring $A' = A/aA$ and its maximal ideal $\mathfrak{m}' = \mathfrak{m}/aA$; it is clear that $\mathrm{rg}_k(\mathfrak{m}'/\mathfrak{m}'^2) = n-1$. By (17.3.1.4), $\mathfrak{m}/a\mathfrak{m}$ is an A'-module of finite projective dimension, hence so is $\mathfrak{m}' = \mathfrak{m}/aA$, which is a direct factor of it (17.3.1.3) and (17.2.1). The induction hypothesis implies therefore that $A' = A/aA$ is regular, which proves by (17.1.8) that A is regular.

(17.3.2) Corollary. *If A is a regular local ring, $A_\mathfrak{p}$ is regular for every prime ideal $\mathfrak{p}$ of A.*

Proof. Indeed, we have seen (17.2.10) that $\dim.\,\mathrm{coh}(A_\mathfrak{p}) \leq \dim.\,\mathrm{coh}(A)$, so the conclusion follows from (17.3.1). □

(17.3.3) Proposition. *Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, $\mathfrak{m}$ (resp. $\mathfrak{n}$) the maximal ideal of A (resp. B), $k = A/\mathfrak{m}$ (resp. $k' = B/\mathfrak{n}$) the residue field of A (resp. B). We thus have a canonical homomorphism of k'-vector spaces*

$$\psi : (\mathfrak{m}/\mathfrak{m}^2) \otimes_k k' \to \mathfrak{n}/\mathfrak{n}^2. \tag{17.3.3.1}$$

(i) *If B is regular and B is a flat A-module, A is regular.*

(ii) *The following conditions are equivalent:*

a) *B is regular and the homomorphism ψ (17.3.3.1) is injective.*

b) *A and B are regular, and for a regular system of parameters $(x_i)_{1\leq i\leq m}$ of A, the $\varphi(x_i)$ are part of a regular system of parameters of B (in which case this property holds for every regular system of parameters of A).*

c) *B and $B\otimes_A k$ are regular, and B is a flat A-module.*

d) *A and $B\otimes_A k$ are regular, and B is a flat A-module.*

e) *A and $B\otimes_A k$ are regular, and we have*

$$\dim(B) = \dim(A) + \dim(B\otimes_A k). \tag{17.3.3.2}$$

Proof. (i) We have $\dim.\,\mathrm{coh}(A) \leq \dim.\,\mathrm{coh}(B)$ by (17.2.13), so it suffices to apply (17.3.1).

(ii) When A is assumed regular and (x_i) is a regular system of parameters of A, saying that B is a flat A-module is equivalent, by (15.1.21), to saying that the sequence of $y_i = \varphi(x_i)$ is B-regular (since $B\otimes_A k$ is a flat k-module). On the other hand, since $\dim(A) = m$ and the sequence (y_i) generates the ideal $\mathfrak{m}B$, the relation (17.3.3.2), which can also be written $\dim(B/\mathfrak{m}B) = \dim(B) - m$, is equivalent to saying that the sequence $(y_i)_{1\leq i\leq m}$ is part of a system of parameters of B (16.3.7). We thus see that conditions b), d) and e) are respectively equivalent to the following: [$0_{\text{IV-1}}$ | 49]

b') A and B are regular and $(y_i)_{1\leq i\leq m}$ is part of a regular system of parameters of B.

d') A is regular, $B/(\sum y_i B)$ is regular and the sequence (y_i) is B-regular.

e') A is regular, $B/(\sum y_i B)$ is regular, (y_i) is part of a system of parameters of B.

Now, b') and e') are equivalent by (17.1.7), and since d') implies e') and is implied by b') (17.1.7), it is equivalent to both. The conjunction of b) and d) trivially implies c), and by (i), c) implies d); we have thus proved the equivalence of b), c), d) and e). Moreover, it is clear that b) implies a), the classes of the x_i in $\mathfrak{m}/\mathfrak{m}^2$ then forming a basis of this k-vector space and the classes of the y_i in $\mathfrak{n}/\mathfrak{n}^2$ a free system of this k'-vector space. It thus remains to prove that a) implies e). Set $V = \mathfrak{m}/\mathfrak{m}^2$, $W = \mathfrak{n}/\mathfrak{n}^2$; it is immediate that $\psi(V\otimes_k k') = (\mathfrak{n}^2 + \mathfrak{m}B)/\mathfrak{n}^2$. On the one hand, by (16.3.9)

$$\dim(B) \leq \dim(A) + \dim(B\otimes_A k); \tag{17.3.3.3}$$

secondly (16.2.6), we have

$$\dim(A) \leq \mathrm{rg}_k(V\otimes_k k'). \tag{17.3.3.4}$$

Finally, in the local ring $B\otimes_A k = B/\mathfrak{m}B$, $\mathfrak{n}' = \mathfrak{n}/\mathfrak{m}B$ is the maximal ideal, k' the residue field, and $\mathfrak{n}'/\mathfrak{n}'^2$ is isomorphic to $\mathfrak{n}/(\mathfrak{n}^2+\mathfrak{m}B) = W/\psi(V\otimes_k k')$; we thus have, by (16.2.6)

$$\dim(B\otimes_A k) \leq \mathrm{rg}_{k'} W - \mathrm{rg}_{k'}\,\psi(V\otimes_k k'). \tag{17.3.3.5}$$

Finally, since B is assumed regular, we have $\dim(B) = \mathrm{rg}_{k'} W$ (17.1.1); we thus conclude from (17.3.3.3), (17.3.3.4) and (17.3.3.5) that

$$\mathrm{rg}_{k'} W \leq \dim(A) + \dim(B\otimes_A k) \leq \mathrm{rg}_{k'} W + \mathrm{rg}_{k'}(V\otimes_k k') - \mathrm{rg}_{k'}\,\psi(V\otimes_k k')$$

and saying that the two extreme terms of this inequality are equal means that ψ is injective. Condition a) thus necessarily implies that in each of the relations (17.3.3.3), (17.3.3.4) and (17.3.3.5), the two sides are equal; now, equality in (17.3.3.4) (resp. (17.3.3.5)) means that A (resp. $B\otimes_A k$) is regular (17.1.1); we have thus proved that a) implies e). □

(17.3.4) Proposition. *Let A be a regular local ring of dimension n, $\mathfrak{m}$ its maximal ideal. For every non-zero A-module of finite type M, we have*

$$\operatorname{prof}(M) + \dim.\operatorname{proj}(M) = n. \tag{17.3.4.1}$$

Proof. We argue by induction on $m = \operatorname{prof}(M)$. If $m = 0$, we know (16.4.6)[(i)] that there exists a sub-A-module N of M isomorphic to $k = A/\mathfrak{m}$; applying the Tor exact sequence to the exact sequence $0 \to N \to M \to M/N \to 0$, we obtain an exact sequence

$$\operatorname{Tor}_{n+1}^A(M/N, k) \to \operatorname{Tor}_n^A(N, k) \to \operatorname{Tor}_n^A(M, k),$$

and the hypothesis that A is regular implies $\operatorname{Tor}_{n+1}^A(M/N, k) = 0$ ((17.3.1.1) and (17.2.6)), so $\operatorname{Tor}_n^A(k, k)$ is isomorphic to a submodule of $\operatorname{Tor}_n^A(M, k)$; applying again (17.3.1.1) and (17.2.6), we see that $\operatorname{Tor}_n^A(M, k) \neq 0$, so $\dim.\operatorname{proj}(M) \geq n$ by (17.2.6); but since $\dim.\operatorname{proj}(M) \leq n$ by (17.3.1.1), we indeed have $\dim.\operatorname{proj}(M) = n$. Suppose now $m > 0$, and let x be an M-regular element belonging to $\mathfrak{m}$; we then know (16.4.6)[(ii)] that $\operatorname{prof}(M/xM) = m - 1$, and on the other hand (17.2.7) $\dim.\operatorname{proj}(M/xM) = \dim.\operatorname{proj}(M) + 1$; the induction hypothesis immediately proves the relation (17.3.4.1). □

[$0_{\text{IV-1}}$ | 50] **(17.3.5) Corollary.**

(i) *Let A be a regular local ring of dimension n; for an A-module $M \neq 0$ of finite type to be free, it is necessary and sufficient that M be a Cohen-Macaulay A-module of dimension n.*

(ii) *Let A be a regular local ring, B a local ring, $\rho : A \to B$ a local homomorphism making B an A-module of finite type. For B to be a free A-module, it is necessary and sufficient that B be a Cohen-Macaulay ring and that ρ be injective (or, equivalently (16.1.5), that* $\dim(B) = \dim(A)$*).*

Proof. (i) This follows from (17.3.4.1) and from the fact that for an A-module of finite type, it is equivalent to saying that this module is projective or free (Bourbaki, *Alg. comm.*, chap. II, §3, n° 2, cor. 2 of prop. 5); the free A-modules of finite type M are thus characterised by the relation $\dim.\operatorname{proj}(M) = 0$ (17.2.2)[(i)].

(ii) To say that B is a Cohen-Macaulay ring is equivalent to saying that B is a Cohen-Macaulay A-module (16.5.3), so it suffices to apply (i), since $\dim B = \dim A$ (16.1.5). □

(17.3.6) We say that a Noetherian ring A is *regular* if for every prime ideal $\mathfrak{p}$ of A, the local ring $A_{\mathfrak{p}}$ is regular; when A is itself a local ring, it follows from (17.3.2) that this definition is equivalent to that of (17.1.2). For A to be regular, it suffices, by (17.3.2), that $A_{\mathfrak{m}}$ be regular for every *maximal* ideal $\mathfrak{m}$ of A. Moreover, it follows immediately from this definition that for every multiplicative subset S of A, $S^{-1}A$ is regular.

(17.3.7) Proposition. *If A is a regular Noetherian ring, every polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ is regular.*

Proof. It clearly suffices to prove that the polynomial ring $B = A[\mathrm{T}]$ is regular; since B is a free A-module, for every prime ideal $\mathfrak{q}$ of B, $B_{\mathfrak{q}}$ is a flat $A_{\mathfrak{p}}$-module, where $\mathfrak{p} = \mathfrak{q} \cap A$ (0_{I}, 6.3.1); it thus suffices, by (17.3.3) [$\mathrm{Err}_{\mathrm{IV}}$], to prove that $B_{\mathfrak{q}}/\mathfrak{p}B_{\mathfrak{q}}$ is regular, and since this ring is a local ring at a prime ideal of $A_{\mathfrak{p}}[\mathrm{T}]/\mathfrak{p}A_{\mathfrak{p}}[\mathrm{T}] = k[\mathrm{T}]$ (where k is the residue field $A_{\mathfrak{p}}/\mathfrak{p}A_{\mathfrak{p}}$), it suffices to prove that $k[\mathrm{T}]$ is regular; now, $\mathrm{C} = k[\mathrm{T}]$ being principal, the local rings of C are discrete valuation rings or a field (for the ideal (0)), thus regular (17.1.4), which concludes the proof. □

(17.3.8) Corollary. *If A is a regular ring, every formal power series ring $A[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is regular.*

Proof. Let $\mathfrak{J}$ be the ideal generated by the T_i in the polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; since the latter is regular by (17.3.7), and $A[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is the completion of $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$ for the $\mathfrak{J}$-preadic topology (Bourbaki, *Alg. comm.*, chap. III, §2, n° 12, *Example* 1), the conclusion follows from the following lemma. □

(17.3.8.1) Lemma. *Let A be a regular ring, $\mathfrak{J}$ an ideal of A, $\widehat{A}$ the separated completion of A for the $\mathfrak{J}$-preadic topology. Then $\widehat{A}$ is regular.*

Proof. It suffices in fact (17.3.6) to see that for every maximal ideal $\mathfrak{n}$ of $\widehat{A}$, the local ring $\widehat{A}_{\mathfrak{n}}$ is regular; we know (Bourbaki, *Alg. comm.*, chap. III, §3, n° 4, prop. 8) that $\mathfrak{n}$ is [$0_{\text{IV-1}}$ | 51] of the form $\mathfrak{m}\widehat{A}$, where $\mathfrak{m}$ is a maximal ideal of A containing $\mathfrak{J}$, and that the canonical homomorphism $A \to \widehat{A}$ gives an injective homomorphism $A_{\mathfrak{m}} \to \widehat{A}_{\mathfrak{n}}$, such that the $\mathfrak{n}\widehat{A}_{\mathfrak{n}}$-preadic topology of $\widehat{A}_{\mathfrak{n}}$ induces on $A_{\mathfrak{m}}$ the $\mathfrak{m}A_{\mathfrak{m}}$-preadic topology, and that $A_{\mathfrak{m}}$ is dense in $\widehat{A}_{\mathfrak{n}}$ for the $\mathfrak{n}\widehat{A}_{\mathfrak{n}}$-preadic topology; consequently the completions of the Noetherian local rings $A_{\mathfrak{m}}$ and $\widehat{A}_{\mathfrak{n}}$ are canonically isomorphic. Now, by hypothesis $A_{\mathfrak{m}}$ is regular, hence so is its completion (17.1.5) and since the completion of $\widehat{A}_{\mathfrak{n}}$ is regular, it follows that $\widehat{A}_{\mathfrak{n}}$ is regular by (17.1.5). □

(17.3.9) Corollary. *Let A be a Noetherian ring, quotient of a regular Noetherian ring B. If C is an A-algebra of finite type, every ring of fractions $S^{-1}C$ of C is a quotient of a regular ring.*

Proof. Indeed, C is a quotient of a polynomial ring $A[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; since $A = B/\mathfrak{J}$, where $\mathfrak{J}$ is an ideal of B, we have $A[\mathrm{T}_1, \ldots, \mathrm{T}_n] = B[\mathrm{T}_1, \ldots, \mathrm{T}_n]/\mathfrak{J}B[\mathrm{T}_1, \ldots, \mathrm{T}_n]$; by (17.3.7), we may restrict to the case where C is a quotient of a regular ring B'; but if S' is the inverse image of S in B', S' is a multiplicative subset of B' and $S^{-1}C$ is a quotient ring of $S'^{-1}B'$, so that ultimately everything reduces to seeing that when C is regular, $S^{-1}C$ is also regular, which we saw in (17.3.6). □

The importance of quotients of regular rings comes among other things from the property that they are *catenary* rings (16.5.12).

All the important rings in the applications to algebraic geometry are quotients of regular rings.

§18 Supplement on extensions of algebras

This paragraph assembles a certain number of functorial constructions on rings, which will be used repeatedly in §§ 19 and 20; it contains no non-trivial result.

18.1 Inverse images of augmented rings

(18.1.1) Given a ring A (not necessarily commutative), the category of *A-rings* has as objects the pairs (B, ρ) formed of a ring B and a homomorphism of rings $\rho : A \to B$, for morphisms (also called *A-homomorphisms*) the homomorphisms of rings $u : B \to C$ such that, if $\rho : A \to B$ and $\sigma : A \to C$ are the homomorphisms (called *structural*) defining the structure of A-ring on B and C respectively, the diagram

$$\begin{array}{ccc} B & \xrightarrow{u} & C \\ & {\scriptstyle\rho}\nwarrow \quad \uparrow{\scriptstyle\sigma} & \\ & A & \end{array} \tag{18.1.1.1}$$

is commutative. The *kernel* $\mathfrak{J}$ of u is a bilateral ideal that is an *A-bimodule* (for ρ).

If $f : A' \to A$ is a homomorphism of rings, for every A-ring (B, ρ), $(B, \rho \circ f)$ is an
[$0_{\text{IV-1}}$ | 52] A'-ring, and if $u : B \to C$ is an A-homomorphism from the A-ring (B, ρ) to the A-ring (C, σ), it is also an A'-homomorphism from the A'-ring $(B, \rho \circ f)$ to the A'-ring $(C, \sigma \circ f)$; one thus defines a canonical functor from the category of A-rings into that of A'-rings.

(18.1.2) Let B, E, F be three A-rings, $f : E \to B$, $g : F \to B$ two A-homomorphisms. Recall that one calls *fibre product* of E and F over B (for the homomorphisms f and g) and one denotes $E \times_B F$ the subring of the product $E \times F$ formed of the pairs (x, y) such that $f(x) = g(y)$; the restrictions $p_1 : G \to E$, $p_2 : G \to F$ of the projections pr_1 and pr_2 to G are still called the *canonical projections*; the structure of A-ring of G is defined by the homomorphism $\alpha \mapsto (\rho(\alpha), \sigma(\alpha))$ (where $\rho : A \to E$ and $\sigma : A \to F$ are the structural homomorphisms), which indeed maps A into G by virtue of (18.1.1). The characteristic property of $E \times_B F$ is that, for every pair of A-homomorphisms $u : C \to E$, $v : C \to F$ such that $f \circ u = g \circ v$, there exists one and only one A-homomorphism $w : C \to G$ such that $u = p_1 \circ w$, $v = p_2 \circ w$. One can still say that $E \times_B F$ is the *projective limit* of the projective system formed by B, E, F and the A-homomorphisms f, g, in the category of A-rings (**0$_{\text{III}}$**, 8.1.9).

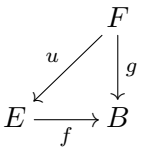
(18.1.3) Let $\mathfrak{J}$ be the bilateral ideal of E, kernel of f; it is immediate that the kernel $\mathfrak{J}'$ of $p_2 : G \to F$ is the ideal formed of the elements $(x, 0)$ where $x \in \mathfrak{J}$; the restriction $i_1 : \mathfrak{J}' \to \mathfrak{J}$ of p_1 is an isomorphism of rings without identity, and also an isomorphism of A-bimodules. Similarly, if $\mathfrak{R}$ is the kernel of g, the kernel $\mathfrak{R}'$ of $p_1 : G \to E$ is the ideal of the elements $(0, y)$ where $y \in \mathfrak{R}$, and the restriction $i_2 : \mathfrak{R}' \to \mathfrak{R}$ of p_2 is an isomorphism (in the same sense). Finally, it is clear that the kernel of the A-homomorphism $q = f \circ p_1 = g \circ p_2$ of $E \times_B F$ into B is $\mathfrak{J} \times \mathfrak{R} = \mathfrak{J}' \oplus \mathfrak{R}'$, so that one has a commutative diagram

$$\begin{array}{ccccccc} 0 & & & & 0 & & 0 \\ & \searrow & & & \downarrow & & \downarrow \\ & & \mathfrak{J}' \oplus \mathfrak{R}' & \longrightarrow & \mathfrak{R}' & \xrightarrow[\sim]{i_2} & \mathfrak{R} \\ & & \downarrow & \searrow & \downarrow{\scriptstyle j} & & \downarrow{\scriptstyle p_2} \\ 0 & \longrightarrow & \mathfrak{J}' & \longrightarrow & G & \longrightarrow & F \\ & & \sim\downarrow{\scriptstyle i_1} & & \downarrow{\scriptstyle p_1} & \overset{q}{\searrow} & \downarrow{\scriptstyle g} \\ 0 & \longrightarrow & \mathfrak{J} & \longrightarrow & E & \xrightarrow[f]{} & B \end{array} \tag{18.1.3.1}$$

The definitions and results of (18.1.2) and (18.1.3) extend immediately to the fibre product of any *family* $(E_\lambda)_{\lambda\in I}$ of A-rings defined by a family of A-homomorphisms $f_\lambda : E_\lambda \to B$. We leave the formulation of these results to the reader.

(18.1.4) Following the terminology of (M, VIII), we call an A-ring E equipped with a *surjective* A-homomorphism (called the *augmentation* of E), $f : E \to B$, an *A-ring augmented over B*; the kernel $\mathfrak{J}$ of f is called the *augmentation ideal*. One says that the A-augmented ring E is *trivial* if there exists an A-homomorphism $s : B \to E$ that is *right inverse* of the augmentation $f : E \to B$ (in other words $f \circ s = 1_B$). The exact sequence of A-bimodules

$$0 \to \mathfrak{J} \to E \xrightarrow{f} B \to 0$$



is then *split*; in other words, one can identify the A-bimodule E with $B \times \mathfrak{J}$, and the multiplication in E is then given by [$0_{\text{IV-1}}$ | 53]

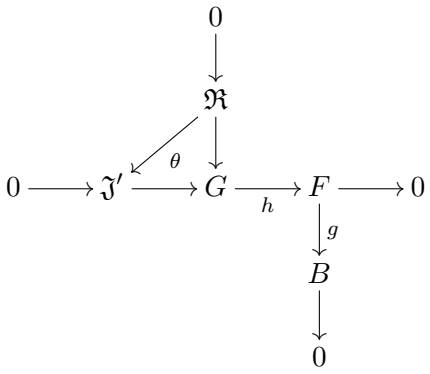
$$(b, z)(b', z') = (bb', bz' + zb' + zz'),$$

$\mathfrak{J}$ being considered as a B-bimodule by means of $s : B \to E$.

(18.1.5) With the notations of (18.1.2), suppose that the A-homomorphism f makes E into an A-ring *augmented over B*. Then it is clear that $p_2 : G \to F$ is also surjective, in other words G is given a structure of A-ring *augmented over F*, that one calls the *inverse image* by $g : F \to B$ of the augmented A-ring E.

(18.1.6) Proposition. *For the inverse image $G = E \times_B F$ by $g : F \to B$ of the augmented A-ring E to be a trivial augmented A-ring, it is necessary and sufficient that there exists an A-homomorphism $u : F \to E$ making the diagram*

commutative.



Proof. The condition is evidently necessary, taking $u = p_1 \circ s$, where $s : F \to G$ is an A-homomorphism right inverse of p_2. Conversely, if there exists such an A-homomorphism u, the existence of the right inverse s of p_2 follows from the universal property of the fibre product (18.1.2) applied to the A-homomorphisms $u : F \to E$ and $1_F : F \to F$.

This result implies in particular that if E is a trivial augmented A-ring, so is every inverse image. □

(18.1.7) Let us take up again the situation described in (18.1.2) and (18.1.3); on $\mathfrak{R}$ one has evidently a structure of *G-bimodule*, coming from its structure of F-bimodule and the homomorphism of rings $p_2 : G \to F$. As i_2 is bijective one has moreover an injection $\theta = j \circ i_2^{-1} : \mathfrak{R} \to G$, which is a homomorphism of *G-bimodules*. We shall now see conversely that, when one supposes moreover that f and g are *surjective*, in other words that E and F are A-rings *augmented* over B, the data of such a homomorphism θ allows us to reconstruct the augmented ring E (over B) from the augmented ring G (over F).

More precisely, suppose we are given an A-ring F augmented over B and an A-ring G augmented over F, the augmentation ideals being denoted $\mathfrak{R}$ and $\mathfrak{J}'$ respectively:

(18.1.7.1)

[$0_{\text{IV-1}}$ | 54] The homomorphism h defines on all the ideals of F (and in particular on $\mathfrak{R}$) a structure of G-bimodule. Let $\theta : \mathfrak{R} \to G$ be a homomorphism of G-bimodules making the diagram (18.1.7.1) commutative; this implies that θ is *injective* and that $\mathfrak{J}' \cap \theta(\mathfrak{R}) = 0$; as $\theta(\mathfrak{R})$ is a bilateral ideal of G, and $h(\theta(\mathfrak{R})) = \mathfrak{R}$, the composite homomorphism $g \circ h : G \to B$ factors as $G \xrightarrow{q} G/\theta(\mathfrak{R}) \xrightarrow{f} B$, where f is surjective; moreover the image $\mathfrak{J}$ of $\mathfrak{J}'$ in $E = G/\theta(\mathfrak{R})$ is the kernel of f (the kernel of $g \circ h$ being $\mathfrak{J}' \oplus \theta(\mathfrak{R})$), and the restriction to $\mathfrak{J}'$ of the canonical homomorphism $q : G \to E$ is injective. One can therefore form the *fibre product* $G' = E \times_B F$, and as the two A-homomorphisms $q : G \to E$ and $h : G \to F$ are such that $f \circ q = g \circ h$, they define a unique A-homomorphism $u : G \to G'$ by the universal property of G' (18.1.2); we shall now see that u is *bijective*. It suffices to prove this when u is considered as a homomorphism of A-bimodules; but one then notes that u is compatible with the finite filtrations on G and G' formed respectively by G and $\mathfrak{J}'$, and by G' and $\mathfrak{J}'' = \mathrm{Ker}(G' \to F)$; moreover, one has seen (18.1.3) that $\mathrm{gr}_0 u : F \to F$ is the identity and that $\mathrm{gr}_1 u : \mathfrak{J}' \to \mathfrak{J}''$ is bijective, hence u itself is bijective (Bourbaki, *Alg. comm.*, chap. III, § 2, no. 8, cor. 3 of th. 1).

18.2 Extensions of a ring by a bimodule

(18.2.1) Let E be an A-ring augmented over B, $f : E \to B$ the augmentation, $\mathfrak{J} = \mathrm{Ker}(f)$ the augmentation ideal. If $\mathfrak{J}^2 = 0$, $\mathfrak{J}$ is not only an E-bimodule but also a B-*bimodule* since B is isomorphic to $E/\mathfrak{J}$; more precisely, every $b \in B$ is of the form $f(x)$ with $x \in E$, and if z, z' are in $\mathfrak{J}$, one has $(x + z)z' = xz'$ (resp. $z'(x + z) = z'x$) so that the value of xz' (resp. $z'x$) does not depend on the element $x \in f^{-1}(b)$, and one can write bz' (resp. $z'b$) which defines the structure of B-bimodule considered. Conversely, if $\mathfrak{J}$ is equipped with a structure of B-bimodule such that $xz' = f(x)z'$ and $z'x = z'f(x)$ for $x \in E$ and $z' \in \mathfrak{J}$, it is clear that $\mathfrak{J}^2 = 0$.

(18.2.2) One calls *A-extension of an A-ring B by a B-bimodule L* an *exact* sequence of homomorphisms of A-bimodules

$$0 \to L \xrightarrow{j} E \xrightarrow{f} B \to 0$$

where E is an A-ring, f an A-homomorphism of rings and one has, for $x \in E$ and $z \in L$,

$$j(f(x)z) = xj(z), \quad j(zf(x)) = j(z)x$$

hence (18.2.1) $j(L)$ is a bilateral ideal of square zero of E. By abuse of language one also says that E is an extension of B by L. One says that two A-extensions E, E' of B

by L are *A-equivalent* if there exists an isomorphism of A-rings $u : E \xrightarrow{\sim} E'$ making the diagram

$$\begin{array}{ccccccc} & & & & E & & & & \\ & & & \nearrow & \downarrow u & \searrow & & & \\ 0 & \longrightarrow & L & & & & B & \longrightarrow & 0 \\ & & & \searrow & & \nearrow & & & \\ & & & & E' & & & & \end{array} \tag{18.2.2.1}$$

commutative.

(18.2.3) One says that an A-extension E of B by a B-bimodule L is *A-trivial* if E is a trivial augmented A-ring (over B) (18.1.4). One defines on the A-bimodule product $B \times L$ a structure of A-ring by setting $(x, s)(y, t) = (xy, xt + sy)$, as one easily checks, and the canonical maps $j : L \to B \times L$ and $f : B \times L \to B$ define an A-extension of B by L that is A-trivial, the canonical map $g : B \to B \times L$ being an A-homomorphism right inverse of f. One says this extension is the *trivial type extension* of B by L and one denotes it $D_B(L)$; it is immediate that every A-trivial A-extension of B by L is A-equivalent to $D_B(L)$. [$0_{\text{IV-1}}$ | 55]

One will note that every extension of the A-ring A itself by an A-bimodule is necessarily A-trivial.

(18.2.4) Given two A-extensions $L \xrightarrow{j} E \xrightarrow{f} B$, $L' \xrightarrow{j'} E' \xrightarrow{f'} B'$, a *morphism* of the first into the second is by definition a triplet of homomorphisms of A-bimodules (u, v, w) such that the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L & \xrightarrow{j} & E & \xrightarrow{f} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle w} & & \downarrow{\scriptstyle u} & & \downarrow{\scriptstyle v} & & \\ 0 & \longrightarrow & L' & \xrightarrow[j']{} & E' & \xrightarrow[f']{} & B' & \longrightarrow & 0 \end{array} \tag{18.2.4.1}$$

is commutative, u and v being A-homomorphisms of *rings* and w being such that $w(bz) = v(b)w(z)$ and $w(zb) = w(z)v(b)$ for $z \in L$ and $b \in B$ (in other words, the pair (v, w) constitutes a *di-homomorphism* of the B-bimodule L into the B'-bimodule L'); it is clear that if (u', v', w') is a morphism from $L' \to E' \to B'$ into an A-extension $L'' \to E'' \to B''$, $(u' \circ u, v' \circ v, w' \circ w)$ is still a morphism, which justifies the terminology.

The consideration of the two commutative squares of the diagram (18.2.4.1) will lead us to two operations on extensions of A-rings.

(18.2.5) In the first place, consider an A-extension E' of B' by L'

$$0 \to L' \xrightarrow{j'} E' \xrightarrow{f'} B' \to 0$$

and an A-homomorphism of rings $v : B \to B'$, and let $F = E' \times_{B'} B$ be the *inverse image* of E' (18.1.5), so that one has a commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L_0 & \longrightarrow & F & \xrightarrow{p_2} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle i} & & \downarrow{\scriptstyle p_1} & & \downarrow{\scriptstyle v} & & \\ 0 & \longrightarrow & L' & \xrightarrow[j']{} & E' & \xrightarrow[f']{} & B' & \longrightarrow & 0 \end{array}$$

where the two lines are exact, p_1 and p_2 are canonical homomorphisms and i is bijective; one sees from the definition (18.1.2) and (18.1.3) that $L_0^2 = 0$, so that one can consider F

as an A-extension of B by L', called the *inverse image by* v of the extension E' of B' by L' (where L' is naturally considered as a B-bimodule by means of the homomorphism of
[$0_{\text{IV-1}}$ | 56] rings v). The functorial character of the fibre product with respect to each of the factors shows moreover that if one has a morphism of two extensions of B'

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L'_1 & \longrightarrow & E'_1 & \longrightarrow & B' & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle h} & & \downarrow{\scriptstyle g} & & \downarrow{\scriptstyle 1_{B'}} & & \\ 0 & \longrightarrow & L'_2 & \longrightarrow & E'_2 & \longrightarrow & B' & \longrightarrow & 0 \end{array}$$

one deduces from it a morphism *inverse image by* v

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L'_1 & \longrightarrow & E'_1 \times_{B'} B & \longrightarrow & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle h} & & \downarrow{\scriptstyle g\times_{B'} 1_B} & & \downarrow{\scriptstyle 1_B} & & \\ 0 & \longrightarrow & L'_2 & \longrightarrow & E'_2 \times_{B'} B & \longrightarrow & B & \longrightarrow & 0. \end{array}$$

In particular, if E'_1 and E'_2 are A-equivalent A-extensions of B' by L', their inverse images by v are A-equivalent A-extensions of B by L'.

The definition of the fibre product shows that when one has a morphism (18.2.4.1) of A-extensions, it *factors through* the inverse image of E' by v; more precisely, there exists a unique A-homomorphism $u_0 : E \to F = E' \times_{B'} B$ making the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L & \xrightarrow{j} & E & \xrightarrow{f} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle w_0} & & \downarrow{\scriptstyle u_0} & & \downarrow{\scriptstyle 1_B} & & \\ 0 & \longrightarrow & L_0 & \longrightarrow & F & \xrightarrow{p_2} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle i} & & \downarrow{\scriptstyle p_1} & & \downarrow{\scriptstyle v} & & \\ 0 & \longrightarrow & L' & \xrightarrow[j']{} & E' & \xrightarrow[f']{} & B' & \longrightarrow & 0 \end{array}$$

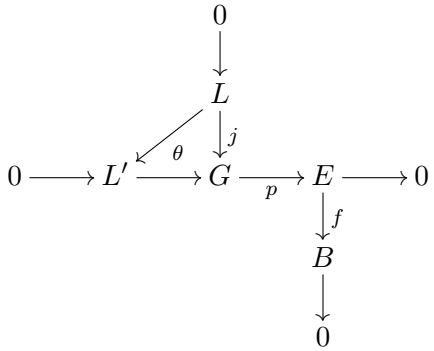
commutative, where w_0 is the restriction of u_0 to L and $p_1 \circ u_0 = u$, $i \circ w_0 = w$.

(18.2.6) Let us study the inverse image of extensions by surjective A-homomorphisms. Consider a surjective A-homomorphism $v : B \to B'$, an A-extension F of B by a B-bimodule L, and the bilateral ideal $\mathfrak{R}$ of B, kernel of v (which can be considered as an F-bimodule by means of the augmentation $F \to B$); one has seen (18.1.7) that every homomorphism of F-bimodules $\theta : \mathfrak{R} \to F$ making the diagram

$$\begin{array}{ccc} & & \mathfrak{R} \\ & \swarrow^{\theta} & \downarrow \\ F & \longrightarrow & B \end{array}$$

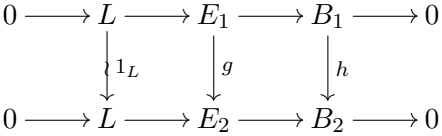
commutative determines an extension E' of $B' = B/\mathfrak{R}$ by L whose inverse image by $v : B \to B'$ is A-equivalent to F, and that every A-extension E of B' by L having this last property is obtained in this way (up to A-equivalence). Moreover, for two homomorphisms θ_1, θ_2 of F-bimodules of $\mathfrak{R}$ into F to give two A-equivalent A-extensions of B' by L, it is necessary and sufficient that there exists an A-*equivalence* u of the A-
[$0_{\text{IV-1}}$ | 57] extension F onto itself such that $\theta_2 = u \circ \theta_1$; this follows at once from what was seen in (18.2.5) and from the definition of the canonical bijection of F onto the fibre product $E' \times_{B'} B$ (18.1.7).

(18.2.7) Consider now the left square of (18.2.4.1), and recall first the notion of *amalgamated sum* in the category of A-bimodules: given three A-bimodules X, Y, Z and two A-homomorphisms $f : X \to Y$, $g : X \to Z$, the amalgamated sum $Y \oplus_X Z$ is the *inductive limit* of the inductive system formed by X, Y, Z and the A-homomorphisms f, g in the category of A-bimodules (**0**$_{\mathbf{III}}$, 8.1.11). One defines this A-bimodule as quotient of the product $Y \times Z$ by the sub-A-bimodule M image of X by the homomorphism $x \mapsto (f(x), -g(x))$. Its characteristic property is that, for every pair of homomorphisms of A-bimodules $u : Y \to T$, $v : Z \to T$ such that $u \circ f = v \circ g$, there exists a unique homomorphism $w : Y \oplus_X Z \to T$ such that $u = w \circ j_1$ and $v = w \circ j_2$, where $j_1 : Y \to Y \oplus_X Z$ and $j_2 : Z \to Y \oplus_X Z$ are the canonical maps.



(18.2.8) Consider now an A-extension E of B by a B-bimodule L:

$$0 \to L \xrightarrow{j} E \xrightarrow{f} B \to 0$$



and let moreover $w : L \to L'$ be a homomorphism of *B-bimodules*. Let H be the A-bimodule amalgamated sum $E \oplus_L L'$; let us show how one can equip it with a structure of *A-ring* and define an *A-extension*

$$0 \to L' \to H \to B \to 0.$$

Let us note for this that L' is equipped with a structure of *E-bimodule* by means of the augmentation homomorphism $E \to B$; one can therefore form the A-extension of trivial type $G = D_E(L')$ (18.2.3). Consider then the map $\theta : z \mapsto (j(z), -w(z))$ from L into G; it is a homomorphism of *G-bimodules* (L being considered as a G-bimodule by means of the canonical homomorphism $\rho : G \to E$). Indeed, for $(x, z') \in G$ and $z \in L$, one has $(j(z), -w(z))(x, z') = (j(z)x, j(z)z' - w(z)f(x))$; but $j(z)z' = f(j(z))z' = 0$ by definition of the structure of E-bimodule on L', and $w(z)f(x) = w(zf(x))$ by definition of the structure of B-bimodule on L'; one thus verifies that θ is also a homomorphism of G-modules on the left. One can then apply the result of (18.1.7) to the diagram

As $H = G/\theta(L)$ by definition, our assertion is an immediate consequence of (18.1.7).
One says that the A-extension H of B by L' is *deduced from E by the homomorphism* $w : L \to L'$. The functorial character of the amalgamated sum in each of the summands shows moreover that if one has a morphism of extensions [$0_{\text{IV-1}}$ | 58]

one deduces from it canonically a morphism of deduced extensions

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L' & \longrightarrow & E_1 \oplus_L L' & \longrightarrow & B_1 & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle 1_{L'}} & & \downarrow{\scriptstyle g\oplus_L 1_{L'}} & & \downarrow{\scriptstyle h} & & \\ 0 & \longrightarrow & L' & \longrightarrow & E_2 \oplus_L L' & \longrightarrow & B_2 & \longrightarrow & 0 \end{array}$$

In particular, if E_1 and E_2 are A-equivalent A-extensions of B by L, the extensions of B by L' obtained by w are A-equivalent.

When one has a morphism (18.2.4.1) of A-extensions, it factors through the A-extension H of B by L' deduced from E by the homomorphism $w : L \to L'$ (where L' being considered as B-bimodule by means of the homomorphism of rings $v : B \to B'$): in fact, the definition of the amalgamated sum shows that there exists a unique A-homomorphism $u_0 : H \to E'$ of A-bimodules, making the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L & \xrightarrow{j} & E & \xrightarrow{f} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle w_0} & & \downarrow{\scriptstyle j_1} & & \downarrow{\scriptstyle 1_B} & & \\ 0 & \longrightarrow & L'_0 & \xrightarrow{j_2} & H & \xrightarrow{f_0} & B & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle j_0} & & \downarrow{\scriptstyle u_0} & & \downarrow{\scriptstyle v} & & \\ 0 & \longrightarrow & L' & \xrightarrow[j']{} & E' & \xrightarrow[f']{} & B' & \longrightarrow & 0 \end{array}$$

commutative, with $u = u_0 \circ j_1$, $w = j_0 \circ w_0$, j_1 and j_2 being the canonical homomorphisms; one verifies immediately that u_0 is also a homomorphism of rings.

Let us note moreover the functorial properties relative to trivial extensions:

(18.2.9) Proposition. *Let B, B' be two A-rings, L a B-bimodule, L' a B'-bimodule, $v : B \to B'$ an A-homomorphism of rings, $w : L \to L'$ a homomorphism of A-bimodules such that (v, w) is a di-homomorphism of bimodules. Then there exists a unique A-homomorphism of rings $u : D_B(L) \to D_{B'}(L')$ making the diagrams commutative*

$$\begin{array}{ccc} D_B(L) & \xrightarrow{u} & D_{B'}(L') \\ \uparrow & & \uparrow \\ B & \xrightarrow[v]{} & B' \end{array} \qquad\qquad \begin{array}{ccc} D_B(L) & \xrightarrow{u} & D_{B'}(L') \\ \uparrow & & \uparrow \\ L & \xrightarrow[w]{} & L' \end{array}$$

where the vertical arrows are the canonical injections.

Proof. Indeed, u cannot be other than the map $(x, s) \mapsto (v(x), w(s))$ and it remains to verify that it is an A-homomorphism of rings, which follows trivially from the definition (18.2.3). One notes that u also makes commutative the diagram [0IV-1 | 59]

$$\begin{array}{ccc} D_B(L) & \xrightarrow{u} & D_{B'}(L') \\ \downarrow & & \downarrow \\ B & \xrightarrow[v]{} & B' \end{array}$$

where this time the vertical arrows are the augmentations. □

(18.2.10) Proposition. *Let B be an A-ring, L a B-bimodule, and E an A-extension of B by L. There is a bijection from the set G of homomorphisms of B-rings from B*

into E (in other words, the set of A-homomorphisms right inverse to the augmentation $E \to B$) onto the set G' of A-equivalences from $D_B(L)$ onto E: to every $g \in G$ it assigns the A-equivalence $g' : (x, s) \mapsto g(x) + s$, and the inverse map assigns to every $g' \in G'$ the B-homomorphism $x \mapsto g'(x, 0)$.

Proof. This follows immediately from the definitions. □

18.3 The group of classes of A-extensions

(18.3.1) Consider a fixed A-ring B and a fixed B-bimodule L; then the relation "E and E' are A-equivalent" between A-extensions E, E' of B by L is an equivalence relation and for this relation one can speak of the *set* of classes of A-equivalent A-extensions of B by L. To see this, it suffices to remark that, for every $x \in B$, if c_x is an element of E whose image in B is x, every $z \in E$ can be written in one and only one way in the form $c_x + t$, where $t \in L$, and one can write $c_{x+y} = c_x + c_y + \varphi(x, y)$, $c_{xy} = c_x c_y + \psi(x, y)$, where $\varphi(x, y)$ and $\psi(x, y)$ are elements of L, the maps φ and ψ from $B \times B$ into L being the expressions of the fact that E is an A-ring, which we shall not write out here. Every A-extension of B by L is therefore A-equivalent to an A-extension whose underlying set is $B \times L$, whence our conclusion follows immediately.

(18.3.2) The A-ring B being fixed, denote provisionally by $T(L)$ the set of classes of A-extensions of B by L. For every B-homomorphism of B-bimodules $w : L \to L'$, one defines canonically a map $T(w) : T(L) \to T(L')$ by associating to the class of an A-extension E of B by L the class of the A-extension $E \oplus_L L'$ deduced from E by w, by virtue of (18.2.8). If $w' : L' \to L''$ is a second homomorphism of B-bimodules, one has also

$$T(w' \circ w) = T(w') \circ T(w). \tag{18.3.2.1}$$

Indeed, one knows that there exists a canonical isomorphism of A-bimodules

$$E \oplus_L L'' \xrightarrow{\sim} (E \oplus_L L') \oplus_{L'} L''$$

by virtue of the general properties of inductive limits (cf. for example (**I**, 3.3.9)), and it is immediate to verify that it is indeed an A-equivalence of A-extensions, hence relation (18.3.2.1). If $\mathbf{C}_B$ denotes the category of B-bimodules, one sees that one has thus defined a *covariant functor* $T : \mathbf{C}_B \to \mathbf{Sets}$. [0IV-1 | 60]

(18.3.3) Consider now a family $(L_\alpha)_{\alpha \in I}$ of B-bimodules and their product $L = \prod_\alpha L_\alpha$; the projections $\mathrm{pr}_\alpha : L \to L_\alpha$ define applications

$$T(\mathrm{pr}_\alpha) : T(L) \to T(L_\alpha),$$

hence a canonical map

$$\prod_\alpha T(\mathrm{pr}_\alpha) : T(L) \to \prod_{\alpha \in I} T(L_\alpha). \tag{18.3.3.1}$$

We shall see that this map is *bijective*. Indeed, for every $\alpha \in I$, let E_α be an A-extension of B by L_α, and let F be the *fibre product* of the E_α on B (18.1.3); it is immediate that F is an A-extension of B by $L = \prod_\alpha L_\alpha$, and that if one replaces each E_α by an A-equivalent A-extension E'_α, the fibre product F' of the E'_α on B is A-equivalent to F. One has thus defined a map $\prod_\alpha T(L_\alpha) \to T(L)$ and it is clear that this map is the inverse of (18.3.3.1), hence our assertion. One will identify canonically $T(L)$ with $\prod_\alpha T(L_\alpha)$ by the preceding map. One verifies also immediately that if $(L'_\alpha)_{\alpha \in I}$ is a second

family of B-bimodules and, for each α, $w_\alpha : L_\alpha \to L'_\alpha$ a homomorphism of B-bimodules, then, setting $w = \prod_\alpha w_\alpha : L \to L' = \prod_\alpha L'_\alpha$, $T(w)$ identifies with $\prod_\alpha T(w_\alpha)$ when one makes the preceding identification.

(18.3.4) For a B-bimodule L, the addition is a homomorphism $s : L \times L \to L$ of B-*bimodules*, and so is the symmetry $t : L \to L$ of the additive law of L. One deduces from them a law of composition

$$T(s) : T(L) \times T(L) \to T(L)$$

in $T(L)$ by virtue of (18.3.3), and this law is a law of *commutative group* of which $T(t)$ is the symmetry, as it follows from the definition of an object in groups by means of commutative diagrams ($\mathbf{0}_{\mathrm{III}}$, 8.2.5 and 8.2.6). We shall denote by $\mathrm{Exan}_A(B, L)$ the commutative group thus defined and we say it is the *group of classes of A-extensions of B by L*.

(18.3.5) Denote by $\boldsymbol{K}$ the category whose objects are the triplets (A, B, L) where A is a ring, B an A-ring and L a B-bimodule; the *morphisms* of this category are the triplets (u, v, w) where $u : A' \to A$ and $v : B' \to B$ are two homomorphisms of rings making commutative the left square of the diagram

$$\begin{array}{ccc} A & \longrightarrow & B \\ {\scriptstyle u}\uparrow & & \uparrow{\scriptstyle v} \\ A' & \longrightarrow & B' \end{array} \qquad \begin{array}{c} L \\ \big\downarrow{\scriptstyle w} \\ L' \end{array}$$

where the horizontal arrows are the structural homomorphisms; finally $w : L \to L'$ is a homomorphism of commutative groups such that one has $w(v(b')z) = b'w(z)$ and
[$0_{\text{IV-1}}$ | 61] $w(zv(b')) = w(z)b'$ for all $z \in L$ and $b' \in B'$ (in other words, w is a homomorphism of B'-bimodules when L is equipped with its structure of B'-bimodule defined by v). The composition of morphisms is defined by $(u', v', w') \circ (u, v, w) = (u \circ u', v \circ v', w' \circ w)$, which is immediately verified. We propose to show that

$$(A, B, L) \mapsto \mathrm{Exan}_A(B, L) \tag{18.3.5.1}$$

is a *covariant functor* from the category $\boldsymbol{K}$ into the category $\boldsymbol{Ab}$ of commutative groups. It is therefore a matter of defining for every triplet (u, v, w) as above, a homomorphism of commutative groups

$$(u, v, w)_* : \mathrm{Exan}_A(B, L) \to \mathrm{Exan}_{A'}(B', L').$$

By virtue of the definition of morphisms in $\boldsymbol{K}$, one can write

$$(u, v, w) = (1_{A'}, 1_{B'}, w) \circ (1_{A'}, v, 1_L) \circ (u, 1_B, 1_L)$$

where, in the first factor, L is equipped with its structure of B'-bimodule defined by v; we shall therefore define $(u, v, w)_*$ when two of the three homomorphisms u, v, w are reduced to the identity.

(18.3.6) We take first $(1_A, 1_B, w)_*$ the map

$$w_* : \mathrm{Exan}_A(B, L) \to \mathrm{Exan}_A(B, L') \tag{18.3.6.1}$$

denoted $T(w)$ in (18.3.2); it is immediate to verify that it is a homomorphism of groups, this property expressing the commutativity of diagrams, transformed by T of analogous diagrams for L and L'.

The map $(1_A, v, 1_L)_*$ is the map

$$v^* : \mathrm{Exan}_A(B, L) \to \mathrm{Exan}_A(B', L) \tag{18.3.6.2}$$

defined in the following way: if E is an A-extension of B by L, one has seen that $E \times_B B'$ is an A-extension of B' by L (18.2.5) and that if one replaces E by an A-equivalent A-extension E', $E' \times_B B'$ is A-equivalent to $E \times_B B'$; the image by v^* of the class of E is the class of $E \times_B B'$. One verifies immediately that if $w : L \to L'$ is a homomorphism of B-bimodules, the diagram

$$\begin{array}{ccc} \mathrm{Exan}_A(B, L) & \xrightarrow{v^*} & \mathrm{Exan}_A(B', L) \\ {\scriptstyle w_*}\downarrow & & \downarrow{\scriptstyle w_*} \\ \mathrm{Exan}_A(B, L') & \xrightarrow[v^*]{} & \mathrm{Exan}_A(B', L') \end{array} \tag{18.3.6.3}$$

is commutative, L and L' being considered as B'-bimodules by means of v in the right column. Replacing L and L' by $L \times L$ and L, and w by the addition s in L, one concludes as above that v^* is indeed a *homomorphism of groups*.

(18.3.6.4) Finally, the map $(u, 1_B, 1_L)_*$ is the map [$0_{\text{IV-1}}$ | 62]

$$u^* : \mathrm{Exan}_A(B, L) \to \mathrm{Exan}_{A'}(B, L) \tag{1}$$

which is obtained by associating to an A-extension E of B by L the ring E considered as an A'-*ring* by means of u (18.1.1), which is evidently also an A'-extension of B by L, B being also considered as A'-ring by means of u; it is clear that an A-equivalence is also an A'-equivalence, whence the map (18.3.6.4), which, for every homomorphism $w : L \to L'$ of B-bimodules, also makes the diagram commutative:

$$\begin{array}{ccc} \mathrm{Exan}_A(B, L) & \xrightarrow{u^*} & \mathrm{Exan}_{A'}(B, L) \\ {\scriptstyle w_*}\downarrow & & \downarrow{\scriptstyle w_*} \\ \mathrm{Exan}_A(B, L') & \xrightarrow[u^*]{} & \mathrm{Exan}_{A'}(B, L') \end{array} \tag{18.3.6.5}$$

One deduces as above that u^* is indeed a homomorphism of groups.

This being so, one sets $(u, v, w)_* = (1_{A'}, 1_{B'}, w)_* \circ (1_{A'}, v, 1_L)_* \circ (u, 1_B, 1_L)_*$ and one verifies easily, by reason of the commutativity of the diagrams (18.3.6.3) and (18.3.6.5), that one has $(u \circ u', v \circ v', w' \circ w)_* = (u', v', w')_* \circ (u, v, w)_*$, which finishes the proof that (18.3.5.1) is a functor.

The existence of the homomorphism of groups (18.3.6.1) shows in particular that if E is a trivial A-extension of B by L, the extension $E \oplus_L L'$ of B by L' defined in (18.2.8) is also trivial, which one moreover verifies directly without difficulty.

On the other hand, for every element z of the *centre* Z of B, the homothety $h_z : y \mapsto yz$ is an endomorphism of the B-bimodule L, hence $(h_z)_*$ is an endomorphism of the commutative group $\mathrm{Exan}_A(B, L)$, and by functoriality, these endomorphisms define on $\mathrm{Exan}_A(B, L)$ a structure of Z-*module*.

(18.3.7) Let A, A' be two rings, $u : A' \to A$ a homomorphism, B an A-ring and L a B-bimodule. The *kernel* of the homomorphism of groups

$$u^* : \mathrm{Exan}_A(B, L) \to \mathrm{Exan}_{A'}(B, L)$$

is formed by definition of classes of A-extensions of B by L that are A'-trivial when one considers them as A'-extensions by means of u. One denotes this kernel by the notation $\mathrm{Exan}_{A/A'}(B,L)$ when this causes no confusion.

If Λ is a ring, and if one has a commutative diagram of Λ-*homomorphisms* of Λ-rings

$$\begin{array}{ccc} B' & \longrightarrow & B \\ \uparrow & & \uparrow \\ A' & \longrightarrow & A \end{array} \tag{18.3.7.1}$$

[$0_{\text{IV-1}}$ | 63] one deduces from it canonically homomorphisms

$$\mathrm{Exan}_{A/\Lambda}(B,L) \to \mathrm{Exan}_{A'/\Lambda}(B,L) \to \mathrm{Exan}_{A'/\Lambda}(B',L) \tag{18.3.7.2}$$

which arise from the commutativity of the diagram

$$\begin{array}{ccccc} \mathrm{Exan}_A(B,L) & \longrightarrow & \mathrm{Exan}_{A'}(B,L) & \longrightarrow & \mathrm{Exan}_{A'}(B',L) \\ \downarrow & & \downarrow & & \downarrow \\ \mathrm{Exan}_\Lambda(B,L) & \longrightarrow & \mathrm{Exan}_\Lambda(B,L) & \longrightarrow & \mathrm{Exan}_\Lambda(B',L) \end{array}$$

where the arrows are deduced from those of (18.3.7.1) by functoriality.

(18.3.8) Proposition. *Let B be a ring, $\mathfrak{J}$ a bilateral ideal of B, and $C = B/\mathfrak{J}$ the quotient ring; $\mathfrak{J}/\mathfrak{J}^2$ is then canonically equipped with a structure of C-bimodule. For every C-bimodule L, let $\mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L)$ denote the additive group of homomorphisms of C-bimodules from $\mathfrak{J}/\mathfrak{J}^2$ into L. One defines then an isomorphism of commutative groups*

$$\eta_L : \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \mathrm{Exan}_B(C,L) \tag{18.3.8.1}$$

by associating to every C-homomorphism $w : \mathfrak{J}/\mathfrak{J}^2 \to L$ (which is a fortiori *a B-homomorphism) the class of the extension $(B/\mathfrak{J}^2) \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} L$ deduced from the extension $B/\mathfrak{J}^2$ of C by $\mathfrak{J}/\mathfrak{J}^2$ by means of w; the inverse isomorphism associates to a class of B-extension E of C by L the homomorphism w such that the composite $\mathfrak{J} \to \mathfrak{J}/\mathfrak{J}^2 \xrightarrow{w} L$ is the restriction to $\mathfrak{J}$ of the structural homomorphism $B \to E$.*

Proof. Let $F = B/\mathfrak{J}^2$, which is a B-extension of C by $\mathfrak{J}/\mathfrak{J}^2$. For every B-extension $0 \to L \xrightarrow{j} E \xrightarrow{p} C \to 0$ of C by L, the structural homomorphism $f : B \to E$ is such that the composite $B \xrightarrow{f} E \xrightarrow{p} C$ is the canonical homomorphism $B \to B/\mathfrak{J} = C$. As the image of $\mathfrak{J}$ by $p \circ f$ is zero, $f(\mathfrak{J})$ is contained in the kernel $j(L)$, and as $j(L)$ is of square zero, $f(\mathfrak{J}^2) = 0$; hence f factors as $B \to B/\mathfrak{J}^2 = F \xrightarrow{u} E$, and if w is the restriction of u to $\mathfrak{J}/\mathfrak{J}^2$, one has a commutative diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathfrak{J}/\mathfrak{J}^2 & \longrightarrow & F & \xrightarrow{g} & C & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle w} & & \downarrow{\scriptstyle u} & & \downarrow{\scriptstyle 1_C} & & \\ 0 & \longrightarrow & L & \xrightarrow[j]{} & E & \xrightarrow[p]{} & C & \longrightarrow & 0 \end{array}$$

in other words $(u, 1_C, w)$ is a morphism of extensions (18.2.4). One deduces from it a morphism of extensions

$$\begin{array}{ccccccccc} 0 & \longrightarrow & L & \longrightarrow & E' & \longrightarrow & C & \longrightarrow & 0 \\ & & \downarrow{\scriptstyle 1_L} & & \downarrow{\scriptstyle u'} & & \downarrow{\scriptstyle 1_C} & & \\ 0 & \longrightarrow & L & \xrightarrow[j]{} & E & \xrightarrow[p]{} & C & \longrightarrow & 0 \end{array}$$

where $E' = F \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} L$ (18.2.8); it remains to prove that u' is a *B-equivalence*, which will establish that η_L is bijective. By the construction in (18.2.8), it suffices (in view of (18.1.7)) to prove that the inverse image G of the extension E of C by the canonical homomorphism $g : F \to C$ is *F-trivial*, which is evident since g factors as $F \xrightarrow{u} E \xrightarrow{p} C$ (18.1.6). [$0_{\text{IV-1}}$ | 64]

It remains to see that η_L is a homomorphism of *groups*; now, for every B-homomorphism $h : L \to L'$, it is immediate that the diagram

$$\begin{array}{ccc} \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) & \xrightarrow{\eta_L} & \mathrm{Exan}_B(C, L) \\ \Big\downarrow{\scriptstyle \mathrm{Hom}(1,h)} & & \Big\downarrow{\scriptstyle h_*} \\ \mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L') & \xrightarrow[\eta_{L'}]{} & \mathrm{Exan}_B(C, L') \end{array}$$

is commutative. It suffices to apply this remark to the homomorphism $L \times L \to L$ defining the addition to conclude. □

18.4 Extensions of algebras

(18.4.1) Let A be a *commutative* ring. The category of *A-algebras* is then a full subcategory of that of A-rings, characterized by the fact that the structural homomorphisms $\rho : A \to B$ are *central*.

If B is an A-algebra and L a B-bimodule whose two A-module structures induced through B coincide, it is immediate that the A-extension of trivial type $D_B(L)$ is an A-algebra. Similarly, in the construction of (18.2.5) (resp. of (18.2.8)), if B, B' and E' (resp. B and E) are A-algebras, it is the same for $E' \times_{B'} B$ (resp. for $E \oplus_L L'$). Finally, if B is an A-algebra and E an A-extension of B by a B-bimodule L that is an A-algebra, every A-extension E' of B by L, *A-equivalent* to E, is also an A-algebra. One deduces then immediately from the definition (18.3.4) that the classes of equivalent A-extensions of B by L which are *A-algebras* form a *subgroup*, denoted $\mathrm{Exal}_A(B, L)$, of $\mathrm{Exan}_A(B, L)$. Let $\boldsymbol{K}'$ be the full subcategory of $\boldsymbol{K}$ defined in (18.3.5), whose objects (A, B, L) are such that A is commutative, B is an A-algebra, and the two A-module structures on L induced through B coincide. Then what precedes shows that

$$(A, B, L) \mapsto \mathrm{Exal}_A(B, L)$$

is a *covariant functor* from $\boldsymbol{K}'$ to $\boldsymbol{Ab}$. The results of (18.3.7) are unchanged when one replaces Exan everywhere by Exal.

(18.4.2) Suppose always A commutative. The remarks of (18.4.1) remain valid when one replaces "algebra" by "commutative algebra" and "bimodule" by "module". If B is a commutative A-algebra and L a B-module,
the classes of equivalent A-extensions of B by L which are commutative *A-algebras* (or, what amounts to the same thing, commutative *A-rings*) form a *subgroup* of $\mathrm{Exal}_A(B, L)$, denoted $\mathrm{Exalcom}_A(B, L)$. If $\boldsymbol{K}''$ is the full subcategory of $\boldsymbol{K}'$ where A and B are commutative and L a B-module, [$0_{\text{IV-1}}$ | 65]

$$(A, B, L) \mapsto \mathrm{Exalcom}_A(B, L)$$

is still a *covariant functor* from $\boldsymbol{K}''$ to $\boldsymbol{Ab}$. One can also replace Exan by Exalcom in (18.3.7). Finally, if in (18.3.8), one supposes B to be a commutative ring and L a *C-module*, the same reasoning gives a canonical isomorphism

$$\mathrm{Hom}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \mathrm{Exalcom}_B(C, L) \qquad (18.4.2.1)$$

where the first member is the group of homomorphisms of C-*modules*.

(18.4.3) Let A be a commutative ring. An important case of extensions of A-algebras is formed of A-algebras E, extensions of an A-algebra B by a B-bimodule L such that E, as A-*module*, is the *trivial* extension of the A-module B by the A-module L; in other words, the exact sequence of A-*modules* $0 \to L \to E \to B \to 0$ is *split*. One says then that E is a *Hochschild extension* of B by L. This will always be the case when B is a *projective* A-module, and in particular when A is a commutative *field*. As an A-module, one can identify E with $B \times L$, the multiplication in E being given by $(x, s)(y, t) = (xy, xt+sy+f(x, y))$ with $f(x, y) \in L$. If one writes that this multiplication defines on $B \times L$ a structure of A-algebra, one finds (M, XIV, 2) that f must be an A-*bilinear* map of $B \times B$ into L, such that

$$f(xy, z) + f(x, y)z = xf(y, z) + f(x, yz) \tag{18.4.3.1}$$

in other words, f is a 2-*cocycle* on B with values in L, in the sense of Hochschild; for the extension E to be A-trivial, it is necessary and sufficient that

$$f(x, y) = xg(y) - g(xy) + g(x)y \tag{18.4.3.2}$$

where g is an A-*linear* map of B into L, in other words f must be a 2-*coboundary* in the sense of Hochschild. One deduces from it that the classes of Hochschild extensions of B by L form a subgroup of $\mathrm{Exal}_A(B, L)$, isomorphic to the *Hochschild cohomology group* $\mathrm{H}^2_A(B, L)$.

If B is a commutative A-algebra, and L a B-module, the commutative Hochschild extensions of B by L correspond to the *symmetric* 2-cocycles, i.e. those such that $f(y, x) = f(x, y)$. The classes of commutative Hochschild extensions of B by L form therefore a subgroup of $\mathrm{Exalcom}_A(B, L)$, isomorphic to the subgroup of $\mathrm{H}^2_A(B, L)$ image of the group of symmetric 2-cocycles, which we shall denote $\mathrm{H}^2_A(B, L)^s$.

(18.4.4) Let us restrict to the case where A and B are *commutative* and L a B-module, and recall in this case the equivalent definition of the Hochschild cohomology groups $\mathrm{H}^i_A(B, L)$ (M, IX, 6). One considers a complex $\mathrm{P}_\bullet = (\mathrm{P}_n)_{n\geqslant 0}$ of B-modules, where $\mathrm{P}_n = B^{\otimes(n+1)} = B \otimes_A B \otimes \cdots \otimes_A B$ ($n+1$ times), the structure of B-module being defined
[$0_{\text{IV-1}}$ | 66] by $x(y_1 \otimes y_2 \otimes \cdots \otimes y_{n+1}) = (xy_1) \otimes y_2 \otimes \cdots \otimes y_{n+1}$; the differential, of degree -1, $d_n : \mathrm{P}_n \to \mathrm{P}_{n-1}$, is defined by

$$\begin{aligned} d_n(x_1 \otimes x_2 \otimes \cdots \otimes x_{n+1}) = {} & (x_1x_2) \otimes x_3 \otimes \cdots \otimes x_{n+1} - x_1 \otimes (x_2x_3) \otimes \cdots \otimes x_{n+1} + \cdots \\ & + (-1)^{n-1} x_1 \otimes x_2 \otimes \cdots \otimes (x_nx_{n+1}) + (-1)^n (x_{n+1}x_1) \otimes x_2 \otimes \cdots \otimes x_n \end{aligned}$$

which is B-linear since B is commutative.

A 2-cocycle of this complex with values in L is a B-linear map h from $B \otimes_A B \otimes_A B$ to L such that $h(d_3(x \otimes y \otimes z \otimes t)) = 0$; but since $h(x \otimes y \otimes z) = xh(1 \otimes y \otimes z)$, the cocycle h is determined by the A-bilinear map $(y, z) \mapsto f(y, z) = h(1 \otimes y \otimes z)$ from $B \times B$ to L, and writing the preceding condition for h gives back condition (18.4.3.1) for f. Similarly, a 2-coboundary is a map of the form $x \otimes y \otimes z \mapsto h'(d_2(x \otimes y \otimes z))$, where $h' : B \otimes_A B \to L$ is linear; here again h' is determined by the A-linear map $g : y \mapsto h'(1 \otimes y)$ from B to L. One then obtains $h'(d_2(1 \otimes x \otimes y)) = xg(y) - g(xy) + yg(x)$, which gives back (18.4.3.2). One proceeds similarly for the 1-cocycles and one sees that one has

$$\mathrm{H}^i_A(B, L) = \mathrm{H}^i(\mathrm{Hom}_B(\mathrm{P}_\bullet, L)). \tag{18.4.4.1}$$

(18.4.5) Under the conditions of (18.4.4), one can reinterpret in the same way the group $\mathrm{H}^2_A(B,L)^s$ (18.4.3). For this, modify the complex $\mathrm{P}_\bullet$ in degree 3 considering a new complex

$$\mathrm{P}'_\bullet : \mathrm{P}'_3 \xrightarrow{d'_3} \mathrm{P}_2 \xrightarrow{d_2} \mathrm{P}_1;$$

we take $\mathrm{P}'_3 = \mathrm{P}_3 \oplus (B \otimes_A B \otimes_A B)$, d'_3 coinciding with d_3 on P_3, and being given by

$$d'_3(x \otimes y \otimes z) = x \otimes y \otimes z - x \otimes z \otimes y.$$

The relation $d_2 d'_3 = 0$ follows from the above with the commutativity of B. With the notations introduced above, a 2-cocycle of $\mathrm{P}'_\bullet$ corresponds now to an A-bilinear map f of $B \times B$ into L that is *symmetric* and satisfies (18.4.3.1); consequently, one has $\mathrm{H}^2_A(B,L)^s = \mathrm{H}^2(\mathrm{Hom}_B(\mathrm{P}'_\bullet, L))$.

(18.4.6) In the particular case where one considers a commutative *field* k, an extension K of k, one has $\mathrm{Ext}^1_K(M,L) = 0$ whatever the K-vector spaces L, M and consequently (M, VI, 3.3 *a*), one has a canonical isomorphism

$$\mathrm{H}^i_k(K,L) \simeq \mathrm{Hom}_K(\mathrm{H}_i(\mathrm{P}_\bullet), L) \tag{18.4.6.1}$$

and similarly

$$\mathrm{H}^2_k(K,L)^s \simeq \mathrm{Hom}_K(\mathrm{H}_2(\mathrm{P}'_\bullet), L). \tag{18.4.6.2}$$

18.5 Case of topological rings

(18.5.1) Let A and B be two *topological* rings whose topologies are *linear*, $\rho : A \to B$ a continuous homomorphism, L a topological B-bimodule, and suppose that there exists an *open* bilateral ideal $\mathfrak{R}_0$ of B such that $\mathfrak{R}_0.L = L.\mathfrak{R}_0 = 0$, so that L can be considered as a $(B/\mathfrak{R})$-bimodule for every open bilateral ideal $\mathfrak{R} \subset \mathfrak{R}_0$. Let then $\mathfrak{R} \subset \mathfrak{R}_0$ be an open bilateral ideal of B and $\mathfrak{J}$ an open bilateral ideal of A such that $\rho(\mathfrak{J}) \subset \mathfrak{R}$, so that $B/\mathfrak{R}$ can be considered as a discrete $(A/\mathfrak{J})$-ring; the preceding remark proves that the group $\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ is defined. Moreover, if $\mathfrak{R}' \subset \mathfrak{R}$ and $\mathfrak{J}' \subset \mathfrak{J}$ are open bilateral ideals of B and A, respectively, such that $\rho(\mathfrak{J}') \subset \mathfrak{R}'$, one has by (18.3.5.1) a canonical homomorphism [$0_{\text{IV-1}}$ | 67]

$$\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Exan}_{A/\mathfrak{J}'}(B/\mathfrak{R}', L). \tag{18.5.1.1}$$

The set of pairs of open bilateral ideals $(\mathfrak{J}, \mathfrak{R})$ such that $\rho(\mathfrak{J}) \subset \mathfrak{R} \subset \mathfrak{R}_0$ is evidently directed for the relation "$\mathfrak{J} \supset \mathfrak{J}'$ and $\mathfrak{R} \supset \mathfrak{R}'$" and the maps (18.5.1.1) define an *inductive system* of additive groups with this set as index set. One sets, by abuse of notation (since it is no longer a matter of a group of extensions in bijective natural correspondence with a set of extensions)

$$\mathrm{Exantop}_A(B,L) = \varinjlim \mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L). \tag{18.5.1.2}$$

To say that the second member of (18.5.1.2) is *zero* means therefore that, for every pair of open bilateral ideals $\mathfrak{J} \subset A$, $\mathfrak{R} \subset B$ such that $\rho(\mathfrak{J}) \subset \mathfrak{R} \subset \mathfrak{R}_0$ and every $(A/\mathfrak{J})$-extension E of $B/\mathfrak{R}$ by L, there exist two open ideals $\mathfrak{J}' \subset \mathfrak{J}$, $\mathfrak{R}' \subset \mathfrak{R}$ such that $\rho(\mathfrak{J}') \subset \mathfrak{R}'$ and the inverse image of E by the homomorphism $B/\mathfrak{R}' \to B/\mathfrak{R}$ is *trivial*.

We leave to the reader the analogous definition of the inductive limits $\mathrm{Exaltop}_A(B,L)$ and $\mathrm{Exalcotop}_A(B,L)$ from $\mathrm{Exal}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ and $\mathrm{Exalcom}_{A/\mathfrak{J}}(B/\mathfrak{R}, L)$ when A is commutative and B is a topological A-algebra (resp. a commutative topological A-algebra).

(18.5.2) If one has a commutative diagram of continuous homomorphisms of rings

$$\begin{array}{ccc} B' & \longrightarrow & B \\ \uparrow & & \uparrow \\ A' & \longrightarrow & A \end{array}$$

one deduces from it canonically two homomorphisms of additive groups

$$\mathrm{Exantop}_A(B, L) \to \mathrm{Exantop}_{A'}(B, L) \to \mathrm{Exantop}_{A'}(B', L)$$

by passage to the inductive limit from (18.3.5.1).

By virtue of the exactness of the $\varinjlim$ functor in the category of commutative groups, the kernel of the homomorphism

$$\mathrm{Exantop}_A(B, L) \to \mathrm{Exantop}_{A'}(B, L)$$

is the inductive limit of the kernels of the homomorphisms

$$\mathrm{Exan}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Exan}_{A'/\mathfrak{J}'}(B/\mathfrak{R}, L)$$

where one took for $\mathfrak{J}'$ the inverse image of $\mathfrak{J}$; one denotes this kernel $\mathrm{Exantop}_{A/A'}(B, L)$. One defines similarly $\mathrm{Exaltop}_{A/A'}(B, L)$ and $\mathrm{Exalcotop}_{A/A'}(B, L)$. Finally, if one has a homomorphism
[$0_{\text{IV-1}}$ | 68] of B-bimodules $L \to L'$, one obtains canonically a homomorphism of additive groups

$$\mathrm{Exantop}_A(B, L) \to \mathrm{Exantop}_A(B, L')$$

by passage to the inductive limit from (18.3.6.1).

(18.5.3) Given a topological ring C and two topological C-bimodules M, N, one denotes Hom. $\mathrm{cont}_C(M, N)$ the additive group of C-homomorphisms *continuous* from M into N.

(18.5.3.1) Lemma. *Let C be a topological ring, E, L two topological C-bimodules; suppose that the topologies are linear, that L is discrete and annihilated by an open bilateral ideal of C. Then one has a canonical isomorphism*

$$\varinjlim \mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \xrightarrow{\sim} \text{Hom. } \mathrm{cont}_C(E, L) \tag{18.5.3.2}$$

where in the first member the inductive limit is taken over the directed set of pairs $(\mathfrak{R}, V)$ such that $\mathfrak{R}$ is an open bilateral ideal of C, V an open sub-C-bimodule of E, such that $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{R}.E \subset V$, $E.\mathfrak{R} \subset V$.

Proof. As $C/\mathfrak{R}$ and E/V are discrete, one has canonical homomorphisms

$$w_{\mathfrak{R},V} : \mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \longrightarrow \text{Hom. } \mathrm{cont}_C(E, L)$$

forming an inductive system, hence a homomorphism from the first member of (18.5.3.2) to Hom. $\mathrm{cont}_C(E, L)$. As the homomorphism $E/V' \to E/V$ is surjective for $V' \subset V$, it follows immediately from the definition that

$$\mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \to \mathrm{Hom}_{C/\mathfrak{R}}(E/V', L)$$

is injective whenever $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{R}.E \subset V'$, and $E.\mathfrak{R} \subset V'$. The same is clearly true of

$$\mathrm{Hom}_{C/\mathfrak{R}}(E/V, L) \to \mathrm{Hom}_{C/\mathfrak{R}'}(E/V, L)$$

for $\mathfrak{R}' \subset \mathfrak{R}$; hence the homomorphism (18.5.3.2) is injective. On the other hand, if u is a continuous C-homomorphism from E to L, its kernel is an open sub-bimodule V_0 of E. Choose an open bilateral ideal $\mathfrak{R}_0$ of C such that $\mathfrak{R}_0.L = L.\mathfrak{R}_0 = 0$, $\mathfrak{R}_0.E \subset V_0$, and $E.\mathfrak{R}_0 \subset V_0$. Then u is the canonical image of a $(C/\mathfrak{R}_0)$-homomorphism from E/V_0 to L, so (18.5.3.2) is surjective. □

This being so, the proposition (18.3.8) generalizes as follows to topological rings:

(18.5.4) Proposition. *Let B be a topological ring linearly topologized, $\mathfrak{J}$ a bilateral ideal of B, $C = B/\mathfrak{J}$ the quotient topological ring; $\mathfrak{J}/\mathfrak{J}^2$ (where $\mathfrak{J}$ is equipped with the topology induced by that of B and $\mathfrak{J}/\mathfrak{J}^2$ with the quotient topology of that of $\mathfrak{J}$) is then canonically equipped with a structure of topological C-bimodule. For every discrete C-bimodule L annihilated by an open bilateral ideal of C, there exists then a canonical isomorphism*

$$\text{Hom. cont}_C(\mathfrak{J}/\mathfrak{J}^2, L) \xrightarrow{\sim} \text{Exantop}_B(C, L). \tag{18.5.4.1}$$

Proof. Indeed, for every open $\mathfrak{R}$ of B such that $(\mathfrak{J} + \mathfrak{R})/\mathfrak{J}$ annihilates L, one has, by (18.3.8), a canonical isomorphism[18]

$$\text{Hom}_{B/(\mathfrak{J}+\mathfrak{R})}((\mathfrak{J} + \mathfrak{R})/(\mathfrak{J}^2 + \mathfrak{R}), L) \xrightarrow{\sim} \text{Exan}_{B/\mathfrak{R}}(B/(\mathfrak{J} + \mathfrak{R}), L)$$

and it suffices to pass to the inductive limit, taking into account (18.5.3.1). □

§19 Formally smooth algebras and Cohen rings

19.0 Introduction

(19.0.1) In Chapter IV, we will introduce and study, among other things, an important class of morphisms of preschemes, the *smooth* morphisms[19]. One of their fundamental properties (and which, together with a finiteness condition, characterizes them) is a property of *lifting of morphisms*: if $f : X \to Y$ is a smooth morphism, $g : Y' \to Y$ a morphism, then for every morphism $h : Y'' \to Y'$ making Y'' a prescheme "slightly different" from Y', every Y-morphism $Y'' \to X$ factorizes as $Y'' \xrightarrow{h} Y' \to X$. More precisely, let us restrict to the case where $Y = \text{Spec}(A)$, $X = \text{Spec}(B)$ are affine; B is then called a *formally smooth* A-algebra if, for every A-algebra C and every nilpotent ideal $\mathfrak{J}$ of C, every A-homomorphism $B \to C/\mathfrak{J}$ *lifts to* $B \to C \to C/\mathfrak{J}$. In other words, the map [$0_{\text{IV-1}}$ | 69]

$$\text{Hom}_A(B, C) \to \text{Hom}_A(B, C/\mathfrak{J})$$

is *surjective*. In many applications, X will appear as a contravariant representable functor $Y' \mapsto F(Y')$ from the category of Y-preschemes to that of sets, so that (**0$_{\text{III}}$**, 8.1.8) one will have $F(Y') = \text{Hom}_Y(Y', X)$. In the affine case, setting $F^0(C) = F(\text{Spec}(C))$, the verification of the fact that, under the conditions above, $F^0(C) \to F^0(C/\mathfrak{J})$ is *surjective* (which can be done even without knowing that F is representable) will establish that f is smooth, provided the additional finiteness condition is satisfied.

(19.0.2) For *topological algebras* over a topological ring A, there is an analogous notion of *formally smooth algebra* that we will not specify here (cf. (19.3.1)). The study of these

[18] The French source prints "(18.3.9)", but § 18.3 ends at (18.3.8), which is precisely the isomorphism used here.

[19] Also called *simple* morphisms in certain recent works (inspired by the classical terminology of "simple point"); this terminology lends itself however to confusion, notably in the theory of algebraic groups.

notions is first done from an elementary point of view in § 19, then, with the aid of the properties of differentials that will be developed in §§ 20 and 21, more delicate theorems will be proved in § 22. Let us summarize here the main results on formally smooth algebras:

I. — Let A, B be two Noetherian local rings, $\varphi : A \to B$ a local homomorphism, k the residue field of A, and let $B_0 = B \otimes_A k$; we equip A, B, and B_0 with their preadic topologies and k with the discrete topology. Then, for B to be a formally smooth A-algebra, it is necessary and sufficient that B be a *flat* A-module and that B_0 be a formally smooth k-algebra (19.7.1). This theorem thus reduces formal smoothness, for Noetherian local rings, to the same question for Noetherian local rings that are algebras over a field.

II. — Let k be a field, A a Noetherian local ring that is a k-algebra. For A to be formally smooth, it is necessary and sufficient that A be *geometrically regular* over k, that is to say that for every finite extension k' of k, the semi-local ring $A \otimes_k k'$ be
[$0_{\text{IV-1}}$ | 70] regular (22.5.8); the completion $\widehat{A}$ of A is then isomorphic to a power series ring $K[[T_1, \ldots, T_n]]$ (19.6.5). Moreover, the k-algebra structure of A, when A is assumed complete and formally smooth over k, is entirely determined by the residue field K of A and the dimension of A; the latter can furthermore be arbitrary subject to the inequality $\dim(A) \geq \mathrm{rg}_k(\Gamma_{K/k})$, where $\Gamma_{K/k}$ is the "module of imperfection" of K (22.2.6).

In particular, for an extension K of k to be formally smooth, it is necessary and sufficient that K be a *separable* extension of k (19.6.1).

III. — Let A be a Noetherian local ring, $\mathfrak{J}$ an ideal of A distinct from A, $A_0 = A/\mathfrak{J}$, B_0 a complete Noetherian local ring, $A_0 \to B_0$ a local homomorphism making B_0 a formally smooth A_0-algebra. Then there exists a complete Noetherian local ring B, a local homomorphism $A \to B$ making B a flat A-module, and an A_0-isomorphism $B \otimes_A A_0 \xrightarrow{\sim} B_0$ (so that, by I), B is a formally smooth A-algebra); moreover B is determined by these properties up to isomorphism (19.7.2). This theorem contains in particular the *theorems of Cohen* on the structure of complete Noetherian local rings (19.8), which will play an important role in §§ 6 and 7 of Chapter IV.

IV. — The interest in the study of formally smooth Noetherian local rings over another comes from the following "pointwise" characterization of smooth morphisms: if X and Y are locally Noetherian preschemes, $f : X \to Y$ a morphism locally of finite type, then, for f to be smooth, it is necessary and sufficient that for every $x \in X$, the ring $\mathscr{O}_x$ be formally smooth over $\mathscr{O}_{f(x)}$. In particular, if $Y = \mathrm{Spec}(k)$, where k is a perfect field, to say that f is smooth is equivalent to saying that X is a *regular* prescheme.

V. — Finally, we will see in §§ 20, 21, and 22 that the notion of formally smooth algebra is introduced naturally in the theory of *Kähler differentials*, the two theories shedding light on each other.

(19.0.3) Throughout this section and the following ones, topological rings and modules will be assumed to be *linearly topologized* ($\mathbf{0_I}$, 7.1.1); the topological rings considered will be assumed to be *commutative*, unless explicit mention to the contrary. Recall that if A and B are two topological rings, $\rho : A \to B$ a ring homomorphism defining on B a structure of A-algebra, we say that B is a *topological A-algebra* if ρ is continuous for the topologies considered.

For brevity, in a topological ring A (resp. a topological A-module M), we will say "fundamental system of open ideals (resp. submodules)" instead of "fundamental system of neighbourhoods of 0 consisting of ideals (resp. submodules)".

Given a topological ring A and a topological A-module M, the sets $\mathfrak{J}M$, where $\mathfrak{J}$ ranges over a fundamental system of open ideals in A, form a fundamental system of

open submodules of a topology on M making M a topological A-module, called the topology *derived* from that of A.

Let M be a topological A-module whose topology is *less fine* than the topology derived from that of A; then, if N is an open submodule of M, the discrete A-module M/N is annihilated by an open ideal $\mathfrak{R}$ of A, since by hypothesis there exists such an ideal $\mathfrak{R}$ with $\mathfrak{R} \cdot M \subset N$.

If M and N are two topological A-modules whose topologies are both derived from that of A, then every A-homomorphism $u : M \to N$ is *continuous*, since for every neighbourhood V of 0 in N, there exists by hypothesis an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}N \subset V$, and one thus has $u(\mathfrak{J}M) \subset \mathfrak{J}N \subset V$. [$0_{\text{IV-1}}$ | 71]

When B is a topological A-algebra, the topology on B *derived* from that of A is *finer* than the topology given on B, since for every open ideal $\mathfrak{R}$ of B, there is by hypothesis an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}B \subset \mathfrak{R}$.

19.1 Formal epimorphisms and monomorphisms

(19.1.1) Proposition. *Let A be a topological ring, M, N two topological A-modules, (W_λ) a fundamental system of open submodules in N, $u : M \to N$ a continuous A-homomorphism, $\widehat{M}$, $\widehat{N}$ the separated completions of M and N, $\hat{u} : \widehat{M} \to \widehat{N}$ the continuous extension of u to the separated completions.*

(i) The following conditions are equivalent:

a) $u(M)$ is dense in N.

a′) $\hat{u}(\widehat{M})$ is dense in $\widehat{N}$.

a″) For all λ, the composite homomorphism $M \xrightarrow{u} N \to N/W_\lambda$ is surjective.

(ii) The following conditions are equivalent:

b) The inverse image by u of the topology of N is equal to the topology of M.

b′) $\hat{u}$ is an isomorphism of the topological $\widehat{A}$-module $\widehat{M}$ onto the sub-$\widehat{A}$-module $\hat{u}(\widehat{M})$ of $\widehat{N}$ (which is necessarily closed).

b″) The $u^{-1}(W_\lambda)$ form a fundamental system of neighbourhoods of 0 in M.

This follows immediately from the definition of separated completions, and from the fact that N/W_λ is discrete.

(19.1.2) When the equivalent conditions of (i) (resp. (ii)) in (19.1.1) are satisfied, we say that u is a *formal epimorphism* (resp. a *formal monomorphism*). We say that u is a *formal bimorphism* if it is both a formal epimorphism and a formal monomorphism; this amounts to the same, by virtue of (19.1.1), as saying that $\hat{u}$ is an *isomorphism* of the topological $\widehat{A}$-module $\widehat{M}$ onto the topological $\widehat{A}$-module $\widehat{N}$.

(19.1.3) Proposition. *Let A be a topological ring, M, N two topological A-modules, $u : M \to N$ a continuous A-homomorphism, (V_λ), (W_λ) two fundamental systems of open submodules in M and N respectively, having the same index set, and such that $u(V_\lambda) \subset W_\lambda$ for all λ; let $u_\lambda : M/V_\lambda \to N/W_\lambda$ be the homomorphism induced by u by passing to quotients. Then:*

(i) For u to be a formal epimorphism, it is necessary and sufficient that, for all λ, u_λ be surjective.

(ii) *For u to be a formal monomorphism, it is necessary and sufficient that, for all λ, there exist μ such that $V_\mu \subset V_\lambda$ and that $\mathrm{Ker}(u_\mu)$ be contained in the kernel V_λ/V_μ of the canonical map $M/V_\mu \to M/V_\lambda$.*

(iii) *For u to be a formal bimorphism, it is necessary and sufficient that, for all λ, u_λ be surjective and that there exist μ such that $V_\mu \subset V_\lambda$ and that the canonical homomorphism $M/V_\mu \to M/V_\lambda$*

[$0_{IV\text{-}1}$ / 72] *factorize as $M/V_\mu \xrightarrow{u_\mu} N/W_\mu \xrightarrow{h} M/V_\lambda$ (where the homomorphism $N/W_\mu \to M/V_\lambda$ is necessarily unique).*

Proof. Assertion (i) is immediate; on the other hand, $\mathrm{Ker}(u_\mu) = u^{-1}(W_\mu)/V_\mu$, and the kernel of the canonical map $M/V_\mu \to M/V_\lambda$ is V_λ/V_μ; the condition of (ii) thus amounts to saying that $u^{-1}(W_\mu) \subset V_\lambda$, and assertion (ii) follows immediately; finally, when u_μ is surjective, to say that $\mathrm{Ker}(u_\mu)$ is contained in V_λ/V_μ, or to say that $M/V_\mu \to M/V_\lambda$ factorizes as $v \circ u_\mu$, where v is a homomorphism $N/W_\mu \to M/V_\lambda$, is the same thing, since N/W_μ then identifies with $(M/V_\mu)/\mathrm{Ker}(u_\mu)$. □

(19.1.4) Corollary. *Let A be a topological ring, M, N two topological A-modules whose topologies are derived from that of A, $u : M \to N$ a formal epimorphism. Let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For u to be a formal bimorphism, it is necessary and sufficient that for all λ, the homomorphism $u_\lambda : M/\mathfrak{J}_\lambda M \to N/\mathfrak{J}_\lambda N$ induced by u by passing to quotients is bijective.*

Proof. Indeed, $u(\mathfrak{J}_\lambda M) \subset \mathfrak{J}_\lambda N$ and one can apply the criterion (19.1.3), (iii); but if one has a factorization $M/\mathfrak{J}_\mu M \xrightarrow{u_\mu} N/\mathfrak{J}_\mu N \xrightarrow{v} M/\mathfrak{J}_\lambda M$, the image of $\mathfrak{J}_\lambda M/\mathfrak{J}_\mu M$ by u_μ is $\mathfrak{J}_\lambda N/\mathfrak{J}_\mu N$, hence the image of $\mathfrak{J}_\lambda N/\mathfrak{J}_\mu N$ by v is 0 and v factorizes as

$$N/\mathfrak{J}_\mu N \to N/\mathfrak{J}_\lambda N \xrightarrow{v'} M/\mathfrak{J}_\lambda M;$$

but then the automorphism identical to that of $M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\lambda M \xrightarrow{u_\lambda} N/\mathfrak{J}_\lambda N \xrightarrow{v'} M/\mathfrak{J}_\lambda M,$$

which shows that u_λ is injective, and as we already know it is surjective, this proves the corollary. □

(19.1.5) Proposition. *Let A be a topological ring, M, N two topological A-modules, and $u : M \to N$ a continuous A-homomorphism. The following conditions are equivalent:*

a) *For every discrete topological A-module E and every continuous A-homomorphism $v : M \to E$, there exists a continuous A-homomorphism $w : N \to E$ such that $v = w \circ u$.*

b) *For every open submodule V' of M, there exist an open submodule W'' of N, an open submodule $V'' \subset V' \cap u^{-1}(W'')$, and a homomorphism $h : N/W'' \to M/V'$ such that the canonical homomorphism $M/V'' \to M/V'$ factorizes as*

$$M/V'' \xrightarrow{u''} N/W'' \xrightarrow{h} M/V',$$

where u'' is induced by u by passing to quotients.

Proof. To see that a) implies b), apply a) to $E = M/V'$ and to the canonical homomorphism $v : M \to M/V'$. Then $W'' = w^{-1}(0)$ is an open submodule of N and $V'' = u^{-1}(W'')$ is an open submodule of M contained in V'; these submodules and the homomorphism $h : N/W'' \to M/V'$ induced by w answer the question. Conversely, to show that b) implies a), one may restrict to the case where v is surjective, replacing E by $v(M)$; then $V' = \mathrm{Ker}(v)$ is an open submodule of M, so E is isomorphic to the discrete A-module M/V', and applying b) gives

the desired continuous A-homomorphism w by taking the composite $N \to N/W'' \xrightarrow{h}$ [$0_{\text{IV-1}}$ | 73]
M/V', the diagram

$$\begin{array}{ccc} M & \xrightarrow{\ u\ } & N \\ \downarrow & & \downarrow \\ M/V'' & \xrightarrow[u'']{} & N/W'' \end{array}$$

being commutative. □

When the equivalent conditions of (19.1.5) are satisfied, we say that u is *formally left invertible*; since condition b) of (19.1.5) implies $u^{-1}(W'') \subset V'$, u is then a formal monomorphism. The terminology is further justified by the following corollaries.

(19.1.6) Corollary. *If there exists a continuous $\widehat{A}$-homomorphism $s : \widehat{N} \to \widehat{M}$ such that $s \circ \widehat{u} = 1_{\widehat{M}}$, then u is formally left invertible.*

Note that $\widehat{u}$ is then a topological isomorphism of $\widehat{M}$ onto a *topological direct summand* of $\widehat{N}$. To prove (19.1.6), it suffices to note that, with the notation of (19.1.5), a), $v : M \to E$ extends to a continuous $\widehat{A}$-homomorphism $\widehat{v} : \widehat{M} \to E$ since E is discrete; let $j : M \to \widehat{M}$ and $j' : N \to \widehat{N}$ be the canonical homomorphisms. Then, setting $w = \widehat{v} \circ s \circ j'$, one has $w \circ u = \widehat{v} \circ s \circ \widehat{u} \circ j = \widehat{v} \circ j = v$.

(19.1.7) Corollary. *Suppose that the topologies of M and N are derived from that of A, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For u to be formally left invertible, it is necessary and sufficient that, for every λ, the homomorphism*

$$u_\lambda : M/\mathfrak{J}_\lambda M \longrightarrow N/\mathfrak{J}_\lambda N$$

induced by u by passing to quotients be left invertible (in other words, be an isomorphism of $M/\mathfrak{J}_\lambda M$ onto a direct summand of $N/\mathfrak{J}_\lambda N$).

Indeed, the condition is sufficient, since for $V' = \mathfrak{J}_\lambda M$ in condition b) of (19.1.5), one answers the question by taking $W'' = \mathfrak{J}_\lambda N$, $V'' = V'$, and h such that $h \circ u_\lambda$ is the identity on $M/\mathfrak{J}_\lambda M$. Conversely, if u is formally left invertible, then for every λ, by (19.1.5), b), there are μ with $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ and a homomorphism $h : N/\mathfrak{J}_\mu N \to M/\mathfrak{J}_\lambda M$ such that the canonical homomorphism $M/\mathfrak{J}_\mu M \to M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\mu M \xrightarrow{u_\mu} N/\mathfrak{J}_\mu N \xrightarrow{h} M/\mathfrak{J}_\lambda M.$$

But since $h(\mathfrak{J}_\lambda(N/\mathfrak{J}_\mu N)) \subset \mathfrak{J}_\lambda(M/\mathfrak{J}_\lambda M) = 0$, h factorizes canonically as

$$N/\mathfrak{J}_\mu N \longrightarrow N/\mathfrak{J}_\lambda N \xrightarrow{s} M/\mathfrak{J}_\lambda M,$$

and it is immediate that s is a left inverse of u_λ.

(19.1.8) Proposition. *Let A be a topological ring admitting a countable decreasing fundamental system $(\mathfrak{J}_n)$ of open ideals. Let M, N be two topological A-modules whose*

topologies are derived from that of A, and let $u : M \to N$ be an A-homomorphism. Set $M_n = M/\mathfrak{J}_n M$, $N_n = N/\mathfrak{J}_n N$, and let $u_n : M_n \to N_n$ be the $(A/\mathfrak{J}_n)$-homomorphism induced by u by passing to quotients. Suppose that, for every n, $P_n = \mathrm{Coker}(u_n)$ is a projective $(A/\mathfrak{J}_n)$-module and that M is separated and complete. Then u is formally left invertible if and only if u is left invertible (and u is then a topological isomorphism of M onto a topological direct summand of N).

Proof. By (19.1.7), one has commutative diagrams [$0_{\text{IV-1}}$ | 74]

$$\begin{array}{ccccccccc} 0 & \longrightarrow & M_n & \xrightarrow{u_n} & N_n & \xrightarrow{p_n} & P_n & \longrightarrow & 0 \\ & & \uparrow{\scriptstyle f} & & \uparrow{\scriptstyle g} & & \uparrow{\scriptstyle h} & & \\ 0 & \longrightarrow & M_{n+1} & \xrightarrow[u_{n+1}]{} & N_{n+1} & \xrightarrow[p_{n+1}]{} & P_{n+1} & \longrightarrow & 0 \end{array}$$

whose rows are split exact sequences; in other words, for every n there exists a homomorphism $s_n : P_n \to N_n$ such that $p_n \circ s_n = 1_{P_n}$. We show by induction on n that homomorphisms $s'_n : P_n \to N_n$ can be defined so that $p_n \circ s'_n = 1_{P_n}$ and the diagrams

$$\begin{array}{ccc} P_n & \xrightarrow{s'_n} & N_n \\ {\scriptstyle h}\uparrow & & \uparrow{\scriptstyle g} \\ P_{n+1} & \xrightarrow[s'_{n+1}]{} & N_{n+1} \end{array}$$

are commutative. Indeed, $g \circ s_{n+1} - s'_n \circ h$ is a homomorphism from P_{n+1} into

$$u_n(M_n) = u_{n+1}(M_{n+1})/\mathfrak{J}_n u_{n+1}(M_{n+1});$$

since P_{n+1} is a projective $(A/\mathfrak{J}_{n+1})$-module, this homomorphism factorizes as

$$P_{n+1} \xrightarrow{t_{n+1}} u_{n+1}(M_{n+1}) \longrightarrow u_{n+1}(M_{n+1})/\mathfrak{J}_n u_{n+1}(M_{n+1}),$$

whence $s'_{n+1} = s_{n+1} - t_{n+1}$ answers the question. The decomposition of N_n as the direct sum of $u_n(M_n)$ and $s'_n(P_n)$ then immediately gives a homomorphism $w_n : N_n \to M_n$ which is a left inverse of u_n and makes the diagrams

$$\begin{array}{ccc} N_n & \xrightarrow{w_n} & M_n \\ {\scriptstyle g}\uparrow & & \uparrow{\scriptstyle f} \\ N_{n+1} & \xrightarrow[w_{n+1}]{} & M_{n+1} \end{array}$$

commutative. The inverse system (w_n) therefore has an inverse limit $\widehat{w} : \widehat{N} \to \widehat{M} = M$. Composing with the canonical homomorphism $N \to \widehat{N}$ gives a homomorphism $w : N \to M$ such that, for every n, the endomorphism $(w \circ u)_n$ of $M_n = M/\mathfrak{J}_n M$ induced by $w \circ u$ is the identity. Thus $w \circ u = 1_M$ because M is separated and complete. □

(19.1.9) Proposition. *Let A be a preadmissible topological ring (**0**$_{\mathbf{I}}$, 7.1.2), $\mathfrak{Q}$ an ideal of definition of A, and $(\mathfrak{J}_\lambda)$ a fundamental system of open ideals in A. Let M, N be two topological A-modules whose topologies are derived from that of A, such that for every λ, $N/\mathfrak{J}_\lambda N$ is a projective $(A/\mathfrak{J}_\lambda)$-module (cf. (19.2.3)). Let $u : M \to N$ be an A-homomorphism. Then the following conditions are equivalent:*

a) u is formally left invertible.

b) The homomorphism $u_0 : M/\mathfrak{Q}M \to N/\mathfrak{Q}N$ induced by u by passing to quotients is left invertible. [$0_{IV\text{-}1}$ | 75]

Proof. By (19.1.7), condition a) is equivalent to u_λ being left invertible for every λ. Since $\mathfrak{Q}$ is open, and therefore contains some $\mathfrak{J}_\lambda$, it follows at once that u_0 is left invertible. Conversely, to show that b) implies a), note that for every λ, $\mathfrak{Q}/\mathfrak{J}_\lambda$ is by hypothesis a nilpotent ideal of $A/\mathfrak{J}_\lambda$. The assertion follows from the next proposition. □

(19.1.10) Proposition. *Let A be a ring, M, N two A-modules, with N projective, and let $u : M \to N$ be an A-homomorphism. Let $\mathfrak{J}$ be an ideal of A; suppose that one of the following conditions holds:*

(i) $\mathfrak{J}$ is nilpotent.

(ii) $\mathfrak{J}$ is contained in the radical of A and M is of finite type.

Then u is left invertible if and only if the homomorphism $u_0 : M/\mathfrak{J}M \to N/\mathfrak{J}N$ of $(A/\mathfrak{J})$-modules induced by u by passing to quotients is left invertible.

Proof. The condition is plainly necessary; let us prove that it is sufficient. Let v_0 be a left inverse of u_0. The composite $N \to N/\mathfrak{J}N \xrightarrow{v_0} M/\mathfrak{J}M$ factorizes as $N \xrightarrow{v} M \to M/\mathfrak{J}M$ because N is projective. Then $w = v \circ u$ is an endomorphism of M whose induced endomorphism w_0 of $M/\mathfrak{J}M$ is the identity, and it is enough to prove that w is bijective (for then $w^{-1} \circ v$ is a left inverse of u). We distinguish the two cases.

(i) For every n one has the commutative diagram

$$\begin{array}{ccc} (\mathfrak{J}^n/\mathfrak{J}^{n+1}) \otimes_{A/\mathfrak{J}} (M/\mathfrak{J}M) & \longrightarrow & \mathfrak{J}^n M/\mathfrak{J}^{n+1}M \\ \downarrow{\scriptstyle 1\otimes \mathrm{gr}^0(w)} & & \downarrow{\scriptstyle \mathrm{gr}^n(w)} \\ (\mathfrak{J}^n/\mathfrak{J}^{n+1}) \otimes_{A/\mathfrak{J}} (M/\mathfrak{J}M) & \longrightarrow & \mathfrak{J}^n M/\mathfrak{J}^{n+1}M \end{array}$$

in which the horizontal arrows are surjective. Since $\mathrm{gr}^0(w) = w_0$ is the identity, so is $\mathrm{gr}^n(w)$, which is therefore, a fortiori, bijective. The $\mathfrak{J}$-preadic filtration on M is finite because $\mathfrak{J}$ is nilpotent, so w is bijective (Bourbaki, *Alg. comm.*, Chap. III, § 2, no. 8, Cor. 3 of Th. 1).

(ii) It suffices to show that, for every maximal ideal $\mathfrak{m}$ of A, the endomorphism $w_\mathfrak{m}$ of $M_\mathfrak{m}$ is bijective (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 3, Th. 1). Since $\mathfrak{J}A_\mathfrak{m} \subset \mathfrak{m}A_\mathfrak{m}$ and $A_\mathfrak{m}/\mathfrak{J}A_\mathfrak{m} = (A/\mathfrak{J})_\mathfrak{m}$, we are reduced to proving the proposition when A is local. Moreover, one may suppose that $\mathfrak{J}$ is the maximal ideal $\mathfrak{J}_0$ of A, because if u_0 is left invertible, so is
$u_{00} : M/\mathfrak{J}_0M \to N/\mathfrak{J}_0N$, obtained by tensoring u_0 with $1_{A/\mathfrak{J}_0}$, since [$0_{IV\text{-}1}$ | 76]

$$M/\mathfrak{J}_0M = (M/\mathfrak{J}M) \otimes_{A/\mathfrak{J}} (A/\mathfrak{J}_0).$$

[20] Suppose then that $\mathfrak{J}$ is maximal, so that $A/\mathfrak{J}$ is a field. It plainly suffices to prove that M is a free A-module under the hypotheses of the statement: indeed, $\det(w_0)$ is then the canonical image of $\det(w)$ in $A/\mathfrak{J}$, hence $\det(w) \notin \mathfrak{J}$ and is therefore invertible. Now $M/\mathfrak{J}M$ is a finite-dimensional free $(A/\mathfrak{J})$-vector space, so there are a finite free

[20] The French source prints $N/\mathfrak{J}_0M$ as the codomain of u_{00}; the module type requires $N/\mathfrak{J}_0N$.

A-module L and an A-homomorphism $f : L \to M$ such that the induced homomorphism $f_0 : L/\mathfrak{J}L \to M/\mathfrak{J}M$ is bijective. Since M is of finite type, f is surjective by Nakayama's lemma (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 2, Cor. 1 of Prop. 4). Moreover, if $g = u \circ f$, then the induced homomorphism $g_0 : L/\mathfrak{J}L \to N/\mathfrak{J}N$ is left invertible, and since L is free, the preceding observation shows that g itself is left invertible. This plainly implies that f is injective, completing the proof. □

Let us mention in passing the following corollaries of (19.1.10).

(19.1.11) Corollary. *Let A be a local ring, k its residue field, M a finite-type A-module, N a projective A-module, and $u : M \to N$ a homomorphism. Then u is left invertible if and only if there exists a system of generators $(x_i)_{1\leq i\leq m}$ of M such that the images of the $x_i \otimes 1$ under $u \otimes 1 : M \otimes_A k \to N \otimes_A k$ are linearly independent in $N \otimes_A k$; the x_i then form a basis of M.*

The condition is plainly necessary, since if u is left invertible, M is a finite-type projective A-module and hence free. Conversely, if the condition holds, the $x_i \otimes 1$ plainly form a basis of $M \otimes_A k$ and $u \otimes 1$ is left invertible; apply (19.1.10) to the maximal ideal $\mathfrak{J}$ of A.

(19.1.12) Corollary. *Let A be a ring, M a finite-type A-module, N a projective A-module, and $u : M \to N$ a homomorphism. For every prime ideal $\mathfrak{p} \in \mathrm{Spec}(A)$, the following conditions are equivalent:*

a) $u_\mathfrak{p} : M_\mathfrak{p} \to N_\mathfrak{p}$ is left invertible.

b) $u \otimes 1 : M \otimes_A k(\mathfrak{p}) \to N \otimes_A k(\mathfrak{p})$ is injective (where $k(\mathfrak{p})$ denotes the residue field of A at $\mathfrak{p}$).

c) There is a finite system of elements $x_i \in M$ $(1 \leq i \leq m)$ whose images generate $M_\mathfrak{p}$, and a system of m linear forms y_i^* on N $(1 \leq i \leq m)$ such that $\det(\langle y_i^*, u(x_j)\rangle) \notin \mathfrak{p}$.

d) There exists $f \in A - \mathfrak{p}$ such that $u_f : M_f \to N_f$ is left invertible.

Moreover, the set of $\mathfrak{p} \in \mathrm{Spec}(A)$ satisfying these conditions is open in $\mathrm{Spec}(A)$.

The last assertion is an immediate consequence of d). Since N is projective, it is a direct summand of a free A-module $A^{(I)}$; and since M is of finite type, $u(M)$ is contained in a submodule of $A^{(I)}$ of the form A^n for finite n. Since each of a), b), c), and d) is equivalent to the corresponding assertion with N replaced by $N \oplus P$ (with u still mapping M into N), we are reduced to the case where N is free of finite type. Clearly d) implies a), and a) and b) are equivalent by (19.1.11). Moreover, a) implies that $M_\mathfrak{p}$ is free by (19.1.11), so a) implies c) by choosing the x_i so that their images form a basis of this
[$0_{\text{IV-1}}$ | 77] $A_\mathfrak{p}$-module and noting that, because N is free of finite type, every linear form on $N_\mathfrak{p}$ can be written v/f, where $f \in A - \mathfrak{p}$ and v is a linear form on N. Clearly c) implies b), so it remains to see that a) implies d). Since N is finitely presented, $(\mathrm{Hom}_A(N, M))_\mathfrak{p}$ identifies canonically with $\mathrm{Hom}_{A_\mathfrak{p}}(N_\mathfrak{p}, M_\mathfrak{p})$ (Bourbaki, *Alg. comm.*, Chap. II, § 2, no. 7, Prop. 19). If $w_\mathfrak{p}$ is a left inverse of $u_\mathfrak{p}$, there are a homomorphism $w : N \to M$ and an element $f \in A - \mathfrak{p}$ such that $w_\mathfrak{p} = w \otimes (1/f)1_{A_\mathfrak{p}}$. The relation $w_\mathfrak{p} \circ u_\mathfrak{p} = 1_{M_\mathfrak{p}}$ can therefore also be written $(w \circ u) \otimes 1_{A_\mathfrak{p}} = f.1_{M_\mathfrak{p}}$. Since M is of finite type, there is $g \in A - \mathfrak{p}$ such that the endomorphism $g((w \circ u) - f.1_M)$ vanishes on all generators of M, and hence is zero. Put $h = fg$, $u_h = u \otimes 1_{A_h}$, and $w_h = w \otimes 1_{A_h}$. Then $w_h(u_h(z)) = (f/1)z$ for every $z \in M_h$; since $h/1$ is invertible in A_h, so is $f/1$, and $(f/1)^{-1}w_h$ is a left inverse of u_h. This completes the proof.

(19.1.13) Proposition. *Suppose the hypotheses of (19.1.9) hold, and suppose in addition that $(\mathfrak{J}_\lambda)$ is a decreasing sequence $(\mathfrak{J}_n)$ and that M is separated and complete. Then conditions a) and b) of (19.1.9) are also equivalent to:*

c) u is left invertible.

We already know that c) implies a) by (19.1.6). Conversely, if a) holds, then with the notation of (19.1.8), M_n is a direct summand of the projective $(A/\mathfrak{J}_n)$-module N_n; hence P_n is also isomorphic to a direct summand of N_n and is therefore projective. It remains only to apply (19.1.8).

Finally, note the following proposition.

(19.1.14) Proposition. *Let A be a ring, M a finite-type A-module, N a projective A-module, and $u : M \to N$ an A-homomorphism.*

(i) The homomorphism u is left invertible if and only if, for every maximal ideal $\mathfrak{m}$ of A, $u_\mathfrak{m} : M_\mathfrak{m} \to N_\mathfrak{m}$ is left invertible.

(ii) Let A' be an A-algebra which is a faithfully flat A-module. Then u is left invertible if and only if $u \otimes 1 : M \otimes_A A' \to N \otimes_A A'$ is left invertible.

As in (19.1.12), it suffices to consider the case where N is free of finite type. Then saying that u is left invertible means that u is injective and that the quotient module $P = N/u(M)$ is projective, since $u(M)$ is then a direct summand of N. Also, since M is of finite type, P is finitely presented.

(i) Necessity is clear. Conversely, if the condition holds, u is injective (Bourbaki, *Alg. comm.*, Chap. II, § 3, no. 3, Th. 1), and since $P_\mathfrak{m} = N_\mathfrak{m}/u_\mathfrak{m}(M_\mathfrak{m})$ is projective for every $\mathfrak{m}$, it follows that P is projective (*loc. cit.*, § 5, no. 2, Th. 1).

(ii) Again, necessity is immediate. Conversely, if the condition holds, u is injective (**0$_\mathbf{I}$**, 6.4.1), and since $P \otimes_A A' = \mathrm{Coker}(u \otimes 1)$ is projective, hence flat, it follows that P is a flat A-module (**0$_\mathbf{I}$**, 6.6.3), and therefore projective because it is finitely presented (Bourbaki, *Alg. comm.*, Chap. II, § 5, no. 2, Cor. 2 of Th. 1).

(19.1.15) Remark. The notion dual to that of a formally left invertible homomorphism is that of a *formally right invertible* homomorphism. Such a continuous A-homomorphism $u : M \to N$ satisfies, by definition, the following condition: for every open submodule W' of N, there exist an open submodule $V' \subset u^{-1}(W')$ of M, an open submodule $W'' \subset W'$ of N, and a homomorphism $h : N/W'' \to M/V'$ such that the canonical homomorphism $N/W'' \to N/W'$ factorizes as [0$_{\text{IV-1}}$ | 78]

$$N/W'' \xrightarrow{h} M/V' \xrightarrow{u'} N/W',$$

where u' is induced by u by passing to quotients. This implies that u is a formal epimorphism. If there exists a continuous $\widehat{A}$-homomorphism $r : \widehat{N} \to \widehat{M}$ such that $\widehat{u} \circ r = 1_{\widehat{N}}$, then u is immediately seen to be formally right invertible. Under the hypotheses of (19.1.7), u is formally right invertible if and only if every u_λ is right invertible (that is, if $\mathrm{Ker}(u_\lambda)$ is a direct summand of $M/\mathfrak{J}_\lambda M$ and u_λ is an isomorphism from a complement of $\mathrm{Ker}(u_\lambda)$ onto $N/\mathfrak{J}_\lambda N$). We leave to the reader the statements and proofs of the propositions corresponding to (19.1.8) and (19.1.9): in the analogue of (19.1.8), one must suppose M separated and complete and M_n a projective $(A/\mathfrak{J}_n)$-module; in the analogue of (19.1.9), one must omit the hypothesis on the $N/\mathfrak{J}_\lambda N$, but instead suppose that, for every λ, $M/\mathfrak{J}_\lambda M$ is a projective $(A/\mathfrak{J}_\lambda)$-module.

19.2 Formally projective modules

(19.2.1) Definition. Let A be a topological ring. A topological A-module M is said to be *formally projective* if it satisfies the following condition: for every open ideal $\mathfrak{J}$ of A, every pair of discrete $(A/\mathfrak{J})$-modules P, Q, every surjective A-homomorphism $u : P \to Q$, and every continuous A-homomorphism $v : M \to Q$, there exists a continuous A-homomorphism $w : M \to P$ such that $v = u \circ w$.

(19.2.2) To verify the condition of (19.2.1), one may plainly restrict, replacing Q by $v(M)$ and P by $u^{-1}(v(M))$, to the case where v itself is surjective. Then Q is isomorphic to M/V, where V is an open submodule of M such that $\mathfrak{J}M \subset V$. The condition of (19.2.1) is therefore equivalent to requiring that, for every discrete $(A/\mathfrak{J})$-module P and every surjective A-homomorphism $u : P \to M/V$, there exist an open submodule $V' \subset V$ of M and an A-homomorphism $w : M/V' \to P$ such that the canonical homomorphism $M/V' \to M/V$ factorizes as

$$M/V' \xrightarrow{w} P \xrightarrow{u} M/V.$$

It suffices to verify this condition when $\mathfrak{J}$ ranges over a fundamental system of neighbourhoods of 0 in A formed of ideals.

(19.2.3) Suppose that there exist a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals in A and a fundamental system (V_λ) of open submodules of M, with the same index set, such that for every λ, M/V_λ is a projective $(A/\mathfrak{J}_\lambda)$-module. Then M is formally projective. Indeed, with the notation of (19.2.2), choose λ such that $\mathfrak{J}_\lambda \subset \mathfrak{J}$ and $V_\lambda \subset V$. Since P is also an $(A/\mathfrak{J}_\lambda)$-module, the factorization of the canonical homomorphism $M/V_\lambda \to M/V$ as $M/V_\lambda \to P \to M/V$ follows from its being an $(A/\mathfrak{J}_\lambda)$-homomorphism and from the projectivity of M/V_λ.

When the stronger condition in this paragraph holds, M is said to be *strictly formally projective.*

(19.2.4) Proposition. *Let A be a topological ring, and let M be a topological A-module whose topology is derived from that of A. Then M is formally projective if and only if it is strictly formally projective.*

Proof. We have just seen that the condition is sufficient. Conversely, suppose that M is formally projective, and let $(\mathfrak{J}_\lambda)$ be a fundamental system of open ideals in A. For each λ, let P be a free $(A/\mathfrak{J}_\lambda)$-module and let $u : P \to M/\mathfrak{J}_\lambda M$ be a surjective $(A/\mathfrak{J}_\lambda)$-homomorphism. There is then a $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$ such that the canonical homomorphism $M/\mathfrak{J}_\mu M \to M/\mathfrak{J}_\lambda M$ factorizes as

$$M/\mathfrak{J}_\mu M \xrightarrow{w} P \xrightarrow{u} M/\mathfrak{J}_\lambda M.$$

But since $w(\mathfrak{J}_\lambda(M/\mathfrak{J}_\mu M)) \subset \mathfrak{J}_\lambda P = 0$, w factorizes through a map $v : M/\mathfrak{J}_\lambda M \to P$, and it is clear that $u \circ v$ is the identity on $M/\mathfrak{J}_\lambda M$. Thus this $(A/\mathfrak{J}_\lambda)$-module is projective. □

[$0_{\text{IV-1}}$ | 79]

(19.2.5) Proposition. *Let A be a topological ring, M a topological A-module.*

(i) The module M is formally projective (resp. strictly formally projective) if and only if the topological $\widehat{A}$-module $\widehat{M}$ is so.

(ii) Let A' be a topological A-algebra. If M is formally projective (resp. strictly formally projective), then $M \otimes_A A'$, equipped with the tensor-product topology, is a formally projective (resp. strictly formally projective) topological A'-module.

Proof. (i) When $\mathfrak{J}$ (resp. V) ranges over the open ideals of A (resp. the open submodules of M), the separated completion $\widehat{\mathfrak{J}}$ (resp. $\widehat{V}$) ranges over the open ideals of $\widehat{A}$ (resp. the open submodules of $\widehat{M}$), and $\widehat{A}/\widehat{\mathfrak{J}} = A/\mathfrak{J}$ (resp. $\widehat{M}/\widehat{V} = M/V$), up to canonical isomorphism. Since formal projectivity (resp. strict formal projectivity) involves only the $A/\mathfrak{J}$ and the M/V, assertion (i) follows immediately.

(ii) Suppose first that M is formally projective and put $M' = M \otimes_A A'$. Let $\mathfrak{J}'$ be an open ideal of A', let P' and Q' be two discrete $(A'/\mathfrak{J}')$-modules, let $u' : P' \to Q'$ be a surjective A'-homomorphism, and let $v' : M' \to Q'$ be a continuous A'-homomorphism. There is an open ideal $\mathfrak{J}$ of A such that $\mathfrak{J}A' \subset \mathfrak{J}'$, so P' and Q' are also discrete $(A/\mathfrak{J})$-modules. Applying formal projectivity to the continuous composite $v : M \xrightarrow{j} M' \xrightarrow{v'} Q'$, one obtains a continuous A-homomorphism $w : M \to P'$ such that $v = u' \circ w$. Since P' is a topological A'-module, w factorizes as $M \xrightarrow{j} M' \xrightarrow{w'} P'$, where w' is a continuous A'-homomorphism; from $v' \circ j = (u' \circ w') \circ j$ one concludes that $v' = u' \circ w'$.

Now suppose that M is strictly formally projective. Let $(\mathfrak{J}_\lambda)$ (resp. (V_λ)) be a fundamental system of open ideals (resp. open submodules) in A (resp. M), with M/V_λ projective over $A/\mathfrak{J}_\lambda$, and let $(\mathfrak{J}'_\mu)$ be a fundamental system of open ideals in A'. A fundamental system of neighbourhoods of 0 in M' is formed by

$$W_{\lambda\mu} = \mathrm{Im}(M \otimes_A \mathfrak{J}'_\mu) + \mathrm{Im}(V_\lambda \otimes_A A'),$$

where λ and μ satisfy $\mathfrak{J}_\lambda A' \subset \mathfrak{J}'_\mu$. Since

$$(M \otimes_A A')/W_{\lambda\mu} = (M/V_\lambda) \otimes_{A/\mathfrak{J}_\lambda} (A'/\mathfrak{J}'_\mu)$$

and M/V_λ is projective over $A/\mathfrak{J}_\lambda$, the module $M'/W_{\lambda\mu}$ is projective over $A'/\mathfrak{J}'_\mu$. □

19.3 Formally smooth algebras

(19.3.1) Definition. Let A be a topological ring, B a topological A-algebra. We say that B is a *formally smooth* A-algebra if, for every discrete topological A-algebra C, and every nilpotent ideal $\mathfrak{J}$ of C, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ *factorizes* as $B \xrightarrow{v} C \xrightarrow{\varphi} C/\mathfrak{J}$, where v is a continuous A-homomorphism and φ the canonical homomorphism.

The definition (19.3.1) amounts to saying that the following property holds: [0IV-1 | 80]

(P) For every open ideal $\mathfrak{R}$ of the A-algebra B and every A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{J}$, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ of B such that the homomorphism $B \to B/\mathfrak{R} \xrightarrow{u'} C/\mathfrak{J}$ factorizes as

$$B \to B/\mathfrak{R}' \xrightarrow{v'} C \to C/\mathfrak{J},$$

where v' is an A-homomorphism.

Indeed, if $u : B \to C/\mathfrak{J}$ is a continuous A-homomorphism, its kernel $\mathfrak{R}$ is an open ideal of B, and if (P) is satisfied, it suffices to take u' and to take for v the composition $B \to B/\mathfrak{R} \xrightarrow{v'} C$ to satisfy the conditions of (19.3.1). Conversely, suppose B is a formally smooth A-algebra; let there be given an open ideal $\mathfrak{R}$ of B and a continuous A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{J}$; if $v : B \to C$ is a continuous A-homomorphism such

that u factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, the ideal $\mathfrak{R}' = \mathrm{Ker}(v) \cap \mathfrak{R}$ of B is open and contained in $\mathfrak{R}$; by taking v' to factorize as $B \to B/\mathfrak{R}' \xrightarrow{v'} C$, and v' clearly satisfies the condition (P).

(19.3.2) Proposition. *Let A be a discrete ring, V a projective A-module; the symmetric algebra $B = \mathrm{S}_A^\bullet(V)$, equipped with the discrete topology, is a formally smooth A-algebra.*

Proof. Indeed, the notations C and $\mathfrak{J}$ having the same meaning as in (19.3.1), let $u : B \to C/\mathfrak{J}$; as V is projective, u_1, the restriction of u to V, lifts to a homomorphism of A-modules $v_1 : V \to C$ such that u_1 factorizes as $V \xrightarrow{v_1} C \xrightarrow{\varphi} C/\mathfrak{J}$; and v_1 extends to a homomorphism of A-algebras $v : \mathrm{S}_A^\bullet(V) \to C$, and v coincides with u in V, hence $\varphi \circ v = u$, which proves the proposition. □

(19.3.3) Corollary. *If A is a discrete ring, every polynomial algebra $B = A[T_\alpha]_{\alpha \in I}$, equipped with the discrete topology, is a formally smooth A-algebra.*

(19.3.4) Proposition. *Let A be a topological ring, and let $B = A[[T_\alpha]]_{\alpha \in I}$ be a ring of formal power series $\sum c_\lambda T^\lambda$ (algebra large over A of the monoid $\mathbf{N}^{(I)}$, identified as a topological A-module with the product $A^{\mathbf{N}^{(I)}}$). If one equips B with the product topology, B is a formally smooth topological A-algebra.*

Let $(\mathfrak{L}_\mu)_{\mu \in M}$ be a fundamental system of open ideals of A. For every finite subset H of I, every $\mu \in M$, and every integer n, let $\mathfrak{K}_{H,\mu,n}$ be the neighbourhood of 0 in B consisting of the families (c_λ) such that $c_\lambda \in \mathfrak{L}_\mu$ whenever $\lambda = (\lambda_\alpha)_{\alpha \in I}$ satisfies $\lambda_\alpha = 0$ for $\alpha \notin H$ and $\sum_{\alpha \in H} \lambda_\alpha \leq n$. The $\mathfrak{K}_{H,\mu,n}$ plainly form a fundamental system of neighbourhoods of 0 in B and are ideals of B; hence the product topology is compatible with the A-algebra structure of B.

We first record the following lemma.

(19.3.4.1) Lemma. *Let E be a discrete A-algebra.*

(i) *If $f : B \to E$ is a continuous A-homomorphism, there exists a finite subset H of I such that $f(T_\alpha) = 0$ for $\alpha \notin H$, and $f(T_\alpha)$ is nilpotent in E for every $\alpha \in H$.*

(ii) *Conversely, let H be a finite subset of I and $(z_\alpha)_{\alpha \in H}$ a family of nilpotent elements of E. There exists a unique continuous A-homomorphism $g : B \to E$ such that $g(T_\alpha) = z_\alpha$ for $\alpha \in H$ and $g(T_\alpha) = 0$ for $\alpha \notin H$.*

Proof. Assertion (i) follows immediately from the fact that $f^{-1}(0)$ is a neighbourhood of 0 in the product A-module $A^{\mathbf{N}^{(I)}}$: thus $f(T^\lambda) = 0$ except for finitely many $\lambda \in \mathbf{N}^{(I)}$. [$0_{\text{IV-1}}$ | 81]

For (ii), the polynomial ring $B' = A[T_\alpha]_{\alpha \in I}$ is dense in B. Existence and uniqueness on B' are immediate. Continuity follows from nilpotence: if $z_\alpha^n = 0$ for all $\alpha \in H$, then $g(T^\lambda) = 0$ unless $\lambda_\alpha = 0$ for $\alpha \notin H$ and $\lambda_\alpha \leq n$ for $\alpha \in H$, and there are only finitely many such λ. □

Proof of Proposition (19.3.4). Let C and $\mathfrak{J}$ have the meaning of (19.3.1), and let $u : B \to C/\mathfrak{J}$ be a continuous A-homomorphism. By (19.3.4.1), $u(T_\alpha) = 0$ except for the indices in a finite subset H of I, and the elements $z_\alpha = u(T_\alpha)$, $\alpha \in H$, are nilpotent in $C/\mathfrak{J}$. Since $\mathfrak{J}$ is nilpotent, choose nilpotent elements $x_\alpha \in C$ lifting the z_α. The lemma gives a continuous A-homomorphism $v : B \to C$ such that $v(T_\alpha) = x_\alpha$ for $\alpha \in H$ and $v(T_\alpha) = 0$ otherwise. Then u is the composite $B \xrightarrow{v} C \to C/\mathfrak{J}$. □

(19.3.5) Proposition. *Let A be a topological ring.*

(i) A is a formally smooth A-algebra.

(ii) If B is a formally smooth A-algebra and C a formally smooth B-algebra, then C is a formally smooth A-algebra.

(iii) Let B be a formally smooth A-algebra, A' a topological A-algebra; then the topological A'-algebra $B \otimes_A A'$ ($\mathbf{0_I}$, 7.7.5 and 7.7.6) is formally smooth.

(iv) Let B be a topological A-algebra, S (resp. T) a multiplicative subset of A (resp. B) such that the canonical image of S in B is contained in T. If B is a formally smooth A-algebra, then $T^{-1}B$ is an $S^{-1}A$-algebra formally smooth.

(v) Let B_i ($1 \leq i \leq n$) be topological A-algebras. For $\prod_{i=1}^n B_i$ to be a formally smooth A-algebra, it is necessary and sufficient that each of the B_i be so.

Proof. (i) If C is a discrete A-algebra and $\varphi : C \to C/\mathfrak{J}$ is the canonical homomorphism onto any quotient A-algebra of C, the *only* A-homomorphism from A to $C/\mathfrak{J}$ is the composite $A \xrightarrow{\psi} C \xrightarrow{\varphi} C/\mathfrak{J}$, where ψ defines the A-algebra structure of C; since ψ is continuous, the condition of (19.3.1) is trivially satisfied. [$0_{\text{IV-1}}$ | 82]

(ii) Let $\alpha : A \to B$ and $\beta : B \to C$ be the continuous homomorphisms defining respectively the A-algebra structure on B and the B-algebra structure on C, so that $\beta \circ \alpha$ defines the A-algebra structure on C. Let E be a discrete A-algebra, $\mathfrak{L}$ a nilpotent ideal of E, and $u : C \to E/\mathfrak{L}$ a continuous A-homomorphism. Since B is a formally smooth A-algebra, $u \circ \beta : B \to E/\mathfrak{L}$ factorizes as $B \xrightarrow{v} E \to E/\mathfrak{L}$, where v is a continuous A-homomorphism. The homomorphisms v and $u \circ \beta$ then define on E and $E/\mathfrak{L}$ respectively topological B-algebra structures for which $E/\mathfrak{L}$ is still the discrete quotient algebra of E. Moreover, u is a continuous B-homomorphism, and hence factorizes as $C \xrightarrow{w} E \to E/\mathfrak{L}$, where w is a continuous B-homomorphism; since $w \circ \beta \circ \alpha$ is the homomorphism defining the A-algebra structure on E, w is indeed a continuous A-homomorphism.

(iii) Let C be a discrete topological A'-algebra, $\mathfrak{J}$ a nilpotent ideal of C, and $u : B \otimes_A A' \to C/\mathfrak{J}$ a continuous A'-homomorphism. Composing u with the canonical homomorphism $\rho : B \to B \otimes_A A'$ gives a continuous A-homomorphism, which by hypothesis factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$. If $\sigma : A' \to B \otimes_A A'$ and $w : A' \to C$ are the canonical homomorphisms, equality of the composites $A \to B \xrightarrow{v} C$ and $A \to A' \xrightarrow{w} C$ gives a continuous ring homomorphism $f : B \otimes_A A' \to C$ such that $v = f \circ \rho$ and $w = f \circ \sigma$ ($\mathbf{0_I}$, 7.7.6). Comparing the composites from B and A' shows that u factorizes as $B \otimes_A A' \xrightarrow{f} C \to C/\mathfrak{J}$, proving (iii).

(iv) The topology on $S^{-1}A$ (resp. $T^{-1}B$) has as a fundamental system of neighbourhoods of 0 the ideals $S^{-1}\mathfrak{J}$ (resp. $T^{-1}\mathfrak{R}$), where $\mathfrak{J}$ (resp. $\mathfrak{R}$) ranges over a fundamental system of open ideals of A (resp. B) ($\mathbf{0_I}$, 7.6.1). Let C be a discrete topological $S^{-1}A$-algebra, $\mathfrak{J}$ a nilpotent ideal of C, and $u : T^{-1}B \to C/\mathfrak{J}$ a continuous $S^{-1}A$-homomorphism. The composite $B \to T^{-1}B \xrightarrow{u} C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$. For every $t \in T$, $u(t/1)$ is invertible in $C/\mathfrak{J}$; since $\mathfrak{J}$ is nilpotent, $v(t)$ is invertible in C ($\mathbf{0_I}$, 7.1.12). Thus v factorizes through a continuous homomorphism $w : T^{-1}B \to C$ ($\mathbf{0_I}$, 7.6.6). The canonical diagrams show that w is an $S^{-1}A$-homomorphism and that u is the composite $T^{-1}B \xrightarrow{w} C \to C/\mathfrak{J}$.

(v) Necessity follows from (iv), since each B_i is the localization of $B = \prod_{i=1}^{n} B_i$ at its canonical idempotent. Conversely, let C be a discrete A-algebra, $\mathfrak{J}$ a nilpotent ideal of C, and $u : B \to C/\mathfrak{J}$ a continuous A-homomorphism. The images under u of the canonical idempotents of B form a finite family of pairwise orthogonal idempotents with sum 1; lift this family to pairwise orthogonal idempotents e_i of C with sum 1. Writing $C_i = e_i C$ and $\mathfrak{J}_i = e_i\mathfrak{J}$, the restriction of u to B_i is a continuous A-homomorphism $B_i \to C_i/\mathfrak{J}_i$. Formal smoothness of B_i lifts it to a continuous A-homomorphism $B_i \to C_i$. The product of these lifts is a continuous A-homomorphism $B \to C$ lifting u.

□

[$0_{\text{IV-1}}$ | 83] **(19.3.6) Proposition.** *Let A be a topological ring, B a topological A-algebra, $\widehat{A}$ and $\widehat{B}$ the separated completions of A and B, so that $\widehat{B}$ is a topological $\widehat{A}$-algebra. The following conditions are equivalent:*

a) B is a formally smooth A-algebra.

b) $\widehat{B}$ is a formally smooth A-algebra.

c) $\widehat{B}$ is a formally smooth $\widehat{A}$-algebra.

Proof. Of course, the structure of $\widehat{A}$-algebra on $\widehat{B}$ is defined by the homomorphism $\hat{\varphi}$, where $\varphi : A \to B$ is the homomorphism defining the structure of A-algebra on B. As every discrete A-algebra C is separated and complete, it is also a $\widehat{A}$-algebra (by canonical prolongation of the homomorphism from A to C), and a continuous A-homomorphism from B to C gives by extension a canonical $\widehat{A}$-homomorphism (and *a fortiori* an A-homomorphism) from $\widehat{B}$ to C (in other words, every continuous A-homomorphism $B \to C$ factorizes as $B \to \widehat{B} \to C$ uniquely). These remarks and the definition (19.3.1) immediately imply the proposition. □

(19.3.7) Corollary. *Under the hypotheses of (19.3.5), (iv), the topological $A\{S^{-1}\}$-algebra $B\{T^{-1}\}$ is formally smooth.*

This follows from the definitions (**0_{I}**, 7.6.1 and 7.6.7), (19.3.5), (iv), and (19.3.6).

(19.3.8) Proposition. *Let A be a topological ring, B a topological A-algebra, and suppose that for every open ideal $\mathfrak{R}$ of B, $\mathfrak{R}^2$ is also open. Let A', B' be the rings A and B equipped with topologies finer than the initial topologies, and suppose that the canonical homomorphism $\varphi : A \to B$ is still a continuous homomorphism from A' to B'. Then, if B' is a formally smooth A'-algebra, B is a formally smooth A-algebra.*

Proof. It suffices to apply the following lemma: □

(19.3.8.1) Lemma. *Let C be a discrete A-algebra, $\mathfrak{J}$ a nilpotent ideal of C. Suppose that the square of every open ideal of B is also open. Then, if a composite homomorphism $v : B \xrightarrow{u} C \to C/\mathfrak{J}$ is continuous, the homomorphism u is continuous.*

Proof. Indeed, $\mathfrak{R} = u^{-1}(\mathfrak{J})$ is the kernel of v, and it is open by hypothesis; as $\mathfrak{J}^n = 0$, $\mathfrak{R}^n$ is contained in $\mathrm{Ker}(u)$; but by induction on h, it follows from the hypothesis that $\mathfrak{R}^{2^h}$ is also open, hence $\mathfrak{R}^n$ for all n, and consequently $\mathrm{Ker}(u)$ is also open, which proves our assertion. □

Note that the hypothesis on B means that the topology of B is the supremum of the $\mathfrak{R}$-preadic topologies, where $\mathfrak{R}$ ranges over the open ideals of B. If B is a preadic ring (**0**$_{\mathbf{I}}$, 7.1.9), this condition is always satisfied.

(19.3.9) We will now see that the property of being formally smooth implies properties of "lifting" of homomorphisms under more general conditions than those of the definition (19.3.1).

(19.3.10) Proposition. *Let A be a topological ring, B a formally smooth topological A-algebra. Let C be a topological A-algebra, $\mathfrak{J}$ an ideal of C, satisfying the following conditions:* [$0_{\text{IV-1}}$ | 84]

1° *C is metrizable and complete.*

2° *$\mathfrak{J}$ is closed and the sequence $(\mathfrak{J}^n)$ tends to 0.*

Then, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

Proof. Let $(\mathfrak{Q}_n)$ be a decreasing sequence of ideals of C forming a fundamental system of neighbourhoods of 0 in this algebra; as there exists k such that $\mathfrak{J}^k \subset \mathfrak{Q}_n$, $(\mathfrak{J}+\mathfrak{Q}_n)/\mathfrak{Q}_n$ is nilpotent. For all n, let u_n be the continuous A-homomorphism $B \xrightarrow{u} C/\mathfrak{J} \to C/(\mathfrak{J} + \mathfrak{Q}_n) = (C/\mathfrak{Q}_n)/((\mathfrak{J} + \mathfrak{Q}_n)/\mathfrak{Q}_n)$; by hypothesis u_n factorizes as $B \xrightarrow{v_n} C/\mathfrak{Q}_n \xrightarrow{\varphi_n} C/(\mathfrak{J} + \mathfrak{Q}_n)$, where v_n is a continuous A-homomorphism. Let us show that one can choose step by step the v_n so that v_n factorizes as

$$B \xrightarrow{v_{n+1}} C/\mathfrak{Q}_{n+1} \to C/\mathfrak{Q}_n$$

for all n (in other words, the v_n form a *projective system* of homomorphisms). This will follow from the following lemma: □

(19.3.10.1) Lemma. *Let B be a formally smooth A-algebra, E, E' two discrete topological A-algebras, $\mathfrak{R}$ (resp. $\mathfrak{R}'$) a nilpotent ideal of E (resp. E'), $f : E \to E'$ a surjective A-homomorphism such that $f(\mathfrak{R}) \subset \mathfrak{R}'$, $f' : E/\mathfrak{R} \to E'/\mathfrak{R}'$ the homomorphism induced by f by passing to quotients. Let $u : B \to E/\mathfrak{R}$ be a continuous A-homomorphism, u' the composite homomorphism $B \xrightarrow{u} E/\mathfrak{R} \xrightarrow{f'} E'/\mathfrak{R}'$, and let $v' : B \to E'$ be a continuous A-homomorphism such that u' factorizes as $B \xrightarrow{v'} E' \to E'/\mathfrak{R}'$. Then there exists a continuous A-homomorphism $v : B \to E$ such that v' factorizes as $B \xrightarrow{v} E \xrightarrow{f} E'$.*

Proof. In the commutative diagram

$$\begin{array}{ccc} E & \xrightarrow{f} & E' \\ \downarrow & & \downarrow \\ E/\mathfrak{R} & \xrightarrow[f']{} & E'/\mathfrak{R}' \end{array}$$

all the homomorphisms are surjective. If $\mathfrak{L} = \mathrm{Ker}(f)$, then E' is identified with $E/\mathfrak{L}$ and $\mathfrak{R}'$ with $(\mathfrak{R} + \mathfrak{L})/\mathfrak{L}$. We shall use the following elementary lemma. □

(19.3.10.2) Lemma. *Let F be a ring, not necessarily commutative, and let $\mathfrak{a}$ and $\mathfrak{b}$ be two-sided ideals of F. Then the fibre product*

$$(F/\mathfrak{a}) \times_{F/(\mathfrak{a}+\mathfrak{b})} (F/\mathfrak{b})$$

is canonically identified with $F/(\mathfrak{a} \cap \mathfrak{b})$.

Proof. This is the special case of (18.1.7) obtained by replacing, in diagram (18.1.7.1), G by $F/(\mathfrak{a}\cap\mathfrak{b})$, $\mathfrak{J}'$ by $\mathfrak{b}/(\mathfrak{a}\cap\mathfrak{b})$, F by $F/\mathfrak{b}$, $\mathfrak{R}$ by $(\mathfrak{a}+\mathfrak{b})/\mathfrak{b}$, B by $F/(\mathfrak{a}+\mathfrak{b})$, and θ by the canonical isomorphism

$$(\mathfrak{a}+\mathfrak{b})/\mathfrak{b} \xrightarrow{\sim} \mathfrak{a}/(\mathfrak{a}\cap\mathfrak{b}).$$

□

Continuation of the proof of Lemma (19.3.10.2). By the commutativity of (19.3.10.1),

[$0_{\text{IV-1}}$ | 85]

$$\begin{array}{ccc} B & \xrightarrow{v'} & E' = E/\mathfrak{L} \\ {\scriptstyle u}\downarrow & & \downarrow \\ E/\mathfrak{R} & \xrightarrow[f']{} & E'/\mathfrak{R}' \end{array}$$

gives a homomorphism $w : B \to E/(\mathfrak{R}\cap\mathfrak{L})$ through which both v' and u factor. Its kernel contains $\mathrm{Ker}(u) \cap \mathrm{Ker}(v')$, and is therefore open; thus w is continuous. The ideal $\mathfrak{R}\cap\mathfrak{L}$ is nilpotent, so formal smoothness of B gives a continuous A-homomorphism $v : B \to E$ lifting w. It follows at once that $f \circ v = v'$, as required. □

Continuation of the proof of Proposition (19.3.10). Apply (19.3.10.1) with

$$E = C/\mathfrak{Q}_{n+1}, \quad E' = C/\mathfrak{Q}_n,$$

$$\mathfrak{R} = (\mathfrak{J}+\mathfrak{Q}_{n+1})/\mathfrak{Q}_{n+1}, \quad \mathfrak{R}' = (\mathfrak{J}+\mathfrak{Q}_n)/\mathfrak{Q}_n,$$

and with u, u', v' replaced respectively by u_{n+1}, u_n, v_n. It produces v_{n+1} compatible with v_n.

Since C is separated and complete, $C = \varprojlim C/\mathfrak{Q}_n$, and $v = \varprojlim v_n$ is a continuous A-homomorphism $B \to C$. Because $\mathfrak{J}$ is closed, $\mathfrak{J} = \bigcap_n(\mathfrak{J} + \overline{\mathfrak{Q}_n})$. Moreover, $C/\mathfrak{J}$ is metrizable and complete and the ideals $(\mathfrak{J}+\mathfrak{Q}_n)/\mathfrak{J}$ form a fundamental system of neighbourhoods of 0; hence

$$C/\mathfrak{J} = \varprojlim C/(\mathfrak{J}+\mathfrak{Q}_n).$$

Thus $\varprojlim \varphi_n$ is the canonical map $\varphi : C \to C/\mathfrak{J}$, while $\varprojlim u_n = u$. Consequently $u = \varphi \circ v$. □

(19.3.11) Corollary. *Let A be a topological ring, B a formally smooth topological A-algebra, C a Noetherian complete local ring, $\mathfrak{J}$ an ideal distinct from C, $\varphi : A \to C$ a continuous homomorphism making C a topological A-algebra. Then every continuous A-homomorphism $u_0 : B \to C_0 = C/\mathfrak{J}$ factorizes as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous A-homomorphism.*

Proof. All the conditions of (19.3.10) are indeed satisfied (**0$_{\text{I}}$**, 7.3.5). □

(19.3.12) Proposition. *Let A be a topological ring, B a formally smooth A-algebra, C a topological A-algebra, and $\mathfrak{J}$ an ideal of C, satisfying the following conditions:*

1° *There exists a fundamental system of open ideals $\mathfrak{Q}_\lambda$ of C, such that the $C_\lambda = C/\mathfrak{Q}_\lambda$ are Artinian rings and that $C \xrightarrow{\sim} \varprojlim C_\lambda$.*

2° *$\mathfrak{J}$ is closed in C and topologically nilpotent.*

3° *The square of every open ideal of B is open.*

Under these conditions, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

Proof. Let $\mathfrak{J}_\lambda = (\mathfrak{J} + \mathfrak{Q}_\lambda)/\mathfrak{Q}_\lambda$ be the canonical image of $\mathfrak{J}$ in C_λ, which is a nilpotent ideal, and let u_λ be the composite $B \xrightarrow{u} C/\mathfrak{J} \to C_\lambda/\mathfrak{J}_\lambda = C/(\mathfrak{J}+\mathfrak{Q}_\lambda)$. We first show that every A-homomorphism $w : B \to C$ through which u factorizes is necessarily continuous. For every λ, there is an open ideal $\mathfrak{R}$ of B such that $u(\mathfrak{R}) \subset (\mathfrak{J} + \mathfrak{Q}_\lambda)/\mathfrak{J}$, and hence $w(\mathfrak{R}) \subset \mathfrak{J} + \mathfrak{Q}_\lambda$. There is therefore a power $\mathfrak{R}^{2^m}$ such that $w(\mathfrak{R}^{2^m}) \subset \mathfrak{Q}_\lambda$; this proves the assertion, since $\mathfrak{R}^{2^m}$ is open in B. It is thus enough to find an A-homomorphism w with the preceding property without separately requiring continuity.

Now

$$\mathrm{Hom}_A(B, C) = \varprojlim_\lambda \mathrm{Hom}_A(B, C_\lambda).$$

For each λ, $\mathrm{Hom}_A(B, C_\lambda)$ is closed in the C_λ-module C_λ^B with its product topology, for which it is linearly compact because C_λ is Artinian. For each λ, let W_λ be the set of $w_\lambda \in \mathrm{Hom}_A(B, C_\lambda)$ such that u_λ factorizes as $B \xrightarrow{w_\lambda} C_\lambda \to C_\lambda/\mathfrak{J}_\lambda$. The set W_λ is a closed affine subspace of the C_λ-module $\mathrm{Hom}_A(B, C_\lambda)$ and is nonempty because B is formally smooth. In $E_\lambda = \prod_{\mu\leq\lambda} \mathrm{Hom}_A(B, C_\mu)$, let U_λ be the closed affine subspace of the families $(w_\mu)_{\mu\leq\lambda}$ such that $w_\mu = \varphi_{\mu\lambda} \circ w_\lambda$ for $\mu \leq \lambda$ and $w_\lambda \in W_\lambda$, where $\varphi_{\mu\lambda} : C_\lambda \to C_\mu$ is the canonical homomorphism. Finally let V_λ be the closed affine subspace in $\prod_\mu \mathrm{Hom}_A(B, C_\mu)$ equal to the product of U_λ and the $\mathrm{Hom}_A(B, C_\mu)$ for $\mu \not\leq \lambda$. It remains to observe that the intersection of the V_λ is nonempty, for an element w of this intersection belongs by definition to $\varprojlim_\lambda \mathrm{Hom}_A(B, C_\lambda)$. [21] [$0_{\text{IV-1}}$ | 86]

Moreover, since $\mathfrak{J}$ is closed and $C = \varprojlim_\lambda C_\lambda$ is linearly compact, $C/\mathfrak{J}$ identifies with $\varprojlim_\lambda C_\lambda/\mathfrak{J}_\lambda$, and the canonical map $\psi : C \to C/\mathfrak{J}$ with $\varprojlim_\lambda \psi_\lambda$, where $\psi_\lambda : C_\lambda \to C_\lambda/\mathfrak{J}_\lambda$ is canonical. As in (19.3.10), we conclude that $\psi \circ w = u$. □

19.4 First criteria for formal smoothness

(19.4.1) Proposition. *Let A be a topological ring, B a topological A-algebra; suppose that there exist two decreasing filtering families $(\mathfrak{J}_\alpha)_{\alpha\in I}$, $(\mathfrak{R}_\alpha)_{\alpha\in I}$ of ideals of A and B respectively, such that:*

1° *$(\mathfrak{J}_\alpha)$ tends to 0 in A and $(\mathfrak{R}_\alpha)$ tends to 0 in B;*

2° *for all $\alpha \in I$, we have $\mathfrak{J}_\alpha B \subset \mathfrak{R}_\alpha$ (so that $B/\mathfrak{R}_\alpha$ is an $(A/\mathfrak{J}_\alpha)$-topological algebra);*

3° *for all $\alpha \in I$, $B/\mathfrak{R}_\alpha$ is a formally smooth $(A/\mathfrak{J}_\alpha)$-algebra.*

Then B is a formally smooth A-algebra.

[21] The printed proof has a gap here: sets of algebra homomorphisms are not modules under pointwise addition, and for a general nilpotent ideal the lift fibre need not be an affine subspace. Thus the stated linear-compactness argument does not by itself prove that this intersection is nonempty; a separate compatible-lifting argument is required.

Proof. Let C be a discrete A-algebra, $\mathfrak{L}$ a nilpotent ideal of C, and $\mathfrak{R}$ an open ideal of B; by hypothesis there exists $\alpha \in I$ such that $\mathfrak{R}_\alpha \subset \mathfrak{R}$, so $B/\mathfrak{R}$ is a quotient of $B/\mathfrak{R}_\alpha$. Every A-homomorphism $u' : B/\mathfrak{R} \to C/\mathfrak{L}$ is also an $(A/\mathfrak{J}_\alpha)$-homomorphism, so there exists an open ideal $\mathfrak{R}'$ of B such that $\mathfrak{R}_\alpha \subset \mathfrak{R}' \subset \mathfrak{R}$ and the composite $B/\mathfrak{R}_\alpha \to B/\mathfrak{R} \xrightarrow{u'} C/\mathfrak{L}$ factorizes as $B/\mathfrak{R}_\alpha \to B/\mathfrak{R}' \to C \to C/\mathfrak{L}$, where the second homomorphism is an $(A/\mathfrak{J}_\alpha)$-homomorphism. The conclusion follows from the remark after (19.3.1). □

(19.4.2) Corollary. *Let A be a topological ring, B a topological A-algebra, $(\mathfrak{J}_\alpha)_{\alpha\in I}$ a decreasing filtering family of ideals of A tending to 0. For B to be a formally smooth A-algebra, it is necessary and sufficient that for all $\alpha \in I$, setting $A_\alpha = A/\mathfrak{J}_\alpha$, $B_\alpha = B/\mathfrak{J}_\alpha B$, B_α be a formally smooth A_α-algebra.*

Proof. The condition is sufficient by (19.4.1), and it is also necessary by (19.3.5), (iii). □

(19.4.3) Proposition. *Let A be a topological ring, B a topological A-algebra. Suppose that for every discrete A-algebra C and every ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, every continuous A-homomorphism $u : B \to C/\mathfrak{J}$ factorizes as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism. Then B is a formally smooth A-algebra.*

Proof. With the same notation, let $\mathfrak{R}$ be any nilpotent ideal of C, and consider a continuous A-homomorphism $u' : B \to C/\mathfrak{R}$. Suppose $\mathfrak{R}^m = 0$, and set $C_i = C/\mathfrak{R}^i$ for $1 \leq i \leq m$, so that $C_m = C$, that $\mathfrak{R}^{i-1}/\mathfrak{R}^i$ is an ideal of square zero in C_i, and $C_i = C_{i+1}/\mathfrak{J}_{i+1}$; the hypothesis then gives by induction on i the existence of continuous A-homomorphisms $u_i : B \to C_i$ such that $u_1 = u'$ and that u_i factorizes as $B \xrightarrow{u_{i+1}} C_{i+1} \to C_{i+1}/\mathfrak{J}_{i+1} = C_i$; whence the conclusion. □

(19.4.4) Proposition. *Let A be a topological ring, B a topological A-algebra (commutative). For B to be a formally smooth A-algebra, it is necessary and sufficient that* [$0_{IV\text{-}1}$ / 87] *for every discrete topological B-module L, annihilated by an open ideal of B, we have (cf. (18.5.1))*

$$\mathrm{Exalcotop}_A(B, L) = 0.$$

Proof. Let $(\mathfrak{R}_\lambda)$ be a fundamental decreasing system of open ideals of B and set $B_\lambda = B/\mathfrak{R}_\lambda$. Consider a discrete topological A-algebra C and an ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, so that C is an A-extension of $C/\mathfrak{J}$ by $\mathfrak{J}$; suppose given an A-homomorphism $u : B_\lambda \to C/\mathfrak{J}$ and form the A-extension E_λ of B_λ by $\mathfrak{J}$, inverse image of C by the homomorphism u (18.2.5); it is a topological A-algebra for the discrete topology. If $\mathrm{Exalcotop}_A(B, \mathfrak{J}) = 0$, there exists by definition (18.5.1) a μ such that $\mathfrak{R}_\mu \subset \mathfrak{R}_\lambda$ and the inverse image extension E_μ is A-trivial; but this means (18.1.6) that there exists a continuous A-homomorphism $v : B_\mu \to E_\lambda$ such that the canonical homomorphism $B_\mu \to B_\lambda$ factorizes as $B_\mu \xrightarrow{v} E_\lambda \to B_\lambda$; we conclude immediately that $B_\mu \to B_\lambda \xrightarrow{u} C/\mathfrak{J}$ factorizes as $B_\mu \xrightarrow{v} E_\lambda \to C \to C/\mathfrak{J}$, and this proves, by virtue of (19.3.1) and (19.4.3), that B is a formally smooth A-algebra. The converse is immediate, applying (19.3.1) to the case where C is a topological A-algebra which is an A-extension of B_λ by L, and to the identical homomorphism $B_\lambda \to B_\lambda = C/L$. □

When A and B are discrete rings, the criterion of formal smoothness (19.4.4) reduces to

$$\mathrm{Exalcom}_A(B, L) = 0 \qquad \text{for all } B\text{-modules } L; \tag{19.4.4.1}$$

in other words, *every commutative A-extension of B by a B-module must be A-trivial.*

(19.4.5) Corollary. *Let A be a topological ring (commutative), B a topological A-algebra (commutative).*

(i) *Suppose that B is a formally smooth A-algebra. Then, for every open ideal $\mathfrak{R}$ of B, every $(B/\mathfrak{R})$-module L, and every Hochschild A-bilinear symmetric 2-cocycle f of $(B/\mathfrak{R}) \times (B/\mathfrak{R})$ in L (18.4.3), there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ such that, if $\varphi : B/\mathfrak{R}' \to B/\mathfrak{R}$ is the canonical homomorphism, $f \circ (\varphi \times \varphi)$ is a Hochschild A-bilinear 2-coboundary of $(B/\mathfrak{R}') \times (B/\mathfrak{R}')$ in L.*

(ii) *If B is a formally projective A-module (19.2.1) and if the condition of* (i) *is satisfied, B is a formally smooth A-algebra.*

Proof. (i) The 2-cocycle f defines an A-extension of Hochschild C of $B/\mathfrak{R}$ by L (18.4.3). Applying (19.3.1) to C, to the ideal of square zero L of C, and to the identical homomorphism $B/\mathfrak{R} \to B/\mathfrak{R} = C/L$, we deduce the condition (i) by virtue of (18.4.3).

(ii) Let us apply the criterion (19.4.3), considering an open ideal $\mathfrak{J}$ of A, an open ideal $\mathfrak{R}$ of B such that $\mathfrak{J}B \subset \mathfrak{R}$, and an $(A/\mathfrak{J})$-extension E of $B/\mathfrak{R}$ by L. As B is a formally projective A-module, the canonical continuous A-linear map $\rho : B \to B/\mathfrak{R}$ factorizes as $B \xrightarrow{w} E \to B/\mathfrak{R}$, where w is a continuous A-linear map (19.2.1), which itself factorizes as $B \to B/\mathfrak{R}' \xrightarrow{w'} E$ where $\mathfrak{R}'$ is an open ideal of B contained in $\mathfrak{R}$; replacing $\mathfrak{J}$ by a smaller ideal, one can suppose that $\mathfrak{J}B \subset \mathfrak{R}'$. Then the inverse image of the extension E of $B/\mathfrak{R}$ by L, via the canonical homomorphism $B/\mathfrak{R}' \to B/\mathfrak{R}$, is an $(A/\mathfrak{J})$-extension *of Hochschild* E' of $B/\mathfrak{R}'$ by L; applying (i) [$0_{\text{IV-1}}$ | 88] to a cocycle defining this extension (18.4.3), we conclude that there exists an open ideal $\mathfrak{R}'' \subset \mathfrak{R}'$ of B such that the inverse image E'' of E by $B/\mathfrak{R}'' \to B/\mathfrak{R}$ is A-trivial, Q.E.D.

□

(19.4.6) Corollary. *Let A be a topological ring, B a topological A-algebra which is a formally projective A-module. Let A' be an A-algebra equipped with the topology derived from that of A. Suppose furthermore that A' is a faithfully flat A-module, and that one of the following conditions is satisfied:*

1° *There exists a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals of A and a fundamental system $(\mathfrak{M}_\lambda)$ of open ideals of B, with the same index set, such that for all λ we have $\mathfrak{J}_\lambda B \subset \mathfrak{M}_\lambda$ and $B/\mathfrak{M}_\lambda$ is a projective $(A/\mathfrak{J}_\lambda)$-module of finite type.*

2° *A' is a projective A-module of finite type.*

Then, for $B' = B \otimes_A A'$ (equipped with the tensor product topology) to be a formally smooth A'-algebra, it is necessary and sufficient that B be a formally smooth A-algebra.

Proof. The sufficiency of the condition is contained in (19.3.5), (iii), without any additional hypothesis on B or A'. To prove the converse, we apply the criterion (19.4.5); under hypothesis 2°, we will again denote by $(\mathfrak{M}_\lambda)$ a fundamental system of open ideals of B, and for each λ, by $\mathfrak{J}_\lambda$ an open ideal of A such that $\mathfrak{J}_\lambda B \subset \mathfrak{M}_\lambda$; in both cases, we set $A_\lambda = A/\mathfrak{J}_\lambda$, $B_\lambda = B/\mathfrak{M}_\lambda$, $A'_\lambda = A_\lambda \otimes_A A'$, $B'_\lambda = B_\lambda \otimes_A A'$. Let f be a Hochschild A_λ-bilinear symmetric 2-cocycle of $B_\lambda \times B_\lambda$ in a B_λ-module L; by extension of scalars, we deduce a Hochschild A'_λ-bilinear symmetric 2-cocycle $f' = f \otimes 1$ of $B'_\lambda \times B'_\lambda$ in $L' = L \otimes_A A'$. As B' is by hypothesis a formally smooth A'-algebra, there exists by (19.4.5), (i), a μ such that $\mathfrak{M}_\mu \subset \mathfrak{M}_\lambda$ and such that, if $\varphi' : B'_\mu \to B'_\lambda$ is the canonical homomorphism, the image c' of $f' \circ (\varphi' \times \varphi')$ in the Hochschild group $\mathrm{H}^2_{A'_\mu}(B'_\mu, L')^s$ is zero; it is clear that if $\varphi : B_\mu \to B_\lambda$ is the canonical homomorphism, and c the class of $f \circ (\varphi \times \varphi)$ in the group $\mathrm{H}^2_{A_\mu}(B_\mu, L)^s$, then c' is the canonical image of c. Now, if $\mathrm{P}_\bullet$ is the complex relative to the rings A_μ and B_μ defined in (18.4.5), the analogous complex relative to the rings A'_μ and B'_μ is evidently $\mathrm{P}_\bullet \otimes_A A'$; under hypothesis 1°, the construction of $\mathrm{P}_\bullet$ shows that it is a projective A_μ-module of finite type. One concludes from Bourbaki, *Alg.*, chap. II, 3e éd., § 5, n° 3, prop. 7 that, under both hypotheses, one has, up to canonical isomorphism,

$$\mathrm{Hom}_{A'_\mu}(\mathrm{P}_\bullet \otimes_A A', L \otimes_A A') = \mathrm{Hom}_{A_\mu}(\mathrm{P}_\bullet, L) \otimes_A A'.$$

As A' is a flat A-module, one has by (18.4.5)

$$\mathrm{H}^2_{A'_\mu}(B'_\mu, L')^s = (\mathrm{H}^2_{A_\mu}(B_\mu, L)^s) \otimes_A A'$$

and one can therefore write $c' = c \otimes 1$; but as A' is a faithfully flat A-module, the hypothesis $c' = 0$ implies $c = 0$, which completes the proof. □

(19.4.7) Proposition. *Let A be a preadmissible topological ring, $\mathfrak{J}$ an ideal of definition of A (**0**$_\mathrm{I}$, 7.1.2), B a topological A-algebra which is a formally projective A-module. Consider the topological quotient rings $A_0 = A/\mathfrak{J}$, $B_0 = B/\mathfrak{J}B$; then, for B to be a formally smooth A-algebra, it is necessary and sufficient that B_0 be a formally smooth A_0-algebra.*

Proof. The necessity of the condition follows from (19.4.2). To see that it is sufficient, we first [0IV-1 | 89] note that, by considering a fundamental system of open neighbourhoods of 0 in A formed by ideals $\mathfrak{J}_\lambda$ contained in $\mathfrak{J}$, one can by virtue of (19.4.2) reduce to the case where A is discrete, since $B/\mathfrak{J}_\lambda B$ is a formally projective $(A/\mathfrak{J}_\lambda)$-module (19.2.5); by definition of a preadmissible ring, $\mathfrak{J}$ is then nilpotent. It furthermore suffices to prove the proposition when $\mathfrak{J}^2 = 0$, for if $\mathfrak{J}^m = 0$, one applies it successively to the rings $A_k = A/\mathfrak{J}^k$ and $B_k = B/\mathfrak{J}^k B$ and to the ideal $\mathfrak{J}^{k-1}/\mathfrak{J}^k$ of A_k for $k = 2, 3, \ldots, m$, noting (19.2.5) that $B_k = B \otimes_A A_k$ is a formally projective A_k-module. Let us apply the criterion (19.4.5), (ii), considering an open ideal $\mathfrak{R}$ of B and a Hochschild A-bilinear symmetric 2-cocycle f of $(B/\mathfrak{R}) \times (B/\mathfrak{R})$ in a $(B/\mathfrak{R})$-module L. Consider first the special case where $\mathfrak{J}L = 0$, so that L can also be viewed as a $(B_0/\mathfrak{R}B_0)$-module, and f factorizes as

$$(B/\mathfrak{R}) \times (B/\mathfrak{R}) \to (B_0/\mathfrak{R}B_0) \times (B_0/\mathfrak{R}B_0) \xrightarrow{f_0} L$$

where f_0 is a Hochschild bilinear symmetric 2-cocycle. By hypothesis, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ in B and an A_0-linear map $g_0 : B_0/\mathfrak{R}'B_0 \to L$ such that $f_0(\varphi_0(x), \varphi_0(y)) = xg_0(y) - g_0(xy) + g_0(x)y$ for x, y in $B_0/\mathfrak{R}'B_0$, where $\varphi_0 : B_0/\mathfrak{R}'B_0 \to B_0/\mathfrak{R}B_0$ is the canonical homomorphism. One concludes immediately that the composite A-linear map

$g : B/\mathfrak{R}' \to B_0/\mathfrak{R}'B_0 \xrightarrow{g_0} L$ is such that $dg = f \circ (\varphi \times \varphi)$, where $\varphi : B/\mathfrak{R}' \to B/\mathfrak{R}$ is the canonical homomorphism.

Let us now pass to the general case, and consider first the $(B/\mathfrak{R})$-module $L/\mathfrak{J}L = L'$, for which $\mathfrak{J}L' = 0$; if f' is the composite A-bilinear map $(B/\mathfrak{R}) \times (B/\mathfrak{R}) \xrightarrow{f} L \to L'$, f' is again a symmetric Hochschild 2-cocycle, and by the preceding, there exists an open ideal $\mathfrak{R}' \subset \mathfrak{R}$ in B and an A-linear map $g' : B/\mathfrak{R}' \to L'$ satisfying $dg' = f' \circ (\varphi' \times \varphi')$ for the canonical map $\varphi' : B/\mathfrak{R}' \to B/\mathfrak{R}$. As B is a formally projective A-module, there exists an open ideal $\mathfrak{R}'_1 \subset \mathfrak{R}'$ and an A-linear map $g_1 : B/\mathfrak{R}'_1 \to L$ lifting $B/\mathfrak{R}'_1 \to B/\mathfrak{R}' \xrightarrow{g'} L'$. Let $\varphi_1 : B/\mathfrak{R}'_1 \to B/\mathfrak{R}$ be the canonical homomorphism. Consider then the Hochschild 2-cocycle

$$f_1(x, y) = f(\varphi_1(x), \varphi_1(y)) - xg_1(y) + g_1(xy) - g_1(x)y,$$

a symmetric A-bilinear map of $(B/\mathfrak{R}'_1) \times (B/\mathfrak{R}'_1)$ in L. The choice of g_1 implies that f_1 takes its values in $\mathfrak{J}L$. As $\mathfrak{J}(\mathfrak{J}L) = 0$, one can again apply the first case, so there exists an open ideal $\mathfrak{R}'' \subset \mathfrak{R}'_1$ and an A-linear map $g_2 : B/\mathfrak{R}'' \to \mathfrak{J}L$ such that

$$f_1(\varphi_2(x), \varphi_2(y)) = xg_2(y) - g_2(xy) + g_2(x)y$$

in $(B/\mathfrak{R}'') \times (B/\mathfrak{R}'')$, where $\varphi_2 : B/\mathfrak{R}'' \to B/\mathfrak{R}'_1$ is the canonical map; the A-linear map $g = g_2 + g_1 \circ \varphi_2 : B/\mathfrak{R}'' \to L$ therefore satisfies $dg = f \circ (\varphi \times \varphi)$ for the canonical map $\varphi : B/\mathfrak{R}'' \to B/\mathfrak{R}$. □

19.5 Formal smoothness and associated graded rings

(19.5.1) Let C be a topological ring (commutative), V a topological C-module, and consider the symmetric algebra $\mathbf{S}^*_C(V) = \bigoplus_{n\geq 0} \mathbf{S}^n_C(V)$, which we will canonically equip with a *linear topology*, compatible with its C-algebra structure. For this, consider an open submodule U of V, and the *graded ideal* $U.\mathbf{S}^*_C(V)$ it generates in $\mathbf{S}^*_C(V)$; we take as fundamental system of neighbourhoods of 0 in $\mathbf{S}^*_C(V)$ the set of sums $\mathfrak{a}.\mathbf{S}^*_C(V)+U.\mathbf{S}^*_C(V)$, where $\mathfrak{a}$ (resp. U) runs through a fundamental system of open ideals (resp. of open submodules) of C (resp. V). We note that if the topology of V is less fine than the topology derived from that of C, one can restrict to pairs $(\mathfrak{a}, U)$ such that $\mathfrak{a}V \subset U$, so $\mathfrak{a}.\mathbf{S}^*_C(V) + U.\mathbf{S}^*_C(V) = \mathfrak{a}.1_C + U.\mathbf{S}^*_C(V)$; in this case the topology induced on each $\mathbf{S}^n_C(V)$ for $n \geq 1$ has as a fundamental system of neighbourhoods of 0 the $U.\mathbf{S}^{n-1}_C(V)$, where U runs through the open submodules of V; in particular, on $V = \mathbf{S}^1_C(V)$, it coincides with the given topology (in general it is less fine than the latter). Furthermore, in all cases, the *topological algebra* $\mathbf{S}^*_C(V)$ thus defined is, for the categories of topological C-modules and of topological C-algebras, the solution of the same universal problem as for the categories of C-modules and C-algebras. Indeed, let E be a topological C-algebra, $u : V \to E$ a homomorphism of C-modules, $\mathbf{S}(u) = \widetilde{u}$ its canonical extension to $\mathbf{S}^*_C(V)$. Suppose u continuous; then, if $\mathfrak{b}$ is an open ideal of E, its inverse image $U = u^{-1}(\mathfrak{b})$ is an open C-submodule of V, and the image by $\widetilde{u}$ of $U.\mathbf{S}^*_C(V)$ is therefore contained in $\mathfrak{b}$; as moreover there exists an open ideal $\mathfrak{a}$ of C such that $\mathfrak{a}.E \subset \mathfrak{b}$, hence $\widetilde{u}(\mathfrak{a}.\mathbf{S}^*_C(V)) \subset \mathfrak{b}$, this proves that $\widetilde{u}$ is continuous. Conversely, if $\widetilde{u}$ is continuous, and if $\mathfrak{b}$ is an open ideal of E, there exists an open submodule U of V such that $\widetilde{u}(U.\mathbf{S}^*_C(V)) \subset \mathfrak{b}$, and in particular $\widetilde{u}(U.1_C) \subset \mathfrak{b}$, that is $u(U) \subset \mathfrak{b}$, so u is continuous. We also recall that one has a canonical isomorphism of topological C-modules (discrete) [0IV-1 | 90]

$$\mathbf{S}^n_C(V)/U.\mathbf{S}^{n-1}_C(V) \xrightarrow{\sim} \mathbf{S}^n_C(V/U). \tag{19.5.1.1}$$

(19.5.2) Let A be a topological ring, B a topological A-algebra (commutative), $\mathfrak{J}$ an ideal of B (not necessarily open or closed); in all that follows, we equip $\mathfrak{J}$ and the $\mathfrak{J}^n$ ($n \geq 2$) with the topology induced from that of B, the quotients $C = B/\mathfrak{J}$, $\mathfrak{J}^n/\mathfrak{J}^{n+1} = \mathrm{gr}^n_{\mathfrak{J}}(B)$ with the quotient topology, so that the $\mathfrak{J}^n/\mathfrak{J}^{n+1}$ are topological C-modules; the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to \mathrm{gr}^*_{\mathfrak{J}}(B)$ extends to a homomorphism (not topological at first) of C-algebras

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}^*_{\mathfrak{J}}(B)$$

which for each n gives a surjective homomorphism of C-modules

$$\varphi_n : \mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathfrak{J}^n/\mathfrak{J}^{n+1} = \mathrm{gr}^n_{\mathfrak{J}}(B). \tag{19.5.2.1}$$

[$0_{\text{IV-1}}$ | 91] When $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ is equipped with the topology defined in (19.5.1), the homomorphisms φ_n are continuous, by virtue of the universal property (19.5.1) of $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ applied to the topological algebra $E = \mathrm{gr}_{\mathfrak{J}/\mathfrak{J}^{n+1}}(B/\mathfrak{J}^{n+1})$ equipped with the product topology of those of the $\mathfrak{J}^k/\mathfrak{J}^{k+1}$, and to the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to E$. Note that here the topology of $\mathfrak{J}/\mathfrak{J}^2$ is less fine than that of C (this latter topology on $\mathfrak{J}/\mathfrak{J}^2$ being also the topology derived from that of B).

(19.5.3) Theorem. *Let A be a topological ring, B a topological A-algebra, $\mathfrak{J}$ an ideal of B, $C = B/\mathfrak{J}$ the topological quotient A-algebra. Suppose that the discrete A-algebra C is formally smooth. Then:*

(i) *If B is a formally smooth A-algebra, $\mathfrak{J}/\mathfrak{J}^2$ is a topologically formally projective C-module (19.2.1).*

(ii) *If B is a formally smooth A-algebra and a preadmissible ring (**0_{I}**, 7.1.2), the homomorphisms φ_n (19.5.2) are formal bimorphisms (19.1.2).*

(iii) *Conversely, suppose that B is preadmissible, that the sequence $(\mathfrak{J}^n)$ tends to 0 in B, that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module, and that the φ_n are formal bimorphisms. Then B is a formally smooth A-algebra.*

The proof of this theorem is long and encumbered with technical details; we will therefore begin by proving a simpler corollary, where the guiding ideas appear more clearly; this corollary is moreover the particular case of the theorem (19.5.3) that will be most frequently used in the sequel.

(19.5.4) Corollary. *Let A be a topological ring, B a topological A-algebra, $\mathfrak{J}$ an ideal of B such that the topology of B is the $\mathfrak{J}$-preadic topology. Suppose that the discrete A-algebra $C = B/\mathfrak{J}$ is formally smooth. Then the three following conditions are equivalent:*

a) B is a formally smooth A-algebra.

b) $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module and the canonical homomorphism

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}_{\mathfrak{J}}(B)$$

is bijective.

c) The separated completion $\widehat{B}$ of B is a topological $\widehat{A}$-algebra isomorphic to an $\widehat{A}$-algebra of the form $\widehat{B'}$, where $B' = \mathbf{S}^*_C(V)$, V being a projective C-module and B' being equipped with the B'^+-preadic topology, where B'^+ is the ideal of augmentation.

(19.5.4.1) Let us first prove that *a*) implies that $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module. Let P and Q be two C-modules, $u : P \to Q$ a surjective C-homomorphism, and $v : \mathfrak{J}/\mathfrak{J}^2 \to Q$ a C-homomorphism. The ring $B/\mathfrak{J}^2$ being viewed as a B-extension of C by $\mathfrak{J}/\mathfrak{J}^2$, we deduce from v a B-extension $E = (B/\mathfrak{J}^2) \oplus_{(\mathfrak{J}/\mathfrak{J}^2)} Q$ of C by Q (18.2.8). As C is a discrete formally smooth A-algebra, the extension E is A-trivial (19.4.4) and can therefore be identified with $\mathrm{D}_C(Q)$ (18.2.3). The surjective homomorphism $u : P \to Q$ then canonically defines a surjective A-homomorphism $\psi : \mathrm{D}_C(P) \to \mathrm{D}_C(Q)$ (18.2.9) whose kernel is an ideal $\mathfrak{L}$ of the extension $E' = \mathrm{D}_C(P)$, contained in P, and *a fortiori* of square zero. Let $f : B \to E = E'/\mathfrak{L}$ be the homomorphism defining the B-algebra structure of E: as $\mathfrak{L}$ is of square zero and B is a formally smooth A-algebra, f factorizes as $B \xrightarrow{g} E' \to E'/\mathfrak{L}$, [$0_{\text{IV-1}}$ | 92] where g is a continuous A-homomorphism. The diagram

$$\begin{array}{ccc} E' & \xrightarrow{\psi} & E \\ {\scriptstyle g}\uparrow & & \uparrow{\scriptstyle v'} \\ B & \xrightarrow[\theta]{} & B/\mathfrak{J}^2 \end{array}$$

where v' is deduced from v (18.2.8), is commutative. Moreover, the image of $\mathfrak{J}$ by $\psi \circ g$ is contained in Q, so the image of $\mathfrak{J}$ by g is contained in P, and the image of $\mathfrak{J}^2$ by g is zero. Restricting g and θ to $\mathfrak{J}$, one obtains a commutative diagram

$$\begin{array}{ccc} P & \xrightarrow{u} & Q \\ {\scriptstyle w}\uparrow & \nearrow_{v} & \\ \mathfrak{J}/\mathfrak{J}^2 & & \end{array}$$

which proves that the C-module $\mathfrak{J}/\mathfrak{J}^2$ is projective.

(19.5.4.2) Let us prove secondly that *a*) implies that φ is bijective, which will complete the proof that *a*) implies *b*). Set $E_n = B/\mathfrak{J}^{n+1}$, and denote by F_n the quotient of $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ by the $(n+1)$-th power of its ideal of augmentation. As $\mathfrak{J}/\mathfrak{J}^{n+1}$ is nilpotent in E_n and C is a discrete formally smooth A-algebra, the identity automorphism of C factorizes as $C \xrightarrow{f} E_n \to C = E_n/(\mathfrak{J}/\mathfrak{J}^{n+1})$ where f is an A-homomorphism; moreover, $\mathfrak{J}/\mathfrak{J}^2$ being a projective C-module, the identity of $\mathfrak{J}/\mathfrak{J}^2$ factorizes as $\mathfrak{J}/\mathfrak{J}^2 \xrightarrow{g} \mathfrak{J}/\mathfrak{J}^{n+1} \to \mathfrak{J}/\mathfrak{J}^2$, and from f and g one obtains canonically a homomorphism of C-algebras $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to E_n$ which annihilates on the $(n+1)$-th power of the ideal of augmentation, whence, passing to the quotient, a surjective homomorphism of algebras $v : F_n \to E_n$ such that $\mathrm{gr}^0(v)$ and $\mathrm{gr}^1(v)$ are the identity automorphisms of C and of $\mathfrak{J}/\mathfrak{J}^2$. By definition of the canonical homomorphism φ, we see that $\mathrm{gr}^j(v) = \varphi_j$ for all $j \leq n$. Note now that the kernel $\mathfrak{R}$ is a nilpotent ideal of F_n, so that E_n is identified with $F_n/\mathfrak{R}$. As B is a formally smooth A-algebra, the canonical A-homomorphism $p_n : B \to E_n = B/\mathfrak{J}^{n+1}$, which is continuous, factorizes as $B \xrightarrow{w} F_n \xrightarrow{v} E_n$, where w is a continuous A-homomorphism; as $\mathrm{gr}^0(v)$ is the identity, $w(\mathfrak{J})$ is contained in the ideal of augmentation of F_n, hence $w(\mathfrak{J}^{n+1}) = 0$, so w factorizes as $B \xrightarrow{p_n} E_n \xrightarrow{w'} F_n$, and the composite $E_n \xrightarrow{w'} F_n \xrightarrow{v} E_n$ is the identity. Moreover, since $\mathrm{gr}^0(v)$ and $\mathrm{gr}^1(v)$ are the identity automorphisms of C and $\mathfrak{J}/\mathfrak{J}^2$, the same is true of $\mathrm{gr}^0(w')$ and $\mathrm{gr}^1(w')$. Since $\mathrm{gr}^*(E_n)$ is generated by $\mathrm{gr}^1(E_n)$, the composite

$$\mathrm{gr}^j(F_n) \xrightarrow{\varphi_j} \mathrm{gr}^j(E_n) \xrightarrow{\mathrm{gr}^j(w')} \mathrm{gr}^j(F_n)$$

is the identity for every $j \leq n$, because this is true for $j = 0$ and $j = 1$. Taking $j = n$ proves that φ_n is injective, which completes the proof that *a*) implies *b*).

[0IV-1 | 93] **(19.5.4.3)** Let us next prove that *b*) implies *a*). The same reasoning as at the beginning of (19.5.4.2) proves the existence of a surjective A-homomorphism of algebras $v : F_n \to E_n$ such that $\mathrm{gr}^j(v) = \varphi_j$ for all j; since φ_j is bijective for every j and the filtrations of F_n and E_n are finite, we conclude that v is *bijective* (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1). Let now G be a discrete topological A-algebra, $\mathfrak{R}$ an ideal of square zero in G, $f : B \to G/\mathfrak{R}$ a continuous A-homomorphism of algebras. As G is discrete, there exists an integer m such that f annihilates on $\mathfrak{J}^m$, so f factorizes as $B \to E_n \xrightarrow{f_n} G/\mathfrak{R}$, where we take $n = 2m$. One has therefore by composition a continuous A-homomorphism $r : C \to F_n \xrightarrow{v} E_n \xrightarrow{f_n} G/\mathfrak{R}$, and as C is a discrete formally smooth A-algebra, r factorizes as $C \xrightarrow{r'} G \to G/\mathfrak{R}$, so G is thus equipped with a structure of C-algebra. On the other hand, the restriction to $\mathfrak{J}/\mathfrak{J}^2$ of the C-homomorphism $f'_n : F_n \xrightarrow{v} E_n \xrightarrow{f_n} G/\mathfrak{R}$ is a C-linear map $g : \mathfrak{J}/\mathfrak{J}^2 \to G/\mathfrak{R}$. As $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module, g factorizes as $\mathfrak{J}/\mathfrak{J}^2 \xrightarrow{h} G \to G/\mathfrak{R}$, where h is a C-linear map. By extension, one deduces a homomorphism of C-algebras $w : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to G$, and by construction every element of degree m has as its image under w an element of $\mathfrak{R}$, so every element of degree $n = 2m$ has zero image since $\mathfrak{R}^2 = 0$; in other words, w factorizes as $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to F_n \xrightarrow{w'} G$. By construction, the composite $F_n \xrightarrow{w'} G \xrightarrow{\theta} G/\mathfrak{R}$ coincides with f'_n in C and in $\mathfrak{J}/\mathfrak{J}^2$, hence is equal to f'_n. Finally, the composite $B \to E_n \xrightarrow{w' \circ v^{-1}} G$ being equal to f, one sees that B is a formally smooth A-algebra.

(19.5.4.4) It remains to prove the equivalence of *a*) and *c*). In the first place, *c*) implies that B' is a formally smooth C-algebra for the discrete topology (19.3.2), hence also for the B'^+-preadic topology (19.3.8). As C is a formally smooth A-algebra, B' is also a formally smooth A-algebra (19.3.5), (ii), and finally $\widehat{B'}$ is a formally smooth $\widehat{A}$-algebra (19.3.6); hence B is a formally smooth A-algebra (19.3.6). It remains to see that *a*) implies *c*). Note first that C is a formally smooth A-algebra, the identical homomorphism $C \to B/\mathfrak{J}$ factorizes as $C \to \widehat{B} \to B/\mathfrak{J}$, where $C \to \widehat{B}$ is an A-homomorphism (19.3.10); hence $\widehat{B}$, and therefore all the $B/\mathfrak{J}^{n+1}$, are equipped with structures of C-algebras. On the other hand, as $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module by *b*), the canonical injection $\mathfrak{J}/\mathfrak{J}^2 \to B/\mathfrak{J}^2$ allows one to form a projective system of C-homomorphisms $u_n : \mathfrak{J}/\mathfrak{J}^2 \to B/\mathfrak{J}^{n+1}$ for $n \geq 1$, hence also (by the universal property of the symmetric algebra) a projective system of homomorphisms of C-algebras $v_n : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) = B' \to B/\mathfrak{J}^{n+1}$; moreover it is clear that v_n annihilates on $(B'^+)^{n+1}$ and as $\mathrm{gr}^0(v_n) = \varphi_0$ and $\mathrm{gr}^1(v_n) = \varphi_1$, one has $\mathrm{gr}^j(v_n) = \varphi_j$ for $0 \leq j \leq n$. As the φ_j are isomorphisms by *b*), and the filtrations
[0IV-1 | 94] of $B'/(B'^+)^{n+1}$ and of $B/\mathfrak{J}^{n+1}$ are finite, one concludes that v_n is *bijective* for all n (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1); whence *c*) by passage to the projective limit.

(19.5.5) Remark. Under the general hypotheses of (19.5.4), suppose furthermore that $\mathfrak{J}$ is a *maximal* ideal of B, so that $C = B/\mathfrak{J}$ is a field, and that $\mathfrak{J}/\mathfrak{J}^2$ is a vector space of *finite* dimension. Then the conditions *a*), *b*) and *c*) of (19.5.4) are also equivalent to the following:

d) *Given* a polynomial algebra $E = C[T_1, \ldots, T_n]$ over the field C, and denoting by $\mathfrak{n}$ the maximal ideal of E generated by the T_i $(1 \leq i \leq n)$, then for every ideal $\mathfrak{b}$ of E containing a power $\mathfrak{n}^k$, every homomorphism $v : B \to E/\mathfrak{b}$ of C-augmented A-algebras factorizes as

$$B \xrightarrow{w} E/\mathfrak{n}^k \to E/\mathfrak{b},$$

where w is an A-homomorphism.

Indeed, $\mathfrak{J}/\mathfrak{J}^2$ being here a free C-module, it suffices to verify that condition d) implies that the canonical homomorphism $\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}^*_{\mathfrak{J}}(B)$ is bijective. Here $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2)$ identifies with the polynomial algebra $E = C[T_1, \ldots, T_n]$, where $n = \mathrm{rg}_C(\mathfrak{J}/\mathfrak{J}^2)$, and the ideal of augmentation of E is the ideal $\mathfrak{n}$ generated by the T_i. For every integer $k \geq 0$, formal smoothness of the discrete A-algebra C gives, as in (19.5.4.2), a surjective A-homomorphism

$$f : E/\mathfrak{n}^{k+1} \to B/\mathfrak{J}^{k+1}$$

such that $\mathrm{gr}^j(f) = \varphi_j$ for every $j \leq k$. If $\mathfrak{b}/\mathfrak{n}^{k+1} = \mathrm{Ker}(f)$, then $B/\mathfrak{J}^{k+1}$ identifies with $E/\mathfrak{b}$, and condition d) factorizes the canonical homomorphism $B \to B/\mathfrak{J}^{k+1}$ as

$$B \xrightarrow{w} E/\mathfrak{n}^{k+1} \xrightarrow{f} B/\mathfrak{J}^{k+1}.$$

Since $\mathrm{gr}^0(f)$ is the identity, $w(\mathfrak{J}) \subset \mathfrak{n}/\mathfrak{n}^{k+1}$, hence $w(\mathfrak{J}^{k+1}) = 0$. As in (19.5.4.2), it follows that φ_k is injective for every k, which proves the assertion.

(19.5.6) *Proof of the theorem* (19.5.3). — Let $(\mathfrak{b}_\alpha)$ be a fundamental decreasing system of open ideals of B. Set

$$B_\alpha = B/\mathfrak{b}_\alpha, \qquad C_\alpha = B/(\mathfrak{b}_\alpha + \mathfrak{J}), \qquad \mathfrak{J}_\alpha = (\mathfrak{b}_\alpha + \mathfrak{J})/\mathfrak{b}_\alpha,$$

so that

$$C_\alpha = B_\alpha/\mathfrak{J}_\alpha \qquad \text{and} \qquad \mathfrak{J}^n_\alpha/\mathfrak{J}^{n+1}_\alpha = (\mathfrak{b}_\alpha + \mathfrak{J}^n)/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}).$$

The C-modules

$$((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1})/\mathfrak{J}^{n+1}$$

of $\mathfrak{J}^n/\mathfrak{J}^{n+1}$ form a fundamental system of open submodules of the topological C-module $\mathfrak{J}^n/\mathfrak{J}^{n+1}$. Since

$$(\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1} = \mathfrak{J}^n \cap (\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}),$$

we have

$$\begin{aligned}\mathfrak{J}^n/((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1}) &= \mathfrak{J}^n/(\mathfrak{J}^n \cap (\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})) \\ &= (\mathfrak{b}_\alpha + \mathfrak{J}^n)/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}) = \mathfrak{J}^n_\alpha/\mathfrak{J}^{n+1}_\alpha.\end{aligned}$$

(19.5.6.1) Let P, Q be two discrete C_α-modules and let $u : P \to Q$ be a surjective C_α-homomorphism. The discrete ring $B/(\mathfrak{b}_\alpha + \mathfrak{J}^2)$ is a B-extension of C_α by the square-zero ideal $\mathfrak{J}_\alpha/\mathfrak{J}^2_\alpha$. Let $v : \mathfrak{J}/\mathfrak{J}^2 \to Q$ be a continuous C-homomorphism. After replacing $\mathfrak{b}_\alpha$, if necessary, by a smaller open ideal of B, we may suppose that the kernel of v contains the open C-submodule $((\mathfrak{b}_\alpha \cap \mathfrak{J}) + \mathfrak{J}^2)/\mathfrak{J}^2$. Passing to the quotient gives a C_α-homomorphism of discrete modules $v' : \mathfrak{J}_\alpha/\mathfrak{J}^2_\alpha \to Q$. Let E_α be the B_α-extension of C_α by Q deduced from $B/(\mathfrak{b}_\alpha + \mathfrak{J}^2)$ by means of v', and let $v'_* : B/(\mathfrak{b}_\alpha + \mathfrak{J}^2) \to E_\alpha$ be the corresponding B_α-homomorphism (18.2.8). The algebra E_α is a discrete topological A-algebra, and the canonical isomorphism $C_\alpha \xrightarrow{\sim} E_\alpha/Q$ gives by composition a continuous A-homomorphism $f : C \to C_\alpha \to E_\alpha/Q$. Since Q is square zero in E_α and C is a formally smooth A-algebra, f factorizes as $C \xrightarrow{g} E_\alpha \to E_\alpha/Q$, where g is a continuous A-homomorphism. As g is continuous and E_α discrete, there exists $\beta \geq \alpha$ such that g factorizes as $C \to C_\beta \xrightarrow{g'} E_\alpha$. Let E_β be the A-extension of C_β by Q which is the inverse image of E_α under the canonical homomorphism $C_\beta \to C_\alpha$. The existence of g' (with composite $C_\beta \to E_\alpha \to C_\alpha$ equal to the canonical homomorphism) is equivalent to E_β being an A-*trivial* extension, so it may be identified with $\mathrm{D}_{C_\beta}(Q)$. The surjective homomorphism $u : P \to Q$ then canonically defines a

[$0_{\text{IV-1}}$ | 95] surjective homomorphism $\mathrm{D}_{C_\beta}(P) \to \mathrm{D}_{C_\beta}(Q)$ (18.2.9), whose kernel is an ideal $\mathfrak{L}$ of the extension $E'_\beta = \mathrm{D}_{C_\beta}(P)$, contained in P, and *a fortiori* square zero. Let $f' : B \to E_\beta = E'_\beta/\mathfrak{L}$ be the continuous A-homomorphism defining the topological B-algebra structure of E_β. Since $\mathfrak{L}$ is square zero and B is a formally smooth A-algebra, f' factorizes as $B \xrightarrow{h'} E'_\beta \to E'_\beta/\mathfrak{L}$, where h' is a continuous A-homomorphism. The construction of E'_β gives by composition an A-homomorphism $\psi : E'_\beta \to E_\beta \to E_\alpha$, and the diagram

$$\begin{array}{ccc} E'_\beta & \xrightarrow{\psi} & E_\alpha \\ {\scriptstyle h'}\uparrow & & \uparrow{\scriptstyle v'_*} \\ B & \xrightarrow[\theta]{} & B/(\mathfrak{b}_\alpha + \mathfrak{J}^2) \end{array}$$

is commutative. Moreover, the image of $\mathfrak{J}$ under $\psi \circ h'$ is contained in Q, so its image under h' is contained in P, and the image of $\mathfrak{J}^2$ under h' is zero. Restricting h' and θ to $\mathfrak{J}$ gives a commutative diagram

$$\begin{array}{ccc} P & \xrightarrow{u} & Q \\ {\scriptstyle w}\uparrow & \nearrow_{v} & \\ \mathfrak{J}/\mathfrak{J}^2 & & \end{array}$$

where w is continuous. Thus $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module.

(19.5.6.2) For all $n \geq 0$, we set $E_n = B/\mathfrak{J}^{n+1}$, so that $E_0 = C$; and we set

$$E_{\alpha,n} = B/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1}) = B_\alpha/\mathfrak{J}_\alpha^{n+1},$$

a discrete quotient ring. Likewise, in $\mathrm{gr}^n_{\mathfrak{J}}(B) = \mathfrak{J}^n/\mathfrak{J}^{n+1}$, we have seen that the $((\mathfrak{b}_\alpha \cap \mathfrak{J}^n) + \mathfrak{J}^{n+1})/\mathfrak{J}^{n+1}$ form a fundamental system of open submodules. Consider the symmetric algebra $\mathbf{S}^*_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$; we denote by $F_{\alpha,n}$ the quotient of $\mathbf{S}^*_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$ by the $(n+1)$-th power of its ideal of augmentation. For a fixed $n \geq 1$, it follows from (19.5.1.1) that the $\mathbf{S}^n_{C_\alpha}(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2)$ are the quotients of $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ by a fundamental system of open submodules within this topological C-module.

To abbreviate the language, we will say that for $\alpha \leq \beta$, the canonical homomorphisms $B_\beta \to B_\alpha$, $C_\beta \to C_\alpha$, $\mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2$, $E_{\beta,n} \to E_{\alpha,n}$, $F_{\beta,n} \to F_{\alpha,n}$, etc., are *homomorphisms of transition*.

(19.5.6.3) Lemma. *Suppose that C is a formally smooth A-algebra, that the ring B is preadmissible, and that the C-module $\mathfrak{J}/\mathfrak{J}^2$ is formally projective. Then:*

(i) *For every α, there exists $\beta \geq \alpha$ and a surjective A-algebra homomorphism*

$$v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$$

such that $\mathrm{gr}^0(v_{\alpha\beta}) : C_\beta \to C_\alpha$ and $\mathrm{gr}^1(v_{\alpha\beta}) : \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2$ are the homomorphisms of transition;

(ii) *If β and $v_{\alpha\beta}$ satisfy the conditions of* (i)*, then for every $\gamma \geq \beta$, there exists $\delta \geq \gamma$ and a surjective A-algebra homomorphism $v_{\gamma\delta} : F_{\delta,n} \to E_{\gamma,n}$ satisfying the conditions of* (i) *(for γ and δ) and making commutative the diagram*

$$\begin{array}{ccc} F_{\beta,n} & \xrightarrow{v_{\alpha\beta}} & E_{\alpha,n} \\ \uparrow & & \uparrow \\ F_{\delta,n} & \xrightarrow[v_{\gamma\delta}]{} & E_{\gamma,n} \end{array}$$

where the vertical arrows are the homomorphisms of transition.

(19.5.6.4)

(i) In the discrete topological A-algebra $E_{\alpha,n}$, the ideal $\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ is nilpotent, and the isomorphism $C_\alpha \xrightarrow{\sim} E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$ gives by composition a continuous A-homomorphism $C \to C_\alpha \to E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$;

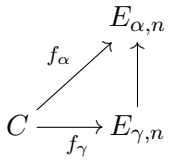
as C is a formally smooth A-algebra, this homomorphism factorizes as $C \xrightarrow{f_\alpha} E_{\alpha,n} \to E_{\alpha,n}/(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1})$, where f_α is a continuous A-homomorphism; hence $\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ becomes, by means of f_α, a topological C-module annihilated by an open ideal of C. The hypothesis that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module then implies the existence of a continuous C-linear map $g_\alpha : \mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$ making commutative the diagram [$0_{\text{IV-1}}$ | 96]

$$\begin{array}{ccc} \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1} & \longrightarrow & \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^2 \\ & \overset{g_\alpha}{\nwarrow} & \uparrow \\ & & \mathfrak{J}/\mathfrak{J}^2 \end{array}$$

As f_α and g_α are continuous, there exists $\beta \geq \alpha$ such that these homomorphisms factorize through

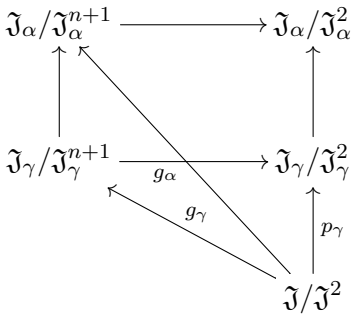
$$C \to C_\beta \xrightarrow{f'_{\alpha\beta}} E_{\alpha,n}$$

$$\mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \xrightarrow{g'_{\alpha\beta}} \mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}$$



and from $f'_{\alpha\beta}$ and $g'_{\alpha\beta}$, one obtains a homomorphism of C_β-algebras

$$\mathbf{S}^*_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2) \to E_{\alpha,n}$$



which, by the definition of $g'_{\alpha\beta}$, vanishes on the $(n+1)$-th power of the augmentation ideal of $\mathbf{S}^*_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2)$; passing to the quotient by this power gives the desired homomorphism $v_{\alpha\beta}$, taking into account the definitions of f_α and g_α; the surjectivity of $v_{\alpha\beta}$ follows from that of the two homomorphisms $\mathrm{gr}^0(v_{\alpha\beta})$ and $\mathrm{gr}^1(v_{\alpha\beta})$, since this implies that $\mathrm{gr}(v_{\alpha\beta})$ is surjective (the graded algebra $\mathrm{gr}^*(E_{\alpha,n})$ being generated by $\mathrm{gr}^0(E_{\alpha,n})$ and $\mathrm{gr}^1(E_{\alpha,n})$), and as the filtrations considered are finite, one can apply Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1.

(ii) The hypothesis that B is preadmissible means that one can suppose all the $\mathfrak{b}_\alpha$ contained in the same $\mathfrak{b}_{\alpha_0}$, whose powers tend to 0. This implies in particular that the kernel of the transition homomorphism $E_{\gamma,n} \to E_{\alpha,n}$, equal to $(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})/(\mathfrak{b}_\gamma +$

$\mathfrak{J}^{n+1}$), is *nilpotent*; applying the lemma (19.3.10.1), one sees that one can choose f_γ so that the diagram

(where the vertical arrow is the transition homomorphism) is commutative. The hypothesis that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module furthermore allows one to choose $g_\gamma : \mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^{n+1}$ so that the diagram

is commutative. Indeed, the image of $\mathfrak{J}/\mathfrak{J}^2$ under (g_α, p_γ) in $(\mathfrak{J}_\alpha/\mathfrak{J}_\alpha^{n+1}) \times (\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2)$ is contained, by the definition of g_α and the relation $\beta \leq \gamma$, in the canonical image Q of $P = \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^{n+1}$ in this product module. Apply the definition (19.2.1) to the surjective homomorphism $P \to Q$ and to $(g_\alpha, p_\gamma) : \mathfrak{J}/\mathfrak{J}^2 \to Q$. This choice of f_γ and g_γ allows $v_{\gamma\delta}$ to be constructed as in (i) while also making the diagram (19.5.6.4) commutative.

[$0_{\text{IV-1}}$ | 97] **(19.5.6.5) Lemma.** *Suppose that the A-algebras B and C are formally smooth and that B is preadmissible (so that, by (19.5.6.1), the conditions of (19.5.6.3) are satisfied). For every pair of indices $\alpha \leq \beta$ and every homomorphism $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$ satisfying the conditions of (19.5.6.3),* (i)*, there exists an index $\lambda \geq \beta$ and an A-algebra homomorphism*

$$w_{\beta\lambda} : E_{\lambda,n} \to F_{\beta,n}$$

such that: 1° $\mathrm{gr}^0(w_{\beta\lambda}) : C_\lambda \to C_\beta$ *and* $\mathrm{gr}^1(w_{\beta\lambda}) : \mathfrak{J}_\lambda/\mathfrak{J}_\lambda^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2$ *are the transition homomorphisms;* 2° *the composite $E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n}$ is the transition homomorphism.*

Proof. Apply (19.5.6.3), (ii), with $\gamma = \beta$. This gives $\delta \geq \beta$ and $v_{\beta\delta} : F_{\delta,n} \to E_{\beta,n}$. Recall that $v_{\beta\delta}$ is surjective. Its kernel $\mathfrak{R}$ is nilpotent: the augmentation ideal $F_{\delta,n}^+$ is nilpotent by definition, while the kernel of $\mathrm{gr}^0(v_{\beta\delta}) : C_\delta \to C_\beta$ is nilpotent because B is preadmissible. Thus $E_{\beta,n}$ identifies with $F_{\delta,n}/\mathfrak{R}$. Since B is a formally smooth A-algebra, the continuous canonical A-homomorphism $p_{\beta,n} : B \to E_{\beta,n}$ factorizes as

$$B \xrightarrow{w} F_{\delta,n} \xrightarrow{v_{\beta\delta}} E_{\beta,n},$$

where w is continuous. As $F_{\delta,n}$ is discrete, there exists $\lambda \geq \delta$ such that w vanishes on $\mathfrak{b}_\lambda$, and hence w factorizes as

$$B \to B/\mathfrak{b}_\lambda \xrightarrow{w'_\lambda} F_{\delta,n}.$$

Consider the composite

$$B/\mathfrak{b}_\lambda \xrightarrow{w'_\lambda} F_{\delta,n} \xrightarrow{q_{\beta\delta}} F_{\beta,n},$$

where $q_{\beta\delta}$ is the transition homomorphism. We have $\mathrm{gr}^0(q_{\beta\delta}) = \mathrm{gr}^0(v_{\beta\delta}) : C_\delta \to C_\beta$, the transition homomorphism. Since $v_{\alpha\beta} \circ q_{\beta\delta} \circ w'_\lambda$ is the canonical homomorphism $B/\mathfrak{b}_\lambda \to B/(\mathfrak{b}_\alpha + \mathfrak{J}^{n+1})$, the image of $\mathfrak{J}_\lambda = (\mathfrak{b}_\lambda + \mathfrak{J})/\mathfrak{b}_\lambda$ under $q_{\beta\delta} \circ w'_\lambda$ is contained in the augmentation ideal $F^+_{\beta,n}$. Consequently the image of $\mathfrak{J}_\lambda^{n+1} = (\mathfrak{b}_\lambda + \mathfrak{J}^{n+1})/\mathfrak{b}_\lambda$ is zero. Thus $q_{\beta\delta} \circ w'_\lambda$ factorizes as

$$B/\mathfrak{b}_\lambda \to B/(\mathfrak{b}_\lambda + \mathfrak{J}^{n+1}) = E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n},$$

and $E_{\lambda,n} \xrightarrow{w_{\beta\lambda}} F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n}$ is the transition homomorphism. The preceding argument also shows that $\mathrm{gr}^0(w_{\beta\lambda})$ is the transition homomorphism $C_\lambda \to C_\beta$, because it is the composite

$$B/(\mathfrak{b}_\lambda + \mathfrak{J}) \to \mathrm{gr}^0(F_{\delta,n}) \xrightarrow{\mathrm{gr}^0(q_{\beta\delta})} \mathrm{gr}^0(F_{\beta,n})$$

and $v_{\beta\delta} \circ w$ is canonical. Moreover, $\mathrm{gr}^1(q_{\beta\delta}) = \mathrm{gr}^1(v_{\beta\delta})$ by (19.5.6.3), and the same argument shows that $\mathrm{gr}^1(w_{\beta\lambda})$ is the transition homomorphism. □

(19.5.6.6) *Proof of* (19.5.3), (ii). — To show that φ_n is a formal bimorphism, we apply the criterion of (19.1.3); the conditions of (19.5.6.5) being satisfied by hypothesis, choose, for every α, homomorphisms $v_{\alpha\beta}$ and $w_{\beta\lambda}$ satisfying the conclusions of that lemma. The homomorphism

$$\mathrm{gr}^n(v_{\alpha\beta}) : \mathrm{gr}^n(F_{\beta,n}) \to \mathrm{gr}^n(E_{\alpha,n})$$

is the homomorphism

$$\varphi_{\alpha\beta,n} : \mathbf{S}^n_{C_\beta}(\mathfrak{J}_\beta/\mathfrak{J}_\beta^2) \to \mathfrak{J}_\alpha^n/\mathfrak{J}_\alpha^{n+1}$$

deduced from (19.5.2.1) by passage to quotients. Indeed, (19.5.6.3) and the definition of φ show inductively that $\mathrm{gr}^j(v_{\alpha\beta}) = \varphi_{\alpha\beta,j}$ for all $j \leq n$. Since φ_n is surjective, it is *a fortiori* a formal epimorphism. Moreover, the composite

$$\mathrm{gr}^j(F_{\lambda,n}) \xrightarrow{\varphi_{\lambda\lambda,j}} \mathrm{gr}^j(E_{\lambda,n}) \xrightarrow{\mathrm{gr}^j(w_{\beta\lambda})} \mathrm{gr}^j(F_{\beta,n})$$

is the transition homomorphism: this holds for $j = 0, 1$ by (19.5.6.5), and then for every $j \leq n$ because $\mathrm{gr}^*(E_{\lambda,n})$ is generated by $\mathrm{gr}^1(E_{\lambda,n})$. After composing with the transition map to $\mathrm{gr}^n(F_{\alpha,n})$, the transition homomorphism $\mathrm{gr}^n(F_{\lambda,n}) \to \mathrm{gr}^n(F_{\alpha,n})$ therefore factors as

$$\mathrm{gr}^n(F_{\lambda,n}) \xrightarrow{\varphi_{\lambda\lambda,n}} \mathrm{gr}^n(E_{\lambda,n}) \to \mathrm{gr}^n(F_{\alpha,n}),$$

which is precisely the criterion of (19.1.3).

(19.5.6.7) Lemma. *Suppose that B is preadmissible, that $\mathfrak{J}/\mathfrak{J}^2$ is a formally projective C-module, that C is a formally smooth A-algebra, and that the φ_n are formal bimorphisms. Then, for every pair $\alpha \leq \beta$ and every homomorphism $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$ satisfying (19.5.6.3),* (i)*, there exists $\gamma \geq \beta$ such that, for every $\mu \geq \gamma$, there is a commutative diagram* [$0_{IV\text{-}1}$ / 98]

$$\begin{array}{ccc} F_{\beta,n} & \xrightarrow{v_{\alpha\beta}} & E_{\alpha,n} \\ & \nwarrow^{u_{\beta\mu}} & \uparrow{\scriptstyle p_{\alpha\mu}} \\ & & E_{\mu,n} \end{array}$$

of A-homomorphisms, where $p_{\alpha\mu}$ is the transition homomorphism.

Proof. Apply the criterion of (19.1.3) to each φ_j, $0 \leq j \leq n$. There exist $\gamma \geq \beta$ and uniquely determined surjective C_γ-linear homomorphisms

$$w^j_{\beta\gamma} : \mathrm{gr}^j(E_{\gamma,n}) \to \mathrm{gr}^j(F_{\beta,n})$$

such that

$$\mathrm{gr}^j(F_{\gamma,n}) \xrightarrow{\varphi_{\gamma\gamma,j}} \mathrm{gr}^j(E_{\gamma,n}) \xrightarrow{w^j_{\beta\gamma}} \mathrm{gr}^j(F_{\beta,n})$$

is the transition homomorphism. The same γ may be chosen for all j, since there are only finitely many of them. By uniqueness and because φ is a homomorphism of graded algebras, the family $w_{\beta\gamma} = (w^j_{\beta\gamma})_{0\leq j\leq n}$ is a homomorphism of graded C_γ-algebras

$$\mathrm{gr}^\bullet(E_{\gamma,n}) \to \mathrm{gr}^\bullet(F_{\beta,n}) = F_{\beta,n}.$$

Since $\varphi_{\gamma\gamma,0}$ and $\varphi_{\gamma\gamma,1}$ are the identity homomorphisms, $w^0_{\beta\gamma} : C_\gamma \to C_\beta$ and $w^1_{\beta\gamma} : \mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2$ are the transition homomorphisms. The same therefore holds for $\mathrm{gr}^0(v_{\alpha\beta} \circ w_{\beta\gamma})$ and $\mathrm{gr}^1(v_{\alpha\beta} \circ w_{\beta\gamma})$; since $\mathrm{gr}^\bullet(E_{\gamma,n})$ is generated by $\mathrm{gr}^1(E_{\gamma,n})$, it follows that $\mathrm{gr}^j(v_{\alpha\beta} \circ w_{\beta\gamma})$ is also the transition homomorphism for $0 \leq j \leq n$.

Apply now (19.5.6.3), (ii), to α, β, and γ; this gives diagram (19.5.6.4) with $\delta \geq \gamma$. Repeat the argument at the beginning after replacing α and β by γ and δ. One obtains $\lambda \geq \delta$ and a commutative diagram

$$\begin{array}{ccccc}
\mathrm{gr}^\bullet(E_{\gamma,n}) & \xrightarrow{w_{\beta\gamma}} & F_{\beta,n} & \xrightarrow{v_{\alpha\beta}} & E_{\alpha,n} \\
\uparrow{\scriptstyle \mathrm{gr}^\bullet(p_{\gamma\lambda})} & & \uparrow{\scriptstyle q_{\beta\delta}} & \nwarrow^{u_{\beta\gamma}} & \uparrow{\scriptstyle p_{\alpha\gamma}} \\
\mathrm{gr}^\bullet(E_{\lambda,n}) & \xrightarrow[w_{\delta\lambda}]{} & F_{\delta,n} & \xrightarrow[v_{\gamma\delta}]{} & E_{\gamma,n}
\end{array}$$

whose vertical arrows are the transition homomorphisms. It remains to prove the existence of $u_{\beta\gamma}$ making the diagram commute, and for this it plainly suffices to show

$$\mathrm{Ker}(v_{\gamma\delta}) \subset \mathrm{Ker}(q_{\beta\delta}),$$

since $v_{\gamma\delta}$ and $q_{\beta\delta}$ are surjective. As $w_{\delta\lambda}$ is surjective, this relation is equivalent to

$$\begin{aligned}\mathrm{Ker}(v_{\gamma\delta} \circ w_{\delta\lambda}) &\subset \mathrm{Ker}(q_{\beta\delta} \circ w_{\delta\lambda}) \\ &= \mathrm{Ker}\big(w_{\beta\gamma} \circ \mathrm{gr}(p_{\gamma\lambda})\big).\end{aligned}$$

But we saw above that $\mathrm{gr}(p_{\gamma\lambda}) = \mathrm{gr}(v_{\gamma\delta} \circ w_{\delta\lambda})$, and clearly

$$\begin{aligned}\mathrm{Ker}(v_{\gamma\delta} \circ w_{\delta\lambda}) &\subset \mathrm{Ker}\big(\mathrm{gr}(v_{\gamma\delta} \circ w_{\delta\lambda})\big) \\ &= \mathrm{Ker}(\mathrm{gr}(p_{\gamma\lambda})) \subset \mathrm{Ker}\big(w_{\beta\gamma} \circ \mathrm{gr}(p_{\gamma\lambda})\big).\end{aligned}$$

This proves the lemma: for every $\mu \geq \gamma$, define $u_{\beta\mu}$ as the composite

$$E_{\mu,n} \xrightarrow{p_{\gamma\mu}} E_{\gamma,n} \xrightarrow{u_{\beta\gamma}} F_{\beta,n}.$$

□

(19.5.6.8) *Proof of* (19.5.3), (iii). — Let G be a discrete topological A-algebra, $\mathfrak{R}$ an ideal of square zero in G, and $f : B \to G/\mathfrak{R}$ a continuous A-homomorphism of algebras.

As $G/\mathfrak{R}$ is discrete, there exists α such that f annihilates $\mathfrak{b}_\alpha$; moreover, as $\mathfrak{J}^m \subset \mathfrak{b}_\alpha$ for a sufficiently large m, f factors as

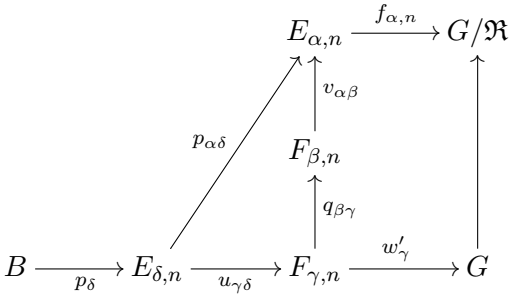
$$B \xrightarrow{p_\alpha} E_{\alpha,n} \xrightarrow{f_{\alpha,n}} G/\mathfrak{R},$$

where $n = 2m$. By (19.5.6.3), there exist $\beta \geq \alpha$ and $v_{\alpha\beta} : F_{\beta,n} \to E_{\alpha,n}$; thus

$$F_{\beta,n} \xrightarrow{v_{\alpha\beta}} E_{\alpha,n} \xrightarrow{f_{\alpha,n}} G/\mathfrak{R} \tag{19.5.6.9}$$

is a continuous A-homomorphism. Since $F_{\beta,n}$ is a C_β-algebra, hence *a fortiori* a discrete topological C-algebra, (19.5.6.9) gives by composition a continuous A-homomorphism $r : C \to F_{\beta,n} \to G/\mathfrak{R}$. Since, on the other hand, C is a formally smooth A-algebra,

this homomorphism factorizes as $r : C \xrightarrow{r'} G \to G/\mathfrak{R}$, where r' is a continuous A- [0IV-1 | 99]
homomorphism, thereby giving G the structure of a discrete topological C-algebra. Composing (19.5.6.9) with



$$\mathfrak{J}/\mathfrak{J}^2 \to \mathfrak{J}_\beta/\mathfrak{J}_\beta^2 \to F_{\beta,n}$$

gives a continuous C-homomorphism $g : \mathfrak{J}/\mathfrak{J}^2 \to G/\mathfrak{R}$. Since $\mathfrak{J}/\mathfrak{J}^2$ is formally projective, g lifts to a continuous C-homomorphism $h : \mathfrak{J}/\mathfrak{J}^2 \to G$. As G is discrete, there exists $\gamma \geq \beta$ such that h annihilates the image of $((\mathfrak{b}_\gamma \cap \mathfrak{J}) + \mathfrak{J}^2)/\mathfrak{J}^2$ and r' annihilates the image of $(\mathfrak{b}_\gamma + \mathfrak{J})/\mathfrak{J}$. Thus h factors through a C_γ-homomorphism $\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2 \to G$, and hence extends to

$$w_\gamma : \mathbf{S}^*_{C_\gamma}(\mathfrak{J}_\gamma/\mathfrak{J}_\gamma^2) \to G.$$

Every element of degree m has image in $\mathfrak{R}$, so every element of degree $n = 2m$ has image zero; consequently w_γ factors as $F_{\gamma,n} \xrightarrow{w'_\gamma} G$.

Applying (19.5.6.7) to $v_{\alpha\gamma} = v_{\alpha\beta} \circ q_{\beta\gamma} : F_{\gamma,n} \to E_{\alpha,n}$ gives $\delta \geq \gamma$ and $u_{\gamma\delta} : E_{\delta,n} \to F_{\gamma,n}$ such that $v_{\alpha\gamma} \circ u_{\gamma\delta} = p_{\alpha\delta}$. One obtains the commutative diagram

of continuous A-homomorphisms. The composite $f' : B \to G$ along the bottom row satisfies $f = (G \to G/\mathfrak{R}) \circ f'$, proving that B is a formally smooth A-algebra. The proof of (19.5.3) is complete.

(19.5.7) Corollary. *Let A be a topological ring, B a topological A-algebra, $(\mathfrak{b}_\lambda)$ a fundamental system of open ideals of B, $\mathfrak{J}$ an ideal of B, and $C = B/\mathfrak{J}$ the topological quotient A-algebra. Set $C_\lambda = B/(\mathfrak{b}_\lambda + \mathfrak{J})$. Suppose that:*

1° *for all n, the topology induced on $\mathfrak{J}^n$ by that of B is also the topology of the B-module $\mathfrak{J}^n$ deduced from the topology of B (19.0.2); this condition is satisfied in particular if B is Noetherian and its topology is preadic (**0_I**, 7.3.2);*

2° *C is a formally smooth A-algebra.*

Under these conditions:

(i) *If B is a formally smooth A-algebra, then, for all λ, $(\mathfrak{J}/\mathfrak{J}^2)\otimes_C C_\lambda$ is a projective C_λ-module.*

(ii) *If B is a formally smooth A-algebra and a preadmissible ring, then, for all λ, the canonical homomorphism*

$$\varphi_\lambda = \varphi\otimes 1_{C_\lambda} : \mathbf{S}^*_{C_\lambda}((\mathfrak{J}/\mathfrak{J}^2)\otimes_C C_\lambda) \to \mathrm{gr}_{\mathfrak{J}}(B)\otimes_C C_\lambda \tag{19.5.7.1}$$

[$0_{IV\text{-}1}$ / 100] *is bijective.*

(iii) *Conversely, suppose that B is preadmissible, that the sequence $(\mathfrak{J}^n)$ tends to 0, and that, for all λ, $(\mathfrak{J}/\mathfrak{J}^2)\otimes_C C_\lambda$ is a projective C_λ-module and the homomorphism (19.5.7.1) is bijective. Then B is a formally smooth A-algebra.*

Proof. Indeed, the topology of $\mathfrak{J}/\mathfrak{J}^2$ and those of the $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ are then also deduced from that of B (19.5.1); the conclusions are immediate consequences of (19.5.3) and of the criteria of (19.1.4) and (19.2.4) specialized to this type of topology. □

(19.5.8) Remark. Suppose that $\mathfrak{J}/\mathfrak{J}^2$ is a C-module of finite type and that, for the quotient topology inherited from B, C is a Zariski ring. Let $\mathfrak{r}$ be an ideal of definition of C, so that the $\mathfrak{r}^n$ form a fundamental system of neighbourhoods of 0 in C. Then the conclusions of (i) and (ii) in (19.5.7) may be replaced by the following:

(i') $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module.

(ii') The canonical homomorphism

$$\varphi : \mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}_{\mathfrak{J}}(B)$$

is bijective.

Indeed, it is clear that (i') implies the conclusion of (i) in (19.5.7). Conversely, if $(\mathfrak{J}/\mathfrak{J}^2)\otimes_C C_\lambda$ is a projective C_λ-module for all λ, then $(\mathfrak{J}/\mathfrak{J}^2)\otimes_C (C/\mathfrak{r}^n)$ is a projective, hence flat, $(C/\mathfrak{r}^n)$-module for every n; one concludes that $\mathfrak{J}/\mathfrak{J}^2$ is a flat C-module (**0$_{\mathbf{III}}$**, 10.2.2), hence projective since it is finitely presented (Bourbaki, *Alg. comm.*, chap. II, §5, n° 2, cor. 2 of th. 1). On the other hand, the C-modules $\mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2)$ and $\mathrm{gr}^n_{\mathfrak{J}}(B)$ are of finite type, and when C is a Zariski ring it is equivalent to saying that φ_n is bijective or that $\varphi_n\otimes 1_{C_\lambda}$ is bijective for all λ (Bourbaki, *Alg. comm.*, chap. III, §3, n° 5, prop. 9); therefore (ii) is equivalent to (ii').

19.6 The case of algebras over a field

(19.6.1) Theorem (Cohen). *Let k be a field, K an extension of k, k and K being equipped with the discrete topologies. For K to be a formally smooth k-algebra, it is necessary and sufficient that K be a separable extension of k.*

Proof. The necessity of the condition will be established in (19.6.5.1) (and of course is not used until then); we will content ourselves here with proving that the condition is *sufficient*. We distinguish two cases:

I. — K is a separable extension of finite type of k. We know then (Bourbaki, *Alg.*, chap. V, § 9, n° 3, th. 2) that there exists a pure sub-extension $K' = k(T_1,\dots,T_n)$ of K such that K is a finite separable algebraic extension of K'. In view of (19.3.5), (iii), one

can therefore reduce to the case where $K = K'$, or to the case where K is algebraically finite over k. In the first case, $A = k[T_1, \ldots, T_n]$ is a formally smooth k-algebra (19.3.3), hence $k(T_1, \ldots, T_n) = S^{-1}A$ where $S = A - \{0\}$ is also formally smooth (19.3.5), (iv). In the second case, *all* Hochschild cohomology groups $\mathrm{H}^n_k(K, L)$ are zero for every (K, K)-bimodule L: indeed, if one considers the k-algebra tensor product $C = K \otimes_k K$, L is a C-module on the left and the cohomology group $\mathrm{H}^n_k(K, L)$ is equal to $\mathrm{Ext}^n_C(K, L)$, where K is also viewed as (K, K)-bimodule, hence as a left C-module (M, IX, 4). Now, as K is [$0_{\text{IV-1}}$ | 101] a finite separable extension of k, we know that $K \otimes_k K$ is a direct product of extensions of k, one of which is K itself (Bourbaki, *Alg.*, chap. VIII, § 8, prop. 3); this implies that K is a *projective* C-module, whence our assertion. Every k-extension of K of zero kernel L is therefore k-trivial, and *a fortiori* all commutative k-extensions are trivial, whence the theorem in this case (19.4.4).

II. — General case. — With the notation of (18.4.5), it suffices to prove that $\mathrm{Hom}_K(\mathrm{H}_2(\mathrm{P}'_\bullet), L) = 0$ for *every* K-vector space L, which means that $\mathrm{H}_2(\mathrm{P}'_\bullet) = 0$. If K is a union of a filtering family of sub-extensions $K^{(\alpha)}$ of k, $\mathrm{P}'_\bullet$ is the *inductive limit* of the corresponding complexes $\mathrm{P}'^{(\alpha)}_\bullet$, since the $\varinjlim$ functor commutes with the tensor product in the category of k-modules; by the exactness of the $\varinjlim$ functor in this category, one has $\mathrm{H}_2(\mathrm{P}'_\bullet) = \varinjlim \mathrm{H}_2(\mathrm{P}'^{(\alpha)}_\bullet)$. As K is separable, it follows that the same holds for every sub-extension of K and that K is a union of sub-extensions of finite type, so the first part of the proof implies that K is a formally smooth k-algebra, Q.E.D. □

(19.6.2) Corollary. *Let A be a separated complete local ring, K its residue field, k a subfield of K such that K is a separable extension of k. Then there exists a subfield K' of A containing k, such that the restriction to K' of the canonical homomorphism $A \to K$ is an isomorphism of K' onto K.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of A. By the hypothesis and (19.6.1), K is a formally smooth k-algebra; applying (19.3.10) (replacing C by A and $\mathfrak{J}$ by $\mathfrak{m}$), one sees that the identity automorphism of $K = A/\mathfrak{m}$ factorizes as $K \xrightarrow{u} A \to A/\mathfrak{m}$, where u is a k-homomorphism, hence necessarily a k-isomorphism of K onto a subfield K' of A containing k. □

(19.6.3) Corollary. *Let A be a Noetherian complete local ring, $\mathfrak{m}$ its maximal ideal, k its residue field. The following conditions are equivalent:*

a) A contains a subfield.

b) If p is the characteristic of k, one has $pA = 0$.

c) There exists a field K such that A is isomorphic to a quotient ring of a formal power series ring $B = K[[T_1, \ldots, T_n]]$.

When this is the case, one can suppose that A is isomorphic to $B/\mathfrak{b}$, where $\mathfrak{b}$ is contained in the square of the maximal ideal of B.

Proof. It is immediate that *c*) implies *a*), since A is $\neq 0$ because it is a local ring; as K is a field and the composite homomorphism $K \xrightarrow{\varphi} B \to A$ (where φ is the canonical injection) is not zero, it is injective. To see that *a*) implies *b*), it suffices to remark that if K is a subfield of A, K is isomorphic to a subfield of k and has therefore the same characteristic p; as $p.1 = 0$ in K, hence in A, one has $pA = 0$. Conversely, *b*) implies *a*), for the composite of the canonical homomorphisms $\mathbf{Z} \xrightarrow{j} A \to k$ has kernel $p\mathbf{Z}$, and one

has $j(p\mathbf{Z}) = 0$, hence $\mathrm{Ker}(j) = p\mathbf{Z}$ and A contains a ring A' isomorphic to $\mathbf{Z}/p\mathbf{Z}$ and not meeting $\mathfrak{m}$; if $p > 0$, A' is a field; otherwise,
[0IV-1 | 102] every nonzero element of A' being invertible in A, the field of fractions of A' (isomorphic to $\mathbf{Q}$) is also contained in A.

Let us prove finally that *a*) implies *c*); the condition *a*) implies that A contains a prime subfield k_0, isomorphic to the prime subfield of k, and whose k is therefore a separable extension. Applying (19.6.2), one sees that there exists an isomorphism f of k onto a subfield K of A. On the other hand, let $(x_i)_{1\leq i\leq n}$ be a system of elements of $\mathfrak{m}$ such that the classes mod. $\mathfrak{m}^2$ of the x_i form a basis (over k) of $\mathfrak{m}/\mathfrak{m}^2$. Since A is complete, there exists a continuous ring homomorphism $u : k[[T_1, \ldots, T_n]] \to A$ such that u equals f on k and $u(T_i) = x_i$ for all i, and this homomorphism is surjective by virtue of the choice of the x_i (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 9, prop. 11). □

(19.6.4) Theorem. *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, $K = A/\mathfrak{m}$ its residue field, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that K is a separable extension of k. Then the following conditions are equivalent:*

a) A is a formally smooth k-algebra.

b) The completion $\widehat{A}$ of A is k-isomorphic to a formal power series ring $K[[T_1, \ldots, T_n]]$ (where the k-algebra structure is defined by the composite homomorphism $k \xrightarrow{\varphi} K \xrightarrow{\psi} K[[T_1, \ldots, T_n]]$, where ψ is the canonical injection and φ the homomorphism defining the extension structure of K).

b') $\widehat{A}$ is a formal power series ring isomorphic to $K[[T_1, \ldots, T_n]]$.

c) A is a regular local ring.

Proof. The fact that *a*) implies *b*) is the particular case of (19.5.4) (equivalence of *a*) and *c*)) obtained by replacing A by k, B by A, and $\mathfrak{J}$ by $\mathfrak{m}$, taking into account (19.6.1). It is clear that *b*) implies *b'*) and *b'*) implies *c*) by (17.1.1). Finally, if *c*) holds, it follows from (17.1.1), *a*), and from (19.5.4) (equivalence of *b*) and *a*)), applied with $A = k$, $B = A$, $\mathfrak{J} = \mathfrak{m}$, and $C = K = A/\mathfrak{m}$, that A is a formally smooth k-algebra. □

(19.6.5) Corollary. *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that A is a formally smooth k-algebra; then A is* geometrically regular *over k, in other words (cf.* **IV***, 6.7.6), for every finite extension k' of k, the semi-local ring $A' = A \otimes_k k'$ is regular (17.3.6). Furthermore, if K is the residue field of A, $\widehat{A}$ is isomorphic to a formal power series ring $K[[T_1, \ldots, T_n]]$.*

Proof. As $\widehat{A}' = \widehat{A} \otimes_k k'$, it follows from (19.3.6) and (17.1.5) (applied to the local rings of A' at its maximal ideals) that one can reduce to the case where A is complete; then A' is a formally smooth k'-algebra (19.3.5), (iii) and is moreover a direct product of k'-local algebras, which are also formally smooth (19.3.5), (v). One is therefore reduced to proving that A is *regular*. Let k_0 be the prime subfield of k; as k is a separable extension of k_0, it is a formally smooth k_0-algebra (19.6.1), and by the hypothesis, so is A (19.3.5), (ii). As the residue field K of A is a separable extension of k_0, one can then apply (19.6.4) to A and k_0, whence the conclusion. □

(19.6.5.1) Corollary. *Let A be a Noetherian local ring, k a subfield of A such that A is a formally smooth k-algebra (for its preadic topology). Then every field K such that $k \subset K \subset A$ is a separable extension of k.* [$0_{\text{IV-1}}$ | 103]

Proof. Indeed, for every finite extension k' of k, the ring $K \otimes_k k'$ is identified with a subring of $A' = A \otimes_k k'$; as A' is a regular ring, hence reduced, so is $K \otimes_k k'$, which proves that K is a separable extension of k (Bourbaki, *Alg.*, chap. VIII, § 7, n° 3, th. 1). □

We note that this proves the necessity of the condition in the statement of (19.6.1).

(19.6.5.2) Remark. If K is a *non-separable* extension of k, the formal power series ring $K[[T_1, \ldots, T_n]]$ is therefore *not* a formally smooth k-algebra (for the usual k-algebra structure recalled in (19.6.4)). On the other hand, there exist formally smooth k-algebras A which are complete Noetherian local rings whose residue field K is a non-separable extension of k (for example the completions of the localizations of $B = k[T_1, \ldots, T_n]$ at maximal ideals $\mathfrak{n}$ such that $B/\mathfrak{n}$ is a finite non-separable algebraic extension of k); such a ring cannot therefore be k-isomorphic to $K[[T_1, \ldots, T_n]]$ even though it is *isomorphic* to it by virtue of (19.6.5).

One can in certain cases sharpen the corollary (19.6.5):

(19.6.6) Proposition. *Let k be a field, A a local Noetherian k-algebra, $\mathfrak{m}$ its maximal ideal, A being equipped with the $\mathfrak{m}$-preadic topology. Suppose that the residue field $K = A/\mathfrak{m}$ of A is such that there exists a finite radicial extension k_0 of k for which the residue field of the local ring $K \otimes_k k_0$ is a separable extension of k_0 (we will express this property later by saying that K is of* finite radicial multiplicity *over k (**IV**, 4.7.4) and we will see that this condition is always satisfied when K is an extension of finite type of k). Then the following conditions are equivalent:*

a) A is a formally smooth k-algebra.

b) There exists a finite radicial extension k' of k such that $\widehat{A} \otimes_k k'$ is k'-isomorphic to a formal power series algebra $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k'.

b') There exists a finite extension k' of k such that the semi-local ring $\widehat{A} \otimes_k k'$ has at least one local component which is k'-isomorphic to a formal power series algebra $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k'.

c) A is geometrically regular over k (19.6.5).

Proof. Note first that if k' is a finite radicial extension of k, there is only a single maximal ideal of $A' = A \otimes_k k'$ above $\mathfrak{m}$, formed of elements whose p^h-th power (p being the characteristic of k) is in $\mathfrak{m}$ for a suitable h (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 3, lemma 4); A' is therefore a local ring, and so is $K \otimes_k k' = (A \otimes_k k')/(\mathfrak{m} \otimes_k k')$; moreover, these two local rings have the same residue field. We recall, on the other hand, that if K is a separable extension of k, then, for every finite extension k'' of k, $K \otimes_k k''$ is a direct product of fields (Bourbaki, *Alg.*, chap. VIII, § 7, n° 3, cor. 1 of th. 1); therefore $\mathfrak{m} \otimes_k k''$ is the radical of $A \otimes_k k''$, and the field components of $K \otimes_k k''$ are the residue fields at the maximal ideals of $A \otimes_k k''$;
furthermore, these fields are separable extensions of k'', since for every extension k_1 of k'', $K \otimes_k k_1 = (K \otimes_k k'') \otimes_{k''} k_1$ has no radical (*loc. cit.*, th. 1). Applying these remarks [$0_{\text{IV-1}}$ | 104]

to the field K of finite radicial multiplicity over k, one sees that for *every* finite extension k'' of k_0, $(K \otimes_k k'')_{\mathrm{red}}$ is separable over k''.

Let us pass to the proof of (19.6.6). It is trivial that b) implies b'). Let us show that b') implies a). Set $B' = K'[[T_1, \ldots, T_n]]$. The hypothesis that K' is separable over k' entails, by the preceding remarks, that for every finite extension k'' of k', the components of the complete semi-local ring $B' \otimes_{k'} k''$ (equal to the formal power series ring $(K' \otimes_{k'} k'')[[T_1, \ldots, T_n]]$) are the rings $K_i''[[T_1, \ldots, T_n]]$, where the K_i'' are the field components of $K' \otimes_{k'} k''$. Since the local components of $B' \otimes_{k'} k''$ are also local components of

$$\widehat{A} \otimes_k k'' = (\widehat{A} \otimes_k k') \otimes_{k'} k'',$$

the hypothesis b') remains true when k' is replaced by any one of its finite extensions. In particular, one can suppose k' *quasi-Galois*, hence a Galois extension of a radicial extension k'_0 of k; $A' = \widehat{A} \otimes_k k'$ can then be written $A'_0 \otimes_{k'_0} k'$, where $A'_0 = \widehat{A} \otimes_k k'_0$ is a complete local ring. The Galois group of k'/k'_0 acts transitively on the local components of A' (Bourbaki, *Alg.*, chap. VIII, § 8, prop. 4), so these components are mutually Galois-conjugate. By hypothesis one of them is k'-isomorphic to a formal power series ring $K'[[T_1, \ldots, T_n]]$, where K' is a separable extension of k', and is therefore a formally smooth k'-algebra by (19.6.4). Its conjugates are likewise formally smooth over k', hence their product A' is formally smooth over k' by (19.3.5), (v). Since k' is faithfully flat, projective and of finite type over k'_0, it follows from (19.4.6) that A'_0 is formally smooth over k'_0. Finally, as k'_0 has the same properties over k, a second application of (19.4.6) shows that $\widehat{A}$ is a formally smooth k-algebra.

We have already seen (19.6.5) that a) implies c); it remains to verify that c) implies b). If c) holds, then, for every finite radicial extension k' of k containing k_0, $A \otimes_k k'$ is a regular local ring whose residue field K' is a separable extension of k'. It follows from (19.6.4) that its completion $\widehat{A} \otimes_k k'$ is k'-isomorphic to a formal power series ring $K'[[T_1, \ldots, T_n]]$. □

(19.6.7) Remarks.

(i) We note that the hypothesis that K is of finite radicial multiplicity over k was only used in the proof of the implication $b') \Rightarrow a)$.

(ii) We will prove later (22.5.8) that a) and c) are equivalent, *without* any hypothesis on the extension K of k.

19.7 The case of local homomorphisms; existence and uniqueness theorems

In this section, whenever a semi-local ring is considered as a topological ring, it is always understood that it is endowed with its $\mathfrak{r}$-preadic topology, where $\mathfrak{r}$ is its radical. Every local homomorphism of local rings is thus automatically continuous.

(19.7.1) Theorem. *Let A, B be two local Noetherian rings, $\mathfrak{m}$, $\mathfrak{n}$ their respective maximal ideals, $k = A/\mathfrak{m}$ the residue field of A; suppose that A and B are equipped respectively with the $\mathfrak{m}$-preadic and $\mathfrak{n}$-preadic topologies. Let $\varphi : A \to B$ be a local homomorphism, and set $B_0 = B \otimes_A k$. The following properties are equivalent:*

[$0_{IV\text{-}1}$ / 105] a) *B is a formally smooth A-algebra.*

b) *B is a flat A-module and $B_0 = B/\mathfrak{m}B$ (equipped with the quotient topology) is a formally smooth k-algebra.*

Proof. The proof is carried out in several steps.

(19.7.1.1) Let us first show that *b*) implies *a*); we will apply the criterion (19.4.7), with $\mathfrak{J} = \mathfrak{m}$; by virtue of the second hypothesis in *b*), it suffices to show that B is a *formally projective* A-module. The hypothesis implies that for all $h > 0$, $B/\mathfrak{m}^h B$ is a flat $(A/\mathfrak{m}^h)$-module (**0$_{\mathbf{III}}$**, 10.2.1); as the $\mathfrak{m}^h$ form a fundamental system of neighbourhoods of 0 in A and $(B/\mathfrak{m}^h B) \otimes_{A/\mathfrak{m}^h} k = B_0$, we can replace A and B by $A/\mathfrak{m}^h$ and $B/\mathfrak{m}^h B$ respectively, and thus suppose that A is *Artinian* (hence discrete). As B_0 is a k-algebra formally smooth, it is a regular ring (19.6.5); let $(x_i^0)_{1\leq i\leq n}$ be a regular system of parameters for B_0 (17.1.6), and for each i, let $x_i \in B$ be such that x_i^0 is its image in $B_0 = B/\mathfrak{m}B$; as the x_i^0 generate the maximal ideal $\mathfrak{n}_0 = \mathfrak{n}/\mathfrak{m}B$ of B_0, the ideals $\mathfrak{Q}_m = \sum_{i=1}^n (x_i^0)^m B_0$ (for $m > 0$) form a fundamental system of neighbourhoods of 0 in B_0, since $\mathfrak{Q}_m$ is evidently contained in $\mathfrak{n}_0^m$, and on the other hand contains $\mathfrak{n}_0^{mn}$. Set $\mathfrak{J}_m = \sum_{i=1}^n x_i^m B$ for all $m > 0$; it is clear that $\mathfrak{n} = \mathfrak{J}_1 + \mathfrak{m}B$; as there exists $h > 0$ such that $\mathfrak{m}^h = 0$, one has $\mathfrak{n}^m \subset \mathfrak{J}_1^{m-h} \subset \mathfrak{n}^{m-h}$ for $m > h$, and as we have seen that $\mathfrak{J}_m \supset \mathfrak{J}_1^{mn}$, the $\mathfrak{J}_m$ form a fundamental system of neighbourhoods of 0 in B. The whole argument then amounts to proving that the $B/\mathfrak{J}_m$ are *free* A-modules, and it amounts to the same to verify that these are *flat* A-modules (**0$_{\mathbf{III}}$**, 10.1.3). Now, the hypothesis that (x_i^0) is a B_0-regular sequence of elements of the maximal ideal of B_0 implies the same property for the sequence $(x_i^0)^m$ $(1 \leq i \leq n)$ for all $m > 0$ (15.1.20); the conclusion thus follows from (15.1.16), *b*) and *c*). □

(19.7.1.2) Lemma. *Let A be a topological ring, B, C two topological A-algebras that are local Noetherian rings, $\mathfrak{m}$, $\mathfrak{n}'$ their respective maximal ideals. Suppose further that C is complete and that the residue field $B/\mathfrak{m}$ of B is an A-module of finite type. Let E be the completed tensor product $B\widehat{\otimes}_A C$. Then:*

(i) *E is a complete semi-local Noetherian ring.*

(ii) *The ideal $\mathfrak{m}E$ is contained in the radical of E, and for all $h > 0$, $E/\mathfrak{m}^h E$ is isomorphic to $(B/\mathfrak{m}^h) \otimes_A C$.*

(iii) *If C is a flat A-module, E is a flat B-module.*

Proof. By definition, E is the separated completion of the tensor product $B \otimes_A C$ for the topology defined by the ideals $\mathrm{Im}(\mathfrak{m}^i \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{n}'^j)$ (**0$_{\mathbf{I}}$**, 7.7.5). If one sets $\mathfrak{r} = \mathrm{Im}(\mathfrak{m} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{n}')$, one has $\mathfrak{r}^{2i} \subset \mathrm{Im}(\mathfrak{m}^i \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{n}'^i) \subset \mathfrak{r}^i$, so E is also the separated completion of $B \otimes_A C$ for the $\mathfrak{r}$-preadic topology. By hypothesis, $(B \otimes_A C)/\mathfrak{r} = (B/\mathfrak{m}) \otimes_A (C/\mathfrak{n}')$ is a $(C/\mathfrak{n}')$-module of finite type, hence an Artinian ring; moreover, $\mathfrak{r}/\mathfrak{r}^2$, being a quotient of $((\mathfrak{m}/\mathfrak{m}^2) \otimes_A C) \oplus (B \otimes_A (\mathfrak{n}'/\mathfrak{n}'^2))$, is a $(B \otimes_A C)$-module of finite type; applying (**0$_{\mathbf{I}}$**, 7.2.11), one sees that E is a *Noetherian* ring; moreover, $E/\mathfrak{r}E$, isomorphic to $(B \otimes_A C)/\mathfrak{r}$, being Artinian, E is *semi-local*. Note now that E, which is isomorphic to $\varprojlim_{i,j} ((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j))$, is also isomorphic, by the theorem of the double projective limit, to $\varprojlim_i (\varprojlim_j ((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j)))$; but $\varprojlim_j ((B/\mathfrak{m}^i) \otimes_A (C/\mathfrak{n}'^j))$ is the [0$_{\text{IV-1}}$ | 106] separated completion of $(B/\mathfrak{m}^i) \otimes_A C$, and as C is complete, this is none other than $(B/\mathfrak{m}^i) \otimes_A C$ itself, since $B/\mathfrak{m}^i$ is an A-module of finite type (as $\mathfrak{m}/\mathfrak{m}^i$ is a $(B/\mathfrak{m})$-module of finite type (**0$_{\mathbf{I}}$**, 7.3.6)). One therefore has $E = \varprojlim_i ((B/\mathfrak{m}^i) \otimes_A C)$. For every integer $h > 0$, $\mathfrak{m}^h E$, being an ideal of E, is closed in E (**0$_{\mathbf{I}}$**, 7.3.5), hence complete, and on the other hand it is evidently dense in $\varprojlim_i (\mathrm{Im}(\mathfrak{m}^h/\mathfrak{m}^{h+i}) \otimes_A C)$, hence equal to this projective limit. Moreover, all the projective systems considered are defined by *surjective* homomorphisms; it follows therefore from (**0$_{\mathbf{III}}$**, 13.2.2) that $E/\mathfrak{m}^h E$ is isomorphic to

$(B/\mathfrak{m}^h) \otimes_A C = (B \otimes_A C)/\operatorname{Im}(\mathfrak{m}^h \otimes_A C)$. In particular $\operatorname{Im}(\mathfrak{m} \otimes_A C) \subset \mathfrak{r}$, which shows that $\mathfrak{m}E$ is contained in $\mathfrak{r}E$, hence in the radical of E. Finally, the hypothesis that C is a flat A-module implies that $(B/\mathfrak{m}^h) \otimes_A C = E/\mathfrak{m}^h E$ is a flat $(B/\mathfrak{m}^h)$-module for all $h > 0$: since B and E are Noetherian and $\mathfrak{m}E$ is contained in the radical of E, it follows from ($\mathbf{0_{III}}$, 10.2.2) that E is a flat B-module. □

(19.7.1.3) Lemma. *Let A be a local Noetherian ring, $\mathfrak{m}$ its maximal ideal, k its residue field, B_0 a local Noetherian k-algebra; suppose that B_0 is complete and regular. Then there exists a topological A-algebra B that is a complete local Noetherian ring, a flat A-module, and such that B_0 is k-isomorphic to $B \otimes_A k = B/\mathfrak{m}B$.*

Proof. As $\widehat{A}$ is flat over A and has the same residue field, we can restrict to the case where A is *complete*.

Let K be the residue field of B_0, and let us distinguish two cases:

Case I: K is a *separable* extension of k. By virtue of (19.6.4), B_0 is k-isomorphic to a formal power series ring $K[[T_1, \dots, T_n]]$. When $B_0 = K$, the lemma has already been proved ($\mathbf{0_{III}}$, 10.3.1); let C be a complete local Noetherian ring that is a flat A-module and such that $C \otimes_A k$ is isomorphic to K. For $n \geq 1$, it suffices to take (using the preceding notation) $B = C[[T_1, \dots, T_n]]$; indeed it is known (Bourbaki, *Alg. comm.*, chap. III, § 3, n° 4, cor. 3 of th. 1) that B is a flat C-module, hence also a flat A-module, and on the other hand, it is immediate that $C[[T_1, \dots, T_n]] \otimes_A k$ is isomorphic to $(C/\mathfrak{m}C)[[T_1, \dots, T_n]] = B_0$.

Case II: K is of *characteristic* $p > 0$, and is therefore of the same characteristic as k. Denote by P the prime field $\mathbf{F}_p$, and by $W(P)$ the complete local ring of p-adic numbers $\mathbf{Z}_p$, which is a complete discrete valuation ring (hence *regular*), with P as residue field. Let us first show that there exists a continuous ring homomorphism $W(P) \to A$, thus making A into a $W(P)$-*topological algebra*. Indeed, if $j : \mathbf{Z} \to A$ is the canonical homomorphism, one has $j(p\mathbf{Z}) \subset \mathfrak{m}$ by hypothesis, whence $j^{-1}(\mathfrak{m}) = p\mathbf{Z}$, and j therefore factors as $\mathbf{Z} \to \mathbf{Z}_{p\mathbf{Z}} \xrightarrow{f} A$, where f is a local homomorphism, hence continuous, which (since A is complete) extends by continuity to the desired homomorphism $W(P) \to A$.

As k is a separable extension of P, case I) shows that there is a local homomorphism $W(P) \to W(k)$, where $W(k)$ is a complete local Noetherian ring and a flat $W(P)$-module, such that $W(k) \otimes_{W(P)} P$ is isomorphic to k. Moreover, as the uniformiser p of $W(P)$ is
[$0_{\text{IV-1}}$ | 107] a $W(k)$-regular element by flatness ($\mathbf{0_I}$, 6.3.4), and as $W(k)/pW(k) = k$, the maximal ideal of $W(k)$ is $pW(k)$, which implies that this ring is a *complete discrete valuation ring* (Bourbaki, *Alg. comm.*, chap. VI, § 3, n° 5, prop. 9). By (19.7.1.1) (as k is separable over P, hence a formally smooth P-algebra (19.6.1)), one sees that $W(k)$ is a $W(P)$-algebra *formally smooth*. The continuous $W(P)$-homomorphism $W(k) \to k$ therefore factors as $W(k) \to A \to k$ (19.3.11), which allows us to consider A as a $W(k)$-topological algebra. Applying now case I) to B_0 considered as a P-algebra and to $W(P)$, one sees that there exists a $W(P)$-algebra B_P which is a complete local Noetherian ring, a flat $W(P)$-module, and such that $B_P \otimes_{W(P)} P$ is P-isomorphic to B_0. Using again the fact that $W(k)$ is a $W(P)$-algebra formally smooth, one sees by (19.3.11) that the homomorphism $W(k) \to k \to B_0$ factors as $W(k) \to B_P \to B_0$; moreover, as $k = W(k)/pW(k)$, one has $B_P \otimes_{W(k)} k = B_P/pB_P = B_P \otimes_{W(P)} P = B_0$. Let us show that B_P is a flat $W(k)$-module; as $W(k)$ is a discrete valuation ring with p as uniformiser, it suffices to verify that B_P is a $W(k)$-module *without torsion* ($\mathbf{0_I}$, 6.3.4), or equivalently that p is a B_P-regular element, which follows from the fact that B_P is a flat $W(P)$-module ($\mathbf{0_I}$, 6.3.4).

Set now

$$B = B_P \widehat{\otimes}_{W(k)} A$$

and note that the residue field of A being equal to that of $W(k)$, is *a fortiori* a $W(k)$-module of finite type. It follows first from (19.7.1.2) that B is a complete semi-local Noetherian ring, $\mathfrak{m}B$ is contained in the radical of B; moreover $B/\mathfrak{m}B$ is k-isomorphic to $B_P \otimes_{W(k)} k = B_0$, hence B is in fact a *local* ring. As B_P is a flat $W(k)$-module, (19.7.1.2) shows finally that B is a flat A-module. Q.E.D. □

(19.7.1.4) Lemma. *Let A be a ring, $\mathfrak{J}$ an ideal of A, M, N two A-modules separated for the $\mathfrak{J}$-preadic topology. Suppose further that N is complete for the $\mathfrak{J}$-preadic topology and that M is a flat A-module. Let $u : N \to M$ be an A-homomorphism; if $u \otimes 1 : N \otimes_A (A/\mathfrak{J}) \to M \otimes_A (A/\mathfrak{J})$ is bijective, then u is bijective.*

Proof. The graded modules being taken relative to the $\mathfrak{J}$-preadic filtrations, it follows from the hypotheses on M and N relative to the $\mathfrak{J}$-preadic topologies that it suffices to prove that $\mathrm{gr}(u) : \mathrm{gr}_\bullet(N) \to \mathrm{gr}_\bullet(M)$ is *bijective* (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1). Now, there is a commutative diagram

$$\begin{array}{ccc} \mathrm{gr}_0(N) \otimes_{A_0} \mathrm{gr}_\bullet(A) & \xrightarrow{\mathrm{gr}_0(u)\otimes 1} & \mathrm{gr}_0(M) \otimes_{A_0} \mathrm{gr}_\bullet(A) \\ \downarrow{\scriptstyle \varphi_N} & & \downarrow{\scriptstyle \varphi_M} \\ \mathrm{gr}_\bullet(N) & \xrightarrow[\mathrm{gr}(u)]{} & \mathrm{gr}_\bullet(M) \end{array}$$

where $A_0 = A/\mathfrak{J} = \mathrm{gr}_0(A)$, and φ_M and φ_N are the canonical maps (**0$_{\mathrm{III}}$**, 10.1.1.2). [0$_{\text{IV-1}}$ | 108]
By hypothesis, $\mathrm{gr}_0(u)$ is bijective as well as φ_M (**0$_{\mathrm{III}}$**, 10.2.1), and φ_N is surjective; one deduces first that $\mathrm{gr}_0(u) \otimes 1$ is bijective, then that φ_N is injective, hence bijective, and finally that $\mathrm{gr}(u)$ is bijective. □

(19.7.1.5) Lemma. *Let A be a Noetherian ring, $\mathfrak{J}$ an ideal of A, B, B' two A-algebras that are local Noetherian rings, the homomorphisms $A \to B$, $A \to B'$ being continuous for the $\mathfrak{J}$-preadic topology on A. Suppose that:*

1° *B and B' are complete for the $\mathfrak{J}$-preadic topologies;*

2° *B is a formally smooth A-algebra;*

3° *B' is a flat A-module.*

Set $A_0 = A/\mathfrak{J}$, and let $u_0 : B \otimes_A A_0 \to B' \otimes_A A_0$ be an A_0-isomorphism; then there exists an A-isomorphism $u : B \to B'$ such that $u_0 = u \otimes 1$ (which implies that B' is also a formally smooth A-algebra and B is a flat A-module).

Proof. Set $B_0 = B \otimes_A A_0$, $B'_0 = B' \otimes_A A_0$. Note that if $\mathfrak{m}$ and $\mathfrak{m}'$ are the maximal ideals of B and B', the $\mathfrak{J}$-preadic topologies on B and B' are separated since $\mathfrak{J}B \subset \mathfrak{m}$ and $\mathfrak{J}B' \subset \mathfrak{m}'$; moreover, as $\mathfrak{J}B'$ is closed in B' for the $\mathfrak{J}$-preadic topology, the composite homomorphism $B \to B_0 \xrightarrow{u_0} B'_0$, which is continuous for the $\mathfrak{J}$-preadic topologies, factors as $B \xrightarrow{u} B' \to B'_0$, where u is a continuous A-homomorphism (19.3.10). One has $u_0 = u \otimes 1$, and the hypothesis that u_0 is bijective implies that u is bijective, by virtue of (19.7.1.4). □

(19.7.1.6) *End of the proof of* (19.7.1). — To finish proving (19.7.1), it remains to show that *a*) implies *b*); it is already known that *a*) implies that B_0 is a k-algebra formally smooth (19.3.5), (iii), hence it suffices to prove that B is a flat A-module. It amounts to the same to establish that $\widehat{B}$ is a flat $\widehat{A}$-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4), and one knows that $\widehat{B}$ is an $\widehat{A}$-algebra formally smooth (19.3.6); one can therefore restrict to the case where A and B are *complete*. As B_0 is a k-algebra formally smooth, it is a regular ring (19.6.5) and complete (**0**$_{\mathbf{I}}$, 6.3.5); applying (19.7.1.3), one sees that there exists an A-algebra B' which is a complete local Noetherian ring and a flat A-module, a local homomorphism $A \to B'$, and a k-isomorphism $B_0 \simeq B'_0 = B' \otimes_A k$. It then suffices to apply (19.7.1.5) (taking $\mathfrak{J}$ to be the maximal ideal of A) to obtain that B is A-isomorphic to B', hence is a flat A-module. Q.E.D.

(19.7.2) Theorem. *Let A be a local Noetherian ring, $\mathfrak{J}$ an ideal contained in the maximal ideal of A, $A_0 = A/\mathfrak{J}$, B_0 a complete local Noetherian ring, $A_0 \to B_0$ a local homomorphism making B_0 into a formally smooth A_0-algebra. Then there exists a complete local Noetherian ring B, a local homomorphism $A \to B$ making B into a flat A-module, and an A_0-isomorphism $u : B \otimes_A A_0 \xrightarrow{\sim} B_0$. If (B', u') is a pair satisfying the same conditions as (B, u), there exists an A-isomorphism $v : B \xrightarrow{\sim} B'$ making the diagram*

$$\begin{array}{ccc} B \otimes_A A_0 & \xrightarrow[\sim]{v\otimes 1} & B' \otimes_A A_0 \\ & {\scriptstyle u}\searrow \quad \swarrow{\scriptstyle u'} & \\ & B_0 & \end{array}$$

commutative.

Proof. Let $\mathfrak{m}$ be the maximal ideal of A, so that $\mathfrak{m}_0 = \mathfrak{m}/\mathfrak{J}$ is the maximal ideal of A_0, A and A_0 having the same residue field k. Set $B_{00} = B_0 \otimes_{A_0} k$; as B_{00} is a formally smooth k-algebra (19.3.5), (iii), it is a regular local ring (19.6.5); applying (19.7.1.3), one sees that there exists a topological A-algebra B which is a complete local Noetherian ring, a flat A-module, and for which one has a k-isomorphism $u_{00} : B \otimes_A k \xrightarrow{\sim} B_{00}$. Note that by virtue of (19.7.1), B is a formally smooth A-algebra, hence $B \otimes_A A_0 = B/\mathfrak{J}B$ is a formally smooth A_0-algebra (19.3.5), (iii) and a complete local Noetherian ring; moreover, B_0 is a flat A_0-module by virtue of the hypothesis and of (19.7.1); as one has a k-isomorphism $u_{00} : B \otimes_A k = (B \otimes_A A_0) \otimes_{A_0} k \xrightarrow{\sim} B_0 \otimes_{A_0} k = B_{00}$, one deduces from (19.7.1.5), applied by replacing A by A_0 and $\mathfrak{J}$ by $\mathfrak{m}_0$, that there exists an A_0-isomorphism $u : B \otimes_A A_0 \xrightarrow{\sim} B_0$ such that $u_{00} = u \otimes 1$. As for the uniqueness assertion, note that the ideals $\mathfrak{J}^h B$ (resp. $\mathfrak{J}^h B'$) are closed in B (resp. B') (**0**$_{\mathbf{I}}$, 7.3.5), hence B and B' are separated and complete for the $\mathfrak{J}$-preadic topologies (Bourbaki, *Top. gén.*, chap. III, 3e éd., § 3, n° 5, cor. 2 of prop. 9); one has by hypothesis an A_0-isomorphism $v_0 : B \otimes_A A_0 \xrightarrow{\sim} B' \otimes_A A_0$ such that $u' v_0 = u$; as B is a formally smooth A-algebra and B' a flat A-module, one can apply (19.7.1.5), whence the existence of the A-isomorphism v answering the question. □

[0$_{\text{IV-1}}$ | 109]

(19.7.3) Remarks.

(i) We note that the uniqueness assertion in (19.7.2) is still valid if one only supposes that B and B' are complete *for the $\mathfrak{J}$-preadic topologies*. We do not know whether one can similarly improve the existence assertion, that is, whether one can dispense with assuming the local ring B_0 to be complete (for its $\mathfrak{n}_0$-preadic topology, where $\mathfrak{n}_0$ denotes its maximal ideal) by only requiring that B be complete for the $\mathfrak{J}$-preadic topology. When A_0 is complete for the $\mathfrak{m}$-preadic topology, one can see that this problem reduces to the following: if B_0 is a regular local Noetherian ring

(not necessarily complete) containing the prime field $\mathbf{F}_p = \mathbf{Z}/p\mathbf{Z}$, does there exist for every $n > 1$ a flat $(\mathbf{Z}/p^n\mathbf{Z})$-algebra B such that B/pB is isomorphic to B_0?

(ii) We note that in general, the isomorphism v whose existence is asserted in (19.7.2) is *not unique* (cf. (19.8.7)).

19.8 Cohen algebras and Cohen rings; application to the structure of complete local rings

The results of this section are immediate applications of the theorems of (19.7), but deserve to be stated explicitly because of their practical importance.

(19.8.1) Definition. Let A, B be two local Noetherian rings, $\mathfrak{m}$ the maximal ideal of A, $k = A/\mathfrak{m}$ its residue field, $\varphi : A \to B$ a local homomorphism, making B into an A-algebra. We say that B is a *Cohen A-algebra* if it satisfies the following conditions:

(i) B is a complete ring.

(ii) B is a flat A-module.

(iii) $B \otimes_A k$ is a field (in other words, $\mathfrak{m}B$ is the maximal ideal of B) which is a separable extension of k.

(19.8.2) Theorem. *Let A be a local Noetherian ring, k its residue field.* [$0_{\text{IV-1}}$ | 110]

(i) *If B is a Cohen A-algebra, B is a formally smooth A-algebra. For every complete local Noetherian ring C, every local homomorphism $A \to C$ and every ideal $\mathfrak{J} \neq C$ in C, every A-homomorphism $B \to C/\mathfrak{J}$ therefore factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is an A-homomorphism (necessarily local).*

(ii) *For every field K, separable extension of k, there exists a Cohen A-algebra B such that $B \otimes_A k$ is k-isomorphic to K, and such an A-algebra is unique up to isomorphism.*

Proof. As $B \otimes_A k$ is a separable field extension of k, it is a formally smooth k-algebra (19.6.1), so assertion (i) follows from (19.7.1). To prove (ii), one can restrict to the case where A is *complete*, for it amounts to the same to say that B is a flat A-module or a flat $\widehat{A}$-module ($\mathbf{0_{III}}$, 10.2.3), one has $\mathfrak{m}B = \mathfrak{m}\widehat{A}B$ and k is the residue field of $\widehat{A}$. It then suffices to apply (19.7.2) taking $\mathfrak{J} = \mathfrak{m}$ and $B_0 = K$ (and using (19.6.1)). □

(19.8.3) Definition. A *prime local ring* is a local ring of the form $\mathbf{Z}_{p\mathbf{Z}}$, where $p\mathbf{Z}$ is a prime ideal of $\mathbf{Z}$. A *complete prime local ring* is the completion of a prime local ring.

The prime local rings are therefore of two kinds:

1° Those corresponding to maximal ideals $p\mathbf{Z}$ where $p \neq 0$ is a prime number; $\mathbf{Z}_{p\mathbf{Z}}$ is a discrete valuation ring, whose completion is the ring of p-adic integers usually denoted $\mathbf{Z}_p$.[22]

[22] This notation, now universally used, is in conflict with the notation A_f adopted in ($\mathbf{0_I}$, 1.2.3): with $A = \mathbf{Z}$ and $f = p$, A_f denotes the ring of rational numbers of the form k/p^n ($k \in \mathbf{Z}$, n an integer ≥ 0); we will always avoid using the notation $\mathbf{Z}_p$ to denote this latter ring.

2° For the prime ideal $p\mathbf{Z} = (0)$, $\mathbf{Z}_{p\mathbf{Z}}$ is the field of rational numbers $\mathbf{Q}$, which is identical to its completion (the topology being naturally the topology of a local Noetherian ring, hence discrete here).

The terminology of (19.8.3), analogous to that of "prime fields", is justified in the same way: for every local ring A, consider the canonical homomorphism $\varphi : \mathbf{Z} \to A$, and let $p\mathbf{Z}$ be the inverse image under this homomorphism of the maximal ideal $\mathfrak{m}$ of A; $p\mathbf{Z}$ is a prime ideal of $\mathbf{Z}$ and the preceding homomorphism therefore factors as $\mathbf{Z} \to \mathbf{Z}_{p\mathbf{Z}} \xrightarrow{\psi} A$; moreover, as φ is the *unique* homomorphism of $\mathbf{Z}$ into A, p and ψ are determined in a unique way. In other words, for every local ring A, there is a unique homomorphism $\psi : P \to A$, where P is a prime local ring; if moreover A is separated and complete, one can extend this homomorphism by completion, and there is thus a unique homomorphism $\hat{\psi} : \widehat{P} \to A$, where $\widehat{P}$ is a complete prime local ring. Moreover, ψ gives by passage to quotients a homomorphism of the residue field $\mathbf{F}_p$ if $p > 0$ (resp. $\mathbf{Q}$ if $p = 0$) into the residue field k of A, and p is therefore the *characteristic* of k.

If one takes in particular A to be a prime local ring (resp. complete prime local ring), one sees that there exists in such a ring only *a single endomorphism*, namely the identity.

[$0_{\text{IV-1}}$ | 111] **(19.8.4) Definition.** Let A be a local ring, $P \to A$ the unique homomorphism from a prime local ring P into A, p the characteristic of the residue fields of P and A. We say that A is a *Cohen ring* if it is a Cohen P-algebra, that is (19.8.1), if:

1° A is Noetherian and complete.

2° A is a flat P-module (which also amounts to saying that A is a flat $\widehat{P}$-module (Bourbaki, *Alg. comm.*, chap. III, § 5, n° 4, prop. 4)).

3° A/pA is a field (necessarily separable over the residue field of P, this field being prime).

If $p = 0$, these conditions are equivalent to saying that A is a field of characteristic 0. If $p > 0$, one necessarily has $pA \neq 0$; condition 3° means that pA is the maximal ideal $\mathfrak{m}$ of A; condition 2° means that p is A-regular, since P is a discrete valuation ring ($\mathbf{0}_{\mathbf{I}}$, 6.3.4). Hence A is a regular ring (17.1.1), *d*)) of dimension 1, and therefore a discrete valuation ring, complete by virtue of 1°; in summary:

(19.8.5) Proposition. *The Cohen rings are the fields of characteristic* 0 *and the complete discrete valuation rings whose residue field has characteristic* $p > 0$*, and whose maximal ideal is generated by* $p \cdot 1$ *(*1 *being the unity of the ring).*

We note that in the second case, $p \cdot 1 \neq 0$ since p is A-regular, hence one can identify $p \cdot 1$ with the integer p; the canonical homomorphism $\mathbf{Z}_p \to A$ is injective, and one identifies $p \cdot 1$ with the element p of $\mathbf{Z}_p$; one says in this case that A is a *p-ring* (or *Cohen p-ring*).

(19.8.6) Theorem. (Cohen). —

(i) *Let* W *be a Cohen ring,* C *a complete local Noetherian ring,* $\mathfrak{J}$ *an ideal of* C *distinct from* C*. Then every local homomorphism* $u : W \to C/\mathfrak{J}$ *factors as* $W \xrightarrow{v} C \to C/\mathfrak{J}$ *where* v *is a local homomorphism.*

(ii) *Let* K *be a field. There exists a Cohen ring* W *whose residue field is isomorphic to* K*. If* W' *is a second Cohen ring,* K' *its residue field, every isomorphism* $u : K \xrightarrow{\sim} K'$ *arises by passage to quotients from an isomorphism* $v : W \xrightarrow{\sim} W'$*.*

Proof. This is nothing other than (19.8.2) applied to the case where A is a prime local ring. □

(19.8.7) Remarks.

(i) When K is of characteristic 0, part (ii) of (19.8.6) becomes trivial.

(ii) The homomorphism v of (19.8.6), (i) is *not* necessarily determined uniquely by u, as is shown already by the case where W is a field of characteristic 0, $\mathfrak{J}^2 = 0$ and u is an isomorphism (cf. (21.5.5)). Similarly, in (19.8.6), (ii), the isomorphism v is not necessarily determined uniquely by u (cf. (21.5.5)). However, when K is *perfect* and of characteristic $p > 0$, one will see (21.5.5) that in (19.8.6), (ii) the isomorphism v is unique. One will also see later that in this case W identifies with the ring $W_\infty(K)$ of *Witt vectors of infinite length* over K.

(iii) In (19.8.6), (i), one can weaken the hypotheses on C by using (19.3.10) and (19.3.12).

(19.8.8) Theorem. (Cohen). — *Let A be a complete local Noetherian ring, k its residue field.* *[$0_{IV\text{-}1}$ / 112]*

(i) *There exists a Cohen ring W such that A is isomorphic to a quotient ring of a formal power series ring $W[[T_1, \dots, T_n]]$ (and in particular A is isomorphic to a quotient of a complete regular local ring (17.3.8)). If A contains a field, it is isomorphic to a quotient ring of $k[[T_1, \dots, T_n]]$.*

(ii) *Suppose moreover that A is an integral domain. Then there exists a subring B of A such that: 1° B is isomorphic to a formal power series ring over a ring C which is a field or a Cohen ring (which implies that B is a complete regular local ring (17.3.8)); 2° B has the same residue field as A and the injection $B \to A$ is a local homomorphism; 3° A is a finite B-algebra.*

Proof. Let $\mathfrak{m}$ be the maximal ideal of A. There exists a Cohen ring W whose residue field is isomorphic to k (19.8.6), (ii); one therefore has a homomorphism $W \to A/\mathfrak{m}$, which then factors as $W \xrightarrow{u} A \to A/\mathfrak{m}$, where u is a local homomorphism (19.8.6), (i). For every finite family $(x_i)_{1 \leq i \leq n}$ of elements of $\mathfrak{m}$, there then exists a local homomorphism $v : W[[T_1, \dots, T_n]] \to A$ extending u and such that $v(T_i) = x_i$ for all i (Bourbaki, *Alg. comm.*, chap. III, § 4, n° 5, prop. 6). When A contains a field, it contains a prime field P, of which k is an extension (necessarily separable), and therefore A contains a field isomorphic to k (19.6.2); one can then replace W by k in the preceding definition of v.

(i) Let us first take the x_i to be a system of generators of $\mathfrak{m}$. As W has the same residue field as A, and the classes of the x_i generate the graded ring $\mathrm{gr}_\bullet(A)$ as a k-algebra, $\mathrm{gr}(v) : \mathrm{gr}_\bullet(W[[T_1, \dots, T_n]]) \to \mathrm{gr}_\bullet(A)$ is surjective; one deduces that v is itself surjective (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 2 of th. 1). We recall that the case where A contains a field has already been seen and is included here only for convenience (19.6.3).

(ii) If A contains a field, it contains a field k' isomorphic to k as we have seen; one then considers a system of parameters $(y_j)_{1 \leq j \leq m}$ of A (16.3.6), one takes $B = k[[T_1, \dots, T_m]]$ and one considers the local homomorphism $w : B \to A$ which coincides in k with an isomorphism $k \to k'$ and is such that $w(T_j) = y_j$ for $1 \leq j \leq m$. If A does not contain a

field, the unique homomorphism $\mathbf{Z}_{p\mathbf{Z}} \to A$ (19.8.3) is necessarily injective (for otherwise, as A is an integral domain, its kernel would be the maximal ideal of $\mathbf{Z}_{p\mathbf{Z}}$ and its image would be isomorphic to a field; moreover one has $p > 0$ by hypothesis, $\mathbf{Z}_{p\mathbf{Z}}$ being a field if $p = 0$); the element $p \cdot 1$ of A (identified with p) is a non-zero-divisor in A, and is contained in $\mathfrak{m}$, hence (16.3.4) and (16.3.7) there exists a family $(z_i)_{1\leq i\leq m-1}$ which, with p, forms a system of parameters of A. The Cohen ring W considered at the beginning of the proof is then a discrete valuation ring whose residue field is isomorphic to k, in which p generates the maximal ideal (19.8.5), and the homomorphism $u : W \to A$ defined at the beginning maps p to itself. One then takes $B = W[[T_1, \ldots, T_{m-1}]]$ and considers the local homomorphism $w : B \to A$ which coincides with u in W and is such that $w(T_i) = z_i$
[$0_{\text{IV-1}}$ | 113] for $1 \leq i \leq m-1$. In both cases, if $\mathfrak{n}$ is the maximal ideal of B, it is clear that $\mathfrak{n}A$ is an ideal of definition of A; as moreover $B/\mathfrak{n}$ and $A/\mathfrak{m}$ are isomorphic, A is a quasi-finite B-module ($\mathbf{0_I}$, 7.4.4), hence a B-module of finite type since B is complete and A is separated for the $\mathfrak{n}$-preadic topologies ($\mathbf{0_I}$, 7.4.1). On the other hand, in both cases one has $\dim(B) = \dim(A) = m$; in the first case, this follows from (17.1.4), (iii); in the second, one sees directly that p and the T_i $(1 \leq i \leq m-1)$ form a B-regular sequence generating $\mathfrak{n}$, or one can also use the fact that these elements generate $\mathfrak{n}$ and that $\dim(B) \geq \dim(A)$ by (16.3.10). As A and B are integral domains, one finally deduces from (16.3.10) that w is injective, which completes the proof. □

(19.8.9) Corollary. *Let A be a complete local Noetherian integral domain containing a field k_0; let k be the residue field of A, and suppose that k is finite over k_0. Then, in the conclusion of (19.8.8), (ii), one can replace 1° and 2° by the condition that B is of the form $k_0[[T_1, \ldots, T_n]]$, the canonical injection $B \to A$ being a local k_0-homomorphism (for the usual k_0-algebra structure of B).*

Proof. Indeed, taking up the proof of (19.8.8), (ii), one defines this time $w : k_0[[T_1, \ldots, T_n]] \to A$ as coinciding in k_0 with the identity and mapping T_j to y_j for $1 \leq j \leq n$. The hypothesis that k is of finite degree over k_0 again implies that A is a quasi-finite B-module, hence of finite type by ($\mathbf{0_I}$, 7.4.1), and one concludes as in (19.8.8). □

(19.8.10) Corollary. *Let A be a local Artinian ring whose maximal ideal $\mathfrak{m}$ is of square zero; then there exists a regular local Noetherian ring B, with maximal ideal $\mathfrak{n}$, such that A is isomorphic to $B/\mathfrak{n}^2$.*

Proof. Let K be the residue field $A/\mathfrak{m}$ of A, and n the rank of $\mathfrak{m}/\mathfrak{m}^2 = \mathfrak{m}$ over K. If A contains a field, it follows from (19.6.3) that A is isomorphic to $B/\mathfrak{b}$, where $B = K[[T_1, \ldots, T_n]]$ and $\mathfrak{b}$ is contained in the square of the maximal ideal $\mathfrak{n}$ of B; but as $\operatorname{long}(B/\mathfrak{n}^2) = n + 1 = \operatorname{long}(A)$, one necessarily has $\mathfrak{b} = \mathfrak{n}^2$.

Suppose next that A does not contain a field; this implies that K is of characteristic $p > 0$ and that $p \cdot 1 \neq 0$ in A (19.6.3); hence $p \cdot 1$ is an element of $\mathfrak{m}$, and there are therefore $n-1$ other elements x_i $(2 \leq i \leq n)$ of $\mathfrak{m}$ forming with $p \cdot 1$ a basis of $\mathfrak{m}$ over K. Let W be a Cohen ring whose residue field is isomorphic to K; W is a discrete valuation ring in which p generates the maximal ideal; one has seen in the proof of (19.8.8) that there is a homomorphism $u : W \to A$ mapping p to itself and which by passage to quotients gives the identity on K. One takes $B = W[[T_2, \ldots, T_n]]$ and considers the local homomorphism $w : B \to A$ which coincides with u in W and is such that $w(T_i) = x_i$ for $2 \leq i \leq n$. It is clear that w is surjective and that its kernel $\mathfrak{b}$ is contained in the square of the maximal

ideal $\mathfrak{n} = pB + BT_2 + \ldots + BT_n$ of B; as $\log(B/\mathfrak{n}^2) = n + 1 = \log(A)$, one again has $\mathfrak{b} = \mathfrak{n}^2$. □

(19.8.11) Proposition. *Let A be a local Artinian ring, $\mathfrak{m}$ its maximal ideal, k its residue field. For A to be isomorphic to a quotient ring of a Cohen ring, it is necessary and sufficient that $\mathfrak{m}$ be generated by $p \cdot 1$, where p is the characteristic of k.*

Proof. The condition is evidently necessary (19.8.5). To see that it is sufficient, one observes, as at the beginning of the proof of (19.8.8), that there exists a Cohen ring W whose residue field is isomorphic to k and a local homomorphism $u : W \to A$. Moreover, if one considers the composite homomorphism $\mathbf{Z}_{p\mathbf{Z}} \to W \xrightarrow{u} A$ (which is necessarily the unique homomorphism of $\mathbf{Z}_{p\mathbf{Z}}$ into A), one sees that the image under u of the element $p \cdot 1$ of W is the element $p \cdot 1$ of A; as the element $p \cdot 1$ of W generates the maximal ideal of this ring, one deduces immediately from the hypothesis that $\mathrm{gr}(u) : \mathrm{gr}_\bullet(W) \to \mathrm{gr}_\bullet(A)$ is surjective, and therefore so is u (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 2 of th. 1). □ [$0_{\text{IV-1}}$ | 114]

19.9 Relatively formally smooth algebras

(19.9.1) Definition. Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. We say that B is a *formally smooth A-algebra relative to Λ* if, for every discrete topological A-algebra C, and every nilpotent ideal $\mathfrak{J}$ of C, every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.

It follows from this definition that if B is a *formally smooth* A-algebra, then B is also formally smooth relative to Λ, for every structure of topological Λ-algebra defined on A (in other words, every continuous ring homomorphism $\Lambda \to A$).

(19.9.2) Proposition. *Let Λ be a topological ring, A a topological Λ-algebra.*

(i) *A is a Λ-algebra formally smooth relative to Λ.*

(ii) *If B is an A-algebra formally smooth relative to Λ and C is a B-algebra formally smooth relative to Λ, then C is an A-algebra formally smooth relative to Λ.*

(iii) *Let B be an A-algebra formally smooth relative to Λ, A' a topological A-algebra, then the topological A'-algebra $B \otimes_A A'$ is formally smooth relative to Λ.*

(iv) *Let B be a topological A-algebra, S (resp. T) a multiplicative subset of A (resp. B) such that the canonical image of S in B is contained in T. If B is an A-algebra formally smooth relative to Λ, then $T^{-1}B$ is an $S^{-1}A$-algebra formally smooth relative to Λ.*

(v) *Let B_i ($1 \leq i \leq n$) be topological A-algebras. For $\prod_{i=1}^n B_i$ to be an A-algebra formally smooth relative to Λ, it is necessary and sufficient that each of the B_i be so.*

Proof. Assertion (i) is trivial, and the proof of the others closely follows the proofs of (19.3.5); it is therefore left to the reader. □

(19.9.3) Corollary. *Let A be a topological ring, A' and B two topological A-algebras. Then the topological A-algebra $B' = B \otimes_A A'$ is a B-algebra formally smooth relative to A.*

Proof. This follows from (19.9.2), (i) and (iii). □

(19.9.4) Proposition. *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. The following conditions are equivalent:*

a) *B is an A-algebra formally smooth relative to Λ.*

b) *$\widehat{B}$ is an A-algebra formally smooth relative to Λ.*

c) *$\widehat{B}$ is an $\widehat{A}$-algebra formally smooth relative to Λ.*

d) *$\widehat{B}$ is an $\widehat{A}$-algebra formally smooth relative to $\widehat{\Lambda}$.*

Proof. The proof is again left to the reader, modelled on that of (19.3.6). □

[$0_{\text{IV-1}}$ | 115] **(19.9.5)** Similarly, the statement (19.3.8) is still valid (with the same proof) when one replaces "formally smooth" by "formally smooth relative to Λ". If in the statement of (19.3.10) one replaces "formally smooth" by "formally smooth relative to Λ", the conclusion is replaced by the following (the proof remaining essentially unchanged): *every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism.*

(19.9.6) The criteria for formal smoothness (19.4.1) and (19.4.2) are also valid when one replaces "formally smooth" by "formally smooth relative to Λ", the proofs remaining practically unchanged.

(19.9.7) Proposition. *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. Suppose that for every discrete A-algebra C and every ideal $\mathfrak{J}$ of C such that $\mathfrak{J}^2 = 0$, every continuous A-homomorphism $u_0 : B \to C/\mathfrak{J}$ which factors as $B \xrightarrow{u} C \to C/\mathfrak{J}$, where u is a continuous Λ-homomorphism, also factors as $B \xrightarrow{v} C \to C/\mathfrak{J}$, where v is a continuous A-homomorphism. Then B is an A-algebra formally smooth relative to Λ.*

Proof. The proof of (19.4.3) transcribes immediately. □

(19.9.8) Proposition. *Let Λ be a topological ring, A a topological Λ-algebra, B a topological A-algebra. For B to be an A-algebra formally smooth relative to Λ, it is necessary and sufficient that for every discrete topological B-module L, annihilated by an open ideal of B, one has (cf. 18.4.2)*

$$\mathrm{Exalcotop}_{A/\Lambda}(B, L) = 0.$$

Proof. Using the notation of the proof of (19.4.4), it suffices to note here that one can suppose that the extension E_Λ of B_Λ is Λ-trivial; the rest of the proof is then unchanged. □

When Λ, A and B are discrete rings, the criterion (19.9.8) reduces to

$$\mathrm{Exalcom}_{A/\Lambda}(B, L) = 0 \quad \text{for every } B\text{-module } L; \tag{19.9.8.1}$$

in other words, *every commutative A-extension of B by a B-module, which is also Λ-trivial, is also A-trivial.*

19.10 Formally unramified algebras and formally étale algebras

(19.10.1) We will also need two notions closely related to that of a formally smooth algebra.

(19.10.2) Definition. Let A be a topological ring, B a topological A-algebra. We say that B is a *formally unramified* A-algebra if, for every A-homomorphism $p : E \to C$ of discrete A-algebras, whose kernel is nilpotent, and every continuous A-homomorphism $u : B \to C$, there exists *at most one* continuous A-homomorphism $v : B \to E$ such that u factors as $B \xrightarrow{v} E \xrightarrow{p} C$. We say that B is a *formally étale* A-algebra if it is formally smooth and formally unramified, in other words, if, for every surjective A-homomorphism $p : E \to C$ of discrete A-algebras, whose kernel is nilpotent, and for every continuous A-homomorphism $u : B \to C$, there exists *one and only one* continuous A-homomorphism $v : B \to E$ such that u factors as $B \xrightarrow{v} E \xrightarrow{p} C$.

(19.10.3) Examples. We restrict here to *discrete* rings. [$0_{\text{IV-1}}$ | 116]

(i) If the structural homomorphism $\rho : A \to B$ is *surjective*, B is a *formally unramified* A-algebra, for with the notation of (19.10.2), the composite homomorphism $A \xrightarrow{\rho} B \xrightarrow{v} E$ must be the structural homomorphism, hence v is unique (if it exists). On the other hand, B is formally smooth if and only if $\ker(\rho) = \ker(\rho)^2$.

(ii) Let A be a ring, S a multiplicative subset of A; then $B = S^{-1}A$ is a *formally étale* A-algebra. Indeed, let $j : A \to B$ be the canonical homomorphism, $\rho : A \to E$ a ring homomorphism, $\mathfrak{J}$ a nilpotent ideal of E, $p : E \to C = E/\mathfrak{J}$ the canonical homomorphism. If $u : B \to C$ is an A-homomorphism, $u(s/1)$ is invertible in C for $s \in S$ since $s/1$ is invertible in B; but $u(s/1) = p(\rho(s))$, and as $\mathfrak{J}$ is nilpotent, the fact that the image of $\rho(s)$ in $E/\mathfrak{J}$ is invertible implies that $\rho(s)$ is itself invertible in E ($\mathbf{0_I}$, 7.1.12); one concludes that ρ factors in a unique way as $A \xrightarrow{j} B \xrightarrow{v} E$, and one evidently has $u \circ j = (p \circ v) \circ j$, whence $u = p \circ v$, which proves our assertion.

(iii) A finite separable extension k' of a field k is a formally smooth k-algebra (19.6.1); we will see later that for a *finite type* extension K of a field k to be a formally étale k-algebra, it is necessary and sufficient that it be formally unramified, and this is also equivalent to K being a finite and separable extension of k (21.7.4).

(iv) A polynomial algebra $A[X_\alpha]_{\alpha \in I}$ over a ring A is *formally smooth* (19.3.3) but *not formally étale* if I is non-empty, as follows immediately from the definitions.

(19.10.4) Remark. The same reasoning as in (19.4.3) shows that in order to verify that a topological A-algebra B is formally unramified, one can, in the definition (19.10.2), restrict to the case where the kernel of $p : E \to C$ is of *square zero*; one can moreover restrict to the case where $u(B) \subset p(E)$ (for otherwise there is no v factoring u) and, replacing C by $u(B)$ and E by $p^{-1}(u(B))$, suppose u and p *surjective*.

§20 Derivations and differentials

[$0_{\text{IV-1}}$ | 116] The notions introduced in this section will be taken up again in geometric form in chapter IV, § 16, and will play an important role in the study of preschemes. Their importance in this chapter stems first from their relations with the notion of a formally smooth algebra, and in particular from the theorems (20.4.9), (20.5.7) and (20.5.12), which will be translated into geometric language in the section of chapter IV devoted to smooth morphisms, and are in constant use in the applications. On the other hand, the differential notions will serve to prove in § 22 important criteria for regularity which will play an essential role in the detailed study of Noetherian local rings made in § 7 of chapter IV.

20.1 Derivations and algebra extensions

[$0_{\text{IV-1}}$ | 117] **(20.1.1) Proposition.** *Let A be a ring (not necessarily commutative), B, E, C A-rings, $p : E \to C$ an A-homomorphism whose kernel $\mathfrak{Q}$ is of square zero, $u : B \to C$ an A-homomorphism. Suppose that there exists an A-homomorphism $v_0 : B \to E$ such that u factors as $B \xrightarrow{v_0} E \xrightarrow{p} C$. Then the set of A-homomorphisms $v : B \to E$ such that $u = p \circ v$ is identical to the set of maps $v_0 + D$, where $D : B \to \mathfrak{Q}$ is a map satisfying the two following conditions:*

(i) *D is a homomorphism of A-bimodules.*

(ii) *For all f, g in B, one has*

$$D(fg) = f.D(g) + D(f).g. \tag{20.1.1.1}$$

Proof. To say that $p(v(f)) = p(v_0(f))$ for $f \in B$ means that $D(f) = v(f) - v_0(f)$ belongs to $\mathfrak{Q}$; if one writes $v(fg) = v(f)v(g)$, one obtains the relation (20.1.1.1), $\mathfrak{Q}$ being of square zero, and condition (i) follows from the fact that v and v_0 are A-homomorphisms.

If $\rho : A \to B$ is the structural homomorphism, one deduces from (20.1.1.1) that one has $D(\rho(a)f) = \rho(a)D(f) + D(\rho(a))f$ for all $a \in A$; but one must also have $D(\rho(a)f) = \rho(a)D(f)$ by (i), hence, setting $f = 1$, one obtains

$$D(\rho(a)) = 0 \qquad \text{for} \quad a \in A;$$

conversely, if D is null on $\rho(A)$ and satisfies (20.1.1.1), it also satisfies (i). □

(20.1.2) Definition. Given an A-ring B and a B-bimodule L, we call an *A-derivation* of B into L a map $D : B \to L$ satisfying conditions (i) and (ii) of (20.1.1).

It follows from (20.1.1) that the kernel of an A-derivation $D : B \to L$ is a sub-A-ring of B.

One sometimes calls a *derivation* of B into L a $\mathbf{Z}$-derivation, that is, an additive map of B into L satisfying (20.1.1.1); one then has $D(1) = 0$ for such a map. If B is an algebra over a *prime field* P, every $\mathbf{Z}$-derivation of B is a P-derivation: this is evident from the above if P is of characteristic > 0, and otherwise, the relation $n \cdot n^{-1} = 1$ for $n \in \mathbf{Z} - \{0\}$ gives

$$nD(n^{-1}) = 0$$

hence $D(n^{-1}) = 0$ since P is of characteristic 0.

It follows immediately from the definition (20.1.2) that if D, D' are two A-derivations of B into L, then so is $D - D'$. In other words, the set of A-derivations of B into L is endowed with a structure of *additive group*; we denote this group $\mathrm{Der}_A(B, L)$. If A is

commutative, B a commutative A-*algebra*, and L a B-module, then, for every A-derivation D of B into L and every $b \in B$, bD is again an A-derivation of B into L, in other words $\mathrm{Der}_A(B, L)$ is then endowed with a structure of B-*module*.
Proposition (20.1.1) can be interpreted in the following way: [$0_{\text{IV-1}}$ | 118]

(20.1.3) Corollary. *Given two A-homomorphisms of A-rings $p : E \to C$, $u : B \to C$ where the first has kernel $\mathfrak{Q}$ of square zero, the set of A-homomorphisms $v : B \to E$ such that $u = p \circ v$ is either empty or a principal homogeneous space for the group $\mathrm{Der}_A(B, \mathfrak{Q})$.*

In particular:

(20.1.4) Corollary. *Let A be a ring, C an A-ring, L a C-bimodule, E an A-extension of C by L, $p : E \to C$ the augmentation. The map which, to every derivation $D \in \mathrm{Der}_A(C, L)$, associates the map $x \mapsto x + D(p(x))$ is an isomorphism of the group $\mathrm{Der}_A(C, L)$ onto the group of A-equivalences of E with itself.*

Proof. Apply (20.1.1) for $B = E$, $v_0 = \mathrm{I}_E$: the set of A-homomorphisms $v : E \to E$ such that $p \circ v = p$ is identical to the set of maps $v = \mathrm{I}_E + D'$, where $D' \in \mathrm{Der}_A(E, L)$. To say that such an A-homomorphism v is an A-equivalence amounts to saying that v restricts to the canonical injection on L, or equivalently that $D'(x) = 0$ in L; but this also means that D' factors as $E \xrightarrow{p} C \xrightarrow{D} L$, where D is an A-derivation. Whence the corollary. □

For trivial extensions, (20.1.3) gives:

(20.1.5) Corollary. *Let A be a ring, B, C two A-rings, L a C-bimodule, $u : B \to C$ an A-homomorphism; the map which, to every derivation $D \in \mathrm{Der}_A(B, L)$, associates the map $\alpha : x \mapsto (u(x), D(x))$ is a bijection onto the set of A-homomorphisms $v : B \to D_C(L)$ (cf. 18.2.3) such that u factors as $B \xrightarrow{v} D_C(L) \to C$.*

More particularly:

(20.1.6) Corollary. *Let A be a ring, B an A-ring, L a B-bimodule. If, to every derivation $D \in \mathrm{Der}_A(B, L)$, one associates: 1° the A-equivalence $(x, y) \mapsto (x, y + D(x))$ of the extension $D_B(L)$ with itself; 2° the A-homomorphism $x \mapsto (x, D(x))$ of B into $D_B(L)$, inverse on the right of the augmentation homomorphism $D_B(L) \to B$; one defines canonical bijections between:*

(i) *the set $\mathrm{Der}_A(B, L)$;*

(ii) *the set of A-equivalences of $D_B(L)$ with itself;*

(iii) *the set of A-homomorphisms inverse on the right of the augmentation homomorphism $D_B(L) \to B$.*

We note that the bijection thus established between (i) and (ii) respects the group structures, and that the bijection between (ii) and (iii) is none other than the bijection already defined in (18.3.8).

(20.1.7) Corollary. *Let A be a ring, C an A-ring, L a C-bimodule, E a trivial A-extension of C by L, $p : E \to C$ the augmentation. The set of A-derivations D of E into L such that $D(x) = x$ in L is identical to the set of maps $x \mapsto x - w(p(x))$, where w runs through the set of A-homomorphisms inverse on the right of p.*

Proof. It suffices to apply (20.1.1) for $B = E$, $v_0 = \mathrm{I}_E$; if $v = \mathrm{I}_E - D$, the condition $D(x) = x$ for $x \in L$ is equivalent to $v(x) = 0$ for $x \in L$, that is, $v = w \circ p$, where $w : C \to E$ is an A-homomorphism; the condition $p \circ v = p$ then gives $p \circ w = \mathrm{I}_C$, i.e., w is inverse on the right of p. □

20.2 Functorial properties of derivations

[$0_{\text{IV-1}}$ | 119] **(20.2.1)** Let A be a ring, B an A-ring, L a B-bimodule; if L' is a second B-bimodule and $w : L \to L'$ a homomorphism of B-bimodules, it is clear that the map $D \mapsto w \circ D$ is a homomorphism of additive groups

$$w_0 : \mathrm{Der}_A(B, L) \to \mathrm{Der}_A(B, L') \tag{20.2.1.1}$$

and if $w' : L' \to L''$ is a second homomorphism of B-bimodules, one has $(w' \circ w)_0 = w'_0 \circ w_0$. When A is commutative, B a commutative A-algebra and L a B-module, (20.2.1.1) is a homomorphism of B-*modules*.

In the second place, let B' be an A-ring, $v : B' \to B$ an A-homomorphism which makes L into a B'-bimodule; then the map $D \mapsto D \circ v$ is a homomorphism of additive groups,

$$v^0 : \mathrm{Der}_A(B, L) \to \mathrm{Der}_A(B', L) \tag{20.2.1.2}$$

as follows from (20.1.1.1); if $v' : B'' \to B'$ is a second A-homomorphism, one has $(v \circ v')^0 = v'^0 \circ v^0$. When A, B and B' are commutative and L a B-module, (20.2.1.2) is a homomorphism of B-modules.

Finally, let $u : A' \to A$ be a ring homomorphism making B into an A'-ring; every A-derivation $D \in \mathrm{Der}_A(B, L)$ is also an A'-derivation, whence a canonical injection of groups

$$u^0 : \mathrm{Der}_A(B, L) \to \mathrm{Der}_{A'}(B, L) \tag{20.2.1.3}$$

and if $u' : A'' \to A'$ is a second ring homomorphism, one has $(u \circ u')^0 = u'^0 \circ u^0$; when A, A' and B are commutative and L a B-module, (20.2.1.3) is a homomorphism of B-modules.

One can also say that

$$(A, B, L) \rightsquigarrow \mathrm{Der}_A(B, L)$$

is a *covariant functor* from the category $\boldsymbol{K}$ defined in (18.3.5) into the category $\boldsymbol{Ab}$ of commutative groups, by associating to every triplet (u, v, w) constituting a morphism of $\boldsymbol{K}$ the homomorphism $w_0 \circ v^0 \circ u^0$; the verification of the functoriality follows from the commutativity of the diagrams

$$\begin{array}{ccc} \mathrm{Der}_A(B, L) & \xrightarrow{v^0} & \mathrm{Der}_A(B', L) \\ {\scriptstyle w_0}\downarrow & & \downarrow{\scriptstyle w_0} \\ \mathrm{Der}_A(B, L') & \xrightarrow{v^0} & \mathrm{Der}_A(B', L') \end{array} \qquad \begin{array}{ccc} \mathrm{Der}_A(B, L) & \xrightarrow{u^0} & \mathrm{Der}_{A'}(B, L) \\ {\scriptstyle w_0}\downarrow & & \downarrow{\scriptstyle w_0} \\ \mathrm{Der}_A(B, L') & \xrightarrow{u^0} & \mathrm{Der}_{A'}(B, L') \end{array}$$

for every homomorphism $w : L \to L'$ of B-bimodules.

[$0_{\text{IV-1}}$ | 120] **(20.2.2) Theorem.** *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms, L a C-bimodule. There is a canonical exact sequence of commutative groups*

$$0 \to \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \tag{20.2.2.1}$$
$$\to \mathrm{Exan}_B(C, L) \xrightarrow{u^1} \mathrm{Exan}_A(C, L) \xrightarrow{v^1} \mathrm{Exan}_A(B, L)$$

where u^0, v^0 are the homomorphisms (20.2.1.3) and (20.2.1.2) respectively, u^1, v^1 are the homomorphisms defined in (18.3.4.1) and (18.3.3.1) respectively, and where ∂ is defined as follows: for every A-derivation D of B into L, $\partial(D)$ is the class of the B-extension of C by L defined by the A-homomorphism $\alpha : x \mapsto (v(x), D(x))$ (cf. (20.1.5)). Moreover, the exact sequence (20.2.2.1) is functorial in L (for the homomorphisms defined in (20.2.1.1) and (18.3.1.1) respectively).

Proof. As D is an A-derivation (and *a fortiori* a $\mathbf{Z}$-derivation) of B into L, the A-homomorphism $\alpha : x \mapsto (v(x), D(x))$ indeed defines on $D_C(L)$ a structure of B-extension, hence $\partial(D)$ is well defined (20.1.5). We must verify the exactness at the 5 places:

1) The exactness at $\mathrm{Der}_B(C, L)$ is trivial (cf. (20.2.1)).

2) By definition (20.2.1) the kernel of v^0 is the set of A-derivations of C which vanish on $v(B)$, that is, those which are also B-derivations; whence the exactness at $\mathrm{Der}_A(C, L)$.

3) The kernel of ∂ is formed of the derivations $D \in \mathrm{Der}_A(B, L)$ for which the B-extension defined by $\alpha : x \mapsto (v(x), D(x))$ is B-trivial; this means (18.2.3) that there exists a B-homomorphism $z \mapsto (z, w(z))$ of C into $D_C(L)$ (the structure of B-ring of $D_C(L)$ being defined by α); but such a homomorphism, being *a fortiori* an A-homomorphism, is of the form $z \mapsto (z, D'(z))$ where $D' \in \mathrm{Der}_A(C, L)$ (20.1.6); and writing that this is a B-homomorphism, we get

$$D(x)z + v(x)D'(z) = D'(v(x)z) = v(x)D'(z) + D'(v(x))z$$

for $x \in B$, $z \in C$, which gives $D'(v(x)) = D(x)$; the kernel of ∂ is therefore the image of v^0.

4) The kernel of u^1 is the set of classes of B-extensions of C by L which are A-trivial, hence (up to equivalence) of the form $D_C(L)$, where the structure of A-ring of $D_C(L)$ is defined by the homomorphism $t \mapsto (v(u(t)), 0)$. Now, every structure of B-extension on $D_C(L)$ is defined by a homomorphism $\alpha : x \mapsto (v(x), D(x))$, where D is a $\mathbf{Z}$-derivation of B into L (20.1.5); to say that the structure of A-ring of this B-extension is deduced from its structure of B-ring by means of $u : A \to B$ means that $D(u(t)) = 0$ for $t \in A$, hence that D is an A-derivation, or equivalently that the class of the B-extension considered is of the form $\partial(D)$; whence the exactness at $\mathrm{Exan}_B(C, L)$.

5) The kernel of v^1 is the set of classes of A-extensions E of C by L which trivialise on $v(B)$, that is, for which there is an A-homomorphism $w : B \to E$ such that v factors as $B \xrightarrow{w} E \to C$; now such an A-homomorphism defines on E a structure of B-extension whose class has as its image under u^1 the class of the given A-extension; the converse being trivially true, this proves the exactness at $\mathrm{Exan}_A(C, L)$.

Finally, the functoriality in L follows trivially from the definitions. □

(20.2.3) Corollary. *Let A, B, C be three commutative rings, $u : A \to B$, $v : B \to C$ two ring homomorphisms, L a C-module. There is a canonical exact sequence of A-modules* [$0_{\text{IV-1}}$ | 121]

$$0 \to \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \tag{20.2.3.1}$$
$$\to \mathrm{Exalcom}_B(C, L) \xrightarrow{u^1} \mathrm{Exalcom}_A(C, L) \xrightarrow{v^1} \mathrm{Exalcom}_A(B, L)$$

functorial in L.

Proof. The reasoning is the same as in (20.2.2) once one has verified that for every derivation $D \in \mathrm{Der}_A(B, L)$, $\partial(D)$ is indeed the class of a B-extension of C by L which is a commutative B-algebra; but this follows immediately from the commutativity of C and from the fact that L is a C-module. □

(20.2.4) Corollary. *Under the hypotheses of (20.2.2) (resp. (20.2.3)), there is a canonical exact sequence, functorial in L,*

$$0 \to \mathrm{Der}_B(C, L) \xrightarrow{u^0} \mathrm{Der}_A(C, L) \xrightarrow{v^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \mathrm{Exan}_{B/A}(C, L) \to 0 \tag{20.2.4.1}$$

(*resp.*

$$0 \to \mathrm{Der}_B(C,L) \xrightarrow{u^0} \mathrm{Der}_A(C,L) \xrightarrow{v^0} \mathrm{Der}_A(B,L) \xrightarrow{\partial} \mathrm{Exalcom}_{B/A}(C,L) \to 0). \quad (20.2.4.2)$$

This follows from the definition of $\mathrm{Exan}_{B/A}(C,L)$ (*resp.* $\mathrm{Exalcom}_{B/A}(C,L)$) (*(18.3.7) and (18.4.2)*).

(20.2.5) Remark. Suppose that one has a commutative diagram of ring homomorphisms

$$\begin{array}{ccccc} A & \longrightarrow & B & \longrightarrow & C \\ \uparrow & & \uparrow & & \uparrow \\ A' & \longrightarrow & B' & \longrightarrow & C' \end{array}$$

Then there is a commutative diagram

$$\begin{array}{ccccccccc} 0 \to \mathrm{Der}_B(C,L) & \longrightarrow & \mathrm{Der}_A(C,L) & \longrightarrow & \mathrm{Der}_A(B,L) & \xrightarrow{\partial} & \mathrm{Exan}_B(C,L) & \longrightarrow & \mathrm{Exan}_A(C,L) \longrightarrow \mathrm{Exan}_A(B,L) \\ \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \quad\quad \downarrow \\ 0 \to \mathrm{Der}_{B'}(C',L) & \to & \mathrm{Der}_{A'}(C',L) & \to & \mathrm{Der}_{A'}(B',L) & \xrightarrow{\partial} & \mathrm{Exan}_{B'}(C',L) & \to & \mathrm{Exan}_{A'}(C',L) \to \mathrm{Exan}_{A'}(B',L) \end{array}$$

and similarly for the exact sequences (20.2.3.1), (20.2.4.1) and (20.2.4.2).

20.3 Continuous derivations in topological rings

(20.3.1) Given two topological rings A, B (linearly topologised, as always), we will denote by Hom. $\mathrm{cont}(A,B)$ the set of continuous homomorphisms from A to B. Given a topological ring A, the category of topological A-rings is defined as that of A-rings (18.1.4) by replacing throughout "ring" by "topological ring" and "homomorphism" by "continuous homomorphism"; if B
[$0_{\text{IV-1}}$ | 122] and C are two topological A-rings, we denote Hom. $\mathrm{cont}_A(B,C)$ the set of continuous A-homomorphisms from B to C.

Let A be a topological ring, B a topological A-ring, L a topological B-bimodule; we denote Dér. $\mathrm{cont}_A(B,L)$ the set of *continuous* A-derivations of B into L; it is clear that this is a *subgroup* of $\mathrm{Der}_A(B,L)$ (and a sub-A-module when A and B are commutative and L a B-module).

(20.3.2) It is immediate that the proposition (20.1.1) remains valid when one replaces "ring" by "topological ring" and "homomorphism" by "continuous homomorphism". Similarly, (20.1.3) and (20.1.4) remain valid by replacing Der by Dér. cont, "ring" (resp. "bimodule") by "topological ring" (resp. "topological bimodule"), "homomorphism" by "continuous homomorphism"; one must naturally suppose in (20.1.4) that p is continuous, and replace "A-equivalences" by "continuous A-equivalences". One has the same results for (20.1.5) and (20.1.6), provided one takes as topology on $D_C(L)$ (resp. $D_B(L)$) the product topology (on $C \times L$, resp. $B \times L$).

(20.3.3) Proposition. *Let A be a topological ring, B a topological A-ring, L a discrete topological B-bimodule annihilated by an open bilateral ideal of B. If in B the square of every open bilateral ideal is open, one has* Dér. $\mathrm{cont}_A(B,L) = \mathrm{Der}_A(B,L)$.

Proof. Indeed, if $\mathfrak{R}$ is an open bilateral ideal of B annihilating L, and D an A-derivation of B into L, one has $D(\mathfrak{R}^2) \subset \mathfrak{R}.D(\mathfrak{R}) + D(\mathfrak{R}).\mathfrak{R} = 0$ (20.1.1.1), hence D is continuous. □

(20.3.4) All the results of (20.2.1) remain valid when one replaces "ring" by "topological ring", "bimodule" by "topological bimodule", "homomorphism" by "continuous homomorphism" and Der by Dér. cont.

(20.3.5) Proposition. *Let A be a topological ring, B a topological A-ring, L a discrete topological B-bimodule annihilated by an open bilateral ideal of B. There is then a canonical isomorphism*

$$\varinjlim \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \xrightarrow{\sim} \text{Dér. } \mathrm{cont}_A(B, L) \tag{20.3.5.1}$$

where in the first member the inductive limit is taken over the ordered filtered set of pairs $(\mathfrak{J}, \mathfrak{R})$ of bilateral ideals such that $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{J}.B \subset \mathfrak{R}$, $B.\mathfrak{J} \subset \mathfrak{R}$.

Proof. As $A/\mathfrak{J}$ and $B/\mathfrak{R}$ are discrete, one has canonical homomorphisms $w_{\mathfrak{J},\mathfrak{R}} : \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \text{Dér. } \mathrm{cont}_A(B, L)$ forming an inductive system (20.3.4), whence the homomorphism (20.3.5.1) by passage to the inductive limit. As the homomorphism $B/\mathfrak{R}' \to B/\mathfrak{R}$ is surjective for $\mathfrak{R} \supset \mathfrak{R}'$, it follows immediately from the definition that the homomorphism $\mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}', L)$ (with $\mathfrak{R}.L = L.\mathfrak{R} = 0$, $\mathfrak{J}.B \subset \mathfrak{R}'$, $B.\mathfrak{J} \subset \mathfrak{R}'$) is injective, and it follows similarly that the homomorphism $\mathrm{Der}_{A/\mathfrak{J}}(B/\mathfrak{R}, L) \to \mathrm{Der}_{A/\mathfrak{J}'}(B/\mathfrak{R}, L)$ for $\mathfrak{J}' \subset \mathfrak{J}$ (20.2.1) is injective; one concludes that the homomorphism (20.3.5.1) is injective. On the other hand, if D is a continuous A-derivation of B into L, its kernel contains an open bilateral ideal $\mathfrak{R}_0$ of B, and if $\mathfrak{J}_0$ is an open bilateral ideal of A such that $\mathfrak{J}_0 B \subset \mathfrak{R}_0$ and $B\mathfrak{J}_0 \subset \mathfrak{R}_0$, it is clear that D is the canonical image of an $(A/\mathfrak{J}_0)$-derivation of $B/\mathfrak{R}_0$ into L, hence (20.3.5.1) is surjective. □

(20.3.6) Proposition. *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings, L a discrete C-bimodule annihilated by an open bilateral ideal of C. There is a canonical exact sequence* [0IV-1 | 123]

$$\begin{aligned} 0 \to \text{Dér. } \mathrm{cont}_B(C, L) \xrightarrow{u^0} \text{Dér. } \mathrm{cont}_A(C, L) \xrightarrow{v^0} \text{Dér. } \mathrm{cont}_A(B, L) \xrightarrow{\partial} \\ \to \mathrm{Exantop}_B(C, L) \xrightarrow{u^1} \mathrm{Exantop}_A(C, L) \xrightarrow{v^1} \mathrm{Exantop}_A(B, L) \end{aligned} \tag{20.3.6.1}$$

where ∂ is defined by passage to the inductive limit from the homomorphism ∂ of (20.2.2.1); this exact sequence is functorial in L (in the category of discrete C-bimodules annihilated by open bilateral ideals).

Proof. This follows from the exactness of the functor $\varinjlim$, from (20.2.2). □

(20.3.7) Corollary. *Let A, B, C be three commutative topological rings, $u : A \to B$, $v : B \to C$ two continuous homomorphisms, L a discrete C-module annihilated by an open ideal of C. There is a canonical exact sequence of A-modules, functorial in L,*

$$\begin{aligned} 0 \to \text{Dér. } \mathrm{cont}_B(C, L) \xrightarrow{u^0} \text{Dér. } \mathrm{cont}_A(C, L) \xrightarrow{v^0} \text{Dér. } \mathrm{cont}_A(B, L) \xrightarrow{\partial} \\ \to \mathrm{Exalcotop}_B(C, L) \xrightarrow{u^1} \mathrm{Exalcotop}_A(C, L) \xrightarrow{v^1} \mathrm{Exalcotop}_A(B, L). \end{aligned} \tag{20.3.7.1}$$

(20.3.8) Corollary. *Under the hypotheses of (20.3.6) (resp. (20.3.7)) there is a canonical exact sequence, functorial in L*

$$0 \to \text{Dér. } \mathrm{cont}_B(C, L) \xrightarrow{u^0} \text{Dér. } \mathrm{cont}_A(C, L) \xrightarrow{v^0} \text{Dér. } \mathrm{cont}_A(B, L) \to \mathrm{Exantop}_{B/A}(C, L) \to 0 \tag{20.3.8.1}$$

(*resp.*

$$0 \to \text{Dér. } \mathrm{cont}_B(C,L) \xrightarrow{u^0} \text{Dér. } \mathrm{cont}_A(C,L) \xrightarrow{v^0} \text{Dér. } \mathrm{cont}_A(B,L) \to \mathrm{Exalcotop}_{B/A}(C,L) \to 0). \tag{20.3.8.2}$$

We leave to the reader the task of writing the diagrams analogous to those of (20.2.5).

20.4 Principal parts and differentials

In the remainder of this section and in the three following sections, all rings are assumed *commutative*.

(20.4.1) Let A be a topological ring, B a topological A-algebra; the A-algebra $B \otimes_A B$ will be equipped with the *tensor product* topology, which in fact makes it into a topological A-algebra; we denote by p (or $p_{B/A}$) the surjective continuous A-homomorphism

$$p : B \otimes_A B \to B \tag{20.4.1.1}$$

such that $p(b \otimes b') = bb'$; it is immediate that p is continuous. The *kernel* of p will be denoted $\mathfrak{J}_{B/A}$ (or simply $\mathfrak{J}$ if there is no risk of confusion). We denote by $j_1 : B \to B \otimes_A B$ and $j_2 : B \to B \otimes_A B$ the two canonical A-homomorphisms, such that

$$j_1(b) = b \otimes 1, \qquad j_2(b) = 1 \otimes b$$

which are continuous.

[$0_{\text{IV-1}}$ | 124] **(20.4.2) Definition.** The *augmented B-algebra of principal parts of order* 1 of B over A is the topological A-algebra quotient

$$\mathrm{P}^1_{B/A} = (B \otimes_A B)/\mathfrak{J}^2 \tag{20.4.2.1}$$

equipped with the structure of B-algebra defined by the homomorphism $\bar{j}_1 : B \to \mathrm{P}^1_{B/A}$ (deduced from j_1 by composition with the canonical map $B \otimes_A B \to \mathrm{P}^1_{B/A}$), and with the augmentation of B-algebra $\varepsilon : \mathrm{P}^1_{B/A} \to B$ (also denoted $\varepsilon_{B/A}$) deduced from p by passage to the quotient. As $p(b \otimes 1) = b$ by definition, it is clear that ε is indeed an augmentation of B-algebra.

(20.4.3) Definition. The kernel of the augmentation $\varepsilon : \mathrm{P}^1_{B/A} \to B$,

$$\Omega^1_{B/A} = \mathfrak{J}_{B/A}/(\mathfrak{J}_{B/A})^2 \tag{20.4.3.1}$$

equipped with the topology induced by that of $\mathrm{P}^1_{B/A}$, which in fact makes it into a topological B-module, is called the B-module of 1-*differentials* (or simply *differentials*) of B over A.

We note that the topology of $\Omega^1_{B/A}$ is also the quotient topology of the topology induced on $\mathfrak{J}_{B/A}$ by that of $B \otimes_A B$ (Bourbaki, *Top. gén.*, chap. III, 3e éd., § 2, n° 7, prop. 20). If B is discrete it follows that so is $\Omega^1_{B/A}$. We denote $\widehat{\Omega}^1_{B/A}$ the *separated completion* of the topological B-module $\Omega^1_{B/A}$.

Every topological ring B can be considered as a topological $\mathbf{Z}$-algebra (where $\mathbf{Z}$ is equipped with the discrete topology), so one can define the topological B-module $\Omega^1_{B/\mathbf{Z}}$, which is sometimes also called the B-module of *absolute differentials* over B and which one denotes Ω^1_B. If B is a topological algebra over a prime field P (discrete), one has $B \otimes_P B = B \otimes_{\mathbf{Z}} B$, hence $\Omega^1_{B/P} = \Omega^1_B$.

(20.4.4) Lemma. *Let A be a ring, B an A-algebra. The ideal $\mathfrak{J}_{B/A}$ of $B \otimes_A B$ is generated by the elements $1 \otimes s - s \otimes 1$, where s runs through a set of generators of the A-algebra B.*

Proof. It is clear that for every $x \in B$, one has $x \otimes 1 - 1 \otimes x \in \mathfrak{J}$; on the other hand, for all x, y in B, one has $x \otimes y = xy \otimes 1 + (x \otimes 1)(1 \otimes y - y \otimes 1)$. If $\sum_i (x_i \otimes y_i) \in \mathfrak{J}$, one has by definition $\sum_i x_i y_i = 0$, hence

$$\sum_i (x_i \otimes y_i) = \sum_i (x_i \otimes 1)(1 \otimes y_i - y_i \otimes 1) \tag{20.4.4.1}$$

which proves that $\mathfrak{J}$ is generated by the elements $1 \otimes x - x \otimes 1$. Moreover, if $x = st$, one has

$$x \otimes 1 - 1 \otimes x = (s \otimes 1)(t \otimes 1 - 1 \otimes t) + (s \otimes 1 - 1 \otimes s)(1 \otimes t) \tag{20.4.4.2}$$

which immediately completes the proof by induction. □

(20.4.5) Proposition. *Let A be a topological ring, B a topological A-algebra. The topology of $\Omega^1_{B/A}$ is less fine than the topology deduced from that of B (19.0.2); if in B the square of every open ideal is open, these two topologies are identical.*

Proof. The first assertion is trivial, the tensor product topology on $B \otimes_A B$ being less fine than the topology deduced from that of B; *a fortiori* the topology induced on $\mathfrak{J} = \mathfrak{J}_{B/A}$ by that of $B \otimes_A B$ is less fine than the topology on $\mathfrak{J}$ deduced from that of B. To prove the second assertion, write, by abuse of notation, $M \otimes N$ for the submodule $\mathrm{Im}(M \otimes_A N)$ for two sub-A-modules M, N of B. Using the relation [$0_{\text{IV-1}}$ | 125]

$$\begin{aligned}(xy) \otimes z - x \otimes (yz) &= (x \otimes 1)(1 \otimes z)(y \otimes 1 - 1 \otimes y) \\ &= xz \cdot (y \otimes 1 - 1 \otimes y) \\ &\quad - x \cdot (z \otimes 1 - 1 \otimes z)(y \otimes 1 - 1 \otimes y)\end{aligned}$$

in the B-module $B \otimes_A B$ (defined by j_1), and taking into account (20.4.4), one sees immediately that, if $\mathfrak{R}$ is an ideal of B, one has

$$((\mathfrak{R}^2 \otimes B) + (B \otimes \mathfrak{R}^2)) \cap \mathfrak{J} \subset (\mathfrak{R} \otimes \mathfrak{R}) \cap \mathfrak{J} + \mathfrak{R}\mathfrak{J} + \mathfrak{J}^2.$$

On the other hand, if x_i, y_i are elements of $\mathfrak{R}$ such that $\sum_i (x_i \otimes y_i) \in \mathfrak{J}$, it follows from (20.4.4.1) that $\sum_i (x_i \otimes y_i) \in \mathfrak{R}\mathfrak{J}$, and hence finally

$$(\mathfrak{R}^2 \otimes B + B \otimes \mathfrak{R}^2) \cap \mathfrak{J} \subset \mathfrak{R}\mathfrak{J} + \mathfrak{J}^2. \tag{20.4.5.1}$$

Now, there is a fundamental system of neighbourhoods of 0 in $\mathfrak{J}$ (for the topology induced by that of $B \otimes_A B$) obtained by taking for neighbourhoods of 0 the sets $(\mathfrak{R} \otimes B + B \otimes \mathfrak{R}) \cap \mathfrak{J}$, where $\mathfrak{R}$ runs through the set of open ideals. As the topology of $\Omega^1_{B/A}$ deduced from that of B is also the quotient by $\mathfrak{J}^2$ of the topology of $\mathfrak{J}$ deduced from that of B, the hypothesis on the open ideals of B and the relation (20.4.5.1) complete the proof of the second assertion. □

(20.4.6) Definition. Let p_1 and p_2 be the composite maps $B \xrightarrow{j_1} B \otimes_A B \to \mathrm{P}^1_{B/A}$, $B \xrightarrow{j_2} B \otimes_A B \to \mathrm{P}^1_{B/A}$, which are continuous A-homomorphisms such that $\varepsilon \circ p_1 = \varepsilon \circ p_2 = \mathrm{I}_B$. The continuous A-module homomorphism

$$d_{B/A} = p_1 - p_2 : B \to \Omega^1_{B/A} \tag{20.4.6.1}$$

is called the *exterior differential* of B relative to A; for every $x \in B$, $d_{B/A}(x)$ (also denoted $d(x)$ or dx) is called the *differential* of x (relative to A).

When $A = \mathbf{Z}$, one writes d_B instead of $d_{B/\mathbf{Z}}$; if B is an algebra over a prime field P, one has $d_B = d_{B/P}$.

(20.4.7) Proposition. *The B-module $\Omega^1_{B/A}$ is generated by the elements $d_{B/A}(x)$, where x runs through a system of generators of the A-algebra B.*

Proof. As $d_{B/A}(x)$ is the canonical image of $x \otimes 1 - 1 \otimes x$ in $\Omega^1_{B/A}$, the proposition is an immediate consequence of (20.4.4). □

(20.4.8) Theorem. *Let A be a topological ring, B a topological A-algebra.*

(i) *There exists a unique isomorphism of augmented topological B-algebras*

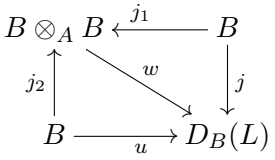
$$\varphi : \mathrm{P}^1_{B/A} \xrightarrow{\sim} D_B(\Omega^1_{B/A}) \tag{20.4.8.1}$$

which reduces to the identity on $\Omega^1_{B/A}$.

(ii) *The homomorphism $d_{B/A}$ is an A-derivation of B into $\Omega^1_{B/A}$, having the following universal property: for every topological B-module L, the map $u \mapsto u \circ d_{B/A}$ is an isomorphism of A-modules*

$$\text{Hom. cont}_B(\Omega^1_{B/A}, L) \xrightarrow{\sim} \text{Dér. cont}_A(B, L). \tag{20.4.8.2}$$

Proof. [0IV-1 | 126] (i) It is immediate that φ (using the notation of (20.4.6)) is necessarily the map $z \mapsto (\varepsilon(z), z - p_1(\varepsilon(z)))$, and the inverse isomorphism the map $(b, x) \mapsto p_1(b) + x$; these two maps being continuous, this proves the first assertion. We note that the topology of B identifies (by p_1) with the *quotient* of the topology of $B \otimes_A B$ by $\mathfrak{J}_{B/A}$.



(ii) The fact that $d_{B/A}$ is an A-derivation of B follows from the definition (20.4.6) and from (20.1.1).

To prove the universal property, recall that Dér. $\mathrm{cont}_A(B, L)$ identifies canonically with the set G of continuous A-algebra homomorphisms $u : B \to D_B(L)$ such that the composite $B \xrightarrow{u} D_B(L) \xrightarrow{q} B$ is the identity (where $q(b, x) = b$ is the projection; cf. (20.1.6) and (20.3.2)). On the other hand, by virtue of the isomorphism φ, Hom. $\mathrm{cont}_B(\Omega^1_{B/A}, L)$ identifies canonically with the set of continuous B-algebra homomorphisms $v : \mathrm{P}^1_{B/A} \to D_B(L)$ such that the composite $\mathrm{P}^1_{B/A} \xrightarrow{v} D_B(L) \xrightarrow{q} B$ is the augmentation ε. As $p_2 = p_1 - d_{B/A}$ by definition, it suffices to prove that every $u \in G$ factors as

$$\begin{array}{ccc} B & \xrightarrow{u} & D_B(L) \\ {\scriptstyle p_2}\downarrow & \nearrow_{v} & \\ \mathrm{P}^1_{B/A} & & \end{array}$$

where v is a continuous B-homomorphism. Now, one already has a continuous A-algebra homomorphism $j : b \mapsto (b, 0)$ from B into $D_B(L)$, which belongs to G; by definition of

the topological tensor product of topological algebras (**0**$_{\mathbf{I}}$, 7.7.6), there therefore exists a continuous A-algebra homomorphism $w : B \otimes_A B \to D_B(L)$ making the diagram

commutative. One therefore has by definition $w(b \otimes 1 - 1 \otimes b) = j(b) - u(b) \in L$, and by virtue of (20.4.4), this implies $w(\mathfrak{J}) \subset L$, hence $w(\mathfrak{J}^2) = 0$; w therefore factors as $B \otimes_A B \to \mathrm{P}^1_{B/A} \xrightarrow{v} D_B(L)$, where v is a continuous A-algebra homomorphism; moreover, as $v \circ p_1 = j$ is a homomorphism of B-algebras, v is a B-algebra homomorphism by the definition of the B-algebra structure of $\mathrm{P}^1_{B/A}$; as one has by definition $u = v \circ p_2$, this completes the proof. □

(20.4.9) Theorem. *Suppose that B is a topological A-algebra formally smooth. Then the topological B-module $\Omega^1_{B/A}$ is* formally projective.

Proof. Indeed, the hypothesis implies that $B \otimes_A B$ (equipped with the B-algebra structure defined by j_1) is a topological B-algebra formally smooth (19.3.5), (iii), and therefore also a topological A-algebra formally smooth (19.3.5), (ii); as B is topologically isomorphic to the A-algebra quotient $(B \otimes_A B)/\mathfrak{J}$ and is a formally smooth A-algebra, the conclusion follows from (19.5.3). □

(20.4.10) Corollary. *Suppose moreover that in B the square of every open ideal is open; then, for every open ideal $\mathfrak{R}$ of B, $\Omega^1_{B/A} \otimes_B (B/\mathfrak{R}) = \Omega^1_{B/A}/\mathfrak{R}.\Omega^1_{B/A}$ is a projective $(B/\mathfrak{R})$-module.* [0$_{\text{IV-1}}$ | 127]

Proof. Indeed, the topology of $\Omega^1_{B/A}$ is then deduced from that of B (20.4.5), and it suffices to apply (19.2.4). □

(20.4.11) Corollary. *Let A, B be two local Noetherian rings, $\rho : A \to B$ a local homomorphism, making B a topological A-algebra formally smooth (for the preadic topologies). Then, for every ideal of definition $\mathfrak{b}$ of B, $\Omega^1_{B/A} \otimes_B (B/\mathfrak{b})$ is a* free $(B/\mathfrak{b})$*-module.*

Proof. Indeed, it follows from (20.4.10) that this module is projective, and as $B/\mathfrak{b}$ is an Artinian ring, every projective $(B/\mathfrak{b})$-module is free (**0**$_{\mathbf{III}}$, 10.1.3). □

(20.4.12) Proposition. *Let A be a topological ring, B a topological A-algebra. If the structural homomorphism $A \to B$ is surjective, one has $\Omega^1_{B/A} = 0$.*

Proof. Indeed, one has $\mathrm{Der}_A(B, L) = 0$ for every B-module L by virtue of (20.1.1), and the proposition follows immediately from (20.4.8). □

(20.4.13) Examples.

(i) Let A be a ring, $B = A[X_\alpha]_{\alpha\in I}$ a polynomial algebra over A. Then $\Omega^1_{B/A}$ is a free B-module, of which the dX_α form a *basis*. Indeed, the dX_α generate this B-module (20.4.7). On the other hand, if L is a free B-module with basis $(z_\alpha)_{\alpha\in I}$ whose index set I is the same, there exists an A-homomorphism u of B into $D_B(L)$ such that $u(X_\alpha) = (X_\alpha, z_\alpha)$ for every $\alpha \in I$, hence (20.1.5) a derivation D of B into L such that $D(X_\alpha) = z_\alpha$ for every α; by virtue of (20.4.8.1), this proves that the dX_α are linearly independent.

(ii) Let A be a ring, L an A-module, and B the square-zero A-algebra $D_A(L)$. For every B-module M, restriction to L identifies $\mathrm{Der}_A(B, M)$ with the A-linear maps $u : L \to M$ such that

$$(0, x)u(y) + (0, y)u(x) = 0 \quad \text{for all } x, y \in L.$$

Consequently, $\Omega^1_{B/A}$ has the presentation

$$B \otimes_A (L \otimes_A L) \longrightarrow B \otimes_A L \longrightarrow \Omega^1_{B/A} \longrightarrow 0,$$

where the first arrow sends $b \otimes (x \otimes y)$ to $b((0, x) \otimes y + (0, y) \otimes x)$ and the second sends $b \otimes x$ to $b\, d_{B/A}(0, x)$.

(iii) Suppose that B is the product of two topological A-algebras B_1, B_2 (identified with ideals of B). Then the images of $B_1 \otimes_A B_2$ and $B_2 \otimes_A B_1$ by the homomorphism p (20.4.1.1) are zero, whence it follows immediately that $\mathrm{P}^1_{B/A}$ identifies with the *product* (topological) $\mathrm{P}^1_{B_1/A} \times \mathrm{P}^1_{B_2/A}$, and that the B-module $\Omega^1_{B/A}$ is the *direct sum* (topological) of the B-modules $\Omega^1_{B_1/A}$ and $\Omega^1_{B_2/A}$ (annihilated by B_2 and B_1 respectively).

(iv) Let A, B be two integral domains such that $A \subset B$, B integral over A, and the field of fractions of B a *separable* extension of that of A. Then the B-module $\Omega^1_{B/A}$ is a *torsion* module. Indeed, for every $x \in B$, let f be the minimal polynomial of x over the field of fractions K of A; there exists a nonzero $a \in A$ such that $af[T] \in A[T]$; as x is separable over K, one has $f'(x) \neq 0$, and on the other hand from the relation $af(x) = 0$ one deduces that $af'(x)d_{B/A}x = 0$, whence our assertion by virtue of (20.4.7).

(20.4.14) Remarks.

(i) We note that the B-module $\Omega^1_{B/A}$, stripped of its topology, is independent of the topologies of A and of B.

(ii) We will introduce later the "algebra of principal parts of order n" of B over A, $\mathrm{P}^n_{B/A} = (B \otimes_A B)/(\mathfrak{J}_{B/A})^{n+1}$, which is the basis of the "differential calculus of order n".

20.5 Fundamental functorial properties of $\Omega^1_{B/A}$

[$0_{\text{IV-1}}$ | 128] **(20.5.1)** In this section and the following, unless expressly stated otherwise, all rings and modules considered are assumed equipped with the *discrete* topology.

(20.5.2) Let A be a ring, B, C two A-algebras, $u : B \to C$ an A-homomorphism; there is a commutative diagram

$$\begin{array}{ccc} B \otimes_A B & \xrightarrow{u \otimes u} & C \otimes_A C \\ {\scriptstyle p_{B/A}}\downarrow & & \downarrow{\scriptstyle p_{C/A}} \\ B & \xrightarrow{u} & C \end{array} \tag{20.5.2.1}$$

whence by passage to quotients, an A-homomorphism of algebras

$$u' : \mathrm{P}^1_{B/A} \to \mathrm{P}^1_{C/A} \tag{20.5.2.2}$$

such that the diagram

$$\begin{array}{ccc} \mathrm{P}^1_{B/A} & \xrightarrow{u'} & \mathrm{P}^1_{C/A} \\ {\scriptstyle p_1}\uparrow & & \uparrow{\scriptstyle p_1} \\ B & \xrightarrow{u} & C \end{array}$$

is commutative; as $u \otimes u$ maps $\mathfrak{J}_{B/A}$ into $\mathfrak{J}_{C/A}$, one obtains, by restricting u' to $\Omega^1_{B/A}$, a map

$$u'' : \Omega^1_{B/A} \to \Omega^1_{C/A} \tag{20.5.2.3}$$

such that the pair (u'', u) is a *di-homomorphism* for the B-module structure of $\Omega^1_{B/A}$ and the C-module structure of $\Omega^1_{C/A}$; this last fact allows one to deduce canonically a *homomorphism of C-modules*

$$u_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}. \tag{20.5.2.4}$$

Moreover, as the diagram [$0_{\text{IV-1}}$ | 129]

$$\begin{array}{ccc} \mathrm{P}^1_{B/A} & \xrightarrow{u'} & \mathrm{P}^1_{C/A} \\ {\scriptstyle p_2}\uparrow & & \uparrow{\scriptstyle p_2} \\ B & \xrightarrow{u} & C \end{array} \tag{20.5.2.5}$$

is also commutative, one deduces that the diagram

$$\begin{array}{ccc} \Omega^1_{B/A} & \xrightarrow{u''} & \Omega^1_{C/A} \\ {\scriptstyle d_{B/A}}\uparrow & & \uparrow{\scriptstyle d_{C/A}} \\ B & \xrightarrow{u} & C \end{array} \tag{20.5.2.6}$$

is commutative. Finally, if $w : C \to D$ is a second homomorphism of A-algebras, one has the transitivity property

$$(w \circ u)_{D/B/A} = w_{D/C/A} \circ (u_{C/B/A} \otimes \mathrm{I}_D) \tag{20.5.2.7}$$

as follows from the definition.

(20.5.3) Let now A, B be two rings, $v : A \to B$ a homomorphism of rings, C a B-algebra which becomes an A-algebra by means of v; then the canonical map $v_0 : C \otimes_A C \to C \otimes_B C$ is a surjective *di-homomorphism* of algebras (relative to $v : A \to B$) such that the diagram

$$\begin{array}{ccc} C \otimes_A C & \xrightarrow{v_0} & C \otimes_B C \\ {\scriptstyle p_{C/A}}\downarrow & & \downarrow{\scriptstyle p_{C/B}} \\ C & \xrightarrow{\mathrm{I}_C} & C \end{array} \tag{20.5.3.1}$$

is commutative; by passage to quotients, one deduces a di-homomorphism of algebras

$$v' : \mathrm{P}^1_{C/A} \to \mathrm{P}^1_{C/B} \tag{20.5.3.2}$$

such that the diagram

$$\begin{array}{ccc} \mathrm{P}^1_{C/A} & \xrightarrow{v'} & \mathrm{P}^1_{C/B} \\ {\scriptstyle p_1}\uparrow & & \uparrow{\scriptstyle p_1} \\ C & \xrightarrow{\mathrm{I}_C} & C \end{array}$$

is commutative. As v_0 maps $\mathfrak{J}_{C/A}$ into $\mathfrak{J}_{C/B}$, one obtains, by restricting v' to $\Omega^1_{C/A}$, a map

$$v_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B} \tag{20.5.3.3}$$

[$0_{\text{IV-1}}$ | 130] which is a *homomorphism of C-modules*. Moreover, since the diagram

$$\begin{array}{ccc} \mathrm{P}^1_{C/A} & \xrightarrow{v'} & \mathrm{P}^1_{C/B} \\ {\scriptstyle p_2}\uparrow & & \uparrow{\scriptstyle p_2} \\ C & \xrightarrow{\mathrm{I}_C} & C \end{array} \tag{20.5.3.4}$$

is commutative, it follows that the diagram

$$\begin{array}{ccc} \Omega^1_{C/A} & \xrightarrow{v_{C/B/A}} & \Omega^1_{C/B} \\ {\scriptstyle d_{C/A}}\uparrow & & \uparrow{\scriptstyle d_{C/B}} \\ C & \xrightarrow{\mathrm{I}_C} & C \end{array} \tag{20.5.3.5}$$

is commutative. Finally, if $s : A' \to A$ is a second ring homomorphism, one has the transitivity property

$$(v \circ s)_{C/B/A'} = v_{C/B/A} \circ s_{C/A/A'}. \tag{20.5.3.6}$$

(20.5.4) If now one has a commutative diagram of ring homomorphisms

$$\begin{array}{ccc} B & \xrightarrow{v} & B' \\ {\scriptstyle f}\uparrow & & \uparrow{\scriptstyle g} \\ A & \xrightarrow{u} & A' \end{array}$$

one deduces from (20.5.2.4) and (20.5.3.3), by composition, a homomorphism of B'-modules

$$\Omega^1_{B/A} \otimes_B B' \xrightarrow{v_{B'/B/A}} \Omega^1_{B'/A} \xrightarrow{u_{B'/A'/A}} \Omega^1_{B'/A'} \tag{20.5.4.1}$$

such that the diagram of A-homomorphisms

$$\begin{array}{ccc} \Omega^1_{B/A} \otimes_B B' & \longrightarrow & \Omega^1_{B'/A'} \\ {\scriptstyle x \mapsto d_{B/A}x \otimes 1}\uparrow & & \uparrow{\scriptstyle d_{B'/A'}} \\ B & \xrightarrow{v} & B' \end{array} \tag{20.5.4.2}$$

is commutative. The homomorphism (20.5.4.1) corresponds moreover to a di-homomorphism of B-modules

$$\Omega^1_{B/A} \to \Omega^1_{B'/A'}. \tag{20.5.4.3}$$

(20.5.5) Proposition. *If A', B are two A-algebras and $B' = B \otimes_A A'$, the canonical homomorphism (20.5.4.1)*

$$\Omega^1_{B/A} \otimes_B B' \to \Omega^1_{B'/A'} \tag{20.5.5.1}$$

is bijective.

Proof. The first member of (20.5.5.1) is none other than $\Omega^1_{B/A} \otimes_A A'$. One can write $B' \otimes_{A'} B' = (B \otimes_A B) \otimes_A A'$ up to canonical isomorphism, and $p_{B'/A'}$ then identifies with $p_{B/A} \otimes \mathrm{I}_{A'}$; hence (as $p_{B/A}$ is surjective) $\mathfrak{J}_{B'/A'} = \mathrm{Im}(\mathfrak{J}_{B/A} \otimes_A A')$ and $\mathfrak{J}^2_{B'/A'} = \mathrm{Im}(\mathfrak{J}^2_{B/A} \otimes_A A')$, whence $\mathrm{P}^1_{B'/A'} = \mathrm{P}^1_{B/A} \otimes_A A'$ up to canonical isomorphism, which transforms the augmentation ideals into each other; as the A-module $\mathrm{P}^1_{B/A}$ identifies canonically with the direct sum of B and $\Omega^1_{B/A}$, one has [0IV-1 | 131]

$$\Omega^1_{B/A} \otimes_A A' = \Omega^1_{B'/A'} \tag{20.5.5.2}$$

by the same isomorphism, and one verifies immediately that the composite of this isomorphism and the canonical isomorphism $\Omega^1_{B/A} \otimes_B B' \xrightarrow{\sim} \Omega^1_{B/A} \otimes_A A'$ is none other than (20.5.5.1). □

(20.5.6) The canonical homomorphisms (20.5.2.4) and (20.5.3.3) give, by functoriality, for every C-module L, canonical homomorphisms

$$\mathrm{Hom}_C(\Omega^1_{C/A}, L) \to \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) = \mathrm{Hom}_B(\Omega^1_{B/A}, L) \tag{20.5.6.1}$$

$$\mathrm{Hom}_C(\Omega^1_{C/B}, L) \to \mathrm{Hom}_C(\Omega^1_{C/A}, L). \tag{20.5.6.2}$$

In view of (20.4.8.2) and of the commutative diagrams (20.5.2.6) and (20.5.3.5), these homomorphisms are none other (up to canonical identification) than the homomorphisms (20.2.1.2) and (20.2.1.3) respectively.

(20.5.7) Theorem. *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms.*

(i) *The sequence of C-modules*

$$\Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \to 0 \tag{20.5.7.1}$$

is exact.

(ii) *For $v_{C/B/A}$ to be left-invertible, it is necessary and sufficient that C be a B-algebra formally smooth relative to A (for the discrete topologies (cf. (19.9.1))); in particular, it suffices that C be a B-algebra formally smooth (for the discrete topologies).*

Proof. (i) The exactness of the sequence (20.2.4.2) shows, taking into account (20.5.6), that the sequence

$$0 \to \mathrm{Hom}_C(\Omega^1_{C/B}, L) \to \mathrm{Hom}_C(\Omega^1_{C/A}, L) \to \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L)$$

is exact for every C-module L. It is known that this implies the exactness of the sequence (20.5.7.1) (Bourbaki, *Alg.*, chap. II, 3e éd., § 2, n° 1, th. 1).

(ii) By virtue of the exactness of (20.5.7.1), to say that $v_{C/B/A}$ is left-invertible means that the sequence

$$0 \to \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \to 0 \tag{20.5.7.2}$$

is *exact and split*; it is known (Bourbaki, *loc. cit.*, n° 1, prop. 1) that this is equivalent to saying that for every C-module L, the sequence

$$0 \to \mathrm{Hom}_C(\Omega^1_{C/B}, L) \to \mathrm{Hom}_C(\Omega^1_{C/A}, L) \to \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) \to 0$$

is exact; taking into account (20.5.6) and (20.2.4.2), this condition is equivalent to

$$\mathrm{Exalcom}_{B/A}(C, L) = 0$$

for every C-module L, and the conclusion follows from (19.9.8.1). □

[$0_{\text{IV-1}}$ | 132] We note moreover that if one has a commutative diagram of ring homomorphisms

$$\begin{array}{ccccc} A' & \longrightarrow & B' & \longrightarrow & C' \\ \uparrow & & \uparrow & & \uparrow \\ A & \longrightarrow & B & \longrightarrow & C \end{array}$$

one deduces a commutative diagram

$$\begin{array}{ccccccc} \Omega^1_{B/A} \otimes_B C & \longrightarrow & \Omega^1_{C/A} & \longrightarrow & \Omega^1_{C/B} & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ \Omega^1_{B'/A'} \otimes_{B'} C' & \longrightarrow & \Omega^1_{C'/A'} & \longrightarrow & \Omega^1_{C'/B'} & \longrightarrow & 0 \end{array} \tag{20.5.7.3}$$

where the vertical arrows come from the di-homomorphisms (20.5.4.3).

(20.5.8) Corollary. *Suppose that the homomorphism $v : B \to C$ makes C into a B-algebra formally étale (for the discrete topologies (19.10.2)); then the homomorphism (20.5.2.4)*

$$v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$$

is bijective.

Proof. Indeed, if C is a B-algebra formally unramified for the discrete topologies, it follows from (19.10.4), (20.4.8) and (20.1.1) that one has $\mathrm{Hom}_C(\Omega^1_{C/B}, L) = 0$ for *every* C-module L, hence $\Omega^1_{C/B} = 0$ (cf. (20.7.4)); on the other hand, if C is a B-algebra formally smooth for the discrete topologies, the sequence (20.5.7.2) is exact; whence the corollary. □

(20.5.9) Corollary. *Let A be a ring, B an A-algebra, S a multiplicative subset of B; then the canonical homomorphism*

$$S^{-1}\Omega^1_{B/A} \to \Omega^1_{S^{-1}B/A} \tag{20.5.9.1}$$

is bijective.

Proof. It suffices to apply (20.5.8) to $C = S^{-1}B$, which is a B-algebra formally étale for the discrete topologies (19.10.3), (ii). □

Taking into account (20.5.5), one can therefore write

$$\Omega^1_{S^{-1}B/S^{-1}A} = S^{-1}\Omega^1_{B/A} = \Omega^1_{S^{-1}B/A}, \tag{20.5.9.2}$$

up to canonical isomorphisms.

(20.5.10) Corollary. *If k is a field and $K = k(X_\alpha)_{\alpha\in I}$ a pure transcendental extension of k, the dX_α form a basis of the K-vector space $\Omega^1_{K/k}$.*

Proof. As K is the field of fractions of the polynomial ring $k[X_\alpha]_{\alpha\in I}$, this follows from (20.4.13), (i) and (20.5.9). □

(20.5.11) Let A be a ring, B an A-algebra, $\mathfrak{R}$ an ideal of B, C the A-algebra quotient $B/\mathfrak{R}$, and consider the composite homomorphism of A-modules [$0_{\text{IV-1}}$ | 133]

$$\delta : \mathfrak{R} \to B \xrightarrow{d_{B/A}} \Omega^1_{B/A} \tag{20.5.11.1}$$

where the first arrow is the canonical injection; as $d(xy) = xdy + ydx$, we see that $\delta(\mathfrak{R}^2) \subset \mathfrak{R}.\Omega^1_{B/A}$, whence, by passing to quotients, a homomorphism of A-modules

$$\delta_{C/B/A} : \mathfrak{R}/\mathfrak{R}^2 \to \Omega^1_{B/A} \otimes_B C = \Omega^1_{B/A}/(\mathfrak{R}.\Omega^1_{B/A}). \tag{20.5.11.2}$$

But in fact, $\delta_{C/B/A}$ is a homomorphism of *C-modules*, since for $x \in B$ and $y \in \mathfrak{R}$, we have $ydx \in \mathfrak{R}.\Omega^1_{B/A}$, hence $d(xy) \equiv xdy \pmod{\mathfrak{R}.\Omega^1_{B/A}}$, which proves first that (20.5.11.2) is a homomorphism of B-modules, and as $\mathfrak{R}$ annihilates both members, this establishes our assertion.

If B' is a second A-algebra, $u : B \to B'$ an A-homomorphism, $\mathfrak{R}'$ an ideal of B' such that $u(\mathfrak{R}) \subset \mathfrak{R}'$ and $C' = B'/\mathfrak{R}'$ the quotient algebra, one has a commutative diagram

$$\begin{array}{ccc} \mathfrak{R}/\mathfrak{R}^2 & \xrightarrow{\delta_{C/B/A}} & \Omega^1_{B/A} \otimes_B C \\ \downarrow & & \downarrow \\ \mathfrak{R}'/\mathfrak{R}'^2 & \xrightarrow{\delta_{C'/B'/A}} & \Omega^1_{B'/A} \otimes_{B'} C' \end{array} \tag{20.5.11.3}$$

where the vertical arrows come from u (20.5.2.4).

(20.5.12) Theorem. *Let A be a ring, B an A-algebra, C the A-algebra quotient $B/\mathfrak{R}$, $u : B \to C$ the canonical homomorphism.*

(i) *One has an exact sequence of C-modules*

$$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \to 0 \tag{20.5.12.1}$$

where $u_{C/B/A}$ and $\delta_{C/B/A}$ are defined by (20.5.2.4) and (20.5.11.2) respectively.

(ii) *If one sets $E = B/\mathfrak{R}^2$, the canonical homomorphism (20.5.2.4)*

$$\Omega^1_{B/A} \otimes_B C \to \Omega^1_{E/A} \otimes_E C$$

is bijective.

(iii) *The three following conditions are equivalent:*

a) *$\delta_{C/B/A}$ is left-invertible.*

b) *Every A-extension of C by a C-module L, whose inverse image by $u : B \to C$ is A-trivial, is itself A-trivial.*

c) *The A-algebra $E = B/\mathfrak{R}^2$ is an A-trivial extension of C by $\mathfrak{R}/\mathfrak{R}^2$.*

(iv) *There is a canonical bijective correspondence between the left inverses of $\delta_{C/B/A}$ and the right inverses of the canonical homomorphism $E \to C$.*

Proof.

(i) As u is surjective, one has $\mathrm{Der}_B(C, L) = 0$ for every C-module L by virtue of (20.1.1).
[0IV-1 | 134] The exact sequence (20.2.3.1) therefore becomes

$$0 \to \mathrm{Der}_A(C, L) \xrightarrow{u^0} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \mathrm{Exalcom}_B(C, L) \xrightarrow{v^1} \mathrm{Exalcom}_A(C, L) \xrightarrow{u^1} \mathrm{Exalcom}_A(B, L) \tag{20.5.12.2}$$

where v denotes the homomorphism $A \to B$. Recall on the other hand that $\mathrm{Exalcom}_B(C, L)$ is canonically identified with $\mathrm{Hom}_C(\mathfrak{R}/\mathfrak{R}^2, L)$ (18.3.8); one deduces therefore from (20.5.12.2) and (20.4.8) the exact sequence

$$0 \to \mathrm{Hom}_C(\Omega^1_{C/A}, L) \to \mathrm{Hom}_C(\Omega^1_{B/A} \otimes_B C, L) \xrightarrow{\varphi} \mathrm{Hom}_C(\mathfrak{R}/\mathfrak{R}^2, L) \xrightarrow{\psi} \mathrm{Ker}(u^1) \to 0 \tag{20.5.12.3}$$

with $\varphi = \partial \circ \eta^{-1}$ and $\psi = v^1 \circ \eta$. Returning to the definitions of ∂ (20.2.2) and of η (18.3.8), one verifies immediately that φ is precisely the homomorphism $\mathrm{Hom}(\delta_{C/B/A}, 1_L)$. The existence of the exact sequence formed by the first 4 terms of (20.5.12.3) shows therefore that the sequence (20.5.12.1) is exact (Bourbaki, *Alg.*, chap. II, 3e éd., § 2, n° 1, th. 1).

(ii) Apply to B and the ideal $\mathfrak{R}^2$ the exact sequence (20.5.12.1), which gives

$$\mathfrak{R}^2/\mathfrak{R}^4 \to \Omega^1_{B/A} \otimes_B E \to \Omega^1_{E/A} \to 0 \tag{20.5.12.4}$$

whence, by tensoring with C (considered as an E-algebra), the exact sequence

$$\mathfrak{R}^2/\mathfrak{R}^4 \otimes_E C \to \Omega^1_{B/A} \otimes_B C \to \Omega^1_{E/A} \otimes_E C \to 0.$$

But if x, y are two elements of $\mathfrak{R}$ and ζ the class of xy modulo $\mathfrak{R}^4$, the image $\delta'(\zeta \otimes 1)$ is $(x d_{B/A}(y) + y d_{B/A}(x)) \otimes 1$; but as the images of x and of y in C are zero, one has also $d_{B/A}(xy) \otimes 1 = 0$ in $\Omega^1_{B/A} \otimes_B C$, which proves our assertion.

(iii) To say that $\delta_{C/B/A}$ is left-invertible amounts, taking into account the exactness of (20.5.12.1), to saying that the sequence

$$0 \to \mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \to 0 \tag{20.5.12.5}$$

is *exact and split*, and it is known (Bourbaki, *loc. cit.*) that to say that $\mathrm{Ker}(u^1) = 0$ in the exact sequence (20.5.12.3) for every L, which shows the equivalence of the conditions *a*) and *b*) (cf. (18.3.6.2)).

The fact that *b*) implies *c*) comes from the fact that the inverse image by $u : B \to C$ of the A-extension E of C by $\mathfrak{R}/\mathfrak{R}^2$ is A-trivial, u being composed of the canonical homomorphisms $B \to E \to C$ (18.1.6). Conversely, *c*) implies *b*), since every B-extension of C by L is B-equivalent to $E \otimes_{\mathfrak{R}/\mathfrak{R}^2} L$ (18.3.8), in other words its class is the image of the
[0IV-1 | 135] class of E (considered as B-extension) by the homomorphism $w_* : \mathrm{Exan}_B(C, \mathfrak{R}/\mathfrak{R}^2) \to$

$\mathrm{Exan}_B(C, L)$ corresponding to a B-homomorphism $w : \mathfrak{R}/\mathfrak{R}^2 \to L$. The fact that c) implies b) then follows from the commutativity of the diagram (18.3.6.5)

$$\begin{array}{ccc} \mathrm{Exan}_B(C, \mathfrak{R}/\mathfrak{R}^2) & \xrightarrow{w_*} & \mathrm{Exan}_B(C, L) \\ \downarrow{\scriptstyle u^*} & & \downarrow{\scriptstyle u^*} \\ \mathrm{Exan}_A(C, \mathfrak{R}/\mathfrak{R}^2) & \xrightarrow[w_*]{} & \mathrm{Exan}_A(C, L) \end{array}$$

(iv) We have seen (20.1.7) that the right inverses of $E \to C$ correspond bijectively, in a canonical fashion, to the set of elements $D \in \mathrm{Der}_A(E, \mathfrak{R}/\mathfrak{R}^2)$ such that $D(x) = x$ in $\mathfrak{R}/\mathfrak{R}^2$, hence also, by (20.4.8), to the set of E-homomorphisms $h : \Omega^1_{E/A} \to \mathfrak{R}/\mathfrak{R}^2$ such that the composite $\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{d_{E/A}} \Omega^1_{E/A} \xrightarrow{h} \mathfrak{R}/\mathfrak{R}^2$ is the identity. By tensorization with C, one deduces that the composite

$$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{h\otimes 1} \mathfrak{R}/\mathfrak{R}^2$$

is the identity; or, since $\mathfrak{R}/\mathfrak{R}^2$ is a C-module, $h \mapsto h \otimes 1$ is an isomorphism of the set $\mathrm{Hom}_E(\Omega^1_{E/A}, \mathfrak{R}/\mathfrak{R}^2)$ onto $\mathrm{Hom}_C(\Omega^1_{E/A} \otimes_E C, \mathfrak{R}/\mathfrak{R}^2)$; and by (ii) elsewhere one can canonically identify $\Omega^1_{E/A} \otimes_E C$ and $\Omega^1_{B/A} \otimes_B C$, $\delta_{C/E/A}$ being identified with $\delta_{C/B/A}$. □

(20.5.13) Example. Let $B = A[X_\alpha]_{\alpha\in I}$ be a polynomial algebra over A, $\mathfrak{R}$ an ideal of B and $C = B/\mathfrak{R}$; we know that $\Omega^1_{B/A}$ is a free B-module whose dX_α form a basis (20.4.13), (i), hence the dX_α also form a basis of the free C-module $\Omega^1_{B/A} \otimes_B C$. On the other hand, from the definition it follows immediately that the image of $\mathfrak{R}/\mathfrak{R}^2$ by $\delta_{C/B/A}$ is the sub-C-module generated by the

$$dP_\lambda = \sum_\alpha \frac{\partial P_\lambda}{\partial X_\alpha}\, dX_\alpha.$$

One concludes that $\Omega^1_{C/A}$ is isomorphic to the quotient of the free C-module with basis the dX_α by the sub-C-module generated by the dP_λ, which gives a description of the module of differentials of an *arbitrary* A-algebra C that can always be obtained in the above manner.

(20.5.14) Corollary. *If C is an A-algebra formally smooth (for the discrete topologies), the sequence*

$$0 \to \mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{u_{C/B/A}} \Omega^1_{C/A} \to 0 \qquad (20.5.14.1)$$

is exact and split.

Proof. Indeed, every A-extension of C by a C-module is then trivial (19.4.1). □

(20.5.15) Remark. Let $u : A \to B$ be a *surjective* homomorphism of rings; then, for every homomorphism of rings $v : B \to C$, the canonical homomorphism [$0_{\text{IV-1}}$ | 136]

$$u_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B} \qquad (20.5.15.1)$$

is *bijective*; this indeed follows from the exact sequence (20.5.7.1), since $\Omega^1_{B/A} = 0$ (20.4.12).

20.6 Modules of imperfection and characteristic homomorphisms

(20.6.1) Definition. Given two ring homomorphisms $u : A \to B$, $v : B \to C$, one calls the *module of imperfection* of the B-algebra C relative to A, and one denotes by $\Upsilon_{C/B/A}$, the kernel of the C-module homomorphism $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$. One therefore has by definition (cf. (20.5.7)) the exact sequence

$$0 \to \Upsilon_{C/B/A} \to \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \to 0. \tag{20.6.1.1}$$

When $A = \mathbf{Z}$ (so that $\Omega^1_{B/A}$ and $\Omega^1_{C/A}$ are the modules of "absolute" differentials), one writes $\Upsilon_{C/B}$ instead of $\Upsilon_{C/B/\mathbf{Z}}$; when B and C are algebras over a prime field P, one has $\Upsilon_{C/B/P} = \Upsilon_{C/B}$.

Let R, S be multiplicative subsets of B and C respectively, such that the image of R is contained in S. It then follows from the exact sequence (20.6.1.1) and (20.5.9) that one has

$$\Upsilon_{S^{-1}C/R^{-1}B/A} = S^{-1}\Upsilon_{C/B/A}. \tag{20.6.1.2}$$

(20.6.2) Proposition. *If C is a B-algebra formally smooth relative to A (and in particular if C is a B-algebra formally smooth), one has $\Upsilon_{C/B/A} = 0$.*

Proof. This follows from (20.5.7), (ii). □

(20.6.3) Proposition. *Let k be a field, K an extension of k. For K to be a separable extension of k, it is necessary and sufficient that $\Upsilon_{K/k} = 0$ (or equivalently, the canonical homomorphism $\Omega^1_k \otimes_k K \to \Omega^1_K$ is injective, or again (20.4.8), every derivation of k in K extends to a derivation of K in K).*

Proof. Indeed, it is equivalent to saying that K is separable over k or that K is a k-algebra formally smooth (19.6.1); on the other hand, if P is the prime field of k, K is separable over P, hence also a P-algebra formally smooth, and it follows that K is a k-algebra formally smooth relative to P. Finally, to say that K is a k-algebra formally smooth relative to P amounts, by (20.5.7), (ii), to saying that the homomorphism $v_{K/k/P} : \Omega^1_k \otimes_k K \to \Omega^1_K$ is left-invertible; but as K is a field, this last condition is equivalent to saying that the kernel of $v_{K/k/P}$, that is to say $\Upsilon_{K/k/P}$, is zero. □

(20.6.4) Consider a commutative diagram of ring homomorphisms

$$\begin{array}{ccccc} A' & \xrightarrow{u'} & B' & \xrightarrow{v'} & C' \\ {\scriptstyle f}\uparrow & & {\scriptstyle g}\uparrow & & {\scriptstyle h}\uparrow \\ A & \xrightarrow{u} & B & \xrightarrow{v} & C \end{array} \tag{20.6.4.1}$$

The commutativity of the diagram corresponding to (20.5.7.3) implies the existence of a unique C-homomorphism

$$\Upsilon_{C/B/A} \to \Upsilon_{C'/B'/A'} \tag{20.6.4.2}$$

deduced canonically from (20.6.4.1) and rendering commutative the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \Upsilon_{C/B/A} & \longrightarrow & \Omega^1_{B/A} \otimes_B C & \xrightarrow{v_{C/B/A}} & \Omega^1_{C/A} & \xrightarrow{u_{C/B/A}} & \Omega^1_{C/B} \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & \Upsilon_{C'/B'/A'} & \longrightarrow & \Omega^1_{B'/A'} \otimes_{B'} C' & \xrightarrow[v_{C'/B'/A'}]{} & \Omega^1_{C'/A} & \xrightarrow[u_{C'/B'/A'}]{} & \Omega^1_{C'/B'} \longrightarrow 0 \end{array} \tag{20.6.4.3}$$

where the vertical arrows come from the di-homomorphisms (20.5.4.3).

The definition of (20.6.4.2) is also equivalent to that of a C'-homomorphism

$$\Upsilon_{C/B/A} \otimes_C C' \to \Upsilon_{C'/B'/A'} \tag{20.6.4.4}$$

which, composed with the canonical homomorphism $\Upsilon_{C/B/A} \to \Upsilon_{C/B/A} \otimes_C C'$, gives back (20.6.4.2). It is clear that (20.6.4.2) enjoys an evident transitivity property, allowing us to say that $\Upsilon_{C/B/A}$ is a *functor* in the triple (A, B, C).

(20.6.5) It will be convenient for us in what follows, under the conditions of (20.6.1), to introduce a *complex* (of chains) *of C-modules* $\mathrm{K}_\bullet(C/B/A)$ whose terms are zero except in degrees 0 and 1, where one takes

$$\begin{cases} \mathrm{K}_0(C/B/A) = \Omega^1_{C/A} \\ \mathrm{K}_1(C/B/A) = \Omega^1_{B/A} \otimes_B C \end{cases} \tag{20.6.5.1}$$

the differential operator being $v_{C/B/A} : \mathrm{K}_1 \to \mathrm{K}_0$. This allows writing (up to canonical isomorphisms) $\Omega^1_{C/B}$ and $\Upsilon_{C/B/A}$ as the *homology modules* of this complex

$$\mathrm{H}_0(\mathrm{K}_\bullet(C/B/A)) = \Omega^1_{C/B}, \qquad \mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)) = \Upsilon_{C/B/A}. \tag{20.6.5.2}$$

Similarly:

(20.6.6) Proposition. *Under the hypotheses of (20.6.1), for every C-module L, one has canonical C-isomorphisms*

$$\mathrm{H}^0(\mathrm{K}_\bullet(C/B/A), L) \simeq \mathrm{Der}_B(C, L) \tag{20.6.6.1}$$

$$\mathrm{H}^1(\mathrm{K}_\bullet(C/B/A), L) \simeq \mathrm{Exalcom}_{B/A}(C, L). \tag{20.6.6.2}$$

Proof. Indeed, the complex of cochains $\mathrm{Hom}_C(\mathrm{K}_\bullet(C/B/A), L)$ is none other, by virtue of (20.4.8) and (20.5.6), than the complex

$$\cdots \to 0 \to \mathrm{Der}_A(C, L) \to \mathrm{Der}_A(B, L) \to 0 \to \cdots$$

where the differential operator is v^0 (with the notations of (20.2.1)). The proposition follows from the exact sequence (20.2.4.2) and from the definition of the cohomology modules [$0_{\text{IV-1}}$ | 138]

$$\mathrm{H}^i(\mathrm{K}_\bullet, L) = \mathrm{H}^i(\mathrm{Hom}_C(\mathrm{K}_\bullet, L)). \tag{20.6.6.3}$$

□

If one has a commutative diagram of ring homomorphisms

$$\begin{array}{ccccc} A' & \longrightarrow & B' & \longrightarrow & C' \\ \uparrow & & \uparrow & & \uparrow \\ A & \longrightarrow & B & \longrightarrow & C \end{array}$$

the di-homomorphisms (20.5.4.3) define a di-homomorphism of complexes of modules

$$\mathrm{K}_\bullet(C/B/A) \to \mathrm{K}_\bullet(C'/B'/A') \tag{20.6.6.4}$$

and the di-homomorphisms that one deduces for the homology or the cohomology are identified, by the formulas (20.6.5.2), (20.6.6.1) and (20.6.6.2), with the di-homomorphisms already defined in (20.5.4.3), (20.6.4.2), (20.2.1) and (18.3.7.2) (taking into account, for the last, the definition of the operator ∂ in the exact sequence (20.2.4.2)).

(20.6.7) One knows that for a complex $\mathrm{K}_\bullet$ of C-modules and a C-module L, one has canonical homomorphisms

$$\alpha_i : \mathrm{H}^i(\mathrm{K}_\bullet, L) \to \mathrm{Hom}_C(\mathrm{H}_i(\mathrm{K}_\bullet), L)$$

(M, IV, 6). Here, the canonical homomorphism

$$\alpha_1 : \mathrm{H}^1(\mathrm{K}_\bullet(C/B/A), L) \to \mathrm{Hom}_C(\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)), L)$$

is defined immediately as obtained by passing to the quotient by the image of $\mathrm{Hom}_C(\mathrm{K}_0, L)$ of the restriction homomorphism

$$\mathrm{Hom}_C(\mathrm{K}_1(C/B/A), L) \to \mathrm{Hom}_C(\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A)), L)$$

since $\mathrm{H}_1(\mathrm{K}_\bullet(C/B/A))$ is none other than the kernel of $\mathrm{K}_1 \to \mathrm{K}_0$; taking into account (20.6.6.2) and (20.6.5.2), one obtains therefore a canonical C-homomorphism

$$\mathrm{Exalcom}_{B/A}(C, L) \to \mathrm{Hom}_C(\Upsilon_{C/B/A}, L) \tag{20.6.7.1}$$

which can be described explicitly as follows: by virtue of (20.2.4.2), every B-extension of C by L which is A-trivial comes from the datum of an A-derivation D of B in L, hence (20.4.8) of a C-homomorphism f of $\Omega^1_{B/A} \otimes_B C$ in L; one associates to this extension the *restriction* of f to $\Upsilon_{C/B/A}$, which in fact depends only on the class of this extension and not on the choice of D.

(20.6.8) Definition. Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms. For every B-extension E of C by a C-module L, which is A-trivial (18.3.7), one calls the *characteristic homomorphism* of E, and one denotes by χ_E, the C-homomorphism $\Upsilon_{C/B/A} \to L$, image of the class of E by the canonical homomorphism (20.6.7.1).

[$0_{\text{IV-1}}$ | 139] One can define the homomorphism χ_E in another way:

(20.6.9) Proposition. *Let E be a B-extension of C by a C-module L, which is A-trivial (18.3.7); then the diagram*

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \Upsilon_{C/B/A} & \longrightarrow & \Omega^1_{B/A} \otimes_B C & \xrightarrow{v_{C/B/A}} & \Omega^1_{C/A} & & \\ & & \downarrow{\scriptstyle \chi_E} & & \downarrow{\scriptstyle q_{E/B/A} \otimes 1_C} & & \downarrow{\scriptstyle 1} & & \\ 0 & \longrightarrow & L & \xrightarrow[\delta_{C/E/A}]{} & \Omega^1_{E/A} \otimes_E C & \xrightarrow{p_{C/E/A}} & \Omega^1_{C/A} & \longrightarrow & 0 \end{array} \tag{20.6.9.1}$$

where $q : B \to E$ defines the structure of B-extension of E and $p : E \to C$ is the augmentation, is commutative and its rows are exact.

Proof. The bottom row of the diagram is the sequence (20.5.12.5) relative to the two homomorphisms $A \xrightarrow{q \circ u} E$ and $p : E \to C = E/L$; as p is surjective and E is an A-trivial extension, this sequence is exact and split by virtue of (20.5.12), (iii). The commutativity of the right-hand square of (20.6.9.1) follows from the relation $v = p \circ q$ (20.5.2.7); the

image by $q_{E/B/A} \otimes 1_C$ of the kernel $\Upsilon_{C/B/A}$ of $v_{C/B/A}$ is therefore contained in the kernel L of $p_{C/E/A}$. On the other hand, let $h : C \to E$ be an A-homomorphism that is a right inverse of p, and let $j : L \to E$ be the canonical injection, so that one has $q(b) = h(v(b)) + j(D(b))$ for $b \in B$, where D is the A-derivation of B in L defining the B-extension E; one can write $D = f \circ d_{B/A}$, where $f : \Omega^1_{B/A} \to L$ is a B-homomorphism. By virtue of (20.5.2.6), one has $q_{E/B/A}(d_{B/A}(b)) = d_{E/A}(q(b)) = d_{E/A}(h(v(b))) + d_{E/A}(j(f(d_{B/A}(b))))$ for $b \in B$. Let then $z = \sum_i d_{B/A}(b_i) \otimes c_i$, where $b_i \in B$ and $c_i \in C$, be an element of $\Omega^1_{B/A} \otimes_B C$; one has

$$(q_{E/B/A} \otimes 1_C)(z) = \sum_i d_{E/A}(h(v(b_i))) \otimes c_i + \sum_i d_{E/A}(j(f(d_{B/A}(b_i)))) \otimes c_i.$$

In the first sum, one has $d_{E/A}(h(v(b_i))) = h_{E/C/A}(d_{C/A}(v(b_i)))$, hence this sum equals $(h_{E/C/A} \otimes 1_C)(v_{C/B/A}(z))$. So if one takes $z \in \Upsilon_{C/B/A}$, this sum is zero, and it remains, by definition of $\delta_{C/E/A}$,

$$(q_{E/B/A} \otimes 1_C)(z) = \sum_i \delta_{C/E/A}(c_i f(d_{B/A}(b_i))) = \delta_{C/E/A}(f(z))$$

which proves the commutativity of the left-hand square in (20.6.9.1). □

One notes that when one only assumes that $\delta_{C/E/A}$ is *injective* (and not necessarily left-invertible), this interpretation would still allow one to *define* χ_E as the restriction of $q_{E/B/A} \otimes 1_C$ to $\Upsilon_{C/B/A}$.

(20.6.10) Corollary. *If $\mathfrak{R}$ is an ideal of B, $C = B/\mathfrak{R}$, $E = B/\mathfrak{R}^2$, and if E is a B-extension A-trivial (18.3.7) of C by $\mathfrak{R}/\mathfrak{R}^2$, then the characteristic homomorphism $\chi_E : \Upsilon_{C/B/A} \to \mathfrak{R}/\mathfrak{R}^2$ is bijective.*

Proof. Indeed, in the diagram (20.6.9.1), the two right-hand vertical arrows are bijective (20.5.12), (ii). □ [0IV-1 | 140]

(20.6.11) Theorem. *Let $u : A \to B$, $v : B \to C$ be two ring homomorphisms, L a C-module. Suppose one of the following conditions satisfied:*

(i) *L is an injective C-module.*

(ii) *$\Upsilon_{C/B/A}$ is a direct factor of $\Omega^1_{B/A} \otimes_B C$ and $u_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B}$ is right-invertible.*

Then the canonical homomorphism (20.6.7.1)

$$\mathrm{Exalcom}_{B/A}(C, L) \to \mathrm{Hom}_C(\Upsilon_{C/B/A}, L)$$

is bijective.

In particular, if $\Omega^1_{C/B}$ and $\Omega^1_{C/A}$ are projective C-modules, the canonical homomorphism (20.6.7.1) is bijective.

Proof. The fact that each of the conditions (i), (ii) implies that (20.6.7.1) is bijective follows in both cases from the definition of α_1. We note moreover that condition (ii) is *necessary and sufficient* for the homomorphism (20.6.7.1) to be bijective for *every* C-module L (Bourbaki, *Alg.*, chap. II, 3e éd., § 2, n° 1, prop. 1). If one assumes that $\Omega^1_{C/B}$

and $\Omega^1_{C/A}$ are projective C-modules, then, in the exact sequence (20.6.1.1), $\mathrm{Ker}(u_{C/B/A})$ is a projective C-module, since the sequence

$$0 \to \mathrm{Ker}(u_{C/B/A}) \to \Omega^1_{C/A} \to \Omega^1_{C/B} \to 0$$

is split, $\Omega^1_{C/B}$ being projective; as $\mathrm{Ker}(u_{C/B/A}) = \mathrm{Im}(v_{C/B/A})$, the sequence

$$0 \to \Upsilon_{C/B/A} \to \Omega^1_{B/A} \otimes_B C \to \mathrm{Im}(v_{C/B/A}) \to 0$$

is split. □

(20.6.12) Corollary. *Suppose that C is an A-algebra formally smooth. Then there exists a canonical homomorphism*

$$\mathrm{Exalcom}_B(C, L) \to \mathrm{Hom}_C(\Upsilon_{C/B/A}, L). \tag{20.6.12.1}$$

Moreover, this homomorphism is bijective if one of the conditions (i), (ii) *of (20.6.11) is verified.*

Proof. Indeed, it follows from the hypothesis on C that $\mathrm{Exalcom}_B(C, L) = \mathrm{Exalcom}_{B/A}(C, L)$, and the homomorphism (20.6.12.1) is none other than (20.6.7.1). □

(20.6.13) Corollary. *If C is an A-algebra formally smooth and if $\Omega^1_{C/B}$ is a projective C-module, the homomorphism (20.6.12.1) is bijective.*

Proof. Indeed, one knows then that $\Omega^1_{C/A}$ is a projective C-module (20.4.9), the discrete topologies being considered. □

(20.6.14) The notations remaining the same, suppose now in addition that A, B, C are Λ-algebras and u, v are Λ-homomorphisms, which amounts to giving three ring homomorphisms $\Lambda \xrightarrow{s} A \xrightarrow{u} B \xrightarrow{v} C$.

[0IV-1 | 141] One has therefore, apart from the module of imperfection $\Upsilon_{C/B/A}$, the modules of imperfection $\Upsilon_{B/A/\Lambda}$, $\Upsilon_{C/A/\Lambda}$ and $\Upsilon_{C/B/\Lambda}$, and one has already defined canonical C-module homomorphisms (20.6.4.2)

$$u' : \Upsilon_{C/A/\Lambda} \to \Upsilon_{C/B/\Lambda} \tag{20.6.14.1}$$

$$s' : \Upsilon_{C/B/\Lambda} \to \Upsilon_{C/B/A}. \tag{20.6.14.2}$$

As in the commutative diagram (20.5.7.3)

$$\begin{array}{ccccccc} \Omega^1_{A/\Lambda} \otimes_A B & \longrightarrow & \Omega^1_{B/\Lambda} & \longrightarrow & \Omega^1_{B/A} & \longrightarrow & 0 \\ \downarrow & & \downarrow & & \downarrow & & \\ \Omega^1_{A/\Lambda} \otimes_A C & \longrightarrow & \Omega^1_{C/\Lambda} & \longrightarrow & \Omega^1_{C/A} & \longrightarrow & 0 \end{array} \tag{20.6.14.3}$$

the bottom row is formed of C-modules, one deduces by tensorization a commutative diagram

$$\begin{array}{ccccccc} \Omega^1_{A/\Lambda} \otimes_A C & \longrightarrow & \Omega^1_{B/\Lambda} \otimes_B C & \longrightarrow & \Omega^1_{B/A} \otimes_B C & \longrightarrow & 0 \\ \| & & \downarrow & & \downarrow & & \\ \Omega^1_{A/\Lambda} \otimes_A C & \longrightarrow & \Omega^1_{C/\Lambda} & \longrightarrow & \Omega^1_{C/A} & \longrightarrow & 0 \end{array} \tag{20.6.14.4}$$

where the first row is still exact and the left vertical arrow is the identity; if one puts

$$\Upsilon^C_{B/A/\Lambda} = \mathrm{Ker}(u_{B/A/\Lambda} \otimes 1_C) = \mathrm{Ker}(\Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C) \tag{20.6.14.5}$$

one sees, taking into account the definition of $\Upsilon_{C/A/\Lambda}$, that one has a unique C-homomorphism

$$v' : \Upsilon^C_{B/A/\Lambda} \to \Upsilon_{C/A/\Lambda} \tag{20.6.14.6}$$

rendering commutative the diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \Upsilon^C_{B/A/\Lambda} & \longrightarrow & \Omega^1_{A/\Lambda} \otimes_A C & \longrightarrow & \Omega^1_{B/\Lambda} \otimes_B C & \longrightarrow & \Omega^1_{B/A} \otimes_B C \longrightarrow 0 \\
 & & \downarrow{\scriptstyle v'} & & \| & & \downarrow & & \downarrow \\
0 & \longrightarrow & \Upsilon_{C/A/\Lambda} & \longrightarrow & \Omega^1_{A/\Lambda} \otimes_A C & \longrightarrow & \Omega^1_{C/\Lambda} & \longrightarrow & \Omega^1_{C/A} \longrightarrow 0
\end{array} \tag{20.6.14.7}$$

whose rows are exact.

When $\Lambda = \mathbf{Z}$, one writes $\Upsilon^C_{B/A}$ instead of $\Upsilon^C_{B/A/\mathbf{Z}}$. If Λ is a prime field, one has $\Upsilon^C_{B/A} = \Upsilon^C_{B/A/\Lambda}$.

(20.6.15) To study the relations between the preceding modules, we introduce on the one hand the complex of B-modules $\mathrm{K}_\bullet(B/A/\Lambda)$ (20.6.5), and on the other hand the complexes of C-modules $\mathrm{K}_\bullet(C/A/\Lambda)$ and $\mathrm{K}_\bullet(C/B/\Lambda)$. We shall also set [$0_{\text{IV-1}}$ | 142]

$$\mathrm{K}^C_\bullet(B/A/\Lambda) = \mathrm{K}_\bullet(B/A/\Lambda) \otimes_B C. \tag{20.6.15.1}$$

On the other hand, we denote by $\mathrm{T}_\bullet(C/B/\Lambda)$ the complex of C-modules whose terms are zero except in degrees 0 and 1, and where

$$\mathrm{T}_0(C/B/\Lambda) = \mathrm{T}_1(C/B/\Lambda) = \Omega^1_{B/\Lambda} \otimes_B C \tag{20.6.15.2}$$

the differential operator being the identity, so that this complex is homotopic to 0; finally let us set

$$\mathrm{K}'_\bullet(C/A/\Lambda) = \mathrm{K}_\bullet(C/A/\Lambda) \oplus \mathrm{T}_\bullet(C/B/\Lambda). \tag{20.6.15.3}$$

By virtue of the trivial character of $\mathrm{T}_\bullet$, it is clear that one has

$$\mathrm{H}^i(\mathrm{K}'_\bullet, L) = \mathrm{H}^i(\mathrm{K}_\bullet, L) \quad \text{and} \quad \mathrm{H}_i(\mathrm{K}'_\bullet, L) = \mathrm{H}_i(\mathrm{K}_\bullet, L) \tag{20.6.15.4}$$

for every C-module L and every i.

(20.6.16) Let us now define an exact sequence of complexes, *split* in each degree

$$0 \to \mathrm{K}^C_\bullet(B/A/\Lambda) \xrightarrow{j} \mathrm{K}'_\bullet(C/A/\Lambda) \xrightarrow{p} \mathrm{K}_\bullet(C/B/\Lambda) \to 0 \tag{20.6.16.1}$$

in the following way: let us denote temporarily by

$$f : \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C, \quad g : \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{C/\Lambda}$$

the canonical homomorphisms $u_{B/A/\Lambda} \otimes 1_C$ and $v_{C/B/\Lambda}$ respectively, whose composite is $g \circ f = (v \circ u)_{C/A/\Lambda}$ (cf. (20.6.14.4)). One will take $j_1(x) = (x, f(x))$, $p_1(y, z) = z - f(y)$, $j_0(x) = (g(x), x)$, $p_0(y, z) = g(z) - y$ so that $\mathrm{Im}(j_1) = \mathrm{Ker}(p_1)$ is the graph of f, and

$\mathrm{Im}(j_0) = \mathrm{Ker}(p_0)$ is the graph of g, complementary to $\{0\} \oplus \mathrm{T}_1$ and $\mathrm{K}_1(C/A/\Lambda) \oplus \{0\}$ respectively; the verification of the commutativity of the diagram

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{K}_1^C(B/A/\Lambda) & \xrightarrow{j_1} & \mathrm{K}'_1(C/A/\Lambda) & \xrightarrow{p_1} & \mathrm{K}_1(C/B/\Lambda) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{K}_0^C(B/A/\Lambda) & \xrightarrow[j_0]{} & \mathrm{K}'_0(C/A/\Lambda) & \xrightarrow[p_0]{} & \mathrm{K}_0(C/B/\Lambda) & \longrightarrow & 0 \end{array}$$

where the vertical arrows are the differential operators, is immediate.

(20.6.17) Theorem. *One has an exact sequence of C-modules*

$$0 \to \Upsilon^C_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{u'} \Upsilon_{C/B/\Lambda} \xrightarrow{\partial} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \to 0 \tag{20.6.17.1}$$

[$0_{IV\text{-}1}$ / 143] *where the boundary operator ∂ is the composite*

$$\Upsilon_{C/B/\Lambda} \xrightarrow{s'} \Upsilon_{C/B/A} \to \Omega^1_{B/A} \otimes_B C \tag{20.6.17.2}$$

the second arrow being the canonical injection.

Proof. Writing the long exact homology sequence for the exact sequence of complexes (20.6.16.1), one obtains (20.6.17.1), the homology being zero in degrees distinct from 0 and 1; the fact that the homomorphisms of this exact sequence come from the functoriality of j and p is immediate. It remains to verify that ∂ is equal to (20.6.17.2); but an element $z \in \Upsilon_{C/B/\Lambda}$ is the image by p_1 of $(0, z)$, whence one deduces immediately that $\partial(z)$ is the image of z by the canonical homomorphism $s_{B/A/\Lambda} \otimes 1_C : \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{B/A} \otimes_B C$. Our assertion follows from the commutativity of the diagram

$$\begin{array}{ccc} \Upsilon_{C/B/\Lambda} & \xrightarrow{s'} & \Upsilon_{C/B/A} \\ \downarrow & & \downarrow \\ \Omega^1_{B/\Lambda} \otimes_B C & \longrightarrow & \Omega^1_{B/A} \otimes_B C \end{array} \tag{20.6.17.3}$$

(cf. (20.6.4.3)). □

(20.6.18) Corollary.

(i) *The sequence of C-modules*

$$0 \to \Upsilon^C_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{u'} \Upsilon_{C/B/\Lambda} \xrightarrow{s'} \Upsilon_{C/B/A} \to 0 \tag{20.6.18.1}$$

is exact.

(ii) *If B is an A-algebra formally smooth relative to Λ, one has $\Upsilon^C_{B/A/\Lambda} = 0$.*

Proof. (i) In (20.6.17.1), the image of $\Upsilon_{C/B/\Lambda}$ by ∂ is the kernel of $v_{C/B/A}$, hence $\Upsilon_{C/B/A}$ by definition.

(ii) The hypothesis implies that the sequence

$$0 \to \Omega^1_{A/\Lambda} \otimes_A B \to \Omega^1_{B/\Lambda} \to \Omega^1_{B/A} \to 0$$

is exact and split (20.5.7); by tensorization with C, the sequence

$$0 \to \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{B/A} \otimes_B C \to 0$$

remains therefore exact, whence our assertion. □

(20.6.19) Corollary. *Let K be a field, E, F two extensions of K such that $K \subset E \subset F$.*

(i) *If F is a separable extension of E, one has $\Upsilon_{F/E/K} = 0$ (or equivalently, the canonical homomorphism $\Omega^1_{E/K} \otimes_E F \to \Omega^1_{F/K}$ is injective).*

(ii) *Conversely, if F is a separable extension of K and if $\Upsilon_{F/E/K} = 0$, then F is a separable extension of E.*

Proof. If P is the prime field of K, one has the exact sequence (20.6.18)

$$\Upsilon_{F/K/P} \to \Upsilon_{F/E/P} \to \Upsilon_{F/E/K} \to 0.$$

If $\Upsilon_{F/E/P} = \Upsilon_{F/E} = 0$, one therefore has $\Upsilon_{F/E/K} = 0$, whence (i) by virtue of (20.6.3); conversely, if $\Upsilon_{F/E/K} = 0$ and $\Upsilon_{F/K/P} = \Upsilon_{F/K} = 0$, one has $\Upsilon_{F/E/P} = \Upsilon_{F/E} = 0$, whence (ii) by virtue of (20.6.3). □

(20.6.20) Corollary. [$0_{\text{IV-1}}$ | 144]

(i) *If K is an algebraic separable extension of k, one has $\Omega^1_{K/k} = 0$.*

(ii) *Let k be a field of characteristic 0, K an extension of k. For $\Omega^1_{K/k} = 0$, it is necessary and sufficient that K be an algebraic extension of k. In particular, for a field K of characteristic 0 to satisfy $\Omega^1_K = 0$, it is necessary and sufficient that K be an algebraic extension of $\mathbf{Q}$ (cf. (21.4.4) and (21.7.5)).*

Proof. (i) For every $x \in K$, let f be the minimal polynomial of x over k; as $f'(x) \neq 0$ and $d_{K/k}(f(x)) = f'(x)d_{K/k}(x) = 0$, one has $d_{K/k}(x) = 0$ and our assertion follows from (20.4.7).

(ii) There exists a pure extension L of k such that $k \subset L \subset K$ and K is an algebraic extension of L. As K is separable over L, it follows from (20.6.19), (i) that the sequence

$$0 \to \Omega^1_{L/k} \otimes_L K \to \Omega^1_{K/k} \to \Omega^1_{K/L} \to 0$$

is exact, and from (i) that $\Omega^1_{K/L} = 0$. The relation $\Omega^1_{K/k} = 0$ is therefore equivalent to $\Omega^1_{L/k} = 0$, and as L is a pure extension of k, it follows from (20.5.10) that the relation $\Omega^1_{L/k} = 0$ is equivalent to $L = k$. □

(20.6.21) Remarks.

(i) As $\Upsilon_{B/A/\Lambda}$ is the kernel of $u_{B/A/\Lambda} : \Omega^1_{A/\Lambda} \otimes_A B \to \Omega^1_{B/\Lambda}$ and $\Upsilon^C_{B/A/\Lambda}$ the kernel of $u_{B/A/\Lambda} \otimes 1_C$, one has a canonical homomorphism

$$\Upsilon_{B/A/\Lambda} \otimes_B C \to \Upsilon^C_{B/A/\Lambda}. \tag{20.6.21.1}$$

This homomorphism is bijective when the sequence

$$0 \to \Upsilon_{B/A/\Lambda} \otimes_B C \to \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{B/A} \otimes_B C \to 0 \tag{20.6.21.2}$$

is exact, which occurs in the following cases:

1° C is a flat B-module.

2° The B-modules $\Omega^1_{B/\Lambda}$ and $\Omega^1_{B/A}$ are *flat*: indeed, the kernel of $\Omega^1_{B/\Lambda} \to \Omega^1_{B/A}$ is then also flat ($\mathbf{0_I}$, 6.1.2), and the sequence (20.6.21.2) is then exact by virtue of ($\mathbf{0_I}$, 6.1.2).

(ii) Consider a commutative diagram of ring homomorphisms

$$\begin{array}{ccccccc} \Lambda' & \longrightarrow & A' & \longrightarrow & B' & \longrightarrow & C' \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ \Lambda & \longrightarrow & A & \longrightarrow & B & \longrightarrow & C \end{array}$$

Then the definitions of (20.6.16) show that one has a commutative diagram (where the vertical arrows come from (20.6.6.4))

$$\begin{array}{ccccccccc} 0 & \longrightarrow & \mathrm{K}^C_\bullet(B/A/\Lambda) & \longrightarrow & \mathrm{K}'_\bullet(C/A/\Lambda) & \longrightarrow & \mathrm{K}_\bullet(C/B/\Lambda) & \longrightarrow & 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \\ 0 & \longrightarrow & \mathrm{K}^{C'}_\bullet(B'/A'/\Lambda') & \longrightarrow & \mathrm{K}'_\bullet(C'/A'/\Lambda') & \longrightarrow & \mathrm{K}_\bullet(C'/B'/\Lambda') & \longrightarrow & 0 \end{array}$$

[$0_{\text{IV-1}}$ | 145] whence, by passage to homology, a *commutative diagram*

$$\begin{array}{ccccccccccc} 0 & \longrightarrow & \Upsilon^C_{B/A/\Lambda} & \longrightarrow & \Upsilon_{C/A/\Lambda} & \longrightarrow & \Upsilon_{C/B/\Lambda} & \longrightarrow & \Omega^1_{B/A} \otimes_B C & \longrightarrow & \Omega^1_{C/A} \longrightarrow \Omega^1_{C/B} \to 0 \\ & & \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \quad\quad \downarrow \\ 0 & \to & \Upsilon^{C'}_{B'/A'/\Lambda'} & \to & \Upsilon_{C'/A'/\Lambda'} & \to & \Upsilon_{C'/B'/\Lambda'} & \to & \Omega^1_{B'/A'} \otimes_{B'} C' & \to & \Omega^1_{C'/A'} \to \Omega^1_{C'/B'} \to 0 \end{array} \tag{20.6.21.3}$$

One has an analogous commutative diagram for (20.6.18.1).

(20.6.22) Proposition. *Let $s : \Lambda \to A$, $u : A \to B$ be two ring homomorphisms, $\mathfrak{R}$ an ideal of B, C the quotient ring $B/\mathfrak{R}$. Suppose that $E = B/\mathfrak{R}^2$ is a B-extension Λ-trivial of C by $\mathfrak{R}/\mathfrak{R}^2$. One then has an exact sequence*

$$0 \to \Upsilon^C_{B/A/\Lambda} \xrightarrow{v'} \Upsilon_{C/A/\Lambda} \xrightarrow{\chi_E} \mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \to 0. \tag{20.6.22.1}$$

Proof. Indeed, as $v : B \to C$ is surjective, one has $\Omega^1_{C/B} = 0$ (20.4.12). Moreover, it follows from (20.6.10) that $\Upsilon_{C/B/\Lambda}$ is canonically identified with $\mathfrak{R}/\mathfrak{R}^2$. It suffices

then to apply the exact sequences (20.6.17.1) and (20.6.18.1), noting that one has a commutative diagram

$$\begin{array}{ccccc}
 & & \Upsilon_{C/A/\Lambda} & \longrightarrow & \Omega^1_{A/\Lambda}\otimes_A C \\
 & & \downarrow{\scriptstyle \chi_E} & & \downarrow \\
\Upsilon_{C/E/\Lambda} = \Upsilon_{C/B/\Lambda} & = & \mathfrak{R}/\mathfrak{R}^2 & \xrightarrow{\delta_{C/B/A}} & \Omega^1_{B/A}\otimes_B C = \Omega^1_{E/A}\otimes_E C \\
 & & \downarrow{\scriptstyle \ell} & & \downarrow \\
 & & \mathfrak{R}/\mathfrak{R}^2 & \xrightarrow{\delta_{C/B/A}} & \Omega^1_{B/A}\otimes_B C
\end{array}$$

and using the commutativity of the diagram (20.6.17.3). □

One has thus determined the *kernel* of $\delta_{C/B/A}$ in the case where there exists a ring Λ such that A is a Λ-algebra and $B/\mathfrak{R}^2$ is Λ-trivial; one observes that this is the case in particular when C is a Λ-*algebra formally smooth* (for the discrete topology).

Suppose in addition that one has a commutative diagram of ring homomorphisms

$$\begin{array}{ccccc}
\Lambda' & \longrightarrow & A' & \longrightarrow & B' \\
\uparrow & & \uparrow & & \uparrow{\scriptstyle f} \\
\Lambda & \longrightarrow & A & \longrightarrow & B
\end{array}$$

that $\mathfrak{R}'$ is an ideal of B' such that $f(\mathfrak{R}) \subset \mathfrak{R}'$, and that $E' = B'/\mathfrak{R}'^2$ is a B'-extension Λ'-trivial of $C' = B'/\mathfrak{R}'$ by $\mathfrak{R}'/\mathfrak{R}'^2$. One then has a commutative diagram [$0_{\text{IV-1}}$ | 146]

$$\begin{array}{ccccccccc}
0 \to \Upsilon^{C'}_{B'/A'/\Lambda'} & \to & \Upsilon_{C'/A'/\Lambda'} & \to & \mathfrak{R}'/\mathfrak{R}'^2 & \to & \Omega^1_{B'/A'}\otimes_{B'} C' & \to & \Omega^1_{C'/A'} \to 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow & & \uparrow \\
0 \to \Upsilon^{C}_{B/A/\Lambda} & \to & \Upsilon_{C/A/\Lambda} & \to & \mathfrak{R}/\mathfrak{R}^2 & \to & \Omega^1_{B/A}\otimes_B C & \to & \Omega^1_{C/A} \to 0
\end{array} \tag{20.6.22.2}$$

as follows from (20.6.21.3) and (20.5.11.3).

(20.6.23) Corollary. *Under the hypotheses of (20.6.22), suppose in addition that B is an A-algebra formally smooth. Then one has an exact sequence*

$$0 \to \Upsilon_{C/A/\Lambda} \xrightarrow{\chi_E} \mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A}\otimes_B C \to \Omega^1_{C/A} \to 0. \tag{20.6.23.1}$$

Proof. This follows from (20.6.18), (ii). □

(20.6.24) When the hypotheses of (20.6.22) are satisfied, we also say that the characteristic homomorphism χ_E is the *characteristic homomorphism of the A-algebra B, relative to Λ and to the ideal $\mathfrak{R}$* (suppressing these last details when there is no danger of confusion); it is sometimes denoted by χ_B or $\chi_{B/A}$.

(20.6.25) Proposition. *Let $s : \Lambda \to A$, $u : A \to B$, $v : B \to C$ be three ring homomorphisms, L a C-module. One then has an exact sequence*

$$\begin{aligned}
0 \to \mathrm{Der}_B(C, L) \xrightarrow{u^1} \mathrm{Der}_A(C, L) \xrightarrow{v^1} \mathrm{Der}_A(B, L) \xrightarrow{\partial} \\
\to \mathrm{Exalcom}_{B/\Lambda}(C, L) \xrightarrow{u^1} \mathrm{Exalcom}_{A/\Lambda}(C, L) \xrightarrow{v^1} \mathrm{Exalcom}_{A/\Lambda}(B, L) \to 0
\end{aligned} \tag{20.6.25.1}$$

where u^1, v^1 are homomorphisms defined in (18.3.6.4) and (18.3.6.2), and ∂ is defined as in (20.2.2).

Proof. Indeed, as the exact sequence (20.6.16.1) is split, one deduces from it an exact sequence

$$0 \to \mathrm{Hom}_C(\mathrm{K}_\bullet(C/B/\Lambda), L) \to \mathrm{Hom}_C(\mathrm{K}'_\bullet(C/A/\Lambda), L) \to \mathrm{Hom}_C(\mathrm{K}^C_\bullet(B/A/\Lambda), L) \to 0.$$

If one applies to this complex the long exact cohomology sequence, taking into account (20.6.15.4) and (20.6.6), one obtains (20.6.25.1) since one has

$$\mathrm{Hom}_C(\mathrm{K}^C_\bullet(B/A/\Lambda), L) = \mathrm{Hom}_B(\mathrm{K}_\bullet(B/A/\Lambda), L)$$

by definition; the identification of u^1 and v^1 with the homomorphisms (18.3.6.4) and (18.3.6.2), respectively, follows from (20.6.6.4).[23] □

(20.6.26) Remark. In this section, the complexes $\mathrm{K}_\bullet(C/B/A)$ have appeared as a technical device intended to simplify the exposition of certain functorial behaviours. In
[$0_{\text{IV-1}}$ | 147] reality, these complexes, considered as objects of the category of complexes of C-modules "up to homotopy" (that is to say where the morphisms are the classes of homotopic homomorphisms) are remarkable invariants, finer than the pair formed by $\Omega^1_{C/B}$ and $\Upsilon_{C/B/A}$. When k is a prime field, and C a k-algebra formally smooth (for example a regular ring of finite type over an extension of k) (cf. (**IV**, 6.8.6)), one can show that the complex $\mathrm{K}_\bullet(C/A/k)$ can be described solely by making intervene C and A (to the exclusion of k): one expresses C as a quotient of a polynomial algebra B over A by an ideal $\mathfrak{Q}$, and one considers the complex $\mathrm{F}_\bullet(C/A)$ with 2 nonzero terms

$$\cdots \to 0 \to \mathfrak{Q}/\mathfrak{Q}^2 \to \Omega^1_{B/A} \otimes_B C \to 0 \to \cdots$$

(whose homology coincides with that of $\mathrm{K}_\bullet(C/A/k)$ by virtue of (20.6.23.1)). These complexes $\mathrm{F}_\bullet(C/A)$, from the point of view of homological algebra, play the role of a conormal bundle for $\mathrm{Spec}(C)$ over $\mathrm{Spec}(A)$, and will be of great importance in the chapters of this work devoted to the duality of coherent sheaves and to the theorem of Riemann-Roch.

20.7 Generalizations to topological rings

(20.7.1) It follows immediately from the definitions that if, in (20.5.2) and (20.5.3), the rings A, B, C are assumed to be topological rings and the ring homomorphisms u, v continuous, then the homomorphisms $u_{C/B/A}$ and $v_{C/B/A}$ are *continuous* (one must naturally take on $\Omega^1_{B/A} \otimes_B C$ the tensor product topology).

Moreover, $u_{C/B/A} : \Omega^1_{C/A} \to \Omega^1_{C/B}$ is a *strict surjective morphism* of topological C-modules; indeed, it is also so of the canonical homomorphism $C \otimes_A C \to C \otimes_B C$, taking into account the definition of the tensor product topology; by passing to quotients one deduces that the corresponding homomorphism $\mathrm{P}^1_{C/A} \to \mathrm{P}^1_{C/B}$ is a strict surjective morphism, and $u_{C/B/A}$ is the restriction of this last to $\Omega^1_{C/A}$.

In (20.5.5), if A' and B are topological A-algebras, and if B' and $\Omega^1_{B/A} \otimes_B B'$ are equipped with the tensor product topologies, the homomorphism (20.5.5.1) is a topological isomorphism, taking into account that $\mathrm{P}^1_{B/A}$ is the same as the direct topological sum of B and $\Omega^1_{B/A}$.

[23] The French source prints the nonexistent locator "(18.3.4.2)"; the two homomorphisms are defined in (18.3.6.4) and (18.3.6.2).

(20.7.2) Proposition. *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings. For the continuous homomorphism $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$ to be formally left-invertible (cf. (19.1.5)), it is necessary and sufficient that C be a B-algebra formally smooth relative to A (19.9.1) (and* a fortiori *it suffices that C be a B-algebra formally smooth).*

Proof. To say that $v_{C/B/A}$ is formally left-invertible means, given that the topologies of $\Omega^1_{C/A}$ and $\Omega^1_{B/A} \otimes_B C$ are less fine than those deduced from the topology of C (20.4.5), that for every discrete C-module L, annihilated by an open ideal of C, the canonical homomorphism

$$\mathrm{Hom}\,.\,\mathrm{cont}_C(\Omega^1_{C/A}, L) \to \mathrm{Hom}\,.\,\mathrm{cont}_C(\Omega^1_{B/A} \otimes_B C, L)$$

is *surjective* (19.1.5); as $\mathrm{Hom}\,.\,\mathrm{cont}_C(\Omega^1_{B/A}\otimes_B C, L) = \mathrm{Hom}\,.\,\mathrm{cont}_C(\Omega^1_{B/A}, L)$ by definition [0IV-1 | 148]
of the tensor product topology, it amounts to the same, by virtue of (20.4.8), to say that the canonical homomorphism

$$\text{Dér. } \mathrm{cont}_A(C, L) \to \text{Dér. } \mathrm{cont}_A(B, L)$$

is surjective. But the exact sequence (20.3.8.2) shows that this condition is equivalent to $\mathrm{Exalcotop}_{B/A}(C, L) = 0$, that is to say precisely that C is formally smooth relative to A (19.9.8). □

(20.7.3) Corollary. *Suppose that in B and in C, the square of every open ideal is also open. For C to be a B-algebra formally smooth relative to A, it is necessary and sufficient that, if one denotes by $(\mathfrak{R}_\lambda)$ a fundamental system of neighbourhoods of 0 formed of ideals of C, then for every λ, the homomorphism*

$$v_{C/B/A} \otimes 1_{C/\mathfrak{R}_\lambda} : \Omega^1_{B/A} \otimes_B (C/\mathfrak{R}_\lambda) \to \Omega^1_{C/A} \otimes_C (C/\mathfrak{R}_\lambda) \tag{20.7.3.1}$$

is left-invertible.

Proof. Indeed, one then knows that the topology of $\Omega^1_{B/A}$ (respectively $\Omega^1_{C/A}$) is deduced from that of B (respectively C) (20.4.5); it follows immediately that the topology of $\Omega^1_{B/A} \otimes_B C$ is also deduced from that of C. The corollary then follows from (20.7.2) and (19.1.7). □

(20.7.4) Proposition. *Let A be a topological ring, B a topological A-algebra. For B to be formally non-ramified (19.10.2), it is necessary and sufficient that the separated completion $\widehat{\Omega}^1_{B/A}$ is zero.*

Proof. Indeed, it follows immediately from (19.10.4) and (20.1.1) that, for B to be formally non-ramified, it is necessary and sufficient that for every open ideal $\mathfrak{R}$ of B, every open ideal $\mathfrak{H}$ of A such that $\mathfrak{H}.B \subset \mathfrak{R}$ and every $(B/\mathfrak{R})$-module L, one has $\mathrm{Der}_{A/\mathfrak{H}}(B/\mathfrak{R}, L) = 0$, that is to say Dér. $\mathrm{cont}_A(B, L) = 0$ for every discrete B-module L annihilated by an open ideal; by virtue of (20.4.8), this is equivalent to $\mathrm{Hom}\,.\,\mathrm{cont}_B(\Omega^1_{B/A}, L) = 0$ for every such B-module, whence the proposition.

When B is discrete, the condition of (20.7.4) is equivalent to $\Omega^1_{B/A} = 0$. □

(20.7.5) Corollary. *Let A be a ring, $\mathfrak{m}$ an ideal of A, and B an A-algebra; equip A with the $\mathfrak{m}$-preadic topology and B with the topology deduced from that of A, and set $A_0 = A/\mathfrak{m}$, $B_0 = B/\mathfrak{m}B = B \otimes_A A_0$. Then, for B to be an A-algebra formally non-ramified, it is necessary and sufficient that $\Omega^1_{B_0/A_0} = 0$ (or equivalently that B_0 is an A_0-algebra formally non-ramified).*

Proof. Indeed, one has $\Omega^1_{B/A} \otimes_B B_0 = \Omega^1_{B/A}/\mathfrak{m}.\Omega^1_{B/A} = \Omega^1_{B_0/A_0}$ by virtue of (20.5.5); to say that every open submodule of $\Omega^1_{B/A}$ is equal to $\Omega^1_{B/A}$ is equivalent by (20.4.5) to writing that $\mathfrak{m}.\Omega^1_{B/A} = \Omega^1_{B/A}$, whence the conclusion. □

(20.7.6) Proposition. *Let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms of topological rings, and suppose that v makes C into a B-algebra formally étale; then $v_{C/B/A} : \Omega^1_{B/A} \otimes_B C \to \Omega^1_{C/A}$ is a formal bimorphism (19.1.2).*

Proof. Indeed, for every discrete C-module L annihilated by an open ideal of C, one has then (20.7.4) Dér. $\mathrm{cont}_B(C, L) = 0$ and by virtue of (20.3.6.1) the canonical homo-
[$0_{\text{IV-1}}$ | 149] morphism Dér. $\mathrm{cont}_A(C, L) \to$ Dér. $\mathrm{cont}_A(B, L)$ is injective; it is moreover surjective by virtue of (20.7.2), hence it is bijective. It follows that the image of $v_{C/B/A}$ is necessarily dense in $\Omega^1_{C/A}$, otherwise the quotient of $\Omega^1_{C/A}$ by the closure of $\mathrm{Im}(v_{C/B/A})$ would be separated and nonzero and would therefore have a nonzero discrete quotient L, contrary to what has just been seen (taking into account (20.4.8)). Consequently $v_{C/B/A}$, which is a formal monomorphism by virtue of (20.7.2), is also a formal epimorphism (19.1.2), hence a formal bimorphism. □

(20.7.7) Corollary. *Suppose that in B and in C, the square of every open ideal is also open. If C is a B-algebra formally étale, then, for every open ideal $\mathfrak{R}_\lambda$ of C, the homomorphism (20.7.3.1) is bijective.*

Proof. Indeed, by virtue of (19.1.1), this homomorphism is surjective, and it is injective by (20.7.3). □

(20.7.8) Proposition. *Let $u : A \to B$ be a continuous homomorphism of topological rings, $\mathfrak{R}$ an ideal of B, C the topological quotient $B/\mathfrak{R}$, $v : B \to C$ the canonical homomorphism.*

(i) *In the exact sequence (20.5.12.1)*

$$\mathfrak{R}/\mathfrak{R}^2 \xrightarrow{\delta_{C/B/A}} \Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \to 0$$

the homomorphism $\delta_{C/B/A}$ is continuous and the homomorphism $v_{C/B/A}$ is a strict morphism of topological C-modules.

(ii) *For $\delta_{C/B/A}$ to be formally left-invertible (19.1.5), it is necessary and sufficient that for every discrete C-module L annihilated by an open ideal of C, the canonical homomorphism*

$$\mathrm{Exalcotop}_A(C, L) \to \mathrm{Exalcotop}_A(B, L) \tag{20.7.8.1}$$

is injective.

Proof. (i) The first assertion is evident. On the other hand, the canonical homomorphism $v \otimes v : B \otimes_A B \to C \otimes_A C$ is a strict morphism by definition of the tensor product topology, and one deduces immediately that it is the same for $v_{C/B/A}$.

(ii) To say that $\delta_{C/B/A}$ is formally left-invertible means that for every discrete C-module L annihilated by an open ideal of C, the canonical homomorphism

$$\mathrm{Hom}\,.\,\mathrm{cont}_C(\Omega^1_{B/A} \otimes_B C, L) \to \mathrm{Hom}\,.\,\mathrm{cont}_C(\mathfrak{R}/\mathfrak{R}^2, L)$$

is surjective. But, taking into account (18.4.3) and (20.4.8), this amounts to saying that the canonical homomorphism

$$\text{Dér. } \mathrm{cont}_A(B, L) \to \mathrm{Exalcotop}_B(C, L)$$

is surjective, and the conclusion follows from the exact sequence (20.3.6.1).

The injectivity of (20.7.8.1) can also be expressed as follows, taking into account the definition of its two members (18.4.1): for every open ideal $\mathfrak{M}$ of A, every open ideal $\mathfrak{N}$ of B such that $\mathfrak{M}B \subset \mathfrak{N}$, and every $(A/\mathfrak{M})$-extension E of $B/(\mathfrak{R}+\mathfrak{N})$ by a $(B/(\mathfrak{R}+\mathfrak{N}))$-module L, such that the inverse image of E under the canonical homomorphism $B/\mathfrak{N} \to B/(\mathfrak{R}+\mathfrak{N})$ is $(A/\mathfrak{M})$-trivial, there exists an open ideal $\mathfrak{M}' \subset \mathfrak{M}$ of A, an open ideal $\mathfrak{N}' \subset \mathfrak{N}$ of B such that $\mathfrak{M}'B \subset \mathfrak{N}'$ and such that the inverse image of E under the canonical homomorphism $B/(\mathfrak{R}+\mathfrak{N}') \to B/(\mathfrak{R}+\mathfrak{N})$ is $(A/\mathfrak{M}')$-trivial. □ [$0_{\text{IV-1}}$ | 150]

(20.7.9) Corollary. *If the topological A-algebra $C = B/\mathfrak{R}$ is formally smooth, the canonical homomorphism $\delta_{C/B/A}$ is formally left-invertible.*

(20.7.10) In (20.6.1), when A, B, C are topological rings and u and v continuous homomorphisms, one equips $\Upsilon_{C/B/A}$ with the topology induced by that of $\Omega^1_{B/A} \otimes_B C$; the homomorphisms (20.6.4.2) and (20.6.4.4) are then continuous provided the same is true of those in diagram (20.6.4.1). Moreover, if in (20.6.7) one assumes that L is a discrete C-module annihilated by an open ideal of C, one deduces, by passage to the inductive limit, the canonical C-homomorphism

$$\mathrm{Exalcotop}_{B/A}(C, L) \to \mathrm{Hom}\,.\,\mathrm{cont}_C(\Upsilon_{C/B/A}, L) \tag{20.7.10.1}$$

which can be described explicitly as follows (taking into account (18.5.3.1)): for every open ideal $\mathfrak{M}$ of A, every open ideal $\mathfrak{R}$ of B such that $\mathfrak{M}B \subset \mathfrak{R}$, every open ideal $\mathfrak{P}$ of C such that $\mathfrak{R}C \subset \mathfrak{P}$ and $\mathfrak{P}.L = 0$, every $(B/\mathfrak{R})$-extension E of $C/\mathfrak{P}$ by L which is $(A/\mathfrak{M})$-trivial comes from the datum of a continuous C-homomorphism f of $\Omega^1_{B/A} \otimes_B C$ in L, and the homomorphism (20.7.10.1) associates to the class of E the restriction of f to $\Upsilon_{C/B/A}$, called the *characteristic homomorphism of E* and again denoted χ_E.

(20.7.11) Proposition. *Suppose that the topology of C is such that the square of every open ideal is also open. If C is a topological A-algebra formally smooth and if $\Omega^1_{C/B}$ is a formally projective C-module, one has a canonical isomorphism*

$$\mathrm{Exalcotop}_B(C, L) \xrightarrow{\sim} \mathrm{Hom}\,.\,\mathrm{cont}_C(\Upsilon_{C/B/A}, L) \tag{20.7.11.1}$$

for every discrete C-module L annihilated by an open ideal of C.

Proof. One has indeed, in the exact sequence (20.3.7.1), $\mathrm{Exalcotop}_A(C, L) = 0$ (19.4.4), hence $\mathrm{Exalcotop}_B(C, L) = \mathrm{Exalcotop}_{B/A}(C, L)$ and the homomorphism (20.7.10.1) is none other than (20.7.8.1); the fact that it is bijective is deduced from (20.6.13) by passage to the inductive limit by (20.4.5) and (19.2.4). □

(20.7.12) In (20.6.14) one also equips $\Upsilon^C_{B/A/\Lambda}$ with the topology induced by that of $\Omega^1_{A/\Lambda}\otimes_A C$ and the homomorphism (20.6.14.6) is continuous, when the considered rings are topological and the homomorphisms of rings are continuous.

(20.7.13) If, in (20.6.23), one assumes that the rings Λ, A, B, C are topological, the homomorphisms s, u, v continuous and L a discrete C-module annihilated by an open ideal of C, one can pass to the inductive limit as in (20.3.6), and one obtains an exact sequence

$$\begin{aligned}0 \to \text{Dér. } \mathrm{cont}_B(C,L) \to \text{Dér. } \mathrm{cont}_A(C,L) \to \text{Dér. } \mathrm{cont}_A(B,L) \to \\ \to \mathrm{Exalcotop}_{B/\Lambda}(C,L) \to \mathrm{Exalcotop}_{A/\Lambda}(C,L) \to \mathrm{Exalcotop}_{A/\Lambda}(B,L) \to 0.\end{aligned} \tag{20.7.13.1}$$

(20.7.14) Let A be a topological ring, B a topological A-algebra, $\mathfrak{M}'$ an open ideal of A, $\mathfrak{R}'$ an open ideal of B such that $\mathfrak{M}'B\subset\mathfrak{R}'$; set $A'=A/\mathfrak{M}'$, $B'=B/\mathfrak{R}'$; the kernel of the homomorphism $B\otimes_A B\to B'\otimes_{A'}B'$ is $\mathfrak{U}=\mathrm{Im}(\mathfrak{R}'\otimes B+B\otimes\mathfrak{R}')$, whence it follows immediately that the kernel of the homomorphism [$0_{\text{IV-1}}\,|\,151$]

$$\varphi_{(\mathfrak{M}',\mathfrak{R}')}:\Omega^1_{B/A}\to\Omega^1_{B'/A'} \tag{20.7.14.1}$$

is $((\mathfrak{J}\cap\mathfrak{U})+\mathfrak{J}^2)/\mathfrak{J}^2$; moreover, the homomorphism (20.7.14.1) is *surjective*, as it follows from (20.4.7). If $\mathfrak{M}''$ (resp. $\mathfrak{R}''$) is a second open ideal of A (resp. B) such that $\mathfrak{M}''\subset\mathfrak{M}'$, $\mathfrak{R}''\subset\mathfrak{R}'$ and $\mathfrak{M}''B\subset\mathfrak{R}''$, and if one sets $A''=A/\mathfrak{M}''$, $B''=B/\mathfrak{R}''$, one has a surjective homomorphism

$$\varphi_{(\mathfrak{M}'',\mathfrak{R}''),(\mathfrak{M}',\mathfrak{R}')}:\Omega^1_{B''/A''}\to\Omega^1_{B'/A'}$$

and these homomorphisms form a *projective system*. If one notices that the $((\mathfrak{J}\cap\mathfrak{U})+\mathfrak{J}^2)/\mathfrak{J}^2$ form a fundamental system of neighbourhoods of 0 in $\Omega^1_{B/A}$, one sees therefore that the *separated completion* $\widehat{\Omega}^1_{B/A}$ of the topological B-module $\Omega^1_{B/A}$ is given, up to a canonical isomorphism, by

$$\widehat{\Omega}^1_{B/A}=\varprojlim(\Omega^1_{B'/A'}). \tag{20.7.14.2}$$

Moreover, the canonical homomorphism $j:\Omega^1_{B/A}\to\widehat{\Omega}^1_{B/A}$ is the projective limit of the $\varphi_{(\mathfrak{M}',\mathfrak{R}')}$, hence $\varphi_{(\mathfrak{M}',\mathfrak{R}')}$ factors as $\Omega^1_{B/A}\xrightarrow{j}\widehat{\Omega}^1_{B/A}\to\Omega^1_{B'/A'}$, and as it is surjective one concludes that the canonical homomorphism

$$\widehat{\Omega}^1_{B/A}\to\Omega^1_{B'/A'} \tag{20.7.14.3}$$

is *surjective* for every pair $(\mathfrak{M}',\mathfrak{R}')$. One can moreover replace A' by A everywhere in the above.

Finally, if L is a separated and *complete* topological B-module, every continuous B-homomorphism from $\Omega^1_{B/A}$ to L extends uniquely to a continuous $\widehat{B}$-homomorphism from $\widehat{\Omega}^1_{B/A}$ to L and conversely such a homomorphism gives by composition with $\Omega^1_{B/A}\to\widehat{\Omega}^1_{B/A}$ a continuous B-homomorphism, so that one has a canonical isomorphism

$$\mathrm{Hom}\,.\,\mathrm{cont}_B(\Omega^1_{B/A},L)\xrightarrow{\sim}\mathrm{Hom}\,.\,\mathrm{cont}_{\widehat{B}}(\widehat{\Omega}^1_{B/A},L).$$

More particularly, if L is a discrete B-module annihilated by an open ideal of B, one sees that the canonical isomorphism (20.4.8.2) can also be written

$$\mathrm{Hom}\,.\,\mathrm{cont}_{\widehat{B}}(\widehat{\Omega}^1_{B/A},L)\xrightarrow{\sim}\text{Dér. }\mathrm{cont}_A(B,L). \tag{20.7.14.4}$$

(20.7.15) Proposition. *Let A be a discrete ring, B a topological adic A-algebra (**0**$_{\mathbf{I}}$, 7.1.9), $\mathfrak{n}$ an ideal of definition of B, $B_0 = B/\mathfrak{n}$. Suppose that $\Omega^1_{B_0/A}$ and $\mathfrak{n}/\mathfrak{n}^2$ are B_0-modules of finite type. Then $\widehat{\Omega}^1_{B/A}$ is a $\widehat{B}$-module of finite type.*

Proof. As the square of every open ideal of B is open, the topology of $\Omega^1_{B/A}$ is the $\mathfrak{n}$-preadic topology (20.4.5). Taking into account the hypothesis that B is an adic ring, it therefore suffices, by virtue of (**0**$_{\mathbf{I}}$, 7.2.7 and 7.2.9), to prove that $\Omega^1_{B/A}/\mathfrak{n}\Omega^1_{B/A} = \Omega^1_{B/A} \otimes_B B_0$ is a B_0-module of finite type. But this follows from the hypothesis and from the exact sequence (20.5.12.1) [0$_{\text{IV-1}}$ | 152]

$$\mathfrak{n}/\mathfrak{n}^2 \longrightarrow \Omega^1_{B/A} \otimes_B B_0 \longrightarrow \Omega^1_{B_0/A} \longrightarrow 0.$$

□

(20.7.16) Proposition (20.7.15) applies, for example, when A is a field k, $B = k'[[T_1, \ldots, T_n]]$ is a formal power series algebra equipped with its usual topology, and k' is a finite extension of k (cf. (21.9.2)). One will note that the field of fractions K of B has infinite transcendence degree over k; when k has characteristic 0, it follows immediately (with the aid, in particular, of (20.4.13), (i), and (20.5.9), also using the fact that every derivation of a field of characteristic 0 extends to every extension) that $\Omega^1_{B/k}$ is *not* a B-module of finite type.

(20.7.17) Let A, B, C be three topological rings, and let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms. Replacing A, B, C by quotients by open ideals $A' = A/\mathfrak{M}'$, $B' = B/\mathfrak{N}'$, $C' = C/\mathfrak{P}'$, with $u(\mathfrak{M}') \subset \mathfrak{N}'$ and $v(\mathfrak{N}') \subset \mathfrak{P}'$, so that one has homomorphisms $u' : A' \to B'$, $v' : B' \to C'$, one obtains canonical homomorphisms $u_{C'/B'/A'}$ and $v_{C'/B'/A'}$ which, by virtue of (20.5.4), form projective systems and consequently give, by passage to the limit, canonical homomorphisms extending to the separated completions the homomorphisms of the exact sequence (20.5.7.1)

$$\Omega^1_{B/A} \otimes_B C \xrightarrow{v_{C/B/A}} \Omega^1_{C/A} \xrightarrow{u_{C/B/A}} \Omega^1_{C/B} \longrightarrow 0 :$$

$$\widehat{v}_{C/B/A} : \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \longrightarrow \widehat{\Omega}^1_{C/A}, \tag{20.7.17.1}$$

$$\widehat{u}_{C/B/A} : \widehat{\Omega}^1_{C/A} \longrightarrow \widehat{\Omega}^1_{C/B}. \tag{20.7.17.2}$$

In the sequence

$$\widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \xrightarrow{\widehat{v}_{C/B/A}} \widehat{\Omega}^1_{C/A} \xrightarrow{\widehat{u}_{C/B/A}} \widehat{\Omega}^1_{C/B} \longrightarrow 0, \tag{20.7.17.3}$$

the composite of two consecutive homomorphisms is 0, but the sequence is *not necessarily exact*. However, if B and C are metrizable, the homomorphism $\widehat{u}_{C/B/A}$ is *surjective*, and $\mathrm{Im}(\widehat{v}_{C/B/A})$ is *dense* in $\ker(\widehat{u}_{C/B/A})$: this follows immediately (cf. **0**$_{\mathbf{I}}$, 7.3.1) from the fact that, if $(\mathfrak{M}_k)$ (resp. $(\mathfrak{N}_k)$) is a decreasing sequence of ideals of B (resp. C) forming a fundamental system of neighbourhoods of 0, and if one sets $B_k = B/\mathfrak{M}_k$, $C_k = C/\mathfrak{N}_k$, the transition homomorphisms $\Omega^1_{C_{k+1}/B_{k+1}} \to \Omega^1_{C_k/B_k}$, $\Omega^1_{C_{k+1}/A} \to \Omega^1_{C_k/A}$ and $\Omega^1_{B_{k+1}/A} \to \Omega^1_{B_k/A}$ are surjective (20.7.14).

(20.7.18) Proposition. *Let A, B, C be three topological rings, and let $u : A \to B$, $v : B \to C$ be two continuous homomorphisms. Suppose that B and C are admissible (**0**$_{\mathbf{I}}$, 7.1.2) and metrizable. For the canonical homomorphism*

$$\widehat{v}_{C/B/A} : \widehat{\Omega}^1_{B/A} \widehat{\otimes}_{\widehat{B}} \widehat{C} \longrightarrow \widehat{\Omega}^1_{C/A}$$

to admit a left inverse which is a continuous C-homomorphism, it is necessary and sufficient that C be a B-algebra formally smooth relative to A.

Proof. The condition is necessary by virtue of (20.7.2) and (19.1.6). To see that it is sufficient, note that the topological C-module

$$L = \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C}$$

is metrizable and complete by virtue of the hypotheses, hence $E = D_C(L)$, equipped
[$0_{\text{IV-1}}$ | 153] with the product topology, is metrizable and complete; it is moreover admissible, for if $\mathfrak{R}$ is an ideal of definition in C, the sequence $(\mathfrak{R}\oplus L)^n = \mathfrak{R}^n \oplus \mathfrak{R}^{n-1}L$ tends to 0. Since the composite map

$$D : B \xrightarrow{d_{B/A}} \Omega^1_{B/A} \longrightarrow \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C} = L$$

is a continuous A-derivation of B into L, the continuous A-homomorphism

$$f : x \longmapsto (v(x), D(x))$$

from B into E defines on E a structure of B-extension. Since L is a closed ideal in E, it follows from (19.9.5) and from the hypothesis that the identity map $C \to E/L$ (which is a B-homomorphism) factors as $C \xrightarrow{g} E \to E/L$, where g is a continuous homomorphism such that $g \circ v = f$; consequently (20.1.3), g is of the form $y \mapsto (y, D'(y))$, where D' is a continuous B-derivation of C into L, in other words $D' \circ v = D$. Taking into account (20.7.14.4), one has $D' = h \circ \widehat{d}_{C/A}$, where $h : \widehat{\Omega}^1_{C/A} \to L$ is a continuous C-homomorphism; but one has $\widehat{d}_{C/A} \circ v = \widehat{v}_{C/B/A} \circ D$ by definition, and since the image of B under D generates topologically the C-module L (20.4.7), the relation $D' \circ v = D$ gives $h \circ \widehat{v}_{C/B/A} = 1_L$. □

(20.7.19) Corollary. *Under the hypotheses of (20.7.18), if one supposes in addition that in B and C the square of every open ideal is open, then, for C to be a B-algebra formally smooth relative to A, it is necessary and sufficient that $\widehat{v}_{C/B/A}$ be left-invertible.*

Proof. Indeed, the topologies of $\widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C}$ and $\widehat{\Omega}^1_{C/A}$ are then deduced from that of C (20.4.5), and every C-homomorphism from one to the other is necessarily continuous. □

(20.7.20) Let A be a topological ring, B a topological A-algebra, metrizable and complete, $\mathfrak{R}$ a closed ideal of B, and $C = B/\mathfrak{R}$ the quotient topological ring, which is metrizable and complete. Let $(\mathfrak{M}_k)$ be a decreasing fundamental system of neighbourhoods of 0 in B formed of ideals, and set $B_k = B/\mathfrak{M}_k$, $\mathfrak{R}_k = (\mathfrak{R}+\mathfrak{M}_k)/\mathfrak{M}_k$, $C_k = B_k/\mathfrak{R}_k$. One has a projective system of homomorphisms

$$\delta_{C_k/B_k/A} : \mathfrak{R}_k/\mathfrak{R}_k^2 \longrightarrow \Omega^1_{B_k/A} \otimes_{B_k} C_k$$

(20.5.11.3), from which one obtains by passage to the limit a canonical homomorphism

$$\widehat{\delta}_{C/B/A} : \mathfrak{R}/\mathfrak{R}^2 \longrightarrow \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C};$$

and, reasoning as in (20.7.17), one sees that the canonical homomorphism

$$\widehat{u}_{C/B/A} : \widehat{\Omega}^1_{B/A}\widehat{\otimes}_{\widehat{B}}\widehat{C} \longrightarrow \widehat{\Omega}^1_{C/A}$$

is *surjective* and that $\mathrm{Im}(\widehat{\delta}_{C/B/A})$ is *dense* in $\ker(\widehat{u}_{C/B/A})$.

§21 Differentials in rings of characteristic p

The results of the present section, of a more specialized and technical nature than those of §§ 19, 20 and 22, will only serve occasionally in chapter IV. Their principal role here is in the proofs of three theorems of § 22 (22.3.3, 22.5.8 and 22.7.3), the first and last of which intervene in an essential way in the "fine" theory of Noetherian local rings of chapter IV, § 7.

21.1 Systems of p-generators and p-bases

[$0_{IV\text{-}1}$ | 154]

(21.1.1) Given a number p which is either 0, or a prime number, we say that a ring A is *of characteristic p* if there exists a ring homomorphism $P \to A$, where P is the *prime field* of characteristic p; we note that this homomorphism is then unique, the composite $\mathbf{Z} \to P \to A$ being the unique homomorphism of $\mathbf{Z}$ into A. If $A \neq 0$, this amounts to saying that A *contains a field of characteristic p*, the image of P being necessarily the only subfield of A isomorphic to P (and moreover the only subfield of A isomorphic to P).

(21.1.2) If $p > 0$, to say that A is of characteristic p is equivalent to saying that, in A, $p.1 = 0$, or equivalently $pA = 0$. If $p = 0$, to say that A is of characteristic p is equivalent to saying that for every integer $n \neq 0$, $n.1$ is *invertible* in A. If $A \neq 0$, there can exist only one p (prime or 0) such that A is of characteristic p; this follows from the identity of Bezout $ap + bq = 1$ for two distinct primes p, q. On the other hand, the reduced ring 0 is of characteristic p for *every* p.

(21.1.3) If A is of characteristic p, then so is every *algebra* over A. In particular, for every prime ideal $\mathfrak{p}$ of A, the *residue field* of A at $\mathfrak{p}$ is of characteristic p. Conversely, if $p = 0$ and if for every *maximal* ideal $\mathfrak{m}$ of A, the residue field of A at $\mathfrak{m}$ is of characteristic 0, then so is A, since for every integer $n \neq 0$, $n.1$ is then invertible in all the $A_{\mathfrak{m}}$, hence also in A. On the other hand, if $p > 0$, a local ring can have its residue field of characteristic p without being itself of characteristic p, as shown by the example of the *prime integer ring* $\mathbf{Z}_{p\mathbf{Z}}$ (19.8.3) or of the local Artinian ring $\mathbf{Z}/p^n\mathbf{Z}$ for $n \geq 2$, which do not contain a field.

We note finally that for a ring (even reduced), the residue fields at its prime ideals can have different characteristics, as shown by the example of $\mathbf{Z}$.

(21.1.4) In all the rest of this section, we fix a *prime number* p and all rings will be assumed *of characteristic p*, unless express mention to the contrary. For such a ring A, the map $x \mapsto x^p$ is an *endomorphism* of A, which we denote F_A; if A is *reduced*, F_A is *injective*. We set $A^p = \mathrm{F}_A(A)$ (subring of A formed by the x^p for $x \in A$); one can naturally consider A as an A^p-algebra.

One can also consider A as an A-algebra *by means of the homomorphism* $\mathrm{F}_A : x \mapsto x^p$ of A into A; in other words, this is the A-algebra $A_{[\mathrm{F}_A]}$, for which the product $\lambda.x$ of $x \in A$ by a scalar $\lambda \in A$ is the product $\lambda^p x$ in the ring A; we denote this A-algebra $A^{(p)}$. It is clear that for every ring homomorphism $u : A \to B$ the pair (u, u) is a *di-homomorphism* of A-algebras $A^{(p)} \to B^{(p)}$. For every A-module E, we set $E^{(p)} = E \otimes_A A^{(p)}$ where $A^{(p)}$ is considered as an (A, A)-bimodule, the structure of A-module on the left being that which one has just defined, and the structure of A-module on the right coming from the structure of A-module of $A^{(p)}$ provenant of the ring structure, so that for $x \in E$, α, β in A, one has

$$\alpha(x \otimes \beta) = x \otimes (\alpha\beta) \quad \text{and} \quad (\alpha x) \otimes \beta = x \otimes \alpha^p\beta.$$

[0IV-1 | 155] Setting $x^{(p)} = x \otimes 1$, one therefore has $(\alpha x)^{(p)} = \alpha^p x^{(p)}$. When F_A is *injective*, one can identify $A^{(p)}$ as an algebra over its *subring* A^p.

(21.1.5) Proposition. *Let A, B be two rings, $u : A \to B$ a homomorphism.*

(i) *Every A-derivation of B in a B-module L is zero in $A[B^p]$ (hence is an $A[B^p]$-derivation).*

(ii) *For every sub-A-algebra A' of $A[B^p]$, if $j : A' \to B$ is the canonical injection, the canonical homomorphism*

$$j_{B/A'/A} : \Omega^1_{B/A} \to \Omega^1_{B/A'}$$

is bijective.

(iii) *Suppose that there exists an integer $s \geq 0$ such that $u(A) \supset B^{p^s}$. Then, in the ring $B \otimes_A B$, $\mathfrak{J}_{B/A}$ is a nilideal.*

Proof. (i) By induction from (20.1.1), one deduces, for every A-derivation $D : B \to L$, that $D(x^k) = kx^{k-1}D(x)$, whence in particular $D(x^p) = 0$.

(ii) In view of (20.4.8), the assertion (ii) is only a translation of (i), this last being written $\mathrm{Der}_{A[B^p]}(B, L) = \mathrm{Der}_A(B, L)$ for every B-module L.

(iii) For every $x \in B$, one has $(x \otimes 1 - 1 \otimes x)^{p^s} = x^{p^s} \otimes 1 - 1 \otimes x^{p^s} = 0$, since $x^{p^s} \in u(A)$. The conclusion follows from the fact that the elements $1 \otimes x - x \otimes 1$ generate $\mathfrak{J}_{B/A}$ (20.4.4). □

It follows immediately from (21.1.5) that one has, for every pair of ring homomorphisms $A \to B \to C$,

$$\Upsilon_{C/B/A} = \Upsilon_{C/B/A'} \tag{21.1.5.1}$$

for every sub-A-algebra A' of $A[B^p]$.

On the other hand, (21.1.5) also shows in particular that for the modules of "absolute" differentials

$$\Omega^1_A = \Omega^1_{A/A^p} \tag{21.1.5.2}$$

(21.1.6) Corollary. *Suppose that B is an A-algebra of finite type and that there exists an integer $s \geq 0$ such that $u(A) \supset B^{p^s}$. If $\Omega^1_{B/A} = 0$, u is surjective.*

Proof. By (21.1.5), (iii), $\mathfrak{J}_{B/A}$ is a nilideal; moreover, by virtue of (20.4.4) and the hypothesis [0IV-1 | 156] $\Omega^1_{B/A} = 0$, the relation $\Omega^1_{B/A} = 0$ signifies that $\mathfrak{J}_{B/A} = \mathfrak{J}^2_{B/A}$, whence one concludes that $\mathfrak{J}_{B/A} = 0$, or equivalently that $\pi : B \otimes_A B \to B$ is bijective. But every element of B has its p^s-th power in $u(A)$, B is *integral* over A, and being of finite type over A, B is thus reduced to proving the following lemma (where one *does not assume* that the rings considered are of characteristic p): □

(21.1.6.1) Lemma. *Let R be a ring, S a finite R-algebra; if the canonical homomorphism $\pi : S \otimes_R S \to S$ is bijective, then the structural homomorphism $u : R \to S$ is surjective.*

Proof. It suffices to show that for every maximal ideal $\mathfrak{m}$ of R, if one sets $T = R - \mathfrak{m}$, the homomorphism $u_{\mathfrak{m}} : R_{\mathfrak{m}} \to T^{-1}S$ is surjective (Bourbaki, *Alg. comm.*, chap. II, § 3, n° 3, th. 1); or the hypothesis implies that the homomorphism $(T^{-1}S) \otimes_{R_{\mathfrak{m}}} (S/\mathfrak{m}S) \to T^{-1}S$ is bijective, and as $T^{-1}S$ is a finite $R_{\mathfrak{m}}$-algebra, one sees that one can reduce to the case where R is a local ring. Denoting again by $\mathfrak{m}$ its maximal ideal, it suffices to prove that $u \otimes 1 : R/\mathfrak{m} \to S/\mathfrak{m}S$ is surjective, by virtue of the lemma of Nakayama; as the canonical homomorphism $(S/\mathfrak{m}S) \otimes_{R/\mathfrak{m}} (S/\mathfrak{m}S) \to S/\mathfrak{m}S$ is bijective and $S/\mathfrak{m}S$ is a finite $(R/\mathfrak{m})$-algebra, one is finally reduced to the case where R is a *field*; but then the ranks of $S \otimes_R S$ and of S over R must be equal, which is possible only if S is of rank 0 or 1, hence $u : R \to S$ is surjective. □

(21.1.7) Proposition. *Let A be a ring, B an A-algebra, $(x_\alpha)_{\alpha\in I}$ a family of elements of B. Consider the following properties:*

a) *$B = A[B^p, (x_\alpha)]$, or equivalently the $A[B^p]$-algebra B is generated by the family $(x_\alpha)_{\alpha\in I}$.*

b) *The $A[B^p]$-module B is generated by the monomials $\prod_\alpha x_\alpha^{n(\alpha)}$, where $(n(\alpha))_{\alpha\in I}$ is a family of integers with finite support such that $0 \leq n(\alpha) < p$ for all $\alpha \in I$.*

c) *The B-module $\Omega^1_{B/A}$ is generated by the $d_{B/A}(x_\alpha)$ $(\alpha \in I)$.*

Then the properties a) *and* b) *are equivalent and imply* c)*; if in addition B is an $A[B^p]$-algebra of finite type,* c) *is equivalent to* a) *and* b).

Proof. It is clear that b) implies a), and conversely a) implies b), since every monomial $\prod_\alpha x_\alpha^{m(\alpha)}$, where the $m(\alpha)$ are integers ≥ 0 (forming a family with finite support), can be written $(\prod_\alpha x_\alpha^{q(\alpha)})^p \prod_\alpha x_\alpha^{r(\alpha)}$, by dividing each $m(\alpha)$ by p, which gives $m(\alpha) = p.q(\alpha) + r(\alpha)$ with $0 \leq r(\alpha) < p$. The fact that a) implies c) follows from (21.1.5), (ii) and (20.4.7).

Suppose conversely c) satisfied and that B is an $A[B^p]$-algebra of finite type; let B' be the sub-$A[B^p]$-algebra of B generated by the x_α; in the exact sequence (20.5.7.1)

$$\Omega^1_{B'/A[B^p]} \otimes_{B'} B \to \Omega^1_{B/A[B^p]} \to \Omega^1_{B/B'} \to 0$$

the hypothesis implies that the left arrow is surjective (taking into account (21.1.5), (ii)); one therefore has $\Omega^1_{B/B'} = 0$, and as $B^p \subset B' \subset B$ and B is a B'-algebra of finite type, one necessarily has $B' = B$ by (21.1.6). □

(21.1.8) Remark. When B is a *field*, we will demonstrate the equivalence of properties a), b) and c) without hypothesis of finiteness (21.4.5).

(21.1.9) Definition. Let A be a ring (of characteristic p), B an A-algebra. One says that a family $(x_\alpha)_{\alpha\in I}$ of elements of B is *p-free over A* (resp. a *system of p-generators* of B over A, resp. a *p-base* of B over A) if the family of monomials $\prod_\alpha x_\alpha^{n(\alpha)}$ $(0 \leq n(\alpha) < p$, $(n(\alpha))_{\alpha\in I}$ with finite support) is a free family (resp. a system of generators, resp. a base) in the $A[B^p]$-module B.

One has corresponding definitions for a *subset* M of elements of B, by considering the family defined by the canonical injection $M \to B$. When one takes for A the *prime field* $\mathbf{F}_p$ (in which case $A[B^p] = B^p$), one omits the mention of A in the preceding definition

(or also says that a family is "absolutely" p-free, resp. an absolute system of p-generators, resp. an absolute p-base).

[0IV-1 | 157] **(21.1.10) Lemma.** *Let C be a sub-A-algebra of B such that $B^p \subset C$, M a subset of C, N a subset of B.*

(i) *If M is a system of p-generators of C over A and N a system of p-generators of B over C, then $M \cup N$ is a system of p-generators of B over A.*

(ii) *Suppose that M is a p-base of C over A; then, for N to be p-free over C, it is necessary and sufficient that $M \cup N$ is p-free over A.*

Proof. One can reduce to the case where $B^p \subset A \subset C \subset B$. Then (i) is a particular case from the fact that if P (resp. Q) is a system of generators of the A-module C (resp. the C-module B), the set of products xy, $x \in P$ and $y \in Q$, is a system of generators of the A-module B. Preserving the same notations, if P is a base of the A-module C, to say that Q is a free family on C signifies that the relation $\sum_{\lambda,\mu} a_{\lambda\mu} x_\lambda y_\mu = 0$, where $a_{\lambda\mu} \in A$, $x_\lambda \in P$, $y_\mu \in Q$ (with x_λ (resp. y_μ) pairwise distinct) is equivalent to $a_{\lambda\mu} = 0$ for every pair (λ, μ), or equivalently $\sum_\lambda a_{\lambda\mu} x_\lambda = 0$ for every μ, whence the assertion (ii). □

21.2 p-bases and formal smoothness

(21.2.1) Theorem. *Let B be a ring, A a subring of B such that $B^p \subset A \subset B$, $(x_\alpha)_{\alpha\in I}$ a p-base of B over A. Let E be an A-algebra, $u : A \to E$ the structural homomorphism, $q : E \to B$ a surjective A-homomorphism, $\mathfrak{R}$ its kernel, and suppose that $\mathfrak{R}^p = 0$. Then:*

(i) *For there to exist an A-homomorphism right inverse $v : B \to E$ of the homomorphism $q : E \to B$, it is necessary and sufficient that $u(q(z)^p) = z^p$ for every $z \in E$.*

(ii) *When the condition of* (i) *is satisfied, for every family $(z_\alpha)_{\alpha\in I}$ of elements of E such that $q(z_\alpha) = x_\alpha$ for all $\alpha \in I$, there exists an A-homomorphism $v : B \to E$ and* a unique one *such that $v(x_\alpha) = z_\alpha$ for all $\alpha \in I$, and v is right inverse to q.*

Proof. If there exists an A-homomorphism $v : B \to E$ right inverse to q, then $v(a) = u(a)$ for every $a \in A \subset B$, and hence $v(q(z)^p) = u(q(z)^p)$ for every $z \in E$, since $B^p \subset A$. Moreover $v(q(z)) \equiv z \pmod{\mathfrak{R}}$, so $(v(q(z)))^p = z^p$ because $\mathfrak{R}^p = 0$; as $v(q(z)^p) = (v(q(z)))^p$, this proves the necessity of (i). The sufficiency of condition (i) follows from (ii).

Under the hypotheses of (ii), uniqueness is clear because the monomials $\prod_\alpha x_\alpha^{n(\alpha)}$ generate the A-module B. As these monomials, for finitely supported families with $0 \leq n(\alpha) < p$, form an A-basis of B, there is an A-linear map $v : B \to E$ such that

$$v\left(\prod_\alpha x_\alpha^{n(\alpha)}\right) = \prod_\alpha z_\alpha^{n(\alpha)}.$$

It remains to prove that v is multiplicative. One can write

$$\left(\prod_\alpha x_\alpha^{m(\alpha)}\right)\left(\prod_\alpha x_\alpha^{n(\alpha)}\right) = a\prod_\alpha x_\alpha^{r(\alpha)},$$

where $r(\alpha) = m(\alpha)+n(\alpha)$ if this sum is less than p, and $r(\alpha) = m(\alpha)+n(\alpha)-p$ otherwise,
[0IV-1 | 158] while $a \in A$ is the product of the x_α^p over the indices for which $m(\alpha) + n(\alpha) \geq p$. Thus it suffices to prove $u(a) = \prod_\alpha z_\alpha^p$, and this follows from $q(z_\alpha) = x_\alpha$ and condition (i). □

(21.2.2) Corollary. *If there exists a p-base of B over A, B is an A-algebra formally smooth relative to B^p (for the discrete topologies).*

Proof. Indeed, let E be an A-extension of B by a B-module L, $q : E \to B$ the augmentation, $u : A \to E$ the structural homomorphism. To say that E is B^p-trivial means that there exists an A-homomorphism $v : B \to E$ such that $q(v(b)) = b$ and $v(b^p) = u(b^p)$ for all $b \in B$. But one has $u(q(z)^p) = v(q(z)^p) = (v(q(z)))^p$; but by the relation $L^2 = 0$, one also has $L^p = 0$, and as $v(q(z)) - z \in L$, one has $(v(q(z)))^p = z^p$; the condition of (21.2.1), (i) is therefore satisfied, and E is B-trivial. □

(21.2.3) Corollary. *Let B be a ring, A a subring of B such that $B^p \subset A \subset B$, L a B-module. Then:*

(i) *For a derivation D of A in L to extend to a derivation of B in L, it is necessary and sufficient that D annihilate B^p.*

(ii) *If D annihilates B^p, then, for every family $(y_\alpha)_{\alpha\in I}$ of elements of L, there exists a unique derivation D' of B in L extending D and such that $D'(x_\alpha) = y_\alpha$ for all $\alpha \in I$.*

Proof. Given a derivation D of A in L, consider the ring $E = \mathrm{D}_B(L)$ and the homomorphism $u : A \to E$ defined by $u(a) = (a, D(a))$; an A-homomorphism right inverse $v : B \to E$ is then of the form $x \mapsto (x, D'(x))$, where D' is a derivation of B in L extending D (20.1.5); as $u(q(z)^p) = (q(z)^p, D(q(z)^p))$ for $z \in E$, the corollary follows immediately from (21.2.1) applied to E. □

It follows from (21.2.3) that the sequence

$$0 \to \mathrm{Der}_A(B, L) \to \mathrm{Der}_{B^p}(B, L) \to \mathrm{Der}_{B^p}(A, L) \to 0 \tag{21.2.3.1}$$

(cf. (20.2.2.1)) is *exact*, and that the map

$$D' \mapsto (D'(x_\alpha))_{\alpha\in I} \tag{21.2.3.2}$$

is an isomorphism of the B-module $\mathrm{Der}_A(B, L)$ onto the B-module product L^I (by taking $D = 0$ in (21.2.3)).

(21.2.4) Corollary. *Under the hypotheses of (21.2.3), the sequence*

$$0 \to \Omega^1_{A/B^p} \otimes_A B \to \Omega^1_{B/B^p} \to \Omega^1_{B/A} \to 0 \tag{21.2.4.1}$$

is exact and split, and the family $(d_{B/A}(x_\alpha))_{\alpha\in I}$ is a base of the B-module $\Omega^1_{B/A}$.

Proof. This follows immediately from (21.2.3) and from the formula $\mathrm{Der}_A(B, L) = \mathrm{Hom}_B(\Omega^1_{B/A}, L)$. □

(21.2.5) Corollary. *Let A be a ring, B an A-algebra, $(x_\alpha)_{\alpha\in I}$ a p-base of B over A. Then $(d_{B/A}(x_\alpha))_{\alpha\in I}$ is a base of the B-module $\Omega^1_{B/A}$.*

Proof. By using (21.1.5), (ii), one reduces to the case where $A = A[B^p]$ and it suffices then to apply (21.2.4). □

[0IV-1 | 159] **(21.2.6)** Let A, B be two rings, $u : A \to B$ a ring homomorphism; one has (with the notations of (21.1.4)) a commutative diagram

$$\begin{array}{ccc} A^{(p)} & \xrightarrow{u} & B^{(p)} \\ {\scriptstyle \mathrm{F}_A}\uparrow & & \uparrow{\scriptstyle \mathrm{F}_B} \\ A & \xrightarrow{u} & B \end{array} \tag{21.2.6.1}$$

One deduces therefore canonically a homomorphism of B-algebras

$$u \otimes 1 : A^{(p)} \otimes_A B \to B^{(p)} \tag{21.2.6.2}$$

whose image is the ring $A[B^p]$ (which is a B-algebra for the homomorphism $\mathrm{F}_B : B \to B^p$).

(21.2.7) Theorem. *Let A be a ring, B an A-algebra, $u : A \to B$ the structural homomorphism. One assumes the following conditions satisfied:*

(i) *The homomorphism (21.2.6.2) deduced from u is injective.*

(ii) *B admits a p-base $(x_\alpha)_{\alpha\in I}$ relative to A.*

*Then B is an A-algebra formally smooth (for the discrete topologies). More precisely, let E be a topological A-algebra admissible (**0**$_{\mathbf{I}}$, 7.1.2), $\mathfrak{R}$ an ideal of definition of E, $C = E/\mathfrak{R}$, $v : B \to C$ an A-homomorphism, $q : E \to C$ the augmentation. Then, for every family $(z_\alpha)_{\alpha\in I}$ of elements of E such that $q(z_\alpha) = v(x_\alpha)$ for all $\alpha \in I$, there exists an A-homomorphism $w : B \to E$ and* a unique one *such that $v = q \circ w$ and $w(x_\alpha) = z_\alpha$ for all $\alpha \in I$.*

Proof. Consider first the case where E is discrete, hence $\mathfrak{R}$ is nilpotent. One can restrict to the case where v is surjective; moreover, the reasoning of (19.4.3) allows one to suppose $\mathfrak{R}^2 = 0$ and consequently $\mathfrak{R}^p = 0$. Finally, by considering the inverse image under v of the extension E of C by $\mathfrak{R}$, one can restrict to the case where $C = B$ and v is the identity (19.4.4). As the ring homomorphism $\mathrm{F}_E : z \rightsquigarrow z^p$ vanishes on $\mathfrak{R}$, it factors as $E \xrightarrow{q} B \xrightarrow{\mathrm{F}'} E$, and F', considered as a homomorphism from B to $E^{(p)}$, is an A-*homomorphism* by definition of the A-algebra structure on $E^{(p)}$ using the composite homomorphism $A \xrightarrow{r} E \xrightarrow{\mathrm{F}_E} E^{(p)}$, where $r : A \to E$ is the structural homomorphism of the A-algebra E; moreover, $r : A^{(p)} \to E^{(p)}$ is also an A-homomorphism. There is therefore a unique A-homomorphism $f : A^{(p)} \otimes_A B \to E^{(p)}$ such that the composites of f with the canonical homomorphisms $A^{(p)} \to A^{(p)} \otimes_A B$ and $B \to A^{(p)} \otimes_A B$ are respectively r and F'. Now, by hypothesis, one can identify $A^{(p)} \otimes_A B$ with $A[B^p]$, the canonical homomorphisms $A^{(p)} \to A^{(p)} \otimes_A B$ and $B \to A^{(p)} \otimes_A B$ being identified respectively with u and F_B. One can therefore now consider E as an $A[B^p]$-algebra by means of the homomorphism f, and, by construction, one has $f(q(z)^p) = z^p$ for every $z \in E$; the conditions for applying (21.2.1) are therefore satisfied, whence the theorem in this case.

To pass to the general case, consider a fundamental system $(\mathfrak{J}_\lambda)$ of open ideals of E, and put $E_\lambda = E/\mathfrak{J}_\lambda$, $\mathfrak{R}_\lambda = (\mathfrak{R} + \mathfrak{J}_\lambda)/\mathfrak{J}_\lambda$, $C_\lambda = E_\lambda/\mathfrak{R}_\lambda = E/(\mathfrak{R} + \mathfrak{J}_\lambda)$; as E is admissible, one has $E = \varprojlim E_\lambda$ (**0**$_{\mathbf{I}}$, 7.2.2). For every pair (α, λ), denote by $z_{\alpha\lambda}$ the canonical image
[0IV-1 | 160] of z_α in E_λ, by $p_\lambda : C \to C_\lambda$ the canonical homomorphism, and by q_λ the canonical homomorphism $E_\lambda \to C_\lambda$. Since by hypothesis $\mathfrak{R}_\lambda$ is nilpotent in E_λ, the first part of the proof establishes the existence and uniqueness of an A-homomorphism $w_\lambda : B \to E_\lambda$

such that $p_\lambda \circ v = q_\lambda \circ w_\lambda$ and $w_\lambda(x_\alpha) = z_{\alpha\lambda}$ for every α. The uniqueness of the w_λ then immediately shows that (w_λ) is a projective system of homomorphisms, and $w = \varprojlim w_\lambda$ answers the question. □

(21.2.8) Remark. The verification of the existence and uniqueness of the homomorphism $w : B \to E$ such that $w(x_\alpha) = z_\alpha$ for all α can also be deduced directly from the fact that B is an A-algebra formally smooth and from the fact that the $d_{B/A}(x_\alpha)$ form a base of the B-module $\Omega^1_{B/A}$ (21.2.4), without invoking the existence of a p-base (so that the result is valid without supposing the rings of characteristic p). Indeed, one can reduce to the case where $\mathfrak{R}^2 = 0$; as $\mathrm{Der}_A(B, \mathfrak{R}) = \mathrm{Hom}_B(\Omega^1_{B/A}, \mathfrak{R})$ by (20.4.8), there exists an A-derivation D of B in $\mathfrak{R}$ and a unique one such that $D(x_\alpha) = z'_\alpha$ for every family (z'_α) of elements of $\mathfrak{R}$; the conclusion follows from (20.1.1).

21.3 p-bases and modules of imperfection

(21.3.1) Let A, B be two rings (of characteristic p), $i : A \to B$, $j : B \to A$ two ring homomorphisms such that one has

$$j(i(a)) = a^p \quad \text{for all } a \in A, \tag{21.3.1.1}$$

$$i(j(b)) = b^p \quad \text{for all } b \in B. \tag{21.3.1.2}$$

Most often, i will be *injective*, so that A is identified with a subring of B; once this identification is made, the existence of j implies that $B^p \subset A$, and j is then identified with F_B.

(21.3.2) If $h : A^p \to A$ is the canonical injection, one has, by (21.3.1.2) and (21.3.1.1), a commutative diagram

$$\begin{array}{ccc} B & \xrightarrow{j} & A \\ {\scriptstyle i}\uparrow & & \uparrow{\scriptstyle h} \\ A & \xrightarrow{\mathrm{F}_A} & A^p \end{array} \tag{21.3.2.1}$$

so that the pair (j, F_A) can be considered as a *di-homomorphism* of the A-algebra B (for i) in the A^p-algebra A (for h). One deduces a *canonical homomorphism of A-modules*

$$\pi_{B/A} : \Omega^1_{B/A} \otimes_B A_{[j]} \to \Omega^1_{A/A^p} = \Omega^1_A \tag{21.3.2.2}$$

(cf. (20.5.4); the identification of Ω^1_{A/A^p} and of the module of absolute differentials Ω^1_A comes from (21.1.5), (ii)).

One will set

$$\Theta_{B/A} = \Omega^1_{B/A} \otimes_B A_{[j]} \tag{21.3.2.3}$$

$$\Xi_{B/A} = \mathrm{Ker}(\pi_{B/A}) \tag{21.3.2.4}$$

so that one has the exact sequence [$0_{\text{IV-1}}$ | 161]

$$0 \to \Xi_{B/A} \to \Theta_{B/A} \xrightarrow{\pi_{B/A}} \Omega^1_A \tag{21.3.2.5}$$

(one notes that these notations can be confusing since $\Theta_{B/A}$ and $\pi_{B/A}$ depend not only on A and B, but also on i and j).

(21.3.3) As by (21.3.1.2), one has $\mathrm{F}_B = i \circ j$, one can write for every B-module M (cf. (21.1.4))

$$M^{(p)} = M \otimes_B B^{(p)} = (M \otimes_B A_{[j]}) \otimes_A B_{[i]} \tag{21.3.3.1}$$

whence in particular

$$(\Omega^1_{B/A})^{(p)} = \Theta_{B/A} \otimes_A B_{[i]} \tag{21.3.3.2}$$

and one deduces therefore from (21.3.2.2) a *canonical homomorphism of B-modules*

$$\pi_{B/A} \otimes 1_B : (\Omega^1_{B/A})^{(p)} \to \Omega^1_A \otimes_A B_{[i]}. \tag{21.3.3.3}$$

Taking into account (20.5.4.2), the image of this homomorphism is the B-module generated by the elements $d_A(j(b)) \otimes 1$ for $b \in B$. Their image by the canonical homomorphism $i_{B/A} : \Omega^1_A \otimes_A B \to \Omega^1_B$ deduced from i (20.5.2) is therefore contained in the sub-B-module of Ω^1_B generated by the $d_B(i(j(b)))$ for $b \in B$; by virtue of (21.3.1.2), this image is *zero*. In other words, one has a sequence of homomorphisms

$$0 \to \Xi_{B/A} \otimes_A B_{[i]} \to (\Omega^1_{B/A})^{(p)} \to \Upsilon_{B/A} \tag{21.3.3.4}$$

which is not necessarily exact, but where the composite of two consecutive homomorphisms is zero.

(21.3.4) Proposition. *If B is a flat A-module (for i), the sequence (21.3.3.4) is exact.*

Proof. This follows from the definition of flatness. The proposition (21.3.4) applies in particular when $B^p \subset A \subset B$, i and j being respectively the canonical injection and F_B (so that B is then a free A-module). But even in this case the kernel $\Xi_{B/A}$ is not necessarily zero. However: □

(21.3.5) Proposition. *Let B be a* reduced *ring, A a subring of B such that $B^p \subset A \subset B$. Suppose that there exists a p-base $(x_\lambda)_{\lambda \in L}$ of B over A and a p-base $(y_\mu)_{\mu \in M}$ of A over B^p; then the canonical homomorphism (21.3.3.4)*

$$(\Omega^1_{B/A})^{(p)} \to \Upsilon_{B/A} \tag{21.3.5.1}$$

is bijective, and the elements $d_A(x^p_\lambda) \otimes 1$ form a base of the B-module $\Upsilon_{B/A}$.

Proof. As B is reduced, $x \mapsto x^p$ is an isomorphism of structure of B onto B^p, and by transport of structure via this isomorphism, one sees that (x^p_λ) and the y_μ form a p-base of B^p over A^p (21.1.10); by consequence (21.1.5), (ii) and (21.2.5) the $d_A(x^p_\lambda)$ and the $d_A(y_\mu)$ form a *base* of the A-module Ω^1_A. But, the image of $d_A(x_\lambda) \otimes 1$ by $i_{B/A}$ is $d_B(x^p_\lambda) = 0$; on the other hand, the image of $d_A(y_\mu)$ by $i_{B/A}$ is $d_B(i(y_\mu))$, and as the y_μ and the x_λ form a p-base of B over B^p (21.1.10), the $d_B(y_\mu)$ are part of a base of Ω^1_B (21.2.5), and are thus linearly independent over B. Hence the kernel of $i_{B/A}$ has a base formed by the $d_A(x^p_\lambda) \otimes 1$, and as these are the images by (21.3.5.1), these last form a base of the B-module $\Omega^1_{B/A} \otimes_B B^{(p)}$ (21.2.5), the homomorphism (21.3.5.1) of B-modules is bijective. □ [$0_{\text{IV-1}}$ | 162]

(21.3.6) Remarks.

(i) Let A', B' be two rings of characteristic p, and suppose one has two homomorphisms $i' : A' \to B'$, $j' : B' \to A'$ verifying (21.3.1.1) and (21.3.1.2), and ring homomorphisms $f : A \to A'$, $g : B \to B'$ rendering commutative the diagram

$$\begin{array}{ccccc} A' & \xrightarrow{i'} & B' & \xrightarrow{j'} & A' \\ {\scriptstyle f}\uparrow & & {\scriptstyle g}\uparrow & & {\scriptstyle f}\uparrow \\ A & \xrightarrow{i} & B & \xrightarrow{j} & A \end{array}$$

Then the canonical homomorphism $\Omega^1_{B/A} \to \Omega^1_{B'/A'}$ (20.5.4.3) gives a dihomomorphism $\Theta_{B/A} \to \Theta_{B'/A'}$ rendering commutative the diagram

$$\begin{array}{ccccccc} 0 & \longrightarrow & \Xi_{B/A} & \longrightarrow & \Theta_{B/A} & \xrightarrow{\pi_{B/A}} & \Omega^1_A \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & \Xi_{B'/A'} & \longrightarrow & \Theta_{B'/A'} & \xrightarrow{\pi_{B'/A'}} & \Omega^1_{A'} \end{array}$$

(ii) Let A' be any A-algebra, and set $B' = B \otimes_A A'$; then $i' = i \otimes 1 : A' \to B'$ and $j' = j \otimes 1 : B' \to A'$ verify (21.3.1.1) and (21.3.1.2), and one has

$$\Omega^1_{B'/A'} = \Omega^1_{B/A} \otimes_A A' = \Omega^1_{B/A} \otimes_B B'$$

(20.5.5); one deduces a canonical A'-isomorphism

$$\Theta_{B/A} \otimes_A A' \xrightarrow{\sim} \Theta_{B'/A'} \tag{21.3.6.1}$$

and also a canonical B'-homomorphism

$$(\Omega^1_{B/A})^{(p)} \otimes_B B' \xrightarrow{\sim} (\Omega^1_{B'/A'})^{(p)}. \tag{21.3.6.2}$$

21.4 The case of field extensions

(21.4.0) Let K be a field of characteristic $p > 0$, k a subfield of K; then the ring $k[K^p]$ is equal to the field $k(K^p)$ since k is algebraic over K^p. One can therefore apply the results of the preceding sections everywhere replacing A, B and $A[B^p]$ by k, K and $k(K^p)$.

(21.4.1) Lemma. *Let k be a field of characteristic $p > 0$, K an extension of k. For an element $x \in K$ to be p-free over k, it is necessary and sufficient that $x \notin k(K^p)$.*

Proof. Indeed, x is a root of the polynomial $X^p - x^p$ of $k(K^p)[X]$, and one knows (Bourbaki, *Alg.*, chap. V, § 8, n° 1, prop. 1) that if $x \notin k(K^p)$ this polynomial is irreducible, so that the elements $1, x, \ldots, x^{p-1}$ form a base of the $k(K^p)$-module $k(K^p)(x)$. □

(21.4.2) Theorem. *Let k be a field of characteristic $p > 0$, K an extension of k, S a system of p-generators of K over k, $L \subset S$ a p-free subset over k. There exists then a p-base B of K over k such that $L \subset B \subset S$. In particular, every extension of k admits a p-base over k.*

Proof. One can reduce to the case where $K^p \subset k$. By virtue of Zorn's theorem, there exists in K a subset B such that $L \subset B \subset S$, p-free over k and *maximal* amongst the subsets of S having these properties. It suffices to see that the subfield K' of K generated by k and B is equal to K. In the opposite case, there would exist $x \in S$ not in K'; as $K^p \subset k$, one has $K' = K'(K^p)$; hence x would be p-free over K' (21.4.1), and hence $B \cup \{x\}$ would be p-free over k (21.1.10), contradicting the maximality of B. The last assertion of (21.4.2) is obtained by taking $L = \emptyset$, $S = K$. □ □

(21.4.3) Corollary. *Let k be a field of characteristic $p > 0$, K an extension of k. For a family (x_α) of elements of K to be p-free over k, it is necessary and sufficient that, for all α, x_α does not belong to the field K_α generated by $k(K^p)$ and the x_β of index $\beta \neq \alpha$.*

Proof. The condition is necessary by virtue of (21.1.10). Conversely, suppose it is satisfied; one can reduce to the case where (x_α) is a system of p-generators of K. There exists then a sub-family of (x_α) which is a p-base of K (21.4.2), but this sub-family cannot be distinct from (x_α), since by hypothesis it would not be a family of p-generators of K. □

[$0_{\text{IV-1}}$ | 163] **(21.4.4) Corollary.** *Let k be a field of characteristic $p > 0$, K an extension of k. For $\Omega^1_{K/k} = 0$, it is necessary and sufficient that $K = k(K^p)$. In particular, for $\Omega^1_K = 0$, it is necessary and sufficient that K be a* perfect field.

Proof. Indeed, if (x_α) is a p-base of K over k, the $d_{K/k}(x_\alpha)$ form a base of the K-vector space $\Omega^1_{K/k}$ (21.2.5). □

(21.4.5) Theorem. *Let k be a field of characteristic $p > 0$, K an extension of k, (x_α) a family of elements of K. For (x_α) to be p-free over k (resp. a family of p-generators of K over k, resp. a p-base of K over k), it is necessary and sufficient that the family $(d_{K/k}(x_\alpha))$ be a free family (resp. a system of generators, resp. a base) in the K-vector space $\Omega^1_{K/k}$.*

Proof: Let K' be the subfield (equal to the subring) of K generated by $k(K^p)$ and the x_α; taking
[$0_{\text{IV-1}}$ | 164] into account (21.4.3), it suffices to see that, for each α, x_α does not belong to K_α. But, in the exact sequence

$$\Omega^1_{K_\alpha/k(K^p)} \otimes_{K_\alpha} K \to \Omega^1_{K/k(K^p)} \to \Omega^1_{K/K_\alpha} \to 0$$

the images by the left arrow of the $d_{K_\alpha/k}(x_\beta)$ for $\beta \neq \alpha$ are the $d_{K/k}(x_\beta)$, hence generate a sub-vector space of $\Omega^1_{K/k(K^p)}$ not containing $d_{K/k}(x_\alpha)$, and as this sub-vector space is the kernel of the right arrow, we see that $d_{K/K_\alpha}(x_\alpha) \neq 0$, hence $x_\alpha \notin K_\alpha$.

If now (x_α) is a p-free family, it is a sub-family of a p-base of K over k (21.4.2), hence the $d_{K/k}(x_\alpha)$ are part of a base of $\Omega^1_{K/k}$ (21.2.5), and are thus linearly independent over K. Let us prove conversely that if the $d_{K/k}(x_\alpha)$ are linearly independent over K, the family (x_α) is p-free over k. □

(21.4.6) Corollary. *Let k be a field of characteristic $p > 0$, K an extension of k, x an element of K. The three following conditions are equivalent:*

a) $x \notin k(K^p)$.

b) $d_{K/k}(x) \neq 0$.

c) *The element x is p-free over k.*

(21.4.7) Proposition. *Let L be a field of characteristic $p > 0$, K a subfield of L such that $L^p \subset K \subset L$. Then the sequence of L-vector spaces*

$$0 \to \Omega^1_{K/L^p} \otimes_K L \to \Omega^1_{L/L^p} \to \Omega^1_{L/K} \to 0 \tag{21.4.7.1}$$

is exact; in other words, one has $\Upsilon_{L/K/L^p} = 0$.

Proof. This is a particular case of (21.2.4), taking into account (21.4.2). □

(21.4.8) Proposition. *Under the hypotheses of (21.4.7), the canonical homomorphism*

$$(\Omega^1_{L/K})^{(p)} \to \Upsilon_{L/K} \tag{21.4.8.1}$$

is bijective; if (x_λ) is a p-base of L over K, the elements $d_K(x_\lambda^p) \otimes 1$ form a base of the L-vector space $\Upsilon_{L/K}$.

Proof. This is a particular case of (21.3.5). □

21.5 Application: criteria for separability

In this and the following numbers, *we no longer assume* that the rings considered are of characteristic $p > 0$.

(21.5.1) Let us first note that the criterion (21.2.7) allows us to prove one part of the Cohen theorem on separable extensions (19.6.1), namely that if k is a field of characteristic $p > 0$ and if K is a separable extension of k, then K is a formally smooth k-algebra. Indeed, K admits a p-base over k (21.4.2), and on the other hand, it follows from the criterion of MacLane (Bourbaki, *Alg.*, chap. V, § 8, no. 2, prop. 3) that in an algebraic closure of K, $k^{p^{-1}}$ and K are linearly disjoint over k, and consequently the canonical homomorphism $k^{p^{-1}} \otimes_k K \to k^{p^{-1}}(K)$ is bijective, which is precisely the condition (i) of (21.2.7), after transport of structure by the isomorphism $x \mapsto x^p$.

(21.5.2) Proposition. (MacLane). *Let A, B be two complete discrete valuation rings, $\mathfrak{m}$, $\mathfrak{n}$ their respective maximal ideals, $K = A/\mathfrak{m}$ and $L = B/\mathfrak{n}$ their residue fields, $u : A \to B$ a homomorphism such that $Bu(\mathfrak{m}) = \mathfrak{n}$, $u_0 = u \otimes 1 : K \to L$ the corresponding homomorphism for the residue fields. Consider the following conditions:*

a) *L is a separable extension of K (for u_0).*

b) *For every complete discrete valuation ring B' with maximal ideal $\mathfrak{n}'$ and residue field L', every homomorphism $u' : A \to B'$ such that $B'u'(\mathfrak{m}) = \mathfrak{n}'$ and every K-isomorphism $\sigma : L \to L'$ (relative to u_0 and $u'_0 = u' \otimes 1 : K \to L'$), there exists an isomorphism $w : B \to B'$ such that $u' = w \circ u$ and that $w_0 = w \otimes 1 : L \to L'$ is equal to σ.*

b′) *For every homomorphism $u' : A \to B$ such that $Bu'(\mathfrak{m}) = \mathfrak{n}$ and such that $u'_0 = u' \otimes 1 : K \to L$ is equal to u_0, there exists an automorphism w of B such that $u' = w \circ u$ and that $w_0 = w \otimes 1 : L \to L$ is the identity.*

c) *Denoting by* $u_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ *the homomorphism deduced from* u *by passage to quotients, then for every local homomorphism* $u'_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ *such that* $\mathrm{gr}_0(u'_1) = \mathrm{gr}_0(u_1)(= u_0)$, *there exists an automorphism* w_1 *of* $B/\mathfrak{n}^2$ *such that* $\mathrm{gr}_0(w_1)$ *is the identity and that* $u'_1 = w_1 \circ u_1$.

c′) *For every local homomorphism* $u'_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$ *such that* $\mathrm{gr}_0(u'_1) = \mathrm{gr}_0(u_1)$ *and* $\mathrm{gr}_1(u'_1) = \mathrm{gr}_1(u_1)$ (*homomorphism of* $\mathfrak{m}/\mathfrak{m}^2$ *into* $\mathfrak{n}/\mathfrak{n}^2$), *there exists an automorphism* w_1 *of* $B/\mathfrak{n}^2$ *such that* $\mathrm{gr}_0(w_1)$ *is the identity and that* $u'_1 = w_1 \circ u_1$.

Then one has the implications c) $\Leftrightarrow$ c′) $\Leftrightarrow$ a) $\Rightarrow$ b) $\Rightarrow$ b′).

If moreover A *is a Cohen ring, the five conditions are equivalent.*

Proof. The implications b) $\Rightarrow$ b′) and c) $\Rightarrow$ c′) are trivial. Let us show that a) implies b). The homomorphism u makes B into a torsion-free A-module, since it transforms a uniformizer of A into a uniformizer of B; it follows that B is a *flat* A-module ($\mathbf{0_I}$, 6.3.4), hence a *Cohen* A*-algebra* (19.8.1); the fact that a) implies b) is then a consequence of (19.8.2), (i) applied to $C = B'$, $\mathfrak{J} = \mathfrak{n}'$, B' being considered as an A-algebra for u' and the homomorphism $B \to B'/\mathfrak{n}'$ being the composite $B \to B/\mathfrak{n} \xrightarrow{\sigma} B'/\mathfrak{n}'$, which is an A-homomorphism by virtue of the hypothesis $u'_0 = \sigma \circ u_0$. The same reasoning proves that a) implies c), taking $C = B/\mathfrak{n}^2$, $\mathfrak{J} = \mathfrak{n}/\mathfrak{n}^2$, C being considered as an A-algebra for u'_1.

Let us prove next that c′) implies a). The two homomorphisms u_1 and u'_1 are such that $u'_1 = u_1 + D$, where D is a derivation of $A/\mathfrak{m}^2$ into $\mathfrak{n}/\mathfrak{n}^2$ (20.1.1); moreover, the hypothesis $\mathrm{gr}_1(u'_1) = \mathrm{gr}_1(u_1)$ means that D is zero in $\mathfrak{m}/\mathfrak{m}^2$, and can thus be considered as a derivation of $K = A/\mathfrak{m}$ into $\mathfrak{n}/\mathfrak{n}^2$, and $\mathfrak{n}/\mathfrak{n}^2$ identifies (by choice of a uniformizer of B) with the K-module L (for u_0). On the other hand, the conditions imposed on w_1 imply that $\mathrm{gr}_1(w_1)$ is also the identity (since $u_1(\mathfrak{m}/\mathfrak{m}^2)$ generates $\mathfrak{n}/\mathfrak{n}^2$); w_1 is thus of the form $z \mapsto z + D'(z)$, where D' is this time a derivation of $B/\mathfrak{n}^2$ in the $(B/\mathfrak{n}^2)$-module $\mathfrak{n}/\mathfrak{n}^2$; as w_1 is the identity on $\mathfrak{n}/\mathfrak{n}^2$, D' can again (by the preceding identification of $\mathfrak{n}/\mathfrak{n}^2$ and of L) be considered as a derivation *of* L *into* L; finally, the relation $u'_1 = w_1 \circ u_1$ means that D' *extends* D. Let us note, on the other hand, that every derivation D of K into L corresponds to a homomorphism u'_1 satisfying the conditions of c′) (20.1.1); condition c′) therefore means that every derivation of K into L extends to a derivation of L into itself, that is to say (20.6.5), that L is separable over K.

Let us prove finally that, when A is a Cohen ring, b′) implies c′). Let us show first that under the hypotheses of c′), there exists a homomorphism $u' : A \to B$ satisfying the hypotheses of b′) and that, by passage to quotients, gives $u'_1 : A/\mathfrak{m}^2 \to B/\mathfrak{n}^2$. Indeed, this follows from (19.8.6), (i) applied to the composite homomorphism $v' : A \to A/\mathfrak{m}^2 \xrightarrow{u'_1}$
[$0_{\text{IV-1}}$ | 166] $B/\mathfrak{n}^2$; this last thus factors as $A \xrightarrow{u'} B \to B/\mathfrak{n}^2$ and the hypotheses on $\mathrm{gr}_0(u'_1)$ and $\mathrm{gr}_1(u'_1)$ imply $\mathrm{gr}_0(u') = \mathrm{gr}_0(u) = u_0$ and $\mathrm{gr}_1(u') = \mathrm{gr}_1(u)$, hence the image by u' of a uniformizer of A is a uniformizer of B, and therefore $Bu'(\mathfrak{m}) = \mathfrak{n}$. It then suffices, to obtain an automorphism w_1 satisfying the question, to take the automorphism deduced by passage to quotients from the automorphism w of B provided by the application of b′) to the homomorphism u'. □

(21.5.3) Remarks.

(i) The differential properties of fields allow us to solve the question of the *uniqueness* of the representative field in a complete local Noetherian ring C (19.8.7), (ii). Let $\mathfrak{J}$ be the maximal ideal of C, $K = C/\mathfrak{J}$ the residue field of C; we can restrict to the case $\mathfrak{J} \neq 0$. Suppose there exists a homomorphism $u : K \to C$ that, composed

with the augmentation $C \to K$, gives the identity; then, *for this homomorphism to be unique, it is necessary and sufficient that* $\Omega^1_K = 0$. Indeed, the condition $\Omega^1_K = 0$ implies that K is formally unramified on its prime field (20.7.4); if there existed a second homomorphism $v \neq u$ satisfying the question, there would exist a largest integer n such that $\mathfrak{J}^n$ contains the set of the $u(x) - v(x)$ for $x \in K$; by passage to the quotient, u and v would give two distinct homomorphisms u', v' of K into $C/\mathfrak{J}^{n+1}$, whose composites with $C/\mathfrak{J}^{n+1} \to C/\mathfrak{J}^n$ would be equal, which contradicts the definition (19.10.2). Conversely, suppose $\Omega^1_K \neq 0$; then there exists a derivation $D \neq 0$ of K into $\mathfrak{J}/\mathfrak{J}^2$ (20.4.8), hence a homomorphism $v_1 : K \to C/\mathfrak{J}^2$ such that, if $u_1 : K \to C/\mathfrak{J}^2$ is obtained by passage to quotients from u, one has $v_1 = u_1 + D$ (20.1.1). If k is the prime field of K, C is a k-algebra and K a formally smooth k-algebra (19.6.1), and the restrictions of u_1 and v_1 to k coincide, hence v_1 factors as $K \xrightarrow{v} C \to C/\mathfrak{J}^2$ and one has $v \neq u$.

Let us recall (20.6.20) and (21.4.4) that the condition $\Omega^1_K = 0$ means that K is *perfect* if it is of characteristic $\neq 0$, and an algebraic extension of $\mathbf{Q}$ if it is of characteristic 0.

(ii) In the same way, let W be a Cohen ring, C a complete local Noetherian ring, $\mathfrak{J}$ a nonzero ideal of C contained in the maximal ideal; for the factorization $W \xrightarrow{v} C \to C/\mathfrak{J}$ in (19.8.6), (i) to be *unique*, it is necessary and sufficient that the residue field K of the Cohen ring W is such that $\Omega^1_K = 0$. Indeed, if $\Omega^1_K \neq 0$ and if $\mathfrak{m}$ denotes the maximal ideal of W, it suffices to compose a derivation $D \neq 0$ of K into $\mathfrak{J}/\mathfrak{m}\mathfrak{J}$ to obtain a derivation $D' \neq 0$ of W into $\mathfrak{J}/\mathfrak{m}\mathfrak{J}$ and one finishes the reasoning as in (i) by forming the homomorphism $v_1 : W \to C/\mathfrak{m}\mathfrak{J}$ distinct from the homomorphism $u_1 : W \to C/\mathfrak{m}\mathfrak{J}$ deduced from u by passage to quotients; one finishes by invoking (19.8.6), (i). If on the contrary $\Omega^1_K = 0$, the uniqueness of v already follows from (i) when W is a field of characteristic 0. In the opposite case, one has $\widehat{\Omega}^1_W = 0$; in fact, one then has $\mathfrak{m} = pW$, p being the characteristic of K (19.8.5), and the canonical homomorphism $\mathfrak{m}/\mathfrak{m}^2 \to \Omega^1_W/\mathfrak{m}\Omega^1_W$ (20.5.11.2) is consequently zero. The exact sequence (20.5.12.1) applied to W and to $K = W/\mathfrak{m}$ then implies that $\Omega^1_W = \mathfrak{m}\Omega^1_W$, whence our assertion. But then (20.7.4) W is formally unramified (for its adic topology) over $\mathbf{Z}$, and the uniqueness of v is proved as in (i).

21.6 Admissible fields for an extension

(21.6.1) Given four fields $k_0 \subset k \subset K \subset L$, it follows from (20.6.16) and (20.6.17) that one has an exact sequence

$$0 \to \Upsilon_{K/k/k_0} \otimes_K L \xrightarrow{v} \Upsilon_{L/k/k_0} \xrightarrow{u} \Upsilon_{L/K/k_0} \xrightarrow{s} \Upsilon_{L/K/k} \to 0. \tag{21.6.1.1}$$

When one fixes k_0, K, and L and one lets the intermediate field k between k_0 and K "vary", one evidently has $\Upsilon_{L/K/k_0} = \Upsilon_{L/K/k}$ when $k = k_0$. When the canonical homomorphism s of (21.6.1.1) is still *bijective*, one says that k is a *k_0-admissible field for the extension L of K*. The interest of the existence, under certain conditions, of such fields k, which are however "sufficiently close" to K (for example such that $[K : k]$ is finite) is that they allow us to replace in certain questions the modules of differentials Ω^1_{K/k_0} and Ω^1_{L/k_0} (which can be "too large", for example when k_0 is the prime field) by $\Omega^1_{K/k}$ and $\Omega^1_{L/k}$, which are more easily handled.

When k_0 is the *prime field*, one says "admissible field" instead of "k_0-admissible field".

We set

(21.6.1.2)

$$\Delta(L/K, k/k_0) = \mathrm{Coker}(\Upsilon_{K/k/k_0} \otimes_K L \to \Upsilon_{L/k/k_0}) \simeq \mathrm{Ker}(\Upsilon_{L/K/k_0} \to \Upsilon_{L/K/k})$$

(vector space over L); its rank will be denoted $d(L/K, k/k_0)$ and called the *defect of k_0-admissibility of k for the extension L of K* (it is evidently zero if and only if k is k_0-admissible for this extension). When k_0 is the prime field, one writes $\Delta(L/K, k)$ and $d(L/K, k)$ instead of $\Delta(L/K, k/k_0)$ and $d(L/K, k/k_0)$.

(21.6.2) Proposition. *Let $k_0 \subset k \subset K \subset L$ be four fields.*

(i) *The following conditions are equivalent:*

a) *The field k is k_0-admissible for the extension L of K (in other words, the homomorphism $\Upsilon_{L/K/k_0} \to \Upsilon_{L/K/k}$ is injective, hence bijective).*

b) *The canonical homomorphism $u : \Upsilon_{K/k/k_0} \to \Upsilon_{L/k/k_0}$ is zero.*

c) *The canonical homomorphism $v : \Upsilon_{K/k/k_0} \otimes_K L \to \Upsilon_{L/k/k_0}$ is surjective (hence bijective).*

d) *One has $d(L/K, k/k_0) = 0$ (or $\Delta(L/K, k/k_0) = 0$).*

(ii) *The equivalent conditions of* (i) *are satisfied when one is in one of the following cases: α) L is separable over k; β) L is separable over K; γ) one has $k \subset k_0(K^p)$, where p denotes the characteristic exponent of k_0.*

Proof. (i) The assertions follow trivially from the exactness of the sequence (21.6.1.1).

(ii) If L is separable over k, one has $\Upsilon_{L/k/k_0} = 0$ (20.6.19), hence condition b) of (i) is satisfied; if L is separable over K, one has $\Upsilon_{L/K/k_0} = 0$ (20.6.19), hence condition a) of (i) is satisfied; finally, if $k \subset k_0(K^p)$, it follows that $\Upsilon_{L/K/k_0} = \Upsilon_{L/K/k}$ by virtue of (21.1.5.1), and the condition a) of (i) is satisfied.

□

(21.6.3) Suppose that one has a commutative diagram of monomorphisms of fields

$$\begin{array}{ccccccc} k_0' & \longrightarrow & k' & \longrightarrow & K' & \longrightarrow & L' \\ \uparrow & & \uparrow & & \uparrow & & \uparrow \\ k_0 & \longrightarrow & k & \longrightarrow & K & \longrightarrow & L \end{array}$$

It then follows from (20.6.17), (ii) that one has a canonical homomorphism

$$\Delta(L/K, k/k_0) \to \Delta(L'/K', k'/k_0') \tag{21.6.3.1}$$

with an evident transitivity property, so that one can say that $\Delta(L/K, k/k_0)$ is a *functor* in the quadruplet (k_0, k, K, L).

(21.6.4) Proposition.

(i) *Let $k \subset k' \subset k'' \subset K \subset L$ be five fields. One has an exact sequence of canonical homomorphisms*

$$0 \to \Delta(L/K, k'/k) \to \Delta(L/K, k''/k) \to \Delta(L/K, k''/k') \to 0 \tag{21.6.4.1}$$

and consequently the equality

$$d(L/K, k''/k) = d(L/K, k''/k') + d(L/K, k'/k). \tag{21.6.4.2}$$

(ii) *Let $k_0 \subset k \subset K \subset L \subset M$ be five fields. One has an exact sequence of canonical homomorphisms*

$$0 \to \Delta(L/K, k/k_0) \otimes_L M \to \Delta(M/K, k/k_0) \to \Delta(M/L, k/k_0) \to 0 \tag{21.6.4.3}$$

and consequently the equality

$$d(M/K, k/k_0) = d(M/L, k/k_0) + d(L/K, k/k_0). \tag{21.6.4.4}$$

Proof. (i) Consider the commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \Upsilon_{K/k'/k} \otimes_K L & \longrightarrow & \Upsilon_{K/k''/k} \otimes_K L & \longrightarrow & \Upsilon_{K/k''/k'} \otimes_K L & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \Upsilon_{L/k'/k} & \longrightarrow & \Upsilon_{L/k''/k} & \longrightarrow & \Upsilon_{L/k''/k'} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \Delta(L/K, k'/k) & \longrightarrow & \Delta(L/K, k''/k) & \longrightarrow & \Delta(L/K, k''/k') & \longrightarrow & 0
\end{array}$$

where one can consider the three rows as *complexes* $T_1^\bullet$, $T_2^\bullet$, $T_3^\bullet$ respectively; the exact sequence (21.6.1.1) and the definition of Δ (21.6.1.2) show that one has an exact sequence of complexes $0 \to T_1^\bullet \to T_2^\bullet \to T_3^\bullet \to 0$; applying the exact cohomology sequence to it, and noting that, by virtue of the exactness of (21.6.1.1), the cohomology of $T_1^\bullet$ and that of $T_2^\bullet$ are zero except in a single degree, for which the cohomology modules are both equal to $\Upsilon_{k''/k'/k} \otimes_{k''} L$; as $T_1^\bullet$ and $T_2^\bullet$ have the same cohomology, that of $T_3^\bullet$ is necessarily zero, which proves (i).

(ii) Consider similarly the commutative diagram

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \Delta(L/K, k/k_0) \otimes_L M & \longrightarrow & \Delta(M/K, k/k_0) & \longrightarrow & \Delta(M/L, k/k_0) & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & \Upsilon_{L/K/k_0} \otimes_L M & \longrightarrow & \Upsilon_{M/K/k_0} & \longrightarrow & \Upsilon_{M/L/k_0} & \longrightarrow & 0 \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & \Upsilon_{L/K/k} \otimes_L M & \longrightarrow & \Upsilon_{M/K/k} & \longrightarrow & \Upsilon_{M/L/k} & \longrightarrow & 0
\end{array}$$

where again one considers the three rows as *complexes* $T_1'^\bullet$, $T_2'^\bullet$, and $T_3'^\bullet$; the exact sequence (21.6.1.1) and the definition of Δ (21.6.1.2) give here a short exact sequence of complexes $0 \to T_1'^\bullet \to T_2'^\bullet \to T_3'^\bullet \to 0$; applying the exact cohomology sequence to it again, this time, by virtue of the exactness of (21.6.1.1), the cohomology of $T_2'^\bullet$ and that of $T_3'^\bullet$ are zero except in a single degree, for which the cohomology modules are both equal to $\Upsilon_{M/L/k_0}$; one concludes therefore that the cohomology of $T_1'^\bullet$ is zero, which establishes (ii).

□

(21.6.5) Corollary.

(i) *Given five fields $k \subset k' \subset k'' \subset K \subset L$, for k'' to be k-admissible for the extension L of K, it is necessary and sufficient that k' be k-admissible and that k'' be k'-admissible for the extension L of K.*

(ii) *Given five fields $k_0 \subset k \subset K \subset L \subset M$, for k to be k_0-admissible for the extension M of K, it is necessary and sufficient that it be so for the extension L of K and for the extension M of L.*

This follows immediately from the relations (21.6.4.2) and (21.6.4.4), the values of d being $\geqslant 0$.

(21.6.6) Corollary. *Let $k_0 \subset k \subset K \subset L$ be four fields, and suppose that k is k_0-admissible for the extension L of K. Then, if k'_0, k', K', L' are four fields such that $k_0 \subset k'_0 \subset k' \subset k \subset K \subset K' \subset L' \subset L$, k' is k'_0-admissible for the extension L' of K'.*

21.7 Cartier's equality

The following result translates in terms of differentials a theorem of MacLane on derivations:

(21.7.1) Theorem. (Cartier). *Let K be a field, L a finite type extension of K. Then $\Omega^1_{L/K}$ and $\Upsilon_{L/K}$ are L-vector spaces of finite rank, and one has*

$$\operatorname{rg} \Omega^1_{L/K} - \operatorname{rg} \Upsilon_{L/K} = \deg . \operatorname{tr}_K L. \tag{21.7.1.1}$$

Proof. If L' is a field such that $K \subset L' \subset L$, one has the exact sequence (20.6.15.1) (applied to $\Lambda = P$, $A = K$, $B = L'$, $C = L$)

$$0 \to \Upsilon_{L'/K} \otimes_{L'} L \to \Upsilon_{L/K} \to \Omega^1_{L'/K} \otimes_{L'} L \to \Omega^1_{L/K} \to \Omega^1_{L/L'} \to 0$$

hence (**0$_{\mathbf{III}}$**, 11.10.2)

$$\operatorname{rg}_L \Omega^1_{L/K} - \operatorname{rg}_L \Upsilon_{L/K} = (\operatorname{rg}_{L'} \Omega^1_{L/L'} - \operatorname{rg}_{L'} \Upsilon_{L/L'}) + (\operatorname{rg}_{L'} \Omega^1_{L'/K} - \operatorname{rg}_{L'} \Upsilon_{L'/K}).$$

Since moreover $\deg . \operatorname{tr}_K L = \deg . \operatorname{tr}_K L' + \deg . \operatorname{tr}_{L'} L$, one sees, by induction on the number of generators of the extension L, that one is reduced to proving (21.7.1.1) when $L = K(x)$. We then distinguish three cases:

a) x is transcendent over K; as L is separable over K, one has $\Upsilon_{L/K} = 0$ (20.6.3); on the other hand, (20.5.9) and (20.4.13) show that $\Omega^1_{L/K}$ is of rank 1, hence (21.7.1.1) in this case.

b) L is a finite algebraic separable extension of K, so that one has again $\Upsilon_{L/K} = 0$ (20.6.3). On the other hand, one has $\Omega^1_{L/K} = 0$ by (20.6.20), hence again (21.7.1.1).

c) L is a finite algebraic inseparable extension of K; the reasoning at the beginning shows that one can restrict to the case where $L^p \subset K$; it then follows from (21.4.8) that one has $\operatorname{rg}_L \Upsilon_{L/K} = \operatorname{rg}_L \Omega^1_{L/K}$, hence again (21.7.1.1). □

(21.7.2) Corollary. *Let K be a field, L a finite type extension of K, k a subfield of K. Then $\Omega^1_{L/K}$ and $\Upsilon_{L/K/k}$ are vector spaces of finite rank over L, and one has*

$$\operatorname{rg} \Omega^1_{L/K} - \operatorname{rg} \Upsilon_{L/K/k} = \deg . \operatorname{tr}_K L + d(L/K, k). \tag{21.7.2.1}$$

Moreover, one has the inequality

$$\operatorname{rg}\Omega^1_{L/K} - \operatorname{rg}\Upsilon_{L/K/k} \geqslant \deg.\operatorname{tr}_K L. \tag{21.7.2.2}$$

Furthermore, for the two members of (21.7.2.2) to be equal, it is necessary and sufficient that k be an admissible field for the extension L of K.

Proof. Indeed, as the homomorphism $\Upsilon_{L/K} \to \Upsilon_{L/K/k}$ is surjective, one has by definition (21.6.1.2) $\operatorname{rg}\Upsilon_{L/K} - \operatorname{rg}\Upsilon_{L/K/k} = d(L/K,k)$, and the corollary follows immediately from (21.7.1) and from (21.6.2). □

(21.7.3) Corollary. *Let $k \subset K \subset L$ be three fields such that L is a finite type extension of k. Then one has*

$$\operatorname{rg}_L\Omega^1_{L/k} - \operatorname{rg}_K\Omega^1_{K/k} = \deg.\operatorname{tr}_K L + d(L/K,k). \tag{21.7.3.1}$$

Moreover, one has the inequality [$0_{IV\text{-}1}$ / 171]

$$\operatorname{rg}_L\Omega^1_{L/k} - \operatorname{rg}_K\Omega^1_{K/k} \geqslant \deg.\operatorname{tr}_K L \tag{21.7.3.2}$$

the equality being attained if and only if k is an admissible field for the extension L of K.

Proof. One has the exact sequence (20.6.1.1)

$$0 \to \Upsilon_{L/K/k} \to \Omega^1_{K/k} \otimes_K L \to \Omega^1_{L/k} \to \Omega^1_{L/K} \to 0$$

hence the first member of (21.7.3.1) is equal to

$$\operatorname{rg}_L\Omega^1_{L/k} - \operatorname{rg}_L\Upsilon_{L/K/k}$$

and it suffices to apply (21.7.2). □

The interest of this last corollary is that it only involves modules of differentials, to the exclusion of modules of imperfection. We shall see moreover below (21.8.6) that for every finite type extension L of K, there exists a subfield k of K such that $[K : k]$ is finite, and which is admissible for the extension L of K, so that the two members of (21.7.3.2) are then equal.

(21.7.4) Corollary. *Let K be a finite type extension of a field k. The following conditions are equivalent:*

a) *K is a finite separable extension of k.*

b) *K is a formally unramified k-algebra (19.10.2).*

c) *K is a formally étale k-algebra (19.10.2).*

d) *One has $\Omega^1_{K/k} = 0$.*

Proof. Indeed, one knows (the topologies being discrete) that the conditions *b*) and *d*) are equivalent (20.7.4) and that *a*) implies that K is a formally smooth k-algebra (19.6.1), hence the conjunction of *a*) and *b*) is equivalent to *c*). The whole thing reduces to seeing that *d*) implies *a*). Now, by virtue of (21.7.1.1), the relation $\Omega^1_{K/k} = 0$ implies that K is algebraic (hence finite) over k and that $\Upsilon_{K/k} = 0$, that is to say (20.6.3) that K is separable over k. □

(21.7.5) Remark. By virtue of (20.6.5.2) and (**0$_{\mathbf{III}}$**, 11.10.2) the first member of (21.7.1.1) is none other than the *Euler-Poincaré characteristic* of the complex $\mathrm{K}_\bullet(C/B/A)$ introduced in (20.6.5), for $C = L$, $B = K$ and $A = P$ (prime field of K).[24] In the chapter devoted to intersection theory and to the theorem of Riemann-Roch, an important role will be played equally by generalized Euler-Poincaré characteristics (with values in groups of classes of $\mathscr{O}_X$-Modules) of complexes generalizing the complexes $\mathrm{F}_\bullet(C/A)$ considered in (20.6.22).

21.8 Criteria for admissibility

We return to our previous conventions and suppose therefore that all fields considered in this number are of characteristic $p > 0$.

(21.8.1) Lemma. *Let K be a field, k a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K such that $k = \bigcap_\alpha k_\alpha$. Let V be a vector space over K, $(a_i)_{1\leqslant i\leqslant n}$ a finite family of vectors of V; if the family (a_i) is free over k, there exists an index γ such that it is also free over k_γ.*

Proof. Let r be the rank of the family $(a_i)_{1\leqslant i\leqslant n}$ over K, and let us reason by induction on $n-r$; [$0_{\text{IV-1}}$ | 172] the proposition is evident for $n = r$, for the family $(a_i)_{1\leqslant i\leqslant r}$ is then free over K, hence over every subfield of K. Suppose for example that $(a_i)_{1\leqslant i\leqslant r}$ is free over K, and write $a_{r+1} = \sum_{i=1}^r \lambda_i a_i$ with $\lambda_i \in K$; the family $(a_i)_{1\leqslant i\leqslant r+1}$ being free over k, the λ_i cannot all belong to k; suppose for example that $\lambda_{i_0} \notin k$. Then there is an index β such that $\lambda_{i_0} \notin k_\beta$; one concludes that the family $(a_i)_{1\leqslant i\leqslant r+1}$ is *free over k_β*; indeed, if the family $(a_i)_{1\leqslant i\leqslant r+1}$ were not free over k_β, a_{r+1} would be equal to a linear combination of the a_i with coefficients in k_β, and as these coefficients are necessarily the λ_i, one would arrive at a contradiction. It now suffices to apply the induction hypothesis by replacing K by k_β and the family $(k_\alpha)_{\alpha\in I}$ by the sub-family of the k_α contained in k_β. □

(21.8.2) Lemma. *Let K be a field, p its exponential characteristic, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K such that $\bigcap_\alpha k_\alpha(K^p) = k_0(K^p)$. If $(x_i)_{1\leqslant i\leqslant n}$ is a finite family of elements of K that is p-free over k_0, there exists an index α such that (x_i) is also p-free over k_α.*

Proof. Indeed, to say that the family (x_i) is p-free over a subfield k of K means that the finite family of monomials $\prod_{i=1}^n x_i^{m(i)}$ with $0 \leqslant m(i) < p$ is free over $k(K^p)$; it suffices therefore to apply the lemma (21.8.1) to this family of monomials in the vector space $V = K$, and to the subfields $k_\alpha(K^p)$ and $k_0(K^p)$ of K. □

(21.8.3) Theorem. *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K containing k_0. The following conditions are equivalent:*

a) $\bigcap_\alpha k_\alpha(K^p) = k_0(K^p)$.

b) *For every extension L of K such that $\Upsilon_{L/K/k_\alpha}$ is an L-vector space of finite rank (which holds in particular if L is a finite type extension by virtue of (21.7.2)), there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K.*

[24] The French source prints "(20.6.3.2)", which does not exist; the homology identities used here are (20.6.5.2).

b′) *For every extension $L = K(x)$ of K, with $x^p \in K$, there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K.*

c) *The canonical map*

$$\Omega^1_{K/k_0} \to \varprojlim_\alpha \Omega^1_{K/k_\alpha} \tag{21.8.3.1}$$

is injective.

Proof. The canonical map (21.8.3.1) is understood as passage to the projective limit in the projective system of homomorphisms $\Omega^1_{K/k_0} \to \Omega^1_{K/k_\alpha}$ (20.5.3.3). We shall prove the logical scheme *c*) ⇒ *b*) ⇒ *b′*) ⇒ *a*) ⇒ *c*).

To say that k_α is k_0-admissible for the extension L of K means that the canonical homomorphism $\Upsilon_{L/K/k_0} \to \Upsilon_{L/K/k_\alpha}$ is injective; or, if N_α is the kernel of this homomorphism, the N_α form a decreasing filtering system of sub-vector spaces of $\Upsilon_{L/K/k_0}$, and as $\Upsilon_{L/K/k_0}$ is by hypothesis of *finite* rank, it amounts to the same to say that one of the N_α is 0 or that their *intersection* is 0. But this intersection is none other than the kernel of the projective limit homomorphism $\Upsilon_{L/K/k_0} \to \varprojlim_\alpha \Upsilon_{L/K/k_\alpha}$. Now, one has the commutative diagram

$$\begin{array}{ccc} \Upsilon_{L/K/k_0} & \longrightarrow & \varprojlim \Upsilon_{L/K/k_\alpha} \\ \downarrow & & \downarrow \\ \Omega^1_{K/k_0} \otimes_K L & \longrightarrow & \varprojlim(\Omega^1_{K/k_\alpha} \otimes_K L) \end{array}$$

where the left vertical arrow is injective by definition. To prove that *c*) implies *b*), it suffices therefore to show that the canonical map

$$\Omega^1_{K/k_0} \otimes_K V \to \varprojlim_\alpha (\Omega^1_{K/k_\alpha} \otimes_K V) \tag{21.8.3.2}$$

is injective for every vector space V over K (and in particular for $V = L$). Now this is evident if $V = K^n$ since then $W \otimes_K V = W^n$ for every vector space W over K and projective limits and products commute. On the other hand, for every element z of the first member of (21.8.3.2) there exists a subspace V' of V of finite rank such that $z \in \Omega^1_{K/k_0} \otimes_K V'$ (identified canonically with a subspace of $\Omega^1_{K/k_0} \otimes_K V$); if $z \neq 0$, its image in $\varprojlim(\Omega^1_{K/k_\alpha} \otimes_K V')$ is also non-zero; as the $\varprojlim$ functor is exact on the left, the image of z in the second member of (21.8.3.2) is therefore also $\neq 0$, which finishes the proof that *c*) implies *b*).

It is trivial that *b*) implies *b′*); let us show that *b′*) implies *a*). Using the notations of *b′*), one can suppose $L \neq K$. It then follows from (21.4.7) that one has $\operatorname{rg} \Upsilon_{L/K} \leqslant 1$. If $\Upsilon_{L/K/k_\alpha} = 0$ there is nothing to prove by virtue of (21.6.1.1). Otherwise, $\Upsilon_{L/K/k_\alpha}$ is identified canonically with $\Upsilon_{L/K}$, and if one sets $a = x^p$, $\Upsilon_{L/K}$ is a one-dimensional space generated by the single element $d_K(a) \otimes 1$ (21.4.7); $\Upsilon_{L/K/k_\alpha}$ is thus a one-dimensional space generated by the single element $d_{K/k_\alpha}(a) \otimes 1$, i.e., to say that a subfield k_α is k_0-admissible for the extension L of K means that one has $d_{K/k_\alpha}(a) \neq 0$, or equivalently (21.4.6) that $a \notin k_\alpha(K^p)$. Now, for every $a \notin k_0(K^p)$, one has $d_{K/k_0}(a) \neq 0$ and $K(a^{1/p}) \neq K$, hence one can apply *b′*), which proves the existence of an α such that $a \notin k_\alpha(K^p)$; as this holds for every $a \notin k_0(K^p)$, we have shown *b′*) ⇒ *a*).

It remains to show that *a*) implies *c*). Let $(x_\mu)_{\mu \in M}$ be a p-base of K over k_0; then the $d_{K/k_0}(x_\mu)$ form a base of the K-vector space Ω^1_{K/k_0} (21.4.5), and the condition *c*) means that for every finite subset J of the set of indices M, there exists $\alpha \in I$ such that

the $d_{K/k_\alpha}(x_\mu)$ for $\mu \in J$ are linearly independent in Ω^1_{K/k_α}; but this means also (21.4.5) that the x_μ for $\mu \in J$ form a p-free family *over* k_α, and the existence of an α having this property follows from (21.8.2) and from the hypothesis a). □

[$0_{\text{IV-1}}$ | 174] **(21.8.4) Corollary.** *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K, containing k_0, such that*

$$\bigcap_\alpha k_\alpha(K^p) = k_0(K^p).$$

Let L be an extension of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank; then, for every field K' such that $K \subset K' \subset L$, there exists $\alpha \in I$ such that k_α is k_0-admissible for the extension L of K'.

Proof. It suffices to apply (21.8.3) and (21.6.6). □

(21.8.5) Corollary. *Let K be a field of characteristic $p > 0$, k_0 a subfield of K, $(k_\alpha)_{\alpha\in I}$ a decreasing filtering family of subfields of K containing k_0, such that*

$$\bigcap_\alpha k_\alpha(K^p) = k_0(K^p).$$

Then, for every extension L of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank, one has $\bigcap_\alpha k_\alpha(L^p) = k_0(L^p)$.

Proof. Suppose indeed that M is an extension of L such that $\Upsilon_{M/L/k_0}$ is an M-vector space of finite rank. The exact sequence (21.6.1.1)

$$0 \to \Upsilon_{L/K/k_0} \otimes_L M \to \Upsilon_{M/K/k_0} \to \Upsilon_{M/L/k_0}$$

and the hypothesis show that $\Upsilon_{M/K/k_0}$ is also an M-vector space of finite rank. There exists therefore an index α such that k_α is k_0-admissible for the extension M of K (21.8.3); this holding also for the extension M of L (21.6.6); the equivalence of a) and b) in (21.8.3) gives the corollary. □

(21.8.6) Corollary. *Let K be a field, p its characteristic exponent, and k_0 a subfield of K. If L is an extension of K such that $\Upsilon_{L/K/k_0}$ is an L-vector space of finite rank, then there exists a subfield k of K, containing $k_0(K^p)$, such that $[K : k]$ is finite, and which is k_0-admissible for the extension L of K.*

Proof. It suffices indeed, by virtue of (21.8.3), to construct a decreasing filtering family $(k_\alpha)_{\alpha\in I}$ of subfields of K, containing K^p and k_0, for which $[K : k_\alpha] < +\infty$ and $\bigcap_\alpha k_\alpha = k_0(K^p)$. For this one considers a p-base $(x_\lambda)_{\lambda\in J}$ of K over k_0 and, for every finite subset H of J, one considers the subfield k_H of K generated by $k_0(K^p)$ and the x_λ for $\lambda \in J - H$; it follows from this definition that $(x_\lambda)_{\lambda\in H}$ is a p-base of K over k_H, and one concludes immediately that the k_H satisfy the required conditions. □

(21.8.7) Remarks.

(i) One has already seen (21.7.2) that if L is a *finite type* extension of K, $\Upsilon_{L/K/k_0}$ is of finite rank for every subfield k_0 of K. It is the same if L is a *separable* extension of K, for by virtue of (20.6.19), one has $\Upsilon_{L/K/k_0} = 0$. Finally, if L is a *finite type extension of a separable extension* L_0 *of* K, the same reasoning as in (21.8.5) shows that $\Upsilon_{L/K/k_0}$ is still of finite rank (and in fact is isomorphic to a subspace of $\Upsilon_{L/L_0/k_0}$). [$0_{\text{IV-1}}$ | 175]

(ii) In the statement of (21.8.5), and consequently in that of (21.8.3), *b*)), one cannot omit the hypothesis that $\Upsilon_{L/K/k_0}$ is of finite rank over L. Let us take for k_0 the prime field $\mathbf{F}_p$, for K a field such that $[K : K^p]$ is countably infinite (for example the field of rational functions $\mathbf{F}_p(X_1, \ldots, X_n, \ldots)$ with a countable infinity of indeterminates); the construction procedure of (21.8.6) then shows that there exists an infinite strictly decreasing sequence (K_n) of subfields of K such that $K_0 = K$ and $\bigcap_n K_n = K^p$. We shall construct increasing finite extensions M_n of K^p, such that if M is the union of the M_n, the extension $L = M^{1/p}$ of K gives (21.8.5) a counterexample. Namely, take an element x of $K - K^p$, set $M_0 = K^p$, and $M_n = K^p(a_1 x, a_2 x, \ldots, a_n x)$ for $n \geqslant 1$, where the a_n are constructed by induction so that $a_n \in K_n$ and $a_{n+1} \notin M_n(x)$ for all n: this is possible, since $M_n(x)$ is of finite degree over K^p, while K_n is not of finite degree over K^p. One concludes also that $x \notin M = L^p$, but as $x = (a_n x)a_n^{-1}$, one has $x \in K_n(M) = K_n(L^p)$ for all n, hence $x \in \bigcap_n K_n(L^p)$, which proves our assertion.

(21.8.8) Proposition. *Let k be a field of characteristic $p > 0$, and let $A = k[[T_1, \ldots, T_r]]$ be the ring of formal power series in r indeterminates over k, $K = k((T_1, \ldots, T_r))$ its field of fractions. Then there exists a decreasing filtering family (A_α) of Noetherian subrings of A such that A is an A_α-module* free of finite type *for all α and that, if K_α is the field of fractions of A_α, one has $\bigcap_\alpha K_\alpha = K^p$.*

Proof. One can write $K^p = k^p((T_1^p, \ldots, T_r^p))$; as one has seen in the proof of (21.8.6), there exists a decreasing family (k_α) of subfields of k such that $[k : k_\alpha]$ is finite for all α and $\bigcap_\alpha k_\alpha = k^p$; it is clear that if one sets $A_\alpha = k_\alpha[[T_1^p, \ldots, T_r^p]]$, A is an A_α-module *free of finite type*; the whole thing therefore reduces to proving the relation

$$\bigcap_\alpha k_\alpha((T_1^p, \ldots, T_r^p)) = k^p((T_1^p, \ldots, T_r^p)). \tag{21.8.8.1}$$

Since $\bigcap_\alpha k_\alpha = k^p$, this will follow from the following two lemmas: □

(21.8.8.2) Lemma. *If k' is an extension of a field k, one has*

$$k'[[T_1, \ldots, T_r]] \cap k((T_1, \ldots, T_r)) = k[[T_1, \ldots, T_r]].$$

Proof. Indeed, set $C = k[[T_1, \ldots, T_r]]$, $D = k'[[T_1, \ldots, T_r]]$; as $k((T_1, \ldots, T_r))$ is the field of fractions of C, it will suffice to prove that D is a C-module *faithfully flat* (Bourbaki, *Alg. comm.*, chap. I, § 3, no. 5, prop. 10). Now, C and D are Noetherian local rings, and if $\mathfrak{m}$ is the maximal ideal of C, one has $D/\mathfrak{m}^j D = (C/\mathfrak{m}^j) \otimes_k k'$, hence $D/\mathfrak{m}^j D$ is a flat $(C/\mathfrak{m}^j)$-module; it suffices to apply (**0**$_{\mathbf{III}}$, 10.2.1) and (**0**$_{\mathbf{I}}$, 6.6.2). □

(21.8.8.3) Lemma. *Let k be a field, (k_α) a decreasing filtering family of subfields of k, and set $k_0 = \bigcap_\alpha k_\alpha$. Suppose there exists a power q of the characteristic exponent of k such that $k^q \subset k_0$. Then one has*

$$\bigcap_\alpha k_\alpha((T_1, \dots, T_r)) = k_0((T_1, \dots, T_r)). \tag{21.8.8.4}$$

Proof. It suffices to prove that a nonzero element f of the first member of (21.8.8.4) belongs to the second member. Let γ be an index, $g \in k_\gamma[[T_1, \dots, T_r]]$ such that $gf \in k_\gamma[[T_1, \dots, T_r]]$; replacing g by g^q, one can suppose that $g \in k_0[[T_1, \dots, T_r]]$. Then, for all $\alpha \geqslant \gamma$, one has

[$0_{\text{IV-1}}$ | 176]

$$gf \in k_\gamma[[T_1, \dots, T_r]] \cap k_\alpha((T_1, \dots, T_r)) = k_\alpha[[T_1, \dots, T_r]]$$

by virtue of the lemma (21.8.8.2). But it is clear that the intersection of the rings $k_\alpha[[T_1, \dots, T_r]]$ is $k_0[[T_1, \dots, T_r]]$, and one has thus $f \in k_0((T_1, \dots, T_r))$. □

21.9 Completed modules of differentials in formal power series rings

In this number, the fields are no longer necessarily supposed to be of characteristic > 0.

(21.9.1) Lemma. *Let k be a field, A a complete Noetherian local ring that is a k-algebra, K the residue field of A. If K is a finite type extension of k, the A-module $\widehat{\Omega}^1_{A/k}$ is of finite type.*

Proof. By virtue of (20.7.15), it suffices to prove that $\Omega^1_{K/k}$ is a K-vector space of finite rank. Now, by hypothesis, K is the field of fractions of a k-algebra of finite type B; as $\Omega^1_{B/k}$ is a B-module of finite type by virtue of (20.4.7), the conclusion follows from (20.5.9). □

(21.9.2) Proposition. *Let k_0 be a field, A a complete Noetherian local ring that is a formally smooth k_0-algebra, $\mathfrak{m}$ its maximal ideal, $K = A/\mathfrak{m}$ its residue field (so that in particular A is isomorphic to a formal power series ring $K[[T_1, \dots, T_r]]$ (19.6.5)). If K is a finite type extension of k_0, then $\widehat{\Omega}^1_{A/k_0}$ is an A-module* free *of rank equal to* $\dim(A) + \deg.\operatorname{tr}_{k_0} K$. *Furthermore, for every subfield k of k_0 such that $\Omega^1_{k_0/k}$ is of finite rank, $\widehat{\Omega}^1_{A/k}$ is an A-free module of rank equal to* $\dim(A) + \deg.\operatorname{tr}_{k_0} K + \operatorname{rg}_{k_0}(\Omega^1_{k_0/k})$.

Proof. It is clear that, if P is the prime subfield of k_0, K is a formally smooth P-algebra (19.6.1). Let us note, on the other hand, that $\Upsilon^K_{A/k_0/P} = 0$: indeed, this amounts to seeing that the homomorphism

$$u_{A/k_0/P} \otimes 1_K : \Omega^1_{k_0/P} \otimes_{k_0} K \longrightarrow \Omega^1_{A/P} \otimes_A K$$

is injective (20.6.14.5), where u denotes the structural homomorphism $k_0 \to A$. But since A is a formally smooth k_0-algebra by hypothesis, it follows from (20.7.2) that $u_{A/k_0/P}$ is formally left invertible; hence (19.1.7), $u_{A/k_0/P} \otimes 1_K$ is left invertible and *a fortiori* injective, proving our assertion. Applying the exact sequence (20.6.22.1), with Λ, A, B, C replaced by P, k_0, A, K, gives the exact sequence

$$0 \longrightarrow \Upsilon^K_{A/k_0} \longrightarrow \mathfrak{m}/\mathfrak{m}^2 \longrightarrow \Omega^1_{A/k_0} \otimes_A K \longrightarrow \Omega^1_{K/k_0} \longrightarrow 0,$$

so that

$$\begin{aligned}\mathrm{rg}_K(\Omega^1_{A/k_0}\otimes_A K) &= \mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) + (\mathrm{rg}_K(\Omega^1_{K/k_0}) - \mathrm{rg}_K(\Upsilon_{K/k_0}))\\ &= \mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) + \deg.\mathrm{tr}_{k_0} K\end{aligned}$$

by virtue of (21.7.1). On the other hand, $\widehat{\Omega}^1_{A/k_0}$ is a formally projective A-module (20.4.9); since its topology is the $\mathfrak{m}$-preadic topology (20.4.5), $\widehat{\Omega}^1_{A/k_0}/\mathfrak{m}^{j+1}\widehat{\Omega}^1_{A/k_0}$ is a projective $(A/\mathfrak{m}^{j+1})$-module for every j (19.2.4), hence free (**0$_{\mathbf{III}}$**, 10.1.2) and of rank $n = \mathrm{rg}_K(\Omega^1_{A/k_0}\otimes_A K)$. By virtue of (21.9.1), $\widehat{\Omega}^1_{A/k_0}$ is an A-module of finite type; moreover this A-module is flat by virtue of (**0$_{\mathbf{III}}$**, 10.2.1), and is therefore free (**0$_{\mathbf{III}}$**, 10.1.3) of rank n, proving the first assertion. [0$_{\text{IV-1}}$ | 177]

Since, by hypothesis, $\Omega^1_{k_0/k}$ has finite rank over k_0, the completed tensor product $\Omega^1_{k_0/k}\widehat{\otimes}_{k_0}A$ identifies with $\Omega^1_{k_0/k}\otimes_{k_0}A$. As A is a formally smooth k_0-algebra, it follows from (20.7.18) that the homomorphism

$$\widehat{u}_{A/k_0/k} : \Omega^1_{k_0/k}\otimes_{k_0} A \longrightarrow \widehat{\Omega}^1_{A/k}$$

has a left inverse which is a continuous A-homomorphism; in particular, its image is closed in $\widehat{\Omega}^1_{A/k}$. Consequently the exact sequence

$$0 \longrightarrow \Omega^1_{k_0/k}\otimes_{k_0} A \xrightarrow{\widehat{u}_{A/k_0/k}} \widehat{\Omega}^1_{A/k} \longrightarrow \widehat{\Omega}^1_{A/k_0} \longrightarrow 0$$

is exact and split by virtue of (20.7.17) and what precedes; this completes the proof. □

(21.9.3) Corollary. *Let k be a field, A the ring of formal power series $k[[T_1,\dots,T_r]]$, equipped with its usual structure as a k-algebra. Then $\widehat{\Omega}^1_{A/k}$ is an A-free module of rank $r = \dim(A)$.*

Proof. It suffices to note that A is a k-algebra formally smooth (19.3.4), and to apply (21.9.2) with $k_0 = k = K$. □

(21.9.4) Lemma. *Let k be a field of characteristic $p > 0$, A a k-algebra that is a local Noetherian complete ring, B a sub-k-algebra of A isomorphic to a topological algebra of the form $k[[T_1,\dots,T_r]]$ and such that A is a B-algebra of finite type. If B_1 is the subalgebra $k[[T_1^p,\dots,T_r^p]]$ of B, $\widehat{\Omega}^1_{A/k}$ identifies canonically with Ω^1_{A/B_1}.*

Proof. Every continuous derivation of B_1 into a topological A-module P, which is the restriction of a continuous k-derivation of A into P, is *zero*, for it is zero in the subring $k[T_1^p,\dots,T_r^p]$ of polynomials, and this last is dense in B_1. The exact sequence (20.3.7.1) then shows that the canonical homomorphism

$$\text{Dér. cont}_{B_1}(A,P) \to \text{Dér. cont}_k(A,P)$$

is bijective; the conclusion follows from (20.7.14.4), taking into account that Ω^1_{A/B_1} is an A-module of finite type (20.4.7), hence separated and complete since A is a local Noetherian complete ring. □

(21.9.5) Proposition. *Let A be a local Noetherian complete integral ring, A_0 a subring of A isomorphic to a formal power series ring $k[[T_1, \dots, T_r]]$ over a field k, such that A is a finite A_0-algebra and that the field of fractions E of A is a separable extension of the field of fractions L_0 of A_0. Then one has*

$$\operatorname{rg}_A \widehat{\Omega}^1_{A/k} = \operatorname{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) = \dim(A). \tag{21.9.5.1}$$

Proof. Let us note that if $\mathfrak{m}_0$ is the maximal ideal of A_0, the topology of A is the $\mathfrak{m}_0$-adic topology since A is a finite A_0-algebra (Bourbaki, *Alg. comm.*, chap. IV, § 2, no. 5, cor. 3 of prop. 9) and it induces on A_0 the $\mathfrak{m}_0$-adic topology (Bourbaki, *Alg. comm.*, chap. III,
[0IV-1 | 178] § 3, no. 4, th. 3). One knows (21.9.1) that $\widehat{\Omega}^1_{A/k}$ is an A-module of finite type. By virtue of (21.9.3), $\widehat{\Omega}^1_{A_0/k}$ is a free A_0-module of rank $r = \dim(A_0) = \dim(A)$ (16.1.5); the tensor product $\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} A$ is therefore a free A-module of rank r, identical with its separated completion. Finally, $\widehat{\Omega}^1_{A/A_0}$ is an A-module of finite type (20.4.7), hence identical with its separated completion (7.3.6). This being so, in the sequence of homomorphisms

$$\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} A \xrightarrow{u} \widehat{\Omega}^1_{A/k} \xrightarrow{v} \widehat{\Omega}^1_{A/A_0} \to 0, \tag{21.9.5.2}$$

one knows that v is surjective and that $\operatorname{Im}(u)$ is dense in $\ker(v)$ (20.7.17); but every sub-A_0-module of $\widehat{\Omega}^1_{A/k}$ is closed for the $\mathfrak{m}_0$-adic topology (7.3.5), so the sequence (21.9.5.2) is exact. On the other hand, since A is integral over A_0, A_0 is integrally closed, and E is separable over L_0, $\widehat{\Omega}^1_{A/A_0}$ is a torsion A-module (20.4.13), (iv). Tensoring the exact sequence (21.9.5.2) by E, one obtains an exact sequence

$$\widehat{\Omega}^1_{A_0/k} \otimes_{A_0} E \longrightarrow \widehat{\Omega}^1_{A/k} \otimes_A E \longrightarrow 0,$$

whence $\operatorname{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) \leqslant r$.

It remains to show that there exist in $\widehat{\Omega}^1_{A/k} \otimes_A E$ r elements linearly independent over E. Let $D_i = \partial/\partial T_i$ be the canonical derivations of A_0 into itself ($1 \leqslant i \leqslant r$). They extend uniquely to derivations (still denoted D_i) of E into itself, since E is a finite separable extension of L_0. By restriction to A, these derivations give derivations of A into E, and it is immediate that they take their values in one and the same finite type sub-A-module of E. Since they are continuous on A_0 and the topology of A is the $\mathfrak{m}_0$-adic topology, one has thus obtained r continuous derivations of A into a topological A-module; they are evidently linearly independent, since $D_i(T_j) = \delta_{ij}$. This completes the proof. □

(21.9.6) Proposition. *Let $k_0 \subset k \subset K_0$ be three fields of characteristic $p > 0$, such that $[K_0 : k] < +\infty$; set*

$$L_0 = K_0((T_1, \dots, T_r)), \quad M_0 = K_0((T_1^p, \dots, T_r^p))$$

$$L = k((T_1, \dots, T_r)), \quad M = k((T_1^p, \dots, T_r^p)), \quad N = k((T_1^{p^2}, \dots, T_r^{p^2})).$$

Let E be a finite type extension of L_0.

(i) *If Υ_{K_0/k_0} is of finite rank, one has*

$$\operatorname{rg}_E \Omega^1_{E/M} - \operatorname{rg}_{K_0} \Omega^1_{K_0/k} = (r + \deg . \operatorname{tr}_{L_0} E) + d(E/K_0, k_0) + d(E/M_0, N/k_0) \tag{21.9.6.1}$$

(notations of (21.6.1)), and in particular one has

$$\operatorname{rg}_E \Omega^1_{E/M} - \operatorname{rg}_{K_0} \Omega^1_{K_0/k} \geqslant r + \deg . \operatorname{tr}_{L_0} E + d(E/K_0, k_0). \tag{21.9.6.2}$$

Furthermore, if the two members of (21.9.6.2) are equal, they remain so when one replaces k by a subfield k' such that $k_0 \subset k' \subset k$.

(ii) *Suppose moreover that* $[k_0 : k_0^p] < +\infty$. *Let* (k_α) *be a decreasing filtering family of subfields of* K_0 *containing* k_0, *such that* $[K_0 : k_\alpha] < +\infty$ *for all* α *and that* $\bigcap_\alpha k_\alpha(K_0^p) = k_0(K_0^p)$; *then there exists* α *such that, for* $k = k_\alpha$, *the two members of (21.9.6.2) are equal.*

Proof. One knows (21.1.5), (ii) that $\mathrm{rg}_E\,\Omega^1_{E/M}$ does not change when one replaces M by $M(L_0^p)$; as $L_0^p = K_0^p((T_1^p, \dots, T_r^p))$ and that $[k(K_0^p) : k] < +\infty$, one has $M(L_0^p) = k(K_0^p)((T_1^p, \dots, T_r^p))$; similarly $\Omega^1_{K_0/k}$ does not change when one replaces k by $k(K_0^p)$, so that one can *suppose that* $K_0^p \subset k$, which we shall do in what follows. We introduce also the fields [$0_{\text{IV-1}}$ | 179]

$$k_0' = k_0(K_0^p), \quad N' = k_0'((T_1^{p^2}, \dots, T_r^{p^2}))$$

so that one has the diagram of fields

$$\begin{array}{ccccccc}
K_0 & \longrightarrow & M_0 & \longrightarrow & L_0 & \longrightarrow & E \\
\uparrow & & \uparrow & & \uparrow & & \uparrow \\
k & \longrightarrow & N & \longrightarrow & M & \longrightarrow & L \\
\uparrow & & \uparrow & & \uparrow & & \\
k_0 & \longrightarrow & k_0' & \longrightarrow & N' & &
\end{array}$$

We propose to evaluate the difference δ of the first and second members of (21.9.6.2).

It follows from (21.7.3) that one has

$$\mathrm{rg}_E\,\Omega^1_{E/M} - \mathrm{rg}_{M_0}\,\Omega^1_{M_0/M} = \deg\,.\,\mathrm{tr}_{M_0}\,E + d(E/M_0, M)$$

and as L_0 is a finite extension of M_0, one has $\deg\,.\,\mathrm{tr}_{L_0}\,E = \deg\,.\,\mathrm{tr}_{M_0}\,E$. On the other hand, a p-base of K_0 over $k = k(K_0^p)$ is also a p-base of M_0 over M, hence (21.4.5), one has

$$\mathrm{rg}_{M_0}\,\Omega^1_{M_0/M} = \mathrm{rg}_{K_0}\,\Omega^1_{K_0/k},$$

so that

$$\delta = d(E/M_0, M) - d(E/K_0, k_0) - r. \tag{21.9.6.3}$$

Let us now note the following classical lemma.

(21.9.6.4) Lemma. *For every field* k, *the formal power series field* $K = k((T_1, \dots, T_r))$ *is a separable extension of* k.

Proof. Let us briefly recall the proof for completeness. It suffices (Bourbaki, *Alg.*, chap. VIII, § 7, no. 3, proof of th. 1) to prove that for every finite extension k' of k, $K \otimes_k k'$ has no nilpotent element. Set $A = k[[T_1, \dots, T_r]]$ and $S = A - \{0\}$. Then $K \otimes_k k' = S^{-1}(A \otimes_k k')$, while $A \otimes_k k'$ identifies canonically with the integral ring $A' = k'[[T_1, \dots, T_r]]$ and A with a subring of A'; the conclusion follows. □

Using this lemma and (21.6.2), (ii), one has $d(L_0/K_0, k_0) = 0$, and formula (21.6.4.4) therefore gives

$$d(E/K_0, k_0) = d(E/L_0, k_0).$$

[$0_{\text{IV-1}}$ | 180] Formulas (21.6.4.4) and (21.6.4.2) give, on the other hand,

$$d(E/M_0, M) = d(E/L_0, M) + d(L_0/M_0, M),$$

$$d(L_0/M_0, M) = d(L_0/M_0, M/N) + d(L_0/M_0, N),$$

whence

$$\delta = d(E/L_0, M) + d(L_0/M_0, N) - d(E/L_0, k_0) + d(L_0/M_0, M/N) - r.$$

We shall show that

$$d(L_0/M_0, M/N) = r. \tag{21.9.6.5}$$

Indeed, by definition,

$$d(L_0/M_0, M/N) = \mathrm{rg}_{L_0}\, \Upsilon_{L_0/M/N} - \mathrm{rg}_{M_0}\, \Upsilon_{M_0/M/N}.$$

Taking account of the two exact sequences

$$0 \longrightarrow \Upsilon_{L_0/M/N} \longrightarrow \Omega^1_{M/N} \otimes_M L_0 \longrightarrow \Omega^1_{L_0/N} \longrightarrow \Omega^1_{L_0/M} \longrightarrow 0,$$
$$0 \longrightarrow \Upsilon_{M_0/M/N} \longrightarrow \Omega^1_{M/N} \otimes_M M_0 \longrightarrow \Omega^1_{M_0/N} \longrightarrow \Omega^1_{M_0/M} \longrightarrow 0,$$

one obtains

$$\begin{aligned} d(L_0/M_0, M/N) = {} & \mathrm{rg}_{L_0}\, \Omega^1_{L_0/M} - \mathrm{rg}_{L_0}\, \Omega^1_{L_0/N} \\ & - \mathrm{rg}_{M_0}\, \Omega^1_{M_0/M} + \mathrm{rg}_{M_0}\, \Omega^1_{M_0/N}. \end{aligned}$$

Now $N(L_0^p) \supset M$, hence $\Omega^1_{L_0/N} = \Omega^1_{L_0/M}$ (21.1.5), (ii). On the other hand, the T_i^p $(1 \leqslant i \leqslant r)$ form a p-basis of M over N, and a p-basis of K_0 over k is also a p-basis of M_0 over M. Since $M_0^p \subset N$, it follows from (21.4.5) and (21.1.10) that

$$\mathrm{rg}_{M_0}\, \Omega^1_{M_0/N} = r + \mathrm{rg}_{M_0}\, \Omega^1_{M_0/M} = r + \mathrm{rg}_{K_0}\, \Omega^1_{K_0/k},$$

proving (21.9.6.5).

One has again, by (21.6.4.2),

$$d(E/L_0, M) = d(E/L_0, k_0) + d(E/L_0, M/k_0)$$

and

$$d(L_0/M_0, N) = d(L_0/M_0, N/k) + d(L_0/M_0, k).$$

Since L_0 is separable over K_0 (21.9.6.4), one has $d(L_0/K_0, k) = 0$, and consequently also $d(L_0/M_0, k) = 0$ by (21.6.2) and (21.6.4). Thus

$$\delta = d(E/L_0, M/k_0) + d(L_0/M_0, N/k).$$

Applying (21.6.4.2) twice more to the first term on the right gives

$$d(E/L_0, M/k_0) = d(E/L_0, M/N) + d(E/L_0, N/k) + d(E/L_0, k/k_0).$$

Since $M \subset N(L_0^p)$, one has $d(E/L_0, M/N) = 0$ (21.6.2); hence, by (21.6.4.4),

$$\delta = d(E/L_0, k/k_0) + d(E/M_0, N/k).$$

But M_0 and L_0 are separable extensions of K_0 (21.9.6.4), so

$$d(L_0/K_0, k/k_0) = d(M_0/K_0, k/k_0) = 0$$

by (21.6.2). Applying (21.6.4.4) twice more, one has [$0_{\text{IV-1}}$ | 181]

$$d(E/L_0, k/k_0) = d(E/K_0, k/k_0) = d(E/M_0, k/k_0),$$

and a final application of (21.6.4.2) gives

$$\delta = d(E/M_0, N/k_0),$$

which proves (21.9.6.1).

Furthermore, when k is replaced by an intermediate field k' with $k_0 \subset k' \subset k$, N is replaced by a subextension N', and therefore $d(E/M_0, N'/k_0) \leqslant d(E/M_0, N/k_0)$ (21.6.4.2). This proves the last assertion of (i).

(ii) For all α, set $N_\alpha = k_\alpha((T_1^{p^2}, \ldots, T_r^{p^2}))$. By virtue of (21.9.6.1) and of (21.8.3), it suffices to show (taking into account the fact that E is a finite type extension of M_0) that one has

$$\bigcap_\alpha N_\alpha = k_0(M_0^p).$$

Or, one has

$$\bigcap_\alpha N_\alpha = N' = (k_0(K_0^p))((T_1^{p^2}, \ldots, T_r^{p^2})) \tag{21.9.6.6}$$

by virtue of (21.8.8.3) and of the relation $\bigcap_\alpha k_\alpha = k_0(K_0^p)$ (21.8.6). On the other hand, one has $k_0(M_0^p) = k_0(K_0^p((T_1^{p^2}, \ldots, T_r^{p^2})))$. To finish the proof of (21.9.6), (ii), it therefore remains to prove the following lemma.

(21.9.6.7) Lemma. *Let k_0 be a field of characteristic $p > 0$ such that $[k_0 : k_0^p] < +\infty$, and let K_0 be an extension of k_0. Then*

$$(k_0(K_0^p))((T_1, \ldots, T_r)) = k_0\big(K_0^p((T_1, \ldots, T_r))\big). \tag{21.9.6.8}$$

Proof. Since $k_0^p \subset K_0^p$, one has

$$k_0^p(K_0^p((T_1, \ldots, T_r))) = K_0^p((T_1, \ldots, T_r)).$$

If $(c_i)_{1 \leqslant i \leqslant n}$ is a basis of k_0 over k_0^p, it is immediate that (c_i) is also a system of generators of each side of (21.9.6.8) over $K_0^p((T_1, \ldots, T_r))$. □

□

(21.9.7) Remark. The assertion of (21.9.6), (ii) *does not extend* to the case where $[k_0 : k_0^p]$ is infinite. Take for k_0 the field $\mathbf{F}_p(X_n)_{n \geqslant 0}$ of rational functions in infinitely many indeterminates, so that the X_n form a p-basis of k_0 over $\mathbf{F}_p$, and consequently $[k_0 : k_0^p] = +\infty$. In the statement of (21.9.6), take $K_0 = k_0$ (hence necessarily $k = k_0$), $L_0 = k_0((T))$, and let $E = L_0(y)$, where y is a root of

$$Y^p - \sum_{n=0}^{\infty} X_n T^{np} \in L_0[Y].$$

Then the difference δ between the two sides of (21.9.6.2) is nonzero. Indeed, E is separable over k_0; otherwise y^p would belong to $k_0(L_0^p)$, which is plainly impossible because the X_n are infinitely many algebraically independent elements. Thus $d(E/K_0, k_0) = 0$, formula

(21.9.6.3) reduces to $\delta = d(E/M_0, M_0) - 1$, and it is clear that $d(E/M_0, M_0) = \mathrm{rg}_E\, \Upsilon_{E/M_0}$. It remains to check that this rank is 2. Now $E^p \subset M_0$; a p-basis of E over L_0 consists of the single element y, and L_0 has the single-element p-basis T over M_0. Since E is algebraic over M_0, the assertion follows from (21.7.1) and (21.4.5).

(21.9.8) Proposition. *Let k_0 be a field (of arbitrary characteristic), K_0 a separable extension of k_0, A a local Noetherian complete ring, which is a k_0-algebra and whose* [$0_{IV\text{-}1}$ | 182] *residue field is a finite extension of K_0. For every prime ideal $\mathfrak{p}$ of A, let $k(\mathfrak{p})$ be the residue field of A at $\mathfrak{p}$. Then, for every field k such that $k_0 \subset k \subset K_0$ and such that $[K_0 : k] < +\infty$, one has*

$$\mathrm{rg}_{k(\mathfrak{p})}(\widehat{\Omega}^1_{(A/\mathfrak{p})/k} \otimes_{A/\mathfrak{p}} k(\mathfrak{p})) - \mathrm{rg}_{K_0}\, \Omega^1_{K_0/k} \geqslant \dim(A/\mathfrak{p}) + \mathrm{rg}_{k(\mathfrak{p})}\, \Upsilon_{k(\mathfrak{p})/k_0}. \qquad (21.9.8.1)$$

Suppose moreover that $[k_0 : k_0^p] < +\infty$ (where p is the exponential characteristic of k_0). Then one can find a field k such that $k_0(K_0^p) \subset k \subset K_0$ and $[K_0 : k] < +\infty$, for which the two members of (21.9.8.1) are equal.

Proof. As $A/\mathfrak{p}$ has the same residue field K as A and is complete, one can restrict to the case where A is integral and $\mathfrak{p} = 0$; one will then set $E = k(\mathfrak{p})$, field of fractions of A. As K_0 is formally smooth over k_0 (19.6.1), there exists a k_0-monomorphism $K_0 \to A$ making A into a K_0-algebra; one knows in particular that there exists a sub-K_0-algebra A_0 of A, K_0-isomorphic to a formal power series algebra $K_0[[T_1, \ldots, T_r]]$ and such that A is an A_0-algebra *finite* (19.8.9), which implies that E is a finite extension of the field of fractions $L_0 = K_0((T_1, \ldots, T_r))$ of A_0. One has $\Upsilon_{K_0/k_0} = 0$ since K_0 is separable over k_0, and $\deg . \mathrm{tr}_{L_0} E = 0$; moreover, as A is a finite A_0-algebra, $\dim(A) = \dim(A_0)$ (16.1.5).

If $p = 1$, one has $\mathrm{rg}_E(\widehat{\Omega}^1_{A/k} \otimes_A E) = r$ by (21.9.5) and (17.1.4), (iii), and $\Omega^1_{K_0/k} = 0$ since K_0 being a separable finite extension of k (21.7.4); on the other hand $\Upsilon_{E/k_0} = 0$, E being a separable extension of k_0; the two members of (21.9.8.1) are therefore equal in this case.

Suppose now $p > 1$; if $B = k[[T_1, \ldots, T_r]]$, A is a finite B-algebra. Setting $B_1 = k[[T_1^p, \ldots, T_r^p]]$, $\widehat{\Omega}^1_{A/k}$ identifies with Ω^1_{A/B_1} (21.9.4); and if M denotes the field of fractions $k((T_1^p, \ldots, T_r^p))$, it follows from (20.5.9) that $\widehat{\Omega}^1_{A/k} \otimes_A E$ identifies with $\Omega^1_{E/M}$. The inequality (21.9.8.1) is then none other than (21.9.6.2), and the last assertion follows from (21.9.6), (ii). □

§22 Differential criteria for smoothness and regularity

[$0_{IV\text{-}1}$ | 182] The main results of this section are:

a) The criteria (22.2.2) and (22.5.8), which give necessary and sufficient conditions for a complete Noetherian local ring A containing a field k to be formally smooth over k; the criterion (22.5.8) is stated without involving differential notions, and completes (19.6.6); the statement (22.2.2), of a slightly more technical nature, permits giving a *classification*, for fixed k, of the local rings A in question (22.2.5): they are determined by their dimension n and their residue field K, under the sole condition $n \geq \mathrm{rg}_{\mathrm{K}}\, \Upsilon_{\mathrm{K}/k}$.

b) The theorem (22.3.3), and the corollary (22.7.6) of the Jacobian criterion of Nagata (22.7.3), which give conditions allowing one to assert that a *localized* ring of a complete Noetherian local ring A containing a field k is geometrically regular over k; they will play an important role in the study of the "fine" properties of local

rings carried out in chap. IV, § 7. We do not possess for the moment any proof of (22.7.6) independent of the Jacobian criterion of Nagata.

c) The Jacobian criterion of Zariski (22.6.7) and its variants, which are easy consequences of (20.7.8).

22.1 Lifting of formal smoothness

(22.1.1) Theorem. *Let $s : \Lambda \to A$, $u : A \to B$ be two ring homomorphisms, $\mathfrak{J}$ an ideal of B, C the quotient ring $B/\mathfrak{J}$. Suppose that C is a Λ-algebra formally smooth for the discrete topology.* [$0_{IV\text{-}1}$ | 183]

(i) Suppose the following conditions are satisfied:

α) $\mathfrak{J}/\mathfrak{J}^2$ is a projective C-module.

β) The canonical homomorphism $\mathbf{S}^*_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathrm{gr}^*_{\mathfrak{J}}(B)$ (19.5.2) is bijective.

γ) The characteristic homomorphism $\chi : \Upsilon_{C/B/\Lambda} \to \mathfrak{J}/\mathfrak{J}^2$ (20.6.20) is injective.

δ) The C-module $\Omega^1_{B/A} \otimes_B C$ is projective.

Then B, equipped with the $\mathfrak{J}$-preadic topology, is a formally smooth Λ-algebra.

(ii) Conversely, suppose that B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology, and that A is a Λ-algebra formally smooth for the discrete topology. Then the conditions α), β), γ), δ) of (i) are satisfied.

Proof. By virtue of the exact sequence (20.6.22.1) (which is applicable, since $B/\mathfrak{J}^2$ is a Λ-trivial extension of C by $\mathfrak{J}/\mathfrak{J}^2$, C being assumed to be a formally smooth Λ-algebra (19.4.4)), the condition γ) is equivalent to $\Upsilon^C_{B/A/\Lambda} = 0$, or equivalently to the following:

γ') *The homomorphism $u_{B/A/\Lambda} \otimes 1_C : \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C$ is injective.*

(i) The conditions α) and β) imply that B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology (19.5.4). It amounts to the same thing to say that B is an A-algebra formally smooth, or an A-algebra formally smooth *relative to* Λ, for the $\mathfrak{J}$-preadic topology. To see that B is an A-algebra formally smooth, it suffices therefore, by virtue of (20.7.2), to prove that the continuous homomorphism of topological B-modules $u_{B/A/\Lambda} : \Omega^1_{A/\Lambda} \otimes_A B \to \Omega^1_{B/\Lambda}$ is *formally invertible on the left.* But since B is a Λ-algebra formally smooth, the topological B-module $\Omega^1_{B/\Lambda}$ is formally projective (20.4.9), and its topology is deduced from that of B (20.4.5). By virtue of (19.1.9), it suffices therefore, for $u_{B/A/\Lambda}$ to be formally invertible on the left, that $u_{B/A/\Lambda} \otimes 1_C$ be invertible on the left. But by virtue of γ'), this last map is injective, and one therefore has the exact sequence (20.6.14.7)

$$0 \to \Omega^1_{A/\Lambda} \otimes_A C \to \Omega^1_{B/\Lambda} \otimes_B C \to \Omega^1_{B/A} \otimes_B C \to 0.$$

Finally, by virtue of δ), the C-module $\Omega^1_{B/A} \otimes_B C$ is projective, so the preceding exact sequence is split, which finishes proving (i).

(ii) If B is a Λ-algebra formally smooth for the $\mathfrak{J}$-preadic topology, and A is a Λ-algebra formally smooth for the discrete topology, then B is an A-algebra formally smooth for the $\mathfrak{J}$-preadic topology (19.3.5); the conditions α) and β) therefore follow from (19.5.6). Moreover, (20.7.2) shows that $u_{B/A/\Lambda}$ is formally invertible on the left, so $u_{B/A/\Lambda} \otimes 1_C$ is invertible on the left (19.1.7), and *a fortiori* injective. Finally, $\Omega^1_{B/A}$ is a formally projective B-module (20.4.9), and consequently $\Omega^1_{B/A} \otimes_B C$ is a projective C-module (19.2.4). □ [$0_{IV\text{-}1}$ | 184]

(22.1.2) Corollary. *Let* $s : \Lambda \to \mathrm{A}$, $u : \mathrm{A} \to \mathrm{B}$ *be two ring homomorphisms,* $\mathfrak{m}$ *a maximal ideal of* B, $\mathrm{K} = \mathrm{B}/\mathfrak{m}$ *the quotient field. Suppose that the* Λ*-algebras* A *and* K *are formally smooth for the discrete topology. Then the following conditions are equivalent:*

a) B *is an* A*-algebra formally smooth for the* $\mathfrak{m}$*-preadic topology.*

b) The canonical homomorphism

$$\mathbf{S}^*_{\mathrm{K}}(\mathfrak{m}/\mathfrak{m}^2) \to \mathrm{gr}^*_{\mathfrak{m}}(\mathrm{B}) \tag{22.1.2.1}$$

is bijective, and the characteristic homomorphism

$$\chi : \Upsilon_{\mathrm{K/B}/\Lambda} \to \mathfrak{m}/\mathfrak{m}^2 \tag{22.1.2.2}$$

is injective.

Proof. This follows immediately from (22.1.1), the conditions α) and δ) being trivially satisfied here, since K is a field. □

(22.1.3) Remark. Suppose the hypotheses of (22.1.2) are satisfied, and suppose in addition that $\mathfrak{m}/\mathfrak{m}^2$ is a K-vector space of *finite* rank. Then, for B to be an A-algebra formally smooth for the $\mathfrak{m}$-preadic topology, it suffices that the following conditions be satisfied:

(22.1.3.1) Given a polynomial algebra $\mathrm{E} = \mathrm{K}[\mathrm{T}_1, \ldots, \mathrm{T}_n]$, the maximal ideal $\mathfrak{n}$ of E generated by the T_i $(1 \leq i \leq n)$, and an ideal $\mathfrak{b} \supset \mathfrak{n}^k$ in E, every Λ-homomorphism $v : \mathrm{B} \to \mathrm{E}/\mathfrak{b}$ which, by passing to quotients, gives the identity $\mathrm{K} \to \mathrm{K}$, factors as $\mathrm{B} \xrightarrow{w} \mathrm{E}/\mathfrak{n}^k \to \mathrm{E}/\mathfrak{b}$, where w is a Λ-homomorphism.

(22.1.3.2) If F is the trivial extension $\mathrm{D_K(K)}$ ("algebra of dual numbers over K"), $\rho : \mathrm{A} \to \mathrm{F}$ a ring homomorphism such that the composition $\mathrm{A} \xrightarrow{\rho} \mathrm{F} \to \mathrm{K}$ is the canonical homomorphism, then every Λ-homomorphism $v : \mathrm{B} \to \mathrm{K}$ which, by passing to quotients, gives the identity $\mathrm{K} \to \mathrm{K}$, factors as $\mathrm{B} \xrightarrow{w} \mathrm{F} \to \mathrm{K}$, where w is a Λ-homomorphism (for the A-algebra structure on F defined by ρ).

Indeed, it was seen (19.5.5) that the condition (22.1.3.1) implies that the canonical homomorphism (22.1.2.1) is bijective. By virtue of (22.1.2), it suffices then to see that $u_{\mathrm{B/A}/\Lambda} \otimes 1_{\mathrm{K}} : \Omega^1_{\mathrm{A}/\Lambda} \otimes_{\mathrm{A}} \mathrm{K} \to \Omega^1_{\mathrm{B}/\Lambda} \otimes_{\mathrm{B}} \mathrm{K}$ is injective, or equivalently (since these are vector spaces over K) that for every K-vector space L, the canonical homomorphism $\mathrm{Der}_\Lambda(\mathrm{B}, \mathrm{L}) \to \mathrm{Der}_\Lambda(\mathrm{A}, \mathrm{L})$ *is surjective* (by virtue of (20.4.8)); it is clear that for this, it is necessary and sufficient that the canonical homomorphism $\mathrm{Der}_\Lambda(\mathrm{B}, \mathrm{K}) \to \mathrm{Der}_\Lambda(\mathrm{A}, \mathrm{K})$ be surjective, and our assertion follows, by virtue of (20.1.5).

Note that the two conditions (22.1.3.1) and (22.1.3.2) are implied by the following:

(22.1.3.3) For every local Artinian Λ-algebra E with residue field equal to K, and every nilpotent ideal $\mathfrak{r}$ of E, every Λ-homomorphism $\mathrm{B} \to \mathrm{E}/\mathfrak{r}$ which, by passing to quotients, gives the identity $\mathrm{K} \to \mathrm{K}$, factors as $\mathrm{B} \xrightarrow{u} \mathrm{E} \to \mathrm{E}/\mathfrak{r}$, where u is a Λ-homomorphism.

[$0_{\text{IV-1}}$ | 185] **(22.1.4) Proposition.** *Let* $\varphi : \mathrm{A} \to \mathrm{B}$ *be a local homomorphism of local Noetherian rings, k (resp.* K*) the residue field of* A *(resp.* B*). For* B *to be a formally smooth* A*-algebra (for the preadic topologies), it is necessary and sufficient that for every local Artinian ring* C*, with residue field isomorphic to* K*, every local homomorphism* $\mathrm{A} \to \mathrm{C}$ *(making* C *a topological* A*-algebra), and every nilpotent ideal* $\mathfrak{J}$ *of* C*, every local* A*-homomorphism* $\mathrm{B} \to \mathrm{C}/\mathfrak{J}$ *such that the homomorphism* $\mathrm{K} \to \mathrm{K}$ *obtained by passing to quotients is the identity, factors as* $\mathrm{B} \xrightarrow{f} \mathrm{C} \to \mathrm{C}/\mathfrak{J}$*, where* f *is a local* A*-homomorphism.*

Proof. The condition being necessary by definition (19.3.1), let us show that it is sufficient. Since the local $\widehat{\mathrm{A}}$-homomorphisms from $\widehat{\mathrm{B}}$ into a discrete local $\widehat{\mathrm{A}}$-algebra arise by extension from the local A-homomorphisms from B into that algebra, we may restrict ourselves to the case where A and B are *complete*, by virtue of (19.3.6). When A is a *field* k, the proposition follows from (22.1.3.3), where one takes Λ to be the prime subfield of k, and (19.6.1). In the general case, set $\mathrm{B}_0 = \mathrm{B} \otimes_{\mathrm{A}} k = \mathrm{B}/\mathfrak{m}\mathrm{B}$ ($\mathfrak{m}$ the maximal ideal of A), which is complete. If C_0 is a local Artinian k-algebra with residue field isomorphic to K, $\mathfrak{J}_0$ a nilpotent ideal of C_0, every k-local homomorphism $g_0 : \mathrm{B}_0 \to \mathrm{C}_0/\mathfrak{J}_0$ giving the identity on K by passing to quotients, gives by composition an A-local homomorphism

$$g : \mathrm{B} \to \mathrm{B}_0 \xrightarrow{g_0} \mathrm{C}_0/\mathfrak{J}_0$$

which by hypothesis factors as $\mathrm{B} \xrightarrow{f} \mathrm{C}_0 \to \mathrm{C}_0/\mathfrak{J}_0$, where f is a local A-homomorphism; but as C_0 is a k-algebra, f factors as $\mathrm{B} \to \mathrm{B}_0 \xrightarrow{f_0} \mathrm{C}_0$, where f_0 is a local k-homomorphism. We thus see that the hypotheses of the statement are still fulfilled when one substitutes B_0 and k for B and A respectively; therefore B_0 is a k-algebra *formally smooth* from what we have just seen. Applying (19.7.2) and (19.7.1), we see that there exists a local Noetherian complete ring B', a local homomorphism $\mathrm{A} \to \mathrm{B}'$ making B' a flat A-module and an A-algebra *formally smooth*, and a k-isomorphism $u'_0 : \mathrm{B}'_0 = \mathrm{B}' \otimes_{\mathrm{A}} k \xrightarrow{\sim} \mathrm{B}_0$. Let v'_0 be the inverse isomorphism of u'_0; we now propose to show that there exists a local A-homomorphism $v : \mathrm{B} \to \mathrm{B}'$ such that v'_0 comes from v by passing to quotients. For this, let us denote by $\mathfrak{n}$ and $\mathfrak{n}'$ the maximal ideals of B and B' respectively, and for every j, let $w_j : \mathrm{B}/(\mathfrak{n}^{j+1} + \mathfrak{m}\mathrm{B}) \to \mathrm{B}'/(\mathfrak{n}'^{j+1} + \mathfrak{m}\mathrm{B}')$ be the A-local homomorphism deduced from v'_0 by passing to quotients; it will suffice to form for each j an A-local homomorphism $v_j : \mathrm{B}/\mathfrak{n}^{j+1} \to \mathrm{B}'/\mathfrak{n}'^{j+1}$ such that the diagrams

$$\begin{array}{ccc} \mathrm{B}/\mathfrak{n}^{j+1} & \xrightarrow{v_j} & \mathrm{B}'/\mathfrak{n}'^{j+1} \\ \downarrow & & \downarrow \\ \mathrm{B}/\mathfrak{n}^{j} & \xrightarrow[v_{j-1}]{} & \mathrm{B}'/\mathfrak{n}'^{j} \end{array} \qquad \begin{array}{ccc} \mathrm{B}/\mathfrak{n}^{j+1} & \xrightarrow{\quad v_j \quad} & \mathrm{B}'/\mathfrak{n}'^{j+1} \\ \downarrow & & \downarrow \\ \mathrm{B}/(\mathfrak{n}^{j+1} + \mathfrak{m}\mathrm{B}) & \xrightarrow[w_j]{} & \mathrm{B}'/(\mathfrak{n}'^{j+1} + \mathfrak{m}\mathrm{B}') \end{array}$$

are commutative; B and B' being complete, the homomorphism $v = \varprojlim v_j$ will give the answer. The inductive construction of v_j follows from the hypothesis on B and from the same reasoning as in (19.3.10.1), using the lemma (19.3.10.2), and the fact that [$0_{\text{IV-1}}$ | 186] $\mathfrak{n}'^{j} + (\mathfrak{n}'^{j+1} + \mathfrak{m}\mathrm{B}') = \mathfrak{n}'^{j} + \mathfrak{m}\mathrm{B}'$. It follows then from (19.7.1.4) that v is an A-*isomorphism*, for B' is a flat A-module, and B is complete for the $\mathfrak{m}$-preadic topology, the ideals $\mathfrak{m}^i\mathrm{B}$ being closed in B for the $\mathfrak{n}$-adic topology ($\mathbf{0}_{\mathrm{I}}$, 7.3.5). Q.E.D. □

22.2 Differential characterization of local algebras formally smooth over a field

(22.2.1) Let k be a field, P its prime subfield, A a k-algebra that is a *local* ring, $\mathfrak{m}$ its maximal ideal, $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ its residue field. As K is separable over P, K is a P-algebra formally smooth for the discrete topology (19.6.1), and consequently the P-extension $\mathrm{A}/\mathfrak{m}^2$ of K by $\mathfrak{m}/\mathfrak{m}^2$ is P-*trivial*, and the characteristic homomorphism

$$\chi_{\mathrm{A}/k} : \Upsilon_{\mathrm{K}/k} \to \mathfrak{m}/\mathfrak{m}^2 \tag{22.2.1.1}$$

is therefore defined (20.6.23).

(22.2.2) Theorem. *Under the conditions of (22.2.1), for* A *to be a k-algebra formally smooth for the $\mathfrak{m}$-preadic topology, it is necessary and sufficient that the following conditions be satisfied:*

(i) The canonical homomorphism $\mathbf{S}^*_{\mathrm{K}}(\mathfrak{m}/\mathfrak{m}^2) \to \mathrm{gr}^*_{\mathfrak{m}}(\mathrm{A})$ is bijective.

(ii) The characteristic homomorphism $\chi_{\mathrm{A}/k} : \Upsilon_{\mathrm{K}/k} \to \mathfrak{m}/\mathfrak{m}^2$ is injective.

This is a particular case of (22.1.2), where one replaces Λ *by* P, A *by* k, *and* B *by* A; K *and* k, *being separable over* P, *are indeed formally smooth* P*-algebras (19.6.1).*

(22.2.3) Remark. The condition (ii) of (22.2.2) can be replaced by any one of the following:

a) The canonical homomorphism $\Omega^1_k \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$ is injective.

b) For every n, the canonical homomorphism $\Omega^1_k \otimes_k (\mathrm{A}/\mathfrak{m}^{n+1}) \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{m}^{n+1})$ is invertible on the left.

c) The canonical homomorphism $\Omega^1_k \widehat{\otimes}_k \mathrm{A} \to \widehat{\Omega}^1_{\mathrm{A}}$ is invertible on the left.

d) A is a k-algebra formally smooth (for the $\mathfrak{m}$-preadic topology) *relative to the prime field.*

Indeed, it was already noted in (22.1.1) that the injectivity of $\chi_{\mathrm{A}/k}$ is equivalent to *a*), and that the conjunction of *a*) and condition (i) of (22.2.2) is equivalent to that of (i) and *d*). Finally, we have also seen in (22.1.1) that *b*) and *d*) are equivalent, and the equivalence of *b*) and *c*) follows from (19.1.8).

(22.2.4) The main application of (22.2.2) concerns Noetherian local k-algebras that are *complete* (the case where $\mathfrak{m}/\mathfrak{m}^2$ is a K-vector space of *finite* rank). More precisely, [$0_{\text{IV-1}}$ | 187] let k be a field, K an extension of k, V a K-vector space of finite rank; we consider the triplets $(\mathrm{A}, \alpha, \beta)$, where A is a complete Noetherian local k-algebra *formally smooth* with maximal ideal $\mathfrak{m}$, $\alpha : \mathrm{A}/\mathfrak{m} \xrightarrow{\sim} \mathrm{K}$ a k-algebra isomorphism, $\beta : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} \mathrm{V}$ a di-isomorphism of vector spaces (for the isomorphism α). Given two such triplets $(\mathrm{A}, \alpha, \beta)$, $(\mathrm{A}', \alpha', \beta')$, an *equivalence* from the first to the second is a k-isomorphism $u : \mathrm{A} \xrightarrow{\sim} \mathrm{A}'$ such that (if $\mathfrak{m}'$ is the maximal ideal of A′), the diagrams

$$\begin{array}{ccc} \mathrm{A}/\mathfrak{m} & \xrightarrow{\mathrm{gr}^0(u)} & \mathrm{A}'/\mathfrak{m}' \\ \downarrow{\scriptstyle \alpha} & & \downarrow{\scriptstyle \alpha'} \\ \mathrm{K} & \xrightarrow{1_{\mathrm{K}}} & \mathrm{K} \end{array} \qquad \begin{array}{ccc} \mathfrak{m}/\mathfrak{m}^2 & \xrightarrow{\mathrm{gr}^1(u)} & \mathfrak{m}'/\mathfrak{m}'^2 \\ \downarrow{\scriptstyle \beta} & & \downarrow{\scriptstyle \beta'} \\ \mathrm{V} & \xrightarrow{1_{\mathrm{V}}} & \mathrm{V} \end{array}$$

are commutative. It is immediate that the *equivalence classes* of triplets $(\mathrm{A}, \alpha, \beta)$ form a *set* that we shall denote $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$. We now note that to every triplet $(\mathrm{A}, \alpha, \beta)$ is associated the K-homomorphism composition of vector spaces $\Upsilon_{\mathrm{K}/k} \xrightarrow{\chi_{\mathrm{A}/k}} \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\beta} \mathrm{V}$ (where $\chi_{\mathrm{A}/k}$ is considered as a di-homomorphism relative to α^{-1}); the preceding definition shows (by (20.6.22.2)) that this K-homomorphism *depends only on the equivalence class* of $(\mathrm{A}, \alpha, \beta)$ in $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$; in other words we have thus defined a canonical map

$$\mathrm{FL}(\mathrm{K}/k, \mathrm{V}) \to \mathrm{Hom}_{\mathrm{K}}(\Upsilon_{\mathrm{K}/k}, \mathrm{V}). \tag{22.2.4.1}$$

(22.2.5) Proposition. *Let* k *be a field,* K *an extension of* k, V *a* K*-vector space of finite rank. The canonical map (22.2.4.1) is a bijection from* $\mathrm{FL}(\mathrm{K}/k, \mathrm{V})$ *to the set of injective* K*-homomorphisms from* $\Upsilon_{\mathrm{K}/k}$ *to* V.

Proof. (i) To show that (22.2.4.1) is injective, it must be proved that the following is true: let A, A′ be two complete Noetherian local k-algebras formally smooth, $\mathfrak{m}$, $\mathfrak{m}'$ their respective maximal ideals, $\alpha : \mathrm{A}/\mathfrak{m} \xrightarrow{\sim} \mathrm{K}$, $\alpha' : \mathrm{A}'/\mathfrak{m}' \xrightarrow{\sim} \mathrm{K}$ two k-isomorphisms; let us be given two k-isomorphisms $v^0 : \mathrm{A}/\mathfrak{m} \xrightarrow{\sim} \mathrm{A}'/\mathfrak{m}'$, $v^1 : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} \mathfrak{m}'/\mathfrak{m}'^2$ such that the diagrams

$$\begin{array}{ccc} \mathrm{A}/\mathfrak{m} & \xrightarrow{v^0} & \mathrm{A}'/\mathfrak{m}' \\ \downarrow{\scriptstyle \alpha} & \swarrow{\scriptstyle \alpha'} & \\ \mathrm{K} & & \end{array} \qquad \begin{array}{ccc} \mathfrak{m}/\mathfrak{m}^2 & \xrightarrow{v^1} & \mathfrak{m}'/\mathfrak{m}'^2 \\ \uparrow{\scriptstyle \chi_{\mathrm{A}}} & \nearrow{\scriptstyle \chi_{\mathrm{A}'}} & \\ \Upsilon_{\mathrm{K}/k} & & \end{array} \tag{22.2.5.1}$$

are commutative. One must prove that there exists a k-isomorphism $u : \mathrm{A} \xrightarrow{\sim} \mathrm{A}'$ such that $\mathrm{gr}^0(u) = v^0$ and $\mathrm{gr}^1(u) = v^1$. We note first that since K is a field, the canonical [0IV-1 | 188] homomorphism (20.6.7.1) is *bijective* (20.6.11), so there already exists a k-isomorphism $v : \mathrm{A}/\mathfrak{m}^2 \xrightarrow{\sim} \mathrm{A}'/\mathfrak{m}'^2$ such that $\mathrm{gr}^0(v) = v^0$ and $\mathrm{gr}^1(v) = v^1$. We now note that since A′ is metrizable and complete, and A a k-algebra formally smooth, the composite homomorphism $\mathrm{A} \to \mathrm{A}/\mathfrak{m}^2 \xrightarrow{v} \mathrm{A}'/\mathfrak{m}'^2$ factors as $\mathrm{A} \xrightarrow{u} \mathrm{A}' \to \mathrm{A}'/\mathfrak{m}'^2$, where u is a k-homomorphism (19.3.11), and one has thus already $\mathrm{gr}^0(u) = v^0$ and $\mathrm{gr}^1(u) = v^1$. One has the commutative diagram

$$\begin{array}{ccc} \mathbf{S}^*_{\mathrm{K}}(\mathfrak{m}/\mathfrak{m}^2) & \longrightarrow & \mathrm{gr}^*_{\mathfrak{m}}(\mathrm{A}) \\ \downarrow{\scriptstyle w} & & \downarrow{\scriptstyle \mathrm{gr}^*(u)} \\ \mathbf{S}^*_{\mathrm{K}}(\mathfrak{m}'/\mathfrak{m}'^2) & \longrightarrow & \mathrm{gr}^*_{\mathfrak{m}'}(\mathrm{A}') \end{array}$$

where the horizontal arrows are the canonical homomorphisms and w is induced by v^0 and v^1. Since v^0 and v^1 are bijective, so is w; and since A and A′ are k-algebras formally smooth, one deduces from (22.2.2), (i) that $\mathrm{gr}(u)$ is *bijective*; but since A and A′ are separated and complete, this implies that u itself is *bijective* (Bourbaki, *Alg. comm.*, chap. III, § 2, n° 8, cor. 3 of th. 1).

(ii) It remains to show that the image of (22.2.4.1) is the set of *injective* homomorphisms of $\Upsilon_{\mathrm{K}/k}$ in V; one already knows by (22.2.2), (ii) that it is contained in this set, so it remains to prove the □

(22.2.5.2) Lemma. *For every* K*-homomorphism* $h : \Upsilon_{\mathrm{K}/k} \to \mathrm{V}$*, there exists a* k*-algebra* A *that is a local Noetherian ring, regular and complete, with maximal ideal* $\mathfrak{m}$*, with residue field* K*, and a* K*-isomorphism* $\beta : \mathfrak{m}/\mathfrak{m}^2 \xrightarrow{\sim} \mathrm{V}$ *such that* $h = \beta \circ \chi_{\mathrm{A}/k}$.

Proof. Indeed, if this lemma is proved, the fact that A is regular implies that condition (i) of (22.2.2) is satisfied (17.1.1); if moreover h is injective, (22.2.2) will show that A is a k-algebra formally smooth whose equivalence class maps to h under (22.2.4.1) (while if h is not injective, the k-algebra A of which (22.2.5.2) proves the existence is not formally smooth).

To prove (22.2.5.2), let B be the K-algebra $\mathbf{S}^*_{\mathrm{K}}(\mathrm{V})$, let $\mathfrak{n}$ be the augmentation ideal of B, and let $\mathrm{A} = \widehat{\mathrm{B}}$ be the completion of B for the $\mathfrak{n}$-preadic topology (so that A is isomorphic to a formal power series algebra $\mathrm{K}[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ if $n = \mathrm{rg}_{\mathrm{K}}\,\mathrm{V}$). By virtue of (20.6.11), there exists on $\mathrm{A}/\mathfrak{m}^2$ (where $\mathfrak{m} = \mathfrak{n}\mathrm{A}$) a structure of k-extension of K by V, in general distinct from the k-trivial structure defined by the canonical injection $k \to \mathrm{K} \to \mathrm{A}$, such that h is the characteristic homomorphism of this extension. If $f : k \to \mathrm{A}/\mathfrak{m}^2$ is the structural homomorphism, the fact that k is separable over the prime field permits (19.6.1) factoring f as $k \xrightarrow{g} \mathrm{A} \to \mathrm{A}/\mathfrak{m}^2$, and the k-algebra A thus defined answers the question (20.6.22.2). □

(22.2.6) Theorem. *Let k be a field,* K *an extension of k. For there to exist a k-algebra* A*, which is a local Noetherian ring, with maximal ideal $\mathfrak{m}$, such that* $\mathrm{A}/\mathfrak{m} = \mathrm{K}$ *and such that* A *is formally smooth (for the $\mathfrak{m}$-preadic topology), it is necessary and sufficient that $\Upsilon_{\mathrm{K}/k}$ is a* K*-vector space of finite rank. The k-algebra* A *is then determined (up to k-isomorphism inducing the identity* $\mathrm{K} \to \mathrm{K}$ *on residue fields) by its dimension alone, which is subject to the sole condition of being* $\geq \mathrm{rg}_{\mathrm{K}}\, \Upsilon_{\mathrm{K}/k}$.

Proof. Since $\mathfrak{m}/\mathfrak{m}^2$ is of finite rank over K, the necessity of the condition follows from (22.2.2), (ii); conversely, (22.2.5) shows that the condition is sufficient and that one can take for $\mathfrak{m}/\mathfrak{m}^2$ a K-vector space of rank any $\geq \mathrm{rg}_{\mathrm{K}}(\Upsilon_{\mathrm{K}/k})$. □

[$0_{\text{IV-1}}$ | 189] In particular, the identity homomorphism of $\Upsilon_{\mathrm{K}/k}$ associates *canonically* to K a complete Noetherian k-algebra, formally smooth, for which $\Upsilon_{\mathrm{K}/k}$ is isomorphic to $\mathfrak{m}/\mathfrak{m}^2$.

(22.2.7) Remark.

(i) Let Λ be a local Noetherian ring, with residue field k; it follows from (19.7.1) and (19.7.2) that the determination of the Λ-algebras A that are complete Noetherian local rings and are formally smooth is *equivalent* to the same problem where Λ is replaced by k, and is thus in principle entirely solved by (22.2.5), which reduces the question to the structure of the *residue fields* of the k-algebras sought, as extensions of k.

(ii) The fact that $\Upsilon_{\mathrm{K}/k}$ is of finite rank over K does *not imply* that K is of "finite radicial multiplicity" over k (cf. (19.6.6)). For example, let k_0 be a perfect field of characteristic $p > 0$, $k = k_0(\mathrm{T})$ the field of rational functions in one indeterminate over k_0, so that $\mathrm{K} = k^{p^{-\infty}}$ is the smallest perfect extension of k. Then $\Omega^1_{\mathrm{K}} = \Omega^1_{\mathrm{K}/k} = 0$ (21.4.4), therefore $\Upsilon_{\mathrm{K}/k} = \Omega^1_k \otimes_k \mathrm{K}$, and since $k^p = k_0(\mathrm{T}^p)$, T is a p-base of k over k^p, therefore (21.4.5), Ω^1_k is of rank 1 over k, and hence $\Upsilon_{\mathrm{K}/k}$ is of rank 1 over K. But for every n the residue field of the local ring $\mathrm{K} \otimes_k k^{p^{-n}}$ is isomorphic to K, which is therefore not separable over $k^{p^{-n}}$.

(22.2.8) Proposition. *Under the conditions of (22.2.1), suppose that the characteristic p of k is > 0; let (k_α) be a decreasing filtering family of subfields of k, such that $\bigcap k_\alpha(k^p) = k^p$. Then the condition (ii) of (22.2.2) can be replaced by any one of the following:*

a) There exists α_0 such that the canonical homomorphism

$$\Omega^1_{k/k_\alpha} \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} \mathrm{K}$$

is injective for every $\alpha \geq \alpha_0$.

b) There exists α_0 such that A *is a k-algebra formally smooth (for the $\mathfrak{m}$-preadic topology) relative to k_α, for every $\alpha \geq \alpha_0$.*

c) For every α and every integer $n \geq 0$, the canonical homomorphism

$$\Omega^1_{k/k_\alpha} \otimes_k (\mathrm{A}/\mathfrak{m}^{n+1}) \to \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{m}^{n+1})$$

is invertible on the left.

Proof. Indeed, if A is a formally smooth k-algebra, it is so *a fortiori* relative to every subfield of k, which implies c) by virtue of (20.7.2) and (19.1.7); it is clear that c) implies b), and that b) implies a). Finally, taking into account (22.2.3), it remains to prove that a) implies that the canonical homomorphism $u : \Omega^1_k \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$ is *injective*. But for every α, one has a commutative diagram

$$\begin{array}{ccc} \Omega^1_k \otimes_k \mathrm{K} & \xrightarrow{u} & \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \\ {\scriptstyle v_\alpha}\downarrow & & \downarrow \\ \Omega^1_{k/k_\alpha} \otimes_k \mathrm{K} & \xrightarrow[u_\alpha]{} & \Omega^1_{\mathrm{A}/k_\alpha} \otimes_{\mathrm{A}} \mathrm{K} \end{array}$$

and the hypothesis that u_α is injective for $\alpha \geq \alpha_0$ implies that $\mathrm{Ker}(u)$ is contained in the intersection of the $\mathrm{Ker}(v_\alpha)$. But one has seen (21.8.3) that this intersection is zero by virtue of the hypothesis $\bigcap k_\alpha(k^p) = k^p$, which finishes the proof. □ [0IV-1 | 190]

(22.2.9) Proposition. *Under the hypotheses of (22.2.1), the following conditions are equivalent:*

a) $\mathrm{A}/\mathfrak{m}^2$ *is a* k*-extension* k*-trivial of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

b) $\chi_{\mathrm{A}/k} = 0$.

c) The canonical homomorphism (20.5.11.2)

$$\delta_{\mathrm{K/A}/k} : \mathfrak{m}/\mathfrak{m}^2 \to \Omega^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{K}$$

is injective (in other words, the sequence

$$0 \to \mathfrak{m}/\mathfrak{m}^2 \to \Omega^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{K} \to \Omega^1_{\mathrm{K}/k} \to 0 \tag{22.2.9.1}$$

is exact*).*

Proof. The equivalence of b) and c) follows from the exact sequence (20.6.22.1); the equivalence of c) and a) follows from (20.5.12), this sequence being split if it is exact, since these are vector spaces.

Note that if K is *separable* over k, the equivalent conditions of (22.2.9) are satisfied, by virtue of the definition of $\chi_{\mathrm{A}/k}$ (22.2.1) and of (20.6.3). □

(22.2.10) Corollary. *Under the hypotheses of (22.2.1), consider a subfield* k_0 *of* k*. The following conditions are equivalent:*

a) $\mathrm{A}/\mathfrak{m}^2$ *is a* k_0*-extension* k_0*-trivial of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

b) The composite homomorphism $\Upsilon_{\mathrm{K}/k_0} \to \Upsilon_{\mathrm{K}/k} \xrightarrow{\chi_{\mathrm{A}/k}} \mathfrak{m}/\mathfrak{m}^2$ *is zero.*

c) The characteristic homomorphism $\chi_{\mathrm{A}/k} : \Upsilon_{\mathrm{K}/k} \to \mathfrak{m}/\mathfrak{m}^2$ *factors through* $\Upsilon_{\mathrm{K}/k} \to \Upsilon_{\mathrm{K}/k/k_0} \xrightarrow{\chi'} \mathfrak{m}/\mathfrak{m}^2$.

Moreover, when these conditions are satisfied, the homomorphism χ' *is determined in a unique and canonical way, and coincides with the characteristic homomorphism of the* k_0*-extension* k_0*-trivial* $\mathrm{A}/\mathfrak{m}^2$ *of* K *by* $\mathfrak{m}/\mathfrak{m}^2$.

Proof. Since the composition in b) is nothing other than χ_{A/k_0}, the equivalence of a) and b) follows from (22.2.9); on the other hand, b) and c) are equivalent by virtue of the exact sequence (20.6.18.1)

$$\Upsilon_{K/k_0} \to \Upsilon_{K/k} \to \Upsilon_{K/k/k_0} \to 0,$$

and since the canonical homomorphism $\Upsilon_{K/k} \to \Upsilon_{K/k/k_0}$ is surjective, this implies the uniqueness of χ'; the fact that χ' is the characteristic homomorphism of the k_0-extension $A/\mathfrak{m}^2$ follows from (20.6.22.2). □

(22.2.11) Corollary. *Under the hypotheses of (22.2.1), let p be the characteristic exponent of k, and let (k_α) be a decreasing filtering family of subfields of k such that $\bigcap k_\alpha(k^p) = k^p$. If $\Upsilon_{K/k}$ is of finite rank over* K*, there exists an index α such that $A/\mathfrak{m}^2$ is a k_α-extension k_α-trivial of* K *by $\mathfrak{m}/\mathfrak{m}^2$.*

Proof. It is known (21.8.3) that there exists then α such that the canonical homomorphism $\Upsilon_{K/k} \to \Upsilon_{K/k/k_\alpha}$ is bijective, so the condition b) of (22.2.10) (where k_α replaces k_0) is satisfied. □

22.3 Application to relations between certain local rings and their completions

[$0_{IV\text{-}1}$ | 191] **(22.3.1) Lemma.** *Let A_0 be a semi-local Noetherian ring,* A *a finite A_0-algebra (which is thus a semi-local Noetherian ring, cf. Bourbaki,* Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9). If $\widehat{A}_0$ and $\widehat{A}$ are the completions of A_0 and* A *for their preadic topologies respectively, then, when one equips A_0,* A *and $\widehat{A}$ with discrete topologies, $\widehat{A}$ is an* A*-algebra formally smooth relative to A_0 (19.9.1).*

Proof. It is known that $\widehat{A} = A \otimes_{A_0} \widehat{A}_0$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. 3 of prop. 9 and chap. III, § 3, n° 4, th. 1), so the proposition follows from (19.9.3). □

(22.3.2) Proposition. *Let* A *be a local Noetherian regular ring,* K *its field of fractions, p the characteristic of* K*. Suppose that one of the following hypotheses is satisfied:*

(i) *$p = 0$.*

(ii) *$p > 0$ and there exists a filtering decreasing family (A_α) of Noetherian subrings of* A*, such that* A *is a finite A_α-algebra for every α, such that $A^{p^{h(\alpha)}} \subset A_\alpha$ for a suitable integer $h(\alpha)$, and such that, if K_α denotes the field of fractions of A_α, we have $\bigcap K_\alpha(K^p) = K^p$.*

Let then B *be a finite* A*-algebra that is an integral domain and contains* A*, $\mathfrak{n}$ a prime ideal of* B*,* C *the local ring $B_\mathfrak{n}$, $\mathfrak{q}$ a prime ideal of the completion $\widehat{C}$, such that $\mathfrak{q} \cap C = 0$, so that the local ring $\widehat{C}_\mathfrak{q}$ is an algebra over the field of fractions* L *of* B*. Then $\widehat{C}_\mathfrak{q}$ is an* L*-algebra formally smooth for its $\mathfrak{q}$-adic topology, and is therefore a geometrically regular ring over* L *(19.6.5).*

Proof. We distinguish two cases.

I) Suppose that $\mathfrak{n}$ contains the maximal ideal $\mathfrak{m}$ of A, so that $\mathfrak{n} \cap A = \mathfrak{m}$. Then $\mathfrak{n}$ is maximal (Bourbaki, *Alg. comm.*, chap. V, § 2, n° 1, prop. 1). If $\mathfrak{r}$ is the radical of the semi-local ring B, $\widehat{C}$ is the separated completion of B for the $\mathfrak{n}$-preadic topology, and a component of the semi-local ring $\widehat{B}$, the completion of B for the $\mathfrak{r}$-preadic topology

(Bourbaki, *Alg. comm.*, chap. III, § 3, n° 4, prop. 8); one can thus write $\widehat{C}_{\mathfrak{q}} = \widehat{B}_{\mathfrak{q}'}$, where $\mathfrak{q}'$ is the prime ideal of $\widehat{B}$ that is the inverse image of $\mathfrak{q}$. Let us now note that B is a subring of $\widehat{B}$, and the hypothesis $\mathfrak{q} \cap C = 0$ implies $\mathfrak{q}' \cap B = 0$, so $\widehat{B}_{\mathfrak{q}'}$ is also a localization of $\widehat{B} \otimes_B L$ at one of its prime ideals $\mathfrak{q}''$, of which $\mathfrak{q}'$ is the inverse image in $\widehat{B}$; moreover we have $\widehat{B} = \widehat{A} \otimes_A B$ (Bourbaki, *Alg. comm.*, chap. IV, § 2, n° 5, cor. of prop. 9 and chap. III, § 3, n° 4, th. 1), so $\widehat{B} \otimes_B L = \widehat{A} \otimes_A L$; finally, if $\mathfrak{p}$ is the prime ideal of $\widehat{A}$ that is the inverse image of $\mathfrak{q}''$, the fact that $A \to B$ is injective and the commutativity of the diagram

$$\begin{array}{ccc} B & \longrightarrow & \widehat{B} \\ \uparrow & & \uparrow \\ A & \longrightarrow & \widehat{A} \end{array}$$

imply that $\mathfrak{p} \cap A = 0$, so $(\widehat{A} \otimes_A L)_{\mathfrak{q}''}$ is also a localization of the ring $\widehat{A}_{\mathfrak{p}} \otimes_A L = (\widehat{A}_{\mathfrak{p}} \otimes_A K) \otimes_K L$.

To show that this local ring is an L-algebra formally smooth, it suffices therefore to prove that $\widehat{A}_{\mathfrak{p}} \otimes_A K$ is a K-algebra formally smooth (19.3.5), (iii) and (iv); moreover $\widehat{A}_{\mathfrak{p}} \otimes_A K = \widehat{A}_{\mathfrak{p}}$ since $\mathfrak{p} \cap A = 0$. We shall apply the criteria (22.2.2) and (22.2.8). First of all, as A is regular, so is $\widehat{A}$ (17.1.5), and hence so is $\widehat{A}_{\mathfrak{p}}$ (17.3.2); condition (i) of (22.2.2) is therefore satisfied (17.1.1). It therefore suffices (when $p > 0$) to verify condition *b*) of (22.2.8). But (22.3.1) shows that, for every α, $\widehat{A}$ is an A-algebra formally smooth relative to A_α (for the discrete topologies); hence $\widehat{A} \otimes_{A_\alpha} K_\alpha = \widehat{A} \otimes_A (A \otimes_{A_\alpha} K_\alpha)$ is an $(A \otimes_{A_\alpha} K_\alpha)$-algebra formally smooth relative to K_α, for the discrete topologies (19.9.2), (iii). Since A is an A_α-algebra *finite*, we have $A \otimes_{A_\alpha} K_\alpha = K$; as $\widehat{A}_{\mathfrak{p}}$ is a ring of fractions of $\widehat{A} \otimes_A K$, we deduce (19.9.2), (iv) that $\widehat{A}_{\mathfrak{p}}$ is a K-algebra formally smooth *relative* to K_α, for the discrete topology, and *a fortiori* for its $\mathfrak{p}$-adic topology (19.3.8) and (19.9.5). But this is precisely condition *b*) of (22.2.8), so the proposition is proved in this case for $p > 0$. When $p = 0$, the residue field of $\widehat{A}_{\mathfrak{p}}$ is separable over K, and since $\widehat{A}_{\mathfrak{p}}$ is a regular ring, it is a K-algebra formally smooth by virtue of (19.6.4). [$0_{\text{IV-1}}$ | 192]

II) General case. Let $\mathfrak{s}$ be the prime ideal $\mathfrak{n} \cap A$ of A, and set $S = A - \mathfrak{s}$, so that $S^{-1}A = A_{\mathfrak{s}}$, and $C = (S^{-1}B)_{S^{-1}\mathfrak{n}}$, where this time $S^{-1}\mathfrak{n}$ contains the maximal ideal $\mathfrak{s}A_{\mathfrak{s}}$ of $A_{\mathfrak{s}}$. As $A_{\mathfrak{s}}$ is regular (17.3.2) and $S^{-1}B$ is a finite $A_{\mathfrak{s}}$-algebra that is an integral domain and contains $A_{\mathfrak{s}}$, it remains only to verify condition (ii) for $A_{\mathfrak{s}}$ when $p > 0$: set $\mathfrak{s}_\alpha = \mathfrak{s} \cap A_\alpha$ and consider the local ring $(A_\alpha)_{\mathfrak{s}_\alpha}$. For every $t \notin \mathfrak{s}$, one has by hypothesis, setting $q = p^{h(\alpha)}$, $t^q \in A_\alpha$ and $t^q \notin \mathfrak{s}$, hence $t^q \notin \mathfrak{s}_\alpha$; if one sets $S_\alpha = A_\alpha - \mathfrak{s}_\alpha$, one sees therefore that $A_{\mathfrak{s}} = S_\alpha^{-1}A$, and the hypothesis implies that $A_{\mathfrak{s}}$ is a finite $(A_\alpha)_{\mathfrak{s}_\alpha}$-algebra; moreover, K_α is also the field of fractions of $(A_\alpha)_{\mathfrak{s}_\alpha}$, which finishes the proof. □

(22.3.3) Theorem. *Let* A *be a local Noetherian complete ring,* $\mathfrak{p}$ *a prime ideal of* A, B *the localized ring* $A_{\mathfrak{p}}$, $\mathfrak{q}$ *a prime ideal of the completion* $\widehat{B}$, $\mathfrak{r} = \mathfrak{q} \cap B$. *Then the localized ring* $\widehat{B}_{\mathfrak{q}}$ *is a* $B_{\mathfrak{r}}$*-algebra formally smooth for the preadic topologies.*

Proof. The prime ideal $\mathfrak{r}$ of B is of the form $\mathfrak{n}_{\mathfrak{p}}$, where $\mathfrak{n} \subset \mathfrak{p}$ is a prime ideal of A, and $B_{\mathfrak{r}} = A_{\mathfrak{n}}$; let k be the residue field of $B_{\mathfrak{r}}$, which is also the field of fractions of the complete integral local ring $A' = A/\mathfrak{n}$. As $\widehat{B}$ is a flat B-module (**0**$_{\text{I}}$, 7.3.5), $\widehat{B}_{\mathfrak{q}}$ is a flat $B_{\mathfrak{r}}$-module (**0**$_{\text{I}}$, 6.3.2), and to prove that $\widehat{B}_{\mathfrak{q}}$ is a $B_{\mathfrak{r}}$-algebra formally smooth, it suffices to prove that

$$\widehat{B}_{\mathfrak{q}} \otimes_{B_{\mathfrak{r}}} k = \widehat{B}_{\mathfrak{q}}/\mathfrak{r}\widehat{B}_{\mathfrak{q}}$$

is a k-algebra formally smooth (19.7.1). But $\widehat{B}_{\mathfrak{q}}/\mathfrak{r}\widehat{B}_{\mathfrak{q}} = (\widehat{B}/\mathfrak{r}\widehat{B})_{\mathfrak{q}'}$, where $\mathfrak{q}'$ is the canonical image of $\mathfrak{q}$ in $\widehat{B}/\mathfrak{r}\widehat{B}$; one has by definition $\mathfrak{q}' \cap (B/\mathfrak{r}) = 0$ and $B/\mathfrak{r} = A_{\mathfrak{p}'}$, where $\mathfrak{p}' = \mathfrak{p}/\mathfrak{n}$; moreover $\widehat{B}/\mathfrak{r}\widehat{B}$ is the completion of $B/\mathfrak{r}$.

We are thus reduced to proving the following corollary: □

(22.3.4) Corollary. *Let* A *be a complete Noetherian local integral domain,* K *its field of fractions,* $\mathfrak{p}$ *a prime ideal of* A, B *the localized ring* $A_{\mathfrak{p}}$. *Then, for every prime ideal* $\mathfrak{q}$ *of the completion* $\widehat{B}$, *such that* $\mathfrak{q} \cap B = 0$, *the local ring* $\widehat{B}_{\mathfrak{q}}$ *is a* K*-algebra formally smooth for its* $\mathfrak{q}$*-adic topology, and is therefore a geometrically regular ring over* K.

[$0_{IV\text{-}1}$ | 193]

Proof. Indeed, it follows from (19.8.9) that there exists a subring A_0 of A that is a power series ring over a field of characteristic $p > 0$ or over a Cohen ring (recall that Cohen rings have a field of fractions of characteristic 0), and such that A is a finite A_0-algebra. Now, we know that the ring A_0 is *regular* (17.3.8), and it satisfies one of the hypotheses (i), (ii) of (22.3.2), by virtue of (21.8.8); it suffices therefore to apply (22.3.2), replacing B by A and A by A_0. □

22.4 Preliminary results on finite extensions of local rings whose maximal ideal has square zero

(22.4.1) Proposition. *Let* A *be a local ring whose maximal ideal* $\mathfrak{m}$ *has square zero,* $K = A/\mathfrak{m}$ *its residue field; let us denote by* V *the ideal* $\mathfrak{m}$ *considered as a* K*-vector space. Let* T_i $(1 \leq i \leq r)$ *be indeterminates, and for each* i, *let* F_i *be a monic polynomial of* $A[T_i]$, *of degree* d_i; *let* A' *be the quotient of the polynomial ring* $A[T_1, \ldots, T_r]$ *by the ideal* $\mathfrak{b}$ *generated by the* r *polynomials* F_i. *Suppose that* A' *is a local ring, and let* $\mathfrak{m}'$ *and* $K' = A'/\mathfrak{m}'$ *be its maximal ideal and residue field. Then:*

(i) *If one sets* $d = \prod_{i=1}^{r} d_i$, A' *is a free* A*-module of rank* d, *and we have* $[K' : K] \leq d$.

(ii) *For* $[K' : K] = d$, *it is necessary and sufficient that* $A' \otimes_A K = A'/\mathfrak{m}A'$ *be a field (necessarily isomorphic to* K′*), in other words, that* $\mathfrak{m}' = \mathfrak{m}A'$. *In this case,* $\mathfrak{m}'^2 = 0$, *and if* V′ *denotes the ideal* $\mathfrak{m}'$ *considered as a* K′*-vector space, the canonical homomorphism* $V \otimes_K K' \to V'$ *is bijective (and consequently* $\mathrm{rg}_{K'} V' = \mathrm{rg}_K V$*).*

Proof. Without assuming A' local, it is evident by Euclidean division and induction on r that, if t_i is the class of T_i modulo $\mathfrak{b}$, the monomials $M_\nu = t_1^{\nu_1} t_2^{\nu_2} \cdots t_r^{\nu_r}$, where $0 \leq \nu_i \leq d_i - 1$, form a basis of A' as an A-module. If A' is assumed local, K' is a quotient of $A'/\mathfrak{m}A' = A' \otimes_A K$, so $[K' : K] \leq [A' \otimes_A K : K] = d$, and there cannot be equality unless $\mathfrak{m}' = \mathfrak{m}A'$, which proves (i) and the first assertion of (ii). On the other hand, it is clear that when $\mathfrak{m}' = \mathfrak{m}A'$, we have $\mathfrak{m}'^2 = 0$, and $V \otimes_K K' = \mathfrak{m} \otimes_A A' = \mathfrak{m}A' = V'$ since A' is a free A-module. □

(22.4.2) Remark. When A is Artinian (that is to say $\mathrm{rg}_K(V)$ is finite), the hypothesis that A' is local always implies $\mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2) \geq \mathrm{rg}_K(V)$, as we shall see further on (22.5.2). Note that these two ranks can be equal without having $\mathfrak{m}' = \mathfrak{m}A'$.

(22.4.3) Proposition. *With the hypotheses and notations of (22.4.1), suppose that the* F_i *are of the form*

$$F_i(T_i) = T_i^{d_i} + \sum_{1 \leq k \leq d_i} c_{ik} T_i^{d_i - k} \tag{22.4.3.1}$$

where $d_i \geq 2$ *for every* i *and* $c_{ik} \in \mathfrak{m}$ *("Eisenstein polynomials"). Then:*

(i) A' *is a local ring, and its residue field* $K' = A'/\mathfrak{m}'$ *is isomorphic to* K.

(ii) *The kernel of the canonical homomorphism* $V \to V' = \mathfrak{m}'/\mathfrak{m}'^2$ *is the ideal* $\mathfrak{n}$ *of* A *generated by the elements* $\xi_i = c_{i,d_i}$, *and its cokernel has as a basis over* K' *the images of the* T_i. *In particular,* [0IV-1 / 194]

$$\mathrm{rg}_{K'}(V') = \mathrm{rg}_K(V) + r - r', \tag{22.4.3.2}$$

where $r' = \mathrm{rg}_K(\mathfrak{n})$. *When* $\mathrm{rg}_K(V)$ *is finite, equivalently when* A *is Artinian, equality* $\mathrm{rg}_{K'}(V') = \mathrm{rg}_K(V)$ *holds if and only if the* ξ_i *are linearly independent over* K.

Proof. (i) It is clear that $A' \otimes_A K = A'/\mathfrak{m}A'$ is isomorphic to $K[T_1, \ldots, T_r]/\mathfrak{b}'$, where $\mathfrak{b}'$ is the ideal generated by the r polynomials $T_i^{d_i}$; this is therefore a local ring of residue field K, and it is the same for A', from which (i) follows.

(ii) Let t_i $(1 \leq i \leq r)$ be the class of T_i mod. $\mathfrak{b}$; it follows from (i) that the maximal ideal $\mathfrak{m}'$ of A' is given by

$$\mathfrak{m}' = \mathfrak{m}A' + \sum_i t_i A'$$

from which, taking into account that $\mathfrak{m}^2 = 0$,

$$\mathfrak{m}'^2 = \sum_{i,j} t_i t_j A' + \sum_i t_i \mathfrak{m} A'.$$

One deduces that $A'/\mathfrak{m}'^2$ is isomorphic to the ring $A[T_1, \ldots, T_r]/\mathfrak{c}$, where $\mathfrak{c}$ is the ideal generated by the elements

$$F_i \ (1 \leq i \leq r), \quad T_i T_j \ (1 \leq i \leq r, \ 1 \leq j \leq r), \quad xT_i \ (1 \leq i \leq r, \ x \in \mathfrak{m}).$$

Since $d_i \geq 2$ and $T_i^2 \in \mathfrak{c}$, the hypotheses show that $\mathfrak{c}$ is also generated by

$$\xi_i \ (1 \leq i \leq r), \quad T_i T_j \ (1 \leq i \leq r, \ 1 \leq j \leq r), \quad T_i x \ (1 \leq i \leq r, \ x \in \mathfrak{m}).$$

Let $\mathfrak{c}_1 = \sum_{i,j} T_i T_j A[T_1, \ldots, T_r]$, $\mathfrak{c}_2 = \mathfrak{c}_1 + \sum_i \mathfrak{m} T_i A[T_1, \ldots, T_r]$, then $\mathfrak{c} = \mathfrak{c}_2 + \sum_i \xi_i A[T_1, \ldots, T_r]$. It is clear that $A[T_1, \ldots, T_r]/\mathfrak{c}_1$ is the A-module direct sum of A and of $At_i^{(1)}$, where $t_i^{(1)}$ is the class of T_i mod. $\mathfrak{c}_1$. One deduces that $A[T_1, \ldots, T_r]/\mathfrak{c}_2$ is the direct sum of A and of the $Kt_i^{(2)}$, where $t_i^{(2)}$ is the class of T_i mod. $\mathfrak{c}_2$. Finally $A[T_1, \ldots, T_r]/\mathfrak{c}$ is the direct sum of $A/\mathfrak{n}$ and of the Kt_i', where t_i' is the class of T_i mod. $\mathfrak{c}$, and $\mathfrak{n}$ is the ideal of A generated by the ξ_i; in the identification of $A'/\mathfrak{m}'^2$ with $A[T_1, \ldots, T_r]/\mathfrak{c}$, the image of V identifies with $\mathfrak{m}/\mathfrak{n}$, and this proves (ii). □

(22.4.4) Proposition. *With the hypotheses and notations of (22.4.1), suppose that* K *is of characteristic* $p > 0$ *(hence* $p.1 \in \mathfrak{m}$ *in* A*) and that the* F_i *are of the form*

$$F_i(T_i) = T_i^p + p \sum_{k=1}^{p-1} c_{ik} T_i^{p-k} - f_i \tag{22.4.4.1}$$

with $c_{ik} \in A$ *and* $f_i \in A$ *for every* i *and every* k *such that* $1 \leq k \leq p-1$; *furthermore, if* a_i *is the class of* f_i *modulo* $\mathfrak{m}$, *suppose that the family* $(a_i)_{1 \leq i \leq r}$ *is* p*-free over* K^p *("absolutely* p*-free"). Then:*

(i) A' *is a local ring, with maximal ideal* $\mathfrak{m}A'$, *whose residue field* K' *is isomorphic to the extension of* K *obtained by adjunction of the* $a_i^{1/p}$ $(1 \leq i \leq r)$.

[$0_{IV\text{-}1}$ / 195]

(ii) *The elements* $d_{\mathrm{A}} f_i \otimes 1_{\mathrm{K}'}$ *form a basis of the kernel* $\mathrm{N} = \Upsilon^{\mathrm{K}'}_{\mathrm{A}'/\mathrm{A}}$ *of the canonical homomorphism*

$$\Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}' \longrightarrow \Omega^1_{\mathrm{A}'} \otimes_{\mathrm{A}'} \mathrm{K}'.$$

Proof. (i) This time $\mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K} = \mathrm{A}'/\mathfrak{m}\mathrm{A}'$ is isomorphic to $\mathrm{K}[\mathrm{T}_1, \ldots, \mathrm{T}_r]/\mathfrak{b}'$, where $\mathfrak{b}'$ is the ideal generated by the polynomials $\mathrm{T}_i^p - a_i$ $(1 \leq i \leq r)$; the hypothesis made on the a_i implies that this quotient ring is a field (21.1.8), from which the assertions of (i) follow.

Before proving (ii), we shall establish the

(22.4.4.2) Lemma. *Let* Λ *be a ring,* A *a* Λ*-algebra,* $\mathfrak{J}$ *an ideal of* A *such that the ring* $\mathrm{C} = \mathrm{A}/\mathfrak{J}$ *is of characteristic* $p > 0$ *(which is equivalent to saying that* $p.1 \in \mathfrak{J}$ *in* A*). Let* π *be the canonical image of* $p.1$ *in* $\mathfrak{J}/\mathfrak{J}^2$*. If* C *is a* $(\Lambda/p\Lambda)$*-algebra formally smooth for the discrete topologies, one has a canonical exact sequence*

$$0 \longrightarrow (\mathfrak{J}/\mathfrak{J}^2)/\mathrm{C} \cdot \pi \longrightarrow \Omega^1_{\mathrm{A}/\Lambda} \otimes_{\mathrm{A}} \mathrm{C} \longrightarrow \Omega^1_{\mathrm{C}/\Lambda} \longrightarrow 0. \tag{22.4.4.3}$$

Proof of the lemma. Indeed, set $\mathrm{A}' = \mathrm{A}/p\mathrm{A}$, $\mathfrak{J}' = \mathfrak{J}/p\mathrm{A}$, so that $\mathrm{C} = \mathrm{A}'/\mathfrak{J}'$. As $\mathrm{A}' = \mathrm{A} \otimes_{\Lambda} (\Lambda/p\Lambda)$, we have $\Omega^1_{\mathrm{A}/\Lambda} \otimes_{\mathrm{A}} \mathrm{A}' = \Omega^1_{\mathrm{A}'/\Lambda'}$ up to canonical isomorphism, where Λ' denotes $\Lambda/p\Lambda$ (20.5.5). Applying the exact sequence (20.5.14.1) to the formally smooth Λ'-algebra $\mathrm{C} = \mathrm{A}'/\mathfrak{J}'$, one obtains the exact sequence

$$0 \longrightarrow \mathfrak{J}'/\mathfrak{J}'^2 \longrightarrow \Omega^1_{\mathrm{A}'/\Lambda'} \otimes_{\mathrm{A}'} \mathrm{C} \longrightarrow \Omega^1_{\mathrm{C}/\Lambda'} \longrightarrow 0.$$

Since the homomorphism $\Lambda \to \Lambda'$ is surjective, one has $\Omega^1_{\mathrm{C}/\Lambda'} = \Omega^1_{\mathrm{C}/\Lambda}$ up to canonical isomorphism (20.5.15); hence the exact sequence (22.4.4.3) follows from the preceding observations. □

(ii) As $\mathfrak{m}'^2 = 0$, we shall also denote by V' the ideal $\mathfrak{m}'$ considered as a K'-vector space, and we shall set

$$\mathrm{V}_0 = \mathrm{V}/\mathrm{K} \cdot p = \mathfrak{m}/(\mathfrak{m}^2 + p\mathrm{A}), \qquad \mathrm{V}'_0 = \mathrm{V}'/\mathrm{K}' \cdot p = \mathfrak{m}'/(\mathfrak{m}'^2 + p\mathrm{A}'). \tag{22.4.4.4}$$

Applying the exact sequence (22.4.4.3) in the case where $\Lambda = \mathbf{Z}$, to the $\mathbf{Z}$-algebra A (resp. A') and to its ideal $\mathfrak{m}$ (resp. $\mathfrak{m}'$), it follows, since K (resp. K') is separable over the prime field $\mathbf{Z}/p\mathbf{Z}$, hence a $(\mathbf{Z}/p\mathbf{Z})$-algebra formally smooth (19.6.1), that the following sequences are exact:

$$0 \longrightarrow \mathrm{V}_0 \longrightarrow \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \longrightarrow \Omega^1_{\mathrm{K}} \longrightarrow 0, \qquad 0 \longrightarrow \mathrm{V}'_0 \longrightarrow \Omega^1_{\mathrm{A}'} \otimes_{\mathrm{A}'} \mathrm{K}' \longrightarrow \Omega^1_{\mathrm{K}'} \longrightarrow 0. \tag{22.4.4.5}$$

Consider then the diagram (22.4.4.6) in which the two middle columns are the second exact sequence (22.4.4.5) and the first exact sequence (22.4.4.5) tensorized by K'; as the first exact sequence (22.4.4.5) is formed of K-vector spaces, the two middle columns of (22.4.4.6) are exact; moreover, the diagram formed by these columns and the horizontal arrows connecting them is commutative, by virtue of the proof of (22.4.4.2) and the commutativity of the diagram (20.5.11.3). The last line of (22.4.4.6) is the exact sequence obtained from (20.6.1.1) by replacing A, B, C by $\mathbf{Z}$, K and K'; the middle line is obtained by tensorization with K' from the K-module exact sequence deduced from (20.6.1.1) by replacing A, B, C by $\mathbf{Z}$, A, K respectively. The diagram formed by these two lines and the vertical arrows connecting them is commutative by virtue of the commutativity of (20.6.4.3). We note moreover that we are in the conditions of application of (22.4.1), (ii), so the upper line of the diagram (22.4.4.6) is *exact*; the extreme columns of the diagram

[$0_{\text{IV-1}}$ | 196]

$$\begin{array}{ccccccccc}
 & & 0 & & 0 & & & & \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & \mathrm{V}_0 \otimes_{\mathrm{K}} \mathrm{K}' & \longrightarrow & \mathrm{V}'_0 & \longrightarrow & 0 & & \\
 & & \downarrow & & \downarrow & & & & \\
0 & \longrightarrow & \mathrm{N} & \longrightarrow & \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}' & \longrightarrow & \Omega^1_{\mathrm{A}'} \otimes_{\mathrm{A}'} \mathrm{K}' & \longrightarrow & \Omega^1_{\mathrm{A}'/\mathrm{A}} \otimes_{\mathrm{A}'} \mathrm{K}' \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \Upsilon_{\mathrm{K}'/\mathrm{K}} & \longrightarrow & \Omega^1_{\mathrm{K}} \otimes_{\mathrm{K}} \mathrm{K}' & \longrightarrow & \Omega^1_{\mathrm{K}'} & \longrightarrow & \Omega^1_{\mathrm{K}'/\mathrm{K}} \longrightarrow 0 \\
 & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 & & 0 & & 0 & & 0 & & 0
\end{array} \tag{22.4.4.6}$$

are therefore formed respectively of the *kernels* and the *cokernels* of the middle horizontal arrows, which finishes proving that the diagram is *commutative*. Furthermore:

(22.4.4.7) Lemma. *The homomorphisms*

$$\mathrm{N} \longrightarrow \Upsilon_{\mathrm{K}'/\mathrm{K}} \qquad \textit{and} \qquad \Omega^1_{\mathrm{A}'/\mathrm{A}} \otimes_{\mathrm{A}'} \mathrm{K}' \longrightarrow \Omega^1_{\mathrm{K}'/\mathrm{K}}$$

of diagram (22.4.4.6) are bijective.

Proof. Indeed, the snake diagram (Bourbaki, *Alg. comm.*, chap. I, § 1, n° 4, prop. 2) applied to the two middle columns of (22.4.4.6) gives an exact sequence

$$0 \longrightarrow \mathrm{N} \longrightarrow \Upsilon_{\mathrm{K}'/\mathrm{K}} \longrightarrow 0 \longrightarrow \Omega^1_{\mathrm{A}'/\mathrm{A}} \otimes_{\mathrm{A}'} \mathrm{K}' \longrightarrow \Omega^1_{\mathrm{K}'/\mathrm{K}} \longrightarrow 0.$$

But, if t_i is the canonical image of T_i in A', the relation $\mathrm{F}_i(t_i) = 0$, together with the fact that $p.1 \in \mathfrak{m}\mathrm{A}' \subset \mathfrak{m}'$, shows immediately that $d_{\mathrm{A}'} f_i \in \mathfrak{m}'\Omega^1_{\mathrm{A}'}$, hence $d_{\mathrm{A}'} f_i \otimes 1_{\mathrm{K}'} = 0$; this proves that the $d_{\mathrm{A}} f_i \otimes 1_{\mathrm{K}'}$ belong to N. Moreover, their images in $\Upsilon_{\mathrm{K}'/\mathrm{K}}$ are the $d_{\mathrm{K}} a_i \otimes 1_{\mathrm{K}'}$, which form a basis of $\Upsilon_{\mathrm{K}'/\mathrm{K}}$ over K' (21.4.7); taking into account (22.4.4.7), this finishes proving (22.4.4). □

□

(22.4.5) Now consider two rings A, B of *characteristic* $p > 0$, and two homomorphisms

$$\mathrm{A} \xrightarrow{i} \mathrm{B} \xrightarrow{j} \mathrm{A}$$

satisfying the conditions of (21.3.1). Let furthermore $\mathfrak{m}$ be an ideal *of square zero* in A; [$0_{\text{IV-1}}$ | 197] set

$$\mathrm{K} = \mathrm{A}/\mathfrak{m}, \qquad \mathrm{B}_{(\mathrm{K})} = \mathrm{B} \otimes_{\mathrm{A}} \mathrm{K} = \mathrm{B}/\mathrm{B}i(\mathfrak{m})$$

and let

$$\varphi : \mathrm{A} \to \mathrm{K}, \qquad \psi : \mathrm{B} \to \mathrm{B}_{(\mathrm{K})}$$

be the canonical homomorphisms. Since φ is surjective, $\Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}}$ identifies canonically with $\Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ (20.5.15). We note that, since $p \geq 2$, for every $x \in \mathfrak{m}$, one has $j(i(x)) = x^p = 0$, in other words $j(i(\mathfrak{m})) = 0$; by passing to quotients, one deduces from j a homomorphism

$$j' : \mathrm{B}_{(\mathrm{K})} \to \mathrm{A}$$

such that, if $i' = \psi \circ i : \mathrm{A} \to \mathrm{B}_{(\mathrm{K})}$, we have

$$j'(i'(x)) = x^p \quad \text{and} \quad i'(j'(y)) = y^p \quad \text{for} \quad x \in \mathrm{A} \quad \text{and} \quad y \in \mathrm{B}_{(\mathrm{K})}.$$

Setting, following the notations of (21.3.2)

$$\Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} = \Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \otimes_{\mathrm{B}_{(\mathrm{K})}} \mathrm{A}_{[j']} = \Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \otimes_{\mathrm{B}_{(\mathrm{K})}} \mathrm{A}_{[j']}$$

one has therefore (21.3.2.2) a canonical homomorphism

$$\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} : \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \to \Omega^1_{\mathrm{A}}. \tag{22.4.5.1}$$

On the other hand, one deduces from i and j, by passing to quotients (taking into account that $j(i(\mathfrak{m})) = 0$) homomorphisms

$$\mathrm{K} \xrightarrow{i_0} \mathrm{B}_{(\mathrm{K})} \xrightarrow{j_0} \mathrm{K}$$

so that one has the commutative diagram

$$\begin{array}{ccccc} \mathrm{A} & \xrightarrow{i} & \mathrm{B} & \xrightarrow{j} & \mathrm{A} \\ {\scriptstyle\varphi}\downarrow & & \downarrow{\scriptstyle\psi} & \nearrow_{j'} & \downarrow{\scriptstyle\varphi} \\ \mathrm{K} & \xrightarrow[i_0]{} & \mathrm{B}_{(\mathrm{K})} & \xrightarrow[j_0]{} & \mathrm{K} \end{array}$$

It is clear furthermore that

$$j_0(i_0(s)) = s^p \quad \text{and} \quad i_0(j_0(t)) = t^p \quad \text{for} \quad s \in \mathrm{K} \quad \text{and} \quad t \in \mathrm{B}_{(\mathrm{K})}.$$

One therefore defines in the same way

$$\Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \Omega^1_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \otimes_{\mathrm{B}_{(\mathrm{K})}} \mathrm{K}_{[j_0]} = \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$$

hence, tensorizing (22.4.5.1) by K, one obtains a *canonical* K-homomorphism

$$\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{A}} \otimes 1_{\mathrm{K}} : \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}. \tag{22.4.5.2}$$

[$0_{\text{IV-1}}$ | 198] It follows immediately from the definitions that the diagram

$$\begin{array}{ccc} \Theta_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} & \xrightarrow{\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}} & \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \\ & {\scriptstyle\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}}\searrow & \downarrow{\scriptstyle\varphi_{\mathrm{K}/\mathrm{A}}} \\ & & \Omega^1_{\mathrm{K}} \end{array}$$

is commutative, $\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ being the canonical homomorphism corresponding to i_0 and j_0 (21.3.2.2). By *restriction* to $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \mathrm{Ker}(\pi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}})$, the homomorphism $\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ therefore defines a canonical homomorphism

$$\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \to \mathrm{Ker}(\Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \to \Omega^1_{\mathrm{K}}) = \Upsilon_{\mathrm{K}/\mathrm{A}}. \tag{22.4.5.3}$$

(22.4.6) With the hypotheses and notations of (22.4.5), suppose in addition that $\mathfrak{m}$ be a *maximal* ideal of square zero, hence K a *field*, and let V denote the ideal $\mathfrak{m}$ considered as a K-vector space. As K is a formally smooth algebra over its prime field $\mathbf{F}_p$ (21.5.2) (so

that A is an algebra over $\mathbf{F}_p$, in the sense that $\Omega^1_{\mathrm{A}} = \Omega^1_{\mathrm{A}/\mathbf{F}_p}$), one deduces from (20.5.14) that one has an *exact sequence*

$$0 \to \mathrm{V} \to \Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K} \to \Omega^1_{\mathrm{K}} \to 0. \tag{22.4.6.1}$$

One has therefore by (22.4.5.3) a homomorphism denoted

$$\chi'_{\mathrm{B/A}} : \Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \to \mathrm{V} \tag{22.4.6.2}$$

that we shall call the *characteristic homomorphism* of the A-algebra B (relative to i, j and $\mathfrak{m}$). It follows from the definitions that for $\chi'_{\mathrm{B/A}}$ to be *injective*, it is necessary and sufficient that $\pi'_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$ is injective, the kernel of the latter being obviously contained in $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}}$.

(22.4.7) Proposition. *Let* A *be a local Artinian ring whose maximal ideal* $\mathfrak{m}$ *is of square zero,* $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ *its residue field,* V *the ideal* $\mathfrak{m}$ *considered as a* K*-vector space; we suppose that* A *is of characteristic* $p > 0$*; let*

$$\mathrm{F}_i(\mathrm{T}_i) = \mathrm{T}_i^p - f_i \qquad \textit{with} \quad f_i \in \mathrm{A} \quad (1 \leq i \leq r) \tag{22.4.7.1}$$

and let B *be the quotient ring of* $\mathrm{A}[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ *by the ideal generated by the* r *polynomials* F_i*. Then:*

(i) B *is a local ring.*

(ii) *If* $\mathfrak{m}'$ *is the maximal ideal of* B, $\mathrm{K}' = \mathrm{B}/\mathfrak{m}'$ *its residue field,* V′ *the* B*-module* $\mathfrak{m}'/\mathfrak{m}'^2$ *considered as a* K′*-vector space, then, for* $\mathrm{rg}_{\mathrm{K}}(\mathrm{V}) = \mathrm{rg}_{\mathrm{K}'}(\mathrm{V}')$*, it is necessary and sufficient that the characteristic homomorphism of* K*-vector spaces*

$$\chi'_{\mathrm{B/A}} : \Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \to \mathrm{V} \tag{22.4.7.2}$$

(cf. (22.4.6.2)) is injective.

Proof. Let us again denote by a_i $(1 \leq i \leq r)$ the class of f_i mod. $\mathfrak{m}$; the a_i are not necessarily p-independent over K^p, but one can always suppose that the subfamily $(a_i)_{s+1 \leq i \leq r}$ [0IV-1 | 199] is p-free over K^p and forms a p-base over K^p of the field $\mathrm{K}^p(a_1, \ldots, a_r)$ so that

$$a_i \in \mathrm{K}^p(a_{s+1}, \ldots, a_r) \qquad \text{for} \quad 1 \leq i \leq s.$$

Let us denote by A'' the quotient ring of $\mathrm{A}[\mathrm{T}_{s+1}, \ldots, \mathrm{T}_r]$ by the ideal generated by the F_i of index $i \geq s+1$; then, by (22.4.4), A'' is a local ring whose maximal ideal is $\mathfrak{m}'' = \mathfrak{m}\mathrm{A}''$ and the residue field is $\mathrm{K}'' = \mathrm{K}(a_{s+1}^{1/p}, \ldots, a_r^{1/p})$. One has thus $a_i \in \mathrm{K}''^p$ for $1 \leq i \leq s$ and hence, in A'', the element f_i, for $1 \leq i \leq s$, can be written

$$f_i = g_i^p + h_i \tag{22.4.7.3}$$

where $g_i \in \mathrm{A}''$ and $h_i \in \mathfrak{m}''$ (since $\mathfrak{m}''^2 = 0$ and $p\mathfrak{m}'' = 0$, it is immediate that h_i is uniquely determined by these conditions). Replacing T_i by $\mathrm{T}_i + g_i$, one sees thus that if one sets

$$\mathrm{G}_i(\mathrm{T}_i) = \mathrm{T}_i^p + \sum_{k=1}^{p-1} \binom{p}{k} g_i^{p-k} \mathrm{T}_i^k - h_i \qquad (1 \leq i \leq s)$$

B is the quotient ring of $\mathrm{A}''[\mathrm{T}_1, \ldots, \mathrm{T}_s]$ by the ideal generated by the G_i; but, all the coefficients of G_i except the leading coefficient belong to $\mathfrak{m}''$, we are in the situation of

(22.4.3), which proves (i) (which indeed follows directly from the fact that $B^p \subset A$, and by consequence B has only a single ideal above $\mathfrak{m}$), and furthermore the residue field K' is *isomorphic* to K''.

Now let us note that for (22.4.7.2) to be injective, it is necessary and sufficient that

$$\pi'_{B_{(K)}/K} : \Omega^1_{B_{(K)}/K} \otimes_{B_{(K)}} K \to \Omega^1_A \otimes_A K$$

is injective (by (22.4.6)). But $B_{(K)} = B/\mathfrak{m}B$ is the quotient algebra $C = K[T_1, \ldots, T_r]$ by the ideal generated by the polynomials $\overline{F}_i = T_i^p - a_i$, and since $d_{C/K}\overline{F}_i = 0$ it follows from (20.5.13) that $\Omega^1_{B_{(K)}/K}$ is a free $B_{(K)}$-module with base $d_{B_{(K)}/K}t_i$, where t_i is the canonical image of T_i. But by definition (22.4.5), the canonical image under $j' : B_{(K)} \to A$ of the class modulo $\mathfrak{m}B$ of an element $x \in B$ is the element $x^p \in A$; one deduces immediately, since $t_i^p = f_i$, that the image of $d_{B_{(K)}/K}t_i \otimes 1$ under $\pi'_{B_{(K)}/K}$ is $d_A f_i \otimes 1$ in $\Omega^1_A \otimes_A K$; the condition that $\pi'_{B_{(K)}/K}$ is injective is thus equivalent to the fact that the $d_A f_i \otimes 1_K$ are *linearly independent over* K, or equivalently that their images $d_A f_i \otimes 1_{K'}$ are *linearly independent over* K' in $\Omega^1_A \otimes_A K'$.

Now, if one applies (22.4.4) to the A-algebra A'', one sees that the kernel of the canonical homomorphism $\Omega^1_A \otimes_A K' \to \Omega^1_{A''} \otimes_{A''} K'$ has as its *basis* the $d_A f_i \otimes 1_{K'}$ for $s+1 \leq i \leq r$. The preceding condition thus also amounts to saying that the $d_{A''} f_i \otimes 1_{K'}$ for $1 \leq i \leq s$ are linearly independent in $\Omega^1_{A''} \otimes_{A''} K'$ (taking into account that $d_{A''} f_i = d_{A''} h_i$ by (22.4.7.3)); on the other hand, if V'' is the K'-vector space $\mathfrak{m}''$, one has $\mathrm{rg}_{K'}(V'') = \mathrm{rg}_K(V)$ (22.4.1), (ii), and the condition $\mathrm{rg}_{K'}(V') = \mathrm{rg}_K(V)$ is therefore equivalent to $\mathrm{rg}_{K'}(V'') = \mathrm{rg}_{K'}(V')$. But it follows from (22.4.3) that this last relation is equivalent to the
[$0_{IV\text{-}1}$ | 200] classes h_i being linearly independent over K' in V''. Now, in $\Omega^1_{A''} \otimes_{A''} K'$, the $d_{A''} h_i \otimes 1_{K'}$ are the canonical images (20.5.11.2) of the h_i under the injection $V'' \to \Omega^1_{A''} \otimes_{A''} K'$ (cf. (22.4.6.1)), and this finishes the proof of (22.4.7). □

(22.4.7.4) Corollary. *For* $\mathrm{rg}_K(V) = \mathrm{rg}_{K'}(V')$*, it is necessary and sufficient that the elements* $d_A f_i \otimes 1_K$ $(1 \leq i \leq r)$ *be linearly independent in the* K*-vector space* $\Omega^1_A \otimes_A K$.

(22.4.8) Remark. One can define the homomorphisms (22.4.5.2) and (22.4.6.2) in slightly different conditions. Let A be a ring, $\mathfrak{m}$ an ideal *of square zero* in A, $K = A/\mathfrak{m}$, p a prime number such that $p.1 \in \mathfrak{m}$ (in other words, K is of characteristic p, but not necessarily A). Let furthermore B be an A-algebra that is an A-module *faithfully flat* (so that $A \subset B$), and suppose that we have

$$y^p \in A + pB \subset A + \mathfrak{m}B \tag{22.4.8.1}$$

for every $y \in B$. If $y^p = x + pz$ with $x \in A$, $z \in B$, the *class modulo* $(A \cap pB)$ of x is well determined, and since $A \cap pB = pA$ as B is a faithfully flat A-module, one has thus defined a canonical map $j : B \to A/pA$, such that, for $x \in A$, $j(x)$ is the class of x^p mod. pA. Furthermore, if $y' \in B$ and $y'^p = x' + pz'$ with $x' \in A$, $z' \in B$, it is immediate that the elements $(y+y')^p - x - x'$ and $(yy')^p - xx'$ belong to pB by virtue of the fact that the binomial coefficients $\binom{p}{i}$ are multiples of p for $1 \leq i \leq p-1$. The map j is therefore a *ring homomorphism*. By composition, one deduces from j a homomorphism $j' : B \xrightarrow{j} A/pA \to A/\mathfrak{m} = K$ and hence a homomorphism $j_0 : B_{(K)} \to K$ such that j' is the composite $B \to B_{(K)} = B \otimes_A K \xrightarrow{j_0} K$; moreover, if $i_0 : K \to B_{(K)}$ is the canonical map, i_0 and j_0 satisfy the conditions of (21.3.1) for the rings *of characteristic* p, K and $B_{(K)}$. This being so, in order to define a K-homomorphism $\pi'_{B_{(K)}/K} : \Omega^1_{B_{(K)}/K} \otimes_{B_{(K)}} K_{[j_0]} \to \Omega^1_A \otimes_A K$, it suffices (20.4.8) to define a K-*derivation*

$$D_0 : B_{(K)} \to \Omega^1_A \otimes_A K \tag{22.4.8.2}$$

where the second member is considered as a $B_{(K)}$-module by means of j_0. For this, it suffices to define an A-*derivation*

$$D : B \to \Omega^1_A \otimes_A K \tag{22.4.8.3}$$

that *vanishes on* $\mathfrak{m}B$ (the second member being considered as a B-module by means of j'). Indeed, if $y^p = x + pz$ with $y \in B$, $x \in A$, $z \in B$, the element $d_A x \otimes 1_K$ of $\Omega^1_A \otimes_A K$ depends only on the *class* $j(y)$ mod. pA of x (for since $d_A(pt) = pd_A(t)$, hence $d_A(pt) \otimes 1 = 0$ in $\Omega^1_A \otimes_A K = \Omega^1_A/\mathfrak{m}\Omega^1_A$, since $p.1 \in \mathfrak{m}$). One can therefore take

$$D(y) = d_A x \otimes 1_K.$$

The fact that D is a derivation follows easily from the fact that j is a ring homomorphism; moreover, for $t \in A$, one has $d_A(t^p x) = t^p d_A(x) + pt^{p-1} x d_A(t)$ and one deduces that $D(ty) = tD(y)$, hence D is an A-derivation; finally, if in addition $t \in \mathfrak{m}$, one has $D(ty) = tD(y) = 0$ since $\Omega^1_A \otimes_A K$ is annihilated by $\mathfrak{m}$. We have thus defined the desired homomorphism (22.4.5.2), and it is immediate to verify that the composition [$0_{IV\text{-}1}$ | 201]

$$\Theta_{B_{(K)}/K} \xrightarrow{\pi'_{B_{(K)}/K}} \Omega^1_A \otimes_A K \to \Omega^1_K$$

is again the canonical homomorphism $\pi_{B_{(K)}/K}$ (relative to i_0 and j_0). One therefore also has a canonical homomorphism analogous to (22.4.5.3).

Now if K is a *field*, A/pA is an $\mathbf{F}_p$-algebra, and one has the exact sequence (20.5.14)

$$0 \to V/pA \to \Omega^1_{A/pA} \otimes_{A/pA} K \to \Omega^1_K \to 0$$

and, on the other hand, one has the exact sequence (20.5.12.1)

$$pA \to \Omega^1_A \otimes_A (A/pA) \to \Omega^1_{A/pA} \to 0$$

which shows, tensorizing with K, that $\Omega^1_A \otimes_A K$ and $\Omega^1_{A/pA} \otimes_{A/pA} K$ are isomorphic. The analog of (22.4.6.2) is therefore a homomorphism

$$\Xi_{B_{(K)}/K} \to V/pA = \mathfrak{m}/(\mathfrak{m}^2 + pA). \tag{22.4.8.4}$$

That said, the *criterion* (22.4.7), in which one replaces V and V′ by V/pA and V'/pB respectively, *remains valid assuming only that* K *is of characteristic* $p > 0$ (in other words, that $p.1 \in \mathfrak{m}$ in A), *and that the* $F_i(T_i)$ *are of the more general form* (22.4.4.1): indeed, B is a free A-module (hence faithfully flat), and it suffices to redo the argument of (22.4.7), replacing (22.4.6.2) by (22.4.8.4) and V″ by V''/pA''.

22.5 Geometrically regular algebras and formally smooth algebras

(22.5.1) Proposition. *Let* A *be a regular local ring,* A′ *a local ring containing* A *and being a finite* A*-algebra,* $\mathfrak{m}$ *(resp.* $\mathfrak{m}'$*) the maximal ideal of* A *(resp.* A′*),* $K = A/\mathfrak{m}$ *(resp.* $K' = A'/\mathfrak{m}'$*) its residue field. For* A′ *to be a regular ring, it is necessary and sufficient that*

$$\mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) = \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2). \tag{22.5.1.1}$$

Proof. Indeed, the first member of (22.5.1.1) is dim(A) (17.1.1) and since $A' \supset A$ and A′ is a finite A-algebra, dim(A′) = dim(A) (16.1.5); the equality (22.5.1.1) is therefore necessary and sufficient for A′ to be regular (17.1.1). □

(22.5.2) Remark.

(i) Let $A_1 = A/\mathfrak{m}^2$, $A'_1 = A' \otimes_A A_1 = A'/\mathfrak{m}^2A'$; as $\mathfrak{m}^2A' \subset \mathfrak{m}'^2$, $\mathfrak{m}'_1 = \mathfrak{m}'/\mathfrak{m}^2A'$ is the maximal ideal of A'_1 and $\mathfrak{m}'_1/\mathfrak{m}'^2_1$ is a K'-vector space isomorphic to $\mathfrak{m}'/\mathfrak{m}'^2$; the condition of regularity of A' depends therefore only on the structure of the A_1-*algebra* A'_1, which will allow us below to apply the preliminary results of (22.4) on algebras finite over Artinian rings.

(ii) It follows from the proof of (22.5.1) and from (16.2.6.1) that one has in all cases

$$\mathrm{rg}_K(\mathfrak{m}/\mathfrak{m}^2) \leq \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2). \tag{22.5.2.1}$$

[$0_{IV\text{-}1}$ | 202]

(iii) Suppose that A and A' verify the general hypotheses of (22.4.1). It is known (19.8.10) that there exists a regular local ring B, with maximal ideal $\mathfrak{n}$, such that A is isomorphic to $B/\mathfrak{n}^2$; let us denote by $G_i \in B[T_i]$ a monic polynomial whose canonical image in $A[T_i]$ is F_i $(1 \leq i \leq r)$; then, if B' is the quotient ring of $B[T_1, \ldots, T_r]$ by the ideal generated by the G_i, it is clear that B' is a free B-module of rank d and $A' = B' \otimes_B A = B'/\mathfrak{n}^2B'$; as A' is assumed to be a local ring, so is B', and if $\mathfrak{n}'$ is the maximal ideal of B', $B'/\mathfrak{n}'$ is isomorphic to K' and $\mathfrak{n}'/\mathfrak{n}'^2$ is isomorphic to $\mathfrak{m}'/\mathfrak{m}'^2$ as a K'-vector space; the inequality (22.5.2.1) shows thus that we have, under the hypotheses of (22.4.1)

$$\mathrm{rg}_K(V) \leq \mathrm{rg}_{K'}(\mathfrak{m}'/\mathfrak{m}'^2). \tag{22.5.2.2}$$

(22.5.3) Corollary. *Let* A *be a regular local ring,* $\mathfrak{m}$ *its maximal ideal,* T_i $(1 \leq i \leq r)$ *indeterminates, and for each* i*, let*

$$F_i(T_i) = T_i^{d_i} + \sum_{1 \leq k \leq d_i} c_{ik} T_i^{d_i - k} \tag{22.5.3.1}$$

be a unitary polynomial of $A[T_i]$*, with* $d_i \geq 2$ *for every* i *and* $c_{ik} \in \mathfrak{m}$*. Let* A' *be the quotient of the polynomial ring* $A[T_1, \ldots, T_r]$ *by the ideal* $\mathfrak{b}$ *generated by the* r *polynomials* F_i*. Then:*

(i) A' *is a local ring, and its residue field* K' *is isomorphic to the residue field* K *of* A*.*

(ii) *For* A' *to be regular, it is necessary and sufficient that the classes* ξ_i *mod.* $\mathfrak{m}^2$ *of the elements* c_{i,d_i} $(1 \leq i \leq r)$ *be linearly independent over* K*.*

Proof. Indeed, with the notations of (22.5.2), (i), if $\overline{F}_i$ denotes the polynomial of $A_1[T_i]$ obtained by applying to the coefficients of F_i the homomorphism $A \to A_1$, A'_1 is defined from A_1 and the polynomials $\overline{F}_i$ as in (22.4.1), and the conclusion follows from (22.5.1) and (22.4.3). □

(22.5.4) Theorem. *Let* A *be a regular local ring,* K *its residue field; suppose that* K *is of characteristic* $p > 0$*; let*

$$F_i(T_i) = T_i^p + p \sum_{k=1}^{p-1} c_{ik} T_i^{p-k} - f_i \tag{22.5.4.1}$$

with $c_{ik} \in A$ *and* $f_i \in A$ $(1 \leq i \leq r)$*; let* B *be the quotient ring of* $A[T_1, \ldots, T_r]$ *by the ideal generated by the* r *polynomials* F_i*. Then* B *is a local ring, and the following conditions are equivalent:*

a) B *is regular;*

b) the elements $d_{\mathrm{A}} f_i \otimes 1_{\mathrm{K}}$ $(1 \leq i \leq r)$ *are linearly independent in the* K*-vector space* $\Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$*;*

c) if $\mathrm{B}' = \mathrm{B}/\mathfrak{m}^2\mathrm{B}$ *and if one sets* $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} = \Xi_{\mathrm{B}'_{(\mathrm{K})}/\mathrm{K}}$ *(22.4.5), the characteristic homomorphism* $\Xi_{\mathrm{B}_{(\mathrm{K})}/\mathrm{K}} \to \mathfrak{m}/\mathfrak{m}^2$ *(22.4.6.2) is injective.*

Proof. Indeed, B' is defined again from $\mathrm{A}_1 = \mathrm{A}/\mathfrak{m}^2$ and the polynomials $\overline{\mathrm{F}}_i$ obtained by applying the homomorphism $\mathrm{A} \to \mathrm{A}_1$ to the coefficients. Taking into account that $\Omega^1_{\mathrm{A}} \otimes_{\mathrm{A}} \mathrm{K}$ is canonically isomorphic to $\Omega^1_{\mathrm{A}_1} \otimes_{\mathrm{A}_1} \mathrm{K}$ (20.5.12), (ii), the theorem follows from (22.5.1) and (22.4.7.4), using remark (22.4.8) when A_1 is not of characteristic p. □

(22.5.5) Let k be a field of characteristic $p > 0$, A a local ring, k' a *finite radicial* extension of k such that $k'^p \subset k$, $\mathfrak{m}$ the maximal ideal of A, $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ its residue field; recall that $\mathrm{A}' = \mathrm{A} \otimes_k k'$ is a local ring whose residue field is the same as that of the local ring $\mathrm{K} \otimes_k k'$ (Bourbaki, *Alg. comm.*, chap. V, § 2, No. 3, lemma 4). We note that one has $\mathrm{A}'_{(\mathrm{K})} = \mathrm{A}' \otimes_{\mathrm{A}} \mathrm{K} = \mathrm{K} \otimes_k k'$, and hence (21.3.6) [$0_{\mathrm{IV}\text{-}1}$ | 203]

$$\Theta_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}} = \Theta_{k'/k} \otimes_k \mathrm{K} \tag{22.5.5.1}$$

to a canonical isomorphism. Furthermore, it is known (21.4.7) that one has $\Xi_{k'/k} = 0$, in other words the canonical homomorphism (21.3.2.2)

$$\pi_{k'/k} : \Theta_{k'/k} \to \Omega^1_k$$

is injective, so that one has a canonical *injection*

$$\Theta_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}} \to \Omega^1_k \otimes_k \mathrm{K} \tag{22.5.5.2}$$

which can be described explicitly as follows (taking into account (22.5.5.1)): for every $x' \in k'$, to the element $d_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}}(x' \otimes 1_{\mathrm{K}}) \otimes 1_{\mathrm{K}}$ of $\Omega^1_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}} \otimes_{\mathrm{A}'_{(\mathrm{K})}} \mathrm{K}$, one associates the element $d_k(x'^p) \otimes 1_{\mathrm{K}}$ of $\Omega^1_k \otimes_k \mathrm{K}$.

(22.5.6) Lemma. *With the notations of (22.5.5):*

(i) *The kernel of the canonical homomorphism* $\pi_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}}$ *(21.3.2.2) identifies by (22.5.5.2) with* $(\Theta_{k'/k} \otimes_k \mathrm{K}) \cap \Upsilon_{\mathrm{K}/k}$.

(ii) *Let* $\mathrm{A}_1 = \mathrm{A}/\mathfrak{m}^2$, $\mathrm{A}'_1 = \mathrm{A}_1 \otimes_k k' = \mathrm{A}'/\mathfrak{m}^2\mathrm{A}'$*; then the characteristic homomorphism* $\chi'_{\mathrm{A}'_1/\mathrm{A}_1}$ *(22.4.6.2) identifies with the restriction of the characteristic homomorphism* $\chi_{\mathrm{A}/k} : \Upsilon_{\mathrm{K}/k} \to \mathrm{V} = \mathfrak{m}/\mathfrak{m}^2$ *to* $(\Theta_{k'/k} \otimes_k \mathrm{K}) \cap \Upsilon_{\mathrm{K}/k}$ *(20.6.24).*

Proof. (i) By virtue of (20.6.9), applied by replacing A with the prime field, B with k, C with K and E with $\mathrm{A}_1 = \mathrm{A}/\mathfrak{m}^2$ (extension of K by $\mathrm{V} = \mathfrak{m}/\mathfrak{m}^2$), it suffices (cf. (22.5.5)) to verify that if $x' \in k'$ and if $z \in \mathrm{A}_1$ is an element whose class mod. $\mathfrak{m}/\mathfrak{m}^2$ is $x'^p \in k$, then the image of $d_k(x'^p) \otimes 1_{\mathrm{K}}$ under the canonical homomorphism $\Omega^1_k \otimes_k \mathrm{K} \to \Omega^1_{\mathrm{A}_1} \otimes_{\mathrm{A}_1} \mathrm{K}$ is $d_{\mathrm{A}_1} z \otimes 1_{\mathrm{K}}$, which follows from the definitions.

(ii) As $\mathrm{A}'_{(\mathrm{K})} = \mathrm{K} \otimes_k k' = (\mathrm{A}'_1)_{(\mathrm{K})}$ (by virtue of the relation $\mathrm{K} = \mathrm{A}_1/(\mathfrak{m}/\mathfrak{m}^2)$), $\Theta_{\mathrm{A}'_{(\mathrm{K})}/\mathrm{K}}$ identifies with $\Theta_{(\mathrm{A}'_1)_{(\mathrm{K})}/\mathrm{K}}$, and the verification follows from the same calculation as in (i) and from the definition of $\pi'_{(\mathrm{A}'_1)_{(\mathrm{K})}/\mathrm{K}}$. □

(22.5.7) Proposition. *Let k be a field of characteristic $p > 0$, A a k-algebra that is a regular local ring, $\mathfrak{m}$ its maximal ideal, $\mathrm{K} = \mathrm{A}/\mathfrak{m}$ its residue field; let $\mathrm{V} = \mathfrak{m}/\mathfrak{m}^2$, considered as a K-vector space. Let k' be a finite extension of k such that $k'^p \subset k$, and $\mathrm{A}' = \mathrm{A} \otimes_k k'$; for A' to be a regular local ring, it is necessary and sufficient that the restriction of the characteristic homomorphism $\chi_{\mathrm{A}/k} : \Upsilon_{\mathrm{K}/k} \to \mathrm{V}$ (20.6.24) to $(\Theta_{k'/k} \otimes_k \mathrm{K}) \cap \Upsilon_{\mathrm{K}/k}$ is injective.*

Proof. We must prove that the condition in the statement is equivalent to (22.5.1.1), denoting by $\mathfrak{m}'$ the maximal ideal of A' and by $\mathrm{K}' = \mathrm{A}'/\mathfrak{m}'$ its residue field. With the notations of remark (22.5.2), (i), one has $\mathrm{A}'_1 = \mathrm{A}_1 \otimes_k k'$. Now, let $(a_i)_{1 \leq i \leq r}$ be a p-basis of k' over k, so that $a_i^p = b_i \in k$, and k' is isomorphic to the quotient of the polynomial
[$0_{\text{IV-1}}$ | 204] ring $k[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ by the ideal generated by the polynomials $\mathrm{F}_i = \mathrm{T}_i^p - b_i$ $(1 \leq i \leq r)$; it follows that A'_1 is isomorphic to the quotient of the polynomial ring $\mathrm{A}_1[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ by the ideal generated by the F_i. One can then apply the criterion (22.4.7), and the condition in the statement is therefore equivalent to $\chi'_{\mathrm{A}'_1/\mathrm{A}_1}$ being injective; the conclusion follows from (22.5.6). □

(22.5.8) Theorem. *Let k be a field, p its characteristic exponent, A a local Noetherian k-algebra. The following conditions are equivalent:*

a) A *is a k-algebra formally smooth (for its preadic topology).*

b) A *is geometrically regular over k.*

b') *For every finite extension k' of k such that $k'^p \subset k$, $\mathrm{A}' = \mathrm{A} \otimes_k k'$ is a regular ring.*

Proof. Taking into account (19.6.6), one can restrict oneself to the case $p > 1$.

The fact that *a)* implies *b)* is none other than (19.6.5), and *b)* trivially implies *b')*. Let us show that *b')* implies the conditions of (22.2.2) are satisfied; it is evident for the first (17.1.1) since *b')* implies first of all that A is regular. Next, let $(x_\alpha)_{\alpha \in \mathrm{I}}$ be a p-base of $k^{1/p}$ over k; we know that the elements $d_k(x_\alpha^p)$ form a base of the k-vector space Ω^1_k (21.4.5), hence the elements $d_k(x_\alpha^p) \otimes 1_{\mathrm{K}}$ form a base of the K-vector space $\Omega^1_k \otimes_k \mathrm{K}$. One concludes (cf. (22.5.5)) that when k' ranges over the finite subextensions of $k^{1/p}$, the family of subspaces $\Theta_{k'/k} \otimes_k \mathrm{K}$ is filtering increasing and has as union $\Omega^1_k \otimes_k \mathrm{K}$. It follows then from (22.5.7) that the condition *b')* implies that $\chi_{\mathrm{A}/k}$ is injective, which is none other than condition (ii) of (22.2.2). □

(22.5.9) Corollary. *Let k be a field, A a local Noetherian k-algebra that is formally smooth. Then, for every prime ideal $\mathfrak{p}$ of A, the local ring $\mathrm{A}_\mathfrak{p}$ is a k-algebra formally smooth (for the $\mathfrak{p}$-preadic topology).*

Proof. Indeed, with the notations of (22.5.8), *b')*, it suffices to show that the local ring $\mathrm{A}_\mathfrak{p} \otimes_k k'$ is regular; but since this is a ring of fractions of the local ring $\mathrm{A} \otimes_k k'$ and the latter is regular by hypothesis, it is the same by (17.3.6). □

(22.5.10) Remark.

(i) The conclusion of (22.5.8) fails when, in condition b'), one restricts to *monogenic* extensions $k' = k(x)$ of k (with $x^p \in k$). It can indeed happen that for all these extensions k', one has $\Upsilon_{K/k} \cap (\Theta_{k'/k} \otimes_k K) = 0$, although $\Upsilon_{K/k} \neq 0$; this means that for every $x \in k^{1/p}$ such that $x \notin k$, one must have $d_k(x^p) \otimes 1_K \notin \Upsilon_{K/k}$, or equivalently $d_K(x^p) \neq 0$, that is, $x^p \notin K^p$; in other words, one must have $K^p \cap k = k^p$, even though K is an *inseparable* extension of k. Now, one easily constructs examples of such extensions: start from a perfect field k_0 of characteristic $p > 0$, let X, Y, Z be three indeterminates and set $k = k_0(X, Y)$ and $K = k(X^{1/p} + ZY^{1/p})$; one verifies easily that K satisfies the preceding conditions, hence $\Upsilon_{K/k} \neq 0$. Applying now the lemma (22.2.5.2) taking $V = K$ and for h the zero homomorphism; A is then a valuation ring of discrete valuation having K as residue field, with $\chi_{A/k} = 0$, and is not a k-algebra formally smooth by (22.2.2); however $A \otimes_k k'$ is a regular ring for every *monogenic* subextension $k' \subset k^{1/p}$ of k. [$0_{IV\text{-}1}$ | 205]

(ii) The corollary (22.5.9) leads to the following question: if A is a Noetherian k-algebra, under what conditions is the set of prime ideals $\mathfrak{p} \in \mathrm{Spec}(A)$ such that $A_\mathfrak{p}$ is a k-algebra formally smooth an *open* set? We will address this later in certain particular cases.

22.6 Zariski's Jacobian criterion

(22.6.1) Theorem. (Jacobian criterion for formal smoothness.) *Let* A, B *be two topological rings,* $u : A \to B$ *a continuous homomorphism making* B *a formally smooth* A*-algebra,* $\mathfrak{J}$ *an ideal of* B *(not necessarily closed),* $C = B/\mathfrak{J}$ *the quotient topological algebra. For* C *to be a formally smooth* A*-algebra, it is necessary and sufficient that the canonical homomorphism (cf. (20.5.11.2))*

$$\delta_{C/B/A} : \mathfrak{J}/\mathfrak{J}^2 \to \Omega^1_{B/A} \otimes_B C \tag{22.6.1.1}$$

be formally invertible on the left *(cf. (19.1.5)).*

Proof. Indeed, saying that B (resp. C) is a formally smooth A-algebra signifies (19.4.4) that $\mathrm{Exalcotop}_A(B, L) = 0$ (resp. $\mathrm{Exalcotop}_A(C, L) = 0$) for every B-module (resp. C-module) discrete L annihilated by an open ideal of B (resp. C). By hypothesis $\mathrm{Exalcotop}_A(B, L) = 0$ for every such discrete C-module L annihilated by an open ideal of C, saying that C is a formally smooth A-algebra thus signifies that the canonical homomorphism $\mathrm{Exalcotop}_A(C, L) \to \mathrm{Exalcotop}_A(B, L)$ is *injective*, and the theorem follows from (20.7.8). □

Recall (19.5.3) that when B and C are formally smooth A-algebras, $\mathfrak{J}/\mathfrak{J}^2$ is a C-module topologically *formally projective*; moreover, the canonical homomorphisms $\varphi_n : \mathbf{S}^n_C(\mathfrak{J}/\mathfrak{J}^2) \to \mathfrak{J}^n/\mathfrak{J}^{n+1}$ are *formal bimorphisms* when B is assumed to be a preadmissible ring.

(22.6.2) Corollary. *With the hypotheses and notations of (22.6.1), suppose furthermore that the square of every open ideal of* B *is open, and that on* $\mathfrak{J}$ *the topology induced by that of* B *is identical to the topology deduced from that of* B *(19.0) (note that these two conditions are satisfied when* B *is Noetherian and its topology is preadic* ($\mathbf{0}_I$, 7.3.2)*, or if the topology of* B *is the* $\mathfrak{J}$*-preadic topology). Let* $(\mathfrak{b}_\lambda)$ *be a fundamental system of open ideals of* B *and set* $B_\lambda = B/\mathfrak{b}_\lambda$ *for every* λ*. Then:*

(i) *The following conditions are equivalent:*

a) C *is a formally smooth* A*-algebra.*

b) For every λ*, the homomorphism of* B_λ*-modules*

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{B}} \mathrm{B}_\lambda \longrightarrow \Omega^1_{\mathrm{B/A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda \tag{22.6.2.1}$$

deduced from $\delta_{\mathrm{C/B/A}}$ *by tensorization, is invertible on the left (in other words, an isomorphism onto a direct factor of* $\Omega^1_{\mathrm{B/A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda$*).*

(ii) *Suppose furthermore that the topological ring* C *is preadmissible* (**0**$_{\mathrm{I}}$, 7.1.2) *and let* $\mathfrak{L}$ *be an ideal of definition of* C*; then conditions a) and b) of (i) are also equivalent to:* [$0_{IV\text{-}1}$ | 206]

c) The homomorphism of $(\mathrm{C}/\mathfrak{L})$*-modules*

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{C}} (\mathrm{C}/\mathfrak{L}) \longrightarrow \Omega^1_{\mathrm{B/A}} \otimes_{\mathrm{B}} (\mathrm{C}/\mathfrak{L})$$

is invertible on the left.

Proof. The hypotheses imply that on $\Omega^1_{\mathrm{B/A}}$ the topology is deduced from that of B (20.4.5), hence (i) follows from (22.6.1) and (19.1.7). On the other hand, recall (20.4.9) that since B is a formally smooth A-algebra, $\Omega^1_{\mathrm{B/A}}$ is a formally projective B-module, hence $\Omega^1_{\mathrm{B/A}} \otimes_{\mathrm{B}} \mathrm{B}_\lambda$ is a projective B_λ-module for every λ (19.2.4); the equivalence of *c*) with *a*) and *b*), when C is preadmissible, then follows from (19.1.9). □

In particular:

(22.6.3) Corollary. *Let* A *be a ring,* B *an* A*-algebra,* $\mathfrak{J}$ *an ideal of* B*,* $\mathrm{C} = \mathrm{B}/\mathfrak{J}$*; we suppose* A*,* B*,* C *equipped with the discrete topologies and that* B *is a formally smooth* A*-algebra. For* C *to be a formally smooth* A*-algebra, it is necessary and sufficient that the canonical homomorphism (22.6.1.1) be invertible on the left.*

Note that since *every* A-algebra C is a quotient of a polynomial algebra $\mathrm{A}[\mathrm{T}_\alpha]_{\alpha\in\mathrm{I}}$, and the latter is formally smooth (19.3.3), the criterion (22.6.3) allows in principle to determine whether C is a formally smooth A-algebra.

(22.6.4) Proposition. *Let* A *be a ring,* B *a formally smooth* A*-algebra (for the discrete topologies),* $\mathfrak{J}$ *an ideal of* B*,* $\mathrm{C} = \mathrm{B}/\mathfrak{J}$*; suppose that* $\mathfrak{J}/\mathfrak{J}^2$ *is a* C*-module of finite type. Let* $\mathfrak{p}$ *be a prime ideal of* C*,* $k(\mathfrak{p})$ *the residue field of* $\mathrm{C}_\mathfrak{p}$*,* $\mathfrak{p}'$ *the inverse image of* $\mathfrak{p}$ *in* B*, and* $\mathfrak{q}$ *the prime ideal of* A *which is the inverse image of* $\mathfrak{p}'$*. The following conditions are equivalent:*

a) $\mathrm{C}_\mathfrak{p}$ *is a formally smooth* $\mathrm{A}_\mathfrak{q}$*-algebra (for the discrete topologies).*

a') $\mathrm{C}_\mathfrak{p}$ *is a formally smooth* A*-algebra (for the discrete topologies).*

b) The canonical homomorphism

$$(\mathfrak{J}/\mathfrak{J}^2) \otimes_{\mathrm{C}} k(\mathfrak{p}) \to \Omega^1_{\mathrm{B/A}} \otimes_{\mathrm{B}} k(\mathfrak{p}) \tag{22.6.4.1}$$

is injective.

c) There exists $f \in \mathrm{C} - \mathfrak{p}$ *such that* C_f *is a formally smooth* A*-algebra.*

If furthermore B *is* Noetherian*, the preceding conditions are also equivalent to:*

d) $C_{\mathfrak{p}}$ *is a formally smooth* $A_{\mathfrak{q}}$*-algebra for the* $\mathfrak{p}$*-preadic topology on* $C_{\mathfrak{p}}$ *and the discrete topology (or the* $\mathfrak{q}$*-preadic topology) on* $A_{\mathfrak{q}}$*.*

Proof. Since $A_{\mathfrak{q}}$ is a formally smooth A-algebra (19.3.5), (iv) and (ii), conditions *a)* and *a′)* are already known to be equivalent (19.3.5), (ii). We have $C_{\mathfrak{p}} = B_{\mathfrak{p}'}/\mathfrak{J}B_{\mathfrak{p}'}$, and $B_{\mathfrak{p}'}$ is a formally smooth A-algebra for the discrete topology (19.3.5), (iv); moreover, $\Omega^1_{B_{\mathfrak{p}'}/A} = (\Omega^1_{B/A})_{\mathfrak{p}'}$ (20.5.9). The equivalence of *a′)* and *b)* therefore follows by applying (22.6.3) to $B_{\mathfrak{p}'}$ and $C_{\mathfrak{p}}$, taking into account that $\Omega^1_{B/A}$ is a projective B-module (20.4.9), (19.2.11), that $\mathfrak{J}/\mathfrak{J}^2$ is a B-module of finite type, and using (19.1.12). Applying (19.1.12) also proves the equivalence of *b)* and *c)*. Finally, since $B_{\mathfrak{p}'}$ is a formally smooth $A_{\mathfrak{q}}$-algebra for the
discrete topologies (19.3.5), (iv), it remains formally smooth when $B_{\mathfrak{p}'}$ is given its $\mathfrak{p}'$- [$0_{IV\text{-}1}$ | 207]
preadic topology and $A_{\mathfrak{q}}$ is given either the discrete or the $\mathfrak{q}$-preadic topology (19.3.8). To prove the equivalence of *b)* and *d)* when B is Noetherian, apply (22.6.2) to $A_{\mathfrak{q}}$ with the discrete (or $\mathfrak{q}$-preadic) topology and to $B_{\mathfrak{p}'}$ with the $\mathfrak{p}'$-preadic topology. Since $C_{\mathfrak{p}}$ is preadmissible and $\mathfrak{p}C_{\mathfrak{p}}$ is an ideal of definition for its topology, the equivalence of *c)* and *a)* in (22.6.2) applies. □

(22.6.5) Corollary. *Under the general hypotheses of (22.6.4), the set of* $\mathfrak{p} \in \mathrm{Spec}(C)$ *such that* $C_{\mathfrak{p}}$ *is a formally smooth* A*-algebra (or a formally smooth* $A_{\mathfrak{q}}$*-algebra, where* $\mathfrak{q}$ *denotes the inverse image of* $\mathfrak{p}$ *in* A*), for the discrete topologies, is open in* Spec(C)*.*

Proof. This follows from form *c)* of (22.6.4). Note that when B is Noetherian, one can replace the discrete topologies by the preadic topologies. □

(22.6.6) Corollary. *Under the general hypotheses of (22.6.4), the following conditions are equivalent:*

a) C *is a formally smooth* A*-algebra (for the discrete topologies).*

b) For every $\mathfrak{p} \in \mathrm{Spec}(C)$ *(or only for every* maximal *ideal* $\mathfrak{p}$ *of* C*),* $C_{\mathfrak{p}}$ *is a formally smooth* A*-algebra (or a formally smooth* $A_{\mathfrak{q}}$*-algebra, where* $\mathfrak{q}$ *denotes the inverse image of* $\mathfrak{p}$ *in* A*)* for the discrete topologies*.*

Furthermore, when B *is Noetherian, one can replace in b) the discrete topologies by the preadic topologies on* $A_{\mathfrak{q}}$ *and* $C_{\mathfrak{p}}$*.*

Proof. The last assertion follows from (22.6.4). By virtue of (22.6.3), condition *a)* is equivalent to the fact that the homomorphism (22.6.1.1) is invertible on the left; the equivalence of *a)* and *b)* therefore follows from (19.1.14), taking into account that $\Omega^1_{B/A}$ is a projective B-module and $\mathfrak{J}/\mathfrak{J}^2$ a C-module of finite type. □

(22.6.7) Proposition. *Let* k_0 *be a field,* k *a separable extension of* k_0*,* C *a* k*-algebra of finite type.*

(i) *Let* $\mathfrak{p}$ *be a prime ideal of* C*. The following conditions are equivalent:*

a) $C_{\mathfrak{p}}$ *is a* k_0*-algebra formally smooth for the discrete topology.*

b) $C_{\mathfrak{p}}$ *is a* k_0*-algebra formally smooth for the* $\mathfrak{p}$*-preadic topology.*

c) There exists $f \in \mathrm{C} - \mathfrak{p}$ *such that* C_f *is a* k_0*-algebra formally smooth for the discrete topology.*

d) $\mathrm{C}_\mathfrak{p}$ *is a geometrically regular ring over* k_0 *(19.6.5).*

Furthermore the set of $\mathfrak{p} \in \mathrm{Spec(C)}$ *having any of these properties is open in* Spec(C).

(ii) *The following conditions are equivalent:*

a) C *is a* k_0*-algebra formally smooth for the discrete topology.*

b) Every $\mathfrak{p} \in \mathrm{Spec(C)}$ *satisfies the equivalent conditions of (i).*

c) Every maximal ideal $\mathfrak{m}$ *of* C *satisfies the equivalent conditions of (i).*

d) For every extension k' *of* k_0, $\mathrm{C} \otimes_{k_0} k'$ *is a regular ring (17.3.6); we also say that* C *is a geometrically regular ring over* k_0.

[$0_{IV\text{-}1}$ / 208] (iii) *Let* $\mathrm{B} = k[\mathrm{T}_1, \ldots, \mathrm{T}_r]$ *be a polynomial algebra and* $\mathfrak{J}$ *an ideal of* B *such that* C *is isomorphic to* $\mathrm{B}/\mathfrak{J}$. *Let* $\mathfrak{q}$ *be a prime ideal of* B *containing* $\mathfrak{J}$ *and set* $\mathfrak{p} = \mathfrak{q}/\mathfrak{J}$. *The conditions of (i) are then also equivalent to the following (the "Jacobian criterion of Zariski"):*

e) There exists a system $(f_i)_{1 \leq i \leq m}$ *of elements of* $\mathfrak{J}$ *generating the ideal* $\mathfrak{J}_\mathfrak{q}$ *in* $\mathrm{B}_\mathfrak{q}$, *and* k_0*-derivations* D_j *of* B *into itself* $(1 \leq j \leq m)$, *such that* $\det(\mathrm{D}_j(f_i)) \notin \mathfrak{q}$.

Proof. One knows that C is always isomorphic to a k-algebra of the form $\mathrm{B}/\mathfrak{J}$. Since B is a formally smooth k-algebra (19.3.3), and k, being separable over k_0, is a formally smooth k_0-algebra (19.6.1), B is a formally smooth k_0-algebra (19.3.5), (ii). The equivalence of conditions *a*), *b*), *c*) of (i) therefore follows from (22.6.4), and that of *a*), *b*), *c*) in (ii) follows from (22.6.6); the equivalence of *a*) and *d*) in (i) follows from (22.5.8). Since every localization of $\mathrm{C} \otimes_{k_0} k'$ is also a localization of $\mathrm{C}_\mathfrak{p} \otimes_{k_0} k'$ for a suitable prime ideal $\mathfrak{p} \in \mathrm{Spec(C)}$, the equivalence of *d*) and *b*) in (ii) follows from the equivalence of *d*) and *a*) in (i). Finally, since $\Omega^1_{\mathrm{B}/k_0}$ is a projective B-module, the equivalence of the Zariski criterion *e*) and the other conditions in (i) follows from (19.1.12) and (22.6.3), taking (20.4.8) into account. □

Zariski was in fact interested in a differential criterion of regularity for the local rings $\mathrm{C}_\mathfrak{p}$. Since saying that a Noetherian local ring containing a field is regular is equivalent to saying that it is formally smooth as an algebra over its prime subfield (19.6.4), such a criterion follows immediately by replacing k_0 by the prime subfield of k in (22.6.7). In particular, one obtains the following result, which will be recovered later in (IV, 6.12.5) as a special case of more general results of Nagata:

(22.6.8) Corollary. (Zariski.) *Let* C *be an algebra of finite type over a field. Then the set of* $\mathfrak{p} \in \mathrm{Spec(C)}$ *such that* $\mathrm{C}_\mathfrak{p}$ *is a regular local ring is open in* Spec(C).

(22.6.9) Remark.

(i) The statements of (22.6.7) are still valid if instead of supposing k separable over k_0, one assumes only that it is of *finite radiciel multiplicity*, that is to say (19.6.6) that there exists a finite radiciel extension k'_0 of k_0 such that the residue field of the local Artinian ring $k \otimes_{k_0} k'_0$ is a *separable* extension k' of k'_0. There exists then a k'_0-monomorphism $k' \to k \otimes_{k_0} k'_0$ which, composed with the canonical homomorphism $k \otimes_{k_0} k'_0 \to k'$, gives the identity, since k' is a formally smooth k'_0-algebra (19.6.1).

One concludes that $C \otimes_{k_0} k'_0$ is equipped with the structure of a k'-algebra of finite type, and since k' is separable over k'_0, one can apply (22.6.7) to this k'-algebra; the assertion follows by applying (19.4.7). Since we shall not need this generalization, we leave the details to the reader. We do not know whether the results of (22.6.7) are valid without *any* hypothesis on the extension k of k_0.

(ii) Under the general hypotheses of (22.6.7), let (k_α) be a decreasing filtering family of subfields of k containing k_0 and such that $\bigcap k_\alpha(k^p) = k_0(k^p)$ (where p is the characteristic exponent of k_0). Using a dimension counting method due to Nagata, one can show that, in the Jacobian criterion (22.6.7), (iii), one may restrict the derivations D_j of B to be k_α-derivations for a suitable α.

The interest of this result is that there always exist such families (k_α) for which [0IV-1 | 209] $[k : k_\alpha]$ is finite (21.8.6). We shall not prove this refinement of the Zariski criterion, which we shall not need. In (22.7), we give, for complete local rings, a variant (also due to Nagata) of the Zariski criterion, proved essentially by the same method (with somewhat greater technical difficulties).

22.7 Nagata's Jacobian criterion

(22.7.1) The Jacobian criterion of Nagata is the analog of the Jacobian criterion of Zariski, but for quotient rings of *formal power series* rings over a field. We shall give, as Nagata [31], two versions, presented here as criteria of formal smoothness.

(22.7.2) Proposition. *Let k be a field, $A = k[[T_1, \ldots, T_r]]$ a formal power series ring, equipped with its usual k-algebra structure, $\mathfrak{q}$ an ideal of A, $B = A/\mathfrak{q}$. Let $\mathfrak{p}$ be a prime ideal of A containing $\mathfrak{q}$. Suppose that there exists a sub-k-algebra C' of $C = A/\mathfrak{p}$, isomorphic to a formal power series ring $k[[X_1, \ldots, X_s]]$, such that C is finite over C' and that the field of fractions L of C is a separable extension of $L' = k((X_1, \ldots, X_s))$ (this hypothesis is always satisfied if k is of characteristic 0). Then the following conditions are equivalent:*

a) $B_\mathfrak{p} = A_\mathfrak{p}/\mathfrak{q}A_\mathfrak{p}$ *is a k-algebra formally smooth for the $\mathfrak{p}$-preadic topology.*

b) There exist k-derivations D_i of A into itself $(1 \leq i \leq m)$, and elements f_i of $\mathfrak{q}$ $(1 \leq i \leq m)$, such that the images of the f_i in $\mathfrak{q}A_\mathfrak{p}$ generate this ideal of $A_\mathfrak{p}$, and that $\det(D_i f_j) \notin \mathfrak{p}$.

c) $B_\mathfrak{p}$ *is a regular ring.*

Proof. The residue field of $B_\mathfrak{p}$ is $k(\mathfrak{p})$. Since $k((X_1, \ldots, X_s))$ is separable over k (21.9.6.4), the field $k(\mathfrak{p}) = L$ is separable over k by hypothesis; hence conditions *a*) and *c*) are equivalent by (19.6.4). Furthermore, $A_\mathfrak{p}$ is regular (17.1.4), (17.3.2), and therefore formally smooth over k for its $\mathfrak{p}$-preadic topology (19.6.4). By (22.6.2), (ii), condition *a*) is consequently equivalent to injectivity of

$$j_0 : (\mathfrak{q}/\mathfrak{q}^2) \otimes_A L \longrightarrow \Omega^1_{A_\mathfrak{p}/k} \otimes_{A_\mathfrak{p}} L = \widehat{\Omega}^1_{A/k} \otimes_A L. \tag{22.7.2.1}$$

Consider also

$$j : (\mathfrak{q}/\mathfrak{q}^2) \otimes_A L \xrightarrow{j_0} \Omega^1_{A/k} \otimes_A L \longrightarrow \widehat{\Omega}^1_{A/k} \otimes_A L. \tag{22.7.2.2}$$

We show first that b) is equivalent to injectivity of j. Indeed,

$$(\mathfrak{q}/\mathfrak{q}^2) \otimes_{\mathrm{A}} \mathrm{L} = (\mathfrak{q}\mathrm{A}_{\mathfrak{p}}/\mathfrak{q}^2\mathrm{A}_{\mathfrak{p}}) \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{L}.$$

If $F_i = j(f'_i \otimes 1)$, condition b) says that the matrix $(\langle F_i, \mathrm{D}_j \otimes 1\rangle)$ is invertible. Thus the F_i, and hence the generators $f'_i \otimes 1$, are linearly independent, so j is injective. Conversely, if j is injective, choose f_i so that the $f'_i \otimes 1$ form
[$0_{\text{IV-1}}$ | 210] a basis of the source. Then the F_i are linearly independent. By (21.9.3), $\widehat{\Omega}^1_{\mathrm{A}/k}$ is free of rank r, and the k-derivations of A into itself generate its dual; hence there exist derivations D_j for which $(\langle F_i, \mathrm{D}_j \otimes 1\rangle)$ is invertible. This is condition b).

These observations show already that b) implies a). Conversely, assume a), so that j_0 is injective, and consider

$$\begin{array}{ccc} (\mathfrak{q}/\mathfrak{q}^2) \otimes_{\mathrm{A}} \mathrm{L} & \xrightarrow{\ j\ } & \widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L} \\ {\scriptstyle\alpha}\big\downarrow & & \big\| \\ (\mathfrak{p}/\mathfrak{p}^2) \otimes_{\mathrm{A}} \mathrm{L} & \xrightarrow[\ i\ ]{} & \widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L}. \end{array} \tag{22.7.2.3}$$

We shall use the following lemma. □

(22.7.2.4) Lemma. *Let* R *be a regular local ring,* $\mathfrak{m}$ *its maximal ideal,* $\mathrm{K} = \mathrm{R}/\mathfrak{m}$ *its residue field. If* $\mathfrak{n}$ *is an ideal of* R *such that* $\mathrm{R}/\mathfrak{n}$ *is regular, then the canonical homomorphism*

$$\alpha : (\mathfrak{n}/\mathfrak{n}^2) \otimes_{\mathrm{R}} \mathrm{K} \to (\mathfrak{m}/\mathfrak{m}^2) \otimes_{\mathrm{R}} \mathrm{K} \tag{22.7.2.5}$$

is injective.

Proof. Indeed, one knows (17.1.6) that $\mathfrak{n}$ is generated by a subset $(x_i)_{1\leq i\leq l}$ forming part of a regular system of parameters $(x_i)_{1\leq i\leq n}$ of R; the images of the x_i for $1 \leq i \leq l$ form a base of $(\mathfrak{n}/\mathfrak{n}^2) \otimes_{\mathrm{R}} \mathrm{K}$, and their images by α form part of the base of $(\mathfrak{m}/\mathfrak{m}^2) \otimes_{\mathrm{R}} \mathrm{K}$ formed by the images of the x_i for $1 \leq i \leq n$, from which the lemma. □

Continuation of the proof of Proposition (22.7.2). By the lemma and the diagram (22.7.2.3), it remains only to prove that i is injective. Consider the sequence

$$\mathfrak{p}/\mathfrak{p}^2 \xrightarrow{h} \widehat{\Omega}^1_{\mathrm{A}/k}\widehat{\otimes}_{\mathrm{A}}(\mathrm{A}/\mathfrak{p}) \xrightarrow{g} \widehat{\Omega}^1_{(\mathrm{A}/\mathfrak{p})/k} \to 0. \tag{22.7.2.6}$$

By (20.7.20), g is surjective and the image of h is dense in $\mathrm{Ker}(g)$ for the $\mathfrak{m}$-adic topology. Since $\widehat{\Omega}^1_{\mathrm{A}/k}$ is an A-module of finite type, every submodule of

$$\widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} (\mathrm{A}/\mathfrak{p}) = \widehat{\Omega}^1_{\mathrm{A}/k}\widehat{\otimes}_{\mathrm{A}}(\mathrm{A}/\mathfrak{p})$$

is closed for the $\mathfrak{m}$-adic topology (I, 7.3.5); therefore (22.7.2.6) is exact. After tensoring with L, one obtains the exact sequence

$$(\mathfrak{p}/\mathfrak{p}^2) \otimes_{\mathrm{A}} \mathrm{L} \xrightarrow{i} \widehat{\Omega}^1_{\mathrm{A}/k} \otimes_{\mathrm{A}} \mathrm{L} \to \widehat{\Omega}^1_{(\mathrm{A}/\mathfrak{p})/k} \otimes_{\mathrm{A}/\mathfrak{p}} \mathrm{L} \to 0.$$

The separability hypothesis and (21.9.5) show that the last module has rank s over L; the middle module has rank r by (21.9.3). Thus $\mathrm{rg}_{\mathrm{L}}(\mathrm{Im}\, i) = r - s$. Since $\mathrm{A}/\mathfrak{p}$ is finite over a subalgebra isomorphic to $k[[\mathrm{T}_1, \ldots, \mathrm{T}_s]]$, one has $\dim(\mathrm{A}/\mathfrak{p}) = s$ by (17.1.4) and (16.1.5), and hence

$$r - s = \dim(\mathrm{A}) - \dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{A}_{\mathfrak{p}})$$

[$0_{\text{IV-1}}$ | 211] by (16.5.11). Finally, $\mathrm{A}_{\mathfrak{p}}$ is regular, so $\dim(\mathrm{A}_{\mathfrak{p}})$ is the rank over L of $(\mathfrak{p}/\mathfrak{p}^2) \otimes_{\mathrm{A}} \mathrm{L}$ (17.1.1). The source and image of i therefore have the same rank, and i is injective. □

(22.7.3) Theorem. *Let k be a field,* A *a local Noetherian complete ring with residue field* K*. Suppose that:*

1° $[k : k^p] < +\infty$ *(where p is the characteristic exponent of k);*

2° K *is a finite extension of a separable extension* K_0 *of k;*

3° A *is equipped with a structure of* K_0*-algebra formally smooth (for the preadic topology).*

Let $\mathfrak{q}$ *be an ideal of* A, $\mathrm{B} = \mathrm{A}/\mathfrak{q}$, $\mathfrak{p}$ *a prime ideal of* A *containing* $\mathfrak{q}$*. The following conditions are equivalent:*

a) $\mathrm{B}_\mathfrak{p}$ *is a k-algebra formally smooth for the $\mathfrak{p}$-preadic topology.*

b) There exist k-derivations D_i *of* A *into itself* $(1 \leq i \leq m)$*, and elements* f_i $(1 \leq i \leq m)$ *of* $\mathfrak{q}$*, such that the images of the f_i in* $\mathfrak{q}\mathrm{A}_\mathfrak{p}$ *generate this ideal of* $\mathrm{A}_\mathfrak{p}$*, and that* $\det(\mathrm{D}_i f_j) \notin \mathfrak{p}$*.*

b') There exists a sub-extension k' of K_0*, containing* K_0^p*, such that* $[\mathrm{K}_0 : k'] < +\infty$*, k'-derivations* D_i *of* A *into itself, and elements f_i of* $\mathfrak{q}$ $(1 \leq i \leq m)$*, such that the images of the f_i in* $\mathfrak{q}\mathrm{A}_\mathfrak{p}$ *generate this ideal of* $\mathrm{A}_\mathfrak{p}$*, and that* $\det(\mathrm{D}_i f_j) \notin \mathfrak{p}$*.*

Proof. We distinguish two cases, according to whether $p = 1$ or $p > 1$.

A) k is of characteristic 0. Since K is then a separable extension of K_0, (19.6.4) shows that A is K_0-isomorphic to a formal power series ring $\mathrm{K}[[\mathrm{T}_1, \ldots, \mathrm{T}_r]]$ equipped with its usual K-algebra structure. Taking (19.8.8), (ii), applied to $\mathrm{A}/\mathfrak{p}$ into account, the general hypotheses of (22.7.2) are satisfied after replacing k by K. Moreover, by (19.6.4), saying that $\mathrm{B}_\mathfrak{p}$ is formally smooth as a k-algebra or as a K-algebra amounts to the same thing, both conditions being equivalent to regularity of $\mathrm{B}_\mathfrak{p}$. We may therefore apply (22.7.2), which immediately proves the equivalence of *a*), *b*), and *b'*) (with $k' = \mathrm{K}_0$ in *b'*)).

B) k is of characteristic $p > 0$. Since A is a formally smooth K_0-algebra and K_0 is separable over k, it follows from (19.3.5), (ii), and (19.6.1) that A is a formally smooth k-algebra; by (22.5.9), $\mathrm{A}_\mathfrak{p}$ is also formally smooth over k for the $\mathfrak{p}$-preadic topology. It follows therefore from (22.6.2), (ii) that the condition *a*) is equivalent to the fact that the homomorphism j_0 defined in (22.7.2.1) (where $\mathrm{L} = k(\mathfrak{p})$) is injective. Therefore (19.1.12), *c*) shows already that *b*) implies *a*); and since moreover *b'*) trivially implies *b*), it all amounts to showing that the hypothesis that j_0 is injective implies *b'*).

Let us first denote by k' a sub-extension of K_0 such that $[\mathrm{K}_0 : k'] < +\infty$. Note that $\widehat{\Omega}^1_{\mathrm{A}/k'}$ is a free A-module of finite type. By the argument of (22.7.2), it is enough to prove that (for a suitable choice of k') the composite homomorphism

$$j' : (\mathfrak{q}/\mathfrak{q}^2) \otimes_\mathrm{A} \mathrm{L} \xrightarrow{j_0} \Omega^1_{\mathrm{A}/k} \otimes_\mathrm{A} \mathrm{L} \to \widehat{\Omega}^1_{\mathrm{A}/k'} \otimes_\mathrm{A} \mathrm{L} \tag{22.7.3.1}$$

is injective. Consider again the commutative diagram [$0_{\text{IV-1}}$ | 212]

$$\begin{array}{ccccc} (\mathfrak{q}/\mathfrak{q}^2) \otimes_\mathrm{A} \mathrm{L} & \xrightarrow{j_0} & \Omega^1_{\mathrm{A}/k} \otimes_\mathrm{A} \mathrm{L} & \longrightarrow & \widehat{\Omega}^1_{\mathrm{A}/k'} \otimes_\mathrm{A} \mathrm{L} \\ \downarrow{\scriptstyle \alpha} & & \| & & \| \\ (\mathfrak{p}/\mathfrak{p}^2) \otimes_\mathrm{A} \mathrm{L} & \xrightarrow[i_0]{} & \Omega^1_{\mathrm{A}/k} \otimes_\mathrm{A} \mathrm{L} & \longrightarrow & \widehat{\Omega}^1_{\mathrm{A}/k'} \otimes_\mathrm{A} \mathrm{L} \end{array} \tag{22.7.3.2}$$

Since j_0 is injective, we have $\mathrm{Ker}(i_0 \circ \alpha) = 0$. But as $\mathrm{A}_{\mathfrak{p}}$ is regular, and the hypothesis a) implies that $\mathrm{B}_{\mathfrak{p}} = \mathrm{A}_{\mathfrak{p}}/\mathfrak{q}\mathrm{A}_{\mathfrak{p}}$ is also regular (19.6.5), the lemma (22.7.2.4) shows that α is injective, from which $\alpha^{-1}(\mathrm{Ker}(i_0)) = 0$. If i' is the composite homomorphism of the second line of (22.7.3.2), one likewise has $\mathrm{Ker}(j') = \alpha^{-1}(\mathrm{Ker}(i'))$; it therefore remains to prove that, for a suitable choice of k',

$$\mathrm{Ker}(i') = \mathrm{Ker}(i). \tag{22.7.3.3}$$

But the same argument as in (22.7.2) gives an exact sequence

$$(\mathfrak{p}/\mathfrak{p}^2) \otimes_{\mathrm{A}} \mathrm{L} \xrightarrow{i'} \widehat{\Omega}^1_{\mathrm{A}/k'} \otimes_{\mathrm{A}} \mathrm{L} \longrightarrow \widehat{\Omega}^1_{(\mathrm{A}/\mathfrak{p})/k'} \otimes_{\mathrm{A}/\mathfrak{p}} \mathrm{L} \longrightarrow 0.$$

The hypotheses allow us to apply (21.9.8); hence there exists a sub-extension k' of K_0 containing K_0^p, with $[\mathrm{K}_0 : k'] < +\infty$, for which

$$\mathrm{rg}_{\mathrm{L}}\big(\widehat{\Omega}^1_{(\mathrm{A}/\mathfrak{p})/k'} \otimes_{\mathrm{A}/\mathfrak{p}} \mathrm{L}\big) = \dim(\mathrm{A}/\mathfrak{p}) + \mathrm{rg}_{\mathrm{L}}\, \Upsilon_{\mathrm{L}/k} + \mathrm{rg}_{\mathrm{K}_0}\, \Omega^1_{\mathrm{K}_0/k'}.$$

But

$$\dim(\mathrm{A}/\mathfrak{p}) = \dim(\mathrm{A}) - \dim(\mathrm{A}_{\mathfrak{p}})$$

by (16.5.11),

$$\dim(\mathrm{A}_{\mathfrak{p}}) = \mathrm{rg}_{\mathrm{L}}\big((\mathfrak{p}/\mathfrak{p}^2) \otimes_{\mathrm{A}} \mathrm{L}\big)$$

because $\mathrm{A}_{\mathfrak{p}}$ is regular (17.1.1), and

$$\dim(\mathrm{A}) + \mathrm{rg}_{\mathrm{K}_0}\, \Omega^1_{\mathrm{K}_0/k'} = \mathrm{rg}_{\mathrm{L}}\big(\widehat{\Omega}^1_{\mathrm{A}/k'} \otimes_{\mathrm{A}} \mathrm{L}\big)$$

by (21.9.2). Consequently

$$\mathrm{rg}_{\mathrm{L}}(\mathrm{Ker}(i')) = \mathrm{rg}_{\mathrm{L}}\, \Upsilon_{\mathrm{L}/k}. \tag{22.7.3.4}$$

On the other hand, since the residue field of $\mathrm{A}_{\mathfrak{p}}$ is formally smooth over the prime field of k, there is an exact sequence (20.6.22.1)

$$\Upsilon_{\mathrm{L}/k} \xrightarrow{\chi_{\mathrm{A}_{\mathfrak{p}}/k}} (\mathfrak{p}\mathrm{A}_{\mathfrak{p}})/(\mathfrak{p}\mathrm{A}_{\mathfrak{p}})^2 \xrightarrow{i} \Omega^1_{\mathrm{A}_{\mathfrak{p}}/k} \otimes_{\mathrm{A}_{\mathfrak{p}}} \mathrm{L}.$$

Since $\mathrm{A}_{\mathfrak{p}}$ is a formally smooth k-algebra for the $\mathfrak{p}$-preadic topology, (22.2.2) shows that $\chi_{\mathrm{A}_{\mathfrak{p}}/k}$ is injective. Thus $\mathrm{Ker}(i)$ is isomorphic to $\Upsilon_{\mathrm{L}/k}$; taking (22.7.3.4) and $\mathrm{Ker}(i) \subset \mathrm{Ker}(i')$ into account proves (22.7.3.3), and hence the theorem. □

[$0_{\text{IV-1}}$ | 213] **(22.7.4) Remark.** It was shown in fact (using (21.9.6)) that condition b') is even equivalent to the other conditions of (22.7.3) when one subjects k' to be one of the fields of a decreasing filtering family (k_α) of subfields of K_0, containing K_0^p, such that $[\mathrm{K}_0 : k_\alpha] < +\infty$ for every α and that $\bigcap k_\alpha = \mathrm{K}_0^p$.

(22.7.5) Corollary. *Under the general hypotheses of (22.7.3), the set of prime ideals* $\mathfrak{n} \in \mathrm{Spec}(\mathrm{B})$ *such that* $\mathrm{B}_{\mathfrak{n}}$ *is a* k*-algebra formally smooth (for the* $\mathfrak{n}$*-preadic topology) is open in* $\mathrm{Spec}(\mathrm{B})$.

Proof. With the notations of (22.7.3), it suffices to see that if $\mathrm{B}_{\mathfrak{p}}$ is formally smooth over k, then the same is true of $\mathrm{B}_{\mathfrak{p}'}$ for every $\mathfrak{p}' \in \mathrm{V}(\mathfrak{q})$ sufficiently near to $\mathfrak{p}$ in $\mathrm{Spec}(\mathrm{A})$. But, if the k-derivations D_i and the elements f_i of $\mathfrak{q}$ satisfy criterion b) of (22.7.3), one has also $f = \det(\mathrm{D}_i f_j) \notin \mathfrak{p}'$ for every $\mathfrak{p}' \in \mathrm{D}(f)$; on the other hand, there exists $g \notin \mathfrak{p}$ such that the images of f_i in $\mathfrak{q}\mathrm{A}_{\mathfrak{p}'}$ generate this ideal of $\mathrm{A}_{\mathfrak{p}'}$ for every $\mathfrak{p}' \in \mathrm{D}(g)$, which finishes the proof of the corollary. □

(22.7.6) Corollary. (Nagata.) *Let* B *be a local Noetherian complete ring containing a field. Then the set of* $\mathfrak{n} \in \mathrm{Spec(B)}$ *such that* $\mathrm{B}_\mathfrak{n}$ *is regular is open in* Spec(B).

Proof. Indeed, B is an algebra over a *prime* field k, hence by (19.8.8)[ii] it is of the form $\mathrm{A}/\mathfrak{q}$, where $\mathrm{A} = \mathrm{K}_0[[\mathrm{T}_1, \ldots, \mathrm{T}_n]]$ is a formal power series ring and K_0 an extension of k; on the other hand, saying that $\mathrm{B}_\mathfrak{n}$ is regular is equivalent to saying that it is a k-algebra formally smooth for the $\mathfrak{n}$-preadic topology (19.6.4). All the conditions of application of (22.7.5) are thus realized. □

(22.7.7) Remark.

(i) We shall see further on, using (22.7.6), that the conclusion of (22.7.6) can be extended to the case of any complete Noetherian local ring (**IV**, 6.12.7).

(ii) The conclusion of the theorem (22.7.3) is no longer necessarily exact when one no longer assumes that $[k : k^p]$ is finite. Take for example $k = \mathbf{F}_p(\mathrm{X}_n)_{n\geq 0}$, $\mathrm{A} = k[[\mathrm{T}, \mathrm{U}]]$, $\mathfrak{q}$ the principal ideal $\mathrm{A}f$, where $f = \mathrm{U}^p - \sum_{n=0}^{\infty} \mathrm{X}_n \mathrm{T}^{np}$; A is a factorial ring in which f is an extremal element, for it is extremal in the polynomial ring $k((\mathrm{T}))[\mathrm{U}]$, hence also in the formal power series ring $k((\mathrm{T}))[[\mathrm{U}]]$ (Bourbaki, *Alg. comm.*, chap. VII, § 3), and *a fortiori* in A. Take $\mathfrak{p} = \mathfrak{q}$, so that $\mathrm{B}_\mathfrak{p}$ is the field of fractions denoted by E in (21.9.7), which is separable over k (*loc. cit.*), hence a k-algebra formally smooth. But one has, with the notations of (22.7.3), $k = \mathrm{K}_0 = \mathrm{K}$, and the k-derivations of A into itself are combinations of $\partial/\partial\mathrm{T}$ and $\partial/\partial\mathrm{U}$; as one has $\partial f/\partial\mathrm{T} = \partial f/\partial\mathrm{U} = 0$, the criteria b) and b') of (22.7.3) are not satisfied.

§23 Japanese rings

The results of this section will be completed in **IV**, (IV, 7.6) and (IV, 7.7). [$0_{\text{IV-1}}$ | 213]

23.1 Japanese rings

(23.1.1) Definition. We say that an integral ring A is a *Japanese ring* if, for every finite extension K' of its field of fractions K, the integral closure A' of A in K' is an [$0_{\text{IV-1}}$ | 214] A-module of finite type (in other words, a finite A-algebra). We say that a ring A is *universally Japanese* if every integral A-algebra of finite type is a Japanese ring.

It is clear that if A is a Japanese ring, then every ring of fractions $S^{-1}A$ is also a Japanese ring, since (with the preceding notation) $S^{-1}A'$ is the integral closure of $S^{-1}A$ in K', and is evidently an $S^{-1}A$-module of finite type.

A Noetherian integral ring, even a *discrete valuation ring*, is not necessarily a Japanese ring [30].

(23.1.2) Proposition. *Let A be a Noetherian integral ring, K its field of fractions. If, for every finite radicial extension K' of K, the integral closure of A in K' is an A-module of finite type, then A is a Japanese ring.*

Proof. Since A is Noetherian, it suffices, to verify that A is a Japanese ring, to see that for every finite *quasi-Galois* extension L of K, the integral closure B of A in L is an A-module of finite type. Now L is a *Galois* extension of the largest *radicial* extension K'

of K contained in L; and if A' is the integral closure of A in K', B is the integral closure of A' in L. But we know that in a *separable* extension, the integral closure of A' is an A'-module of finite type (Bourbaki, *Alg. comm.*, chap. V, §1, n° 6, cor. 1 of prop. 20), whence the proposition. □

It follows from (23.1.2) that when K is of *characteristic* 0, saying that A is a Japanese ring means that its *integral closure* A' is an A-module of finite type.

(23.1.3) Theorem. (Tate) *Let A be a Noetherian integral ring, $x \neq 0$ an element of A. Suppose the following conditions are satisfied:*

(i) *A is integrally closed.*

(ii) *$\mathfrak{p} = xA$ is prime and A is separated and complete for the $\mathfrak{p}$-preadic topology.*

(iii) *A/xA is a Japanese ring.*

Then A is a Japanese ring.

We will use the following lemma:

(23.1.3.1) Lemma. *Let A be a ring, x an element of A that is a non-zero-divisor in A and such that $xA = \mathfrak{p}$ is prime; then, for every integer $n > 0$, the inverse image of $x^n A_{\mathfrak{p}}$ in A is $x^n A$.*

Proof. Indeed, suppose that $b \in A$ is an element such that $b/1 = x^n a/s$ in $A_{\mathfrak{p}}$, where $a \in A$ and $s \notin \mathfrak{p}$; then there exists $s' \notin \mathfrak{p}$ such that $s'sb = x^n as'$, whence $s'sb \in \mathfrak{p}$, and since $s's \notin \mathfrak{p}$, this implies $b \in \mathfrak{p}$, that is to say $b = xb'$ with $b' \in A$; since x is a non-zero-divisor, we conclude that $s'sb' = x^{n-1}as'$[25], and it suffices to argue by induction on n. □

Proof of Theorem (23.1.3). To prove the theorem, we can restrict to the case where the field of fractions K of A is of characteristic $p > 0$, since A is integrally closed. Let K' be a finite radicial extension of K, so that there exists a power $q = p^e$ such that $K'^q \subset K$; by replacing K' by a larger radicial extension, we may even suppose that there exists $y \in K'$ such that $y^q = x$. Let A' be the integral closure of A in K'; since A is integrally closed, A' is the set of $x' \in K'$ such that $x'^q \in A' \cap K = A$. Set $V = A_{\mathfrak{p}}$; the maximal ideal $\mathfrak{m} = xV$ of V being principal, we know that the local Noetherian ring V is a *discrete* [$0_{\text{IV-1}}$ | 215] *valuation ring* (17.1.4); since V is integrally closed, the same argument as above shows that the integral closure V' of V in K' is the set of $x' \in K'$ such that $x'^q \in V$; we know (Bourbaki, *Alg. comm.*, chap. VI, §8, n° 6, prop. 6, and chap. V, §2, n° 3, lemma 4) that V' is a *discrete valuation ring*, whose maximal ideal $\mathfrak{m}'$ is the set of $x' \in K'$ such that $x'^q \in \mathfrak{m}$, and moreover the residue field $V'/\mathfrak{m}'$ is a *finite* extension of $V/\mathfrak{m}$ (*loc. cit.*, chap. VI, §8, n° 1, lemma 2). Let us show that, for every integer $n > 0$, we have

$$\mathfrak{m}'^n \cap A' = y^n A'. \tag{23.1.3.2}$$

Indeed, since $y^q = x$, we have $y \in \mathfrak{m}'$, hence $y^n A' \subset \mathfrak{m}'^n \cap A'$. Conversely, let $x' \in \mathfrak{m}'^n \cap A'$, and set $x' = z'y^n$ with $z' \in K'$. We have $x'^q \in A'$; on the other hand, x' is a sum of products $t'_1 \cdots t'_n$ with $t'_i \in \mathfrak{m}'$, hence $t'^q_i \in \mathfrak{m}$, and we conclude that $x'^q \in \mathfrak{m}^n \cap A$. Now the lemma (23.1.3.1) proves that $\mathfrak{m}^n \cap A = x^n A$, hence we have $z'^q x^n \in x^n A$, or equivalently $z'^q \in A$ since $x \neq 0$, which establishes (23.1.3.2).

[25] The printed source has *as* here; cancelling x in $s'sxb' = x^n as'$ retains the factor s'.

Let us show secondly that on A' the xA'-preadic topology is *separated*; this topology is also the yA'-preadic topology of A', and it follows from (23.1.3.2) that this topology is induced by the $\mathfrak{m}'$-*preadic* topology of V', which is separated since V' is a discrete valuation ring.

Let us then prove that A'/xA' is an A-module of *finite type*. Since $x = y^q$ and $y^k A'/y^{k+1}A'$ is isomorphic to A'/yA', it suffices to show that A'/yA' is an A-module of finite type; but the formula (23.1.3.2) applied for $n = 1$ shows that A'/yA' is a subring of $V'/\mathfrak{m}'$, that is to say of the *residue field* of V', which is a *finite* extension of the residue field $V/\mathfrak{m}$. Now $V/\mathfrak{m}$ is the field of fractions of $A/\mathfrak{p}$, and since A' is integral over A, A'/yA' is integral over $A/\mathfrak{p}$, hence contained in the integral closure of $A/\mathfrak{p}$ in $V'/\mathfrak{m}'$; since by hypothesis $A/\mathfrak{p}$ is a Japanese Noetherian ring, A'/yA' is an $(A/\mathfrak{p})$-module of finite type, and *a fortiori* an A-module of finite type.

This being the case, the xA'-preadic topology of A' being separated, A' is a subring of its completion $\hat{A}'$ for this topology; but since A'/xA' is an A-module of finite type and A is separated and complete for the xA-preadic topology, $\hat{A}'$ is an A-module of finite type by virtue of (0_{I}, 7.2.9), hence so is A'. □

(23.1.4) Corollary. *Let A be a Japanese Noetherian and integrally closed ring. Then every formal power series ring $A[[T_1, \ldots, T_r]]$ is a Japanese ring.*

Proof. We know that for every integrally closed Noetherian ring B, the formal power series ring $B[[T]]$ is Noetherian and integrally closed (Bourbaki, *Alg. comm.*, chap. V, §1, n° 4, prop. 14); we can thus, by induction on r[26], restrict to proving that $A[[T]]$ is a Japanese ring. Now the element $x = T$ satisfies all the conditions of (23.1.3), whence the conclusion. □

(23.1.5) Theorem. (Nagata) *Every complete local Noetherian integral ring A is a Japanese ring.*

Proof. We know (19.8.8)[ii] that there exists a subring B of A that is a complete local ring and is in addition *regular*, such that A is a finite B-algebra; it clearly suffices to [$0_{\text{IV-1}}$ | 216] prove that B is a Japanese ring, that is to say, we can restrict to the case where A is in addition regular. Let us argue by induction on $n = \dim(A)$, the theorem being evident for $n = 0$. Suppose then $n > 0$, and, denoting by $\mathfrak{m}$ the maximal ideal of A, let x be an element of $\mathfrak{m} - \mathfrak{m}^2$; we know (17.1.8) that A/xA is a regular ring, and in addition ((17.1.7) and (16.3.4)) that $\dim(A/xA) = n - 1$; moreover, the ideal xA is closed in A (0_{I}, 7.3.5), hence A/xA is complete. By the induction hypothesis, A/xA is thus a Japanese ring, and it then follows from (23.1.3) that the same is true of A. □

(23.1.6) Corollary. *Let A be a complete local Noetherian integral ring, K its field of fractions, K' a finite extension of K; then the integral closure A' of A in K' is a complete local ring.*

Proof. We already know from (23.1.5) that A' is a finite A-algebra, hence a complete semi-local Noetherian ring, and consequently a *direct product* of local rings; but since A' is integral, it is necessarily a local ring. □

[26] The printed source has n; the induction is on the number r of variables in the statement.

(23.1.7) Proposition. *Let A be a local Noetherian integral ring, K its field of fractions, K' a finite extension of K, A' the integral closure of A in K'. Suppose that the completion $\hat{A}$ is reduced, and let R denote its total ring of fractions.*

(i) *If the ring $R \otimes_K K'$ is* reduced *(which will be the case in particular when K' is a* separable *extension of K, R being a direct product of fields, hence extensions of K* (Bourbaki, *Alg.*, chap. VIII, §7, n° 3, cor. 1 of th. 1)*), then A' is an A-module of finite type.*

(ii) If in particular R is a separable K-algebra, then A is a Japanese ring.

Proof. (i). Set $A_1 = \hat{A}$, $A'_1 = A' \otimes_A A_1$, $K'_1 = K' \otimes_A A_1$. Since A_1 is a flat A-module (0_{I}, 7.3.5), A'_1 is identified with a subring of K'_1 and is evidently integral over A_1. On the other hand, if we set $K_1 = K \otimes_A A_1$, we can write $K'_1 = K' \otimes_K K_1$; since A is integral and A_1 is a flat A-module, every element $\neq 0$ of A is A_1-regular (0_{I}, 6.3.4); since $K = S^{-1}A$, where $S = A - \{0\}$, we have $K_1 = S^{-1}A_1$, and the preceding remark proves that K_1 is identified with a *subring* of the total ring of fractions R of A_1. Since every K-module is flat, K'_1 is identified with a *subring* of $K' \otimes_K R$, which by hypothesis is *reduced* and is a *finite* R-algebra. Denoting by $\mathfrak{q}_i$ $(1 \leq i \leq n)$ the minimal prime ideals of A_1, by B_i the integral ring $A_1/\mathfrak{q}_i$, by L_i the field of fractions of B_i, we see that R is the direct product of the L_i, and $K' \otimes_K R$ the direct product of the $K' \otimes_K L_i$; these latter K-algebras, being reduced, are direct products of fields, *finite* extensions of the L_i. Since B_i is a complete local Noetherian integral ring, the theorem of Nagata (23.1.5) proves that the integral closure of B_i in $K' \otimes_K L_i$ is a B_i-module of finite type, and *a fortiori* an A_1-module of finite type; since every element of $K' \otimes_K L_i$ that is integral over A_1 is also integral over B_i (being annihilated by $\mathfrak{q}_i$), we conclude finally that the integral closure of A_1 in $K' \otimes_K R$ is an A_1-module of finite type. But since A'_1 is contained in this integral closure and A_1 is Noetherian, A'_1 is also an A_1-module of finite type. Finally, since A_1 is a faithfully flat A-module (0_{I}, 7.3.5), we conclude that A' is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. I, §3, n° 6, prop. 11).

[$0_{\mathrm{IV\text{-}1}}$ | 217] (ii). The hypothesis implies that the L_i are separable extensions of K, hence $K' \otimes_K L_i$ is reduced (Bourbaki, *Alg.*, chap. VIII, §7, n° 3, th. 1) and we can apply (i) to *every* finite extension K' of K, which proves our assertion. □

23.2 Integral closure of a local Noetherian integral ring

(23.2.1) In what follows, for every ring A, we will write A_{red} for short for the quotient of A by its nilradical (so that if $X = \mathrm{Spec}(A)$, we have $X_{\mathrm{red}} = \mathrm{Spec}(A_{\mathrm{red}})$). We will say that a *local* ring A is *unibranch* if A_{red} is integral and if the integral closure of A_{red} is a *local* ring, which generalizes the definition given in (III, 4.3.6). We will say that A is *geometrically unibranch* if it is unibranch and if the residue field of the local ring that is the integral closure of A_{red} is a *radicial* extension of that of A. It is clear that a local ring that is integrally closed is geometrically unibranch; it follows from (23.1.6) that a complete local Noetherian integral ring is unibranch.

(23.2.2) Lemma. *Let A be an integral ring, A' its integral closure; for the canonical morphism $f : \mathrm{Spec}(A') \to \mathrm{Spec}(A)$ to be radiciel, it is necessary and sufficient that for every $\mathfrak{p} \in \mathrm{Spec}(A)$, $A_{\mathfrak{p}}$ be geometrically unibranch; when this is so, f is a homeomorphism.*[27]

[27] In the remainder of this item, we use notions and results set out in chap. IV, §§2 and 5; since the results of this item are not used before chap. IV, §6, this does not lead to circular reasoning.

Proof. Indeed, for every $\mathfrak{p} \in \mathrm{Spec}(A)$, the integral closure of $A_{\mathfrak{p}}$ is $A'_{\mathfrak{p}}$ (Bourbaki, *Alg. comm.*, chap. V, §1, n° 5, prop. 16), and all the prime ideals of $A'_{\mathfrak{p}}$ above $\mathfrak{p}A_{\mathfrak{p}}$ are maximal (*loc. cit.*, §2, n° 1, prop. 1). Saying that f is *injective* thus means that for every $\mathfrak{p} \in \mathrm{Spec}(A)$, $A'_{\mathfrak{p}}$ is a *local* ring, that is to say that the $A_{\mathfrak{p}}$ are unibranch. Saying that every $A_{\mathfrak{p}}$ is geometrically unibranch then means that f is radiciel by virtue of (I, 3.5.8). When this is so, f is surjective and closed (II, 6.1.10), hence a homeomorphism. □

(23.2.3) Lemma. *Let A be an integral ring, K its field of fractions, B a Noetherian ring, $\varphi : A \to B$ a ring homomorphism making B an A-module that is flat. Let K' be an extension of K; set $B_1 = B_{\mathrm{red}}$, and let R be the total ring of fractions of B_1. Then, for every sub-A-algebra A' of K', the canonical homomorphism*

$$(A' \otimes_A B)_{\mathrm{red}} \to (K' \otimes_A R)_{\mathrm{red}} \tag{23.2.3.1}$$

is injective.[28]

Proof. We can in fact consider the canonical homomorphism $h : A' \otimes_A B \to K' \otimes_A R$ as the composition of the following homomorphisms

$$A' \otimes_A B \xrightarrow{u} K' \otimes_A B \xrightarrow{v} K' \otimes_A B_1 \xrightarrow{w} K' \otimes_A R.$$

Since B is a flat A-module, u is injective; similarly, K' being a flat K-module and K a flat A-module, K' is a flat A-module, and w is therefore injective since B_1 is reduced, hence the homomorphism $B_1 \to R$ is injective. Finally, for the same reason, if $\mathfrak{R}$ is the nilradical of B, the kernel of v is $K' \otimes_A \mathfrak{R}$, hence it is contained in the nilradical of $K' \otimes_A B$; we immediately conclude that if the image by $h = w \circ v \circ u$ of an element $x \in A' \otimes_A B$ is nilpotent, then x is nilpotent, which proves the lemma. □ [$0_{\text{IV-1}}$ | 218]

(23.2.4) Proposition. *Let A be an integral ring, K its field of fractions, B a Noetherian ring, $\mathfrak{q}_i$ $(1 \leq i \leq n)$ its minimal prime ideals, $\varphi : A \to B$ a ring homomorphism. Suppose that the $B/\mathfrak{q}_i$ are Japanese rings, and that B is a flat A-module. Let K' be a finite extension of K, and let (C_α) be the increasing filtering family of subrings of K' that are finite A-algebras and admit K' as their field of fractions; the union A' of the C_α is thus the integral closure of A in K'. Then:*

(i) *There exists an index α such that for $\lambda \geq \alpha$, the canonical homomorphism*

$$(C_\alpha \otimes_A B)_{\mathrm{red}} \to (C_\lambda \otimes_A B)_{\mathrm{red}} \tag{23.2.4.1}$$

is bijective.

(ii) *If in addition B is a faithfully flat A-module, the morphism* $\mathrm{Spec}(A') \to \mathrm{Spec}(C_\alpha)$ *is* radiciel.

Proof. (i). Let $B_1 = B_{\mathrm{red}}$, and let R be the total ring of fractions of B_1; since A is integral and B is a flat A-module, every element $\neq 0$ of A is B-regular (0_{I}, 6.3.4), hence the composite homomorphism $A \to B \to B_1$ extends to a homomorphism $K \to R$. We can therefore write $K' \otimes_A R = (K' \otimes_A K) \otimes_K R$, and since $K' \otimes_A K$ is identified with K', we have $K' \otimes_A R = K' \otimes_K R$. Since R is the direct product of the fields of fractions

[28] The French source prints "(23.1.8.1)"; the formula occurs in Lemma 23.2.3 and is therefore numbered (23.2.3.1) here.

L_i of the $B/\mathfrak{q}_i$, $K' \otimes_A R$ is the direct product of the $K' \otimes_K L_i$, and hence $(K' \otimes_A R)_{\mathrm{red}}$ is the direct product of a finite number of finite extensions of the L_i. By hypothesis, the integral closure of $B/\mathfrak{q}_i$ in a finite extension of L_i is a finite $(B/\mathfrak{q}_i)$-module, hence a finite B-module; it follows that the integral closure B' of B in $(K' \otimes_A R)_{\mathrm{red}}$ is a finite B-module. By virtue of (23.2.3), the $(C_\lambda \otimes_A B)_{\mathrm{red}}$ are canonically identified with subrings of $(K' \otimes_A R)_{\mathrm{red}}$ which are *finite* B-algebras, hence contained in B'. Since B is Noetherian and B' a B-module of finite type, the filtering family of the $(C_\alpha \otimes_A B)_{\mathrm{red}}$ admits a *greatest element* $(C_\alpha \otimes_A B)_{\mathrm{red}}$, which proves (i).

(ii). Since B is a faithfully flat A-module, it suffices (IV, 2.6.1)[v] to show that the morphism $\mathrm{Spec}(A' \otimes_A B) \to \mathrm{Spec}(C_\alpha \otimes_A B)$ is radiciel, or, what amounts to the same (I, 5.1.6), that the morphism $\mathrm{Spec}(A' \otimes_A B)_{\mathrm{red}} \to \mathrm{Spec}(C_\alpha \otimes_A B)_{\mathrm{red}}$ is radiciel; but we have $A' \otimes_A B = \varinjlim (C_\lambda \otimes_A B)$, hence (IV, 5.13.2) $(A' \otimes_A B)_{\mathrm{red}} = \varinjlim (C_\lambda \otimes_A B)_{\mathrm{red}}$, and the conclusion follows from (i). □

(23.2.5) Corollary. *Let A be a local Noetherian integral ring, K its field of fractions, K' a finite extension of K. Let (C_α) be the increasing filtering family of subrings of K' that are finite A-algebras (hence Noetherian semi-local rings* (Bourbaki, *Alg. comm.*, chap. IV, §2, n° 5, cor. 3 of prop. 9)*) and admit K' as their field of fractions. Then there exists α such that the homomorphism $(\hat{C}_\alpha)_{\mathrm{red}} \to (\hat{C}_\lambda)_{\mathrm{red}}$ is an isomorphism for $\lambda \geq \alpha$, and if A' is the integral closure of A in K', the morphism* $\mathrm{Spec}(A') \to \mathrm{Spec}(C_\alpha)$ *is radiciel* (cf. (23.2.2)).

Proof. We apply (23.2.4) taking $B = \hat{A}$; since the $B/\mathfrak{q}_i$ are complete local Noetherian rings, [$0_{\text{IV-1}}$ | 219] they are Japanese rings (23.1.5) and B is a faithfully flat A-module (0_{I}, 7.3.5); moreover we have $C_\lambda \otimes_A B = \hat{C}_\lambda$ (Bourbaki, *Alg. comm.*, chap. III, §3, n° 4, th. 3 and chap. IV, §2, n° 5, cor. 3 of prop. 9). □

(23.2.6) Corollary. *Under the hypotheses of (23.2.5), the integral closure A' of A in K' is a semi-local ring; if $\mathfrak{m}$ is the maximal ideal of A, then, for every maximal ideal $\mathfrak{m}'$ of A', $A'/\mathfrak{m}'$ is a finite extension of $A/\mathfrak{m}$.*

Proof. The fact that the homomorphism $(\hat{C}_\alpha)_{\mathrm{red}} \to (\hat{C}_\lambda)_{\mathrm{red}}$ is bijective for $\lambda \geq \alpha$ implies that the number of maximal ideals of C_λ is *constant* for $\lambda \geq \alpha$, and that if $\mathfrak{m}_\alpha$ is a maximal ideal of C_α and $\mathfrak{m}_\lambda$ is the unique maximal ideal of C_λ above $\mathfrak{m}_\alpha$, the fields $C_\alpha/\mathfrak{m}_\alpha$ and $C_\lambda/\mathfrak{m}_\lambda$ are canonically isomorphic. The conclusion follows from the fact that $\mathfrak{m}' = \varinjlim \mathfrak{m}_\lambda$ and $A'/\mathfrak{m}' = \varinjlim C_\lambda/\mathfrak{m}_\lambda$ (0_{III}, 10.3.1.3). □

(23.2.7) Proposition. (Y. Mori) *Let A be a local Noetherian integral ring, K its field of fractions, and A' the integral closure of A. Then A' is a Krull ring* (Bourbaki, *Alg. comm.*, chap. VII, §1) *that is semi-local; in other words, there exists a family (V_λ) of discrete valuation rings having K as their field of fractions, such that $A' = \bigcap V_\lambda$ and that every $x \in K$ belongs to all but a finite number of the V_λ. Moreover, there exists a subalgebra C of K which is a finite A-algebra, and such that the V_λ are the integral closures of the rings $C_{\mathfrak{p}_\lambda}$, where $(\mathfrak{p}_\lambda)$ is the family of prime ideals of height* 1 *of the local ring C.*

We will first prove the following lemma:

(23.2.7.1) Lemma. *Let A, B be two rings, $\varphi : A \to B$ a homomorphism making B a faithfully flat A-module. Suppose that A is integral; then, if $C = B_{\mathrm{red}}$, the composite homomorphism $\psi : A \to B \to B_{\mathrm{red}} = C$ is injective and extends to an injective*

homomorphism of the field of fractions K of A into the total ring of fractions R of C; moreover, if C' is the integral closure of C in R, $C' \cap K$ is the integral closure of A.

Proof. Since A is integral and φ is injective, the intersection of $\varphi(A)$ and the nilradical $\mathfrak{R}$ of B is 0, and since $C = B/\mathfrak{R}$, ψ is injective. Every $a \neq 0$ in A being a non-zero-divisor does not become a zero-divisor in B by flatness (0_{I}, 6.3.4); we deduce that a is also a non-zero-divisor in C, since if $ax \in \mathfrak{R}$ for an $x \notin \mathfrak{R}$ in B, we would have $a^n x^n = 0$ for some integer n, which contradicts the above since $x^n \neq 0$. We can thus extend ψ to an injective homomorphism of K into R. To prove the last assertion, note that the integral closure A' of A is contained in $C' \cap K$. Conversely, let $x \in C' \cap K$; x is then integral over C, and *a fortiori* over B, that is to say $B[x]$ is a finite B-algebra; moreover, K is identified with a subring of $B \otimes_A K$, and the subring $B[x]$ of $B \otimes_A K$ is identified with $B \otimes_A A[x]$ by flatness; we conclude that $A[x]$ is an A-module of finite type (Bourbaki, *Alg. comm.*, chap. Ier, §3, n° 6, prop. 11), hence $x \in A'$. □

Proof of Proposition (23.2.7). This lemma being established, let us apply it to the canonical injection of A into its completion $\hat{A}$, which is a faithfully flat A-module; $B = (\hat{A})_{\mathrm{red}} = \hat{A}/\mathfrak{R}$ (where $\mathfrak{R}$ is the nilradical of $\hat{A}$) is a complete local Noetherian reduced ring, whose total ring of fractions R is a direct product of a finite number of fields L_i; the canonical [$0_{\mathrm{IV\text{-}1}}$ | 220]
image B_i of B in L_i is a complete local Noetherian *integral* ring, whose field of fractions is L_i, and the integral closure B' of B in R is the *direct product* of the B'_i, where B'_i is the integral closure of B_i. But by virtue of (23.1.5), B'_i is a finite B_i-algebra, hence an integrally closed local Noetherian ring. We know (Bourbaki, *Alg. comm.*, chap. VII, §1, n° 3, cor. of th. 2) that B'_i is a Krull ring. Now, for every i, there is a homomorphism $\varphi_i : K \to L_i$, which is injective, and so $\varphi_i^{-1}(B'_i)$ is a Krull ring in K. But since $A' = B' \cap K$ by virtue of the lemma and $A' = \bigcap \varphi_i^{-1}(B'_i)$, A' is an intersection of a finite number of Krull rings and is therefore a Krull ring.[29] To prove the last assertion of the proposition, note that there exists a finite A-algebra $C \subset K$ such that the morphism $\mathrm{Spec}(A') \to \mathrm{Spec}(C)$ is radiciel and a homeomorphism (23.2.4); for every prime ideal $\mathfrak{p}' \in \mathrm{Spec}(A')$, $\mathfrak{p}'$ is thus the only prime ideal of A' above $\mathfrak{p} = \mathfrak{p}' \cap C$ and $A'_{\mathfrak{p}'}$ the integral closure of $C_{\mathfrak{p}}$; on the other hand the fact that $\mathrm{Spec}(A') \to \mathrm{Spec}(C)$ is a homeomorphism implies that the map $\mathfrak{p}' \mapsto \mathfrak{p}' \cap C$ is a *bijection* of the set of prime ideals of height 1 of A' onto the set of prime ideals of height 1 of C; whence the conclusion, by virtue of Bourbaki, *Alg. comm.*, chap. VII, §1, n° 6, th. 4. □

(23.2.8) Remarks.

(i) We should take care to note, in the application of (23.2.6) and (23.2.7), that the ring A' is *not necessarily Noetherian*, as an example of Nagata shows with $\dim(A) = 3$ [30].

(ii) The conclusions of (23.2.7) remain valid if A' is the integral closure of A in a finite extension K' of K; it suffices in fact to consider a finite A-algebra B whose field of fractions is K'; B is a semi-local Noetherian ring, hence an intersection of a finite number of local Noetherian rings $B_{\mathfrak{m}_i}$ ($\mathfrak{m}_i$ the maximal ideals of B), and its integral closure (which is equal to A') is the intersection of the $A'_{\mathfrak{m}_i}$ (Bourbaki, *Alg. comm.*, chap. II, §3, n° 3, cor. 4 of th. 1) which are the integral closures of the $B_{\mathfrak{m}_i}$, hence Krull rings by (23.2.7); consequently A' is a Krull ring.

[29] The French source prints $B' = \bigcap_i \varphi_i^{-1}(B'_i)$ here; the required intersection inside K is $A' = \bigcap_i \varphi_i^{-1}(B'_i)$.

(iii) One can show ([30], 3.3.10) that for every Noetherian integral ring A (not necessarily local), the integral closure of A is a Krull ring.

(23.2.9) Corollary. *Let A be a Noetherian integral ring, A' its integral closure. Suppose that for every ring C such that $A \subset C \subset A'$ and such that C is a finite A-algebra, and for every prime ideal $\mathfrak{q}$ of height 1 in C, $\mathfrak{q} \cap A$ is a prime ideal of height 1 in A. Let P be the set of prime ideals of height 1 in A; we then have*

$$A' = \bigcap_{\mathfrak{p} \in P} A'_{\mathfrak{p}}.$$

Proof. Since A' is an A-module without torsion, we have $A' = \bigcap A'_{\mathfrak{m}}$, where $\mathfrak{m}$ ranges over the set of maximal ideals of A (Bourbaki, *Alg. comm.*, chap. II, §3, n° 3, cor. 4 of
[$0_{\text{IV-1}}$ | 221] th. 1); it will thus suffice to prove that $A'_{\mathfrak{m}}$ is the intersection of the $A'_{\mathfrak{p}}$ for the prime ideals $\mathfrak{p} \subset \mathfrak{m}$ of height 1, and since $A'_{\mathfrak{m}}$ is the integral closure of $A_{\mathfrak{m}}$, we see that it suffices to prove the corollary for $A_{\mathfrak{m}}$. Now there is, by virtue of (23.2.7), a finite $A_{\mathfrak{m}}$-algebra B contained in $A'_{\mathfrak{m}}$ such that $A'_{\mathfrak{m}}$ is the intersection of the integral closures of the rings $B_{\mathfrak{q}}$, where $\mathfrak{q}$ ranges over the set of prime ideals of height 1 of B. But B is of the form $C_{\mathfrak{m}}$, where C is a finite A-algebra; hence, for every prime ideal $\mathfrak{q}$ of height 1 in B, $\mathfrak{q} \cap A$ is by hypothesis a prime ideal of height 1 in A; since the integral closure of $B_{\mathfrak{q}}$ contains that of $A_{\mathfrak{q} \cap A}$ and the latter contains $A'_{\mathfrak{m}}$, it follows that $A'_{\mathfrak{m}}$ is indeed the intersection of the $A'_{\mathfrak{p}}$ for $\mathfrak{p} \in P$ and $\mathfrak{p} \subset \mathfrak{m}$, which finishes the proof. □

(23.2.10) Remarks.

(i) We will see (IV, 5.6.3) and (IV, 5.6.10) that the hypothesis of (23.2.9) is satisfied when A is *universally catenary*, in particular (IV, 5.10.17) and (IV, 5.11.2) when A is a *quotient of a regular ring*; finally, it is evidently satisfied if $\operatorname{Spec}(A') \to \operatorname{Spec}(A)$ is a homeomorphism, in particular if this morphism is radiciel (23.2.2).

(ii) The conclusion of (23.2.9) is no longer necessarily exact when one omits the hypothesis on the finite sub-A-algebras of A'. Indeed, one can define a local Noetherian integral ring A, of dimension 2, whose integral closure A' is a finite A-algebra, but such that there is a prime ideal $\mathfrak{p}'$ of A' of height 1 above the maximal ideal $\mathfrak{m}$ (of height 2) of A, and such moreover that for every prime ideal $\mathfrak{p}$ of height 1 in A, $A_{\mathfrak{p}}$ is integrally closed (IV, 5.6.11); the intersection of these rings $A_{\mathfrak{p}}$ can then not be equal to A' since A' is a Krull ring (Bourbaki, *Alg. comm.*, chap. VII, §1, n° 5, prop. 9).

Chapter I. The language of schemes

§1 Affine schemes

1.1 The prime spectrum of a ring

(1.1.1) *Notation*: Let A be a (commutative) ring and M an A-module. In this chapter and the following ones, we shall constantly use the following notation: [I | 80]

$\mathrm{Spec}(A)$ = *set of prime ideals* of A, also called the *prime spectrum* of A; for an $x \in X = \mathrm{Spec}(A)$, it will often be convenient to write $\mathfrak{j}_x$ instead of x. For $\mathrm{Spec}(A)$ to be *empty*, it is necessary and sufficient that the ring A consist of 0 alone.

$A_x = A_{\mathfrak{j}_x}$ = *(local) ring of fractions* $S^{-1}A$, where $S = A - \mathfrak{j}_x$.

$\mathfrak{m}_x = \mathfrak{j}_x A_{\mathfrak{j}_x}$ = *maximal ideal of* A_x.

$k(x) = A_x/\mathfrak{m}_x$ = *residue field of* A_x, canonically isomorphic to the field of fractions of the integral domain $A/\mathfrak{j}_x$, with which it is identified.

$f(x)$ = *class of* f *mod.* $\mathfrak{j}_x$, in $A/\mathfrak{j}_x \subset k(x)$, for $f \in A$ and $x \in X$. We also say that $f(x)$ is the *value* of f at the point $x \in \mathrm{Spec}(A)$; the relations $f(x) = 0$ and $f \in \mathfrak{j}_x$ are *equivalent.*

$M_x = M \otimes_A A_x$ = *module of fractions with denominators in* $A - \mathfrak{j}_x$.

$\mathfrak{r}(E)$ = *radical of the ideal of* A *generated by a subset* E *of* A.

$V(E)$ = *set of* $x \in X$ *such that* $E \subset \mathfrak{j}_x$ (or equivalently the set of $x \in X$ such that $f(x) = 0$ for all $f \in E$), for $E \subset A$. We therefore have

$$\mathfrak{r}(E) = \bigcap_{x \in V(E)} \mathfrak{j}_x. \tag{1.1.1.1}$$

$V(f) = V(\{f\})$ for $f \in A$.

$D(f) = X - V(f)$ = *set of* $x \in X$ *where* $f(x) \neq 0$.

(1.1.2) Proposition. *We have the following properties:*

(i) $V(0) = X$, $V(1) = \varnothing$.

(ii) *The relation* $E \subset E'$ *implies* $V(E) \supset V(E')$.

(iii) *For every family* (E_λ) *of subsets of* A,

$$V\left(\bigcup_\lambda E_\lambda\right) = V\left(\sum_\lambda E_\lambda\right) = \bigcap_\lambda V(E_\lambda).$$

(iv) $V(EE') = V(E) \cup V(E')$.

(v) $V(E) = V(\mathfrak{r}(E))$.

Properties (i), (ii), (iii) are trivial, and (v) follows from (ii) and from formula (1.1.1.1). It is clear that $V(EE') \supset V(E) \cup V(E')$; conversely, if $x \notin V(E)$ and $x \notin V(E')$, there exist $f \in E$ and $f' \in E'$ such that $f(x) \neq 0$ and $f'(x) \neq 0$ in $k(x)$, whence $f(x)f'(x) \neq 0$, in other words $x \notin V(EE')$, which proves (iv).

Proposition (1.1.2) shows, among other things, that the sets of the form $V(E)$ (where E runs through the set of subsets of A) are the *closed sets* of a topology on X, which we shall call the *spectral topology*[30]; unless expressly stated otherwise, we shall always assume $X = \mathrm{Spec}(A)$ endowed with the spectral topology.

[I | 81] **(1.1.3)** For every subset Y of X, we shall denote by $\mathfrak{j}(Y)$ the set of $f \in A$ such that $f(y) = 0$ for all $y \in Y$; it amounts to the same to say that $\mathfrak{j}(Y)$ is the intersection of the prime ideals $\mathfrak{j}_y$ for $y \in Y$. It is clear that the relation $Y \subset Y'$ implies $\mathfrak{j}(Y) \supset \mathfrak{j}(Y')$ and that we have

$$\mathfrak{j}\left(\bigcup_\lambda Y_\lambda\right) = \bigcap_\lambda \mathfrak{j}(Y_\lambda) \tag{1.1.3.1}$$

for every family (Y_λ) of subsets of X. Finally, we have

$$\mathfrak{j}(\{x\}) = \mathfrak{j}_x. \tag{1.1.3.2}$$

(1.1.4) Proposition.

(i) *For every subset E of A, we have $\mathfrak{j}(V(E)) = \mathfrak{r}(E)$.*

(ii) *For every subset Y of X, $V(\mathfrak{j}(Y)) = \overline{Y}$, the closure of Y in X.*

(i) is an immediate consequence of the definitions and of (1.1.1.1); on the other hand, $V(\mathfrak{j}(Y))$ is closed and contains Y; conversely, if $Y \subset V(E)$, we have $f(y) = 0$ for all $f \in E$ and all $y \in Y$, hence $E \subset \mathfrak{j}(Y)$, $V(E) \supset V(\mathfrak{j}(Y))$, which proves (ii).

(1.1.5) Corollary. *The closed subsets of $X = \mathrm{Spec}(A)$ and the ideals of A equal to their radicals (in other words, the intersections of prime ideals) correspond one-to-one under the decreasing maps $Y \mapsto \mathfrak{j}(Y)$, $\mathfrak{a} \mapsto V(\mathfrak{a})$; to the union $Y_1 \cup Y_2$ of two closed subsets corresponds $\mathfrak{j}(Y_1) \cap \mathfrak{j}(Y_2)$, and to the intersection of an arbitrary family (Y_λ) of closed subsets corresponds the radical of the sum of the $\mathfrak{j}(Y_\lambda)$.*

(1.1.6) Corollary. *If A is a Noetherian ring, $X = \mathrm{Spec}(A)$ is a Noetherian space.*

Note that the converse of this corollary is false, as is shown by the example of a non-Noetherian integral domain having only one prime ideal $\neq \{0\}$, for example a non-discrete valuation ring of rank 1.

As an example of a ring A whose spectrum is not a Noetherian space, one may mention the ring $\mathcal{C}(Y)$ of continuous real-valued functions on an infinite compact space Y; it is known that, as a set, Y can be identified with the set of maximal ideals of A, and it is easy to see that the topology induced on Y by that of $X = \mathrm{Spec}(A)$ is the original topology of Y. Since Y is not a Noetherian space, the same is therefore true of X.

(1.1.7) Corollary. *For every $x \in X$, the closure of $\{x\}$ is the set of $y \in X$ such that $\mathfrak{j}_x \subset \mathfrak{j}_y$. For $\{x\}$ to be closed, it is necessary and sufficient that $\mathfrak{j}_x$ be maximal.*

[30] The introduction of this topology into algebraic geometry is due to Zariski. It is therefore often called the "Zariski topology" of X.

(1.1.8) Corollary. *The space $X = \mathrm{Spec}(A)$ is a Kolmogorov space.*

Indeed, if x, y are two distinct points of X, we have either $\mathfrak{j}_x \not\subset \mathfrak{j}_y$ or $\mathfrak{j}_y \not\subset \mathfrak{j}_x$, hence one of the points x, y does not belong to the closure of the other.

(1.1.9) By Proposition (1.1.2, (iv)), for two elements f, g of A, we have

$$D(fg) = D(f) \cap D(g). \tag{1.1.9.1}$$

Note also that the relation $D(f) = D(g)$ means, by Proposition (1.1.4, (i)) and Proposition (1.1.2, (v)), that $\mathfrak{r}(f) = \mathfrak{r}(g)$, or equivalently that the minimal prime ideals containing (f) and (g) are the same; in particular, this is the case when $f = ug$, where u is invertible.

(1.1.10) Proposition. [I | 82]

(i) *As f runs through A, the sets $D(f)$ form a base for the topology of X.*

(ii) *For every $f \in A$, $D(f)$ is quasi-compact. In particular, $X = D(1)$ is quasi-compact.*

(i) Let U be an open set in X; by definition, we have $U = X - V(E)$, where E is a subset of A, and $V(E) = \bigcap_{f\in E} V(f)$, whence $U = \bigcup_{f\in E} D(f)$.

(ii) By (i), it suffices to prove that if $(f_\lambda)_{\lambda\in L}$ is a family of elements of A such that $D(f) \subset \bigcup_{\lambda\in L} D(f_\lambda)$, there exists a finite subset J of L such that $D(f) \subset \bigcup_{\lambda\in J} D(f_\lambda)$. Let $\mathfrak{a}$ be the ideal of A generated by the f_λ; by hypothesis we have $V(f) \supset V(\mathfrak{a})$, hence $\mathfrak{r}(f) \subset \mathfrak{r}(\mathfrak{a})$; since $f \in \mathfrak{r}(f)$, there exists an integer $n \geq 0$ such that $f^n \in \mathfrak{a}$. But then f^n belongs to the ideal $\mathfrak{b}$ generated by a finite subfamily $(f_\lambda)_{\lambda\in J}$, and we have $V(f) = V(f^n) \supset V(\mathfrak{b}) = \bigcap_{\lambda\in J} V(f_\lambda)$, that is to say, $D(f) \subset \bigcup_{\lambda\in J} D(f_\lambda)$.

(1.1.11) Proposition. *For every ideal $\mathfrak{a}$ of A, $\mathrm{Spec}(A/\mathfrak{a})$ is canonically identified with the closed subspace $V(\mathfrak{a})$ of $\mathrm{Spec}(A)$.*

Indeed, it is known that there is a canonical one-to-one correspondence, respecting the order structure given by inclusion, between the ideals (resp. prime ideals) of $A/\mathfrak{a}$ and the ideals (resp. prime ideals) of A containing $\mathfrak{a}$.

Recall that the set $\mathfrak{N}$ of nilpotent elements of A (or *nilradical* of A) is an ideal equal to $\mathfrak{r}(0)$, the intersection of all the prime ideals of A (0, 1.1.1).

(1.1.12) Corollary. *The topological spaces $\mathrm{Spec}(A)$ and $\mathrm{Spec}(A/\mathfrak{N})$ are canonically isomorphic.*

(1.1.13) Proposition. *For $X = \mathrm{Spec}(A)$ to be irreducible (0, 2.1.1), it is necessary and sufficient that the ring $A/\mathfrak{N}$ be an integral domain (or, what amounts to the same, that the ideal $\mathfrak{N}$ be prime).*

By Corollary (1.1.12), we may restrict ourselves to the case where $\mathfrak{N} = 0$. If X is reducible, there exist two closed subsets Y_1, Y_2 distinct from X such that $X = Y_1 \cup Y_2$, whence $\mathfrak{j}(X) = \mathfrak{j}(Y_1) \cap \mathfrak{j}(Y_2) = 0$, the ideals $\mathfrak{j}(Y_1)$ and $\mathfrak{j}(Y_2)$ being distinct from (0) (1.1.5); hence A is not an integral domain. Conversely, if there are in A two elements $f \neq 0$, $g \neq 0$ such that $fg = 0$, we have $V(f) \neq X$, $V(g) \neq X$ (since the intersection of the prime ideals of A is (0)), and $X = V(fg) = V(f) \cup V(g)$.

(1.1.14) Corollary.

(i) *Under the one-to-one correspondence between closed subsets of $X = \mathrm{Spec}(A)$ and ideals of A equal to their radicals, the irreducible closed subsets of X correspond to the prime ideals of A. In particular, the irreducible components of X correspond to the minimal prime ideals of A.*

(ii) *The map* $x \mapsto \overline{\{x\}}$ *establishes a one-to-one correspondence between* X *and the set of irreducible closed subsets of* X *(in other words, every irreducible closed subset of* X *has one and only one generic point).*

(i) follows at once from (1.1.13) and (1.1.11); and to prove (ii) we may, by virtue of (1.1.11), restrict ourselves to the case where X is irreducible; then, by Proposition (1.1.13), there exists in A a smallest prime ideal $\mathfrak{N}$, which therefore corresponds to a
[I | 83] generic point of X; moreover, X has only one generic point, since it is a Kolmogorov space ((1.1.8) and (0, 2.1.3)).

(1.1.15) Proposition. *If* $\mathfrak{J}$ *is an ideal of* A *contained in the radical* $\mathfrak{R}(A)$*, the only neighbourhood of* $V(\mathfrak{J})$ *in* $X = \mathrm{Spec}(A)$ *is the whole space* X*.*

Indeed, every maximal ideal of A belongs by definition to $V(\mathfrak{J})$. Since every ideal $\mathfrak{a} \neq A$ of A is contained in a maximal ideal, we have $V(\mathfrak{a}) \cap V(\mathfrak{J}) \neq \varnothing$, whence the proposition.

1.2 Functorial properties of the prime spectra of rings

(1.2.1) Let A, A' be two rings and

$$\varphi : A' \longrightarrow A$$

a ring homomorphism. For every prime ideal $x = \mathfrak{j}_x \in \mathrm{Spec}(A) = X$, the ring $A'/\varphi^{-1}(\mathfrak{j}_x)$ is canonically isomorphic to a subring of $A/\mathfrak{j}_x$, hence is an integral domain; in other words, $\varphi^{-1}(\mathfrak{j}_x)$ is a prime ideal of A'; we shall denote it by ${}^a\varphi(x)$, and we have thus defined a map

$${}^a\varphi : X = \mathrm{Spec}(A) \longrightarrow X' = \mathrm{Spec}(A')$$

(also denoted $\mathrm{Spec}(\varphi)$), which we shall call the map associated with the homomorphism φ. We shall denote by φ^x the injective homomorphism of $A'/\varphi^{-1}(\mathfrak{j}_x)$ into $A/\mathfrak{j}_x$ deduced from φ by passing to the quotients, as well as its canonical extension to a monomorphism of fields

$$\varphi^x : k({}^a\varphi(x)) \longrightarrow k(x) \ ;$$

for every $f' \in A'$, we therefore have by definition

$$\varphi^x(f'({}^a\varphi(x))) = (\varphi(f'))(x) \qquad (x \in X). \tag{1.2.1.1}$$

(1.2.2) Proposition.

(i) *For every subset* E' *of* A'*, we have*

$${}^a\varphi^{-1}(V(E')) = V(\varphi(E')) \tag{1.2.2.1}$$

and in particular, for every $f' \in A'$*,*

$${}^a\varphi^{-1}(D(f')) = D(\varphi(f')). \tag{1.2.2.2}$$

(ii) *For every ideal* $\mathfrak{a}$ *of* A*, we have*

$$\overline{{}^a\varphi(V(\mathfrak{a}))} = V(\varphi^{-1}(\mathfrak{a})). \tag{1.2.2.3}$$

Indeed, the relation ${}^a\varphi(x) \in V(E')$ is by definition equivalent to $E' \subset \varphi^{-1}(\mathfrak{j}_x)$, hence to $\varphi(E') \subset \mathfrak{j}_x$, and finally to $x \in V(\varphi(E'))$, whence (i). To prove (ii), we may assume $\mathfrak{a}$ equal to its radical, since $V(\mathfrak{r}(\mathfrak{a})) = V(\mathfrak{a})$ (1.1.2 (v)) and $\varphi^{-1}(\mathfrak{r}(\mathfrak{a})) = \mathfrak{r}(\varphi^{-1}(\mathfrak{a}))$; if we set $Y = V(\mathfrak{a})$ and $\mathfrak{a}' = \mathfrak{j}({}^a\varphi(Y))$, we have $\overline{{}^a\varphi(Y)} = V(\mathfrak{a}')$ (Proposition (1.1.4 (ii))); the relation $f' \in \mathfrak{a}'$ is by definition equivalent to $f'(x') = 0$ for all $x' \in {}^a\varphi(Y)$; hence, by formula (1.2.1.1), it is also equivalent to $\varphi(f')(x) = 0$ for all $x \in Y$, or again to $\varphi(f') \in \mathfrak{j}(Y) = \mathfrak{a}$, since $\mathfrak{a}$ is equal to its radical; whence (ii).

(1.2.3) Corollary. *The map ${}^a\varphi$ is continuous.*

Observe that if A'' is a third ring and φ' a homomorphism $A'' \to A'$, we have ${}^a(\varphi\circ\varphi') = {}^a\varphi' \circ {}^a\varphi$; this result and Corollary (1.2.3) mean that $\mathrm{Spec}(A)$ is a contravariant functor in A, from the category of rings to that of topological spaces.

(1.2.4) Corollary. *Suppose that φ is such that every $f \in A$ can be written $f = h\varphi(f')$, where h is invertible in A (which is in particular the case when φ is surjective). Then ${}^a\varphi$ is a homeomorphism of X onto ${}^a\varphi(X)$.* [I/84]

Let us show that for every subset $E \subset A$, there exists a subset E' of A' such that $V(E) = V(\varphi(E'))$; by virtue of axiom (T_0) (1.1.8) and of formula (1.2.2.1), this will imply first that ${}^a\varphi$ is injective, and then, again by (1.2.2.1), that ${}^a\varphi$ is a homeomorphism. Now, for each $f \in E$ it suffices to take an $f' \in A'$ such that $h\varphi(f') = f$ with h invertible in A; the set E' of these elements f' has the required property.

(1.2.5) In particular, when φ is the canonical homomorphism of A onto a quotient ring $A/\mathfrak{a}$, we recover (1.1.12), and ${}^a\varphi$ is the canonical injection of $V(\mathfrak{a})$, identified with $\mathrm{Spec}(A/\mathfrak{a})$, into $X = \mathrm{Spec}(A)$.

Another special case of (1.2.4) gives:

(1.2.6) Corollary. *If S is a multiplicative subset of A, the spectrum $\mathrm{Spec}(S^{-1}A)$ is canonically identified (together with its topology) with the subspace of $X = \mathrm{Spec}(A)$ consisting of the x such that $\mathfrak{j}_x \cap S = \varnothing$.*

Indeed, it is known (0, 1.2.6) that the prime ideals of $S^{-1}A$ are the ideals $S^{-1}\mathfrak{j}_x$ such that $\mathfrak{j}_x \cap S = \varnothing$, and that we have $\mathfrak{j}_x = ({}^Si_A)^{-1}(S^{-1}\mathfrak{j}_x)$. It therefore suffices to apply Corollary (1.2.4) to ${}^Si_A$.

(1.2.7) Corollary. *For ${}^a\varphi(X)$ to be dense in X', it is necessary and sufficient that every element of the kernel $\mathrm{Ker}\,\varphi$ be nilpotent.*

Indeed, applying formula (1.2.2.3) to the ideal $\mathfrak{a} = (0)$, we get $\overline{{}^a\varphi(X)} = V(\mathrm{Ker}\,\varphi)$, and for $V(\mathrm{Ker}\,\varphi) = X'$ it is necessary and sufficient that $\mathrm{Ker}\,\varphi$ be contained in all the prime ideals of A', that is to say, in the nilradical $\mathfrak{N}'$ of A'.

1.3 Sheaf associated with a module

(1.3.1) Let A be a commutative ring, M an A-module, f an element of A, and S_f the multiplicative set of the f^n, where $n \geq 0$. Recall that we set $A_f = S_f^{-1}A$, $M_f = S_f^{-1}M$. If S'_f is the saturated multiplicative subset of A consisting of the $g \in A$ that divide an element of S_f, it is known that A_f and M_f are canonically identified with ${S'_f}^{-1}A$ and ${S'_f}^{-1}M$ (0, 1.4.3).

(1.3.2) Lemma. *The following conditions are equivalent:*

(a) $g \in S'_f$;

(b) $S'_g \subset S'_f$;

(c) $f \in \mathfrak{r}(g)$;

(d) $\mathfrak{r}(f) \subset \mathfrak{r}(g)$;

(e) $V(g) \subset V(f)$;

(f) $D(f) \subset D(g)$.

This follows immediately from the definitions and from (1.1.5).

(1.3.3) If $D(f) = D(g)$, Lemma (1.3.2, b)) shows that $M_f = M_g$. More generally, if $D(f) \supset D(g)$, and hence $S'_f \subset S'_g$, it is known (0, 1.4.1) that there exists a canonical functorial homomorphism

$$\rho_{g,f} : M_f \longrightarrow M_g,$$

and if $D(f) \supset D(g) \supset D(h)$, we have (0, 1.4.4)

$$\rho_{h,g} \circ \rho_{g,f} = \rho_{h,f}. \tag{1.3.3.1}$$

[I | 85] As f runs through $A - \mathfrak{j}_x$ (for a given x in $X = \mathrm{Spec}(A)$), the sets S'_f form an increasing directed set of subsets of $A - \mathfrak{j}_x$, since for two elements f, g of $A - \mathfrak{j}_x$, S'_f and S'_g are contained in S'_{fg}; since the union of the S'_f for $f \in A - \mathfrak{j}_x$ is $A - \mathfrak{j}_x$, we conclude (0, 1.4.5) that the A_x-module M_x is canonically identified with the *inductive limit* $\varinjlim M_f$ with respect to the family of homomorphisms $(\rho_{g,f})$. We shall denote by

$$\rho_x^f : M_f \longrightarrow M_x$$

the canonical homomorphism for $f \in A - \mathfrak{j}_x$ (or, what amounts to the same, $x \in D(f)$).

(1.3.4) Definition. We call *structure sheaf of the prime spectrum* $X = \mathrm{Spec}(A)$ (resp. *sheaf associated with the A-module M*), and denote by $\widetilde{A}$ or $\mathscr{O}_X$ (resp. $\widetilde{M}$), the sheaf of rings (resp. the $\widetilde{A}$-module) associated with the presheaf $D(f) \mapsto A_f$ (resp. $D(f) \mapsto M_f$) on the base $\mathfrak{B}$ of X consisting of the $D(f)$, where $f \in A$ ((1.1.10), (0, 3.2.1 and 3.5.6)).

We have seen (0, 3.2.4) that the stalk $\widetilde{A}_x$ (resp. $\widetilde{M}_x$) *is identified with the ring* A_x (resp. *with the A_x-module* M_x); we shall denote by

$$\theta_f : A_f \longrightarrow \Gamma(D(f), \widetilde{A})$$

$$(\text{resp. } \theta_f : M_f \longrightarrow \Gamma(D(f), \widetilde{M})),$$

the canonical map, so that for every $x \in D(f)$ and every $\xi \in M_f$, we have

$$(\theta_f(\xi))_x = \rho_x^f(\xi). \tag{1.3.4.1}$$

(1.3.5) Proposition. *$\widetilde{M}$ is an exact covariant functor in M, from the category of A-modules to the category of $\widetilde{A}$-modules.*

Indeed, let M, N be two A-modules and u a homomorphism $M \to N$; for every $f \in A$, there corresponds canonically to u a homomorphism u_f of the A_f-module M_f into the A_f-module N_f, and the diagram (for $D(g) \subset D(f)$)

$$\begin{array}{ccc} M_f & \xrightarrow{u_f} & N_f \\ {\scriptstyle \rho_{g,f}}\downarrow & & \downarrow{\scriptstyle \rho_{g,f}} \\ M_g & \xrightarrow[u_g]{} & N_g \end{array}$$

is commutative (0, 1.4.1); these homomorphisms therefore define a homomorphism of $\widetilde{A}$-modules $\widetilde{u} : \widetilde{M} \to \widetilde{N}$ (0, 3.2.3). Moreover, for every $x \in X$, $\widetilde{u}_x$ is the inductive limit of the u_f for $x \in D(f)$ ($f \in A$), and consequently (0, 1.4.5), if we canonically identify $\widetilde{M}_x$ and $\widetilde{N}_x$ with M_x and N_x respectively, $\widetilde{u}_x$ is identified with the homomorphism u_x deduced canonically from u. If P is a third A-module, v a homomorphism $N \to P$ and $w = v \circ u$, it is immediate that $w_x = v_x \circ u_x$, hence $\widetilde{w} = \widetilde{v} \circ \widetilde{u}$. We have therefore indeed defined a *covariant functor* $\widetilde{M}$ in M, from the category of A-modules to that of $\widetilde{A}$-modules. *This functor is exact*, since for every $x \in X$, M_x is an exact functor in M (0, 1.3.2); moreover, we have $\mathrm{Supp}(M) = \mathrm{Supp}(\widetilde{M})$ by the definitions of the two sides (0, 1.7.1 and 3.1.6).

(1.3.6) Proposition. *For every $f \in A$, the open set $D(f) \subset X$ is canonically identified* [I | 86] *with the prime spectrum* $\mathrm{Spec}(A_f)$*, and the sheaf $\widetilde{M_f}$ associated with the A_f-module M_f is canonically identified with the restriction $\widetilde{M}|D(f)$.*

The first assertion is a special case of (1.2.6). Moreover, if $g \in A$ is such that $D(g) \subset D(f)$, M_g is canonically identified with the module of fractions of M_f whose denominators are the powers of the canonical image of g in A_f (0, 1.4.6). The canonical identification of $\widetilde{M_f}$ with $\widetilde{M}|D(f)$ then follows from the definitions.

(1.3.7) Theorem. *For every A-module M and every $f \in A$, the homomorphism*

$$\theta_f : M_f \longrightarrow \Gamma(D(f), \widetilde{M})$$

is bijective (in other words, the presheaf $D(f) \mapsto M_f$ is a sheaf*). In particular, M is identified by means of θ_1 with $\Gamma(X, \widetilde{M})$.*

Note that, if $M = A$, θ_f is a homomorphism of ring structures; Theorem (1.3.7) will therefore imply that, if we identify the rings A_f and $\Gamma(D(f), \widetilde{A})$ by means of θ_f, the homomorphism $\theta_f : M_f \to \Gamma(D(f), \widetilde{M})$ will be an isomorphism of *modules*.

Let us first show that θ_f is *injective*. Indeed, if $\xi \in M_f$ is such that $\theta_f(\xi) = 0$, this means that for every prime ideal $\mathfrak{p}$ of A_f, there exists $h \notin \mathfrak{p}$ such that $h\xi = 0$; since the annihilator of ξ is contained in no prime ideal of A_f, it is the whole of A_f, hence $\xi = 0$.

It remains to show that θ_f is *surjective*; we may reduce to the case where $f = 1$, the general case being deduced from it by "localizing" with the help of (1.3.6). So let s be a section of $\widetilde{M}$ over X; by virtue of (1.3.4) and of (1.1.10, (ii)), there exists a *finite* covering $(D(f_i))_{i \in I}$ of X ($f_i \in A$) such that, for every $i \in I$, the restriction $s_i = s|D(f_i)$ is of the form $\theta_{f_i}(\xi_i)$, where $\xi_i \in M_{f_i}$. If i, j are two indices in I, writing that the restrictions of s_i and of s_j to $D(f_i) \cap D(f_j) = D(f_i f_j)$ are equal, we obtain, by definition of $\widetilde{M}$,

$$\rho_{f_i f_j, f_i}(\xi_i) = \rho_{f_i f_j, f_j}(\xi_j). \tag{1.3.7.1}$$

By definition, we can write, for each $i \in I$, $\xi_i = z_i / f_i^{n_i}$, where $z_i \in M$, and since I is finite, by multiplying each z_i by a power of f_i, we may assume all the n_i equal to one and the same n. Then, by definition, (1.3.7.1) means that there exists an integer $m_{ij} \geq 0$ such that $(f_i f_j)^{m_{ij}}(f_j^n z_i - f_i^n z_j) = 0$, and we may further assume all the m_{ij} equal to one and the same integer m; replacing z_i by $f_i^m z_i$, we are then reduced to the case where $m = 0$, in other words to the case where we have

$$f_j^n z_i = f_i^n z_j \tag{1.3.7.2}$$

for all i, j. Now, we have $D(f_i^n) = D(f_i)$, and since the $D(f_i)$ form a covering of X, the ideal generated by the f_i^n is A; in other words, there exist elements $g_i \in A$ such

that $\sum_i g_i f_i^n = 1$. Consider then the element $z = \sum_i g_i z_i$ of M; by (1.3.7.2), we have $f_i^n z = \sum_j g_j f_i^n z_j = (\sum_j g_j f_j^n) z_i = z_i$, whence by definition $\xi_i = z/1$ in M_{f_i}. We conclude
[I | 87] that s_i is the restriction to $D(f_i)$ of $\theta_1(z)$, which proves that $s = \theta_1(z)$ and completes the proof.

(1.3.8) Corollary. *Let M, N be two A-modules; the canonical homomorphism $u \mapsto \widetilde{u}$ of $\mathrm{Hom}_A(M,N)$ into $\mathrm{Hom}_{\widetilde{A}}(\widetilde{M},\widetilde{N})$ is bijective. In particular, the relations $M = 0$ and $\widetilde{M} = 0$ are equivalent.*

Indeed, consider the canonical homomorphism $v \mapsto \Gamma(v)$ of $\mathrm{Hom}_{\widetilde{A}}(\widetilde{M},\widetilde{N})$ into $\mathrm{Hom}_{\Gamma(\widetilde{A})}(\Gamma(\widetilde{M}),\Gamma(\widetilde{N}))$; the latter module is canonically identified with $\mathrm{Hom}_A(M,N)$ by virtue of Theorem (1.3.7). It remains to verify that $u \mapsto \widetilde{u}$ and $v \mapsto \Gamma(v)$ are inverse to each other; now, it is obvious that $\Gamma(\widetilde{u}) = u$ by definition of $\widetilde{u}$; on the other hand, if we set $u = \Gamma(v)$ for $v \in \mathrm{Hom}_{\widetilde{A}}(\widetilde{M},\widetilde{N})$, the map $w : \Gamma(D(f),\widetilde{M}) \to \Gamma(D(f),\widetilde{N})$ deduced canonically from v is such that the diagram

$$\begin{array}{ccc} M & \xrightarrow{u} & N \\ {\scriptstyle \rho_{f,1}}\downarrow & & \downarrow{\scriptstyle \rho_{f,1}} \\ M_f & \xrightarrow[w]{} & N_f \end{array}$$

is commutative; we therefore necessarily have $w = u_f$ for every $f \in A$ (0, 1.2.4), which shows that $\widetilde{\Gamma(v)} = v$.

(1.3.9) Corollary.

(i) *Let u be a homomorphism of an A-module M into an A-module N; then the sheaves associated with $\mathrm{Ker}\, u$, $\mathrm{Im}\, u$, $\mathrm{Coker}\, u$ are respectively $\mathrm{Ker}\, \widetilde{u}$, $\mathrm{Im}\, \widetilde{u}$, $\mathrm{Coker}\, \widetilde{u}$. In particular, for $\widetilde{u}$ to be injective (resp. surjective, bijective), it is necessary and sufficient that u be so.*

(ii) *If M is an inductive limit (resp. direct sum) of a family of A-modules (M_λ), $\widetilde{M}$ is the inductive limit (resp. direct sum) of the family $(\widetilde{M_\lambda})$, up to a canonical isomorphism.*

(i) It suffices to apply the fact that $\widetilde{M}$ is an exact functor in M (1.3.5) to the two exact sequences of A-modules

$$0 \to \mathrm{Ker}\, u \to M \to \mathrm{Im}\, u \to 0$$

$$0 \to \mathrm{Im}\, u \to N \to \mathrm{Coker}\, u \to 0$$

The second assertion then follows from Theorem (1.3.7).

(ii) Let $(M_\lambda, g_{\mu\lambda})$ be an inductive system of A-modules, with inductive limit M, and let g_λ be the canonical homomorphism $M_\lambda \to M$. Since we have $\widetilde{g_{\nu\mu}} \circ \widetilde{g_{\mu\lambda}} = \widetilde{g_{\nu\lambda}}$ and $\widetilde{g_\lambda} = \widetilde{g_\mu} \circ \widetilde{g_{\mu\lambda}}$ for $\lambda \leq \mu \leq \nu$, $(\widetilde{M_\lambda}, \widetilde{g_{\mu\lambda}})$ is an inductive system of sheaves on X, and if we denote by h_λ the canonical homomorphism $\widetilde{M_\lambda} \to \varinjlim \widetilde{M_\lambda}$, there is a unique homomorphism $v : \varinjlim \widetilde{M_\lambda} \to \widetilde{M}$ such that $v \circ h_\lambda = \widetilde{g_\lambda}$. To see that v is bijective, it suffices to verify that, for every $x \in X$, v_x is a bijection of $(\varinjlim \widetilde{M_\lambda})_x$ onto $\widetilde{M}_x$; but $\widetilde{M}_x = M_x$ and

$$(\varinjlim \widetilde{M_\lambda})_x = \varinjlim (\widetilde{M_\lambda})_x = \varinjlim (M_\lambda)_x = M_x \quad (0, 1.3.3).$$

On the other hand, it follows from the definitions that $(\widetilde{g_\lambda})_x$ and $(h_\lambda)_x$ are both equal to the canonical map of $(M_\lambda)_x$ into M_x; since $(\widetilde{g_\lambda})_x = v_x \circ (h_\lambda)_x$, v_x is the identity. Finally, [I | 88] if M is the direct sum of two A-modules N, P, it is immediate that $\widetilde{M} = \widetilde{N} \oplus \widetilde{P}$; since every direct sum is the inductive limit of finite direct sums, the assertions of (ii) are proved.

Note that (1.3.8) proves that the sheaves isomorphic to sheaves associated with A-modules form an *abelian category* (T, I, 1.4).

Note also that it follows from (1.3.9) that if M is an A-module *of finite type*, that is to say, if there exists a surjective homomorphism $A^n \to M$, then there exists a surjective homomorphism $\widetilde{A^n} \to \widetilde{M}$; in other words, the $\widetilde{A}$-module $\widetilde{M}$ is *generated by a finite family of sections over* X (0, 5.1.1), and conversely.

(1.3.10) If N is a submodule of an A-module M, the canonical injection $j : N \to M$ gives, by (1.3.9), an injective homomorphism $\widetilde{N} \to \widetilde{M}$, which makes it possible to identify $\widetilde{N}$ canonically with a *sub-$\widetilde{A}$-module* of $\widetilde{M}$; we shall always assume this identification made. If N and P are two submodules of M, we then have

$$\widetilde{(N + P)} = \widetilde{N} + \widetilde{P} \tag{1.3.10.1}$$

$$\widetilde{(N \cap P)} = \widetilde{N} \cap \widetilde{P} \tag{1.3.10.2}$$

since $N + P$ and $N \cap P$ are respectively the image of the canonical homomorphism $N \oplus P \to M$ and the kernel of the canonical homomorphism $M \to (M/N) \oplus (M/P)$, and it suffices to apply (1.3.9).

We conclude from (1.3.10.1) and (1.3.10.2) that if $\widetilde{N} = \widetilde{P}$, then $N = P$.

(1.3.11) Corollary. *On the category of sheaves isomorphic to sheaves associated with A-modules, the functor Γ is exact.*

Indeed, let $\widetilde{M} \xrightarrow{\widetilde{u}} \widetilde{N} \xrightarrow{\widetilde{v}} \widetilde{P}$ be an exact sequence corresponding to two homomorphisms $u : M \to N$, $v : N \to P$ of A-modules. If $Q = \operatorname{Im} u$ and $R = \operatorname{Ker} v$, we have $\widetilde{Q} = \operatorname{Im} \widetilde{u} = \operatorname{Ker} \widetilde{v} = \widetilde{R}$ (Corollary (1.3.9)), hence $Q = R$.

(1.3.12) Corollary. *Let M, N be two A-modules.*

(i) *The sheaf associated with $M \otimes_A N$ is canonically identified with $\widetilde{M} \otimes_{\widetilde{A}} \widetilde{N}$.*

(ii) *If moreover M admits a finite presentation, the sheaf associated with* $\operatorname{Hom}_A(M, N)$ *is canonically identified with $\mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$.*

(i) The sheaf $\mathscr{F} = \widetilde{M} \otimes_{\widetilde{A}} \widetilde{N}$ is associated with the presheaf

$$U \mapsto \mathscr{F}(U) = \Gamma(U, \widetilde{M}) \otimes_{\Gamma(U, \widetilde{A})} \Gamma(U, \widetilde{N})$$

U running through the base (1.1.10, (i)) of X consisting of the $D(f)$, where $f \in A$. Now, $\mathscr{F}(D(f))$ is canonically identified with $M_f \otimes_{A_f} N_f$ by virtue of (1.3.7) and (1.3.6). It is known, moreover, that the A_f-module $M_f \otimes_{A_f} N_f$ is canonically isomorphic to $(M \otimes_A N)_f$ (0, 1.3.4), which is itself canonically isomorphic to $\Gamma(D(f), \widetilde{(M \otimes_A N)})$ (1.3.7 and 1.3.6). Further, one verifies at once that the canonical isomorphisms

$$\mathscr{F}(D(f)) \simeq \Gamma(D(f), \widetilde{(M \otimes_A N)})$$

[I | 89] thus obtained satisfy the conditions of compatibility with the restriction operators (0, 1.4.2), and hence define a canonical functorial isomorphism

$$\widetilde{M} \otimes_{\widetilde{A}} \widetilde{N} \simeq \widetilde{(M \otimes_A N)}$$

(ii) The sheaf $\mathscr{G} = \mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N})$ is associated with the presheaf

$$U \longmapsto \mathscr{G}(U) = \mathrm{Hom}_{\widetilde{A}|U}(\widetilde{M}|U, \widetilde{N}|U)$$

U running through the base of X consisting of the $D(f)$. Now, $\mathscr{G}(D(f))$ is canonically identified with $\mathrm{Hom}_{A_f}(M_f, N_f)$ (1.3.6 and 1.3.8), which is itself, by virtue of the hypothesis on M, canonically identified with $(\mathrm{Hom}_A(M, N))_f$ (0, 1.3.5). Finally, $(\mathrm{Hom}_A(M, N))_f$ is canonically identified with $\Gamma(D(f), \widetilde{(\mathrm{Hom}_A(M, N))})$ (1.3.6 and 1.3.7), and the canonical isomorphisms $\mathscr{G}(D(f)) \simeq \Gamma(D(f), \widetilde{(\mathrm{Hom}_A(M, N))})$ thus obtained are compatible with the restriction operators (0, 1.4.2); they therefore define a canonical isomorphism

$$\mathscr{H}om_{\widetilde{A}}(\widetilde{M}, \widetilde{N}) \simeq \widetilde{(\mathrm{Hom}_A(M, N))}.$$

(1.3.13) Now let B be a (commutative) A-algebra; this can be interpreted by saying that B is an A-module and that we are given an element $e \in B$ and an A-homomorphism $\varphi : B \otimes_A B \to B$ such that: 1° the diagrams

$$\begin{array}{ccc} B \otimes_A B \otimes_A B & \xrightarrow{\varphi \otimes 1} & B \otimes_A B \\ {\scriptstyle 1 \otimes \varphi}\downarrow & & \downarrow{\scriptstyle \varphi} \\ B \otimes_A B & \xrightarrow[\varphi]{} & B \end{array} \qquad \begin{array}{ccc} B \otimes_A B & \xrightarrow{\sigma} & B \otimes_A B \\ & {\scriptstyle \varphi}\searrow \quad \swarrow{\scriptstyle \varphi} & \\ & B & \end{array}$$

(σ being the canonical symmetry) are commutative; 2° $\varphi(e \otimes x) = \varphi(x \otimes e) = x$. By virtue of (1.3.12), the homomorphism $\widetilde{\varphi} : \widetilde{B} \otimes_{\widetilde{A}} \widetilde{B} \to \widetilde{B}$ of $\widetilde{A}$-modules satisfies the analogous conditions, and therefore defines on $\widetilde{B}$ a structure of $\widetilde{A}$-algebra. In the same way, giving a B-module N amounts to giving an A-module N and an A-homomorphism $\psi : B \otimes_A N \to N$ such that the diagram

$$\begin{array}{ccc} B \otimes_A B \otimes_A N & \xrightarrow{\varphi \otimes 1} & B \otimes_A N \\ {\scriptstyle 1 \otimes \psi}\downarrow & & \downarrow{\scriptstyle \psi} \\ B \otimes_A N & \xrightarrow[\psi]{} & N \end{array}$$

is commutative and $\psi(e \otimes n) = n$; the homomorphism $\widetilde{\psi} : \widetilde{B} \otimes_{\widetilde{A}} \widetilde{N} \to \widetilde{N}$ will satisfy the analogous condition, and therefore defines on $\widetilde{N}$ a structure of $\widetilde{B}$-module.

In the same way, one sees that if $u : B \to B'$ (resp. $v : N \to N'$) is a homomorphism of A-algebras (resp. of B-modules), $\widetilde{u}$ (resp. $\widetilde{v}$) is a homomorphism of $\widetilde{A}$-algebras (resp. of $\widetilde{B}$-modules) and $\mathrm{Ker}\,\widetilde{u}$ is a $\widetilde{B}$-Ideal (resp. $\mathrm{Ker}\,\widetilde{v}$, $\mathrm{Coker}\,\widetilde{v}$ and $\mathrm{Im}\,\widetilde{v}$ are $\widetilde{B}$-modules). If N is a B-module, $\widetilde{N}$ is a $\widetilde{B}$-module of finite type if and only if N is a B-module of finite type
[I | 90] (0, 5.2.3). If M, N are two B-modules, the $\widetilde{B}$-module $\widetilde{M} \otimes_{\widetilde{B}} \widetilde{N}$ is canonically identified with $\widetilde{(M \otimes_B N)}$; similarly, $\mathscr{H}om_{\widetilde{B}}(\widetilde{M}, \widetilde{N})$ is canonically identified with $\widetilde{(\mathrm{Hom}_B(M, N))}$ when M admits a finite presentation; the proofs are the same as in (1.3.12).

If $\mathfrak{J}$ is an ideal of B and N a B-module, we have $\widetilde{(\mathfrak{J}N)} = \widetilde{\mathfrak{J}} \cdot \widetilde{N}$.

Finally, if B is an A-algebra graded by sub-A-modules B_n ($n \in \mathbb{Z}$), the $\widetilde{A}$-algebra $\widetilde{B}$, the direct sum of the $\widetilde{A}$-modules $\widetilde{B_n}$ (1.3.9), is graded by these sub-$\widetilde{A}$-modules, the axiom of the grading expressing that the image of the homomorphism $B_m \otimes_A B_n \to B$ is contained in B_{m+n}. Similarly, if M is a B-module graded by submodules M_n, $\widetilde{M}$ is a $\widetilde{B}$-module graded by the $\widetilde{M_n}$.

(1.3.14) If B is an A-algebra and M a submodule of B, the sub-$\widetilde{A}$-algebra of $\widetilde{B}$ generated by $\widetilde{M}$ (0, 4.1.3) is the sub-$\widetilde{A}$-algebra $\widetilde{C}$, where C denotes the subalgebra of B generated by M. Indeed, C is the sum of the submodules of B that are the images of the homomorphisms $\bigotimes_A^n M \to B$ ($n \geq 0$), and it suffices to apply (1.3.9) and (1.3.12).

1.4 Quasi-coherent sheaves on a prime spectrum.

(1.4.1) Theorem. *Let X be the prime spectrum of a ring A, V a quasi-compact open subset of X, and $\mathscr{F}$ an $(\mathscr{O}_X|V)$-module. The following four conditions are equivalent:*

a) There exists an A-module M such that $\mathscr{F}$ is isomorphic to $\widetilde{M}|V$.

b) There exists a finite open covering (V_i) of V by sets of the form $D(f_i)$ ($f_i \in A$) contained in V, such that, for every i, $\mathscr{F}|V_i$ is isomorphic to a sheaf of the form $\widetilde{M}_i$, where M_i is an A_{f_i}-module.

c) The sheaf $\mathscr{F}$ is quasi-coherent (0, 5.1.3).

d) The following two properties hold:

d 1) For every $f \in A$ such that $D(f) \subset V$ and every section $s \in \Gamma(D(f), \mathscr{F})$, there exists an integer $n \geq 0$ such that $f^n s$ extends to a section of $\mathscr{F}$ over V.

d 2) For every $f \in A$ such that $D(f) \subset V$ and every section $t \in \Gamma(V, \mathscr{F})$ such that the restriction of t to $D(f)$ is 0, there exists an integer $n \geq 0$ such that $f^n t = 0$.

(In writing conditions *d* 1) and *d* 2), we have tacitly identified A and $\Gamma(\widetilde{A})$ by virtue of 1.3.7.)

That *a*) implies *b*) is an immediate consequence of (1.3.6) and of the fact that the $D(f_i)$ form a base for the topology of X (1.1.10). Since every A-module is isomorphic to the cokernel of a homomorphism $A^{(I)} \to A^{(J)}$, (1.3.9) proves that every sheaf associated with an A-module is quasi-coherent; hence *b*) implies *c*). Conversely, if $\mathscr{F}$ is quasi-coherent, every $x \in V$ has a neighbourhood of the form $D(f) \subset V$ such that $\mathscr{F}|D(f)$ is isomorphic to the cokernel of a homomorphism $\widetilde{A_f}^{(I)} \to \widetilde{A_f}^{(J)}$, hence to the sheaf associated with the module $\widetilde{N}$, the cokernel of the corresponding homomorphism $A_f^{(I)} \to A_f^{(J)}$ (1.3.8 and 1.3.9); since V is quasi-compact, it is clear that *c*) implies *b*). To prove that *b*) implies *d* 1) and *d* 2), suppose first that $V = D(g)$ for some $g \in A$, and that $\mathscr{F}$ is isomorphic to a sheaf $\widetilde{N}$ associated with an A_g-module N; replacing X by V and A by A_g (1.3.6), we may reduce to the case where $g = 1$. Then $\Gamma(D(f), \widetilde{N})$ and N_f are canonically identified (1.3.6 and 1.3.7), so a section $s \in \Gamma(D(f), \widetilde{N})$ is identified with an element of the form z/f^n, where $z \in N$; the section $f^n s$ is identified with the element $z/1$ of N_f, and is consequently the restriction to $D(f)$ of the section of $\widetilde{N}$ over X identified with the element $z \in N$; whence *d* 1) in this case. Similarly, $t \in \Gamma(X, \widetilde{N})$ is identified with an element $z' \in N$, the restriction of t to $D(f)$ is identified with the image $z'/1$ [I | 91]

of z' in N_f, and to say that this image is zero means that there exists $n \geq 0$ such that $f^n z' = 0$ in N, or, what amounts to the same, $f^n t = 0$.

To finish proving that *b*) implies *d* 1) and *d* 2), it will suffice to establish the following lemma:

(1.4.1.1) Lemma. *Suppose that V is a finite union of sets of the form $D(g_i)$, and that each of the sheaves $\mathscr{F}|D(g_i)$, $\mathscr{F}|(D(g_i) \cap D(g_j)) = \mathscr{F}|D(g_i g_j)$ satisfies d 1) and d 2); then $\mathscr{F}$ has the following two properties:*

d' 1) For every $f \in A$ and every section $s \in \Gamma(D(f) \cap V, \mathscr{F})$, there exists an integer $n \geq 0$ such that $f^n s$ extends to a section of $\mathscr{F}$ over V.

d' 2) For every $f \in A$ and every section $t \in \Gamma(V, \mathscr{F})$ such that the restriction of t to $D(f) \cap V$ is 0, there exists an integer $n \geq 0$ such that $f^n t = 0$.

Let us first prove *d'* 2): since $D(f) \cap D(g_i) = D(f g_i)$, there exists for each i an integer n_i such that the restriction of $(f g_i)^{n_i} t$ to $D(g_i)$ is zero: since the image of g_i in A_{g_i} is invertible, the restriction of $f^{n_i} t$ to $D(g_i)$ is also zero; taking for n the largest of the n_i, we have *d'* 2).

To prove *d'* 1), let us apply *d* 1) to the sheaf $\mathscr{F}|D(g_i)$: there exist an integer $n_i \geq 0$ and a section s_i' of $\mathscr{F}$ over $D(g_i)$ extending the restriction of $(f g_i)^{n_i} s$ to $D(f g_i)$; since the image of g_i in A_{g_i} is invertible, there is a section s_i of $\mathscr{F}$ over $D(g_i)$ such that $s_i' = g_i^{n_i} s_i$, and s_i extends the restriction of $f^{n_i} s$ to $D(f g_i)$; we may moreover assume all the n_i equal to one and the same integer n. By construction, the restriction of $s_i - s_j$ to $D(f) \cap D(g_i) \cap D(g_j) = D(f g_i g_j)$ is zero; by *d* 2) applied to the sheaf $\mathscr{F}|D(g_i g_j)$, there exists an integer $m_{ij} \geq 0$ such that the restriction to $D(g_i g_j)$ of $(f g_i g_j)^{m_{ij}}(s_i - s_j)$ is zero; since the image of $g_i g_j$ in $A_{g_i g_j}$ is invertible, the restriction of $f^{m_{ij}}(s_i - s_j)$ to $D(g_i g_j)$ is zero. We may then assume all the m_{ij} equal to one and the same integer m, and there therefore exists a section $s' \in \Gamma(V, \mathscr{F})$ extending the $f^m s_i$; this section consequently extends $f^{n+m} s$, whence *d'* 1).

It remains to prove that *d* 1) and *d* 2) imply *a*). Let us first show that *d* 1) and *d* 2) imply that these conditions are satisfied by every sheaf $\mathscr{F}|D(g)$, where $g \in A$ is such that $D(g) \subset V$. This is obvious for *d* 1); on the other hand, if $t \in \Gamma(D(g), \mathscr{F})$ is such that its restriction to $D(f) \subset D(g)$ is zero, there exists by *d* 1) an integer $m \geq 0$ such
[I | 92] that $g^m t$ extends to a section s of $\mathscr{F}$ over V; applying *d* 2), we see that there exists an integer $n \geq 0$ such that $f^n g^m t = 0$, and since the image of g in A_g is invertible, $f^n t = 0$.

That being so, since V is quasi-compact, Lemma (1.4.1.1) proves that conditions *d'* 1) and *d'* 2) are satisfied. Consider then the A-module $M = \Gamma(V, \mathscr{F})$, and let us define a homomorphism of $\widetilde{A}$-modules $u : \widetilde{M} \to j_*(\mathscr{F})$, where j is the canonical injection $V \to X$. Since the $D(f)$ form a base for the topology of X, it suffices, for each $f \in A$, to define a homomorphism $u_f : M_f \to \Gamma(D(f), j_*(\mathscr{F})) = \Gamma(D(f) \cap V, \mathscr{F})$, satisfying the usual compatibility conditions (0, 3.2.5). Since the canonical image of f in A_f is invertible, the restriction homomorphism $M = \Gamma(V, \mathscr{F}) \to \Gamma(D(f) \cap V, \mathscr{F})$ factors as $M \longrightarrow M_f \xrightarrow{u_f} \Gamma(D(f) \cap V, \mathscr{F})$ (0, 1.2.4), and the verification of the compatibility conditions for $D(g) \subset D(f)$ is immediate. That being so, let us show that condition *d'* 1) (resp. *d'* 2)) implies that each of the u_f is surjective (resp. injective), which will prove that u is *bijective*, and consequently that $\mathscr{F}$ is the restriction to V of an $\widetilde{A}$-module isomorphic to $\widetilde{M}$. Now, if $s \in \Gamma(D(f) \cap V, \mathscr{F})$, there exists by *d'* 1) an integer $n \geq 0$ such that $f^n s$ extends to a section $z \in M$; we then have $u_f(z/f^n) = s$, hence u_f is surjective. Similarly, if $z \in M$ is such that $u_f(z/1) = 0$, this means that the restriction to $D(f) \cap V$ of the section z is zero; by *d'* 2), there exists an integer $n \geq 0$ such that $f^n z = 0$, whence $z/1 = 0$ in M_f, and u_f is therefore injective.

Q.E.D.

(1.4.2) Corollary. *Every quasi-coherent sheaf on a quasi-compact open subset of X is induced by a quasi-coherent sheaf on X.*

(1.4.3) Corollary. *Every quasi-coherent $\mathscr{O}_X$-algebra on $X = \mathrm{Spec}(A)$ is isomorphic to an $\mathscr{O}_X$-algebra of the form $\widetilde{B}$, where B is an algebra over A; every quasi-coherent $\widetilde{B}$-module is isomorphic to a $\widetilde{B}$-module of the form $\widetilde{N}$, where N is a B-module.*

Indeed, a quasi-coherent $\mathscr{O}_X$-algebra is a quasi-coherent $\mathscr{O}_X$-module, hence of the form $\widetilde{B}$, where B is an A-module; the fact that B is an A-algebra follows from the characterization of the structure of $\mathscr{O}_X$-algebra by means of the homomorphism $\widetilde{B}\otimes_{\widetilde{A}}\widetilde{B} \to \widetilde{B}$ of $\widetilde{A}$-modules, together with (1.3.12). If $\mathscr{G}$ is a quasi-coherent $\widetilde{B}$-module, it suffices to show that $\mathscr{G}$ is also a quasi-coherent $\widetilde{A}$-module in order to conclude afterwards in the same way; since the question is local, we may, by restricting ourselves to an open subset of X of the form $D(f)$, assume that $\mathscr{G}$ is the cokernel of a homomorphism $\widetilde{B}^{(I)} \to \widetilde{B}^{(J)}$ of $\widetilde{B}$-modules (and *a fortiori* of $\widetilde{A}$-modules); the proposition then follows from (1.3.8) and (1.3.9).

1.5 Coherent sheaves on a prime spectrum.

(1.5.1) Theorem. *Let A be a* Noetherian *ring, $X = \mathrm{Spec}(A)$ its prime spectrum, V an open subset of X, and $\mathscr{F}$ an $(\mathscr{O}_X|V)$-module. The following conditions are equivalent:*

a) $\mathscr{F}$ is coherent.

b) $\mathscr{F}$ is of finite type and quasi-coherent.

c) There exists an A-module M of finite type such that $\mathscr{F}$ is isomorphic to the sheaf $\widetilde{M}|V$.

a) trivially implies *b*). To see that *b*) implies *c*), let us first note, since V is quasi-compact [I | 93]
(0, 2.2.3), that $\mathscr{F}$ is isomorphic to a sheaf $\widetilde{N}|V$, where N is an A-module (1.4.1). Now, we have $N = \varinjlim M_\lambda$, where M_λ runs through the set of sub-A-modules of finite type of N, whence (1.3.9) $\mathscr{F} = \widetilde{N}|V = \varinjlim \widetilde{M_\lambda}|V$; but since $\mathscr{F}$ is of finite type, and V quasi-compact, there exists an index λ such that $\mathscr{F} = \widetilde{M_\lambda}|V$ (0, 5.2.3).

Let us finally show that *c*) implies *a*). It is clear that $\mathscr{F}$ is then of finite type (1.3.6 and 1.3.9); moreover, the question being local, we may restrict ourselves to the case where $V = D(f)$, $f \in A$. Since A_f is Noetherian, we finally see that everything comes down to proving that the kernel of a homomorphism $\widetilde{A^n} \to \widetilde{M}$, where M is an A-module, is of finite type. Now, such a homomorphism is of the form $\widetilde{u}$, where u is a homomorphism $A^n \to M$ (1.3.8), and if $P = \mathrm{Ker}\, u$, we have $\widetilde{P} = \mathrm{Ker}\, \widetilde{u}$ (1.3.9). Since A is Noetherian, P is of finite type, which completes the proof.

(1.5.2) Corollary. *Under the hypotheses of (1.5.1), the sheaf $\mathscr{O}_X$ is a coherent sheaf of rings.*

(1.5.3) Corollary. *Under the hypotheses of (1.5.1), every coherent sheaf on an open subset of X is induced by a coherent sheaf on X.*

(1.5.4) Corollary. *Under the hypotheses of (1.5.1), every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is the inductive limit of the coherent sub-$\mathscr{O}_X$-modules of $\mathscr{F}$.*

Indeed, $\mathscr{F} = \widetilde{M}$, where M is an A-module, and M is the inductive limit of its submodules of finite type; we conclude by (1.3.9) and (1.5.1).

1.6 Functorial properties of quasi-coherent sheaves on a prime spectrum.

(1.6.1) Let A, A' be two rings,

$$\varphi : A' \to A$$

a homomorphism, and

$$^a\varphi : X = \mathrm{Spec}(A) \to X' = \mathrm{Spec}(A')$$

the continuous map associated with φ (1.2.1). We are going to define a *canonical homomorphism*

$$\widetilde{\varphi} : \mathscr{O}_{X'} \to {}^a\varphi_*(\mathscr{O}_X)$$

of sheaves of rings. For every $f' \in A'$, set $f = \varphi(f')$; we have $^a\varphi^{-1}(D(f')) = D(f)$ (1.2.2.2). The rings $\Gamma(D(f'), \widetilde{A'})$ and $\Gamma(D(f), \widetilde{A})$ are identified with $A'_{f'}$ and A_f respectively (1.3.6 and 1.3.7). Now, the homomorphism φ canonically defines a homomorphism $\varphi_{f'} : A'_{f'} \to A_f$ (0, 1.5.1); in other words, we have a ring homomorphism

$$\Gamma(D(f'), \widetilde{A'}) \to \Gamma({}^a\varphi^{-1}(D(f')), \widetilde{A}) = \Gamma(D(f'), {}^a\varphi_*(\widetilde{A})).$$

[I | 94] Moreover, these homomorphisms satisfy the usual compatibility conditions: for $D(f') \supset D(g')$, the diagram

$$\begin{array}{ccc} \Gamma(D(f'), \widetilde{A'}) & \longrightarrow & \Gamma(D(f'), {}^a\varphi_*(\widetilde{A})) \\ \downarrow & & \downarrow \\ \Gamma(D(g'), \widetilde{A'}) & \longrightarrow & \Gamma(D(g'), {}^a\varphi_*(\widetilde{A})) \end{array}$$

is commutative (0, 1.5.1); we have therefore indeed defined a homomorphism of $\mathscr{O}_{X'}$-algebras, the $D(f')$ forming a base for the topology of X' (0, 3.2.3). The pair $\Phi = ({}^a\varphi, \widetilde{\varphi})$ is therefore a *morphism* of ringed spaces

$$\Phi : (X, \mathscr{O}_X) \to (X', \mathscr{O}_{X'})$$

(0, 4.1.1).

Note moreover that, if we set $x' = {}^a\varphi(x)$, the homomorphism $\widetilde{\varphi}^{\#}_x$ (0, 3.7.1) is none other than the homomorphism

$$\varphi_x : A'_{x'} \to A_x$$

deduced canonically from $\varphi : A' \to A$ (0, 1.5.1). Indeed, every $z' \in A'_{x'}$ can be written g'/f', where f', g' are in A' and $f' \notin \mathfrak{j}_{x'}$; $D(f')$ is therefore a neighbourhood of x' in X', and the homomorphism $\Gamma(D(f'), \widetilde{A'}) \to \Gamma({}^a\varphi^{-1}(D(f')), \widetilde{A})$ deduced from $\widetilde{\varphi}$ is none other than $\varphi_{f'}$; by considering the section $s' \in \Gamma(D(f'), \widetilde{A'})$ corresponding to $g'/f' \in A'_{f'}$, we indeed obtain $\widetilde{\varphi}^{\#}_x(z') = \varphi(g')/\varphi(f')$ in A_x.

(1.6.2) Example. Let S be a multiplicative subset of A and φ the canonical homomorphism $A \to S^{-1}A$; we have already seen (1.2.6) that $^a\varphi$ is a *homeomorphism* of $Y = \mathrm{Spec}(S^{-1}A)$ onto the subspace of $X = \mathrm{Spec}(A)$ consisting of the x such that $\mathfrak{j}_x \cap S = \varnothing$. Moreover, for every x belonging to this subspace, hence of the form $^a\varphi(y)$ with $y \in Y$, the homomorphism $\widetilde{\varphi}^{\#}_y : \mathscr{O}_x \to \mathscr{O}_y$ is *bijective* (0, 1.2.6); in other words, $\mathscr{O}_Y$ is identified with the sheaf induced on Y by $\mathscr{O}_X$.

(1.6.3) Proposition. *For every A-module M, there exists a canonical functorial isomorphism of the $\mathscr{O}_{X'}$-module $(M_{[\varphi]})^\sim$ onto the direct image $\Phi_*(\widetilde{M})$.*

To abbreviate, set $M' = M_{[\varphi]}$, and for every $f' \in A'$, set again $f = \varphi(f')$. The modules of sections $\Gamma(D(f'), \widetilde{M'})$ and $\Gamma(D(f), \widetilde{M})$ are identified respectively with the modules $M'_{f'}$ and M_f (over $A'_{f'}$ and A_f respectively); moreover, the $A'_{f'}$-module $(M_f)_{[\varphi_{f'}]}$ is canonically isomorphic to $M'_{f'}$ (0, 1.5.2). We therefore have a functorial isomorphism of $\Gamma(D(f'), \widetilde{A'})$-modules: $\Gamma(D(f'), \widetilde{M'}) \xrightarrow{\sim} \Gamma({}^a\varphi^{-1}(D(f')), \widetilde{M})_{[\varphi_{f'}]}$, and these isomorphisms satisfy the usual conditions of compatibility with the restrictions (0, 1.5.6), hence define the announced functorial isomorphism. Note that, more precisely, if $u : M_1 \to M_2$ is a homomorphism of A-modules, it can be regarded as a homomorphism $(M_1)_{[\varphi]} \to (M_2)_{[\varphi]}$ of A'-modules; if we denote this homomorphism by $u_{[\varphi]}$, $\Phi_*(\widetilde{u})$ is identified with $(u_{[\varphi]})^\sim$.

This proof also shows that for every A-algebra B, the canonical functorial isomorphism $(B_{[\varphi]})^\sim \xrightarrow{\sim} \Phi_*(\widetilde{B})$ is an isomorphism of $\mathscr{O}_{X'}$-algebras; if M is a B-module, the canonical functorial isomorphism $(M_{[\varphi]})^\sim \xrightarrow{\sim} \Phi_*(\widetilde{M})$ is an isomorphism of $\Phi_*(\widetilde{B})$-modules. [I | 95]

(1.6.4) Corollary. *The direct image functor Φ_* is exact on the category of quasi-coherent $\mathscr{O}_X$-modules.*

Indeed, it is clear that $M_{[\varphi]}$ is an exact functor in M, and $\widetilde{M'}$ an exact functor in M' (1.3.5).

(1.6.5) Proposition. *Let N' be an A'-module and N the A-module $N' \otimes_{A'} A_{[\varphi]}$; there exists a canonical functorial isomorphism of the $\mathscr{O}_X$-module $\Phi^*(\widetilde{N'})$ onto $\widetilde{N}$.*

Observe first that $j : z' \mapsto z' \otimes 1$ is an A'-homomorphism of N' into $N_{[\varphi]}$; indeed, by definition, for $f' \in A'$, we have $(f'z') \otimes 1 = z' \otimes \varphi(f') = \varphi(f')(z' \otimes 1)$. We deduce from it (1.3.8) a homomorphism $\widetilde{j} : \widetilde{N'} \to (N_{[\varphi]})^\sim$ of $\mathscr{O}_{X'}$-modules, and by virtue of (1.6.3), we may regard $\widetilde{j}$ as mapping $\widetilde{N'}$ into $\Phi_*(\widetilde{N})$. To this homomorphism $\widetilde{j}$ there corresponds canonically a homomorphism $h = \widetilde{j}^\#$ of $\Phi^*(\widetilde{N'})$ into $\widetilde{N}$ (0, 4.4.3); we shall see that on each stalk, h_x is *bijective*. Set $x' = {}^a\varphi(x)$ and let $f' \in A'$ be such that $x' \in D(f')$; let $f = \varphi(f')$. The ring $\Gamma(D(f), \widetilde{A})$ is identified with A_f, and the modules $\Gamma(D(f), \widetilde{N})$ and $\Gamma(D(f'), \widetilde{N'})$ with N_f and $N'_{f'}$ respectively; let $s' \in \Gamma(D(f'), \widetilde{N'})$, identified with n'/f'^p ($n' \in N'$), and let s be its image under $\widetilde{j}$ in $\Gamma(D(f), \widetilde{N})$; s is identified with $(n' \otimes 1)/f^p$. On the other hand, let $t \in \Gamma(D(f), \widetilde{A})$, identified with g/f^q ($g \in A$); then, by definition, we have $h_x(s'_{x'} \otimes t_x) = t_x \cdot s_x$ (0, 4.4.3). But we can canonically identify N_f with $N'_{f'} \otimes_{A'_{f'}} (A_f)_{[\varphi_{f'}]}$ (0, 1.5.4); s then corresponds to the element $(n'/f'^p) \otimes 1$, and the section $y \mapsto t_y \cdot s_y$ to $(n'/f'^p) \otimes (g/f^q)$. The compatibility diagrams of (0, 1.5.6) show that h_x is none other than the canonical isomorphism

$$N'_{x'} \otimes_{A'_{x'}} (A_x)_{[\varphi_x]} \xrightarrow{\sim} N_x = (N' \otimes_{A'} A_{[\varphi]})_x. \tag{1.6.5.1}$$

Moreover, let $v : N'_1 \to N'_2$ be a homomorphism of A'-modules; since $\widetilde{v}_{x'} = v_{x'}$ for every $x' \in X'$, it follows at once from what precedes that $\Phi^*(\widetilde{v})$ is canonically identified with $(v \otimes 1)^\sim$, which completes the proof of (1.6.5).

If B' is an A'-algebra, the canonical isomorphism of $\Phi^*(\widetilde{B'})$ onto $(B' \otimes_{A'} A_{[\varphi]})^\sim$ is an isomorphism of $\mathscr{O}_X$-algebras; if moreover N' is a B'-module, the canonical isomorphism of $\Phi^*(\widetilde{N'})$ onto $(N' \otimes_{A'} A_{[\varphi]})^\sim$ is an isomorphism of $\Phi^*(\widetilde{B'})$-modules.

(1.6.6) Corollary. *The sections of $\Phi^*(\widetilde{N'})$ that are the canonical images of the sections s', where s' runs through the A'-module $\Gamma(\widetilde{N'})$, generate the A-module $\Gamma(\Phi^*(\widetilde{N'}))$.*

Indeed, these images are identified with the elements $z' \otimes 1$ of N when N' and N are identified with $\Gamma(\widetilde{N'})$ and $\Gamma(\widetilde{N})$ respectively (1.3.7) and z' runs through N'.

(1.6.7) In the proof of (1.6.5), we proved in passing that the canonical map (0, 4.4.3.2)
[I | 96] $\rho : \widetilde{N'} \to \Phi_*(\Phi^*(\widetilde{N'}))$ is none other than the homomorphism $\widetilde{j}$, where $j : N' \to N' \otimes_{A'} A_{[\varphi]}$ is the homomorphism $z' \mapsto z' \otimes 1$. Similarly, the canonical map (0, 4.4.3.3) $\sigma : \Phi^*(\Phi_*(\widetilde{M})) \to \widetilde{M}$ is none other than $\widetilde{p}$, where $p : M_{[\varphi]} \otimes_{A'} A_{[\varphi]} \to M$ is the canonical homomorphism which maps every tensor product $z \otimes a$ ($z \in M$, $a \in A$) to $a \cdot z$; this follows at once from the definitions (0, 3.7.1, 0, 4.4.3, and I, 1.3.7).

We conclude from this (0, 4.4.3 and 3.5.4.4) that if $v : N' \to M_{[\varphi]}$ is an A'-homomorphism, we have $\widetilde{v}^{\#} = (v \otimes 1)^{\sim}$.

(1.6.8) Let N'_1, N'_2 be two A'-modules, N'_1 being assumed to have a *finite presentation*; it then follows from (1.6.7) and (1.3.12, (ii)) that the canonical homomorphism (0, 4.4.6)

$$\Phi^*(\mathscr{H}om_{\widetilde{A'}}(\widetilde{N'_1}, \widetilde{N'_2})) \longrightarrow \mathscr{H}om_{\widetilde{A}}(\Phi^*(\widetilde{N'_1}), \Phi^*(\widetilde{N'_2}))$$

is none other than $\widetilde{\gamma}$, where γ denotes the canonical homomorphism of A-modules

$$\mathrm{Hom}_{A'}(N'_1, N'_2) \otimes_{A'} A \longrightarrow \mathrm{Hom}_A(N'_1 \otimes_{A'} A, N'_2 \otimes_{A'} A).$$

(1.6.9) Let $\mathfrak{J}'$ be an ideal of A' and M an A-module; since, by definition, $\widetilde{\mathfrak{J}'}\widetilde{M}$ is the image of the canonical homomorphism $\Phi^*(\widetilde{\mathfrak{J}'}) \otimes_{\widetilde{A}} \widetilde{M} \to \widetilde{M}$, it follows from (1.6.5) and (1.3.12, (i)) that $\widetilde{\mathfrak{J}'}\widetilde{M}$ is canonically identified with $(\mathfrak{J}'M)^{\sim}$; in particular, $\Phi^*(\widetilde{\mathfrak{J}'})\widetilde{A}$ is identified with $(\mathfrak{J}'A)^{\sim}$, and, taking into account the right exactness of the functor Φ^*, the $\widetilde{A}$-algebra $\Phi^*((A'/\mathfrak{J}')^{\sim})$ is identified with $(A/\mathfrak{J}'A)^{\sim}$.

(1.6.10) Let A'' be a third ring and φ' a homomorphism $A'' \to A'$, and set $\varphi'' = \varphi \circ \varphi'$. It follows at once from the definitions that ${}^a\varphi'' = ({}^a\varphi') \circ ({}^a\varphi)$ and $\widetilde{\varphi''} = \widetilde{\varphi} \circ \widetilde{\varphi'}$ (0, 1.5.7). We conclude that we have $\Phi'' = \Phi' \circ \Phi$; in other words, $(\mathrm{Spec}\, A, \widetilde{A})$ is a *functor* in A from the category of rings to that of ringed spaces.

1.7 Characterization of morphisms of affine schemes.

(1.7.1) Definition. A ringed space $(X, \mathscr{O}_X)$ is called an *affine scheme* if it is isomorphic to a ringed space of the form $(\mathrm{Spec}(A), \widetilde{A})$, where A is a ring; we then say that $\Gamma(X, \mathscr{O}_X)$, which is canonically identified with the ring A (1.3.7), is the ring of the affine scheme $(X, \mathscr{O}_X)$, and we denote it by $A(X)$ when no confusion can result.

By abuse of language, when we speak of the *affine scheme* $\mathrm{Spec}(A)$, we shall always mean the ringed space $(\mathrm{Spec}(A), \widetilde{A})$.

(1.7.2) Let A, B be two rings, and $(X, \mathscr{O}_X)$, $(Y, \mathscr{O}_Y)$ the corresponding affine schemes on the prime spectra $X = \mathrm{Spec}(A)$, $Y = \mathrm{Spec}(B)$. We have seen (1.6.1) that to every ring homomorphism $\varphi : B \to A$ there corresponds a morphism $\Phi = ({}^a\varphi, \widetilde{\varphi}) = \mathrm{Spec}(\varphi) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$. Note that φ is entirely determined by Φ, since by definition we have

$$\varphi = \Gamma(\widetilde{\varphi}) : \Gamma(\widetilde{B}) \longrightarrow \Gamma({}^a\varphi_*(\widetilde{A})) = \Gamma(\widetilde{A}).$$

(1.7.3) Theorem. *Let $(X, \mathscr{O}_X)$, $(Y, \mathscr{O}_Y)$ be two affine schemes. For a morphism of ringed spaces $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ to be of the form $({}^a\varphi, \widetilde{\varphi})$, where φ is a ring homomorphism $A(Y) \to A(X)$, it is necessary and sufficient that, for every $x \in X$, $\theta^{\#}_x$ be a local homomorphism: $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.*

Set $A = A(X)$, $B = A(Y)$. The condition is necessary, since we have seen (1.6.1) that $\widetilde{\varphi}_x^{\#}$ [I | 97] is the homomorphism of $B_{{}^a\varphi(x)}$ into A_x deduced canonically from φ, and, by definition of ${}^a\varphi(x) = \varphi^{-1}(\mathfrak{j}_x)$, this homomorphism is local.

Let us prove that the condition is sufficient. By definition, θ is a homomorphism $\mathscr{O}_Y \to \psi_*(\mathscr{O}_X)$, and from it we deduce canonically a ring homomorphism

$$\varphi = \Gamma(\theta) : B = \Gamma(Y, \mathscr{O}_Y) \longrightarrow \Gamma(Y, \psi_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X) = A.$$

The hypothesis on $\theta_x^{\#}$ makes it possible to deduce from this homomorphism, by passing to the quotients, a monomorphism θ^x of the residue field $k(\psi(x))$ into the residue field $k(x)$ such that, for every section $f \in \Gamma(Y, \mathscr{O}_Y) = B$, we have $\theta^x(f(\psi(x))) = \varphi(f)(x)$. The relation $f(\psi(x)) = 0$ is therefore equivalent to $\varphi(f)(x) = 0$, which means that $\mathfrak{j}_{\psi(x)} = \mathfrak{j}_{{}^a\varphi(x)}$, which can also be written $\psi(x) = {}^a\varphi(x)$ for every $x \in X$, or $\psi = {}^a\varphi$. We also know that the diagram

$$\begin{array}{ccc} B = \Gamma(Y, \mathscr{O}_Y) & \xrightarrow{\varphi} & \Gamma(X, \mathscr{O}_X) = A \\ \downarrow & & \downarrow \\ B_{\psi(x)} & \xrightarrow[\theta_x^{\#}]{} & A_x \end{array}$$

is commutative (0, 3.7.2), which means that $\theta_x^{\#}$ is equal to the homomorphism $\varphi_x : B_{\psi(x)} \to A_x$ deduced canonically from φ (0, 1.5.1). Since the data of the $\theta_x^{\#}$ completely characterize $\theta^{\#}$, and consequently also θ (0, 3.7.1), we conclude that $\theta = \widetilde{\varphi}$, by definition of $\widetilde{\varphi}$ (1.6.1).

We shall say that a morphism (ψ, θ) of ringed spaces satisfying the condition of (1.7.3) is a *morphism of affine schemes*.

(1.7.4) Corollary. *If $(X, \mathscr{O}_X)$, $(Y, \mathscr{O}_Y)$ are two affine schemes, there exists a canonical isomorphism of the set of morphisms of affine schemes* $\mathrm{Hom}((X, \mathscr{O}_X), (Y, \mathscr{O}_Y))$ *onto the set of ring homomorphisms of B into A, where $A = \Gamma(\mathscr{O}_X)$ and $B = \Gamma(\mathscr{O}_Y)$.*

One can also say that the functors $(\mathrm{Spec}(A), \widetilde{A})$ in A and $\Gamma(X, \mathscr{O}_X)$ in $(X, \mathscr{O}_X)$ define an *equivalence* between the category of commutative rings and the category dual to the category of affine schemes (T, I, 1.2).

(1.7.5) Corollary. *If $\varphi : B \to A$ is surjective, the corresponding morphism $({}^a\varphi, \widetilde{\varphi})$ is a monomorphism of ringed spaces* (cf. (4.1.7)).

Indeed, we know that ${}^a\varphi$ is injective (1.2.5), and since φ is surjective, for every $x \in X$, $\varphi_x^{\#} : B_{{}^a\varphi(x)} \to A_x$, which is deduced from φ by passing to the rings of fractions, is also surjective (0, 1.5.1); whence the conclusion (0, 4.1.1).

§2 Preschemes and morphisms of preschemes

2.1 Definition of preschemes.

(2.1.1) Given a ringed space $(X, \mathscr{O}_X)$, we say that an open subset V of X is an *affine open set* if the ringed space $(V, \mathscr{O}_X|V)$ is an affine scheme (1.7.1).

(2.1.2) Definition. We call *prescheme* a ringed space $(X, \mathscr{O}_X)$ such that every point of X has an affine open neighbourhood.

[I | 98] **(2.1.3) Proposition.** *If $(X, \mathscr{O}_X)$ is a prescheme, the affine open sets form a base for the topology of X.*

Indeed, if V is an arbitrary open neighbourhood of $x \in X$, there exists by hypothesis an open neighbourhood W of x such that $(W, \mathscr{O}_X|W)$ is an affine scheme; let A denote its ring. In the space W, $V \cap W$ is an open neighbourhood of x; hence there exists $f \in A$ such that $D(f)$ is an open neighbourhood of x contained in $V \cap W$ (1.1.10 (i)). The ringed space $(D(f), \mathscr{O}_X|D(f))$ is then an affine scheme with ring isomorphic to A_f (1.3.6), whence the proposition.

(2.1.4) Proposition. *The underlying space of a prescheme is a Kolmogorov space.*

Indeed, if x, y are two distinct points of a prescheme X, it is obvious that there exists an open neighbourhood of one of these points not containing the other if x, y are not in one and the same affine open set; and if they are in one and the same affine open set, this follows from (1.1.8).

(2.1.5) Proposition. *If $(X, \mathscr{O}_X)$ is a prescheme, every irreducible closed subset of X has one and only one generic point, and the map $x \longmapsto \overline{\{x\}}$ is therefore a bijection of X onto the set of its irreducible closed subsets.*

Indeed, if Y is an irreducible closed subset of X and $y \in Y$, and if U is an affine open neighbourhood of y in X, $U \cap Y$ is dense in Y and is irreducible (0, 2.1.1 and 2.1.4); hence (1.1.14) $U \cap Y$ is the closure in U of a point x, and consequently $Y \subset \overline{U}$ is the closure of x in X. The uniqueness of the generic point of Y follows from (2.1.4) and from (0, 2.1.3).

(2.1.6) If Y is an irreducible closed subset of X and y its generic point, the local ring $\mathscr{O}_y$ is also denoted by $\mathscr{O}_{X/Y}$ and is called the *local ring of X along Y*, or the *local ring of Y in X*.

If X itself is irreducible and x is its generic point, we also say that $\mathscr{O}_x$ is the *ring of rational functions on X* (cf. § 7).

(2.1.7) Proposition. *If $(X, \mathscr{O}_X)$ is a prescheme, then for every open subset U of X, the ringed space $(U, \mathscr{O}_X|U)$ is a prescheme.*

This follows at once from Definition (2.1.2) and Proposition (2.1.3).

We say that $(U, \mathscr{O}_X|U)$ is the prescheme *induced* on U by $(X, \mathscr{O}_X)$, or the *restriction* of $(X, \mathscr{O}_X)$ to U.

(2.1.8) A prescheme $(X, \mathscr{O}_X)$ is said to be *irreducible* (resp. *connected*) if the underlying space X is irreducible (resp. connected). A prescheme is said to be *integral* if it is *irreducible and reduced* (cf. (5.1.4)). A prescheme $(X, \mathscr{O}_X)$ is said to be *locally integral* if every $x \in X$ has an open neighbourhood U such that the prescheme induced on U by $(X, \mathscr{O}_X)$ is integral.

2.2 Morphisms of preschemes.

(2.2.1) Definition. Given two preschemes $(X, \mathscr{O}_X)$, $(Y, \mathscr{O}_Y)$, we call *morphism (of preschemes)* of $(X, \mathscr{O}_X)$ into $(Y, \mathscr{O}_Y)$ every morphism of ringed spaces (ψ, θ) such that, for every $x \in X$, $\theta_x^\sharp$ is a local homomorphism: $\mathscr{O}_{\psi(x)} \longrightarrow \mathscr{O}_x$.

[I | 99] By passing to the quotients, the map $\theta_x^\sharp : \mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ therefore gives a monomorphism $\theta^x : k(\psi(x)) \to k(x)$, which makes it possible to regard $k(x)$ as an *extension* of the field $k(\psi(x))$.

(2.2.2) The composite (ψ'', θ'') of two morphisms of preschemes (ψ, θ) and (ψ', θ') is again a morphism of preschemes, as follows from the formula $\theta''^{\sharp} = \theta^{\sharp} \circ \psi^*(\theta'^{\sharp})$ (0, 3.5.5). We conclude that the preschemes form a *category*; in accordance with the general notation, we shall write $\mathrm{Hom}(X, Y)$ for the set of morphisms of a prescheme X into a prescheme Y.

(2.2.3) Example. If U is an open subset of X, the canonical injection (0, 4.1.2) of the induced prescheme $(U, \mathscr{O}_X|U)$ into $(X, \mathscr{O}_X)$ is a morphism of preschemes; it is moreover a *monomorphism* of ringed spaces (and *a fortiori* a monomorphism of preschemes), as follows at once from (0, 4.1.1).

(2.2.4) Proposition. *Let $(X, \mathscr{O}_X)$ be a prescheme and $(S, \mathscr{O}_S)$ an affine scheme with ring A. There is a canonical one-to-one correspondence between the morphisms of the prescheme $(X, \mathscr{O}_X)$ into the prescheme $(S, \mathscr{O}_S)$ and the homomorphisms of A into the ring $\Gamma(X, \mathscr{O}_X)$.*

Let us first note that, if $(X, \mathscr{O}_X)$ and $(Y, \mathscr{O}_Y)$ are two arbitrary ringed spaces, a morphism (ψ, θ) of $(X, \mathscr{O}_X)$ into $(Y, \mathscr{O}_Y)$ canonically defines a ring homomorphism $\Gamma(\theta) : \Gamma(Y, \mathscr{O}_Y) \to \Gamma(Y, \psi_*(\mathscr{O}_X)) = \Gamma(X, \mathscr{O}_X)$. In the case under consideration, everything comes down to showing that an arbitrary homomorphism $\varphi : A \to \Gamma(X, \mathscr{O}_X)$ is of the form $\Gamma(\theta)$ for one and only one θ. Now, by hypothesis there is a covering (V_α) of X by affine open sets; by composing φ with the restriction homomorphism $\Gamma(X, \mathscr{O}_X) \to \Gamma(V_\alpha, \mathscr{O}_X|V_\alpha)$, we obtain a homomorphism $\varphi_\alpha : A \to \Gamma(V_\alpha, \mathscr{O}_X|V_\alpha)$, which corresponds to a unique morphism $(\psi_\alpha, \theta_\alpha)$ of the prescheme $(V_\alpha, \mathscr{O}_X|V_\alpha)$ into $(S, \mathscr{O}_S)$, by virtue of (1.7.3). Moreover, for every pair of indices (α, β), every point of $V_\alpha \cap V_\beta$ has an affine open neighbourhood W contained in $V_\alpha \cap V_\beta$ (2.1.3); it is clear that by composing φ_α and φ_β with the restriction homomorphisms to W, we obtain the same homomorphism $\Gamma(S, \mathscr{O}_S) \to \Gamma(W, \mathscr{O}_X|W)$; hence, by virtue of the relations $(\theta_\alpha^\sharp)_x = (\varphi_\alpha)_x$ for every $x \in V_\alpha$ and every α (1.6.1), the restrictions to W of the morphisms $(\psi_\alpha, \theta_\alpha)$ and $(\psi_\beta, \theta_\beta)$ coincide. We conclude that there is one and only one morphism of ringed spaces $(\psi, \theta) : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ whose restriction to each V_α is $(\psi_\alpha, \theta_\alpha)$, and it is clear that this morphism is a morphism of preschemes and is such that $\Gamma(\theta) = \varphi$.

Let $u : A \to \Gamma(X, \mathscr{O}_X)$ be a ring homomorphism, and let $v = (\psi, \theta)$ be the corresponding morphism $(X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$. For every $f \in A$, we have

$$\psi^{-1}(D(f)) = X_{u(f)} \tag{2.2.4.1}$$

with the notation of (0, 5.5.2) relative to the locally free sheaf $\mathscr{O}_X$. Indeed, it suffices to verify this formula when X itself is affine, and then it is none other than (1.2.2.2).

(2.2.5) Proposition. *Under the hypotheses of (2.2.4), let $\varphi : A \to \Gamma(X, \mathscr{O}_X)$ be a ring homomorphism, $f : (X, \mathscr{O}_X) \to (S, \mathscr{O}_S)$ the corresponding morphism of preschemes, $\mathscr{G}$ (resp. $\mathscr{F}$) a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_S$-module), and let $M = \Gamma(S, \mathscr{F})$. There is then a canonical one-to-one correspondence between the f-morphisms $\mathscr{F} \to \mathscr{G}$* [I/100] *(0, 4.4.1) and the A-homomorphisms $M \to (\Gamma(X, \mathscr{G}))_{[\varphi]}$.*

Indeed, by reasoning as in (2.2.4), we are at once reduced to the case where X is affine, and the proposition then follows from (1.6.3) and (1.3.8).

(2.2.6) A morphism of preschemes $(\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ is said to be *open* (resp. *closed*) if for every open subset U of X (resp. every closed subset F of X), $\psi(U)$ is open in Y (resp. $\psi(F)$ is closed in Y). We say that (ψ, θ) is *dominant* if $\psi(X)$ is dense in Y, and *surjective* if ψ is surjective. Note that these conditions involve only the continuous map ψ.

(2.2.7) Proposition. *Let*

$$f = (\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y), \qquad g = (\psi', \theta') : (Y, \mathscr{O}_Y) \to (Z, \mathscr{O}_Z)$$

be two morphisms of preschemes.

(i) *If f and g are both open (resp. closed, dominant, surjective), so is $g \circ f$.*

(ii) *If f is surjective and $g \circ f$ is closed, g is closed.*

(iii) *If $g \circ f$ is surjective, g is surjective.*

Assertions (i) and (iii) are obvious. Set $g \circ f = (\psi'', \theta'')$. If F is closed in Y, $\psi^{-1}(F)$ is closed in X, hence $\psi''(\psi^{-1}(F))$ is closed in Z; but since ψ is surjective, $\psi(\psi^{-1}(F)) = F$, hence $\psi''(\psi^{-1}(F)) = \psi'(F)$, which proves (ii).

(2.2.8) Proposition. *Let $f = (\psi, \theta)$ be a morphism $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ and (U_α) an open covering of Y. For f to be open (resp. closed, surjective, dominant), it is necessary and sufficient that its restriction to each of the induced preschemes $(\psi^{-1}(U_\alpha), \mathscr{O}_X|\psi^{-1}(U_\alpha))$, regarded as a morphism of this induced prescheme into the induced prescheme $(U_\alpha, \mathscr{O}_Y|U_\alpha)$, be open (resp. closed, surjective, dominant).*

The proposition follows at once from the definitions, taking into account the fact that a subset F of Y is closed (resp. open, dense) in Y if and only if each of the sets $F \cap U_\alpha$ is closed (resp. open, dense) in U_α.

(2.2.9) Let $(X, \mathscr{O}_X)$, $(Y, \mathscr{O}_Y)$ be two preschemes; suppose that X and Y have the same *finite* number of irreducible components X_i (resp. Y_i) $(1 \leq i \leq n)$; let ξ_i (resp. η_i) be the generic point of X_i (resp. Y_i) (2.1.5). A morphism

$$f = (\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$$

is said to be *birational* if, for every i, $\psi^{-1}(\eta_i) = \{\xi_i\}$ and $\theta^\sharp_{\xi_i} : \mathscr{O}_{\eta_i} \to \mathscr{O}_{\xi_i}$ is an *isomorphism*. It is clear that a birational morphism is *dominant* (0, 2.1.8), and hence surjective if it is also closed.

(2.2.10) Notation. Throughout the rest of this work, and when this is not likely to cause confusion, we shall *suppress* from the notation for a prescheme (resp. a morphism) the structure sheaf (resp. the morphism of structure sheaves). If U is an open subset of the underlying space of a prescheme X, when we speak of U as a prescheme, it will always be the prescheme induced on U.

2.3 Gluing of preschemes

[I | 101] **(2.3.1)** It follows from Definition (2.1.2) that every ringed space obtained by *gluing* preschemes (0, 4.1.6) is again a prescheme. In particular, since every prescheme has by definition a covering consisting of affine open sets, we see that every prescheme can be obtained by *gluing affine schemes*.

(2.3.2) Example. Let K be a field, $B = K[s]$, $C = K[t]$ two polynomial rings in one indeterminate over K, and let $X_1 = \mathrm{Spec}(B)$, $X_2 = \mathrm{Spec}(C)$, which are two isomorphic affine schemes. In X_1 (resp. X_2), let U_{12} (resp. U_{21}) be the affine open set $D(s)$ (resp. $D(t)$), whose ring B_s (resp. C_t) consists of the rational fractions of the form $f(s)/s^m$ (resp. $g(t)/t^n$) with $f \in B$ (resp. $g \in C$). Let u_{12} be the isomorphism of preschemes

$U_{21} \to U_{12}$ corresponding (2.2.4) to the isomorphism of B_s onto C_t which maps $f(s)/s^m$ to the rational fraction $f(1/t)/(1/t^m)$. We can glue X_1 and X_2 along U_{12} and U_{21} by means of u_{12}, since there is obviously no gluing condition. We shall meet the prescheme X thus obtained again later, as a special case of a general method of construction (II, 2.4.3). Let us only show here that X *is not an affine scheme*; this will follow from the fact that the ring $\Gamma(X, \mathscr{O}_X)$ is *isomorphic* to K, and therefore has a spectrum consisting of a single point. Indeed, a section of $\mathscr{O}_X$ over X has a restriction over X_1 (resp. X_2), identified with an affine open set of X, which is a polynomial $f(s)$ (resp. $g(t)$), and it follows from the definitions that we must have $g(t) = f(1/t)$, which is possible only if $f = g \in K$.

2.4 Local schemes

(2.4.1) We call *local scheme* an affine scheme whose ring A is local; there is then in $X = \mathrm{Spec}(A)$ a single *closed point* a, and for every other point $b \in X$, we have $a \in \overline{\{b\}}$ (1.1.7).

For every prescheme Y and every point $y \in Y$, the local scheme $\mathrm{Spec}(\mathscr{O}_y)$ is called the *local scheme of* Y *at the point* y. Let V be an affine open set of Y containing y, and B the ring of the affine scheme V; $\mathscr{O}_y$ is canonically identified with B_y (1.3.4), and the canonical homomorphism $B \to B_y$ consequently corresponds (1.6.1) to a morphism of preschemes $\mathrm{Spec}(\mathscr{O}_y) \to V$. If we compose this morphism with the canonical injection $V \to Y$, we therefore obtain a morphism $\mathrm{Spec}(\mathscr{O}_y) \to Y$, which is *independent* of the affine open set V (containing y) chosen: indeed, if V' is a second affine open set containing y, there exists a third affine open set W containing y and such that $W \subset V \cap V'$ (2.1.3); we may therefore restrict ourselves to the case where $V \subset V'$, and if B' is the ring of V', everything comes down to observing that the diagram

$$\begin{array}{ccc} B' & \longrightarrow & B \\ & \searrow \quad \swarrow & \\ & \mathscr{O}_y & \end{array}$$

is commutative (0, 1.5.1). The morphism

$$\mathrm{Spec}(\mathscr{O}_y) \to Y$$

thus defined is called *canonical*.

(2.4.2) Proposition. *Let $(Y, \mathscr{O}_Y)$ be a prescheme; for every $y \in Y$, let (ψ, θ) be the canonical morphism $(\mathrm{Spec}(\mathscr{O}_y), \widetilde{\mathscr{O}}_y) \to (Y, \mathscr{O}_Y)$. Then ψ is a homeomorphism of $\mathrm{Spec}(\mathscr{O}_y)$ onto the subspace S_y of Y consisting of the z such that $y \in \overline{\{z\}}$ (in other words, of the generizations of y (0, 2.1.2)); moreover, if $z = \psi(\mathfrak{p})$, $\theta_z^\sharp : \mathscr{O}_z \to (\mathscr{O}_y)_\mathfrak{p}$ is an isomorphism; (ψ, θ) is therefore a monomorphism of ringed spaces.* [I/102]

Since the unique closed point a of $\mathrm{Spec}(\mathscr{O}_y)$ lies in the closure of every point of this space, and since $\psi(a) = y$, the image of $\mathrm{Spec}(\mathscr{O}_y)$ under the continuous map ψ is contained in S_y. Since S_y is contained in every affine open set containing y, we may reduce to the case where Y is an affine scheme; but in that case the proposition follows from (1.6.2).

We therefore see (2.1.5) that there is a one-to-one correspondence between $\mathrm{Spec}(\mathscr{O}_y)$ *and the set of irreducible closed subsets of* Y *containing* y.

(2.4.3) Corollary. *For $y \in Y$ to be the generic point of an irreducible component of Y, it is necessary and sufficient that the only prime ideal of the local ring $\mathscr{O}_y$ be its maximal ideal (in other words, that $\mathscr{O}_y$ be of dimension zero).*

(2.4.4) Proposition. *Let $(X, \mathscr{O}_X)$ be a local scheme with ring A, a its unique closed point, and $(Y, \mathscr{O}_Y)$ a prescheme. Every morphism $u = (\psi, \theta) : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ factors uniquely as $X \to \mathrm{Spec}(\mathscr{O}_{\psi(a)}) \to Y$, where the second arrow denotes the canonical morphism and the first corresponds to a local homomorphism $\mathscr{O}_{\psi(a)} \to A$. This establishes a canonical one-to-one correspondence between the set of morphisms $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ and the set of local homomorphisms $\mathscr{O}_y \to A$ $(y \in Y)$.*

Indeed, for every $x \in X$, we have $a \in \overline{\{x\}}$, hence $\psi(a) \in \overline{\{\psi(x)\}}$, which proves that $\psi(X)$ is contained in every affine open set containing $\psi(a)$. We may therefore reduce to the case where $(Y, \mathscr{O}_Y)$ is an affine scheme with ring B, and we then have $u = ({}^a\varphi, \widetilde{\varphi})$, where $\varphi \in \mathrm{Hom}(B, A)$ (1.7.3). Moreover, we have $\varphi^{-1}(\mathfrak{j}_a) = \mathfrak{j}_{\psi(a)}$, and consequently the image under φ of every element of $B - \mathfrak{j}_{\psi(a)}$ is invertible in the local ring A; the factorization in the statement therefore follows from the universal property of rings of fractions (0, 1.2.4). Conversely, to every local homomorphism $\mathscr{O}_y \to A$ there corresponds a unique morphism $(\psi, \theta) : X \to \mathrm{Spec}(\mathscr{O}_y)$ such that $\psi(a) = y$ (1.7.3), and by composing it with the canonical morphism $\mathrm{Spec}(\mathscr{O}_y) \to Y$, we obtain a morphism $X \to Y$, which completes the proof of the proposition.

(2.4.5) The affine schemes whose ring is a *field* K have an underlying space consisting of a single point. If A is a local ring with maximal ideal $\mathfrak{m}$, every local homomorphism $A \to K$ has kernel equal to $\mathfrak{m}$, and therefore factors as $A \to A/\mathfrak{m} \to K$, where the second arrow is a monomorphism. The morphisms $\mathrm{Spec}(K) \to \mathrm{Spec}(A)$ therefore correspond one-to-one to the monomorphisms of fields $A/\mathfrak{m} \to K$.

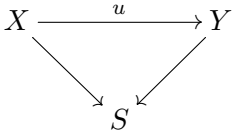
Let $(Y, \mathscr{O}_Y)$ be a prescheme; for every $y \in Y$ and every ideal $\mathfrak{a}_y$ of $\mathscr{O}_y$, the canonical homomorphism $\mathscr{O}_y \to \mathscr{O}_y/\mathfrak{a}_y$ defines a morphism $\mathrm{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to \mathrm{Spec}(\mathscr{O}_y)$; if we compose it with the canonical morphism $\mathrm{Spec}(\mathscr{O}_y) \to Y$, we obtain a morphism $\mathrm{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to Y$, also called *canonical*. For $\mathfrak{a}_y = \mathfrak{m}_y$, that is to say $\mathscr{O}_y/\mathfrak{a}_y = k(y)$, Proposition (2.4.4) therefore implies:

[I / 103] **(2.4.6) Corollary.** *Let $(X, \mathscr{O}_X)$ be a local scheme whose ring is a field K, ξ the unique point of X, and $(Y, \mathscr{O}_Y)$ a prescheme. Every morphism $u : (X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ factors uniquely as $X \to \mathrm{Spec}(k(\psi(\xi))) \to Y$, where the second arrow denotes the canonical morphism and the first corresponds to a monomorphism $k(\psi(\xi)) \to K$. This establishes a canonical one-to-one correspondence between the set of morphisms $(X, \mathscr{O}_X) \to (Y, \mathscr{O}_Y)$ and the set of monomorphisms $k(y) \to K$ $(y \in Y)$.*

(2.4.7) Corollary. *For every $y \in Y$, every canonical morphism $\mathrm{Spec}(\mathscr{O}_y/\mathfrak{a}_y) \to Y$ is a monomorphism of ringed spaces.*

We have already seen this when $\mathfrak{a}_y = 0$ (2.4.2), and it suffices to apply (1.7.5).

(2.4.8) Remark. Let X be a local scheme and a its unique closed point. Since every affine open set containing a is necessarily the whole of X, every *invertible* $\mathscr{O}_X$-module (0, 5.4.1) is necessarily *isomorphic to* $\mathscr{O}_X$ (or, as one also says, is *trivial*). This property does not hold in general for an arbitrary affine scheme $\mathrm{Spec}(A)$; we shall see in Chapter V that if A is a normal ring, it holds when A is *factorial*.



2.5 Preschemes over a prescheme

(2.5.1) Definition. Given a prescheme S, we say that the data of a prescheme X and of a morphism of preschemes $\varphi : X \to S$ define a prescheme X *over the prescheme* S, or an *S-prescheme*; we say that S is the *base prescheme* of the S-prescheme X. The morphism φ is called the *structural morphism* of the S-prescheme X. When S is an affine scheme with ring A, we also say that X endowed with φ is a prescheme over the ring A (or an A-prescheme).

It follows from (2.2.4) that giving a prescheme over a ring A is equivalent to giving a prescheme $(X, \mathscr{O}_X)$ whose structure sheaf $\mathscr{O}_X$ is a sheaf of *A-algebras. An arbitrary prescheme can therefore always be regarded in a unique way as a* **Z***-prescheme.*

If $\varphi : X \to S$ is the structural morphism of an S-prescheme X, we say that a point $x \in X$ *lies over a point* $s \in S$ if $\varphi(x) = s$. We say that X *dominates* S if φ is a dominant morphism (2.2.6).

(2.5.2) Let X, Y be two S-preschemes; we say that a morphism of preschemes $u : X \to Y$ is a *morphism of preschemes over* S (or an *S-morphism*) if the diagram

(where the oblique arrows are the structural morphisms) is commutative: this implies that for every $s \in S$ and every $x \in X$ lying over s, $u(x)$ must also lie over s.

This definition shows at once that the composite of two S-morphisms is an S-morphism; the S-preschemes therefore form a *category*.

We shall denote by $\mathrm{Hom}_S(X, Y)$ the set of S-morphisms of an S-prescheme X into an S-prescheme Y; the identity morphism of an S-prescheme X will be denoted by 1_X.

When S is an affine scheme with ring A, we shall also say *A-morphism* instead of S-morphism.

(2.5.3) If X is an S-prescheme and $v : X' \to X$ a morphism of preschemes, the composite morphism $X' \xrightarrow{v} X \to S$ defines X' as an S-prescheme; in particular, every prescheme induced on an open set U of X can be regarded as an S-prescheme by means of the canonical injection. [I | 104]

If $u : X \to Y$ is an S-morphism of S-preschemes, the restriction of u to every prescheme induced on an open set U of X is therefore an S-morphism $U \to Y$. Conversely, let (U_α) be an open covering of X and, for each α, let $u_\alpha : U_\alpha \to Y$ be an S-morphism; if, for every pair of indices (α, β), the restrictions of u_α and of u_β to $U_\alpha \cap U_\beta$ coincide, there exists one and only one S-morphism $X \to Y$ whose restriction to each U_α is u_α.

If $u : X \to Y$ is an S-morphism such that $u(X) \subset V$, where V is an open subset of Y, then u, regarded as a morphism of X into V, is again an S-morphism.

(2.5.4) Let $S' \to S$ be a morphism of preschemes; for every S'-prescheme, the composite morphism $X \to S' \to S$ defines X as an S-prescheme. Conversely, suppose that S' is the prescheme induced on an open subset of S; let X be an S-prescheme, and suppose that the structural morphism $f : X \to S$ is such that $f(X) \subset S'$; then X can be regarded as an S'-prescheme. In this latter case, if Y is an S-prescheme whose structural morphism also maps the underlying space into S', every S-morphism of X into Y is also an S'-morphism.

(2.5.5) If X is an S-prescheme and $\varphi : X \to S$ the structural morphism, we call an *S-section of X* an S-morphism of S into X, that is to say, a morphism of preschemes $\psi : S \to X$ such that $\varphi \circ \psi$ is the identity of S. We denote by $\Gamma(X/S)$ the set of S-sections of X.

§3 Product of preschemes

3.1 Sum of preschemes.

Let (X_α) be an arbitrary family of preschemes; let X be a topological space which is the *sum* of the underlying spaces X_α; X is then the union of pairwise disjoint open subspaces X'_α, and for each α there is a homeomorphism φ_α of X_α onto X'_α. If each of the X'_α is endowed with the sheaf $(\varphi_\alpha)_*(\mathscr{O}_{X_\alpha})$, it is clear that X becomes a prescheme, which is called the *sum* of the family of preschemes (X_α) and which is denoted by $\bigsqcup_\alpha X_\alpha$. If Y is a prescheme, the map $f \mapsto (f \circ \varphi_\alpha)$ is a *bijection* of the set $\mathrm{Hom}(X, Y)$ onto the product set $\prod_\alpha \mathrm{Hom}(X_\alpha, Y)$. In particular, if the X_α are S-preschemes, with structural morphisms ψ_α, X is an S-prescheme by means of the unique morphism $\psi : X \to S$ such that $\psi \circ \varphi_\alpha = \psi_\alpha$ for all α. The sum of two preschemes X, Y is denoted by $X \sqcup Y$. It is immediate that if $X = \mathrm{Spec}(A)$, $Y = \mathrm{Spec}(B)$, then $X \sqcup Y$ is canonically identified with $\mathrm{Spec}(A \times B)$.

3.2 Product of preschemes.

(3.2.1) Definition. Given two S-preschemes X, Y, we say that a triple (Z, p_1, p_2) consisting of an S-prescheme Z and of two S-morphisms $p_1 : Z \to X$, $p_2 : Z \to Y$
[I | 105] is a product of the S-preschemes X and Y if, for every S-prescheme T, the map $f \mapsto (p_1 \circ f, p_2 \circ f)$ is a bijection of the set of S-morphisms from T to Z onto the set of pairs consisting of an S-morphism $T \to X$ and an S-morphism $T \to Y$ (in other words, a bijection

$$\mathrm{Hom}_S(T, Z) \xrightarrow{\sim} \mathrm{Hom}_S(T, X) \times \mathrm{Hom}_S(T, Y)).$$

This is therefore the general notion of the *product* of two objects of a category, applied to the category of S-preschemes (T, I, 1.1); in particular, a product of two S-preschemes is *unique* up to a unique S-isomorphism. Because of this uniqueness, a product of two S-preschemes X, Y is most often denoted by $X \times_S Y$ (or simply $X \times Y$ if no confusion is to be feared), the morphisms p_1, p_2 (called the *canonical projections* of $X \times_S Y$ to X and Y respectively) being omitted from the notation. If $g : T \to X$, $h : T \to Y$ are two S-morphisms, we shall denote by $(g, h)_S$, or simply (g, h), the S-morphism $f : T \to X \times_S Y$ such that $p_1 \circ f = g$, $p_2 \circ f = h$. If X', Y' are two S-preschemes, p'_1, p'_2 the canonical projections of $X' \times_S Y'$ (assumed to exist), and $u : X' \to X$, $v : Y' \to Y$ two S-morphisms, we shall write $u \times_S v$ (or simply $u \times v$) for the S-morphism $(u \circ p'_1, v \circ p'_2)_S$ from $X' \times_S Y'$ to $X \times_S Y$.

When S is an affine scheme with ring A, we often replace S by A in the preceding notation.

(3.2.2) Proposition. *Let X, Y, S be three affine schemes, and B, C, A their respective rings. Let $Z = \mathrm{Spec}(B \otimes_A C)$, and let p_1, p_2 be the S-morphisms corresponding (2.2.4) to the canonical A-homomorphisms $u : b \mapsto b \otimes 1$ and $v : c \mapsto 1 \otimes c$ of B and C into $B \otimes_A C$; then (Z, p_1, p_2) is a product of X and Y.*

By virtue of (2.2.4), everything comes down to verifying that if, to every A-homomorphism $f : B \otimes_A C \to L$ (where L is an A-algebra), we associate the pair $(f \circ u, f \circ v)$, we define a bijection

$$\mathrm{Hom}_A(B \otimes_A C, L) \xrightarrow{\sim} \mathrm{Hom}_A(B, L) \times \mathrm{Hom}_A(C, L)^{31},$$

which follows immediately from the definitions and from the relation $b \otimes c = (b \otimes 1)(1 \otimes c)$.

(3.2.3) Corollary. *Let T be an affine scheme with ring D, and $\alpha = ({}^a\rho, \widetilde{\rho})$ (resp. $\beta = ({}^a\sigma, \widetilde{\sigma})$) an S-morphism $T \to X$ (resp. $T \to Y$), where ρ (resp. σ) is an A-homomorphism of B (resp. C) into D; then $(\alpha, \beta)_S = ({}^a\tau, \widetilde{\tau})$, where τ is the homomorphism $B \otimes_A C \to D$ such that $\tau(b \otimes c) = \rho(b)\sigma(c)$.*

(3.2.4) Proposition. *Let $f : S' \to S$ be a monomorphism of preschemes (T, I, 1.1), and X, Y two S'-preschemes, which are also regarded as S-preschemes by means of f. Then every product of the S-preschemes X, Y is a product of the S'-preschemes X, Y, and conversely.*

Let $\varphi : X \to S'$, $\psi : Y \to S'$ be the structural morphisms. If T is an S-prescheme and $u : T \to X$, $v : T \to Y$ are two S-morphisms, we have by definition $f \circ \varphi \circ u = f \circ \psi \circ v = \theta$, the structural morphism of T; the hypothesis on f implies $\varphi \circ u = \psi \circ v = \theta'$, and we see that we can regard T as an S'-prescheme with structural morphism θ', and u and v as S'-morphisms. The conclusion of the proposition follows immediately, taking into account (3.2.1).

(3.2.5) Corollary. *Let X, Y be two S-preschemes, $\varphi : X \to S$, $\psi : Y \to S$ their structural morphisms, and S' an open subset of S such that $\varphi(X) \subset S'$, $\psi(Y) \subset S'$. Every product of the S-preschemes X, Y is also a product of the S'-preschemes X, Y, and conversely.*

It suffices to apply (3.2.4) to the canonical injection $S' \to S$. [I | 106]

(3.2.6) Theorem. *Given two S-preschemes X, Y, there exists a product $X \times_S Y$.*

We shall proceed in several steps.

(3.2.6.1) Lemma. *Let (Z, p, q) be a product of X and Y, and U, V open subsets of X, Y respectively. If we set $W = p^{-1}(U) \cap q^{-1}(V)$, the triple consisting of W and of the restrictions of p and q to W* (regarded as morphisms $W \to U$, $W \to V$ respectively) *is a product of U and V.*

Indeed, if T is an S-prescheme, we can identify the S-morphisms $T \to W$ with the S-morphisms $T \to Z$ mapping T into W. If then $g : T \to U$, $h : T \to V$ are two arbitrary S-morphisms, we can regard them as S-morphisms of T into X and Y respectively, and by hypothesis there is therefore one and only one S-morphism $f : T \to Z$ such that $g = p \circ f$, $h = q \circ f$. Since $p(f(T)) \subset U$, $q(f(T)) \subset V$, we have

$$f(T) \subset p^{-1}(U) \cap q^{-1}(V) = W,$$

whence our assertion.

(3.2.6.2) Lemma. *Let Z be an S-prescheme, $p : Z \to X$, $q : Z \to Y$ two S-morphisms, (U_α) an open covering of X, and (V_λ) an open covering of Y. Suppose that for every pair (α, λ), the S-prescheme $W_{\alpha\lambda} = p^{-1}(U_\alpha) \cap q^{-1}(V_\lambda)$ and the restrictions of p and q to $W_{\alpha\lambda}$ constitute a product of U_α and V_λ. Then (Z, p, q) is a product of X and Y.*

[31] The notation Hom_A here denotes the set of homomorphisms of A-algebras.

Let us first show that, if f_1, f_2 are two S-morphisms $T \to Z$, the relations $p \circ f_1 = p \circ f_2$ and $q \circ f_1 = q \circ f_2$ imply $f_1 = f_2$. Indeed, Z is the union of the $W_{\alpha\lambda}$, so the $f_1^{-1}(W_{\alpha\lambda})$ form an open covering of T, and the same holds for the $f_2^{-1}(W_{\alpha\lambda})$. Moreover, we have

$$\begin{aligned} f_1^{-1}(W_{\alpha\lambda}) &= f_1^{-1}(p^{-1}(U_\alpha)) \cap f_1^{-1}(q^{-1}(V_\lambda)) \\ &= f_2^{-1}(p^{-1}(U_\alpha)) \cap f_2^{-1}(q^{-1}(V_\lambda)) = f_2^{-1}(W_{\alpha\lambda}) \end{aligned}$$

by hypothesis, and everything comes down to seeing that the restrictions of f_1 and f_2 to $f_1^{-1}(W_{\alpha\lambda}) = f_2^{-1}(W_{\alpha\lambda})$ are identical for every pair of indices. But since these restrictions can be regarded as S-morphisms of $f_1^{-1}(W_{\alpha\lambda})$ into $W_{\alpha\lambda}$, our assertion follows from the hypotheses and from Definition (3.2.1).

Suppose now that two S-morphisms $g : T \to X$, $h : T \to Y$ are given. Set $T_{\alpha\lambda} = g^{-1}(U_\alpha) \cap h^{-1}(V_\lambda)$; the $T_{\alpha\lambda}$ form an open covering of T. By hypothesis, there exists an S-morphism $f_{\alpha\lambda}$ such that $p \circ f_{\alpha\lambda}$ and $q \circ f_{\alpha\lambda}$ are the respective restrictions of g and h to $T_{\alpha\lambda}$. Moreover, let us show that the restrictions of $f_{\alpha\lambda}$ and $f_{\beta\mu}$ to $T_{\alpha\lambda} \cap T_{\beta\mu}$ coincide, which will complete the proof of (3.2.6.2). Now, the images of $T_{\alpha\lambda} \cap T_{\beta\mu}$ under $f_{\alpha\lambda}$ and under $f_{\beta\mu}$ are contained in $W_{\alpha\lambda} \cap W_{\beta\mu}$ by definition. Since

$$W_{\alpha\lambda} \cap W_{\beta\mu} = p^{-1}(U_\alpha \cap U_\beta) \cap q^{-1}(V_\lambda \cap V_\mu),$$

it follows from (3.2.6.1) that $W_{\alpha\lambda} \cap W_{\beta\mu}$ and the restrictions of p and q to this prescheme constitute a product of $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$. Since $p \circ f_{\alpha\lambda}$ and $p \circ f_{\beta\mu}$ coincide in $T_{\alpha\lambda} \cap T_{\beta\mu}$ and the same holds for $q \circ f_{\alpha\lambda}$ and $q \circ f_{\beta\mu}$, we see that $f_{\alpha\lambda}$ and $f_{\beta\mu}$ coincide in $T_{\alpha\lambda} \cap T_{\beta\mu}$, Q.E.D.

[I | 107] **(3.2.6.3) Lemma.** *Let (U_α) be an open covering of X, (V_λ) an open covering of Y, and suppose that for every pair (α, λ) there exists a product of U_α and V_λ; then there exists a product of X and Y.*

Applying Lemma (3.2.6.1) to the open sets $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$, we see that there exists a product of the S-preschemes induced by X and Y respectively on these open sets; moreover, the uniqueness of the product shows that, if we set $i = (\alpha, \lambda)$, $j = (\beta, \mu)$, there is a canonical isomorphism h_{ij} (resp. h_{ji}) of this product onto an S-prescheme W_{ij} (resp. W_{ji}) induced by $U_\alpha \times_S V_\lambda$ (resp. $U_\beta \times_S V_\mu$) on an open set; $f_{ij} = h_{ij} \circ h_{ji}^{-1}$ is therefore an isomorphism of W_{ji} onto W_{ij}. Moreover, for a third pair $k = (\gamma, \nu)$, we have $f_{ik} = f_{ij} \circ f_{jk}$ in $W_{ki} \cap W_{kj}$, as follows from applying (3.2.6.1) to the open sets $U_\alpha \cap U_\beta \cap U_\gamma$ and $V_\lambda \cap V_\mu \cap V_\nu$, in U_β and V_μ respectively. Consequently there exist a prescheme Z, an open covering (Z_i) of the underlying space of Z and, for each i, an isomorphism g_i of the induced prescheme Z_i onto the prescheme $U_\alpha \times_S V_\lambda$, such that for every pair (i, j) we have $f_{ij} = g_i \circ g_j^{-1}$ (2.3.1); moreover, we have $g_i(Z_i \cap Z_j) = W_{ij}$. If p_i, q_i, θ_i are the projections and the structural morphism of the S-prescheme $U_\alpha \times_S V_\lambda$, one verifies at once that $p_i \circ g_i = p_j \circ g_j$ in $Z_i \cap Z_j$, and likewise for the two other morphisms. We can therefore define morphisms of preschemes $p : Z \to X$ (resp. $q : Z \to Y$, $\theta : Z \to S$) by the condition that p (resp. q, θ) coincides with $p_i \circ g_i$ (resp. $q_i \circ g_i$, $\theta_i \circ g_i$) in each of the Z_i; Z, endowed with θ, is then an S-prescheme. Let us now show that $Z_i' = p^{-1}(U_\alpha) \cap q^{-1}(V_\lambda)$ is equal to Z_i. For every index $j = (\beta, \mu)$, we have $Z_j \cap Z_i' = g_j^{-1}(p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda))$. Now,

$$p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda) = p_j^{-1}(U_\alpha \cap U_\beta) \cap q_j^{-1}(V_\lambda \cap V_\mu) \ ;$$

by virtue of (3.2.6.1), the restrictions of p_j and q_j to $p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda)$ define on this S-prescheme a structure of product of $U_\alpha \cap U_\beta$ and $V_\lambda \cap V_\mu$; but the uniqueness of the product then implies that $p_j^{-1}(U_\alpha) \cap q_j^{-1}(V_\lambda) = W_{ji}$. Consequently we have $Z_j \cap Z_i' = Z_j \cap Z_i$ for

all j, whence $Z'_i = Z_i$. We then deduce from (3.2.6.2) that (Z, p, q) is a product of X and Y.

(3.2.6.4) Lemma. *Let $\varphi : X \to S$, $\psi : Y \to S$ be the structural morphisms of X and Y, (S_i) an open covering of S, and set $X_i = \varphi^{-1}(S_i)$, $Y_i = \psi^{-1}(S_i)$. If each of the products $X_i \times_S Y_i$ exists, then $X \times_S Y$ exists.*

By (3.2.6.3), everything comes down to proving that the products $X_i \times_S Y_j$ exist for all i and j. Set $X_{ij} = X_i \cap X_j = \varphi^{-1}(S_i \cap S_j)$, $Y_{ij} = Y_i \cap Y_j = \psi^{-1}(S_i \cap S_j)$; by virtue of (3.2.6.1), the product $Z_{ij} = X_{ij} \times_S Y_{ij}$ exists. Now note that if T is an S-prescheme and $g : T \to X_i$, $h : T \to Y_j$ are S-morphisms, we necessarily have $\varphi(g(T)) = \psi(h(T)) \subset S_i \cap S_j$, by the definition of an S-morphism, hence $g(T) \subset X_{ij}$ and $h(T) \subset Y_{ij}$; it is then immediate that Z_{ij} is a product of X_i and Y_j.

(3.2.6.5) We can now complete the proof of Theorem (3.2.6). If S is an *affine scheme*, there are coverings (U_α), (V_λ) of X and Y respectively, consisting of affine open sets; since $U_\alpha \times_S V_\lambda$ exists by virtue of (3.2.2), the same holds for $X \times_S Y$ by (3.2.6.3). If S is an arbitrary prescheme, there is a covering (S_i) of S consisting of affine open sets. If $\varphi : X \to S$, $\psi : Y \to S$ are the structural morphisms, and if we set $X_i = \varphi^{-1}(S_i)$, $Y_i = \psi^{-1}(S_i)$, the products $X_i \times_{S_i} Y_i$ exist by the foregoing; but then the products $X_i \times_S Y_i$ also exist (3.2.5), hence the same holds for $X \times_S Y$ by (3.2.6.4). [I | 108]

(3.2.7) Corollary. *Let $Z = X \times_S Y$ be the product of two S-preschemes, p, q the projections of Z to X and Y, and φ (resp. ψ) the structural morphism of X (resp. Y). Let S' be an open subset of S, and U (resp. V) an open subset of X (resp. Y) contained in $\varphi^{-1}(S')$ (resp. $\psi^{-1}(S')$). Then the product $U \times_{S'} V$ is canonically identified with the prescheme induced by Z on $p^{-1}(U) \cap q^{-1}(V)$ (regarded as an S'-prescheme). Moreover, if $f : T \to X$, $g : T \to Y$ are S-morphisms such that $f(T) \subset U$, $g(T) \subset V$, the S'-morphism $(f, g)_{S'}$ is identified with the restriction of $(f, g)_S$ to $p^{-1}(U) \cap q^{-1}(V)$.*

This follows from (3.2.5) and (3.2.6.1).

(3.2.8) Let (X_α), (Y_λ) be two families of S-preschemes, and X (resp. Y) the sum of the family (X_α) (resp. (Y_λ)) (3.1). Then $X \times_S Y$ is identified with the *sum* of the family $(X_\alpha \times_S Y_\lambda)$; this follows at once from (3.2.6.3).

3.3 Formal properties of the product; change of base prescheme.

(3.3.1) The reader will note that all the properties stated in this section, except (3.3.13), (3.3.15) and the assertion about sums in the last sentence of (3.3.10), are valid without modification in *every category*, whenever the products which occur in the statements *exist* (for it is clear that the notions of S-object and of S-morphism can be defined exactly as in (2.5) for every object S of the category).

(3.3.2) In the first place, $X \times_S Y$ is a *covariant bifunctor* in X and Y on the category of S-preschemes: indeed, it suffices to note that the diagram

$$\begin{array}{ccccc} X \times Y & \xrightarrow{f\times 1} & X' \times Y & \xrightarrow{f'\times 1} & X'' \times Y \\ \downarrow & & \downarrow & & \downarrow \\ X & \xrightarrow[f]{} & X' & \xrightarrow[f']{} & X'' \end{array}$$

is commutative.

(3.3.3) Proposition. *For every S-prescheme X, the first (resp. second) projection of $X \times_S S$ (resp. $S \times_S X$) is a functorial isomorphism of $X \times_S S$ (resp. $S \times_S X$) onto X, whose inverse isomorphism is $(1_X, \varphi)_S$ (resp. $(\varphi, 1_X)_S$), where φ denotes the structural morphism $X \to S$; we can therefore write, up to canonical isomorphism,*

$$X \times_S S = S \times_S X = X.$$

It suffices to prove that the triple $(X, 1_X, \varphi)$ is a product of X and S. Now, if T is an S-prescheme, the only S-morphism of T into S is necessarily the structural morphism $\psi : T \to S$. If f is an S-morphism of T into X, we necessarily have $\psi = \varphi \circ f$, whence our assertion.

(3.3.4) Corollary. *Let X, Y be two S-preschemes, and $\varphi : X \to S$, $\psi : Y \to S$ their structural morphisms. If X is canonically identified with $X \times_S S$ and Y with $S \times_S Y$, the projections $X \times_S Y \to X$ and $X \times_S Y \to Y$ are identified with $1_X \times \psi$ and $\varphi \times 1_Y$ respectively.*

The verification is immediate and is left to the reader.

[I | 109] **(3.3.5)** One can define, in the same way as in (3.2), the product of an arbitrary finite number n of S-preschemes; the existence of these products follows from (3.2.6) by induction on n, noting that $(X_1 \times_S X_2 \times_S \cdots \times_S X_{n-1}) \times_S X_n$ satisfies the definition of the product. The uniqueness of the product implies, as in every category, its *commutativity* and *associativity* properties. If, for example, p_1, p_2, p_3 denote the projections of $X_1 \times_S X_2 \times_S X_3$, and if this prescheme is identified with $(X_1 \times_S X_2) \times_S X_3$, the projection to $X_1 \times_S X_2$ is identified with $(p_1, p_2)_S$.

(3.3.6) Let S, S' be two preschemes, and $\varphi : S' \to S$ a morphism, which makes S' an S-prescheme. For every S-prescheme X, consider the product $X \times_S S'$, and let p and π' be its projections to X and S' respectively. Endowed with π', this product is an S'-prescheme; when it is regarded as such, it is denoted by $X_{(S')}$ or $X_{(\varphi)}$, and it is said to be the prescheme obtained by *extension of the base prescheme* from S to S', by means of the morphism φ, or the *inverse image* of X under φ. Note that if π is the structural morphism of X and θ the structural morphism of $X \times_S S'$ regarded as an S-prescheme, the diagram

$$\begin{array}{ccc} X & \xleftarrow{p} & X_{(S')} \\ {\scriptstyle\pi}\downarrow & \swarrow{\scriptstyle\theta} & \downarrow{\scriptstyle\pi'} \\ S & \xleftarrow[\varphi]{} & S' \end{array}$$

is commutative.

(3.3.7) With the notation of (3.3.6), for every S-morphism $f : X \to Y$, we also denote by $f_{(S')}$ the S'-morphism $f \times_S 1 : X_{(S')} \to Y_{(S')}$, and we say that $f_{(S')}$ is the *inverse image* of the morphism f under φ. $X_{(S')}$ is therefore a *covariant functor* in X, from the category of S-preschemes to that of S'-preschemes.

(3.3.8) The prescheme $X_{(S')}$ can also be regarded as the solution of a *universal mapping problem*: every S'-prescheme T is also an S-prescheme by means of φ; every S-morphism $g : T \to X$ can then be written in one and only one way as $g = p \circ f$, where f is an S'-morphism $T \to X_{(S')}$, as follows from the definition of the product applied to the S-morphisms g and $\psi : T \to S'$ (the structural morphism of T).

(3.3.9) Proposition. ("transitivity of the extension of base preschemes"). *Let S'' be a prescheme and $\varphi' : S'' \to S'$ a morphism. For every S-prescheme X, there exists a canonical functorial isomorphism of the S''-prescheme $(X_{(\varphi)})_{(\varphi')}$ onto the S''-prescheme $X_{(\varphi\circ\varphi')}$.*

Indeed, let T be an S''-prescheme, ψ its structural morphism, and g an S-morphism of T into X (T being regarded as an S-prescheme with structural morphism $\varphi\circ\varphi'\circ\psi$). Since T is also an S'-prescheme with structural morphism $\varphi'\circ\psi$, we can write $g = p\circ g'$, where g' is an S'-morphism $T \to X_{(\varphi)}$, and then $g' = p'\circ g''$, where g'' is an S''-morphism $T \to (X_{(\varphi)})_{(\varphi')}$:

$$\begin{array}{ccccc} X & \xleftarrow{p} & X_{(\varphi)} & \xleftarrow{p'} & (X_{(\varphi)})_{(\varphi')} \\ \downarrow{\scriptstyle\pi} & & \downarrow{\scriptstyle\pi'} & & \downarrow{\scriptstyle\pi''} \\ S & \xleftarrow[\varphi]{} & S' & \xleftarrow[\varphi']{} & S'' \end{array}$$

Whence the proposition, because of the uniqueness of the solution of a universal mapping problem. [I | 110]

This result can also be expressed by writing the equality (up to canonical isomorphism) $(X_{(S')})_{(S'')} = X_{(S'')}$, if no confusion is to be feared, or also

$$(X \times_S S') \times_{S'} S'' = X \times_S S'' \ ; \tag{3.3.9.1}$$

the functorial character of the isomorphism defined in (3.3.9) is likewise expressed by the formula of *transitivity of inverse images of morphisms*

$$(f_{(S')})_{(S'')} = f_{(S'')} \tag{3.3.9.2}$$

for every S-morphism $f : X \to Y$.

(3.3.10) Corollary. *If X and Y are two S-preschemes, there exists a canonical functorial isomorphism of the S'-prescheme $X_{(S')} \times_{S'} Y_{(S')}$ onto the S'-prescheme $(X \times_S Y)_{(S')}$.*

Indeed, we have, up to canonical isomorphisms,

$$(X \times_S S') \times_{S'} (Y \times_S S') = X \times_S (Y \times_S S') = (X \times_S Y) \times_S S'$$

by virtue of (3.3.9.1) and of the associativity of products of S-preschemes.

The functorial character of the isomorphism defined in (3.3.10) is expressed by the formula

$$(u_{(S')}, v_{(S')})_{S'} = ((u, v)_S)_{(S')} \tag{3.3.10.1}$$

for every pair of S-morphisms $u : T \to X$, $v : T \to Y$.

In other words, the inverse image functor $X_{(S')}$ *commutes with the formation of products*; it also commutes with the formation of sums (3.2.8).

(3.3.11) Corollary. *Let Y be an S-prescheme, and $f : X \to Y$ a morphism which makes X a Y-prescheme (and consequently also an S-prescheme). The prescheme $X_{(S')}$ is then identified with the product $X \times_Y Y_{(S')}$, the projection $X \times_Y Y_{(S')} \to Y_{(S')}$ being identified with $f_{(S')}$.*

Let $\psi : Y \to S$ be the structural morphism of Y; we have the commutative diagram

$$\begin{array}{ccccc} S' & \xleftarrow{\psi_{(S')}} & Y_{(S')} & \xleftarrow{f_{(S')}} & X_{(S')} \\ \downarrow & & \downarrow & & \downarrow \\ S & \xleftarrow[\psi]{} & Y & \xleftarrow[f]{} & X \end{array}$$

Now $Y_{(S')}$ is identified with $S'_{(\psi)}$, and $X_{(S')}$ with $S'_{(\psi\circ f)}$; taking into account (3.3.9) and (3.3.4), the corollary follows.

(3.3.12) Let $f : X \to X'$, $g : Y \to Y'$ be two S-morphisms which are *monomorphisms* of preschemes (T, I, 1.1); then $f \times_S g$ is a *monomorphism*. Indeed, if p and q are the projections of $X \times_S Y$, p', q' those of $X' \times_S Y'$, and u, v two S-morphisms $T \to X \times_S Y$, the relation $(f \times_S g) \circ u = (f \times_S g) \circ v$ implies $p' \circ (f \times_S g) \circ u = p' \circ (f \times_S g) \circ v$, in other words $f \circ p \circ u = f \circ p \circ v$, and since f is a monomorphism, $p \circ u = p \circ v$; using the
[I | 111] fact that g is a monomorphism, we likewise obtain $q \circ u = q \circ v$, whence $u = v$. It follows that for every extension $S' \to S$ of the base prescheme,

$$f_{(S')} : X_{(S')} \to X'_{(S')}$$

is a monomorphism.

(3.3.13) Let S, S' be two affine schemes with respective rings A, A'; a morphism $S' \to S$ therefore corresponds to a ring homomorphism $A \to A'$. If X is an S-prescheme, we shall then also denote by $X_{(A')}$ or $X \otimes_A A'$ the S'-prescheme $X_{(S')}$; when X is itself affine with ring B, $X_{(A')}$ is affine with ring $B_{(A')} = B \otimes_A A'$, obtained by extending to A' the ring of scalars of the A-algebra B.

(3.3.14) With the notation of (3.3.6), for every *S-morphism* $f : S' \to X$, $f' = (f, 1_{S'})_S$ is an S'-morphism $S' \to X' = X_{(S')}$ such that $p \circ f' = f$, $\pi' \circ f' = 1_{S'}$, in other words an *S'-section of X'*; and conversely, if f' is such an S'-section, $f = p \circ f'$ is an S-morphism $S' \to X$. We thus define a canonical *one-to-one correspondence*

$$\mathrm{Hom}_S(S', X) \xrightarrow{\sim} \mathrm{Hom}_{S'}(S', X').$$

We say that f' is the *graph morphism* of f, and we denote it by Γ_f.

(3.3.15) Given a prescheme X, which can always be regarded as a $\mathbf{Z}$-prescheme, it follows in particular from (3.3.14) that the X-sections of $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (where T is an indeterminate) correspond one-to-one to the *morphisms* $X \to \mathbf{Z}[T]$. Let us show that these X-sections also correspond one-to-one to the *sections of the structure sheaf $\mathcal{O}_X$ over X*. Indeed, let (U_α) be a covering of X by affine open sets; let $u : X \to X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ be an X-morphism and let u_α be its restriction to U_α; if A_α is the ring of the affine scheme U_α, $U_\alpha \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ is an affine scheme with ring $A_\alpha[T]$ (3.2.2), and u_α corresponds canonically to an A_α-homomorphism $A_\alpha[T] \to A_\alpha$ (1.7.3). Now, such a homomorphism is completely determined by giving the image of T in A_α, say $s_\alpha \in A_\alpha = \Gamma(U_\alpha, \mathcal{O}_X)$, and if we express that the restrictions of u_α and of u_β to an affine open set $V \subset U_\alpha \cap U_\beta$ coincide, we see at once that s_α and s_β coincide in V; hence the family (s_α) consists of the restrictions to the U_α of a section s of $\mathcal{O}_X$ over X; and conversely, it is clear that such a section defines a family (u_α) of morphisms which are the restrictions to the U_α of an X-morphism $X \to X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$. This result will be generalized in II, 1.7.12.

3.4 Points of a prescheme with values in a prescheme; geometric points

(3.4.1) Let X be a prescheme; for every prescheme T, we also denote by $X(T)$ the set $\mathrm{Hom}(T, X)$ of morphisms $T \to X$, and the elements of this set are also called *points of X with values in T*. If to every morphism $f : T \to T'$ we associate the map $u' \mapsto u' \circ f$ of $X(T')$ into $X(T)$, we see that, for fixed X, $X(T)$ is a *contravariant functor in T*, from the category of preschemes to that of sets. Moreover, every morphism of preschemes

$g : X \to Y$ defines a functorial homomorphism $X(T) \to Y(T)$, which assigns $g \circ v$ to $v \in X(T)$.

(3.4.2) Given three sets P, Q, R and two maps $\varphi : P \to R$, $\psi : Q \to R$, we give the name *fibre product of P and Q over R* (relative to φ and ψ) to the subset of the [I | 112] product set $P \times Q$ consisting of the pairs (p, q) such that $\varphi(p) = \psi(q)$; it is denoted by $P \times_R Q$. Definition (3.2.1) of the product of S-preschemes can also be interpreted, with the notation of (3.4.1), by the formula

$$(X \times_S Y)(T) = X(T) \times_{S(T)} Y(T) \tag{3.4.2.1}$$

the maps $X(T) \to S(T)$ and $Y(T) \to S(T)$ corresponding to the structural morphisms $X \to S$ and $Y \to S$.

(3.4.3) If we are given a prescheme S and consider only S-preschemes and S-morphisms, we shall also denote by $X(T)_S$ the set $\mathrm{Hom}_S(T, X)$ of S-morphisms $T \to X$, allowing ourselves to omit the subscript S when no confusion is possible; we also say that the elements of $X(T)_S$ are the *points* (or *S-points* when confusions are to be feared) *of the S-prescheme X with values in the S-prescheme T*. In particular, an *S-section* of X is nothing but a *point of X with values in S*. Formula (3.4.2.1) can then also be written

$$(X \times_S Y)(T)_S = X(T)_S \times Y(T)_S \ ; \tag{3.4.3.1}$$

more generally, if Z is an S-prescheme and X, Y, T are Z-preschemes (hence *ipso facto* S-preschemes), we have

$$(X \times_Z Y)(T)_S = X(T)_S \times_{Z(T)_S} Y(T)_S. \tag{3.4.3.2}$$

Note that in order to prove that a triple (W, r, s) consisting of an S-prescheme W and of two S-morphisms $r : W \to X$, $s : W \to Y$ is a product of X and Y (over Z), it suffices by definition to verify that for *every S-prescheme T*, the diagram

$$\begin{array}{ccc} W(T)_S & \xrightarrow{r'} & X(T)_S \\ {\scriptstyle s'}\downarrow & & \downarrow{\scriptstyle \varphi'} \\ Y(T)_S & \xrightarrow[\psi']{} & Z(T)_S \end{array}$$

makes $W(T)_S$ the fibre product of $X(T)_S$ and $Y(T)_S$ over $Z(T)_S$, r' and s' corresponding to r and s, and φ' and ψ' to the structural morphisms $\varphi : X \to Z$, $\psi : Y \to Z$.

(3.4.4) When, in the above, T (resp. S) is an affine scheme with ring B (resp. A), we replace T (resp. S) by B (resp. A) in the preceding notation, and we then speak of *points of X with values in the ring B*, or of *points of the A-prescheme X with values in the A-algebra B*, for the elements of $X(B)$ and of $X(B)_A$ respectively. Note that $X(B)$ and $X(B)_A$ are now functors *covariant in B*. We shall likewise write $X(T)_A$ for the set of points of the A-prescheme X with values in the A-prescheme T.

(3.4.5) Consider in particular the case where T is of the form $\mathrm{Spec}(A)$, where A is a *local* ring; the elements of $X(A)$ then correspond one-to-one to the *local* homomorphisms $\mathcal{O}_x \to A$ for $x \in X$ (2.4.4); we say that the point x of the underlying space of X is the *locality* of the point of X with values in A to which it corresponds.

More particularly, we shall call *geometric points* of a prescheme X the *points of X*
[I | 113] *with values in a field K*: giving such a point therefore amounts to giving its locality x in the underlying space of X and an *extension* K of $k(x)$; K will be called the *field of values* of the corresponding geometric point, and we also say that this geometric point is *localized at x*. We thus define a map $X(K) \to X$, sending a geometric point with values in K to its locality.

If $S' = \mathrm{Spec}(K)$ is an S-prescheme (in other words, if K is regarded as an extension of a residue field $k(s)$, where $s \in S$) and if X is an S-prescheme, an element of $X(K)_S$, or, as one also says, a *geometric point of X over s with values in K*, consists of giving a $k(s)$-monomorphism of a residue field $k(x)$ into K, where x is a point of X *over* s (hence $k(x)$ an extension of $k(s)$).

More particularly, if $S = \mathrm{Spec}(K) = \{\xi\}$, *the geometric points of X with values in K are identified with the points $x \in X$ such that $k(x) = K$*; we also say that the latter are the *points of the K-prescheme X rational over K*; if K' is an extension of K, the geometric points of X with values in K' therefore correspond one-to-one to the points of $X' = X_{(K')}$ rational over K' (3.3.14).

(3.4.6) Lemma. *Let X_i $(1 \leq i \leq n)$ be S-preschemes, s a point of S, and x_i $(1 \leq i \leq n)$ a point of X_i over s. Then there exist an extension K of $k(s)$ and a geometric point of the product $Y = X_1 \times_S X_2 \times_S \cdots \times_S X_n$, with values in K, whose projections are localized at the x_i.*

Indeed, there exist $k(s)$-monomorphisms $k(x_i) \to K$ into one and the same extension K of $k(s)$ (Bourbaki, *Alg.*, Chap. V, § 4, Prop. 2). The composites $k(s) \to k(x_i) \to K$ are all identical, so the morphisms $\mathrm{Spec}(K) \to X_i$ corresponding to $k(x_i) \to K$ are S-morphisms, and we conclude that they define a unique morphism $\mathrm{Spec}(K) \to Y$. If y is the corresponding point of Y, it is clear that its projection to each of the X_i is x_i.

(3.4.7) Proposition. *Let X_i $(1 \leq i \leq n)$ be S-preschemes, and for each index i, let x_i be a point of X_i. For there to exist a point y of $Y = X_1 \times_S X_2 \times_S \cdots \times_S X_n$ whose projection of index i is x_i for $1 \leq i \leq n$, it is necessary and sufficient that the x_i lie over one and the same point s of S.*

The condition is obviously necessary; Lemma (3.4.6) proves that it is sufficient.

In other words, if (X) denotes the underlying set of X, we see that there is a canonical *surjective* map $(X \times_S Y) \to (X) \times_{(S)} (Y)$; it should be noted that this map *is not injective* in general; in other words, *there can exist several distinct points z in $X \times_S Y$ having the same projections $x \in X$, $y \in Y$*; this can already be seen when S, X, Y are prime spectra of fields k, K, K', since the tensor product $K \otimes_k K'$ in general has several distinct prime ideals (cf. 3.4.9).

(3.4.8) Corollary. *Let $f : X \to Y$ be an S-morphism, and $f_{(S')} : X_{(S')} \to Y_{(S')}$ the S'-morphism deduced from f by an extension $S' \to S$ of the base prescheme. Let p (resp. q) be the projection $X_{(S')} \to X$ (resp. $Y_{(S')} \to Y$); for every subset M of X, we have*

$$q^{-1}(f(M)) = f_{(S')}(p^{-1}(M)).$$

[I | 114] Indeed (3.3.11), $X_{(S')}$ is identified with the product $X \times_Y Y_{(S')}$ by means of the commutative diagram

$$\begin{array}{ccc} X & \xleftarrow{p} & X_{(S')} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f_{(S')}} \\ Y & \xleftarrow[q]{} & Y_{(S')} \end{array}$$

By virtue of (3.4.7), the relation $q(y') = f(x)$ for $x \in M$, $y' \in Y_{(S')}$ is equivalent to the existence of an $x' \in X_{(S')}$ such that $p(x') = x$ and $f_{(S')}(x') = y'$, whence the corollary.

Lemma (3.4.6) can be made more precise as follows:

(3.4.9) Proposition. *Let X, Y be two S-preschemes, x a point of X, and y a point of Y, lying over the same point $s \in S$. The set of points of $X \times_S Y$ having x and y as projections is in canonical one-to-one correspondence with the set of types of composite extensions of $k(x)$ and $k(y)$, regarded as extensions of $k(s)$ (Bourbaki,* Alg.*, Chap. VIII, § 8, Prop. 2).*

Let p (resp. q) be the projection of $X \times_S Y$ to X (resp. Y) and let E be the subspace $p^{-1}(x) \cap q^{-1}(y)$ of the underlying space of $X \times_S Y$. Note first that the morphisms $\mathrm{Spec}(k(x)) \to S$ and $\mathrm{Spec}(k(y)) \to S$ factorize as $\mathrm{Spec}(k(x)) \to \mathrm{Spec}(k(s)) \to S$ and $\mathrm{Spec}(k(y)) \to \mathrm{Spec}(k(s)) \to S$; since $\mathrm{Spec}(k(s)) \to S$ is a monomorphism (2.4.7), it follows from (3.2.4) that we have

$$P = \mathrm{Spec}(k(x)) \times_S \mathrm{Spec}(k(y)) = \mathrm{Spec}(k(x)) \times_{\mathrm{Spec}(k(s))} \mathrm{Spec}(k(y)) = \mathrm{Spec}\big(k(x) \otimes_{k(s)} k(y)\big).$$

We shall define two maps $\alpha : P_0 \to E$, $\beta : E \to P_0$, inverse to each other (P_0 denoting the underlying set of the prescheme P). If $i : \mathrm{Spec}(k(x)) \to X$ and $j : \mathrm{Spec}(k(y)) \to Y$ are the canonical morphisms (2.4.5), we take for α the map of underlying spaces corresponding to the morphism $i \times_S j$. On the other hand, every $z \in E$ defines by hypothesis two $k(s)$-monomorphisms $k(x) \to k(z)$ and $k(y) \to k(z)$, hence a tensor product $k(s)$-homomorphism $k(x) \otimes_{k(s)} k(y) \to k(z)$ and consequently a morphism $\mathrm{Spec}(k(z)) \to P$; $\beta(z)$ will be the image of z in P_0 under this morphism. The verification that $\alpha \circ \beta$ and $\beta \circ \alpha$ are the identity maps follows from (2.4.5) and from the definition of the product (3.2.1). Finally, we know that P_0 is in one-to-one correspondence with the set of types of composite extensions of $k(x)$ and $k(y)$ (Bourbaki, *Alg.*, Chap. VIII, § 8, Prop. 1).

3.5 Surjections and injections

(3.5.1) In general, consider a property **P** of morphisms of preschemes, and the following two propositions:

(i) If $f : X \to X'$, $g : Y \to Y'$ are two S-morphisms having property **P**, then $f \times_S g$ has property **P**.

(ii) If $f : X \to Y$ is an S-morphism having property **P**, every S'-morphism $f_{(S')} : X_{(S')} \to Y_{(S')}$ deduced from f by extension of the base prescheme has property **P**.

Since $f_{(S')} = f \times_S 1_{S'}$, we see that if for every prescheme X the *identity* 1_X has property **P**, then (i) implies (ii); since, on the other hand, $f \times_S g$ is the composite morphism [I | 115]

$$X \times_S Y \xrightarrow{f \times 1_Y} X' \times_S Y \xrightarrow{1_{X'} \times g} X' \times_S Y'$$

we see that if the *composite* of two morphisms having property **P** also has this property, then (ii) implies (i).

A first application of this remark is the following

(3.5.2) Proposition.

(i) If $f : X \to X'$, $g : Y \to Y'$ are surjective S-morphisms, then $f \times_S g$ is surjective.

(ii) If $f : X \to Y$ is a surjective S-morphism, then $f_{(S')}$ is surjective for every extension S' of the base prescheme.

Since the composite of two surjections is a surjection, it suffices to prove (ii); but this proposition follows at once from (3.4.8) applied to $M = X$.

(3.5.3) Proposition. *For a morphism $f : X \to Y$ to be surjective, it is necessary and sufficient that for every field K and every morphism $\mathrm{Spec}(K) \to Y$, there exist an extension K' of K and a morphism $\mathrm{Spec}(K') \to X$ making the diagram*

$$\begin{array}{ccc} X & \longleftarrow & \mathrm{Spec}(K') \\ {\scriptstyle f}\downarrow & & \downarrow \\ Y & \longleftarrow & \mathrm{Spec}(K) \end{array}$$

commutative.

The condition is sufficient, since for every $y \in Y$ it suffices to apply it to a morphism $\mathrm{Spec}(K) \to Y$ corresponding to a monomorphism $k(y) \to K$, K being an extension of $k(y)$ (2.4.6). Conversely, suppose f surjective, and let $y \in Y$ be the image of the unique point of $\mathrm{Spec}(K)$; there exists $x \in X$ such that $f(x) = y$; consider the corresponding monomorphism $k(y) \to k(x)$ (2.2.1); it then suffices to take for K' an extension of $k(y)$ such that there exist $k(y)$-monomorphisms of $k(x)$ and of K into K' (Bourbaki, *Alg.*, Chap. V, § 4, Prop. 2); the morphism $\mathrm{Spec}(K') \to X$ corresponding to $k(x) \to K'$ answers the question.

In the language introduced in (3.4.5), we can also say that *every geometric point of Y with values in K comes from a geometric point of X with values in an extension of K.*

(3.5.4) Definition. A morphism of preschemes $f : X \to Y$ is said to be *universally injective*, or a *radicial morphism*, if for every field K, the corresponding map $X(K) \to Y(K)$ is injective.

It follows at once from the definitions that every *monomorphism of preschemes* (T, 1.1) is radicial.

(3.5.5) For a morphism $f : X \to Y$ to be radicial, it suffices that the condition of Definition (3.5.4) be satisfied for every *algebraically closed* field. Indeed, if K is an arbitrary field and K' an algebraically closed extension of K, the diagram

$$\begin{array}{ccc} X(K) & \xrightarrow{\alpha} & Y(K) \\ {\scriptstyle \varphi}\downarrow & & \downarrow{\scriptstyle \varphi'} \\ X(K') & \xrightarrow[\alpha']{} & Y(K') \end{array}$$

[I | 116] is commutative, φ and φ' coming from the morphism $\mathrm{Spec}(K') \to \mathrm{Spec}(K)$, and α and α' corresponding to f. Now, φ is injective, and so is α' by hypothesis; hence α is necessarily injective.

(3.5.6) Proposition. *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms of preschemes.*

(i) If f and g are radicial, so is $g \circ f$.

(ii) Conversely, if $g \circ f$ is radicial, so is f.

Taking into account Definition (3.5.4), the proposition reduces to the corresponding assertions for the maps $X(K) \to Y(K) \to Z(K)$, which are obvious.

(3.5.7) Proposition.

(i) If the S-morphisms $f : X \to X'$, $g : Y \to Y'$ are radicial, so is $f \times_S g$.

(ii) If the S-morphism $f : X \to Y$ is radicial, so is $f_{(S')} : X_{(S')} \to Y_{(S')}$ for every extension $S' \to S$ of the base prescheme.

In view of (3.5.1), it suffices to prove (i). We have seen (3.4.2.1) that

$$(X \times_S Y)(K) = X(K) \times_{S(K)} Y(K), \qquad (X' \times_S Y')(K) = X'(K) \times_{S(K)} Y'(K)$$

the map $(X \times_S Y)(K) \to (X' \times_S Y')(K)$ corresponding to $f \times_S g$ is then identified with $(u, v) \mapsto (f \circ u, g \circ v)$, and the proposition follows at once.

(3.5.8) Proposition. *For a morphism $f = (\psi, \theta) : X \to Y$ to be radicial, it is necessary and sufficient that ψ be injective and that, for every $x \in X$, the monomorphism $\theta^x : k(\psi(x)) \to k(x)$ make $k(x)$ a radicial extension of $k(\psi(x))$.*

Suppose f radicial, and let us first show that the relation $\psi(x_1) = \psi(x_2) = y$ necessarily implies $x_1 = x_2$. Indeed, there exist a field K, an extension of $k(y)$, and $k(y)$-monomorphisms $k(x_1) \to K$, $k(x_2) \to K$ (Bourbaki, *Alg.*, Chap. V, § 4, Prop. 2); the corresponding morphisms $u_1 : \mathrm{Spec}(K) \to X$, $u_2 : \mathrm{Spec}(K) \to X$ are therefore such that $f \circ u_1 = f \circ u_2$, hence $u_1 = u_2$ by hypothesis, and this implies in particular $x_1 = x_2$. Now regard $k(x)$ as an extension of $k(\psi(x))$ by means of θ^x: if $k(x)$ is not a radicial extension of $k(\psi(x))$, there exist two distinct $k(\psi(x))$-monomorphisms of $k(x)$ into an algebraically closed extension K of $k(\psi(x))$, and the two corresponding morphisms $\mathrm{Spec}(K) \to X$ would violate the hypothesis. Conversely, taking into account (2.4.6), it is immediate that the conditions of the statement are sufficient for f to be radicial.

(3.5.9) Corollary. *If A is a ring and S a multiplicative subset of A, the canonical morphism $\mathrm{Spec}(S^{-1}A) \to \mathrm{Spec}(A)$ is radicial.*

Indeed, this morphism is a monomorphism (1.6.2).

(3.5.10) Corollary. *Let $f : X \to Y$ be a radicial morphism, $g : Y' \to Y$ a morphism, and let $X' = X_{(Y')} = X \times_Y Y'$. Then the radicial morphism $f_{(Y')}$ (3.5.7 (ii)) is a bijection of the underlying space X' onto $g^{-1}(f(X))$; moreover, for every field K, the set $X'(K)$ is identified with the subset of $Y'(K)$ which is the inverse image, under the map $Y'(K) \to Y(K)$ (corresponding to g), of the subset $X(K)$ of $Y(K)$.*

The first assertion follows at once from (3.5.8) and from (3.4.8); the second, from the commutativity of the diagram [I | 117]

$$\begin{array}{ccc} X'(K) & \longrightarrow & Y'(K) \\ \downarrow & & \downarrow \\ X(K) & \longrightarrow & Y(K) \end{array}$$

(3.5.11) Remark. We shall say that a morphism $f = (\psi, \theta)$ of preschemes is *injective* if the map ψ is injective. For a morphism $f = (\psi, \theta) : X \to Y$ to be radicial, it is necessary and sufficient that for every morphism $Y' \to Y$, the morphism $f_{(Y')} : X_{(Y')} \to Y'$ be injective (which justifies the terminology of *universally injective* morphism). Indeed, the condition is necessary by virtue of (3.5.7, (ii)) and of (3.5.8). Conversely, the condition first implies that ψ is injective; if for some $x \in X$ the monomorphism $\theta^x : k(\psi(x)) \to k(x)$ were not radicial, there would be an extension K of $k(\psi(x))$ and two distinct morphisms $\mathrm{Spec}(K) \to X$ corresponding to the same morphism $\mathrm{Spec}(K) \to Y$ (3.5.8). But then, on setting $Y' = \mathrm{Spec}(K)$, there would be two distinct Y'-sections of $X_{(Y')}$ (3.3.14), which contradicts the hypothesis that $f_{(Y')}$ is injective.

3.6 Fibres.

(3.6.1) Proposition. *Let $f : X \to Y$ be a morphism, y a point of Y, and $\mathfrak{a}_y$ an ideal of definition of $\mathcal{O}_y$ for the $\mathfrak{m}_y$-preadic topology. The projection $p : X \times_Y \mathrm{Spec}(\mathcal{O}_y/\mathfrak{a}_y) \to X$ is a homeomorphism of the underlying space of the prescheme $X \times_Y \mathrm{Spec}(\mathcal{O}_y/\mathfrak{a}_y)$ onto the fibre $f^{-1}(y)$ endowed with the topology induced by that of the underlying space of X.*

Since $\mathrm{Spec}(\mathcal{O}_y/\mathfrak{a}_y) \to Y$ is radicial (3.5.4 and 2.4.7) and $\mathrm{Spec}(\mathcal{O}_y/\mathfrak{a}_y)$ is reduced to a single point, the ideal $\mathfrak{m}_y/\mathfrak{a}_y$ being nilpotent by hypothesis (1.1.12), we already know (3.5.10 and 3.3.4) that p identifies, *as a set*, the underlying space of $X \times_Y \mathrm{Spec}(\mathcal{O}_y/\mathfrak{a}_y)$ with $f^{-1}(y)$; everything comes down to proving that p is a homeomorphism. By virtue of (3.2.7), the question is local on X and Y, and we may therefore assume that $X = \mathrm{Spec}(B)$, $Y = \mathrm{Spec}(A)$, B being an A-algebra. The morphism p then corresponds to the homomorphism $1 \otimes \varphi : B \to B \otimes_A A'$, where $A' = A_y/\mathfrak{a}_y$ and φ is the canonical map of A into A'. Now, every element of $B \otimes_A A'$ can be written

$$\sum_i b_i \otimes \varphi(a_i)/\varphi(s) = \left(\sum_i (a_i b_i \otimes 1)\right)(1 \otimes \varphi(s))^{-1},$$

where $s \notin \mathfrak{j}_y$, and Proposition (1.2.4) is applicable.

(3.6.2) Throughout the rest of this Treatise, when we regard a fibre $f^{-1}(y)$ of a morphism as endowed with a structure of $k(y)$-prescheme, *it will always be the prescheme obtained by transporting the structure of $X \times_Y \mathrm{Spec}(k(y))$ by the projection to X.* We shall also write this last product as $X \otimes_Y k(y)$, or $X \otimes_{\mathcal{O}_Y} k(y)$; more generally, if B is an $\mathcal{O}_y$-algebra, we shall denote by $X \otimes_Y B$ or $X \otimes_{\mathcal{O}_Y} B$ the product $X \times_Y \mathrm{Spec}(B)$.

With the preceding convention, it follows from (3.5.10) that the points of X with values in an extension K of $k(y)$ are identified with the *points of $f^{-1}(y)$ with values in K*.

(3.6.3) Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, and $h = g \circ f$ their composite; for every $z \in Z$, the fibre $h^{-1}(z)$ is a prescheme isomorphic to

$$X \times_Z \mathrm{Spec}(k(z)) = (X \times_Y Y) \times_Z \mathrm{Spec}(k(z)) = X \times_Y g^{-1}(z)$$

[I | 118] In particular, if U is an open subset of X, the prescheme induced on $U \cap f^{-1}(y)$ by the prescheme $f^{-1}(y)$ is isomorphic to $f_U^{-1}(y)$ (f_U being the restriction of f to U).

(3.6.4) Proposition ("transitivity of fibres"). *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms; set $X' = X \times_Y Y' = X_{(Y')}$, and $f' = f_{(Y')} : X' \to Y'$. For every $y' \in Y'$, if we set $y = g(y')$, the prescheme $f'^{-1}(y')$ is isomorphic to $f^{-1}(y) \otimes_{k(y)} k(y')$.*

Indeed, this amounts to noting that the two preschemes $(X \otimes_Y k(y)) \otimes_{k(y)} k(y')$ and $(X \times_Y Y') \otimes_{Y'} k(y')$ are both canonically isomorphic to $X \times_Y \mathrm{Spec}(k(y'))$ by (3.3.9.1).

In particular, if V is an open neighbourhood of y in Y, and if f_V denotes the restriction of f to the prescheme induced on $f^{-1}(V)$, the preschemes $f^{-1}(y)$ and $f_V^{-1}(y)$ are canonically identified.

(3.6.5) Proposition. *Let $f : X \to Y$ be a morphism, y a point of Y, Z the local prescheme $\mathrm{Spec}(\mathcal{O}_y)$, and $p = (\psi, \theta)$ the projection $X \times_Y Z \to X$; then p is a homeomorphism of the underlying space of $X \times_Y Z$ onto the subspace $f^{-1}(Z)$ of X (when the underlying space of Z is identified with a subspace of Y, cf. (2.4.2)), and for every $t \in X \times_Y Z$, if we set $z = \psi(t)$, $\theta_t^\sharp$ is an isomorphism of $\mathcal{O}_z$ onto $\mathcal{O}_t$.*

Since Z (identified with a subspace of Y) is contained in every affine open set containing y (2.4.2), we can, as in (3.6.1), reduce to the case where $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$ are affine schemes, A being a B-algebra. Then $X \times_Y Z$ is the prime spectrum of $A \otimes_B B_y$, and this ring is canonically identified with $S^{-1}A$, where S is the image of $B - \mathfrak{j}_y$ in A (0, 1.5.2); since p then corresponds to the canonical homomorphism $A \to S^{-1}A$, the proposition follows from (1.6.2).

3.7 Application: reduction of a prescheme mod. $\mathfrak{J}$[32]

(3.7.1) Let A be a ring, X an A-prescheme, and $\mathfrak{J}$ an ideal of A; then $X_0 = X \otimes_A (A/\mathfrak{J})$ is an $(A/\mathfrak{J})$-prescheme, which is sometimes said to be deduced from X by *reduction* mod. $\mathfrak{J}$.

(3.7.2) This terminology is used above all when A is a *local ring* and $\mathfrak{J}$ its maximal ideal, so that X_0 is a prescheme over the residue field $k = A/\mathfrak{J}$ of A.

When moreover A is an integral domain, with field of fractions K, one can also consider the K-prescheme $X' = X \otimes_A K$. By an abuse of language which we shall not use, it was customary until now to say that X_0 is *deduced from* X' by reduction mod. $\mathfrak{J}$. In the cases where this language was used, A was a local ring of dimension 1 (most often a discrete valuation ring), and it was understood (more or less explicitly) that the given K-prescheme X' was a closed sub-prescheme of a K-prescheme P' (in fact, a standard projective space $\mathbf{P}^r_K$, cf. II, 4.1.1), itself of the form $P' = P \otimes_A K$, where P is a given A-prescheme (in fact, the A-scheme $\mathbf{P}^r_A$, with the notation of II, 4.1.1). In our language, the definition of X_0 in terms of X' is formulated as follows:

Consider the affine scheme $Y = \mathrm{Spec}(A)$, consisting of two points, the unique closed [I | 119]
point $y = \mathfrak{J}$ and the generic point (0), the set U reduced to the generic point therefore being an open set $U = \mathrm{Spec}(K)$ in Y. If X is an A-prescheme (in other words a Y-prescheme), $X \otimes_A K = X'$ is nothing but the prescheme induced by X on $\psi^{-1}(U)$, where ψ denotes the structural morphism $X \to Y$. In particular, if φ is the structural morphism $P \to Y$, a closed sub-prescheme X' of $P' = \varphi^{-1}(U)$ is therefore a (locally closed) sub-prescheme of P. If P is Noetherian (for example if A is Noetherian and P is of finite type over A), there exists a smallest closed sub-prescheme $X = \overline{X'}$ of P which majorizes X' (9.5.10), and X' is the prescheme induced by X on the open set $\varphi^{-1}(U) \cap X$, hence is isomorphic to $X \otimes_A K$ (9.5.10). *The immersion of X' into $P' = P \otimes_A K$ therefore makes it possible to regard X' canonically as being of the form $X' = X \otimes_A K$, where X is an A-prescheme.* One can then consider the prescheme reduced mod. $\mathfrak{J}$, $X_0 = X \otimes_A k$, which is moreover nothing but the fibre $\psi^{-1}(y)$ of the closed point y. Until now, for lack of an adequate terminology, one had avoided introducing the A-prescheme X explicitly. It should however be noted that all the assertions usually made about the prescheme "reduced mod. $\mathfrak{J}$" X_0 must be regarded as consequences of more complete assertions concerning X itself, and can be formulated and understood satisfactorily only by interpreting them in this way. It seems moreover that the hypotheses made always amount to hypotheses on X itself (independently of an immersion of X' into a $\mathbf{P}^r_K$ being given beforehand), which makes it possible to give more intrinsic statements.

(3.7.3) Finally, let us point out a very special fact, which has no doubt contributed to delaying the conceptual clarification of the situation considered here: if A is a discrete

[32] This subsection, which makes use of notions and results from the rest of Chapter I and from Chapter II, will not be used in the sequel, and is intended only for readers familiar with classical algebraic geometry.

valuation ring and X is *proper over* A (which is in fact the case if X is a closed subprescheme of a $\mathbf{P}^r_A$, cf. II, 5.5.4), the points of X with values in A and the points of X' with values in K are in one-to-one correspondence (II, 7.3.8). This is why one has often believed oneself to be proving results concerning X', whereas in reality one was proving statements concerning X, which remain valid (in this form) when the local base ring is no longer assumed to be of dimension 1.

§4 Subpreschemes and immersion morphisms

4.1 Subpreschemes.

(4.1.1) Since the notion of quasi-coherent sheaf (0, 5.1.3) is local, a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on a prescheme X can be defined by the condition that, for every affine open set V of X, $\mathscr{F}|V$ is isomorphic to a sheaf associated with a $\Gamma(V, \mathscr{O}_X)$-module (1.4.1). It is clear that, on a prescheme X, the structure sheaf $\mathscr{O}_X$ is quasi-coherent, and that kernels, cokernels and images of homomorphisms of quasi-coherent $\mathscr{O}_X$-modules, and inductive limits and direct sums of quasi-coherent $\mathscr{O}_X$-modules, are quasi-coherent (1.3.7 and 1.3.9).

(4.1.2) Proposition. *Let X be a prescheme, and $\mathscr{I}$ a quasi-coherent sheaf of ideals in $\mathscr{O}_X$. Then the support Y of the sheaf $\mathscr{O}_X/\mathscr{I}$ is closed, and if we denote by $\mathscr{O}_Y$ the restriction of $\mathscr{O}_X/\mathscr{I}$ to Y, $(Y, \mathscr{O}_Y)$ is a prescheme.*

[I | 120] It obviously suffices (2.1.3) to consider the case where X is an affine scheme, and to show that in this case Y is closed in X and is an *affine scheme*. Indeed, if $X = \mathrm{Spec}(A)$, we have $\mathscr{O}_X = \widetilde{A}$ and $\mathscr{I} = \widetilde{\mathfrak{I}}$, where $\mathfrak{I}$ is an ideal of A (1.4.1); Y is then equal to the closed subset $V(\mathfrak{I})$ of X and is identified with the prime spectrum of the ring $B = A/\mathfrak{I}$ (1.1.11); moreover, if φ is the canonical homomorphism $A \to B = A/\mathfrak{I}$, the direct image ${}^a\varphi_*(\widetilde{B})$ is canonically identified with the sheaf $\widetilde{A}/\widetilde{\mathfrak{I}} = \mathscr{O}_X/\mathscr{I}$ (1.6.3 and 1.3.9), which completes the proof.

We shall say that $(Y, \mathscr{O}_Y)$ is the *sub-prescheme* of $(X, \mathscr{O}_X)$ *defined by the sheaf of ideals* $\mathscr{I}$; this is a special case of the general notion of *sub-prescheme*:

(4.1.3) Definition. A ringed space $(Y, \mathscr{O}_Y)$ is said to be a *sub-prescheme* of a prescheme $(X, \mathscr{O}_X)$ if:

1° Y is a locally closed subspace of X;

2° If U denotes the largest open set of X containing Y and such that Y is closed in U (in other words, the complement in X of the boundary of Y relative to $\overline{Y}$), $(Y, \mathscr{O}_Y)$ is a sub-prescheme of $(U, \mathscr{O}_X|U)$ defined by a quasi-coherent sheaf of ideals of $\mathscr{O}_X|U$.

The sub-prescheme $(Y, \mathscr{O}_Y)$ of $(X, \mathscr{O}_X)$ is said to be *closed* if Y is closed in X (in which case $U = X$).

It follows at once from this definition and from (4.1.2) that the closed sub-preschemes of X are in *canonical one-to-one correspondence* with the quasi-coherent sheaves of ideals $\mathscr{J}$ of $\mathscr{O}_X$, since the fact that two such sheaves $\mathscr{J}$, $\mathscr{J}'$ have the same (closed) support Y and are such that the restrictions of $\mathscr{O}_X/\mathscr{J}$ and of $\mathscr{O}_X/\mathscr{J}'$ to Y are identical implies at once that $\mathscr{J}' = \mathscr{J}$.

(4.1.4) Let $(Y, \mathscr{O}_Y)$ be a sub-prescheme of X, U the largest open set of X containing Y and in which Y is closed, and V an open set of X contained in U; then $V \cap Y$ is closed

in V. Moreover, if Y is defined by the quasi-coherent sheaf $\mathscr{J}$ of ideals of $\mathscr{O}_X|U$, then $\mathscr{J}|V$ is a quasi-coherent sheaf of ideals of $\mathscr{O}_X|V$, and it is immediate that the prescheme induced by Y on $Y \cap V$ is the closed sub-prescheme of V defined by the sheaf of ideals $\mathscr{J}|V$. Conversely:

(4.1.5) Proposition. *Let $(Y, \mathscr{O}_Y)$ be a ringed space such that Y is a subspace of X and such that there exists a covering (V_α) of Y by open sets of X such that for every α, $Y \cap V_\alpha$ is closed in V_α and the ringed space $(Y \cap V_\alpha, \mathscr{O}_Y|(Y \cap V_\alpha))$ is a closed sub-prescheme of the prescheme induced on V_α by X. Then $(Y, \mathscr{O}_Y)$ is a sub-prescheme of X.*

The hypothesis implies that Y is locally closed in X and that the largest open set U containing Y and in which Y is closed contains all the V_α; we can therefore reduce to the case where $U = X$ and Y is closed in X. We then define a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$ by taking for $\mathscr{J}|V_\alpha$ the sheaf of ideals of $\mathscr{O}_X|V_\alpha$ which defines the closed sub-prescheme $(Y \cap V_\alpha, \mathscr{O}_Y|(Y \cap V_\alpha))$ and, for every open set W of X not meeting Y, $\mathscr{J}|W = \mathscr{O}_X|W$. One verifies immediately, by virtue of (4.1.3) and (4.1.4), that there exists one and only one sheaf of ideals $\mathscr{J}$ satisfying these conditions and that it defines the closed sub-prescheme $(Y, \mathscr{O}_Y)$.

In particular, the prescheme *induced* by X on an *open set* of X is a *sub-prescheme* of X.

(4.1.6) Proposition. *A sub-prescheme (resp. a closed sub-prescheme) of a subprescheme (resp. closed sub-prescheme) of X is canonically identified with a sub-prescheme (resp. closed sub-prescheme) of X.* *[I/121]*

Since a locally closed subset of a locally closed subspace of X is a locally closed subspace of X, it is clear (4.1.5) that the question is local and that we can therefore assume X affine; the proposition then follows from the canonical identification of $A/\mathfrak{J}'$ and $(A/\mathfrak{J})/(\mathfrak{J}'/\mathfrak{J})$ when $\mathfrak{J}$, $\mathfrak{J}'$ are two ideals of a ring A such that $\mathfrak{J} \subset \mathfrak{J}'$.

We shall always make the preceding identification from now on.

(4.1.7) Let Y be a sub-prescheme of a prescheme X, and denote by ψ the canonical injection $Y \to X$ of the *underlying spaces*; we know that the inverse image $\psi^*(\mathscr{O}_X)$ is the restriction $\mathscr{O}_X|Y$ (0, 3.7.1). If, for every $y \in Y$, we denote by ω_y the canonical homomorphism $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y$, these homomorphisms are the restrictions to the stalks of a *surjective* homomorphism ω of sheaves of rings $\mathscr{O}_X|Y \to \mathscr{O}_Y$: indeed, it suffices to verify this locally on Y, that is to say, we can assume X affine and the sub-prescheme Y closed; if in this case $\mathscr{I}$ is the sheaf of ideals in $\mathscr{O}_X$ which defines Y, the ω_y are nothing but the restrictions to the stalks of the homomorphism $\mathscr{O}_X|Y \to (\mathscr{O}_X/\mathscr{I})|Y$.

We have thus defined a *monomorphism of ringed spaces* (0, 4.1.1) $j = (\psi, \omega^b)$, which is obviously a morphism $Y \to X$ of preschemes (2.2.1), and which we shall call the *canonical injection morphism.*

If $f : X \to Z$ is a morphism, we shall also say that the composite morphism $Y \xrightarrow{j} X \xrightarrow{f} Z$ is the *restriction* of f to the sub-prescheme Y.

(4.1.8) In accordance with the general definitions (T, I, 1.1), we shall say that a morphism of preschemes $f : Z \to X$ is *majorized* by the injection morphism $j : Y \to X$ of a sub-prescheme Y of X if f factorizes as $Z \xrightarrow{g} Y \xrightarrow{j} X$, where g is a morphism of preschemes; g is necessarily *unique*, since j is a monomorphism.

(4.1.9) Proposition. *For a morphism $f : Z \to X$ to be* majorized by an injection morphism *$j : Y \to X$, it is necessary and sufficient that $f(Z) \subset Y$ and that, for every $z \in Z$, if we set $y = f(z)$, the homomorphism $(\mathscr{O}_X)_y \to \mathscr{O}_z$ corresponding to f factorize*

as $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y \to \mathscr{O}_z$ *(or, what amounts to the same, that the kernel of* $(\mathscr{O}_X)_y \to \mathscr{O}_z$ *contain that of* $(\mathscr{O}_X)_y \to (\mathscr{O}_Y)_y$*).*

The conditions are obviously necessary. To see that they are sufficient, we can reduce to the case where Y is a *closed* sub-prescheme of X, by replacing X if necessary by an open set U such that Y is closed in U (4.1.3); Y is then defined by a quasi-coherent sheaf $\mathscr{I}$ of ideals of $\mathscr{O}_X$. Set $f = (\psi, \theta)$, and let $\mathscr{J}$ be the sheaf of ideals of $\psi^*(\mathscr{O}_X)$ which is the kernel of $\theta^\sharp : \psi^*(\mathscr{O}_X) \to \mathscr{O}_Z$; taking into account the properties of the functor ψ^* (0, 3.7.2), the hypothesis implies that for every $z \in Z$ we have $(\psi^*(\mathscr{I}))_z \subset \mathscr{J}_z$, and consequently $\psi^*(\mathscr{I}) \subset \mathscr{J}$. Hence $\theta^\sharp$ factorizes as

$$\psi^*(\mathscr{O}_X) \longrightarrow \psi^*(\mathscr{O}_X)/\psi^*(\mathscr{I}) = \psi^*(\mathscr{O}_X/\mathscr{I}) \xrightarrow{\omega} \mathscr{O}_Z,$$

the first arrow being the canonical homomorphism. Let ψ' be the continuous map $Z \to Y$ coinciding with ψ; it is clear that we have $\psi'^*(\mathscr{O}_Y) = \psi^*(\mathscr{O}_X/\mathscr{I})$; on the other hand, ω
[I | 122] is obviously a local homomorphism, so $g = (\psi', \omega^b)$ is a morphism $Z \to Y$ of preschemes (2.2.1) which, by virtue of the foregoing, is such that $f = j \circ g$, whence the proposition.

(4.1.10) Corollary. *For an injection morphism* $Z \to X$ *to be* majorized by the injection morphism $Y \to X$*, it is necessary and sufficient that* Z *be a sub-prescheme of* Y*.*

We then write $Z \leq Y$, and this relation is obviously an *order relation* on the set of sub-preschemes of X.

4.2 Immersion morphisms

(4.2.1) Definition. A morphism $f : Y \to X$ is said to be an *immersion* (resp. a *closed immersion*, an *open immersion*) if it factorizes as $Y \xrightarrow{g} Z \xrightarrow{j} X$, where g is an isomorphism, Z a sub-prescheme of X (resp. a closed sub-prescheme, a sub-prescheme induced on an open set) and j the injection morphism.

The sub-prescheme Z and the isomorphism g are then determined *uniquely*, for if Z' is a second sub-prescheme of X, j' the injection $Z' \to X$ and g' an isomorphism $Y \to Z'$ such that $j \circ g = j' \circ g'$, we deduce $j' = j \circ g \circ g'^{-1}$, whence $Z' \leq Z$ (4.1.10), and one shows likewise that $Z \leq Z'$, so $Z' = Z$, and since j is a monomorphism of preschemes, $g' = g$.

We say that $f = j \circ g$ is the *canonical factorization* of the immersion f, and the sub-prescheme Z and the isomorphism g are said to be *associated with* f.

It is clear that an immersion is a *monomorphism* of preschemes (4.1.7) and *a fortiori* a *radicial* morphism (3.5.4).

(4.2.2) Proposition.

a) For a morphism $f = (\psi, \theta) : Y \to X$ *to be an* open immersion*, it is necessary and sufficient that* ψ *be a homeomorphism of* Y *onto an open subset of* X*, and that for every* $y \in Y$ *the homomorphism* $\theta^\sharp_y : \mathscr{O}_{\psi(y)} \to \mathscr{O}_y$ *be bijective.*

b) For a morphism $f = (\psi, \theta) : Y \to X$ *to be an* immersion *(resp. a* closed immersion*), it is necessary and sufficient that* ψ *be a homeomorphism of* Y *onto a locally closed (resp. closed) subset of* X*, and that for every* $y \in Y$ *the homomorphism* $\theta^\sharp_y : \mathscr{O}_{\psi(y)} \to \mathscr{O}_y$ *be surjective.*

a) The conditions are obviously necessary. Conversely, if they are satisfied, it is clear that $\theta^\sharp$ is an isomorphism of $\psi^*(\mathscr{O}_X)$ onto $\mathscr{O}_Y$, and $\psi^*(\mathscr{O}_X)$ is the sheaf deduced by transport of structure by means of ψ^{-1} from $\mathscr{O}_X|\psi(Y)$; whence the conclusion.

b) The conditions being obviously necessary, let us prove that they are sufficient. Consider first the special case where it is assumed that X is an affine scheme and that $Z = \psi(Y)$ is *closed* in X. We know (0, 3.4.6) that $\psi_*(\mathscr{O}_Y)$ then has support Z and that, if we denote by $\mathscr{O}'_Z$ its restriction to Z, the ringed space $(Z, \mathscr{O}'_Z)$ is deduced from $(Y, \mathscr{O}_Y)$ by transport of structure by means of the homeomorphism ψ, regarded as a map of Y onto Z. Let us show that $f_*(\mathscr{O}_Y) = \psi_*(\mathscr{O}_Y)$ is a *quasi-coherent* $\mathscr{O}_X$-module. Indeed, for every $x \notin Z$, $\psi_*(\mathscr{O}_Y)$, restricted to a suitable neighbourhood of x, is zero. If on the contrary $x \in Z$, we have $x = \psi(y)$ for a well-determined $y \in Y$; let V be an affine open neighbourhood of y in Y; $\psi(V)$ is then open in Z, hence is the trace on Z of an open set U of X, and the restriction to U of $\psi_*(\mathscr{O}_Y)$ is identical to the restriction to U of the direct image $(\psi_V)_*(\mathscr{O}_Y|V)$, where [I | 123] ψ_V is the restriction of ψ to V. Now, the restriction to $(V, \mathscr{O}_Y|V)$ of the morphism (ψ, θ) is a morphism of this prescheme into $(X, \mathscr{O}_X)$, and is consequently of the form $({}^a\varphi, \widetilde{\varphi})$, where φ is a homomorphism of the ring $A = \Gamma(X, \mathscr{O}_X)$ into the ring $\Gamma(V, \mathscr{O}_Y)$ (1.7.3); we conclude that $(\psi_V)_*(\mathscr{O}_Y|V)$ is a quasi-coherent $\mathscr{O}_X$-module (1.6.3), which proves our assertion, because of the local character of quasi-coherent sheaves. Moreover, the hypothesis that ψ is a homeomorphism implies (0, 3.4.5) that for every $y \in Y$, ψ_y is an isomorphism $(\psi_*(\mathscr{O}_Y))_{\psi(y)} \to \mathscr{O}_y$; since the diagram

$$\begin{array}{ccc} \mathscr{O}_{\psi(y)} & \xrightarrow{\theta_{\psi(y)}} & (\psi_*(\mathscr{O}_Y))_{\psi(y)} \\ \downarrow{\scriptstyle \psi_y \circ \rho_{\psi(y)}} & & \downarrow{\scriptstyle \psi_y} \\ (\psi^*(\mathscr{O}_X))_y & \xrightarrow{\theta_y^\sharp} & \mathscr{O}_y \end{array}$$

is commutative and the two vertical arrows are isomorphisms (0, 3.7.2), the hypothesis that $\theta_y^\sharp$ is surjective implies that so is $\theta_{\psi(y)}$. Since the support of $\psi_*(\mathscr{O}_Y)$ is $Z = \psi(Y)$, θ is a *surjective* homomorphism of $\mathscr{O}_X = \widetilde{A}$ into the quasi-coherent $\mathscr{O}_X$-module $f_*(\mathscr{O}_Y)$. Consequently there exists a unique isomorphism ω of a quotient sheaf $\widetilde{A}/\widetilde{\mathfrak{J}}$ ($\mathfrak{J}$ an ideal of A) onto $f_*(\mathscr{O}_Y)$ which, composed with the canonical homomorphism $\widetilde{A} \to \widetilde{A}/\widetilde{\mathfrak{J}}$, gives θ (1.3.8); if $\mathscr{O}_Z$ denotes the restriction of $\widetilde{A}/\widetilde{\mathfrak{J}}$ to Z, then $(Z, \mathscr{O}_Z)$ is a sub-prescheme of $(X, \mathscr{O}_X)$, and f factorizes into the canonical injection of this sub-prescheme into X and the isomorphism (ψ_0, ω_0), where ψ_0 is ψ regarded as a map of Y onto Z, and ω_0 the restriction of ω to $\mathscr{O}_Z$.

Let us pass to the general case. Let U be an affine open set in X such that $U \cap \psi(Y)$ is closed in U and non-empty. By restricting f to the prescheme induced by Y on the open set $\psi^{-1}(U)$, and regarding it as a morphism of this prescheme into the prescheme induced by X on U, we are reduced to the first case; the restriction of f to $\psi^{-1}(U)$ is therefore a closed immersion $\psi^{-1}(U) \to U$, factorizing canonically as $j_U \circ g_U$, where g_U is an isomorphism of the prescheme $\psi^{-1}(U)$ onto a sub-prescheme Z_U of U, and j_U the canonical injection $Z_U \to U$. Let V be a second affine open set of X such that $V \subset U$; since the restriction Z'_V of Z_U to V is a sub-prescheme of the prescheme V, the restriction of f to $\psi^{-1}(V)$ factorizes as $j'_V \circ g'_V$, where j'_V is the canonical injection $Z'_V \to V$ and g'_V an isomorphism of $\psi^{-1}(V)$ onto Z'_V. By the uniqueness of the canonical factorization of an immersion (4.2.1), we necessarily have $Z'_V = Z_V$ and $g'_V = g_V$. We conclude (4.1.5) that there is a sub-prescheme Z of X whose underlying space is $\psi(Y)$ and whose restriction to each $U \cap \psi(Y)$ is

Z_U; the g_U are then the restrictions to the $\psi^{-1}(U)$ of an isomorphism $g : Y \to Z$ such that $f = j \circ g$, where j is the canonical injection $Z \to X$.

(4.2.3) Corollary. *Let X be an affine scheme. For a morphism $f = (\psi, \theta) : Y \to X$ to be a closed immersion, it is necessary and sufficient that Y be an affine scheme and that the homomorphism $\Gamma(\theta) : \Gamma(\mathscr{O}_X) \to \Gamma(\mathscr{O}_Y)$ be surjective.*

(4.2.4) Corollary.

a) Let f be a morphism $Y \to X$, and (V_λ) a covering of $f(Y)$ by open sets of X. For [I/124] *f to be an immersion (resp. an open immersion), it is necessary and sufficient that its restriction to each of the induced preschemes $f^{-1}(V_\lambda)$ be an immersion (resp. an open immersion) into V_λ.*

b) Let f be a morphism $Y \to X$, and (V_λ) an open covering of X. For f to be a closed immersion, it is necessary and sufficient that its restriction to each of the induced preschemes $f^{-1}(V_\lambda)$ be a closed immersion into V_λ.

Let $f = (\psi, \theta)$; in case a), $\theta_y^\sharp$ is surjective (resp. bijective) for every $y \in Y$, and in case b) $\theta_y^\sharp$ is surjective for every $y \in Y$; it therefore suffices to verify that ψ, in case a), is a homeomorphism of Y onto a locally closed (resp. open) subset of X, and in case b), a homeomorphism of Y onto a closed subset of X. Now, ψ is obviously injective and transforms every neighbourhood of y in Y into a neighbourhood of $\psi(y)$ in $\psi(Y)$ for every $y \in Y$, by virtue of the hypothesis; in case a), $\psi(Y) \cap V_\lambda$ is locally closed (resp. open) in V_λ, so $\psi(Y)$ is locally closed (resp. open) in the union of the V_λ, and *a fortiori* in X; in case b), $\psi(Y) \cap V_\lambda$ is closed in V_λ, so $\psi(Y)$ is closed in X since $X = \bigcup_\lambda V_\lambda$.

(4.2.5) Proposition. *The composite of two immersions (resp. of two open immersions, of two closed immersions) is an immersion (resp. an open immersion, a closed immersion).*

This follows trivially from (4.1.6).

4.3 Product of immersions.

(4.3.1) Proposition. *Let $\alpha : X' \to X$, $\beta : Y' \to Y$ be two S-morphisms; if α and β are immersions (resp. open immersions, closed immersions), then $\alpha \times_S \beta$ is an immersion (resp. an open immersion, a closed immersion). Moreover, if α (resp. β) identifies X' (resp. Y') with a sub-prescheme X'' (resp. Y'') of X (resp. Y), then $\alpha \times_S \beta$ identifies the underlying space of $X' \times_S Y'$ with the subspace $p^{-1}(X'') \cap q^{-1}(Y'')$ of the underlying space of $X \times_S Y$, where p and q denote the projections of $X \times_S Y$ to X and Y respectively.*

Taking into account Definition (4.2.1), we can restrict ourselves to the case where X' and Y' are sub-preschemes, and α and β the injection morphisms. The proposition has already been established for the sub-preschemes induced on open sets (3.2.7); since every sub-prescheme is a closed sub-prescheme of a prescheme induced on an open set (4.1.3), we are reduced to the case where X' and Y' are *closed* sub-preschemes.

Let us first show that we can assume that S is *affine*. Indeed, let (S_λ) be a covering of S consisting of affine open sets; if φ and ψ are the structural morphisms of X and Y, let $X_\lambda = \varphi^{-1}(S_\lambda)$, $Y_\lambda = \psi^{-1}(S_\lambda)$. The restriction X'_λ (resp. Y'_λ) of X' (resp. Y') to $X_\lambda \cap X'$ (resp. $Y_\lambda \cap Y'$) is a closed sub-prescheme of X_λ (resp. Y_λ), the preschemes X_λ, Y_λ, X'_λ, Y'_λ can be regarded as S_λ-preschemes, and the products $X_\lambda \times_S Y_\lambda$ and $X_\lambda \times_{S_\lambda} Y_\lambda$ (resp.

$X'_\lambda \times_S Y'_\lambda$ and $X'_\lambda \times_{S_\lambda} Y'_\lambda$) are identical (3.2.5). If the proposition is true when S is affine, the restriction of $\alpha \times_S \beta$ to each of the $X'_\lambda \times_S Y'_\lambda$ will therefore be an immersion (3.2.7). Since the product $X'_\lambda \times_S Y'_\mu$ (resp. $X_\lambda \times_S Y_\mu$) is identified with $(X'_\lambda \cap X'_\mu) \times_S (Y'_\lambda \cap Y'_\mu)$ (resp. $(X_\lambda \cap X_\mu) \times_S (Y_\lambda \cap Y_\mu)$) (3.2.6.4), the restriction of $\alpha \times_S \beta$ to each of the $X'_\lambda \times_S Y'_\mu$ [I | 125] is again an immersion; consequently the same holds for $\alpha \times_S \beta$ by virtue of (4.2.4).

In the second place, let us prove that we can also assume that X and Y are *affine*. Indeed, let (U_i) (resp. (V_j)) be a covering of X (resp. Y) by affine open sets, and let X'_i (resp. Y'_j) be the restriction of X' (resp. Y') to $X' \cap U_i$ (resp. $Y' \cap V_j$), which is a closed sub-prescheme of U_i (resp. V_j); $U_i \times_S V_j$ is identified with the restriction of $X \times_S Y$ to $p^{-1}(U_i) \cap q^{-1}(V_j)$ (3.2.7); and likewise, if p', q' are the projections of $X' \times_S Y'$, $X'_i \times_S Y'_j$ is identified with the restriction of $X' \times_S Y'$ to ${p'}^{-1}(X'_i) \cap {q'}^{-1}(Y'_j)$. Set $\gamma = \alpha \times_S \beta$; by definition we have $p \circ \gamma = \alpha \circ p'$, $q \circ \gamma = \beta \circ q'$; since $X'_i = \alpha^{-1}(U_i)$, $Y'_j = \beta^{-1}(V_j)$, we also have ${p'}^{-1}(X'_i) = \gamma^{-1}(p^{-1}(U_i))$, ${q'}^{-1}(Y'_j) = \gamma^{-1}(q^{-1}(V_j))$, whence

$$ {p'}^{-1}(X'_i) \cap {q'}^{-1}(Y'_j) = \gamma^{-1}\big(p^{-1}(U_i) \cap q^{-1}(V_j)\big) = \gamma^{-1}(U_i \times_S V_j) $$

we conclude as in the first part of the argument.

Suppose therefore that X, Y, S are affine, and let B, C, A be their respective rings. Then B and C are A-algebras, and X' and Y' are affine schemes whose rings are quotient algebras B', C' of B and C respectively. Moreover, we have $\alpha = ({}^a\rho, \widetilde{\rho})$, $\beta = ({}^a\sigma, \widetilde{\sigma})$, where ρ and σ are respectively the canonical homomorphisms $B \to B'$, $C \to C'$ (1.7.3). This being so, we know that $X \times_S Y$ (resp. $X' \times_S Y'$) is an affine scheme with ring $B \otimes_A C$ (resp. $B' \otimes_A C'$), and $\alpha \times_S \beta = ({}^a\tau, \widetilde{\tau})$, where τ is the homomorphism $\rho \otimes \sigma$ of $B \otimes_A C$ into $B' \otimes_A C'$ (3.2.2 and 3.2.3); since this homomorphism is surjective, $\alpha \times_S \beta$ is indeed an immersion. Moreover, if $\mathfrak{b}$ (resp. $\mathfrak{c}$) is the kernel of ρ (resp. σ), the kernel of τ is the sum of the ideals generated by $u(\mathfrak{b})$ and $v(\mathfrak{c})$, where u (resp. v) is the homomorphism $b \mapsto b \otimes 1$ (resp. $c \mapsto 1 \otimes c$). Since $p = ({}^a u, \widetilde{u})$ and $q = ({}^a v, \widetilde{v})$, this kernel corresponds, in the prime spectrum of $B \otimes_A C$, to the closed set $p^{-1}(X') \cap q^{-1}(Y')$ (1.2.2.1 and 1.1.2 (iii)), which completes the proof.

(4.3.2) Corollary. *If $f : X \to Y$ is an immersion (resp. an open immersion, a closed immersion) and an S-morphism, then $f_{(S')}$ is an immersion (resp. an open immersion, a closed immersion) for every extension $S' \to S$ of the base prescheme.*

4.4 Inverse image of a sub-prescheme.

(4.4.1) Proposition. *Let $f : X \to Y$ be a morphism, Y' a sub-prescheme (resp. a closed sub-prescheme, a prescheme induced on an open set) of Y, and $j : Y' \to Y$ the injection morphism. Then the projection $p : X \times_Y Y' \to X$ is an immersion (resp. a closed immersion, an open immersion); the sub-prescheme of X associated with p has $f^{-1}(Y')$ as underlying space; moreover, if j' is the injection morphism of this sub-prescheme into X, then for a morphism $h : Z \to X$ to be such that $f \circ h : Z \to Y$ is majorized by j, it is necessary and sufficient that h be majorized by j'.*

Since $p = 1_X \times_Y j$ (3.3.4), the first assertion follows from (4.3.1); the second is a special case of (3.5.10) (where the roles of X and of Y' must be interchanged). Finally, if we have $f \circ h = j \circ h'$, where h' is a morphism $Z \to Y'$, it follows from the definition of the product that we have $h = p \circ u$, where u is a morphism $Z \to X \times_Y Y'$, whence the last assertion.

We shall say that the sub-prescheme of X thus defined is the *inverse image* of the sub-prescheme Y' of Y under the morphism f, a terminology which agrees with the one

[I | 126] introduced more generally in (3.3.6). When we speak of $f^{-1}(Y')$ as a sub-prescheme of X, it will always be this sub-prescheme that is meant.

When the preschemes $f^{-1}(Y')$ and X are identical, j' is the identity and every morphism $h : Z \to X$ is therefore majorized by j', so *the morphism $f : X \to Y$ then factorizes as $X \xrightarrow{g} Y' \xrightarrow{j} Y$.*

When y is a *closed* point of Y and $Y' = \mathrm{Spec}(k(y))$ the smallest closed sub-prescheme of Y having $\{y\}$ as underlying space (4.1.9), the closed sub-prescheme $f^{-1}(Y')$ is canonically isomorphic to the *fibre* $f^{-1}(y)$ defined in (3.6.2), with which we shall identify it.

(4.4.2) Corollary. *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, and $h = g \circ f$ their composite. For every sub-prescheme Z' of Z, the sub-preschemes $f^{-1}(g^{-1}(Z'))$ and $h^{-1}(Z')$ of X are identical.*

This follows from the existence of the canonical isomorphism $X \times_Y (Y \times_Z Z') \xrightarrow{\sim} X \times_Z Z'$ (3.3.9.1).

(4.4.3) Corollary. *Let X', X'' be two sub-preschemes of X, and $j' : X' \to X$, $j'' : X'' \to X$ the injection morphisms; then ${j'}^{-1}(X'')$ and ${j''}^{-1}(X')$ are both equal to the greatest lower bound $\inf(X', X'')$ of X' and X'' for the order relation between sub-preschemes, and canonically isomorphic to $X' \times_X X''$.*

This follows at once from (4.4.1) and (4.1.10).

(4.4.4) Corollary. *Let $f : X \to Y$ be a morphism, and Y', Y'' two sub-preschemes of Y; we have*

$$f^{-1}(\inf(Y', Y'')) = \inf(f^{-1}(Y'), f^{-1}(Y'')).$$

This follows from the existence of the canonical isomorphism between $(X \times_Y Y') \times_X (X \times_Y Y'')$ and $X \times_Y (Y' \times_Y Y'')$ (3.3.9.1).

(4.4.5) Proposition. *Let $f : X \to Y$ be a morphism, and Y' a closed sub-prescheme of Y defined by a quasi-coherent sheaf $\mathscr{K}$ of ideals of $\mathscr{O}_Y$ (4.1.3); then the closed sub-prescheme $f^{-1}(Y')$ of X is defined by the quasi-coherent sheaf of ideals $f^*(\mathscr{K})\mathscr{O}_X$ of $\mathscr{O}_X$.*

The question is obviously local on X and Y; it then suffices to note that if A is a B-algebra and $\mathfrak{K}$ an ideal of B, we have $A \otimes_B (B/\mathfrak{K}) = A/\mathfrak{K}A$, and to apply (1.6.9).

(4.4.6) Corollary. *Let X' be a closed sub-prescheme of X defined by a quasi-coherent sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_X$, and i the injection $X' \to X$; for the restriction $f \circ i$ of f to X' to be majorized by the injection $j : Y' \to Y$ (in other words, to factorize as $j \circ g$, where g is a morphism $X' \to Y'$), it is necessary and sufficient that $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$.*

It suffices to apply Proposition (4.4.1) to i, taking into account (4.4.5).

4.5 Local immersions and local isomorphisms.

(4.5.1) Definition. Let $f : X \to Y$ be a morphism of preschemes. We say that f is a *local immersion at a point $x \in X$* if there exist an open neighbourhood U of x in X and an open neighbourhood V of $f(x)$ in Y such that the restriction of f to the induced prescheme U is a closed immersion of U into the induced prescheme V. We say that f is a local immersion if f is a local immersion at every point of X.

[I | 127] **(4.5.2) Definition.** A morphism $f : X \to Y$ is said to be a local isomorphism at a point $x \in X$ if there exists an open neighbourhood U of x in X such that the restriction

of f to the induced prescheme U is an open immersion of U into Y. We say that f is a local isomorphism if f is a local isomorphism at every point of X.

(4.5.3) An immersion (resp. a closed immersion) $f : X \to Y$ can therefore be characterized as a local immersion such that f is a homeomorphism of the underlying space of X onto a subset (resp. a closed subset) of Y. An open immersion f can be characterized as an *injective* local isomorphism.

(4.5.4) Proposition. *Let X be an irreducible prescheme, and $f : X \to Y$ an injective dominant morphism. If f is a local immersion, then f is an immersion and $f(X)$ is open in Y.*

Indeed, let $x \in X$, and let U be an open neighbourhood of x and V an open neighbourhood of $f(x)$ in Y such that the restriction of f to U is a closed immersion into V; since U is dense in X, $f(U)$ is dense in Y by hypothesis, so $f(U) = V$ and f is a homeomorphism of U onto V; the hypothesis that f is injective implies that $f^{-1}(V) = U$, whence the proposition at once.

(4.5.5) Proposition.

(i) *The composite of two local immersions (resp. of two local isomorphisms) is a local immersion (resp. a local isomorphism).*

(ii) *Let $f : X \to X'$, $g : Y \to Y'$ be two S-morphisms. If f and g are local immersions (resp. local isomorphisms), so is $f \times_S g$.*

(iii) *If an S-morphism f is a local immersion (resp. a local isomorphism), so is $f_{(S')}$ for every extension $S' \to S$ of the base prescheme.*

By (3.5.1), it suffices to prove (i) and (ii).

(i) follows at once from the transitivity of closed (resp. open) immersions (4.2.5) and from the fact that if f is a homeomorphism of X onto a closed subset of Y, then for every open set $U \subset X$, $f(U)$ is open in $f(X)$, so there exists an open subset V of Y such that $f(U) = V \cap f(X)$, and $f(U)$ is consequently closed in V.

To prove (ii), let $z \in X \times_S Y$ and set $z' = (f \times_S g)(z)$; let p, q be the projections of $X \times_S Y$, and p', q' those of $X' \times_S Y'$. By hypothesis there exist open neighbourhoods U, U', V, V' of $x = p(z)$, $x' = p'(z')$, $y = q(z)$, $y' = q'(z')$ respectively, such that the restrictions of f and g to U and V respectively are closed (resp. open) immersions into U' and V' respectively. Since the underlying space of $U \times_S V$ and that of $U' \times_S V'$ are identified with the open neighbourhoods $p^{-1}(U) \cap q^{-1}(V)$ and $p'^{-1}(U') \cap q'^{-1}(V')$ of z and z' respectively (3.2.7), the proposition follows from (4.3.1).

§5 Reduced preschemes; separation condition

5.1 Reduced preschemes.

(5.1.1) Proposition. *Let $(X, \mathscr{O}_X)$ be a prescheme and $\mathscr{B}$ a quasi-coherent $\mathscr{O}_X$-algebra. There exists one and only one quasi-coherent $\mathscr{O}_X$-module $\mathscr{N}$ whose stalk $\mathscr{N}_x$ at every $x \in X$ is the nilradical of the ring $\mathscr{B}_x$. When X is affine, and consequently $\mathscr{B} = \widetilde{B}$, where B is an algebra over $A(X)$, we have $\mathscr{N} = \widetilde{\mathfrak{N}}$, where $\mathfrak{N}$ is the nilradical of B.*

The question being local, we are reduced to proving the last assertion. We know that $\widetilde{\mathfrak{N}}$ [I | 128] is a quasi-coherent $\mathscr{O}_X$-module (1.4.1) and that its stalk at the point $x \in X$ is the ideal

$\mathfrak{N}_x$ of the ring of fractions B_x; it all comes down to proving that the nilradical of B_x is contained in $\mathfrak{N}_x$, the opposite inclusion being evident. Now let z/s be an element of the nilradical of B_x, with $z \in B$, $s \notin \mathfrak{j}_x$; by hypothesis, there exists an integer k such that $(z/s)^k = 0$, which means that there exists $t \notin \mathfrak{j}_x$ such that $tz^k = 0$. We conclude that $(tz)^k = 0$, and consequently $z/s = (tz)/(ts)$ belongs to $\mathfrak{N}_x$.

We will say that the quasi-coherent $\mathscr{O}_X$-module $\mathscr{N}$ thus defined is the *nilradical* of the $\mathscr{O}_X$-algebra $\mathscr{B}$; in particular, we will denote by $\mathscr{N}_X$ the nilradical of $\mathscr{O}_X$.

(5.1.2) Corollary. *Let X be a prescheme; the closed sub-prescheme of X defined by the sheaf of ideals $\mathscr{N}_X$ is the only reduced sub-prescheme (0, 4.1.4) of X having X as underlying space; it is also the smallest sub-prescheme of X having X as underlying space.*

As the structural sheaf of the closed sub-prescheme Y defined by $\mathscr{N}_X$ is $\mathscr{O}_X/\mathscr{N}_X$, it is immediate that Y is reduced and has X as underlying space, since $\mathscr{N}_x \neq \mathscr{O}_x$ for every $x \in X$. To prove the other assertions, note that a sub-prescheme Z of X having X as underlying space is defined by a sheaf of ideals $\mathscr{J}$ (4.1.3) such that $\mathscr{J}_x \neq \mathscr{O}_x$ for every $x \in X$. We may restrict to the case where X is affine, say $X = \mathrm{Spec}(A)$ and $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an ideal of A; then, for every $x \in X$, we have $\mathfrak{J} \subset \mathfrak{j}_x$, so $\mathfrak{J}$ is contained in all the prime ideals of A, that is, in their intersection $\mathfrak{N}$, the nilradical of A. This proves that Y is the smallest sub-prescheme of X having X as underlying space (4.1.9); moreover, if Z is distinct from Y, we necessarily have $\mathscr{J}_x \neq \mathscr{N}_x$ for at least one $x \in X$, and consequently (5.1.1) Z is not reduced.

(5.1.3) Definition. We call the reduced prescheme associated to a prescheme X, and denote by X_{red}, the unique reduced sub-prescheme of X having X as underlying space.

To say that a prescheme X is reduced therefore means that $X = X_{\mathrm{red}}$.

(5.1.4) Proposition. *For the prime spectrum of a ring A to be a reduced (resp. integral) prescheme (2.1.8), it is necessary and sufficient that A be a reduced (resp. integral) ring.*

Indeed, it follows immediately from (5.1.1) that the condition $\mathscr{N} = (0)$ is necessary and sufficient for $X = \mathrm{Spec}(A)$ to be reduced; the assertion concerning integral rings is then a consequence of (1.1.13).

Since every ring of fractions $\neq \{0\}$ of an integral ring is integral, it follows from (5.1.4) that for every *locally integral* prescheme X, $\mathscr{O}_x$ is an *integral* ring for every $x \in X$. The converse is true when the underlying space of X is *locally Noetherian*: indeed X is then reduced, and if U is an affine open subset of X which is a Noetherian space, U has only finitely many irreducible components, so its ring A has only finitely many minimal prime ideals (1.1.14). If two of these components U_i had a common point x, $\mathscr{O}_x$ would have at least two distinct minimal prime ideals, and so would not be integral; consequently the U_i are pairwise disjoint open subsets, and each of them is therefore integral.

[I | 129] **(5.1.5)** Let $f = (\psi, \theta) : X \to Y$ be a morphism of preschemes; the homomor- phism $\theta^\sharp_x : \mathscr{O}_{\psi(x)} \to \mathscr{O}_x$ maps every nilpotent element of $\mathscr{O}_{\psi(x)}$ to a nilpotent element of $\mathscr{O}_x$; by passing to quotients, we therefore deduce from $\theta^\sharp$ a homomorphism

$$\omega : \psi^*(\mathscr{O}_Y/\mathscr{N}_Y) \longrightarrow \mathscr{O}_X/\mathscr{N}_X$$

it is clear that for every $x \in X$, $\omega_x : \mathscr{O}_{\psi(x)}/\mathscr{N}_{\psi(x)} \to \mathscr{O}_x/\mathscr{N}_x$ is a local homomorphism, so (ψ, ω^b) is a morphism of preschemes $X_{\mathrm{red}} \to Y_{\mathrm{red}}$, which we will denote by f_{red} and call the *reduced* morphism associated to f. It is immediate that for two morphisms

$f : X \to Y$, $g : Y \to Z$, we have $(g \circ f)_{\mathrm{red}} = g_{\mathrm{red}} \circ f_{\mathrm{red}}$, so we have defined X_{red} as a *covariant functor* in X.

The preceding definition shows that the diagram

$$\begin{array}{ccc} X_{\mathrm{red}} & \xrightarrow{f_{\mathrm{red}}} & Y_{\mathrm{red}} \\ \downarrow & & \downarrow \\ X & \xrightarrow[f]{} & Y \end{array}$$

is commutative, the vertical arrows being the injection morphisms; in other words, $X_{\mathrm{red}} \to X$ is a *functorial* morphism. Note in particular that if X is *reduced*, every morphism $f : X \to Y$ factors as $X \xrightarrow{f_{\mathrm{red}}} Y_{\mathrm{red}} \to Y$; in other words, f is *dominated* by the injection morphism $Y_{\mathrm{red}} \to Y$.

(5.1.6) Proposition. *Let $f : X \to Y$ be a morphism; if f is surjective (resp. radicial, an immersion, a closed immersion, an open immersion, a local immersion, a local isomorphism), then so is f_{red}. Conversely, if f_{red} is surjective (resp. radicial), then so is f.*

The proposition is trivial if f is surjective; if f is radicial, it follows from the fact that for every $x \in X$, the field $k(x)$ is the same for the preschemes X and X_{red} (3.5.8). Finally, if $f = (\psi, \theta)$ is an immersion, a closed immersion or a local immersion (resp. an open immersion, or a local isomorphism), the proposition follows from the fact that if $\theta_x^\sharp$ is surjective (resp. bijective), then so is the homomorphism obtained by passing to the quotients by the nilradicals of $\mathscr{O}_{\psi(x)}$ and $\mathscr{O}_x$ (5.1.2 and 4.2.2) (cf. (5.5.12)).

(5.1.7) Proposition. *If X, Y are two S-preschemes, the preschemes $X_{\mathrm{red}} \times_{S_{\mathrm{red}}} Y_{\mathrm{red}}$ and $X_{\mathrm{red}} \times_S Y_{\mathrm{red}}$ are identical, and are canonically identified with a sub-prescheme of $X \times_S Y$ having the same underlying space as this product.*

The canonical identification of $X_{\mathrm{red}} \times_S Y_{\mathrm{red}}$ with a sub-prescheme of $X \times_S Y$ having the same underlying space follows from (4.3.1). On the other hand, if φ and ψ are the structural morphisms $X_{\mathrm{red}} \to S$, $Y_{\mathrm{red}} \to S$, they factor through S_{red} (5.1.5), and since $S_{\mathrm{red}} \to S$ is a monomorphism, the first assertion follows from (3.2.4).

(5.1.8) Corollary. *The preschemes $(X \times_S Y)_{\mathrm{red}}$ and $(X_{\mathrm{red}} \times_{S_{\mathrm{red}}} Y_{\mathrm{red}})_{\mathrm{red}}$ are canonically identified.*

This follows from (5.1.2 and 5.1.7).

Note that if X and Y are reduced preschemes, the same is not necessarily true of $X \times_S Y$, because the tensor product of two reduced algebras can have nilpotent elements.

(5.1.9) Proposition. *Let X be a prescheme and $\mathscr{J}$ a quasi-coherent sheaf of ideals of $\mathscr{O}_X$ such that $\mathscr{J}^n = 0$ for some integer $n > 0$. Let X_0 be the closed sub-prescheme $(X, \mathscr{O}_X/\mathscr{J})$ of X; for X to be an affine scheme, it is necessary and sufficient that X_0 be one.* [I/130]

The condition being evidently necessary, let us prove that it is sufficient. If we set $X_k = (X, \mathscr{O}_X/\mathscr{J}^{k+1})$, it all comes down to proving by induction on k that the X_k are affine, so we are reduced to the case where $\mathscr{J}^2 = 0$. Set

$$A = \Gamma(X, \mathscr{O}_X), \qquad A_0 = \Gamma(X_0, \mathscr{O}_{X_0}) = \Gamma(X, \mathscr{O}_X/\mathscr{J}).$$

From the canonical homomorphism $\mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$ we deduce a ring homomorphism $\varphi : A \to A_0$. We will see below that φ is *surjective*, so that the sequence

$$0 \to \Gamma(X, \mathscr{J}) \to \Gamma(X, \mathscr{O}_X) \to \Gamma(X, \mathscr{O}_X/\mathscr{J}) \to 0 \qquad (5.1.9.1)$$

is *exact*. Suppose this point established, and let us show that it implies the proposition. Note that $\mathfrak{K} = \Gamma(X, \mathscr{J})$ is an ideal of square zero in A, and is therefore a module over $A_0 = A/\mathfrak{K}$. By hypothesis, we have $X_0 = \mathrm{Spec}(A_0)$, and since the underlying topological spaces X_0 and X are identical, $\mathfrak{K} = \Gamma(X_0, \mathscr{J})$; moreover, since $\mathscr{J}^2 = 0$, $\mathscr{J}$ is a quasi-coherent $(\mathscr{O}_X/\mathscr{J})$-module, so we have $\mathscr{J} \simeq \widetilde{\mathfrak{K}}$ and $\mathfrak{K}_x = \mathscr{J}_x$ for every $x \in X_0$ (1.4.1).

This being so, let $X' = \mathrm{Spec}(A)$, and consider the morphism of preschemes $f = (\psi, \theta) : X \to X'$ corresponding to the identity map $A \to \Gamma(X, \mathscr{O}_X)$ (2.2.4). For every affine open subset V in X, the diagram

$$\begin{array}{ccc} A & \longrightarrow & \Gamma(V, \mathscr{O}_X|V) \\ \downarrow & & \downarrow \\ A_0 = A/\mathfrak{K} & \longrightarrow & \Gamma(V, \mathscr{O}_{X_0}|V) \end{array}$$

is commutative, from which we conclude that the diagram

$$\begin{array}{ccc} X' & \xleftarrow{f} & X \\ {\scriptstyle j'}\uparrow & & \uparrow{\scriptstyle j} \\ X'_0 & \xleftarrow[f_0]{} & X_0 \end{array}$$

is commutative, X'_0 being the closed sub-prescheme of X' defined by the quasi-coherent sheaf of ideals $\widetilde{\mathfrak{K}}$, and j, j' the canonical injection morphisms. But since X_0 is affine, f_0 is an isomorphism, and since the continuous maps underlying j and j' are the identity maps, we see first of all that $\psi : X \to X'$ is a homeomorphism. Moreover, the relation $\mathfrak{K}_x = \mathscr{J}_x$ shows that the restriction of $\theta^\sharp : \psi^*(\mathscr{O}_{X'}) \to \mathscr{O}_X$ is an *isomorphism* of $\psi^*(\widetilde{\mathfrak{K}})$ onto $\mathscr{J}$; on the other hand, by passing to quotients, $\theta^\sharp$ gives an *isomorphism* $\psi^*(\mathscr{O}_{X'}/\widetilde{\mathfrak{K}}) \to \mathscr{O}_X/\mathscr{J}$, since f_0 is an isomorphism; we conclude immediately by the five lemma (M, I, 1.1) that $\theta^\sharp$ is itself an isomorphism, hence that f is an *isomorphism*, and consequently that X is affine.

Everything therefore comes down to proving the exactness of (5.1.9.1), which will follow from

[I | 131] $H^1(X, \mathscr{J}) = 0$. Now $H^1(X, \mathscr{J}) = H^1(X_0, \mathscr{J})$, and we have seen that $\mathscr{J}$ is a quasi-coherent $\mathscr{O}_{X_0}$-module. Our assertion will therefore follow from the

(5.1.9.2) Lemma. *If Y is an affine scheme and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_Y$-module, then $H^1(Y, \mathscr{F}) = 0$.*

This lemma will be proved in Chapter III, § 1, as a consequence of the more general theorem that $H^i(Y, \mathscr{F}) = 0$ for every $i > 0$. To give an independent proof of it, observe that $H^1(Y, \mathscr{F})$ is identified with the module $\mathrm{Ext}^1_{\mathscr{O}_Y}(Y; \mathscr{O}_Y, \mathscr{F})$ of classes of extensions of the $\mathscr{O}_Y$-module $\mathscr{O}_Y$ by the $\mathscr{O}_Y$-module $\mathscr{F}$ (T, 4.2.3); it all comes down, therefore, to proving that such an extension $\mathscr{G}$ is trivial. Now, for every $y \in Y$, there is a neighbourhood V of y in Y such that $\mathscr{G}|V$ is isomorphic to $\mathscr{F}|V \oplus \mathscr{O}_Y|V$ (0, 5.4.9); we conclude that $\mathscr{G}$ is a quasi-coherent $\mathscr{O}_Y$-module. If A is the ring of Y, we therefore have $\mathscr{F} = \widetilde{M}$, $\mathscr{G} = \widetilde{N}$, where M and N are A-modules, and by hypothesis N is an extension of the A-module A by the A-module M (1.3.11). Since this extension is necessarily trivial, the lemma is proved, and consequently so is (5.1.9).

(5.1.10) Corollary. *Let X be a prescheme such that $\mathscr{N}_X$ is nilpotent. For X to be an affine scheme, it is necessary and sufficient that X_{red} be one.*

5.2 Existence of a sub-prescheme with a given underlying space.

(5.2.1) Proposition. *For every locally closed subspace Y of the underlying space of a prescheme X, there exists one and only one reduced sub-prescheme of X having Y as underlying space.*

Since uniqueness follows from (5.1.2), it remains to prove the existence of the sub-prescheme in question.

If X is affine with ring A, and Y is closed in X, the proposition is immediate: $\mathfrak{j}(Y)$ is the largest ideal $\mathfrak{a} \subset A$ such that $V(\mathfrak{a}) = Y$, and it is equal to its radical (1.1.4 (i)), so $A/\mathfrak{j}(Y)$ is a reduced ring.

In the general case, for every affine open subset $U \subset X$ such that $U \cap Y$ is closed in U, consider the closed sub-prescheme Y_U of U defined by the sheaf of ideals associated to the ideal $\mathfrak{j}(U \cap Y)$ of $A(U)$, which is reduced. Let us show that, if V is an affine open subset of X contained in U, Y_V is *induced* by Y_U on $V \cap Y$; now, this induced prescheme is a closed sub-prescheme of V which is reduced and has $V \cap Y$ as underlying space; the uniqueness of Y_V therefore implies our assertion.

(5.2.2) Proposition. *Let X be a reduced prescheme, $f : X \to Y$ a morphism, and Z a closed sub-prescheme of Y such that $f(X) \subset Z$; then f factors as $X \xrightarrow{g} Z \xrightarrow{j} Y$, where j is the injection morphism.*

It follows from the hypothesis that the closed sub-prescheme $f^{-1}(Z)$ of X has the whole of X as underlying space (4.4.1); since X is reduced, this closed sub-prescheme coincides with X (5.1.2), and the proposition therefore follows from (4.4.1).

(5.2.3) Corollary. *Let X be a reduced sub-prescheme of a prescheme Y; if Z is the reduced closed sub-prescheme of Y having $\overline{X}$ as underlying space, then X is a sub-prescheme induced on an open subset of Z.*

Indeed, there is an open subset U of Y such that $X = U \cap \overline{X}$; since X is a reduced [I | 132]
sub-prescheme of Z by virtue of (5.2.2), the sub-prescheme X is induced by Z on the open subspace X by virtue of the uniqueness (5.2.1).

(5.2.4) Corollary. *Let $f : X \to Y$ be a morphism, and X' (resp. Y') a closed sub-prescheme of X (resp. Y) defined by a quasi-coherent sheaf of ideals $\mathscr{J}$ (resp. $\mathscr{K}$) of $\mathscr{O}_X$ (resp. $\mathscr{O}_Y$). Suppose that X' is reduced and that $f(X') \subset Y'$. Then we have $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$.*

Since the restriction of f to X' factors as $X' \to Y' \to Y$ by (5.2.2), it suffices to apply (4.4.6).

5.3 Diagonal; graph of a morphism.

(5.3.1) Let X be an S-prescheme; we call the *diagonal morphism* of X into $X \times_S X$, and denote by $\Delta_{X|S}$, or Δ_X, or even Δ if no confusion is possible, the S-morphism $(1_X, 1_X)_S$, in other words, the unique S-morphism Δ_X such that

$$p_1 \circ \Delta_X = p_2 \circ \Delta_X = 1_X \tag{5.3.1.1}$$

denoting by p_1, p_2 the projections of $X \times_S X$ (Definition 3.2.1). If $f : T \to X$, $g : T \to Y$ are two S-morphisms, we verify immediately that

$$(f, g)_S = (f \times_S g) \circ \Delta_{T|S} \tag{5.3.1.2}$$

The reader will observe that the preceding definition and the results stated in n^{os} (5.3.1) to (5.3.8) are valid in any category, *provided that the products that appear in them exist in that category.*

(5.3.2) Proposition. *Let X, Y be two S-preschemes; if we canonically identify the product $(X \times Y) \times (X \times Y)$ with $(X \times X) \times (Y \times Y)$, the morphism $\Delta_{X\times Y}$ is identified with $\Delta_X \times \Delta_Y$.*

Indeed, if p_1, q_1 are the first projections $X \times X \to X$, $Y \times Y \to Y$, the first projection $(X \times Y) \times (X \times Y) \to X \times Y$ is identified with $p_1 \times q_1$, and we have

$$(p_1 \times q_1) \circ (\Delta_X \times \Delta_Y) = (p_1 \circ \Delta_X) \times (q_1 \circ \Delta_Y) = 1_{X\times Y}$$

the same reasoning applies to the second projections.

(5.3.4) Corollary. *For every extension $S' \to S$ of the base prescheme, $\Delta_{X_{(S')}}$ is canonically identified with $(\Delta_X)_{(S')}$.*

It suffices to note that $(X \times_S X)_{(S')}$ is canonically identified with $X_{(S')} \times_{S'} X_{(S')}$ (3.3.10).

(5.3.5) Proposition. *Let X, Y be two S-preschemes and $\varphi : S \to T$ a morphism, making every S-prescheme a T-prescheme. Let $f : X \to S$, $g : Y \to S$ be the structural morphisms, p, q the projections of $X \times_S Y$, and $\pi = f \circ p = g \circ q$ the structural morphism $X \times_S Y \to S$. Then the diagram*

$$\begin{array}{ccc} X \times_S Y & \xrightarrow{(p,q)_T} & X \times_T Y \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle f\times_T g} \\ S & \xrightarrow[\Delta_{S|T}]{} & S \times_T S \end{array} \tag{5.3.5.1}$$

[I/133] is commutative, and identifies $X \times_S Y$ with the product of the $(S \times_T S)$-preschemes S and $X \times_T Y$, the projections being identified with π and $(p, q)_T$.

By virtue of (3.4.3), we are reduced to proving the corresponding proposition *in the category of sets*, by replacing X, Y, S by $X(Z)_T$, $Y(Z)_T$, $S(Z)_T$, Z being an arbitrary T-prescheme. But for the category of sets, the verification is immediate and is left to the reader.

(5.3.6) Corollary. *The morphism $(p, q)_T$ is identified (setting $P = S \times_T S$) with $1_{X\times_T Y} \times_P \Delta_S$.*

This follows from (5.3.5) and (3.3.4).

(5.3.7) Corollary. *If $f : X \to Y$ is an S-morphism, the diagram*

$$\begin{array}{ccc} X & \xrightarrow{(1_X,f)_S} & X \times_S Y \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f\times_S 1_Y} \\ Y & \xrightarrow[\Delta_Y]{} & Y \times_S Y \end{array}$$

is commutative, and identifies X with the product of the $(Y \times_S Y)$-preschemes Y and $X \times_S Y$.

It suffices to apply (5.3.5), replacing S by Y and T by S, and noting that $X \times_Y Y = X$ (3.3.3).

(5.3.8) Proposition. *For $f : X \to Y$ to be a monomorphism of preschemes, it is necessary and sufficient that $\Delta_{X|Y}$ be an isomorphism of X onto $X \times_Y X$.*

Indeed, to say that f is a monomorphism means that for every Y-prescheme Z, the corresponding map $f' : X(Z)_Y \to Y(Z)_Y$ is an injection, and since $Y(Z)_Y$ consists of a single element, this means that $X(Z)_Y$ has at most one element. But this can also be expressed by saying that $X(Z)_Y \times X(Z)_Y$ is canonically isomorphic to $X(Z)_Y$, and since the first of these sets is $(X \times_Y X)(Z)_Y$ (3.4.3.1), this means that $\Delta_{X|Y}$ is an isomorphism.

(5.3.9) Proposition. *The diagonal morphism Δ_X is an immersion of X into $X \times_S X$.*

To obtain a correct proof, it suffices to use (4.2.4, *a*): for every $x \in X$, choose an affine open neighbourhood $V \subset S$ of its image and an affine open neighbourhood U of x in X whose image is contained in V. Then $U \times_S U = U \times_V U$ is an affine open neighbourhood of $\Delta_X(x)$; taking into account (5.3.16) (whose proof uses only the definition (5.3.1.1)), we are reduced to proving (5.3.9) when $S = \mathrm{Spec}(B)$ and $X = \mathrm{Spec}(A)$ are affine schemes; it is then clear by virtue of (5.3.1.1) that Δ_X corresponds to the canonical homomorphism $A \otimes_B A \to A$ which sends $x \otimes y$ to xy; this homomorphism being surjective, Δ_X is in this case a closed immersion (4.2.3), which completes the proof.

We say that the sub-prescheme of $X \times_S X$ associated to the immersion Δ_X (4.2.1) is *the diagonal* of $X \times_S X$.

(5.3.10) Corollary. *Under the hypotheses of (5.3.5), $(p, q)_T$ is an immersion.*

This follows from (5.3.6) and (4.3.1).

We say (under the hypotheses of (5.3.5)) that $(p, q)_T$ is the *canonical immersion* of $X \times_S Y$ into $X \times_T Y$.

(5.3.11) Corollary. *Let X, Y be two S-preschemes and $f : X \to Y$ an S-morphism; then the graph morphism $\Gamma_f = (1_X, f)_S$ of f (3.3.14) is an immersion of X into $X \times_S Y$.*

This is the particular case of Corollary (5.3.10) where we replace S by Y and T by S (cf. (5.3.7)).

The sub-prescheme of $X \times_S Y$ associated to the immersion Γ_f (4.2.1) is called the *graph* of the morphism f; the sub-preschemes of $X \times_S Y$ that are graphs of morphisms $X \to Y$ are characterized by the fact that the restriction to such a sub-prescheme G of the projection $p_1 : X \times_S Y \to X$ is an *isomorphism* g of G onto X: G is then the graph of the morphism $p_2 \circ g^{-1}$, where p_2 is the projection $X \times_S Y \to Y$. [I | 134]

When in particular we take $X = S$, the S-morphisms $S \to Y$, which are none other than the S-sections of Y (2.5.5), are equal to their graph morphisms; the sub-preschemes of Y that are graphs of S-sections (in other words, those that are isomorphic to S via the restriction of the structural morphism $Y \to S$) are also called the *images* of these sections, or, by abuse of language, the *S-sections* of Y.

(5.3.12) Corollary. *The hypotheses and notation being those of (5.3.11), for every morphism $g : S' \to S$, let f' be the inverse image of f by g (3.3.7); then $\Gamma_{f'}$ is the inverse image of Γ_f by g.*

This is a particular case of formula (3.3.10.1).

(5.3.13) Corollary. *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms; if $g \circ f$ is an immersion (resp. a local immersion), then so is f.*

Indeed, f factors as

$$X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y.$$

On the other hand, p_2 is identified with $(g \circ f) \times_Z 1_Y$ (3.3.4); if $g \circ f$ is an immersion (resp. a local immersion), then so is p_2 (4.3.1 and 4.5.5), and since Γ_f is an immersion (5.3.11), we conclude by (4.2.5) (resp. (4.5.5)).

(5.3.14) Corollary. *Let $j : X \to Y$, $g : X \to Z$ be two S-morphisms. If j is an immersion (resp. a local immersion), then so is $(j, g)_S$.*

Indeed, if $p : Y \times_S Z \to Y$ is the first projection, we have $j = p \circ (j, g)_S$, and it suffices to apply (5.3.13).

(5.3.15) Proposition. *If $f : X \to Y$ is an S-morphism, the diagram*

$$\begin{array}{ccc} X & \xrightarrow{\Delta_X} & X \times_S X \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle f \times_S f} \\ Y & \xrightarrow[\Delta_Y]{} & Y \times_S Y \end{array} \tag{5.3.15.1}$$

is commutative (in other words, Δ_X is a functorial morphism in the category of preschemes).

The verification is immediate and is left to the reader.

(5.3.16) Corollary. *If X is a sub-prescheme of Y, the diagonal $\Delta_X(X)$ is identified with a sub-prescheme of $\Delta_Y(Y)$, whose underlying space is identified with*

$$\Delta_Y(Y) \cap p_1^{-1}(X) = \Delta_Y(Y) \cap p_2^{-1}(X)$$

(p_1, p_2 being the projections of $Y \times_S Y$).

Let us apply (5.3.15) to the injection morphism $f : X \to Y$; we then know that $f \times_S f$ is an immersion, identifying the underlying space of $X \times_S X$ with the subspace $p_1^{-1}(X) \cap p_2^{-1}(X)$ of $Y \times_S Y$ (4.3.1); moreover, if $z \in \Delta_Y(Y) \cap p_1^{-1}(X)$, we have $z = \Delta_Y(y)$
[I | 135] and $y = p_1(z) \in X$, so $y = f(y)$, and $z = \Delta_Y(f(y))$ belongs to $\Delta_X(X)$ by virtue of the commutativity of the diagram (5.3.15.1).

(5.3.17) Corollary. *Let $f_1 : Y \to X$, $f_2 : Y \to X$ be two S-morphisms, and y a point of Y such that $f_1(y) = f_2(y) = x$ and such that the homomorphisms $k(x) \to k(y)$ corresponding to f_1 and f_2 are identical. Then, if $f = (f_1, f_2)_S$, the point $f(y)$ belongs to the diagonal $\Delta_{X|S}(X)$.*

The two homomorphisms $k(x) \to k(y)$ corresponding to f_i $(i = 1, 2)$ define two S-morphisms $g_i : \mathrm{Spec}(k(y)) \to \mathrm{Spec}(k(x))$ such that the diagrams

$$\begin{array}{ccc} \mathrm{Spec}(k(y)) & \xrightarrow{g_i} & \mathrm{Spec}(k(x)) \\ \downarrow & & \downarrow \\ Y & \xrightarrow[f_i]{} & X \end{array}$$

are commutative. The diagram

$$\begin{array}{ccc} \mathrm{Spec}(k(y)) & \xrightarrow{(g_1, g_2)_S} & \mathrm{Spec}(k(x)) \times_S \mathrm{Spec}(k(x)) \\ \downarrow & & \downarrow \\ Y & \xrightarrow[(f_1, f_2)_S]{} & X \times_S X \end{array}$$

is therefore also commutative. Now it follows from the equality $g_1 = g_2$ that the image under $(g_1, g_2)_S$ of the unique point of $\mathrm{Spec}(k(y))$ belongs to the diagonal of $\mathrm{Spec}(k(x)) \times_S \mathrm{Spec}(k(x))$; the conclusion therefore follows from (5.3.15).

5.4 Separated morphisms and preschemes.

(5.4.1) Definition. We say that a morphism of preschemes $f : X \to Y$ is *separated* if the diagonal morphism $X \to X \times_Y X$ is a *closed immersion*; we then also say that X is a *prescheme separated over* Y, or a Y*-scheme*. We say that a prescheme X is separated if it is separated over $\mathrm{Spec}(\mathbf{Z})$; we then also say that X is a *scheme* (cf. (5.5.7)).

By virtue of (5.3.9), for X to be separated over Y, it is necessary and sufficient that $\Delta_X(X)$ be a *closed subspace* of the underlying space of $X \times_Y X$.

(5.4.2) Proposition. *Let $S \to T$ be a separated morphism. If X and Y are two S-preschemes, the canonical immersion $X \times_S Y \to X \times_T Y$ (5.3.10) is closed.*

Indeed, referring to the diagram (5.3.5.1), we see that $(p, q)_T$ can be regarded as obtained from $\Delta_{S|T}$ by the extension $f \times_T g : X \times_T Y \to S \times_T S$ of the base prescheme $S \times_T S$; the proposition then follows from (4.3.2).

(5.4.3) Corollary. *Let Y be an S-scheme and $f : X \to Y$ an S-morphism. Then the graph morphism $\Gamma_f : X \to X \times_S Y$ (5.3.11) is a closed immersion.*

This is the particular case of (5.4.2) where we replace S by Y and T by S.

(5.4.4) Corollary. *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms, g being separated. If $g \circ f$ is a closed immersion, then so is f.*

The proof from (5.4.3) is the same as that of (5.3.13) from (5.3.11).

(5.4.5) Corollary. *Let Z be an S-scheme and $j : X \to Y$, $g : X \to Z$ two S-morphisms. If j is a closed immersion, then so is $(j, g)_S : X \to Y \times_S Z$.* [I | 136]

The proof from (5.4.4) is the same as that of (5.3.14) from (5.3.13).

(5.4.6) Corollary. *If X is an S-scheme, every S-section of X (2.5.5) is a closed immersion.*

If $\varphi : X \to S$ is the structural morphism and $\psi : S \to X$ an S-section of X, it suffices to apply (5.4.5) to $\varphi \circ \psi = 1_S$.

(5.4.7) Corollary. *Let S be an integral prescheme, s its generic point, and X an S-scheme. If two S-sections f, g of X are such that $f(s) = g(s)$, then $f = g$.*

Indeed, if $x = f(s) = g(s)$, the homomorphisms $k(x) \to k(s)$ corresponding to f and g are necessarily identical. If $h = (f, g)_S$, we deduce from this (5.3.17) that $h(s)$ belongs to the diagonal $Z = \Delta_X(X)$; but since $S = \overline{\{s\}}$ and Z is closed by hypothesis, we have $h(S) \subset Z$. It then follows from (5.2.2) that h factors as $S \to Z \to X \times_S X$, and we conclude that $f = g$ by the definition of the diagonal.

(5.4.8) Remark. If we suppose conversely that the conclusion of (5.4.3) holds when $f = 1_Y$, we conclude that Y is separated over S; similarly, if we suppose that the conclusion of (5.4.4) applies to the two morphisms

$$Y \xrightarrow{\Delta_Y} Y \times_Z Y \xrightarrow{p_1} Y,$$

we deduce that Δ_Y is a closed immersion, hence that Y is separated over Z; finally, the validity of the conclusion of (5.4.6) for the Y-section Δ_Y of the Y-prescheme $Y \times_S Y \to Y$ implies that Y is separated over S.

5.5 Criteria for separatedness.

(5.5.1) Proposition.

(i) *Every monomorphism of preschemes (and in particular every immersion) is a separated morphism.*

(ii) *The composite of two separated morphisms is separated.*

(iii) *If $f : X \to X'$, $g : Y \to Y'$ are two separated S-morphisms, $f \times_S g$ is separated.*

(iv) *If $f : X \to Y$ is a separated S-morphism, the S'-morphism $f_{(S')}$ is separated for every extension $S' \to S$ of the base prescheme.*

(v) *If the composite $g \circ f$ of two morphisms is separated, f is separated.*

(vi) *For a morphism f to be separated, it is necessary and sufficient that f_{red} (5.1.5) be separated.*

(i) follows immediately from (5.3.8). If $f : X \to Y$, $g : Y \to Z$ are two morphisms, the diagram

$$\begin{array}{ccc} X & \xrightarrow{\Delta_{X|Z}} & X \times_Z X \\ & {\scriptstyle \Delta_{X|Y}} \searrow \quad \nearrow {\scriptstyle j} & \\ & X \times_Y X & \end{array} \tag{5.5.1.1}$$

where j denotes the canonical immersion (5.3.10), is commutative, as we verify immediately. If f and g are separated, $\Delta_{X|Y}$ is a closed immersion by definition, and j is a closed immersion by virtue of (5.4.2), so $\Delta_{X|Z}$ is a closed immersion by (4.2.4), which
[I | 137] proves (ii). In view of (i) and (ii), (iii) and (iv) are equivalent (3.5.1), and it suffices to prove (iv). Now $X_{(S')} \times_{Y_{(S')}} X_{(S')}$ is canonically identified with $(X \times_Y X) \times_Y Y_{(S')}$ by virtue of (3.3.11) and (3.3.9.1), and we verify immediately that the diagonal morphism $\Delta_{X_{(S')}}$ is then identified with $\Delta_X \times_Y 1_{Y_{(S')}}$; the proposition therefore follows from (4.3.1).

To establish (v), consider, as in (5.3.13), the factorization $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$ of f, noting that $p_2 = (g \circ f) \times_Z 1_Y$; the hypothesis that $g \circ f$ is separated implies that p_2 is separated by (iii) and (i), and since Γ_f is an immersion, Γ_f is separated by (i), so f is separated by (ii). Finally, to prove (vi), recall that the preschemes $X_{\mathrm{red}} \times_{Y_{\mathrm{red}}} X_{\mathrm{red}}$ and $X_{\mathrm{red}} \times_Y X_{\mathrm{red}}$ are canonically identified (5.1.7); if we denote by j the injection $X_{\mathrm{red}} \to X$, the diagram

$$\begin{array}{ccc} X_{\mathrm{red}} & \xrightarrow{\Delta_{X_{\mathrm{red}}}} & X_{\mathrm{red}} \times_Y X_{\mathrm{red}} \\ {\scriptstyle j}\downarrow & & \downarrow{\scriptstyle j \times_Y j} \\ X & \xrightarrow[\Delta_X]{} & X \times_Y X \end{array}$$

is commutative (5.3.15), and the proposition follows from the fact that the vertical arrows are homeomorphisms of the underlying spaces (4.3.1).

(5.5.2) Corollary. *If $f : X \to Y$ is separated, the restriction of f to every subprescheme of X is separated.*

This follows from (5.5.1, (i) and (ii)).

(5.5.3) Corollary. *If X, Y are two S-preschemes such that Y is separated over S, then $X \times_S Y$ is separated over X.*

This is a particular case of (5.5.1, (iv)).

(5.5.4) Proposition. *Let X be a prescheme, and suppose that its underlying space is the union of a finite family of closed subsets X_k $(1 \leq k \leq n)$; for each k we consider the reduced sub-prescheme of X having X_k as underlying space (5.2.1), and we again denote it by X_k. Let $f : X \to Y$ be a morphism, and for each k, let Y_k be a closed subset of Y such that $f(X_k) \subset Y_k$; we again denote by Y_k the reduced sub-prescheme of Y having Y_k as underlying space, so that the restriction $X_k \to Y$ of f to X_k factors as $X_k \xrightarrow{f_k} Y_k \to Y$ (5.2.2). For f to be separated, it is necessary and sufficient that the f_k be separated.*

Necessity follows from (5.5.1, (i), (ii) and (v)). Conversely, if the condition of the statement is satisfied, each of the restrictions $X_k \to Y$ of f is separated (5.5.1, (i) and (ii)); if p_1, p_2 are the projections of $X \times_Y X$, the subspace $\Delta_{X_k}(X_k)$ is identified with the subspace $\Delta_X(X) \cap p_1^{-1}(X_k)$ of the underlying space of $X \times_Y X$ (5.3.16); since these subspaces are closed in $X \times_Y X$, so is their union $\Delta_X(X)$.

Suppose in particular that the X_k are the *irreducible components* of X; then we may suppose that the Y_k are irreducible components of Y (0, 2.1.5); in this case Proposition (5.5.4) therefore reduces the notion of separatedness to the case of *integral* preschemes (2.1.7).

(5.5.5) Proposition. *Let (Y_λ) be an open covering of a prescheme Y; for a morphism $f : X \to Y$ to be separated, it is necessary and sufficient that each of its restrictions $f^{-1}(Y_\lambda) \to Y_\lambda$ be separated.* [I | 138]

If we set $X_\lambda = f^{-1}(Y_\lambda)$, it all comes down, taking into account (4.2.4, b)) and the identity of the products $X_\lambda \times_Y X_\lambda$ and $X_\lambda \times_{Y_\lambda} X_\lambda$ (3.2.5), to proving that the $X_\lambda \times_Y X_\lambda$ form a covering of $X \times_Y X$. Now, if we set $Y_{\lambda\mu} = Y_\lambda \cap Y_\mu$ and $X_{\lambda\mu} = X_\lambda \cap X_\mu = f^{-1}(Y_{\lambda\mu})$, $X_\lambda \times_Y X_\mu$ is identified with the product $X_{\lambda\mu} \times_{Y_{\lambda\mu}} X_{\lambda\mu}$ (3.2.6.4), hence also with $X_{\lambda\mu} \times_Y X_{\lambda\mu}$ (3.2.5), and finally with an open subset of $X_\lambda \times_Y X_\lambda$, which establishes our assertion (3.2.7).

Proposition (5.5.4) makes it possible, by taking a covering of Y by affine open subsets, to reduce the study of separated morphisms to that of separated morphisms with values in affine schemes.

(5.5.6) Proposition. *Let Y be an affine scheme, X a prescheme, and (U_α) a covering of X by affine open subsets. For a morphism $f : X \to Y$ to be separated, it is necessary and sufficient that, for every pair of indices (α, β), $U_\alpha \cap U_\beta$ be an affine open subset, and that the ring $\Gamma(U_\alpha \cap U_\beta, \mathscr{O}_X)$ be generated by the union of the canonical images of the rings $\Gamma(U_\alpha, \mathscr{O}_X)$ and $\Gamma(U_\beta, \mathscr{O}_X)$.*

The $U_\alpha \times_Y U_\beta$ form an open covering of $X \times_Y X$ (3.2.7); denoting by p and q the projections of $X \times_Y X$, we have

$$\begin{aligned}\Delta_X^{-1}(U_\alpha \times_Y U_\beta) &= \Delta_X^{-1}\big(p^{-1}(U_\alpha) \cap q^{-1}(U_\beta)\big) \\ &= \Delta_X^{-1}\big(p^{-1}(U_\alpha)\big) \cap \Delta_X^{-1}\big(q^{-1}(U_\beta)\big) = U_\alpha \cap U_\beta\ ;\end{aligned}$$

it all comes down, therefore, to expressing that the restriction of Δ_X to $U_\alpha \cap U_\beta$ is a closed immersion into $U_\alpha \times_Y U_\beta$. Now this restriction is none other than $(j_\alpha, j_\beta)_Y$, denoting by j_α (resp. j_β) the injection morphism of $U_\alpha \cap U_\beta$ into U_α (resp. U_β), as follows from the definitions. Since $U_\alpha \times_Y U_\beta$ is an affine scheme whose ring is canonically isomorphic to $\Gamma(U_\alpha, \mathscr{O}_X) \otimes_{\Gamma(Y, \mathscr{O}_Y)} \Gamma(U_\beta, \mathscr{O}_X)$ (3.2.2), we see that $U_\alpha \cap U_\beta$ must be an affine scheme and that the map $h_\alpha \otimes h_\beta \to h_\alpha h_\beta$ from the ring $A(U_\alpha \times_Y U_\beta)$ to $\Gamma(U_\alpha \cap U_\beta, \mathscr{O}_X)$ must be surjective (4.2.3), which completes the proof.

(5.5.7) Corollary. *An affine scheme is separated (and is consequently a scheme, which justifies the terminology of (5.4.1)).*

(5.5.8) Corollary. *Let Y be an affine scheme; for $f : X \to Y$ to be a separated morphism, it is necessary and sufficient that X be separated (in other words, that X be a scheme).*

Indeed, we observe that the criterion of (5.5.6) does not depend on f.

(5.5.9) Corollary. *For a morphism $f : X \to Y$ to be separated, it is necessary that for every open subset U on which Y induces a separated prescheme, the induced prescheme $f^{-1}(U)$ be separated, and it is sufficient that this be so for every affine open subset $U \subset Y$.*

The necessity of the condition follows from (5.5.4) and (5.5.1, (ii)); the sufficiency follows from (5.5.4) and (5.5.8), taking into account the existence of affine open coverings of Y.

In particular, if X and Y are affine schemes, *every* morphism $X \to Y$ is separated.

(5.5.10) Proposition. *Let Y be a scheme and $f : X \to Y$ a morphism. For every affine open subset U of X and every affine open subset V of Y, $U \cap f^{-1}(V)$ is affine.*

Let p_1, p_2 be the projections of $X \times_{\mathbf{Z}} Y$; the subspace $U \cap f^{-1}(V)$ is the image under p_1 of $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$. Now $p_1^{-1}(U) \cap p_2^{-1}(V)$ is identified with the underlying space of the

[I | 139] prescheme $U \times_{\mathbf{Z}} V$ (3.2.7), and is consequently an affine scheme (3.2.2); since $\Gamma_f(X)$ is closed in $X \times_{\mathbf{Z}} Y$ (5.4.3), $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$ is closed in $U \times_{\mathbf{Z}} V$, and consequently the prescheme induced by the sub-prescheme of $X \times_{\mathbf{Z}} Y$ associated to Γ_f (4.2.1) on the open subset $\Gamma_f(X) \cap p_1^{-1}(U) \cap p_2^{-1}(V)$ of its underlying space is a closed sub-prescheme of an affine scheme, hence an affine scheme (4.2.3). The proposition then follows from the fact that Γ_f is an immersion.

(5.5.11) Examples. The prescheme of Example (2.3.2) ("projective line over a field K") is *separated*, because for the covering (X_1, X_2) of X by affine open subsets, $X_1 \cap X_2 = U_{12}$ is affine and $\Gamma(U_{12}, \mathscr{O}_X)$, the ring of rational fractions of the form $f(s)/s^m$ with $f \in K[s]$, is generated by $K[s]$ and by $1/s$, so the conditions of (5.5.6) are satisfied.

With the same choice of X_1, X_2, U_{12} and U_{21} as in Example (2.3.2), let us this time take for u_{12} the isomorphism which sends $f(s)$ to $f(t)$; this time we obtain by gluing an *integral non-separated* prescheme X, because the first condition of (5.5.6) is satisfied, but not the second. It is immediate here that $\Gamma(X, \mathscr{O}_X) \to \Gamma(X_1, \mathscr{O}_X) = K[s]$ is an isomorphism; the inverse isomorphism defines a morphism $f : X \to \mathrm{Spec}(K[s])$ which is surjective, and for every $y \in \mathrm{Spec}(K[s])$ such that $\mathfrak{j}_y \neq (0)$, $f^{-1}(y)$ consists of a single point, but for $\mathfrak{j}_y = (0)$, $f^{-1}(y)$ consists of *two* distinct points (we say that X is the "affine line over K, with the point 0 doubled").

We can also give examples where *neither* of the two conditions of (5.5.6) is satisfied. Let us first note that in the prime spectrum Y of the polynomial ring $A = K[s, t]$ in two indeterminates over a field K, the open subset U, the union of $D(s)$ and $D(t)$, *is not an affine open subset*. Indeed, if z is a section of $\mathscr{O}_Y$ over U, there exist two integers $m \geq 0$, $n \geq 0$ such that $s^m z$ and $t^n z$ are the restrictions to U of polynomials in s and t (1.4.1), which is evidently possible only if the section z extends to a section over the whole of Y, identified with a polynomial in s and t. If U were an affine open subset, the injection morphism $U \to Y$ would therefore be an isomorphism (1.7.3), which is absurd since $U \neq Y$.

This being so, take two affine schemes Y_1, Y_2, the prime spectra of the rings $A_1 = K[s_1, t_1]$, $A_2 = K[s_2, t_2]$; take $U_{12} = D(s_1) \cup D(t_1)$, $U_{21} = D(s_2) \cup D(t_2)$, and for u_{12} the

restriction to U_{21} of the isomorphism $Y_2 \to Y_1$ corresponding to the ring isomorphism which sends $f(s_1, t_1)$ to $f(s_2, t_2)$; we thus have an example where none of the conditions of (5.5.6) is satisfied (the integral prescheme thus obtained is called the "affine plane over K, with the point 0 doubled").

(5.5.12) Remark. Given a property **P** of morphisms of preschemes, consider the following propositions:

(i) *Every closed immersion has the property* ***P****.*

(ii) *The composite of two morphisms having the property* ***P*** *has the property* ***P****.*

(iii) *If $f : X \to X'$, $g : Y \to Y'$ are two S-morphisms having the property* ***P****, then $f \times_S g$ has the property* ***P****.*

(iv) *If $f : X \to Y$ is an S-morphism having the property* ***P****, every S'-morphism $f_{(S')}$ obtained by an extension $S' \to S$ of the base prescheme has the property* ***P****.* [I | 140]

(v) *If the composite $g \circ f$ of two morphisms $f : X \to Y$, $g : Y \to Z$ has the property* ***P****, and if g is separated, then f has the property* ***P****.*

(vi) *If a morphism $f : X \to Y$ has the property* ***P****, then so does f_{red} (5.1.5).*

Under these conditions, if we suppose (i) and (ii) satisfied, (iii) and (iv) are *equivalent*, and (v) and (vi) are *consequences* of (i), (ii) and (iii).

The first assertion has already been proved (3.5.1). Consider the factorization (5.3.13) of f as $X \xrightarrow{\Gamma_f} X \times_Z Y \xrightarrow{p_2} Y$; the relation $p_2 = (g \circ f) \times_Z 1_Y$ shows that if $g \circ f$ has the property **P**, then so does p_2 by virtue of (iii); if g is separated, Γ_f is a closed immersion (5.4.3), and so also has the property **P** by (i); finally, by virtue of (ii), f has the property **P**.

Finally, consider the commutative diagram

$$\begin{array}{ccc} X_{\mathrm{red}} & \xrightarrow{f_{\mathrm{red}}} & Y_{\mathrm{red}} \\ \downarrow & & \downarrow \\ X & \xrightarrow[f]{} & Y \end{array}$$

where the vertical arrows are closed immersions (5.1.5), and therefore have the property **P** by (i). The hypothesis that f has the property **P** therefore implies by (ii) that $X_{\mathrm{red}} \xrightarrow{f_{\mathrm{red}}} Y_{\mathrm{red}} \to Y$ has the property **P**; finally, since a closed immersion is separated (5.5.1, (i)), f_{red} has the property **P** by virtue of (v).

Note that if we consider the propositions:

(i') *Every immersion has the property* ***P****.*

(v') *If $g \circ f$ has the property* ***P****, then so does f;*

then the reasoning above shows that (v') is a consequence of (i'), (ii) and (iii).

(5.5.13) Note that (v) and (vi) are also consequences of (i), (iii) and

(ii') *If $j : X \to Y$ is a closed immersion and $g : Y \to Z$ a morphism having the property* ***P****, then $g \circ j$ has the property* ***P****.*

Similarly, (v') is a consequence of (i'), (iii) and

(ii") *If $j : X \to Y$ is an immersion and $g : Y \to Z$ a morphism having the property $\boldsymbol{P}$, then $g \circ j$ has the property $\boldsymbol{P}$.*

Indeed, this follows immediately from the arguments of (5.5.12).

§6 Finiteness conditions

6.1 Noetherian and locally Noetherian preschemes.

(6.1.1) Definition. We say that a prescheme X is *Noetherian* (resp. *locally Noetherian*) if it is a finite union (resp. a union) of affine open subsets V_α such that the ring of each of the schemes induced on the V_α is Noetherian.

It follows immediately from (1.5.2) that if X is locally Noetherian, the structural sheaf $\mathscr{O}_X$ is a *coherent sheaf of rings*, the question being local. *Every quasi-coherent sub-$\mathscr{O}_X$-*

[I | 141] *module (resp. every quasi-coherent quotient $\mathscr{O}_X$-module)* of a *coherent* $\mathscr{O}_X$-module $\mathscr{F}$ is then *coherent*, because the question is again local, and it suffices to apply (1.5.1), (1.4.1) and (1.3.10), together with the fact that a submodule (resp. quotient module) of a module of finite type over a Noetherian ring is of finite type. More particularly, *every quasi-coherent sheaf of ideals* of $\mathscr{O}_X$ is *coherent*.

If a prescheme X is a finite union (resp. a union) of open subsets W_λ such that the preschemes induced on the W_λ are Noetherian (resp. locally Noetherian), it is clear that X is Noetherian (resp. locally Noetherian).

(6.1.2) Proposition. *For a prescheme X to be Noetherian, it is necessary and sufficient that it be locally Noetherian and that its underlying space be quasi-compact. The underlying space of X is then Noetherian.*

Proof. The first assertion follows immediately from the definitions and from (1.1.10 (ii)). The second follows from (1.1.6) and from the fact that every space that is a finite union of Noetherian subspaces is Noetherian (0, 2.2.3). □

(6.1.3) Proposition. *Let X be an affine scheme with ring A. The following conditions are equivalent: a) X is Noetherian; b) X is locally Noetherian; c) A is Noetherian.*

Proof. The equivalence of a) and b) follows from (6.1.2) and from the fact that every affine scheme has a quasi-compact underlying space (1.1.10); moreover, it is clear that c) implies a). To see that a) implies c), note that there is a finite covering (V_i) of X by affine open subsets such that the ring A_i of the prescheme induced on V_i is Noetherian. Let then $(\mathfrak{a}_n)$ be an increasing sequence of ideals of A; there corresponds to it canonically and bijectively (1.3.7) an increasing sequence $(\widetilde{\mathfrak{a}}_n)$ of sheaves of ideals in $\widetilde{A} \equiv \mathscr{O}_X$; to see that the sequence $(\mathfrak{a}_n)$ is stationary, it suffices to prove that the sequence $(\widetilde{\mathfrak{a}}_n)$ is. Now the restriction $\widetilde{\mathfrak{a}}_n|V_i$ is a quasi-coherent sheaf of ideals in $\mathscr{O}_X|V_i$, being the inverse image of $\widetilde{\mathfrak{a}}_n$ under the canonical injection $V_i \to X$ (0, 5.1.4); $\widetilde{\mathfrak{a}}_n|V_i$ is therefore of the form $\widetilde{\mathfrak{a}}_{ni}$, where $\mathfrak{a}_{ni}$ is an ideal of A_i (1.3.7). Since A_i is Noetherian, the sequence $(\mathfrak{a}_{ni})$ is stationary for every i, whence the proposition. □

Note that the preceding argument also proves that *if X is a Noetherian prescheme, every increasing sequence of coherent sheaves of ideals of $\mathscr{O}_X$ is stationary.*

(6.1.4) Proposition. *Every sub-prescheme of a Noetherian (resp. locally Noetherian) prescheme is Noetherian (resp. locally Noetherian).*

Proof. It suffices to give the proof for a Noetherian prescheme X; moreover, we are immediately reduced by Definition (6.1.1) to the case where X is an affine scheme. Since every sub-prescheme of X is a closed sub-prescheme of a prescheme induced on an open subset (4.1.3), we may restrict to considering the case of a sub-prescheme Y that is closed or induced on an open subset of X. The case where Y is closed is immediate, because if A is the ring of X, we know that Y is an affine scheme with ring $A/\mathfrak{J}$, where $\mathfrak{J}$ is an ideal of A (4.2.3); since A is Noetherian (6.1.3), so is $A/\mathfrak{J}$.

Suppose now that Y is open in X; the underlying space Y is Noetherian (6.1.2), hence quasi-compact, and consequently a finite union of open subsets $D(f_i)$ ($f_i \in A$); it [I | 142] all comes down to proving the proposition when $Y = D(f)$ with $f \in A$. But then Y is an affine scheme whose ring is isomorphic to A_f (1.3.6); since A is Noetherian (6.1.3), so is A_f. □

(6.1.5) Note that the *product* of two Noetherian S-preschemes is not necessarily Noetherian, even if these preschemes are affine, because the tensor product of two Noetherian algebras is not necessarily a Noetherian ring (cf. (6.3.8)).

(6.1.6) Proposition. *If X is a Noetherian prescheme, the nilradical $\mathscr{N}_X$ of $\mathscr{O}_X$ is nilpotent.*

Indeed, we can cover X by finitely many affine open subsets U_i, and it suffices to prove that there exist integers n_i such that $(\mathscr{N}_X|U_i)^{n_i} = 0$; if n is the largest of the n_i, we will then have $\mathscr{N}_X^n = 0$. We are therefore reduced to the case where $X = \mathrm{Spec}(A)$ is affine, A being a Noetherian ring; by virtue of (5.1.1) and (1.3.13), it suffices to observe that the nilradical of A is nilpotent ([11], p. 127, cor. 4).

(6.1.7) Corollary. *Let X be a Noetherian prescheme; for X to be an affine scheme, it is necessary and sufficient that X_{red} be one.*

This follows from (6.1.6) and (5.1.10).

(6.1.8) Lemma. *Let X be a topological space, x a point of X, and U an open neighbourhood of x having only finitely many irreducible components. Then there exists a neighbourhood V of x such that every open neighbourhood of x contained in V is connected.*

Let U_i ($1 \leq i \leq m$) be the irreducible components of U not containing x; the complement in U of the union of the U_i is an open neighbourhood V of x in U, hence also in X; it is moreover the intersection with U of the complement in X of the union of the irreducible components of X that do not contain x (0, 2.1.6). Let then W be an open neighbourhood of x contained in V. The irreducible components of W are the traces on W of the irreducible components of U that meet W (0, 2.1.6), so these components contain x; since they are connected, so is W.

(6.1.9) Corollary. *A locally Noetherian topological space is locally connected (which implies, among other things, that its connected components are open).*

(6.1.10) Proposition. *Let X be a locally Noetherian topological space. The following conditions are equivalent:*

a) The irreducible components of X are open.

b) The irreducible components of X are identical with its connected components.

c) The connected components of X are irreducible.

d) Two distinct irreducible components of X do not meet.

Finally, if X is a prescheme, these conditions are also equivalent to:

e) For every $x \in X$, $\mathrm{Spec}(\mathscr{O}_x)$ is irreducible (in other words, the nilradical of $\mathscr{O}_x$ is prime).

It is immediate that a) implies b), because an irreducible space is connected, and a) implies that the irreducible components of X are sets that are both open and closed. It
[I | 143] is trivial that b) implies c); conversely, a closed set F containing a connected component C of X and distinct from C cannot be irreducible, because this set, not being connected, is the union of two non-empty disjoint sets that are both open and closed in F, hence closed in X; consequently c) implies b). We conclude immediately that c) implies d), two distinct connected components having no point in common.

So far we have not used the fact that X is locally Noetherian. Suppose now that this hypothesis is satisfied, and let us show that d) implies a): by virtue of (0, 2.1.6), we may restrict to the case where the space X is Noetherian, and so has only finitely many irreducible components. Since these are closed and pairwise disjoint, they are open.

Finally, the equivalence of d) and e) holds without assuming that the underlying space of the prescheme X is locally Noetherian. Indeed, we can reduce to the case where $X = \mathrm{Spec}(A)$ is affine by virtue of (0, 2.1.6); to say that x is contained in only one irreducible component of X then means that $\mathfrak{j}_x$ contains only one minimal ideal of A (1.1.14), which is equivalent to saying that $\mathfrak{j}_x\mathscr{O}_x$ contains only one minimal ideal of $\mathscr{O}_x$, whence the conclusion.

(6.1.11) Corollary. *Let X be a locally Noetherian space. For X to be irreducible, it is necessary and sufficient that X be connected and non-empty, and that two distinct irreducible components of X do not meet. If X is a prescheme, this last condition is equivalent to* $\mathrm{Spec}(\mathscr{O}_x)$ *being irreducible for every $x \in X$.*

The last part was seen in (6.1.10); it therefore only remains to prove the sufficiency of the conditions of the first assertion. But by (6.1.10), these conditions imply that the irreducible components of X are its connected components, and since X is connected and non-empty, it is irreducible.

(6.1.12) Corollary. *Let X be a locally Noetherian prescheme. For X to be integral, it is necessary and sufficient that X be connected and non-empty, and that $\mathscr{O}_x$ be integral for every $x \in X$.*

(6.1.13) Proposition. *Let X be a locally Noetherian prescheme, and let $x \in X$ be a point such that the nilradical $\mathscr{N}_x$ of $\mathscr{O}_x$ is prime (resp. such that $\mathscr{O}_x$ is reduced, resp. integral); then there exists an open neighbourhood U of x which is irreducible (resp. reduced, resp. integral).*

It suffices to consider the two cases where $\mathscr{N}_x$ is prime and where $\mathscr{N}_x = 0$, the third hypothesis being the conjunction of the first two. If $\mathscr{N}_x$ is prime, x belongs to only one irreducible component Y of X (6.1.10); the union of the irreducible components of X not containing x is closed (the set of these components being locally finite), and the

complement U of this union is therefore open and contained in Y, hence irreducible (0, 2.1.6). If $\mathscr{N}_x = 0$, we also have $\mathscr{N}_y = 0$ for every y in a neighbourhood of x, because $\mathscr{N}$ is quasi-coherent (5.1.1), and consequently coherent since X is locally Noetherian, and the conclusion follows from (0, 5.2.2).

6.2 Artinian preschemes.

(6.2.1) Definition. We say that a prescheme is *Artinian* if it is affine and its ring is Artinian.

(6.2.2) Proposition. *Given a prescheme X, the following conditions are equivalent:* [I | 144]

a) X is an Artinian scheme;

b) X is Noetherian and its underlying space is discrete;

c) X is Noetherian and the points of its underlying space are closed (condition T_1).

When this is so, the underlying space of X is finite, and the ring A of X is the direct product of the (Artinian) local rings of the points of X.

We know that a) implies the last assertion ([13], p. 205, th. 3); every prime ideal of A is then maximal and is the inverse image of the maximal ideal of one of the local components of A, so the space X is finite and discrete; a) therefore implies b), and b) evidently implies c). To see that c) implies a), let us first show that X is then finite; indeed, we can reduce to the case where X is affine, and we know that a Noetherian ring all of whose prime ideals are maximal is Artinian ([13], p. 203), whence our assertion. The underlying space X is then discrete, the topological sum of finitely many points x_i, and the local rings $\mathscr{O}_{x_i} = A_i$ are Artinian; it is clear that X is isomorphic to the affine scheme that is the prime spectrum of the ring A, the direct product of the A_i (1.7.3).

6.3 Morphisms of finite type.

(6.3.1) Definition. We say that a morphism $f : X \to Y$ is *of finite type* if Y is the union of a family (V_α) of affine open subsets having the following property:

(P) $f^{-1}(V_\alpha)$ is a finite union of affine open subsets $U_{\alpha i}$ such that each of the rings $A(U_{\alpha i})$ is an algebra of finite type over $A(V_\alpha)$.

We then also say that X is a prescheme of finite type over Y, or a Y-prescheme of finite type.

(6.3.2) Proposition. *If $f : X \to Y$ is a morphism of finite type, every affine open subset W of Y has the property (P) of Definition (6.3.1).*

We will first prove the

(6.3.2.1) Lemma. *If $T \subset Y$ is an affine open subset having the property (P), then, for every $g \in A(T)$, $D(g)$ has the property (P).*

Indeed, by hypothesis, $f^{-1}(T)$ is a finite union of affine open subsets Z_j such that $A(Z_j)$ is an algebra of finite type over $A(T)$; let $\varphi_j : A(T) \to A(Z_j)$ be the ring homomorphism corresponding to the restriction of f to Z_j (2.2.4), and set $g_j = \varphi_j(g)$; we then have $f^{-1}(D(g)) \cap Z_j = D(g_j)$ (1.2.2.2). Now $A(D(g_j)) = A(Z_j)_{g_j} = A(Z_j)[1/g_j]$ is of

finite type over $A(Z_j)$, and *a fortiori* over $A(T)$ by virtue of the hypothesis, hence also over $A(D(g)) = A(T)[1/g]$, which proves the lemma.

This lemma being established, since W is quasi-compact (1.1.10), there exists a finite covering of W by sets of the form $D(g_i)$, where each g_i belongs to a ring $A(V_{\alpha(i)})$. Each $D(g_i)$, being quasi-compact, is a finite union of sets $D(h_{ik})$ where $h_{ik} \in A(W)$; if $\varphi_i : A(W) \to A(D(g_i))$ is the canonical map, we have $D(h_{ik}) = D(\varphi_i(h_{ik}))$ by virtue of (1.2.2.2). By virtue of (6.3.2.1), each of the $f^{-1}(D(h_{ik}))$ admits a finite covering by affine open subsets U_{ijk} such that $A(U_{ijk})$ is an algebra of finite type over $A(D(h_{ik})) = A(W)[1/h_{ik}]$, whence the proposition.

[I | 145] We can therefore say that the notion of prescheme of finite type over Y is *local on* Y.

(6.3.3) Proposition. *Let X, Y be two affine schemes; for X to be of finite type over Y, it is necessary and sufficient that $A(X)$ be an algebra of finite type over $A(Y)$.*

The condition being evidently sufficient, let us prove that it is necessary. Set $A = A(Y)$, $B = A(X)$; by virtue of (6.3.2), there exists a finite affine open covering (V_i) of X such that each of the rings $A(V_i)$ is an A-algebra of finite type. Moreover, the V_i being quasi-compact, we can cover each of them by finitely many open subsets of the form $D(g_{ij}) \subset V_i$, where $g_{ij} \in B$; if φ_i is the homomorphism $B \to A(V_i)$ corresponding to the canonical injection $V_i \to X$, we have

$$B_{g_{ij}} = (A(V_i))_{\varphi_i(g_{ij})} = A(V_i)[1/\varphi_i(g_{ij})],$$

so $B_{g_{ij}}$ is an A-algebra of finite type. We can therefore reduce to the case where $V_i = D(g_i)$ with $g_i \in B$. By hypothesis, there exist a finite subset F_i of B and an integer $n_i \geq 0$ such that B_{g_i} is the algebra generated over A by the elements $b_i/g_i^{n_i}$, where b_i runs through F_i. Since there are only finitely many g_i, we may moreover suppose all the n_i equal to one and the same integer n. Furthermore, since the $D(g_i)$ form a covering of X, the ideal generated in B by the g_i is equal to B; in other words, there exist $h_i \in B$ such that $\sum_i h_i g_i = 1$. Let then F be the finite subset of B that is the union of the F_i, of the set of the g_i and of the set of the h_i; let us show that the subring $B' = A[F]$ of B is equal to B. By hypothesis, for every $b \in B$ and every i, the canonical image of b in B_{g_i} is of the form $b'_i/g_i^{m_i}$, where $b'_i \in B'$; by multiplying the b'_i by suitable powers of the g_i, we may further suppose all the m_i equal to one and the same integer m. By the definition of rings of fractions, there is therefore an integer N (depending on b) such that $N \geq m$ and $g_i^N b \in B'$ for every i; now, *in the ring* B', the g_i^N generate the ideal B', since the g_i do (the h_i belonging to B'); there are therefore $c_i \in B'$ such that $\sum_i c_i g_i^N = 1$, whence $b = \sum_i c_i g_i^N b \in B'$, Q.E.D.

(6.3.4) Proposition.

(i) Every closed immersion is of finite type.

(ii) The composite of two morphisms of finite type is of finite type.

(iii) If $f : X \to X'$, $g : Y \to Y'$ are two S-morphisms of finite type, $f \times_S g$ is of finite type.

(iv) If $f : X \to Y$ is an S-morphism of finite type, $f_{(S')}$ is of finite type for every extension $g : S' \to S$ of the base prescheme.

(v) If the composite $g \circ f$ of two morphisms is of finite type, and if g is separated, f is of finite type.

(vi) If a morphism f is of finite type, then so is f_{red}.

By virtue of (5.5.12), it suffices to prove (i), (ii) and (iv).

To establish (i), we may restrict to the case of a canonical injection $X \to Y$, X being a closed sub-prescheme of Y; moreover (6.3.2), we may suppose Y affine, in which case X is also affine (4.2.3) and its ring is isomorphic to a quotient ring $A/\mathfrak{J}$, where A is the ring of Y and $\mathfrak{J}$ an ideal of A; since $A/\mathfrak{J}$ is of finite type over A, the conclusion follows.

Let us now prove (ii). Let $f : X \to Y$, $g : Y \to Z$ be two morphisms of finite type, and let U be an affine open subset of Z; $g^{-1}(U)$ admits a finite covering by affine open subsets V_i such that $A(V_i)$ is an algebra of finite type over $A(U)$ (6.3.2); similarly, each of the $f^{-1}(V_i)$ admits a finite covering by affine open subsets W_{ij} such that $A(W_{ij})$ [I | 146] is an algebra of finite type over $A(V_i)$, and consequently also an algebra of finite type over $A(U)$; whence the conclusion.

Finally, to prove (iv), we may restrict to the case where $S = Y$; indeed, $f_{(S')}$ is also equal to $f_{(Y_{(S')})}$, f being considered as a Y-morphism and the base extension being $Y_{(S')} \to Y$ (3.3.9). Let then p, q be the projections $X_{(S')} \to X$ and $X_{(S')} \to S'$. Let V be an affine open subset in S; $f^{-1}(V)$ is a finite union of affine open subsets W_i each of which is such that $A(W_i)$ is an algebra of finite type over $A(V)$ (6.3.2). Let V' be an affine open subset of S' contained in $g^{-1}(V)$; since $f \circ p = g \circ q$, $q^{-1}(V')$ is contained in the union of the $p^{-1}(W_i)$; on the other hand, the intersection $p^{-1}(W_i) \cap q^{-1}(V')$ is identified with the product $W_i \times_V V'$ (3.2.7), which is an affine scheme with ring isomorphic to $A(W_i) \otimes_{A(V)} A(V')$ (3.2.2); since the latter is by hypothesis an algebra of finite type over $A(V')$, the proposition is proved.

(6.3.5) Corollary. *Let $f : X \to Y$ be an immersion morphism. If the underlying space of Y (resp. X) is locally Noetherian (resp. Noetherian), f is of finite type.*

We may always suppose Y affine (6.3.2); if the underlying space of Y is locally Noetherian, we may moreover suppose it Noetherian, and then the underlying space of X, which is a subspace of it, is Noetherian. In other words, we may suppose Y affine and the underlying space of X Noetherian; there then exists a covering of X by finitely many affine open subsets $D(g_i) \subset Y$, where $g_i \in A(Y)$, such that $X \cap D(g_i)$ is closed in $D(g_i)$ (hence an affine scheme (4.2.3)), since X is locally closed in Y (4.1.3). Then $A(X \cap D(g_i))$ is an algebra of finite type over $A(D(g_i))$, by (6.3.4, (i)) and (6.3.3), and $A(D(g_i)) = A(Y)_{g_i} = A(Y)[1/g_i]$ is of finite type over $A(Y)$, which completes the proof.

(6.3.6) Corollary. *Let $f : X \to Y$, $g : Y \to Z$ be two morphisms. If $g \circ f$ is of finite type, and if X is Noetherian, or $X \times_Z Y$ locally Noetherian, then f is of finite type.*

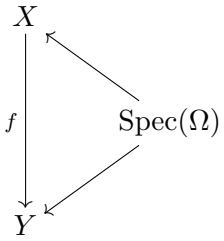
This follows immediately from the proof of (5.5.12) and from (6.3.5) applied to the immersion morphism Γ_f.

(6.3.7) Proposition. *Let $f : X \to Y$ be a morphism of finite type; if Y is Noetherian (resp. locally Noetherian), then X is Noetherian (resp. locally Noetherian).*

We may restrict to giving the proof when Y is Noetherian. Then Y is a finite union of affine open subsets V_i such that the $A(V_i)$ are Noetherian rings. By virtue of (6.3.2), each of the $f^{-1}(V_i)$ is a union of finitely many affine open subsets W_{ij} such that the $A(W_{ij})$ are algebras of finite type over $A(V_i)$, hence Noetherian rings; this proves that X is Noetherian.

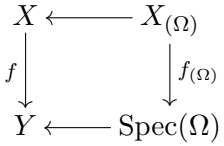
(6.3.8) Corollary. *Let X be a prescheme of finite type over S. For every base extension $S' \to S$ such that S' is Noetherian (resp. locally Noetherian), $X_{(S')}$ is Noetherian (resp. locally Noetherian).*

This follows from (6.3.7), $X_{(S')}$ being of finite type over S' by virtue of (6.3.4, (iv)).



[I | 147] We can also say that in a product $X \times_S Y$ of S-preschemes, if *one* of the factors X, Y is *of finite type* over S and *the other Noetherian* (resp. *locally Noetherian*), then $X \times_S Y$ is *Noetherian* (resp. *locally Noetherian*).

(6.3.9) Corollary. *Let X be a prescheme of finite type over a locally Noetherian prescheme S. Then every S-morphism $f : X \to Y$ is of finite type.*



Indeed, we may suppose S Noetherian; if $\varphi : X \to S$, $\psi : Y \to S$ are the structural morphisms, we have $\varphi = \psi \circ f$, and X is Noetherian by virtue of (6.3.7); f is therefore of finite type by virtue of (6.3.6).

(6.3.10) Proposition. *Let $f : X \to Y$ be a morphism of finite type. For f to be surjective, it is necessary and sufficient that, for every algebraically closed field Ω, the map $X(\Omega) \to Y(\Omega)$ corresponding to f (3.4.1) be surjective.*

The condition is sufficient, as we see by considering, for every $y \in Y$, an algebraically closed extension Ω of $k(y)$, and the commutative diagram

(*cf.* (3.5.3)). Conversely, suppose f surjective, and let $g : \{\xi\} = \mathrm{Spec}(\Omega) \to Y$ be a morphism, Ω being an algebraically closed field. If we consider the diagram

it therefore suffices to show that there exists in $X_{(\Omega)}$ a *point rational over* Ω (3.3.14, 3.4.3 and 3.4.4). Since f is surjective, $X_{(\Omega)}$ is not empty (3.5.10), and since f is of finite type, so is $f_{(\Omega)}$ (6.3.4, (iv)); hence $X_{(\Omega)}$ contains a non-empty affine open subset Z such that $A(Z)$ is a nonzero algebra of finite type over Ω. By virtue of Hilbert's Nullstellensatz [21], there exists an Ω-homomorphism $A(Z) \to \Omega$, hence a section of $X_{(\Omega)}$ over $\mathrm{Spec}(\Omega)$, which proves the proposition.

6.4 Algebraic preschemes.

(6.4.1) Definition. Given a field K, we call a prescheme X of finite type over K an *algebraic K-prescheme*; K is called the *base field* of X. If moreover X is a scheme (or, what amounts to the same thing (5.5.8), if X is a K-scheme), we also say that X is an *algebraic K-scheme*.

Every algebraic K-prescheme is *Noetherian* (6.3.7).

(6.4.2) Proposition. *Let X be an algebraic K-prescheme. For a point $x \in X$ to be closed, it is necessary and sufficient that $k(x)$ be an algebraic extension of K of finite degree.*

We may suppose X affine, the ring A of X being a K-algebra of finite type. Indeed, the affine open subsets U of X such that $A(U)$ is a K-algebra of finite type form a covering

of X (6.3.1). The closed points of X are then the points such that $\mathfrak{j}_x$ is a maximal ideal of A, in other words such that $A/\mathfrak{j}_x$ is a field (necessarily equal to $k(x)$). Since $A/\mathfrak{j}_x$ is a K-algebra of finite type, we see that if x is closed, $k(x)$ is a field which is an algebra of finite type over K, hence necessarily a K-algebra of *finite rank* [21]. Conversely, if $k(x)$ is of finite rank over K, so is $A/\mathfrak{j}_x \subset k(x)$, and since every integral ring that is a K-algebra of finite rank is a field, we have $A/\mathfrak{j}_x = k(x)$, so x is closed. [I | 148]

(6.4.3) Corollary. *Let K be an algebraically closed field and X an algebraic K-prescheme; the closed points of X are then the points rational over K (3.4.4) and are canonically identified with the points of X with values in K.*

(6.4.4) Proposition. *Let X be an algebraic prescheme over a field K. The following properties are equivalent:*

(a) *X is Artinian.*

(b) *The underlying space of X is discrete.*

(c) *The underlying space of X has only finitely many closed points.*

(c') *The underlying space of X is finite.*

(d) *The points of X are closed.*

(e) *X is isomorphic to* $\mathrm{Spec}(A)$*, where A is a K-algebra of finite rank.*

Since X is Noetherian, it follows from (6.2.2) that the conditions a), b), d) are equivalent and imply c) and c'); moreover, it is clear that e) implies a). It remains to see that c) implies d) and e); we may restrict to the case where X is affine. Then $A(X)$ is a K-algebra of finite type (6.3.3), hence a Jacobson ring ([1, p. 3-11 and 3-12]), in which there are by hypothesis only finitely many maximal ideals. Since a finite intersection of prime ideals can be a prime ideal only if it is equal to one of them, every prime ideal of $A(X)$ is therefore maximal, whence d). Moreover, we then know (6.2.2) that $A(X)$ is an Artinian K-algebra of finite type, hence necessarily of *finite rank* [21].

(6.4.5) When the conditions of (6.4.4) are satisfied, we say that X is a scheme *finite over K* (*cf.* (II, 6.1.1)), or a *finite K-scheme*, of *rank* $[A : K]$, which we also denote by $\mathrm{rg}_K(X)$; if X, Y are two schemes finite over K, we have

$$\mathrm{rg}_K(X \amalg Y) = \mathrm{rg}_K(X) + \mathrm{rg}_K(Y) \tag{6.4.5.1}$$

$$\mathrm{rg}_K(X \times_K Y) = \mathrm{rg}_K(X)\,\mathrm{rg}_K(Y) \tag{6.4.5.2}$$

as follows from (3.2.2).

(6.4.6) Corollary. *Let X be a scheme finite over a field K. For every extension K' of K, $X \otimes_K K'$ is a scheme finite over K', and its rank over K' is equal to the rank of X over K.*

Indeed, if $A = A(X)$, we have $[A \otimes_K K' : K'] = [A : K]$.

(6.4.7) Corollary. *Let X be a scheme finite over a field K; set $n = \sum_{x \in X} [k(x) : K]_s$* (recall that if K' is an extension of K, $[K' : K]_s$ is the *separable rank* of K' over K, the rank of the largest separable algebraic extension of K contained in K')*; then, for every algebraically closed extension Ω of K, the underlying space of $X \otimes_K \Omega$ has exactly n points, which are identified with the points of X with values in Ω.* [I | 149]

We may evidently restrict to the case where the ring $A = A(X)$ is local (6.2.2); let $\mathfrak{m}$ be its maximal ideal and $L = A/\mathfrak{m}$ its residue field, an algebraic extension of K. The points of X with values in Ω then correspond bijectively to the Ω-sections of $X \otimes_K \Omega$ (3.4.1 and 3.3.14), and also to the K-homomorphisms of L into Ω (1.7.3), whence the proposition (Bourbaki, *Alg.*, chap. V, §7, n° 5, prop. 8), taking into account (6.4.3).

(6.4.8) The number n defined in (6.4.7) is called the *separable rank* of A (or of X) over K, or also the *geometric number of points of* X; it is therefore equal to the number of elements of $X(\Omega)_K$. It follows immediately from this definition that, for every extension K' of K, $X \otimes_K K'$ has the same geometric number of points as X. If we denote this number by $n(X)$, it is clear that if X, Y are two schemes finite over K, we have

$$n(X \amalg Y) = n(X) + n(Y). \tag{6.4.8.1}$$

Under the same hypotheses, we also have

$$n(X \times_K Y) = n(X)n(Y) \tag{6.4.8.2}$$

as follows immediately from the interpretation of $n(X)$ as the number of elements of $X(\Omega)_K$ and from formula (3.4.3.1).

(6.4.9) Proposition. *Let K be a field, X, Y two algebraic K-preschemes, $f : X \to Y$ a K-morphism, and Ω an algebraically closed extension of K of infinite transcendence degree over K. For f to be surjective, it is necessary and sufficient that the map $X(\Omega)_K \to Y(\Omega)_K$ corresponding to f (3.4.1) be surjective.*

The necessity follows from (6.3.10), noting that f is necessarily of finite type (6.3.9). To see that the condition is sufficient, we argue as in (6.3.10), noting that for every $y \in Y$, $k(y)$ is an extension of K of finite type, and consequently is K-isomorphic to a subfield of Ω.

(6.4.10) Remark. We will see in Chapter IV that the conclusion of (6.4.9) still holds without any hypothesis on the transcendence degree of Ω over K.

(6.4.11) Proposition. *If $f : X \to Y$ is a morphism of finite type, then for every $y \in Y$, the fibre $f^{-1}(y)$ is an algebraic prescheme over the residue field $k(y)$, and for every $x \in f^{-1}(y)$, $k(x)$ is an extension of finite type of $k(y)$.*

Since $f^{-1}(y) = X \otimes_Y k(y)$ (3.6.3), the proposition follows from (6.3.4, (iv)) and (6.3.3).

(6.4.12) Proposition. *Let $f : X \to Y$, $g : Y' \to Y$ be two morphisms; set $X' = X \times_Y Y'$ and let $f' = f_{(Y')} : X' \to Y'$. Let $y' \in Y'$ and $y = g(y')$; if the fibre $f^{-1}(y)$ is a finite algebraic scheme over $k(y)$, then the fibre $f'^{-1}(y')$ is a finite algebraic scheme over $k(y')$, having the same rank and the same geometric number of points as $f^{-1}(y)$.*

Taking into account the transitivity of fibres (3.6.5), this follows immediately from (6.4.6) and (6.4.8).

(6.4.13) Proposition (6.4.11) shows that morphisms of finite type correspond intuitively
[I | 150] to "algebraic families of algebraic varieties", the points of Y playing the role of "parameters", which gives these morphisms a "geometric" meaning. Morphisms that are not of finite type will occur later mainly in questions of "change of the base prescheme", for example by localization or completion.

6.5 Local determination of a morphism

(6.5.1) Proposition. *Let X, Y be two S-preschemes, Y being of finite type over S; let $x \in X$, $y \in Y$ lie above the same point $s \in S$.*

(i) If two S-morphisms $f = (\psi, \theta)$, $f' = (\psi', \theta')$ from X to Y are such that $\psi(x) = \psi'(x) = y$ and the (local) $\mathscr{O}_s$-homomorphisms $\theta_x^\sharp$ and $\theta'^\sharp_x$ from $\mathscr{O}_y$ to $\mathscr{O}_x$ are identical, then f and f' coincide in an open neighbourhood of x.

(ii) Suppose moreover that S is locally Noetherian. For every local $\mathscr{O}_s$-homomorphism $\varphi : \mathscr{O}_y \to \mathscr{O}_x$, there exist an open neighbourhood U of x in X and an S-morphism $f = (\psi, \theta)$ from U to Y such that $\psi(x) = y$ and $\theta_x^\sharp = \varphi$.

(i) The question being local on S, X and Y, we may suppose S, X, Y affine with respective rings A, B, C, f and f' being of the form $({}^a\varphi, \widetilde{\varphi})$ and $({}^a\varphi', \widetilde{\varphi}')$ respectively, where φ and φ' are two A-homomorphisms from C to B such that $\varphi^{-1}(\mathfrak{j}_x) = \varphi'^{-1}(\mathfrak{j}_x) = \mathfrak{j}_y$, and the homomorphisms φ_x and φ'_x from C_y to B_x deduced from φ and φ' are identical; we may moreover suppose that C is an A-algebra of finite type. Let c_i $(1 \leq i \leq n)$ be generators of the A-algebra C, and set $b_i = \varphi(c_i)$, $b'_i = \varphi'(c_i)$; by hypothesis, we have $b_i/1 = b'_i/1$ in the ring of fractions B_x $(1 \leq i \leq n)$. This means that there exist elements $s_i \in B - \mathfrak{j}_x$ such that $s_i(b_i - b'_i) = 0$ for $1 \leq i \leq n$, and we may evidently suppose all the s_i equal to one and the same element $g \in B - \mathfrak{j}_x$. We conclude that $b_i/1 = b'_i/1$ for $1 \leq i \leq n$ in the ring of fractions B_g; if i_g is the canonical homomorphism $B \to B_g$, we consequently have $i_g \circ \varphi = i_g \circ \varphi'$; hence the restrictions of f and f' to $D(g)$ are identical.

(ii) We may reduce to the same situation as in (i), and suppose moreover that the ring A is Noetherian. Let c_i $(1 \leq i \leq n)$ be generators of the A-algebra C, and let $\alpha : A[X_1, \ldots, X_n] \to C$ be the homomorphism of the polynomial algebra $A[X_1, \ldots, X_n]$ onto C sending X_i to c_i for $1 \leq i \leq n$. On the other hand, let i_y be the canonical homomorphism $C \to C_y$, and consider the composite homomorphism

$$\beta : A[X_1, \ldots, X_n] \xrightarrow{\alpha} C \xrightarrow{i_y} C_y \xrightarrow{\varphi} B_x.$$

Denote by $\mathfrak{a}$ the kernel of β; since A is Noetherian, so is $A[X_1, \ldots, X_n]$, and consequently $\mathfrak{a}$ admits a finite system of generators $Q_j(X_1, \ldots, X_n)$ $(1 \leq j \leq m)$. On the other hand, each of the elements $\varphi(i_y(c_i))$ can be written b_i/s_i, where $b_i \in B$ and $s_i \notin \mathfrak{j}_x$; we may moreover suppose all the s_i equal to one and the same element $g \in B - \mathfrak{j}_x$. This being so, we have by hypothesis $Q_j(b_1/g, \ldots, b_n/g) = 0$ in B_x; set

$$Q_j(X_1/T, \ldots, X_n/T) = P_j(X_1, \ldots, X_n, T)/T^{k_j}$$

where P_j is homogeneous of degree k_j. Then let $d_j = P_j(b_1, \ldots, b_n, g) \in B$. By hypothesis, we have $t_j d_j = 0$ for some $t_j \in B - \mathfrak{j}_x$ $(1 \leq j \leq m)$, and we may evidently suppose all the t_j equal to one and the same element $h \in B - \mathfrak{j}_x$; we conclude that $P_j(hb_1, \ldots, hb_n, hg) = 0$ for $1 \leq j \leq m$. This being so, consider the homomorphism ρ of $A[X_1, \ldots, X_n]$ into the ring of fractions B_{hg} which maps X_i to hb_i/hg $(1 \leq i \leq n)$; the image of $\mathfrak{a}$ under this homomorphism is 0, and *a fortiori* so is the image under ρ of the kernel $\alpha^{-1}(0)$. Hence ρ factors as $A[X_1, \ldots, X_n] \xrightarrow{\alpha} C \xrightarrow{\gamma}$ [I | 151]

B_{hg}, with $\gamma(c_i) = hb_i/hg$, and it is clear that if i_x is the canonical homomorphism $B_{hg} \to B_x$, the diagram

$$\begin{array}{ccc} C & \xrightarrow{\gamma} & B_{hg} \\ {\scriptstyle i_y}\downarrow & & \downarrow{\scriptstyle i_x} \\ C_y & \xrightarrow[\varphi]{} & B_x \end{array} \tag{6.5.1.1}$$

is commutative; we therefore have $\varphi = \gamma_x$, and since φ is a local homomorphism, ${}^a\gamma(x) = y$; $f = ({}^a\gamma, \widetilde{\gamma})$ is therefore an S-morphism of the neighbourhood $D(hg)$ of x into Y which answers the question.

(6.5.2) Corollary. *Under the hypotheses of (6.5.1, (ii)), if moreover X is of finite type over S, we may suppose the morphism f to be of finite type.*

This follows from (6.3.6).

(6.5.3) Corollary. *Suppose the hypotheses of (6.5.1, (ii)) are satisfied, and suppose moreover that Y is integral and φ an injective homomorphism. Then we may suppose that $f = ({}^a\gamma, \widetilde{\gamma})$, where γ is injective.*

Indeed, we may suppose C integral (5.1.4), hence i_y injective; it then follows from the diagram (6.5.1.1) that γ is injective.

(6.5.4) Proposition. *Let $f = (\psi, \theta) : X \to Y$ be a morphism of finite type, x a point of X, $y = \psi(x)$.*

(i) For f to be a local immersion at the point x (4.5.1), it is necessary and sufficient that $\theta_x^\sharp : \mathscr{O}_y \to \mathscr{O}_x$ be surjective.

(ii) Suppose moreover that Y is locally Noetherian. For f to be a local isomorphism at the point x (4.5.2), it is necessary and sufficient that $\theta_x^\sharp$ be an isomorphism.

(ii) By virtue of (6.5.1), there then exist an open neighbourhood V of y and a morphism $g : V \to X$ such that $g \circ f$ (resp. $f \circ g$) is defined and coincides with the identity in a neighbourhood of x (resp. y), from which one easily deduces that f is a local isomorphism.

(i) The question being local on X and Y, we may suppose X and Y affine, with respective rings A, B; we have $f = ({}^a\varphi, \widetilde{\varphi})$, where φ is a ring homomorphism $B \to A$ which makes A a B-algebra of finite type; we have $\varphi^{-1}(\mathfrak{j}_x) = \mathfrak{j}_y$ and the homomorphism $\varphi_x : B_y \to A_x$ deduced from φ is surjective. Let (t_i) $(1 \leq i \leq n)$ be a system of generators of the B-algebra A; the hypothesis on φ_x implies that there exist elements $b_i \in B$ and an element $c \in B - \mathfrak{j}_y$ such that, in the ring of fractions A_x, we have $t_i/1 = \varphi(b_i)/\varphi(c)$ for $1 \leq i \leq n$. Consequently (1.3.3), there exists $a \in A - \mathfrak{j}_x$ such that, if we set $g = a\varphi(c)$, we also have $t_i/1 = a\varphi(b_i)/g$ *in the ring of fractions A_g*. This being so, there exists by hypothesis a polynomial
[I | 152] $Q(X_1, \ldots, X_n)$ with coefficients in the ring $\varphi(B)$, such that $a = Q(t_1, \ldots, t_n)$; set

$$Q(X_1/T, \ldots, X_n/T) = P(X_1, \ldots, X_n, T)/T^m,$$

where P is homogeneous of degree m. In the ring A_g, we have

$$a/1 = a^m P(\varphi(b_1), \ldots, \varphi(b_n), \varphi(c))/g^m = a^m \varphi(d)/g^m$$

where $d \in B$. Since, in A_g, $g/1 = (a/1)(\varphi(c)/1)$ is invertible by definition, so are $a/1$ and $\varphi(c)/1$, and we can therefore write

$$a/1 = (\varphi(d)/1)(\varphi(c)/1)^{-m}.$$

We conclude that $\varphi(d)/1$ is also invertible in A_g. Then set $h = cd$; since $\varphi(h)/1$ is invertible in A_g, the composite homomorphism

$$B \xrightarrow{\varphi} A \longrightarrow A_g$$

factors as

$$B \longrightarrow B_h \xrightarrow{\gamma} A_g$$

(0, 1.2.4). Let us show that γ is *surjective*; it suffices to verify that the image of B_h in A_g contains the $t_i/1$ and $(g/1)^{-1}$. Now, we have

$$(g/1)^{-1} = (\varphi(c)/1)^{m-1}(\varphi(d)/1)^{-1} = \gamma(c^m/h),$$

and

$$a/1 = \gamma(d^{m+1}/h^m),$$

hence

$$(a\varphi(b_i))/1 = \gamma(b_i d^{m+1}/h^m),$$

and since $t_i/1 = (a\varphi(b_i)/1)(g/1)^{-1}$, our assertion is proved. The choice of h implies that $\psi(D(g)) \subset D(h)$, and the restriction of f to $D(g)$ is equal to $({}^a\gamma, \widetilde{\gamma})$; since γ is surjective, this restriction is a closed immersion of $D(g)$ into $D(h)$ (4.2.3).

(6.5.5) Corollary. *Let $f = (\psi, \theta) : X \to Y$ be a morphism of finite type. Suppose X irreducible, denote by x its generic point, and set $y = \psi(x)$.*

(i) For f to be a local immersion at a point of X, it is necessary and sufficient that $\theta_x^\sharp : \mathscr{O}_y \to \mathscr{O}_x$ be surjective.

(ii) Suppose moreover that Y is irreducible and locally Noetherian. For f to be a local isomorphism at a point of X, it is necessary and sufficient that y be the generic point of Y (or, what amounts to the same (0, 2.1.4), that f be a dominant *morphism) and that $\theta_x^\sharp$ be an isomorphism (in other words, that f be* birational *(2.2.9)).*

It is clear that (i) follows from (6.5.4, (i)), taking into account the fact that every non-empty open subset of X contains x; similarly, (ii) follows from (6.5.4, (ii)).

6.6 Quasi-compact morphisms and morphisms locally of finite type

(6.6.1) Definition. We say that a morphism $f : X \to Y$ is *quasi-compact* if the inverse image under f of every quasi-compact open subset of Y is quasi-compact.

Let $\mathfrak{B}$ be a basis of the topology of Y consisting of quasi-compact open subsets (for example of affine open subsets); for f to be quasi-compact, it is necessary and sufficient that the inverse image under f of every set of $\mathfrak{B}$ be quasi-compact (or, what amounts to the same, a *finite* union of affine open subsets), since every quasi-compact open subset of Y is a finite union of sets of $\mathfrak{B}$. For example, if X is *quasi-compact* and Y *affine*, then *every* morphism $f : X \to Y$ is quasi-compact: indeed, X is a finite union of affine open

sets U_i, and for every affine open subset V of Y, $U_i \cap f^{-1}(V)$ is affine (5.5.10), hence quasi-compact.

If $f : X \to Y$ is a quasi-compact morphism, it is clear that for every open subset V of Y, the restriction of f to $f^{-1}(V)$ is a quasi-compact morphism $f^{-1}(V) \to V$. Conversely, if (U_α) is an open covering of Y and $f : X \to Y$ a morphism such that the restrictions $f^{-1}(U_\alpha) \to U_\alpha$ are quasi-compact, then f is quasi-compact.

(6.6.2) Definition. We say that a morphism $f : X \to Y$ is *locally of finite type* if, for every $x \in X$, there exist an open neighbourhood U of x and an open neighbourhood
[I | 153] $V \supset f(U)$ of $f(x)$ such that the restriction of f to U is a morphism of finite type from U to V. We then also say that X is a prescheme locally of finite type over Y, or a Y-prescheme locally of finite type.

It follows immediately from (6.3.2) that if f is locally of finite type, then, for every open subset W of Y, the restriction of f to $f^{-1}(W)$ is a morphism $f^{-1}(W) \to W$ which is locally of finite type.

If Y is locally Noetherian and X is locally of finite type over Y, then X is locally Noetherian by virtue of (6.3.7).

(6.6.3) Proposition. *A morphism $f : X \to Y$ is of finite type if and only if it is quasi-compact and locally of finite type.*

The necessity of the conditions is immediate, in view of (6.3.1) and the remark following (6.6.1). Conversely, suppose these conditions are satisfied and let U be an affine open subset of Y, with ring A; for every $x \in f^{-1}(U)$, there are by hypothesis a neighbourhood $V(x) \subset f^{-1}(U)$ of x and a neighbourhood $W(x) \subset U$ of $y = f(x)$, containing $f(V(x))$ and such that the restriction of f to $V(x)$ is a morphism $V(x) \to W(x)$ which is of finite type. Replacing $W(x)$ by a neighbourhood $W_1(x) \subset W(x)$ of y of the form $D(g)$ (with $g \in A$), and $V(x)$ by $V(x) \cap f^{-1}(W_1(x))$, we may suppose that $W(x)$ is of the form $D(g)$, hence of finite type over U (since its ring can be written $A[1/g]$); consequently $V(x)$ is of finite type over U. Moreover, $f^{-1}(U)$ is quasi-compact by hypothesis, hence a union of finitely many open subsets $V(x_i)$, which completes the proof.

(6.6.4) Proposition.

(i) An immersion $X \to Y$ is quasi-compact if it is closed, or if the underlying space of Y is locally Noetherian, or if the underlying space of X is Noetherian.

(ii) The composite of two quasi-compact morphisms is quasi-compact.

(iii) If $f : X \to Y$ is a quasi-compact S-morphism, then so is $f_{(S')} : X_{(S')} \to Y_{(S')}$ for every extension $g : S' \to S$ of the base prescheme.

(iv) If $f : X \to X'$ and $g : Y \to Y'$ are two quasi-compact S-morphisms, then $f \times_S g$ is quasi-compact.

(v) If the composite of two morphisms $f : X \to Y$, $g : Y \to Z$ is quasi-compact and if g is separated or the underlying space of X is locally Noetherian, then f is quasi-compact.

(vi) For a morphism f to be quasi-compact, it is necessary and sufficient that f_{red} be so.

Note that (vi) is evident, since the property of being quasi-compact for a morphism depends only on the corresponding continuous map of the underlying spaces. Let us

likewise prove the part of (v) corresponding to the case where the underlying space X is assumed to be locally Noetherian. Set $h = g \circ f$, and let U be a quasi-compact open subset of Y; $g(U)$ is quasi-compact (not necessarily open) in Z, hence contained in a finite union of quasi-compact open subsets V_j (2.1.3), and $f^{-1}(U)$ is consequently contained in the union of the $h^{-1}(V_j)$, which are quasi-compact subspaces of X, hence Noetherian subspaces. We conclude (0, 2.2.3) that $f^{-1}(U)$ is a Noetherian space, and *a fortiori* quasi-compact.

To prove the other assertions, it suffices to prove (i), (ii) and (iii) (5.5.12). Now, (ii) is evident, and (i) follows from (6.3.5) when the space Y is locally Noetherian or the space X Noetherian, and is evident for a closed immersion. To establish (iii), we may [I | 154] restrict to the case where $S = Y$ (3.3.11); set $f' = f_{(S')}$, and let U' be a quasi-compact open subset of S'. For every $s' \in U'$, let T be an affine open neighbourhood of $g(s')$ in S, and let W be an affine open neighbourhood of s' contained in $U' \cap g^{-1}(T)$; it will suffice to show that $f'^{-1}(W)$ is quasi-compact; in other words, we may reduce to proving that, when S and S' are affine, the underlying space of $X \times_S S'$ is quasi-compact. But since X is then, by hypothesis, a finite union of affine open subsets V_j, $X \times_S S'$ is the union of the underlying spaces of the affine schemes $V_j \times_S S'$ (3.2.2 and 3.2.7), which completes the proof of the proposition.

We note also that if $X = X' \amalg X''$ is the sum of two preschemes, a morphism $f : X \to Y$ is quasi-compact if and only if its restrictions to X' and X'' are.

(6.6.5) Proposition. *Let $f : X \to Y$ be a quasi-compact morphism. For f to be dominant, it is necessary and sufficient that for every generic point y of an irreducible component of Y, $f^{-1}(y)$ contain the generic point of an irreducible component of X.*

It is immediate that the condition is sufficient (without supposing f quasi-compact). To see that it is necessary, consider an affine open neighbourhood U of y; $f^{-1}(U)$ is quasi-compact, hence a *finite* union of affine open subsets V_i, and the hypothesis that f is dominant implies that y belongs to the closure in U of one of the $f(V_i)$. We may evidently suppose X and Y reduced; since the closure in X of an irreducible component of V_i is an irreducible component of X (0, 2.1.6), we may replace X by V_i, and Y by the reduced closed sub-prescheme of U having $\overline{f(V_i)} \cap U$ as underlying space (5.2.1), and we are thus reduced to proving the proposition when $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$ are affine and reduced. Since f is dominant, B is then a subring of A (1.2.7), and the proposition then follows from the fact that every minimal prime ideal of B is the intersection of B with a minimal prime ideal of A (0, 1.5.8).

(6.6.6) Proposition.

(i) Every local immersion is locally of finite type.

(ii) If two morphisms $f : X \to Y$, $g : Y \to Z$ are locally of finite type, then so is $g \circ f$.

(iii) If $f : X \to Y$ is an S-morphism locally of finite type, then $f_{(S')} : X_{(S')} \to Y_{(S')}$ is locally of finite type for every extension $S' \to S$ of the base prescheme.

(iv) If $f : X \to X'$ and $g : Y \to Y'$ are two S-morphisms locally of finite type, then $f \times_S g$ is locally of finite type.

(v) If the composite $g \circ f$ of two morphisms is locally of finite type, then f is locally of finite type.

(vi) If a morphism f is locally of finite type, then so is f_{red}.

By virtue of (5.5.12), it suffices to prove (i), (ii) and (iii). If $j : X \to Y$ is a local immersion, then for every $x \in X$ there are an open neighbourhood V of $j(x)$ in Y and an open neighbourhood U of x in X such that the restriction of j to U is a closed immersion $U \to V$ (4.5.1), hence this restriction is of finite type. To establish (ii), consider a point $x \in X$; there are by hypothesis an open neighbourhood W of $g(f(x))$ and an open neighbourhood V of $f(x)$ such that $g(V) \subset W$ and V is of finite type over W; moreover, $f^{-1}(V)$ is locally of finite type over V (6.6.2), hence there is an open neighbourhood
[I | 155] U of x which is contained in $f^{-1}(V)$ and of finite type over V; consequently we have $g(f(U)) \subset W$ and U is of finite type over W (6.3.4, (ii)). Finally, to prove (iii), we may restrict to the case where $Y = S$ (3.3.11); for every $x' \in X' = X_{(S')}$, let x be the image of x' in X, s the image of x in S, T an open neighbourhood of s, T' its inverse image in S', U an open neighbourhood of x whose image is contained in T and which is of finite type over T; then $U \times_S T' = U \times_T T'$ is an open neighbourhood of x' (3.2.7) which is of finite type over T' (6.3.4, (iv)).

(6.6.7) Corollary. *Let X, Y be two S-preschemes which are locally of finite type over S. If S is locally Noetherian, then $X \times_S Y$ is locally Noetherian.*

Indeed, X, being locally of finite type over S, is locally Noetherian, and $X \times_S Y$ is locally of finite type over X, hence is also locally Noetherian.

(6.6.8) Remark. Proposition (6.3.10) and its proof extend immediately to the case where we suppose only that the morphism f is locally of finite type. Likewise, Propositions (6.4.2) and (6.4.9) remain valid when we suppose only that the preschemes X, Y appearing in their statement are locally of finite type over the field K.

§7 Rational maps

7.1 Rational maps and rational functions

(7.1.1) Let X, Y be two preschemes, U, V two dense open subsets of X, f (resp. g) a morphism from U (resp. V) to Y; we will say that f and g are *equivalent* if they coincide on an open subset dense in $U \cap V$. Since a finite intersection of dense open subsets of X is a dense open subset of X, it is clear that this relation is an *equivalence relation.*

(7.1.2) Definition. Given two preschemes X, Y, a *rational map from X to Y* is an equivalence class of morphisms from dense open subsets of X to Y, for the relation defined in (7.1.1). If X and Y are S-preschemes, we say that such a class is a *rational S-map* if there exists a representative of this class which is an S-morphism. Every rational S-map from S to X is called a *rational S-section of X*. Every rational X-section of the X-prescheme $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (where T is an indeterminate) is called a *rational function on a prescheme X*.

By abuse of language, when only S-preschemes are under consideration, we will say "rational map" instead of "rational S-map" if no confusion can result.

Let f be a rational map from X to Y, and U an open subset of X; if f_1, f_2 are morphisms belonging to the class f, defined respectively on dense open subsets V, W of X, the restrictions $f_1|(U \cap V)$, $f_2|(U \cap W)$ coincide on an open subset of $U \cap V \cap W$ which is dense in U; the class of morphisms f therefore defines a rational map from U to Y, called the *restriction of f to U* and denoted $f|U$.

[I | 156] If to every S-morphism $f : X \to Y$ we assign the rational S-map to which f belongs, we define a canonical map from $\mathrm{Hom}_S(X, Y)$ to the set of rational S-maps from X to

Y. We denote by $\Gamma_{\mathrm{rat}}(X/Y)$ the set of rational Y-sections of X, and we therefore have a canonical map $\Gamma(X/Y) \to \Gamma_{\mathrm{rat}}(X/Y)$. It is moreover clear that if X and Y are two S-preschemes, the set of rational S-maps from X to Y is canonically identified with $\Gamma_{\mathrm{rat}}((X \times_S Y)/X)$ (3.3.14).

(7.1.3) It follows immediately from (7.1.2) and (3.3.14) that the rational functions on X are canonically identified with the *equivalence classes of sections of the structural sheaf* $\mathscr{O}_X$ over everywhere dense open subsets of X, two such sections being equivalent if they coincide on an everywhere dense open subset contained in the intersection of their sets of definition. In particular, it follows that the rational functions on X form a *ring* $R(X)$.

(7.1.4) When X is an *irreducible* prescheme, every non-empty open subset is dense in X; we can also say that the non-empty open subsets of X are the *open neighbourhoods of the generic point* x of X. To say that two morphisms of non-empty open subsets of X into Y are equivalent therefore means in this case that they have *the same germ* at the point x. In other words, the rational maps (resp. rational S-maps) $X \to Y$ are identified with the *germs of morphisms* (resp. of S-morphisms) of non-empty open subsets of X into Y at the generic point x of X. In particular:

(7.1.5) Proposition. *If X is an irreducible prescheme, the ring $R(X)$ of rational functions on X is canonically identified with the local ring $\mathscr{O}_x$ of the generic point x of X. It is a local ring of dimension 0, and consequently an Artinian local ring when X is Noetherian; it is a field when X is integral, and it is identified with the field of fractions of $A(X)$ when moreover X is an affine scheme.*

In view of the above and of the identification of rational functions with sections of $\mathscr{O}_X$ over an everywhere dense open subset, the first assertion is nothing but the definition of the stalk of a sheaf at a point. For the other assertions, we may restrict to the case where X is affine with ring A; then $\mathfrak{j}_x$ is the nilradical of A, and $\mathscr{O}_x$ is therefore of dimension 0; if A is integral, $\mathfrak{j}_x = (0)$, and $\mathscr{O}_x$ is therefore the field of fractions of A. Finally, if A is Noetherian, we know ([11], p. 127, cor. 4) that $\mathfrak{j}_x$ is nilpotent and $\mathscr{O}_x = A_{\mathfrak{j}_x}$ Artinian.

If X is *integral*, the ring $\mathscr{O}_z$ is integral for every $z \in X$; every affine open subset U containing z also contains x, and $R(U)$, equal to the field of fractions of $A(U)$, is therefore identified with $R(X)$; we conclude that $R(X)$ is also identified with the *field of fractions of* $\mathscr{O}_z$: the canonical identification of $\mathscr{O}_z$ with a subring of $R(X)$ consists in assigning to every germ of section $s \in \mathscr{O}_z$ the unique rational function on X that is the class of a section of $\mathscr{O}_X$ (necessarily defined on an everywhere dense open subset) having s as its germ at the point z.

(7.1.6) Suppose now that X has a *finite* number of irreducible components X_i ($1 \leq i \leq n$) (which is the case when the underlying space of X is *Noetherian*); let X'_i be the open subset of X which is the complement, relative to X_i, of the union of the $X_j \cap X_i$ for $j \neq i$; X'_i is irreducible, its generic point x_i is the generic point of X_i, and the X'_i are pairwise disjoint, their union being dense in X (0, 2.1.6). For each everywhere dense [I | 157] open subset U of X, $U_i = U \cap X'_i$ is a non-empty open subset dense in X'_i, the U_i having pairwise no point in common, hence $U' = \bigcup_i U_i$ is dense in X. To give a morphism from U' to Y amounts to giving (arbitrarily) a morphism from each of the U_i to Y. Hence:

(7.1.7) Proposition. *Let X, Y be two preschemes (resp. S-preschemes) such that X has a finite number of irreducible components X_i, with generic points x_i ($1 \leq i \leq n$). If R_i is the set of germs of morphisms (resp. S-morphisms) of open subsets of X into Y at the point x_i, the set of rational maps (resp. rational S-maps) from X to Y is identified with the product of the R_i ($1 \leq i \leq n$).*

(7.1.8) Corollary. *Let X be a Noetherian prescheme. The ring of rational functions on X is an Artinian ring, whose local components are the rings $\mathscr{O}_{x_i}$ of the generic points x_i of the irreducible components of X.*

(7.1.9) Corollary. *Let A be a Noetherian ring, and let $X = \mathrm{Spec}(A)$. If Q is the complement of the union of the minimal prime ideals of A, the ring of rational functions on X is canonically identified with the ring of fractions $Q^{-1}A$.*

This will follow from the following lemma:

(7.1.9.1) Lemma. *For an element $f \in A$ to be such that $D(f)$ is everywhere dense in X, it is necessary and sufficient that $f \in Q$; every dense open subset of X contains an open subset of the form $D(f)$, where $f \in Q$.*

Indeed, suppose this lemma proved; since the ring of sections $\Gamma(D(f), \mathscr{O}_X)$ is identified with A_f (1.3.6 and 1.3.7), it follows from the fact that the $D(f)$ with $f \in Q$ form a cofinal set in the set (ordered by $\supset$) of dense open subsets of X, and from the definition (7.1.1), that the ring of rational functions on X is identified with the inductive limit of the A_f for $f \in Q$ (for the preorder relation "g is a multiple of f"), that is, with $Q^{-1}A$ (0, 1.4.5).

To prove (7.1.9.1), again denote by X_i the irreducible components of X $(1 \leq i \leq n)$; if $D(f)$ is dense in X, then $D(f) \cap X_i \neq \varnothing$ for $1 \leq i \leq n$, and conversely; but this means that $f \notin \mathfrak{p}_i$ for $1 \leq i \leq n$, setting $\mathfrak{p}_i = \mathfrak{j}(X_i)$, and since the $\mathfrak{p}_i$ are the minimal prime ideals of A (1.1.14), the relations $f \notin \mathfrak{p}_i$ $(1 \leq i \leq n)$ are equivalent to $f \in Q$, whence the first assertion of the lemma. On the other hand, if U is a dense open subset of X, the complement of U is a set of the form $V(\mathfrak{a})$, where $\mathfrak{a}$ is an ideal which is contained in none of the $\mathfrak{p}_i$; it is therefore not contained in their union ([10], p. 13), and so there exists an $f \in \mathfrak{a}$ belonging to Q; whence $D(f) \subset U$, which completes the proof.

(7.1.10) Suppose again that X is irreducible, with generic point x. Since every non-empty open subset U of X contains x, and consequently also contains every $z \in X$ such that $x \in \overline{\{z\}}$, every morphism $U \to Y$ can be composed with the canonical morphism $\mathrm{Spec}(\mathscr{O}_x) \to X$ (2.4.1); and two morphisms into Y of two non-empty open subsets of X which coincide on a non-empty open subset of X give, by composition, the same morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$. In other words, to every rational map from X to Y there thus corresponds a well-determined morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$.

[I | 158] **(7.1.11) Proposition.** *Let X, Y be two S-preschemes; suppose X irreducible, with generic point x, and Y of finite type over S. Two rational S-maps from X to Y to which the same S-morphism $\mathrm{Spec}(\mathscr{O}_x) \to Y$ corresponds are identical. If we suppose moreover that S is locally Noetherian, every S-morphism from $\mathrm{Spec}(\mathscr{O}_x)$ to Y corresponds to a rational S-map (and only one) from X to Y.*

Taking into account the fact that every non-empty open subset of X is everywhere dense, this follows immediately from (6.5.1).

(7.1.12) Corollary. *Suppose S locally Noetherian, and the other hypotheses of (7.1.11) satisfied. The rational S-maps from X to Y are then identified with the points of the S-prescheme Y with values in the S-prescheme $\mathrm{Spec}(\mathscr{O}_x)$.*

This is nothing but (7.1.11), with the terminology introduced in (3.4.1).

(7.1.13) Corollary. *Suppose the conditions of (7.1.12) are fulfilled. Let s be the image of x in S. To give a rational S-map from X to Y is equivalent to giving a point y of Y above s and a local $\mathscr{O}_s$-homomorphism $\mathscr{O}_y \to \mathscr{O}_x = R(X)$.*

This follows from (7.1.11) and (2.4.4).

In particular:

(7.1.14) Corollary. *Under the conditions of (7.1.12), the rational S-maps from X to Y depend (for given Y) only on the S-prescheme* $\mathrm{Spec}(\mathscr{O}_x)$*, and in particular remain the same when X is replaced by* $\mathrm{Spec}(\mathscr{O}_z)$*, for any $z \in X$.*

Indeed, since $z \in \overline{\{x\}}$, x is the generic point of $Z = \mathrm{Spec}(\mathscr{O}_z)$, and $\mathscr{O}_{X,x} = \mathscr{O}_{Z,x}$.

When X is integral, $R(X) = \mathscr{O}_x = k(x)$ is a field (7.1.5); the preceding corollaries then specialize to:

(7.1.15) Corollary. *Suppose the conditions of (7.1.12) are satisfied and moreover that X is integral. Let s be the image of x in S. Then the rational S-maps from X to Y are identified with the geometric points of $Y \otimes_S k(s)$ with values in the extension $R(X)$ of $k(s)$; in other words, each of them is equivalent to giving a point $y \in Y$ above s and a $k(s)$-monomorphism from $k(y)$ to $k(x) = R(X)$.*

Indeed, the points of Y above s are identified with those of $Y \otimes_S k(s)$ (3.6.3), and the local $\mathscr{O}_s$-homomorphisms $\mathscr{O}_y \to R(X)$ with the $k(s)$-monomorphisms $k(y) \to R(X)$.

More particularly:

(7.1.16) Corollary. *Let k be a field, X, Y two algebraic preschemes (6.4.1) over k; suppose moreover that X is integral. Then the rational k-maps from X to Y are identified with the geometric points of Y with values in the extension $R(X)$ of k (3.4.4).*

7.2 Domain of definition of a rational map

(7.2.1) Let X, Y be two preschemes, f a rational map from X to Y. We say that f is *defined at a point $x \in X$* if there exist an everywhere dense open set U containing x and a morphism $U \to Y$ belonging to the equivalence class f. The set of points $x \in X$ where f is defined is called the *domain of definition of f*; it is clear that it is an everywhere dense open subset of X.

(7.2.2) Proposition. *Let X, Y be two S-preschemes such that X is reduced and Y is separated over S. Let f be a rational S-map from X to Y, and U_0 its domain of definition. Then there exists one and only one S-morphism $U_0 \to Y$ belonging to the class f.* [I | 159]

Since for every morphism $U \to Y$ belonging to the class f we necessarily have $U \subset U_0$, it is clear that the proposition will be a consequence of

(7.2.2.1) Lemma. *Under the hypotheses of (7.2.2), let U_1, U_2 be two everywhere dense open subsets of X, and $f_i : U_i \to Y$ $(i = 1, 2)$ two S-morphisms such that there exists an open subset $V \subset U_1 \cap U_2$, dense in X, on which f_1 and f_2 coincide. Then f_1 and f_2 coincide on $U_1 \cap U_2$.*

We may evidently restrict to the case where $X = U_1 = U_2$. Since X (hence V) is reduced, X is the smallest closed sub-prescheme of X dominating V (5.2.2). Let $g = (f_1, f_2)_S : X \to Y \times_S Y$; since by hypothesis the diagonal $T = \Delta_Y(Y)$ is a closed sub-prescheme of $Y \times_S Y$, $Z = g^{-1}(T)$ is a closed sub-prescheme of X (4.4.1). If $h : V \to Y$ is the common restriction of f_1 and f_2 to V, the restriction of g to V is $g' = (h, h)_S$, which factors as $g' = \Delta_Y \circ h$; since $\Delta_Y^{-1}(T) = Y$, we have $g'^{-1}(T) = V$, and consequently Z is a closed sub-prescheme of X inducing V, hence dominating V, which implies $Z = X$. From the relation $g^{-1}(T) = X$ we deduce (4.4.1) that g factors as $\Delta_Y \circ f$, where f is a morphism $X \to Y$, which implies, by the definition of the diagonal morphism, that $f_1 = f_2 = f$.

It is clear that the morphism $U_0 \to Y$ defined in (7.2.2) is the unique morphism of the class f which *cannot be extended* to a morphism of an open subset of X strictly containing U_0. *Under the hypotheses of (7.2.2)*, we can therefore *identify* the rational maps from X to Y with the *non-extendable* morphisms (to strictly larger open subsets) of everywhere dense open subsets of X into Y. With this identification, Proposition (7.2.2) implies:

(7.2.3) Corollary. *The hypotheses on X and Y being those of (7.2.2), let U be an everywhere dense open subset of X. There exists a canonical bijective correspondence between the S-morphisms from U to Y and the rational S-maps from X to Y defined at all points of U.*

Indeed, by virtue of (7.2.2), for every S-morphism f from U to Y there exists one and only one rational S-map $\overline{f}$ from X to Y which extends f.

(7.2.4) Corollary. *Let S be a scheme, X a reduced S-prescheme, Y an S-scheme, and $f : U \to Y$ an S-morphism of a dense open subset U of X into Y. If $\overline{f}$ is the rational $\mathbf{Z}$-map from X to Y which extends f, then $\overline{f}$ is an S-morphism (and is consequently the rational S-map from X to Y extending f).*

Indeed, if $\varphi : X \to S$, $\psi : Y \to S$ are the structural morphisms, U_0 the domain of definition of $\overline{f}$, and j the injection $U_0 \to X$, it suffices to prove that $\psi \circ \overline{f} = \varphi \circ j$, which follows immediately from (7.2.2.1), since f is an S-morphism.

(7.2.5) Corollary. *Let X, Y be two S-preschemes; suppose X reduced, and X and Y separated over S. Let $p : Y \to X$ be an S-morphism (making Y an X-prescheme), U an everywhere dense open subset of X, and f a U-section of Y; then the rational map $\overline{f}$ from X to Y extending f is a rational X-section of Y.*

[I | 160] We must prove that $p \circ \overline{f}$ is the identity on the domain of definition of $\overline{f}$; since X is separated over S, this again follows from (7.2.2.1).

(7.2.6) Corollary. *Let X be a reduced prescheme, and U an everywhere dense open subset of X. There is a canonical bijective correspondence between the sections of $\mathscr{O}_X$ over U and the rational functions f on X defined at every point of U.*

Taking into account (7.2.3), (7.1.2) and (7.1.3), it suffices to note that the X-prescheme $X \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ is separated over X (5.5.1, (iv)).

(7.2.7) Corollary. *Let Y be a reduced prescheme, $f : X \to Y$ a separated morphism, U an everywhere dense open subset of Y, $g : U \to f^{-1}(U)$ a U-section of $f^{-1}(U)$, and Z the reduced sub-prescheme of X having $\overline{g(U)}$ as underlying space (5.2.1). For g to be the restriction of a Y-section of X (in other words (7.2.5), for the rational map from Y to X extending g to be everywhere defined), it is necessary and sufficient that the restriction of f to Z be an isomorphism of Z onto Y.*

The restriction of f to $f^{-1}(U)$ is a separated morphism (5.5.1, (i)), hence g is a closed immersion (5.4.6), and consequently $g(U) = Z \cap f^{-1}(U)$ and the sub-prescheme induced by Z on the open subset $g(U)$ of Z is identical to the closed sub-prescheme of $f^{-1}(U)$ associated to g (5.2.1). It is then clear that the condition of the statement is sufficient, since if it is fulfilled, and if $f_Z : Z \to Y$ is the restriction of f to Z and $\overline{g} : Y \to Z$ the inverse isomorphism, then $\overline{g}$ extends g. Conversely, if g is the restriction to U of a Y-section h of X, then h is a closed immersion (5.4.6), hence $h(Y)$ is closed, and since it is contained in Z, it is equal to Z, and it follows from (5.2.1) that h is necessarily an isomorphism of Y onto the closed sub-prescheme Z of X.

(7.2.8) Let X, Y be two S-preschemes, X being assumed reduced and Y separated over S. Let f be a rational S-map from X to Y, and let x be a point of X; we can compose f with the canonical S-morphism $\mathrm{Spec}(\mathscr{O}_x) \to X$ (2.4.1) provided that the trace on $\mathrm{Spec}(\mathscr{O}_x)$ of the domain of definition of f is dense in $\mathrm{Spec}(\mathscr{O}_x)$ (identified with the set of $z \in X$ such that $x \in \overline{\{z\}}$ (2.4.2)). This will be so in the following cases:

1° X is irreducible (hence integral), since then the generic point ξ of X is the generic point of $\mathrm{Spec}(\mathscr{O}_x)$; since the domain of definition U of f contains ξ, $U \cap \mathrm{Spec}(\mathscr{O}_x)$ contains ξ, hence is dense in $\mathrm{Spec}(\mathscr{O}_x)$.

2° X is locally Noetherian; indeed, our assertion then follows from

(7.2.8.1) Lemma. *Let X be a prescheme whose underlying space is locally Noetherian, and x a point of X. The irreducible components of* $\mathrm{Spec}(\mathscr{O}_x)$ *are the traces on* $\mathrm{Spec}(\mathscr{O}_x)$ *of the irreducible components of X containing x. For an open subset $U \subset X$ to be such that $U \cap \mathrm{Spec}(\mathscr{O}_x)$ is dense in* $\mathrm{Spec}(\mathscr{O}_x)$*, it is necessary and sufficient that it meet the irreducible components of X containing x (which is the case in particular if U is dense in X).*

The second assertion evidently follows from the first, and it therefore suffices to prove the latter. Since $\mathrm{Spec}(\mathscr{O}_x)$ is contained in every affine open subset U containing x, and the irreducible components of U containing x are the traces on U of the irreducible components of X containing x (0, 2.1.6), we may suppose X affine with ring A. Since the prime ideals of A_x correspond bijectively to the prime ideals of A contained in $\mathfrak{j}_x$ [I | 161] (0, 1.2.6), the minimal prime ideals of A_x correspond to the minimal prime ideals of A contained in $\mathfrak{j}_x$, whence the lemma (1.1.14).

This being so, suppose we are in one of the two cases mentioned above. If U is the domain of definition of the rational S-map f, denote by f' the rational map from $\mathrm{Spec}(\mathscr{O}_x)$ to Y which coincides (taking into account (2.4.2)) with f on $U \cap \mathrm{Spec}(\mathscr{O}_x)$; we will say that this rational map is *induced by f*.

(7.2.9) Proposition. *Let S be a locally Noetherian prescheme, X a reduced S-prescheme, and Y an S-scheme of finite type. Suppose moreover that X is irreducible or locally Noetherian. Let then f be a rational S-map from X to Y, and x a point of X. For f to be defined at the point x, it is necessary and sufficient that the rational map f' from* $\mathrm{Spec}(\mathscr{O}_x)$ *to Y induced by f (7.2.8) be a morphism.*

The condition being evidently necessary (since $\mathrm{Spec}(\mathscr{O}_x)$ is contained in every open subset containing x), let us prove that it is sufficient. By virtue of (6.5.1), there exist an open neighbourhood U of x in X and an S-morphism g from U to Y inducing f' on $\mathrm{Spec}(\mathscr{O}_x)$. If X is irreducible, U is dense in X, and by virtue of (7.2.3) we may suppose that g is a rational S-map. Moreover, the generic point of X belongs to $\mathrm{Spec}(\mathscr{O}_x)$ and to the domain of definition of f, hence f and g coincide at this point, and consequently on a non-empty open set of X (6.5.1). But since f and g are rational S-maps, they are identical (7.2.3), hence f is defined at x.

If we now suppose X locally Noetherian, we may suppose U Noetherian; there are then only finitely many irreducible components X_i of X containing x (7.2.8.1), and we may suppose that they are the only ones meeting U, replacing U if necessary by a smaller open subset (since there are only finitely many irreducible components of X meeting U, U being Noetherian). We then see as above that f and g coincide on a non-empty open subset of each of the X_i. Taking into account the fact that each of the X_i is contained in $\overline{U}$, consider then the morphism f_1, defined on a dense open subset of $U \cup (X - \overline{U})$,

equal to g on U and to f on the intersection of $X - \overline{U}$ and the domain of definition of f. Since $U \cup (X - \overline{U})$ is dense in X, f_1 and f coincide on a dense open subset of X, and since f is a rational map, f is an extension of f_1 (7.2.3), hence is defined at the point x.

7.3 Sheaf of rational functions

(7.3.1) Let X be a prescheme. For every open subset $U \subset X$, denote by $R(U)$ the ring of rational functions on U (7.1.3); it is a $\Gamma(U, \mathscr{O}_X)$-algebra. Moreover, if $V \subset U$ is a second open subset of X, every section of $\mathscr{O}_X$ over an everywhere dense open subset of U gives, by restriction to V, a section over an everywhere dense open subset of V, and if two sections coincide over an everywhere dense open subset of U, their restrictions to V coincide over an everywhere dense open subset of V. We thus define a di-homomorphism of algebras $\rho_{V,U} : R(U) \to R(V)$, and it is clear that if $U \supset V \supset W$ are three open subsets of X, we have $\rho_{W,U} = \rho_{W,V} \circ \rho_{V,U}$; the $R(U)$ therefore define a *presheaf* of algebras on X.

[I | 162] **(7.3.2) Definition.** The *sheaf of rational functions* on a prescheme X, denoted by $\mathscr{R}(X)$, is the $\mathscr{O}_X$-algebra associated to the presheaf formed by the $R(U)$.

For every prescheme X and every open subset $U \subset X$, it is clear that the induced sheaf $\mathscr{R}(X)|U$ is nothing but $\mathscr{R}(U)$.

(7.3.3) Proposition. *Let X be a prescheme such that the family (X_λ) of its irreducible components is locally finite (which is in particular the case when the underlying space of X is locally Noetherian). Then the $\mathscr{O}_X$-module $\mathscr{R}(X)$ is quasi-coherent, and for every open subset U of X meeting only finitely many components X_λ, $R(U)$ is equal to $\Gamma(U, \mathscr{R}(X))$ and is canonically identified with the direct product of the local rings of the generic points of the X_λ such that $U \cap X_\lambda \neq \varnothing$.*

We may evidently restrict to the case where X has only finitely many irreducible components X_i, with generic points x_i $(1 \leq i \leq n)$. The fact that $R(U)$ is canonically identified with the direct product of the $\mathscr{O}_{x_i} = R(X_i)$ such that $U \cap X_i \neq \varnothing$ then follows from (7.1.7). Let us show moreover that the presheaf $U \to R(U)$ satisfies the sheaf axioms, which will prove that $R(U) = \Gamma(U, \mathscr{R}(X))$. Indeed, it satisfies (F 1) by the above. To see that it satisfies (F 2), consider a covering of an open subset U of X by open subsets $V_\alpha \subset U$; if the $s_\alpha \in R(V_\alpha)$ are such that the restrictions of s_α and s_β to $V_\alpha \cap V_\beta$ coincide for every pair of indices, we conclude that for every index i such that $U \cap X_i \neq \varnothing$, the components in $R(X_i)$ of all the s_α such that $V_\alpha \cap X_i \neq \varnothing$ are the same; denoting this component by t_i, it is clear that the element of $R(U)$ having the t_i as components has restriction s_α to each V_α. Finally, to see that $\mathscr{R}(X)$ is quasi-coherent, we may restrict to the case where $X = \mathrm{Spec}(A)$ is affine; taking for U the affine open subsets of the form $D(f)$, where $f \in A$, it follows from the above and from the definition (1.3.4) that $\mathscr{R}(X) = \widetilde{M}$, where M is the direct sum of the A-modules A_{x_i}.

(7.3.4) Corollary. *Let X be a reduced prescheme having only finitely many irreducible components, and let X_i $(1 \leq i \leq n)$ be the reduced closed sub-preschemes of X having the irreducible components of X as underlying spaces (5.2.1). If h_i is the canonical injection $X_i \to X$, then $\mathscr{R}(X)$ is the direct product of the $\mathscr{O}_X$-algebras $(h_i)_*(\mathscr{R}(X_i))$.*

(7.3.5) Corollary. *If X is irreducible, every quasi-coherent $\mathscr{R}(X)$-module $\mathscr{F}$ is a simple sheaf.*

It suffices to show that every $x \in X$ admits a neighbourhood U such that $\mathscr{F}|U$ is a simple sheaf (0, 3.6.2); in other words, we are reduced to the case where X is affine;

we may moreover suppose that $\mathscr{F}$ is the cokernel of a homomorphism $(\mathscr{R}(X))^{(I)} \to (\mathscr{R}(X))^{(J)}$ (0, 5.1.3), and everything comes down to seeing that $\mathscr{R}(X)$ is a simple sheaf; but this is evident since $\Gamma(U, \mathscr{R}(X)) = R(X)$ for every non-empty open subset U, U containing the generic point of X.

(7.3.6) Corollary. *If X is irreducible, then for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is a simple sheaf; if moreover X is reduced (hence integral), $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$ is isomorphic to a sheaf of the form $(\mathscr{R}(X))^{(I)}$.*

The second assertion follows from the fact that $R(X)$ is then a field.

(7.3.7) Proposition. *Suppose that the prescheme X is locally integral or locally Noetherian. Then $\mathscr{R}(X)$ is a quasi-coherent $\mathscr{O}_X$-algebra; if moreover X is reduced (which is the case when X is locally integral), the canonical homomorphism $\mathscr{O}_X \to \mathscr{R}(X)$ is injective.* [I/163]

The question being local, the first assertion follows from (7.3.3); the second follows immediately from (7.2.3).

(7.3.8) Let X, Y be two integral preschemes, which implies that $\mathscr{R}(X)$ (resp. $\mathscr{R}(Y)$) is a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module) (7.3.3). Let $f : X \to Y$ be a dominant morphism; then there exists a canonical homomorphism of $\mathscr{O}_X$-modules

$$\tau : f^*(\mathscr{R}(Y)) \to \mathscr{R}(X). \tag{7.3.8.1}$$

First suppose $X = \mathrm{Spec}(A)$ and $Y = \mathrm{Spec}(B)$ affine with integral rings A and B, f thus corresponding to an injective homomorphism $B \to A$, which extends to a monomorphism $L \to K$ from the field of fractions L of B into the field of fractions K of A. The homomorphism (7.3.8.1) then corresponds to the canonical homomorphism

$$L \otimes_B A \to K$$

(1.6.5). In the general case, for every pair of non-empty affine open subsets $U \subset X$, $V \subset Y$ such that $f(U) \subset V$, we define a homomorphism $\tau_{U,V}$ in the preceding manner, and we see immediately that if $U' \subset U$, $V' \subset V$, $f(U') \subset V'$, then $\tau_{U,V}$ extends $\tau_{U',V'}$, whence our assertion. If x, y are the generic points of X and Y respectively, we have $f(x) = y$,

$$\left(f^*(\mathscr{R}(Y))\right)_x = \mathscr{O}_y \otimes_{\mathscr{O}_y} \mathscr{O}_x = \mathscr{O}_x$$

(0, 4.3.1), and τ_x is therefore an isomorphism.

7.4 Torsion sheaves and torsion-free sheaves

(7.4.1) Let X be an *integral* prescheme. For every $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphism $\mathscr{O}_X \to \mathscr{R}(X)$ defines, by tensoring, a homomorphism (also called *canonical*)

$$\mathscr{F} \to \mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X)$$

which, on each stalk, is nothing but the homomorphism $z \to z \otimes 1$ from $\mathscr{F}_x$ to $\mathscr{F}_x \otimes_{\mathscr{O}_x} R(X)$. The *kernel* $\mathscr{T}$ of this homomorphism is a sub-$\mathscr{O}_X$-module of $\mathscr{F}$, called the *torsion sheaf of* $\mathscr{F}$; it is quasi-coherent if $\mathscr{F}$ is quasi-coherent (4.1.1 and 7.3.6). We say that $\mathscr{F}$ is *torsion-free* if $\mathscr{T} = 0$, and that $\mathscr{F}$ is a *torsion sheaf* if $\mathscr{T} = \mathscr{F}$. For every $\mathscr{O}_X$-module $\mathscr{F}$, $\mathscr{F}/\mathscr{T}$ is torsion-free. We deduce from (7.3.5) that:

(7.4.2) Proposition. *If X is an integral prescheme, every torsion-free quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is isomorphic to a sub-sheaf $\mathscr{G}$ of a simple sheaf of the form $(\mathscr{R}(X))^{(I)}$, generated (as an $\mathscr{R}(X)$-module) by $\mathscr{G}$.*

The cardinal of I is called the *rank of* $\mathscr{F}$; for every non-empty affine open subset U of X, the rank of $\mathscr{F}$ is equal to the rank of $\Gamma(U, \mathscr{F})$ as a $\Gamma(U, \mathscr{O}_X)$-module, as is seen immediately by considering the generic point of X, which is contained in U. In particular:

(7.4.3) Corollary. *On an integral prescheme X, every torsion-free quasi-coherent $\mathscr{O}_X$-module of rank 1 (in particular every invertible $\mathscr{O}_X$-module) is isomorphic to a nonzero quasi-coherent sub-$\mathscr{O}_X$-module of $\mathscr{R}(X)$, and conversely.*

(7.4.4) Corollary. *Let X be an integral prescheme, $\mathscr{L}$, $\mathscr{L}'$ two torsion-free $\mathscr{O}_X$-modules, and f (resp. f') a section of $\mathscr{L}$ (resp. $\mathscr{L}'$) over X. For $f \otimes f' = 0$, it is necessary and sufficient that one of the sections f, f' be zero.*

Let x be the generic point of X; by hypothesis we have $(f \otimes f')_x = f_x \otimes f'_x = 0$. Since $\mathscr{L}_x$ and $\mathscr{L}'_x$ are vector spaces over the field $\mathscr{O}_x$, the preceding relation implies $f_x = 0$ or $f'_x = 0$, and consequently $f = 0$ or $f' = 0$, since $\mathscr{L}$ and $\mathscr{L}'$ are torsion-free (7.3.5).

(7.4.5) Proposition. *Let X, Y be two integral preschemes, and $f : X \to Y$ a dominant morphism. For every torsion-free quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $f_*(\mathscr{F})$ is a torsion-free $\mathscr{O}_Y$-module.*

Proof. Since f_* is left exact (0, 4.2.1), it suffices, by virtue of (7.4.2), to prove the proposition [I | 164] when $\mathscr{F} = (\mathscr{R}(X))^{(I)}$. Now, every non-empty open subset U of Y contains the generic point of Y, hence $f^{-1}(U)$ contains the generic point of X (0, 2.1.5), so that we then have

$$\Gamma(U, f_*(\mathscr{F})) = \Gamma(f^{-1}(U), \mathscr{F}) = (R(X))^{(I)} ;$$

in other words, $f_*(\mathscr{F})$ is the simple sheaf with stalk $(R(X))^{(I)}$, regarded as an $\mathscr{R}(Y)$-module, and it is evidently torsion-free. □

(7.4.6) Proposition. *Let X be an integral prescheme and x its generic point. For every quasi-coherent $\mathscr{O}_X$-module of finite type $\mathscr{F}$, the following conditions are equivalent: a) $\mathscr{F}$ is a torsion sheaf; b) $\mathscr{F}_x = 0$; c)* $\mathrm{Supp}(\mathscr{F}) \neq X$.

By virtue of (7.3.5) and (7.4.1), the relations $\mathscr{F}_x = 0$ and $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{R}(X) = 0$ are equivalent, hence a) and b) are equivalent; on the other hand, $\mathrm{Supp}(\mathscr{F})$ is closed in X (0, 5.2.2), and since every non-empty open subset of X contains x, b) and c) are equivalent.

(7.4.7) We extend (by abuse of language) the definitions of (7.4.1) to the case where X is a *reduced* prescheme having only a *finite* number of irreducible components; it then follows from (7.3.4) that the equivalence of a) and c) in (7.4.6) is still valid for such a prescheme, provided c) is replaced by the condition that $\mathrm{Supp}(\mathscr{F})$ contains no irreducible component of X.

§8 Chevalley schemes

8.1 Related local rings

For every local ring A, we denote by $\mathfrak{m}(A)$ the maximal ideal of A.

(8.1.1) Lemma. *Let A, B be two local rings such that $A \subset B$; the following conditions are equivalent:*

(i) $\mathfrak{m}(B) \cap A = \mathfrak{m}(A)$;

(ii) $\mathfrak{m}(A) \subset \mathfrak{m}(B)$;

(iii) 1 *does not belong to the ideal of* B *generated by* $\mathfrak{m}(A)$.

It is evident that (i) implies (ii) and (ii) implies (iii); finally, if (iii) holds, $\mathfrak{m}(B) \cap A$ contains $\mathfrak{m}(A)$ and does not contain 1, hence is equal to $\mathfrak{m}(A)$.

When the equivalent conditions of (8.1.1) are fulfilled, we say that B *dominates* A; it amounts to the same to say that the injection $A \to B$ is a *local* homomorphism. It is clear that, in the set of local subrings of a ring R, the relation of domination is an order relation.

(8.1.2) Consider now a *field* R. For every subring A of R, we denote by $L(A)$ the set of local rings $A_\mathfrak{p}$, where $\mathfrak{p}$ runs through the prime spectrum of A; they are identified with subrings of R containing A. Since $\mathfrak{p} = (\mathfrak{p}A_\mathfrak{p}) \cap A$, the map $\mathfrak{p} \mapsto A_\mathfrak{p}$ from $\mathrm{Spec}(A)$ to $L(A)$ is bijective.

(8.1.3) Lemma. *Let R be a field and A a subring of R. For a local subring M of R to dominate a ring $A_\mathfrak{p} \in L(A)$, it is necessary and sufficient that $A \subset M$; the local ring $A_\mathfrak{p}$ dominated by M is then unique and corresponds to $\mathfrak{p} = \mathfrak{m}(M) \cap A$.*

Indeed, if M dominates $A_\mathfrak{p}$, we have $\mathfrak{m}(M) \cap A_\mathfrak{p} = \mathfrak{p}A_\mathfrak{p}$ by (8.1.1), whence the uniqueness of $\mathfrak{p}$; on the other hand, if $A \subset M$, then $\mathfrak{m}(M) \cap A = \mathfrak{p}$ is prime in A, and since $A - \mathfrak{p} \subset M$, we have $A_\mathfrak{p} \subset M$ and $\mathfrak{p}A_\mathfrak{p} \subset \mathfrak{m}(M)$, hence M dominates $A_\mathfrak{p}$.

(8.1.4) Lemma. *Let R be a field, M, N two local subrings of R, and P the subring of R generated by $M \cup N$. The following conditions are equivalent:* [I | 165]

(i) There exists a prime ideal $\mathfrak{p}$ of P such that $\mathfrak{m}(M) = \mathfrak{p} \cap M$, $\mathfrak{m}(N) = \mathfrak{p} \cap N$.

(ii) The ideal $\mathfrak{a}$ generated in P by $\mathfrak{m}(M) \cup \mathfrak{m}(N)$ is distinct from P.

(iii) There exists a local subring Q of R dominating both M and N.

It is clear that (i) implies (ii); conversely, if $\mathfrak{a} \neq P$, then $\mathfrak{a}$ is contained in a maximal ideal $\mathfrak{n}$ of P, and since $1 \notin \mathfrak{n}$, $\mathfrak{n} \cap M$ contains $\mathfrak{m}(M)$ and is distinct from M, hence $\mathfrak{n} \cap M = \mathfrak{m}(M)$, and similarly $\mathfrak{n} \cap N = \mathfrak{m}(N)$. It is clear that if Q dominates M and N, we have $P \subset Q$, and

$$\mathfrak{m}(M) = \mathfrak{m}(Q) \cap M = (\mathfrak{m}(Q) \cap P) \cap M, \qquad \mathfrak{m}(N) = (\mathfrak{m}(Q) \cap P) \cap N,$$

hence (iii) implies (i); the converse is evident by taking $Q = P_\mathfrak{p}$.

When the conditions of (8.1.4) are satisfied, we say, following C. Chevalley, that the local rings M and N are *related*.

(8.1.5) Proposition. *Let A, B be two subrings of a field R, and C the subring of R generated by $A \cup B$. The following conditions are equivalent:*

(i) For every local ring Q containing A and B, we have $A_\mathfrak{p} = B_\mathfrak{q}$, where $\mathfrak{p} = \mathfrak{m}(Q) \cap A$, $\mathfrak{q} = \mathfrak{m}(Q) \cap B$.

(ii) For every prime ideal $\mathfrak{r}$ of C, we have $A_\mathfrak{p} = B_\mathfrak{q}$, where $\mathfrak{p} = \mathfrak{r} \cap A$, $\mathfrak{q} = \mathfrak{r} \cap B$.

(iii) If $M \in L(A)$ and $N \in L(B)$ are related, they are identical.

(iv) We have $L(A) \cap L(B) = L(C)$.

Lemmas (8.1.3) and (8.1.4) prove that (i) and (iii) are equivalent; it is clear that (i) implies (ii), by applying it to $Q = C_{\mathfrak{r}}$; conversely, (ii) implies (i), since if Q contains $A \cup B$, it contains C, and if $\mathfrak{r} = \mathfrak{m}(Q) \cap C$, we have $\mathfrak{p} = \mathfrak{r} \cap A$ and $\mathfrak{q} = \mathfrak{r} \cap B$ by (8.1.3). It is immediate that (iv) implies (i), since if Q contains $A \cup B$, it dominates a local ring $C_{\mathfrak{r}} \in L(C)$ by (8.1.3); by hypothesis we have $C_{\mathfrak{r}} \in L(A) \cap L(B)$, and (8.1.1) and (8.1.3) prove that $C_{\mathfrak{r}} = A_{\mathfrak{p}} = B_{\mathfrak{q}}$. Finally, let us prove that (iii) implies (iv). Let $Q \in L(C)$; Q dominates an $M \in L(A)$ and an $N \in L(B)$ (8.1.3), hence M and N, being related, are identical by hypothesis. Since we then have $C \subset M$, M dominates a $Q' \in L(C)$ (8.1.3), hence Q dominates Q', which (8.1.3) necessarily implies $Q = Q' = M$, hence $Q \in L(A) \cap L(B)$. Conversely, if $Q \in L(A) \cap L(B)$, we have $C \subset Q$, hence (8.1.3) Q dominates a $Q'' \in L(C) \subset L(A) \cap L(B)$; Q and Q'', being related, are identical, hence $Q'' = Q \in L(C)$, which completes the proof.

8.2 Local rings of an integral scheme

(8.2.1) Let X be an *integral* prescheme and R its field of rational functions, identical to the local ring of the generic point a of X; for every $x \in X$, we know that $\mathscr{O}_x$ is canonically identified with a subring of R (7.1.5), and for every rational function $f \in R$, the domain of definition $\delta(f)$ of f is the open set of $x \in X$ such that $f \in \mathscr{O}_x$. It follows (7.2.6) that for every open subset $U \subset X$, we have

$$\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x. \tag{8.2.1.1}$$

[I | 166] **(8.2.2) Proposition.** *Let X be an integral prescheme and R its field of rational functions. For X to be a scheme, it is necessary and sufficient that the relation "$\mathscr{O}_x$ and $\mathscr{O}_y$ are related" (8.1.4) between points x, y of X imply $x = y$.*

Suppose this condition holds, and let us show that X is separated. Let U and V be two distinct affine open subsets of X, and A and B their rings, identified with subrings of R; U (resp. V) is therefore identified (8.1.2) with $L(A)$ (resp. $L(B)$), and the hypothesis implies (8.1.5) that, if C is the subring of R generated by $A \cup B$, $W = U \cap V$ is identified with $L(A) \cap L(B) = L(C)$. Moreover, we know ([1], p. 5-03, prop. 4 *bis*) that every subring E of R is equal to the intersection of the local rings belonging to $L(E)$; C is therefore identified with the intersection of the rings $\mathscr{O}_z$ for $z \in W$, in other words (8.2.1.1) with $\Gamma(W, \mathscr{O}_X)$. Consider then the sub-prescheme induced by X on W; to the identity homomorphism $\varphi : C \to \Gamma(W, \mathscr{O}_X)$ there corresponds (2.2.4) a morphism $\Phi = (\psi, \theta) : W \to \mathrm{Spec}(C)$; we will see that Φ is an *isomorphism* of preschemes, from which it will follow that W is an *affine* open subset. The identification of W with $L(C) = \mathrm{Spec}(C)$ shows that ψ is *bijective*. On the other hand, for every $x \in W$, $\theta_x^\sharp$ is the injection $C_{\mathfrak{r}} \to \mathscr{O}_x$, where $\mathfrak{r} = \mathfrak{m}_x \cap C$, and by definition $C_{\mathfrak{r}}$ is identified with $\mathscr{O}_x$, hence $\theta_x^\sharp$ is bijective. It therefore remains to see that ψ is a *homeomorphism*, in other words that for every closed subset $F \subset W$, $\psi(F)$ is closed in $\mathrm{Spec}(C)$. Now, F is the trace on W of a closed subset of U, of the form $V(\mathfrak{a})$, where $\mathfrak{a}$ is an ideal of A; let us show that $\psi(F) = V(\mathfrak{a}C)$, which will prove our assertion. Indeed, the prime ideals of C containing $\mathfrak{a}C$ are the prime ideals of C containing $\mathfrak{a}$, hence the ideals of the form $\psi(x) = \mathfrak{m}_x \cap C$

where $\mathfrak{a} \subset \mathfrak{m}_x$ and $x \in W$; since $\mathfrak{a} \subset \mathfrak{m}_x$ is equivalent to $x \in V(\mathfrak{a}) = W \cap F$ for $x \in U$, we indeed have $\psi(F) = V(\mathfrak{a}C)$.

It follows that X is separated, since $U \cap V$ is affine and its ring C is generated by the union $A \cup B$ of the rings of U and V (5.5.6).

Conversely, suppose X separated, and let x, y be two points of X such that $\mathscr{O}_x$ and $\mathscr{O}_y$ are related. Let U (resp. V) be an affine open subset containing x (resp. y), with ring A (resp. B); we then know that $U \cap V$ is affine and that its ring C is generated by $A \cup B$ (5.5.6). If $\mathfrak{p} = \mathfrak{m}_x \cap A$, $\mathfrak{q} = \mathfrak{m}_y \cap B$, we have $A_\mathfrak{p} = \mathscr{O}_x$, $B_\mathfrak{q} = \mathscr{O}_y$, and since $A_\mathfrak{p}$ and $B_\mathfrak{q}$ are related, there exists a prime ideal $\mathfrak{r}$ of C such that $\mathfrak{p} = \mathfrak{r} \cap A$, $\mathfrak{q} = \mathfrak{r} \cap B$ (8.1.4). But then there exists a point $z \in U \cap V$ such that $\mathfrak{r} = \mathfrak{m}_z \cap C$, since $U \cap V$ is affine, and we evidently have $x = z$ and $y = z$, whence $x = y$.

(8.2.3) Corollary. *Let X be an integral scheme, and x, y two points of X. For $x \in \overline{\{y\}}$, it is necessary and sufficient that $\mathscr{O}_x \subset \mathscr{O}_y$, in other words that every rational function defined at x be defined at y.*

The condition is evidently necessary, since the domain of definition $\delta(f)$ of a rational function $f \in R$ is open; let us show that it is sufficient. If $\mathscr{O}_x \subset \mathscr{O}_y$, there exists a prime ideal $\mathfrak{p}$ of $\mathscr{O}_x$ such that $\mathscr{O}_y$ dominates $(\mathscr{O}_x)_\mathfrak{p}$ (8.1.3); now (2.4.2) there exists $z \in X$ such that $x \in \overline{\{z\}}$ and $\mathscr{O}_z = (\mathscr{O}_x)_\mathfrak{p}$; since $\mathscr{O}_z$ and $\mathscr{O}_y$ are related, we have $z = y$ by (8.2.2), whence the corollary.

(8.2.4) Corollary. *If X is an integral scheme, the map $x \mapsto \mathscr{O}_x$ is injective; in other words, if x, y are two distinct points of X, there exists a rational function defined at one of these points and not at the other.*

This follows from (8.2.3) and the axiom (T_0) (2.1.4). [I | 167]

(8.2.5) Corollary. *Let X be an integral scheme whose underlying space is Noetherian; when f runs through the field R of rational functions on X, the sets $\delta(f)$ generate the topology of X.*

Indeed, every closed subset of X is then a finite union of irreducible closed sets, that is, of sets of the form $\overline{\{y\}}$ (2.1.5). Now, if $x \notin \overline{\{y\}}$, there exists a rational function f defined at x and not at y (8.2.3); in other words, we have $x \in \delta(f)$ and $\delta(f)$ does not meet $\overline{\{y\}}$. The complement of $\overline{\{y\}}$ is consequently a union of sets of the form $\delta(f)$, and by virtue of the first remark, every open subset of X is a union of finite intersections of open subsets of the form $\delta(f)$.

(8.2.6) Corollary (8.2.5) shows that the topology of X is entirely characterized by the family of local rings $(\mathscr{O}_x)_{x \in X}$ having R as field of fractions. It amounts to the same, moreover, to say that the closed subsets of X are defined in the following way: given a finite subset $\{x_1, \ldots, x_n\}$ of X, we consider the set of $y \in X$ such that $\mathscr{O}_y \subset \mathscr{O}_{x_i}$ for at least one index i, and these sets (for all choices of $\{x_1, \ldots, x_n\}$) are the closed sets of X. Moreover, once the topology of X is known, the structural sheaf $\mathscr{O}_X$ is also determined by the family of the $\mathscr{O}_x$, since $\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x$ (8.2.1.1). The family $(\mathscr{O}_x)_{x \in X}$ therefore completely determines the prescheme X when X is an integral scheme whose underlying space is Noetherian.

(8.2.7) Proposition. *Let X, Y be two integral schemes, $f : X \to Y$ a dominant morphism (2.2.6), and K (resp. L) the field of rational functions on X (resp. Y). Then L is identified with a subfield of K, and for every $x \in X$, $\mathscr{O}_{f(x)}$ is the unique local ring of Y dominated by $\mathscr{O}_x$.*

Indeed, if $f = (\psi, \theta)$ and a is the generic point of X, then $\psi(a)$ is the generic point of Y (0, 2.1.5); $\theta^\sharp_a$ is consequently a monomorphism of the field $L = \mathscr{O}_{\psi(a)}$ into the field

$K = \mathscr{O}_a$. Since every non-empty affine open subset U of Y contains $\psi(a)$, it follows from (2.2.4) that the homomorphism $\Gamma(U, \mathscr{O}_Y) \to \Gamma(\psi^{-1}(U), \mathscr{O}_X)$ corresponding to f is the restriction of $\theta_a^\sharp$ to $\Gamma(U, \mathscr{O}_Y)$. Hence, for every $x \in X$, $\theta_x^\sharp$ is the restriction of $\theta_a^\sharp$ to $\mathscr{O}_{\psi(x)}$, and is consequently a monomorphism. We know moreover that $\theta_x^\sharp$ is a local homomorphism; hence, if we identify L with a subfield of K by $\theta_a^\sharp$, $\mathscr{O}_{\psi(x)}$ is dominated by $\mathscr{O}_x$ (8.1.1); it is moreover the only local ring of Y dominated by $\mathscr{O}_x$, since two local rings of Y which are related are identical (8.2.2).

(8.2.8) Proposition. *Let X be an irreducible prescheme and $f : X \to Y$ a local immersion (resp. a local isomorphism); suppose moreover that the morphism f is separated. Then f is an immersion (resp. an open immersion).*

Let $f = (\psi, \theta)$; it suffices, in both cases, to prove that ψ is a *homeomorphism* of X onto $\psi(X)$ (4.5.3). Replacing f by f_{red} (5.1.6 and 5.1.1, (vi)), we may suppose X and Y reduced. If Y' is the reduced closed sub-prescheme of Y having $\overline{\psi(X)}$ as underlying space, f factors as $X \xrightarrow{f'} Y' \xrightarrow{j} Y$, where j is the canonical injection (5.2.2). It follows from (5.5.1, (v)) that f' is again a separated morphism; moreover, f' is again
[I | 168] a local immersion (resp. a local isomorphism), since, the question being local on X and Y, we may restrict, in order to prove it, to the case where f is a closed immersion (resp. an open immersion), and our assertion then follows immediately from (4.2.2).

We may therefore suppose that f is a *dominant* morphism, which implies that Y is irreducible as well (0, 2.1.5), hence that X and Y are both *integral*. Moreover, the question being local on Y, we may suppose that Y is an affine scheme; since f is separated, X is a scheme (5.5.1, (ii)), and we are finally under the hypotheses of (8.2.7). Then, for every $x \in X$, $\theta_x^\sharp$ is injective; but the hypothesis that f is a local immersion implies that $\theta_x^\sharp$ is surjective (4.2.2), hence $\theta_x^\sharp$ is bijective; in other words (with the identification of (8.2.7)), we have $\mathscr{O}_{\psi(x)} = \mathscr{O}_x$. By (8.2.4), this implies that ψ is an *injective* map, which already proves the proposition when f is a local isomorphism (4.5.3). When we suppose only that f is a local immersion, for every $x \in X$ there exist an open neighbourhood U of x in X and an open neighbourhood V of $\psi(x)$ in Y such that the restriction of ψ to U is a homeomorphism of U onto a *closed* subset of V. Now, U is dense in X, hence $\psi(U)$ is dense in Y and *a fortiori* in V, which proves that $\psi(U) = V$; since ψ is injective, $\psi^{-1}(V) = U$, and this completes the proof that ψ is a homeomorphism of X onto $\psi(X)$.

8.3 Chevalley schemes

(8.3.1) Let X be a *Noetherian* integral scheme and R its field of rational functions; denote by X' the set of local subrings $\mathscr{O}_x \subset R$, where x runs through X. The set X' satisfies the following three conditions:

(Sch. 1) *For every $M \in X'$, R is the field of fractions of M.*

(Sch. 2) *There exists a finite set of Noetherian subrings A_i of R such that $X' = \bigcup_i L(A_i)$ and such that, for every pair of indices i, j, the subring A_{ij} of R generated by $A_i \cup A_j$ is an algebra of finite type over A_i.*

(Sch. 3) *Two elements M, N of X' which are related are identical.*

Indeed, we have seen in (8.2.1) that (Sch. 1) is satisfied, and (Sch. 3) follows from (8.2.2). To prove (Sch. 2), it suffices to cover X by finitely many affine open subsets U_i with Noetherian rings, and to take $A_i = \Gamma(U_i, \mathscr{O}_X)$; the hypothesis that X is a scheme implies that $U_i \cap U_j$ is affine and that $\Gamma(U_i \cap U_j, \mathscr{O}_X) = A_{ij}$ (5.5.6); moreover, since the

space U_i is Noetherian, the immersion $U_i \cap U_j \to U_i$ is of finite type (6.3.5), hence A_{ij} is an A_i-algebra of finite type (6.3.3).

(8.3.2) The structures whose axioms are (Sch. 1), (Sch. 2) and (Sch. 3) generalize the "schemes" in the sense of C. Chevalley, who assumes moreover that R is an extension of finite type of a field K and that the A_i are K-algebras of finite type (which makes part of (Sch. 2) superfluous) [1]. Conversely, if we have such a structure on a set X', we can associate with it an integral scheme X by using the remarks of (8.2.6): the underlying space of X is equal to X' endowed with the topology defined in (8.2.6), and with the sheaf $\mathscr{O}_X$
such that $\Gamma(U, \mathscr{O}_X) = \bigcap_{x \in U} \mathscr{O}_x$ for every open subset $U \subset X$, with an evident definition [I | 169]
of the restriction homomorphisms. We leave it to the reader to verify that we do indeed obtain in this way an integral scheme, whose local rings are the elements of X'; we will not use this result in what follows.

§9 Supplement on quasi-coherent sheaves

9.1 Tensor product of quasi-coherent sheaves.

(9.1.1) Proposition. *Let X be a prescheme (resp. a locally Noetherian prescheme). Let $\mathscr{F}$ and $\mathscr{G}$ be two quasi-coherent (resp. coherent) $\mathscr{O}_X$-modules; then $\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G}$ is quasi-coherent (resp. coherent), and of finite type if $\mathscr{F}$ and $\mathscr{G}$ are of finite type. If $\mathscr{F}$ admits a finite presentation and if $\mathscr{G}$ is quasi-coherent (resp. coherent), then $\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$ is quasi-coherent (resp. coherent).*

The question being local, we may suppose X affine (resp. affine Noetherian); moreover, if $\mathscr{F}$ is coherent, we may suppose that it is the cokernel of a homomorphism $\mathscr{O}_X^m \to \mathscr{O}_X^n$. The assertions concerning quasi-coherent sheaves then follow from (1.3.12) and (1.3.9); the assertions concerning coherent sheaves follow from (1.5.1) and from the fact that, if M and N are modules of finite type over a Noetherian ring A, $M \otimes_A N$ and $\mathrm{Hom}_A(M, N)$ are A-modules of finite type.

(9.1.2) Definition. Let X, Y be two S-preschemes, p, q the projections of $X \times_S Y$, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module). We call tensor product of $\mathscr{F}$ and $\mathscr{G}$ over $\mathscr{O}_S$ (or over S), and denote by $\mathscr{F} \otimes_{\mathscr{O}_S} \mathscr{G}$ (or $\mathscr{F} \otimes_S \mathscr{G}$), the tensor product $p^*(\mathscr{F}) \otimes_{\mathscr{O}_{X \times_S Y}} q^*(\mathscr{G})$ on the prescheme $X \times_S Y$.

If X_i $(1 \leq i \leq n)$ are S-preschemes and $\mathscr{F}_i$ is a quasi-coherent $\mathscr{O}_{X_i}$-module $(1 \leq i \leq n)$, we define in the same way the tensor product $\mathscr{F}_1 \otimes_S \mathscr{F}_2 \otimes_S \cdots \otimes_S \mathscr{F}_n$ on the prescheme $Z = X_1 \times_S X_2 \times_S \cdots \times_S X_n$; it is a *quasi-coherent* $\mathscr{O}_Z$-module by virtue of (9.1.1) and (0, 5.1.4); it is *coherent* if the $\mathscr{F}_i$ are and if Z is *locally Noetherian*, by virtue of (9.1.1), (0, 5.3.11) and (6.1.1).

Note that if we take $X = Y = S$, definition (9.1.2) gives back the tensor product of $\mathscr{O}_S$-modules. Moreover, since $q^*(\mathscr{O}_Y) = \mathscr{O}_{X \times_S Y}$ (0, 4.3.4), the product $\mathscr{F} \otimes_S \mathscr{O}_Y$ is canonically identified with $p^*(\mathscr{F})$, and likewise $\mathscr{O}_X \otimes_S \mathscr{G}$ is canonically identified with $q^*(\mathscr{G})$. More particularly, if we take $Y = S$ and denote by f the structural morphism $X \to Y$, we have $\mathscr{O}_X \otimes_Y \mathscr{G} = f^*(\mathscr{G})$: the ordinary tensor product and the inverse image thus appear as particular cases of the general tensor product.

Definition (9.1.2) immediately implies that, for fixed X and Y, $\mathscr{F} \otimes_S \mathscr{G}$ is a *covariant, additive and right exact bifunctor* in $\mathscr{F}$ and $\mathscr{G}$.

(9.1.3) Proposition. *Let S, X, Y be three affine schemes with respective rings A, B, C, B and C being A-algebras. Let M (resp. N) be a B-module (resp. C-module), and*

$\mathscr{F} = \widetilde{M}$ (resp. $\mathscr{G} = \widetilde{N}$) the associated quasi-coherent sheaf; then $\mathscr{F} \otimes_S \mathscr{G}$ is canonically isomorphic to the sheaf associated to the $(B \otimes_A C)$-module $M \otimes_A N$.

Proof. Indeed, by virtue of (1.6.5), $\mathscr{F} \otimes_S \mathscr{G}$ is canonically isomorphic to the sheaf associated to [I | 170] the $(B \otimes_A C)$-module

$$\big(M \otimes_B (B \otimes_A C)\big) \otimes_{B \otimes_A C} \big((B \otimes_A C) \otimes_C N\big)$$

and, owing to the canonical isomorphisms between tensor products, the latter is isomorphic to

$$M \otimes_B (B \otimes_A C) \otimes_C N = (M \otimes_B B) \otimes_A (C \otimes_C N) = M \otimes_A N.$$

□

(9.1.4) Proposition. *Let $f : T \to X$, $g : T \to Y$ be two S-morphisms, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module). Then we have*

$$(f, g)^*_S(\mathscr{F} \otimes_S \mathscr{G}) = f^*(\mathscr{F}) \otimes_{\mathscr{O}_T} g^*(\mathscr{G}).$$

Proof. If p, q are the projections of $X \times_S Y$, the formula indeed follows from the relations $(f, g)^*_S \circ p^* = f^*$ and $(f, g)^*_S \circ q^* = g^*$ (0, 3.5.5), and from the fact that an inverse image of a tensor product of algebraic sheaves is the tensor product of their inverse images (0, 4.3.3). □

(9.1.5) Corollary. *Let $f : X \to X'$, $g : Y \to Y'$ be two S-morphisms, and $\mathscr{F}'$ (resp. $\mathscr{G}'$) a quasi-coherent $\mathscr{O}_{X'}$-module (resp. $\mathscr{O}_{Y'}$-module). Then we have*

$$(f \times_S g)^*(\mathscr{F}' \otimes_S \mathscr{G}') = f^*(\mathscr{F}') \otimes_S g^*(\mathscr{G}').$$

Proof. This follows from (9.1.4) and from the fact that $f \times_S g = (f \circ p, g \circ q)_S$, p and q being the projections of $X \times_S Y$. □

(9.1.6) Corollary. *Let X, Y, Z be three S-preschemes, and $\mathscr{F}$ (resp. $\mathscr{G}$, $\mathscr{H}$) a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module, $\mathscr{O}_Z$-module); the sheaf $\mathscr{F} \otimes_S \mathscr{G} \otimes_S \mathscr{H}$ is the inverse image of $(\mathscr{F} \otimes_S \mathscr{G}) \otimes_S \mathscr{H}$ under the canonical isomorphism of $X \times_S Y \times_S Z$ onto $(X \times_S Y) \times_S Z$.*

Proof. Indeed, this isomorphism can be written $(p_1, p_2)_S \times_S p_3$, denoting by p_1, p_2, p_3 the projections of $X \times_S Y \times_S Z$.

Likewise, the inverse image of $\mathscr{G} \otimes_S \mathscr{F}$ under the canonical isomorphism of $X \times_S Y$ onto $Y \times_S X$ is $\mathscr{F} \otimes_S \mathscr{G}$. □

(9.1.7) Corollary. *If X is an S-prescheme, every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is the inverse image of $\mathscr{F} \otimes_S \mathscr{O}_S$ under the canonical isomorphism of X onto $X \times_S S$ (3.3.3).*

Proof. Indeed, this isomorphism is $(1_X, \varphi)_S$, where φ is the structural morphism $X \to S$, and the corollary follows from (9.1.4) and from the fact that $\varphi^*(\mathscr{O}_S) = \mathscr{O}_X$. □

(9.1.8) Let X be an S-prescheme, $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module, and $\varphi : S' \to S$ a morphism; we denote by $\mathscr{F}_{(\varphi)}$ or $\mathscr{F}_{(S')}$ the quasi-coherent sheaf $\mathscr{F} \otimes_S \mathscr{O}_{S'}$ on $X \times_S S' = X_{(\varphi)} = X_{(S')}$; thus $\mathscr{F}_{(S')} = p^*(\mathscr{F})$, where p is the projection $X_{(S')} \to X$.

(9.1.9) Proposition. *Let $\varphi' : S'' \to S'$ be a morphism. For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ on the S-prescheme X, $(\mathscr{F}_{(\varphi)})_{(\varphi')}$ is the inverse image of $\mathscr{F}_{(\varphi\circ\varphi')}$ under the canonical isomorphism $(X_{(\varphi)})_{(\varphi')} \xrightarrow{\sim} X_{(\varphi\circ\varphi')}$ (3.3.9).*

Proof. This follows immediately from the definitions and from (3.3.9), and can also be written

$$(\mathscr{F} \otimes_S \mathscr{O}_{S'}) \otimes_{S'} \mathscr{O}_{S''} = \mathscr{F} \otimes_S \mathscr{O}_{S''}. \tag{9.1.9.1}$$

□

(9.1.10) Proposition. *Let Y be an S-prescheme and $f : X \to Y$ an S-morphism. For every quasi-coherent $\mathscr{O}_Y$-module $\mathscr{G}$ and every morphism $S' \to S$, we have*

$$(f_{(S')})^*(\mathscr{G}_{(S')}) = (f^*(\mathscr{G}))_{(S')}.$$

Proof. This follows immediately from the commutativity of the diagram [I | 171]

$$\begin{array}{ccc} X_{(S')} & \xrightarrow{f_{(S')}} & Y_{(S')} \\ \downarrow & & \downarrow \\ X & \xrightarrow[f]{} & Y \end{array}$$

□

(9.1.11) Corollary. *Let X, Y be two S-preschemes, and $\mathscr{F}$ (resp. $\mathscr{G}$) a quasi-coherent $\mathscr{O}_X$-module (resp. $\mathscr{O}_Y$-module). The inverse image of the sheaf $(\mathscr{F}_{(S')} \otimes_{S'} \mathscr{G}_{(S')})$ under the canonical isomorphism $(X \times_S Y)_{(S')} \xrightarrow{\sim} (X_{(S')}) \times_{S'} (Y_{(S')})$ (3.3.10) is equal to $(\mathscr{F} \otimes_S \mathscr{G})_{(S')}$.*

Proof. If p, q are the projections of $X \times_S Y$, the isomorphism in question is none other than $(p_{(S')}, q_{(S')})_{S'}$; the corollary follows from Propositions (9.1.4) and (9.1.10). □

(9.1.12) Proposition. *With the notation of (9.1.2), let z be a point of $X \times_S Y$, $x = p(z)$, $y = q(z)$; the stalk $(\mathscr{F} \otimes_S \mathscr{G})_z$ is isomorphic to $(\mathscr{F}_x \otimes_{\mathscr{O}_x} \mathscr{O}_z) \otimes_{\mathscr{O}_z} (\mathscr{G}_y \otimes_{\mathscr{O}_y} \mathscr{O}_z) = \mathscr{F}_x \otimes_{\mathscr{O}_x} \mathscr{O}_z \otimes_{\mathscr{O}_y} \mathscr{G}_y$.*

Proof. Since we can reduce to the affine case, the proposition follows from formula (1.6.5.1). □

(9.1.13) Corollary. *If $\mathscr{F}$ and $\mathscr{G}$ are of finite type, we have*

$$\mathrm{Supp}(\mathscr{F} \otimes_S \mathscr{G}) = p^{-1}(\mathrm{Supp}(\mathscr{F})) \cap q^{-1}(\mathrm{Supp}(\mathscr{G})).$$

Proof. Since $p^*(\mathscr{F})$ and $q^*(\mathscr{G})$ are of finite type over $\mathscr{O}_{X\times_S Y}$, we are reduced, by (9.1.12) and (0, 1.7.5), to the particular case where $\mathscr{G} = \mathscr{O}_Y$, that is, to proving the formula

$$\mathrm{Supp}(p^{-1}(\mathscr{F})) = p^{-1}(\mathrm{Supp}(\mathscr{F})). \tag{9.1.13.1}$$

The same reasoning as in (0, 1.7.5) reduces us to verifying that, for every $z \in X\times_S Y$, we have $\mathscr{O}_z/\mathfrak{m}_x\mathscr{O}_z \neq 0$ (with $x = p(z)$), which follows from the fact that the homomorphism $\mathscr{O}_x \to \mathscr{O}_z$ is *local* by hypothesis. □

We leave it to the reader to extend the results proved in this subsection for two factors to a product of an arbitrary number of factors.

9.2 Direct image of a quasi-coherent sheaf.

(9.2.1) Proposition. *Let $f : X \to Y$ be a morphism of preschemes. Suppose that there exists a covering (Y_α) of Y by affine open subsets having the following property: each of the $f^{-1}(Y_\alpha)$ admits a finite covering $(X_{\alpha i})$ by affine open subsets contained in $f^{-1}(Y_\alpha)$, such that each of the intersections $X_{\alpha i}\cap X_{\alpha j}$ is itself a finite union of affine open subsets. Under these conditions, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$, $f_*(\mathscr{F})$ is a quasi-coherent $\mathscr{O}_Y$-module.*

Proof. The question being local on Y, we may suppose Y equal to one of the Y_α, and hence suppress the indices α.

a) Suppose first that the $X_i\cap X_j$ are themselves *affine* open subsets. Set $\mathscr{F}_i = \mathscr{F}|X_i$, $\mathscr{F}_{ij} = \mathscr{F}|(X_i\cap X_j)$, and let $\mathscr{F}'_i$ and $\mathscr{F}'_{ij}$ be the images of $\mathscr{F}_i$ and $\mathscr{F}_{ij}$ respectively under the restrictions of f to X_i and $X_i\cap X_j$; we know that the $\mathscr{F}'_i$ and the $\mathscr{F}'_{ij}$ are quasi-coherent (1.6.3). Set $\mathscr{G} = \bigoplus_i \mathscr{F}'_i$, $\mathscr{H} = \bigoplus_{i,j}\mathscr{F}'_{ij}$; $\mathscr{G}$ and $\mathscr{H}$ are quasi-coherent $\mathscr{O}_Y$-modules; we will define a homomorphism $u : \mathscr{G}\to\mathscr{H}$ such that $f_*(\mathscr{F})$ is the *kernel* of u; it will follow that $f_*(\mathscr{F})$ is quasi-coherent (1.3.9). It suffices to
[I | 172] define u as a homomorphism of presheaves; taking into account the definitions of $\mathscr{G}$ and $\mathscr{H}$, it therefore suffices, for every open set $W\subset Y$, to define a homomorphism

$$u_W : \bigoplus_i \Gamma(f^{-1}(W)\cap X_i, \mathscr{F}) \longrightarrow \bigoplus_{i,j}\Gamma(f^{-1}(W)\cap X_i\cap X_j, \mathscr{F})$$

so as to satisfy the usual compatibility conditions when W varies. If, for every section $s_i \in \Gamma(f^{-1}(W)\cap X_i, \mathscr{F})$, we denote by $s_{i|j}$ its restriction to $f^{-1}(W)\cap X_i\cap X_j$, we set

$$u_W((s_i)) = (s_{i|j} - s_{j|i})$$

and the compatibility conditions are evidently satisfied. To prove that the kernel $\mathscr{R}$ of u is $f_*(\mathscr{F})$, let us define a homomorphism of $f_*(\mathscr{F})$ into $\mathscr{R}$ by assigning to every section $s\in\Gamma(f^{-1}(W),\mathscr{F})$ the family (s_i), where s_i is the restriction of s to $f^{-1}(W)\cap X_i$; the axioms (F 1) and (F 2) of sheaves (G, II, 1.1) imply that this homomorphism is *bijective*, which proves the assertion in this case.

b) In the general case the same argument works as soon as we know that the $\mathscr{F}'_{ij}$ are quasi-coherent. Now, by hypothesis, $X_i\cap X_j$ is a finite union of affine open subsets X_{ijk}; and since the X_{ijk} are affine open subsets *in a scheme*, the intersection of any two of them is again an affine open subset (5.5.6). We are therefore reduced to the first case, and (9.2.1) is thus proved.

□

(9.2.2) Corollary. *The conclusion of (9.2.1) holds in each of the following cases:*

a) f is separated and quasi-compact.

b) f is separated and of finite type.

c) f is quasi-compact and the underlying space of X is locally Noetherian.

Proof. In case a), the $X_{\alpha i} \cap X_{\alpha j}$ are affine (5.5.6). Case b) is a particular case of a) (6.6.3). Finally, in case c), we can reduce to the case where Y is affine and the underlying space of X is Noetherian; then X admits a finite affine open covering (X_i), and the $X_i \cap X_j$, being quasi-compact, are finite unions of affine open subsets (2.1.3). □

9.3 Extension of sections of quasi-coherent sheaves.

(9.3.1) Theorem. *Let X be a prescheme whose underlying space is Noetherian, or a scheme whose underlying space is quasi-compact. Let $\mathscr{L}$ be an invertible $\mathscr{O}_X$-module (0, 5.4.1), f a section of $\mathscr{L}$ over X, X_f the open set of the $x \in X$ where $f(x) \neq 0$ (0, 5.5.1), and $\mathscr{F}$ a quasi-coherent $\mathscr{O}_X$-module.*

(i) If $s \in \Gamma(X, \mathscr{F})$ is such that $s|X_f = 0$, there exists an integer $n > 0$ such that $s \otimes f^{\otimes n} = 0$.

(ii) For every section $s \in \Gamma(X_f, \mathscr{F})$, there exists an integer $n > 0$ such that $s \otimes f^{\otimes n}$ extends to a section of $\mathscr{F} \otimes \mathscr{L}^{\otimes n}$ over X.

Proof. (i) Since the underlying space of X is quasi-compact, hence a finite union of affine open subsets U_i such that $\mathscr{L}|U_i$ is isomorphic to $\mathscr{O}_X|U_i$, we are reduced to the case where X is affine and $\mathscr{L} = \mathscr{O}_X$. In this case, f is identified with an element of $A(X)$ and we have $X_f = D(f)$; s is identified with an element of an $A(X)$-module M and $s|X_f$ with the corresponding element of M_f, and the result is trivial, taking into account the definition of a module of fractions. [I | 173]

(ii) Again X is a finite union of affine open subsets U_i $(1 \leq i \leq r)$ such that $\mathscr{L}|U_i \simeq \mathscr{O}_X|U_i$, and for each i, $(s \otimes f^{\otimes n})|(U_i \cap X_f)$ is identified, by the preceding isomorphism, with $(f|(U_i \cap X_f))^n (s|(U_i \cap X_f))$. We then know (1.4.1) that there exists an integer $n > 0$ such that for each i, $(s \otimes f^{\otimes n})|(U_i \cap X_f)$ extends to a section s_i of $\mathscr{F} \otimes \mathscr{L}^{\otimes n}$ over U_i. Let $s_{i|j}$ be the restriction of s_i to $U_i \cap U_j$; by definition we have $s_{i|j} - s_{j|i} = 0$ in $X_f \cap U_i \cap U_j$. Now, if X is a Noetherian space, $U_i \cap U_j$ is quasi-compact; if X is a scheme, $U_i \cap U_j$ is an affine open subset (5.5.6), hence again quasi-compact. By virtue of (i), there therefore exists an integer m (independent of i and j) such that $(s_{i|j} - s_{j|i}) \otimes f^{\otimes m} = 0$. We conclude immediately that there exists a section s' of $\mathscr{F} \otimes \mathscr{L}^{\otimes (n+m)}$ over X, inducing $s_i \otimes f^{\otimes m}$ over each U_i, and consequently inducing $s \otimes f^{\otimes (n+m)}$ over X_f.

□

The corollaries that follow give an interpretation of Theorem (9.3.1) in a more algebraic language:

(9.3.2) Corollary. *The hypotheses being those of (9.3.1), consider the graded ring* $A_* = \Gamma_*(\mathscr{L})$ *and the graded* A_**-module* $M_* = \Gamma_*(\mathscr{L}, \mathscr{F})$ *(0, 5.4.6). If* $f \in A_n$*, where* $n \in \mathbb{Z}$*, then we have a canonical isomorphism*

$$\Gamma(X_f, \mathscr{F}) \xrightarrow{\sim} ((M_*)_f)_0$$

(the subgroup of the module of fractions $(M_*)_f$ *consisting of the elements of degree* 0*).*

(9.3.3) Corollary. *Suppose that the hypotheses of (9.3.1) are satisfied, and suppose moreover that* $\mathscr{L} = \mathscr{O}_X$*. Then if we set* $A = \Gamma(X, \mathscr{O}_X)$*,* $M = \Gamma(X, \mathscr{F})$*, the* A_f*-module* $\Gamma(X_f, \mathscr{F})$ *is canonically isomorphic to* M_f*.*

(9.3.4) Proposition. *Let* X *be a Noetherian prescheme,* $\mathscr{F}$ *a coherent* $\mathscr{O}_X$*-module, and* $\mathscr{J}$ *a coherent sheaf of ideals in* $\mathscr{O}_X$ *such that the support of* $\mathscr{F}$ *is contained in that of* $\mathscr{O}_X/\mathscr{J}$*. Then there exists an integer* $n > 0$ *such that* $\mathscr{J}^n\mathscr{F} = 0$*.*

Proof. Since X is a finite union of affine open subsets whose rings are Noetherian, we may suppose X affine with Noetherian ring A; then $\mathscr{F} = \widetilde{M}$, where $M = \Gamma(X, \mathscr{F})$ is an A-module of finite type, and $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J} = \Gamma(X, \mathscr{J})$ is an ideal of A (1.4.1 and 1.5.1). Since A is Noetherian, $\mathfrak{J}$ admits a finite system of generators f_i $(1 \leq i \leq m)$. By hypothesis, every section of $\mathscr{F}$ over X is zero in each of the $D(f_i)$; if s_j $(1 \leq j \leq q)$ are sections of $\mathscr{F}$ generating M, there therefore exists an integer h, independent of i and j, such that $f_i^h s_j = 0$ (1.4.1), hence $f_i^h s = 0$ for every $s \in M$. We conclude that if $n = mh$, we have $\mathfrak{J}^n M = 0$, and consequently the corresponding $\mathscr{O}_X$-module $\mathscr{J}^n\mathscr{F} = \widetilde{\mathfrak{J}^n M}$ (1.3.13) is zero. □

(9.3.5) Corollary. *Under the hypotheses of (9.3.4), there exists a closed sub-prescheme* Y *of* X *whose underlying space is the support of* $\mathscr{O}_X/\mathscr{J}$*, and such that, if* $j : Y \to X$ *is the canonical injection, we have* $\mathscr{F} = j_*(j^*(\mathscr{F}))$*.*

Proof. Let us note first that the supports of $\mathscr{O}_X/\mathscr{J}$ and of $\mathscr{O}_X/\mathscr{J}^n$ are the same, since if $\mathscr{J}_x = \mathscr{O}_x$, we also have $\mathscr{J}_x^n = \mathscr{O}_x$, and on the other hand we have $\mathscr{J}_x^n \subset \mathscr{J}_x$ for every $x \in X$. We may therefore, by virtue of (9.3.4), suppose that $\mathscr{J}\mathscr{F} = 0$; we then take for Y the closed sub-prescheme of X defined by $\mathscr{J}$, and since $\mathscr{F}$ is then an $(\mathscr{O}_X/\mathscr{J})$-module, the conclusion is immediate. □

[I | 174] 9.4 Extension of quasi-coherent sheaves.

(9.4.1) Let X be a topological space, $\mathscr{F}$ a sheaf of sets (resp. of groups, of rings) on X, U an open subset of X, $\psi : U \to X$ the canonical injection, and $\mathscr{G}$ a sub-sheaf of $\mathscr{F}|U = \psi^*(\mathscr{F})$. Since ψ_* is left exact, $\psi_*(\mathscr{G})$ is a sub-sheaf of $\psi_*(\psi^*(\mathscr{F}))$; if we consider the canonical homomorphism $\rho : \mathscr{F} \to \psi_*(\psi^*(\mathscr{F}))$ (0, 3.5.3), we will denote by $\overline{\mathscr{G}}$ the sub-sheaf $\rho^{-1}(\psi_*(\mathscr{G}))$ of $\mathscr{F}$. It follows immediately from the definitions that for every open subset V of X, $\Gamma(V, \overline{\mathscr{G}})$ consists of the sections $s \in \Gamma(V, \mathscr{F})$ whose restriction to $V \cap U$ is a section of $\mathscr{G}$ over $V \cap U$. We therefore have $\overline{\mathscr{G}}|U = \psi^*(\overline{\mathscr{G}}) = \mathscr{G}$, and $\overline{\mathscr{G}}$ is the *largest* sub-sheaf of $\mathscr{F}$ inducing $\mathscr{G}$ on U; we will say that $\overline{\mathscr{G}}$ is the *canonical extension* of the sub-sheaf $\mathscr{G}$ of $\mathscr{F}|U$ to a sub-sheaf of $\mathscr{F}$.

(9.4.2) Proposition. *Let X be a prescheme and U an open subset of X such that the canonical injection $j : U \to X$ is a quasi-compact morphism* (which will be satisfied for *every* U if the underlying space X is *locally Noetherian* (6.6.4, (i))). *Then:*

(i) For every quasi-coherent $(\mathscr{O}_X|U)$-module $\mathscr{G}$, $j_*(\mathscr{G})$ is a quasi-coherent $\mathscr{O}_X$-module and we have $j_*(\mathscr{G})|U = j^*(j_*(\mathscr{G})) = \mathscr{G}$.

(ii) For every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent sub-$(\mathscr{O}_X|U)$-module $\mathscr{G}$, the canonical extension $\overline{\mathscr{G}}$ of $\mathscr{G}$ (9.4.1) is a quasi-coherent sub-$\mathscr{O}_X$-module of $\mathscr{F}$.

Proof. If $j = (\psi, \theta)$ (ψ being the injection $U \to X$ of the underlying spaces), we have by definition $j_*(\mathscr{G}) = \psi_*(\mathscr{G})$ for every $(\mathscr{O}_X|U)$-module $\mathscr{G}$, and moreover $j^*(\mathscr{H}) = \psi^*(\mathscr{H}) = \mathscr{H}|U$ for every $\mathscr{O}_X$-module $\mathscr{H}$, by reason of the definition of a prescheme induced on an open subset. (i) is therefore a particular case of (9.2.2, a)); for the same reason, $j_*(j^*(\mathscr{F}))$ is quasi-coherent, and since $\overline{\mathscr{G}}$ is the inverse image of $j_*(\mathscr{G})$ under the homomorphism $\rho : \mathscr{F} \to j_*(j^*(\mathscr{F}))$, (ii) follows from (4.1.1). □

Note that the hypothesis that the morphism $j : U \to X$ is quasi-compact is also satisfied when the open subset U is *quasi-compact* and X is a *scheme*: indeed, U is then a finite union of affine open subsets U_i, and for every affine open subset V of X, $V \cap U_i$ is an affine open subset (5.5.6), hence quasi-compact.

(9.4.3) Corollary. *Let X be a prescheme and U a quasi-compact open subset of X such that the injection morphism $j : U \to X$ is quasi-compact. Suppose moreover that every quasi-coherent $\mathscr{O}_X$-module is the inductive limit of its quasi-coherent sub-$\mathscr{O}_X$-modules of finite type* (which is the case when X is an *affine scheme*). *Let then $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module, and $\mathscr{G}$ a quasi-coherent sub-$(\mathscr{O}_X|U)$-module of finite type of $\mathscr{F}|U$. Then there exists a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{G}'$ of $\mathscr{F}$ such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. Indeed, we have $\mathscr{G} = \overline{\mathscr{G}}|U$, and $\overline{\mathscr{G}}$ is quasi-coherent by (9.4.2), hence the inductive limit of its quasi-coherent sub-$\mathscr{O}_X$-modules of finite type $\mathscr{H}_\lambda$. Consequently $\mathscr{G}$ is the inductive limit of the $\mathscr{H}_\lambda|U$, hence equal to one of the $\mathscr{H}_\lambda|U$ since it is of finite type (0, 5.2.3). □

(9.4.4) Remark. Suppose that for *every* affine open subset $U \subset X$ the injection morphism $U \to X$ is quasi-compact. Then if the conclusion of (9.4.3) holds for every affine open subset U and every quasi-coherent sub-$(\mathscr{O}_X|U)$-module of finite type $\mathscr{G}$ of $\mathscr{F}|U$, it follows that $\mathscr{F}$ is the inductive limit of its quasi-coherent sub-$\mathscr{O}_X$-modules of finite type. Indeed, for every affine open subset $U \subset X$, we have $\mathscr{F}|U = \widetilde{M}$, where M is an $A(U)$-module, and since the latter is the inductive limit of its submodules of finite type, $\mathscr{F}|U$ is the inductive limit of its quasi-coherent sub-$(\mathscr{O}_X|U)$-modules of finite type (1.3.9). Now, by hypothesis, each of these submodules is induced on U by a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{G}_{\lambda,U}$ of $\mathscr{F}$. The finite sums of the $\mathscr{G}_{\lambda,U}$ are again quasi-coherent $\mathscr{O}_X$-modules of finite type, since the question is local and the case where X is affine has been treated in (1.3.10); it is then clear that $\mathscr{F}$ is the inductive limit of these finite sums, whence our assertion. [I | 175]

(9.4.5) Corollary. *Under the hypotheses of (9.4.3), for every quasi-coherent $(\mathscr{O}_X|U)$-module of finite type $\mathscr{G}$, there exists a quasi-coherent $\mathscr{O}_X$-module of finite type $\mathscr{G}'$ such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. Since $\mathscr{F} = j_*(\mathscr{G})$ is quasi-coherent (9.4.2) and $\mathscr{F}|U = \mathscr{G}$, it suffices to apply (9.4.3) to $\mathscr{F}$. □

(9.4.6) Lemma. *Let X be a prescheme, L a well-ordered set, $(V_\lambda)_{\lambda\in L}$ a covering of X by affine open subsets, and U an open subset of X; for every $\lambda \in L$, set $W_\lambda = \bigcup_{\mu<\lambda} V_\mu$. Suppose that:*

1º For every $\lambda \in L$, $V_\lambda \cap W_\lambda$ is quasi-compact;

2º The immersion morphism $U \to X$ is quasi-compact.

Then, for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent sub-$(\mathscr{O}_X|U)$-module of finite type $\mathscr{G}$ of $\mathscr{F}|U$, there exists a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{G}'$ of $\mathscr{F}$ such that $\mathscr{G}'|U = \mathscr{G}$.

Proof. Let κ be the order type of L; let us index the given covering by $\lambda < \kappa$.[33] For $0 \leq \lambda \leq \kappa$, set $W_\lambda = \bigcup_{\mu<\lambda} V_\mu$ and $U_\lambda = U \cup W_\lambda$. We construct by transfinite induction a quasi-coherent sub-$(\mathscr{O}_X|U_\lambda)$-module of finite type $\mathscr{G}'_\lambda$ of $\mathscr{F}|U_\lambda$ such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ for $\mu < \lambda$ and $\mathscr{G}'_\lambda|U = \mathscr{G}$. We begin with $\mathscr{G}'_0 = \mathscr{G}$ on $U_0 = U$; since $U_\kappa = X$, the module $\mathscr{G}' = \mathscr{G}'_\kappa$ will answer the question. Suppose therefore that $0 < \lambda \leq \kappa$ and that the $\mathscr{G}'_\mu$ have been constructed with these properties for $\mu < \lambda$. If λ is a limit ordinal, we take for $\mathscr{G}'_\lambda$ the unique sub-$(\mathscr{O}_X|U_\lambda)$-module of $\mathscr{F}|U_\lambda$ such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ for every $\mu < \lambda$; the U_μ with $\mu < \lambda$ then cover U_λ, and quasi-coherence and finite type are local properties. If, on the contrary, $\lambda = \mu + 1$, we have $U_\lambda = U_\mu \cup V_\mu$, and it will suffice to define a quasi-coherent sub-$(\mathscr{O}_X|V_\mu)$-module of finite type $\mathscr{G}''_\mu$ of $\mathscr{F}|V_\mu$ such that

$$\mathscr{G}''_\mu|(U_\mu \cap V_\mu) = \mathscr{G}'_\mu|(U_\mu \cap V_\mu)\ ;$$

we will then take for $\mathscr{G}'_\lambda$ the sub-$(\mathscr{O}_X|U_\lambda)$-module of $\mathscr{F}|U_\lambda$ such that $\mathscr{G}'_\lambda|U_\mu = \mathscr{G}'_\mu$ and $\mathscr{G}'_\lambda|V_\mu = \mathscr{G}''_\mu$ (0, 3.3.1). Now, since V_μ is affine, the existence of $\mathscr{G}''_\mu$ is ensured by (9.4.3) as soon as we have proved that $U_\mu \cap V_\mu$ is quasi-compact; but $U_\mu \cap V_\mu$ is the union of $U \cap V_\mu$ and $W_\mu \cap V_\mu$, both of which are quasi-compact by virtue of the hypothesis. □

(9.4.7) Theorem. *Let X be a prescheme and U an open subset of X. Suppose that one of the following conditions is satisfied:*

(a) The underlying space of X is locally Noetherian.

(b) X is a quasi-compact scheme and U a quasi-compact open subset.

Then for every quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ and every quasi-coherent sub-$(\mathscr{O}_X|U)$-module of finite type $\mathscr{G}$ of $\mathscr{F}|U$, there exists a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{G}'$ of $\mathscr{F}$ such that $\mathscr{G}'|U = \mathscr{G}$.

Proof. Let $(V_\lambda)_{\lambda\in L}$ be a covering of X by affine open subsets, L being supposed finite in case b); L being endowed with a structure of well-ordered set, it suffices to verify that the conditions of Lemma (9.4.6) are satisfied. This is evident under hypothesis a), the spaces V_λ being Noetherian. Under hypothesis b), the $V_\lambda \cap V_\mu$ are affine (5.5.6), hence quasi-compact, and since L is finite, $V_\lambda \cap W_\lambda$ is quasi-compact. Whence the theorem. □

[I | 176]

[33] Editorial clarification: the printed induction omits the initial case and, if L has a largest element, the final step. The steps $0 \leq \lambda \leq \kappa$ complete the proof without changing the hypotheses.

(9.4.8) Corollary. *Under the hypotheses of (9.4.7), for every quasi-coherent $(\mathscr{O}_X|U)$-module of finite type $\mathscr{G}$, there exists a quasi-coherent $\mathscr{O}_X$-module of finite type $\mathscr{G}'$ such that $\mathscr{G}'|U = \mathscr{G}$.*

Proof. It suffices to apply (9.4.7) to $\mathscr{F} = j_*(\mathscr{G})$, which is quasi-coherent (9.4.2) and such that $\mathscr{F}|U = \mathscr{G}$. □

(9.4.9) Corollary. *Let X be a prescheme whose underlying space is locally Noetherian, or a quasi-compact scheme. Then every quasi-coherent $\mathscr{O}_X$-module is the inductive limit of its quasi-coherent sub-$\mathscr{O}_X$-modules of finite type.*

Proof. This follows from (9.4.7) and from Remark (9.4.4). □

(9.4.10) Corollary. *Under the hypotheses of (9.4.9), if a quasi-coherent $\mathscr{O}_X$-module $\mathscr{F}$ is such that every quasi-coherent sub-$\mathscr{O}_X$-module of finite type of $\mathscr{F}$ is generated by its sections over X, then $\mathscr{F}$ is generated by its sections over X.*

Proof. Indeed, let U be an affine open neighbourhood of a point $x \in X$, and let s be a section of $\mathscr{F}$ over U; the sub-$\mathscr{O}_X$-module $\mathscr{G}$ of $\mathscr{F}|U$ generated by s is quasi-coherent and of finite type, so there exists a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{G}'$ of $\mathscr{F}$ such that $\mathscr{G}'|U = \mathscr{G}$ (9.4.7). By hypothesis, there are therefore finitely many sections t_i of $\mathscr{G}'$ over X and sections a_i of $\mathscr{O}_X$ over a neighbourhood $V \subset U$ of x such that $s|V = \sum_i a_i \cdot (t_i|V)$, which proves the corollary. □

9.5 Closed image of a prescheme. Closure of a sub-prescheme.

(9.5.1) Proposition. *Let $f : X \to Y$ be a morphism of preschemes such that $f_*(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_Y$-module (which is the case if f is quasi-compact and if moreover f is separated or X is locally Noetherian (9.2.2)). Then there exists a smallest closed sub-prescheme Y' of Y such that the canonical injection $j : Y' \to Y$ dominates f (or, what amounts to the same (4.4.1), such that the sub-prescheme $f^{-1}(Y')$ of X is* identical *to X).*

More precisely:

(9.5.2) Corollary. *Under the conditions of (9.5.1), let $f = (\psi, \theta)$ and let $\mathscr{J}$ be the (quasi-coherent) kernel of the homomorphism $\theta : \mathscr{O}_Y \to f_*(\mathscr{O}_X)$. Then the closed sub-prescheme Y' of Y defined by $\mathscr{J}$ satisfies the conditions of (9.5.1).*

Proof. Since the functor ψ^* is exact, the canonical factorization $\theta : \mathscr{O}_Y \to \mathscr{O}_Y/\mathscr{J} \xrightarrow{\theta'} \psi_*(\mathscr{O}_X)$ gives (0, 3.5.4.3) a factorization

$$\theta^\sharp : \psi^*(\mathscr{O}_Y) \to \psi^*(\mathscr{O}_Y)/\psi^*(\mathscr{J}) \xrightarrow{\theta'^\sharp} \mathscr{O}_X \ ;$$

since for every $x \in X$, $\theta^\sharp_x$ is a local homomorphism, the same is true of ${\theta'}^\sharp_x$; if we denote by ψ_0 the continuous map ψ considered as a map from X to X', and by θ_0 the restriction $\theta'|X' : (\mathscr{O}_Y/\mathscr{J})|X' \to \psi_*(\mathscr{O}_X)|X' = (\psi_0)_*(\mathscr{O}_X)$, we therefore see that $f_0 = (\psi_0, \theta_0)$ is a morphism of preschemes $X \to X'$ (2.2.1) such that $f = j \circ f_0$. If now X'' is a second [I | 177] closed sub-prescheme of Y, defined by a quasi-coherent sheaf of ideals $\mathscr{J}'$ of $\mathscr{O}_Y$, and such that the injection $j' : X'' \to Y$ dominates f, we must first of all have $X'' \supset \psi(X)$, hence $X' \subset X''$ since X'' is closed. Moreover, for every $y \in X''$, θ must factor as

$\mathscr{O}_y \to \mathscr{O}_y/\mathscr{J}'_y \to (\psi_*(\mathscr{O}_X))_y$, which by definition implies $\mathscr{J}'_y \subset \mathscr{J}_y$, and consequently X' is a closed sub-prescheme of X'' (4.1.10). □

(9.5.3) Definition. When there exists a smallest closed sub-prescheme Y' of Y such that the canonical injection $j : Y' \to Y$ dominates f, we say that Y' is the closed image prescheme of X under the morphism f.

(9.5.4) Proposition. *If $f_*(\mathscr{O}_X)$ is a quasi-coherent $\mathscr{O}_Y$-module, the underlying space of the closed image of X under f is the closure $\overline{f(X)}$ in Y.*

Proof. Since the support of $f_*(\mathscr{O}_X)$ is contained in $\overline{f(X)}$, we have (with the notation of (9.5.2)) $\mathscr{J}_y = \mathscr{O}_y$ for $y \notin \overline{f(X)}$, hence the support of $\mathscr{O}_Y/\mathscr{J}$ is contained in $\overline{f(X)}$. Moreover, this support is closed and contains $f(X)$: indeed, if $y \in f(X)$, the unit element of the ring $(\psi_*(\mathscr{O}_X))_y$ is not zero, being the germ at y of the section

$$1 \in \Gamma(X, \mathscr{O}_X) = \Gamma(Y, \psi_*(\mathscr{O}_X)) \ ;$$

since it is the image under θ of the unit element of $\mathscr{O}_y$, the latter does not belong to $\mathscr{J}_y$, hence $\mathscr{O}_y/\mathscr{J}_y \neq 0$; this completes the proof. □

(9.5.5) Proposition. (transitivity of closed images). *Let $f : X \to Y$ and $g : Y \to Z$ be two morphisms of preschemes; suppose that the closed image Y' of X under f exists, and that, if g' is the restriction of g to Y', the closed image Z' of Y' under g' exists. Then the closed image of X under $g \circ f$ exists and is equal to Z'.*

Proof. It suffices (9.5.1) to show that Z' is the smallest closed sub-prescheme Z_1 of Z such that the closed sub-prescheme $(g \circ f)^{-1}(Z_1)$ of X (equal to $f^{-1}(g^{-1}(Z_1))$ by (4.4.2)) is equal to X; it amounts to the same to say that Z' is the smallest closed sub-prescheme of Z such that f is dominated by the injection $g^{-1}(Z_1) \to Y$ (4.4.1). Now, by virtue of the existence of the closed image Y', every Z_1 having this property is such that $g^{-1}(Z_1)$ dominates Y', which is equivalent to saying that $j^{-1}(g^{-1}(Z_1)) = g'^{-1}(Z_1) = Y'$, denoting by j the injection $Y' \to Y$. By definition of Z', we indeed conclude that Z' is the smallest closed sub-prescheme of Z satisfying the preceding condition. □

(9.5.6) Corollary. *Let $f : X \to Y$ be an S-morphism such that Y is the closed image of X under f. Let Z be an S-scheme; if two S-morphisms g_1, g_2 from Y to Z are such that $g_1 \circ f = g_2 \circ f$, then $g_1 = g_2$.*

Proof. Let $h = (g_1, g_2)_S : Y \to Z \times_S Z$; since the diagonal $T = \Delta_Z(Z)$ is a closed sub-prescheme of $Z \times_S Z$, $Y' = h^{-1}(T)$ is a closed sub-prescheme of Y (4.4.1). Set $u = g_1 \circ f = g_2 \circ f$; we then have, by definition of the product, $h' = h \circ f = (u, u)_S$, hence $h \circ f = \Delta_Z \circ u$; since $\Delta_Z^{-1}(T) = Z$, we have $h'^{-1}(T) = u^{-1}(Z) = X$, hence $f^{-1}(Y') = X$. We conclude (4.4.1) that the canonical injection $Y' \to Y$ dominates f, hence $Y' = Y$ by hypothesis; consequently (4.4.1), h factors as $\Delta_Z \circ v$, where v is a morphism $Y \to Z$, which implies $g_1 = g_2 = v$. □

[I | 178] **(9.5.7) Remark.** If X and Y are S-schemes, Proposition (9.5.6) means that when Y is the closed image of X under f, f is an *epimorphism* in the category of S-schemes (T, 1.1). We will prove in Chapter V that, conversely, if the closed image Y' of X under f exists and if f is an epimorphism of S-schemes, then we necessarily have $Y' = Y$.

(9.5.8) Proposition. *Suppose that the hypotheses of (9.5.1) are satisfied, and let Y' be the closed image of X under f. For every open subset V of Y, let $f_V : f^{-1}(V) \to V$ be the restriction of f; then the closed image of $f^{-1}(V)$ under f_V in V exists and is equal to the prescheme induced by Y' on the open subset $V \cap Y'$ of Y' (in other words, to the sub-prescheme* $\inf(V, Y')$ *of Y (4.4.3)).*

Proof. Set $X' = f^{-1}(V)$; since the direct image of $\mathscr{O}_{X'}$ under f_V is none other than the restriction of $f_*(\mathscr{O}_X)$ to V, it is clear that the kernel $\mathscr{J}'$ of the homomorphism $\mathscr{O}_V \to (f_V)_*(\mathscr{O}_{X'})$ is the restriction of $\mathscr{J}$ to V, whence the proposition immediately. □

Note that this result can be interpreted by saying that the formation of the closed image commutes with an extension $Y_1 \to Y$ of the base prescheme which is an *open immersion*. We will see in Chapter IV that the same holds for an extension $Y_1 \to Y$ which is a *flat* morphism, provided that f is separated and quasi-compact.

(9.5.9) Proposition. *Let $f : X \to Y$ be a morphism such that the closed image Y' of X under f exists.*

(i) If X is reduced, so is Y'.

(ii) If we suppose that the hypotheses of (9.5.1) are satisfied and if X is irreducible (resp. integral), so is Y'.

Proof. By hypothesis, the morphism f factors as $X \xrightarrow{g} Y' \xrightarrow{j} Y$, where j is the canonical injection. Since X is reduced, g factors as $X \xrightarrow{h} Y'_{\mathrm{red}} \xrightarrow{j'} Y'$, where j' is the canonical injection (5.2.2), and it then follows from the definition of Y' that $Y'_{\mathrm{red}} = Y'$. If moreover the conditions of (9.5.1) are fulfilled, it follows from (9.5.4) that $f(X)$ is dense in Y'; if X is irreducible, the same is therefore true of Y' (0, 2.1.5). The assertion concerning integral preschemes follows from the conjunction of the other two. □

(9.5.10) Proposition. *Let Y be a sub-prescheme of a prescheme X such that the canonical injection $i : Y \to X$ is a quasi-compact morphism. Then there exists a smallest closed sub-prescheme $\overline{Y}$ of X dominating Y; its underlying space is the closure of that of Y; the latter is open in its closure, and the prescheme Y is induced on this open subset by $\overline{Y}$.*

Proof. It suffices to apply (9.5.1) to the injection j, which is separated (5.5.1) and quasi-compact by hypothesis; (9.5.1) therefore proves the existence of $\overline{Y}$ and (9.5.4) shows that its underlying space is the closure of Y in X; since Y is locally closed in X, it is open in $\overline{Y}$, and the last assertion comes from (9.5.8) applied to an open subset V of X such that Y is closed in V. □

With this notation, if the injection $V \to X$ is quasi-compact, and if $\mathscr{J}$ is the quasi-coherent sheaf of ideals of $\mathscr{O}_X|V$ defining the closed sub-prescheme Y of V, it follows from (9.5.1) that the quasi-coherent sheaf of ideals of $\mathscr{O}_X$ defining $\overline{Y}$ is the canonical extension (9.4.1) $\overline{\mathscr{J}}$ of $\mathscr{J}$, since it is evidently the largest quasi-coherent sub-sheaf of ideals of $\mathscr{O}_X$ inducing $\mathscr{J}$ on V. [I | 179]

(9.5.11) Corollary. *Under the hypotheses of (9.5.10), every section of $\mathscr{O}_{\overline{Y}}$ over an open subset V of $\overline{Y}$ which is zero in $V \cap Y$ is zero.*

Proof. By virtue of (9.5.8), we can reduce to the case where $V = \overline{Y}$. If we take into account that the sections of $\mathscr{O}_{\overline{Y}}$ over $\overline{Y}$ correspond canonically to the $\overline{Y}$-sections of $\overline{Y} \otimes_{\mathbb{Z}} \mathbb{Z}[T]$ (3.3.15) and that the latter is separated over $\overline{Y}$, the corollary appears as a particular case of (9.5.6). □

When there exists a smallest closed sub-prescheme Y' of X dominating a sub-prescheme Y of X, we say that Y' is the *closure* of Y in X, when no confusion can result.

9.6 Quasi-coherent sheaves of algebras; change of the structural sheaf.

(9.6.1) Proposition. *Let X be a prescheme and $\mathscr{B}$ a quasi-coherent $\mathscr{O}_X$-algebra (0, 5.1.3). For a $\mathscr{B}$-module $\mathscr{F}$ to be quasi-coherent (on the ringed space $(X, \mathscr{B})$), it is necessary and sufficient that $\mathscr{F}$ be a quasi-coherent $\mathscr{O}_X$-module.*

Proof. Since the question is local, we may suppose X affine with ring A, and then $\mathscr{B} = \widetilde{B}$, where B is an A-algebra (1.4.3). If $\mathscr{F}$ is quasi-coherent on the ringed space $(X, \mathscr{B})$, we may also suppose that $\mathscr{F}$ is the cokernel of a $\mathscr{B}$-homomorphism $\mathscr{B}^{(I)} \to \mathscr{B}^{(J)}$; since this homomorphism is also an $\mathscr{O}_X$-homomorphism of $\mathscr{O}_X$-modules, and $\mathscr{B}^{(I)}$ and $\mathscr{B}^{(J)}$ are quasi-coherent $\mathscr{O}_X$-modules (1.3.9, (ii)), $\mathscr{F}$ is also a quasi-coherent $\mathscr{O}_X$-module (1.3.9, (i)).

Conversely, if $\mathscr{F}$ is a quasi-coherent $\mathscr{O}_X$-module, we have $\mathscr{F} = \widetilde{M}$, where M is a B-module (1.4.3); M is isomorphic to a cokernel of a B-homomorphism $B^{(I)} \to B^{(J)}$, hence $\mathscr{F}$ is a $\mathscr{B}$-module isomorphic to the cokernel of the corresponding homomorphism $\mathscr{B}^{(I)} \to \mathscr{B}^{(J)}$ (1.3.13), which completes the proof. □

In particular, if $\mathscr{F}$ and $\mathscr{G}$ are two quasi-coherent $\mathscr{B}$-modules, $\mathscr{F} \otimes_{\mathscr{B}} \mathscr{G}$ is a quasi-coherent $\mathscr{B}$-module; the same is true of $\mathscr{H}om_{\mathscr{B}}(\mathscr{F}, \mathscr{G})$ when we suppose moreover that $\mathscr{F}$ admits a finite presentation (1.3.13).

(9.6.2) Given a prescheme X, we will say that a quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ is of *finite type* if for every $x \in X$ there exists an *affine* open neighbourhood U of x such that $\Gamma(U, \mathscr{B}) = B$ is an algebra of finite type over $\Gamma(U, \mathscr{O}_X) = A$. We then have $\mathscr{B}|U = \widetilde{B}$, and for every $f \in A$, the induced $(\mathscr{O}_X|D(f))$-algebra $\mathscr{B}|D(f)$ is of finite type, since it is isomorphic to $\widetilde{B_f}$, and $B_f = B \otimes_A A_f$ is evidently an algebra of finite type over A_f. Since the $D(f)$ form a base of the topology of U, we conclude that if $\mathscr{B}$ is a quasi-coherent $\mathscr{O}_X$-algebra of finite type, then for every open subset V of X, $\mathscr{B}|V$ is a quasi-coherent $(\mathscr{O}_X|V)$-algebra of finite type.

(9.6.3) Proposition. *Let X be a locally Noetherian prescheme. Then every quasi-coherent $\mathscr{O}_X$-algebra of finite type $\mathscr{B}$ is a coherent sheaf of rings (0, 5.3.7).*

Proof. We may again restrict to the case where X is an affine scheme with Noetherian ring A, and where $\mathscr{B} = \widetilde{B}$, B being an A-algebra of finite type; B is therefore a Noetherian ring. That being so, we must prove that the kernel $\mathscr{N}$ of a $\mathscr{B}$-homomorphism $\mathscr{B}^m \to \mathscr{B}$
[I | 180] is a $\mathscr{B}$- module of finite type; now, it is isomorphic (as a $\mathscr{B}$-module) to $\widetilde{N}$, where N is the kernel of the corresponding homomorphism of B-modules $B^m \to B$ (1.3.13). Since B is Noetherian, the submodule N of B^m is a B-module of finite type, hence there exists a homomorphism $B^p \to B^m$ with image N; the sequence $B^p \to B^m \to B$ being exact, so is the corresponding sequence $\mathscr{B}^p \to \mathscr{B}^m \to \mathscr{B}$ (1.3.5), and since $\mathscr{N}$ is the image of $\mathscr{B}^p \to \mathscr{B}^m$ (1.3.9, (i)), the proposition is proved. □

(9.6.4) Corollary. *Under the hypotheses of (9.6.3), for a $\mathscr{B}$-module $\mathscr{F}$ to be coherent, it is necessary and sufficient that it be a quasi-coherent $\mathscr{O}_X$-module and a $\mathscr{B}$-module of finite type. If this is so, and if $\mathscr{G}$ is a sub-$\mathscr{B}$-module or a quotient $\mathscr{B}$-module of $\mathscr{F}$, then for $\mathscr{G}$ to be a coherent $\mathscr{B}$-module, it is necessary and sufficient that $\mathscr{G}$ be a quasi-coherent $\mathscr{O}_X$-module.*

Proof. Taking into account (9.6.1), the conditions on $\mathscr{F}$ are evidently necessary; let us show that they are sufficient. We may restrict to the case where X is affine with Noetherian ring A, $\mathscr{B} = \widetilde{B}$, where B is an A-algebra of finite type, $\mathscr{F} = \widetilde{M}$, where M is a B-module, and where there exists a surjective $\mathscr{B}$-homomorphism $\mathscr{B}^m \to \mathscr{F} \to 0$. We then have a corresponding exact sequence $B^m \to M \to 0$, hence M is a B-module of finite type; moreover, the kernel P of the homomorphism $B^m \to M$ is then a B-module of finite type, since B is Noetherian. We conclude (1.3.13) that $\mathscr{F}$ is the cokernel of a $\mathscr{B}$-homomorphism $\mathscr{B}^n \to \mathscr{B}^m$, and is therefore coherent since $\mathscr{B}$ is a coherent sheaf of rings (0, 5.3.4). The same reasoning shows that a quasi-coherent sub-$\mathscr{B}$-module (resp. quotient $\mathscr{B}$-module) of $\mathscr{F}$ is of finite type, whence the second part of the corollary. □

(9.6.5) Proposition. *Let X be a quasi-compact scheme or a prescheme whose underlying space is Noetherian. For every quasi-coherent $\mathscr{O}_X$-algebra of finite type $\mathscr{B}$, there exists a quasi-coherent sub-$\mathscr{O}_X$-module of finite type $\mathscr{E}$ of $\mathscr{B}$ such that $\mathscr{E}$ generates (0, 4.1.4) the $\mathscr{O}_X$-algebra $\mathscr{B}$.*

Proof. Indeed, by hypothesis there exists a finite covering (U_i) of X consisting of affine open subsets such that $\Gamma(U_i, \mathscr{B}) = B_i$ is an algebra of finite type over $\Gamma(U_i, \mathscr{O}_X) = A_i$; let E_i be a sub-A_i-module of finite type of B_i generating the A_i-algebra B_i; by virtue of (9.4.7), there exists a sub-$\mathscr{O}_X$-module $\mathscr{E}_i$ of $\mathscr{B}$, quasi-coherent and of finite type, such that $\mathscr{E}_i|U_i = \widetilde{E_i}$. It is clear that the sum $\mathscr{E}$ of the $\mathscr{E}_i$ answers the question. □

(9.6.6) Proposition. *Let X be a prescheme whose underlying space is locally Noetherian, or a quasi-compact scheme. Then every quasi-coherent $\mathscr{O}_X$-algebra $\mathscr{B}$ is the inductive limit of its quasi-coherent sub-$\mathscr{O}_X$-algebras of finite type.*

Proof. Indeed, it follows from (9.4.9) that $\mathscr{B}$ is the inductive limit (as an $\mathscr{O}_X$-module) of its quasi-coherent sub-$\mathscr{O}_X$-modules of finite type; the latter generate quasi-coherent sub-$\mathscr{O}_X$-algebras of finite type of $\mathscr{B}$ (1.3.14), of which $\mathscr{B}$ is *a fortiori* the inductive limit. □

§10 Formal schemes

10.1 Affine formal schemes.

(10.1.1) Let A be an *admissible* topological ring (0, 7.1.2); for every ideal of definition $\mathfrak{J}$ of A, $\mathrm{Spec}(A/\mathfrak{J})$ is identified with the closed subspace $V(\mathfrak{J})$ of $\mathrm{Spec}(A)$ (1.1.11), the set of *open* prime ideals of A; this topological space does not depend on the ideal of definition [I | 181] $\mathfrak{J}$ considered; let us denote it by $\mathfrak{X}$. Let $(\mathfrak{J}_\lambda)$ be a fundamental system of neighbourhoods of 0 in A consisting of ideals of definition, and for every λ, let $\mathscr{O}_\lambda$ be the structural sheaf of $\mathrm{Spec}(A/\mathfrak{J}_\lambda)$; this sheaf is induced on $\mathfrak{X}$ by $\widetilde{A}/\widetilde{\mathfrak{J}}_\lambda$ (which is zero outside $\mathfrak{X}$).

For $\mathfrak{J}_\mu \subset \mathfrak{J}_\lambda$, the canonical homomorphism $A/\mathfrak{J}_\mu \to A/\mathfrak{J}_\lambda$ therefore defines a homomorphism $u_{\lambda\mu} : \mathscr{O}_\mu \to \mathscr{O}_\lambda$ of sheaves of rings (1.6.1), and $(\mathscr{O}_\lambda)$ is a *projective system of sheaves of rings* for these homomorphisms. Since the topology of $\mathfrak{X}$ has a basis consisting

of quasi-compact open subsets, we can associate to every $\mathscr{O}_\lambda$ a *pseudo-discrete sheaf of topological rings* (0, 3.8.1) which has $\mathscr{O}_\lambda$ as its underlying sheaf of rings (without topology), and which we will again denote by $\mathscr{O}_\lambda$; and the $\mathscr{O}_\lambda$ again form a *projective system of sheaves of topological rings* (0, 3.8.2). We will denote by $\mathscr{O}_\mathfrak{X}$ the *sheaf of topological rings* on $\mathfrak{X}$ that is the projective limit of the system $(\mathscr{O}_\lambda)$; for every *quasi-compact* open subset U of $\mathfrak{X}$, $\Gamma(U, \mathscr{O}_\mathfrak{X})$ is therefore the topological ring that is the projective limit of the system of *discrete* rings $\Gamma(U, \mathscr{O}_\lambda)$ (0, 3.2.6).

(10.1.2) Definition. Given an admissible topological ring A, we call formal spectrum of A, and denote by $\mathrm{Spf}(A)$, the closed subspace $\mathfrak{X}$ of $\mathrm{Spec}(A)$ consisting of the open prime ideals of A. We say that a topologically ringed space is an affine formal scheme if it is isomorphic to a formal spectrum $\mathrm{Spf}(A) = \mathfrak{X}$ endowed with the sheaf of topological rings $\mathscr{O}_\mathfrak{X}$ that is the projective limit of the pseudo-discrete sheaves of rings $(\widetilde{A/\mathfrak{J}_\lambda})|\mathfrak{X}$, where $\mathfrak{J}_\lambda$ runs through the filtered set of ideals of definition of A.

When we speak of a *formal spectrum* $\mathfrak{X} = \mathrm{Spf}(A)$ as an affine formal scheme, we will always mean the topologically ringed space $(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ where $\mathscr{O}_\mathfrak{X}$ is defined as above.

Note that every *affine scheme* $X = \mathrm{Spec}(A)$ can be considered as an affine formal scheme in a unique way, by considering A as a discrete topological ring: the topological rings $\Gamma(U, \mathscr{O}_X)$ are then discrete when U is quasi-compact (but not in general when U is an arbitrary open subset of X).

(10.1.3) Proposition. *If $\mathfrak{X} = \mathrm{Spf}(A)$, where A is an admissible ring, $\Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ is topologically isomorphic to A.*

Proof. Indeed, since $\mathfrak{X}$ is closed in $\mathrm{Spec}(A)$, it is quasi-compact, and consequently $\Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ is topologically isomorphic to the projective limit of the discrete rings $\Gamma(\mathfrak{X}, \mathscr{O}_\lambda)$; but $\Gamma(\mathfrak{X}, \mathscr{O}_\lambda)$ is isomorphic to $A/\mathfrak{J}_\lambda$ (1.3.7); since A is separated and complete, it is topologically isomorphic to $\varprojlim A/\mathfrak{J}_\lambda$ (0, 7.2.1), whence the proposition. □

(10.1.4) Proposition. *Let A be an admissible ring, $\mathfrak{X} = \mathrm{Spf}(A)$, and for every $f \in A$, let $\mathfrak{D}(f) = D(f) \cap \mathfrak{X}$; the topologically ringed space $(\mathfrak{D}(f), \mathscr{O}_\mathfrak{X}|\mathfrak{D}(f))$ is isomorphic to the affine formal spectrum $\mathrm{Spf}(A_{\{f\}})$ (0, 7.6.15).*

Proof. For every ideal of definition $\mathfrak{J}$ of A, the discrete ring $S_f^{-1}A/S_f^{-1}\mathfrak{J}$ is canonically identified with $A_{\{f\}}/\mathfrak{J}_{\{f\}}$ (0, 7.6.9), hence (1.2.5 and 1.2.6) the topological space $\mathrm{Spf}(A_{\{f\}})$ is canonically identified with $\mathfrak{D}(f)$. Moreover, for every quasi-compact open subset U of $\mathfrak{X}$ contained in $\mathfrak{D}(f)$, $\Gamma(U, \mathscr{O}_\lambda)$ is identified with the module of sections of the structural sheaf of $\mathrm{Spec}(S_f^{-1}A/S_f^{-1}\mathfrak{J}_\lambda)$ over U (1.3.6); hence, if we set $\mathfrak{Y} = \mathrm{Spf}(A_{\{f\}})$, $\Gamma(U, \mathscr{O}_\mathfrak{X})$ is identified with the module of sections $\Gamma(U, \mathscr{O}_\mathfrak{Y})$, which proves the proposition. □

[I | 182] **(10.1.5)** As a sheaf of rings *without topology*, the structural sheaf $\mathscr{O}_\mathfrak{X}$ of $\mathrm{Spf}(A)$ has, for every $x \in \mathfrak{X}$, a stalk which, by virtue of (10.1.4), is identified with the inductive limit $\varinjlim_{f \notin \mathfrak{j}_x} A_{\{f\}}$. Consequently (0, 7.6.17 and 7.6.18):

(10.1.6) Proposition. *For every $x \in \mathfrak{X} = \mathrm{Spf}(A)$, the stalk $\mathscr{O}_x$ is a local ring whose residue field is isomorphic to $k(x) = A_x/\mathfrak{j}_x A_x$. If moreover A is adic and Noetherian, $\mathscr{O}_x$ is a Noetherian ring.*

Since $k(x)$ does not consist of 0 alone, we conclude from this result that the *support* of the sheaf of rings $\mathscr{O}_\mathfrak{X}$ is *equal to* $\mathfrak{X}$.

10.2 Morphisms of affine formal schemes.

(10.2.1) Let A, B be two admissible rings, and let $\varphi : B \to A$ be a *continuous* homomorphism. The continuous map ${}^a\varphi : \mathrm{Spec}(A) \to \mathrm{Spec}(B)$ (1.2.1) then maps $\mathfrak{X} = \mathrm{Spf}(A)$ into $\mathfrak{Y} = \mathrm{Spf}(B)$, since the inverse image under φ of an open prime ideal of A is an open prime ideal of B. On the other hand, for every $g \in B$, φ defines a continuous homomorphism

$$\Gamma(\mathfrak{D}(g), \mathscr{O}_{\mathfrak{Y}}) \longrightarrow \Gamma(\mathfrak{D}(\varphi(g)), \mathscr{O}_{\mathfrak{X}})$$

by virtue of (10.1.4), (10.1.3) and (0, 7.6.7); since these homomorphisms satisfy the compatibility conditions for the restrictions corresponding to the passage from g to a multiple of g, and since $\mathfrak{D}(\varphi(g)) = {}^a\varphi^{-1}(\mathfrak{D}(g))$, they define a *continuous* homomorphism of sheaves of topological rings $\mathscr{O}_{\mathfrak{Y}} \to {}^a\varphi_*(\mathscr{O}_{\mathfrak{X}})$ (0, 3.2.5), which we will again denote by $\widetilde{\varphi}$; we have thus obtained a morphism $\Phi = ({}^a\varphi, \widetilde{\varphi})$ of topologically ringed spaces $\mathfrak{X} \to \mathfrak{Y}$. Note that, as a homomorphism of sheaves of rings without topology, $\widetilde{\varphi}$ defines a homomorphism $\widetilde{\varphi}^\sharp_x : \mathscr{O}_{{}^a\varphi(x)} \to \mathscr{O}_x$ on the stalks, for every $x \in \mathfrak{X}$.

(10.2.2) Proposition. *Let A, B be two admissible topological rings, and let $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$. For a morphism $u = (\psi, \theta) : \mathfrak{X} \to \mathfrak{Y}$ of topologically ringed spaces to be of the form $({}^a\varphi, \widetilde{\varphi})$, where φ is a continuous ring homomorphism $B \to A$, it is necessary and sufficient that for every $x \in \mathfrak{X}$, $\theta^\sharp_x$ be a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.*

Proof. The condition is necessary: indeed, let $\mathfrak{p} = \mathfrak{j}_x \in \mathrm{Spf}(A)$, and let $\mathfrak{q} = \varphi^{-1}(\mathfrak{j}_x)$; if $g \notin \mathfrak{q}$, we therefore have $\varphi(g) \notin \mathfrak{p}$, and it is immediate that the homomorphism $B_{\{g\}} \to A_{\{\varphi(g)\}}$ deduced from φ (0, 7.6.7) transforms $\mathfrak{q}_{\{g\}}$ into a subset of $\mathfrak{p}_{\{\varphi(g)\}}$; passing to the inductive limit, we therefore see (taking into account (10.1.5) and (0, 7.6.17)) that $\widetilde{\varphi}^\sharp_x$ is a local homomorphism.

Conversely, let (ψ, θ) be a morphism satisfying the condition of the statement; by virtue of (10.1.3), θ defines a continuous ring homomorphism

$$\varphi = \Gamma(\theta) : B = \Gamma(\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}) \longrightarrow \Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}) = A.$$

By virtue of the hypothesis on θ, for the section $\varphi(g)$ of $\mathscr{O}_{\mathfrak{X}}$ over $\mathfrak{X}$ to have an invertible germ at the point x, it is necessary and sufficient that g have an invertible germ at the point $\psi(x)$. But by virtue of (0, 7.6.17), the sections of $\mathscr{O}_{\mathfrak{X}}$ (resp. $\mathscr{O}_{\mathfrak{Y}}$) over $\mathfrak{X}$ (resp. $\mathfrak{Y}$) whose germ is not invertible at the point x (resp. $\psi(x)$) are exactly the elements of $\mathfrak{j}_x$ (resp. $\mathfrak{j}_{\psi(x)}$); the preceding remark therefore shows that ${}^a\varphi = \psi$. Finally, for every [I | 183] $g \in B$, the diagram

$$\begin{array}{ccc} B = \Gamma(\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}) & \xrightarrow{\quad\varphi\quad} & \Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}) = A \\ \downarrow & & \downarrow \\ B_{\{g\}} = \Gamma(\mathfrak{D}(g), \mathscr{O}_{\mathfrak{Y}}) & \xrightarrow[\Gamma(\theta_{\mathfrak{D}(g)})]{} & \Gamma(\mathfrak{D}(\varphi(g)), \mathscr{O}_{\mathfrak{X}}) = A_{\{\varphi(g)\}} \end{array}$$

is commutative; by the universal property of complete rings of fractions (0, 7.6.6), $\theta_{\mathfrak{D}(g)}$ is equal to $\widetilde{\varphi}_{\mathfrak{D}(g)}$ for every $g \in B$, hence (0, 3.2.5) we have $\theta = \widetilde{\varphi}$. □

We will say that a morphism (ψ, θ) of topologically ringed spaces satisfying the condition of (10.2.2) is a *morphism of affine formal schemes*. We can say that the functors $\mathrm{Spf}(A)$ in A and $\Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$ in $\mathfrak{X}$ define an *equivalence* between the category of admissible rings and the dual category of the category of affine formal schemes (T, I, 1.2).

(10.2.3) As a particular case of (10.2.2), note that, for $f \in A$, the canonical injection of the affine formal scheme induced by $\mathfrak{X}$ on $\mathfrak{D}(f)$ corresponds to the canonical continuous homomorphism $A \to A_{\{f\}}$. Under the hypotheses of (10.2.2), let h be an element of B and g an element of A that is a multiple of $\varphi(h)$; we then have $\psi(\mathfrak{D}(g)) \subset \mathfrak{D}(h)$; the restriction of u to $\mathfrak{D}(g)$, considered as a morphism from $\mathfrak{D}(g)$ to $\mathfrak{D}(h)$, is the unique morphism v making the diagram

$$\begin{array}{ccc} \mathfrak{D}(g) & \xrightarrow{v} & \mathfrak{D}(h) \\ \downarrow & & \downarrow \\ \mathfrak{X} & \xrightarrow[u]{} & \mathfrak{Y} \end{array}$$

commutative. This morphism corresponds to the unique continuous homomorphism $\varphi' : B_{\{h\}} \to A_{\{g\}}$ (0, 7.6.7) making the diagram

$$\begin{array}{ccc} A & \xleftarrow{\varphi} & B \\ \downarrow & & \downarrow \\ A_{\{g\}} & \xleftarrow{\varphi'} & B_{\{h\}} \end{array}$$

commutative.

10.3 Ideals of definition of an affine formal scheme.

(10.3.1) Let A be an admissible ring, $\mathfrak{J}$ an open ideal of A, and $\mathfrak{X}$ the affine formal scheme $\mathrm{Spf}(A)$. Let $(\mathfrak{J}_\lambda)$ be the set of ideals of definition of A contained in $\mathfrak{J}$; then $\widetilde{\mathfrak{J}}/\widetilde{\mathfrak{J}}_\lambda$ is a sheaf of ideals of $\widetilde{A}/\widetilde{\mathfrak{J}}_\lambda$. Let us denote by $\mathfrak{J}^\Delta$ the projective limit of the sheaves induced on $\mathfrak{X}$ by $\widetilde{\mathfrak{J}}/\widetilde{\mathfrak{J}}_\lambda$, which is identified with a *sheaf of ideals* of $\mathscr{O}_\mathfrak{X}$ (0, 3.2.6). For every $f \in A$, $\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta)$ is the projective limit of $S_f^{-1}\mathfrak{J}/S_f^{-1}\mathfrak{J}_\lambda$, in other words it is identified with the open ideal $\mathfrak{J}_{\{f\}}$ of the ring $A_{\{f\}}$ (0, 7.6.9), and in particular $\Gamma(\mathfrak{X}, \mathfrak{J}^\Delta) = \mathfrak{J}$; we conclude (the $\mathfrak{D}(f)$ forming a base of the topology of $\mathfrak{X}$) that we have

$$\mathfrak{J}^\Delta | \mathfrak{D}(f) = (\mathfrak{J}_{\{f\}})^\Delta. \tag{10.3.1.1}$$

[I | 184] **(10.3.2)** With the notation of (10.3.1), for every $f \in A$, the canonical map of $A_{\{f\}} = \Gamma(\mathfrak{D}(f), \mathscr{O}_\mathfrak{X})$ into $\Gamma(\mathfrak{D}(f), (\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}) = S_f^{-1}A/S_f^{-1}\mathfrak{J}$ is *surjective* and has kernel $\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta) = \mathfrak{J}_{\{f\}}$ (0, 7.6.9); these maps therefore define a continuous *surjective* homomorphism, called *canonical*, of the sheaf of topological rings $\mathscr{O}_\mathfrak{X}$ onto the sheaf of discrete rings $(\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}$, whose kernel is $\mathfrak{J}^\Delta$; this homomorphism is moreover none other than $\widetilde{\varphi}$ (10.2.1), where φ is the continuous homomorphism $A \to A/\mathfrak{J}$; the morphism $({}^a\varphi, \widetilde{\varphi}) : \mathrm{Spec}(A/\mathfrak{J}) \to \mathfrak{X}$ of affine formal schemes (where ${}^a\varphi$ is a homeomorphism onto the closed subspace $V(\mathfrak{J})$ of $\mathfrak{X}$)[34] is also called *canonical*. We therefore have, by what precedes, a *canonical isomorphism*

$$\mathscr{O}_\mathfrak{X}/\mathfrak{J}^\Delta \xrightarrow{\sim} (\widetilde{A}/\widetilde{\mathfrak{J}})|\mathfrak{X}. \tag{10.3.2.1}$$

[34] Editorial correction: for an arbitrary open ideal, the image is not necessarily all of $\mathfrak{X}$. For example, if $A = k[t]$ is discrete and $\mathfrak{J} = (t)$, the image is the proper closed subset $V(t)$. The printed assertion holds when $\mathfrak{J}$ is an ideal of definition.

It is clear (by virtue of $\Gamma(\mathfrak{X}, \mathfrak{J}^\Delta) = \mathfrak{J}$) that the map $\mathfrak{J} \to \mathfrak{J}^\Delta$ is *strictly increasing*; by what precedes, for $\mathfrak{J} \subset \mathfrak{J}'$, the sheaf $\mathfrak{J}'^\Delta/\mathfrak{J}^\Delta$ is canonically isomorphic to $\widetilde{\mathfrak{J}'}/\widetilde{\mathfrak{J}} = \widetilde{\mathfrak{J}'/\mathfrak{J}}$.

(10.3.3) The hypotheses and notation still being those of (10.3.1), we will say that a sheaf of ideals $\mathscr{J}$ of $\mathscr{O}_\mathfrak{X}$ is a *sheaf of ideals of definition of* $\mathfrak{X}$ (or an *ideal of definition of* $\mathfrak{X}$) if, for every $x \in \mathfrak{X}$, there exists an open neighbourhood of x of the form $\mathfrak{D}(f)$, where $f \in A$, such that $\mathscr{J}|\mathfrak{D}(f)$ is of the form $\mathfrak{H}^\Delta$, where $\mathfrak{H}$ is an ideal of definition of $A_{\{f\}}$.

(10.3.4) Proposition. *For every $f \in A$, every ideal of definition of $\mathfrak{X}$ induces an ideal of definition of $\mathfrak{D}(f)$.*

Proof. This follows from (10.3.1.1). □

(10.3.5) Proposition. *If A is an admissible ring, every ideal of definition of $\mathfrak{X} = \mathrm{Spf}(A)$ is of the form $\mathfrak{J}^\Delta$, where $\mathfrak{J}$ is an ideal of definition of A, uniquely determined.*

Proof. Indeed, let $\mathscr{J}$ be an ideal of definition of $\mathfrak{X}$; by hypothesis, and since $\mathfrak{X}$ is quasi-compact, there are finitely many elements $f_i \in A$ such that the $\mathfrak{D}(f_i)$ cover $\mathfrak{X}$ and $\mathscr{J}|\mathfrak{D}(f_i) = \mathfrak{H}_i^\Delta$, where $\mathfrak{H}_i$ is an ideal of definition of $A_{\{f_i\}}$. For every i, there therefore exists an open ideal $\mathfrak{K}_i$ of A such that $(\mathfrak{K}_i)_{\{f_i\}} = \mathfrak{H}_i$ (0, 7.6.9); let $\mathfrak{K}$ be an ideal of definition of A contained in all the $\mathfrak{K}_i$. The canonical image of $\mathscr{J}/\mathfrak{K}^\Delta$ in the structural sheaf $\widetilde{A/\mathfrak{K}}$ of $\mathrm{Spec}(A/\mathfrak{K})$ (10.3.2) is therefore such that its restriction to $\mathfrak{D}(f_i)$ is equal to that of $\widetilde{\mathfrak{K}_i/\mathfrak{K}}$; we conclude that this canonical image is a quasi-coherent sheaf on $\mathrm{Spec}(A/\mathfrak{K})$, hence of the form $\widetilde{\mathfrak{J}/\mathfrak{K}}$, where $\mathfrak{J}$ is an ideal of A containing $\mathfrak{K}$ (1.4.1), whence $\mathscr{J} = \mathfrak{J}^\Delta$ (10.3.2); moreover, since for every i there exists an integer n_i such that $\mathfrak{H}_i^{n_i} \subset \mathfrak{K}_{\{f_i\}}$, we will have, denoting by n the largest of the n_i, $(\mathscr{J}/\mathfrak{K}^\Delta)^n = 0$, and consequently (10.3.2) $(\widetilde{\mathfrak{J}/\mathfrak{K}})^n = 0$, whence finally $(\mathfrak{J}/\mathfrak{K})^n = 0$ (1.3.13), which proves that $\mathfrak{J}$ is an ideal of definition of A (0, 7.1.4). □

(10.3.6) Proposition. *Let A be an adic ring and $\mathfrak{J}$ an ideal of definition of A such that $\mathfrak{J}/\mathfrak{J}^2$ is an $A/\mathfrak{J}$-module of finite type. Then for every integer $n > 0$ we have $(\mathfrak{J}^\Delta)^n = (\mathfrak{J}^n)^\Delta$.*

Proof. Indeed, for every $f \in A$, we have (since $\mathfrak{J}^n$ is an open ideal)

$$\big(\Gamma(\mathfrak{D}(f), \mathfrak{J}^\Delta)\big)^n = (\mathfrak{J}_{\{f\}})^n = (\mathfrak{J}^n)_{\{f\}} = \Gamma\big(\mathfrak{D}(f^n), (\mathfrak{J}^n)^\Delta\big)$$

by virtue of (10.3.1.1) and (0, 7.6.12). Since $(\mathfrak{J}^\Delta)^n$ is associated to the presheaf $U \mapsto (\Gamma(U, \mathfrak{J}^\Delta))^n$ (0, 4.1.6), the conclusion follows, since the $\mathfrak{D}(f)$ form a base of the topology of $\mathfrak{X}$. □ [I | 185]

(10.3.7) We say that a family $(\mathscr{J}_\lambda)$ of ideals of definition of $\mathfrak{X}$ is a *fundamental system of ideals of definition* if every ideal of definition of $\mathfrak{X}$ contains one of the $\mathscr{J}_\lambda$; since $\mathscr{J}_\lambda = \mathfrak{J}_\lambda^\Delta$, it amounts to the same to say that the $\mathfrak{J}_\lambda$ form a *fundamental system of neighbourhoods of 0* in A. Let (f_α) be a family of elements of A such that the $\mathfrak{D}(f_\alpha)$ cover $\mathfrak{X}$. If $(\mathscr{J}_\lambda)$ is a decreasing filtered family of ideals of $\mathscr{O}_\mathfrak{X}$ such that for every α the family $(\mathscr{J}_\lambda|\mathfrak{D}(f_\alpha))$ is a fundamental system of ideals of definition of $\mathfrak{D}(f_\alpha)$, then $(\mathscr{J}_\lambda)$ is a fundamental system of ideals of definition of $\mathfrak{X}$. Indeed, for every ideal of definition $\mathscr{J}$ of $\mathfrak{X}$, there is a finite covering of $\mathfrak{X}$ by sets $\mathfrak{D}(f_i)$ such that, for every i, $\mathscr{J}_{\lambda_i}|\mathfrak{D}(f_i)$ is an ideal of definition of $\mathfrak{D}(f_i)$ contained in $\mathscr{J}|\mathfrak{D}(f_i)$. If μ is an index such

that $\mathscr{J}_\mu \subset \mathscr{J}_{\lambda_i}$ for every i, it follows from (10.3.3) that $\mathscr{J}_\mu$ is an ideal of definition of $\mathfrak{X}$, evidently contained in $\mathscr{J}$, whence our assertion.

10.4 Formal preschemes and morphisms of formal preschemes.

(10.4.1) Given a topologically ringed space $\mathfrak{X}$, we say that an open subset $U \subset \mathfrak{X}$ is an *affine formal open subset* (resp. an *adic affine formal open subset*, resp. a *Noetherian affine formal open subset*) if the topologically ringed space induced by $\mathfrak{X}$ on U is an affine formal scheme (resp. such a scheme whose ring is adic, resp. adic and Noetherian).

(10.4.2) Definition. We call formal prescheme a topologically ringed space $\mathfrak{X}$ every point of which has an affine formal open neighbourhood. We say that the formal prescheme $\mathfrak{X}$ is adic (resp. locally Noetherian) if every point of $\mathfrak{X}$ has an adic (resp. Noetherian) affine formal open neighbourhood. We say that $\mathfrak{X}$ is Noetherian if it is locally Noetherian and its underlying space is quasi-compact (hence Noetherian).

(10.4.3) Proposition. *If $\mathfrak{X}$ is a formal prescheme (resp. a locally Noetherian one), the affine formal open sets (resp. Noetherian affine formal open sets) form a base of the topology of $\mathfrak{X}$.*

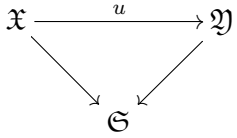
Proof. This follows from (10.4.2) and (10.1.4), taking into account that if A is a Noetherian adic ring, so is $A_{\{f\}}$ for every $f \in A$ (0, 7.6.11). □

(10.4.4) Corollary. *If $\mathfrak{X}$ is a formal prescheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian one), the topologically ringed space induced on any open subset of $\mathfrak{X}$ is again a formal prescheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian one).*

(10.4.5) Definition. Given two formal preschemes $\mathfrak{X}$, $\mathfrak{Y}$, we call morphism (of formal preschemes) from $\mathfrak{X}$ to $\mathfrak{Y}$ every morphism (ψ, θ) of topologically ringed spaces such that, for every $x \in \mathfrak{X}$, $\theta_x^\sharp$ is a local homomorphism $\mathscr{O}_{\psi(x)} \to \mathscr{O}_x$.

It is immediate that the composite of two morphisms of formal preschemes is again such a morphism; the formal preschemes therefore form a *category*, and we will denote by $\mathrm{Hom}(\mathfrak{X}, \mathfrak{Y})$ the set of morphisms from a formal prescheme $\mathfrak{X}$ to a formal prescheme $\mathfrak{Y}$.

[I | 186] If U is an open subset of $\mathfrak{X}$, the canonical injection into $\mathfrak{X}$ of the formal prescheme induced by $\mathfrak{X}$ on U is a morphism of formal preschemes (and even a *monomorphism* of topologically ringed spaces (0, 4.1.1)).



(10.4.6) Proposition. *Let $\mathfrak{X}$ be a formal prescheme and $\mathfrak{S} = \mathrm{Spf}(A)$ an affine formal scheme. There is a canonical bijective correspondence between the morphisms of the formal prescheme $\mathfrak{X}$ into the formal prescheme $\mathfrak{S}$ and the continuous homomorphisms of the ring A into the topological ring $\Gamma(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$.*

The proof is the same as that of (2.2.4), replacing "homomorphism" by "continuous homomorphism" and "affine open subset" by "affine formal open subset", and using (10.2.2) instead of (1.7.3); we leave the details to the reader.

(10.4.7) Given a formal prescheme $\mathfrak{S}$, we say that the data of a formal prescheme $\mathfrak{X}$ and of a morphism $\varphi : \mathfrak{X} \to \mathfrak{S}$ define a formal prescheme $\mathfrak{X}$ *over* $\mathfrak{S}$, or a *formal $\mathfrak{S}$-prescheme*, φ being called the *structural morphism* of the $\mathfrak{S}$-prescheme $\mathfrak{X}$. If $\mathfrak{S} = \mathrm{Spf}(A)$, where A is

an admissible ring, we also say that the formal $\mathfrak{S}$-prescheme $\mathfrak{X}$ is a *formal A-prescheme* or a formal prescheme *over* A. An arbitrary formal prescheme can always be considered as a formal prescheme over $\mathbf{Z}$ (endowed with the discrete topology).

If $\mathfrak{X}$, $\mathfrak{Y}$ are two formal $\mathfrak{S}$-preschemes, we say that a morphism $u : \mathfrak{X} \to \mathfrak{Y}$ is an $\mathfrak{S}$-*morphism* if the diagram

(where the oblique arrows are the structural morphisms) is commutative. With this definition, the formal $\mathfrak{S}$-preschemes (for fixed $\mathfrak{S}$) form a *category*. We denote by $\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y})$ the set of $\mathfrak{S}$-morphisms from the formal $\mathfrak{S}$-prescheme $\mathfrak{X}$ to the formal $\mathfrak{S}$-prescheme $\mathfrak{Y}$. When $\mathfrak{S} = \mathrm{Spf}(A)$, we also say A-*morphism* instead of $\mathfrak{S}$-*morphism*.

(10.4.8) Since every affine scheme can be considered as an affine formal scheme (10.1.2), every (ordinary) prescheme can be considered as a formal prescheme. It follows moreover from (10.4.5) that for *ordinary* preschemes, the morphisms (resp. S-morphisms) of *formal* preschemes coincide with the morphisms (resp. S-morphisms) defined in § 2.

10.5 Ideals of definition of formal preschemes.

(10.5.1) Let $\mathfrak{X}$ be a formal prescheme; we say that an $\mathscr{O}_{\mathfrak{X}}$-ideal $\mathscr{J}$ is a *sheaf of ideals of definition* (or an *ideal of definition*) of $\mathfrak{X}$ if every $x \in \mathfrak{X}$ has an affine formal open neighbourhood U such that $\mathscr{J}|U$ is an ideal of definition of the affine formal scheme induced by $\mathfrak{X}$ on U (10.3.3); by virtue of (10.3.1.1) and (10.4.3), for every open subset $V \subset \mathfrak{X}$, $\mathscr{J}|V$ is then an ideal of definition of the formal prescheme induced by $\mathfrak{X}$ on V.

We say that a family $(\mathscr{J}_\lambda)$ of ideals of definition of $\mathfrak{X}$ is a *fundamental system of ideals of definition* if there exists a covering (U_α) of $\mathfrak{X}$ by affine formal open subsets such that, for every α, the family of the $\mathscr{J}_\lambda|U_\alpha$ is a fundamental system of ideals of definition (10.3.7) of the affine formal scheme induced by $\mathfrak{X}$ on U_α. It follows from the final remark of (10.3.7) that when $\mathfrak{X}$ is an affine formal scheme, this definition coincides with the definition given in (10.3.7). For every open subset V of $\mathfrak{X}$, the restrictions $\mathscr{J}_\lambda|V$ then form a fundamental system of ideals of definition of the formal prescheme induced on V, by virtue of (10.3.1.1). If $\mathfrak{X}$ is a *locally Noetherian* formal prescheme and $\mathscr{J}$ an ideal of definition of $\mathfrak{X}$, it follows from (10.3.6) that the powers $\mathscr{J}^n$ form a fundamental system of ideals of definition of $\mathfrak{X}$. [I | 187]

(10.5.2) Let $\mathfrak{X}$ be a formal prescheme and $\mathscr{J}$ an ideal of definition of $\mathfrak{X}$. Then the ringed space $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$ is an (ordinary) *prescheme*, which is affine (resp. locally Noetherian, resp. Noetherian) when $\mathfrak{X}$ is an affine formal scheme (resp. a locally Noetherian formal prescheme, resp. a Noetherian one); indeed, we are immediately reduced to the affine case, and then the proposition has already been proved in (10.3.2). Moreover, if $\theta : \mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ is the canonical homomorphism, $u = (1_{\mathfrak{X}}, \theta)$ is a *morphism* (called *canonical*) of formal preschemes $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$, since here again this was seen in the affine case (10.3.2), to which we immediately reduce.

(10.5.3) Proposition. *Let $\mathfrak{X}$ be a formal prescheme and $(\mathscr{J}_\lambda)$ a fundamental system of ideals of definition of $\mathfrak{X}$. Then the sheaf of topological rings $\mathscr{O}_{\mathfrak{X}}$ is the projective limit of the pseudo-discrete sheaves of rings (0, 3.8.1) $\mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda$.*

Proof. Since the topology of $\mathfrak{X}$ has a basis of quasi-compact affine formal open subsets (10.4.3), we are reduced to the affine case, where the proposition is a consequence of (10.3.5), (10.3.2) and of the definition (10.1.1). □

It is not certain that every formal prescheme admits ideals of definition. However:

(10.5.4) Proposition. *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme. There exists a largest ideal of definition $\mathscr{T}$ of $\mathfrak{X}$; it is the only ideal of definition $\mathscr{J}$ such that the prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$ is reduced. If $\mathscr{J}$ is an ideal of definition of $\mathfrak{X}$, $\mathscr{T}$ is the inverse image under $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ of the nilradical of $\mathscr{O}_{\mathfrak{X}}/\mathscr{J}$.*

Proof. Suppose first that $\mathfrak{X} = \mathrm{Spf}(A)$, where A is a Noetherian adic ring. The existence and the properties of $\mathscr{T}$ follow immediately from (10.3.4) and (5.1.1), taking into account the existence and the properties of the largest ideal of definition of A (0, 7.1.6 and 7.1.7).

To prove the existence and the properties of $\mathscr{T}$ in the general case, it suffices to show that if $U \supset V$ are two Noetherian affine formal open subsets of $\mathfrak{X}$, the largest ideal of definition $\mathscr{T}_U$ of U induces the largest ideal of definition $\mathscr{T}_V$ of V; but since $(V, (\mathscr{O}_{\mathfrak{X}}|V)/(\mathscr{T}_U|V))$ is reduced, this follows from what precedes. □

We denote by $\mathfrak{X}_{\mathrm{red}}$ the reduced (ordinary) prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{T})$.

(10.5.5) Corollary. *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme and $\mathscr{T}$ the largest ideal of definition of $\mathfrak{X}$; for every open subset V of $\mathfrak{X}$, $\mathscr{T}|V$ is the largest ideal of definition of the formal prescheme induced by $\mathfrak{X}$ on V.*

[I | 188] **(10.5.6) Proposition.** *Let $\mathfrak{X}$, $\mathfrak{Y}$ be two formal preschemes, $\mathscr{J}$ (resp. $\mathscr{K}$) an ideal of definition of $\mathfrak{X}$ (resp. $\mathfrak{Y}$), and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism of formal preschemes.*

(i) *If $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$, there exists a unique morphism $f' : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$ of ordinary preschemes making the diagram*

$$\begin{array}{ccc} (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}) & \xrightarrow{f} & (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}) \\ \uparrow & & \uparrow \\ (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) & \xrightarrow[f']{} & (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}) \end{array} \tag{10.5.6.1}$$

commutative, where the vertical arrows are the canonical morphisms.

(ii) *Suppose that $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$ are affine formal schemes, $\mathscr{J} = \mathfrak{J}^{\Delta}$, $\mathscr{K} = \mathfrak{K}^{\Delta}$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of definition of A (resp. B), and $f = ({}^a\varphi, \widetilde{\varphi})$, where $\varphi : B \to A$ is a continuous homomorphism; for $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$, it is necessary and sufficient that $\varphi(\mathfrak{K}) \subset \mathfrak{J}$, and f' is then the morphism $({}^a\varphi', \widetilde{\varphi'})$, where $\varphi' : B/\mathfrak{K} \to A/\mathfrak{J}$ is the homomorphism deduced from φ by passing to the quotients.*

Proof.

(i) If $f = (\psi, \theta)$, the hypothesis implies that the image under $\theta^\sharp : \psi^*(\mathscr{O}_{\mathfrak{Y}}) \to \mathscr{O}_{\mathfrak{X}}$ of the sheaf of ideals $\psi^*(\mathscr{K})$ of $\psi^*(\mathscr{O}_{\mathfrak{Y}})$ is contained in $\mathscr{J}$ (0, 4.3.5). By passing to the quotients, we therefore deduce from $\theta^\sharp$ a homomorphism of sheaves of rings

$$\omega : \psi^*(\mathscr{O}_{\mathfrak{Y}}/\mathscr{K}) = \psi^*(\mathscr{O}_{\mathfrak{Y}})/\psi^*(\mathscr{K}) \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J} \ ;$$

moreover, since for every $x \in \mathfrak{X}$, $\theta_x^\sharp$ is a *local* homomorphism, the same is true of ω_x. The morphism of ringed spaces (ψ, ω^b) is therefore (2.2.1) the unique morphism f' of ringed spaces answering the question.

(ii) The canonical functorial correspondence between morphisms of affine formal preschemes and continuous ring homomorphisms (10.2.2) shows that in the case under consideration, the relation $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ implies that we have $f' = ({}^a\varphi', \widetilde{\varphi'})$, where $\varphi' : B/\mathfrak{K} \to A/\mathfrak{J}$ is the unique homomorphism making the diagram

$$\begin{array}{ccc} B & \xrightarrow{\varphi} & A \\ \downarrow & & \downarrow \\ B/\mathfrak{K} & \xrightarrow[\varphi']{} & A/\mathfrak{J} \end{array} \tag{10.5.6.2}$$

commutative. The existence of φ' therefore implies that $\varphi(\mathfrak{K}) \subset \mathfrak{J}$. Conversely, if this condition is satisfied, denoting by φ' the unique homomorphism making the diagram (10.5.6.2) commutative and setting $f' = ({}^a\varphi', \widetilde{\varphi'})$, it is clear that the diagram (10.5.6.1) is commutative; the consideration of the homomorphisms ${}^a\varphi^*(\mathscr{O}_{\mathfrak{Y}}) \to \mathscr{O}_{\mathfrak{X}}$ and ${}^a\varphi'^*(\mathscr{O}_{\mathfrak{Y}}/\mathscr{K}) \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}$ corresponding to f and f' respectively then shows that this implies the relation $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$.

□

It is clear that the correspondence $f \mapsto f'$ defined above is *functorial*.

10.6 Formal preschemes as inductive limits of preschemes.

(10.6.1) Let $\mathfrak{X}$ be a formal prescheme, $(\mathscr{J}_\lambda)$ a fundamental system of ideals of definition of $\mathfrak{X}$; for every λ, let f_λ be the canonical morphism $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda) \to \mathfrak{X}$ (10.5.2); for $\mathscr{J}_\mu \subset \mathscr{J}_\lambda$, the canonical homomorphism $\mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\mu \to \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda$ defines a canonical morphism $f_{\mu\lambda} : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda) \to (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\mu)$ of (ordinary) preschemes such that $f_\lambda = f_\mu \circ f_{\mu\lambda}$. [I | 189] The preschemes $X_\lambda = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda)$ and the morphisms $f_{\mu\lambda}$ therefore form (by virtue of 10.4.8) an *inductive system* in the category of formal preschemes.

(10.6.2) Proposition. *With the notation of (10.6.1), the formal prescheme $\mathfrak{X}$ and the morphisms f_λ form an inductive limit (T, I, 1.8) of the system $(X_\lambda, f_{\mu\lambda})$ in the category of formal preschemes.*

Proof. Let $\mathfrak{Y}$ be a formal prescheme, and for each index λ, let

$$g_\lambda = (\psi_\lambda, \theta_\lambda) : X_\lambda \to \mathfrak{Y}$$

be a morphism such that $g_\lambda = g_\mu \circ f_{\mu\lambda}$ for $\mathscr{J}_\mu \subset \mathscr{J}_\lambda$. This last condition and the definition of the X_λ first of all imply that all the ψ_λ are identical to one and the same continuous map $\psi : \mathfrak{X} \to \mathfrak{Y}$ of the underlying spaces; moreover, the homomorphisms $\theta_\lambda^\sharp : \psi^*(\mathscr{O}_{\mathfrak{Y}}) \to \mathscr{O}_{X_\lambda} = \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda$ form a *projective system* of homomorphisms of sheaves of rings. By passing to the projective limit, we therefore deduce from them a homomorphism

$$\omega : \psi^*(\mathscr{O}_{\mathfrak{Y}}) \to \varprojlim \mathscr{O}_{\mathfrak{X}}/\mathscr{J}_\lambda = \mathscr{O}_{\mathfrak{X}},$$

and it is clear that the morphism $g = (\psi, \omega^b)$ of *ringed spaces* is the *only* one making the diagrams

$$\begin{array}{ccc} X_\lambda & \xrightarrow{g_\lambda} & \mathfrak{Y} \\ & {\scriptstyle f_\lambda}\searrow \quad \nearrow{\scriptstyle g} & \\ & \mathfrak{X} & \end{array} \tag{10.6.2.1}$$

commutative. It therefore remains to prove that g is a morphism of *formal preschemes*; the question being local on $\mathfrak{X}$ and $\mathfrak{Y}$, we may therefore suppose $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$, A and B being admissible rings, with $\mathscr{J}_\lambda = \mathfrak{J}_\lambda^\Delta$, where $(\mathfrak{J}_\lambda)$ is a fundamental system of ideals of definition of A (10.3.5); since $A = \varprojlim A/\mathfrak{J}_\lambda$, the existence of a morphism g of affine formal schemes making the diagrams (10.6.2.1) commutative then follows from the bijective correspondence (10.2.2) between morphisms of affine formal schemes and continuous ring homomorphisms, and from the definition of the projective limit. But the uniqueness of g as a morphism of ringed spaces shows that it coincides with the morphism denoted in the same way at the beginning of the proof. □

Under certain additional conditions, the next proposition shows that a given inductive system of (ordinary) preschemes has an inductive limit in the category of formal preschemes:

(10.6.3) Proposition. *Let $\mathfrak{X}$ be a topological space, $(\mathscr{O}_i, u_{ji})$ a projective system of sheaves of rings on $\mathfrak{X}$, having $\mathbf{N}$ as index set. Let $\mathscr{J}_i$ be the kernel of $u_{0i} : \mathscr{O}_i \to \mathscr{O}_0$. Suppose that:*

a) The ringed space $(\mathfrak{X}, \mathscr{O}_i)$ is a prescheme X_i.

b) For every $x \in X$ and every i, there exists an open neighbourhood U_i of x in $\mathfrak{X}$ such that the restriction $\mathscr{J}_i|U_i$ is nilpotent.

c) The homomorphisms u_{ji} are surjective.

[I/190] *Let $\mathscr{O}_\mathfrak{X}$ be the sheaf of topological rings that is the projective limit of the pseudo-discrete sheaves of rings $\mathscr{O}_i$, and let $u_i : \mathscr{O}_\mathfrak{X} \to \mathscr{O}_i$ be the canonical homomorphism. Then the topologically ringed space $(\mathfrak{X}, \mathscr{O}_\mathfrak{X})$ is a formal prescheme; the homomorphisms u_i are surjective; their kernels $\mathscr{J}^{(i)}$ form a fundamental system of ideals of definition of $\mathfrak{X}$, and $\mathscr{J}^{(0)}$ is the projective limit of the sheaves of ideals $\mathscr{J}_i$.*

Proof. Let us first note that on each stalk, u_{ji} is a surjective homomorphism and *a fortiori* a local homomorphism; hence $v_{ij} = (1_\mathfrak{X}, u_{ji})$ is a morphism of preschemes $X_j \to X_i$ $(i \geq j)$ (2.2.1). Suppose first that each X_i is an affine scheme with ring A_i. There exists a homomorphism *of rings* $\varphi_{ji} : A_i \to A_j$ such that $u_{ji} = \widetilde{\varphi_{ji}}$ (1.7.3); consequently (1.6.3), the sheaf $\mathscr{O}_j$ is a quasi-coherent $\mathscr{O}_i$-module on X_i (for the external law defined by u_{ji}), associated to A_j regarded as an A_i-module by means of φ_{ji}. For every $f \in A_i$, let $f' = \varphi_{ji}(f)$; by hypothesis, the open subsets $D(f)$ and $D(f')$ are identical in $\mathfrak{X}$, and the homomorphism from $\Gamma(D(f), \mathscr{O}_i) = (A_i)_f$ to $\Gamma(D(f), \mathscr{O}_j) = (A_j)_{f'}$ corresponding to u_{ji} is none other than $(\varphi_{ji})_f$ (1.6.1). But when A_j is regarded as an A_i-module, $(A_j)_{f'}$ is the $(A_i)_f$-module $(A_j)_f$, so we also have $u_{ji} = \widetilde{\varphi_{ji}}$ when φ_{ji} is this time regarded as a homomorphism of A_i-modules. Then, since u_{ji} is surjective, we conclude that φ_{ji} is surjective as well (1.3.9), and if $\mathfrak{J}_{ji}$ is the kernel of φ_{ji}, the kernel of u_{ji} is a quasi-coherent $\mathscr{O}_i$-module equal to $\widetilde{\mathfrak{J}_{ji}}$. In particular, we have $\mathscr{J}_i = \widetilde{\mathfrak{J}_i}$, where $\mathfrak{J}_i$ is the kernel of $\varphi_{0i} : A_i \to A_0$. Hypothesis b) implies that $\mathscr{J}_i$ is *nilpotent*: indeed, since $\mathfrak{X}$ is quasi-compact, we can cover $\mathfrak{X}$ by finitely many open subsets U_k such that $(\mathscr{J}_i|U_k)^{n_k} = 0$, and,

taking for n the largest of the n_k, we have $\mathscr{J}_i^n = 0$. We conclude that $\mathfrak{J}_i$ is nilpotent (1.3.13). Then the ring $A = \varprojlim A_i$ is admissible (0, 7.2.2), the canonical homomorphism $\varphi_i : A \to A_i$ is surjective and its kernel $\mathfrak{J}^{(i)}$ is equal to the projective limit of the $\mathfrak{J}_{ik}$ for $k \geq i$; the $\mathfrak{J}^{(i)}$ form a fundamental system of neighbourhoods of 0 in A. The assertions of (10.6.3) follow in this case from (10.1.1) and (10.3.2), $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$ being none other than $\mathrm{Spf}(A)$.

Still in this same particular case, let us note that if $f = (f_i)$ is an element of the projective limit $A = \varprojlim A_i$, all the open subsets $D(f_i)$ (an affine open subset in X_i) are identified with the open subset $\mathfrak{D}(f)$ of $\mathfrak{X}$, the prescheme induced by X_i on $\mathfrak{D}(f)$ therefore being identified with the affine scheme $\mathrm{Spec}((A_i)_{f_i})$.

In the general case, let us first remark that for every quasi-compact open subset U of $\mathfrak{X}$, each of the $\mathscr{J}_i|U$ is nilpotent, as the argument given above shows. We will see that for every $x \in \mathfrak{X}$, there is an open neighbourhood U of x in $\mathfrak{X}$ which is an *affine open subset for all the* X_i. Indeed, take for U an affine open subset for X_0, and observe that $\mathscr{O}_{X_0} = \mathscr{O}_{X_i}/\mathscr{J}_i$. Since $\mathscr{J}_i|U$ is nilpotent, by virtue of the foregoing, U is also an affine open subset for each X_i by virtue of (5.1.9). This being so, for every U satisfying the preceding conditions, the study of the affine case made above shows that $(U, \mathscr{O}_{\mathfrak{X}}|U)$ is a formal prescheme of which the $\mathscr{J}^{(i)}|U$ form a fundamental system of ideals of definition, and $\mathscr{J}^{(0)}|U$ is the projective limit of the $\mathscr{J}_i|U$; whence the conclusion. □

(10.6.4) Corollary. *Suppose that, for $i \geq j$, the kernel of u_{ji} is $\mathscr{J}_i^{j+1}$ and that $\mathscr{J}_1/\mathscr{J}_1^2$ is of finite type over $\mathscr{O}_0 = \mathscr{O}_1/\mathscr{J}_1$. Then $\mathfrak{X}$ is an adic formal prescheme, and if $\mathscr{J}^{(n)}$* [I/191] *is the kernel of $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_n$, we have $\mathscr{J}^{(n)} = \mathscr{J}^{n+1}$ and $\mathscr{J}/\mathscr{J}^2$ is isomorphic to $\mathscr{J}_1$. If moreover X_0 is locally Noetherian (resp. Noetherian), $\mathfrak{X}$ is locally Noetherian (resp. Noetherian).*

Proof. Since the underlying spaces of $\mathfrak{X}$ and X_0 are the same, the question is local and we may suppose all the X_i affine; taking into account the relations $\mathscr{J}_{ij} = \widetilde{\mathfrak{J}_{ji}}$ (with the notation of (10.6.3)), we are immediately reduced to the corresponding assertions of (0, 7.2.7 and 7.2.8), noting that $\mathfrak{J}_1/\mathfrak{J}_1^2$ is then an A_0-module of finite type (1.3.9). □

In particular, *every locally Noetherian formal prescheme* $\mathfrak{X}$ is the inductive limit of a sequence (X_n) of locally Noetherian (ordinary) preschemes satisfying the conditions of (10.6.3) and (10.6.4): it suffices to consider an ideal of definition $\mathscr{J}$ of $\mathfrak{X}$ (10.5.4) and to take $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ ((10.5.1) and (10.6.2)).

(10.6.5) Corollary. *Let A be an admissible ring. In order that the affine formal scheme $\mathfrak{X} = \mathrm{Spf}(A)$ be Noetherian, it is necessary and sufficient that A be adic and Noetherian.*

Proof. The condition is evidently sufficient. Conversely, suppose that $\mathfrak{X}$ is Noetherian, and let $\mathfrak{J}$ be an ideal of definition of A and $\mathscr{J} = \mathfrak{J}^{\Delta}$ the corresponding ideal of definition of $\mathfrak{X}$. The (ordinary) preschemes $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ are then affine and Noetherian, so the rings $A_n = A/\mathfrak{J}^{n+1}$ are Noetherian (6.1.3), from which we conclude that $\mathfrak{J}/\mathfrak{J}^2$ is an $A/\mathfrak{J}$-module of finite type. Since the $\mathscr{J}^n$ form a fundamental system of ideals of definition of $\mathfrak{X}$ (10.5.1), we have $\mathscr{O}_{\mathfrak{X}} = \varprojlim(\mathscr{O}_{\mathfrak{X}}/\mathscr{J}^n)$ (10.5.3); we conclude from this (10.1.3) that A is topologically isomorphic to $\varprojlim A/\mathfrak{J}^n$, and is therefore adic and Noetherian (0, 7.2.8). □

(10.6.6) Remark. With the notation of (10.6.3), let $\mathscr{F}_i$ be an $\mathscr{O}_i$-module, and suppose given, for $i \geq j$, a v_{ij}-morphism $\theta_{ji} : \mathscr{F}_i \to \mathscr{F}_j$, in such a way that $\theta_{kj} \circ \theta_{ji} = \theta_{ki}$ for

$k \leq j \leq i$. Since the continuous map underlying v_{ij} is the identity, θ_{ji} is a homomorphism of sheaves of abelian groups on the space $\mathfrak{X}$; moreover, if $\mathscr{F}$ is the projective limit of the projective system $(\mathscr{F}_i)$ of sheaves of abelian groups, the fact that the θ_{ji} are v_{ij}-morphisms makes it possible to define on $\mathscr{F}$ a structure of $\mathscr{O}_{\mathfrak{X}}$-module by passing to the projective limit; we will say that $\mathscr{F}$, endowed with this structure, is the *projective limit* (for the θ_{ji}) of the system of $\mathscr{O}_i$-modules $(\mathscr{F}_i)$. In the particular case where $v_{ij}^*(\mathscr{F}_i) = \mathscr{F}_j$ and θ_{ji} is the *identity*, we will say for brevity that $\mathscr{F}$ is the projective limit of a system $(\mathscr{F}_i)$ such that $v_{ij}^*(\mathscr{F}_i) = \mathscr{F}_j$ for $j \leq i$ (without mentioning the θ_{ji}).

(10.6.7) Let $\mathfrak{X}$, $\mathfrak{Y}$ be two formal preschemes, $\mathscr{J}$ (resp. $\mathscr{K}$) an ideal of definition of $\mathfrak{X}$ (resp. $\mathfrak{Y}$), and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism such that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$. We then have, for every integer $n > 0$, $f^*(\mathscr{K}^n)\mathscr{O}_{\mathfrak{X}} = (f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}})^n \subset \mathscr{J}^n$; we can therefore (10.5.6) deduce from f a morphism of (ordinary) preschemes $f_n : X_n \to Y_n$, by setting $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$, $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}^{n+1})$, and it follows immediately from the definitions that the diagrams

$$\begin{array}{ccc} X_m & \xrightarrow{f_m} & Y_m \\ \downarrow & & \downarrow \\ X_n & \xrightarrow[f_n]{} & Y_n \end{array} \tag{10.6.7.1}$$

[I | 192] are commutative for $m \leq n$; in other words, (f_n) is an *inductive system* of morphisms.

(10.6.8) Conversely, let (X_n) (resp. (Y_n)) be an inductive system of (ordinary) preschemes satisfying conditions b) and c) of (10.6.3), and let $\mathfrak{X}$ (resp. $\mathfrak{Y}$) be its inductive limit. By definition of inductive limits, every sequence (f_n) of morphisms $X_n \to Y_n$ forming an inductive system has an *inductive limit* $f : \mathfrak{X} \to \mathfrak{Y}$, which is the unique morphism of formal preschemes making the diagrams

$$\begin{array}{ccc} X_n & \xrightarrow{f_n} & Y_n \\ \downarrow & & \downarrow \\ \mathfrak{X} & \xrightarrow[f]{} & \mathfrak{Y} \end{array}$$

commutative.

(10.6.9) Proposition. *Let $\mathfrak{X}$, $\mathfrak{Y}$ be two locally Noetherian formal preschemes, and $\mathscr{J}$ (resp. $\mathscr{K}$) an ideal of definition of $\mathfrak{X}$ (resp. $\mathfrak{Y}$); the map $f \mapsto (f_n)$ defined in (10.6.7) is a bijection of the set of morphisms $f : \mathfrak{X} \to \mathfrak{Y}$ such that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ onto the set of sequences (f_n) of morphisms making the diagrams (10.6.7.1) commutative.*

Proof. If f is the inductive limit of such a sequence, we must show that $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$. The question being local on $\mathfrak{X}$ and $\mathfrak{Y}$, we may restrict to the case where $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$ are affine, A and B being Noetherian adic rings, $\mathscr{J} = \mathfrak{J}^{\Delta}$, $\mathscr{K} = \mathfrak{K}^{\Delta}$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of definition of A (resp. B). We then have $X_n = \mathrm{Spec}(A_n)$, $Y_n = \mathrm{Spec}(B_n)$, with $A_n = A/\mathfrak{J}^{n+1}$ and $B_n = B/\mathfrak{K}^{n+1}$, by virtue of (10.3.6) and (10.3.2); $f_n = ({}^a\varphi_n, \widetilde{\varphi_n})$, where the homomorphisms $\varphi_n : B_n \to A_n$ form a projective system, hence $f = ({}^a\varphi, \widetilde{\varphi})$, where $\varphi = \varprojlim \varphi_n$. The commutativity of the diagram (10.6.7.1) for $m = 0$ then gives the condition $\varphi_n(\mathfrak{K}/\mathfrak{K}^{n+1}) \subset \mathfrak{J}/\mathfrak{J}^{n+1}$ for every n, hence, by passing to the projective limit, $\varphi(\mathfrak{K}) \subset \mathfrak{J}$, and this implies $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{J}$ (10.5.6, (ii)). □

(10.6.10) Corollary. *Let $\mathfrak{X}$, $\mathfrak{Y}$ be two locally Noetherian formal preschemes, and $\mathscr{T}$ the largest ideal of definition of $\mathfrak{X}$ (10.5.4).*

(i) *For every ideal of definition $\mathscr{K}$ of $\mathfrak{Y}$ and every morphism $f : \mathfrak{X} \to \mathfrak{Y}$, we have $f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{T}$.*

(ii) *There is a canonical bijective correspondence between* $\mathrm{Hom}(\mathfrak{X}, \mathfrak{Y})$ *and the set of sequences (f_n) of morphisms making the diagrams (10.6.7.1) commutative, where $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{T}^{n+1})$, $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K}^{n+1})$.*

Proof. (ii) follows immediately from (i) and from (10.6.9). To prove (i), we may restrict to the case where $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$, A and B being Noetherian, $\mathscr{T} = \mathfrak{T}^{\Delta}$, $\mathscr{K} = \mathfrak{K}^{\Delta}$, where $\mathfrak{T}$ is the largest ideal of definition of A and $\mathfrak{K}$ an ideal of definition of B. Let $f = ({}^a\varphi, \widetilde{\varphi})$, where $\varphi : B \to A$ is a continuous homomorphism; since the elements of $\mathfrak{K}$ are topologically nilpotent (0, 7.1.4, (ii)), the same is true of those of $\varphi(\mathfrak{K})$, hence $\varphi(\mathfrak{K}) \subset \mathfrak{T}$, since $\mathfrak{T}$ is the set of topologically nilpotent elements of A (0, 7.1.6); whence the conclusion by virtue of (10.5.6, (ii)). □

(10.6.11) Corollary. *Let $\mathfrak{S}$, $\mathfrak{X}$, $\mathfrak{Y}$ be three locally Noetherian formal preschemes, and $f : \mathfrak{X} \to \mathfrak{S}$, $g : \mathfrak{Y} \to \mathfrak{S}$ morphisms making $\mathfrak{X}$ and $\mathfrak{Y}$ into formal $\mathfrak{S}$-preschemes. Let $\mathscr{J}$ (resp. $\mathscr{K}$, $\mathscr{L}$) be an ideal of definition of $\mathfrak{S}$ (resp. $\mathfrak{X}$, $\mathfrak{Y}$), and suppose that $f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{K}$, $g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}} = \mathscr{L}$; set $S_n = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}^{n+1})$, $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$, $Y_n = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{L}^{n+1})$. There is then a canonical bijective correspondence between* $\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y})$ *and the set of sequences (u_n) of S_n-morphisms $u_n : X_n \to Y_n$ making the diagrams (10.6.7.1) commutative.* [I/193]

Proof. For every $\mathfrak{S}$-morphism $u : \mathfrak{X} \to \mathfrak{Y}$, we have $f = g \circ u$ by definition, hence

$$u^*(\mathscr{L})\mathscr{O}_{\mathfrak{X}} = u^*(g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}})\mathscr{O}_{\mathfrak{X}} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} \subset \mathscr{K}$$

the corollary therefore follows from (10.6.9). □

Note that, for $m \leq n$, the datum of a morphism $f_n : X_n \to Y_n$ determines one and only one morphism $f_m : X_m \to Y_m$ making the diagram (10.6.7.1) commutative, as one sees immediately by reducing to the affine case; we have thus defined a map $\varphi_{mn} : \mathrm{Hom}_{S_n}(X_n, Y_n) \to \mathrm{Hom}_{S_m}(X_m, Y_m)$, and the $\mathrm{Hom}_{S_n}(X_n, Y_n)$ form a *projective system of sets* for the φ_{mn}; (10.6.11) can also be stated by saying that there exists a canonical bijection

$$\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y}) \xrightarrow{\sim} \varprojlim_n \mathrm{Hom}_{S_n}(X_n, Y_n).$$

10.7 Product of formal preschemes.

(10.7.1) Let $\mathfrak{S}$ be a formal prescheme; since the formal $\mathfrak{S}$-preschemes form a category, we can define the notion of *product* of formal $\mathfrak{S}$-preschemes.

(10.7.2) Proposition. *Let $\mathfrak{X} = \mathrm{Spf}(B)$, $\mathfrak{Y} = \mathrm{Spf}(C)$ be two affine formal schemes over an affine formal scheme $\mathfrak{S} = \mathrm{Spf}(A)$. Let $\mathfrak{Z} = \mathrm{Spf}(B\widehat{\otimes}_A C)$, and let p_1, p_2 be the $\mathfrak{S}$-morphisms corresponding (10.2.2) to the canonical (continuous) A-homomorphisms ρ and σ from B and C to $B\widehat{\otimes}_A C$; then $(\mathfrak{Z}, p_1, p_2)$ is a product of the affine formal $\mathfrak{S}$-schemes $\mathfrak{X}$ and $\mathfrak{Y}$.*

Proof. By virtue of (10.4.6), everything comes down to verifying that if, to every continuous A-homomorphism $\varphi : B\widehat{\otimes}_A C \to D$, where D is an admissible ring which is a topological A-algebra, we associate the pair $(\varphi\circ\rho, \varphi\circ\sigma)$, we define a bijection

$$\mathrm{Hom}_A(B\widehat{\otimes}_A C, D) \xrightarrow{\sim} \mathrm{Hom}_A(B, D)\times \mathrm{Hom}_A(C, D)$$

which is none other than the universal property of the completed tensor product (0, 7.7.6). □

(10.7.3) Proposition. *Given two formal $\mathfrak{S}$-preschemes $\mathfrak{X}$, $\mathfrak{Y}$, the product $\mathfrak{X}\times_{\mathfrak{S}}\mathfrak{Y}$ exists.*

Proof. The proof is identical to that of (3.2.6), replacing in it the affine schemes (resp. the affine open subsets) by the affine formal schemes (resp. the affine formal open subsets), and Proposition (3.2.2) by (10.7.2). □

All the formal properties of the product of preschemes (3.2.7 and 3.2.8, 3.3.1 to 3.3.12) are valid without any modification for the product of formal preschemes.

(10.7.4) Let $\mathfrak{S}$, $\mathfrak{X}$, $\mathfrak{Y}$ be three formal preschemes and let $f : \mathfrak{X}\to\mathfrak{S}$, $g : \mathfrak{Y}\to\mathfrak{S}$ be two morphisms. Suppose that there exist in $\mathfrak{S}$, $\mathfrak{X}$, $\mathfrak{Y}$ respectively three fundamental systems of ideals of definition $(\mathscr{J}_\lambda)$, $(\mathscr{K}_\lambda)$, $(\mathscr{L}_\lambda)$ respectively, having the same index set I, such that $f^*(\mathscr{J}_\lambda)\mathscr{O}_{\mathfrak{X}}\subset\mathscr{K}_\lambda$ and $g^*(\mathscr{J}_\lambda)\mathscr{O}_{\mathfrak{Y}}\subset\mathscr{L}_\lambda$ for every λ. Set $S_\lambda = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}_\lambda)$, $X_\lambda = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}_\lambda)$, $Y_\lambda = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{L}_\lambda)$; for $\mathscr{J}_\mu\subset\mathscr{J}_\lambda$, $\mathscr{K}_\mu\subset\mathscr{K}_\lambda$, $\mathscr{L}_\mu\subset\mathscr{L}_\lambda$, note that S_λ (resp. X_λ, Y_λ) is a closed sub-prescheme of S_μ (resp. X_μ, Y_μ) having the same
[I | 194] underlying space (10.6.1). Since $S_\lambda\to S_\mu$ is a monomorphism of preschemes, we therefore see first that the products $X_\lambda\times_{S_\lambda}Y_\lambda$ and $X_\lambda\times_{S_\mu}Y_\lambda$ are identical (3.2.4), and then that $X_\lambda\times_{S_\mu}Y_\lambda$ is identified with a closed sub-prescheme of $X_\mu\times_{S_\mu}Y_\mu$ having the same underlying space (4.3.1). This being so, the product $\mathfrak{X}\times_{\mathfrak{S}}\mathfrak{Y}$ is the *inductive limit* of the ordinary preschemes $X_\lambda\times_{S_\lambda}Y_\lambda$: indeed, we see as in (10.6.2) that we can reduce to the case where $\mathfrak{S}$, $\mathfrak{X}$ and $\mathfrak{Y}$ are affine formal schemes. Taking into account (10.5.6, (ii)) and the hypothesis on the fundamental systems of ideals of definition of $\mathfrak{S}$, $\mathfrak{X}$ and $\mathfrak{Y}$, we see immediately that our assertion follows from the definition of the completed tensor product of two algebras (0, 7.7.1).

Moreover, let $\mathfrak{Z}$ be a formal $\mathfrak{S}$-prescheme, $(\mathscr{M}_\lambda)$ a fundamental system of ideals of definition of $\mathfrak{Z}$ having I as index set, and $u : \mathfrak{Z}\to\mathfrak{X}$, $v : \mathfrak{Z}\to\mathfrak{Y}$ two $\mathfrak{S}$-morphisms such that $u^*(\mathscr{K}_\lambda)\mathscr{O}_{\mathfrak{Z}}\subset\mathscr{M}_\lambda$ and $v^*(\mathscr{L}_\lambda)\mathscr{O}_{\mathfrak{Z}}\subset\mathscr{M}_\lambda$. If we set $Z_\lambda = (\mathfrak{Z}, \mathscr{O}_{\mathfrak{Z}}/\mathscr{M}_\lambda)$, and if $u_\lambda : Z_\lambda\to X_\lambda$ and $v_\lambda : Z_\lambda\to Y_\lambda$ are the S_λ-morphisms corresponding to u and v (10.5.6), we verify immediately that $(u, v)_{\mathfrak{S}}$ is the inductive limit of the S_λ-morphisms $(u_\lambda, v_\lambda)_{S_\lambda}$.

The considerations of this subsection apply in particular when $\mathfrak{S}$, $\mathfrak{X}$ and $\mathfrak{Y}$ are locally Noetherian, by taking as fundamental systems of ideals of definition the systems formed by the powers of an ideal of definition (10.5.1). But note that $\mathfrak{X}\times_{\mathfrak{S}}\mathfrak{Y}$ is not necessarily locally Noetherian (see however (10.13.5)).

10.8 Formal completion of a prescheme along a closed subset.

(10.8.1) Let X be a locally Noetherian (ordinary) prescheme, and X' a closed subset of the underlying space of X; denote by Φ the set of coherent sheaves of ideals $\mathscr{J}$ in $\mathscr{O}_X$ such that the support of $\mathscr{O}_X/\mathscr{J}$ is X'. The set Φ is not empty (5.2.1, 4.1.4 and 6.1.1); we order it by the relation $\supset$.

(10.8.2) Lemma. *The ordered set Φ is filtered; if X is Noetherian, then for every $\mathscr{J}_0 \in \Phi$, the set of powers $\mathscr{J}_0^n$ $(n > 0)$ is cofinal in Φ.*

Proof. Indeed, if $\mathscr{J}_1$ and $\mathscr{J}_2$ belong to Φ, and if we set $\mathscr{J} = \mathscr{J}_1 \cap \mathscr{J}_2$, then $\mathscr{J}$ is coherent since $\mathscr{O}_X$ is coherent (6.1.1 and 0, 5.3.4), and we have $\mathscr{J}_x = (\mathscr{J}_1)_x \cap (\mathscr{J}_2)_x$ for every $x \in X$, hence $\mathscr{J}_x = \mathscr{O}_x$ for $x \notin X'$ and $\mathscr{J}_x \neq \mathscr{O}_x$ for $x \in X'$, which proves that $\mathscr{J} \in \Phi$. On the other hand, if X is Noetherian, and if $\mathscr{J}_0$ and $\mathscr{J}$ belong to Φ, there exists an integer $n > 0$ such that $\mathscr{J}_0^n(\mathscr{O}_X/\mathscr{J}) = 0$ (9.3.4), which means that $\mathscr{J}_0^n \subset \mathscr{J}$. □

(10.8.3) Now let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module; for every $\mathscr{J} \in \Phi$, $\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ is a coherent $\mathscr{O}_X$-module (9.1.1), with support contained in X', which we will most often identify with its restriction to X'. As $\mathscr{J}$ runs through Φ, these sheaves form a *projective system* of sheaves of abelian groups.

(10.8.4) Definition. Given a closed subset X' of a locally Noetherian prescheme X and a coherent $\mathscr{O}_X$-module $\mathscr{F}$, we call *completion of $\mathscr{F}$ along X'*, and denote by $\mathscr{F}_{/X'}$ or by $\widehat{\mathscr{F}}$ (when no confusion is possible), the restriction to X' of the sheaf $\varprojlim_{\Phi}(\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}))$; we say that its sections over X' are the *formal sections of $\mathscr{F}$ along X'*. [I | 195]

It is immediate that for every open subset $U \subset X$, we have $(\mathscr{F}|U)_{/(U\cap X')} = (\mathscr{F}_{/X'})|(U \cap X')$.

By passing to the projective limit, it is clear that $(\mathscr{O}_X)_{/X'}$ is a sheaf of rings, and that $\mathscr{F}_{/X'}$ can be regarded as an $(\mathscr{O}_X)_{/X'}$-module. Moreover, since there exists a basis of the topology of X' formed by quasi-compact open subsets, we can regard $(\mathscr{O}_X)_{/X'}$ (resp. $\mathscr{F}_{/X'}$) as a *sheaf of topological rings* (resp. of *topological groups*) that is the projective limit of the *pseudo-discrete* sheaves of rings (resp. groups) $\mathscr{O}_X/\mathscr{J}$ (resp. $\mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}) = \mathscr{F}/\mathscr{J}\mathscr{F}$), and, by passing to the projective limit, $\mathscr{F}_{/X'}$ then becomes a *topological $(\mathscr{O}_X)_{/X'}$-module* (0, 3.8.1 and 3.8.2); recall that for every *quasi-compact* open subset $U \subset X$, $\Gamma(U \cap X', (\mathscr{O}_X)_{/X'})$ (resp. $\Gamma(U \cap X', \mathscr{F}_{/X'})$) is then the projective limit of the discrete rings (resp. groups) $\Gamma(U, \mathscr{O}_X/\mathscr{J})$ (resp. $\Gamma(U, \mathscr{F}/\mathscr{J}\mathscr{F})$).

If now $u : \mathscr{F} \to \mathscr{G}$ is a homomorphism of $\mathscr{O}_X$-modules, we canonically deduce from it homomorphisms $u_{\mathscr{J}} : \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}) \to \mathscr{G} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ for every $\mathscr{J} \in \Phi$, and these homomorphisms form a projective system. By passing to the projective limit and restricting to X', they therefore give a continuous $(\mathscr{O}_X)_{/X'}$-homomorphism $\mathscr{F}_{/X'} \to \mathscr{G}_{/X'}$, denoted $u_{/X'}$ or $\widehat{u}$, and called the *completion of the homomorphism u along X'*. It is clear that if $v : \mathscr{G} \to \mathscr{H}$ is a second homomorphism of $\mathscr{O}_X$-modules, we have $(v \circ u)_{/X'} = (v_{/X'}) \circ (u_{/X'})$, so $\mathscr{F}_{/X'}$ is a *covariant additive functor* in $\mathscr{F}$, from the category of coherent $\mathscr{O}_X$-modules to the category of topological $(\mathscr{O}_X)_{/X'}$-modules.

(10.8.5) Proposition. *The support of $(\mathscr{O}_X)_{/X'}$ is X'; the topologically ringed space $(X', (\mathscr{O}_X)_{/X'})$ is a locally Noetherian formal prescheme, and if $\mathscr{J} \in \Phi$, $\mathscr{J}_{/X'}$ is an ideal of definition of this formal prescheme. If $X = \operatorname{Spec}(A)$ is an affine scheme with Noetherian ring, $\mathscr{J} = \widetilde{\mathfrak{J}}$, where $\mathfrak{J}$ is an ideal of A, and $X' = V(\mathfrak{J})$, then $(X', (\mathscr{O}_X)_{/X'})$ is canonically identified with $\operatorname{Spf}(\widehat{A})$, where $\widehat{A}$ is the separated completion of A for the $\mathfrak{J}$-preadic topology.*

Proof. We may evidently restrict ourselves to proving the last assertion. We know (0, 7.3.3) that the separated completion $\widehat{\mathfrak{J}}$ of $\mathfrak{J}$ for the $\mathfrak{J}$-preadic topology is identified with the ideal $\mathfrak{J}\widehat{A}$ of $\widehat{A}$, and that $\widehat{A}$ is a Noetherian $\widehat{\mathfrak{J}}$-adic ring such that $\widehat{A}/\widehat{\mathfrak{J}}^n = A/\mathfrak{J}^n$ (0, 7.2.6).

This last relation shows that the open prime ideals of $\widehat{A}$ are the ideals $\widehat{\mathfrak{p}} = \mathfrak{p}\widehat{A}$, where $\mathfrak{p}$ is a prime ideal of A containing $\mathfrak{J}$, and that we have $\widehat{\mathfrak{p}} \cap A = \mathfrak{p}$, whence $\mathrm{Spf}(\widehat{A}) = X'$. Since $\mathscr{O}_X/\mathscr{J}^n = (A/\mathfrak{J}^n)^\sim$, the proposition follows immediately from the definitions. □

We say that the formal prescheme thus defined is the *completion of X along X'*, and we denote it by $X_{/X'}$, or by $\widehat{X}$ if no confusion is to be feared. When we take $X' = X$, we can take $\mathscr{J} = 0$, and we therefore have $X_{/X} = X$.

It is clear that if U is a sub-prescheme induced on an open subset of X, then $U_{/(U\cap X')}$ is canonically identified with the formal sub-prescheme induced by $X_{/X'}$ on the open subset $U \cap X'$ of X'.

(10.8.6) Corollary. *The (ordinary) prescheme $\widehat{X}_{\mathrm{red}}$ is the unique reduced sub-prescheme of X having X' as underlying space (5.2.1). In order that $\widehat{X}$ be Noetherian, it is necessary and sufficient that $\widehat{X}_{\mathrm{red}}$ be so, and it suffices that X be so.*

[I | 196] The determination of $\widehat{X}_{\mathrm{red}}$ being local (10.5.4), we may again suppose that X is an affine scheme with Noetherian ring; with the notation of (10.8.5), the ideal $\mathfrak{T}$ of topologically nilpotent elements of $\widehat{A}$ is the inverse image, under the canonical map $\widehat{A} \to \widehat{A}/\widehat{\mathfrak{J}} = A/\mathfrak{J}$, of the nilradical of $A/\mathfrak{J}$ (0, 7.1.3), so $\widehat{A}/\mathfrak{T}$ is isomorphic to the quotient of $A/\mathfrak{J}$ by its nilradical. The first assertion therefore follows from (10.5.4) and (5.1.1). If $\widehat{X}_{\mathrm{red}}$ is Noetherian, its underlying space X' is also Noetherian, hence the $X'_n = \mathrm{Spec}(\mathscr{O}_X/\mathscr{J}^n)$ are Noetherian (6.1.2), and the same holds for $\widehat{X}$ (10.6.4); the converse is immediate, by virtue of (6.1.2).

(10.8.7) The canonical homomorphisms $\mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$ (for $\mathscr{J} \in \Phi$) form a projective system and therefore give, by passing to the projective limit, a homomorphism of sheaves of rings $\theta : \mathscr{O}_X \to \psi_*((\mathscr{O}_X)_{/X'}) = \varprojlim_{\Phi}(\mathscr{O}_X/\mathscr{J})$, where ψ denotes the canonical injection $X' \to X$ of the underlying spaces. We denote by i (or i_X) the (so-called canonical) morphism

$$(\psi, \theta) : X_{/X'} \to X$$

of ringed spaces.

By tensoring, for every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the canonical homomorphisms $\mathscr{O}_X \to \mathscr{O}_X/\mathscr{J}$ give homomorphisms $\mathscr{F} \to \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J})$ of $\mathscr{O}_X$-modules which again form a projective system, and therefore give, by passing to the projective limit, a canonical functorial homomorphism $\gamma : \mathscr{F} \to \psi_*(\mathscr{F}_{/X'})$ of $\mathscr{O}_X$-modules.

(10.8.8) Proposition.

(i) *The functor $\mathscr{F}_{/X'}$ (in $\mathscr{F}$) is exact.*

(ii) *The functorial homomorphism $\gamma^\sharp : i^*(\mathscr{F}) \to \mathscr{F}_{/X'}$ of $(\mathscr{O}_X)_{/X'}$-modules is an isomorphism.*

(i) It suffices to prove that if $0 \to \mathscr{F}' \to \mathscr{F} \to \mathscr{F}'' \to 0$ is an exact sequence of coherent $\mathscr{O}_X$-modules, and U an affine open subset of X with Noetherian ring A, the sequence

$$0 \to \Gamma(U \cap X', \mathscr{F}'_{/X'}) \to \Gamma(U \cap X', \mathscr{F}_{/X'}) \to \Gamma(U \cap X', \mathscr{F}''_{/X'}) \to 0$$

is exact. We then have $\mathscr{F}|U = \widetilde{M}$, $\mathscr{F}'|U = \widetilde{M'}$, $\mathscr{F}''|U = \widetilde{M''}$, where M, M', M'' are three A-modules of finite type such that the sequence $0 \to M' \to M \to M'' \to 0$ is

exact (1.5.1 and 1.3.11); let $\mathscr{J} \in \Phi$ and let $\mathfrak{J}$ be an ideal of A such that $\mathscr{J}|U = \widetilde{\mathfrak{J}}$. We then have

$$\Gamma(U \cap X', \mathscr{F} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\mathscr{J}^n)) = M \otimes_A (A/\mathfrak{J}^n)$$

(1.3.12); hence, by definition of the projective limit, we have

$$\Gamma(U \cap X', \mathscr{F}_{/X'}) = \varprojlim_n (M \otimes_A (A/\mathfrak{J}^n)) = \widehat{M}$$

the separated completion of M for the $\mathfrak{J}$-preadic topology, and similarly

$$\Gamma(U \cap X', \mathscr{F}'_{/X'}) = \widehat{M'}, \qquad \Gamma(U \cap X', \mathscr{F}''_{/X'}) = \widehat{M''}\ ;$$

our assertion then follows from the fact that, when A is Noetherian, the functor $\widehat{M}$ in M is exact on the category of A-modules of finite type (0, 7.3.3).

(ii) The question being local, we may suppose that we have an exact sequence $\mathscr{O}_X^m \to \mathscr{O}_X^n \to \mathscr{F} \to 0$ (0, 5.3.2); since $\gamma^\sharp$ is functorial, and the functors $i^*(\mathscr{F})$ and $\mathscr{F}_{/X'}$ are right exact (by (i) and (0, 4.3.1)), we have the commutative diagram [I | 197]

$$\begin{array}{ccccccc} i^*(\mathscr{O}_X^m) & \longrightarrow & i^*(\mathscr{O}_X^n) & \longrightarrow & i^*(\mathscr{F}) & \longrightarrow & 0 \\ \downarrow{\scriptstyle \gamma^\sharp} & & \downarrow{\scriptstyle \gamma^\sharp} & & \downarrow{\scriptstyle \gamma^\sharp} & & \\ (\mathscr{O}_X^m)_{/X'} & \longrightarrow & (\mathscr{O}_X^n)_{/X'} & \longrightarrow & \mathscr{F}_{/X'} & \longrightarrow & 0 \end{array} \qquad (10.8.8.1)$$

whose rows are exact. Moreover, the two functors $i^*(\mathscr{F})$ and $\mathscr{F}_{/X'}$ commute with finite direct sums (0, 3.2.6 and 4.3.2), and we are therefore reduced to proving our assertion for $\mathscr{F} = \mathscr{O}_X$. We then have $i^*(\mathscr{O}_X) = (\mathscr{O}_X)_{/X'} = \mathscr{O}_{\widehat{X}}$ (0, 4.3.4), and $\gamma^\sharp$ is a homomorphism of $\mathscr{O}_{\widehat{X}}$-modules; it therefore suffices to verify that $\gamma^\sharp$ transforms the unit section of $\mathscr{O}_{\widehat{X}}$ over an open subset of X' into itself, which is immediate and therefore shows that in this case $\gamma^\sharp$ is the identity.

(10.8.9) Corollary. *The morphism of ringed spaces $i : X_{/X'} \to X$ is flat.*

Indeed, this follows from (0, 6.7.3) and from (10.8.8, (i)).

(10.8.10) Corollary. *If $\mathscr{F}$ and $\mathscr{G}$ are coherent $\mathscr{O}_X$-modules, there exist canonical isomorphisms, functorial (in $\mathscr{F}$ and $\mathscr{G}$),*

$$(\mathscr{F}_{/X'}) \otimes_{(\mathscr{O}_X)_{/X'}} (\mathscr{G}_{/X'}) \xrightarrow{\sim} (\mathscr{F} \otimes_{\mathscr{O}_X} \mathscr{G})_{/X'} \qquad (10.8.10.1)$$

$$(\mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G}))_{/X'} \xrightarrow{\sim} \mathscr{H}om_{(\mathscr{O}_X)_{/X'}}(\mathscr{F}_{/X'}, \mathscr{G}_{/X'}) \qquad (10.8.10.2)$$

This follows from the canonical identification of $i^*(\mathscr{F})$ and $\mathscr{F}_{/X'}$; the existence of the first isomorphism is then a result valid for all morphisms of ringed spaces (0, 4.3.3.1), and that of the second is a result valid for all flat morphisms (0, 6.7.6), and therefore follows from (10.8.9).

(10.8.11) Proposition. *For every coherent $\mathscr{O}_X$-module $\mathscr{F}$, the kernel of the canonical homomorphism $\Gamma(X, \mathscr{F}) \to \Gamma(X', \mathscr{F}_{/X'})$ deduced from $\mathscr{F} \to \mathscr{F}_{/X'}$ consists of the sections that are zero in a neighbourhood of X'.*

It follows from the definition of $\mathscr{F}_{/X'}$ that the canonical image of such a section is zero. Conversely, if $s \in \Gamma(X, \mathscr{F})$ has zero image in $\Gamma(X', \mathscr{F}_{/X'})$, it suffices to see that

every $x \in X'$ has a neighbourhood in X in which s is zero, and we can therefore reduce to the case where $X = \mathrm{Spec}(A)$ is affine, A Noetherian, $X' = V(\mathfrak{J})$, where $\mathfrak{J}$ is an ideal of A, and $\mathscr{F} = \widetilde{M}$, where M is an A-module of finite type. Then $\Gamma(X', \mathscr{F}_{/X'})$ is the separated completion $\widehat{M}$ of M for the $\mathfrak{J}$-preadic topology, and the homomorphism $\Gamma(X, \mathscr{F}) \to \Gamma(X', \mathscr{F}_{/X'})$ is the canonical homomorphism $M \to \widehat{M}$. We know (0, 7.3.7) that the kernel of this homomorphism is the set of $z \in M$ annihilated by an element of $1 + \mathfrak{J}$. We therefore have $(1 + f)s = 0$ for some $f \in \mathfrak{J}$; for every $x \in X'$ we deduce from this that $(1_x + f_x)s_x = 0$, and since $1_x + f_x$ is invertible in $\mathscr{O}_x$ ($\mathfrak{J}_x\mathscr{O}_x$ being contained in the maximal ideal of $\mathscr{O}_x$), we have $s_x = 0$, which proves the proposition.

(10.8.12) Corollary. *The support of $\mathscr{F}_{/X'}$ is equal to* $\mathrm{Supp}(\mathscr{F}) \cap X'$.

It is clear that $\mathscr{F}_{/X'}$ is an $(\mathscr{O}_X)_{/X'}$-module of finite type (10.8.8, (ii)) and (0, 5.2.4), so its support is closed (0, 5.2.2) and evidently contained in $\mathrm{Supp}(\mathscr{F}) \cap X'$. To show that it is equal to this latter set, we are immediately reduced to proving that the relation $\Gamma(X', \mathscr{F}_{/X'}) = 0$ implies $\mathrm{Supp}(\mathscr{F}) \cap X' = \varnothing$; now this follows from (10.8.11) and from (1.4.1). [I | 198]

(10.8.13) Corollary. *Let $u : \mathscr{F} \to \mathscr{G}$ be a homomorphism of coherent $\mathscr{O}_X$-modules. In order that $u_{/X'} : \mathscr{F}_{/X'} \to \mathscr{G}_{/X'}$ be zero, it is necessary and sufficient that u be zero in a neighbourhood of X'.*

Indeed, by (10.8.8, (ii)), $u_{/X'}$ is identified with $i^*(u)$, so if we regard u as a section over X of the sheaf $\mathscr{H} = \mathscr{H}om_{\mathscr{O}_X}(\mathscr{F}, \mathscr{G})$, then $u_{/X'}$ is the section of $i^*(\mathscr{H}) = \mathscr{H}_{/X'}$ over X' that corresponds to it canonically ((10.8.10.2) and (0, 4.4.6)). It therefore suffices to apply (10.8.11) to the coherent $\mathscr{O}_X$-module $\mathscr{H}$.

(10.8.14) Corollary. *Let $u : \mathscr{F} \to \mathscr{G}$ be a homomorphism of coherent $\mathscr{O}_X$-modules. In order that $u_{/X'}$ be a monomorphism (resp. an epimorphism), it is necessary and sufficient that u be a monomorphism (resp. an epimorphism) in a neighbourhood of X'.*

Let $\mathscr{P}$ and $\mathscr{N}$ be the cokernel and the kernel of u, so that we have the exact sequence

$$0 \to \mathscr{N} \xrightarrow{v} \mathscr{F} \xrightarrow{u} \mathscr{G} \xrightarrow{w} \mathscr{P} \to 0,$$

whence (10.8.8, (i)) the exact sequence

$$0 \to \mathscr{N}_{/X'} \xrightarrow{v_{/X'}} \mathscr{F}_{/X'} \xrightarrow{u_{/X'}} \mathscr{G}_{/X'} \xrightarrow{w_{/X'}} \mathscr{P}_{/X'} \to 0.$$

If $u_{/X'}$ is a monomorphism (resp. an epimorphism), we have $v_{/X'} = 0$ (resp. $w_{/X'} = 0$), so there is a neighbourhood of X' in which $v = 0$ (resp. $w = 0$), by virtue of (10.8.13).

10.9 Extension of a morphism to the completions.

(10.9.1) Let X, Y be two locally Noetherian (ordinary) preschemes, $f : X \to Y$ a morphism, and X' (resp. Y') a closed subset of the underlying space X (resp. Y), such that $f(X') \subset Y'$. Let $\mathscr{J}$ (resp. $\mathscr{K}$) be a sheaf of ideals of $\mathscr{O}_X$ (resp. $\mathscr{O}_Y$) such that the support of $\mathscr{O}_X/\mathscr{J}$ (resp. $\mathscr{O}_Y/\mathscr{K}$) is X' (resp. Y') and that $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$; note that such sheaves of ideals always exist, since we can for example take for $\mathscr{J}$ the largest sheaf of ideals of $\mathscr{O}_X$ defining a sub-prescheme of X having X' as underlying space (5.2.1), and the hypothesis $f(X') \subset Y'$ then implies $f^*(\mathscr{K})\mathscr{O}_X \subset \mathscr{J}$ (5.2.4). We therefore have, for every integer $n > 0$, $f^*(\mathscr{K}^n)\mathscr{O}_X \subset \mathscr{J}^n$ (0, 4.3.5); consequently (4.4.6), if we set

$$X'_n = (X', \mathscr{O}_X/\mathscr{J}^{n+1}), \qquad Y'_n = (Y', \mathscr{O}_Y/\mathscr{K}^{n+1}),$$

we deduce from f a morphism $f_n : X'_n \to Y'_n$, and it is immediate that the f_n form an inductive system. We denote its inductive limit (10.6.8) by $\widehat{f} : X_{/X'} \to Y_{/Y'}$, and we will say (by abuse of language) that $\widehat{f}$ is the *extension of f to the completions of X and Y along X' and Y'*. It is immediate to verify that this morphism does not depend on the choice of the sheaves of ideals $\mathscr{J}$, $\mathscr{K}$ satisfying the above conditions. Indeed, it suffices to see this when X and Y are Noetherian affine schemes with rings A, B; then $\mathscr{J} = \widetilde{\mathfrak{J}}$, $\mathscr{K} = \widetilde{\mathfrak{K}}$, where $\mathfrak{J}$ (resp. $\mathfrak{K}$) is an ideal of A (resp. B), and f corresponds to a ring homomorphism $\varphi : B \to A$ such that $\varphi(\mathfrak{K}) \subset \mathfrak{J}$ (4.4.6 and 1.7.4); *$\widehat{f}$ is then the morphism which corresponds (10.2.2) to the continuous homomorphism $\widehat{\varphi} : \widehat{B} \to \widehat{A}$*, where $\widehat{A}$ (resp. $\widehat{B}$) is the separated completion of A (resp. B) for the $\mathfrak{J}$-preadic (resp. $\mathfrak{K}$-preadic) topology (10.6.8); and we know that if we replace $\mathscr{J}$ by another sheaf of ideals $\mathscr{J}' = \widetilde{\mathfrak{J}'}$ such that the support of $\mathscr{O}_X/\mathscr{J}'$ is still X', the $\mathfrak{J}$-preadic and $\mathfrak{J}'$-preadic topologies on A are the same (10.8.2). [I | 199]

Note that, according to this definition, the continuous map $X' \to Y'$ of the underlying spaces of $X_{/X'}$ and $Y_{/Y'}$ which corresponds to $\widehat{f}$ is none other than the restriction of f to X'.

(10.9.2) It follows immediately from the preceding definition that the diagram of morphisms of ringed spaces

$$\begin{array}{ccc} \widehat{X} & \xrightarrow{\widehat{f}} & \widehat{Y} \\ {\scriptstyle i_X}\downarrow & & \downarrow{\scriptstyle i_Y} \\ X & \xrightarrow[f]{} & Y \end{array} \tag{10.9.2.1}$$

is commutative, the vertical arrows being the canonical morphisms (10.8.7).

(10.9.3) Let Z be a third prescheme, $g : Y \to Z$ a morphism, and Z' a closed subset of Z such that $g(Y') \subset Z'$. If $\widehat{g}$ denotes the completion along Y' and Z' of the morphism g, it follows immediately from (10.9.1) that $\widehat{(g \circ f)} = \widehat{g} \circ \widehat{f}$.

(10.9.4) Proposition. *Let X, Y be two locally Noetherian S-preschemes, Y being of finite type over S. Let f, g be two S-morphisms from X to Y such that $f(X') \subset Y'$, $g(X') \subset Y'$. In order that $\widehat{f} = \widehat{g}$, it is necessary and sufficient that f and g coincide in a neighbourhood of X'.*

The condition is evidently sufficient (without any finiteness hypothesis on Y). To see that it is necessary, let us first remark that the hypothesis $\widehat{f} = \widehat{g}$ implies $f(x) = g(x)$ for every $x \in X'$. On the other hand, the question being local, we may suppose that X and Y are affine open neighbourhoods of x and of $y = f(x) = g(x)$ respectively, with Noetherian rings, that S is affine and that $\Gamma(Y, \mathscr{O}_Y)$ is a $\Gamma(S, \mathscr{O}_S)$-algebra of finite type (6.3.3). Then f and g correspond to two $\Gamma(S, \mathscr{O}_S)$-homomorphisms ρ, σ from $\Gamma(Y, \mathscr{O}_Y)$ to $\Gamma(X, \mathscr{O}_X)$ (1.7.3), and by hypothesis, the extensions by continuity of these homomorphisms to the separated completion of $\Gamma(Y, \mathscr{O}_Y)$ are the same. We conclude from (10.8.11) that for every section $s \in \Gamma(Y, \mathscr{O}_Y)$, the sections $\rho(s)$ and $\sigma(s)$ coincide in a neighbourhood of X' (depending on s); since $\Gamma(Y, \mathscr{O}_Y)$ is an algebra of finite type over $\Gamma(S, \mathscr{O}_S)$, we deduce immediately that there exists a neighbourhood V of X' such that $\rho(s)$ and $\sigma(s)$ coincide in V for *every* section $s \in \Gamma(Y, \mathscr{O}_Y)$. If $h \in \Gamma(X, \mathscr{O}_X)$ is such that $D(h)$ is a neighbourhood of x contained in V, we conclude from the foregoing and from (1.4.1, d)) that f and g coincide in $D(h)$.

(10.9.5) Proposition. *Under the hypotheses of (10.9.1), for every coherent $\mathscr{O}_Y$-module $\mathscr{G}$, there exists a canonical functorial isomorphism of $(\mathscr{O}_X)_{/X'}$-modules*

$$(f^*(\mathscr{G}))_{/X'} \xrightarrow{\sim} \widehat{f}^*(\mathscr{G}_{/Y'})$$

If we canonically identify $(f^*(\mathscr{G}))_{/X'}$ with $i_X^*(f^*(\mathscr{G}))$ and $\widehat{f}^*(\mathscr{G}_{/Y'})$ with $\widehat{f}^*(i_Y^*(\mathscr{G}))$ (10.8.8), the proposition follows immediately from the commutativity of the diagram of (10.9.2).

(10.9.6) Now let $\mathscr{F}$ be a coherent $\mathscr{O}_X$-module and $\mathscr{G}$ a coherent $\mathscr{O}_Y$-module. If $u : \mathscr{G} \to \mathscr{F}$ is an f-morphism from $\mathscr{G}$ to $\mathscr{F}$, there corresponds to it an $\mathscr{O}_X$-homomorphism $u^\sharp : f^*(\mathscr{G}) \to \mathscr{F}$, hence by completion a continuous $(\mathscr{O}_X)_{/X'}$-homomorphism $(u^\sharp)_{/X'} : (f^*(\mathscr{G}))_{/X'} \to \mathscr{F}_{/X'}$, and by virtue of (10.9.5) there exists an $\widehat{f}$-morphism $v : \mathscr{G}_{/Y'} \to$ [I | 200] $\mathscr{F}_{/X'}$,

and only one, such that $v^\sharp = (u^\sharp)_{/X'}$. If we regard the triples $(\mathscr{F}, X, X')$ ($\mathscr{F}$ being a coherent $\mathscr{O}_X$-module and X' a closed subset of X) as a *category*, the morphisms $(\mathscr{F}, X, X') \to (\mathscr{G}, Y, Y')$ consisting of a morphism of preschemes $f : X \to Y$ such that $f(X') \subset Y'$ and an f-morphism $u : \mathscr{G} \to \mathscr{F}$, we can therefore say that $(X_{/X'}, \mathscr{F}_{/X'})$ is a *functor* in $(\mathscr{F}, X, X')$, taking its values in the category of pairs $(\mathfrak{Z}, \mathscr{H})$ formed by a locally Noetherian formal prescheme $\mathfrak{Z}$ and an $\mathscr{O}_\mathfrak{Z}$-module $\mathscr{H}$, the morphisms of this latter category consisting of the pairs formed by a morphism g of formal preschemes and a g-morphism.

(10.9.7) Proposition. *Let S, X, Y be three locally Noetherian preschemes, $g : X \to S$, $h : Y \to S$ two morphisms, S' a closed subset of S, and X' (resp. Y') a closed subset of X (resp. Y) such that $g(X') \subset S'$ (resp. $h(Y') \subset S'$); let $Z = X \times_S Y$; suppose Z locally Noetherian, and let $Z' = p^{-1}(X') \cap q^{-1}(Y')$, where p and q are the projections of $X \times_S Y$. Under these conditions, the completion $Z_{/Z'}$ is identified with the product of formal $S_{/S'}$-preschemes $(X_{/X'}) \times_{S_{/S'}} (Y_{/Y'})$, the structural morphisms being identified with $\widehat{g}$ and $\widehat{h}$, and the projections with $\widehat{p}$ and $\widehat{q}$.*

It is immediate that the question is local for S, X and Y, and we are therefore reduced to the case where $S = \mathrm{Spec}(A)$, $X = \mathrm{Spec}(B)$, $Y = \mathrm{Spec}(C)$, $S' = V(\mathfrak{J})$, $X' = V(\mathfrak{K})$, $Y' = V(\mathfrak{L})$, where $\mathfrak{J}$, $\mathfrak{K}$, $\mathfrak{L}$ are three ideals such that $\varphi(\mathfrak{J}) \subset \mathfrak{K}$ and $\psi(\mathfrak{J}) \subset \mathfrak{L}$, denoting by φ and ψ the homomorphisms $A \to B$ and $A \to C$ which correspond to g and h. Then we know that $Z = \mathrm{Spec}(B \otimes_A C)$ and that $Z' = V(\mathfrak{M})$, where $\mathfrak{M}$ is the ideal $\mathrm{Im}(\mathfrak{K} \otimes_A C) + \mathrm{Im}(B \otimes_A \mathfrak{L})$. The conclusion follows (10.7.2) from the fact that the completed tensor product $(\widehat{B} \otimes_{\widehat{A}} \widehat{C})^\wedge$ (where $\widehat{A}$, $\widehat{B}$, $\widehat{C}$ are respectively the separated completions of A, B, C for the $\mathfrak{J}$-, $\mathfrak{K}$- and $\mathfrak{L}$-preadic topologies) is the separated completion of the tensor product $B \otimes_A C$ for the $\mathfrak{M}$-preadic topology (0, 7.7.2).

Note moreover that if T is a locally Noetherian S-prescheme, $u : T \to X$, $v : T \to Y$ two S-morphisms, and T' a closed subset of T such that $u(T') \subset X'$, $v(T') \subset Y'$, then the extension to the completions $((u, v)_S)^\wedge$ is identified with $(\widehat{u}, \widehat{v})_{S_{/S'}}$.

(10.9.8) Corollary. *Let X, Y be two locally Noetherian S-preschemes such that $X \times_S Y$ is locally Noetherian; let S' be a closed subset of S, and X' (resp. Y') a closed subset of X (resp. Y) whose image in S is contained in S'. For every S-morphism $f : X \to Y$ such that $f(X') \subset Y'$, the graph morphism $\Gamma_{\widehat{f}}$ is identified with the extension $(\Gamma_f)^\wedge$ of the graph morphism of f.*

(10.9.9) Corollary. *Let X, Y be two locally Noetherian preschemes, $f : X \to Y$ a morphism, Y' a closed subset of Y, and $X' = f^{-1}(Y')$. Then the formal prescheme $X_{/X'}$*

is identified, by means of the commutative diagram

$$\begin{array}{ccc} X & \longleftarrow & X_{/X'} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle \widehat{f}} \\ Y & \longleftarrow & Y_{/Y'} \end{array} \tag{10.9.9.1}$$

with the product $X \times_Y (Y_{/Y'})$ of formal preschemes.

It suffices to apply (10.9.7), replacing S and S' by Y, and X and X' by X. [I | 201]

(10.9.10) Remark. If X is the sum $X_1 \amalg X_2$ (3.1) and X' the union $X'_1 \cup X'_2$, where X'_i is a closed subset of X_i $(i = 1, 2)$, we see immediately that $X_{/X'} = X_{1/X'_1} \amalg X_{2/X'_2}$.

10.10 Application to coherent sheaves on affine formal schemes.

(10.10.1) Throughout this section, A will denote a *Noetherian adic ring*, and $\mathfrak{J}$ an ideal of definition of A. Let $X = \mathrm{Spec}(A)$, and $\mathfrak{X} = \mathrm{Spf}(A)$, which is identified with the closed subset $V(\mathfrak{J})$ of X (10.1.2). Moreover, the definition (10.1.2) and the definition (10.8.4) show that the *affine formal scheme* $\mathfrak{X}$ is identical with the *completion* $X_{/\mathfrak{X}}$ of the affine scheme X along the closed subset $\mathfrak{X}$ of its underlying space. To every coherent $\mathscr{O}_X$-module $\mathscr{F}$ there therefore corresponds an $\mathscr{O}_{\mathfrak{X}}$-module of finite type $\mathscr{F}_{/\mathfrak{X}}$, which is moreover a sheaf of topological modules over the sheaf of topological rings $\mathscr{O}_{\mathfrak{X}}$. But every coherent $\mathscr{O}_X$-module $\mathscr{F}$ is of the form $\widetilde{M}$, where M is an A-module of finite type (1.5.1); we set $(\widetilde{M})_{/\mathfrak{X}} = M^{\Delta}$. Moreover, if $u : M \to N$ is an A-homomorphism of A-modules of finite type, there corresponds to it a homomorphism $\widetilde{u} : \widetilde{M} \to \widetilde{N}$, and consequently also a continuous homomorphism $\widetilde{u}_{/\mathfrak{X}} : (\widetilde{M})_{/\mathfrak{X}} \to (\widetilde{N})_{/\mathfrak{X}}$, which we will denote by u^{Δ}. It is immediate that $(v \circ u)^{\Delta} = v^{\Delta} \circ u^{\Delta}$; we have thus defined a *covariant additive functor* M^{Δ} from the category of A-modules of finite type to that of $\mathscr{O}_{\mathfrak{X}}$-modules of finite type. When A is a *discrete* ring, we have $M^{\Delta} = \widetilde{M}$.

(10.10.2) Proposition.

(i) *M^{Δ} is an exact functor in M, and there exists a canonical functorial isomorphism of A-modules $\Gamma(\mathfrak{X}, M^{\Delta}) \xrightarrow{\sim} M$.*

(ii) *If M and N are two A-modules of finite type, there exist canonical functorial isomorphisms*

$$(M \otimes_A N)^{\Delta} \xrightarrow{\sim} M^{\Delta} \otimes_{\mathscr{O}_{\mathfrak{X}}} N^{\Delta} \tag{10.10.2.1}$$

$$(\mathrm{Hom}_A(M, N))^{\Delta} \xrightarrow{\sim} \mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(M^{\Delta}, N^{\Delta}) \tag{10.10.2.2}$$

(iii) *The map $u \to u^{\Delta}$ is a functorial isomorphism*

$$\mathrm{Hom}_A(M, N) \xrightarrow{\sim} \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(M^{\Delta}, N^{\Delta}) \tag{10.10.2.3}$$

The exactness of M^{Δ} follows from the exactness of the functors $\widetilde{M}$ (1.3.5) and $\mathscr{F}_{/\mathfrak{X}}$ (10.8.8). By definition, $\Gamma(\mathfrak{X}, M^{\Delta})$ is the separated completion of the A-module $\Gamma(X, \widetilde{M}) = M$ for the $\mathfrak{J}$-preadic topology; but since A is complete and M of finite type, we know (0, 7.3.6) that M is separated and complete, which completes the proof of (i). The isomorphism (10.10.2.1) (resp. 10.10.2.2) comes from the composition of the isomorphisms (1.3.12, (i)) and (10.8.10.1) (resp. (1.3.12, (ii)) and (10.8.10.2)). Finally,

since $\mathrm{Hom}_A(M,N)$ is an A-module of finite type, we can apply (i) to it, which identifies $\Gamma(\mathfrak{X},(\mathrm{Hom}_A(M,N))^\Delta)$ with $\mathrm{Hom}_A(M,N)$, and use (10.10.2.2), which proves that the homomorphism (10.10.2.3) is an isomorphism.

From (10.10.2) we deduce a whole series of consequences analogous to those deduced
[I | 202] from (1.3.7) and (1.3.12); we leave it to the reader to formulate them.

Note that the exactness property of M^Δ, applied to the exact sequence $0 \to \mathfrak{J} \to A \to A/\mathfrak{J} \to 0$, shows that the sheaf of ideals of $\mathscr{O}_\mathfrak{X}$ denoted here by $\mathfrak{J}^\Delta$ coincides with the one that was denoted in the same way in (10.3.1), by virtue of (10.3.2).

(10.10.3) Proposition. *Under the hypotheses of (10.10.1), $\mathscr{O}_\mathfrak{X}$ is a coherent sheaf of rings.*

If $f \in A$, we know that $A_{\{f\}}$ is a Noetherian adic ring (0, 7.6.11), and since the question is local, we are reduced (10.1.4) to proving that the kernel of a homomorphism $v : \mathscr{O}_\mathfrak{X}^n \to \mathscr{O}_\mathfrak{X}$ is an $\mathscr{O}_\mathfrak{X}$-module of finite type. We then have $v = u^\Delta$, where u is an A-homomorphism $A^n \to A$ (10.10.2); since A is Noetherian, the kernel of u is of finite type, in other words we have a homomorphism $A^m \xrightarrow{w} A^n$ such that the sequence $A^m \xrightarrow{w} A^n \xrightarrow{u} A$ is exact. We conclude from this (10.10.2) that the sequence $\mathscr{O}_\mathfrak{X}^m \xrightarrow{w^\Delta} \mathscr{O}_\mathfrak{X}^n \xrightarrow{v} \mathscr{O}_\mathfrak{X}$ is exact, which proves that the kernel of v is of finite type.

(10.10.4) With the preceding notation, set $A_n = A/\mathfrak{J}^{n+1}$, and let X_n be the affine scheme $\mathrm{Spec}(A_n) = (\mathfrak{X}, \mathscr{O}_\mathfrak{X}/\mathscr{J}^{n+1})$, $\mathscr{J} = \mathfrak{J}^\Delta$ being the sheaf of ideals of definition of $\mathscr{O}_\mathfrak{X}$ corresponding to the ideal $\mathfrak{J}$. Let u_{mn} be the morphism of preschemes $X_m \to X_n$ corresponding to the canonical homomorphism $A_n \to A_m$ for $m \leq n$; the formal scheme $\mathfrak{X}$ is the inductive limit of the X_n for the u_{mn} (10.6.3).

(10.10.5) Proposition. *Under the hypotheses of (10.10.1), let $\mathscr{F}$ be an $\mathscr{O}_\mathfrak{X}$-module. The following conditions are equivalent:*

a) $\mathscr{F}$ is a coherent $\mathscr{O}_\mathfrak{X}$-module.

b) $\mathscr{F}$ is isomorphic to the projective limit (10.6.6) of a sequence $(\mathscr{F}_n)$ of coherent $\mathscr{O}_{X_n}$-modules such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$.

c) There exists an A-module of finite type M (determined up to canonical isomorphism by (10.10.2, (i))) such that $\mathscr{F}$ is isomorphic to M^Δ.

Let us first show that b) implies c). We have $\mathscr{F}_n = \widetilde{M_n}$, where M_n is an A_n-module of finite type, and the hypothesis implies that $M_m = M_n \otimes_{A_n} A_m$ for $m \leq n$ (1.6.5); the M_n therefore form a projective system for the canonical di-homomorphisms $M_n \to M_m$ $(m \leq n)$, and it follows immediately from the definition of the A_n that this projective system satisfies the conditions of (0, 7.2.9); its projective limit M is consequently an A-module of finite type such that $M_n = M \otimes_A A_n$ for every n. We deduce from this that $\mathscr{F}_n$ is induced on X_n by $\widetilde{M} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\widetilde{\mathfrak{J}}^{n+1})$, hence $\mathscr{F} = M^\Delta$ by definition (10.8.4).

Conversely, c) implies b); indeed, if u_n is the immersion morphism $X_n \to X$, then $u_n^*(\widetilde{M}) = (M \otimes_A A_n)^\sim$ is induced on X_n by $\widetilde{M} \otimes_{\mathscr{O}_X} (\mathscr{O}_X/\widetilde{\mathfrak{J}}^{n+1})$, and $M^\Delta = \varprojlim u_n^*(\widetilde{M})$ by definition (10.8.4); since $u_m = u_n \circ u_{mn}$ for $m \leq n$, the $\mathscr{F}_n = u_n^*(\widetilde{M})$ satisfy the conditions of b), whence our assertion.

Let us now show that c) implies a): indeed, we have by definition $\mathscr{O}_\mathfrak{X} = A^\Delta$; M being the cokernel of a homomorphism $A^m \to A^n$, it follows from (10.10.2) that M^Δ is the cokernel of a homomorphism $\mathscr{O}_\mathfrak{X}^m \to \mathscr{O}_\mathfrak{X}^n$, and since the sheaf of rings $\mathscr{O}_\mathfrak{X}$ is coherent
[I | 203] (10.10.3), so is M^Δ (0, 5.3.4).

Finally, a) implies b). As an $\mathscr{O}_{\mathfrak{X}}$-module, we have $\mathscr{O}_{X_n} = \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1} = A_n^{\Delta}$; $\mathscr{F}_n = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-module (0, 5.3.5), and since it is also an $\mathscr{O}_{X_n}$-module and $\mathscr{J}^{n+1}$ is coherent, we conclude that $\mathscr{F}_n$ is a coherent $\mathscr{O}_{X_n}$-module (0, 5.3.10), and it is immediate that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leq n$ (remembering that the continuous map $X_m \to X_n$ of the underlying spaces is the identity of $\mathfrak{X}$). The sheaf $\mathscr{G} = \varprojlim \mathscr{F}_n$ is therefore a coherent $\mathscr{O}_{\mathfrak{X}}$-module, since we have seen that b) implies a). The canonical homomorphisms $\mathscr{F} \to \mathscr{F}_n$ form a projective system, which by passing to the limit gives a canonical homomorphism $w : \mathscr{F} \to \mathscr{G}$, and everything comes down to proving that w is bijective. The question now being local, we may restrict to the case where $\mathscr{F}$ is the cokernel of a homomorphism $\mathscr{O}_{\mathfrak{X}}^p \to \mathscr{O}_{\mathfrak{X}}^q$; this homomorphism being of the form v^{Δ}, where v is a homomorphism $A^p \to A^q$ (10.10.2), $\mathscr{F}$ is isomorphic to M^{Δ}, where $M = \operatorname{Coker} v$ (10.10.2). We then have, by virtue of (10.10.2), $\mathscr{F}_n = M^{\Delta} \otimes_{\mathscr{O}_{\mathfrak{X}}} A_n^{\Delta} = (M \otimes_A A_n)^{\Delta}$, and since the $\mathfrak{J}$-adic topology on $M \otimes_A A_n$ is discrete, we have $(M \otimes_A A_n)^{\Delta} = (M \otimes_A A_n)^{\sim}$ (as an $\mathscr{O}_{X_n}$-module); we have seen above that $M^{\Delta} = \varprojlim \mathscr{F}_n$, and w is therefore indeed the identity in this case.

Q.E.D.

(10.10.6) Corollary. *If $\mathscr{F}$ satisfies condition b) of (10.10.5), the projective system $(\mathscr{F}_n)$ is isomorphic to the system of the $\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$.*

(10.10.7) Now let A, B be two Noetherian adic rings, and $\varphi : B \to A$ a continuous homomorphism; we denote by $\mathfrak{J}$ (resp. $\mathfrak{K}$) an ideal of definition of A (resp. B), such that $\varphi(\mathfrak{K}) \subset \mathfrak{J}$, and we set $X = \operatorname{Spec}(A)$, $Y = \operatorname{Spec}(B)$, $\mathfrak{X} = \operatorname{Spf}(A)$, $\mathfrak{Y} = \operatorname{Spf}(B)$. Let $f : X \to Y$ be the morphism of preschemes corresponding to φ (1.6.1), and $\widehat{f} : \mathfrak{X} \to \mathfrak{Y}$ its extension to the completions (10.9.1), which is also the morphism of formal preschemes corresponding to φ (10.2.2).

(10.10.8) Proposition. *For every B-module N of finite type, there exists a canonical functorial isomorphism of $\mathscr{O}_{\mathfrak{X}}$-modules*

$$\widehat{f}^*(N^{\Delta}) \xrightarrow{\sim} (N \otimes_B A)^{\Delta}.$$

Indeed, denoting by $i_X : \mathfrak{X} \to X$ and $i_Y : \mathfrak{Y} \to Y$ the canonical morphisms, we have (10.8.8), up to canonical functorial isomorphisms, $N^{\Delta} = i_Y^*(\widetilde{N})$ and

$$(N \otimes_B A)^{\Delta} = i_X^*((N \otimes_B A)^{\sim}) = i_X^*(f^*(\widetilde{N}))$$

(1.6.5); the proposition therefore follows from the commutativity of the diagram (10.9.2).

(10.10.9) Corollary. *For every ideal $\mathfrak{b}$ of B, we have $\widehat{f}^*(\mathfrak{b}^{\Delta})\mathscr{O}_{\mathfrak{X}} = (\mathfrak{b}A)^{\Delta}$.*

Indeed, let j be the canonical injection $\mathfrak{b} \to B$, to which there corresponds the canonical injection $j^{\Delta} : \mathfrak{b}^{\Delta} \to \mathscr{O}_{\mathfrak{Y}}$ of sheaves of $\mathscr{O}_{\mathfrak{Y}}$-modules; by definition, $\widehat{f}^*(\mathfrak{b}^{\Delta})\mathscr{O}_{\mathfrak{X}}$ is the image of the homomorphism $\widehat{f}^*(j^{\Delta}) : \widehat{f}^*(\mathfrak{b}^{\Delta}) \to \mathscr{O}_{\mathfrak{X}} = \widehat{f}^*(\mathscr{O}_{\mathfrak{Y}})$; but this homomorphism is identified with $(j \otimes 1)^{\Delta} : (\mathfrak{b} \otimes_B A)^{\Delta} \to \mathscr{O}_{\mathfrak{X}} = (B \otimes_B A)^{\Delta}$ by (10.10.8). Since the image of $j \otimes 1$ is the ideal $\mathfrak{b}A$ of A, the image of $(j \otimes 1)^{\Delta}$ is therefore $(\mathfrak{b}A)^{\Delta}$ by virtue of (10.10.2), whence the conclusion. [I | 204]

10.11 Coherent sheaves on formal preschemes.

(10.11.1) Proposition. *If $\mathfrak{X}$ is a locally Noetherian formal prescheme, the sheaf of rings $\mathscr{O}_{\mathfrak{X}}$ is coherent and every sheaf of ideals of definition of $\mathfrak{X}$ is coherent.*

The question being local, we are reduced to the case of a Noetherian affine formal scheme, and the proposition therefore follows from (10.10.3) and (10.10.5).

(10.11.2) Let $\mathfrak{X}$ be a locally Noetherian formal prescheme, $\mathscr{J}$ a sheaf of ideals of definition of $\mathfrak{X}$, X_n the locally Noetherian (ordinary) prescheme $(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$, so that $\mathfrak{X}$ is the inductive limit of the sequence (X_n) for the canonical morphisms $u_{mn} : X_m \to X_n$ (10.6.3). With this notation:

(10.11.3) Theorem. *For an $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ to be coherent, it is necessary and sufficient that it be isomorphic to a projective limit of a sequence $(\mathscr{F}_n)$, where $\mathscr{F}_n$ is a coherent $\mathscr{O}_{X_n}$-module, such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leq n$ (10.6.6). The projective system $(\mathscr{F}_n)$ is then isomorphic to the system of the $u_n^*(\mathscr{F}) = \mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$, u_n being the canonical morphism $X_n \to \mathfrak{X}$.*

The question being local, we are reduced to the case where $\mathfrak{X}$ is a Noetherian affine formal scheme, and the theorem is then a consequence of (10.10.5) and (10.10.6).

We can therefore say that *giving a coherent $\mathscr{O}_{\mathfrak{X}}$-module is equivalent to giving a projective system $(\mathscr{F}_n)$ of coherent $\mathscr{O}_{X_n}$-modules such that $u_{mn}^*(\mathscr{F}_n) = \mathscr{F}_m$ for $m \leq n$.*

(10.11.4) Corollary. *If $\mathscr{F}$ and $\mathscr{G}$ are two coherent $\mathscr{O}_{\mathfrak{X}}$-modules, we can (with the notation of (10.11.3)) define a canonical functorial isomorphism*

$$\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \xrightarrow{\sim} \varprojlim_n \mathrm{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n). \tag{10.11.4.1}$$

The projective limit on the right-hand side is to be understood with respect to the maps $\theta_n \mapsto u_{mn}^*(\theta_n)$ $(m \leq n)$ from $\mathrm{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$ to $\mathrm{Hom}_{\mathscr{O}_{X_m}}(\mathscr{F}_m, \mathscr{G}_m)$. The homomorphism (10.11.4.1) assigns to an element $\theta \in \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ the sequence $(u_n^*(\theta))$; we see immediately that we define a homomorphism inverse to the preceding one by assigning to the projective system $(\theta_n) \in \varprojlim_n \mathrm{Hom}_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$ its projective limit in $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$, taking into account (10.11.3).

(10.11.5) Corollary. *For a homomorphism $\theta : \mathscr{F} \to \mathscr{G}$ to be surjective, it is necessary and sufficient that the corresponding homomorphism $\theta_0 = u_0^*(\theta) : \mathscr{F}_0 \to \mathscr{G}_0$ be so.*

The question being local, we are reduced to the case where $\mathfrak{X} = \mathrm{Spf}(A)$, A being a Noetherian adic ring, $\mathscr{F} = M^{\Delta}$, $\mathscr{G} = N^{\Delta}$ and $\theta = u^{\Delta}$, where M and N are A-modules of finite type and u a homomorphism $M \to N$; moreover, we then have $\theta_0 = \widetilde{u_0}$, where u_0 is the homomorphism $u \otimes 1 : M \otimes_A A/\mathfrak{J} \to N \otimes_A A/\mathfrak{J}$; the conclusion follows from the fact that θ and u (resp. θ_0 and u_0) are simultaneously surjective (1.3.9 and 10.10.2) and from the fact that u and u_0 are simultaneously surjective (0, 7.1.14).

(10.11.6) Theorem (10.11.3) shows that we can consider every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$ as a *topological* $\mathscr{O}_{\mathfrak{X}}$-module, by regarding it as the projective limit of the *pseudo-discrete* sheaves of groups $\mathscr{F}_n$ (0, 3.8.1). It then follows from (10.11.4) that every homomorphism $u : \mathscr{F} \to \mathscr{G}$ of coherent $\mathscr{O}_{\mathfrak{X}}$-modules is automatically *continuous*

[I | 205] (0, 3.8.2). Moreover, if $\mathscr{H}$ is a coherent sub-$\mathscr{O}_{\mathfrak{X}}$-module of a coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, then for every open subset $U \subset \mathfrak{X}$, $\Gamma(U, \mathscr{H})$ is a *closed* subgroup of the topological group $\Gamma(U, \mathscr{F})$, because, the functor Γ being left exact, $\Gamma(U, \mathscr{H})$ is the kernel of the homomorphism $\Gamma(U, \mathscr{F}) \to \Gamma(U, \mathscr{F}/\mathscr{H})$, which is *continuous* by the above, since $\mathscr{F}/\mathscr{H}$ is coherent (0, 5.3.4); our assertion follows from the fact that $\Gamma(U, \mathscr{F}/\mathscr{H})$ is a separated topological group.

(10.11.7) Proposition. *Let $\mathscr{F}$ and $\mathscr{G}$ be two coherent $\mathscr{O}_{\mathfrak{X}}$-modules. We can define (with the notation of (10.11.3)) canonical functorial isomorphisms of topological $\mathscr{O}_{\mathfrak{X}}$-modules (10.11.6)*

$$\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G} \xrightarrow{\sim} \varprojlim_n (\mathscr{F}_n \otimes_{\mathscr{O}_{X_n}} \mathscr{G}_n) \tag{10.11.7.1}$$

$$\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \xrightarrow{\sim} \varprojlim_n \mathscr{H}om_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n) \tag{10.11.7.2}$$

The existence of the isomorphism (10.11.7.1) follows from the formula

$$\mathscr{F}_n \otimes_{\mathscr{O}_{X_n}} \mathscr{G}_n = (\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}) \otimes_{\mathscr{O}_{X_n}} (\mathscr{G} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}) = (\mathscr{F} \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{G}) \otimes_{\mathscr{O}_{\mathfrak{X}}} \mathscr{O}_{X_n}$$

and from (10.11.3). The isomorphism (10.11.7.2), where the two sides are considered as sheaves of modules without topology, follows from the definition of the sections of $\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ and $\mathscr{H}om_{\mathscr{O}_{X_n}}(\mathscr{F}_n, \mathscr{G}_n)$ and from the existence of the isomorphism (10.11.4.1), applied to the prescheme induced on an arbitrary Noetherian affine formal open subset of $\mathfrak{X}$. It remains to prove that the isomorphism (10.11.7.2) is bicontinuous over a quasi-compact set, and we are therefore reduced to the case where $\mathfrak{X} = \mathrm{Spf}(A)$, A being a Noetherian adic ring, whence (10.10.5) $\mathscr{F} = M^{\Delta}$, $\mathscr{G} = N^{\Delta}$, M, N being A-modules of finite type; taking into account (10.10.2.1), (10.10.2.3) and (1.3.12, (ii)), we are reduced to showing that the canonical isomorphism $\mathrm{Hom}_A(M, N) \xrightarrow{\sim} \varprojlim_n \mathrm{Hom}_{A_n}(M_n, N_n)$ (with $M_n = M \otimes_A A_n$, $N_n = N \otimes_A A_n$) is continuous, which was proved in (0, 7.8.2).

(10.11.8) Since $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ is the group of sections of the sheaf of topological groups $\mathscr{H}om_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$, it is endowed with a group topology. If $\mathfrak{X}$ is *Noetherian*, it follows from (10.11.7.2) that a fundamental system of neighbourhoods of 0 in this group is obtained by taking the subgroups $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{J}^n\mathscr{G})$ (n arbitrary).

(10.11.9) Proposition. *Let $\mathfrak{X}$ be a Noetherian formal prescheme, $\mathscr{F}$ and $\mathscr{G}$ two coherent $\mathscr{O}_{\mathfrak{X}}$-modules. In the topological group $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ the surjective (resp. injective, bijective) homomorphisms form an open subset.*

By virtue of (10.11.5), the set of surjective homomorphisms in $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ is the inverse image under the continuous map $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \to \mathrm{Hom}_{\mathscr{O}_{X_0}}(\mathscr{F}_0, \mathscr{G}_0)$ of a subset of the discrete group $\mathrm{Hom}_{\mathscr{O}_{X_0}}(\mathscr{F}_0, \mathscr{G}_0)$, whence the first assertion. To prove the second, let us cover $\mathfrak{X}$ by finitely many Noetherian affine formal open subsets U_i. For $\theta \in \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G})$ to be injective, it is necessary and sufficient that all its images under the (continuous) restriction maps $\mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}}}(\mathscr{F}, \mathscr{G}) \to \mathrm{Hom}_{\mathscr{O}_{\mathfrak{X}|U_i}}(\mathscr{F}|U_i, \mathscr{G}|U_i)$ be so; we are therefore reduced to the affine case, and in that case this has already been proved in (0, 7.8.3).

10.12 Adic morphisms of formal preschemes. [I | 206]

(10.12.1) Let $\mathfrak{X}$, $\mathfrak{S}$ be two *locally Noetherian* formal preschemes; we will say that a morphism $f : \mathfrak{X} \to \mathfrak{S}$ is *adic* if there exists an ideal of definition $\mathscr{J}$ of $\mathfrak{S}$ such that $\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$; we then also say that $\mathfrak{X}$ is an *adic $\mathfrak{S}$-prescheme* (for f). When this is the case, for *every* ideal of definition $\mathscr{J}_1$ of $\mathfrak{S}$, $\mathscr{K}_1 = f^*(\mathscr{J}_1)\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$. Indeed, the question being local, we may suppose $\mathfrak{X}$ and $\mathfrak{S}$ affine and Noetherian; there therefore exists an integer n such that $\mathscr{J}^n \subset \mathscr{J}_1$ and $\mathscr{J}_1^n \subset \mathscr{J}$ (10.3.6 and 0, 7.1.4), whence $\mathscr{K}^n \subset \mathscr{K}_1$ and $\mathscr{K}_1^n \subset \mathscr{K}$. The first of these relations proves that $\mathscr{K}_1 = \mathfrak{K}_1^{\Delta}$, where $\mathfrak{K}_1$ is an open ideal of $A = \Gamma(\mathfrak{X}, \mathscr{O}_{\mathfrak{X}})$, and the second proves that $\mathfrak{K}_1$ is an ideal of definition of A (0, 7.1.4), whence our assertion.

It follows immediately from the above that if $\mathfrak{X}$ and $\mathfrak{Y}$ are two adic $\mathfrak{S}$-preschemes, *every $\mathfrak{S}$-morphism $u : \mathfrak{X} \to \mathfrak{Y}$ is adic*: indeed, if $f : \mathfrak{X} \to \mathfrak{S}$, $g : \mathfrak{Y} \to \mathfrak{S}$ are the structural morphisms, and $\mathscr{J}$ an ideal of definition of $\mathfrak{S}$, we have $f = g \circ u$, so $u^*(g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}})\mathscr{O}_{\mathfrak{X}} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$, and by hypothesis $g^*(\mathscr{J})\mathscr{O}_{\mathfrak{Y}}$ is an ideal of definition of $\mathfrak{Y}$.

(10.12.2) In what follows, we will suppose fixed a locally Noetherian formal prescheme $\mathfrak{S}$ and an ideal of definition $\mathscr{J}$ of $\mathfrak{S}$; we will set $S_n = (\mathfrak{S}, \mathscr{O}_{\mathfrak{S}}/\mathscr{J}^{n+1})$. The (locally Noetherian) adic $\mathfrak{S}$-preschemes evidently form a *category*. We will say that an inductive system (X_n) of locally Noetherian (ordinary) S_n-preschemes is an *adic (S_n)-inductive system* if the structural morphisms $f_n : X_n \to S_n$ are such that, for $m \leq n$, the diagrams

$$\begin{array}{ccc} X_n & \longleftarrow & X_m \\ {\scriptstyle f_n}\downarrow & & \downarrow{\scriptstyle f_m} \\ S_n & \longleftarrow & S_m \end{array} \tag{10.12.2.1}$$

are commutative and *identify X_m with the product $X_n \times_{S_n} S_m = (X_n)_{(S_m)}$*. The adic inductive systems form a *category*: indeed, it suffices to define a morphism $(X_n) \to (Y_n)$ of such systems as an *inductive system of S_n-morphisms $u_n : X_n \to Y_n$* such that u_m is identified with $(u_n)_{(S_m)}$ for $m \leq n$. This being so:

(10.12.3) Theorem. *There is a canonical equivalence between the category of adic $\mathfrak{S}$-preschemes and the category of adic (S_n)-inductive systems.*

The equivalence in question is obtained as follows: if $\mathfrak{X}$ is an adic $\mathfrak{S}$-prescheme and $f : \mathfrak{X} \to \mathfrak{S}$ the structural morphism, $\mathscr{K} = f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}}$ is an ideal of definition of $\mathfrak{X}$, and we assign to $\mathfrak{X}$ the inductive system of the $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$, the structural morphism $f_n : X_n \to S_n$ corresponding to f (10.5.6). Let us first show that (X_n) is an *adic inductive system*: if $f = (\psi, \theta)$, we have $\psi^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} = \mathscr{K}$, hence $\psi^*(\mathscr{J}^n)\mathscr{O}_{\mathfrak{X}} = \mathscr{K}^n$ for every n, and (by the exactness of the functor ψ^*) $\mathscr{K}^{m+1}/\mathscr{K}^{n+1} = \psi^*(\mathscr{J}^{m+1}/\mathscr{J}^{n+1})(\mathscr{O}_{\mathfrak{X}}/\mathscr{K}^{n+1})$ for $m \leq n$; our conclusion therefore follows from (4.4.5). It is moreover immediate to verify that to an $\mathfrak{S}$-morphism $u : \mathfrak{X} \to \mathfrak{Y}$ of adic $\mathfrak{S}$-preschemes there corresponds (with evident notation)

[I | 207] an inductive system of S_n-morphisms $u_n : X_n \to Y_n$ such that u_m is identified with $(u_n)_{(S_m)}$ for $m \leq n$.

The fact that we have indeed defined an equivalence in this way will follow from the following more precise proposition:

(10.12.3.1) Proposition. *Let (X_n) be an inductive system of S_n-preschemes; suppose that the structural morphisms $f_n : X_n \to S_n$ are such that the diagrams (10.12.2.1) are commutative and identify X_m with $X_n \times_{S_n} S_m$ for $m \leq n$. Then the inductive system (X_n) satisfies conditions b) and c) of (10.6.3); let $\mathfrak{X}$ be its inductive limit, and $f : \mathfrak{X} \to \mathfrak{S}$ the morphism that is the inductive limit of the inductive system (f_n). Then, if X_0 is locally Noetherian, $\mathfrak{X}$ is locally Noetherian and f is an adic morphism.*

Since the sheaf of ideals of $\mathscr{O}_{S_n}$ which defines the sub-prescheme S_m of S_n is nilpotent, the same is true, by virtue of (4.4.5), of the sheaf of ideals of $\mathscr{O}_{X_n}$ defining the sub-prescheme X_m of X_n, so the conditions of (10.6.3) are indeed satisfied. The question is consequently local on $\mathfrak{X}$ and $\mathfrak{S}$, and we may suppose that $\mathfrak{S} = \mathrm{Spf}(A)$, $\mathscr{J} = \mathfrak{J}^{\Delta}$, A being a Noetherian $\mathfrak{J}$-adic ring, and $X_n = \mathrm{Spec}(B_n)$; if $A_n = A/\mathfrak{J}^{n+1}$, the hypothesis implies that B_0 is Noetherian and that, if we set $\mathfrak{J}_n = \mathfrak{J}/\mathfrak{J}^{n+1}$, $B_m = B_n/\mathfrak{J}_n^{m+1}B_n$. The kernel of $B_n \to B_0$ is therefore $\mathfrak{K}_n = \mathfrak{J}_n B_n$ and the kernel of $B_n \to B_m$ is $\mathfrak{K}_n^{m+1}$ for

$m \leq n$; moreover, since A_1 is Noetherian, $\mathfrak{J}_1$ is of finite type over A_1, hence $\overline{\mathfrak{K}}_1 = \mathfrak{K}_1/\mathfrak{K}_1^2$ is of finite type over B_1, and *a fortiori* over $B_0 = B_1/\mathfrak{K}_1$; the fact that $\mathfrak{X}$ is Noetherian then follows from (10.6.4); if $B = \varprojlim B_n$, we have $\mathfrak{X} = \mathrm{Spf}(B)$, and if $\mathfrak{K}$ is the kernel of $B \to B_0$, $B_n = B/\mathfrak{K}^{n+1}$. If $\rho_n : A/\mathfrak{J}^{n+1} \to B/\mathfrak{K}^{n+1}$ is the homomorphism corresponding to f_n, we therefore have

$$\mathfrak{K}/\mathfrak{K}^{n+1} = (B/\mathfrak{K}^{n+1})\rho_n(\mathfrak{J}/\mathfrak{J}^{n+1})$$

since the homomorphism $\rho : A \to B$ corresponding to f is equal to $\varprojlim \rho_n$, the ideal $\mathfrak{J}B$ of B is dense in $\mathfrak{K}$, and since every ideal of B is closed (0, 7.3.5), we have $\mathfrak{K} = \mathfrak{J}B$. If $\mathscr{K} = \mathfrak{K}^{\Delta}$, the relation $f^*(\mathscr{J})\mathscr{O}_{\mathfrak{X}} = \mathscr{K}$ then follows from (10.10.9) and completes the proof.

(10.12.3.2) The preceding equivalence provides, for two adic $\mathfrak{S}$-preschemes $\mathfrak{X}$, $\mathfrak{Y}$, a *canonical bijection*

$$\mathrm{Hom}_{\mathfrak{S}}(\mathfrak{X}, \mathfrak{Y}) \xrightarrow{\sim} \varprojlim_n \mathrm{Hom}_{S_n}(X_n, Y_n)$$

the projective limit being taken with respect to the maps $u_n \to (u_n)_{(S_m)}$ for $m \leq n$.

10.13 Morphisms of finite type.

(10.13.1) Proposition. *Let $\mathfrak{Y}$ be a locally Noetherian formal prescheme, $\mathscr{K}$ an ideal of definition of $\mathfrak{Y}$, and $f : \mathfrak{X} \to \mathfrak{Y}$ a morphism of formal preschemes. The following conditions are equivalent:*

a) $\mathfrak{X}$ is locally Noetherian, f is an adic morphism (10.12.1) and, if we set $\mathscr{J} = f^*(\mathscr{K})\mathscr{O}_{\mathfrak{X}}$, the morphism $f_0 : (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}) \to (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$ deduced from f is of finite type.

b) $\mathfrak{X}$ is locally Noetherian, and is the inductive limit of an adic (Y_n)-inductive system (X_n) such that the morphism $X_0 \to Y_0$ is of finite type.

c) Every point of $\mathfrak{Y}$ has a Noetherian affine formal open neighbourhood V having the following property: *[I / 208]*

*(**Q**) $f^{-1}(V)$ is the union of a finite family of Noetherian affine formal open subsets U_i such that the Noetherian adic ring $\Gamma(U_i, \mathscr{O}_{\mathfrak{X}})$ is topologically isomorphic to the quotient of an algebra of restricted formal power series (0, 7.5.1) over $\Gamma(V, \mathscr{O}_{\mathfrak{Y}})$ by a (necessarily closed) ideal.*

It is immediate that a) implies b), by virtue of (10.12.3). To show that b) implies c), we may, since the question is local on $\mathfrak{Y}$, suppose that $\mathfrak{Y} = \mathrm{Spf}(B)$, where B is a Noetherian adic ring; let $\mathscr{K} = \mathfrak{K}^{\Delta}$, $\mathfrak{K}$ being an ideal of definition of B. Since by hypothesis X_0 is of finite type over Y_0, X_0 is a finite union of affine open subsets U_i such that the ring A_{i0} of the affine scheme induced by X_0 on U_i is an algebra of finite type over the ring $B/\mathfrak{K}$ of Y_0 (6.3.2). By virtue of (5.1.9), U_i is also an affine open subset in each of the Noetherian preschemes X_n, and if A_{in} is the ring of the affine scheme induced by X_n on U_i, hypothesis b) implies that for $m \leq n$, A_{im} is isomorphic to $A_{in}/\mathfrak{K}^{m+1}A_{in}$. Consequently, the formal prescheme induced on U_i by $\mathfrak{X}$ is isomorphic to $\mathrm{Spf}(A_i)$, where $A_i = \varprojlim_n A_{in}$ (10.6.4); A_i is a $\mathfrak{K}A_i$-adic ring, and $A_i/\mathfrak{K}A_i$, isomorphic to A_{i0}, is an algebra of finite type over $B/\mathfrak{K}$. We conclude from this (0, 7.5.5) that A_i is topologically isomorphic to a quotient of an algebra of restricted formal power series over B (by a necessarily closed ideal, since such an algebra is Noetherian (0, 7.5.4)).

To prove that c) implies a), we may restrict to the case where $\mathfrak{X} = \mathrm{Spf}(A)$ is also affine, A being a Noetherian adic ring isomorphic to the quotient of an algebra of restricted formal power series over B by a closed ideal. Then (0, 7.5.5), $A/\mathfrak{K}A$ is an algebra of finite type over $B/\mathfrak{K}$, and $\mathfrak{K}A = \mathfrak{J}$ is an ideal of definition of A, so, by virtue of (10.10.9), the conditions of a) are satisfied.

Note that if the conditions of Proposition (10.13.1) are fulfilled, property a) holds for *every ideal of definition* $\mathscr{K}$ of $\mathfrak{Y}$ (by virtue of c)), and consequently, in property b), *all the* f_n *are morphisms of finite type.*

(10.13.2) Corollary. *If the conditions of (10.13.1) are satisfied, every Noetherian affine formal open subset* V *of* $\mathfrak{Y}$ *has property* ($\boldsymbol{Q}$)*, and if* $\mathfrak{Y}$ *is Noetherian, so is* $\mathfrak{X}$*.*

This follows immediately from (10.13.1) and from (6.3.2).

(10.13.3) Definition. When the equivalent properties a), b), c) of (10.13.1) are satisfied, we say that the morphism f is *of finite type*, or that $\mathfrak{X}$ is a *formal* $\mathfrak{Y}$*-prescheme of finite type*, or a *formal prescheme of finite type over* $\mathfrak{Y}$.

(10.13.4) Corollary. *Let* $\mathfrak{X} = \mathrm{Spf}(A)$, $\mathfrak{Y} = \mathrm{Spf}(B)$ *be two Noetherian affine formal schemes; for* $\mathfrak{X}$ *to be of finite type over* $\mathfrak{Y}$*, it is necessary and sufficient that the Noetherian adic ring* A *be isomorphic to the quotient of an algebra of restricted formal power series over* B *by a closed ideal.*

Indeed, with the notation of (10.13.1), if $\mathfrak{X}$ is of finite type over $\mathfrak{Y}$, $A/\mathfrak{K}A$ is then a $(B/\mathfrak{K})$-algebra of finite type by virtue of (6.3.3), and $\mathfrak{K}A$ is an ideal of definition of A (10.10.9). We therefore conclude by (0, 7.5.5).

(10.13.5) Proposition.

(i) *The composite of two morphisms of formal preschemes which are of finite type is of finite type.*

[I/209] (ii) *Let* $\mathfrak{X}$*,* $\mathfrak{S}$*,* $\mathfrak{S}'$ *be three locally Noetherian (resp. Noetherian) formal preschemes, and* $f : \mathfrak{X} \to \mathfrak{S}$*,* $g : \mathfrak{S}' \to \mathfrak{S}$ *two morphisms. If* f *is of finite type,* $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ *is locally Noetherian (resp. Noetherian) and is of finite type over* $\mathfrak{S}'$*.*

(iii) *Let* $\mathfrak{S}$ *be a locally Noetherian formal prescheme, and* $\mathfrak{X}'$*,* $\mathfrak{Y}'$ *two locally Noetherian formal* $\mathfrak{S}$*-preschemes such that* $\mathfrak{X}' \times_{\mathfrak{S}} \mathfrak{Y}'$ *is locally Noetherian. If* $\mathfrak{X}$*,* $\mathfrak{Y}$ *are locally Noetherian formal* $\mathfrak{S}$*-preschemes and* $f : \mathfrak{X} \to \mathfrak{X}'$*,* $g : \mathfrak{Y} \to \mathfrak{Y}'$ *two* $\mathfrak{S}$*-morphisms of finite type, then* $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ *is locally Noetherian and* $f \times_{\mathfrak{S}} g$ *is an* $\mathfrak{S}$*-morphism of finite type.*

(iii) is deduced from (i) and (ii) by the formal argument of (3.5.1), and it therefore suffices to prove (i) and (ii).

Let $\mathfrak{X}$, $\mathfrak{Y}$, $\mathfrak{Z}$ be three locally Noetherian formal preschemes, and $f : \mathfrak{X} \to \mathfrak{Y}$, $g : \mathfrak{Y} \to \mathfrak{Z}$ two morphisms of finite type. If $\mathscr{L}$ is an ideal of definition of $\mathfrak{Z}$, $\mathscr{K} = g^*(\mathscr{L})\mathscr{O}_{\mathfrak{Y}}$ is one for $\mathfrak{Y}$ and $\mathscr{J} = f^*(g^*(\mathscr{L}))\mathscr{O}_{\mathfrak{X}}$ is one for $\mathfrak{X}$. Set $X_0 = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J})$, $Y_0 = (\mathfrak{Y}, \mathscr{O}_{\mathfrak{Y}}/\mathscr{K})$, $Z_0 = (\mathfrak{Z}, \mathscr{O}_{\mathfrak{Z}}/\mathscr{L})$, and let $f_0 : X_0 \to Y_0$, $g_0 : Y_0 \to Z_0$ be the morphisms corresponding to f and g. Since by hypothesis f_0 and g_0 are of finite type, so is $g_0 \circ f_0$ (6.3.4), which corresponds to $g \circ f$; hence $g \circ f$ is of finite type by (10.13.1).

Under the conditions of (ii), $\mathfrak{S}$ (resp. $\mathfrak{X}$, $\mathfrak{S}'$) is the inductive limit of a sequence (S_n) (resp. (X_n), (S'_n)) of locally Noetherian preschemes, and we may suppose (10.13.1) that

$X_m = X_n \times_{S_n} S_m$ for $m \leq n$. The formal prescheme $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is then the inductive limit of the preschemes $X_n \times_{S_n} S'_n$ (10.7.4), and we have

$$X_m \times_{S_m} S'_m = (X_n \times_{S_n} S_m) \times_{S_m} S'_m = (X_n \times_{S_n} S'_n) \times_{S'_n} S'_m.$$

Moreover, $X_0 \times_{S_0} S'_0$ is locally Noetherian since X_0 is of finite type over S_0 (6.3.8). We conclude first (10.12.3.1) that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is locally Noetherian; moreover, since $X_0 \times_{S_0} S'_0$ is of finite type over S'_0 (6.3.8), it follows from (10.12.3.1) and from (10.13.1) that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{S}'$ is of finite type over $\mathfrak{S}'$, which completes the proof of (ii) (the assertion concerning Noetherian preschemes being an immediate consequence of (6.3.8)).

(10.13.6) Corollary. *Under the hypotheses of (10.9.9), if f is a morphism of finite type, so is its extension $\widehat{f}$ to the completions.*

10.14 Closed sub-preschemes of formal preschemes.

(10.14.1) Proposition. *Let $\mathfrak{X}$ be a locally Noetherian formal prescheme and $\mathscr{A}$ a coherent sheaf of ideals of $\mathscr{O}_{\mathfrak{X}}$. If $\mathfrak{Y}$ is the (closed) support of $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$, the topologically ringed space $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$ is a locally Noetherian formal prescheme, which is Noetherian if $\mathfrak{X}$ is.*

Note that $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$ is coherent by virtue of (10.10.3) and (0, 5.3.4), so its support $\mathfrak{Y}$ is closed (0, 5.2.2). Let $\mathscr{J}$ be an ideal of definition of $\mathfrak{X}$, and let $X_n = (\mathfrak{X}, \mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$; the sheaf of rings $\mathscr{O}_{\mathfrak{X}}/\mathscr{A}$ is the projective limit of the sheaves $\mathscr{O}_{\mathfrak{X}}/(\mathscr{A}+\mathscr{J}^{n+1}) = (\mathscr{O}_{\mathfrak{X}}/\mathscr{A}) \otimes_{\mathscr{O}_{\mathfrak{X}}} (\mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$ (10.11.3), which all have support $\mathfrak{Y}$. The sheaf $(\mathscr{A} + \mathscr{J}^{n+1})/\mathscr{J}^{n+1}$ is a coherent $\mathscr{O}_{\mathfrak{X}}$-module, since $\mathscr{J}^{n+1}$ is coherent, so $(\mathscr{A} + \mathscr{J}^{n+1})/\mathscr{J}^{n+1}$ is also a coherent $(\mathscr{O}_{\mathfrak{X}}/\mathscr{J}^{n+1})$-module (0, 5.3.10); if Y_n is the closed sub-prescheme of X_n defined by this sheaf of ideals, it is immediate that $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$
is the formal prescheme that is the inductive limit of the Y_n, and since the conditions of [I | 210]
(10.6.4) are satisfied, this proves that this formal prescheme is locally Noetherian, and Noetherian if $\mathfrak{X}$ is (since then Y_0 is, by virtue of (6.1.4)).

(10.14.2) Definition. We call a *closed sub-prescheme* of a formal prescheme $\mathfrak{X}$ any formal prescheme $(\mathfrak{Y}, (\mathscr{O}_{\mathfrak{X}}/\mathscr{A})|\mathfrak{Y})$ where $\mathscr{A}$ is a coherent ideal of $\mathscr{O}_{\mathfrak{X}}$; we say that this prescheme is the closed sub-prescheme defined by $\mathscr{A}$.

It is clear that the correspondence thus defined between coherent ideals of $\mathscr{O}_{\mathfrak{X}}$ and closed sub-preschemes of $\mathfrak{X}$ is bijective.

The morphism of topologically ringed spaces $j = (\psi, \theta) : \mathfrak{Y} \to \mathfrak{X}$, where ψ is the injection $\mathfrak{Y} \to \mathfrak{X}$ and $\theta^\sharp$ the canonical homomorphism $\mathscr{O}_{\mathfrak{X}} \to \mathscr{O}_{\mathfrak{X}}/\mathscr{A}$, is evidently (10.4.5) a morphism of formal preschemes, which we call the *canonical injection* of $\mathfrak{Y}$ into $\mathfrak{X}$. Note that if $\mathfrak{X} = \mathrm{Spf}(A)$, where A is a Noetherian adic ring, we have $\mathscr{A} = \mathfrak{a}^\Delta$, where $\mathfrak{a}$ is an ideal of A (10.10.5), and it follows immediately from the above that we then have $\mathfrak{Y} = \mathrm{Spf}(A/\mathfrak{a})$ up to isomorphism, and that j corresponds (10.2.2) to the canonical homomorphism $A \to A/\mathfrak{a}$.

We say that a morphism $f : \mathfrak{Z} \to \mathfrak{X}$ of locally Noetherian formal preschemes is a *closed immersion* if it factors as $\mathfrak{Z} \xrightarrow{g} \mathfrak{Y} \xrightarrow{j} \mathfrak{X}$, where g is an isomorphism of $\mathfrak{Z}$ onto a closed sub-prescheme $\mathfrak{Y}$ of $\mathfrak{X}$ and j the canonical injection. Since j is a monomorphism of ringed spaces, g and $\mathfrak{Y}$ are necessarily *unique*.

(10.14.3) Proposition. *A closed immersion is a morphism of finite type.*

We are immediately reduced to the case where $\mathfrak{X}$ is an affine formal scheme $\mathrm{Spf}(A)$ and $\mathfrak{Y} = \mathrm{Spf}(A/\mathfrak{a})$; the proposition follows from (10.13.1, c)).

(10.14.4) Lemma. *Let $f : \mathfrak{Y} \to \mathfrak{X}$ be a morphism of locally Noetherian formal preschemes, and let (U_α) be a covering of $f(\mathfrak{Y})$ by Noetherian affine formal open subsets of $\mathfrak{X}$ such that the $f^{-1}(U_\alpha)$ are Noetherian affine formal open subsets of $\mathfrak{Y}$. For f to be a closed immersion, it is necessary and sufficient that $f(\mathfrak{Y})$ be a closed subset of $\mathfrak{X}$ and that, for every α, the restriction of f to $f^{-1}(U_\alpha)$ correspond (10.4.6) to a surjective homomorphism $\Gamma(U_\alpha, \mathscr{O}_\mathfrak{X}) \to \Gamma(f^{-1}(U_\alpha), \mathscr{O}_\mathfrak{Y})$.*

The conditions are evidently necessary. Conversely, if they are fulfilled, and if we denote by $\mathfrak{a}_\alpha$ the kernel of $\Gamma(U_\alpha, \mathscr{O}_\mathfrak{X}) \to \Gamma(f^{-1}(U_\alpha), \mathscr{O}_\mathfrak{Y})$, we define a coherent sheaf of ideals $\mathscr{A}$ of $\mathscr{O}_\mathfrak{X}$ by taking $\mathscr{A}|U_\alpha = \mathfrak{a}_\alpha^\Delta$, and by taking $\mathscr{A}$ equal to $\mathscr{O}_\mathfrak{X}$ in the complement of the union of the U_α. Indeed, since $f(\mathfrak{Y})$ is closed and the support of $(\mathscr{O}_\mathfrak{X}|U_\alpha)/\mathfrak{a}_\alpha^\Delta$ is $U_\alpha \cap f(\mathfrak{Y})$, everything comes down to verifying that $\mathfrak{a}_\alpha^\Delta$ and $\mathfrak{a}_\beta^\Delta$ induce the same sheaf on a Noetherian affine formal open subset $V \subset U_\alpha \cap U_\beta$. Now, the restriction of f to $f^{-1}(U_\alpha)$ being a closed immersion of this formal prescheme into U_α, $f^{-1}(V)$ is a Noetherian affine formal open subset in $f^{-1}(U_\alpha)$ and the restriction of f to $f^{-1}(V)$ is a closed immersion; if $\mathfrak{b}$ is the kernel of the surjective homomorphism $\Gamma(V, \mathscr{O}_\mathfrak{X}) \to \Gamma(f^{-1}(V), \mathscr{O}_\mathfrak{Y})$ corresponding to this restriction, it is immediate (10.10.2) that $\mathfrak{a}_\alpha^\Delta$ induces $\mathfrak{b}^\Delta$ on V. The sheaf of ideals $\mathscr{A}$ being thus defined, it is then clear that $f = j \circ g$, where $j : \mathfrak{Z} \to \mathfrak{X}$ is the canonical injection of the closed sub-prescheme $\mathfrak{Z}$ of $\mathfrak{X}$ defined by $\mathscr{A}$, and g an isomorphism of $\mathfrak{Y}$ onto $\mathfrak{Z}$.

(10.14.5) Proposition.

(i) *If $f : \mathfrak{Z} \to \mathfrak{Y}$, $g : \mathfrak{Y} \to \mathfrak{X}$ are closed immersions of locally Noetherian formal preschemes, $g \circ f$ is a closed immersion.*

(ii) *Let $\mathfrak{X}$, $\mathfrak{Y}$, $\mathfrak{S}$ be three locally Noetherian formal preschemes, $f : \mathfrak{X} \to \mathfrak{S}$ a closed immersion, and $g : \mathfrak{Y} \to \mathfrak{S}$ a morphism. Then the morphism $\mathfrak{X} \times_\mathfrak{S} \mathfrak{Y} \to \mathfrak{Y}$ is a closed immersion.* [I/211]

(iii) *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and $\mathfrak{X}'$, $\mathfrak{Y}'$ two locally Noetherian formal $\mathfrak{S}$-preschemes such that $\mathfrak{X}' \times_\mathfrak{S} \mathfrak{Y}'$ is locally Noetherian. If $\mathfrak{X}$, $\mathfrak{Y}$ are locally Noetherian formal $\mathfrak{S}$-preschemes and $f : \mathfrak{X} \to \mathfrak{X}'$, $g : \mathfrak{Y} \to \mathfrak{Y}'$ two $\mathfrak{S}$-morphisms which are closed immersions, then $f \times_\mathfrak{S} g$ is a closed immersion.*

By virtue of (3.5.1), it again suffices to prove (i) and (ii).

To prove (i), we may suppose that $\mathfrak{Y}$ (resp. $\mathfrak{Z}$) is a closed sub-prescheme of $\mathfrak{X}$ (resp. $\mathfrak{Y}$) defined by a coherent sheaf $\mathscr{J}$ (resp. $\mathscr{K}$) of ideals of $\mathscr{O}_\mathfrak{X}$ (resp. $\mathscr{O}_\mathfrak{Y}$); if ψ is the injection $\mathfrak{Y} \to \mathfrak{X}$ of the underlying spaces, $\psi_*(\mathscr{K})$ is a coherent sheaf of ideals of $\psi_*(\mathscr{O}_\mathfrak{Y}) = \mathscr{O}_\mathfrak{X}/\mathscr{J}$ (0, 5.3.12), hence also a coherent $\mathscr{O}_\mathfrak{X}$-module (0, 5.3.10); the kernel $\mathscr{K}_1$ of $\mathscr{O}_\mathfrak{X} \to (\mathscr{O}_\mathfrak{X}/\mathscr{J})/\psi_*(\mathscr{K})$ is therefore a coherent sheaf of ideals of $\mathscr{O}_\mathfrak{X}$ (0, 5.3.4), and $\mathscr{O}_\mathfrak{X}/\mathscr{K}_1$ is isomorphic to $\psi_*(\mathscr{O}_\mathfrak{Y}/\mathscr{K})$, which proves that $\mathfrak{Z}$ is isomorphic to a closed sub-prescheme of $\mathfrak{X}$.

To prove (ii), it is immediate that we may restrict to the case where $\mathfrak{S} = \mathrm{Spf}(A)$, $\mathfrak{X} = \mathrm{Spf}(B)$, $\mathfrak{Y} = \mathrm{Spf}(C)$, A being a Noetherian $\mathfrak{J}$-adic ring, $B = A/\mathfrak{a}$, where $\mathfrak{a}$ is an ideal of A, and C an adic and Noetherian topological A-algebra. Everything comes down to proving that the homomorphism $C \to C\widehat{\otimes}_A(A/\mathfrak{a})$ is *surjective*: now, $A/\mathfrak{a}$ is an A-module of finite type, and its topology is the $\mathfrak{J}$-adic topology; it then follows from (0, 7.7.8) that $C\widehat{\otimes}_A(A/\mathfrak{a})$ is identified with $C \otimes_A (A/\mathfrak{a}) = C/\mathfrak{a}C$, whence our assertion.

(10.14.6) Corollary. *Under the hypotheses of (10.14.5, (ii)), let $p : \mathfrak{X} \times_\mathfrak{S} \mathfrak{Y} \to \mathfrak{X}$,*

$q : \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \to \mathfrak{Y}$ be the projections, so that the diagram

$$\begin{array}{ccc} \mathfrak{X} & \xleftarrow{p} & \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y} \\ {\scriptstyle f}\downarrow & & \downarrow{\scriptstyle q} \\ \mathfrak{S} & \xleftarrow[g]{} & \mathfrak{Y} \end{array}$$

is commutative. For every coherent $\mathscr{O}_{\mathfrak{X}}$-module $\mathscr{F}$, we then have a canonical isomorphism of $\mathscr{O}_{\mathfrak{Y}}$-modules

$$u : g^*(f_*(\mathscr{F})) \xrightarrow{\sim} q_*(p^*(\mathscr{F})). \tag{10.14.6.1}$$

To define a homomorphism $g^*(f_*(\mathscr{F})) \to q_*(p^*(\mathscr{F}))$, we know that this amounts to defining a homomorphism $f_*(\mathscr{F}) \to g_*(q_*(p^*(\mathscr{F}))) = f_*(p_*(p^*(\mathscr{F})))$ (0, 4.4.3): we will take for u the homomorphism corresponding by adjunction to $f_*(\rho)$, where ρ is the canonical homomorphism $\mathscr{F} \to p_*(p^*(\mathscr{F}))$ (0, 4.4.3). To see that u is an isomorphism, we are immediately reduced to the case where $\mathfrak{S}$, $\mathfrak{X}$, $\mathfrak{Y}$ are formal spectra of Noetherian adic rings A, B, C, with the conditions seen above in (10.14.5, (ii)); we then have $\mathscr{F} = M^{\Delta}$, where M is an $(A/\mathfrak{a})$-module of finite type (10.10.5), and the two sides of (10.14.6.1) are identified respectively, by virtue of (10.10.8), with $(C \otimes_A M)^{\Delta}$ and with $((C/\mathfrak{a}C) \otimes_{A/\mathfrak{a}} M)^{\Delta}$, whence the corollary, since $(C/\mathfrak{a}C) \otimes_{A/\mathfrak{a}} M = (C \otimes_A (A/\mathfrak{a})) \otimes_{A/\mathfrak{a}} M$ is canonically identified with $C \otimes_A M$.

(10.14.7) Corollary. *Let X be a locally Noetherian ordinary prescheme, Y a closed sub-prescheme of X, j the canonical injection $Y \to X$, X' a closed subset of X, and $Y' = Y \cap X'$; then $\widehat{j} : Y_{/Y'} \to X_{/X'}$ is a closed immersion, and for every coherent $\mathscr{O}_Y$-module $\mathscr{F}$, we have* [I | 212]

$$\widehat{j}_*(\mathscr{F}_{/Y'}) = (j_*(\mathscr{F}))_{/X'}.$$

Since $Y' = j^{-1}(X')$, it suffices to use (10.9.9) and to apply (10.14.5) and (10.14.6).

10.15 Separated formal preschemes.

(10.15.1) Definition. Let $\mathfrak{S}$ be a formal prescheme, $\mathfrak{X}$ a formal $\mathfrak{S}$-prescheme, and $f : \mathfrak{X} \to \mathfrak{S}$ the structural morphism. We call the morphism $(1_{\mathfrak{X}}, 1_{\mathfrak{X}})_{\mathfrak{S}}$ the diagonal morphism $\Delta_{\mathfrak{X}|\mathfrak{S}} : \mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$ (also denoted $\Delta_{\mathfrak{X}}$). We say that $\mathfrak{X}$ is separated over $\mathfrak{S}$, or is a formal $\mathfrak{S}$-scheme, or that f is a separated morphism, if the image under $\Delta_{\mathfrak{X}}$ of the underlying space $\mathfrak{X}$ is a closed subset of the space underlying $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$. We say that a formal prescheme $\mathfrak{X}$ is separated, or is a formal scheme, if it is separated over $\mathbf{Z}$.

(10.15.2) Proposition. *Suppose that the formal preschemes $\mathfrak{S}$, $\mathfrak{X}$ are respectively the inductive limits of the sequences (S_n), (X_n) of ordinary preschemes, and that the morphism $f : \mathfrak{X} \to \mathfrak{S}$ is the inductive limit of a sequence of morphisms $f_n : X_n \to S_n$. For f to be separated, it is necessary and sufficient that the morphism $f_0 : X_0 \to S_0$ be so.*

Indeed, $\Delta_{\mathfrak{X}|\mathfrak{S}}$ is then the inductive limit of the sequence of morphisms $\Delta_{X_n|S_n}$ (10.7.4), and the image under $\Delta_{\mathfrak{X}|\mathfrak{S}}$ of the underlying space $\mathfrak{X}$ (resp. the underlying space $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$) is identical to the image under $\Delta_{X_0|S_0}$ of the underlying space X_0 (resp. to the underlying space $X_0 \times_{S_0} X_0$); whence the conclusion.

(10.15.3) Proposition. *In what follows, we suppose that all the formal preschemes (resp. morphisms of formal preschemes) under consideration are inductive limits of sequences of ordinary preschemes (resp. of morphisms of ordinary preschemes).*

(i) *The composite of two separated morphisms is separated.*

(ii) *If $f : \mathfrak{X} \to \mathfrak{X}'$, $g : \mathfrak{Y} \to \mathfrak{Y}'$ are two separated $\mathfrak{S}$-morphisms, $f \times_{\mathfrak{S}} g$ is separated.*

(iii) *If $f : \mathfrak{X} \to \mathfrak{Y}$ is a separated $\mathfrak{S}$-morphism, the $\mathfrak{S}'$-morphism $f_{(\mathfrak{S}')}$ is separated for every extension $\mathfrak{S}' \to \mathfrak{S}$ of the base formal prescheme.*

(iv) *If the composite $g \circ f$ of two morphisms is separated, f is separated.*

(It is understood in this statement that if the same formal prescheme $\mathfrak{Z}$ occurs several times in the same proposition, it is regarded as the inductive limit of the *same* sequence (Z_n) of ordinary preschemes wherever it appears, and the morphisms from $\mathfrak{Z}$ to a formal prescheme (resp. from a formal prescheme to $\mathfrak{Z}$) as inductive limits of morphisms from the Z_n to ordinary preschemes (resp. from ordinary preschemes to the Z_n)).

With the notation of (10.15.2), we indeed have $(g \circ f)_0 = g_0 \circ f_0$ and $(f \times_{\mathfrak{S}} g)_0 = f_0 \times_{S_0} g_0$; the assertions of (10.15.3) are then immediate consequences of (10.15.2) and of the corresponding assertions of (5.5.1) for ordinary preschemes.

We leave it to the reader to state, for the same kind of formal preschemes and morphisms as in (10.15.3), the propositions corresponding to (5.5.5),
[I | 213] (5.5.9) and (5.5.10) (replacing in them "affine open subset" by "affine formal open subset satisfying condition b) of (10.6.3)").

An analogous argument also shows that every *Noetherian* affine formal scheme is separated, which justifies the terminology.

(10.15.4) Proposition. *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and $\mathfrak{X}$, $\mathfrak{Y}$ two locally Noetherian formal $\mathfrak{S}$-preschemes such that $\mathfrak{X}$ or $\mathfrak{Y}$ is of finite type over $\mathfrak{S}$ (so that $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is locally Noetherian) and that $\mathfrak{Y}$ is separated over $\mathfrak{S}$. Let $f : \mathfrak{X} \to \mathfrak{Y}$ be an $\mathfrak{S}$-morphism; then the graph morphism $\Gamma_f = (1_{\mathfrak{X}}, f)_{\mathfrak{S}} : \mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is a closed immersion.*

We may suppose that $\mathfrak{S}$ is the inductive limit of a sequence (S_n) of locally Noetherian preschemes, $\mathfrak{X}$ (resp. $\mathfrak{Y}$) the inductive limit of a sequence (X_n) (resp. (Y_n)) of S_n-preschemes, and f the inductive limit of a sequence of S_n-morphisms $f_n : X_n \to Y_n$; then $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ is the inductive limit of the sequence $(X_n \times_{S_n} Y_n)$, and Γ_f that of the sequence (Γ_{f_n}) (10.7.4); by hypothesis, Y_0 is separated over S_0 (10.15.2), so the space $\Gamma_{f_0}(X_0)$ is a closed subspace of $X_0 \times_{S_0} Y_0$; since the underlying spaces of $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$ (resp. $\Gamma_f(\mathfrak{X})$) and $X_0 \times_{S_0} Y_0$ (resp. $\Gamma_{f_0}(X_0)$) are the same, we already see that $\Gamma_f(\mathfrak{X})$ is a *closed* subspace of $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$. Let us now remark that when (U, V) runs through the set of pairs consisting of a Noetherian affine formal open subset U (resp. V) of $\mathfrak{X}$ (resp. $\mathfrak{Y}$) such that $f(U) \subset V$, the open subsets $U \times_{\mathfrak{S}} V$ form a covering of $\Gamma_f(\mathfrak{X})$ in $\mathfrak{X} \times_{\mathfrak{S}} \mathfrak{Y}$, and if $f_U : U \to V$ is the restriction of f to U, $\Gamma_{f_U} : U \to U \times_{\mathfrak{S}} V$ is the restriction of Γ_f to U. If we show that Γ_{f_U} is a closed immersion, the same will therefore be true of Γ_f (10.14.4); in other words, we are reduced to the case where $\mathfrak{S} = \mathrm{Spf}(A)$, $\mathfrak{X} = \mathrm{Spf}(B)$, $\mathfrak{Y} = \mathrm{Spf}(C)$ are affine (A, B, C Noetherian adic rings), f corresponding to a continuous A-homomorphism $\varphi : C \to B$; Γ_f then corresponds to the unique continuous homomorphism $\omega : B \widehat{\otimes}_A C \to B$ which, composed with the canonical homomorphisms $B \to B \widehat{\otimes}_A C$ and $C \to B \widehat{\otimes}_A C$, gives the identity and φ respectively. Now, it is clear that ω is *surjective*, whence our assertion.

(10.15.5) Corollary. *Let $\mathfrak{S}$ be a locally Noetherian formal prescheme, and $\mathfrak{X}$ an $\mathfrak{S}$-prescheme of finite type; for $\mathfrak{X}$ to be separated over $\mathfrak{S}$, it is necessary and sufficient that the diagonal morphism $\mathfrak{X} \to \mathfrak{X} \times_{\mathfrak{S}} \mathfrak{X}$ be a closed immersion.*

(10.15.6) Proposition. *A closed immersion $j : \mathfrak{Y} \to \mathfrak{X}$ of locally Noetherian formal preschemes is a separated morphism.*

With the notation of (10.14.2), $j_0 : Y_0 \to X_0$ is a closed immersion, hence a separated morphism, and it suffices to apply (10.15.2).

(10.15.7) Proposition. *Let X be a locally Noetherian (ordinary) prescheme, X' a closed subset of X, and $\widehat{X} = X_{/X'}$. For $\widehat{X}$ to be separated, it is necessary and sufficient that $\widehat{X}_{\mathrm{red}}$ be so, and it suffices that X be so.*

Indeed, with the notation of (10.8.5), for $\widehat{X}$ to be separated, it is necessary and sufficient that X'_0 be so (10.15.2), and since $\widehat{X}_{\mathrm{red}} = (X'_0)_{\mathrm{red}}$, it is equivalent to saying that $\widehat{X}_{\mathrm{red}}$ is so (5.5.1, (vi)).

Chapter II. Elementary global study of some classes of morphisms

§1 Affine morphisms

Most of the results of this section are the "global" counterparts of those of Chapter I, § 1; they are therefore not essentially new, and simply provide a convenient language for what follows.

1.1 S-preschemes and $\mathcal{O}_S$-algebras

(1.1.1) Let S be a prescheme, X an S-prescheme, and $f : X \to S$ its structural morphism. We know (0, 4.2.4) that the direct image $f_*(\mathcal{O}_X)$ is an $\mathcal{O}_S$-algebra, which we will denote by $\mathcal{A}(X)$ when no confusion can result; if U is an open subset of S, we have [II | 6]

$$\mathcal{A}(f^{-1}(U)) = \mathcal{A}(X)|U.$$

Similarly, for every $\mathcal{O}_X$-module $\mathcal{F}$ (resp. every $\mathcal{O}_X$-algebra $\mathcal{B}$), we will write $\mathcal{A}(\mathcal{F})$ (resp. $\mathcal{A}(\mathcal{B})$) for the direct image $f_*(\mathcal{F})$ (resp. $f_*(\mathcal{B})$), which is an $\mathcal{A}(X)$-module (resp. an $\mathcal{A}(X)$-algebra), and not only an $\mathcal{O}_S$-module (resp. $\mathcal{O}_S$-algebra).

(1.1.2) Let Y be a second S-prescheme, $g : Y \to S$ its structural morphism, and $h : X \to Y$ an S-morphism; we therefore have the commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\quad h \quad} & Y \\ & {\scriptstyle f}\searrow \quad \swarrow{\scriptstyle g} & \\ & S & \end{array} \tag{1.1.2.1}$$

By definition we have $h = (\psi, \theta)$, where $\theta : \mathcal{O}_Y \to h_*(\mathcal{O}_X) = \psi_*(\mathcal{O}_X)$ is a homomorphism of sheaves of rings; from it we deduce (0, 4.2.2) a homomorphism of $\mathcal{O}_S$-algebras

$$g_*(\theta) : g_*(\mathcal{O}_Y) \to g_*(h_*(\mathcal{O}_X)) = f_*(\mathcal{O}_X),$$

in other words, a homomorphism of $\mathcal{O}_S$-algebras $\mathcal{A}(Y) \to \mathcal{A}(X)$, which we will also denote by $\mathcal{A}(h)$. If $h' : Y \to Z$ is a second S-morphism, it is immediate that $\mathcal{A}(h' \circ h) = \mathcal{A}(h) \circ \mathcal{A}(h')$. We have therefore defined a *contravariant functor* $\mathcal{A}(X)$ on the category of S-preschemes, with values in the category of $\mathcal{O}_S$-algebras.

Now let $\mathcal{F}$ be an $\mathcal{O}_X$-module, $\mathcal{G}$ an $\mathcal{O}_Y$-module, and $u : \mathcal{G} \to \mathcal{F}$ an h-morphism, that is (0, 4.4.1), a homomorphism of $\mathcal{O}_Y$-modules $\mathcal{G} \to h_*(\mathcal{F})$. Then

$$g_*(u) : g_*(\mathcal{G}) \to g_*(h_*(\mathcal{F})) = f_*(\mathcal{F})$$

is a homomorphism $\mathcal{A}(\mathcal{G}) \to \mathcal{A}(\mathcal{F})$ of $\mathcal{O}_S$-modules, which we will denote by $\mathcal{A}(u)$; moreover, the pair $(\mathcal{A}(h), \mathcal{A}(u))$ constitutes a *di-homomorphism* from the $\mathcal{A}(Y)$-module $\mathcal{A}(\mathcal{G})$ to the $\mathcal{A}(X)$-module $\mathcal{A}(\mathcal{F})$.

(1.1.3) The prescheme S being fixed, we can regard the pairs $(X, \mathcal{F})$, where X is an S-prescheme and $\mathcal{F}$ an $\mathcal{O}_X$-module, as forming a *category*, by defining a *morphism* $(X, \mathcal{F}) \to (Y, \mathcal{G})$ as a pair (h, u), where $h : X \to Y$ is an S-morphism and $u : \mathcal{G} \to \mathcal{F}$ an h-morphism. We can then say that $(\mathcal{A}(X), \mathcal{A}(\mathcal{F}))$ is a *contravariant functor* with values in the category whose objects are the pairs consisting of an $\mathcal{O}_S$-algebra and a module over this algebra, and whose morphisms are the di-homomorphisms.

1.2 Preschemes affine over a prescheme

(1.2.1) Definition. Let X be an S-prescheme and $f : X \to S$ its structural morphism. We say that X is *affine over* S if there exists a covering (S_α) of S by affine open subsets such that, for every α, the prescheme induced by X on the open set $f^{-1}(S_\alpha)$ is affine.

(1.2.2) Example. Every closed sub-prescheme of S is an S-prescheme affine over S (I, 4.2.3 and 4.2.4).

(1.2.3) Remark. A prescheme X affine over S is not necessarily an affine scheme, as the example $X = S$ shows (1.2.2). On the other hand, if an affine scheme X is an
[II | 7] S-prescheme, X is not necessarily affine over S (see (1.3.3)). However, let us recall that if S is a *scheme*, every S-prescheme which is an affine scheme is affine over S (I, 5.5.10).

(1.2.4) Proposition. *Every S-prescheme which is affine over S is separated over S (in other words, is an S-scheme).*

This follows immediately from (I, 5.5.5) and (I, 5.5.8).

(1.2.5) Proposition. *Let X be an S-scheme affine over S, and $f : X \to S$ the structural morphism. For every open subset $U \subset S$, $f^{-1}(U)$ is affine over U.*

By virtue of Definition (1.2.1), we are reduced to the case where $S = \mathrm{Spec}(A)$ and $X = \mathrm{Spec}(B)$ are affine, and then $f = ({}^a\varphi, \widetilde{\varphi})$, where $\varphi : A \to B$ is a homomorphism. Since the $D(g)$, where $g \in A$, form a basis of S, we are reduced to the case where $U = D(g)$; but we then know that $f^{-1}(U) = D(\varphi(g))$ (I, 1.2.2.2), whence the proposition.

(1.2.6) Proposition. *Let X be an S-scheme affine over S, and $f : X \to S$ the structural morphism. For every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, $f_*(\mathcal{F})$ is a quasi-coherent $\mathcal{O}_S$-module.*

Taking into account (1.2.4), this follows from (I, 9.2.2, a)).

In particular, the $\mathcal{O}_S$-algebra $\mathcal{A}(X) = f_*(\mathcal{O}_X)$ is *quasi-coherent*.

(1.2.7) Proposition. *Let X be an S-scheme affine over S. For every S-prescheme Y, the map $h \mapsto \mathcal{A}(h)$ from the set $\mathrm{Hom}_S(Y, X)$ to the set $\mathrm{Hom}(\mathcal{A}(X), \mathcal{A}(Y))$ (1.1.2) is bijective.*

Let $f : X \to S$, $g : Y \to S$ be the structural morphisms. Suppose first that $S = \mathrm{Spec}(A)$ and $X = \mathrm{Spec}(B)$ are affine; we must prove that for every homomorphism $\omega : f_*(\mathcal{O}_X) \to g_*(\mathcal{O}_Y)$ of $\mathcal{O}_S$-algebras, there exists one and only one S-morphism $h : Y \to X$ such that $\mathcal{A}(h) = \omega$. By definition, for every open subset $U \subset S$, ω defines a homomorphism

$$\omega_U = \Gamma(U, \omega) : \Gamma(f^{-1}(U), \mathcal{O}_X) \to \Gamma(g^{-1}(U), \mathcal{O}_Y)$$

of $\Gamma(U, \mathcal{O}_S)$-algebras. In particular, for $U = S$, this gives a homomorphism $\varphi : \Gamma(X, \mathcal{O}_X) \to \Gamma(Y, \mathcal{O}_Y)$ of $\Gamma(S, \mathcal{O}_S)$-algebras, to which there corresponds a well-determined S-morphism $h : Y \to X$, since X is affine (I, 2.2.4). It remains to prove that $\mathcal{A}(h) = \omega$, in other words, that for every open subset U in a basis of S, ω_U coincides with the algebra homomorphism φ_U corresponding to the S-morphism $g^{-1}(U) \to f^{-1}(U)$ that is the restriction of h. We may restrict to the case where $U = D(\lambda)$, with $\lambda \in S$; then, if $f = ({}^a\rho, \widetilde{\rho})$, where $\rho : A \to B$ is a ring homomorphism, we have $f^{-1}(U) = D(\mu)$, where $\mu = \rho(\lambda)$, and $\Gamma(f^{-1}(U), \mathcal{O}_X)$ is the ring of fractions B_μ; now, the diagram

$$\begin{array}{ccc} B & \xrightarrow{\varphi} & \Gamma(Y, \mathcal{O}_Y) \\ \downarrow & & \downarrow \\ B_\mu & \xrightarrow[\varphi_U]{} & \Gamma(g^{-1}(U), \mathcal{O}_Y) \end{array}$$

is commutative, and so is the analogous diagram in which φ_U is replaced by ω_U; the equality $\varphi_U = \omega_U$ then follows from the universal property of rings of fractions (0, 1.2.4).

Let us pass to the general case, and let (S_α) be a covering of S by affine open subsets such that the $f^{-1}(S_\alpha)$ are affine. Then every homomorphism $\omega : \mathcal{A}(X) \to \mathcal{A}(Y)$ of [II | 8] $\mathcal{O}_S$-algebras gives, by restriction, a family of homomorphisms

$$\omega_\alpha : \mathcal{A}(f^{-1}(S_\alpha)) \to \mathcal{A}(g^{-1}(S_\alpha))$$

of $\mathcal{O}_{S_\alpha}$-algebras, hence a family of S_α-morphisms $h_\alpha : g^{-1}(S_\alpha) \to f^{-1}(S_\alpha)$ by the above. Everything comes down to seeing that for every affine open subset U in a basis of $S_\alpha \cap S_\beta$, the restrictions of h_α and of h_β to $g^{-1}(U)$ coincide, which is evident since, by virtue of the above, these restrictions both correspond to the homomorphism $\mathcal{A}(X)|U \to \mathcal{A}(Y)|U$ that is the restriction of ω.

(1.2.8) Corollary. *Let X, Y be two S-schemes which are affine over S. For an S-morphism $h : Y \to X$ to be an isomorphism, it is necessary and sufficient that $\mathcal{A}(h) : \mathcal{A}(X) \to \mathcal{A}(Y)$ be an isomorphism.*

This follows immediately from (1.2.7) and from the functorial character of $\mathcal{A}(X)$.

1.3 Prescheme affine over S associated to an $\mathcal{O}_S$-algebra

(1.3.1) Proposition. *Let S be a prescheme. For every quasi-coherent $\mathcal{O}_S$-algebra $\mathcal{B}$, there exists a prescheme X affine over S, determined up to a unique S-isomorphism, such that $\mathcal{A}(X) = \mathcal{B}$.*

The uniqueness follows from (1.2.8); let us prove the existence of X. For every affine open subset $U \subset S$, let X_U be the prescheme $\mathrm{Spec}(\Gamma(U, \mathcal{B}))$; since $\Gamma(U, \mathcal{B})$ is a $\Gamma(U, \mathcal{O}_S)$-algebra, X_U is an S-prescheme (I, 1.6.1). Moreover, since $\mathcal{B}$ is quasi-coherent, the $\mathcal{O}_S$-algebra $\mathcal{A}(X_U)$ is canonically identified with $\mathcal{B}|U$ (I, 1.3.7, 1.3.13 and 1.6.3). Let V be a second affine open subset of S, and let $X_{U,V}$ be the prescheme induced by X_U on $f_U^{-1}(U \cap V)$, where f_U denotes the structural morphism $X_U \to S$; $X_{U,V}$ and $X_{V,U}$ are affine over $U \cap V$ (1.2.5), and by definition $\mathcal{A}(X_{U,V})$ and $\mathcal{A}(X_{V,U})$ are canonically identified with $\mathcal{B}|(U \cap V)$. There is therefore (1.2.8) a canonical S-isomorphism $\theta_{U,V} : X_{V,U} \to X_{U,V}$; moreover, if W is a third affine open subset of S, and if $\theta'_{U,V}$, $\theta'_{V,W}$, $\theta'_{U,W}$ are the restrictions of $\theta_{U,V}$, $\theta_{V,W}$, $\theta_{U,W}$ to the inverse images of $U \cap V \cap W$ in X_V, X_W and X_W respectively under the structural morphisms, we have $\theta'_{U,V} \circ \theta'_{V,W} = \theta'_{U,W}$. Consequently there exist a prescheme X, a covering (T_U) of X by affine open subsets,

and for each U an isomorphism $\varphi_U : X_U \to T_U$, such that φ_U maps $f_U^{-1}(U \cap V)$ onto $T_U \cap T_V$ and that we have $\theta_{U,V} = \varphi_U^{-1} \circ \varphi_V$ (I, 2.3.1). The morphism $g_U = f_U \circ \varphi_U^{-1}$ makes T_U into an S-prescheme, and the morphisms g_U and g_V coincide in $T_U \cap T_V$, so X is an S-prescheme. Moreover, it is clear by definition that X is affine over S and that $\mathcal{A}(T_U) = \mathcal{B}|U$, hence $\mathcal{A}(X) = \mathcal{B}$.

We say that the S-scheme X thus defined is *associated to the $\mathcal{O}_S$-algebra $\mathcal{B}$*, or is the *spectrum of $\mathcal{B}$*, and we denote it by $\mathrm{Spec}(\mathcal{B})$.

(1.3.2) Corollary. *Let X be a prescheme affine over S, and $f : X \to S$ the structural morphism. For every affine open subset $U \subset S$, the prescheme induced on $f^{-1}(U)$ is an affine scheme with ring $\Gamma(U, \mathcal{A}(X))$.*

[II | 9] Since we can suppose X associated to an $\mathcal{O}_S$-algebra, by virtue of (1.2.6) and (1.3.1), the corollary follows from the construction of X described in (1.3.1).

(1.3.3) Example. Let S be the affine plane over a field K in which the point 0 has been doubled (I, 5.5.11); with the notation of (I, 5.5.11), S is the union of two affine open subsets Y_1, Y_2; if f is the open immersion $Y_1 \to S$, $f^{-1}(Y_2) = Y_1 \cap Y_2$ is not an affine open subset in Y_1 (*loc. cit.*), so we have an example of an affine scheme which is not affine over S.

(1.3.4) Corollary. *Let S be an affine scheme; for an S-prescheme X to be affine over S, it is necessary and sufficient that X be an affine scheme.*

(1.3.5) Corollary. *Let X be a prescheme affine over a prescheme S, and Y an X-prescheme. For Y to be affine over S, it is necessary and sufficient that Y be affine over X.*

We are immediately reduced to the case where S is an affine scheme, and then so is X (1.3.4); the two conditions of the statement then express that Y is an affine scheme (1.3.4).

(1.3.6) Let X be a prescheme affine over S. Defining a prescheme Y affine *over X* amounts, by virtue of (1.3.5), to giving a prescheme Y affine *over S* and an S-morphism $g : Y \to X$; in other words (1.3.1 and 1.2.7), it amounts to giving a quasi-coherent $\mathcal{O}_S$-algebra $\mathcal{B}$ and a homomorphism $\mathcal{A}(X) \to \mathcal{B}$ of $\mathcal{O}_S$-algebras (which we can regard as defining on $\mathcal{B}$ a structure of $\mathcal{A}(X)$-algebra). If $f : X \to S$ is the structural morphism, we then have $\mathcal{B} = f_*(g_*(\mathcal{O}_Y))$.

(1.3.7) Corollary. *Let X be a prescheme affine over S; for X to be of finite type over S, it is necessary and sufficient that the quasi-coherent $\mathcal{O}_S$-algebra $\mathcal{A}(X)$ be of finite type (I, 9.6.2).*

By definition (I, 9.6.2), we are reduced to the case where S is affine; then X is an affine scheme (1.3.4), and if $S = \mathrm{Spec}(A)$, $X = \mathrm{Spec}(B)$, $\mathcal{A}(X)$ is the $\mathcal{O}_S$-algebra $\widetilde{B}$; since $\Gamma(U, \widetilde{B}) = B$, the corollary follows from (I, 9.6.2) and (I, 6.3.3).

(1.3.8) Corollary. *Let X be a prescheme affine over S; for X to be reduced it is necessary and sufficient that the quasi-coherent $\mathcal{O}_S$-algebra $\mathcal{A}(X)$ be reduced (0, 4.1.4).*

Indeed, the question is evidently local on S; by virtue of (1.3.2), the corollary follows from (I, 5.1.1) and (I, 5.1.4).

1.4 Quasi-coherent sheaves on a prescheme affine over S

(1.4.1) Proposition. *Let X be a prescheme affine over S, Y an S-prescheme, and $\mathcal{F}$ (resp. $\mathcal{G}$) a quasi-coherent $\mathcal{O}_X$-module (resp. $\mathcal{O}_Y$-module). Then the map $(h,u) \mapsto (\mathcal{A}(h), \mathcal{A}(u))$ from the set of morphisms $(Y,\mathcal{G}) \to (X,\mathcal{F})$ to the set of di-homomorphisms $(\mathcal{A}(X), \mathcal{A}(\mathcal{F})) \to (\mathcal{A}(Y), \mathcal{A}(\mathcal{G}))$ (1.1.2 and 1.1.3) is bijective.*

The proof follows exactly the same lines as that of (1.2.7), using (I, 2.2.5) and (I, 2.2.4), and the details are left to the reader.

(1.4.2) Corollary. *If, in addition to the hypotheses of (1.4.1), we suppose Y affine over S, then, for (h,u) to be an isomorphism, it is necessary and sufficient that $(\mathcal{A}(h), \mathcal{A}(u))$ be a di-isomorphism.*

(1.4.3) Proposition. *For every pair $(\mathcal{B},\mathcal{M})$ consisting of a quasi-coherent $\mathcal{O}_S$-algebra $\mathcal{B}$ and a quasi-coherent $\mathcal{B}$-module $\mathcal{M}$ (as an $\mathcal{O}_S$-module or as a $\mathcal{B}$-module, which comes to the same thing (I, 9.6.1)), there exists a pair $(X,\mathcal{F})$ consisting of a prescheme X affine over S and a quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, such that $\mathcal{A}(X) = \mathcal{B}$ and $\mathcal{A}(\mathcal{F}) = \mathcal{M}$; moreover, this pair is determined up to a unique isomorphism.* [II | 10]

The uniqueness follows from (1.4.1) and (1.4.2); the existence is proved as in (1.3.1), and we again leave the details to the reader. We denote by $\widetilde{\mathcal{M}}$ the $\mathcal{O}_X$-module $\mathcal{F}$, and we say that it is *associated* to the quasi-coherent $\mathcal{B}$-module $\mathcal{M}$; for every affine open subset $U \subset S$, $\widetilde{\mathcal{M}}|p^{-1}(U)$ (where p is the structural morphism $X \to S$) is canonically isomorphic to $(\Gamma(U,\mathcal{M}))^{\sim}$.

(1.4.4) Corollary. *In the category of quasi-coherent $\mathcal{B}$-modules, $\widetilde{\mathcal{M}}$ is a covariant, additive and exact functor in $\mathcal{M}$, which commutes with inductive limits and with direct sums.*

Indeed, we are immediately reduced to the case where S is affine, and the corollary then follows from (I, 1.3.5), (I, 1.3.9) and (I, 1.3.11).

(1.4.5) Corollary. *Under the hypotheses of (1.4.3), for $\widetilde{\mathcal{M}}$ to be an $\mathcal{O}_X$-module of finite type, it is necessary and sufficient that $\mathcal{M}$ be a $\mathcal{B}$-module of finite type.*

We are immediately reduced to the case where $S = \mathrm{Spec}(A)$ is an affine scheme. Then $\mathcal{B} = \widetilde{B}$, where B is an A-algebra of finite type (I, 9.6.2), and $\mathcal{M} = \widetilde{M}$, where M is a B-module (I, 1.3.13); *on the prescheme X*, $\mathcal{O}_X$ is associated to the ring B and $\widetilde{\mathcal{M}}$ to the B-module M; for $\widetilde{\mathcal{M}}$ to be of finite type, it is therefore necessary and sufficient that M be of finite type (I, 1.3.13), whence our assertion.

(1.4.6) Proposition. *Let Y be a prescheme affine over S, and X, X' two preschemes affine over Y (hence also over S (1.3.5)). Let $\mathcal{B} = \mathcal{A}(Y)$, $\mathcal{A} = \mathcal{A}(X)$, $\mathcal{A}' = \mathcal{A}(X')$. Then $X \times_Y X'$ is affine over Y (hence also over S) and $\mathcal{A}(X \times_Y X')$ is canonically identified with $\mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$.*

Indeed (I, 9.6.1), $\mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$ is a quasi-coherent $\mathcal{B}$-algebra, hence also a quasi-coherent $\mathcal{O}_S$-algebra (I, 9.6.1); let Z be the spectrum of $\mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$ (1.3.1). The canonical $\mathcal{B}$-homomorphisms $\mathcal{A} \to \mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$ and $\mathcal{A}' \to \mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$ correspond (1.2.7) to Y-morphisms $p : Z \to X$ and $p' : Z \to X'$. To see that the triple (Z,p,p') is a product $X \times_Y X'$, we may restrict to the case where S is an affine scheme with ring C (I, 3.2.6.4). But then Y, X, X' are affine schemes (1.3.4) whose rings B, A, A' are C-algebras such that $\mathcal{B} = \widetilde{B}$, $\mathcal{A} = \widetilde{A}$, $\mathcal{A}' = \widetilde{A'}$. We then know (I, 1.3.13) that $\mathcal{A} \otimes_{\mathcal{B}} \mathcal{A}'$ is canonically identified with the $\mathcal{O}_S$-algebra $\widetilde{A \otimes_B A'}$, so the ring $A(Z)$ is identified with $A \otimes_B A'$ and the morphisms

p, p' correspond to the canonical homomorphisms $A \to A \otimes_B A'$, $A' \to A \otimes_B A'$. The proposition then follows from (I, 3.2.2).

(1.4.7) Corollary. *Let $\mathcal{F}$ (resp. $\mathcal{F}'$) be a quasi-coherent $\mathcal{O}_X$-module (resp. $\mathcal{O}_{X'}$-module); then $\mathcal{A}(\mathcal{F} \otimes_Y \mathcal{F}')$ is canonically identified with $\mathcal{A}(\mathcal{F}) \otimes_{\mathcal{A}(Y)} \mathcal{A}(\mathcal{F}')$.*

We know that $\mathcal{F} \otimes_Y \mathcal{F}'$ is quasi-coherent on $X \times_Y X'$ (I, 9.1.2). Let $g : Y \to S$, $f : X \to Y$, $f' : X' \to Y$ be the structural morphisms, so that the structural morphism
[II | 11] $h : Z \to S$ is equal to $g \circ f \circ p$ and to $g \circ f' \circ p'$. We define a canonical homomorphism

$$\mathcal{A}(\mathcal{F}) \otimes_{\mathcal{A}(Y)} \mathcal{A}(\mathcal{F}') \longrightarrow \mathcal{A}(\mathcal{F} \otimes_Y \mathcal{F}')$$

as follows: for every open subset $U \subset S$, we have canonical homomorphisms

$$\Gamma(f^{-1}(g^{-1}(U)), \mathcal{F}) \longrightarrow \Gamma(h^{-1}(U), p^*(\mathcal{F})) \quad \text{and} \quad \Gamma(f'^{-1}(g^{-1}(U)), \mathcal{F}') \longrightarrow \Gamma(h^{-1}(U), p'^*(\mathcal{F}')).$$

(0, 4.4.3), from which we deduce a canonical homomorphism

$$\Gamma(f^{-1}(g^{-1}(U)), \mathcal{F}) \otimes_{\Gamma(g^{-1}(U), \mathcal{O}_Y)} \Gamma(f'^{-1}(g^{-1}(U)), \mathcal{F}') \longrightarrow \Gamma(h^{-1}(U), p^*(\mathcal{F})) \otimes_{\Gamma(h^{-1}(U), \mathcal{O}_Z)} \Gamma(h^{-1}(U), p'^*(\mathcal{F}')).$$

To see that this indeed gives an isomorphism of $\mathcal{A}(Z)$-modules, we may restrict to the case where S (and consequently X, X', Y, $X \times_Y X'$) are affine schemes, and (with the notation of (1.4.6)), $\mathcal{F} = \widetilde{M}$, $\mathcal{F}' = \widetilde{M'}$, M (resp. M') being an A-module (resp. an A'-module). Then $\mathcal{F} \otimes_Y \mathcal{F}'$ is identified with the sheaf on $X \times_Y X'$ associated to the $(A \otimes_B A')$-module $M \otimes_B M'$ (I, 9.1.3), and the corollary follows from the canonical identification of the $\mathcal{O}_S$-modules $\widetilde{M \otimes_B M'}$ and $\widetilde{M} \otimes_{\widetilde{B}} \widetilde{M'}$ (where M, M' and B are regarded as C-modules) (I, 1.3.13 and I, 1.6.3).

If we apply (1.4.7) in particular to the case where $X = Y$ and $\mathcal{F}' = \mathcal{O}_{X'}$, we see that the $\mathcal{A}'$-module $\mathcal{A}(f'^*(\mathcal{F}))$ is identified with $\mathcal{A}(\mathcal{F}) \otimes_{\mathcal{B}} \mathcal{A}'$.

(1.4.8) In particular, when $X = X' = Y$ (X being affine over S), we see that if $\mathcal{F}$, $\mathcal{G}$ are two quasi-coherent $\mathcal{O}_X$-modules, we have

$$\mathcal{A}(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G}) = \mathcal{A}(\mathcal{F}) \otimes_{\mathcal{A}(X)} \mathcal{A}(\mathcal{G}) \tag{1.4.8.1}$$

up to canonical functorial isomorphism. If moreover $\mathcal{F}$ admits a finite presentation, it follows from (I, 1.6.3 and I, 1.3.12) that

$$\mathcal{A}(\mathcal{H}om_X(\mathcal{F}, \mathcal{G})) = \mathcal{H}om_{\mathcal{A}(X)}(\mathcal{A}(\mathcal{F}), \mathcal{A}(\mathcal{G})) \tag{1.4.8.2}$$

up to canonical isomorphism.

(1.4.9) Remark. If X, X' are two preschemes affine over S, the sum $X \sqcup X'$ is also affine over S, the sum of two affine schemes being an affine scheme.

(1.4.10) Proposition. *Let S be a prescheme, $\mathcal{B}$ a quasi-coherent $\mathcal{O}_S$-algebra, and $X = \mathrm{Spec}(\mathcal{B})$. For every quasi-coherent sheaf of ideals $\mathcal{J}$ of $\mathcal{B}$, $\widetilde{\mathcal{J}}$ is a quasi-coherent sheaf of ideals of $\mathcal{O}_X$, and the closed sub-prescheme Y of X defined by $\widetilde{\mathcal{J}}$ is canonically isomorphic to* $\mathrm{Spec}(\mathcal{B}/\mathcal{J})$.

Indeed, it follows immediately from (I, 4.2.3) that Y is affine over S; by virtue of (1.3.1), we are therefore reduced to the case where S is affine, and the proposition then follows immediately from (I, 4.1.2).

We can also express the result of (1.4.10) by saying that if $h : \mathcal{B} \to \mathcal{B}'$ is a *surjective* homomorphism of quasi-coherent $\mathcal{O}_S$-algebras, then ${}^a h : \mathrm{Spec}(\mathcal{B}') \to \mathrm{Spec}(\mathcal{B})$ is a *closed immersion.*

(1.4.11) Proposition. *Let S be a prescheme, $\mathcal{B}$ a quasi-coherent $\mathcal{O}_S$-algebra, and $X = \mathrm{Spec}(\mathcal{B})$. For every quasi-coherent ideal $\mathcal{K}$ of $\mathcal{O}_S$, we have (denoting by f the structural morphism $X \to S$) $f^*(\mathcal{K})\mathcal{O}_X = \widetilde{\mathcal{K}\mathcal{B}}$ up to canonical isomorphism.* [II | 12]

The question being local on S, we are reduced to the case where $S = \mathrm{Spec}(A)$ is affine, and in this case the proposition is none other than (I, 1.6.9).

1.5 Change of the base prescheme

(1.5.1) Proposition. *Let X be a prescheme affine over S. For every extension $g : S' \to S$ of the base prescheme, $X' = X_{(S')} = X \times_S S'$ is affine over S'.*

If f' is the projection $X' \to S'$, it suffices to prove that $f'^{-1}(U')$ is an affine open subset for every affine open subset U' of S' such that $g(U')$ is contained in an affine open subset U of S (1.2.1); we may therefore restrict to the case where S and S' are affine, and it suffices to prove that X' is then an affine scheme (1.3.4). But then (1.3.4) X is an affine scheme, and if A, A' and B are the rings of S, S' and X respectively, we know that X' is an affine scheme with ring $A' \otimes_A B$ (I, 3.2.2).

(1.5.2) Corollary. *Under the hypotheses of (1.5.1), let $f : X \to S$ be the structural morphism, and $f' : X' \to S'$, $g' : X' \to X$ the projections, so that the diagram*

$$\begin{array}{ccc} X & \xleftarrow{g'} & X' \\ \downarrow & & \downarrow{\scriptstyle f'} \\ S & \xleftarrow{g} & S' \end{array}$$

is commutative. For every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, there exists a canonical isomorphism of $\mathcal{O}_{S'}$-modules

$$u : g^*(f_*(\mathcal{F})) \xrightarrow{\sim} f'_*(g'^*(\mathcal{F})). \tag{1.5.2.1}$$

In particular, there exists a canonical isomorphism of $\mathcal{A}(X')$ onto $g^*(\mathcal{A}(X))$.

To define u, it suffices to define a homomorphism

$$v : f_*(\mathcal{F}) \longrightarrow g_*(f'_*(g'^*(\mathcal{F}))) = f_*(g'_*(g'^*(\mathcal{F})))$$

and to take $u = v^\sharp$ (0, 4.4.3). We will take $v = f_*(\rho)$, where ρ is the canonical homomorphism $\mathcal{F} \to g'_*(g'^*(\mathcal{F}))$ (0, 4.4.3). To prove that u is an isomorphism, we may restrict to the case where S and S', and hence X and X', are affine; with the notation of (1.5.1), we then have $\mathcal{F} = \widetilde{M}$, where M is a B-module. We then see immediately that $g^*(f_*(\mathcal{F}))$ and $f'_*(g'^*(\mathcal{F}))$ are both equal to the $\mathcal{O}_{S'}$-module associated to the A'-module $A' \otimes_A M$ (where M is regarded as an A-module), and that u is the homomorphism associated to the identity (I, 1.6.3, 1.6.5 and 1.6.7).

(1.5.3) Remark. One should beware of believing that (1.5.2) remains valid when X is no longer assumed to be affine over S, even when $S' = \mathrm{Spec}(k(s))$ ($s \in S$) and $S' \to S$ is the canonical morphism (I, 2.4.5) — in which case X' is none other than the *fibre* $f^{-1}(s)$ (I, 3.6.2). In other words, when X is not affine over S, the operation "direct image of quasi-coherent sheaves" does not commute with the operation of "passage to fibres". We will nevertheless see in Chapter III (III, 4.2.4) a result in this direction, of [II | 13]

an "asymptotic" nature, valid for *coherent* sheaves on X when f is proper (5.4) and S Noetherian.

(1.5.4) Corollary. *For every prescheme X affine over S and every $s \in S$, the fibre $f^{-1}(s)$ (where f denotes the structural morphism $X \to S$) is an affine scheme.*

It suffices to apply (1.5.1) to $S' = \mathrm{Spec}(k(s))$ and to use (1.3.4).

(1.5.5) Corollary. *Let X be an S-prescheme, and S' a prescheme affine over S; then $X' = X_{(S')}$ is a prescheme affine over X. Moreover, if $f : X \to S$ is the structural morphism, there is a canonical isomorphism of $\mathcal{O}_X$-algebras $\mathcal{A}(X') \xrightarrow{\sim} f^*(\mathcal{A}(S'))$, and, for every quasi-coherent $\mathcal{A}(S')$-module $\mathcal{M}$, a canonical di-isomorphism $f^*(\mathcal{M}) \xrightarrow{\sim} \mathcal{A}(f'^*(\widetilde{\mathcal{M}}))$, where we denote by $f' = f_{(S')}$ the structural morphism $X' \to S'$.*

It suffices to interchange the roles of X and S' in (1.5.1) and (1.5.2).

(1.5.6) Now let S, S' be two preschemes, $q : S' \to S$ a morphism, $\mathcal{B}$ (resp. $\mathcal{B}'$) a quasi-coherent $\mathcal{O}_S$-algebra (resp. $\mathcal{O}_{S'}$-algebra), and $u : \mathcal{B} \to \mathcal{B}'$ a q-morphism (that is, a homomorphism $\mathcal{B} \to q_*(\mathcal{B}')$ of $\mathcal{O}_S$-algebras). If $X = \mathrm{Spec}(\mathcal{B})$ and $X' = \mathrm{Spec}(\mathcal{B}')$, we canonically deduce from this a morphism

$$v = \mathrm{Spec}(u) : X' \to X$$

such that the diagram

$$\begin{array}{ccc} X' & \xrightarrow{v} & X \\ \downarrow & & \downarrow \\ S' & \xrightarrow[q]{} & S \end{array} \tag{1.5.6.1}$$

is commutative (the vertical arrows being the structural morphisms). Indeed, giving u is equivalent to giving a homomorphism of quasi-coherent $\mathcal{O}_{S'}$-algebras $u^\sharp : q^*(\mathcal{B}) \to \mathcal{B}'$ (0, 4.4.3); it therefore canonically defines an S'-morphism

$$w : \mathrm{Spec}(\mathcal{B}') \to \mathrm{Spec}(q^*(\mathcal{B}))$$

such that $\mathcal{A}(w) = u^\sharp$ (1.2.7). On the other hand, it follows from (1.5.2) that $\mathrm{Spec}(q^*(\mathcal{B}))$ is canonically identified with $X \times_S S'$; the morphism v is the composite $X' \xrightarrow{w} X \times_S S' \xrightarrow{p_1} X$ of w with the first projection, and the commutativity of (1.5.6.1) follows from the definitions. Let U (resp. U') be an affine open subset of S (resp. S') such that $q(U') \subset U$, $A = \Gamma(U, \mathcal{O}_S)$, $A' = \Gamma(U', \mathcal{O}_{S'})$ their rings, $B = \Gamma(U, \mathcal{B})$, $B' = \Gamma(U', \mathcal{B}')$; the restriction of u as a $(q|U')$-morphism $\mathcal{B}|U \to \mathcal{B}'|U'$ corresponds to a di-homomorphism of algebras $B \to B'$; if V, V' are the inverse images of U, U' in X, X' respectively under the structural morphisms, the morphism $V' \to V$ that is the restriction of v corresponds (I, 1.7.3) to the preceding di-homomorphism.

(1.5.7) Under the same hypotheses as in (1.5.6), let $\mathcal{M}$ be a quasi-coherent $\mathcal{B}$-module; there is then a canonical isomorphism of $\mathcal{O}_{X'}$-modules

$$v^*(\widetilde{\mathcal{M}}) \xrightarrow{\sim} (q^*(\mathcal{M}) \otimes_{q^*(\mathcal{B})} \mathcal{B}')^\sim \tag{1.5.7.1}$$

[II | 14] Indeed, the canonical isomorphism (1.5.2.1) provides a canonical isomorphism of $p_1^*(\widetilde{\mathcal{M}})$ onto the sheaf on $\mathrm{Spec}(q^*(\mathcal{B}))$ associated to the $q^*(\mathcal{B})$-module $q^*(\mathcal{M})$, and it then suffices to apply (1.4.7).

1.6 Affine morphisms

(1.6.1) We will say that a morphism $f : X \to Y$ of preschemes is *affine* if it defines X as a prescheme affine over Y. The properties of preschemes affine over another one translate as follows into this language:

(1.6.2) Proposition.

(i) *A closed immersion is affine.*

(ii) *The composite of two affine morphisms is affine.*

(iii) *If $f : X \to Y$ is an affine S-morphism, $f_{(S')} : X_{(S')} \to Y_{(S')}$ is affine for every extension $S' \to S$ of the base.*

(iv) *If $f : X \to Y$ and $f' : X' \to Y'$ are two affine S-morphisms,*

$$f \times_S f' : X \times_S X' \to Y \times_S Y'$$

is affine.

(v) *If $f : X \to Y$ and $g : Y \to Z$ are two morphisms such that $g \circ f$ is affine and g separated, then f is affine.*

(vi) *If f is affine, so is f_{red}.*

By virtue of (I, 5.5.12), it suffices to prove (i), (ii) and (iii). Now (i) is none other than Example (1.2.2), and (ii) is none other than (1.3.5); finally, (iii) follows from (1.5.1) since $X_{(S')}$ is identified with the product $X \times_Y Y_{(S')}$ (I, 3.3.11).

(1.6.3) Corollary. *If X is an affine scheme and Y a scheme, every morphism $X \to Y$ is affine.*

(1.6.4) Proposition. *Let Y be a locally Noetherian prescheme, and $f : X \to Y$ a morphism of finite type. For f to be affine, it is necessary and sufficient that f_{red} be so.*

In view of (1.6.2, (vi)), we only have to prove the sufficiency of the condition. It suffices to prove that if Y is affine and Noetherian, X is affine; now Y_{red} is then affine, so the same is true of X_{red}, by hypothesis. Now, X is Noetherian, so the conclusion follows from (I, 6.1.7).

1.7 Vector bundle associated to a sheaf of modules

(1.7.1) Let A be a ring and E an A-module. Recall that the *symmetric algebra* on E, denoted by $\mathbf{S}(E)$ (or $\mathbf{S}_A(E)$), is the quotient algebra of the tensor algebra $\mathbf{T}(E)$ by the two-sided ideal generated by the elements $x \otimes y - y \otimes x$, where x, y run through E. The algebra $\mathbf{S}(E)$ is characterized by the following universal property: if σ is the canonical map $E \to \mathbf{S}(E)$ (obtained by composing $E \to \mathbf{T}(E)$ with the canonical map $\mathbf{T}(E) \to \mathbf{S}(E)$), every A-linear map $E \to B$, where B is a *commutative* A-algebra, factors uniquely as $E \xrightarrow{\sigma} \mathbf{S}(E) \xrightarrow{g} B$, where g is an A-homomorphism *of algebras*. We deduce immediately from this characterization that for two A-modules E, F, we have

$$\mathbf{S}(E \oplus F) = \mathbf{S}(E) \otimes \mathbf{S}(F)$$

[II | 15] up to canonical isomorphism; moreover, $\mathbf{S}(E)$ is a covariant functor in E, from the category of A-modules to that of commutative A-algebras; finally, the preceding characterization also shows that if $E = \varinjlim E_\lambda$, we have $\mathbf{S}(E) = \varinjlim \mathbf{S}(E_\lambda)$ up to canonical isomorphism. By abuse of language, a product $\sigma(x_1)\sigma(x_2)\cdots\sigma(x_n)$, where the $x_i \in E$, is often written $x_1x_2\cdots x_n$ if no confusion results. The algebra $\mathbf{S}(E)$ is *graded*, $\mathbf{S}_n(E)$ being the set of linear combinations of products of n elements of E ($n \geq 0$); the algebra $\mathbf{S}(A)$ is canonically isomorphic to the polynomial algebra $A[T]$ in one indeterminate, and the algebra $\mathbf{S}(A^n)$ to the polynomial algebra in n indeterminates $A[T_1, \ldots, T_n]$.

(1.7.2) Let φ be a ring homomorphism $A \to B$. If F is a B-module, the canonical map $F \to \mathbf{S}(F)$ gives a canonical map $F_{[\varphi]} \to \mathbf{S}(F)_{[\varphi]}$, which therefore factors as $F_{[\varphi]} \to \mathbf{S}(F_{[\varphi]}) \to \mathbf{S}(F)_{[\varphi]}$; the canonical homomorphism $\mathbf{S}(F_{[\varphi]}) \to \mathbf{S}(F)_{[\varphi]}$ is surjective, but not necessarily bijective. If E is an A-module, every di-homomorphism $E \to F$ (that is, every A-homomorphism $E \to F_{[\varphi]}$) therefore canonically gives an A-homomorphism of algebras $\mathbf{S}(E) \to \mathbf{S}(F_{[\varphi]}) \to \mathbf{S}(F)_{[\varphi]}$, that is, a di-homomorphism of algebras $\mathbf{S}(E) \to \mathbf{S}(F)$.

With the same notation, for every A-module E, $\mathbf{S}(E \otimes_A B)$ is canonically identified with the algebra $\mathbf{S}(E) \otimes_A B$; this follows immediately from the universal property of $\mathbf{S}(E)$ (1.7.1).

(1.7.3) Let R be a multiplicative subset of the ring A; applying (1.7.2) to the ring $B = R^{-1}A$, and recalling that $R^{-1}E = E \otimes_A R^{-1}A$, we see that we have $\mathbf{S}(R^{-1}E) = R^{-1}\mathbf{S}(E)$ up to canonical isomorphism. Moreover, if $R' \supset R$ is a second multiplicative subset of A, the diagram

$$\begin{array}{ccc} R^{-1}E & \longrightarrow & R'^{-1}E \\ \downarrow & & \downarrow \\ \mathbf{S}(R^{-1}E) & \longrightarrow & \mathbf{S}(R'^{-1}E) \end{array}$$

is commutative.

(1.7.4) Now let $(S, \mathcal{A})$ be a ringed space, and let $\mathcal{E}$ be an $\mathcal{A}$-module on S. If to every open subset $U \subset S$ we associate the $\Gamma(U, \mathcal{A})$-module $\mathbf{S}(\Gamma(U, \mathcal{E}))$, we define (in view of the functorial character of $\mathbf{S}(E)$ (1.7.2)) a presheaf of algebras; we say that the associated sheaf, which we denote by $\mathbf{S}(\mathcal{E})$ or $\mathbf{S}_{\mathcal{A}}(\mathcal{E})$, is the *symmetric* $\mathcal{A}$-algebra of the $\mathcal{A}$-module $\mathcal{E}$. It follows immediately from (1.7.1) that $\mathbf{S}(\mathcal{E})$ is the solution of a universal problem: every homomorphism of $\mathcal{A}$-modules $\mathcal{E} \to \mathcal{B}$, where $\mathcal{B}$ is a commutative $\mathcal{A}$-algebra, factors in exactly one way as $\mathcal{E} \to \mathbf{S}(\mathcal{E}) \to \mathcal{B}$, the second arrow being a homomorphism of $\mathcal{A}$-algebras. There is therefore a bijective correspondence between homomorphisms $\mathcal{E} \to \mathcal{B}$ of $\mathcal{A}$-modules and homomorphisms $\mathbf{S}(\mathcal{E}) \to \mathcal{B}$ of $\mathcal{A}$-algebras. In particular, every homomorphism $u : \mathcal{E} \to \mathcal{F}$ of $\mathcal{A}$-modules defines a homomorphism $\mathbf{S}(u) : \mathbf{S}(\mathcal{E}) \to \mathbf{S}(\mathcal{F})$ of $\mathcal{A}$-algebras, and $\mathbf{S}(\mathcal{E})$ is therefore a covariant functor in $\mathcal{E}$.

[II | 16] By virtue of (1.7.2) and of the commutation of $\mathbf{S}$ with inductive limits, we have $(\mathbf{S}(\mathcal{E}))_s = \mathbf{S}(\mathcal{E}_s)$ for every point $s \in S$. If $\mathcal{E}$, $\mathcal{F}$ are two $\mathcal{A}$-modules, $\mathbf{S}(\mathcal{E} \oplus \mathcal{F})$ is canonically identified with $\mathbf{S}(\mathcal{E}) \otimes_{\mathcal{A}} \mathbf{S}(\mathcal{F})$, as one sees on the corresponding presheaves.

Note also that $\mathbf{S}(\mathcal{E})$ is a graded $\mathcal{A}$-algebra, the infinite direct sum of the $\mathbf{S}_n(\mathcal{E})$, where the $\mathcal{A}$-module $\mathbf{S}_n(\mathcal{E})$ is the sheaf associated to the presheaf $U \mapsto \mathbf{S}_n(\Gamma(U, \mathcal{E}))$. If in particular we take $\mathcal{E} = \mathcal{A}$, we see that $\mathbf{S}_{\mathcal{A}}(\mathcal{A})$ is identified with $\mathcal{A}[T] = \mathcal{A} \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (T an indeterminate, $\mathbf{Z}$ being regarded as a simple sheaf).

(1.7.5) Let $(T, \mathcal{B})$ be a second ringed space and f a morphism $(S, \mathcal{A}) \to (T, \mathcal{B})$. If $\mathcal{F}$ is a $\mathcal{B}$-module, $\mathbf{S}(f^*(\mathcal{F}))$ is canonically identified with $f^*(\mathbf{S}(\mathcal{F}))$; indeed, if $f = (\psi, \theta)$, we

have by definition (0, 4.3.1)

$$\mathbf{S}(f^*(\mathcal{F})) = \mathbf{S}(\psi^*(\mathcal{F}) \otimes_{\psi^*(\mathcal{B})} \mathcal{A}) = \mathbf{S}(\psi^*(\mathcal{F})) \otimes_{\psi^*(\mathcal{B})} \mathcal{A}$$

(1.7.2); for every open subset U of S and every section h of $\mathbf{S}(\psi^*(\mathcal{F}))$ over U, h coincides, in a neighbourhood V of each point $s \in U$, with an element of $\mathbf{S}(\Gamma(V, \psi^*(\mathcal{F})))$; if we refer to the definition of $\psi^*(\mathcal{F})$ (0, 3.7.1) and take into account that every element of $\mathbf{S}(E)$, for a module E, is a linear combination of finitely many products of elements of E, we see that there are a neighbourhood W of $\psi(s)$ in T, a section h' of $\mathbf{S}(\mathcal{F})$ over W and a neighbourhood $V' \subset V \cap \psi^{-1}(W)$ of s such that h coincides with $t \mapsto h'(\psi(t))$ over V'; whence our assertion.

(1.7.6) Proposition. *Let A be a ring, $S = \mathrm{Spec}(A)$ its prime spectrum, and $\mathcal{E} = \widetilde{M}$ the $\mathcal{O}_S$-module associated to an A-module M; then the $\mathcal{O}_S$-algebra $\mathbf{S}(\mathcal{E})$ is associated to the A-algebra $\mathbf{S}(M)$.*

Proof. Indeed, for every $f \in A$, $\mathbf{S}(M_f) = (\mathbf{S}(M))_f$ (1.7.3), and the proposition therefore follows from the definitions (I, 1.3.4). □

(1.7.7) Corollary. *If S is a prescheme and $\mathcal{E}$ a quasi-coherent $\mathcal{O}_S$-module, the $\mathcal{O}_S$-algebra $\mathbf{S}(\mathcal{E})$ is quasi-coherent. If moreover $\mathcal{E}$ is of finite type, each of the $\mathcal{O}_S$-modules $\mathbf{S}_n(\mathcal{E})$ is of finite type.*

Proof. The first assertion is an immediate consequence of (1.7.6) and (I, 1.4.1); the second follows from the fact that, if E is an A-module of finite type, $\mathbf{S}_n(E)$ is an A-module of finite type; we then apply (I, 1.3.13). □

(1.7.8) Definition. Let $\mathcal{E}$ be a quasi-coherent $\mathcal{O}_S$-module. We call *vector bundle over S defined by $\mathcal{E}$*, and denote by $\mathbf{V}(\mathcal{E})$, the spectrum (1.3.1) of the quasi-coherent $\mathcal{O}_S$-algebra $\mathbf{S}(\mathcal{E})$.

By virtue of (1.2.7), for every S-prescheme X, there is a canonical bijective correspondence between the S-morphisms $X \to \mathbf{V}(\mathcal{E})$ and the homomorphisms of $\mathcal{O}_S$-algebras $\mathbf{S}(\mathcal{E}) \to \mathcal{A}(X)$, hence also between these S-morphisms and the homomorphisms of $\mathcal{O}_S$-modules $\mathcal{E} \to \mathcal{A}(X) = f_*(\mathcal{O}_X)$ (where f is the structural morphism $X \to S$). In particular:

(1.7.9) Take for X a sub-prescheme induced by S on an open subset $U \subset S$. Then the S-morphisms $U \to \mathbf{V}(\mathcal{E})$ are none other than the U-sections (I, 2.5.5) of the U-prescheme induced by $\mathbf{V}(\mathcal{E})$ on the open subset $p^{-1}(U)$ (where p is the structural morphism $\mathbf{V}(\mathcal{E}) \to S$). By what we have just seen, these U-sections correspond bijectively to the homomorphisms of $\mathcal{O}_S$-modules $\mathcal{E} \to j_*(\mathcal{O}_S|U)$ (where j is the canonical injection $U \to S$), or,
what amounts to the same (0, 4.4.3), to the $(\mathcal{O}_S|U)$-homomorphisms $j^*(\mathcal{E}) = \mathcal{E}|U \to$ [II | 17]
$\mathcal{O}_S|U$. Moreover, it is immediate that to the restriction to an open subset $U' \subset U$ of an S-morphism $U \to \mathbf{V}(\mathcal{E})$ there corresponds the restriction to U' of the corresponding homomorphism $\mathcal{E}|U \to \mathcal{O}_S|U$. We conclude that *the sheaf of germs of S-sections* of $\mathbf{V}(\mathcal{E})$ is canonically identified with the *dual* $\check{\mathcal{E}}$ of $\mathcal{E}$.

In particular, if we take $X = U = S$, to the *zero* homomorphism $\mathcal{E} \to \mathcal{O}_S$ there corresponds a canonical S-section of $\mathbf{V}(\mathcal{E})$, called the *zero S-section* (cf. (8.3.3)).

(1.7.10) Now take for X the spectrum $\{\xi\}$ of a field K; the structural morphism $f : X \to S$ therefore corresponds to a monomorphism $k(s) \to K$, where $s = f(\xi)$ (I,

2.4.6); the S-morphisms $\{\xi\} \to \mathbf{V}(\mathcal{E})$ are therefore none other than the *geometric points of* $\mathbf{V}(\mathcal{E})$ *with values in the extension* K *of* $k(s)$ (I, 3.4.5), points which are localized at the points of $p^{-1}(s)$. The set of these points, which we may also call *the geometric fibre rational over* K *of* $\mathbf{V}(\mathcal{E})$ *above the point* s, is identified by (1.7.8) with the set of homomorphisms of $\mathcal{O}_S$-modules $\mathcal{E} \to f_*(\mathcal{O}_X)$, or, what amounts to the same (0, 4.4.3), with the set of homomorphisms of $\mathcal{O}_X$-modules $f^*(\mathcal{E}) \to \mathcal{O}_X = K$. But by definition (0, 4.3.1) we have $f^*(\mathcal{E}) = \mathcal{E}_s \otimes_{\mathcal{O}_s} K = \mathcal{E}^s \otimes_{k(s)} K$, setting $\mathcal{E}^s = \mathcal{E}_s/\mathfrak{m}_s\mathcal{E}_s$; the geometric fibre of $\mathbf{V}(\mathcal{E})$ rational over K above s is therefore identified with the *dual* of the K*-vector space* $\mathcal{E}^s \otimes_{k(s)} K$; if $\mathcal{E}^s$ or K is of finite dimension over $k(s)$, this dual is also identified with $(\mathcal{E}^s)^\vee \otimes_{k(s)} K$, where $(\mathcal{E}^s)^\vee$ denotes the dual of the $k(s)$-vector space $\mathcal{E}^s$.

(1.7.11) Proposition.

(i) $\mathbf{V}(\mathcal{E})$ *is a contravariant functor in* $\mathcal{E}$ *from the category of quasi-coherent* $\mathcal{O}_S$*-modules to the category of affine* S*-schemes.*

(ii) *If* $\mathcal{E}$ *is an* $\mathcal{O}_S$*-module of finite type,* $\mathbf{V}(\mathcal{E})$ *is of finite type over* S*.*

(iii) *If* $\mathcal{E}$ *and* $\mathcal{F}$ *are two quasi-coherent* $\mathcal{O}_S$*-modules,* $\mathbf{V}(\mathcal{E} \oplus \mathcal{F})$ *is canonically identified with* $\mathbf{V}(\mathcal{E}) \times_S \mathbf{V}(\mathcal{F})$*.*

(iv) *Let* $g : S' \to S$ *be a morphism; for every quasi-coherent* $\mathcal{O}_S$*-module* $\mathcal{E}$*,* $\mathbf{V}(g^*(\mathcal{E}))$ *is canonically identified with* $\mathbf{V}(\mathcal{E})_{(S')} = \mathbf{V}(\mathcal{E}) \times_S S'$*.*

(v) *To a surjective homomorphism* $\mathcal{E} \to \mathcal{F}$ *of quasi-coherent* $\mathcal{O}_S$*-modules there corresponds a closed immersion* $\mathbf{V}(\mathcal{F}) \to \mathbf{V}(\mathcal{E})$*.*

Proof. (i) is an immediate consequence of (1.2.7), taking into account that every homomorphism of $\mathcal{O}_S$-modules $\mathcal{E} \to \mathcal{F}$ canonically defines a homomorphism of $\mathcal{O}_S$-algebras $\mathbf{S}(\mathcal{E}) \to \mathbf{S}(\mathcal{F})$. (ii) follows immediately from the definitions (I, 6.3.1) and from the fact that if E is an A-module of finite type, $\mathbf{S}(E)$ is an A-algebra of finite type. To prove (iii), it suffices to start from the canonical isomorphism $\mathbf{S}(\mathcal{E} \oplus \mathcal{F}) \simeq \mathbf{S}(\mathcal{E}) \otimes_{\mathcal{O}_S} \mathbf{S}(\mathcal{F})$ (1.7.4) and to apply (1.4.6). Similarly, to prove (iv), it suffices to start from the canonical isomorphism $\mathbf{S}(g^*(\mathcal{E})) \simeq g^*(\mathbf{S}(\mathcal{E}))$ (1.7.5) and to apply (1.5.2). Finally, to establish (v), it suffices to remark that if the homomorphism $\mathcal{E} \to \mathcal{F}$ is surjective, so is the corresponding homomorphism $\mathbf{S}(\mathcal{E}) \to \mathbf{S}(\mathcal{F})$ of $\mathcal{O}_S$-algebras, and the conclusion follows from (1.4.10). □

(1.7.12) Take in particular $\mathcal{E} = \mathcal{O}_S$; the prescheme $\mathbf{V}(\mathcal{O}_S)$ is the affine S-scheme which is the spectrum of the $\mathcal{O}_S$-algebra $\mathbf{S}(\mathcal{O}_S)$, and the latter is identified with the $\mathcal{O}_S$-algebra
[II | 18] $\mathcal{O}_S[T] = \mathcal{O}_S \otimes_{\mathbf{Z}} \mathbf{Z}[T]$ (T an indeterminate); this is evident when $S = \mathrm{Spec}(\mathbf{Z})$, by virtue of (1.7.6), and we pass from there to the general case by considering the structural morphism $S \to \mathrm{Spec}(\mathbf{Z})$ and using (1.7.11, (iv)). Because of this result, we also set $\mathbf{V}(\mathcal{O}_S) = S[T]$, and we therefore have the formula

$$S[T] = S \otimes_{\mathbf{Z}} \mathbf{Z}[T]. \tag{1.7.12.1}$$

The identification of the sheaf of germs of S-sections of $S[T]$ with $\mathcal{O}_S$, already seen in (I, 3.3.15), is recovered here in a more general context, as a particular case of (1.7.9).

(1.7.13) For every S-prescheme X, we have seen (1.7.8) that $\mathrm{Hom}_S(X, S[T])$ is canonically identified with $\mathrm{Hom}_{\mathcal{O}_S}(\mathcal{O}_S, \mathcal{A}(X))$, which is canonically isomorphic to $\Gamma(S, \mathcal{A}(X))$,

and is consequently endowed with a ring structure; moreover, to every S-morphism $h : X \to Y$ there corresponds a morphism $\Gamma(\mathcal{A}(h)) : \Gamma(S, \mathcal{A}(Y)) \to \Gamma(S, \mathcal{A}(X))$ for the ring structures (1.1.2). When we endow $\mathrm{Hom}_S(X, S[T])$ with the ring structure thus defined, we therefore see that we can regard $\mathrm{Hom}_S(X, S[T])$ as a *contravariant functor in* X, from the category of S-preschemes to that of rings. On the other hand, $\mathrm{Hom}_S(X, \mathbf{V}(\mathcal{E}))$ is likewise identified with $\mathrm{Hom}_{\mathcal{O}_S}(\mathcal{E}, \mathcal{A}(X))$ (where $\mathcal{A}(X)$ is regarded as an $\mathcal{O}_S$*-module*); we can consequently endow it canonically with a structure of *module* over the ring $\mathrm{Hom}_S(X, S[T])$, and we see as above that the pair

$$(\mathrm{Hom}_S(X, S[T]), \mathrm{Hom}_S(X, \mathbf{V}(\mathcal{E})))$$

is a contravariant functor in X, with values in the category whose elements are the pairs (A, M) consisting of a ring A and an A-module M, the morphisms being the di-homomorphisms.

We will interpret these facts by saying that $S[T]$ is an S*-scheme of rings* and that $\mathbf{V}(\mathcal{E})$ is an S*-scheme of modules* over the S-scheme of rings $S[T]$ (cf. chap. 0, §8).

(1.7.14) We will see that the structure of S-scheme of modules defined on the S-scheme $\mathbf{V}(\mathcal{E})$ makes it possible to reconstruct the $\mathcal{O}_S$-module $\mathcal{E}$ up to unique isomorphism: to this end, we will show that $\mathcal{E}$ is canonically isomorphic to a sub-$\mathcal{O}_S$-module of $\mathbf{S}(\mathcal{E}) = \mathcal{A}(\mathbf{V}(\mathcal{E}))$ defined by means of this structure. Indeed (1.7.4), the set $\mathrm{Hom}_{\mathcal{O}_S}(\mathbf{S}(\mathcal{E}), \mathcal{A}(X))$ of homomorphisms of $\mathcal{O}_S$*-algebras* is canonically identified with $\mathrm{Hom}_{\mathcal{O}_S}(\mathcal{E}, \mathcal{A}(X))$, a set of homomorphisms of $\mathcal{O}_S$*-modules*: if h, h' are two elements of the latter set, s_i $(1 \leq i \leq n)$ sections of $\mathcal{E}$ over an open subset $U \subset S$, and t a section of $\mathcal{A}(X)$ over U, we have by definition

$$(h + h')(s_1 s_2 \cdots s_n) = \prod_{i=1}^{n} (h(s_i) + h'(s_i))$$

and

$$(t.h)(s_1 s_2 \cdots s_n) = t^n \prod_{i=1}^{n} h(s_i).$$

This being so, if z is a section of $\mathbf{S}(\mathcal{E})$ over U, $h \mapsto h(z)$ is a map from $\mathrm{Hom}_S(X, \mathbf{V}(\mathcal{E})) = \mathrm{Hom}_{\mathcal{O}_S}(\mathbf{S}(\mathcal{E}), \mathcal{A}(X))$ to $\Gamma(U, \mathcal{A}(X))$. We will show that $\mathcal{E}$ is identified [II | 19] with the submodule of $\mathbf{S}(\mathcal{E})$ such that, *for every open subset $U \subset S$, every section z of this sub-$\mathcal{O}_S$-module over U and every S-prescheme X, the map $h \mapsto h(z)$ from $\mathrm{Hom}_{\mathcal{O}_S|U}(\mathbf{S}(\mathcal{E})|U, \mathcal{A}(X)|U)$ to $\Gamma(U, \mathcal{A}(X))$ is a homomorphism of $\Gamma(U, \mathcal{A}(X))$-modules.*

It is indeed immediate that $\mathcal{E}$ has this property; to prove the converse, we may restrict to proving that when $S = \mathrm{Spec}(A)$, $\mathcal{E} = \widetilde{M}$, a section z of $\mathbf{S}(\mathcal{E})$ over S which (for $U = S$) has the property stated above is necessarily a section of $\mathcal{E}$; we then have $z = \sum_{n=0}^{\infty} z_n$, where $z_n \in \mathbf{S}_n(M)$, and we must prove that $z_n = 0$ for $n \neq 1$. Set $B = \mathbf{S}(M)$ and take for X the prescheme $\mathrm{Spec}(B[T])$, where T is an indeterminate. The set $\mathrm{Hom}_{\mathcal{O}_S}(\mathbf{S}(\mathcal{E}), \mathcal{A}(X))$ is identified with the set of ring homomorphisms $h : B \to B[T]$ (I, 1.3.13), and by what we saw above, we have $(T.h)(z) = \sum_{n=0}^{\infty} T^n h(z_n)$: the hypothesis on z implies that $\sum_{n=0}^{\infty} T^n h(z_n) = T. \sum_{n=0}^{\infty} h(z_n)$ for every homomorphism h. Taking in particular for h the canonical injection, we get $\sum_{n=0}^{\infty} T^n z_n = T. \sum_{n=0}^{\infty} z_n$, which indeed implies the conclusion $z_n = 0$ for $n \neq 1$.

(1.7.15) Proposition. *Let Y be a prescheme whose underlying space is Noetherian, or a quasi-compact scheme. Every affine Y-scheme X of finite type over Y is Y-isomorphic to a closed sub-Y-scheme of a Y-scheme of the form $\mathbf{V}(\mathcal{E})$, where $\mathcal{E}$ is a quasi-coherent $\mathcal{O}_Y$-module of finite type.*

Proof. Indeed, the quasi-coherent $\mathcal{O}_Y$-algebra $\mathcal{A}(X)$ is of finite type (1.3.7). The hypotheses made imply that $\mathcal{A}(X)$ is generated by a quasi-coherent sub-$\mathcal{O}_Y$-module of finite type $\mathcal{E}$ (I, 9.6.5); by definition, this implies that the canonical homomorphism $\mathbf{S}(\mathcal{E}) \to \mathcal{A}(X)$ canonically extending the injection $\mathcal{E} \to \mathcal{A}(X)$ is *surjective*; the conclusion then follows from (1.4.10). □

§2 Homogeneous prime spectra

2.1 Generalities on graded rings and modules.

(2.1.1) Notation. Given a ring S *graded* in positive degrees, we denote by S_n the subset of S consisting of the homogeneous elements of degree n ($n \geq 0$), and by S_+ the (direct) sum of the S_n such that $n > 0$; we have $1 \in S_0$, S_0 is a subring of S, S_+ is a graded ideal of S, and S is the direct sum of S_0 and S_+. If M is a *graded module* over S (with positive or negative degrees), we similarly denote by M_n the S_0-module consisting of the homogeneous elements of degree n of M (with $n \in \mathbf{Z}$).

For every integer $d > 0$, we denote by $S^{(d)}$ the direct sum of the S_{nd}; regarding the elements of S_{nd} as homogeneous of degree n, the S_{nd} define a graded ring structure on $S^{(d)}$.

[II | 20] For every integer k such that $0 \leq k \leq d-1$, we denote by $M^{(d,k)}$ the direct sum of the M_{nd+k} ($n \in \mathbf{Z}$); it is a graded $S^{(d)}$-module when the elements of M_{nd+k} are regarded as homogeneous of degree n. We write $M^{(d)}$ instead of $M^{(d,0)}$.

With the preceding notation, for every integer n (positive or negative), we denote by $M(n)$ the graded S-module defined by $(M(n))_k = M_{n+k}$ for every $k \in \mathbf{Z}$. In particular, $S(n)$ will be a graded S-module such that $(S(n))_k = S_{n+k}$, with the convention $S_n = 0$ for $n < 0$. We say that a graded S-module M is *free* if it is isomorphic, as a *graded module*, to a direct sum of modules of the form $S(n)$; since $S(n)$ is a monogenic S-module, generated by the element 1 of S regarded as an element of degree $-n$, it amounts to the same to say that M admits a *basis* over S consisting of *homogeneous* elements.

We say that a graded S-module M *admits a finite presentation* if there exists an exact sequence $P \to Q \to M \to 0$, where P and Q are finite direct sums of modules of the form $S(n)$ and the homomorphisms are of degree 0 (cf. (2.1.2)).

(2.1.2) Let M, N be two graded S-modules; we define on $M \otimes_S N$ a structure of *graded* S-module as follows. On the tensor product $M \otimes_{\mathbf{Z}} N$, we can define a structure of graded $\mathbf{Z}$-module (where $\mathbf{Z}$ is graded by $\mathbf{Z}_0 = \mathbf{Z}$, $\mathbf{Z}_n = 0$ for $n \neq 0$) by setting

$$(M \otimes_{\mathbf{Z}} N)_q = \bigoplus_{m+n=q} M_m \otimes_{\mathbf{Z}} N_n$$

(since M and N are the direct sums of the M_m and of the N_n respectively, we know that $M \otimes_{\mathbf{Z}} N$ can be canonically identified with the direct sum of all the $M_m \otimes_{\mathbf{Z}} N_n$). This being so, we have $M \otimes_S N = (M \otimes_{\mathbf{Z}} N)/P$, where P is the sub-$\mathbf{Z}$-module of $M \otimes_{\mathbf{Z}} N$ generated by the elements $(xs) \otimes y - x \otimes (sy)$ for $x \in M$, $y \in N$, $s \in S$; it is clear that P is a *graded* sub-$\mathbf{Z}$-module of $M \otimes_{\mathbf{Z}} N$, and we see immediately that passing to the quotient indeed gives a structure of graded S-module on $M \otimes_S N$.

For two graded S-modules M, N, recall that a homomorphism $u : M \to N$ of S-modules is said to be *of degree* k if $u(M_j) \subset N_{j+k}$ for every $j \in \mathbf{Z}$. If H_n denotes the set of all homomorphisms of degree n from M to N, we denote by $\mathrm{Hom}_S(M,N)$ the (direct) *sum* of the H_n ($n \in \mathbf{Z}$) in the S-module H of all homomorphisms (of S-modules) from M to N; in general $\mathrm{Hom}_S(M,N)$ is not equal to the latter. However, we have

$H = \mathrm{Hom}_S(M, N)$ when M is *of finite type*; indeed, we may then suppose M generated by finitely many homogeneous elements x_i $(1 \leq i \leq n)$, and every homomorphism $u \in H$ can be written in exactly one way as $\sum_{k\in\mathbf{Z}} u_k$, where for each k, $u_k(x_i)$ is equal to the homogeneous component of degree $k + \deg(x_i)$ of $u(x_i)$ $(1 \leq i \leq n)$, which implies $u_k = 0$ except for finitely many indices; by definition we have $u_k \in H_k$, whence the conclusion.

We say that the elements of degree 0 of $\mathrm{Hom}_S(M, N)$ are *homomorphisms of graded S-modules*. It is clear that $S_m H_n \subset H_{m+n}$, so the H_n define a structure of graded S-module on $\mathrm{Hom}_S(M, N)$.

It follows immediately from these definitions that we have

$$M(m) \otimes_S N(n) = (M \otimes_S N)(m + n), \tag{2.1.2.1}$$

$$\mathrm{Hom}_S(M(m), N(n)) = (\mathrm{Hom}_S(M, N))(n - m) \tag{2.1.2.2}$$

for two graded S-modules M, N. Let S, S' be two graded rings; a homomorphism of [II | 21] *graded rings* $\varphi : S \to S'$ is a ring homomorphism such that $\varphi(S_n) \subset S'_n$ for every $n \in \mathbf{Z}$ (in other words, φ must be a homomorphism *of degree* 0 of graded $\mathbf{Z}$-modules). Such a homomorphism defines on S' a structure of *graded* S-module; endowed with this structure and with its graded ring structure, S' is said to be a *graded S-algebra*.

If then M is a graded S-module, the tensor product $M \otimes_S S'$ of graded S-modules is naturally endowed with a structure of *graded* S'-module, the grading being the one defined above.

(2.1.3) Lemma. *Let S be a ring graded in positive degrees. For a subset E of S_+ consisting of homogeneous elements to generate S_+ as an S-module, it is necessary and sufficient that E generate S as an S_0-algebra.*

Proof. The condition is evidently sufficient; let us show that it is necessary. Let E_n (resp. E^n) be the set of elements of E of degree equal to n (resp. $\leq n$); it will suffice to show, by induction on $n > 0$, that S_n is the S_0-module generated by the elements of degree n which are products of elements of E^n. Now this is evident for $n = 1$ by virtue of the hypothesis; the latter moreover shows that $S_n = \sum_{p=0}^{n-1} S_p E_{n-p}$, and the induction argument is then immediate. □

(2.1.4) Corollary. *For S_+ to be an ideal of finite type, it is necessary and sufficient that S be an S_0-algebra of finite type.*

Proof. Indeed, we can always suppose that a finite system of generators of the S_0-algebra S (resp. of the S-ideal S_+) consists of homogeneous elements, by replacing each of the generators considered by its homogeneous components. □

(2.1.5) Corollary. *For S to be Noetherian, it is necessary and sufficient that S_0 be Noetherian and that S be an S_0-algebra of finite type.*

Proof. The condition is evidently sufficient; it is necessary, since S_0 is isomorphic to S/S_+ and S_+ must be an ideal of finite type (2.1.4). □

(2.1.6) Lemma. *Let S be a ring graded in positive degrees which is an S_0-algebra of finite type. Let M be a graded S-module of finite type. Then:*

(i) *The M_n are S_0-modules of finite type, and there exists an integer n_0 such that $M_n = 0$ for $n \leq n_0$.*

(ii) *There exist an integer n_1 and an integer $h > 0$ such that, for every integer $n \geq n_1$, we have $M_{n+h} = S_h M_n$.*

(iii) *For every pair of integers (d, k) such that $d > 0$, $0 \leq k \leq d-1$, $M^{(d,k)}$ is an $S^{(d)}$-module of finite type.*

(iv) *For every integer $d > 0$, $S^{(d)}$ is an S_0-algebra of finite type.*

(v) *There exists an integer $h > 0$ such that $S_{mh} = (S_h)^m$ for every $m > 0$.*

(vi) *For every integer $n > 0$, there exists an integer m_0 such that $S_m \subset S_+^n$ for every $m \geq m_0$.*

Proof. We may suppose S generated (as an S_0-algebra) by homogeneous elements f_i of degree h_i $(1 \leq i \leq r)$, and M generated (as an S-module) by homogeneous elements x_j
[II | 22] of degree k_j $(1 \leq j \leq s)$. It is clear that M_n consists of the linear combinations, with coefficients in S_0, of the elements $f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ such that the α_i are integers ≥ 0 satisfying $k_j + \sum_i \alpha_i h_i = n$; for each j, there are only finitely many systems (α_i) satisfying this equation, since the h_i are > 0, whence the first assertion of (i); the second is evident. On the other hand, let h be the l.c.m. of the h_i and set $g_i = f_i^{h/h_i}$ $(1 \leq i \leq r)$, so that all the g_i are of degree h; let z_μ be the elements of M of the form $f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ with $0 \leq \alpha_i < h/h_i$ for $1 \leq i \leq r$; these elements are finite in number; let n_1 be the largest of their degrees. It is clear that for $n \geq n_1$, every element of M_{n+h} is a linear combination of the z_μ whose coefficients are monomials of degree > 0 in the g_i, hence we have $M_{n+h} = S_h M_n$, which establishes (ii). In the same way, we see (for every $d > 0$) that an element of $M^{(d,k)}$ is a linear combination, with coefficients in S_0, of elements of the form $g^d f_1^{\alpha_1} \cdots f_r^{\alpha_r} x_j$ with $0 \leq \alpha_i < d$, g being a homogeneous element of S; whence (iii); (iv) then follows from (iii) and from Lemma (2.1.3), taking $M = S_+$, since $(S_+)^{(d)} = (S^{(d)})_+$. Assertion (v) follows from (ii) by taking $M = S$. Finally, for a given n, there are only finitely many systems (α_i) such that $\alpha_i \geq 0$ and $\sum_i \alpha_i < n$, so if m_0 is the largest value of the sum $\sum_i \alpha_i h_i$ for these systems, we have $S_m \subset S_+^n$ for $m > m_0$, which proves (vi). □

(2.1.7) Corollary. *If S is Noetherian, so is $S^{(d)}$ for every integer $d > 0$.*

Proof. This follows from (2.1.5) and (2.1.6, (iv)). □

(2.1.8) Let $\mathfrak{p}$ be a graded prime ideal of the graded ring S; $\mathfrak{p}$ is therefore the direct sum of the subgroups $\mathfrak{p}_n = \mathfrak{p} \cap S_n$. Suppose that $\mathfrak{p}$ does not contain S_+. Then, if $f \in S_+$ does not belong to $\mathfrak{p}$, the relation $f^n x \in \mathfrak{p}$ is equivalent to $x \in \mathfrak{p}$; in particular, if $f \in S_d$ $(d > 0)$, for every $x \in S_{m-nd}$, the relation $f^n x \in \mathfrak{p}_m$ is equivalent to $x \in \mathfrak{p}_{m-nd}$.

(2.1.9) Proposition. *Let n_0 be an integer > 0; for every $n \geq n_0$ let $\mathfrak{p}_n$ be a subgroup of S_n. For there to exist a graded prime ideal $\mathfrak{p}$ of S not containing S_+ and such that $\mathfrak{p} \cap S_n = \mathfrak{p}_n$ for every $n \geq n_0$, it is necessary and sufficient that the following conditions be satisfied:*

1° *$S_m \mathfrak{p}_n \subset \mathfrak{p}_{m+n}$ for every $m \geq 0$ and every $n \geq n_0$.*

2° *For $m \geq n_0$, $n \geq n_0$, $f \in S_m$, $g \in S_n$, the relation $fg \in \mathfrak{p}_{m+n}$ implies $f \in \mathfrak{p}_m$ or $g \in \mathfrak{p}_n$.*

3° $\mathfrak{p}_n \neq S_n$ *for at least one* $n \geq n_0$.

Moreover, the graded prime ideal $\mathfrak{p}$ *is then unique.*

Proof. It is evident that conditions 1° and 2° are necessary. Moreover, if $\mathfrak{p} \not\supset S_+$, there exists at least one $k > 0$ such that $\mathfrak{p} \cap S_k \neq S_k$; if $f \in S_k$ does not belong to $\mathfrak{p}$, the relation $\mathfrak{p} \cap S_n = S_n$ implies $\mathfrak{p} \cap S_{n-mk} = S_{n-mk}$ by (2.1.8); hence, if $\mathfrak{p} \cap S_n = S_n$ from some value of n onwards, we would have $\mathfrak{p} \supset S_+$, contrary to the hypothesis, which proves that 3° is necessary. Conversely, suppose conditions 1°, 2° and 3° are satisfied. Note that if, for an integer $d \geq n_0$, $f \in S_d$ does not belong to $\mathfrak{p}_d$, then, if $\mathfrak{p}$ exists, $\mathfrak{p}_m$, for $m < n_0$, is necessarily equal to the set of $x \in S_m$ such that $f^r x \in \mathfrak{p}_{m+rd}$ except for finitely many values of r. This already proves that if $\mathfrak{p}$ exists, it is unique. It remains to show that if we define the $\mathfrak{p}_m$ for $m < n_0$ by the preceding condition, then $\mathfrak{p} = \sum_{n=0}^{\infty} \mathfrak{p}_n$ is a prime ideal. Note first that by virtue of 2°, for $m \geq n_0$, $\mathfrak{p}_m$ is also defined as the set of $x \in S_m$ such that $f^r x \in \mathfrak{p}_{m+rd}$ except for finitely many values of r. This being so, [II | 23] if $g \in S_m$, $x \in \mathfrak{p}_n$, we have $f^r gx \in \mathfrak{p}_{m+n+rd}$ except for finitely many values of r, hence $gx \in \mathfrak{p}_{m+n}$, which proves that $\mathfrak{p}$ is an ideal of S. To establish that this ideal is prime, in other words that the ring $S/\mathfrak{p}$, graded by the subgroups $S_n/\mathfrak{p}_n$, is an integral ring, it suffices (by considering the components of highest degree of two elements of $S/\mathfrak{p}$) to prove that if $x \in S_m$, $y \in S_n$ are such that $x \notin \mathfrak{p}_m$, $y \notin \mathfrak{p}_n$, then $xy \notin \mathfrak{p}_{m+n}$. Otherwise, for r sufficiently large, we would have $f^{2r}xy \in \mathfrak{p}_{m+n+2rd}$; but we have $f^r y \notin \mathfrak{p}_{n+rd}$ for every $r > 0$; it then follows from 2° that, except for finitely many values of r, we have $f^r x \in \mathfrak{p}_{m+rd}$, and we would conclude that $x \in \mathfrak{p}_m$, contrary to the hypothesis. □

(2.1.10) We will say that a subset $\mathfrak{J}$ of S_+ is an *ideal of* S_+ if it is an ideal of S, and that $\mathfrak{J}$ is a *graded prime ideal of* S_+ if it is the intersection of S_+ and a graded prime ideal of S *not containing* S_+ (this prime ideal is moreover unique by (2.1.9)). If $\mathfrak{J}$ is an ideal of S_+, the *radical of* $\mathfrak{J}$ *in* S_+ is the set of elements of S_+ some power of which belongs to $\mathfrak{J}$; in other words, it is the set $r_+(\mathfrak{J}) = r(\mathfrak{J}) \cap S_+$; in particular, the radical of 0 in S_+ is also called the *nilradical* of S_+ and denoted by $\mathfrak{N}_+$: it is thus the set of nilpotent elements of S_+. If $\mathfrak{J}$ is a *graded* ideal of S_+, its radical $r_+(\mathfrak{J})$ is a graded ideal: passing to the quotient ring $S/\mathfrak{J}$, we can reduce to the case $\mathfrak{J} = 0$, and everything comes down to seeing that if $x = x_h + x_{h+1} + \cdots + x_k$ is nilpotent, then so are the $x_i \in S_i$ $(1 \leq h \leq i \leq k)$; we may suppose $x_k \neq 0$, and the component of largest degree of x^n is then x_k^n, so x_k is nilpotent, and we then argue by induction on k. We say that the graded ring S is *essentially reduced* if $\mathfrak{N}_+ = 0$, in other words if S_+ contains no nilpotent elements $\neq 0$.

(2.1.11) Note that if, in the graded ring S, an element x is a divisor of 0, then so is its component of highest degree. We say that a ring S is *essentially integral* if the ring S_+ (*without unit element*) contains no divisor of 0 and is $\neq 0$; for this it suffices that no homogeneous element $\neq 0$ in S_+ be a divisor of 0 in this ring. It is clear that if $\mathfrak{p}$ is a graded prime ideal of S_+, then $S/\mathfrak{p}$ is essentially integral.

Let S be an essentially integral graded ring, and let $x_0 \in S_0$; if there then exists *one* homogeneous element $f \neq 0$ of S_+ such that $x_0 f = 0$, we have $x_0 S_+ = 0$, for we have $(x_0 g)f = (x_0 f)g = 0$ for every $g \in S_+$, and the hypothesis therefore implies $x_0 g = 0$. Hence, for S to be integral, it is necessary and sufficient that S_0 be integral and that the annihilator of S_+ in S_0 consist of 0 alone.

2.2 Rings of fractions of a graded ring.

(2.2.1) Let S be a ring graded in positive degrees, and f a *homogeneous* element of S of degree $d > 0$; then the ring of fractions $S' = S_f$ is graded, taking for S'_n the set of x/f^k, where $x \in S_{n+kd}$ with $k \geq 0$ (observe here that n can take arbitrary negative values); we denote the subring $S'_0 = (S_f)_0$ of S' consisting of the elements *of degree* 0 by $S_{(f)}$.

If $f \in S_d$, the monomials $(f/1)^h$ in S_f (h a positive or negative integer) form a *linearly independent family* over the ring $S_{(f)}$, and the set of their linear combinations is
[II | 24] none other than the ring $(S^{(d)})_f$, which is therefore *isomorphic to* $S_{(f)}[T, T^{-1}] = S_{(f)} \otimes_{\mathbf{Z}} \mathbf{Z}[T, T^{-1}]$ (where T is an indeterminate). Indeed, if we have a relation $\sum_{h=-a}^{b} z_h (f/1)^h = 0$ with $z_h = x_h/f^m$, where all the x_h belong to S_{md}, this relation is equivalent by definition to the existence of a $k \geq a$ such that $\sum_{h=-a}^{b} f^{h+k} x_h = 0$, and since the degrees of the terms of this sum are distinct, we have $f^{h+k} x_h = 0$ for every h, whence $z_h = 0$ for every h.

If M is a graded S-module, $M' = M_f$ is a graded S_f-module, M'_n being the set of z/f^k with $z \in M_{n+kd}$ ($k \geq 0$); we denote by $M_{(f)}$ the set of homogeneous elements of degree 0 of M'; it is immediate that $M_{(f)}$ is an $S_{(f)}$-module and that we have $(M^{(d)})_f = M_{(f)} \otimes_{S_{(f)}} (S^{(d)})_f$.

(2.2.2) Lemma. *Let d, e be two integers > 0, $f \in S_d$, $g \in S_e$. There exists a canonical ring isomorphism*

$$S_{(fg)} \xrightarrow{\sim} (S_{(f)})_{g^d/f^e} \ ;$$

if we canonically identify these two rings, there exists a canonical module isomorphism

$$M_{(fg)} \xrightarrow{\sim} (M_{(f)})_{g^d/f^e}.$$

Proof. Indeed, fg divides $f^e g^d$, and the latter element divides $(fg)^{de}$, so the graded rings S_{fg} and $S_{f^e g^d}$ are canonically identified; on the other hand, $S_{f^e g^d}$ is also identified with $(S_{f^e})_{g^d/1}$ (0, I.4.6), and since $f^e/1$ is invertible in S_{f^e}, $S_{f^e g^d}$ is also identified with $(S_{f^e})_{g^d/f^e}$. Now the element g^d/f^e is of degree 0 in S_{f^e}; we conclude immediately that the subring of $(S_{f^e})_{g^d/f^e}$ consisting of the elements of degree 0 is $(S_{(f^e)})_{g^d/f^e}$, and since evidently $S_{(f^e)} = S_{(f)}$, this proves the first part of the proposition; the second is established in the same way. □

(2.2.3) With the hypotheses of (2.2.2), it is clear that the canonical homomorphism $S_f \to S_{fg}$ (0, I.4.1), which maps x/f^k to $g^k x/(fg)^k$, is of degree 0, and therefore gives by restriction a *canonical homomorphism* $S_{(f)} \to S_{(fg)}$ such that the diagram

$$\begin{array}{ccc} & S_{(f)} & \\ \swarrow & & \searrow \\ S_{(fg)} & \xrightarrow{\sim} & (S_{(f)})_{g^d/f^e} \end{array}$$

is commutative. We define in the same way a canonical homomorphism $M_{(f)} \to M_{(fg)}$.

(2.2.4) Lemma. *If f, g are two homogeneous elements of S_+, the ring $S_{(fg)}$ is generated by the union of the canonical images of $S_{(f)}$ and $S_{(g)}$.*

Proof. By virtue of (2.2.2), it suffices to see that $1/(g^d/f^e) = f^{d+e}/(fg)^d$ belongs to the canonical image of $S_{(g)}$ in $S_{(fg)}$, which is evident by definition. □

(2.2.5) Proposition. *Let d be an integer > 0 and let $f \in S_d$. Then there exists a canonical ring isomorphism $S_{(f)} \xrightarrow{\sim} S^{(d)}/(f-1)S^{(d)}$; if we identify these two rings by this isomorphism, there exists a canonical module isomorphism $M_{(f)} \xrightarrow{\sim} M^{(d)}/(f-1)M^{(d)}$.*

Proof. The first of these isomorphisms is defined by assigning to x/f^n, where $x \in S_{nd}$, the element $\overline{x}$, the class of x mod. $(f-1)S^{(d)}$; this map is well defined, since we have the congruence $f^h x \equiv x \pmod{(f-1)S^{(d)}}$ for every $x \in S^{(d)}$, so if $f^h x = 0$ for some $h > 0$, we have $\overline{x} = 0$. On the other hand, if $x \in S_{nd}$ is such that $x = (f-1)y$ with [II | 25] $y = y_{hd} + y_{(h+1)d} + \cdots + y_{kd}$, where $y_{jd} \in S_{jd}$ and $y_{hd} \neq 0$, we necessarily have $h = n$ and $x = -y_{hd}$, as well as the relations $y_{(j+1)d} = f y_{jd}$ for $h \leq j \leq k-1$, $f y_{kd} = 0$, which finally gives $f^{k-n+1}x = 0$; to every class $\overline{x}$ mod. $(f-1)S^{(d)}$ of an element $x \in S_{nd}$ we can therefore assign the element x/f^n of $S_{(f)}$, since the preceding remark shows that this map is well defined. It is immediate that the two maps thus defined are ring homomorphisms, inverse to each other. We proceed in exactly the same way for M. □

(2.2.6) Corollary. *If S is Noetherian, so is $S_{(f)}$ for every homogeneous f of degree > 0.*

Proof. This follows immediately from (2.1.7) and (2.2.5). □

(2.2.7) Let T be a multiplicative subset of S_+ consisting of *homogeneous* elements; $T_0 = T \cup \{1\}$ is then a multiplicative subset of S; since the elements of T_0 are homogeneous, the ring $T_0^{-1}S$ is again graded in an evident way; we denote by $S_{(T)}$ the subring of $T_0^{-1}S$ consisting of the elements of order 0, that is, the elements of the form x/h, where $h \in T$ and x is homogeneous of degree equal to that of h. We know (0, 1.4.5) that $T_0^{-1}S$ is canonically identified with the inductive limit of the rings S_f, where f runs through T (for the canonical homomorphisms $S_f \to S_{fg}$); since this identification respects degrees, it identifies $S_{(T)}$ with the *inductive limit* of the $S_{(f)}$ for $f \in T$. For every graded S-module M, we define in the same way the module $M_{(T)}$ (over the ring $S_{(T)}$) consisting of the elements of degree 0 of $T_0^{-1}M$, and we see that this module is the inductive limit of the $M_{(f)}$ for $f \in T$.

If $\mathfrak{p}$ is a graded prime ideal of S_+, we denote by $S_{(\mathfrak{p})}$ and $M_{(\mathfrak{p})}$ the ring $S_{(T)}$ and the module $M_{(T)}$ respectively, where T is the set of *homogeneous* elements of S_+ which do not belong to $\mathfrak{p}$.

2.3 Homogeneous prime spectrum of a graded ring.

(2.3.1) Given a ring S graded in positive degrees, we call *homogeneous prime spectrum* of S, and denote by $\mathrm{Proj}(S)$, the set of graded prime ideals of S_+ (2.1.10), or, what amounts to the same, the set of graded prime ideals of S *not containing* S_+; we are going to define a *scheme* structure having $\mathrm{Proj}(S)$ as underlying set.

(2.3.2) For every subset E of S, let $V_+(E)$ be the set of graded prime ideals of S containing E and not containing S_+; it is thus the subset $V(E) \cap \mathrm{Proj}(S)$ of $\mathrm{Spec}(S)$. From (I, 1.1.2) we therefore deduce:

$$V_+(0) = \mathrm{Proj}(S), \quad V_+(S) = V_+(S_+) = \varnothing \tag{2.3.2.1}$$

$$V_+\left(\bigcup_\lambda E_\lambda\right) = \bigcap_\lambda V_+(E_\lambda) \tag{2.3.2.2}$$

$$V_+(EE') = V_+(E) \cup V_+(E') \tag{2.3.2.3}$$

$V_+(E)$ does not change when E is replaced by the graded ideal generated by E; moreover, if $\mathfrak{J}$ is a graded ideal of S, we have

$$V_+(\mathfrak{J}) = V_+\left(\bigcup_{q\geq n} (\mathfrak{J} \cap S_q)\right) \tag{2.3.2.4}$$

[II | 26] for every $n > 0$: indeed, if $\mathfrak{p} \in \mathrm{Proj}(S)$ contains the homogeneous elements of $\mathfrak{J}$ of degree $\geq n$, then, since by hypothesis there exists a homogeneous element $f \in S_d$ not contained in $\mathfrak{p}$, for every $m \geq 0$ and every $x \in S_m \cap \mathfrak{J}$ we have $f^r x \in \mathfrak{J} \cap S_{m+rd}$ for every $r \geq 0$; except for finitely many values of r, we have $m + rd \geq n$, hence $f^r x \in \mathfrak{p} \cap S_{m+rd}$, which implies $x \in \mathfrak{p} \cap S_m$ (2.1.8).

Finally, for every graded ideal $\mathfrak{J}$ of S, we have

$$V_+(\mathfrak{J}) = V_+(r_+(\mathfrak{J})). \tag{2.3.2.5}$$

(2.3.3) By definition, the $V_+(E)$ are the closed subsets of $X = \mathrm{Proj}(S)$ for the topology induced by the spectral topology of $\mathrm{Spec}(S)$, which we will also call the *spectral topology* on X. For every $f \in S$ we set

$$D_+(f) = D(f) \cap \mathrm{Proj}(S) = \mathrm{Proj}(S) \setminus V_+(f) \tag{2.3.3.1}$$

and consequently, for two elements f, g of S (I, 1.1.9.1), we have

$$D_+(fg) = D_+(f) \cap D_+(g). \tag{2.3.3.2}$$

(2.3.4) Proposition. *When f runs through the set of homogeneous elements of S_+, the $D_+(f)$ form a basis of the topology of $X = \mathrm{Proj}(S)$.*

Proof. Indeed, it follows from (2.3.2.2) and (2.3.2.4) that every closed subset of X is an intersection of sets of the form $V_+(f)$, where f is homogeneous of degree > 0. □

(2.3.5) Let f be a *homogeneous* element of S_+, of degree $d > 0$; for every graded prime ideal $\mathfrak{p}$ of S not containing f, we know that the set of x/f^n, where $x \in \mathfrak{p}$ and $n \geq 0$, is a prime ideal of the ring of fractions S_f (0, 1.2.6); its trace on $S_{(f)}$ is therefore a prime ideal of this ring, which we denote by $\psi_f(\mathfrak{p})$: it is the set of x/f^n for $n \geq 0$, $x \in \mathfrak{p} \cap S_{nd}$. We have thus defined a map

$$\psi_f : D_+(f) \longrightarrow \mathrm{Spec}(S_{(f)})\ ;$$

moreover, if $g \in S_e$ is a second homogeneous element of S_+, we have a commutative diagram

$$\begin{array}{ccc} D_+(f) & \xrightarrow{\psi_f} & \mathrm{Spec}(S_{(f)}) \\ \uparrow & & \uparrow \\ D_+(fg) & \xrightarrow[\psi_{fg}]{} & \mathrm{Spec}(S_{(fg)}) \end{array} \tag{2.3.5.1}$$

where the left vertical arrow is the inclusion, and the right one is the map ${}^a\omega_{fg,f}$ deduced from the canonical homomorphism $\omega = \omega_{fg,f} : S_{(f)} \to S_{(fg)}$ (I, 1.2.1). Indeed, if $x/f^n \in \omega^{-1}(\psi_{fg}(\mathfrak{p}))$, where $fg \notin \mathfrak{p}$, we have by definition $g^n x/(fg)^n \in \psi_{fg}(\mathfrak{p})$, hence $g^n x \in \mathfrak{p}$ and consequently $x \in \mathfrak{p}$, and the converse is evident.

(2.3.6) Proposition. *The map ψ_f is a homeomorphism of $D_+(f)$ onto* $\mathrm{Spec}(S_{(f)})$.

Proof. In the first place, ψ_f is continuous; for if $h \in S_{nd}$ is such that $h/f^n \in \psi_f(\mathfrak{p})$, we have by definition $h \in \mathfrak{p}$, and conversely, hence

$$\psi_f^{-1}(D(h/f^n)) = D_+(hf)$$

and our assertion follows from formula (2.3.3.2). Moreover, the $D_+(hf)$, where h runs through the sets S_{nd}, form a basis of the topology of $D_+(f)$, by virtue of (2.3.4) and of formula (2.3.3.2); the foregoing therefore proves, taking into account the axiom (T_0), [II | 27] which holds in $D_+(f)$ and in $\mathrm{Spec}(S_{(f)})$, that ψ_f is injective and that the inverse map $\psi_f(D_+(f)) \longrightarrow D_+(f)$ is continuous. Finally, to see that ψ_f is surjective, we remark that if $\mathfrak{q}_0$ is a prime ideal of $S_{(f)}$ and if, for every $n > 0$, we denote by $\mathfrak{p}_n$ the set of $x \in S_n$ such that $x^d/f^n \in \mathfrak{q}_0$, the $\mathfrak{p}_n$ satisfy the conditions of (2.1.9): indeed, if $x \in S_n$, $y \in S_n$ are such that $x^d/f^n \in \mathfrak{q}_0$ and $y^d/f^n \in \mathfrak{q}_0$, we have $(x+y)^{2d}/f^{2n} \in \mathfrak{q}_0$, whence $(x+y)^d/f^n \in \mathfrak{q}_0$ since $\mathfrak{q}_0$ is prime; this proves that the $\mathfrak{p}_n$ are subgroups of the S_n, and the verification of the other conditions of (2.1.9) is immediate, taking into account that $\mathfrak{q}_0$ is prime. If $\mathfrak{p}$ is the graded prime ideal of S thus defined, we indeed have $\psi_f(\mathfrak{p}) = \mathfrak{q}_0$, since for $x \in S_{nd}$, the relations $x/f^n \in \mathfrak{q}_0$ and $x^d/f^{nd} \in \mathfrak{q}_0$ are equivalent, $\mathfrak{q}_0$ being prime. □

(2.3.7) Corollary. *In order that $D_+(f) = \varnothing$, it is necessary and sufficient that f be nilpotent.*

Proof. Indeed, in order that $\mathrm{Spec}(S_{(f)}) = \varnothing$, it is necessary and sufficient that $S_{(f)} = 0$, or again that $1 = 0$ in S_f, which by definition means that f is nilpotent. □

(2.3.8) Corollary. *Let E be a subset of S_+. The following conditions are equivalent:*

a) $V_+(E) = X = \mathrm{Proj}(S)$.

b) *Every element of E is nilpotent.*

c) *The homogeneous components of every element of E are nilpotent.*

Proof. It is clear that c) implies b) and that b) implies a). If $\mathfrak{J}$ is the graded ideal of S generated by E, condition a) is equivalent to $V_+(\mathfrak{J}) = X$; *a fortiori*, a) implies that every homogeneous element $f \in \mathfrak{J}$ is such that $V_+(f) = X$, hence f is nilpotent by virtue of (2.3.7). □

(2.3.9) Corollary. *If $\mathfrak{J}$ is a graded ideal of S_+, $r_+(\mathfrak{J})$ is the intersection of the graded prime ideals of S_+ which contain $\mathfrak{J}$.*

Proof. By considering the graded ring $S/\mathfrak{J}$, we can reduce to the case where $\mathfrak{J} = 0$. We must prove that if $f \in S_+$ is not nilpotent, there is a graded prime ideal of S not containing f; now, at least one of the homogeneous components of f is not nilpotent, and we may therefore suppose f homogeneous; the assertion then follows from (2.3.7). □

(2.3.10) For every subset Y of $X = \mathrm{Proj}(S)$, let $\mathfrak{j}_+(Y)$ be the set of $f \in S_+$ such that $Y \subset V_+(f)$; it amounts to the same to say that $\mathfrak{j}_+(Y) = \mathfrak{j}(Y) \cap S_+$; $\mathfrak{j}_+(Y)$ is therefore an ideal of S_+, equal to its radical in S_+.

(2.3.11) Proposition.

(i) *For every subset E of S_+, $\mathfrak{j}_+(V_+(E))$ is the radical in S_+ of the graded ideal of S_+ generated by E.*

(ii) *For every subset Y of X, $V_+(\mathfrak{j}_+(Y)) = \overline{Y}$, the closure of Y in X.*

Proof. (i) If $\mathfrak{J}$ is the graded ideal of S_+ generated by E, we have $V_+(E) = V_+(\mathfrak{J})$, and the assertion then follows from (2.3.9).

(ii) Since $V_+(\mathfrak{J}) = \bigcap_{f\in\mathfrak{J}} V_+(f)$, the relation $Y \subset V_+(\mathfrak{J})$ implies $Y \subset V_+(f)$ for every $f \in \mathfrak{J}$, and consequently $\mathfrak{j}_+(Y) \supset \mathfrak{J}$, whence $V_+(\mathfrak{j}_+(Y)) \subset V_+(\mathfrak{J})$, which proves (ii) by definition of the closed sets.

□

(2.3.12) Corollary. *The closed subsets Y of $X = \mathrm{Proj}(S)$ and the graded ideals of S_+ equal to their radical in S_+ correspond bijectively to each other under the decreasing maps $Y \longmapsto \mathfrak{j}_+(Y)$, $\mathfrak{J} \longmapsto V_+(\mathfrak{J})$; to the union $Y_1 \cup Y_2$ of two closed subsets of X corresponds* [II/28] *$\mathfrak{j}_+(Y_1) \cap \mathfrak{j}_+(Y_2)$, and to the intersection of an arbitrary family (Y_λ) of closed subsets corresponds the radical in S_+ of the sum of the $\mathfrak{j}_+(Y_\lambda)$.*

(2.3.13) Corollary. *Let $\mathfrak{J}$ be a graded ideal in S_+; in order that $V_+(\mathfrak{J}) = \varnothing$, it is necessary and sufficient that every element of S_+ have a power in $\mathfrak{J}$.*

This last corollary can also be expressed in any of the following equivalent forms:

(2.3.14) Corollary. *Let (f_α) be a family of homogeneous elements of S_+. For the $D_+(f_\alpha)$ to form a covering of $X = \mathrm{Proj}(S)$, it is necessary and sufficient that every element of S_+ have a power in the ideal generated by the f_α.*

(2.3.15) Corollary. *Let (f_α) be a family of homogeneous elements of S_+, and f an element of S_+. The following relations are equivalent:*

a) *$D_+(f) \subset \bigcup_\alpha D_+(f_\alpha)$;*

b) *$V_+(f) \supset \bigcap_\alpha V_+(f_\alpha)$;*

c) *some power of f belongs to the ideal generated by the f_α.*

(2.3.16) Corollary. *For $X = \mathrm{Proj}(S)$ to be empty, it is necessary and sufficient that every element of S_+ be nilpotent.*

(2.3.17) Corollary. *In the bijective correspondence described in (2.3.12), the irreducible closed subsets of X correspond to the graded prime ideals in S_+.*

Proof. Indeed, if $Y = Y_1 \cup Y_2$, where Y_1 and Y_2 are closed and distinct from Y, we have

$$\mathfrak{j}_+(Y) = \mathfrak{j}_+(Y_1) \cap \mathfrak{j}_+(Y_2)$$

the ideals $\mathfrak{j}_+(Y_1)$ and $\mathfrak{j}_+(Y_2)$ being distinct from $\mathfrak{j}_+(Y)$, so $\mathfrak{j}_+(Y)$ is not prime. Conversely, if $\mathfrak{J}$ is a non-prime graded ideal of S_+, there exist two elements f, g of S_+ such that $f \notin \mathfrak{J}$, $g \notin \mathfrak{J}$, $fg \in \mathfrak{J}$; then $V_+(f) \not\supset V_+(\mathfrak{J})$, $V_+(g) \not\supset V_+(\mathfrak{J})$, but $V_+(\mathfrak{J}) \subset V_+(f) \cup V_+(g)$ by (2.3.2.3); we conclude that $V_+(\mathfrak{J})$ is the union of the closed sets $V_+(f) \cap V_+(\mathfrak{J})$ and $V_+(g) \cap V_+(\mathfrak{J})$, which are distinct from $V_+(\mathfrak{J})$. □

2.4 The scheme structure on $\mathrm{Proj}(S)$.

(2.4.1) Let f, g be two homogeneous elements of S_+; consider the affine schemes $Y_f = \mathrm{Spec}(S_{(f)})$, $Y_g = \mathrm{Spec}(S_{(g)})$ and $Y_{fg} = \mathrm{Spec}(S_{(fg)})$. By virtue of (2.2.2), the morphism $w_{fg,f} = ({}^a\omega_{fg,f}, \widetilde{\omega}_{fg,f})$ from Y_{fg} to Y_f corresponding to the canonical homomorphism $\omega_{fg,f} : S_{(f)} \to S_{(fg)}$ is an *open immersion* (I, 1.3.6). By means of the inverse homeomorphism of $\psi_f : D_+(f) \to Y_f$ (2.3.6), we can transport to $D_+(f)$ the affine scheme structure of Y_f; by virtue of the commutativity of the diagram (2.3.5.1), the affine scheme $D_+(fg)$ is thereby identified with the scheme induced on the open set $D_+(fg)$ of the space underlying the affine scheme $D_+(f)$. It is then clear (taking into account (2.3.4)) that $X = \mathrm{Proj}(S)$ is endowed with a unique *prescheme* structure whose restriction to each $D_+(f)$ is the affine scheme just defined. Moreover:

(2.4.2) Proposition. *The prescheme* $\mathrm{Proj}(S)$ *is a scheme.*

Proof. It suffices (I, 5.5.6) to show that, for all homogeneous f, g in S_+, $D_+(f) \cap D_+(g) = D_+(fg)$ is affine and its ring is generated by the canonical images of the rings of $D_+(f)$ and $D_+(g)$; the first point is evident by definition, and the second follows from (2.2.4). □

Whenever we speak of the homogeneous prime spectrum $\mathrm{Proj}(S)$ as a *scheme*, it will always be with the structure just defined. [II | 29]

(2.4.3) Example. Take $S = K[T_1, T_2]$, K being a field, T_1, T_2 two indeterminates, and S being graded by total degree. It follows from (2.3.14) that $\mathrm{Proj}(S)$ is the union of $D_+(T_1)$ and $D_+(T_2)$; we see immediately that these affine schemes are canonically isomorphic to $K[T]$, and that $\mathrm{Proj}(S)$ is obtained by the gluing of these two affine schemes described in (I, 2.3.2) (cf. (7.4.14)).

(2.4.4) Proposition. *Let S be a ring graded in positive degrees, and let X be the scheme* $\mathrm{Proj}(S)$.

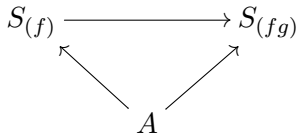
(i) *If $\mathfrak{N}_+$ is the nilradical of S_+ (2.1.10), the scheme X_{red} is canonically isomorphic to* $\mathrm{Proj}(S/\mathfrak{N}_+)$*; in particular, if S is essentially reduced,* $\mathrm{Proj}(S)$ *is reduced.*

(ii) *Suppose S essentially reduced. Then, for X to be integral, it is necessary and sufficient that S be essentially integral.*

Proof. (i) Let $\overline{S}$ be the graded ring $S/\mathfrak{N}_+$, and denote by $x \mapsto \overline{x}$ the canonical homomorphism $S \to \overline{S}$, of degree 0. For every $f \in S_d$ $(d > 0)$, the canonical homomorphism $S_f \to \overline{S}_{\overline{f}}$ (0, 1.5.1) is surjective and of degree 0, and therefore gives by restriction a surjective homomorphism $S_{(f)} \to \overline{S}_{(\overline{f})}$; if we suppose $f \notin \mathfrak{N}_+$, we verify immediately that $\overline{S}_{(\overline{f})}$ is reduced and that the kernel of the preceding homomorphism is the nilradical of $S_{(f)}$, in other words $\overline{S}_{(\overline{f})} = (S_{(f)})_{\mathrm{red}}$. To this homomorphism there therefore corresponds a closed immersion $D_+(\overline{f}) \to D_+(f)$ which identifies $D_+(\overline{f})$ with $(D_+(f))_{\mathrm{red}}$ (I, 5.1.2), and is in particular a homeomorphism of the underlying spaces of these two affine schemes. Moreover, if $g \notin \mathfrak{N}_+$ is a second homogeneous element of S_+, the diagram

$$\begin{array}{ccc} S_{(f)} & \longrightarrow & \overline{S}_{(\overline{f})} \\ \downarrow & & \downarrow \\ S_{(fg)} & \longrightarrow & \overline{S}_{(\overline{fg})} \end{array}$$

is commutative; since moreover the $D_+(f)$, for f homogeneous of degree > 0 and $f \notin \mathfrak{N}_+$, form a covering of $X = \mathrm{Proj}(S)$ (2.3.7), we see that the morphisms $D_+(\overline{f}) \to D_+(f)$ are the restrictions of a closed immersion $\mathrm{Proj}(\overline{S}) \to \mathrm{Proj}(S)$ which is a homeomorphism of the underlying spaces; whence the conclusion (I, 5.1.2).



(ii) Suppose that S is essentially integral, in other words that (0) is a graded prime ideal of S_+ distinct from S_+; then X is reduced by virtue of (i) and irreducible by virtue of (2.3.17). Conversely, suppose that S is essentially reduced and X integral; then, for $f \neq 0$ homogeneous in S_+, we have $D_+(f) \neq \varnothing$ (2.3.7); the hypothesis that X is irreducible implies that $D_+(f) \cap D_+(g) \neq \varnothing$ for f, g homogeneous and $\neq 0$ in S_+; hence $fg \neq 0$ by virtue of (2.3.3.2), and we conclude that S_+ has no zero divisors, whence the first assertion.

□

(2.4.5) Given a commutative ring A, recall that a graded ring S is said to be a *graded A-algebra* if it is endowed with an A-algebra structure such that each of the subgroups
[II | 30] S_n is an A-module; moreover, for this it suffices that S_0 be an A-algebra; in other words, we define a graded A-algebra structure on S by defining an A-algebra structure on S_0 and setting, for $\alpha \in A$, $x \in S_n$, $\alpha \cdot x = (\alpha \cdot 1)x$.

(2.4.6) Proposition. *Suppose that S is a graded A-algebra. Then on $X = \mathrm{Proj}(S)$, the structural sheaf $\mathcal{O}_X$ is an A-algebra (A being regarded as a simple sheaf on X); in other words, X is a scheme over* $\mathrm{Spec}(A)$.

Proof. It suffices to note that for every homogeneous f in S_+, $S_{(f)}$ is an algebra over A, and that the diagram

is commutative, for homogeneous f, g in S_+. □

(2.4.7) Proposition. *Let S be a ring graded in positive degrees.*

(i) *For every integer $d > 0$, there exists a canonical isomorphism of the scheme* $\mathrm{Proj}(S)$ *onto the scheme* $\mathrm{Proj}(S^{(d)})$.

(ii) *Let S' be the graded ring such that $S'_0 = \mathbf{Z}$, $S'_n = S_n$ (regarded as a $\mathbf{Z}$-module) for $n > 0$. There exists a canonical isomorphism of the scheme* $\mathrm{Proj}(S)$ *onto the scheme* $\mathrm{Proj}(S')$.

Proof. (i) Let us first show that the map $\mathfrak{p} \mapsto \mathfrak{p} \cap S^{(d)}$ is a bijection of the set $\mathrm{Proj}(S)$ onto $\mathrm{Proj}(S^{(d)})$. Indeed, suppose given a graded prime ideal $\mathfrak{p}' \in \mathrm{Proj}(S^{(d)})$, and set $\mathfrak{p}_{nd} = \mathfrak{p}' \cap S_{nd}$ $(n \geq 0)$. For every $n > 0$ which is not a multiple of d, define $\mathfrak{p}_n$ as the set of $x \in S_n$ such that $x^d \in \mathfrak{p}_{nd}$; if $x \in \mathfrak{p}_n$, $y \in \mathfrak{p}_n$, we have $(x+y)^{2d} \in \mathfrak{p}_{2nd}$, hence $(x+y)^d \in \mathfrak{p}_{nd}$ since $\mathfrak{p}'$ is prime; it is immediate that the $\mathfrak{p}_n$ thus defined for every $n \geq 0$ satisfy the conditions of (2.1.9), so there exists a unique prime ideal $\mathfrak{p} \in \mathrm{Proj}(S)$ such that $\mathfrak{p} \cap S^{(d)} = \mathfrak{p}'$. Since for every homogeneous f in S_+ we have $V_+(f) = V_+(f^d)$ (2.3.2.3), we see that the preceding bijection is a homeomorphism

of topological spaces. Finally, with the same notation, $S_{(f)}$ and $S^{(d)}_{(f^d)}$ are canonically identified (2.2.2), so $\mathrm{Proj}(S)$ and $\mathrm{Proj}(S^{(d)})$ are canonically identified as schemes.

(ii) If to every $\mathfrak{p} \in \mathrm{Proj}(S)$ we assign the unique prime ideal $\mathfrak{p}' \in \mathrm{Proj}(S')$ such that $\mathfrak{p}' \cap S_n = \mathfrak{p} \cap S_n$ for every $n > 0$ (2.1.9), it is clear that we define a canonical homeomorphism $\mathrm{Proj}(S) \xrightarrow{\sim} \mathrm{Proj}(S')$ of the underlying spaces, since $V_+(f)$ is the same set for S and S' when f is a homogeneous element of S_+. Since moreover $S_{(f)} = S'_{(f)}$, $\mathrm{Proj}(S)$ and $\mathrm{Proj}(S')$ are identified as schemes.

□

(2.4.8) Corollary. *If S is a graded A-algebra and S'_A the graded A-algebra such that $(S'_A)_0 = A$, $(S'_A)_n = S_n$ for $n > 0$, there exists a canonical isomorphism of* $\mathrm{Proj}(S)$ *onto* $\mathrm{Proj}(S'_A)$.

Proof. Indeed, these two schemes are canonically isomorphic to $\mathrm{Proj}(S')$, with the notation of (2.4.7, (ii)). □

2.5 Sheaf associated to a graded module.

(2.5.1) Let M be a graded S-module. For every homogeneous f in S_+, $M_{(f)}$ is an $S_{(f)}$-module, and there therefore corresponds to it an associated quasi-coherent sheaf $\widetilde{M_{(f)}}$ on the affine scheme $\mathrm{Spec}(S_{(f)})$, identified with $D_+(f)$ (I, 1.3.4).

(2.5.2) Proposition. *There exists on $X = \mathrm{Proj}(S)$ one and only one quasi-coherent $\mathcal{O}_X$-module $\widetilde{M}$ such that for every homogeneous f in S_+ we have $\Gamma(D_+(f), \widetilde{M}) = M_{(f)}$, the restriction homomorphism $\Gamma(D_+(f), \widetilde{M}) \to \Gamma(D_+(fg), \widetilde{M})$, for homogeneous f, g in S_+, being the canonical homomorphism $M_{(f)} \to M_{(fg)}$ (2.2.3).* [II | 31]

Proof. Suppose $f \in S_d$, $g \in S_e$. Since $D_+(fg)$ is identified with the prime spectrum of $(S_{(f)})_{g^d/f^e}$ by virtue of (2.2.2), the restriction to $D_+(fg)$ of the sheaf $\widetilde{M_{(f)}}$ on $D_+(f)$ is canonically identified with the sheaf associated to the module $(M_{(f)})_{g^d/f^e}$ (I, 1.3.6), hence also with $\widetilde{M_{(fg)}}$ (2.2.2); we conclude that there exists a canonical isomorphism

$$\theta_{g,f} : \widetilde{M_{(f)}}|D_+(fg) \xrightarrow{\sim} \widetilde{M_{(g)}}|D_+(fg)$$

such that, if h is a third homogeneous element of S_+, we have $\theta_{f,h} = \theta_{f,g} \circ \theta_{g,h}$ in $D_+(fgh)$. Consequently (0, 3.3.1) there exist on X a quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ and, for each homogeneous f in S_+, an isomorphism η_f of $\mathcal{F}|D_+(f)$ onto $\widetilde{M_{(f)}}$, such that $\theta_{g,f} = \eta_g \circ \eta_f^{-1}$. If we then consider the sheaf $\mathcal{G}$ associated to the presheaf (on the basis of the topology of X formed by the $D_+(f)$) defined by $D_+(f) \to M_{(f)}$, with the canonical homomorphisms $M_{(f)} \to M_{(fg)}$ as restriction homomorphisms, the foregoing proves that $\mathcal{F}$ and $\mathcal{G}$ are isomorphic (taking into account (I, 1.3.7)); the sheaf $\mathcal{G}$ will be denoted by $\widetilde{M}$, and it indeed satisfies the conditions of the statement. In particular, we have $\widetilde{S} = \mathcal{O}_X$. □

(2.5.3) Definition. We say that the quasi-coherent $\mathcal{O}_X$-module $\widetilde{M}$ defined in (2.5.2) is *associated* to the graded S-module M.

Recall that the graded S-modules form a category when the homomorphisms of graded modules are restricted to the homomorphisms *of degree* 0. With this convention:

(2.5.4) Proposition. *The functor $M \mapsto \widetilde{M}$ is an exact additive covariant functor from the category of graded S-modules to that of quasi-coherent $\mathcal{O}_X$-modules, which commutes with inductive limits and direct sums.*

Proof. Indeed, since these properties are local, it suffices to verify them on the sheaves $\widetilde{M}|D_+(f) = \widetilde{M_{(f)}}$; now the functor $M \mapsto M_f$, the functor $N \mapsto N_0$ (on the category of graded S_f-modules) and the functor $P \mapsto \widetilde{P}$ (on the category of $S_{(f)}$-modules) all three have the properties of exactness and of commutation with inductive limits and direct sums (I, 1.3.5 and I, 1.3.9); whence the proposition. □

We denote by $\widetilde{u}$ the homomorphism $\widetilde{M} \to \widetilde{N}$ corresponding to a homomorphism of degree 0, $u : M \to N$. We deduce immediately from (2.5.4) that the results of (I, 1.3.9 and I, 1.3.10) remain valid for graded S-modules and homomorphisms of degree 0 (with the meaning given here to $\widetilde{M}$), the proofs being purely formal.

(2.5.5) Proposition. *For every $\mathfrak{p} \in X = \mathrm{Proj}(S)$, we have $\widetilde{M}_{\mathfrak{p}} = M_{(\mathfrak{p})}$.*

Proof. Indeed, by definition $\widetilde{M}_{\mathfrak{p}} = \varinjlim \Gamma(D_+(f), \widetilde{M})$, where f runs through the set of homogeneous elements of S_+ such that $f \notin \mathfrak{p}$; since $\Gamma(D_+(f), \widetilde{M}) = M_{(f)}$, the proposition follows from the definition of $M_{(\mathfrak{p})}$ (2.2.7). □

[II | 32] In particular, *the local ring* $(\mathcal{O}_X)_{\mathfrak{p}}$ is none other than the ring $S_{(\mathfrak{p})}$, the set of fractions x/f, where f is homogeneous in S_+ and does not belong to $\mathfrak{p}$, and x is homogeneous of the same degree as f.

More particularly, if S is *essentially integral*, so that $\mathrm{Proj}(S) = X$ is *integral* (2.4.4), and if $\xi = (0)$ is the generic point of X, the *field of rational functions* $R(X) = \mathcal{O}_\xi$ is the field consisting of the elements fg^{-1}, where f and g are homogeneous of the same degree in S_+ and $g \neq 0$.

(2.5.6) Proposition. *If, for every $z \in M$ and every homogeneous f in S_+, there exists a power of f annihilating z, then $\widetilde{M} = 0$. This sufficient condition is also necessary when the S_0-algebra S is generated by the set S_1 of homogeneous elements of degree* 1.

Proof. Indeed, the condition $\widetilde{M} = 0$ is equivalent to $M_{(f)} = 0$ for every homogeneous f in S_+. On the other hand, if $f \in S_d$, to say that $M_{(f)} = 0$ means that for every $z \in M$ homogeneous of degree a multiple of d, there is a power f^n such that $f^n z = 0$. If $M_{(f)} = 0$ for every $f \in S_1$, the condition of the statement is therefore satisfied for every $f \in S_1$; it is satisfied *a fortiori* for every homogeneous f in S_+ when S_1 generates S, since every homogeneous element of S_+ is then a linear combination of products of elements of S_1. □

(2.5.7) Proposition. *Let d be an integer > 0, and $f \in S_d$. Then, for every $n \in \mathbf{Z}$, the $(\mathcal{O}_X|D_+(f))$-module $\widetilde{S(nd)}|D_+(f)$ is canonically isomorphic to $\mathcal{O}_X|D_+(f)$.*

Proof. Indeed, multiplication by the invertible element $(f/1)^n$ of S_f is a bijection of $S_{(f)} = (S_f)_0$ onto $(S_f)_{nd} = (S_f(nd))_0 = (S(nd)_f)_0 = S(nd)_{(f)}$; in other words, the $S_{(f)}$-modules $S_{(f)}$ and $S(nd)_{(f)}$ are canonically isomorphic, whence the proposition. □

(2.5.8) Corollary. *On the open set*

$$U = \bigcup_{f \in S_d} D_+(f),$$

the restriction of the $\mathcal{O}_X$-module $\widetilde{S(nd)}$ is an invertible $(\mathcal{O}_X|U)$-module (0, 5.4.1).

(2.5.9) Corollary. *If the ideal S_+ of S is generated by the set S_1 of homogeneous elements of degree 1, the $\mathcal{O}_X$-modules $\widetilde{S(n)}$ are invertible for every $n \in \mathbf{Z}$.*

Proof. It suffices to note that $X = \bigcup_{f \in S_1} D_+(f)$ by virtue of the hypothesis (2.3.14) and to apply (2.5.8) with $U = X$. □

(2.5.10) Throughout the rest of this section, we set

$$\mathcal{O}_X(n) = \widetilde{S(n)} \tag{2.5.10.1}$$

for every $n \in \mathbf{Z}$, and, for every open subset U of X and every $(\mathcal{O}_X|U)$-module $\mathcal{F}$,

$$\mathcal{F}(n) = \mathcal{F} \otimes_{\mathcal{O}_X|U} (\mathcal{O}_X(n)|U) \tag{2.5.10.2}$$

for every $n \in \mathbf{Z}$. If the ideal S_+ is generated by S_1, the functor $\mathcal{F}(n)$ is *exact* in $\mathcal{F}$ for every $n \in \mathbf{Z}$, since $\mathcal{O}_X(n)$ is then an invertible $\mathcal{O}_X$-module.

(2.5.11) Let M and N be two graded S-modules. For every $f \in S_d$ $(d > 0)$ we define a canonical functorial homomorphism of $S_{(f)}$-modules

$$\lambda_f : M_{(f)} \otimes_{S_{(f)}} N_{(f)} \longrightarrow (M \otimes_S N)_{(f)} \tag{2.5.11.1}$$

[II | 33]

by composing the homomorphism $M_{(f)} \otimes_{S_{(f)}} N_{(f)} \to M_f \otimes_{S_f} N_f$ (coming from the injections $M_{(f)} \to M_f$, $N_{(f)} \to N_f$ and $S_{(f)} \to S_f$) with the canonical isomorphism $M_f \otimes_{S_f} N_f \xrightarrow{\sim} (M \otimes_S N)_f$ (0, 1.3.4), and noting that, by definition of the tensor product of two graded modules, the latter isomorphism preserves degrees; for $x \in M_{md}$, $y \in N_{nd}$ $(m \geq 0,\ n \geq 0)$, we therefore have

$$\lambda_f((x/f^m) \otimes (y/f^n)) = (x \otimes y)/f^{m+n}.$$

It follows immediately from this definition that if $g \in S_e$ $(e > 0)$, the diagram

$$\begin{array}{ccc} M_{(f)} \otimes_{S_{(f)}} N_{(f)} & \xrightarrow{\lambda_f} & (M \otimes_S N)_{(f)} \\ \downarrow & & \downarrow \\ M_{(fg)} \otimes_{S_{(fg)}} N_{(fg)} & \xrightarrow[\lambda_{fg}]{} & (M \otimes_S N)_{(fg)} \end{array}$$

(where the right vertical arrow is the canonical homomorphism and the left one comes from the canonical homomorphisms) is commutative. We therefore deduce from the λ a canonical functorial homomorphism of $\mathcal{O}_X$-modules

$$\lambda : \widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N} \longrightarrow \widetilde{M \otimes_S N}. \tag{2.5.11.2}$$

Consider in particular two graded ideals $\mathfrak{J}$, $\mathfrak{K}$ of S; since $\widetilde{\mathfrak{J}}$ and $\widetilde{\mathfrak{K}}$ are sheaves of ideals of $\mathcal{O}_X$, we have a canonical homomorphism $\widetilde{\mathfrak{J}} \otimes_{\mathcal{O}_X} \widetilde{\mathfrak{K}} \to \mathcal{O}_X$; the diagram

$$\begin{array}{ccc} \widetilde{\mathfrak{J}} \otimes_{\mathcal{O}_X} \widetilde{\mathfrak{K}} & \xrightarrow{\lambda} & \widetilde{\mathfrak{J} \otimes_S \mathfrak{K}} \\ & \searrow \quad \swarrow & \\ & \mathcal{O}_X & \end{array} \tag{2.5.11.3}$$

is then commutative. Indeed, we are reduced to verifying this in each open subset $D_+(f)$ (f homogeneous in S_+), and it follows immediately from the definition (2.5.11.1) of λ_f and from (I, 1.3.13).

Finally, note that if M, N, P are three graded S-modules, the diagram

$$\begin{array}{ccc} \widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N} \otimes_{\mathcal{O}_X} \widetilde{P} & \xrightarrow{\lambda \otimes 1} & \widetilde{M \otimes_S N} \otimes_{\mathcal{O}_X} \widetilde{P} \\ \downarrow{\scriptstyle 1 \otimes \lambda} & & \downarrow{\scriptstyle \lambda} \\ \widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N \otimes_S P} & \xrightarrow[\lambda]{} & \widetilde{M \otimes_S N \otimes_S P} \end{array} \tag{2.5.11.4}$$

[II | 34]

is commutative. Again it suffices to verify this in each $D_+(f)$, and it follows immediately from the definitions and from (I, 1.3.13).

(2.5.12) Under the hypotheses of (2.5.11), we define a canonical functorial homomorphism of $S_{(f)}$-modules

$$\mu_f : \big(\mathrm{Hom}_S(M, N)\big)_{(f)} \longrightarrow \mathrm{Hom}_{S_{(f)}}(M_{(f)}, N_{(f)}) \tag{2.5.12.1}$$

by assigning to u/f^n, where u is a homomorphism of degree nd, the homomorphism $M_{(f)} \to N_{(f)}$ which maps x/f^m ($x \in M_{md}$) to $u(x)/f^{m+n}$. For $g \in S_e$ ($e > 0$), we again have a commutative diagram

$$\begin{array}{ccc} \big(\mathrm{Hom}_S(M, N)\big)_{(f)} & \xrightarrow{\mu_f} & \mathrm{Hom}_{S_{(f)}}(M_{(f)}, N_{(f)}) \\ \downarrow & & \downarrow \\ \big(\mathrm{Hom}_S(M, N)\big)_{(fg)} & \xrightarrow[\mu_{fg}]{} & \mathrm{Hom}_{S_{(fg)}}(M_{(fg)}, N_{(fg)}) \end{array}$$

(the left arrow being the canonical homomorphism, the right one coming from the canonical homomorphisms). We again conclude (taking into account (I, 1.3.8)) that the μ_f define a canonical functorial homomorphism of $\mathcal{O}_X$-modules

$$\mu : \widetilde{\mathrm{Hom}_S(M, N)} \longrightarrow \mathcal{H}om_{\mathcal{O}_X}(\widetilde{M}, \widetilde{N}). \tag{2.5.12.2}$$

(2.5.13) Proposition. *Suppose the ideal S_+ is generated by S_1. Then the homomorphism λ (2.5.11.2) is an isomorphism; so is the homomorphism μ (2.5.12.2) when the graded S-module M admits a finite presentation (2.1.1).*

Proof. Since X is the union of the $D_+(f)$ for $f \in S_1$ (2.3.14), we are reduced to proving that λ_f and μ_f are isomorphisms, under the hypotheses considered, when f is homogeneous and *of degree* 1. Now, we then define a $\mathbf{Z}$-bilinear map

$$M_m \times N_n \longrightarrow M_{(f)} \otimes_{S_{(f)}} N_{(f)}$$

by assigning to (x, y) the element $(x/f^m) \otimes (y/f^n)$ (when $m < 0$, we write x/f^m for $f^{-m}x/1$); these maps define a $\mathbf{Z}$-linear map

$$M \otimes_{\mathbf{Z}} N \longrightarrow M_{(f)} \otimes_{S_{(f)}} N_{(f)},$$

and if $s \in S_q$, this map sends $(sx) \otimes y$ to

$$(s/f^q)\big((x/f^m) \otimes (y/f^n)\big)$$

(for $x \in M_m$, $y \in N_n$). We therefore deduce a di-homomorphism of modules

$$\gamma_f : M \otimes_S N \longrightarrow M_{(f)} \otimes_{S_{(f)}} N_{(f)},$$

relative to the canonical homomorphism $S \to S_{(f)}$ (sending $s \in S_q$ to s/f^q). Suppose moreover that for an element $\sum_i (x_i \otimes y_i)$ of $M \otimes_S N$ (x_i, y_i homogeneous of respective degrees m_i, n_i) we have

$$f^r \sum_i (x_i \otimes y_i) = 0,$$

in other words $\sum_i (f^r x_i \otimes y_i) = 0$. We deduce by virtue of (0, 1.3.4) that

$$\sum_i (f^r x_i / f^{m_i + r}) \otimes (y_i / f^{n_i}) = 0,$$

that is, $\gamma_f(\sum_i (x_i \otimes y_i)) = 0$. Consequently γ_f factors as

$$M \otimes_S N \longrightarrow (M \otimes_S N)_f \xrightarrow{\gamma'_f} M_{(f)} \otimes_{S_{(f)}} N_{(f)} \ ;$$

if λ'_f is the restriction of γ'_f to $(M \otimes_S N)_{(f)}$, we verify immediately that λ_f and λ'_f are [II | 35]
mutually inverse $S_{(f)}$-homomorphisms, whence the first part of the proposition.

To prove the second part, suppose that M is the cokernel of a homomorphism $P \to Q$ of graded S-modules, P and Q being direct sums of finitely many modules of the form $S(n)$; using the left exactness of $\mathrm{Hom}_S(L, N)$ in L and the exactness of $M_{(f)}$ in M, we are immediately reduced to proving that μ_f is an isomorphism when $M = S(n)$. Now, for every homogeneous z in N, let u_z be the homomorphism from $S(n)$ to N such that $u_z(1) = z$; we see immediately that $\eta : z \mapsto u_z$ is an isomorphism of degree 0 of $N(-n)$ onto $\mathrm{Hom}_S(S(n), N)$. To it there corresponds an isomorphism

$$\eta_f : \big(N(-n)\big)_{(f)} \longrightarrow \big(\mathrm{Hom}_S(S(n), N)\big)_{(f)}.$$

On the other hand, let η'_f be the isomorphism

$$N_{(f)} \longrightarrow \mathrm{Hom}_{S_{(f)}}\big(S(n)_{(f)}, N_{(f)}\big)$$

which assigns to every $z' \in N_{(f)}$ the homomorphism $v_{z'}$ such that $v_{z'}(s/f^k) = sz'/f^{n+k}$ (for $s \in S_{n+k} = (S(n))_k$). We easily check that the composite map

$$\big(N(-n)\big)_{(f)} \xrightarrow{\eta_f} \big(\mathrm{Hom}_S(S(n), N)\big)_{(f)} \xrightarrow{\mu_f} \mathrm{Hom}_{S_{(f)}}\big(S(n)_{(f)}, N_{(f)}\big) \xrightarrow{{\eta'_f}^{-1}} N_{(f)}$$

is the isomorphism $z/f^h \mapsto z/f^{h-n}$ of $\big(N(-n)\big)_{(f)}$ onto $N_{(f)}$, so μ_f is an isomorphism. □

If the ideal S_+ is generated by S_1, we deduce from (2.5.13) that for every graded ideal $\mathfrak{J}$ of S and every graded S-module M, we have

$$\widetilde{\mathfrak{J}} \cdot \widetilde{M} = \widetilde{\mathfrak{J} \cdot M} \tag{2.5.13.1}$$

up to canonical isomorphism; indeed, this follows from the commutativity of the diagram

$$\begin{array}{ccc} \widetilde{\mathfrak{J}} \otimes_{\mathcal{O}_X} \widetilde{M} & \xrightarrow{\lambda} & \widetilde{\mathfrak{J} \otimes_S M} \\ & \searrow \quad \swarrow & \\ & \widetilde{M} & \end{array}$$

which is verified like that of (2.5.11.3).

(2.5.14) Corollary. *Suppose S is generated by S_1. Then, for all m, n in $\mathbf{Z}$, we have:*

$$\mathcal{O}_X(m) \otimes_{\mathcal{O}_X} \mathcal{O}_X(n) = \mathcal{O}_X(m+n) \tag{2.5.14.1}$$

$$\mathcal{O}_X(n) = (\mathcal{O}_X(1))^{\otimes n} \tag{2.5.14.2}$$

up to canonical isomorphisms.

Proof. The first formula follows from (2.5.13) and from the existence of the canonical isomorphism of degree 0, $S(m) \otimes_S S(n) \xrightarrow{\sim} S(m+n)$, which maps the element $1 \otimes 1$ (where the first factor 1 is in $(S(m))_{-m}$ and the second in $(S(n))_{-n}$) to the element $1 \in (S(m+n))_{-m-n}$. It then suffices to prove the second formula for $n = -1$, and by virtue of (2.5.13), this amounts to seeing that $\mathrm{Hom}_S(S(1), S)$ is canonically isomorphic to $S(-1)$, an immediate verification by going back to the definitions (2.1.2) and remembering that $S(1)$ is a monogenic S-module. □

[II | 36] **(2.5.15) Corollary.** *Suppose S is generated by S_1. For every graded S-module M and every $n \in \mathbf{Z}$, we have*

$$\widetilde{M(n)} = \widetilde{M}(n) \tag{2.5.15.1}$$

up to canonical isomorphism.

Proof. This follows from the definitions (2.5.10.2) and (2.5.10.1), from Proposition (2.5.13) and from the existence of a canonical isomorphism $M(n) \xrightarrow{\sim} M \otimes_S S(n)$ of degree 0 which maps every $z \in (M(n))_h = M_{n+h}$ to $z \otimes 1 \in M_{n+h} \otimes (S(n))_{-n} \subset (M \otimes_S S(n))_h$. □

(2.5.16) Denote by S' the graded ring such that $S'_0 = \mathbf{Z}$, $S'_n = S_n$ for $n > 0$. Then, if $f \in S_d$ $(d > 0)$, we have $(S(n))_{(f)} = (S'(n))_{(f)}$ for every $n \in \mathbf{Z}$, since an element of $(S'(n))_{(f)}$ is of the form x/f^k with $x \in S'_{n+kd}$ $(k > 0)$, and we can always take k such that $n + kd \neq 0$. Since $X = \mathrm{Proj}(S)$ and $X' = \mathrm{Proj}(S')$ are canonically identified (2.4.7, (ii)), we see that for every $n \in \mathbf{Z}$, $\mathcal{O}_X(n)$ and $\mathcal{O}_{X'}(n)$ are images of each other under the preceding identification.

Note on the other hand that for every $d > 0$ and every $n \in \mathbf{Z}$, we have

$$(S^{(d)}(n))_h = S_{(n+h)d} = (S(nd))_{hd}$$

for $f \in S_d$, we therefore have $(S^{(d)}(n))_{(f)} = (S(nd))_{(f)}$. We know that the schemes $X = \mathrm{Proj}(S)$ and $X^{(d)} = \mathrm{Proj}(S^{(d)})$ are canonically identified (2.4.7, (i)); the foregoing

shows that if the S_0-algebra $S^{(d)}$ is generated by S_d, then $\mathcal{O}_X(nd)$ and $\mathcal{O}_{X^{(d)}}(n)$ are images of each other under this identification, for every $n \in \mathbf{Z}$.

(2.5.17) Proposition. *Let d be an integer > 0, and let $U = \bigcup_{f\in S_d} D_+(f)$. The restriction to U of the canonical homomorphism $\mathcal{O}_X(nd) \otimes_{\mathcal{O}_X} \mathcal{O}_X(-nd) \to \mathcal{O}_X$ is an isomorphism for every integer n.*

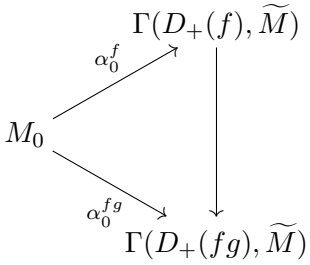
Proof. By virtue of (2.5.16), we may restrict to the case where $d = 1$, and the conclusion then follows from the proof of (2.5.13). □

2.6 Graded S-module associated to a sheaf on $\mathrm{Proj}(S)$.

Throughout this number, we suppose that the ideal S_+ of S is generated by the set S_1 of homogeneous elements of degree 1.

(2.6.1) The $\mathcal{O}_X$-module $\mathcal{O}_X(1)$ is then *invertible* (2.5.9); we then set, for every $\mathcal{O}_X$-module $\mathcal{F}$ (0, 5.4.6),

$$\Gamma_*(\mathcal{F}) = \Gamma_*(\mathcal{O}_X(1), \mathcal{F}) = \bigoplus_{n\in\mathbf{Z}} \Gamma(X, \mathcal{F}(n)) \tag{2.6.1.1}$$



taking into account (2.5.14.2). Recall (0, 5.4.6) that $\Gamma_*(\mathcal{O}_X)$ is endowed with a structure of *graded ring*, and $\Gamma_*(\mathcal{F})$ with a structure of *graded module* over $\Gamma_*(\mathcal{O}_X)$.

Since $\mathcal{O}_X(n)$ is locally free, $\Gamma_*(\mathcal{F})$ is an additive covariant functor in $\mathcal{F}$ which is *left exact*; in particular, if $\mathcal{J}$ is a sheaf of ideals of $\mathcal{O}_X$, $\Gamma_*(\mathcal{J})$ is canonically identified with a *graded ideal* of $\Gamma_*(\mathcal{O}_X)$.

(2.6.2) Let M be a graded S-module; for every $f \in S_d$ ($d > 0$), $x \mapsto x/1$ is a homomorphism of abelian groups $M_0 \to M_{(f)}$, and since $M_{(f)}$ is canonically identified with $\Gamma(D_+(f), \widetilde{M})$, we thus obtain a homomorphism of abelian groups [II | 37]

$$\alpha_0^f : M_0 \longrightarrow \Gamma(D_+(f), \widetilde{M}).$$

It is clear that, for every $g \in S_e$ ($e > 0$), the diagram

is commutative; this means that for every $x \in M_0$, the sections $\alpha_0^f(x)$ and $\alpha_0^g(x)$ of $\widetilde{M}$ coincide in $D_+(f) \cap D_+(g)$, and consequently there exists a unique section $\alpha_0(x) \in \Gamma(X, \widetilde{M})$ whose restriction to each $D_+(f)$ is $\alpha_0^f(x)$. We have thus defined (without using the hypothesis that S is generated by S_1) a homomorphism of abelian groups

$$\alpha_0 : M_0 \longrightarrow \Gamma(X, \widetilde{M}). \tag{2.6.2.1}$$

Applying this result to the graded S-module $M(n)$ (for every $n \in \mathbf{Z}$), we obtain for each $n \in \mathbf{Z}$ a homomorphism of abelian groups

$$\alpha_n : M_n = (M(n))_0 \longrightarrow \Gamma(X, \widetilde{M}(n)) \tag{2.6.2.2}$$

(taking into account (2.5.15)); whence a functorial homomorphism (of degree 0) of graded abelian groups

$$\alpha : M \longrightarrow \Gamma_*(\widetilde{M}) \tag{2.6.2.3}$$

(also denoted by α_M) which coincides with α_n on each M_n.

If in particular we take $M = S$, we verify immediately (taking into account the definition of the multiplication in $\Gamma_*(\mathcal{O}_X)$ (0, 5.4.6)) that $\alpha : S \to \Gamma_*(\mathcal{O}_X)$ is a homomorphism of graded rings, and that for every graded S-module M, (2.6.2.3) is a di-homomorphism of graded modules.

(2.6.3) Proposition. *For every $f \in S_d$ $(d > 0)$, $D_+(f)$ is identical to the set of $\mathfrak{p} \in X$ where the section $\alpha_d(f)$ of $\mathcal{O}_X(d)$ does not vanish (0, 5.5.2).*

Proof. Since $X = \bigcup_{g \in S_1} D_+(g)$ by hypothesis, it suffices to verify that for every $g \in S_1$, the set of $\mathfrak{p} \in D_+(g)$ where $\alpha_d(f)$ does not vanish is identical to $D_+(fg)$. Now, the restriction of $\alpha_d(f)$ to $D_+(g)$ is by definition the section corresponding to the element $f/1$ of $(S(d))_{(g)}$; under the canonical isomorphism $(S(d))_{(g)} \xrightarrow{\sim} S_{(g)}$ (2.5.7), this section of $\mathcal{O}_X(d)$ over $D_+(g)$ is identified with the section of $\mathcal{O}_X$ over $D_+(g)$ which corresponds to the element f/g^d of $S_{(g)}$; to say that this section vanishes at $\mathfrak{p} \in D_+(g)$ means that $f/g^d \in \mathfrak{q}$, where $\mathfrak{q}$ is the prime ideal of $S_{(g)}$ corresponding to $\mathfrak{p}$ (2.3.6); by definition this means that $f \in \mathfrak{p}$, whence the proposition. □

(2.6.4) Now let $\mathcal{F}$ be an $\mathcal{O}_X$-module, and set $M = \Gamma_*(\mathcal{F})$; by virtue of the existence of the homomorphism of graded rings $\alpha : S \to \Gamma_*(\mathcal{O}_X)$, M can be regarded as a graded S-module. For every $f \in S_d$ $(d > 0)$, it follows from (2.6.3) that the restriction to $D_+(f)$ of the section $\alpha_d(f)$ of $\mathcal{O}_X(d)$ is invertible; hence so is the restriction to $D_+(f)$ of the section $\alpha_d(f^n)$ of $\mathcal{O}_X(nd)$, for every $n > 0$. Let then $z \in M_{nd} = \Gamma(X, \mathcal{F}(nd))$ $(n > 0)$; if there exists an integer $k \geq 0$ such that the restriction to $D_+(f)$ of $f^k z$,
[II | 38] that is, the section $(z|D_+(f))(\alpha_d(f^k)|D_+(f))$ of $\mathcal{F}((n+k)d)$, is zero, then, because of the preceding remark, we also have $z|D_+(f) = 0$. This shows that we define an $S_{(f)}$-homomorphism $\beta_f : M_{(f)} \to \Gamma(D_+(f), \mathcal{F})$ by assigning to the element z/f^n the section $(z|D_+(f))(\alpha_d(f^n)|D_+(f))^{-1}$ of $\mathcal{F}$ over $D_+(f)$. Moreover, we verify immediately that the diagram

$$\begin{array}{ccc} M_{(f)} & \xrightarrow{\beta_f} & \Gamma(D_+(f), \mathcal{F}) \\ \downarrow & & \downarrow \\ M_{(fg)} & \xrightarrow[\beta_{fg}]{} & \Gamma(D_+(fg), \mathcal{F}) \end{array} \tag{2.6.4.1}$$

is commutative for $g \in S_e$ $(e > 0)$. If we recall that $M_{(f)}$ is canonically identified with $\Gamma(D_+(f), \widetilde{M})$ and that the $D_+(f)$ form a basis of the topology of X (2.3.4), we see that the β_f come from a unique canonical homomorphism of $\mathcal{O}_X$-modules

$$\beta : \widetilde{\Gamma_*(\mathcal{F})} \longrightarrow \mathcal{F} \tag{2.6.4.2}$$

(also denoted by $\beta_{\mathcal{F}}$), which is evidently functorial.

(2.6.5) Proposition. *Let M be a graded S-module and $\mathcal{F}$ an $\mathcal{O}_X$-module; then the composite homomorphisms*

$$\widetilde{M} \xrightarrow{\widetilde{\alpha}} \widetilde{\Gamma_*(\widetilde{M})} \xrightarrow{\beta} \widetilde{M} \tag{2.6.5.1}$$

$$\Gamma_*(\mathcal{F}) \xrightarrow{\alpha} \Gamma_*(\widetilde{\Gamma_*(\mathcal{F})}) \xrightarrow{\Gamma_*(\beta)} \Gamma_*(\mathcal{F}) \tag{2.6.5.2}$$

are the identity isomorphisms.

Proof. The verification of (2.6.5.1) is local: in an open subset $D_+(f)$, it follows immediately from the definitions and from the fact that β, applied to quasi-coherent sheaves, is determined by its action on the sections over $D_+(f)$ (I, 1.3.8). The verification of (2.6.5.2) is done for each degree separately: if we set $M = \Gamma_*(\mathcal{F})$, we have $M_n = \Gamma(X, \mathcal{F}(n))$ and $(\Gamma_*(\widetilde{M}))_n = \Gamma(X, \widetilde{M}(n)) = \Gamma(X, \widetilde{M(n)})$. Now, if $f \in S_1$ and $z \in M_n$, $\alpha_n^f(z)$ is the element $z/1$ of $(M(n))_{(f)}$, equal to $(f/1)^n(z/f^n)$; to it there corresponds under β_f the section

$$((\alpha_1(f))^n|D_+(f))((z|D_+(f))((\alpha_1(f))^n|D_+(f))^{-1})$$

over $D_+(f)$, that is, the restriction of z to $D_+(f)$, which verifies (2.6.5.2). □

2.7 Finiteness conditions.

(2.7.1) Proposition.

(i) *If S is a Noetherian graded ring, $X = \mathrm{Proj}(S)$ is a Noetherian scheme.*

(ii) *If S is a graded A-algebra of finite type, $X = \mathrm{Proj}(S)$ is a scheme of finite type over $Y = \mathrm{Spec}(A)$.*

Proof. (i) If S is Noetherian, the ideal S_+ admits a finite system of homogeneous generators f_i $(1 \leq i \leq p)$, so (2.3.14) the underlying space X is the union of the $D_+(f_i) = \mathrm{Spec}(S_{(f_i)})$, and everything comes down to showing that each of the $S_{(f_i)}$ is Noetherian, which follows from (2.2.6). [II | 39]

(ii) The hypothesis implies that S_0 is an A-algebra of finite type and S an S_0-algebra of finite type, so S_+ is an ideal of finite type (2.1.4). We are then reduced, as in (i), to proving that for $f \in S_d$, $S_{(f)}$ is an A-algebra of finite type. By virtue of (2.2.5), it suffices to show that $S^{(d)}$ is an A-algebra of finite type, which follows from (2.1.6).

□

(2.7.2) In what follows we will consider the following finiteness conditions for a graded S-module M:

(TF) There exists an integer n such that the submodule $\bigoplus_{k \geq n} M_k$ is an S-module of finite type.

(TN) There exists an integer n such that $M_k = 0$ for $k \geq n$.

If M satisfies (TN), we have $M_{(f)} = 0$ for every homogeneous f in S_+, hence $\widetilde{M} = 0$.

Let M, N be two graded S-modules; we say that a homomorphism $u : M \to N$ of degree 0 is (TN)-*injective* (resp. (TN)-*surjective*, (TN)-*bijective*) if there exists an integer n such that $u_k : M_k \to N_k$ is injective (resp. surjective, bijective) for $k \geq n$. To say that u is (TN)-injective (resp. (TN)-surjective) therefore amounts to saying that $\mathrm{Ker}\, u$ (resp. $\mathrm{Coker}\, u$) satisfies (TN). By virtue of (2.5.4), if u is (TN)-injective (resp. (TN)-surjective, (TN)-bijective), $\widetilde{u}$ is injective (resp. surjective, bijective); when u is (TN)-bijective, we also say that u is a (TN)-*isomorphism*.

(2.7.3) Proposition. *Let S be a graded ring such that the ideal S_+ is of finite type, and M a graded S-module.*

(i) *If M satisfies condition (TF), the $\mathcal{O}_X$-module $\widetilde{M}$ is of finite type.*

(ii) *Suppose that M satisfies (TF); in order that $\widetilde{M} = 0$, it is necessary and sufficient that M satisfy (TN).*

Proof. We have just seen that condition (TN) implies $\widetilde{M} = 0$. If M satisfies (TF), the graded submodule $M' = \bigoplus_{k \geq n} M_k$, which is of finite type by hypothesis, is such that M/M' satisfies (TN); consequently $\widetilde{M/M'} = 0$, and the exactness of the functor $M \mapsto \widetilde{M}$ (2.5.4) implies $\widetilde{M} = \widetilde{M'}$; to prove that $\widetilde{M}$ is of finite type, we are therefore reduced to the case where M is of finite type. The question being local, it suffices to prove that $M_{(f)}$ is an $S_{(f)}$-module of finite type (I, 1.3.9); but $M^{(d)}$ is an $S^{(d)}$-module of finite type (2.1.6, (iii)) and our assertion then follows from (2.2.5).

Suppose now that M satisfies (TF) and that $\widetilde{M} = 0$; then, with the same notation as above, we have $\widetilde{M'} = 0$, and condition (TN) for M' is equivalent to condition (TN) for M; so, to prove that $\widetilde{M} = 0$ implies that M satisfies (TN), we may again restrict to the case where M is generated by finitely many homogeneous elements x_i $(1 \leq i \leq p)$; on the other hand, let $(f_j)_{1 \leq j \leq q}$ be a system of homogeneous generators of the ideal S_+. By hypothesis we have $M_{(f_j)} = 0$ for every j, so there exists an integer n such that $f_j^n x_i = 0$ for all i and j. Let n_j be the degree of f_j, and let m be the largest value of $\sum_j r_j n_j$ for the systems of integers (r_j), finite in number, such that $\sum_j r_j \leq nq$; it is then clear
[II | 40] that if $k > m$, we have $S_k x_i = 0$ for every i; if h is the largest of the degrees of the x_i, we conclude that $M_k = 0$ for $k > h + m$, which completes the proof. □

(2.7.4) Corollary. *Let S be a graded ring such that the ideal S_+ is of finite type; in order that $X = \mathrm{Proj}(S) = \varnothing$, it is necessary and sufficient that there exist n such that $S_k = 0$ for $k \geq n$.*

Proof. Indeed, the condition $X = \varnothing$ is equivalent to $\mathcal{O}_X = \widetilde{S} = 0$, and S is a monogenic S-module. □

(2.7.5) Theorem. *Suppose that the ideal S_+ is generated by finitely many homogeneous elements of degree 1; let $X = \mathrm{Proj}(S)$. Then, for every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, the canonical homomorphism $\beta : \widetilde{\Gamma_*(\mathcal{F})} \to \mathcal{F}$ (2.6.4) is an isomorphism.*

Proof. Indeed, if S_+ is generated by finitely many elements $f_i \in S_1$, X is the union of the subspaces $\mathrm{Spec}(S_{(f_i)})$ (2.3.6), which are quasi-compact, and is therefore quasi-compact; moreover X is a scheme (2.4.2); by (I, 9.3.2), (2.5.14.2) and (2.6.3) we have, for every $f \in S_d$ $(d > 0)$, a canonical isomorphism $(\Gamma_*(\mathcal{F}))_{(\alpha_d(f))} \xrightarrow{\sim} \Gamma(D_+(f), \mathcal{F})$; besides, by definition, $(\Gamma_*(\mathcal{F}))_{(\alpha_d(f))}$ (where $\Gamma_*(\mathcal{F})$ is regarded as a $\Gamma_*(\mathcal{O}_X)$-module) is none other than $(\Gamma_*(\mathcal{F}))_{(f)}$ (where $\Gamma_*(\mathcal{F})$ is regarded as an S-module); if we refer to the definition (I, 9.3.1) of the preceding canonical isomorphism, we see that it coincides with the homomorphism β_f, whence the theorem. □

(2.7.6) Remark. If the graded ring S is assumed to be *Noetherian*, the condition of (2.7.5) is satisfied *ipso facto* as soon as the ideal S_+ is assumed to be generated by the set S_1 of homogeneous elements of degree 1.

(2.7.7) Corollary. *Under the hypotheses of (2.7.5), every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ is isomorphic to an $\mathcal{O}_X$-module of the form $\widetilde{M}$, where M is a graded S-module.*

(2.7.8) Corollary. *Under the hypotheses of (2.7.5), every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ of finite type is isomorphic to an $\mathcal{O}_X$-module of the form $\widetilde{N}$, where N is a graded S-module of finite type.*

Proof. We may suppose $\mathcal{F} = \widetilde{M}$, where M is a graded S-module (2.7.7). Let $(f_\lambda)_{\lambda\in L}$ be a system of homogeneous generators of M; for every finite subset H of L, let M_H be the graded submodule of M generated by the f_λ such that $\lambda \in H$; it is clear that M is the inductive limit of its submodules M_H, so $\mathcal{F}$ is the inductive limit of its sub-$\mathcal{O}_X$-modules $\widetilde{M_H}$ (2.5.4). But since $\mathcal{F}$ is of finite type and the underlying space X is quasi-compact, it follows from (0, 5.2.3) that $\mathcal{F} = \widetilde{M_H}$ for some finite subset H of L. □

(2.7.9) Corollary. *Under the hypotheses of (2.7.5), let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type. Then there exists an integer n_0 such that, for every $n \geq n_0$, $\mathcal{F}(n)$ is isomorphic to a quotient of an $\mathcal{O}_X$-module of the form $\mathcal{O}_X^k$ ($k > 0$ depending on n), and consequently is generated by finitely many of its sections over X (0, 5.1.1).*

Proof. By virtue of (2.7.8), we may suppose that $\mathcal{F} = \widetilde{M}$, where M is a quotient of a finite direct sum of S-modules of the form $S(m_i)$; by virtue of (2.5.4) we may therefore restrict to the case where $M = S(m)$, so that $\mathcal{F}(n) = \widetilde{S(m+n)} = \mathcal{O}_X(m+n)$ (2.5.15). It will therefore suffice to prove

(2.7.9.1) Lemma. *Under the hypotheses of (2.7.5), for every $n \geq 0$, there exist an integer k (depending on n) and a surjective homomorphism $\mathcal{O}_X^k \to \mathcal{O}_X(n)$.* [II | 41]

Indeed, it suffices (2.7.2) to show that, for a suitable k, there is a (TN)-surjective homomorphism u *of degree* 0 from the product graded S-module S^k to $S(n)$. Now, we have $(S(n))_0 = S_n$, and by hypothesis $S_h = S_1^h$ for every $h > 0$, so $SS_n = S_n + S_{n+1} + \cdots$. Since S_n is an S_0-module of finite type (2.1.5 and 2.1.6, (i)), consider a system of generators $(a_i)_{1\leq i\leq k}$ of this module; the homomorphism u will send the i-th element of the canonical basis of S^k to a_i ($1 \leq i \leq k$); since $\operatorname{Coker} u$ is then identified with $(S(n))_{-n} + \cdots + (S(n))_{-1}$, u indeed meets the requirement. □

(2.7.10) Corollary. *Under the hypotheses of (2.7.5), let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type. There exists an integer n_0 such that, for every $n \geq n_0$, $\mathcal{F}$ is isomorphic to a quotient of an $\mathcal{O}_X$-module of the form $(\mathcal{O}_X(-n))^k$ (k depending on n).*

(2.7.11) Proposition. *Suppose that the hypotheses of (2.7.5) are satisfied, and let M be a graded S-module. Then:*

(i) *The canonical homomorphism $\widetilde{\alpha} : \widetilde{M} \to \widetilde{\Gamma_*(\widetilde{M})}$ is an isomorphism.*

(ii) *Let $\mathcal{G}$ be a quasi-coherent sub-$\mathcal{O}_X$-module of $\widetilde{M}$, and let N be the graded sub-S-module of M that is the inverse image of $\Gamma_*(\mathcal{G})$ under α. Then we have $\widetilde{N} = \mathcal{G}$ ($\widetilde{N}$ being identified, by virtue of (2.5.4), with a sub-$\mathcal{O}_X$-module of $\widetilde{M}$).*

Proof. Since $\beta : \widetilde{\Gamma_*(\widetilde{M})} \to \widetilde{M}$ is an isomorphism by virtue of (2.7.5), $\widetilde{\alpha}$ is the inverse isomorphism by virtue of (2.6.5.1), whence (i). Let P be the graded submodule $\alpha(M)$ of $\Gamma_*(\widetilde{M})$; since $M \mapsto \widetilde{M}$ is an exact functor (2.5.4), the image of $\widetilde{M}$ under $\widetilde{\alpha}$ is equal to $\widetilde{P}$, so, by virtue of (i), $\widetilde{P} = \widetilde{\Gamma_*(\widetilde{M})}$. Set $Q = \Gamma_*(\mathcal{G}) \cap P$; by virtue of the foregoing and of (2.5.4), we have $\widetilde{Q} = \widetilde{\Gamma_*(\mathcal{G})}$, so the restriction of β to $\widetilde{Q}$ is an *isomorphism* of this

$\mathcal{O}_X$-module onto $\mathcal{G}$ by (2.7.5). But by the definition of N and (2.5.4), the restriction of the isomorphism $\widetilde{\alpha}$ to $\widetilde{N}$ is an isomorphism of $\widetilde{N}$ onto $\widetilde{Q}$, whence the conclusion by (2.6.5.1). □

2.8 Functorial behaviour.

(2.8.1) Let S, S' be two rings graded in positive degrees, and $\varphi : S' \to S$ a homomorphism of graded rings. We denote by $G(\varphi)$ the open subset of $X = \mathrm{Proj}(S)$ complementary to $V_+(\varphi(S'_+))$, or, what amounts to the same, the union of the $D_+(\varphi(f'))$, where f' runs through the set of homogeneous elements of S'_+. The restriction to $G(\varphi)$ of the continuous map ${}^a\varphi$ from $\mathrm{Spec}(S)$ to $\mathrm{Spec}(S')$ (I, 1.2.1) is therefore a continuous map from $G(\varphi)$ to $\mathrm{Proj}(S')$, which we again denote by ${}^a\varphi$ by abuse of language. If $f' \in S'_+$ is homogeneous, we have

$$ {}^a\varphi^{-1}(D_+(f')) = D_+(\varphi(f')) \tag{2.8.1.1} $$

taking into account the fact that ${}^a\varphi$ maps $G(\varphi)$ into $\mathrm{Proj}(S')$, and (I, 1.2.2.2). On the other hand, the homomorphism φ canonically defines (with the same notation) a homomorphism of graded rings $S'_{f'} \to S_f$, whence, by restriction to the elements of degree 0,

[II | 42] a homomorphism $S'_{(f')} \to S_{(f)}$, which we denote by $\varphi_{(f)}$; to it there corresponds (I, 1.6.1) a morphism $({}^a\varphi_{(f)}, \widetilde{\varphi}_{(f)}) : \mathrm{Spec}(S_{(f)}) \to \mathrm{Spec}(S'_{(f')})$ of affine schemes. If we canonically identify $\mathrm{Spec}(S_{(f)})$ with the scheme induced by $\mathrm{Proj}(S)$ on $D_+(f)$ (2.3.6), we have defined a morphism $\Phi_f : D_+(f) \to D_+(f')$, and ${}^a\varphi_{(f)}$ is identified with the restriction of ${}^a\varphi$ to $D_+(f)$. On the other hand, it is immediate that if g' is a second homogeneous element of S'_+ and $g = \varphi(g')$, the diagram

$$ \begin{array}{ccc} D_+(f) & \xrightarrow{\Phi_f} & D_+(f') \\ \uparrow & & \uparrow \\ D_+(fg) & \xrightarrow[\Phi_{fg}]{} & D_+(f'g') \end{array} $$

is commutative, because of the commutativity of the diagram

$$ \begin{array}{ccc} S'_{(f')} & \xrightarrow{\varphi_{(f)}} & S_{(f)} \\ {\scriptstyle \omega_{f'g',f'}}\downarrow & & \downarrow{\scriptstyle \omega_{fg,f}} \\ S'_{(f'g')} & \xrightarrow[\varphi_{(fg)}]{} & S_{(fg)} \end{array} $$

Taking into account the definition of $G(\varphi)$ and (2.3.3.2), we therefore see that:

(2.8.2) Proposition. *Given a homomorphism of graded rings $\varphi : S' \to S$, there exists one and only one morphism $({}^a\varphi, \widetilde{\varphi})$ from the induced prescheme $G(\varphi)$ to* $\mathrm{Proj}(S')$ *(said to be* associated to φ *and denoted* $\mathrm{Proj}(\varphi)$*) such that, for every homogeneous element $f' \in S'_+$, the restriction of this morphism to $D_+(\varphi(f'))$ coincides with the morphism associated to the homomorphism $S'_{(f')} \to S_{(\varphi(f'))}$ corresponding to φ.*

Proof. We note that, with the preceding notation, if $f' \in S'_d$, the diagram

$$ \begin{array}{ccc} S'_{(f')} & \xrightarrow{\qquad\varphi_{(f)}\qquad} & S_{(f)} \\ {\scriptstyle\sim}\downarrow & & \downarrow{\scriptstyle\sim} \\ S'^{(d)}/(f'-1)S'^{(d)} & \longrightarrow & S^{(d)}/(f-1)S^{(d)} \end{array} \tag{2.8.2.1} $$

is commutative (the vertical arrows being the isomorphisms (2.2.5)). □

(2.8.3) Corollary.

(i) *The morphism* $\mathrm{Proj}(\varphi)$ *is affine.*

(ii) *If* $\mathrm{Ker}(\varphi)$ *is nilpotent (and in particular if* φ *is injective), the morphism* $\mathrm{Proj}(\varphi)$ *is dominant.*

Proof. (i) is an immediate consequence of (2.8.2) and (2.8.1.1). On the other hand, if $\mathrm{Ker}(\varphi)$ is nilpotent, then for every homogeneous f' in S'_+ we verify immediately that $\mathrm{Ker}(\varphi_f)$ (with $f = \varphi(f')$) is nilpotent, hence so is $\mathrm{Ker}(\varphi_{(f)})$; the conclusion therefore follows from (2.8.2) and (I, 1.2.7). □

We note that there are in general morphisms from $\mathrm{Proj}(S)$ to $\mathrm{Proj}(S')$ that are not affine, and therefore do not come from homomorphisms of graded rings $S' \to S$; an example is the structural morphism $\mathrm{Proj}(S) \to \mathrm{Spec}(A)$ when A is a field ($\mathrm{Spec}(A)$ being identified with $\mathrm{Proj}(A[T])$ (cf. (3.1.7))); indeed, this follows from (I, 2.3.2). [II | 43]

(2.8.4) Let S'' be a third ring graded in positive degrees, $\varphi' : S'' \to S'$ a homomorphism of graded rings, and set $\varphi'' = \varphi \circ \varphi'$. Because of (2.8.1.1) and the formula ${}^a\varphi'' = ({}^a\varphi') \circ ({}^a\varphi)$, we verify immediately that $G(\varphi'') \subset G(\varphi)$ and that, if Φ, Φ' and Φ'' are the morphisms associated to φ, φ' and φ'', we have $\Phi'' = \Phi' \circ (\Phi | G(\varphi''))$.

(2.8.5) Suppose that S (resp. S') is a graded A-algebra (resp. a graded A'-algebra), and let $\psi : A' \to A$ be a ring homomorphism such that the diagram

$$\begin{array}{ccc} A' & \xrightarrow{\psi} & A \\ \downarrow & & \downarrow \\ S' & \xrightarrow[\varphi]{} & S \end{array} \tag{2.8.5.1}$$

is commutative. We can then regard $G(\varphi)$ and $\mathrm{Proj}(S')$ as schemes over $\mathrm{Spec}(A)$ and $\mathrm{Spec}(A')$ respectively; if Φ and Ψ are the morphisms associated respectively to φ and ψ, the diagram

$$\begin{array}{ccc} G(\varphi) & \xrightarrow{\Phi} & \mathrm{Proj}(S') \\ \downarrow & & \downarrow \\ \mathrm{Spec}(A) & \xrightarrow[\Psi]{} & \mathrm{Spec}(A') \end{array}$$

is then commutative: indeed, it suffices to prove this for the restriction of Φ to $D_+(f)$, where $f = \varphi(f')$, f' homogeneous in S'_+; and then it follows from the commutativity of the diagram

$$\begin{array}{ccc} A' & \xrightarrow{\psi} & A \\ \downarrow & & \downarrow \\ S'_{(f')} & \xrightarrow[\varphi_{(f)}]{} & S_{(f)} \end{array}$$

(2.8.6) Now let M be a graded S-module, and consider the S'-module $M_{[\varphi]}$, which is evidently graded. Let f' be homogeneous in S'_+, and let $f = \varphi(f')$; we know

(0, 1.5.2) that there is a canonical isomorphism $(M_{[\varphi]})_{f'} \xrightarrow{\sim} (M_f)_{[\varphi_f]}$, and it is immediate that this isomorphism preserves degrees, so there is a canonical isomorphism $(M_{[\varphi]})_{(f')} \xrightarrow{\sim} (M_{(f)})_{[\varphi_{(f)}]}$. To this isomorphism there canonically corresponds an isomorphism of sheaves $\widetilde{M_{[\varphi]}}|D_+(f') \xrightarrow{\sim} (\Phi_f)_*(\widetilde{M}|D_+(f))$ (2.5.2 and I, 1.6.3). Moreover,
[II | 44] if g' is a second homogeneous element of S'_+ and $g = \varphi(g')$, the diagram

$$\begin{array}{ccc} (M_{[\varphi]})_{(f')} & \xrightarrow{\sim} & (M_{(f)})_{[\varphi_{(f)}]} \\ \downarrow & & \downarrow \\ (M_{[\varphi]})_{(f'g')} & \xrightarrow{\sim} & (M_{(fg)})_{[\varphi_{(fg)}]} \end{array}$$

is commutative, from which we immediately conclude that the isomorphism

$$\widetilde{M_{[\varphi]}}|D_+(f'g') \xrightarrow{\sim} (\Phi_{fg})_*(\widetilde{M}|D_+(fg))$$

is the restriction to $D_+(f'g')$ of the isomorphism $\widetilde{M_{[\varphi]}}|D_+(f') \xrightarrow{\sim} (\Phi_f)_*(\widetilde{M}|D_+(f))$. Since Φ_f is the restriction to $D_+(f)$ of the morphism Φ, we therefore see, taking into account (2.8.1.1), and setting $X' = \mathrm{Proj}(S')$:

(2.8.7) Proposition. *There exists a canonical functorial isomorphism of the $\mathcal{O}_{X'}$-module $\widetilde{M_{[\varphi]}}$ onto the $\mathcal{O}_{X'}$-module $\Phi_*(\widetilde{M}|G(\varphi))$.*

From this we immediately deduce a canonical functorial map from the set of φ-morphisms $M' \to M$ of a graded S'-module into the graded S-module M to the set of Φ-morphisms $\widetilde{M'} \to \widetilde{M}|G(\varphi)$. With the notation of (2.8.4), if M'' is a graded S''-module, to the composite of a φ-morphism $M' \to M$ and a φ'-morphism $M'' \to M'$ there canonically corresponds the composite of $\widetilde{M'}|G(\varphi') \to \widetilde{M}|G(\varphi'')$ and $\widetilde{M''} \to \widetilde{M'}|G(\varphi')$.

(2.8.8) Proposition. *Under the hypotheses of (2.8.1), let M' be a graded S'-module. There exists a canonical functorial homomorphism ν from the $(\mathcal{O}_X|G(\varphi))$-module $\Phi^*(\widetilde{M'})$ to the $(\mathcal{O}_X|G(\varphi))$-module $\widetilde{M' \otimes_{S'} S}|G(\varphi)$. If the ideal S'_+ is generated by S'_1, ν is an isomorphism.*

Proof. Indeed, for $f' \in S'_d$ $(d > 0)$, we define a canonical functorial homomorphism of $S_{(f)}$-modules (where $f = \varphi(f')$)

$$\nu_f : M'_{(f')} \otimes_{S'_{(f')}} S_{(f)} \longrightarrow (M' \otimes_{S'} S)_{(f)} \tag{2.8.8.1}$$

by composing the homomorphism $M'_{(f')} \otimes_{S'_{(f')}} S_{(f)} \to M'_{f'} \otimes_{S'_{f'}} S_f$ and the canonical isomorphism $M'_{f'} \otimes_{S'_{f'}} S_f \xrightarrow{\sim} (M' \otimes_{S'} S)_f$ (0, 1.5.4), and noting that the latter preserves degrees. We verify immediately that the ν_f are compatible with the restriction operators from $D_+(f)$ to $D_+(fg)$ (for a second $g' \in S'_+$ and $g = \varphi(g')$), whence the definition of the homomorphism

$$\nu : \Phi^*(\widetilde{M'}) \longrightarrow \widetilde{M' \otimes_{S'} S}|G(\varphi)$$

taking into account (I, 1.6.5). To prove the second assertion, it suffices to show that ν_f is an isomorphism for every $f' \in S'_1$, since $G(\varphi)$ is then the union of the $D_+(\varphi(f'))$. We first define a $\mathbf{Z}$-bilinear map $M'_m \times S_n \to M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}$ by sending (x', s) to the element $(x'/f'^m) \otimes (s/f^n)$ (with the convention that x'/f'^m is $f'^{-m}x'/1$

when $m < 0$). We see, as in the proof of (2.5.13), that this map gives rise to a di- [II | 45]
homomorphism of modules

$$\eta_f : M' \otimes_{S'} S \longrightarrow M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}.$$

Moreover, if, for $r > 0$, we have $f^r \sum_i (x'_i \otimes s_i) = 0$, this can also be written $\sum_i (f'^r x'_i \otimes s_i) = 0$, whence, by (0, 1.5.4), $\sum_i (f'^r x'_i / f'^{m_i+r}) \otimes (s_i/f^{n_i}) = 0$, that is, $\eta_f(\sum_i x'_i \otimes s_i) = 0$, which proves that η_f factors as

$$M' \otimes_{S'} S \longrightarrow (M' \otimes_{S'} S)_f \xrightarrow{\eta'_f} M'_{(f')} \otimes_{S'_{(f')}} S_{(f)} \ ;$$

finally, we verify that η'_f and ν_f are isomorphisms inverse to each other.

In particular, it follows from (2.1.2.1) that we have a canonical homomorphism

$$\Phi^*(\mathcal{O}_{X'}(n)) \xrightarrow{\sim} \mathcal{O}_X(n)|G(\varphi) \tag{2.8.8.2}$$

for every $n \in \mathbf{Z}$. □

(2.8.9) Let A, A' be two rings, and $\psi : A' \to A$ a ring homomorphism, defining a morphism $\Psi : \mathrm{Spec}(A) \to \mathrm{Spec}(A')$. Let S' be an A'-algebra graded in positive degrees, and set $S = S' \otimes_{A'} A$, which is, in an evident way, an A-algebra graded by the $S'_n \otimes_{A'} A$; the map $\varphi : s' \mapsto s' \otimes 1$ is then a homomorphism of graded rings making the diagram (2.8.5.1) commutative. Since here S_+ is the A-module generated by $\varphi(S'_+)$, we have $G(\varphi) = \mathrm{Proj}(S) = X$; whence, setting $X' = \mathrm{Proj}(S')$, a commutative diagram

$$\begin{array}{ccc} X & \xrightarrow{\Phi} & X' \\ {\scriptstyle p}\downarrow & & \downarrow \\ Y & \xrightarrow[\Psi]{} & Y' \end{array} \tag{2.8.9.1}$$

Now let M' be a graded S'-module, and set $M = M' \otimes_{A'} A = M' \otimes_{S'} S$. Under these conditions:

(2.8.10) Proposition. *The diagram (2.8.9.1) identifies the scheme X with the product $X' \times_{Y'} Y$; moreover, the canonical homomorphism $\nu : \Phi^*(\widetilde{M'}) \to \widetilde{M}$ (2.8.8) is an isomorphism.*

Proof. The first assertion will be established if we prove that, for every homogeneous f' in S'_+, setting $f = \varphi(f')$, the restrictions of Φ and p to $D_+(f)$ identify this scheme with the product $D_+(f') \times_{Y'} Y$ (I, 3.2.6.2); in other words, it suffices (I, 3.2.2) to prove that $S_{(f)}$ is canonically identified with $S'_{(f')} \otimes_{A'} A$, which is immediate by virtue of the existence of the canonical degree-preserving isomorphism $S_f \xrightarrow{\sim} S'_{f'} \otimes_{A'} A$ (0, 1.5.4). The second assertion follows from the fact that $M'_{(f')} \otimes_{S'_{(f')}} S_{(f)}$ is identified, by the foregoing, with $M'_{(f')} \otimes_{A'} A$, and the latter with $M_{(f)}$, since M_f is canonically identified with $M'_{f'} \otimes_{A'} A$ by a degree-preserving isomorphism. □

(2.8.11) Corollary. *For every integer $n \in \mathbf{Z}$, $\widetilde{M(n)}$ is identified with $\Phi^*(\widetilde{M'(n)}) = \widetilde{M'(n)} \otimes_{Y'} \mathcal{O}_Y$; in particular $\mathcal{O}_X(n) = \Phi^*(\mathcal{O}_{X'}(n)) = \mathcal{O}_{X'}(n) \otimes_{Y'} \mathcal{O}_Y$.*

Proof. This follows from (2.8.10) and (2.5.15). □

[II | 46] **(2.8.12)** Under the hypotheses of (2.8.9), for $f' \in S'_d$ $(d > 0)$ and $f = \varphi(f')$, the diagram

$$\begin{array}{ccc} M'_{(f')} & \longrightarrow & \widetilde{M'^{(d)}/(f'-1)M'^{(d)}} \\ \downarrow & & \downarrow \\ M_{(f)} & \longrightarrow & \widetilde{M^{(d)}/(f-1)M^{(d)}} \end{array} \tag{2.8.12.1}$$

(cf. (2.2.5)) is commutative.

(2.8.13) We keep the notation and hypotheses of (2.8.9), and let $\mathcal{F}'$ be an $\mathcal{O}_{X'}$-module; if we set $\mathcal{F} = \Phi^*(\mathcal{F}')$, we have, for every $n \in \mathbf{Z}$, $\mathcal{F}(n) = \Phi^*(\mathcal{F}'(n))$ by virtue of (2.8.11) and (0, 4.3.3). Consequently (0, 3.7.1), we have a canonical homomorphism

$$\Gamma(\rho) : \Gamma(X', \mathcal{F}'(n)) \longrightarrow \Gamma(X, \mathcal{F}(n))$$

which gives a canonical di-homomorphism of graded modules

$$\Gamma_\bullet(\mathcal{F}') \longrightarrow \Gamma_\bullet(\mathcal{F}).$$

Suppose that the ideal S_+ is generated by S_1, and that $\mathcal{F}' = \widetilde{M'}$, so that $\mathcal{F} = \widetilde{M}$ with $M = M' \otimes_{A'} A$. If f' is homogeneous in S'_+ and $f = \varphi(f')$, we have seen that $M_{(f)} = M'_{(f')} \otimes_{A'} A$, and the diagram

$$\begin{array}{ccc} M'_0 & \longrightarrow & M'_{(f')} \\ \downarrow & & \downarrow \\ M_0 & \longrightarrow & M_{(f)} \end{array} \qquad \begin{array}{l} = \Gamma(D_+(f'), \widetilde{M'}) \\ \\ = \Gamma(D_+(f), \widetilde{M}) \end{array}$$

is therefore commutative; from this remark and from the definition of the homomorphism α (2.6.2) we immediately conclude that the diagram

$$\begin{array}{ccc} M' & \xrightarrow{\alpha_{M'}} & \Gamma_\bullet(\widetilde{M'}) \\ \downarrow & & \downarrow \\ M & \xrightarrow[\alpha_M]{} & \Gamma_\bullet(\widetilde{M}) \end{array} \tag{2.8.13.1}$$

is commutative. Likewise, the diagram

$$\begin{array}{ccc} \widetilde{\Gamma_\bullet(\mathcal{F}')} & \xrightarrow{\beta_{\mathcal{F}'}} & \mathcal{F}' \\ \downarrow & & \downarrow \\ \widetilde{\Gamma_\bullet(\mathcal{F})} & \xrightarrow[\beta_{\mathcal{F}}]{} & \mathcal{F} \end{array} \tag{2.8.13.2}$$

is commutative (the right-hand vertical arrow being the canonical Φ-morphism $\mathcal{F}' \to \Phi^*(\mathcal{F}') = \mathcal{F}$).

[II | 47] **(2.8.14)** Still keeping the hypotheses and notation of (2.8.9), let N' be a second graded S'-module, and let $N = N' \otimes_{A'} A$. It is immediate that the canonical di-homomorphisms $M' \to M$, $N' \to N$ give a di-homomorphism $M' \otimes_{S'} N' \to M \otimes_S N$ (relative to the

canonical ring homomorphism $S' \to S$), and consequently also an S-homomorphism of degree 0

$$(M' \otimes_{S'} N') \otimes_{A'} A \longrightarrow M \otimes_S N,$$

to which there corresponds (taking into account (2.8.10)) a homomorphism of $\mathcal{O}_X$-modules

$$\Phi^*(\widetilde{M' \otimes_{S'} N'}) \longrightarrow \widetilde{M \otimes_S N}. \tag{2.8.14.1}$$

Moreover, we verify immediately that the diagram

$$\begin{array}{ccc} \Phi^*(\widetilde{M'} \otimes_{\mathcal{O}_{X'}} \widetilde{N'}) & \xrightarrow{\sim} & \widetilde{M} \otimes_{\mathcal{O}_X} \widetilde{N} \\ {\scriptstyle \Phi^*(\lambda)}\downarrow & & \downarrow{\scriptstyle \lambda} \\ \Phi^*(\widetilde{M' \otimes_{S'} N'}) & \longrightarrow & \widetilde{M \otimes_S N} \end{array} \qquad = \Phi^*(\widetilde{M'}) \otimes_{\mathcal{O}_X} \Phi^*(\widetilde{N'}) \tag{2.8.14.2}$$

is commutative, the first row being the canonical isomorphism (0, 4.3.3). If the ideal S'_+ is generated by S'_1, it is clear that S_+ is generated by S_1, and the two vertical arrows of (2.8.14.2) are then isomorphisms (2.5.13); the same is therefore true of (2.8.14.1).

Likewise, we have a canonical di-homomorphism $\mathrm{Hom}_{S'}(M', N') \to \mathrm{Hom}_S(M, N)$, by assigning to a homomorphism u' of degree k the homomorphism $u' \otimes 1$, which is also of degree k; from this we again deduce an S-homomorphism of degree 0

$$(\mathrm{Hom}_{S'}(M', N')) \otimes_{A'} A \longrightarrow \mathrm{Hom}_S(M, N)$$

whence a homomorphism of $\mathcal{O}_X$-modules

$$\Phi^*(\widetilde{\mathrm{Hom}_{S'}(M', N')}) \longrightarrow \widetilde{\mathrm{Hom}_S(M, N)}. \tag{2.8.14.3}$$

Moreover, the diagram

$$\begin{array}{ccc} \Phi^*(\widetilde{\mathrm{Hom}_{S'}(M', N')}) & \longrightarrow & \widetilde{\mathrm{Hom}_S(M, N)} \\ {\scriptstyle \Phi^*(\mu)}\downarrow & & \downarrow{\scriptstyle \mu} \\ \Phi^*(\mathcal{H}om_{\mathcal{O}_{X'}}(\widetilde{M'}, \widetilde{N'})) & \longrightarrow & \mathcal{H}om_{\mathcal{O}_X}(\widetilde{M}, \widetilde{N}) \end{array}$$

is commutative (the second horizontal row being the canonical homomorphism (0, 4.4.6)).

(2.8.15) The notation and hypotheses being those of (2.8.1), it follows from (2.4.7) that [II | 48] the morphism Φ does not change, up to isomorphisms, if we replace S_0 and S'_0 by $\mathbf{Z}$ and φ_0 by the identity map, and then replace S and S' by $S^{(d)}$ and $S'^{(d)}$ respectively ($d > 0$) and φ by its restriction $\varphi^{(d)}$ to $S^{(d)}$.

2.9 Closed subschemes of a scheme $\mathrm{Proj}(S)$.

(2.9.1) If $\varphi : S \to S'$ is a homomorphism of graded rings, we say that φ is (TN)-*surjective* (resp. (TN)-*injective*, (TN)-*bijective*) if there exists an integer n such that, for $k \geq n$, $\varphi_k : S_k \to S'_k$ is surjective (resp. injective, bijective). It then follows from (2.8.15) that the study of Φ can be reduced to the case where φ is *surjective* (resp. *injective*, *bijective*). Instead of saying that φ is (TN)-bijective, we also say that it is then a (TN)-*isomorphism*.

(2.9.2) Proposition. *Let S be a ring graded in positive degrees and let $X = \mathrm{Proj}(S)$.*

(i) *If $\varphi : S \to S'$ is a (TN)-surjective homomorphism of graded rings, the corresponding morphism Φ (2.8.1) is defined on the whole of* $\mathrm{Proj}(S')$ *and is a closed immersion of* $\mathrm{Proj}(S')$ *into X. If $\mathfrak{J}$ is the kernel of φ, the closed subscheme of X associated to Φ is defined by the quasi-coherent sheaf of ideals $\widetilde{\mathfrak{J}}$ of $\mathcal{O}_X$.*

(ii) *Suppose moreover that the ideal S_+ is generated by finitely many homogeneous elements of degree* 1. *Let X' be a closed subscheme of X, defined by a quasi-coherent sheaf of ideals $\mathcal{J}$ of $\mathcal{O}_X$. Let $\mathfrak{J}$ be the graded ideal of S that is the inverse image of $\Gamma_\bullet(\mathcal{J})$ under the canonical homomorphism $\alpha : S \to \Gamma_\bullet(\mathcal{O}_X)$ (2.6.2), and set $S' = S/\mathfrak{J}$. Then X' is the subscheme associated to the closed immersion* $\mathrm{Proj}(S') \to X$ *corresponding to the canonical homomorphism of graded rings $S \to S'$.*

Proof. (i) We may suppose φ surjective (2.9.1). Since by hypothesis $\varphi(S_+)$ generates S'_+, we have $G(\varphi) = \mathrm{Proj}(S')$. On the other hand, the second assertion can be verified locally on X; so let f be a homogeneous element of S_+ and set $f' = \varphi(f)$. Since φ is a surjective homomorphism of graded rings, we verify immediately that $\varphi_{(f')} : S_{(f)} \to S'_{(f')}$ is surjective and that its kernel is $\mathfrak{J}_{(f)}$, which completes the proof of (i) (I, 4.2.3).

(ii) By virtue of (i), we are reduced to verifying that the homomorphism $\widetilde{j} : \widetilde{\mathfrak{J}} \to \mathcal{O}_X$ deduced from the canonical injection $j : \mathfrak{J} \to S$ is an isomorphism of $\widetilde{\mathfrak{J}}$ onto $\mathcal{J}$, which follows from (2.7.11).

□

We note that $\mathfrak{J}$ is the *largest* of the graded ideals $\mathfrak{J}'$ of S such that $\widetilde{j}(\widetilde{\mathfrak{J}'}) = \mathcal{J}$, since we verify immediately, by going back to the definitions (2.6.2), that this relation implies $\alpha(\mathfrak{J}') \subset \Gamma_\bullet(\mathcal{J})$.

(2.9.3) Corollary. *Suppose that the hypotheses of (2.9.2, (i)) are satisfied and moreover that the ideal S_+ is generated by S_1; then $\Phi^*(\widetilde{S(n)})$ is canonically isomorphic to $\widetilde{S'(n)}$ for every $n \in \mathbf{Z}$, and consequently $\Phi^*(\mathcal{F}(n))$ to $\Phi^*(\mathcal{F})(n)$ for every $\mathcal{O}_X$-module $\mathcal{F}$.*

Proof. This is a particular case of (2.8.8), taking into account (2.5.10.2). □

(2.9.4) Corollary. *Suppose that the hypotheses of (2.9.2, (ii)) are satisfied. For the closed sub-prescheme X' of X to be integral, it is necessary and sufficient that the graded ideal $\mathfrak{J}$ be prime in S.*

Proof. Since X' is isomorphic to $\mathrm{Proj}(S/\mathfrak{J})$, the condition is sufficient by virtue of (2.4.4). To [II | 49] see that it is necessary, consider the exact sequence $0 \to \mathcal{J} \to \mathcal{O}_X \to \mathcal{O}_X/\mathcal{J}$, which gives an exact sequence

$$0 \longrightarrow \Gamma_\bullet(\mathcal{J}) \longrightarrow \Gamma_\bullet(\mathcal{O}_X) \longrightarrow \Gamma_\bullet(\mathcal{O}_X/\mathcal{J}).$$

It suffices to prove that if $f \in S_m$, $g \in S_n$ are such that the image of $\alpha_{n+m}(fg)$ in $\Gamma_\bullet(\mathcal{O}_X/\mathcal{J})$ is zero, then one of the images of $\alpha_m(f)$, $\alpha_n(g)$ is zero. Now, by definition, these images are sections of the invertible $(\mathcal{O}_X/\mathcal{J})$-modules $\mathcal{L} = (\mathcal{O}_X/\mathcal{J})(m)$ and $\mathcal{L}' = (\mathcal{O}_X/\mathcal{J})(n)$ over the integral scheme X'; the hypothesis implies that the product of these two sections is zero in $\mathcal{L} \otimes \mathcal{L}'$ ((2.9.3) and (2.5.14.1)), so one of them is zero by virtue of (I, 7.4.4). □

(2.9.5) Corollary. *Let A be a ring, M an A-module, S a graded A-algebra generated by the set S_1 of homogeneous elements of degree 1, $u : M \to S_1$ a surjective homomorphism of A-modules, and $\overline{u} : \mathbf{S}(M) \to S$ the homomorphism (of A-algebras) from the symmetric algebra $\mathbf{S}(M)$ of M to S that extends u. The morphism corresponding to $\overline{u}$ is then a closed immersion of* $\mathrm{Proj}(S)$ *into* $\mathrm{Proj}(\mathbf{S}(M))$.

Proof. Indeed, $\overline{u}$ is surjective by hypothesis and it suffices to apply (2.9.2). □

§3 Homogeneous spectrum of a sheaf of graded algebras

3.1 Homogeneous spectrum of a quasi-coherent graded $\mathcal{O}_Y$-algebra.

(3.1.1) Let Y be a prescheme, $\mathcal{S}$ a graded $\mathcal{O}_Y$-algebra, and $\mathcal{M}$ a graded $\mathcal{S}$-module. If $\mathcal{S}$ is *quasi-coherent*, each of its homogeneous components $\mathcal{S}_n$ is a *quasi-coherent* $\mathcal{O}_Y$-module, being the image of $\mathcal{S}$ under a homomorphism of $\mathcal{S}$ into itself ((I, 1.3.8) and (I, 1.3.9)); likewise, if $\mathcal{M}$ is quasi-coherent as an $\mathcal{O}_Y$-module, so are its homogeneous components $\mathcal{M}_n$, and conversely. If d is an integer > 0, we denote by $\mathcal{S}^{(d)}$ the direct sum of the $\mathcal{O}_Y$-modules $\mathcal{S}_{nd}$ ($n \in \mathbf{Z}$), which is quasi-coherent if $\mathcal{S}$ is (I, 1.3.9); for every integer k such that $0 \leq k \leq d-1$, we denote by $\mathcal{M}^{(d,k)}$ (or $\mathcal{M}^{(d)}$ for $k = 0$) the direct sum of the $\mathcal{M}_{nd+k}$ ($n \in \mathbf{Z}$), which is a graded $\mathcal{S}^{(d)}$-module, quasi-coherent when $\mathcal{S}$ and $\mathcal{M}$ are quasi-coherent (I, 9.6.1). We denote by $\mathcal{M}(n)$ the graded $\mathcal{S}$-module such that $(\mathcal{M}(n))_k = \mathcal{M}_{n+k}$ for every $k \in \mathbf{Z}$; if $\mathcal{S}$ and $\mathcal{M}$ are quasi-coherent, $\mathcal{M}(n)$ is a quasi-coherent graded $\mathcal{S}$-module (I, 9.6.1).

We will say that $\mathcal{M}$ is a graded $\mathcal{S}$-module *of finite type* (resp. that it admits a *finite presentation*) if, for every $y \in Y$, there exist an open neighbourhood U of y and integers n_i (resp. integers m_i and n_j) such that there is a surjective homomorphism of degree 0

$$\bigoplus_{i=1}^{r}(\mathcal{S}(n_i)|U) \longrightarrow \mathcal{M}|U$$

(resp. such that $\mathcal{M}|U$ is isomorphic to the cokernel of a homomorphism of degree 0

$$\bigoplus_{i=1}^{r}(\mathcal{S}(m_i)|U) \longrightarrow \bigoplus_{j=1}^{s}(\mathcal{S}(n_j)|U)).$$

Let U be an affine open subset of Y and $A = \Gamma(U, \mathcal{O}_Y)$ its ring; by hypothesis, the graded $(\mathcal{O}_Y|U)$-algebra $\mathcal{S}|U$ is isomorphic to $\widetilde{S}$, where $S = \Gamma(U, \mathcal{S})$ is a graded A-algebra (I, 1.4.3); set $X_U = \mathrm{Proj}(\Gamma(U, \mathcal{S}))$. Let $U' \subset U$ be a second affine open subset of Y, A' [II | 50] its ring, and $j : U' \to U$ the canonical injection, which corresponds to the restriction homomorphism $A \to A'$; we have $\mathcal{S}|U' = j^*(\mathcal{S}|U)$, and consequently $S' = \Gamma(U', \mathcal{S})$ is canonically identified with $S \otimes_A A'$ (I, 1.6.4). We conclude from this (2.8.10) that $X_{U'}$ is canonically identified with $X_U \times_U U'$, and consequently also with $f_U^{-1}(U')$, where f_U denotes the structural morphism $X_U \to U$ (I, 4.4.1). We denote by $\sigma_{U',U}$ the canonical isomorphism $f_U^{-1}(U') \xrightarrow{\sim} X_{U'}$ thus defined, and by $\rho_{U',U}$ the open immersion $X_{U'} \to X_U$ obtained by composing $\sigma_{U',U}^{-1}$ and the canonical injection $f_U^{-1}(U') \to X_U$. It is immediate that if $U'' \subset U'$ is a third affine open subset of Y, we have $\rho_{U'',U} = \rho_{U',U} \circ \rho_{U'',U'}$.

(3.1.2) Proposition. *Let Y be a prescheme. For every quasi-coherent $\mathcal{O}_Y$-algebra $\mathcal{S}$ graded in positive degrees, there exists a prescheme X over Y, unique up to Y-isomorphism, having the following property: if f is the structural morphism $X \to Y$, then for every affine open subset U of Y there exists an* isomorphism η_U *of the induced*

prescheme $f^{-1}(U)$ onto $X_U = \mathrm{Proj}(\Gamma(U, \mathcal{S}))$ such that, if V is a second affine open subset of Y contained in U, the diagram

$$\begin{array}{ccc} f^{-1}(V) & \xrightarrow{\eta_V} & X_V \\ \downarrow & & \downarrow{\scriptstyle \rho_{V,U}} \\ f^{-1}(U) & \xrightarrow[\eta_U]{} & X_U \end{array} \tag{3.1.2.1}$$

is commutative.

Proof. For two affine open subsets U, V of Y, let $X_{U,V}$ be the prescheme induced by X_U on $f_U^{-1}(U \cap V)$; we are going to define a Y-isomorphism $\theta_{U,V} : X_{V,U} \xrightarrow{\sim} X_{U,V}$. To this end, consider an affine open subset $W \subset U \cap V$: by composing the isomorphisms

$$f_U^{-1}(W) \xrightarrow{\sigma_{W,U}} X_W \xrightarrow{\sigma_{W,V}^{-1}} f_V^{-1}(W),$$

we obtain an isomorphism τ_W, and we verify immediately that if $W' \subset W$ is an affine open subset, $\tau_{W'}$ is the restriction of τ_W to $f_U^{-1}(W')$; the τ_W are therefore indeed the restrictions of a Y-isomorphism $\theta_{V,U}$. Moreover, if U, V, W are three affine open subsets of Y, and $\theta'_{U,V}$, $\theta'_{V,W}$ and $\theta'_{U,W}$ are the restrictions of $\theta_{U,V}$, $\theta_{V,W}$, $\theta_{U,W}$ to the inverse images of $U \cap V \cap W$ in X_V, X_W, X_W respectively, it follows from the preceding definitions that $\theta'_{U,V} \circ \theta'_{V,W} = \theta'_{U,W}$. The existence of X satisfying the stated properties therefore follows from (I, 2.3.1); its uniqueness up to Y-isomorphism is trivial, taking into account (3.1.2.1). □

(3.1.3) We will say that the prescheme X defined in (3.1.2) is the *homogeneous spectrum* of the quasi-coherent graded $\mathcal{O}_Y$-algebra $\mathcal{S}$, and we will denote it by $\mathrm{Proj}(\mathcal{S})$. It is immediate that $\mathrm{Proj}(\mathcal{S})$ is *separated over Y* ((2.4.2) and (I, 5.5.5)); if $\mathcal{S}$ is an $\mathcal{O}_Y$-algebra *of finite type* (I, 9.6.2), $\mathrm{Proj}(\mathcal{S})$ is *of finite type* over Y ((2.7.1, (ii)) and (I, 6.3.1)).

If f is the structural morphism $X \to Y$, it is immediate that, for every prescheme induced by Y on an open subset U of Y, $f^{-1}(U)$ is identified with the homogeneous spectrum $\mathrm{Proj}(\mathcal{S}|U)$.

(3.1.4) Proposition. *Let $f \in \Gamma(Y, \mathcal{S}_d)$ for $d > 0$. There exists an open subset X_f of the underlying space of $X = \mathrm{Proj}(\mathcal{S})$ having the following property: for every affine open subset U of Y,*

[II/51] *$X_f \cap \varphi^{-1}(U) = D_+(f|U)$ in $\varphi^{-1}(U)$ identified with $X_U = \mathrm{Proj}(\Gamma(U, \mathcal{S}))$ (φ denoting the structural morphism $X \to Y$). Moreover, the prescheme induced on X_f is affine over Y and is canonically isomorphic to $\mathrm{Spec}(\mathcal{S}^{(d)}/(f-1)\mathcal{S}^{(d)})$ (1.3.1).*

Proof. We have $f|U \in \Gamma(U, \mathcal{S}_d) = (\Gamma(U, \mathcal{S}))_d$. If U, U' are two affine open subsets of Y such that $U' \subset U$, $f|U'$ is the image of $f|U$ under the restriction homomorphism

$$\Gamma(U, \mathcal{S}) \longrightarrow \Gamma(U', \mathcal{S}),$$

so $D_+(f|U')$ is equal (with the notation of (3.1.1)) to the prescheme induced on the inverse image $\rho_{U',U}^{-1}(D_+(f|U))$ in $X_{U'}$ (2.8.1); whence the first assertion. Moreover, the prescheme induced by X_U on $D_+(f|U)$ is canonically identified with $\mathrm{Spec}((\Gamma(U, \mathcal{S}))_{(f|U)})$, these identifications being compatible with the restriction homomorphisms (2.8.1); the second assertion then follows from (2.2.5) and the commutativity of the diagram (2.8.2.1). □

We will also say that X_f (as an open subset of the underlying space X) is the set of $x \in X$ where f *does not vanish.*

(3.1.5) Corollary. *If $f \in \Gamma(Y, \mathcal{S}_d)$, $g \in \Gamma(Y, \mathcal{S}_e)$, we have*

$$X_{fg} = X_f \cap X_g. \tag{3.1.5.1}$$

Proof. Indeed, it suffices to consider the intersection of the two sides with a set $\varphi^{-1}(U)$, where U is an affine open subset of Y, and to apply the formula (2.3.3.2). □

(3.1.6) Corollary. *Let (f_α) be a family of sections of $\mathcal{S}$ over Y such that $f_\alpha \in \Gamma(Y, \mathcal{S}_{d_\alpha})$; if the sheaf of ideals of $\mathcal{S}$ generated by this family (0, 5.1.1) contains all the $\mathcal{S}_n$ from some index on, the underlying space X is the union of the X_{f_α}.*

Proof. Indeed, for every affine open subset U of Y, $\varphi^{-1}(U)$ is the union of the $X_{f_\alpha} \cap \varphi^{-1}(U)$ (2.3.14). □

(3.1.7) Corollary. *Let $\mathcal{A}$ be a quasi-coherent $\mathcal{O}_Y$-algebra; set*

$$\mathcal{S} = \mathcal{A}[T] = \mathcal{A} \otimes_{\mathbf{Z}} \mathbf{Z}[T]$$

where T is an indeterminate ($\mathbf{Z}$ and $\mathbf{Z}[T]$ being regarded as simple sheaves on Y). Then $X = \operatorname{Proj}(\mathcal{S})$ is canonically identified with $\operatorname{Spec}(\mathcal{A})$. In particular, $\operatorname{Proj}(\mathcal{O}_Y[T])$ is identified with Y.

Proof. Applying (3.1.6) to the unique section $f \in \Gamma(Y, \mathcal{S})$ equal to T at every point of Y, we see that $X_f = X$. Moreover, here we have $d = 1$, and $\mathcal{S}^{(1)}/(f-1)\mathcal{S}^{(1)} = \mathcal{S}/(f-1)\mathcal{S}$ is canonically isomorphic to $\mathcal{A}$, whence the corollary (3.1.4). □

Let $g \in \Gamma(Y, \mathcal{O}_Y)$; if we take $\mathcal{S} = \mathcal{O}_Y[T]$, we then have $g \in \Gamma(Y, \mathcal{S}_0)$; let

$$h = gT \in \Gamma(Y, \mathcal{S}_1).$$

If $X = \operatorname{Proj}(\mathcal{S})$, the canonical identification defined in (3.1.7) identifies X_h with the open subset Y_g of Y (in the sense of (0, 5.5.2)): indeed, we may restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, and everything then comes down (taking into account (2.2.5)) to the fact that the ring of fractions A_g is canonically identified with $A[T]/(gT-1)A[T]$ (0, 1.2.3).

(3.1.8) Proposition. *Let $\mathcal{S}$ be a quasi-coherent $\mathcal{O}_Y$-algebra graded in positive degrees.*

(i) *For every $d > 0$, there exists a canonical Y-isomorphism of $\operatorname{Proj}(\mathcal{S})$ onto $\operatorname{Proj}(\mathcal{S}^{(d)})$.*

(ii) *Let $\mathcal{S}'$ be the graded $\mathcal{O}_Y$-algebra that is the direct sum of $\mathcal{O}_Y$ and the $\mathcal{S}_n$ ($n > 0$); then $\operatorname{Proj}(\mathcal{S}')$ and $\operatorname{Proj}(\mathcal{S})$ are canonically Y-isomorphic.* *[II / 52]*

(iii) *Let $\mathcal{L}$ be an invertible $\mathcal{O}_Y$-module (0, 5.4.1) and let $\mathcal{S}_{(\mathcal{L})}$ be the graded $\mathcal{O}_Y$-algebra that is the direct sum of the $\mathcal{S}_d \otimes \mathcal{L}^{\otimes d}$ ($d \geq 0$); then $\operatorname{Proj}(\mathcal{S})$ and $\operatorname{Proj}(\mathcal{S}_{(\mathcal{L})})$ are canonically Y-isomorphic.*

Proof. In each of the three cases, it suffices to define the isomorphism locally on Y, the verification of the compatibilities with the operations of restriction from an open subset to a smaller one being trivial. We may therefore suppose Y affine, and then (i) follows from (2.4.7, (i)) and (ii) from (2.4.8). As for (iii), when we suppose moreover that $\mathcal{L}$ is isomorphic to $\mathcal{O}_Y$ (which is permissible, the question being local on Y), the fact that $\mathrm{Proj}(\mathcal{S})$ and $\mathrm{Proj}(\mathcal{S}_{(\mathcal{L})})$ are isomorphic is evident; to define a *canonical* isomorphism, let $Y = \mathrm{Spec}(A)$, $\mathcal{S} = \widetilde{S}$, where S is a graded A-algebra, and let c be a generator of the free A-module L such that $\mathcal{L} = \widetilde{L}$; then, for every $n > 0$, $x_n \mapsto x_n \otimes c^{\otimes n}$ is an A-isomorphism of S_n onto $S_n \otimes L^{\otimes n}$, and these A-isomorphisms define an A-isomorphism of graded algebras

$$\varphi_c : S \longrightarrow S_{(L)} = \bigoplus_{n \geq 0} S_n \otimes L^{\otimes n}.$$

Now let $f \in S_+$ be homogeneous of degree d; for every $x \in S_{nd}$, we have

$$\frac{x \otimes c^{\otimes nd}}{(f \otimes c^{\otimes d})^n} = \frac{x \otimes (\varepsilon c)^{\otimes nd}}{(f \otimes (\varepsilon c)^{\otimes d})^n}$$

for every invertible element $\varepsilon \in A$, which shows that the isomorphism $S_{(f)} \to (S_{(L)})_{(f \otimes c^d)}$ deduced from φ_c is *independent* of the generator c of L under consideration, and completes the proof. □

(3.1.9) Recall ((0, 4.1.3) and (I, 1.3.14)) that, for the quasi-coherent graded $\mathcal{O}_Y$-algebra $\mathcal{S}$ to be *generated by the $\mathcal{O}_Y$-module* $\mathcal{S}_1$, it is necessary and sufficient that there exist a covering (U_α) of Y by affine open subsets such that the graded algebra $\Gamma(U_\alpha, \mathcal{S})$ over $\Gamma(U_\alpha, \mathcal{S}_0)$ is generated by the set $\Gamma(U_\alpha, \mathcal{S}_1)$ of its homogeneous elements of degree 1. For every open subset V of Y, $\mathcal{S}|V$ is then generated by the $(\mathcal{O}_Y|V)$-module $\mathcal{S}_1|V$.

(3.1.10) Proposition. *Suppose that there exists a finite affine open covering (U_i) of Y such that each of the graded algebras $\Gamma(U_i, \mathcal{S})$ is of finite type over $\Gamma(U_i, \mathcal{O}_Y)$. Then there exists $d > 0$ such that $\mathcal{S}^{(d)}$ is generated by $\mathcal{S}_d$, $\mathcal{S}_d$ being an $\mathcal{O}_Y$-module of finite type.*

Proof. Indeed, it follows from (2.1.6, (v)) that for each i there exists an integer m_i such that $\Gamma(U_i, \mathcal{S}_{nm_i}) = (\Gamma(U_i, \mathcal{S}_{m_i}))^n$ for every $n > 0$; it suffices to take for d a common multiple of the m_i, taking into account (2.1.6, (i)). □

(3.1.11) Corollary. *Under the hypotheses of (3.1.10),* $\mathrm{Proj}(\mathcal{S})$ *is Y-isomorphic to a homogeneous spectrum* $\mathrm{Proj}(\mathcal{S}')$*, where $\mathcal{S}'$ is a graded $\mathcal{O}_Y$-algebra generated by $\mathcal{S}'_1$, $\mathcal{S}'_1$ being assumed to be an $\mathcal{O}_Y$-module of finite type.*

Proof. Indeed, it suffices to take $\mathcal{S}' = \mathcal{S}^{(d)}$, d being determined by the property of (3.1.10), and to apply (3.1.8, (i)). □

(3.1.12) If $\mathcal{S}$ is a quasi-coherent $\mathcal{O}_Y$-algebra graded in positive degrees, we know (I, 5.1.1) that its *nilradical* $\mathcal{N}$ is a quasi-coherent $\mathcal{O}_Y$-module; we will say that $\mathcal{N}_+ = \mathcal{N} \cap \mathcal{S}_+$ is the *nilradical of* $\mathcal{S}_+$; it is a quasi-coherent graded $\mathcal{S}_0$-module, since we are immediately reduced to the case where Y is affine, and the proposition then follows from (2.1.10). For every $y \in Y$, $(\mathcal{N}_+)_y$ is then the nilradical of $(\mathcal{S}_+)_y = (\mathcal{S}_y)_+$ (I, 5.1.1). We say that the graded $\mathcal{O}_Y$-algebra $\mathcal{S}$ is *essentially reduced* if $\mathcal{N}_+ = 0$, which is equivalent
[II | 53] to saying that $\mathcal{S}_y$ is an essentially reduced graded $\mathcal{O}_y$-algebra for every $y \in Y$. For every graded $\mathcal{O}_Y$-algebra $\mathcal{S}$, $\mathcal{S}/\mathcal{N}_+$ is essentially reduced.

We will say that $\mathcal{S}$ is *integral* if $\mathcal{S}_y$ is an integral ring for every $y \in Y$ and if moreover $(\mathcal{S}_y)_+ = (\mathcal{S}_+)_y \neq 0$ for every $y \in Y$.

(3.1.13) Proposition. *Let $\mathcal{S}$ be an $\mathcal{O}_Y$-algebra graded in positive degrees. If $X = \mathrm{Proj}(\mathcal{S})$, the Y-scheme X_{red} is canonically isomorphic to $\mathrm{Proj}(\mathcal{S}/\mathcal{N}_+)$; in particular, if $\mathcal{S}$ is essentially reduced, X is reduced.*

Proof. The fact that $X' = \mathrm{Proj}(\mathcal{S}/\mathcal{N}_+)$ is reduced follows immediately from (2.4.4, (i)), the property being local; moreover, for every affine open subset $U \subset Y$, ${\varphi'}^{-1}(U)$ is equal to $(\varphi^{-1}(U))_{\mathrm{red}}$ (denoting by φ and φ' the structural morphisms $X \to Y$, $X' \to Y$); we verify immediately that the canonical U-morphisms ${\varphi'}^{-1}(U) \to \varphi^{-1}(U)$ are compatible with the restriction operations and consequently define a closed immersion $X' \to X$ that is a homeomorphism of the underlying spaces; whence the conclusion (I, 5.1.2). □

(3.1.14) Proposition. *Let Y be an integral prescheme and $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra such that $\mathcal{S}_0 = \mathcal{O}_Y$.*

(i) *If $\mathcal{S}$ is integral (3.1.12), then $X = \mathrm{Proj}(\mathcal{S})$ is integral and the structural morphism $\varphi : X \to Y$ is dominant.*

(ii) *Suppose moreover that $\mathcal{S}$ is essentially reduced. Then, conversely, if X is integral and φ is dominant, $\mathcal{S}$ is integral.*

Proof. (i) If (U_α) is a basis of Y consisting of non-empty affine open subsets, it suffices to prove the proposition when Y is replaced by one of the U_α and $\mathcal{S}$ by $\mathcal{S}|U_\alpha$: indeed, it will follow on the one hand that the underlying spaces $\varphi^{-1}(U_\alpha)$ are irreducible (hence non-empty) open subsets of X such that $\varphi^{-1}(U_\alpha) \cap \varphi^{-1}(U_\beta) \neq \varnothing$ for every pair of indices (since $U_\alpha \cap U_\beta$ contains some U_γ), hence that X is irreducible (0, 2.1.4); on the other hand X will be reduced, since this is a local property, so X will indeed be integral and $\varphi(X)$ dense in Y.

So suppose that $Y = \mathrm{Spec}(A)$, where A is integral (I, 5.1.4), and $\mathcal{S} = \widetilde{S}$, where S is a graded A-algebra; the hypothesis is that, for every $y \in Y$, $\widetilde{S}_y = S_y$ is an integral graded ring such that $(S_y)_+ \neq 0$. It suffices to prove that S is an *integral* ring, since we will then have $S_+ \neq 0$ and we will be able to apply (2.4.4, (ii)). Now let f, g be two elements $\neq 0$ of S and suppose that $fg = 0$; for every $y \in Y$ we will then have $(f/1)(g/1) = 0$ in S_y, so $f/1 = 0$ or $g/1 = 0$ by hypothesis. Suppose for example that $f/1 = 0$ in S_y; this means that there exists $a \in A$ such that $a \notin \mathfrak{j}_y$ and $af = 0$; we then have, for every $z \in Y$, $(a/1)(f/1) = 0$ in the *integral* ring S_z, and since $a/1 \neq 0$ (because A is integral), $f/1 = 0$, which implies $f = 0$.

(ii) The question being local on Y, we may again suppose that $Y = \mathrm{Spec}(A)$, with A integral, and $\mathcal{S} = \widetilde{S}$. By hypothesis, for every $y \in Y$, $(S_y)_+$ contains no nilpotent element $\neq 0$, and the same is true of $(S_0)_y = A_y$ by hypothesis; so S_y is a reduced ring for every $y \in Y$, and we conclude first that S itself is reduced (I, 5.1.1). On the other hand, the hypothesis that X is integral implies that S is essentially integral (2.4.4, (ii)), and everything then comes down to showing that the annihilator $\mathfrak{J}$ of S_+ in $A = S_0$ is reduced

to 0 (2.1.11). Otherwise, we would have $(S_h)_+ = 0$ for some $h \neq 0$ in $\mathfrak{J}$, hence (3.1.1) [II | 54]
$\varphi^{-1}(D(h)) = \varnothing$, and $\varphi(X)$ would not be dense in Y, contrary to the hypothesis (since $D(h) \neq \varnothing$, h not being nilpotent).

□

3.2 Sheaf on $\mathrm{Proj}(\mathcal{S})$ associated to a graded $\mathcal{S}$-module.

(3.2.1) Let Y be a prescheme, $\mathcal{S}$ a quasi-coherent $\mathcal{O}_Y$-algebra graded in positive degrees, and $\mathcal{M}$ a quasi-coherent graded $\mathcal{S}$-module (on $(Y, \mathcal{O}_Y)$ or on the ringed space $(Y, \mathcal{S})$, which amounts to the same (I, 9.6.1)). With the notation of (3.1.1), denote by $\widetilde{\mathcal{M}}_U$ the quasi-coherent $\mathcal{O}_{X_U}$-module $\widetilde{\Gamma(U, \mathcal{M})}$; for $U' \subset U$, $\Gamma(U', \mathcal{M})$ is canonically identified with $\Gamma(U, \mathcal{M}) \otimes_A A'$ (I, 1.6.4); hence we have $\widetilde{\mathcal{M}}_{U'} = \rho^*_{U',U}(\widetilde{\mathcal{M}}_U)$ (2.8.11).

(3.2.2) Proposition. *There exists on* $\mathrm{Proj}(\mathcal{S}) = X$ *one and only one quasi-coherent* $\mathcal{O}_X$*-module* $\widetilde{\mathcal{M}}$ *such that, for every affine open subset* U *of* Y*, we have*

$$\eta^*_U(\widetilde{\Gamma(U, \mathcal{M})}) = \widetilde{\mathcal{M}}|f^{-1}(U)$$

(denoting by η_U *the isomorphism* $f^{-1}(U) \xrightarrow{\sim} \mathrm{Proj}(\Gamma(U, \mathcal{S}))$*, where* f *is the structural morphism* $X \to Y$*).*

Proof. Since $\rho_{U',U}$ is identified with the injection morphism $f^{-1}(U') \to f^{-1}(U)$ (3.1.2.1), the proposition follows immediately from the relation $\widetilde{\mathcal{M}}_{U'} = \rho^*_{U',U}(\widetilde{\mathcal{M}}_U)$ and the principle of gluing sheaves (0, 3.3.1). □

We say that $\widetilde{\mathcal{M}}$ is the $\mathcal{O}_X$-module associated to the quasi-coherent graded $\mathcal{S}$-module $\mathcal{M}$.

(3.2.3) Proposition. *Let* $\mathcal{M}$ *be a quasi-coherent graded* $\mathcal{S}$*-module, and let* $f \in \Gamma(Y, \mathcal{S}_d)$ *(*$d > 0$*). If* ξ_f *is the canonical isomorphism of* X_f *onto the* Y*-prescheme* $Z_f = \mathrm{Spec}(\mathcal{S}^{(d)}/(f-1)\mathcal{S}^{(d)})$ *(3.1.4), then* $(\xi_f)_*(\widetilde{\mathcal{M}}|X_f)$ *is the* $\mathcal{O}_{Z_f}$*-module* $\widetilde{\mathcal{M}^{(d)}/(f-1)\mathcal{M}^{(d)}}$ *(1.4.3).*

Proof. The question being local on Y, we are immediately reduced to (2.2.5), taking into account the commutativity of the diagram (2.8.12.1). □

(3.2.4) Proposition. *The* $\mathcal{O}_X$*-module* $\widetilde{\mathcal{M}}$ *is an exact additive covariant functor in* $\mathcal{M}$*, from the category of quasi-coherent graded* $\mathcal{S}$*-modules to that of quasi-coherent* $\mathcal{O}_X$*-modules, which commutes with inductive limits and with direct sums.*

Proof. The question, being local on Y, reduces to (I, 1.3.11 and I, 1.3.9) and to (2.5.4). □

In particular, if $\mathcal{N}$ is a quasi-coherent graded sub-$\mathcal{S}$-module of $\mathcal{M}$, $\widetilde{\mathcal{N}}$ is canonically identified with a quasi-coherent sub-$\mathcal{O}_X$-module of $\widetilde{\mathcal{M}}$; more particularly, for every quasi-coherent graded sheaf of ideals $\mathcal{J}$ of $\mathcal{S}$, $\widetilde{\mathcal{J}}$ is a quasi-coherent sheaf of ideals of $\mathcal{O}_X$.

If $\mathcal{M}$ is a quasi-coherent graded $\mathcal{S}$-module and $\mathcal{I}$ a quasi-coherent sheaf of ideals of $\mathcal{O}_Y$, $\mathcal{I}\mathcal{M}$ is a quasi-coherent graded sub-$\mathcal{S}$-module of $\mathcal{M}$ and we have

$$\widetilde{\mathcal{I}\mathcal{M}} = \mathcal{I} \cdot \widetilde{\mathcal{M}} \tag{3.2.4.1}$$

(the right-hand side having the meaning defined in (0, 4.3.5)). Indeed, it suffices to verify this formula when $Y = \mathrm{Spec}(A)$ is affine, $\mathcal{S} = \widetilde{S}$, where S is a graded A-algebra, $\mathcal{M} = \widetilde{M}$,
[II | 55] where M is a graded S-module, and $\mathcal{I} = \widetilde{\mathfrak{I}}$, where $\mathfrak{I}$ is an ideal of A. For every homogeneous f in S_+, the restriction to $D_+(f) = \mathrm{Spec}(S_{(f)})$ of the left-hand side of (3.2.4.1) is associated to $(\mathfrak{I}M)_{(f)} = \mathfrak{I} \cdot M_{(f)}$, and the same is true of the restriction of the right-hand side, in view of (I, 1.3.13 and I, 1.6.9).

(3.2.5) Proposition. *Let $f \in \Gamma(Y, \mathcal{S}_d)$ $(d > 0)$. On the open subset X_f, the $(\mathcal{O}_X|X_f)$-module $\widetilde{\mathcal{S}(nd)}|X_f$ is canonically isomorphic to $\mathcal{O}_X|X_f$ for every $n \in \mathbf{Z}$. In particular, if the $\mathcal{O}_Y$-algebra $\mathcal{S}$ is generated by $\mathcal{S}_1$ (3.1.9), the $\mathcal{O}_X$-modules $\widetilde{\mathcal{S}(n)}$ are invertible for every $n \in \mathbf{Z}$.*

Proof. Indeed, for every affine open subset U of Y, we have defined in (2.5.7) a canonical isomorphism of $\widetilde{\mathcal{S}(nd)}|(X_f \cap \varphi^{-1}(U))$ onto $\mathcal{O}_X|(X_f \cap \varphi^{-1}(U))$, taking into account (3.1.4) (where φ is the structural morphism $X \to Y$); it is immediately verified that these isomorphisms are compatible with the restriction from U to an affine open subset $U' \subset U$, whence the first assertion. To establish the second, it suffices to remark that if $\mathcal{S}$ is generated by $\mathcal{S}_1$, there is a covering (U_α) of Y by affine open subsets such that $\Gamma(U_\alpha, \mathcal{S})$ is generated by $\Gamma(U_\alpha, \mathcal{S})_1 = \Gamma(U_\alpha, \mathcal{S}_1)$; we are then reduced to applying the result of (2.5.9), the property of being invertible being local. □

We also set, for every $n \in \mathbf{Z}$,

$$\mathcal{O}_X(n) = \widetilde{\mathcal{S}(n)} \tag{3.2.5.1}$$

and, for every $\mathcal{O}_X$-module $\mathcal{F}$,

$$\mathcal{F}(n) = \mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{O}_X(n). \tag{3.2.5.2}$$

It follows immediately from these definitions that, for every open subset U of Y, we have

$$\widetilde{(\mathcal{S}|U)}(n) = \mathcal{O}_X(n)|f^{-1}(U)$$

f being the structural morphism $X \to Y$.

(3.2.6) Proposition. *Let $\mathcal{M}$ and $\mathcal{N}$ be two quasi-coherent graded $\mathcal{S}$-modules; there exist a canonical homomorphism, functorial (in $\mathcal{M}$ and $\mathcal{N}$),*

$$\lambda : \widetilde{\mathcal{M}} \otimes_{\mathcal{O}_X} \widetilde{\mathcal{N}} \longrightarrow \widetilde{\mathcal{M} \otimes_{\mathcal{S}} \mathcal{N}} \tag{3.2.6.1}$$

and a canonical homomorphism, functorial (in $\mathcal{M}$ and $\mathcal{N}$),

$$\mu : \widetilde{\mathcal{H}om_{\mathcal{S}}(\mathcal{M}, \mathcal{N})} \longrightarrow \mathcal{H}om_{\mathcal{O}_X}(\widetilde{\mathcal{M}}, \widetilde{\mathcal{N}}). \tag{3.2.6.2}$$

Moreover, if $\mathcal{S}$ is generated by $\mathcal{S}_1$ (3.1.9), λ is an isomorphism; if in addition $\mathcal{M}$ admits a finite presentation (3.1.1), μ is an isomorphism.

Proof. The homomorphisms λ and μ were defined in (2.5.11.2) and (2.5.12.2) when Y is affine; these definitions, being local, carry over immediately to the general case considered here, taking into account (2.8.14). □

(3.2.7) Corollary. *If $\mathcal{S}$ is generated by $\mathcal{S}_1$, we have, for all m, n in $\mathbf{Z}$,*

$$\mathcal{O}_X(m) \otimes_{\mathcal{O}_X} \mathcal{O}_X(n) = \mathcal{O}_X(m+n) \tag{3.2.7.1}$$

$$\mathcal{O}_X(n) = (\mathcal{O}_X(1))^{\otimes n} \tag{3.2.7.2}$$

up to canonical isomorphisms.

(3.2.8) Corollary. *Suppose that $\mathcal{S}$ is generated by $\mathcal{S}_1$. For every graded $\mathcal{S}$-module $\mathcal{M}$ and every $n \in \mathbf{Z}$, we have* [II | 56]

$$(\mathcal{M}(n))^{\sim} = \widetilde{\mathcal{M}}(n) \tag{3.2.8.1}$$

up to canonical isomorphism.

Proof. This follows from the corresponding properties for Y affine (2.5.14 and 2.5.15), as well as from (2.8.11). □

Remarks (3.2.9). —

(i) If $\mathcal{S} = \mathcal{A}[T]$, $\mathcal{A}$ being a quasi-coherent $\mathcal{O}_Y$-algebra (3.1.7), we verify immediately that all the invertible $\mathcal{O}_X$-modules $\mathcal{O}_X(n)$ are canonically isomorphic to $\mathcal{O}_X$.

Moreover, let $\mathcal{N}$ be a quasi-coherent $\mathcal{A}$-module, and set $\mathcal{M} = \mathcal{N} \otimes_{\mathcal{A}} \mathcal{A}[T]$. It then follows from (3.2.3) and (3.1.7) that, under the canonical identification of $X = \mathrm{Proj}(\mathcal{A}[T])$ and $X' = \mathrm{Spec}(\mathcal{A})$, the $\mathcal{O}_X$-module $\widetilde{\mathcal{M}}$ is identified with the $\mathcal{O}_{X'}$-module $\widetilde{\mathcal{N}}$ associated to $\mathcal{N}$ (in the sense of (1.4.3)).

(ii) Let $\mathcal{S}$ be an arbitrary graded $\mathcal{O}_Y$-algebra, and $\mathcal{S}'$ the graded $\mathcal{O}_Y$-algebra such that $\mathcal{S}'_0 = \mathcal{O}_Y$, $\mathcal{S}'_n = \mathcal{S}_n$ for every $n > 0$; the canonical isomorphism of $X = \mathrm{Proj}(\mathcal{S})$ onto $X' = \mathrm{Proj}(\mathcal{S}')$ (3.1.8, (ii)) identifies $\mathcal{O}_X(n)$ and $\mathcal{O}_{X'}(n)$ for every $n \in \mathbf{Z}$: this follows from the same proposition for the affine case (2.5.16) and from the fact that these identifications, for the affine open subsets of Y, commute with the restriction operations. Likewise, let $X^{(d)} = \mathrm{Proj}(\mathcal{S}^{(d)})$; the canonical isomorphism of X onto $X^{(d)}$ (3.1.8, (i)) identifies $\mathcal{O}_X(nd)$ and $\mathcal{O}_{X^{(d)}}(n)$ for every $n \in \mathbf{Z}$.

(3.2.10) Proposition. *Let $\mathcal{L}$ be an invertible $\mathcal{O}_Y$-module and g the canonical isomorphism $X_{(\mathcal{L})} = \mathrm{Proj}(\mathcal{S}_{(\mathcal{L})}) \to X = \mathrm{Proj}(\mathcal{S})$ (3.1.8, (iii)). For every integer $n \in \mathbf{Z}$, $g_*(\mathcal{O}_{X_{(\mathcal{L})}}(n))$ is canonically isomorphic to $\mathcal{O}_X(n) \otimes_Y \mathcal{L}^{\otimes n}$.*

Proof. Suppose first that Y is affine, with ring A, and that $\mathcal{L} = \widetilde{L}$, where L is a monogenic free A-module. With the notation of the proof of (3.1.8, (iii)), we define, for $f \in S_d$, an isomorphism of $(S(n))_{(f)} \otimes_A L^{\otimes n}$ onto $(S_{(L)}(n))_{(f \otimes c^{\otimes d})}$ by sending $(x/f^k) \otimes c^{\otimes n}$, where $x \in S_{kd+n}$, to the element $(x \otimes c^{\otimes (n+kd)})/(f \otimes c^{\otimes d})^k$; it is immediate that this isomorphism is independent of the generator c chosen for L; moreover, the isomorphisms thus defined for each $f \in S_+$ are compatible with the restriction operations $D_+(f) \to D_+(fg)$. Finally, in the general case, we see without difficulty, by going back to the definitions (3.1.1), that the isomorphisms thus defined for each affine open subset U of Y are compatible with the passage from U to an affine open subset $U' \subset U$. □

3.3 Graded $\mathcal{S}$-module associated to a sheaf on $\mathrm{Proj}(\mathcal{S})$.

Throughout this subsection we suppose that the graded $\mathcal{O}_Y$-algebra $\mathcal{S}$ is generated by $\mathcal{S}_1$ (3.1.9). Recall that, because of (3.1.8, (i)), this restriction is not essential, subject to the finiteness conditions (3.1.10).

(3.3.1) Let p be the structural morphism $X = \mathrm{Proj}(\mathcal{S}) \to Y$. For every $\mathcal{O}_X$-module $\mathcal{F}$, we set

$$\Gamma_*(\mathcal{F}) = \bigoplus_{n \in \mathbf{Z}} p_*(\mathcal{F}(n)) \tag{3.3.1.1}$$

[II | 57] and in particular

$$\Gamma_*(\mathcal{O}_X) = \bigoplus_{n \in \mathbf{Z}} p_*(\mathcal{O}_X(n)). \tag{3.3.1.2}$$

We know (0, 4.2.2) that there exists a canonical homomorphism

$$p_*(\mathcal{F}) \otimes_{\mathcal{O}_Y} p_*(\mathcal{G}) \longrightarrow p_*(\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G})$$

for two $\mathcal{O}_X$-modules $\mathcal{F}$ and $\mathcal{G}$; we therefore deduce from (3.2.7.1) that $\Gamma_*(\mathcal{O}_X)$ is endowed with a structure of *graded $\mathcal{O}_Y$-algebra*, and (3.2.5.2) likewise defines on $\Gamma_*(\mathcal{F})$ a structure of *graded module* over $\Gamma_*(\mathcal{O}_X)$.

By virtue of (3.2.5) and of the left exactness of the functor p_* (0, 4.2.1), $\Gamma_*(\mathcal{F})$ is a covariant additive and *left exact* functor in $\mathcal{F}$ on the category of $\mathcal{O}_X$-modules, with values in the category of graded $\mathcal{O}_Y$-modules (where the morphisms are the homomorphisms of degree 0). In particular, if $\mathcal{J}$ is a sheaf of ideals in $\mathcal{O}_X$, $\Gamma_*(\mathcal{J})$ is identified with a *graded sheaf of ideals* of $\Gamma_*(\mathcal{O}_X)$.

(3.3.2) Let $\mathcal{M}$ be a quasi-coherent graded $\mathcal{S}$-module. For every affine open subset U of Y, we have defined in (2.6.2) a homomorphism of abelian groups

$$\alpha_{0,U} : \Gamma(U, \mathcal{M}_0) \longrightarrow \Gamma(p^{-1}(U), \widetilde{\mathcal{M}}).$$

It is immediate that these homomorphisms commute with the restriction operations (2.8.13.1) and therefore define (without using the hypothesis that $\mathcal{S}$ is generated by $\mathcal{S}_1$) a homomorphism of sheaves of abelian groups

$$\alpha_0 : \mathcal{M}_0 \longrightarrow p_*(\widetilde{\mathcal{M}}). \tag{3.3.2.1}$$

Applying this result to each of the $\mathcal{M}_n = (\mathcal{M}(n))_0$, and taking into account (3.2.8.1), we define a homomorphism of sheaves of abelian groups

$$\alpha_n : \mathcal{M}_n \longrightarrow p_*(\widetilde{\mathcal{M}}(n)) \qquad \text{for every } n \in \mathbf{Z}, \tag{3.3.2.2}$$

whence a functorial homomorphism (of degree 0) of graded sheaves of abelian groups

$$\alpha : \mathcal{M} \longrightarrow \Gamma_*(\widetilde{\mathcal{M}}) \tag{3.3.2.3}$$

(also denoted $\alpha_{\mathcal{M}}$).

Taking in particular $\mathcal{M} = \mathcal{S}$, we verify that $\alpha : \mathcal{S} \to \Gamma_*(\mathcal{O}_X)$ is a homomorphism of graded $\mathcal{O}_Y$-algebras and that (3.3.2.3) is a di-homomorphism of graded modules, relative to this homomorphism of graded algebras.

Note also that to each of the α_n there corresponds (0, 4.4.3) a canonical homomorphism of $\mathcal{O}_X$-modules

$$\alpha_n^\sharp : p^*(\mathcal{M}_n) \longrightarrow \widetilde{\mathcal{M}}(n). \tag{3.3.2.4}$$

We verify without difficulty that this homomorphism is none other than the one that corresponds functorially (3.2.4) to the canonical homomorphism (of degree 0) of graded $\mathcal{O}_Y$-modules

$$\mathcal{M}_n \otimes_{\mathcal{O}_Y} \mathcal{S} \longrightarrow \mathcal{M}(n) \tag{3.3.2.5}$$

where the grading of the right-hand side comes naturally from that of $\mathcal{M}$. Indeed, we may restrict to the case where $Y = \operatorname{Spec}(A)$ is affine, $\mathcal{M} = \widetilde{M}$ and $\mathcal{S} = \widetilde{S}$, the graded A-algebra S being generated by S_1, so that, as f runs through S_1, the $D_+(f)$ form a covering of X. Going back to the definitions (2.6.2), we then see, taking into account (I, 1.6.7), that the restriction to $D_+(f)$ of the homomorphism (3.3.2.4) corresponds (I, 1.3.8) to the homomorphism of $S_{(f)}$-modules $M_n \otimes_A S_{(f)} \to (S(n))_{(f)}$ which sends $x \otimes 1$ ($x \in M_n$) to $x/1$; this proves our assertion. [II | 58]

(3.3.3) Proposition. *For every section $f \in \Gamma(Y, \mathcal{S}_d)$ ($d > 0$), X_f is identical to the set of points of X where $\alpha_d(f)$ (regarded as a section of $\mathcal{O}_X(d)$) does not vanish (0, 5.5.2).*

Proof. ($\alpha_d(f)$ is a section of $p_*(\mathcal{O}_X(d))$ over Y, but by definition such a section is also a section of $\mathcal{O}_X(d)$ over X (0, 4.2.1)). The definition of X_f (3.1.4) reduces us to the case where Y is affine, which was treated in (2.6.3). □

(3.3.4) From now on we will suppose, in addition to the hypothesis made at the beginning of this subsection, that for every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ the $p_*(\mathcal{F}(n))$ are *quasi-coherent* on Y, and consequently $\Gamma_*(\mathcal{F}) = \bigoplus_{n\in\mathbf{Z}} p_*(\mathcal{F}(n))$ is also a quasi-coherent $\mathcal{O}_Y$-module (I, 1.4.1 and I, 1.3.9); this will always be the case in particular if X is *of finite type* over Y (I, 9.2.2). We conclude that $(\Gamma_*(\mathcal{F}))^\sim$ is defined and is a quasi-coherent $\mathcal{O}_X$-module. For every affine open subset U of Y, we have (I, 1.3.9 and 2.5.4)

$$\begin{aligned}\left(\Gamma\left(U, \bigoplus_{n\in\mathbf{Z}} p_*(\mathcal{F}(n))\right)\right)^\sim &= \bigoplus_{n\in\mathbf{Z}} (\Gamma(U, p_*(\mathcal{F}(n))))^\sim \\ &= \bigoplus_{n\in\mathbf{Z}} (\Gamma(p^{-1}(U), \mathcal{F}(n)))^\sim \\ &= \left(\bigoplus_{n\in\mathbf{Z}} \Gamma(p^{-1}(U), \mathcal{F}(n))\right)^\sim \\ &= (\Gamma_*(\mathcal{F}|p^{-1}(U)))^\sim\end{aligned}$$

and consequently (2.6.4) we have a canonical homomorphism

$$\beta_U : \left(\Gamma\left(U, \bigoplus_{n\in\mathbf{Z}} p_*(\mathcal{F}(n))\right)\right)^\sim \longrightarrow \mathcal{F}|p^{-1}(U).$$

Moreover, the commutativity of (2.8.13.2) shows that these homomorphisms commute with the restriction operations on Y; we therefore deduce a canonical functorial homomorphism

$$\beta : (\Gamma_*(\mathcal{F}))^\sim \longrightarrow \mathcal{F} \tag{3.3.4.1}$$

(also denoted $\beta_{\mathcal{F}}$) for quasi-coherent $\mathcal{O}_X$-modules.

(3.3.5) Proposition. *Let $\mathcal{M}$ be a quasi-coherent graded $\mathcal{S}$-module and $\mathcal{F}$ a quasi-coherent $\mathcal{O}_X$-module; the composite homomorphisms*

$$\widetilde{\mathcal{M}} \xrightarrow{\widetilde{\alpha}} (\Gamma_*(\widetilde{\mathcal{M}}))^\sim \xrightarrow{\beta} \widetilde{\mathcal{M}} \tag{3.3.5.1}$$

$$\Gamma_*(\mathcal{F}) \xrightarrow{\alpha} \Gamma_*((\Gamma_*(\mathcal{F}))^\sim) \xrightarrow{\Gamma_*(\beta)} \Gamma_*(\mathcal{F}) \tag{3.3.5.2}$$

are the identity isomorphisms.

Proof. Indeed, the question is local on Y, and we are reduced to (2.6.5). □

3.4 Finiteness conditions.

[II | 59] **(3.4.1) Proposition.** *Let Y be a prescheme, and $\mathcal{S}$ a quasi-coherent $\mathcal{O}_Y$-algebra generated by $\mathcal{S}_1$ (3.1.9); suppose moreover that $\mathcal{S}_1$ is of finite type. Then $X = \mathrm{Proj}(\mathcal{S})$ is of finite type over Y.*

Proof. Indeed, the question being local on Y, we may suppose Y affine with ring A; we then have $\mathcal{S} = \widetilde{S}$, where $S = \Gamma(Y, \mathcal{S})$, and by hypothesis S is an A-algebra generated by $S_1 = \Gamma(Y, \mathcal{S}_1)$, where we may moreover suppose that S_1 is an A-module of finite type (I, 1.3.9 and I, 1.3.12). Consequently S is a graded A-algebra of finite type, and we are reduced to (2.7.1, (ii)). □

(3.4.2) Let $\mathcal{S}$ be a quasi-coherent graded $\mathcal{O}_Y$-algebra; for a quasi-coherent graded $\mathcal{S}$-module $\mathcal{M}$, we will consider the following finiteness conditions:

(**TF**) *There exists an integer n such that the $\mathcal{S}$-module $\bigoplus_{k\geq n} \mathcal{M}_k$ is of finite type.*

(**TN**) *There exists an integer n such that $\mathcal{M}_k = 0$ for $k \geq n$.*

If $\mathcal{M}$ satisfies (**TN**), we have $\widetilde{\mathcal{M}} = 0$, the question being local on Y (2.7.2).

Let $\mathcal{M}$, $\mathcal{N}$ be two quasi-coherent graded $\mathcal{S}$-modules; we say that a homomorphism $u : \mathcal{M} \to \mathcal{N}$ of degree 0 is (**TN**)-*injective* (resp. (**TN**)-*surjective*, (**TN**)-*bijective*) if there exists an integer n such that $u_k : \mathcal{M}_k \to \mathcal{N}_k$ is injective (resp. surjective, bijective) for $k \geq n$; then $\widetilde{u} : \widetilde{\mathcal{M}} \to \widetilde{\mathcal{N}}$ is injective (resp. surjective, bijective) by virtue of (2.7.2), the question being local on Y, and taking into account (I, 1.3.9); when u is (**TN**)-bijective, we also say that u is a (**TN**)-*isomorphism*.

(3.4.3) Proposition. *Let Y be a prescheme, $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra generated by $\mathcal{S}_1$, $\mathcal{S}_1$ being supposed of finite type. Let $\mathcal{M}$ be a quasi-coherent graded $\mathcal{S}$-module.*

(i) *If $\mathcal{M}$ satisfies condition (**TF**), $\widetilde{\mathcal{M}}$ is of finite type.*

(ii) *Suppose that $\mathcal{M}$ satisfies (**TF**); for $\widetilde{\mathcal{M}} = 0$, it is necessary and sufficient that $\mathcal{M}$ satisfy (**TN**).*

Proof. The questions being local on Y, we are reduced to the case where Y is affine with ring A, $\mathcal{S} = \widetilde{S}$, where S is a graded A-algebra such that the ideal S_+ is of finite type, and $\mathcal{M} = \widetilde{M}$ where M is a graded S-module; the proposition then follows from (2.7.3). □

(3.4.4) Theorem. *Let Y be a prescheme, $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra generated by $\mathcal{S}_1$, $\mathcal{S}_1$ being supposed of finite type; let $X = \mathrm{Proj}(\mathcal{S})$. For every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$, the canonical homomorphism β (3.3.4) is an isomorphism.*

Proof. Note first that β is defined by virtue of (3.4.1). To see that β is an isomorphism, we are reduced to the case where Y is affine with ring A, $\mathcal{S} = \widetilde{S}$, where S is a graded A-algebra generated by S_1 and S_1 is an A-module of finite type. It then suffices to apply (2.7.5). □

(3.4.5) Corollary. *Under the hypotheses of (3.4.4), every quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ is isomorphic to an $\mathcal{O}_X$-module of the form $\widetilde{\mathcal{M}}$, where $\mathcal{M}$ is a quasi-coherent graded $\mathcal{S}$-module. If moreover $\mathcal{F}$ is of finite type, and if we suppose that Y is a quasi-compact scheme, or that the underlying space of Y is Noetherian, we may suppose $\mathcal{M}$ of finite type.*

Proof. The first assertion follows immediately from (3.4.4) by taking $\mathcal{M} = \Gamma_*(\mathcal{F})$. To establish
[II | 60] the second, it will suffice to establish that $\mathcal{M}$ is the inductive limit of its graded sub-$\mathcal{S}$-modules $\mathcal{N}_\lambda$ of finite type: indeed, it will follow that $\widetilde{\mathcal{M}}$ is the inductive limit of the $\widetilde{\mathcal{N}_\lambda}$ (3.2.4), hence $\mathcal{F}$ is the inductive limit of the $\beta(\widetilde{\mathcal{N}_\lambda})$; since X is quasi-compact ((3.4.1) and I, 6.3.1) and $\mathcal{F}$ is of finite type, $\mathcal{F}$ will necessarily be equal to one of the $\beta(\widetilde{\mathcal{N}_\lambda})$ (0, 5.2.3).

To define the $\mathcal{N}_\lambda$ having $\mathcal{M}$ as inductive limit, it suffices to consider, for each $n \in \mathbf{Z}$, the quasi-coherent $\mathcal{O}_Y$-module $\mathcal{M}_n$, which is the inductive limit of its sub-$\mathcal{O}_Y$-modules $\mathcal{M}_n^{(\mu_n)}$ of finite type, because of the hypotheses on Y (I, 9.4.9); it is immediate that $\mathcal{P}_{\mu_n} = \mathcal{S}\cdot\mathcal{M}_n^{(\mu_n)}$ is a graded $\mathcal{S}$-module of finite type, and we verify at once that, by taking for $\mathcal{N}_\lambda$ the finite sums of $\mathcal{S}$-modules of the form $\mathcal{P}_{\mu_n}$, we do answer the question. □

(3.4.6) Corollary. *Suppose that the hypotheses of (3.4.4) are satisfied, and moreover that the underlying space Y is quasi-compact; let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type. There exists n_0 such that, for $n \geq n_0$, the canonical homomorphism $\sigma : p^*(p_*(\mathcal{F}(n))) \to \mathcal{F}(n)$ (0, 4.4.3) is surjective.*

Proof. Indeed, for every $y \in Y$, let U be an affine open neighbourhood of y in Y. There exists an integer $n_0(U)$ such that, for $n \geq n_0(U)$, $\mathcal{F}(n)|p^{-1}(U)$ is generated by finitely many of its sections over $p^{-1}(U)$ (2.7.9); but these sections are canonical images of sections of $p^*(p_*(\mathcal{F}(n)))$ over $p^{-1}(U)$ (0, 3.7.1 and 0, 4.4.3), hence $\mathcal{F}(n)|p^{-1}(U)$ is equal to the canonical image of $p^*(p_*(\mathcal{F}(n)))|p^{-1}(U)$. Finally, since Y is quasi-compact, there exists a finite covering of Y by affine open subsets U_i, and by taking for n_0 the largest of the $n_0(U_i)$, we complete the proof. □

Remarks (3.4.7). — If $p = (\psi, \theta) : X \to Y$ is a morphism of ringed spaces and $\mathcal{F}$ an $\mathcal{O}_X$-module, the fact that the canonical homomorphism $\sigma : p^*(p_*(\mathcal{F})) \to \mathcal{F}$ is surjective can be stated explicitly as follows (0, 4.4.1): for every $x \in X$ and every section s of $\mathcal{F}$ over an open neighbourhood V of x, there exist an open neighbourhood U of $p(x)$ in Y, finitely many sections t_i $(1 \leq i \leq m)$ of $\mathcal{F}$ over $p^{-1}(U)$, a neighbourhood $W \subset V \cap p^{-1}(U)$ of x and sections a_i $(1 \leq i \leq m)$ of $\mathcal{O}_X$ over W such that

$$s|W = \sum_i a_i \cdot (t_i|W).$$

When Y is an *affine scheme* and $p_*(\mathcal{F})$ is *quasi-coherent*, this condition is equivalent to the fact that $\mathcal{F}$ is *generated by its sections over* X (0, 5.5.1): indeed, if $Y = \mathrm{Spec}(A)$, we may suppose that $U = D(f)$ with $f \in A$; there exist an integer $n > 0$ and sections s_i of $\mathcal{F}$ over X such that t_i is the restriction to $p^{-1}(U)$ of $s_i g^n$, with $g = \theta(f)$ (by applying (I, 1.4.1) to $p_*(\mathcal{F})$); since g is invertible over $p^{-1}(U)$, we therefore have

$$s|W = \sum_i b_i \cdot (s_i|W)$$

with $b_i = a_i(g|W)^{-n}$, whence our assertion. When Y is affine, Corollary (3.4.6) therefore recovers (2.7.9).

[II | 61] We conclude that when Y is an arbitrary prescheme, the following three conditions, for a quasi-coherent $\mathcal{O}_X$-module $\mathcal{F}$ such that $p_*(\mathcal{F})$ is *quasi-coherent*, are equivalent:

a) *The canonical homomorphism $\sigma : p^*(p_*(\mathcal{F})) \to \mathcal{F}$ is surjective.*

b) *There exist a quasi-coherent $\mathcal{O}_Y$-module $\mathcal{G}$ and a surjective homomorphism $p^*(\mathcal{G}) \to \mathcal{F}$.*

c) *For every affine open subset U of Y, $\mathcal{F}|p^{-1}(U)$ is generated by its sections over $p^{-1}(U)$.*

We have indeed just proved the equivalence of *a)* and *c)*. On the other hand, it is clear that *a)* implies *b)*, $p_*(\mathcal{F})$ being quasi-coherent by hypothesis. Conversely, every homomorphism $u : p^*(\mathcal{G}) \to \mathcal{F}$ factors as $p^*(\mathcal{G}) \to p^*(p_*(\mathcal{F})) \xrightarrow{\sigma} \mathcal{F}$ (0, 3.5.4.4), hence if u is surjective so is σ, which proves that *b)* implies *a)*.

(3.4.8) Corollary. *Suppose that the hypotheses of (3.4.4) are satisfied, and suppose moreover that Y is a quasi-compact scheme or that the underlying space of Y is Noetherian. Let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module of finite type; there then exists an integer n_0 such that, for $n \geq n_0$, $\mathcal{F}$ is isomorphic to a quotient of an $\mathcal{O}_X$-module of the form $(p^*(\mathcal{G}))(-n)$, where $\mathcal{G}$ is a quasi-coherent $\mathcal{O}_Y$-module of finite type (depending on n).*

Proof. Since the structural morphism $X \to Y$ is separated and of finite type, $p_*(\mathcal{F}(n))$ is quasi-coherent (I, 9.2.2, b)), hence is the inductive limit of its quasi-coherent sub-$\mathcal{O}_Y$-modules of finite type, by virtue of the hypothesis on Y (I, 9.4.9). We deduce from this, by (3.4.6), (0, 4.3.2) and (0, 5.2.3), that $\mathcal{F}(n)$ is the canonical image of an $\mathcal{O}_X$-module of the form $p^*(\mathcal{G})$, where $\mathcal{G}$ is a quasi-coherent sub-$\mathcal{O}_Y$-module of finite type of $p_*(\mathcal{F}(n))$; the corollary then follows from (3.2.5.2) and (3.2.7.1). □

3.5 Functorial behaviour.

(3.5.1) Let Y be a prescheme, and $\mathcal{S}$, $\mathcal{S}'$ two quasi-coherent $\mathcal{O}_Y$-algebras graded in positive degrees; set $X = \mathrm{Proj}(\mathcal{S})$, $X' = \mathrm{Proj}(\mathcal{S}')$, and let p, p' be the structural morphisms of X and X' to Y. Let $\varphi : \mathcal{S}' \to \mathcal{S}$ be an $\mathcal{O}_Y$-homomorphism of graded algebras. For every affine open subset U of Y, set $S_U = \Gamma(U, \mathcal{S})$, $S'_U = \Gamma(U, \mathcal{S}')$; the homomorphism φ defines a homomorphism $\varphi_U : S'_U \to S_U$ of graded A_U-algebras, where we set $A_U = \Gamma(U, \mathcal{O}_Y)$. To it there correspond in $p^{-1}(U)$ an open set $G(\varphi_U)$ and a morphism $\Phi_U : G(\varphi_U) \to p'^{-1}(U)$ (2.8.1). Moreover, if $V \subset U$ is an affine open subset, the diagram

$$\begin{array}{ccc} S'_U & \xrightarrow{\varphi_U} & S_U \\ \downarrow & & \downarrow \\ S'_V & \xrightarrow[\varphi_V]{} & S_V \end{array} \tag{3.5.1.1}$$

is commutative, and we verify at once, from the definitions (2.8.1), that we have

$$G(\varphi_V) = G(\varphi_U) \cap p^{-1}(V)$$

and that Φ_V is the restriction of Φ_U to $G(\varphi_V)$. We have thus defined an open subset $G(\varphi)$ of X such that $G(\varphi) \cap p^{-1}(U) = G(\varphi_U)$ for every affine open subset $U \subset Y$, and an affine Y-morphism
$\Phi : G(\varphi) \to X'$, which is said to be *associated* to φ and which we will denote by $\mathrm{Proj}(\varphi)$. When, for every $y \in Y$, there is an affine neighbourhood U of y such that the $\Gamma(U, \mathcal{O}_Y)$-module $\Gamma(U, \mathcal{S}_+)$ is generated by $\varphi(\Gamma(U, \mathcal{S}'_+))$, we have $G(\varphi_U) = p^{-1}(U)$, and consequently $G(\varphi) = X$. [II | 62]

(3.5.2) Proposition.

(i) *If $\mathcal{M}$ is a quasi-coherent graded $\mathcal{S}$-module, there exists a canonical functorial isomorphism of the $\mathcal{O}_{X'}$-module $(\mathcal{M}_{[\varphi]})^\sim$ onto the $\mathcal{O}_{X'}$-module $\Phi_*(\widetilde{\mathcal{M}}|G(\varphi))$.*

(ii) *If $\mathcal{M}'$ is a quasi-coherent graded $\mathcal{S}'$-module, there exists a canonical functorial homomorphism ν from the $(\mathcal{O}_X|G(\varphi))$-module $\Phi^*(\widetilde{\mathcal{M}'})$ to the $(\mathcal{O}_X|G(\varphi))$-module $(\mathcal{M}' \otimes_{\mathcal{S}'} \mathcal{S})^\sim|G(\varphi)$. If $\mathcal{S}'$ is generated by $\mathcal{S}'_1$, ν is an isomorphism.*

Proof. The homomorphisms in question have indeed already been defined when Y is affine (2.8.7 and 2.8.8), and in the general case it suffices to verify that they are compatible with the operations of restriction from an affine open subset of Y to a smaller open subset, which follows immediately from the commutativity of (3.5.1.1). □

In particular, for every $n \in \mathbf{Z}$, we have a canonical homomorphism

$$\Phi^*(\mathcal{O}_{X'}(n)) \longrightarrow \mathcal{O}_X(n)|G(\varphi). \tag{3.5.2.1}$$

(3.5.3) Proposition. *Let Y, Y' be two preschemes, $\psi : Y' \to Y$ a morphism, $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra, and set $\mathcal{S}' = \psi^*(\mathcal{S})$. Then the Y'-scheme $X' = \mathrm{Proj}(\mathcal{S}')$ is canonically identified with $\mathrm{Proj}(\mathcal{S}) \times_Y Y'$. Moreover, if $\mathcal{M}$ is a quasi-coherent graded $\mathcal{S}$-module, the $\mathcal{O}_{X'}$-module $(\psi^*(\mathcal{M}))^\sim$ is identified with $\widetilde{\mathcal{M}} \otimes_Y \mathcal{O}_{Y'}$.*

Proof. Note in the first place that $\psi^*(\mathcal{S})$ and $\psi^*(\mathcal{M})$ are quasi-coherent $\mathcal{O}_{Y'}$-modules, as are their homogeneous components (0, 5.1.4). Let U be an affine open subset of Y, $U' \subset \psi^{-1}(U)$ an affine open subset of Y', and A, A' the rings of U and U' respectively; we then have $\mathcal{S}|U = \widetilde{S}$, where S is a graded A-algebra, and $\mathcal{S}'|U'$ is identified with $(S \otimes_A A')^\sim$ (I, 1.6.5); the first assertion then follows from (2.8.10) and from (I, 3.2.6.2), because we verify at once that the projection $\mathrm{Proj}(\mathcal{S}'|U') \to \mathrm{Proj}(\mathcal{S}|U)$ defined by the preceding identification is compatible with the operations of restriction on U and U' and therefore does define a morphism $\mathrm{Proj}(\mathcal{S}') \to \mathrm{Proj}(\mathcal{S})$. Now let

$$q : \mathrm{Proj}(\mathcal{S}) \to Y, \qquad q' : \mathrm{Proj}(\mathcal{S}') \to Y'$$

be the structural morphisms; $q'^{-1}(U')$ is then identified with $q^{-1}(U) \times_U U'$, and the two sheaves $(\psi^*(\mathcal{M}))^\sim|q'^{-1}(U')$ and $(\widetilde{\mathcal{M}} \otimes_Y \mathcal{O}_{Y'})|q'^{-1}(U')$ are then both canonically identified with $(M \otimes_A A')^\sim$, where we have set $M = \Gamma(U, \mathcal{M})$, by virtue of (2.8.10) and of (I, 1.6.5); whence the second assertion, because we again verify immediately the compatibility of the preceding identifications with the operations of restriction. □

(3.5.4) Corollary. *With the notation of (3.5.3), $\mathcal{O}_{X'}(n)$ is canonically identified with $\mathcal{O}_X(n) \otimes_Y \mathcal{O}_{Y'}$ for every $n \in \mathbf{Z}$ (with $X = \mathrm{Proj}(\mathcal{S})$).*

Proof. Indeed, with the notation of (3.5.3), it is clear that $\psi^*(\mathcal{S}(n)) = \mathcal{S}'(n)$ for every $n \in \mathbf{Z}$. □

(3.5.5) Keeping the preceding notation, let us denote by Ψ the canonical projection $X' \to X$, and set $\mathcal{M}' = \psi^*(\mathcal{M})$; we will moreover suppose that $\mathcal{S}$ is generated by $\mathcal{S}_1$
[II | 63] and that X is of finite type over Y; it then follows that $\mathcal{S}'$ is generated by $\mathcal{S}'_1$ (as we see by reducing to the case where Y and Y' are affine) and that X' is of finite type over Y' (I, 6.3.4). Let $\mathcal{F}$ be an $\mathcal{O}_X$-module and set $\mathcal{F}' = \Psi^*(\mathcal{F})$; it then follows from (3.5.4) and from (0, 4.3.3) that we have $\mathcal{F}'(n) = \Psi^*(\mathcal{F}(n))$ for every $n \in \mathbf{Z}$. We moreover define a

canonical ψ-homomorphism $\theta_n : q_*(\mathcal{F}(n)) \to q'_*(\mathcal{F}'(n))$ in the following way: in view of the commutativity of the diagram

$$\begin{array}{ccc} X & \xleftarrow{\Psi} & X' \\ {\scriptstyle q}\downarrow & & \downarrow{\scriptstyle q'} \\ Y & \xleftarrow[\psi]{} & Y' \end{array}$$

we have to define a homomorphism $q_*(\mathcal{F}(n)) \to \psi_*(q'_*(\Psi^*(\mathcal{F}(n)))) = q_*(\Psi_*(\Psi^*(\mathcal{F}(n))))$, and it suffices to take the homomorphism $\theta_n = q_*(\rho_n)$, where ρ_n is the canonical homomorphism $\mathcal{F}(n) \to \Psi_*(\Psi^*(\mathcal{F}(n)))$ (0, 4.4.3). It is immediate that for every affine open subset U of Y and every affine open subset U' of Y' such that $U' \subset \psi^{-1}(U)$, the homomorphism θ_n gives on sections the canonical homomorphism (0, 3.7.2) $\Gamma(q^{-1}(U), \mathcal{F}(n)) \to \Gamma(q'^{-1}(U'), \mathcal{F}'(n))$.

The commutativity of (2.8.13.2) then shows that if $\mathcal{F}$ is quasi-coherent, the diagram

$$\begin{array}{ccc} \mathcal{F} & \xrightarrow{\rho} & \mathcal{F}' \\ {\scriptstyle \beta_{\mathcal{F}}}\uparrow & & \uparrow{\scriptstyle \beta_{\mathcal{F}'}} \\ (\Gamma_*(\mathcal{F}))^\sim & \xrightarrow[\widetilde{\theta}]{} & (\Gamma_*(\mathcal{F}'))^\sim \end{array}$$

is commutative (the top horizontal arrow being the canonical Ψ-morphism $\mathcal{F} \to \Psi^*(\mathcal{F})$).

Similarly, the commutativity of (2.8.13.1) shows that the diagram

$$\begin{array}{ccc} \Gamma_*(\widetilde{\mathcal{M}}) & \xrightarrow{\theta} & \Gamma_*(\widetilde{\mathcal{M}'}) \\ {\scriptstyle \alpha_{\mathcal{M}}}\uparrow & & \uparrow{\scriptstyle \alpha_{\mathcal{M}'}} \\ \mathcal{M} & \xrightarrow[\rho]{} & \mathcal{M}' \end{array}$$

is commutative (the bottom horizontal arrow being the canonical ψ-morphism $\mathcal{M} \to \psi^*(\mathcal{M})$).

(3.5.6) Now consider two preschemes Y, Y', a morphism $g : Y' \to Y$, a quasi-coherent graded $\mathcal{O}_Y$-algebra (resp. $\mathcal{O}_{Y'}$-algebra) $\mathcal{S}$ (resp. $\mathcal{S}'$) and a g-morphism of graded algebras $u : \mathcal{S} \to \mathcal{S}'$, that is, an $\mathcal{O}_Y$-homomorphism of graded algebras $\mathcal{S} \to g_*(\mathcal{S}')$; we know moreover that it amounts to the same thing to give an $\mathcal{O}_{Y'}$-homomorphism of graded algebras $u^\sharp : g^*(\mathcal{S}) \to \mathcal{S}'$. We then deduce canonically from $u^\sharp$ a Y'-morphism $W = \mathrm{Proj}(u^\sharp) : G(u^\sharp) \to \mathrm{Proj}(g^*(\mathcal{S}))$, where $G(u^\sharp)$ is an open subset of $X' = \mathrm{Proj}(\mathcal{S}')$ (3.5.1). On the other hand, $X'' = \mathrm{Proj}(g^*(\mathcal{S}))$ is canonically identified
with $X \times_Y Y'$, where we set $X = \mathrm{Proj}(\mathcal{S})$ (3.5.3); composing with $\mathrm{Proj}(u^\sharp)$ the first [II | 64]
projection $p : X \times_Y Y' \to X$, we therefore obtain a morphism $v : G(u^\sharp) \to X$, which we will denote by $\mathrm{Proj}(u)$, and which is such that the diagram

$$\begin{array}{ccc} G(u^\sharp) & \xrightarrow{v} & X \\ \downarrow & & \downarrow \\ Y' & \xrightarrow[g]{} & Y \end{array}$$

is commutative.

Moreover, for every quasi-coherent graded $\mathcal{S}$-module $\mathcal{M}$, we have a canonical v-morphism

$$\nu : \widetilde{\mathcal{M}} \longrightarrow (g^*(\mathcal{M}) \otimes_{g^*(\mathcal{S})} \mathcal{S}')^\sim | G(u^\sharp). \tag{3.5.6.1}$$

Indeed, $\nu^\sharp$ is obtained by composing the homomorphisms

$$v^*(\widetilde{\mathcal{M}}) = W^*(p^*(\widetilde{\mathcal{M}})) \longrightarrow W^*((g^*(\mathcal{M}))^\sim) \longrightarrow (g^*(\mathcal{M}) \otimes_{g^*(\mathcal{S})} \mathcal{S}')^\sim | G(u^\sharp)$$

where the first arrow comes from the isomorphism (3.5.3) and the second is the homomorphism (3.5.2, (ii)); when $\mathcal{S}$ is generated by $\mathcal{S}_1$, it follows from (3.5.2) that $\nu^\sharp$ is an isomorphism.

As a particular case of (3.5.6.1), we have, for every $n \in \mathbf{Z}$, a canonical v-morphism

$$\nu : \mathcal{O}_X(n) \longrightarrow \mathcal{O}_{X'}(n) | G(u^\sharp). \tag{3.5.6.2}$$

3.6 Closed sub-preschemes of a prescheme $\mathrm{Proj}(\mathcal{S})$.

(3.6.1) Let Y be a prescheme, and $\varphi : \mathcal{S} \to \mathcal{S}'$ a homomorphism of quasi-coherent graded $\mathcal{O}_Y$-algebras, of degree 0. We say that φ is (**TN**)-*surjective* (resp. (**TN**)-*injective*, (**TN**)-*bijective*) if there exists n such that, for $k \geq n$, $\varphi_k : \mathcal{S}_k \to \mathcal{S}'_k$ is surjective (resp. injective, bijective). When this is so, we reduce the study of the corresponding morphism $\Phi : \mathrm{Proj}(\mathcal{S}') \to \mathrm{Proj}(\mathcal{S})$ to the case where φ is surjective (resp. injective, bijective). This is proved as in (2.9.1) (which is its particular case corresponding to Y affine) by using (3.1.8). Instead of saying that φ is (**TN**)-bijective, we also say that it is then a (**TN**)-isomorphism.

(3.6.2) Proposition. *Let Y be a prescheme, $\mathcal{S}$ a quasi-coherent graded $\mathcal{O}_Y$-algebra, and let $X = \mathrm{Proj}(\mathcal{S})$.*
