0.3 Subgroups of type (C) of group preschemes over an arbitrary prescheme

Theorem 3.1. *Let S be a prescheme, let G be a smooth S-group prescheme, and let $\mathfrak{g}$ be its Lie algebra, which is a locally free module of finite type over S. Let $\mathfrak{h}$ be a Lie subalgebra of $\mathfrak{g}$ that, as a module, is locally a direct factor in $\mathfrak{g}$, and suppose that, for every $s \in S$, the geometric fiber $\mathfrak{h}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$. Let a be a quasi-regular section of $\mathfrak{g}$ (2.5). Then*

$$M_a = \mathrm{Transp}_G(a, \mathfrak{h}),$$

the subfunctor of G whose S'-valued points are the $g \in G(S')$ such that

$$\mathrm{ad}(g) \cdot a_{S'} \in \Gamma(S', \mathfrak{h}_{S'}),$$

is represented by a closed subprescheme of G, smooth over S, whose structure morphism to S is surjective. [4]

Proof. Consider the canonical morphism

$$\varphi\colon G \times_S W(\mathfrak{h}) \longrightarrow W(\mathfrak{g}), \qquad (g, x) \longmapsto \mathrm{ad}(g) \cdot x.$$

Then M_a is S-isomorphic to $\varphi^{-1}(a)$, the inverse image under φ of a, viewed as a section of $W(\mathfrak{g})$ over S. To prove that M_a is smooth, it is enough to show that φ is smooth at the points of $G \times_S W(\mathfrak{h})$ lying over $\mathrm{Im}(a)$. More generally, φ is smooth at every point lying over a point of $W(\mathfrak{g})$ that is regular in its fiber $W(\mathfrak{g}(s))$ over S.

Indeed, the source and target of φ are smooth over S, and hence are flat and locally of finite presentation over S. We may therefore check the assertion fiber by fiber. This reduces us to the case in which S is the spectrum of an algebraically closed field k, G is a locally algebraic group over k, $\mathfrak{h}$ is a Lie subalgebra of its Lie algebra $\mathfrak{g}$ containing a Cartan subalgebra of $\mathfrak{g}$, and a is a regular point of $\mathfrak{g}$.

Since φ is a G-morphism, we may suppose that the point of $G \times W(\mathfrak{h})$ under consideration is of the form (e, a). We may also suppose that G is connected, and hence of finite type over k. The assertion is then precisely XIII 5.4.

It is also immediate that M_a is a closed subprescheme of G of finite presentation over S: it is the inverse image of $W(\mathfrak{h})$ under the morphism

$$G \longrightarrow W(\mathfrak{g}), \qquad g \longmapsto \mathrm{ad}(g) \cdot a.$$

Finally, the surjectivity of $M_a \to S$ likewise reduces to the case of an algebraically closed base field. By hypothesis, $\mathfrak{h}$ then contains a Cartan subalgebra $\mathfrak{d}'$. By the conjugacy theorem XIII 6.1(a), $\mathfrak{d}'$ is conjugate to

$$\mathfrak{d} = \mathrm{Nil}(a, \mathfrak{g}).$$

It follows that $\mathfrak{h}$ contains a conjugate of a. This completes the proof.

Corollary 3.2. *Let G and $\mathfrak{g}$ be as in 3.1, with G of finite type over S, and let $\mathfrak{k}$ and $\mathfrak{h}$ be two Lie subalgebras of $\mathfrak{g}$ that are locally direct factors as modules. Suppose that one of the following two hypotheses holds:*

[4] Editors' note: This transporter is denoted $\mathrm{Transp}_G(a, \mathfrak{h})$.

a) *For every $s \in S$, the geometric fiber $\mathfrak{k}_{\bar{s}}$ is nilpotent and contains a regular element of $\mathfrak{g}_{\bar{s}}$, while the geometric fiber $\mathfrak{h}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$.*

b) *$\mathfrak{k}$ is a Cartan subalgebra of $\mathfrak{g}$.*

Then $\mathrm{Transp}_G(\mathfrak{k}, \mathfrak{h})$ *is a closed subprescheme of G, smooth over S. Moreover, in case* a), *its structure morphism to S is surjective.*

The representability of the transporter by a closed subprescheme of G of finite presentation is immediate and is left to the reader. We first prove smoothness in case a). Suppose first that $\mathfrak{k}$ has a section a that is quasi-regular in $\mathfrak{g}$. It is then enough to apply 3.1 and the following lemma.

Lemma 3.3. *Under the hypotheses of 3.2*(a), *if a is a section of $\mathfrak{k}$ that is quasi-regular in $\mathfrak{g}$, then*

$$\mathrm{Transp}_G(\mathfrak{k}, \mathfrak{h}) = \mathrm{Transp}_G(a, \mathfrak{h}).$$

Indeed, by the definitions it is enough to show that, if a is also a section of $\mathfrak{h}$, then $\mathfrak{k} \subset \mathfrak{h}$. Since $\mathfrak{k}$ is locally nilpotent by hypothesis, 2.1 gives

$$\mathfrak{k} \subset \mathrm{Nil}(a, \mathfrak{g}).$$

On the other hand,

$$\mathrm{Nil}(a, \mathfrak{g}) \subset \mathfrak{h},$$

because

$$\mathrm{ad}(a)_{\mathfrak{g}/\mathfrak{h}}$$

is injective; this can be checked fiber by fiber by XIII 4.8(b). The lemma follows.

In the general case, the usual standard argument first reduces us to the case where S is affine noetherian, and then to the case where S is local artinian, smoothness being an infinitesimal property. By flat descent we may further suppose that the residue field is infinite. The fiber of $\mathfrak{k}$ then contains an element regular in the corresponding fiber of $\mathfrak{g}$. Lifting this element to a section of $\mathfrak{k}$ reduces us to the preceding case.

Thus the transporter is smooth in case a). Its structure morphism is surjective because this may be checked after reducing to the case where S is the spectrum of an algebraically closed field; $\mathfrak{k}$ then contains a regular point of $\mathfrak{g}$, and 3.3 and 3.1 apply.

For case b), the definition of smoothness (XI 1.1) reduces the assertion to the following lifting statement. Let S be affine, let S_0 be a closed subscheme defined by a quasi-coherent nilpotent ideal J, and let $g_0 \in G(S_0)$ transport $\mathfrak{k}_0$ into $\mathfrak{h}_0$. Then g_0 lifts to an element $g \in G(S)$ that transports $\mathfrak{k}$ into $\mathfrak{h}$. The hypothesis on g_0 places this lifting problem under case a), already proved. This completes the proof.

Of course, if in 3.2(b) the subalgebra $\mathfrak{h}$ satisfies the stronger hypothesis of 3.1, then, and only then, the structure morphism

$$\mathrm{Transp}_G(\mathfrak{k}, \mathfrak{h}) \longrightarrow S$$

is surjective. Using Hensel's lemma XI 1.10, one obtains from 3.1 and 3.2 the following corollary.

Corollary 3.4. *Under the hypotheses of 3.1 for G and $\mathfrak{h}$, and assuming that G is of finite type over S, the following assertions hold:*

a) *For every quasi-regular section a of $\mathfrak{g}$, étale locally there is a conjugate of a that is a section of $\mathfrak{h}$.*

b) *For every Cartan subalgebra $\mathfrak{d}$ of $\mathfrak{g}$, étale locally $\mathfrak{d}$ is conjugate to a subalgebra of $\mathfrak{h}$.*

In particular, when $\mathfrak{h}$ is itself a Cartan subalgebra of $\mathfrak{g}$, one obtains the following.

Corollary 3.5. *Let G be a smooth S-prescheme in groups of finite type, let $\mathfrak{g}$ be its Lie algebra, and let $\mathfrak{d}$ and $\mathfrak{d}'$ be two Cartan subalgebras of $\mathfrak{g}$. Then* $\mathrm{Transp}_G(\mathfrak{d},\mathfrak{d}')$ *is identical to the strict transporter of $\mathfrak{d}$ into $\mathfrak{d}'$, and is a closed subprescheme of G, smooth over S, whose structure morphism is surjective. Étale locally, $\mathfrak{d}$ and $\mathfrak{d}'$ are conjugate.*

Here the transporter is identical to the strict transporter simply because $\mathfrak{d}$ and $\mathfrak{d}'$ are locally direct factors in $\mathfrak{g}$ and have the same rank at every point. Thus 3.5 is a special case of 3.4. Taking $\mathfrak{d} = \mathfrak{d}'$ gives the following.

Corollary 3.6. *Let G be as in 3.5, and let $\mathfrak{d}$ be a Cartan subalgebra of $\mathfrak{g}$. Then* $\mathrm{Norm}_G(\mathfrak{d})$ *is a closed subprescheme in groups of G, smooth over S, and its Lie algebra is $\mathfrak{d}$.*

Indeed, the last assertion says that $\mathfrak{d}$ is its own normalizer in $\mathfrak{g}$, and this follows at once because it is true fiber by fiber.

Corollary 3.7. *Let G and $\mathfrak{g}$ be as in 3.5. Then the conditions* (C_2), (C_1'), *and* (C_1) *of 2.9 are equivalent. In other words, if $\mathfrak{g}$ admits a Cartan subalgebra fpqc locally, then every quasi-regular section of $\mathfrak{g}$ is regular.*

Indeed, let a be a quasi-regular section; we prove that it is regular. Since the question is fpqc local, we may suppose that $\mathfrak{g}$ admits a Cartan subalgebra $\mathfrak{d}$. By 3.4(a), étale locally a is conjugate to a section of $\mathfrak{d}$. We are thereby reduced to the case in which a is a section of $\mathfrak{d}$, where the conclusion follows immediately from the definition.

Definition 3.8. *Let G be a smooth prescheme in groups over a prescheme S. A* subgroup of type (C) *of G is a subprescheme in groups $D \subset G$, smooth over S and with connected fibers, such that*

$$\mathfrak{d} = \mathrm{Lie}(D)$$

is a Cartan subalgebra (2.4) *of $\mathfrak{g} = \mathrm{Lie}(G)$. Equivalently, for every $s \in S$, the fiber D_s is a subgroup of type* (C) *of the algebraic group G_s* (XIII 6.2).

Theorem 3.9. *Let G be a smooth S-prescheme in groups of finite presentation, and let $\mathfrak{g}$ be its Lie algebra. Then:*

a) *The map*

$$D \longmapsto \mathfrak{d} = \mathrm{Lie}(D)$$

establishes a bijective correspondence between the subgroups of type (C) *of G and the Cartan subalgebras of $\mathfrak{g}$.*

b) *If D and $\mathfrak{d}$ correspond, then*

$$\mathrm{Norm}_G(D) = \mathrm{Norm}_G(\mathfrak{d}).$$

This is a closed subprescheme of G, smooth over S, and

$$D = \mathrm{Norm}_G(D)^0 = \mathrm{Norm}_G(\mathfrak{d})^0.$$

c) *Any two subgroups D and D' of type* (C) *in G are conjugate étale locally.*

Proof. Let D be a subgroup of type (C) of G, and let $\mathfrak{d}$ be its Lie algebra. Then

$$D \subset \mathrm{Norm}_G(\mathfrak{d}).$$

By Definition 3.8 and Corollary 3.6, this is an inclusion of smooth preschemes in groups over S that induces an isomorphism on Lie algebras. Since D has connected fibers, it follows that

$$D = \mathrm{Norm}_G(\mathfrak{d})^0.$$

Thus the map in a) is injective. We prove that it is surjective. Let $\mathfrak{d}$ be a Cartan subalgebra of $\mathfrak{g}$. By 3.6,

$$N = \mathrm{Norm}_G(\mathfrak{d})$$

is a closed subprescheme in groups of G, smooth over S, and has Lie algebra $\mathfrak{d}$. Since G is of finite presentation over S, so is N. Consequently, as noted in XII after 7.3, the union of the connected components of the fibers of N is the underlying set of an open subprescheme in groups $N^\circ \subset N$. Evidently N° is a subgroup of type (C) of G with Lie algebra $\mathfrak{d}$. This proves a). The first assertion of b) follows at once, and the formula

$$D = \mathrm{Norm}_G(\mathfrak{d})^0$$

has already been proved. Finally, c) follows from a) and 3.5.

Corollary 3.10. *Suppose that $\mathfrak{g}$ admits a Cartan subalgebra fpqc locally, or equivalently by 3.9*(a)*, that G admits a subgroup of type* (C) *fpqc locally. Consider the functor*

$$\mathcal{D}\colon (\mathrm{Sch})^\circ/S \longrightarrow (\mathrm{Sets}),$$

where $\mathcal{D}(S')$ is the set of subgroups of type (C) *of $G_{S'}$. This functor is representable by a quasi-projective prescheme, smooth over S, with connected geometric fibers. If $S = \mathrm{Spec}(k)$, so that G is a smooth algebraic group over k, and if $\mathfrak{g}$ admits a regular point—a condition automatically satisfied when k is infinite—then $\mathcal{D}$ is a rational variety over k.*

Indeed, by 3.9(a) the functor $\mathcal{D}$ is canonically isomorphic to the functor considered in 2.16. On the other hand, by 3.7 condition (C_2) is satisfied. Therefore 3.10 follows from 2.16 and 2.17.

Corollary 3.11. *Let D be a subgroup of type* (C) *of G, and let N be its normalizer in G. Then the quotient sheaf G/N is canonically isomorphic to the functor $\mathcal{D}$ of 3.10. It is therefore representable by a quasi-projective prescheme, smooth over S, with connected geometric fibers.*

Proposition 3.12. *Let G be a smooth S-prescheme in groups of finite presentation over S. Let H and K be two subpreschemes in groups, smooth and of finite presentation over S, with K having connected fibers, and let $\mathfrak{g}, \mathfrak{h}, \mathfrak{k}$ be the corresponding Lie algebras. Suppose that one of the following conditions holds on their geometric fibers:*

a) *For every $s \in S$, $\mathfrak{k}_{\bar{s}}$ contains a regular element of $\mathfrak{g}_{\bar{s}}$, and $\mathfrak{h}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$.*

b) *For every $s \in S$, $\mathfrak{k}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$.*

Under these conditions, $H \supset K$ if and only if $\mathfrak{h} \supset \mathfrak{k}$.

It remains only to prove that $\mathfrak{h} \supset \mathfrak{k}$ implies $H \supset K$. In case b), the inclusion $\mathfrak{h} \supset \mathfrak{k}$ places us under the hypotheses of case a), so it is enough to prove a). Proceeding as in 3.2(a), by reduction to the case where S is local artinian, we reduce to the case in which there exists a section a of $\mathfrak{k}$ that is quasi-regular in $\mathfrak{g}$. Arguing then as in XIII 5.5 reduces us to the following statement.

Corollary 3.13. *Let G be a smooth S-prescheme in groups of finite presentation over S, let $H \subset G$ be a subprescheme in groups smooth and of finite presentation over S, and let $\mathfrak{g}$ and $\mathfrak{h}$ be their Lie algebras. Let a be a section of $\mathfrak{h}$ that is quasi-regular in $\mathfrak{g}$. Suppose that for every $s \in S$, the geometric fiber $\mathfrak{h}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$. Put*

$$M_a = \mathrm{Transp}_G(a, \mathfrak{h}).$$

This is a closed subprescheme of G, smooth over S (cf. 3.1)*. Hence M_a^0, the union in the fibers of M_a of the connected components containing the identity, is an open subset of M_a, endowed with the structure induced from M_a. Then*

$$H^0 = M_a^0.$$

Clearly $H \subset M_a$, and therefore $H^0 \subset M_a^0$. Since this is an inclusion of preschemes smooth over S, it is enough to check equality on the fibers. This reduces us to the case where S is the spectrum of an algebraically closed field, which was treated in XIII 5.4.

Corollary 3.14. *Let G be a smooth S-prescheme in groups of finite presentation, let D be a subgroup of type* (C) *of G, and let $H \subset G$ be a subprescheme in groups smooth and of finite presentation over S. If $\mathfrak{d}$ and $\mathfrak{h}$ are their Lie algebras, then*

$$\mathrm{Transp}_G(D, H) = \mathrm{Transp}_G(\mathfrak{d}, \mathfrak{h}),$$

and this functor is representable by a closed subprescheme of G, smooth over S.

Indeed, the identity between the two transporters follows from 3.12(b), after which 3.2 applies.

Corollary 3.15. *Let G and H be as in 3.14, and suppose that for every $s \in S$, the geometric fiber $\mathfrak{h}_{\bar{s}}$ contains a Cartan subalgebra of $\mathfrak{g}_{\bar{s}}$. Suppose also that $\mathfrak{g}$ admits a Cartan subalgebra fpqc locally. Then, étale locally, H contains a subgroup of type* (C) *of G.*

By 3.7 and 3.9(a), G admits a subgroup of type (C) étale locally. We may therefore suppose that G admits such a subgroup D. The hypothesis on $\mathfrak{h}$ then also says that the structure morphism of the transporter in 3.14 is surjective, by the conjugacy theorem XIII 6.1(a). The conclusion follows from Hensel's lemma XI 1.10.

Corollary 3.16. *Let G, H, K be as in 3.12*(a)*, and suppose in addition that every geometric fiber $\mathfrak{k}_{\bar{s}}$ is nilpotent, that is, that $\mathfrak{k}$ is locally nilpotent. Then*

$$\mathrm{Transp}_G(K, H) = \mathrm{Transp}_G(\mathfrak{k}, \mathfrak{h}),$$

and this functor is representable by a closed subprescheme of G, smooth over S, whose structure morphism to S is surjective. Étale locally, H contains a subgroup conjugate to K.

The identity between the two transporters is again contained in 3.12(a). The assertion about its structure is precisely 3.2(a), and the last assertion of 3.16 then follows from Hensel's lemma.

Remarks 3.17. a) In 3.12 and 3.16, the hypothesis that K be smooth over S may be replaced by the weaker hypothesis that the sheaf

$$e_K^*(\Omega^1_{K/S}) = \omega^1_K$$

of relative 1-differentials along the identity section be locally free. In this form, 3.12 includes XIII 5.5.

b) Let $G, \mathfrak{g}, \mathfrak{h}$ be as in 3.1, with G of finite presentation over S. Then

$$N = \mathrm{Norm}_G(\mathfrak{h})$$

need not be smooth over S along the identity section. Equivalently, there need not exist a subprescheme in groups $H \subset G$, smooth over S, whose Lie algebra is $\mathfrak{h}$, even when S is the spectrum of a field. When such an H exists, taking H with connected fibers gives

$$N = \mathrm{Norm}_G(H);$$

I do not know whether N is then smooth over S. In this question one may plainly reduce to the case where S is local artinian.

To conclude this section, we examine the case in which G is "semisimple" over S.

Theorem 3.18. *Let S be a prescheme and let G be a smooth S-prescheme in groups whose geometric fibers are semisimple "adjoint" groups, that is, semisimple groups whose reductive center* (XII 4.1 and 4.4) *is the identity group. Then the subgroups of type* (C) *of G are precisely its maximal tori, and hence also precisely its Cartan subgroups* (XII 3.1).

In view of the definitions, it is enough to treat the case where S is the spectrum of an algebraically closed field. We must then show that, for a maximal torus T of G, its Lie algebra $\mathfrak{t}$ is a Cartan subalgebra of $\mathfrak{g}$. Put $r = \dim T = \mathrm{rank}\,\mathfrak{t}$. Taking into account the inequality

$$\mathrm{nil\,rank}(\mathfrak{g}) \geq \mathrm{nil\,rank}(G) = \dim T = \mathrm{rank}\,\mathfrak{t} = r,$$

it is enough to find $x \in \mathfrak{t}$ such that

$$\dim \mathrm{Nil}(x, \mathfrak{g}) = r.$$

Since $\mathfrak{t}$ is abelian, and therefore nilpotent, this is equivalent to finding $a \in \mathfrak{t}$ for which

$$\mathrm{ad}(a)_{\mathfrak{g}/\mathfrak{t}}$$

is injective (XIII 5.7(a)).

Consider the characters α of T occurring in the representation of T induced by the adjoint representation of G. The structure theory of the semisimple group *G (Bible)*, 13, Theorem 1(a), and Theorem 3, Corollary 2, or more precisely the "big cell" of G, shows that the eigenspace of $\mathfrak{g}$ for the trivial character is exactly $\mathfrak{t}$. The other eigenspaces are one-dimensional, and their characters are precisely the roots of G relative to T. Here the big cell is built from T and the subgroups P_α, each isomorphic to the additive group $\mathbf{G}_a$, stable under T, and corresponding to the root characters.

The reductive center of G is the intersection of the kernels of the characters of T occurring in the adjoint representation (XII 4.8). Thus the assertion that G is adjoint says that its roots generate the lattice

$$M = \mathrm{Hom}(T, \mathbf{G}_m).$$

A familiar lemma from root theory says that every root belongs to a system of simple roots, hence to a basis of the group generated by the roots, and therefore to a basis of the dual lattice of T. We obtain the following.

Corollary 3.19. *Let G be an adjoint semisimple algebraic group over an algebraically closed field k, and let T be a maximal torus of G. For every root*

$$\alpha\colon T \longrightarrow \mathbf{G}_m$$

of G relative to T, the corresponding homomorphism

$$\alpha'\colon \mathfrak{t} \longrightarrow k$$

is nonzero.

This assertion is essentially equivalent to Theorem 3.18. Indeed, for $t \in \mathfrak{t}$, the endomorphism $\mathrm{ad}(t)$ is semisimple, and its eigenvalues on $\mathfrak{g}/\mathfrak{t}$ are precisely the numbers $\alpha'(t)$. Hence $\mathrm{ad}(t)_{\mathfrak{g}/\mathfrak{t}}$ is injective if and only if all the $\alpha'(t)$ are nonzero; and such a $t \in \mathfrak{t}$ exists if and only if every α' is nonzero.

Corollary 3.20. *Let S be a prescheme and let G be a smooth S-prescheme in groups of finite presentation over S, whose geometric fibers are connected reductive algebraic groups, that is, extensions of a semisimple group by a torus. For every $s \in S$ there is an open neighborhood U of s such that $G|_U$ admits a maximal torus.*[5]

We shall see in Exposé XVI that the hypothesis on G implies that G is affine over S and has locally constant reductive rank. Hence, by XII 4.7(c), G admits a reductive center Z, the quotient

$$G' = G/Z$$

is a smooth affine group over S whose reductive center is the identity group, and the maximal tori of G correspond bijectively to those of G'. Moreover, the geometric fibers of G' are plainly connected semisimple groups, and are adjoint by definition because their reductive center is trivial.

It is therefore enough to treat the case where G is semisimple and adjoint. By 3.18, the problem reduces to finding an open neighborhood U of s and a subgroup of type (C) of $G|_U$, or equivalently by 3.9(a), a Cartan subalgebra of $\mathfrak{g}|_U$. This is possible when $k(s)$ is infinite: by 3.7, $\mathfrak{g}$ satisfies condition (C_2) of 2.9, and 2.11(b) applies.

In fact, 3.20 remains true without assuming that $k(s)$ is infinite. By the preceding argument, it is enough to know that, for every adjoint semisimple group G over a finite field k, the Lie algebra $\mathfrak{g}$ contains a regular element. Chevalley proved this assertion using the properties of a Coxeter element of the Weyl group; see the appendix below by J.-P. Serre.

Remarks 3.21. a) Assertion 3.20 remains valid, with essentially the same proof, if G is replaced by a closed subprescheme in groups H, smooth over S, whose rank is everywhere the same as that of G (for example, a "parabolic subgroup" of G), provided that $k(s)$ is infinite. I do not know whether the infinitude hypothesis is again superfluous. It can at least be removed when H is parabolic: constructing the radical U of H and the quotient H/U reduces the question to the semisimple case. Unfortunately, the method of regular elements seems powerless here. One readily constructs examples—for instance, the projective group with its "standard" Borel subgroup—in which the Lie algebra $\mathfrak{h}$ of H contains no regular element.

b) When $k(s)$ is infinite, the proof of 3.20 in fact gives the following sharper statement, using 3.9(b): every maximal torus T_0 of G_s is induced by a maximal torus T over an

[5] This result, as well as 2.11 on which it rests, immediately generalizes to the case in which s is replaced by a finite subset of S contained in an affine open.

open neighborhood of s. I do not know whether this remains true without the infinitude hypothesis. The evident difficulty is that the Lie algebra $\mathfrak{t}_0$ of T_0 need not contain a regular element of the Lie algebra $\mathfrak{g}_0$ of the fiber G_s.

An affirmative answer would imply the following assertion, which is known only when the residue field is infinite or when A is separated and complete. Let A be a local ring with residue field k, and let M be an "Azumaya algebra" over A, meaning an algebra that is a finite free A-module and whose reduction

$$M_0 = M \otimes_A k$$

is a central simple algebra over k. Let $D_0 \subset M_0$ be a commutative subalgebra separable over k, with

$$[M_0 : k] = [D_0 : k]^2.$$

Then there should exist a commutative subalgebra $D \subset M$ that is a direct summand as an A-module and satisfies

$$D \otimes_A k = D_0.$$

The datum of M is equivalent to that of a principal homogeneous bundle under the projective group $\mathrm{PGL}(n)_A$, and hence to an inner twisted form G of $\mathrm{PGL}(n)$. The maximal tori of G correspond bijectively to the commutative subalgebras $D \subset M$ that are étale of rank n over A.

c) Applying 3.20 to the centralizer of a subtorus Q of a reductive S-prescheme in groups G, one sees that every such Q is contained, Zariski locally, in a maximal torus of G.

0.4 A Digression on Borel Subgroups

Definition 4.1. *Let G be a smooth algebraic group over an algebraically closed field. A* Borel subgroup *of G is a smooth, solvable, connected algebraic subgroup that is maximal with these properties.*

When G is affine, this agrees with the terminology of *(Bible)*, 6, Definition 1. Observe at once that if Z is a connected smooth subgroup of G contained in its center (or, more generally, if Z is solvable and normal), then, for every Borel subgroup B of G, the image BZ of $B \times Z$ under the morphism

$$(b, z) \longmapsto bz$$

from $B \times Z$ to G is a smooth, solvable, connected subgroup of G containing B. It is therefore equal to B. Thus B contains Z, and consequently B is the inverse image of an algebraic subgroup B' of $G' = G/Z$; it is immediate that B' is a Borel subgroup of G'.

Taking

$$Z = \mathrm{Centr}(G^0)^0_{\mathrm{red}},$$

the quotient $G' = G/Z$ is affine by XII 6.1. Hence the Borel subgroups of G' are conjugate, and G'/B' is a projective variety for every such B' *(Bible)*, 6, Theorem 4. Consequently:

Proposition 4.2. *Let G be as in 4.1. Then the Borel subgroups of G are conjugate. If B is a Borel subgroup, then G/B is a projective variety. The maximal tori of B are maximal tori of G; and, when G is connected, the Cartan subgroups of B are Cartan subgroups of G.*

It remains to prove the last assertion, and we may plainly suppose that $G = G^0$. For Cartan subgroups, it follows from the analogous assertion in G' *(Bible)*, 6, Theorem 4,

Corollary 4 and XII 6.6(e). The assertion for maximal tori follows from this one, since by XII 6.6(c) the maximal tori of a smooth algebraic group are precisely the maximal tori of its Cartan subgroups.

Corollary 4.3. *Suppose that G is connected. Then every element of G is contained in a Borel subgroup of G.*

This reduces to the same assertion in G', where it is well known *(Bible)*, 6, Theorem 5(d).

Corollary 4.4. *Let B be a Borel subgroup of G, let C be a Cartan subgroup of B, and let N be its normalizer in G. Then*

$$N \cap B = C.$$

Indeed,

$$N \cap B = \mathrm{Norm}_B(C),$$

so it remains to show that, when G is connected and solvable, a Cartan subgroup C is its own connected normalizer. With the preceding notation, C is the inverse image of a Cartan subgroup C' of G', and we are therefore reduced to the case in which G is affine. The normalizer of a Cartan subgroup is smooth (C being its own connected normalizer; see, for example, XII 6.6(c)). It is thus enough to check that C and N have the same k-valued points, which is exactly *(Bible)*, Theorem 6(d).

Definition 4.5. *Let G be a smooth prescheme in groups of finite presentation over a prescheme S. A* Borel subgroup *of G is a smooth subprescheme in groups B of G, of finite presentation, such that for every $s \in S$ the geometric fiber $B_{\bar{s}}$ is a Borel subgroup of $G_{\bar{s}}$.*

As is immediately verified, this notion is stable under base change and is local for the fpqc topology. Indeed, if k' is an algebraically closed extension of an algebraically closed field k, then an algebraic subgroup B of a smooth algebraic group G over k is a Borel subgroup of G if and only if $B_{k'}$ is a Borel subgroup of $G_{k'}$.

It follows from the definition that, if G is a smooth algebraic group over an arbitrary field k and B is a Borel subgroup of G, then G/B is a projective variety; every maximal torus T of B is a maximal torus of G; and the normalizer of T in B equals its centralizer C, which is a Cartan subgroup of G when G is connected.

Remarks 4.6. Unfortunately, it is no longer true in general that two Borel subgroups of G are locally conjugate for the fpqc topology. This can fail even when G is affine over S and S is the spectrum of the algebra of dual numbers over an algebraically closed field k.

As a consequence of this regrettable fact, let us point out that if G is a smooth, affine, connected algebraic group over a nonperfect field k, it is in general impossible to define naturally a homogeneous space D under G that plays the role of a flag variety, that is, of the variety of Borel subgroups of G. Over the algebraic closure $\bar{k}$ of k, such a space would have to be isomorphic to $G_{\bar{k}}/B$, where B is a Borel subgroup of $G_{\bar{k}}$.

Indeed, suppose that the quotient of $G_{\bar{k}}$ by its radical $\bar{R}$ is an adjoint semisimple group. The kernel of

$$G_{\bar{k}} \longrightarrow \mathrm{Aut}_{\bar{k}}(\bar{D})$$

is then the radical of $G_{\bar{k}}$. Consequently, if $\bar{D}$ came from a homogeneous space D under G, the radical $\bar{R}$ would come from a subgroup R of G. But examples are easily constructed for which $G_{\bar{k}}/\bar{R}$ is adjoint while $\bar{R}$ is not defined over k.

Under these conditions, the functor

$$\mathfrak{B}\colon (\mathrm{Sch}/S)^\circ \longrightarrow \mathrm{Ens}, \qquad \mathfrak{B}(S') = \{\text{Borel subgroups of } G_{S'}\},$$

is not representable by a smooth S-prescheme. From the infinitesimal point of view (III, §3), the failure of the conjugacy theorem is expressed by the fact that, if B is a Borel subgroup of the smooth algebraic group G, the cohomology group

$$H^1(B, \mathfrak{g}/\mathfrak{b})$$

may be nonzero.[6]

We shall see, on the other hand, in a later exposé that when G is semisimple, or more generally reductive, such unpleasant phenomena do not occur. These phenomena, together no doubt with the absence of good existence theorems, explain why Borel subgroups play only a relatively unobtrusive role in the scheme-theoretic study of general group schemes, whereas they dominate the theory of semisimple group schemes in the later exposés.

Proposition 4.8. *Let G be a smooth S-prescheme in groups of finite presentation with connected fibers, and let B be a Borel subgroup of G. Then B is its own normalizer and is a closed subprescheme of G.*

By XII 7.10, it is enough to prove that, over an algebraically closed field k, every element of $G(k)$ that normalizes B belongs to $B(k)$. When G is affine this is a fundamental result of Chevalley *(Bible)*, 9, Theorem 1; the general case reduces immediately to it by the reduction already used in 4.2.

Remarks 4.8.1. Definition 4.5 may be generalized by also introducing the notion of a *parabolic subgroup* of G. This means a subprescheme in groups P of G, smooth and of finite presentation over S, such that for every $s \in S$ the geometric fiber $P_{\bar{s}}$ is a parabolic subgroup of $G_{\bar{s}}$, that is, contains a Borel subgroup of $G_{\bar{s}}$.

Proposition 4.8 extends to a parabolic subgroup P of G, by the same reduction to the known set-theoretic assertion. We note the following consequence (compare Exposé XVI). If P is a parabolic subgroup of G, then G/P is representable by a quasi-projective prescheme of finite presentation over S; here G is assumed to have connected fibers. Moreover, G/P is plainly smooth over S, and its geometric fibers are connected and proper. It follows readily from EGA III, 5.5.1 that

$$D = G/P$$

is proper, hence projective, over S. If its relative dimension is n, it is known that the inverse of the invertible sheaf $\Omega^n_{D/S}$ induces ample sheaves on the geometric fibers of D/S; hence, by EGA III, 4.7.1,

$$\left(\Omega^n_{D/S}\right)^{-1}$$

is ample on D relative to S.

It is readily seen, by reduction to the affine case and to an algebraically closed base field, that if

$$u\colon G \longrightarrow G'$$

[6] Here $\mathfrak{b}$ denotes the Lie algebra of B.

is an epimorphism of smooth algebraic groups, then $u(B) = B'$ is a Borel subgroup of G' for every Borel subgroup B of G. We now consider the case in which this gives a bijective correspondence between the Borel subgroups of G and those of G'.

Proposition 4.9. *Let G and G' be smooth S-preschemes in groups of finite presentation with connected fibers, and let*

$$u\colon G \longrightarrow G'$$

be a faithfully flat, that is, surjective, homomorphism of groups.[7] *Put $N = \ker u$, and suppose that one of the following two conditions holds:*

a) *N is central in G.*

b) *$S = \mathrm{Spec}(k)$ for a field k, and, if $\bar{k}$ is an algebraic closure of k, then*

$$N_{\bar{k}} = \ker(u_{\bar{k}})$$

is contained in the radical of $G_{\bar{k}}$, that is, in its largest smooth, connected, solvable, normal subgroup.

Then the map

$$B' \longmapsto u^{-1}(B')$$

induces a bijection from the set of Borel subgroups of G' onto the set of Borel subgroups of G.

Case b) follows immediately from the correspondence between algebraic subgroups of G' and algebraic subgroups of G containing N, together with the fact that, over an algebraically closed field, the Borel subgroups of G contain its radical. The latter fact follows at once from the argument preceding 4.2.

We prove case a). By XII 7.12, the map

$$H' \longmapsto H = u^{-1}(H')$$

gives a bijection between the subpreschemes in groups H' of G' that are smooth and of finite presentation over S, have connected fibers, and at every $s \in S$ have the same reductive rank and the same nilpotent rank as G', and the subpreschemes in groups H of G having the analogous properties. Borel subgroups of G' and of G have these properties.

It remains to show that, when H' and H correspond, H' is a Borel subgroup of G' if and only if H is a Borel subgroup of G. By definition, this question reduces to the case where S is the spectrum of an algebraically closed field. Since N is central in G, and hence in H, the group H is solvable if and only if H' is solvable. Finally, the correspondence between algebraic subgroups of G' and algebraic subgroups of G containing N shows immediately that H' has the maximality property of Definition 4.1 if and only if H does. This completes the proof.

Corollary 4.10. *With the notation of 4.9, if B' and B are corresponding Borel subgroups of G' and G, then*

$$\mathfrak{b} = \mathrm{Lie}(u)^{-1}(\mathfrak{b}'),$$

where $\mathfrak{g}, \mathfrak{g}', \mathfrak{b}, \mathfrak{b}'$ are the Lie algebras of G, G', B, B', respectively, and

$$\mathrm{Lie}(u)\colon \mathfrak{g} \longrightarrow \mathfrak{g}'$$

[7] The editors ask whether a reference should be added here.

is the homomorphism induced by u.

This follows immediately from the definitions and the identity

$$u^{-1}(B') = B.$$

We can now prove the principal result of this section.

Theorem 4.11. *Let G be a smooth algebraic group over an algebraically closed field k, and let $\mathfrak{g}$ be its Lie algebra. Then $\mathfrak{g}$ is the union of the Lie algebras $\mathfrak{b}$ of the Borel subgroups B of G.*

We may plainly suppose that G is connected. Let R be the radical of G, and put $G' = G/R$. By 4.9(b) and 4.10, it is enough to prove the theorem for G'; thus we may suppose that G is semisimple.

Let Z be the center of G, which is its reductive center, and put $G' = G/Z$. The same argument, now using 4.9(a), reduces the theorem to G'. We may therefore suppose that G is semisimple and adjoint.

Let B be a Borel subgroup of G, let T be a maximal torus of B, hence of G, and let $\mathfrak{b}$ and $\mathfrak{t}$ be their Lie algebras. By 3.18, T is a subgroup of type (C) of G, that is, $\mathfrak{t}$ is a Cartan subalgebra of $\mathfrak{g}$. The union of the conjugates of $\mathfrak{t}$ is consequently dense in $\mathfrak{g}$ (XIII 5.1, (i)⇒(vii)). *A fortiori*, the union of the conjugates of $\mathfrak{b}$ is dense in $\mathfrak{g}$.

Let X be the closed subscheme of

$$G/B \times W(\mathfrak{g})$$

whose k-valued points are the pairs (gB, x) such that

$$x \in \mathrm{Ad}(g)\mathfrak{b}$$

(compare XIII 1). The morphism

$$\psi\colon X \longrightarrow W(\mathfrak{g})$$

induced by the second projection is proper because G/B is proper over k. We have just seen that it is dominant; it is therefore surjective. This proves 4.11.

The only result of this section that we shall use in the remainder of this exposé is the following corollary.

Corollary 4.12. *Let k be an infinite field, let G be a smooth algebraic group over k, and let T be a maximal torus of G. Write $\mathfrak{g}$ and $\mathfrak{t}$ for their Lie algebras. Let*

$$u\colon G \longrightarrow \mathrm{GL}(V)$$

be a linear representation, where V is finite-dimensional over k, and let

$$u'\colon \mathfrak{g} \longrightarrow \mathfrak{gl}(V)$$

be the induced representation of Lie algebras. Then the minimum of the nullity of $u'(x)$, for $x \in \mathfrak{g}$, is attained at an element $x \in \mathfrak{t}$.

We reduce immediately to the case where k is algebraically closed. We may plainly suppose that G is connected, and, after dividing G by $(\ker u)_{\mathrm{red}}$, that G is affine. Using 4.11 and the conjugacy theorem for the maximal tori of G, we reduce to the further case in which G is solvable.

Then G is a semidirect product $T \cdot U$, where U is the unipotent part of G, a smooth connected unipotent group *(Bible)*, 6, Theorem 3. Thus, as a vector space,

$$\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{u}, \qquad \mathfrak{u} = \mathrm{Lie}(U).$$

By the Lie–Kolchin theorem *(Bible)*, 6, Theorem 1, the representation space V has a composition series by stable subspaces V_i, with one-dimensional quotients

$$W_i = V_i/V_{i+1}.$$

For every i there is therefore an induced representation

$$u_i \colon G \longrightarrow \mathrm{GL}(W_i) = \mathbb{G}_m$$

and a corresponding homomorphism of Lie algebras

$$u_i' \colon \mathfrak{g} \longrightarrow k.$$

For every $x \in \mathfrak{g}$, the nullity of $u'(x)$ is the number of indices i for which $u_i'(x) = 0$.

Since U is unipotent, every u_i is trivial on U, and hence every u_i' vanishes on $\mathfrak{u}$. If

$$x = t + v, \qquad t \in \mathfrak{t}, \quad v \in \mathfrak{u},$$

then $u_i'(x) = u_i'(t)$ for every i. Thus $u'(x)$ and $u'(t)$ have the same nullity, and 4.12 follows.

0.5 Relations Between Cartan Subgroups and Cartan Subalgebras

Applying 4.12 to the adjoint representation of G, we obtain:

Theorem 5.1. *Let G be a smooth algebraic group over an infinite field, let T be a maximal torus of G, and let $\mathfrak{g} \supset \mathfrak{t}$ be their Lie algebras. Then $\mathfrak{t}$ contains a regular element of $\mathfrak{g}$.*

Corollary 5.2. *Let G be a smooth S-prescheme in groups of finite presentation, and let $\mathfrak{g}$ be its Lie algebra.*

a) *Conditions* (C_0) *through* (C_2) *of 2.9 for $\mathfrak{g}$ are equivalent. In particular, if the infinitesimal rank of the fibers of $\mathfrak{g}$ at the points of S is locally constant, then, étale locally, $\mathfrak{g}$ admits a Cartan subalgebra and hence, by 3.9*(a)*, G admits a subgroup of type* (C).

b) *Let H be a subprescheme in groups of G, smooth and of finite presentation over S, whose fibers are connected and at every $s \in S$ have the same reductive rank as G; for example, H may be a maximal torus or a Cartan subgroup of G. Let D be a subgroup of type* (C) *of G. Then*

$$H \subset D \quad \Longleftrightarrow \quad \mathfrak{h} \subset \mathfrak{d}.$$

c) *Suppose that condition* (C_0) *holds, that is, the infinitesimal rank of G is locally constant. Let H be a subprescheme in groups of G, smooth and of finite presentation over S, with connected nilpotent fibers, and having at every point the same reductive rank as G; for example, H may be a maximal torus or a Cartan subgroup of G. Then H is contained in a unique subgroup D of type* (C) *of G.*

d) *If G admits a Cartan subgroup fpqc locally, then so does every subgroup D of type* (C) *of G.*

Proof. a) Assume (C_0), and let us prove (C_2), that is, that every quasi-regular section a of $\mathfrak{g}$ is regular. As usual, we reduce first to S affine noetherian and then, since the question is infinitesimal by 2.15(b), to S local Artinian. In this last case (C_0) is automatic. We may moreover suppose that the residue field k of S is infinite.

By 3.7, it is enough to show that $\mathfrak{g}$ admits a Cartan subalgebra. Let T be a maximal torus of G. By 5.1 there is a quasi-regular element t in the Lie algebra $\mathfrak{t}$ of T. We shall show that t is regular.

Consider the linear representation of T on $\mathfrak{g}$ induced by the adjoint representation of G. There is a finite set of characters $(u_i)_{i\in I}$ of T and a direct-sum decomposition

$$\mathfrak{g} = \bigoplus_{i\in I} \mathfrak{g}_i$$

into T-stable submodules such that T acts on $\mathfrak{g}_i$ through u_i (I, §4.7.3). Let

$$u_i' \colon \mathfrak{t} \longrightarrow A$$

be the homomorphism of Lie algebras induced by $u_i \colon T \to \mathbb{G}_m$, where A is the ring of S. Let u_{i0} and u_{i0}' be their reductions under $A \to k$. Put

$$I' = \{i \in I \mid u_{i0}' \neq 0\}, \qquad I'' = I \setminus I'.$$

The regularity of t_0 is expressed by

$$u_{i0}'(t_0) \neq 0 \qquad (i \in I'),$$

and therefore $u_i'(t)$ is invertible for $i \in I'$.

The Cartan subalgebra of $\mathfrak{g}_0$ defined by t_0, that is, the kernel of the semisimple endomorphism $\mathrm{ad}(t_0)$, is

$$\bigoplus_{i\in I''} (\mathfrak{g}_i)_0.$$

Set

$$\mathfrak{d} = \bigoplus_{i\in I''} \mathfrak{g}_i.$$

Then $\mathrm{ad}(t)$ is nilpotent on $\mathfrak{d}$, and is an automorphism of

$$\mathfrak{g}/\mathfrak{d} \simeq \bigoplus_{i\in I'} \mathfrak{g}_i.$$

By 2.6, t is regular.

b) This follows from 3.12(a). By 5.1, H satisfies the required hypothesis that every geometric fiber of $\mathfrak{h}$ contains a regular element of the corresponding fiber of $\mathfrak{g}$.

c) By b), it is enough to show that $\mathfrak{h}$ is contained in a unique Cartan subalgebra of $\mathfrak{g}$. By a), $\mathfrak{g}$ satisfies (C_2). We are therefore reduced to the following lemma.

Lemma 5.3. *Let $\mathfrak{g}$ be a Lie algebra over S, locally free of finite type as a module, and satisfying condition* (C_2) *of 2.9. Let $\mathfrak{h}$ be a Lie subalgebra of $\mathfrak{g}$ such that $\mathfrak{h}$ is locally a direct summand, is locally nilpotent, and, for every $s \in S$, the geometric fiber $\mathfrak{h}_{\bar{s}}$ contains a regular element of $\mathfrak{g}_{\bar{s}}$. Then $\mathfrak{h}$ is contained in a unique Cartan subalgebra of $\mathfrak{g}$.*

In the situation at hand, $\mathfrak{h}$ has these properties: it is locally nilpotent because H has nilpotent fibers, and the condition on regular elements follows from 5.1.

Since 5.3 is fpqc local, it is enough, at a point $s \in S$ with $\kappa(s)$ infinite, to find an open neighborhood U of s on which existence and uniqueness hold after every base change $S' \to S$ factoring through U. Choose a regular element of $\mathfrak{g} \otimes \kappa(s)$ lying in $\mathfrak{h} \otimes \kappa(s)$, and extend it to a section a of $\mathfrak{h}$ over an open neighborhood U of s. Condition (C_2) and 2.10 allow us to shrink U so that a is regular. We may thus suppose $U = S$.

Every Cartan subalgebra of $\mathfrak{g}$ containing $\mathfrak{h}$ contains a, and hence equals

$$\mathfrak{d} = \mathrm{Nil}(a, \mathfrak{g})$$

by 2.6; this proves uniqueness. Conversely, $\mathfrak{h} \subset \mathfrak{d}$ because $\mathfrak{h}$ is locally nilpotent, which proves existence.

d) This is a special case of XII 7.9(d).

Corollary 5.4. *Let G be a smooth connected algebraic group over an algebraically closed field k. Let H be a connected algebraic subgroup such that $\mathfrak{h}$ contains a Cartan subalgebra of $\mathfrak{g}$, or equivalently such that H contains a subgroup of type* (C) *of G. Then the number of conjugates of H containing a regular element of $G(k)$ equals the number of conjugates of $\mathfrak{h}$ containing a regular element of $\mathfrak{g}$.*

Indeed, let g be a regular element of $G(k)$, and let C be the unique Cartan subgroup of G containing g (XIII 2). The conjugates of H that contain g are exactly those that contain C (XIII 2.8(b)).

Similarly, let x be a regular element of $\mathfrak{g}$. If a conjugate $\mathfrak{h}'$ of $\mathfrak{h}$ contains x, then

$$\mathrm{ad}(x)_{\mathfrak{g}/\mathfrak{h}'}$$

is injective by XIII 5.4, and therefore

$$\mathfrak{h}' \supset \mathrm{Nil}(x, \mathfrak{g}) = \mathfrak{d}.$$

Thus the number of conjugates of $\mathfrak{h}$ containing x equals the number containing the Cartan subalgebra $\mathfrak{d}$.

The subalgebra $\mathfrak{d}$ is the Lie algebra of a subgroup D of type (C) of G. We may suppose that $C \subset D$. It remains to show that

$$H \supset C \quad \Longleftrightarrow \quad \mathfrak{h} \supset \mathfrak{d}.$$

By XIII 5.5, the inclusion $\mathfrak{h} \supset \mathfrak{d}$ implies $H \supset D$, and *a fortiori* $H \supset C$. Conversely, by 5.1 the Lie algebra $\mathfrak{t}$ of C contains a regular element x of $\mathfrak{g}$. Hence $H \supset C$ implies $x \in \mathfrak{h}$, and, as observed above, this implies $\mathfrak{h} \supset \mathfrak{d}$. This completes the proof.

Let G be as in 5.2, and suppose that the infinitesimal rank of its fibers is locally constant, that is, condition (C_0) holds. By 5.2(c), there is a morphism of functors on $(\mathrm{Sch}/S)^\circ$,

$$\mathcal{C} \longrightarrow \mathcal{D},$$

where

$$\mathcal{C}(S') = \{\text{Cartan subgroups of } G_{S'}\},$$
$$\mathcal{D}(S') = \{\text{subgroups of type (C) of } G_{S'}\}.$$

By 3.10 and 5.2(a), the functor $\mathcal{D}$ is represented by a smooth quasi-projective prescheme over S. Let D be the universal subgroup of type (C) of $G_{\mathcal{D}}$. One may then define the functor

$$\mathcal{C}_D \colon (\mathrm{Sch}\,/\mathcal{D})^\circ \longrightarrow \mathrm{Ens}$$

for the $\mathcal{D}$-group D, exactly as $\mathcal{C}$ was defined for the S-group G.

Proposition 5.5. *Under the preceding hypotheses, regard $\mathcal{C}$ as a functor over $\mathcal{D}$. Then $\mathcal{C}$ is $\mathcal{D}$-isomorphic to the functor $\mathcal{C}_D$ of Cartan subgroups of D.*

This follows immediately from the next corollary.

Corollary 5.6. *Let G be a smooth S-prescheme in groups of finite presentation, and let D be a subgroup of type* (C) *of G. There is a bijective correspondence between the Cartan subgroups of G contained in D and the Cartan subgroups of D. More precisely, for a subgroup $H \subset D$, H is a Cartan subgroup of G if and only if it is a Cartan subgroup of D.*

This is a special case of XII 7.9(c), taking into account that, over an algebraically closed field, every subgroup of type (C) of G contains a Cartan subgroup of G.

For the next section, the principal result obtained here is 5.2(c) with H a Cartan subgroup of G. It permits the formulation of 5.5 and thus gives a useful dévissage of $\mathcal{C}$.

0.6 Applications to the Structure of Algebraic Groups

Theorem 6.1. *Let G be a smooth algebraic group over a field k. Consider the scheme $\mathcal{T}$ of maximal tori of G, isomorphic to the scheme $\mathcal{C}$ of Cartan subgroups of G. This is a homogeneous space under G^0 and a smooth affine connected algebraic scheme* (XII 7.1(d)). *Then $\mathcal{C}$ is a rational variety: its field of rational functions is a purely transcendental extension of k.*

We first prove the theorem when k is infinite. We may plainly suppose that G is connected, since $\mathcal{T}$, and hence $\mathcal{C}$, is unchanged when G is replaced by G^0. Moreover, by XII 7.6, $\mathcal{C}$ is unchanged when G is divided by a central subgroup. We may therefore first divide by the center of G and suppose that G is affine (XII 6.1), and then divide by its reductive center (XII 4.1 and 4.4) and suppose that the reductive center of G is trivial (XII 4.7(b)).

We proceed by induction on $n = \dim G$, assuming the result for dimensions $n' < n$. If G is nilpotent, then $\mathcal{C}$ consists of a single k-rational point and the assertion is trivial. Otherwise, the Lie algebra of G is not nilpotent (1.3). Its Cartan subalgebras, and therefore the subgroups of type (C) of G, have some dimension $n' < n$. Consider the morphism

$$\mathcal{C} \longrightarrow \mathcal{D}$$

of 5.5. By 3.10, since the infinite-field Lie algebra $\mathfrak{g}$ contains a regular element, $\mathcal{D}$ is a rational variety. Thus its function field K is purely transcendental over k.

Let x be the generic point of $\mathcal{D}$. By 5.5, the fiber of $\mathcal{C}$ at x is the scheme of Cartan subgroups of a smooth connected algebraic group D_x over $K = \kappa(x)$, namely the generic subgroup of type (C) of G. The function field L of $\mathcal{C}$ is therefore the function field of $\mathcal{C}_{D_x}$. Since $\dim D_x = n' < n$, the induction hypothesis makes L purely transcendental over K, and hence, by transitivity, purely transcendental over k.

Suppose now that k is finite. A different argument is required. We may again suppose that G is affine and connected. Since k is perfect, the radical of $G_{\bar{k}}$ descends to a subgroup R of G. Suppose first that $R \neq G$, so that G is not solvable, and let

$$u\colon G \longrightarrow G' = G/R$$

be the canonical morphism. By XII 7.1(e), it induces

$$v\colon \mathcal{C}_G \longrightarrow \mathcal{C}_{G'}, \qquad C \longmapsto u(C).$$

Let x be the generic point of $\mathcal{C}_{G'}$, and put $K = \kappa(x)$. The fiber $v^{-1}(x)$ is the scheme of Cartan subgroups of G_K whose image in G'_K is the generic Cartan subgroup C'_x of G'. By XII 7.9(c), it is also the scheme of Cartan subgroups of

$$H = u_K^{-1}(C'_x).$$

The field K is infinite. The infinite-field case just proved therefore shows that the function field L of $\mathcal{C}_G$, which is also that of $\mathcal{C}_H$, is purely transcendental over K.

It remains to prove that K is purely transcendental over k, and we are thus reduced to the case in which G is semisimple. Dividing by its reductive center, we may further suppose that G is adjoint. Then 3.18 gives $\mathcal{C}_G \simeq \mathcal{D}_G$, and by 3.10 it is enough to show that $\mathfrak{g}$ has a regular point. As noted in 3.20, this is an unpublished result of Chevalley.[8]

It remains only to treat the case in which k is finite and G is connected, affine, and solvable. In fact, the next result holds over an arbitrary field.

Corollary 6.2. *Let G be a smooth solvable algebraic group over a field k. Then the variety $\mathcal{C}$ of Cartan subgroups of G is isomorphic to an affine space* $\operatorname{Spec} k[t_1, \ldots, t_N]$.

We may suppose that G is connected and affine. Let G_∞ be the terminal group in the descending central series

$$G_0 = G, \qquad G_{i+1} = [G, G_i].$$

Thus G_∞ is the smallest invariant algebraic subgroup of G for which G/G_∞ is nilpotent. Let C be a Cartan subgroup of G, which exists by 1.1. Its image in G/G_∞ is a Cartan subgroup and hence is all of G/G_∞. Consequently the morphism

$$G_\infty \longrightarrow \mathcal{C}, \qquad g \longmapsto \operatorname{Ad}(g)C$$

is an epimorphism and identifies

$$\mathcal{C} \simeq G_\infty/(N \cap G_\infty),$$

where N is the normalizer of C in G. In fact $N = C$, as recalled in 4.4, but that is immaterial here.

The group $U = G_\infty$ is smooth, connected, and unipotent: over $\bar{k}$ it lies in the unipotent part of G, by the known structure of smooth affine solvable groups *Bible* 6, Theorem 3. If k is perfect, as in the finite-field case needed for 6.1, it follows easily that U is k-unipotent: it has a composition series by algebraic subgroups U_i with $U_i/U_{i+1} \simeq \mathbb{G}_a$.

Rosenlicht proved that a group of the form G_∞ above is k-unipotent without any restriction on k (M. Rosenlicht, *Questions of rationality for solvable algebraic groups over non perfect fields*, Annali di Matematica, 1963, pp. 97–120, Theorem 4, Corollary 2). We admit this substantially more delicate result and apply the following lemma.

[8] See the Appendix by J.-P. Serre.

Lemma 6.3. *Let U be a smooth connected algebraic group over a field k, and let $X = U/V$ be a homogeneous space under U having a k-rational point. If U is k-unipotent, then, as a k-scheme, X is isomorphic to an affine space* $\operatorname{Spec} k[t_1, \ldots, t_N]$.

Choose a composition series

$$U = U_0 \supset U_1 \supset \cdots \supset U_n = (e)$$

by smooth connected normal subgroups of U, with $U_i/U_{i+1} \simeq \mathbb{G}_a$. The groups

$$K_i = U_i V$$

are algebraic subgroups of U. They need not be smooth or connected when V is not, but this does not matter, and K_{i+1} is normal in K_i. The canonical epimorphism

$$U_i/U_{i+1} \longrightarrow K_i/K_{i+1}$$

shows that K_i/K_{i+1} is either the unit group or isomorphic to $\mathbb{G}_a/H_i$, where H_i is a finite subgroup of $\mathbb{G}_a$. Rosenlicht's Theorem 2 in the cited paper gives

$$K_i/K_{i+1} \simeq \mathbb{G}_a;$$

this last assertion is immediate when k is perfect.

Put $X_i = U/K_i$. We prove inductively that every X_i is an affine space. If K_i/K_{i+1} is trivial, then $X_i = X_{i+1}$. Otherwise X_{i+1} is a principal $\mathbb{G}_a$-bundle over X_i. Since X_i is affine, the bundle is trivial, so

$$X_{i+1} \simeq X_i \times \mathbb{G}_a.$$

The induction proves the lemma. It proves 6.2 and thereby completes the proof of 6.1.

Corollary 6.4. *Let G be a smooth algebraic group over an infinite field k. Then the set of k-rational points of $\mathcal{C}$, in the notation of 6.1, is Zariski dense. The union of the Cartan subgroups of G is dense in G.*

The first assertion holds for every rational variety over an infinite field and is, for us, the most important arithmetic consequence of the rationality result. The second follows from the first and the density theorem XIII 2.1.

Corollary 6.5. *Let G be a smooth connected algebraic group over k. Then the variety Z of regular semisimple points of G* (XIII 3.5) *is unirational. In particular, if k is infinite, its k-rational points are dense in Z.*

Indeed, Z is an open subscheme of a torus over $\mathcal{C}$. Its function field L is therefore the function field of a torus over the function field K of $\mathcal{C}$, namely the generic maximal torus of G. Thus L is unirational over K by XIII 3.4. Since 6.1 makes K purely transcendental over k, L is unirational over k.

Corollary 6.6. *Let G be a smooth connected algebraic group over k, and let H be the subgroup generated by the subvariety Z of regular semisimple points. Equivalently* (XII 8.2), *H is the smallest invariant algebraic subgroup of G for which G/H has reductive rank zero; over $\bar{k}$, G/H is an extension of an abelian variety by a smooth connected unipotent group. Then H is unirational.*

In particular, suppose $G = H$; equivalently (XII 8.4), *suppose G is affine and there is no nontrivial homomorphism $G_{\bar{k}} \to \mathbb{G}_a$. Then G is unirational. If, in addition, k is infinite, $G(k)$ is dense in G.*

This follows immediately from 6.5. Indeed, if Z_i are smooth connected unirational k-preschemes and $u_i\colon Z_i \to G$ are morphisms, then the algebraic subgroup of G generated by the u_i is unirational ($\mathrm{VI_B}$ 7.1).

An interesting special case of either 6.5 or 6.6 is the following.

Corollary 6.7. *Let G be a smooth connected affine algebraic group of unipotent rank zero. Then G is unirational.*

The conclusion of 6.4 may be sharpened as follows.

Corollary 6.8. *Let G be a smooth connected algebraic group over an infinite field k, and let C be a Cartan subgroup of G. Then the union of the conjugates of C by regular semisimple elements of $G(k)$ is dense in G.*

This follows at once from 6.4 and XIII 3.6, which says that the morphism

$$\varphi\colon Z \times C \longrightarrow G, \qquad \varphi(t,c) = \mathrm{Ad}(t)c,$$

is dominant. The same result also implies the next corollary, without any assumption that k is infinite.

Corollary 6.9. *Let G be a smooth connected algebraic group over k, and let H be a smooth connected algebraic subgroup having the same reductive rank and the same nilpotent rank as G. Equivalently, over $\bar{k}$, the group $H_{\bar{k}}$ contains a Cartan subgroup of $G_{\bar{k}}$. If H is unirational, so is G. If $H(k)$ is dense in H, then $G(k)$ is dense in G.*

The morphism

$$\varphi\colon Z \times H \longrightarrow G, \qquad \varphi(t,h) = \mathrm{Ad}(t)h,$$

is dominant. By 6.5, Z is unirational, and by hypothesis so is H, hence so are $Z \times H$ and G. The density assertion is proved in the same way.

We recover the following well-known result, due to Chevalley in characteristic zero and to Rosenlicht in characteristic $p > 0$.

Corollary 6.10. *Let G be a smooth connected affine algebraic group over a perfect field k. Then G is unirational. If k is also infinite, $G(k)$ is dense in G.*

By 1.1, G has a Cartan subgroup C. By 6.9, it is enough to prove that C is unirational. Since k is perfect, Galois descent from the algebraically closed case *Bible* 6, Theorem 2 gives

$$C = T \times C_u,$$

where T is the maximal torus of C and C_u is smooth, connected, and unipotent. The torus T is unirational by XIII 3.4. Moreover, C_u is k-unipotent because k is perfect, so 6.3 applies to C_u.

Remarks 6.11. (a) Rosenlicht gave examples of twisted forms of $\mathbb{G}_a$ over a nonperfect field having only finitely many rational points; *a fortiori*, they are not unirational. Chevalley, on the other hand, gave an example of a torus over a field of characteristic zero that is not rational. By contrast, Chevalley's theory of semisimple groups shows that, over an algebraically closed field, every smooth connected affine algebraic group is rational. In any case, the question of unirationality arises only for affine algebraic groups: by Chevalley's structure theorem, a unirational algebraic group is necessarily affine.

(b) With the notation of 6.6, it is tempting to seek a criterion for the unirationality of G in terms of G/H, which is unipotent when G is affine. Clearly G/H must be unirational;

is that condition also sufficient? An example of Rosenlicht shows that a smooth connected unipotent algebraic group U may be rational without being k-unipotent.

(c) Over a finite field k, it would be interesting to study questions of "density" such as the following one, raised by Rosenlicht: if G is a smooth connected algebraic group over k, is G generated by its Cartan subgroups?[9]

Editors' note. The editors did not identify this result in Steinberg's *Collected Papers*; here is a proof based on the Bruhat decomposition.

Let G/k be semisimple over the finite field k, and let $G^\sharp$ be the subgroup generated by its k-subtori. The question is stable under central isogeny and restriction of scalars, so, as in Lemma 1 of the Appendix below, it is enough to treat the geometrically simple case. The group G is quasi-split by Lang's theorem and admits a Killing pair (T, B). By definition $T \subset G^\sharp$, hence T normalizes $G^\sharp$. The big cell

$$R_u(B^-)\, T\, R_u(B)$$

shows that it suffices to prove $R_u(B) \subset G^\sharp$. Let S be the maximal split k-torus of T. For the relative root system $\Phi(G, S)$, choose a basis Δ_k, and denote by $U(\alpha)$ the unipotent subgroup associated with α (A. Borel, *Linear Algebraic Groups*, second edition, 1991, Proposition 21.9). Since $R_u(B)$ is generated by the $U(\alpha)$, $\alpha \in \Delta_k$, it is enough to show $U(\alpha) \subset G^\sharp$.

The classification supplies a quasi-split semisimple subgroup G_α of type A_1, ${}^2A_1$, ${}^3A_1$, or ${}^2A_2$, with

$$U(\alpha) \subset G_\alpha \subset G.$$

Thus it is enough to consider $G = \mathrm{PGL}_2$ or $G = \mathrm{SU}_3(K)$, where K/k is the unique quadratic extension.

For PGL_2, since $G^\sharp$ contains the standard split torus T, the possibilities up to $G(k)$-conjugacy are

$$G^\sharp = T, \qquad G^\sharp = B, \qquad G^\sharp = \mathrm{PGL}_2\,.$$

The first is excluded because $G^\sharp$ contains the k-torus $R_{K/k}(\mathbb{G}_m)/\mathbb{G}_m$. The preceding discussion also shows that $G^\sharp = B$ forces $G^\sharp = \mathrm{PGL}_2$. Hence $G^\sharp = \mathrm{PGL}_2$.

For $G = \mathrm{SU}_3(K)$, one has $\Delta_k = \{\alpha\}$, and the possibilities up to conjugacy are

$$\begin{aligned} G^\sharp = T, \quad B, \quad U(2\alpha) \rtimes T, \\ \langle U(2\alpha), U(-2\alpha), T\rangle = \mathrm{SL}_2 \cdot T, \quad \text{or } G. \end{aligned}$$

The case B is excluded as for PGL_2. The case $\mathrm{SL}_2 \cdot T$ is excluded because $G^\sharp$ contains the k-torus

$$R^1_{K/k}\Big(R^1_{K_3/K}(\mathbb{G}_m)\Big)\,,$$

where K_3/K is the degree-three extension, and the isogeny class of this torus is irreducible. The same torus excludes T and $U(2\alpha) \rtimes T$. Hence $G^\sharp = G$.

For Rosenlicht's question one may reduce to the affine case by dividing by the center. In the semisimple case, an affirmative answer would also follow from a strengthening of Chevalley's existence result for regular points mentioned in 3.20: one would need a regular element of $\mathfrak{g}$ outside $\mathfrak{h} = \mathrm{Lie}(H)$, where $H \neq G$ is a prescribed smooth algebraic subgroup of an adjoint semisimple group G over the finite field k.

[9] This question was subsequently answered in the affirmative by Steinberg.

0.7 Appendix: Existence of Regular Elements over Finite Fields

by J.-P. Serre

Throughout the Appendix, k denotes a finite field, $\bar{k}$ its algebraic closure, and $\mathcal{G} = \mathrm{Gal}(\bar{k}/k)$. If $q = \mathrm{Card}(k)$, then $\mathcal{G}$ is topologically generated by the Frobenius element

$$F\colon x \longmapsto x^q.$$

We shall prove the following theorem.[10]

Theorem. *Let G be an adjoint semisimple group defined over k, and let $\mathfrak{g}$ be its Lie algebra. Then the k-Lie algebra $\mathfrak{g}(k)$ contains a regular element.*

Remarks. (1) Recall that "adjoint" means that the center of G, as a subgroup scheme, is trivial. In view of the Chevalley seminar, this also means that, for a maximal torus T of G, the character group $X(T)$ of $T_{\bar{k}}$ is generated by the set R of roots. In particular, the rank of $\mathfrak{g}$ equals $\dim T$, the rank of G.

(2) The editor does not know whether the adjoint hypothesis is indispensable.

Lemma 1. *It is enough to prove the theorem when G is geometrically simple.*

Here geometrically simple means that $G_{\bar{k}}$ has no smooth normal subgroup scheme other than $G_{\bar{k}}$ and (e); equivalently, the associated root system is irreducible.

We may first suppose that G is indecomposable over k. Then $G_{\bar{k}}$ is a product of geometrically simple components S, permuted transitively by $\mathcal{G}$. If $\mathcal{H} \subset \mathcal{G}$ fixes one component S, and K is its fixed field, then S is defined over K, and the standard restriction-of-scalars argument gives

$$G = R_{K/k}(S).$$

Similarly,

$$\mathfrak{g} = R_{K/k}(\mathfrak{s}),$$

where $\mathfrak{s}$ is the Lie algebra of S. If the theorem holds for S, there is an element

$$x \in \mathfrak{s}(K) = \mathfrak{g}(k)$$

regular in $\mathfrak{s}$, and one checks immediately that it is regular in $\mathfrak{g}$. This proves the lemma.

Henceforth assume that G is geometrically simple, and choose a maximal torus T of G. Let X be the character group of $T_{\bar{k}}$, let R be its root system, W its Weyl group, and E the group of automorphisms of X preserving R. Then W is normal in E.

For another maximal torus T', write X', R', W', E' for the corresponding objects. If $y \in G(\bar{k})$ satisfies

$$yT_{\bar{k}}y^{-1} = T'_{\bar{k}},$$

then $\mathrm{int}(y)$ identifies (X', R', W', E') with (X, R, W, E). Replacing y changes this identification by an element of W.

Frobenius acts on X' while preserving R', and thus defines an element $f_{T'} \in E'$. Put $f = f_T$. After the above identification $E' \simeq E$, the element $f_{T'}$ becomes an element $f' \in E$, well defined up to W-conjugacy. We now compare f' with f.

[10] The theorem is due to Chevalley. The editor wishes to express his gratitude to American Express which, by misplacing a trunk of Chevalley's manuscripts, obliged him to reconstruct the proof.

Lemma 2. *One has $f' \equiv f \pmod{W}$. Conversely, every $f' \in E$ satisfying this condition arises from a maximal torus T' of G.*

Put $\bar{T} = T_{\bar{k}}$ and $\bar{T}' = T'_{\bar{k}}$, and choose $y \in G(\bar{k})$ such that

$$y\bar{T}y^{-1} = \bar{T}'.$$

Since $y^q\bar{T}y^{-q} = \bar{T}'$, the element

$$n = y^{-1}y^q$$

belongs to the normalizer $N(T)(\bar{k})$. The action of f' on the points of $\bar{T}$ is

$$\begin{aligned} f'(t) &= y^{-1}(yty^{-1})^q y \\ &= y^{-1}y^q\, t^q\, y^{-q}y = nt^q n^{-1}. \end{aligned}$$

If $w \in W$ is represented by n, then f' and $f \circ w$ have the same action on $\bar{T}(\bar{k})$, hence on its characters. Thus $f' = f \circ w$, and $f' \equiv f \pmod{W}$.

Conversely, represent a given $w \in W$ by $n \in N(T)(\bar{k})$. Lang's theorem gives

$$n = y^{-1}y^q$$

for some $y \in G(\bar{k})$. Then $y\bar{T}y^{-1}$ is defined over k, and the preceding calculation shows that its corresponding element is $f \circ w$.

Lemma 3. *Let X, R, W, E be as above, with R irreducible, and let $\varphi \in E/W$. There exist a representative $f \in E$ of φ and roots $\theta_1, \ldots, \theta_n$ such that:*

1. *$(\theta_1, \ldots, \theta_n)$ is a basis of X;*
2. *R is the union of the orbits of the θ_i under the powers of f: every $a \in R$ has the form $a = f^m\theta_i$ for suitable m and i.*

The proof will be given below. We first need a lemma of linear algebra.

Lemma 4. *Let V be a vector space over k, and let $(\theta_1, \ldots, \theta_n)$ be a basis of the dual of $V \otimes_k \bar{k}$. Then there is an $x \in V$ such that $\theta_i(x) \neq 0$ for every i.*

Let V^* be the dual of V, and let W_i be the $\bar{k}$-subspace of $V^* \otimes_k \bar{k}$ generated by the Galois conjugates of θ_i. It descends to a k-subspace, again denoted W_i. The natural map

$$W_1 \otimes \cdots \otimes W_n \longrightarrow \bigwedge^n V^*$$

is nonzero: after extension to $\bar{k}$, it contains $\theta_1 \wedge \cdots \wedge \theta_n \neq 0$. Hence V^* has a basis $u_1, \ldots, u_n$ with $u_i \in W_i$. Choose $x \in V$ with $u_i(x) \neq 0$ for all i, for example with $u_i(x) = 1$. If $\theta_i(x) = 0$, every Galois conjugate of θ_i vanishes at x, and so does u_i, a contradiction.

End of the proof of the theorem. By Lemmas 2 and 3, choose a maximal torus T whose element f has the properties of Lemma 3. Let Y be the dual of X. The Lie algebra of T satisfies

$$\mathfrak{t}(\bar{k}) \simeq Y \otimes_{\mathbb{Z}} \bar{k},$$

compatibly with the Galois action. Put $V = \mathfrak{t}(k)$. An element $x \in V$ is regular precisely when it is annihilated by no root $\alpha \in R$, viewed as a linear form in $V^* \otimes_k \bar{k}$.

Lemma 4 supplies $x \in V$ annihilated by none of the θ_i. Every root is a Galois conjugate of one of the θ_i, by property (2) of Lemma 3. Hence no root annihilates x, and x is regular. This proves the theorem.

Proof of Lemma 3. The proof uses Coxeter transformations. Let $a_1, \ldots, a_n$ be a simple system of roots of R, and let r_i be the reflection corresponding to a_i. Put

$$c = r_1 \cdots r_n.$$

Then $c \in W$. Although c depends on the simple system and on its ordering, its conjugacy class does not. It is called the Coxeter element. We shall use, without proof, the fact that 1 is not an eigenvalue of c.

Lemma 5. Put

$$\theta_i = r_n \cdots r_{i+1}(a_i).$$

Then:

(a) the θ_i form a basis of the group X generated by the roots;

(b) $\theta_i > 0$ and $c(\theta_i) < 0$ for every i;

(c) every root $a \in R$ such that $a > 0$ and $c(a) < 0$ is one of the θ_i;

(d) R is the union of the orbits of the θ_i under the powers of c.

Indeed,

$$\theta_i = a_i + \sum_{j>i} m_{ij} a_j, \qquad m_{ij} \in \mathbb{Z},$$

which proves (a). Assertions (b) and (c) follow from the observation that r_i preserves the sign of every root other than $\pm a_i$, and reverses the sign of $\pm a_i$.

For (d), an orbit of c cannot consist entirely of positive roots, nor entirely of negative roots. Otherwise the sum of the roots in that orbit would give a nonzero element of X fixed by c, contrary to the fact that 1 is not an eigenvalue. Hence every orbit contains a root $a > 0$ for which $c(a) < 0$, and (c) applies.

Remark. The proof was recalled only for the reader's convenience; one could instead refer to the standard texts on Coxeter transformations, for example Koszul, Séminaire Bourbaki 1959/1960, Exposé 191. They also show that all orbits of c have the same number h of elements and each contains exactly one θ_i. In particular,

$$h = \frac{\mathrm{Card}(R)}{n}.$$

We return to Lemma 3 and distinguish three cases.

(1) Suppose that $\varphi \in E/W$ is the identity. We must choose $f \in W$; take $f = c$. Lemma 5 shows that this works.

(2) Suppose that R has type A_n, where $n \geq 2$ is even, and that φ is the unique nontrivial element of E/W. Then $-1 \notin W$, and we take

$$f = -c.$$

The Coxeter element c has order $h = n + 1$, which is odd. If $a \in R$, Lemma 5 gives $a = c^m \theta_i$ for suitable m, i. Adding h to m if necessary, we may suppose that m is even. Then

$$a = (-c)^m \theta_i = f^m \theta_i.$$

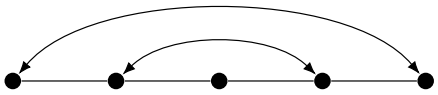
Thus the orbits of the θ_i under f fill R.

(3) Suppose that $\varphi \in E/W$ is nontrivial and that R has one of the following types:

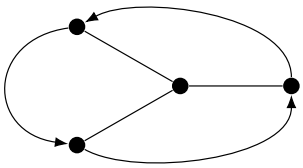
$$A_n \ (n \geq 3 \text{ odd}), \qquad D_4, \qquad D_n \ (n \geq 5), \qquad E_6.$$

These, together with the even A_n case treated separately above, are exactly the cases in which E/W is nontrivial. The following diagrams record the corresponding Dynkin-diagram automorphisms.

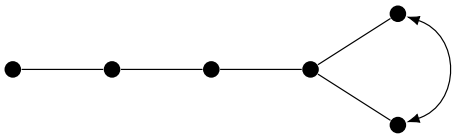
$A_n,\ n$ odd ≥ 3



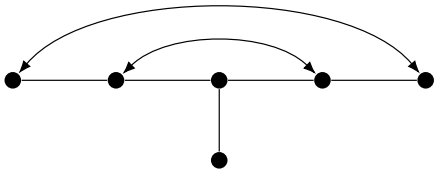
D_4



$D_n,\ n \geq 5$



E_6.



Let S be a simple system of roots, not yet ordered. The group E is the semidirect product of W with the group Ψ of permutations of S preserving the Cartan matrix, or equivalently the Dynkin diagram. Thus $E/W \simeq \Psi$, and φ corresponds to some $\psi \in \Psi$.

Inspection of the diagrams shows that each ψ-orbit in S consists of pairwise orthogonal roots. This fails for A_n with n even, which is why that case was separated. If σ is such an orbit, the reflections r_a, $a \in \sigma$, commute; write

$$\rho_\sigma = \prod_{a \in \sigma} r_a.$$

Plainly ρ_σ commutes with ψ.

Choose a total order on S for which every ψ-orbit is a segment, and write $S = \{a_1, \ldots, a_n\}$. Let $\theta_1, \ldots, \theta_n$ and $c = r_1 \cdots r_n$ be defined as above. The element c is a product of the ρ_σ, with the orbits in some order, so it commutes with ψ. Put

$$f = c\psi.$$

The automorphism ψ permutes the θ_i. Indeed, $\psi(\theta_i) > 0$, and, since c commutes with ψ,

$$c(\psi(\theta_i)) = \psi(c(\theta_i)) < 0.$$

Lemma 5(c) therefore gives $\psi(\theta_i) = \theta_j$ for some j.

Finally, if $a \in R$, Lemma 5 gives $a = c^m\theta_i$ for some m, i. Hence

$$a = f^m(\psi^{-m}\theta_i) = f^m\theta_j$$

for a suitable j. Thus f and the θ_i satisfy both conditions of Lemma 3, completing its proof.

Remark. Except in case (2), one can prove that every orbit of f has exactly

$$h = \frac{\mathrm{Card}(R)}{n}$$

elements and contains exactly one θ_i. In case (2), some of the θ_i are superfluous.

Exposé XV
Complements on Sub-tori of a Group Prescheme
Application to Smooth Groups

by M. Raynaud[1]

0. Introduction

This Exposé supplements and partly recasts Exposés XI and XII; knowledge of Exposés XIII and XIV is not indispensable. Continuing the effort begun in XII, we shall work with S-group preschemes that are not necessarily affine and not necessarily separated over S.

Sections 1, 2, 3, and 4 are devoted to the study of sub-tori of a group prescheme. We obtain infinitesimal lifting theorems (§2) and a global lifting theorem (§4), in which points of finite order (§1) play an essential role.

Sections 5, 6, and 7 are independent of the preceding sections. The consideration of infinitesimal neighbourhoods leads to the representability of the functor of smooth subgroups equal to their connected normalizer (§5). In §§6 and 7 we turn more particularly to Cartan subgroups.

Finally, in §8 we give a necessary and sufficient condition for the functor of sub-tori of a smooth group, or the functor of maximal tori, to be representable.

1. Lifting finite subgroups

1.1. Finite, smooth, central subgroups of multiplicative type

Proposition 1.1.— *Let S be an affine scheme, let S_0 be a closed subscheme of S defined by a square-zero ideal, let G be an S-group prescheme, and let H_0 be a subgroup scheme of $G_0 = G \times_S S_0$ that is smooth and of finite type over S_0, and of multiplicative type. A subgroup scheme of G, of multiplicative type, lifting H_0 exists if and only if there exists a subscheme H' of G, flat over S, lifting H_0.*

The necessity of the condition is clear; let us prove its sufficiency. The group H_0 of multiplicative type is quasi-isotrivial (X 4.5). By Exposé X 2.1, there exist an S-group H

[1]This Exposé and the two following ones (Exposés XVI and XVII) do not correspond to oral lectures delivered at the seminar. With some additional material, they develop the substance of concise manuscript notes written by A. Grothendieck in 1964 for the present seminar.

of multiplicative type and an S_0-isomorphism of groups

$$u_0 : H \times_S S_0 \xrightarrow{\sim} H_0.$$

Since H' is flat over S and $H' \times_S S_0$ is of finite presentation over S_0 (Exposé IX 2.1(b)), H' is of finite presentation over S. Its fibres are smooth, so H' is smooth over S (EGA IV 17.5.1). Since S is affine, u_0 therefore lifts to an S-morphism of preschemes

$$u : H \longrightarrow H'.$$

It then follows from Exposé III 2.1 and Exposé IX 3.1 that the composite

$$v_0 : H \times_S S_0 \xrightarrow{\sim} H_0 \longrightarrow G_0$$

also lifts to an S-homomorphism

$$v : H \longrightarrow G.$$

Since v_0 is an immersion, so is v. The image of H under v is therefore a subgroup scheme of G, of multiplicative type, lifting H_0.

Proposition 1.2.— *Let S be a prescheme, let S_0 be a subprescheme of S defined by a locally nilpotent sheaf of ideals, let G be an S-group prescheme flat and of finite presentation over S, and let H_0 be a subgroup scheme of $G_0 = G \times_S S_0$ that is smooth, finite over S_0, of multiplicative type, and central. Then there exists a unique subgroup scheme H of G, of multiplicative type, lifting H_0. Moreover, H is central. (See XVII, Appendix III, 1.)*

Proposition 1.2 bis.— *Let S, G, S_0, G_0 be as above, let H be an S-group scheme of multiplicative type, smooth and finite over S, and let $u_0 : H_0 = H \times_S S_0 \to G_0$ be a central homomorphism. Then u_0 lifts uniquely to a homomorphism $u : H \to G$. Moreover, u is central.*

The existence of the lifting u in Proposition 1.2 bis follows readily from Proposition 1.2 by considering the graph of u_0. The lifting u is unique and central by Exposé IX 3.4 and Exposé IX 5.1.

Proof of Proposition 1.2. The uniqueness of H, and the fact that H is central, follow from Exposé IX 5.6(b) and Exposé IX 3.4 bis. In view of uniqueness, to prove existence we may assume that S is affine and that S_0 is defined by a square-zero ideal; by Proposition 1.1 it is enough to find a subscheme of G, flat over S, lifting H_0.

Since H_0 is smooth and finite over S_0, after possibly restricting S we may assume that there is an integer $n > 0$, invertible on S, such that $H_0 = {}_nH_0$. Consider the n-th power morphism on G:

$$u : G \longrightarrow G, \qquad x \longmapsto x^n.$$

We continue to denote by ${}_nG$ the "kernel of u", that is, the inverse image under u of the identity section of G. Notice that u is not, in general, a group homomorphism. We first admit the following lemma.

Lemma 1.3.— *Let k be a field, let G be a group scheme locally of finite type over k, let n be an integer prime to the characteristic of k, and let u be the n-th power morphism on G. Then u is étale at every point x of G that belongs to the centre of G.*

Since G is flat and of finite presentation over S, the preceding lemma and EGA IV 17.8.2 show that, if $x \in G$ lies above $s \in S$ and belongs to the centre of G_s, then u is étale at x. If in addition $x \in {}_nG$, then ${}_nG$ is étale over S at x. By hypothesis, H_0

is central and is contained in ${}_nG_0$; it is therefore contained in the largest open subset V of ${}_nG$ that is étale over S. Since H_0 and $V \times_S S_0 = V_0$ are étale over S_0, H_0 is an open subscheme of V_0 (EGA IV 17.8.7 and 17.9.1). The open subprescheme of V having the same underlying space as H_0 is consequently a subscheme of G, flat over S, lifting H_0.

It remains to prove Lemma 1.3. The largest open subset of G on which u is étale is invariant under extension of the base field (EGA IV 17.8.2), so we may reduce to the case in which x is k-rational. Let t_x denote translation by x, a k-automorphism of G. Since x belongs to the centre of G, the diagram

$$\begin{array}{ccc} G & \xrightarrow{u} & G \\ {\scriptstyle t_x}\downarrow & & \downarrow{\scriptstyle t_x^n} \\ G & \xrightarrow{u} & G. \end{array}$$

is commutative. It is therefore enough to prove that u is étale at the identity; this was established in VII_A 8.4.

1.2. Global lifting of finite groups

Lemma 1.4.— *Let A be a local ring, separated and complete for the topology defined by its maximal ideal $\mathfrak{m}$, let*

$$S = \mathrm{Spec}(A), \qquad S_n = \mathrm{Spec}(A/\mathfrak{m}^n).$$

Then, for every prescheme X (respectively, for every S-prescheme X), the canonical map

$$(*) \qquad \mathrm{Hom}(S, X) \longrightarrow \varprojlim_n \mathrm{Hom}(S_n, X)$$

(respectively,

$$(**) \qquad \Gamma(X/S) \longrightarrow \varprojlim_n \Gamma(X_n/S_n), \qquad X_n = X \times_S S_n)$$

is bijective.

Statement $(**)$ is an easy consequence of $(*)$. Let us prove $(*)$. Let

$$u_n : S_n \longrightarrow X \qquad (n \in \mathbb{N})$$

be a coherent system of morphisms. The image y of the closed point of S_n is independent of n, and u_n factors through $\mathrm{Spec}\,\mathcal{O}_y$. On passing to the inverse limit, the morphisms u_n define a ring homomorphism

$$\widetilde{u} : \mathcal{O}_y \longrightarrow \varprojlim_n (A/\mathfrak{m}^n) = A.$$

This proves that $(*)$ is surjective; it is injective as soon as A is separated for the $\mathfrak{m}$-adic topology.

Corollary 1.5.— *Let A be a complete noetherian local ring, let $\mathfrak{m}$ be its maximal ideal, let*

$$S = \mathrm{Spec}(A), \qquad S_n = \mathrm{Spec}(A/\mathfrak{m}^n),$$

let X be a finite scheme over S, and let Y be an S-prescheme. Then the canonical map

$$\mathrm{Hom}_S(X,Y) \longrightarrow \varprojlim_n \mathrm{Hom}_{S_n}(X_n,Y_n)$$

(where $X_n = X \times_S S_n$, and similarly for Y_n) is bijective.

Indeed, it follows from EGA II 6.2.5 that X is a finite disjoint sum of local S-schemes finite over S. We are thus reduced to the case in which X itself is the spectrum of a complete noetherian local ring. But

$$\mathrm{Hom}_S(X,Y) = \Gamma(Z/X), \qquad Z = Y \times_S X,$$

and the preceding lemma applies.

Proposition 1.6.— *Let A, S, S_n be as above, and let G and M be two S-group preschemes, with M finite over S. Then:*

a) *The canonical map*

$$\mathrm{Hom}_{S\text{-gr}}(M,G) \longrightarrow \varprojlim_n \mathrm{Hom}_{S_n\text{-gr}}(M_n,G_n)$$

is bijective.

b) *If M is of multiplicative type and G is smooth over S, the canonical map*

$$\varphi : \mathrm{Hom}_{S\text{-gr}}(M,G) \longrightarrow \mathrm{Hom}_{S_0\text{-gr}}(M_0,G_0)$$

is surjective. Moreover, if $\varphi(u) = \varphi(u') = u_0$, then u and u' are conjugate by an element of $G(S)$ that reduces to the identity element of $G(S_0)$.

c) *If M is of multiplicative type and smooth over S, if G is flat and of finite type over S, and if $u_0 : M_0 \to G_0$ is a central homomorphism, then u_0 lifts uniquely to a homomorphism*

$$u : M \longrightarrow G.$$

Moreover, u is central if G has connected fibres.

Proof. *a)* This follows from 1.5, from the fact that $M \times_S M$ is finite over S, and from the characterization of group morphisms as the morphisms for which the familiar diagram

$$\begin{array}{ccc} M \times_S M & \xrightarrow{u\times u} & G \times_S G \\ \downarrow & & \downarrow \\ M & \xrightarrow[u]{} & G \end{array}$$

is commutative.

b) By Exposé IX 3.6, one can construct a coherent system of homomorphisms $u_n : M_n \to G_n$ lifting a homomorphism $u_0 : M_0 \to G_0$. In view of part a), this proves the first assertion of b).

If u and u' are two liftings of u_0, then u_n and u'_n are conjugate by an element $g_n \in G(S_n)$ lifting the identity element of $G(S_0)$ (Exposé IX 3.6). The same reference also implies that the g_n may be chosen coherently; by 1.4 they therefore arise from a section $g \in G(S)$. The morphisms u and $\mathrm{Int}(g)u'$ then agree modulo $\mathfrak{m}^n$ for every n, and hence agree by 1.5.

c) The existence and uniqueness of u follow from part a) and 1.2 bis. If G has connected fibres, u is central by Exposé IX 5.6(a).

2. Infinitesimal lifting of sub-tori

2.1. Statement of the theorem

We shall give an infinitesimal lifting theorem for sub-tori of a group prescheme that does not require smoothness hypotheses (in contrast with Exposé IX 3.6 bis) and that also answers a very natural question:[2] is it enough to be able to lift "sufficiently many" points of finite order of a sub-torus T_0 in order to ensure that T_0 itself can be lifted (infinitesimally, of course)?

Theorem 2.1.— *Let S be a noetherian affine scheme, let S_0 be a closed subscheme of S defined by a square-zero ideal J, let G be an S-group prescheme of finite type, let $G_0 = G \times_S S_0$, let T_0 be a sub-torus of G_0, and let $q > 0$ be an integer invertible on S. Suppose that, for every integer n equal to a power of q, there exists a subscheme M_n of G, flat over S, such that*

$$M_n \times_S S_0 = {}_nT_0.$$

Then there exists a sub-torus T of G such that $T \times_S S_0 = T_0$.

Theorem 2.1 will be useful to us through the following two corollaries.

Corollary 2.2.— *Let S be a locally noetherian prescheme, let S_0 be a closed subprescheme of S defined by a locally nilpotent sheaf of ideals, let G be an S-group prescheme of finite type, let T_0 be a sub-torus of $G_0 = G \times_S S_0$, and let $q > 0$ be an integer invertible on S. As n ranges over the powers of q, let (M_n) be a coherent system of S-subgroup schemes of G, of multiplicative type, lifting the ${}_nT_0$. (The system (M_n) is said to be coherent if*

$$M_m = {}_m(M_n)$$

whenever m divides n.) Then there exists a unique sub-torus T of G such that

$$T \times_S S_0 = T_0 \qquad \text{and} \qquad {}_nT = M_n$$

for every n.

Corollary 2.3.— *Let G be an S-group prescheme, flat and of finite presentation over S, let S_0 be a closed subprescheme of S defined by a locally nilpotent sheaf of ideals of finite type, and let T_0 be a central torus of $G_0 = G \times_S S_0$. Then there exists a unique sub-torus T of G lifting T_0. Moreover, T is central.*

Remark 2.4.— *We leave it to the reader to formulate the analogues of statements 2.1, 2.2, and 2.3 in which, instead of lifting a sub-torus of G_0, one is given a torus T over S and asks to lift a morphism*

$$u_0 : T_0 \longrightarrow G_0.$$

One reduces to the preceding cases by considering the graph of u_0.

Let us show how Corollaries 2.2 and 2.3 follow from Theorem 2.1.

Proof of Corollary 2.2. The uniqueness of T follows from Exposé IX 4.8(b) and Exposé IX 4.10. To prove existence, we may therefore reduce to the case in which S is affine, hence noetherian, and S_0 is defined by a square-zero ideal.

[2] Editor's note: The idea of approximating a torus by its finite subgroups occurs in Grothendieck's proof of the connectedness of centralizers of tori; see §4.6 of *BIBLE*.

Lemma 2.5.— *Let G be an S-group prescheme of finite presentation, and let H be a subgroup scheme of G, of multiplicative type and smooth over S. Then* $\mathrm{Centr}_G(H)$ *is representable by an S-group subprescheme of G, of finite presentation.*

When G is separated over S, the lemma follows from Exposé VIII 6.5(e), without any smoothness hypothesis on H. In the present case, observe that the assertion is local for the fpqc topology. We may therefore assume that H is diagonalizable, hence of the form $D_S(M)$. We may also assume that S is affine and then, by EGA IV 8, noetherian. Since H is smooth and of finite type over S, the order q of the torsion subgroup of M is invertible on S (Exposé VIII 2.1(e)). It is then immediate (cf. Exposé IX 4.10) that the subgroups ${}_nH$, with n ranging over the powers of q, are schematically dense in H (Exposé IX 4.1). But ${}_nH$ is a completely split covering of S, that is, it is isomorphic to a finite disjoint sum of copies of S. Consequently

$$\mathrm{Centr}_G({}_nH) = Z_n$$

is representable as the intersection of the centralizers in G of the sections of ${}_nH$ over S. It remains to apply the following lemma.

Lemma 2.5 bis.— *Let S be a noetherian prescheme, let G be an S-group prescheme of finite type, let H be a subgroup of G of multiplicative type, and let (H_i) be an increasing filtered family of subgroups of G of multiplicative type. Suppose that*

$$Z_i = \mathrm{Centr}_G(H_i)$$

is representable by a group subprescheme of G. Then the family (Z_i) is stationary. If, in addition, the H_i are schematically dense in H, then

$$Z_i = \mathrm{Centr}_G(H)$$

for all sufficiently large i.

To see that the family (Z_i) is stationary, it is enough to prove that the family of underlying sets $\mathrm{ens}(Z_i)$ is stationary. Indeed, the stationary value will then be a closed subset of an open subset U of G. After replacing G by U, we are reduced to studying a decreasing filtered family of closed subpreschemes of a noetherian prescheme. An elementary constructibility argument reduces us to the case in which S is integral. We then have to show that $\mathrm{ens}(Z_i)$ is stationary over some nonempty open subset of S. The generic fibre of G is separated (Exposé $\mathrm{VI_A}$ 0.3); after restricting S, we may therefore assume that G is separated over S (EGA IV 8). Then Z_i is closed in G (Exposé VIII 6.5(e)).

To prove the last assertion of the lemma, let Z denote the stationary value of the family (Z_i). It is clear that $\mathrm{Centr}_G(H)$ is a subfunctor of Z; we show that Z centralizes H. Let E be the subprescheme of $H \times_S Z$ that is the kernel of the pair of morphisms

$$\begin{aligned} H \times_S Z &\rightrightarrows G, \\ (h, c) &\longmapsto c, \\ (h, c) &\longmapsto hch^{-1}. \end{aligned}$$

The prescheme E contains $H_i \times_S Z$ for every i. The H_i are flat over S, so EGA IV 11.10.9 shows that, for every point s of S, the $(H_i)_s$ are schematically dense in H_s, and $H_i \times_S Z$ is schematically dense in $H \times_S Z$. Since G_s is separated, E_s is closed in $(H \times_S Z)_s$, and is therefore equal to it. Thus E is closed in $H \times_S Z$, and hence equals $H \times_S Z$. This says that Z centralizes H.

Returning to the proof of 2.2, Lemma 2.5 shows that

$$Z_n = \mathrm{Centr}_G(M_n)$$

is representable, and Lemma 2.5 bis shows that the decreasing family of subpreschemes (Z_n) is stationary; let Z be its stationary value. The group Z contains T_0 and all the M_n. After replacing G by Z, we may therefore suppose that the M_n are central.

The hypotheses of Theorem 2.1 are now satisfied, so there exists a sub-torus T of G lifting T_0. The groups ${}_nT$ and M_n are two liftings of ${}_nT_0$; they are therefore conjugate (Exposé IX 3.2 bis), and consequently coincide because M_n is central. This torus T has the required properties.

Proof of Corollary 2.3. The uniqueness of T follows from Exposé IX 5.1 bis, and its centrality follows from Exposé IX 5.6(b). By the usual procedure, this observation reduces us first to the case in which S is affine (and hence S_0 is defined by a nilpotent ideal of finite type), and then to the noetherian case. After restricting S if necessary, we may suppose that there exists an integer q invertible on S. Corollary 2.3 then follows from 2.2 and 1.2.

Remark 2.6.— *Corollary 2.3 remains true if the torus T_0 is replaced by a smooth central subgroup of multiplicative type of G_0.*

2.2. Proof of Theorem 2.1

a) Reduction to the case $T_0 = \mathbb{G}_{m,S_0}$.

By 1.1, we may assume that M_n is a subgroup of multiplicative type. Using Exposé IX 3.2 bis, we may suppose that the family (M_n) is coherent (2.2). The centralizer Z_n of M_n in G is representable (2.5), and the filtered family (Z_n) is stationary (2.5 bis). After replacing G by Z_n for sufficiently large n, we may therefore suppose that T_0 and the M_n are central. The uniqueness of a lifting of T_0 is then guaranteed by Exposé IX 5.1 bis.

Proceeding as in the proof of 1.1, we may suppose that there exist an S-torus T and an S_0-isomorphism

$$u_0 : T \times_S S_0 \xrightarrow{\sim} T_0.$$

Lifting u_0 is equivalent to lifting T_0. By uniqueness, it is enough to prove the existence of a lifting of u_0 after an affine faithfully flat extension $S' \to S$ of finite type (fpqc descent). This allows us to suppose that

$$T = \mathbb{G}_{m,S}^r$$

(Exposé X 4.5). If the restriction of u_0 to each factor $\mathbb{G}_m$ lifts to an S-morphism—necessarily central—then these liftings immediately give a lifting of u_0. In short, we may suppose that $T_0 = \mathbb{G}_{m,S_0}$.

b) Definition of the obstruction to the existence of a lifting of T_0.

By 1.1, to prove Theorem 2.1 it is enough to find a subscheme of G, flat over S, lifting T_0. We shall see that the obstruction to the existence of such a lifting can be defined as an element of a certain Ext^1 group of sheaves of modules.

Let U be an open subset of G in which T_0 is closed, and again denote by U (respectively, U_0) the open subscheme of G (respectively, G_0) having this open subset as its underlying space. The sheaf $\mathcal{O}_{T_0}$, regarded as a sheaf on U, is therefore a quotient of $\mathcal{O}_{U_0}$. Let

$$h : \mathcal{O}_{U_0} \longrightarrow \mathcal{O}_{T_0}$$

be the canonical epimorphism.

Lemma 2.7.— *The canonical map*

$$h' = \mathrm{id}_J \otimes h : J \otimes_{S_0} \mathcal{O}_{U_0} \longrightarrow J \otimes_{S_0} \mathcal{O}_{T_0}$$

factors, necessarily uniquely, as $i \circ j_U$*, where* j_U *is the canonical epimorphism*

$$J \otimes_{S_0} \mathcal{O}_{U_0} \longrightarrow J\mathcal{O}_U \simeq J\mathcal{O}_{U_0}.$$

We must show that $h'(K) = 0$, where K is the kernel of j_U. For every integer n equal to a power of q, there is an epimorphism

$$h_n : \mathcal{O}_{T_0} \longrightarrow \mathcal{O}_{{}_nT_0}.$$

Since ${}_nT_0$ lifts to a scheme M_n flat over S, the canonical morphism

$$j_n : J \otimes_{S_0} \mathcal{O}_{{}_nT_0} \xrightarrow{\sim} J\mathcal{O}_{M_n}$$

is an isomorphism. The commutative diagram

$$\begin{array}{ccccccc}
K & \longrightarrow & J \otimes_{S_0} \mathcal{O}_{U_0} & \xrightarrow{j_U} & J\mathcal{O}_U & \hookrightarrow & \mathcal{O}_U \\
 & & \downarrow{\scriptstyle h'} & \swarrow{\scriptstyle i} & & & \\
 & & J \otimes_{S_0} \mathcal{O}_{T_0} & & & & \\
 & & \downarrow{\scriptstyle h'_n} & & & & \\
 & & J \otimes_{S_0} \mathcal{O}_{{}_nT_0} & \xrightarrow[j_n]{\sim} & J\mathcal{O}_{M_n} & \hookrightarrow & \mathcal{O}_{M_n}
\end{array}$$

shows that $h'(K)$ is contained in $\ker h'_n$ for every n. It is therefore contained in $\bigcap_n \ker h'_n$, and it remains to prove that this intersection is zero. Now

$$\mathcal{O}_{T_0} = \mathcal{O}_{S_0}[\mathbb{Z}], \qquad \mathcal{O}_{{}_nT_0} = \mathcal{O}_{S_0}[\mathbb{Z}/n\mathbb{Z}].$$

Let

$$a = \sum_{m \in \mathbb{Z}} a_m \otimes m \in J \otimes_{S_0} \mathcal{O}_{T_0}.$$

The a_m are sections of J, almost all zero. Choose n large enough that the indices m for which $a_m \neq 0$ have distinct images in $\mathbb{Z}/n\mathbb{Z}$. If $a \in \ker h'_n$, then necessarily $a = 0$. Thus $\bigcap_n \ker h'_n = 0$, proving 2.7.

Let K_0 be the kernel of h. Consider the diagram

$$\begin{array}{ccccccccc}
 & & & & & & 0 & & \\
 & & & & & & \downarrow & & \\
 & & J\mathcal{O}_U & & & & K_0 & & \\
 & & \downarrow{\scriptstyle \sim} & & & & \downarrow & & \\
0 & \longrightarrow & J\mathcal{O}_{U_0} & \longrightarrow & \mathcal{O}_U & \longrightarrow & \mathcal{O}_{U_0} & \longrightarrow & 0 \\
 & & \downarrow{\scriptstyle i} & & & & \downarrow{\scriptstyle h} & & \\
 & & J \otimes_{S_0} \mathcal{O}_{T_0} & & & & \mathcal{O}_{T_0} & & \\
 & & & & & & \downarrow & & \\
 & & & & & & 0. & &
\end{array}$$

The sheaf $\mathcal{O}_U$ defines an element

$$\Phi \in \mathrm{Ext}^1_{\mathcal{O}_U}(\mathcal{O}_{U_0}, J\mathcal{O}_{U_0}).$$

Let Ψ be the element of

$$\mathrm{Ext}^1_{\mathcal{O}_U}(K_0, J \otimes_{S_0} \mathcal{O}_{T_0})$$

obtained from Φ, by the bifunctoriality of Ext^1, through the morphisms

$$K_0 \longrightarrow \mathcal{O}_{U_0}, \qquad i : J\mathcal{O}_{U_0} \longrightarrow J \otimes_{S_0} \mathcal{O}_{T_0}.$$

It follows from Exposé III 4.1 and the infinitesimal criterion of flatness (cf. Exposé III 4.3) that a subscheme of U, flat over S and lifting T_0, exists if and only if $\Psi = 0$.

Since T_0 is affine, Exposé III 4.5 and 4.6 show that it is enough to construct, locally on U, a subscheme flat over S lifting T_0. It therefore suffices to show that the image of Ψ in the sheaf

$$\mathscr{E} = \mathcal{E}xt^1_{\mathcal{O}_U}(K_0, J \otimes_{S_0} \mathcal{O}_{T_0})$$

is zero. We again denote this element of $\Gamma(U, \mathscr{E})$ by Ψ.

c) Reduction to the case in which S is local artinian with algebraically closed residue field.

Since K_0 and $J \otimes_{S_0} \mathcal{O}_{T_0}$ are coherent sheaves, so is $\mathscr{E}$; moreover, $\mathscr{E}$ is supported on T_0, because the same is true of $J \otimes_{S_0} \mathcal{O}_{T_0}$. To show that the section Ψ of $\mathscr{E}$ is zero, it is enough to show that, for every point u of T_0, its image in the fibre of $\mathscr{E}$ at u is zero. Formation of the $\mathcal{E}xt^i$ of coherent sheaves commutes with flat extensions of the base,[3] so we are reduced to proving the existence of a lifting of

$$T_0 \cap \mathrm{Spec}\, \mathcal{O}_u$$

flat over S. Let s be the image of u in S. We may replace S by $\mathrm{Spec}\, \mathcal{O}_s$ and G by $G \times_S \mathrm{Spec}\, \mathcal{O}_s$.

After another faithfully flat extension if necessary, we may suppose that $\mathcal{O}_s$ has an algebraically closed residue field (EGA 0_{III}, 10.3.1). Let $\mathfrak{m}$ be the maximal ideal of $\mathcal{O}_s$, and set

$$S_n = \mathrm{Spec}(\mathcal{O}_s/\mathfrak{m}^n).$$

Suppose that, for every $n > 0$, the obstruction to lifting

$$T_0 \times_S S_n = (T_0)_n$$

to a subscheme of $G_n = G \times_S S_n$, flat over S_n, has been shown to vanish, and let T_n be the unique flat lifting of $(T_0)_n$ over S_n that is a sub-torus of G_n. If $n > n'$, it is clear that

$$T_n \times_{S_n} S_{n'} = T_{n'}.$$

If u is a point of T_0 lying over s, the lemma below, applied to the coherent system of liftings

$$T_n \cap \mathrm{Spec}\, \mathcal{O}_u$$

of $(T_0)_n \cap \mathrm{Spec}\, \mathcal{O}_u$, shows that $T_0 \cap \mathrm{Spec}\, \mathcal{O}_u$ indeed has a lifting flat over $\mathcal{O}_s$. We are therefore reduced to proving that $\Psi = 0$ when $S = S_n$ is the spectrum of an artinian local ring with algebraically closed residue field, and to proving the following lemma.

[3] Editor's note: cf. EGA 0_{III}, 12.3.5.

Lemma 2.8.— *Let $A \to B$ be a local homomorphism of noetherian local rings, let $\mathfrak{m}$ be the maximal ideal of A, let J be a square-zero ideal of A, let M be a finite-type B-module, and set*

$$A_0 = A/J, \qquad B_0 = B/JB, \qquad M_0 = M/JM.$$

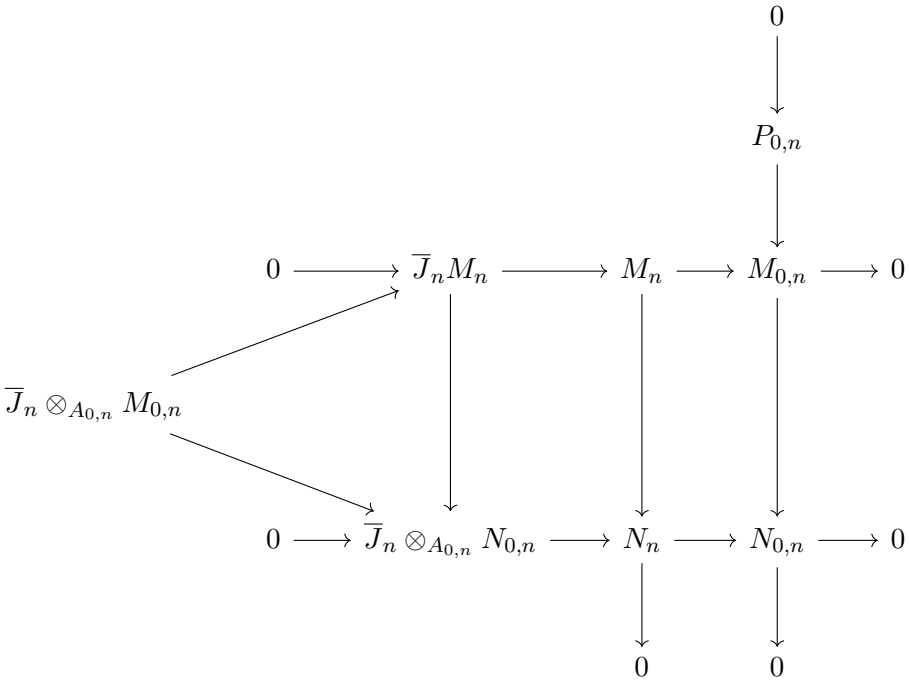
Let N_0 be a quotient B_0-module of M_0, flat over A_0. For every $n > 0$, let $A_n, A_{0,n}$, and so forth denote the objects obtained by the base extension

$$A \longrightarrow A/\mathfrak{m}^n = A_n,$$

and let $\overline{J}_n$ be the image of J in A_n. For every $n > 0$, let N_n be a quotient B_n-module of M_n, flat over A_n, lifting $N_{0,n}$, and suppose that, for $n \geq n'$, $N_{n'}$ is obtained from N_n by the base extension $A_n \to A_{n'}$. Then there exists a quotient B-module N of M, flat over A, lifting N_0.

Proof of 2.8. Let P_0 be the kernel of the epimorphism $M_0 \to N_0$. For every $n > 0$, there is a commutative diagram with exact horizontal rows:

$(*_n)$



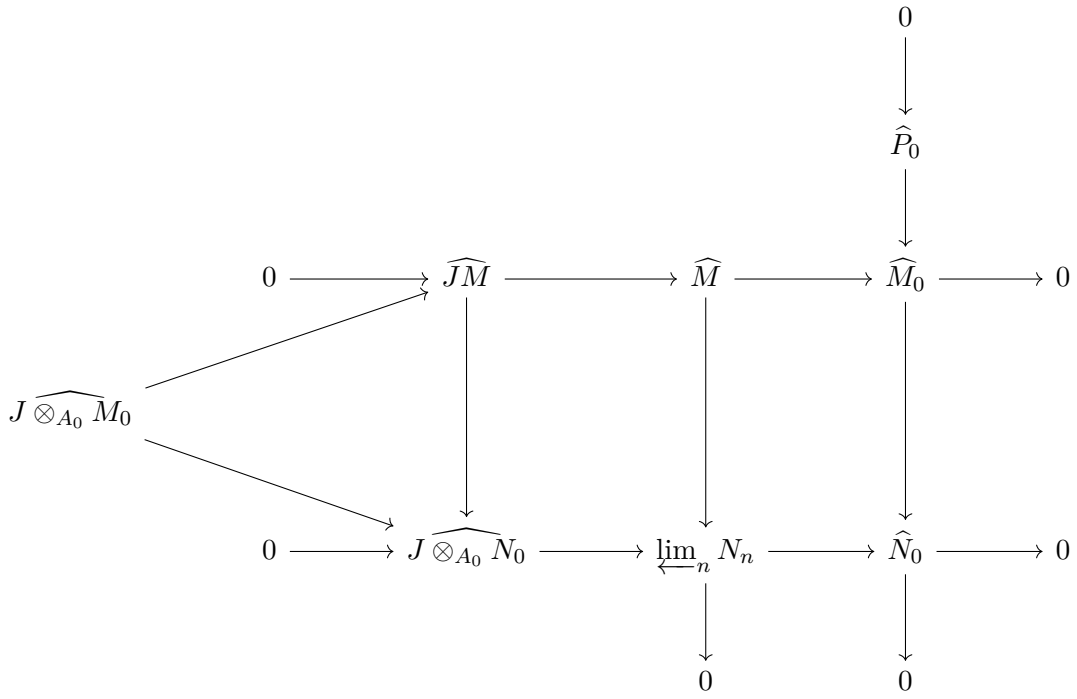
Moreover, by hypothesis, the diagram $(*)_{n+1}$ reduces modulo $\mathfrak{m}^n$ to $(*)_n$.

The Artin–Rees lemma (Bourbaki, *Algèbre commutative*, Chapter III, §3, Corollary 1) shows that the filtrations on JM, $J \otimes_{A_0} M_0$, and $J \otimes_{A_0} N_0$, defined by the kernels of the respective morphisms

$$JM \longrightarrow \overline{J}_n M_n,$$
$$J \otimes_{A_0} M_0 \longrightarrow \overline{J}_n \otimes_{A_{0,n}} M_{0,n},$$
$$J \otimes_{A_0} N_0 \longrightarrow \overline{J}_n \otimes_{A_{0,n}} N_{0,n},$$

are $\mathfrak{m}B$-good. Passing to the inverse limit in the diagrams $(*)_n$, and writing $\widehat{Q}$ for the separated completion of a B-module Q for the $\mathfrak{m}B$-adic topology, we obtain a commutative

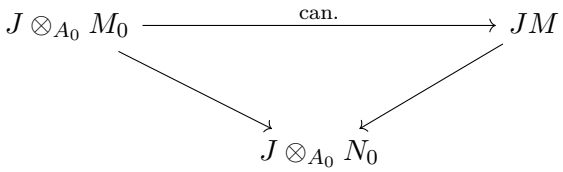
diagram in which the two horizontal rows remain exact:
$(\widehat{*})$



Now $(B, \mathfrak{m}B)$ is a Zariski ring and $J \otimes_{A_0} N_0$ is of finite type over B, hence separated for the $\mathfrak{m}B$-adic topology. The diagram $(\widehat{*})$ then shows that the morphism

$$J \otimes_{A_0} M_0 \longrightarrow J \otimes_{A_0} N_0$$

induced by the epimorphism $M_0 \to N_0$ factors through JM:



Under these conditions, Exposé III 4.1 and 4.3 show that a quotient B-module N of M, flat over A and lifting N_0, exists if and only if a certain element

$$g \in E = \mathrm{Ext}^1_B(P_0, J \otimes_{A_0} N_0)$$

vanishes. More precisely, the exact sequence

$$0 \longrightarrow JM \longrightarrow M \longrightarrow M_0 \longrightarrow 0$$

defines an element $f \in F$, where

$$F = \mathrm{Ext}^1_B(M_0, JM),$$

and g is the image of f under the natural morphism $F \to E$ arising by bifunctoriality from

$$P_0 \longrightarrow M_0, \qquad JM \longrightarrow J \otimes_{A_0} N_0.$$

The diagram $(\hat{*})$ and Exposé III 4.1 show that the image of g in

$$\widehat{E} \simeq \mathrm{Ext}^1_{\widehat{B}}(\widehat{P}_0, J\widehat{\otimes}_{A_0} N_0)$$

is zero. But E is of finite type over B, and hence separated for the $\mathfrak{m}B$-adic topology. Consequently $g = 0$, which completes the proof of 2.8.

d) Study of $\mathscr{E}$.

We now suppose that S is the spectrum of an artinian local ring A with algebraically closed residue field k. Let A_0 be the ring of S_0, and let $\mathfrak{m}_0$ be the maximal ideal of A_0. Since S_0 is artinian, T_0 is closed in G (Exposé $\mathrm{VI_B}$ 1.4.2). We may therefore take $U = G$, so that

$$\mathscr{E} = \mathcal{E}xt^1_{\mathcal{O}_G}(K_0, J \otimes_{S_0} \mathcal{O}_{T_0}).$$

Let B_0 be the ring of the affine S_0-scheme $T_0 = \mathbb{G}_{m,S_0}$, and let $\overline{B}_0$ be the ring of its special fibre

$$T_0 \times_{S_0} \mathrm{Spec}(k) = \mathbb{G}_{m,k}.$$

The sheaf $\mathscr{E}$ is a coherent $\mathcal{O}_{T_0}$-module, hence is defined by a finite-type B_0-module, which we denote by E.

Consider the graded module associated with E and the $\mathfrak{m}_0 B_0$-adic filtration:

$$E_r = \mathfrak{m}_0^r E/\mathfrak{m}_0^{r+1}E.$$

Each E_r is a finite-type $\overline{B}_0$-module, and $E_r = 0$ for all sufficiently large r, since S_0 is artinian.

Let g be a section of G over S whose restriction to S_0 is a section g_0 of T_0. Left translation by g defines an "automorphism of the situation" from the point of view of the obstruction problem. In particular, g induces an S_0-automorphism of the sheaf $\mathscr{E}$ that fixes the obstruction Ψ. More precisely, g defines a semilinear automorphism of the B_0-module E, relative to the A_0-automorphism of B_0 defined by translation by g_0 in T_0. Reducing modulo $\mathfrak{m}_0^{r+1}$, g therefore defines a semilinear automorphism of E_r, relative to the k-automorphism of $\overline{B}_0$ defined by translation by

$$g_0 \times_{S_0} \mathrm{Spec}(k)$$

in $T_0 \times_{S_0} \mathrm{Spec}(k)$.

Lemma 2.9.— *For every integer $r \geq 0$, E_r is a locally free $\overline{B}_0$-module.*

Let x be a point of T_0, let $\kappa(x)$ be its residue field, and let

$$(E_r)_x = E_r \otimes_{\overline{B}_0} \kappa(x)$$

be the "fibre" of E_r at x. Denote by $\ell(x)$ the rank of $(E_r)_x$ over $\kappa(x)$, and by ℓ the maximum of $\ell(x)$ as x ranges over the points of T_0. Let L be the largest closed subscheme of

$$\mathrm{Spec}\,\overline{B}_0 = \mathbb{G}_{m,k}$$

over which E_r is locally free of rank ℓ (TDTE IV, Lemma 3.6). Let $\beta \in L(k)$, which exists because L is of finite type over the algebraically closed field k, and let $\alpha \in \mathbb{G}_{m,k}(k)$ be a point whose order is a power n of q. The point α is k-rational. Since, by hypothesis, ${}_nT_0$ lifts to a subscheme M_n étale over S, there is a section a of G over S lifting α and whose restriction to S_0 is a section of T_0.

The preceding observations show that the fibres of E_r at the points β and $\alpha\beta$ of $\mathbb{G}_{m,k}(k)$ are k-isomorphic. The points whose order is a power of q are dense in $\mathbb{G}_{m,k}$, as are their translates by β. Since L is closed in $\mathbb{G}_{m,k}$ and $\mathbb{G}_{m,k}$ is reduced, $L = \mathbb{G}_{m,k}$, and E_r is locally free of rank ℓ over $\overline{B}_0$.

e) Completion of the proof of Theorem 2.1.

Let $K_0(n)$ be the sheaf of ideals of $\mathcal{O}_{G_0}$ defining the closed subscheme ${}_nT_0$. The sheaf ${K_0}^4$ is therefore a subsheaf of $K_0(n)$. For brevity, set

$$R = J \otimes_{S_0} \mathcal{O}_{T_0}, \qquad R(n) = J \otimes_{S_0} \mathcal{O}_{{}_nT_0}.$$

The sheaf $R(n)$ is a quotient of R, and we have the diagram

$$\begin{array}{ccccccccc} & & & & K_0 & & & & \\ & & & & \downarrow & & & & \\ & & & & K_0(n) & & & & \\ & & & & \downarrow & & & & \\ 0 & \longrightarrow & J\mathcal{O}_G & \longrightarrow & \mathcal{O}_G & \longrightarrow & \mathcal{O}_{G_0} & \longrightarrow & 0 \\ & & \downarrow & & & & & & \\ & & R & & & & & & \\ & & \downarrow & & & & & & \\ & & R(n) & & & & & & \end{array}$$

Using the bifunctoriality of $\mathrm{Ext}^1_{\mathcal{O}_G}$, we obtain the commutative diagram

$$\begin{array}{ccccc} \mathcal{E}xt^1_{\mathcal{O}_G}(\mathcal{O}_{G_0}, J\mathcal{O}_G) & & & & \\ & \searrow & & & \\ & & \mathcal{E}xt^1_{\mathcal{O}_G}(K_0(n), R) & \longrightarrow & \mathcal{E}xt^1_{\mathcal{O}_G}(K_0, R) = \mathscr{E} \\ & & \downarrow & & \downarrow \\ & & \mathcal{E}xt^1_{\mathcal{O}_G}(K_0(n), R(n)) & \longrightarrow & \mathcal{E}xt^1_{\mathcal{O}_G}(K_0, R(n)). \end{array}$$

Again let Φ denote the element of $\mathrm{Ext}^1_{\mathcal{O}_G}(\mathcal{O}_{G_0}, J\mathcal{O}_G)$ defined by the exact sequence

$$0 \longrightarrow J\mathcal{O}_G \longrightarrow \mathcal{O}_G \longrightarrow \mathcal{O}_{G_0} \longrightarrow 0,$$

so that Ψ is the image of Φ in $\mathscr{E}$. Since ${}_nT_0$ lifts to a subscheme M_n of G, flat over S, the image of Φ in

$$\mathrm{Ext}^1_{\mathcal{O}_G}(K_0(n), R(n))$$

is zero (Exposé III 4.1). A fortiori, the image of Φ in $\mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R(n))$, which is also the image of Ψ, is zero.

[4] Editor's note: Introduced after Lemma 2.7.

Lemma 2.10.— *For every integer n, the canonical morphism*

$$\mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R) \otimes_{B_0} \mathcal{O}_{{}_nT_0} \longrightarrow \mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R(n))$$

is injective.

Indeed, the affine scheme $T_0 = \mathbb{G}_{m,S_0}$ has ring

$$B_0 = A_0[T, T^{-1}].$$

The subscheme ${}_nT_0$ is defined by the vanishing of

$$h(n) = T^n - 1.$$

This section is regular (EGA 0_{IV}, 15.2.2) and remains regular after every base change $S'_0 \to S_0$. Hence there is an exact sequence of sheaves

$$0 \longrightarrow \mathcal{O}_{T_0} \xrightarrow{h(n)} \mathcal{O}_{T_0} \longrightarrow \mathcal{O}_{{}_nT_0} \longrightarrow 0.$$

Since ${}_nT_0$ is flat over S, tensoring over $\mathcal{O}_{S_0}$ with J gives the exact sequence

$$0 \longrightarrow R \xrightarrow{h(n)} R \longrightarrow R(n) \longrightarrow 0,$$

and then the exact sequence of Ext groups

$$\cdots \longrightarrow \mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R) \xrightarrow{h(n)} \mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R) \longrightarrow \mathrm{Ext}^1_{\mathcal{O}_G}(K_0, R(n)),$$

which proves the lemma.

The foregoing shows that, for every integer n equal to a power of q, the image of Ψ in $\mathscr{E}/h(n)\mathscr{E}$ is zero. To prove that $\Psi = 0$, it is enough to show that

$$\Psi \in \mathfrak{m}_0^r \mathscr{E} \quad \Longrightarrow \quad \Psi \in \mathfrak{m}_0^{r+1} \mathscr{E}.$$

Let $\overline{\Psi}$ be the image of Ψ in E_r. There is an element $\Psi(n) \in \mathscr{E}$ such that

$$\Psi = \Psi(n)h(n) \qquad (n \text{ a power of } q).$$

We observed that the image $\overline{h(n)}$ of $h(n)$ in $\overline{B}_0$ is again $\overline{B}_0$-regular. Since E_s is locally free over $\overline{B}_0$ for every s (2.9), multiplication by $\overline{h(n)}$ on E_s is injective. It follows immediately that $\Psi(n) \in \mathfrak{m}_0^r \mathscr{E}$. Let $\overline{\Psi(n)}$ be its image in E_r; then

$$\overline{\Psi} = \overline{h(n)}\,\overline{\Psi(n)} \qquad (n \text{ a power of } q).$$

Thus the set F of points of $\mathbb{G}_{m,k}$ at which $\overline{\Psi}$ vanishes contains the dense set of points whose order is a power of q. Moreover, F is closed because E_r is locally free over $\overline{B}_0$, and $\mathbb{G}_{m,k}$ is reduced. Therefore $\overline{\Psi} = 0$.

This completes the proof of Theorem 2.1.

3. Characterization of a sub-torus by its underlying set

3.1. Statement of the theorem

Notation.—If X is a prescheme, $\mathrm{ens}(X)$ denotes the underlying set of X. If X and S' are two S-preschemes,

$$X_{S'} = X \times_S S', \qquad u : X_{S'} \longrightarrow X$$

is the canonical morphism, and if E is a subset of $\mathrm{ens}(X)$, we denote by $E_{S'}$ (or $E \times_S S'$) the subset $u^{-1}(E)$ of $\mathrm{ens}(X_{S'})$.

Theorem 3.1.— *Let S be a locally noetherian prescheme, let G be an S-group prescheme of finite type, let $q > 0$ be an integer invertible on S, and let E be a subset of* $\mathrm{ens}(G)$. *Consider the following assertions about E:*

(i) *The set E is the underlying set of a sub-torus T of G.*

(ii) a) *For every point s of S, there is a sub-torus T_s of G_s such that*

$$E \cap \mathrm{ens}(G_s) = E_s$$

is the underlying set of T_s.

b) *As n ranges over the powers of q, there is a coherent family (cf. 2.2) M_n of subgroup schemes of G, of multiplicative type, such that for every point s of S,*

$$(M_n)_s = {}_nT_s.$$

(iii) a) *As in* (ii) a).

b) *The set E is locally closed in* $\mathrm{ens}(G)$, *and the dimension of the fibers of E over S is locally constant.*

(iv) a) *As in* (ii) a).

b) *For every S-scheme S' that is the spectrum of a complete discrete valuation ring with algebraically closed residue field, $E_{S'}$ is the underlying set of a sub-torus of $G_{S'}$.*

Then the following implications hold:

A) (i) $\Longleftrightarrow$ (ii) $\Longrightarrow$ (iii) $\Longrightarrow$ (iv).

B) *If G is separated over S, then* (iii) $\Longleftrightarrow$ (iv), *and moreover E is closed.*

C) *Conditions* (i), (ii), *and* (iii) *(and also* (iv) *if G is separated over S) are equivalent in the following two cases:*

First case: a) *The prescheme S is reduced, or G is flat over S; and*
b) *for every point s of S, T_s is a central torus of G_s.*

Second case: *S is normal.*

Moreover, in the two cases above, the torus T with underlying set E is unique.

Remarks 3.2.— a) *When S is reduced, there is no need in* (ii) *to assume that the family M_n is coherent, since this condition follows from the other hypotheses. Indeed, if m divides n, the subgroups ${}_mM_n$ and M_m are étale over S, hence reduced, and have the same underlying space; they therefore coincide.*

b) *If S is no longer assumed normal, it is in general no longer true that* (iii) $\Rightarrow$ (i), *even when S is reduced and geometrically unibranch and G is a smooth group scheme over S. Indeed, consider the Borel subgroup of* $\mathrm{SL}_{2,S}$ *consisting of matrices of the form*

$$\begin{pmatrix} t & u \\ 0 & t^{-1} \end{pmatrix},$$

where S is the affine curve over a field k with ring

$$k[x,y]/(y^2 - x^3).$$

Define E as follows. Above the cusp of S, where $x = y = 0$, take the diagonal torus $u = 0$. Above the complementary open subset $x \neq 0$, take the torus obtained from the diagonal torus by conjugation by

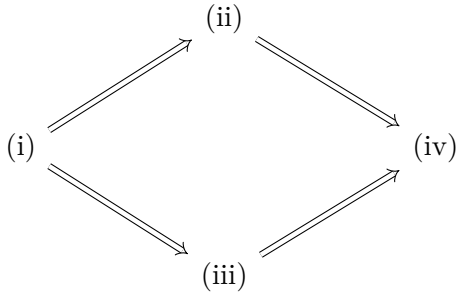
$$\begin{pmatrix} 1 & y/x \\ 0 & 1 \end{pmatrix}.$$

The resulting set E satisfies (iii) a)*; it is also closed in G, and the reduced subscheme having E as its underlying set has equations*

$$\begin{cases} xu + y(t - t^{-1}) = 0, \\ u^2 - x(t - t^{-1})^2 = 0. \end{cases}$$

It is therefore not a sub-torus of G, since its fiber above the cusp is not reduced.

Plan of the proof of 3.1. In a first part we shall establish the following "easy" implications:



and

$$\text{(iv)} \Longrightarrow [\,\text{(iii) and } E \text{ is closed}\,] \quad \text{if } G \text{ is separated over } S.$$

The more delicate implications will be proved in three stages:

I) Reduction of (iii) $\Rightarrow$ (i), under the hypotheses of C), first case, to the case in which S is normal.

II) (iii) $\Rightarrow$ (ii) when S is normal.

III) (ii) $\Rightarrow$ (i).

3.2. Proof of the "easy" assertions in 3.1

The implications (i) $\Rightarrow$ (ii) and (i) $\Rightarrow$ (iii) are trivial.

(iii) $\Rightarrow$ (iv). After replacing S by S', we may assume that S is the spectrum of a discrete valuation ring. Let t be the generic point of S, and let s be its closed point.

Since E is locally closed, there is a reduced subprescheme of G with underlying space E; we also denote it by E. Its generic fiber E_t is therefore the sub-torus T_t of G_t, of rank r, by (iii) a). Let E' be the schematic closure of E_t in E. The prescheme E' is irreducible, and its closed fiber E'_s is nonempty (it contains the unit section of G_s); hence E'_s has dimension r (EGA IV 14.3.10). But E'_s is a closed subscheme of E_s, while E_s has dimension r by (iii) b) and is irreducible because it has the same underlying space as T_s. Thus E'_s and E_s have the same underlying space, and consequently $E' = E$. This proves that E is flat over S.

Let E'' now be the schematic closure of E_t in G. Then E'' is a subgroup prescheme of G, flat over S (Exposé VIII 7.1), which contains E', and therefore E. Its closed fiber E''_s is an algebraic subgroup of G_s of dimension r (*loc. cit.*). Since T_s is a closed irreducible subset of G_s of dimension r, E_s has the same underlying set as the identity component $(E''_s)^0$ of E''_s. Let $(E'')^0$ denote the "identity component" of E'', that is, the open subgroup of E'' complementary to the union of the irreducible components of E''_s that do not contain the origin. Then

$$E = \mathrm{ens}((E'')^0).$$

Since E and E'' are reduced, one even has $E = (E'')^0$. Finally, E is a subgroup prescheme of G, flat and of finite type over S, with connected fibers, hence separated (Exposé $\mathrm{VI_B}$ 5.2); its generic fiber is the torus T_t, and its reduced closed fiber is the torus T_s. It follows that E is a torus (Exposé X 8.8).

(ii) $\Rightarrow$ (iv). Again we may assume that S is the spectrum of a discrete valuation ring, and we retain the notation introduced above. The schematic closure T of T_t in G is a subgroup prescheme of G, flat over S, and it contains M_n for every n that is a power of q. Consequently, its closed fiber is a closed subscheme of G_s containing $(M_n)_s$ for every n, hence containing T_s. For dimension reasons, the "identity component" T^0 of T has E as its underlying set, and the preceding argument shows that T^0 is a sub-torus of G.

(iv) $\Rightarrow$ [(iii) and E is closed], if G is separated over S. Let us show that E is closed.[5] We first prove the following lemma.

Lemma 3.3.— *If the conditions stated in 3.1* (iv) *are satisfied, E is a locally constructible subset of* $\mathrm{ens}(G)$.

By the usual method, we are reduced to the case in which S is noetherian and integral, with generic point η. After shrinking S, we may assume (Exposé $\mathrm{VI_B}$ 10.10) that there is a subgroup scheme H of G, flat over S and with connected fibers, whose generic fiber H_η is T_η. To prove Lemma 3.3 it is enough to show that $\mathrm{ens}(H) = E$.

Let s be a point of S. By EGA II 7.1.9 there is an S-scheme S', the spectrum of a discrete valuation ring which we may assume complete with algebraically closed residue field, whose generic point t' maps to η and whose closed point s' maps to s. By (iv) b), there is a sub-torus $T_{S'}$ of $G_{S'}$ having $E_{S'}$ as its underlying space. The two subgroup preschemes $T_{S'}$ and $H_{S'} = H \times_S S'$ of $G_{S'}$ are flat over S', have connected fibers, and have the same generic fiber $T_{t'}$. Therefore both coincide with the identity component of the schematic closure of $T_{t'}$ in $G_{S'}$. Hence $\mathrm{ens}(H_s) = E_s$, and therefore $\mathrm{ens}(H) = E$, proving the lemma.

Now that E is known to be locally constructible, to see that it is closed it is enough to prove that every specialization in G of a point of E again belongs to E. By the usual technique, we are reduced to the case in which S is the spectrum of a complete discrete valuation ring with algebraically closed residue field. In that case the sub-torus of G with

[5] Editor's note: The implication (iv) $\Rightarrow$ (iii) will appear in the course of the proof.

underlying space E, supplied by (iv) b), is closed in G, because G is separated (Exposé VIII 7.12).

3.3. Continuation of the proof of 3.1

I) Reduction of (iii) ⇒ (i), case C, first case, to the case in which S is normal.

a) Reduction to the case in which S is affine and reduced. We therefore assume that, for every point s of S, E_s is the underlying space of a central sub-torus of G_s. The uniqueness of T then follows from Exposé IX 5.1 bis, and moreover T will necessarily be central (*loc. cit.*). In view of this uniqueness, in order to prove the existence of T we may suppose that S is noetherian and affine, with ring A. If S is not reduced, G is flat over S by hypothesis. By 2.3 it is then enough to solve the problem for S_{red} and $G \times_S S_{\mathrm{red}}$. We may therefore suppose in addition that S is reduced.

b) Reduction to the case in which A is an algebra of finite type over $\mathbb{Z}$. We shall use the following lemma.

Lemma 3.4.— *Let k be a field, G an algebraic k-group, and E a subset of G. Let k'/k be a field extension, and suppose that $E_{k'}$ is the underlying set of a sub-torus $T_{k'}$ of $G_{k'}$. If $T_{k'}$ is central in $G_{k'}$, or if k is perfect, then E is the underlying set of a sub-torus T of G.*

Proof. By fpqc descent it is enough to prove that the two inverse images of $T_{k'}$ in $G_{k''}$, where

$$k'' = k' \otimes_k k',$$

coincide. They have the same underlying set. If $T_{k'}$ is central, they therefore coincide by Exposé IX 5.1 bis. If k is perfect, k'' is reduced; the two inverse images, being smooth over k'', are reduced and consequently coincide.

Remarks 3.5.— (1) *Lemma 3.4 applies in particular when the residue fields of S are perfect.*

(2) *Under the hypotheses of the first case in Theorem 3.1 C, for every S-scheme S' as in 3.1* (iv) b)*, the sub-torus of $G_{S'}$ having $E_{S'}$ as its underlying space is central.*

Lemma 3.6.— *Let S be the projective limit of a filtered inverse system of affine schemes S_i, and let H be an S-group of multiplicative type and of finite type. There exist an index i, a group H_i of multiplicative type over S_i, and an S-isomorphism*

$$H_i \times_{S_i} S \xrightarrow{\sim} H.$$

If H is isotrivial, H_i may be chosen isotrivial.

Proof. Since H is of finite presentation over S, there are an index i, an S_i-group prescheme H_i, of finite presentation over S_i, and an S-isomorphism

$$H_i \times_{S_i} S \xrightarrow{\sim} H$$

(Exposé $\mathrm{VI_B}$ 10.16). After increasing i, we may suppose that H_i is of multiplicative type (Exposé IX 2.11). It remains to prove that H_i can be chosen quasi-isotrivial, and isotrivial when H is isotrivial.

We may thus suppose that H is trivialized by an étale, surjective morphism $S' \to S$ of finite presentation. For i sufficiently large, there are an S_i-prescheme S'_i, an étale, surjective morphism $S'_i \to S_i$ of finite presentation, and an S-isomorphism

$$S'_i \times_{S_i} S \xrightarrow{\sim} S'$$

(EGA IV 17.16). For j sufficiently large set

$$S'_j = S'_i \times_{S_i} S_j, \qquad H'_j = H_j \times_{S_j} S'_j, \qquad H' = H \times_S S'.$$

By the choice of S', there are a finitely generated abelian group M and an S'-isomorphism of group schemes

$$D_{S'}(M) \xrightarrow{\sim} H'.$$

Since the S'_i are quasi-compact and $S' = \varprojlim S'_i$, Exposé $\mathrm{VI_B}$ 10 shows that there are an index j and an S'_j-isomorphism of group schemes

$$D_{S'_j}(M) \xrightarrow{\sim} H'_j.$$

This says precisely that H_j is a quasi-isotrivial group of multiplicative type. When H is isotrivial, one argues similarly using a trivialization of H by a finite étale morphism $S' \to S$.

We can now carry out reduction b). The ring A of S is the filtered direct limit of its subrings A_i of finite type over $\mathbb{Z}$. Put $S_i = \operatorname{Spec} A_i$, and let

$$u_j : S \longrightarrow S_j, \qquad u_{jk} : S_k \longrightarrow S_j \quad (k \geq j)$$

be the transition morphisms. Since S is noetherian and G is of finite presentation over S, there are an index i and an S_i-group prescheme G_i, of finite type over S_i, such that G is S-isomorphic to $G_i \times_{S_i} S$. Likewise, since E is locally closed in G, we may suppose that there is a locally closed subset E_i of G_i such that

$$E = E_i \times_{S_i} S$$

(EGA IV 8.3.11). For $j > i$, put

$$G_j = G_i \times_{S_i} S_j, \qquad E_j = E_i \times_{S_i} S_j,$$

and let Q_j be the set of points s of S_j for which $(E_j)_s$ is the underlying set of a central sub-torus of $(G_j)_s$.

It follows from 3.4 that

$$Q_k = u_{jk}^{-1}(Q_j) \quad (k \geq j),$$

and by hypothesis

$$\operatorname{ens}(S) = u_j^{-1}(Q_j) \quad (j \geq i).$$

I further claim that Q_j is ind-constructible (EGA IV 1.9.4). Indeed, since S_j is noetherian, it is enough (EGA IV 1.9.10) to see the following. Let S be a noetherian integral scheme with generic point η, and suppose that E_η is the underlying set of a central sub-torus T_η of G_η. Then there is a neighborhood U of η such that E_s has the same property for every $s \in U$. After shrinking S, we may suppose that the center Z of G is representable and that there is a subgroup scheme T of G whose generic fiber is T_η (Exposé $\mathrm{VI_B}$, §10). The two locally closed subsets $\operatorname{ens}(T)$ and E of $\operatorname{ens}(G)$ coincide on the generic fiber. We can therefore find a neighborhood U of η such that, above U,

$$\operatorname{ens}(T) = E$$

(EGA IV 8.3.11). For the same reasons, we may suppose that T is central above U; it is a torus by 3.6.

Now that Q_j is known to be ind-constructible, EGA IV 8.3.4 implies that $Q_j = \mathrm{ens}(S_j)$ for j sufficiently large. We may then replace S, G, E by S_j, G_j, E_j, which reduces us to the case in which S is an affine reduced scheme of finite type over $\mathbb{Z}$.

c) Reduction to the case in which S is the spectrum of a complete reduced noetherian local ring. Because the torus with underlying space E is unique, the usual technique (EGA IV 8) and Lemma 3.6 allow us to replace S by the spectrum of the local ring A at a point of S. Let $\widehat{S}$ be the spectrum of the completion $\widehat{A}$ of A for the topology defined by its maximal ideal. Since A is the localization of an algebra of finite type over $\mathbb{Z}$, $\widehat{S}$ is still reduced (EGA IV 7.6.5).

I claim that it is enough to solve the problem after the base extension $\widehat{S} \to S$. Indeed, let $\widehat{T}$ be the sub-torus of $G_{\widehat{S}}$ with underlying space $E_{\widehat{S}}$. Its two inverse images in $G_{\widehat{S}\times_S\widehat{S}}$ are central sub-tori with the same underlying space; they therefore coincide (Exposé IX 5.1 bis). By fpqc descent, $\widehat{T}$ comes from a torus T of G that solves the problem (cf. 3.4).

d) A descent lemma. Recall the following properties of finite morphisms, noted in TDTE I. Let S, S' be two preschemes and $u : S' \to S$ a finite morphism. Then:

(1) The morphism u is an epimorphism if and only if the canonical morphism of sheaves

$$\mathcal{O}_S \longrightarrow u_*(\mathcal{O}_{S'})$$

is injective.

(2) The morphism u is an effective epimorphism (Exposé IV 1.3) if and only if the canonical diagram

$$0 \longrightarrow \mathcal{O}_S \longrightarrow u_*(\mathcal{O}_{S'}) \rightrightarrows u_*(\mathcal{O}_{S'}) \otimes_{\mathcal{O}_S} u_*(\mathcal{O}_{S'})$$

is exact.

(3) If in addition S is noetherian and u is an epimorphism, u is the composite of a finite sequence of finite effective epimorphisms.

We can now prove the following lemma, whose proof uses a non-flat descent technique.

Lemma 3.7.— *Let S be a locally noetherian prescheme, G an S-group prescheme of finite type, S' a prescheme, and $u : S' \to S$ a finite morphism. For every S-prescheme T, let* $\mathrm{M}(T)$ *be the set of subgroups of G_T of multiplicative type* (respectively, the set of central subgroups of G_T of multiplicative type)*, so that* M *is naturally a contravariant functor on* Sch/S*. If u is an effective epimorphism* (respectively, an epimorphism)*, then the diagram of sets*

$$(*) \qquad \mathrm{M}(S) \longrightarrow \mathrm{M}(S') \rightrightarrows \mathrm{M}(S' \times_S S')$$

is exact.

Proof. *i) Reduction to the case in which u is an effective epimorphism.* Here we consider the functor of central subgroups of G of multiplicative type. The injectivity of $\mathrm{M}(S) \to \mathrm{M}(S')$ is local on S; once this injectivity is granted, the exactness of $(*)$ is also local on S. We may therefore suppose that S is affine and noetherian.

Consider the case in which $u : S' \to S$ is the composite of two finite epimorphisms

$$S' \xrightarrow{v} S'' \xrightarrow{w} S.$$

I claim that if both diagrams

$$(*') \qquad \mathrm{M}(S'') \longrightarrow \mathrm{M}(S') \rightrightarrows \mathrm{M}(S' \times_{S''} S')$$

and

$$(*'') \qquad \mathrm{M}(S) \longrightarrow \mathrm{M}(S'') \rightrightarrows \mathrm{M}(S'' \times_S S'')$$

are exact, then so is $(*)$.

Indeed, the injectivity of $\mathrm{M}(S) \to \mathrm{M}(S')$ is clear. If T' belongs to

$$\mathrm{Ker}\big(\mathrm{M}(S') \rightrightarrows \mathrm{M}(S' \times_S S')\big),$$

then, a fortiori, T' belongs to

$$\mathrm{Ker}\big(\mathrm{M}(S') \rightrightarrows \mathrm{M}(S' \times_{S''} S')\big).$$

By the exactness of $(*')$, it therefore comes from a unique element T'' of $\mathrm{M}(S'')$. It is enough to show that T'' belongs to

$$\mathrm{Ker}\big(\mathrm{M}(S'') \rightrightarrows \mathrm{M}(S'' \times_S S'')\big),$$

for then the exactness of $(*'')$ descends T'' to S. Let T_1'', T_2'' be the two inverse images of T'' in $\mathrm{M}(S'' \times_S S'')$. These are central subgroups of $G_{S'' \times_S S''}$ of multiplicative type, so to prove that $T_1'' = T_2''$ it is enough to see that they have the same fibers (Exposé IX 5.1 bis). Consider the commutative diagram

$$\begin{array}{ccc} S' & \leftleftarrows & S' \times_S S' \\ {\scriptstyle v}\downarrow & & \downarrow{\scriptstyle v \times v} \\ S'' & \leftleftarrows & S'' \times_S S''. \end{array}$$

The morphism v is a finite epimorphism, hence dominant by property (1) above, and closed; it is therefore surjective, and so is $v \times v$. Let x'' be a point of $S'' \times_S S''$, and let x' be a point of $S' \times_S S'$ lying above x''. The commutativity of the diagram shows that the two inverse images of $(T_1'')_{x''}$ and $(T_2'')_{x''}$ in $G_{x'}$ coincide. Thus

$$(T_1'')_{x''} = (T_2'')_{x''}$$

(EGA IV 2.2.15).

The preceding argument and an immediate induction on the number of factors in a factorization of $u : S' \to S$ into effective epimorphisms, supplied by property (3) above, show that in order to prove the exactness of $(*)$ for central subgroups of multiplicative type it is enough to treat the case in which u is an effective epimorphism. Finally, another application of Exposé IX 5.1 bis shows that it is enough to prove 3.7 when M is the functor of all subgroups of G of multiplicative type and u is an effective epimorphism.

ii) Injectivity of $\mathrm{M}(S) \to \mathrm{M}(S')$. Since $u : S' \to S$ is an epimorphism, the canonical morphism

$$\mathcal{O}_S \longrightarrow u_*(\mathcal{O}_{S'})$$

is injective. Moreover, an S-group of multiplicative type is flat over S. The injectivity of $\mathrm{M}(S) \to \mathrm{M}(S')$ is therefore a consequence of the following more general lemma.

Lemma 3.8.— *Let $f : X \to S$ and $g : S' \to S$ be morphisms of preschemes, let $\mathcal{F}$ be a quasi-coherent $\mathcal{O}_X$-module, and put*

$$X' = X \times_S S', \qquad \mathcal{F}' = \mathcal{F} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}.$$

Let $\mathrm{Q}(\mathcal{F})$ be the set of quotient $\mathcal{O}_X$-modules $\mathcal{G}$ of $\mathcal{F}$ that are quasi-coherent and flat over S, and define $\mathrm{Q}(\mathcal{F}')$ analogously relative to $\mathcal{F}', X'$, and S'. Suppose that g is quasi-compact and that

$$\mathcal{O}_S \longrightarrow g_*(\mathcal{O}_{S'})$$

is injective. Then the canonical map

$$\begin{aligned} \mathrm{Q}(\mathcal{F}) &\longrightarrow \mathrm{Q}(\mathcal{F}'), \\ \mathcal{G} &\longmapsto \mathcal{G} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'} \end{aligned}$$

is injective.

Proof. Indeed, we may suppose that S is affine, and then that X is affine. Since S' is quasi-compact, it has a finite covering by affine open subsets. Replacing S' by the disjoint union of these open subsets, we may therefore suppose that S' is affine. We are then reduced to the following lemma, whose proof is immediate.

Lemma 3.9.— *Let $A \to A'$ be an injective homomorphism of rings, let M be an A-module, let $N = M/P$ be a quotient A-module flat over A, and put*

$$M' = M \otimes_A A', \qquad N' = N \otimes_A A' = M'/P'.$$

Then P is the inverse image of P' under the canonical homomorphism $M \to M'$. Thus N and P are determined by N' and P'.

iii) Exactness of 3.7 $(*)$ at $\mathrm{M}(S')$. Let

$$T' \in \mathrm{Ker}(\mathrm{M}(S') \rightrightarrows \mathrm{M}(S' \times_S S')).$$

Suppose that iii) has been proved when S is the spectrum of a noetherian local ring. For every point s of S, there then exists a subgroup T_s of multiplicative type in $G \times_S \mathrm{Spec}(\mathcal{O}_{S,s})$, obtained by descent from

$$T' \times_{S'} u^{-1}(\mathrm{Spec}(\mathcal{O}_{S,s})).$$

By Exposé $\mathrm{VI_B}$, §10, and 3.6, there is an open neighborhood U of s in S and a subgroup scheme T of G over U, of multiplicative type, that extends T_s. Let U' be the inverse image of U in S'. We then have two subschemes of $G'|_{U'}$, namely $T'|_{U'}$ and $T \times_U U'$, which coincide over $u^{-1}(\mathrm{Spec}(\mathcal{O}_{S,s}))$.

Regarding the latter scheme as the projective limit of the $u^{-1}(V)$, where V runs through the open neighborhoods of s in U, EGA IV 8 shows that there is an open subset $V \subset U$, containing s, over whose inverse image $T \times_U U'$ and T' coincide. Thus, under the stated hypotheses, T' descends locally on S; by the uniqueness proved in ii), it consequently descends globally. In short, it is enough to prove iii) when S is the spectrum of a noetherian local ring.

Let $\widehat{S}$ be the spectrum of the completion of the ring of S, and put

$$S'' = S' \times_S S', \qquad \widehat{S}' = \widehat{S} \times_S S', \qquad \widehat{S}'' = \widehat{S} \times_S S'' = \widehat{S}' \times_S S'.$$

I claim that it is enough to show that

$$(\widehat{*}) \qquad \mathrm{M}(\widehat{S}) \longrightarrow \mathrm{M}(\widehat{S}') \rightrightarrows \mathrm{M}(\widehat{S}'')$$

is exact at $\mathrm{M}(\widehat{S}')$. This follows from the commutative diagram

$$\begin{array}{ccccc}
\mathrm{M}(S) & \longrightarrow & \mathrm{M}(S') & \rightrightarrows & \mathrm{M}(S'') \\
\downarrow & & \downarrow & & \downarrow \\
\mathrm{M}(\widehat{S}) & \longrightarrow & \mathrm{M}(\widehat{S}') & \rightrightarrows & \mathrm{M}(\widehat{S}'') \\
\downarrow\downarrow & & \downarrow\downarrow & & \\
\mathrm{M}(\widehat{S} \times_S \widehat{S}) & \xrightarrow{f} & \mathrm{M}(\widehat{S}' \times_{S'} \widehat{S}'). & &
\end{array}$$

Here the second row is exact at $\mathrm{M}(\widehat{S}')$ by hypothesis, the first two columns are exact by fpqc descent, and f is injective by ii), applied to the finite epimorphism

$$\widehat{S}' \times_{S'} \widehat{S}' \longrightarrow \widehat{S} \times_S \widehat{S}$$

deduced from $S' \to S$ by the flat base change $\widehat{S} \times_S \widehat{S} \to S$. The diagram chase is left to the reader. The characterization of finite effective epimorphisms recalled in d)(2) shows that $\widehat{S}' \to \widehat{S}$, obtained from $S' \to S$ by the flat base change $\widehat{S} \to S$, is again a finite effective epimorphism. We are therefore reduced to the case in which S is, in addition, the spectrum of a complete noetherian local ring.

Let S_0 be the reduced closed subscheme of S whose underlying space is the closed point. Let T' be as above and write T'' for its common image in $\mathrm{M}(S'')$. Since

$$S'_0 = S' \times_S S_0$$

is faithfully flat over S_0, there is a subgroup T_0 of G_{S_0}, of multiplicative type, whose inverse image in $G_{S'_0}$ is $T'_{S'_0}$, by fpqc descent. Since S is complete noetherian local, there exist an S-group T of multiplicative type and an S_0-morphism

$$u_0 : T \times_S S_0 \longrightarrow T_0$$

(Exposé X 3.3). The inverse image of u_0 over S'_0 extends uniquely to an S'-isomorphism

$$u' : T_{S'} \xrightarrow{\sim} T',$$

again by Exposé X 3.3. Notice here that, because S' is finite over the complete local scheme S, it is a finite disjoint sum of complete local schemes.

The two inverse images of u' over S'' are morphisms from $T_{S''}$ to T'' that coincide over $S_0 \times_S S''$; hence they coincide everywhere by the same result. Since T is flat over S and $S' \to S$ is a finite effective epimorphism, TDTE I, page 8, gives an exact diagram

$$\mathrm{Hom}_S(T, G) \longrightarrow \mathrm{Hom}_{S'}(T_{S'}, G_{S'}) \rightrightarrows \mathrm{Hom}_{S''}(T_{S''}, G_{S''}).$$

Thus u' comes from a morphism of preschemes $u : T \to G$. Likewise, $T \times_S T$ is flat over S, and therefore

$$\mathrm{Hom}_S(T \times_S T, G) \longrightarrow \mathrm{Hom}_{S'}(T_{S'} \times_{S'} T_{S'}, G_{S'})$$

is injective. It follows at once that u is a homomorphism of groups, since u' is one.

Moreover, u is a monomorphism. First observe that $\mathrm{Ker}(u)$ is flat over S. To prove this we may suppose that S is artinian local (EGA 0_{III}, 10.2.2), hence that G is separated

(Exposé $\mathrm{VI_A}$, 0.3); then $\mathrm{Ker}(u)$ is of multiplicative type (Exposé IX 6.8), and is therefore flat over S. Since

$$\mathrm{Ker}(u) \times_S S' = \mathrm{Ker}(u') = 0,$$

Lemma 3.8 gives $\mathrm{Ker}(u) = 0$. Finally, a monomorphism u is an immersion (Exposé VIII, Remarks 7.13), and its image $u(T)$ is an element of $\mathrm{M}(S)$ whose image in $\mathrm{M}(S')$ is T'. This proves Lemma 3.7.

e) End of the proof of I). By reduction c), we are reduced to the case in which S is the spectrum of a complete reduced noetherian local ring A. Let S' be the spectrum of the normalization A' of A. Nagata's theorem says that A' is finite over A (EGA 0_{IV}, 23.1.5), and $S' \to S$ is an epimorphism because $A \to A'$ is injective. Suppose that $G_{S'}$ has a torus T' whose underlying space is $E_{S'}$. The two inverse images of T' in $G_{S' \times_S S'}$ are central sub-tori with the same underlying space, so they coincide (Exposé IX 5 bis). By Lemma 3.7, T' therefore comes from a central sub-torus T of G_S, which plainly has E as its underlying space. It is thus enough to prove the existence of T'. This reduces us to the normal case and completes the proof of I).

II) Proof that (iii) *implies* (ii) *when S is normal.* We may restrict ourselves to the case in which S is integral; let t be its generic point. For every integer n that is a power of q, let ${}_nG$ be the "kernel" in G of raising to the n-th power. Since E is locally closed in G, by (iii)(b), the intersection of $\mathrm{ens}({}_nG)$ with E is locally closed in $\mathrm{ens}(G)$. Let $E(n)$ denote the reduced subscheme of G whose underlying space is $\mathrm{ens}({}_nG) \cap E$.

We show that the structural morphism

$$E(n) \longrightarrow S$$

is separated and universally open. Both properties have a valuative criterion (EGA II 7.2.3 and EGA IV 14.5.8). Let S' therefore be an S-scheme that is the spectrum of a complete discrete valuation ring with algebraically closed residue field. We have proved that 3.1(iii) implies 3.1(iv), so there is a sub-torus T' of $G_{S'}$ whose underlying space is $E_{S'}$. Now ${}_nT'$ is finite étale over S', hence is separated and universally open over S'; the same is therefore true of $E(n) \times_S S'$, which has the same underlying space.

The fibers of $E(n)$, moreover, all have the same number of geometric points, namely n^r if r is the rank of the torus T_t. Finally, the generic fiber $E(n)_t$, being reduced, is equal to ${}_nT_t$, and hence is étale over $\mathrm{Spec}(t)$. Since S is normal, SGA I 10.11 now shows that $E(n)$ is an étale covering of S.

If s is a point of S, then $E(n)_s$ is étale over $\mathrm{Spec}\,\kappa(s)$, hence reduced, and consequently coincides with the group ${}_nT_s$ of multiplicative type. We show that $E(n)$ is a group subscheme of G. Let

$$m : E(n) \times_S E(n) \longrightarrow G$$

be the morphism induced by multiplication in G. The underlying map $\mathrm{ens}(m)$ factors through $E(n)$, so m itself factors through the scheme $E(n)$, because its source $E(n) \times_S E(n)$ is étale over S, and hence reduced. It then follows from Exposé X 4.8(a) that $E(n)$ is a subgroup of multiplicative type. As observed already in 3.2(a), the family of subgroups $E(n)$ is necessarily coherent. This proves that (iii) implies (ii) when S is normal.

III) Proof that (ii) *implies* (i). In fact, we shall show that there is a unique sub-torus T of G, with underlying space E, such that

$${}_nT = M_n$$

for every n that is a power of q. Uniqueness follows immediately from Exposé IX 4.8(b). In proving existence, in view of this uniqueness, we may successively suppose that:

a) S is noetherian.

b) The M_n are central subgroups. Indeed, it is enough to replace G by

$$Z_n = \mathrm{Centr}_G(M_n)$$

for sufficiently large n, by 2.5 and 2.5 bis.

c) S is the spectrum of a local ring. Suppose that the problem has been solved after every base change $\mathrm{Spec}(\mathcal{O}_{S,s}) \to S$, for $s \in S$, and let T_s be the resulting sub-torus of $G \times_S \mathrm{Spec}(\mathcal{O}_{S,s})$. There is then an open neighborhood U of s and a sub-torus T of $G|_U$ extending T_s, by Exposé $\mathrm{VI_B}$, §10, and 3.6. We have proved that 3.1(ii) implies 3.1(iv); since S is noetherian, E is therefore constructible by 3.3. After shrinking U, we may consequently suppose that

$$\mathrm{ens}(T) = E \times_S U$$

(EGA IV 9.5.2). For every n that is a power of q, the groups ${}_nT$ and $M_n \times_S U$ are then two subgroups of multiplicative type in $G|_U$, with the same fibers; because M_n is central, they coincide by Exposé IX 5.3 bis. Thus the problem has a local solution on S, and uniqueness makes these local solutions into a global one.

d) S is the spectrum of a complete noetherian local ring and, if s is the closed point, T_s is trivial. This follows from EGA 0_{III}, 10.3.1, and fpqc descent.

e) S is reduced. Apply 2.2.

f) S is normal. Apply Nagata's finiteness theorem (EGA 0_{IV}, 23.1.5) and Lemma 3.7 for central sub-tori.

After these reductions, T_s is trivial, and hence $(M_n)_s$ is trivial. It follows from Exposé X 3.3 that M_n itself is trivial. If t is any point of S, all the subgroups ${}_nT_t$ of T_t, for n a power of q, are therefore trivial; Exposé X 1.4 then shows at once that T_t itself is trivial. It remains only to prove the following lemma.

Lemma 3.10.— *Under the hypotheses of 3.1(ii), suppose in addition that S is noetherian and normal and that, for every point s of S, T_s is a trivial torus. Then there exists a unique sub-torus T of G, with underlying space E, such that*

$${}_nT = M_n$$

for every n that is a power of q. Moreover, T is trivial.

Proof. Uniqueness follows from the fact that T, being smooth over S, is reduced. To prove existence, we may suppose that S is irreducible, with generic point η. Let r be the rank of T_η, put

$$T' = \mathbb{G}_{m,S}^r,$$

and choose an isomorphism

$$u_\eta : T'_\eta \xrightarrow{\sim} T_\eta.$$

Write ${}_nu_\eta$ for its restriction to ${}_nT'_\eta$. Since ${}_nT'$ and M_n are trivial, ${}_nu_\eta$ has a unique extension to an S-isomorphism

$${}_nu : {}_nT' \xrightarrow{\sim} M_n.$$

I claim that, for every point s of S, there is a necessarily unique group isomorphism

$$u_s : T'_s \xrightarrow{\sim} T_s$$

that extends ${}_nu)_s$ for every n that is a power of q.

Indeed, let S^1 be an S-scheme that is the spectrum of a complete discrete valuation ring with algebraically closed residue field, whose generic point t_1 maps to η and whose closed point s_1 maps to s (EGA II 7.1.9). The proof that 3.1(ii) implies 3.1(iv) gives a sub-torus T^1 of G_{S^1} such that

$$(M_n)_{S^1} = {}_nT^1$$

for every n that is a power of q. Since S^1 is normal, T^1 is isotrivial by Exposé X 5.16. The classification of isotrivial tori (Exposé X 1.2) and SGA I, Exposé V 8.2, together with the fact that the generic fiber of T^1 is trivial, show that T^1 is trivial. We may therefore extend

$$u_\eta \times_\eta t_1$$

to an S^1-isomorphism of group schemes

$$u^1 : T' \times_S S^1 \xrightarrow{\sim} T^1.$$

On ${}_nT' \times_S S^1$, the morphisms u^1 and ${}_nu \times_S S^1$ agree on the generic fiber, and hence agree everywhere. Restricting u^1 to the closed fiber gives the required u_s after the field extension $\kappa(s) \to \kappa(s_1)$; it descends to $\kappa(s)$ by Exposé IX 4.8(a) and fpqc descent.

The scheme T' is smooth over the normal scheme S, hence is normal. The extension criterion for rational maps in EGA IV_4, 20.4.6, now shows that there is an S-morphism

$$u : T' \longrightarrow G$$

whose restriction to each fiber T'_s is the composite

$$T'_s \xrightarrow{u_s} T_s \longrightarrow G_s.$$

Indeed, for every base change $S^1 \to S$ of the kind used above, the preceding construction gives precisely the required extension over S^1.

It remains to show that u is a homomorphism. Let $m_{T'}$ and m_G denote multiplication in T' and G, respectively. The coincidence subscheme of

$$m_G \circ (u \times_S u) \quad \text{and} \quad u \circ m_{T'}$$

contains every fiber, since every u_s is a homomorphism. It therefore has the same underlying space as $T' \times_S T'$, and so equals $T' \times_S T'$, because the latter is smooth over S and hence reduced. Finally, u is a monomorphism because it is one on every fiber; it is therefore an immersion (Exposé VIII 7.9). The image of T' under u is a sub-torus of G whose underlying set is E.

This completes the proof of Theorem 3.1.

4. Characterization of a sub-torus T by the subgroups ${}_nT$

4.1. Statement of the main theorem

Theorem 4.1.— *Let S be a connected locally noetherian prescheme, let G be an S-group prescheme of finite type over S, let $q > 1$ be an integer invertible on S, and let r be a positive integer. For every integer n that is a power of q, let $M(n)$ be a subgroup scheme of G, of multiplicative type and of type $(\mathbb{Z}/n\mathbb{Z})^r$. Suppose that:*

a) *the family $M(n)$ is coherent: if $m \mid n$, then*

$$ {}_mM(n) = M(m); $$

b) *there exist a point $s \in S$ and a sub-torus T_s of G_s such that*

$$ M(n)_s = {}_nT_s \qquad \text{for every } n; $$

c) *for every point $t \in S$, there exists a closed affine subscheme F_t of G_t containing $M(n)_t$ for every n.*

Then there exists a unique sub-torus T of G such that ${}_nT = M(n)$ for every n that is a power of q.

There is an analogous theorem for lifting morphisms.

Theorem 4.1 bis.— *Let S, G, q be as above, let T be an S-torus, and, for every n that is a power of q, let $u(n) : {}_nT \to G$ be an S-homomorphism. Suppose that:*

a) *the family $u(n)$ is coherent: if $m \mid n$, then*

$$ u(m) = u(n)|_{{}_mT}; $$

b) *there exist a point $s \in S$ and a homomorphism $u_s : T_s \to G_s$ such that*

$$ u_s|_{{}_nT_s} = u(n)_s \qquad \text{for every } n \text{ that is a power of } q; $$

c) *for every point $t \in S$, there exists a closed affine subscheme F_t of G_t containing $u(n)_t({}_nT_t)$ for every n.*

Then there exists a unique homomorphism $u : T \to G$ whose restriction to ${}_nT$ equals $u(n)$ for every n that is a power of q.

Remark 4.2.— *Using the lower semicontinuity of the abelian rank of a flat group prescheme of finite type over the spectrum of a discrete valuation ring (cf. Exposé X 8.7), condition (c) in Theorems 4.1 and 4.1 bis may be weakened by requiring the closed affine subscheme F_t only for every maximal point t of S.*

Let us deduce Theorem 4.1 bis from Theorem 4.1. Put $G' = G \times_S T$. For every n that is a power of q, consider the homomorphism

$$ v(n) : {}_nT \longrightarrow G' $$

whose projections to G and T are respectively $u(n)$ and the canonical immersion ${}_nT \to T$. Thus $v(n)$ is an immersion; let $M(n)$ be its image subgroup. The family $M(n)$ is coherent in the sense of Theorem 4.1. The group $M(n)_s$ equals ${}_nT'_s$, where T'_s is the sub-torus of G'_s that is the graph of u_s, and, for every $t \in S$, the closed affine subscheme $F_t \times_t T_t$ of G'_t contains all the groups $M(n)_t$. By Theorem 4.1 there is therefore a sub-torus T' of G' such that ${}_nT' = M(n)$ for every n.

Let $f : T' \to T$ be the restriction of the projection $G' \to T$, and let $f(n)$ be its restriction to $M(n)$. Then

$$ f(n) \circ v(n) = \mathrm{id}_{{}_nT}\,. $$

The fibre T'_s is the graph of u_s (Exposé IX 4.8(b)), so f_s is an isomorphism. The groups $\ker f$ and $\operatorname{coker} f$ are of multiplicative type (Exposé IX 2.7) and of constant type, since S is connected. They are therefore trivial, and f is an isomorphism. If $v = f^{-1}$, then

$$ v|_{{}_nT} = v(n). $$

Composing v with the projection $G' \to G$ gives the required homomorphism $u : T \to G$. This proves existence; uniqueness follows from Exposé IX 4.8(a).

4.2. Application

We shall generalize Theorem IX 7.1. Let A be a complete noetherian local ring, let I be its maximal ideal, and put

$$S = \operatorname{Spec} A, \qquad S_m = \operatorname{Spec}(A/I^m).$$

For every prescheme X, put $X_m = X \times_S S_m$.

Let G be an S-group prescheme of finite type, let T be an S-torus, let q be an integer invertible on S, and let

$$u_m : T_m \longrightarrow G_m \qquad (m \in \mathbb{N})$$

be a coherent family of homomorphisms. For n ranging over the powers of q, denote by $u_m(n)$ the restriction of u_m to ${}_nT_m$, and by

$$u(n) : {}_nT \longrightarrow G$$

the unique homomorphism extending the morphisms $u_m(n)$ for all m (Proposition 1.6(a)). We call the family $(u_m)_{m\in\mathbb{N}}$ *admissible* if, for every point $t \in S$, there exists a closed affine subprescheme F_t of G_t containing $u(n)_t({}_nT_t)$ for every n that is a power of q. As will be seen, this property does not depend on q.

Proposition 4.3.— *With the preceding notation, the canonical map*

$$\operatorname{Hom}_{S\text{-gr}}(T, G) \longrightarrow \varprojlim_m \operatorname{Hom}_{S_m\text{-gr}}(T_m, G_m)$$

identifies its source with the subset of the target consisting of admissible coherent families.

Indeed, apply Theorem 4.1 bis with s the closed point of S.

Corollary 4.4.— *With the preceding notation, suppose in addition that G has affine fibres. Then the canonical map*

$$\operatorname{Hom}_{S\text{-gr}}(T, G) \longrightarrow \varprojlim_m \operatorname{Hom}_{S_m\text{-gr}}(T_m, G_m)$$

is an isomorphism.

Indeed, when G has affine fibres every coherent family is admissible.

Remark 4.5.— *When G is separated, the ring A in Proposition 4.3 may be replaced by a noetherian I-adic ring: one uses EGA III 5.4.1 in place of Proposition 1.6(a).*

4.3. Proof of Theorem 4.1

Lemma 4.6.— *Let k be a field, let G be a k-algebraic group, let q be an integer prime to the characteristic of k, let $r > 0$, and let $M(n)$, for n ranging over the powers of q, be a coherent family of subgroups of G, of multiplicative type and of type $(\mathbb{Z}/n\mathbb{Z})^r$. There exists a smallest closed subscheme H of G containing all the $M(n)$. Moreover, H is a smooth, connected, commutative algebraic subgroup of G, and its formation commutes with extension of the base field.*

Let $M \subseteq \operatorname{ens}(G)$ be the union of the underlying sets of all the $M(n)$, and let H be the reduced closed subscheme of G whose underlying space is the closure of M. Each $M(n)$ is étale over k, hence reduced, and is therefore contained in H. Thus H is the smallest closed subscheme containing all the $M(n)$.

Let $\bar{k}$ be an algebraically closed extension of k. By construction the $M(n)$ are schematically dense in H (Exposé IX 4.1), hence the $M(n)_{\bar{k}}$ are schematically dense in $H_{\bar{k}}$ (Exposé IX 4.5). Since every $M(n)_{\bar{k}}$ is reduced, $H_{\bar{k}}$ is the reduced closed subscheme of $G_{\bar{k}}$ whose underlying space is the closure of $M_{\bar{k}}$. Thus H is geometrically reduced (EGA IV 4.6.1).

Coherence of the family implies that M is stable under the group law. The subset $M \times_k M$ is dense in $\mathrm{ens}(H \times_k H)$, and $H \times_k H$ is reduced (EGA IV 4.6.5); it follows that H is an algebraic subgroup of G. It is smooth over k, since it is geometrically reduced (Exposé $\mathrm{VI_A}$ 1.3.1), and it is commutative because all the $M(n)$ are commutative.

It remains to prove connectedness. Let H^0 be the identity component of H, let m be the number of geometric points of H/H^0, and let q^s be the q-primary part of m. For every n that is a power of q, the subgroup ${}_{q^s}M(n)$ is contained in H^0. Coherence and the prescribed type of $M(n)$ give

$$ {}_{q^s}M(nq^s) = M(n). $$

Hence H^0 contains every $M(n)$, and therefore $H^0 = H$.

We can now sharpen condition (c) of Theorem 4.1. By Lemma 4.6 there is, for each $t \in S$, a smallest closed subscheme H_t of G_t containing all the $M(n)_t$. Its formation commutes with extension of the residue field. Thus $H_t \otimes_t \bar{t}$ is contained in the affine closed subset F_t, and is affine; hence H_t itself is affine. Lemma 4.6 also says that H_t is a smooth, connected, commutative algebraic group. The structure theorem for such affine groups over an algebraically closed field (*Bible*, 4, Theorem 4) expresses H_t as a direct product of a torus T_t and a unipotent group U_t. Since every $M(n)_t$ is contained in T_t, minimality gives $H_t = T_t$. Consequently H_t is a torus.

We begin the proof of Theorem 4.1.

a) Uniqueness. This is Exposé IX 4.8(b).

b) The case in which S is the spectrum of a complete discrete valuation ring A with algebraically closed residue field k. Let K be the fraction field of A, let s and t be the closed and generic points of S, let J be the maximal ideal of A, and put

$$ S_m = \mathrm{Spec}(A/J^m), \qquad X_m = X \times_S S_m. $$

First case: the point in Theorem 4.1(b) is the generic point t. Let T' be the schematic closure of T_t in G. Its closed fibre T'_s is an algebraic subgroup of G_s, of dimension r, containing every $M(n)_s$, hence containing H_s. The torus H_s contains every $M(n)_s$, so it has rank at least r. Consequently H_s has the same underlying space as the identity component of T'_s.

The identity component $(T')^0$ of T' is then a subgroup prescheme of G, flat and separated (Exposé $\mathrm{VI_B}$ 5.2), whose generic fibre T_t is a torus and whose reduced closed fibre H_s is a torus. Hence $(T')^0$ is a torus (Exposé X 8.8); denote it by T. The groups ${}_nT$ and $M(n)$ are smooth over S, hence reduced, and have the same underlying space. They therefore coincide, and T is the required solution.

Second case: the point in Theorem 4.1(b) is the closed point s. After replacing G by the schematic closure in G of the smallest algebraic subgroup H_t containing the family $M(n)_t$ (Lemma 4.6), we may suppose that G_t is affine.

For every $m \geq 0$, Proposition 2.2 gives a unique sub-torus T_m of G_m lifting T_s and satisfying

$$ {}_nT_m = M(n)_m \qquad \text{for every } n \text{ that is a power of } q. $$

Put $T' = \mathbb{G}^r_{m,S}$. Since k is algebraically closed, T_s is split, and there is a k-isomorphism

$$ u_s : T'_s \xrightarrow{\sim} T_s. $$

It lifts uniquely to an S_m-isomorphism $u_m : T'_m \to T_m$ (Exposé IX 3.3). The coherent family $(u_m)_{m\in\mathbb{N}}$ defines a morphism of formal completions $\widehat{u} : \widehat{T'} \to \widehat{G}$, fitting into

$$\begin{array}{ccc} \widehat{T'} & \xrightarrow{\widehat{u}} & \widehat{G} \\ {\scriptstyle i}\downarrow & & \downarrow{\scriptstyle j} \\ T' & & G, \end{array}$$

We shall prove that $\widehat{u}$ is algebraizable, reducing first to the case in which G is affine.

Lemma 4.7.— *Let $S = \operatorname{Spec} A$, where A is a discrete valuation ring, and let X, Y be S-preschemes that are quasi-compact, quasi-separated, and flat over S. Then the canonical map*

$$\Gamma(X, \mathcal{O}_X) \otimes_A \Gamma(Y, \mathcal{O}_Y) \longrightarrow \Gamma(X \times_S Y, \mathcal{O}_{X\times_S Y})$$

is an isomorphism.

Let $f : X \to S$ and $g : Y \to S$ be the structural morphisms. Because X and Y are quasi-compact and quasi-separated, EGA I 9.2.2 and EGA IV 1.7.4 show that $f_*\mathcal{O}_X$ and $g_*\mathcal{O}_Y$ are quasi-coherent $\mathcal{O}_S$-algebras. Let $\widetilde{X}$ and $\widetilde{Y}$ be the corresponding affine S-schemes. Since Y is flat over S, EGA III 1.4.15 and EGA IV 1.7.21 give an isomorphism

$$\Gamma(\widetilde{X} \times_S Y, \mathcal{O}_{\widetilde{X}\times_S Y}) \xrightarrow{\sim} \Gamma(X \times_S Y, \mathcal{O}_{X\times_S Y}).$$

The scheme $\widetilde{X}$ is flat over S, because over A flatness is equivalent to torsion-freeness. Applying EGA III 1.4.15 again, with X and Y interchanged, yields

$$\begin{aligned} \Gamma(\widetilde{X}, \mathcal{O}_{\widetilde{X}}) \otimes_A \Gamma(\widetilde{Y}, \mathcal{O}_{\widetilde{Y}}) &\xrightarrow{\sim} \Gamma(\widetilde{X} \times_S \widetilde{Y}, \mathcal{O}_{\widetilde{X}\times_S \widetilde{Y}}) \\ &\xrightarrow{\sim} \Gamma(\widetilde{X} \times_S Y, \mathcal{O}_{\widetilde{X}\times_S Y}), \end{aligned}$$

which proves the lemma.

The S-group G is flat and of finite type over S, hence quasi-compact and quasi-separated. Applying the lemma to $G \times_S G$ gives

$$\Gamma(G, \mathcal{O}_G) \otimes_A \Gamma(G, \mathcal{O}_G) \xrightarrow{\sim} \Gamma(G \times_S G, \mathcal{O}_{G\times_S G}).$$

Thus the multiplication $m_G : G \times_S G \to G$ determines a homomorphism

$$\Gamma(G, \mathcal{O}_G) \longrightarrow \Gamma(G, \mathcal{O}_G) \otimes_A \Gamma(G, \mathcal{O}_G),$$

and hence an S-morphism

$$m_{\widetilde{G}} : \widetilde{G} \times_S \widetilde{G} \longrightarrow \widetilde{G},$$

where $\widetilde{G}$ is the affine S-scheme corresponding to $\Gamma(G, \mathcal{O}_G)$. The usual identities show that $m_{\widetilde{G}}$ makes $\widetilde{G}$ an S-group scheme and that the canonical morphism $v : G \to \widetilde{G}$ is a homomorphism.

Remark 4.8.— *The group $\widetilde{G}$ plays the role of a largest affine quotient of G. In fact it is an fpqc quotient of G, and is therefore of finite type over S (XVII, Appendix III, 2).*

In our situation the generic fibre G_t is affine, so $v_t : G_t \to \widetilde{G}_t$ is an isomorphism (EGA I 9.3.3). Since $\widetilde{G}$ is affine, the coherent family

$$w_m = v_m \circ u_m : T'_m \longrightarrow \widetilde{G}_m \qquad (m \in \mathbb{N})$$

comes from a unique S-homomorphism (Exposé IX 7.1)

$$w : T' \longrightarrow \widetilde{G}.$$

Let T_t be the sub-torus

$$T_t = v_t^{-1}(w_t(T'_t))$$

of G_t. Its rank is at most r. We show that it contains every $M(n)_t$. Let

$$u(n)_m : ({}_nT')_m \xrightarrow{\sim} M(n)_m$$

be the restriction of u_m. This coherent family comes from a unique S-isomorphism

$$u(n) : {}_nT' \xrightarrow{\sim} M(n),$$

because $M(n)$ is finite over S. For every $m \geq 0$,

$$w_m|_{({}_nT')_m} = (v_m \circ u_m)|_{({}_nT')_m} = (v \circ u(n))_m.$$

It follows from Proposition 1.6(a) that

$$w|_{{}_nT'} = v \circ u(n).$$

On the generic fibre,

$$v_t^{-1}(w_t(({}_nT')_t)) = u(n)_t(({}_nT')_t) = M(n)_t.$$

Thus T_t contains every $M(n)_t$, and consequently has rank r.

We conclude as in the first case. Let T'' be the schematic closure of T_t in G. Since T_t contains every $M(n)_t$, the closed fibre T''_s contains every $M(n)_s$, and hence contains T_s by the density theorem. On the other hand T'' is flat over S and T_t has dimension r, so T''_s has dimension r (Exposé $\mathrm{VI_B}$ 4). Therefore T_s has the same underlying space as the identity component of T''_s, and the identity component of T'' is the required sub-torus of G.

c) End of the proof. To prove existence of T, we may assume that S is reduced (Proposition 2.2). By Theorem 3.1, (ii)⇒(i), it is then enough to show that the set U of points $x \in S$ for which there exists a sub-torus T_x of G_x satisfying

$${}_nT_x = M(n)_x \qquad \text{for every } n \text{ that is a power of } q$$

equals $\mathrm{ens}(S)$. Such a torus is necessarily unique, and fpqc descent reduces its existence to existence after an extension of the residue field of x (Exposé IX 4.8(b)).

Since S is locally noetherian and connected and U is nonempty (it contains the point s of Theorem 4.1(b)), it is enough to prove the following: if $x, x' \in S$, if x is a specialization of x', and if one of these two points lies in U, then both lie in U. The usual method (EGA II 7.1.9) reduces this to the case where S is the spectrum of a complete discrete valuation ring with algebraically closed residue field, which was treated in part (b). This completes the proof of Theorem 4.1.

5. Representability of the functor of smooth subgroups equal to their connected normalizer

Proposition 5.1.— *Let S be a prescheme, let G be an S-group prescheme of finite presentation, and let H be a subgroup prescheme of G, smooth with connected fibres. Then:*

a) *the normalizer N of H in G is represented by a closed subprescheme of G, of finite presentation over S;*

b) *the following conditions are equivalent:*

   i) *the canonical immersion $H \to N$ is an open immersion;*

   ii) *N is smooth along the identity section, and its identity component, which is then representable (Exposé VI_B 3.10), equals H;*

   iii) *for every $s \in S$, one has $H_s = (N_s)^0$.*

Proof. The group prescheme H is locally of finite presentation over S, since it is smooth, and has connected fibres; it is therefore of finite presentation over S (Exposé $\mathrm{VI_B}$ 5.3.3). Part (a) follows from Exposé XI 6.11. The equivalence in (b), recalled here for reference, was proved in Exposé $\mathrm{VI_B}$ 6.5.1.

We can now state the main theorem of this section.

Theorem 5.2.— *Let S be a prescheme and G an S-group prescheme of finite presentation over S. Let $\mathcal{L}_G$, or simply $\mathcal{L}$, be the S-functor defined, for every S-prescheme S', by*

$$\mathcal{L}_G(S') = \left\{ \begin{array}{c} \text{subgroup preschemes of } G_{S'}, \text{ smooth over } S', \\ \text{with connected fibres, equal to their connected normalizer} \end{array} \right\}.$$

Then $\mathcal{L}$ is represented by an S-prescheme that is the union of an increasing family $(U_i)_{i\in\mathbb{N}}$ of open subpreschemes, each quasi-projective and of finite presentation over S, and hence in particular separated over S.

Initial reductions. For every $r \geq 0$, let $\mathcal{L}_r$ be the subfunctor of $\mathcal{L}$ defined by

$$\mathcal{L}_r(S') = \left\{ \begin{array}{c} H \subseteq G_{S'} : \ H \text{ is smooth with connected fibres,} \\ H \text{ equals its connected normalizer, and } \dim(H/S') = r \end{array} \right\}.$$

The fibre dimension of a smooth group is locally constant. Hence $\mathcal{L}_r \to \mathcal{L}$ is represented by an immersion that is both open and closed. It is therefore enough to prove the asserted representability and finiteness properties for every $\mathcal{L}_r$, for then

$$\mathcal{L} = \coprod_{r\in\mathbb{N}} \mathcal{L}_r.$$

For $n \geq 0$, an S-prescheme S', and a subgroup prescheme H of $G_{S'}$, denote by $H^{(n)}$ the n-th normal invariant of the identity section $S' \to H$ (EGA IV 16.1.2). Thus $H^{(n)}$ is a finite-type $\mathcal{O}_{S'}$-module corresponding to the n-th infinitesimal neighbourhood of the identity section of H. If H is smooth of relative dimension r, then $H^{(n)}$ is locally free of a rank $\varphi(n,r)$ depending only on n, r. Since H is a subprescheme of $G_{S'}$, there is a canonical epimorphism, compatible with base change,

$$G^{(n)} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'} \xrightarrow{\sim} G^{(n)}_{S'} \longrightarrow H^{(n)}.$$

Introduce the projective S-scheme

$$P_{\varphi(n,r)} = \mathrm{Grass}_{\varphi(n,r)}(G^{(n)})$$

(EGA I, 2nd ed., 9.7; see also Cartan Seminar 1960/61, Exposé 14 by A. Grothendieck). The assignment

$$H \longmapsto H^{(n)}$$

therefore defines a canonical morphism

$$u_{n,r} : \mathcal{L}_r \longrightarrow P_{\varphi(n,r)}.$$

The group G acts naturally on $G^{(n)}$, and hence on $P_{\varphi(n,r)}$, through

$$\mathrm{int} : G \longrightarrow \mathrm{Aut}_{S\text{-gr}}(G), \qquad g \longmapsto \mathrm{int}(g).$$

If S' is quasi-compact over S and $H \in \mathcal{L}_r(S')$, then for sufficiently large n one has (Exposé XI 6.11)

$$\mathrm{Norm}_{G_{S'}}(H) = \mathrm{Norm}_{G_{S'}}(H^{(n)}).$$

For each $n \geq 0$, define the subfunctor $\mathcal{L}_r^n$ of $\mathcal{L}_r$ by

$$\mathcal{L}_r^n(S') = \left\{ H \in \mathcal{L}_r(S') \;\middle|\; \mathrm{Norm}_{G_{S'}}(H) = \mathrm{Norm}_{G_{S'}}(H^{(n)}) \right\}.$$

Representability of $\mathcal{L}_r^n$. The integer r remains fixed through the proof, so we write $\mathcal{L}, \mathcal{L}^n, P_n, u_n$ in place of $\mathcal{L}_r, \mathcal{L}_r^n, P_{\varphi(n,r)}, u_{n,r}$. Let

$$v_n : \mathcal{L}^n \longrightarrow P_n$$

be the restriction of u_n. The definition of $\mathcal{L}^n$ and Proposition 5.1(b)(ii) show that v_n is a monomorphism. More precisely:

Lemma 5.3.— *The morphism v_n is an immersion of finite presentation. Consequently $\mathcal{L}^n$ is represented by an S-prescheme, quasi-projective and of finite presentation over S.*

After replacing S by P_n, the usual method reduces the assertion to the following. Let $Q \in P_n(S)$, and define a subfunctor F of the final functor h_S by

$$F(S') = \begin{cases} h_S(S'), & \text{if there exists } H \in \mathcal{L}^n(S') \text{ with } H^{(n)} = Q_{S'}, \\ \varnothing, & \text{otherwise.} \end{cases}$$

We must prove that $F \to S$ is an immersion of finite presentation.

Let N be the normalizer of Q in G. It is a subgroup prescheme of finite presentation over S, namely the inverse image of Q under

$$G \longrightarrow P_n, \qquad g \longmapsto g \cdot Q.$$

We claim that F is equivalently described by

$$F(S') = \begin{cases} h_S(S'), & N_{S'} \text{ is smooth along the identity section, of} \\ & \text{relative dimension } r, \text{ and } (N_{S'})^{(n)} = Q_{S'}, \\ \varnothing, & \text{otherwise.} \end{cases}$$

Call the first and second descriptions F_1 and F_2. Suppose $F_1(S') = h_S(S')$, and let $H \in \mathcal{L}^n(S')$ with $H^{(n)} = Q_{S'}$. Then

$$\begin{aligned}\mathrm{Norm}_{G_{S'}}(H) &= \mathrm{Norm}_{G_{S'}}(H^{(n)}) \\ &= \mathrm{Norm}_{G_{S'}}(Q_{S'}) = N_{S'}.\end{aligned}$$

By Proposition 5.1(b)(ii), $N_{S'}$ is smooth along the identity section and its identity component is H. Thus it has relative dimension r; since H is open in $N_{S'}$,

$$(N_{S'})^{(n)} = H^{(n)} = Q_{S'}.$$

Hence $F_2(S') = h_S(S')$.

Conversely, suppose $F_2(S') = h_S(S')$. The identity component of $N_{S'}$ is then represented (Exposé $\mathrm{VI_B}$ 3.10) by a subgroup prescheme H, smooth over S', with connected fibres of dimension r. Since H is invariant and open in $N_{S'}$,

$$\begin{aligned}N_{S'} &\subseteq \mathrm{Norm}_{G_{S'}}(H) \subseteq \mathrm{Norm}_{G_{S'}}(H^{(n)}) \\ &= \mathrm{Norm}_{G_{S'}}((N_{S'})^{(n)}) = \mathrm{Norm}_{G_{S'}}(Q_{S'}) = N_{S'}.\end{aligned}$$

All inclusions are equalities. The first says that H equals its connected normalizer, and the second says $H \in \mathcal{L}^n(S')$. Hence $F_1 = F_2$.

We retain the second description. Condition (a) is represented by an immersion of finite presentation, by the following lemma.

Lemma 5.4.— *Let S be a prescheme, let X be locally of finite presentation over S, let $\sigma : S \to X$ be a section, let $r \geq 0$, and define the subfunctor L of S by*

$$L(S') = \begin{cases} h_S(S'), & X_{S'} \text{ is smooth along } \sigma_{S'}, \text{ of relative} \\ & \text{dimension } r \text{ at the points of } \sigma_{S'}(S'), \\ \varnothing, & \text{otherwise.} \end{cases}$$

Then:

a) *$L \to S$ is an immersion of finite presentation;*

b) *let $\mathcal{J}$ be the conormal sheaf of $S \to X$. If for every $s \in S$ the vector space $\mathcal{J} \otimes_{\mathcal{O}_{S,s}} \kappa(s)$ has rank at most r, then $L \to S$ is a closed immersion.*

Proof. The functor L is local on S, so we may suppose S affine. After replacing X by a neighbourhood of $\sigma(S)$, we may suppose X of finite presentation, and then reduce to noetherian S by EGA IV 8.9. In part (b), use also compatibility of the conormal sheaf with base change (EGA IV 16.6.4) and constructibility of the rank of the fibres of $\mathcal{J}$.

For an S-prescheme S', let $\mathcal{J}' = \mathcal{J}_{S'}$, let $S^\bullet(\mathcal{J}')$, canonically isomorphic to $S^\bullet(\mathcal{J})_{S'}$, be the symmetric algebra of $\mathcal{J}'$ over $\mathcal{O}_{S'}$, let $\mathrm{Gr}^\bullet(\sigma_{S'})$ be the graded algebra associated with $\sigma_{S'}$ (EGA IV 16), and let

$$\sigma_{n,S'} : S^n(\mathcal{J}') \longrightarrow \mathrm{Gr}^n(\sigma_{S'})$$

be the canonical epimorphism. By EGA IV 17.12.3 and EGA 0_{IV} 19.5.4, $X_{S'}$ is smooth along $\sigma_{S'}$ of relative dimension r if and only if:

i) $\mathcal{J}'$ is locally free of rank r;

ii) $\sigma_{n,S'}$ is an isomorphism for every $n \geq 1$.

TDTE IV, Lemma 3.6, shows that the functor making $\mathcal{J}$ locally free of rank r is represented by a subprescheme S_1, closed in S in case (b). Replacing S by S_1, assume that $\mathcal{J}$ is locally free of rank r. Proceed by induction on n. Suppose a closed subprescheme S_{n-1} represents the functor making $\sigma_{q,S'}$ injective for $q \leq n-1$. The subfunctor[6] making $\sigma_{n,S'}$ injective is represented by a closed subprescheme S_n of S_{n-1}.

Indeed, after replacing S by S_{n-1}, all $\sigma_{q,S}$ for $q \leq n-1$ are isomorphisms. The $(n-1)$-st normal invariant $X^{(n-1)}$ of σ_S has a filtration with successive quotients $\mathrm{Gr}^0(\sigma_S), \ldots, \mathrm{Gr}^{n-1}(\sigma_S)$, all locally free; hence $X^{(n-1)}$ is flat over S. Compatibility of the normal invariants with base change gives

$$\mathrm{Gr}^n(\sigma_{S'}) = \ker\Big(X^{(n)}_{S'} \to X^{(n-1)}_{S'}\Big) = \mathrm{Gr}^n(\sigma)_{S'},$$
$$\sigma_{n,S'} = (\sigma_{n,S})_{S'}.$$

Thus we must represent the functor making $\sigma_{n,S}$ injective. Locally we may suppose S affine and $S^n(\mathcal{J})$ free. The required functor is represented by the closed subscheme defined by the ideal generated by the coordinates of $\ker \sigma_{n,S}$ in a basis of $S^n(\mathcal{J})$.

Since S is noetherian, the descending chain (S_n) stabilizes. Its stable value represents L, proving the lemma.

Return to $\mathcal{L}^n$. After replacing S by the subprescheme provided by Lemma 5.4, assume N smooth along the identity section of relative dimension r. Then $\mathcal{L}^n$ is the coincidence functor of two sections $h, g : S \to P_n$, corresponding to Q and $N^{(n)}$. It is therefore represented by the inverse image of the diagonal of $P_n \times_S P_n$ under the finite-presentation morphism $h \times_S g$. This proves Lemma 5.3.

The transition morphisms $\mathcal{L}^n \to \mathcal{L}^m$. If $H \in \mathcal{L}^n(S')$, then $H \in \mathcal{L}^m(S')$ for every $m \geq n$. Thus there are natural monomorphisms

$$u^m_n : \mathcal{L}^n \longrightarrow \mathcal{L}^m \qquad (m \geq n).$$

Lemma 5.5.— *The morphism u^m_n is an open immersion.*

After a base change, it is enough to consider $H \in \mathcal{L}^m(S)$ and

$$N = \mathrm{Norm}_G(H) = \mathrm{Norm}_G(H^{(m)}), \qquad N' = \mathrm{Norm}_G(H^{(n)}).$$

Let D be the coincidence functor of N, N': $D(S') = h_S(S')$ if $N_{S'} = N'_{S'}$, and $D(S') = \varnothing$ otherwise. We must show that $D \to S$ is an open immersion.

The same functor is obtained by requiring that the immersion $H \to N'$ become open. One implication follows from Proposition 5.1. Conversely, if $H_{S'} \to N'_{S'}$ is open, then, because H has connected fibres, $H_{S'}$ is the identity component of $N'_{S'}$ (Exposé $\mathrm{VI_B}$ 3.10), hence is invariant in $N'_{S'}$. Thus $N'_{S'} \subseteq N_{S'}$. The opposite inclusion always holds, so equality follows. Since H, N' are of finite presentation and H is flat over S, Exposé $\mathrm{VI_B}$ 2.6 shows that $D \to S$ is open.

End of the proof of Theorem 5.2. The functors $\mathcal{L}^n$ are represented, and the transition morphisms u^m_n are compatible open immersions. There is therefore an S-prescheme X, the union of an increasing sequence of open subpreschemes $(X_i)_{i\in\mathbb{N}}$, such that X_i represents

[6] The editors replaced "functor" by "subfunctor" here, and ask whether the intended wording is instead "which makes $\sigma_{q,S'}$ injective for $q \leq n$".

$\mathcal{L}^i$ and $X_i \to X_j$ corresponds to u_i^j. In the category of sheaves for the Zariski topology on Sch/S,

$$X = \varinjlim_i X_i, \qquad \mathcal{L} = \varinjlim_i \mathcal{L}^i.$$

Thus X represents $\mathcal{L}$, completing the proof.

Remark 5.6.— *Suppose all residue characteristics of S are zero. Then, for every $r \geq 0$, $\mathcal{L}_r = \mathcal{L}_r^1$, so $\mathcal{L}_r$ is represented by an S-prescheme quasi-projective and of finite presentation over S.*

Indeed, for $H \in \mathcal{L}_r(S')$, it suffices to prove that

$$H \longrightarrow N = \mathrm{Norm}_{G_{S'}}(H^{(1)})$$

is an open immersion. Because H is flat and both H, N are of finite presentation, this may be checked on the fibres (Exposé $\mathrm{VI_B}$ 2.6). Cartier's theorem (Exposé $\mathrm{VI_B}$ 1.6) gives, for a connected algebraic subgroup H of an algebraic group in characteristic zero,

$$\mathrm{Norm}_G(H) = \mathrm{Norm}_G(\mathrm{Lie}\, H) = \mathrm{Norm}_G(H^{(1)}).$$

7

In nonzero residue characteristic the subfunctors $\mathcal{L}_r^n$ can form a strictly increasing sequence, even when S is quasi-compact, and then $\mathcal{L}_r$ is not represented by an S-prescheme quasi-compact over S. For example, over a field k of characteristic $p > 0$, let

$$T = \mathbb{G}_m \times \mathbb{G}_m, \qquad U = \mathbb{G}_a \times \mathbb{G}_a,$$

and let $G = T \ltimes U$, where $(t, t') \cdot (u, u') = (tu, t'u')$. For $n > 0$, let $U_n \subset U$ be defined by $u' = u^{p^n}$, and let $T_n \subset T$ be defined by $t' = t^{p^n}$. Then T_n acts on U_n, and $G_n = T_n U_n$ is smooth, connected, and equal to its normalizer in G. For every m, the distinct groups G_n, $n \geq m$, have the same infinitesimal neighbourhood of order p^m.

Remark 5.7.— *There is a canonical invertible sheaf L on $\mathcal{L}$ whose restriction to every open subset of $\mathcal{L}$ quasi-compact over S is S-ample. One may take*

$$L = (\det(\mathrm{Lie}\, H))^{-1},$$

where $H \subseteq G_{\mathcal{L}}$ is the universal subgroup.

Recall that for a finite-rank locally free sheaf $\mathcal{F}$, its determinant restricts on the open-and-closed locus where $\mathrm{rank}\, \mathcal{F} = r$ to $\bigwedge^r \mathcal{F}$. It is enough to restrict to $\mathcal{L}_r^n$. Let $v_n : \mathcal{L}_r^n \to P_n$ be the canonical immersion, and let Q be the universal locally free quotient on the Grassmannian P_n. By construction,

$$v_n^* Q = H^{(n)}.$$

Since $\det Q$ is the canonical ample sheaf on P_n (EGA I, 2nd ed., 9.7), $\det H^{(n)}$ is ample relative to S (EGA II 4.6.13(i) bis).

Let $\mathcal{J} = H^{(1)}$ be the conormal sheaf, and let $S^q(\mathcal{J})$ be the homogeneous degree-q part of its symmetric algebra. Smoothness of H gives

$$\det H^{(n)} \xrightarrow{\sim} \bigotimes_{1 \leq q \leq n} \det S^q(\mathcal{J}).$$

[7] For example, one may apply Proposition II.6.1 of M. Demazure and P. Gabriel, *Groupes algébriques* I, Masson–North Holland, 1970.

For every locally free $\mathcal{J}$ of rank r and every $q > 0$ there is a canonical isomorphism

$$\det S^q(\mathcal{J}) \xrightarrow{\sim} (\det \mathcal{J})^{\otimes s},$$

where $s > 0$ depends only on r, q. Thus, for some $s > 0$,

$$\det H^{(n)} \simeq (\det \mathcal{J})^{\otimes s}.$$

Since $\det \mathcal{J} = (\det \operatorname{Lie} H)^{-1}$, EGA II 4.5.6 proves that L is S-ample.

Remark 5.8.— *Let G, H be S-group preschemes of finite presentation and let $i : H \to G$ be a monomorphism. Suppose H is smooth over S with connected fibres. The normalizer $N = \operatorname{Norm}_G(H)$ is then represented by a closed subgroup prescheme of G, of finite presentation over S (Exposé XI 6.11). If, in addition, N is smooth along the identity section and has the same relative dimension as H, then $H = N^0$; in particular H is a subgroup prescheme of G.*

Indeed, N^0 is represented by an open subgroup prescheme of N, smooth over S (Exposé $\mathrm{VI_B}$ 3.10), and i factors through N^0. For every $s \in S$, the connected smooth algebraic groups $H_s, (N^0)_s$ have the same dimension and hence coincide. Since H is flat, $H \to N^0$ is an isomorphism (EGA IV 17.9.5). Thus the functor $\mathcal{L}$ of this section may equivalently be described as the functor of subgroup preschemes H of G that are smooth over S, have connected fibres, and equal their connected normalizer.

6. Functor of Cartan subgroups and functor of parabolic subgroups

When G is a smooth connected algebraic group defined over an algebraically closed field k, sub-tori of G, maximal sub-tori, Cartan subgroups (Exposé XII 1), Borel subgroups (Exposé XIV 4.1), and parabolic subgroups (Exposé XIV 4.8 bis) have already been defined. We extend these notions to a group prescheme over an arbitrary base as follows.

Definition 6.1. *Let S be a prescheme, let G be an S-group prescheme of finite presentation, let H be an S-group prescheme, and let $i : H \to G$ be an S-monomorphism making H a subgroup of G. We say that H is a sub-torus of G (respectively, a maximal sub-torus, a Cartan subgroup, a Borel subgroup, or a parabolic subgroup) if:*

i) *i) H is smooth over S.*

ii) *ii) For every geometric point $\bar{s}$ above S, $H_{\bar{s}}$ is a sub-torus of $(G_{\bar{s}})^0_{\mathrm{red}}$ (respectively, a maximal sub-torus, a Cartan subgroup, a Borel subgroup, or a parabolic subgroup).*

Remarks 6.1 bis.

a) If the S-group H is a sub-torus of G (respectively, ...), its fibres are connected, and consequently H is of finite presentation over S (Exposé $\mathrm{VI_B}$ 5.3.3).

b) If H is a sub-torus of G, then H is a torus in the sense of Exposé IX, as follows immediately from Exposé X 8.1. Moreover, the monomorphism $i : H \to G$ is an immersion (see 8.3 below).

c) If G is smooth over S, with connected fibres, and if H is a Cartan subgroup of G (respectively, a Borel subgroup or a parabolic subgroup), the monomorphism $i : H \to G$ is an immersion. Thus our definitions coincide with those introduced in Exposés XII and XIV. Indeed, H is then equal to its connected normalizer (by XII 6.6(c), XIV 4.8 and 4.8 bis), and it suffices to apply 5.8.

Definition 6.1 ter. *Let S be a prescheme, let G be an S-group prescheme locally of finite type, and let s be a point of S. The* ***nilpotent rank*** *of G at s, denoted by $\rho_n(s)$, is the dimension of the Cartan subgroups of $(G_s)^0_{\mathrm{red}}$. The reductive rank $\rho_r(s)$, unipotent rank $\rho_u(s)$, and abelian rank $\rho_{\mathrm{ab}}(s)$ are defined similarly (see Exposé X 8.7).*

If G is now a smooth connected algebraic group defined over an algebraically closed field k, recall that the **radical** of G, denoted by $\mathrm{rad}(G)$, is the largest invariant smooth connected solvable algebraic subgroup of G; $G/\mathrm{rad}(G)$ is then semisimple (use Exposé XII 6.1 to reduce to the affine case). If G is moreover affine, the **unipotent radical** $\mathrm{rad}^u(G)$ is defined as the largest invariant smooth connected unipotent algebraic subgroup of G; $G/\mathrm{rad}^u(G)$ is then reductive.

Proposition 6.2. *Let S be a prescheme, let G and H be two S-group preschemes of finite presentation, and let $i : H \to G$ be an S-monomorphism making H a subgroup of G. Let $P(s)$ be one of the following properties concerning a point s of S:*

i) *$(G_{\bar{s}})^0_{\mathrm{red}}$ is an abelian variety (respectively, is affine, is a torus, or is unipotent).*

ii) *$(H_{\bar{s}})^0_{\mathrm{red}}$ is a maximal torus of $G_{\bar{s}}$.*

iii) *$(H_{\bar{s}})^0_{\mathrm{red}}$ is the centralizer in $(G_{\bar{s}})^0_{\mathrm{red}}$ of a torus of $G_{\bar{s}}$ (respectively, is a Cartan subgroup of $G_{\bar{s}}$).*

iv) *$(H_{\bar{s}})^0_{\mathrm{red}}$ is a Borel subgroup (respectively, a parabolic subgroup) of $G_{\bar{s}}$.*

v) *$(H_{\bar{s}})^0_{\mathrm{red}}$ is the radical of $G_{\bar{s}}$ (respectively, $(G_{\bar{s}})^0_{\mathrm{red}}$ is semisimple).*

vi) *$G_{\bar{s}}$ is affine and $(H_{\bar{s}})^0_{\mathrm{red}}$ is the unipotent radical of $G_{\bar{s}}$ (respectively, $(G_{\bar{s}})^0_{\mathrm{red}}$ is reductive).*

Then the set E of points s of S for which $P(s)$ holds is locally constructible (EGA 0_{III}, 9.1.11).

Remark 6.2.1. This proposition complements Exposé $\mathrm{VI_B}$, §10. The structure of E can be described more precisely by using semicontinuity theorems (see Exposé X 8.7); we shall see an example below.

Proof of 6.2. Note that if S is the spectrum of a field, E is invariant under extension of that field. A standard reduction (EGA IV 9) then allows us to reduce to the case where S is noetherian and integral, with generic point η. One must show that E or $\mathrm{ens}(S) \setminus E$ contains a neighbourhood of η (EGA IV 9.2.1). One may assume S affine of ring A and field of fractions K. If L is a finite extension of K, it is immediate that there exists an A-subalgebra B of L, finite over A, having L as field of fractions. The canonical morphism $S' \to S$, where $S' = \mathrm{Spec}\, B$, is dominant, of finite presentation, so the image of a non-empty open subset of S' contains a non-empty open subset of S (EGA IV 1.8.4). From the viewpoint that interests us, we may therefore replace S by S', hence replace K by a finite extension L. Thus we may choose L so that $(G_L)_{red}$ and $(H_L)_{red}$ are smooth over L (EGA IV 4.6.6). Possibly restricting S', we may assume that G_{red} and H_{red} are group preschemes smooth over S (Exposé $\mathrm{VI_B}$, §10, and EGA IV 17). In view of the properties to be proved, we may replace G and H by their reduced identity components (Exposé $\mathrm{VI_B}$ 10.9), and hence assume that G and H are smooth over S with connected fibres. Finally, we may assume that H is a closed subgroup prescheme of G (Exposé $\mathrm{VI_B}$ 10.4).

Proof of i). Possibly after a finite extension of K, we may assume that G_η admits a "Chevalley decomposition", i.e. is an extension of an abelian variety D_η by a smooth connected linear algebraic group F_η (Séminaire Bourbaki 1956/57, no. 145). By Exposé

$\mathrm{VI_B}$ 10.16, there is an open neighbourhood U of η over which this generic extension comes from an extension

$$1 \longrightarrow F \longrightarrow G|_U \longrightarrow D \longrightarrow 1.$$

One may moreover assume that F and D are smooth over U with connected fibres, that F is affine over U, and that D is proper over U (EGA IV 8, 9 and 17). For every point s of U, (D_s, F_s) is then the Chevalley decomposition of G_s. Consequently, G_s is an abelian variety (respectively, is affine) if and only if F_s (respectively, D_s) is the unit group; this is a constructible condition (EGA IV 9.2.6.1).

To establish the last two assertions of (i), we may, by the preceding, assume that G is affine over S. Let q be a prime number invertible on S, and let ${}_qG$ be the "kernel" of the q-th-power morphism in G. It follows easily from the structure of affine algebraic groups that G_s is a torus (respectively, is unipotent) if and only if

a) ${}_qG_s$ is quasi-finite, which is a constructible property (EGA IV 9.3.2), and

b) ${}_qG_s$ has q^r geometric points, where r is the relative dimension of G over S (respectively, ${}_qG_s$ has a single point).

The function

$$s \longmapsto (\text{number of geometric points of } {}_qG_s)$$

is constructible (EGA IV 9.7.9). This completes the proof of (i).

Proof of iii). **a) Case of the centralizer of a torus.** Suppose

$$H_\eta = \mathrm{Centr}_{G_\eta}(T_\eta),$$

where T_η is a torus of G_η. We shall show that H_s is the centralizer of a sub-torus of G_s for s in a neighbourhood of η. By (i), after possibly restricting S, we may assume that T_η comes from a sub-torus T of G. Then $Z = \mathrm{Centr}_G(T)$ is represented (Exposé XI 6.11) by a subgroup prescheme of G. Since H and Z coincide generically, they coincide over a neighbourhood of η. Thus the set E of points s of S for which H_s is the centralizer in G_s of a sub-torus of G_s is ind-constructible (EGA IV 1). This will suffice in Lemma 6.6 below to prove that E is open in S, and hence, *a fortiori*, locally constructible.

b) Case of a Cartan subgroup. Suppose that H_η is a Cartan subgroup of G_η. We shall show that H_s is a Cartan subgroup of G_s for every s in a neighbourhood of η. The group H_η is the centralizer in G_η of a torus of G_η, and is nilpotent (Exposé XII 6.6). By (a) and Exposé $\mathrm{VI_B}$ 8.4, H_s has the same properties for every s in some neighbourhood U of η. For every $s \in U$, the group H_s therefore has the same reductive rank as G_s, and its unique maximal torus is central (Exposé XII 6.7). Hence H_s is the centralizer of a maximal torus of G_s, that is, a Cartan subgroup of G_s.

Suppose now that H is not a Cartan subgroup of G, and let us show that H_s is not a Cartan subgroup of G_s for s in a neighborhood U of η. In view of the assertion provisionally admitted in (a) above, we may restrict to the case where H is the centralizer in G of a sub-torus T. But then H_η contains a Cartan subgroup C_η of H_η. We have just seen that, possibly restricting S, C_η extends to a Cartan subgroup C of G, which one may assume contained in H. By hypothesis H_η strictly contains C_η, so H_s strictly contains C_s for s in a neighborhood U of η (EGA IV 9.5.2); *a fortiori*, H_s is not

a Cartan subgroup of G_s for s in U.

Proof of ii). Suppose H_η is a maximal torus of G_η and let C_η be its centralizer in G_η. By i) and iii), H is a torus over a neighborhood U of η and $C = \mathrm{Centr}_{G|U}(H|U)$ is a Cartan subgroup of $G|U$. To prove that H is a maximal torus of G over a neighborhood of η, we

may then replace G by C, then by the linear component F of a Chevalley decomposition of C (cf. i)). Let q be an integer invertible on S, ${}_qF$ the kernel of the q-th-power morphism in F. Since F_s is affine, nilpotent, smooth and connected, F_s is the direct product of its maximal torus T_s by a unipotent group (*Bible* 6-04), so ${}_qF_s = {}_qT_s$. Since H_η is a maximal torus, ${}_qH_\eta = {}_qF_\eta$, and consequently ${}_qH = {}_qF$ over a neighborhood V of η. For every point s of V, ${}_qH_s = {}_qT_s$, so $H_s = T_s$ is a maximal torus.

Suppose now that H_η is not a maximal torus of G_η. By i), we may restrict to the case where H_η is a torus, then assume that it is contained in a strictly larger torus T_η. The latter extends to a torus T strictly containing H over a neighborhood U of η. *A fortiori*, H_s is not a maximal torus for $s \in U$.

Proof of iv). Possibly restricting S, we may assume that the center Z of G is representable (Exp. $\mathrm{VI_B}$ 10.11) and flat over S, as well as the quotient G/Z (*loc. cit.*). The property "H_s contains Z_s" is constructible (EGA IV 9.5.2) and every parabolic subgroup of G_s contains Z_s (Exp. XIV 4.9 a)); this allows us to replace G by G/Z, hence assume G affine over S (Exp. XII 6.1 and i)). We may further

assume that G/H is representable, but then H_s is a parabolic subgroup of G_s if and only if $(G/H)_s$ is proper (*Bible* 6 Th. 4 b)), which is an ind-constructible property (EGA IV 9.3.5). So E is ind-constructible, and this will suffice for us to prove that E is open (Lemma 6.6), hence locally constructible.

Let us now examine the case of Borel subgroups. If H_η is a Borel subgroup of G_η, i.e. a solvable parabolic subgroup of G_η, what precedes and Exposé $\mathrm{VI_B}$, 8.4, entail that these properties remain true at every point s of a neighborhood of η. If now H_η is not a Borel subgroup of G_η, to prove that the same holds at points s of a neighborhood of η, we may restrict (in view of what precedes) to the case where H_η is a parabolic subgroup, then assume that H_η contains a Borel subgroup B_η. We have just shown that the latter extends to a Borel subgroup B of G over a neighborhood U of η. Since H_η strictly contains B_η, H_s strictly contains B_s at every point of an open subset V, and H_s is not a Borel subgroup of G_s for $s \in V$.

Proof of v). Suppose H_η is the radical of G_η. The group H_η is then invariant in G_η, solvable (smooth and connected); the same is therefore true for H_s for s belonging to a neighborhood U of η (Exp. $\mathrm{VI_B}$ 8 and 10), so for $s \in U$, H_s is contained in the radical of G_s. Replacing G by G/H (Exp. $\mathrm{VI_B}$ 10), we must

prove that if G_η is semisimple, then G_s is semisimple at every point of a neighborhood V of η. Using i) and ii), one may assume that G is affine over S and possesses a maximal torus T. Let W be the Weyl group of T (Exp. XII 2), which is quasi-finite and étale over S, hence finite and étale over an open subset V. It then follows from the elementary properties of roots (Exp. XIX 1.12) that G is semisimple over V.

Suppose now that H_η is not the radical of G_η. Possibly replacing K by a finite extension L, we may assume that G_η admits a radical R_η. By what precedes, R_η extends to a subgroup prescheme R of $G|_U$ such that for every $s \in U$, R_s is the radical of G_s. By hypothesis, $R_\eta \neq H_\eta$. So $R_s \neq H_s$ for $s \in V$. It remains to prove that if G_η is not semisimple, neither is G_s at neighboring points, but this is a particular case of what precedes (take $H =$ unit group).

Proof of vi). The proof is entirely analogous to that of v), in view of i), and is left to the care of the reader.

Corollary 6.3. *Let S_0 be a quasi-compact prescheme, let $(S_i)_{i\in L}$ be a projective system of S_0-preschemes affine over S_0, and let $S = \varprojlim S_i$ (EGA IV 8.2). Let G_0 be a group prescheme of finite presentation over S_0, set*

$$G_i = G_0 \times_{S_0} S_i, \qquad G = G_0 \times_{S_0} S,$$

and let H be a subgroup of G. If H is a sub-torus of G (respectively, a maximal sub-torus, a Cartan subgroup, a Borel subgroup, or a parabolic subgroup), then there exist an index $i \in L$ and a subgroup H_i of G_i such that

$$H = H_i \times_{S_i} S$$

and H_i is a sub-torus of G_i (respectively, ...).

Indeed, H is smooth with connected fibres, hence of finite presentation over S (Exposé $\mathrm{VI_B}$ 5.3.3). By Exposé $\mathrm{VI_B}$, §10, there exist $i \in L$ and a subgroup H_i of G_i, smooth over S_i, such that $H = H_i \times_{S_i} S$. Corollary 6.3 then follows from Definition 6.1, Proposition 6.2 and EGA IV 9.3.3.

Corollary 6.3 bis. *Let S be a prescheme and let G be an S-group prescheme of finite presentation. Then the functions $\rho_n, \rho_r, \rho_u, \rho_{\mathrm{ab}}$ (cf. 6.1 ter) are locally constructible on S.*

It suffices to show (EGA IV 9.) that if S is a noetherian integral scheme with generic point η, the functions in question are constant on a neighborhood of η. Possibly replacing S by a scheme S' finite over S and dominating S, we may assume that G_η admits a Cartan subgroup C_η with a Chevalley decomposition $1 \to L_\eta \to C_\eta \to A_\eta \to 1$. The argument made in 6.2 i) proves that this decomposition extends to a Chevalley decomposition over a neighborhood of η:

$$1 \longrightarrow L \longrightarrow C \longrightarrow A \longrightarrow 1.$$

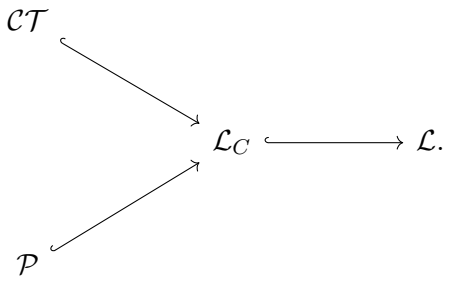
Moreover, one may assume that C is a Cartan subgroup of G (6.3) and that the maximal torus T_η of L_η extends to a maximal torus T of L (6.3). The corollary follows immediately from this and from the definitions.

6.4.0. Let S be a prescheme, G an S-prescheme in groups of finite presentation, and $\mathcal{L}$ the functor of subgroups of G that are smooth, have connected fibres, and are equal to their connected normalizer (cf. §5). The functor $\mathcal{L}$ is representable (5.2 and 5.8). The rest of this section is devoted to certain subfunctors of $\mathcal{L}$. More precisely, define $\mathcal{L}_C$ (resp. $\mathcal{CT}$, resp. $\mathcal{P}$) as follows: for every S-prescheme S', the set $\mathcal{L}_C(S')$ (resp. $\mathcal{CT}(S')$, resp. $\mathcal{P}(S')$) consists of the subgroups H of $G_{S'}$ that are smooth over S', have connected fibres, are equal to their connected normalizer, and are such that, for every point s' of S', $H_{s'}$ contains a Cartan subgroup (6.1) of $G_{s'}$ (resp. is the centralizer in $(G_{s'})^0_{\mathrm{red}}$ of a subtorus of $G_{s'}$, resp. is a parabolic subgroup (6.1) of $G_{s'}$).

Theorem 6.4. *Let S be a prescheme and G an S-prescheme in groups of finite presentation. The S-functors $\mathcal{L}_C$, $\mathcal{CT}$, and $\mathcal{P}$ defined in 6.4.0 are representable by S-preschemes that are quasi-projective and of finite presentation over S.*

Remark 6.5. If G has smooth fibres—for example, if G is smooth over S, or if the residue characteristics of S are zero (Exposé $\mathrm{VI_B}$, 1.6.1)—then every subgroup H of G, smooth over S with connected fibres, such that H_s contains a Cartan subgroup of $(G_s)^0$ for every point s of S, is necessarily equal to its connected normalizer (and hence is an element of $\mathcal{L}_C(S)$). Indeed, by 5.1 iii) we may assume that S is the spectrum of a field, in which case the property was noted at the end of the statement of Exposé XIII, 2.1.

There are natural monomorphisms



Let us show that these monomorphisms are open immersions of finite presentation (which will already prove, in view of 5.2, that $\mathcal{L}_C$, $\mathcal{CT}$, $\mathcal{P}$ are representable by S-preschemes, union of an increasing sequence of open subpreschemes, quasi-projective and of finite presentation over S). Now this will follow, by the usual technique, from the following lemma:

Lemma 6.6. *Let S be a prescheme, G an S-prescheme in groups of finite presentation, and H a subgroup of G, smooth with connected fibres. The set of points s of S such that H_s contains a Cartan subgroup of G_s (resp. is equal to the centralizer in $(G_s)^0_{\mathrm{red}}$ of a torus of G_s) is open in S. If, moreover, H is equal to its connected normalizer,*[8] *then the set of points s of S such that H_s is a parabolic subgroup of G_s is also open in S.*

The assertion to be proved is local on S, which allows us to assume S affine, then, by EGA IV 8.1 and 6.3, S noetherian. Denote by E the set of points of S having the property in question. It then follows from the assertions effectively proved in 6.2 that E is ind-constructible. But S is noetherian, so to prove that E is open, it suffices to show that E is stable under generizations (EGA IV 1.10.1). Using EGA II 7.1.9, we are finally led to prove that if S is the spectrum of a discrete valuation ring, and if the closed point s belongs to E, then so does the generic point t.

We shall need the following lemma:

Lemma 6.7. *Let A be a complete noetherian local ring, $S = \operatorname{Spec} A$, s the closed point of S, H an S-prescheme in groups, smooth with connected fibres, and T_s a subtorus of H_s. Then:*

i) there exists a closed subgroup prescheme C of H, smooth with connected fibres, such that $C_s = \operatorname{Centr}_{H_s}(T_s)$;

ii) for every point t of S, C_t is the centralizer in H_t of a subtorus T_t of H_t.

Proof of 6.7. Let T' be an S-torus for which there is an isomorphism $u_0 : T'_s \xrightarrow{\sim} T_s$ (Exposé X, 4.6). Let $\mathfrak{m}$ be the maximal ideal of A, and put $A_n = A/\mathfrak{m}^n$, $S_n = \operatorname{Spec} A_n$, $H_n = H \times_S S_n$, and so on. Since H is smooth over S, for every integer $n > 0$ there is an S_n-group morphism

$$u_n : T'_n \longrightarrow H_n$$

lifting u_0 (Exposé IX, 3.6), and by induction on n we may assume that u_n lifts u_{n-1}. Let q be a prime invertible on S. For every integer ℓ that is a power of q, write ${}_\ell u_n$ for the restriction of u_n to ${}_\ell T'_n$. For fixed ℓ and varying n, the morphisms ${}_\ell u_n$ form a projective system and therefore arise from a unique S-group morphism

$${}_\ell u : {}_\ell T' \longrightarrow H$$

[8] This hypothesis is in fact superfluous; see Exposé XVII, Appendix III, 3.

(1.6 a)). Since H is separated (Exposé $\mathrm{VI_B}$, 5.2) and u_0 is a monomorphism, ${}_\ell u$ is a monomorphism (Exposé IX, 6.8), and even a closed immersion because it is finite, ${}_\ell T'$ being finite over S. Denote its image by $M(\ell)$. The family of subgroups of multiplicative type $M(\ell)$ is clearly coherent in the sense of 4.1. Put

$$C_\ell = \mathrm{Centr}_H(M(\ell)).$$

This is represented by a closed subgroup prescheme (2.5), since H is separated, and is smooth over S (Exposé XI, 2.4). The C_ℓ form a filtered decreasing family of closed subschemes and are therefore stationary, since H is noetherian. Their stationary value is a smooth closed subgroup C such that $C_s = \mathrm{Centr}_{H_s}(T_s)$, by the density theorem (Exposé IX, 4.7). It remains to show that for every point t of S, C_t is the centralizer in H_t of a subtorus T_t; this will also imply that C_t is connected. This follows from the more precise lemma below, applied to the family $M(\ell)_t$ of subgroups of H_t.

Lemma 6.8. *Let G be a connected algebraic group over a field k, let $r > 0$ be an integer, and let q be an integer prime to the characteristic*[9] *of k. Let $M(\ell)$, where ℓ ranges over the powers of q, be a coherent family of subgroups of G, of multiplicative type and of type $(\mathbb{Z}/\ell\mathbb{Z})^r$ (cf. 4.6). Let M be the algebraic subgroup of G generated by the $M(\ell)$ (*loc. cit.*), and let T be the unique maximal torus of M (cf. 3.4). Then, for all sufficiently large ℓ,*

$$\mathrm{Centr}_G(T) = \mathrm{Centr}_G(M) = \mathrm{Centr}_G(M(\ell)).$$

The last equality is clear. To prove the first, introduce the centre Z of G, put $G' = G/Z$, let M' (resp. T') be the image of M (resp. T) in G', and let K be the inverse image of T' in G, that is, the algebraic subgroup of G generated by T and Z. It plainly suffices to prove $K \supset M$, or equivalently $T' = M'$. Now M is smooth and connected (4.6), while G' is affine (Exposé XII, 6.1); hence M' is the direct product of its maximal torus T' (Exposé XII, 6.6 d)) and a unipotent group (*Bible* 4, Th. 4), after assuming k algebraically closed. The image of $M(\ell)$ in M' is therefore contained in T'. Thus the inverse image of T' in M contains $M(\ell)$ for every ℓ, and consequently is equal to M. Hence $M' = T'$. This proves 6.8, and therefore 6.7.

We now prove 6.6. We have reduced to the case where S is the spectrum of a discrete valuation ring A, which we may moreover assume complete with algebraically closed residue field. After replacing A, if necessary, by its normalization in a finite extension of its fraction field, we may assume that $(G_t)_{\mathrm{red}}$ is smooth.[10] To prove 6.6 we may clearly replace G by the identity component of the schematic closure in G of $(G_t)^0_{\mathrm{red}}$, and therefore assume that G is flat over S, has connected fibres, and has smooth generic fibre G_t.

a) Suppose that H_s is the centralizer in $(G_s)_{\mathrm{red}}$ of a torus T_s. We show that H_t is then the centralizer in G_t of a subtorus of G_t. By Lemma 6.7 there is a subgroup scheme C of H, smooth over S, whose closed fibre is H_s, such that $C_t = \mathrm{Centr}_{H_t}(T_t)$ for a subtorus T_t of H_t. Since H is smooth over S with connected fibres, dimension considerations give $C = H$. With the notation of 6.7, $H = C = C_\ell$ for all sufficiently large ℓ. Similarly, put $C'_\ell = \mathrm{Centr}_G(M(\ell))$ (2.5), and let C' be the stationary value of the C'_ℓ for large ℓ (2.5 bis). The group scheme C' contains H, and

$$C'_t = \mathrm{Centr}_{G_t}(T_t) \quad (6.8), \qquad C'_s = \mathrm{Centr}_{G_s}(T_s).$$

The hypothesis on H_s gives $\dim H_s = \dim C'_s$. Moreover, $\dim H_s = \dim H_t$, since H is smooth over S, and $\dim C'_t \leq \dim C'_s$ (Exposé $\mathrm{VI_B}$, 4.1). Hence $\dim H_t = \dim C'_t$.

[9] Editor's note: the word "residual" has been removed.

[10] Editor's note: details or references should be supplied here.

Since G_t is smooth and connected, $C'_t = \mathrm{Centr}_{G_t}(T_t)$ is smooth and connected; finally,

$$H_t = C'_t = \mathrm{Centr}_{G_t}(T_t).$$

b) Suppose that H_s contains a Cartan subgroup C_s of G_s, that is, the centralizer in $(G_s)_{\mathrm{red}}$ of a maximal torus T_s of G_s. By 6.7 there is a subgroup scheme C of H, smooth over S with connected fibres, lifting C_s. It suffices to prove that C_t contains a Cartan subgroup of G_t. By part a), applied with $H = C$, C_t is the centralizer in G_t of a subtorus of G_t, and hence contains a Cartan subgroup of G_t.

c) Suppose that H_s is a parabolic subgroup of G_s. Let $N = \mathrm{Norm}_G(H)$. By hypothesis H is equal to its connected normalizer, so N_s is smooth and consequently

$$N_s = \mathrm{Norm}_{(G_s)_{\mathrm{red}}}(H_s) = H_s \qquad \text{(Exposé XII, 8 bis)}.$$

Thus N is flat over S. We shall see in Exposé XVI that under these conditions G/N is representable. Since $H_s = N_s$ is a parabolic subgroup, $(G/N)_s$ is proper. Since G/N is flat over S with connected fibres, EGA III, 5.5.1 implies that G/N is proper over S. Thus $(G/N)_t = G_t/N_t$ is proper over t, and so is G_t/H_t, because N_t/H_t is finite. It remains only to apply the following lemma.

Lemma 6.9. *Let k be a field, G a k-algebraic group, H a smooth connected algebraic subgroup of G, and $N = \mathrm{Norm}_G(H)$. If $\dim H = \dim N$ and G/H is proper, then H is a parabolic subgroup of G.*

Indeed, we may assume that k is algebraically closed and that G is smooth and connected. The centre Z of G is contained in N, and $\dim H = \dim N$ implies that $Z' = (Z)^0_{\mathrm{red}}$ is contained in H. Hence $G' = G/Z'$ is affine (Exposé XII, 6.1). Replacing G by G' and H by its image in G', we reduce to the case in which G is affine (Exposé XIV, 4.9), and Lemma 6.9 then follows from *Bible* 6, Th. 4. This proves Lemma 6.6.

To complete the proof of 6.4, we must show that the S-preschemes representing $\mathcal{L}_C$ (respectively $\mathcal{CT}$ and $\mathcal{P}$) are of finite presentation over S. This assertion is local on S, so we may assume first that S is affine and then, since G is of finite presentation, that S is noetherian (EGA IV, 8.9). We have just seen that the natural inclusions $\mathcal{CT} \to \mathcal{L}$ and $\mathcal{P} \to \mathcal{L}$ are immersions. The same is therefore true of $\mathcal{CT} \to \mathcal{L}_C$ and $\mathcal{P} \to \mathcal{L}_C$. Consequently, it is enough to prove that $\mathcal{L}_C$ is represented by an S-prescheme of finite presentation.

Resume the notation introduced in 5.2. For every integer $n \geq 0$, let $\mathcal{L}^n$ be the subfunctor of $\mathcal{L}$ defined by

$$\mathcal{L}^n(S') = \left\{ H \in \mathcal{L}(S') \;\middle|\; \mathrm{Norm}_{G_{S'}}(H) = \mathrm{Norm}_{G_{S'}}\left(H^{(n)}\right) \right\}.$$

The S-functor $\mathcal{L}^n$ is thus represented by an open subprescheme of $\mathcal{L}$, the disjoint union of the $\mathcal{L}^n_r$. Each $\mathcal{L}^n_r$ is of finite presentation over S (5.3), and is empty for

$$r > \sup_{s \in S} \dim G_s,$$

which is a finite number because S is quasi-compact. Hence $\mathcal{L}^n$ is of finite presentation over S. It remains to prove that $\mathcal{L}_C$ is contained in $\mathcal{L}^n$ for all sufficiently large n.

For each point s of S, let $d(s)$ be the least integer n, finite or infinite, such that

$$\mathcal{L}_{C,G_s} \subset \mathcal{L}^n_{G_s}.$$

It is enough to show that d is bounded on S. Indeed, if M is an upper bound, then $\mathcal{L}_C$ is set-theoretically contained in $\mathcal{L}^M$, and hence is contained in $\mathcal{L}^M$, since the latter is open in $\mathcal{L}$. A direct constructibility argument reduces us to showing that, when S is noetherian and integral with generic point t, the function d is bounded on a neighbourhood of t.

a) **Reduction to the case in which G is smooth over S.** Proceeding as in 6.2, we see that, after possibly changing S, we may assume that G_{red} is a group prescheme smooth over S; denote it by G'. Put

$$X = \mathcal{L}_{C,G}, \qquad X' = \mathcal{L}_{C,G'},$$

and let H (respectively H') be the subgroup prescheme of G_X (respectively $G'_{X'}$) universal for the functor $\mathcal{L}_{C,G}$ (respectively $\mathcal{L}_{C,G'}$). Since H is smooth over X, the prescheme $H \times_X X_{\mathrm{red}}$ is reduced, and is therefore contained in $G'_{X_{\mathrm{red}}}$. It is an element of $\mathcal{L}_{C,G'}(X_{\mathrm{red}})$, and hence defines a canonical morphism

$$p : X_{\mathrm{red}} \longrightarrow X'.$$

It is clear that p is a monomorphism; we show that it is in fact an immersion. Let N' be the normalizer of H' in $G_{X'}$. The set of points $s \in X'$ for which $H'_s \to N'_s$ is an open immersion is an open subset U, and

$$H'|_U \longrightarrow N'|_U$$

is an open immersion (Exposé $\mathrm{VI_B}$, 2.5, and EGA IV, 17.9.5). It follows from 5.1(iii) that U is the largest open subset of X' over which H' equals its connected normalizer in $G_{X'}$. Thus $H'|_U \in \mathcal{L}_{C,G}(U)$, and it follows at once that p is an isomorphism of X_{red} onto U_{red}. If $\mathcal{L}_{C,G}$ is known to be of finite type when G is smooth, then X' is of finite type over S; consequently X_{red} is of finite type (since S is noetherian), and is therefore contained in $\mathcal{L}_G^M$ for all sufficiently large M. The same then holds for X.

b) **The case in which S is the spectrum of an algebraically closed field k of characteristic $p > 0$, and G is a smooth algebraic group over k.** Instead of the infinitesimal neighbourhoods $H^{(n)}$ of a subgroup prescheme H of G, we use the radicial subgroups $F_n(H)$, the kernels of the iterates of the Frobenius morphism of H (Exposé $\mathrm{VII_A}$, 4). This is legitimate here because $F_n(H)$ is contained in the infinitesimal neighbourhood of order p^n of the unit section of H. If T is a subtorus of G, then

$$F_n(T) = {}_{p^n}T,$$

and duality immediately shows that $\mathrm{Centr}_G({}_{p^n}T) = \mathrm{Centr}_G(T)$ for all sufficiently large n. We have the following more precise proposition.

Proposition 6.10. *Let k be a field of characteristic $p > 0$, let G be a smooth k-algebraic group, let T be a maximal torus of $G_{\bar{k}}$, and let m be the least integer such that*

$$\mathrm{Centr}_G({}_{p^m}T)^0 = \mathrm{Centr}_G(T)^0.$$

Then, for every k-prescheme S and every $H \in \mathcal{L}_C(S)$, one has

$$\mathrm{Norm}_{G_S}(H) = \mathrm{Norm}_{G_S}(F_m(H)).$$

In particular, $\mathcal{L}_C$ is contained in $\mathcal{L}^{p^m}$.

Since H is smooth and of finite presentation over S, and has constant nilpotent rank, namely that of G, we shall see in the next section (7.3) that the functor $\mathcal{C}_H$ of Cartan subgroups of H is represented by an S-prescheme smooth over S. The reader will verify that the proof given there does not use the finite-type property of $\mathcal{L}_{C,H}$. It follows from Exposé XIII, 3.1, that we may consider the open subset U of regular points of H.

Let S' be an S-prescheme and let $g \in G(S')$ normalize $F_m(H)_{S'}$. To prove that g normalizes $H_{S'}$, it is enough to prove that

$$\mathrm{int}(g)U_{S'} \subset H_{S'}.$$

Indeed, $H_{S'} \cap \mathrm{int}(g)H_{S'}$ would then contain an open subgroup of $\mathrm{int}(g)H_{S'}$, and hence would equal it, since the latter has connected fibres. After replacing S' by a suitable covering S'', and then replacing S'' by S, we are reduced to proving the following: if $g \in G(S)$ normalizes $F_m(H)$ and $u \in U(S)$, then $\mathrm{int}(g)u \in H(S)$.

Let C be the unique Cartan subgroup of H "containing" u (Exposé XIII, 3.2). It is enough to show that

$$C' = \mathrm{int}(g)C \subset H.$$

Since $H \in \mathcal{L}_{C,G}(S)$, the group C is also a Cartan subgroup of G. The latter admits maximal tori, so C is the centralizer in G_S^0 of its unique maximal torus T (Exposé XII, 7.1(a)). By the definition of m, and because any two maximal tori of G are locally conjugate for the fpqc topology (Exposé XII, 7.1),

$$C = \mathrm{Centr}_G(T)^0 = \mathrm{Centr}_G({}_{p^m}T)^0.$$

Conjugating by g, we obtain

$$C' = \mathrm{Centr}_G\big(\mathrm{int}(g)({}_{p^m}T)\big)^0.$$

Now $\mathrm{int}(g)({}_{p^m}T)$ is a subgroup of multiplicative type of

$$\mathrm{int}(g)\big(F_m(H)\big) = F_m(H),$$

because g normalizes $F_m(H)$; it is therefore contained in H. Exposé XIII, 2.1 (proved there when the base is a field, but extending at once to an arbitrary base) then shows that, in order to prove $C' \subset H$, it is enough to prove

$$\mathrm{Lie}\, C' \subset \mathrm{Lie}\, H.$$

But

$$\mathrm{Lie}\, C' = \mathrm{int}(g)(\mathrm{Lie}\, C) \subset \mathrm{int}(g)(\mathrm{Lie}\, H).$$

On the other hand, we may assume $m \geq 1$, and Exposé $\mathrm{VII_A}$, 4.1.2, gives

$$\mathrm{Lie}\, H = \mathrm{Lie}\big(F_m(H)\big) = \mathrm{Lie}\big(\mathrm{int}(g)(F_m(H))\big) = \mathrm{int}(g)(\mathrm{Lie}\, H).$$

Thus $\mathrm{Lie}\, C' \subset \mathrm{Lie}\, H$, which completes the proof of 6.10.

We shall need another description of the integer m introduced in 6.10.

Lemma 6.11. *Let G be a smooth algebraic group over an algebraically closed field k of characteristic $p > 0$, let T be a maximal torus of G, put $\mathfrak{g} = \mathrm{Lie}\, G$, and let R be the set of nonzero characters of T occurring in the representation of T on $\mathfrak{g}$ induced by the*

adjoint representation of G. For $r \in R$, let e_r be the greatest integer n such that p^n divides r in the character group of T. Then

$$m = \sup_{r \in R}(e_r + 1)$$

if $R \neq \varnothing$, and $m = 0$ otherwise.

Indeed, $\mathrm{Centr}_G(T)$ is smooth and is contained in $\mathrm{Centr}_G({}_{p^m}T)$. Hence

$$\begin{aligned} \mathrm{Centr}_G(T)^0 &= \mathrm{Centr}_G({}_{p^m}T)^0 \\ &\iff \mathrm{Lie}\big(\mathrm{Centr}_G(T)\big) = \mathrm{Lie}\big(\mathrm{Centr}_G(F_m(T))\big) \\ &\iff \mathfrak{g}^T = \mathfrak{g}^{{}_{p^m}T} \qquad \text{(Exposé II, 5.2.3).} \end{aligned}$$

With the usual notation,

$$\mathfrak{g} = \mathfrak{g}_0 \oplus \bigoplus_{r \in R} \mathfrak{g}_r.$$

Thus $\mathfrak{g}^T = \mathfrak{g}_0$, whereas

$$\mathfrak{g}^{{}_{p^m}T} = \mathfrak{g}_0 \oplus \bigoplus_{r \in R'} \mathfrak{g}_r,$$

where R' is the subset of R formed by the characters whose restriction to ${}_{p^m}T$ is zero. A nonzero character r of T has trivial restriction to ${}_{p^m}T$ if and only if $m \leq e_r$, which proves the lemma.

c) **Return to the proof of 6.4.** By part a) and the paragraph preceding it, we have reduced to the case in which S is a noetherian integral scheme and G is smooth over S. We must show that d is bounded on a neighbourhood of the generic point t of S. After possibly changing S, we may assume that G has a split maximal torus (6.2)

$$T = D_S(M).$$

Let

$$\mathfrak{g} = \bigoplus_{\lambda \in M} \mathfrak{g}^\lambda$$

be the decomposition of the Lie algebra of G according to the characters of T, and let R be the finite set of nonzero $\lambda \in M$ for which $\mathfrak{g}^\lambda \neq 0$. We distinguish two cases.

First case: t, and hence every point of S, has positive residue characteristic p. It is clear from the foregoing that d is then bounded by p^m, where m is defined as in 6.11.

Second case: t has residue characteristic zero. For each $\lambda \in R$, let n_λ be the greatest integer dividing λ in the group M, and put

$$n = \prod_{\lambda \in R} n_\lambda.$$

For every prime number q dividing n, let S_q be the closed subset of S formed by the points of residue characteristic q, and let U be the nonempty open subset, containing t, complementary to the union of the S_q. If $s \in U$, then either s has residue characteristic zero, in which case $d(s) = 1$ by 5.6, or s has residue characteristic $p > 0$ not dividing n. In the latter case the integer m attached to G_s in 6.11 is at most one. Moreover, Exposé VII[11] gives

$$\mathrm{Norm}_{G_{S'}}(F_1(H)) = \mathrm{Norm}_{G_{S'}}(\mathrm{Lie}\, H) = \mathrm{Norm}_{G_{S'}}(H^{(1)}).$$

[11] Editor's note: the argument should be made explicit.

Finally, 6.10 shows that, for $H \in \mathcal{L}_{C,G_s}(S')$,

$$\mathrm{Norm}_{G_{S'}}(H) = \mathrm{Norm}_{G_{S'}}(H^{(1)}).$$

Consequently $d(s) \leq 1$, so d is bounded by 1 on U. This completes the proof of 6.4.

Corollary 6.12. *Let S be a prescheme and G an S-prescheme in groups of finite presentation. Suppose that the nilpotent rank of the fibres of G (respectively the dimension of their Borel subgroups) is locally constant on S. Then the functor $\mathcal{C}$ of Cartan subgroups of G (respectively the functor $\mathcal{B}$ of Borel subgroups of G) is represented by an S-prescheme of finite presentation over S.*

Indeed, after restricting S, we may assume that the nilpotent rank ν of the fibres is constant. Then $\mathcal{C}$ is represented by the open-and-closed subprescheme of the prescheme X representing $\mathcal{L}_C$ (6.4) over which the universal subgroup of G_X for the functor $\mathcal{L}_C$ has relative dimension ν. The proof is analogous for $\mathcal{B}$, using the representability of $\mathcal{P}$.

7. Cartan subgroups of a smooth group

Proposition 7.1.— *Let S be a prescheme and let G be an S-group prescheme of finite presentation, smooth over S, with connected fibres.*

i) *Let $\mathcal{CT}$ be the S-functor defined by*

$$\mathcal{CT}(S') = \left\{ \begin{array}{c} \text{subgroup preschemes } H \text{ of } G_{S'}, \text{ smooth over } S', \\ \text{such that every } H_{s'} \text{ is the centralizer in } G_{s'} \\ \text{of a sub-torus of } G_{s'} \end{array} \right\}.$$

Then $\mathcal{CT}$ is represented by an S-prescheme of finite presentation, smooth and quasi-projective over S.

ii) *If S is artinian and $H \in \mathcal{CT}(S)$, then H is the centralizer in G of a sub-torus of G. If S is the spectrum of a henselian local ring and $H \in \mathcal{CT}(S)$, then H is the centralizer in G of a subgroup of multiplicative type that is étale over S.*

iii) *Let L be an S-group prescheme smooth and of finite presentation, let $i : L \to G$ be an S-group monomorphism, and let $H \in \mathcal{CT}(S)$. Then $\mathrm{Transp}_G(H, L)$ and $\mathrm{Transpstr}_G(H, L)$ (Exposé VIII 6.5(e)) are represented by closed subpreschemes of G, smooth over S.*

iv) *If $H \in \mathcal{CT}(S)$, then H is closed in G; $N = \mathrm{Norm}_G(H)$ is represented by a closed subgroup prescheme of G, smooth over S; N/H is represented by an S-group prescheme, separated, étale, and of finite type over S; and G/N is represented by an S-prescheme smooth and quasi-projective over S.*

v) *Let G' be an S-group prescheme of finite presentation and let $u : G \to G'$ be faithfully flat. Then G' satisfies the same hypotheses as G (Exposé VI$_B$ 9). If $H \in \mathcal{CT}_G(S)$, its image is represented by a subgroup prescheme $H' \in \mathcal{CT}_{G'}(S)$, and $H \to H'$ is faithfully flat. If $H = \mathrm{Centr}_G(T)$ for a torus T, then*

$$H' = \mathrm{Centr}_{G'}(T'), \qquad T' = u(T).$$

vi) *Under the hypotheses of (v), the S-morphism*

$$\widetilde{u} : \mathcal{CT}_G \longrightarrow \mathcal{CT}_{G'}, \qquad H \longmapsto H' = u(H),$$

is quasi-compact and faithfully flat. If, moreover, $\ker u$ *is central, then* $\widetilde{u}$ *is an isomorphism, with inverse* $H' \mapsto u^{-1}(H')$.

Proof of (ii). For the first assertion we may suppose that S is local artinian, with closed point s. Let $H \in \mathcal{CT}(S)$, and let T_s be the maximal central torus of H_s, which is defined over $\kappa(s)$ (cf. Lemma 3.4). Since

$$H_s = \mathrm{Centr}_{G_s}(T_s),$$

and H is smooth, T_s lifts uniquely to a sub-torus T of H, central in H (Exposé IX 3.6 bis and 5.6). Then $H' = \mathrm{Centr}_G(T)$ contains H and has the same fibre as H. Because H is flat, $H = H'$ (Exposé $\mathrm{VI_B}$ 2.5).

Suppose now that S is the spectrum of a henselian local ring, which the usual reductions allow us to take noetherian. Let s be its closed point, let T_s be the maximal central torus of H_s, let q be invertible on S, let ℓ be a power of q, and let T be an S-torus whose closed fibre is isomorphic to T_s (Exposé X 4.6). Let ${}_\ell H$ denote the "kernel" of the ℓ-th power morphism in H, and let U_ℓ be the largest open subset of ${}_\ell H$ étale over S. Lemma 1.3 and flatness of H show that U_ℓ contains ${}_\ell T_s$. Hensel's lemma gives a unique S-morphism

$$u_\ell : {}_\ell T \longrightarrow U_\ell$$

inducing the canonical immersion ${}_\ell T_s \to (U_\ell)_s$ on the closed fibre. Uniqueness shows that u_ℓ is a central homomorphism (Exposé IX 5.6(a)). Proceeding as in 6.6 and 6.7, one proves that u_ℓ is an immersion and, if $M_\ell = u_\ell({}_\ell T)$, that

$$\mathrm{Centr}_G(M_\ell) = H$$

for all sufficiently large ℓ. This is where noetherianity of S is used.

Proof of (i). If $H \in \mathcal{CT}(S)$, then H has connected fibres (Exposé XII 6.6(b)) and equals its connected normalizer (6.5). Hence the present functor $\mathcal{CT}$ is the functor of 6.4.0. Theorem 6.4 therefore represents it by an S-prescheme of finite presentation, quasi-projective over S. It remains to prove smoothness.

EGA IV 8 reduces us to affine noetherian S. By Exposé XI 1.5 it then suffices to prove the following infinitesimal lifting property: if S is local artinian, S_0 is defined by a nilpotent ideal, and $H_0 \in \mathcal{CT}(S_0)$, then H_0 lifts to a smooth subgroup prescheme H of G. By part (ii),

$$H_0 = \mathrm{Centr}_{G_0}(T_0)$$

for a sub-torus T_0 of G_0. Since G is smooth, T_0 lifts to a sub-torus T of G (Exposé IX 3.6 bis), and $H = \mathrm{Centr}_G(T)$ works; it is smooth by Exposé XI 2.4 and Lemma 2.5.

Proof of (iii). Because H is smooth with connected fibres, Exposé XI 6.11 represents $\mathrm{Transp}_G(H, L)$ by a closed subprescheme of G, of finite presentation over S. Smoothness reduces to the following lifting problem. Let S be local artinian, S_0 a closed subprescheme, and $g_0 \in G(S_0)$ such that

$$\mathrm{int}(g_0)H_0 \subseteq L_0.$$

We must lift g_0 to $g \in G(S)$ with $\mathrm{int}(g)H \subseteq L$.

Smoothness of G gives $g_1 \in G(S)$ lifting g_0. Put $H' = \mathrm{int}(g_1)H$. Then $H' \in \mathcal{CT}(S)$ and $H'_0 \subseteq L_0$. By (ii), $H' = \mathrm{Centr}_G(T')$ for a torus $T' \subseteq G$. Since L is smooth, $T'_0 \subseteq L_0$ lifts to a torus $T'' \subseteq L$ (Exposé IX 3.6 bis). The group $\mathrm{Centr}_L(T'')$ lies in $\mathrm{Centr}_G(T'')$, has the same closed fibre as the latter, namely H'_0, and is smooth. Hence

$$\mathrm{Centr}_L(T'') = \mathrm{Centr}_G(T'').$$

The sub-tori T' and T'' of G lift the same T'_0, so they are conjugate by an element $h \in G(S)$ reducing to the identity (Exposé IX 3.3 bis). Their centralizers are therefore conjugate. Then $g = hg_1$ lifts g_0 and satisfies $\mathrm{int}(g)H \subseteq L$.

For $g \in \mathrm{Transp}_G(H, L)(S)$, the equality $\mathrm{int}(g)H = L$ holds if and only if $\dim H_s = \dim L_s$ for every $s \in S$. If U is the open-and-closed subprescheme over which these dimensions agree, then

$$\mathrm{Transpstr}_G(H, L) = U \times_S \mathrm{Transp}_G(H, L).$$

Proof of (iv). To prove H closed in G, reduce first to affine noetherian S, then, by EGA IV 8, to the spectrum of a complete local ring. Part (ii) writes H as the centralizer in G of a subgroup of multiplicative type, so H is closed because G is separated (Exposé $\mathrm{VI_B}$ 5.2).

By (iii),

$$N = \mathrm{Norm}_G(H) = \mathrm{Transpstr}_G(H, H)$$

is represented by a subgroup prescheme smooth over S and closed in G. The morphism

$$G \longrightarrow \mathcal{CT}, \qquad g \longmapsto \mathrm{int}(g)H$$

is smooth by (iii), so its image is an open subset U of $\mathcal{CT}$. As in Exposé XI 5.3, G/N is represented by U; it is therefore quasi-projective.

We now treat N/H. By EGA IV 8, assume S affine noetherian and then $S = \mathrm{Spec}\, A$, with A local of finite dimension[12]. We use induction on $\dim S$. When $\dim S = 0$, the assertion is Exposé $\mathrm{VI_A}$, §4. If N/H is representable, it is separated because H is closed in N, of finite type and étale because N is smooth of finite type and H is open. It is therefore quasi-affine (SGA 1, VIII 6.2). Effective descent for quasi-affine schemes (*loc. cit.*, 7.9) permits replacement of A by its completion.

Thus assume S complete noetherian local, with closed point s, and put $U = S \setminus \{s\}$. By induction, $(N|_U)/(H|_U)$ is represented by a U-group K. Let T_s be the maximal central torus of H_s, choose q invertible on S, let ℓ be a power of q, and let M_ℓ be the unique central subgroup of multiplicative type of H lifting ${}_\ell T_s$, as in (ii). Choose ℓ so large that

$$\mathrm{Centr}_G(M_\ell) = H,$$

and put $N' = \mathrm{Norm}_G(M_\ell)$.

The torus T_s, and hence $(M_\ell)_s$, is characteristic in H_s. Therefore N_s normalizes $(M_\ell)_s$, and $N_s = N'_s$. The proof of Exposé XI 5.9 represents

$$N'/H = \mathrm{Norm}_G(M_\ell)/\,\mathrm{Centr}_G(M_\ell)$$

by an S-group K'. Since N' is smooth and $N'_s = N_s$, it is an open subgroup of N containing H (Exposé $\mathrm{VI_B}$ 2.5). Its image over U is an open subgroup of K, isomorphic to $K'|_U$. Glue K and K' along this open subgroup to obtain L, and glue the projections $N|_U \to K$ and $N' \to K'$ to obtain $p : N \to L$. Then (L, p) represents N/H.

[12] Krull dimension.

Proof of (v). First suppose $S = \operatorname{Spec} k$. The image H' of H is a smooth subgroup of G'. The required assertion follows from:

Lemma 7.2.— *Let $u : G \to G'$ be an epimorphism of smooth connected algebraic groups over a field k, let T be a torus of G, and let T' be its image in G'. Then*

$$u(\operatorname{Centr}_G(T)) = \operatorname{Centr}_{G'}(T').$$

Put $H = \operatorname{Centr}_G(T)$, $H' = \operatorname{Centr}_{G'}(T')$, and $H'' = u(H)$. We have $H'' \subseteq H'$. After extending the base field, assume k algebraically closed. It suffices to prove that every Cartan subgroup of H' lies in H'': then H'' contains the open subset of regular points of H', so is open, and equals the connected group H'.

Let C' be a Cartan subgroup of H'. It is also a Cartan subgroup of G', since H', being the centralizer of the torus T', has the same reductive and nilpotent ranks as G'. Put

$$K = (u^{-1}(C'))^0_{\mathrm{red}}.$$

Because T' is central in H', C' contains T', and K contains T. Let C be a Cartan subgroup of K containing T. The torus T lies in the unique maximal torus of C, central in C (Exposé XII 6.6(c)); hence $C \subseteq H$. Any two Cartan subgroups of G are conjugate, and the image of a Cartan subgroup of G is a Cartan subgroup of G' (Exposé XII 6.6). It follows that C is a Cartan subgroup of G, and its image is a Cartan subgroup of G' contained in C'. Thus $u(C) = C'$, proving $C' \subseteq H''$.

This proves (v) over a field. In general, finite presentation and the usual reductions permit us to assume S affine noetherian, then local, and finally the spectrum of a complete noetherian local ring A, by fpqc descent of subpreschemes of G'.

Use the notation of (ii). Let T_s be the maximal central torus of H_s, and let $M_\ell \subset H$ lift ${}_\ell T_s$, with $H = \operatorname{Centr}_G(M_\ell)$. Let $T'_s = u_s(T_s)$. Since G' is separated, $u(M_\ell)$ is represented by a subgroup M'_ℓ of multiplicative type (Exposé IX 6.8). Put

$$H' = \operatorname{Centr}_{G'}(M'_\ell),$$

which is smooth. For every power ℓ' of q, a sufficiently large ℓ makes $(M'_\ell)_s$ contain ${}_{\ell'}T'_s$. We may therefore choose ℓ such that

$$H'_s = \operatorname{Centr}_{G'_s}(T'_s) = u_s(H_s),$$

the last equality being Lemma 7.2.

The restriction $v : H \to H'$ of u is flat. Indeed, H, H' are flat over S, $H_s \to H'_s$ is flat, and hence v is flat near H_s (EGA IV 11.3.10 and 11.3.1). It is therefore flat on an open subgroup of H (Exposé $\mathrm{VI_B}$ 2.2), and thus everywhere because the fibres of H are connected. The set-theoretic image of H is consequently an open subset of H', necessarily $(H')^0$, and with its induced structure represents the fpqc image sheaf $u(H)$. Lemma 7.2 shows that it belongs to $\mathcal{CT}_{G'}(S)$.

If $H = \operatorname{Centr}_G(T)$, then $T' = u(T)$ is a sub-torus of G' (Exposé IX 6.8). The image $u(H)$ is contained in $\operatorname{Centr}_{G'}(T')$, agrees with it fibrewise by Lemma 7.2, and is smooth. Hence

$$u(H) = \operatorname{Centr}_{G'}(T').$$

Proof of (vi). Since $\mathcal{CT}_G, \mathcal{CT}_{G'}$ are smooth over S, it is enough to prove faithful flatness on geometric fibres. Thus take $S = \operatorname{Spec} k$, with k algebraically closed. Let $H' \in \mathcal{CT}_{G'}(k)$, let T' be its maximal central torus, choose a sub-torus $T \subset G$ mapping onto T', and put

$$H = \operatorname{Centr}_G(T), \qquad N = \operatorname{Norm}_G(H), \qquad N' = \operatorname{Norm}_{G'}(H').$$

By Lemma 7.2, $H' = u(H)$. Part (iv) identifies G/N and G'/N' with open neighbourhoods of H and H' in the two $\mathcal{CT}$-spaces. On these neighbourhoods, $\widetilde{u}$ is

$$w : G/N \longrightarrow G'/N',$$

obtained from u by passage to quotients. This is an epimorphism of homogeneous spaces under G, hence faithfully flat. Therefore $\widetilde{u}$ is flat and its image is an open subset of $\mathcal{CT}_{G'}$ containing all k-points. Since $\mathcal{CT}_{G'}$ is of finite type, $\widetilde{u}$ is surjective and hence faithfully flat. If $\ker u$ is central, the remaining assertions are Exposé XII 7.12.

The next theorem generalizes Exposé XII 7.1.

Theorem 7.3.— *Let S be a prescheme and let G be an S-group prescheme of finite presentation, smooth over S, with connected fibres. Define the functor*

$$\mathcal{C}(S') = \{\textit{Cartan subgroups of } G_{S'}\}.$$

i) *The following are equivalent:*

   a) *$\mathcal{C}$ is representable;*

   b) *$\mathcal{C}$ is represented by an S-prescheme smooth, quasi-projective, and of finite presentation over S, with affine fibres;*

   c) *G admits a Cartan subgroup locally for the étale topology;*

   d) *G admits a Cartan subgroup locally for the faithfully flat topology;*

   e) *the nilpotent rank of the fibres of G is locally constant on S.*

ii) *If these conditions hold, any two Cartan subgroups of G are locally conjugate for the étale topology. The regular locus of the fibres of G (Exposé XIII 2.7) is an open subprescheme G_{reg}, of finite presentation over S, and every section of G_{reg} over S is contained in a unique Cartan subgroup of G.*

iii) *Let G' be an S-group prescheme of finite presentation and $u : G \to G'$ faithfully flat. Then, for every Cartan subgroup C of G, its image $C' = u(C)$ is represented by a Cartan subgroup of G', and $C \to C'$ is faithfully flat.*

iv) *Under the conditions of (i) and (iii), the morphism*

$$\widetilde{u} : \mathcal{C}_G \longrightarrow \mathcal{C}_{G'}, \qquad C \longmapsto u(C),$$

   is faithfully flat. If $\ker u$ is central, it is an isomorphism.

v) *Further information on transporters and relations with maximal tori is given in Proposition 7.1 and Exposé XII 7.1.*

Proof. For (i) we prove

$$\text{(b)} \Rightarrow \text{(c)} \Rightarrow \text{(d)} \Rightarrow \text{(e)} \Rightarrow \text{(b)} \Rightarrow \text{(a)} \Rightarrow \text{(d)}.$$

Assume (b), and let $s \in S$. Since $\mathcal{C}_s$ is smooth over $\kappa(s)$, it has points with residue field a finite separable extension of $\kappa(s)$. Exposé XI 1.10 gives an open neighbourhood U of s and an étale surjective morphism $U' \to U$ such that $G_{U'}$ admits a Cartan subgroup. Thus (b)⇒(c), while (c)⇒(d) is clear.

Assume (d), and let $s \in S$. There is a flat S-prescheme S', whose image contains s, such that $G_{S'}$ admits a Cartan subgroup. For $s' \in S'$ above s, the nilpotent rank of the

fibres of $G_{S'}$ is constant on $\operatorname{Spec}\mathcal{O}_{S',s'}$. Hence the nilpotent rank of the fibres of G is constant on $\operatorname{Spec}\mathcal{O}_{S,s}$, which is the image of that local spectrum (EGA IV 2.3.4(ii)). Let the value be r. By 6.3 bis, the set E_r where the nilpotent rank equals r is ind-constructible; it contains a neighbourhood of s by EGA IV 1.10.1. Thus (d)⇒(e).

Assume (e). Locally on S, the nilpotent rank is a constant r. For every S', the Cartan subgroups of $G_{S'}$ are exactly the smooth subgroup preschemes of relative dimension r whose geometric fibres are centralizers of tori. By Proposition 7.1, $\mathcal{C}$ is the open-and-closed subprescheme of $\mathcal{CT}$ representing the relative-dimension-r subfunctor. It has all the properties in (b); affineness of its fibres is Exposé XII 7.1(d). This proves (e)⇒(b), and (b)⇒(a) is immediate.

Finally assume (a). By 6.2(iii), $\mathcal{C}$ commutes with filtered inductive limits of rings, so its representing prescheme is locally of finite presentation (EGA IV 8.14.2). To prove it smooth, it is enough to show that, when S is affine and $S_0 \subseteq S$ is defined by a nilpotent ideal, every Cartan subgroup C_0 of G_0 lifts to a Cartan subgroup of G. Existence of C_0 implies (e) on S_0, hence on S, which has the same underlying space. Since (e)⇒(b), $\mathcal{C}$ is smooth. It is also surjective over S, so (a)⇒(d).

For (ii), if C, C' are Cartan subgroups, then $\operatorname{Transp}_G(C, C')$ is represented by a smooth S-prescheme (Proposition 7.1(iii)) with nonempty fibres (Exposé XII 6.6(a),(c)). Hensel's lemma (Exposé XI 1.10) gives local conjugacy for the étale topology. The assertions about regular points follow from Exposé XIII 3.1 and 3.2.

For (iii), Proposition 7.1(v) represents $u(C)$ by a smooth subgroup C' of G'. Its fibres are Cartan subgroups of the fibres of G' (Exposé XII 6.6(d)), so C' is a Cartan subgroup.

For (iv), faithful flatness is proved as in Proposition 7.1(vi). If $\ker u$ is central and C' is a Cartan subgroup of G', then $C = u^{-1}(C')$ is smooth with connected fibres (Proposition 7.1(vi)), and its fibres are Cartan subgroups (Exposé XII 6.6(f)). Thus C is a Cartan subgroup, and Proposition 7.1(vi) completes the proof.

8. Representability criterion for the functor of sub-tori of a smooth group

8.0. In this section, if S is a prescheme and G an S-group prescheme, $\mathcal{T}_G$ (or simply $\mathcal{T}$, if there is no ambiguity) denotes the S-functor

$$(\mathrm{Sch}\,/S)^\circ \longrightarrow \mathrm{Ens}$$

such that, for every S-prescheme S',

$$\mathcal{T}(S') = \{\text{sub-tori of } G_{S'}\}.$$

The functor $\mathcal{T}_C$ of central sub-tori of G is defined similarly.

Proposition 8.1.— *Let S be a locally noetherian prescheme and let G be an S-group prescheme of finite type. Then the following conditions are equivalent:*

i) *The functor $\mathcal{T}_G$ "commutes with adic limits of local artinian rings": for every S-prescheme $S' = \operatorname{Spec}(A)$, where A is a complete noetherian local ring for the topology defined by its maximal ideal $\mathfrak{m}$, the canonical map*

$$\mathcal{T}(S') \longrightarrow \varprojlim_n \mathcal{T}(S'_n), \qquad S'_n = \operatorname{Spec}(A/\mathfrak{m}^n),$$

is bijective.

ii) *The assertion in* i), *restricted to the case in which A is a complete discrete valuation ring with algebraically closed residue field.*

iii) *The assertion in* ii), *restricted to the subfunctor $\mathcal{T}^{(1)}$ of $\mathcal{T}$ formed by sub-tori of G of relative dimension* 1.

i bis) *For every S-prescheme S' as in* i) *and every S'-torus T, the canonical map*

$$\mathrm{Hom}_{S'\text{-}gr}(T, G_{S'}) \longrightarrow \varprojlim_n \mathrm{Hom}_{S'_n\text{-}gr}(T_{S'_n}, G_{S'_n})$$

is bijective.

ii bis) *The assertion in* i bis), *restricted to the case in which A is a complete discrete valuation ring with algebraically closed residue field.*

iii bis) *The assertion in* ii bis), *restricted to $T = \mathbb{G}_{m,S'}$.*

Remark 8.2. There is an analogous proposition in which one restricts to central sub-tori of G and to central homomorphisms from a torus into G.

Proof. We shall use the following lemma.

Lemma 8.3.— *Let S be a prescheme, G an S-group prescheme, T an S-torus, and $u : T \to G$ an S-group morphism. Suppose, moreover, either that G is of finite presentation over S, or that S is locally noetherian and G is locally of finite type. Then:*

a) $\ker u$ *is a subgroup of multiplicative type of T;*

b) *the quotient $T' = T/\ker u$ is a torus;*

c) *the canonical monomorphism $T' \to G$ induced by u after passage to the quotient is an immersion.*

When G is separated over S, this lemma follows from Exposé IX 6.8. In the general case, the usual reduction allows us to suppose that S is noetherian. We first show that $K = \ker u$ is flat. We may suppose that S is the spectrum of a local artinian ring (EGA 0_{III}, 10.2.6); then G is separated (Exposé $\mathrm{VI_B}$ 5.2), so K is of multiplicative type (Exposé IX 6.8), and hence is flat over S. We next show that $\ker u$ is closed in T. This reduces us to the case in which S is the spectrum of a discrete valuation ring (EGA II 7.2.1). Since T is flat with connected fibres, u factors through the identity component of the schematic closure in G of the generic fibre of G. We may thus suppose that G is flat with connected fibres; it is then separated (Exposé $\mathrm{VI_B}$ 5.2), and K is closed. It follows from Exposé X 4.8(b) that K is a subgroup of multiplicative type of T. The quotient $T' = T/K$ is therefore representable and is a group of multiplicative type (Exposé IX 2.7) whose fibres are tori; hence T' is a torus. Finally, the monomorphism $T' \to G$ is an immersion by Exposé VIII 7.9.

Proof of Proposition 8.1. i)⇒i bis). Put $T_n = T_{S'_n}$, $G_n = G_{S'_n}$, and let

$$(u_n)_{n\in\mathbb{N}} \in \varprojlim_n \mathrm{Hom}_{S'_n\text{-gr}}(T_n, G_n).$$

For every n, $u_n(T_n)$ is a sub-torus T'_n of G_n (Lemma 8.3). By hypothesis, there is a unique sub-torus T' of G lifting T'_n for every n. Since T' has affine fibres, the assertion follows from 4.4.

i bis)⇒i). Let $(T_n)_{n\in\mathbb{N}} \in \varprojlim_n \mathcal{T}(S'_n)$. By Exposé X 4.6 there are an S'-torus T^0 and an S'_0-isomorphism

$$u_0 : T^0_0 \xrightarrow{\sim} T_0.$$

Since T_n is smooth over S'_n, u_0 lifts to an S'_n-morphism $u_n : T^0_n \to T_n$ (Exposé IX 3.6), and the family $(u_n)_{n\in\mathbb{N}}$ may be chosen coherent. It therefore comes from a morphism $u : T^0 \to G$. By Lemma 8.3, the image of T^0 under u is a sub-torus of G, and it lifts T_n for every n.

The implications

$$\text{i)} \Rightarrow \text{ii)} \Rightarrow \text{iii)} \quad \text{and} \quad \text{i bis)} \Rightarrow \text{ii bis)} \Rightarrow \text{iii bis)}$$

are immediate. The implication iii) ⇒ iii bis) is proved in the same way as i) ⇒ i bis). It remains to prove

$$\text{iii bis)} \Rightarrow \text{ii bis)} \Rightarrow \text{i bis)}.$$

ii bis)⇒i bis). In the terminology of 4.3, assertion i bis) holds if and only if every element

$$(u_n)_{n\in\mathbb{N}} \in \varprojlim_n \mathrm{Hom}_{S'_n\text{-gr}}(T_n, G_n)$$

is admissible. For every point t of S' distinct from its closed point s, there is an S-scheme S'', the spectrum of a complete discrete valuation ring with algebraically closed residue field, whose generic point maps to t and whose closed point maps to s (EGA II 7.1.9). This gives at once a valuative criterion for a family of morphisms to be admissible, and proves the implication.

iii bis)⇒ii bis). Let T be an S-torus, where S is the spectrum of a complete discrete valuation ring with algebraically closed residue field. The torus T is split (Exposé X 4.6), say

$$T \simeq \mathbb{G}^r_{m,S}.$$

Let

$$(u_n)_{n\in\mathbb{N}} \in \varprojlim_n \mathrm{Hom}_{S_n\text{-gr}}\big((\mathbb{G}_m)^r_{S_n}, G_n\big).$$

By hypothesis, the restriction of u_n to each factor of $\mathbb{G}^r_{m,S}$ comes from a group morphism $\mathbb{G}_{m,S} \to G$. Their product, followed by the composition law $G^r \to G$, gives a morphism

$$v : \mathbb{G}^r_{m,S} \longrightarrow G.$$

Clearly $u_n = v_n$ for every n. It remains to prove that v is a group morphism. Equivalently, two evident morphisms

$$f, g : X = \mathbb{G}^r_{m,S} \times_S \mathbb{G}^r_{m,S} \longrightarrow G$$

must coincide. Let Z be their coincidence subscheme. Since $\mathbb{G}^r_{m,S}$ has connected fibres and its image under v contains the unit section, the argument of Lemma 8.3 shows that v factors through the identity component of G. We may therefore suppose that G is separated (Exposé $\mathrm{VI_B}$ 5.2), so Z is closed. On the other hand, v_n is a group morphism, hence $f_n = g_n$ for every n. Thus Z contains a neighbourhood of the closed fibre of X (EGA I 10.9.4), which is schematically dense in X, since X has smooth irreducible fibres (Exposé IX 4.6). Consequently $Z = X$, and $f = g$.

Definition 8.4.— *Let S be a locally noetherian prescheme and G an S-group prescheme of finite type. Let $\mathcal{S}$ be the set of S-schemes S' that are spectra of complete discrete valuation rings with algebraically closed residue field. Write s and t for the closed and generic*

points of S', and require that $(G_t)^0_{\mathrm{red}}$ be smooth and admit a Chevalley decomposition: an extension of an abelian variety by a smooth connected linear algebraic subgroup L_t. This decomposition is then unique. For $S' \in \mathcal{S}$, let G', respectively L, denote the schematic closure in $G_{S'}$ of G_t, respectively of L_t.

We say that "the abelian part of G does not degenerate into a toric part", or briefly that G has property AT*, if, for every $S' \in \mathcal{S}$, L_s has the same reductive rank as G'_s. Intuitively, suppose that the quotient $A = G'/L$ is representable. Then A is a flat group prescheme and $(A_t)^0_{\mathrm{red}}$ is an abelian variety; property* AT *says that A_s has reductive rank zero, so that $(A_s)^0_{\mathrm{red}}$ is an extension of an abelian variety by a unipotent group.*

Similarly, if G has connected fibres, we say that G has property ATC *if, for every $S' \in \mathcal{S}$, the schematic closure Z of the centre Z_t of G_t has property* AT*.*

These technical definitions are justified by the following proposition.

Proposition 8.5.— *Let S be a locally noetherian prescheme and let G be an S-group prescheme of finite type.*

a) *The functor $\mathcal{T}$ of sub-tori of G commutes with adic limits of local artinian rings (cf. Proposition 8.1) if and only if G has property* AT*.*

b) *If G has connected fibres, the functor $\mathcal{T}_C$ of central sub-tori of G commutes with adic limits of local artinian rings if and only if G has property* ATC*.*

We need the following technical lemma.

Lemma 8.6.— *Let S be the spectrum of a discrete valuation ring, with closed point s, let G be an S-group prescheme flat and of finite type, and let T_s be a sub-torus of G_s. There are an S-scheme S', the spectrum of a discrete valuation ring faithfully flat over S, with closed point s', and a subgroup scheme C of $G_{S'}$, flat over S', commutative, and with connected fibres, such that $C_{s'}$ contains $T_s \times_s s'$.*

After replacing S by the spectrum S' of a discrete valuation ring faithfully flat over it, we may suppose that $T_s = \mathbb{G}^r_{m,s}$ and that the transcendence degree of $\kappa(s)$ over its prime field is at least r (EGA 0_{III}, 10.3.1, and EGA II 7.1.9). There is then an element $x \in T_s(s)$ such that every algebraic subgroup of G_s containing x contains T_s (cf. Exposé XIII, proof of 2.1, ii) $\Rightarrow$ vii)). Since G is flat over S, a quasi-section passes through x (EGA IV 14.5.8). After another such replacement of S, we may therefore suppose that x lifts to a section $\widetilde{x}$ of G over S. Let C_t be the commutative algebraic subgroup of G_t generated by $\widetilde{x}_t$ (Exposé $\mathrm{VI_B}$ 7), and let C be its schematic closure in G. Clearly C_s contains x, hence contains T_s. The identity component of C is therefore a flat commutative group scheme with connected fibres having the required property.

Proof of Proposition 8.5(a). Suppose first that $\mathcal{T}$ commutes with adic limits of artinian rings. Let $S' \in \mathcal{S}$, and let T_s be a maximal torus of G'_s. We must show that $T_s \subset L_s$. The formation of L and G' plainly commutes with faithfully flat extensions $S'' \to S'$ of discrete valuation rings. By Lemma 8.6, we may therefore replace S' so that there is a flat commutative subgroup scheme C of $G'_{S'}$ for which C_s contains T_s. The torus T_s is central in C_s, and hence lifts infinitesimally to a central sub-torus (Corollary 2.3). By the hypothesis on G, T_s lifts to a sub-torus T of G. Clearly T_t lies in the linear part L_t of G_t, and therefore $T \subset L$.

Conversely, suppose that G has property AT. We prove condition 8.1 iii bis). Let $S = \mathrm{Spec}(A)$, where A is a complete discrete valuation ring with algebraically closed residue field, let $\mathfrak{m}$ be its maximal ideal, put $S_n = \mathrm{Spec}(A/\mathfrak{m}^n)$, and let

$$u_n : (\mathbb{G}_{m,S})_n \longrightarrow G_n = G \times_S S_n, \qquad n \in \mathbb{N},$$

be a coherent system of group morphisms. Let q be a prime invertible on S. As ℓ ranges over the powers of q, there is a unique S-group morphism

$$ {}_\ell u : {}_\ell \mathbb{G}_{m,S} \longrightarrow G $$

lifting the restriction of u_n to ${}_\ell(\mathbb{G}_{m,S})_n$ for every n (Proposition 1.6(a)). Consequently, if an S-group morphism $u : \mathbb{G}_{m,S} \to G$ lifting every u_n exists, its restriction to ${}_\ell\mathbb{G}_{m,S}$ is uniquely determined. The density theorem (Exposé IX 4.8(a)) proves both the uniqueness of u and that, for its existence, we may make a faithfully flat extension of the base.

Now $(G_t)^0_{\mathrm{red}}$ admits a Chevalley decomposition, already defined over a finite extension L of the fraction field K of A. After replacing S by its normalization in L, we may suppose that $S \in \mathcal{S}$. The morphism ${}_\ell u_t$ factors through $(G_t)_{\mathrm{red}}$, and ${}_\ell u$ therefore factors through the schematic closure G'' of $(G_t)_{\mathrm{red}}$ in G'. The density theorem then shows that every u_n factors through G''_n. Since G has property AT, every sub-torus of G'_s, and hence of G''_s, is contained in L_s; thus u_s factors through L_s. In fact every u_n factors through L_n. Indeed, L_t is invariant in G''_t, so L is invariant in G''; moreover L is flat over S, and the quotient

$$ H_n = G''_n / L_n $$

is representable for every n (Exposé $\mathrm{VI_A}$, §4). The image of $(\mathbb{G}_{m,S})_n$ in H_n is a sub-torus (Exposé IX 6.8) whose closed fibre is zero. It is therefore zero, and u_n factors through L_n. Since L_t is affine, Proposition 4.3 now shows that the family (u_n) is admissible.

The proof of Proposition 8.5(b) is entirely analogous, in view of Remark 8.2 and Exposé IX 5.6(a).

Proposition 8.7.— *Let S be a locally noetherian prescheme and let G be an S-group prescheme of finite type.*

i) *If G has connected fibres and has property* AT*, then it has property* ATC*.*

ii) *If G has property* AT*, every subgroup prescheme of G has property* AT*.*

iii) *If G is flat over S and the abelian rank of its fibres is a locally constant function on S, then G has property* AT*.*

Assertion (i) follows at once from Proposition 8.5 and Exposé IX 5.6(a).

For (ii), let H be a subgroup prescheme of G. To prove that H has property AT, we may suppose that S is the spectrum of a complete discrete valuation ring. We must show that every coherent family of S_n-group morphisms

$$ u_n : (\mathbb{G}_{m,S})_n \longrightarrow H_n $$

is admissible (Proposition 8.5 and 8.1 iii bis)). By hypothesis, G has property AT, so there is an S-group morphism

$$ u : \mathbb{G}_{m,S} \longrightarrow G $$

lifting every u_n. As in the proof of Proposition 8.5, the restriction of u to ${}_\ell\mathbb{G}_{m,S}$, with ℓ ranging over powers of a prime q invertible on S, factors through H. By density, u_t factors through H_t on the generic fibre. Since $\mathbb{G}_{m,S}$ is reduced, u itself factors through H.

For (iii), let $S' \in \mathcal{S}$, with the notation of Definition 8.4. The group L is flat over S, and its generic fibre L_t is affine. Under these conditions L_s is necessarily affine (Exposé XVII, Appendix III 2). Since G and L are flat, $G = G'$, and the dimensions of the fibres of G and L are constant on S (Exposé $\mathrm{VI_B}$ 4). Consequently

$$ \mathrm{rk_{ab}}\, G_s \leq \dim G_s - \dim L_s = \dim G_t - \dim L_t = \mathrm{rk_{ab}}\, G_t. $$

By hypothesis these inequalities are equalities. Thus $(G_s/L_s)^0_{\mathrm{red}}$ is an abelian variety and has reductive rank zero. It follows that L_s has the same reductive rank as G_s.

We can now prove the principal theorems of this section.

Theorem 8.8.— *Let G be a group prescheme of finite type over a locally noetherian prescheme S. Suppose that G is flat over S and has connected fibres.*

a) *The functor $\mathcal{T}_C$ of central sub-tori of G is representable if and only if G has property* ATC. *In that case, $\mathcal{T}_C$ is represented by an S-prescheme étale and separated over S.*

b) *Under the hypotheses of* (a), *for every S-torus T, the functor* $\mathrm{Hom}^{\mathrm{cent}}_{S\text{-}gr}(T,G)$ *of central homomorphisms from T into G is represented by an S-prescheme étale and separated over S.*

Theorem 8.9.— *Let S be a locally noetherian prescheme and let G be an S-group prescheme of finite type, smooth over S.*

a) *The functor $\mathcal{T}$ of sub-tori of G is representable if and only if G has property* AT. *In that case, $\mathcal{T}$ is represented by an S-prescheme smooth and separated over S. More precisely, its structural morphism admits a canonical factorization*

$$\mathcal{T} \xrightarrow{u} Y \xrightarrow{v} S,$$

where v is smooth and quasi-projective (hence of finite type) and u is étale and separated.

b) *Under the hypotheses of* (a), *for every S-torus T, the functor* $\mathrm{Hom}_{S\text{-}gr}(T,G)$ *of homomorphisms from T into G is represented by an S-prescheme smooth and separated over S.*

Proof of Theorem 8.8(a). If the functor $\mathcal{T}_C$ is representable, it commutes with adic limits of artinian rings. Consequently, by 8.2 and Proposition 8.5(b), G has property ATC. To prove the converse, we shall use the following result, which will be proved in EGA VI and may also be found in Murre's exposé, *Séminaire Bourbaki*, May 1965, no. 294, Theorem 1, Corollary 2.

Lemma 8.10.— *Let S be a locally noetherian prescheme and let F be a contravariant functor from* Sch $/S$ *to the category of sets. In order that F be representable by an S-prescheme étale and separated over S, it is necessary and sufficient that F satisfy the following five properties:*

i) *F is a sheaf for the fpqc topology (Exposé IV).*

ii) *F commutes with filtered inductive limits of rings (Exposé XI 3.2).*

iii) *F commutes with adic limits of local artinian rings (8.1*(i)*).*

iv) *F satisfies the valuative criterion for separatedness: for every S-prescheme S' that is the spectrum of a discrete valuation ring, with generic point t, the canonical map*

$$F(S') \longrightarrow F(t)$$

is injective.

v) *F is infinitesimally étale (Exposé XI 1.8).*

We show that the functor $\mathcal{T}_C$ of Theorem 8.8 satisfies the five conditions of Lemma 8.10.

i) The functor $\mathcal{T}$, and likewise $\mathcal{T}_C$, is a sheaf for the fpqc topology whenever G is of finite presentation over S. Indeed, every monomorphism from a torus into G is then an immersion (Exposé VIII 7.9), and the assertion follows from fpqc descent for subpreschemes.

ii) Corollary 6.3 proves that $\mathcal{T}$ commutes with filtered inductive limits of rings when G is of finite presentation over S; the same property for $\mathcal{T}_C$ follows immediately.

iii) By Proposition 8.5, condition (iii) is precisely equivalent to property ATC.

iv) If S is the spectrum of a discrete valuation ring, two sub-tori of G with the same generic fibre coincide. More precisely, each is the identity component of the schematic closure in G of that common generic fibre.

v) This follows from Proposition 2.3 because G is flat over S.

Proof of Theorem 8.8(b). Proceeding as in Exposé XI 4.2, it is enough to prove that the product group $T \times_S G$ again has property ATC, which is immediate from the definition.

Proof of Theorem 8.9(a). After replacing G, if necessary, by its identity component (Exposé $\mathrm{VI_B}$ 3.10), we may suppose that G has connected fibres. If T is a sub-torus of G, its centralizer $\mathrm{Centr}_G(T)$ is represented (Exposé XI 6.11) by a subgroup prescheme of G, smooth over S (Exposé XI 2.4), with connected fibres (Exposé XII 6.6(b)). It is therefore an element of $\mathcal{CT}(S)$, where $\mathcal{CT}$ is the functor defined in 7.1(i). The rule

$$T \longmapsto \mathrm{Centr}_G(T)$$

clearly defines an S-morphism

$$u : \mathcal{T} \longrightarrow \mathcal{CT}.$$

Since $\mathcal{CT}$ is represented by an S-prescheme smooth and quasi-projective over S (7.1(i)), it remains only to prove that u is representable by a separated étale morphism.

After a suitable base change $S' \to S$, with $S' = \mathcal{CT}$ and hence S' locally noetherian, we are reduced to the following problem. Let S be a locally noetherian prescheme, let G be an S-group prescheme smooth and of finite type over S, with connected fibres, and let H be a subgroup of G, smooth over S, with connected fibres. Consider the subfunctor X of $\mathcal{T}_{C,H}$ such that, for every S-prescheme S', $X(S')$ is the set of central sub-tori T of $H_{S'}$ for which

$$\mathrm{Centr}_{G_{S'}}(T) = H_{S'}.$$

We shall show that X is represented by an S-prescheme étale and separated over S.

Indeed, G has property AT by hypothesis, and so does H by Proposition 8.7(ii). Since H has connected fibres, it also has property ATC by Proposition 8.7(i). Moreover, H is smooth over S, hence flat. Theorem 8.8(a) therefore represents $\mathcal{T}_{C,H}$ by an S-prescheme étale and separated over S. It is enough to show that the canonical monomorphism

$$X \longrightarrow \mathcal{T}_{C,H}$$

is represented by an open immersion.

Put $S' = \mathcal{T}_{C,H}$, and let K be the centralizer in $G_{S'}$ of the universal central torus of $H_{S'}$. The group K is a smooth group scheme over S', with connected fibres, and contains $H_{S'}$. By definition,

$$X = \prod_{K/S'} H_{S'}/K,$$

which is represented by the open-and-closed subprescheme of S' over which $H_{S'}$ and K have the same relative dimension.

The proof of Theorem 8.9(b) is analogous to that of Theorem 8.8(b).

Corollary 8.11.— *Let S be a prescheme and let G be an S-group prescheme smooth and of finite presentation over S. If the abelian rank of the fibres of G is a locally constant function on S—in particular, if the fibres of G are affine—then the functor of sub-tori of G is represented by an S-prescheme smooth and separated over S. The same holds for the functor* $\mathrm{Hom}_{S\text{-}gr}(T, G)$*, for every S-torus T.*

The assertion is local on S, so we may suppose that S is affine and that the abelian rank of the fibres of G is constant. There are then a noetherian affine scheme S_0 and an S_0-group prescheme G_0, smooth and of finite type over S_0, such that

$$G \simeq G_0 \times_{S_0} S$$

as S-group preschemes (Exposé $\mathrm{VI_B}$, §10). The abelian rank of the fibres of an S-group prescheme of finite presentation is an ind-constructible function (6.3 bis). A standard argument (EGA IV 8) therefore allows us, in the present situation, to choose G_0 so that the abelian rank of its fibres is constant on S_0. Proposition 8.7(iii) gives property AT for G_0, and Theorem 8.9 then represents its functor of sub-tori by an S_0-prescheme smooth and separated over S_0. Base change gives the assertion for G. The argument for $\mathrm{Hom}_{S\text{-gr}}(T, G)$ is analogous.

Generalization of Theorem 8.9. The functor $\mathcal{T}$ of sub-tori of a smooth group G need not be representable. We now give sufficient conditions for a subfunctor of $\mathcal{T}$ to be representable.

Proposition 8.12.— *Let S be a locally noetherian prescheme, let G be an S-group prescheme smooth over S with connected fibres, and let F be an S-subfunctor of the functor $\mathcal{T}$ of sub-tori of G. Suppose that:*

i) *F is a sheaf for the fpqc topology (Exposé IV);*

ii) *F commutes with filtered inductive limits of rings (Exposé XI 3.2);*

iii) *F commutes with adic limits of local artinian rings (Exposé XI 3.3);*

iv) *F is infinitesimally smooth over S (Exposé XI 1.8);*

v) *F is stable under inner automorphisms of G: for every S-prescheme S',*

$$T \in F(S'), \quad g \in G(S') \quad \Longrightarrow \quad \mathrm{int}(g)T \in F(S').$$

Then F is represented by an S-prescheme smooth and separated over S.

Proposition 8.12 bis.— *Let S and G be as in Proposition 8.12, let T be an S-torus, and let F be a subfunctor of* $\mathrm{Hom}_{S\text{-}gr}(T, G)$*. Suppose that F satisfies conditions* (i)–(iv)

of Proposition 8.12 and is stable under inner automorphisms of G: for every S-prescheme S',

$$u \in F(S'), \quad g \in G(S') \quad \Longrightarrow \quad \mathrm{int}(g)u \in F(S').$$

Then F is represented by an S-prescheme smooth and separated over S.

Proof of Proposition 8.12. The proof of Proposition 8.12 bis is entirely analogous and is left to the reader. Let

$$u : F \longrightarrow \mathcal{CT}$$

be the S-morphism which assigns to every $T \in F(S')$ the element $\mathrm{Centr}_{G_{S'}}(T)$ of $\mathcal{CT}(S')$ (7.1(i)). Since $\mathcal{CT}$ is represented by an S-prescheme smooth and quasi-projective over S, we are reduced to proving that u is representable.

After the base change $\mathcal{CT} \to S$, the problem is the following. Given S and G as above and a smooth subgroup H of G with connected fibres, represent the functor F_H defined by

$$F_H(S') = \left\{ T \in F(S') \;\middle|\; H_{S'} = \mathrm{Centr}_{G_{S'}}(T) \right\}.$$

We show that F_H is étale and separated over S by verifying the five conditions of Lemma 8.10.

The first three conditions follow directly from Proposition 8.12(i)–(iii). We have already observed that $\mathcal{T}_{C,H}$ is separated and infinitesimally étale. Thus F_H, being a subfunctor of $\mathcal{T}_{C,H}$, is separated and infinitesimally unramified (Exposé XI 1.8). It remains to prove that F_H is infinitesimally smooth.

Let S be the spectrum of a local artinian ring, let $S_0 \subseteq S$ be defined by a nilpotent ideal, and let $T_0 \in F_H(S_0)$. By Proposition 8.12(iv), T_0 lifts to an element $T' \in F(S)$. Since H is smooth, T_0 also lifts to a sub-torus T'' of H_S (Exposé IX 3.6 bis). This sub-torus is conjugate to T' by an element $g \in G(S)$ (*loc. cit.*), and hence $T'' \in F(S)$ by Proposition 8.12(v). The centralizer $\mathrm{Centr}_{G_S}(T'')$ is smooth over S and agrees with H_{S_0} over S_0. Therefore T'' lies in the centre of H_S (Exposé IX 5.6(a)), and its centralizer in G equals H_S. Thus $T'' \in F_H(S)$, and we take $T = T''$.

Corollary 8.13.— *Let S be a prescheme and let G be an S-group prescheme smooth and of finite presentation over S, with connected fibres. Let $\mathcal{T}_D$ be the subfunctor of $\mathcal{T}$ for which $\mathcal{T}_D(S')$ is the set of sub-tori T of $G_{S'}$ such that, for every $s' \in S'$, $T_{s'}$ is contained in the derived subgroup of $G_{s'}$ (Exposé VI$_B$ 7). Then $\mathcal{T}_D$ is represented by an S-prescheme smooth and separated over S.*

Corollary 8.13 bis.— *Let S and G be as in Corollary 8.13, and let T be an S-torus. Let*

$$\mathrm{Hom}^{\mathrm{der}}_{S\text{-}gr}(T, G)$$

be the subfunctor of $\mathrm{Hom}_{S\text{-}gr}(T, G)$ *whose S'-points are the S'-morphisms $u : T_{S'} \to G_{S'}$ such that, for every $s' \in S'$, the morphism $u_{s'}$ factors through the derived group of $G_{s'}$. Then this functor is represented by an S-prescheme smooth and separated over S.*

The two corollaries have analogous proofs; we prove Corollary 8.13 bis. By the usual procedure, we reduce to the case in which S is noetherian. We verify the five conditions of Proposition 8.12 bis.

Conditions (i) and (iv) follow immediately from the corresponding properties of the functor

$$\mathrm{Hom}_{S\text{-gr}}(T, G).$$

Condition (v) holds because the derived group of an algebraic group is invariant (Exposé $\mathrm{VI_B}$, §7).

For condition (ii), a standard reduction (EGA IV 8) reduces us to the following assertion. Let S be an integral noetherian scheme with generic point η, and let $u : T \to G$ be an S-group morphism whose generic fibre factors through the derived group of G_η. Then there is a neighbourhood U of η such that, for every $s \in U$, u_s factors through the derived group of G_s. This is an immediate consequence of Exposé $\mathrm{VI_B}$ 10.12.

For condition (iii), retain the notation of Proposition 4.3. We must show that an element

$$(u_m)_{m\in\mathbb{N}} \in \varprojlim_m \mathrm{Hom}^{\mathrm{der}}_{S_m\text{-gr}}(T_m, G_m)$$

is admissible in the sense of Proposition 4.3 and comes from an element of $\mathrm{Hom}^{\mathrm{der}}_{S\text{-gr}}(T, G)$. As in 8.1, we reduce immediately to the case in which S is the spectrum of a complete discrete valuation ring. Let t be its generic point, s its closed point, and let D be the schematic closure in G of the derived group D_t of G_t.

a) The group D_s contains the derived group of G_s. Indeed, D_t is invariant in G_t, and G is flat over S, so D is invariant in G. Moreover, the morphism

$$G \times_S G \longrightarrow G, \qquad (x, y) \longmapsto xyx^{-1}y^{-1},$$

factors through D_t on the generic fibre and therefore factors through D. Consequently G_s/D_s is commutative.

b) If $u_m \in \mathrm{Hom}^{\mathrm{der}}_{S_m\text{-gr}}(T_m, G_m)$, then u_m factors through D_m. Its closed fibre u_s factors through the derived group of G_s, hence through D_s by (a). Since D_m is flat over S_m and invariant in G_m, the quotient

$$H_m = G_m/D_m$$

is representable (Exposé $\mathrm{VI_A}$, §4). The image of T_m in H_m is a torus (Exposé IX 6.8) with trivial closed fibre, hence is trivial. Thus u_m factors through D_m.

c) The family $(u_m)_{m\in\mathbb{N}}$ is admissible and lifts to a morphism $T \to G$ belonging to $\mathrm{Hom}^{\mathrm{der}}_{S\text{-gr}}(T, G)$. By what precedes and Proposition 4.1 bis, it is enough to prove that D_t is affine. This follows from the next lemma.

Lemma 8.14.— *Let G be a smooth connected algebraic group over a field k. Then the derived group D of G is affine.*

Formation of D commutes with extension of the base field (Exposé $\mathrm{VI_B}$ 7), so we may suppose that k is algebraically closed. The group G is then an extension of an abelian variety A by a linear group L. Since A is commutative, D is necessarily contained in L, and is therefore affine.

Maximal tori.

Theorem 8.15.— *Let S be a locally noetherian prescheme and let G be an S-group prescheme smooth and of finite type over S. The following conditions are equivalent:*

i) *The S-functor $\mathcal{T}_M$, whose S'-points are the maximal tori of $G_{S'}$ (Exposé XII 1.3), is representable.*

ii) *The functor $\mathcal{T}_M$ is represented by an S-prescheme smooth and quasi-projective over S, with affine fibres.*

iii) *The group G admits a maximal torus locally for the étale topology.*

iv) *The group G admits a maximal torus locally for the faithfully flat topology.*

v) *The group G has property* AT*, and the reductive rank of its fibres is a locally constant function on S.*

Proof. (ii)⇒(i) is clear.

(i)⇒(iii). Since G is of finite presentation over S, Corollary 6.3 shows that $\mathcal{T}_M$ commutes with filtered inductive limits of rings. If representable, it is therefore locally of finite presentation (EGA IV 8.14). Moreover, $\mathcal{T}_M$ is formally smooth (Exposé XI 2.1 bis). Hence its representing prescheme is smooth over S, and (iii) follows from Hensel's lemma (Exposé XI 1.10).

(iii)⇒(iv) is clear.

(iv)⇒(v). Let $s \in S$. There is an S-prescheme S', flat over S and with image containing s, such that $G_{S'}$ has a maximal torus T'. If $s' \in S'$ lies over s, the reductive rank of the fibres of $G_{S'}$ is constant on $\operatorname{Spec} \mathcal{O}_{S',s'}$. Thus the reductive rank of the fibres of G is constant on its image $\operatorname{Spec} \mathcal{O}_{S,s}$ (EGA IV 2.3.4(ii)). Since this rank is a locally constructible function on S (6.3 bis), it is constant on a neighbourhood of s (EGA IV 1.10.1).

To prove property AT, let S_1 be an S-scheme which is the spectrum of a discrete valuation ring, whose closed point s_1 maps to s. The prescheme

$$S'_1 = S_1 \times_S S'$$

is faithfully flat over S_1, and $G_{S'_1}$ has a maximal torus. Let A and A' be the rings of S_1 and S'_1, respectively. Writing A' as the filtered inductive limit of its finitely generated A-subalgebras and applying Corollary 6.3, we obtain an S_1-scheme S''_1 such that $G_{S''_1}$ has a maximal torus and $S''_1 \to S_1$ is of finite type and surjective. By EGA II 7.1.9, we may reduce to the case in which S'_1 is the spectrum of a discrete valuation ring. Then $G_{S'_1}$, and hence G_{S_1}, has property AT. Since this holds for every such S_1, G has property AT.

(v)⇒(i). By Theorem 8.9 the functor $\mathcal{T}$ of sub-tori of G is representable. If the reductive rank of G is the constant function r, then $\mathcal{T}_M$ is represented by the open-and-closed subprescheme of $\mathcal{T}$ representing the subfunctor of tori of rank r.

(iii)⇒(ii). Under condition (iii), the results of Exposé XII 7.1 identify $\mathcal{T}_M$ canonically with the functor of Cartan subgroups of G. The assertion follows from Theorem 7.3(i).

Remark 8.16. The prescheme $\mathcal{T}_M$ of maximal tori of G can in fact be shown to be affine over S,[13] generalizing Exposé XII 5.4.

Corollary 8.17.— *Let S be a prescheme and let G be an S-group prescheme smooth and of finite presentation over S. If the abelian and reductive ranks of the fibres of G are locally constant functions on S, then G satisfies the equivalent conditions* (i)–(iv) *of Theorem 8.15.*

We may suppose that the abelian and reductive ranks of the fibres of G are constant. Proceeding as in Corollary 8.11 and using 6.3 bis, we reduce to the case in which S is noetherian. Then G has property AT by Proposition 8.7, and the conclusion follows from Theorem 8.15(v).

[13] Cf. M. Raynaud, *Faisceaux amples sur les schémas en groupes et les espaces homogènes* (thesis, forthcoming). Editor's note: see *Lecture Notes in Mathematics* 119 (1970), Springer, especially IX 2.9.

Corollary 8.18.— *Let S be a prescheme and let G be an S-group prescheme smooth over S. The following conditions are equivalent:*

a) *The unipotent rank ρ_u and the abelian rank ρ_{ab} of the fibres of G are locally constant functions on S.*

b) *The unipotent rank ρ_u is locally constant, and G admits maximal tori locally for the fpqc topology.*

c) *The reductive rank ρ_r and the abelian rank ρ_{ab} of the fibres of G are locally constant functions on S.*

Remark 8.19. Under the hypotheses of Corollary 8.18, a more precise argument using lower semicontinuity of the abelian rank, announced in Exposé X 8.7, shows that if two of the three ranks $\rho_u, \rho_r, \rho_{\mathrm{ab}}$ are locally constant, then so is the third.

Proof of Corollary 8.18. After replacing G, if necessary, by its identity component, we may suppose that G is of finite presentation over S (Exposé $\mathrm{VI_B}$ 5.3.3).

(a)⇒(c). Let $s \in S$. Since ρ_{ab} is locally constant, Corollary 8.11 allows us, after an étale extension covering S, to suppose that G has a sub-torus T whose fibre T_s is a maximal torus of G_s. Put

$$C = \mathrm{Centr}_G(T).$$

This is a subgroup prescheme of G, smooth over S, with connected fibres. For every $t \in S$, the group C_t contains a Cartan subgroup C'_t of G_t. After shrinking S, we may suppose that ρ_u, ρ_{ab}, and the relative dimension of C over S are constant. We then have

$$\begin{aligned}\dim C_s = \dim C_t &\geq \dim C'_t \\ &\geq \rho_u(t) + \rho_{\mathrm{ab}}(t) + \dim T_t \\ &= \rho_u(s) + \rho_{\mathrm{ab}}(s) + \dim T_s \\ &= \rho_\nu(s) = \dim C_s.\end{aligned}$$

It follows that $C_t = C'_t$. Thus T is a maximal torus of G, and in particular $\rho_r(t) = \rho_r(s)$.

(c)⇒(b) follows from Corollary 8.17.

(b)⇒(a). Since G admits maximal tori locally for the fpqc topology, it also admits Cartan subgroups locally for that topology. Hence, by Exposé XII 7.3, the nilpotent rank

$$\rho_\nu = \rho_u + \rho_r + \rho_{\mathrm{ab}}$$

is locally constant. The existence of maximal tori makes ρ_r locally constant, while ρ_u is locally constant by hypothesis; therefore ρ_{ab} is locally constant.

Exposé XVI
Groups of Unipotent Rank Zero

by M. Raynaud[(*)]

1. An Immersion Criterion

1.1. Examples of Monomorphisms of Group Preschemes That Are Not Immersions

We shall construct a prescheme S, two S-group preschemes G and H, and an S-group monomorphism

$$u : G \longrightarrow H$$

that is not an immersion. The groups G and H will be of finite presentation over S, flat over S, and G will even be smooth over S (cf. Exposé VIII, the paragraph and note $(*)$ preceding 7.1; see also XVII, Appendix III, 4).

First take S to be the spectrum of a discrete valuation ring A of unequal characteristic and residue characteristic 2. Let t be the generic point of S and s the closed point.

a) Take for G the open subgroup of the constant group

$$G' = (\mathbb{Z}/2\mathbb{Z})_S$$

obtained by removing the point of the closed fiber $(\mathbb{Z}/2\mathbb{Z})_s$ distinct from the identity element, and take for H the group of multiplicative type $(\mu_2)_S$ of square roots of unity (Exposé I, 4.4.4). By the choice of S, H_t is isomorphic to $(\mathbb{Z}/2\mathbb{Z})_t$, whereas H_s is a radicial group. There is an evident morphism $G' \to H$, defined by the section (-1) of H, hence a morphism $u : G \to H$ which is a monomorphism but not an immersion (otherwise it would necessarily be an isomorphism; cf. Exposé VIII, 7). Here Exposé VIII, 7.9 does not apply, since ${}_2G = G$ is not finite over S.

b) Let K denote the étale, nonseparated S-group prescheme obtained from the identity group by "doubling" the unique point of the closed fiber. Take for H the product group

$$(\mu_2)_S \times_S K.$$

Let a (respectively b) be the unique section of μ_2 (respectively K) over S distinct from the identity section, and let $h = (a, b)$ be the corresponding section of H. The datum of h defines an S-group morphism

$$u : G = (\mathbb{Z}/2\mathbb{Z})_S \longrightarrow H.$$

[0] xy version of December 1, 2008.

[*] Cf. the note on page 1 of Exposé XV.

It is clear that u is a monomorphism and is not an immersion. Here Exposé VIII, 7.9 does not apply, since ${}_2H = H$ is not separated over S.

c) More interesting is the following example, in which G is a smooth group with connected fibers (and even $G = (\mathbb{G}_a)_S$); cf. Exposé VIII, 7.10.

Take for S the spectrum of a discrete valuation ring A of equal characteristic 2, and let π be a uniformizer of A and $\mathfrak{m}$ the maximal ideal of A.

Consider the additive group $(\mathbb{G}_a)_S$, the product group $(\mathbb{G}_a \times \mathbb{G}_a)_S$ with ring $A[X, Y]$, and let G_1 be the closed subgroup defined by

$$X^2 + X - \pi Y = 0. \tag{1}$$

The group G_1 is smooth over S; its generic fiber is isomorphic to $(\mathbb{G}_a)_t$, and its closed fiber is isomorphic to the product of $(\mathbb{G}_a)_s$ with $(\mathbb{Z}/2\mathbb{Z})_s$. For the $(\mathbb{Z}/2\mathbb{Z})_s$-factor one may take the subgroup N_s of $(G_1)_s$ defined by

$$Y = X^2 + X = 0. \tag{2}$$

Let N' and N'' be two group subschemes of G_1, isomorphic to $(\mathbb{Z}/2\mathbb{Z})_S$, whose closed fibers coincide with N_s and whose generic fibers are distinct. Thus N' and N'' are defined by two sections of G_1 over S, with coordinates (a', b') and (a'', b''), respectively, such that

$$\begin{cases} a'^2 + a' - \pi b' = a''^2 + a'' - \pi b'' = 0, \\ a' \text{ and } a'' \equiv 1 \pmod{\mathfrak{m}}, \qquad a' \neq a'', \\ b' \text{ and } b'' \equiv 0 \pmod{\mathfrak{m}}. \end{cases} \tag{3}$$

(For example, one may take $(1, 0)$ and $(1 + \pi^2, \pi + \pi^3)$.)

The quotient groups

$$G' = G_1/N' \qquad \text{and} \qquad G'' = G_1/N''$$

are representable (Exposé V, 4.1). Let u be the canonical morphism

$$u : G_1 \longrightarrow G' \times_S G'',$$

and let H be the group subscheme of $G' \times_S G''$ equal to the schematic closure in $G' \times_S G''$ of $u_t((G_1)_t)$, so that u factors through H. The kernel of u is

$$K = N' \cap N'',$$

whose generic fiber is the identity group and whose closed fiber is equal to N_s; in particular, K is not flat over S. On the generic fiber, u_t is therefore an isomorphism from $(G_1)_t$ onto H_t. On the other hand, H_s is not smooth. Indeed, if H_s were smooth, then, since u_s is a morphism with finite kernel and $(G_1)_s$ and H_s have the same dimension, namely 1, u_s would be flat. Since G_1 and H are flat, u would then be flat, and consequently $\operatorname{Ker} u$ would be flat over S, which it is not. It is clear that the restriction of u to the identity component G of G_1 is a monomorphism: the fibers of $K \cap G$ are identity groups, so $K \cap G$ is the identity group (Exposé $\mathrm{VI_B}$, 2.9). But it is not an immersion, for otherwise it would be an open immersion and H_s would be smooth. Here Exposé VIII, 7.9 does not apply, since ${}_2G = G$ is not finite over S.

For lovers of equations, in the preceding example one may take for H the closed subgroup of $(\mathbb{G}_a \times_S \mathbb{G}_a)_S$ with ring $A[V, W]/(F)$, where

$$F = (a''b' - b''a')(a''^2 V - a'^2 W) - (a''V - a'W)^2$$

(where a', a'', b', b'' satisfy (3)). For G one takes the group $(\mathbb{G}_a)_S$ with ring $A[T]$, and for the morphism $u : G \to H$ the S-morphism defined by

$$V \longmapsto a'(a'T + \pi T^2), \qquad W \longmapsto a''(a''T + \pi T^2).$$

Remark 1.2. — The preceding construction is inspired by the method of Koizumi–Shimura.[1] It does not apply when S is the spectrum of a ring of unequal characteristic, because the points of finite order of G are then "too rigid."

1.3. Statement of the Immersion Criterion

Theorem 1.3. — *Let S be a locally noetherian prescheme, let G be an S-group prescheme, smooth and of finite type over S, possessing Cartan subgroups locally for the fpqc topology (Exposé XV, 6.1 and 7.3 (i)), let H be an S-group prescheme locally of finite type, and let $u : G \to H$ be an S-group monomorphism. Then:*

a) If G has connected fibers, then u is an immersion if and only if, for every S-scheme S' that is the spectrum of a complete discrete valuation ring with algebraically closed residue field, and every Cartan subgroup C of $G_{S'}$, the restriction of $u_{S'}$ to C is an immersion.

b) The morphism u is an immersion (respectively a closed immersion) if and only if, for every S' as above and every Cartan subgroup C of the identity component $(G_{S'})^0$ of $G_{S'}$, the restriction of $u_{S'}$ to the normalizer N of C in $G_{S'}$ (Exposé XI, 6.11) is an immersion (respectively a closed immersion).

Before proving 1.3, let us state some applications.

Corollary 1.4. — *Let S be a prescheme, let G be an S-group prescheme, smooth and of finite presentation over S, of unipotent rank zero (Exposé XV, 6.1 ter), possessing maximal tori locally for the fpqc topology, let H be an S-group prescheme, and let $u : G \to H$ be an S-group monomorphism. Suppose in addition either that H is of finite presentation over S, or that S is locally noetherian and H is locally of finite type. Then:*

a) If G has connected fibers, u is an immersion.

b) If H is separated over S, and if for every S' over S and every maximal torus T of $G_{S'}$, the Weyl group

$$W = \mathrm{Norm}_{G_{S'}}(T)/\,\mathrm{Centr}_{G^0_{S'}}(T)$$

is representable (a condition always satisfied when G has connected fibers; Exposé XV, 7.1 (iv)) and finite over S, then u is a closed immersion.

Corollary 1.5. — *Let S be a prescheme, let G be an S-group prescheme, smooth and of finite presentation over S, with connected fibers, let H be an S-group prescheme, and let $u : G \to H$ be an S-group monomorphism. Suppose either that H is of finite presentation over S, or that S is locally noetherian and H is locally of finite type. Then:*

a) If G is reductive, that is, affine over S with reductive fibers (cf. Exposé XIX), u is an immersion, and a closed immersion if H is separated.

[1] Editor's note: S. Koizumi and G. Shimura, "Specialization of abelian varieties," *Sci. Papers Coll. Gen. Ed. Univ. Tokyo* 9 (1959), 187–211.

b) If G has affine, solvable, connected fibers of unipotent rank zero, u is an immersion, and a closed immersion if H is separated.

Proof of 1.4 from 1.3.

Reduction to the noetherian case. If S is locally noetherian, the reduction is immediate, since the properties to be proved are local on S. In the second case G and H are of finite presentation over S. After shrinking S, we may suppose that S is affine. By Exposé $\mathrm{VI_B}$, §10, there exist a noetherian scheme S_0, an S_0-group prescheme G_0, smooth over S_0 (with connected fibers in case a)) and of finite type over S_0, an S_0-group prescheme H_0 of finite type (separated in case b)), and an S_0-group morphism

$$u_0 : G_0 \longrightarrow H_0$$

such that G, H, u are obtained from G_0, H_0, u_0 by the base extension $S \to S_0$. The assertion that u is a monomorphism means that $\operatorname{Ker} u$ is the identity group; we may therefore suppose that u_0 is a monomorphism.

Since G has unipotent rank $\rho_u = 0$ and possesses maximal tori locally for the fpqc topology, the abelian rank ρ_{ab} of the fibers of G is locally constant (Exposé XV, 8.18). But ρ_u and ρ_{ab} are locally constructible functions (Exposé XV, 6.3 bis). A standard argument (cf. EGA IV, 8.3.4) shows that one may choose S_0 and G_0 so that the unipotent rank (respectively the abelian rank) of the fibers of G_0 is zero (respectively locally constant). Then G_0 possesses maximal tori locally for the fpqc topology (Exposé XV, 8.18), and the functor $\mathcal{TM}_{G_0}$ of maximal tori of G_0 is representable by an S_0-scheme X_0 of finite type over S_0 (Exposé XV, 8.15). Let T_0 be the "universal" maximal torus of $(G_0)_{X_0}$, let $X = X_0 \times_{S_0} S$, and let $T = T_0 \times_{S_0} S$, the universal maximal torus for G. By hypothesis, in case b), the Weyl group relative to T is representable and finite over X. These two properties are compatible with projective limits of preschemes (Exposé $\mathrm{VI_B}$, 10.1 iii, and EGA IV, 8.10.5). We may therefore choose S_0 so that the Weyl group of T_0 is finite over X_0. Under these conditions, to prove 1.4 we may replace S, G, u, H by S_0, G_0, u_0, H_0, and hence suppose that S is noetherian.

Use the valuative criterion furnished by 1.3. We are reduced to the case where S is the spectrum of a discrete valuation ring and where G^0 possesses a Cartan subgroup C.

Proof of 1.4 a). We must show that the restriction of u to C is an immersion (1.3 a)), which reduces us to the case where $G = C$ has connected, nilpotent fibers. Standard reductions (cf. the proof of Exposé VIII, 7.1) reduce us to the case where H is flat over S, u is an isomorphism on the generic fiber, and u is an isomorphism of the underlying spaces on the closed fiber. The group H then has connected fibers and is therefore separated over S (Exposé $\mathrm{VI_B}$, 5.2). Grant for a moment the following lemma.

Lemma 1.6. — *Let S be a prescheme and let G be an S-group prescheme, smooth over S, with connected, nilpotent fibers and unipotent rank zero. Then:*

i) G is commutative.

ii) For every integer $n > 0$, ${}_nG$ is an S-group prescheme, flat and quasi-finite over S, and it is finite over S if and only if the abelian rank, or the reductive rank, of G is locally constant on S.

iii) For every integer $q > 0$ invertible on S, the family of subgroups ${}_{q^n}G$ is universally schematically dense in G relative to S (EGA IV, 11.10.8).

Lemma 1.6 applies to G, and since G possesses maximal tori locally, the reductive rank of the fibers of G is locally constant. Thus, by 1.6 ii), ${}_nG$ is finite over S for every integer $n > 0$. It follows from Exposé VIII, 7.9 that u is an immersion.

Proof of 1.6. Let us first examine the case where S is the spectrum of a field.

Lemma 1.7. — *Let k be a field of characteristic p, and let G be a smooth, connected, nilpotent algebraic k-group of unipotent rank zero. Then G is a commutative group, an extension of an abelian variety A by a torus T. For every integer $n > 0$, ${}_nG$ is a finite group, étale if $(n,p) = 1$, defined by a k-algebra of rank $n^{\rho_r+2\rho_{ab}}$. If $(q,p) = 1$, the family of subgroups ${}_{q^n}G$, $n \in \mathbb{N}$, is schematically dense in G.*

Proof of 1.7. Let Z be the center of G. The group G/Z is affine (Exposé XII, 6.1), smooth, connected, and of unipotent rank zero; hence it is a torus (BIBLE 4, th. 4). It follows that G is commutative (Exposé XII, 6.4). If T is the unique maximal torus of G (Exposé XV, 3.4), Chevalley's theorem (Séminaire Bourbaki 1956/57, no. 145) immediately shows that G is an extension of an abelian variety A by T. For every integer $n > 0$, raising to the n-th power is an epimorphism on T, whence the exact sequence

$$0 \longrightarrow {}_nT \longrightarrow {}_nG \longrightarrow {}_nA \longrightarrow 0.$$

A classical theorem of Weil (A. Weil, *Variétés abéliennes et courbes algébriques*, §IX, th. 33, cor. 1) says that ${}_nA$ is a finite group defined by a k-algebra of rank $n^{2\rho_{ab}}$. Since ${}_nT$ is a finite group of rank n^{ρ_r}, the asserted structure of ${}_nG$ follows.

Now let H be the smallest closed subscheme of G containing ${}_{q^n}G$ for every n. It follows from the preceding discussion and Exposé XV, 4.6 that H is a smooth, connected subgroup, hence of the same type as G. Raising to the q-th power on H is an epimorphism (since ${}_qH$ is finite), so there is an exact sequence

$$0 \longrightarrow {}_qH \longrightarrow {}_qG \longrightarrow {}_q(G/H) \longrightarrow 0.$$

It follows that ${}_q(G/H) = 0$, and therefore $G/H = 0$. Thus the subgroups ${}_{q^n}G$ are schematically dense in G.

Continuation of the proof of 1.6 i). To show that G is commutative, the usual procedure reduces us first to the case where S is noetherian, and then to the case where S is the spectrum of a local ring with closed point s. The center of G is represented by a closed group subscheme Z of G (Exposé XI, 6.11). To prove that $Z = G$, it suffices to prove this after reduction modulo every power of the maximal ideal of the ring of S: Z will then be an open subgroup of G, and hence equal to G, since G has connected fibers. This reduces us to the case where S is local Artinian.

Let q be an integer invertible on S. For every integer n, ${}_{q^n}G_s$ is an étale, central subgroup of multiplicative type of G_s (1.7). Since G is smooth, ${}_{q^n}(G_s)$ lifts to an étale, central S-group subscheme M_n of G (Exposé XV, 1.2). The family of flat subgroups M_n, $n \in \mathbb{N}$, is then schematically dense in G (1.7 and EGA IV, 11.10.9). Since Z is closed in G and contains every M_n, we have $Z = G$.

Proof of 1.6 ii). To see that ${}_nG$ is flat and quasi-finite over S, it suffices to show that the n-th power map on G is flat and quasi-finite. Since G is flat over S, we are reduced to the case where S is the spectrum of a field (EGA IV, 11.3.10), and we observed in the proof of 1.7 that the n-th power map is an epimorphism. Moreover, ${}_nG$ is separated over S, since G is separated over S (Exposé $\mathrm{VI_B}$, 5.2). For ${}_nG$ to be finite over S, it is necessary and sufficient that the fibers of ${}_nG$ be spectra of finite algebras of locally constant rank. This is seen immediately by reducing to the case where S is the spectrum of a henselian local

ring. By 1.7, this condition is equivalent to saying that the abelian rank, or the reductive rank, of the fibers of G is locally constant.

Proof of 1.6 iii). To see that the family of subgroups ${}_{q^n}G$, $n \in \mathbb{N}$, is universally schematically dense in G, we again reduce to the noetherian case. In view of 1.7 and 1.6 ii), it suffices to apply EGA IV, 11.10.9.

Proof of 1.4 b). We have reduced to the case where S is the spectrum of a discrete valuation ring and where G^0 possesses a Cartan subgroup C. Let

$$N = \mathrm{Norm}_G(C) = \mathrm{Norm}_G(T),$$

where T is the unique maximal torus of C (Exposé XII, 7.1 a) and b)). Since H is separated over S, it follows from 1.6 ii) and Exposé VIII, 7.12 that the restriction of u to C is a closed immersion. On the other hand, to prove that u is a closed immersion, it suffices to prove this for $u|_N$ (1.3 b)). Since, by hypothesis, $W = N/C$ is represented by a finite group scheme, the assertion follows from the next lemma, applied to the exact sequence

$$0 \longrightarrow C \longrightarrow N \longrightarrow W \longrightarrow 1.$$

(Recall that a proper immersion is a closed immersion.)

Lemma 1.8. — *Let S be a prescheme and let G be an S-group prescheme of finite presentation over S, an extension of an S-group prescheme G'', proper and of finite presentation over S, by an S-group prescheme G', flat and of finite presentation over S:*

$$1 \longrightarrow G' \longrightarrow G \longrightarrow G'' \longrightarrow 1.$$

Let H be an S-group prescheme of finite presentation over S (or locally of finite presentation if S is locally noetherian), and let $u : G \to H$ be an S-group morphism. If the restriction of u to G' is proper, then u is proper.

Proof of 1.8. As usual, we reduce to the case where S is noetherian (Exposé $\mathrm{VI_B}$, §10, and Exposé XV, 6.2), and we may then apply the valuative criterion of properness (EGA II, 7.3.8). We therefore suppose that S is the spectrum of a discrete valuation ring A, with closed point s and generic point t. Let $\bar{x} \in G(t)$ and $h \in H(S)$ satisfy

$$u_t(\bar{x}) = h(t).$$

We must show that $\bar{x}$ comes from a unique element $x \in G(S)$. It is enough to prove the existence and uniqueness of x after a faithfully flat extension of the discrete valuation ring A. Let $\bar{y}$ be the image of $\bar{x}$ in $G''(t)$. Since G'' is proper over S, $\bar{y}$ comes from a unique element $y \in G''(S)$. Let X be the inverse image of y in G. The prescheme X is faithfully flat over S, since G' is faithfully flat over S, as is the morphism $G \to G''$ (Exposé $\mathrm{VI_B}$, §9). After a faithfully flat change of discrete valuation ring, we may suppose that X has a section ℓ over S (EGA IV, 14.5.8). Replacing $\bar{x}$ by $\bar{x}\ell_t^{-1}$, we may suppose that $\bar{x} \in G'(t)$. The existence and uniqueness of x now follow from the properness of $u|_{G'}$.

Proof of 1.5.

a) We shall see in Exposé XIX that, if G is reductive, then G possesses maximal tori locally for the faithfully flat topology, has a finite Weyl group, and has unipotent rank zero. Assertion a) therefore follows from 1.4.

b) If G has affine fibers and unipotent rank zero, then G possesses maximal tori locally for the fpqc topology (Exposé XV, 8.18). It remains only to apply 1.4, observing that,

since G has connected, smooth, affine, solvable fibers, its Weyl group is the identity group (BIBLE 6, th. 1, cor. 3).

Proof of 1.3 a). Since u is already a monomorphism, to prove that u is an immersion it suffices to prove that u is proper at the points of $u(G)$ (EGA IV, 15.7.1); for this we may use the valuative criterion of local properness (EGA IV, 15.7.5). We are therefore reduced to the case where S is the spectrum of a complete discrete valuation ring with algebraically closed residue field, closed point s, and generic point t. Since G is flat over S, standard reductions (cf. the proof of Exposé VIII, 7.1) reduce us to the case where H is flat over S, u_t is an isomorphism, and u_s is an isomorphism of underlying spaces. To say that u is an immersion is then equivalent to saying that u is an isomorphism.

By hypothesis, G possesses Cartan subgroups locally for the fpqc topology, so we may speak of the open subset U of regular points of G (Exposé XV, 7.3 i) and ii)).

Lemma 1.9. — *Under the preceding hypotheses, for u to be an immersion it suffices that $u|_U$ be an immersion.*

Indeed, to say that $u|_U$ is an immersion means that there exist an open subscheme V of H and a closed subscheme F of V such that $u|_U$ factors through F and induces an isomorphism from U onto F. Since H_t, and therefore V_t, is irreducible, one necessarily has $V_t = F_t$. Then F contains the schematic closure of V_t in V, which equals V because H is flat over S. Thus $V = F$. It follows that $u|_U$ is an open immersion, and hence that u is an open immersion (Exposé $\mathrm{VI_B}$, 2.6).

It remains to prove that $u|_U$ is an immersion. For this we apply the valuative criterion of local properness. After replacing S by the spectrum of a discrete valuation ring faithfully flat over S, we must show the following: if h is a section of H over S whose image $h(S)$ is contained in $u(U)$, then h is the image of a section g of U over S. It suffices to show that h is contained in the image of a Cartan subgroup C of G. Indeed, by hypothesis $u|_C$ is an immersion, so h is the image of a section g of C, necessarily a section of U.

Let $a \in U(s)$ and $b \in U(t)$ satisfy, respectively,

$$u_s(a) = h(s), \qquad u_t(b) = h(t).$$

Since u_t is an isomorphism, $h(t)$ is a regular point of H_t, and is therefore contained in a unique Cartan subgroup D_t of H_t (Exposé XIII, 3.2). Let D be the schematic closure of D_t in H.

Lemma 1.10. —

i) *D_s is a nilpotent algebraic group (Exposé VI_B, §8).*

ii) $\dim D_s = \nu$, *where ν is the nilpotent rank of G, and also the nilpotent rank of $(H_s)_{\mathrm{red}}$.*

iii) $h(s) \in D_s(\kappa(s))$.

i) Since H is separated (Exposé $\mathrm{VI_B}$, 5.2), so is D. Moreover, D is flat over S and its generic fiber is nilpotent. It follows from Exposé $\mathrm{VI_B}$, 8.4 that D_s is nilpotent.

ii) Since $(H_s)_{\mathrm{red}} \simeq G_s$, these two groups have the same nilpotent rank. Since G possesses Cartan subgroups locally for the fpqc topology, G_s and G_t have the same nilpotent rank ν. Finally, since D is flat over S,

$$\dim D_s = \dim D_t = \nu$$

(Exposé $\mathrm{VI_B}$, §4).

iii) Since h_t factors through D_t, the section h plainly factors through D, which proves iii).

The next lemma now shows that $(D_s)_{\mathrm{red}}$ is a Cartan subgroup of

$$(H_s)_{\mathrm{red}} \simeq G_s.$$

Lemma 1.11. — *Let G be a smooth, connected algebraic group over an algebraically closed field k, and let D be a smooth, nilpotent algebraic subgroup containing a regular element $a \in G(k)$. Then D^0 is contained in a Cartan subgroup of G. If, in addition, $\dim D$ equals the nilpotent rank of G, then D is a Cartan subgroup of G, and in particular is connected.*

Let Z be the center of G, let $G' = G/Z$, which is affine (Exposé XII, 6.1), and let a' and D' be the images of a and D in G'. The correspondence between Cartan subgroups of G and Cartan subgroups of G' (Exposé XII, 6.6 e)) shows at once that a' is a regular element of G' and that it suffices to prove the lemma for the pair (D', G'). Thus we may suppose that G is affine.

Let s be the semisimple component of a. It belongs to $D(k)$ (BIBLE 4, th. 3) and is regular (BIBLE 7, th. 2, cor. 1). By BIBLE 6, th. 2, s centralizes D^0; hence D^0 is contained in the connected centralizer of s, which is a Cartan subgroup of G (BIBLE 7, th. 2). If now $\dim D$ equals the nilpotent rank of G, then D^0 is a Cartan subgroup of G, equal to $\mathrm{Centr}_G(T)$, where T is the unique maximal torus of D^0 (Exposé XII, 6.6). But D is nilpotent, and therefore centralizes T (BIBLE 6, th. 2), so $D = D^0$.

Return now to the group G. The group

$$C_t = u_t^{-1}(D_t)$$

is the unique Cartan subgroup of G_t containing b. Let C be the schematic closure of C_t in G.

By functoriality of schematic closure, $u|_C$ factors through D, and therefore $u_s(C_s) \subset D_s$. Since u_s is an isomorphism from G_s onto $(H_s)_{\mathrm{red}}$, since

$$\dim C_s = \dim C_t = \nu = \dim D_s$$

by 1.10, and since D_s is connected by 1.11, u_s induces an isomorphism from $(C_s)_{\mathrm{red}}$ onto $(D_s)_{\mathrm{red}}$. Thus $(C_s)_{\mathrm{red}}$ is a Cartan subgroup of G_s. The next lemma shows that C itself is a Cartan subgroup of G.

Lemma 1.12. — *Let S be the spectrum of a discrete valuation ring, let G be a smooth S-group prescheme of finite type, and let C be a group subscheme of G, flat over S, such that the generic fiber C_t is a Cartan subgroup of G_t and the geometric reduced closed fiber $(C_{\bar{s}})_{\mathrm{red}}$ is a Cartan subgroup of $G_{\bar{s}}$. Then C is a Cartan subgroup of G.*

We must prove that C is smooth over S, and it suffices to establish this after a faithfully flat extension of the base. The hypotheses on C imply that the nilpotent rank of the fibers of G is constant; hence we may speak of the open subset U of regular points of G (Exposé XV, 7.3). Since $(C_{\bar{s}})_{\mathrm{red}}$ is a Cartan subgroup of $G_{\bar{s}}$, $C_{\bar{s}}$ contains a regular point $a_{\bar{s}}$ of $G_{\bar{s}}$. Since C is flat over S, after a faithfully flat extension of the base if necessary (EGA IV, 14.5.8), we may suppose that $a_{\bar{s}}$ is an element of $G(s)$ which lifts to a section $a \in C(S)$. Since U is open and contains $a(s)$, it contains a. Let C' be the unique Cartan subgroup of G containing a (Exposé XV, 7.3). Necessarily $C_t = C'_t$, and consequently C' and C coincide with the identity component of the schematic closure of C_t in G (observe that both C' and C are flat over S).

End of the proof of 1.3 a). By hypothesis, the restriction of u to the Cartan subgroup C of G is an immersion. It is clear that $h(S)$ is contained in $u(C) = D$, and hence h is the image of a section $g \in C(S)$. □

Proof of 1.3 b). We shall again use the valuative criterion of local properness (EGA IV, 15.5) in the case of an immersion (respectively, the valuative criterion of properness (EGA II, 7.3.6) in the case of a closed immersion). This reduces us to the case where S is the spectrum of a complete discrete valuation ring with algebraically closed residue field. Let s be the closed point and t the generic point of S. Replacing H by the schematic closure in H of $u_t(G_t)$, we may suppose that H is flat over S and that u_t is an isomorphism.

Let G^0 be the connected component of G. By 1.2 a), the restriction $u|_{G^0}$ is an immersion; denote by H^0 the group subprescheme of H that is the image of G^0. Thus

$$H^0_s = (H_s)^0_{\mathrm{red}}.$$

To verify the valuative criterion, we must show that every section h of H over S such that $h(S)$ is contained in $u(G)$, in the case of an immersion (respectively, every section h of H over S, in the case of a closed immersion), is the image of a section g of G over S.

Let C be a Cartan subgroup of G, and let $D = u(C)$ be the Cartan subgroup of H^0 that is the image of C. The S-group

$$D' = \mathrm{int}(h)D$$

has connected fibers, so its underlying space is contained in that of H^0; on the other hand, since it is smooth over S, it is reduced, and hence D' is a smooth group subprescheme of H^0. The fibers of D' are Cartan subgroups of the fibers of H^0; therefore D' is a Cartan subgroup of H^0, and

$$C' = u^{-1}(D')$$

is a Cartan subgroup of G. But $\mathrm{Transpstr}_G(C, C')$ is smooth and surjective over S (Exposé XII, 7.1 b)). Since S is henselian with algebraically closed residue field, there exists $g \in G(S)$ such that $\mathrm{int}(g)C = C'$. Replacing h by $u(g)^{-1}h$, we may suppose that $h(t)$ normalizes D_t (and that $h(s)$ is the image of an element of the normalizer of C_s in G_s, in the case of an immersion). Let

$$N = \mathrm{Norm}_G(C).$$

By hypothesis, $u|_N$ is an immersion (respectively, a closed immersion); hence h is indeed the image of a section of N over S, which completes the proof. □

2. A Representability Theorem for Quotients

Let us "recall" the following result.

Theorem 2.1. — *Let S be a prescheme, let X and Y be two S-preschemes, and let $f : X \to Y$ be an S-morphism. Suppose that one is in one of the following two cases:*

a) The morphism f is locally of finite presentation.

b) The prescheme S is locally noetherian and X is locally of finite type over S.

Then the following conditions are equivalent:

i) There exist an S-prescheme X' and a factorization of f

$$f : X \xrightarrow{f'} X' \xrightarrow{f''} Y,$$

where f' is a faithfully flat S-morphism, locally of finite presentation, and f'' is a monomorphism.

ii) The first projection

$$p_1 : X \times_Y X \longrightarrow X$$

is a flat morphism.

Moreover, if the preceding conditions hold, then (X', f') is a quotient of X, for the fpqc topology, by the equivalence relation defined by f. Consequently the factorization $f = f'' \circ f'$ in i) is unique up to isomorphism.

The proof of this delicate theorem will be given in EGA V. One may also consult the lecture by J.-P. Murre, *Séminaire Bourbaki*, May 1965, no. 294, theorem 2, corollary 2, which treats the case where Y is locally noetherian and X is of finite type over Y. We shall see that one can reduce to that case.

Let us first make a few remarks.

a) The implication i) $\Rightarrow$ ii) is trivial. Indeed, the first projection

$$p_1' : X \times_{X'} X \longrightarrow X$$

factors through $X \times_Y X$:

$$p_1' : X \times_{X'} X \xrightarrow{u} X \times_Y X \xrightarrow{p_1} X.$$

The morphism u is an isomorphism because f'' is a monomorphism, and p_1' is flat because f' is flat; therefore p_1 is flat.

b) The assertions of 2.1 are local on Y (hence local on S); they are also local on X, as follows readily from the fact that a flat morphism locally of finite presentation is open (EGA IV, 11.3.1).

c) Under the hypotheses of 2.1 a), the foregoing reduces us to the case where X and Y are affine and f is of finite presentation. Replacing S by Y, we may suppose that X and Y are of finite presentation over S. We then reduce to the noetherian case for S by EGA IV, 11.2.6.

d) Under the hypotheses of 2.1 b), we may suppose that S, X, and Y are affine, that S is noetherian, and that X is of finite type over S. Regard Y as a filtered projective limit of affine schemes Y_i of finite type over S. The schemes $X \times_{Y_i} X$ form a decreasing filtered family of closed subschemes of $X \times_S X$, whose projective limit is $X \times_Y X$. Since $X \times_S X$ is noetherian, one has

$$X \times_{Y_i} X = X \times_Y X$$

for all sufficiently large i. Thus

$$f_i : X \xrightarrow{f} Y \longrightarrow Y_i$$

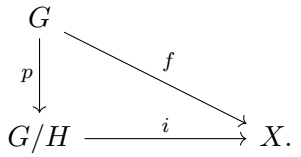
satisfies the hypotheses of 2.1 ii) if f does. Since the equivalence relation on X defined by f coincides with the one defined by f_i, it is clear that it suffices to prove ii) $\Rightarrow$ i) for f_i. This reduces us to the case where Y is of finite type over S.

Application to Group Preschemes

Theorem 2.2. — *Let S be a prescheme and let G be an S-group prescheme locally of finite presentation over S, acting on an S-prescheme X. Let $\xi \in X(S)$ be a section of X over S, such that the stabilizer H of ξ in G is an S-group subprescheme of G, flat over S. If X is locally of finite type over S, or if S is locally noetherian, then the homogeneous quotient space G/H is representable by an S-prescheme locally of finite presentation over S, and the S-morphism*

$$f : G \longrightarrow X, \qquad g \longmapsto g \cdot \xi$$

factors as



where p is the canonical projection, a faithfully flat morphism locally of finite presentation, and i is a monomorphism. (For definiteness, we have supposed that G acts on the left on X.)

Proof. The morphism f makes G into an X-prescheme. By the definition of the stabilizer of ξ, the morphism

$$G \times_S H \longrightarrow G \times_X G, \qquad (g, h) \longmapsto (g, gh)$$

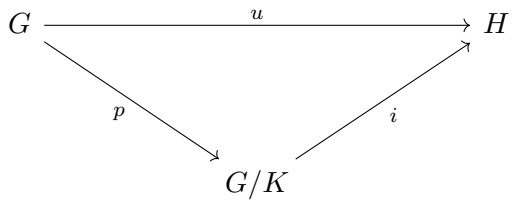
is an isomorphism. Since H is flat over S, $G \times_S H$ is flat over G; hence the first projection

$$p_1 : G \times_X G \longrightarrow G$$

is flat. Moreover, if X is locally of finite type over S, then f is locally of finite presentation (EGA IV, 1.4.3 v)); otherwise S is locally noetherian by hypothesis. It therefore suffices to apply 2.1 to f.

It remains only to show that G/H is locally of finite presentation over S, and this follows immediately from Exposé V, 9.1. □

Corollary 2.3. — *Let S be a prescheme, let G and H be two S-group preschemes, and let $u : G \to H$ be an S-homomorphism. Suppose that G is locally of finite presentation over S, and that either H is locally of finite type over S, or S is locally noetherian. If $K = \mathrm{Ker}(u)$ is flat over S, then the quotient group G/K is representable by an S-group prescheme locally of finite presentation over S, and u factors as*



where p is the canonical projection and i is a monomorphism.

Proof. Apply 2.2 with $X = H$ and with ξ the unit section of H. □

Corollary 2.4. — *Let S be a prescheme, let G be an S-group prescheme of finite presentation over S, let H be an S-group prescheme smooth over S with connected fibers*

(and hence of finite presentation over S, by Exposé VI_B, 5.5), and let $i : H \to G$ be a monomorphism of S-groups, so that H is a subgroup of G. Suppose that

$$N = \mathrm{Norm}_G(H),$$

which is representable by a closed group subprescheme of G, of finite presentation over S (Exposé XI, 6.11), is flat over S. Then G/N is representable by an S-prescheme of finite presentation over S and quasi-projective over S.

All the assertions to be proved, except the last one, are local on S. To establish them, we may therefore suppose that S is quasi-compact and that the relative dimension of H over S is constant, equal to r. Proceed as in Exposé XV, §5. For every integer $n > 0$, let $G^{(n)}$ (respectively $H^{(n)}$) be the n-th normal invariant of the unit section of G (respectively of H) (EGA IV, 16). The sheaf of $\mathcal{O}_S$-modules $H^{(n)}$ is a quotient of $G^{(n)}$. Since H is smooth over S of dimension r, $H^{(n)}$ canonically defines an element ξ_n of

$$X_n = \mathrm{Grass}_{\varphi(n,r)} G^{(n)}$$

(EGA I, second edition, §9), for a suitable integer $\varphi(n, r)$. On the other hand, G acts naturally on $G^{(n)}$, and hence also on X_n, through the representation

$$G \longrightarrow \mathrm{Aut}_{S\text{-gr}}(G), \qquad g \longmapsto \mathrm{int}(g).$$

Since S is quasi-compact, there exists an integer m such that, for $n \geq m$,

$$N = \mathrm{Norm}_G(H) = \mathrm{Norm}_G H^{(n)} \qquad \text{(Exposé XI, 6.11 b))}.$$

In other words, N is the stabilizer of ξ_n for sufficiently large n. The representability of G/N therefore follows from 2.2. The fact that G/N is of finite presentation over S is a consequence of Exposé V, 9.1. It remains to prove that G/N is quasi-projective over S. For this, we shall exhibit a canonical invertible sheaf on G/N that is ample relative to S. Consider the functor

$$\mathscr{F} : (\mathbf{Sch}/S)^\circ \longrightarrow \mathbf{Ens}$$

such that, for every S-prescheme T,

$$\mathscr{F}(T) = \left\{ \begin{array}{c} T\text{-subgroups } H \text{ of } G_T, \text{ representable and smooth over } T, \\ \text{with connected fibers} \end{array} \right\}.$$

Such a group H is of finite presentation over S (Exposé $\mathrm{VI_B}$, 5.5), and $H \to G_T$ is a quasi-affine morphism (EGA IV, 8.11.2). By effective descent for quasi-affine morphisms (SGA 1, VIII, 7.9), it follows that $\mathscr{F}$ is a sheaf for the fpqc topology. Since G/N is the sheaf associated with a subfunctor of $\mathscr{F}$, there is a canonical monomorphism

$$G/N \longrightarrow \mathscr{F}.$$

Consequently there exists a subgroup H' of $G \times_S (G/N)$, representable and smooth over G/N, with connected fibers, that is "universal" for the functor G/N. I claim that the invertible sheaf

$$\mathscr{L} = \left(\det(\mathrm{Lie}\, H')\right)^{-1}$$

is ample relative to S. In this form the assertion is local on S, and its proof is analogous to the one given in Exposé XV, 5.8.

The following corollary was announced in Exposé XIV, 4.8 bis.

Corollary 2.5. — *Let S be a prescheme, let G be an S-group prescheme smooth and of finite presentation over S, with connected fibers, and let P be a parabolic subgroup of G (Exposé XIV, 4.8 bis). Then G/P is representable by an S-prescheme smooth and projective over S.*

It remains only to show (*loc. cit.*) that G/P is representable by an S-prescheme that is quasi-projective and of finite presentation. This follows from 2.4, since

$$P = \mathrm{Norm}_G(P)$$

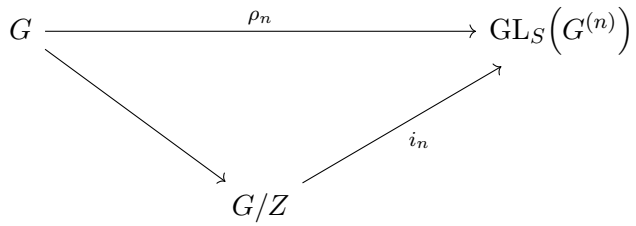
(*loc. cit.*) and is therefore flat over S. □

3. Groups with Flat Center

Proposition 3.1. — *Let S be a prescheme and let G be an S-group prescheme smooth and of finite presentation over S, with connected fibers. Suppose that the center Z of G, which is representable by Exposé XI, 6.11, is flat over S. For every integer $n > 0$, let $G^{(n)}$ denote the locally free $\mathcal{O}_S$-module equal to the n-th normal invariant of G along the unit section, and let ρ_n be the natural "adjoint representation" of G in $\mathrm{GL}_S(G^{(n)})$. Then:*

a) The quotient $G' = G/Z$ is representable by an S-group prescheme that is smooth, of finite presentation over S, quasi-affine, and has affine connected fibers.

b) The representation ρ_n factors through G':



If S is quasi-compact, then i_n is a monomorphism for all sufficiently large n.

c) The functor $\mathscr{T}_{G'}$ of subtori of G' is representable by an S-prescheme smooth over S, and, if S is quasi-compact, this prescheme is a sum of a family of preschemes affine over S.

Proof. The assertions in a) are local on S, which allows us to suppose that S is quasi-compact. By Exposé XI, 6.11 b), one has

$$Z = \mathrm{Ker}\, \rho_n$$

for all sufficiently large n; this kernel is therefore flat over S. The representability of G/Z and the fact that i_n is a monomorphism now follow from 2.3. Since G is smooth and of finite presentation over S, the same is true of G' (Exposé $\mathrm{VI_B}$, §9). The group $\mathrm{GL}_S(G^{(n)})$ is affine over S, and a monomorphism of finite presentation is quasi-affine (EGA IV, 8.11.2). Hence G' is quasi-affine over S and has affine fibers. Since G' is smooth over S, the functor $\mathscr{T}_{G'}$ is formally smooth (Exposé XI, 2.1 bis). Taking Exposé XI, 4.6 and 4.3 into account, the assertions of 3.1 c) will therefore follow from the next lemma.

Lemma 3.2. — *Let S be a prescheme, let G and H be two S-group preschemes of finite presentation over S, let $u : G \to H$ be an S-group monomorphism, and let $\mathscr{T}_G$ (respectively*

$\mathscr{T}_H$) be the functor of subtori of G (respectively of H) (cf. Exposé XV, §8). Then the map $T \mapsto u(T)$ defines a monomorphism (Exposé XV, 8.3 c))

$$\widetilde{u} : \mathscr{T}_G \longrightarrow \mathscr{T}_H$$

that is representable by a closed immersion of finite presentation.

By the usual procedure, we reduce to the following problem. Let T be a subtorus of H, let

$$T' = G \times_H T$$

be its inverse image in G, and let $u_T : T' \to T$ be the S-group monomorphism induced by u. One must show that the S-functor

$$\prod_{T/S} (T'/T)$$

is representable by a closed subprescheme of S, of finite presentation. But T, being a torus, is smooth over S with connected fibers, and it suffices to apply Exposé XI, 6.10. □

Theorem 3.3. — *Let S be a prescheme, let G be an S-group prescheme smooth and of finite presentation over S, with connected fibers, and let Z be the center of G. Suppose that Z is flat over S and that the unipotent rank of G (Exposé XV, 6.1 ter) equals that of Z. Then:*

a) The group $G' = G/Z$ is representable; if S is quasi-compact, the canonical morphism

$$i_n : G' \longrightarrow \mathrm{GL}_S(G^{(n)})$$

(cf. 3.1 b)) is an immersion for all sufficiently large n.

b) The group G' is quasi-affine over S, with affine fibers; its center is the unit group, and G' has unipotent rank zero.

c) Locally for the étale topology, G' possesses maximal tori, and these are also Cartan subgroups of G'. The functor $\mathscr{TM}_{G'}$ of maximal tori of G' (Exposé XV, §8) is representable by an S-prescheme smooth and affine over S.

d) Locally for the étale topology, G possesses Cartan subgroups, and the functor $\mathscr{C}_G$ of Cartan subgroups of G is representable by an S-prescheme smooth and affine over S.

Proof. By 3.1, the group G' is represented by an S-prescheme that is smooth and quasi-affine over S, with affine fibers. In view of the correspondence between Cartan subgroups of the fibers of G and those of the fibers of G' (Exposé XII, 6.6 e)), the hypothesis on the unipotent rank of Z implies that G' has unipotent rank zero. Exposé XV, 8.18 now shows that, locally for the étale topology, G' possesses maximal tori. The fact that i_n is an immersion for all sufficiently large n then follows from 3.1 b) and 1.4 a). This proves a).

We now prove c). Since G' has unipotent rank zero, every maximal torus of G' is plainly also a Cartan subgroup of G'. The functor of maximal tori of G' is represented by a subprescheme that is both open and closed in the functor of subtori of G'; moreover it is of finite type over S (Exposé XV, 8.15). It follows from 3.1 c) that this functor is represented by an S-prescheme smooth and affine over S.

Since, locally for the étale topology, G' possesses Cartan subgroups, the same is true of G; and the functor of Cartan subgroups of G is canonically isomorphic to that of G' (Exposé XV, 7.3 iv)). Thus c) implies d).

It remains to prove b), and more precisely to prove that the center Z' of G' is the unit group. Since Z' is representable (Exposé XI, 6.11) and of finite presentation over S, it suffices to show that the fibers of Z' are reduced to the unit group (Exposé $\mathrm{VI_B}$, 2.9). We are thereby reduced to the case where S is the spectrum of an algebraically closed field. The center Z' is evidently contained in every Cartan subgroup of G', hence, by c), in every maximal torus of G'; it is therefore of multiplicative type. On the other hand, we shall see in Exposé XVII that, if G is a connected algebraic group with center Z, the center Z' of G/Z is unipotent. In the present case, Z', being at once of multiplicative type and unipotent, is reduced to the unit group (cf. Exposé XVII). □

Examples of Groups Whose Center Is Flat

Proposition 3.4. — *Let S be a prescheme, let G be an S-group prescheme of finite presentation over S, smooth, with connected fibers, and let Z be the center of G. Then Z is flat over S in either of the following two cases:*

a) The unipotent rank ρ_u of the fibers of G (Exposé XV, 6.1 ter) is zero.

b) i) S is reduced; ii) the dimension of the fibers of Z is a locally constant function on S; iii) the unipotent rank of G equals that of Z.

Proof of 3.4 a). We shall prove at the same time the following proposition.

Proposition 3.5. — *Under the hypotheses of 3.4 a), suppose moreover that G possesses a maximal torus T, and let*

$$C = \mathrm{Centr}_G(T)$$

be the Cartan subgroup of G associated with T (Exposé XII, 7.1). Then:

(i) $Z \cap T$ is a subgroup of multiplicative type of G.

(ii) C is commutative and equals $T \cdot Z$.

(iii) If the quotients $Z/(Z \cap T)$ and C/T are representable, then they are represented by abelian preschemes (that is, S-group preschemes smooth over S, whose fibers are abelian varieties), and the canonical monomorphism

$$Z/(Z \cap T) \longrightarrow C/T$$

is an isomorphism.

Using the general properties of passage to the limit established in Exposé $\mathrm{VI_B}$, §10 and Exposé XV, 6.2, 6.3, and 6.3 bis, we reduce as usual to the case where S is noetherian (observe that the assertions of 3.4 and 3.5 are local on S). We noted in 3.1 that the hypotheses on G imply that Z is representable. To prove that Z is flat over S, EGA 0_{III}, 10.2.6 reduces us to the case where S is local artinian. Since G is then smooth, it possesses maximal tori locally for the étale topology (Exposé XV, 8.17). After a finite flat extension of S, if necessary (which is permissible when proving that Z is flat), we may therefore suppose that G possesses a maximal torus T.

Let us show, in the same way, that to establish 3.5 we may reduce to the case where S is artinian.

i) Since Z is closed in G (Exposé XI, 6.11), $Z \cap T$ is a closed group subscheme of T. It follows from Exposé X, 4.8 b), that $Z \cap T$ is of multiplicative type if and only if it is flat over S. As above, it suffices to establish that $Z \cap T$ is flat when S is artinian.

ii) Since G has unipotent rank zero, every Cartan subgroup C of G satisfies the hypotheses of Lemma 1.6, and is therefore commutative. The equality $C = T \cdot Z$ will follow from iii).

iii) If C/T is representable, then C/T is smooth over S (Exposé $\mathrm{VI_B}$, §9), and its fibers are abelian varieties (1.7); thus C/T is an abelian prescheme. To show that the canonical monomorphism

$$i : Z/(Z \cap T) \longrightarrow C/T$$

is an isomorphism, it suffices to verify this when S is local artinian. Indeed, one then deduces successively that $Z/(Z \cap T)$ is flat over S (EGA 0_{III}, 10.2.6), that i is flat (EGA IV, 11.3.10), that i is an open immersion (EGA IV, 17.9.1), and finally that i is an isomorphism (because C/T has connected fibers).

We henceforth suppose that S is local artinian, with closed point s, and that G possesses a maximal torus T. Put

$$C = \mathrm{Centr}_G(T).$$

The group C is a Cartan subgroup of G (Exposé XII, 7.1) and contains Z.

The algebraic group $M_s = Z_s \cap T_s$ is a central subgroup of multiplicative type of G_s. Since T is smooth over S, M_s lifts to a group subscheme M of T, of multiplicative type (Exposé IX, 3.6 bis), and contained in the center of G (Exposé IX, 3.9), hence contained in $Z \cap T$. Since S is artinian and M and T are flat over S, the quotient groups

$$(Z \cap T)/M, \qquad Z' = Z/M, \qquad A = C/T$$

are representable (Exposé $\mathrm{VI_A}$, §§4 and 5). By construction, $\big((Z \cap T)/M\big)_s$ is the unit group, so $Z \cap T = M$ (Exposé $\mathrm{VI_B}$, 2.9); in particular it is flat over S, which proves 3.5 i).

Passing to the quotient gives a canonical monomorphism

$$i : Z' \longrightarrow A,$$

which is therefore a closed immersion (Exposé $\mathrm{VI_B}$, 1.4.2). We have already observed that A is an abelian prescheme. It remains to show that i is an isomorphism. This will prove 3.5 iii) and will imply that Z' is flat over S, and hence that Z is flat over S (as an extension of Z' by the flat group M; Exposé $\mathrm{VI_B}$, §9). Since Z_s has the same abelian rank as G_s (Exposé XII, 6.1), i_s is an epimorphism, hence an isomorphism. Let $q > 0$ be an integer invertible on S. By the density theorem of 1.6 iii), to see that $i(Z') = A$, it suffices to show that, for every integer n equal to a power of q, $i(Z')$ contains ${}_nA$. Now let M_s^0 be the identity component of M_s. It follows immediately by duality that raising to the q-th power in M_s^0 is an epimorphism. Consequently, if m_0 is the exponent of q in the prime factorization of $\mathrm{card}(M_s/M_s^0)$, the image of ${}_{nm_0}Z_s$ in

$$A_s \simeq Z_s/M_s$$

contains ${}_nA_s$. There is therefore a subgroup $M_s(n)$ of multiplicative type of Z_s whose image in A_s is ${}_nA_s$. As above, $M_s(n)$ lifts to a central subgroup $M(n)$ of multiplicative type of G. The image of $M(n)$ in A is a subgroup of multiplicative type (Exposé IX, 6.8),

and is necessarily equal to ${}_nA$, since it is so on the reduced fiber (Exposé IX, 5.1 bis). This completes the proof of 3.4 a) and of 3.5.

Proof of 3.4 b). The assertion to be proved is local on S, so we may suppose that S is affine, with ring A. Regarding A as the inductive limit of its finitely generated $\mathbb{Z}$-subalgebras, we reduce as above to the case where S is noetherian and reduced.

To prove that Z is flat, we may use the valuative criterion for flatness (EGA IV, 11.8.1), which reduces us to the case where S is the spectrum of a complete discrete valuation ring with algebraically closed residue field, with generic point t and closed point s. Let Z' be the schematic closure of Z_t in Z. We must show that $Z' = Z$, and it even suffices to show that $Z_s = Z'_s$ (Exposé $\mathrm{VI_B}$, 2.6). By Exposé $\mathrm{VI_B}$, §4, one has the inequalities

$$\dim Z_t = \dim Z'_t = \dim Z'_s \leq \dim Z_s.$$

By hypothesis, however, $\dim Z_t = \dim Z_s$; hence $\dim Z'_s = \dim Z_s$, and consequently Z'_s contains $(Z_s)^0_{\mathrm{red}}$. It follows that

$$G'_s = G_s/Z'_s$$

is affine (Exposé XII, 6.1). In view of the correspondence between Cartan subgroups of G and G' (Exposé XII, 6.6 e)), hypothesis 3.4 b) iii) implies that the unipotent rank of G'_s is zero, and consequently its Cartan subgroups are also its maximal tori. The image Z''_s of Z_s in G'_s is a central algebraic subgroup of G'_s, hence is contained in every Cartan subgroup of G'_s, that is, in every maximal torus; Z''_s is therefore a subgroup of multiplicative type of G'_s. Under these conditions, we shall show in Exposé XVII, §7, that there exists a finite subgroup M_s of multiplicative type of Z_s whose image in Z_s/Z'_s is Z''_s (we used this fact in the proof of 3.4 a) when Z''_s is étale). Since G is smooth over S and S is the spectrum of a complete local ring, M_s lifts to an S-subgroup M of multiplicative type of G (Exposé IX, 3.6 bis and Exposé XV, 1.6 b)), which is central (Exposé IX, 5.6 a)). Thus M_t is contained in $Z'_t = Z_t$, and, since M is flat, M is contained in Z'. The group M_s is therefore contained in Z'_s, but this implies that Z''_s is the unit group, that is, $Z_s = Z'_s$. This completes the proof of 3.4 b).

Example of a Smooth Group Prescheme with Connected Fibers Whose Center Is Not Flat

Let S be the spectrum of a discrete valuation ring A, let π be a uniformizer of A, and let t and s be the generic and closed points of S, respectively. Let G be the smooth affine S-group whose ring is

$$B = A[T, T^{-1}, U]/F, \qquad F = 1 - T + \pi U,$$

the composition law being defined by

$$(t, u), (t', u') \longmapsto (tt', \pi uu' + u + u').$$

The generic fiber G_t is therefore isomorphic to the multiplicative group $(\mathbb{G}_m)_t$, while the closed fiber G_s is isomorphic to the additive group $(\mathbb{G}_a)_s$. The function T is invertible in $\Gamma(G, \mathcal{O}_G)$ and defines an S-group morphism

$$\varphi : G \longrightarrow (\mathbb{G}_m)_S$$

which is an isomorphism on the generic fiber and the trivial morphism on the closed fiber. The datum of φ permits one to construct the semidirect-product group

$$H = G \cdot (\mathbb{G}_a)_S$$

(note that $(\mathbb{G}_m)_S$ acts on $(\mathbb{G}_a)_S$). The center Z of H is the unit group on the generic fiber and is equal to H_s on the closed fiber, and is therefore not flat over S.

4. Groups with Affine Fibers, of Unipotent Rank Zero

Theorem 4.1. — *Let S be a prescheme and let G be an S-group prescheme smooth over S, of finite presentation, with affine, connected fibers, of unipotent rank zero (Exposé XV, 6.1 ter). Then:*

a) The center Z of G is a group of multiplicative type (and is therefore a reductive center of G; Exposé XII, 4.1).

b) G satisfies conditions a) through d) of 3.3.

c) Locally for the étale topology, G possesses maximal tori, and these are also Cartan subgroups of G. The functor $\mathscr{TM}_G$ of maximal tori of G is representable by an S-prescheme smooth and affine over S.

d) G is quasi-affine over S. Moreover, if T is a maximal torus of G, if

$$N = \mathrm{Norm}_G(T)$$

is its normalizer in G, and if $W = N/T$ is the Weyl group relative to T, the following conditions are equivalent:

(i) G is affine over S;

(ii) $G' = G/Z$ is affine over S;

(iii) N is affine over S;

(iv) W is affine over S.

These conditions are always satisfied if S is locally noetherian of dimension at most 1.

Proof. Since G has affine fibers (and hence abelian rank zero) and unipotent rank zero, G possesses maximal tori locally for the étale topology (Exposé XV, 8.18), and every maximal torus of G is plainly a Cartan subgroup of G. This proves the first part of c). To see that Z is of multiplicative type, we may suppose, by what precedes, that G possesses a maximal torus T. Since T is also a Cartan subgroup, it contains Z (because $T = \mathrm{Centr}_G(T)$ by Exposé XII, 7.1), and

$$Z = Z \cap T$$

is of multiplicative type by 3.5 i). This proves a). Assertion b) is clear in view of a). On the other hand, the functor $\mathscr{TM}_G$ is isomorphic to the functor of Cartan subgroups of G (Exposé XII, 7.1), and is therefore smooth and affine over S by 3.3 c). This finishes the proof of c). It remains to prove d).

Proof of d). Since G' is quasi-affine (3.3 b)) and Z is of multiplicative type, hence affine over S, G is quasi-affine (Exposé $\mathrm{VI_B}$, §9).

i) $\Longleftrightarrow$ ii). If G is affine, then G' is affine by Exposé IX, 2.3. If G' is affine, then G is affine as an extension of an affine group by an affine group (Exposé $\mathrm{VI_B}$, §9).

i) $\Longleftrightarrow$ iii). If G is affine, then N is affine, since it is closed in G (Exposé XI, 6.11 a)). Moreover, G/N is isomorphic to the functor $\mathscr{T}\mathscr{M}_G$ (conjugacy of maximal tori; cf. Exposé XII, 7.1 b)), and is therefore affine over S by c). Thus if N is affine over S, then G is affine, as an "extension" of an affine homogeneous space by an affine group (Exposé $\mathrm{VI_B}$, §9).

iii) $\Longleftrightarrow$ iv). If N is affine, then $W = N/T$ is affine (Exposé IX, 2.3), and the converse follows from Exposé $\mathrm{VI_B}$, §9.

Moreover, N/T is representable by an S-group prescheme that is étale, separated, and of finite type over S (Exposé XV, 7.1 iv)), hence quasi-finite over S. The last assertion of d) therefore follows from the next lemma, applied with $X = W$ and $Y = S$.

Lemma 4.2. — *Let S be a locally noetherian prescheme of dimension 1, let X and Y be two S-preschemes locally of finite type over S, and let $u : X \to Y$ be a quasi-finite and separated S-morphism. Suppose that, for every point s of S, the morphism*

$$u_s : X_s \longrightarrow Y_s$$

induced from u by the base change $\operatorname{Spec}\kappa(s) \to S$ is finite. Then u is an affine morphism.

The assertion to be proved is local on Y, which allows us to suppose that Y (and hence also X) is of finite type over S. By EGA IV, §8, it suffices to prove 4.2 when S is the spectrum of a local ring A. By fpqc descent we may suppose that A is complete, then that A is reduced (EGA II, 1.6.4), and then that A is normal (Nagata's theorem, EGA 0_{IV}, §22, and Chevalley's theorem, EGA II, 6.7.1). If A is a field, then u is finite by hypothesis, hence affine. Otherwise A is a discrete valuation ring; let s and t be the closed and generic points of S, and let π be a uniformizer of A. Let y be a point of Y_s. Applying EGA IV, §8, once more, we may replace Y by the spectrum Y' of $\mathcal{O}_{Y,y}$, and X by

$$X' = X \times_Y Y';$$

we may even suppose that $\mathcal{O}_{Y,y}$ is complete. Since u is quasi-finite and separated, EGA II, 6.2.6, shows that X' is the disjoint union of two schemes X_1 and X_2, where X_1 is finite over Y' (hence affine), while $u(X_2)$ does not contain the closed point y of Y'. I claim that, under these conditions, X_2 does not meet the closed fiber X'_s. Indeed, by hypothesis,

$$X'_s \longrightarrow Y'_s$$

is finite, so the restriction of this morphism to the closed subset $(X_2)_s$ is finite, and its image in $(Y')_s$ is closed. Since this image does not contain the closed point of the local scheme $(Y')_s$, $(X_2)_s$ is empty. Since u_t is finite, the restriction to $(X_2)_t = X_2$ of the morphism

$$X'_t \longrightarrow Y'_t$$

is finite. Moreover $Y'_t = Y'_\pi$, so the open immersion $Y'_t \to Y'$ is affine. In short, the composite morphism

$$X_2 \longrightarrow Y'_t \longrightarrow Y'$$

is affine, and it follows that

$$X' = X_1 \amalg X_2 \longrightarrow Y'$$

is affine.

Corollary 4.3. — *Let S be a prescheme, and let G be an S-group prescheme smooth and of finite presentation over S, with affine, solvable, connected fibers, of unipotent rank*

zero. Then G is affine over S. If, moreover, the center of G is the unit group and S is quasi-compact, the canonical morphism

$$i_n : G \longrightarrow \mathrm{GL}_S(G^{(n)}) \qquad \textit{(cf. 3.1 b))}$$

is a closed immersion for all sufficiently large n.

To prove that G is affine over S, we may suppose that G possesses a maximal torus T (4.1 c)). Since G has solvable fibers, the Weyl group relative to T is the unit group (BIBLE, 6, Th. 1, Cor. 3), and condition 4.1 d) iv) is satisfied. If the center of G is the unit group, i_n is a monomorphism for all sufficiently large n (3.1), and is therefore a closed immersion (1.5 b)).

5. Application to Reductive and Semisimple Groups

Definition 5.1. — *An S-group prescheme G is said to be* reductive *(respectively* semisimple*) if G is smooth and affine over S, with reductive (respectively semisimple) fibers.*

5.1.1. Reductive groups will be studied systematically beginning with Exposé XIX. In this section we shall need the following properties, which will be proved in Exposé XIX (without using the developments of the present Exposé).

a) Let S be a prescheme, let G be an S-group prescheme smooth and affine over S, with connected fibers, and let s be a point of S such that G_s is reductive (respectively semisimple). Then there exists a neighborhood U of s such that $G|_U$ is reductive (respectively semisimple).

b) If G is reductive, then locally for the étale topology G possesses maximal tori; and if T is a maximal torus of G, the Weyl group

$$W = \mathrm{Norm}_G(T)/T$$

is finite over S.

c) A reductive group has unipotent rank zero.

Admitting these facts, we propose to strengthen assertion a) above.

Theorem 5.2. — *Let S be a prescheme, let G be an S-group prescheme smooth and of finite presentation over S, with connected fibers, and let s be a point of S. Then:*

(i) If the fibers of G are affine and G_s is reductive, there exists an open neighborhood U of s such that $G|_U$ is reductive.

(ii) If G_s is semisimple, there exists an open neighborhood U of s such that $G|_U$ is semisimple.

Using Exposé XV, 6.2 i), and Exposé $\mathrm{VI_B}$, §10, we reduce to the case where S is noetherian.

In case ii), consider the center Z of G, which is representable (Exposé XI, 6.11 a)). Since G_s is semisimple, it is well known that Z_s is finite. Consequently (Exposé $\mathrm{VI_B}$, §4), there exists a neighborhood U of s such that Z is quasi-finite over U. For every point t of U, G_t is then affine (Exposé XII, 6.1). Shrinking S if necessary, we may therefore suppose that the fibers of G are affine, in case ii) as well as in case i).

In view of a), to prove 5.2 it suffices to prove that G is affine over S. Since G has affine fibers, we know that the functor of subtori of G is representable by a smooth S-prescheme (Exposé XV, 8.11 and 8.9). After making an étale extension covering s, which is permissible, we may therefore suppose that there is a subtorus T of G such that T_s is a maximal torus of G_s. But then

$$C = \mathrm{Centr}_G(T)$$

is a smooth subgroup of G, with connected fibers, containing T, such that $C_s = T_s$ (because C_s is a Cartan subgroup of G_s, and G_s has unipotent rank zero by c)). It follows that $C = T$, so T is a Cartan subgroup and a maximal torus of G; in particular, the unipotent rank of G is zero, and 4.1 applies.

By 4.1 d), it suffices to show that the Weyl group W relative to T is affine over a neighborhood U of s. In fact, we shall show that W is even finite over a neighborhood of s. Since W is quasi-finite over S (Exposé XV, 7.1 iv)), saying that W is finite over a neighborhood U of s is equivalent to saying that the morphism

$$W \longrightarrow S$$

is proper at s (EGA IV, 15.7, and EGA III, 4.4.2). To establish this, the valuative criterion of local properness (EGA IV, 15.7) reduces us to the case where S is the spectrum of a discrete valuation ring, with closed point s. But then, by the last assertion of 4.1 d), G is affine over S, and we may apply property a) recalled above to conclude that G is reductive (respectively semisimple). Applying property b), we conclude that W is indeed finite over S, which completes the proof of 5.2.

6. Applications: Extension of Certain Rigidity Properties of Tori to Groups of Unipotent Rank Zero

Proposition 6.1. — *Let S be a prescheme and let G be an S-group prescheme smooth over S, of finite presentation, with connected affine fibers, and whose center is of multiplicative type (for example, G of unipotent rank zero; cf. 4.1 a)). Then every closed normal subgroup K of G, of finite presentation over S and quasi-finite over S, is finite over S.*

Indeed, for every geometric point $\bar{s}$ above S, $(K_{\bar{s}})_{\mathrm{red}}$ is a finite étale subgroup of $G_{\bar{s}}$, normal and therefore central (since $G_{\bar{s}}$ is connected). Consequently

$$K' = Z \cap K,$$

where Z denotes the center of G, has the same underlying space as K, and it suffices to show that K' is finite over S. Now K' is a closed quasi-finite subgroup of the group of multiplicative type Z, and is therefore finite, as is immediate (locally on S, K' is contained in ${}_nZ$ for a suitable integer n, and ${}_nZ$ is finite over S).

Corollary 6.2. — *Let S and G be as above, let K be an S-group subprescheme of G, of finite presentation over S, normal and closed in G, and let s be a point of S. If K_s is finite (respectively is the unit group), there exists an open neighborhood U of s such that $K|_U$ is finite over S (respectively is the unit group).*

In view of the upper semicontinuity of the dimension of the fibers of K (Exposé VI_B, §4), after shrinking S we may already suppose that K is quasi-finite over S, and hence finite by 6.1. If, moreover, K_s is the unit group, then Nakayama's lemma easily implies that K is the unit group over $\mathrm{Spec}\,\mathcal{O}_s$, and hence over a neighborhood of s.

Proposition 6.3. — *Let S be a prescheme, let G be an S-group prescheme smooth and of finite presentation over S, with affine, connected fibers, of unipotent rank zero, let H be an S-group prescheme, let s be a point of S, and let*

$$u : G \longrightarrow H$$

be an S-group morphism such that $\operatorname{Ker} u_s$ is central. Suppose, moreover, that H is of finite presentation over S, or that S is locally noetherian and G is locally of finite type over S. Then there exists an open neighborhood U of s such that, if $K = \operatorname{Ker} u$, $K|_U$ is central and of multiplicative type. Moreover,

$$G' = (G|_U)/(K|_U)$$

is representable, and the morphism

$$u' : G' \longrightarrow H|_U$$

induced from u by passage to the quotient is an immersion.

Proof. Let Z be the center of G, and put $K' = K \cap Z$.

a) K' is a subgroup of multiplicative type over a neighborhood U of s. Indeed, after making an étale extension over a neighborhood U of s, which is legitimate, we may suppose that G possesses a maximal torus T (4.1 c)). But then $T \cap K$ is a group of multiplicative type (Exposé XV, 8.3) whose fiber at s is central by hypothesis; therefore $T \cap K$ is central over a neighborhood of s (Exposé IX, 5.6 a)), and consequently coincides with K'.

b) Let us show that $K' = K$ over a neighborhood U of s. By a), we may already suppose that K' is of multiplicative type, and hence flat over S. Since $K'_s = K_s$, the natural immersion

$$K' \longrightarrow K$$

is then open over a neighborhood U of s (Exposé $\mathrm{VI_B}$, 2.6). If $t \in U$, the image of K_t in the group

$$G'_t = G_t/Z_t$$

is a finite étale group, normal in G'_t (since K_t is normal in G_t), hence central, and therefore reduced to the unit group (3.3 b)). This says that K_t is contained in Z_t, and hence is equal to K'_t, whence $K = K'$ over U.

c) The representability of G' now follows from 2.3; the fact that u' is an immersion is contained in 1.3 a), in view of 4.1 c) applied to G'.

Proposition 6.4. — *Let S be a prescheme, let G be an S-group prescheme smooth and of finite presentation over S, with connected fibers, and let s be a point of S such that G_s is generated by its subtori (Exposé XII, 8.2) (for example, G_s affine of unipotent rank zero). Let H be an S-group prescheme, and let*

$$u, v : G \longrightarrow H$$

be two S-homomorphisms such that $u_s = v_s$ and u_s is central. Suppose, moreover, that H is of finite presentation over S, or that S is locally noetherian. Then there exists a neighborhood U of s such that

$$u|_U = v|_U.$$

We reduce as usual to the case where S is noetherian (to study the condition "G_s is generated by its subtori," one uses Exposé $\mathrm{VI_B}$, 7.4). Since G has connected fibers, to prove that $u = v$ over a neighborhood U of s, it suffices to prove that $u = v$ after reduction modulo every power of the maximal ideal of the local ring $\mathcal{O}_{S,s}$, which reduces us to the case where S is local artinian.

But then the functor of maximal subtori of G is representable by an S-scheme X, smooth and of finite type over S (Exposé XV, 8.17). Let T be the maximal subtorus of G_X universal for the functor X. The hypothesis on G_s means that the algebraic subgroup of G_s generated (Exposé $\mathrm{VI_B}$, §7) by the $\kappa(s)$-morphism

$$f : T_s \longrightarrow G_s$$

(the composite of the immersion $T_s \to G_{X_s}$ and the canonical projection $G_{X_s} \to G_s$) is all of G_s. But X_s is geometrically connected (for if $\overline{T}$ is a maximal torus of $G_{\bar{s}}$, and N its normalizer in $G_{\bar{s}}$, then $X_{\bar{s}}$ is isomorphic to $G_{\bar{s}}/N$), and the image of T_s under f contains the unit section of G_s. It follows from Exposé $\mathrm{VI_B}$, 7.4, that there exist an integer $N > 0$ and an S-morphism

$$f^N : T^N \longrightarrow G, \qquad T^N = T \times_S \cdots \times_S T \quad (N \text{ factors}),$$

where f^N depends only on f and the multiplication law of G, such that $(f^N)_s$ is surjective.

Consider the base change $X \to S$ and the restrictions of u_X and v_X to the subtorus T of G_X. By hypothesis,

$$u_{X_s} = v_{X_s},$$

and

$$u_{X_s} : T_{X_s} \longrightarrow H_{X_s}$$

is a central homomorphism. It then follows from Exposé IX, 5.1, that

$$u_X|_T = v_X|_T.$$

Making the definition of f^N explicit, and taking account of the fact that u and v are homomorphisms, one immediately deduces that

$$uf^N = vf^N.$$

But the $\kappa(s)$-morphism f_s^N is surjective and G_s is smooth, hence reduced; consequently f_s^N is generically flat. Since T is smooth over S, hence flat, there exists a nonempty open subset V of T^N such that

$$f^N|_V$$

is flat (EGA IV, 11.3.10). The image of V is an open subset W of G (EGA IV, 11.3.1), and

$$f^N : V \longrightarrow W$$

is faithfully flat and of finite presentation, hence covering for the fpqc topology. The equality $uf^N = vf^N$ then implies

$$u|_W = v|_W.$$

Since W is schematically dense in G (EGA IV, 11.10.10), and H is separated over S (Exposé $\mathrm{VI_A}$, 0.3), it follows immediately that $u = v$.

EXPOSÉ XVII

UNIPOTENT ALGEBRAIC GROUPS. EXTENSIONS BETWEEN UNIPOTENT GROUPS AND GROUPS OF MULTIPLICATIVE TYPE

by M. Raynaud[*]

0. Some notation[0]

In this chapter we shall be concerned chiefly with algebraic groups defined over a field k. The number $p \geq 0$ will always denote the characteristic of k; $\mathbf{F}_p$ will denote the prime field with p elements when $p > 0$; $\bar{k}$ will denote an algebraically closed extension of k; and q will denote a prime number different from p.

For every S-prescheme, $(\mathbb{G}_a)_S$ (respectively $(\mathbb{G}_m)_S$) denotes the additive group (respectively the multiplicative group) over S (cf. Exposé I, 4.3). For every integer $n > 0$, $(\boldsymbol{\mu}_n)_S$ (respectively $(\mathbb{Z}/n\mathbb{Z})_S$) denotes the group of n-th roots of unity (Exposé I, 4.4.4) (respectively the constant group over S associated with the abstract group $\mathbb{Z}/n\mathbb{Z}$ (Exposé I, 4.1)). The group $(\mathbb{Z}/n\mathbb{Z})_S$ is finite and étale over S; the group $(\boldsymbol{\mu}_n)_S$ is flat and finite over S, and is étale over S if and only if n is invertible on S (Exposé VIII, 2.1).

Suppose that S is a prescheme of characteristic $p > 0$. For every integer $n > 0$ and every S-group prescheme G, we denote by $F^n(G)$ the radicial S-subgroup prescheme of G equal to the kernel of the n-th iterate of the relative Frobenius morphism of G (Exposé VII_A). In particular, if $G = (\mathbb{G}_a)_S$, we set

$$F^n(G) = (\boldsymbol{\alpha}_{p^n})_S.$$

This is a radicial S-group, flat and finite over S, representing the following functor: for every S-prescheme S', $(\boldsymbol{\alpha}_{p^n})_S(S')$ is the set of $x' \in \Gamma(S', \mathcal{O}_{S'})$ such that $x'^{p^n} = 0$.

The already defined group $(\boldsymbol{\mu}_{p^n})_S$ is canonically isomorphic to $F^n((\mathbb{G}_m)_S)$.

When there is no ambiguity about the base scheme S, we shall simply write $\mathbb{G}_a$, $\mathbb{G}_m$, $\boldsymbol{\alpha}_{p^n}$, and so on, in place of $(\mathbb{G}_a)_S$, $(\mathbb{G}_m)_S$, $(\boldsymbol{\alpha}_{p^n})_S$, and so on.

[*] Cf. the note on page 1 of Exposé XV.

[0] Version x.y of 18 November 2008.

If G is a commutative S-group prescheme, then for every integer $n > 0$, ${}_nG$ denotes the subgroup prescheme of G equal to the kernel of raising to the n-th power in G.

For the reader's convenience, we have collected in an appendix some properties of algebraic groups proved in Exposés VI and VII, together with elementary properties of Hochschild cohomology that will be useful in this chapter.

1. Definition of unipotent algebraic groups

Definition 1.1.— *An algebraic group G defined over an algebraically closed field k is called* unipotent *if G admits a composition series whose successive quotients are isomorphic to algebraic subgroups of $(\mathbb{G}_a)_k$.*

Proposition 1.2.— *Let k be an algebraically closed field, let K be an algebraically closed extension of k, and let G be an algebraic group defined over k. Then G is unipotent if and only if G_K is unipotent.*

The necessity is clear, since a composition series remains a composition series after extension of the base.

The proof of sufficiency is standard. The field K is the filtered direct limit of its finitely generated k-subalgebras. By Exposé $\mathrm{VI_B}$, §10, one can find a finitely generated k-subalgebra A of K, a composition series G_i of G_S, where $S = \operatorname{Spec} A$, and immersions

$$u_i : H_i = G_i/G_{i+1} \longrightarrow (\mathbb{G}_a)_S.$$

To prove that G is unipotent, it therefore suffices to make a k-valued base change $A \to k$. This is possible because $\mathrm{Hom}_{k\text{-alg}}(A, k)$ is nonempty: A is a nonzero finitely generated algebra over the algebraically closed field k.

Definition 1.3.— *Let G be an algebraic group defined over a field k. We say that G is* unipotent *if there exists an algebraically closed extension $\bar{k}$ of k such that $G_{\bar{k}}$ is unipotent in the sense of Definition 1.1.*

By Proposition 1.2, this property is independent of the chosen algebraically closed extension $\bar{k}$.

Definition 1.4.— *Let G be an algebraic group defined over a field k, and let H be an algebraic group defined over an extension k' of k. We say that H is a* form *of G over k' if the algebraic groups $G_{\bar{k}'}$ and $H_{\bar{k}'}$ become isomorphic over an algebraic closure $\bar{k}'$ of k'. As above, this property is independent of the choice of $\bar{k}'$. We shall also say that H is a* twisted form *of G.*

We can now describe the algebraic subgroups of $\mathbb{G}_a$.

Proposition 1.5.— *Let k be a field of characteristic $p \geq 0$. An algebraic subgroup H of $(\mathbb{G}_a)_k$ is of one of the following types:*

(i) *$H = 0$;*

(ii) *$H = \mathbb{G}_a$;*

(iii) *if $p > 0$, H is an extension of a twisted constant group $(\mathbb{Z}/p\mathbb{Z})^r$ by a radicial group $\boldsymbol{\alpha}_{p^n}$, where $r, n \geq 0$ and $r + n > 0$. If, moreover, k is perfect, this extension is necessarily trivial.*

Proof. If $\dim H = 1$, then clearly $H = \mathbb{G}_a$. Otherwise H has dimension zero and is therefore an extension[3] of an étale group H'' by its identity component H', which is radicial. To describe $H''_{\bar{k}}$, it is enough to know the abstract group $H''(\bar{k})$, which is isomorphic to $H(\bar{k})$.

The latter is a finite subgroup of $\mathbb{G}_a(\bar{k})$. It is therefore zero when $p = 0$, and otherwise is of the form $(\mathbb{Z}/p\mathbb{Z})^r$, since it is annihilated by p. The group H' is closed in $\mathbb{G}_a$ and is defined by a single equation (the coordinate ring $\bar{k}[T]$ of $\mathbb{G}_a$ is principal). Since this equation has 0 as its only root over $\bar{k}$, it is of the form $T^n = 0$. Compatibility with the group law implies that $(T+T')^n$ belongs to the ideal generated by T^n and T'^n in $\bar{k}[T, T']$. Thus, if $p = 0$, then $n = 1$ and H' is the trivial group; while if $p > 0$, then $n = p^m$ and $H' = \boldsymbol{\alpha}_{p^m}$.

The last assertion of Proposition 1.5 follows more generally from the following lemma.

Lemma 1.6.— *If k is a perfect field, every extension H of an étale algebraic group H'' by a radicial group H' is trivial. Moreover, H'' has a unique lifting in H, namely H_{red}.*

Indeed, since k is perfect, the reduced k-scheme H_{red} is an algebraic subgroup of H (Exposé $\mathrm{VI_A}$, 0.2), is geometrically reduced and hence smooth over k (Exposé $\mathrm{VI_A}$, 1.3.1), and is therefore étale because H has dimension zero. To see that the canonical projection $H_{\mathrm{red}} \to H''$ is an isomorphism, it is enough to check this after the base-field extension $k \to \bar{k}$; there it is enough to check that it induces an isomorphism on $\bar{k}$-valued points, which is clear. The final assertion follows because every lifting of H'' in H, being étale over k, is reduced and hence necessarily contained in H_{red}.

Notice that $\boldsymbol{\alpha}_{p^n}$ is an iterated extension of groups isomorphic to $\boldsymbol{\alpha}_p$. Proposition 1.5 therefore gives the following corollary.

Corollary 1.7.— *Let G be an algebraic group defined over an algebraically closed field k. Then G is unipotent if and only if it has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$ when $p = 0$, and to one of the groups $\mathbb{G}_a, \mathbb{Z}/p\mathbb{Z}, \boldsymbol{\alpha}_p$ when $p > 0$. We shall call these the* elementary unipotent groups*.*

2. First properties of unipotent groups

Proposition 2.1.— *A unipotent algebraic group defined over a field k is affine over k.*

By fpqc descent for affine morphisms, it suffices to prove the assertion when k is algebraically closed. In that case, G is by definition an iterated extension of affine algebraic groups, and is therefore affine by Exposé $\mathrm{VI_B}$, 9.2 (viii), applied to affine morphisms.[4]

Proposition 2.2.—

(i) *The property that an algebraic group is unipotent is invariant under extension of the base field.*

(ii) *Every algebraic subgroup of a unipotent group is unipotent.*

(iii) *Every algebraic quotient group of a unipotent group is unipotent.*

(iv) *Every extension of a unipotent algebraic group by a unipotent algebraic group is likewise unipotent.*

[3] Editor's note: reference to Exposé $\mathrm{VII_A}$?

[4] Editor's note: verify this reference.

Proof. Assertion (i) follows immediately from Definitions 1.3 and Proposition 1.2. To prove the remaining assertions, we may suppose that k is algebraically closed. Assertion (iv) is then immediate from the definition.

Let G be a unipotent algebraic group, G' an algebraic subgroup of G, G'' an algebraic quotient group of G, and let G_i, $1 \leq i \leq n$, be a composition series of G such that

$$H_i = G_i/G_{i+1}$$

is an elementary unipotent group (Corollary 1.7).

For (ii), consider the composition series of G' induced by that of G: $G'_i = G_i \cap G'$. The group G'_i/G'_{i+1} identifies with an algebraic subgroup of H_i, hence is isomorphic to a subgroup of $\mathbb{G}_a$. It follows that G' is unipotent.

For (iii), consider the composition series of G'' obtained as the image of that of G: let G''_i be the image of G_i in G''. Then G''_i/G''_{i+1} is a quotient of H_i, so it remains only to prove the following lemma.

Lemma 2.3.— *Let H be an elementary unipotent group (Corollary 1.7) defined over a field k. Every algebraic quotient group H'' of H is either zero or isomorphic to H over k.*

Proof. If $H = \mathbb{G}_a$ in characteristic zero, or if $H = \boldsymbol{\alpha}_p$ or $\mathbb{Z}/p\mathbb{Z}$ in characteristic $p > 0$, it is enough to observe from Proposition 1.5 that H has no algebraic subgroups other than 0 and H. Indeed, a nonzero algebraic subgroup of $\boldsymbol{\alpha}_p$ is defined by a k-algebra of rank at least p over k, by Proposition 1.5(iii), and is therefore $\boldsymbol{\alpha}_p$.

Now let $H = \mathbb{G}_a$ in characteristic $p > 0$, so that there is an exact sequence

$$0 \longrightarrow N \longrightarrow \mathbb{G}_a \longrightarrow H'' \longrightarrow 0.$$

If $N = \mathbb{G}_a$, then $H'' = 0$. Otherwise, arguing by induction on the length of a composition series of N, we may suppose that $N = \boldsymbol{\alpha}_p$, or that N is a form of $(\mathbb{Z}/p\mathbb{Z})^r$.

(a) If $N \simeq \boldsymbol{\alpha}_p$, the proof of Proposition 1.5(iii) shows that N is necessarily the kernel of the Frobenius morphism F of $\mathbb{G}_a$, and the assertion follows from the exact sequence

$$0 \longrightarrow \boldsymbol{\alpha}_p \longrightarrow \mathbb{G}_a \xrightarrow{F} \mathbb{G}_a \longrightarrow 0.$$

(b) If $N \simeq \mathbb{Z}/p\mathbb{Z}$, there is plainly an $a \in k^\times$ such that N is the closed subscheme of $\mathbb{G}_a = \operatorname{Spec} k[X]$ defined by $X^p - aX = 0$. The assertion then follows from the exact sequence

$$0 \longrightarrow N \longrightarrow \mathbb{G}_a \xrightarrow{P} \mathbb{G}_a \longrightarrow 0,$$

where P is the Artin–Schreier morphism $x \mapsto x^p - ax$.

(c) If N is a form of $(\mathbb{Z}/p\mathbb{Z})^r$, there is a finite Galois extension k'/k that trivializes N. By (b) and an evident induction on r, the quotient $\mathbb{G}_a/N$ is a form of $\mathbb{G}_a$ trivialized by k'. It remains to apply the next lemma.

Lemma 2.3 bis.— *Let k be a field, and let G be a k-algebraic group that is a form of $\mathbb{G}_a$, trivialized by a finite separable extension k'/k. Then G is isomorphic to $\mathbb{G}_a$.*

Proof of Lemma 2.3 bis. Indeed, the group of k'-automorphisms of the algebraic group $(\mathbb{G}_a)_{k'}$ is the group of nonzero homotheties $(k')^\times$ (*Bible*, Exposé 9, Lemma 1), and the Galois cohomology group $H^1(k'/k, \mathbb{G}_m)$ is zero (we may suppose that k' is a Galois extension of k), by Hilbert's Theorem 90. Lemma 2.3 bis then follows from the classification of

the k-forms of an algebraic group (cf. J.-P. Serre, *Cohomologie galoisienne*, Chapter III, 1.3).

This completes the proof of 2.2.

Proposition 2.4.— *Let k be a field, let M be a k-group of multiplicative type (Exposé VIII) and of finite type, and let U be a unipotent k-algebraic group. Then:*

(i) $\underline{\mathrm{Hom}}_{k\text{-}gr}(M,U) = \underline{e}$ *(a fortiori* $\mathrm{Hom}_{k\text{-}gr}(M,U) = e$*);*

(ii) $\mathrm{Hom}_{k\text{-}gr}(U,M) = e$.

To prove (i), we must establish that, for every prescheme S over k,

$$\mathrm{Hom}_{S\text{-gr}}(M_S, U_S) = e.$$

This follows from the next lemma.

Lemma 2.5.— *Let S be a prescheme, let M be an S-group of multiplicative type and of finite type over S, and let U be an S-group prescheme, of finite presentation over S, whose fibers are unipotent. Then* $\mathrm{Hom}_{S\text{-}gr}(M,U) = e$.

Proof. Under these hypotheses, for an S-group morphism $u : M \to U$ to be the unit homomorphism, it suffices that the restriction of u to the fibers of M over the points of S be the zero morphism (Exposé IX, 5.2). We are therefore reduced to the case in which S is the spectrum of a field, which we may moreover suppose to be algebraically closed. In view of Definition 1.1, it is enough to take $U = \mathbb{G}_a$, in which case the assertion has already been proved (Exposé XII, 4.4.1).

We now prove Proposition 2.4(ii). Let $u : U \to M$ be a k-group morphism. The image $u(U)$ is represented by an algebraic subgroup U'' of M (Exposé $\mathrm{VI_B}$, 5.4).[5] The group U'' is unipotent as a quotient of a unipotent group (2.2(iii)), and is of multiplicative type as a subgroup of a group of multiplicative type (cf. *Bible*, Exposé 4, Theorem 2, Corollary 1, or Exposé IX, 6.8). Thus U'' is the unit group by Proposition 2.4(i).

Remark 2.6.— *Keeping the notation of Proposition 2.4, it is no longer true in general that the functor* $\underline{\mathrm{Hom}}_{k\text{-}gr}(U,M)$ *is equal to* $\underline{e}$*. Indeed, let S be a prescheme such that* $\Gamma(S,\mathcal{O}_S)$ *contains a nonzero element ε with $\varepsilon^2 = 0$ (for example, the spectrum of the algebra of dual numbers over a ring A). For every S' over S, the map*

$$u \longmapsto 1 + \varepsilon_{S'} u$$

defines, functorially in S', a homomorphism from the additive group $\Gamma(S',\mathcal{O}_{S'})$ *to the multiplicative group* $\Gamma(S',\mathcal{O}_{S'}^{\times})$*. It therefore defines an S-group morphism*

$$(\mathbb{G}_a)_S \longrightarrow (\mathbb{G}_m)_S,$$

and, since $\varepsilon \neq 0$, this morphism is not zero.

Recall (Exposé $\mathrm{VII_A}$, §3) that when G is a commutative S-group prescheme, finite and flat over S, Cartier duality is available and G is reflexive in the sense of Exposé VIII, §1. More precisely, the functor

$$G \longmapsto \underline{\mathrm{Hom}}_{S\text{-gr}}(G, \mathbb{G}_m)$$

is represented

[5] Editor's note: verify this reference.

by a commutative S-group prescheme $D(G)$, finite and flat over S, and the canonical morphism

$$G \longrightarrow D(D(G))$$

is an isomorphism. In particular:

(i) $D(\boldsymbol{\mu}_n) \simeq \mathbb{Z}/n\mathbb{Z}$, and consequently $D(\mathbb{Z}/n\mathbb{Z}) \simeq \boldsymbol{\mu}_n$;

(ii) if S has characteristic $p > 0$, then $D(\boldsymbol{\alpha}_p) \simeq \boldsymbol{\alpha}_p$.

3. Unipotent groups acting on a vector space

Recall (Exposé I, 4.6.1) that if S is a prescheme and M is a sheaf of $\mathcal{O}_S$-modules, $\mathbf{W}(M)$ denotes the S-functor

$$(\mathrm{Sch}\,/S)^\circ \longrightarrow (\mathrm{Ens})$$

defined, for every S-prescheme S', by

$$\mathbf{W}(M)(S') = \Gamma\big(S', M \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}\big)\,.$$

Recall also that if an S-group G acts on an S-functor V, the S-functor V^G of invariants of V under G is the subfunctor of V whose S'-valued points, for S' over S, are those $x \in V(S')$ such that $x_{S''}$ is fixed under $G(S'')$ for every S'' over S'.

We then have the following lemma.

Lemma 3.1.— *Let S be a prescheme, and let G be an S-group prescheme, affine over S, defined by the quasi-coherent $\mathcal{O}_S$-algebra A. Suppose that G acts on a quasi-coherent sheaf M of $\mathcal{O}_S$-modules. Let*

$$\mu : M \longrightarrow A \otimes_{\mathcal{O}_S} M$$

be the comorphism defining the action of G on M (Exposé I, 4.7.2), and let

$$\nu : M \longrightarrow A \otimes_{\mathcal{O}_S} M$$

be the morphism $x \mapsto \mu(x) - 1 \otimes x$. Then:

(i) $\underline{M}^G(S) = \Gamma\,\mathrm{Ker}(\nu)$;

(ii) if S is the spectrum of a field k, then $\underline{M}^G$ is of the form $\mathbf{W}(N)$, where N is a vector subspace of M;

(iii) if S is the spectrum of a field k, every element x of M is contained in a finite-dimensional k-vector subspace of M stable under the action of G.

Proof. Assertion (iii) is recalled here for reference and was already proved in Exposé $\mathrm{VI_B}$, 11.2.

For (i), it is clear that $\underline{M}^G(S)$ contains $\Gamma\,\mathrm{Ker}(\nu)$. To prove the reverse inclusion, we may suppose that S is affine, with ring B. Let $m \in \underline{M}^G(S)$. For every B-algebra B' and every

$$u \in \mathrm{Hom}_{B\text{-alg}}(A, B')$$

(where u corresponds to an element of $G(\mathrm{Spec}\,B')$), we have

$$(u \otimes 1_M)\nu(m) = 0 \qquad \text{in } B' \otimes_B M.$$

Taking $B' = A$ and u to be the identity of A, we obtain $\nu(m) = 0$.

For (ii), let N be the kernel of ν, equal to $\underline{M}^G(k)$ by (i). Every k-prescheme S is flat over k; hence

$$\underline{M}^G(S) = \Gamma \operatorname{Ker}(\nu \otimes_k S) = \Gamma(N \otimes_k S).$$

Thus $\underline{M}^G$ is isomorphic to the functor $\mathbf{W}(N)$.

Proposition 3.2.— *Let G be a unipotent algebraic group, defined over a field k, acting on a k-vector space V. If $V \neq 0$, then $V^G \neq 0$.*

In view of 3.1(ii) and (iii), we may suppose that k is algebraically closed and that V is finite-dimensional over k.

Let

$$0 \longrightarrow G' \longrightarrow G \longrightarrow G'' \longrightarrow 0$$

be an exact sequence of algebraic groups, and suppose that G acts on a sheaf V (for the fpqc topology). Of course $V^G \subset V^{G'}$, and the quotient presheaf G/G' acts naturally on $V^{G'}$. But $V^{G'}$ is a sheaf, being the kernel of the familiar pair of morphisms

$$V \rightrightarrows \underline{\operatorname{Hom}}(G', V).$$

Consequently the sheaf associated with G/G', namely G'', acts on $V^{G'}$, and it is immediate that

$$\left(V^{G'}\right)^{G''} = V^G = \left(V^{G'}\right)^{G/G'}.$$

This remark reduces the proof of 3.2 to the case in which G is an elementary unipotent group (1.7).

(a) $G = \mathbb{G}_a$, $p = 0$. It follows from (BIBLE 4, Proposition 4) that a morphism from $\mathbb{G}_a$ to the linear group $\mathrm{GL}(V)$ is given by an exponential map

$$T \longmapsto \sum_{q=0}^{\infty} T^q \frac{n^q}{q!},$$

where n is a nilpotent endomorphism of V. But then $V \neq 0$ implies $\operatorname{Ker} n \neq 0$, and it is clear that every vector of V annihilated by n is fixed by G.

Suppose now that $p > 0$.

(b) $G = \boldsymbol{\alpha}_p$. Since $\boldsymbol{\alpha}_p$ is a radicial group of height 1 (Exposé VII_A, §7), giving a representation of $\boldsymbol{\alpha}_p$ in V amounts to giving a representation of the p-Lie algebra $\boldsymbol{\alpha}_p$ in $\mathfrak{gl}(V)$ (Appendix II, 2.2), that is, in this case, an element $X \in \mathrm{End}(V)$ such that $X^p = 0$ (Appendix II, 2.1). But then

$$V \neq 0 \quad \Longrightarrow \quad W = \operatorname{Ker}(X) \neq 0,$$

and, again by Appendix II, 2.2, one has $W = V^{\boldsymbol{\alpha}_p}$.

(c) $G = \mathbb{Z}/p\mathbb{Z}$. A representation of G in V is equivalent to the choice of an element $x \in \mathrm{Aut}(V)$ such that $x^p = 1$, that is, $(1 - x)^p = 0$. Thus x is of the form $1 + n$, with n nilpotent, and $W = \operatorname{Ker} n$ is fixed by x.

(d) $G = \mathbb{G}_a$. Let G_i, $i \in I$, be the increasing filtered family of étale algebraic subgroups of $\mathbb{G}_a$, hence groups isomorphic to $(\mathbb{Z}/p\mathbb{Z})^{r_i}$ (Proposition 1.5), and put $V_i = V^{G_i}$. Since V has finite nonzero dimension and each V_i is nonzero by (c), the decreasing filtered family of the V_i is stationary, and

$$W = \bigcap_{i \in I} V_i \neq 0.$$

We shall use the following lemma.

Lemma 3.3.— *The family of étale subgroups of $(\mathbb{G}_a)_S$, where S is a prescheme of characteristic $p > 0$, is schematically dense in G (Exposé IX, 4.1).*

By Exposé IX, 4.4, it suffices to prove the lemma when S is the spectrum of the prime field $\mathbb{F}_p$. In that case it is enough to consider the family of étale subgroups G_n, $n \geq 1$, defined by

$$X^{p^n} - X = 0.$$

This family is schematically dense in $(\mathbb{G}_a)_{\mathbb{F}_p}$, since it contains every closed point.

With this established, let us return to the proof of 3.2(d). If $w \in W$, its stabilizer in G is an algebraic subgroup of $\mathbb{G}_a$ containing G_i for every $i \in I$; it is therefore equal to $\mathbb{G}_a$ by 3.3. Consequently $W = V^G$.

Proposition 3.2 immediately gives the following.

Corollary 3.4.— *Let k be a field, and let G be a unipotent k-algebraic group acting on a finite-dimensional k-vector space V. Then V has a sequence of vector subspaces V_i, defined over k and stable under G,*

$$0 = V_0 \subset V_1 \subset \cdots \subset V_n = V,$$

such that G acts trivially on V_{i+1}/V_i. Moreover, the V_i may be chosen so that V_{i+1}/V_i has dimension 1.

We shall now summarize and supplement the properties of unipotent groups already proved in the following theorem.

Theorem 3.5.— *Let G be an algebraic group defined over a field k. The following properties are equivalent:*

(i) G is unipotent.

(ii) G has a composition series defined over k, whose successive quotients are isomorphic to $\mathbb{G}_a$ if $p = 0$, and, respectively, to $\boldsymbol{\alpha}_p$, $\mathbb{G}_a$, or a twisted form of $(\mathbb{Z}/p\mathbb{Z})^r$ (1.4) if $p > 0$.

(iii) As in (ii), with the additional requirement that the composition series be central.

(iv) G has a characteristic composition series (Exposé VI$_B$) defined over k, whose successive quotients are isomorphic to $(\mathbb{G}_a)^r$ if $p = 0$, and, respectively, to $(\boldsymbol{\alpha}_p)^r$, a twisted form of $(\mathbb{G}_a)^s$, or a twisted form of $(\mathbb{Z}/p\mathbb{Z})^t$, taken in this order, if $p > 0$.

(v) G is isomorphic to an algebraic subgroup of the group $\mathrm{Trigstr}(n)_k$ of strictly upper-triangular matrices in the linear group $\mathrm{GL}(n)_k$, for a suitable integer $n \geq 0$.

(vi) G is affine, and for every linear representation of G on a nonzero finite-dimensional k-vector space V, one has $V^G \neq 0$.

Proof. The implication (i)⇒(vi) follows from 2.1 and 3.2.

For (vi)⇒(v), since the algebraic group G is affine, it is an algebraic subgroup of a suitable linear group $\mathrm{GL}(V)$ (Exposé VI$_\mathrm{B}$, 11.3). Applying 3.4 to the representation of G on V defined by this embedding gives (v).

For (v)⇒(iii), the algebraic group $\mathrm{Trigstr}(n)$ is known to have a central composition series whose successive quotients are isomorphic to $\mathbb{G}_a$. The composition series induced on G gives property (iii), in view of 1.5.

The implications

$$\text{(iii)} \Rightarrow \text{(ii)} \Rightarrow \text{(i)} \qquad \text{and} \qquad \text{(iv)} \Rightarrow \text{(i)}$$

are clear.

We shall prove (i)⇒(iv) shortly, but first note some consequences of what has already been proved.

Definition 3.6.— *A p-Lie algebra $\mathfrak{g}$, $p > 0$ (cf. Exposé VII$_A$, §5), is called* unipotent *if the map*

$$x \longmapsto x^{(p)}$$

is nilpotent; that is, if for every $x \in \mathfrak{g}$ there is an integer $n > 0$ such that $x^{(p^n)} = 0$.

Corollary 3.7.— *A unipotent algebraic group G is nilpotent (Exposé VI$_B$, §8); its Lie algebra $\mathfrak{g}$ is nilpotent (Bourbaki,* Groupes et algèbres de Lie*, Chap. I, §4) and is isomorphic to a Lie algebra of nilpotent endomorphisms of a finite-dimensional vector space. In characteristic $p > 0$, $\mathfrak{g}$ is a unipotent p-Lie algebra (3.6).*

Since (i) implies (v), it is enough to prove 3.7 when $G = \mathrm{Trigstr}(n)$. We have already used the fact that $\mathrm{Trigstr}(n)$ is a nilpotent algebraic group. Moreover, the Lie algebra $\mathfrak{h}$ of $\mathrm{Trigstr}(n)$ consists of the upper-triangular endomorphisms of V that have zeros on the main diagonal. These endomorphisms are therefore nilpotent, and consequently $\mathfrak{h}$ is nilpotent (Bourbaki, *loc. cit.*, Chap. I, §4, Cor. 3). If $p > 0$, the p-th power in the p-Lie algebra $\mathfrak{gl}(V) = \mathrm{End}(V)$ coincides with the p-th power of endomorphisms of V (Exposé VII$_\mathrm{A}$, 6.4.4); hence $\mathfrak{h}$ is unipotent.

Corollary 3.8.— *Let k be an algebraically closed field, and let G be a smooth affine algebraic group over k. Then the following properties are equivalent:*

(i) G is unipotent.

(ii) $G(k)$ consists of unipotent elements (BIBLE 4, Prop. 4, Cor. 1); that is, G is unipotent in the sense of BIBLE.

The implication (i)⇒(ii) follows because, by 3.2, (i)⇒(v), G is isomorphic to an algebraic subgroup of a group $\mathrm{Trigstr}(n)$.

For (ii)⇒(i), suppose that G is a unipotent algebraic group in the sense of BIBLE, and write G^0 for its identity component. The maximal tori of G^0, being made up of unipotent elements, are trivial; thus G^0 is equal to each of its Cartan subgroups. It follows that G^0 is solvable (BIBLE 6, Th. 6), and hence triangularizable (BIBLE 6, Th. 1). In short, G^0 is an algebraic subgroup of a group $\mathrm{Trigstr}(n)$, and is therefore unipotent in the sense of this Exposé.

The group $(G/G^0)(k)$ is a finite group consisting of unipotent elements. It is therefore trivial if $p = 0$, and is a finite p-group if $p > 0$ (BIBLE 4, Prop. 4). But then G/G^0 is unipotent in the sense of this Exposé, since it is an iterated extension of groups isomorphic to $\mathbb{Z}/p\mathbb{Z}$. This proves that G is unipotent.

Completion of the proof of 3.5. It remains to prove (i)⇒(iv).

(a) $p > 0$. Consider the increasing sequence of algebraic subgroups of G

$$\{e\} \subset F(G) \subset F^2(G) \subset \cdots \subset F^n(G) \subset G^0 \subset G.$$

This gives a characteristic composition series of G (Appendix II, 1), and for n sufficiently large, $G/F^n(G)$ is smooth (Appendix II, 3.1). Thus its successive quotients are, in order:

(1) radicial groups of height 1;

(2) a smooth connected group;

(3) an étale group.

To prove (i)⇒(iv), it is therefore enough to prove the following lemma.

Lemma 3.9.— *Let G be a unipotent algebraic group defined over a field k of characteristic $p > 0$. Then G has a characteristic composition series, defined over k, whose successive quotients are isomorphic to:*

(i) $(\boldsymbol{\alpha}_p)^r$*, if G is radicial;*

(ii) a twisted form of $(\mathbb{G}_a)^r$*, if G is smooth and connected;*

(iii) a twisted form of $(\mathbb{Z}/p\mathbb{Z})^r$*, if G is étale.*

Proof of 3.9(i). The group G is radicial. Filtering G by the $F^n(G)$, we reduce to the case in which G is radicial of height 1. Since G is nilpotent (3.5, (i)⇒(iii)), and since the center of an algebraic group is representable (Exposé VIII, 6.5(e)), we may consider the ascending central series of G. This series is plainly characteristic in G, and reduces us to the case in which G is also commutative.

Put $\mathfrak{g} = \mathrm{Lie}(G)$. The p-th-power morphism π is then additive on $\mathfrak{g}$ (Exposé VII_A); we shall reduce to the case in which it is zero. For every prescheme S over k, set

$$\mathfrak{g}_S = \mathfrak{g} \otimes_k \mathcal{O}_S,$$

and let $\mathfrak{h}_S$ be the subsheaf of abelian groups of $\mathfrak{g}_S$ that is the image of $\mathfrak{g}_S$ under π_S. Finally, let $\overline{\mathfrak{h}}_S$ be the subsheaf of $\mathcal{O}_S$-modules of $\mathfrak{g}_S$ generated by $\mathfrak{h}_S$. It is clear that

$$\overline{\mathfrak{h}}_S = \overline{\mathfrak{h}}_k \otimes_k \mathcal{O}_S$$

and that $\overline{\mathfrak{h}}_S$[4] is a characteristic p-Lie subalgebra of $\mathfrak{g}_S$; that is, it is stable under the S-functor $\mathrm{Aut}_{p\text{-Lie}}(\mathfrak{g})$. It follows from Appendix II, 2.2 that $\overline{\mathfrak{h}}_k$ is the Lie algebra of an algebraic subgroup H of G that is characteristic in G.

Moreover, in view of 3.7 and Lemma 3.9 bis below, if $G \neq \{e\}$, then $H \neq G$, since $\overline{\mathfrak{h}}_k \neq \mathfrak{g}$. On the other hand, if $G/H = G''$, then

$$\mathrm{Lie}\, G'' = \mathfrak{g}/\overline{\mathfrak{h}}_k \qquad \text{(Appendix II, 2.2)},$$

and consequently the p-th power is zero in $\mathrm{Lie}\, G''$. Induction on $\dim \mathrm{Lie}\, G$ therefore reduces us to the case in which $\mathrm{Lie}\, G$ is a p-Lie algebra whose p-th power is zero. But then $\mathrm{Lie}\, G''$ is isomorphic to $\mathrm{Lie}((\boldsymbol{\alpha}_p)^r)$ for some suitable integer $r \geq 0$ (Appendix II, 2.1), and hence G'' is isomorphic to $(\boldsymbol{\alpha}_p)^r$ (Appendix II, 2.2). It remains to prove the following lemma.

Lemma 3.9 bis.— *Let k be a field of characteristic $p > 0$, let $\mathfrak{g}$ be a commutative unipotent p-Lie algebra (3.6) of finite dimension over k, and let $\mathfrak{h}$ be the p-Lie subalgebra of $\mathfrak{g}$ generated by the image of the p-th power in $\mathfrak{g}$. If $\mathfrak{g} \neq 0$, then $\mathfrak{h} \neq \mathfrak{g}$.*

Indeed, since $\mathfrak{g}$ is commutative, $\mathfrak{h}$ is simply the k-vector subspace of $\mathfrak{g}$ generated by the $X^{(p)}$, $X \in \mathfrak{g}$. If $\mathfrak{g} \neq 0$ and is unipotent, there exists an $X \in \mathfrak{g}$, $X \neq 0$, such that $X^{(p)} = 0$.

[4]Editor's note: $\mathfrak{h}$ has been changed to $\overline{\mathfrak{h}}$.

Let $X_1, \ldots, X_n$ be a basis of a complement in $\mathfrak{g}$ to the line kX. The Lie algebra $\mathfrak{h}$ is then the k-vector subspace of $\mathfrak{g}$ generated by

$$X_1^{(p)}, \ldots, X_n^{(p)};$$

it therefore has dimension at most $n = \dim \mathfrak{g} - 1$.

Proof of 3.9(ii). The group G is smooth and connected. In this case the descending central series of G is represented by smooth, connected, characteristic algebraic subgroups G_i (Exposé $\mathrm{VI_B}$, 8.3 and 7.4), and $G_i = 0$ for sufficiently large i, since G is nilpotent (3.5, (i)⇒(iii)). It is enough to prove 3.9 for the groups G_i/G_{i+1}, which reduces us to the case in which G is also commutative.

For every integer $n > 0$, let G_n be the algebraic subgroup of G that is the image of G under the p^n-th-power morphism. The group G_n is therefore smooth, connected, and characteristic; and it follows from Definition 1.1 of unipotent groups that $G_n = 0$ for sufficiently large n. Replacing G by G_n/G_{n+1}, we may further suppose that G is annihilated by raising to the p-th power. But then, by J.-P. Serre, *Groupes algébriques et corps de classes*, Chap. VII, Prop. 11, G is a form of $(\mathbb{G}_a)^r$ for a suitable integer r.

Proof of 3.9(iii). The group G is étale. Proceeding as in (ii), we reduce first to the case in which G is commutative, and then to the case in which G is annihilated by p. But then

$$G_{\overline{k}} \simeq (\mathbb{Z}/p\mathbb{Z})^r.$$

Proof of 3.5, (i)⇒(iv), in case (b), $p = 0$. The group G is then smooth and connected; proceeding as in 3.9(ii), we reduce to the case in which G is also commutative. We then have the following more precise result.

Lemma 3.9 ter.— *Let k be a field of characteristic 0, let G be a commutative unipotent k-algebraic group, and put $\mathfrak{g} = \operatorname{Lie} G$. There is a canonical isomorphism*

$$\exp : \mathbf{W}(\mathfrak{g}) \xrightarrow{\sim} G.$$

The morphism exp *is the unique homomorphism $\mathbf{W}(\mathfrak{g}) \to G$ that induces the identity on Lie algebras.*

Since G is unipotent, it can be realized as an algebraic subgroup of $\mathrm{Trigstr}(n)$, for a suitable integer n (3.5, (i)⇒(v)). Choosing such an embedding identifies $\mathfrak{g}$ with a Lie subalgebra of $\mathfrak{gl}(n)$ consisting of nilpotent endomorphisms. We thereby obtain a k-morphism

$$\begin{aligned} \exp : \mathbf{W}(\mathfrak{g}) &\longrightarrow \mathrm{GL}(n), \\ T &\longmapsto \sum_{i \geq 0} \frac{T^i}{i!}. \end{aligned}$$

Since G is commutative, the morphism exp is a homomorphism. Let G' be the algebraic group that is the image of $\mathbf{W}(\mathfrak{g})$ under exp. Under the canonical identification $\operatorname{Lie} \mathbf{W}(\mathfrak{g}) = \mathfrak{g}$, the tangent linear map of exp is simply the inclusion $\mathfrak{g} \hookrightarrow \mathfrak{gl}(n)$. Hence

$$\operatorname{Lie}(G \cap G') = \mathfrak{g} \cap \mathfrak{g} = \mathfrak{g}.$$

Since $G \cap G'$ is smooth (Exposé $\mathrm{VI_B}$, 1.6.1) and G is connected—being an iterated extension of groups $\mathbb{G}_a$ (3.5, (i)⇒(ii))—one necessarily has $G = G'$. The kernel $\ker(\exp)$ is an étale unipotent group, and hence is the trivial group. Consequently exp is an isomorphism from $\mathbf{W}(\mathfrak{g})$ onto G.

If $h : \mathbf{W}(\mathfrak{g}) \to G$ is another homomorphism such that $\mathrm{Lie}(h)$ is the identity map of $\mathfrak{g}$, then $h - \exp$ is a homomorphism, since G is commutative, and its tangent linear map is zero. Because k has characteristic 0 and $\mathbf{W}(\mathfrak{g})$ is connected, Cartier's theorem again implies that $h = \exp$.

Proposition 3.10.— *Let G be an algebraic group defined over an algebraically closed field k. The following properties are equivalent:*

(i) Every homomorphism from a group M of multiplicative type into G is trivial.

(i bis) G has no nontrivial subgroup of multiplicative type.

(ii) (a) If $p = 0$, then $G(k)$ has no point of finite order other than e.

(b) If $p \neq 0$, then:

- *for every prime number $q \neq p$, if $x \in G(k)$ and $x^q = e$, then $x = e$;*
- *for every $X \in \mathfrak{g} = \mathrm{Lie}\, G$ such that $X^{(p)} = X$, one has $X = 0$.*

(ii bis) (a) If $p = 0$, the condition is the same as in (ii)(a).

(b) If $p \neq 0$, then:

- *every finite subgroup of $G(k)$ is a p-group;*
- *for every $X \in \mathfrak{g} = \mathrm{Lie}\, G$ such that $X^{(p)} = X$, one has $X = 0$.*

Proof. The equivalence (i)⇔(i bis) follows because the image of a group of multiplicative type is of multiplicative type (Exposé IX, 2.7).

The equivalence (ii)⇔(ii bis) follows from the following observation. If an ordinary finite group H has order that is not a power of p, then there exist a prime number $q \neq p$ and an element $x \in H$, distinct from e, such that $x^q = e$ (Sylow's theorem; cf. J.-P. Serre, *Corps locaux*, Chapter IX, §2).

The implication (i)⇒(ii) follows from the next lemma.

Lemma 3.11.— *Let G be an algebraic group defined over a field k.*

(a) If k contains the n-th roots of unity, where n is prime to p, then

$$\mathrm{Hom}_{k\text{-gr}}(\mu_n, G) \simeq \mathrm{Hom}_{k\text{-gr}}(\mathbb{Z}/n\mathbb{Z}, G) \simeq {}_nG(k),$$

where ${}_nG(k)$ denotes the points of order n in $G(k)$.

(b) If $p > 0$, then

$$\mathrm{Hom}_{k\text{-gr}}(\mu_p, G) \simeq \{X \in \mathfrak{g} = \mathrm{Lie}\, G \mid X^{(p)} = X\}.$$

Indeed, for (a), note that μ_n is then isomorphic over k to $\mathbb{Z}/n\mathbb{Z}$; assertion (b) follows from Appendix II, 2.1.

For (ii)⇒(i bis), Lemma 3.11 shows that (ii) is equivalent to the assertion that, for every prime number r, the group G contains no subgroup μ_r. The implication now follows from:

Lemma 3.12.— *Let G be a diagonalizable S-group, of finite type over S, and distinct from the trivial group. There exist a prime number r and a subgroup of G isomorphic to $(\mu_r)_S$.*

Write $G = D_S(M)$, where M is a finitely generated abelian group, hence an extension of a free group M'' by a finite group M'. If $M'' \neq 0$, it is clear that M has quotients

isomorphic to $\mathbb{Z}/r\mathbb{Z}$ for every integer r. If $M'' = 0$, then M' has a quotient isomorphic to $\mathbb{Z}/r\mathbb{Z}$ for every prime number r dividing the order of M. The lemma follows by duality.

We saw in Proposition 2.4 that a unipotent group satisfies the equivalent conditions of 3.10. The purpose of the next section is to prove the converse.

4. A Characterization of Unipotent Groups

As announced, we shall prove that an algebraic group G defined over an algebraically closed field k, and containing no nontrivial subgroup of multiplicative type, is unipotent. In fact, it is enough that G contain none of certain particular "elementary" subgroups of multiplicative type, which depend on the hypotheses imposed on G. Before stating the general theorem, let us study some special cases in detail.

4.1. Smooth, Connected, Affine Algebraic Groups

Proposition 4.1.1.— *Let k be a field, let G be a smooth, connected, affine k-algebraic group, and put $\mathfrak{g} = \operatorname{Lie} G$. The following properties are equivalent:*

(i) G is unipotent.

(ii) G has a central composition series whose successive quotients are forms of $\mathbb{G}_a$.

(iii) G has a central, characteristic composition series whose successive quotients are forms of $(\mathbb{G}_a)^r$.

(iv) There is an integer $n > 1$ such that $G_{\overline{k}}$ contains no subgroup isomorphic to μ_n.

(v) Every maximal torus of G is the trivial group.

Suppose, moreover, that G is an algebraic subgroup of a linear group $\mathrm{GL}(n)$. The preceding conditions are then also equivalent to:

(vi) $\mathfrak{g} \subset \mathfrak{gl}(n)$ consists of nilpotent endomorphisms.

(vii) $\mathfrak{g}$ is nilpotent, and its center contains no nonzero semisimple endomorphism.

Proof. The implication (ii)⇒(i) is clear, and (i)⇒(iii) was proved in 3.9. The implication (iii)⇒(ii) will follow from the next lemma.

Lemma 4.1.2.— *Let k be a field, and let G be a k-algebraic group that is a form of $(\mathbb{G}_a)^r$. Then:*

(a) G can be realized as an algebraic subgroup of $(\mathbb{G}_a)^n$, for a suitable integer n.

(b) G has a composition series whose successive quotients are forms of $\mathbb{G}_a$.

Indeed, by hypothesis there is an extension k' of k such that $G_{k'}$ is isomorphic to $(\mathbb{G}_{a,k'})^r$. By the principle of finite extension (EGA IV, 9.1.1), we may assume that k'/k is finite. For (a), it then suffices to consider the canonical closed immersion (EGA V[5])

$$G \longrightarrow \prod_{k'/k} (G_{k'})_{/k'} \xrightarrow{\sim} (\mathbb{G}_{a,k})^n, \qquad n = r \deg(k'/k).$$

[5]Editor's note: provide another reference here...

To prove (b), in view of (a), we may assume that G is a closed subgroup of $G' = (\mathbb{G}_a)^n$. If $G \neq 0$, there is a hyperplane $\mathfrak{h}$ in $\mathfrak{g}' = \operatorname{Lie} G'$ that does not contain $\mathfrak{g}$. Let H be the vector subgroup $\mathbf{W}(\mathfrak{h})$ of $\mathbf{W}(\mathfrak{g}') = G'$. Since H is defined by one equation in G', the intersection $G \cap H$ is defined by one equation in G, and

$$\begin{aligned} \dim G - 1 &\leq \dim(G \cap H) \\ &\leq \dim \operatorname{Lie}(G \cap H) = \dim_k(\mathfrak{g} \cap \mathfrak{h}) \\ &= \dim_k \mathfrak{g} - 1 = \dim G - 1. \end{aligned}$$

Thus $\dim(G \cap H) = \dim \operatorname{Lie}(G \cap H)$, and consequently $G \cap H$ is smooth. The group

$$G_1 = (G \cap H)^0$$

is a smooth, connected algebraic subgroup of G such that G/G_1 is smooth, connected, and one-dimensional, hence is a form of $\mathbb{G}_a$ (4.1, (i)⇒(iii)). Induction on the dimension of G completes the proof.

Before continuing the proof of 4.1, note that the equivalence (i)⇔(ii), together with 2.3 bis, gives the following corollary.

Corollary 4.1.3.— *If k is a perfect field, a smooth, connected k-algebraic group is unipotent if and only if it has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$.*

Continuation of the proof of 4.1. The implication (i)⇒(iv) follows from 2.4(i).

For (iv)⇒(v), by Exposé XIV, 4.1, the group G has a maximal torus T defined over k. If $r = \dim T$, then

$$({}_nT)_{\overline{k}} \simeq (\mu_n)^r.$$

It follows that $r = 0$.

The implication (v)⇒(i) follows from the observation made in the proof of 3.8.

For (i)⇒(vi), by 3.4 the group G is in fact contained in an algebraic subgroup of $\mathrm{GL}(n)$ isomorphic to $\mathrm{Trigstr}(n)$. Hence $\mathfrak{g}$ consists of nilpotent endomorphisms.

For (vi)⇒(vii), the Lie algebra $\mathfrak{g}$ is nilpotent by Engel's theorem (Bourbaki, *Groupes et algèbres de Lie*, Chapter I, §4, Corollary 3).

For (vii)⇒(v), let T be a maximal subtorus of G (Exposé XIV, 1.1), and let $\mathfrak{t}$ be its Lie algebra. The embedding of G in $\mathrm{GL}(n)$ defines a representation of T, which is necessarily semisimple; this can be seen after passing to an algebraic closure $\overline{k}$ of k and applying Exposé I, 4.7.3. Thus, if $X \in \mathfrak{t}$, then X is a semisimple endomorphism in $\mathfrak{gl}(n)$. It follows at once that

$$\operatorname{ad} X : \ Y \longmapsto [X, Y]$$

is a semisimple endomorphism of $\mathfrak{gl}(n)$, and hence of $\mathfrak{g}$. This endomorphism is also nilpotent, since $\mathfrak{g}$ is nilpotent. Therefore $\operatorname{ad} X = 0$, so X is central. Consequently $\mathfrak{t}$ is central and consists of semisimple endomorphisms; by hypothesis it is zero. A fortiori, T is the trivial group.

Remark 4.1.4.—

(a) *We shall give below (4.3.1) an infinitesimal characterization of unipotent groups in characteristic $p > 0$ that is independent of an embedding in* $\mathrm{GL}(n)$.

(b) *When k is perfect, conditions (ii) and (iii) of 4.1.1 simplify by virtue of the following lemma.*

Lemma 4.1.5.— *If k is a perfect field, every k-algebraic group G that is a form of $(\mathbb{G}_a)^r$ is isomorphic to $(\mathbb{G}_a)^r$.*

The lemma follows from 3.9 ter when the characteristic p of k is zero, and from 2.3 bis when $r = 1$. In the general case ($p > 0$), realize G as an algebraic subgroup of $(\mathbb{G}_a)^n$, for a suitable integer n (4.1.2), and argue by induction on $n - r$. If $r = n$, then indeed $G = (\mathbb{G}_a)^r$. Otherwise, the quotient $(\mathbb{G}_a)^n/G$ is a nonzero smooth, connected, unipotent group. By 4.1.1, (i)⇒(ii), and 2.3 bis, it has a composition series whose quotients are isomorphic to $\mathbb{G}_a$. It follows that there is a smooth, connected algebraic subgroup G_1 of $(\mathbb{G}_a)^n$, containing G, such that

$$(\mathbb{G}_a)^n/G_1 = \mathbb{G}_a.$$

By induction, it suffices to show that G_1 is isomorphic to $(\mathbb{G}_a)^{n-1}$.

It is immediate that a homomorphism

$$\operatorname{Spec} k[X_1, \dots, X_n] = (\mathbb{G}_a)^n \longrightarrow \mathbb{G}_a = \operatorname{Spec} k[T]$$

is defined by an additive polynomial of the form

$$\sum_{i,j} a_{i,j} X_i^{p^j}.$$

Since G_1 is smooth, the linear part of this polynomial is nonzero. After a linear change of the coordinates X_i, we may assume that G_1 is the algebraic subgroup of $(\mathbb{G}_a)^n$ defined by

$$(*) \qquad P(X) = -X_1 + \sum_{j=1}^{q} a_j X_1^{p^j} + Q(X_2, \dots, X_n) = 0,$$

where

$$Q(X_2, \dots, X_n) = \sum_{\substack{i>1 \\ j>0}} b_{i,j} X_i^{p^j}.$$

We now argue by induction on the degree of P. If $\deg P = 1$, it is clear that

$$G_1 \xrightarrow{\sim} (\mathbb{G}_a)^{n-1}.$$

Otherwise, since k is perfect, one has $Q(X) = Q_1(X)^p$, and we may define an endomorphism v of $(\mathbb{G}_a)^n$ by

$$X_i \longmapsto X_i \qquad \text{for } i > 1,$$
$$X_1 \longmapsto \sum_{j=1}^{q} a_j^{1/p} X_1^{p^{j-1}} + Q_1(X).$$

It is clear that v induces an isomorphism on G_1, and that $v(G_1)$ is defined in $(\mathbb{G}_a)^n$ by the equation

$$(*_1) \qquad P_1(X) = -X_1 + \sum_{j=1}^{q} a_j^{1/p} X_1^{p^j} + Q_1(X_2, \dots, X_n) = 0.$$

We distinguish two cases.

First case. $\deg Q = \deg P > p^q$. Then $\deg P_1 < \deg P$, and the induction hypothesis applies.

Second case. $\deg P = p^q$, with $a_q \neq 0$. Then

$$\deg P_1 = \deg P = p^q \qquad \text{and} \qquad \deg Q_1 < p^q.$$

We cannot have $Q = 0$, for otherwise G_1 would not be connected. If the polynomial Q_1 has no linear part, the preceding transformation may be repeated. Continuing in this fashion, we eventually obtain an equation of the form

$$(*_s) \qquad P_s(X) = -X_1 + \sum_{j=1}^{q} a_j^{1/p^s} X_1^{p^j} + Q_s(X),$$

where

$$Q_s(X) = Q(X_2, \ldots, X_n)^{1/p^s}$$

is an additive polynomial with a nonzero linear part, and moreover $\deg Q_s < p^q$. Suppose, for example, that the coefficient of X_2 in Q_s is nonzero, and let $-L$ be the linear part of $P_s(X)$. After a linear change of coordinates, the equation of G_1 becomes

$$P'(X) = -L + \sum_{j=1}^{q} a_j^{1/p^s} X_1^{p^j} + Q'(L, X_3, \ldots, X_n),$$

where Q' is an additive polynomial without a linear part and $\deg Q' < p^q$. We are thereby reduced to the first case.[6]

4.2. Radicial Groups

Proposition 4.2.1.— *Let G be a radicial algebraic group defined over a field k of characteristic $p > 0$. The following conditions are equivalent:*

(i) G is unipotent.

(ii) G has a central composition series whose successive quotients are isomorphic to $\boldsymbol{\alpha}_p$.

(iii) G has a central, characteristic composition series whose successive quotients are isomorphic to $(\boldsymbol{\alpha}_p)^r$.

(iv) $G_{\overline{k}}$ contains no subgroup isomorphic to $\boldsymbol{\mu}_p$.

(v) $\mathfrak{g} = \operatorname{Lie} G$ is a unipotent p-Lie algebra (3.6).

Proof. The implications (iii)⇒(ii)⇒(i) are clear; (i)⇒(iii) is 3.9(i), and (i)⇒(iv) follows from 2.4(i).

We shall need the following lemma on abelian p-Lie algebras.

Lemma 4.2.2.— *Let $\mathfrak{g}$ be an abelian, finite-dimensional p-Lie algebra over a perfect field k. Then $\mathfrak{g}$ can be written uniquely as a direct sum*

$$\mathfrak{g} = \mathfrak{r} \oplus \mathfrak{u}$$

of a p-Lie subalgebra $\mathfrak{r}$ on which the p-th power is bijective and a unipotent p-Lie subalgebra $\mathfrak{u}$ (3.6). The algebra $\mathfrak{r}$ is called the reductive part *of $\mathfrak{g}$, and $\mathfrak{u}$ its* unipotent part.

[6] Editor's note: replace X_1 by L.

The formation of $\mathfrak{r}$ *and* $\mathfrak{u}$ *is compatible with extension of the field* k*. If, moreover,* k *is algebraically closed, then* $\mathfrak{r}$ *has a basis* e_i *such that*

$$e_i^{(p)} = e_i.$$

The proof of this lemma is easy and is left to the reader; see Bourbaki, *Groupes et algèbres de Lie*, Chapter I, §1, Exercise 23. We merely note that $\mathfrak{u}$ is the kernel of a suitable iterate of the map $X \mapsto X^{(p)}$, while $\mathfrak{r}$ is the image of that same iterate.

We now prove (iv)⇒(v). After extending the base field if necessary, we may suppose that k is algebraically closed. Let $X \in \mathfrak{g}$, and let $\mathfrak{h}$ be the p-Lie subalgebra of $\mathfrak{g}$ generated by X. The algebra $\mathfrak{h}$ is plainly commutative, and its reductive part (4.2.2) is zero. Otherwise, by the cited result, $\mathfrak{h}$ would contain an element $Y \neq 0$ such that $Y^{(p)} = Y$, and consequently, by Appendix II, 2.1 and 2.2, G would contain a subgroup isomorphic to $\boldsymbol{\mu}_p$, contrary to the hypothesis. Thus $\mathfrak{h}$, and hence $\mathfrak{g}$, is a unipotent p-Lie algebra.

It remains to prove (v)⇒(i), the least immediate implication in 4.2.1.

(a) The case in which G *has height* 1 (Exposé $\mathrm{VII_A}$, 4.1.3). Since G is radicial, it is affine and hence isomorphic to an algebraic subgroup of a linear group $\mathrm{GL}(V)$ (Exposé $\mathrm{VI_B}$, §11). This embedding identifies $\mathfrak{g}$ with a p-Lie subalgebra of $\mathrm{End}(V)$, and the p-th power of X in $\mathfrak{g}$ agrees with the p-th power of the endomorphism X (Exposé $\mathrm{VII_A}$, 6.4.4). Since $\mathfrak{g}$ is unipotent by hypothesis, it is therefore an algebra of nilpotent endomorphisms of V. By Engel's theorem (Bourbaki, *Groupes et algèbres de Lie*, Chapter I, §4, Theorem 1), it is a Lie subalgebra of the Lie algebra $\mathfrak{h}$ of the group of strictly upper-triangular matrices $\mathrm{Trigstr}(n)$, relative to a suitable basis of V. Since G has height 1, Appendix II, 2.2 then shows that G itself is an algebraic subgroup of $\mathrm{Trigstr}(n)$, and hence is unipotent by 3.5(v)⇒(i).

(b) The general case. We argue by induction on the height h of G.* The case $h = 1$ has just been treated. Suppose that $h > 1$, and put

$$G' = {}_F G, \qquad G'' = G/G'.$$

The group G' has height 1, and $\mathrm{Lie}\, G' = \mathrm{Lie}\, G$ is unipotent. Consequently G' is unipotent by (a). To prove that G is unipotent, it is therefore enough to show that G'' is unipotent (2.2). But G'' has height $h - 1$, so the induction hypothesis reduces us to proving that $\mathrm{Lie}\, G''$ is unipotent.

In view of (iv)⇒(v), it suffices to prove that $G''_{\overline{k}}$ contains no subgroup isomorphic to $\boldsymbol{\mu}_p$. Suppose, then, that such a subgroup has been given, and let H be its inverse image in $G_{\overline{k}}$. Since G' is unipotent, we shall prove in §5 that the extension

$$e \longrightarrow G'_{\overline{k}} \longrightarrow H \longrightarrow \boldsymbol{\mu}_p \longrightarrow e$$

is necessarily trivial; the proof of that fact is independent of the results of the present section. In short, $\boldsymbol{\mu}_p$ lifts to H. Being of height 1, it is then necessarily contained in

$$G'_{\overline{k}} = {}_F(G_{\overline{k}}),$$

which is impossible because G' is unipotent.

*That is, the least integer h such that $F^h = \mathrm{id}_G$; see Appendix II, 1.

4.3. Connected Affine Groups in Characteristic $p > 0$

Proposition 4.3.1.— *Let G be a connected affine algebraic group over a field k of characteristic $p > 0$. The following conditions are equivalent:*

(i) *G is unipotent.*

(ii) *G has a composition series whose successive quotients are isomorphic to $\boldsymbol{\alpha}_p$ and $\mathbb{G}_a$, taken in that order.*

(iii) *G has a characteristic composition series whose successive quotients are isomorphic to $(\boldsymbol{\alpha}_p)^r$ and $(\mathbb{G}_a)^s$, taken in that order.*

(iv) *$G_{\overline{k}}$ contains no subgroup isomorphic to $\boldsymbol{\mu}_p$.*

(v) *$\mathfrak{g} = \mathrm{Lie}\, G$ is unipotent (3.6).*

(vi) *$\mathfrak{g}$ is nilpotent, and the reductive part of the center of $\mathfrak{g}$ (4.2.2) is trivial.*

(vi bis) *$\mathfrak{g}$ is nilpotent, and every subgroup of multiplicative type of the identity component of the center of G is trivial.*

(vi ter) *G is nilpotent, and every subgroup of multiplicative type in the identity component of the center of G is trivial.*

Proof. The implications (iii)⇒(ii)⇒(i) are clear. To prove (i)⇒(iii), we shall need the following lemma.

Lemma 4.3.2.— *Let k be a field of characteristic $p > 0$, let $n \in \mathbb{N}$, and let k' be a radicial extension of k such that $(k')^{p^n}$ is contained in k. For every k-prescheme X (respectively, every k'-prescheme X'), denote by $X^{(p^n)}$ (respectively, $(X')^{\phi}$) the k-prescheme obtained from X (respectively, from X') by the base change*

$$F^n : k \longrightarrow k, \qquad x \longmapsto x^{p^n}, \qquad (\textit{respectively, } \phi : k' \longrightarrow k, \qquad x' \longmapsto (x')^{p^n}).$$

Then, for every k-prescheme X, there is a functorial isomorphism

$$(X_{k'})^{\phi} \xrightarrow{\sim} X^{(p^n)}.$$

Consequently, if X and Y are two k-preschemes for which there exists a k'-isomorphism

$$u' : X_{k'} \xrightarrow{\sim} Y_{k'},$$

then there exists a k-isomorphism

$$v : X^{(p^n)} \xrightarrow{\sim} Y^{(p^n)}.$$

If, moreover, X and Y are endowed with structures of k-group preschemes and u' is a k'-homomorphism, then v is a k-homomorphism.

The lemma follows immediately from the transitivity of base changes and from the fact that the composite

$$k \longrightarrow k' \xrightarrow{\phi} k$$

is F^n.

Continuation of the proof of 4.3.1.

(i)⇒(iii). We argue by induction on $\dim G$. If $\dim G = 0$, then, because G is connected, it is radicial, and 3.9(i) applies. If $\dim G > 0$, there exists an integer $m \geq 0$ such that the quotient $G/F_m G$ is a smooth group (Appendix II, 3.1), plainly connected and nonzero. Applying 4.1.1(i)⇒(iii) to this quotient, we see that G has an algebraic subgroup G' which is characteristic and connected, and for which the quotient

$$G'' = G/G'$$

is a form of $(\mathbb{G}_a)^r$, where $r > 0$. By 4.1.5, if K is a perfect closure of k, then

$$G''_K \xrightarrow{\sim} (\mathbb{G}_{a,K})^r.$$

Since G'' is of finite type over k, there exists a finite radicial extension k' of k such that

$$G''_{k'} \xrightarrow{\sim} (\mathbb{G}_{a,k'})^r$$

(Exposé $\mathrm{VI_B}$, §10). Choose $n > 0$ such that $(k')^{p^n} \subset k$. Retaining the notation of 4.3.2, we deduce a k-isomorphism of algebraic groups

$$(\mathbb{G}_{a,k})^r = \left((\mathbb{G}_{a,k'})^r\right)^{\phi} \xrightarrow{\sim} (G'')^{(p^n)}.$$

Now consider the Frobenius homomorphism relative to G'' (Exposé $\mathrm{VII_A}$, §4):

$$F^n : G'' \longrightarrow (G'')^{(p^n)}.$$

Since G'', and hence also $(G'')^{(p^n)}$, is smooth over k, while F^n is radicial, F^n is an epimorphism for the fpqc topology. Thus $(G'')^{(p^n)}$ is identified with $G''/F_n(G'')$, and we have shown that

$$G''/F_n(G'') \xrightarrow{\sim} (\mathbb{G}_a)^r$$

as algebraic groups. The inverse image G'_n of $F_n(G'')$ in G is a connected, characteristic subgroup of G, of dimension strictly less than that of G; the induction hypothesis therefore applies to G'_n.

(i)⇒(iv). This follows from 2.4(i).

(iv)⇒(i). Regard G as an extension of a smooth connected group G'' by a radicial group G' (Appendix II, 3.1). The group G' is unipotent by 4.2.1(iv)⇔(i). It is therefore enough to prove that G'' is unipotent, and for this it is enough to show that $G''_{\overline{k}}$ contains no subgroup isomorphic to $\boldsymbol{\mu}_p$, by 4.1.1(i)⇔(iv). If $G''_{\overline{k}}$ contained such a subgroup, it would lift to $G_{\overline{k}}$ by the result 5.1, already used above, whose proof is given in §5. This would contradict (iv).

Continuation of the proof of 4.3.1.

(i)⇒(v). This follows from 3.7.

(v)⇒(vi). Indeed, since

$$(\operatorname{ad} X)^{p^r} = \operatorname{ad}(X^{(p^r)}) \qquad (\text{Exposé } \mathrm{VII_A}, 5.2),$$

$\operatorname{ad} X$ is nilpotent when $\mathfrak{g}$ is unipotent; hence $\mathfrak{g}$ is nilpotent by Engel's theorem. Moreover, if $\mathfrak{g}$ is unipotent, then its center plainly is as well, and the reductive part of that center is therefore trivial (4.2.2).

(vi)⇒(iv). Indeed, if $G_{\overline{k}}$ contained a subgroup isomorphic to $\boldsymbol{\mu}_p$, its Lie algebra would contain a nonzero element X such that

$$X^{(p)} = X \qquad \text{(Appendix II, 2.1)},$$

and hence $X^{(p^r)} = X$ for every $r > 0$. Since $\operatorname{ad} X$ is nilpotent because $\mathfrak{g}$ is nilpotent, and

$$(\operatorname{ad} X)^{p^r} = \operatorname{ad}(X^{(p^r)}),$$

we necessarily have $\operatorname{ad} X = 0$. Thus X belongs to the reductive part of the center of $\mathfrak{g}_{\overline{k}}$, contradicting (vi).

(i)⇒(vi ter). This follows from 2.4(i) and 3.5(i)⇒(iii).

(vi ter)⇒(vi bis). Indeed, if G is nilpotent, then so is its subgroup ${}_FG$. Appendix II, 2.2 shows that ${}_FG$ is nilpotent if and only if

$$\operatorname{Lie}({}_FG) = \operatorname{Lie} G \qquad \text{(Exposé VII}_\text{A}\text{)}$$

is nilpotent.

(vi bis)⇒(vi). Let Z be the identity component of the center of G, and let $\mathfrak{r}$ be the reductive part of the center of $\mathfrak{g}$. We must prove that $\mathfrak{r} = 0$. It is immediate that $\mathfrak{r}$ is a characteristic p-Lie subalgebra of

$$\mathfrak{g} = \operatorname{Lie}({}_FG);$$

that is, it is stable under the functor $\operatorname{Aut}_{p\text{-Lie}}(\mathfrak{g})$. Consequently $\mathfrak{r}$ is the Lie algebra of a characteristic radicial subgroup R of ${}_FG$ (Appendix II, 2.2). The last assertion of 4.2.2 and Appendix II, 2.1 show moreover that R is a form of $(\boldsymbol{\mu}_p)^r$. Since R is characteristic in ${}_FG$, which is itself characteristic in G (Appendix II, 1), it is invariant in G, and hence central because G is connected (Exposé IX, 5.5). By (vi bis), $R = 0$, and therefore $\mathfrak{r} = 0$.

4.4. Étale Groups

The following proposition is an easy consequence of the Sylow theorems and of the structure of finite q-groups (cf. J.-P. Serre, *Corps locaux*, Chapter IX, §1).

Proposition 4.4.1.— *Let G be a finite étale algebraic group over an algebraically closed field. Then G is unipotent if and only if, for every prime number q distinct from the characteristic p of the field, G contains no subgroup isomorphic to $\boldsymbol{\mu}_q$.*

4.5. Abelian Varieties

Let G be an abelian variety over an algebraically closed field k. The following conditions are equivalent:

(i) G is unipotent.

(ii) $G = 0$.

(iii) There exists an integer n, relatively prime to the characteristic p of k, such that G contains no subgroup isomorphic to $\boldsymbol{\mu}_n$.

Indeed, if G is an abelian variety of dimension d, it is known (cf. S. Lang, *Abelian Varieties*, Chapter IV, §3, Theorem 6) that the group ${}_nG(k)$, for n prime to p, is isomorphic to

$$(\mathbb{Z}/n\mathbb{Z})^{2d},$$

and hence to $(\boldsymbol{\mu}_n)^{2d}$. Thus (iii)⇒(ii), while (ii)⇒(i)⇒(iii) are clear.

4.6. The General Case

If G and H are two algebraic groups defined over an algebraically closed field k, we shall denote by $P(G, H)$ the property

"there is no algebraic subgroup of G isomorphic to H."

We then obtain the following characterizations of unipotent groups.

Theorem 4.6.1.— *Let G be an algebraic group defined over an algebraically closed field k of characteristic p. Then:*

(i) If G is smooth, affine, and connected, then

$$G \text{ is unipotent} \iff \text{there exists } n > 1 \text{ such that } P(G, \boldsymbol{\mu}_n) \text{ holds} \iff P(G, \mathbb{G}_m) \text{ holds.}$$

(ii) If G is smooth and connected, then

$$G \text{ is unipotent} \iff \text{there exists } n \text{ prime to } p \text{ such that } P(G, \boldsymbol{\mu}_n) \text{ holds.}$$

(iii) If G is smooth, then

$$G \text{ is unipotent} \iff P(G, \boldsymbol{\mu}_n) \text{ holds for every prime } n \neq p.$$

(iv) If G is affine and connected and $p > 0$, then

$$G \text{ is unipotent} \iff P(G, \boldsymbol{\mu}_p) \text{ holds.}$$

(v) If G is connected and $p > 0$, then

$$G \text{ is unipotent} \iff \text{there exists } n \text{ prime to } p \text{ such that } P(G, \boldsymbol{\mu}_n) \text{ and } P(G, \boldsymbol{\mu}_p) \text{ both hold.}$$

(vi) For an arbitrary algebraic group G,

$$G \text{ is unipotent} \iff P(G, \boldsymbol{\mu}_n) \text{ holds for every prime } n.$$

Proof. Assertion (i) follows from 4.1.1, and (iv) from 4.3.1. We shall prove (vi); assertions (ii), (iii), and (v) are proved in the same way and are left to the reader.

Let G be an algebraic group. If G is unipotent, then $P(G, \boldsymbol{\mu}_n)$ holds for every $n > 1$ by 2.4(i). Conversely, suppose that $P(G, \boldsymbol{\mu}_n)$ holds for every prime n, and let us prove that G is unipotent. Write G^0 for the identity component of G. If G^0 is smooth, a classical theorem of Chevalley[*] shows that G^0 is an extension of an abelian variety A by a smooth connected affine group L. If G is not smooth—which entails $p > 0$ (Exposé $\mathrm{VI_B}$, 1.6.1)—there is an integer $n > 0$ such that

$$G'' = G^0/_{F^n}(G)$$

[*] *Séminaire Bourbaki*, no. 145, 1956/57.

is smooth (Appendix II, 3.1). Thus G'' is an extension of an abelian variety A by a smooth connected linear group L''. Let L be the inverse image of L'' in G^0. It is still affine and connected, since ${}_{F^n}(G)$ is radicial. In every case, therefore, G has a composition series

$$0 \subset L \subset G^0 \subset G$$

such that L is affine and connected, $G^0/L = A$ is an abelian variety, and G/G^0 is an étale group.

If $P(G, \boldsymbol{\mu}_n)$ holds, then a fortiori $P(L, \boldsymbol{\mu}_n)$ holds, and hence L is unipotent (4.1.1 and 4.3.1). If $A \neq 0$, there are a prime number n and a subgroup of A isomorphic to $\boldsymbol{\mu}_n$ (4.5). By 5.1 below, this subgroup lifts to G, contradicting $P(G, \boldsymbol{\mu}_n)$. Hence $A = 0$. Finally, if G/G^0 is not unipotent, there are an integer q and a subgroup of G/G^0 isomorphic to $\boldsymbol{\mu}_q$ (4.4.1). As above, it follows that $P(G, \boldsymbol{\mu}_q)$ does not hold. Thus G/G^0 is unipotent, and consequently so is G.

5. Extensions of Groups of Multiplicative Type by Unipotent Groups

5.1. Statement of the Theorem

Definition 5.1.0.— *Let k be a field and G an algebraic k-group. Following the terminology introduced by Rosenlicht (*Questions of rationality for solvable algebraic groups over non perfect fields*, Annali di Matematica 61 (1963)), we shall say that G is* k-solvable *if it satisfies the following equivalent conditions:*

(i) G has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$.

(ii) G has a characteristic composition series (G_i) such that the successive quotients G_i/G_{i+1} are commutative and themselves have composition series whose successive quotients are isomorphic to $\mathbb{G}_a$.

The implication (i)⇒(ii) is proved in *loc. cit.* In fact, for the composition series (G_i) one may take the series introduced in the proof of 3.9(ii).

Theorem 5.1.1.— *Let k be a field, U a unipotent algebraic k-group, H a k-group of multiplicative type, and E an algebraic k-group which is an extension of H by U, so that there is an exact sequence*

$$1 \longrightarrow U \longrightarrow E \longrightarrow H \longrightarrow 1.$$

Then:

(i) The extension E is trivial in each of the following cases:

  (a) k is algebraically closed;

  (b) k is perfect and one of the groups U or H is connected;

  (c) U is k-solvable;

  (d) U is smooth and H is connected.

(ii) If H' and H'' are two lifts of H in E, then they are conjugate by an element of $U(k)$ in each of the following cases:

(a) k is algebraically closed and H is smooth;

(b) k is algebraically closed and U is smooth.

(During the proof we shall indicate other cases in which the conclusion of (ii) is true without assuming that k is algebraically closed.)

If U is an algebraic group (respectively, a commutative algebraic group) defined over a field k, we denote by $H^1(k,U)$ (respectively, by $H^i(k,U)$, $i \geq 0$) the pointed set (respectively, the i-th group) of Galois cohomology of k with values in U; see J.-P. Serre, *Cohomologie galoisienne*, Lecture Notes in Mathematics no. 5, Springer.

If S is a prescheme, H a commutative S-group prescheme, and G an S-group prescheme acting on H, we denote by $H^i(G,H)$[7] the i-th Hochschild cohomology group of G with values in H (Appendix I, 1).

To prove 5.1.1, we shall proceed in several steps.

5.2. Proof of 5.1.1(i) and (ii) when U is smooth and H is étale

Lemma 5.2.1.— *With the notation of 5.1.1, suppose that H is étale. The canonical morphism $E \to H$ has a section $s : H \to E$, defined over k, in each of the following cases:*

(a) k is algebraically closed;

(b) k is perfect and U is smooth and connected;

(c) U is k-solvable.

Assertion (a) follows simply from the surjectivity of $E(k) \to H(k)$. We have (b)⇒(c) by 4.1.2(b) and 2.3 bis, so it is enough to treat case (c). Let x be a point of H. It is an open and closed subset of H, and the induced subscheme is isomorphic to $\operatorname{Spec} K$, where K is a finite separable extension of k. Let X be the inverse image in E of the scheme x. The K-scheme X is a principal homogeneous K-space under U_K. But U_K has a composition series whose successive quotients are isomorphic to $(\mathbb{G}_a)_K$; hence

$$H^1(K, U_K) = 0$$

(J.-P. Serre, *Cohomologie galoisienne*, Chapter III, Proposition 6). Consequently X is trivial and has a K-rational point. Thus, over every point x of H, we obtain a k-section of $E \to H$, and these give a section $H \to E$.

Lemma 5.2.3.— [8] *With the notation of 5.1.1, suppose that H is étale. Then:*

(i) The extension E is trivial in each of the following cases:

(a) U is commutative and $E \to H$ has a section;

(b) k is algebraically closed;

(c) k is perfect and U is connected;

(d) U is k-solvable.

Moreover, in each of the preceding cases, two lifts H' and H'' of H in E are conjugate by an element of $U(k)$.

[7] Editor's note: H_0^i has been replaced by H^i, in agreement with the notation of Appendix I and Exposé I.

[8] Editor's note: there is no item numbered 5.2.2.

(ii) Let R be the k-functor

$$(\mathrm{Sch}\,/k)^\circ \longrightarrow \mathrm{Ens}$$

for which, for every k-prescheme S, $R(S)$ is the set of lifts of H_S in E_S. If U is commutative, then R is representable by a nonempty affine k-scheme. The group U acts on R by inner automorphisms, and this action makes R a homogeneous space under U for the fpqc topology (cf. Exposé IV).

Proof of (i). We shall reduce cases (b), (c), and (d) to case (a).

Case (b). Since U has a characteristic composition series with commutative successive quotients (3.5, (i)⇔(iv)), we immediately reduce to the case in which U is commutative. Moreover, $E \to H$ has a section by 5.2.1(a), so we are reduced to case (a).

Case (d). We argue in the same way, using 5.1.0(ii) and 5.2.1(c).

Case (c). Let E_{red} be the reduced subgroup associated with E. Since H is smooth, E_{red} is an extension of H by

$$U_0 = U \cap E_{\mathrm{red}},$$

and we may replace E by E_{red}. The group U, and therefore U_0, is connected, and U_0 is plainly the identity component of E_{red}; in particular it is smooth. Thus U_0 is smooth and connected and k is perfect, so U_0 is k-solvable by 4.1.4(b), reducing us to case (d).

The preceding reductions show that in cases (b), (c), and (d) we may suppose that U has a characteristic composition series (U_i) such that U_i/U_{i+1} is commutative and the maps

$$U_i(k) \longrightarrow (U_i/U_{i+1})(k)$$

are surjective. (In cases (c) and (d), the latter assertion follows from $H^1(k, \mathbb{G}_a) = 0$.) An immediate dévissage then shows that it is enough to prove the conjugacy of two lifts H' and H'' in E when U is commutative. In short, it is enough to prove (i)(a). In that case the extension E is trivial provided that $H^2(H, U) = 0$ (Appendix I, 3.1), and H' and H'' are conjugate provided that $H^1(H, U) = 0$. We now use the following lemma.

Lemma 5.2.4.— *Let S be a prescheme, U a commutative S-group prescheme, and H an étale finite S-group prescheme of rank n acting on U. Then the groups $H^i(H, U)$, for $i > 0$, are annihilated by n in each of the following cases:*

(a) H is a constant S-group (Exposé I, 4.1);

(b) S is the spectrum of a field.

Proof of (a). By hypothesis, H is the constant group associated with an ordinary group $\{H\}$ of order n. It is clear[9] that $H^i(H, U)$ is isomorphic to the i-th cohomology group

$$H^i(\{H\}, U(S))$$

of the group $\{H\}$ with values in the ordinary group $U(S)$. It is classical that these groups are annihilated by n (J.-P. Serre, *Corps locaux*, Chapter VIII, Proposition 4, Corollary 1).

Proof of (b). Let $x \in H^i(H, U)$, where $i > 0$, and represent it by an i-cocycle

$$f : H^{(i)} \longrightarrow U,$$

[9]Editor's note: this is Proposition III.6.4.2 of M. Demazure and P. Gabriel, *Groupes algébriques I*, Masson & North-Holland (1970).

where $H^{(i)}$ denotes the product over k of i copies of H. If K is a finite Galois extension of k which splits H, assertion (a) shows that nf_K is a coboundary. More precisely, a direct computation shows that, if one defines the K-morphism

$$F_K : H_K^{(i-1)} \longrightarrow U_K$$

by

$$F_K(h_1, \ldots, h_{i-1}) = \sum_{h \in H(K)} f_K(h_1, \ldots, h_{i-1}, h),$$

then, up to sign,

$$d(F_K) = nf_K, \qquad d \text{ denoting the coboundary operator.}$$

An immediate Galois argument shows that F_K descends to a k-morphism $F : H^{(i-1)} \to U$, and consequently

$$d(F) = nf.$$

Corollary 5.2.4 bis.— *With the notation of 5.2.4, suppose in addition that U is flat and of finite presentation over S, with unipotent fibres, and that n is prime to the residue characteristics of S. Then, in cases (a) and (b) above,*

$$H^i(H, U) = 0 \qquad (i > 0).$$

Proof. It is enough to show that the n-th power map on U is an isomorphism, for it will then follow that multiplication by n on $H^i(H, U)$ is both an isomorphism and the zero morphism, and hence that $H^i(H, U) = 0$. Under the hypotheses made on U, it is enough to check that the n-th power map is an isomorphism on the fibres of U (EGA IV, 17.9.5). We are thus reduced to the case in which S is the spectrum of a field k of characteristic p. Since $(n, p) = 1$, the n-th power map on U is étale (Exposé VII); it is also a monomorphism (2.4(i)), and hence an open immersion (EGA IV, 17.9.1). This already shows that its restriction to the identity component U^0 is an isomorphism. Since U/U^0 is a finite p-group, the proof is complete.

This completes the proof of 5.2.3(i)(a), since an étale group of multiplicative type H has order prime to p.

Proof of 5.2.3(ii). It is clear that R is a sheaf for the fpqc topology. Moreover, in view of descent for affine schemes, the assertions of 5.2.3(ii) are local for the fpqc topology. We may therefore suppose that k is algebraically closed. The group H is then split and the extension E is trivial by (i)(b); let H' be a lift of H in E. For every k-prescheme S and every lift H'' of H_S in E_S, the groups H'_S and H'' are conjugate by an element of $U(S)$, since

$$H^1(H_S, U_S) = 0$$

by 5.2.4 bis.

Let $U^{H'}$ be the sheaf of invariants of U under H'. It is representable by an algebraic subgroup of U (Exposé VIII, 6.5(d)). The preceding remarks show that the k-morphism

$$U \longrightarrow R, \qquad u \longmapsto \mathrm{int}(u)H' \quad (u \in U(S))$$

induces a k-isomorphism

$$U/U^{H'} \xrightarrow{\sim} R.$$

This proves that R is representable and affine (2.1).

Remark 5.2.5.— *The assertions of 5.2.3(ii) can also be proved when U is not commutative, but we shall not need this in order to prove 5.1.1.*

5.3. The Case Where H Is Smooth

Proposition 5.3.1.— *The assertions of 5.2.3(i) remain true when the hypothesis "H is étale" is replaced by "H is smooth."*

Proceeding as in the proof of 5.2.3(i), we reduce to the case in which U is also commutative.

Let N' be the set of positive integers prime to p, ordered by divisibility. For every $n \in N'$, the group ${}_nH$ is étale, and the family of groups ${}_nH$, $n \in N'$, is schematically dense in H, since H is smooth (Exposé IX, 4.10). Let E_n be the inverse image of ${}_nH$ in E, so that E_n is an extension of ${}_nH$ by U, and let R_n be the k-functor of lifts of ${}_nH$ in E_n (cf. 5.2.3(ii)). If n divides m, there is plainly a natural k-morphism

$$R_m \longrightarrow R_n,$$

so the R_n form an inverse system of k-functors.

By 5.2.3(ii), R_n is representable by a nonempty affine k-scheme. Since a filtered direct limit of nonzero rings is nonzero, the functor

$$R = \varprojlim_n R_n$$

is representable by a nonempty affine k-scheme (EGA IV, 8 and 1.9.1). There are therefore an extension K of k and a point $u \in R(K)$. The image u_n of u in $R_n(K)$ corresponds to a lift H'_n of $({}_nH)_K$ in $(E_n)_K$. By construction,

$$H'_n = {}_n(H'_m) \qquad \text{if } n \text{ divides } m.$$

Put

$$U_n = (U_K)^{H'_n}.$$

The choice of H'_n identifies $(R_n)_K$ with U_K/U_n. The family of groups H'_n is filtered increasing, and hence the family U_n is filtered decreasing. It is therefore stationary for sufficiently large n, since U_K is noetherian. It follows that the family $(R_n)_K$ is stationary, and consequently so is the family R_n. In short,

$$R_n = R$$

for sufficiently large n.

Under the hypotheses in force, 5.2.3(i) shows that $R_n(k)$ is nonempty. We may therefore find a coherent system of lifts H'_n of ${}_nH$, for $n \in N'$. Let H' be the smallest closed subscheme of E containing H'_n for every n (Exposé $\mathrm{VI_B}$, §7). The argument of Exposé XV, 4.6 shows that H' is a smooth commutative algebraic group whose formation commutes with extension of the base field. To prove that H' is a lift of H in E, we may therefore suppose that k is algebraically closed. According to BIBLE 4, Theorem 4, H' is then the direct product of a smooth group M of multiplicative type and a unipotent group V. The groups H'_n are necessarily contained in M by 2.4; the definition of H' then gives $H' = M$. Thus H' is of multiplicative type, and hence

$$H' \cap U = 0.$$

The morphism $H' \to H$ is consequently a monomorphism, and the density theorem of Exposé IX, 4.10 shows that it is an epimorphism. It is therefore an isomorphism.

Now let H' and H'' be two lifts of H in E. For each $n \in N'$, let

$$T_n = \mathrm{Transp}({}_nH', {}_nH'')$$

be the transporter of ${}_nH'$ into ${}_nH''$. It is representable by a closed subscheme of U (Exposé VIII, 6.5(e)). The T_n form a filtered decreasing family of closed subschemes of U, and they are nonempty by 5.2.3(i)(a). Let T be their stationary value. Under the hypotheses of 5.2.3(i), $T_n(k)$ is nonempty. Thus there is an element $u \in U(k)$ such that

$${}_nH'' = \mathrm{int}(u)({}_nH') \qquad \text{for every } n \in N'.$$

It follows that

$$H'' = \mathrm{int}(u)H'$$

by Exposé IX, 4.8(b).

5.4. The Case Where U Is Radicial

Proposition 5.4.1.— *If k is a perfect field of characteristic $p > 0$, and if U is radicial, then the extension E of 5.1.1 is trivial.*

Using a characteristic composition series of U, we may restrict ourselves to the case

$$U = (\boldsymbol{\alpha}_p)^r$$

by 3.9.

It follows from Appendix II, 2.2 and 2.1 that there are isomorphisms of k-functors

$$\mathrm{Aut}_{k\text{-gr}}\big((\boldsymbol{\alpha}_p)^r\big) \xrightarrow{\sim} \mathrm{Aut}_{p\text{-Lie}}\big(\mathrm{Lie}((\boldsymbol{\alpha}_p)^r)\big) \xrightarrow{\sim} \mathrm{GL}\big(\mathrm{Lie}((\boldsymbol{\alpha}_p)^r)\big).$$

Let V be a k-vector space of rank r, let $\mathbf{W}(V)$ be the corresponding vector k-group (Exposé I, 4.6), and identify $(\boldsymbol{\alpha}_p)^r$ with ${}_FV$. The preceding remarks show that the action of H on ${}_FV$ defined by the extension E comes from a linear representation v of H on V. Consider the exact sequence

$$(*) \qquad 0 \longrightarrow {}_FV \longrightarrow V \xrightarrow{F} V^{(p)} \longrightarrow 0,$$

where F is the Frobenius morphism.

The sequence $(*)$ is an exact sequence of H-groups, provided that H acts on $V^{(p)}$ through the linear representation

$$H \xrightarrow{v} \mathrm{GL}(V) \xrightarrow{F} \mathrm{GL}(V^{(p)}).$$

Since k is perfect, the morphism $F : V \to V^{(p)}$ induces a surjective map

$$V(k) \longrightarrow V^{(p)}(k).$$

It follows from Appendix I, 2.1 that the exact sequence $(*)$ defines an exact sequence

$$(**) \qquad H^1(H, V^{(p)}) \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(H, {}_FV) \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(H, V).$$

We shall show that

$$\mathrm{Ext}_{\mathrm{alg}}(H, V) = 0.$$

Let E' be an algebraic group which is an extension of H by V:

$$1 \longrightarrow V \longrightarrow E' \xrightarrow{h} H \longrightarrow 1.$$

The scheme E' is a torsor over H under $\mathbb{G}_a^r$, and hence defines an element of

$$H^1(H, \mathcal{O}_H^r)$$

in coherent-sheaf cohomology. Since H is affine,

$$H^1(H, \mathcal{O}_H^r) = 0$$

by EGA III, §1. Thus $E' \to H$ has a section. Consequently, $\mathrm{Ext}_{\mathrm{alg}}(H, V)$ is isomorphic to $H^2(H, V)$ by Appendix I, 3.1. But

$$H^i(H, V) = H^i(H, \mathbf{W}(V)) = 0 \qquad (i > 0)$$

by Exposé IX, 3.1. The exact sequence $(**)$ now gives

$$\mathrm{Ext}_{\mathrm{alg}}(H, {}_F V) = 0,$$

and hence E is a trivial extension.

5.5. Proof of 5.1.1(i)

If k has characteristic 0, then U is k-solvable by 4.1.3 and H is smooth. It follows from 5.3.1 and 5.2.3(d) that E is a trivial extension. The same argument shows that two lifts of H in E are conjugate by an element of $U(k)$.

Henceforth we suppose that k is a field of characteristic $p > 0$.

Proof of (i)(b): the case where k is perfect and U is connected. We shall reduce to the case in which U is radicial. Since k is perfect, H_{red} is smooth; let E' be its inverse image in E. By 5.3.1 and 5.2.3(i)(c), the extension

$$1 \longrightarrow U \longrightarrow E' \longrightarrow H_{\mathrm{red}} \longrightarrow 1$$

is trivial. Let H_1 be a lift of H_{red} in E. By Appendix II, 3.1, there is an integer $n > 0$ such that

$$E^{(n)} = E/{}_{F^n}(E)$$

is smooth. Let E'' be the algebraic subgroup of E generated by H_1 and ${}_{F^n}(E)$; equivalently, E'' is the inverse image in E of the image of H_1 in $E^{(n)}$. Let H'' be the image of E'' in H. We claim that $H'' = H$.

Indeed, let R be the image of ${}_{F^n}(E)$ in H, so that H'' is generated by R and H_{red}. The group H/R is a quotient of $E^{(n)}$, and is therefore smooth. Consequently the canonical morphism

$$H_{\mathrm{red}} \longrightarrow H/R$$

is an epimorphism. Thus H is generated by R and H_{red}, and hence equals H''. We have obtained an exact sequence

$$(\dagger) \qquad 1 \longrightarrow U'' = U \cap E'' \longrightarrow E'' \longrightarrow H \longrightarrow 1.$$

But E'' has the same underlying space as H_1, so U'' is radicial. It is plainly enough to prove that the extension $(\dagger)$ is trivial, and this follows from 5.4.1.

Proof of (i)(b): the case where k is perfect and H is connected. The group U is an extension of an étale group by its identity component U^0. The case where U is connected having just been treated, it is enough to consider the case where U is étale. We shall use the following more precise lemma.

Lemma 5.5.1.— *With the notation of 5.1.1, suppose in addition that U is étale. Then:*

(i) If H is connected, it has a unique lift in E, namely the identity component E^0 of E.

(ii) If k is algebraically closed, then E is trivial, and any two lifts of H in E are conjugate by an element of $U(k)$.

Proof of (i). Since formation of the identity component commutes with extension of the base field, we may restrict ourselves to the case where k is algebraically closed. If H is a torus, then E is trivial by 5.3.1 and 5.2.3(i)(b), and E^0 is plainly the unique lift of H. This already proves that in the general case $E^0 \cap U$ is radicial. It is also étale, since U is étale, and is therefore zero. The morphism

$$E^0 \longrightarrow H$$

is consequently a monomorphism; it is flat because E^0 is open in E, and it is surjective because H is connected. It is therefore an isomorphism. If H' is any other lift of H, then H' is connected, hence contained in E^0, and thus equal to E^0.

Proof of (ii). Let H^0 be the identity component of H. By (i), E^0 is the unique lift of H^0 in E. Put

$$E' = E/E^0, \qquad H' = H/H^0.$$

There is then an extension

$$1 \longrightarrow U \longrightarrow E' \longrightarrow H' \longrightarrow 1.$$

Since H' is étale, this extension is trivial by 5.2.3(i)(b). If H'_1 is a lift of H' in E', and H_1 is its inverse image in E, then H_1 plainly lifts H in E. If H_2 is a second lift of H in E, then it contains E^0. By 5.2.3(i)(b), the image of H_2 in E' is conjugate to H'_1 by an element $u \in U(k)$, and hence

$$H_2 = \mathrm{int}(u)H_1.$$

Remark 5.5.2.— *Under the hypotheses of 5.5.1(i), the group E^0 centralizes U.*

Proof of 5.1.1(i)(a). Using the composition series

$$1 \longrightarrow U^0 \longrightarrow U \longrightarrow U/U^0 \longrightarrow 1,$$

assertion (i)(a) follows by combining (i)(b) with 5.5.1(ii).

Before proving 5.1.1(i)(c) and (d), we shall first establish 5.1.1(ii).

Proof of 5.1.1(ii)(a). For want of a satisfactory general statement, we shall describe a number of cases in which, when H is smooth, two lifts of H in E are conjugate.

Proposition 5.6.1.— *With the notation of 5.1.1, suppose in addition that H is smooth, and let H' and H'' be two lifts of H in E. Then H' and H'' are conjugate by an element of $U(k)$ in each of the following cases:*

(a) k is algebraically closed.

(b) U is commutative.

(c) k is perfect and U is connected.

(d) U is k-solvable.

(e) The centralizer of H' in U is k-solvable.

(f) The group of multiplicative type H is split by a finite Galois extension K/k of degree prime to p.

Proof. Parts (a), (b), (c), and (d) follow from 5.3.1.

(e) Let Z be the centralizer of H' in U, and let T be the transporter of H' into H''. By (a), T is nonempty; hence T is a principal homogeneous space under Z. The hypothesis on Z therefore implies that T is trivial.

(f) Proceeding as in 5.3.1, we see that it is enough to consider the case where H is étale. Suppose first that H is diagonalizable, defined by an abstract group M of order m prime to p. The two lifts H' and H'' determine a one-cocycle of M with values in $U(k)$, that is, a map

$$h : M \longrightarrow U(k)$$

such that

$$h(mn) = h(m)\,{}^m h(n)$$

for every pair m, n of elements of M. The groups H' and H'' are conjugate by an element of $U(k)$ if and only if there exists $a \in U(k)$ such that

$$h(m) = a^{-1}({}^m a).$$

Now the abstract group $U(k)$ has a composition series whose successive quotients are commutative and annihilated by a power of p (in view of 5.6.1(c), we may suppose that $p > 0$). It follows at once in this case that h is a coboundary.

Consider now the general case. Again let Z denote the centralizer of H' in U, and T the transporter of H' into H''; thus T is a torsor under Z. By hypothesis there is a finite Galois extension K/k, with Galois group G of order prime to p, which splits H. By the preceding case, H'_K and H''_K are conjugate by an element of $U(K)$, and therefore T_K is trivial. Consequently T is defined by an element of

$$H^1(G, Z).$$

For the same reasons as above, the hypothesis on G implies that

$$H^1(G, Z) = e;$$

hence T is trivial.

5.7. Proof of 5.1.1(ii)(b)

Lemma 5.7.1.— *Let S be a prescheme, let G be an S-group prescheme, separated and smooth over S, and let H be an S-group of multiplicative type acting on G. Then the S-functor*

$$Z = G^H$$

of invariants of G under H is representable by a closed smooth S-group subprescheme of G.

The representability of G^H by a closed group subprescheme of G follows from Exposé VIII, 6.5(d). Consider the semidirect product

$$K = G \rtimes_S H.$$

The centralizer of H in K is then $Z \times_S H$. To prove that Z is smooth, we must verify the following. Suppose that S is affine, that S_0 is a closed subscheme of S defined by a square-zero ideal, and that $u_0 \in Z(S_0)$. We must lift u_0 to an element of $Z(S)$.

Since G is smooth over S, there is an element $u \in G(S)$ lifting u_0. Let i be the canonical immersion of H into K, and consider the two S-group morphisms

$$H \rightrightarrows K, \qquad i \quad \text{and} \quad j = \mathrm{int}(u)i.$$

Since $u_0 \in Z(S_0)$, we have $i_{S_0} = j_{S_0}$. By Exposé IX, 3.2, there exists $v \in K(S)$, lifting the identity section in $K(S_0)$, such that

$$i = \mathrm{int}(v)j = \mathrm{int}(vu)i.$$

Thus

$$vu = (u', v') \in (Z \times_S H)(S).$$

It follows that $u' \in Z(S)$, and u' lifts u_0.

Lemma 5.7.2.— *Let k be a field and H a k-algebraic group, and let $P(H)$ denote the following property:*

> *For every smooth unipotent k-group U, and every extension E of H by U, any two lifts of H in E are conjugate by an element of $U(k)$.*

Suppose that H is an algebraic group which is an extension of a group H'' of multiplicative type by a group H' of multiplicative type. If $P(H')$ and $P(H'')$ hold, then $P(H)$ holds.

Indeed, let U be a smooth unipotent k-group, let E be an extension of H by U, and let H_1, H_2 be two lifts of H in E. Let H_1', H_2' be the corresponding lifts of H'. Since $P(H')$ holds, there exists $u \in U(k)$ such that

$$H_2' = \mathrm{int}(u)H_1'.$$

After replacing H_1 by $\mathrm{int}(u)H_1$, we may suppose that $H_1' = H_2'$; denote this common group simply by H'. Put

$$E' = \mathrm{Centr}_E(H') = U^{H'}H_1 = U^{H'}H_2.$$

By 5.7.1, $U^{H'} = U'$ is smooth. We then have an extension

$$1 \longrightarrow U' \longrightarrow E' \longrightarrow H \longrightarrow 1.$$

By construction H' is central in E', and hence invariant. Passing to the quotient gives an exact sequence

$$1 \longrightarrow U' \longrightarrow E'' \longrightarrow H'' \longrightarrow 1.$$

Since U' is smooth and $P(H'')$ holds, the images of H_1 and H_2 in E'' are conjugate by an element $u \in U'(k)$. It follows that

$$H_1 = \mathrm{int}(u)H_2.$$

To prove 5.1.1(ii)(b), observe that, since k is algebraically closed, H has a composition series whose successive quotients are smooth or, when $p > 0$, isomorphic to $\boldsymbol{\mu}_p$. Repeated application of 5.7.2 reduces us to the case where H is smooth or $H = \boldsymbol{\mu}_p$. In the first case it is enough to apply 5.1.1(ii)(a). It remains to consider $H = \boldsymbol{\mu}_p$. Since U is smooth, U has a characteristic composition series whose successive quotients are étale or isomorphic to $\mathbb{G}_a^r$, by 3.9. If U is étale, apply 5.5.1. We are finally reduced to

$$H = \boldsymbol{\mu}_p, \qquad U = \mathbb{G}_a^r.$$

We must prove that

$$H^1(\boldsymbol{\mu}_p, U) = 0.$$

The method used in 5.4.1 no longer applies, because $\boldsymbol{\mu}_p$ does not in general act linearly on $\mathbb{G}_a^r$. Fix the following notation: H' denotes a lift of H in E, and

$$\mathfrak{e} = \operatorname{Lie} E, \qquad \mathfrak{u} = \operatorname{Lie} U, \qquad \mathfrak{h} = \operatorname{Lie} H, \qquad \mathfrak{h}' = \operatorname{Lie} H'.$$

Let X be a nonzero element of $\mathfrak{h}$ such that

$$X^{(p)} = X$$

(Appendix II, 3.1), and let X' be its lift in $\mathfrak{h}'$.

Since $\boldsymbol{\mu}_p$ is a radicial group of height 1, the set of lifts of H in E is in bijective correspondence with the set A of elements $Y \in \mathfrak{e}$ such that

$$Y^{(p)} = Y$$

and whose image is X (Appendix II, 2.2). Likewise, if $Y \in A$ corresponds to a lift H'' of H in E, and if $u \in U(k)$, then

$$\operatorname{int}(u)H' = H'' \quad \Longleftrightarrow \quad \operatorname{Ad}(u)X' = Y.$$

Let B be the subset of $\mathfrak{e}$ consisting of the elements $\operatorname{Ad}(u)X'$, with $u \in U(k)$. Plainly $B \subset A$, and it remains only to prove $A = B$ when k is algebraically closed.

(a) *Study of A.* Since $\mathfrak{u}$ is commutative and normalized by $\mathfrak{h}'$, Jacobson's formula (Exposé $\mathrm{VII_A}$, 5.2) gives, for $u \in \mathfrak{u}$,

$$(X' + u)^{(p)} = X'^{(p)} + u^{(p)} + (\operatorname{ad} X')^{p-1}(u) = X' + (\operatorname{ad} X')^{p-1}(u).$$

Consequently,

$$X' + u \in A \quad \Longleftrightarrow \quad u = (\operatorname{ad} X')^{p-1}(u).$$

Let

$$\mathfrak{u} = \bigoplus_{n \in \mathbb{Z}/p\mathbb{Z}} \mathfrak{u}_n = \mathfrak{u}_0 \oplus \bigoplus_{n \in (\mathbb{Z}/p\mathbb{Z})^\times} \mathfrak{u}_n$$

be the canonical decomposition of $\mathfrak{u}$ under the action of H'. If $u \in \mathfrak{u}_0$, then $\operatorname{ad} X'(u) = 0$. If $u \in \mathfrak{u}_n$, with $n \in (\mathbb{Z}/p\mathbb{Z})^\times$, then

$$(\operatorname{ad} X')^{p-1}(u) = u.$$

Thus $Y = X' + u$ belongs to A if and only if

$$u \in \bigoplus_{n \in (\mathbb{Z}/p\mathbb{Z})^\times} \mathfrak{u}_n.$$

In particular, A is the set of k-rational points of an irreducible subscheme of $\mathbf{W}(\mathfrak{e})$, of dimension

$$\operatorname{rk}\mathfrak{u} - \operatorname{rk}\mathfrak{u}_0 = \operatorname{rk}\mathfrak{u} - \operatorname{rk}\operatorname{Centr}_{\mathfrak{u}}(X').$$

(b) *Study of B.* We shall need the following lemma.

Lemma 5.7.3 (Rosenlicht).— *Let U be a unipotent algebraic group over a field k, acting on a quasi-affine k-scheme X. Then the orbit of every point $x \in X(k)$ is closed in X. Here, by the orbit of x, we mean the subset of* $\operatorname{ens}(X)$ *which is the image of U under the morphism $g \mapsto g \cdot x$.*

By functoriality, U acts on the affine envelope of X, that is,

$$\operatorname{Spec}\Gamma(X, \mathcal{O}_X),$$

so we may suppose that X is affine. We may then suppose that k is algebraically closed, X is reduced, and U is smooth (observe that U_{red} acts on X_{red} when k is perfect). Let Y be the schematic image of U (EGA I, 9.5.1) under the morphism $g \mapsto g \cdot x$. It is a closed reduced subscheme of X, on which U acts. It follows readily from EGA IV, 1.8.6 that the orbit of x is an open subset Z of Y, dense in Y. We must prove that

$$Z = \operatorname{ens}(Y).$$

Let F be the closed reduced subscheme of Y whose underlying space is $Y \setminus Z$. Thus $F = V(J)$, where J is a nonzero ideal of $\Gamma(Y, \mathcal{O}_Y)$. Since U is smooth, U acts on F, hence on J, and therefore

$$J^U \neq 0$$

by 3.2. If a is a nonzero element of J^U, then a is constant on the orbit Z, and hence on Y, because Z is dense in Y. The ideal J consequently contains k, and $F = \varnothing$.

Apply the preceding lemma to the group U acting on the affine space $\mathbf{W}(\mathfrak{e})$ through the adjoint representation. The orbit of X' is the underlying set of a closed subscheme of $\mathbf{W}(\mathfrak{e})$. Moreover, the stabilizer Z of X' is its centralizer in U, and there is a closed immersion

$$U/Z \longrightarrow \mathbf{W}(\mathfrak{e}).$$

Thus the orbit of X' is the underlying space of a closed subscheme of $\mathbf{W}(\mathfrak{e})$ of dimension

$$\dim U - \dim Z.$$

(c) *End of the proof of 5.1.1(ii)(b).* When k is algebraically closed, the canonical map

$$U(k) \longrightarrow (U/Z)(k)$$

is surjective. By (b), B is therefore the set of k-rational points of a closed subscheme of $\mathbf{W}(\mathfrak{e})$ of dimension $\dim U - \dim Z$. In view of (a), to prove $A = B$ it is enough to show that

$$\operatorname{rk}\mathfrak{u} - \operatorname{rk}\operatorname{Centr}_{\mathfrak{u}}(X') \leq \dim U - \dim \operatorname{Centr}_U(X').$$

Since U is smooth,

$$\dim U = \operatorname{rk}\mathfrak{u}.$$

On the other hand, Exposé II, 5.3.3 gives

$$\dim \operatorname{Centr}_U(X') \leq \operatorname{rk}\operatorname{Centr}_{\mathfrak{u}}(X'),$$

which proves the assertion. Notice in fact that

$$\dim \operatorname{Centr}_U(X') = \operatorname{rk}\operatorname{Centr}_{\mathfrak{u}}(X');$$

this also proves once more that Z is smooth, as in 5.7.1.

5.8. End of the proof of 5.1.1(i)

It remains to prove (i)(c) and (i)(d).

Proof of 5.1.1(i)(d): U smooth and H connected. We shall need the following lemma.

Lemma 5.8.1.— *With the notation of 5.1.1, suppose that U is smooth and H is radicial, and let H_1 be an algebraic subgroup of H which has a lift H_1' in E. Then H has a lift H' in E which contains H_1'.*

Proof. By induction on the height of H/H_1, we may suppose that H/H_1 has height 1. Put

$$C' = \mathrm{Centr}_E(H_1').$$

We claim that the canonical morphism $C' \longrightarrow H$ is an epimorphism. To prove this, we may suppose that k is algebraically closed. The extension E is then trivial, by 5.1.1(i)(a). Let H'' be a lift of H in E, and let H_1'' be the inverse image of H_1 in H''. The groups H_1' and H_1'' are two lifts of H_1 in E; hence they are conjugate by an element of $U(k)$, since k is algebraically closed and U is smooth, by 5.1.1(ii)(b). Consequently, to prove the assertion about C', it is enough to prove it for

$$C'' = \mathrm{Centr}_E(H_1'').$$

But C'' contains H'', so the assertion is clear.

It also follows from 5.7.1 that $C' \cap U$ is smooth. We may therefore replace E by C', and thus suppose that H_1' is central. Passing then to the quotient by H_1', we may suppose that $H_1 = 0$ and that H has height 1.

Since U is smooth, we have the following exact sequence of p-Lie algebras (Appendix II, 3.2):

$$(*) \qquad 0 \longrightarrow \mathrm{Lie}\, U \longrightarrow \mathrm{Lie}\, E \longrightarrow \mathrm{Lie}\, H \longrightarrow 0.$$

In view of Appendix II, 2.2, to say that E is trivial is equivalent to saying that $(*)$ is a trivial extension of p-Lie algebras. Suppose that $H \neq 0$, and hence that $\mathrm{Lie}\, H \neq 0$. Suppose also that we have found a nonzero p-Lie subalgebra

$$\mathfrak{h}_1 \subset \mathfrak{h} = \mathrm{Lie}\, H$$

which lifts to a p-Lie subalgebra $\mathfrak{h}_1' \subset \mathrm{Lie}\, E$. By the cited result, there is a subgroup H_1 of H, with $\mathrm{Lie}\, H_1 = \mathfrak{h}_1$, and a lift H_1' of H_1 in E, with $\mathrm{Lie}\, H_1' = \mathfrak{h}_1'$. Applying once more the reduction just described, we are brought back to the same problem with H replaced by H/H_1. Since H has height 1,

$$\mathrm{Lie}(H/H_1) = \mathrm{Lie}\, H/\mathrm{Lie}\, H_1$$

(loc. cit.), and consequently

$$\mathrm{rk}\,\mathrm{Lie}(H/H_1) \leq \mathrm{rk}\,\mathrm{Lie}\, H - 1.$$

Thus, by induction on the rank of $\mathrm{Lie}\, H$, it is enough, when $\mathfrak{h} \neq 0$, to find a nonzero Lie subalgebra of $\mathrm{Lie}\, H$ which lifts to $\mathrm{Lie}\, E$. This follows from the next lemma.

Lemma 5.8.2.— *Let k be a field of characteristic $p > 0$, and let*

$$\varphi : \mathfrak{g} \longrightarrow \mathfrak{h}$$

be a surjective morphism of finite-rank p-Lie algebras over k. Then:

(i) If $\mathfrak{h}_{\overline{k}}$ is reductive (4.2.2) and nonzero, there exists a reductive Lie subalgebra $\mathfrak{h}_1$ of $\mathfrak{g}$ whose image in $\mathfrak{h}$ is nonzero.

(ii) If k is perfect and u is a unipotent element of $\mathfrak{h}$, that is, if $u^{(p^n)} = 0$ for some n, then u lifts to a unipotent element of $\mathfrak{g}$.

Proof. Let X be a nonzero element of $\mathfrak{h}$ in case (i), and let $X = u$ in case (ii); choose a lift X' of X in $\mathfrak{g}$. The p-Lie subalgebra $\mathfrak{h}'$ of $\mathfrak{g}$ generated by X' is abelian (Exposé VII).

Case (i). The description given in 4.2.2 shows that the reductive part (loc. cit.) of $\mathfrak{h}'_{\overline{k}}$ is already defined over k; denote it by $\mathfrak{r}'$. We claim that the image of $\mathfrak{r}'$ in $\mathfrak{h}$ is nonzero. We may suppose that k is algebraically closed, so that

$$\mathfrak{h}' = \mathfrak{r}' \oplus \mathfrak{u}',$$

where $\mathfrak{u}'$ is the unipotent part of $\mathfrak{h}'$. If the image of $\mathfrak{r}'$ in $\mathfrak{h}$ were zero, then the image of $\mathfrak{h}'$ in $\mathfrak{h}$ would be unipotent, and hence zero because $\mathfrak{h}$ is reductive (2.4(ii)); but by construction that image contains X, a contradiction.

Case (ii). The same argument applies, with the roles of $\mathfrak{r}'$ and $\mathfrak{u}'$ interchanged.

End of the proof of 5.8.1. Suppose that $H \neq 0$. By 5.8.2 there exists a nonzero reductive p-Lie subalgebra $\mathfrak{h}'_1 \subset \operatorname{Lie} E$. Since $\operatorname{Lie} U$ is unipotent, by 4.3(i), we necessarily have

$$(\operatorname{Lie} U) \cap \mathfrak{h}'_1 = 0.$$

Thus $\mathfrak{h}'_1$ is a lift of a p-Lie subalgebra of $\operatorname{Lie} H$.

End of the proof of 5.1.1(i)(d). By 5.8.1 there is a family of algebraic subgroups H'_n ($n \in \mathbb{N}$) of E such that H'_{n+1} contains H'_n, and such that H'_n lifts ${}_{F^n}H$. The descending sequence of subgroups

$$\operatorname{Centr}_E(H'_n)$$

is stationary; let C be its stationary value. The center Z of C contains H'_n for every n. Hence the image of Z in H contains ${}_{F^n}(H)$ for every n, and is therefore an open subgroup of H (Exposé VII$_\mathrm{A}$, §4). It is consequently equal to H, since H is connected. To prove that E is trivial, we may thus replace E by Z, and hence suppose that E is commutative. We shall see in 7.2.1 that E then contains a maximal subgroup M of multiplicative type, whose formation commutes with extension of the base field. Since $E_{\overline{k}}$ is a trivial extension, by 5.1.1(i)(a), and U is unipotent, it is clear that M is the unique lift of H in E.

Proof of 5.1.1(i)(c): U k-solvable. Since $(H/H^0)(\overline{k})$ has order prime to p, duality immediately shows that there exists an integer n such that ${}_nH$ is an étale subgroup and the canonical morphism

$${}_nH \longrightarrow H/H^0$$

is an epimorphism. Thus $H/{}_nH$ is connected. By 5.2.3(d), there exists a lift H' of ${}_nH$ in E. As at the beginning of the proof of 5.8.1, one sees that

$$C = \operatorname{Centr}_E(H')$$

is a subgroup of E such that $C \longrightarrow H$ is an epimorphism and $C \cap U$ is smooth. Replacing E by C and passing to the quotient by H', we are reduced to the case where U is smooth and H is connected, namely case (i)(d).

This completes the proof of 5.1.1.

5.9. Counterexamples

Let us first indicate a procedure for obtaining nontrivial extensions of a k-group H of multiplicative type by a unipotent k-group U. Suppose that an action of H on U is given, and let

$$E = U \rtimes H$$

be the semidirect product. Let, moreover, a class in $\mathrm{H}^1(k, U)$ be represented by a 1-cocycle a. The group U acts on E by inner automorphisms, and a therefore defines a k-form of E, denoted by E_a. Suppose in addition that U is commutative. Then U acts trivially on U and on the quotient $E/U = H$, so E_a is again an extension of H by U.

For simplicity, suppose that H is an étale diagonalizable group, so that the Galois group $\mathscr{G} = \mathrm{Gal}(\overline{k}/k)$ acts trivially on $H(\overline{k})$. Its action on $E_a(\overline{k})$ is then given by

$$^g(u, h) = (^g u + a(g) - {}^h a(g), h) \qquad (g \in \mathscr{G},\ u \in U(\overline{k}),\ h \in H(\overline{k})).$$

If $h \in H(k)$, and X is its inverse image in E_a, then X is a torsor under U defined by the class of the 1-cocycle

$$g \longmapsto a(g) - {}^h a(g)$$

of $\mathscr{G}$ with values in U. It follows that if there is a point $h \in H(k)$ for which this cocycle is nontrivial, then the extension E_a is nontrivial. We apply this construction in the following two particular cases.

(a) A nontrivial extension of an étale diagonalizable group H by $\mathbb{Z}/p\mathbb{Z}$. Take

$$H = (\mathbb{Z}/p\mathbb{Z})^\times, \qquad U = \mathbb{Z}/p\mathbb{Z},$$

with H acting on U by multiplication. Let k be a field of characteristic p, let K/k be a Galois extension whose Galois group $\mathscr{G}$ is isomorphic to $\mathbb{Z}/p\mathbb{Z}$, and take a nonzero element

$$a \in \mathrm{H}^1(\mathscr{G}, U) = \mathrm{Hom}(\mathscr{G}, U).$$

Then E_a is the required example.

(b) A nontrivial extension of an étale diagonalizable group H by a smooth connected unipotent group U. Choose a nonperfect field k admitting a k-form U of $\mathbb{G}_a$ such that $\mathrm{H}^1(k, U) \neq 0$. For example (see J.-P. Serre, *Cohomologie Galoisienne*), one may take for k the fraction field of a discrete valuation ring of equal characteristic $p > 0$, and for U the algebraic subgroup of $\mathbb{G}_a \times_k \mathbb{G}_a$ defined by

$$X^p + X + tY^p = 0,$$

where t is a uniformizer of k. Indeed, suppose for simplicity that k contains the $(p-1)$-st roots of unity. There is then an exact sequence of algebraic groups

$$0 \longrightarrow \mathbb{Z}/p\mathbb{Z} \longrightarrow U \longrightarrow \mathbb{G}_a \longrightarrow 0, \qquad (x, y) \longmapsto y,$$

and hence an exact cohomology sequence

$$\mathbb{G}_a(k) \xrightarrow{d} \mathrm{H}^1(k, \mathbb{Z}/p\mathbb{Z}) \longrightarrow \mathrm{H}^1(k, U) \longrightarrow 0,$$

where d associates to x the homogeneous space under $\mathbb{Z}/p\mathbb{Z}$ defined by

$$X^p + X + tx^p = 0.$$

Moreover,

$$\mathrm{H}^1(k, \mathbb{Z}/p\mathbb{Z}) \simeq k/P(k), \qquad P(x) = x^p + x,$$

and therefore

$$\mathrm{H}^1(k, U) \simeq k/(P(k) + tk^p).$$

If, in addition, $p \neq 2$, then t^2 does not belong to $P(k) + tk^p$; consequently $\mathrm{H}^1(k, U) \neq 0$.

The group $\boldsymbol{\mu}_{p-1}$ acts on U by

$$(h, x, y) \longmapsto (hx, hy).$$

Let $\mathscr{G}$ be the Galois group of the extension K/k defined by

$$X^p + X + t^2 = 0,$$

and let $a \in \mathrm{H}^1(\mathscr{G}, U)$ be the nonzero class described above. It follows immediately that E_a is a nontrivial extension of $\boldsymbol{\mu}_{p-1}$ by U.

(c) A nontrivial extension of $\mathbb{G}_m$ by $\boldsymbol{\alpha}_p$. By 5.1.1(i)(b), such an extension can exist only over a nonperfect field. Let k therefore be nonperfect, and let G be the semidirect product of $U = \mathbb{G}_a$ by $H = \mathbb{G}_m$, where $\mathbb{G}_m$ acts on $\mathbb{G}_a$ by homotheties. Since U is invariant in G, so is ${}_FU$. Put

$$G' = G/{}_FU.$$

The group G' is isomorphic to $\mathbb{G}_a \rtimes \mathbb{G}_m$, where $\mathbb{G}_m$ acts on $\mathbb{G}_a$ by

$$(h, u) \longmapsto h^p u.$$

The functor $\mathscr{T}_G$ (respectively $\mathscr{T}_{G'}$) of subtori of G (respectively G') (see Exposé XV) is isomorphic to $\mathbb{G}_a$, and the morphism

$$\mathscr{T}_G \longrightarrow \mathscr{T}_{G'}$$

induced by $G \longrightarrow G'$ identifies with

$$u \longmapsto u^p.$$

It follows that if T' is a subtorus of G' corresponding to a point $x \in k \simeq \mathbb{G}_a(k)$ such that $x^{1/p} \notin k$, then its inverse image E in G is an extension of the torus T' by ${}_FU = \boldsymbol{\alpha}_p$. It has no maximal torus defined over k, and hence is nontrivial. As a subgroup of

$$G = \operatorname{Spec} k[U, T, T^{-1}],$$

the group E is defined by

$$U^p = x - xT^p.$$

Remark 5.9.1.— *This last example shows that a nonsmooth algebraic group defined over a nonperfect field need not possess a maximal torus, and thus answers the question posed in Exposé XIV, 1.5(b).*

(d) A trivial extension with nonconjugate lifts. We now give an example of a trivial extension E of a group H of multiplicative type by a unipotent group U, and of two lifts H' and H'' of H which are not conjugate by an element of $U(k)$.

Take for E the semidirect product of $U = \mathbb{G}_a$ by

$$\boldsymbol{\mu}_p = \operatorname{Spec} k[T]/(T^p - 1),$$

where the action of $\boldsymbol{\mu}_p$ on $\mathbb{G}_a = \operatorname{Spec} k[U]$ is defined by the comorphism

$$U \longmapsto (U + U^p)T - U^p.$$

The centralizer of $\boldsymbol{\mu}_p$ in U is then the étale group Z defined by

$$U + U^p = 0.$$

It follows that if k is not algebraically closed, the canonical map

$$U(k) \longrightarrow (U/Z)(k)$$

is not in general surjective. In view of 5.1.1(ii)(b), two lifts of $\boldsymbol{\mu}_p$ in E therefore need not be conjugate by an element of $U(k)$.

Here is another example, with k algebraically closed of characteristic $p > 0$. Let G be the radicial semidirect product in which $\boldsymbol{\mu}_p$ acts on $\boldsymbol{\alpha}_p$ by homotheties. There is an exact sequence of algebraic groups with $\boldsymbol{\mu}_p$-operators

$$0 \longrightarrow \boldsymbol{\alpha}_p \longrightarrow \mathbb{G}_a \xrightarrow{x \longmapsto x^p} \mathbb{G}_a \longrightarrow 0,$$

where $\boldsymbol{\mu}_p$ acts by homotheties on the first $\mathbb{G}_a$ and trivially on the second. The exact cohomology sequence (Appendix I, Proposition 11) gives

$$0 \longrightarrow \mathbb{G}_a(k) \longrightarrow \mathrm{H}^1(\boldsymbol{\mu}_p, \boldsymbol{\alpha}_p) \longrightarrow \mathrm{H}^1(\boldsymbol{\mu}_p, \mathbb{G}_a).$$

Since the last term is zero by I, 5.3.3, the group $\mathrm{H}^1(\boldsymbol{\mu}_p, \boldsymbol{\alpha}_p)$ is nonzero. Thus two lifts of $\boldsymbol{\mu}_p$ in G need not be conjugate.

6. Extensions of a Unipotent Group by a Group of Multiplicative Type

6.1. Statement of the Theorem

Theorem 6.1.1.— *Let k be a field, U a unipotent algebraic k-group, H a k-group of multiplicative type, and E an algebraic k-group which is an extension of U by H, so that there is an exact sequence*

$$1 \longrightarrow H \longrightarrow E \longrightarrow U \longrightarrow 1.$$

Then the extension E is trivial and there exists a unique lift of U in E in each of the following cases:

(A) The group U is smooth and one of the following conditions holds:

- *(i) U is connected and the canonical morphism $E \longrightarrow U$ admits a section.*
- *(ii) U has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$.*
- *(iii) H is étale.*
- *(iv) k is perfect.*

(B) $U = \boldsymbol{\alpha}_p$ and k is perfect.

(C) E is commutative and k is perfect.

6.2. Proof of 6.1.1(A)

We first establish three lemmas.

Lemma 6.2.1.— *Let S be a prescheme, E an S-group prescheme which is an extension of an S-group prescheme U, with connected fibres, by an S-group H of multiplicative type and finite type (that is, U is the quotient of E by H for the fpqc topology). Then E is a central extension.*

Proof. Since H is commutative, U acts on H by inner automorphisms, through an S-morphism of groups

$$u : U \longrightarrow \mathrm{Aut}_{S\text{-gr}}(H).$$

The functor $\mathrm{Aut}_{S\text{-gr}}(H)$ is representable by an étale S-scheme (Exposé X, 5.10), and consequently its identity section is both an open and a closed immersion. Since U has connected fibres, it follows that u is the unit morphism.

Lemma 6.2.2.— *With the notation of 6.1.1, if E is trivial, there exists a unique lift of U in E.*

Proof. Let U' and U'' be two lifts of U in E. To prove that $U' = U''$, we may suppose that k is algebraically closed, and it is enough to prove that $\mathrm{H}^1(U, H) = 0$. If U is connected, then U centralizes H by 6.2.1, and hence

$$\mathrm{H}^1(U, H) = \mathrm{Hom}_{k\text{-gr}}(U, H) = 0$$

by 2.4(ii).

In the general case, let U'_1 denote the unique lift in E of the identity component U^0 of U, and put

$$N = \mathrm{Norm}_E(U'_1).$$

If $g \in E(k)$, then $\mathrm{int}(g)U'_1$ is a lift of U^0, and is therefore equal to U'_1; thus $N(k) \supset E(k)$. Moreover, N contains H, by 6.2.1, as well as U'_1, and it follows at once that $N = E$. On passing to the quotient by U'_1, we are reduced to the case in which U is étale. Since k is algebraically closed, in this case $\mathrm{H}^1(U, H)$ identifies with the ordinary cohomology group[10]

$$\mathrm{H}^1\big(U(k), H(k)\big),$$

and is therefore zero, since $U(k)$ is a finite p-group and $H(k)$ is uniquely p-divisible.

Corollary 6.2.3.— *To prove that E is trivial, it is enough to prove that it becomes trivial after a finite separable extension of the base field. In particular, we may suppose that H is diagonalizable.*

Lemma 6.2.4.— *In order that every central extension E of U by a diagonalizable k-group H be trivial, it is enough that every central extension of U by $\mathbb{G}_m$ be trivial.*

Proof. Induction on r first shows that the hypothesis implies that E is trivial when $H = \mathbb{G}_m^r$. In the general case, H embeds in $\mathbb{G}_m^r$ for a suitable integer r (this is immediate by duality); put

$$H'' = \mathbb{G}_m^r / H.$$

[10] Editor's note: see, for example, Proposition III.6.4.2 of M. Demazure and P. Gabriel, *Groupes algébriques I*, Masson & North-Holland (1970).

We obtain the exact sequence (Appendix I, 2.1)

$$\mathrm{Z}^1(U, H'') \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(U, H) \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(U, \mathbb{G}_m^r) = 0,$$

where U acts trivially on H, H'', and $\mathbb{G}_m^r$. But

$$\mathrm{Z}^1(U, H'') = \mathrm{Hom}_{k\text{-gr}}(U, H'') = 0$$

by 2.4(ii), and hence $\mathrm{Ext}_{\mathrm{alg}}(U, H) = 0$.

Proof of 6.1.1(A)(i). Since $E \longrightarrow U$ admits a section, E defines an element f of $\mathrm{H}^2(U, H)$ (Appendix I, 3.1). We must prove that f is zero. For this it is enough to prove that a 2-cocycle

$$f : U \times_k U \longrightarrow H$$

is a constant morphism, which follows from the next lemma.

Lemma 6.2.5.— *Let U be a smooth connected unipotent algebraic k-group, and H a k-group of multiplicative type. Then every k-morphism of preschemes*

$$f : U \longrightarrow H$$

is constant.

Proof. We may suppose that k is algebraically closed. We argue by induction on $\dim U$. If $\dim U > 0$, then U has a composition series (see 3.9)

$$1 \longrightarrow U' \longrightarrow U \xrightarrow{\pi} U'' \longrightarrow 1, \qquad U' \simeq \mathbb{G}_a, \quad \dim U'' < \dim U.$$

It is enough to show that f factors through U''. Since the graph of the equivalence relation defined by π is smooth over k, and hence reduced, it is enough to show that if $x, y \in U(k)$ have the same image z in $U''(k)$, then $f(x) = f(y)$. Now $\pi^{-1}(z)$ is isomorphic to $\mathbb{G}_a$, so the restriction of f to $\pi^{-1}(z)$ factors through a reduced irreducible component of H, and hence through a k-scheme isomorphic to $\mathbb{G}_m^r$. It remains only to note that every morphism from $\mathbb{G}_a$ to $\mathbb{G}_m^r$ is constant, since every invertible regular function on $\mathbb{G}_a$ is constant.

Proof of 6.1.1(A)(ii). By 6.2.1, 6.2.3, and 6.2.4, we may suppose that $H = \mathbb{G}_m$. By hypothesis, U has a composition series

$$U \supset U_1 \supset \cdots$$

such that U_i/U_{i+1} is isomorphic to $\mathbb{G}_a$. Let E_1 be the inverse image of U_1 in E. By induction on $\dim U$, we may suppose that the extension E_1 is trivial; let U_1' be the unique lift of U_1. Arguing as in the normalizer argument of 6.2.2, we find that U_1' is invariant in E. After taking the quotient by U_1', we are reduced to the case $U = \mathbb{G}_a$. The S-scheme E, where $S = U$, is then a torsor under the S-group $\mathbb{G}_m \times_k S$, and therefore admits a section, since $\mathrm{Pic}(S) = 0$ (Exposé VIII, 4.3). The extension E is then trivial by (A)(i).

Proof of 6.1.1(A)(iii) (U smooth, H étale). Suppose first that U is connected. The group $U_{\overline{k}}$ then has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$, so $E_{\overline{k}}$ is trivial by (A)(ii). Since H is étale, the unique lift of $U_{\overline{k}}$ in $E_{\overline{k}}$ is plainly the identity component of $E_{\overline{k}}$; this lift is therefore already defined over k. In the general case, after quotienting by the identity component of E, we are reduced to the case where E is étale, and then to the case where E is completely split (6.2.3). Since $U(k)$ is a p-group and $H(k)$ has order prime to p, we may take the Sylow p-subgroup of $E(k)$ as a lift of $U(k)$.

Proof of 6.1.1(A)(iv) (U smooth, k perfect). If U is connected, it has a composition series whose successive quotients are isomorphic to $\mathbb{G}_a$ (4.1.2(b)), and we apply (A)(ii). In the general case, the preceding argument reduces us to the case in which U is étale, and then to the case in which U is completely split and H is diagonalizable (6.2.3). Using a characteristic composition series of H,

$$H \supset H^0 \supset {}_{F^n}(H) \supset 0,$$

we are reduced to the case in which H is of one of the following three types:

(a) H is étale;

(b) $H = \mathbb{G}_m^r$;

(c) H is radicial.

In case (a) we apply (A)(iii), and in case (c) we apply 1.6. Finally, in case (b), Hilbert's Theorem 90 shows that $E \longrightarrow U$ admits a section, so it is enough to show that

$$\mathrm{H}^2(U, \mathbb{G}_m^r) = \mathrm{H}^2\big(U(k), \mathbb{G}_m^r(k)\big) = 0.$$

But $U(k)$ is a finite p-group, whereas $\mathbb{G}_m^r(k)$ is uniquely p-divisible, since k is perfect.

6.3. Proof of 6.1.1(B) and (C)

By 6.2.1, 6.2.3, and 6.2.4, it is enough to prove (B) when $H = \mathbb{G}_m$. We therefore have an exact sequence

$$1 \longrightarrow \mathbb{G}_m \longrightarrow E \longrightarrow \boldsymbol{\alpha}_p \longrightarrow 1.$$

Since $\mathbb{G}_m$ is smooth, it gives an exact sequence of restricted Lie algebras (Appendix II, 3.2)

$$(*) \qquad 0 \longrightarrow \operatorname{Lie}\mathbb{G}_m \longrightarrow \operatorname{Lie} E \longrightarrow \operatorname{Lie}\boldsymbol{\alpha}_p \longrightarrow 0.$$

The group $\boldsymbol{\alpha}_p$ has height 1, so the extension E is trivial if and only if the exact sequence $(*)$ of restricted Lie algebras splits (Appendix II, 2.2). The algebra $\operatorname{Lie}\boldsymbol{\alpha}_p$ is generated by an element $X \neq 0$ such that $X^{(p)} = 0$ (Appendix II, 2.1). It is therefore enough to show that X lifts to an element Z of $\operatorname{Lie} E$ for which $Z^{(p)} = 0$. By 5.8.2(ii), there is a unipotent element Z of $\operatorname{Lie} E$ which lifts X. Since the unipotent part of $\operatorname{Lie} E$ plainly has dimension at most 1, it follows necessarily that $Z^{(p)} = 0$.

Proof of 6.1.1(C). If U_1' is a lift in E of an algebraic subgroup U_1 of U, then U_1' is invariant in E, since E is assumed commutative, and we may pass to the quotient by U_1'. Using a composition series of U (3.5(ii)), the preceding remark reduces us to the case in which U is smooth or equal to $\boldsymbol{\alpha}_p$. But then E is trivial by (A)(iv) and (B).

6.4. Examples of nontrivial extensions of a unipotent group U by a group H of multiplicative type

In view of 6.1.1(A)(iv), the question arises only in characteristic $p > 0$.

(a) $H = \mathbb{G}_m$, and U is a nontrivial form of $\mathbb{G}_a$ (cf. Appendix III, §5).

Let k be a nonperfect field of characteristic 2, and let $u \in k$ be such that $u^{1/2} \notin k$. Consider the affine group E with coordinate ring

$$k\big[X, Y, (X^2 + uY^2)^{-1}\big],$$

whose multiplication is given by the comorphism

$$(X, Y) \longmapsto (XX' + uYY',\ XY' + YX').$$

The group E is smooth, connected, commutative, and of dimension 2; the subscheme $Y = 0$ defines a subgroup $H \simeq \mathbb{G}_m$. The kernel K of the squaring map on E has equation

$$X^2 + uY^2 = 1,$$

and hence has dimension 1. The group K contains the unipotent radical of E, defined over $\bar{k}$, as well as the contribution of H, which is isomorphic to $\boldsymbol{\mu}_2$. Since K is reduced over $\bar{k}$, the unipotent radical of E is not defined over k, and $U = E/H$ does not lift in E.

One checks immediately that U is the form of $\mathbb{G}_a$ with coordinate ring

$$k[V, W]/(V + uV^2 + W^2),$$

the morphism $E \longrightarrow U$ corresponding to the comorphism

$$V \longmapsto \frac{Y^2}{X^2 + uY^2}, \qquad W \longmapsto \frac{XY}{X^2 + uY^2}.$$

(b) $H = \mathbb{G}_m$, $U = \mathbb{Z}/2\mathbb{Z}$, and k is nonperfect of characteristic 2.

Choose k and u as in (a), and consider the subgroup E of GL_2 generated by the element

$$X = \begin{pmatrix} 0 & 1 \\ u & 0 \end{pmatrix} = \begin{pmatrix} u^{1/2} & 0 \\ 0 & u^{1/2} \end{pmatrix} \begin{pmatrix} 0 & u^{-1/2} \\ u^{1/2} & 0 \end{pmatrix}.$$

The group E is an extension of $\mathbb{Z}/2\mathbb{Z}$ by $\mathbb{G}_m$, but this extension is not trivial because the unipotent part of X is not defined over k.

(c) $H = \boldsymbol{\mu}_p$, $U = \boldsymbol{\alpha}_p$, and k is nonperfect.

Let $\mathfrak{e}$ be the commutative restricted Lie algebra generated by two elements X and Y such that

$$X^{(p)} = X, \qquad Y^{(p)} = aX.$$

By Appendix II, 2.2, $\mathfrak{e}$ is the restricted Lie algebra of an algebraic group E which is an extension of $\boldsymbol{\alpha}_p$ by $\boldsymbol{\mu}_p$. This extension is trivial if and only if there exists $b \in k$ such that $b^p = a$, for then

$$(Y - bX)^{(p)} = 0.$$

(d) $H = \boldsymbol{\mu}_2$, $U = \boldsymbol{\alpha}_2 \times \boldsymbol{\alpha}_2$, E noncommutative, and k a field of characteristic 2.

Consider the special linear group $\mathrm{SL}_{2,k}$, and put $E = F(\mathrm{SL}_{2,k})$. The group E is a radicial group of height 1, whose Lie algebra is generated by three elements X, Y, Z satisfying

$$[X, Y] = Z, \qquad [X, Z] = [Y, Z] = 0,$$
$$X^{(p)} = Y^{(p)} = 0, \qquad Z^{(p)} = Z.$$

Consequently, E is a central extension of $U \simeq \boldsymbol{\alpha}_2 \times \boldsymbol{\alpha}_2$ by $\boldsymbol{\mu}_2$. Each factor $\boldsymbol{\alpha}_2$ of U lifts uniquely in E, but U itself does not lift in E, since $[X, Y] \neq 0$.

7. Nilpotent Affine Algebraic Groups

7.1. Extensions of Groups of Multiplicative Type

Proposition 7.1.1.— *Let S be a prescheme, let H and K be two S-group preschemes of multiplicative type and finite type, and let E be an S-group prescheme which is an extension of K by H (that is, K is the quotient of E by H for the fpqc topology). Then E is of multiplicative type in either of the following two cases:*

(a) E is commutative.

(b) The fibres of K are connected.

Proof.

(i) Suppose first that S is the spectrum of a field k. The assertion is local for the fpqc topology, so we may suppose that k is algebraically closed and hence that H and K are diagonalizable. Notice that K acts trivially on H by inner automorphisms: this is clear in case (a), and follows from 6.2.1 in case (b). Induction on the length of a suitable composition series of K reduces us to the case where K is of one of the following three types:

$$\text{(a) } K = \mathbb{G}_m, \qquad \text{(b) } K = \boldsymbol{\mu}_p, \qquad \text{(c) } K = \boldsymbol{\mu}_q, \quad (q,p) = 1,$$

and in case (c), E is commutative. Now embed H in $\mathbb{G}_m^r$. It follows that E embeds in an extension of K by $\mathbb{G}_m^r$, and we may therefore suppose that $H = \mathbb{G}_m^r$.

(a) If $K = \mathbb{G}_m$, then E is a smooth, connected, affine algebraic group (Exposé $\mathrm{VI_B}$, 9.2) of unipotent rank zero, and is therefore a torus.

(b) Let $K = \boldsymbol{\mu}_p$. In this case E is a trivial extension. Indeed, since H is smooth, the canonical morphism

$$\operatorname{Lie} E \longrightarrow \operatorname{Lie} \boldsymbol{\mu}_p$$

is surjective (Appendix II, 3.2), and the assertion follows from 5.8.2(i), in view of Appendix II, 2.2.

(c) Let $K = \boldsymbol{\mu}_q$, where $(q,p) = 1$, and suppose that E is commutative. Again the extension E is trivial. Indeed, let $x \in E(\bar{k})$ lift a generator $\bar{x}$ of $\boldsymbol{\mu}_q(\bar{k})$. The element x^q belongs to $H(\bar{k})$, and hence has the form y^q, with $y \in H(\bar{k})$ (notice that $\mathbb{G}_m^r(\bar{k})$ is q-divisible). Since E is commutative, $y^{-1}x$ is a lift of $\bar{x}$ having order q.

(ii) Consider now the general case. The groups H and K are flat, affine, and of finite presentation over S (Exposé IX, 2.1), and consequently so is E (Exposé $\mathrm{VI_B}$, 9.2). Using the general technique of Exposé $\mathrm{VI_B}$, §10, we reduce to the case where S is noetherian. To prove that E is of multiplicative type, it then suffices to prove that E is commutative and that ${}_nE$ is finite over S for every n (Exposé X, 4.8(b)).

(a) E is commutative. We must verify that the morphism

$$E \times_S E \longrightarrow E, \qquad (x,y) \longmapsto [x,y] = xyx^{-1}y^{-1}$$

factors through the unit section of E, and it is enough to verify this when S is the spectrum of an artinian local ring. But then E is of multiplicative type by (i) and Exposé X, 2.3.

(b) The group ${}_nE$ is finite over S. Indeed, there is an exact sequence

$$0 \longrightarrow {}_nH \longrightarrow {}_nE \longrightarrow {}_nK \xrightarrow{u} H_n,$$

where H_n is the cokernel of the n-th power map on H. We know that H_n is of multiplicative type (Exposé IX, 2.7), and hence separated, and that ${}_nH$ and ${}_nK$ are finite over S. The group $\ker u$ is a closed subgroup of ${}_nK$, and hence is finite over S; consequently ${}_nE$ is finite over S, as an extension of one finite group by another (Exposé $\mathrm{VI_B}$, 9.2).

7.2. Structure of Commutative Affine Algebraic Groups

Theorem 7.2.1.— *Let k be a field and G a commutative affine algebraic k-group. Then:*

(a) G contains a largest subgroup M of multiplicative type. The group M is characteristic in G, the quotient G/M is unipotent, and the formation of M commutes with extension of the ground field k.

(b) If k is perfect, G is the direct product of M and a unipotent algebraic subgroup U, uniquely so.

Proof.

(i) Suppose that k is algebraically closed. When G is smooth, 7.2.1(b) is well known (BIBLE 4, Theorem 4). If G is radicial of height 1, the decomposition of $\mathrm{Lie}\, G$ described in 4.2.2 corresponds, in view of 4.3.1(v) and Appendix II, 2.2, to a decomposition of G of the kind asserted in 7.2.1(b). In general, G has a composition series whose successive quotients are smooth or radicial of height 1 (Appendix II, 3.1). To prove 7.2.1(b), it therefore suffices to observe the following. Suppose there is an exact sequence of commutative algebraic groups

$$0 \longrightarrow G' \longrightarrow G \longrightarrow G'' \longrightarrow 0,$$

in which G', respectively G'', is the product of a group of multiplicative type and a unipotent group,

$$G' = M' \cdot U', \qquad G'' = M'' \cdot U''.$$

Then the same is true of G. Indeed, consider the exact sequence

$$0 \longrightarrow G'/U' \longrightarrow G/U' \longrightarrow G'' \longrightarrow 0.$$

By 7.1.1(a), the inverse image of M'' in G/U' is a subgroup M_1 of multiplicative type. The group M_1 lifts to a subgroup M of G by 5.1.1(i)(a). Likewise, now using 6.1.1(C), one proves that there is a unipotent subgroup U of G which is an extension of U'' by U'. Clearly $G = M \cdot U$.

(ii) Let k now be arbitrary. By (i), $G_{\bar{k}}$ is the direct product of a group $M_{\bar{k}}$ of multiplicative type and a unipotent group $U_{\bar{k}}$. Put

$$S = \bar{k} \times_k \bar{k},$$

and let M_1 and M_2 be the two inverse images of $M_{\bar{k}}$ under the two projections $S \rightrightarrows \bar{k}$. The group

$$G_S/M_2 = (G/M_{\bar{k}})_S$$

has unipotent fibres; hence the image of M_1 in G_S/M_2 is trivial by 2.4(i), and $M_1 \subset M_2$. The converse inclusion follows in the same way, so $M_1 = M_2$. By fpqc descent, $M_{\bar{k}}$ therefore descends to an algebraic subgroup M of G. It is clear that M is of multiplicative type, that G/M is unipotent, and that the formation of M is compatible with every extension of k. For every k-prescheme S, every subgroup H of multiplicative type in G_S is contained in M_S. Indeed, its image in the group with unipotent fibres

$$(G/M)_S = G_S/M_S$$

is trivial by 2.5.

Taking H, in particular, to be the transform of M_S under an automorphism of G_S, we conclude that M is characteristic in G.

Finally, if k is perfect, G/M lifts in G to a unipotent group, uniquely so by 6.1.1(C).

Remark 7.2.2.—

(i) If k is not perfect, the unipotent component of $G_{\bar{k}}$ need not be defined over k, as Example 6.4(a) shows.

(ii) In contrast to the multiplicative-type component M, the unipotent component U is not in general characteristic in G, whatever the characteristic of k. Of course, the uniqueness of the decomposition in 7.2.1(b) implies that U is invariant under every k-automorphism of G. But if U and M are such that there exist a k-prescheme S and a nonzero S-homomorphism

$$h : U_S \longrightarrow M_S$$

(cf. 2.6), then one obtains an S-automorphism of G_S,

$$(u, m) \longmapsto (u, h(u) + m),$$

which does not leave U_S invariant.

(iii) If G is finite over k, then under Cartier duality (2.6) the quotient G/M corresponds to the connected component of the identity in the dual $D(G)$ of G.

7.3. Structure of Nilpotent Affine Algebraic Groups

Theorem 7.3.1.— *Let k be a field and G a nilpotent (Exposé VI$_B$, §8), affine, connected algebraic k-group. Then G has a largest subgroup M of multiplicative type. The group M is central and characteristic, and G/M is a unipotent algebraic group.*

Let Z be the centre of G, and let M be the largest subgroup of multiplicative type in Z, as supplied by 7.2.1. Since Z is characteristic in G, and M is characteristic in Z, the group M is characteristic in G. It remains to show that G/M is unipotent. By induction on the length of the ascending central series of G, this follows from the following more general lemma.

Lemma 7.3.2 (Rosenlicht).— *Let G be a connected algebraic k-group and let Z be its centre. Then the centre Z' of $G' = G/Z$ is unipotent.*

Proof. We may suppose that k is algebraically closed. It is then enough to show that Z' contains no subgroup isomorphic to $\boldsymbol{\mu}_\ell$, for any prime number ℓ, by 4.6.1(vi). Let $\boldsymbol{\mu}_\ell$ be such a subgroup of Z', and let N be its inverse image in G. Since $\boldsymbol{\mu}_\ell$ is central in G', the group N is invariant in G.

(i) Suppose that $(\ell, p) = 1$. We can find an element $x \in N(k)$ and an integer n with the following properties:

(a) x lifts a generator $\bar{x}$ of $\boldsymbol{\mu}_\ell$;
(b) $x^{\ell^n} \in Z^0(k)$.

Indeed, it suffices to choose a lift of $\bar{x}$ whose image in $(N/Z^0)(k)$ belongs to the ℓ-Sylow subgroup. Raising to the ℓ-th power in the commutative group Z^0 is an étale morphism, so $Z^0(k)$ is ℓ-divisible. Consequently, after multiplying x by an element of $Z^0(k)$, we may suppose that $x^{\ell^n} = 0$. The group N is then generated by two commuting commutative groups, namely Z and the group generated by x, and is therefore commutative. The group ${}_{\ell^n}N$ is of multiplicative type and is characteristic in N; hence it is invariant in G, and consequently central because G is connected (Exposé IX, 5.5). Thus ${}_{\ell^n}N$ is contained in Z, contradicting the fact that its image in G' contains $\boldsymbol{\mu}_\ell$.

(ii) Suppose that $\ell = p$. There is then an integer n such that the image of F_nN in G' contains $\boldsymbol{\mu}_p$, and hence an exact sequence

$$(*) \qquad 1 \longrightarrow K \longrightarrow F_nN \longrightarrow \boldsymbol{\mu}_p \longrightarrow 1.$$

The group K is contained in Z, and is therefore commutative. It follows from 7.2.1, 7.1.1(b), and 5.5.1 that there is a subgroup of multiplicative type in F_nN whose image in the quotient by K is $\boldsymbol{\mu}_p$. As in (i), we deduce that F_nN is commutative. Its multiplicative-type component (7.2.1) is characteristic in F_nN, hence invariant in G, and therefore central (Exposé IX, 5.5). Since its image in G' contains $\boldsymbol{\mu}_p$, this is a contradiction.

A. Appendix I. Hochschild Cohomology and Extensions of Algebraic Groups

A.1. Definition of the Cohomology Groups

Let k be a field, let G be an algebraic k-group, and let $(\mathrm{Ab})_G$ be the abelian category of commutative algebraic k-groups on which G acts. If $A \in \mathrm{Ob}(\mathrm{Ab})_G$, the functor

$$h_A : (\mathrm{Sch}\,/k)^\circ \longrightarrow \mathrm{Ens}$$

canonically defined by A is a G-$\mathbb{Z}$-module in the sense of Exposé I, 3.2. We may therefore consider the standard complex $C^\bullet(G, A)$ of algebraic cochains of G with values in A (Exposé I, 5.1), together with the group $Z^i(G, A)$ of i-cocycles, the group $B^i(G, A)$ of i-coboundaries, and the i-th cohomology group $H^i(G, A)$. As usual, $H^0(G, A)$ is identified with the group $A^G(k)$, where A^G is the k-functor of invariants of A under G. The group $H^1(G, A)$ classifies the trivial principal homogeneous spaces under A on which G acts.

In general, the functor

$$A \longmapsto H^\bullet(G, A)$$

from $(\mathrm{Ab})_G$ to Ab is not a cohomological functor. Nevertheless, we have the following proposition.

Proposition A.1.1.— *Let*

$$0 \longrightarrow A' \xrightarrow{u} A \xrightarrow{v} A'' \longrightarrow 0$$

be an exact sequence in $(\mathrm{Ab})_G$. *Then:*

(a) *if v has a section—that is, if there is a k-morphism of preschemes $s : A'' \to A$ such that $vs = 1_{A''}$—then there is the usual exact cohomology sequence*

$$\cdots \longrightarrow H^i(G, A) \longrightarrow H^i(G, A'') \xrightarrow{d} H^{i+1}(G, A') \longrightarrow \cdots ;$$

(b) *if $A(k) \to A''(k)$ is surjective, then the sequence*

(1)

$$0 \longrightarrow A'^G(k) \longrightarrow A^G(k) \longrightarrow A''^G(k) \xrightarrow{d} H^1(G, A') \longrightarrow H^1(G, A) \longrightarrow H^1(G, A'')$$

is exact.

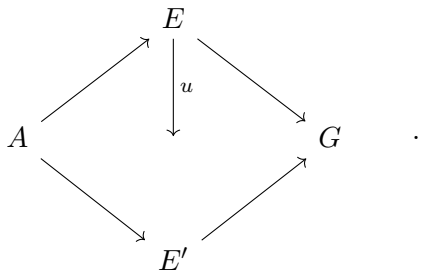
Proof. For (a), observe that the existence of a section implies the exactness of the sequence of complexes

$$0 \longrightarrow C^\bullet(G, A') \longrightarrow C^\bullet(G, A) \longrightarrow C^\bullet(G, A'') \longrightarrow 0.$$

For (b), if $x'' \in A''^G(k)$, its inverse image in A is a trivial principal homogeneous space under A' (because $A(k) \to A''(k)$ is assumed to be surjective) on which G acts, and therefore defines an element $d(x'') \in H^1(G, A')$. The exactness of the sequence (1) is then immediate.

A.2. The Group $\mathrm{Ext}_{\mathrm{alg}}(G, A)$

Let A and G be two algebraic k-groups, and let E and E' be two algebraic k-groups that are extensions of G by A. These two extensions are said to be *isomorphic* if there is a k-morphism of groups $u : E \to E'$ that makes the following diagram commutative:



The group E acts on A by inner automorphisms. If A is commutative, this action factors through G, so that G acts on A. Conversely, if $A \in \mathrm{Ob}(\mathrm{Ab})_G$, we denote by $\mathrm{Ext}_{\mathrm{alg}}(G, A)$ the set of classes of algebraic extensions E of G by A for which the action of G on A defined by E agrees with the action coming from the structure of A as an object of $(\mathrm{Ab})_G$.

The set $\mathrm{Ext}_{\mathrm{alg}}(G, A)$ is naturally a bifunctor, covariant in A and contravariant in G. More precisely:

(a) if $f : A \to B$ is a morphism in $(\mathrm{Ab})_G$, and if E represents an element of $\mathrm{Ext}_{\mathrm{alg}}(G, A)$, then $f_*(E) \in \mathrm{Ext}_{\mathrm{alg}}(G, B)$ is defined to be the class of the extension of G by B equal to the quotient of the semidirect product $B \cdot E$ (where E acts on B through G) by the algebraic subgroup that is the image of A under the morphism (f, i). This quotient is representable by Exposé $\mathrm{VI_A}$, §5, and there is therefore a commutative diagram

$$\begin{array}{ccccccccc} 1 & \longrightarrow & A & \xrightarrow{i} & E & \longrightarrow & G & \longrightarrow & 1 \\ & & \downarrow{\scriptstyle f} & & \downarrow & & \downarrow{\scriptstyle 1_G} & & \\ 1 & \longrightarrow & B & \longrightarrow & f_*(E) & \longrightarrow & G & \longrightarrow & 1 \end{array} .$$

(b) if $g : H \to G$ is a k-morphism of algebraic k-groups, and if E is an extension of G by A, the fiber product $E \times_G H$ is naturally an extension of H by A, denoted by $g^*(E)$. Thus there is a commutative diagram

$$\begin{array}{ccccccccc} 1 & \longrightarrow & A & \longrightarrow & g^*(E) & \longrightarrow & H & \longrightarrow & 1 \\ & & \downarrow{\scriptstyle 1_A} & & \downarrow & & \downarrow{\scriptstyle g} & & \\ 1 & \longrightarrow & A & \longrightarrow & E & \longrightarrow & G & \longrightarrow & 1 \end{array} .$$

By adapting the proofs given in J.-P. Serre, *Groupes algébriques et corps de classe*, Chapter VII, one endows $\mathrm{Ext}_{\mathrm{alg}}(G, A)$ with a natural abelian-group structure, functorial in A and G.

Proposition A.2.1.— *Let*

$$0 \longrightarrow A' \longrightarrow A \longrightarrow A'' \longrightarrow 0$$

be an exact sequence in $(\mathrm{Ab})_G$. *Then:*

(a) there is a canonical exact sequence of abelian groups

$$Z^1(G, A) \longrightarrow Z^1(G, A'') \xrightarrow{d} \mathrm{Ext}_{\mathrm{alg}}(G, A') \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(G, A) \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(G, A'');$$

(b) if $A(k) \to A''(k)$ is surjective, one deduces from (a) the exact sequence

$$(2)\quad H^1(G, A) \longrightarrow H^1(G, A'') \xrightarrow{d} \mathrm{Ext}_{\mathrm{alg}}(G, A') \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(G, A) \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(G, A'').$$

The exact sequence in (a) generalizes the usual exact $\mathrm{Hom}(\,\cdot\,,\,\cdot\,)$ sequence valid for commutative extensions (*loc. cit.*), and is proved in the same way. We recall only the definition of the coboundary

$$d : Z^1(G, A'') \longrightarrow \mathrm{Ext}_{\mathrm{alg}}(G, A').$$

For this purpose, consider the extension

$$1 \longrightarrow A' \longrightarrow A \cdot G \longrightarrow A'' \cdot G \longrightarrow 1,$$

obtained in the evident way from the exact sequence $0 \to A' \to A \to A'' \to 0$. If $u \in Z^1(G, A'')$, then u defines in the usual way a section homomorphism

$$u : G \longrightarrow A'' \cdot G.$$

One then has

$$d(u) = u^*(A \cdot G).$$

A.3. Comparison of $H^2(G, A)$ and $\mathrm{Ext}_{\mathrm{alg}}(G, A)$

It is well known that, for abstract groups, there is a functorial isomorphism between the abelian groups $H^2(G, A)$ and $\mathrm{Ext}(G, A)$. Likewise in the present setting, if A is an object of $(\mathrm{Ab})_G$, one can associate with every 2-cocycle $u \in Z^2(G, A)$ an algebraic-group structure on the prescheme $A \times_k G$, making it an element of $\mathrm{Ext}_{\mathrm{alg}}(G, A)$. Moreover, this extension

is trivial if and only if $u \in B^2(G, A)$ (see Exposé III, 1.2.2). Recall that the composition law on $A \times G$ is defined by

$$(a, g)(a', g') = a + {}^g a' + u(g, g').$$

It is clear that the extensions of G by A obtained in this way are not arbitrary, since they possess a section. Conversely, however, if $E \in \mathrm{Ext}_{\mathrm{alg}}(G, A)$ possesses a section s, then E is isomorphic to the extension of G by A associated with the 2-cocycle u such that

$$u(g, g') = s(g)s(g')s(gg')^{-1}.$$

We thus obtain the following proposition.

Proposition A.3.1.— *There is a functorial isomorphism between the bifunctors with values in abelian groups*

$$(G, A) \longmapsto H^2(G, A) \qquad \textit{and} \qquad (G, A) \longmapsto \mathrm{Ext}_s(G, A),$$

where $\mathrm{Ext}_s(G, A)$ *denotes the subgroup of* $\mathrm{Ext}_{\mathrm{alg}}(G, A)$ *formed by the classes of extensions of* G *by* A *that possess a section.*

B. Appendix II. Review and Supplements on Radicial Groups

Let $p > 1$ be a prime number, and let S be an $\mathbb{F}_p$-prescheme.

B.1. The Frobenius morphism

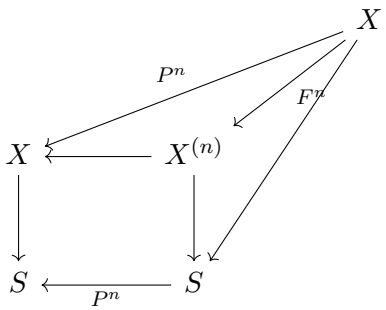
For every S-prescheme X and every integer $n > 0$, let

$$P^n : X \longrightarrow X$$

denote the $\mathbb{F}_p$-endomorphism corresponding to raising sections of $\mathcal{O}_X$ to the p^n-th power, and let $X^{(n)}$ denote the S-prescheme obtained from X by base change along $P^n : S \to S$. There is then a unique S-morphism

$$F^n : X \longrightarrow X^{(n)}$$

that makes the following diagram commutative:



It is clear that F^n identifies with the "n-th iterate" of $F^1 = F$, called the Frobenius morphism of X/S.

If G is an S-group prescheme, then $G^{(n)}$ is an S-group prescheme and

$$F^n : G \longrightarrow G^{(n)}$$

is an S-group morphism. Its kernel ${}_{F^n}(G)$ is a characteristic subgroup prescheme of G (that is, it is stable under the functor $\mathrm{Aut}_{S\text{-gr}}(G)$), and is radicial over S. If G is a radicial S-group prescheme, we say that G has height at most h if ${}_{F^h}(G) = G$.

B.2. Groups and restricted p-Lie algebras

If G is an S-group prescheme, then $\mathrm{Lie}(G)$ (Exposé II) is naturally a restricted p-Lie algebra (Exposé $\mathrm{VII_A}$, §§5 and 6). In particular, one has the following result (cf. Exposé $\mathrm{VII_A}$).

Proposition B.2.1.—

(i) $\mathrm{Lie}(\boldsymbol{\alpha}_p)_S = \mathrm{Lie}(\mathbb{G}_a)_S$[11] *is a sheaf of $\mathcal{O}_S$-modules, free of rank* 1 *over $\mathcal{O}_S$, generated by an element X such that $X^{(p)} = 0$.*

(ii) $\mathrm{Lie}(\boldsymbol{\mu}_p)_S = \mathrm{Lie}(\mathbb{G}_m)_S$ *is a sheaf of $\mathcal{O}_S$-modules, free of rank* 1 *over $\mathcal{O}_S$, with a canonical basis X such that $X^{(p)} = X$.*

We now recall the fundamental result proved in Exposé $\mathrm{VII_A}$, §7.

Theorem B.2.2.— *Suppose that S is affine, with ring A. Then the functor*

$$G \longmapsto \mathrm{Lie}\, G$$

defines an equivalence between, on the one hand, the category of S-group preschemes G that are of finite presentation and flat over S, of height 1*, and whose Lie algebra is locally free over $\mathcal{O}_S$, and, on the other hand, the category of restricted p-A-Lie algebras that are locally free of finite rank.*

Moreover, if G is as above and H is any S-group prescheme of finite presentation, the canonical morphism

$$\mathrm{Hom}_{S\text{-gr}}(G, H) \longrightarrow \mathrm{Hom}_{p\text{-}A\text{-Lie}}\big(\mathrm{Lie}\, G(S), \mathrm{Lie}\, H(S)\big)$$

is an isomorphism.

B.3. Radicial groups and smooth groups

We now suppose that S is the spectrum of a field k of characteristic p. Recall that Exposé $\mathrm{VI_A}$, §5 proves that, if G is an algebraic k-group and H an algebraic subgroup of G, then the sheaf G/H (for the fpqc topology) is representable. We also recall ($\mathrm{VII_A}$, 8.3):

Proposition B.3.1.— *Let G be an algebraic k-group. There exists an integer m such that, for every $n \geq m$, the algebraic group*

$$G/_{F^n}(G)$$

is smooth over k.

Proposition B.3.2.— *Consider an exact sequence of algebraic k-groups*

$$1 \longrightarrow G' \longrightarrow G \xrightarrow{u} G'' \longrightarrow 1$$

and the following assertions:

(i) the morphism u is smooth;

(ii) G' is smooth over k;

[11] Editor's note: the definition of $\boldsymbol{\alpha}_p$, already given at the beginning of this Exposé, has been omitted here.

(iii) for every integer $n > 0$, the sequence

$$1 \longrightarrow {}_{F^n}(G') \longrightarrow {}_{F^n}(G) \longrightarrow {}_{F^n}(G'') \longrightarrow 1$$

is exact;

(iv) the morphism ${}_FG \to {}_FG''$ is an epimorphism;

(v) the morphism

$$(\mathrm{Lie}\, G)(k) \longrightarrow (\mathrm{Lie}\, G'')(k)$$

is surjective.

Then

$$\text{(i)} \Longleftrightarrow \text{(ii)} \Longrightarrow \text{(iii)} \Longrightarrow \text{(iv)} \Longleftrightarrow \text{(v)}.$$

Moreover, if G is smooth, all five assertions are equivalent.

The equivalence (i)$\Longleftrightarrow$(ii) follows from Exposé $\mathrm{VI_B}$, 9.2(vii).
For (ii)$\Longrightarrow$(iii), if G' is smooth, then

$$F^n : G' \longrightarrow G'^{(n)}$$

is an epimorphism, and (iii) follows from the snake diagram. The implication (iii)$\Longrightarrow$(iv) is clear, while (iv)$\Longleftrightarrow$(v) follows from Theorem B.2.2. Finally, suppose that G is smooth and that (v) holds. Then G'' is smooth, and (v) implies

$$\dim G' = \dim_k (\mathrm{Lie}\, G')(k),$$

so G' is smooth.

C. Appendix III. Remarks and Supplements Concerning Exposés XV, XVI, and XVII

C.1.

It may be that Propositions 1.2 and 1.2 bis of Exposé XV remain valid if the hypothesis that H_0 is smooth over S_0 is removed. This is the case, in particular, if G is finite, flat, and commutative.

C.2. Complement to Exposé XV, 4.8

The following proposition, as well as Theorems C.3.1 and C.4.1 below, will appear in a forthcoming article by M. Raynaud on group schemes over a discrete valuation ring.[12]

Proposition C.2.1.— *Let S be the spectrum of a discrete valuation ring, let t be its generic point, let G be a flat S-group prescheme of finite type, and put*

$$\widetilde{G} = \mathrm{Spec}\, \Gamma(G, \mathcal{O}_G).$$

Let $u : G \to \widetilde{G}$ be the canonical morphism. Then:

(1) $\widetilde{G}$ is naturally an S-group scheme, and u is a homomorphism.

[12]Editor's note: comments are to be added here, including references to Exposé $\mathrm{VI_B}$, ...

(2) $\ker(u)$ *is flat over* S*, and* $(\widetilde{G}, u)$ *is the fpqc quotient of* G *by* $\ker(u)$*. Thus* $\widetilde{G}$ *is the largest affine quotient of* G*.*

(3) If G_t *is affine, then* $\ker(u)$ *is an étale group over* S*, and it is the trivial group if and only if* G *is separated over* S*. In particular, a flat, separated* S*-group scheme of finite type whose generic fiber is affine is affine.*

C.3.

In the statement of Exposé XV, 6.6, the hypothesis that H be equal to its connected normalizer is unnecessary in order that the set of points s of S for which H_s is a parabolic subgroup of G_s be open. Indeed, repeat the proof given in paragraph c) preceding Lemma 6.9, and let N denote the scheme-theoretic closure of N_t in G. Then N is a closed subgroup scheme of G, flat over S, which contains H and is contained in $\mathcal{N}$. The theorem below shows that G/N is representable. Since G_s/N_s is proper and connected, the proof concludes as in *loc. cit.*

Theorem C.3.1[13]**.**— *Let* S *be the spectrum of a henselian discrete valuation ring, let* G *be an* S*-group prescheme locally of finite type, and let* H *be a closed subgroup prescheme of* G*, flat over* S*. Then* G/H *is representable.*

C.4. Complement to Exposé XVI, 1.1

The following theorem refines Exposé VIII, 7.9.

Theorem C.4.1.— *Let* S *be the spectrum of a discrete valuation ring with residue characteristic* $p > 0$*, and let* G *be a commutative, smooth, separated* S*-group scheme of finite type. Then the following conditions are equivalent:*

(i) ${}_pG$ *is finite over* S*.*

(ii) For every S*-prescheme* S'*, every separated* S'*-group prescheme* H' *of finite presentation over* S'*, and every* S'*-monomorphism*

$$u : G_{S'} \longrightarrow H',$$

the morphism u *is an immersion.*

C.5.

Example XVII, 6.4(a), gives a smooth group over a field k whose unipotent radical is not defined over k. The following proposition gives a general method for obtaining such groups.

Proposition C.5.1.— *Let* k *be a field, let* K *be a finite radicial extension of* k *of degree greater than* 1*, and let* H *be a smooth, connected* K*-algebraic group of dimension* r*. Put*

$$G = \prod_{K/k} H/K,$$

[13]Editor's note: see Theorem 4C in S. Anantharaman, "Schémas en groupes, espaces homogènes et espaces algébriques sur une base de dimension 1," *Bull. Soc. Math. France, Mém.* 33 (1976), 5–79.

which is a smooth, connected k-algebraic group of dimension $r[K:k]$. Let

$$u : G_K \longrightarrow H$$

be the canonical homomorphism, and put $R = \ker(u)$. Then:

(i) u is an epimorphism, and R is a smooth, connected, unipotent algebraic group.

(ii) If U is a smooth algebraic subgroup of G such that U_K contains R, then $U = G$.

Corollary.— *Retain the notation of the preceding proposition.*

(a) If H is not unipotent, then the unipotent radical of $G_{\bar{k}}$ is not defined over k.

(b) If H is a nonzero abelian variety, then G is not an extension of an abelian variety by a smooth linear group.

(c) If H is not solvable, then the solvable radical of $G_{\bar{k}}$ is not defined over k, and G has no Borel subgroup defined over k.

Let us first show how the corollary follows from the proposition.

(a) Let U be a unipotent radical of G. Then U_K is the unipotent radical of G_K, and hence contains R, since R is smooth, connected, and unipotent by (i). Thus $U = G$ by (ii). But G_K has H as a quotient, and H is not unipotent by hypothesis. Therefore G is not unipotent, a contradiction.

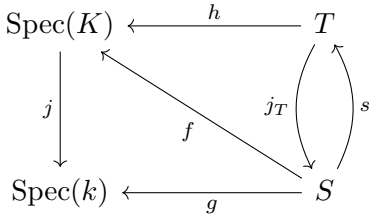
(b) Suppose that G is an extension of an abelian variety by a linear group L that is smooth over k. Then L_K necessarily contains R, so $L = G$. But G cannot be a linear group, because G_K has a nonzero abelian variety as a quotient.

(c) Let S be a solvable radical of G, and let B be a Borel subgroup of G. Then S_K and B_K contain R, so $S = G$ and $B = G$. But then G is solvable, contradicting the fact that G_K has a quotient that is not solvable.

Proof of Proposition C.5.1. *(i)* We begin by describing the morphism u. A K-scheme

$$f : S \longrightarrow \mathrm{Spec}(K)$$

gives rise to the diagram



where

$$g = j \circ f, \qquad T = \mathrm{Spec}(K) \times_{\mathrm{Spec}(k)} S,$$

h and j_T are the two projections, and s is the section of T over S such that $h \circ s = f$. The map

$$u(S) : G_K(S) \longrightarrow H(S)$$

is simply the composite

$$G_K(S) \xrightarrow{\sim} H(T) \longrightarrow H(S),$$

where the last arrow is defined by the section s.

Take, in particular, S to be the spectrum of an algebraic closure $\bar{k}$ of k, and let f be the unique k-morphism induced by $K \to \bar{k}$, so that T is a local Artinian scheme. To prove (i), it is enough to do so after extending the base field from K to $\bar{k}$. It is clear that

$$G_S = \prod_{T/S} H_T/T$$

represents the Greenberg functor of H_T relative to S (M. J. Greenberg, "Schemata over local rings," *Ann. of Math.* 73 (1961), 624–648). Under this identification, the description above shows that u_S is the canonical transition morphism

$$\mathrm{Green}(H_T) \longrightarrow H_S = H_T \times_T S.$$

Assertion (i) now follows from the smoothness of H over K and M. J. Greenberg, "Schemata over local rings II," *Ann. of Math.* 78 (1963), 256–266.

(ii) To prove (ii), we may suppose that k is separably closed. Let U be a smooth algebraic subgroup of G such that $U_K \supset R$, and let us prove that $U = G$. Since G is connected, we may suppose that U is connected. Let $V = u(U_K)$, a smooth, connected algebraic subgroup of H, and put

$$V' = \prod_{K/k} V/K,$$

a smooth, connected algebraic subgroup of G. The group V'_K is an algebraic subgroup of G_K, and the canonical morphism $V'_K \to V$ is the restriction of u to V'_K. By hypothesis, U_K contains R, hence *a fortiori* contains $\ker(V'_K \to V)$; by construction, moreover, the image of U_K in H is V. It follows that U_K contains V'_K, and hence that U contains V'.

On the other hand, the canonical isomorphism

$$G(k) \hookrightarrow G(K) \xrightarrow{u(K)} H(K)$$

plainly sends $U(k)$ into $V(K) = V'(k)$. Thus $U(k) \subset V'(k)$. Since U is smooth and k is separably closed, it follows that $U \subset V'$, whence $U = V'$. We then have

$$([K : k] - 1) \dim V = \dim \ker(V'_K \to V) = \dim R = ([K : k] - 1) \dim H.$$

Since $K \neq k$, we conclude that $\dim V = \dim H$, hence that $V = H$, and finally that $U = V' = G$.

Exposé XVIII
Weil's Theorem on the Construction of a Group from a Rational Law

by Michael Artin

0. Introduction

This Exposé is devoted to the well-known theorem of Weil [1], which constructs a group variety from a birational law. It seems that the generalization of this result to the case where the base is the spectrum of a discrete valuation ring was already known to several people; see, for example, [2]. Here we shall prove the theorem for a flat group of finite presentation over an arbitrary base prescheme S. Since the hypotheses must be formulated somewhat more carefully, the statement is not in the form given by Weil; but when S is the spectrum of a field, the form given here is seen to be essentially equivalent to Weil's. We use the following suggestion of Grothendieck: given a "group germ" X over a prescheme S, one should construct the group as the quotient of $X \times_S X$ by a suitable equivalence relation.

1. "Recollections" on Rational Maps

Let X/S be a relative prescheme and let $U \subseteq X$ be an open subset. We say that U is *schematically dense in X relative to S*, or that $U \hookrightarrow X$ is *relatively schematically dense*, if, for every base change $S' \to S$, the open subset $U \times_S S'$ is schematically dense in $X \times_S S'$. For the definition and properties of this notion, we refer to Exposé IX, §4.*

Proposition 1.1. *(i) A finite intersection, as well as a union of a nonempty family, of open subsets schematically dense relative to S, is schematically dense relative to S.*

(ii) If $U \subseteq X$ is schematically dense relative to S, and if $S \to T$ is a morphism, then $U_T \subseteq X_T$ is schematically dense relative to T.

(iii) Let $U \subseteq V \subseteq X$ be open immersions. For U to be schematically dense in X relative to S, it is necessary and sufficient that it be so in V, and that V be so in X.

[0] Version of May 8, 2009.

* See also EGA IV$_3$, 11.9 and 11.10 (especially 11.10.8), where the term "universally schematically dense relative to S" is used.

(iv) If $U \subseteq X$ and $V \subseteq Y$ are relatively schematically dense, then $U \times_S V$ is schematically dense in $X \times_S Y$ relative to S.

In Exposé IX one finds the following criterion:

Proposition 1.2. *Let X/S be locally of finite presentation and flat, and let U be an open subset of X. If, for every $s \in S$, the fiber U_s is schematically dense in X_s, then U is schematically dense in X relative to S.*

In particular:

Corollary 1.3. *Suppose that X/S is locally of finite presentation and flat, and that every fiber X_s is "without embedded components." Then U is schematically dense in X relative to S if and only if, for every $s \in S$, U_s is dense in X_s in the topological sense.*

One easily deduces from the definition the following proposition.

Proposition 1.4. *Let $U \subseteq X$ be schematically dense relative to S, and let $f, g : X \to Y$ be two morphisms of functors over S, where Y satisfies one of the following conditions:*

(i) *Y is a prescheme over S, and every fiber Y_s is separated.*

(ii) *Y is a presheaf[1] over S, such that the diagonal morphism $Y \to Y \times_S Y$ is representable by a closed immersion.*[2]

Then, if $f = g$ on U, one has $f = g$.

Proof. In case (i), the standard argument following IX, 4.1 shows that f and g are equal on every fiber; hence the subprescheme $\mathrm{Ker}(f, g)$ of X is set-theoretically equal to X, and is therefore closed. Since it contains U, it is equal to X, that is, $f = g$. Case (ii) is proved as in *loc. cit.*[3]

Definition 1.5. [*] *Let X be a prescheme over S, and let Y be a presheaf over S. A* rational map *$f : X \dashrightarrow Y$ over S is an equivalence class of morphisms $f : U \to Y$ over S, where U is an open subset of X that is schematically dense relative to S. One sets*

$$(f : U \to Y) \sim (f' : U' \to Y)$$

if and only if there exists an open subset $U'' \subseteq U' \cap U$, schematically dense relative to S, such that $f = f'$ on U''.

This definition is made in such a way that, for every base change $S' \to S$, the rational map $f \times_S S'$ may be defined in the obvious way.

If U is an open subset of X, we say that the rational map f is *defined on U* if there exists a morphism representing f whose set of definition contains U.

[1] Editor's note: specify for which topology; a priori, the fpqc topology.

[2] Editor's note: Let us recall here the definition of a closed immersion. A morphism of S-functors $F \to G$ is *relatively representable* if, for every S-morphism $T \to G$, where T is an S-prescheme, the T-functor $F_T = F \times_G T$ is representable by a T-prescheme. A morphism of S-functors $F \to G$ is an open (respectively, closed) immersion if it is relatively representable and if, for every S-morphism $T \to G$, where T is an S-prescheme, the T-morphism $F_T \to T$ is an open (respectively, closed) immersion.

[3] Editor's note: Give details on this point...

[*] See EGA IV_4, 20.5, where the term "pseudo-morphism from X to Y relative to S" is used in order not to conflict with EGA I, 7.12.

Definition 1.5.1. [4] *If Y satisfies one of conditions (i), (ii) of 1.4, it is clear that there exists a largest open subset U of X on which f is defined, and this U is schematically dense relative to S. It is called the* domain of definition of f over S, *and is denoted* $\mathrm{Dom}(f)$.

This notion does not in general commute with base change, but one has:

Proposition 1.6. *Let X be an S-prescheme and Y an S-functor satisfying one of hypotheses (i), (ii) of 1.4. Let $f : X \dashrightarrow Y$ be a rational map over S, let $S' \to S$ be a flat morphism locally of finite presentation, and put $f' = f \times_S S'$. Then*

$$\mathrm{Dom}(f') = \mathrm{Dom}(f) \times_S S'.$$

Proof. Put $U = \mathrm{Dom}(f)$. It is clear that $V' = \mathrm{Dom}(f')$ contains $U \times_S S'$. Let V be the image of V'; it is an open subset of X, because $X' \to X$ is open. We must prove that $V = U$, that is, we must find a morphism $V \to Y$ representing f. Put $S'' = S' \times_S S'$, and

$$X'' = X \times_S S'', \qquad U'' = U \times_S S'', \qquad V'' = V' \times_V V'.$$

Then U'' is schematically dense in X'' relative to S''; hence U'' is schematically dense in V'' relative to S'', since $U'' \subseteq V'' \subseteq X''$. The restriction of $f' : V' \to Y'$ to U' is obtained from $f : U \to Y$ by base change. The two morphisms $V'' \to Y$ obtained from f' by the two projections agree on U'', and hence agree. Since $V' \to V$ is flat and locally of finite presentation, it is an fppf covering (Exposé IV, 6.3), and the morphism $V \to Y$ is obtained by descent.

We shall frequently use the following triviality:

Proposition 1.7. *Let X/S be faithfully flat and locally of finite presentation, and let $U \subseteq X$ be a relatively schematically dense open subset. Then there exists an fppf covering base change $S' \to S$, and a section $x \in X(S')$ contained in $U(S')$.*

Indeed, U/S is an fppf covering. Take $S' = U$, and as the section take the S-graph of the inclusion $U \hookrightarrow X$.

2. Local Determination of a Group Homomorphism

Let G and H be groups, and let $U \subseteq G$ be a subset such that $U \cdot U = G$. If f and g are homomorphisms from G to H such that $f = g$ on U, then $f = g$. Likewise:

Proposition 2.1. *Let S be a site (cf. Exposé IV[4]), let G be a sheaf of groups on S, and let $U \subseteq G$ be a subsheaf of sets such that the morphism $U \times U \to G$ induced by multiplication is an epimorphism. If f and g are homomorphisms from G to a sheaf of groups H and are equal on U, then $f = g$.*

Corollary 2.2. *Let G be an S-group prescheme that is locally of finite presentation and flat, let $U \subseteq G$ be a relatively schematically dense open subset, and let H be a sheaf of groups on S for the fppf topology. Then every homomorphism $f : G \to H$ is determined by its restriction to U.*

Indeed, since G is flat over S, the composition law on G is a flat morphism ($\mathrm{VI_B}$, 9.2(xi)); it follows that $U \times_S U \to G$ is faithfully flat and locally of finite presentation, hence an fppf covering, and therefore an epimorphism.

[4] Editor's note: The number 1.5.1 has been added.

[4] Editor's note: that is, a category endowed with a topology; cf. IV, §4.2.

Proposition 2.3. *Let G be a group prescheme locally of finite presentation and flat over S, let $U \subseteq G$ be a relatively schematically dense open subset, and let H be a sheaf of groups for the fppf topology. Write m_G for the multiplication on G and m_H for that on H.*

Let $\bar{f} : U \to H$ be an S-morphism, and suppose that there exists a relatively schematically dense open subset V of $m_G^{-1}(U) \cap (U \times_S U)$ such that the following diagram is commutative:

$$\begin{array}{ccc} V & \xrightarrow{(\bar{f}\times\bar{f})|_V} & H \times_S H \\ \downarrow{\scriptstyle m_G} & & \downarrow{\scriptstyle m_H} \\ U & \xrightarrow{\bar{f}} & H \end{array}$$

Then there exists a morphism of S-groups $f : G \to H$, necessarily unique, extending $\bar{f}$, in each of the following situations:

(i) *H is representable.*

(ii) *The diagonal morphism $H \to H \times_S H$ is representable by a closed immersion.*[5]

(iii) *For every section $a \in U(S)$, the open subset $\mathrm{pr}_2((a \times_S U) \cap V)$ is relatively schematically dense in U*[*] *, and this assertion remains true after every base change $S' \to S$.*

Proof. First note that V is relatively schematically dense in $G \times_S G$. Indeed, V is relatively schematically dense in

$$m_G^{-1}(U) \cap (U \times_S G) \cap (G \times_S U),$$

and each of the three factors is obtained from $U \subseteq G$ by an evident base change $G \times_S G \to G$. The assertion therefore follows from 1.1.

To construct $f : G \to H$, since $U \times_S U \to G$ is an fppf covering, it is enough to construct a morphism $U \times_S U \to H$ whose two pullbacks to

$$(U \times_S U) \times_G (U \times_S U)$$

are equal. Take the morphism

$$m_H \circ (\bar{f} \times \bar{f}) : U \times_S U \longrightarrow H.$$

For sections $a, b, c, d \in U(S')$, where $S' \to S$ is arbitrary, such that $ab = cd$, we must prove

$$\bar{f}(a)\bar{f}(b) = \bar{f}(c)\bar{f}(d).$$

If (a, b) and (c, d) belong to $V(S')$, the desired equality follows at once. Thus it holds on $(V \times_G V)(S')$.

I claim that $V \times_G V$ is a relatively schematically dense open subset of

$$(U \times_S U) \times_G (U \times_S U).$$

This will complete the proof in cases (i) and (ii) by 1.4, because the morphism f constructed in this way extends $\bar{f}$, and its being a homomorphism is then evident, again by 1.4. Now

$$V \times_G V = (V \times_G (G \times_S G)) \cap ((G \times_S G) \times_G V).$$

[5] Editor's note: See the note at 1.4.

[*] Or in G, which is equivalent by 1.1(iv).

By symmetry and 1.1, it is enough to check that $V \times_G (G \times_S G)$ is relatively schematically dense in $(G \times_S G) \times_G (G \times_S G)$. The latter prescheme is isomorphic over S to $G \times_S G \times_S G$, the isomorphism being given by

$$(a, b, c, d) \longmapsto (a, b, c).$$

What remains is therefore the relative schematic density of $V \times_S G$ in $G \times_S G \times_S G$, which follows from that of V in $G \times_S G$.

It remains to treat case (iii). To prove $\bar{f}(a)\bar{f}(b) = \bar{f}(c)\bar{f}(d)$, we may make an fppf covering base change. Suppose that, after such a base change $S' \to S$, there is a section $x \in G(S')$ such that

$$(b, x), \quad (a, bx), \quad (d, x), \quad (c, dx)$$

all belong to V. Then

$$\begin{aligned}\bar{f}(a)\bar{f}(b)\bar{f}(x) &= \bar{f}(a)\bar{f}(bx) = \bar{f}(abx) = \bar{f}(cdx)\\ &= \bar{f}(c)\bar{f}(dx) = \bar{f}(c)\bar{f}(d)\bar{f}(x),\end{aligned}$$

which gives the desired equality.

To find such an x[5], set, for every $z \in U(S')$,

$$V_z = \mathrm{pr}_{2/S'}((z \times_{S'} U_{S'}) \cap V_{S'}).$$

The conditions imposed on x say exactly that $x \in W$, where

$$W = V_b(S') \cap V_d(S') \cap b^{-1}V_a(S') \cap d^{-1}V_c(S').$$

By hypothesis (iii), W is relatively schematically dense in G. Proposition 1.7 therefore supplies such a section x after an fppf covering base change.

Let us verify that the morphism thus constructed is multiplicative. Let $a, b \in G(S')$, where $S' \to S$ is arbitrary; after this base change, rename S' as S. Choose an fppf covering base extension $S' \to S$ and a section $x \in G(S')$ such that

$$x \in U(S') \qquad \text{and} \qquad ax^{-1} \in U(S'),$$

that is, $x \in (a^{-1}U)^{-1}(S')$. Choose in addition another fppf covering extension $S'' \to S'$ and a section $y \in G(S'')$ such that

$$y, \quad by^{-1}, \quad aby^{-1} \in U(S''),$$

and

$$by^{-1} \in V_x, \qquad xby^{-1} \in V_{ax^{-1}}.$$

Then, by the definition of f, over S'' we have

$$f(a) = \bar{f}(ax^{-1})\bar{f}(x), \qquad f(b) = \bar{f}(by^{-1})\bar{f}(y), \qquad f(ab) = \bar{f}(aby^{-1})\bar{f}(y).$$

Furthermore,

$$\begin{aligned}f(a)f(b) &= \bar{f}(ax^{-1})\bar{f}(x)\bar{f}(by^{-1})\bar{f}(y)\\ &= \bar{f}(ax^{-1})\bar{f}(xby^{-1})\bar{f}(y)\\ &= \bar{f}(aby^{-1})\bar{f}(y) = f(ab),\end{aligned}$$

[5]Editor's note: The beginning of the following sentence has been added.

which proves multiplicativity.

It is now easy to see that f extends $\bar{f}$. Let $a \in U(S')$; after base change, rename S' as S, and choose an fppf covering $S' \to S$ and sections $x, y \in G(S')$ such that

$$(x, y), \qquad (ax, y), \qquad (a, xy)$$

belong to $V(S')$. Then

$$f(xy) = \bar{f}(x)\bar{f}(y) = \bar{f}(xy), \qquad f(axy) = \bar{f}(ax)\bar{f}(y) = \bar{f}(axy).$$

Consequently,

$$\begin{aligned} f(a) &= f(axy)f\big((xy)^{-1}\big) = f(axy)f(xy)^{-1} \\ &= \bar{f}(axy)\bar{f}(xy)^{-1} = \bar{f}(a). \end{aligned}$$

□

Remark 2.3.1. In many cases hypothesis (iii) holds, for it will still hold if U is replaced by a smaller open subset U', still relatively schematically dense in G. For example:

Proposition 2.4. *In the situation of 2.3, suppose that every geometric fiber of G/S is irreducible. Put*

$$U' = \mathrm{pr}_1 V \qquad \textit{and} \qquad V' = V \cap m_G^{-1}(U') \cap (U' \times_S U').$$

Then $U' \subseteq U$ is an open subset relatively schematically dense in G, and U', $\bar{f}|_{U'}$, and V' satisfy hypothesis (iii).

Proof. The subset U' is open because $G \times_S G \to G$ is flat and locally of finite presentation. All the other verifications are immediate except for hypothesis (iii).

Let $a \in U(S')$; after base change, rename S' as S. To verify that

$$\mathrm{pr}_2\big((a \times_S U') \cap V'\big)$$

is relatively schematically dense in U', it suffices by Corollary 1.3 to do so fiber by fiber. Thus it is enough to treat the case where S is the spectrum of a field, and in that case it is enough to prove that U' is nonempty, since G is irreducible and has no embedded components (cf. $\mathrm{VI_A}$, 1.1.1). Now

$$\begin{aligned} \mathrm{pr}_2\big((a \times_S U') \cap V'\big) = \mathrm{pr}_2\big((a \times_S U') \cap V\big) \\ \cap\, \mathrm{pr}_2\big((a \times_S U') \cap m_G^{-1}(U')\big). \end{aligned}$$

The second factor on the right is dense in G. It therefore remains only to prove that

$$\mathrm{pr}_2\big((a \times_S U') \cap V\big)$$

is dense in G, that is, nonempty; and this is clear because $a \in U' = \mathrm{pr}_1 V$. □

3. Construction of a Group from a Rational Law

3.0. Suppose given an S-prescheme X/S and a rational map

$$X \times_S X \dashrightarrow X$$

over S. We seek an S-group G/S and a birational map relative to S[6]

$$X \dashrightarrow G$$

that commutes with the composition laws. We treat only the case in which X/S satisfies the following hypothesis:

($\diamond$) X/S is faithfully flat and of finite presentation, with separated fibers and without embedded components.

(The last two conditions hold for a group prescheme.[7])

We shall often omit the symbol S from fiber products.

Let X/S be a prescheme having the properties ($\diamond$) above, and let W be a subprescheme of finite presentation of $X \times X \times X$ having the following property:

(*) the three morphisms $W \to X \times X$ induced by the projections from X^3 onto X^2 are relatively schematically dense open immersions over S.

Notation. We shall use the following terminology. Given sections $a, b, c \in X(S')$, where $S' \to S$ is arbitrary, such that $(a, b, c) \in W(S')$, we write

$$c = ab, \qquad b = a^{-1}c, \qquad a = cb^{-1}.$$

Definition 3.0.1. [8] Given a section $(a, b) \in X^2(S')$, we say that ab is *defined* if, and only if, there exists a section $c \in X(S')$ such that $(a, b, c) \in W(S')$; equivalently, if and only if $(a, b) \in \mathrm{pr}_{12} W(S')$. Similarly, to say that $a^{-1}b$ or ab^{-1} is defined has the analogous meaning, and we extend this terminology also to products of several factors.

Remark 3.0.2. Let us note at once the following fact. By (*), W defines a rational map $X^2 \dashrightarrow X$ over S, namely the one given by $(a, b) \mapsto ab$. This rational map may well have a domain of definition larger than $\mathrm{pr}_{12} W$. Nevertheless, we say that ab is defined only if $(a, b) \in \mathrm{pr}_{12} W(S')$.

Definition 3.1. A *group germ* is an S-prescheme X/S having the properties ($\diamond$) above, together with a subprescheme W of finite presentation of $X \times X \times X$, having the following properties:

(i) W satisfies property (*) above.

[6] Editor's note: The notion of a birational map (relative to S) should be made explicit, perhaps in an addition to 1.5.2.

[7] Editor's note: Cf. VI_A; the reference is to be specified.

[8] Editor's note: The numbering 3.0.1 and 3.0.2 has been introduced.

(ii) For every section $a \in X(S)$, the sets

$$\begin{aligned} &\mathrm{pr}_i\big((a \times X \times X) \cap W\big), \quad i = 2, 3, \\ &\mathrm{pr}_i\big((X \times a \times X) \cap W\big), \quad i = 3, 1, \\ &\mathrm{pr}_i\big((X \times X \times a) \cap W\big), \quad i = 1, 2, \end{aligned}$$

are schematically dense in X relative to S, and this assertion remains true after every base change $S' \to S$. (Condition (i) implies that these sets are open in X.) Intuitively, this says that ax is defined for sufficiently general x, and similarly for the other products.

(iii) The law is associative: if $(a, b, c) \in X^3(S')$, for an arbitrary $S' \to S$, and both $(ab)c$ and $a(bc)$ are defined, then

$$(ab)c = a(bc).$$

Remarks. (a) In (i), the condition that W be schematically dense in X^2 relative to S may be replaced by the condition that, for every $s \in S$, the fiber W_s be topologically dense in X_s^2, by the hypotheses on X and by 1.2.

(b) Condition (iii) is equivalent to the following. Let V_1 (respectively V_2) be the open subset of X^3 on which the rational map

$$(a, b, c) \longmapsto a(bc) \qquad \big(\text{respectively } (a, b, c) \longmapsto (ab)c\big)$$

is defined* . Then there exists an open subset $V \subseteq V_1 \cap V_2$, schematically dense in X^3 relative to S, on which the two maps agree. This follows from 1.4, since V_1 and V_2 are schematically dense in X^3 relative to S.

(c) Hypothesis (ii) will be used below to ensure that X is a subobject of the group prescheme that it defines. In many cases one can deduce (ii) from (i), provided that X is replaced by a relatively schematically dense open subset X' and W by a relatively schematically dense open subset of $W \cap X'^3$. More precisely:

Proposition 3.2. *Suppose that every geometric fiber of X/S is irreducible, and let W be a subprescheme of X^3 satisfying condition (i) of 3.1. Then there exist a relatively schematically dense open subset $X' \subseteq X$ and a relatively schematically dense open subset $W' \subseteq W \cap X'^3$ such that the pair (X', W') satisfies conditions (i) and (ii). If (iii) holds for (X, W), then it holds for (X', W').*

Proof. Set

$$X' = \bigcap_{i=1}^{3} \mathrm{pr}_i\, W.$$

Each $\mathrm{pr}_i\, W$ is open in X, because $W \to X^2$ is an open immersion and the projections $X^2 \to X$ are flat and of finite presentation. Moreover, $\mathrm{pr}_i\, W$ is schematically dense in X relative to S, because W is so in X^2 and the projections $X^2 \to X$ are surjective; it is enough here to check topological density. Put

$$W' = W \cap X'^3.$$

*In the sense explained in 3.0.1; one could also replace these open subsets by the domains of definition (cf. 1.5) of the rational maps under consideration.

To verify (i), note that

$$W' = (W \cap (X' \times X' \times X)) \cap (W \cap (X \times X' \times X')) \\ \cap (W \cap (X' \times X \times X')).$$

Now

$$W \cap (X' \times X' \times X) \simeq \mathrm{pr}_{12} W \cap (X' \times X'),$$

so this term is schematically dense in W relative to S. The other two terms on the right are likewise schematically dense in W, and hence W' is schematically dense in W. Consequently $\mathrm{pr}_{ij} W'$ is schematically dense in $\mathrm{pr}_{ij} W$, hence in $X \times X$, and therefore in $X' \times X'$.

To verify (ii), let $a \in X'(S')$. After this base change, rename S' as S. We must show, for example, that

$$\mathrm{pr}_2((a \times X' \times X') \cap W')$$

is schematically dense in X' relative to S. By 1.3 it is enough to check this fiber by fiber. Thus it is enough to treat the case in which S is the spectrum of a field, and in that case it is enough to show that the open subset is nonempty, since the fibers of X/S are irreducible and have no embedded components. Since

$$\mathrm{pr}_2((a \times X \times X) \cap W)$$

is nonempty, because a is a section of X', this open subset is dense in X. We have

$$\mathrm{pr}_2((a \times X \times X) \cap W) = \mathrm{pr}_2((a \times X) \cap \mathrm{pr}_{12} W).$$

Therefore

$$\mathrm{pr}_2((a \times X) \cap \mathrm{pr}_{12} W) \cap X' \\ = \mathrm{pr}_2((a \times X') \cap \mathrm{pr}_{12} W) = \mathrm{pr}_2((a \times X' \times X) \cap W)$$

is dense in X, and hence in X'.

Similarly, $\mathrm{pr}_3((a \times X \times X') \cap W)$ is dense in X, hence dense in $\mathrm{pr}_3((a \times X \times X) \cap W)$. Equivalently, $(a \times X \times X') \cap W$ is dense in $(a \times X \times X) \cap W$, and therefore

$$\mathrm{pr}_2((a \times X \times X') \cap W)$$

is dense in $\mathrm{pr}_2((a \times X \times X) \cap W)$, hence in X, and thus in X'.

Finally,

$$\mathrm{pr}_2((a \times X' \times X') \cap W') = \mathrm{pr}_2((a \times X' \times X') \cap W) \\ = \mathrm{pr}_2((a \times X' \times X) \cap W) \cap \mathrm{pr}_2((a \times X \times X') \cap W),$$

which is indeed dense in X'. This is what was required. The other assertions in (ii) follow by symmetry, and preservation of condition (iii) is immediate.[8] This proves Proposition 3.2. □

[8]Editor's note: The following sentence has been added.

3.2.1. [9] Fix a group germ (X, W) over S. We first make some preliminary observations about the situation, collected below as rules. These rules will often be used without explicit mention in what follows.

Let $a \in X(S')$, and after base change rename S' as S. There is then a birational map φ over S from X to itself, sending a section x to ax whenever the latter is defined. By 3.1(ii), the domain of definition of φ contains the relatively schematically dense open subset

$$\mathrm{pr}_2\big((a \times X \times X) \cap W\big),$$

and φ defines an isomorphism from this open subset onto the open subset

$$\mathrm{pr}_3\big((a \times X \times X) \cap W\big),$$

on which $a^{-1}x$ is defined. This observation is generalized in the evident way in Rule 1 below.

Rule 1. Let $P = P(x, t_1, \ldots, t_n)$ be a "product" of the symbols $x, t_1, \ldots, t_n$, obtained recursively as follows: $P_0 = x$, and P_{i+1} is one of the expressions

$$P_i t, \qquad t P_i, \qquad P_i^{-1} t, \qquad t P_i^{-1}, \qquad P_i t^{-1}, \qquad t^{-1} P_i,$$

where t is one of the t_j; and $P_r = P$. Let $a_1, \ldots, a_n \in X(S')$. Then there exists a relatively schematically dense open subset U of $X_{S'}$ such that the product $P(x, a_1, \ldots, a_n)$ is defined (in the sense of Remark 3.0.2) for a section $x \in X(S'')$ if and only if $x \in U(S'')$, and the map

$$x \longmapsto P(x, (a))$$

gives an isomorphism from U onto another relatively schematically dense open subset of $X_{S'}$, denoted $P(U, (a))$.

Rule 2. Let $a, b \in X(S')$. Then:

if ab is defined, so is $a^{-1}(ab)$, and $a^{-1}(ab) = b$;
if $a^{-1}b$ is defined, so is $a(a^{-1}b)$, and $a(a^{-1}b) = b$;
if ba^{-1} is defined, so is $(ba^{-1})a$, and $(ba^{-1})a = b$.

Rule 3. Let $a, b, b' \in X(S')$. If

$$ab = ab', \qquad ba = b'a, \qquad a^{-1}b = a^{-1}b', \qquad \text{or} \qquad ba^{-1} = b'a^{-1},$$

then $b = b'$. It is understood here that an equality entails that both of its sides are defined.

Rule 4. Let $a, b, c \in X(S')$. Whenever both sides are defined, one has

$$a\big((ba)^{-1}c\big) = b^{-1}c.$$

Similarly,

$$(c(ab)^{-1})a = cb^{-1}, \qquad a^{-1}\big((ab^{-1})c\big) = b^{-1}c, \qquad \big(c(b^{-1}a)\big)a^{-1} = cb^{-1}.$$

[9] Editor's note: The numbering 3.2.1, as well as 3.2.2, has been introduced.

Rule 5. All the following associativity laws hold whenever both sides are defined:

$$(a^{-1}b)c = a^{-1}(bc), \qquad (ab^{-1})c = a(b^{-1}c), \qquad (ab)c^{-1} = a(bc^{-1}),$$
$$(ab)^{-1}c = b^{-1}(a^{-1}c), \quad (a^{-1}b)c^{-1} = a^{-1}(bc^{-1}), \quad (ab^{-1})c^{-1} = a(cb)^{-1}.$$

3.2.2. Verification of the rules. (1) This follows by an evident induction on the length r of P, the case $r = 1$ being a direct consequence of 3.1(ii).

(2) This is immediate from the definition.

(3) Indeed, by Rule 2, in the first case for example,

$$b = a^{-1}(ab) = a^{-1}(ab') = b'.$$

(4) Let us verify the first relation, for example. On the right-hand side, left multiplication by b is defined and gives c, by Rule 2. Suppose that it is also defined on the left-hand side. Then

$$b(a((ba)^{-1}c)) = (ba)((ba)^{-1}c) = c.$$

Indeed, ba is defined by hypothesis, since it occurs in the expression. The middle term is therefore defined and equal to c by Rule 2, and it is equal to the left-hand term by associativity (cf. 3.1(iii)). Rule 3 thus implies that the desired equality holds whenever this multiplication by b is defined.

Now fix a and b. Rule 1 implies that $b(a((ba)^{-1}c))$ is defined for c "in" a relatively schematically dense open subset U of X. Hence, on this relatively schematically dense open subset, the two rational maps

$$c \longmapsto b^{-1}c \qquad \text{and} \qquad c \longmapsto a((ba)^{-1}c)$$

are equal. By 1.4, they are equal on every common domain of definition, which proves the desired result.

(5) The argument is of the same kind as the preceding one. For example, let us verify

$$(ab^{-1})c^{-1} = a(cb)^{-1}.$$

If right multiplication by c is defined on the right-hand side, equality follows from Rule 4. Since it is enough to verify such a formula on a relatively schematically dense open subset, we are reduced to the case in which this multiplication is defined.

3.2.3. Consider the relation R on $X \times X$ defined as follows. For $a, b, a', b' \in X(S')$, one has

$$(a, b) \sim (a', b') \pmod{R(S')}$$

if and only if there exist an fppf covering $S'' \to S'$ and a section $x \in X(S'')$ such that $(xa)b$ and $(xa')b'$ are defined and equal. Then R is an equivalence relation.

Indeed, this relation is evidently symmetric. By Rule 1, the product $(xa)b$ is defined when x is "in" a suitable relatively schematically dense open subset. Thus 1.7 asserts that there exist an fppf covering $S'' \to S'$ and an $x \in X(S'')$ for which $(xa)b$ is defined. The relation is therefore reflexive. Its transitivity follows from the next lemma.

Lemma 3.3. *Let x, y, a, b, a', b' be sections of $X(S')$ such that $(xa)b$, $(xa')b'$, $(ya)b$, and $(ya')b'$ are defined. If*

$$(xa)b = (xa')b',$$

then

$$(ya)b = (ya')b'.$$

Indeed, the lemma says that one may test $(a, b) \sim (a', b')$ using any $x \in X(S')$, with $S' \to S$ an fppf covering, for which both products are defined. Given

$$a, b, a', b', a'', b'' \in X(S),$$

Rules 1, 1.1, and 1.7 allow us to find an fppf covering $S' \to S$ and a section $x \in X(S')$ such that the three products in question are defined; transitivity follows.

Proof of Lemma 3.3. Let us begin by writing formally

$$(za)b = \big(((zx^{-1})x)a\big)b = \big((zx^{-1})(xa)\big)b = (zx^{-1})\big((xa)b\big),$$
$$(za')b' = \big(((zx^{-1})x)a'\big)b' = \big((zx^{-1})(xa')\big)b' = (zx^{-1})\big((xa')b'\big).$$

The appropriate rules show that these equalities do hold whenever their terms are defined.[10] It follows that

$$(za)b = (za')b'$$

whenever all these expressions are defined. Moreover, by Rule 1 and the hypotheses already made, these expressions are defined when $z \in X(S'')$ belongs to $V(S'')$, where V is a certain relatively schematically dense open subset of X (we have taken $S' = S$). Therefore the two rational self-maps of X given by

$$z \longmapsto (za)b \qquad \text{and} \qquad z \longmapsto (za')b'$$

are equal, and consequently

$$(ya)b = (ya')b'.$$

□

Lemma 3.4. *Consider the rational map*

$$\varphi\colon X^3 \dashrightarrow X$$

over S, defined by

$$(a, b, c) \longmapsto c^{-1}(ab).$$

Let U be the domain of definition of φ, and let Γ be the graph of the morphism $f\colon U \to X$ induced by φ, regarded as a subprescheme of X^4. Then a section $(a, b, c, d) \in X^4(S)$ belongs to $\Gamma(S)$ if and only if

$$(a, b) \sim (c, d).$$

[10] Editor's note: To be made precise...

Proof. First observe that the rational map φ is also given by the formula

$$(a,b,c) \longmapsto (xc)^{-1}\big((xa)b\big)$$

for an arbitrary section $x \in X(S)$. Equivalently,

$$c^{-1}(ab) = (xc)^{-1}\big((xa)b\big)$$

whenever both sides are defined. We leave the verification to the reader.

We now show that φ is defined at a section $(a,b,c) \in X^3(S)$ if and only if there exists a d such that $(a,b) \sim (c,d)$, and that in this case

$$d = \varphi(a,b,c).$$

Suppose first that $(a,b) \sim (c,d)$. To verify that φ is defined, we may make an fppf-covering base change (Proposition 1.6), and may therefore suppose that there exists a section $x \in X(S')$ such that $(xa)b$ and $(xc)d$ are defined and equal. It follows from Rule 2 that

$$(xc)^{-1}\big((xa)b\big)$$

is defined and equal to d.

Conversely, suppose that φ is defined at (a,b,c), and put $d = \varphi(a,b,c)$. Choose an fppf covering $S' \to S$ and a section $x \in X(S')$ such that $(xa)b$ and $(xc)d$ are defined. We wish to show that they are equal. It is enough to show that the two rational self-maps of X over S, given by

$$b \longmapsto (xa)b \qquad \text{and} \qquad b \longmapsto (xc)\varphi(a,b,c),$$

are equal; this follows from the observation in the first paragraph. □

Proposition 3.5. *The equivalence relation*

$$R \rightrightarrows X^2$$

is representable, and it is a flat relation of finite presentation; that is, the projections of R onto X^2 are flat morphisms of finite presentation.

Proof. We may suppose that S is affine. Since (X,W) is of finite presentation over S, we may descend the entire situation to an S of finite type over $\operatorname{Spec}\mathbb{Z}$, hence to a noetherian S. We may therefore suppose that S is noetherian. It is then immediate that the graph Γ of 3.4 is of finite presentation over X^2. The projection $\mathrm{pr}_{12}|_\Gamma$ is flat because

$$\Gamma \xrightarrow{\sim} \mathrm{pr}_{123}\,\Gamma,$$

the latter being an open subset of X^3, and because the projection

$$\mathrm{pr}_{12}\colon X^3 \longrightarrow X^2$$

is flat, since X is flat over S.

I claim that Γ represents R. There is something to prove here, because the domain of definition of a rational map does not in general commute with base change. Let $S'' \to S$. What is clear from 3.4 applied over S'' is that

$$R(S'') \supseteq \Gamma(S''),$$

because $\varphi \times_S S''$ is certainly defined on $U \times_S S''$. Now let

$$(a, b, c, d) \in R(S'').$$

We must prove that $(a, b, c, d) \in \Gamma(S'')$. This can be checked locally, say for the étale topology. We may therefore suppose that S'' is strictly local, that is, the spectrum of a henselian ring with separably closed residue field. Moreover, by applying 1.6 and the usual passage-to-the-limit arguments, we are reduced to the case in which S is strictly local and $S'' \to S$ is local.

Suppose that there is a section $x \in X(S)$ such that over S'' the products $(xa)b$ and $(xc)d$ are defined. This implies that

$$(xc)^{-1}((xa)b)$$

is defined and equal to d. Now there is a relatively schematically dense open subset V of X^3 such that $(xc)^{-1}((xa)b)$ is defined if and only if $(a, b, c) \in V(S'')$, and $V \subseteq U$. Consequently, $(a, b, c, d) \in \Gamma(S'')$ if such an x exists. By 1.6, we may make an fppf-covering base change $S' \to S$ in order to find such an x. Since S is strictly local, we can find* a faithfully flat, local, finite morphism $S' \to S$ and a section $x \in X(S')$ that passes through an arbitrary closed point of the closed fiber of X/S. To say that $(xa)b$ and $(xc)d$ are defined means that, over S'', x lies in a certain relatively schematically dense open subset; this can be checked on the closed fiber of $X_{S''}$. Thus the required section exists. □

Let G now be the quotient of X^2 by R, as a sheaf for the fppf topology. We define a composition law on G as follows. Let

$$(g, g') \in G(S')$$

be represented by a section

$$((a, b), (c, d)) \in (X^2 \times_S X^2)(S''),$$

where $S'' \to S'$ is an fppf covering. Suppose moreover that there is a section $x \in X(S'')$ such that $a(b(cx))$ and $x^{-1}d$ are defined; this is permitted by Rule 1 and 1.7. We define gg' to be the class in $G(S')$ represented by the section

$$(a(b(cx)), x^{-1}d) \in X^2(S'').$$

Let us verify that gg' is independent of the choice of the section x and of the representative $((a, b), (c, d))$. Let

$$(a', b') \sim (a, b), \qquad (c', d') \sim (c, d),$$

and let x' be such that $a'(b'(c'x'))$ and ${x'}^{-1}d'$ are defined. We may suppose that all these are sections over S''. We must prove that

$$(a(b(cx)), x^{-1}d) \sim (a'(b'(c'x')), {x'}^{-1}d');$$

that is, for a suitable fppf covering $S''' \to S''$ and a suitable section $z \in X(S''')$, we must have

$$(z(a(b(cx))))(x^{-1}d) = (z(a'(b'(c'x'))))({x'}^{-1}d').$$

*Combining Exposé $\mathrm{VI_A}$, 1.1.1 and EGA $\mathrm{IV_4}$, 17.16.2.

Whenever all the products involved are defined,

$$\begin{aligned}(z(a(b(cx))))(x^{-1}d) &= ((za)(b(cx)))(x^{-1}d)\\ &= (((za)b)(cx))(x^{-1}d)\\ &= ((((za)b)c)x)(x^{-1}d)\\ &= (((za)b)c)(x(x^{-1}d))\\ &= (((za)b)c)d,\end{aligned}$$

and the same identities hold with primes. By Rule 1 and 1.7, such a z exists. It therefore remains to prove that

$$(((za)b)c)d = (((za')b')c')d'.$$

But $(za)b = (za')b'$, since $(a,b) \sim (a',b')$ by 3.3; the desired equality now follows from $(c,d) \sim (c',d')$.

Consider the natural morphism

$$i\colon X \longrightarrow G$$

defined as follows. For $a \in X(S')$, choose an fppf covering $S'' \to S'$ and a section $b \in X(S'')$ such that ab^{-1} is defined, and put

$$i(a) = \text{the class in } G \text{ of } (ab^{-1}, b).$$

It is readily verified that this class, which a priori lies in $G(S'')$, is independent of the choice of b, and therefore defines a well-determined element of $G(S')$.

The reader may enjoy verifying the following proposition.

Proposition 3.6. *The morphism i commutes with the composition laws on X and G. In other words, if $a, b \in X(S')$ are sections for which ab is defined, then*

$$i(a)i(b) = i(ab).$$

The goal of this section is the following theorem.

Theorem 3.7. [11] *Let (X, W) be a group germ over S, with X/S faithfully flat and of finite presentation, and with separated fibers having no embedded component. With the notation above:*

(i) *G is a sheaf of groups.*

(ii) *$i\colon X \to G$ is representable by an open immersion.*

(iii) *G is representable fppf-locally over S.*

(iv) *If G/S is representable, then it is a flat group of finite presentation, and $i\colon X \to G$ is schematically dense relative to S.*

Observe that G is plainly characterized by properties (i)–(iv); one may therefore forget its explicit construction.

The proof proceeds in several stages.

[11] Editor's note: If X is smooth and separated over S, faithfully flat and of finite presentation over S, then G/S is representable by a smooth S-group scheme of finite type over S. This is Theorem 6.6.1 of *Néron Models*, by Bosch–Lütkebohmert–Raynaud, Springer (1990).

Lemma 3.8.

(i) *Let c be a section of $X(S)$. Then the morphism from the prescheme $c \times X$, which is S-isomorphic to X, into G, given by*

$$c \times X \hookrightarrow X \times X \longrightarrow G,$$

is a monomorphism.

(ii) *Let $\{c_i\}_{i\in I}$ be sections of $X(S)$, put*

$$Z = \coprod_i c_i \times X,$$

and let $R' \rightrightarrows Z$ be the equivalence relation induced on Z by the evident morphism $Z \to X^2$. Then R' is a "gluing" of the $c_i \times X \simeq X$.

Proof. (i) For two sections (c, a) and (c, a') of $(c \times X)(S')$ to have the same image in G, one must have $(c, a) \sim (c, a')$; that is, for a suitable section $x \in X(S'')$, where $S'' \to S'$ is an fppf covering,

$$(xc)a = (xc)a'$$

. It follows from Rule 3 that $a = a'$.

(ii) Let c_i, c_j be two sections, and consider the birational self-map ψ_{ji} of X over S, given by

$$x \longmapsto c_j^{-1}(c_i x).$$

For $y \in X(S)$, this is the same map as

$$x \longmapsto (yc_j)^{-1}\big((yc_i)x\big),$$

as is readily seen. Moreover, ψ_{ji} is defined at a section $b \in X(S')$ if and only if there exists a section b' such that

$$(c_i, b) \sim (c_j, b'),$$

and then $b' = \psi_{ji}(b)$. Let U_{ji} be the domain of definition of ψ_{ji} over S. It remains to prove that this domain of definition is universal: if $b \in X(S'')$, for an arbitrary $S'' \to S$, and ψ_{ji} is defined at b, then $b \in U_{ji}(S'')$. Equivalently, one must prove that if $b, b' \in X(S'')$ satisfy

$$(c_i, b) \sim (c_j, b'),$$

then $b \in U_{ji}(S'')$. We leave to the reader the verification of this fact, which is analogous to that in 3.5. □

Lemma 3.9. *Suppose that $\{c_i\}_{i\in I}$ are sections of $X(S)$ such that*

$$\coprod_i c_i \times X \longrightarrow G$$

is surjective as a morphism of sheaves. Then G is representable, flat, and of finite presentation over S, and the structural morphism

$$X^2 \longrightarrow G$$

is flat and of finite presentation.

Proof. The representability of G is an immediate consequence of Lemma 3.8, and it follows that

$$\coprod_i c_i \times X \longrightarrow G$$

is an open covering. To prove that $X^2 \to G$ is flat, it is enough to do so locally, hence to prove that the rational map

$$X^2 \dashrightarrow c_i \times X$$

induces a flat morphism on its domain of definition. This rational map is given by

$$(a, b) \longmapsto (c_i, ((xc_i)^{-1}(xa))b),$$

where x is an arbitrary section. If it is defined at $(a, b) \in X^2(S')$, one can find an fppf covering $S'' \to S'$ and a section $x \in X(S'')$ such that $((xc_i)^{-1}(xa))b$ is defined. It is then readily seen that this morphism is flat. The same argument shows that it is locally of finite presentation, and hence is fppf-covering.

By construction the relation R is effective. Proposition 3.5 therefore shows that $X^2 \to G$ becomes a morphism of finite presentation after the fppf-covering base change $G \leftarrow X^2$. Thus $X^2 \to G$ is of finite presentation.

Let us prove that $G \to S$ is flat and of finite presentation. It is flat and locally of finite presentation because G is covered by the $c_i \times X \simeq X$. Moreover, X^2/S is quasi-compact and $X^2 \to G$ is surjective, so G/S is quasi-compact. To prove that $G \to S$ is quasi-separated, note the following cartesian diagram:

$$\begin{array}{ccc} R & \xrightarrow{\alpha} & X^2 \times_S X^2 \\ {\scriptstyle\gamma}\downarrow & & \downarrow{\scriptstyle\beta} \\ G & \xrightarrow{\Delta} & G \times_S G. \end{array}$$

Here γ is surjective and α, β are quasi-compact. Hence $\beta\alpha$ is quasi-compact, and therefore so is Δ.[10] □

Lemma 3.10. *Let $\{c_i\}_{i\in I}$ be sections of $X(S)$. For*

$$\coprod_i c_i \times X \longrightarrow G$$

to be surjective as a morphism of fppf sheaves, it is enough that the following condition hold: for every $S' \to S$ and every $(a, b) \in X^2(S')$, there exist an open covering $\{S'_\nu\}_{\nu\in N}$ of S' and a function

$$N \longrightarrow I, \qquad \nu \longmapsto i(\nu),$$

such that $(c_{i(\nu)}^{-1}a)b$ is defined over S'_ν.

Proof. Let $S'' \to S$ be arbitrary, and let $g \in G(S'')$. Choose an fppf covering $S' \to S''$ and a section $(a, b) \in X^2(S')$ representing g. Take the open covering $\{S'_\nu\}$ supplied by the hypothesis. Over each S'_ν one has

$$(a, b) \sim (c_{i(\nu)}, (c_{i(\nu)}^{-1}a)b).$$

Thus, locally over S'_ν, the element g is represented by a section of $c_{i(\nu)} \times X$. Since the family $\{S'_\nu \to S''\}$ is fppf-covering, the desired surjectivity follows. □

[10] Editor's note: Another way to conclude here is by faithfully flat descent (EGA IV$_2$, 2.7.1), since β is an fppf covering.

Lemma 3.11. *Let Y/S be a prescheme of finite presentation, and let $\{a_i\}_{i\in I}$ be sections of $Y(S)$. Let s_0, s_1 be points of S, with s_0 a specialization of s_1, and let Y_j be the fiber of Y/S at s_j. Let C_j be the closure in Y_j of the set of points $\{a_i(s_j)\}_{i\in I}$. Then*

$$\dim C_1 \geq \dim C_0.$$

Proof. It is enough to verify the assertion after a base change $S' \to S$ together with chosen points s_0', s_1' such that $s_j' \mapsto s_j$ and s_0' is a specialization of s_1'. By EGA II, 7.1.4, we are therefore reduced to the case in which S is the spectrum of a valuation ring A, s_0 is its closed point, and s_1 is its generic point.

Let V be the closure of C_1 in Y. Clearly $C_0 \subseteq V$. The lemma is consequently a special case of the "well-known" fact that an irreducible closed subprescheme V of a prescheme Y/S of finite presentation satisfies

$$\dim(V \times_S s_1) \geq \dim(V \times_S s_0)$$

when S is the spectrum of a valuation ring and $V \times_S s_1 \neq \varnothing$ (EGA IV, 13.1.6). □

Lemma 3.12. *Suppose that S is the spectrum of a local ring, with closed point s_0, and let $\{c_i\}_{i\in I}$ be sections such that the closure C_0, in the closed fiber X_0, of the set $\{c_i(s_0)\}_{i\in I}$ has dimension*

$$\dim C_0 = \dim X_0 = n.$$

Then the condition of Lemma 3.9 is satisfied.

Proof. First note that all the fibers of X/S have the same dimension. This follows from EGA IV, 12.1.1(i), and from the fact that X has a rational composition law. Lemma 3.11 therefore implies that, for every morphism $S_1 \to S$, with S_1 the spectrum of a field, the closure of $\{c_i \times_S S_1\}_{i\in I}$ in X_{S_1} has dimension n.

Let us verify the condition of Lemma 3.10. Let $(a, b) \in X^2(S')$. For $(c_i^{-1}a)b$ to be defined, it is necessary and sufficient that c_i lie in a certain open subset $U \subseteq X_{S'}$ that is schematically dense relative to S' (Rule 1). We must show that this holds for a suitable i, locally on S'. It is therefore enough to treat the case in which S' is the spectrum of a local ring; membership of c_i in $U(S')$ can then be checked on the closed fiber. We are thus reduced to $S' = \operatorname{Spec} k$, where k is a field.

With the notation above, take $S' = S_1$. Then

$$\dim C_1 = \dim X_{S_1},$$

and U is relatively schematically dense in X_{S_1}. Hence $U \cap C_1 \neq \varnothing$, and therefore

$$U \cap \{c_i \times_S S_1\}_{i\in I} \neq \varnothing.$$

This proves the assertion. □

Proof of Theorem 3.7. The proof is now easy. First note the following consequence of the finiteness assertion in Lemma 3.9. Let $\{A_i\}$ be a directed system of rings over S, put

$$\widetilde{A} = \varinjlim_i A_i,$$

and suppose that the hypotheses of Lemma 3.9 hold over $S = \operatorname{Spec} \widetilde{A}$. Then the object representing the quotient G of

$$R \rightrightarrows X^2$$

descends to some $S_i = \operatorname{Spec} A_i$, together with the finiteness and flatness properties stated in Lemma 3.9. This is the usual passage to the limit (EGA IV, 8 and 11).

It follows that, in proving Theorem 3.7(iii) and (iv), we may restrict ourselves to the case

$$S = \operatorname{Spec} A,$$

where A is a strictly local ring. Let x_0 be a closed point of the closed fiber X_0 of X/S. There exists* a local, finite, free extension A' of A, and a section of

$$X' = X \times_S S'$$

passing through the unique point x'_0 of X' lying over x_0. Notice that $X'_0 \to X_0$ is radicial because S is strictly local, and hence the residue field of A is separably closed.

It follows that there exists a directed system $\{A_i\}$ of local rings, flat and finite over A, such that, on putting

$$\widetilde{A} = \varinjlim_i A_i, \qquad \widetilde{X} = X \times_S \operatorname{Spec} \widetilde{A},$$

the prescheme $\widetilde{X}$ has a set of sections inducing a dense set on its closed fiber $\widetilde{X}_0$. Indeed, for each closed point x_0 of X_0, choose an extension $A(x_0)$ such that the corresponding base change of X admits a section "passing through x_0", and take for the directed system the finite tensor products of the $A(x_0)$. Notice that $\widetilde{A}$ is local, being a direct limit of local rings. Thus Lemmas 3.12 and 3.10 give the quotient G over $\operatorname{Spec} \widetilde{A}$, hence, by the preceding remarks, over one of the $\operatorname{Spec} A_i$, and therefore fppf-locally.

In fact, it follows from the constructions that fppf-locally one can find a finite set of sections $\{c_i\}$, $i = 1, \ldots, r$, such that G is covered by the $c_i \times X$. Assertions (ii) and (iv) follow easily from this fact, and we leave the verification of (i) to the reader.

Corollary 3.13. *The group sheaf G determined by a group germ (X, W) over S is representable in each of the following situations:*

(i) *S is Artinian.*

(ii) *For every local scheme $S' \to S$ at a closed point s of S, the scheme $X_{S'}$ has a set of sections whose restrictions to the closed fiber form a set with closure of dimension $\dim X_s$.*

(iii) *S is strictly local and X/S is smooth.*

(iv) *There exists an fppf covering $S' \to S$ such that $G_{S'}$ is representable and affine over S.*

Indeed, (ii) follows from Lemmas 3.10 and 3.12; (iii) follows directly from (ii) and Hensel's lemma; (iv) follows from descent for affine schemes; and (i) follows from descent for group schemes, which is possible here because every finite subset of a group over a field is known to be contained in an affine open subset (Exposé VI).

*Cf. the note at the foot of page 15 in Exposé VII.

EXPOSÉ XIX

REDUCTIVE GROUPS—GENERALITIES

by M. Demazure

The remainder of this Seminar is devoted to the study of reductive groups. Its principal aim is to generalize Chevalley's classical results (the *Bible* and *Tôhoku*)[1] to arbitrary base schemes. The two central results are the uniqueness theorem (Exposé XXIII, Theorem 4.1 and Corollaries 5.1–5.10) and the existence theorem (Exposé XXV, Theorem 1.1) for pinned reductive group schemes corresponding to prescribed root data. The proofs used here are inspired by Chevalley's; the language of schemes makes it possible to give them greater effectiveness.

The results of the first volume of the *Bible* (Exposés 1–13) will be used systematically. By contrast, we shall prove directly over an arbitrary scheme the results of the second volume (in particular the isomorphism theorem); knowledge of the proofs over an algebraically closed field is therefore not absolutely indispensable.

In proving these two fundamental results, we shall use only the most elementary results from the theory of groups of multiplicative type, found essentially in Exposés VIII and IX; on the other hand, we shall make essential use of the results of Exposé XVIII.[2] The reader interested specifically in the existence and uniqueness theorems may, on a first reading, skip Exposés X–XVII.

1. Review of groups over an algebraically closed field

1.1. Throughout this subsection, k will denote an algebraically closed field. As announced above, the only results from the *Bible* used below are contained in its first volume (Exposés 1–13).

All the results of the *Bible* (*loc. cit.*) concerning semisimple groups hold more generally for reductive groups (defined below), and their proofs are identical after the following harmless modifications:

- Exposé 9, §4, Definition 3: see 1.6.1 below;

[0] Editor's note: version of 13 October 2024.

[1] Editor's note: see the bibliographical references at the end of this Exposé. In particular, the 2005 re-edition of the Chevalley Seminar 1956–1958, cited as *Bible*, was revised by P. Cartier; see [Ch05].

[2] Editor's note: more precisely, Proposition XVIII 2.3 (extension of a "generic homomorphism" between groups) is used in XXII 4.1.11 and then in the proof of uniqueness in XXIII, as well as in XXIV. Theorem XVIII 3.7 (construction of a group from a group germ) is used only in XXV.

- Exposé 12, §4, Theorem 2(e): omit "finite";
- Exposé 13, §3, Theorem 2: replace "rank" by "semisimple rank";
- Exposé 13, §4, Corollary 2 to Theorem 3: replace "rank" by "reductive rank".

1.2. Let G be a smooth affine connected k-group. The *radical* of G (*Bible*, §9.4, Proposition 2)[3] is the reduced subgroup associated with the identity component of the intersection of the Borel subgroups of G; it is also the largest smooth connected solvable normal subgroup of G. We denote it by $\mathrm{rad}(G)$.

The *unipotent radical* of G is the unipotent part of the radical of G; it is also the largest smooth connected unipotent normal subgroup of G. We denote it by $\mathrm{rad}^u(G)$.

1.3. Let G be a smooth affine connected k-group, and let Q be a torus in G. Then the centralizer $\underline{\mathrm{Centr}}_G(Q)$ of Q in G is a closed subgroup of G (Exposé VIII, 6.7), smooth (Exposé XI, 2.4), and connected (cf. *Bible*, §6.6, Theorem 6(a), or [Ch05], §6.7, Theorem 7(a)).

We have the fundamental relation

$$\mathrm{rad}^u(\underline{\mathrm{Centr}}_G(Q)) = \mathrm{rad}^u(G) \cap \underline{\mathrm{Centr}}_G(Q). \tag{1.3.1}$$

First,[4]

$$U = \mathrm{rad}^u(G) \cap \underline{\mathrm{Centr}}_G(Q)$$

is a normal unipotent subgroup of $\underline{\mathrm{Centr}}_G(Q)$; let us show that it is smooth and connected. Let Q act on $\mathrm{rad}^u(G)$ by inner automorphisms. Then U is precisely the scheme of fixed points of this action. This scheme is smooth and connected by Lemma 1.4 below.

Consequently, U is a closed subgroup of $\mathrm{rad}^u(\underline{\mathrm{Centr}}_G(Q))$. On the other hand, by the *Bible*, Exposé 12, §3, Corollary to Theorem 1,

$$\mathrm{rad}^u(\underline{\mathrm{Centr}}_G(Q))(k) \subset \mathrm{rad}^u(G)(k).$$

Equality (1.3.1) follows.

Let us record one special case of the preceding result. If G is a smooth affine connected k-group and T is a maximal torus of G, then

$$\underline{\mathrm{Centr}}_G(T) = T \cdot (\underline{\mathrm{Centr}}_G(T) \cap \mathrm{rad}^u(G)). \tag{1.3.2}$$

Indeed (cf. *Bible*, §6.6, Theorem 6(c), or [Ch05], §6.7, Theorem 7(c)), $\underline{\mathrm{Centr}}_G(T)$ is solvable and hence is the semidirect product of its maximal torus T and its unipotent radical.

By the density theorem (cf. *Bible*, §6.5, Theorem 5(a), or [Ch05], §6.6, Theorem 6(a)), the union of $\underline{\mathrm{Centr}}_G(T)$, as T ranges over the maximal tori of G, contains a dense open subset of G. It therefore follows from (1.3.2) that:

Corollary 1.3.3.— *If G is a smooth affine connected k-group, then the union of $T \cdot \mathrm{rad}^u(G)$, where T ranges over the maximal tori of G, contains a dense open subset of G.*

Notation 1.4.0.—[5] *We shall systematically use the following notation. If S is a scheme and s is a point of S, then $\bar{s}$ denotes the spectrum of an algebraic closure $\overline{\kappa(s)}$ of $\kappa(s)$.*

Lemma 1.4.—[5] *Let S be a scheme and let Q be an S-torus acting on an S-group scheme H, separated and smooth over S.*

[3] Editor's note: the reference 9-06 (that is, Exposé 9, p. 6) has been replaced by §9.4 (that is, Exposé 9, §4), which applies both to the *Bible* and to [Ch05]. When the numbering in [Ch05] differs from that in the *Bible*, as happens in Exposé 6, both references will be given explicitly.

[4] Editor's note: the argument that follows has been expanded.

[5] Editor's note: this notation, which appeared in 2.3 of the original, has been inserted here; moreover, the statement and proof of 1.4 have been expanded.

(i) The fixed-point functor H^Q is representable by a closed subscheme of H, smooth over S.

(ii) If, moreover, H is affine over S and has connected fibers, then the same holds for H^Q.

Proof. First, by VIII 6.5(d),[6] since H is separated over S and Q is essentially free over S, H^Q is representable by a closed subscheme of H. In particular, if H is affine over S, then so is H^Q.

Now consider the semidirect product $G = H \cdot Q$; it is smooth and separated over S. The centralizer $\underline{\mathrm{Centr}}_G(Q)$ is then representable by a closed subscheme of G, of finite presentation over G, by Exposé XI 6.11(a),[6] and it is smooth over S by Exposé XI 2.4.

Since

$$\underline{\mathrm{Centr}}_G(Q) = H^Q \cdot Q,$$

it follows that H^Q is smooth over S. Indeed, using the section

$$\sigma : H^Q \longrightarrow \underline{\mathrm{Centr}}_G(Q)$$

deduced from the identity section ϵ_Q of Q, one sees at once that H^Q is formally smooth over S; and since ϵ_Q is of finite presentation, H^Q is locally of finite presentation over S. This proves (i).

Finally, suppose that H is affine over S and has connected fibers. Then every geometric fiber $G_{\bar{s}}$ of G is a smooth affine connected $\kappa(\bar{s})$-group. Hence, by the first assertion of 1.3, the group

$$\underline{\mathrm{Centr}}_{G_{\bar{s}}}(Q_{\bar{s}}) = \left(\underline{\mathrm{Centr}}_G(Q)\right)_{\bar{s}} = (H^Q)_{\bar{s}} \cdot Q_{\bar{s}}$$

is also connected, and this implies that $(H^Q)_{\bar{s}}$ is connected. □

1.5. Recall that the *reductive rank* of a smooth affine k-group G is the common dimension of its maximal tori. We denote it by $\mathrm{rgred}(G/k)$ or $\mathrm{rgred}(G)$. The equality $\mathrm{rgred}(G/k) = 0$ holds if and only if G is unipotent (that is, $G = \mathrm{rad}^u(G)$), by the *Bible*, §6.4, Corollary 1 to Theorem 4, or [Ch05], §6.5, Corollary 1 to Theorem 5.

If H is a normal subgroup of the smooth affine k-group G, then the quotient G/H is affine and smooth (Exposé $\mathrm{VI_B}$, 11.17 and $\mathrm{VI_A}$, 3.3.2(iii)). Moreover (*Bible*, §7.3, Theorem 3(a),(c)),

$$\mathrm{rgred}(G) = \mathrm{rgred}(G/H) + \mathrm{rgred}(H).$$

Definition 1.6.1.—[7] *A k-group G is said to be* reductive *if it is smooth, affine, and connected, and if* $\mathrm{rad}(G)$ *is a torus; that is, if*

$$\mathrm{rad}^u(G) = \{e\}.$$

Lemma 1.6.2.— *Let G be a reductive k-group.*

(i) If Q is a torus of G, then $\underline{\mathrm{Centr}}_G(Q)$ is reductive.

(ii) In particular, if T is a maximal torus of G, then $\underline{\mathrm{Centr}}_G(T) = T$.

[6] Editor's note: see also the additions made in $\mathrm{VI_B}$, 6.2.4(d) and 6.5.5(a).

[7] Editor's note: the former number 1.6 has been replaced by numbers 1.6.1 through 1.6.3. Note that in this Seminar every reductive k-group (respectively, every semisimple k-group; cf. 1.8) is connected by definition.

(iii) The center of G is contained in every maximal torus and is therefore diagonalizable.

(iv) The radical of G is the unique maximal torus of $\underline{\mathrm{Centr}}(G)$.

Proof. Indeed, (i) follows from (1.3.1), (ii) from (1.3.2), and (iii) follows from (ii). Finally, the maximal torus of $\underline{\mathrm{Centr}}(G)$, that is, the neutral component $\underline{\mathrm{Centr}}(G)^0$, is a smooth connected solvable subgroup normal in G, and hence is contained in $\mathrm{rad}(G)$. Conversely, $\mathrm{rad}(G)$ is a torus normal in G, and hence central (*Bible*, §4.3, Corollary to Proposition 2); this proves (iv). □

Remark 1.6.3.— *If G is reductive and* $\dim(G) \neq \mathrm{rgred}(G)$*, then*

$$\dim(G) - \mathrm{rgred}(G) \geq 2.$$

Indeed, this difference is always even (cf. 1.10 below).

1.7. Let G be a smooth affine connected k-group, and let H be a smooth connected normal subgroup. Then

$$\mathrm{rad}(H) = \big(\mathrm{rad}(G) \cap H\big)^0_{\mathrm{red}}, \qquad \mathrm{rad}^u(H) = \big(\mathrm{rad}^u(G) \cap H\big)^0_{\mathrm{red}}, \tag{1.7.1}$$

as is seen immediately. In particular, if G is reductive, then so is H.

Let $f : G \longrightarrow G'$ be a surjective morphism of smooth affine connected k-groups. Then

$$f\big(\mathrm{rad}^u(G)\big) = \mathrm{rad}^u(G'). \tag{1.7.2}$$

In particular, if G is reductive, then so is G'.

Let us prove (1.7.2). First, $f\big(\mathrm{rad}^u(G)\big)$ is contained in $\mathrm{rad}^u(G')$. On introducing

$$H = \big(f^{-1}(\mathrm{rad}^u(G'))\big)^0_{\mathrm{red}},$$

which contains $\mathrm{rad}^u(G)$, we have $\mathrm{rad}^u(H) = \mathrm{rad}^u(G)$; thus we are reduced to the case $G = H$, that is, to the case in which G' is unipotent. As T runs over the maximal tori of G, the union of the groups $T\,\mathrm{rad}^u(G)$ is dense in G. Hence the union of the groups $f(T)\,f\big(\mathrm{rad}^u(G)\big)$ is dense in G'. But $f(T)$ consists of semisimple elements, so $f(T) = \{e\}$, since G' is unipotent. It follows that $f\big(\mathrm{rad}^u(G)\big)$ is dense in G'. Therefore, by *Bible*, §5.4, Lemma 4, or [Ch05], §6.1, Lemma 1,[8] $f\big(\mathrm{rad}^u(G)\big)$ is an open subgroup of G'. Since G' is connected, it follows that

$$f\big(\mathrm{rad}^u(G)\big) = G'.$$

N.B. Under the same hypotheses one can prove that

$$f\big(\mathrm{rad}(G)\big) = \mathrm{rad}(G').$$

1.8. A k-group G is said to be *semisimple* if it is smooth, affine, and connected, and if

$$\mathrm{rad}(G) = \{e\},$$

that is, if G is reductive and $\underline{\mathrm{Centr}}(G)$ is finite. If G is an arbitrary smooth affine connected k-group, then $G/\mathrm{rad}(G)$ is semisimple (*Bible*, §9.4, Proposition 2), and $G/\mathrm{rad}^u(G)$ is reductive. The *semisimple rank of G*, denoted by $\mathrm{rgss}(G/k)$, or simply by $\mathrm{rgss}(G)$, is the reductive rank of $G/\mathrm{rad}(G)$.

[8] Editor's note: the following argument has been supplied in detail.

Thus, if G is reductive,

$$\operatorname{rgred}(G) = \operatorname{rgss}(G) + \dim\bigl(\operatorname{rad}(G)\bigr).$$

If G is a smooth affine connected k-group and Q is a central subtorus of G, then G/Q is semisimple if and only if G is reductive and $Q = \operatorname{rad}(G)$. Indeed, if G/Q is semisimple, then $Q \supset \operatorname{rad}(G)$; hence $\operatorname{rad}(G)$ is a torus, so G is reductive, and $\operatorname{rad}(G)$ is the maximal torus of $\underline{\operatorname{Centr}}(G)$, whence $\operatorname{rad}(G) = Q$. If G is reductive and Q is a central subgroup, then G/Q is reductive and

$$\operatorname{rgss}(G) = \operatorname{rgss}(G/Q).$$

1.9. Let K be an algebraically closed extension of k, and let G be a smooth affine connected k-group. Then G is reductive (respectively, semisimple) if and only if G_K is, and

$$\operatorname{rgred}(G/k) = \operatorname{rgred}(G_K/K), \qquad \operatorname{rgss}(G/k) = \operatorname{rgss}(G_K/K).$$

1.10. Let G be a smooth connected k-group and let T be a torus of G.[9] Write $\mathfrak{g}$ for the k-Lie algebra of G, that is, $\mathfrak{g} = \operatorname{Lie}(G) = \operatorname{Lie}(G/k)(k)$, and similarly write $\mathfrak{t} = \operatorname{Lie}(T)$. Under the action of T, through $T \longrightarrow G$ and the adjoint representation of G, the Lie algebra $\mathfrak{g}$ decomposes as

$$\mathfrak{g} = \mathfrak{g}^0 \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha, \tag{1.10.1}$$

where the elements $\alpha \in R$ are nontrivial characters of T and the spaces $\mathfrak{g}^\alpha$ are nonzero. The characters $\alpha \in R$ are called the *roots of G relative to T*. By Exposé II, 5.2.3(i),

$$\mathfrak{g}^0 = \operatorname{Lie}\bigl(\underline{\operatorname{Centr}}_G(T)\bigr). \tag{1.10.2}$$

In particular,[10] since $\underline{\operatorname{Centr}}_G(T)$ is connected (by 1.3 when G is affine, and by Exposé XII, 6.6(b), in general), T is its own centralizer if and only if $\mathfrak{g}^0 = \operatorname{Lie}(T)$. This condition implies that T is maximal and that $\underline{\operatorname{Centr}}(G) \subset T$; hence, by Exposé XII, 8.8(d),

$$\underline{\operatorname{Centr}}(G) = \operatorname{Ker}(T \longrightarrow \operatorname{GL}(\mathfrak{g})) = \bigcap_{\alpha \in R} \operatorname{Ker}(\alpha). \tag{1.10.3}$$

Moreover, $\underline{\operatorname{Centr}}(G)$ is then affine, and therefore the morphism $G \longrightarrow G/\underline{\operatorname{Centr}}(G)$ is affine. Since the latter group is affine (Exposé XII, 6.1),[11] G is affine.

When G is reductive and T is maximal, the roots in the preceding sense coincide with the roots in the sense of *Bible*, §12.2, Definition 1. The latter are indeed roots in the sense of this number (*Bible*, §13.2, Theorem 1(c)), and their number is $\dim(G) - \dim(T)$ (*Bible*, §13.4, Corollary 2 to Theorem 3). Moreover, if α is a root, then so is $-\alpha$ (*Bible*, §12.2, Corollary to Proposition 1). As usual, we write the group law of $\operatorname{Hom}_{k\text{-gr}}(T, \mathbb{G}_{m,k})$ indifferently additively or multiplicatively. It follows that, for reductive G,

$$\dim(G) - \operatorname{rgred}(G) = \operatorname{Card}(R) \tag{1.10.4}$$

is always even.

[9] Editor's note: the following sentence has been added.
[10] Editor's note: the following argument has been given in detail.
[11] Editor's note: see also Addition $\mathrm{VI_B}$, 6.2.6.

The semisimple rank of the reductive group G is the rank of the subset R of the $\mathbb{Q}$-vector space

$$\mathrm{Hom}_{k\text{-gr}}(T, \mathbb{G}_{m,k}) \otimes_{\mathbb{Z}} \mathbb{Q}$$

(*Bible*, §13.3, Theorem 2).

Lemma 1.11.— *Let k be an algebraically closed field, G a smooth affine connected k-group, and T a torus of G. Put*

$$W(T) = \underline{\mathrm{Norm}}_G(T)/\underline{\mathrm{Centr}}_G(T),$$

the Weyl group of G relative to T. The following conditions are equivalent:

(i) *G is reductive, T is maximal, and* $\mathrm{rgss}(G) = 1$.

(ii) *G is reductive, T is maximal, and $G \neq T$; there exists a subtorus Q of T, of codimension 1 in T, that is central in G.*

(iii) *G is not solvable and* $\dim(G) - \dim(T) \leq 2$.

(iv) *$W(T) \neq \{e\}$ and* $\dim(G) - \dim(T) \leq 2$.

(v) *$W(T) = (\mathbb{Z}/2\mathbb{Z})_k$ and* $\dim(G) - \dim(T) = 2$.

Moreover, under these conditions there are exactly two roots of G relative to T, and they are opposite. Under the conditions of (ii), *$Q = \mathrm{rad}(G)$.*

Proof. The implication (v)⇒(iv) is clear, and (iv)⇒(iii) follows from *Bible*, §6.1, Corollary 3 to Theorem 1, or [Ch05], §6.2, Corollary 3 to Theorem 2.

Let us prove (iii)⇒(ii). Let U be the unipotent radical of G. The group G/U is reductive and is not a torus (otherwise G would be solvable); hence, by (1.10.4),

$$\dim(G/U) - \mathrm{rgred}(G/U) = \mathrm{Card}(R) \geq 2.$$

On the other hand,

$$\mathrm{rgred}(G) = \mathrm{rgred}(G/U) + \mathrm{rgred}(U) = \mathrm{rgred}(G/U),$$

and therefore

$$\begin{aligned}\dim(G) - \dim(U) - \mathrm{rgred}(G) &= \dim(G/U) - \mathrm{rgred}(G/U)\\ &\geq 2 \geq \dim(G) - \dim(T) \geq \dim(G) - \mathrm{rgred}(G).\end{aligned}$$

It follows that $\dim(U) = 0$, so G is reductive, and that $\mathrm{rgred}(G) = \dim(T)$; thus T is maximal and $\dim(G) - \dim(T) = 2$. By *Bible*, §10.4, Proposition 8, there exists a singular torus Q of codimension 1 in T. Then $\underline{\mathrm{Centr}}_G(Q)$ is reductive (1.6.2(i)) and not solvable (by the definition of a singular torus), and hence

$$\dim(\underline{\mathrm{Centr}}_G(Q)) - \mathrm{rgred}(G) \geq 2.$$

This proves that $G = \underline{\mathrm{Centr}}_G(Q)$, and that Q is central in G.

Let us prove (ii)⇒(i). We know that G/Q is reductive by 1.7 and that $\mathrm{rgred}(G/Q) = 1$; hence $\mathrm{rgss}(G/Q)$ is either 0 or 1. The first case is impossible, since it would imply $\mathrm{rgss}(G) = 0$, and therefore $G = T$. Thus

$$\mathrm{rgred}(G/Q) = \mathrm{rgss}(G/Q) = 1,$$

which proves that G/Q is semisimple. Consequently Q is the radical of G and $\mathrm{rgss}(G) = 1$. Let us finally prove (i)⇒(v). If Q is the radical of G, then $\dim(T) - \dim(Q) = 1$, and Q is central in G. Hence $G = \underline{\mathrm{Centr}}_G(Q)$, which proves that Q is a singular torus. By *Bible*, §11.3, Theorem 2,

$$W_G(T) = (\mathbb{Z}/2\mathbb{Z})_k,$$

and, by *Bible*, §12.1, Lemma 1, $\dim(G) - \dim(T) = 2$. Thus G has at most two roots relative to T, while it has at least two, opposite to one another, by 1.10.

Proposition 1.12.— *Let k be an algebraically closed field, G a smooth connected k-group, T a torus of G, and R the set of roots of G relative to T. Write*

$$\mathfrak{g} = \mathfrak{g}^0 \oplus \bigoplus_{\alpha\in R} \mathfrak{g}^\alpha, \qquad \mathfrak{g}^\alpha \neq 0,$$

for the decomposition of $\mathfrak{g}$ under $\mathrm{Ad}(T)$. For every $\alpha \in R$, put

$$T_\alpha = \mathrm{Ker}(\alpha)^0, \qquad Z_\alpha = \underline{\mathrm{Centr}}_G(T_\alpha).$$

[12] *The following conditions are equivalent:*

(i) G is affine and reductive, and T is maximal.

(ii) $\mathfrak{g}^0 = \mathfrak{t}$, and every Z_α, for $\alpha \in R$, is reductive.

(iii) $\mathfrak{g}^0 = \mathfrak{t}$; every $\mathfrak{g}^\alpha$, for $\alpha \in R$, has dimension 1; if $\alpha, \beta \in R$ and $\beta = q\alpha$ for some $q \in \mathbb{Q}$, then $q = \pm 1$; and, for every $\alpha \in R$, there exists $w_\alpha \in G(k)$ which normalizes T, centralizes T_α, but does not centralize T.

Moreover, under these conditions every Z_α has semisimple rank 1, and

$$\mathrm{Lie}(Z_\alpha) = \mathfrak{t} \oplus \mathfrak{g}^\alpha \oplus \mathfrak{g}^{-\alpha}.$$

Proof. Suppose first that G is affine and reductive and that T is maximal. Every Z_α is then affine and reductive by 1.6.2(i), with maximal torus T; furthermore, T is its own centralizer by 1.6.2(ii). Thus $\mathfrak{g}^0 = \mathfrak{t}$, proving (i)⇒(ii).

Conversely, the equality $\mathfrak{g}^0 = \mathfrak{t}$ implies that T is maximal and that G is affine, by 1.10. Hence every Z_α is affine, smooth, and connected, by 1.3. In all cases, Exposé II, 5.2.2 gives

$$\mathrm{Lie}(Z_\alpha) = \mathfrak{g}^{T_\alpha} = \mathfrak{g}^0 \oplus \bigoplus_{\beta\in R\cap\mathbb{Q}\alpha} \mathfrak{g}^\beta.$$

Consequently,

$$\mathrm{Lie}(Z_\alpha) \supset \mathfrak{t} \oplus \mathfrak{g}^\alpha \oplus \mathfrak{g}^{-\alpha},$$

so $Z_\alpha \neq T$. Since T_α is a central subtorus of Z_α, of codimension 1 in T, Lemma 1.11 applied to Z_α proves the equivalence of (ii) and (iii), together with the additional assertions.

It remains to prove (ii)⇒(i). We already know that (ii) implies that T is maximal and that G is affine. Let U be the unipotent radical of G. It is invariant in G, and its Lie algebra is invariant under $\mathrm{Ad}(T)$; hence

$$\mathrm{Lie}(U) = \big(\mathrm{Lie}(U) \cap \mathfrak{g}^0\big) \oplus \bigoplus_{\alpha\in R} \big(\mathrm{Lie}(U) \cap \mathfrak{g}^\alpha\big).$$

[12] Editor's note: thus T_α is the identity component of $\mathrm{Ker}(\alpha)$.

By (1.3.1),

$$U \cap T = U \cap \underline{\mathrm{Centr}}_G(T) = \mathrm{rad}^u\big(\underline{\mathrm{Centr}}_G(T)\big) = \mathrm{rad}^u(T) = \{e\},$$
$$U \cap Z_\alpha = U \cap \underline{\mathrm{Centr}}_G(T_\alpha) = \mathrm{rad}^u\big(\underline{\mathrm{Centr}}_G(T_\alpha)\big) = \mathrm{rad}^u(Z_\alpha) = \{e\}.$$

It follows[13] that

$$\mathrm{Lie}(U) \cap \mathfrak{g}^0 = \mathrm{Lie}(U) \cap \mathfrak{t} = \mathrm{Lie}(U \cap T) = 0,$$
$$\mathrm{Lie}(U) \cap \mathfrak{g}^\alpha \subset \mathrm{Lie}(U) \cap \mathrm{Lie}(Z_\alpha) = \mathrm{Lie}(U \cap Z_\alpha) = 0.$$

Thus $\mathrm{Lie}(U) = 0$, and therefore $U = \{e\}$; in other words, G is reductive.

Corollary 1.13.— *Let k, G, T, R, and*

$$\mathfrak{g} = \mathfrak{g}^0 \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha$$

be as in Proposition 1.12. For every $\alpha \in R$, let T_α be the maximal torus of $\mathrm{Ker}(\alpha)$ and put $Z_\alpha = \underline{\mathrm{Centr}}_G(T_\alpha)$. The following conditions are equivalent:

(i) G is affine and semisimple, and T is maximal.

(ii) $\mathfrak{g}^0 = \mathfrak{t}$, every Z_α is reductive, and $\bigcap_{\alpha \in R} \mathrm{Ker}(\alpha)$ is finite.

[14]

2. Reductive group schemes: definitions and first properties

Scholium 2.1.— *For an S-group scheme G, the following properties are equivalent:*

(i) G is affine and smooth over S, with connected fibers.

(ii) G is affine and flat over S, of finite presentation over S, with geometrically integral fibers.

These properties are stable under base change and are local for the fpqc topology.

[15] Indeed, suppose that (i) holds. Since G is affine and smooth over S, it is of finite presentation over S; and since its fibers are smooth and connected, they are geometrically integral, by Exposé $\mathrm{VI_A}$, 2.4.

Conversely, if (ii) holds, the fibers of G are connected and geometrically reduced, and hence smooth (Exposé $\mathrm{VI_A}$, 1.3.1). It follows that G is smooth over S, by EGA IV_4, 17.5.2.

These properties are plainly stable under base change: see EGA II, 1.5.1 for "affine", EGA IV_1, 1.6.2(iii) for "of finite presentation", EGA IV_2, 2.1.4 for "flat", and EGA IV_2, 4.6.5(i) for "with geometrically integral fibers".

They are also clearly local for the Zariski topology. It is therefore enough to check that, if $S' \longrightarrow S$ is faithfully flat and quasi-compact and $G_{S'} \longrightarrow S'$ has the indicated properties, then so does $G \longrightarrow S$. This follows from EGA IV_2, 2.5.1 for "flat", 2.7.1(vi) and (xiii) for "of finite presentation" and "affine", and 4.6.5(i) for "with geometrically integral fibers"; for "smooth", see also EGA IV_4, 17.7.3(ii).

[13] Editor's note: if U and L are two subgroup schemes of G, then $\mathrm{Lie}(U) \cap \mathrm{Lie}(L) = \mathrm{Lie}(U \cap L)$.

[14] Editor's note: this follows from the equalities $\mathrm{rad}(G) = \underline{\mathrm{Centr}}(G)^0$ and $\underline{\mathrm{Centr}}(G) = \bigcap_{\alpha \in R} \mathrm{Ker}(\alpha)$, established in 1.6.2(iv) and (1.10.3).

[15] Editor's note: the following details have been added.

2.2. Let G be an S-group scheme satisfying the preceding conditions, and let Q be a torus of G in the sense of Exposé IX, Definition 1.3.[16] By Exposé XI, 6.11(a) and 2.4, $\underline{\mathrm{Centr}}_G(Q)$ is represented by a closed subgroup scheme of G; it is therefore affine over S, and it is of finite presentation and smooth over S. Moreover, every geometric fiber $G_{\bar{s}}$ is a smooth affine connected $\kappa(\bar{s})$-group. The first assertion of 1.3 therefore shows that the same is true of

$$\underline{\mathrm{Centr}}_{G_{\bar{s}}}(Q_{\bar{s}}) = \left(\underline{\mathrm{Centr}}_G(Q)\right)_{\bar{s}}.$$

Lemma 2.3.— *Let S be a scheme, let G be an S-group scheme that is smooth and affine over S, with connected fibers, and let T be a torus of G. The set of points $s \in S$ for which $G_{\bar{s}}$ is reductive, of semisimple rank* 1*, with maximal torus $T_{\bar{s}}$, is an open subset U of S.*

Proof. Since G and T are flat over S, the function

$$s \longmapsto \dim(G_{\bar{s}}/\bar{s}) - \dim(T_{\bar{s}}/\bar{s})$$

is locally constant. Let U_1 be the open subset of S on which this function has the value 2.

[17] By 6.3 the Weyl group

$$W_G(T) = \underline{\mathrm{Norm}}_G(T)/\underline{\mathrm{Centr}}_G(T)$$

is represented by an S-group scheme that is étale and separated over S, and the function

$$s \longmapsto \text{the number of points of } W_G(T)_{\bar{s}}$$

is lower semicontinuous. Let U_2 be the locus on which this number is greater than 1; it is open. By Lemma 1.11, the locus on which $G_{\bar{s}}$ is reductive, of semisimple rank 1, with maximal torus $T_{\bar{s}}$, is

$$U = U_1 \cap U_2.$$

Furthermore, $W_G(T)_{\bar{s}}$ has exactly two points for every $s \in U$. Consequently, by SGA 1, I, 10.9 and EGA IV_3, 15.5.1 and IV_4, 18.12.4, $W_G(T)_U$ is finite and étale over U.

Remark 2.4.— *The group $W_G(T)_U$ is isomorphic to $(\mathbb{Z}/2\mathbb{Z})_U$.*

Indeed, the preceding argument shows that it is finite and étale over U. Since the automorphism functor of $(\mathbb{Z}/2\mathbb{Z})_U$ is the trivial group, it is enough to verify the assertion locally. It is immediate whenever the algebra $\mathscr{A}$ defining $W_G(T)_U$ is a free $\mathcal{O}_U$-module.[18]

Notations and reminders 2.5.0.—[19] Let S be a scheme, let G be an S-group scheme, and let $\epsilon\colon S \to G$ be the unit section of G. We saw in II, §4.11 that the functor $\underline{\mathrm{Lie}}(G/S)$ is represented by the vector bundle $\mathbb{V}(\omega^1_{G/S})$, where $\omega^1_{G/S} = \epsilon^*(\Omega^1_{G/S})$, and we write

$$\mathfrak{g} = \mathrm{Lie}(G/S) = \left(\omega^1_{G/S}\right)^\vee$$

[16] Editor's note: the following argument has been given in detail.

[17] Editor's note: the following details have been added. Note also that §6 is independent of the rest of this Exposé.

[18] Editor's note: the hypothesis implies that $\mathscr{A}$ is locally free of rank 2. Since the augmentation ideal $\mathscr{I}$ is a direct summand of $\mathscr{A}$, after replacing U by a sufficiently small affine open $\mathrm{Spec}(R)$, one may suppose that $I = \Gamma(U, \mathscr{I})$ is a free R-module of rank 1. If x is a generator of I, then $x^2 = ax$ for some $a \in R$; the assumption that $A = \Gamma(U, \mathscr{A})$ is étale implies that a is invertible, which gives the asserted local identification.

[19] Editor's note: this paragraph of notations and reminders has been added.

for the sheaf of sections of this vector bundle. Suppose in addition that G is smooth over S. Then $\omega^1_{G/S}$, and hence $\mathrm{Lie}(G/S)$, are finite locally free $\mathcal{O}_S$-modules, and (cf. I, 4.6.5.1)

$$\underline{\mathrm{Lie}}(G/S) = \mathbb{W}(\mathrm{Lie}(G/S));$$

that is, for every S-scheme S',

$$\underline{\mathrm{Lie}}(G/S)(S') = \Gamma\big(S', \mathrm{Lie}(G/S) \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}\big)\,.$$

By II, 4.1.1.1, the adjoint action of G gives $\underline{\mathrm{Lie}}(G/S) = \mathbb{W}(\mathrm{Lie}(G/S))$ the structure of a G-$\mathcal{O}_S$-module; thus $\mathrm{Lie}(G/S)$ is a G-$\mathcal{O}_S$-module (cf. I, 4.7.1). If G is moreover affine over S, this says, by I, 4.7.2, that $\mathrm{Lie}(G/S)$ is an $A(G)$-comodule.

If T is a torus over S (IX, Definition 1.3), we say that T is *split* ("trivial" in the original) if it is isomorphic to $\mathbb{G}^r_{m,S}$ for some integer $r \geq 0$, and that T is *trivialized* if such an isomorphism has been fixed, or more generally if an isomorphism

$$T \simeq D_S(M)$$

has been fixed, where M is a free abelian group of rank r.

Finally, recall (XII, Definition 1.3) that a torus T of G is called *maximal* if, for every $s \in S$, $T_{\bar{s}}$ is a maximal torus of $G_{\bar{s}}$.

Theorem 2.5.— *Let S be a scheme, let G be an S-group scheme that is affine and of finite presentation over S, with connected fibers, and let s_0 be a point of S. Suppose that G is flat over S at $\epsilon(s_0)$, and that the geometric fiber $G_{\bar{s}_0}$ is (reduced and) reductive* (resp. semisimple)*. Then there exist an open subset $U \subset S$, containing s_0, and an étale surjective morphism $S' \to U$ such that:*

(i) G_U is smooth, with reductive (resp. semisimple) *geometric fibers, and its reductive rank and semisimple rank are constant.*

(ii) $G_{S'}$ has a split[20] *maximal torus T, and the Weyl group* (cf. 6.3)

$$W_{G_{S'}}(T) = \underline{\mathrm{Norm}}_{G_{S'}}(T)/\underline{\mathrm{Centr}}_{G_{S'}}(T) = \underline{\mathrm{Norm}}_{G_{S'}}(T)/T$$

is finite over S'.

Proof. [21] Write $\pi\colon G \to S$ for the structure morphism and $\epsilon\colon S \to G$ for the unit section. Since G is flat over S at $\epsilon(s_0)$, and since $G_{\bar{s}_0}$ is reduced (hence smooth over $\bar{s}_0$, by $\mathrm{VI_A}$, 1.3.1), G is smooth over S at $\epsilon(s_0)$ (EGA IV_4, 17.5.1). Thus there is an open neighborhood V of $\epsilon(s_0)$ on which π is smooth. Then $S' = \epsilon^{-1}(V)$ is open in S, and $G_{S'}$ is smooth over S' at the points of $\epsilon(S')$. Since G has connected fibers, $\mathrm{VI_B}$, 3.10 shows that $G_{S'}$ is smooth over S'. Replacing S by S', we may therefore suppose that G is smooth over S.

By Exposé XI, Theorem 4.1, the functor of subgroups of multiplicative type of G is represented by an S-scheme $\mathscr{M}$, smooth and separated over S. Let r_0 be the rank of $G_{\bar{s}_0}$, and consider the open subscheme $\mathscr{M}_{r_0} \subset \mathscr{M}$ representing the functor of subtori of rank r_0 of G (IX, 1.4). Smoothness implies that $\mathscr{M}_{r_0}$ has a rational point over a finite separable extension of $\kappa(s_0)$ (EGA IV_4, 17.15.10(iii)). Consequently there is an étale morphism $S' \to S$, together with a point s'_0 above s_0, such that $G_{s'_0}$ has a torus of rank r_0. Replacing S by S', we may therefore suppose that G_{s_0} has a torus of rank r_0.

[20] Editor's note: the word "split" has been added.

[21] Editor's note: the proof has been expanded.

By "Hensel's lemma" (XI, 1.10), the smoothness of $\mathscr{M}_{r_0}$ allows this torus to be lifted to an S'-torus T of G, where $S' \to S$ is étale and is equipped with a point s'_0 above s_0. By Exposé X, 4.5 (see also 6.1[22]), there is an étale morphism $f\colon S'' \to S'$ that splits T and for which $f^{-1}(s'_0) \neq \varnothing$. Because an étale morphism is open, and the assertions in (i) are local for the étale topology, we may thus suppose that G has a split torus T,[23] maximal at s_0. Write $T = D_S(M)$, and let

$$\mathfrak{g} = \coprod_{m\in M} \mathfrak{g}^m$$

be the decomposition of $\mathfrak{g} = \mathrm{Lie}(G/S)$ under $\mathrm{Ad}(T)$ (Exposé I, 4.7.3).

Put $\mathfrak{t} = \mathrm{Lie}(T)$, and, for every $m \in M$, write

$$\mathfrak{g}^m(s_0) = \mathfrak{g}^m \otimes_{\mathcal{O}_S} \kappa(s_0).$$

[24] Let R be the set of $m \in M$, $m \neq 0$, such that $\mathfrak{g}^m(s_0) \neq 0$.[25] Since $G_{\bar{s}_0}$ is reductive, $\mathfrak{g}^0(s_0) = \mathfrak{t}(s_0)$, and hence

$$\mathfrak{g}(s_0) = \mathfrak{t}(s_0) \oplus \coprod_{\alpha\in R} \mathfrak{g}^\alpha(s_0).$$

Since the modules in question are locally free, after shrinking S we may suppose that the $\mathfrak{g}^\alpha$ are free and that

$$\mathfrak{g} = \mathfrak{t} \oplus \coprod_{\alpha\in R} \mathfrak{g}^\alpha.$$

Recall from Exposé XII, 1.12 that a group of multiplicative type has a unique maximal torus (this also follows almost immediately by descent, the diagonalizable case being evident). Let T_α be the maximal torus of $\ker(\alpha)$, and put

$$Z_\alpha = \underline{\mathrm{Centr}}_G(T_\alpha).$$

[26] By 2.2, Z_α is affine and smooth over S, with connected fibers; and by 1.12, its fiber $(Z_\alpha)_{\bar{s}_0}$ is reductive, of semisimple rank 1, with maximal torus $T_{\bar{s}_0}$. By 2.3 there is therefore an open subset $U_\alpha \subset S$, containing s_0, on which Z_α has reductive fibers.

Set

$$U = \bigcap_{\alpha\in R} U_\alpha.$$

By 1.12, for every $s \in U$, $G_{\bar{s}}$ is reductive, with maximal torus $T_{\bar{s}}$, and the set of roots of $G_{\bar{s}}$ relative to $T_{\bar{s}}$ is identified with R. Consequently

$$\mathrm{rgred}(G_{\bar{s}}) = \dim(T) = \mathrm{rg}(M), \qquad \mathrm{rgss}(G_{\bar{s}}) = \mathrm{rg}(R) \quad \text{(cf. 1.10)}.$$

This proves (i) and the first assertion of (ii). It remains to prove that $W_{G_U}(T_U)$ is finite over U, that is, that it has the same number of points in every geometric fiber (SGA 1, I, 10.9; EGA IV$_3$, 15.5.1; and EGA IV$_4$, 8.12.4).

For this it is enough to observe that, for $s \in U$, the geometric fiber of this group is determined by the configuration $R \subset M$: it is the constant group associated with the abstract Weyl group of this root system. In particular it is independent of s; see the *Bible*, §11.3, Theorem 2 (and also Exposé XXII, no. 3). □

[22] Editor's note: §6.1 is independent of the rest of this Exposé.
[23] Editor's note: throughout this volume, "trivial torus" has been replaced by "split torus".
[24] Editor's note: the preceding sentence has been added.
[25] Editor's note: since $\mathfrak{g}$ is a finite locally free $\mathcal{O}_S$-module, R is finite.
[26] Editor's note: the following argument has been expanded.

Corollary 2.6.— *Let G be an S-group scheme that is affine and smooth over S, with connected fibers. The set of points $s \in S$ for which $G_{\bar{s}}$ is reductive* (resp. semisimple) *is an open subset U of S, and the functions*

$$s \longmapsto \mathrm{rgred}(G_{\bar{s}}/\bar{s}), \qquad s \longmapsto \mathrm{rgss}(G_{\bar{s}}/\bar{s})$$

are locally constant on U.

Definition 2.7.— *An S-group* (that is, an S-group scheme) *G is called* reductive (resp. *semisimple*) *if it is affine and smooth over S, with connected reductive* (resp. semisimple) *geometric fibers.*

For an S-group scheme G, the property of being reductive (resp. semisimple) is stable under base change and local for the fpqc topology.

2.8.— Let G be a reductive S-group. For every torus (resp. maximal torus) Q of G,

$$Z(Q) = \underline{\mathrm{Centr}}_G(Q)$$

is reductive (resp. is equal to Q). This follows at once from 2.2 and 1.6. Applying 2.5 to $\underline{\mathrm{Centr}}_G(Q)$, we deduce that Q is contained, locally for the étale topology, in a maximal torus.

Remark 2.9.— *Using, as usual, the technique of EGA IV$_3$, §8, the finite-presentation hypotheses, and Theorem 2.5, one sees that if G is a reductive group over S, there is an open cover $\{U_i\}$ of S such that each G_{U_i} is obtained by base change from a reductive group over a noetherian ring* (in fact, over a finitely generated $\mathbb{Z}$-algebra). *Likewise, if G has a split maximal torus T, one may further suppose that T_{U_i} comes from a split maximal torus of the preceding group, ...*

3. Roots and root systems of reductive group schemes

3.1.— Let S be a scheme, and let T be an S-torus acting linearly on a finite locally free $\mathcal{O}_S$-module F (cf. I, §4.7). For every character α of T, that is,

$$\alpha \in \mathrm{Hom}_{S\text{-gr.}}(T, \mathbb{G}_{m,S}),$$

define a subfunctor of $\mathbb{W}(F)$ by

$$\mathbb{W}(F)^\alpha(S') = \left\{x \in \mathbb{W}(F)(S') \mid t \cdot x = \alpha(t)x \text{ for every } t \in T(S''),\ S'' \to S'\right\}.$$

Lemma.—[27] *Then $\mathbb{W}(F)^\alpha = \mathbb{W}(F^\alpha)$, where F^α is a submodule of F, locally a direct summand of F, and hence also locally free.*

Indeed, the assertion is local for the fpqc topology, and we may suppose that $T = D_S(M)$, where M is a finite-type (free) abelian group. Then α is identified with a locally constant function from S to M (Exposé VIII, 1.3), and, after restricting S if necessary, we may suppose that this function is constant. We are then reduced to Exposé I, 4.7.3.

Definition 3.2.— *Let S be a scheme, let G be an S-group scheme smooth over S and with connected fibers,*[28] *and let T be a torus of G. Put $\mathfrak{g} = \mathrm{Lie}(G/S)$, and let T act on $\mathfrak{g}$ through the adjoint representation of G.*

[27] Editor's note: this statement has been made into a lemma in order to bring it out.

[28] Editor's note: the original also assumed that G was of finite presentation over S, an assumption that does not appear to be used below. In any case, since G is smooth over S and has connected fibers, it is quasi-compact and separated over S (VI$_B$, 5.5), and hence of finite presentation over S.

A character α of T is called a root *of G with respect to T if the following equivalent conditions are satisfied:*

(i) For every $s \in S$, α_s is a root of G_s with respect to T_s (1.10).

(ii) α is nontrivial on every fiber, and $\mathfrak{g}^\alpha(s) \neq 0$ for every $s \in S$.

Lemma 3.3.— *Let S be a scheme, let T be an S-torus, and let α be a character of T. The following conditions are equivalent:*

(i) α is nontrivial on every fiber; that is, for every $s \in S$, α_s is distinct from the unit character of T_s.

(ii) For every $S' \to S$ with $S' \neq \varnothing$, $\alpha_{S'}$ is distinct from the unit character of $T_{S'}$.

(iii) The morphism α is faithfully flat.

[29] It is clear that (ii) implies (i), and it is easy to see that (iii) implies (i). Condition (i) implies (ii): if $s' \in S'$ lies over s, and $\alpha_{s'}$ is the unit character, then so is α_s. Finally, to prove that (i) implies (iii), we reduce to the case in which T is diagonalizable and conclude by Exposé VIII, 3.2(a).

3.4.—[30] Let G be a reductive S-group scheme, let T be a maximal torus of G, and let α be a root of G with respect to T. Then, by 2.5.0 and 1.12, $\mathfrak{g}^\alpha$ is a locally free $\mathcal{O}_S$-module of rank one. Moreover, by 1.10, $-\alpha$ is also a root of G with respect to T. In particular, if G has semisimple rank one, 1.11 and 1.12 give the following statement.

Lemma 3.5.— *Let S be a scheme, let G be a reductive S-group of semisimple rank one, and let T be a maximal torus of G. If α is a root of G with respect to T, then so is $-\alpha$, and*

$$\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{g}^\alpha \oplus \mathfrak{g}^{-\alpha},$$

where $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ are locally free of rank one.

Definition 3.6.— *Let S be a scheme, let G be a reductive S-group, let T be a maximal torus of G, and let R be a set of roots of G with respect to T. We say that R is a* root system *of G with respect to T if the following equivalent conditions are satisfied:*

(i) For every $s \in S$, the map $\alpha \mapsto \alpha_s$ is a bijection from R onto the set of roots of G_s with respect to T_s.

(ii) The elements of R are distinct on every fiber (that is, if $\alpha, \alpha' \in R$ and $\alpha \neq \alpha'$, then $\alpha - \alpha' = \alpha\alpha'^{-1}$ is nontrivial on every fiber)*, and, for every $s \in S$,*

$$\dim(G_s/\kappa(s)) - \dim(T_s/\kappa(s)) = \mathrm{Card}(R).$$

(iii) One has

$$\mathfrak{g} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R} \mathfrak{g}^\alpha.$$

[29] Editor's note: the original has been simplified; it invoked Exposé IX, 5.2. Note, however, that loc. cit., 5.3 shows that, if S is connected, the conditions of the lemma hold as soon as (i) holds at one point s of S.

[30] Editor's note: what follows has been modified so as to recall the hypotheses of 3.2 and to add that T is a maximal torus.

The equivalence of these conditions is immediate.

Lemma 3.7.— *Let S be a scheme, let G be a reductive S-group, let T be a maximal torus of G, and let R be a root system of G with respect to T. Every root of G with respect to T is locally on S equal to an element of R.*

Proof. This follows from condition (iii).

Put

$$\mathcal{M} = \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, \mathbb{G}_{m,S});$$

this is a twisted constant S-group scheme (Exposé X, 5.6). If G has a root system R with respect to T, then the inclusion $R \hookrightarrow \mathcal{M}(S)$ defines a morphism

$$R_S \longrightarrow \mathcal{M},$$

where R_S is the constant S-scheme defined by R. By condition (ii), this morphism is an open and closed immersion whose image is precisely

$$\bigcup_{\alpha \in R} \alpha(S),$$

where each $\alpha \in R$ is regarded as a section $S \to \mathcal{M}$.

Let $\mathcal{R}$ be the functor of roots of G with respect to T. By definition, $\mathcal{R}(S')$ is the set of roots of $G_{S'}$ with respect to $T_{S'}$, for every $S' \to S$. If $S' = \varnothing$, set $\mathcal{R}(\varnothing) = \{e\}$; if $S' \neq \varnothing$, the inclusion $R \hookrightarrow \mathcal{M}(S')$ identifies R with a root system of $G_{S'}$ with respect to $T_{S'}$. Thus, by 3.7,

$$\mathcal{R}(S') = \mathrm{Hom}_{\text{loc. const.}}(S', R),$$

which shows that $\mathcal{R}$ is represented by R_S.

Now drop the assumption that G necessarily has a root system with respect to T. The functor $\mathcal{R}$ is in any case an fpqc subsheaf of $\mathcal{M}$. Locally for this topology, G does have a root system with respect to T (for example, make T split and use the proof of Theorem 2.5). By Exposé IV, 4.6.8 and the descent theory of open (respectively closed) subschemes,[31] we obtain the following proposition.

Proposition 3.8.— *Let S be a scheme, let G be an S-group, and let T be a maximal torus of G. The functor $\mathcal{R}$ of roots of G with respect to T is represented by a finite twisted constant S-scheme* (Exposé X, 5.1) *which is an open and closed subscheme of*

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(T, \mathbb{G}_{m,S}).$$

A subset $R \subset \mathrm{Hom}_{S\text{-}gr.}(T, \mathbb{G}_{m,S})$ is a root system of G with respect to T if and only if the morphism

$$R_S \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, \mathbb{G}_{m,S}),$$

defined by the preceding inclusion, induces an isomorphism

$$R_S \xrightarrow{\sim} \mathcal{R}.$$

3.9.— Let S be a scheme, let G be a reductive S-group, let T be a maximal torus of G, and let α be a root of G with respect to T, that is, a section of $\mathcal{R}$. Consider the kernel $\mathrm{Ker}(\alpha)$ of α, its unique maximal torus T_α, and the centralizer of the latter,

$$Z_\alpha = \underline{\mathrm{Centr}}_G(T_\alpha).$$

[31] Editor's note: see SGA 1, VIII, 4.4 or EGA IV_2, 2.7.1.

This is a closed S-subgroup of G, reductive (2.8), and of semisimple rank one (1.12). Moreover,

$$\mathrm{Lie}(Z_\alpha/S) = \mathfrak{t} \oplus \mathfrak{g}^\alpha \oplus \mathfrak{g}^{-\alpha};$$

hence $\{\alpha, -\alpha\}$ is a root system of Z_α with respect to T.

3.10.— Let S be a scheme, let G be a reductive S-group, let T be a maximal torus of G, and let α be a root of G with respect to T. If $q \in \mathbb{Q}$ and $q\alpha$ is a root of G with respect to T, then $q = 1$ or $q = -1$. This follows at once from 1.12.

4. Roots and vector group schemes

4.1.— Let S be a scheme and let F be a finite locally free $\mathcal{O}_S$-module. The S-scheme $\mathbb{W}(F)$ is smooth over S. Its Lie algebra is canonically isomorphic to F. Indeed, there is a canonical isomorphism

$$\mathbb{W}(F) \xrightarrow{\sim} \mathrm{Lie}(\mathbb{W}(F)/S) = \mathbb{W}\big(\mathrm{Lie}(\mathbb{W}(F)/S)\big)$$

(Exposé II, 4.4.1 and 4.4.2). We shall always identify F with $\mathrm{Lie}(\mathbb{W}(F)/S)$.

Lemma 4.2.— *Let S be a scheme and let V be a vector bundle over S, smooth over S. There is then a unique isomorphism of $\mathcal{O}_S$-modules*

$$\exp\colon \mathbb{W}\big(\mathrm{Lie}(V/S)\big) \xrightarrow{\sim} V$$

which induces the identity on Lie algebras. [32]

Proof. We have $V = \mathbb{V}(\mathscr{F})$ for some quasi-coherent $\mathcal{O}_S$-module $\mathscr{F}$. Since V is smooth over S, the module $\mathscr{F} \simeq \omega^1_{V/S}$ is finite locally free, and hence

$$\mathrm{Lie}(V/S) = \mathbb{V}(\omega^1_{V/S}) \simeq \mathbb{W}\big(\mathrm{Lie}(V/S)\big).$$

[32] Editor's note: the proof in the original edition has been retained; it may also be expanded as follows.

Let $\mathscr{F}$ be a quasi-coherent $\mathcal{O}_S$-module and put $V = \mathbb{V}(\mathscr{F})$. Write $\pi\colon V \to S$ for the projection and $\epsilon\colon S \to V$ for the zero section. Then $\Omega^1_{V/S} = \pi^*\mathscr{F}$, whence

$$\omega^1_{V/S} = \epsilon^*\Omega^1_{V/S} \simeq \epsilon^*\pi^*\mathscr{F} \simeq \mathscr{F}, \tag{1}$$

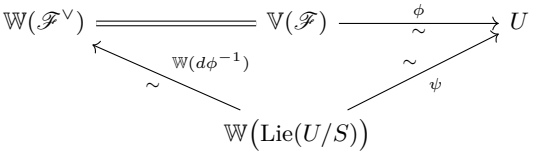
and therefore $\mathrm{Lie}(V/S) = (\omega^1_{V/S})^\vee \simeq \mathscr{F}^\vee$. If V is smooth over S, then by (1) $\mathscr{F}$ is finite locally free, and hence

$$V = \mathbb{V}(\mathscr{F}) \simeq \mathbb{W}(\mathscr{F}^\vee) \simeq \mathbb{W}\big(\mathrm{Lie}(V/S)\big). \tag{2}$$

Now let U be an S-scheme equipped with a section $\tau\colon S \to U$, and suppose that an isomorphism $\phi\colon V \xrightarrow{\sim} U$ of pointed S-schemes has been given, that is, $\phi \circ \epsilon = \tau$ (for example, when U is an S-group). Then ϕ induces an isomorphism

$$d\phi\colon \mathscr{F}^\vee \xrightarrow{\sim} \mathrm{Lie}(U/S),$$

and therefore an isomorphism ψ displayed by



which identifies U with $\mathbb{W}(\mathrm{Lie}(U/S))$. Since the functor $\mathbb{W}$ is fully faithful, there is a unique isomorphism

$$\exp\colon \mathbb{W}\big(\mathrm{Lie}(U/S)\big) \xrightarrow{\sim} U$$

such that $\mathrm{Lie}(\psi^{-1} \circ \exp) = \mathrm{id}$. In fact, one sees directly that $\mathrm{Lie}(\psi) = \mathrm{id}$, so that $\exp = \psi$.

Moreover, by Exposé II, loc. cit., there is a canonical isomorphism

$$V \xrightarrow{\sim} \mathrm{Lie}(V/S) \simeq \mathbb{W}(\mathrm{Lie}(V/S)),$$

and the uniqueness of exp follows at once because $\mathbb{W}$ is fully faithful. □

4.3. Notation.— If V is a vector bundle over S, let $V^\times$ denote the open subset obtained from V by removing the zero section. Write the group law of V multiplicatively. The action of $\mathcal{O}_S$ on V which defines its module structure will then be written exponentially:

$$\mathcal{O}_S \times_S V \longrightarrow V, \qquad (x, v) \longmapsto v^x.$$

Thus

$$(vv')^x = v^x (v')^x, \qquad v^{x+x'} = v^x v^{x'}, \qquad v^{xx'} = (v^x)^{x'}.$$

In particular, upon restricting the operator action to $\mathbb{G}_{m,S}$, the open subset $V^\times$ is stable and is therefore an object with operator group $\mathbb{G}_{m,S}$. We shall continue to write this action as $(z, v) \longmapsto v^z$.

Definition 4.4.1.[33]— *Let L be an invertible module on S, and let $\mathbb{W}(L)$ be the associated vector bundle. Then $\mathbb{W}(L)^\times$ is a* (locally trivial) *principal homogeneous bundle under $\mathbb{G}_{m,S}$. We write*

$$\Gamma(S, L)^\times = \mathbb{W}(L)^\times(S).$$

Scholium 4.4.2.— *There are natural bijections among the isomorphisms of $\mathcal{O}_S$-modules $\mathcal{O}_S \simeq L$, the isomorphisms of $\mathcal{O}_S$-modules $\mathcal{O}_S \simeq \mathbb{W}(L)$,*[34] *and the sections $S \to \mathbb{W}(L)^\times$.*

The correspondence is

$$f \longmapsto \mathbb{W}(f) \longmapsto \mathbb{W}(f)(1).$$

It is compatible with base change. Thus $\mathbb{W}(L)^\times$ may be regarded as the "scheme of trivializations of $\mathbb{W}(L)$".

4.5.— Let S be a scheme, let T be an S-torus, let P be an S-group with operator group $\mathbb{G}_{m,S}$ (for example, a vector bundle), and let α be a character of T. We write $T \cdot_\alpha P$ for the semidirect product of P by T, where T acts on P through the composite morphism

$$T \xrightarrow{\alpha} \mathbb{G}_{m,S} \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(P).$$

Definition 4.6.— *Let S be a scheme, let G be an S-group scheme, let T be a subgroup of G, let α be a character of T, and let L be an $\mathcal{O}_S$-module. Let*

$$p\colon \mathbb{W}(L) \longrightarrow G$$

be a morphism of S-group functors.[35] *We say that p is* normalized by T with multiplier α *if it satisfies the following equivalent conditions:*

[33] Editor's note: for purposes of later references, paragraph 4.4 has been divided into 4.4.1 and 4.4.2.

[34] Editor's note: here the vector bundle $\mathbb{W}(L)$ is identified with the $\mathcal{O}_S$-module functor which it represents.

[35] Editor's note: the edition uses a bold $\mathbf{W}(L)$ here because, for an arbitrary $\mathcal{O}_S$-module L, the functor need not be representable. Below, however, L is assumed finite locally free (indeed, invertible), in which case the functor is represented by the vector bundle $\mathbb{V}(L^\vee)$, and the notation $\mathbb{W}(L)$ is used without this distinction.

(i) p is a morphism of objects with operator group T, where T acts on $\mathbb{W}(L)$ through α, and on G by inner automorphisms. In other words, for every $S' \to S$, every $t \in T(S')$, and every

$$x \in \mathbb{W}(L)(S') = \Gamma(S', L \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}),$$

one has

$$\mathrm{int}(t)p(x) = p(\alpha(t)x).$$

(ii) The morphism

$$T \cdot_\alpha \mathbb{W}(L) \longrightarrow G, \qquad (t, x) \longmapsto t\,p(x),$$

defined by multiplication in G, is a group morphism.

Lemma 4.7.— *Under the hypotheses of 4.6, suppose in addition that G is smooth with connected fibers,*[36] *that T is a maximal torus of G, and that L is invertible. If p is a monomorphism and α is nonzero on every fiber, then α is a root of G with respect to T.*

Indeed,

$$\mathrm{Lie}(p)\colon L \longrightarrow \mathfrak{g}$$

is a monomorphism which factors through $\mathfrak{g}^\alpha$.

Proposition 4.8.— *Under the hypotheses of 4.7, suppose that G is reductive and that p is a monomorphism. Then α is a root of G with respect to T, and* $\mathrm{Lie}(p)$ *induces an isomorphism*

$$\mathrm{Lie}(p)\colon L \xrightarrow{\sim} \mathfrak{g}^\alpha.$$

Indeed, by 4.7 and the fact that $\mathfrak{g}^\alpha$ is invertible, it is enough to prove that α is nonzero on every fiber. Let $s \in S$ be such that $\alpha_{\bar{s}} = 0$ ($= 1$ in multiplicative notation). If X is a nonzero section of $L \otimes_S \kappa(\bar{s})$, then $p(X)$ is a unipotent element different from the identity in $G(\bar{s})$ which centralizes $T_{\bar{s}}$. This is impossible, since $T_{\bar{s}}$ is its own centralizer.

Corollary 4.9.— *Under the hypotheses of 4.8, there exists a monomorphism of groups with operator group T* (that is, normalized by T with multiplier α)

$$\mathbb{W}(\mathfrak{g}^\alpha) \longrightarrow G$$

which induces on Lie algebras the canonical morphism $\mathfrak{g}^\alpha \to \mathfrak{g}$.

We shall soon see that 4.9 in fact holds whenever G is a reductive group and α is a root of G with respect to T, and that such a morphism is unique.

Reminder 4.10.— *Let k be an algebraically closed field, let G be a reductive k-group, let T be a maximal torus of G, and let α be a root of G with respect to T. There exists a monomorphism*

$$p\colon \mathbb{G}_{a,k} \longrightarrow G$$

normalized by T with multiplier α.

See the *Bible*, §13.1, Theorem 1.

4.11.— We finish this section with a technical result which will be useful to us. Let S be a scheme, and let L be an invertible $\mathcal{O}_S$-module. Let $q > 0$ be an integer such that $x \longmapsto x^q$ is an endomorphism of the S-group $\mathbb{G}_{a,S}$. If $S \neq \varnothing$, then $q = 1$, or $q = p^n$, where

[36] Editor's note: compare editor's note (28).

p is a prime number which vanishes on S. This follows at once from the elementary fact that the greatest common divisor of the binomial coefficients $\binom{q}{i}$, for $i \neq 0, q$, is p if $q = p^n$ with p prime, and is 1 otherwise.

The morphism defined by taking the q-th power,

$$L \longrightarrow L^{\otimes q},$$

is a morphism of sheaves of abelian groups. By base change it defines a morphism of S-group schemes

$$\mathbb{W}(L) \longrightarrow \mathbb{W}(L^{\otimes q}).$$

In particular, if L' is another invertible module and an $\mathcal{O}_S$-linear morphism

$$h\colon L^{\otimes q} \longrightarrow L'$$

is given, one obtains a morphism of S-group schemes

$$\mathbb{W}(L) \longrightarrow \mathbb{W}(L'), \qquad x \longmapsto h(x^q).$$

With this notation, we have the following result.

Proposition 4.12.— *Let S be a scheme, let T* (resp. T') *be an S-torus, let L* (resp. L') *be an invertible $\mathcal{O}_S$-module, and let α* (resp. α') *be a character of T* (resp. T'). *Let $f\colon T \to T'$ be a group morphism and let*

$$g\colon \mathbb{W}(L) \longrightarrow \mathbb{W}(L')$$

be a morphism of S-schemes (not necessarily a morphism of S-groups) *satisfying*

$$(\star) \qquad g\big(\alpha(t)x\big) = \alpha'\big(f(t)\big)g(x)$$

for every $S' \to S$, every $x \in \mathbb{W}(L)(S')$, and every $t \in T(S')$. Let $s_0 \in S$ be such that $\alpha_{\bar{s}_0} \neq 0$. [37]

(a) *Suppose that g sends the zero section to the zero section and that, for every integer $n > 0$,*

$$(\alpha' \circ f)_{\bar{s}_0} \neq n\alpha_{\bar{s}_0}.$$

Then $g = 0$ in a neighborhood of s_0.

(b) *Suppose that g is a group morphism and that $g_{\bar{s}_0} \neq 0$. There then exist an open subset $U \subset S$ containing s_0 and an integer $q > 0$ such that $x \longmapsto x^q$ is an endomorphism of $\mathbb{G}_{a,U}$ and*

$$(\alpha' \circ f)_U = q\alpha_U.$$

[37] Editor's note: the phrases "consider the semidirect product $T \cdot_\alpha \mathbb{W}(L)$, respectively $T' \cdot_{\alpha'} \mathbb{W}(L')$" have been deleted. On the other hand, in part (b) the hypothesis that g be a group morphism, together with $(\star)$, is equivalent to requiring

$$(t, x) \longmapsto \big(f(t), g(x)\big)$$

to be a group morphism from $T \cdot_\alpha \mathbb{W}(L)$ to $T' \cdot_{\alpha'} \mathbb{W}(L')$.

(c) *Suppose that*

$$(\alpha' \circ f)_{\bar{s}_0} = q\alpha_{\bar{s}_0},$$

where $q > 0$ is an integer such that $x \longmapsto x^q$ is an endomorphism of $\mathbb{G}_{a,S}$. There then exist an open subset $U \subset S$ containing s_0 and a unique morphism of $\mathcal{O}_S$-modules

$$h\colon L^{\otimes q}|_U \longrightarrow L'|_U$$

such that g_U is the composite

$$\mathbb{W}(L)_U \xrightarrow{x\mapsto x^q} \mathbb{W}(L^{\otimes q})_U \xrightarrow{\mathbb{W}(h)} \mathbb{W}(L')_U.$$

Proof of Proposition 4.12.. Let us prove (a). Since the conclusion is local on S, we may suppose that $\mathbb{W}(L) = \mathbb{W}(L') = \mathbb{G}_{a,S}$, and hence that g is given by a polynomial

$$g(X) = \sum_{n\geq 0} a_n X^n, \qquad a_n \in \Gamma(S, \mathcal{O}_S).$$

Condition $(\star)$, which relates f and g, is the identity in $\Gamma(S', \mathcal{O}_{S'})[X]$

$$\sum_{n\geq 0} a_n \alpha'(f(t)) X^n = \sum_{n\geq 0} a_n \alpha(t)^n X^n.$$

Thus, for every $n \geq 0$, every $S' \to S$, and every $t \in T(S')$,

$$a_n(\alpha'(f(t)) - \alpha(t)^n) = 0.$$

For every $n \geq 0$, let S_n be the set of points $s \in S$ such that

$$(\alpha' \circ f)_{\bar{s}} = n\alpha_{\bar{s}}.$$

It is known (Exposé IX, 5.3) that the S_n are both open and closed and that

$$(\alpha' \circ f)_{S_n} = n\alpha_{S_n}.$$

Moreover, since $\alpha_{\bar{s}_0} \neq 0$, after shrinking S we may suppose that α is nonzero on every fiber (same reference); it follows that the S_n are pairwise disjoint. After shrinking S once more, we may therefore suppose that one of the following two cases holds: $S = S_n$ for some n, or every S_n is empty.

Let $m \geq 0$ be such that $S_m = \varnothing$. We claim that $a_m = 0$. Indeed, $\alpha' \circ f$ and $m\alpha$ are distinct on every fiber of S, and we have:

Lemma 4.13.— *Let S be a scheme, let T be an S-torus, and let α, α' be two characters of T which are distinct on every fiber. There exist an fpqc covering family $\{S_i \to S\}$ and, for every i, an element $t_i \in T(S_i)$ such that*

$$\alpha(t_i) - \alpha'(t_i) = 1.$$

The lemma is immediate by reduction first to the diagonalizable case, and then to $T = \mathbb{G}_{m,S}$.

We return to the proof of Proposition 4.12. We have just proved (a). In cases (b) and (c), there is an integer n such that $S = S_n$ ($n = q$ in (c)). The preceding argument gives $a_m = 0$ for $m \neq n$, and therefore

$$g(X) = a_n X^n, \qquad a_n \in \Gamma(S, \mathcal{O}_S).$$

This proves (c) at once. In case (b), we know that $a_n(s_0) \neq 0$; we may therefore suppose that a_n is invertible on S. It follows that $x \longmapsto x^n$ is an endomorphism of $\mathbb{G}_{a,S}$, by the hypothesis in (b), and this completes the proof.

5. An instructive example

5.1.— Let k be an algebraically closed field of characteristic 0. Put $A = k[t]$, the polynomial ring in one variable over k, and let $S = \mathrm{Spec}(A)$. Consider the following Lie algebra $\mathfrak{g}$ over $\mathcal{O}_S$. As a module it is free of rank 3, with basis $\{X, Y, H\}$, and its multiplication table is

$$[X, Y] = 2tH, \qquad [H, X] = X, \qquad [H, Y] = -Y.$$

For $s \in S$, $s \neq s_0$, where s_0 is the point defined by $t = 0$, the fiber

$$\mathfrak{g}(s) = \mathfrak{g} \otimes_A \kappa(s)$$

is isomorphic to the Lie algebra of $\mathrm{PGL}_{2,\kappa(s)}$. For $s = s_0$, it is a solvable Lie algebra.

5.2.— Let G_1 be the group scheme of automorphisms of $\mathfrak{g}$: for every $S' \to S$, $G_1(S')$ is the group of automorphisms of the $\mathcal{O}_{S'}$-Lie algebra $\mathfrak{g} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}$. It is a closed subscheme of the group $\mathrm{GL}(\mathfrak{g})$ of automorphisms of the $\mathcal{O}_S$-module $\mathfrak{g}$.

Let $S' \to S$, and let

$$u \in M_3(\Gamma(S', \mathcal{O}_{S'}))$$

be viewed as an endomorphism of the $\mathcal{O}_{S'}$-module $\mathfrak{g} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}$:

$$\begin{aligned} u(X) &= aX + bY + eH, \\ u(Y) &= b'X + a'Y + e'H, \\ u(H) &= cX + c'Y + dH. \end{aligned}$$

It is immediate that u is a section of G_1 if and only if $\det(u)$ is invertible and the following relations hold:

(1)	$a(d-1) = ec$,	(1')	$a'(d-1) = e'c'$,
(2)	$b(d+1) = ec'$,	(2')	$b'(d+1) = e'c$,
(3)	$e = 2t(bc - ac')$,	(3')	$e' = 2t(b'c' - a'c)$,
(4)	$2tc = eb' - ae'$,	(4')	$2tc' = be' - ea'$,
(5)	$2t(aa' - bb') = 2td$.		

38

Lemma 5.3.— *Relations* (1), (1'), (2), *and* (2') *imply*

$$\det(u) = aa'(2-d) + bb'(d+2), \qquad aa' - bb' = d\det(u).$$

Indeed, the first assertion follows at once by substituting relations (1), (1'), (2), and (2') in the expansion of $\det(u)$:

$$\begin{aligned} \det(u) &= aa'd + be'c + b'c'e - a'ec - ae'c' - bb'd \\ &= aa'd + bb'(d+1) + bb'(d+1) - aa'(d-1) - bb'd - aa'(d-1) \\ &= aa'(d - d + 1 - d + 1) + bb'(d + 1 + d + 1 - d) \\ &= aa'(2-d) + bb'(d+2). \end{aligned}$$

[38] Editor's note: the equality $[u(X), u(Y)] = 2t\,u(H)$ gives relations (4), (4'), and (5); the equality $[u(H), u(X)] = u(X)$ gives (1)–(3); and the equality $[u(H), u(Y)] = -u(Y)$ gives (1')–(3').

Multiplying this relation by d, we obtain

$$d\det(u) = aa'(2d - d^2) + bb'(d^2 + 2d).$$

On the other hand, the relation (1) × (1') = (2) × (2') gives at once

$$aa'(d-1)^2 = bb'(d+1)^2.$$

Combining the last two relations immediately yields the second formula of Lemma 5.3.

5.4.— Now consider

$$G = G_1 \cap \mathrm{SL}(\mathfrak{g}).$$

This is the closed subgroup of G_1 defined by the equation $\det(u) = 1$; hence it is an affine group over S.

Proposition 5.5.— *The group G is smooth over S.*

To prove the proposition, we shall need the following lemmas.

Lemma 5.6.— *Let U be the open subset of*

$$\mathrm{End}_A(\mathfrak{g}) \simeq \mathbb{W}(M_3(\mathcal{O}_S))$$

defined by the condition that ad be invertible; that is, the principal open subset $\mathrm{End}_A(\mathfrak{g})_f$, where $f(u) = ad$. Then $U \cap G$ is the closed subscheme of U defined by the six equations

$$(1), \quad (2), \quad (2'), \quad (3), \quad (3'), \quad (\mathrm{D}): aa' - bb' = d.$$

It is clear that these six relations are satisfied by every point of G, by Lemma 5.3, and therefore by every point of $U \cap G$. Conversely, suppose that $u \in U(S')$, for some $S' \to S$, satisfies the six conditions in the statement. We must show that $\det(u) = 1$, and that u also satisfies (1'), (4), (4'), and (5).

First, (D) implies (5). Relations (2) and (2') give

$$bb'(d+1) = bce' = b'c'e.$$

On the other hand, from (3) and (3'), writing $2t(bc - ac')(b'c' - a'c)$ in two ways, we obtain

$$(bc - ac')e' = (b'c' - a'c)e.$$

Together with the preceding relation, this gives

$$ac'e' = a'ce.$$

By (1), however,

$$a'ce = a'a(d-1).$$

Thus

$$a(a'(d-1) - e'c') = 0,$$

and this implies (1'), since a is invertible.

Consequently, (1), (2), (2'), and (1') hold. Lemma 5.3 and (D) now give

$$d\big(\det(u) - 1\big) = 0.$$

Since d is invertible, it follows that $\det(u) = 1$.

It remains to prove (4) and (4'). We prove (4'); the other calculation follows by symmetry. From (3), (3'), and (D), we have

$$a'e + be' = -2t(aa' - bb')c' = -2tdc'.$$

Combining (1') and (2), we also have

$$a'e + be' = -d(be' - ea'),$$

[39] which proves (4'), since d is invertible.

Lemma 5.7.— *The group G is smooth over S along the identity section.*

Proof. By 5.6 and SGA 1, II 4.10, it is enough to prove that the differentials of the functions

$$a(d-1) - ec, \qquad b(d+1) - ec', \qquad b'(d+1) - e'c,$$
$$e - 2t(bc - ac'), \qquad e' - 2t(b'c' - a'c), \qquad aa' - bb' - d$$

at the points of the identity section of G are linearly independent. If the differential of a lower-case letter is denoted by the corresponding capital letter, these differentials are

$$D, \qquad 2B, \qquad 2B', \qquad E + 2tC', \qquad E' + 2tC, \qquad A + A' - D,$$

[40] and they are indeed linearly independent modulo every $(t - \lambda)$, $\lambda \in k$. [41]

Lemma 5.8.— *For $s \in S$, $s \neq s_0$, the fiber G_s is connected and semisimple.*

Proof. Indeed, since $s \neq s_0$, $\mathfrak{g}(s)$ is isomorphic to the Lie algebra of $\mathrm{PGL}_{2,\kappa(s)}$, and, on the other hand, $G_s = (G_1)_s$. The automorphism group of the Lie algebra of PGL_2 over a field of characteristic 0 is known to be PGL_2 itself, which is connected and semisimple. [42]

Lemma 5.9.— *The fiber G_{s_0} is solvable and has two connected components, of the following form:*

$$G^0_{s_0} = \left\{ \begin{pmatrix} a & 0 & 0 \\ 0 & a^{-1} & 0 \\ c & c' & 1 \end{pmatrix} \right\}, \quad G^-_{s_0} = \left\{ \begin{pmatrix} 0 & b & 0 \\ b^{-1} & 0 & 0 \\ c & c' & -1 \end{pmatrix} \right\}.$$

Proof. We have $e = e' = 0$, since $t = 0$ at s_0. The equations (1), (1'), ..., (5), and (D) can then be solved immediately.

Lemma 5.10.— *The matrix*

$$w = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

is a section of G over S, such that $w(s_0) \in G^-_{s_0}$.

Let us now prove Proposition 5.5. Denote by G^0 the union of the identity components of the fibers of G, that is, the complement of $G^-_{s_0}$. Since G is smooth over S along the identity section by Lemma 5.7, G^0 is an open subgroup of G, smooth over S, by Exposé $\mathrm{VI_B}$, 3.10. By translation, G is also plainly smooth at the points of $w(S)$; hence G is smooth over S. [43]

[39] Editor's note: the sign has been corrected.
[40] Editor's note: $A + A' + B$ has been corrected to $A + A' - D$.
[41] Editor's note: "$(t - a)$, $a \in A$" has been corrected to "$(t - \lambda)$, $\lambda \in k$".
[42] Editor's note: the preceding sentence has been slightly modified.
[43] Editor's note: the preceding sentence has been modified, and the reference to Exposé $\mathrm{VI_B}$, 3.10 has been added.

5.11.— Consider the morphism

$$\mathbb{G}_{m,S} \longrightarrow G^0, \qquad z \longmapsto \begin{pmatrix} z & 0 & 0 \\ 0 & z^{-1} & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

It is a monomorphism defining a torus T of G^0. We claim that

$$T = \mathrm{Centr}_G(T) = \mathrm{Centr}_{G^0}(T).$$

It is enough to verify the first equality. Since the two sides are smooth S-subgroups of G, it is enough to check that they have the same geometric points. In the fibers over points $s \neq s_0$, this follows because $\mathrm{PGL}_{2,\kappa(s)}$ is reductive and T_s is a maximal torus in it for dimensional reasons (cf. 1.11). In the fiber over s_0, the verification is immediate. In particular, T is a maximal torus of both G and G^0.

5.12.— The section w of G defined in Lemma 5.10 normalizes T. It follows immediately (cf. 2.4) that the Weyl group of G is isomorphic to $(\mathbb{Z}/2\mathbb{Z})_S$, and is therefore finite over S:

$$W_G(T) = \mathrm{Norm}_G(T)/T = (\mathbb{Z}/2\mathbb{Z})_S.$$

By contrast, $W_{G^0}(T)$ is not finite over S: it "lacks one point" above s_0.

5.13.— The open immersion $G^0 \to G$ is not a closed immersion, since G^0 is dense in G; it is nevertheless an affine morphism (and hence G^0 is affine over S). Indeed, $G^0_{s_0}$ is closed in G_{s_0}, which is closed in G, so its complement U in G is open. The open subsets G^0 and U cover G, and it is enough to verify that the immersions

$$G^0 \longrightarrow G^0 \qquad \text{and} \qquad G^0 \cap U \longrightarrow U$$

are affine. This is trivial for the first; for the second, observe that $U \cap G^0$ is defined in U by the condition $b \neq 0$.

We have thus constructed a smooth affine S-group G^0, with connected fibers, possessing a self-centralizing maximal torus T whose Weyl group $W_{G^0}(T)$ is not finite (compare Theorem 2.5).

6. Local existence of maximal tori. The Weyl group

In the proof of Theorem 2.5 we used a result from Exposé XI on the local existence, for the étale topology, of maximal tori. The proof in Exposé XI uses a deep representability result (XI 4.1). In the particular case under consideration, one can give another, far more elementary proof, based on the ideas of Exposé XII, no. 7.

Proposition 6.1.— *Let S be a scheme, let G be a smooth affine S-group scheme with connected fibers over S, and let $s_0 \in S$ be a point such that the maximal tori of the geometric fiber $G_{\bar{s}_0}$ are self-centralizing. There exist an étale morphism $S' \to S$ whose image contains s_0 and a split maximal torus T of $G_{S'}$.*

Proof. First, we may suppose that S is affine. [44] Since G is of finite presentation over S, we may successively suppose that S is noetherian, local, and then henselian with separably closed residue field (cf. EGA IV, 8.12, §§8.8 and 18.8). Thus let

$$S = \mathrm{Spec}(A), \qquad k = \kappa(s_0),$$

[44] Editor's note: the preceding sentence and the reference to EGA IV below have been added.

where A is henselian and k is separably closed. Choose a maximal torus T_0 of $G_0 = G_k$. Such a torus exists, for example because the scheme of maximal tori of G_0 is smooth over k (Exposé XII, 7.1(c)). Since k is separably closed, T_0 is split (cf. Exposé X, 1.4), and is therefore given by a group monomorphism

$$f_0 \colon \mathbb{G}_{m,k}^r \longrightarrow G_0.$$

Let $m > 1$ be an integer prime to the characteristic of k. By Exposé VIII, 6.7, for every $h > 0$, $\mathrm{Centr}_{G_0}({}_{m^h}T_0)$ is represented by a closed subscheme of G_0. The subgroup schemes ${}_{m^h}T_0$ are schematically dense in T_0 (cf. Exposé IX, 4.10), and G_0 is noetherian. Consequently there is an h such that

$$\mathrm{Centr}_{G_0}({}_{m^h}T_0) = \mathrm{Centr}_{G_0}(T_0) = T_0.$$

Put $n = m^h$. Since n is invertible on S, ${}_n\mathbb{G}_{m,S}$ is isomorphic to $(\mathbb{Z}/n\mathbb{Z})_S$, so f_0 defines a group monomorphism

$$u_0 \colon (\mathbb{Z}/n\mathbb{Z})_k^r \longrightarrow G_0$$

such that $\mathrm{Centr}_{G_0}(u_0) = T_0$.

Now the S-functor

$$P = \mathrm{Hom}_{S\text{-gr}}\big((\mathbb{Z}/n\mathbb{Z})_S^r, G\big)$$

is represented by an S-scheme of finite type: it is a closed subscheme of r copies of

$${}_nG = \mathrm{Hom}_{S\text{-gr}}\big((\mathbb{Z}/n\mathbb{Z})_S, G\big) = \mathrm{Ker}\big(G \xrightarrow{n} G\big).$$

But P is smooth over S (Exposé IX, 3.6). Therefore $u_0 \in P(k)$ lifts to a section $u \in P(S)$, by Hensel's lemma (Exposé XI, 1.11):

$$u \colon (\mathbb{Z}/n\mathbb{Z})_S^r \longrightarrow G.$$

Consider $H = \mathrm{Centr}_G(u)$. It is a closed subgroup scheme of G, by Exposé VIII, 6.5(e), and its special fiber is $H_0 = T_0$. Moreover, H is smooth over S. Indeed, let $S' = \mathrm{Spec}(A')$ be an affine S-scheme, let

$$u' \colon ({}_n\mathbb{G}_{m,S'})^r \longrightarrow G_{S'}$$

be obtained from u by base change, put $S'_J = \mathrm{Spec}(A'/J)$, where J is a square-zero ideal, and let $x \in H(S'_J)$. Since G is smooth, x lifts to an element $g \in G(S')$. Then

$$v = \mathrm{int}(g)(u')$$

satisfies $v_J = u'_J$. By Exposé IX, 3.2, there is therefore an element $g' \in G(S')$ such that $g'_J = e$ and $\mathrm{int}(g')(v) = u'$. It follows that $h = g'g$ belongs to $H(S')$ and satisfies $h_J = x$.[45]

Let H^0 be the identity component of H. It is a subgroup scheme of G, smooth and with connected fibers, whose special fiber is a torus. By Exposé X, 8.1, it is a torus, necessarily split by Exposé X, 4.6. Put $T = H^0$, and let

$$C = \mathrm{Centr}_G(T).$$

This is a closed subgroup of G (Exposé VIII, 6.5(e)) and is smooth (Exposé XI, 2.4). Consider C^0 (in fact $C^0 = C$, but we do not need this). Then $C^0 \supset T$, and both are

[45] Editor's note: the reference to Exposé VIII, 6.5(e) was added above, and the preceding smoothness argument has been expanded.

smooth groups with connected fibers. They coincide at s_0, hence in a neighborhood of s_0. After shrinking S, we may therefore suppose that $C^0 = T$; then, a fortiori, T is maximal.

Remark 6.2.— *The proof shows in particular that the reductive rank of $G_{\bar{s}}$ is constant in a neighborhood of $s = s_0$.*

Proposition 6.3.— *Let S be a scheme, let G be an S-group scheme that is smooth and of finite presentation over S, and let Q be a subtorus of G.*

(i) $\mathrm{Centr}_G(Q)$ *and* $\mathrm{Norm}_G(Q)$ *are represented by closed subgroup schemes, smooth* (and hence of finite presentation) *over S.*

(ii) $\mathrm{Centr}_G(Q)$ *is an open and closed subscheme of* $\mathrm{Norm}_G(Q)$. *The quotient*

$$W_G(Q) = \mathrm{Norm}_G(Q)/\mathrm{Centr}_G(Q)$$

is represented by an open subgroup scheme of $\mathrm{Aut}_{S\text{-gr}}(Q)$*; it is therefore a quasi-finite, étale, separated S-group scheme.*

(iii) *For every $s \in S$, put*

$$w(s) = \left|\mathrm{Norm}_{G(\bar{s})}(Q(\bar{s}))/\mathrm{Centr}_{G(\bar{s})}(Q(\bar{s}))\right|.$$

Then $s \longmapsto w(s)$ is lower semicontinuous, and is constant in a neighborhood of s if and only if $W_G(Q)$ is finite over S in a neighborhood of s.

Proof. By Exposé XI, 6.11, $\mathrm{Centr}_G(Q)$ and $\mathrm{Norm}_G(Q)$ are represented by closed subschemes of G of finite presentation. They are smooth by Exposé XI, 2.4 and 2.4 bis, which proves (i). Assertions (ii) and (iii) are then proved as in Exposé XI, 5.9 and 5.10; those proofs in fact use only (i), and not the deeper theorems of Exposé XI, 4.1 and 4.2.

Exposé XX
Reductive Groups of Semisimple Rank 1

by M. Demazure

0.1 Elementary systems. The groups U_α and $U_{-\alpha}$

Recollection 1.1. *Let $S = \mathrm{Spec}(k)$, where k is an algebraically closed field, and let G be a reductive S-group of semisimple rank one and T a maximal torus of G, necessarily split. Then*

$$\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{g}^{\alpha} \oplus \mathfrak{g}^{-\alpha},$$

where α and $-\alpha$ are the roots of G with respect to T. Moreover, there exist two group monomorphisms

$$p_\alpha \colon \mathbb{G}_{a,S} \longrightarrow G, \qquad p_{-\alpha} \colon \mathbb{G}_{a,S} \longrightarrow G$$

such that

$$t\, p_\alpha(x)\, t^{-1} = p_\alpha(\alpha(t)x), \qquad t\, p_{-\alpha}(x)\, t^{-1} = p_{-\alpha}(\alpha(t)^{-1}x)$$

for every $S' \to S$, $t \in T(S')$, and $x \in \mathbb{G}_a(S')$, and such that the morphism

$$\mathbb{G}_{a,S} \times_S T \times_S \mathbb{G}_{a,S} \longrightarrow G, \qquad (y,t,x) \longmapsto p_{-\alpha}(y)\, t\, p_\alpha(x),$$

is radicial and dominant (*Bible*, Section 13.4, Corollary 2 to Theorem 3).

Since its tangent map at the identity is bijective, this morphism is also separable, hence birational. Zariski's Main Theorem (EGA III_1, 4.4.9) therefore shows that it is an open immersion.

Lemma 1.2. *Let S be a scheme, G an S-group scheme, T a torus of G, Q a subtorus of T, and α a character of T whose restriction to Q is nontrivial on every fiber. Let*

$$p_\alpha \colon \mathbb{G}_{a,S} \longrightarrow G \quad \text{and} \quad p_{-\alpha} \colon \mathbb{G}_{a,S} \longrightarrow G$$

be group morphisms normalized by T, with multipliers α and $-\alpha$, respectively. Suppose that the morphism

$$u \colon \mathbb{G}_{a,S} \times_S T \times_S \mathbb{G}_{a,S} \longrightarrow G, \qquad u(y,t,x) = p_{-\alpha}(y)\, t\, p_\alpha(x),$$

[0]Editors' note: version of 13 October 2024.

defined on points by the displayed formula, is an open immersion. Finally, let $q \geq 0$ be an integer and let

$$p\colon \mathbb{G}_{a,S} \longrightarrow G$$

be a group morphism such that, for every $S' \to S$, $t \in Q(S')$, and $x \in \mathbb{G}_a(S')$,

$$\operatorname{int}(t)^q\big(p(x)\big) = p\big(\alpha(t)x\big).$$

Then there is a unique $\nu \in \mathbb{G}_a(S)$ such that

$$p(x) = p_\alpha(\nu x^q).$$

Indeed, let Ω be the image of u, and put $U = p^{-1}(\Omega)$. This is an open subset of $\mathbb{G}_{a,S}$ containing the zero section. For every section t of Q, multiplication by $\alpha(t)$ leaves U globally invariant. We have $U = \mathbb{G}_{a,S}$. It is enough to check this when S is the spectrum of an algebraically closed field k; then

$$\alpha\colon Q(k) \longrightarrow k^\times$$

is surjective, so $U(k) \supset k^\times$, and hence $U = \mathbb{G}_{a,k}$.

There are consequently three morphisms

$$a\colon \mathbb{G}_{a,S} \longrightarrow \mathbb{G}_{a,S}, \qquad b\colon \mathbb{G}_{a,S} \longrightarrow T, \qquad c\colon \mathbb{G}_{a,S} \longrightarrow \mathbb{G}_{a,S}$$

such that

$$p(x) = p_{-\alpha}\big(a(x)\big)\, b(x)\, p_\alpha\big(c(x)\big).$$

The condition on p becomes

$$a\big(\alpha(t)x\big) = \alpha(t)^{-q}a(x), \qquad b\big(\alpha(t)x\big) = b(x), \qquad c\big(\alpha(t)x\big) = \alpha(t)^q c(x).$$

For the same reason, for every $S' \to S$ and $z \in \mathbb{G}_m(S')$,

$$a(zx) = z^{-q}a(x), \qquad b(zx) = b(x), \qquad c(zx) = z^q c(x),$$

and therefore

$$z^q a(z) = a(1), \qquad b(z) = b(1), \qquad c(z) = z^q c(1).$$

Since $\mathbb{G}_{m,S}$ is schematically dense in $\mathbb{G}_{a,S}$, for every $S' \to S$ and $x \in \mathbb{G}_a(S')$ we obtain

$$\begin{aligned} x^q a(x) = a(1) = a(0) = 0, &\quad \text{hence } a = 0,\\ c(x) = x^q c(1) = \nu x^q, &\quad \text{for some } \nu \in \mathbb{G}_a(S),\\ b(x) = b(1) = b(0) = e, &\quad \text{hence } b = e. \end{aligned}$$

This completes the proof.

Definition 1.3. *An S-elementary system is a triple (G, T, α) in which*

(i) *G is a reductive S-group of semisimple rank one* (Exposé XIX, 2.7)*;*

(ii) *T is a maximal torus of G;*

(iii) *α is a root of G with respect to T* (Exposé XIX, 3.2).

Thus there is a direct-sum decomposition (Exposé XIX, 3.5)

$$\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{g}^\alpha \oplus \mathfrak{g}^{-\alpha},$$

where $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ are locally free of rank one.[1]

[1] As $\mathcal{O}_S$-modules.

1.4. If (G, T, α) is an S-elementary system, then $(G_{S'}, T_{S'}, \alpha_{S'})$ is an S'-elementary system for every $S' \to S$. If (G, T, α) is an S-elementary system, then so is $(G, T, -\alpha)$.

If S is a scheme, G a reductive S-group, T a maximal torus of G, and α a root of G with respect to T, then (Z_α, T, α) is an S-elementary system (Exposé XIX, 3.9).

Let (G, T, α) be an S-elementary system. The invertible module $\mathfrak{g}^\alpha$ is canonically endowed with a T-module structure. Hence the vector bundle $W(\mathfrak{g}^\alpha)$ is also a T-module. On the other hand, the inner automorphisms by elements of T make G a group equipped with a group of operators T.

Theorem 1.5. *Let (G, T, α) be an S-elementary system.*

(i) *There exists a unique morphism of groups with operator group T*

$$\exp\colon W(\mathfrak{g}^\alpha) \longrightarrow G$$

whose induced morphism on Lie algebras is the canonical map $\mathfrak{g}^\alpha \to \mathfrak{g}$.[2] *Equivalently,* exp *is the unique morphism such that, for every $S' \to S$, $t \in T(S')$, and $X, X' \in W(\mathfrak{g}^\alpha)(S')$,*

$$\begin{aligned} \exp(X + X') &= \exp(X)\exp(X'), \\ \operatorname{int}(t)\big(\exp(X)\big) &= \exp\big(\alpha(t)X\big), \\ \operatorname{Lie}(\exp)(X) &= X. \end{aligned}$$

(ii) *Define analogously, in the S-elementary system $(G, T, -\alpha)$,*

$$\exp\colon W(\mathfrak{g}^{-\alpha}) \longrightarrow G.$$

Then the morphism

$$W(\mathfrak{g}^{-\alpha}) \times_S T \times_S W(\mathfrak{g}^\alpha) \longrightarrow G, \qquad (Y, t, X) \longmapsto \exp(Y)\, t\, \exp(X),$$

defined on points by the displayed formula, is an open immersion.

Suppose for the moment that the required exponential morphisms exist, and prove the other assertions. We first prove (ii). Both sides are of finite presentation and flat over S, so it is enough to work when S is the spectrum of an algebraically closed field (SGA 1, I 5.7 and VIII 5.5). Put $S = \operatorname{Spec}(k)$, and choose

$$X \in \Gamma(S, \mathfrak{g}^\alpha)^\times, \qquad Y \in \Gamma(S, \mathfrak{g}^{-\alpha})^\times.$$

It is enough to prove that

$$\mathbb{G}_{a,k} \times_k T \times_k \mathbb{G}_{a,k} \longrightarrow G, \qquad (y, t, x) \longmapsto \exp(yY)\, t\, \exp(xX),$$

is an open immersion. By 1.1 and 1.2, there exist $a, b \in k$ such that

$$\exp(yY) = p_{-\alpha}(ay), \qquad \exp(xX) = p_\alpha(bx).$$

Since $\exp\colon W(\mathfrak{g}^{-\alpha}) \to G$ induces a monomorphism on Lie algebras, $a \neq 0$; likewise $b \neq 0$. The assertion is therefore reduced to 1.1.

The uniqueness of exp may be proved locally on S. We reduce to the case in which $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ are free, and then apply 1.2 with $Q = T$ and $q = 1$.

[2] It will be seen below, in Corollary 5.9, that exp is an isomorphism from $W(\mathfrak{g}^\alpha)$ onto a closed subgroup of G.

It remains to prove existence. Faithfully flat descent, together with the uniqueness just proved, shows that it is enough to prove existence locally on S for the fpqc topology. The usual finite-presentation arguments reduce first to S noetherian and then to S noetherian local. We may therefore assume that

$$S = \mathrm{Spec}(A),$$

where A is a complete noetherian local ring with algebraically closed residue field k. Let

$$p_0 \colon \mathbb{G}_{a,k} \longrightarrow G_k$$

be a monomorphism of k-groups normalized by T_k, with multiplier $\alpha_0 = \alpha \otimes_A k$; such a morphism exists by 1.1. By 1.1 and 1.2, the associated morphism

$$T_k \cdot_{\alpha_0} \mathbb{G}_{a,k} \longrightarrow G_k$$

is an immersion and hence, in particular, a monomorphism. We provisionally admit the following two lemmas.

Lemma 1.6. *Let S be a scheme, G an S-group of finite presentation, T an S-torus, α a character of T that is nontrivial on every fiber, and $s_0 \in S$. Let*

$$f \colon T \cdot_\alpha \mathbb{G}_{a,S} \longrightarrow G$$

be an S-group morphism such that f_{s_0} is a monomorphism and the restriction of f to T is a monomorphism. There exists an open neighborhood U of s_0 such that $f|_U$ is a monomorphism.

Lemma 1.7. *Let A be a complete noetherian local ring with algebraically closed residue field k, let (G, T, α) be an A-elementary system, and let*

$$p_0 \colon \mathbb{G}_{a,k} \longrightarrow G_k$$

be a morphism of k-groups normalized by T_k, with multiplier $\alpha \otimes_A k$. There exists a group morphism

$$p \colon \mathbb{G}_{a,A} \longrightarrow G$$

normalized by T, with multiplier α.

Let p be the morphism asserted by 1.7, and let

$$f \colon T \cdot_\alpha \mathbb{G}_{a,S} \longrightarrow G$$

be the corresponding morphism. It satisfies the hypotheses of 1.6, so it is a monomorphism; in particular, p is a monomorphism. The theorem now follows from Exposé XIX, 4.9.

Proof of 1.6. Let

$$\epsilon \colon S \longrightarrow T \cdot_\alpha \mathbb{G}_{a,S}$$

be the identity section. Since f is unramified at $\epsilon(s_0)$, it is unramified at $\epsilon(s)$ for all s in an open neighborhood U of s_0. Hence $f|_U$ is unramified (Exposé X, 3.5),[3] and its kernel $\mathrm{Ker}(f)_U$ is unramified over U. To prove that $f|_U$ is a monomorphism, it is therefore enough[4] to prove that $\mathrm{Ker}(f)_U$ is radicial over U, which is a set-theoretic question. We are reduced to the following assertion.

[3] See also Exposé VI_B, 2.5.

[4] By EGA IV_4, 17.9.1.

Lemma 1.8. *Let k be an algebraically closed field, and let N be an invariant subgroup of $T \cdot_\alpha \mathbb{G}_{a,k}$, where α is a nontrivial character of the torus T. Suppose that N is étale over k and that $N \cap T = \{e\}$. Then $N = \{e\}$.*

We have

$$\mathrm{int}(t')(t,x) = (t, \alpha(t')x).$$

If (t,x) is a point of N with $x \neq 0$, then (t,zx) is also a point of N for every $z \in k^\times$. Thus (t,x) is not isolated, contradicting the quasi-finiteness of N. Set-theoretically, therefore, $N \subset T$, and the hypothesis $N \cap T = \{e\}$ completes the proof.

Proof of 1.7. Let $\mathfrak{m}$ be the radical of A, and put

$$S_n = \mathrm{Spec}(A/\mathfrak{m}^{n+1}), \qquad n \geq 0.$$

We first show, by induction on n, that p_0 can be extended, for every n, to a morphism of S_n-groups

$$p_n \colon \mathbb{G}_{a,S_n} \longrightarrow G_{S_n},$$

normalized by T_{S_n} with multiplier α_{S_n}, in such a way that

$$p_{n+1} \times_{S_{n+1}} S_n = p_n.$$

Let $H = T \cdot_\alpha \mathbb{G}_{a,S}$. Denote by f_n the morphism $H_{S_n} \to G_{S_n}$ defined by p_n. We provisionally admit the following lemma.

Lemma 1.9. *Let (G,T,α) be a k-elementary system, where k is algebraically closed, and let*

$$p \colon \mathbb{G}_{a,k} \longrightarrow G$$

be a monomorphism normalized by T, with multiplier α. Then

$$\mathrm{H}^2\big(T \cdot_\alpha \mathbb{G}_{a,k}, \mathfrak{g}\big) = 0.$$

Here $T \cdot_\alpha \mathbb{G}_{a,k}$ acts on $\mathfrak{g}$ through the morphism $T \cdot_\alpha \mathbb{G}_{a,k} \to G$ defined by p and through the adjoint representation of G.

By Exposé III, 2.8, f_n therefore extends to a morphism of S_{n+1}-groups

$$f'_{n+1} \colon H_{S_{n+1}} \longrightarrow G_{S_{n+1}}.$$

The morphism f'_{n+1} and the canonical immersion of $T_{S_{n+1}}$ into $G_{S_{n+1}}$ have the same restriction to T_{S_n}. By Exposé III, 2.5, there is an element $g \in G(S_{n+1})$ such that

$$g \times_{S_{n+1}} S_n = e$$

and such that

$$f_{n+1} = \mathrm{int}(g) \circ f'_{n+1}$$

restricts to $T_{S_{n+1}}$ by the canonical immersion. Let p_{n+1} be the restriction of f_{n+1} to $\mathbb{G}_{a,S_{n+1}}$. It is normalized by $T_{S_{n+1}}$, has multiplier $\alpha_{S_{n+1}}$, and extends p_n.

We have thus constructed a coherent system (f_n); it remains to algebraize it. For this we use:

Lemma 1.10. *Let A be a complete noetherian local ring, $\mathfrak{m}$ its maximal ideal,*

$$S = \mathrm{Spec}(A), \qquad S_n = \mathrm{Spec}(A/\mathfrak{m}^{n+1}),$$

let T be an S-torus, let α be a nonzero character of T, and let X be an affine S-scheme on which T acts. Let T act on $\mathbb{G}_{a,S}$ through α. Let $q \geq 0$, and let $(f_n)_{n\geq 0}$ be a coherent system of morphisms

$$f_n \colon \mathbb{G}_{a,S_n}^{q} \longrightarrow X_{S_n}$$

of objects with operators T_{S_n}. There exists a unique morphism of objects with operators T

$$f \colon \mathbb{G}_{a,S}^{q} \longrightarrow X$$

that induces the f_n (compare Exposé IX, 7.1).

Corollary 1.11. *If X is a group with operator group T, and if the f_n are group morphisms, then f is also a group morphism.*

Indeed, apply the uniqueness assertion of the lemma to the two morphisms $\mathbb{G}_{a,S}^{2q} \to X$ deduced from f in the usual way.

Proof of 1.10. Suppose that T is split, as it is in the application of 1.10 to the proof of 1.5. By Exposé I, 4.7.3.1, the functor

$$X \longmapsto \mathscr{A}(X)$$

defines an equivalence between the category of affine S-schemes equipped with an action of T and the category opposite to that of M-graded S-algebras, where

$$M = \mathrm{Hom}_{S\text{-gr.}}(T, \mathbb{G}_{m,S}).$$

Thus there are gradings

$$B = \mathscr{A}(X) = \bigoplus_{m\in M} B_m, \qquad C = \mathscr{A}(\mathbb{G}_{a,S}^{q}) = \bigoplus_{m\in M} C_m.$$

Each C_m is visibly a finite free A-module. Indeed, $C_m = 0$ if m is not a multiple of α, whereas, if $m = d\alpha$, then C_m is isomorphic to the A-module of homogeneous polynomials of degree d in q variables. Put

$$\widehat{B}_m = \varprojlim_n B_m \otimes_A (A/\mathfrak{m}^{n+1}),$$
$$\widehat{C}_m = \varprojlim_n C_m \otimes_A (A/\mathfrak{m}^{n+1}),$$
$$\widehat{B} = \bigoplus_{m\in M} \widehat{B}_m, \qquad \widehat{C} = \bigoplus_{m\in M} \widehat{C}_m.$$

There are canonical morphisms of M-graded algebras

$$g_B \colon B \longrightarrow \widehat{B}, \qquad g_C \colon C \longrightarrow \widehat{C}.$$

The preceding observation shows that g_C is an isomorphism. Giving a coherent system (f_n) as in the statement is equivalent to giving a morphism of graded A-algebras

$$\widehat{F} \colon \widehat{B} \longrightarrow \widehat{C}.$$

Finding a morphism f as in the statement is equivalent to finding a morphism of graded A-algebras $F\colon B \to C$ making the diagram

$$\begin{array}{ccc} B & \xrightarrow{F} & C \\ {\scriptstyle g_B}\downarrow & & \downarrow{\scriptstyle g_C} \\ \widehat{B} & \xrightarrow{\widehat{F}} & \widehat{C} \end{array}$$

commute. Since g_C is an isomorphism, the existence and uniqueness of F are immediate. This proves 1.10.

To complete the proof of 1.5, it remains only to prove 1.9.

1.12. Proof of 1.9. We have

$$\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{g}^{\alpha} \oplus \mathfrak{g}^{-\alpha}.$$

As explained in 1.9, regard $\mathfrak{g}$ as a $T \cdot_{\alpha} \mathbb{G}_{a,k}$-module. Clearly $\mathfrak{t} \oplus \mathfrak{g}^{\alpha}$ is a submodule of $\mathfrak{g}$, and the quotient is isomorphic to $\mathfrak{g}^{-\alpha}$ as a k-vector space and even as a T-module. The group $\mathbb{G}_{a,k}$ acts trivially on this one-dimensional quotient, since every group morphism $\mathbb{G}_{a,k} \to \mathbb{G}_{m,k}$ is trivial. Likewise, $\mathfrak{g}^{\alpha}$ is a submodule of $\mathfrak{t} \oplus \mathfrak{g}^{\alpha}$; the quotient is isomorphic to $\mathfrak{t}$ as a T-module, and $\mathbb{G}_{a,k}$ acts trivially on it. In summary:

Lemma 1.13. *Under the hypotheses of 1.9, $\mathfrak{g}$, as a $T \cdot_{\alpha} \mathbb{G}_{a,k}$-module, has a composition series whose successive quotients are*

$$\mathfrak{g}^{-\alpha}, \qquad \mathfrak{t}, \qquad \mathfrak{g}^{\alpha},$$

regarded as $T \cdot_{\alpha} \mathbb{G}_{a,k}$-modules through the projection $T \cdot_{\alpha} \mathbb{G}_{a,k} \to T$.

We are thus reduced to computing the cohomology of $T \cdot_{\alpha} \mathbb{G}_{a,k}$ acting on $W(k)$ through the projection $T \cdot_{\alpha} \mathbb{G}_{a,k} \to T$ and a character β of T (here $\beta = 0, \alpha$, or $-\alpha$). [5] Write $k[x_1, \ldots, x_n]$ for the polynomial algebra over k in n variables, and $k_q[x_1, \ldots, x_n]$ for its subspace of homogeneous polynomials of degree q.

Lemma 1.14. *With the preceding notation,*

$$\mathrm{H}^n(T \cdot_{\alpha} \mathbb{G}_{a,k}, k) = \mathrm{H}^n(C^*_{\alpha,\beta}),$$

where the complex $C^*_{\alpha,\beta}$ is defined by

$$C^n_{\alpha,\beta} = \begin{cases} k_q[x_1, \ldots, x_n], & \text{if } \beta = q\alpha, \text{ with } q \in \mathbb{N}^*, \\ 0, & \text{otherwise,} \end{cases}$$

and

$$\begin{aligned} (\delta f)(x_1, x_2, \ldots, x_{n+1}) = {} & f(x_2, \ldots, x_{n+1}) \\ & + \sum_{i=1}^{n} (-1)^i f(x_1, \ldots, x_i x_{i+1}, \ldots, x_{n+1}) \\ & + (-1)^{n+1} f(x_1, \ldots, x_n). \end{aligned}$$

[5] The editors added the sentence that follows.

Indeed, by Exposé I, 5.3.2, the functor $M \mapsto \mathrm{H}^0(T, M)$ is exact on the category of T-modules, and the $\mathrm{H}^q(T, -)$ vanish. It follows, as in the usual theory of group cohomology, that $\mathrm{H}^n(T \cdot_\alpha \mathbb{G}_{a,k}, k)$ may be computed as the n-th cohomology group of the complex of cochains of $\mathbb{G}_{a,k}$ in k that are invariant under T, that is, those satisfying

$$f(\alpha(t)x_1, \ldots, \alpha(t)x_n) = \beta(t)f(x_1, \ldots, x_n).$$

This is precisely the complex just displayed.

To prove 1.9, it is therefore enough to show that $\mathrm{H}^2(C^*_{\alpha,\beta}) = 0$ for $\beta = 0, \alpha, -\alpha$, which is immediate.

Remark 1.15. The groups $\mathrm{H}^n(C^*_{\alpha,\beta})$ can be computed explicitly when $\beta = q\alpha$; see M. Lazard, *Lois de groupes et analyseurs*, Annales E.N.S., 1955. In particular,

$$\mathrm{H}^n(C^*_{\alpha,q\alpha}) = 0 \qquad \text{for } n > q.$$

Notations 1.16. The image of the canonical immersion

$$W(\mathfrak{g}^{-\alpha}) \times_S T \times_S W(\mathfrak{g}^{\alpha}) \longrightarrow G$$

will be denoted by Ω. It is an open subset of G containing the identity section. The images of

$$W(\mathfrak{g}^{-\alpha}), \qquad W(\mathfrak{g}^{\alpha}), \qquad W(\mathfrak{g}^{-\alpha}) \times_S T, \qquad T \times_S W(\mathfrak{g}^{\alpha})$$

will be denoted, respectively,[6]

$$U_{-\alpha}, \qquad U_{\alpha}, \qquad U_{-\alpha} \cdot T, \qquad T \cdot U_{\alpha}.$$

Then U_α (respectively $U_{-\alpha}$) is a subgroup of G, canonically endowed with a vector-bundle structure, and

$$\mathrm{int}(t)(x) = x^{\alpha(t)} \qquad (\text{respectively } x^{-\alpha(t)})$$

for every $S' \to S$, $t \in T(S')$, and $x \in U_\alpha(S')$ (respectively $x \in U_{-\alpha}(S')$).

There are canonical isomorphisms

$$T \cdot U_\alpha \simeq T \cdot_\alpha U_\alpha, \qquad T \cdot U_{-\alpha} \simeq T \cdot_{-\alpha} U_{-\alpha}.$$

The open subset Ω is stable under $\mathrm{int}(T)$, and

$$\mathrm{int}(t')(y \cdot t \cdot x) = y^{-\alpha(t')} \cdot t \cdot x^{\alpha(t')}.$$

Corollary 1.17. *We have*

$$\mathrm{Lie}(U_\alpha/S) = \mathfrak{g}^{\alpha}, \qquad \mathrm{Lie}(U_{-\alpha}/S) = \mathfrak{g}^{-\alpha}.$$

The isomorphisms

$$W(\mathfrak{g}^{\alpha}) \xrightarrow[\sim]{\exp} U_\alpha, \qquad W(\mathfrak{g}^{-\alpha}) \xrightarrow[\sim]{\exp} U_{-\alpha}$$

are those of Exposé XIX, 4.2.

Corollary 1.18. *The open subset Ω is relatively schematically dense in G* (cf. Exposé XVIII, §1).

This follows immediately from Exposé XVIII, 1.3.[7]

[6] The editors replaced $P_{-\alpha}$ and P_α by $U_{-\alpha}$ and U_α.

[7] See also EGA IV$_3$, 11.10.10.

Corollary 1.19. *The center of G is*

$$\mathrm{Centr}(G) = \mathrm{Ker}(\alpha).$$

It is therefore a closed subgroup of G, of multiplicative type and of finite type.

The second assertion follows from the first by Exposé IX, 2.7. Let us prove the first. The inner automorphism defined by a section of $\mathrm{Ker}(\alpha)$ acts trivially on Ω, by the last formula of 1.16, and hence on G, by 1.18. Conversely, if $g \in G(S)$ centralizes G, then it centralizes T and U_α. It is therefore a section of T, by Exposé XIX, 2.8, and annihilates α. Since the same argument applies after every base change, we indeed have $\mathrm{Centr}(G) = \mathrm{Ker}(\alpha)$.

Corollary 1.20. *A monomorphism*

$$p_\alpha \colon \mathbb{G}_{a,S} \longrightarrow G$$

normalized by T, with multiplier α, exists if and only if the $\mathscr{O}_S$-module $\mathfrak{g}^\alpha$ is free. More precisely, the assignments

$$X_\alpha \longmapsto (x \longmapsto \exp(xX_\alpha)), \qquad p_\alpha \longmapsto \mathrm{Lie}(p_\alpha)$$

give a bijection between $\Gamma(S, \mathfrak{g}^\alpha)^\times$ and the set of such monomorphisms p_α, which is also the set of isomorphisms of vector group schemes

$$\mathbb{G}_{a,S} \xrightarrow{\sim} U_\alpha.$$

8

Corollary 1.21. *The subgroups U_α and $U_{-\alpha}$ of G commute on no fiber.*

Indeed, if $(U_\alpha)_s$ and $(U_{-\alpha})_s$ commute, then Ω_s is a subgroup of G_s, and hence $\Omega_s = G_s$.[9] It follows that G_s is solvable, contrary to the hypothesis that G_s is reductive of semisimple rank 1.

0.2 Structure of elementary systems

Theorem 2.1. *Let S be a scheme and (G, T, α) an S-elementary system. There exist a morphism of $\mathscr{O}_S$-modules*

$$\mathfrak{g}^\alpha \otimes_{\mathscr{O}_S} \mathfrak{g}^{-\alpha} \longrightarrow \mathscr{O}_S, \qquad (X, Y) \longmapsto \langle X, Y \rangle,$$

and a morphism of S-groups

$$\alpha^* \colon \mathbb{G}_{m,S} \longrightarrow T$$

such that, for every $S' \to S$ and all

$$X \in \Gamma\big(S', \mathfrak{g}^\alpha \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}\big), \qquad Y \in \Gamma\big(S', \mathfrak{g}^{-\alpha} \otimes_{\mathscr{O}_S} \mathscr{O}_{S'}\big),$$

one has

$$\exp(X) \cdot \exp(Y) \in \Omega(S') \quad \Longleftrightarrow \quad 1 + \langle X, Y \rangle \in \mathbb{G}_m(S').$$

[8] Indeed, $\mathrm{Lie}(\mathbb{G}_{a,S}) = \mathscr{O}_S$, and $\mathrm{Lie}(p_\alpha)$ is an element of $\mathrm{Hom}_{\mathscr{O}_S}(\mathscr{O}_S, \mathfrak{g}^\alpha) = \Gamma(S, \mathfrak{g}^\alpha)$.

[9] By 1.18.

Under these conditions,

$$\text{(F)} \qquad \exp(X)\cdot\exp(Y) = \exp\left(\frac{Y}{1+\langle X,Y\rangle}\right)\alpha^*(1+\langle X,Y\rangle)\exp\left(\frac{X}{1+\langle X,Y\rangle}\right).$$

Moreover, the morphisms $(X,Y)\mapsto\langle X,Y\rangle$ and α^* are uniquely determined. The first is an isomorphism, and therefore places $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ in duality; furthermore,

$$\alpha\circ\alpha^* = 2,$$

where 2 denotes squaring on $\mathbb{G}_{m,S}$.

In view of the uniqueness assertions, it is enough to prove the theorem locally on S. We may therefore assume that $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ are free on S. Choose

$$X\in\Gamma(S,\mathfrak{g}^\alpha)^\times, \qquad Y\in\Gamma(S,\mathfrak{g}^{-\alpha})^\times,$$

and put

$$p_\alpha(x)=\exp(xX), \qquad p_{-\alpha}(y)=\exp(yY)$$

for $x,y\in\mathbb{G}_a(S')$, $S'\to S$. By 1.5 and 1.21, it is enough to prove the following proposition.

Proposition 2.2. *Let S be a scheme, G an S-group, T a torus of G, and α a character of T that is nontrivial on every fiber. Let*

$$p_\alpha\colon\mathbb{G}_{a,S}\longrightarrow G, \qquad p_{-\alpha}\colon\mathbb{G}_{a,S}\longrightarrow G$$

be group monomorphisms normalized by T, with multipliers α and $-\alpha$, respectively. Suppose that:

(i) *the morphism*

$$\mathbb{G}_{a,S}\times_S T\times_S\mathbb{G}_{a,S}\longrightarrow G, \qquad (y,t,x)\longmapsto p_{-\alpha}(y)\,t\,p_\alpha(x),$$

is an open immersion; denote its image by Ω;

(ii) *for every $s\in S$, the groups*

$$(p_\alpha)_s(\mathbb{G}_{a,\kappa(s)}) \quad\text{and}\quad (p_{-\alpha})_s(\mathbb{G}_{a,\kappa(s)})$$

do not commute.

Then there exist unique elements

$$a\in\mathbb{G}_a(S), \qquad \alpha^*\in\mathrm{Hom}_{S\text{-gr.}}(\mathbb{G}_{m,S},T)$$

with the following properties: for every $S'\to S$ and all $x,y\in\mathbb{G}_a(S')$,

$$p_\alpha(x)p_{-\alpha}(y)\in\Omega(S') \iff 1+axy\in\mathbb{G}_m(S'),$$

and, under this condition,

$$p_\alpha(x)p_{-\alpha}(y)=p_{-\alpha}\left(\frac{y}{1+axy}\right)\alpha^*(1+axy)p_\alpha\left(\frac{x}{1+axy}\right).$$

Moreover, a is invertible, that is, $a \in \mathbb{G}_m(S)$, and $\alpha \circ \alpha^* = 2$.

Proof. A) Consider the morphism

$$\mathbb{G}_{a,S}^2 \longrightarrow G, \qquad (x, y) \longmapsto p_\alpha(x)p_{-\alpha}(y).$$

Let U be the inverse image of Ω. It is an open subset of $\mathbb{G}_{a,S}^2$ containing $0 \times_S \mathbb{G}_{a,S}$ and $\mathbb{G}_{a,S} \times_S 0$. There are therefore unique morphisms of S-schemes

$$A\colon U \longrightarrow \mathbb{G}_{a,S}, \qquad C\colon U \longrightarrow \mathbb{G}_{a,S}, \qquad B\colon U \longrightarrow T$$

satisfying the set-theoretic identity

$$p_\alpha(u)p_{-\alpha}(v) = p_{-\alpha}(A(u, v))\, B(u, v)\, p_\alpha(C(u, v)).$$

Immediately,

$$A(0, v) = v, \qquad A(u, 0) = 0, \qquad C(u, 0) = u, \qquad C(0, v) = 0,$$
$$B(u, 0) = B(0, v) = e.$$

Let S' be a separated S-scheme and let $t \in T(S')$. Since $\Omega_{S'}$ is stable under $\mathrm{int}(t)$, the last formula of 1.16 shows that $U_{S'}$ is stable under the automorphism

$$(x, y) \longmapsto (\alpha(t)x, \alpha(t)^{-1}y)$$

of $\mathbb{G}_{a,S'}^2$, and

$$A(\alpha(t)u, \alpha(t)^{-1}v) = \alpha(t)^{-1}A(u, v),$$
$$C(\alpha(t)u, \alpha(t)^{-1}v) = \alpha(t)C(u, v),$$
$$B(\alpha(t)u, \alpha(t)^{-1}v) = B(u, v).$$

Because α is faithfully flat, it follows that for every $S' \to S$ and every $z \in \mathbb{G}_m(S')$, the open subset $U_{S'}$ is stable under $(x, y) \mapsto (zx, z^{-1}y)$, and

$$A(zu, z^{-1}v) = z^{-1}A(u, v),$$
$$C(zu, z^{-1}v) = zC(u, v),$$
$$B(zu, z^{-1}v) = B(u, v).$$

Suppose first that v is invertible. Taking $z = v$, we see that if (u, v) is a section of U, then $(uv, 1)$ is also a section of U, and

$$A(uv, 1) = v^{-1}A(u, v), \qquad B(uv, 1) = B(u, v).$$

Let V be the open subset of $\mathbb{G}_{a,S}^2$ defined by[10]

$$(u, v) \in V(S') \iff (u, v),\ (uv, 1),\ \text{and } (1, uv) \text{ belong to } U(S').$$

Since U contains $0 \times_S \mathbb{G}_{a,S}$ and $\mathbb{G}_{a,S} \times_S 0$, the open subset V is a neighborhood of the zero section of $\mathbb{G}_{a,S}^2$. The preceding calculation shows that, on $V \cap (\mathbb{G}_{a,S} \times_S \mathbb{G}_{m,S})$, the two morphisms

$$(u, v) \longmapsto A(u, v), \qquad (u, v) \longmapsto vA(uv, 1)$$

[10]The editors added the condition "$(1, uv) \in U(S')$".

coincide, as do

$$(u,v) \longmapsto B(u,v), \qquad (u,v) \longmapsto B(uv,1).$$

Since $\mathbb{G}_{a,S} \times_S \mathbb{G}_{m,S}$ is schematically dense in $\mathbb{G}_{a,S}^2$, these morphisms coincide on V.

We have $A(0,1) = 1$. Hence there is an open subset W_1 of $\mathbb{G}_{a,S}$, containing the zero section, such that $A(x,1)$ is invertible for every section x of W_1. Put

$$A(x,1)^{-1} = F(x).$$

If $(u,v) \in V(S')$[11] and $uv \in W_1(S')$, then

$$A(u,v) = vA(uv,1) = vF(uv)^{-1}.$$

The same argument applied to C gives an open subset W_2 of $\mathbb{G}_{a,S}$, containing the zero section, and an element $E \in \mathscr{O}(W_2)^{\times}$[12] such that

$$C(u,v) = uC(1,uv) = uE(uv)^{-1}$$

whenever $(u,v) \in V(S')$ and $uv \in W_2(S')$.

Consequently, with $W = W_1 \cap W_2$, there are S-morphisms

$$\begin{aligned} &F\colon W \to \mathbb{G}_{m,S}, && F(0) = 1,\\ &H\colon W \to T, && H(0) = e,\\ &E\colon W \to \mathbb{G}_{m,S}, && E(0) = 1, \end{aligned}$$

such that, if $(u,v) \in V(S')$ and $uv \in W(S')$, then

$$(+) \qquad p_\alpha(u)p_{-\alpha}(v) = p_{-\alpha}\big(vF(uv)^{-1}\big)\, H(uv)\, p_\alpha\big(uE(uv)^{-1}\big).$$

B) We now use the associativity of G to write

$$p_\alpha(u)p_{-\alpha}(v)p_{-\alpha}(w) = p_\alpha(u)p_{-\alpha}(v+w).$$

There is an open subset L of $\mathbb{G}_{a,S}^3$, containing the zero section, such that $(u,v,w) \in L(S')$ is equivalent to

$$\begin{aligned} &(u,v) \in V(S'), \qquad \big(uE(uv)^{-1}, w\big) \in V(S'), \qquad (u, v+w) \in V(S'),\\ &uv \in W(S'), \qquad uwE(uv)^{-1} \in W(S'), \qquad u(v+w) \in W(S'). \end{aligned}$$

Using formula $(+)$, we immediately obtain, for $(u,v,w) \in L(S')$,

$$(1) \qquad E(uv+uw) = E\big(uwE(uv)^{-1}\big)E(uv),$$

$$(2) \qquad H(uv+uw) = H\big(uwE(uv)^{-1}\big)H(uv),$$

and

$$(3) \qquad \begin{aligned} (v+w)F(uv+uw)^{-1} = {}& \alpha\big(H(uv)^{-1}\big)\, wF\big(uwE(uv)^{-1}\big)^{-1}\\ &+ vF(uv)^{-1}. \end{aligned}$$

[11] Here and below, the editors replaced $U(S')$ by $V(S')$.

[12] The editors use E for the element denoted G in the original, since G already denotes the S-group under consideration.

It follows immediately from the definition of L that $(1,0,0) \in L(S)$. Consider therefore

$$L \cap_T \left(1 \times_S \mathbb{G}_{a,S} \times_S \mathbb{G}_{a,S}\right) = 1 \times_S M.$$

The scheme M is an open subset of $\mathbb{G}_{a,S}^2$ containing the section $(0,0)$. For $(v,w) \in M(S')$, the elements

$$v, \qquad wE(v)^{-1}, \qquad v+w$$

belong to $W(S')$, and

(1') $$E(v+w) = E\big(wE(v)^{-1}\big)E(v),$$

(2') $$H(v+w) = H\big(wE(v)^{-1}\big)H(v),$$

(3') $$\begin{aligned}(v+w)F(v+w)^{-1} = \alpha\big(H(v)\big)^{-1} wF\big(wE(v)^{-1}\big)^{-1} \\ + vF(v)^{-1}.\end{aligned}$$

Finally, consider the morphism from M to $\mathbb{G}_{a,S}^2$ defined set-theoretically by

$$(v,w) \longmapsto \big(v, wE(v)^{-1}\big).$$

[13] It preserves the section $(0,0)$ and induces an isomorphism of M onto an open subset N of $\mathbb{G}_{a,S}^2$ containing the zero section; the inverse isomorphism is

$$(x,y) \longmapsto \big(x, yE(x)\big).$$

[14] We have therefore proved the following assertion:

There is an open subset N of $\mathbb{G}_{a,S}^2$, containing the zero section, such that, if $(x,y) \in N(S')$, then x, y, and $x + yE(x)$[15] belong to $W(S')$, and

(1") $$E\big(x+yE(x)\big) = E(x)E(y),$$

(2") $$H\big(x+yE(x)\big) = H(x)H(y),$$

(3") $$\begin{aligned}\big(x+yE(x)\big)F\big(x+yE(x)\big)^{-1} = xF(x)^{-1} \\ + \alpha\big(H(x)\big)^{-1} yE(x)F(y)^{-1}.\end{aligned}$$

C) Arguing in the same way with left associativity, we obtain the following assertion.[16]

There is an open subset N' of $\mathbb{G}_{a,S}^2$, containing the zero section, such that, if $(x,y) \in N'(S')$, then x, y, and $x + yF(x)$[17] belong to $W(S')$, and

(4") $$F\big(x+yF(x)\big) = F(x)F(y),$$

[13] The editors corrected what follows.

[14] Thus the editors made the change of variables $x = v,\ y = wE(v)^{-1}$, or equivalently $v = x,\ w = yE(x)$.

[15] The editors corrected $yE(x)$ to $x + yE(x)$.

[16] That is, one writes the equalities resulting from $p_\alpha(t)p_\alpha(u)p_{-\alpha}(v) = p_\alpha(t+u)p_{-\alpha}(v)$, and sets $v = 1,\ x = u,\ t = yF(u)$, or equivalently $y = tF(u)^{-1}$.

[17] The editors corrected $yF(x)$ to $x + yF(x)$.

(5") $$H\big(x+yF(x)\big) = H(x)H(y),$$

(6") $$\big(x+yF(x)\big)E\big(x+yF(x)\big)^{-1} = xE(x)^{-1} + \alpha\big(H(x)\big)^{-1}yF(x)E(y)^{-1}.$$

We are thus led to solve the "functional equation" $(1'')$.

Lemma 2.3. *Let S be a scheme, let W be an open subset of $\mathbb{G}_{a,S}$ containing the zero section, and let*

$$F\colon W \longrightarrow \mathbb{G}_{m,S}$$

be an S-morphism. Suppose that $F(0) = 1$ and that there is an open subset N of $\mathbb{G}_{a,S}^2$, containing the zero section, such that, for $(x,y) \in N(S')$, the elements x, y, and $x+yF(x)$ belong to $W(S')$, and

(†) $$F\big(x+yF(x)\big) = F(x)F(y).$$

(i) *If $S = \mathrm{Spec}(k)$ for a field k, there is an $a \in k$ such that $F(x) = 1+ax$.*

(ii) *If $a = F'(0) \in \Gamma(S, \mathscr{O}_S)$ is invertible, then $F(x) = 1+ax$.*

Proof. Under the hypotheses, we may differentiate the given equation at $x = 0$, respectively at $y = 0$, and obtain

(∗) $$F'(y)\big(1+yF'(0)\big) = F'(0)F(y) \qquad \text{for } (0,y) \in N(S'),$$

respectively

$$F'(x)F(x) = F(x)F'(0) \qquad \text{for } (x,0) \in N(S').$$

Since F takes its values in $\mathbb{G}_m$, the second relation gives

(∗′) $$F'(x) = F'(0) \qquad \text{for } (x,0) \in N(S').$$

The first relation therefore gives

$$F'(0)\big(1+yF'(0)\big) = F'(0)F(y) \qquad \text{for } (y,0),(0,y) \in N(S').$$

If $a = F'(0)$ is invertible, it follows that

$$F(y) = 1+ay$$

for y a section of an open subset of W containing the zero section, hence schematically dense in W. This proves (ii), and also proves (i) when $F'(0) \neq 0$.

Suppose $F'(0) = 0$. Then (∗′) shows that $F'(x) = 0$ for x near 0, and hence $F' = 0$ by schematic density. If k has characteristic zero, F is a rational function with zero derivative, and is therefore constant and equal to $F(0) = 1$.

Suppose now that k has characteristic p, and that F is not constant.[18] There are an integer $n > 0$ and a rational function $F_1 \in k(X)$ such that $F_1'(X) \neq 0$ and

$$F(X) = F_1\big(X^{p^n}\big) = F_1(X)^{p^n}.$$

[18]The editors corrected what follows.

Substitution in the functional equation gives

$$(\dagger_1) \qquad F_1(x + yF_1(x)^{p^n}) = F_1(x)F_1(y).$$

Differentiating at $x = 0$ gives

$$(*_1) \qquad F_1'(y) = F_1'(0)F_1(y),$$

whereas differentiation of $(\dagger_1)$ at $y = 0$ gives

$$(*_1') \qquad F_1'(x)F_1(x)^{p^n} = F_1(x)F_1'(0).$$

By hypothesis, $F_1'(X)$ is invertible in $k(X)$; these two equalities therefore imply

$$F_1(X)^{p^n} = 1.$$

Thus F_1 is constant, contrary to the choice of F_1. Consequently F is constant and equal to $1 = F(0)$. □

D) Suppose first that S is the spectrum of a field. If $F'(0) = 0$, then $F = 1$. Formula $(5'')$ then gives

$$H(x + y) = H(x)H(y),$$

which shows that H extends to a group morphism

$$\mathbb{G}_{a,S} \longrightarrow T$$

(Exposé XVIII, 2.3), necessarily the constant morphism with value e. On the other hand, Lemma 2.3 also gives

$$E(x) = 1 + bx$$

for some $b \in k$. Formula $(6'')$ therefore gives, for $(x, y) \in N(S')$,

$$(x + y)E(x + y)^{-1} = xE(x)^{-1} + yE(y)^{-1}.$$

Thus,[19] again by Exposé XVIII, 2.3, the map

$$x \longmapsto xE(x)^{-1}$$

extends to a morphism of k-groups $\mathbb{G}_{a,k} \to \mathbb{G}_{a,k}$. Consequently

$$\frac{x}{1 + bx} = cx$$

for some $c \in k$, whence $b = 0$ and $c = 1$.

Thus F, H, E are constant with values $(1, e, 1)$ in a neighborhood of the zero section, and hence everywhere. Formula $(+)$ then shows that U_α and $U_{-\alpha}$ commute, contrary to hypothesis (ii).

For arbitrary S, we have therefore proved that $F'(0)$ is nonzero on every fiber, and hence invertible. The same is plainly true of $E'(0)$. Lemma 2.3 now shows that there are $a, b \in \mathbb{G}_m(S)$ such that

$$(\diamondsuit_1) \qquad F(x) = 1 + ax, \qquad E(x) = 1 + bx \qquad \text{for } x \in W(S').$$

[19] The editors added the sentence that follows. One may also see by direct calculation that the preceding equality implies $0 = xyb\big(2 + (x + y)b\big)$, hence $0 = b\big(2 + (x + y)b\big)$, and finally $b = 0$.

E) The rest is now easy. Substitution of the preceding results in $(3'')$ gives

$$y\,\alpha\big(H(x)\big)(1+ay) = y\big(1+ax+ay(1+bx)\big)(1+ax).$$

This formula holds for every section (x,y) of N. Since $\mathbb{G}_{a,S}\times_S\mathbb{G}_{m,S}$ is schematically dense in $\mathbb{G}_{a,S}^2$, it follows that

$$(1+ay)\alpha\big(H(x)\big) = \big(1+ax+ay(1+bx)\big)(1+ax).$$

Setting $y=0$ gives

$$\alpha\big(H(x)\big) = (1+ax)^2.$$

Substitution in the preceding equality gives[20]

$$a^2xy = abxy.$$

Since $\mathbb{G}_{m,S}$ is schematically dense in $\mathbb{G}_{a,S}$, we obtain $a^2=ab$. As a is invertible,

$$(\diamondsuit_2) \qquad a=b, \qquad \alpha\big(H(x)\big) = (1+ax)^2.$$

Because a is invertible, the map $x\mapsto 1+ax$ is an automorphism of $\mathbb{G}_{a,S}$. There are therefore an open subset W' of $\mathbb{G}_{a,S}$, containing the section 1, and a morphism

$$P\colon W' \longrightarrow T$$

such that

$$P(1+ax) = H(x).$$

[21] Substitution in $(2')$ gives immediately, for $(x,y)\in N(S')$,

$$P(1+ax+ay) = P\left(\frac{1+ax+ay}{1+ax}\right)P(1+ax).$$

Thus there is an open neighborhood of 1 in $\mathbb{G}_{m,S}$ on which

$$P(x)P(y) = P(xy).$$

By Exposé XVIII, 2.3, there is a group morphism

$$(\diamondsuit_3) \qquad \alpha^*\colon \mathbb{G}_{m,S} \longrightarrow T$$

extending P. Since $\alpha(H(x)) = (1+ax)^2$ near the zero section, we have $\alpha(\alpha^*(z)) = z^2$ near the section 1, and hence

$$(\diamondsuit_4) \qquad \alpha\circ\alpha^* = 2.$$

F)[22] Combining $(+)$ and $(\diamondsuit_1)$–$(\diamondsuit_4)$, we see that there are

$$a\in\mathbb{G}_m(S), \qquad \alpha^*\in \mathrm{Hom}_{S\text{-gr.}}(\mathbb{G}_{m,S},T)$$

[20] In the three preceding equalities, the editors corrected the original by replacing the factor $1+bx$ on the right by $1+ax$. Substitution of the third equality in the second, and use of the invertibility of $1+ax$, gives precisely $a^2xy=abxy$.

[21] This is the change of variables $x'=1+ax$, or $x=(x'-1)/a$.

[22] The editors slightly modified what follows, since an open subset V had already been introduced in part A.

such that $\alpha \circ \alpha^* = 2$, and such that, whenever $(u, v) \in V(S')$ and $uv \in W(S')$, the element $1 + auv$ is invertible and

$$p_\alpha(u)p_{-\alpha}(v) = p_{-\alpha}\left(\frac{v}{1+auv}\right)\alpha^*(1+auv)p_\alpha\left(\frac{u}{1+auv}\right).$$

Let V' be the open subset of $\mathbb{G}_{a,S}^2$ defined by the invertibility of $1 + auv$; thus

$$V' = \left(\mathbb{G}_{a,S}^2\right)_f, \qquad f(u,v) = 1 + auv.$$

The two sides of the preceding formula define morphisms $V' \to G$ which agree in a neighborhood of the zero section, and hence agree on V'. Thus the formula holds for every section (u, v) of V', and in particular $V' \subset U$, where U is the open subset introduced at the beginning of part A.

We prove that $U = V'$. Returning to the notation of part A, there is a morphism

$$A\colon U \longrightarrow \mathbb{G}_{a,S}$$

whose restriction to V' is

$$A(u,v) = v(1+auv)^{-1}.$$

The equality $U = V'$ is a set-theoretic question and may therefore be checked when $S = \mathrm{Spec}(k)$ for a field k. It then reduces to the evident assertion that the domain of definition of the rational map

$$\mathbb{G}_{a,k}^2 \dashrightarrow \mathbb{G}_{a,k}, \qquad (X,Y) \longmapsto \frac{Y}{1+aXY},$$

is the open subset defined by $1 + aXY$.

G) We have proved the existence of a and α^*, as well as the two asserted supplementary properties. It remains to prove uniqueness. Let a' and $\alpha^{*\prime}$ also satisfy the required conditions. For $u, v \in \mathbb{G}_a(S')$, we immediately have

$$1 + auv \text{ invertible} \implies 1 + a'uv \text{ invertible},$$
$$\frac{v}{1+auv} = \frac{v}{1+a'uv}.$$

Hence, for every $u \in \mathbb{G}_a(S')$,

$$1 + au \text{ invertible} \implies 1 + au = 1 + a'u,$$

which proves $a = a'$. With the same notation,

$$1 + au \text{ invertible} \implies \alpha^*(1+au) = \alpha^{*\prime}(1+au),$$

and therefore $\alpha^* = \alpha^{*\prime}$. □

Corollary 2.4. *Let*

$$\exp(Y)t\exp(X) \quad \text{and} \quad \exp(Y')t'\exp(X')$$

be two elements of $\Omega(S')$. *Their product belongs to* $\Omega(S')$ *if and only if*

$$u = 1 + \langle X, Y' \rangle$$

is invertible; in that case,

(F') $$\begin{aligned}&\exp(Y)t\exp(X)\cdot\exp(Y')t'\exp(X')\\ &\quad= \exp\bigl(Y + u^{-1}\alpha(t)^{-1}Y'\bigr)\,tt'\alpha^*(u)\,\exp\bigl(u^{-1}\alpha(t')^{-1}X + X'\bigr).\end{aligned}$$

Remark 2.5. *Formula* (F) *of Theorem 2.1 may also be written without using the morphisms* exp. *Transporting the duality* $\mathfrak{g}_\alpha \otimes \mathfrak{g}_{-\alpha} \to \mathscr{O}_S$ *through those morphisms gives a canonical pairing of vector bundles*

$$U_\alpha \times_S U_{-\alpha} \longrightarrow \mathbb{G}_{a,S},$$

which we continue to denote by $(x, y) \mapsto \langle x, y\rangle$. *Thus*

$$\langle \exp X, \exp Y\rangle = \langle X, Y\rangle.$$

If $x \in U_\alpha(S')$, $y \in U_{-\alpha}(S')$, *and* $1 + \langle x, y\rangle \in \mathbb{G}_m(S')$, *then*

$$x \cdot y = y^{(1+\langle x,y\rangle)^{-1}}\, \alpha^*\big(1 + \langle x, y\rangle\big)\, x^{(1+\langle x,y\rangle)^{-1}}.$$

Corollary 2.6. *The pairing*

$$W(\mathfrak{g}_\alpha) \times_S W(\mathfrak{g}_{-\alpha}) \longrightarrow \mathbb{G}_{a,S}$$

induces a pairing of principal $\mathbb{G}_{m,S}$*-bundles*

$$W(\mathfrak{g}_\alpha)^\times \times_S W(\mathfrak{g}_{-\alpha})^\times \longrightarrow \mathbb{G}_{m,S}.$$

We denote this pairing by $(X, Y) \mapsto \langle X, Y\rangle$, *or simply* $(X, Y) \mapsto XY$.

For every $X \in \Gamma(S, \mathfrak{g}_\alpha)^\times$, there is therefore a unique

$$X^{-1} \in \Gamma(S, \mathfrak{g}_{-\alpha})^\times$$

such that $XX^{-1} = 1$. Moreover,

$$(zX)^{-1} = z^{-1}X^{-1}.$$

The morphism

$$s\colon W(\mathfrak{g}_\alpha)^\times \longrightarrow W(\mathfrak{g}_{-\alpha})^\times$$

so defined is an isomorphism of schemes, compatible with the isomorphism $s\colon z \mapsto z^{-1}$ of their operator groups.

Definition 2.6.1. *The elements* X *and* $s(X) = X^{-1}$ *are said to be paired.*

Apply Corollary 2.4 with $Y = 0 = X'$ and

$$Y' = aX^{-1}, \qquad a \in \mathscr{O}_S(S).$$

Then $u = 1 + a$, and

$$u^{-1}Y' = u^{-1}(u-1)X^{-1} = (1 - u^{-1})X^{-1}.$$

Hence:

Corollary 2.7. *Let* $X \in \Gamma(S, \mathfrak{g}_\alpha)^\times$ *and* $u \in \Gamma(S, \mathscr{O}_S)^\times$. *Then*

$$\alpha^*(u) = \exp\big((u^{-1} - 1)X^{-1}\big)\, \exp(X)\, \exp\big((u-1)X^{-1}\big)\, \exp(-u^{-1}X).$$

Definition 2.8. *The morphism* α^* *is called the coroot associated with the root* α.

Remark 2.9. *If (G,T,α) is an S-elementary system, then so is $(G,T,-\alpha)$. Theorem 2.1 therefore gives a duality between $\mathfrak{g}_{-\alpha}$ and $\mathfrak{g}_\alpha$, and a coroot $(-\alpha)^*$. Taking the inverse of formula* (F) *gives immediately*

$$\langle X,Y\rangle = \langle Y,X\rangle, \qquad (-\alpha)^* = -\alpha^*.$$

We now pass to the Lie algebra of G. The root α and the coroot α^* define linear forms

$$\mathscr{O}_S \xrightarrow{\overline{\alpha^*}} \mathfrak{t} \xrightarrow{\bar\alpha} \mathscr{O}_S.$$

Put

$$H_\alpha = \overline{\alpha^*}(1).$$

We call $\bar\alpha$ the infinitesimal root associated with α, and H_α the corresponding infinitesimal coroot.

Lemma 2.10. *Let $S' \to S$, and let*

$$X, X' \in W(\mathfrak{g}_\alpha)(S'), \qquad H \in W(\mathfrak{t})(S'), \qquad Y, Y' \in W(\mathfrak{g}_{-\alpha})(S'), \qquad t \in T(S').$$

Then

(1) $$\mathrm{Ad}(t)H = H, \qquad \mathrm{Ad}(t)X = \alpha(t)X, \qquad \mathrm{Ad}(t)Y = \alpha(t)^{-1}Y;$$

(2) $$\begin{aligned} &\mathrm{Ad}(\exp X)H = H - \bar\alpha(H)X, && \mathrm{Ad}(\exp X)X' = X', \\ &\mathrm{Ad}(\exp X)Y = Y + \langle X,Y\rangle H_\alpha - \langle X,Y\rangle X; \end{aligned}$$

(2') $$\begin{aligned} &\mathrm{Ad}(\exp Y)H = H + \bar\alpha(H)Y, && \mathrm{Ad}(\exp Y)Y' = Y', \\ &\mathrm{Ad}(\exp Y)X = X + \langle X,Y\rangle H_{-\alpha} - \langle X,Y\rangle Y; \end{aligned}$$

(3) $$\begin{aligned} [H,X] = \bar\alpha(H)X, \qquad [H,Y] = -\bar\alpha(H)Y, \\ [X,Y] = \langle X,Y\rangle H_\alpha; \end{aligned}$$

(4) $$H_{-\alpha} = -H_\alpha,$$

(5) $$\bar\alpha(H_\alpha) = 2.$$

The proof of these formulas is either immediate or an immediate consequence of formula (F) of 2.1.

Corollary 2.11. *Suppose that H_α is nonzero on every fiber; by* (5)*, this holds in particular if* 2 *is invertible on S. Then*

$$X_\alpha \in \Gamma(S,\mathfrak{g}_\alpha)^\times, \qquad X_{-\alpha} \in \Gamma(S,\mathfrak{g}_{-\alpha})^\times$$

are paired if and only if

$$[X_\alpha, X_{-\alpha}] = H_\alpha.$$

2.12. Let (G, T, α) be an S-elementary system. By 1.19,

$$\mathrm{Centr}(G) = \ker(\alpha)$$

is a group of multiplicative type and finite type. If Q is a subgroup of multiplicative type of $\mathrm{Centr}(G)$, then G/Q is affine over S (Exposé IX, 2.5), smooth over S (Exposé $\mathrm{VI_B}$, 9.2), and has connected reductive fibers of semisimple rank 1 (Exposé XIX, 1.8).

Put $G' = G/Q$. It is a reductive S-group of semisimple rank 1, and $T' = T/Q$ is a maximal torus of G'. The open subset

$$U_{-\alpha} \cdot T \cdot U_\alpha$$

of G is stable under Q, and its quotient is isomorphic to

$$U_{-\alpha} \times_S (T/Q) \times_S U_\alpha.$$

If α' denotes the character of T' induced by α, the canonical morphism $G \to G'$ induces isomorphisms

$$\mathfrak{g}_\alpha \xrightarrow{\sim} \mathfrak{g}'_{\alpha'}, \qquad \mathfrak{g}_{-\alpha} \xrightarrow{\sim} \mathfrak{g}'_{-\alpha'}.$$

In particular, α' is a root of G' relative to T'. Writing α/Q for the character

$$T/Q \longrightarrow \mathbb{G}_{m,S}$$

induced by α, we obtain:

Lemma 2.13. *If Q is a subgroup of multiplicative type of* $\ker(\alpha)$*, then*

$$(G/Q, T/Q, \alpha/Q)$$

is an elementary system.

Lemma 2.14. *Under the preceding conditions, the following diagrams are commutative:*

$$\begin{array}{ccccc}
\mathrm{W}(\mathfrak{g}^\alpha) & \xrightarrow{\exp} & G & \xleftarrow[\exp]{} & \mathrm{W}(\mathfrak{g}^{-\alpha}) \\
{\scriptstyle \mathrm{can}}\downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \mathrm{can}} & & {\scriptstyle \mathrm{can}}\downarrow{\scriptstyle \sim} \\
\mathrm{W}(\mathfrak{g}'^{\alpha'}) & \xrightarrow{\exp} & G' & \xleftarrow[\exp]{} & \mathrm{W}(\mathfrak{g}'^{-\alpha'})
\end{array}$$

$$\begin{array}{ccc}
\mathfrak{g}^\alpha \otimes \mathfrak{g}^{-\alpha} & \xrightarrow{\sim} & \mathcal{O}_S \\
{\scriptstyle \mathrm{can}}\downarrow{\scriptstyle \sim} & & \downarrow{\scriptstyle \mathrm{id}} \\
\mathfrak{g}'^{\alpha'} \otimes \mathfrak{g}'^{-\alpha'} & \xrightarrow{\sim} & \mathcal{O}_S
\end{array}$$

$$\begin{array}{ccccc}
 & & T & & \\
 & {\scriptstyle \alpha^*}\nearrow & \downarrow{\scriptstyle \mathrm{can}} & \searrow{\scriptstyle \alpha} & \\
\mathbb{G}_{m,S} & & & & \mathbb{G}_{m,S} \\
 & {\scriptstyle \alpha'^*}\searrow & & \nearrow{\scriptstyle \alpha'} & \\
 & & T' & &
\end{array}$$

0.3 The Weyl group

Notations 3.0. [23] If (G, T, α) is an S-elementary system, write

$$N = \mathrm{Norm}_G(T), \qquad W = \mathrm{Norm}_G(T)/T$$

(cf. Exposé XIX, 6.3). The group N is a closed subgroup of G, smooth over S. Write

$$N^\times = N - T$$

for the open subscheme of N induced on the complement of T.[24]

Let R be the unique maximal torus of $\mathrm{Ker}(\alpha)$, and let T' be the image of

$$\alpha^* \colon \mathbb{G}_{m,S} \longrightarrow T;$$

it is a one-dimensional subtorus of T. The morphism

$$T' \times_S R \longrightarrow T$$

induced by multiplication in T is surjective, hence faithfully flat. Indeed, it is enough to check this on the geometric fibers, where it follows at once from the formula

$$\alpha \circ \alpha^* = 2.$$

Theorem 3.1. *With the preceding notation:*

(i) *W is isomorphic to the constant group $(\mathbb{Z}/2\mathbb{Z})_S$.*

(ii) *$N^\times$ is a locally trivial principal homogeneous bundle under T, on the left by the law $(t, q) \mapsto tq$, and on the right by the law $(q, t) \mapsto qt$.*

(iii) *One has*

$$\mathrm{int}(w)t = t \cdot \alpha^*(\alpha(t)^{-1})$$

for $w \in N^\times(S')$, $t \in T(S')$, and $S' \to S$. In the decomposition $T_{S'} = T'_{S'} \cdot R_{S'}$, $\mathrm{int}(w)$ induces the identity on $R_{S'}$ and inversion on $T'_{S'}$. One has the relations

$$\alpha \circ \mathrm{int}(w) = \alpha^{-1}, \qquad \mathrm{int}(w) \circ \alpha^* = (\alpha^*)^{-1}.$$

(iv) *For $X \in W(\mathfrak{g}^\alpha)^\times(S')$, $S' \to S$, set*

$$w_\alpha(X) = \exp(X)\exp(-X^{-1})\exp(X).$$

Then $w_\alpha(X) \in N^\times(S')$, and the morphism $w_\alpha \colon W(\mathfrak{g}^\alpha)^\times \to N^\times$ so defined satisfies

$$w_\alpha(zX) = \alpha^*(z)w_\alpha(X) = w_\alpha(X)\alpha^*(z)^{-1}$$

for $z \in \mathbb{G}_m(S')$, $X \in W(\mathfrak{g}^\alpha)^\times(S')$, and $S' \to S$.

(v) *For $X, Y \in W(\mathfrak{g}^\alpha)^\times(S')$, $S' \to S$, one has, with the notation of 2.6,*

$$w_\alpha(X)w_\alpha(Y) = \alpha^\vee(-XY^{-1}).$$

[25] *In particular,*

$$w_\alpha(X)^2 = \alpha^*(-1) \in {}_2T(S) \cap \mathrm{Centr}(G)(S),$$

[23] The editors added the number 3.0 for later references.

[24] The editors replaced Q by the more suggestive notation $N^\times$.

[25] The editors corrected the first formula of the original.

$$w_\alpha(X)^{-1} = w_\alpha(-X) = \alpha^*(-1)w_\alpha(X).$$

(vi) *If, similarly, one defines for* $Y \in W(\mathfrak{g}^{-\alpha})^\times(S')$

$$w_{-\alpha}(Y) = \exp(Y)\exp(-Y^{-1})\exp(Y),$$

then, in addition to the formulas analogous to the preceding ones,

$$w_{-\alpha}(X^{-1}) = w_\alpha(X)^{-1} = w_\alpha(-X), \qquad w_\alpha(X)w_{-\alpha}(Y) = \alpha^*(XY).$$

Proof. Assertion (i) was already proved in Exposé XIX, 2.4. It follows at once that $N^\times$ is indeed a principal homogeneous bundle under T for the laws defined in (ii); its local triviality for the Zariski topology follows in particular from (iv).

Let us prove (iii). If $w \in N^\times(S)$, it is clear that $\alpha \circ \mathrm{int}(w)$ is a root of G relative to T, and hence is locally equal to α or $-\alpha$. Since it is $-\alpha$ on every fiber (Bible, 12-05, proof of the corollary to Proposition 1), one has

$$\alpha \circ \mathrm{int}(w) = -\alpha.$$

By transport of structure, it follows that

$$-\alpha^* = \mathrm{int}(w)^{-1} \circ \alpha^* = \mathrm{int}(w) \circ \alpha^*,$$

since $\mathrm{int}(w)^2 = \mathrm{int}(w^2)$ and w^2 is a section of T. Thus $\mathrm{int}(w)$ induces inversion on T'; since R is central, it induces the identity on R. The formula in (iii) defines a morphism $T \to T$ having the same properties, and therefore coincides with $\mathrm{int}(w)$.

Let us prove (iv). Successively,

$$\begin{aligned} w_\alpha(X)tw_\alpha(X)^{-1} &= \exp(X)\exp(-X^{-1})\exp(X)t\exp(-X)\exp(X^{-1})\exp(-X) \\ &= \exp(X)\exp(-X^{-1})\exp\big(X - \alpha(t)X\big)\exp\big(\alpha(t)^{-1}X^{-1}\big)\exp\big(-\alpha(t)X\big)t. \end{aligned}$$

Applying formula (F) gives

$$\begin{aligned} \exp(-X^{-1})\exp\big((1-\alpha(t))X\big) = {} & \exp\big((\alpha(t)^{-1}-1)X\big)\alpha^*\big(\alpha(t)^{-1}\big) \\ & \cdot \exp\big(-\alpha(t)^{-1}X^{-1}\big). \end{aligned}$$

Substitution in the preceding relation yields

$$\begin{aligned} \mathrm{int}(w_\alpha(X))t &= \exp\big(\alpha(t)^{-1}X\big)\alpha^*\big(\alpha(t)^{-1}\big)\exp\big(-\alpha(t)X\big)t \\ &= \exp(aX)\alpha^*\big(\alpha(t)^{-1}\big)t, \end{aligned}$$

where

$$a = \alpha(t)^{-1} - (\alpha \circ \alpha^*)\big(\alpha(t)^{-1}\big)\alpha(t).$$

But $\alpha \circ \alpha^* = 2$, which gives $a = 0$ at once and shows that $w_\alpha(X) \in N^\times(S')$.

We now prove the second assertion of (iv). One has[26]

$$\begin{aligned} \alpha^*(z)w_\alpha(X) &= \exp(z^2X)\exp(-z^{-2}X^{-1})\exp(z^2X)\alpha^*(z) \\ &= \exp(zX)\exp\big((z^2-z)X\big)\exp(-z^{-2}X^{-1})\exp(z^2X)\alpha^*(z) \\ &= \exp(zX)\exp(-z^{-1}X^{-1})\alpha^*(z)^{-1}\exp\big((z^3-z^2)X\big)\exp(z^2X)\alpha^*(z) \\ &= \exp(zX)\exp(-z^{-1}X^{-1})\exp(zX) = w_\alpha(zX). \end{aligned}$$

[26]The first equality follows from 1.5 (i), which, together with $\alpha \circ \alpha^* = 2$, gives $\alpha^*(z)\exp(X)\alpha^*(z)^{-1} = \exp(z^2X)$ and $\alpha^*(z)\exp(X^{-1})\alpha^*(z)^{-1} = \exp(z^{-2}X)$. The third equality follows from formula (F), and the fourth again from these formulas. Finally, an analogous calculation gives $w_\alpha(X)\alpha^*(z^{-1}) = w_\alpha(zX)$.

Let us prove (v). By the preceding result, the first formula in (v) follows at once from the second; we prove the latter:

$$\begin{aligned} w_\alpha(X)^2 &= \exp(X)\exp(-X^{-1})\exp(2X)\exp(-X^{-1})\exp(X) \\ &= \exp(X)\exp(-X^{-1})\exp(X^{-1})\alpha^*(-1)\exp(-2X)\exp(X) \\ &= \exp(X)\alpha^*(-1)\exp(-X) = \alpha^*(-1), \end{aligned}$$

since

$$\alpha(\alpha^*(-1)) = (-1)^2 = 1.$$

This also proves that $\alpha^*(-1) \in \mathrm{Centr}(G)(S)$.

Finally, let us prove (vi). The first assertion is a special case of the second, so we prove the latter. Its two sides define morphisms

$$W(\mathfrak{g}^\alpha)^\times \times_S W(\mathfrak{g}^{-\alpha})^\times \longrightarrow G.$$

To prove that they coincide, it suffices to do so on a nonempty open subset of every fiber (Exposé XVIII, 1.4). We may therefore suppose that $1 + XY$ is invertible. Then, successively,

$$\begin{aligned} w_\alpha(X)w_{-\alpha}(Y) &= \exp(X)\exp(-X^{-1})\exp(X)\exp(Y) \\ &\qquad \exp(-Y^{-1})\exp(Y) \\ &= \exp(X)\exp(-X^{-1})\exp\left(\frac{Y}{1+XY}\right)\alpha^*(1+XY) \\ &\qquad \exp\left(\frac{X}{1+XY}\right)\exp(-Y^{-1})\exp(Y) \\ &= \exp(X)\exp\left(\frac{-X^{-1}}{1+XY}\right)\alpha^*(1+XY)\exp\left(\frac{-Y^{-1}}{1+XY}\right)\exp(Y) \\ &= \exp(-X^{-2}Y^{-1})\alpha^*\left(\frac{XY}{1+XY}\right)\exp(X+Y^{-1})\alpha^*(1+XY) \\ &\qquad \cdot \exp\left(\frac{-Y^{-1}}{1+XY}\right)\exp(Y) \\ &= \exp(-X^{-2}Y^{-1})\alpha^*(XY)\exp\left(\frac{Y^{-1}+X}{(1+XY)^2}\right) \\ &\qquad \exp\left(\frac{-Y^{-1}}{1+XY}\right)\exp(Y) \\ &= \alpha^*(XY)\exp(-Y)\exp(Y) = \alpha^*(XY). \end{aligned}$$

Corollary 3.2. *Let $n \in \mathbb{Z}$, $n \neq 0$. For every $w \in G(S)$, the following conditions are equivalent:*

(i) *$w \in N^\times(S)$;*

(ii) *$\mathrm{int}(w) \circ n\alpha^* = -n\alpha^*$, where $(n\alpha^*)(z) = \alpha^*(z)^n$.*

One has (i)⇒(ii) by Theorem 3.1 (iii). Conversely, one may suppose that $N^\times$ has a section, and one is reduced to proving:

Lemma 3.3. *For $n \neq 0$, one has*

$$\mathrm{Centr}_G(n\alpha^*) = T.$$

Indeed, the image T' of $n\alpha^*$ is a subtorus of G. It follows from Exposé XIX, 2.8 that $\mathrm{Centr}_G(n\alpha^*)$ is a reductive subgroup of G containing T. On every fiber,

$$\mathrm{Centr}_{G_s}(n\alpha_s^*) \neq G_s,$$

and hence

$$\mathrm{Centr}_{G_s}(n\alpha_s^*) = T_s$$

by Exposé XIX, 1.6.3.[27] Therefore

$$\mathrm{Centr}_G(n\alpha^*) = T,$$

since these are smooth subgroups of G.

Remark 3.4. *The construction of w_α, and the fact that $w_\alpha(X)$ normalizes T, depend only on formula* (F)*. In particular, if G is an S-group satisfying the conditions of 2.2, then* $\mathrm{Norm}_G(T)$ *differs from T on every fiber. Consequently, if G is an affine S-group with connected fibers satisfying the conditions of 2.2, then G is reductive of semisimple rank* 1*. Indeed, it is smooth in a neighborhood of the identity section, hence smooth, and the criterion of Exposé XIX, 1.11 applies.*

3.5. Before stating the following theorem, let us make a few remarks. As usual, we identify $\mathfrak{g}^{-\alpha}$ with $(\mathfrak{g}^\alpha)^{\otimes -1}$. Similarly, we identify

$$\mathrm{Hom}_{\mathscr{O}_S}(\mathfrak{g}^{-\alpha}, \mathfrak{g}^\alpha) \quad \text{with} \quad (\mathfrak{g}^\alpha)^{\otimes 2},$$

and hence

$$\mathrm{Isom}_{\mathscr{O}_S\text{-mod.}}\big(W(\mathfrak{g}^{-\alpha}), W(\mathfrak{g}^\alpha)\big) \simeq W\big((\mathfrak{g}^\alpha)^{\otimes 2}\big)^\times.$$

If $w \in N^\times(S)$, then $\mathrm{Ad}(w)$ permutes $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$ (3.1 (iii)), and therefore defines an isomorphism

$$a_\alpha(w)\colon \mathfrak{g}^{-\alpha} \xrightarrow{\sim} \mathfrak{g}^\alpha.$$

We thus identify it with a section

$$a_\alpha(w) \in \Gamma\big(S, (\mathfrak{g}^\alpha)^{\otimes 2}\big)^\times.$$

This construction is compatible with base change and therefore defines a morphism

$$a_\alpha\colon N^\times \longrightarrow W\big((\mathfrak{g}^\alpha)^{\otimes 2}\big)^\times$$

such that

$$a_\alpha(w)Y = \mathrm{Ad}(w)Y$$

for every $w \in N^\times(S')$, $Y \in \Gamma(S', \mathfrak{g}^{-\alpha})^\times$, and $S' \to S$.

[27] The hypothesis $\mathrm{Centr}_{G_s}(n\alpha_s^*) \neq G_s$ implies

$$\dim \mathrm{Centr}_{G_s}(n\alpha_s^*) - \dim T_s < 2;$$

this difference is even by the cited result.

Theorem 3.6. (i) *For every $S' \to S$, $w \in N^\times(S')$, and $Y \in W(\mathfrak{g}^{-\alpha})(S')$, one has*

$$\operatorname{int}(w)\exp(Y) = \exp\bigl(a_\alpha(w)Y\bigr).$$

(ii) *One has*

$$a_\alpha(tw) = \alpha(t)a_\alpha(w), \qquad a_\alpha(wt) = \alpha(t)^{-1}a_\alpha(w).$$

(iii) *If one similarly defines*

$$a_{-\alpha}\colon N^\times \longrightarrow W\bigl((\mathfrak{g}^{-\alpha})^{\otimes 2}\bigr)^\times,$$

then

$$a_{-\alpha}(w) = a_\alpha(w)^{-1}.$$

[28]

(iv) *For every $X \in W(\mathfrak{g}^\alpha)^\times(S')$, $S' \to S$, one has*

$$a_\alpha(w_\alpha(X)) = -X^2.$$

Proof. Assertion (i) is immediate from the characterization of the morphisms exp given in 1.5. Assertion (ii) is immediate, as is (iii). Let us prove (iv). Let

$$X \in \Gamma(S', \mathfrak{g}^\alpha)^\times, \qquad Z \in \Gamma(S', \mathfrak{g}^\alpha).$$

By definition,[29]

$$\begin{aligned} a_\alpha(w_\alpha(X))^{-1}(Z) &= \operatorname{Ad}(w_\alpha(X))(Z) \\ &= \operatorname{Ad}(\exp(X))\operatorname{Ad}(\exp(-X^{-1}))\operatorname{Ad}(\exp(X))(Z). \end{aligned}$$

Applying formulas (2′) and (2) of Lemma 2.10, together with

$$H_{-\alpha} = -H_\alpha, \qquad \bar{\alpha}(H_\alpha) = 2$$

(loc. cit., (4) and (5)), and $\langle X, X^{-1}\rangle = 1$ (2.6), the expression on the right is, successively,

$$\begin{aligned} &\operatorname{Ad}(\exp(X))\operatorname{Ad}(\exp(-X^{-1}))(Z) \\ &\quad= \operatorname{Ad}(\exp(X))(Z + \langle X^{-1}, Z\rangle(H_\alpha - X^{-1})) \\ &\quad= Z + \langle X^{-1}, Z\rangle(H_\alpha - 2X - X^{-1} - H_\alpha + X) \\ &\quad= Z - \langle X^{-1}, Z\rangle X - \langle X^{-1}, Z\rangle X^{-1}. \end{aligned}$$

But

$$Z = \langle X^{-1}, Z\rangle X, \qquad \langle X^{-1}, Z\rangle X^{-1} = X^{-2}Z.$$

Thus

$$a_\alpha(w_\alpha(X))^{-1} = -X^{-2},$$

and consequently

$$a_\alpha(w_\alpha(X)) = -X^2.$$

[28] That is, $a_{-\alpha}(w)$ and $a_\alpha(w)$ are paired; cf. 2.6.1.

[29] The editors supplied the details that follow.

Corollary 3.7. *In particular, one has*

$$\operatorname{int}\bigl(w_\alpha(X)\bigr)\exp(X) = \exp(-X^{-1}).$$

Hence, by the definition of $w_\alpha(X)$,

$$w_\alpha(X)\exp(X)w_\alpha(X)^{-1} = \exp(-X)w_\alpha(X)\exp(-X),$$

and therefore, by an immediate calculation,

$$\bigl(w_\alpha(X)\exp(X)\bigr)^3 = e.$$

Corollary 3.8. *Let* $X \in \Gamma(S, \mathfrak{g}^\alpha)^\times$, *and let* $n \in \mathbb{Z}$, $n \neq 0$. *Then* $w_\alpha(X)$ *is the unique section* $w \in G(S)$ *satisfying*

(i) $\operatorname{int}(w) \circ n\alpha^* = -n\alpha^*$;

(ii) $\bigl(w\exp(X)\bigr)^3 = e$.

We know that $w_\alpha(X)$ satisfies these conditions. Conversely, let $w \in G(S)$ satisfy (i) and (ii). By 3.2 and 3.1 (ii), there exists $t \in T(S)$ such that

$$w = w_\alpha(X)t.$$

Set $u = \exp(X)$. Then

$$\begin{aligned} wuw^{-1} &= w_\alpha(X)t\exp(X)t^{-1}w_\alpha(X)^{-1} \\ &= \exp\bigl(-\alpha(t)X^{-1}\bigr), \end{aligned}$$

whereas

$$\begin{aligned} u^{-1}wu^{-1} &= \exp(-X)w_\alpha(X)t\exp(-X) \\ &= \exp(-X)w_\alpha(X)\exp(-X)\exp\bigl(X - \alpha(t)X\bigr)t \\ &= \exp(-X^{-1})\exp\bigl(X - \alpha(t)X\bigr)t \\ &= \exp(-X^{-1})t\exp(H). \end{aligned}$$

Now

$$(wu)^3 = e \quad\Longleftrightarrow\quad wuw^{-1} = u^{-1}wu^{-1}.$$

Comparing the two decompositions of this element in

$$U_{-\alpha} \cdot T \cdot U_\alpha$$

gives $t = e$.

Remark 3.9. We may summarize a number of the results of this section by the following diagram of principal homogeneous bundles (on the left):

$$\begin{array}{ccccc} \mathrm{W}(\mathfrak{g}^\alpha)^\times & \xrightarrow{\quad w_\alpha \quad} & N^\times & \xrightarrow{\quad a_\alpha \quad} & \mathrm{W}\bigl((\mathfrak{g}^\alpha)^{\otimes 2}\bigr)^\times \\ \mathbb{G}_{m,S} & \xrightarrow{\quad \alpha^* \quad} & T & \xrightarrow{\quad \alpha \quad} & \mathbb{G}_{m,S} \end{array}$$

Notice that a_α is faithfully flat (since α is), and that w_α is a monomorphism if and only if α^* is a monomorphism. We leave to the reader the task of writing down the corresponding diagrams for right principal-bundle structures, analogous diagrams for the root $-\alpha$, and of studying the relations among these various diagrams.

Lemma 3.10. *Let S be a scheme, and let $q > 0$ be an integer such that $x \mapsto x^q$ defines an endomorphism of $\mathbb{G}_{a,S}$. Let (G, T, α) and (G', T', α') be two elementary S-systems, and let $f\colon G \to G'$ be a morphism of S-groups. Let*

$$h\colon (\mathfrak{g}^{\alpha})^{\otimes q} \xrightarrow{\sim} \mathfrak{g}'^{\alpha'}$$

be an isomorphism of $\mathcal{O}_S$-modules, and let

$$h^{\vee}\colon (\mathfrak{g}^{-\alpha})^{\otimes q} \xrightarrow{\sim} \mathfrak{g}'^{-\alpha'}$$

be the contragredient isomorphism. Suppose that, for every $S' \to S$ and every $X \in W(\mathfrak{g}^{\alpha})(S')$,

$$f\big(\exp(X)\big) = \exp\big(h(X^q)\big).$$

Then the following conditions are equivalent:

(i) $f\big(\alpha^*(z)\big) = \alpha'^*(z)^q$.

(ii) $f\big(w_{\alpha}(Z)\big) = w_{\alpha'}\big(h(Z^q)\big)$.

(iii) $f\big(\exp(Y)\big) = \exp\big(h^{\vee}(Y^q)\big)$.

Each condition is to be read as holding for every $S' \to S$ and every

$$z \in \mathbb{G}_m(S'), \qquad Z \in W(\mathfrak{g}^{\alpha})^{\times}(S'), \qquad Y \in W(\mathfrak{g}^{-\alpha})(S'),$$

respectively. Indeed, (i) implies (ii) by 3.8, (ii) implies (iii) by 3.7, and (iii) implies (i) by 2.7.

Proposition 3.11. *Let S be a scheme, and let $q \in \mathbb{Z}$, $q > 0$, be such that $x \mapsto x^q$ defines an endomorphism of $\mathbb{G}_{a,S}$. Let (G, T, α) and (G', T', α') be two elementary S-systems, and let $f\colon G \to G'$ be a morphism of S-groups. The following conditions on f are equivalent:*

(i) *The restriction of f to T factors through a morphism $f_T\colon T \to T'$ making the diagram*

$$\begin{array}{ccccc}
\mathbb{G}_{m,S} & \xrightarrow{\alpha^*} & T & \xrightarrow{\alpha} & \mathbb{G}_{m,S} \\
\Big\downarrow{\scriptstyle q} & & \Big\downarrow{\scriptstyle f_T} & & \Big\downarrow{\scriptstyle q} \\
\mathbb{G}_{m,S} & \xrightarrow{\alpha'^*} & T' & \xrightarrow{\alpha'} & \mathbb{G}_{m,S}
\end{array}$$

commutative.

(ii) *There exists a unique isomorphism of $\mathcal{O}_S$-modules*

$$h\colon (\mathfrak{g}^{\alpha})^{\otimes q} \xrightarrow{\sim} \mathfrak{g}'^{\alpha'}$$

such that

$$f\big(\exp(X)\big) = \exp\big(h(X^q)\big), \qquad f\big(\exp(Y)\big) = \exp\big(h^{\vee}(Y^q)\big)$$

for every $S' \to S$, $X \in W(\mathfrak{g}^{\alpha})(S')$, and $Y \in W(\mathfrak{g}^{-\alpha})(S')$. Consequently, f also satisfies the equivalent conditions of 3.10.

We first prove that (ii) implies (i). By 3.10, condition (ii) gives

$$f \circ \alpha^* = q\alpha'^*;$$

hence, by 3.3, $f|_T$ factors through T'. It remains to prove

$$\alpha'\big(f(t)\big) = \alpha(t)^q,$$

which follows at once from the fact that f induces a morphism of groups

$$T \cdot U_\alpha \longrightarrow T' \cdot U_{\alpha'}.$$

We now prove that (i) implies (ii). Let

$$X \in \Gamma(S, \mathfrak{g}^\alpha), \qquad Y \in \Gamma(S, \mathfrak{g}^{-\alpha}),$$

and set

$$p_+(x) = f\big(\exp(xX)\big), \qquad p_-(y) = f\big(\exp(yY)\big).$$

These are morphisms of groups

$$p_+, p_- \colon \mathbb{G}_{a,S} \longrightarrow G.$$

Now

$$\begin{aligned} \mathrm{int}\big(\alpha'^*(z)\big)^q\big(p_+(x)\big) &= \mathrm{int}\big(f_T(\alpha^*(z))\big)\big(f(\exp(xX))\big) \\ &= f\Big(\mathrm{int}\big(\alpha^*(z)\big)\big(\exp(xX)\big)\Big) \\ &= f\big(\exp(z^2 xX)\big) = p_+(z^2 x). \end{aligned}$$

Applying Lemma 1.2 with $Q = \alpha'^*(\mathbb{G}_{m,S})$, we obtain a section

$$X' \in \Gamma(S, \mathfrak{g}'^{\alpha'})$$

such that

$$f\big(\exp(xX)\big) = p_+(x) = \exp(x^q X').$$

Similarly, there exists a section

$$Y' \in \Gamma(S, \mathfrak{g}'^{-\alpha'})$$

such that

$$f\big(\exp(yY)\big) = \exp(y^q Y').$$

Since f is a group morphism, it respects formula (F); hence

$$X^q Y^q = (XY)^q = X'Y'.$$

It follows readily that $X^q \mapsto X'$ and $Y^q \mapsto Y'$ define the announced isomorphisms h and $h^\vee$.

Proposition 3.12. *Let (G, T, α) be an elementary S-system and let $w \in N^\times(S)$. Put*

$$\Omega_0 = \Omega \cap \mathrm{int}(w^{-1})(\Omega).$$

Let d be the function on Ω defined by

$$d\big(\exp(Y) \cdot t \cdot \exp(X)\big) = \alpha(t)^{-1} + XY.$$

Then $\Omega_0 = \Omega_d$, and, for $\exp(Y) \cdot t \cdot \exp(X) \in \Omega_0(S')$, one has the following formula, where $z = d(\exp(Y) \cdot t \cdot \exp(X))$:

$$(\star) \qquad \mathrm{int}(w)\big(\exp(Y) \cdot t \cdot \exp(X)\big) = \exp\big(z^{-1} a_\alpha(w)^{-1} X\big) \cdot t\alpha^*(z) \cdot \exp\big(z^{-1} a_\alpha(w) Y\big).$$

Moreover,

$$d \circ \mathrm{int}(w) = d^{-1}.$$

Indeed, one immediately has[30]

$$\begin{aligned}\operatorname{int}(w)\big(\exp(Y)\cdot t\cdot\exp(X)\big) &= \exp\big(a_\alpha(w)Y\big)\cdot t\alpha^*\big(\alpha(t)^{-1}\big)\cdot\exp\big(a_\alpha(w)^{-1}X\big)\\ &= \exp\big(a_\alpha(w)Y\big)\cdot\exp\big(\alpha(t)a_\alpha(w)^{-1}X\big)\cdot t\alpha^*\big(\alpha(t)^{-1}\big).\end{aligned}$$

By 2.1, this is a section of Ω if and only if $1+\alpha(t)XY$ is invertible, which proves $\Omega_0=\Omega_d$. Applying formula (F) of the same paragraph then gives $(\star)$ by an immediate computation. Finally, $(\star)$ gives

$$\begin{aligned}(d\circ\operatorname{int}(w))\big(\exp(Y)\cdot t\cdot\exp(X)\big) &= \alpha\big(t\alpha^*(z)\big)^{-1}+z^{-2}XY\\ &= z^{-2}\big(\alpha(t)^{-1}+XY\big)=z^{-1},\end{aligned}$$

which proves the last assertion.

N.B. The function d is independent of the choice of w.

0.4 The Isomorphism Theorem

Theorem 4.1. *Let S be a scheme and let $q\in\mathbb{Z}$, $q>0$, be such that $x\mapsto x^q$ is an endomorphism of $\mathbb{G}_{a,S}$. Let (G,T,α) and (G',T',α') be two elementary S-systems. Let*

$$h\colon(\mathfrak{g}^\alpha)^{\otimes q}\xrightarrow{\sim}\mathfrak{g}'^{\alpha'},\qquad h^\vee\colon(\mathfrak{g}^{-\alpha})^{\otimes q}\xrightarrow{\sim}\mathfrak{g}'^{-\alpha'}$$

be mutually contragredient isomorphisms. Let $f_T\colon T\to T'$ be a morphism of S-groups making the following diagram commute:

$$\begin{array}{ccc}\mathbb{G}_{m,S} & \xrightarrow{\ q\ } & \mathbb{G}_{m,S}\\ {\scriptstyle\alpha^*}\downarrow & & \downarrow{\scriptstyle\alpha'^*}\\ T & \xrightarrow{\ f_T\ } & T'\\ {\scriptstyle\alpha}\downarrow & & \downarrow{\scriptstyle\alpha'}\\ \mathbb{G}_{m,S} & \xrightarrow{\ q\ } & \mathbb{G}_{m,S}\end{array}$$

There exists a unique morphism of S-groups $f\colon G\to G'$ extending f_T and satisfying

$$f\big(\exp(X)\big)=\exp\big(h(X^q)\big)$$

for every $S'\to S$ and $X\in W(\mathfrak{g}^\alpha)(S')$. Moreover, this morphism also satisfies

$$f\big(\exp(Y)\big)=\exp\big(h^\vee(Y^q)\big),\qquad f\big(w_\alpha(Z)\big)=w_{\alpha'}\big(h(Z^q)\big)$$

for every $S'\to S$, $Y\in\Gamma(S',\mathfrak{g}^{-\alpha})$, and $Z\in\Gamma(S',\mathfrak{g}^\alpha)^\times$.

If $f\colon G\to G'$ extends f_T, then

$$f\circ\alpha^*=(\alpha'^*)^q.$$

If, in addition, f satisfies the second displayed condition in the statement, then it satisfies the other two conditions as well by 3.10. It follows that f is determined on Ω by

$$f\big(\exp(Y)t\exp(X)\big)=\exp\big(h^\vee(Y^q)\big)\,f_T(t)\,\exp\big(h(X^q)\big).$$

[30] The editors corrected the original by interchanging $a_\alpha(w)$ and $a_\alpha(w)^{-1}$, and supplied the details of the proof of $d\circ\operatorname{int}(w)=d^{-1}$.

Since Ω is schematically dense in G, this already proves the uniqueness of f. To prove existence, it is enough, by Exposé XVIII, 2.3, to show that the preceding formula defines a "generically multiplicative" morphism from Ω to G'. By 2.4, this amounts to checking

$$\alpha' \circ f = \alpha^q,$$

which follows from the fact that f extends f_T.

Scholium 4.2. Theorem 4.1 may also be interpreted as follows. Let $\mathcal{E}$ be the category of elementary S-systems, and let $\mathcal{D}$ be the category of tuples

$$(\mathbb{G}_{m,S} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} \mathbb{G}_{m,S},\ L),$$

where T is a torus, α and α^* are group morphisms such that $\alpha \circ \alpha^* = 2$, and L is an invertible $\mathcal{O}_S$-module. The reader may specify the morphisms in the two categories under consideration. Define a functor

$$\mathcal{E} \longrightarrow \mathcal{D},$$
$$(G, T, \alpha) \longmapsto (\mathbb{G}_{m,S} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} \mathbb{G}_{m,S},\ \mathfrak{g}^\alpha).$$

The preceding theorem says that this functor is fully faithful. In fact, it is an equivalence of categories, as will be seen in the next section. We already have:

Corollary 4.3. *If $q = 1$ and f_T is an isomorphism, then f is an isomorphism.*

Corollary 4.4. *If $q = 1$ and f_T is faithfully flat with kernel Q* (cf. Exposé IX, 2.7)*, then f is faithfully flat and quasi-compact with kernel Q, and hence identifies G' with G/Q.*

Indeed, if f_T is faithfully flat with kernel Q, then

$$Q = \mathrm{Ker}(f_T) \subset \mathrm{Ker}(\alpha' \circ f_T) = \mathrm{Ker}(\alpha).$$

Introduce the elementary S-system $(G/Q, T/Q, \alpha/Q)$ of 2.13. By 2.14, we are reduced to proving that f/Q induces an isomorphism from G/Q onto G', which follows immediately from 4.3.

0.5 Examples of Elementary Systems; Applications

5.1. Let S be a scheme and L an invertible $\mathcal{O}_S$-module. Consider the group GL_L over S defined by

$$\mathrm{GL}_L(S') = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \;\middle|\; \begin{array}{ll} a, d \in \mathbb{G}_a(S'), & b \in W(L)(S'), \\ c \in W(L^{-1})(S'), & ad - bc \in \mathbb{G}_m(S') \end{array} \right\},$$

equipped with the usual matrix-multiplication law. It is locally isomorphic to $\mathrm{GL}_{2,S}$. It is therefore an affine smooth S-group scheme with connected fibers.

Remark. Let L' and L'' be invertible sheaves on S such that

$$L = L' \otimes L''^{-1}.$$

Then there is an isomorphism of S-groups

$$\mathrm{GL}_L \xrightarrow{\sim} \mathrm{GL}(L' \oplus L'')$$

defined as follows: if x (respectively y) is a section of L' (respectively L'') on an open subset V of S, then

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ax+by \\ cx+dy \end{pmatrix}.$$

31

5.2. Denote by SL_L the closed subgroup of GL_L defined by $ad-bc=1$. It too is an affine smooth S-group scheme with connected fibers; under the preceding isomorphism it is isomorphic to $\mathrm{SL}(L'\oplus L'')$.

Likewise, consider the morphism

$$\mathbb{G}_{m,S} \longrightarrow \mathrm{GL}_L, \qquad z \longmapsto \begin{pmatrix} z & 0 \\ 0 & z \end{pmatrix}.$$

It is a central monomorphism. Passage to the quotient gives a smooth affine S-group P_L with connected fibers (cf. Exposé VIII, 5.7). By passing to the quotient in the isomorphism of the preceding remark, one sees that P_L identifies with the automorphism group of the projective bundle $\mathbb{P}(L'\oplus L'')$ (cf. EGA II, 4.2.7). Write i and p for the canonical morphisms

$$\mathrm{SL}_L \xrightarrow{i} \mathrm{GL}_L \xrightarrow{p} \mathrm{P}_L.$$

Here i is a closed immersion, while p is faithfully flat and affine.

5.3. Consider the group morphisms

$$t_G\colon \mathbb{G}_{m,S}^2 \longrightarrow \mathrm{GL}_L, \quad t_G(z,z') = \begin{pmatrix} z & 0 \\ 0 & z' \end{pmatrix},$$

$$t_S\colon \mathbb{G}_{m,S} \longrightarrow \mathrm{SL}_L, \qquad t_S(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix},$$

$$t_P\colon \mathbb{G}_{m,S} \longrightarrow \mathrm{P}_L, \qquad t_P(z) = p(t_G(z,1)).$$

They are group monomorphisms and define in each group a split torus of relative codimension 2. For $s\in S$, let

$$X \in \Gamma(s, L\otimes s)^{\times}.$$

The section $\left(\begin{smallmatrix} 0 & X \\ -X^{-1} & 0 \end{smallmatrix}\right)$ of $\mathrm{GL}_{L,s}$ normalizes $t_G(\mathbb{G}_{m,s}^2)$ and does not centralize it. Exposé XIX, 1.6 therefore shows that GL_L is reductive of semisimple rank 1, with maximal torus $t_G(\mathbb{G}_{m,S}^2)$. The same argument shows that SL_L and P_L are reductive of semisimple rank 1, with respective maximal tori $t_S(\mathbb{G}_{m,S})$ and $t_P(\mathbb{G}_{m,S})$.

5.4. The Lie algebras of these groups, and the adjoint actions of the chosen maximal tori, are determined in the usual way. For GL_L, Exposé II, 4.8 immediately gives

$$\mathrm{Lie}(\mathrm{GL}_L/S) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \;\middle|\; a,d\in\mathcal{O}_S,\ b\in L,\ c\in L^{-1} \right\},$$

with the usual bracket, and

$$\mathrm{Ad}(t_G(z,z')) \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & zz'^{-1}b \\ z'z^{-1}c & d \end{pmatrix}.$$

[31] The editors corrected $L''\otimes L'^{-1}$ to $L'\otimes L''^{-1}$ and expanded the sentence that follows.

Put $\mathfrak{g} = \mathrm{Lie}(\mathrm{GL}_L/S)$, and define

$$\alpha_G \colon t_G(\mathbb{G}_{m,S}^2) \longrightarrow \mathbb{G}_{m,S}, \qquad \alpha_G(t_G(z,z')) = zz'^{-1}.$$

The preceding identity shows that α_G is a root of GL_L relative to $t_G(\mathbb{G}_{m,S}^2)$, and that

$$u \colon L \longrightarrow \mathfrak{g}, \quad X \longmapsto \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix}, \qquad u^- \colon L^{-1} \longrightarrow \mathfrak{g}, \quad Y \longmapsto \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix}$$

identify L with $\mathfrak{g}^{\alpha_G}$ and L^{-1} with $\mathfrak{g}^{-\alpha_G}$, respectively. Thus

$$(\mathrm{GL}_L, t_G(\mathbb{G}_{m,S}^2), \alpha_G)$$

is an elementary S-system.

Similarly, setting

$$\alpha_S(t_S(z)) = z^2, \qquad \alpha_P(t_P(z)) = z,$$

one finds elementary S-systems

$$(\mathrm{SL}_L, t_S(\mathbb{G}_{m,S}), \alpha_S), \qquad (\mathrm{P}_L, t_P(\mathbb{G}_{m,S}), \alpha_P),$$

and corresponding identifications of L and L^{-1} with the root summands of their Lie algebras.

5.5. Set

$$\exp \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix}.$$

This defines a morphism

$$W(\mathfrak{g}^{\alpha_G}) \longrightarrow \mathrm{GL}_L$$

whose tangent map is the canonical inclusion; it is therefore the unique morphism of this kind by 1.5. Likewise, set

$$\exp \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix}.$$

Direct calculation of formula (F) gives

$$\left\langle \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix} \right\rangle = XY, \qquad \alpha_G^*(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix} = t_G(z, z^{-1}).$$

[32]

The open subset $N^\times = N_G^\times$ defined before 3.1 is

$$N_G^\times(S') = \left\{ \begin{pmatrix} 0 & P \\ Q & 0 \end{pmatrix} \;\middle|\; P \in W(\mathfrak{g}^\alpha)^\times(S'),\ Q \in W(\mathfrak{g}^{-\alpha})^\times(S') \right\}.$$

For $X \in W(\mathfrak{g}^\alpha)^\times(S')$,

$$w_{\alpha_G}(X) = \begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix}.$$

[32] The editors expanded the calculations that follow.

Moreover, if

$$w = \begin{pmatrix} 0 & P \\ Q & 0 \end{pmatrix} \in N_G^{\times}(S'),$$

then

$$a_{\alpha_G}(w) = PQ^{-1} \in W\big((\mathfrak{g}^{\alpha})^{\otimes 2}\big)^{\times}(S');$$

that is, for $Y \in W(\mathfrak{g}^{-\alpha})^{\times}(S')$,

$$a_{\alpha_G}(w)(Y) = PQ^{-1}Y \in W(\mathfrak{g}^{\alpha})^{\times}(S').$$

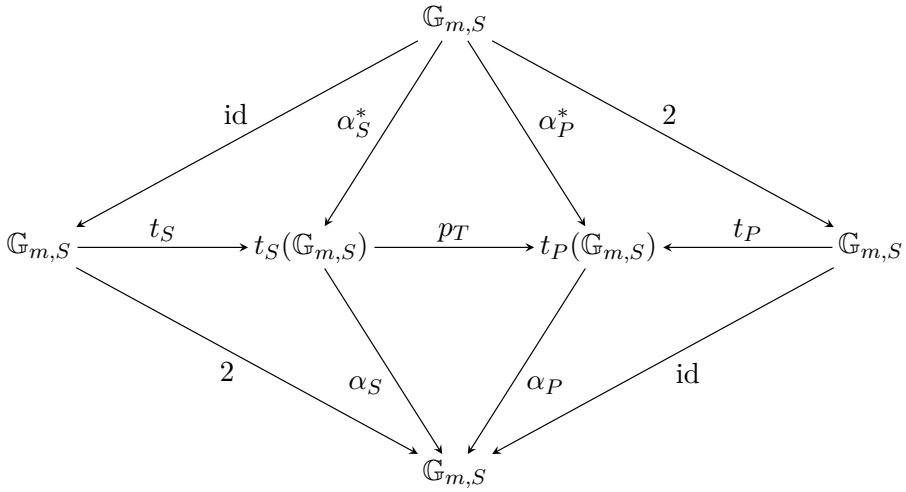
5.6. We leave the analogous calculations for SL_L and P_L to the reader. One obtains the same duality formula and the coroots

$$\alpha_S^*(z) = t_S(z), \qquad \alpha_P^*(z) = t_P(z^2).$$

Let p_T be the morphism induced by $p\colon \mathrm{GL}_L \to \mathrm{P}_L$ on $t_S(\mathbb{G}_{m,S})$, namely

$$p_T(t_S(z)) = t_P(z^2).$$

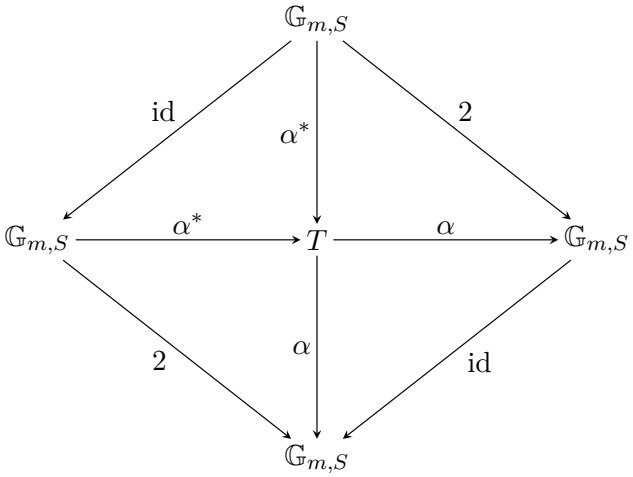
Thus the following diagram is commutative: [33]



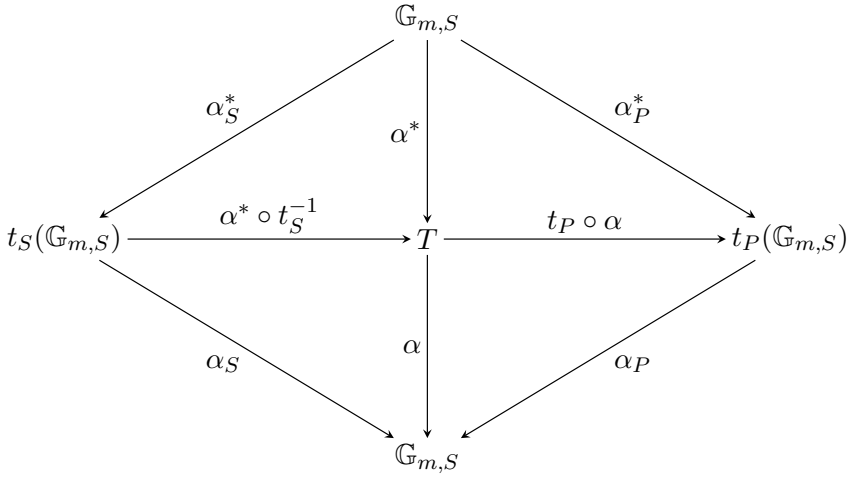
Its central portion is the commutative diagram of 4.1 [34] associated with the canonical morphism $p \circ i\colon \mathrm{SL}_L \to \mathrm{P}_L$, which induces a morphism between the preceding elementary S-systems.

5.7. Let (G, T, α) now be an arbitrary elementary S-system. Consider the commutative diagram

[33] Here t_S and t_P are isomorphisms.
[34] With $q = 1$.



Combining this diagram with that of 5.6 gives a commutative diagram



Using 4.1, one obtains:

Proposition 5.8. *Let S be a scheme and let (G, T, α) be an elementary S-system. Put $L = \mathfrak{g}^\alpha$, so that $L^{-1} = \mathfrak{g}^{-\alpha}$.*

(i) *There exists a unique group morphism $f\colon \mathrm{SL}_L \to G$ satisfying the following equivalent conditions:*

$$\text{(a)}\quad f\begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix} = \alpha^*(z), \qquad f\begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X);$$

$$\text{(b)}\quad f\begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X), \qquad f\begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix} = \exp(Y);$$

$$\text{(c)}\quad f\begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix} = \exp(X), \qquad f\begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix} = w_\alpha(X).$$

(ii) *There exists a unique group morphism $g\colon G \to \mathrm{P}_L$ satisfying*

$$g(t) = \begin{pmatrix} \alpha(t) & 0 \\ 0 & 1 \end{pmatrix}, \qquad g(\exp(X)) = p\begin{pmatrix} 1 & X \\ 0 & 1 \end{pmatrix}.$$

Moreover,

$$g(\exp(Y)) = p\begin{pmatrix} 1 & 0 \\ Y & 1 \end{pmatrix}, \qquad g(w_\alpha(X)) = p\begin{pmatrix} 0 & X \\ -X^{-1} & 0 \end{pmatrix}.$$

The morphism g is faithfully flat and quasi-compact, with

$$\mathrm{Ker}(g) = \mathrm{Ker}(\alpha) = \mathrm{Centr}(G),$$

and $g \circ f$ is the canonical morphism $\mathrm{SL}_L \to \mathrm{P}_L$.

Notice that condition (b) in (i) gives an explicit description of the duality between $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$.

Corollary 5.9. *Let (G, T, α) be an elementary S-system. The subgroups*

$$T \cdot U_\alpha, \qquad T \cdot U_{-\alpha}, \qquad U_\alpha, \qquad U_{-\alpha}$$

are closed.

Since U_α is a closed subgroup scheme of $T \cdot U_\alpha$, it suffices to prove the assertion for the latter. By Noether's theorem (Exposé IV, 5.3.1 and 6.4.1), it is enough to show that

$$(T \cdot U_\alpha)/\mathrm{Ker}(\alpha)$$

is a closed subgroup of $G/\mathrm{Ker}(\alpha)$. By 5.8, this reduces to the evident fact that the subgroup of P_L defined by $c = 0$ is closed; one may equivalently work in GL_L, by another application of Noether's theorem. Consequently, the exponential morphisms of Theorem 1.5(i) are closed immersions.

N.B. The corollary also follows from the fact that $T \cdot U_\alpha$ and $T \cdot U_{-\alpha}$ are "Borel subgroups" of G (cf. Exposé XII, 7.10).

5.10. Let L be an invertible $\mathcal{O}_S$-module, and let

$$\mathbb{G}_{m,S} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} \mathbb{G}_{m,S}$$

be a diagram of groups, where T is a torus,[35] such that $\alpha \circ \alpha^* = 2$. Let R be the maximal torus of $\mathrm{Ker}(\alpha)$, and put $K = \alpha^{*-1}(R)$. Then K is a subgroup of multiplicative type of $\mathbb{G}_{m,S}$; since $\alpha \circ \alpha^* = 2$, it is even a subgroup of $\mu_{2,S}$. In particular,

$$K \longrightarrow \mathrm{SL}_L, \qquad z \longmapsto \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix}$$

is central. Hence there is a central group monomorphism

$$K \longrightarrow R \times \mathrm{SL}_L, \qquad z \longmapsto \left(\alpha^*(z), \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix}\right).$$

Let

$$G = (R \times \mathrm{SL}_L)/K.$$

This is an affine smooth group over S, with connected fibers. The sequence

$$1 \longrightarrow K \longrightarrow R \times t_S(\mathbb{G}_{m,S}) \xrightarrow{u} T \longrightarrow 1, \qquad u(x, t_S(z)) = x\alpha^*(z),$$

[35] This qualification is supplied by the editors.

is exact. The image of $R \times t_S(\mathbb{G}_{m,S})$ in G is therefore a torus T' isomorphic to T. If α' is the character of T' transported from α, one readily checks that (G, T', α') is an elementary S-system, that $\mathfrak{g}^{\alpha'}$ is isomorphic to L, and that α'^* is obtained from α^* under the isomorphism $T \xrightarrow{\sim} T'$. Thus the object

$$\left(\mathbb{G}_{m,S} \xrightarrow{\alpha'^*} T' \xrightarrow{\alpha'} \mathbb{G}_{m,S},\, \mathfrak{g}^{\alpha'}\right)$$

of the category $\mathcal{D}$ defined in 4.2 is isomorphic to

$$\left(\mathbb{G}_{m,S} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} \mathbb{G}_{m,S},\, L\right).$$

We have therefore proved:

Theorem 5.11. *With the notation of 4.2, the functor*

$$(G, T, \alpha) \longmapsto \left(\mathbb{G}_{m,S} \xrightarrow{\alpha^*} T \xrightarrow{\alpha} \mathbb{G}_{m,S},\, \mathfrak{g}^{\alpha}\right)$$

is an equivalence of categories between $\mathcal{E}$ and $\mathcal{D}$.

0.6 Generators and Relations for an Elementary System

6.1. Let S be a scheme and let (G, T, α) be an elementary S-system. Let

$$X \in W(\mathfrak{g}^{\alpha})^{\times}(S), \qquad u = \exp(X).$$

As observed in 3.8, the element $w = w_\alpha(X)$ satisfies, in particular,

$$(wu)^3 = e.$$

[36] Let s_α denote the automorphism of T induced by $\mathrm{int}(w)$. By Theorem 3.1(iii), for every $S' \to S$ and every $t \in T(S')$,

$$s_\alpha(t) = \mathrm{int}(w)(t) = t\,\alpha^*(\alpha(t)^{-1}).$$

Theorem 6.2. *Let H be a sheaf of groups over S for the fppf topology. Let*

$$f_T \colon T \longrightarrow H, \qquad f_\alpha \colon U_\alpha \longrightarrow H$$

be group morphisms, and let $h \in H(S)$. There exists a (necessarily unique) *group morphism*

$$f \colon G \longrightarrow H$$

extending f_T and f_α and satisfying $f(w) = h$ if and only if the following conditions hold:

(i) *For every $S' \to S$, $t \in T(S')$, and $x \in U_\alpha(S')$,*

$$f_T(t) f_\alpha(x) f_T(t)^{-1} = f_\alpha(txt^{-1}) = f_\alpha\big(x^{\alpha(t)}\big). \tag{1}$$

Equivalently, f_T and f_α extend to a group morphism $T \cdot U_\alpha \to H$.

(ii) *For every $S' \to S$ and $t \in T(S')$,*

$$h f_T(t) h^{-1} = f_T(s_\alpha(t)) = f_T\Big(t\,\alpha^*(\alpha(t)^{-1})\Big). \tag{2}$$

[36] The editors added the sentence that follows.

(iii) *The following two relations hold in $H(S)$:*

$$h^2 = f_T(\alpha^*(-1)), \tag{3}$$

$$\big(hf_\alpha(u)\big)^3 = e. \tag{4}$$

Proof. Write the laws on U_α and $U_{-\alpha}$ additively, while writing their vector-space structures multiplicatively. If f has the asserted properties, then for $y \in U_{-\alpha}(S')$ one necessarily has

$$f(y) = f(w^{-1}wyw^{-1}w) = hf_\alpha(w^{-1}yw)h^{-1}.$$

Define a morphism $f_{-\alpha}\colon U_{-\alpha} \to H$ by

$$f_{-\alpha}(y) = hf_\alpha(w^{-1}yw)h^{-1}. \tag{$*_1$}$$

It is a group morphism. On the big cell Ω, the morphism f is forced to satisfy

$$f(ytx) = f_{-\alpha}(y)f_T(t)f_\alpha(x).$$

This proves uniqueness. The conditions in the statement are manifestly necessary; let us prove that they are sufficient.

Relation (4) gives

$$hf_\alpha(u)h^{-1}h^2 = f_\alpha(-u)h^{-1}f_\alpha(-u).$$

By (3) and (1), $h^2 = f_T(\alpha^*(-1))$ commutes with $f_\alpha(-u)$, and hence

$$hf_\alpha(u)h^{-1} = f_\alpha(-u)hf_\alpha(-u).$$

By definition,

$$hf_\alpha(u)h^{-1} = f_{-\alpha}(wuw^{-1}),$$

whereas 3.7 gives

$$wuw^{-1} = -\widetilde{u}, \tag{$*_2$}$$

with $\widetilde{u}$ the element paired with u. Therefore

$$f_{-\alpha}(-\widetilde{u}) = f_\alpha(-u)hf_\alpha(-u). \tag{$*_3$}$$

Let t be a section of T over a variable $S' \to S$. Apply $\mathrm{int}(f_T(t))$ to this identity. On the left one obtains[37]

$$\begin{aligned} f_T(t)f_{-\alpha}(-\widetilde{u})f_T(t)^{-1} &= f_T(t)hf_\alpha(u)h^{-1}f_T(t)^{-1} \\ &= h\big(h^{-1}f_T(t)h\big)f_\alpha(u)\big(h^{-1}f_T(t)^{-1}h\big)h^{-1} \\ &= hf_T(s_\alpha(t))f_\alpha(u)f_T(s_\alpha(t))^{-1}h^{-1} \\ &= hf_\alpha(\alpha(s_\alpha(t))u)h^{-1} \\ &= hf_\alpha(\alpha(t)^{-1}u)h^{-1} \\ &= f_{-\alpha}(-\alpha(t)^{-1}\widetilde{u}). \end{aligned}$$

Here we used (2), (1), $s_\alpha(t) = t\alpha^*(\alpha(t)^{-1})$, and $\alpha \circ \alpha^* = 2$.

[37] The editors corrected the calculation that follows.

The right-hand side of $(*_3)$, after conjugation, becomes

$$f_\alpha(-\alpha(t)u)\, f_T(t) h f_T(t)^{-1} h^{-1}\, h f_\alpha(-\alpha(t)u).$$

Since

$$h f_T(t)^{-1} h^{-1} = f_T(s_\alpha(t^{-1})) = f_T\big(t\,\alpha^*(\alpha(t))\big),$$

this equals

$$f_\alpha(-\alpha(t)u)\, f_T\big(\alpha^*(\alpha(t))\big)\, h f_\alpha(-\alpha(t)u).$$

Comparison gives

$$f_{-\alpha}(-\alpha(t)^{-1}\widetilde{u}) = f_\alpha(-\alpha(t)u)\, f_T\big(\alpha^*(\alpha(t))\big)\, h f_\alpha(-\alpha(t)u).$$

Since $\alpha\colon T \to \mathbb{G}_{m,S}$ is faithfully flat and H is a separated presheaf, $-\alpha(t)^{-1}$ may be replaced by an arbitrary section of $\mathbb{G}_{m,S}$. Thus:

Lemma 6.2.1. *For every $S' \to S$ and every $z \in \mathbb{G}_m(S')$,*

$$f_{-\alpha}(z\widetilde{u}) = f_\alpha(z^{-1}u)\, f_T\big(\alpha^*(-z^{-1})\big)\, h f_\alpha(z^{-1}u).$$

Let $x, y \in \mathbb{G}_a(S')$, where $S' \to S$, and suppose that y and $1 + xy$ are invertible. Applying Lemma 6.2.1 first with $z = y$, one obtains[38]

$$f_\alpha(xu) f_{-\alpha}(y\widetilde{u}) = f_\alpha\big((x + y^{-1})u\big)\, f_T\big(\alpha^*(-y^{-1})\big)\, h f_\alpha(y^{-1}u).$$

Now $x + y^{-1} = y^{-1}(1 + xy)$. Applying the lemma with $z = y/(1 + xy)$ gives

$$\begin{aligned} f_\alpha\big((x + y^{-1})u\big) = f_{-\alpha}\left(\frac{y}{1+xy}\widetilde{u}\right) & f_\alpha\big(-(x + y^{-1})u\big) \\ & \cdot h\, f_T\left(\alpha^*\left(-\frac{y}{1+xy}\right)\right). \end{aligned}$$

Substitution in the preceding identity yields

$$\begin{aligned} f_\alpha(xu) f_{-\alpha}(y\widetilde{u}) = f_{-\alpha}\left(\frac{y}{1+xy}\widetilde{u}\right) & f_\alpha\big(-(x + y^{-1})u\big) h^{-1} \\ & \cdot f_T\big(\alpha^*(1 + xy)^{-1}\big) h f_\alpha(y^{-1}u). \end{aligned}$$

Since $h^{-1} f_T(t) h = f_T(s_\alpha(t))$ by (2) (recall that $s_\alpha^2 = \mathrm{id}$), and $s_\alpha \circ \alpha^* = -\alpha^*$, this is

$$f_{-\alpha}\left(\frac{y}{1+xy}\widetilde{u}\right) f_\alpha\big(-(x + y^{-1})u\big) f_T\big(\alpha^*(1 + xy)\big) f_\alpha(y^{-1}u).$$

For $x' \in U_\alpha(S')$ and $z \in \mathbb{G}_m(S')$, one has

$$f_\alpha(x') f_T(\alpha^*(z)) = f_T(\alpha^*(z)) f_\alpha(z^{-2}x').$$

Consequently,

$$\begin{aligned} f_\alpha(xu) f_{-\alpha}(y\widetilde{u}) &= f_{-\alpha}\left(\frac{y}{1+xy}\widetilde{u}\right) f_T\big(\alpha^*(1 + xy)\big) \\ &\quad \cdot f_\alpha\left(\left[-\frac{y^{-1}(1+xy)}{(1+xy)^2} + y^{-1}\right] u\right) \\ &= f_{-\alpha}\left(\frac{y}{1+xy}\widetilde{u}\right) f_T\big(\alpha^*(1 + xy)\big) f_\alpha\left(\frac{x}{1+xy}u\right). \end{aligned}$$

We have proved:

[38] The editors expanded the calculations that follow.

Lemma 6.2.2. *Let $S' \to S$. If $a \in U_\alpha(S')$, $b \in U^\times_{-\alpha}(S')$, and $1 + ab \in \mathbb{G}_m(S')$, then*

$$f_\alpha(a) f_{-\alpha}(b) = f_{-\alpha}\left(\frac{b}{1+ab}\right) f_T(\alpha^*(1+ab)) f_\alpha\left(\frac{a}{1+ab}\right).$$

By schematic density, this formula remains valid for $b \in U_{-\alpha}(S')$, with $1+ab$ invertible. Define

$$f\colon \Omega \longrightarrow H, \qquad f(ytx) = f_{-\alpha}(y) f_T(t) f_\alpha(x).$$

It follows at once from Lemma 6.2.2, condition 6.2(i), and formula (F') of 2.4 that whenever $g, g' \in \Omega(S')$ and $gg' \in \Omega(S')$, one has

$$f(gg') = f(g) f(g').$$

By Exposé XVIII, 2.3(iii) and 2.4,[39] there is therefore a group morphism $G \to H$ extending f. Denote it again by f. It remains only to prove that $f(w_\alpha) = h$. Since

$$w_\alpha = u \cdot (-\widetilde{u}) \cdot u,$$

formula $(*_3)$ gives[40]

$$f(w_\alpha) = f_\alpha(u) f_{-\alpha}(-\widetilde{u}) f_\alpha(u) = h.$$

This completes the proof of Theorem 6.2.

Remark 6.3. *These results will be completed in Exposé XXIII, 3.5.*

[39] Each geometric fiber of G is connected, for example by 1.1.

[40] The editors simplified the original argument by invoking $(*_3)$.

Exposé XXI. Root Data

This Exposé[1] collects, in the absence of a suitable reference,[2] known results on root data (that is, "abstract" root systems), most of which will be used below.

Notation. We denote by $\mathbb{Q}_+$ the set of positive (or zero) rational numbers; $\mathbb{Z} \cap \mathbb{Q}_+ = \mathbb{N}$. Let V be a $\mathbb{Q}$-vector space. If A (respectively B) is a subset of $\mathbb{Q}$ (respectively of V), we denote by $A \cdot B$ the image of $A \otimes B$ under the morphism $\mathbb{Q} \otimes V \to V$, in other words the set of linear combinations of elements of B with coefficients in A. We write $-B = \{-1\}B$. We denote by $E - F$ the set of elements of E that do not belong to F.

0.1 Generalities

0.1.1 Definitions and first properties

Definition 0.1.1.1. Let M and M^* be two free finite-type $\mathbb{Z}$-modules in duality. Write

$$V = M \otimes \mathbb{Q}, \qquad V^* = M^* \otimes \mathbb{Q};$$

these are two $\mathbb{Q}$-vector spaces in duality. We identify M (respectively M^*) with a subset of V (respectively V^*). The canonical bilinear form on $M^* \times M$ (respectively $V^* \times V$) is denoted $(\ ,\ )$.

Let R be a finite subset of M. Suppose given a map $\alpha \mapsto \alpha^*$ from R to M^*; the set of α^*, for $\alpha \in R$, is denoted R^*. To every $\alpha \in R$ associate the endomorphism s_α (respectively s_α^*) of M and V (respectively of M^* and V^*) given by

$$(1) \qquad s_\alpha(x) = x - (\alpha^*, x)\alpha, \qquad s_\alpha = \mathrm{id} - \alpha^* \otimes \alpha,$$
$$(1^*) \qquad s_\alpha^*(u) = u - (u, \alpha)\alpha^*, \qquad s_\alpha^* = \mathrm{id} - \alpha \otimes \alpha^*.$$

The pair (R, R^*) (more precisely, the pair $(R, R \to M^*)$) is called a *root datum* in (M, M^*), and (M, M^*, R, R^*) is called a root datum, if the following axioms hold:

$$\text{(DR I)} \quad (\alpha^*, \alpha) = 2 \qquad \text{for every } \alpha \in R,$$
$$\text{(DR II)} \quad s_\alpha(R) \subset R, \qquad s_\alpha^*(R^*) \subset R^* \qquad \text{for every } \alpha \in R.$$

The set R is called the *root system* of the root datum $\mathcal{R} = (M, M^*, R, R^*)$. The elements of R (respectively R^*) are called the *roots* (respectively *coroots*) of the root datum.

Remark 0.1.1.2. Axiom (DR I) is equivalent to any one of the following properties:

$$(2,2^*) \qquad s_\alpha s_\alpha = \mathrm{id}, \qquad s_\alpha^* s_\alpha^* = \mathrm{id},$$
$$(3,3^*) \qquad s_\alpha(\alpha) = -\alpha, \qquad s_\alpha^*(\alpha^*) = -\alpha^*.$$

[1] Editors' note: Version of 13 October 2024.

[2] Editors' note: For results on root systems (Sections 1–5), one may consult *Groupes et algèbres de Lie*, Chapter VI.

Remark 0.1.1.3. Axioms (DR I) and (DR II) imply

$$R = -R, \qquad R^* = -R^*, \qquad 0 \notin R, \qquad 0 \notin R^*.$$

Lemma 0.1.1.4. *The map $R \to R^*$ is a bijection. More generally, if $\alpha, \beta \in R$ and $(\alpha^*, x) = (\beta^*, x)$ for every $x \in R$, then $\alpha = \beta$.*

Proof. Indeed, one then has

$$s_\beta(\alpha) = \alpha - 2\beta, \qquad s_\alpha(\beta) = \beta - 2\alpha.$$

It follows at once that

$$s_\beta s_\alpha(\alpha) = 2\beta - \alpha = \alpha + 2(\beta - \alpha), \qquad s_\beta s_\alpha(\beta - \alpha) = s_\beta(\beta - \alpha) = \beta - \alpha.$$

Hence, by (DR II),

$$(s_\beta s_\alpha)^n(\alpha) = \alpha + 2n(\beta - \alpha) \in R.$$

Since R is finite, $\beta - \alpha = 0$. □

Corollary 0.1.1.5. *The inverse map $R^* \to R$ defines a root datum*

$$\mathcal{R}^* = (M^*, M, R^*, R),$$

called the dual *of $\mathcal{R}$.*[3]

Definition 0.1.1.6. We denote by $\Gamma_0(R)$ the subgroup of M generated by R. We denote by $\mathcal{V}(R)$ the vector subspace of V generated by R, that is,

$$\mathcal{V}(R) = \Gamma_0(R) \otimes \mathbb{Q}.$$

Applying these definitions to $\mathcal{R}^*$, one likewise obtains $\Gamma_0(R^*)$ and $\mathcal{V}(R^*)$.

The *reductive rank* of $\mathcal{R}$ is the number

$$\mathrm{rgred}(\mathcal{R}) = \mathrm{rank}(M) = \dim(V) = \dim(V^*) = \mathrm{rank}(M^*) = \mathrm{rgred}(\mathcal{R}^*).$$

The *semisimple rank* of $\mathcal{R}$ is the number

$$\mathrm{rgss}(\mathcal{R}) = \mathrm{rank}(R) = \mathrm{rank}(\Gamma_0(R)) = \dim(\mathcal{V}(R)).$$

Thus $\mathrm{rgss}(\mathcal{R}) \leq \mathrm{rgred}(\mathcal{R})$.

We shall see below that $\mathrm{rgss}(\mathcal{R}) = \mathrm{rgss}(\mathcal{R}^*)$, that is, that $\mathcal{V}(R)$ and $\mathcal{V}(R^*)$ have the same dimension.

Definition 0.1.1.7.

The root datum $\mathcal{R}$ is called *semisimple* (respectively *trivial*) if $\mathrm{rgss}(\mathcal{R}) = \mathrm{rgred}(\mathcal{R})$ (respectively $\mathrm{rgss}(\mathcal{R}) = 0$). Thus $\mathcal{R}$ is trivial if and only if R is empty. The trivial root datum of reductive rank zero is denoted

$$0 = (\{0\}, \{0\}, \varnothing, \varnothing).$$

[3] Editors' note: $(\alpha^*)^* = \alpha$.

Definition 0.1.1.8. We denote by $W(\mathcal{R})$ the group of transformations of M generated by the s_α, $\alpha \in R$. It is called the *Weyl group* of $\mathcal{R}$. We write

$$W^*(\mathcal{R}) = W(\mathcal{R}^*).$$

Then $W(\mathcal{R})$ acts on R, $\Gamma_0(R)$, $\mathcal{V}(R)$, M, and V. If $w \in W(\mathcal{R})$ and $x \in M$ (respectively $x \in V$), then

$$wx - x \in \Gamma_0(R) \quad \text{(respectively } wx - x \in \mathcal{V}(R)\text{)};$$

this follows immediately from formula (1). Likewise for $W^*(\mathcal{R})$.

Lemma 0.1.1.9. *For every $\alpha \in R$, $x \in V$, and $u \in V^*$, one has*

$$(s_\alpha^*(u), s_\alpha(x)) = (u, x). \tag{4}$$

Proof. Taking the scalar product of (1) and (1*), the left-hand side is

$$(u,x) + (u,\alpha)(\alpha^*,x)\big((\alpha^*,\alpha) - 2\big) = (u,x).$$

□

Remark 0.1.1.10. If one assumes $0 \notin R$ and $0 \notin R^*$, then Lemma 0.1.1.9 is equivalent to (DR I).

Corollary 0.1.1.11. *Let $h \mapsto h^\vee$ denote the isomorphism from $\mathrm{GL}(M)$ onto $\mathrm{GL}(M^*)$ that associates to h its contragredient. Formula (4) may then also be written*

$$(s_\alpha)^\vee = s_\alpha^*. \tag{5}$$

Corollary 0.1.1.12. *The preceding isomorphism induces an isomorphism from $W(\mathcal{R})$ onto $W^*(\mathcal{R})$.*

Scholium 0.1.1.13. *By the preceding result, we shall identify W and W^*, and regard W as a group of transformations of*

$$R,\ R^*,\ M,\ M^*,\ \Gamma_0(R),\ \Gamma_0(R^*),\ V,\ V^*,\ \mathcal{V}(R),\ \mathcal{V}(R^*).$$

We shall write s_α for s_α^*.

0.1.2 The map p

Lemma 0.1.2.1. *Let $p : M \to M^*$ (respectively $V \to V^*$) be the linear map defined by*

$$p(x) = \sum_{u \in R^*} (u,x)u. \tag{6}$$

Write $\ell(x) = (p(x), x)$. Then:

$$\ell(x) \geq 0, \qquad \ell(\alpha) > 0 \qquad \text{for } \alpha \in R, \tag{7}$$

$$\ell(wx) = \ell(x) \qquad \text{for } w \in W, \tag{8}$$

$$(p(x), y) = (p(y), x) \qquad \text{for } x, y \in V, \tag{9}$$

$$\ell(\alpha)\alpha^* = 2p(\alpha) \qquad \text{for } \alpha \in R. \tag{10}$$

Proof. The first three relations are immediate.[4] We prove the last one. By (1), for $u \in V^*$,

$$\begin{aligned}(u,\alpha)^2\alpha^* &= (u,\alpha)u - (u,\alpha)s_\alpha(u)\\ &= (u,\alpha)u + (u,s_\alpha(\alpha))s_\alpha(u)\\ &= (u,\alpha)u + (s_\alpha(u),\alpha)s_\alpha(u) \qquad (s_\alpha^2 = \mathrm{id}).\end{aligned}$$

Since s_α permutes R^* by (DR II), summing over $u \in R^*$ gives the result. □

Scholium 0.1.2.2. *Relation* (10) *says that the map* $\alpha \mapsto \ell(\alpha)\alpha^*$ *is the restriction to* R *of a linear map from* M *to* M^**. In particular,*

$$(-\alpha)^* = -\alpha^*.$$

Corollary 0.1.2.3. *The map* p *induces an isomorphism from* $\mathcal{V}(R)$ *onto* $\mathcal{V}(R^*)$*.*

Proof. The map p sends $\mathcal{V}(R)$ onto $\mathcal{V}(R^*)$. Hence

$$\dim \mathcal{V}(R) \geq \dim \mathcal{V}(R^*).$$

Applying this inequality to the dual root datum gives

$$\dim \mathcal{V}(R) = \dim \mathcal{V}(R^*),$$

so the surjective map p is also bijective. □

Corollary 0.1.2.4. *One has* $\dim \mathcal{V}(R) = \dim \mathcal{V}(R^*)$*, and therefore*

$$\mathrm{rgss}(\mathcal{R}) = \mathrm{rgss}(\mathcal{R}^*).$$

Corollary 0.1.2.5. *The bilinear form* (u,x) *is nondegenerate on* $\mathcal{V}(R^*) \times \mathcal{V}(R)$*, and thus puts these* $\mathbb{Q}$*-vector spaces in duality.*

Proof. If $(u,x) = 0$ for every $u \in R^*$, then $p(x) = 0$. □

Corollary 0.1.2.6. *The symmetric bilinear form* $(p(x),y)$ *is positive and nondegenerate on* $\mathcal{V}(R)$*.*

Corollary 0.1.2.7. *The group* W *acts faithfully on* R *(and hence on the other sets listed in Scholium 0.1.1.13).*

Proof. Let $u \in V^*$, and suppose $w \in W$ satisfies $w(\alpha) = \alpha$ for every $\alpha \in R$. We prove $w(u) = u$. For every $\alpha \in R$,

$$(w(u) - u, \alpha) = (w(u),\alpha) - (u,\alpha) = (u, w^{-1}(\alpha)) - (u,\alpha) = 0.$$

But $w(u) - u \in \mathcal{V}(R^*)$. Since it is orthogonal to every root, it vanishes by Corollary 0.1.2.5. □

Corollary 0.1.2.8. *The group* W *is finite.*

Proposition 0.1.2.9. *The operations of* W *respect the correspondence between roots and coroots. In other words, for* $\alpha \in R$ *and* $w \in W$*,*

$$w(\alpha^*) = w(\alpha)^*.$$

[4] Editors' note: Formula (8) follows from (4), (2,2*), and (DR II).

Proof. It suffices to verify this for $w = s_\beta$, $\beta \in R$, that is, to verify

$$s_\beta(\alpha^*) = s_\beta(\alpha)^*.$$

Now $\ell(s_\beta(\alpha))s_\beta(\alpha)^*/2$ equals

$$\begin{aligned} p(s_\beta(\alpha)) &= \sum_{u \in R^*} (u, s_\beta(\alpha))u \\ &= \sum_{u \in R^*} (s_\beta(u), \alpha)u \\ &= \sum_{u \in R^*} (u, \alpha)s_\beta(u) = s_\beta(p(\alpha)). \end{aligned}$$

Since $\ell(s_\beta(\alpha)) = \ell(\alpha)$, we obtain

$$s_\beta(\alpha)^* = s_\beta\left(\frac{2p(\alpha)}{\ell(\alpha)}\right) = s_\beta(\alpha^*).$$

□

Corollary 0.1.2.10. *If $\alpha \in R$ and $w \in W$, then*

$$ws_\alpha w^{-1} = s_{w(\alpha)}.$$

Proof. For $x \in V$,

$$ws_\alpha w^{-1}(x) = x - (\alpha^*, w^{-1}(x))w(\alpha) = x - (w(\alpha^*), x)w(\alpha).$$

By Proposition 0.1.2.9, the last expression is

$$x - (w(\alpha)^*, x)w(\alpha) = s_{w(\alpha)}(x).$$

□

Corollary 0.1.2.11.
Let $R' \subset R$. The quadruple (M, M^*, R', R'^*) is a root datum if and only if $\alpha, \beta \in R'$ implies $s_\alpha(\beta) \in R'$.

0.2 Relations between two roots

0.2.1 Proportional roots

Proposition 0.2.1.1. *Let α and β be two roots. The following conditions are equivalent:*

(i) there exists $k \in \mathbb{Q}$ such that $\alpha = k\beta$;

(ii) $s_\alpha = s_\beta$.

Under these conditions, $\alpha^* = k^{-1}\beta^*$, and k is one of

$$1,\ -1,\ 2,\ -2,\ \tfrac{1}{2},\ -\tfrac{1}{2}.$$

Proof. Assume first (i). Then

$$\alpha^* = \ell(\alpha)^{-1} 2p(\alpha) = k^{-2}\ell(\beta)^{-1} 2k\, p(\beta) = k^{-1}\beta^*.$$

This immediately gives $s_\alpha = s_\beta$. Conversely, if $s_\alpha = s_\beta$, then

$$\alpha = s_\alpha(-\alpha) = s_\beta(-\alpha) = (\beta^*, \alpha)\beta - \alpha,$$

so

$$2\alpha = (\beta^*, \alpha)\beta, \qquad (\beta^*, \alpha) \in \mathbb{Z};$$

thus (ii) implies (i). Finally, if $\alpha = k\beta$, then $\alpha^* = k^{-1}\beta^*$, whence

$$(\alpha^*, \beta) = 2k^{-1}, \qquad (\beta^*, \alpha) = 2k.$$

Thus $2k$ and $2k^{-1}$ are integers, which gives the stated list. □

Application 0.2.1.2. *Root data $\mathcal{R}$ with* $\mathrm{rgss}(\mathcal{R}) = 1$ *are of one of the following two types:*

(i) Type A_1: there exists $\alpha \in M$ such that the roots are α and $-\alpha$. The coroots are then α^* and $-\alpha^*$.

(ii) Type A_1': there exists $\alpha \in M$ such that the roots are $\alpha, -\alpha, 2\alpha, -2\alpha$. The coroots are then $\alpha^*, -\alpha^*, \alpha^*/2, -\alpha^*/2$.

Definition 0.2.1.3. A root $\alpha \in R$ is called *indivisible* if $\alpha/2 \notin R$. The root datum $\mathcal{R}$ is called *reduced* if every root is indivisible.

The root datum $\mathcal{R}$ is reduced if and only if $\mathcal{R}^*$ is reduced. If α is indivisible and $w \in W$, then $w(\alpha)$ is indivisible.

Definition 0.2.1.4. Let $\alpha \in R$. If α is indivisible, set $\mathrm{ind}(\alpha) = \alpha$; otherwise set $\mathrm{ind}(\alpha) = \alpha/2$.

Corollary 0.2.1.5. *If $\alpha \in R$ is indivisible and $k\alpha \in R$, where $k \in \mathbb{Q}$, then $k \in \mathbb{Z}$.*

Proposition 0.2.1.6. *Let $\mathcal{R}$ be a root datum. Then*

$$\mathrm{ind}(\mathcal{R}) = \big(M, M^*, \mathrm{ind}(R), \mathrm{ind}(R)^*\big)$$

is a reduced root datum, and

$$W\big(\mathrm{ind}(\mathcal{R})\big) = W(\mathcal{R}).$$

Proof. The quadruple $\mathrm{ind}(\mathcal{R})$ is a root datum by Corollary 0.1.2.11, since the Weyl group permutes the indivisible roots. The second assertion follows from Proposition 0.2.1.1. □

Remark 0.2.1.7. If $\mathcal{R}$ is not reduced, then

$$\mathrm{ind}(R)^* \neq \mathrm{ind}(R^*), \qquad \mathrm{ind}(\mathcal{R}^*) \neq \mathrm{ind}(\mathcal{R})^*.$$

0.2.2 Orthogonal roots

Lemma 0.2.2.1. *Let α and β be two roots. Then*

$$\ell(\alpha)(\alpha^*, \beta) = \ell(\beta)(\beta^*, \alpha). \tag{11}$$

Proof. This follows immediately from Lemma 0.1.2.1, formulas (9) and (10). □

Corollary 0.2.2.2. *Let $\alpha, \beta \in R$. The following conditions are equivalent:*

(i) $(\alpha^*, \beta) = 0$;

(i bis) $(\beta^*, \alpha) = 0$;

(ii) $(p(\alpha), \beta) = 0$;

(iii) $s_\alpha(\beta) = \beta$;

(iii bis) $s_\beta(\alpha) = \alpha$;

(iv) $s_\alpha(\beta^*) = \beta^*$;

(iv bis) $s_\beta(\alpha^*) = \alpha^*$;

(v) $s_\alpha \neq s_\beta$, *and* s_α *and* s_β *commute.*

Proof. All the equivalences are immediate except those involving (v). We first show that (i), together with its equivalent condition (i bis), implies (v). One has

$$s_\alpha s_\beta(x) = x - (\beta^*, x)\beta - (\alpha^*, x)\alpha + (\beta^*, x)(\alpha^*, \beta)\alpha.$$

If $(\alpha^*, \beta) = 0$, then $(\beta^*, \alpha) = 0$, and consequently

$$s_\alpha s_\beta(x) = s_\beta s_\alpha(x).$$

Conversely, suppose (v). Then

$$s_\alpha = s_\beta s_\alpha s_\beta = s_{s_\beta(\alpha)} \qquad \text{by Corollary 0.1.2.10.}$$

By Proposition 0.2.1.1, there is a $k \in \mathbb{Q}^*$ such that

$$\alpha = k\, s_\beta(\alpha) = k\alpha - k(\beta^*, \alpha)\beta.$$

Since $s_\alpha \neq s_\beta$, the roots α and β are not proportional, again by Proposition 0.2.1.1. It follows that $(\beta^*, \alpha) = 0$. □

Definition 0.2.2.3. Two roots satisfying the equivalent conditions of Corollary 0.2.2.2 are called *orthogonal*.

Remark 0.2.2.4. The roots α and β are orthogonal if and only if the coroots α^* and β^* are orthogonal.

Lemma 0.2.2.5. *If α and β are two orthogonal roots, then $\alpha + \beta \in R$ if and only if $\alpha - \beta \in R$.*

Proof. Indeed,

$$s_\beta(\alpha + \beta) = s_\beta(\alpha) + s_\beta(\beta) = \alpha - \beta.$$

□

Lemma 0.2.2.6. *Let α and β be two nonorthogonal roots. For a coroot γ^*, define $\ell(\gamma^*)$ to be the value of ℓ on the root γ^* of $\mathcal{R}^*$. Then*

$$\ell(\alpha)\ell(\alpha^*) = \ell(\beta)\ell(\beta^*). \tag{12}$$

Proof. Multiply formula (11) by the corresponding formula for $\mathcal{R}^*$, and use $(\gamma^*)^* = \gamma$ for every $\gamma \in R$. This gives

$$(\beta^*, \alpha)(\alpha^*, \beta)\ell(\alpha)\ell(\alpha^*) = (\beta^*, \alpha)(\alpha^*, \beta)\ell(\beta)\ell(\beta^*).$$

The common integer factor is nonzero because the roots are not orthogonal, so it may be cancelled. □

0.2.3 General case

Proposition 0.2.3.1. *If α and β are any two roots, then*

$$0 \leq (\alpha^*, \beta)(\beta^*, \alpha) \leq 4. \tag{13}$$

If α and β are neither proportional nor orthogonal, then

$$1 \leq (\alpha^*, \beta)(\beta^*, \alpha) \leq 3.$$

Proof. One has

$$4(p(\alpha), \beta)^2 = \ell(\alpha)\ell(\beta)(\alpha^*, \beta)(\beta^*, \alpha).$$

On the other hand, by Corollary 0.1.2.6, the symmetric bilinear form $(p(x), y)$ is positive and nondegenerate on $\mathcal{V}(R)$. Hence

$$(p(x), y)^2 \leq \ell(x)\ell(y).$$

[5] The first inequality follows. In the nonproportional, nonorthogonal case, the product is a nonzero integer and cannot equal 4, which gives the second inequality. □

Corollary 0.2.3.2. *Let α and β be two nonorthogonal roots. If $\ell(\alpha) = \ell(\beta)$, then there is a $w \in W$ such that $w(\alpha) = \beta$.*

Proof. If α and β are proportional, equality of their ℓ-values gives $\alpha = \beta$ or $\alpha = -\beta$; take $w = 1$ or $w = s_\alpha$, respectively. If they are neither proportional nor orthogonal, formula (11) and Proposition 0.2.3.1 give

$$(\beta^*, \alpha) = (\alpha^*, \beta) = \pm 1.$$

If both integers are 1, take $w = s_\beta s_\alpha s_\beta$. If both are -1, take $w = s_\alpha s_\beta$. □

Corollary 0.2.3.3. *Let α and β be roots. If $\alpha \neq \beta$ and $(\beta^*, \alpha) > 0$, then $\alpha - \beta$ is a root. Respectively, if $\alpha \neq -\beta$ and $(\beta^*, \alpha) < 0$, then $\alpha + \beta$ is a root.*

Proof. The second case follows from the first by replacing β by $-\beta$. Suppose first that α and β are proportional and that $(\beta^*, \alpha) > 0$. Then

$$\beta = \alpha, \qquad 2\beta = \alpha, \qquad \text{or} \qquad \beta = 2\alpha.$$

[5] Editors' note: equality holds if and only if x and y are proportional.

The first case is excluded. In the other two cases, $\alpha - \beta = \beta \in R$ and $\alpha - \beta = -\alpha \in R$, respectively.

If α and β are not proportional, then (α^*, β) and (β^*, α) are strictly positive integers whose product is at most 3. Thus one of them equals 1. If $(\beta^*, \alpha) = 1$, then

$$\alpha - \beta = s_\beta(\alpha) \in R;$$

if $(\alpha^*, \beta) = 1$, then

$$\alpha - \beta = -s_\alpha(\beta) \in R.$$

□

Lemma 0.2.3.4. *Let α and β be two nonproportional roots. If $\beta - \alpha$ is not a root, then $\beta + k\alpha \in R$ for $k = -(\alpha^*, \beta)$, but not for $k = -(\alpha^*, \beta) + 1$.*

Proof. Indeed,

$$\beta - (\alpha^*, \beta)\alpha = s_\alpha(\beta) \in R,$$

whereas

$$\beta + (-(\alpha^*, \beta) + 1)\alpha = s_\alpha(\beta - \alpha) \notin R.$$

□

Proposition 0.2.3.5. *Let α and β be two nonproportional roots. The set of integers k for which $\beta + k\alpha \in R$ is an interval $[p, q]$, with $p \leq 0$ and $q \geq 0$, and*

$$p + q = -(\alpha^*, \beta).$$

Proof. For the first assertion it suffices, for example, to show that if $\beta + k\alpha \in R$ and $k > 0$ is an integer, then $\beta + (k-1)\alpha \in R$. This is trivial if $k = 1$. If $k \geq 2$, then

$$(\alpha^*, \beta + k\alpha) = (\alpha^*, \beta) + 2k \geq -3 + 4 > 0,$$

and the assertion follows from Corollary 0.2.3.3.

Let $[p, q]$ be the interval in question. Applying Lemma 0.2.3.4 to $\beta + p\alpha$, one obtains

$$q - p = -(\alpha^*, \beta + p\alpha) = -(\alpha^*, \beta) - 2p.$$

[6] The asserted formula follows. □

Remark 0.2.3.6. The preceding formula contains the qualitative statements of Lemma 0.2.2.5 and Corollary 0.2.3.3.

Complements 0.2.3.7. [7] *By formulas* (9) *and* (10)*, and by Corollary 0.1.2.6, the bilinear form on $\mathcal{V}(R)$ defined by*

$$\langle x, y \rangle = (p(x), y)$$

is symmetric and positive definite. For every $\alpha \in R$ and $y \in \mathcal{V}(R)$,

$$\langle \alpha, y \rangle = \frac{\ell(\alpha)}{2}(\alpha^*, y), \qquad \ell(\alpha) = \langle \alpha, \alpha \rangle.$$

Consequently, Corollary 0.2.3.3 gives the following corollary.

Corollary. *Let $\alpha \neq \beta$ in R. If $\alpha - \beta \notin R$, then*

$$\langle \alpha, \beta \rangle \leq 0.$$

[6] Editors' note: in this equality, $+2p$ was corrected to $-2p$.

[7] Editors' note: these complements, useful for the proof of Proposition 0.3.1.5, were added by the editors.

0.3 Simple roots, positive roots

0.3.1 Systems of simple roots

Lemma 0.3.1.1. *Let α and α_i, $i = 1, \dots, n$, be roots, and suppose that α is distinct from the α_i. If*

$$\alpha = \sum_{i=1}^{n} q_i \alpha_i, \qquad q_i \in \mathbb{Q}_+,$$

then there is an index i such that

$$q_i \neq 0, \qquad (\alpha^*, \alpha_i) > 0, \qquad \alpha - \alpha_i \in R.$$

Proof. Write

$$2 = (\alpha^*, \alpha) = \sum_{i=1}^{n} q_i (\alpha^*, \alpha_i).$$

This proves the first two assertions. The third then follows from Corollary 0.2.3.3. □

Proposition 0.3.1.2. *Let α and α_i, $i = 1, \dots, n$, be roots. If*

$$\alpha = \sum_{i=1}^{n} m_i \alpha_i, \qquad m_i \in \mathbb{N},$$

then there is a sequence $\beta_1, \dots, \beta_m$ of roots chosen from among the α_i, not necessarily pairwise distinct, such that, on setting

$$\gamma_p = \sum_{i=1}^{p} \beta_i, \qquad p = 1, \dots, m,$$

one has $\gamma_p \in R$ and $\gamma_m = \alpha$.

Proof. We argue by induction on the integer $m' = \sum_i m_i$. If α equals one of the α_i, say α_{i_0}, which necessarily happens when $m' = 1$, take

$$m = 1, \qquad \beta_1 = \alpha_{i_0}.$$

Otherwise, Lemma 0.3.1.1 gives an index i for which $m_i \neq 0$ and $\alpha - \alpha_i$ is a root. Then $m_i - 1 \in \mathbb{N}$ and

$$\alpha - \alpha_i = (m_i - 1)\alpha_i + \sum_{j \neq i} m_j \alpha_j.$$

Apply the induction hypothesis to $\alpha - \alpha_i$, and append α_i to the resulting sequence. □

Corollary 0.3.1.3. *Let $R' \subset R$. The following conditions are equivalent:*

(i) if $\alpha, \beta \in R'$ and $\alpha + \beta \in R$, then $\alpha + \beta \in R'$;

(ii) $(\mathbb{N} \cdot R') \cap R \subset R'$.

Proof. Clearly (ii) implies (i). The converse follows immediately from Proposition 0.3.1.2. □

Definition 0.3.1.4. A set of roots satisfying the equivalent conditions of Corollary 0.3.1.3 is called *closed*.

Proposition 0.3.1.5. *Let $\Delta \subset R$ be a set of roots. The following conditions are equivalent:*

(i) the elements of Δ are indivisible and linearly independent, and

$$R \subset (\mathbb{Q}_+ \cdot \Delta) \cup (-\mathbb{Q}_+ \cdot \Delta);$$

(ii) the elements of Δ are linearly independent, and

$$R \subset (\mathbb{N} \cdot \Delta) \cup (-\mathbb{N} \cdot \Delta);$$

(iii) every root can be written uniquely as a linear combination of the elements of Δ, with integer coefficients all of the same sign.

Proof. [8] It is clear that (ii) implies (iii). Write $\alpha_1, \ldots, \alpha_n$ for the distinct elements of Δ.

Assume (i), and let $\alpha \in R$. There is a unique expression

$$\varepsilon\alpha = \sum_i q_i\alpha_i, \qquad q_i \in \mathbb{Q}_+, \qquad \varepsilon = \pm 1.$$

We show that the q_i are integers. This is immediate when all but one of them vanish, by Corollary 0.2.1.5. Otherwise, $\varepsilon\alpha$ is distinct from the α_i, and Lemma 0.3.1.1 gives an i_0 such that

$$\alpha' = \varepsilon\alpha - \alpha_{i_0} \in R, \qquad q_{i_0} \neq 0.$$

Thus

$$\alpha' = (q_{i_0} - 1)\alpha_{i_0} + \sum_{i \neq i_0} q_i\alpha_i.$$

At least one q_i, with $i \neq i_0$, is nonzero, so (i) forces $q_{i_0} - 1 \geq 0$. Repeating this operation with α', after finitely many steps we find that all q_i are integers. This proves (ii).

Assume now (iii). We first prove that $\alpha_1, \ldots, \alpha_n$ are linearly independent over $\mathbb{Q}$. Otherwise there would be an equality

$$x = \sum_{i \in I} a_i\alpha_i = \sum_{j \in J} b_j\alpha_j,$$

where I and J are disjoint subsets of $\{1, \ldots, n\}$, at least one of them, say I, is nonempty, and $a_i, b_j \in \mathbb{N}^*$. By the corollary in Complements 0.2.3.7, one has $\langle \alpha_i, \alpha_j \rangle \leq 0$ for $i \in I$ and $j \in J$. Therefore $\langle x, x \rangle \leq 0$, and hence $x = 0$.

Choose $i_0 \in I$. The two expressions

$$\alpha_{i_0} = \alpha_{i_0} + \sum_{i \in I} a_i\alpha_i = \alpha_{i_0} + \sum_{j \in J} b_j\alpha_j$$

then imply, by (iii), that $a_i = 0 = b_j$ for all i, j, a contradiction. Thus the elements of Δ are linearly independent over $\mathbb{Q}$.

It remains to show that they are indivisible. Suppose that $\beta \in \Delta$ is divisible. Then $\beta/2 \in R$, so

$$\frac{\beta}{2} = \varepsilon \sum_{\alpha \in \Delta} m_\alpha\alpha, \qquad m_\alpha \in \mathbb{N}, \qquad \varepsilon = \pm 1.$$

Consequently,

$$\beta = 2\varepsilon \sum_{\alpha \in \Delta} m_\alpha\alpha.$$

Uniqueness gives $m_\alpha = 0$ for $\alpha \neq \beta$ and $2\varepsilon m_\beta = 1$, a contradiction. □

[8] Editors' note: in the argument that follows, the order was changed and the proof of the implication (iii)⇒(i) was spelled out.

Definition 0.3.1.6. A set Δ of roots satisfying the conditions of Proposition 0.3.1.5 is called a *system of simple roots*, or a *base* of $\mathcal{R}$.

If $w \in W$ and Δ is a system of simple roots, then $w(\Delta)$ is a system of simple roots.

Remark 0.3.1.7. This definition involves only R, not $\mathcal{R}$; indeed, it involves only $\mathrm{ind}(R)$.

Remark 0.3.1.8. If Δ is a system of simple roots, then Δ is a basis of the free abelian group $\Gamma_0(R)$. Hence

$$\mathrm{Card}(\Delta) = \mathrm{rgss}(\mathcal{R}).$$

Remark 0.3.1.9. The conditions of Proposition 0.3.1.5 are therefore equivalent to the following:

(i′) the elements of Δ are indivisible, their number is at most $\mathrm{rgss}(\mathcal{R})$, and

$$R \subset (\mathbb{Q}_+ \cdot \Delta) \cup (-\mathbb{Q}_+ \cdot \Delta);$$

(ii′) $\mathrm{Card}(\Delta) \leq \mathrm{rgss}(\mathcal{R})$, and

$$R \subset (\mathbb{N} \cdot \Delta) \cup (-\mathbb{N} \cdot \Delta).$$

Corollary 0.3.1.10. *If Δ is a system of simple roots, then* $\mathrm{ind}(\Delta^*)$ *is a system of simple coroots* (i.e. *a system of simple roots of $\mathcal{R}^*$*).

Proof. If

$$\beta = \sum_{\alpha \in \Delta} a_\alpha \alpha, \qquad a_\alpha \in \mathbb{N},$$

then

$$p(\beta) = \sum_{\alpha \in \Delta} a_\alpha p(\alpha).$$

Consequently, by (10),

$$\beta^* = \sum_{\alpha \in \Delta} a_\alpha \frac{\ell(\alpha)}{\ell(\beta)} \alpha^*,$$

which shows that $\mathrm{ind}(\Delta^*)$ satisfies condition (i′) of Remark 0.3.1.9. □

By Proposition 0.2.1.1, if α^* is not indivisible, then

$$\alpha^* = 2u^*, \qquad u^* \in \mathrm{ind}(\Delta^*) \quad \text{and} \quad u = 2\alpha.$$

It follows that:[9]

Corollary 0.3.1.11. *Let Δ be a system of simple roots, and let*

$$\beta = \sum_{\alpha \in \Delta} a_\alpha \alpha, \qquad a_\alpha \in \mathbb{Z},$$

be the expression of β relative to Δ. Then $\ell(\beta)$ divides $2a_\alpha \ell(\alpha)$; it even divides $a_\alpha \ell(\alpha)$ if α^* is indivisible.

Before continuing to state the properties of systems of simple roots, we show that such systems exist.

[9] Editors' note: The preceding sentence was added, and in Corollary 3.1.11 the expression $4a_\alpha \ell(\alpha)$ was replaced by $2a_\alpha \ell(\alpha)$.

0.3.2 Systems of positive roots

Definition 0.3.2.1. A subset $R_+ \subset R$ is called a *system of positive roots* of $\mathcal{R}$ *(or of R; see Remark 0.3.2.2)* if it satisfies:

(P 1) $R_+ \cap (-R_+) = \varnothing$;

(P 2) $R_+ \cup (-R_+) = R$;

(P 3) $(\mathbb{Q}_+ \cdot R_+) \cap R \subset R_+$.

In particular, such a set is closed. We shall see later, in Corollary 0.3.3.8, that a closed set satisfying (P 1) and (P 2) also satisfies (P 3), and hence is a system of positive roots. If $w \in W$ and R_+ is a system of positive roots, then $w(R_+)$ is a system of positive roots.

Remark 0.3.2.2. This definition involves only R. We shall also say that R_+ is a system of positive roots of R.

Remark 0.3.2.3. Conditions (P 1) and (P 2) immediately give

$$\mathrm{Card}(R_+) = \frac{\mathrm{Card}(R)}{2}.$$

It follows that if R_+ and R'_+ are two systems of positive roots and $R_+ \subset R'_+$, then $R_+ = R'_+$.

Remark 0.3.2.4. If R_+ is a system of positive roots, then R^*_+ is a system of positive coroots *(i.e.* a system of positive roots of R^**)*.

This follows immediately from Lemma 0.1.1.4 and Scholium 0.1.2.2.

Definition 0.3.2.5. Let Δ be a system of simple roots. Set

$$\mathscr{P}(\Delta) = (\mathbb{Q}_+ \cdot \Delta) \cap R = (\mathbb{N}_+ \cdot \Delta) \cap R.$$

Proposition 0.3.2.6. *If Δ is a system of simple roots, then $\mathscr{P}(\Delta)$ is a system of positive roots. If Δ is a system of simple roots and R_+ is a system of positive roots, then*

$$\Delta \subset R_+ \quad \Longleftrightarrow \quad R_+ = \mathscr{P}(\Delta).$$

Proof. The first assertion is immediate. If $\Delta \subset R_+$, then $\mathscr{P}(\Delta) \subset R_+$ by (P 3), and therefore $\mathscr{P}(\Delta) = R_+$ by Remark 0.3.2.3. The rest is trivial. □

Remark 0.3.2.7. Systems of positive roots exist: endow $\mathcal{V}(R)$ with the structure of a totally ordered vector space. The set of roots that are ≥ 0 for this order is a system of positive roots.

Theorem 0.3.2.8. *Let R_+ be a system of positive roots. There exists a unique system of simple roots $\mathscr{S}(R_+)$ such that*

$$\mathscr{S}(R_+) \subset R_+, \qquad \textit{i.e.} \qquad R_+ = \mathscr{P}(\mathscr{S}(R_+)).$$

Uniqueness follows immediately from:

Lemma 0.3.2.9. *Let Δ be a system of simple roots. An element $\alpha \in \mathscr{P}(\Delta)$ belongs to Δ if and only if α is not the sum of two elements of $\mathscr{P}(\Delta)$.*

Proof. This follows immediately from the definitions and Proposition 0.3.1.2. □

We now prove the existence of $\mathscr{S}(R_+)$. Consider the set of subsets T of R_+ such that

$$T = \mathrm{ind}(T) \qquad \text{and} \qquad \mathbb{Q}_+ \cdot T \supset R_+.$$

This set is nonempty, since it contains $\mathrm{ind}(R_+)$. Let Δ be a minimal element of this set under inclusion. We show that Δ is a system of simple roots; by Proposition 0.3.1.5(i), it is enough to show that Δ is a linearly independent subset of $M \otimes \mathbb{Q}$.

Lemma 0.3.2.10. *If $\alpha, \beta \in \Delta$ and*

$$q\alpha + q'\beta \in R, \qquad q, q' \in \mathbb{Q},$$

then $qq' \geq 0$.

Proof. If $qq' < 0$, then, after interchanging α and β if necessary, we may write

$$a\alpha - b\beta \in R_+, \qquad a, b \in \mathbb{Q}_+^*.$$

By the defining property of Δ, there is a relation

$$a\alpha - b\beta = \sum_{\gamma \in \Delta} c(\gamma)\gamma, \qquad c(\gamma) \in \mathbb{Q}_+.$$

If $a \leq c(\alpha)$, this becomes

$$-\beta = \frac{c(\alpha) - a}{b}\alpha + \sum_{\gamma \neq \alpha} \frac{c(\gamma)}{b}\gamma.$$

Thus $-\beta \in (\mathbb{Q}_+ \cdot \Delta) \cap R$, which is contained in R_+ by (P 3). This gives $\beta \in R_+ \cap (-R_+)$, contradicting (P 1).

If instead $a > c(\alpha)$, then

$$(a - c(\alpha))\alpha = b\beta + \sum_{\gamma \neq \alpha} c(\gamma)\gamma,$$

which shows that

$$\Delta \subset \mathbb{Q}_+ \cdot (\Delta \setminus \{\alpha\}),$$

contrary to the minimality of Δ. □

Recall from Complements 0.2.3.7 that the bilinear form on $\mathcal{V}(R)$ defined by

$$\langle x, y \rangle = (p(x), y)$$

is a Euclidean inner product. Moreover, for $\alpha \in R$,

$$\langle \alpha, y \rangle = \frac{\ell(\alpha)}{2}(\alpha^*, y),$$

so $\langle \alpha, y \rangle$ and (α^*, y) have the same sign.

Lemma 0.3.2.11. *If $\alpha, \beta \in \Delta$, then*

$$(\beta^*, \alpha) \leq 0 \qquad \textit{and hence} \qquad \langle \beta, \alpha \rangle \leq 0.$$

Proof. Indeed,

$$s_\beta(\alpha) = \alpha - (\beta^*, \alpha)\beta \in R,$$

and therefore $(\beta^*, \alpha) \leq 0$ by Lemma 0.3.2.10. □

We now show that Δ is linearly independent. Otherwise, Lemma 0.3.2.11 would imply, exactly as in the proof of Proposition 0.3.1.5, the existence of a nontrivial relation

$$\sum_{\alpha\in\Delta} m(\alpha)\alpha = 0, \qquad m(\alpha)\in\mathbb{N}.$$

If $m(\alpha_0)\geq 1$, then

$$-\alpha_0 = \big(m(\alpha_0)-1\big)\alpha_0 + \sum_{\alpha\neq\alpha_0} m(\alpha)\alpha.$$

By (P 3), this gives $\alpha_0 \in R_+ \cap (-R_+)$, contradicting (P 1). Thus Δ is a base of $\mathcal{R}$, completing the proof of Theorem 0.3.2.8.

Corollary 0.3.2.12. *Let R_+ be a system of positive roots, let Δ be a base of $\mathcal{R}$, and let $w\in W$. Then*

$$\Delta\subset R_+ \iff R_+ = \mathscr{P}(\Delta) \iff \Delta = \mathscr{S}(R_+),$$

$$\mathscr{P}\big(\mathrm{ind}(\Delta^*)\big) = \mathscr{P}(\Delta)^*, \qquad \mathscr{S}(R_+^*) = \mathrm{ind}\big(\mathscr{S}(R_+)^*\big),$$

and

$$\mathscr{S}\big(w(R_+)\big) = w\big(\mathscr{S}(R_+)\big), \qquad \mathscr{P}\big(w(\Delta)\big) = w\big(\mathscr{P}(\Delta)\big).$$

Definition 0.3.2.13. Once a system of simple roots Δ has been chosen, the elements of $\mathscr{P}(\Delta)$ are called *positive*. Once a system of positive roots R_+ has been chosen, the elements of $\mathscr{S}(R_+)$ are called *simple*.

Corollary 0.3.2.14. *Let R_+ be a system of positive roots, and let $\alpha\in R_+$. The following conditions are equivalent:*

(i) α is simple, that is, $\alpha\in\mathscr{S}(R_+)$;

(ii) α is not the sum of two elements of R_+;

(iii) $R_+\setminus\{\alpha\}$ is closed.

Proof. The equivalence of (i) and (ii) follows immediately from Lemma 0.3.2.9; the equivalence of (ii) and (iii) is immediate from Definition 0.3.1.4. □

Definition 0.3.2.15. Let Δ be a system of simple roots. The sum of the coefficients in the expression of a root α relative to Δ is called the *order of α relative to Δ* and is denoted $\mathrm{ord}_\Delta(\alpha)$.

One has

$$\alpha\in\mathscr{P}(\Delta) \iff \mathrm{ord}_\Delta(\alpha)>0, \qquad \alpha\in\Delta \iff \mathrm{ord}_\Delta(\alpha)=1.$$

Lemma 0.3.2.16. *Let Δ be a system of simple roots and $\alpha\in\mathscr{P}(\Delta)$. There is a sequence $\alpha_i\in\Delta$, $i=1,\dots,m$, such that*

$$\alpha_1+\alpha_2+\cdots+\alpha_p\in\mathscr{P}(\Delta) \quad \textit{for } p=1,\dots,m,$$

and

$$\alpha_1+\alpha_2+\cdots+\alpha_m=\alpha.$$

Moreover, for every sequence satisfying these conditions,

$$m=\mathrm{ord}_\Delta(\alpha).$$

Proof. This is immediate from Proposition 0.3.1.2. □

0.3.3 Characterization and conjugacy of systems of positive roots

Lemma 0.3.3.1. *If $\alpha \in \mathscr{P}(\Delta)$, $\beta \in \Delta$, and α and β are not proportional, then*

$$s_\beta(\alpha) \in \mathscr{P}(\Delta).$$

Proof. One has

$$s_\beta(\alpha) = \alpha - (\beta^*, \alpha)\beta.$$

At least one simple root other than β occurs with a nonzero, and hence strictly positive, coefficient in the expression of α. It occurs with the same coefficient in the expression of $s_\beta(\alpha)$; therefore $s_\beta(\alpha)$ is also positive. □

Corollary 0.3.3.2. *If $\beta \in \Delta$, then the reflection s_β permutes the elements of $\mathscr{P}(\Delta)$ that are not proportional to β.*

Lemma 0.3.3.3. *Let*

$$\alpha \in \mathscr{P}(\Delta) \setminus \Delta$$

be indivisible. There exists $\beta \in \Delta$ such that

$$s_\beta(\alpha) \in \mathscr{P}(\Delta) \qquad \textit{and} \qquad \mathrm{ord}_\Delta\big(s_\beta(\alpha)\big) < \mathrm{ord}_\Delta(\alpha).$$

Proof. By Lemma 0.3.1.1, there is a $\beta \in \Delta$ such that $(\beta^*, \alpha) > 0$. Since $\alpha \notin \Delta$ and α is indivisible, it cannot be proportional to β. Thus $s_\beta(\alpha) \in \mathscr{P}(\Delta)$ by Lemma 0.3.3.1, and

$$\mathrm{ord}_\Delta\big(s_\beta(\alpha)\big) = \mathrm{ord}_\Delta(\alpha) - (\beta^*, \alpha) < \mathrm{ord}_\Delta(\alpha).$$

□

Corollary 0.3.3.4. *If $\alpha \in \mathscr{P}(\Delta)$ is indivisible, then there is a sequence $\beta_p \in \Delta$, $p = 1, \ldots, q$, such that*

$$\alpha_p = s_{\beta_p} \cdots s_{\beta_1}(\alpha) \in \mathscr{P}(\Delta) \quad \textit{for } p = 1, \ldots, q,$$

and $\alpha_q \in \Delta$.

Proof. Apply Lemma 0.3.3.3 repeatedly, inducting on $\mathrm{ord}_\Delta(\alpha)$. □

Proposition 0.3.3.5. *The Weyl group is generated by the s_α, for $\alpha \in \Delta$. Every indivisible root is conjugate under an element of the Weyl group to a simple root.*

Proof. The second assertion follows immediately from Corollary 0.3.3.4. The first then follows from Corollary 0.1.2.10 and Proposition 0.2.1.1. □

Proposition 0.3.3.6. *Let R_+ be a system of positive roots, and let $P' \subset R$ be closed and satisfy (P 2). Then there exists $w \in W$ such that*

$$w(R_+) \subset P'.$$

We first state the corollaries.

Corollary 0.3.3.7. *The Weyl group acts transitively on the set of systems of positive roots, and on the set of systems of simple roots.*

Corollary 0.3.3.8. *A subset of R is a system of positive roots if and only if it is closed and satisfies (P 1) and (P 2).*

Corollary 0.3.3.9. *Suppose that $\Gamma_0(R)$ is endowed with an ordered-group structure for which every root is either > 0 or < 0. Then the set of positive roots for this order is a system of positive roots.*

Proof of Proposition 0.3.3.6. Choose $w \in W$ such that $\mathrm{Card}(w(R_+) \cap P')$ is maximal. Replacing R_+ by $w(R_+)$, we may assume that

$$(*) \qquad \mathrm{Card}(R_+ \cap P') \geq \mathrm{Card}(R_+ \cap s_\alpha(P')) \quad \text{for every } \alpha \in \mathscr{S}(R_+) = \Delta.$$

We show that $R_+ \subset P'$. Otherwise, since P' is closed, there is an $\alpha \in \Delta$ such that $\alpha \notin P'$. As P' satisfies (P 2), one then has $-\alpha \in P'$, and also $-2\alpha \in P'$ if 2α is a root.

For every $\beta \in R_+ \cap P'$, one has $\beta \neq \alpha$. If 2α is not a root, then $s_\alpha(\beta) \in R_+$ by Lemma 0.3.3.1; hence

$$s_\alpha(R_+ \cap P') \subset R_+ \cap s_\alpha(P').$$

But $R_+ \cap s_\alpha(P')$ also contains $\alpha = s_\alpha(-\alpha)$, contradicting $(*)$. If 2α is a root, the same argument applies. □

Thus, to study closed sets of roots satisfying (P 2), it is enough to consider those that contain a system of positive roots.

Proposition 0.3.3.10. *Let R_+ be a system of positive roots, and let P' be a closed subset of R containing R_+. Put*

$$\Delta = \mathscr{S}(R_+), \qquad \Delta' = \Delta \cap (-P').$$

Then P' is the union of R_+ and the set of roots that are linear combinations of the elements of Δ' with negative coefficients.

Proof. We argue by induction on the order of a root $\gamma \in P' \setminus R_+$. If $\mathrm{ord}_\Delta(\gamma) = -1$, then $-\gamma \in \Delta$, and hence $\gamma \in -\Delta'$.

Suppose that $\mathrm{ord}_\Delta(\gamma) < -1$. By Proposition 0.3.1.2, there exists $\beta \in \Delta$ such that $-\gamma - \beta \in R$. Then

$$0 < \mathrm{ord}_\Delta(-\gamma - \beta) = \mathrm{ord}_\Delta(-\gamma) - 1 < \mathrm{ord}_\Delta(-\gamma).$$

The first inequality shows that $-\gamma - \beta \in R_+$. Consequently, since $R_+ \cap (-R_+) = \varnothing$, and since $\gamma + \beta$ is the sum of two roots of P', the root $\gamma + \beta$ belongs to $P' \setminus R_+$ and satisfies

$$\mathrm{ord}_\Delta(\gamma + \beta) > \mathrm{ord}_\Delta(\gamma).$$

By induction, $\gamma + \beta$ is a linear combination of the elements of Δ' with negative coefficients. Since $\gamma = (\gamma + \beta) - \beta$, it remains only to show that $\beta \in -P'$. But $\gamma \in P'$ and $-(\gamma + \beta) \in R_+ \subset P'$, so

$$-\beta = \gamma - (\gamma + \beta) \in P'.$$

□

Definition 3.3.10.1. [10] A subset R' of R is called *symmetric* if

$$-R' = R'.$$

[10] Editors' note: This definition was inserted here.

Scholium 0.3.3.11. *Let P' be a set of roots satisfying (P 2) and closed. There exist a system of simple roots Δ and a subset Δ' of Δ such that*

$$P' = R \cap (\mathbb{N} \cdot \Delta \cup -\mathbb{N} \cdot \Delta').$$

If

$$R_{\Delta'} = (\mathbb{Z} \cdot \Delta') \cap R,$$

which is a closed and symmetric subset of R, then P' is the disjoint union of $R_{\Delta'}$ and the closed subset of $\mathscr{P}(\Delta)$ formed by the

$$\alpha \in \mathscr{P}(\Delta) \setminus \mathbb{N} \cdot \Delta',$$

that is, the positive roots whose decomposition with respect to Δ "contains at least one root of $\Delta \setminus \Delta'$".

0.3.4 Closed and symmetric sets of roots

Proposition 0.3.4.1. *Let*

$$\mathcal{R} = (M, M^*, R, R^*)$$

be a root datum, and let R' be a closed and symmetric subset of R. Then:

(i) $\mathcal{R}' = (M, M^*, R', R'^*)$ is a root datum;

(ii) for every system of positive roots R_+ of R, $R'_+ = R_+ \cap R'$ is a system of positive roots of R';

(iii) the Weyl group $W(\mathcal{R}')$ of $\mathcal{R}'$ is the subgroup of $W(\mathcal{R})$ generated by the s_α, for $\alpha \in R'$.

Proof. The first assertion is immediate from Corollary 0.1.2.11; the second follows from Corollary 0.3.3.8; and the third is evident. □

Corollary 0.3.4.2. *Let $w \in W(\mathcal{R}')$. The order of w is the smallest integer $n > 0$ such that*

$$w^n(\alpha') = \alpha' \qquad \text{for every } \alpha' \in R'.$$

Proof. Apply Corollary 0.1.2.7 to the root datum $\mathcal{R}'$. □

Corollary 0.3.4.3. *Let α and β be two nonproportional roots. Let n be the smallest integer > 0 such that*

$$(s_\alpha s_\beta)^n(\alpha) = \alpha, \qquad (s_\alpha s_\beta)^n(\beta) = \beta.$$

Then the subgroup $W_{\alpha,\beta}$ of W generated by s_α and s_β is defined by the relations

$$s_\alpha^2 = 1, \qquad s_\beta^2 = 1, \qquad (s_\alpha s_\beta)^n = 1.$$

Proof. In view of Corollary 0.3.4.2, it remains only to verify the following lemma. □

Lemma 0.3.4.4. *Let G be the group generated by two elements x and y subject to the relations $x^2 = y^2 = 1$. Every normal subgroup of G containing neither x nor y is generated, as a normal subgroup, by an element of the form $(xy)^n$, where $n > 0$.*

Proof. [11] Every element of G can be written as $(xy)^n$, as $(yx)^n = (xy)^{-n}$, or in one of the forms

$$(a) \qquad x(yx)^{2n} \qquad \text{or } y(xy)^{2n+1},$$
$$(b) \qquad y(xy)^{2n} \qquad \text{or } x(yx)^{2n+1},$$

where $n \in \mathbb{N}$. The elements of type (a), respectively of type (b), are conjugate to x, respectively to y. □

Remark 0.3.4.5. The integer n is computed immediately. Put

$$(\alpha^*, \beta) = p, \qquad (\beta^*, \alpha) = q.$$

Then[12]

$$(s_\alpha s_\beta)(\alpha) = (pq-1)\alpha - q\beta, \qquad (s_\alpha s_\beta)(\beta) = p\alpha - \beta.$$

Thus n is the order of the matrix

$$\begin{pmatrix} pq-1 & p \\ -q & -1 \end{pmatrix}.$$

If $pq = 0$, then $p = q = 0$ by Corollary 0.2.2.2, whence $n = 2$. Otherwise, Proposition 0.2.3.1 shows that pq equals 1, 2, or 3, and one finds respectively $n = 3$, 4, or 6.

N.B. Expressing the finiteness of the order of the preceding matrix recovers inequality (13) of Proposition 0.2.3.1.

Definition 0.3.4.6. Let Δ be a system of simple roots and let $\Delta' \subset \Delta$. We write

$$R_{\Delta'} = R \cap (\mathbb{Q} \cdot \Delta') = R \cap (\mathbb{Z} \cdot \Delta').$$

Lemma 0.3.4.7. *The set $R_{\Delta'}$ is closed and symmetric, and Δ' is a system of simple roots of the root datum*

$$(M, M^*, R_{\Delta'}, R^*_{\Delta'}).$$

Its Weyl group is the subgroup $W_{\Delta'}$ of W generated by the s_α, for $\alpha \in \Delta'$. Moreover,

$$\Delta \cap R_{\Delta'} = \Delta'.$$

Proof. Trivial. □

Proposition 0.3.4.8. *Let $R' \subset R$. The following conditions are equivalent:*

(i) There exists a vector subspace V' of V, or of $\mathcal{V}(R)$, such that $R' = R \cap V'$.

(ii) There exist a system of simple roots Δ of R and a subset Δ' of Δ such that $R' = R_{\Delta'}$.

More precisely, under these conditions, every system of simple roots Δ' of (M, M^*, R', R'^*) is contained in a system of simple roots Δ of R, and one has $R' = R_{\Delta'}$.

Proof. The implication (ii) ⇒ (i) is clear. Suppose (i). Then R' is closed and symmetric, so (M, M^*, R', R'^*) is a root datum. Let Δ' be a system of simple roots of this datum, and put

$$R'_+ = \mathscr{P}(\Delta').$$

[11] Editors' note: The original has been corrected in what follows.
[12] Editors' note: The original has been corrected in what follows.

If $V' = V$, then Δ' is a system of simple roots of $\mathcal{R}$, and there is nothing to prove. Otherwise, there exists $x \in V^*$ such that

$$(x, V') = \{0\}, \qquad (x, \alpha) \neq 0 \quad \text{for every } \alpha \in R \setminus R'.$$

Put

$$R_+(x) = \{\alpha \in R \mid (x, \alpha) > 0\}, \qquad R_+ = R_+(x) \cup R'_+.$$

For every $\alpha \in R$, one has

$$(x, \alpha) > 0 \Longleftrightarrow \alpha \in R_+(x),$$
$$(x, \alpha) < 0 \Longleftrightarrow \alpha \in -R_+(x),$$
$$(x, \alpha) = 0 \Longleftrightarrow \alpha \in R'.$$

It follows at once from Corollary 0.3.3.8 that R_+ is a system of positive roots of R. Put $\Delta = \mathscr{S}(R_+)$. It is enough to prove that $\Delta' \subset \Delta$. Otherwise, let $\alpha \in \Delta' \setminus \Delta$. By Corollary 0.3.2.14, there exist $\beta, \gamma \in R_+$ such that

$$\alpha = \beta + \gamma.$$

If $\beta, \gamma \in R_+(x)$, then $\alpha \in R_+(x)$, which is impossible because $(x, \Delta') = 0$. If one of β, γ, say β, belongs to R'_+, then, since R' is symmetric and closed,

$$\gamma = \alpha - \beta \in R_+ \cap R' = R'_+.$$

But then α is not simple in R'_+, again a contradiction. □

Lemma 0.3.4.9. *Under the preceding conditions, let*

$$\alpha \in \mathscr{P}(\Delta) \setminus R'.$$

For every $w \in W_{\Delta'}$, one has

$$w(\alpha) \in \mathscr{P}(\Delta) \setminus R'.$$

Proof. It suffices to verify the assertion for $w = s_\beta$, $\beta \in \Delta'$. It then follows from Lemma 0.3.3.1 and from $s_\beta(R') = R'$. □

Lemma 0.3.4.10. *Let $w \in W$. Under the conditions of Proposition 0.3.4.8, the following conditions are equivalent:*

(i) $w \in W_{\Delta'}$.

(ii) For every $m \in M$, one has $w(m) - m \in V'$.

(iii) For every $\alpha \in R$, one has $w(\alpha) - \alpha \in V'$.

Proof. Clearly (i) implies (ii), and (ii) implies (iii). Suppose (iii). Write

$$w = s_{\alpha_n} \cdots s_{\alpha_1}, \qquad \alpha_i \in \Delta,$$

and argue by induction on n that every α_i belongs to Δ'. We may assume that

$$w' = s_{\alpha_{n-1}} \cdots s_{\alpha_1} \in W_{\Delta'}.$$

Then, for every $\alpha \in R$,

$$w(\alpha) - \alpha = w'(\alpha) - \alpha - (\alpha_n^*, w'(\alpha))\alpha_n.$$

Taking $\alpha = {w'}^{-1}(\alpha_n)$, one obtains $2\alpha_n \in V'$, hence $\alpha_n \in \Delta'$. Therefore

$$w = s_{\alpha_n} w' \in W_{\Delta'}.$$

□

0.3.5 Miscellaneous remarks

Proposition 0.3.5.1. *Let R_+ be a system of positive roots. Put*

$$\rho_{R_+} = \frac{1}{2} \sum_{\alpha \in \mathrm{ind}(R_+)} \alpha.$$

Then

$$(\beta^*, \rho_{R_+}) = 1 \qquad \text{for every } \beta \in \mathscr{S}(R_+).$$

Proof. One can write

$$2\rho_{R_+} = \beta + \sum_{\substack{\alpha \in \mathrm{ind}(R_+) \\ \alpha \neq \beta}} \alpha.$$

Hence

$$s_\beta(2\rho_{R_+}) = 2\rho_{R_+} - 2\beta$$

by Lemma 0.3.3.2. □

Corollary 0.3.5.2. *Put*

$$\rho^*_{R_+} = \frac{1}{2} \sum_{\alpha^* \in \mathrm{ind}(R^*_+)} \alpha^*.$$

Then:

(i) $(\rho^*_{R_+}, \alpha) > 0$ *for every* $\alpha \in R_+$*; equivalently,* $\rho^*_{R_+} \in \mathcal{C}(R_+)$*, in the notation of Definition 0.3.6.8.*

(ii) For every $\alpha \in R$*,*

$$\mathrm{ord}_{\mathscr{S}(R_+)}(\alpha) = (\rho^*_{R_+}, \alpha).$$

[13]

Remark 0.3.5.3. If $w \in W$, then

$$\rho_{w(R_+)} = w(\rho_{R_+}), \qquad \rho^*_{w(R_+)} = w(\rho^*_{R_+}).$$

Proposition 0.3.5.4. *Let α and γ be two nonproportional roots, with α indivisible. There exist a system of simple roots containing α and a root β such that*

$$\gamma = a\alpha + b\beta, \qquad a, b \in \mathbb{N}.$$

Proof. Choose a basis of the vector space $\mathcal{V}(R)$ containing $\alpha_1 = \alpha$ and $\alpha_2 = \gamma$, and consider the lexicographic order with respect to this basis. Let R_+ be the set of roots > 0. It is clear that R_+ is a system of positive roots and[14] that the least element of R_+ not proportional to α is simple. This element has the form

$$\beta = p\alpha + q\gamma, \qquad 0 < q \leq 1.$$

Consequently

$$\gamma = q^{-1}\beta - q^{-1}p\alpha.$$

Since $q^{-1} > 0$, one has

$$q^{-1} \in \mathbb{N}^*, \qquad -q^{-1}p \in \mathbb{N}.$$

□

[13] Editors' note: By Lemma 0.3.1.5, it is enough to verify the formula for $\alpha \in \Delta$. Proposition 0.3.5.1, applied to R^*, then gives $(\rho^*_{R_+}, \alpha) = 1 = \mathrm{ord}_{\mathscr{S}(R_+)}(\alpha)$.

[14] Editors' note: The original was modified here to take account of the case in which 2α is a root.

We conclude with two remarks on the group $\Gamma_0(R)$.

Proposition 0.3.5.5. *Let G be an abelian group, and let $f : R \to G$ be a map satisfying:*

(i) if $\alpha \in R$, then $f(-\alpha) = -f(\alpha)$;

(ii) if $\alpha, \beta, \alpha + \beta \in R$, then

$$f(\alpha + \beta) = f(\alpha) + f(\beta).$$

There exists a unique group homomorphism

$$\overline{f} : \Gamma_0(R) \longrightarrow G$$

such that $\overline{f}(\alpha) = f(\alpha)$ for every $\alpha \in R$.

Proof. Let Δ be a system of simple roots of R, and write

$$\beta = \sum_{\alpha \in \Delta} a(\alpha)\alpha.$$

Lemma 0.3.2.16 gives at once

$$f(\beta) = \sum_{\alpha \in \Delta} a(\alpha) f(\alpha).$$

Now Δ is a basis of $\Gamma_0(R)$. □

Proposition 0.3.5.6. *Let Δ be a system of simple roots. There exists on $\Gamma_0(R)$ a totally ordered group structure such that the roots > 0 are the elements of $\mathscr{P}(\Delta)$, and such that*

$$\alpha \longmapsto \mathrm{ord}_\Delta(\alpha)$$

is increasing.

Proof. Let

$$\alpha_1, \alpha_2, \ldots, \alpha_n, \qquad n = \mathrm{rgss}(\mathcal{R}),$$

be the elements of Δ. Every $x \in \Gamma_0(R)$ has a decomposition

$$x = \sum_{i=1}^{n} m_i(x)\alpha_i.$$

Take the lexicographic order with respect to the functions

$$\sum_i m_i, \quad m_n, \quad m_{n-1}, \quad \ldots, \quad m_2.$$

□

Remark 0.3.5.7. The first roots, in order, are

$$\alpha_1, \alpha_2, \ldots, \alpha_n;$$

then come, when they are roots,

$$2\alpha_1, \quad \alpha_1 + \alpha_2, \quad \alpha_1 + \alpha_3, \quad \ldots.$$

0.3.6 Weyl chambers

Lemma 0.3.6.1. *Let V be a finite-dimensional real vector space.*[15] *Let f_i be independent linear forms. Put*

$$C = \{x \in V \mid f_i(x) > 0\}.$$

Then C is a maximal convex subset of

$$X = V \setminus \bigcup_i f_i^{-1}(0).$$

Proof. Trivial. □

Definition 0.3.6.2. A subset $C \subset V$ described by the construction of Lemma 0.3.6.1 is called, here, a *chamber* of V.

Definition 0.3.6.3. A hyperplane H of V is called a *wall* of C if

$$H \cap (\overline{C} \setminus C)$$

contains a nonempty open subset of H.

Remark 0.3.6.4. For a convex subset, the closure can be described without reference to the topology of V: it is the set of endpoints of all open segments contained in the given subset.

Lemma 0.3.6.5. *Under the conditions of Lemma 0.3.6.1,*

$$\overline{C} = \{x \in V \mid f_i(x) \geq 0\}.$$

The walls of C are the hyperplanes $f_i^{-1}(0)$.

Proof. The first assertion is clear. The second follows from

$$\overline{C} \setminus C \subset \bigcup_i f_i^{-1}(0)$$

and from the fact that the $f_i^{-1}(0)$ are visibly walls of C. □

Proposition 0.3.6.6. *Let C be a chamber of V. If*

$$H_i, \qquad i = 1, 2, \ldots, n,$$

are the distinct walls of C, then, for every system of linear forms $\{u_i\}$ such that $H_i = u_i^{-1}(0)$, there exist $\varepsilon_i \in \{-1, +1\}$ for which

$$C = \{x \in V \mid \varepsilon_i u_i(x) > 0\}.$$

For every wall H of C,

$$H \cap C = \varnothing, \qquad H \cap \overline{C} = \overline{C_H},$$

where C_H is a chamber in H. The walls of C_{H_i} are the $H_j \cap H_i$, for $j \neq i$.

Proof. This follows immediately from the lemma. □

Definition 0.3.6.7. The C_{H_i} are called the *faces* of C.

[15] Editors' note: The original $\mathbb{Q}$ has been replaced by $\mathbb{R}$.

Let now

$$\mathcal{R} = (M, M^*, R, R^*)$$

be a root datum, and put

$$V_{\mathbb{R}}^* = M^* \otimes \mathbb{R}.$$

Definition 0.3.6.8. [16] For every $\alpha \in R$, put

$$\mathcal{H}_\alpha = \{x \in V_{\mathbb{R}}^* \mid (x, \alpha) = 0\}.$$

Write

$$X = V_{\mathbb{R}}^* \setminus \bigcup_{\alpha \in R} \mathcal{H}_\alpha.$$

For every $x \in X$, put

$$R_+(x) = \{\alpha \in R \mid (x, \alpha) > 0\}.$$

For every system of positive roots R_+, put

$$\mathcal{C}(R_+) = \{x \in V_{\mathbb{R}}^* \mid (x, \alpha) > 0 \text{ for every } \alpha \in R_+\}.$$

Proposition 0.3.6.9. *(i) For every $x \in X$, $R_+(x)$ is a system of positive roots. For every system of positive roots R_+, $\mathcal{C}(R_+)$ is a chamber in $V_{\mathbb{R}}^*$. The $\mathcal{C}(R_+)$ are the maximal convex subsets of X.*

(ii) Let Δ be a system of simple roots. One has

$$\mathcal{C}(\mathscr{P}(\Delta)) = \{x \in V_{\mathbb{R}}^* \mid (x, \alpha) > 0 \text{ for every } \alpha \in \Delta\}.$$

The walls of $\mathcal{C}(\mathscr{P}(\Delta))$ are the hyperplanes

$$\mathcal{H}_\alpha = \alpha^{-1}(0), \qquad \alpha \in \Delta;$$

its faces are

$$C_\alpha = \{x \in V_{\mathbb{R}}^* \mid (x, \alpha) = 0,\ (x, \beta) > 0 \text{ for } \beta \in \Delta,\ \beta \neq \alpha\}.$$

(iii) One has the equivalence

$$R_+(x) = R_+ \quad \Longleftrightarrow \quad x \in \mathcal{C}(R_+).$$

Proof. It is first clear that $R_+(x)$ is a system of positive roots. Since $x \in \mathcal{C}(R_+(x))$, the union of the $\mathcal{C}(R_+(x))$ is X. Property (iii) is immediate; it follows that the $\mathcal{C}(R_+)$ form a partition of X. The first assertion of (ii) is evident. It follows at once that $\mathcal{C}(R_+)$ is a chamber in $V_{\mathbb{R}}^*$, which proves the remainder of (i). Put

$$C = \mathcal{C}(\mathscr{P}(\Delta)).$$

It remains only to note that

$$\overline{C} \cap \left(V_{\mathbb{R}}^* \setminus \bigcup_{\alpha \in R} \alpha^{-1}(0)\right) = \overline{C} \cap \left(V_{\mathbb{R}}^* \setminus \bigcup_{\alpha \in \Delta} \alpha^{-1}(0)\right)$$

to complete the proof of (ii) by Lemma 0.3.6.1. □

[16] Editors' note: The definition of the hyperplanes $\mathcal{H}_\alpha$ was added here.

Definition 0.3.6.10. The $\mathcal{C}(R_+)$ are called the *Weyl chambers* of the root datum. Conversely, for every Weyl chamber C, put

$$R_+(C) = R_+(x)$$

for any $x \in C$.

Corollary 0.3.6.11. *The maps*

$$R_+ \longmapsto \mathcal{C}(R_+), \qquad C \longmapsto R_+(C)$$

give a bijective correspondence between systems of positive roots and Weyl chambers.

This correspondence is invariant under the Weyl group:

Lemma 0.3.6.12. *If $w \in W(\mathcal{R})$, then*

$$\mathcal{C}(w(R_+)) = w(\mathcal{C}(R_+)).$$

Corollary 0.3.6.13. *The correspondences*

$$\Delta \longleftrightarrow R_+ \longleftrightarrow C$$

are isomorphisms of homogeneous spaces under $W(\mathcal{R})$.

We shall see later that these homogeneous spaces are principal (5.5).

Remark 0.3.6.14. If C is a Weyl chamber, then $-C$ is also one; it is called the *opposite* of C. Consequently there exists $w_0 \in W$—and in fact exactly one, cf. 5.5—such that

$$w_0(C) = -C.$$

It is called the *symmetry* of the root datum relative to the Weyl chamber C (or relative to $R_+(C)$, or to $\mathscr{S}(R_+(C))$, and so on).

0.4 Reduced root data of semisimple rank 2

4.0.[17] Let $\mathcal{R}$ be a root datum of semisimple rank 2. Let $\{\alpha, \beta\}$ be a system of simple roots. Suppose that $\ell(\alpha) \leq \ell(\beta)$. By 0.2.3.1 and 0.3.2.1, there are then four possibilities:

Type	$\ell(\beta)/\ell(\alpha)$	$\ell(\beta^*)/\ell(\alpha^*)$	(β^*, α)	(α^*, β)
$A_1 \times A_1$	–	–	0	0
A_2	1	1	-1	-1
B_2	2	1/2	-1	-2
G_2	3	1/3	-1	-3

It follows from Remark 0.3.4.5 that the order of $s_\alpha s_\beta$ is respectively $2, 3, 4, 6$.

We study each of these systems separately and give the list of indivisible roots.

Type $A_1 \times A_1$. The indivisible roots are

$$\alpha, \quad \beta, \quad -\alpha, \quad -\beta.$$

[17] Editors' note: The numbering 4.0 was added for later references.

The corresponding coroots are

$$\alpha^*, \quad \beta^*, \quad -\alpha^*, \quad -\beta^*.$$

Type A_2. The indivisible positive roots are as follows:

root γ	α	β	$\alpha+\beta$
$\ell(\gamma)/\ell(\alpha)$	1	1	1
coroot γ^*	α^*	β^*	$\alpha^*+\beta^*$
$\ell(\gamma^*)/\ell(\beta^*)$	1	1	1

The half-sum of the indivisible positive roots is

$$\rho = \alpha + \beta.$$

Type B_2. The indivisible positive roots are as follows:

root γ	α	β	$\alpha+\beta$	$2\alpha+\beta$
$\ell(\gamma)/\ell(\alpha)$	1	2	1	2
coroot γ^*	α^*	β^*	$2\alpha^*+\beta^*$	$\alpha^*+\beta^*$
$\ell(\gamma^*)/\ell(\beta^*)$	2	1	2	1

The half-sum of the indivisible positive roots is

$$\rho = \frac{4\alpha + 3\beta}{2}.$$

Type G_2. The indivisible positive roots are as follows:

root γ	α	β	$\alpha+\beta$	$2\alpha+\beta$	$3\alpha+\beta$	$3\alpha+2\beta$
$\ell(\gamma)/\ell(\alpha)$	1	3	1	1	3	3
coroot γ^*	α^*	β^*	$\alpha^*+3\beta^*$	$2\alpha^*+3\beta^*$	$\alpha^*+\beta^*$	$\alpha^*+2\beta^*$
$\ell(\gamma^*)/\ell(\beta^*)$	3	1	3	3	1	1

The half-sum of the indivisible positive roots is

$$\rho = 5\alpha + 3\beta.$$

Proposition 0.4.1. [18] *Let n be the order of $s_\alpha s_\beta$. Put $u_0 = 0$, and, for $p \in \mathbb{N}$, define*

$$\begin{cases} u_{2p+1} = u_{2p} + (s_\alpha s_\beta)^p(\alpha), \\ u_{2p+2} = u_{2p+1} + (s_\alpha s_\beta)^p s_\alpha(\beta). \end{cases}$$

Then: [19]

[18] The following numbers 4.1 to 4.4 are used in the proof of Theorem 0.5.1. There are now simpler proofs of that theorem; see *Groupes et algèbres de Lie*, Chapter V, §3, Theorem 1. Editors' note: The reference was made explicit and this note, which occurred at 4.2 in the original, was moved here.

[19] Editors' note: Let ρ be the half-sum of the positive roots, cf. Proposition 0.3.5.1. If, as below, one puts $w_0 = 1$, $w_1 = s_\alpha$, $w_2 = s_\beta s_\alpha$, $w_3 = s_\alpha s_\beta s_\alpha$, and so on, then $u_k = \rho - w_k^{-1}(\rho)$. This proves (i), since $w_{2n} = 1$.

(i) $u_{k+2n} = u_k$, *for every* $k \in \mathbb{N}$.

(ii) $u_0 = 0$, $u_1 = \alpha$, $u_{2n-1} = \beta$, *and* $u_{2n} = 0$.

(iii) If $1 < k < 2n-1$, *then*

$$u_k = a_k\alpha + b_k\beta, \qquad a_k, b_k \in \mathbb{N}^*.$$

Proof. Assertion (i) follows from $(s_\alpha s_\beta)^n = 1$ and $u_{2n} = 0$.

We prove (ii) and (iii). Direct calculation gives, in the four cases, the following sequences of values: [20]

$A_1 \times A_1$	$0, \alpha, \beta+\alpha, \beta, 0,$
A_2	$0, \alpha, \beta+2\alpha, 2\beta+2\alpha, 2\beta+\alpha, \beta, 0,$
B_2	$0, \alpha, \beta+3\alpha, 2\beta+4\alpha, 3\beta+4\alpha, 3\beta+3\alpha, 2\beta+\alpha, \beta, 0,$
G_2	$0, \alpha, \beta+4\alpha, 2\beta+6\alpha, 4\beta+9\alpha, 5\beta+10\alpha, 6\beta+10\alpha,$ $6\beta+9\alpha, 5\beta+6\alpha, 4\beta+4\alpha, 2\beta+\alpha, \beta, 0.$

□

Lemma 0.4.2. *Put*

$$w_{2p} = (s_\beta s_\alpha)^p, \qquad w_{2p+1} = s_\alpha(s_\beta s_\alpha)^p,$$

so that $w_0, \ldots, w_{2n-1}$ *are the distinct elements of* W. *Let* $u_0, \ldots, u_{2n-1}$ *be the elements of* V *defined in Proposition 0.4.1. For every* $x \in V^*$, *one has*

$$x - w_k(x) = n_k\alpha^* + m_k\beta^*,$$

where $n_k, m_k \in \mathbb{Q}$ *and*

$$n_k + m_k = (x, u_k).$$

[21]

Proof. The proof is by induction on k. If $k = 0$, the formula is trivial. We carry out, for example, the passage from w_{2p} to w_{2p+1}. Since $w_{2p+1} = s_\alpha w_{2p}$,

$$\begin{aligned} x - w_{2p+1}(x) &= x - w_{2p}(x) + w_{2p}(x) - s_\alpha w_{2p}(x) \\ &= n_{2p}\alpha^* + m_{2p}\beta^* + (w_{2p}(x), \alpha)\alpha^*. \end{aligned}$$

Consequently

$$\begin{aligned} n_{2p+1} + m_{2p+1} &= n_{2p} + m_{2p} + \big((s_\beta s_\alpha)^p(x), \alpha\big) \\ &= (x, u_{2p}) + \big(x, (s_\alpha s_\beta)^p(\alpha)\big) \\ &= (x, u_{2p+1}). \end{aligned}$$

□

[20] Editors' note: The original was corrected here to agree with the convention $\ell(\alpha) \le \ell(\beta)$ of 4.0.

[21] Editors' note: In view of the preceding editor's note, this follows immediately from Propositions 0.3.5.1 and 0.1.1.9: one has

$$n_k + m_k = (x - w_k(x), \rho) = (x, \rho - w_k^{-1}(\rho)) = (x, u_k).$$

Corollary 0.4.3. [22] *Let $x \in V^*$. For every $w \in W$, put*

$$x - w(x) = a_w\alpha^* + b_w\beta^*.$$

If $(x, \alpha) \geq 0$ and $(x, \beta) \geq 0$, then

$$a_w + b_w \geq 0.$$

If moreover $(x, \alpha) > 0$ (respectively $(x, \beta) > 0$), then

$$a_w + b_w > 0$$

for $w \neq 1, s_\beta$ (respectively for $w \neq 1, s_\alpha$).

Proof. This follows at once from Proposition 0.4.1 and Lemma 0.4.2. □

Corollary 0.4.4. *Let $\mathcal{R}$ be any root datum, and let Δ be a system of simple roots. Let γ be a positive root, let α, β be two simple roots, and let $W_{\alpha,\beta}$ be the subgroup of W generated by s_α and s_β. If*

$$\mathrm{ord}_\Delta(s_\alpha(\gamma)) < \mathrm{ord}_\Delta(\gamma), \qquad \mathrm{ord}_\Delta(s_\beta(\gamma)) \leq \mathrm{ord}_\Delta(\gamma),$$

then, for every $w \in W_{\alpha,\beta}$,

$$\mathrm{ord}_\Delta(w(\gamma)) \leq \mathrm{ord}_\Delta(\gamma).$$

Moreover,

$$\mathrm{ord}_\Delta(w(\gamma)) < \mathrm{ord}_\Delta(\gamma)$$

if $w \neq 1, s_\beta$.

Proof. Consider the dual root datum $\mathcal{R}^*$, and then the datum

$$(M^*, M, R'^*, R'),$$

where R' is the set of roots that are rational linear combinations of α and β. Applying Corollary 0.4.3 to this datum gives the stated result. [23] □

0.5 The Weyl group: generators and relations

Let $\mathcal{R}$ be a root datum. Since the Weyl group is the same for this datum and for the corresponding reduced datum, we may assume $\mathcal{R}$ reduced when studying the Weyl group.

Let

$$\Delta = \{\alpha_1, \ldots, \alpha_n\}$$

be a system of simple roots, where $n = \mathrm{rgss}(\mathcal{R})$. Let n_{ij} be the order of $s_{\alpha_i}s_{\alpha_j}$ in W. In particular $n_{ii} = 1$, and Remarks 0.3.4.2 and 0.3.4.3 show that the subgroup W_{ij} of W generated by s_{α_i} and s_{α_j} is defined by

$$s_{\alpha_i}^2 = s_{\alpha_j}^2 = (s_{\alpha_i}s_{\alpha_j})^{n_{ij}} = 1.$$

Theorem 0.5.1. *The group W is the group generated by the elements*

$$s_{\alpha_i}, \qquad i = 1, 2, \ldots, n,$$

subject to the relations

$$(s_{\alpha_i}s_{\alpha_j})^{n_{ij}} = 1.$$

[22] Editors' note: The statement was corrected.

[23] Editors' note: The hypotheses say that $(\gamma, \alpha^*) > 0$ and $(\gamma, \beta^*) \geq 0$. Consequently $\gamma - w(\gamma) \in \mathbb{N}\alpha + \mathbb{N}\beta$ for every $w \in W_{\alpha,\beta}$, and it is nonzero if $w \notin \{1, s_\beta\}$.

Proof. We have already seen that the theorem is true when $n = 2$; we shall use this fact in the proof. Introduce the group $\widetilde{W}$ generated by elements

$$T_i, \qquad i = 1, 2, \ldots, n,$$

subject to the relations

$$(T_i T_j)^{n_{ij}} = 1.$$

In particular $n_{ii} = 1$, whence $T_i^2 = 1$. Let

$$p : \widetilde{W} \longrightarrow W$$

be the group homomorphism sending T_i to s_{α_i}. We know that p is surjective; we shall prove that it is injective. □

Lemma 0.5.2. *For every $\alpha \in \mathscr{P}(\Delta)$, one can define uniquely an element $T_\alpha \in \widetilde{W}$ with the following properties:*

(i) $p(T_\alpha) = s_\alpha$;

(ii) $T_{\alpha_i} = T_i$;

(iii) if β and α are positive roots such that $s_{\alpha_i}(\alpha) = \beta$, then

$$T_i T_\alpha T_i = T_\beta.$$

Proof. First observe that it follows from 0.1.2.10 and 0.3.3.6 that (i) is a consequence of (ii) and (iii), and that (ii) and (iii) determine the T_α completely. We construct them by induction on $\mathrm{ord}_\Delta(\alpha)$. If $\mathrm{ord}_\Delta(\alpha) = 1$, then $\alpha \in \Delta$, and we put $T_\alpha = T_i$ if $\alpha = \alpha_i$.

Consider the hypothesis

(H_p) there exist T_α, for $\alpha \in \mathscr{P}(\Delta)$ with $\mathrm{ord}_\Delta(\alpha) \leq p$, satisfying (ii), and satisfying (iii) whenever $\mathrm{ord}_\Delta(\alpha) \leq p$ and $\mathrm{ord}_\Delta(\beta) \leq p$.

It holds for $p = 1$. Indeed, if α and $s_{\alpha_i}(\alpha) = \beta$ are simple, then α_i and α are orthogonal. Thus, if $\alpha_j = \alpha = \beta$, one has $n_{ij} = 2$, whence

$$T_i T_j T_i = T_j.$$

Suppose $p > 1$ and (H_{p-1}) holds.

A) Construction of the T_α for $\mathrm{ord}_\Delta(\alpha) \leq p$. It is enough to do this when $\mathrm{ord}_\Delta(\alpha) = p$. There exists $\alpha_i \in \Delta$ such that

$$s_{\alpha_i}(\alpha) \in \mathscr{P}(\Delta), \qquad \mathrm{ord}_\Delta(s_{\alpha_i}(\alpha)) < p$$

by Lemma 0.3.3.3. Put

$$(\star) \qquad T_\alpha = T_i T_{s_{\alpha_i}(\alpha)} T_i.$$

We verify that T_α depends only on α. Let $\alpha_j \in \Delta$ also satisfy

$$s_{\alpha_j}(\alpha) \in \mathscr{P}(\Delta), \qquad \mathrm{ord}_\Delta(s_{\alpha_j}(\alpha)) < p.$$

We must prove

$$(+) \qquad T_i T_{s_{\alpha_i}(\alpha)} T_i = T_j T_{s_{\alpha_j}(\alpha)} T_j.$$

We distinguish two cases.

(1) Suppose that α is a linear combination of α_i and α_j. The same is then true of $s_{\alpha_i}(\alpha)$ and $s_{\alpha_j}(\alpha)$; by (H_{p-1}), the elements $T_{s_{\alpha_i}(\alpha)}$ and $T_{s_{\alpha_j}(\alpha)}$ are words in T_i, T_j. Since the projection of $(+)$ to W holds and the theorem is true for $n = 2$, the restriction of p to the subgroup of $\widetilde{W}$ generated by T_i, T_j is injective. Thus $(+)$ holds.

(2) Suppose that α is not a linear combination of α_i and α_j. Then, for $w \in W_{\alpha_i,\alpha_j}$, all the $w(\alpha)$ are positive (cf. Lemma 0.3.4.9). The relation to be verified can also be written

$$(++) \qquad (T_iT_j)^{n_{ij}-1}T_{s_{\alpha_i}(\alpha)}(T_jT_i)^{n_{ij}-1} = T_{s_{\alpha_j}(\alpha)}.$$

Corollary 0.4.4 shows that all the $w(\alpha)$ have order $< p$ for $w \in W_{\alpha_i,\alpha_j}$, $w \neq 1$. We may therefore apply (H_{p-1}) $2(n_{ij}-1)$ times, which proves the relation.

B) Verification of (H_p)**.** [24] We must verify that, if $\alpha_j \in \Delta$ and $\beta = s_{\alpha_j}(\alpha)$ satisfies $\mathrm{ord}_\Delta(\beta) \leq p$, then

$$T_jT_\alpha T_j = T_\beta.$$

If $\mathrm{ord}_\Delta(\beta) < p$, this follows from the preceding construction, since $T_j^2 = 1$. We may therefore suppose

$$\mathrm{ord}_\Delta(\beta) = p = \mathrm{ord}_\Delta(\alpha).$$

In this case α and α_j are orthogonal, so $\beta = \alpha$, and it remains to prove

$$(\dagger) \qquad T_jT_\alpha T_j = T_\alpha.$$

By $(\star)$,

$$T_\alpha = T_iT_{s_{\alpha_i}(\alpha)}T_i,$$

so it remains to verify

$$(+++) \qquad T_jT_iT_{s_{\alpha_i}(\alpha)}T_iT_j = T_\alpha = T_iT_{s_{\alpha_i}(\alpha)}T_i.$$

□

Proof of Lemma 0.5.2, continued. Put $m = n_{ij}$, $s_i = s_{\alpha_i}$, and $s_j = s_{\alpha_j}$. We have

$$T_jT_i = (T_iT_j)^{m-1}.$$

By Corollary 0.4.4, $\mathrm{ord}_\Delta(w(\alpha)) < p$ for every $w \in W_{ij}$ distinct from

$$1 = (s_is_j)^m \quad \text{and} \quad s_j = s_i(s_is_j)^{m-1}.$$

The induction hypothesis therefore gives

$$\begin{aligned} &T_j(T_iT_j)^{m-2}T_{s_i(\alpha)}(T_jT_i)^{m-2}T_j \\ &\quad = T_{s_j(s_is_j)^{m-2}s_i(\alpha)} = T_{s_is_j(\alpha)} = T_{s_i(\alpha)}. \end{aligned}$$

The last equality holds because $s_j(\alpha) = \alpha$. Hence

$$(T_iT_j)^{m-1}T_{s_i(\alpha)}(T_jT_i)^{m-1} = T_iT_{s_i(\alpha)}T_i,$$

which proves $(+++)$. □

[24] Editors' note: The argument in the original has been expanded in what follows.

Lemma 0.5.3. *Let $h \in \widetilde{W}$. Write*

$$h = T_{\alpha_1} \cdots T_{\alpha_m},$$

where the $\alpha_i \in \Delta$, not necessarily distinct, are chosen so that m is minimal. Then

$$p(h)(\alpha_m) \in -\mathscr{P}(\Delta).$$

Proof. Since

$$p(T_{\alpha_m})(\alpha_m) = s_{\alpha_m}(\alpha_m) = -\alpha_m,$$

if $p(h)(\alpha_m)$ were positive, there would be an index k, $1 \leq k \leq m-1$, such that

$$u = s_{\alpha_{k+1}} \cdots s_{\alpha_m}(\alpha_m) = -s_{\alpha_{k+1}} \cdots s_{\alpha_{m-1}}(\alpha_m) \in -\mathscr{P}(\Delta)$$

and $s_{\alpha_k}(u) \in \mathscr{P}(\Delta)$. Necessarily $u = -\alpha_k$, by Lemma 0.3.3.1, whence

$$s_{\alpha_{k+1}} \cdots s_{\alpha_{m-1}}(\alpha_m) = \alpha_k.$$

Property (iii) of Lemma 0.5.2 then gives

$$T_{\alpha_k} T_{\alpha_{k+1}} \cdots T_{\alpha_{m-1}} T_{\alpha_m} = T_{\alpha_{k+1}} \cdots T_{\alpha_{m-1}},$$

contradicting the minimality of m. □

Let now $h \in \widetilde{W}$ satisfy

$$p(h)(\mathscr{P}(\Delta)) \subset \mathscr{P}(\Delta).$$

Lemma 0.5.3 gives $p(h) = 1$. This proves Theorem 0.5.1 and also the following two corollaries.

Corollary 0.5.4. *If R_+ is a system of positive roots and $w \in W$ satisfies $w(R_+) = R_+$, then $w = 1$.*

Corollary 0.5.5. *The Weyl group acts freely and transitively on the set of systems of positive roots, respectively on the set of systems of simple roots, respectively on the set of Weyl chambers.*

Choose a system of simple roots Δ, and put

$$R^+ = \mathscr{P}(\Delta).$$

[25] For every pair of simple roots $(\alpha, \beta) \in \Delta \times \Delta$, let $R_{\alpha,\beta}$ be the set of roots that are linear combinations of α and β. Put

$$R^+_{\alpha,\beta} = R^+ \cap R_{\alpha,\beta},$$

and let $W_{\alpha,\beta}$ be the Weyl group of $R_{\alpha,\beta}$, that is, the subgroup of W generated by s_α and s_β.

Theorem 0.5.6 (Tits)**.** *Let α and β be two simple roots, and let $w \in W$ satisfy $w(\alpha) = \beta$. There exist a sequence of simple roots $\alpha_0, \ldots, \alpha_m$ and a sequence $w_0, \ldots, w_{m-1}$ of elements of W satisfying:*

(i) $\alpha_0 = \alpha$ and $\alpha_m = \beta$;

[25] Editors' note: The superscript notation R^+, rather than R_+, is used here so that $R^+_{\alpha,\beta} = R_{\alpha,\beta} \cap R^+$.

(ii) $w = w_{m-1}w_{m-2}\cdots w_0$;

(iii) $w_i(\alpha_i) = \alpha_{i+1}$ *for* $0 \leq i \leq m-1$;

(iv) for every i, $0 \leq i \leq m-1$, *such that* $\alpha_i \neq \alpha_{i+1}$, *one has* $w_i \in W_{\alpha_i,\alpha_{i+1}}$;

(v) for every i, $0 \leq i \leq m-1$, *such that* $\alpha_i = \alpha_{i+1}$, *there exists a simple root* β_i *such that* $w_i \in W_{\alpha_i,\beta_i}$.

Proof. Put[26]

$$M(w) = \mathrm{Card}(R^+ \cap w^{-1}(-R^+)) = \mathrm{Card}\{\gamma \in R^+ \mid w(\gamma) \in -R^+\}.$$

If $M(w) = 0$, then $w(R^+) = R^+$, so $w = 1$ by Corollary 0.5.4; the theorem is then trivial: $m = 0$, and assertions (iii)–(v) are empty.

We argue by induction on $M(w)$. Suppose $M(w) > 0$. There exists $\beta_0 \in \Delta$ such that $w(\beta_0) \in -R^+$. Put $\alpha_0 = \alpha$, and consider

$$A = w^{-1}(R^+) \cap R_{\alpha_0,\beta_0}.$$

This is a system of positive roots of R_{α_0,β_0}. Hence there exists $w_0 \in W_{\alpha_0,\beta_0}$ such that

$$w_0^{-1}(R^+_{\alpha_0,\beta_0}) = A.$$

Put $w' = ww_0^{-1}$. Lemma 0.3.4.9 gives

$$R^+ - R^+_{\alpha_0,\beta_0} = w_0(R^+ - R^+_{\alpha_0,\beta_0}),$$

and therefore

$$\begin{aligned}(R^+ - R^+_{\alpha_0,\beta_0}) \cap w^{-1}(-R^+) \\ = w_0\Big((R^+ - R^+_{\alpha_0,\beta_0}) \cap w'^{-1}(-R^+)\Big).\end{aligned} \tag{1}$$

On the other hand,

$$\beta_0 \in R^+_{\alpha_0,\beta_0} \cap w^{-1}(-R^+). \tag{2}$$

Since $w_0(R_{\alpha_0,\beta_0}) = R_{\alpha_0,\beta_0}$, one has

$$w_0(-A) = R_{\alpha_0,\beta_0} \cap w'^{-1}(-R^+),$$

and hence

$$\begin{aligned}R^+_{\alpha_0,\beta_0} \cap w'^{-1}(-R^+) &= R^+_{\alpha_0,\beta_0} \cap w_0(-A) \\ &= R^+_{\alpha_0,\beta_0} \cap (-R^+_{\alpha_0,\beta_0}) = \varnothing.\end{aligned} \tag{2'}$$

It follows from (1), (2), and (2′) that

$$M(w') < M(w).$$

Put $\alpha_1 = w_0(\alpha_0)$. We show that $\alpha_1 \in \Delta$, or equivalently that $\alpha_0 \in w_0^{-1}(\Delta)$. Since $w(\alpha_0) \in \Delta$, we have

$$\alpha_0 \in w^{-1}(\Delta) \cap R_{\alpha_0,\beta_0}.$$

[26]Editors' note: In what follows, the original argument has been expanded, and equality (1) has been corrected.

Thus α_0 is a simple root of

$$A = w^{-1}(R^+) \cap R_{\alpha_0,\beta_0} = w_0^{-1}(R^+_{\alpha_0,\beta_0}),$$

and consequently belongs to

$$w_0^{-1}(\Delta \cap R^+_{\alpha_0,\beta_0}) = w_0^{-1}\{\alpha_0, \beta_0\}$$

by Lemma 0.3.4.8. Hence $\alpha_1 = w_0(\alpha_0)$ equals α_0 or β_0. If $\alpha_1 \neq \alpha_0$, then $\alpha_1 = \beta_0$ and $w_0 \in W_{\alpha_0,\alpha_1}$.

Finally,

$$\beta = w'(\alpha_1) \qquad \text{and} \qquad M(w') < M(w),$$

so the induction hypothesis completes the proof. □

0.6 Morphisms of root data

0.6.1 Definition

Let

$$\mathcal{R} = (M, M^*, R, R^*), \qquad \mathcal{R}' = (M', M'^*, R', R'^*)$$

be two root data. Let $f : M' \to M$ be a linear map and ${}^t f : M^* \to M'^*$ its transpose.

Definition 0.6.1.1. The map f is called a *morphism* from $\mathcal{R}'$ to $\mathcal{R}$, and is denoted

$$f : \mathcal{R}' \longrightarrow \mathcal{R},$$

if f induces a bijection from R' onto R, and ${}^t f$ induces a bijection from R^* onto R'^*.

Then ${}^t f$ is a morphism of the dual root data:

$${}^t f : \mathcal{R}^* \longrightarrow \mathcal{R}'^*.$$

If $f : \mathcal{R}' \to \mathcal{R}$ is a morphism and $\alpha = f(\alpha')$ for $\alpha' \in R'$, then

$$\alpha'^* = {}^t f(\alpha^*).$$

Indeed, if p and p' denote the maps of 0.1.2.1 for $\mathcal{R}$ and $\mathcal{R}'$, respectively, then

$$p' = {}^t f \circ p \circ f,$$

which gives the assertion at once. The reader may verify the statements below, almost all of which are immediate.

Proposition 0.6.1.2. *Let $f : \mathcal{R}' \to \mathcal{R}$ be a morphism of root data. If $\alpha' \in R'$ and $\alpha = f(\alpha')$, then*

$$\alpha'^* = {}^t f(\alpha^*).$$

Moreover, f induces isomorphisms

$$R' \xrightarrow{\sim} R, \qquad \Gamma_0(R') \xrightarrow{\sim} \Gamma_0(R), \qquad \mathcal{V}(R') \xrightarrow{\sim} \mathcal{V}(R),$$

and ${}^t f$ induces isomorphisms

$$R^* \xrightarrow{\sim} R'^*, \qquad \Gamma_0(R^*) \xrightarrow{\sim} \Gamma_0(R'^*), \qquad \mathcal{V}(R^*) \xrightarrow{\sim} \mathcal{V}(R'^*).$$

The last is the transpose of the corresponding morphism induced by f. The map

$$s_{\alpha'} \longmapsto s_{f(\alpha')}$$

extends to an isomorphism

$$W(\mathcal{R}') \xrightarrow{\sim} W(\mathcal{R})$$

compatible with the actions of these two groups on the sets of 0.1.1.13.

Proposition 0.6.1.3. *The maps*

$$\Delta' \longmapsto f(\Delta'), \qquad R'_+ \longmapsto f(R'_+), \qquad C' \longmapsto ({}^t f \otimes \mathbb{R})^{-1}(C')$$

define bijective correspondences between the systems of simple roots, the systems of positive roots, and the Weyl chambers for $\mathcal{R}'$ and $\mathcal{R}$. These correspondences are compatible with the actions of the Weyl groups and with the correspondences

$$\mathscr{S}(R_+) \longleftrightarrow R_+ \longleftrightarrow \mathscr{C}(R_+).$$

Lemma 0.6.1.4. *Morphisms compose. A morphism $f : \mathcal{R}' \to \mathcal{R}$ is an isomorphism if and only if the linear map $f : M' \to M$ is bijective.*

0.6.2 Isogenies

Definition 0.6.2.1. A morphism $f : \mathcal{R}' \to \mathcal{R}$ of root data is called an *isogeny* if $f : M' \to M$ is injective with finite cokernel.

If f is an isogeny, then ${}^t f$ is an isogeny.

Definition 0.6.2.2. Let $f : \mathcal{R}' \to \mathcal{R}$ be an isogeny. Put

$$K(f) = \mathrm{Coker}(M' \xrightarrow{f} M).$$

Lemma 0.6.2.3. *There is a natural pairing*

$$K(f) \times K({}^t f) \longrightarrow \mathbb{Q}/\mathbb{Z}$$

that puts these two finite groups in duality.

Proof. This is classical. □

Lemma 0.6.2.4. *If $f : \mathcal{R}' \to \mathcal{R}$ is a morphism, then*

$$\mathrm{rgss}(\mathcal{R}') = \mathrm{rgss}(\mathcal{R}).$$

If f is moreover an isogeny, then

$$\mathrm{rgred}(\mathcal{R}') = \mathrm{rgred}(\mathcal{R}).$$

Proof. This is immediate. □

Lemma 0.6.2.5. *Every morphism of semisimple root data is an isogeny.*

Proof. The map f must induce an isomorphism from $V' = \mathcal{V}(R')$ onto $V = \mathcal{V}(R)$. □

If $\mathcal{R}'$ and $\mathcal{R}$ are semisimple, every isogeny $f : \mathcal{R}' \to \mathcal{R}$ defines a commutative diagram:

$$\begin{array}{ccc} \Gamma_0(R') & \xrightarrow{\sim} & \Gamma_0(R) \\ \downarrow & & \downarrow \\ M' & \xrightarrow[f]{} & M \end{array}$$

If $M = \Gamma_0(R)$, then f is necessarily an isomorphism.

Definition 0.6.2.6. A root datum is called *adjoint*, respectively *simply connected*, if

$$M = \Gamma_0(R), \qquad \text{respectively} \qquad M^* = \Gamma_0(R^*).$$

An adjoint or simply connected root datum is therefore semisimple. Moreover, $\mathcal{R}$ is adjoint, respectively simply connected, if and only if $\mathcal{R}^*$ is simply connected, respectively adjoint. The preceding result gives the following proposition.

Proposition 0.6.2.7. *Let $\mathcal{R}$ be a semisimple root datum. The following conditions are equivalent:*

(i) $\mathcal{R}$ is adjoint, respectively simply connected;

(ii) every isogeny $\mathcal{R}' \to \mathcal{R}$, respectively $\mathcal{R} \to \mathcal{R}'$, is an isomorphism.

Proposition 0.6.2.8. *Let $\mathcal{R}$ be an adjoint, respectively simply connected, root datum. Every indivisible root, respectively coroot, is an indivisible element of M, respectively of M^*.*

Proof. Every indivisible root belongs to a basis of $\Gamma_0(R)$, by 0.3.3.5. □

0.6.3 Radical and coradical

Let $\mathcal{R}$ be a root datum. Put

$$N = \{x \in M \mid (\alpha^*, x) = 0 \text{ for every } \alpha^* \in R^*\}, \qquad N^* = M^*/(\mathcal{V}(R^*) \cap M^*).$$

Lemma 0.6.3.1. *Consider the canonical morphisms*

$$N \longrightarrow M, \qquad M^* \longrightarrow N^*.$$

They are transposes of one another, and N^* is identified with the dual of N.

Proof. This follows immediately from 0.1.2.5. □

Definition 0.6.3.2. The *coradical* of $\mathcal{R}$, denoted $\mathrm{corad}(\mathcal{R})$, is the trivial root datum

$$\mathrm{corad}(\mathcal{R}) = (N, N^*, \varnothing, \varnothing).$$

If

$$\mathcal{R}^0 = (M, M^*, \varnothing, \varnothing),$$

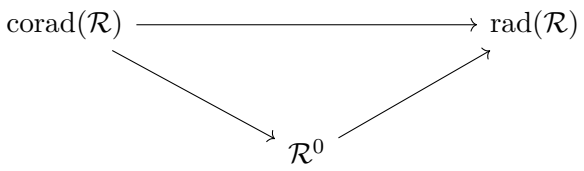
which is a trivial root datum, there is therefore a morphism

$$\mathrm{corad}(\mathcal{R}) \longrightarrow \mathcal{R}^0.$$

Definition 0.6.3.3. The *radical* of $\mathcal{R}$, denoted $\mathrm{rad}(\mathcal{R})$, is the trivial root datum [27]

$$\mathrm{rad}(\mathcal{R}) = \mathrm{corad}(\mathcal{R}^*)^*.$$

Thus there is a diagram



whose transpose is the corresponding diagram for $\mathcal{R}^*$.

Lemma 0.6.3.4. *The canonical morphism*

$$u : \mathrm{corad}(\mathcal{R}) \longrightarrow \mathrm{rad}(\mathcal{R})$$

is an isogeny.

Definition 0.6.3.5. Put

$$N(\mathcal{R}) = K(u) = M \Big/ \left(\big(\mathcal{V}(R) \cap M\big) + \bigcap_{\alpha \in R} \ker(\alpha^*) \right).$$

There is then a canonical pairing

$$N(\mathcal{R}) \times N(\mathcal{R}^*) \longrightarrow \mathbb{Q}/\mathbb{Z}.$$

Lemma 0.6.3.6. *One has*

$$\mathrm{rgred}\big(\mathrm{rad}(\mathcal{R})\big) = \mathrm{rgred}\big(\mathrm{corad}(\mathcal{R})\big) = \mathrm{rgred}(\mathcal{R}) - \mathrm{rgss}(\mathcal{R}),$$

and the following conditions are equivalent:

(i) $\mathcal{R}$ *is semisimple;*

(ii) $\mathrm{rad}(\mathcal{R}) = 0$*;*

(iii) $\mathrm{corad}(\mathcal{R}) = 0$.

0.6.4 Products of root data

Definition 0.6.4.1. Let

$$\mathcal{R} = (M, M^*, R, R^*), \qquad \mathcal{R}' = (M', M'^*, R', R'^*)$$

be two root data. The *product root datum* of $\mathcal{R}$ and $\mathcal{R}'$, denoted

$$\mathcal{R}'' = \mathcal{R} \times \mathcal{R}',$$

is the root datum (M'', M''^*, R'', R''^*), where

$$\begin{aligned} M'' &= M \times M', & M''^* &= M^* \times M'^*, \\ R'' &= (R \times 0) \cup (0 \times R'), & R''^* &= (R^* \times 0) \cup (0 \times R'^*), \end{aligned}$$

and the map $\alpha \mapsto \alpha^*$ is the evident one.

[27] Editors' note: Equivalently, if

$$P = \{y \in M^* \mid (y, \alpha) = 0 \text{ for every } \alpha \in R\}, \qquad P^* = M/\big(\mathcal{V}(R) \cap M\big),$$

then $\mathrm{rad}(\mathcal{R}) = (P^*, P, \varnothing, \varnothing)$.

Proposition 0.6.4.2. *Under the preceding hypotheses there are canonical isomorphisms*

$$\Gamma_0(R'') \simeq \Gamma_0(R) \times \Gamma_0(R'), \qquad \mathcal{V}(R'') \simeq \mathcal{V}(R) \times \mathcal{V}(R'),$$

$$W(\mathcal{R}'') \simeq W(\mathcal{R}) \times W(\mathcal{R}'),$$

and similarly for the other associated constructions. Moreover,

$$\mathrm{rgred}(\mathcal{R}'') = \mathrm{rgred}(\mathcal{R}) + \mathrm{rgred}(\mathcal{R}'), \qquad \mathrm{rgss}(\mathcal{R}'') = \mathrm{rgss}(\mathcal{R}) + \mathrm{rgss}(\mathcal{R}').$$

There is also a canonical isomorphism of root data

$$(\mathcal{R} \times \mathcal{R}')^* \simeq \mathcal{R}^* \times \mathcal{R}'^*.$$

The preceding definitions extend immediately to products of any finite number of factors.

Proposition 0.6.4.3. *Let*

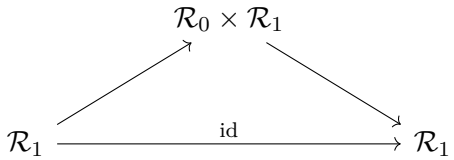
$$\mathcal{R} = \mathcal{R}_1 \times \mathcal{R}_2 \times \cdots \times \mathcal{R}_n$$

be a product of root data. The following conditions are equivalent:

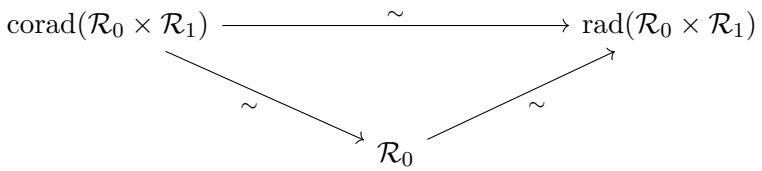
(i) $\mathcal{R}$ *is semisimple, respectively simply connected, respectively adjoint, respectively reduced;*

(ii) every $\mathcal{R}_i$ *is semisimple, respectively simply connected, respectively adjoint, respectively reduced.*

Consider the following special case. Let $\mathcal{R}_0$ be a trivial root datum and $\mathcal{R}_1$ a semisimple root datum. There is then a commutative diagram



Lemma 0.6.4.4. *There are canonical isomorphisms*



In particular,

$$N(\mathcal{R}_0 \times \mathcal{R}_1) = 0.$$

We shall see later that, conversely, if $N(\mathcal{R}) = 0$, then $\mathcal{R}$ is the product of a semisimple root datum and a trivial root datum.

0.6.5 Induced and coinduced root data

Let $\mathcal{R} = (M, M^*, R, R^*)$ be a root datum, and let $N \subset M$ be a subgroup containing the roots, that is,

$$\Gamma_0(R) \subset N \subset M.$$

The canonical linear map $i_N : N \to M$ gives, by transposition, a linear map

$${}^t i_N : M^* \longrightarrow N^*.$$

Put

$$R_N = R, \qquad R_N^* = {}^t i_N(R^*).$$

Lemma 0.6.5.1. *The quadruple*

$$\mathcal{R}_N = (N, N^*, R_N, R_N^*)$$

is a root datum, and i_N is a morphism.

Proof. First, ${}^t i_N$ induces an isomorphism from R^* onto R_N^*. Indeed, if $\alpha, \beta \in R$ and

$${}^t i_N(\alpha^*) = {}^t i_N(\beta^*),$$

then

$$(\alpha^*, x) = (\beta^*, x)$$

for every $x \in N$, in particular for $x \in R$. Hence $\alpha = \beta$ by 0.1.1.4. The rest follows without difficulty. □

Definition 0.6.5.2. The root datum $\mathcal{R}_N$ is called the root datum *induced by* $\mathcal{R}$ *on* N.

Lemma 0.6.5.3. *Let $f : \mathcal{R}' \to \mathcal{R}$ be a morphism, and put*

$$N = f(M') \subset M.$$

Then f factors uniquely through i_N.

In particular, up to isomorphism, the isogenies $\mathcal{R}' \to \mathcal{R}$ correspond bijectively to the finite-index subgroups of

$$M/\Gamma_0(R).$$

This sharpens 0.6.2.7.

Now let $N^* \subset M^*$ be a subgroup containing R^*. Define the root datum *coinduced by* $\mathcal{R}$ *on* N^* by

$$\mathcal{R}^{N^*} = (\mathcal{R}_{N^*}^*)^*.$$

There is a canonical morphism

$$p^{N^*} : \mathcal{R} \longrightarrow \mathcal{R}^{N^*}.$$

Lemma 0.6.5.4. *Let $f : \mathcal{R}' \to \mathcal{R}$ be a morphism. There exist subgroups $N \subset M$ and $N'^* \subset M'^*$ such that f factors as*

$$\begin{array}{ccc} \mathcal{R}' & \xrightarrow{\quad f \quad} & \mathcal{R} \\ {\scriptstyle p^{N'^*}}\downarrow & & \uparrow{\scriptstyle i_N} \\ \mathcal{R}'^{N'^*} & \xrightarrow[\sim]{f_0} & \mathcal{R}_N \end{array}$$

where f_0 is an isomorphism.

Proof. Take $N = f(M')$, as in 0.6.5.3. The resulting morphism $M' \to N$ is surjective, so its transpose is injective. Take its image for N'^*. □

We now treat some special cases. If $N = \Gamma_0(R)$, write

$$\mathcal{R}_N = \mathrm{ad}(\mathcal{R}).$$

If $N = \mathcal{V}(R) \cap M$, write

$$\mathcal{R}_N = \mathrm{ss}(\mathcal{R}).$$

Thus there is a diagram

$$\mathrm{ad}(\mathcal{R}) \longrightarrow \mathrm{ss}(\mathcal{R}) \longrightarrow \mathcal{R}.$$

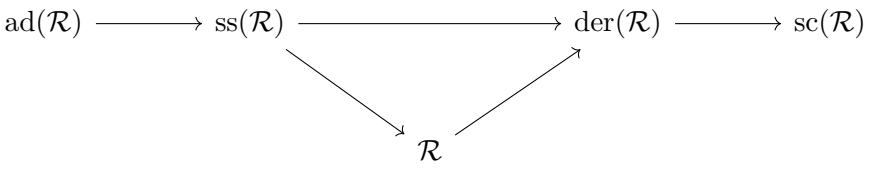
Put

$$\mathrm{der}(\mathcal{R}) = \mathrm{ss}(\mathcal{R}^*)^*, \qquad \mathrm{sc}(\mathcal{R}) = \mathrm{ad}(\mathcal{R}^*)^*.$$

By duality there is a diagram

$$\mathcal{R} \longrightarrow \mathrm{der}(\mathcal{R}) \longrightarrow \mathrm{sc}(\mathcal{R}).$$

Proposition 0.6.5.5. *(i) In the first row of the diagram*



the four root data are semisimple and the three morphisms are isogenies.

(ii) The datum $\mathrm{ad}(\mathcal{R})$ *is adjoint, and* $\mathcal{R}$ *is adjoint if and only if* $\mathrm{ad}(\mathcal{R}) \to \mathcal{R}$ *is an isomorphism.*

(iii) The datum $\mathrm{sc}(\mathcal{R})$ *is simply connected, and* $\mathcal{R}$ *is simply connected if and only if* $\mathcal{R} \to \mathrm{sc}(\mathcal{R})$ *is an isomorphism.*

(iv) The following conditions are equivalent:

- *(a)* $\mathcal{R}$ *is semisimple;*
- *(b)* $\mathrm{ss}(\mathcal{R}) \to \mathcal{R}$ *is an isomorphism;*
- *(c)* $\mathcal{R} \to \mathrm{der}(\mathcal{R})$ *is an isomorphism.*

Consider the morphism

$$\mathrm{ss}(\mathcal{R}) \longrightarrow \mathrm{der}(\mathcal{R}).$$

The definitions immediately give the following result.

Lemma 0.6.5.6. *Let*

$$h : \mathrm{ss}(\mathcal{R}) \longrightarrow \mathrm{der}(\mathcal{R})$$

be the canonical isogeny. Then

$$K(h) \simeq N(\mathcal{R}).$$

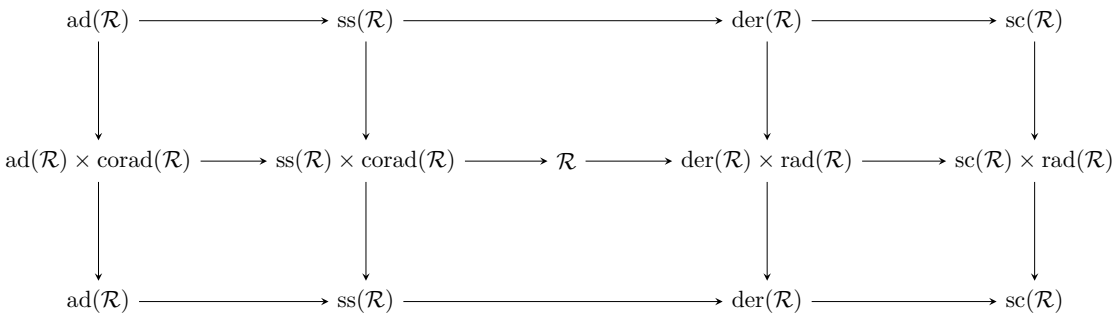
Consider other special cases of induced root data. Put

$$N = \{x \in M \mid (\alpha^*, x) = 0 \text{ for every } \alpha \in R\} \times \Gamma_0(R).$$

The sum is direct by 0.1.2.5. It follows that $\mathcal{R}_N$ is identified with

$$\mathrm{ad}(\mathcal{R}) \times \mathrm{corad}(\mathcal{R}).$$

One may replace $\Gamma_0(R)$ by $\mathcal{V}(R) \cap M$, and then dualize both constructions. This gives the following diagram of root data:



It is commutative, as is checked at once, and is self-dual in the evident sense. The horizontal morphisms are isogenies, and the composites of the vertical arrows are the identity.

Lemma 0.6.5.7. *Let h_1 and h_2 be the canonical isogenies*

$$\mathrm{ss}(\mathcal{R}) \times \mathrm{corad}(\mathcal{R}) \xrightarrow{h_1} \mathcal{R} \xrightarrow{h_2} \mathrm{der}(\mathcal{R}) \times \mathrm{rad}(\mathcal{R}).$$

Then

$$K(h_1) \simeq K(h_2) \simeq N(\mathcal{R}).$$

Proof. This is immediate from the definitions. □

Corollary 0.6.5.8. *For a root datum $\mathcal{R}$, the following conditions are equivalent:*

(i) $N(\mathcal{R}) = 0$, *that is,* $\mathrm{corad}(\mathcal{R}) \to \mathrm{rad}(\mathcal{R})$ *is an isomorphism;*

(ii) the canonical map $\mathrm{ss}(\mathcal{R}) \to \mathrm{der}(\mathcal{R})$ *is an isomorphism;*

(iii) h_1 *is an isomorphism;*

(iv) h_2 *is an isomorphism;*

(v) $\mathcal{R}$ *is the product of a semisimple root datum and a trivial root datum.*

Corollary 0.6.5.9. *For every root datum $\mathcal{R}$, there are isogenies*

$$\mathrm{ad}(\mathcal{R}) \times \mathcal{R}_0 \longrightarrow \mathcal{R} \longrightarrow \mathrm{sc}(\mathcal{R}) \times \mathcal{R}_0,$$

where $\mathcal{R}_0$ is the trivial root datum of rank $\mathrm{rgred}(\mathcal{R}) - \mathrm{rgss}(\mathcal{R})$.

Lemma 0.6.5.10. *Let $\mathcal{R}$ be a root datum, let Δ be a system of simple roots, and let $\Delta' \subset \Delta$. Consider the root datum*

$$\mathcal{R}_{\Delta'} = (M, M^*, R_{\Delta'}, R^*_{\Delta'})$$

of 0.3.4.7.

(i) If $\mathcal{R}$ is simply connected, then $\mathrm{der}(\mathcal{R}_{\Delta'})$ *is simply connected.*

(ii) If $\mathcal{R}$ is adjoint, then $\mathrm{ss}(\mathcal{R}_{\Delta'})$ *is adjoint.*

Proof. The two assertions are equivalent by duality. The second reduces to

$$M \cap \mathcal{V}(R_{\Delta'}) = \Gamma_0(R_{\Delta'}).$$

When $M = \Gamma_0(R)$, both sides are the subgroup of M generated by Δ'. □

0.6.6 Weights

Definition 0.6.6.1. For a root datum $\mathcal{R}$, put [28]

$$\Lambda(\mathcal{R}) = \{x \in \mathcal{V}(R) \mid (\alpha^*, x) \in \mathbb{Z} \text{ for every } \alpha^* \in R^*\}.$$

The elements of $\Lambda(\mathcal{R})$ are called the *weights* of $\mathcal{R}$. The weights of $\mathcal{R}^*$ are called the *coweights* of $\mathcal{R}$.

One has

$$\Gamma_0(R) \subset \Lambda(\mathcal{R}),$$

and $\Lambda(\mathcal{R})$ is stable under $W(\mathcal{R})$.

Lemma 0.6.6.2. *The bilinear map*

$$V^* \times V \longrightarrow \mathbb{Q}$$

induces a duality

$$\Gamma_0(R^*) \times \Lambda(\mathcal{R}) \longrightarrow \mathbb{Z}.$$

Proof. Immediate. □

Corollary 0.6.6.3. *Let*

$$\Delta^* = (\alpha_1^*, \ldots, \alpha_n^*)$$

be a system of simple coroots, and let $p_i \in \mathcal{V}(R)$, $i = 1, \ldots, n$, be defined by

$$(\alpha_i^*, p_j) = \delta_{ij}.$$

Thus

$$s_{\alpha_i}(p_i) = p_i - \alpha_i, \qquad s_{\alpha_i}(p_j) = p_j \quad (i \neq j).$$ [29]

Then $\Lambda(\mathcal{R})$ is the free abelian group generated by the p_i.

The p_i are called the *fundamental weights* corresponding to the system of simple coroots Δ^*.

Corollary 0.6.6.4. *For every $\alpha^* \in \Delta^*$,*

$$\left(\alpha^*, \sum_i p_i\right) = 1.$$

Consequently,

$$\sum_i p_i = \rho_{R_+}, \qquad R_+ = \mathscr{P}(\mathrm{ind}(\Delta)),$$

in the notation of 0.3.5.1.

[28] Editors' note: The notation $\Gamma(\mathcal{R})$ has been replaced by $\Lambda(\mathcal{R})$ to avoid any possible confusion with $\Gamma_0(R)$.

[29] Caution: when the datum is not reduced, the α_i need not form a system of simple roots.

Corollary 0.6.6.5. *For every $x \in \mathcal{V}(R)$,*

$$x = \sum_i (\alpha_i^*, x) p_i.$$

Since

$$R^* \subset \Gamma_0(R^*), \qquad R \subset \Lambda(\mathcal{R}),$$

the quadruple

$$(\Lambda(\mathcal{R}), \Gamma_0(R^*), R, R^*)$$

is a root datum.

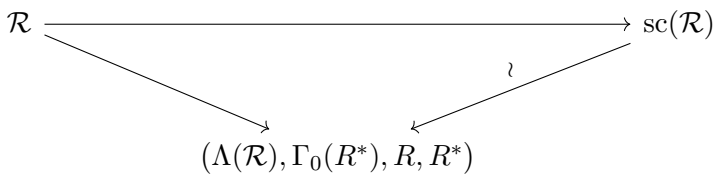
Corollary 0.6.6.6. *The canonical morphism*

$$\Gamma_0(R^*) \longrightarrow M^*$$

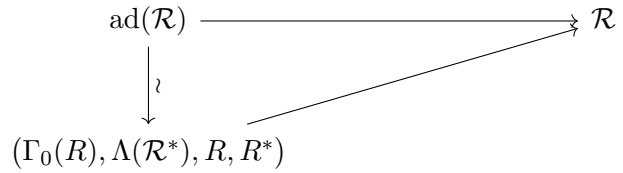
is the transpose of

$$x \longmapsto \sum_i (\alpha_i^*, x) p_i.$$

This map defines a morphism of root data, and there is a commutative diagram



Thus we have an explicit description of $\mathrm{sc}(\mathcal{R})$ in terms of the weights of $\mathcal{R}$. Likewise, one obtains a commutative diagram



Corollary 0.6.6.7. *The datum $\mathcal{R}$ is simply connected if and only if*

$$M = \Lambda(\mathcal{R}).$$

Remark 0.6.6.8. One has

$$\Lambda(\mathcal{R}) \cap M = \mathcal{V}(R) \cap M.$$

Consequently, $\mathcal{R}$ is semisimple if and only if

$$M \subset \Lambda(\mathcal{R}).$$

The results of §0.6.5 also give:

Corollary 0.6.6.9. *The datum $\mathcal{R}$ is the product of a simply connected datum and a trivial datum if and only if*

$$M \supset \Lambda(\mathcal{R}).$$

Consider now the canonical isogeny

$$f : \mathrm{ad}(\mathcal{R}) \longrightarrow \mathrm{sc}(\mathcal{R}),$$

and put $Z(\mathcal{R}) = K(f)$. One has

$$Z(\mathcal{R}) \simeq Z(\mathrm{sc}\,\mathcal{R}) \simeq Z(\mathrm{ad}\,\mathcal{R}).$$

Corollary 0.6.6.10. *There is a canonical isomorphism*

$$Z(\mathcal{R}) = \Lambda(\mathcal{R})/\Gamma_0(R).$$

More precisely, there is an exact sequence of $W(\mathcal{R})$-modules

$$0 \longrightarrow \Gamma_0(R) \longrightarrow \Lambda(\mathcal{R}) \longrightarrow Z(\mathcal{R}) \longrightarrow 0.$$

Corollary 0.6.6.11. *There is a canonical pairing*

$$Z(\mathcal{R}^*) \times Z(\mathcal{R}) \longrightarrow \mathbb{Q}/\mathbb{Z}$$

which puts these groups in duality.

Remark 0.6.6.12. One has

$$Z(\mathcal{R} \times \mathcal{R}') \simeq Z(\mathcal{R}) \times Z(\mathcal{R}').$$

In particular, consider simply connected data $\mathcal{R}_i$, $i = 1, 2, \ldots, n$, and a trivial datum $\mathcal{R}_0$. Put

$$\mathcal{R} = \mathcal{R}_0 \times \mathcal{R}_1 \times \cdots \times \mathcal{R}_n.$$

If

$$\mathcal{R} = (M, M^*, R, R^*), \qquad \mathcal{R}_0 = (M_0, M_0^*, \varnothing, \varnothing),$$

then

$$M/\Gamma_0(R) \simeq M_0 \times Z(\mathcal{R}_1) \times \cdots \times Z(\mathcal{R}_n).$$

0.6.7 Automorphisms

By 0.6.1.4, an automorphism of $\mathcal{R}$ is an automorphism u of M such that

$$u(R) = R, \qquad {}^t u(R^*) = R^*.$$

In particular, every $w \in W(\mathcal{R})$ defines an automorphism of $\mathcal{R}$.

Lemma 0.6.7.1. *The group $W(\mathcal{R})$ is a normal subgroup of $\mathrm{Aut}(\mathcal{R})$. More precisely, if $u \in \mathrm{Aut}(\mathcal{R})$ and $\alpha \in R$, then*

$$u s_\alpha u^{-1} = s_{u(\alpha)}.$$

Proof. The proof is the same as that of 0.1.2.10. □

Proposition 0.6.7.2. *Let Δ be a system of simple roots, and put*

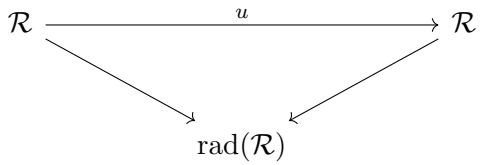
$$E_\Delta(\mathcal{R}) = \{u \in \mathrm{Aut}(\mathcal{R}) \mid u(\Delta) = \Delta\}.$$

Then $\mathrm{Aut}(\mathcal{R})$ is the semidirect product of $W(\mathcal{R})$ by $E_\Delta(\mathcal{R})$.

Proof. This follows at once from the fact that $W(\mathcal{R})$ acts simply transitively on the systems of simple roots and from the fact that, if Δ is a system of simple roots of $\mathcal{R}$, then $u(\Delta)$ is a system of simple roots for every automorphism u of $\mathcal{R}$. □

We shall later give a simpler description of $E_\Delta(\mathcal{R})$ in the case of reduced irreducible root data.[30]

Definition 0.6.7.3. We denote by $\mathrm{Aut}^s(\mathcal{R})$[31] the set of $u \in \mathrm{Aut}(\mathcal{R})$ for which the following diagram is commutative:



We write

$$E^s_\Delta(\mathcal{R}) = E_\Delta(\mathcal{R}) \cap \mathrm{Aut}^s(\mathcal{R}).$$

Remark 0.6.7.4. If $u \in \mathrm{Aut}(\mathcal{R})$, then $u \in \mathrm{Aut}^s(\mathcal{R})$ if and only if

$$(u - \mathrm{id})(M) \subset \mathcal{V}(R).$$

In particular,

$$W(\mathcal{R}) \subset \mathrm{Aut}^s(\mathcal{R}).$$

Proposition 0.6.7.5. *For every system of simple roots Δ, the group $\mathrm{Aut}^s(\mathcal{R})$ is the semidirect product of $W(\mathcal{R})$ by $E^s_\Delta(\mathcal{R})$.*

By functoriality, every automorphism of $\mathcal{R}$ induces an automorphism of $\mathrm{ad}(\mathcal{R})$. Thus there is a canonical homomorphism

$$\mathrm{Aut}(\mathcal{R}) \longrightarrow \mathrm{Aut}(\mathrm{ad}(\mathcal{R})).$$

Lemma 0.6.7.6. *The homomorphism*

$$\mathrm{Aut}^s(\mathcal{R}) \longrightarrow \mathrm{Aut}(\mathrm{ad}(\mathcal{R}))$$

is injective.

Proof. Let u be an automorphism of M such that

$$(u - \mathrm{id})(M) \subset \mathcal{V}(R)$$

and

$$^t u(\alpha^*) = \alpha^* \qquad (\alpha^* \in R^*).$$

For every $x \in M$, one has

$$(\alpha^*, u(x) - x) = (^t u(\alpha^*) - \alpha^*, x) = 0.$$

Hence $u(x) - x = 0$, by 0.1.2.5. □

Lemma 0.6.7.7. *The group $\mathrm{Aut}^s(\mathcal{R})$ is finite.*

Proof. It suffices to prove that $\mathrm{Aut}(\mathcal{R})$ is finite when $\mathcal{R}$ is adjoint. In that case M is generated by R, so every automorphism of $\mathcal{R}$ is determined by the permutation it induces on R. □

Remark 0.6.7.8. It is immediate that $\mathrm{Aut}(\mathcal{R})$ (respectively $E_\Delta(\mathcal{R})$) is finite if and only if

$$\mathrm{rgred}(\mathcal{R}) - \mathrm{rgss}(\mathcal{R}) \leq 1.$$

[30] Editors' note: When $\mathcal{R}$ is simply connected or adjoint, see 7.4.5.

[31] Editors' note: The superscript s is intended to suggest "semisimple."

0.6.8 p-morphisms of reduced root data

Throughout this subsection, p is a fixed positive integer.

Definition 0.6.8.1. Let

$$\mathcal{R} = (M, M^*, R, R^*), \qquad \mathcal{R}' = (M', M'^*, R', R'^*)$$

be two reduced root data. A group homomorphism

$$f : M' \longrightarrow M$$

is called a *p-morphism from $\mathcal{R}'$ to $\mathcal{R}$* if there exist a bijection

$$u : R \xrightarrow{\sim} R'$$

and a map

$$q : R \longrightarrow \{p^n \mid n \in \mathbb{N}\}$$

such that:

(i) $f(u(\alpha)) = q(\alpha)\alpha$ for every $\alpha \in R$;

(ii) ${}^t f(\alpha^*) = q(\alpha)u(\alpha)^*$ for every $\alpha \in R$.[32]

Corollary 0.6.8.2. *A 1-morphism is precisely a morphism.*

Corollary 0.6.8.3. *The transpose of a p-morphism is a p-morphism.*

Lemma 0.6.8.4. *If $w \in W(\mathcal{R})$ and $\alpha \in R$, then*

$$q(w(\alpha)) = q(\alpha).$$

The map

$$s_\alpha \longmapsto s_{u(\alpha)}$$

extends to an isomorphism

$$u : W(\mathcal{R}) \xrightarrow{\sim} W(\mathcal{R}')$$

such that

$$u(w(\alpha)) = u(w)\big(u(\alpha)\big).$$

Proof. It suffices to prove, for $\alpha, \beta \in R$, that

$$u(s_\alpha(\beta)) = s_{u(\alpha)}u(\beta), \qquad q(s_\alpha(\beta)) = q(\beta).$$

Successively, one has

$$\begin{aligned} f\big(s_{u(\alpha)}u(\beta)\big) &= f(u(\beta)) - \big(u(\alpha)^*, u(\beta)\big)f(u(\alpha)) \\ &= q(\beta)\beta - q(\beta)q(\alpha)^{-1}(\alpha^*, \beta)q(\alpha)\alpha \\ &= q(\beta)\big(\beta - (\alpha^*, \beta)\alpha\big) \\ &= q(\beta)s_\alpha(\beta). \end{aligned}$$

[32] Editors' note: These two conditions imply

$$q(\alpha)\big(u(\alpha)^*, u(\beta)\big) = q(\beta)(\alpha^*, \beta)$$

for all $\alpha, \beta \in R$.

If

$$\gamma = u^{-1}\big(s_{u(\alpha)}u(\beta)\big),$$

then

$$q(\gamma)\gamma = f(u(\gamma)) = q(\beta)s_\alpha(\beta).$$

The roots γ and $s_\alpha(\beta)$ are proportional over $\mathbb{Q}$, hence equal or opposite. Since $q(\gamma)$ and $q(\beta)$ are positive, it follows that

$$q(\gamma) = q(\beta), \qquad \gamma = s_\alpha(\beta).$$

□

Definition 0.6.8.5. The numbers $q(\alpha)$ are called the *root exponents* of f.

Example 0.6.8.6. Let $\mathcal{R}$ be a reduced root datum and let $q = p^n$, $n \in \mathbb{N}$. Multiplication by q,

$$M \longrightarrow M, \qquad x \longmapsto qx,$$

is a p-morphism whose root exponents are all equal to q (and for which $u = \mathrm{id}$). It is denoted

$$q : \mathcal{R} \longrightarrow \mathcal{R}.$$

Proposition 0.6.8.7. *In the notation of 0.6.8.1, u induces an isomorphism from the set of systems of simple roots (respectively positive roots) of R onto the corresponding set for R'.*

Proof. This follows immediately from 0.3.1.5 (respectively 0.3.2.1). □

0.7 Structure

0.7.1 Decomposition of a root datum

Proposition 0.7.1.1. *Let $\mathcal{R}$ be a root datum and let Δ be a system of simple roots.*

(i) Let R' and R'' be two closed symmetric sets of roots forming a partition of R. If

$$\Delta' = \Delta \cap R', \qquad \Delta'' = \Delta \cap R'',$$

then

$$R' = R_{\Delta'}, \qquad R'' = R_{\Delta''},$$

and every root of Δ' is orthogonal to every root of Δ''.

(ii) Let Δ' and Δ'' be two orthogonal subsets forming a partition of Δ. Then $R_{\Delta'}$ and $R_{\Delta''}$ form a partition of R.

Proof. We first prove (i).

Lemma 0.7.1.2. *Under the hypotheses of* (i)*, if α, β, and $\alpha+\beta$ are roots, then all three belong to R', or all three belong to R''.*

Suppose, for example, that $\alpha+\beta \in R'$. One cannot have $\alpha, \beta \in R''$, since R'' is closed. Suppose therefore that $\alpha \in R'$. Then $-\alpha \in R'$, and

$$\beta = (\beta+\alpha) - \alpha \in R'.$$

We now prove $R' = R_{\Delta'}$ by induction on the order of a positive root $\alpha \in R' \cap \mathscr{P}(\Delta)$. If $\mathrm{ord}_\Delta(\alpha) = 1$, then

$$\alpha \in R' \cap \Delta = \Delta'.$$

If $\mathrm{ord}_\Delta(\alpha) > 1$, there is $\beta \in \Delta$ such that $\alpha - \beta \in R$. By the lemma,

$$\beta \in \Delta', \qquad \alpha - \beta \in R'.$$

Hence $\alpha - \beta \in R_{\Delta'}$ by induction, and finally

$$\alpha = (\alpha - \beta) + \beta \in R_{\Delta'}.$$

We next prove that Δ' and Δ'' are orthogonal. If $\alpha \in \Delta'$ and $\beta \in \Delta''$, then

$$(\beta^*, \alpha) \leq 0.$$

If $(\beta^*, \alpha) \neq 0$, then $\beta + \alpha$ is a root, contrary to the lemma.

We now prove (ii). If Δ' or Δ'' is empty, the assertion is immediate. Otherwise, if $R_{\Delta'}$ and $R_{\Delta''}$ do not form a partition of R, there is a root α of the form

$$\alpha = \sum_i m'_i \alpha'_i + \sum_j m''_j \alpha''_j, \qquad m'_i, m''_j \in \mathbb{Z}_+,$$

where the α'_i (respectively α''_j) belong to Δ' (respectively Δ''). Applying 0.3.1.2, and interchanging Δ' and Δ'' if necessary, yields a relation

$$\delta = \gamma + \beta, \qquad \gamma \in R_{\Delta'}, \quad \beta \in \Delta'', \quad \delta \in R.$$

But $(\beta^*, \gamma) = 0$, so $\gamma - \beta$ is also a root by 0.2.2.5, which is impossible. □

Proposition 0.7.1.3. *Let $\mathcal{R}$ be a root datum. The following conditions are equivalent:*

(i) There is no nontrivial partition of R into two closed symmetric subsets.

(ii) For some (respectively every) system of simple roots Δ of R, there is no partition of Δ into two nonempty orthogonal subsets.

(iii) The natural representation of $W(\mathcal{R})$ on $\mathcal{V}(R)$ is irreducible.

(iv) For every pair (α, β) of roots, there is a sequence of roots

$$\alpha_0, \alpha_1, \ldots, \alpha_n, \qquad \alpha_0 = \alpha, \quad \alpha_n = \beta,$$

such that α_i and α_{i+1} are nonorthogonal for $i = 0, \ldots, n-1$.

Proof. The equivalence (i)⇔(ii) follows from 0.7.1.1, and (iv)⇒(ii) is immediate. Conversely, if (ii) holds for Δ, then (iv) holds when $\alpha, \beta \in \Delta$. Every root is nonorthogonal to some simple root, by 0.3.1.1, for example. Moreover, (iii)⇒(i): under the hypotheses of 0.7.1.1, the space $\mathcal{V}(R')$ is stable under $W(\mathcal{R})$. It remains to prove (i)⇒(iii).

Let H be a vector subspace of $\mathcal{V}(R)$, stable under $W(\mathcal{R})$. For every $\alpha \in R$, the equality $s_\alpha(H) = H$ immediately gives

$$\alpha \in H \qquad \text{or} \qquad \alpha^* \in H^\perp,$$

where $H^\perp$ denotes the orthogonal complement of H in $\mathcal{V}(R^*)$, which is in duality with $\mathcal{V}(R)$. Put

$$R' = \{\alpha \in R \mid \alpha \in H\}, \qquad R'' = \{\alpha \in R \mid \alpha^* \in H^\perp\}.$$

This gives a partition of R into two closed symmetric subsets. □

Definition 0.7.1.4. A root datum (respectively root system) satisfying the equivalent conditions of 0.7.1.3 and having nonzero semisimple rank is called *irreducible*.

Corollary 0.7.1.5. *For every root datum $\mathcal{R}$, there is a unique partition, up to order, of R into closed symmetric irreducible subsets.*

Corollary 0.7.1.6. *Every adjoint (respectively simply connected) root datum is a product of irreducible adjoint (respectively simply connected) root data.*

Proof. It suffices to consider the adjoint case. The assertion then follows from the fact that, under the hypotheses of 0.7.1.1,

$$\Gamma_0(R) = \Gamma_0(R') \times \Gamma_0(R'').$$

□

Corollary 0.7.1.7. *For every root datum (respectively reduced root datum) $\mathcal{R}$, there is an isogeny*

$$\mathcal{R} \longrightarrow \mathcal{R}',$$

where $\mathcal{R}'$ is a product of a trivial root datum and irreducible simply connected root data (respectively irreducible reduced simply connected root data).

0.7.2 Properties of irreducible root data

Definition 0.7.2.1. Let $\mathcal{R}$ be an irreducible root datum. For every $\alpha \in R$, put

$$\mathrm{long}(\alpha) = \ell(\alpha)/\ell(\alpha_0),$$

where $\alpha_0 \in R$ is such that $\ell(\alpha_0)$ is minimal. The number $\mathrm{long}(\alpha)$ is called the *length* of α.

Lemma 0.7.2.2. *Let $\mathcal{R}$ be an irreducible root datum. The Weyl group acts transitively on the set of roots of a given length.*

Proof. Let $\alpha, \beta \in R$. Since the representation of $W(\mathcal{R})$ on $\mathcal{V}(R)$ is irreducible, α cannot be orthogonal to all $w(\beta)$, $w \in W(\mathcal{R})$. Hence some $w(\beta)$ is nonorthogonal to α. Since

$$\ell(w(\beta)) = \ell(\beta),$$

the assertion follows from 0.2.3.2. □

Lemma 0.7.2.3. *If $\mathcal{R}$ is irreducible and reduced, then*

$$\mathrm{long}(R) \in \{\{1\}, \{1,2\}, \{1,3\}\}.$$

Proof. By the observation used above, for every $\alpha, \beta \in R$ there is $w \in W(\mathcal{R})$ such that $w(\beta)$ is nonorthogonal to α. Therefore, by 0.2.3.1,

$$\frac{\ell(\alpha)}{\ell(\beta)} \in \left\{1, 2, 3, \frac{1}{2}, \frac{1}{3}\right\}.$$

Thus $\mathrm{long}(\alpha)$ is 1, 2, or 3. But lengths 2 and 3 cannot both occur, since their ratio 2/3 is not in the displayed set. □

Remark 0.7.2.4. Reasoning similarly gives the following result. If $\mathcal{R}$ is irreducible and nonreduced, with $\mathrm{rgss}(\mathcal{R}) > 1$, then

$$\mathrm{long}(R) = \{1, 2, 4\}.$$

If $R_i = \mathrm{long}^{-1}(i)$, then

$$\mathrm{ind}(R) = R_1 \cup R_2, \qquad R_4 = 2R_1,$$

and two nonproportional roots of R_1 are orthogonal. Conversely, suppose that R is an irreducible reduced root system such that $\mathrm{long}(R) = \{1, 2\}$. Put $R_i = \mathrm{long}^{-1}(i)$, and suppose that two nonproportional roots of R_1 are orthogonal. Then $R \cup 2R_1$ is irreducible and nonreduced, and

$$\mathrm{ind}(R \cup 2R_1) = R.$$

Lemma 0.7.2.5. *If $\mathcal{R}$ is an irreducible root datum, then $\mathcal{R}^*$ is irreducible as well, and the product*

$$\mathrm{long}(\alpha)\,\mathrm{long}(\alpha^*)$$

is constant as α runs through R.

Proof. This follows immediately from 0.7.1.3 (iv) and 0.2.2.6. □

Definition 0.7.2.6. Let $\mathcal{R}$ be any root datum. The *length* of $\alpha \in R$, denoted $\mathrm{long}(\alpha)$, is the length of α in its irreducible component.

Lemma 0.7.2.7. *There is a unique group homomorphism*

$$u : \Gamma_0(R) \longrightarrow \Gamma_0(R^*)$$

such that

$$u(\alpha) = \mathrm{long}(\alpha)\alpha^* \qquad (\alpha \in R).$$

Proof. By 0.3.5.5, it is enough to verify that, whenever $\alpha, \beta, \alpha + \beta \in R$,

$$\mathrm{long}(\alpha)\alpha^* + \mathrm{long}(\beta)\beta^* = \mathrm{long}(\alpha + \beta)(\alpha + \beta)^*.$$

But $\alpha, \beta, \alpha + \beta$ belong to the same irreducible component of R, by 0.7.1.2; the assertion is therefore reduced to 0.1.2.2. □

Remark 0.7.2.8. Let u be as in 0.7.2.7. For $\alpha, \beta \in R$,

$$(u(\alpha), \beta) = (u(\beta), \alpha).$$

Indeed, this amounts to

$$\mathrm{long}(\alpha)(\alpha^*, \beta) = \mathrm{long}(\beta)(\beta^*, \alpha),$$

which is clear when α and β are orthogonal. If they are not orthogonal, they lie in the same irreducible component of R, and the assertion reduces to 0.1.2.1, formula (9).

Remark 0.7.2.9. The symmetric bilinear form

$$(x, y) \longmapsto (u(x), y)$$

is positive and nondegenerate on $\Gamma_0(R)$.

Proof. Let R_i be the irreducible components of R. Then

$$\Gamma_0(R) = \prod_i \Gamma_0(R_i),$$

and the bilinear form $(u(x), y)$ is the product, on the groups $\Gamma_0(R_i)$, of the forms

$$2^{-1}\ell(\alpha_i)^{-1}(p(x), y),$$

where $\ell(\alpha_i)$ is the minimum of $\ell(\alpha)$ for $\alpha \in R_i$. These symmetric bilinear forms are positive and nondegenerate by 0.1.2.6. □

0.7.3 Cartan matrix

Let $\mathcal{R}$ be a root datum. If Δ is a system of simple roots, the *Cartan matrix* of $\mathcal{R}$ relative to Δ is the square matrix indexed by Δ and defined by

$$a_{\alpha,\beta} = (\alpha^*, \beta), \qquad \alpha, \beta \in \Delta.$$

If Δ' is another system of simple roots and $w \in W(\mathcal{R})$ satisfies $w(\Delta) = \Delta'$, then

$$(w(\alpha)^*, w(\beta)) = (\alpha^*, \beta).$$

Thus the Cartan matrix relative to Δ' is obtained from that relative to Δ by the isomorphism $\Delta \to \Delta'$ of index sets defined by w. Consequently, up to isomorphism of its index set, the Cartan matrix depends only on $\mathcal{R}$.

Proposition 0.7.3.1. *The Cartan matrix has the following properties.*

(i) $a_{\alpha,\alpha} = 2$, *and* $a_{\alpha,\beta} \leq 0$ *for* $\alpha \neq \beta$.

(ii) $a_{\alpha,\beta} = 0$ *implies* $a_{\beta,\alpha} = 0$.

(iii) There are strictly positive integers $m_\alpha = \mathrm{long}(\alpha)$ *such that the matrix*

$$(m_\alpha a_{\alpha,\beta})$$

is symmetric, positive, and nondegenerate.

(iv) The principal minors of $(a_{\alpha,\beta})_{\alpha,\beta\in\Delta}$, *namely*

$$\det(a_{\alpha,\beta})_{\alpha,\beta\in\Delta'} \qquad (\Delta' \subset \Delta),$$

are strictly positive.

(v) One has

$$s_\alpha(\beta) = \beta - a_{\alpha,\beta}\alpha, \qquad s_\alpha(\beta^*) = \beta^* - a_{\beta,\alpha}\alpha^*.$$

Proof. Part (v) is a definition; (i) follows from 0.3.2.11, (ii) from 0.2.2.2, and (iii) from 0.7.2.9. Part (iv) follows immediately from (iii) and

$$\det(m_\alpha a_{\alpha,\beta})_{\alpha,\beta\in\Delta'} = \left(\prod_{\alpha\in\Delta'} m_\alpha\right) \det(a_{\alpha,\beta})_{\alpha,\beta\in\Delta'}.$$

□

Proposition 0.7.3.2. *Let $\mathcal{R}$ and $\mathcal{R}'$ be two reduced simply connected (respectively adjoint) root data, let Δ and Δ' be systems of simple roots of $\mathcal{R}$ and $\mathcal{R}'$, and let $u : \Delta \to \Delta'$ be an isomorphism. Denote the corresponding Cartan matrices by $(a_{\alpha,\beta})$ and $(a'_{\alpha',\beta'})$, and suppose that*

$$a'_{u(\alpha),u(\beta)} = a_{\alpha,\beta}.$$

Then there is a unique isomorphism from $\mathcal{R}$ onto $\mathcal{R}'$ that induces u on Δ.

Proof. It is enough to give the proof in the adjoint case. Then $M = \Gamma_0(R)$ and $M' = \Gamma_0(R')$ are the free abelian groups generated by Δ and Δ'. Hence there is a unique group isomorphism $M \to M'$ inducing u on Δ; denote it again by u.

We show that $u(R) \subset R'$. Every root α of R can be written

$$\alpha = s_{\alpha_1} \cdots s_{\alpha_n}(\alpha_{n+1}), \qquad \alpha_i \in \Delta.$$

By the hypothesis on u and the relations 0.7.3.1 (v),

$$u(\alpha) = s_{u(\alpha_1)} \cdots s_{u(\alpha_n)}(u(\alpha_{n+1})).$$

It remains to prove that ${}^t u(R'^*) \subset R^*$. This follows from the fact that the elements of M^* (respectively M'^*) are determined by their duality with R or Δ (respectively R' or Δ'), by 0.1.2.5. □

Corollary 0.7.3.3. *A reduced simply connected or adjoint root datum is determined up to isomorphism by its Cartan matrix.*

Corollary 0.7.3.4. *Let $\mathcal{R}$ be a reduced simply connected (respectively adjoint) root datum and let Δ be a system of simple roots. The group $E_\Delta(\mathcal{R})$ is identified with the group of automorphisms of the set Δ that preserve the Cartan matrix.*

Remark 0.7.3.5. The existence of a root datum corresponding to a given Cartan matrix satisfying, for example, (i), (ii), and (iv) is not easily settled directly without using the classification.

0.7.4 Dynkin diagrams

Definition 0.7.4.1. A *Dynkin-diagram structure* on a finite set Δ (the word "scheme" being banished for obvious reasons) consists of a set of pairs of distinct elements of Δ, called *linked pairs*, together with a map

$$\Delta \longrightarrow \{1, 2, 3\}.$$

The notion of isomorphism between such structures is evident.

Definition 0.7.4.2. Let $\mathcal{R}$ be a root datum and let Δ be a system of simple roots. The *Dynkin diagram* of $\mathcal{R}$ relative to Δ is the set Δ, in which two simple roots are linked if and only if they are nonorthogonal, and each root is assigned its length.

Proposition 0.7.4.3. *The Dynkin diagram and the Cartan matrix determine one another uniquely.*

Proof. The equivalence

$$\alpha \text{ and } \beta \text{ are not linked} \iff a_{\alpha,\beta} = 0$$

and the relation

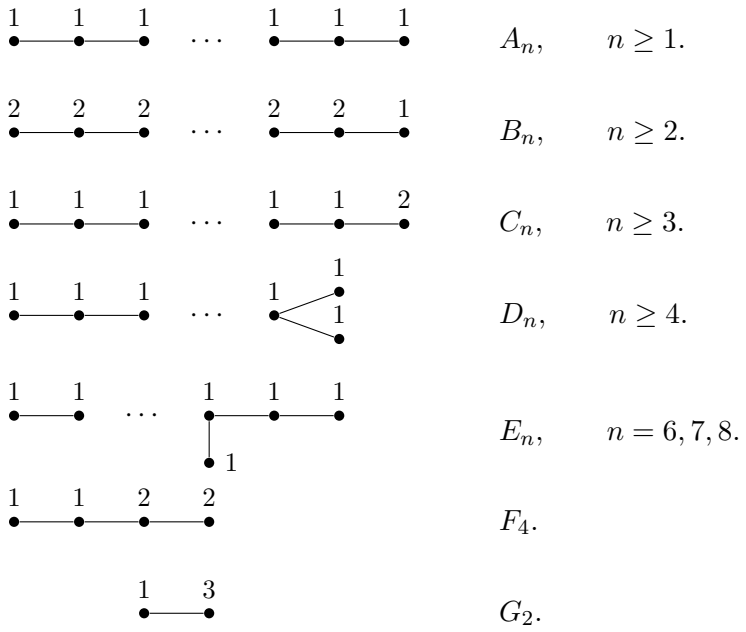
$$\operatorname{long}(\alpha) a_{\alpha,\beta} = \operatorname{long}(\beta) a_{\beta,\alpha},$$

with $\inf \operatorname{long}(\alpha) = 1$ in each connected component of the diagram, determine the $a_{\alpha,\beta}$ from the links and lengths, and conversely. The details are left to the reader. □

Corollary 0.7.4.4. *A reduced simply connected or adjoint root datum is determined by its Dynkin diagram.*

Corollary 0.7.4.5. *Let $\mathcal{R}$ be a reduced simply connected or adjoint root datum and let Δ be a system of simple roots. The group $E_\Delta(\mathcal{R})$ is identified with the group of automorphisms of the Dynkin diagram of $\mathcal{R}$ relative to Δ; that is, with the group of permutations of Δ preserving lengths and links.*

Remark 0.7.4.6. The usual method[33] [34] classifies the connected Dynkin diagrams and shows that each actually corresponds to an irreducible reduced simply connected root datum. One obtains the familiar types:



By 0.7.4.5, the corresponding group $E_\Delta(\mathcal{R})$ is obtained at once:

$$\begin{aligned} E_\Delta(\mathcal{R}) &= \{e\}, && A_1,\ B_n,\ C_n,\ E_7,\ E_8,\ F_4,\ G_2, \\ E_\Delta(\mathcal{R}) &= \mathbb{Z}/2\mathbb{Z}, && A_n\ (n \geq 2),\ D_n\ (n \geq 5),\ E_6, \\ E_\Delta(\mathcal{R}) &= \mathfrak{S}_3, && D_4. \end{aligned}$$

[33] See Bourbaki, *Groupes et algèbres de Lie*, Chapter VI, no. 4.2, or the Sophus Lie Seminar.

[34] Editors' note: for a slightly different proof, see also [De80].

0.7.5 Complements on p-morphisms

Let $f : \mathcal{R} \to \mathcal{R}'$ be a p-morphism (cf. 0.6.8). It is clear from the definitions that the bijection $u : R \xrightarrow{\sim} R'$ associated with f makes the systems of simple roots, the systems of positive roots, the irreducible components, and so forth of R and R' correspond. We may therefore suppose, for simplicity, that R and R' are irreducible.

Lemma 0.7.5.1. *If R and R' are irreducible, there is a $k \in \mathbb{Q}$ such that, for every $\alpha \in R$,*

$$k \operatorname{long}(u(\alpha)) = q(\alpha)^2 \operatorname{long}(\alpha).$$

Proof. One has

$$\operatorname{long}(\alpha)(\alpha^*, \beta) = \operatorname{long}(\beta)(\beta^*, \alpha)$$

and, similarly,

$$\operatorname{long}(u(\alpha))(u(\alpha)^*, u(\beta)) = \operatorname{long}(u(\beta))(u(\beta)^*, u(\alpha)).$$

It follows immediately that, for nonorthogonal α, β,

$$\frac{q(\alpha)^2 \operatorname{long}(\alpha)}{\operatorname{long}(u(\alpha))} = \frac{q(\beta)^2 \operatorname{long}(\beta)}{\operatorname{long}(u(\beta))}.$$

The conclusion then follows from 0.7.1.3 (iv). □

Remark 0.7.5.2. It follows from 0.7.2.2 and 0.6.8.4 that $q(\alpha)$ depends only on $\operatorname{long}(\alpha)$. One then sees readily that, if $q(\alpha)$ is not constant, the product $q(\alpha)\operatorname{long}(\alpha)$ is constant; hence $p = 2$ or 3. Inspection of the preceding diagrams gives the four possible cases (the same letter denotes a Dynkin diagram and the corresponding reduced simply connected root datum):

$$\begin{aligned} &p = 2, \quad B_n \xrightarrow{f_1} C_n, \quad C_n \xrightarrow{f_2} B_n, \quad (C_2 = B_2), \\ &p = 2, \quad F_4 \xrightarrow{g} F_4, \\ &p = 3, \quad G_2 \xrightarrow{h} G_2. \end{aligned}$$

The reader will observe that $f_1 \circ f_2$, $f_2 \circ f_1$, $g \circ g$, and $h \circ h$ are p-morphisms of the form described in 0.6.8.6.

7.5.3. The preceding description shows immediately that, if $\mathcal{R}$ and $\mathcal{R}'$ are two reduced root data of semisimple rank at most 2 and there is a p-morphism from $\mathcal{R}'$ to $\mathcal{R}$, then $\mathcal{R}$ and $\mathcal{R}'$ have the same type. More precisely, one has the following table.

Notation. Let $f : \mathcal{R}' \to \mathcal{R}$ be a p-morphism. The symbols q and q_1 denote arbitrary positive powers of p. For rank-two systems we use the notation of Section 0.4, with α, β the simple roots and $\ell(\alpha) \leq \ell(\beta)$.

Type	p	**values of** f	**values of** ${}^t f$
Trivial	arbitrary	—	—
A_1	arbitrary	$f(\alpha') = q\alpha$	${}^t f(\alpha^*) = q\alpha'^*$
$A_1 \times A_1$	arbitrary	$f(\alpha') = q\alpha$ $f(\beta') = q_1\beta$	${}^t f(\alpha^*) = q\alpha'^*$ ${}^t f(\beta^*) = q_1\beta'^*$
A_2, B_2, G_2	arbitrary	$f(\alpha') = q\alpha$ $f(\beta') = q\beta$	${}^t f(\alpha^*) = q\alpha'^*$ ${}^t f(\beta^*) = q\beta'^*$
B_2	$p = 2$	$f(\alpha') = q\beta$ $f(\beta') = 2q\alpha$	${}^t f(\alpha^*) = 2q\beta'^*$ ${}^t f(\beta^*) = q\alpha'^*$
G_2	$p = 3$	$f(\alpha') = q\beta$ $f(\beta') = 3q\alpha$	${}^t f(\alpha^*) = 3q\beta'^*$ ${}^t f(\beta^*) = q\alpha'^*$

Exposé XXII
Reductive Groups: Splittings, Subgroups, Quotient Groups

by Michel Demazure

[0] This Exposé consists of two parts. The first (§§1–5.5) gathers the technical results needed for the proofs of the uniqueness and existence theorems. The second (§5.6 to the end) will not be used in that proof; the end of §5 will be used in particular in Exposé XXVI, which is devoted to parabolic subgroups; §6 establishes, in the scheme-theoretic setting, the classical results concerning the derived group of a reductive group.

1. Roots and Coroots. Split Groups and Root Data

Theorem 1.1. *Let S be a scheme, G a reductive S-group, T a maximal torus of G, and α a root of G relative to T.*

(i) *There exists a unique T-equivariant homomorphism of group schemes*

$$\exp_\alpha : W(\mathfrak{g}^\alpha) \longrightarrow G$$

which induces on Lie algebras the canonical morphism $\mathfrak{g}^\alpha \to \mathfrak{g}$. This homomorphism is a closed immersion. The corresponding homomorphism

$$T \cdot_\alpha W(\mathfrak{g}^\alpha) \longrightarrow G$$

is likewise a closed immersion.

If $p_\alpha : \mathbb{G}_{a,S} \to G$ is a monomorphism normalized by T, with multiplier α, there exists a unique $X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^{\times 1}$ such that $p_\alpha(x) = \exp_\alpha(xX_\alpha)$; one has $\mathrm{Lie}(p_\alpha)(1) = X_\alpha$, and the preceding two formulas establish a bijective correspondence between $\Gamma(S, \mathfrak{g}^\alpha)^\times$ and the set of monomorphisms $\mathbb{G}_{a,S} \to G$ normalized by T, with multiplier α.

(ii) *There exists a unique duality, denoted $(X, Y) \longmapsto XY$,*

$$\mathfrak{g}^\alpha \otimes_{\mathcal{O}_S} \mathfrak{g}^{-\alpha} \xrightarrow{\sim} \mathcal{O}_S,$$

and a unique homomorphism of group schemes

$$\alpha^* : \mathbb{G}_{m,S} \longrightarrow T,$$

[0] Editor's note: Version dated October 13, 2024.

[1] Editor's note: The set $\Gamma(S, \mathfrak{g}^\alpha)^\times$ is defined in Exposé XIX, 4.4.1.

such that formula (F) *of Exposé XX, 2.1 holds. One has*

$$\alpha \circ \alpha^* = 2, \qquad (-\alpha)^* = -\alpha^*,$$

and α^* *is given by the formula of Exposé XX, 2.7.*

Indeed, a homomorphism normalized by T, with multiplier α, necessarily factors through the closed subgroup

$$Z_\alpha = \underline{\mathrm{Centr}}_G(T_\alpha)$$

of G (cf. Exposé XIX, 3.9). Now (Z_α, T, α) is an elementary S-system (Exposé XX, 1.4), and one is reduced to the results of Exposé XX (1.5, 2.1, and 5.9).

Remark 1.2. Part (i) of Theorem 1.1 remains valid if one assumes only that α is a character of T, nontrivial on every fiber. Indeed, there is then a decomposition

$$S = S' \amalg S'',$$

such that $\alpha|_{S'}$ is a root of $G_{S'}$ relative to $T_{S'}$, and $\mathfrak{g}^\alpha|_{S''} = 0$. If $S = S'$, one is reduced to 1.1; if $S = S''$, the result is trivial; the general case follows at once.

Notations 1.3. As in Exposé XX, let U_α denote the image of $W(\mathfrak{g}^\alpha)$; it is a closed subgroup of G, canonically endowed with a vector-group structure. We call it the *vector group associated with the root* α. We say that α^* is the *coroot associated with* α. Sections

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha) \quad \text{and} \quad X_{-\alpha} \in \Gamma(S, \mathfrak{g}^{-\alpha})$$

are said to be *paired* if $X_\alpha X_{-\alpha} = 1$. Then $X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times$, and likewise for $X_{-\alpha}$. The corresponding homomorphisms p_α and $p_{-\alpha}$ are contragredient to one another in the sense of Exposé XX, 1.5[2], and one has

$$p_\alpha(x)p_{-\alpha}(y) = p_{-\alpha}\left(\frac{y}{1+xy}\right)\alpha^*(1+xy)p_\alpha\left(\frac{x}{1+xy}\right).$$

Proposition 1.4. *Under the hypotheses of 1.1, let* $w \in \underline{\mathrm{Norm}}_G(T)(S)$. *Then*

$$\beta = \alpha \circ \mathrm{int}(w)^{-1} : T \longrightarrow \mathbb{G}_{m,S}$$

is a root of G *relative to* T, $\beta^* = \mathrm{int}(w) \circ \alpha^*$ *is the corresponding coroot, and the following diagram is commutative:*

$$\begin{array}{ccc} W(\mathfrak{g}^\alpha) & \xrightarrow{\exp_\alpha} & G \\ {\scriptstyle \mathrm{Ad}(w)}\downarrow & & \downarrow{\scriptstyle \mathrm{int}(w)} \\ W(\mathfrak{g}^\beta) & \xrightarrow{\exp_\beta} & G. \end{array}$$

Trivial: transport of structure.

[2]Editor's note: That is, if $\langle\ ,\ \rangle$ denotes the duality between $\mathfrak{g}^\alpha$ and $\mathfrak{g}^{-\alpha}$, and if $\mathfrak{g}^\alpha$ is identified with U_α via $p_\alpha(x) = \exp(xX_\alpha)$, and likewise for $-\alpha$, then $\langle p_\alpha(x), p_{-\alpha}(y)\rangle = xy$.

Definitions 1.5. (a) Under the hypotheses of 1.1, let s_α denote the automorphism of T defined by

$$s_\alpha(t) = t \cdot \alpha^*(\alpha(t))^{-1}.$$

Let (,) denote the canonical pairing

$$\underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, T) \times \underline{\mathrm{Hom}}_{S\text{-gr}}(T, \mathbb{G}_{m,S}) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, \mathbb{G}_{m,S}) = \mathbb{Z}_S.$$

Then s_α acts on $\underline{\mathrm{Hom}}_{S\text{-gr}}(T, \mathbb{G}_{m,S})$, respectively on $\underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, T)$, by the following formulas, where χ, respectively u, denotes an arbitrary section of the corresponding scheme:

$$s_\alpha(\chi) = \chi - (\alpha^*, \chi)\alpha, \qquad s_\alpha(u) = u - (u, \alpha)\alpha^*.$$

One has

$$s_\alpha \circ s_\alpha = \mathrm{id}, \qquad s_{-\alpha} = s_\alpha.$$

(b) If $X \in \Gamma(S, \mathfrak{g}^\alpha)^\times$, then the inner automorphism $w_\alpha(X)$ of T, defined by

$$w_\alpha(X) = \exp_\alpha(X) \exp_{-\alpha}(-X^{-1}) \exp_\alpha(X)$$

(cf. Exposé XX, 3.1), coincides with s_α (loc. cit.). Proposition 1.4 therefore gives the following.

Corollary 1.6. *Let S be a scheme, G a reductive S-group, T a maximal torus of G, and α, β two roots of G relative to T. Then*

$$s_\alpha(\beta) = \beta - (\alpha^*, \beta)\alpha$$

is a root of G relative to T, and its corresponding coroot is

$$s_\alpha(\beta)^* = s_\alpha(\beta^*) = \beta^* - (\beta^*, \alpha)\alpha^*.$$

Corollary 1.7. *Under the preceding conditions, $\alpha^* = \beta^*$ implies $\alpha = \beta$.*

Indeed, if $\alpha^* = \beta^*$, one has (cf. Exposé XXI, 1.4)

$$s_\beta(\alpha) = \alpha - 2\beta, \qquad s_\alpha(\beta) = \beta - 2\alpha,$$

and hence immediately

$$(s_\beta s_\alpha)^n(\alpha) = \alpha + 2n(\beta - \alpha).$$

If $\beta \neq \alpha$, there exists $s \in S$ such that $\alpha_s \neq \beta_s$. The preceding formula would then give infinitely many distinct roots of $G_{\bar{s}}$ relative to $T_{\bar{s}}$, which is impossible.

Definitions 1.8.0. [3] If $u : \mathbb{G}_{m,S} \to T$ is a homomorphism of groups, we say that u is a *coroot* of G relative to T if there exists a root α of G relative to T such that $\alpha^* = u$. Consider the functor $\mathcal{R}^*$ of coroots of G relative to T, defined by

$$\mathcal{R}^*(S') = \{\text{coroots of } G_{S'} \text{ relative to } T_{S'}\}.$$

If $\mathcal{R}$ is the functor of roots of G relative to T (Exposé XIX, 3.8), there is a canonical morphism $\mathcal{R} \to \mathcal{R}^*$. By 1.7 and Exposé XIX, 3.8, one has:

[3] Editor's note: We added the numbering 1.8.0 to highlight these definitions.

Corollary 1.8. *The canonical morphism $\mathcal{R} \to \mathcal{R}^*$ is an isomorphism. In particular, $\mathcal{R}^*$ is represented by a twisted finite constant S-scheme that is an open and closed subscheme of*

$$\underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, T).$$

This leads to the following definition.

Definition 1.9. *Let S be a scheme and T an S-torus. A* twisted root datum *in T consists of*

(i) *a finite subscheme $\mathcal{R}$ of*

$$\underline{\mathrm{Hom}}_{S\text{-gr}}(T, \mathbb{G}_{m,S});$$

(ii) *a finite subscheme $\mathcal{R}^*$ of*

$$\underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, T);$$

(iii) *an isomorphism $\mathcal{R} \xrightarrow{\sim} \mathcal{R}^*$, denoted $\alpha \mapsto \alpha^*$,*

satisfying the following conditions:

(DR 1) *For every $S' \to S$ and every $\alpha \in \mathcal{R}(S')$, one has $\alpha \circ \alpha^* = 2$.*

(DR 2) *For every $S' \to S$ and all $\alpha, \beta \in \mathcal{R}(S')$, one has*

$$\alpha - (\beta^*, \alpha)\beta \in \mathcal{R}(S'), \qquad \alpha^* - (\alpha^*, \beta)\beta^* \in \mathcal{R}^*(S').$$

Moreover, the twisted root datum is said to be reduced *if, for every nonempty $S' \to S$ and every $\alpha \in \mathcal{R}(S')$, one has $2\alpha \notin \mathcal{R}(S')$.*

Proposition 1.10. *Let S be a scheme, G a reductive S-group, T a maximal torus of G, and let $\mathcal{R}$, respectively $\mathcal{R}^*$, be the scheme of roots, respectively coroots, of G relative to T. Then $(\mathcal{R}, \mathcal{R}^*)$ is a reduced twisted root datum in T.*

It remains only to verify that this twisted root datum is reduced. This was done in Exposé XIX, 3.10.

1.11. Let $T = \mathrm{D}_S(M)$ be a *trivialized* torus. If M^* denotes the abelian group dual to M, there are canonical isomorphisms (cf. Exposé VIII, 1.5)

$$\underline{\mathrm{Hom}}_{S\text{-gr}}(T, \mathbb{G}_{m,S}) \xrightarrow{\sim} M_S, \qquad \underline{\mathrm{Hom}}_{S\text{-gr}}(\mathbb{G}_{m,S}, T) \xrightarrow{\sim} M_S^*,$$

and hence group isomorphisms

$$\mathrm{Hom}_{S\text{-gr}}(T, \mathbb{G}_{m,S}) \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{loc.const.}}(S, M),$$

$$\mathrm{Hom}_{S\text{-gr}}(\mathbb{G}_{m,S}, T) \xrightarrow{\sim} \mathrm{Hom}_{\mathrm{loc.const.}}(S, M^*).$$

A character of T, respectively a group homomorphism $\mathbb{G}_{m,S} \to T$, is said to be *constant* relative to the given trivialization if the preceding isomorphism carries it to a constant map from S to M, respectively to M^*.

1.12. With the same notation, let (M, M^*, R, R^*) be a root datum (Exposé XXI). Then (R_S, R_S^*) is a twisted root datum in T. Conversely, if $(\mathcal{R}, \mathcal{R}^*)$ is a twisted root datum in a torus T, a *splitting* of this root datum means the data of an ordinary root datum (M, M^*, R, R^*) and an isomorphism

$$T \simeq \mathrm{D}_S(M)$$

that carries $(\mathcal{R}, \mathcal{R}^*)$ to (R_S, R_S^*).

Definition 1.13. *Let S be a scheme, G a reductive S-group, and T a maximal torus of G. A* splitting of G relative to T *consists of*

(i) *an abelian group M and an isomorphism $T \simeq \mathrm{D}_S(M)$;*

(ii) *a system of roots R of G relative to T* (Exposé XIX, 3.6),

satisfying the following two conditions:

(D 1) *S is nonempty, and the roots $\alpha \in R$* (respectively, the corresponding coroots) *identify with constant functions from S to M* (respectively, to M^*).

(D 2) *The $\mathfrak{g}^\alpha$, $\alpha \in R$, are free $\mathcal{O}_S$-modules.*

We say that G is *splittable relative to T* if a splitting of G relative to T exists. A *splitting of G* consists of a maximal torus T of G together with a splitting of G relative to T. We say that G is *splittable* if it admits a splitting. A *split S-group* is a reductive S-group equipped with a splitting; we denote it by a symbol of the form (G, T, M, R), or simply by G when there is no risk of confusion.

Condition (D 1) canonically identifies R, respectively R^*, with a subset of M, respectively of M^*.

Proposition 1.14. *Let S be a nonempty scheme and let (G, T, M, R) be a split S-group. Then*

$$\mathcal{R}(G, T, M, R) = (M, M^*, R, R^*)$$

is a reduced root datum (Exposé XXI, 1.1 and 2.1.3)*; it is a splitting of the twisted root datum of 1.10.*

This follows trivially from 1.10 and Exposé XIX, 3.7.

For brevity we shall sometimes write $\mathcal{R}(G, T, M, R) = \mathcal{R}(G)$. We shall systematically use the notation V, $V(\mathcal{R})$, $W, \ldots$ of Exposé XXI.

Remark 1.15. (a) If S is nonempty and connected, respectively if $\mathrm{Pic}(S) = 0$, condition (D 1), respectively condition (D 2), is automatically satisfied.

(b) If (G, T, M, R) is a split S-group, then for every nonempty $S' \to S$, $(G_{S'}, T_{S'}, M, R)$ is a split S'-group and

$$\mathcal{R}(G, T, M, R) = \mathcal{R}(G_{S'}, T_{S'}, M, R).$$

1.16. Let $T = \mathrm{D}_S(M)$ be a trivialized torus. The Lie algebra $\mathfrak{t}$ of T identifies canonically (Exposé II, 5.1.1) with

$$\mathfrak{t} \simeq M^* \otimes \mathcal{O}_S.$$

For every homomorphism of groups $u : T \to \mathbb{G}_{m,S}$, $\mathrm{Lie}(u)$ is a linear form

$$\mathrm{Lie}(u) : \mathfrak{t} \longrightarrow \mathcal{O}_S = \mathrm{Lie}(\mathbb{G}_{m,S}/S).$$

In particular, if u is defined by an element $\alpha \in M$, then $\mathrm{Lie}(u)$ is the linear form $\bar{\alpha}$ on $M^* \otimes \mathcal{O}_S$ defined by

$$\bar{\alpha}(m \otimes x) = (m, \alpha)x.$$

Symmetrically, for every homomorphism of groups $h : \mathbb{G}_{m,S} \to T$, $\mathrm{Lie}(h)$ is an $\mathcal{O}_S$-linear morphism

$$\mathcal{O}_S = \mathrm{Lie}(\mathbb{G}_{m,S}/S) \longrightarrow \mathfrak{t},$$

canonically determined by the section

$$H = \mathrm{Lie}(h)(1) \in \Gamma(S, \mathfrak{t}).$$

In particular, if h is defined by an element $m \in M^*$, then

$$H = \mathrm{Lie}(h)(1) = m \otimes 1.$$

Comparing the two definitions, we find in particular

$$\bar{\alpha}(H) = (h, \alpha) \cdot 1 \in \Gamma(S, \mathcal{O}_S).$$

1.17. These definitions apply in particular when T is the maximal torus of a split group. Every root $\alpha \in R$ defines an *infinitesimal root*

$$\bar{\alpha} \in \mathrm{Hom}_{\mathcal{O}_S}(\mathfrak{t}, \mathcal{O}_S), \qquad \bar{\alpha}(m \otimes x) = (m, \alpha)x.$$

Every coroot α^*, $\alpha \in R$, defines an *infinitesimal coroot*

$$H_\alpha \in \Gamma(S, \mathfrak{t}), \qquad H_\alpha = \alpha^* \otimes 1.$$

For $\alpha, \beta \in R$, we have

$$\bar{\alpha}(H_\beta) = (\beta^*, \alpha) \cdot 1,$$

and in particular

$$\bar{\alpha}(H_\alpha) = 2.$$

Consequently, if 2 is invertible on S, then $\bar{\alpha}$ and H_α are nonzero on every fiber.

2. Existence of a Splitting. Type of a Reductive Group

Proposition 2.1. *Let S be a scheme, G a reductive S-group, and T a maximal torus of G. Suppose that T is split. Then G is locally splittable relative to T: for every $s_0 \in S$, there exists an open neighborhood U of s_0 such that the U-group G_U is splittable relative to T_U.*

Indeed, write $T \simeq \mathrm{D}_S(M)$ and

$$\mathfrak{g} = \coprod_{m \in M} \mathfrak{g}^m.$$

Let

$$R = \{m \in M \mid m \neq 0,\ \mathfrak{g}^m(s_0) \neq 0\}.$$

After restricting S and replacing it by an open neighborhood of s_0, we may suppose that the $\mathfrak{g}^\alpha$, $\alpha \in R$, are free and that the $\mathfrak{g}^m$, for $m \neq 0$ and $m \notin R$, vanish. We then have

$$\mathfrak{g} = \mathfrak{t} \oplus \coprod_{\alpha \in R} \mathfrak{g}^\alpha,$$

where the $\mathfrak{g}^\alpha$ are free of rank 1. It follows that R is a system of roots of G relative to T (Exposé XIX, 3.6). The coroots α^* corresponding to the $\alpha \in R$ then identify with locally constant functions on S with values in M^*. Shrinking S once more, we may suppose that they are constant, and the proof is complete.

Observe that the proof immediately gives:

Proposition 2.2. *Let S be a nonempty connected scheme such that* $\mathrm{Pic}(S) = 0$*, for example* $\mathrm{Spec}(\mathbb{Z})$ *or a local scheme* (in particular, the spectrum of a field)*. If G is a reductive S-group possessing a split maximal torus T, then G is splittable relative to T.*

We deduce immediately from 2.1 and from the fact that a reductive group locally possesses maximal tori for the étale topology (Exposé XIX, 2.5):

Corollary 2.3. *Let S be a scheme and G a reductive S-group* (respectively, let T also be a maximal torus of G)*. Then G is locally splittable* (respectively, locally splittable relative to T) *for the étale topology on S.*

Corollary 2.4. *Let k be a field and G a reductive k-group. There exists a finite separable extension K/k such that G_K is splittable.*

Remark 2.5. Using 2.1 and Exposé XIX, Remark 2.9, one immediately proves the following result: let $G = (G, T, M, R)$ be a split S-group. There exists an open covering (U_i) of S such that each split group G_{U_i} is obtained by base change from a split group over a noetherian ring (and in fact over a finitely generated $\mathbb{Z}$-algebra). We shall moreover prove that every split group over S is already obtained from a split $\mathbb{Z}$-group (Exposé XXV).

2.6. Let k be an algebraically closed field and G a reductive k-group. We know (for example by 2.4) that splittings of G exist. Let (G, T, M, R) and (G, T', M', R') be two splittings of G. Then the root data

$$\mathcal{R}(G, T, M, R) \qquad \text{and} \qquad \mathcal{R}(G, T', M', R')$$

are isomorphic.

Indeed, we first see that it is enough to reduce to the case $T = T'$: there exists $g \in G(k)$ such that $T' = \mathrm{int}(g)T$, and one readily verifies that transporting a splitting by an automorphism of G produces a root datum isomorphic to the original one. But since $S = \mathrm{Spec}(k)$ is connected, the isomorphism

$$\mathrm{D}_k(M) \xrightarrow{\sim} T \xrightarrow{\sim} \mathrm{D}_k(M')$$

comes from a unique isomorphism $M \simeq M'$. For the same reason, there exists at most one root system of G relative to T.

Definition 2.6.1. [4] If G is a reductive k-group, where k is algebraically closed, the *type of* G is the isomorphism class of the root datum defined by any splitting of G. If G is a torus of type M in the sense of Exposé IX, 1.4, then the type of G as a reductive group is given by the trivial root datum

$$(M, M^*, \varnothing, \varnothing).$$

By 1.15(b)[5], the type is invariant under an (algebraically closed) extension of the base field.

Definition 2.7. If G is a reductive S-group and $s \in S$, the *type of* G *at* s is the type of the reductive $\bar{s}$-group $G_{\bar{s}}$.

For every $S' \to S$ and every $s' \in S'$ mapping to $s \in S$, the type of $G_{S'}$ at s' is equal to the type of G at s.

If G is splittable and (G, T, M, R) is a splitting of G, then the type of G at s is the isomorphism class of $\mathcal{R}(G, T, M, R)$, by 1.15(b)[5]. The following then follows immediately from 2.3:

Proposition 2.8. *Let G be a reductive S-group, where $S \neq \varnothing$. The function*

$$s \longmapsto \textit{the type of } G \textit{ at } s$$

is locally constant on S. In particular, there exists a partition of S into nonempty open subschemes on each of which G has constant type. More precisely, let E be the set of types of the fibers of G, and, for every $t \in E$, let S_t be the set of points $s \in S$ where G has type t. Then $(S_t)_{t \in E}$ is a partition of S, and each S_t is open and closed (and nonempty).

3. The Weyl Group

3.1. Let S be a scheme, G a reductive S-group, and T a maximal torus of G. Then

$$W_G(T) = \underline{\mathrm{Norm}}_G(T)/T$$

is a finite étale S-group (Exposé XIX, 2.5). The morphism $n \mapsto \mathrm{int}(n)$ induces, upon passage to the quotient, a canonical monomorphism (which is moreover an open immersion)

$$W_G(T) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(T).$$

3.2. Suppose now that G is splittable relative to T. Choose a splitting, say (G, T, M, R). We then have a canonical isomorphism (Exposé VIII, 1.5)

$$\underline{\mathrm{Aut}}_{S\text{-gr.}}(T) \simeq \left(\mathrm{Aut}_{\mathrm{gr.}}(M)\right)_S.$$

In particular, if W is the Weyl group of the root datum $\mathcal{R}(G)$ (Exposé XXI, 1.1.8), we have a monomorphism

$$W_S \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(T).$$

[4] Editor's note: The number 2.6.1 was added for later references.

[5] Editor's note: We have corrected the original, which referred to 1.17.

3.3. For every root $\alpha \in R$, the reflection $s_\alpha \in W$ acts on M by

$$s_\alpha(x) = x - (\alpha^*, x)\alpha,$$

and hence acts on T, by the preceding morphism, according to

$$s_\alpha(t) = t \cdot \alpha^*\big(\alpha(t)\big)^{-1}.$$

On the other hand, since $\mathfrak{g}^\alpha$ is assumed to be free, there exists

$$X \in \Gamma(S, \mathfrak{g}^\alpha)^\times.$$

Consider

$$w_\alpha(X) \in \underline{\mathrm{Norm}}_G(T)(S) \qquad \text{(Exposé XX, 3.1)}.$$

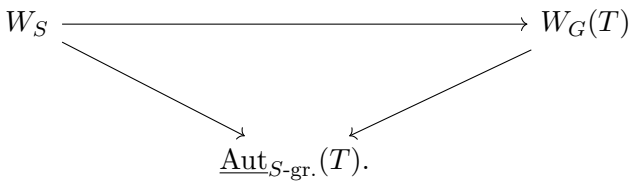
We have (loc. cit.)

$$\mathrm{int}\big(w_\alpha(X)\big)(t) = s_\alpha(t).$$

Since W is generated by the s_α, $\alpha \in R$, it follows from the preceding remarks that, if W and $\underline{\mathrm{Norm}}_G(T)(S)/T(S)$ are regarded as groups of automorphisms of T, then

$$W \subset \underline{\mathrm{Norm}}_G(T)(S)/T(S) \subset W_G(T)(S).$$

By definition of the constant group W_S associated with W (cf. Exposé I, 1.8), we therefore have a commutative diagram:



Proposition 3.4. *Let S be a scheme, let (G, T, M, R) be a split S-group, and let W be the Weyl group of the root datum $\mathcal{R}(G)$. Then the canonical monomorphism*

$$W_S \longrightarrow W_G(T) = \underline{\mathrm{Norm}}_G(T)/T$$

is an isomorphism.

Indeed, these are étale groups over S; it therefore suffices to verify that, for every $s \in S$, the morphism

$$W_S(\bar{s}) \longrightarrow W_G(T)(\bar{s})$$

is an isomorphism.[6] The latter assertion follows, for example, from *Bible*, §11.3, Theorem 2.

Remark 3.5. Using 2.3, the preceding proposition gives a new proof of the fact that the Weyl group of a maximal torus of a reductive S-group G is finite over S (Exposé XIX, 2.5(ii)). [7]

[6] Editor's note: Indeed, since W_S and $W_G(T) = \underline{\mathrm{Norm}}_G(T)/T$ are étale over S, the morphism $f : W_S \to W_G(T) = \underline{\mathrm{Norm}}_G(T)/T$ is étale (EGA IV_4, 17.3.4). If, moreover, each f_s is an isomorphism, then, by loc. cit., 17.9.1, f is a surjective open immersion, hence an isomorphism.

[7] Editor's note: Indeed, let T be a maximal torus of G. The fact that $W_G(T)$ is finite over S is local for the fpqc topology (EGA IV_2, 2.7.1), hence *a fortiori* for the étale topology. By 2.3, we may therefore suppose that G is split relative to T, in which case the assertion follows from 3.4.

3.6. Under the hypotheses of 3.1, for every $w \in W_G(T)(S)$, let N_w[8] denote the fiber product in the following diagram:

$$\begin{array}{ccc} N_w & \longrightarrow & \underline{\mathrm{Norm}}_G(T) \\ \downarrow & & \downarrow \\ S & \xrightarrow{w} & W_G(T). \end{array}$$

It is an open and closed subscheme of $\underline{\mathrm{Norm}}_G(T)$, and is a principal homogeneous bundle under T on the left (respectively, on the right) for the law

$$(t, q) \longmapsto tq \qquad \text{(respectively, } (q, t) \longmapsto qt).$$

If $n \in N_w(S)$, then

$$N_{ww'} = n \cdot N_{w'}, \qquad N_{w'w} = N_{w'} \cdot n.$$

3.7. In particular, if α is a root of G with respect to T, then N_{s_α} is none other than what was denoted by $N^\times$ in Exposé XX, 3.0. If $\mathfrak{g}^\alpha$ is free over S, we therefore have

$$N_{s_\alpha}(S) \neq \varnothing.$$

By 3.4 and condition (D 2) of the splitting, we deduce:

Corollary 3.8. *Under the hypotheses of 3.4, the morphism*

$$\underline{\mathrm{Norm}}_G(T)(S) \longrightarrow W_G(T)(S) = \mathrm{Hom}_{\mathrm{loc.const.}}(S, W)$$

is surjective. In particular, for every $w \in W$, there exists $n_w \in \underline{\mathrm{Norm}}_G(T)(S)$ such that

$$\mathrm{int}(n_w)|_T = w.$$

4. Homomorphisms of Split Groups

4.1. The "Big Cell"

4.1.1. Let (G, T, M, R) be a split reductive S-group. Choose a system of positive roots R_+ of the root datum $\mathcal{R}(G)$ (Exposé XXI, 3.2.1). Put $R_- = -R_+$.

Choose a total ordering on R_+ (respectively, R_-) and consider the morphism induced by multiplication in G:

$$u : \left(\prod_{\alpha \in R_-} U_\alpha\right) \times_S T \times_S \left(\prod_{\alpha \in R_+} U_\alpha\right) \longrightarrow G.$$

This is an open immersion. Indeed, since both sides are flat and of finite presentation over S, it suffices to verify this on every geometric fiber (SGA 1, I, 5.7 and VIII, 5.4). We are thus reduced to the case in which S is the spectrum of an algebraically closed field. But by *Bible*, §13.4, Corollary 2 to Theorem 3, u is radicial and dominant. Since the tangent

[8]Editor's note: We have replaced Q_w by N_w, just as in Exposé XX, 3.0, Q was replaced by $N^\times$.

map of u at the origin is an isomorphism (definition of a root system), u is birational. As G is normal, Zariski's "Main Theorem" (EGA III_1, 4.4.9) applies, and u is an open immersion.

Let us show that the image Ω of this open immersion is independent of the ordering chosen on R_+ (respectively, R_-). Since this amounts to comparing open subsets of G, we are reduced to proving that they have the same geometric points, and may therefore again suppose that S is the spectrum of an algebraically closed field. The assertion is then precisely *Bible*, §13, Proposition 1(c) and Theorem 1(a).

We have therefore proved:

Proposition 4.1.2. *Let (G, T, M, R) be a split S-group, and let R_+ be a system of positive roots of R. There exists an open subset Ω_{R_+} of G such that, for every total ordering on R_+* (respectively, R_-)*, the morphism induced by multiplication in G*

$$\left(\prod_{\alpha\in R_-} U_\alpha\right) \times_S T \times_S \left(\prod_{\alpha\in R_+} U_\alpha\right) \longrightarrow G$$

is an open immersion with image Ω_{R_+}.

Remark 4.1.3. Proposition 4.1.2 may be restated as follows: for every $\alpha \in R$, choose an isomorphism of vector groups

$$p_\alpha : \mathbb{G}_{a,S} \xrightarrow{\sim} U_\alpha \qquad \text{(cf. 1.19)}.$$

Then the morphism (where $N = \mathrm{Card}(R_+) = \mathrm{Card}(R_-)$)

$$\mathbb{G}_{a,S}^N \times_S T \times_S \mathbb{G}_{a,S}^N \longrightarrow G$$

defined on points by

$$\left((x_\alpha)_{\alpha\in R_-}, t, (x_\alpha)_{\alpha\in R_+}\right) \longmapsto \prod_{\alpha\in R_-} p_\alpha(x_\alpha) \cdot t \cdot \prod_{\alpha\in R_+} p_\alpha(x_\alpha)$$

is an open immersion whose image depends only on R_+, and not on the choice of the p_α or of the orderings on R_+ and R_-.

Notation 4.1.4. We write[9]

$$\Omega_{R_+} = \prod_{\alpha\in R_-} U_\alpha \cdot T \cdot \prod_{\alpha\in R_+} U_\alpha.$$

Proposition 4.1.5. *The scheme Ω_{R_+} is of finite presentation over S* (hence quasi-compact in G) *and is universally schematically dense in G relative to S* (cf. Exposé XVIII, 1).

The first assertion is trivial. Thus,[10] Ω_{R_+} is flat and of finite presentation over S, and contains the identity section; it therefore meets every fiber of G in a nonempty, hence dense, open subset. The second assertion thus follows from Exposé XVIII, 1.3.[11]

[9] Editor's note: It is called the "big cell" corresponding to R_+.
[10] Editor's note: We have expanded the original in what follows.
[11] Editor's note: See also EGA IV_3, 11.10.10.

Corollary 4.1.6. *Let (G, T, M, R) be a split reductive S-group. Then*

$$\underline{\mathrm{Centr}}(G) = \bigcap_{\alpha \in R} \mathrm{Ker}(\alpha).$$

Consequently, $\underline{\mathrm{Centr}}(G)$ is representable by a closed diagonalizable subgroup of G. [12]

The second assertion follows immediately from the first. To prove the first, one may invoke Exposé XII, 4.8 and 4.11; alternatively, one may argue directly as follows.[13] Let $S' \to S$. If $t \in T(S')$ and $\alpha(t) = 1$ for every $\alpha \in R$, then $\mathrm{int}(t)$ induces the identity on $T_{S'}$ and on every $(U_\alpha)_{S'}$, $\alpha \in R$, and therefore also on $(\Omega_{R_+})_{S'}$. By schematic density it consequently induces the identity on $G_{S'}$, whence

$$t \in \underline{\mathrm{Centr}}(G)(S').$$

Conversely, since

$$\underline{\mathrm{Centr}}_{G_{S'}}(T_{S'}) = T_{S'} \qquad \text{(cf. Exposé XIX, 2.8)},$$

if $g \in G(S')$ centralizes $T_{S'}$ and the $(U_\alpha)_{S'}$, then g is a section of $T_{S'}$ on which every $\alpha \in R$ vanishes.

Corollary 4.1.7. *Let S be a scheme and G a reductive S-group. Then the center of G is representable by a closed subgroup of G of multiplicative type. It is also "the intersection of the maximal tori of G" in the following sense: for every $S' \to S$, $\underline{\mathrm{Centr}}(G)(S')$ is the set of $g \in G(S')$ such that, for every $S'' \to S'$, the inverse image of g in $G(S'')$ belongs to $T(S'')$ for every maximal torus T of $G_{S''}$.*

In view of 2.3, the first assertion follows from 4.1.6 by descent.[14] Let us prove the second assertion. Let H denote "the intersection of the maximal tori of G" in the preceding sense. Clearly,[15]

$$\underline{\mathrm{Centr}}(G) \subset H.$$

By descent, it is therefore enough to prove $\underline{\mathrm{Centr}}(G) = H$ when G is split. Since H is contained in the intersection of the maximal tori of G in the usual sense, this follows from the following remark: if (G, T, M, R) is a splitting, $\alpha \in R$, and $X \in \Gamma(S, \mathfrak{g}^\alpha)^\times$, then

$$\mathrm{int}\big(\exp_\alpha(X)\big)(T) \cap T = \mathrm{Ker}(\alpha),$$

as a trivial calculation shows. See also Exposé XII, 8.6 and 8.8 for a more general statement.

Remark 4.1.8. In what follows, in the split case we shall systematically identify T with $D_S(M)$. Then

$$\underline{\mathrm{Centr}}(G) = D_S(M/\Gamma_0(R)),$$

where $\Gamma_0(R)$ is the subgroup of M generated by R (cf. Exposé XXI, 1.1.6).
If $\{\alpha_1, \alpha_2, \ldots, \alpha_n\}$ is a system of simple roots of R, then one immediately has (cf. Exposé XX, 1.19)

$$\underline{\mathrm{Centr}}(G) = \bigcap_i \mathrm{Ker}(\alpha_i) = \bigcap_i \underline{\mathrm{Centr}}(Z_{\alpha_i}).$$

[12] Editor's note: We have added the preceding sentence.
[13] Editor's note: We have expanded the original in what follows.
[14] Editor's note: Indeed, representability of the center by a closed subscheme of G is local for the fpqc topology (SGA 1, VIII, 5.2 and 5.4), hence *a fortiori* for the étale topology; the same is true of the property of being of multiplicative type.
[15] Editor's note: We have expanded the original in what follows.

Proposition 4.1.9. *Let S be a scheme, let (G, T, M, R) be a split S-group, let Q be an S-torus, let α_0 be a character of Q, let $\mathcal{L}$ be an invertible $\mathcal{O}_S$-module, and let*

$$f : Q \longrightarrow T, \qquad p : W(\mathcal{L}) \longrightarrow G$$

be group homomorphisms satisfying the following set-theoretic relation:

$$p(\alpha_0(q)x) = \mathrm{int}\big(f(q)\big) \cdot p(x)$$

for every $q \in Q(S')$, $x \in W(\mathcal{L})(S')$, and $S' \to S$. Suppose that f separates the elements of R in the following sense: if $\alpha, \alpha' \in R$ and $m, m' \in \mathbb{Z}$, then[16]

$$m\alpha \circ f = m'\alpha' \circ f \quad \Longrightarrow \quad m\alpha = m'\alpha'.$$

Finally, let $s \in S$ be such that $(\alpha_0)_{\bar{s}} \neq e$ and $p_{\bar{s}} \neq e$.

There then exist an open subset U of S containing s, an integer $q > 0$ such that $x \mapsto x^q$ is an endomorphism of $\mathbb{G}_{a,U}$, a root $\alpha \in R$, and an isomorphism of $\mathcal{O}_U$-modules

$$h : (\mathcal{L}|_U)^{\otimes q} \xrightarrow{\sim} \mathfrak{g}^{\alpha}|_U$$

such that

$$\text{(i)} \quad (\alpha \circ f)|_U = (q\alpha_0)|_U,$$

$$\text{(ii)} \quad p(X) = \exp_{\alpha}\big(h(X^q)\big) \quad \text{for every } X \in W(\mathcal{L})(S'),\ S' \to U.$$

Moreover, once U has been chosen, q, α, and h are uniquely determined.

After shrinking S, we may suppose that α_0 is nonzero on every fiber of S. Choose a system of positive roots R_+ of R, and put

$$V = p^{-1}(\Omega_{R_+}).$$

This is an open subset of $W(\mathcal{L})$ containing the zero section and stable under multiplication by every $\alpha_0(q)$, where $q \in Q(S')$ and $S' \to S$. Since α_0 is nontrivial on every fiber, it follows immediately that $V = W(\mathcal{L})$, and hence that p factors through Ω_{R_+}. Choose arbitrary orderings of R_+ and R_-; every product below is understood to be taken in the chosen ordering. There are therefore unique morphisms

$$a_\alpha : W(\mathcal{L}) \longrightarrow U_\alpha, \qquad \alpha \in R, \qquad b : W(\mathcal{L}) \longrightarrow T$$

such that

$$p(x) = \prod_{\alpha \in R_-} a_\alpha(x) \cdot b(x) \cdot \prod_{\alpha \in R_+} a_\alpha(x).$$

Writing out the covariance condition under Q, one immediately obtains

$$a_\alpha\big(\alpha_0(q)x\big) = \alpha\big(f(q)\big)a_\alpha(x), \qquad \alpha \in R,$$

$$b\big(\alpha_0(q)x\big) = b(x)$$

for every $x \in W(\mathcal{L})(S')$, $q \in Q(S')$, and $S' \to S$. The second condition immediately gives $b = e$.

[16] Editor's note: This is equivalent to the following hypothesis: if $\alpha, \alpha' \in R$, $m, m' \in \mathbb{Z}$, and

$$(m\alpha \circ f)_{\bar{s}} = (m'\alpha' \circ f)_{\bar{s}}$$

for every geometric point $\bar{s}$ of S, then $m\alpha = m'\alpha'$. In particular, this separation hypothesis is stable under base change.

Now let $\alpha \in R$ be such that $(a_\alpha)_{\bar{s}} \neq e$; such an α exists because $p_{\bar{s}} \neq e$ by hypothesis. Applying Exposé XIX, 4.12(a), we find an integer $n > 0$ such that

$$(\alpha \circ f)_{\bar{s}} = (n\alpha_0)_{\bar{s}}.$$

After shrinking S, we may suppose that $\alpha \circ f = n\alpha_0$ (Exposé IX, 5.3). But then, for every $\alpha' \in R$ with $\alpha' \neq \alpha$, one has

$$(\alpha' \circ f)_{\bar{s}} \neq m\alpha_0 \qquad \text{for every integer } m > 0,$$

by the hypothesis on f and the fact that the only roots proportional to α are α and $-\alpha$. Applying Exposé XIX, 4.12(a), now to $a_{\alpha'}$, we find that $a_{\alpha'}$ vanishes in a neighborhood of s. Since R is finite, after shrinking S once more we may suppose that $a_{\alpha'} = 0$ for every $\alpha' \in R$, $\alpha' \neq \alpha$. Thus $p = a_\alpha$, and we may apply Exposé XIX, 4.12(b), followed by 4.12(c), which gives the asserted result. The uniqueness assertions are clear.

Remark 4.1.10. The condition imposed on f in 4.1.9 is satisfied in particular when f is surjective (that is, faithfully flat).

Proposition 4.1.11. *Let (G, T, M, R) be a split S-group, let R_+ be a system of positive roots of R, and let Ω_{R_+} be the corresponding "big cell."*

(i) *Let H be a group-valued S-functor that is separated*[17] *for the fppf topology. If $f, g : G \rightrightarrows H$ are two group homomorphisms that coincide on Ω_{R_+}, then $f = g$.*

(ii) *Let H be an S-sheaf of groups for the fppf topology, and let $f : \Omega_{R_+} \to H$ be an S-morphism with the following property: for every $S' \to S$ and every $x, y \in \Omega_{R_+}(S')$ such that $xy \in \Omega_{R_+}(S')$, one has $f(xy) = f(x)f(y)$. Then there exists a group homomorphism $\bar{f} : G \to H$, unique by* (i)*, extending f.*

Indeed, by 4.1.5, (i) (respectively (ii)) follows immediately from Exposé XVIII, 2.2 (respectively 2.3 and 2.4).

Remark 4.1.12. If $\alpha \in R_+$, then

$$(\dagger) \qquad \Omega_{R_+} \cap Z_\alpha = U_{-\alpha} \cdot T \cdot U_\alpha.$$

Indeed,[18] for every $S' \to S$, if

$$g = \prod_{\beta \in R_-} p_\beta(x_\beta) \cdot t \cdot \prod_{\beta \in R_+} p_\beta(x_\beta)$$

is an element of $\Omega_{R_+}(S')$, and if $t' \in T_\alpha(S')$, then

$$t'gt'^{-1} = \prod_{\beta \in R_-} p_\beta(\beta(t')x_\beta) \cdot t \cdot \prod_{\beta \in R_+} p_\beta(\beta(t')x_\beta).$$

Since α and $-\alpha$ are the only elements of R whose restriction to T_α is 1, it follows that g belongs to $Z_\alpha = \mathrm{Centr}(T_\alpha)$ if and only if $x_\beta = 0$ for $\beta \neq \pm\alpha$.

From (†) and Exposé XX, 2.1, one deduces that if $X \in \Gamma(S, \mathfrak{g}^\alpha)$ and $Y \in \Gamma(S, \mathfrak{g}^{-\alpha})$, then

$$\exp_\alpha(X) \exp_{-\alpha}(Y) \in \Omega_{R_+}(S) \quad \Longleftrightarrow \quad 1 + XY \text{ is invertible.}$$

[17] Editor's note: Recall (cf. Exposé IV, 4.3.5) that an S-presheaf H is separated for a topology $\mathcal{T}$ if, for every $S' \to S$ and every family of S-morphisms $(S'_i \to S')_{i \in I}$ covering for $\mathcal{T}$, the map

$$H(S') \longrightarrow \prod_i H(S'_i)$$

is injective.

[18] Editor's note: We have expanded the original in what follows.

4.2. Morphisms of Split Groups

Definition 4.2.1. Let S be a nonempty scheme, and let (G, T, M, R) and (G', T', M', R') be two split S-groups. An S-group homomorphism $f : G \to G'$ is said to be *compatible with the splittings*, or to define a *morphism of split groups*, if the restriction of f to T factors as a morphism $f_T : T \to T'$ of the form $f_T = D_S(h)$, where $h : M' \to M$ is a group homomorphism satisfying the following condition: there exist a bijection $d : R \xrightarrow{\sim} R'$[19] and, for every $\alpha \in R$, an integer $q(\alpha) > 0$ such that $x \mapsto x^{q(\alpha)}$ is an endomorphism of $\mathbb{G}_{a,S}$ and

$$h(d(\alpha)) = q(\alpha)\alpha, \qquad {}^t h(\alpha^*) = q(\alpha)d(\alpha)^*.$$

Remark 4.2.2. It is immediate that h, d, and the $q(\alpha)$, for $\alpha \in R$, are uniquely determined by f. We write $h = \mathscr{R}(f)$. The $q(\alpha)$ are the radicial exponents of f (or of h).

Let p be the prime number, if one exists, that vanishes on S; put $p = 1$ if no prime number vanishes on S. Then $\mathscr{R}(f)$ is a p-morphism of reduced root data in the sense of Exposé XXI, 6.8. We have thus defined a functor $\mathscr{R}$ from the category of split S-groups to the category of reduced root data (equipped with p-morphisms).

Proposition 4.2.3. *Under the hypotheses of 4.2.1, the following properties hold:*

(i) *For every $\alpha \in R$, there exists a unique isomorphism of $\mathcal{O}_S$-modules*

$$f_\alpha : (\mathfrak{g}^\alpha)^{\otimes q(\alpha)} \xrightarrow{\sim} \mathfrak{g}'^{d(\alpha)}$$

such that

$$f\big(\exp_\alpha(X)\big) = \exp_{d(\alpha)}\big(f_\alpha(X^{q(\alpha)})\big)$$

for every $X \in W(\mathfrak{g}^\alpha)(S')$ and every $S' \to S$.

(ii) *For every $\alpha \in R$, one has $q(-\alpha) = q(\alpha)$, and f_α and $f_{-\alpha}$ are contragredient to one another.*

(iii) *For every $\alpha \in R$, every $Z \in W(\mathfrak{g}^\alpha)^*(S')$, and every $S' \to S$, one has*

$$f\big(w_\alpha(Z)\big) = w_{d(\alpha)}\big(Z^{q(\alpha)}\big).$$

By hypothesis, the following diagram is commutative:

$$\begin{array}{ccccc}
\mathbb{G}_{m,S} & \xrightarrow{\alpha^*} & T & \xrightarrow{\alpha} & \mathbb{G}_{m,S} \\
\Big\downarrow{\scriptstyle q(\alpha)} & & \Big\downarrow{\scriptstyle f_T} & & \Big\downarrow{\scriptstyle q(\alpha)} \\
\mathbb{G}_{m,S} & \xrightarrow{d(\alpha)^*} & T' & \xrightarrow{d(\alpha)} & \mathbb{G}_{m,S}
\end{array}$$

It follows that f maps $\mathrm{Ker}(\alpha)$ into $\mathrm{Ker}(d(\alpha))$, hence T_α into $T'_{d(\alpha)}$, and hence Z_α into $Z'_{d(\alpha)}$. It remains only to apply Exposé XX, 3.10 and 3.11, to the groups Z_α and $Z'_{d(\alpha)}$.

[19] Editor's note: We have replaced the notation $u : R \to R'$ by $d : R \to R'$.

Proposition 4.2.4. *The morphism f induces a morphism f_N from $\underline{\mathrm{Norm}}_G(T)$ to $\underline{\mathrm{Norm}}_{G'}(T')$, hence a morphism f_W from $W_G(T)$ to $W_{G'}(T')$; the latter is an isomorphism. More precisely, let*

$$\bar{d} : W\big(\mathscr{R}(G)\big) = W \longrightarrow W' = W\big(\mathscr{R}(G')\big)$$

be the isomorphism extending $s_\alpha \mapsto s_{d(\alpha)}$ (Exposé XXI, 6.8.4)*. Then there is a commutative diagram of isomorphisms:*

$$\begin{array}{ccc} W_G(T) & \xrightarrow[\sim]{f_W} & W_{G'}(T') \\ \uparrow \sim & & \uparrow \sim \\ W_S & \xrightarrow[\sim]{\bar{d}_S} & W'_S. \end{array}$$

This follows immediately from 3.4, Exposé XXI, 6.8.4, and (iii) above.

Remark 4.2.5. With the notation of 4.2.3, the restriction of f to Ω_{R_+}, for a system of positive roots R_+, can be written explicitly: it maps Ω_{R_+} into $\Omega'_{d(R_+)}$ ($d(R_+)$ is a system of positive roots of R' by Exposé XXI, 6.8.7), and is given by the set-theoretic formula

$$f\Big(\prod_{\alpha\in R_-} \exp_\alpha(X_\alpha)\cdot t \cdot \prod_{\alpha\in R_+} \exp_\alpha(X_\alpha)\Big) = \prod_{\alpha\in R_-} \exp_{d(\alpha)}\Big(f_\alpha(X_\alpha^{q(\alpha)})\Big)\cdot f_T(t)\cdot \prod_{\alpha\in R_+} \exp_{d(\alpha)}\Big(f_\alpha(X_\alpha^{q(\alpha)})\Big).$$

Proposition 4.2.6. (i) *The morphism f is surjective* (= faithfully flat in the present case; cf. Exposé $\mathrm{VI_B}$, 3.11) *if and only if f_T is surjective.*

(ii) *One has* $\mathrm{Ker}(f) \subset \Omega_{R_+}$.

We prove (i). If f is surjective, then $f_T(T) = f(T)$ is a maximal torus of G'. Indeed, $f(T)$ is a subtorus of a maximal torus T' (Exposé IX, 6.8); to verify that $f(T) = T'$, one reduces to the case of an algebraically closed field, where this is *Bible*, §7.3, Theorem 3(a).

If f_T is surjective, the preceding formula shows that f induces a surjection from $\Omega = \Omega_{R_+}$ onto $\Omega' = \Omega'_{d(R_+)}$.[20] Since the fibers of G' are connected, it follows (cf. Exposé $\mathrm{VI_A}$, 0.5) that f is surjective.

We prove (ii), and for this purpose admit a result that will be proved below (5.7.4). For each $w \in W$, choose an $n_w \in \underline{\mathrm{Norm}}_G(T)(S)$ representing it. Then the open subschemes $n_w\Omega$, for $w \in W$, cover G. It is therefore enough to prove that

$$\mathrm{Ker}(f) \cap n_w\Omega \neq \varnothing \quad \Longrightarrow \quad w = 1.$$

If $x \in \Omega(S')$, where $S' \to S$, and $f(n_w x) = 1$, then $f(x) = f(n_w)^{-1}$. But $f(x) \in \Omega'(S')$, whereas

$$f(n_w)^{-1} \in \underline{\mathrm{Norm}}_{G'}(T')(S').$$

By 4.2.4, we are reduced to proving the following.

[20] Editor's note: We have given the reference to Exposé VI in greater detail below.

Lemma 4.2.7. *Under the hypotheses of 4.1.2, one has*

$$\Omega \cap \underline{\mathrm{Norm}}_G(T) = T.$$

Let

$$x = \prod_{\alpha\in R_-} p_\alpha(x_\alpha)\cdot t\cdot \prod_{\alpha\in R_+} p_\alpha(x_\alpha) = vtu \in \Omega(S').$$

If x normalizes $T_{S'}$, then, for every $t' \in T(S')$,

$$xt'x^{-1} = t'' \in T(S'),$$

that is, $xt' = t''x$, which may be written

$$v(tt')(t'^{-1}ut') = (t''vt''^{-1})(t''t)u.$$

This gives $t'^{-1}ut' = u$, hence

$$u \in \mathrm{Centr}_G(T)(S') = T(S'),$$

and therefore $u = 1$. Similarly, $v = 1$.

Corollary 4.2.8. *One has*

$$\mathrm{Ker}(f) = \prod_{\alpha\in R_-} K_\alpha \cdot \mathrm{Ker}(f_T)\cdot \prod_{\alpha\in R_+} K_\alpha,$$

where, for each $\alpha \in R$, K_α denotes the finite S-group

$$K_\alpha = \mathrm{Ker}\Big(U_\alpha \longrightarrow U_\alpha^{\otimes q(\alpha)}\Big) \simeq \boldsymbol{\alpha}_{q(\alpha),S}.$$

To apply this corollary, we make the following definition.

Definition 4.2.9. Let S be a scheme and let G and G' be two reductive S-groups. A faithfully flat and finite morphism of S-groups $f : G \to G'$ (i.e. one that is surjective and has finite kernel over S) is called an *isogeny*. If, moreover, $\mathrm{Ker}(f)$ is a central subgroup of G, then f is called a *central isogeny*.

Proposition 4.2.10. *Let $f : G \to G'$ be a morphism of split groups. For f to be an isogeny* (respectively, a central isogeny)*, it is necessary and sufficient that f_T be an isogeny, i.e. that $\mathscr{R}(f)$ be injective with finite cokernel* (respectively, and that $q(\alpha) = 1$ for every $\alpha \in R$).

Indeed, by 4.2.8, $\mathrm{Ker}(f)$ is finite over S if and only if $\mathrm{Ker}(f_T)$ is finite over S, and $\mathrm{Ker}(f) \subset T$ if and only if every $q(\alpha)$ is equal to 1. In that case $\mathrm{Ker}(f)$ is central, since it is of multiplicative type and invariant; cf. Exposé IX, 5.5.

Remark 4.2.11. (a) Thus $f : G \to G'$ is a central isogeny if and only if

$$\mathscr{R}(f) : \mathscr{R}(G') \longrightarrow \mathscr{R}(G)$$

is an isogeny in the sense of Exposé XXI, 6.2. Moreover, in this case, with the notation of *loc. cit.*, one has

$$\mathrm{Ker}(f) = D_S\big(K(\mathscr{R}(f))\big), \qquad K\big(\mathscr{R}(f)\big) = \mathrm{Coker}\big(\mathscr{R}(f)\big).$$

(b) If G and G' are semisimple, every morphism of split groups $f : G \to G'$ is an isogeny.[21]

(c) If $f : G \to G'$ is faithfully flat and finite and G is reductive (respectively, semisimple), then G' is so as well. Indeed, G' is of finite presentation over S (Exposé V, 9.1), affine over S (EGA II, 6.7.1), smooth over S (Exposé VI, 9.2), and has connected reductive (respectively, semisimple) geometric fibers by Exposé XIX, 1.7.

Definition 4.2.1 may seem arbitrary. It is justified by the following proposition, which, for simplicity, we shall state for semisimple groups.

A morphism $f : G \to G'$ of reductive S-groups is said to be *splittable* if there exist splittings of G and G' with which f is compatible. We then have the following.

Proposition 4.2.12. *Let S be a scheme, let G and G' be two semisimple S-groups, and let $f : G \to G'$ be a morphism of groups. Let $s \in S$. The following conditions are equivalent:*

(i) $\mathrm{Ker}(f_{\bar{s}})$ is finite ($\iff e$ is isolated in $\mathrm{Ker}(f)(\bar{s})$), and $f_{\bar{s}}$ is surjective, i.e. $f_{\bar{s}}$ is an isogeny.

(ii) $f_{\bar{s}}$ is splittable.

(iii) There exists an étale morphism $S' \to S$ covering s such that $f_{S'} : G_{S'} \to G'_{S'}$ is splittable.

Clearly, (iii) is equivalent to (ii), and (ii) implies (i) by 4.2.11(b). This is where the hypothesis that G and G' are semisimple enters; the other implications are valid for reductive groups.

We now prove that (i) implies (iii). We may suppose that G and G' are split in such a way that f induces a morphism

$$f_T : T \longrightarrow T'$$

(2.3 and Exposé XIX, 2.8). After restricting S, we may suppose that $f_T = D_S(h)$, where $h : M' \to M$ is a morphism of groups. Let $\alpha \in R$, and consider the composite morphism

$$p : W(\mathfrak{g}^\alpha) \xrightarrow{\exp_\alpha} G \xrightarrow{f} G'.$$

Since $\mathrm{Ker}(p_{\bar{s}})$ is finite, $p_{\bar{s}} \neq e$. On the other hand, $f_{T_{\bar{s}}}$ is surjective. We may therefore apply 4.1.9: there exist an open subset V_α of S containing s, a root $\alpha' \in R'$, and an integer $q(\alpha)$ such that $x \mapsto x^{q(\alpha)}$ is an endomorphism of $\mathbb{G}_{a,V_\alpha}$, and an isomorphism of $\mathcal{O}_{V_\alpha}$-modules

$$f_\alpha : (\mathfrak{g}^\alpha)^{\otimes q(\alpha)}\Big|_{V_\alpha} \xrightarrow{\sim} \mathfrak{g}'^{\alpha'}\Big|_{V_\alpha},$$

such that

$$f(\exp_\alpha(X_\alpha)) = \exp_{d(\alpha)}(f_\alpha(X_\alpha^{q(\alpha)}))$$

and

$$\alpha' \circ f_T = h(\alpha') = q(\alpha)\alpha.$$

We may replace S by the intersection of the V_α, for $\alpha \in R$. Put $\alpha' = d(\alpha)$. It is clear that

$$d : R \longrightarrow R'$$

[21] Editor's note: Indeed, since G and G' are semisimple, f_T is surjective with finite kernel; hence f is faithfully flat with finite kernel by 4.2.6(i) and 4.2.8.

is a bijection, since the kernel of h is finite ($f_{T_{\bar{s}}}$ being surjective). It remains only to prove that

$$f_T \circ \alpha^* = q(\alpha)\alpha'^*,$$

which follows by a trivial modification of the argument used in Exposé XX, 3.11.

In any event, as we have seen in the course of the proof, (i) implies (iii). We have therefore proved the following.

Corollary 4.2.13. *Let S be a scheme and let $f : G \to G'$ be an isogeny of reductive groups. Then f is locally splittable for the étale topology.*

4.3. Central Quotients of Reductive Groups

We first consider a special case.

Proposition 4.3.1. *Let S be a scheme, let (G, T, M, R) be a split S-group, let N be a subgroup of M containing R, and put*

$$Q = D_S(M/N) \subset \mathrm{Centr}(G).$$

Then:

(i) *$G' = G/Q$ is a reductive S-group, and $T' = T/Q$ is a maximal torus of G';*

(ii) *if T' is identified with $D_S(N)$, then $R \subset N$ is a root system of G' relative to T', (G', T', N, R) is a splitting of G', and $\mathscr{R}(G')$ is canonically identified with the induced root datum* (Exposé XXI, 6.5) *$\mathscr{R}(G)_N$;*

(iii) *the canonical morphism $G \to G'$ is compatible with the splittings, has root exponents equal to* 1*, and, by functoriality, induces the canonical morphism* (loc. cit.)

$$\mathscr{R}(G)_N \longrightarrow \mathscr{R}(G).$$

We know that $G' = G/Q$ is representable by an affine group scheme over S (Exposé VIII, 5.7), smooth over S (Exposé $\mathrm{VI_B}$, 9.2), and with connected reductive geometric fibers (as quotients of reductive groups; cf. Exposé XIX, 1.7). Thus G' is a reductive S-group.

It is clear that

$$T' = T/Q \simeq D_S(N)$$

is a maximal torus of G'. Next, choose a system R_+ of positive roots of R. The open subset Ω_{R_+} of 4.2 is stable under Q, and there is a canonical isomorphism

$$\Omega_{R_+}/Q \simeq \left(\prod_{\alpha\in R_-} U_\alpha\right) \underset{S}{\times} (T/Q) \underset{S}{\times} \left(\prod_{\alpha\in R_+} U_\alpha\right).$$

Moreover, Ω_{R_+}/Q is an open subset of G' containing the identity section (cf. Exposé IV, 4.7.2 and 6.4.1).

It follows that, if $\mathfrak{g}'$ denotes the Lie algebra of G' and $\bar{\alpha}$ the character of T/Q induced by α (or, equivalently, defined by $\alpha \in N$ under the identification $T/Q = D_S(N)$), then the canonical morphism $\mathfrak{g} \to \mathfrak{g}'$ induces, for every $\alpha \in R$, an isomorphism

$$\mathfrak{g}^\alpha \xrightarrow{\sim} \mathfrak{g}'^{\bar{\alpha}}.$$

We have thus proved that R is a root system of G' relative to T', and the proof is completed without difficulty.

Corollary 4.3.2. *Let S be a scheme, let G be a reductive S-group, and let Q be a normal subgroup of G of multiplicative type. Then Q is central in G, the quotient G/Q is representable by a reductive S-group, and the canonical morphism $G \to G/Q$ is locally splittable for the étale topology* (with root exponents equal to 1).

The first assertion follows from Exposé IX, 5.5; the others are local for the étale topology and reduce to 4.3.1.

Definition 4.3.3. Let G be a reductive S-group. We say that G is *adjoint* (respectively, *simply connected*) if, for every $s \in S$, the type of G at s is given by an adjoint (respectively, simply connected) root datum, i.e. (Exposé XXI, 6.2.6) one for which M is generated by R (respectively, M^* is generated by R^*).

Proposition 4.3.4. (i) *An adjoint* (respectively, simply connected) *reductive group is semisimple.*

(ii) *If T is a maximal torus of the adjoint* (respectively, simply connected) *reductive group G, and if α is a root of G relative to T, then the infinitesimal root $\bar{\alpha}$ is nonzero on every fiber* (respectively, α^* is a monomorphism and the infinitesimal coroot H_α is nonzero on every fiber).

Indeed, (i) is trivial; (ii) may be checked on the geometric fibers and follows at once from Exposé XXI, 6.2.8.

Proposition 4.3.5. (i) *The reductive group G is adjoint if and only if*

$$\mathrm{Centr}(G) = \{e\}_S.$$

(ii) *For every reductive group G, the quotient group $G/\mathrm{Centr}(G)$ is an adjoint reductive group.*

Indeed, we may suppose that G is split. Then (i) is immediate, since

$$\mathrm{Centr}(G) = D_S(M/\Gamma_0(R)),$$

and (ii) follows from 4.3.1.

Definition 4.3.6. Let G be a reductive S-group. The *adjoint group* of G, denoted by $\mathrm{ad}(G)$, is the group $G/\mathrm{Centr}(G)$. The *radical* of G, denoted by $\mathrm{rad}(G)$, is the maximal torus (unique by Exposé XII, 1.12) of $\mathrm{Centr}(G)$. The *semisimple group associated with G* is the quotient $G/\mathrm{rad}(G)$.

The preceding definitions are compatible with base change. If $s \in S$, then $\mathrm{rad}(G)_{\bar{s}}$ is indeed the radical of $G_{\bar{s}}$ in the usual sense (Exposé XIX, 1.6).

4.3.7. If (G, T, M, R) is a split group, then

$$\mathrm{rad}(G) = D_S(M/N), \qquad N = M \cap V(R).$$

Thus the semisimple group associated with G (as also the adjoint group of G) is equipped with a canonical splitting (4.3.1), and we have a diagram of split groups

$$G \longrightarrow \mathrm{ss}(G) \longrightarrow \mathrm{ad}(G)$$

corresponding to the canonical diagram of root data (Exposé XXI, 6.5.5)

$$\mathrm{ad}(\mathscr{R}(G)) \longrightarrow \mathrm{ss}(\mathscr{R}(G)) \longrightarrow \mathscr{R}(G).$$

Remark 4.3.8. *Let (G, T, M, R) be a split adjoint* (respectively, simply connected) *S-group, and let Δ be a system of simple roots of R. Then the family $\{\alpha\}_{\alpha\in\Delta}$, respectively $\{\alpha^*\}_{\alpha\in\Delta}$, induces an isomorphism*

$$T \xrightarrow{\sim} (\mathbb{G}_{m,S})^{\Delta}, \qquad \textit{respectively} \qquad (\mathbb{G}_{m,S})^{\Delta} \xrightarrow{\sim} T.$$

Indeed,

$$M = \Gamma_0(R) \qquad (\text{respectively, } M^* = \Gamma_0(R^*)),$$

and Δ (respectively, $\{\alpha^*\}_{\alpha\in\Delta}$) is a basis of the free abelian group $\Gamma_0(R)$ (respectively, $\Gamma_0(R^*)$); see Exposé XXI, 3.1.8.

Remark 4.3.9. The radical of a reductive group is a *characteristic* subgroup (i.e. stable under $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$), by its definition.

5. Subgroups of Type (R)

We are especially interested in reductive groups, but some of the results that we shall establish hold more generally for a wider class of groups: groups of type (RR).

5.1. Groups of Type (RR)

Definition 5.1.1. Let S be a scheme and G an S-group scheme. We say that G is *of type* (RR) if it satisfies the following conditions:

(i) G is smooth and of finite presentation over S, with connected fibers.

(ii) G locally possesses maximal tori for the fpqc topology.

(iii) For every $s \in S$, every maximal torus T of $G_{\bar{s}}$, and every root α of $G_{\bar{s}}$ relative to $T_{\bar{s}}$ (Exposé XIX, 1.10),

$$\mathrm{Lie}(G_{\bar{s}})^{\alpha}$$

has rank 1 (as a vector space over $\overline{\kappa(s)}$).

(iv) For every $s \in S$ and every maximal torus T of $G_{\bar{s}}$, let R denote the set of roots of $G_{\bar{s}}$ relative to T, and let $\Gamma_0(R)$ be the subgroup of

$$\mathrm{Hom}_{\bar{s}\text{-gr.}}(T, \mathbb{G}_{m,\bar{s}})$$

generated by R. Then the content[22] of every root $\alpha \in R$ in the free abelian group $\Gamma_0(R)$ (and hence a positive integer) is invertible on S.

Reminder 5.1.1.1. [23] Let us recall that, if G is a smooth connected algebraic group over an algebraically closed field k, a *Cartan subgroup* of G is the centralizer of a maximal torus of G (Exposé XII, 1.0), and such a subgroup is smooth and connected. For this, as well as for other characterizations of Cartan subgroups, see *Bible*, §7.1, Theorem 1 in the case where G is affine, and Exposé XII, Theorem 6.6 in the general case.

If S is an arbitrary scheme and G is a smooth S-group of finite type, a *Cartan subgroup* of G is a smooth S-subgroup C of G such that, for every $s \in S$, $C_{\bar{s}}$ is a Cartan subgroup of $G_{\bar{s}}$ (Exposé XII, Definition 3.1).

[22] Editor's note: The content of the root α is the positive generator of the ideal $\{f(\alpha) \mid f \in \Gamma_0(R)^*\}$ of $\mathbb{Z}$; it is the greatest integer $c > 0$ such that $\alpha/c \in \Gamma_0(R)$.

[23] Editor's note: This reminder was added.

Remark 5.1.2. (a) By Exposé XII, 7.1 (where the hypothesis that G is separated is satisfied here because G has connected fibers; cf. Exposé $\mathrm{VI_B}$, 5.5), conditions (i) and (ii) imply that G locally possesses, for the étale topology, maximal tori (respectively, Cartan subgroups), which are locally conjugate for the étale topology.

(b) The Cartan subgroups of G have connected fibers (Exposé XII, 6.6).

(c) If G is affine over S, conditions (i) and (ii) are respectively equivalent to:

(i′) G is smooth over S and has connected fibers;

(ii′) the reductive rank of the fibers of G is locally constant (Exposé XII, 1.7).

(d) By Exposé XII, 8.8 (c) and (d), G has a reductive center Z, and for every $s \in S$, in the notation of (iv),[24]

$$Z_{\bar{s}} = \bigcap_{\alpha \in R} \mathrm{Ker}(\alpha),$$

whence

$$\mathrm{Hom}_{\bar{s}\text{-gr.}}\big((T/Z)_{\bar{s}}, \mathbb{G}_{m,\bar{s}}\big) \simeq \Gamma_0(R).$$

(e) Condition (iv) holds in particular in the following two cases:

(1) S has characteristic 0;

(2) every root is an indivisible element of the group generated by the roots.

(f) The property of being of type (RR) is stable under base change and is local for the fpqc topology.

Remarks (c) and (e) immediately give the following proposition.

Proposition 5.1.3. *A reductive group is of type* (RR).

Proposition 5.1.4. *Let S be a scheme, let G be an S-group of type* (RR)*, and let Q be a central subgroup of G, of finite presentation over S, such that the quotient G/Q is representable* (for example, G affine over S and Q of multiplicative type (Exposé IX, 2.3), or S artinian (Exposé $\mathrm{VI_A}$, 3.3.2)). *Then G/Q is an S-group of type* (RR).

Indeed, G/Q is smooth over S (Exposé $\mathrm{VI_B}$, 9.2), of finite presentation over S (Exposé V, 9.1), and has connected fibers, so condition (i) holds. On the other hand, condition (ii) follows from Exposé XII, 7.6; it remains to verify conditions (iii) and (iv).

Put $G' = G/Q$, let

$$u : G \longrightarrow G'$$

be the canonical morphism, and let $T' = u(T)$ be the maximal torus of G' that is the image of T (cf. Exposé XII, 7.1 (e)). For each $\alpha \in R$, again denote by α the character of T' induced by α; indeed,

$$Q \cap T \subset \bigcap_{\alpha \in R} \mathrm{Ker}(\alpha)$$

by 5.1.2 (d). We first prove:

[24] Editor's note: The original said "under the conditions of (iv)," but the last condition of (iv) does not appear to be used here.

Lemma 5.1.5. *Under the hypotheses of 5.1.4, let $T = D_S(M)$ be a trivialized maximal torus of G, and suppose that the decomposition of $\mathfrak{g} = \mathrm{Lie}(G)$ under $\mathrm{Ad}(T)$ has the form*

$$\mathfrak{g} = \mathfrak{g}^0 \oplus \coprod_{\alpha \in R} \mathfrak{g}^\alpha, \qquad R \subset M - \{0\},$$

where, for every $s \in S$, $\mathfrak{g}^\alpha(s) \neq 0$ for $\alpha \in R$ (thus $\mathfrak{g}^\alpha$ is an invertible $\mathcal{O}_S$-module for every $\alpha \in R$, and R is the set of roots of $G_{\bar{s}}$ relative to $T_{\bar{s}}$, for every $s \in S$). *Then the Lie algebra $\mathfrak{g}'$ of G' decomposes under $\mathrm{Ad}(T')$ as follows:*

$$\mathfrak{g}' = \mathfrak{g}'^0 \oplus \coprod_{\alpha \in R} \mathfrak{g}'^\alpha,$$

and $\mathrm{Lie}(u)$ induces an isomorphism from $\mathfrak{g}^\alpha$ onto $\mathfrak{g}'^\alpha$.

Indeed, let

$$p = \mathrm{Lie}(u) : \mathfrak{g} \longrightarrow \mathfrak{g}'.$$

One immediately has $p(\mathfrak{g}^\alpha) \subset \mathfrak{g}'^\alpha$ for every $\alpha \in R$, and $p(\mathfrak{g}^0) \subset \mathfrak{g}'^0$. Since

$$\mathrm{Ker}(p) = \mathrm{Lie}(Q) \subset \mathrm{Lie}\big(\mathrm{Centr}_G(T)\big) = \mathfrak{g}^0,$$

p induces a monomorphism from $\mathfrak{g}^\alpha$ into $\mathfrak{g}'^\alpha$, for every $\alpha \in R$.

To prove the lemma, it is enough to do so when S is the spectrum of an algebraically closed field; in view of the preceding remarks, it is then enough to prove that

$$\mathrm{rk}(\mathfrak{g}') = \mathrm{rk}(\mathfrak{g}'^0) + \mathrm{Card}(R).$$

Set

$$C = \mathrm{Centr}_G(T), \qquad C' = \mathrm{Centr}_{G'}(T').$$

By Exposé XII, 7.1 (e), u induces a faithfully flat morphism $C \to C'$ with kernel Q. Hence

$$\dim C' + \dim Q = \dim C.$$

But G, G', C, and C' are smooth, and therefore

$$\begin{aligned} \dim G = \mathrm{rk}(\mathfrak{g}) &= \mathrm{rk}(\mathfrak{g}^0) + \mathrm{Card}(R) = \dim C + \mathrm{Card}(R) \\ &= \dim Q + \dim C' + \mathrm{Card}(R) = \dim Q + \mathrm{rk}(\mathfrak{g}'^0) + \mathrm{Card}(R), \\ \mathrm{rk}(\mathfrak{g}') &= \dim G' = \dim G - \dim Q. \end{aligned}$$

It follows that

$$\mathrm{rk}(\mathfrak{g}') = \mathrm{rk}(\mathfrak{g}'^0) + \mathrm{Card}(R),$$

which is the desired relation.

We return to the proof of 5.1.4. We may suppose that S is the spectrum of an algebraically closed field. Let T be a maximal torus of G. Applying 5.1.5, we immediately obtain (iii) and (iv) for G/Q.

To use the preceding proposition, we introduce a definition.

Definition 5.1.6. We say that the S-group scheme G is *of type* (RA) if it is of type (RR) and also satisfies condition (iv′) below, which is stronger than (iv):

(iv′) For every $s \in S$ and every maximal torus T of $G_{\bar{s}}$, the content of every root of $G_{\bar{s}}$ relative to T, in

$$\mathrm{Hom}_{\bar{s}\text{-gr.}}(T, \mathbb{G}_{m,\bar{s}}),$$

is invertible on S.

Remarks 5.1.7. (a) An adjoint reductive S-group is of type (RA).

(b) If S has characteristic 0, every group of type (RR) is of type (RA).

(c) The property of being of type (RA) is stable under base change and is local for the fpqc topology.

Remark (a) above admits the following generalization.

Proposition 5.1.8. *Let S be a scheme, let G be an S-group of type* (RR)*, and let Z be its reductive center. Suppose that the quotient G/Z is representable* (for example, if G is affine over S, or if S is artinian)*. Then G/Z is of type* (RA)*.*

Indeed, this follows immediately from 5.1.4, 5.1.5, and 5.1.2 (d).

Remark 5.1.9. If G is of type (RR) and T is a maximal torus of G, Exposé XIX, 6.3 applies. In particular, $W_G(T)$ is étale, quasi-finite, and separated over S.

5.2. Subgroups of Type (R)

Definition 5.2.1. Let S be a scheme, let G be a smooth S-group scheme of finite presentation with connected fibers,[25] and let H be a group subscheme of G. We say that H is *of type* (R) if:

(i) H is smooth and of finite presentation over S, and has connected fibers;[25]

(ii) for every $s \in S$, $H_{\bar{s}}$ contains a Cartan subgroup of $G_{\bar{s}}$.

This notion is stable under base change and is local for the fpqc topology.

Recall 5.2.2. (cf. Exposé XII, 7.9) Under the preceding conditions:

(a)
$$H = \underline{\mathrm{Norm}}_G(H)^0.$$

(b) If G locally possesses Cartan subgroups (respectively maximal tori) for the étale topology, then so does H, and the Cartan subgroups (respectively maximal tori) of H are Cartan subgroups (respectively maximal tori) of G.

Examples 5.2.3. (a) *Borel subgroups.* A Borel subgroup of G is a subgroup H of type (R) whose geometric fibers are Borel subgroups of the corresponding fibers of G.[26]

(b) *Parabolic subgroups.* A parabolic subgroup of G is a subgroup of type (R) whose geometric fibers contain Borel subgroups.

Other examples are given by the following propositions.

Proposition 5.2.4. *Let G be as in 5.2.1, let $K \subset H$ be two group subschemes of G, and suppose that H is of type* (R)*. Then K is a subgroup of type* (R) *of H if and only if it is a subgroup of type* (R) *of G.*

Indeed,[27] let $s \in S$. Since H is of type (R), every maximal torus of $H_{\bar{s}}$ is a maximal torus of $G_{\bar{s}}$, and the same therefore holds for Cartan subgroups.

[25] Editor's note: The hypothesis that G (respectively H) is of finite presentation over S is automatically satisfied: since G (respectively H) is smooth over S with connected fibers, it is quasi-compact and separated over S (Exposé $\mathrm{VI_B}$, 5.5), and hence of finite presentation over S.

[26] Editor's note: Equivalently, H is a smooth subgroup of G such that every geometric fiber $H_{\bar{s}}$ is a Borel subgroup of $G_{\bar{s}}$ (since every Borel subgroup of $G_{\bar{s}}$ is connected and contains a Cartan subgroup of $G_{\bar{s}}$).

[27] Editor's note: We have expanded the argument that follows.

Proposition 5.2.5. *Let G be as in 5.2.1, let T be a maximal torus of G, let Q be a subtorus of T, and put $Z = \underline{\mathrm{Centr}}_G(Q)$. If H is a subgroup of type* (R) *of G containing T, then $H \cap Z$ is a subgroup of type* (R) *of Z.*

First recall that Z is a closed group subscheme of G, of finite presentation (Exposé XI, 6.11), with connected fibers (Exposé XII, 6.6), and smooth over S (Exposé XI, 2.4), so it satisfies the conditions imposed in Definition 5.2.1. Likewise, $H \cap Z$ is of finite presentation, smooth, and has connected fibers (since $H \cap Z = \underline{\mathrm{Centr}}_H(Q)$); moreover,

$$H \cap Z \supset \underline{\mathrm{Centr}}_G(T).$$

Proposition 5.2.6. *Let S be a scheme, let G be an S-group of type* (RR) (respectively (RA))*, and let H be a subgroup of type* (R) *of G. Then H is an S-group of type* (RR) (respectively (RA))*.*

Indeed, (i) is clear, (ii) follows from 5.2.2 (b), and (iii) and (iv) (respectively (iv$'$)) are to be verified when S is the spectrum of an algebraically closed field. Then H contains a maximal torus T of G, and therefore also

$$C = \underline{\mathrm{Centr}}_G(T),^{28}$$

and the assertions to be proved follow immediately from:

Lemma 5.2.7. *Let S be a scheme, let G be an S-group of type* (RR)*, and let T be a maximal torus of G equipped with a trivialization $T \simeq D_S(M)$. Suppose that*

$$\mathfrak{g} = \mathfrak{g}^0 \oplus \coprod_{\alpha \in R} \mathfrak{g}^\alpha$$

(the $\mathfrak{g}^\alpha$ are then invertible $\mathcal{O}_S$-modules)*. Let H be a subgroup of type* (R) *containing $C = \underline{\mathrm{Centr}}_G(T)$* (that is, containing T)*. Then $\mathfrak{h} = \mathrm{Lie}(H/S)$ is locally on S of the form*

$$\mathfrak{g}^0 + \coprod_{\alpha \in R'} \mathfrak{g}^\alpha = \mathfrak{g}_{R'}.$$

More precisely, for each $s \in S$, put

$$R'(s) = \{\alpha \in R \mid \mathfrak{g}^\alpha(s) \subset \mathfrak{h}(s)\}.$$

Then $R'(s)$ is a locally constant function of s. If U is an open subset of S on which $R'(s) = R'$, then

$$\mathfrak{h}_U = \mathfrak{g}^0_U \oplus \coprod_{\alpha \in R'} \mathfrak{g}^\alpha_U.$$

Indeed, $\mathfrak{h}$ is a submodule of $\mathfrak{g}$, locally a direct factor, containing $\mathfrak{g}^0$, and stable under T.

[28] Editor's note: By hypothesis, H contains $\underline{\mathrm{Centr}}_G(T')$ for some maximal torus T' of G. The tori T and T' are then conjugate in H, and hence H also contains $C = \underline{\mathrm{Centr}}_G(T)$.

5.3. Strict Transporter of Two Subgroups of Type (R). Applications

Recall 5.3.0. [29] Let S be a scheme, let G be a smooth S-group, put $\mathfrak{g} = \mathrm{Lie}(G/S)$, and let $\mathfrak{h}$ be an $\mathcal{O}_S$-submodule of $\mathfrak{g}$ that is locally a direct factor. The $\mathcal{O}_S$-algebra

$$\mathscr{A} = \mathrm{Sym}(\omega^1_{G/S})$$

is locally free; hence the S-scheme

$$\underline{\mathrm{Lie}}(G/S) = W(\mathfrak{g}) = \mathrm{Spec}(\mathscr{A})$$

is essentially free in the sense of Exposé VIII, 6.1. Since $W(\mathfrak{h})$ is a closed subscheme of $\underline{\mathrm{Lie}}(G/S)$, of finite presentation over $\underline{\mathrm{Lie}}(G/S)$, it follows from Exposé VIII, 6.5 (a) that

$$N = \underline{\mathrm{Norm}}_G(\mathfrak{h})$$

is represented by a closed group subscheme of G, of finite presentation over G. (See also the additions 6.2.3 and 6.2.4 (a) in Exposé $\mathrm{VI_B}$.) On the other hand, by Exposé II, 5.3.1,

$$\underline{\mathrm{Lie}}(N/S) = \underline{\mathrm{Norm}}_{\underline{\mathrm{Lie}}(G/S)}(\mathfrak{h}).$$

Finally, by Exposé $\mathrm{VI_B}$, 3.10, if N is smooth over S at the points of the unit section, then the group subfunctor N^0 (defined in Exposé $\mathrm{VI_B}$, 3.1) is represented by an open group subscheme of N, smooth over S.

Proposition 5.3.1. *Let S be a scheme, let G be an S-group of type* (RA) (5.1.6)*, let H be a subgroup of type* (R) *of G, and let $\mathfrak{g} \supset \mathfrak{h}$ be their Lie algebras. Then* $\underline{\mathrm{Norm}}_G(\mathfrak{h})$ (which, by 5.3.0, is representable by a closed subscheme of G, of finite presentation over S) *is smooth over S at every point of the unit section, and*

$$\underline{\mathrm{Norm}}_G(\mathfrak{h})^0 = H.$$

[30] *Proof.* Put

$$N = \underline{\mathrm{Norm}}_G(\mathfrak{h}), \qquad \mathfrak{n} = \mathrm{Lie}(N/S).$$

We have $H \subset N$, and by Exposé II, 5.3.1, for every $s \in S$,

$$\mathfrak{h}(s) \subset \mathfrak{n}(s) = \mathrm{Norm}_{\mathfrak{g}(s)}(\mathfrak{h}(s)).$$

Now, by 5.3.2 below,

$$\mathfrak{h}(s) = \mathrm{Norm}_{\mathfrak{g}(s)}(\mathfrak{h}(s)),$$

and since H is smooth over S,

$$\dim_{\kappa(s)} \mathfrak{h}(s) = \dim H_s$$

(cf. [DG70], §II.5, Theorem 2.1). Hence

$$\dim_{\kappa(s)} \mathfrak{n}(s) = \dim_{\kappa(s)} \mathfrak{h}(s) = \dim H_s \leq \dim N_s.$$

It follows that

$$N^0_s = H^0_s = H_s,$$

since H has connected fibers. Consequently the group subfunctor N^0 (defined in Exposé $\mathrm{VI_B}$, 3.1) is represented by the smooth S-group H. This proves 5.3.1, modulo the following lemma.

[29] Editor's note: This reminder was added; it is used in the proofs of 5.3.1 and 5.3.4.
[30] Editor's note: We have expanded the original in the argument that follows.

Lemma 5.3.2. *Under the conditions of 5.2.7, if G is of type* (RA)*, then, for every $s \in S$,*

$$\mathrm{Norm}_{\mathfrak{g}(s)}(\mathfrak{h}(s)) = \mathfrak{h}(s).$$

Indeed, we are reduced to the case where S is the spectrum of a field, and hence where

$$\mathfrak{h} = \mathfrak{g}_{R'}$$

for some $R' \subset R$. But we already have

$$\mathrm{Transp}_{\mathfrak{g}}(\mathfrak{t}, \mathfrak{h}) = \mathfrak{h}.$$

Indeed, if $H \in \mathfrak{t}$ and $X \in \mathfrak{g}^{\alpha}$, then

$$[H, X] = \bar{\alpha}(H)X,$$

where $\bar{\alpha} : \mathfrak{t} \to \mathcal{O}_S$ is the morphism derived from α. Condition (iv′) says precisely that $\bar{\alpha} \neq 0$ for every $\alpha \in R$.

Corollary 5.3.3. *Let S be a scheme, let G be an S-group of type* (RA)*, let H and H' be two subgroups of type* (R) *of G, and let $\mathfrak{h}$ and $\mathfrak{h}'$ be their Lie algebras. Then*

$$H = H' \quad \Longleftrightarrow \quad \mathfrak{h} = \mathfrak{h}'.$$

Corollary 5.3.4. *Under the conditions of 5.2.7, with G of type* (RA)*, the maps*

$$H \longmapsto \mathrm{Lie}(H/S), \qquad \mathfrak{h} \longmapsto \underline{\mathrm{Norm}}_G(\mathfrak{h})^0$$

give a bijective correspondence between the set of subgroups of type (R) *of G containing T, and the set of Lie subalgebras of $\mathfrak{g}$ containing $\mathfrak{g}^0$, stable under T, and whose normalizer in G is smooth over S at every point of the unit section.*

Indeed,[31] let $\mathfrak{h}$ be a Lie subalgebra of $\mathfrak{g}$ satisfying the properties above. By 5.3.0,

$$H = \underline{\mathrm{Norm}}_G(\mathfrak{h})^0$$

is a smooth S-group scheme. Moreover, since

$$C = \underline{\mathrm{Centr}}_G(T)$$

stabilizes every $\mathfrak{g}^{\alpha}$ and has connected fibers (Exposé XII, 6.6), we have $C \subset H$. Therefore H is a subgroup of G of type (R). By Exposé II, 5.3.1,

$$\underline{\mathrm{Lie}}(H) = \underline{\mathrm{Norm}}_{\mathfrak{g}}(\mathfrak{h}).$$

Finally, by the proof of 5.3.2,

$$\underline{\mathrm{Norm}}_{\mathfrak{g}}(\mathfrak{h}) = \mathfrak{h}.$$

[31] Editor's note: The proof that follows was added.

Corollary 5.3.5. *Let S be a scheme, let G be an S-group of type* (RR) (5.1.1)*, let T be a maximal torus of G, and let H and H' be two subgroups of type* (R) *of G, both containing T. Then*

$$H = H' \iff \mathfrak{h} = \mathfrak{h}'.$$

By virtue of the finite-presentation hypotheses, we reduce as usual (cf. EGA IV_3, §8, and Exposé VI_B, §10) to the case where S is noetherian. It is then enough to verify that $\mathfrak{h} = \mathfrak{h}'$ implies

$$H_{S'} = H'_{S'}$$

for every S' that is the spectrum of an artinian quotient of a local ring of S;[32] we are therefore reduced to the case where S is artinian, in which case we may apply 5.1.8.

Let

$$u : G \longrightarrow G' = G/Z$$

be the canonical morphism, and let $T' = T/Z$ be the maximal torus of G' corresponding to T. By Exposé XII, 7.12, there exist subgroups H_1 and H'_1 of type (R) of G', containing T', such that

$$H = u^{-1}(H_1), \qquad H' = u^{-1}(H'_1).$$

It is enough to prove that $H_1 = H'_1$. But by 5.2.7 and 5.1.5,

$$\mathrm{Lie}(H_1) = \mathrm{Lie}(H'_1),$$

and we are reduced to 5.3.3.

Remark 5.3.6. The fact that H and H' contain the same maximal torus is essential for the validity of 5.3.5 when G is not of type (RA). For example, consider the maximal tori of $\mathrm{SL}_{2,k}$, where k has characteristic 2.[33]

Corollary 5.3.7. *Let S be a scheme, let G be an S-group of type* (RR)*, let T be a maximal torus of G, and let H and H' be two subgroups of type* (R) *of G, both containing T. The set U of $s \in S$ such that $H_s = H'_s$ is open and closed in S, and*

$$H_U = H'_U.$$

Indeed, this follows immediately from 5.3.5 and 5.2.7.

Corollary 5.3.8. *The "functor of subgroups of type* (R) *containing T", where T is a given maximal torus in a group G of type* (RR)*, is formally unramified* (Exposé XI, 1.1).

[32] Editor's note: Indeed, let $g \in G$, let s be its image in S, let $\mathfrak{m}$ be the maximal ideal of $\mathcal{O}_{G,g}$, let $\mathfrak{n}$ be that of $\mathcal{O}_{S,s}$, and let I (respectively I') be the kernel of the morphism from $\mathcal{O}_{G,g}$ to $\mathcal{O}_{H,g}$ (respectively $\mathcal{O}_{H',g}$), the latter being the zero ring if $g \notin H$ (respectively $g \notin H'$). Since $\mathcal{O}_{G,g}$ is noetherian, I and I' are closed for the $\mathfrak{m}$-adic topology, hence *a fortiori* for the $\mathfrak{n}$-adic topology. It is therefore enough to prove

$$I + \mathfrak{n}^n \mathcal{O}_{G,g} = I' + \mathfrak{n}^n \mathcal{O}_{G,g}$$

for every $n \in \mathbb{N}$.

[33] Editor's note: Indeed, if k is algebraically closed, all maximal tori of $G = \mathrm{SL}_{2,k}$ are conjugate under $G(k)$, and they all have as Lie algebra the line $k\,\mathrm{id} \subset M_2(k)$, which is invariant under the adjoint action.

Theorem 5.3.9. *Let G be an S-group of type* (RR) (5.1.1)*, and let H and H' be two subgroups of type* (R) (5.2.1)*. Let $\underline{\mathrm{Transt}}_G(H, H')$ be the strict transporter of H into H', defined by*

$$\underline{\mathrm{Transt}}_G(H, H')(S') = \{g \in G(S') \mid \mathrm{int}(g)H_{S'} = H'_{S'}\}.$$

Then $\underline{\mathrm{Transt}}_G(H, H')$ is representable by a closed subscheme of G, smooth and of finite presentation over S.

The fact that $\underline{\mathrm{Transt}}_G(H, H')$ is representable by a closed subscheme of G, of finite presentation over S, follows from Exposé XI, 6.11 (a). To prove that it is smooth over S, it is necessary to prove that if S is affine, if S_0 is the closed subscheme defined by a nilpotent ideal J, and if

$$g_0 \in G(S_0), \qquad \mathrm{int}(g_0)H_0 = H'_0,$$

then there exists $g \in G(S)$, lifting g_0, such that

$$\mathrm{int}(g)H = H'.$$

Since smoothness is local for the étale topology, we may suppose that H contains a maximal torus T of G.

Then T_0 is a maximal torus of H_0, and hence $\mathrm{int}(g_0)T_0$ is a maximal torus of H'_0. By Exposé IX, 3.6 bis, there exists a torus T' of H' such that

$$T'_0 = \mathrm{int}(g_0)T_0;$$

by Exposé IX, 3.3 bis, there therefore exists $g \in G(S)$, lifting g_0, such that

$$\mathrm{int}(g)T = T'.$$

After replacing H by $\mathrm{int}(g)H$, we may therefore suppose that H and H' contain the same maximal torus T and that $H_0 = H'_0$. But then $H = H'$ by 5.3.7. □

Corollary 5.3.10. *Let G be an S-group of type* (RR)*, and let H be a subgroup of type* (R) *of G. Then $\underline{\mathrm{Norm}}_G(H)$ is representable by a closed group subscheme of G, of finite presentation and smooth over S.*

Using now the reasoning employed in Exposé XI to deduce 5.4 bis from 5.2 bis, we obtain:

Corollary 5.3.11. *Under the hypotheses of 5.3.9, the following conditions are equivalent:*

(i) *H and H' are locally conjugate in G for the étale topology;*

(i bis) *the same holds for the fpqc topology;*

(ii) *for every $s \in S$, $H_{\bar{s}}$ and $H'_{\bar{s}}$ are conjugate by an element of $G(\bar{s})$;*

(ii bis) *the structural morphism*

$$\underline{\mathrm{Transt}}_G(H, H') \longrightarrow S$$

is surjective;

(iii) *$\underline{\mathrm{Transt}}_G(H, H')$ is a principal homogeneous bundle under the action of the smooth S-group scheme of finite presentation $\underline{\mathrm{Norm}}_G(H)$.*

We merely note that the nontrivial implication (iii)⇒(i) is Hensel's lemma.

Using now *Bible*, §6.4, Theorem 4 (= [Ch05], §6.5, Theorem 5) and §9.3, Theorem 1, we obtain from 5.3.10 and 5.3.11:

Corollary 5.3.12. *Let G be an S-group of type* (RR)*. The Borel subgroups of G are closed in G, equal to their normalizers, and locally conjugate for the étale topology.*

Definition 5.3.13. *Let S be a scheme, and let G be a smooth S-group scheme of finite presentation with connected fibers.*[34] *A* Killing pair *of G is a pair $T \subset B$, where T is a maximal torus of G and B is a Borel subgroup of G containing T.*

Using now the conjugacy of maximal tori in B (cf. 5.1.2 (a) and 5.2.6, for example), we have:

Corollary 5.3.14. *Let G be an S-group of type* (RR)*. The Killing pairs of G are locally conjugate for the étale topology.*

Corollary 5.3.15. *Let G be an S-group of type* (RR)*. Let T be a maximal torus of G, and let*

$$W_G(T) = \underline{\mathrm{Norm}}_G(T)/\underline{\mathrm{Centr}}_G(T)$$

be the corresponding Weyl group (Exposé XIX, 6.3)*. The "functor of Borel subgroups of G containing T" is formally principal homogeneous under $W_G(T)$.*

This follows immediately from 5.3.14 and from the fact that, if B is a Borel subgroup of G containing T, then

$$\underline{\mathrm{Norm}}_G(T) \cap B = \underline{\mathrm{Centr}}_G(T),$$

cf. Exposé XIV, 4.4.

Proposition 5.3.16. *Let G be an S-group of type* (RR)*, let H be a subgroup of type* (R)*, and let $N = \underline{\mathrm{Norm}}_G(H)$ be its normalizer* (5.3.10)*. Let T be a maximal torus of H, and let $W_H(T)$ and $W_N(T)$ be the corresponding Weyl groups* (étale, quasi-finite, and separated by Exposé XIX, 6.3)*. There is the following exact sequence of sheaves* (for the étale topology)*, whose morphisms are induced by*

$$\underline{\mathrm{Norm}}_H(T) \longrightarrow \underline{\mathrm{Norm}}_N(T) \longrightarrow N/H :$$

$$1 \longrightarrow W_H(T) \longrightarrow W_N(T) \longrightarrow N/H \longrightarrow 1.$$

The only nontrivial point is that the last arrow is an epimorphism. Let $n \in N(S')$, where $S' \to S$. The two maximal tori T and $\mathrm{int}(n)T$ of H are locally conjugate in H for the étale topology. Thus there is a covering family $\{S'_i \to S'\}$ and, for every i, an $h_i \in H(S'_i)$ such that

$$\mathrm{int}(h_i)T = \mathrm{int}(n)T.$$

Consequently

$$nh_i^{-1} \in \underline{\mathrm{Norm}}_N(T),$$

which gives the desired result.

Remark 5.3.17. The group $W_N(T)$ may be described as follows. Suppose that we have reduced to the situation of 5.2.7, with $\mathfrak{h} = \mathfrak{g}_{R'}$. Then $W_N(T)$ is equal to $\underline{\mathrm{Norm}}_W(R')$, the sheaf of sections of $W = W_G(T)$ which, acting on R, normalize R'. Indeed, by 5.3.5,

$$\underline{\mathrm{Norm}}_N(T) = \underline{\mathrm{Norm}}_G(H) \cap \underline{\mathrm{Norm}}_G(T) = \underline{\mathrm{Norm}}_G(\mathfrak{h}) \cap \underline{\mathrm{Norm}}_G(T).$$

[34] Editor's note: See note 25.

Corollary 5.3.18. *Let G be an S-group of type* (RR)*, and let H be a subgroup of type* (R)*. Suppose that "the Weyl groups of G are finite", that is, that for every $S' \to S$ and every maximal torus T of $G_{S'}$, the étale S'-scheme*

$$\underline{\mathrm{Norm}}_{G_{S'}}(T)/\underline{\mathrm{Centr}}_{G_{S'}}(T)$$

is finite (cf. Exposé XIX, 6.3 (iii))*. Then the following conditions are equivalent:*

(i) *H is closed in G;*

(ii) *$\underline{\mathrm{Norm}}_G(H)/H$ is representable by a finite étale S-scheme;*

(iii) *"the Weyl groups of H are finite".*

Indeed, we may suppose that H has a maximal torus T. By 5.3.10, $N = \underline{\mathrm{Norm}}_G(H)$ is closed in G; therefore $W_N(T)$ is closed in $W_G(T)$, and hence is finite over S. Clearly (i) implies (iii), and (iii) implies (ii) by the exact sequence of 5.3.16. Finally, (ii) implies (i), since if N/H is finite, it is separated, so H is closed in N, and hence in G.

Remark 5.3.19. When G is reductive, the preceding conditions on H seem always to be satisfied. We prove them below in most cases.

5.4. Subgroups of Type (R) of a Split Reductive Group (Generalities)

5.4.1. If H is a subgroup of type (R) of the reductive group G, then H locally for the étale topology contains a maximal torus of G (5.2.2). By 2.3, locally for the étale topology we may suppose that G is split relative to this torus. Thus let (G, T, M, R) be a split S-group, and let H be a subgroup of type (R) of G containing T. By 5.3.5, such a subgroup is characterized by its Lie algebra, which (5.2.7) is locally on S of the form $\mathfrak{g}_{R'}$:

$$\mathfrak{g}_{R'} = \mathfrak{t} \oplus \prod_{\alpha \in R'} \mathfrak{g}^{\alpha}.$$

Definition 5.4.2. *Let (G, T, M, R) be a split S-group. A subset R' of R is said to be of type* (R) *if $\mathfrak{g}_{R'}$ is the Lie algebra of a subgroup of type* (R) *of G containing T. This subgroup, uniquely determined by R', is denoted $H_{R'}$.*

Lemma 5.4.3. *Under the preceding conditions, the following equivalences hold:*

$$\begin{aligned} H \cap Z_\alpha = T &\iff \alpha \notin R',\ -\alpha \notin R', \\ H \supset U_\alpha &\iff \alpha \in R', \\ H \cap U_\alpha = e &\iff \alpha \notin R', \\ H \supset Z_\alpha &\iff \alpha \in R',\ -\alpha \in R'. \end{aligned}$$

Indeed, $H \cap Z_\alpha$ is a subgroup of type (R) of Z_α, by 5.2.5; but a subgroup of type (R) of Z_α containing T is locally equal to one of the following subgroups:

$$T, \qquad T \cdot U_\alpha, \qquad T \cdot U_{-\alpha}, \qquad Z_\alpha,$$

by 5.3.5.

Lemma 5.4.4. *Under the conditions of 5.4.2, let R_+ be a system of positive roots; choose orderings on $R' \cap R_+$ and $R' \cap -R_+$. The morphism*

$$\Omega_{R_+,R'} = \prod_{\alpha \in R' \cap -R_+} U_\alpha \underset{S}{\times} T \underset{S}{\times} \prod_{\alpha \in R' \cap R_+} U_\alpha \longrightarrow G,$$

induced by multiplication in G, induces an open immersion

$$\Omega_{R_+,R'} \longrightarrow H_{R'}.$$

Indeed, by 5.4.3 this morphism factors through $H_{R'}$, and therefore induces an immersion $\Omega_{R_+,R'} \to H_{R'}$. We then argue as in 4.1.1.

Proposition 5.4.5. *Let (G, T, M, R) be a split S-group. Let R' and R'' be two subsets of R of type* (R).

(i) *$H_{R'} \cap H_{R''}$ is smooth at every point of the unit section, $R' \cap R''$ is of type* (R)*, and*

$$\left(H_{R'} \cap H_{R''}\right)^0 = H_{R' \cap R''}.$$

(ii) *The following equivalence holds:*

$$H_{R'} \subset H_{R''} \iff R' \subset R''.$$

Indeed, (ii) follows immediately from (i). To prove (i), it suffices to prove that $H_{R'} \cap H_{R''}$ is smooth at every point of the unit section: its neutral component (cf. Exposé $\mathrm{VI_B}$, 3.10) will then be a subgroup of type (R) containing T, and hence equal to $H_{R' \cap R''}$. But

$$\Omega_{R_+,R'} \cap \Omega_{R_+,R''} = \Omega_{R_+,R' \cap R''}$$

is an open subset of $H_{R'} \cap H_{R''}$, contains the unit section, and is smooth over S.

Corollary 5.4.6. *Let S be a scheme, G a reductive S-group, T a maximal torus of G, and s a point of S. If H and H' are two subgroups of type* (R) *containing T, and if $H_s \subset H'_s$, then there is an open subset U of S containing s such that $H_U \subset H'_U$.*

Indeed, we may suppose that G is split relative to T, and the assertion then follows immediately from 5.4.5 (ii).

We are thus led to ask which subsets R' of R are of type (R). We may suppose that the group is adjoint; one must then verify that $\mathfrak{g}_{R'}$ is a Lie algebra and that its normalizer is smooth at every point of the unit section. The most important case is given by the following theorem.

Theorem 5.4.7. *Every closed subset R' of R is of type* (R).

Recall (Exposé XXI, 3.1.4) that a subset R' of R is said to be *closed* if

$$\alpha, \beta \in R', \quad \alpha + \beta \in R \quad \Longrightarrow \quad \alpha + \beta \in R'.$$

Remark 5.4.8. We shall see later (Exposé XXIII, 6.6) that, if $6 \cdot 1_S \neq 0$[35]—for example, if S has residue characteristics different from 2 and 3—the fact that $\mathfrak{g}_{R'}$ is a Lie algebra already implies that R' is closed. In that case a subset R' is of type (R) if and only if it is closed. Thus Theorem 5.4.7 gives all the subsets of type (R) that are "independent of the characteristic."

Let us first prove the following lemma.

[35]Editor's note: In fact, it suffices (cf. loc. cit.) that 2 and 3 be nonzero on S.

Lemma 5.4.9. *For each $\alpha \in R$, choose an element*

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times.$$

Let $\alpha, \beta \in R$, with $\alpha + \beta \neq 0$, and let q be the largest integer i such that $\beta + i\alpha \in R$. There exist uniquely determined sections

$$M_{\alpha,\beta,i} \in \Gamma(S, \mathcal{O}_S)$$

such that

$$\mathrm{Ad}\big(\exp_\alpha(xX_\alpha)\big)(X_\beta) = X_\beta + \sum_{i=1}^{q} M_{\alpha,\beta,i} x^i X_{\beta+i\alpha}$$

for every $x \in \mathbb{G}_a(S')$, where $S' \to S$.

The map

$$x \longmapsto \mathrm{Ad}\big(\exp_\alpha(xX_\alpha)\big)(X_\beta)$$

defines a morphism

$$\mathbb{G}_{a,S} \longrightarrow \mathbf{W}(\mathfrak{g}) \simeq \mathbb{G}_{a,S}^m.$$

There are therefore uniquely determined sections $Y_n \in \Gamma(S, \mathfrak{g})$ such that

$$\mathrm{Ad}\big(\exp_\alpha(xX_\alpha)\big)(X_\beta) = \sum_{n \geq 0} x^n Y_n.$$

Applying the inner automorphism defined by a section t of T, we immediately find

$$\mathrm{Ad}(t)(Y_n) = \beta(t)\alpha(t)^n Y_n,$$

and hence $Y_n \in \Gamma(S, \mathfrak{g}^{\beta+n\alpha})$. Since α and β are not proportional, none of the $\beta + n\alpha$ is zero. Thus $Y_n = 0$ for $n > q$, and

$$Y_n = M_{\alpha,\beta,n} X_{\beta+n\alpha}$$

for $0 \leq n \leq q$, where $M_{\alpha,\beta,n} \in \mathbb{G}_a(S)$ is uniquely determined. Setting $x = 0$ in the formula obtained gives $Y_0 = X_\beta$, which completes the proof.

Remark 5.4.10. Differentiating the preceding formula at $x = 0$, we find

$$[X_\alpha, X_\beta] = \begin{cases} N_{\alpha,\beta} X_{\alpha+\beta}, & \text{where } N_{\alpha,\beta} = M_{\alpha,\beta,1}, \text{ if } \alpha + \beta \in R, \\ 0, & \text{if } \alpha + \beta \notin R \text{ and } \alpha + \beta \neq 0. \end{cases}$$

Let us now prove 5.4.7. If R' is a closed subset of R, then $\mathfrak{g}_{R'}$ is a Lie subalgebra of $\mathfrak{g}$, by 5.4.10 and Exposé XX, 2.10, formula (3). By 5.4.9 and Exposé XX, 2.10, formula (2), U_α normalizes $\mathfrak{g}_{R'}$ for every $\alpha \in R'$. Choose a system of positive roots R_+, and consider the open subset Ω_{R_+} of 4.1.2. Let $\Omega_{R_+,R'}$ be the closed subscheme of Ω_{R_+} defined by

$$\Omega_{R_+,R'} = \left(\prod_{\alpha \in R' \cap -R_+} U_\alpha \right) \cdot T \cdot \left(\prod_{\alpha \in R' \cap R_+} U_\alpha \right).$$

The canonical immersion $\Omega_{R_+,R'} \to G$ factors through

$$i : \Omega_{R_+,R'} \longrightarrow \underline{\mathrm{Norm}}_G(\mathfrak{g}_{R'}).$$

Suppose that G is adjoint. The tangent map of i at the points of the unit section is bijective by 5.3.2. In particular, i is étale at every point of the unit section, and hence is a local immersion[36] at every point of the unit section. Therefore $\underline{\mathrm{Norm}}_G(\mathfrak{g}_{R'})$ is smooth at every point of the unit section, as was to be proved.

[36] Editor's note: By EGA IV$_4$, 17.11.2, i is étale at every point of the unit section (and $\underline{\mathrm{Norm}}_G(\mathfrak{g}_{R'})$ is smooth at every point of the unit section). Moreover, let V be the largest open subset of $\Omega_{R_+,R'}$ on which i is étale. Since i is a monomorphism, i_V is an open immersion (ibid., 17.9.1).

5.5. Borel Subgroups of a Split Reductive Group

Proposition 5.5.1. *Let (G, T, M, R) be a split S-group. For every system of positive roots R_+ of R, the subgroup H_{R_+}* (which exists by 5.4.7) *is a Borel subgroup of G. Moreover, for every ordering on R_+, the morphism induced by multiplication in G,*

$$T \underset{S}{\times} \prod_{\alpha \in R_+} U_\alpha \longrightarrow G,$$

is a closed immersion with image H_{R_+}. We write $B_{R_+} = H_{R_+}$.

By the definition of Borel subgroups, the first assertion may be verified after replacing S by the spectrum of an algebraically closed field. Let B be the Borel subgroup of G containing T and corresponding to the system of positive roots R_+ (*Bible*, §10.4, Proposition 9). The Lie algebra of B is $\mathfrak{g}_{R_+}$; therefore $B = H_{R_+}$ by 5.3.5.

For the second assertion, the morphism in the statement induces an open immersion

$$i : T \underset{S}{\times} \prod_{\alpha \in R_+} U_\alpha \longrightarrow H_{R_+}$$

by 5.4.4. But i is surjective (*Bible*, §15.1, Corollary 1 to Proposition 1).

Corollary 5.5.2. *Choose an arbitrary ordering on R_+, and for each $\alpha \in R_+$ choose an*

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times.$$

Let $\alpha, \beta \in R_+$. For every pair $(i, j) \in \mathbb{N}^* \times \mathbb{N}^*$ such that $i\alpha + j\beta \in R$, there is a unique section

$$C_{i,j,\alpha,\beta} \in \Gamma(S, \mathcal{O}_S)$$

such that, for all $x, y \in \mathbb{G}_a(S')$, where $S' \to S$, one has

$$\exp_\alpha(xX_\alpha) \exp_\beta(yX_\beta) \exp_\alpha(xX_\alpha)^{-1} = \exp_\beta(yX_\beta) \prod_{\substack{i,j \in \mathbb{N}^* \\ i\alpha + j\beta \in R}} \exp_{i\alpha+j\beta}(C_{i,j,\alpha,\beta} x^i y^j X_{i\alpha+j\beta}).$$

If $\alpha = \beta$, the assertion is trivial. Suppose therefore that $\alpha \neq \beta$. By the proposition there are unique morphisms

$$F_0 : \mathbb{G}_{a,S}^2 \longrightarrow T, \qquad F_\gamma : \mathbb{G}_{a,S}^2 \longrightarrow \mathbb{G}_{a,S} \quad (\gamma \in R_+)$$

such that

$$\exp(xX_\alpha) \exp(yX_\beta) \exp(xX_\alpha)^{-1} = F_0(x, y) \prod_{\gamma \in R_+} \exp(F_\gamma(x, y) X_\gamma).$$

Let $t \in T(S')$, where $S' \to S$. Applying $\mathrm{int}(t)$ to this formula, we immediately obtain

$$F_0(\alpha(t)x, \beta(t)y) = F_0(x, y), \tag{1}$$

$$F_\gamma(\alpha(t)x, \beta(t)y) = \gamma(t) F_\gamma(x, y). \tag{2}$$

Since α and β are two linearly independent characters of T over $\mathbb{Q}$, the first relation implies, as usual, that F_0 is constant, and hence $F_0(x, y) = e$. Write next

$$F_\gamma(x, y) = \sum a_{ij} x^i y^j, \qquad a_{ij} \in \Gamma(S, \mathcal{O}_S).$$

Substituting in relation (2) and comparing the polynomials on both sides gives

$$a_{ij}(\alpha(t)^i\beta(t)^j - \gamma(t)) = 0.$$

If $\gamma \neq i\alpha + j\beta$, we know (Exposé XIX, 4.13) that there exist a faithfully flat quasi-compact morphism $S' \to S$ and an element $t \in T(S')$ such that

$$\alpha(t)^i\beta(t)^j - \gamma(t) = 1.$$

Thus $a_{ij} = 0$ over S', and hence over S. If $\gamma = i\alpha + j\beta$, set $a_{ij} = C_{i,j,\alpha,\beta}$. Setting $x = 0$ (respectively, $y = 0$), one obtains

$$C_{0,1,\alpha,\beta} = 1 \qquad \text{(respectively, } C_{1,0,\alpha,\beta} = 0\text{)}.$$

Remark 5.5.3. Differentiating with respect to y at $y = 0$ and comparing with 5.4.9, one finds

$$C_{i,1,\alpha,\beta} = M_{\alpha,\beta,i}.$$

Corollary 5.5.4. *Let S be a scheme, let G be a reductive S-group, let T be a maximal torus of G, and let $\alpha \neq \beta$ be two roots of G relative to T such that $\alpha + \beta$ is nontrivial on every fiber. Order arbitrarily the set of roots $i\alpha + j\beta$, where $(i, j) \in \mathbb{N}^* \times \mathbb{N}^*$. For all $i, j \in \mathbb{N}^*$ such that $i\alpha + j\beta \in R$, there is a unique morphism of $\mathcal{O}_S$-modules*

$$f_{\alpha,\beta,i,j} : (\mathfrak{g}^\alpha)^{\otimes i} \otimes (\mathfrak{g}^\beta)^{\otimes j} \longrightarrow \mathfrak{g}^{i\alpha+j\beta}.$$

such that, for every $S' \to S$ and all $X \in \mathbf{W}(\mathfrak{g}^\alpha)(S')$, $Y \in \mathbf{W}(\mathfrak{g}^\beta)(S')$, one has (the exponentials in the right-hand side being understood in the sense of 1.2)[37]

$$\exp_\alpha(X)\exp_\beta(Y)\exp_\alpha(-X) = \exp_\beta(Y)\prod_{(i,j)}\exp_{i\alpha+j\beta}\big(f_{\alpha,\beta,i,j}(X^{\otimes i} \otimes Y^{\otimes j})\big).$$

The assertion is local for the fpqc topology. By §2 we may therefore suppose that G is split relative to T, with α and β constant in the splitting. Since $\alpha + \beta \neq 0$, there is a system of positive roots R_+ containing α and β (Exposé XXI, 3.5.4), and we are reduced to 5.5.2.

Corollary 5.5.5. *Let S be a scheme and G a reductive S-group.*

(i) *G has Borel subgroups locally for the étale topology. If T is a maximal torus of G, then, locally for the étale topology, G also has Borel subgroups containing T.*

(ii) *If T is a maximal torus of G, the "functor of Borel subgroups of G containing T" is represented by a principal homogeneous bundle under $W_G(T)$.*

(iii) *If (G, T, M, R) is split, every Borel subgroup B of G containing T is locally on S of the form B_{R_+}, where R_+ is a system of positive roots of R.*

(iv) *If $T \subset B$ is a Killing pair of G, there is an étale covering family $\{S_i \to S\}$, and for every i a splitting $(G_{S_i}, T_{S_i}, M_i, R_i)$ and a system of positive roots R_{i+} of R_i, such that $B_{S_i} = B_{R_{i+}}$.*

Indeed, (i) follows from 2.3 and 5.5.1, (ii) from (i) and 5.3.15, (iii) from (ii) and 5.5.1, and (iv) from (iii) and 2.3.

[37] Editor's note: That is, if $\mathfrak{g}^{i\alpha+j\beta} = 0$ on a connected component of S, the corresponding exponential is 1 on that component.

Lemma 5.5.6. *Choose on the group $\Gamma_0(R)$ generated by the roots a totally ordered group structure such that the roots > 0 are the elements of R_+* (cf. Exposé XXI, 3.5.6)[38] *Let $\alpha_1 < \cdots < \alpha_N$ be the elements of R_+. Consider the isomorphism*

$$f : T \underset{S}{\times} U_{\alpha_1} \underset{S}{\times} \cdots \underset{S}{\times} U_{\alpha_N} \longrightarrow B_{R_+}$$

induced by multiplication in G. For $i = 1, \ldots, N$, put

$$U_{\geq i} = f\left(U_{\alpha_i} \underset{S}{\times} \cdots \underset{S}{\times} U_{\alpha_N}\right).$$

(i) *Each $U_{\geq i}$ is an invariant subgroup of B_{R_+}.*

(ii) *For $1 \leq i \leq N-1$, $U_{\geq i}$ identifies with the semidirect product*

$$U_{\geq i} = U_{\alpha_i} \cdot U_{\geq i+1}.$$

(iii) *B_{R_+} identifies with the semidirect product*

$$B_{R_+} = T \cdot U_{\geq 1}.$$

(iv) *For $1 \leq i \leq N-1$, the inner automorphisms of $U_{\geq 1}$ act trivially on $U_{\geq i}/U_{\geq i+1}$, identified with U_{α_i} by* (ii).

We first prove, by descending induction on i, the following assertion:

$U_{\geq i}$ is an invariant subgroup of B_{R_+}, the semidirect product of U_{α_i} and $U_{\geq i+1}$.

This is true for $i = N$; suppose it has been proved for $i+1$, and let us prove it for i. As schemes, we have

$$U_{\geq i} = U_{\alpha_i} \cdot U_{\geq i+1}.$$

We must show that $U_{\geq i}$ is invariant under the inner automorphisms of B_{R_+}. This is clear for $\mathrm{int}(t)$, where $t \in T(S)$; it is therefore enough to consider $\mathrm{int}(x)$, where $x \in U_\alpha(S)$ and $\alpha \in R_+$. Since $U_{\geq i+1}$ is invariant, it is enough to prove that

$$\mathrm{int}(x)(U_{\alpha_i}) \subset U_{\geq i}.$$

By 5.5.2, if $y \in U_{\alpha_i}(S')$, then

$$y^{-1}xyx^{-1} \in U_{\geq i+1}(S'),$$

which implies that

$$\mathrm{int}(x)(y) \in U_{\geq i}(S').$$

It remains to prove that $U_{\geq i}$ is a subgroup. Let $x, y \in U_{\geq i}(S)$, and write

$$x = px', \qquad y = qy',$$

where $p, q \in U_{\alpha_i}(S)$ and $x', y' \in U_{\geq i+1}(S)$. We then have

$$xy = px'qy' = pq(q^{-1}x'q)y' \in U_{\alpha_i}(S')U_{\geq i+1}(S'),$$

and likewise

$$x^{-1} = p^{-1}(px'^{-1}p^{-1}) \in U_{\alpha_i}(S')U_{\geq i+1}(S').$$

We have thus proved (i) and (ii), as well as (iv) along the way. Assertion (iii) is a trivial consequence of 5.5.1.

[38] Editor's note: Such an ordering is necessarily compatible with ord_Δ, where $\Delta = \mathscr{S}(R_+)$ (cf. Exposé XXI, 3.2.15).

Lemma 5.5.7. *With the preceding notation, choose, for each $1 \leq i \leq N$, an element*

$$X_i \in \Gamma(S, \mathfrak{g}^{\alpha_i})^{\times},$$

and consider the isomorphism

$$a : \mathbb{G}_{a,S}^{N} \longrightarrow U_{\geq 1}$$

defined on underlying sets by

$$a(x_1, \ldots, x_N) = \exp_{\alpha_1}(x_1 X_1) \cdots \exp_{\alpha_N}(x_N X_N).$$

There is a unique family $(Q_i)_{1 \leq i \leq N}$ of polynomials

$$Q_i = Q_i(x_1, \ldots, x_N, y_1, \ldots, y_N)$$

with coefficients in $\Gamma(S, \mathcal{O}_S)$, such that

$$\begin{aligned} &a(x_1, \ldots, x_N) a(y_1, \ldots, y_N) \\ &\quad = a\big(Q_1(x_1, \ldots, x_N, y_1, \ldots, y_N), \ldots, Q_N(x_1, \ldots, x_N, y_1, \ldots, y_N)\big). \end{aligned}$$

Moreover, the coefficients of these polynomials belong to the subring of $\Gamma(S, \mathcal{O}_S)$ generated by the $C_{i,j,\alpha,\beta}$ of 5.5.2 $(\alpha, \beta \in R_+,\ i, j \in \mathbb{N}^*)$, and each Q_i is of the form

$$\begin{aligned} Q_i(x_1, \ldots, x_N, y_1, \ldots, y_N) = x_i + y_i \\ + Q_i'(x_1, \ldots, x_{i-1}, y_1, \ldots, y_{i-1}). \end{aligned}$$

The existence and uniqueness of the Q_i are immediate from the fact that a is an isomorphism of schemes. Let z, z', z'' denote sections of $U_{\geq i+1}$. We have

$$\begin{aligned} &a(x_1, \ldots, x_N) a(y_1, \ldots, y_N) \\ &\quad = a(x_1, \ldots, x_{i-1}, 0, \ldots, 0) \exp_{\alpha_i}(x_i X_i) z \\ &\qquad \cdot a(y_1, \ldots, y_{i-1}, 0, \ldots, 0) \exp_{\alpha_i}(y_i X_i) z'. \end{aligned}$$

Using 5.5.6 (i) and (iv), the right-hand side can be written

$$\begin{aligned} &a(x_1, \ldots, x_{i-1}, 0, \ldots, 0) a(y_1, \ldots, y_{i-1}, 0, \ldots, 0) \\ &\qquad \cdot \exp_{\alpha_i}((x_i + y_i) X_i) z'', \end{aligned}$$

and, applying 5.5.6 once again, this gives

$$Q_i(x_1, \ldots, x_N, y_1, \ldots, y_N) = x_i + y_i + Q_i'(x_1, \ldots, x_{i-1}, y_1, \ldots, y_{i-1}),$$

where

$$Q_i'(x_1, \ldots, x_{i-1}, y_1, \ldots, y_{i-1}) = Q_i(x_1, \ldots, x_{i-1}, 0, \ldots, 0, y_1, \ldots, y_{i-1}, 0, \ldots, 0);$$

this is precisely the required form.

It remains to prove the assertion concerning the coefficients of the polynomials Q_i. Let A be the subring of $\Gamma(S, \mathcal{O}_S)$ generated by the $C_{i,j,\alpha,\beta}$, where $\alpha, \beta \in R_+$ and $i, j \in \mathbb{N}^*$. We prove by descending induction on i that, if

$$x_1 = \cdots = x_{i-1} = 0 \qquad \text{and} \qquad y_1 = \cdots = y_{i-1} = 0,$$

that is, if $a(x_1, \dots, x_N)$ and $a(y_1, \dots, y_N)$ are sections of $U_{\geq i}$, then the polynomials

$$R_j(x_i, \dots, x_N, y_i, \dots, y_N) = Q_j(x_1, \dots, x_N, y_1, \dots, y_N)$$

have coefficients in A. This is trivial for $i = N$, and also for $j < i$, since $R_j = 0$ when $j < i$. Let $i < N$; suppose the assertion proved for $i + 1$, and let us prove it for i and $j \geq i$. We have

$$\begin{aligned} a(0, \dots, 0, x_i, \dots, x_N) &= \exp(x_i X_i) a(0, \dots, 0, x_{i+1}, \dots, x_N) \\ &= \exp(x_i X_i) Z_i. \end{aligned}$$

Similarly, write

$$a(0, \dots, y_i, \dots, y_N) = \exp(y_i X_i) T_i.$$

Then

$$\begin{aligned} &a(0, \dots, x_i, \dots, x_N) a(0, \dots, y_i, \dots, y_N) \\ &\quad = \exp\big((x_i + y_i) X_i\big) \operatorname{int}\big(\exp(-y_i X_i)\big)(Z_i) \cdot T_i. \end{aligned}$$

Now

$$\operatorname{int}\big(\exp(-y_i X_i)\big)(Z_i) = \operatorname{int}\big(\exp(-y_i X_i)\big)\big(\exp(x_{i+1} X_{i+1}) \cdots \exp(x_N X_N)\big)$$

is a product of $N - i - 1$ sections of $U_{\geq i+1}$, whose coefficients in the decomposition

$$U_{\geq i+1} = U_{\alpha_{i+1}} \cdots U_{\alpha_N}$$

are polynomials in $y_i, x_{i+1}, \dots, x_N$ with coefficients in A, by 5.5.2. Applying the induction hypothesis, we deduce that the coefficients of

$$\operatorname{int}\big(\exp(-y_i X_i)\big)(Z_i) \cdot T_i$$

are likewise polynomials with coefficients in A, which completes the proof.

The preceding induction immediately gives a proof of the following.

Lemma 5.5.8. *With the notation of 5.5.6, let, for each $i = 1, \dots, N$,*

$$f_i : U_{\alpha_i} \longrightarrow H$$

be a group morphism, where H is an S-group functor. For the morphism

$$f : U_{\geq 1} \longrightarrow H$$

defined by

$$f\big(\exp(x_1 X_1) \cdots \exp(x_N X_N)\big) = f_1\big(\exp(x_1 X_1)\big) \cdots f_N\big(\exp(x_N X_N)\big)$$

to be a group morphism, it is necessary and sufficient that, for every pair $i < j$,

$$\begin{aligned} &f_j\big(\exp(x_j X_j)\big) f_i\big(\exp(x_i X_i)\big) f_j\big(\exp(-x_j X_j)\big) \\ &\quad = f\big(\exp(x_j X_j) \exp(x_i X_i) \exp(-x_j X_j)\big). \end{aligned}$$

5.6. Subgroups of Type (R) with Solvable Fibers

Proposition 5.6.1. *Let (G, T, M, R) be a split S-group, let R' be a subset of R of type* (R) (5.4.2)*, and let $H_{R'}$ be the corresponding subgroup of G. The following conditions are equivalent:*

(i) *$H_{R'}$ has solvable geometric fibers.*

(ii) *There exists a system of positive roots R_+ such that $R' \subset R_+$, and hence $H_{R'} \subset B_{R_+}$* (cf. 5.4.5)*.*

(iii) $R' \cap (-R') = \varnothing$.

(iv) *For every ordering of R', the morphism induced by multiplication in G*

$$T \times_S \prod_{\alpha \in R'} U_\alpha \longrightarrow H_{R'}$$

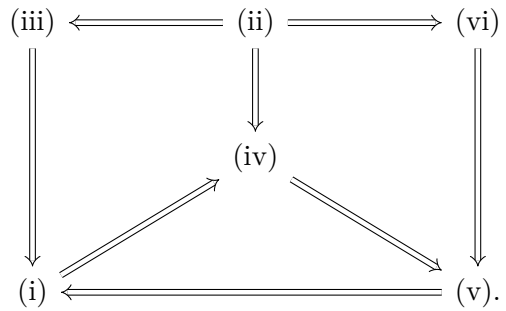
is an isomorphism.

(v) $H_{R'} \cap \underline{\mathrm{Norm}}_G(T) = T$.

(vi) *For every subset R'' of R of type* (R)*, one has* (cf. 5.4.5)

$$H_{R'} \cap \underline{\mathrm{Norm}}_G(H_{R''}) = H_{R' \cap R''}.$$

We shall prove these equivalences according to the following logical scheme.



Clearly (ii) implies (iii), and (vi) implies (v) (take $R'' = \varnothing$). By 5.4.6, it is enough to verify that (i) implies (ii) on the geometric fibers. If S is the spectrum of an algebraically closed field, then $H_{R'}$ is contained in a Borel subgroup containing T, and this subgroup is therefore of the form H_{R_+} (5.5.5(iii)).

Likewise, the implication from (iii) to (i) may be checked on the geometric fibers. Suppose that (iii) holds. If $H_{R'}$ were not solvable, there would exist a subtorus Q of T, of codimension 1 in T, such that

$$\underline{\mathrm{Centr}}_{H_{R'}}(Q)$$

is not solvable (*Bible*, §10.4, Proposition 8). But $\underline{\mathrm{Centr}}_{H_{R'}}(Q)$ has Lie algebra $\mathfrak{g}_{R''}$, where R'' is the set of roots in R' which vanish on Q. Thus, by (iii),

$$R'' = \varnothing \qquad \text{or} \qquad R'' = \{\alpha\}.$$

Consequently, $\underline{\mathrm{Centr}}_{H_{R'}}(Q)$, which is a subgroup of G of type (R), is T or $T \cdot U_\alpha$, and is therefore solvable, contrary to the hypothesis.

Likewise, the implication from (ii) to (iv) may be checked on the geometric fibers (since the schemes in question are flat S-schemes of finite presentation). By *Bible*, §13.2, Theorem 1(d), the morphism in question is bijective. It induces an isomorphism on the tangent spaces at the origin, and the conclusion follows as usual (cf. 4.1.1).

The implication from (iv) to (v) follows from 4.2.7. To prove that (v) implies (i), we may again reduce to the case in which S is the spectrum of an algebraically closed field; the conclusion then follows from *Bible*, §10.3, the corollary to Proposition 6, and §9.3, Corollary 3 to Theorem 1.

It remains only to prove the implication from (ii) to (vi). We may reduce to the case in which G is adjoint. Then, by 5.3.3,

$$\underline{\mathrm{Norm}}_G(H_{R''}) = \underline{\mathrm{Norm}}_G(\mathfrak{g}_{R''}) \subset \underline{\mathrm{Transp}}_G(\mathfrak{t}, \mathfrak{g}_{R''}). \tag{39}$$

[39] By 5.4.5, it is enough to prove

$$H_{R'}(S) \cap \underline{\mathrm{Transp}}_{G(S)}(\mathfrak{t}, \mathfrak{g}_{R''}) \subset H_{R'\cap R''}(S). \tag{x}$$

We first prove a lemma.

Lemma 5.6.2. *With the notation of 5.5.7, let*

$$u = \exp(x_1X_1)\cdots\exp(x_NX_N),$$

where $x_i \in \mathbb{G}_a(S)$. Let m, with $1 \le m \le N$, be such that $x_i = 0$ for $i < m$.

(a) *If $H \in \Gamma(S, \mathfrak{t})$, the component of $\mathrm{Ad}(u)H$ in $\mathfrak{g}^{\alpha_m}$ is*

$$-\overline{\alpha_m}(H)x_mX_m.$$

(b) *If $Y \in \Gamma(S, \mathfrak{g}^{-\alpha_m})$, the component of $\mathrm{Ad}(u)Y$ in $\mathfrak{t}$ is, with the notation of Exposé XX, 2.6,*

$$x_m\langle X_m, Y\rangle H_{\alpha_m}.$$

Proof. Set

$$\mathfrak{u} = \mathfrak{g}^{\alpha_{m+1}} + \cdots + \mathfrak{g}^{\alpha_N}.$$

By 5.4.9, one has

$$\mathrm{Ad}\big(\exp(x_iX_i)\big)\mathfrak{u} \subset \mathfrak{u} \qquad \text{for } i > m.$$

By Exposé XX, 2.10,

$$\mathrm{Ad}\big(\exp(x_iX_i)\big)H = H - \overline{\alpha_i}(H)x_iX_i.$$

It follows immediately that, modulo $\mathfrak{u}$,

$$\mathrm{Ad}(u)H = \mathrm{Ad}\big(\exp(x_mX_m)\big)H = H - \overline{\alpha_m}(H)x_mX_m,$$

which proves the first assertion.

Likewise, set[40]

$$\mathfrak{n} = \mathfrak{g}^{\alpha_1} + \cdots + \mathfrak{g}^{\alpha_N}, \qquad u_1 = \exp(x_{m+1}X_{m+1})\cdots\exp(x_NX_N).$$

[39] Editor's note: The inclusion follows from $\mathfrak{t} \subset \mathfrak{g}_{R''}$.

[40] Editor's note: The original has been corrected in what follows.

For $i > m$, one has $\alpha_i > \alpha_m$; hence, by 5.4.9, modulo $\mathfrak{n}$,

$$\mathrm{Ad}(u_1)Y \equiv Y, \qquad \text{and therefore} \qquad \mathrm{Ad}(u)Y \equiv \mathrm{Ad}\big(\exp(x_m X_m)\big)Y.$$

Applying Exposé XX, 2.10, one therefore obtains, modulo $\mathfrak{n}$,

$$\mathrm{Ad}(u)Y - Y \equiv x_m \langle X_m, Y\rangle H_{\alpha_m},$$

which proves the second assertion.

Let us return to the proof of inclusion (x). Suppose that there exists

$$h \in H_{R'}(S), \qquad h \notin H_{R'\cap R''}(S),$$

such that

$$\mathrm{Ad}(h)\mathfrak{t} \subset \mathfrak{g}_{R''}.$$

We may write

$$h = t\exp(x_1 X_1)\cdots\exp(x_N X_N).$$

Since $h \notin H_{R'\cap R''}(S)$, there is a least m such that

$$t\exp(x_1 X_1)\cdots\exp(x_{m-1}X_{m-1}) \in H_{R'\cap R''}(S), \qquad \alpha_m \notin R'', \qquad x_m \neq 0.$$

Then

$$h' = \exp(x_m X_m)\cdots\exp(x_N X_N)$$

still satisfies the conditions imposed above on h. By Lemma 5.6.2, for every $H \in \Gamma(S, \mathfrak{t})$, the component of $\mathrm{Ad}(h')H$ in $\mathfrak{g}^{\alpha_m}$ is

$$-\overline{\alpha_m}(H)x_m X_m.$$

It therefore follows from the hypothesis on h and from the definition of m that

$$\overline{\alpha_m}(H) = 0 \qquad \text{for every } H \in \Gamma(S, \mathfrak{t}).$$

This is impossible, since G is adjoint and $\overline{\alpha_m}$ is nonzero on every fiber.

Remark 5.6.2 bis. With the notation of Lemma 5.6.2, suppose that $\mathrm{Ad}(u)$ induces the identity on $\mathfrak{t}$ and on $\mathfrak{g}^{-\alpha_m}$. Then $x_m = 0$. Indeed,

$$x_m\overline{\alpha_m} = 0, \qquad x_m H_{\alpha_m} = 0.$$

If $\alpha_m \notin 2M$, then $\overline{\alpha_m}$ is nonzero on every fiber; if $\alpha_m \in 2M$, then $\alpha_m^* \notin 2M^*$, and H_{α_m} is nonzero on every fiber. Thus $x_m = 0$. It follows that $u = e$ if $\mathrm{Ad}(u)$ acts trivially on $\mathfrak{g}$.

Remark 5.6.3. Let H be a subgroup of type (R) of a reductive S-group G, and suppose that its geometric fibers are solvable. Then H is closed in G, and

$$\underline{\mathrm{Norm}}_G(H)/H$$

is represented by a separated finite étale S-scheme. This follows from 5.3.18 and either 3.5 or Exposé XIX, 2.5(ii).

Corollary 5.6.4. *Let (G, T, M, R) be a split reductive S-group. If $R' \subset R$ is closed and $R' \cap (-R') = \varnothing$, then R' is contained in a system of positive roots.* [41]

Proof. By 5.4.7, R' is of type (R), so the result follows from Proposition 5.6.1.

Corollary 5.6.5. *Under the hypotheses of Proposition 5.6.1, multiplication in G induces an isomorphism*

$$\prod_{\alpha \in R'} U_\alpha \xrightarrow{\sim} U_{R'},$$

where $U_{R'}$ is a closed subgroup scheme of G, smooth over S, with connected unipotent geometric fibers, and is independent of the chosen ordering of R'. Moreover, $H_{R'}$ is the semidirect product $T \cdot U_{R'}$, with $U_{R'}$ invariant in $H_{R'}$.

Proof. If $R' \subset R_+$, then

$$U_{R'} = H_{R'} \cap U_{\geq 1},$$

with the notation of 5.5.6, is a closed subgroup of G, of finite presentation, and invariant in $H_{R'}$. By Proposition 5.6.1(iv), one has $H_{R'} = T \cdot U_{R'}$, from which all the assertions follow.

Remark 5.6.6. In particular, U_{R_+} is the group $U_{\geq 1}$ of 5.5.6.

Let us draw some corollaries from the preceding results concerning groups of type $U_{R'}$.

Corollary 5.6.7. *Let (G, T, M, R) be a split reductive S-group, and let R' and R'' be two subsets of R of type* (R)*, with $R' \cap (-R') = \varnothing$.*

(i) *One has*

$$U_{R'} \cap \underline{\mathrm{Norm}}_G(H_{R''}) = U_{R' \cap R''}.$$

(ii) *Suppose that R' is closed. If the conditions $\alpha \in R'$, $\beta \in R''$, and $\alpha + \beta \in R$ imply that $\alpha + \beta \in R'$, then $H_{R''}$ normalizes $U_{R'}$.*

Proof. Assertion (i) follows at once from 5.6.5 and 5.6.1(vi). To prove (ii), it is enough, by 5.4.4, to show that T and each U_β, for $\beta \in R''$, normalize $U_{R'}$.[42] For T this is trivial; for U_β it follows from 5.5.2 and Exposé XXI, 3.1.2.[43]

Corollary 5.6.8. *Let (G, T, M, R) be a split S-group, let R_+ be a system of positive roots, and let α be a simple root of R_+* (that is, an element of R_+ such that $R_+ \setminus \{\alpha\}$ is closed)*. Set*

$$U_{\widehat{\alpha}} = U_{R_+ \setminus \{\alpha\}}.$$

Then:

[41] Editor's note: This is in fact a statement about root systems, supplementing Exposé XXI (cf. *Bible*, VI, §1.7, Proposition 22), and it is proved here indirectly.

[42] Editor's note: Indeed, since G has connected fibers, it is separated over S by Exposé $\mathrm{VI_B}$, 5.5; hence, by Exposé XI, 6.11 (see also Addendum 6.5.5 in Exposé $\mathrm{VI_B}$), $\underline{\mathrm{Norm}}_G(U_{R'})$ is represented by a closed subgroup scheme N of G. If N contains T and the U_β, for $\beta \in R''$, it contains the big cell $\Omega_{R_+, R''}$. This cell is schematically dense in $H_{R''}$ by 5.4.4 and EGA $\mathrm{IV_3}$, 11.10.10 (the fibers of $H_{R''}$ are integral, and $\Omega_{R_+, R''}$ contains a nonempty open subset of every fiber). It follows that $H_{R''} \subset N$, and therefore that $H_{R''}$ normalizes $U_{R'}$.

[43] Editor's note: One must show that, under the hypotheses of (ii), if $\alpha \in R'$ and $\beta \in R''$, then every root of the form $i\alpha + j\beta$, with $i, j \in \mathbb{N}^*$, belongs to R'. For this purpose the reference Exposé XXI, 2.3.5, has been replaced by Exposé XXI, 3.1.2. This may also be seen directly by inspecting the root systems of rank 2.

(i) *$U_{\widehat{\alpha}}$ is a normal subgroup of B_{R_+};*

(ii) *U_{R_+} is the semidirect product of $U_{\widehat{\alpha}}$ by U_α;*

(iii) *$U_{-\alpha}$ normalizes $U_{\widehat{\alpha}}$;*

(iv) *Z_α normalizes $U_{\widehat{\alpha}}$.*

If one similarly defines

$$U_{-\widehat{\alpha}} = U_{R_- \setminus \{-\alpha\}}, \qquad R_- = -R_+,$$

then

$$\Omega_{R_+} = U_{-\widehat{\alpha}} \cdot U_{-\alpha} \cdot T \cdot U_\alpha \cdot U_{\widehat{\alpha}}.$$

Proof. Assertion (ii) follows from 5.6.5, and (i) from 5.6.7(ii). Likewise, (iii) follows from 5.5.2: indeed, if $\beta \in R_+$, with $\beta \neq \alpha$, no combination

$$i(-\alpha) + j\beta, \qquad i, j > 0,$$

can be negative, since β contains at least one simple root different from α. Assertion (iv) then follows from (i) and (iii), because

$$U_{-\alpha} \cdot T \cdot U_\alpha$$

is schematically dense in Z_α. Finally, the last assertion follows from (ii) and its analogue for U_{R_-}.

Let us return to the general situation.

Proposition 5.6.9. *Let S be a scheme, let G be a reductive S-group, and let H be a subgroup of type* (R) *with solvable geometric fibers.*

(i) *The group*

$$\mathrm{D}_S(H) = \underline{\mathrm{Hom}}_{S\text{-gr.}}(H, \mathbb{G}_{m,S})$$

is represented by a twisted constant S-group whose type at $s \in S$ is

$$\mathbb{Z}^{\mathrm{rgred}(G_s)}.$$

The biduality morphism (Exposé VIII, §1)

$$f : H \longrightarrow \mathrm{D}_S\big(\mathrm{D}_S(H)\big)$$

is smooth and surjective.

(ii) *The kernel H^u of f is the largest closed normal subgroup scheme of H, smooth over S, with connected unipotent geometric fibers. It is called the unipotent part of H, and is also denoted*

$$H^u = \mathrm{rad}^u(H).$$

Moreover, H^u is the sheaf of commutators of H: every morphism of groups from H to an S-presheaf of commutative groups that is separated for the fppf topology vanishes on H^u, and therefore factors through

$$H/H^u = \mathrm{D}_S\big(\mathrm{D}_S(H)\big).$$

(iii) *If T is a maximal torus of H, the morphism $T \longrightarrow H$ induces isomorphisms*

$$\mathrm{D}_S(H) \xrightarrow{\sim} \mathrm{D}_S(T), \qquad T \xrightarrow{\sim} \mathrm{D}_S(\mathrm{D}_S(H)).$$

Moreover, H is identified with the semidirect product of H^u by T.

(iv) *In the situation of 5.6.1, if $H = H_{R'}$, then*

$$H^u = U_{R'}.$$

Proof. The assertions of the proposition are local for the étale topology (Exposé X, 5.5). We may therefore reduce to the situation of 5.6.1. We then know from 5.6.5 that $H_{R'}$ is the semidirect product of $U_{R'}$ by T. Let us show that $U_{R'}$ is the sheaf of commutators of $H_{R'}$. Since $H_{R'}/U_{R'} = T$ is commutative, it suffices to prove that every morphism of groups

$$\phi : H_{R'} \longrightarrow V$$

as in (ii) vanishes on $U_{R'}$. It is enough to prove that ϕ vanishes on each U_α, for $\alpha \in R'$. If $t \in T(S')$ and $X \in W(\mathfrak{g}^\alpha)(S')$, then

$$1 = \phi\big(t \exp_\alpha(X) t^{-1} \exp_\alpha(-X)\big) = \phi\big(\exp_\alpha((\alpha(t) - 1)X)\big).$$

Since $\alpha : T \longrightarrow \mathbb{G}_{m,S}$ is faithfully flat, it follows at once that ϕ vanishes on $U_\alpha^\times$. But every section of U_α is locally the sum of two sections of $U_\alpha^\times$. Thus

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(H, V) = \underline{\mathrm{Hom}}_{S\text{-gr.}}(H/U_{R'}, V)$$

for every V as above. Applying this result to $V = \mathbb{G}_{m,S}$, we immediately obtain (i) and (iii), then (iv) and the second assertion of (ii).

It remains to prove the first assertion of (ii). The only nontrivial point is that every closed normal subgroup U of H, smooth over S, with connected unipotent geometric fibers, is a subgroup of H^u. We first have:

Lemma 5.6.10. *Let G be a reductive S-group, T a maximal torus, and U a subgroup scheme of G, smooth over S, with unipotent geometric fibers, and normalized by T. Then*

$$U \cap T = e.$$

Proof. Indeed, since

$$T = \underline{\mathrm{Centr}}_G(T),$$

one has $U \cap T = U^T$, where the right-hand side denotes the invariants under $\mathrm{int}(T)$. By Exposé XIX, 1.4, $U \cap T$ is therefore smooth over S. It is also radicial over S: for every $s \in S$, the group

$$U(\overline{s}) \cap T(\overline{s})$$

consists of elements that are both unipotent and semisimple. This proves the lemma.

We return to the proof of 5.6.9(ii). If U is a normal subgroup of H as above, then the semidirect product $T \cdot U$ is a subgroup of G of type (R), with solvable geometric fibers. We may therefore suppose it to be of the form $H_{R''}$, with $R'' \subset R'$. It is enough to prove that $U = U_{R''}$, and we are thus reduced to the case $H = T \cdot U$. Since H/U is commutative, the French text says that U is a subsheaf of the sheaf of commutators of H, which is H^u.[44] □

Let us note that we have in fact just proved:

[44] Editor's note: The implication in the French is stated in the wrong direction: commutativity of H/U gives $H^u \subset U$. The desired inclusion follows because H/H^u is a torus whereas U has connected unipotent geometric fibers.

Proposition 5.6.11. *Let S be a scheme, G a reductive S-group, and T a maximal torus of G. The maps*

$$H \longmapsto H^u, \qquad U \longmapsto T \cdot U$$

are mutually inverse bijections between the set of subgroups H of G of type (R)*, containing T, and having solvable geometric fibers, and the set of subgroups U of G, smooth over S, normalized by T, and having connected unipotent geometric fibers.*[45]

In particular, when (G, T, M, R) is split, the groups $H_{R'}$ and $U_{R'}$ correspond.

Corollary 5.6.12. *Let S be a scheme, let (G, T, M, R) be a split S-group* (respectively, and let R_+ be a system of positive roots of R defining the Borel subgroup B)*. Every smooth group subscheme of G with connected unipotent geometric fibers* (respectively, every smooth group subscheme of B^u)*, normalized by T, is locally on S of the form $U_{R'}$, where R' is a subset of R contained in a system of positive roots* (respectively, a subset of R_+) *and is of type* (R)*.*

Proof. For the "respectively" case, it is enough to observe that the geometric fibers of the given group are unipotent and connected by the *Bible*, §13.2, Theorem 1(d). □

Proposition 5.6.9 also has the following corollary:

Corollary 5.6.13. *Let S be a scheme, G a reductive S-group, and H a subgroup of type* (R) *with solvable geometric fibers. Let $\underline{\mathrm{Tor}}(H)$ be the functor of maximal tori of H:*

$$\underline{\mathrm{Tor}}(H)(S') = \{\, \text{maximal tori of } H_{S'} \,\}.$$

Then $\underline{\mathrm{Tor}}(H)$ is represented by an affine smooth S-scheme, which is a principal homogeneous bundle under H^u for the action

$$(h, T) \longmapsto \mathrm{int}(h)T.$$

[46]

Proof. Indeed, if T and T' are two maximal tori of $H_{S'}$, there exists a unique section $h \in H^u(S')$ such that $\mathrm{int}(h)T = T'$. The uniqueness of h follows at once from the equality

$$\underline{\mathrm{Norm}}_G(T) \cap H^u = e$$

(cf., for example, 5.6.1); it is therefore enough to prove the existence of h locally for the étale topology. By 5.2.6 and 5.1.2(a), we may suppose that T and T' are conjugate by a section of H, whence the desired conclusion because

$$H = H^u \cdot T$$

by 5.6.9(iii). It follows that $\underline{\mathrm{Tor}}(H)$ is a principal homogeneous sheaf under H^u, which is affine and smooth over S; the assertion follows at once.[47] □

[45] Editor's note: The hypothesis that U be closed has been omitted, since it is automatic. Indeed, for such a U, one has $U \cap T = e$ by 5.6.10, so the semidirect product $H = T \cdot U$ is a subgroup of G of type (R) (cf. 5.2.1), with solvable geometric fibers. Thus, by 5.6.3, H is closed in G; and since U is closed in H, it is closed in G.

[46] Editor's note: This reproves and sharpens Exposé XII, 1.10 (for G reductive).

[47] Editor's note: By SGA 1, VIII, 2.1, and EGA IV_4, 17.7.1.

5.7. Bruhat's Theorem

Recall 5.7.1. *Let k be an algebraically closed field, G a reductive k-group, B a Borel subgroup of G, T a maximal torus of B, and $N = \underline{\mathrm{Norm}}_G(T)$. Then*

$$G(k) = B(k)N(k)B(k);$$

this is Bruhat's theorem (*Bible*, §13.4, Corollary 1 to Theorem 3). *More precisely, with the notation of 3.6, the sets*

$$B(k)N_w(k)B(k) = B^u(k)N_w(k)B^u(k)$$

form a partition of $G(k)$ as w ranges over $(N/T)(k)$. If B' is another Borel subgroup of G containing T, the sets $B'(k)N_w(k)B(k)$ likewise form a partition of $G(k)$. Indeed, if $y \in N(k)$ is such that $\mathrm{int}(y)B = B'$, *then*

$$yB(k)N_w(k)B(k) = B'(k)N_{yw}(k)B(k).$$

Definition 5.7.2. *Let (G, T, M, R) be a split S-group, let R_- be a system of positive roots of R, and let $B' = B_{R_-}$ be the Borel subgroup it defines. For $w \in W$, put* (cf. 5.6.5)

$$R_-^w = R_- \cap w(R_-), \qquad B'^u_w = U_{R_-^w} = \prod_{\alpha \in R_-^w} U_\alpha.$$

If $n_w \in \underline{\mathrm{Norm}}_G(T)(S)$ is a representative of w (3.8), *one may also write*

$$B'^u_w = B'^u \cap \mathrm{int}(n_w)B'^u.$$

Lemma 5.7.3. *Let (G, T, M, R) be a split S-group, let R_+ be a system of positive roots of R, let $R_- = -R_+$, and let B* (respectively B') *be the Borel subgroup of G defined by R_+* (respectively R_-). *Let $w \in W$, and let N_w and B'^u_w be the corresponding subschemes of G* (3.8 and 5.7.2).

(i) *The sheaf $B' \cdot N_w \cdot B$, the image of the morphism*

$$B' \underset{S}{\times} N_w \underset{S}{\times} B \longrightarrow G$$

induced by multiplication in G, is represented by a subscheme of G (in fact, by a closed subscheme of the open subscheme $n_w\Omega_{R_+}$).

(ii) *The morphism*

$$B'^u_w \underset{S}{\times} N_w \underset{S}{\times} B^u \longrightarrow G,$$

induced by multiplication in G, is an immersion whose image is the preceding subscheme.

Proof. Let us first show that the morphism in (ii) is an immersion. By definition, $\mathrm{int}(n_w)^{-1}$ induces a closed immersion of B'^u_w into B'^u; hence the morphism

$$(u, b) \longmapsto n_w^{-1} u\, n_w b$$

induces a closed immersion

$$B'^u_w \underset{S}{\times} B \longrightarrow \Omega_{R_+}.$$

It follows immediately that the morphism in (ii) induces a closed immersion of its source into the open subscheme $n_w\Omega_{R_+}$. To prove (i), it is enough to see that

$$B'(S)N_w(S)B(S) = B'^u_w(S)N_w(S)B^u(S).$$

Now, if $\alpha \in R$, then $\mathrm{int}(n_w)U_\alpha(S) = U_{w(\alpha)}(S)$. Thus, if $w^{-1}(\alpha) \in R_+$,

$$\begin{aligned} U_\alpha(S)N_w(S)B(S) &= U_\alpha(S)n_wT(S)B^u(S) \\ &= n_wU_{w^{-1}(\alpha)}(S)T(S)B^u(S) \\ &= n_wB(S) = N_w(S)B^u(S). \end{aligned}$$

In view of the definition of R^w_-, this immediately gives the desired assertion. □

Theorem 5.7.4. *Let S be a scheme, let (G, T, M, R) be a split S-group, let B be the Borel subgroup defined by the system of positive roots R_+, and let B' be the Borel subgroup defined by $R_- = -R_+$.*

(i) (Bruhat's theorem) *The schemes $B'^u_w \cdot N_w \cdot B$, as w ranges over W, form a partition of the underlying set of G.*

(ii) *For each $w \in W$, let n_w be a representative of w in $\underline{\mathrm{Norm}}_G(T)(S)$ (3.8). Then the open subschemes*

$$n_w\Omega = n_wB'^u \cdot T \cdot B^u$$

as w ranges over W, form an open covering of G.

Proof. Both assertions may be checked on the geometric fibers, where they follow from 5.7.1 and 5.7.3. □

Remark 5.7.5. Assertion (i) implies that if S is the spectrum of a field, then $G(S)$ is the disjoint union of the sets

$$B'^u_w(S) \cdot T(S) \cdot B^u(S).$$

The corresponding assertion for an arbitrary S, even a local or Artinian one, is plainly false. Note, however, that (ii) implies that if S is local, then $G(S)$ is indeed the union of the $n_w\Omega(S)$. In fact:

Corollary 5.7.6. *Let Δ be a system of simple roots of the split group G over the local scheme S.*

(i) *Then $G(S)$ is generated by $T(S)$ and the groups $U_\alpha(S)$, for $\alpha \in \Delta \cup -\Delta$.*

(ii) *If G is simply connected* (4.3.3)*, then $G(S)$ is already generated by the groups $U_\alpha(S)$, for $\alpha \in \Delta \cup -\Delta$.*

Proof. Let H be the subgroup of $G(S)$ generated by the $U_\alpha(S)$, for $\alpha \in \Delta \cup -\Delta$. First observe that H contains a representative of every s_α, for $\alpha \in \Delta$, in $\underline{\mathrm{Norm}}_G(T)(S)$ (Exposé XX, 3.1), and hence a representative n_w of every $w \in W$. Since every $\alpha \in R$ can be written as $w(\alpha_0)$, with $w \in W$ and $\alpha_0 \in \Delta$, we have

$$U_\alpha(S) = \mathrm{int}(n_w)U_{\alpha_0}(S) \subset H.$$

The subgroup generated by H and $T(S)$ therefore contains $\Omega(S)$, and hence, by the preceding observation, is all of $G(S)$.

Now suppose that G is simply connected. Let us prove that $H \supset T(S)$. By Exposé XX, 2.7, H contains $\alpha^*(\mathbb{G}_m(S))$ for every $\alpha \in \Delta$, and it remains only to apply 4.3.8. □

Remark 5.7.6.1. Instead of taking, for each $\alpha \in \Delta$, both $U_\alpha(S)$ and $U_{-\alpha}(S)$, it is enough to take $U_\alpha(S)$ together with a representative w_α of the reflection s_α, or else $U_\alpha(S)$ together with a section of $U_{-\alpha}^\times$, ...

Corollary 5.7.7. *Suppose that G has semisimple rank 1, and choose $u_\alpha \in U_\alpha^\times(S)$. Then Ω and $u_\alpha\Omega$ form an open covering of G.*

Proof. If $u_{-\alpha}$ is the section of $U_{-\alpha}$ paired with u_α (cf. 1.3), then 5.7.4 (ii) gives

$$G = \Omega \cup u_{-\alpha}^{-1} u_\alpha u_{-\alpha}^{-1} \Omega,$$

and hence

$$G = u_{-\alpha} G = u_{-\alpha}\Omega \cup u_\alpha u_{-\alpha}^{-1}\Omega = \Omega \cup u_\alpha \Omega.$$

□

Corollary 5.7.8. *Let S be a scheme and let G be a reductive S-group. Then G is essentially free over S in the sense of Exposé VIII, 6.1.*[48]

Proof. The assertion is local for the fpqc topology, so we may assume that G is split. It then admits an open covering by open subschemes isomorphic to

$$\mathbb{G}_{a,S}^N \underset{S}{\times} \mathbb{G}_{m,S}^n,$$

and these are essentially free. □

Lemma 5.7.9. *Under the hypotheses of 5.7.4, let α be a simple root of R_+, and let $u_\alpha \in U_\alpha^\times(S)$. For every $v \in U_{-\alpha}(S)$, one has*

$$\Omega \cdot v \subset \Omega \cup u_\alpha \cdot \Omega.$$

Proof. We are comparing two open subschemes of G, so it is enough to do so when S is the spectrum of a field k. We must therefore prove

$$\Omega(k)v \subset \Omega(k) \cup u_\alpha \Omega(k).$$

Now

$$\begin{aligned} \Omega(k)v &= B'^u(k)T(k)B^u(k)v \\ &= U_{-\widehat{\alpha}}(k)U_{-\alpha}(k)T(k)U_\alpha(k)U_{\widehat{\alpha}}(k)v \\ &\subset U_{-\widehat{\alpha}}(k)Z_\alpha(k)U_{\widehat{\alpha}}(k)v. \end{aligned}$$

Here we use the decomposition of 5.6.8. Applying 5.6.8 (iii) and then 5.7.7 to the group Z_α, we obtain

$$\begin{aligned} \Omega(k)v &\subset U_{-\widehat{\alpha}}(k)Z_\alpha(k)vU_{\widehat{\alpha}}(k) \\ &\subset U_{-\widehat{\alpha}}(k)Z_\alpha(k)U_{\widehat{\alpha}}(k) \\ &\subset U_{-\widehat{\alpha}}(k)U_{-\alpha}(k)T(k)U_\alpha(k)U_{\widehat{\alpha}}(k) \\ &\quad \cup U_{-\widehat{\alpha}}(k)u_\alpha U_{-\alpha}(k)T(k)U_\alpha(k)U_{\widehat{\alpha}}(k). \end{aligned}$$

Applying 5.6.8 (iii) once more, now with R_- in place of R_+, gives the result. □

[48] Editor's note: See also the additions made in Exposé $\mathrm{VI_B}$, 6.2.1–6.2.6 and 6.5.2–6.5.5.

Proposition 5.7.10. *Under the hypotheses of 5.7.4, choose, for each simple root α, an element $u_\alpha \in U_\alpha^\times(S)$. Let U_1 be the submonoid of $B^u(S)$ generated by the u_α. Then the open subschemes $u\Omega$, for $u \in U_1$, form an open covering of G.*

Proof. Once again, we may assume that S is the spectrum of a field k. In view of 5.7.6, it is enough to prove that

$$\bigcup_{u\in U_1} u\Omega(k)$$

is stable under right multiplication by $T(k)$, $U_\alpha(k)$, and $U_{-\alpha}(k)$, for every simple root α. This is trivial in the first two cases, and in the last it follows from the lemma. □

Remark 5.7.11. Let us point out a special case of 5.7.2. If $w = s_\alpha$ is the reflection with respect to the simple root α, then

$$R_- \cap s_\alpha(R_-) = R_- \setminus \{-\alpha\}$$

(Exposé XXI, 3.3.1), and hence, in the notation of 5.6.8,

$$B'^u_{s_\alpha} = U_{-\widehat{\alpha}}.$$

Remark 5.7.12. In fact, the proof of 5.7.10 immediately gives the following statement. Under the hypotheses of 5.7.10, let Γ be a submonoid of $G(S)$. The open subschemes $g\Omega$, for $g \in \Gamma$, form an open covering of G if and only if, for every $s \in S$ and every simple root α, one has

$$(u_\alpha)_{\bar{s}} B'^u(\bar{s}) \subset \Gamma \cdot B'^u(\bar{s}) \cdot T(\bar{s}) \cdot B^u(\bar{s}).$$

Remark 5.7.13. By 5.5.5 (iii), arguing as in 5.7.1, one immediately obtains the following variant of 5.7.4. Let (G, T, M, R) be a split S-group, and let B and B' be two Borel subgroups of G containing T. For every $w \in W$, the sheaf $B' \cdot N_w \cdot B$ is representable by a subscheme of G; these subschemes, as w ranges over W, form a partition of the underlying set of G. One can also give the analogue of 5.7.3 (ii): one must put

$$B'^u_w = B'^u \cap \mathrm{int}(n_w)\widetilde{B}^u,$$

where $\widetilde{B}$ is the Borel subgroup opposite to B with respect to T (cf. 5.9.2).

Proposition 5.7.14. *Let S be a scheme, let G be a reductive S-group, and let*

$$\mathrm{Ad}\colon G \longrightarrow GL_{\mathcal{O}_S}(\mathfrak{g})$$

be its adjoint representation. Then

$$\mathrm{Ker}(\mathrm{Ad}) = \underline{\mathrm{Centr}}(G).$$

Equivalently, the canonical homomorphism induced by Ad *upon passage to the quotient,*

$$\overline{\mathrm{Ad}}\colon G/\underline{\mathrm{Centr}}(G) = \mathrm{ad}(G) \longrightarrow GL_{\mathcal{O}_S}(\mathfrak{g}),$$

is a monomorphism.[49]

[49] Editor's note: It is even a closed immersion, by Exposé XVI, 1.5(a).

Proof. We may assume that G is split. Choose a total order on $\Gamma_0(R)$ compatible with its group structure, and let R_+ be the set of positive roots. By 5.7.4 (ii) and 4.1.6, it is enough to prove that, if n_w represents $w \in W$, if

$$u \in U(S), \qquad t \in T(S), \qquad v \in U_-(S),$$

and if $\mathrm{Ad}(n_w vtu) = \mathrm{id}$, then $w = e$, $v = e$, and $u = e$. For each $m \in R \cup \{0\}$, put

$$\mathfrak{g}^{>m} = \bigoplus_{n>m} \mathfrak{g}^n, \qquad \mathfrak{g}^{<m} = \bigoplus_{n<m} \mathfrak{g}^n.$$

Let $X \in \Gamma(S, \mathfrak{g}^m)$; write

$$\mathrm{Ad}(tu)X = \mathrm{Ad}(v^{-1}n_w^{-1})X.$$

Now

$$\mathrm{Ad}(t)\,\mathrm{Ad}(u)X - m(t)X \in \Gamma(S, \mathfrak{g}^{>m}),$$
$$\mathrm{Ad}(v^{-1}n_w^{-1})X - \mathrm{Ad}(n_w^{-1})X \in \Gamma\big(S, \mathfrak{g}^{<w^{-1}(m)}\big).$$

If $w \neq e$, there is an $\alpha \in R$ such that $w^{-1}(\alpha) < \alpha$. On taking $m = \alpha$, this gives a contradiction, since

$$\begin{aligned}\mathrm{Ad}(tu)X &\in \Gamma\big(S, \mathfrak{g}^{\alpha} + \mathfrak{g}^{>\alpha}\big) \cap \Gamma\big(S, \mathfrak{g}^{w^{-1}(\alpha)} + \mathfrak{g}^{<w^{-1}(\alpha)}\big)\\ &= 0.\end{aligned}$$

Thus $w = e$, and we may choose $n_w = e$. We then have

$$\mathrm{Ad}(v^{-1})X - X \in \Gamma\big(S, \mathfrak{g}^{<m} \cap (\mathfrak{g}^m + \mathfrak{g}^{>m})\big) = 0,$$

whence $\mathrm{Ad}(v)X = X$ for every $X \in \Gamma(S, \mathfrak{g}^m)$, and therefore $\mathrm{Ad}(v) = \mathrm{id}$. Similarly, $\mathrm{Ad}(u) = \mathrm{id}$. The result now follows from 5.6.2 bis. □

5.8. Schemes Associated with a Reductive Group

Theorem 5.8.1. *Let S be a scheme and let G be a reductive S-group. Let $\mathcal{H}$ be the functor of subgroups of type* (R) *of G: for every $S' \to S$, $\mathcal{H}(S')$ is the set of subgroups of type* (R) *of $G_{S'}$* (cf. 5.2.1). *Then $\mathcal{H}$ is representable by a quasi-projective S-scheme of finite presentation over S.*

Proof.[50] Let

$$G' = G/\underline{\mathrm{Centr}}(G)$$

be the adjoint group of G (4.3.6), and let $u\colon G \to G'$ be the quotient morphism. By Exposé XII, 7.12, the map

$$H' \longmapsto u^{-1}(H')$$

is a bijection from the set of subgroups of type (R) of G' onto the set of subgroups of type (R) of G; this remains true after every base change. Thus, replacing G by G', we may assume that G is adjoint. Consider the morphism

$$u\colon \mathcal{H} \longrightarrow \underline{\mathrm{Grass}}(\mathfrak{g})$$

that assigns to every subgroup of type (R) its Lie algebra (a submodule of $\mathfrak{g}$ that is locally a direct summand[51]). Then u is a monomorphism by 5.3.3. It is enough to prove that it is

[50] Editor's note: The original is expanded in what follows.
[51] Editor's note: Cf. Exposé II, 4.11.8.

representable by an immersion of finite presentation; in other words, it is enough to prove the following assertion. For every $S_1 \to S$, given a locally direct-summand submodule $\mathfrak{h}$ of $\mathfrak{g}_{S_1}$, the morphisms $S' \to S_1$ for which $\mathfrak{h}_{S'}$ is the Lie algebra of a subgroup of type (R) of $G_{S'}$ are exactly those that factor through a certain subscheme Σ of finite presentation over S_1. Replacing S_1 by S, we reduce to $S_1 = S$, and we may moreover assume that S is affine; then there exists an affine Noetherian scheme S_0 such that G (respectively, $\mathfrak{h}$) is obtained by base change from an adjoint reductive S_0-group G_0 (respectively, from a locally direct-summand submodule $\mathfrak{h}_0$ of $\mathfrak{g}_0 = \mathrm{Lie}(G_0/S_0)$). It is enough to show that there exists a subscheme Σ_0 of S_0 having the required properties, for then $\Sigma = \Sigma_0 \times_{S_0} S$. Replacing S by S_0, we may therefore suppose that S is affine and Noetherian (note that then every subscheme of S is of finite presentation over S). Finally, after replacing S by a sufficiently small open subscheme, we may suppose that $\mathfrak{g}$ is free of rank n and that $\mathfrak{h}$ is a direct summand, free of rank r.

We must first express the condition that $\mathfrak{h}_{S'}$ be a Lie subalgebra of $\mathfrak{g}_{S'}$, that is, that the morphism induced by the Lie bracket

$$\varphi\colon \mathfrak{h} \otimes \mathfrak{h} \xrightarrow{[,]} \mathfrak{g}$$

factor through $\mathfrak{h}$. If $(e_1, \ldots, e_n)$ is a basis of $\mathfrak{g}$ such that $(e_1, \ldots, e_r)$ is a basis of $\mathfrak{h}$, then φ is given by sections a_k^{ij} of $\mathcal{O}_S$, where $i, j = 1, \ldots, r$ and $k = 1, \ldots, n$. The preceding condition is equivalent to requiring that $S' \to S$ factor through the closed subscheme of S defined by the equations

$$a_k^{ij} = 0 \qquad \text{for } k = r+1, \ldots, n \text{ and } i, j = 1, \ldots, r.$$

We replace S by this closed subscheme.

Then, by 5.3.0,

$$N = \underline{\mathrm{Norm}}_G(\mathfrak{h})$$

is a closed subgroup scheme of G, of finite presentation over G. We must now express (cf. 5.3.1) the condition that $N_{S'}$ be smooth at every point of the unit section, of relative dimension $r = \mathrm{rank}(\mathfrak{h})$, and that the inclusion of $\mathfrak{h}_{S'}$ in $\mathrm{Lie}(N_{S'}/S')$ be an equality.

Since N is affine over S[52] (being closed in G), the unit section $\varepsilon\colon S \to N$ is a closed immersion. Thus $\varepsilon(S)$ is defined by a quasi-coherent ideal $\mathcal{J}$ of $\mathcal{A}(N)$. Note that

$$\mathfrak{n}_{S/N} = \mathcal{J}/\mathcal{J}^2 \simeq \varepsilon^*(\Omega^1_{N/S}),$$

so its formation commutes with every base change $S' \to S$. By the equivalence $(c') \Longleftrightarrow (a)$ in EGA IV_4, 17.12.1 (applied to $f\colon N \to S$ and $j = \varepsilon$), the morphism $N_{S'} \to S'$ is smooth, of relative dimension r, at every point of $\varepsilon(S')$ if and only if

$$\mathfrak{n}_{S'/N'} = \mathfrak{n}_{S/N} \otimes_{\mathcal{O}_S} \mathcal{O}_{S'}$$

is locally free of rank r, and the morphism

$$\varphi_n(S')\colon \mathrm{Sym}^n(\mathfrak{n}_{S'/N'}) \longrightarrow \mathcal{J}^n_{S'}/\mathcal{J}^{n+1}_{S'}$$

[52]Editor's note: The original then indicated that, denoting by $\mathfrak{n}_{N/G}$ the inverse image of the conormal sheaf $\mathcal{N}_{N/G}$ under the unit section $S \to N$, the condition that $\mathfrak{n}_{N_{S'}/G_{S'}} \to \omega^1_{G_{S'}/S'}$ be universally injective is equivalent to the condition that $S' \to S$ factor through a certain open subscheme of S. We were unable to justify this point, since formation of $\mathcal{N}_{N/G}$ does not commute with base change, and we have replaced that argument by the one that follows, suggested by O. Gabber.

is an isomorphism for every $n \geq 1$. Put

$$K_n(S') = \ker \varphi_n(S').$$

By TDTE I, Lemma 3.6, $\mathfrak{n}_{S/N} \otimes \mathcal{O}_{S'}$ is locally free of rank r if and only if $S' \to S$ factors through a certain subscheme Z of S. Replacing S by Z, we may therefore suppose that $\mathfrak{n}_{S/N} = \mathcal{J}/\mathcal{J}^2$ is locally free of rank r. Then, for every $S' \to S$,

$$(\mathcal{J}^2/\mathcal{J}^3) \otimes \mathcal{O}_{S'} = \mathcal{J}_{S'}^2/\mathcal{J}_{S'}^3,$$

and consequently

$$K_2(S') = K_2(S) \otimes \mathcal{O}_{S'}.$$

It follows that $\varphi_2(S')$ is an isomorphism if and only if $S' \to S$ factors through the closed subscheme S_2 of S defined by the ideal generated by the image of

$$\mathrm{Sym}^2(\mathfrak{n}_{S/N})^* \otimes K_2(S) \longrightarrow \mathcal{O}_S.$$

Over S_2, the module $\mathcal{J}^2/\mathcal{J}^3$ is then isomorphic to $\mathrm{Sym}^2(\mathfrak{n}_{S/N})$, hence is locally free; the same argument shows that $\varphi_3(S')$ is an isomorphism if and only if $S' \to S$ factors through a certain closed subscheme S_3 of S, and so on. We thus obtain that $N_{S'} \to S'$ is smooth, of relative dimension r, at every point of $\varepsilon(S')$ if and only if $S' \to S$ factors through the closed subscheme

$$Z = \bigcap_n S_n.$$

But then, for every $S' \to Z$, $\mathrm{Lie}(N_{S'}/S')$ is locally a direct summand of rank r of $\mathfrak{g}_{S'}$, and hence the inclusion

$$\mathfrak{h}_{S'} \subset \mathrm{Lie}(N_{S'}/S')$$

is an equality. We then put $H = N^0$.

Replacing S by Z, it remains only to express the condition that $H_{s'}$ have the same reductive rank as $G_{s'}$ at every point $s' \in S'$, or, equivalently, that H_s have the same reductive rank as G_s at every point s in the set-theoretic image of S' in S. This condition defines an open subset of S (Exposé XIX, 6.2). □

Remark. In general, the scheme $\mathcal{H}$ is not smooth over S. It is nevertheless smooth if 6 is invertible on S, or if there exists a prime number p such that $p \cdot 1_S = 0$ (that is, if S has characteristic $p > 0$).

Corollary 5.8.2. *Let S be a scheme, let G be a reductive S-group, and let H be a subgroup of type* (R) *of G. Recall from 5.3.10 that $\underline{\mathrm{Norm}}_G(H)$ is representable by a closed subgroup scheme of G, smooth over S. Then the quotient sheaf*

$$G/\underline{\mathrm{Norm}}_G(H)$$

is representable by a quasi-projective S-scheme, smooth and of finite presentation over S (in fact, by an open subscheme of $\mathcal{H}$).

Indeed, consider the morphism

$$f : G \longrightarrow \mathcal{H}$$

defined set-theoretically by

$$f(g) = \mathrm{int}(g)H.$$

By 5.3.9, this morphism is smooth and of finite presentation, hence open. Let $V = f(G)$, equipped with its open-subscheme structure in $\mathcal{H}$. The morphism $f : G \to V$ is a covering morphism with kernel $\underline{\mathrm{Norm}}_G(H)$. Consequently $G/\underline{\mathrm{Norm}}_G(H)$ is representable by V (cf. Exposé IV, 4.6.5). □

Corollary 5.8.3. *Let S be a scheme and let G be a reductive S-group. Consider the functors $\underline{\mathrm{Tor}}(G)$, $\underline{\mathrm{Bor}}(G)$, and $\underline{\mathrm{Kil}}(G)$, defined by*

$$\underline{\mathrm{Tor}}(G)(S') = \{\textit{maximal tori of } G_{S'}\},$$
$$\underline{\mathrm{Bor}}(G)(S') = \{\textit{Borel subgroups of } G_{S'}\},$$
$$\underline{\mathrm{Kil}}(G)(S') = \{\textit{Killing pairs of } G_{S'} \quad (\text{cf. } 5.3.13)\}.$$

(i) *$\underline{\mathrm{Tor}}(G)$, $\underline{\mathrm{Bor}}(G)$, and $\underline{\mathrm{Kil}}(G)$ are representable by smooth S-schemes of finite presentation, with geometrically integral fibres, and are respectively affine, projective, and affine over S.*

(ii) *The canonical morphism*

$$\underline{\mathrm{Kil}}(G) \longrightarrow \underline{\mathrm{Tor}}(G)$$

(respectively, $\underline{\mathrm{Kil}}(G) \to \underline{\mathrm{Bor}}(G)$) *is finite étale and surjective* (respectively, affine, smooth, and surjective).

(iii) *Let T be a maximal torus of G* (respectively, let B be a Borel subgroup of G, or let $B \supset T$ be a Killing pair of G). *The morphism*

$$G \longrightarrow \underline{\mathrm{Tor}}(G), \quad \textit{resp.} \quad G \longrightarrow \underline{\mathrm{Bor}}(G), \quad \textit{resp.} \quad G \longrightarrow \underline{\mathrm{Kil}}(G),$$

defined by

$$g \longmapsto \mathrm{int}(g)T, \quad \textit{respectively} \quad g \longmapsto \mathrm{int}(g)B, \quad \textit{respectively} \quad g \longmapsto (\mathrm{int}(g)B, \mathrm{int}(g)T)$$

induces an isomorphism

$$G/\underline{\mathrm{Norm}}_G(T) \xrightarrow{\sim} \underline{\mathrm{Tor}}(G), \quad \text{resp.} \quad G/B \xrightarrow{\sim} \underline{\mathrm{Bor}}(G), \quad \text{resp.} \quad G/T \xrightarrow{\sim} \underline{\mathrm{Kil}}(G).$$

One first sees that (iii) follows from the conjugacy theorem for maximal tori (respectively, Borel subgroups, respectively, Killing pairs) and from the facts that

$$\underline{\mathrm{Norm}}_G(B) = B, \qquad \underline{\mathrm{Norm}}_G(B) \cap \underline{\mathrm{Norm}}_G(T) = T,$$

all of which were established above (5.1.2, 5.3.12, 5.3.14, 5.6.1).

It follows first that the canonical morphisms

$$\underline{\mathrm{Tor}}(G) \longrightarrow \mathcal{H}, \qquad \underline{\mathrm{Bor}}(G) \longrightarrow \mathcal{H}$$

are representable, locally for the étale topology, by open immersions (5.8.2 and 5.1.2, respectively 5.5.5). Hence, by descent, $\underline{\mathrm{Tor}}(G)$ and $\underline{\mathrm{Bor}}(G)$ are representable by open subschemes of $\mathcal{H}$. Likewise, $\underline{\mathrm{Kil}}(G)$ is locally, for the étale topology, representable by a scheme affine over the base (Exposé IX, 2.3), and hence is representable by an affine S-scheme, by descent for affine schemes.[53]

The assertions of (ii) follow at once from 5.5.5(ii) and 5.6.13. It already follows that $\underline{\mathrm{Tor}}(G)$ is affine over S (EGA II, 6.7.1). It remains only to prove that $\underline{\mathrm{Bor}}(G)$ is projective over S. We already know that it is quasi-projective, so it remains to prove that it is proper;[54] but it has connected fibres, and therefore, by EGA IV_3, 15.7.10, one is reduced to proving this on geometric fibres. If S is the spectrum of an algebraically closed field, then $\underline{\mathrm{Bor}}(G) = G/B$ by (iii), and the conclusion follows from *Bible*, §6.4, Theorem 4 (or [Ch05], §6.5, Theorem 5). □

[53] Editor's note: Cf. SGA 1, VIII, 2.1.

[54] Editor's note: We may suppose that S is affine and, since $\underline{\mathrm{Bor}}(G)$ is of finite presentation over S by (i), reduce to the case in which S is Noetherian; we are then under the hypotheses of EGA IV_3, 15.7.10.

Remark 5.8.4. Under the hypotheses of 5.8.3, let Q be a central subgroup of multiplicative type of G. The evident morphisms define isomorphisms

$$\underline{\mathrm{Tor}}(G) \simeq \underline{\mathrm{Tor}}(G/Q), \qquad \underline{\mathrm{Bor}}(G) \simeq \underline{\mathrm{Bor}}(G/Q), \qquad \underline{\mathrm{Kil}}(G) \simeq \underline{\mathrm{Kil}}(G/Q).$$

Corollary 5.8.5. *Let S be a scheme, G a reductive S-group, and P a subgroup scheme of G, smooth and of finite presentation over S. The following conditions are equivalent:*

(i) *For every $s \in S$, $P_{\bar{s}}$ is a parabolic subgroup of $G_{\bar{s}}$* (that is, the quotient scheme $G_{\bar{s}}/P_{\bar{s}}$ is proper over $\bar{s}$, or equivalently $P_{\bar{s}}$ contains a Borel subgroup of $G_{\bar{s}}$; cf. *Bible*, §6.4, Theorem 4, or [Ch05], §6.5, Theorem 5).

(ii) *The quotient sheaf G/P is representable by an S-scheme smooth and projective over S.*

Moreover, under these conditions, P is closed in G, has connected fibres, and

$$P = \underline{\mathrm{Norm}}_G(P).$$

Clearly (ii) implies (i). If (i) holds, then

$$P(\bar{s}) = \underline{\mathrm{Norm}}_{G(\bar{s})}(P_{\bar{s}})$$

and $P_{\bar{s}}$ is connected (for the first assertion, cf. *Bible*, §12.3, Lemma 4;[55] the second assertion follows from this, since $P' = P^0_{\bar{s}}$ is a parabolic subgroup of $G_{\bar{s}}$ normalized by $P_{\bar{s}}$, whence $P'(\bar{s}) = P(\bar{s})$ and therefore $P' = P_{\bar{s}}$). It follows that P is of type (R) and that

$$P = \underline{\mathrm{Norm}}_G(P),$$

so that P is closed in G. By 5.8.2,

$$G/P = G/\underline{\mathrm{Norm}}_G(P)$$

is representable by a quasi-projective S-scheme. Its fibres are connected and proper, and it is therefore projective by the argument of 5.8.3. □

Remark 5.8.6. The statements 5.8.1, 5.8.2, and 5.8.5 are valid for an S-group of type (RA), or for an S-group of type (RR) satisfying 5.1.8.[56]

Remark 5.8.7. Through the inner automorphisms of G, there are canonical actions

$$G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Tor}}(G)), \quad G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Bor}}(G)), \quad G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Kil}}(G)),$$

which, in the situation of 5.8.3(iii), are identified with the canonical actions

$$G \longrightarrow \underline{\mathrm{Aut}}_S(G/\underline{\mathrm{Norm}}_G(T)), \quad G \longrightarrow \underline{\mathrm{Aut}}_S(G/B), \quad G \longrightarrow \underline{\mathrm{Aut}}_S(G/T).$$

In particular, one obtains

$$\begin{aligned} \ker(G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Tor}}(G))) &= \ker(G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Bor}}(G))) \\ &= \ker(G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Kil}}(G))) \\ &= \underline{\mathrm{Centr}}(G). \end{aligned}$$

[55] Editor's note: We have supplied the details that follow.

[56] Editor's note: Indeed, the proof of 5.8.1 uses only 5.3.3 (which is valid for a group of type (RA)) and Exposé XIX, 6.2, which, by Exposé XII, 1.7(b), is also valid for groups of type (RR).

Indeed, it is clear that $\underline{\mathrm{Centr}}(G)$ acts trivially on each of the three schemes. Conversely, the kernel of

$$G \longrightarrow \underline{\mathrm{Aut}}_S(\underline{\mathrm{Kil}}(G))$$

is "the intersection of the maximal tori of G" in the sense of 4.1.7, and hence equals $\underline{\mathrm{Centr}}(G)$ (loc. cit.). For $\underline{\mathrm{Bor}}(G)$, one observes that "the intersection of the Borel subgroups of G" is also "the intersection of its maximal tori" (see the following section). For $\underline{\mathrm{Tor}}(G)$, one uses Exposé XII, 4.11.

5.9. Properties Peculiar to Borel Subgroups

Most of these properties will be generalized in Exposé XXVI to parabolic subgroups.

Definition 5.9.1. Let S be a scheme, G a reductive S-group, and B, B' two Borel subgroups of G. We say that B and B' are *in general position* (or that B' is in general position relative to B) if $B \cap B'$ is a torus (necessarily maximal) of G.

If T is a maximal torus of G contained in B and B', we say that B and B' are *opposite* (relative to T) if

$$B \cap B' = T.$$

Proposition 5.9.2. *Let S be a scheme, G a reductive S-group, B a Borel subgroup of G, and T a maximal torus of B. There exists a unique Borel subgroup B' of G, opposite to B relative to T.*

If (G, T, M, R) is a splitting of G relative to T, and if $B = B_{R_+}$ (5.5.1), then

$$B' = B_{-R_+}.$$

By faithfully flat descent, it is enough to prove the proposition in the split case, with $B = B_{R_+}$ (5.5.5(iv)). Then B_{-R_+} is indeed opposite to B (4.1.2). Let us show that it is the only Borel subgroup of G containing T that is opposite to B. If B' is a Borel subgroup of G containing T, then locally on S it has the form $B_{R'_+}$, where R'_+ is another system of positive roots of R (5.5.5(iii)). If $R'_+ \neq -R_+$, there exists $\alpha \in R'_+ \cap R_+$, and hence

$$U_\alpha \subset B_{R_+} \cap B_{R'_+}.$$

□

Proposition 5.9.3. *Let S be a scheme, G a reductive S-group, and B a Borel subgroup of G.*

(i) *If B' is a Borel subgroup of G, the following conditions are equivalent:*

(a) *B' is in general position relative to B* (5.9.1).

(b) *$B'^u \cap B^u = e$.*

(b′) *$B'^u \cap B = e$.*

(c) *Multiplication in G induces an open immersion*

$$B'^u \times_S B \longrightarrow G.$$

(c′) *The canonical morphism*

$$B'^u \longrightarrow G/B$$

is an open immersion.

(ii) *The functor* $\underline{\mathrm{Opp}}(B)$,

$$S' \longmapsto \left\{ \begin{array}{c} \textit{Borel subgroups of } G_{S'} \textit{ in general position} \\ \textit{relative to } B_{S'} \end{array} \right\},$$

is representable by an open subscheme of $\underline{\mathrm{Bor}}(G)$ (5.8.3). *The morphism*

$$\underline{\mathrm{Opp}}(B) \longrightarrow \underline{\mathrm{Tor}}(B)$$

defined by $B' \mapsto B \cap B'$ *is an isomorphism. In particular* (5.6.13), *the inner automorphisms of* B^u *equip* $\underline{\mathrm{Opp}}(B)$ *with the structure of a principal homogeneous bundle under* B^u.

Let us first examine (i). We have (a) ⇒ (c). Indeed, (c) is local for the étale topology; by 5.5.5(iv), one reduces to the case in which G is split relative to $B \cap B'$ and B has the form B_{R_+}. By 5.9.2,

$$B'^u = U_{-R_+},$$

and one is reduced to 4.1.2.

Trivially,

$$(\mathrm{c}') \Longleftrightarrow (\mathrm{c}) \Longrightarrow (\mathrm{b}') \Longrightarrow (\mathrm{b}).$$

It remains to prove (b) ⇒ (a). Let us first prove (ii). The second assertion is a formal consequence of 5.9.2, and the third follows at once from it by 5.6.13. Let us prove the first. It is local for the étale topology, and we may therefore suppose that B contains a maximal torus T. Let B'_0 be the Borel subgroup opposite to B relative to T (5.9.2).

By what precedes, the morphism

$$B^u \longrightarrow \underline{\mathrm{Bor}}(G)$$

induced by the canonical morphism

$$G \longrightarrow G/B'_0 \longrightarrow \underline{\mathrm{Bor}}(G)$$

(5.8.3) induces an isomorphism

$$B^u \xrightarrow{\sim} \underline{\mathrm{Opp}}(B).$$

Thus there is a commutative diagram

$$\begin{array}{ccc} B^u & \longrightarrow & G/B'_0 \\ \downarrow \sim & & \downarrow \sim \\ \underline{\mathrm{Opp}}(B) & \longrightarrow & \underline{\mathrm{Bor}}(G). \end{array}$$

Now the morphism $B^u \to G/B'_0$ is an open immersion (by (i), (a) ⇒ (c′)), which completes the proof of (ii). We record at once the following corollary.

Corollary 5.9.4. *Let G be a reductive S-group and let B, B' be two Borel subgroups of G. If $s \in S$ is such that $B_{\bar{s}}$ and $B'_{\bar{s}}$ are in general position, there exists an open subset V of S, containing s, such that B_V and B'_V are in general position.*

It therefore remains only to prove (b) ⇒ (a). By the preceding corollary, it is enough to do so when S is the spectrum of an algebraically closed field k. We may suppose that G is split relative to a maximal torus T of B. Let B'_0 be the Borel subgroup opposite to B. Since the Borel subgroups of G are conjugate under $G(k)$, there exists $g \in G(k)$ such that $\mathrm{int}(g)B'_0 = B'$. By the Bruhat theorem (5.7.4), we may write

$$g = bnb', \qquad b \in B(k), \quad b' \in B'_0(k), \quad n \in \underline{\mathrm{Norm}}_G(T)(k).$$

Thus

$$B' = \mathrm{int}(b)\,\mathrm{int}(n)B'_0$$

and

$$B' \cap B = \mathrm{int}(b)(\mathrm{int}(n)B'_0 \cap B).$$

If $n \notin T(k)$, then

$$\mathrm{int}(n)(B'_0)^u \cap B^u \neq e$$

(cf. the proof of 5.9.2); it follows that (b) implies

$$B' \cap B = \mathrm{int}(b)(B'_0 \cap B) = \mathrm{int}(b)T.$$

□

Proposition 5.9.5. *Let S be a scheme, G a reductive S-group, B a Borel subgroup of G, and B^u its unipotent part. There exists a sequence of subgroups of B,*

$$U_0 = B^u \supset U_1 \supset \cdots \supset U_n \supset \cdots,$$

having the following properties:

(i) *Each U_i is smooth, has connected fibers, and is characteristic in B; the inner automorphisms of B^u act trivially on the* (sheaf) *quotients U_i/U_{i+1}.*

(ii) *For each $i \geq 0$, there exists a locally free $\mathcal{O}_S$-module $\mathcal{E}_i$ and an isomorphism of sheaves of groups on S,*

$$U_i/U_{i+1} \xrightarrow{\sim} W(\mathcal{E}_i).$$

(iii) *For every $s \in S$,*

$$(U_n)_s = e \qquad \textit{for} \qquad n \geq \dim(B^u_s).$$

Suppose first that there exists a splitting (G, T, M, R) of G and a system R_+ of positive roots of R such that $B = B_{R_+}$. Denote by Δ the set of simple roots of R_+. For each $\alpha \in R_+$, denote by $\mathrm{ord}(\alpha)$ the sum of the coefficients of α in the basis Δ of $\Gamma_0(R)$; this is the *order* of α relative to R_+. We have

$$\mathrm{ord}(\alpha) \leq \mathrm{Card}(R_+).$$

For every $i > 0$, let $R^{(i)}$ be the set of roots of order $> i$. This is a closed set of positive roots, and we may therefore construct (5.6.5)

$$U_i = U_{R^{(i)}}.$$

If $\alpha \in R_+$ and $\beta \in R^{(i)}$, then $\alpha + \beta \in R^{(i+1)}$. It follows from 5.5.2 that each U_i is an invariant subgroup of B, and that the inner automorphisms of B^u act trivially on U_i/U_{i+1}. Moreover, this group identifies with

$$\prod_{\mathrm{ord}(\alpha)=i+1} U_\alpha$$

and is therefore endowed with a vector-group structure.

If B is of the form $B_{R'_+}$ for another splitting (G, T', M', R') of G, let us show that the groups U'_i constructed as above using the new splitting coincide with the U_i, and that the vector-group structures on the successive quotients likewise coincide. By 5.6.13, there exists $b \in B^u(S)$ such that $T' = \mathrm{int}(b)T$; the assertion to be proved is local on S, and we may therefore suppose that the isomorphism

$$T \xrightarrow{\sim} T'$$

induced by $\mathrm{int}(b)$ arises by duality from an isomorphism of root data

$$h : (M', M'^*, R', R'^*) \xrightarrow{\sim} (M, M^*, R, R^*).$$

The roots in R'_+ are then the roots

$$\alpha \circ \mathrm{int}(b) = h(\alpha), \qquad \alpha \in R_+,$$

and its simple roots are the $h(\alpha)$, with $\alpha \in \Delta$. Consequently

$$\mathrm{ord}\big(h(\alpha)\big) = \mathrm{ord}(\alpha).$$

By transport of structure, the vector groups $U'_{h(\alpha)}$ are the groups $\mathrm{int}(b)U_\alpha$. It follows that

$$\mathrm{int}(b)U_i = U'_i.$$

But U_i is invariant in B, so that $U_i = U'_i$. Likewise, the isomorphism

$$\mathrm{int}(b) : U_i/U_{i+1} \xrightarrow{\sim} U'_i/U'_{i+1}$$

is the identity.

We now pass to the general case. Let $\{S_i \to S\}$ be an étale covering family such that each (G_i, T_i, M_i, R_i) is a splitting, and choose a system R_{i+} of positive roots such that

$$B \times_S S_i = B_{R_{i+}}$$

(5.5.5(iii)). For every i, the preceding construction gives a sequence

$$B^u_{S_i} = U_{i,0} \supset U_{i,1} \supset \cdots \supset U_{i,j} \supset \cdots$$

and vector-group structures on its successive quotients. By descent, it is enough to verify, for every i, i' and every j, that

$$U_{i,j} \times_{S_i} S_{ii'} = U_{i',j} \times_{S_{i'}} S_{ii'}, \qquad S_{ii'} = S_i \times_S S_{i'},$$

and that the vector-group structures on

$$(U_{i,j}/U_{i,j+1}) \times_{S_i} S_{ii'} \quad \text{and} \quad (U_{i',j}/U_{i',j+1}) \times_{S_{i'}} S_{ii'}$$

coincide. If $S_{ii'} = \varnothing$, there is nothing to prove. Otherwise we are in the situation considered above: $B \times_S S_{ii'}$ is defined by the system of positive roots R_{i+}, respectively $R_{i'+}$, in the splittings

$$(G_{S_{ii'}}, T_i \times_{S_i} S_{ii'}, M_i, R_i), \qquad (G_{S_{ii'}}, T_{i'} \times_{S_{i'}} S_{ii'}, M_{i'}, R_{i'}).$$

This proves the proposition. □

Corollary 5.9.6. *If S is affine, then*

$$H^1(S, B^u) = e;$$

that is, every principal homogeneous bundle under B^u has a section.

Indeed, S is a disjoint union of subschemes on each of which B^u has constant relative dimension. In view of 5.9.5(iii), we may therefore suppose that $U_n = e$. By TDTE I, B.1.1,[56] one has

$$H^1(S, U_i/U_{i+1}) = H^1(S, W(\mathcal{E}_i)) = 0.$$

It follows by induction that $H^1(S, B^u) = e$.

Corollary 5.9.7. *If S is affine, then B has maximal tori. If T is a maximal torus of B, then*

$$H^1(S, T) = H^1(S, B).$$

The first assertion follows at once from 5.9.6 and 5.6.13; the second follows from it in the standard way.[57]

Corollary 5.9.8. *If G is a reductive S-group, the canonical morphism* (cf. 5.8.3)

$$\underline{\mathrm{Kil}}(G) \longrightarrow \underline{\mathrm{Bor}}(G)$$

has sections over every affine open subset.

Corollary 5.9.9. *Under the hypotheses of 5.9.5, suppose that S is affine. Then there exists a locally free $\mathcal{O}_S$-module $\mathcal{E}$ such that B^u, as a scheme, is S-isomorphic to $W(\mathcal{E})$.*

We prove by induction on i that B^u/U_i is S-isomorphic to

$$W(\mathcal{E}_0 \oplus \cdots \oplus \mathcal{E}_{i-1}).$$

This is clear for $i = 0$; suppose that $i \geq 1$. Then B^u/U_i is a principal homogeneous bundle with base

$$X = B^u/U_{i-1}$$

under the group $(U_{i-1}/U_i)_X$. Since B^u/U_{i-1} is affine by the induction hypothesis, and since

$$U_{i-1}/U_i = W(\mathcal{E}_{i-1}),$$

this bundle is trivial. We therefore have, at least, an isomorphism of S-schemes

$$B^u/U_i \xrightarrow{\sim} (B^u/U_{i-1}) \times_S W(\mathcal{E}_{i-1}) = W(\mathcal{E}_0 \oplus \cdots \oplus \mathcal{E}_{i-1}).$$

The conclusion now follows at once from condition 5.9.5(iii).

[56] Editor's note: This is the corollary on page 18 of TDTE I.

[57] Editor's note: Indeed, there is an exact sequence

$$H^1(S, B^u) \longrightarrow H^1(S, B) \xrightarrow{\pi} H^1(S, B/B^u) = H^1(S, T);$$

see [Se64], I §5.5, Proposition 38, or [Gi71], III Proposition 3.3.1. Now $H^1(S, T) \to H^1(S, B)$ is a section of π, so that π is surjective; on the other hand, $H^1(S, B^u) = 0$ by 5.9.6.

Corollary 5.9.10. *Let S be a semilocal scheme, let $\{s_i\}$ be its closed points, and let B be a Borel subgroup of the reductive S-group G. The canonical map*

$$B^u(S) \longrightarrow \prod_i B^u(\operatorname{Spec} \kappa(s_i))$$

is surjective.

Indeed, if $S = \operatorname{Spec}(A)$, $\kappa(s_i) = A/\mathfrak{p}_i$, and $\mathcal{E}$ is defined by the A-module E, then

$$B^u(S) = E \otimes A, \qquad B^u(\operatorname{Spec} \kappa(s_i)) = E \otimes_A (A/\mathfrak{p}_i).$$

The assertion follows at once from the surjectivity of

$$A \longrightarrow \prod_i A/\mathfrak{p}_i.$$

5.10. Subgroups of Type (R) with Reductive Fibers

Proposition 5.10.1. *Let (G, T, M, R) be a split S-group, let R' be a subset of R of type* (R) (5.4.2)*, and let $H_{R'}$ be the corresponding subgroup of G. The following conditions are equivalent:*

(i) *$H_{R'}$ is reductive* (that is, its geometric fibers are reductive)*.*

(ii) *$R' = -R'$, that is, R' is symmetric.*

Moreover, under these conditions, $(H_{R'}, T, M, R')$ is a splitting of $H_{R'}$; for every system R_+ of positive roots of R,

$$R'_+ = R' \cap R_+$$

is a system of positive roots of R', and

$$B_{R_+} \cap H_{R'} = H_{R'_+}.$$

This is a Borel subgroup of $H_{R'}$, whose unipotent part is

$$U_{R_+} \cap H_{R'} = U_{R'_+}.$$

Clearly (i) implies (ii): it is enough to check this fiber by fiber, and R' is the root system of $H_{R'}$ relative to T. To prove that (ii) implies (i), observe, by 5.4.3, that

$$H_{R'} \cap Z_\alpha = \underline{\operatorname{Centr}}_{H_{R'}}(T_\alpha) = Z_\alpha$$

for every $\alpha \in R'$, and apply the criterion of Exposé XIX, 1.12.

If R_+ is a system of positive roots of R, then $R'_+ = R_+ \cap R'$ is plainly a closed subset of R' such that

$$R'_+ \cup (-R'_+) = R', \qquad R'_+ \cap (-R'_+) = \varnothing;$$

it is therefore a system of positive roots of R'. The other two assertions follow respectively from 5.6.1(vi) and 5.6.7(i). □

Corollary 5.10.2. *Let S be a scheme, G a reductive S-group, and H a reductive S-subgroup such that, for every $s \in S$, $G_{\bar{s}}$ and $H_{\bar{s}}$ have the same reductive rank. Then H is closed in G, $\underline{\mathrm{Norm}}_G(H)$ is smooth over S, and*

$$\underline{\mathrm{Norm}}_G(H)/H$$

is representable by a finite étale S-scheme.

If T is a maximal torus of H, and B a Borel subgroup of G containing T, then $B \cap H$ is a Borel subgroup of H, whose unipotent part is

$$(B \cap H)^u = B^u \cap H.$$

The first assertions follow at once from 5.3.10 and 5.3.18, using the fact that the Weyl groups of G and H are finite (Exposé XIX, 2.5). The other assertions are local for the étale topology and reduce to the case studied in 5.10.1. □

Proposition 5.10.3. *Let S be a scheme and G a reductive S-group.*

(a) *If Q is a torus of G, then $\underline{\mathrm{Centr}}_G(Q)$ is a subgroup of G of type* (R) *with reductive fibers. If $Q \subset Q'$ are two tori of G, then*

$$\underline{\mathrm{Centr}}_G(Q) \supset \underline{\mathrm{Centr}}_G(Q').$$

(b) *If H is a subgroup of G of type* (R) *with reductive fibers, then* $\mathrm{rad}(H)$ (4.3.6) *is a torus of G. If $H \subset H'$ are two subgroups of G of type* (R) *with reductive fibers, then*

$$\mathrm{rad}(H) \supset \mathrm{rad}(H').$$

(c) *If Q is a torus of G, then*

$$\mathrm{rad}(\underline{\mathrm{Centr}}_G(Q)) \supset Q \quad \textit{and} \quad \underline{\mathrm{Centr}}_G(\mathrm{rad}(\underline{\mathrm{Centr}}_G(Q))) = \underline{\mathrm{Centr}}_G(Q).$$

(d) *If H is a subgroup of G of type* (R) *with reductive fibers, then*

$$\underline{\mathrm{Centr}}_G(\mathrm{rad}(H)) \supset H \quad \textit{and} \quad \mathrm{rad}(\underline{\mathrm{Centr}}_G(\mathrm{rad}(H))) = \mathrm{rad}(H).$$

Indeed, (a) follows at once from Exposé XIX, 2.8. To prove (b), it is enough to observe that $\mathrm{rad}(H') \subset H$, since H contains, fpqc-locally, a maximal torus of G, hence of H'. The first assertion of (c) (respectively, of (d)) is trivial, and the second follows by the usual argument. □

This proposition leads to the following definition:

Definition 5.10.4. Let S be a scheme, G a reductive S-group, H a reductive subgroup of G of type (R), and Q a subtorus of G.[58]

1) H is called a *critical subgroup* if it is the centralizer of its radical.

2) Q is called a *C-critical torus* if it is the radical of its centralizer.

Proposition 5.10.3 then gives:

[58] Editor's note: We have modified the original by introducing the term "C-critical torus" in place of "critical torus", in order to avoid confusion in later references (cf. Exposé XXVI, 3.9). We have also expanded the statement of 5.10.5 and added Remark 5.10.5.1.

Corollary 5.10.5.

(i) For every subtorus Q of G, $\underline{\mathrm{Centr}}_G(Q)$ is critical.

(ii) For every subgroup H of G of type (R) with reductive fibers, $\mathrm{rad}(H)$ is a C-critical torus of G.

(iii) The maps
$$Q \longmapsto \underline{\mathrm{Centr}}_G(Q), \qquad H \longmapsto \mathrm{rad}(H)$$
are mutually inverse bijections between the set of C-critical tori of G and the set of its critical reductive subgroups of type (R).

(iv) If Q is a torus of G, then
$$\mathrm{rad}(\underline{\mathrm{Centr}}_G(Q))$$
is the smallest C-critical torus of G containing Q.

(v) If H is a reductive subgroup of G of type (R), then
$$\underline{\mathrm{Centr}}_G(\mathrm{rad}(H))$$
is the smallest critical reductive subgroup of G of type (R) containing H.

Remark 5.10.5.1. (58)

1) A torus T of G is a critical subgroup of G if and only if it is a maximal torus.

2) Henceforth, "critical torus" means "C-critical torus".

Proposition 5.10.6. *Let (G, T, M, R) be a split S-group, and let R' be a subset of R. The following conditions are equivalent:*

(i) *R' is of type* (R)*, and $H_{R'}$ is reductive and critical.*

(ii) *There exist a system Δ of simple roots of R and a subset Δ' of Δ such that R' is the set of those elements of R that are linear combinations of elements of Δ'.*

(iii) *R' is closed and symmetric, and every system of simple roots of R' is the intersection with R' of a system of simple roots of R.*

Indeed, by Exposé XXI, 3.4.8, conditions (ii) and (iii) are equivalent; they are also equivalent to the condition that R' be the intersection of R with a $\mathbf{Q}$-vector subspace of $M \otimes \mathbf{Q}$. This last condition follows from (i): if
$$H_{R'} = \underline{\mathrm{Centr}}_G(Q),$$
then R' is the set of elements of R that vanish on Q (Exposé II, 5.2.3(ii)). Conversely, this condition implies (i), because $\mathrm{rad}(H_{R'})$ is the maximal torus of
$$\bigcap_{\alpha \in R'} \mathrm{Ker}(\alpha).$$
Consequently,
$$\underline{\mathrm{Centr}}_G(\mathrm{rad}(H_{R'})) = H_{R''},$$
where R'' is the intersection of R with the vector subspace spanned by R'; hence $R'' = R'$. □

5.10.7. Let us summarize some of the preceding results. Let (G, T, M, R) be a split S-group, let Δ be a system of simple roots of R, and let R_+ be the corresponding system of positive roots. Choose a subset Δ' of Δ, denote by R' the set of those elements of R which are linear combinations of elements of Δ', and put

$$R'_+ = R' \cap R_+.$$

Let $T_{\Delta'}$ be the maximal torus of

$$\bigcap_{\alpha \in \Delta'} \mathrm{Ker}(\alpha)$$

and put

$$Z_{\Delta'} = \underline{\mathrm{Centr}}_G(T_{\Delta'}).$$

Then $Z_{\Delta'}$ is a reductive subgroup of G, with radical $T_{\Delta'}$; $(Z_{\Delta'}, T, M, R')$ is a split S-group; $B_{R_+} \cap Z_{\Delta'}$ is the Borel subgroup of $Z_{\Delta'}$ defined by the system R'_+ of positive roots (or, equivalently, by the system Δ' of simple roots), and its unipotent part is

$$U_{R_+} \cap Z_{\Delta'} = U_{R'_+}.$$

Remark 5.10.8. Under the conditions of 5.10.4, let Q be a critical torus of G, and let

$$L = \underline{\mathrm{Centr}}_G(Q)$$

be its centralizer. Since $Q = \mathrm{rad}(L)$, Q is a characteristic subgroup of L; it follows at once that

$$\underline{\mathrm{Norm}}_G(L) = \underline{\mathrm{Norm}}_G(Q),$$

and hence also that

$$\underline{\mathrm{Norm}}_G(L)/L = \underline{\mathrm{Norm}}_G(Q)/\underline{\mathrm{Centr}}_G(Q) = W_G(Q).$$

By 5.10.2, we deduce:

Proposition 5.10.9. *Let S be a scheme, let G be a reductive S-group, and let Q be a critical torus of G. The Weyl group $W_G(Q)$ is finite* (étale) *over S.*

Remark 5.10.10. Under the conditions of 5.10.7, one may describe explicitly

$$W_G(T_{\Delta'}) = \underline{\mathrm{Norm}}_G(Z_{\Delta'})/Z_{\Delta'}.$$

This is the constant group associated with the quotient W_1/W_2, where W_1 is the subgroup of W consisting of those elements which normalize the subgroup of M generated by Δ', and W_2 is the subgroup of W generated by the s_α, for $\alpha \in \Delta'$.

5.11. Subgroups of Type (RC)

Definition 5.11.1. Let S be a scheme and let G be a reductive S-group. A group subscheme H of G is said to be *of type* (RC) if it is of type (R), that is, if it satisfies the following two conditions from 5.2.1:

(i) H is smooth over S, with connected fibers;

(ii) for every $s \in S$, $H_{\bar{s}}$ contains a maximal torus of $G_{\bar{s}}$;

and if it also satisfies the following condition:

(iii) for every $s \in S$ and every maximal torus T of $H_{\bar{s}}$, the set of roots of $H_{\bar{s}}$ relative to T is a closed subset of the set of all roots of $G_{\bar{s}}$ relative to T.

Remark 5.11.2. As we already observed in 5.4.8, condition (iii) follows from the other two when 6 is invertible on S.[59]

Lemma 5.11.3. *Let (G, T, M, R) be a split S-group, and let R' be a closed subset of R. Put*

$$R_1 = \{\alpha \in R' \mid -\alpha \in R'\}, \qquad R_2 = \{\alpha \in R' \mid -\alpha \notin R'\}.$$

Then R_1 and R_2 are closed. Consider the groups $H_{R'}$, H_{R_1}, and U_{R_2} (5.4.7 and 5.6.5), which are smooth and have connected fibers.

(i) *U_{R_2} is normal in $H_{R'}$, and $H_{R'}$ is the semidirect product of U_{R_2} by H_{R_1}.*

(ii) *The group H_{R_1} is reductive, and U_{R_2} has connected unipotent geometric fibers. Every normal subgroup scheme of $H_{R'}$ that is smooth over S and has connected unipotent geometric fibers is contained in U_{R_2}. Every reductive subgroup of $H_{R'}$ that contains T is contained in H_{R_1}.*

(iii)
$$U_{R_2} \cap \underline{\mathrm{Norm}}_G(H_{R_1}) = e.$$

Let us first prove (iii), which follows from 5.6.7(i). The first assertion of (i) follows from 5.6.7(ii). Since

$$U_{R_2} \cap H_{R_1} = e$$

by (iii), the semidirect product $H_{R_1} \cdot U_{R_2}$ is a subgroup of $H_{R'}$. But these are two subgroups of G of type (R), containing T, and having the same Lie algebra $\mathfrak{g}_{R'}$; they coincide by 5.3.5, which proves (i).

For (ii), the first two assertions are merely 5.10.1 and 5.6.5. Let U be a subgroup scheme of $H_{R'}$, smooth and of finite presentation over S, normal in $H_{R'}$ (and hence normalized by T), and with connected unipotent geometric fibers. By 5.6.12, locally one has $U = U_{R''}$, where $R'' \subset R'$ and

$$R'' \cap (-R'') = \varnothing.$$

If U were not contained in U_{R_2}, then R'' would not be contained in R_2; there would therefore exist $\alpha \in R''$ such that $-\alpha \in R'$. Then $Z_\alpha \subset H_{R'}$ by 5.4.3, so Z_α normalizes U. But U contains U_α, and Z_α has a section w such that

$$\mathrm{int}(w)U_\alpha = U_{-\alpha};$$

thus $-\alpha \in R''$, a contradiction.

Finally, if L is a reductive subgroup of $H_{R'}$ containing T, locally one has $L = H_{R'''}$, where R''' is symmetric and contained in R'; hence $R''' \subset R_1$. □

Proposition 5.11.4. *Let S be a scheme, let G be a reductive S-group, and let H be a subgroup scheme of G of type* (RC).

(i) *H is closed in G, and $\underline{\mathrm{Norm}}_G(H)/H$ is representable by a finite étale S-group scheme.*

(ii) *H has a largest normal subgroup scheme that is smooth and of finite presentation over S, with connected unipotent geometric fibers. It is called the* unipotent radical *of H and is denoted $\mathrm{rad}^u(H)$. The quotient sheaf*

$$H/\mathrm{rad}^u(H)$$

is representable by a reductive S-group.

[59] Editor's note: That is, when every residue characteristic of S is greater than 3.

(iii) *If T is a maximal torus of H, then H has a reductive subgroup L, containing T, of type* (RC)*, with the following properties:*

(a) *every reductive subgroup of H containing T is contained in L;*

(b) *H is the semidirect product*

$$H = L \cdot \mathrm{rad}^u(H);$$

in other words, the canonical morphism

$$L \longrightarrow H/\mathrm{rad}^u(H)$$

is an isomorphism.

Moreover, L is the unique reductive subgroup of H that contains T and satisfies either one of the two preceding conditions. Finally,

$$\underline{\mathrm{Norm}}_H(L) = L, \qquad \underline{\mathrm{Norm}}_H(T) = \underline{\mathrm{Norm}}_L(T), \qquad W_H(T) = W_L(T);$$

in particular, $W_H(T)$ is finite over S.

Proof. First observe that (i) is local for the étale topology. Thus, by Corollary 5.3.18, (i) follows from the last assertion of (iii).

The assertions of (ii) are local for the étale topology. We may therefore suppose ourselves in the situation of 5.11.3, where they follow immediately from (i) and (ii).

By virtue of the uniqueness assertions contained there, (iii) is likewise local for the étale topology, and we may again reduce to the situation of 5.11.3, where properties (a) and (b) have been verified. The uniqueness of an L satisfying (a) is immediate; in view of (a), the uniqueness of an L satisfying (b) is clear. The equality

$$\underline{\mathrm{Norm}}_H(L) = L$$

is precisely 5.11.3(iii). If a section of H normalizes T, then it normalizes L, by the uniqueness of L, and hence is a section of L by what we have just proved. This proves the second equality; the third is then immediate.

Proposition 5.11.5. *Let S be a scheme, let G be a reductive S-group, and let $\mathcal{H}_c$ be the functor of subgroups of G of type* (RC)*, which is a subfunctor of the functor $\mathcal{H}$ of 5.8.1.*

(i) *$\mathcal{H}_c$ is representable by an open subscheme of $\mathcal{H}$, smooth, quasi-projective, and of finite presentation over S.*

(ii) *There exist a finite étale S-scheme $\mathcal{C}\ell_c$ and a morphism*

$$\mathrm{cl}\colon \mathcal{H}_c \longrightarrow \mathcal{C}\ell_c$$

that is smooth, quasi-projective, of finite presentation, surjective, and has connected geometric fibers, with the following property:

For every $S' \to S$ and all $H, H' \in \mathcal{H}_c(S')$, one has $\mathrm{cl}(H) = \mathrm{cl}(H')$ if and only if H and H' are conjugate in G locally for the étale topology (or, equivalently by 5.3.11, if for every $s \in S$, $H_{\bar{s}}$ and $H'_{\bar{s}}$ are conjugate by an element of $G(\bar{s})$).

(iii) *$\mathcal{C}\ell_c$ and* cl *are determined* (up to a unique isomorphism) *by the preceding conditions.*

(iv) *If (G, T, M, R) is a splitting of G, let E be the set of conjugacy classes modulo W of closed subsets of R. Then there is an isomorphism*

$$\mathcal{C}\ell_c \xrightarrow{\sim} E_S$$

such that, for every closed subset R' of R, $\mathrm{cl}(H_{R'})$ corresponds to the canonical image of R' in

$$E_S(S) = \mathrm{Hom}_{\mathrm{loc.const.}}(S, E).$$

It is first of all clear that $\mathcal{H}_c$ is a sheaf for the étale topology, and that (ii) implies that $\mathcal{C}\ell_c$ is simply the quotient sheaf of $\mathcal{H}_c$ by the equivalence relation defined by conjugation.

This first implies (iii), as well as the fact that it suffices to verify (i) and (ii) locally for the étale topology. We are therefore reduced to the situation of (iv); let us first construct a morphism

$$f\colon \mathcal{H}_c \longrightarrow E_S.$$

It suffices to construct a map $\mathcal{H}_c(S) \to E_S(S)$, functorial in S; let H be a subgroup of G of type (RC). Since H locally for the étale topology has maximal tori, and since the maximal tori of G are locally conjugate for the étale topology, there exist a covering family $(S_i \to S)$, elements $g_i \in G(S_i)$, and closed subsets R_i of R such that

$$\mathrm{int}(g_i)(H \times_S S_i) = H_{R_i} \times_S S_i.$$

Each R_i defines a section η_i of E_{S_i}, that is, an element of $E_S(S_i)$. It remains to prove that the family (η_i) comes from a section $\eta = f(H)$ of E_S over S, and that it depends only on H.

For this it is enough to prove that $H_{R'}$ and $H_{R''}$ are locally conjugate for the étale topology if and only if R' and R'' are conjugate by an element of the Weyl group W, which is clear.

For every $\eta \in E$, there exists $H_0 \in \mathcal{H}_c(S)$ such that $f(H_0) = \eta$: take $H_0 = H_{R'}$, where R' is a closed subset whose image is η. If $H \in \mathcal{H}_c(S')$, for $S' \to S$, then H is locally conjugate to H_0 if and only if $f(H) = \eta$. Consequently,

$$f^{-1}(\eta) \simeq G/\underline{\mathrm{Norm}}_G(H_0),$$

which, by 5.8.2, is an open subscheme of $\mathcal{H}$, smooth, quasi-projective, and of finite presentation over S, with nonempty connected fibers. Since E_S is the disjoint union of the open subschemes that are the images of the sections corresponding to the elements $\eta \in E$, $\mathcal{H}_c$ identifies with the disjoint union of the $f^{-1}(\eta)$. This proves (i) and (ii); assertion (iv) follows from the construction.

Corollary 5.11.6. *Let $u \in \mathcal{C}\ell_c(S')$, where $S' \to S$. Then $\mathrm{cl}^{-1}(u)$ is a smooth, quasi-projective S'-scheme of finite presentation, with nonempty connected fibers. It is an open subscheme of $\mathcal{H}_c$ and a "homogeneous" scheme under $G_{S'}$* (acting by inner automorphisms).

In particular, if $H \in \mathrm{cl}^{-1}(u)(S')$, the morphism

$$G_{S'} \longrightarrow (\mathcal{H}_c)_{S'}, \qquad g \longmapsto \mathrm{int}(g)H$$

identifies

$$G_{S'}/\underline{\mathrm{Norm}}_{G_{S'}}(H) \quad \textit{with} \quad \mathrm{cl}^{-1}(u).$$

Examples 5.11.7. There are two canonical sections u_t and u_b of $\mathcal{C}\ell_c$. The section u_t corresponds to maximal tori, for which $R' = \varnothing$. The section u_b corresponds to Borel subgroups, for which R' is a system of positive roots. The schemes $\mathrm{cl}^{-1}(u_t)$ and $\mathrm{cl}^{-1}(u_b)$ are respectively $\underline{\mathrm{Tor}}(G)$ and $\underline{\mathrm{Bor}}(G)$, introduced in 5.8.3. Other examples will be given in Exposé XXVI.

Remark 5.11.8. One can construct an S-scheme $\mathcal{C}\ell$, of finite presentation and unramified over S, and a smooth surjective morphism

$$\mathcal{H} \longrightarrow \mathcal{C}\ell$$

with connected geometric fibers, having properties analogous to those of 5.11.5(ii) and (iii).

6. The Derived Group

6.1. Preliminaries

In this section, we fix a scheme S, a split S-group (G, T, M, R), and a system R_+ of positive roots of R. We write

$$B = B_{R_+}, \qquad B^- = B_{R_-}, \qquad U = B^u, \qquad U^- = (B^-)^u,$$

and

$$\Omega = \Omega_{R_+} = U^- \cdot T \cdot U.$$

6.1.1. Let T' denote the subtorus of T that is the "image of the family α^*, $\alpha \in R$"; in other words, T' is the image of the homomorphism

$$(\mathbb{G}_{m,S})^R \longrightarrow T$$

defined by

$$(z_\alpha)_{\alpha\in R} \longmapsto \prod_{\alpha\in R} \alpha^*(z_\alpha).$$

It follows at once that, if Δ denotes the set of simple roots of R_+, the homomorphism

$$(\mathbb{G}_{m,S})^\Delta \longrightarrow T'$$

defined in the same way is surjective and has finite kernel. If we identify T with $D_S(M)$, then T' identifies with $D_S(M/N)$, where

$$N = M \cap V(R^*)^\perp$$

(we write $V(R^*)^\perp$ for the orthogonal complement of $V(R^*)$ under the duality between V and V^*).

Lemma 6.1.2. *The homomorphism defined by multiplication in T,*

$$\mathrm{rad}(G) \times_S T' \longrightarrow T,$$

is an isogeny (cf. 4.2.9).

Indeed, the canonical homomorphism

$$\mathrm{rad}(T) \longrightarrow T/T'$$

comes by duality from the homomorphism of commutative groups

$$M \cap V(R^*)^\perp \longrightarrow M/(M \cap V(R)),$$

which is immediately seen to be injective with finite cokernel (cf. Exposé XXI, 6.3).

Definition 6.1.3. We put

$$\Omega' = U^- \cdot T' \cdot U;$$

this is a closed subscheme of $\Omega = U^- \cdot T \cdot U$.

Lemma 6.1.4. *Let α be a simple root and let $w_\alpha \in \underline{\mathrm{Norm}}_G(T)(S)$ lift s_α. Then*

$$\mathrm{int}(w_\alpha)\Omega' \cap \Omega \subset \Omega'.$$

It is enough to prove that, if $g \in \Omega'(S)$ and $\mathrm{int}(w_\alpha)g \in \Omega(S)$, then $\mathrm{int}(w_\alpha)g \in \Omega'(S)$. By 5.6.8, write

$$g = a \exp_{-\alpha}(Y) t \exp_\alpha(X) b,$$

where

$$a \in U_{-\widehat{\alpha}}(S), \qquad Y \in \Gamma(S, \mathfrak{g}^{-\alpha}), \qquad t \in T'(S), \qquad X \in \Gamma(S, \mathfrak{g}^{\alpha}), \qquad b \in U_{\widehat{\alpha}}(S).$$

We then have

$$\mathrm{int}(w_\alpha)g = \mathrm{int}(w_\alpha)a \cdot \mathrm{int}(w_\alpha)\big(\exp_{-\alpha}(Y) t \exp_\alpha(X)\big) \cdot \mathrm{int}(w_\alpha)b.$$

By 5.6.8(iv),

$$\mathrm{int}(w_\alpha)a \in U_{-\widehat{\alpha}}(S), \qquad \mathrm{int}(w_\alpha)b \in U_{\widehat{\alpha}}(S).$$

It follows that, on putting

$$h = \exp_{-\alpha}(Y) t \exp_\alpha(X),$$

we have the equivalences

$$\mathrm{int}(w_\alpha)g \in \Omega(S) \quad \Longleftrightarrow \quad \mathrm{int}(w_\alpha)h \in \Omega(S),$$

and

$$\mathrm{int}(w_\alpha)g \in \Omega'(S) \quad \Longleftrightarrow \quad \mathrm{int}(w_\alpha)h \in \Omega'(S).$$

We are therefore reduced to the case $g = h$. Since, by (4.1.12),

$$Z_\alpha \cap \Omega = U_{-\alpha} \cdot T \cdot U_\alpha, \qquad Z_\alpha \cap \Omega' = U_{-\alpha} \cdot T' \cdot U_\alpha,$$

we are reduced to proving the following assertion:

$$\mathrm{int}(w_\alpha)h \in \big(U_{-\alpha} \cdot T \cdot U_\alpha\big)(S) \quad \Longrightarrow \quad \mathrm{int}(w_\alpha)h \in \big(U_{-\alpha} \cdot T' \cdot U_\alpha\big)(S).$$

But this follows at once from Exposé XX, 3.12, which shows that the T-component of $\mathrm{int}(w_\alpha)h$ is of the form

$$t \cdot \alpha^*(z) \in T'(S).$$

Lemma 6.1.5. *For every $w \in \underline{\mathrm{Norm}}_G(T)(S)$, there exists an open subscheme V_w of G, containing the unit section, such that*

$$\mathrm{int}(w)\Omega' \cap V_w \subset \Omega'.$$

For each simple root α, choose an element $n_\alpha \in \underline{\mathrm{Norm}}_G(T)(S)$ lifting s_α. For every point $s \in S$, there exist an open subscheme V of S containing s, an element $t \in T(V)$, and, over V, a relation

$$w = n_{\alpha_1} \cdots n_{\alpha_p} t,$$

where the α_i are simple. We may plainly restrict ourselves to proving the result when $V = S$; we argue by induction on p. If $p = 0$, then $w \in T(S)$, and we take $V_w = G$. Suppose, therefore, that $w = n_\alpha w'$, where w' satisfies the conclusion of the lemma. There is then an open subscheme $V_{w'}$ of G, containing the unit section, such that

$$\mathrm{int}(w')\Omega' \cap V_{w'} \subset \Omega'.$$

We may then write

$$\begin{aligned}\mathrm{int}(w)\Omega' \cap \mathrm{int}(n_\alpha)V_{w'} \cap \Omega &= \mathrm{int}(n_\alpha)\big(\mathrm{int}(w')\Omega' \cap V_{w'}\big) \cap \Omega \\ &\subset \mathrm{int}(n_\alpha)\Omega' \cap \Omega \subset \Omega',\end{aligned}$$

by 6.1.4. We now take

$$V_w = \mathrm{int}(n_\alpha)V_{w'} \cap \Omega,$$

and the proof is complete.

Lemma 6.1.6. *There exists an open subscheme V_0 of G, containing the unit section, such that for every $S' \to S$,*

$$U(S')U^-(S') \cap V_0(S') \subset \Omega'(S').$$

Let n_0 be an element of $\underline{\mathrm{Norm}}_G(T)(S)$ lifting the symmetry w_0 of the Weyl group,[60] that is, such that

$$\mathrm{int}(n_0)U = U^- \qquad \text{(cf. Exposé XXI, 3.6.14).}$$

Then $n_0^2 \in T(S)$. We show that the open subscheme $V_0 = V_{n_0}$ of 6.1.5 has the required property. Indeed,

$$\begin{aligned}U(S')U^-(S') &= \mathrm{int}(n_0)\big(\mathrm{int}(n_0)^{-1}U(S') \cdot \mathrm{int}(n_0)^{-1}U^-(S')\big) \\ &= \mathrm{int}(n_0)\big(U^-(S') \cdot U(S')\big) \subset \mathrm{int}(n_0)\Omega'(S').\end{aligned}$$

Consequently,

$$U(S')U^-(S') \cap V_0(S') \subset \mathrm{int}(n_0)\Omega'(S') \cap V_0(S') \subset \Omega'(S').$$

[60] Editor's note: The symmetry w_0 is defined in Exposé XXI, 3.6.14.

Lemma 6.1.7. *Consider the morphism*

$$f : \Omega = U^- \cdot T \cdot U \longrightarrow T/T'$$

obtained by composing the second projection with the canonical morphism from T to T/T'. Then f is "generically multiplicative": there exists an open subscheme V of $\Omega \times_S \Omega$, containing the unit section (and hence relatively schematically dense, Exposé XVIII, 1.3)*, such that for every $S' \to S$ and every $(x, y) \in V(S')$, one has $xy \in \Omega(S')$ and*

$$f(xy) = f(x)f(y).$$

Let x, y be sections of Ω over S'. Write

$$x = utv, \qquad y = u't'v',$$

where

$$u, u' \in U^-(S'), \qquad t, t' \in T(S'), \qquad v, v' \in U(S').$$

Let V_0 be the open subscheme of 6.1.6, and let V be the open subscheme of $\Omega \times_S \Omega$ defined by the condition

$$vu' \in V_0(S').$$

This open subscheme has the required property. Indeed, if $(x, y) \in V(S')$, then

$$xy = (utv)(u't'v') = (ut)(vu')(t'v').$$

Since $vu' \in \Omega'(S')$, we obtain

$$xy \in U^-(S')\, t\Omega'(S')t'\, U(S') \subset U^-(S')\, tt'T'(S')\, U(S'),$$

and therefore $xy \in \Omega(S')$ and

$$f(xy) = f(tt') = f(t)f(t') = f(x)f(y).$$

Proposition 6.1.8. *There exists a group morphism*

$$f : G \longrightarrow T/T'$$

inducing the canonical projection on T. The kernel $\mathrm{Ker}(f)$ *of f is a closed subgroup scheme of G, smooth over S, with connected fibers. Every group morphism from G to an S-presheaf of commutative groups that is separated for the fppf topology vanishes on* $\mathrm{Ker}(f)$.

The first assertion follows at once from 4.1.11. We immediately have

$$\mathrm{Ker}(f) \cap \Omega = \Omega',$$

which proves that $\mathrm{Ker}(f)$ is smooth over S at every point of the unit section.[61] By 5.6.9(ii), every morphism ϕ from G to an S-presheaf of commutative groups that is separated for the fppf topology vanishes on U and on U^-. By Exposé XX, 2.7, ϕ also vanishes on T', and hence on Ω'. Using the notation of 5.7.10, we see that the monoid U_1 is contained in $\mathrm{Ker}(f)(S)$, which shows that

$$\mathrm{Ker}(f) = \bigcup_{u \in U_1} u\Omega'.$$

It follows, on the one hand, that every ϕ as above vanishes on $\mathrm{Ker}(f)$, and, on the other hand, that $\mathrm{Ker}(f)$ has connected fibers and is therefore smooth over S, by Exposé $\mathrm{VI_B}$, 3.10.

[61] Editor's note: We have added "at every point of the unit section," as well as the reference to Exposé $\mathrm{VI_B}$, 3.10, at the end of the proof. Moreover, in the following sentence "prescheme" has been replaced by "presheaf."

6.2. The Derived Group of a Reductive Group

Theorem 6.2.1. *Let S be a scheme and G a reductive S-group.*

(i) *The group*

$$\mathrm{D}_S(G) = \underline{\mathrm{Hom}}_{S\text{-gr.}}(G, \mathbb{G}_{m,S})$$

is represented by a twisted constant S-group whose type at $s \in S$ is

$$\mathbb{Z}^{\mathrm{rgred}(G_s)-\mathrm{rgss}(G_s)}.$$

(ii) *Write*

$$\mathrm{corad}(G) = \mathrm{D}_S\big(\mathrm{D}_S(G)\big),$$

which is therefore an S-torus. The biduality morphism (cf. Exposé VIII, §1)

$$f_0 : G \longrightarrow \mathrm{corad}(G)$$

is smooth and surjective.

(iii) *The composite morphism*

$$\mathrm{rad}(G) \longrightarrow G \longrightarrow \mathrm{corad}(G)$$

is an isogeny (cf. 4.2.9).

(iv) *The kernel of f_0, denoted*

$$\mathrm{der}(G) = \mathrm{Ker}(f_0),$$

is a closed subgroup scheme of G, semisimple over S, called the derived group of G. If G is semisimple, then $\mathrm{der}(G) = G$.

(v) *Every group morphism from G to an S-presheaf of commutative groups that is separated for the fppf topology vanishes on* $\mathrm{der}(G)$*, and therefore factors through f_0.*

Proof. All the assertions of the theorem are local for the étale topology; we may therefore reduce to the case in which G is split over S. Consider the morphism f of 6.1.8. By the last assertion of 6.1.8, we immediately have an isomorphism

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, \mathbb{G}_{m,S}) \xrightarrow{\sim} \underline{\mathrm{Hom}}_{S\text{-gr.}}(T/T', \mathbb{G}_{m,S}),$$

which proves (i), then (ii), and yields a commutative diagram

$$\begin{array}{ccc} G & \xrightarrow{f_0} & \mathrm{corad}(G) \\ & \searrow^{f} & \downarrow \sim \\ & & T/T'. \end{array}$$

Assertion (v) now follows from 6.1.8, and (iii) from 6.1.2. We also have $\mathrm{Ker}(f) = \mathrm{Ker}(f_0)$, which, by 6.1.8, implies that $\mathrm{der}(G)$ is smooth over S with connected fibers. It remains to verify that its fibers are semisimple. They are reductive by Exposé XIX, 1.7, as invariant subgroups of reductive groups. By (iii), $\mathrm{rad}(G) \cap \mathrm{der}(G)$ is finite, which indeed implies that the fibers of $\mathrm{der}(G)$ are semisimple.

Remark 6.2.2. a) By construction, when G is split, $\mathrm{der}(G)$ is the fppf subsheaf of G generated by the U_α, $\alpha \in R$. It even suffices to take the U_α, $\alpha \in \Delta \cup -\Delta$, where Δ is a base of R.

b)[62] Let C be the presheaf of commutators of G, that is, the S-functor in groups that assigns to every $S' \to S$ the commutator subgroup of $G(S')$ (that is, the subgroup of $G(S')$ generated by the elements $xyx^{-1}y^{-1}$, for $x, y \in G(S')$), and let $\widetilde{C}$ be the associated fppf sheaf. Since the quotient $G/\mathrm{der}(G) = T/T'$ is commutative, $\mathrm{der}(G)$ contains C, and hence $\widetilde{C}$ (cf. Exposé IV, 4.3.12).

On the other hand, the quotient presheaf $G/\widetilde{C}$ is separated (Exposé IV, 4.4.8.1), and therefore, by (v), we have $\mathrm{der}(G) \subset \widetilde{C}$. Thus $\mathrm{der}(G) = \widetilde{C}$; in other words, $\mathrm{der}(G)$ is the fppf sheaf of commutators of G.

Let us finally note that, since C is a subpresheaf of G, it is separated, but it is not equal to $\mathrm{der}(G)$ in general: for example, $\mathrm{der}(\mathrm{SL}_2) = \mathrm{SL}_2$, whereas $\mathrm{SL}_2(\mathbb{F}_2) \simeq \mathfrak{S}_3$ is not equal to its commutator subgroup.

c) When S is the spectrum of an algebraically closed field k, $\mathrm{der}(G)(k)$ is the commutator subgroup of $G(k)$ (Exposé $\mathrm{VI_B}$, 7.10).

6.2.3. Consider now the two exact sequences

$$1 \longrightarrow \mathrm{rad}(G) \longrightarrow G \longrightarrow \mathrm{ss}(G) \longrightarrow 1,$$
$$1 \longrightarrow \mathrm{der}(G) \longrightarrow G \longrightarrow \mathrm{corad}(G) \longrightarrow 1.$$

Since $\mathrm{rad}(G)$ is central in G, multiplication in G defines a group morphism

$$u : \mathrm{rad}(G) \times_S \mathrm{der}(G) \longrightarrow G,$$

which is covering by 6.2.1(iii), and hence surjective and flat (Exposé $\mathrm{VI_B}$, 9.2(xi)). [63] Its kernel is isomorphic to $\mathrm{rad}(G) \cap \mathrm{der}(G)$, which is also the kernel of

$$\mathrm{rad}(G) \longrightarrow \mathrm{corad}(G);$$

it is a finite subgroup of multiplicative type of $\mathrm{rad}(G)$. Similarly, the kernel of the morphism

$$G \longrightarrow \mathrm{corad}(G) \times_S \mathrm{ss}(G)$$

is isomorphic to $\mathrm{der}(G) \cap \mathrm{rad}(G)$.

Proposition 6.2.4. *Let G be a reductive S-group. The three morphisms*

$$\mathrm{rad}(G) \times_S \mathrm{der}(G) \longrightarrow G,$$
$$G \longrightarrow \mathrm{corad}(G) \times_S \mathrm{ss}(G),$$
$$\mathrm{rad}(G) \longrightarrow \mathrm{corad}(G)$$

are central isogenies, and their kernels are isomorphic.

[62] Editor's note: In what follows, we have expanded the original and removed the assertion that "$\mathrm{der}(G)$ is the fppf-separated presheaf of commutators of G."

[63] Editor's note: Indeed, G is the fppf quotient of $\mathrm{rad}(G) \times_S \mathrm{der}(G)$ by $\mathrm{Ker}(u)$, which is a group of multiplicative type and hence is flat over S. Therefore, by Exposé $\mathrm{VI_B}$, 9.2(xi), u is flat.

Corollary 6.2.5. *The following conditions are equivalent:*

(i) *G is the product of a semisimple group and a torus.*

(ii) *The morphism*
$$\mathrm{rad}(G) \times_S \mathrm{der}(G) \xrightarrow{\sim} G$$
is an isomorphism.

(iii) *The morphism*
$$G \xrightarrow{\sim} \mathrm{corad}(G) \times_S \mathrm{ss}(G)$$
is an isomorphism.

(iv) $\mathrm{rad}(G) \cap \mathrm{der}(G) = e$.

6.2.6. Let us return temporarily to the case of a split group. We retain the notation of 6.1. Put
$$N = M \cap V(R^*)^\perp, \qquad \text{so that} \qquad T' = \mathrm{D}_S(M/N).$$
Then $U^- \cdot T' \cdot U$ is an open neighborhood of the unit section in $\mathrm{der}(G)$. Consequently,
$$\mathrm{Lie}\big(\mathrm{der}(G)/S\big) = \mathfrak{t}' \oplus \coprod_{\alpha \in R} \mathfrak{g}^\alpha.$$
Since the characters induced on T' by the $\alpha \in R$ are nonzero and distinct (Exposé XXI, 1.2.5—which we already used in 6.1.2), R is a root system of $\mathrm{der}(G)$ relative to T'. It is then immediate (since $U_\alpha \subset \mathrm{der}(G)$) that the exp-morphisms of $\mathrm{der}(G)$ "are" those of G, and likewise for the coroots.

It follows that:

Proposition 6.2.7. *With the preceding notation,*
$$\big(\mathrm{der}(G), T', M/N, R\big)$$
is a split group with root datum $\mathrm{der}\big(\mathcal{R}(G)\big)$. *The canonical morphism* $\mathrm{der}(G) \to G$ *induces, by functoriality, the canonical morphism of root data*
$$\mathcal{R}(G) \longrightarrow \mathrm{der}\big(\mathcal{R}(G)\big)$$
of Exposé XXI, 6.5.

N.B. As an exercise, the reader may construct the diagram of split groups corresponding to the three left-hand columns of the diagram of root data in Exposé XXI, 6.5.7.

Proposition 6.2.8. *Let S be a scheme, G a reductive S-group, and* $\mathrm{der}(G)$ *its derived group.*

(i) *For every maximal torus T of G, $T \cap \mathrm{der}(G)$ is a maximal torus of* $\mathrm{der}(G)$. *For every maximal torus T' of* $\mathrm{der}(G)$,
$$\underline{\mathrm{Centr}}_G(T') = \mathrm{rad}(G) \cdot T'$$
is a maximal torus of G. These two constructions are inverse to one another and establish a bijective correspondence between the maximal tori of G and those of $\mathrm{der}(G)$.

(ii) *For every Borel subgroup B of G, $B \cap \mathrm{der}(G)$ is a Borel subgroup B' of $\mathrm{der}(G)$. We have $B'^u = B^u$. For every Borel subgroup B' of $\mathrm{der}(G)$,*

$$\underline{\mathrm{Norm}}_G(B') = \mathrm{rad}(G) \cdot B'$$

is a Borel subgroup of G. These constructions are inverse to one another and establish a bijective correspondence between the Borel subgroups of G and those of $\mathrm{der}(G)$.

By the local conjugacy theorem for maximal tori and the construction of the derived group, the only assertion that remains to be proved in (i) is the following: if T is a maximal torus of G, then

$$T = \big(T \cap \mathrm{der}(G)\big) \cdot \mathrm{rad}(G) = \underline{\mathrm{Centr}}_G\big(T \cap \mathrm{der}(G)\big).$$

The first equality is immediate (since we may reduce to the split case); the second follows at once, because $\mathrm{rad}(G)$ is central in G, and hence

$$T = \underline{\mathrm{Centr}}_G(T) = \underline{\mathrm{Centr}}_G\big(T \cap \mathrm{der}(G)\big).$$

The argument for (ii) is the same.

6.3. Subgroups with Commutative Quotients

6.3.1. Let G be a reductive S-group. If H is a subsheaf in groups of G, the following conditions are equivalent:

- H contains $\mathrm{der}(G)$;
- H is normal and G/H is commutative.

In this case, the canonical morphism

$$f_0 : G \longrightarrow \mathrm{corad}(G)$$

maps H onto a subsheaf $f_0(H)$ of $\mathrm{corad}(G)$, and we have

$$G/H \simeq \mathrm{corad}(G)/f_0(H), \qquad H/\mathrm{der}(H) \simeq f_0(H),$$
$$\mathrm{der}(G) = \mathrm{der}(H), \qquad H = f_0^{-1}(f_0(H)).$$

Since $\mathrm{der}(G)$ is smooth over S with connected fibers,[64] it follows from Exposé IV, 5.3.1 and 6.3.1, and Exposé IV_B, 9.2, that the assignment

$$H \longmapsto f_0(H)$$

establishes a bijective correspondence between the group subschemes (respectively, the closed group subschemes) of G that contain $\mathrm{der}(G)$, are smooth over S, and have connected fibers, and the group subschemes (respectively, the closed group subschemes) of $\mathrm{corad}(G)$ that are smooth over S and have connected fibers.

Now, if H' is a group subscheme of $\mathrm{corad}(G)$, smooth over S with connected fibers, then H' is of finite presentation over S (Exposé VI_B, 5.5), and its fibers are tori (because those of $\mathrm{corad}(G)$ are). Hence, by Exposé X, 8.2, H' is a subtorus of $\mathrm{corad}(G)$, and is therefore closed in $\mathrm{corad}(G)$ (Exposé IX, 2.6).

Consequently, every subgroup of G that is smooth with connected fibers and contains $\mathrm{der}(G)$ is closed in G.

[64] Editor's note: We have expanded the original in what follows. In particular, we have added the conclusion, implicit in the original, that every subgroup of G that is smooth with connected fibers and contains $\mathrm{der}(G)$ is closed in G.

6.3.2. If H is a closed group subscheme of G, smooth over S, with connected fibers, and normal in G, then H is reductive. If, moreover, $H \supset \mathrm{der}(G)$, then

$$\mathrm{der}(H) = \mathrm{der}(G) \qquad \text{and} \qquad f_0(H) \simeq \mathrm{corad}(H).$$

We have therefore proved the following proposition.

Proposition 6.3.3. *Let G be a reductive S-group. Every group subscheme H of G that is normal in G, has commutative quotient* (that is, contains $\mathrm{der}(G)$)*, is smooth over S, and has connected fibers*[65] *is closed and reductive. We have*

$$\mathrm{der}(H) = \mathrm{der}(G), \qquad f_0(H) \simeq \mathrm{corad}(H),$$

and

$$G/H \simeq \mathrm{corad}(G)/\mathrm{corad}(H), \qquad H = \big(H \cap \mathrm{rad}(G)\big) \cdot \mathrm{der}(G).$$

Moreover, the assignment $H \mapsto f_0(H)$ defines a bijection between the set of subgroups H of G having the preceding properties and the set of subtori of $\mathrm{corad}(G)$.

By another application of Noether's theorem (Exposé IV, 5.3.1 and 6.3.1), we deduce the following.

Proposition 6.3.4. *Let S be a scheme, G a reductive S-group, and T a maximal torus of G. For every subgroup H of G as above, $T \cap H$ is a maximal torus of H, and*

$$G/H \simeq T/(T \cap H), \qquad H = (T \cap H) \cdot \mathrm{der}(G).$$

Moreover, the assignment $H \mapsto T \cap H$ is a bijection between the set of subgroups H of G as above and the set of subtori of T containing $T \cap \mathrm{der}(G)$.

[65] Editor's note: We have deleted the hypothesis that H be retrocompact in G, which is automatic: by Exposé $\mathrm{VI_B}$, 5.5, both G and H are separated and quasi-compact over S; hence $H \hookrightarrow G$ is quasi-compact by EGA $\mathrm{IV_1}$, 1.1.2(v).

Exposé XXIII
Reductive Groups: Uniqueness of Pinned Groups

by M. Demazure

[1] The aim of this Exposé is to prove the uniqueness theorem (Theorem 4.1). It was proved by Chevalley in the case of an algebraically closed field; the reduction-to-rank-two method used here is likewise due to Chevalley (see *Bible*, Exposés 23 and 24). Along the way, we obtain an explicit description of reductive groups by generators and relations (3.5).

1. Pinnings

Definition 1.1.— *Let S be a scheme and let (G, T, M, R) be an S-split group (XXII, 1.13). A* pinning [2] *of this split group is the datum of a system Δ of simple roots of R, together with, for each $\alpha \in \Delta$, a section*

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times.$$

In other words, a pinning of the reductive group G over the nonempty scheme S is the datum of:

(i) a maximal torus T;

(ii) an abelian group M and an isomorphism $T \simeq D_S(M)$;

(iii) a system of roots R of G with respect to T;

(iv) a system Δ of simple roots of R;

(v) an element $X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times$ for every $\alpha \in \Delta$, that is, an element

$$u_\alpha = \exp_\alpha(X_\alpha) \in U_\alpha^\times(S) \qquad \text{for every } \alpha \in \Delta,$$

[1] *Editors' note.* Version of 13 October 2024.

[2] *Editors' note.* Demazure tells us that behind this terminology lies the image of the butterfly (supplied to him by Grothendieck): the body is a maximal torus T, the wings are two Borel subgroups opposite with respect to T; one spreads the butterfly by laying out the wings and then fixes elements in the additive groups (pins) to rigidify the situation, that is, to eliminate the automorphisms.

satisfying condition (D1) of Exposé XXII, 1.13 (indeed, condition (D2) of *loc. cit.* is automatic[3]).

Every split group admits a pinning; in particular, every reductive group is locally pinnable for the étale topology.

1.2.— If G is a pinned S-group, that is, an S-split group equipped with a pinning, it is canonically endowed with the system of positive roots R^+ defined by Δ, the corresponding Borel subgroup $B = B_{R^+}$, the opposite Borel subgroup $B^- = B_{R^-}$, the unipotent groups $U = B_u$ and $U^- = (B^-)_u$, the open subscheme $U^- \cdot T \cdot U$, and so forth. Likewise, for each $\alpha \in \Delta$, there is a canonical isomorphism of vector groups

$$p_\alpha : \mathbb{G}_{a,S} \xrightarrow{\sim} U_\alpha, \qquad x \longmapsto \exp_\alpha(xX_\alpha) = u_\alpha^x,$$

normalized by T with multiplier α, and whose datum is equivalent to that of X_α (Exposé XXII, 1.1).

By duality one obtains an $X_{-\alpha} \in \Gamma(S, \mathfrak{g}^{-\alpha})^\times$ and an isomorphism

$$p_{-\alpha} : \mathbb{G}_{a,S} \xrightarrow{\sim} U_{-\alpha}$$

which is contragredient to the preceding one (Exposé XXII, 1.3). We set (Exposé XX, 3.1)

$$w_\alpha = w_\alpha(X_\alpha) = p_\alpha(1)p_{-\alpha}(-1)p_\alpha(1) = p_{-\alpha}(-1)p_\alpha(1)p_{-\alpha}(-1).$$

Then (*loc. cit.*, 3.1 and 3.7)

$$w_\alpha^2 = \alpha^*(-1), \qquad \mathrm{int}(w_\alpha)t = s_\alpha(t) = t \cdot \alpha^*\big(\alpha(t)^{-1}\big),$$

$$\mathrm{int}(w_\alpha)p_\alpha(x) = p_{-\alpha}(-x) = p_{-\alpha}(x)^{-1}, \quad \mathrm{Ad}(w_\alpha)X_\alpha = -X_{-\alpha},$$
$$\mathrm{int}(w_\alpha)p_{-\alpha}(x) = p_\alpha(-x) = p_\alpha(x)^{-1}, \quad \mathrm{Ad}(w_\alpha)X_{-\alpha} = -X_\alpha.$$

We shall systematically use the preceding notation in what follows.

Definition 1.3.— *Let S be a scheme, and suppose that*

$$(G, T, M, R, \Delta, (X_\alpha)) \quad \textit{and} \quad (G', T', M', R', \Delta', (X'_{\alpha'}))$$

are two pinned S-groups. The morphism of split groups (Exposé XXII, 4.2.1)

$$f : G \longrightarrow G'$$

is said to be compatible with the pinnings*, or to define a* morphism of pinned groups*, if the associated bijection $d : R \to R'$ (cf. loc. cit.) satisfies $d(\Delta) = \Delta'$ and if, for every $\alpha \in \Delta$,*

$$f\big(\exp_\alpha(X_\alpha)\big) = \exp_{d(\alpha)}\big(X'_{d(\alpha)}\big), \qquad \textit{i.e.} \qquad f(u_\alpha) = u'_{d(\alpha)}.$$

[4]

1.4.— If $q(\alpha)$ denotes the integer of *loc. cit.*, then

$$f\big(p_\alpha(x)\big) = p'_{d(\alpha)}\big(x^{q(\alpha)}\big) \qquad (\alpha \in \Delta),$$

[3] *Editors' note.* It is implied by condition (v), namely the existence of a section $X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times$.

[4] *Editors' note.* The bijection $R \xrightarrow{\sim} R'$ is denoted by d (rather than by u) in order to avoid the notation $u'_{u(\alpha)}$.

and hence

$$f(p_{-\alpha}(x)) = p'_{-d(\alpha)}(x^{q(\alpha)}), \qquad f(w_\alpha) = w'_{d(\alpha)}.$$

Recall (Exposé XXII, 4.2) that, for every $\alpha \in R$, every $z \in \mathbb{G}_m(S')$, and every $t \in T(S')$,

$$f(\alpha^*(z)) = d(\alpha)^*(z)^{q(\alpha)} = d(\alpha)^*(z^{q(\alpha)}), \qquad d(\alpha)(f(t)) = \alpha(t)^{q(\alpha)}.$$

1.5.— We call a root datum equipped with a system of simple roots a *pinned root datum*, and a p-morphism of root data (Exposé XXI, 6.8) that sends simple roots to simple roots a *p-morphism of pinned root data*.

If G is a pinned S-group, we denote by $\mathscr{R}(G)$ the corresponding pinned root datum (the root datum of Exposé XXII, 1.14 equipped with Δ). Let p be the integer defined in Exposé XXII, 4.2.2. Then:

Scholium 1.6.— *The correspondence $G \longmapsto \mathscr{R}(G)$ defines a functor from the category of pinned reductive S-groups to the category of pinned root data (whose morphisms are the p-morphisms).*

1.7. The pinned groups Z_{Δ_1}

Let Δ_1 be a subset of the system Δ of simple roots of the pinned group G. Let T_{Δ_1} be the maximal torus of $\bigcap_{\alpha\in\Delta_1} \ker(\alpha)$, and set

$$Z_{\Delta_1} = \mathrm{Centr}_G(T_{\Delta_1}).$$

Put $R' = \mathbb{Z}\Delta_1 \cap R$. It is known (Exposé XXII, 5.10.7) that Z_{Δ_1} is a reductive S-group with radical T_{Δ_1}, that (T, M, R') is a splitting of this group, and that Δ_1 is a system of simple roots. Thus

$$(Z_{\Delta_1}, T, M, R', \Delta_1, (X_\alpha)_{\alpha\in\Delta_1})$$

is a pinned S-group. We shall always give Z_{Δ_1} this pinning. In particular, we shall consider

$$Z_\alpha = Z_{\{\alpha\}}, \qquad Z_{\alpha\beta} = Z_{\{\alpha,\beta\}}.$$

Write $B_{\Delta_1} = B \cap Z_{\Delta_1}$. It is known (*loc. cit.*) that this is the canonical Borel subgroup [5] of Z_{Δ_1}, and that its unipotent part is $U_{\Delta_1} = U \cap Z_{\Delta_1}$. In particular,

$$B_\alpha = T \cdot U_\alpha.$$

We write

$$U_{\alpha\beta} = U_{\{\alpha,\beta\}} = U \cap Z_{\alpha\beta} = \prod_{\gamma\in R^+_{\alpha\beta}} U_\gamma,$$

where $R^+_{\alpha\beta}$ is the set of positive roots that are linear combinations of α and β.

Now let $f : G \to G'$ be a morphism of pinned S-groups. If $d : R \to R'$ is the corresponding bijection and $\Delta_1 \subset \Delta$, then $d(\Delta_1) = \Delta'_1 \subset \Delta'$. Clearly f maps T_{Δ_1} into $T'_{\Delta'_1}$, and hence Z_{Δ_1} into $Z'_{\Delta'_1}$. The corresponding S-morphism

$$f_{\Delta_1} : Z_{\Delta_1} \longrightarrow Z'_{\Delta'_1}$$

is compatible with the canonical pinnings. It defines a morphism of pinned root data

$$\mathscr{R}(f_{\Delta_1}) : \mathscr{R}(Z_{\Delta_1}, T, M, \ldots) \longrightarrow \mathscr{R}(Z'_{\Delta'_1}, T', M', \ldots),$$

and the underlying morphisms $M' \to M$ of $\mathscr{R}(f)$ and $\mathscr{R}(f_{\Delta_1})$ coincide.

[5] *Editors' note.* That is, the Borel subgroup of Z_{Δ_1} corresponding to $R'^+ = R' \cap R^+$.

1.8. Study of the group $\mathrm{Norm}_G(T)$

For every pair (α, β) of simple roots, let $n_{\alpha\beta}$ be the order of $s_\alpha s_\beta$ in the Weyl group W. In particular $n_{\alpha\alpha} = 1$, and therefore $(w_\alpha w_\beta)^{n_{\alpha\beta}} \in T(S)$.

Definition 1.8.1.— *For every $(\alpha, \beta) \in \Delta \times \Delta$, set*

$$t_{\alpha\beta} = (w_\alpha w_\beta)^{n_{\alpha\beta}} \in T(S).$$

Moreover, set (Exposé XX, 3.1)

$$t_\alpha = t_{\alpha\alpha} = w_\alpha^2 = \alpha^*(-1) \in T(S).$$

Proposition 1.8.2.— *Let H be an S-functor in groups that carries direct sums of schemes to products (for example, a sheaf for the Zariski topology). Let*

$$f_T : T \longrightarrow H$$

be a morphism of groups, and let $h_\alpha \in H(S)$ $(\alpha \in \Delta)$. There exists a necessarily unique morphism of groups

$$f_N : \mathrm{Norm}_G(T) \longrightarrow H$$

inducing f_T on T and satisfying $f_N(w_\alpha) = h_\alpha$ for $\alpha \in \Delta$ if and only if the following two conditions hold:

(i) for every $\alpha \in \Delta$,

$$f_T(s_\alpha(t)) = h_\alpha f_T(t) h_\alpha^{-1}$$

for every $t \in T(S')$, $S' \to S$; equivalently, $f_T \circ s_\alpha = \mathrm{int}(h_\alpha) \circ f_T$;

(ii) for every $(\alpha, \beta) \in \Delta \times \Delta$,

$$f_T(t_{\alpha\beta}) = (h_\alpha h_\beta)^{n_{\alpha\beta}}.$$

Proof. Equip (Sch) with the topology $\mathcal{T}$ generated by the pretopology whose covering families are direct sums. The hypothesis says that H is a $\mathcal{T}$-sheaf. Let L be the free group on the generators $(m_\alpha)_{\alpha \in R}$, and let L_1 be the invariant subgroup generated by

$$(m_\alpha m_\beta)^{n_{\alpha\beta}}, \qquad (\alpha, \beta) \in \Delta \times \Delta.$$

Let $g : L \to W$ be defined by $g(m_\alpha) = s_\alpha$. It is known (Exposé XXI, 5.1) that g induces an isomorphism $\overline{g} : L/L_1 \xrightarrow{\sim} W$. Let L act on T through g, equivalently by $m_\alpha \cdot t = s_\alpha(t)$. Writing L_S for the constant group defined by L, form the semidirect product $N = T \cdot L_S$. There is a unique morphism of S-groups

$$h : N = T \cdot L_S \longrightarrow \mathrm{Norm}_G(T)$$

such that $h(m_\alpha) = w_\alpha$ and $h(t) = t$ for every $t \in T(S')$, $S' \to S$.

Let N_1 be the invariant subgroup sheaf of N generated by

$$t_{\alpha\beta}^{-1}(m_\alpha m_\beta)^{n_{\alpha\beta}}, \qquad (\alpha, \beta) \in \Delta \times \Delta.$$

Clearly $N_1 \subset \ker h$, so h induces

$$h_1 : N/N_1 \longrightarrow \mathrm{Norm}_G(T).$$

We prove that h_1 is an isomorphism. Since $h|_T$ is the canonical immersion, hence a monomorphism, the canonical morphism $T \to N/N_1$ is also a monomorphism and induces an isomorphism $T \xrightarrow{\sim} TN_1/N_1$. Thus h_1 induces an isomorphism $TN_1/N_1 \xrightarrow{\sim} T$. It remains only to show that

$$h_2 : N/TN_1 \longrightarrow \mathrm{Norm}_G(T)/T$$

is an isomorphism. But TN_1 is the invariant $\mathcal{T}$-subgroup sheaf of N generated by T and the $(m_\alpha m_\beta)^{n_{\alpha\beta}}$; hence it is the subgroup sheaf generated by T and L_1, namely $T \cdot (L_1)_S$. Therefore h_2 identifies with

$$\overline{g} : L_S/(L_1)_S \longrightarrow W_S,$$

which is an isomorphism by construction.

The proof of the proposition is now immediate. Necessity is clear. Conversely, condition (i) gives a morphism

$$u : N \longrightarrow H$$

such that $u(m_\alpha) = h_\alpha$ for $\alpha \in \Delta$ and $u|_T = f_T$. Condition (ii) says that u vanishes on N_1, and the result follows.

1.9. Faithfulness of the functor $\mathscr{R}$

Proposition 1.9.1.— *The functor $\mathscr{R}$ of 1.6 is faithful: if*

$$f, g : G \rightrightarrows G'$$

are two morphisms of pinned groups such that $\mathscr{R}(f) = \mathscr{R}(g)$, then $f = g$.

Indeed, f and g agree on T, on every U_α ($\alpha \in \Delta$), and on every $U_{-\alpha}$ ($\alpha \in \Delta$); it therefore suffices to apply:

Lemma 1.9.2.— *Let S be a scheme, let G be a pinned reductive S-group, and let H be an S-presheaf in groups separated for the fppf topology. Let*

$$f, g : G \rightrightarrows H$$

be two morphisms of S-groups. The following conditions are equivalent:

(i) $f = g$;

(ii) f and g agree on T, on every U_α ($\alpha \in \Delta$), and on every $U_{-\alpha}$ ($\alpha \in \Delta$);

(iii) f and g agree on T and on every U_α ($\alpha \in \Delta$), and $f(w_\alpha) = g(w_\alpha)$ for every $\alpha \in \Delta$.

Proof. The implication (i)⇒(ii) is trivial, while (ii)⇒(iii) follows immediately from the definition of w_α in 1.2. It remains to prove (iii)⇒(i). If $\alpha \in R$, there is a sequence $\{\alpha_i\} \subset \Delta$ such that

$$\alpha = s_{\alpha_1} s_{\alpha_2} \cdots s_{\alpha_n}(\alpha_{n+1}),$$

and hence

$$U_\alpha = \mathrm{int}(w_{\alpha_1} \cdots w_{\alpha_n}) U_{\alpha_{n+1}}.$$

Thus f and g agree on every U_α. They consequently agree on Ω, and therefore agree everywhere (Exposé XXII, 4.1.11).

Remark 1.9.3.— *If G is semisimple, the hypothesis that f and g agree on T may be omitted in (ii) and (iii). Indeed, G, as an fppf sheaf, is generated by the U_α, $\alpha \in R$ (Exposé XXII, 6.2.2(a)).*

2. Generators and relations for a pinned group

Throughout this section G is a fixed pinned S-group. For $\alpha, \beta \in \Delta$, we use the notation $Z_\alpha, Z_{\alpha\beta}, U_{\alpha\beta}, R^+_{\alpha\beta}$ of 1.7.

Theorem 2.1.— *Let S be a scheme, let G be a pinned S-group, and let H be an fppf S-sheaf in groups. Suppose given morphisms of groups*

$$f_N : \mathrm{Norm}_G(T) \longrightarrow H, \qquad f_\alpha : U_\alpha \longrightarrow H \quad (\alpha \in R).$$

There exists a necessarily unique morphism of groups

$$f : G \longrightarrow H$$

extending f_N and all the f_α, $\alpha \in R$, if and only if the following conditions hold:

(i) for every $\alpha \in \Delta$ and $\beta \in R$,

$$\mathrm{int}(f_N(w_\alpha)) \circ f_\beta = f_{s_\alpha(\beta)} \circ \mathrm{int}(w_\alpha);$$

(ii) for every $\alpha \in \Delta$, there exists a morphism of groups

$$F_\alpha : Z_\alpha \longrightarrow H$$

extending f_α, $f_{-\alpha}$, and $f_N|_{\mathrm{Norm}_{Z_\alpha}(T)}$;

(iii) for every $(\alpha, \beta) \in \Delta \times \Delta$, there exists a morphism of groups $U_{\alpha\beta} \to H$ inducing f_γ on U_γ for every $\gamma \in R^+_{\alpha\beta}$ (so $U_\gamma \subset U_{\alpha\beta}$).

2.1.1. Proof

The conditions are plainly necessary. Choose a totally ordered group structure on $\Gamma_0(R)$ for which the positive elements of R are precisely R^+ (Exposé XXI, 3.5.6); every product indexed by a subset of R will be taken in this order. Let f_T denote the restriction of f_N to T, and define a morphism of sets

$$f : \Omega \longrightarrow H$$

by

$$f\left(\prod_{\alpha\in R^-} y_\alpha \cdot t \cdot \prod_{\alpha\in R^+} x_\alpha\right) = \prod_{\alpha\in R^-} f_\alpha(y_\alpha) \cdot f_T(t) \cdot \prod_{\alpha\in R^+} f_\alpha(x_\alpha).$$

Every morphism satisfying the theorem must extend this map. Conversely, any morphism of groups $f : G \to H$ extending it also extends f_N: since it extends f_α and $f_{-\alpha}$, one has

$$f(w_\alpha) = F_\alpha(w_\alpha) = f_N(w_\alpha),$$

and it extends f_T by hypothesis. By Exposé XXII, 4.1.11(ii), it therefore remains to prove:

Proposition 2.1.2.— *The morphism $f : \Omega \to H$ defined above is* generically multiplicative*: for every $S' \to S$ and every $x, y \in \Omega(S')$ such that $xy \in \Omega(S')$, one has $f(xy) = f(x)f(y)$.*

Lemma 2.1.3.— *Let $n \in \mathrm{Norm}_G(T)(S')$, $S' \to S$, and let $\alpha, \beta \in R$ satisfy $\mathrm{int}(n)U_\alpha = U_\beta$, equivalently $n(\alpha) = \beta$. Then*

$$\mathrm{int}\big(f_N(n)\big) \circ f_\alpha = f_\beta \circ \mathrm{int}(n).$$

It suffices to verify this formula for a system of generators of $\mathrm{Norm}_G(T)$. It holds for every w_α, $\alpha \in \Delta$, by 2.1(i), so it remains to treat $n \in T(S')$. This is immediate from 2.1(ii) when α is simple. Otherwise choose $w \in W$ with $w^{-1}(\alpha) \in \Delta$. Writing w as a product of simple reflections[6], one reduces to showing that if the formula holds for α and every n, it also holds for $w_{\alpha_0}(\alpha)$ and $t \in T(S')$, where $\alpha_0 \in \Delta$. By 2.1(i),

$$\begin{aligned}\mathrm{int}\big(f_N(t)\big) \circ f_{w_{\alpha_0}(\alpha)} &= \mathrm{int}\big(f_N(tw_{\alpha_0})\big) \circ f_\alpha \circ \mathrm{int}(w_{\alpha_0}^{-1}) \\ &= f_{w_{\alpha_0}(\alpha)} \circ \mathrm{int}(tw_{\alpha_0}) \circ \mathrm{int}(w_{\alpha_0}^{-1}).\end{aligned}$$

Lemma 2.1.4.— *The restriction of f to U (respectively U^-) is a morphism of groups. In particular, this restriction is independent of the chosen ordering of the roots.*

It suffices to prove the assertion for U. By Exposé XXII, 5.5.8, it is enough to show that, for every pair $\alpha < \beta$ of positive roots and every $x_\alpha \in U_\alpha(S')$, $x_\beta \in U_\beta(S')$, $S' \to S$,

$$f_\beta(x_\beta) f_\alpha(x_\alpha) f_\beta(x_\beta^{-1}) = f(x_\beta x_\alpha x_\beta^{-1}).$$

By Exposé XXII, 5.5.2, there are elements $x_\gamma \in U_\gamma(S')$, where $\gamma = i\alpha + j\beta \in R$, $i > 0$, $j \geq 0$ [7], such that

$$x_\beta x_\alpha x_\beta^{-1} = \prod_\gamma x_\gamma.$$

It remains to verify

$$f_\beta(x_\beta) f_\alpha(x_\alpha) f_\beta(x_\beta^{-1}) = \prod_{\substack{\gamma = i\alpha + j\beta \\ i>0,\ j\geq 0}} f_\gamma(x_\gamma).$$

By Exposé XXI, 3.5.4, there is a $w \in W$ such that $w(\alpha) = \alpha_0 \in \Delta$ and $w(\beta) \in A_{\alpha_0\beta_0}$, in the notation of 1.7, for some $\beta_0 \in \Delta$. Lift w to $n \in \mathrm{Norm}_G(T)(S)$ by Exposé XXII, 3.8. It suffices to verify the relation after conjugation by $f_N(n)$; by 2.1.3, this reduces to $\alpha, \beta \in R^+_{\alpha_0\beta_0}$, where condition 2.1(iii) applies.

Lemma 2.1.5.— *Let $n \in \mathrm{Norm}_G(T)(S)$ satisfy $\mathrm{int}(n)U = U^-$, so that n represents the symmetry of the Weyl group[8] (Exposé XXI, 3.6.14). For every $u \in U(S')$, $S' \to S$ (respectively $u \in U^-(S')$), one has*

$$f(nun^{-1}) = f_N(n) f(u) f_N(n^{-1}).$$

This follows immediately from 2.1.3 and 2.1.4.

Lemma 2.1.6.— *Let $u \in B(S')$, $v \in B^-(S')$, and $g \in \Omega(S')$, where $S' \to S$. Then*

$$f(vgu) = f(v) f(g) f(u).$$

Write

$$v = v_1 t_1, \qquad g = v_2 t_2 u_2, \qquad u = t_3 u_3,$$

[6] *Editors' note.* "Fundamental symmetries" was replaced by "simple reflections."

[7] *Editors' note.* The printed $i, j > 0$ was corrected to $i > 0, j \geq 0$, since x_α occurs in the product on the right.

[8] *Editors' note.* Relative to Δ.

with $v_i \in U^-(S')$, $t_i \in T(S')$, and $u_i \in U(S')$. On the one hand,

$$f(v)f(g)f(u) = f(v_1)f_T(t_1)f(v_2)f_T(t_2)f(u_2)f_T(t_3)f(u_3).$$

On the other hand,

$$\begin{aligned} f(vgu) &= f(v_1 t_1 v_2 t_1^{-1}\, t_1 t_2 t_3\, t_3^{-1} u_2 t_3 u_3) \\ &= f(v_1 \cdot t_1 v_2 t_1^{-1}) f_T(t_1 t_2 t_3) f(t_3^{-1} u_2 t_3 \cdot u_3). \end{aligned}$$

Using 2.1.4 on the two outer factors gives

$$f(vgu) = f(v_1)f(t_1 v_2 t_1^{-1})f_T(t_1 t_2 t_3)f(t_3^{-1} u_2 t_3)f(u_3).$$

It remains only to use

$$\begin{aligned} f(t_1 v_2 t_1^{-1}) &= f_T(t_1) f(v_2) f_T(t_1)^{-1}, \\ f(t_3^{-1} u_2 t_3) &= f_T(t_3)^{-1} f(u_2) f_T(t_3), \end{aligned}$$

which follow from the definition of f and 2.1.3.

Lemma 2.1.7.— *Let $\alpha \in \Delta$ and*

$$g \in \Omega(S') \cap \mathrm{int}(w_\alpha)^{-1}\Omega(S'), \qquad S' \to S.$$

Then

$$f(w_\alpha g w_\alpha^{-1}) = f_N(w_\alpha) f(g) f_N(w_\alpha)^{-1}.$$

By Exposé XXII, 5.6.8, write

$$g = a x_{-\alpha} t x_\alpha b,$$

where $a \in U^-_{-\widehat{\alpha}}(S')$, $x_{-\alpha} \in U_{-\alpha}(S')$, $t \in T(S')$, $x_\alpha \in U_\alpha(S')$, and $b \in U_{\widehat{\alpha}}(S')$. By 2.1.3 and 2.1.4, and because s_α permutes the positive roots other than α (Exposé XXI, 3.3.2),

$$\mathrm{int}(w_\alpha) a \in U^-_{-\widehat{\alpha}}(S'), \qquad \mathrm{int}(w_\alpha) b \in U_{\widehat{\alpha}}(S').$$

The desired formula holds for $g = a$ and $g = b$. By 2.1.6 it therefore suffices to treat $g = x_{-\alpha} t x_\alpha \in Z_\alpha(S')$; in that case everything takes place in Z_α, and condition 2.1(ii) applies.

Lemma 2.1.8.— *Let $n \in \mathrm{Norm}_G(T)(S)$. For every $S' \to S$ and every $g \in \Omega(S')$ such that* $\mathrm{int}(n)g \in \Omega(S')$,

$$f(ngn^{-1}) = f_N(n) f(g) f_N(n)^{-1}.$$

This is immediate for $n \in T(S)$, by 2.1.3. The two sides define morphisms from $\Omega \cap \mathrm{int}(n)^{-1}\Omega$ to H. It is enough to find an open $V_n \subset \Omega$, containing the unit section, such that $\mathrm{int}(n)V_n \subset \Omega$, and on which $f \circ \mathrm{int}(n)$ and $\mathrm{int}(f_N(n)) \circ f$ agree. By the structure of $\mathrm{Norm}_G(T)$, it suffices to show that if this is true for n', then it is true for $n = n' w_\alpha$, $\alpha \in \Delta$. Put

$$V_n = \Omega \cap \mathrm{int}(w_\alpha)^{-1} V_{n'}.$$

Then $\mathrm{int}(n)V_n \subset \mathrm{int}(n')V_{n'} \subset \Omega$. If $g \in V_n(S')$, then

$$\mathrm{int}(n)g = \mathrm{int}(n')\,\mathrm{int}(w_\alpha)g.$$

Now $\mathrm{int}(w_\alpha)g \in V_{n'}(S')$, so the induction hypothesis gives

$$f\big(\mathrm{int}(n')\,\mathrm{int}(w_\alpha)g\big) = \mathrm{int}(f_N(n'))f(\mathrm{int}(w_\alpha)g).$$

Lemma 2.1.7 gives

$$f(\mathrm{int}(w_\alpha)g) = \mathrm{int}(f_N(w_\alpha))f(g),$$

and the conclusion follows.

We now prove Proposition 2.1.2. Let $x, x' \in \Omega(S')$, and write

$$x = vtu, \qquad x' = v't'u',$$

so $xx' = vt(uv')t'u'$. By 2.1.6 and $U^-(S')\Omega(S')U(S') = \Omega(S')$, it suffices to show that $f(uv') = f(u)f(v')$ whenever $uv' \in \Omega(S')$. Choose $n \in \mathrm{Norm}_G(T)(S')$ as in 2.1.5. Then

$$f(u) = f_N(n)^{-1} f(nun^{-1}) f_N(n),$$
$$f(v') = f_N(n)^{-1} f(nv'n^{-1}) f_N(n),$$

and hence

$$f(u)f(v') = f_N(n)^{-1} f(nun^{-1}) f(nv'n^{-1}) f_N(n).$$

Since $nun^{-1} \in U^-(S')$ and $nv'n^{-1} \in U(S')$,

$$f(nun^{-1})f(nv'n^{-1}) = f\big((nun^{-1})(nv'n^{-1})\big) = f(nuv'n^{-1}).$$

Thus

$$f(u)f(v') = f_N(n)^{-1} f(nuv'n^{-1}) f_N(n).$$

If $uv' \in \Omega(S')$, Lemma 2.1.8 finishes the proof.

Remark 2.2.— *Instead of prescribing f_N, one may prescribe a morphism $f_T : T \to H$ and sections $h_\alpha \in H(S)$, $\alpha \in \Delta$, satisfying the conditions of 1.8.2. Condition (ii) of Theorem 2.1 must then be replaced by:*

> (ii′) There exists a morphism of groups $F_\alpha : Z_\alpha \to H$ extending $f_\alpha, f_{-\alpha}, f_T$ and satisfying $F_\alpha(w_\alpha) = h_\alpha$.

We now give the preceding theorem a more explicit form, retaining its notation.

Theorem 2.3.— *Let S be a scheme, let G be a pinned S-group, and let H be an fppf S-sheaf in groups. Suppose given morphisms of groups*

$$f_T : T \longrightarrow H, \qquad f_\alpha : U_\alpha \longrightarrow H \quad (\alpha \in \Delta),$$

and sections $h_\alpha \in H(S)$, $\alpha \in \Delta$. There exists a necessarily unique morphism of groups $f : G \to H$ inducing f_T and the f_α and satisfying $f(w_\alpha) = h_\alpha$ for all $\alpha \in \Delta$ if and only if:

(i) for every $S' \to S$, $t \in T(S')$, $\alpha \in \Delta$, and $x \in U_\alpha(S')$,

$$f_T(t)f_\alpha(x)f_T(t)^{-1} = f_\alpha(\mathrm{int}(t)x); \tag{1}$$

(ii) for every $\alpha \in \Delta$, $S' \to S$, and $t \in T(S')$,

$$h_\alpha f_T(t) h_\alpha^{-1} = f_T(s_\alpha(t)) = f_T\big(t\alpha^*(\alpha(t)^{-1})\big); \tag{2}$$

(iii) for every $(\alpha, \beta) \in \Delta \times \Delta$,

$$(h_\alpha h_\beta)^{n_{\alpha\beta}} = f_T(t_{\alpha\beta}); \tag{3}$$

(iv) for every $\alpha \in \Delta$, recalling that $u_\alpha = \exp_\alpha(X_\alpha)$,

$$(h_\alpha f_\alpha(u_\alpha))^3 = e; \tag{4}$$

(v) for every distinct $\alpha, \beta \in \Delta$, there exists a morphism $f_{\alpha\beta} : U_{\alpha\beta} \to H$ such that

$$f_{\alpha\beta}|_{U_\alpha} = f_\alpha, \qquad f_{\alpha\beta}|_{U_\beta} = f_\beta, \tag{5}$$

and, for every $\gamma \in R^+_{\alpha\beta}$ with $\gamma \neq \alpha$ (respectively $\gamma \neq \beta$) and every $x \in U_\gamma(S')$, $S' \to S$,

$$\mathrm{int}(h_\alpha) f_{\alpha\beta}(x) = f_{\alpha\beta}(\mathrm{int}(w_\alpha)x) \tag{6}$$

(respectively $\mathrm{int}(h_\beta) f_{\alpha\beta}(x) = f_{\alpha\beta}(\mathrm{int}(w_\beta)x)$).

Proof. Uniqueness follows from 1.9.2. We prove existence.

Lemma 2.3.1.— *There exists a morphism*

$$f_N : \mathrm{Norm}_G(T) \longrightarrow H$$

extending f_T and satisfying $f_N(w_\alpha) = h_\alpha$.

This is precisely 1.8.2, in view of conditions (2) and (3).

Lemma 2.3.2.— *For every $\alpha \in \Delta$, there is a morphism of groups $F_\alpha : Z_\alpha \to H$ extending f_T and f_α, satisfying $F_\alpha(w_\alpha) = h_\alpha$, and hence extending $f_N|_{\mathrm{Norm}_{Z_\alpha}(T)}$.*

This follows from Exposé XX, 6.2 and conditions (1), (3), and (4).

Lemma 2.3.3.— *Let $(\alpha, \beta) \in \Delta \times \Delta$, $\alpha \neq \beta$. Let $n \in \mathrm{Norm}_{Z_{\alpha\beta}}(T)(S)$ satisfy $n(\alpha) = \alpha$ (respectively $n(\alpha) = \beta$), equivalently $\mathrm{int}(n)U_\alpha = U_\alpha$ (respectively U_β). Then, for every $S' \to S$ and $x \in U_\alpha(S')$,*

$$\mathrm{int}(f_N(n)) f_\alpha(x) = f_\alpha(\mathrm{int}(n)x)$$

(respectively the right-hand side is $f_\beta(\mathrm{int}(n)x)$).

There exist $t \in T(S)$ and a sequence $\{\alpha_i\} \subset \{\alpha, \beta\}$ such that

$$n = t w_{\alpha_k} \cdots w_{\alpha_1}.$$

Condition (1) treats $n = t$, so we may omit t. Proceed by induction on k, and set

$$\gamma_i = s_{\alpha_i} \cdots s_{\alpha_1}(\alpha).$$

If every γ_i is positive, condition (v) yields

$$\mathrm{int}\big(f_N(w_{\alpha_i} \cdots w_{\alpha_1})\big) f_\alpha(x) = f_{\alpha\beta}\big(\mathrm{int}(w_{\alpha_i} \cdots w_{\alpha_1})x\big),$$

and $i = k$ gives the result. Otherwise there is a $j < k$ such that $\gamma_j \in R^+$ but $\gamma_{j+1} \notin R^+$. Since $\gamma_{j+1} = s_{\alpha_j}(\gamma_j)$, Exposé XXI, 3.3.2 gives $\gamma_j = \alpha_j$, hence γ_j is α or β. Decompose

$$n = n' n'', \qquad n' = w_{\alpha_k} \cdots w_{\alpha_{j+1}}, \qquad n'' = w_{\alpha_j} \cdots w_{\alpha_1}.$$

Both n' and n'' satisfy the lemma's hypotheses and involve fewer than k reflections, so induction applies.

Lemma 2.3.4.— *Let $\alpha \in R$. Suppose $n, n' \in \mathrm{Norm}_G(T)(S)$ and $\beta, \beta' \in \Delta$ satisfy $n(\alpha) = \beta$ and $n'(\alpha) = \beta'$. Then, for every $x \in U_\alpha(S')$, $S' \to S$,*

$$\mathrm{int}(f_N(n)^{-1}) f_\beta(nxn^{-1}) = \mathrm{int}(f_N(n')^{-1}) f_{\beta'}(n'xn'^{-1}).$$

It suffices to prove that if $n(\alpha) = \beta$, with $\alpha, \beta \in \Delta$, then

$$\mathrm{int}(f_N(n)) \circ f_\alpha = f_\beta \circ \mathrm{int}(n).$$

By Tits's lemma (Exposé XXI, 5.6), there are simple roots

$$\alpha_0 = \alpha, \alpha_1, \ldots, \alpha_m = \beta$$

and elements $w_i \in W$, $0 \leq i < m$, such that

$$n = w_{m-1} \cdots w_0, \qquad w_i(\alpha_i) = \alpha_{i+1},$$

and for each i there is a simple root β_i such that

$$w_i \in W_{\alpha_i \beta_i}, \qquad \alpha_{i+1} = \alpha_i \text{ or } \beta_i.$$

Induction reduces the assertion to Lemma 2.3.3.

Lemma 2.3.5.— *There is a family of morphisms of groups $f'_\gamma : U_\gamma \to H$, $\gamma \in R$, such that:*

(i) for $\alpha \in \Delta$, $f'_\alpha = f_\alpha$ and $f'_{-\alpha} = F_\alpha|_{U_{-\alpha}}$;

(ii) if $\alpha, \beta \in \Delta$ and $\gamma \in R^+_{\alpha\beta}$, then $f'_\gamma = f_{\alpha\beta}|_{U_\gamma}$;

(iii) if $n \in \mathrm{Norm}_G(T)(S)$ and $\alpha, \beta \in R$ satisfy $n(\alpha) = \beta$, then

$$\mathrm{int}(f_N(n)) f'_\alpha(x) = f'_\beta(\mathrm{int}(n)x)$$

for every $x \in U_\alpha(S')$, $S' \to S$.

For every root α, choose $n \in \mathrm{Norm}_G(T)(S)$ with $n(\alpha) \in \Delta$, and define $f'_\alpha(x)$ by the expression in Lemma 2.3.4. This is independent of n, and f'_α is a morphism of groups. Property (iii) holds by construction. The first part of (i) follows by taking $n = e$, and the second by taking $n = w_\alpha$ and using 2.3.2. If $\gamma \in R^+_{\alpha\beta}$, choose $n \in \mathrm{Norm}_{Z_{\alpha\beta}}(T)(S)$ with $n(\gamma) = \alpha$ or β; then (iii), together with conditions (5) and (6), proves (ii).

2.3.6.— We finish the proof by verifying the conditions of Theorem 2.1 for f_N and f'_α, $\alpha \in R$:

- 2.1(i) follows from 2.3.5(iii);
- 2.1(ii) follows from 2.3.5(i) and 2.3.2;
- 2.1(iii) follows from 2.3.5(ii) and the fact that $f_{\alpha\beta}$ is a morphism of groups.

An immediate corollary is:

Corollary 2.4.— *Let S be a scheme, let G be a pinned S-group of semisimple rank at least 1, and let H be an fppf S-sheaf in groups. For each $(\alpha, \beta) \in \Delta \times \Delta$, let*

$$F_{\alpha\beta} : Z_{\alpha\beta} \longrightarrow H$$

be a morphism of groups. There exists a morphism $f : G \to H$ inducing the $F_{\alpha\beta}$ if and only if, for every $(\alpha, \beta) \in \Delta \times \Delta$,

$$F_{\alpha\beta}|_{Z_\alpha} = F_{\alpha\alpha}.$$

Necessity is clear. Conversely, put

$$f_T = F_{\alpha\alpha}|_T;$$

this is independent of α, since

$$F_{\alpha\alpha}|_T = F_{\alpha\beta}|_T = F_{\beta\beta}|_T.$$

Set

$$f_\alpha = F_{\alpha\alpha}|_{U_\alpha}, \qquad h_\alpha = F_{\alpha\alpha}(w_\alpha), \qquad f_{\alpha\beta} = F_{\alpha\beta}|_{U_{\alpha\beta}}.$$

The conditions of Theorem 2.3 hold: (1), (2), and (4) hold in Z_α, while (3), (5), and (6) hold in $Z_{\alpha\beta}$. Thus there is a morphism $f : G \to H$ extending f_T and all f_α, and satisfying $f(w_\alpha) = h_\alpha$. It agrees with $F_{\alpha\beta}$ on the generators of $Z_{\alpha\beta}$; hence $f|_{Z_{\alpha\beta}} = F_{\alpha\beta}$.

Corollary 2.5.— *Let S be a scheme; let G and G' be two pinned S-groups of semisimple rank 2; let $q > 0$ be an integer such that $x \mapsto x^q$ is an endomorphism of $\mathbf{G}_{a,S}$; and let*

$$h : R(G') \longrightarrow R(G)$$

be a q-morphism of pinned root data. For each $\alpha \in R^+$, choose

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times, \qquad X'_{d(\alpha)} \in \Gamma(S, \mathfrak{g}'^{d(\alpha)})^\times,$$

extending the canonical choices for $\alpha \in \Delta$. Suppose:

(i) if $\Delta = \{\alpha, \beta\}$, then

$$D_S(h)(t_{\alpha\beta}) = t'_{d(\alpha)d(\beta)};$$

(ii) for every $\alpha \in \Delta$ and every $\beta \in R^+$, $\beta \neq \alpha$, if $z \in \mathbf{G}_m(S)$ is defined by

$$\mathrm{Ad}(w_\alpha)X_\beta = zX_{s_\alpha(\beta)},$$

then

$$\mathrm{Ad}(w'_{d(\alpha)})X'_{d(\beta)} = z^{q(\beta)}X'_{d(s_\alpha(\beta))};$$

(iii) there is a morphism of groups $f : U \to U'$ such that, for every $\alpha \in R^+$, every $S' \to S$, and every $x \in \mathbf{G}_a(S')$,

$$f(\exp(xX_\alpha)) = \exp\bigl(x^{q(\alpha)}X'_{d(\alpha)}\bigr).$$

Then there is a morphism of pinned groups $g : G \to G'$ such that $R(g) = h$.

Indeed, define $f_\alpha : U_\alpha \to G'$ by

$$f_\alpha(\exp(xX_\alpha)) = \exp\bigl(x^{q(\alpha)}X'_{d(\alpha)}\bigr),$$

and put

$$f_T = D_S(h), \qquad h_\alpha = w'_{d(\alpha)}.$$

The conditions of Theorem 2.3 hold: note that

$$q(s_\alpha(\beta)) = q(\beta)$$

by Exposé XXI, 6.8.4, and that

$$D_S(h)(t_\alpha) = t'_{d(\alpha)}$$

always holds. The assertion follows at once.

Remark 2.6.— *Condition (v) of Theorem 2.3 may be made more explicit as follows. One must first verify:*

(a) for every word in w_α, w_β whose corresponding word carries α or β to α or β, the corresponding relation of the type occurring in 2.3.3 holds.

The proof of 2.3.3 shows that it suffices to check the words that are minimal, in the sense that no nontrivial initial subword satisfies the imposed conditions.

If (a) holds, define $f_\gamma : U_\gamma \to H$ for every $\gamma \in R^+_{\alpha\beta}$ as in 2.3.5. One must then require:

(b) the map defined by the f_γ,

$$U_{\alpha\beta} = \prod_{\gamma \in R^+_{\alpha\beta}} U_\gamma \longrightarrow H,$$

is a morphism of groups.

By Exposé XXII, 5.5.8, condition (b) follows from:

(b′) the preceding map respects the commutation relations between U_γ and U_δ, for $\gamma, \delta \in R^+_{\alpha\beta}$, $\gamma > \delta$; namely, the relations involving $C_{i,j,\gamma,\delta}$ in Exposé XXII, 5.5.2.

Conversely, the conjunction of (a) and (b′) is equivalent to condition (v).

These conditions may even be reduced to conditions involving only

$$h_\alpha, \quad h_\beta, \quad f_\alpha(u_\alpha), \quad f_\beta(u_\beta)$$

in H. For example, if $s_\alpha s_\beta s_\alpha(\beta) = \alpha$, a condition of type (a) reads

$$\text{int}(h_\alpha h_\beta h_\alpha) f_\beta(x) = f_\alpha(\text{int}(w_\alpha w_\beta w_\alpha)x)\,. \tag{1}$$

Here $x \in U_\beta(S')$, $S' \to S$. In particular, for $x = u_\beta$,

$$\text{int}(w_\alpha w_\beta w_\alpha) u_\beta = u_\alpha^z$$

for a certain $z \in \mathbf{G}_m(S)$, and

$$\text{int}(h_\alpha h_\beta h_\alpha) f_\beta(u_\beta) = f_\alpha(u_\alpha)^z. \tag{1′}$$

Conversely, taking conditions (i)–(iv) of 2.3 into account, (1′) implies (1). If $t \in T(S')$, conjugating (1′) by t, and using (i) and (ii), gives (1) for

$$x = \text{int}(t) u_\beta = u_\beta^{\beta(t)}.$$

The morphism $\beta : T \to \mathbf{G}_{m,S}$ is faithfully flat, so (1) holds for $x \in U_\beta(S')^\times$. It is additive in x, and every section of U_β is locally the sum of two invertible sections. Thus

$$(1') + (\text{i}) + (\text{ii}) \quad \Longrightarrow \quad (1).$$

The same argument applies to conditions of type (b). One uses the fact that, for two distinct positive roots γ, γ', hence linearly independent over $\mathbf{Q}$, the morphism

$$T \longrightarrow \mathbf{G}_{m,S}^2$$

with components γ, γ' is faithfully flat. We leave the details of this transposition to the reader.

3. Groups of Semisimple Rank 2

3.1. Generalities

Lemma 3.1.1.— *Let S be a scheme, let G be a pinned S-group, and let α, β be two roots of G such that $\alpha + \beta \neq 0$.*

(i) If $\alpha + \beta \notin R$, then

$$\exp(X_\alpha)\exp(X_\beta) = \exp(X_\beta)\exp(X_\alpha)$$

for every $S' \to S$, $X_\alpha \in W(\mathfrak{g}^\alpha)(S')$, and $X_\beta \in W(\mathfrak{g}^\beta)(S')$.

(ii) If neither $\alpha + \beta$ nor $\alpha - \beta$ is a root, then

$$w_\alpha(z_\alpha)\exp(X_\beta)w_\alpha(z_\alpha)^{-1} = \exp(X_\beta)$$

for every $X_\beta \in W(\mathfrak{g}^\beta)(S')$ and $z_\alpha \in W(\mathfrak{g}^\alpha)^\times(S')$, and

$$w_\alpha(z_\alpha)w_\beta(z_\beta) = w_\beta(z_\beta)w_\alpha(z_\alpha)$$

for every $z_\alpha \in W(\mathfrak{g}^\alpha)^\times(S')$ and $z_\beta \in W(\mathfrak{g}^\beta)^\times(S')$.

(iii) Let $X_\alpha \in W(\mathfrak{g}^\alpha)^\times(S')$, $X_\beta \in W(\mathfrak{g}^\beta)^\times(S')$, and $w \in \mathrm{Norm}_G(T)(S')$ satisfy $w(\alpha) = \beta$. Define $z \in \mathbf{G}_m(S')$ by

$$\mathrm{Ad}(w)X_\alpha = zX_\beta.$$

Then

$$\begin{aligned}\mathrm{int}(w)\exp(xX_\alpha) &= \exp(xzX_\beta),\\ \mathrm{int}(w)\exp(yX_\alpha^{-1}) &= \exp(yz^{-1}X_\beta^{-1}),\\ \mathrm{int}(w)w_\alpha(X_\alpha) &= \beta^*(z)w_\beta(X_\beta).\end{aligned}$$

In particular, if $z = \pm 1$, then

$$\mathrm{int}(w)w_\alpha(X_\alpha) = w_\beta(X_\beta)^z.$$

(iv) If $t_\alpha = \alpha^*(-1)$ and $t_\beta = \beta^*(-1)$, then

$$s_\alpha(t_\beta) = t_\beta t_\alpha^{(\beta^*,\alpha)}, \qquad \beta(t_\alpha) = (-1)^{(\alpha^*,\beta)}.$$

Proof. Part (i) follows immediately from Exposé XXII, 5.5.2. Part (ii) follows from Exposé XX, 3.1 and from (i) applied to

$$(\beta,\alpha), \quad (\beta,-\alpha), \quad (-\beta,\alpha), \quad (-\beta,-\alpha).$$

Part (iii) is immediate from the definitions; for its last assertion, observe that

$$\beta^*(-1) = w_\beta(X_\beta)^{-2}.$$

Finally, (iv) is tautological.

Proposition 3.1.2 (Groups of type $A_1 \times A_1$).— *Let S be a scheme and G a pinned S-group of type $A_1 \times A_1$. Write $\Delta = R^+ = \{\alpha, \beta\}$.*

(i)
$$t_{\alpha\beta} = (w_\alpha w_\beta)^2 = t_\alpha t_\beta = (w_\beta w_\alpha)^2 = t_{\beta\alpha}.$$

(ii)
$$\mathrm{Ad}(w_\alpha)X_\beta = X_\beta, \qquad \mathrm{Ad}(w_\beta)X_\alpha = X_\alpha.$$

(iii) The groups U_α and U_β commute; in other words, U is commutative.

Proof. Lemma 3.1.1(ii) gives $w_\alpha w_\beta = w_\beta w_\alpha$, whence
$$(w_\alpha w_\beta)^2 = w_\alpha^2 w_\beta^2 = t_\alpha t_\beta,$$
which proves (i). The same lemma gives (ii), and (iii) is Lemma 3.1.1(i).

3.1.3.— Condition (v) of Theorem 2.3 takes the following explicit form. Put
$$v_\alpha = f_\alpha(u_\alpha) \qquad (\alpha \in \Delta).$$
Then the two groups of conditions are
$$\text{(A)} \quad \begin{cases} h_\alpha v_\beta h_\alpha^{-1} = v_\beta, \\ h_\beta v_\alpha h_\beta^{-1} = v_\alpha, \end{cases} \qquad \text{(B)} \quad v_\alpha v_\beta = v_\beta v_\alpha.$$

3.2. Groups of Type A_2

Proposition 3.2.1.— *Let S be a scheme and G a pinned S-group of type A_2. Write*
$$\Delta = \{\alpha, \beta\}, \qquad R^+ = \{\alpha, \beta, \alpha+\beta\}.$$

(i)
$$t_{\alpha\beta} = (w_\alpha w_\beta)^3 = e = (w_\beta w_\alpha)^3 = t_{\beta\alpha}.$$

(ii) Put $\mathrm{Ad}(w_\beta)X_\alpha = X_{\alpha+\beta}$. Then
$$\begin{aligned} \mathrm{Ad}(w_\alpha)X_\beta &= -X_{\alpha+\beta}, \\ \mathrm{Ad}(w_\alpha)X_{\alpha+\beta} &= X_\beta, \\ \mathrm{Ad}(w_\beta)X_{\alpha+\beta} &= -X_\alpha. \end{aligned}$$

(iii) Put
$$p_{\alpha+\beta}(x) = \exp(xX_{\alpha+\beta}) = \mathrm{int}(w_\beta)p_\alpha(x).$$
Then
$$p_\beta(y)p_\alpha(x) = p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(xy).$$

3.2.2.— The proof occupies 3.2.2–3.2.7. First,
$$(\beta^*, \alpha) = (\alpha^*, \beta) = -1,$$
so $\alpha(t_\beta) = \beta(t_\alpha) = -1$. Put
$$\mathrm{Ad}(w_\beta)X_\alpha = X_{\alpha+\beta}.$$
Then
$$\mathrm{Ad}(w_\beta)X_{\alpha+\beta} = \alpha(t_\beta)X_\alpha = -X_\alpha.$$

Write

$$\mathrm{Ad}(w_\alpha)X_\beta = zX_{\alpha+\beta}, \qquad z \in \mathbf{G}_m(S).$$

It follows that

$$\mathrm{Ad}(w_\alpha)X_{\alpha+\beta} = \beta(t_\alpha)z^{-1}X_\beta = -z^{-1}X_\beta.$$

By Exposé XXII, 5.5.2, there is a unique $A \in \mathbf{G}_a(S)$ such that

$$(+) \qquad p_\beta(y)p_\alpha(x) = p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(Axy).$$

Thus (ii) and (iii) reduce to proving $A = -z = 1$.

3.2.3.— Conjugating (+) by w_β gives

$$(++) \qquad p_{-\beta}(-y)p_{\alpha+\beta}(x) = p_{\alpha+\beta}(x)p_{-\beta}(-y)p_\alpha(-Axy).$$

3.2.4.— By definition,

$$w_\beta p_\alpha(x)w_\beta^{-1} = p_{\alpha+\beta}(x).$$

Expanding w_β, this is

$$p_\beta(1)p_{-\beta}(-1)p_\beta(1)p_\alpha(x)p_\beta(-1)p_{-\beta}(1)p_\beta(-1) = p_{\alpha+\beta}(x).$$

Since p_β commutes with $p_{\alpha+\beta}$, this may be written

$$p_\beta(1)p_\alpha(x)p_\beta(-1) = p_{-\beta}(1)p_{\alpha+\beta}(x)p_{-\beta}(-1).$$

Using (+) on the left and (++) on the right gives

$$p_\alpha(x)p_\beta(1)p_{\alpha+\beta}(Ax)p_\beta(-1) = p_{\alpha+\beta}(x)p_{-\beta}(1) \cdot p_\alpha(Ax)p_{-\beta}(-1).$$

Because $\alpha + 2\beta$, $\alpha - \beta$, and $2\alpha + \beta$ are not roots, this reduces to

$$p_\alpha(x)p_{\alpha+\beta}(Ax) = p_\alpha(Ax)p_{\alpha+\beta}(x).$$

Exposé XXII, 4.1.3 now gives $A = 1$.

3.2.5.— Conjugating (+) by w_α, and using $A = 1$, gives

$$(+++) \qquad p_{\alpha+\beta}(zy)p_{-\alpha}(-x) = p_{-\alpha}(-x)p_{\alpha+\beta}(zy)p_\beta(-z^{-1}xy).$$

3.2.6.— As before,

$$w_\alpha p_\beta(y)w_\alpha^{-1} = p_{\alpha+\beta}(zy).$$

Since p_α and $p_{\alpha+\beta}$ commute,

$$p_\alpha(1)p_\beta(y)p_\alpha(-1) = p_{-\alpha}(1)p_{\alpha+\beta}(zy)p_{-\alpha}(-1).$$

Using (+) and (+++), this becomes

$$p_\beta(y)p_{\alpha+\beta}(-y) = p_{\alpha+\beta}(zy)p_\beta(-z^{-1}y).$$

The two factors commute, and hence $z = -1$.

3.2.7.— It remains to prove (i). One has

$$w_\alpha w_\beta w_\alpha = w_\alpha w_\beta w_\alpha^{-1} w_\alpha^2 = w_{\alpha+\beta}^{-1} t_\alpha,$$

and therefore

$$\begin{aligned} w_\beta w_\alpha w_\beta w_\alpha w_\beta &= w_\beta w_{\alpha+\beta}^{-1} t_\alpha w_\beta \\ &= w_\beta w_{\alpha+\beta}^{-1} w_\beta^{-1}\, s_\beta(t_\alpha) t_\beta \\ &= w_\alpha t_\alpha t_\beta t_\beta = w_\alpha t_\alpha = w_\alpha^{-1}. \end{aligned}$$

Thus

$$(w_\alpha w_\beta)^3 = (w_\beta w_\alpha)^3 = e.$$

Remark 3.2.8.— *Put $v_\alpha = f_\alpha(u_\alpha)$. Condition (v) of 2.3 becomes*

$$(A) \quad \begin{cases} \mathrm{int}(h_\alpha h_\beta h_\alpha) v_\beta = v_\beta, \\ \mathrm{int}(h_\beta h_\alpha h_\beta) v_\alpha = v_\alpha, \end{cases}$$

and

$$(B) \quad \begin{cases} v_\beta v_\alpha = v_\alpha v_\beta\, (h_\beta v_\alpha h_\beta^{-1}), \\ v_\beta (h_\beta v_\alpha h_\beta^{-1}) = (h_\beta v_\alpha h_\beta^{-1}) v_\beta, \\ v_\alpha (h_\beta v_\alpha h_\beta^{-1}) = (h_\beta v_\alpha h_\beta^{-1}) v_\alpha. \end{cases}$$

Writing $v_{\alpha+\beta} = \mathrm{int}(h_\beta) v_\alpha$, the latter conditions are equivalently

$$(B) \quad \begin{cases} v_\beta v_\alpha = v_\alpha v_\beta v_{\alpha+\beta}, \\ v_\alpha v_{\alpha+\beta} = v_{\alpha+\beta} v_\alpha, \\ v_\beta v_{\alpha+\beta} = v_{\alpha+\beta} v_\beta. \end{cases}$$

3.3. Groups of Type B_2

Proposition 3.3.1.— *Let S be a scheme and G a pinned S-group of type B_2. Write*

$$\Delta = \{\alpha, \beta\}, \qquad R^+ = \{\alpha, \beta, \alpha+\beta, 2\alpha+\beta\}.$$

(i)

$$t_{\alpha\beta} = (w_\alpha w_\beta)^4 = t_\alpha = (w_\beta w_\alpha)^4 = t_{\beta\alpha}.$$

(ii) If

$$\mathrm{Ad}(w_\beta) X_\alpha = X_{\alpha+\beta}, \qquad \mathrm{Ad}(w_\alpha) X_\beta = X_{2\alpha+\beta},$$

then

$$\begin{aligned} &\mathrm{Ad}(w_\alpha) X_{\alpha+\beta} = -X_{\alpha+\beta}, \quad \mathrm{Ad}(w_\alpha) X_{2\alpha+\beta} = X_\beta, \\ &\mathrm{Ad}(w_\beta) X_{\alpha+\beta} = -X_\alpha, \qquad \mathrm{Ad}(w_\beta) X_{2\alpha+\beta} = X_{2\alpha+\beta}. \end{aligned}$$

(iii) Put

$$\begin{aligned} p_{\alpha+\beta}(x) &= \exp(x X_{\alpha+\beta}) = \mathrm{int}(w_\beta) p_\alpha(x), \\ p_{2\alpha+\beta}(x) &= \exp(x X_{2\alpha+\beta}) = \mathrm{int}(w_\alpha) p_\beta(x). \end{aligned}$$

Then

$$\begin{aligned} p_\beta(y) p_\alpha(x) &= p_\alpha(x) p_\beta(y) p_{\alpha+\beta}(xy) p_{2\alpha+\beta}(x^2 y), \\ p_{\alpha+\beta}(y) p_\alpha(x) &= p_\alpha(x) p_{\alpha+\beta}(y) p_{2\alpha+\beta}(2xy). \end{aligned}$$

3.3.2.— The proof occupies 3.3.2–3.3.6. We have

$$(\beta^*, \alpha) = -1, \qquad (\alpha^*, \beta) = -2,$$

so $\alpha(t_\beta) = -1$ and $\beta(t_\alpha) = 1$. In particular, $\beta(t_\alpha) = \alpha(t_\alpha) = 1$, so t_α is a section of $\mathrm{Centr}(G)$. Put

$$\mathrm{Ad}(w_\beta)X_\alpha = X_{\alpha+\beta}, \qquad \mathrm{Ad}(w_\alpha)X_\beta = X_{2\alpha+\beta}.$$

Then

$$\begin{aligned}\mathrm{Ad}(w_\beta)X_{\alpha+\beta} &= \alpha(t_\beta)X_\alpha = -X_\alpha,\\ \mathrm{Ad}(w_\alpha)X_{2\alpha+\beta} &= \beta(t_\alpha)X_\beta = X_\beta,\\ \mathrm{Ad}(w_\beta)X_{2\alpha+\beta} &= X_{2\alpha+\beta}.\end{aligned}$$

For some $k \in \mathbf{G}_m(S)$,

$$\mathrm{Ad}(w_\alpha)X_{\alpha+\beta} = kX_{\alpha+\beta}.$$

By Exposé XXII, 5.5.2, there are $A, B, C \in \mathbf{G}_a(S)$ such that

$$p_\beta(y)p_\alpha(x) = p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(Axy)p_{2\alpha+\beta}(Bx^2y), \tag{1}$$

$$p_{\alpha+\beta}(y)p_\alpha(x) = p_\alpha(x)p_{\alpha+\beta}(y)p_{2\alpha+\beta}(Cxy). \tag{2}$$

It remains to prove

$$A = B = 1, \qquad C = 2, \qquad k = -1.$$

3.3.3.— Conjugating (1) by w_α gives

$$\begin{aligned}p_{2\alpha+\beta}(y)p_{-\alpha}(-x) = p_{-\alpha}(-x)p_{2\alpha+\beta}(y)\\ \cdot p_{\alpha+\beta}(Akxy)p_\beta(Bx^2y).\end{aligned} \tag{3}$$

Transforming (2) in the same way gives

$$p_{\alpha+\beta}(ky)p_{-\alpha}(-x) = p_{-\alpha}(-x)p_{\alpha+\beta}(ky)p_\beta(Cxy). \tag{4}$$

Conjugating (1) by w_β gives

$$\begin{aligned}p_{-\beta}(-y)p_{\alpha+\beta}(x) = p_{\alpha+\beta}(x)p_{-\beta}(-y)\\ \cdot p_\alpha(-Axy)p_{2\alpha+\beta}(Bx^2y).\end{aligned} \tag{5}$$

3.3.4.— Write

$$w_\beta p_\alpha(x) w_\beta^{-1} = p_{\alpha+\beta}(x).$$

Because $\alpha + 2\beta$ is not a root,

$$p_\beta(1)p_\alpha(x)p_\beta(-1) = p_{-\beta}(1)p_{\alpha+\beta}(x)p_{-\beta}(-1).$$

Using (1) on the left and (5) on the right yields

$$\begin{aligned}&p_\alpha(x)p_\beta(1)p_{\alpha+\beta}(Ax)p_{2\alpha+\beta}(Bx^2)p_\beta(-1)\\ &\quad = p_{\alpha+\beta}(x)p_{-\beta}(1)p_\alpha(Ax)p_{2\alpha+\beta}(-Bx^2)p_{-\beta}(-1).\end{aligned}$$

After commuting the indicated factors and applying (2), this becomes

$$\begin{aligned}p_\alpha(x)p_{\alpha+\beta}(Ax)p_{2\alpha+\beta}(Bx^2) = p_\alpha(Ax)p_{\alpha+\beta}(x)\\ \cdot p_{2\alpha+\beta}((AC-B)x^2).\end{aligned}$$

Hence

$$A = 1, \qquad C = 2B.$$

3.3.5.— Now write

$$w_\alpha p_\beta(y) w_\alpha^{-1} = p_{2\alpha+\beta}(y).$$

Since $3\alpha + \beta$ is not a root,

$$p_\alpha(1) p_\beta(y) p_\alpha(-1) = p_{-\alpha}(1) p_{2\alpha+\beta}(y) p_{-\alpha}(-1).$$

Using (1) on the left and (3) on the right gives

$$p_\beta(y) p_{\alpha+\beta}(-Ay) p_{2\alpha+\beta}(By) = p_{2\alpha+\beta}(y) p_{\alpha+\beta}(Aky) p_\beta(By).$$

The three groups commute, so

$$B = 1, \qquad -A = Ak.$$

Consequently

$$A = B = 1, \qquad C = 2, \qquad k = -1.$$

3.3.6.— We have proved (ii) and (iii). Since

$$s_\beta(t_\alpha) = t_\alpha t_\beta^{(\alpha^*,\beta)} = t_\alpha,$$

one obtains successively

$$\begin{aligned} w_\alpha w_\beta w_\alpha &= w_{2\alpha+\beta} t_\alpha, \\ w_\beta w_\alpha w_\beta w_\alpha w_\beta &= w_{2\alpha+\beta} t_\alpha t_\beta, \\ w_\alpha w_\beta w_\alpha w_\beta w_\alpha w_\beta w_\alpha &= w_\beta^{-1} t_\alpha. \end{aligned}$$

[9] It follows that

$$(w_\beta w_\alpha)^4 = t_\alpha, \qquad (w_\alpha w_\beta)^4 = s_\beta(t_\alpha) = t_\alpha.$$

Remark 3.3.7.— *Put*

$$v_{\alpha+\beta} = \mathrm{int}(h_\beta) v_\alpha, \qquad v_{2\alpha+\beta} = \mathrm{int}(h_\alpha) v_\beta.$$

Condition (v) of 2.3 becomes

$$(A) \quad \begin{cases} \mathrm{int}(h_\alpha h_\beta h_\alpha) v_\beta = v_\beta, \\ \mathrm{int}(h_\beta h_\alpha h_\beta) v_\alpha = v_\alpha, \end{cases}$$

and

$$(B) \quad \begin{cases} v_\beta v_\alpha = v_\alpha v_\beta v_{\alpha+\beta} v_{2\alpha+\beta}, \\ v_{\alpha+\beta} v_\alpha = v_\alpha v_{\alpha+\beta} v_{2\alpha+\beta}^2, \\ v_{\alpha+\beta} v_\beta = v_\beta v_{\alpha+\beta}, \\ v_{2\alpha+\beta} v_\alpha = v_\alpha v_{2\alpha+\beta}, \\ v_{2\alpha+\beta} v_\beta = v_\beta v_{2\alpha+\beta}, \\ v_{2\alpha+\beta} v_{\alpha+\beta} = v_{\alpha+\beta} v_{2\alpha+\beta}. \end{cases}$$

[9] *Editors' note.* The French prints $(\alpha^*, \beta) = 2$; the convention used immediately above gives -2. The conclusion is unchanged because $t_\beta^2 = e$.

3.4. Groups of Type G_2

Proposition 3.4.1.— *Let S be a scheme and G a pinned S-group of type G_2. Write*

$$\Delta = \{\alpha, \beta\}, \qquad R^+ = \{\alpha, \beta, \alpha+\beta, 2\alpha+\beta, 3\alpha+\beta, 3\alpha+2\beta\}.$$

(i)

$$t_{\alpha\beta} = (w_\alpha w_\beta)^6 = e = (w_\beta w_\alpha)^6 = t_{\beta\alpha}.$$

(ii) If

$$\begin{aligned} \mathrm{Ad}(w_\beta)X_\alpha &= X_{\alpha+\beta}, & \mathrm{Ad}(w_\alpha)X_{\alpha+\beta} &= X_{2\alpha+\beta},\\ \mathrm{Ad}(w_\alpha)X_\beta &= -X_{3\alpha+\beta}, & \mathrm{Ad}(w_\beta)X_{3\alpha+\beta} &= X_{3\alpha+2\beta}, \end{aligned}$$

then

$$\begin{aligned} \mathrm{Ad}(w_\alpha)X_{2\alpha+\beta} &= -X_{\alpha+\beta}, & \mathrm{Ad}(w_\alpha)X_{3\alpha+\beta} &= X_\beta,\\ \mathrm{Ad}(w_\alpha)X_{3\alpha+2\beta} &= X_{3\alpha+2\beta}, & \mathrm{Ad}(w_\beta)X_{\alpha+\beta} &= -X_\alpha,\\ \mathrm{Ad}(w_\beta)X_{2\alpha+\beta} &= X_{2\alpha+\beta}, & \mathrm{Ad}(w_\beta)X_{3\alpha+2\beta} &= -X_{3\alpha+\beta}. \end{aligned}$$

(iii) Put

$$\begin{aligned} p_{\alpha+\beta}(x) &= \exp(xX_{\alpha+\beta}) = \mathrm{int}(w_\beta)p_\alpha(x),\\ p_{2\alpha+\beta}(x) &= \exp(xX_{2\alpha+\beta}) = \mathrm{int}(w_\alpha w_\beta)p_\alpha(x),\\ p_{3\alpha+\beta}(x) &= \exp(xX_{3\alpha+\beta}) = \mathrm{int}(w_\alpha)p_\beta(-x),\\ p_{3\alpha+2\beta}(x) &= \exp(xX_{3\alpha+2\beta}) = \mathrm{int}(w_\beta w_\alpha)p_\beta(-x). \end{aligned}$$

Then

$$\begin{aligned} p_\beta(y)p_\alpha(x) &= p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2y)p_{3\alpha+\beta}(x^3y)p_{3\alpha+2\beta}(x^3y^2),\\ p_{\alpha+\beta}(y)p_\alpha(x) &= p_\alpha(x)p_{\alpha+\beta}(y)p_{2\alpha+\beta}(2xy)p_{3\alpha+\beta}(3x^2y)p_{3\alpha+2\beta}(3xy^2),\\ p_{2\alpha+\beta}(y)p_\alpha(x) &= p_\alpha(x)p_{2\alpha+\beta}(y)p_{3\alpha+\beta}(3xy),\\ p_{3\alpha+\beta}(y)p_\beta(x) &= p_\beta(x)p_{3\alpha+\beta}(y)p_{3\alpha+2\beta}(-xy),\\ p_{2\alpha+\beta}(y)p_{\alpha+\beta}(x) &= p_{\alpha+\beta}(x)p_{2\alpha+\beta}(y)p_{3\alpha+2\beta}(3xy). \end{aligned}$$

3.4.2.— The proof occupies 3.4.2–3.4.9. Since

$$(\beta^*, \alpha) = -1, \qquad (\alpha^*, \beta) = -3,$$

we have $\beta(t_\alpha) = \alpha(t_\beta) = -1$. Define the four nonsimple root vectors as in (ii). Then

$$\begin{aligned} \mathrm{Ad}(w_\beta)X_{\alpha+\beta} &= \alpha(t_\beta)X_\alpha = -X_\alpha,\\ \mathrm{Ad}(w_\alpha)X_{2\alpha+\beta} &= \alpha(t_\alpha)\beta(t_\alpha)X_{\alpha+\beta} = -X_{\alpha+\beta},\\ \mathrm{Ad}(w_\alpha)X_{3\alpha+\beta} &= -\beta(t_\alpha)X_\beta = X_\beta,\\ \mathrm{Ad}(w_\beta)X_{3\alpha+2\beta} &= \alpha(t_\beta)^3\beta(t_\beta)X_{3\alpha+\beta} = -X_{3\alpha+\beta}. \end{aligned}$$

Since $(3\alpha+2\beta) \pm \alpha$ and $(2\alpha+\beta) \pm \beta$ are not roots,

$$\mathrm{Ad}(w_\alpha)X_{3\alpha+2\beta} = X_{3\alpha+2\beta}, \qquad \mathrm{Ad}(w_\beta)X_{2\alpha+\beta} = X_{2\alpha+\beta}.$$

3.4.3.— By Exposé XXII, 5.5.2, there are sections

$$A, B, C, D, E, F, G, H, J \in \mathbf{G}_a(S)$$

such that

$$(1)\quad p_\beta(y)p_\alpha(x) = p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(Axy)p_{2\alpha+\beta}(Bx^2y)p_{3\alpha+\beta}(Cx^3y)p_{3\alpha+2\beta}(Dx^3y^2),$$
$$(2)\quad p_{\alpha+\beta}(y)p_\alpha(x) = p_\alpha(x)p_{\alpha+\beta}(y)p_{2\alpha+\beta}(Exy)p_{3\alpha+\beta}(Fx^2y)p_{3\alpha+2\beta}(Gxy^2),$$
$$(3)\quad p_{2\alpha+\beta}(y)p_\alpha(x) = p_\alpha(x)p_{2\alpha+\beta}(y)p_{3\alpha+\beta}(Hxy),$$
$$(4)\quad p_{3\alpha+\beta}(y)p_\beta(x) = p_\beta(x)p_{3\alpha+\beta}(y)p_{3\alpha+2\beta}(Jxy).$$

3.4.4.— Conjugating (1), (3), and (4) by w_β gives

$$p_{-\beta}(-y)p_{\alpha+\beta}(x) = p_{\alpha+\beta}(x)p_{-\beta}(-y)p_\alpha(-Axy)p_{2\alpha+\beta}(Bx^2y)$$
$$(5)\qquad \cdot p_{3\alpha+2\beta}(Cx^3y)p_{3\alpha+\beta}(-Dx^3y^2),$$
$$(6)\qquad p_{2\alpha+\beta}(y)p_{\alpha+\beta}(x) = p_{\alpha+\beta}(x)p_{2\alpha+\beta}(y)p_{3\alpha+2\beta}(Hxy),$$
$$(7)\qquad p_{3\alpha+2\beta}(y)p_{-\beta}(-x) = p_{-\beta}(-x)p_{3\alpha+2\beta}(y)p_{3\alpha+\beta}(-Jxy).$$

Conjugating (1) by w_α gives

$$p_{3\alpha+\beta}(-y)p_{-\alpha}(-x) = p_{-\alpha}(-x)p_{3\alpha+\beta}(-y)p_{2\alpha+\beta}(Axy)p_{\alpha+\beta}(-Bx^2y)$$
$$(8)\qquad \cdot p_\beta(Cx^3y)p_{3\alpha+\beta}(Dx^3y^2).$$

3.4.5.— The identity

$$w_\beta p_\alpha(x)w_\beta^{-1} = p_{\alpha+\beta}(x)$$

may be written, since $\alpha + 2\beta$ is not a root,

$$(9)\qquad p_\beta(1)p_\alpha(x)p_\beta(-1) = p_{-\beta}(1)p_{\alpha+\beta}(x)p_{-\beta}(-1).$$

Using (1) and then (4), its left side becomes

$$(10)\qquad p_\alpha(x)p_{\alpha+\beta}(Ax)p_{2\alpha+\beta}(Bx^2)p_{3\alpha+\beta}(Cx^3)p_{3\alpha+2\beta}((D-CJ)x^3).$$

Using (5) and then (7), its right side becomes

$$p_{\alpha+\beta}(x)p_\alpha(Ax)p_{2\alpha+\beta}(-Bx^2)p_{3\alpha+2\beta}(-Cx^3)p_{3\alpha+\beta}((CJ-D)x^3).$$

Applying (2) transforms this into

$$p_\alpha(Ax)p_{\alpha+\beta}(x)p_{2\alpha+\beta}((AE-B)x^2)p_{3\alpha+\beta}((A^2F+CJ-D)x^3)$$
$$(12)\qquad \cdot p_{3\alpha+2\beta}((AG-C)x^3).$$

Comparing (10) and (12) gives

$$A = 1, \qquad E = 2B, \qquad C + D = F + CJ, \qquad F = G.$$

3.4.6.— Write

$$w_\alpha p_\beta(y)w_\alpha^{-1} = p_{3\alpha+\beta}(-y).$$

Since $4\alpha + \beta$ is not a root,

$$(13)\qquad p_\alpha(1)p_\beta(y)p_\alpha(-1) = p_{-\alpha}(1)p_{3\alpha+\beta}(-y)p_{-\alpha}(-1).$$

Using (1), the left side is

$$p_\beta(y)p_{\alpha+\beta}(-Ay)p_{2\alpha+\beta}(By)p_{3\alpha+\beta}(-Cy)p_{3\alpha+2\beta}(-Dy^2).$$

Using (8), (6), and (4), the right side is

$$p_\beta(Cy)p_{\alpha+\beta}(-By)p_{2\alpha+\beta}(Ay)p_{3\alpha+\beta}(-y)p_{3\alpha+2\beta}((D-CJ-ABH)y^2).$$

Thus

$$C=1, \qquad A=B, \qquad D-CJ-ABH=-D.$$

Together with the preceding identities, this yields

$$A=B=C=1, \quad E=2, \quad F=G, \quad D+1=F+J, \quad 2D=H+J.$$

3.4.7.— From

$$w_\beta p_{3\alpha+\beta}(x)w_\beta^{-1}=p_{3\alpha+2\beta}(x)$$

one obtains

$$p_{3\alpha+\beta}(x)p_{3\alpha+2\beta}(-Jx)=p_{3\alpha+2\beta}(x)p_{3\alpha+\beta}(-Jx),$$

and therefore $J=-1$.

3.4.8.— Finally,

$$w_\alpha p_{\alpha+\beta}(y)w_\alpha^{-1}=p_{2\alpha+\beta}(y),$$

or equivalently

$$p_\alpha(1)p_{\alpha+\beta}(y)p_\alpha(-1)=p_{-\alpha}(1)p_\alpha(-1)p_{2\alpha+\beta}(y)p_\alpha(1)p_{-\alpha}(-1).$$

Using (2) on the left and (3) on the right gives

$$\begin{aligned}&p_{\alpha+\beta}(y)p_{2\alpha+\beta}(-Ey)p_{3\alpha+\beta}(Fy)p_{3\alpha+2\beta}(-Gy^2)\\&\quad=p_{-\alpha}(1)p_{2\alpha+\beta}(y)p_{3\alpha+\beta}(Hy)p_{-\alpha}(-1).\end{aligned}$$

Commuting $p_{-\alpha}(-1)$ first past $p_{3\alpha+\beta}(Hy)$, and then past $p_{2\alpha+\beta}(y)$, introduces no new $p_{3\alpha+\beta}$-factor. Comparing those factors gives $F=H$. Hence

$$2D=D+1, \qquad D=1, \qquad F=G=H=2D-J=3.$$

This determines all the coefficients and proves (iii).

3.4.9.— For (i), one obtains successively

$$\begin{aligned}w_\alpha w_\beta w_\alpha&=w_{3\alpha+\beta}^{-1}t_\alpha,\\w_\beta(w_\alpha w_\beta)^2&=w_{3\alpha+2\beta}^{-1}t_\alpha,\\w_\alpha(w_\beta w_\alpha)^3&=w_{3\alpha+2\beta}^{-1},\\w_\beta(w_\alpha w_\beta)^4&=w_{3\alpha+\beta}t_\beta,\\w_\alpha(w_\beta w_\alpha)^5&=w_\beta^{-1}.\end{aligned}$$

Consequently

$$(w_\alpha w_\beta)^6=(w_\beta w_\alpha)^6=e.$$

Remark 3.4.10.— *Condition (v) of 2.3 consists first of*

$$(A)\quad\begin{cases}\mathrm{int}(h_\alpha h_\beta h_\alpha h_\beta h_\alpha)v_\beta=v_\beta,\\ \mathrm{int}(h_\beta h_\alpha h_\beta h_\alpha h_\beta)v_\alpha=v_\alpha,\end{cases}$$

and, after setting

$$v_{\alpha+\beta} = \mathrm{int}(h_\beta)v_\alpha, \qquad v_{2\alpha+\beta} = \mathrm{int}(h_\alpha h_\beta)v_\alpha,$$
$$v_{3\alpha+\beta} = \mathrm{int}(h_\alpha)v_\beta^{-1}, \quad v_{3\alpha+2\beta} = \mathrm{int}(h_\beta h_\alpha)v_\beta^{-1},$$

of the commutation relations

$$\begin{aligned}
v_\beta v_\alpha &= v_\alpha v_\beta v_{\alpha+\beta} v_{2\alpha+\beta} v_{3\alpha+\beta} v_{3\alpha+2\beta},\\
v_{\alpha+\beta} v_\alpha &= v_\alpha v_{\alpha+\beta} v_{2\alpha+\beta}^2 v_{3\alpha+\beta}^3 v_{3\alpha+2\beta}^3,\\
v_{2\alpha+\beta} v_\alpha &= v_\alpha v_{2\alpha+\beta} v_{3\alpha+\beta}^3,\\
v_{3\alpha+\beta} v_\alpha &= v_\alpha v_{3\alpha+\beta}, \qquad & v_{3\alpha+2\beta} v_\alpha &= v_\alpha v_{3\alpha+2\beta},\\
v_{\alpha+\beta} v_\beta &= v_\beta v_{\alpha+\beta}, & v_{2\alpha+\beta} v_\beta &= v_\beta v_{2\alpha+\beta},\\
v_{3\alpha+\beta} v_\beta &= v_\beta v_{3\alpha+\beta} v_{3\alpha+2\beta}^{-1},\\
v_{3\alpha+2\beta} v_\beta &= v_\beta v_{3\alpha+2\beta},\\
v_{2\alpha+\beta} v_{\alpha+\beta} &= v_{\alpha+\beta} v_{2\alpha+\beta} v_{3\alpha+2\beta}^3,\\
v_{3\alpha+\beta} v_{\alpha+\beta} &= v_{\alpha+\beta} v_{3\alpha+\beta},\\
v_{3\alpha+2\beta} v_{\alpha+\beta} &= v_{\alpha+\beta} v_{3\alpha+2\beta},\\
v_{3\alpha+\beta} v_{2\alpha+\beta} &= v_{2\alpha+\beta} v_{3\alpha+\beta},\\
v_{3\alpha+2\beta} v_{2\alpha+\beta} &= v_{2\alpha+\beta} v_{3\alpha+2\beta},\\
v_{3\alpha+2\beta} v_{3\alpha+\beta} &= v_{3\alpha+\beta} v_{3\alpha+2\beta}.
\end{aligned} \tag{B}$$

3.5. Explicit Form of the Generators-and-Relations Theorem

Theorem 3.5.1.— *Let S be a scheme and G a pinned S-group, with maximal torus T, system of simple roots Δ, and elements*

$$u_\alpha \in U_\alpha(S)^\times, \qquad w_\alpha \in \mathrm{Norm}_G(T)(S) \qquad (\alpha \in \Delta)$$

defined by the pinning. Let H be an fppf S-sheaf in groups, let

$$f_T : T \to H, \qquad f_\alpha : U_\alpha \to H \quad (\alpha \in \Delta)$$

be morphisms of groups, and let $h_\alpha \in H(S)$. Put

$$v_\alpha = f_\alpha(u_\alpha).$$

There exists a morphism of groups $f : G \to H$ extending f_T and all the f_α, and satisfying $f(w_\alpha) = h_\alpha$, if and only if:

(i) for every $S' \to S$, $\alpha \in \Delta$, $t \in T(S')$, and $x \in U_\alpha(S')$,

$$\mathrm{int}(f_T(t))f_\alpha(x) = f_\alpha(\mathrm{int}(t)x) = f_\alpha(x^{\alpha(t)}); \tag{1}$$

(ii) for every $\alpha \in \Delta$, every $S' \to S$, and every $t \in T(S')$,

$$\mathrm{int}(h_\alpha)f_T(t) = f_T(s_\alpha(t)) = f_T\Big(t\alpha^*(\alpha(t)^{-1})\Big); \tag{2}$$

(iii) for every $\alpha \in \Delta$,

$$h_\alpha^2 = f_T(\alpha^*(-1)), \tag{3_1}$$

and

$$(h_\alpha v_\alpha)^3 = e; \tag{4}$$

(iv) for distinct $\alpha, \beta \in \Delta$:

(a) the appropriate braid relation is

$$\begin{cases} (h_\alpha h_\beta)^2 = f_T(\alpha^*(-1)\beta^*(-1)), & (\alpha^*, \beta) = 0, \\ (h_\alpha h_\beta)^3 = e, & (\alpha^*, \beta) = -1, \\ (h_\alpha h_\beta)^4 = f_T(\alpha^*(-1)), & (\alpha^*, \beta) = -2, \\ (h_\alpha h_\beta)^6 = e, & (\alpha^*, \beta) = -3; \end{cases} \tag{3_2}$$

(b) the corresponding relations (A) and (B) of 3.1.3, 3.2.8, 3.3.7, or 3.4.10 hold.

When it exists, f is necessarily unique.

This follows immediately from Theorem 2.3, Remark 2.6, and the calculations in each rank-two case.

Remark 3.5.2.— *The result may equivalently be presented by giving morphisms*

$$a_\alpha : T \cdot U_\alpha \longrightarrow H, \qquad b_\alpha : \mathrm{Norm}_{Z_\alpha}(T) \longrightarrow H \qquad (\alpha \in \Delta),$$

and putting

$$h_\alpha = b_\alpha(w_\alpha), \qquad v_\alpha = a_\alpha(u_\alpha).$$

The required conditions are:

(1) all the a_α and b_α have the same restriction to T;

(2) condition (4) and all the conditions in (iv) of Theorem 3.5.1 hold.

3.5.3.— Further applications will be given in the next Exposé. Here is one. Theorem 3.5.1 describes G by generators and relations in the category of fppf S-sheaves. More explicitly, for every $S' \to S$, let $H(S')$ be the group generated by

$$T(S'), \qquad U_\alpha(S') \ (\alpha \in R), \qquad w_\alpha \ (\alpha \in R),$$

subject to relations analogous to

$$(1),\ (2),\ (3_1),\ (4),\ (3_2),\ (A),\ (B).$$

Then G is the sheaf associated with the presheaf $S' \mapsto H(S')$.

In particular, if S' is the spectrum of an algebraically closed field k, then $G(S') = H(S')$. This follows immediately from the Nullstellensatz in the form: an fppf-covering sieve over an algebraically closed field is trivial. Thus Theorem 3.5.1 gives an explicit presentation by generators and relations of the abstract group $G(k)$.

4. Uniqueness of Pinned Groups: Fundamental Theorem

Theorem 4.1.— *Let S be a nonempty scheme. The functor R of 1.6 is fully faithful. More precisely, let G, G' be pinned S-groups, let $p > 0$ be an integer such that $x \mapsto x^p$ is an endomorphism of $\mathbf{G}_{a,S}$, and let*

$$h : R(G') \longrightarrow R(G)$$

be a p-morphism of pinned root data. There is a unique morphism of pinned groups $f : G \to G'$ such that $R(f) = h$.

Uniqueness was proved in 1.9, so only existence remains. By hypothesis there are a bijection $d : R \xrightarrow{\sim} R'$ and a map

$$q : R \longrightarrow \{p^n \mid n \in \mathbf{N}\}$$

such that, for every $\alpha \in R$,

$$h(d(\alpha)) = q(\alpha)\alpha, \qquad {}^t h(\alpha^*) = q(\alpha)d(\alpha)^*.$$

In particular, G and G' have the same semisimple rank.

4.1.1.— Suppose that both semisimple ranks are 0. Then G, G' are tori:

$$G = T = D_S(M), \qquad G' = T' = D_S(M'),$$

and $h : M' \to M$ is an ordinary homomorphism. Take $f = D_S(h)$.

4.1.2.— Suppose that both semisimple ranks are 1, and put

$$f_T = D_S(h) : T \longrightarrow T'.$$

Writing $\alpha' = d(\alpha)$, the diagram

$$\begin{array}{ccccc}
\mathbf{G}_{m,S} & \xrightarrow{\alpha^*} & T & \xrightarrow{\alpha} & \mathbf{G}_{m,S} \\
\downarrow{\scriptstyle q(\alpha)} & & \downarrow{\scriptstyle f_T} & & \downarrow{\scriptstyle q(\alpha)} \\
\mathbf{G}_{m,S} & \xrightarrow{\alpha'^*} & T' & \xrightarrow{\alpha'} & \mathbf{G}_{m,S}
\end{array}$$

commutes. Apply Exposé XX, 4.1.

4.1.3.— Suppose that both semisimple ranks are 2. Exposé XXI, 7.5.3 lists every possible h; we verify the conditions of Corollary 2.5 in each case. Write

$$\Delta = \{\alpha, \beta\}, \qquad \Delta' = \{\alpha', \beta'\}, \qquad d(\alpha) = \alpha', \quad d(\beta) = \beta'.$$

4.1.4. G and G' of type $A_1 \times A_1$.— Here

$$h(\alpha') = q\alpha, \qquad h(\beta') = q_1\beta.$$

Conditions 2.5(ii) and (iii) follow from Proposition 3.1.2(ii),(iii). For (i),

$$\begin{aligned}
D_S(h)t_{\alpha\beta} &= D_S(h)(t_\alpha t_\beta) \\
&= {}^t h(\alpha^*)(-1)\, {}^t h(\beta^*)(-1) \\
&= \alpha'^*((-1)^q)\, \beta'^*((-1)^{q_1}).
\end{aligned}$$

The assumption on $x \mapsto x^p$, with $S \neq \varnothing$, implies that $p = 1$ or S has characteristic p. Thus $(-1)^q = -1$: if q is even, then $p = 2$ and $1 = -1$. Consequently

$$D_S(h)t_{\alpha\beta} = \alpha'^*(-1)\beta'^*(-1) = t'_{\alpha'\beta'}.$$

4.1.5. G and G' of type A_2.— Here

$$h(\alpha') = q\alpha, \qquad h(\beta') = q\beta.$$

Put

$$X_{\alpha+\beta} = \mathrm{Ad}(w_\beta)X_\alpha, \qquad X'_{\alpha'+\beta'} = \mathrm{Ad}(w'_{\beta'})X'_{\alpha'}.$$

Condition (i) follows as above from Proposition 3.2.1(i), and (ii) follows immediately from Proposition 3.2.1(ii). For (iii), the map

$$p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(z) \longmapsto p'_{\alpha'}(x^q)p'_{\beta'}(y^q)p'_{\alpha'+\beta'}(z^q)$$

must be a homomorphism. The only nontrivial relation is

$$p_\beta(y)p_\alpha(x) = p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(xy),$$

which maps to

$$p'_{\beta'}(y^q)p'_{\alpha'}(x^q) = p'_{\alpha'}(x^q)p'_{\beta'}(y^q)p'_{\alpha'+\beta'}(x^q y^q).$$

4.1.6.— The same argument treats types B_2 and G_2 when the radicial exponents are equal, using Propositions 3.3.1 and 3.4.1. It remains to treat the two exceptional cases in Exposé XXI, 7.5.3.

4.1.7. Type B_2, characteristic 2, $q(\alpha) = 2q$, $q(\beta) = q$.— The positive roots are

$$\{\alpha, \beta, \alpha+\beta, 2\alpha+\beta\}$$

and

$$\{\alpha', \beta', \alpha'+\beta', \alpha'+2\beta'\},$$

where α and β' are the short simple roots. We have

$$\begin{aligned} h(\alpha') &= 2q\alpha, & h(\beta') &= q\beta, \\ h(\alpha'+\beta') &= q(2\alpha+\beta), & h(\alpha'+2\beta') &= 2q(\alpha+\beta), \end{aligned}$$

so

$$\begin{aligned} d(\alpha+\beta) &= \alpha'+2\beta', & q(\alpha+\beta) &= 2q, \\ d(2\alpha+\beta) &= \alpha'+\beta', & q(2\alpha+\beta) &= q. \end{aligned}$$

Put

$$\begin{aligned} X_{\alpha+\beta} &= \mathrm{Ad}(w_\beta)X_\alpha, & X_{2\alpha+\beta} &= \mathrm{Ad}(w_\alpha)X_\beta, \\ X'_{\alpha'+\beta'} &= \mathrm{Ad}(w'_{\alpha'})X'_{\beta'}, & X'_{\alpha'+2\beta'} &= \mathrm{Ad}(w'_{\beta'})X'_{\alpha'}. \end{aligned}$$

For (i), characteristic 2 gives $-1 = 1$, hence

$$t_{\alpha\beta} = t_\alpha = \alpha^*(-1) = e = \beta'^*(-1) = t'_{\beta'} = t'_{\alpha'\beta'}.$$

For (ii), the two defining identities are

$$\begin{aligned} \mathrm{Ad}(w_\alpha)X_\beta &= X_{2\alpha+\beta}, & \mathrm{Ad}(w'_{\alpha'})X'_{\beta'} &= X'_{\alpha'+\beta'} = X'_{d(2\alpha+\beta)}, \\ \mathrm{Ad}(w_\beta)X_\alpha &= X_{\alpha+\beta}, & \mathrm{Ad}(w'_{\beta'})X'_{\alpha'} &= X'_{\alpha'+2\beta'} = X'_{d(\alpha+\beta)}. \end{aligned}$$

Proposition 3.3.1(ii), together with $-1 = 1$, gives the four remaining identities:

$$\begin{aligned}
\mathrm{Ad}(w_\alpha)X_{\alpha+\beta} &= X_{\alpha+\beta}, & \mathrm{Ad}(w'_{\alpha'})X'_{d(\alpha+\beta)} &= X'_{d(\alpha+\beta)},\\
\mathrm{Ad}(w_\alpha)X_{2\alpha+\beta} &= X_\beta, & \mathrm{Ad}(w'_{\alpha'})X'_{d(2\alpha+\beta)} &= X'_{d(\beta)},\\
\mathrm{Ad}(w_\beta)X_{\alpha+\beta} &= X_\alpha, & \mathrm{Ad}(w'_{\beta'})X'_{d(\alpha+\beta)} &= X'_{d(\alpha)},\\
\mathrm{Ad}(w_\beta)X_{2\alpha+\beta} &= X_{2\alpha+\beta}, & \mathrm{Ad}(w'_{\beta'})X'_{d(2\alpha+\beta)} &= X'_{d(2\alpha+\beta)}.
\end{aligned}$$

For (iii), the sole nontrivial relations are

$$\begin{aligned}
p_\beta(y)p_\alpha(x) &= p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2y),\\
p'_{\alpha'}(y')p'_{\beta'}(x') &= p'_{\beta'}(x')p'_{\alpha'}(y')p'_{\alpha'+\beta'}(x'y')p'_{\alpha'+2\beta'}(x'y'^2).
\end{aligned}$$

The proposed map is

$$\begin{aligned}
&p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(z)p_{2\alpha+\beta}(t)\\
&\quad\longmapsto p'_{\alpha'}(x^{2q})p'_{\beta'}(y^q)p'_{\alpha'+2\beta'}(z^{2q})p'_{\alpha'+\beta'}(t^q).
\end{aligned}$$

It respects the first relation because the second, with $y' = x^{2q}$ and $x' = y^q$, reads

$$\begin{aligned}
p'_{\beta'}(y^q)p'_{\alpha'}(x^{2q}) = p'_{\alpha'}(x^{2q})p'_{\beta'}(y^q)p'_{\alpha'+2\beta'}((xy)^{2q})\\
\cdot p'_{\alpha'+\beta'}((x^2y)^q).
\end{aligned}$$

4.1.8. Type G_2, characteristic 3, $q(\alpha) = 3q$, $q(\beta) = q$.— The positive roots are

$$\{\alpha, \beta, \alpha+\beta, 2\alpha+\beta, 3\alpha+\beta, 3\alpha+2\beta\}$$

and

$$\{\alpha', \beta', \alpha'+\beta', \alpha'+2\beta', \alpha'+3\beta', 2\alpha'+3\beta'\},$$

where again α and β' are short. We have

$$\begin{aligned}
h(\alpha') &= 3q\alpha, & h(\beta') &= q\beta,\\
h(\alpha'+\beta') &= q(3\alpha+\beta), & h(\alpha'+2\beta') &= q(3\alpha+2\beta),\\
h(\alpha'+3\beta') &= 3q(\alpha+\beta), & h(2\alpha'+3\beta') &= 3q(2\alpha+\beta),
\end{aligned}$$

and hence

$$\begin{aligned}
d(\alpha+\beta) &= \alpha'+3\beta', & q(\alpha+\beta) &= 3q,\\
d(2\alpha+\beta) &= 2\alpha'+3\beta', & q(2\alpha+\beta) &= 3q,\\
d(3\alpha+\beta) &= \alpha'+\beta', & q(3\alpha+\beta) &= q,\\
d(3\alpha+2\beta) &= \alpha'+2\beta', & q(3\alpha+2\beta) &= q.
\end{aligned}$$

Define

$$\begin{aligned}
X_{\alpha+\beta} &= \mathrm{Ad}(w_\beta)X_\alpha, & X_{2\alpha+\beta} &= \mathrm{Ad}(w_\alpha)X_{\alpha+\beta},\\
X_{3\alpha+\beta} &= -\mathrm{Ad}(w_\alpha)X_\beta, & X_{3\alpha+2\beta} &= \mathrm{Ad}(w_\beta)X_{3\alpha+\beta},\\
X'_{\alpha'+\beta'} &= -\mathrm{Ad}(w'_{\alpha'})X'_{\beta'}, & X'_{\alpha'+2\beta'} &= \mathrm{Ad}(w'_{\beta'})X'_{\alpha'+\beta'},\\
X'_{\alpha'+3\beta'} &= \mathrm{Ad}(w'_{\beta'})X'_{\alpha'}, & X'_{2\alpha'+3\beta'} &= \mathrm{Ad}(w'_{\alpha'})X'_{\alpha'+3\beta'}.
\end{aligned}$$

Condition (i) follows from Proposition 3.4.1(i). Four instances of (ii) hold by definition:

$$\begin{aligned}
\mathrm{Ad}(w_\beta)X_\alpha &= X_{\alpha+\beta}, & \mathrm{Ad}(w'_{\beta'})X'_{\alpha'} &= X'_{d(\alpha+\beta)},\\
\mathrm{Ad}(w_\alpha)X_\beta &= -X_{3\alpha+\beta}, & \mathrm{Ad}(w'_{\alpha'})X'_{\beta'} &= -X'_{d(3\alpha+\beta)},\\
\mathrm{Ad}(w_\beta)X_{3\alpha+\beta} &= X_{3\alpha+2\beta}, & \mathrm{Ad}(w'_{\beta'})X'_{d(3\alpha+\beta)} &= X'_{d(3\alpha+2\beta)},\\
\mathrm{Ad}(w_\alpha)X_{\alpha+\beta} &= X_{2\alpha+\beta}, & \mathrm{Ad}(w'_{\alpha'})X'_{d(\alpha+\beta)} &= X'_{d(2\alpha+\beta)}.
\end{aligned}$$

The remaining instances follow from Proposition 3.4.1(ii); for example,

$$\begin{aligned} \mathrm{Ad}(w_\alpha)X_{2\alpha+\beta} &= -X_{\alpha+\beta}, \qquad \mathrm{Ad}(w'_{\alpha'})X'_{d(2\alpha+\beta)} = -X'_{d(\alpha+\beta)}, \\ \mathrm{Ad}(w_\beta)X_{3\alpha+2\beta} &= -X_{3\alpha+\beta}, \quad \mathrm{Ad}(w'_{\beta'})X'_{d(3\alpha+2\beta)} = -X'_{d(3\alpha+\beta)}. \end{aligned}$$

For (iii), in characteristic 3, the nontrivial relations in U are

$$\begin{aligned} p_\beta(y)p_\alpha(x) &= p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2y)p_{3\alpha+\beta}(x^3y)p_{3\alpha+2\beta}(x^3y^2), \\ p_{\alpha+\beta}(y)p_\alpha(x) &= p_\alpha(x)p_{\alpha+\beta}(y)p_{2\alpha+\beta}(-xy), \\ p_{3\alpha+\beta}(y)p_\beta(x) &= p_\beta(x)p_{3\alpha+\beta}(y)p_{3\alpha+2\beta}(-xy). \end{aligned}$$

The corresponding relations in U' are

$$\begin{aligned} p'_{\alpha'}(y')p'_{\beta'}(x') &= p'_{\beta'}(x')p'_{\alpha'}(y')p'_{\alpha'+\beta'}(-x'y')p'_{\alpha'+2\beta'}(-x'^2y') \\ &\quad \cdot p'_{\alpha'+3\beta'}(-x'^3y')p'_{2\alpha'+3\beta'}(-x'^3y'^2), \\ p'_{\alpha'+\beta'}(y')p'_{\beta'}(x') &= p'_{\beta'}(x')p'_{\alpha'+\beta'}(y')p'_{\alpha'+2\beta'}(x'y'), \\ p'_{\alpha'+3\beta'}(y')p'_{\alpha'}(x') &= p'_{\alpha'}(x')p'_{\alpha'+3\beta'}(y')p'_{2\alpha'+3\beta'}(x'y'). \end{aligned}$$

Define $\phi : U \to U'$ by

$$\begin{aligned} &\phi(p_\alpha(x)p_\beta(y)p_{\alpha+\beta}(t)p_{2\alpha+\beta}(u)p_{3\alpha+\beta}(v)p_{3\alpha+2\beta}(w)) \\ &\quad = p'_{\alpha'}(x^{3q})p'_{\beta'}(y^q)p'_{\alpha'+3\beta'}(t^{3q})p'_{2\alpha'+3\beta'}(u^{3q})p'_{\alpha'+\beta'}(v^q)p'_{\alpha'+2\beta'}(w^q). \end{aligned}$$

Substituting x^{3q}, y^q in the three displayed relations for U' yields exactly the images of the three relations for U; thus ϕ is a homomorphism.

4.1.9. Semisimple rank greater than 2.— For $\alpha \in \Delta$, put $\alpha' = d(\alpha)$. For every (α, β), consider the pinned rank-at-most-two groups

$$Z_{\alpha\beta}, \qquad Z'_{\alpha'\beta'}.$$

The homomorphism $M' \to M$ underlying h induces a p-morphism

$$h_{\alpha\beta} : R(Z'_{\alpha'\beta'}) \longrightarrow R(Z_{\alpha\beta}).$$

By the preceding cases, there is a morphism of pinned groups

$$f_{\alpha\beta} : Z_{\alpha\beta} \longrightarrow Z'_{\alpha'\beta'}$$

with $R(f_{\alpha\beta}) = h_{\alpha\beta}$. The restrictions

$$f_{\alpha\beta}|_{Z_\alpha}, \qquad f_{\alpha\alpha} : Z_\alpha \to Z'_{\alpha'}$$

correspond to the same morphism of pinned root data, and therefore coincide by uniqueness. Corollary 2.4 now glues the $f_{\alpha\beta}$ to a morphism $f : G \to G'$. It is a morphism of pinned groups and satisfies $R(f) = h$, completing the proof.

5. Corollaries of the Fundamental Theorem

The most important is the following.

Corollary 5.1.— *Let S be a nonempty scheme, let G, G' be pinned S-groups, and let*

$$h : R(G') \xrightarrow{\sim} R(G)$$

be an isomorphism of pinned root data. There is a unique isomorphism of pinned S-groups $f : G \xrightarrow{\sim} G'$ such that $R(f) = h$.

This also follows from Theorem 3.5.1, because its relations can be written using only $R(G)$. It also follows from the elementary part of the proof of Theorem 4.1, without the exceptional isogenies of 4.1.7 and 4.1.8.

Corollary 5.2 (Uniqueness theorem).— *Let S be a scheme and let G, G' be two splittable S-groups. If they have the same type, then they are isomorphic.*

Corollary 5.3.— *Let S be a scheme and G, G' two splittable S-groups. The following are equivalent:*

(i) G and G' are isomorphic;

(ii) they are locally isomorphic for the fpqc topology;

(iii) there is $s \in S$ such that G_s and G'_s have the same type.

Clearly (i) implies (ii), which implies (iii). Conversely, (iii) gives

$$R(G) = R(G_s) = R(G'_s) = R(G'),$$

so Corollary 5.2 applies.

Corollary 5.4 (Uniqueness of Chevalley schemes).— *Let G, G' be reductive groups over $\mathbf{Z}$, each possessing a split maximal torus. The following are equivalent:*

(i) G and G' are isomorphic;

(ii) there is $s \in \operatorname{Spec} \mathbf{Z}$ such that G_s and G'_s have the same type;

(iii) $G_{\mathbf{C}}$ and $G'_{\mathbf{C}}$ have the same type.

Indeed, G and G' are splittable by Exposé XXII, 2.2. [10]

Corollary 5.5 (Existence of outer automorphisms).— *Let S be a scheme, G a pinned S-group, and h an automorphism of the pinned root datum $R(G)$. There is a unique automorphism u of G preserving the pinning and satisfying $R(u) = h$.*

Corollary 5.5 bis.— *Let S be a scheme, G a split reductive S-group, and R^+ a system of positive roots. For every simple root α, choose an isomorphism of vector groups*

$$p_\alpha : \mathbf{G}_{a,S} \xrightarrow{\sim} U_\alpha.$$

[10] *Editors' note.* In fact every $\mathbf{Z}$-torus is split: every $\mathbf{Z}$-torus is isotrivial, and every étale cover of $\operatorname{Spec} \mathbf{Z}$ is trivial.

Let h be an automorphism of M permuting the positive roots and the corresponding coroots: if $\alpha \in R^+$, then

$$h(\alpha) \in R^+, \qquad h^\vee(\alpha^*) = h(\alpha)^*.$$

There is a unique automorphism u of G inducing $D_S(h)$ on T and satisfying $u \circ p_\alpha = p_{h(\alpha)}$ for every simple root α.

Corollary 5.6.— *Let G, G' be reductive S-groups. The following are equivalent:*

(i) G, G' are locally isomorphic for the fpqc topology;

(i bis) they are locally isomorphic for the étale topology;

(ii) G_s, G'_s are isomorphic for every $s \in S$;

(iii) the functions $s \mapsto \mathrm{type}(G_s)$ and $s \mapsto \mathrm{type}(G'_s)$ are equal.

The implication (i bis)⇒(i) is immediate; (i)⇒(ii) follows from the principle of finite extension (EGA IV_3, 9.1.4); and (ii)⇒(iii) is immediate. For (iii)⇒(i bis), one may suppose G, G' splittable (Exposé XXII, 2.3), and then apply Corollary 5.3.

Corollary 5.7.— *Let S be a scheme, G a reductive S-group, and G' an affine smooth S-group with connected fibers. If $s \in S$ and $G_s \simeq G'_s$, then there is an étale morphism $S' \to S$, covering s, such that $G_{S'} \simeq G'_{S'}$.*

By Exposés XIX, 2.5 and XXII, 2.1, one may suppose G, G' reductive and splittable, and Corollary 5.3 applies.

Corollary 5.8.— *Let k be a field and G, G' reductive k-groups. The following are equivalent:*

(i) G, G' have the same type;

(ii) $G \otimes_k \bar{k}$ and $G' \otimes_k \bar{k}$ are isomorphic;

(iii) for some finite separable extension K/k, $G \otimes_k K$ and $G' \otimes_k K$ are isomorphic.

Corollary 5.9.— *Let S be a nonempty scheme and R a root datum. The following are equivalent:*

(i) there is a pinned S-group of type R;

(ii) there is an S-group of type R;

(iii) fpqc-locally, there is a reductive S-group of type R.

Only (iii)⇒(i) needs proof. Suppose, for simplicity, that there are a faithfully flat quasi-compact morphism $S' \to S$ and a reductive S'-group G' of type R. We may suppose G' splittable and choose a pinning E', writing $R = R(G', E')$. The two pullbacks of (G', E') to

$$S'' = S' \times_S S'$$

are pinned groups (G''_1, E''_1), (G''_2, E''_2), with canonical isomorphisms

$$p_i : R(G''_i, E''_i) \xrightarrow{\sim} R.$$

Thus

$$p = p_2^{-1} \circ p_1 : R(G_1'', E_1'') \xrightarrow{\sim} R(G_2'', E_2'').$$

The uniqueness theorem gives a unique isomorphism

$$f : (G_1'', E_1'') \xrightarrow{\sim} (G_2'', E_2'')$$

with $R(f) = p$. This is a descent datum on G'. Its cocycle condition may be checked after applying R, since R is fully faithful, and then follows from the construction of p. Because G' is affine, the datum is effective. The pinning is stable under descent, so it descends to a pinned S-group (G, E) of type R.

N.B. In the language of fibered categories, the preceding proof becomes both shorter and more transparent.

Corollary 5.10.— *Let S be a nonempty scheme and R a pinned root datum for which there exists a reductive S-group of type R. Then there is a pinned S-group of type R, unique up to unique isomorphism.*

Definition 5.11.— *Under these hypotheses, denote the unique pinned S-group of type R by $\acute{\mathrm{E}}\mathrm{p}_S(R)$, its canonical maximal torus by $T_S(R)$, its canonical Borel subgroup by $B_S(R)$, and so on.*

For every morphism $S' \to S$, with $S' \neq \varnothing$, one may identify

$$\acute{\mathrm{E}}\mathrm{p}_{S'}(R) = \acute{\mathrm{E}}\mathrm{p}_S(R) \times_S S'.$$

If $\acute{\mathrm{E}}\mathrm{p}_{\mathrm{Spec}\,\mathbf{Z}}(R)$ exists, write it $\acute{\mathrm{E}}\mathrm{p}(R)$; then

$$\acute{\mathrm{E}}\mathrm{p}_S(R) = \acute{\mathrm{E}}\mathrm{p}(R) \times_{\mathrm{Spec}\,\mathbf{Z}} S.$$

The group $\acute{\mathrm{E}}\mathrm{p}(R)$ is called the *Chevalley group scheme of type R.*

5.12.— Thus an S-sheaf in groups G is a reductive S-group of type R if and only if it is locally isomorphic, for the étale or fpqc topology, to $\acute{\mathrm{E}}\mathrm{p}_S(R)$. Similarly, by the conjugacy theorems, giving a reductive S-group of type R with a maximal torus is locally equivalent to

$$(\acute{\mathrm{E}}\mathrm{p}_S(R), T_S(R)).$$

The analogous statements hold for Borel subgroups and Killing pairs.

6. Chevalley Systems

The explicit calculations of Section 3 have important numerical consequences.

Definition 6.1.— *Let S be a scheme and (G, T, M, R) a split S-group. A* Chevalley system *of G is a family*

$$(X_\alpha)_{\alpha \in R}, \qquad X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times,$$

satisfying:

(SC) *for every pair $\alpha, \beta \in R$,*

$$\mathrm{Ad}(w_\alpha(X_\alpha))X_\beta = \pm X_{s_\alpha(\beta)}.$$

Recall that

$$w_\alpha(X_\alpha) = \exp(X_\alpha)\exp(-X_\alpha^{-1})\exp(X_\alpha).$$

Condition (SC) implies, in particular,

$$X_{-\alpha} = \pm X_\alpha$$

by the identity

$$\mathrm{Ad}(w_\alpha(X_\alpha))X_\alpha = -X_\alpha^{-1}.$$

Proposition 6.2.— *Every split group admits a Chevalley system. More precisely, if*

$$(\Delta, (X'_\alpha)_{\alpha\in\Delta})$$

is a pinning of (G, T, M, R)*, there is a Chevalley system* $(X_\alpha)_{\alpha\in R}$ *with* $X_\alpha = X'_\alpha$ *for* $\alpha \in \Delta$*.*

First, it suffices to verify (SC) for $\alpha \in \Delta$. Indeed, for every $\alpha \in R$, choose a sequence $\alpha_i \in \Delta$ such that

$$\alpha = s_{\alpha_1} \cdots s_{\alpha_n}(\alpha_{n+1}).$$

Repeated use of (SC) gives

$$X_\alpha = \pm\,\mathrm{Ad}(w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n}))\, X_{\alpha_{n+1}}.$$

By Lemma 3.1.1(iii),

$$\begin{aligned} w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n}) w_{\alpha_{n+1}}(X_{\alpha_{n+1}}) w_{\alpha_n}(X_{\alpha_n})^{-1} \cdots w_{\alpha_1}(X_{\alpha_1})^{-1} \\ = \alpha^*(\pm 1) w_\alpha(X_\alpha). \end{aligned}$$

Now

$$w_{\alpha_i}(X_{\alpha_i})^{-1} = \alpha_i^*(-1) w_{\alpha_i}(X_{\alpha_i}),$$

and

$$\beta(\gamma^*(-1)) = (-1)^{(\gamma^*,\beta)} = \pm 1.$$

It follows that (SC) for every pair (α_i, γ) implies (SC) for every (α, β).

For each $\alpha \in R$, choose such a sequence and define

$$X_\alpha = \mathrm{Ad}(w_{\alpha_1}(X_{\alpha_1}) \cdots w_{\alpha_n}(X_{\alpha_n}))\, X'_{\alpha_{n+1}}.$$

It remains to prove the following lemma.

Lemma 6.3.— *Let*

$$(G, T, M, R, \Delta, (X_\alpha)_{\alpha\in\Delta})$$

be a pinned S-group. If α_i*,* $0 \le i \le n+1$*, are simple roots such that*

$$s_{\alpha_1} \cdots s_{\alpha_n}(\alpha_{n+1}) = \alpha_0,$$

then

$$\mathrm{Ad}(w_{\alpha_1} \cdots w_{\alpha_n}) X_{\alpha_{n+1}} = \pm X_{\alpha_0}.$$

Arguing as in 2.3.4, using Tits's lemma, reduces the proof to:

(a) G has semisimple rank at most 2; or

(b) $w_{\alpha_1} \cdots w_{\alpha_n}$ is a section of T.

Case (a) is exactly the calculation in 3.1.2(i), 3.2.1(i), 3.3.1(i), or 3.4.1(i).

In case (b), it suffices to show that if

$$s_{\alpha_1} \cdots s_{\alpha_n} = 1,$$

then $t = w_{\alpha_1} \cdots w_{\alpha_n}$ satisfies $\alpha(t) = \pm 1$ for every root α. By the structure of the Weyl group, the word in the free group generated by the s_α lies in the normal subgroup generated by

$$(s_\alpha s_\beta)^{n_{\alpha\beta}}.$$

Thus one reduces to a word

$$s_{\alpha_1} \cdots s_{\alpha_i} (s_{\alpha_{i+1}} s_{\alpha_{i+2}})^{n_{\alpha_{i+1}\alpha_{i+2}}} s_{\alpha_i} \cdots s_{\alpha_1},$$

for which

$$t = s_{\alpha_1} \cdots s_{\alpha_i} (t_{\alpha_{i+1}\alpha_{i+2}}).$$

The assertion is now immediate from the values of $t_{\alpha_1\alpha_2}$ computed in 3.1.2(i), 3.2.1(i), 3.3.1(i), and 3.4.1(i).

Proposition 6.4.— *Let (G, T, M, R) be a split S-group with Chevalley system $(X_\alpha)_{\alpha\in R}$. Let α, β be nonproportional roots, with*

$$\text{length}(\alpha) \leq \text{length}(\beta), \qquad |(\beta^*, \alpha)| \leq |(\alpha^*, \beta)|.$$

Let q and $p-1$ be the nonnegative integers for which the roots of the form $\beta + k\alpha$ are

$$\{\beta - (p-1)\alpha, \ldots, \beta, \ldots, \beta + q\alpha\}.$$

Thus $-(\alpha^*, \beta) = q - p + 1$. Writing $p_\gamma(x) = \exp(xX_\gamma)$, the commutation relation between U_α and U_β is given by:

(p, q)	$p_\beta(y)p_\alpha(x)p_\beta(-y)p_\alpha(-x)$
$(-, 0)$	e
$(1, 1)$	$p_{\alpha+\beta}(\pm xy)$
$(1, 2)$	$p_{\alpha+\beta}(\pm xy)p_{2\alpha+\beta}(\pm x^2y)$
$(1, 3)$	$p_{\alpha+\beta}(\pm xy)p_{2\alpha+\beta}(\pm x^2y)p_{3\alpha+\beta}(\pm x^3y)p_{3\alpha+2\beta}(\pm x^3y^2)$
$(2, 1)$	$p_{\alpha+\beta}(\pm 2xy)$
$(2, 2)$	$p_{\alpha+\beta}(\pm 2xy)p_{2\alpha+\beta}(\pm 3x^2y)p_{\alpha+2\beta}(\pm 3xy^2)$
$(3, 1)$	$p_{\alpha+\beta}(\pm 3xy)$

These are all possibilities, since the root string has length at most 3.

Proof. By Exposé XXI, 3.5.4, there is a system of simple roots Δ such that $\alpha \in \Delta$, and there are $\alpha' \in \Delta$, $a, b \in \mathbf{Q}_+$, with

$$\beta = a\alpha + b\alpha'.$$

The desired relation lies in $U_{\alpha\alpha'}$, so it follows from the rank-two calculations of Section 3 and condition (SC).

Corollary 6.5 (Chevalley's rule).— *Let $(X_\alpha)_{\alpha\in R}$ be a Chevalley system of the split S-group G. If $\alpha, \beta, \alpha + \beta \in R$, then*

$$[X_\alpha, X_\beta] = \pm pX_{\alpha+\beta},$$

where p is the least positive integer for which $\beta - p\alpha$ is not a root.

The assertion is symmetric in α, β; after arranging $\text{length}(\alpha) \leq \text{length}(\beta)$, it follows from Proposition 6.4.

Corollary 6.6.— *Let S be a scheme such that $6 \cdot 1_S \neq 0$, and let (G, T, M, R) be a split S-group. If $R' \subset R$ is such that*

$$(*) \qquad \mathfrak{g}_{R'} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R'} \mathfrak{g}^\alpha$$

is a Lie subalgebra of $\mathfrak{g}$, then R' is a closed subset of R.

Choose a Chevalley system and let $\alpha, \beta \in R'$ with $\alpha + \beta \in R$. By Corollary 6.5 and Proposition 6.4,

$$[X_\alpha, X_\beta] = \pm p X_{\alpha+\beta}, \qquad p \in \{1, 2, 3\}.$$

Since neither 2 nor 3 is zero on S, (*) implies $\mathfrak{g}^{\alpha+\beta} \subset \mathfrak{g}_{R'}$, and hence $\alpha + \beta \in R'$. [11]

6.7.— The exact signs in this section can be determined by studying $\text{Norm}_G(T)$, and more precisely the extended Weyl group

$$W^* = N(\mathbf{Z}), \qquad N = \text{Norm}_{\text{Ép}_{\mathbf{Z}}(R)}(T_{\mathbf{Z}}(R)).$$

It is an extension of $W(R)$ by an abelian group of type $(2, 2, \ldots, 2)$, which accounts for the signs.

Remark 6.7.1.— *By 3.1.2(i) and 3.n.1, $n = 2, 3, 4$, the elements $w_\alpha, w_\beta \in N(\mathbf{Z})$ satisfy the braid relations*

$$w_\alpha w_\beta \cdots = w_\beta w_\alpha \cdots$$

with $n_{\alpha\beta}$ factors on each side.

See also Tits [Ti66], Bourbaki [BLie], IX.4, Ex. 12, and Springer [Sp98, 9.3.2].

[11] *Editors' note.* It suffices that 2 and 3 are nonzero on S; for example the result applies to $S = \text{Spec}(\mathbf{Z}/6\mathbf{Z})$. In the excluded characteristics, short-root subsystems furnish standard counterexamples.

Exposé XXIV
Automorphisms of Reductive Groups

by Michel Demazure

[0] The first part of this Exposé (nos. 1 to 5) is a direct consequence of the existence, for a reductive group, of "sufficiently many outer automorphisms", a result which is itself a consequence of the weakest form of the isomorphism theorem for pinned groups. The second part (nos. 6 and 7) sets out two applications of the more precise results of the preceding Exposé; in particular, no. 7 uses the generators-and- relations theorem in its explicit form. Finally, we have included in an appendix (no. 8) results on "Galois" cohomology used in the text.

Let us specify our cohomological notation. If S is a scheme and G an S-group scheme, we write $H^1(S,G)$ for the first cohomology set of S with coefficients in G, computed for the (fpqc) topology; this is also the set of isomorphism classes of principal homogeneous (fpqc) sheaves under G. We write $H^1_{\text{ét}}(S,G)$ for the corresponding set for the étale topology; it is therefore the part of $H^1(S,G)$ formed by classes of homogeneous sheaves under G which are quasi-isotrivial (that is, locally trivial for the étale topology). We write $\mathrm{Fib}(S,G)$ for the part of $H^1(S,G)$ formed by classes of representable sheaves (principal homogeneous bundles). Thus we have the inclusions

$$H^1_{\text{ét}}(S,G) \subset H^1(S,G), \qquad \mathrm{Fib}(S,G) \subset H^1(S,G).$$

If every principal homogeneous sheaf under G is representable (for example, if G is quasi-affine over S; cf. SGA 1, VIII, 7.9), then

$$\mathrm{Fib}(S,G) = H^1(S,G).$$

If $S' \to S$ is a covering morphism for the (fpqc) topology, we write $H^1(S'/S,G)$ for the kernel of the canonical map

$$H^1(S,G) \longrightarrow H^1(S', G_{S'}).$$

It is known that $H^1(S'/S,G)$ can be computed simplicially (TDTE I, §A.4), which implies that, when $S' \to S$ is a covering for the étale topology, $H^1(S'/S,G)$ is also the kernel of

$$H^1_{\text{ét}}(S,G) \longrightarrow H^1_{\text{ét}}(S', G_{S'}).$$

[0]Editor's note: Version dated October 13, 2024.

Finally, following Exp. VIII, 4.5, the name "Theorem 90" is given to the following assertion: "every principal homogeneous sheaf under $G_{m,S}$ is representable and locally trivial." This assertion is equivalent to

$$H^1(S, G_{m,S}) = \mathrm{Pic}(S),$$

or again to

$$H^1(S, G_{m,S}) = 0$$

when S is local (or, more generally, semilocal).

1. Scheme of Automorphisms of a Reductive Group

1.0.

We must first make precise certain definitions from the preceding Exposé. Let S be a nonempty scheme, let G be a reductive S-group, and let

$$\mathscr{R} = (M, M^*, R, R^*, \Delta)$$

be a pinned reduced root datum (Exp. XXIII, 1.5). A *pinning of G of type $\mathscr{R}$*, or an *$\mathscr{R}$-pinning of G*, consists of:

(i) an isomorphism of $D_S(M)$ onto a maximal torus T of G (or, equivalently, a monomorphism $D_S(M) \to G$ whose image is a maximal torus T of G), identifying R with a root system of G relative to T (Exp. XIX, 3.6) and R^* with the corresponding set of coroots;

(ii) for each $\alpha \in \Delta$, an element

$$X_\alpha \in \Gamma(S, \mathfrak{g}^\alpha)^\times.$$

The group G possesses an $\mathscr{R}$-pinning if and only if it is split and of type $\mathscr{R}$ (Exp. XXII, 2.7).

If $u : G \to G'$ is an isomorphism of reductive S-groups, then every $\mathscr{R}$-pinning $\mathcal{E}$ of G determines, by "transport of structure", an $\mathscr{R}$-pinning $u(\mathcal{E})$ of G'. If $v : \mathscr{R}' \to \mathscr{R}$ is an isomorphism of pinned root data, then every $\mathscr{R}'$-pinning $\mathcal{E}'$ of G' determines, by transport of structure, an $\mathscr{R}$-pinning $v(\mathcal{E}')$ of G.

Call a *pinned group* a triple $(G, \mathscr{R}, \mathcal{E})$, where G is a reductive S-group, $\mathscr{R}$ is a pinned reduced root datum, and $\mathcal{E}$ is a pinning of G of type $\mathscr{R}$. An isomorphism from the pinned group $(G, \mathscr{R}, \mathcal{E})$ onto the pinned group $(G', \mathscr{R}', \mathcal{E}')$ is a pair (u, v), where $u : G \to G'$ is an isomorphism and $v : \mathscr{R}' \to \mathscr{R}$ is an isomorphism of pinned root data, such that

$$u(\mathcal{E}) = v(\mathcal{E}').$$

[1]

N.B. If S is nonempty, v is uniquely determined by u, and by an abuse of language u will also be called an isomorphism of the pinned groups. In particular, if $(G, \mathscr{R}, \mathcal{E})$ is a pinned group, an automorphism of $(G, \mathscr{R}, \mathcal{E})$ is therefore an automorphism u of G for which there exists an automorphism v of $\mathscr{R}$ such that $u(\mathcal{E}) = v(\mathcal{E})$. It is thus an automorphism of G which normalizes T, induces on T an automorphism of the form $D_S(h)$, where h is

[1] Editor's note: Thus $\mathrm{Lie}(u)(X_{v(\alpha)}) = X'_\alpha$ for every $\alpha \in R'$.

an automorphism of M, and permutes the elements X_α, $\alpha \in \Delta$. (As is readily seen, the preceding conditions in fact characterize the automorphisms of $(G, \mathscr{R}, \mathcal{E})$.)

There is an evident contravariant functor

$$\Phi : \quad (G, \mathscr{R}, \mathcal{E}) \longmapsto \mathscr{R}, \qquad (u, v) \longmapsto v,$$

and the principal result of the preceding Exposé (Exp. XXIII, 4.1) shows that this functor is fully faithful (we shall moreover see in the following Exposé that it is an equivalence of categories). In particular, it follows that the automorphism group of $(G, \mathscr{R}, \mathcal{E})$ is canonically isomorphic to the automorphism group of the pinned root datum $\mathscr{R}$ (cf. Exp. XXIII, 5.5).

1.1.

Let S be a scheme; endow $(\mathbf{Sch})/S$ with the (fpqc) topology, and consider the S-sheaf of groups $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$, where G is an S-group scheme. There is an exact sequence of S-sheaves of groups

$$1 \longrightarrow \underline{\mathrm{Centr}}(G) \longrightarrow G \xrightarrow{\mathrm{int}} \underline{\mathrm{Aut}}_{S\text{-gr.}}(G),$$

which defines a monomorphism

$$j : G/\underline{\mathrm{Centr}}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G).$$

The image sheaf of j is the sheaf of inner automorphisms of G. An automorphism u of G is inner if and only if there is a covering family $\{S_i \to S\}$ and, for every i, an element $g_i \in G(S_i)$ such that

$$\mathrm{int}(g_i) = u_{S_i}.$$

In this case, if v is another automorphism of G, one sees at once that

$$\mathrm{int}(v)u = vuv^{-1}$$

is the inner automorphism defined by the family $g_i' = v(g_i)$. It follows that the image of j is normal in $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$. The quotient sheaf of groups, denoted $\underline{\mathrm{Autext}}(G)$, is the sheaf of outer automorphisms of G. Thus there is an exact sequence

$$1 \longrightarrow G/\underline{\mathrm{Centr}}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \longrightarrow \underline{\mathrm{Autext}}(G) \longrightarrow 1.$$

All the preceding definitions are compatible with base change. They are naturally valid in any site.

1.2.

Let S be a scheme and let $(G, \mathscr{R}, \mathcal{E})$ be a pinned reductive S-group. Let E be the (abstract) automorphism group of the pinned root datum $\mathscr{R}$, that is, the group of automorphisms of $\mathscr{R}$ which normalize Δ. By Exp. XXIII, 5.5, there is a canonical monomorphism

$$E \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$$

which associates with $h \in E$ the unique automorphism u of the pinned group G such that $\Phi(u) = h$. This monomorphism canonically defines a monomorphism of sheaves

$$(*) \qquad a : E_S \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G).$$

An automorphism u of G is a section of the image sheaf of a if and only if the following conditions hold:

(i) u normalizes T. It is then known that u permutes the roots of G relative to T. If $\alpha \in R$, then

$$u(\alpha) : t \longmapsto \alpha(u^{-1}(t))$$

is therefore locally on S of the form $t \longmapsto \beta(t)$, with $\beta \in R$. The second condition may then be written as follows:

(ii) If $\alpha \in \Delta$ and U is an open subset of S such that $u(\alpha)_U \in R$, then $u(\alpha)_U \in \Delta$ and

$$\mathrm{Lie}(u_U)(X_\alpha)_U = (X_{u(\alpha)})_U.$$

It follows at once from the definitions that the sections of $a(E_S)$ normalize the subgroups of G defined by the pinning:

$$T, \quad B, \quad B^-, \quad U, \quad U^-.$$

With these definitions in place, we have:

Theorem 1.3. *Let S be a scheme and G a reductive S-group. Consider the canonical exact sequence of S-sheaves of groups* [2]

$$1 \longrightarrow \mathrm{ad}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \xrightarrow{p} \underline{\mathrm{Autext}}(G) \longrightarrow 1.$$

Then:

(i) $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$ is representable by a smooth separated S-scheme;

(ii) $\underline{\mathrm{Autext}}(G)$ is representable by a twisted constant S-scheme of finite generation (Exp. X, 5.1);

(iii) if G is split, the preceding exact sequence is split. More precisely, for every pinning of G, the morphism (cf. 1.2 $(*)$)

$$p \circ a : E_S \longrightarrow \underline{\mathrm{Autext}}(G)$$

is an isomorphism.

Let us first show how the theorem follows from the following lemma.

Lemma 1.4. *Under the hypotheses of* (iii), $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$ *is the semidirect product*

$$a(E_S) \cdot \mathrm{ad}(G).$$

[3]

The lemma immediately implies the theorem when G is split. Since G is locally split for the étale topology (Exp. XXII, 2.3), hence also for the (fppf) topology, and since the latter is "of effective descent" for the fibred category of twisted constant morphisms (Exp. X, 5.5), assertion (ii) follows in the general case (cf. Exp. IV, 4.6.8). To deduce (i), observe that $\mathrm{ad}(G)$ is affine over S; thus p is affine whenever $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$ is representable, and the result follows by descent for affine schemes. [4]

It remains only to prove 1.4. For this, it suffices to prove:

[2] Editor's note: Recall that $\mathrm{ad}(G) = G/\underline{\mathrm{Centr}}(G)$ denotes the adjoint group of G; cf. Exp. XXII, 4.3.6.
[3] Editor's note: Here and below, the notation $\mathrm{int}(G)$ has been replaced by $\mathrm{ad}(G)$.
[4] Editor's note: Cf. SGA 1, VIII, 2.1.

Lemma 1.5. *If $(\mathscr{R}, \mathcal{E})$ and $(\mathscr{R}', \mathcal{E}')$ are two pinnings of the reductive S-group G, there exists a unique inner automorphism u of G over S carrying one pinning to the other; that is, such that there exists an isomorphism*

$$v : \mathscr{R}' \xrightarrow{\sim} \mathscr{R}$$

for which $u(\mathcal{E}) = v(\mathcal{E}')$; cf. 1.0.

1.5.1. Uniqueness.

It suffices to prove that, if G is a pinned S-group and $\mathrm{int}(g)$ is an automorphism of the pinned group ($g \in G(S)$), then $\mathrm{int}(g) = \mathrm{id}$. First,

$$\mathrm{int}(g)T = T, \qquad \mathrm{int}(g)B = B,$$

and hence

$$g \in \underline{\mathrm{Norm}}_G(T)(S) \cap \underline{\mathrm{Norm}}_G(B)(S) = T(S)$$

(cf., for example, Exp. XXII, 5.6.1). It follows that $\mathrm{int}(g)$ normalizes every U_α and that

$$\mathrm{Lie}(\mathrm{int}(g))X_\alpha = \mathrm{Ad}(g)X_\alpha = \alpha(g)X_\alpha$$

for every $\alpha \in \Delta$. Thus $\alpha(g) = 1$ for $\alpha \in \Delta$, and therefore

$$g \in \bigcap_{\alpha \in \Delta} (\ker \alpha)(S) = \underline{\mathrm{Centr}}(G)(S)$$

(Exp. XXII, 4.1.8). □

1.5.2. Existence.

It suffices to prove existence locally for the (fpqc) topology. Let

$$(T, M, R, \Delta, (X_\alpha)_{\alpha \in \Delta}) \quad \text{and} \quad (T', M', R', \Delta', (X'_{\alpha'})_{\alpha' \in \Delta'})$$

be the two pinnings. By conjugacy of maximal tori, we may assume $T = T'$. After restricting S, we may assume that the isomorphism

$$D_S(M) \simeq D_S(M')$$

comes from an isomorphism $M \simeq M'$ carrying R onto R'; we are thus reduced to the situation

$$T = T', \qquad M = M', \qquad R = R'.$$

Since the systems of simple roots are conjugate under the Weyl group (Exp. XXI, 3.3.7), we may also assume $\Delta = \Delta'$. For every $\alpha \in \Delta$, there is then a scalar $z_\alpha \in \mathbb{G}_m(S)$ such that

$$X'_\alpha = z_\alpha X_\alpha,$$

and it is enough to construct, locally for the (fpqc) topology, a section t of T such that $\alpha(t) = z_\alpha$ for every $\alpha \in \Delta$. But the morphism

$$T \longrightarrow (\mathbb{G}_{m,S})^\Delta$$

whose components are the α, $\alpha \in \Delta$, is dual to an injection $\mathbb{Z}^\Delta \to M$, and is therefore faithfully flat. This completes the proof of 1.5.2, and hence of 1.3.

Corollary 1.6. *Let S be a scheme and G a reductive S-group. The following conditions are equivalent:*

(i) $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$ is affine (respectively of finite type, respectively of finite presentation, respectively quasi-compact) over S;

(ii) $\underline{\mathrm{Autext}}(G)$ is finite over S;

(iii) for every $s \in S$,
$$\mathrm{rg}_{\mathrm{red}}(G_s) - \mathrm{rg}_{\mathrm{ss}}(G_s) \leq 1.$$

Indeed, since $\mathrm{ad}(G)$ is affine, flat, and of finite presentation over S, the morphism
$$p : \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \longrightarrow \underline{\mathrm{Autext}}(G)$$
is affine, faithfully flat, and of finite presentation.

If $\underline{\mathrm{Autext}}(G)$ is finite over S, it is affine over S, and hence so is $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$; this proves (ii)⇒(i). If $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$ is quasi-compact over S, it is of finite presentation over S, since it is in any case locally of finite presentation and separated over S. By Exp. V, 9.1, $\underline{\mathrm{Autext}}(G)$ is then of finite presentation over S, and hence finite; this proves (i)⇒(ii). Finally, to prove the equivalence of (ii) and (iii), one may suppose that G is split, and the assertion reduces to Exp. XXI, 6.7.8.

Corollary 1.7. *Let S be a scheme and G a reductive S-group. Then*
$$\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)^0 \simeq \mathrm{ad}(G).$$

Corollary 1.8. *Let S be a scheme, G a reductive S-group, and H an S-group scheme that is smooth, affine, and has connected fibres over S. Then the S-functor*
$$\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, H)$$
is representable by a smooth separated S-scheme, which is affine over S if G is semisimple.

Indeed, let U be the set of points $s \in S$ for which H_s is reductive; this is an open subset (Exp. XIX, 2.6). If S' is an S-scheme, $H_{S'}$ is reductive if and only if $S' \to S$ factors through U. It follows that the canonical morphism
$$\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, H) \longrightarrow S$$
factors through U. We may therefore assume $S = U$, and we are reduced to the following corollary.

Corollary 1.9. *Let S be a scheme, and let G and G' be two reductive S-groups. Then*
$$F = \underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G')$$
is representable by a smooth separated S-scheme, affine if G or G' is semisimple. Moreover, S is the disjoint union of two open subschemes S_1 and S_2 such that $F_{S_1} = \varnothing$, while F_{S_2} is a principal homogeneous bundle on the left (respectively, on the right) *under* $\underline{\mathrm{Aut}}_{S_2\text{-gr.}}(G'_{S_2})$ (respectively, $\underline{\mathrm{Aut}}_{S_2\text{-gr.}}(G_{S_2})$).

Indeed, let S_2 be the set of points of S at which G and G' have the same type, and let S_1 be its complement. Since the type of a reductive group is a locally constant function,

S_1 and S_2 are open. Clearly $F_{S_1} = \varnothing$, and we may assume $S = S_2$. By Exp. XXIII, 5.6, F is a principal homogeneous sheaf under $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$, locally trivial for the étale topology. It follows that

$$F_0 = F/\operatorname{ad}(G)$$

is a principal homogeneous sheaf under $\underline{\mathrm{Autext}}(G)$, locally trivial for the étale topology, and hence representable (Exp. X, 5.5). Since $\operatorname{ad}(G)$ is affine, F is therefore representable as well.

We note that the proof also gives the following result.

Corollary 1.10. *Let S be a scheme, and let G and G' be two reductive S-groups having the same type at every $s \in S$. Then $\operatorname{ad}(G)$ acts freely on the right on $\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G')$. The quotient sheaf*

$$\underline{\mathrm{Isomext}}(G, G') = \underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G')/\operatorname{ad}(G)$$

is representable by a twisted constant S-scheme; it is a principal homogeneous bundle under $\underline{\mathrm{Autext}}(G)$, and is therefore finite over S if G is semisimple. Moreover, the isomorphism

$$\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G') \simeq \underline{\mathrm{Isom}}_{S\text{-gr.}}(G', G), \qquad u \longmapsto u^{-1},$$

induces an isomorphism

$$\underline{\mathrm{Isomext}}(G, G') \simeq \underline{\mathrm{Isomext}}(G', G).$$

Remark 1.11. If $\underline{\mathrm{Isomext}}(G, G')(S) \neq \varnothing$, one says that G is an *inner twisted form* of G'. Then G' is an inner twisted form of G, and the structure group of $\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G')$ can be reduced to $\operatorname{ad}(G)$. More precisely, let

$$u \in \underline{\mathrm{Isomext}}(G, G')(S)$$

and regard u as a section $u : S \to \underline{\mathrm{Isomext}}(G, G')$. Denote by

$$\underline{\mathrm{Isomint}}_u(G, G')$$

the inverse image, under the canonical morphism

$$\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G') \longrightarrow \underline{\mathrm{Isomext}}(G, G'),$$

of the closed subscheme of $\underline{\mathrm{Isomext}}(G, G')$ that is the image of u. The natural action of $\operatorname{ad}(G)$ on $\underline{\mathrm{Isomint}}_u(G, G')$ makes this scheme a principal homogeneous bundle. By extension of the structure group[5]

$$\operatorname{ad}(G) \longrightarrow \underline{\mathrm{Aut}}(G),$$

one recovers $\underline{\mathrm{Isom}}_{S\text{-gr.}}(G, G')$ from $\underline{\mathrm{Isomint}}_u(G, G')$.

By Hensel's lemma (Exp. XI, 1.11), Corollary 1.8 immediately gives:

[5]The source's editorial note corrects $\operatorname{ad}(G) \to \underline{\mathrm{Autext}}(G)$ to $\operatorname{ad}(G) \to \underline{\mathrm{Aut}}(G)$.

Corollary 1.12. *Let S be a henselian local scheme, let G be a reductive S-group, let G' be a smooth affine S-group with connected fibres, and let s be the closed point of S. If G_s and G'_s are isomorphic algebraic groups over $\kappa(s)$, then G and G' are isomorphic. More precisely, every $\kappa(s)$-isomorphism*

$$G_s \simeq G'_s$$

comes from an S-isomorphism $G \simeq G'$.

Applying Corollary 1.7 (respectively, Corollary 1.12) to the scheme of dual numbers over a field, Exp. III, 2.10 (respectively, 3.10) yields part (i) (respectively, part (ii)) of the next corollary.

Corollary 1.13. *Let k be a field and G a reductive k-group.*

(i) *If G is adjoint, then*

$$H^1(G, \mathrm{Lie}(G/k)) = 0.$$

6

(ii) *One has*

$$H^2(G, \mathrm{Lie}(G/k)) = 0.$$

Remark 1.14.

(i) The assertion concerning H^1 was known to Chevalley; the assertion concerning H^2 had been proved in most cases of the classification by Chevalley.

(ii) In fact, the conjunction of Corollary 1.13 and the uniqueness theorem over an algebraically closed field is essentially equivalent to the uniqueness theorem. A direct proof of Corollary 1.13 would therefore give a way to deduce the general uniqueness theorem from Chevalley's uniqueness theorem over a field.

The existence of reductive groups of every type over every scheme (Exp. XXV) shows that the obstructions to lifting a reductive k-group G over artinian rings with residue field k, which by Exp. III, 3.8 are elements of

$$H^3(G, \mathrm{Lie}(G/k) \otimes V) \simeq H^3(G, \mathrm{Lie}(G/k)) \otimes V,$$

where V is a certain k-vector space endowed with the trivial action of G, vanish. This suggests that

$$H^3(G, \mathrm{Lie}(G/k)) = 0.$$

A direct proof, if the assertion is true, would likewise doubtless give a way to deduce the general existence theorem from the existence theorem over a field (Chevalley's Tôhoku).

[6] The source's editorial note corrects the original, which stated (i) without assuming G adjoint. By the description of $H^i(G, -)$ as the derived functors of $\mathrm{Hom}_G(k, -)$ (Exp. I, 5.3.1; see also [Ja87], I, 4.16), one has $H^i(G, V) = \mathrm{Ext}^i_G(k, V)$ for every G-module V. If $\mathrm{char}(k) = p > 0$ and $G = \mathrm{SL}_{p,k}$, then $\mathrm{Lie}(\mathrm{GL}_p/k)$ is a nontrivial extension of k by $\mathfrak{g} = \mathrm{Lie}(\mathrm{SL}_p/k)$, so $H^1(G, \mathfrak{g}) \neq 0$. See also the addition 1.15.1 below.

Corollary 1.15. *Let k be a field,*[7] *and let G be a reductive k-group. Regard k as a trivial G-module. Then*

$$H^1(G,k) = H^2(G,k) = 0.$$

[8] Since

$$H^i(G_{\bar{k}},\bar{k}) = H^i(G,k)\otimes_k \bar{k},$$

we may assume k algebraically closed. An element of $H^1(G,k)$ is simply a morphism of k-groups

$$\varphi : G \longrightarrow \mathbb{G}_{a,k}.$$

Then

$$\varphi(G) = G/\ker(\varphi)$$

is a smooth connected reductive subgroup of $\mathbb{G}_{a,k}$ (cf. XIX, 1.7), and is therefore trivial. Thus $H^1(G,k) = 0$. Now consider the reductive k-group

$$H = G \times_k \mathbb{G}_{m,k}.$$

There is an H-stable decomposition

$$\mathrm{Lie}(H/k) = \mathrm{Lie}(G/k) \oplus k.$$

For every H-module V,

$$H^i(H,V) = H^i\big(G, H^0(\mathbb{G}_{m,k},V)\big).$$

Indeed, the $H^i(H,-)$ are the derived functors of

$$H^0(H,-) = H^0\big(G, H^0(\mathbb{G}_{m,k},-)\big),$$

and the functor $H^0(\mathbb{G}_{m,k},-)$ is exact (cf. Exp. I, 5.3.1 and 5.3.3). In particular, for every i,

$$H^i(H,\mathrm{Lie}(H/k)) = H^i(G,\mathrm{Lie}(G/k)) \oplus H^i(G,k).$$

Applying 1.13(ii) to the reductive group H gives $H^2(G,k) = 0$.

Corollary 1.15.1. — [9] *Let k be a field, G a reductive k-group, Z its center, and $\mathscr{R} = (M, M^*, R, R^*)$ the type of G. Then*

$$H^1(G,\mathrm{Lie}(G/k)) \simeq \mathrm{Ext}^1_{\mathbb{Z}}(M/\Gamma_0(R),k).$$

In particular, $H^1(G,\mathrm{Lie}(G/k)) = 0$ if and only if Z is smooth over k.

Let $\mathfrak{g}$, $\mathfrak{z}$, and $\mathfrak{g}_{\mathrm{ad}}$ be the Lie algebras of G, Z, and $G_{\mathrm{ad}} = G/Z$, respectively. It follows from 1.15 and its proof that

$$H^1(G,\mathfrak{g}) = H^1(G_{\mathrm{ad}},\mathfrak{g}) \simeq H^1(G_{\mathrm{ad}},\mathfrak{g}/\mathfrak{z}).$$

Set $C = \mathrm{Coker}(\mathfrak{g} \to \mathfrak{g}_{\mathrm{ad}})$. There is an exact sequence

$$0 \longrightarrow \mathfrak{g}/\mathfrak{z} \longrightarrow \mathfrak{g}_{\mathrm{ad}} \longrightarrow C \longrightarrow 0.$$

[7] The source's editorial note replaces "scheme" with "field."

[8] Because of the correction made in 1.13, the source's editors supply another proof for H^1. Moreover, a theorem of G. Kempf gives $H^i(G,k) = 0$ for every $i > 0$; cf. [Ja87], II, 4.5 and 4.11.

[9] Editor's note: This corollary, drawn from remarks of O. Gabber, has been added to make 1.13(i) more precise.

Since $H^1(G_{\mathrm{ad}}, \mathfrak{g}_{\mathrm{ad}}) = 0$ by 1.13 and

$$H^0(G_{\mathrm{ad}}, \mathfrak{g}_{\mathrm{ad}}) = 0$$

(cf. Exp. II, 5.2.3), we obtain

$$H^1(G_{\mathrm{ad}}, \mathfrak{g}/\mathfrak{z}) \simeq H^0(G_{\mathrm{ad}}, C).$$

To calculate the right-hand side, we may assume k algebraically closed. Let (G, T, M, R) be a splitting of G. Then

$$Z = D_k(M/\Gamma_0(R))$$

and C is identified with

$$\mathrm{Coker}(\mathrm{Hom}_{\mathbb{Z}}(M, k) \longrightarrow \mathrm{Hom}_{\mathbb{Z}}(\Gamma_0(R), k)) \simeq \mathrm{Ext}^1_{\mathbb{Z}}(M/\Gamma_0(R), k),$$

with trivial G_{ad}-action. The corollary follows, since Z is not smooth over k exactly when $\mathrm{char}(k) = p > 0$ and $M/\Gamma_0(R)$ has p-torsion (Exp. IX, 2.1).

Definition 1.16. — *Let S be a scheme and G a reductive S-group. A* form of G over S *is an S-group scheme G' locally isomorphic to G for the* (fpqc) *topology. It is equivalent to require that G' be locally isomorphic to G for the étale topology (cf. Exp. XXIII, 5.6), or that G' be a reductive S-group of the same type as G at every point of S.*

Corollary 1.17. — *Let S be a scheme and G a reductive S-group.*

(i) The functor

$$G' \longmapsto \underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$$

is an equivalence between the category of forms of G over S and the category of principal homogeneous bundles under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G)$.

(ii) If $S' \to S$ is a covering morphism, forms of G trivialized by S' correspond to bundles trivialized by S'.

(iii) Every principal homogeneous sheaf under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G)$ is representable and quasi-isotrivial, that is, locally trivial for the étale topology.

The first assertion is formal in the category of sheaves, for example for the (fpqc) topology. Every sheaf locally isomorphic to G for the (fpqc) topology is representable, since G is affine over S, and is locally isomorphic to G for the étale topology. Finally, for every form G' of G, the S-sheaf $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$ is representable by 1.8. The corollary follows.

Corollary 1.18. — *The set of isomorphism classes of forms of the reductive group G over S is isomorphic to*

$$H^1\Big(S, \underline{\mathrm{Aut}}_{S\text{-gr}}(G)\Big) = H^1_{\text{ét}}\Big(S, \underline{\mathrm{Aut}}_{S\text{-gr}}(G)\Big) = \mathrm{Fib}\Big(S, \underline{\mathrm{Aut}}_{S\text{-gr}}(G)\Big).$$

If $S' \to S$ is a covering morphism, the subset consisting of forms trivialized by S' is isomorphic to

$$H^1\Big(S'/S, \underline{\mathrm{Aut}}_{S\text{-gr}}(G)\Big).$$

Corollary 1.19. — *Let S be a scheme and $\mathscr{R}$ a pinned reduced root datum such that $\mathrm{Ép}_S(\mathscr{R})$ exists,*[10] *a condition which is automatically satisfied by Exp. XXV. Put*

$$A_S(\mathscr{R}) = \underline{\mathrm{Aut}}_{S\text{-gr}}(\mathrm{Ép}_S(\mathscr{R})) = \mathrm{ad}(\mathrm{Ép}_S(\mathscr{R})) \cdot E(\mathscr{R})_S.$$

[10] Editor's note: Cf. XXIII, Definition 5.11.

(i) The set of isomorphism classes of reductive S-groups of type $\mathscr{R}$ (Exp. XXII, 2.7) is isomorphic, by Exp. XXIII, 5.12, to

$$H^1(S, A_S(\mathscr{R})) = H^1_{\text{ét}}(S, A_S(\mathscr{R})) = \mathrm{Fib}(S, A_S(\mathscr{R})).$$

(ii) If $S' \to S$ is a covering morphism, the subset consisting of classes of groups splittable over S' is isomorphic to $H^1(S'/S, A_S(\mathscr{R}))$.

Remark 1.20. — With the preceding notation, every reductive S-group G of type $\mathscr{R}$ has a canonically associated right principal homogeneous bundle under $A_S(\mathscr{R})$:

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), G) = P.$$

The scheme P may be interpreted as the "scheme of pinnings of G of type $\mathscr{R}$" (cf. 1.0). It is also a principal homogeneous bundle on the left under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G)$, a structure visible immediately from the description above.

Proposition 1.21. — *Let S be a henselian local scheme and s its closed point. The functor*

$$G \longmapsto G_s$$

induces a bijection from the set of isomorphism classes of reductive S-groups onto the set of isomorphism classes of reductive $\kappa(s)$-groups. In particular, for every reductive S-group G, there exists a finite étale surjective morphism $S' \to S$ such that $G_{S'}$ is splittable.

Using the existence of $\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})$ (Exp. XXV), it is enough to prove that, with $H = A_S(\mathscr{R})$, the canonical map

$$\mathrm{Fib}(S, H) \longrightarrow \mathrm{Fib}(\kappa(s), H_s)$$

is bijective, and that every element of $\mathrm{Fib}(S, H)$ has the property just stated. Every finite subset of H is contained in an affine open subscheme: this is clear for a constant group, and H is affine over a constant group. The result proved in the Appendix, 8.1, therefore applies.

2. Automorphisms and Subgroups

Introduce the following notation. If

$$\mathcal{H} = \underline{\mathrm{Aut}}_{S\text{-gr}}(G)$$

and X is a subfunctor of G, set

$$\underline{\mathrm{Aut}}_{S\text{-gr}}(G, X) = \mathrm{Norm}_{\mathcal{H}}(X), \qquad \underline{\mathrm{Aut}}_{S\text{-gr}}(G, \mathrm{id}_X) = \underline{\mathrm{Centr}}_{\mathcal{H}}(X).$$

If Y is a second subfunctor of G, define

$$\underline{\mathrm{Aut}}_{S\text{-gr}}(G, X, Y) = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, X) \cap \underline{\mathrm{Aut}}_{S\text{-gr}}(G, Y).$$

If G' is a second S-group and X' a subfunctor of G', write

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, X; G', X')$$

for the subfunctor of $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$ defined, for every $S' \to S$, by

$$\left\{ u \in \underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')(S') \,\middle|\, u(X_{S'}) = X'_{S'} \right\}.$$

The notation $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, X, Y; G', X', Y')$, and so on, is defined similarly.[11]

Proposition 2.1. — *Let S be a scheme, G a reductive S-group, and T a maximal torus of G (respectively, B a Borel subgroup of G, or $B \supset T$ a Killing couple of G). Let T_{ad} (respectively, B_{ad}) denote the corresponding maximal torus (respectively, Borel subgroup) of* $\mathrm{ad}(G)$*:*

$$B_{\mathrm{ad}} \simeq B/\underline{\mathrm{Centr}}(G) = B/\underline{\mathrm{Centr}}(B), \qquad T_{\mathrm{ad}} \simeq T/\underline{\mathrm{Centr}}(G).$$

Then $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, T)$ (respectively, $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B)$, or $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B, T)$) is represented by a closed subscheme of $\underline{\mathrm{Aut}}_{S\text{-gr}}(G)$, smooth over S, and the exact sequence of Theorem 1.3 induces the exact sequences

$$1 \longrightarrow \mathrm{Norm}_{\mathrm{ad}(G)}(T_{\mathrm{ad}}) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr}}(G, T) \longrightarrow \underline{\mathrm{Autext}}(G) \longrightarrow 1,$$

$$1 \longrightarrow B_{\mathrm{ad}} \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr}}(G, B) \longrightarrow \underline{\mathrm{Autext}}(G) \longrightarrow 1,$$

$$1 \longrightarrow T_{\mathrm{ad}} \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr}}(G, B, T) \longrightarrow \underline{\mathrm{Autext}}(G) \longrightarrow 1.$$

By descent of closed subschemes,[12] we reduce immediately to the case in which G is pinned and $B \supset T$ is its canonical Killing couple (cf. Exp. XXII, 5.5.5(iv)). Since the group E of 1.2 normalizes B and T, the result follows at once from the normalization theorems in $\mathrm{ad}(G)$ (Exp. XXII, 5.3.12 and 5.6.1).

Using now the conjugacy theorems (cf. Exp. XXIII, 5.12), and arguing as in §1, one obtains:

Corollary 2.2. — *Let S be a scheme, let G and G' be two reductive S-groups having the same type at every point, and let $B \supset T$ (respectively, $B' \supset T'$) be a Killing couple of G (respectively, G').*

(i) *The S-functor*

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T')$$

is represented by a closed smooth subscheme of $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$ which is a principal homogeneous space under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, T)$. Moreover, $\mathrm{Norm}_{\mathrm{ad}(G)}(T_{\mathrm{ad}})$ acts freely on this scheme, and there is a canonical isomorphism

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T')/\mathrm{Norm}_{\mathrm{ad}(G)}(T_{\mathrm{ad}}) \simeq \underline{\mathrm{Isomext}}(G, G').$$

(ii) *The S-functor*

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, B; G', B')$$

is represented by a closed smooth subscheme of $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$ which is a principal homogeneous space under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B)$. Moreover, B_{ad} acts freely on this scheme, and there is a canonical isomorphism

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, B; G', B')/B_{\mathrm{ad}} \simeq \underline{\mathrm{Isomext}}(G, G').$$

(iii) *The S-functor*

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, B, T; G', B', T')$$

is represented by a closed smooth subscheme of $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$, which is a principal homogeneous space under $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B, T)$. Moreover, T_{ad} acts freely on this scheme, and there is a canonical isomorphism

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, B, T; G', B', T')/T_{\mathrm{ad}} \simeq \underline{\mathrm{Isomext}}(G, G').$$

[11] Editor's note: The preceding definitions have been made explicit. The original only said that $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, X, Y), \ldots$ and $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, X; G', X'), \ldots$ were defined similarly.

[12] Editor's note: Cf. SGA 1, VIII, 1.9.

Arguing once again as in §1, one obtains:

Corollary 2.3. — *Let S be a scheme, let G be a reductive S-group, and let $B \supset T$ be a Killing couple of G. The functor*

$$(G', T') \longmapsto \underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T'),$$

respectively

$$(G', B') \longmapsto \underline{\mathrm{Isom}}_{S\text{-gr}}(G, B; G', B'),$$

respectively

$$(G', B', T') \longmapsto \underline{\mathrm{Isom}}_{S\text{-gr}}(G, B, T; G', B', T'),$$

is an equivalence between the category of pairs (G', T') (respectively, pairs (G', B'), respectively, triples (G', B', T')), where G' is a form of G and T' is a maximal torus of G' (respectively, B' is a Borel subgroup of G', respectively, $B' \supset T'$ is a Killing couple of G'), and the category of principal homogeneous bundles under the S-group H, where $H = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, T)$ (respectively, $H = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, B)$, respectively, $H = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, B, T)$). Moreover, every principal homogeneous sheaf under H is representable and quasi-isotrivial, so that

$$H^1(S, H) = H^1_{\text{ét}}(S, H) = \mathrm{Fib}(S, H).$$

Remark 2.4. — Under the hypotheses of 2.2, the morphism denoted set-theoretically by $u \mapsto u(T)$ (respectively, $u \mapsto u(B)$, respectively, $u \mapsto (u(B), u(T))$) induces an isomorphism

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')/\underline{\mathrm{Aut}}_{S\text{-gr}}(G, T) \simeq \mathrm{Tor}(G'),$$

respectively,

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')/\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B) \simeq \mathrm{Bor}(G'),$$

respectively,

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')/\underline{\mathrm{Aut}}_{S\text{-gr}}(G, B, T) \simeq \mathrm{Kil}(G').$$

The proof is immediate: it suffices to prove the assertion locally for (fpqc), so one may assume $G \simeq G'$, and the result then reduces to Exp. XXII, 5.8.3(iii).

Remark 2.5. — The preceding results are immediately interpreted in terms of reduction of the structure group. If G' is a form of G, corresponding to the principal bundle $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$, to give a reduction of the structure group of this bundle to $\underline{\mathrm{Aut}}_{S\text{-gr}}(G, T)$ amounts to giving a maximal torus T' of G'. The indicated bijections are, on the one hand, that of 2.4 and, on the other hand, the map

$$T' \longmapsto \underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T').$$

The same applies to Borel subgroups and Killing couples.

Proposition 2.6. — *Let S be a scheme, let G and G' be two reductive S-groups having the same type at every point, and let T (respectively, T') be a maximal torus of G (respectively, G'). Then T_{ad} acts freely on $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T')$, and the quotient*

$$P = \underline{\mathrm{Isom}}_{S\text{-gr}}(G, T; G', T')/T_{\mathrm{ad}}$$

is representable; it is a principal homogeneous bundle under

$$A = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, T)/T_{\mathrm{ad}},$$

where A is represented by a twisted constant S-scheme and is an extension of $\underline{\mathrm{Autext}}(G)$ *by*

$$W_{\mathrm{ad}(G)}(T_{\mathrm{ad}}) = \mathrm{Norm}_{\mathrm{ad}(G)}(T_{\mathrm{ad}})/T_{\mathrm{ad}}.$$

Moreover, if A is made to act on T in the evident way, the bundle associated with P is precisely T'.[13]

The first part of the proposition follows immediately from the preceding results. To prove the second, observe that there is an evident morphism

$$P \times_S T \longrightarrow T', \qquad (u,t) \longmapsto u(t).$$

To show that, after passage to the quotient by A, it induces an isomorphism, one may once again assume $(G,T) \simeq (G',T')$, in which case the assertion is immediate.

In an entirely analogous way, one has:

Proposition 2.7. — *Let S be a scheme, let G and G' be two reductive S-groups having the same type at every point, and let $B \supset T$ (respectively, $B' \supset T'$) be a Killing couple of G (respectively, G'). If*

$$\underline{\mathrm{Aut}}_{S\text{-gr}}(G,B,T)/T_{\mathrm{ad}} \simeq \underline{\mathrm{Autext}}(G)$$

is made to act on T in the evident way, the bundle associated with $\underline{\mathrm{Isomext}}(G,G')$ *is precisely T'.*

Corollary 2.8. — *Let G and G' be two reductive S-groups which are inner twisted forms of one another, and let $B \supset T$ (respectively, $B' \supset T'$) be a Killing couple of G (respectively, G'). Then T and T' are isomorphic.*[14]

Remark 2.9. — It is not true in general that B and B' are isomorphic; they are nevertheless inner twisted forms of one another (cf. §5).

One may develop "Isomint" variants[15] of the preceding results. We mention one:

Proposition 2.10. — *Let S be a scheme, let G and G' be two reductive S-groups having the same type at every point, let $B \supset T$ (respectively, $B' \supset T'$) be a Killing couple of G (respectively, G'), and let $u \in \underline{\mathrm{Isomext}}(G,G')(S)$. Consider*

$$\begin{aligned}&\underline{\mathrm{Isomint}}_u(G,B,T;G',B',T')\\ &\quad = \underline{\mathrm{Isom}}_{S\text{-gr}}(G,B,T;G',B',T') \cap \underline{\mathrm{Isomint}}_u(G,G').\end{aligned}$$

It is a smooth affine S-scheme which is a principal homogeneous bundle under T_{ad}. In particular,

$$\underline{\mathrm{Isomint}}_u(G,B,T;G',B',T')(S) \neq \varnothing$$

if and only if the corresponding element of $H^1(S,T_{\mathrm{ad}})$ is zero.

To conclude this section, we prove two results that will be useful later.

Proposition 2.11. — *Let S be a scheme, let G be a reductive S-group, and let T be a maximal torus of G. The evident morphism*

$$T_{\mathrm{ad}} \xrightarrow{\sim} \underline{\mathrm{Aut}}_{S\text{-gr}}(G, \mathrm{id}_T)$$

[13] Editor's note: Consequently, if P has a section, then T and T' are isomorphic; in particular, T_P and T'_P are isomorphic. See the addition 4.5.1, where this observation is developed in the case $G = \underline{\mathrm{Ép}}_S(\mathscr{R})$.

[14] Editor's note: This follows from 2.7, since $\underline{\mathrm{Isomext}}(G,G')$ has a section (cf. the preceding editor's note).

[15] Editor's note: Recall that $\underline{\mathrm{Isomint}}_u(G,G')$ is defined in 1.11.

is an isomorphism.

This follows from the preceding statements. A direct proof was also given in the course of the proof of 1.5.2.

Corollary 2.12. — *Under the preceding hypotheses, there is an equivalence between the category of pairs (G', f), where G' is a form of G and f is an isomorphism from T onto a maximal torus of G', and the category of principal homogeneous bundles under T_{ad}.*

Corollary 2.13. — *If $H^1(S, T_{\mathrm{ad}}) = 0$, and if G' is a form of G having a maximal torus isomorphic to T, then G' is isomorphic to G.*

Corollary 2.14. — *Let S be a scheme such that $\mathrm{Pic}(S) = 0$, and let G be a reductive S-group of constant type. Then G is splittable if and only if G has a split maximal torus.*

Let G be a reductive group and let $\mathrm{rad}(G)$ be its radical (Exp. XXII, 4.3.9). Since $\mathrm{rad}(G)$ is central and characteristic in G, there is a canonical morphism

$$q : \underline{\mathrm{Autext}}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr}}(\mathrm{rad}(G)).$$

Proposition 2.15. — *Let G be a reductive S-group. The following sequence is exact:*

$$1 \longrightarrow \mathrm{ad}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr}}(G, \mathrm{id}_{\mathrm{rad}(G)}) \xrightarrow{p} \underline{\mathrm{Autext}}(G) \xrightarrow{q} \underline{\mathrm{Aut}}_{S\text{-gr}}(\mathrm{rad}(G)),$$

and $\ker(q) = \mathrm{im}(p)$ is an open and closed subscheme of $\underline{\mathrm{Autext}}(G)$, finite over S.

One may assume that G is split. The first assertion is immediate, and the second follows from Exp. XXI, 6.7.5 and 6.7.7.

Writing

$$H = \underline{\mathrm{Aut}}_{S\text{-gr}}(G, \mathrm{id}_{\mathrm{rad}(G)}),$$

one obtains:

Corollary 2.16. — *There is an equivalence between the category of pairs (G', f), where G' is a form of G and f is an isomorphism from $\mathrm{rad}(G)$ onto the radical of G', and the category of principal bundles under a certain S-group scheme H, where H is such that there is an exact sequence*

$$1 \longrightarrow \mathrm{ad}(G) \longrightarrow H \longrightarrow F \longrightarrow 1,$$

in which the S-group F is étale and finite over S.

3. Dynkin Scheme of a Reductive Group. Quasi-Split Groups

3.1. — Recall (Exp. XXI, 7.4.1) that a Dynkin diagram is a finite set endowed with the structure defined by a set of pairs of distinct elements (bonds) and a map to $\{1, 2, 3\}$ (lengths). To every pinned reduced root datum $\mathscr{R}$ there is associated a Dynkin diagram $\Delta(\mathscr{R})$, whose underlying set is the set of simple roots.

3.2. — Let S be a scheme. A Dynkin S-scheme is a finite twisted constant S-scheme Δ, endowed with the structure defined by a subscheme L of $\Delta \times_S \Delta$ having empty intersection with the diagonal, and by a morphism

$$\Delta \longrightarrow \{1, 2, 3\}_S.$$

If S' is a connected S-scheme,[16] $\Delta(S')$ is naturally endowed with the structure of a Dynkin diagram.

[16]Editor's note: The hypothesis that S' be connected has been added.

The following notions are defined immediately: an isomorphism of two Dynkin schemes, the base extension of a Dynkin scheme, and the constant Dynkin scheme associated with a Dynkin diagram.

Every étale descent datum on a Dynkin scheme is effective.

3.3. — We shall associate a Dynkin S-scheme with every reductive S-group G. First suppose that G is splittable over S. For every pinning E of G, let $\Delta(E)$ be the constant Dynkin scheme associated with the pinned root datum defined by E. If E and E' are two pinnings of G, then by 1.5 there is a unique inner automorphism of G over S carrying E to E'. This automorphism of G defines an isomorphism

$$a_{EE'} : \Delta(E) \xrightarrow{\sim} \Delta(E').$$

The $a_{EE'}$ plainly form a transitive system, so the $\Delta(E)$ may be identified (that is, one takes their inductive limit); the result is a constant Dynkin scheme denoted by $\mathrm{Dyn}(G)$. If now G is an arbitrary reductive S-group, there is an étale covering family $\{S_i \to S\}$ such that

G_{S_i} is splittable. Arguing as above, one therefore obtains a canonical descent datum on the $\mathrm{Dyn}(G_{S_i})$, and by descent this constructs a Dynkin S-scheme $\mathrm{Dyn}(G)$.

3.4. — This construction has the following properties (which, moreover, essentially characterize it):

(i) With every reductive S-group G is associated a Dynkin scheme $\mathrm{Dyn}(G)$; with every isomorphism

$$u : G \xrightarrow{\sim} G'$$

is functorially associated an isomorphism

$$\mathrm{Dyn}(u) : \mathrm{Dyn}(G) \xrightarrow{\sim} \mathrm{Dyn}(G').$$

(ii) If S' is an S-scheme and G is a reductive S-group, then

$$\mathrm{Dyn}(G \times_S S') \simeq \mathrm{Dyn}(G) \times_S S'.$$

(iii) If E is a pinning of G defining the pinned root datum with Dynkin diagram Δ, then

$$\mathrm{Dyn}(G) \simeq \Delta_S.$$

(iv) If u is an inner automorphism of G, then $\mathrm{Dyn}(u)$ is the identity automorphism of $\mathrm{Dyn}(G)$.

3.5. — Let S be a scheme and G a reductive S-group. It is clear that the functor

$$\underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G))$$

of automorphisms of $\mathrm{Dyn}(G)$ as a Dynkin scheme is represented by a finite twisted constant S-scheme. By 3.4(i) and (ii), there is a canonical morphism

$$\underline{\mathrm{Aut}}_{S\text{-gr}}(G) \longrightarrow \underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G)),$$

which, by (iv), factors through a morphism

$$\underline{\mathrm{Autext}}(G) \longrightarrow \underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G)).$$

More generally, if G and G' are two reductive S-groups, there is a canonical morphism

$$\underline{\mathrm{Isomext}}(G, G') \longrightarrow \underline{\mathrm{Isom}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G), \mathrm{Dyn}(G')).$$

In particular, if G' is an inner twisted form of G (1.11), the Dynkin schemes $\mathrm{Dyn}(G)$ and $\mathrm{Dyn}(G')$ are isomorphic.

3.6. — If G is semisimple (respectively, adjoint or simply connected), the morphism

$$\underline{\mathrm{Autext}}(G) \longrightarrow \underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G))$$

is a monomorphism (respectively, an isomorphism). Indeed, one may assume that G is pinned, and the assertion reduces to the corresponding result for pinned reduced root data (cf. Exp. XXI, 7.4.5).

There is an analogous result for the Isom functors. It follows in particular that two semisimple adjoint (respectively, simply connected) S-groups are inner twisted forms of one another if and only if their Dynkin schemes are isomorphic.

3.7. — One can give a different construction of the Dynkin scheme associated with a reductive group. Let $\mathscr{R}$ be a pinned reduced root datum and G a reductive S-group of type $\mathscr{R}$, and write $\Delta(\mathscr{R})$ for the Dynkin diagram defined by $\mathscr{R}$. There is, by 3.5, a canonical morphism

$$A_S(\mathscr{R}) = \underline{\mathrm{Aut}}_{S\text{-gr}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})) \longrightarrow \underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\Delta(\mathscr{R})_S).$$

The reductive S-group G corresponds (1.17) to a bundle

$$\underline{\mathrm{Isom}}_{S\text{-gr}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), G),$$

principal homogeneous under $A_S(\mathscr{R})$. The associated bundle under $\underline{\mathrm{Aut}}_{\mathrm{Dyn}}(\Delta(\mathscr{R})_S)$ corresponds to a form over S of $\Delta(\mathscr{R})_S$: it is $\mathrm{Dyn}(G)$. In other words, this associated bundle is precisely

$$\underline{\mathrm{Isom}}_{\mathrm{Dyn}}(\Delta(\mathscr{R})_S, \mathrm{Dyn}(G)).$$

In this form the proof is immediate.

3.8. Dynkin Scheme and Killing Couples. — Let S be a scheme, G a reductive S-group, and $B \supset T$ a Killing couple of G. There is a canonical morphism

$$i : \mathrm{Dyn}(G) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr}}(T, \mathbb{G}_{m,S})$$

which identifies $\mathrm{Dyn}(G)$ with the "scheme of simple roots of B relative to T." This morphism is defined immediately by descent from the pinned case. Observe also that the data of T and i allow one to reconstruct B (the "one-to-one correspondence between systems of simple roots and systems of positive roots").

It follows from the preceding description of $D = \mathrm{Dyn}(G)$ that there is a canonical root of B_D relative to T_D: this root α_D is the image, under $i(D)$, of the identity morphism of D. One obtains from it a canonical invertible $\mathcal{O}_D$-module $\mathfrak{g}_D$:

$$\mathfrak{g}_D = (\mathfrak{g} \otimes_{\mathcal{O}_S} \mathcal{O}_D)^{\alpha_D}.$$

In the pinned case,

$$D = \coprod_{\alpha \in \Delta} S_\alpha,$$

where every S_α is a copy of S, and $\mathfrak{g}_D$ is then the $\mathcal{O}_D$-module inducing $\mathfrak{g}_\alpha$ on S_α, for every $\alpha \in \Delta$.

3.9. Quasi-Pinnings. Quasi-Pinned Groups. — If G is a reductive S-group, a *quasi-pinning of* G means the data

(i) of a Killing couple $B \supset T$ of G;

(ii) of a section

$$X \in \Gamma\big(\mathrm{Dyn}(G), \mathfrak{g}_D\big)^{\times}.$$

A reductive S-group is called *quasi-splittable* if it has a quasi-pinning. A *quasi-pinned group* is a reductive group equipped with a quasi-pinning.

Let $B \supset T$ be a Killing couple of the reductive S-group G. Then G is quasi-pinnable relative to this Killing couple if and only if $\mathfrak{g}_D$ has a section nonzero at every point, that is, if the element of $\mathrm{Pic}(\mathrm{Dyn}(G))$ defined by $\mathfrak{g}_D$ is zero. Suppose in particular that S is semilocal. Then $\mathrm{Dyn}(G)$ is also semilocal, and hence $\mathrm{Pic}(\mathrm{Dyn}(G)) = 0$. Thus:

Proposition 3.9.1. — *Let S be a semilocal scheme and G a reductive S-group. Then G is quasi-splittable if and only if it has a Borel subgroup.*

[17] Indeed, S is affine, so by the first assertion of Exp. XXII, 5.9.7, if G has a Borel subgroup B, it also has a Killing couple $B \supset T$. Then, because $\mathrm{Pic}(D) = 0$, the module $\mathfrak{g}_D$ has a nowhere-zero section X.

Continue to let A be a semilocal ring and $S = \mathrm{Spec}(A)$. For every reductive S-group G, the morphism

$$\mathrm{Bor}(G) \longrightarrow S$$

is surjective (because G_s has Borel subgroups for every $s \in S$), smooth, and projective (Exp. XXII, 5.8.3). It therefore has sections after a finite, surjective, étale extension of the base.[18] It follows that:

[17] Editor's note: The reference to Exp. XXII, 5.9.7 has been given in detail.

[18] Editor's note: The original referred to EGA IV, §24, which did not appear. The point is to use "Bertini's theorem." We give the details of the argument, which were indicated to us by O. Gabber. Let $X \to S$ be a surjective smooth projective morphism. Replacing S by a connected component, one may assume that X/S has relative dimension d at every point (cf. EGA IV_4, 17.10.2). One may also assume that X is a closed subscheme of a projective space $\mathbb{P}^n_S = \mathbb{P}(E)$, where E is a free A-module of rank $n+1$ (cf. EGA II, 5.3.3). Let $s_1, \ldots, s_r$ be the closed points of S. By Bertini's theorem (see, for example, [Jou83], I, 6.10), there is an open subset U of

$$P = \mathbb{P}(E^*)^d$$

with nonempty fibers such that, for every point $u = (f_1, \ldots, f_d)$ of U_{s_i}, the intersection of $X_{\kappa(u)}$ with the d hyperplanes of $\mathbb{P}^n_{\kappa(u)}$ defined by u is étale over $\kappa(u)$. After shrinking U, one may assume that U is the complement in affine space $\mathbb{A}^{nd}_S$ of the zero locus $V(Q)$ of a polynomial Q of degree $m > 0$. An easy induction on the number of variables then shows that $V(Q)$ cannot contain every rational point of $\mathbb{A}^{nd}_{\kappa(s_i)}$ if $|\kappa(s_i)| > m$. Since the morphism

$$A \longrightarrow \prod_i \kappa(s_i)$$

is surjective, one can find a monic polynomial $R \in A[X]$ of degree m whose image in $\kappa(s_i)[X]$ is irreducible when $\kappa(s_i)$ is finite and has m distinct roots when $\kappa(s_i)$ is infinite. Put

$$A' = A[X]/(R), \qquad S' = \mathrm{Spec}(A').$$

Then $S' \to S$ is étale, finite, and surjective, and the residue field at each of its closed points $s'_1, \ldots, s'_t$ has cardinality at least $2m$. Thus U has a rational point u_i above every closed point of S', and, since

$$A' \longrightarrow \prod_i \kappa(s'_i)$$

is surjective , these points lift to a section u of $P_{S'}$. Let Z be the intersection of $X_{S'}$ with the d hyperplanes of $\mathbb{P}^n_{S'}$ defined by u, and let V be the open subset of Z consisting of the points at which Z is étale over S'. By EGA IV_3, 11.3.8, V contains the fibers $Z_{s'_i}$ for every i. Since $\pi : Z \to S'$ is proper, it follows that the closed set $\pi(Z - V)$ is empty, whence $V = Z$. Thus $Z \to S'$ is surjective, étale, and proper, hence finite, as is the composite $Z \to S$; this gives the desired section of $X \to S$.

Corollary 3.9.2. — *Let S be a semilocal scheme and G a reductive S-group. There is an étale, finite, and surjective morphism $S' \to S$ such that $G_{S'}$ is quasi-splittable.*

Remark 3.9.3. — Under the preceding hypotheses, let T be a maximal torus of G (cf. Exp. XIV, 3.20). One may moreover assume that $G_{S'}$ is quasi-splittable relative to $T_{S'}$: it suffices to apply the preceding argument to the "scheme of Borel subgroups containing T," which is finite and étale over S (Exp. XXII, 5.5.5(ii)).

3.10. — Let E and E' be two quasi-pinnings of the reductive S-group G. There is a unique inner automorphism of G carrying E to E'. Indeed, one reduces immediately to the split case, where the assertion has already been proved (1.5; it suffices to observe that for an inner automorphism of G, preserving a pinning is equivalent to preserving the underlying quasi-pinning). One concludes, as in §1, that a

quasi-pinning of the reductive S-group G defines a splitting h of the exact sequence:

$$1 \longrightarrow \underline{\mathrm{ad}}(G) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \underset{p}{\overset{h}{\leftrightarrows}} \underline{\mathrm{Autext}}(G) \longrightarrow 1$$

the image of h being the subgroup of $\underline{\mathrm{Aut}}_{S\text{-gr}}(G)$ that preserves the quasi-pinning.

Likewise, if G and G' are two quasi-pinned S-groups, one defines naturally the subfunctor

$$\underline{\mathrm{Isom}}_{S\text{-gr},\, q\text{-}ép}(G, G')$$

of $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$. The projection from $\underline{\mathrm{Isom}}_{S\text{-gr}}(G, G')$ to $\underline{\mathrm{Isomext}}(G, G')$ induces an isomorphism

$$(*) \qquad \underline{\mathrm{Isom}}_{S\text{-gr},\, q\text{-}ép}(G, G') \xrightarrow{\sim} \underline{\mathrm{Isomext}}(G, G').$$

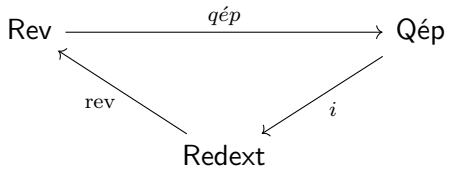
Theorem 3.11. — *Let S be a scheme, let $\mathscr{R}$ be a pinned reduced root datum such that $\mathrm{Ép}_S(\mathscr{R})$ exists (cf. Exp. XXV), and let E be its group of automorphisms. Consider the following three categories:*

(i) the category Rev *of principal Galois coverings of S with group E (the morphisms are isomorphisms of E-bundles);*

(ii) the category Redext*, whose objects are the reductive S-groups of type $\mathscr{R}$ (Exp. XXII, 2.7), the morphisms from G to G' being the elements of $\underline{\mathrm{Isomext}}(G, G')(S)$;*

(iii) the category Qép *of quasi-pinned reductive S-groups of type $\mathscr{R}$ (the morphisms are the isomorphisms preserving the quasi-pinnings).*

These three categories are equivalent. More precisely, there is a diagram of functors, commutative up to functorial isomorphisms:



We describe these three functors below, leaving to the reader the verification that the diagram commutes.[19]

[19] Editor's note: In 3.11.4 we have sketched the verification that the functors i, rev, and *qép* are fully faithful and that the composite rev $\circ i \circ$ *qép* is isomorphic to the identity functor of Rev.

3.11.1. The functor i. — This is the evident functor:

$$i(G) = G, \qquad i(f) = \text{the image of } f \text{ under the isomorphism 3.10 } (*).$$

3.11.2. The functor *qép*. — Let S' be a principal Galois covering of S with group E. Let

$$(G, T, M, \mathscr{R}, \Delta, (X_\alpha)_{\alpha\in\Delta})$$

be a pinning of $G = \text{Ép}_S(\mathscr{R})$, and let $(X'_\alpha)_{\alpha\in\Delta}$ be the corresponding pinning of

$$G' = G_{S'} = \text{Ép}_{S'}(\mathscr{R}).$$

By Exp. XXIII, 5.5 bis, there is a unique group homomorphism

$$\theta : E \longrightarrow \underline{\text{Aut}}_{S\text{-gr}}(\text{Ép}_S(\mathscr{R})) = A(\mathscr{R})(S)$$

such that, for every $h \in E$, the automorphism $\theta(h)$ induces $D_S(h)$ on T, and

$$\text{Lie}(\theta(h))(X_\alpha) = X_{h(\alpha)} \qquad (\alpha \in \Delta).$$

Taking into account the action of E on S', this yields an action of E on G', compatible with the action of E on S' and preserving the canonical quasi-pinning of G'.[20] Since $S' \to S$ is a covering for the (fpqc) topology, it is an effective descent morphism for the fibered category of affine morphisms. Write

$$qép(S') = Q\text{-}\,\text{Ép}_{S'/S}(\mathscr{R})$$

for the quasi-pinned S-group obtained by Galois descent.[21]

3.11.3. The functor rev**.** — Let G be a reductive S-group of type $\mathscr{R}$. Write

$$\text{rev}(G) = \underline{\text{Isomext}}(\text{Ép}_S(\mathscr{R}), G).$$

---

[20] Editor's note: The preceding discussion expands the original in order to show that the action of E on G' is obtained by combining the natural action of E on $\text{Ép}_{S'}(\mathscr{R})$ with the given action on S'. The canonical Killing couple of G' is preserved by this action, as is the quasi-pinning given by the element $\widetilde{X}'$ of

$$\Gamma\left(\Delta_{S'}, \text{Lie}(G'/S')_{\Delta_{S'}}\right),$$

equal to X'_α on the copy of S' indexed by α. Indeed, since E acts on $\Delta_{S'}$ by permuting the copies of S', one has $h(\widetilde{X}') = \widetilde{X}'$ for every $h \in E$.

[21] Editor's note: See, for example, TDTE I, p. 22, Example 1. One may also describe $qép(S')$ as the twist of $G = \text{Ép}_S(\mathscr{R})$ by the E-torsor S'/S, that is, the (fpqc) sheaf quotient of $S' \times_S G$ by the right action of E defined by

$$(s', g) \cdot h = (s'h, h^{-1}(g)).$$

Since G is affine over S, and since E acts on G by group automorphisms, this sheaf is represented by an S-group $G^\sharp$, which is a "twisted" form of G, and $D^\sharp = \text{Dyn}(G^\sharp)$ is the twist of the constant Dynkin scheme Δ_S by the torsor S'/S. Since E normalizes B and T, one obtains likewise a Killing couple $(B^\sharp, T^\sharp)$ of $G^\sharp$. On the other hand, put $\mathfrak{g} = \text{Lie}(G/S)$ and $\mathfrak{g}^\sharp = \text{Lie}(G^\sharp/S)$. For every $U \to S$, the sections of $\mathfrak{g}^\sharp$ over U are the E-equivariant S-morphisms

$$U \times_S S' \longrightarrow W(\mathfrak{g}).$$

Since $D^\sharp \times_S S'$ is E-isomorphic to $\Delta \times S'$, endowed with the action

$$(\alpha, s') \cdot h = (h^{-1}(\alpha), s'h),$$

the morphism $(\alpha, s') \mapsto X_\alpha$ gives a section of $\mathfrak{g}^\sharp$ over $D^\sharp$ which is a quasi-pinning, that is, a nowhere-zero section of

$$\left(\mathfrak{g}^\sharp \otimes_{\mathcal{O}_S} \mathcal{O}_{D^\sharp}\right)^{D^\sharp}$$

(cf. 3.8).

This is a principal homogeneous bundle under E_S (cf. 1.10 and 1.19), that is, an object of Rev.

3.11.4. — [22] It is clear from the isomorphism 3.10 $(*)$ that the functor i is fully faithful. On the other hand, if G_0, G, G' are reductive S-groups, the natural morphism

$$\underline{\mathrm{Isom}}(G_0, G) \times_S \underline{\mathrm{Isom}}(G, G') \longrightarrow \underline{\mathrm{Isom}}(G_0, G')$$

induces a morphism

$$(\star) \qquad \underline{\mathrm{Isomext}}(G_0, G) \times_S \underline{\mathrm{Isomext}}(G, G') \longrightarrow \underline{\mathrm{Isomext}}(G_0, G'),$$

since, for every $S' \to S$, if

$$g_0 \in G_0(S'), \quad g \in G(S'), \quad u \in \underline{\mathrm{Isom}}(G_0, G)(S'), \quad v \in \underline{\mathrm{Isom}}(G, G')(S'),$$

one has

$$v \circ \mathrm{int}(g) \circ u \circ \mathrm{int}(g_0) = v \circ u \circ \mathrm{int}\big(u^{-1}(g) g_0\big).$$

Taking $G_0 = \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})$, one obtains a map

$$\underline{\mathrm{Isomext}}(G, G')(S) \longrightarrow \mathrm{Hom}_{\mathsf{Rev}}\big(\underline{\mathrm{Isomext}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), G), \underline{\mathrm{Isomext}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), G')\big),$$

and, to show that this map is a bijection, one may assume by (fpqc) descent that G and G' are pinned, in which case it is evident.

Similarly, if S_1, S_2 are two objects of Rev, and if one writes

$$S_i \times^E \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})$$

for the S-group $q\acute{e}p(S_i)$ obtained by twisting $\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})$ by the E-torsor S_i (cf. editor's note (21)), there is a natural map

$$\mathrm{Hom}_{\mathsf{Rev}}(S_1, S_2) \longrightarrow \mathrm{Hom}_{\mathsf{Q\acute{e}p}}(S_1 \times^E \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), S_2 \times^E \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})).$$

To show that this map is a bijection, one may assume by (fpqc) descent that S_1 and S_2 are trivial E-bundles, in which case the assertion is evident.

Thus the three functors in the diagram are fully faithful. Moreover, for every object S' of Rev, there is a natural morphism

$$S' \longrightarrow \underline{\mathrm{Isomext}}\Big(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), S' \times^E \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})\Big),$$

and to see that it is an isomorphism, one may assume by (fpqc) descent that S' is a trivial E-bundle, in which case the assertion is evident.

There is therefore an isomorphism of functors

$$\mathrm{Id}_{\mathsf{Rev}} \longrightarrow \mathrm{rev} \circ i \circ q\acute{e}p.$$

Since rev is fully faithful, for every reductive S-group H (not necessarily quasi-split) one obtains a bijection

$$\underline{\mathrm{Isomext}}\Big(Q\text{-}\acute{\mathrm{E}}\mathrm{p}_{\mathrm{rev}(H)/S}(\mathscr{R}), H\Big)(S) \simeq \mathrm{Aut}_{\mathsf{Rev}}(\mathrm{rev}(H)),$$

[22] Editor's note: This subsection number has been added.

functorial in H. In particular, the identity morphism of $\mathrm{rev}(H)$ corresponds to a "canonical" element

$$u_0 \in \underline{\mathrm{Isomext}}\Big(Q\text{-}\,\acute{\mathrm{E}}\mathrm{p}_{\mathrm{rev}(H)/S}(\mathscr{R}), H\Big)\,(S).$$

Moreover, every element u of this same set corresponds to an automorphism φ_u of $\mathrm{rev}(H)$, and $q\acute{e}p(\varphi_u)$ is the unique automorphism of the pinned S-group

$$Q\text{-}\,\acute{\mathrm{E}}\mathrm{p}_{\mathrm{rev}(H)/S}(\mathscr{R})$$

such that

$$u_0 \circ q\acute{e}p(\varphi_u) = u.$$

This proves Theorem 3.11.

We develop one of the corollaries of 3.11.

Corollary 3.12. — *For every reductive S-group G, there is a quasi-pinned S-group $G_{q\text{-}\acute{e}p}$ and an "outer isomorphism"*

$$u \in \underline{\mathrm{Isomext}}(G_{q\text{-}\acute{e}p}, G)(S).$$

The pair $(G_{q\text{-}\acute{e}p}, u)$ is unique up to a unique isomorphism.

Indeed, one may assume that G has constant type $\mathscr{R}$, and one takes

$$G_{q\text{-}\acute{e}p} = Q\text{-}\,\acute{\mathrm{E}}\mathrm{p}_{\mathrm{rev}(G)/S}(\mathscr{R}).$$

3.12.1. — Observe that the data of the pair $(G_{q\text{-}\acute{e}p}, u)$ canonically define the S-scheme (cf. 1.11)

$$Q = \underline{\mathrm{Isomint}}(G_{q\text{-}\acute{e}p}, G),^{23}$$

which is a principal homogeneous bundle under $\mathrm{ad}(G_{q\text{-}\acute{e}p})$, and whose data are "equivalent" to those of the inner twisted form G of $G_{q\text{-}\acute{e}p}$. Moreover, Q is precisely the "scheme of quasi-pinnings of G," a definition that explains its structure as a principal homogeneous bundle (on the left) under $\mathrm{ad}(G)$ (3.10); compare 1.20.

Proposition 3.13. *Let S be a scheme, G a semisimple adjoint (resp. simply connected) S-group, $B \supset T$ a Killing couple of G,* $\mathrm{Dyn}(G)$ *the Dynkin S-scheme of G. There exists a canonical isomorphism of S-group schemes*

$$T \xrightarrow{\sim} \prod_{\mathrm{Dyn}(G)/S} \mathbb{G}_{m,\mathrm{Dyn}(G)}.$$

(Recall (cf. Exp. II, § 1) that the right-hand side is by definition the S-functor which to $S' \to S$ associates $G_m(\mathrm{Dyn}(G) \times_S S')$, or, what amounts to the same, $G_m(Dyn(G_{S'}))$.)

First proof. Let us do it for simplicity in the adjoint case. Consider the composite morphism

$$T \longrightarrow \prod_{D/S} T_D \longrightarrow \prod_{D/S} \mathbb{G}_{m,D}.$$

where the first morphism is the canonical morphism, the second is $\prod_{D/S} \alpha_D$ (we have written $D = \mathrm{Dyn}(G)$). To verify that this morphism is an isomorphism, one may assume G split; now, in this case, this is none other than the morphism $T \to (G_{m,S})^{\Delta}$ with components α, for $\alpha \in \Delta$, and the latter is an isomorphism (Exp. XXII, 4.3.8).

[23] Editor's note: We write $\underline{\mathrm{Isomint}}(G_{q\text{-}\acute{e}p}, G)$ instead of $\underline{\mathrm{Isomint}}_u(G_{q\text{-}\acute{e}p}, G)$ (cf. 1.11), since the pair $(G_{q\text{-}\acute{e}p}, u)$ is unique up to a unique isomorphism.

Second proof. By 2.8, 3.5 and 3.11, one may assume that $G = Q - \acute{E}p_{S'/S}(R)$, T being the canonical maximal torus. On S', one has by Exp. XXII 4.3.8, an isomorphism $T_{S'} \xrightarrow{\sim} (G_{m,S'})^{\Delta}$, defined by the simple roots (resp. the simple coroots). The group E operates on the right-hand side by permutation of Δ. Now the bundle associated to S'/S by $E \to \mathrm{Aut}(\Delta)$ is $\mathrm{Dyn}(G)$ (3.7), and one concludes at once.

Using Prop. 8.4 of the appendix, one deduces:

Corollary 3.14. *Under the preceding conditions, one has*

$$H^1(S,T) \xrightarrow{\sim} H^1(\mathrm{Dyn}(G), \mathbb{G}_m) \xrightarrow{\sim} \mathrm{Pic}\big(\mathrm{Dyn}(G)\big).$$

In particular, $H^1(S,T) = 0$ when S is semi-local.

Remark 3.15. Let S be a scheme, G (resp. G') an S-reductive group, $B \supset T$ (resp. $B' \supset T'$) a Killing couple of G (resp. G'), $u \in Isomext(G,G')(S)$. Set (cf. 2.10)

$$P = \underline{\mathrm{Isomint}}_u(G,B,T;G',B',T').$$

this is a principal homogeneous bundle under T_{ad} (by $(f,t) \mapsto f \circ int(t)$).

Let on the other hand $D = \mathrm{Dyn}(G) = \mathrm{Dyn}(G')$ (identified via u (3.5)), and let $L = Isom_D(g_D, g'_D)$ be the principal homogeneous bundle under $G_{m,D}$ defined by the invertible $\mathcal{O}_D$-module

$$\mathrm{Hom}_{\mathcal{O}_D}(\mathfrak{g}_D, \mathfrak{g}'_D) = \mathfrak{g}'_D \otimes (\mathfrak{g}_D)^{\vee}.$$

Each $f \in P(S')$ defines an isomorphism of $g_D \otimes_{O_S} O_{S'}$ onto $g'_D \otimes_{O_S} O_{S'}$, whence a canonical morphism

$$P \to \prod_{D/S} L.$$

This morphism is an isomorphism, compatible with the isomorphism of operator groups

$$T_{\mathrm{ad}} \xrightarrow{\sim} \prod_{D/S} \mathbb{G}_{m,D}.$$

defined above. Indeed, it suffices to verify it in the case where the two groups are pinned, where it is easy.

It follows in particular that in the isomorphism

$$H^1(S, T_{ad}) \xrightarrow{\sim} \mathrm{Pic}(\mathrm{Dyn}(G))$$

of 3.14, the class of the bundle P is transformed into $c\ell(g'^D) - c\ell(g_D)$. The bundle P is therefore trivial if and only if g'^D and g_D are isomorphic.

If (G,B,T) is quasi-splittable, for example if one takes for G the group $G'_{q-\acute{e}p.}$, with its canonical Killing couple, it follows that the image of the class of P is none other than the obstruction to the quasi-splitting of G' defined in 3.9.

3.16. Symmetries

3.16.1.

Let S be a scheme, G an S-reductive group, $B \supset T$ a Killing couple of G. Write $D = \mathrm{Dyn}(G)$. Recall (Exp. XXII, 5.9.1) that there exists a unique Borel subgroup B^- of G such that $B \cap B^- = T$. If $X \in \Gamma(D, g_D)^{\times}$ defines a quasi-pinning of G relative to (B,T)

(3.9), then $Y = -X^{-1} \in \Gamma(D, (g_D)^\vee)^\times$ defines a quasi-pinning of G relative to (B^-, T); one says that this is the *opposite quasi-pinning*.

If R is a pinned reduced root datum and if E is an R-pinning of the S-reductive group G, one defines an R-pinning E^- said to be *opposite to* E in the following way: one keeps the same maximal torus T, one takes the opposite of the isomorphism $D_S(M) \xrightarrow{\sim} T$, and one "pins" by $Y_\alpha = -X_\alpha^{-1} \in \Gamma(S, g^{-\alpha})^\times$, for $\alpha \in \Delta$. The quasi-pinning underlying E^- is the quasi-pinning opposite to the quasi-pinning underlying E.

Remark. In the notation of Exp. XIX, 3.1, if one sets

$$w_\alpha(X_\alpha) = \exp(X_\alpha)\exp(-X_\alpha^{-1})\exp(X_\alpha).$$

one has $w_\alpha(X_\alpha) = w_{-\alpha}(Y_\alpha)$ (loc. cit., 3.1 (vi)).

Proposition 3.16.2. *Let S be a scheme, G an S-reductive group.*

(i) Let T be a maximal torus of G; there exists a unique

$$i_T \in \left(\underline{\mathrm{Aut}}_{S\text{-gr.}}(G,T)/T_{\mathrm{ad}}\right)(S) \subset \underline{\mathrm{Aut}}_{S\text{-gr.}}(T).$$

such that $i_T(t) = t^{-1}$ for every section t of T.

(ii) Let (B,T) be a Killing couple of G; there exists a unique section

$$w_{B,T} \in \big(\mathrm{Norm}_G(T)/T\big)(S) = W_G(T)(S).$$

such that $int(w_{B,T})(B) = B^-$ (with the obvious abuse of language).

(iii) Let $Q = (B,T,X)$ be a quasi-pinning of G, $Q^- = (B^-,T,Y)$ the opposite quasi-pinning; there exists a unique inner automorphism of G

$$n_Q \in Norm_{ad(G)}(T_{ad})(S) \subset \underline{\mathrm{Aut}}_{S\text{-gr.}}(G)$$

such that $n_Q(Q) = Q^-$, that is, $n_Q(T) = T$, $n_Q(B) = B^-$, $n_Q(X) = Y$.

(iv) Let (R,E) be a pinning of G, (R,E^-) the opposite pinning; there exists a unique automorphism of G

$$u_E \in \underline{\mathrm{Aut}}_{S\text{-gr.}}(G,T) \subset \underline{\mathrm{Aut}}_{S\text{-gr.}}(G).$$

such that $u_E(E) = E^-$, i.e. $u_E(t) = t^{-1}$ for every section t of T, and $Ad(u_E)X_\alpha = Y_\alpha$ for every $\alpha \in \Delta$.

Proof. (ii) follows from Exp. XXII, 5.5.5 (ii), then (iii) follows from 3.10, and (iv) follows from Exp. XXIII, 4.1. Finally to prove (i), one may assume G pinned. Existence follows from (iv) for example, uniqueness from the fact that an automorphism of G inducing the identity on T is given by a section of T_{ad} (2.11).

Corollary 3.16.3. *One has*

$$i_T^2 = w_{B,T}^2 = n_Q^2 = u_E^2 = e.$$

Moreover, i_T (resp. u_E) is $\neq e$ if $G \neq e$, and $w_{B,T}$ (resp. n_Q) is $\neq e$ if G is not a torus.

Corollary 3.16.4. *In the situation of (iii) (resp. (iv)), n_Q projects onto $w_{B,T}$ (resp. u_E projects onto i_T) by the canonical morphism*

$$Norm_{ad(G)}(T_{ad}) \to W_{ad(G)}(T_{ad}) \simeq W_G(T),$$

resp.

$$\underline{\mathrm{Aut}}_{S\text{-gr.}}(G,T) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G,T)/T_{\mathrm{ad}}.$$

Corollary 3.16.5. *The preceding definitions are compatible with base change, and are functorial under isomorphism (in an obvious sense).*

Proposition 3.16.6. *(i) One can define uniquely for each reductive group G over a scheme S an element*

$$s_G \in Autext(G)(S)$$

in such a way that this construction is functorial in G under isomorphism, is compatible with base change, and is such that whenever T is a maximal torus of the S-reductive group G, s_G is the image of i_T under the canonical morphism

$$\underline{\mathrm{Aut}}_{S\text{-gr.}}(G,T)/T_{\mathrm{ad}} \longrightarrow \underline{\underline{\mathrm{Autext}}}(G).$$

(ii) One has $s_G^2 = e$, and s_G is a central element of $Autext(G)$.

(iii) Under the conditions of 3.16.2 (ii), if one identifies $\underline{\mathrm{Aut}}_{S\text{-gr.}}(G,B,T)/T_{ad}$ with $Autext(G)$ (2.2), one has

$$w_{B,T} i_T = i_T w_{B,T} = s_G.$$

(iv) Under the conditions of 3.16.2 (iv), if one identifies $\mathrm{Aut}_{S-gr.-ép}(G,R,E)$ with $Autext(G)$ (1.3 (iii)), one has

$$n_E u_E = u_E n_E = s_G.$$

Proof. (i) is proved without difficulty by descent. On the other hand, since i_T is evidently a central section of square e in $\underline{\mathrm{Aut}}_{S\text{-gr.}}(T)$, (ii) follows immediately; (iii) is a consequence of (iv) by descent. Finally, under the conditions of (iv), it is clear that $n_E u_E = u_E n_E$ and that this automorphism of G respects the pinning; modulo the identification made, it is therefore equal to its image in $Autext(G)$; but n_E is inner and u_E projects onto s_G.

Remark 3.16.7. (i) One determines s_G explicitly in each case of the classification thanks to (iii): for each irreducible pinned root datum it suffices to compose the symmetry through the origin with the symmetry in the Weyl group (i.e. the element w_0 of the Weyl group such that $w_0(\Delta) = -\Delta$). One finds the following results: one has $s_G = e$ except for A_n ($n \geqslant 2$), D_n (n odd) and E_6, in which case s_G is the unique non-trivial "outer automorphism".

(ii) The automorphism u_E is the one used to construct "the compact real forms" in the theory of semisimple Lie algebras.

Remark 3.16.8. We defined in 3.16.1 an involution in the S-scheme

$$Q = Isomint(G_{q-ép.}, G)$$

of quasi-pinnings of G (cf. 3.12.1); by transport of structure from $G_{q-ép.}$ to G, one sees at once that this involution is given by the action of an element of $ad(G_{q-ép.})(S)$: the element n_0 defined (3.16.2 (iii)) by the canonical quasi-pinning of $G_{q-ép.}$.

In the same way, one has defined an involution in the S-scheme

$$P = Isom_{S-gr.}(\acute{E}p_S(R), G)$$

of R-pinnings of G (cf. 1.20). Arguing as before, one sees that this involution is given by the action of the automorphism u_0 of $\acute{E}p_S(R)$ defined (3.16.2 (iv)) by the canonical pinning of $\acute{E}p_S(R)$.

4. Isotriviality of reductive groups and of principal bundles under reductive groups

4.1. Definitions. Isotriviality theorem

Definition 4.1.1. *Let S be a scheme, G an S-group scheme, P a principal homogeneous bundle under G. One says that P is* locally isotrivial *(resp.* semi-locally isotrivial*)* if for every point $s \in S$ (resp. every finite set F of points of S contained in an affine open set) there exist an open set U of S containing s (resp. F) and a finite surjective étale morphism $S' \to U$ such that $P_{S'}$ is trivial.

Definition 4.1.2. *Let S be a scheme, G an S-reductive group. One says that G is* locally isotrivial *(resp.* semi-locally isotrivial*)* if for every point $s \in S$ (resp. every finite set F of points of S contained in an affine open set) there exist an open set U of S containing s (resp. F) and a finite surjective étale morphism $S' \to U$ such that $G_{S'}$ is splittable.*

Remark 4.1.3. (i) The equivalence of categories 4.1.1 of 1.17 respects by definition local (resp. semi-local) isotriviality.

(ii) Add to the conditions of 4.1.1: G locally of finite presentation over S. Then the principal bundle P (or the reductive group G) is locally isotrivial (resp. semi-locally isotrivial) if and only if for every $S' \to S$, S' local (resp. semi-local), $P_{S'}$ is isotrivial (or $G_{S'}$ isotrivial), that is to say, if there exists $S'' \to S'$ finite surjective étale such that $P_{S''}$ is trivial (or $G_{S''}$ split).

(iii) In the case of tori, definition 4.1.2 coincides with that of Exp. IX, 1.1.

4.1.4.

Recall (Exp. XXII, 4.3 and 6.2) that for every reductive group G, we have introduced the groups $rad(G)$, $corad(G)$ and $dér(G)$. The groups $rad(G)$ and $corad(G)$ are tori, which are split when G is split; moreover, there exists an isogeny $rad(G) \to corad(G)$. The S-group $dér(G)$ is semisimple, one has $G/dér(G) = corad(G)$; it follows that for every principal homogeneous bundle P under G, $P/dér(G)$ is a principal homogeneous bundle under $corad(G)$. This said, one has:

Theorem 4.1.5. *Let S be a scheme, G an S-reductive group of constant type.*

(i) The following conditions are equivalent:

(a) G is locally (resp. semi-locally) isotrivial.

(b) The torus $rad(G)$ is.

(b') The torus $corad(G)$ is.

(c) The Galois covering of S associated to G (3.11) is.

If T is a maximal torus of G, these conditions are also equivalent to

(d) The torus T is locally (resp. semi-locally) isotrivial.

(ii) Let P be a principal homogeneous bundle under G; for P to be locally (resp. semi-locally) isotrivial, it is necessary and sufficient that the $corad(G)$-principal bundle $P/dér(G)$ be so.

Corollary 4.1.6. *The conditions of (i) are satisfied when G is semisimple or when S is locally noetherian and normal (or more generally geometrically unibranch). The conditions of (ii) are satisfied when G is locally (resp. semi-locally) isotrivial.*

For (i), the first assertion is trivial from (b), the second follows from (c) and Exp. X, 5.14 and 5.15. For (ii), it suffices to note that by virtue of theorem 90, a principal bundle under a split torus is semi-locally isotrivial.

4.2. Proof: the semisimple case

Let us first prove, for later reference:

Proposition 4.2.1. *Let S be a scheme, G an S-reductive group, T a maximal torus of G (resp. B a Borel subgroup, resp. $B \supset T$ a Killing couple of G), P a principal homogeneous bundle under G, G' the twisted form of G associated to P (via the morphism $int : G \to \mathrm{Aut}_{S-gr.}(G)$). One has canonical isomorphisms*

$$P/\operatorname{Norm}_G(T) \xrightarrow{\sim} \operatorname{Tor}(G'), \qquad P/B \xrightarrow{\sim} \operatorname{Bor}(G'), \qquad P/T \xrightarrow{\sim} \operatorname{Kil}(G').$$

By construction, G' is the quotient of $P \times_S G$ by a certain action of G ($((p, g'))g = (pg, g^{-1}g'g)$); one therefore has a morphism $P \times_S G \to G'$, that is, a morphism

$$P \to \operatorname{Hom}_S(G, G'),$$

which, as one sees at once, factors through a morphism

$$f : P \longrightarrow \operatorname{Isom}_{S\text{-gr.}}(G, G').$$

(to verify this assertion, one may assume $G = P$, in which case one has $G' = G$, $f = int$). The set-theoretic map $p \mapsto f(p)(T)$ defines a morphism

$$P \to Tor(G').$$

To verify that this morphism induces an isomorphism $P/Norm_G(T) \xrightarrow{\sim} Tor(G')$ as announced, one may again assume $P = G$ in which case one is reduced to Exp. XXII, 5.8.3 (iii). (In fact, *loc. cit.* should be replaced by the statement above.) One argues similarly for Bor and Kil.

Proposition 4.2.2. *Let S be a semi-local scheme, G an S-semisimple group of constant type.*

(i) G is isotrivial.

(ii) Every principal bundle under G is isotrivial.

Let us prove (i). Up to making a finite surjective étale extension of the base, one may, by 3.9.2, assume G quasi-split. But then G is isotrivial by construction (3.11, the group E being finite). To prove (ii), one may, by (i), assume G split; one is then reduced to:

Lemma 4.2.3. *Let S be a semi-local scheme. Every principal bundle under a split reductive group is isotrivial.*

Indeed, with the notation of 4.2.1, where $B \supset T$ denotes the canonical Killing couple of the split G, the S-scheme $Kil(G')$ possesses a section, after finite surjective étale extension of the base, by 3.9.2. One may therefore reduce the structure group of G to T; but T is split, so $H^1(S, T) = 0$ (theorem 90).

Corollary 4.2.4. *Let S be a scheme and*

$$1 \to G \to G' \to G'' \to 1$$

an exact sequence of S-group schemes (for (fpqc)), G being semisimple of constant type. Let P be a principal homogeneous bundle under G', suppose the sheaf[24] *P/G associated*

[24] N.D.E.: We have replaced "bundle" by "sheaf", and then G' by G''.

representable (for example G'' affine over S). For P to be locally isotrivial (resp. semi-locally isotrivial), it is necessary and sufficient that P/G be so (as bundle under G'').

If P is trivial, P/G is too, which shows that the condition is necessary. Conversely, suppose S local (resp. semi-local) and P/G isotrivial, so trivialized by a finite surjective étale extension S' of S. Extending the base to S', one may reduce the structure group of $P_{S'}$ to $G_{S'}$. But S' is still semi-local and $G_{S'}$ semisimple of constant type, so the obtained bundle is isotrivial (4.2.2).

4.3. Proof: general case

Let us first note that 4.1.5 (ii) follows at once from the application of 4.2.4 to the exact sequence

$$1 \to dér(G) \to G \to corad(G) \to 1.$$

Let us therefore prove (i). If G is split, $rad(G)$ and $corad(G)$ are split, as is $rev(G)$; so (a) implies (b), (b'), and (c).

4.3.1.

One has (c) $\Rightarrow$ (a). Let R be the type of G; one has an exact sequence

$$1 \to ad(\acute{E}p_S(R)) \to A_S(R) \to E_S \to 1.$$

Applying 4.2.4 to the bundle $P = Isom_{S-gr.}(\acute{E}p_S(R), G)$ and to the associated bundle $rev(G) = P/ad(\acute{E}p_S(R))$, one has (c) $\Rightarrow$ (a).

4.3.2.

One has (b) $\Rightarrow$ (a). It suffices to prove that if $rad(G)$ is split, G is semi-locally isotrivial. Now let $G_0 = \acute{E}p_S(R)$; consider the category of pairs (G', f), where G' is a form of G_0 and f is an isomorphism of $rad(G_0)$ onto $rad(G)$.

One knows (2.16) that this category is equivalent to the category of principal homogeneous bundles under a certain S-group H extension of a finite twisted constant group by a semisimple group. It suffices to prove that every principal bundle under H is semi-locally isotrivial; this follows at once from 4.2.4.

4.3.3.

One has (b') $\Rightarrow$ (a). One can argue as previously (it will moreover be the same group H that arises). One can also see that (b) and (b') are equivalent: a torus isogenous to a locally split torus is also locally split (cf. Exp. IX, 2.11 (iii)).

4.3.4.

One has (d) $\Rightarrow$ (a). It suffices to prove that a group of constant type possessing a split maximal torus is semi-locally isotrivial; this follows at once from 2.14.

4.3.5.

One has (a) ⇒ (d). It suffices to prove that a maximal torus of a split group is semi-locally isotrivial. More precisely:

Lemma 4.3.6. *Let S be a semi-local scheme, G an S-reductive group, T_0 a split maximal torus of G, $W_0 = Norm_G(T_0)/T_0$ (this is a locally constant S-group, constant if G is of constant type, by 2.14), T a maximal torus of G.*

There exists a morphism $S' \to S$ which is principal homogeneous under W_0 (hence étale finite and surjective, and even principal Galois if G is of constant type) such that $T_{S'}$ is conjugate to $(T_0)_{S'}$ by an element of $G(S')$ (and so in particular split).

Indeed, one knows that $Transp_G(T_0, T)$ is a principal homogeneous bundle under $Norm_G(T_0)$ (cf. for example Exp. XI, 5.4 bis). Set $S' = Transp_G(T_0, T)/T_0$; this is a principal homogeneous bundle under W_0. Extending the base from S to S', one can reduce the structure group of $Transp_G(T_0, T)$ to T_0. Now S' is semi-local and T_0 split, so $Transp_G(T_0, T)$ possesses a section over S'.[25] QED

4.4. Use of the existence of maximal tori

Using Grothendieck's existence theorem for maximal tori (Exp. XIV, 3.20), one can considerably sharpen the preceding results. Let us state at once:

Theorem 4.4.1. *Let S be a semi-local scheme, R a pinned reduced root datum, W its Weyl group, E the group of its automorphisms. (Recall that E operates naturally on W and that the semi-direct product $A = W \cdot E$ is identified with the group of automorphisms of R non-pinned, cf. Exp. XXI, 6.7.2).*

(i) Every principal homogeneous bundle under $\acute{E}p_S(R)$ is trivialized by a principal Galois covering $S' \to S$ of group W.

(ii) Let G be an S-reductive group of type R; let $rev(G) = Isomext(\acute{E}p_S(R), G)$ be the associated Galois covering of S with group E. Let W_0 be the form of W_S associated to $rev(G)$. There exists a morphism $S' \to S$, which is a principal homogeneous bundle under W_0, such that $G_{S'}$ is quasi-splittable (i.e. possesses a Borel subgroup).

(iii) Every S-reductive group of type R is split by a principal Galois covering $\tilde{S} \to S$ with group A.

Let us first state:

Proposition 4.4.2. *Let S be a scheme, G an S-reductive group, T a maximal torus of G, P a principal homogeneous bundle under G, G' the twisted form of G associated to P (one then has, cf. 4.2.1, a canonical isomorphism $P/Norm_G(T) \xrightarrow{\sim} Tor(G')$). Let T' be a maximal torus of G', defining a composite morphism*

$$S \longrightarrow \mathrm{Tor}(G') \xrightarrow{\sim} P/\mathrm{Norm}_G(T).$$

Consider the canonical morphisms

$$P \longrightarrow P/T \longrightarrow P/\mathrm{Norm}_G(T).$$

and take their inverse images by the preceding morphism:

$$\begin{array}{ccccc} P & \longrightarrow & P/T & \longrightarrow & P/\mathrm{Norm}_G(T) \\ \uparrow & & \uparrow & & \uparrow \\ H & \longrightarrow & S' & \longrightarrow & S \end{array}$$

[25] N.D.E.: by "theorem 90".

Then S' (resp. H) is a principal homogeneous bundle over S (resp. S') under $W_G(T)$ (resp. $T_{S'}$). Moreover, if one makes $W_G(T)$ operate on T in the obvious way, the bundle associated to S' is isomorphic to T'.

The first two assertions are trivial, the last is proved like the corresponding assertion of 2.6.

Corollary 4.4.3. *Let S be a semi-local scheme, G an S-reductive group, T a maximal torus of G. Suppose one of the two following conditions is satisfied:*

(i) T is split.

(ii) T is contained in a Borel subgroup of G, and G is either adjoint, or simply connected.

Let moreover P be a principal homogeneous bundle under G. There exists an S-scheme S', which is a principal homogeneous bundle under $W_G(T)$, such that $P_{S'}$ is trivial.

Indeed, if G' is the form of G associated to P, then G' possesses a maximal torus T' (Exp. XIV, 3.20). Resuming the notation of the preceding proposition, one sees that $H^1(S', T_{S'}) = 0$ (by theorem 90 for (i), by 3.14 for (ii)). The morphism $H \to S'$ possesses a section, so $P_{S'}$ also possesses a section over S'. QED

Let us now prove the theorem. Assertion (i) is a particular case of the preceding corollary (take $G = \acute{E}p_S(R)$, endowed with its canonical split torus). Let us prove (ii). One knows (3.12) that G is an inner twisted form of

$$G_0 = Q - \acute{E}p_{rev(G)/S}(R).$$

If T_0 is the canonical maximal torus of G_0, $W_{G_0}(T_0)$ is the group W_0 described in the statement. The form G of G_0 corresponds to a principal homogeneous bundle P under $ad(G_0)$ ($P = Isomint(G_0, G)$). The group $W_{ad(G_0)}(T_0^{ad})$ is canonically isomorphic to W_0, and one obtains the wanted result by applying 4.4.3 to the situation $(ad(G_0), T_0^{ad}, P)$, hypothesis (ii) of 4.4.3 being well verified. Let us finally prove (iii). Resume the notation of (ii); one has a diagram

$$\begin{array}{ccc} & & \mathrm{rev}(G) \\ & & \Big\downarrow{\scriptstyle E_S} \\ S' & \xrightarrow[W_0]{} & S \end{array}$$

One knows that $G_{S'}$ is isomorphic to $(G_0)_{S'}$ and that $(G_0)_{rev(G)}$ is splittable. If one sets $\tilde{S} = S' \times_S rev(G)$, $G_{\tilde{S}}$ is splittable, and it only remains to verify that $\tilde{S}$ is indeed a principal Galois covering of S with group A, which follows from the following more general lemma (naturally valid in any site):

Lemma 4.4.4. *Let S be a scheme, G and H two S-group schemes, $G \to \mathrm{Aut}_{S-gr.}(H)$ an action of G on H, E a G-principal homogeneous bundle, F an H_0-principal homogeneous bundle, where H_0 is the form of H associated to E. Then $E \times_S F$ is endowed naturally with a structure of principal homogeneous bundle under the semi-direct product $H \cdot G$.*

Write $(e, g) \mapsto eg$ (resp. $(f, u) \mapsto fu$) for the action (on the right) of G on E (resp. of H_0 on F). Write

$$p : E \times_S H \longrightarrow H_0.$$

for the canonical projection (H_0 is by definition the quotient of $E \times_S H$ by G acting on it by the formula $(e, h)g = (eg, g^{-1}hg)$). Consider the morphism

$$r : E \times_S F \times_S H \times_S G \longrightarrow E \times_S F.$$

defined set-theoretically by

$$r(e, f, h, g) = (eg, f \cdot p(e, h)).$$

The morphism r indeed defines an action of the semi-direct product $H \cdot G$ on $E \times_S F$. Indeed, one has set-theoretically

$$r(r(e, f, h, g), h', g') = (egg', f\, p(e, h)\, p(eg, h')).$$

but

$$p(e, h)p(eg, h') = p(e, h)p(e, gh'g^{-1}) = p(e, hgh'g^{-1}).$$

whence

$$r(r(e, f, h, g), h', g') = r(e, f, hgh'g^{-1}, gg').$$

which had to be proved.

To prove now that this law is indeed a law of principal homogeneous bundle, one may assume that E and F are trivial, in which case one sees at once that $E \times_S F$ is also a trivial bundle.

4.5. Isotriviality of maximal tori of semisimple groups

[26]

Let us bring out here the following result, contained implicitly in 2.6 (cf. the N.D.E. (13)) and which was mentioned at the end of Exp. IX 1.2. Recall (XXIII 5.11) that, for every scheme S and every reduced root datum R, one writes $\acute{E}p_S(R)$ for the unique pinned S-group of type R (which exists by Exp. XXV) and $T_S(R)$ its canonical maximal torus.

Proposition 4.5.1. *Let G be an S-semisimple group of constant type R; assume that G possesses a maximal torus T (which is the case if S is semi-local, by XIV 3.20).*

(i) Then $P = Isom_{S-gr.}(\acute{E}p_S(R), T_S(R); G, T)/T_S(R)_{ad}$ is a principal S-bundle under the finite group $\mathrm{Aut}(R)$, and T_P is a split maximal torus of G_P. Consequently, T is isotrivial.

(ii) Moreover, for every finite set F of points of P contained in an affine open set, there exists an open set U of P containing F such that G_U is split.

Proof. The exact sequence

$$1 \longrightarrow T_S(\mathscr{R})_{\mathrm{ad}} \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}), T_S(\mathscr{R})) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(T_S(\mathscr{R})).$$

induces for every $S' \to S$ a morphism of bundles $P_{S'} \to Isom_{S'-gr.}(T_{S'}(R), T_{S'})$, so if $P_{S'}$ possesses a section, then $T_{S'}(R)$ and $T_{S'}$ are isomorphic. This is in particular the case for $S' = P$.

Note moreover that $\mathrm{Aut}_{S-gr.}(\acute{E}p_S(R), T_S(R))/T_S(R)_{ad}$ is none other than the constant S-group $\mathrm{Aut}(R)_S$, and that P is identified with the $\mathrm{Aut}(R)_S$-torsor $Isom(R, \tilde{R}(G, T))$, where $\tilde{R}(G, T)$ denotes the twisted root datum associated to (G, T) (cf. XXII 1.10).

Then (ii) follows from (i) and from 2.14, taking into account the fact that the g_α (α ranging over the roots of R) are free $\mathcal{O}_U$-modules of rank 1 on a sufficiently small affine open set U containing F.

[26] *Editors' note.* This no. 4.5 has been added.

5. Canonical decomposition of an adjoint or simply connected group

In this section, we shall use the results of no 1 to generalize to the case of schemes a classical decomposition of adjoint (resp. simply connected) groups. So as not to overburden the exposition indefinitely, the proofs are sketched and the details are left to the reader; in fact it is always a matter of absolutely standard proofs in the theory of principal bundles: reduction of the structure group, twisting, etc.

5.1.

Recall (Exp. XXI, 7.4) that a Dynkin diagram is a disjoint union of its connected components, which are Dynkin diagrams. Moreover, every non-empty connected Dynkin diagram corresponding to a root datum is isomorphic to one of the standard diagrams (A_n, B_n, ..., G_2) which were exhibited in Exp. XXI, 7.4.6. In the sequel, we shall be interested only in Dynkin diagrams whose connected components are of one of the preceding types. Let T be the set of these standard diagrams. For every Dynkin diagram D, let $n(t) = n_D(t)$ be the number of connected components of D isomorphic to t, where $t \in T$. The *type* of D is by definition $\sum_{t\in T} n_D(t) \cdot t$.

A Dynkin diagram of type t is said to be *simple of type* t, a Dynkin diagram of type $n \cdot t$ is said to be *isotypic of type* t. Let D_0 be the set of connected components of D and let

$$a : D_0 \to T$$

be the obvious map. The type of D is none other than $\sum_{x\in D_0} a(x)$.

5.2.

Let S be a scheme, D an S-Dynkin scheme (verifying the restrictive condition stated above). The cokernel of the pair of morphisms $L \Rightarrow D$ ($L =^{27}$ scheme of bonds of D) is written D_0. This is the "scheme of connected components" of D (it

exists trivially when D is constant; the general case is deduced from this by descent); it is a finite twisted constant S-scheme. One has a canonical morphism

$$a : D_0 \to T_S.$$

For $t \in T$, set $a^{-1}(t) = D_{0,t}$; this is a subscheme of D_0, whose inverse image in D, written D_t, is the *isotypic component of type* t of the Dynkin scheme D. Each D_t is a subscheme of D, and one has

$$D = \coprod_{t\in T} D_t.$$

Note that the degree of $D_{0,t}$ at $s \in S$ is $n(s,t)$, if the type of D at s is $\sum_t n(s,t) \cdot t$.

5.3.

In what follows, we shall consider only semisimple adjoint (resp. simply connected) groups. To simplify the language, we shall state the results for adjoint groups; all statements will remain valid if one substitutes everywhere "simply connected" for "adjoint".

[27] N.D.E.: We have replaced R by L, as in 3.2.

Recall that an adjoint reduced root datum is determined up to isomorphism by the type of its Dynkin diagrams. We shall therefore say that an adjoint root datum R (resp. a semisimple adjoint group G) is *of type* $\sum n(t)\cdot t$ if its Dynkin diagrams are (resp. if its type is given by an adjoint root datum of type $\sum n(t)\cdot t$). We shall say that R or G is *simple of type* t (resp. *isotypic of type* t) if its type is t (resp. $n\cdot t$, $n>0$).

If G is a semisimple adjoint group, we shall use the symbols $Dyn_0(G)$ and $Dyn_{0,t}(G)$ in the sense defined in 5.2.

5.4.

Let t_i, $i=1,2,\dots,n$, be distinct elements of T, and let R_i be a pinned adjoint root datum isotypic of type t_i. Consider the product $R=R_1\times\cdots\times R_n$ (Exp. XXI, 6.4.1). Let S be a scheme such that the different $\acute{E}p_S(R_i)$ exist (cf. Exp. XXV). One verifies at once that there exists a canonical isomorphism

$$(*)\qquad \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})=\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}_1)\times_S\cdots\times_S\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}_n).$$

Proposition 5.5.— *Let S be a scheme and G an adjoint semisimple S-group. There is a unique decomposition*

$$G\simeq\prod_{t\in\mathrm{T}}G_t,$$

where G_t is an adjoint semisimple S-group, isotypic of type t. Moreover, the preceding decomposition induces isomorphisms

$$\mathrm{Dyn}_t(G)\simeq\mathrm{Dyn}(G_t),\qquad \underline{\mathrm{Aut}}_{S\text{-gr.}}(G)\simeq\prod_{t\in\mathrm{T}}\underline{\mathrm{Aut}}_{S\text{-gr.}}(G_t).$$

This was proved above when G is split. In the general case one may suppose that G has constant type $\mathscr{R}$. Using the preceding decomposition of $A_S(\mathscr{R})$ and 1.17, one obtains the desired decomposition of G. The other assertions then follow by descent.

Remark 5.6.— More generally, if G and H are two adjoint semisimple groups, there are canonical isomorphisms in the following commutative diagram:

$$\begin{array}{ccc}
\underline{\mathrm{Isom}}_{S\text{-gr.}}(G,H) & \xrightarrow{\sim} & \prod_{t\in\mathrm{T}}\underline{\mathrm{Isom}}_{S\text{-gr.}}(G_t,H_t)\\
\downarrow & & \downarrow\\
\underline{\mathrm{Isomext}}(G,H) & \xrightarrow{\sim} & \prod_{t\in\mathrm{T}}\underline{\mathrm{Isomext}}(G_t,H_t)\\
\wr\downarrow & & \downarrow\wr\\
\underline{\mathrm{Isom}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G),\mathrm{Dyn}(H)) & \xrightarrow{\sim} & \prod_{t\in\mathrm{T}}\underline{\mathrm{Isom}}_{\mathrm{Dyn}}(\mathrm{Dyn}(G_t),\mathrm{Dyn}(H_t)).
\end{array}$$

Remark 5.7.— One can give the following intrinsic characterization of G_t, which we state without proof: it is the largest reductive subgroup of G that is invariant (and indeed characteristic) and isotypic of type t.

The preceding proposition reduces the study of adjoint semisimple groups to that of isotypic adjoint semisimple groups. We now undertake this study.

5.8.

Let $\mathscr{R}$ be a pinned reduced adjoint simple root datum of type t, let I be a nonempty finite set, and let $\mathscr{R}^I$ be the product root datum of copies $\mathscr{R}_i$ of $\mathscr{R}$, for $i \in I$. Denote by E the group of automorphisms of $\mathscr{R}$, identified with the group of automorphisms of its Dynkin diagram D. The Dynkin diagram of $\mathscr{R}^I$ is identified with D^I, and hence there is an exact sequence

$$1 \longrightarrow \mathrm{Aut}(D)^I \longrightarrow \mathrm{Aut}(D^I) \longrightarrow \mathrm{Aut}(I) \longrightarrow 1,$$

where $\mathrm{Aut}(I)$ is the group of permutations of I. It follows that the canonical isomorphism

$$\acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R})^I \simeq \acute{\mathrm{E}}\mathrm{p}_S(\mathscr{R}^I)$$

induces an exact sequence

$$1 \longrightarrow A_S(\mathscr{R})^I \longrightarrow A_S(\mathscr{R}^I) \longrightarrow \underline{\mathrm{Aut}}(I_S) \longrightarrow 1.$$

The last group is the constant S-group associated with $\mathrm{Aut}(I)$. Notice also that I is canonically identified with the set of connected components of D^I.

Let G be an S-semisimple group of type $\mathscr{R}^I$, thus defining (cf. 1.17) a principal homogeneous bundle P under $A_S(\mathscr{R}^I)$. The definitions by descent of $\mathrm{Dyn}(G)$ (3.7) and of $\mathrm{Dyn}_0(G)$ (5.2) show that the bundle associated with P by

$$A_S(\mathscr{R}^I) \longrightarrow \underline{\mathrm{Aut}}(I_S)$$

is precisely $\underline{\mathrm{Isom}}_S(I_S, \mathrm{Dyn}_0(G))$, corresponding to the form $\mathrm{Dyn}_0(G)$ of I_S. Using again the equivalence of categories 1.17 and the preceding exact sequence, one deduces formally that there is a reductive $\mathrm{Dyn}_0(G)$-group G_0 of type $\mathscr{R}$, and an S-isomorphism

$$G \simeq \prod_{\mathrm{Dyn}_0(G)/S} G_0.$$

Proposition 5.9.— *Let S be a scheme and G an adjoint semisimple S-group isotypic of type t. There exist an adjoint semisimple $\mathrm{Dyn}_0(G)$-group G_0, simple of type t, and a unique S-isomorphism*

$$G \simeq \prod_{\mathrm{Dyn}_0(G)/S} G_0.$$

Moreover, this isomorphism induces an exact sequence

$$1 \longrightarrow \prod_{\mathrm{Dyn}_0(G)/S} \underline{\mathrm{Aut}}_{\mathrm{gr.}}(G_0) \longrightarrow \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \longrightarrow \underline{\mathrm{Aut}}_S(\mathrm{Dyn}_0(G)) \longrightarrow 1.$$

One may plainly suppose that G has constant type $n\,t$. The first assertion has already been proved (and uniqueness is clear). The second then follows from the split case by descent.

Combining 5.5 and 5.9 gives:

Proposition 5.10.— *Let S be a scheme, let G be an adjoint semisimple S-group, and put $\mathfrak{D} = \mathrm{Dyn}(G)$.*

(i) There is a canonical decomposition

$$G \simeq \prod_{t \in \mathrm{T}} \prod_{\mathfrak{D}_{0,t}/S} G_{0,t} \simeq \prod_{\mathrm{Dyn}_0(G)/S} G_0,$$

where each $G_{0,t}$ is a simple adjoint $\mathrm{Dyn}_{0,t}(G)$-group of type t; equivalently, G_0 is an adjoint semisimple $\mathrm{Dyn}_0(G)$-group whose type at $x \in \mathrm{Dyn}_0(G)$ is $a(x) \in \mathrm{T}$, where $a : \mathrm{Dyn}_0(G) \to \mathrm{T}_S$ was defined in 5.2.

(ii) The preceding decompositions induce isomorphic exact sequences, written vertically below. Here $\underline{\mathrm{Aut}}_{S,a}(\mathfrak{D}_0)$ denotes the scheme of automorphisms of $\mathrm{Dyn}_0(G)$ commuting with $a : \mathrm{Dyn}_0(G) \to \mathrm{T}_S$:

$$\begin{array}{ccc}
1 & & 1 \\
\downarrow & & \downarrow \\
\prod_{t\in \mathrm{T}} \prod_{\mathfrak{D}_{0,t}/S} \underline{\mathrm{Aut}}_{\mathrm{gr.}}(G_{0,t}) & \xrightarrow{\sim} & \prod_{\mathrm{Dyn}_0(G)/S} \underline{\mathrm{Aut}}_{\mathrm{gr.}}(G_0) \\
\downarrow & & \downarrow \\
\underline{\mathrm{Aut}}_{S\text{-gr.}}(G) & = & \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) \\
\downarrow & & \downarrow \\
\prod_{t\in \mathrm{T}} \underline{\mathrm{Aut}}_S(\mathrm{Dyn}_{0,t}(G)) & \xrightarrow{\sim} & \underline{\mathrm{Aut}}_{S,a}(\mathrm{Dyn}_0(G)) \\
\downarrow & & \downarrow \\
1 & & 1
\end{array}$$

Corollary 5.11.— *Under the preceding hypotheses, the following three categories are equivalent:*

(i) the category of principal homogeneous bundles under G;

(ii) the category of principal homogeneous bundles under G_0;

(iii) the product, for $t \in \mathrm{T}$, of the categories of principal homogeneous bundles under the $G_{0,t}$.

This follows formally from the preceding decompositions and 8.4.

Corollary 5.12.— *There are canonical isomorphisms*

$$\underline{\mathrm{Tor}}(G) \simeq \prod_{t\in \mathrm{T}} \prod_{\mathfrak{D}_{0,t}/S} \underline{\mathrm{Tor}}(G_{0,t}) \simeq \prod_{\mathrm{Dyn}_0(G)/S} \underline{\mathrm{Tor}}(G_0),$$

and likewise with Tor *replaced by* Bor*, respectively by* Kil*.*

This is immediate from the split case.

Remark 5.13.— The canonical morphism

$$\mathrm{Dyn}(G) \longrightarrow \mathrm{Dyn}_0(G)$$

allows one to regard $\mathrm{Dyn}(G)$ as a Dynkin scheme over $\mathrm{Dyn}_0(G)$; in fact, it is the Dynkin scheme $\mathrm{Dyn}(G_0)$ of G_0.

Likewise, if $T \subset B$ is a Killing couple of G, corresponding canonically to a Killing couple $T_0 \subset B_0$ of G_0, then the obstructions to the quasi-splitting of G and G_0, which lie by 3.9 in

$$\mathrm{Pic}\big(\mathrm{Dyn}(G)\big) = \mathrm{Pic}\big(\mathrm{Dyn}(G_0)\big),$$

coincide. Hence:

Corollary 5.14.— *The following conditions are equivalent:*

(i) G is quasi-splittable;

(ii) G_0 is quasi-splittable;

(iii) each $G_{0,t}$, $t \in \mathrm{T}$, is quasi-splittable.

6. Automorphisms of Borel Subgroups of Reductive Groups

Lemma 6.1.— *Let S be a scheme, let (G, T, M, R) be a split S-group, let Δ be a system of simple roots of R, and let B be the corresponding Borel subgroup. Then B^u is generated, as an* (fppf) *sheaf of groups, by the U_α, $\alpha \in \Delta$.*

Let H be the subgroup sheaf of B^u generated by the U_α, $\alpha \in \Delta$. We prove $H \supset U_\beta$, for $\beta \in R_+$, by induction on $\mathrm{ord}(\beta) = \mathrm{ord}_\Delta(\beta) > 0$ (cf. Exp. XXI, 3.2.15). The assertion holds by hypothesis when $\mathrm{ord}(\beta) = 1$. Suppose $\mathrm{ord}(\beta) > 1$, and suppose $U_\gamma \subset H$ whenever $\mathrm{ord}(\gamma) < \mathrm{ord}(\beta)$. There is an $\alpha \in \Delta$ such that $\beta - \alpha \in R_+$ (Exp. XXI, 3.1.1). Let p be the largest integer such that $\beta - p\alpha = \beta' \in R_+$. Then $U_\alpha, U_{\beta'} \subset H$ and $\beta' - \alpha \notin R$. Thus it remains to prove:

Lemma 6.2.— *Keep the notation of Exp. XXIII, 6.4. Suppose $p = 1$, that is, $\beta - \alpha$ is not a root. If H is a subgroup sheaf of B^u such that $U_\alpha, U_\beta \subset H$, then $U_{i\alpha+j\beta} \subset H$ whenever $i\alpha + j\beta \in R$, $i > 0$, $j > 0$.*

Distinguish four cases according as $q = 0, 1, 2, 3$. In what follows, x and y denote arbitrary sections of $\mathbb{G}_{a,S'}$, where $S' \to S$.

For $q = 0$, there is nothing to prove.

For $q = 1$, one has

$$p_{\alpha+\beta}(\pm x) = p_\beta(-y)p_\alpha(-x)p_\beta(y)p_\alpha(x) \in H(S'),$$

and hence $U_{\alpha+\beta} \subset H$.

For $q = 2$, one similarly has

$$p_{\alpha+\beta}(\pm xy)p_{2\alpha+\beta}(\pm x^2 y) = p_\beta(-y)p_\alpha(-x)p_\beta(y)p_\alpha(x) \in H(S').$$

Thus, after changing some signs,

$$F(x, y) = p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2 y) \in H(S').$$

Since $p_{\alpha+\beta}$ and $p_{2\alpha+\beta}$ commute,

$$F(x, 1)F(1, -x) = p_{2\alpha+\beta}(x^2 - x).$$

[28] If $a \in \mathbb{G}_a(S)$, the equation $X^2 - X = a$ defines a free surjective extension of S, namely $\mathrm{Spec}\, \mathcal{O}_S[X]/(X^2 - X - a)$. Consequently $p_{2\alpha+\beta}(a) \in H(S')$, so $U_{2\alpha+\beta} \subset H$, and then $U_{\alpha+\beta} \subset H$, since $F(1, a) \in H(S')$.

For $q = 3$, one similarly has

$$F(x, y) = p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2 y)p_{3\alpha+\beta}(x^3 y)p_{3\alpha+2\beta}(x^3 y^2) \in H(S'),$$

[28] *Editors' note.* We corrected $F(-1, x)$ to $F(1, -x)$.

and, since

$$p_{3\alpha+2\beta}(\pm x) = F(1,1)^{-1}p_\beta(-x)F(1,1)p_\beta(x) \in H(S'),$$

one obtains $U_{3\alpha+2\beta} \subset H$, and therefore

$$K(x,y) = p_{\alpha+\beta}(xy)p_{2\alpha+\beta}(x^2y)p_{3\alpha+\beta}(x^3y) \in H(S').$$

Computing

$$K(x+y,1)K(-x,1)K(1,y)^{-1}$$

modulo $U_{3\alpha+2\beta}$, one finds

$$p_{2\alpha+\beta}(2x^2+y^2+2xy-y)p_{3\alpha+\beta}(y^3+3xy^2+3x^2y-y) \in H(S').$$

If $a \in \mathbb{G}_a(S)$, the "equations"

$$x^2 = -xy-y+1-a, \qquad y^2 = 3y-2+3a$$

define a free surjective extension of S. One then has $y^3+3xy^2+3x^2y-y=0$, and the preceding expression gives $p_{2\alpha+\beta}(a) \in H(S')$. [29] Thus H contains $U_{2\alpha+\beta}$ and $U_{3\alpha+2\beta}$, and

$$E(x,y) = p_{\alpha+\beta}(xy)p_{3\alpha+\beta}(x^3y) \in H(S').$$

Since $p_{\alpha+\beta}(xy)$ and $p_{3\alpha+\beta}$ commute, the preceding computation applies:

$$E(1,x)E(1,-x) = p_{3\alpha+\beta}(x^3-x).$$

Hence $U_{3\alpha+\beta} \subset H$, and then $U_{\alpha+\beta} \subset H$.

Remark 6.2.1.— The preceding proof shows that the hypothesis "H contains U_α and U_β" could have been replaced by: "H contains U_α or U_β, and H is invariant under $\mathrm{int}(U_\alpha)$ and $\mathrm{int}(U_\beta)$."

Theorem 6.3.— *Let S be a scheme, let G and G' be two semisimple S-groups, and let B (respectively B') be a Borel subgroup of G (respectively G'). Every isomorphism $B \xrightarrow{\sim} B'$ is induced by a unique isomorphism $G \xrightarrow{\sim} G'$.*

The assertion is local for the étale topology, so we may suppose that G is split: $G = (G,T,M,R)$, with B defined by the system R_+ of positive roots of R. The given isomorphism $u : B \xrightarrow{\sim} B'$ induces an isomorphism from T onto a maximal torus T' of B', hence of G'. The given isomorphism $T \simeq D_S(M)$ gives an isomorphism $T' \simeq D_S(M)$ in which the elements of R_+ become the constant roots of B' relative to T', and hence the elements of R become the constant roots of G' relative to T'. Since G and G' are semisimple, the coroots are determined by duality (Exp. XXI, 1.2.5); this proves that (T',M,R) is a splitting of G' such that $\mathscr{R}(G) = \mathscr{R}(G')$.

Applying Exp. XXIII, 5.1 (the uniqueness theorem), one obtains a unique isomorphism $G \xrightarrow{\sim} G'$ agreeing with u on T and on the U_α, $\alpha \in \Delta$. By 5.1, its restriction to B is u.

Remark 6.3.1.— (i) Using Exp. XXII, 4.1.9 and arguing as in *loc. cit.*, 4.2.12, one may replace "isomorphism" in the theorem by "isogeny" (respectively, "central isogeny").

(ii) The theorem is false for reductive groups. For example, take $G = G' = \mathrm{SL}_2 \times \mathbb{G}_m$, identified with the group

$$\left\{ \begin{pmatrix} a & b & 0 \\ c & d & 0 \\ 0 & 0 & h \end{pmatrix} \;\middle|\; ad-bc=1,\ h \text{ invertible} \right\}.$$

[29] *Editors' note.* We corrected $p_{3\alpha+\beta}(a)$ to $p_{2\alpha+\beta}(a)$ and supplied the end of the argument.

take $B = B'$ to be the Borel subgroup defined by $c = 0$, and let u be the following automorphism of B:

$$u(a, b, d, h) = (a, b, d, ah).$$

Corollary 6.4.— *The functor*

$$(G, B) \longmapsto B$$

from the category of pairs (G, B), where G is an S-semisimple group and B is a Borel subgroup of G, to the category of S-group schemes, with isomorphisms as morphisms, is fully faithful.

Corollary 6.5.— *Let S be a scheme, G an S-semisimple group, B a Borel subgroup of G, and B' an S-group locally isomorphic to B for the* (fpqc) *topology. Then B' is locally isomorphic to B for the local finite étale topology,*[30] *and there exists an S-semisimple group G' of which B' is a Borel subgroup. Moreover, G' is unique up to a unique isomorphism inducing the identity on B'.*

Corollary 6.6.— *Let S be a scheme, G an S-semisimple group, and B a Borel subgroup of G. Then $\underline{\mathrm{Aut}}_{S\text{-gr.}}(B)$ is representable by an affine smooth S-scheme, $\underline{\mathrm{Autext}}(B)$ is representable by an étale finite S-scheme, and the evident morphisms induce an isomorphism of exact sequences.*

$$\begin{array}{ccccccccc}
1 & \longrightarrow & \underline{B}_{\mathrm{ad}}(G) & \longrightarrow & \underline{\mathrm{Aut}}_{S\text{-gr.}}(G, B) & \longrightarrow & \underline{\mathrm{Autext}}(G) & \longrightarrow & 1 \\
 & & \downarrow & & \downarrow & & \downarrow & & \\
1 & \longrightarrow & \underline{B}_{\mathrm{ad}} & \longrightarrow & \underline{\mathrm{Aut}}_{S\text{-gr.}}(G) & \longrightarrow & \underline{\mathrm{Autext}}(B) & \longrightarrow & 1.
\end{array}$$

This follows immediately from 2.1 and the preceding results. We leave to the reader the task of developing the analogues of the results of nos. 1, 2, 3, and 4 in the foregoing setting.

Remark 6.7.— If S is a scheme and B an S-group, then B can be a Borel subgroup of only one semisimple group, uniquely determined by B. It remains to characterize those S-groups B which are Borel subgroups of semisimple groups.[31]

7. Representability of the functors $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H)$, for G reductive

7.1. The split case

7.1.1.

Let S be a scheme, G a pinned S-group, T its maximal torus, and Δ the set of simple roots. For $\alpha \in \Delta$, let

$$u_\alpha \in U_\alpha^\times(S), \qquad w_\alpha \in \mathrm{Norm}_G(T)(S)$$

[30] *Editors' note.* This topology is denoted (étf) in Exposé IV, 6.3. In other words, for every $s \in S$ there exist an open neighborhood U of s and a finite surjective étale morphism $V \to U$ such that $B' \times_S V \simeq B \times_S V$.

[31] *Editors' note.* One may ask whether every smooth affine S-group whose geometric fibers are Borel subgroups of semisimple groups is itself a Borel subgroup of a semisimple S-group. We have suppressed the counterexample in the original, with S the scheme of dual numbers over a field k, because it was erroneous, as M. Demazure pointed out.

be the elements defined by the pinning.

Let H be an S-group scheme. We are interested in the functor $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H)$, and more precisely in the morphism

$$q : \underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(T,H).$$

Let

$$f_T : T \longrightarrow H$$

be an S-group homomorphism and put $q^{-1}(f_T) = \mathscr{F}$. Thus

$$\mathscr{F}(S') = \left\{ f \in \mathrm{Hom}_{S'\text{-gr.}}(G_{S'}, H_{S'}) \;\middle|\; f|_{T_{S'}} = (f_T)_{S'} \right\}.$$

There is a morphism of S-functors

$$i : \mathscr{F} \longrightarrow H^{2n},$$

where $n = \mathrm{Card}(\Delta)$, defined on points by

$$i(f) = \big(f(u_\alpha), f(w_\alpha)\big)_{\alpha\in\Delta}.$$

By Exposé XXIII, 1.9, i is a monomorphism.

Proposition 7.1.2.— *If H is separated over S, then $\mathscr{F}$ is representable and i is a closed immersion.*

The usual technique of relative representability[32] shows that it is enough to prove the following. Given sections

$$v_\alpha, h_\alpha \in H(S), \qquad \alpha \in \Delta,$$

the S-schemes S' for which there exists an S'-homomorphism

$$f : G_{S'} \longrightarrow H_{S'}$$

extending $(f_T)_{S'}$ and satisfying

$$f(u_\alpha) = v_\alpha, \qquad f(w_\alpha) = h_\alpha$$

are exactly those which factor through a certain closed subscheme of S. We may plainly suppose S affine.

For convenience, say that a morphism $Y \to X$[33] of affine schemes satisfies condition (L) if Y is the spectrum of an $\mathcal{O}(X)$-algebra which is a free $\mathcal{O}(X)$-module. Within the category of affine schemes, products and composites of morphisms satisfying (L) again satisfy (L), and (L) is stable under base change.

Lemma 7.1.3.— *Suppose that S is affine, and let $\alpha \in \Delta$. Consider the morphism*

$$a : T \times_S T \longrightarrow G_{a,S}, \qquad a(t,t') = \alpha(t) + \alpha(t').$$

Then:

(i) a is faithfully flat and of finite presentation;

(ii) if R is the fiber square of a, the structure morphism $R \to S$ satisfies (L).

[32] *Editors' note.* See, for example, the proof of Exposé XXII, 5.8.1.

[33] *Editors' note.* We have corrected $X \to Y$ to $Y \to X$.

The morphism a is surjective, since $\alpha : T \to G_{m,S}$ is surjective, and it is plainly of finite presentation. Since α satisfies (L), it is enough, for both assertions, to show that

$$u : G_{m,S}^2 \longrightarrow G_{a,S}, \qquad u(x,y) = x + y$$

satisfies (L). Equivalently, for every ring A, the ring

$$A[X, Y, X^{-1}, Y^{-1}]$$

must be free over its subring $A[X+Y]$.[34] Now $A[X,Y]$ is free with basis $\{1, X\}$ over

$$B = A[X+Y, XY],$$

because $X^2 - (X+Y)X + XY = 0$. Hence

$$A[X^{\pm 1}, Y^{\pm 1}] = A[X,Y]_{XY}$$

is free over

$$B_{XY} = A[X+Y, (XY)^{\pm 1}]$$

with basis $\{1, X\}$, and free over $A[X+Y]$ with basis

$$(XY)^p, \quad X(XY)^p, \qquad p \in \mathbb{Z}.$$

Lemma 7.1.4.— *Let $\alpha \in \Delta$, and let*

$$b : T \times_S T \longrightarrow H$$

be the morphism defined on points by

$$b(t,t') = \mathrm{int}(f_T(t))(v_\alpha)\ \mathrm{int}(f_T(t'))(v_\alpha).$$

Let $f_\alpha : U_\alpha \to H$ be an S-morphism. The following conditions are equivalent:[35]

(i) f_α is a group homomorphism, $f_\alpha(u_\alpha) = v_\alpha$, and

$$f_T(t) f_\alpha(x) f_T(t)^{-1} = f_\alpha(\alpha(t)x)$$

for all $t \in T(S')$, $x \in U_\alpha(S')$, and $S' \to S$;

(ii) $f_\alpha(u_\alpha) = v_\alpha$, and

$$f_\alpha(a(t,t')u_\alpha) = b(t,t')$$

for all $t, t' \in T(S')$ and $S' \to S$.

If f_α satisfies (i), then

$$f_\alpha(\alpha(t)u_\alpha) = \mathrm{int}(f_T(t))(v_\alpha),$$

which immediately gives (ii). Conversely, suppose (ii). Since a is an (fpqc) covering, to prove the last condition in (i) it suffices to show that, for $t, t', t'' \in T(S')$,

$$f_T(t)\, f_\alpha(a(t',t'')u_\alpha)\, f_T(t)^{-1} = f_\alpha(\alpha(t)a(t',t'')u_\alpha).$$

[34] *Editors' note.* We have simplified the proof in the original.

[35] *Editors' note.* In what follows the group law of U_α is written additively. If $p_\alpha : G_{a,S} \xrightarrow{\sim} U_\alpha$ is the isomorphism with $p_\alpha(1) = u_\alpha$, and $x = p_\alpha(z)$, then $\alpha(t)x$ denotes $p_\alpha(\alpha(t)z)$, while $a(t,t')u_\alpha$ denotes $p_\alpha(a(t,t')) = \alpha(t)u_\alpha + \alpha(t')u_\alpha$.

This is the same as

$$f_T(t)b(t',t'')f_T(t)^{-1} = b(tt',tt''),$$

which follows directly from the definition of b.

It remains to prove that f_α is a group homomorphism. The preceding property gives

$$\begin{aligned} f_\alpha(\alpha(t)u_\alpha)f_\alpha(\alpha(t')u_\alpha) &= \big(f_T(t)f_\alpha(u_\alpha)f_T(t)^{-1}\big)\big(f_T(t')f_\alpha(u_\alpha)f_T(t')^{-1}\big) \\ &= b(t,t') \\ &= f_\alpha(\alpha(t)u_\alpha + \alpha(t)\alpha(t')u_\alpha). \end{aligned}$$

Thus $f_\alpha(x+x') = f_\alpha(x)f_\alpha(x')$ whenever x, x' are sections of the schematically dense open subset $U_\alpha^\times \subset U_\alpha$. Exposé XVIII, 1.4 then gives the result.

7.1.5.

Fix provisionally an $\alpha \in \Delta$. Since a is faithfully flat and quasi-compact, $G_{a,S}$ is identified with the quotient of $T \times_S T$ by the equivalence relation R defined by a. Write $i_1, i_2 : R \to T \times_S T$ for its two projections.

$$R \underset{i_2}{\overset{i_1}{\rightrightarrows}} T \times_S T$$

For b to factor through a,[36] it is necessary and sufficient that

$$b \circ i_1 = b \circ i_2.$$

Let K be the equalizer of $b \circ i_1$ and $b \circ i_2$.

$$R \underset{b\circ i_2}{\overset{b\circ i_1}{\rightrightarrows}} H$$

Then the required condition is $K = R$. Since H is separated over S, K is a closed subscheme of R. On the other hand, R is essentially free over S, by 7.1.3.

7.1.6.

It follows that, for an S-scheme S', an f_α satisfying 7.1.4(i) exists over S', and is then unique, if and only if

$$K_{S'} = R_{S'}$$

and the resulting morphism satisfies

$$f_\alpha(u_\alpha) = v_\alpha.$$

The first condition is equivalent to requiring $S' \to S$ to factor through a certain closed subscheme of S (Exposé VIII, 6.4[37]). After replacing S by this closed subscheme, the second condition again defines a closed subscheme of S, since it is the equality of two sections of the separated S-scheme H.

After replacing S by the resulting closed subscheme, we may thus suppose that a morphism $f_\alpha : U_\alpha \to H$ satisfying 7.1.4(i) exists. Intersecting the closed subschemes obtained for all $\alpha \in \Delta$, we may suppose this condition holds for every $\alpha \in \Delta$.

[36] *Editors' note.* That is, for condition 7.1.4(ii) to hold.

[37] *Editors' note.* See also the addition in Exposé $\mathrm{VI_B}$, 6.2.3.

7.1.7.

Similarly, for each $\alpha \in \Delta$, consider the two S-group homomorphisms

$$f_T \circ \mathrm{int}(w_\alpha), \qquad \mathrm{int}(h_\alpha) \circ f_T : T \longrightarrow H.$$

Since H is separated over S and T is essentially free over S, the same reasoning shows that, after replacing S by a closed subscheme, one may suppose that

$$f_T \circ \mathrm{int}(w_\alpha) = \mathrm{int}(h_\alpha) \circ f_T$$

for every $\alpha \in \Delta$.

7.1.8.

The generators-and-relations theorem (Exposé XXIII, 3.5) now shows that a group homomorphism $f : G \to H$ with the required properties exists if and only if a certain finite set of algebraic relations among the sections

$$h_\alpha, \qquad v_\alpha, \qquad f_T(\alpha^*(-1)), \qquad \alpha \in \Delta,$$

is satisfied:

$$R_i\Big((h_\alpha)_\alpha, (v_\alpha)_\alpha, \big(f_T(\alpha^*(-1))\big)_\alpha\Big) = e, \qquad i = 1, \ldots, n.$$

Because H is separated over S, these relations again define a closed subscheme of S, proving Proposition 7.1.2.

Corollary 7.1.9.— *Let S be a scheme, G a split reductive S-group, T its maximal torus, and H a separated S-group scheme. Let $\mathcal{P}$ be a property of morphisms satisfying:*

(i) every closed immersion has $\mathcal{P}$;

(ii) a composite of morphisms having $\mathcal{P}$ has $\mathcal{P}$;

(iii) $\mathcal{P}$ is stable under base change;

(iv) the structure morphism $H \to S$ has $\mathcal{P}$.

Then the canonical morphism

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, H)$$

is relatively representable by a separated morphism having $\mathcal{P}$.[38]

Indeed, we may suppose G pinned. The structure morphism $H^{2n} \to S$ has $\mathcal{P}$, and 7.1.2 gives the assertion.

Corollary 7.1.10.— *Let S be a scheme, G a split reductive S-group, and H a smooth S-group scheme with affine fibers.*[39] *Then $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H)$ is representable by an S-scheme locally of finite presentation and separated over S.*

Since H is smooth over S, its neutral component H^0 is defined; it has affine fibers and is smooth, separated, and of finite presentation over S (Exposé $\mathrm{VI_B}$, 3.10 and 5.5). Since G has connected fibers, H may be replaced by H^0. As G and H are then of finite presentation, we may suppose S noetherian and apply 7.1.9 with $\mathcal{P}$ equal to the property "of finite type". By Exposé XV, 8.9, $\underline{\mathrm{Hom}}_{S\text{-gr.}}(T, H)$ is representable by a separated S-scheme locally of finite type.

Remark 7.1.11.— If H is affine over S, the reference to Exposé XV may be replaced by Exposé XI, 4.2.

[38] *Editors' note.* More explicitly, for every representable $S' \to \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, H)$, the fiber product $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) \times S'$ is representable, and its morphism to S' is separated and has $\mathcal{P}$.

[39] *Editors' note.* We have suppressed the superfluous hypothesis that H be quasi-separated.

7.2. General case

Proposition 7.2.1.— *Let S be a scheme, G a reductive S-group, and T a maximal torus of G. Let H be an S-group scheme whose structure morphism $H \to S$ satisfies:*

> (+) *Every point $s \in S$ has an open neighborhood U such that $H_U \to U$ is quasi-projective.*

Then the canonical morphism

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, H)$$

is relatively representable by a morphism satisfying (+).

When G is split relative to T, apply 7.1.9 with $\mathcal{P} = (+)$. When G is locally isotrivial, for example when G is semisimple (4.2.2), note that the assertion is local for the local finite étale topology. Indeed, quasi-projectivity is local for the global finite étale topology and ensures effectiveness of descent for that topology (SGA 1, VIII, 7.7). The general case follows from the next lemma.

Lemma 7.2.2.— *Let S be a scheme, G a reductive S-group, T a maximal torus of G, G' the derived group of G (Exposé XXII, 6.2), and $T' = T \cap G'$ the maximal torus of G' corresponding to T (Exposé XXII, 6.2.8). The natural diagram involving G, G', T, T' is a pushout in the category of S-group sheaves. Equivalently, for every S-group sheaf H, the corresponding square of Hom-functors is cartesian.*

$$\begin{array}{ccc} G & \longleftarrow & G' \\ \uparrow & & \uparrow \\ T & \longleftarrow & T' \end{array}$$

$$\begin{array}{ccc} \underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) & \longrightarrow & \underline{\mathrm{Hom}}_{S\text{-gr.}}(G', H) \\ \downarrow & & \downarrow \\ \underline{\mathrm{Hom}}_{S\text{-gr.}}(T, H) & \longrightarrow & \underline{\mathrm{Hom}}_{S\text{-gr.}}(T', H) \end{array}$$

If $\mathrm{rad}(G)$ is the radical of G, then $\mathrm{rad}(G) \subset T$, so

$$\mathrm{rad}(G) \cap G' = \mathrm{rad}(G) \cap T' = K.$$

Multiplication in G induces isogenies (Exposé XXII, 6.2)

$$i : G' \times_S \mathrm{rad}(G) \longrightarrow G, \qquad j : T' \times_S \mathrm{rad}(G) \longrightarrow T.$$

Let

$$f_{G'} : G' \to H, \qquad f_T : T \to H, \qquad f_{T'} : T' \to H$$

be S-group homomorphisms such that

$$f_{G'}|_{T'} = f_T|_{T'} = f_{T'}.$$

We show that there is a unique S-group homomorphism $f : G \to H$ inducing $f_{G'}$ and f_T. Put

$$f_{\mathrm{rad}} = f_T|_{\mathrm{rad}(G)}$$

[40] and define

$$f_1 = f_{G'} \cdot f_{\mathrm{rad}} : G' \times_S \mathrm{rad}(G) \longrightarrow H.$$

For f to exist, and it is plainly then unique, it is necessary and sufficient that f_1 be trivial on the kernel of i, that is, that $f_{G'}$ and f_{rad} coincide on K. The existence of f_T similarly shows that $f_{T'}$ and f_{rad} coincide on K. Finally, $f_{G'}$ and $f_{T'}$ coincide on $K \subset T'$, proving the lemma.

Arguing as in 7.1.10, Proposition 7.2.1 gives:

Corollary 7.2.3.— *Let S be a scheme, G a reductive S-group, and H a smooth, quasi-projective S-group scheme with affine fibers. Then $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H)$ is representable by an S-scheme locally of finite presentation and separated over S.*

7.3. Phenomena specific to characteristic zero

If G and H are smooth S-groups, with Lie algebras $\mathfrak{g}$ and $\mathfrak{h}$, there is a canonical morphism

$$\mathrm{Lie} : \underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) \longrightarrow \underline{\mathrm{Hom}}_{\mathcal{O}_S\text{-Lie}}(\mathfrak{g}, \mathfrak{h}),$$

where the functor on the right has the evident meaning.

Proposition 7.3.1.— *Let S be a scheme of characteristic zero, that is, a $\mathbb{Q}$-scheme; let G be a reductive S-group, and H a smooth, quasi-projective S-group scheme with affine fibers.*

(i) $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H)$ *is representable by a smooth separated S-scheme.*

(ii) If G is semisimple, this scheme is affine and of finite presentation over S.

(iii) If G is simply connected (Exposé XXII, 4.3.3), the canonical morphism

$$\mathrm{Lie} : \underline{\mathrm{Hom}}_{S\text{-gr.}}(G, H) \longrightarrow \underline{\mathrm{Hom}}_{\mathcal{O}_S\text{-Lie}}(\mathfrak{g}, \mathfrak{h})$$

is an isomorphism.

Lemma 7.3.2.— *Let k be a field of characteristic zero, G a reductive k-group, V a finite-dimensional k-vector space, and $G \to \mathrm{GL}(V)$ a linear representation. Then*

$$H^0(G, V) = H^0(\mathfrak{g}, V), \qquad H^i(G, V) = 0 \quad (i > 0).$$

The first equality is valid in general for a smooth connected group.[41] For a reductive group it can also be proved as follows. We may suppose k algebraically closed, hence G split and generated by subgroups isomorphic to $G_{m,k}$,[42] and the assertion for this group is immediate.

The first equality shows that the functor $H^0(G, V)$ is exact in V when G is semisimple: $\mathfrak{g}$ is then a semisimple Lie algebra, and one applies [BLie], §I.6, Exercise 1(b). The

[40] *Editors' note.* We have replaced f_r by f_{rad}.

[41] *Editors' note.* The inclusion $V^G \subset V^{\mathfrak{g}}$ is clear. Conversely, $C = \mathrm{Centr}_G(V^{\mathfrak{g}})$ is a closed subgroup of G, smooth because $\mathrm{char}(k) = 0$. By Exposé II, 5.3.1, $\mathrm{Lie}(C) = \mathrm{Centr}_{\mathfrak{g}}(V^{\mathfrak{g}}) = \mathfrak{g}$; because C is smooth and G connected, $C = G$. Thus $V^{\mathfrak{g}} \subset V^G$. See also [DG70], §II.6, Proposition 2.1(c).

[42] *Editors' note.* The union of the maximal tori of G is dense in G; cf. *Bible*, §6.5, Theorem 5, or [Ch05], §6.6, Theorem 6.

assertion remains true when G is reductive. Indeed, introducing the radical R of G[43] and the semisimple quotient G/R, one has

$$H^0(G,V) = H^0(G/R, H^0(R,V)),$$

so $H^0(G,-)$ is a composite of two exact functors. Exposé I, 5.3.1 then gives $H^i(G,V) = 0$ for $i > 0$.

Remark 7.3.3.— Under the preceding hypotheses, if G is semisimple, then

$$H^1(\mathfrak{g},V) = H^2(\mathfrak{g},V) = 0;$$

see [BLie], *loc. cit.*, (b) and (d).

7.3.4.

We prove the proposition. By 7.2.3, $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H)$ is already representable by an S-scheme locally of finite presentation and separated over S. To show it smooth, it suffices to show it infinitesimally smooth (Exposé XI, 1.8),[44] and this follows from Exposé III, 2.8(i) and 7.3.2. This proves (i).

We next show that (ii) follows from (iii). First it is enough to prove that $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H)$ is affine over S, since it is then of finite presentation, being smooth by (i). In any case,

$$\underline{\mathrm{Hom}}_{\mathcal{O}_S\text{-Lie}}(\mathfrak{g},\mathfrak{h})$$

is represented by a closed subscheme of

$$\underline{\mathrm{Hom}}_{\mathcal{O}_S\text{-mod}}(\mathfrak{g},\mathfrak{h}) \simeq \mathrm{W}\left(\mathfrak{g}^\vee \otimes_{\mathcal{O}_S} \mathfrak{h}\right),$$

which is an affine S-scheme. Thus the desired conclusion follows when G is simply connected.

In general, we may suppose G split, so that $G \simeq \mathrm{Ép}_S(\mathscr{R})$. Introduce the simply connected root datum $\mathrm{sc}(\mathscr{R})$ (Exposé XXI, 6.5.5). The existence theorem (Exposé XXV, 1.1) gives a simply connected S-group $\widetilde{G}$ and a central isogeny

$$\widetilde{G} \longrightarrow G.$$

Its kernel K is a finite diagonalizable S-group, hence a twisted constant S-group because S has characteristic zero. The functor $\underline{\mathrm{Hom}}_{S\text{-gr.}}(K,H)$ is plainly represented by a separated S-scheme. For example, if $K \simeq (\mathbb{Z}/n\mathbb{Z})_S$, then it is isomorphic to

$$\ker\Big(H \xrightarrow{n} H\Big).$$

There is an exact sequence of pointed S-schemes

$$1 \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H) \xrightarrow{u} \underline{\mathrm{Hom}}_{S\text{-gr.}}(\widetilde{G},H) \longrightarrow \underline{\mathrm{Hom}}_{S\text{-gr.}}(K,H).$$

Thus u is a closed immersion, and $\underline{\mathrm{Hom}}_{S\text{-gr.}}(G,H)$ is affine over S.

[43] *Editors' note.* Observe that R is a torus.

[44] *Editors' note.* This means that for every local artinian S-scheme S', with closed point s', every homomorphism of $\kappa(s')$-groups $G_{s'} \to H_{s'}$ lifts to an S'-group homomorphism $G_{S'} \to H_{S'}$. By Exposé III, 2.8, this follows from the vanishing of $H^2(G_{s'},V)$, where $V = \mathrm{Lie}(H_{s'}/\kappa(s'))$.

7.3.5.

It remains to prove (iii). As in the proof of (i), and using 7.3.3, one shows that

$$\underline{\mathrm{Hom}}_{\mathcal{O}_S\text{-Lie}}(\mathfrak{g},\mathfrak{h})$$

is smooth over S. We may therefore suppose $S = \mathrm{Spec}(k)$, where k is algebraically closed of characteristic zero. It is enough to show that Lie is bijective on k-points and induces a bijection on tangent spaces at corresponding points. First we show that

$$\mathrm{Hom}_{k\text{-gr.}}(G,H) \longrightarrow \mathrm{Hom}_{k\text{-Lie}}(\mathfrak{g},\mathfrak{h})$$

is bijective.

If $u : G \to H$ is a k-group homomorphism, its graph is a connected subgroup of $G \times_k H$, determined by its Lie algebra, which is the graph of $\mathrm{Lie}(u)$. Hence the map is injective. Conversely, if $v : \mathfrak{g} \to \mathfrak{h}$ is a Lie algebra homomorphism, its graph $\mathfrak{k}$ is a Lie subalgebra of $\mathfrak{g}\times\mathfrak{h}$, isomorphic to $\mathfrak{g}$. Because $\mathfrak{g}$ is its own derived algebra, so is $\mathfrak{k}$. A theorem of Chevalley [Ch51], §14, Theorem 15, therefore shows that $\mathfrak{k}$ is the Lie algebra of a connected subgroup K of $G \times_k H$.[45]

Since $\mathfrak{k} \simeq \mathfrak{g}$ is semisimple, K is a semisimple k-group . Moreover,

$$\dim K = \dim \mathfrak{k} = \dim \mathfrak{g} = \dim G,$$

and $K \cap H$ is finite because its Lie algebra is zero. Thus the canonical morphism

$$\mathrm{pr}_1 : K \longrightarrow G$$

is finite and dominant; because G is connected, it is surjective, and hence an isogeny. Since G is simply connected and K is semisimple, Exposé XXI, 6.2.7 shows that pr_1 is an isomorphism. Consequently K is the graph of a k-group homomorphism $u : G \to H$ with $\mathrm{Lie}(u) = v$.

Finally, let $u : G \to H$ be a k-group homomorphism. The tangent space at u to

$$\underline{\mathrm{Hom}}_{k\text{-gr.}}(G,H)$$

identifies with $Z^1(G,\mathfrak{h})$ (Exposé II, 4.2), where G acts on $\mathfrak{h}$ through $\mathrm{Ad}_H \circ u$. Similarly, the tangent space to

$$\underline{\mathrm{Hom}}_{k\text{-Lie}}(\mathfrak{g},\mathfrak{h})$$

at $\mathrm{Lie}(u)$ identifies with $Z^1(\mathfrak{g},\mathfrak{h})$. We must show that

$$Z^1(G,\mathfrak{h}) \longrightarrow Z^1(\mathfrak{g},\mathfrak{h})$$

is bijective.

$$\begin{array}{ccccccccc}
0 & \longrightarrow & \mathfrak{h}^G & \longrightarrow & \mathfrak{h} & \longrightarrow & Z^1(G,\mathfrak{h}) & \longrightarrow & H^1(G,\mathfrak{h}) \\
 & & \downarrow & & \| & & \downarrow & & \downarrow \\
0 & \longrightarrow & \mathfrak{h}^{\mathfrak{g}} & \longrightarrow & \mathfrak{h} & \longrightarrow & Z^1(\mathfrak{g},\mathfrak{h}) & \longrightarrow & H^1(\mathfrak{g},\mathfrak{h})
\end{array}$$

By 7.3.2 and 7.3.3,

$$\mathfrak{h}^G = \mathfrak{h}^{\mathfrak{g}}, \qquad H^1(G,\mathfrak{h}) = 0 = H^1(\mathfrak{g},\mathfrak{h}),$$

[45] *Editors' note.* See also [Bo91], II 7.9. We have also added the following sentence.

which gives the desired conclusion.

Remark 7.3.6.— It is presumably true that, if S is locally noetherian, G a simply connected semisimple S-group, H a smooth S-group scheme, and $\widehat{G}, \widehat{H}$ their formal completions along the identity section, then every homomorphism $\widehat{G} \to \widehat{H}$ comes from a unique homomorphism $G \to H$. This would generalize 7.3.1(iii). When $S = \mathrm{Spec}(k)$ and H is affine and of finite type, this follows from a theorem of Dieudonné [Di57], §15, Theorem 4.[46]

7.4. An example

As an example, we shall determine

$$\underline{\mathrm{Hom}}_{S\text{-gr.}}(\mathrm{SL}_{2,S}, \mathrm{SL}_{2,S}).$$

7.4.1.

Recall (Exposé XX, no. 5) that $\mathrm{SL}_{2,S}$ is the S-group scheme of matrices

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

over S satisfying $ad - bc = 1$. A maximal torus T is defined by the monomorphism

$$\alpha^* : \mathbb{G}_{m,S} \longrightarrow \mathrm{SL}_{2,S}, \qquad \alpha^*(z) = \begin{pmatrix} z & 0 \\ 0 & z^{-1} \end{pmatrix}.$$

A root of G with respect to T is defined by

$$\alpha(\alpha^*(z)) = z^2,$$

and a corresponding monomorphism is

$$p : \mathbb{G}_{a,S} \longrightarrow \mathrm{SL}_{2,S}, \qquad p(x) = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}.$$

Finally, putting $u = p(1)$, the corresponding representative of the Weyl group is

$$w = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

Recall also (Exposé XX, 6.2) that $\mathrm{SL}_{2,S}$ is generated by T, $p(\mathbb{G}_{a,S})$, and w, subject to the relations

$$\alpha^*(z)p(x)\alpha^*(z^{-1}) = p(z^2x),$$
$$w\alpha^*(z)w^{-1} = \alpha^*(z^{-1}), \qquad w^2 = \alpha^*(-1), \qquad (wu)^3 = 1.$$

[46] *Editors' note.* See Exposé $\mathrm{VII_B}$ for the definition of the formal groups $\widehat{G}$ and $\widehat{H}$. Suppose that $S = \mathrm{Spec}(k)$, where k is a field. By loc. cit., 2.2.1, giving a morphism of formal k-groups $v : \widehat{G} \to \widehat{H}$ is equivalent to giving a morphism of Hopf k-algebras $\phi : \mathrm{Dist}(G) \to \mathrm{Dist}(H)$, where $\mathrm{Dist}(G)$ denotes the algebra of distributions (at the origin) of G; see Exposé $\mathrm{VII_A}$, 2.1, [DG70], §II.4, 6.1, or [Ja87], I 7.7. It is called the hyperalgebra of G in [Di57] and [Ta75]. Theorem 4 of [Di57] (see also [Ta75], 0.3.4 (f) and (g)) generalizes in this context the theorem of Chevalley used in 7.3.5: one obtains a closed connected k-subgroup $K \subset G \times H$ such that $\widehat{K}$ equals the graph of v. Since $\mathrm{Dist}(K) \to \mathrm{Dist}(G)$ is an isomorphism, $K \to G$ is finite étale. It follows that K is semisimple and then, by Exposé XXI, 6.2.7, that $K \to G$ is an isomorphism (because G is simply connected; see also [Ta75], 1.8 and 2.2). More generally, loc. cit. studies the k-groups G having property (SC): every finite étale morphism of k-groups $G' \to G$, with G' connected, is an isomorphism. Finally, the preceding argument shows that every finite-dimensional $\mathrm{Dist}(G)$-module is, uniquely, a G-module; for an extension to a split reductive k-group G (or even to a Borel subgroup of G), see [Ja87], II 1.20 (and the references given there).

7.4.2.

Let f be an endomorphism of $\mathrm{SL}_{2,S}$. It first defines a homomorphism

$$f \circ \alpha^* : \mathbb{G}_{m,S} \longrightarrow \mathrm{SL}_{2,S}.$$

The closed subgroup $\ker(f \circ \alpha^*) \subset \mathbb{G}_{m,S}$ is, locally on S, either $\mu_{n,S}$, with $n \geq 1$, or $\mathbb{G}_{m,S}$. After restricting S, we may therefore assume that there are an integer $n \in \mathbb{N}$ and a monomorphism

$$f' : \mathbb{G}_{m,S} \longrightarrow \mathrm{SL}_{2,S}$$

such that

$$f \circ \alpha^*(z) = f'(z^n).$$

By conjugacy of monomorphisms $\mathbb{G}_{m,S} \to \mathrm{SL}_{2,S}$, after an étale covering extension of the base there is a section g of G such that

$$f \circ \alpha^*(z) = \mathrm{int}(g) \circ \alpha^*(z^n).$$

Replacing f by an inner conjugate, we are thus reduced to the case

$$f \circ \alpha^*(z) = \alpha^*(z^n)$$

for some $n \in \mathbb{N}$.

7.4.3.

Consider now

$$f \circ p : \mathbb{G}_{a,S} \longrightarrow \mathrm{SL}_{2,S}.$$

It satisfies

$$\alpha^*(z^n)(f \circ p)(x)\alpha^*(z^n)^{-1} = (f \circ p)(z^2 x).$$

If $n = 0$, it follows at once that $f \circ p$ is invariant under the homotheties of $\mathbb{G}_{a,S}$, and hence is constant. If $n \neq 0$, Exposé XXII, 4.1.9 applies: the map $x \mapsto x^n$ is an endomorphism of $\mathbb{G}_{a,S}$, and there is a $\lambda \in \mathbb{G}_{m,S}$ such that

$$f \circ p(x) = p(\lambda x^n).$$

This relation is also valid for $n = 0$, on taking $\lambda = 1$. After extending S once more, choose $z \in \mathbb{G}_{m,S}$ with $z^2 = \lambda$. Replacing f by $\mathrm{int}(\alpha^*(z)) \circ f$, we are reduced to

$$f \circ \alpha^*(z) = \alpha^*(z^n), \qquad f \circ p(x) = p(x^n).$$

7.4.4.

Finally, one must have

$$f(w)\alpha^*(z^n)f(w)^{-1} = \alpha^*(z^n)^{-1}, \qquad (f(w)u)^3 = 1.$$

By Exposé XX, 3.8, this implies $f(w) = w^n$. Since G is generated by T, $p(\mathbb{G}_{a,S})$, and w, it follows that, for every $S' \to S$ and every $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in G(S')$,

$$f\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a^n & b^n \\ c^n & d^n \end{pmatrix}.$$

7.4.5.

Summarizing, locally on S for the étale topology, every endomorphism f of $\mathrm{SL}_{2,S}$ can be written

$$f = \phi \circ F_n,$$

where ϕ is an inner automorphism, $n \geq 0$, and

$$F_n \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a^n & b^n \\ c^n & d^n \end{pmatrix}.$$

If $f = \phi \circ F_n$, the integer n is determined by any fiber f_s, for example by $\ker(f_s)$. Consequently n is a locally constant function on S.

7.4.6.

It follows that, for every endomorphism f of $\mathrm{SL}_{2,S}$, the scheme S has a canonical decomposition into open and closed subschemes

$$S_0, \qquad S_1, \qquad S_{p^n},$$

where p^n runs through the positive powers of prime numbers, such that:

(i) f_{S_0} is the zero morphism;

(ii) f_{S_1} is an isomorphism, necessarily an inner automorphism;

(iii) S_{p^n} has characteristic p, and $f_{S_{p^n}}$ has a unique decomposition

$$f_{S_{p^n}} = \phi \circ F_p^n,$$

where ϕ is an inner automorphism and F_p is the Frobenius endomorphism of $\mathrm{SL}_{2,\mathbb{F}_p}$.

7.4.7.

Equivalently,

$$\underline{\mathrm{Hom}}_{\mathbb{Z}\text{-gr.}}(\mathrm{SL}_{2,\mathbb{Z}}, \mathrm{SL}_{2,\mathbb{Z}})$$

is the disjoint-union scheme consisting of:

(i) one scheme isomorphic to $\mathrm{Spec}(\mathbb{Z})$;

(ii) one scheme isomorphic to

$$\underline{\mathrm{Aut}}_{\mathbb{Z}\text{-gr.}}(\mathrm{SL}_{2,\mathbb{Z}}) \simeq \mathrm{ad}(\mathrm{SL}_{2,\mathbb{Z}});$$

(iii) for each prime p and each integer $n > 0$, one scheme isomorphic to

$$\underline{\mathrm{Aut}}_{\mathbb{F}_p\text{-gr.}}(\mathrm{SL}_{2,\mathbb{F}_p}) \simeq \mathrm{ad}(\mathrm{SL}_{2,\mathbb{F}_p}).$$

7.4.8.

In particular:

(i) $\underline{\mathrm{Hom}}_{\mathbb{F}_p\text{-gr.}}(\mathrm{SL}_{2,\mathbb{F}_p}, \mathrm{SL}_{2,\mathbb{F}_p})$ has infinitely many connected components and is therefore not quasi-compact.

(ii) If S is a scheme of unequal characteristics, then $\underline{\mathrm{Hom}}_{S\text{-gr.}}(\mathrm{SL}_{2,S}, \mathrm{SL}_{2,S})$ is not flat over S.

8. Appendix: Cohomology of a smooth group over a henselian ring. Cohomology and the functor $\prod$

Proposition 8.1.— *Let S be a henselian local scheme, s its closed point, and G a smooth S-group scheme such that every finite subset of G is contained in an affine open subset.*[*]

(i) If P is a principal homogeneous bundle under G, there is a finite surjective étale morphism $S' \to S$ which trivializes P. Moreover,

$$\mathrm{Fib}(S, G) \simeq H^1_{ét}(S, G).$$

(ii) For every finite surjective étale morphism $S' \to S$, the canonical map

$$H^1(S'/S, G) \longrightarrow H^1(S' \otimes_S \kappa(s)/\kappa(s), G_s)$$

is bijective.

(iii) The canonical map

$$\mathrm{Fib}(S, G) \longrightarrow \mathrm{Fib}(\kappa(s), G_s)$$

is bijective.

8.1.2.

If K is a finite separable extension of $\kappa(s)$, there is a finite surjective étale morphism $S' \to S$ such that

$$K \simeq S' \otimes_S \kappa(s).$$

[47] If P is a principal homogeneous bundle under G, then P is smooth over S, hence P_s is smooth over $\kappa(s)$. Consequently there is a finite separable extension $K/\kappa(s)$ such that P_K has a section (EGA IV_4, 17.15.10). Representing K as above, Hensel's lemma (EGA IV_4, 18.5.17) shows that $P_{S'}$ has a section. This proves the first assertion of (i).

Conversely, if P is a principal homogeneous sheaf under G for the étale topology, then a finite surjective étale morphism $S' \to S$ trivializes P: every étale covering family of a henselian local scheme is dominated by a family consisting of one morphism of that form. By the descent hypothesis imposed on G, P is representable (SGA 1, VIII, 7.6). This completes the proof of (i), and shows that (ii) implies (iii). It remains to prove (ii).

8.1.3.

The map in (ii) is injective. Let P and Q be two principal homogeneous bundles under G, trivialized by S', and consider the S-group sheaf

$$\mathcal{H} = \underline{\mathrm{Isom}}_{G\text{-bundles}}(P, Q).$$

Since $\mathcal{H}_{S'}$ is isomorphic to $G_{S'}$, $\mathcal{H}$ is representable by the second hypothesis on G, as above. If $\mathcal{H}(\kappa(s)) \neq \varnothing$, Hensel's lemma gives $\mathcal{H}(S) \neq \varnothing$, and hence $P \simeq Q$.

[*] This last condition is in fact unnecessary; see A. Grothendieck, *Le groupe de Brauer III*, in *Dix Exposés sur la cohomologie des schémas*, North-Holland, 1968, Theorem 11.7 and Remarks 11.8.3.

[47] *Editors' note.* The scheme S' is still local and henselian. We have also retained the numbering of the original: there is no no. 8.1.1.

8.1.4.

To prove surjectivity in (ii), it is equivalent to prove that

$$Z^1(S'/S, G) \longrightarrow Z^1(S' \otimes_S \kappa(s)/\kappa(s), G_s)$$

is surjective. Let Z^1 be the S-functor defined by

$$Z^1(T) = Z^1(S' \times_S T/T, G_T).$$

The preceding map is then

$$Z^1(S) \longrightarrow Z^1(\kappa(s)).$$

Another application of Hensel's lemma reduces the assertion to showing that Z^1 is representable by a smooth S-scheme.

8.1.5.

We first show that Z^1 is representable by an S-scheme locally of finite presentation. For $i = 0, 1, \ldots$, define the S-functor C_i by

$$C_i(T) = C_i(S' \times_S T/T, G_T).$$

Equivalently,

$$C_i(T) = G((S'/S)^{i+1} \times_S T), \qquad C_i = \underline{\mathrm{Hom}}_S((S'/S)^{i+1}, G).$$

Since Z^1 is obtained from C_1 and C_2 by fiber products, it is enough to prove that C_i, for $i = 1, 2$, is representable by an S-scheme locally of finite presentation.

8.1.6.

Let $T \to S$ be a finite surjective étale morphism which splits S'. Then

$$C_i \times_S T = \underline{\mathrm{Hom}}_T((S' \times_S T/T)^{i+1}, G_T)$$

is represented by a product of n copies of G_T, where n is the degree of $(S'/S)^{i+1}$. The hypothesis on G, applied once again, shows that C_i is represented by an S-scheme locally of finite presentation (SGA 1, VIII, *loc. cit.*).

8.1.7.

It remains to prove that Z^1 is smooth. By definition, if T is an affine S-scheme and T_0 is the closed subscheme defined by a square-zero ideal J, we must show that

$$Z^1(T) \longrightarrow Z^1(T_0)$$

is surjective. Since G is smooth, the canonical map $G(T) \to G(T_0)$ is surjective, and it is enough to prove that

$$H^1(S' \times_S T/T, G_T) \longrightarrow H^1(S' \times_S T_0/T_0, G_{T_0})$$

is bijective. After a slight change of notation and a harmless generalization of the hypotheses, this reduces to the following lemma.

Lemma 8.1.8.— *Let S and S' be affine schemes, let $S' \to S$ be faithfully flat, let J be a square-zero ideal on S, and let S_0 be the closed subscheme which it defines. Let G be a smooth S-group. Put*

$$S'_0 = S' \times_S S_0, \qquad G_0 = G \times_S S_0.$$

Then the canonical map

$$H^1(S'/S, G) \longrightarrow H^1(S'_0/S_0, G_0)$$

is bijective.

Remark 8.1.9.— If G is commutative, the same assertion holds for every H^i, $i > 0$, with an analogous proof.

Proof. Let M_0 be the quasi-coherent $\mathcal{O}_{S_0}$-module

$$M_0 = \mathrm{Lie}(G_0/S_0) \otimes_{\mathcal{O}_{S_0}} J.$$

For every S_0-scheme T_0, put

$$M_0(T_0) = H^0\Big(T_0, M_0 \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_{T_0}\Big),$$

and define the S-group functors

$$M = \prod_{S_0/S} M_0, \qquad \overline{G} = \prod_{S_0/S} G_0$$

by

$$M(T) = M_0(T_0), \qquad \overline{G}(T) = G_0(T_0), \qquad T_0 = T \times_S S_0.$$

By Exposé III, 0.9 and (0.6.2), for every affine S-scheme T there is a functorial exact sequence

$$1 \longrightarrow M(T) \longrightarrow G(T) \longrightarrow \overline{G}(T) \longrightarrow 1.$$

We must study the map

$$H^1(S'/S, G) \longrightarrow H^1(S'_0/S_0, G_0) = H^1(S'/S, \overline{G}).$$

Suppose first that G is commutative. There is then an exact cohomology sequence

$$H^1(S'/S, M) \longrightarrow H^1(S'/S, G) \longrightarrow H^1(S'/S, \overline{G}) \longrightarrow H^2(S'/S, M).$$

Moreover,

$$H^i(S'/S, M) = H^i(S'_0/S_0, M_0) = H^i(S'_0/S_0, \mathcal{M}_0) = 0 \qquad (i \neq 0),$$

the last equality following from TDTE I, B, Lemma 1.1.

Now suppose that G is not commutative. We use the exact sequence of nonabelian cohomology. If $u \in Z^1(S'/S, \overline{G})$, the elements of $H^1(S'/S, G)$ whose image in $H^1(S'/S, \overline{G})$ equals the class of u lie in the image of the corresponding coboundary map

$$H^1(S'/S, M_u) \longrightarrow H^1(S'/S, G),$$

where M_u is M twisted by u. Similarly, for $v \in Z^1(S'/S, \overline{G})$, there is an obstruction

$$\Delta(v) \in H^2(S'/S, M_v)$$

which vanishes exactly when the class of v is in the image of $H^1(S'/S, G)$. It therefore suffices to prove

$$H^1(S'/S, M_u) = 0, \qquad H^2(S'/S, M_v) = 0.$$

Recall (Exposé III, 0.8) that the action of G on M defined by the exact sequence above is induced functorially by the adjoint representation

$$\mathrm{ad} : G_0 \longrightarrow \underline{\mathrm{Aut}}_{\mathcal{O}_{S_0}}(\mathrm{Lie}(G_0/S_0)).$$

The cocycle u, respectively v, therefore defines a descent datum on $\mathrm{Lie}(G_0/S_0)$; write L_u, respectively L_v, for the resulting quasi-coherent $\mathcal{O}_{S_0}$-module. For $T \to S$,

$$M_u(T) = H^0\Big(T_0, L_u \otimes_{\mathcal{O}_{S_0}} J \otimes_{\mathcal{O}_{S_0}} \mathcal{O}_{T_0}\Big),$$

and similarly with v in place of u. Hence

$$H^1(S'/S, M_u) = H^1(S'_0/S_0, L_u \otimes J),$$

$$H^2(S'/S, M_v) = H^2(S'_0/S_0, L_v \otimes J),$$

and both groups vanish by the result already used. □

Proposition 8.2.— *Let $\mathcal{C}$ be a category with fiber products, endowed with a topology coarser than the canonical topology. Let $S' \to S$ be a morphism of $\mathcal{C}$, let G' be an S'-group sheaf, and let*

$$G = \prod_{S'/S} G'$$

be the corresponding S-group sheaf. Let

$$H^1_S(S', G') \subset H^1(S', G')$$

be the subset of classes of principal homogeneous sheaves under G' which are trivialized by a sieve on S' obtained by base change from a suitable covering sieve on S. The canonical map

$$H^1(S, G) \longrightarrow H^1(S', G'), \qquad P \longmapsto P \times_S S',$$

induces a bijection

$$H^1(S, G) \xrightarrow{\sim} H^1_S(S', G').$$

Its inverse is induced by

$$P' \longmapsto \prod_{S'/S} P'.$$

For every object X of $\mathcal{C}/S$, the definition gives an isomorphism, functorial in X,

$$\mathrm{Hom}_S(X, G) \xrightarrow{\sim} \mathrm{Hom}_{S'}(X \times_S S', G').$$

Thus, for every S-object T, there is a bijection functorial in T,

$$H^1(T/S, G) \xrightarrow{\sim} H^1(T'/S', G'), \qquad T' = T \times_S S'.$$

Replacing the single morphism $T \to S$ by an arbitrary covering family of S, and then passing to the inductive limit, gives the first part of the proposition. The second follows immediately.

Lemma 8.3.— *Under the hypotheses of 8.2, the equality*

$$H^1_S(S', G') = H^1(S', G')$$

is local on S. More precisely, suppose that there is a covering family $\{S_i \to S\}$ such that, for every i,

$$H^1_{S_i}(S' \times_S S_i, G') = H^1(S' \times_S S_i, G').$$

Then $H^1_S(S', G') = H^1(S', G')$.

Indeed, let P' be a principal homogeneous sheaf under G', and put

$$P'_i = P' \times_{S'} (S' \times_S S_i).$$

By hypothesis, there is a covering family $\{S_{ij} \to S_i\}$ such that, for each j,

$$P' \times_{S'} (S' \times_S S_{ij})$$

has a section. But $\{S_{ij} \to S\}$ is a covering family of S, and P' is therefore trivialized by the covering family of S' obtained from it by base change.

Proposition 8.4.— *Let $S' \to S$ be a finite étale morphism of schemes. Let G' be an S'-group sheaf and let*

$$G = \prod_{S'/S} G'$$

be the corresponding S-group sheaf. For the étale topology, respectively the local finite étale topology, respectively the (fpqc) *topology, the following functors induce mutually inverse bijections.*

$$\mathcal{P} \longmapsto \mathcal{P} \times_S S'$$

$$\prod_{S'/S} \mathcal{P}' \longleftarrow\!\shortmid \mathcal{P}'$$

In particular,

$$H^1(S, G) \simeq H^1(S', G').$$

By 8.2, it is enough to show

$$H^1_S(S', G') = H^1(S', G').$$

By 8.3, this may be checked locally for the local finite étale topology. We may therefore suppose that S' is a finite disjoint union of copies of S, say I_S, where I is a finite set. Then G' is given by a family $(G_i)_{i \in I}$ of sheaves on S, and

$$H^1(S', G') \simeq \prod_{i \in I} H^1(S, G_i).$$

On the other hand,

$$H^1(S, G) \simeq \prod_{i \in I} H^1(S, G_i).$$

It follows from 8.2 that $H^1_S(S', G') = H^1(S', G')$. □

Remarks 8.5.— Propositions 8.2 and 8.4 may be interpreted through the following exact sequence, where $f : S' \to S$ is the given morphism:

$$1 \longrightarrow H^1(S, f_*G') \longrightarrow H^1(S', G') \longrightarrow H^0(S, R^1 f_* G').$$

In the commutative case, this exact sequence follows from the Leray spectral sequence. It remains valid in the noncommutative case.[48]

In this form one sees that the result remains valid when f is assumed only finite, or even merely integral, provided that the topology is the étale topology. Indeed, for every G',

$$R^1 f_*(G') = \text{the final sheaf}$$

by SGA 4, VIII, 5.3.[49]

The result becomes false for a topology such as (fpqc) or (fppf), even if

$$S = \mathrm{Spec}(k), \qquad S' = \mathrm{Spec}(k[t]/t^2),$$

where k is an algebraically closed field of characteristic $p \neq 0$, and $G' = \mu_p$ or α_p.

Likewise, 8.2 becomes false, even for the étale topology, if the finiteness hypothesis on f is omitted. For example, take f to be an open immersion with

$$S = \mathrm{Spec}(V),$$

where V is a complete discrete valuation ring with algebraically closed residue field, take S' to be the open subscheme consisting of the generic point, and take G' to be the constant group $(\mathbb{Z}/n\mathbb{Z})_{S'}$, where n is prime to the residue characteristic of V. Then

$$H^1(S, G) = 0, \qquad H^1(S', G') \neq 0.$$

Replacing S' by $S \amalg S'$ gives an analogous example in which $S' \to S$ is étale and surjective, hence a cover for the topology under consideration.

Exposé XXV
The Existence Theorem

by M. Demazure

[1] For completeness, in this Exposé we give a proof of the existence theorem for split groups. Like Chevalley's original proof ("Sur certains schémas de groupes semi-simples", *Séminaire Bourbaki*, May 1961, no. 219), it rests on the existence of complex semisimple algebraic groups of every possible type. Cartier gave the principle of a more satisfactory proof, establishing directly the existence of a simply connected split semisimple $\mathbb{Z}$-group associated with a given Cartan matrix (unpublished).[2] Let us point out, however, that the difficulty is not to give an explicit construction of a group scheme, but to verify that the group so constructed really satisfies the required conditions—essentially, that its fibers are indeed smooth and reductive.

1. Statement of the theorem

Theorem 1.1.— *Let S be a nonempty scheme. The functor*

$$G \longmapsto R(G)$$

is an equivalence from the category of pinned reductive S-groups to the category of pinned reduced root data.

By the uniqueness theorem (Exposé XXIII, 4.1), the preceding statement is equivalent to the following.

Corollary 1.2 (Existence of split groups).— *For every reduced root datum R, there exists a split reductive $\mathbb{Z}$-group G such that $R(G) \simeq R$.*[3]

In particular:

Corollary 1.3.— *Let k be a field. For every splittable reductive k-group G_k, there exists a reductive $\mathbb{Z}$-group G such that*

$$G \otimes_{\mathbb{Z}} k \simeq G_k.$$

[1] Editors' note: Version of 13 October 2024.

[2] Editors' note: Such a principle was also sketched by B. Kostant *[Ko66]*; a complete proof, using quantum groups, was given more recently by G. Lusztig *[Lu09]*.

[3] Editors' note: The work *[BT84]* of F. Bruhat and J. Tits also contains a variant of Chevalley's construction (*loc. cit.*, 2.2.3–2.2.5 and §3.2), which in particular gives a smooth affine $\mathbb{Z}$-group G with connected fibers, possessing a split maximal torus, and whose generic fiber is a reductive $\mathbb{Q}$-group of type R. The reductivity of the geometric fibers of G follows from the study of the unipotent radical of a special fiber in *loc. cit.*, 4.6.12 and 4.6.15 (valid for more general G, associated with a valued root datum); but it is simpler to deduce it from the description of $\mathfrak{g} = \mathrm{Lie}(G)$, from Exposé XIX, 1.12(iii), and from the existence of the elements $w_\alpha(X)$ of Exposé XX, 3.1(iv); see *[BT84]*, 3.2.1.

Conversely, first observe that to prove 1.2 it is enough, by Exposé XXII, 4.3.1, and Exposé XXI, 6.5.10, to consider the case in which the root datum R is simply connected (and even irreducible, if desired, by Exposé XXI, 7.1.6).

On the other hand, under the hypotheses of 1.3 the group scheme G has constant type (since $\mathrm{Spec}(\mathbb{Z})$ is connected), hence type $R(G_k)$. By Exposé XXIII, 5.9, the validity of 1.3 for a given group G_k therefore entails the existence of a split $\mathbb{Z}$-group of type $R(G_k)$.[4]

Thus, to prove 1.2 and hence 1.1, it is enough to prove 1.3 when k has characteristic zero (for example, $k = \mathbb{C}$) and G_k is simply connected (and in particular semisimple), together with the following proposition.

Proposition 1.4.— *For every simply connected reduced root datum R, there exists a semisimple algebraic $\mathbb{C}$-group of type R.*

One may prove 1.4 as follows. First, there exists a complex semisimple Lie algebra $\mathfrak{g}$ of type R; see, for example, N. Jacobson, *Lie Algebras*, Chapter VII, Theorem 5.[5] Then $G = \mathrm{Aut}(\mathfrak{g})^0$ is a semisimple algebraic $\mathbb{C}$-group of type $\mathrm{ad}(R)$.[6] By *Bible*, §23.1, Proposition 1, it follows that there exists a semisimple $\mathbb{C}$-group of type R.

The remainder of this Exposé is devoted to the proof of 1.3 when k has characteristic zero and G_k is semisimple. The proof proceeds in two stages: the construction of a "piece of $\mathbb{Z}$-group scheme" (§2), and the study of the group obtained by applying "Weil's theorem" (§3).

To avoid confusion, in §2 we shall not use the abbreviated notation X_k for the k-scheme $X \otimes_{\mathbb{Z}} k$, where X is a $\mathbb{Z}$-scheme.

2. Existence theorem: construction of a piece of group

2.1.

Choose once and for all a splitting of G_k, denoted

$$(G_k, T_k, M, R)$$

(see Exposé XXII, 1.13), a system Δ of simple roots of R (defining the system R^+ of positive roots), and a Chevalley system $(X_{\alpha,k})_{\alpha\in R}$ of G_k (Exposé XXIII, 6.1 and 6.2) satisfying the additional condition (see Exposé XX, 2.6)

$$X_{\alpha,k}X_{-\alpha,k} = 1 \qquad (\alpha \in R).$$

[4]Editors' note: In fact, Exposé XXIII, 5.9 is unnecessary: the present Exposé constructs, for every semisimple $\mathbb{Q}$-group $G_{\mathbb{Q}}$, a semisimple $\mathbb{Z}$-group G of the same type as $G_{\mathbb{Q}}$, equipped with a split maximal torus T; hence G is split by Exposé XXII, 2.2.

[5]Editors' note: Let Δ be a base of R, and let $\widetilde{\mathfrak{g}}$ be the complex Lie algebra generated by $(e_\alpha, f_\alpha, h_\alpha)_{\alpha\in\Delta}$, subject to the relations $[h_\alpha, h_\beta] = 0$, $[e_\alpha, f_\beta] = h_\alpha$ if $\beta = \alpha$ and $= 0$ otherwise, $[h_\alpha, e_\beta] = (\alpha^*, \beta)e_\beta$, and $[h_\alpha, f_\beta] = -(\alpha^*, \beta)f_\beta$. In *loc. cit.*, $\mathfrak{g}$ is defined as the quotient of $\widetilde{\mathfrak{g}}$ by the intersection of the kernels of its finite-dimensional irreducible representations. In *[Se66]*, §VI.5, Theorem 9 (see also *[BLie]*, VIII, §4.3, Theorem 1), it is shown that $\mathfrak{g}$ is the quotient of $\widetilde{\mathfrak{g}}$ by the relations

$$\mathrm{ad}(e_\alpha)^{1-(\alpha^*,\beta)}(e_\beta) = 0, \qquad \mathrm{ad}(f_\alpha)^{1-(\alpha^*,\beta)}(f_\beta) = 0.$$

For an explicit description of the structure constants, and in particular the choice of signs, see Exposé XXIII, 6.5 and 6.7, as well as *[Ti66]*, §4, Theorem 1, and, for types A, D, E, *[Sp98]*, 10.2.5.

[6]Editors' note: One may suppose R irreducible, hence $\mathfrak{g}$ simple. By a general argument, $\mathrm{Lie}(G)$ is the complex Lie algebra of derivations of $\mathfrak{g}$; see *[DG70]*, §II.4, Proposition 2.3. These derivations are all inner; see *[BLie]*, I, §6.1, Corollary 3 to Proposition 1. Thus $\mathrm{Lie}(G) = \mathfrak{g}$, so G has no invariant subgroup of positive dimension and is semisimple. Its root system is consequently the same as that of $\mathfrak{g}$. Moreover, the center of G acts both trivially and faithfully on $\mathfrak{g}$, and is therefore trivial; hence G is adjoint.

Finally, choose on the subgroup of M generated by R a total order compatible with the group structure and such that the roots > 0 are the elements of R^+. We then write the roots as

$$-\alpha_n < -\alpha_{n-1} < \cdots < -\alpha_1 < \alpha_1 < \alpha_2 < \cdots < \alpha_n.$$

For $\alpha \in R$, let $U_{\alpha,k}$ denote the vector group corresponding to the root α, and let

$$p_{\alpha,k} \colon \mathbb{G}_{a,k} \xrightarrow{\sim} U_{\alpha,k}$$

be the isomorphism of vector groups defined by $X_{\alpha,k}$.

2.2.

The splitting of G_k includes, in particular, an isomorphism of k-groups

$$T_k \simeq D_k(M).$$

Put $T = D(M)$. This is a $\mathbb{Z}$-torus, and the preceding isomorphism may be regarded as an isomorphism

$$T_k \simeq T \otimes_{\mathbb{Z}} k.$$

We have

$$\mathrm{Hom}_{\mathbb{Z}\text{-gr.}}(T, \mathbb{G}_m) = M,$$

and shall regard the elements of $R \subset M$ as characters of T. Likewise, the elements of R^* will be regarded as morphisms of $\mathbb{Z}$-groups $\mathbb{G}_m \to T$.

2.3.

For each $\alpha \in R^+$, let $\mathbb{G}_a(\alpha)$ be a copy of $\mathbb{G}_a$, and consider the $\mathbb{Z}$-scheme

$$U = \mathbb{G}_a(\alpha_1) \times \cdots \times \mathbb{G}_a(\alpha_n).$$

If U_k denotes the unipotent part of the Borel subgroup B_k of G_k defined by R^+, let

$$a \colon U \otimes_{\mathbb{Z}} k \xrightarrow{\sim} U_k$$

be the isomorphism of k-schemes defined by

$$a(x_1, \ldots, x_n) = p_{\alpha_1,k}(x_1) \cdots p_{\alpha_n,k}(x_n).$$

2.4.

The group law of U_k is expressed by relations of the form

$$a(x_1, \ldots, x_n)a(y_1, \ldots, y_n) = a(z_1, \ldots, z_n),$$

where, for $h = 1, \ldots, n$, each z_h is a polynomial

$$z_h = x_h + y_h + Q_h(x_1, \ldots, x_{h-1}, y_1, \ldots, y_{h-1}),$$

whose coefficients are integers (Exposé XXII, 5.5.8, and Exposé XXIII, 6.4). Moreover,

$$Q_h(x_1, \ldots, x_{h-1}, 0, \ldots, 0) = 0.$$

Equip U with the composition law defined by these formulas, which are indeed "defined over $\mathbb{Z}$". Since this law induces the group law on U_k, it is associative, and (0) is a unit element. Indeed, these two assertions are expressed by relations among the polynomials Q_h, and $\mathbb{Z} \to k$ is injective. This is a group law: if (x_i) is a section of U over an arbitrary scheme S, its inverse (y_i) is computed recursively by

$$y_i = -x_i - Q_i(x_1, \ldots, x_{i-1}, y_1, \ldots, y_{i-1}),$$

formulas which are again "defined over $\mathbb{Z}$".

In summary, we have constructed a group law on U for which the isomorphism a above is an isomorphism of groups.

For each $\alpha \in R^+$, consider the morphism

$$p_\alpha \colon \mathbb{G}_a \longrightarrow U$$

defined by $p_\alpha(x) = (x_i)$, where

$$x_i = \begin{cases} x, & \alpha_i = \alpha, \\ 0, & \alpha_i \neq \alpha. \end{cases}$$

It is a closed immersion and a group homomorphism; denote its image by U_α. Since

$$(x_i) = p_{\alpha_1}(x_1) \cdots p_{\alpha_n}(x_n),$$

U is identified with the product

$$U = U_{\alpha_1} U_{\alpha_2} \cdots U_{\alpha_n}.$$

2.5.

Let $T = D(M)$ act on each U_α through the character α. One verifies immediately that this defines an action of T on the group U, and one may form the semidirect product $B = T \ltimes U$. There is a canonical isomorphism of k-groups

$$B \otimes_{\mathbb{Z}} k \xrightarrow{\sim} B_k.$$

If an arbitrary order is now placed on R^+, the morphism

$$\prod_{\alpha \in R^+} U_\alpha \longrightarrow U$$

defined by multiplication in U is still an isomorphism. Indeed, both sides are flat $\mathbb{Z}$-schemes of finite presentation, so it is enough to verify the assertion on geometric fibers. We are then reduced to Lazard's theory (*Bible*, §13.1, Proposition 1): regard U as a group with operators T, and use the fact that the U_α are pairwise nonisomorphic as groups with operators, since the characters $\alpha \in R^+$ of T are pairwise distinct on every fiber.

2.6.

Replacing R^+ by $R^- = -R^+$, one similarly constructs the groups U^-, B^-, and U_α for $\alpha \in R^-$, together with isomorphisms

$$p_\alpha \colon \mathbb{G}_a \xrightarrow{\sim} U_\alpha, \qquad \alpha \in R^-.$$

Finally introduce the product scheme

$$\Omega = U^- \times T \times U.$$

There is a canonical isomorphism of k-schemes

$$\Omega \otimes_{\mathbb{Z}} k \xrightarrow{\sim} U_k^- \times_k T_k \times_k U_k \simeq \Omega_k,$$

where Ω_k is the "big cell" of G_k (Exposé XXII, 4.1.2).

From now on we identify $\Omega \otimes_{\mathbb{Z}} k$ with Ω_k by this isomorphism, and regard U^-, T, and U as subschemes of Ω through their unit sections. Write

$$e = ((0), e, (0))$$

for the "unit section" of Ω. Our aim is now to put a piece-of-group law on Ω.

Lemma 2.7.— *Let $\alpha \in \Delta$, and let $w_{\alpha,k}$ be the element of $\mathrm{Norm}_{G_k}(T_k)(k)$ defined by $X_{\alpha,k}$; recall that, by definition,*

$$w_{\alpha,k} = p_{-\alpha,k}(-1)p_{\alpha,k}(1)p_{-\alpha,k}(-1).$$

There exist an open subset V_α of Ω, containing the section e, and a morphism

$$h_\alpha \colon V_\alpha \longrightarrow \Omega$$

such that:

(i) $h_\alpha(e) = e$;

(ii) $(h_\alpha) \otimes_{\mathbb{Z}} k$ *coincides with the restriction of* $\mathrm{int}(w_{\alpha,k})$ *to* $V_\alpha \otimes_{\mathbb{Z}} k \subset G_k$;

(iii) $T \subset V_\alpha$, *and h_α sends T into T. For every $\beta \in R$, one has $U_\beta \subset V_\alpha$, and h_α sends U_β into $U_{s_\alpha(\beta)}$.*

By the definition of a Chevalley system (Exposé XXIII, 6.1), for every $\beta \in R$ there exists an integer $e_\beta = \pm 1$ such that

$$\mathrm{int}(w_{\alpha,k})p_{\beta,k}(x) = p_{s_\alpha(\beta),k}(e_\beta x)$$

for every $x \in \mathbb{G}_a(S)$ and every $S \to \mathrm{Spec}(k)$.

Let S be any scheme. Write an arbitrary element of $\Omega(S)$ in the form

$$\left(\left(\prod_{\substack{\beta \in R^- \\ \beta \neq -\alpha}} p_\beta(x_\beta) \right) p_{-\alpha}(x_{-\alpha}),\ t,\ p_\alpha(x_\alpha) \left(\prod_{\substack{\beta \in R^+ \\ \beta \neq \alpha}} p_\beta(x_\beta) \right) \right),$$

where arbitrary orders have been chosen on $R^- \setminus \{-\alpha\}$ and $R^+ \setminus \{\alpha\}$, as permitted by 2.5. Define a morphism $d \colon \Omega \to \mathrm{Spec}(\mathbb{Z})$ by

$$d(u) = \alpha(t) + x_\alpha x_{-\alpha}.$$

Let $V_\alpha = \Omega_d$, the open subset of Ω defined by the invertibility of $d(u)$. It contains e, T, and every U_β, $\beta \in R$. Define

$$h_\alpha \colon V_\alpha \longrightarrow \Omega, \qquad h_\alpha(u) = (a(u), b(u), c(u)),$$

where

$$a(u) = \left(\prod_{\substack{\beta \in R^- \\ \beta \neq -\alpha}} p_{s_\alpha(\beta)}(e_\beta x_\beta) \right) p_{-\alpha}\Big(-x_\alpha d(u)^{-1}\Big),$$
$$b(u) = t \cdot \alpha^*(d(u)),$$
$$c(u) = p_\alpha\Big(-x_{-\alpha} d(u)^{-1}\Big) \left(\prod_{\substack{\beta \in R^+ \\ \beta \neq \alpha}} p_{s_\alpha(\beta)}(e_\beta x_\beta) \right).$$

Since s_α permutes the positive roots distinct from α (respectively the negative roots distinct from $-\alpha$), $c(u)$ (respectively $a(u)$) is a section of U (respectively U^-), so the preceding morphism is well defined. It plainly satisfies (i) and (iii). Assertion (ii) follows immediately from the definition of the e_β, $\beta \in R$, and Exposé XX, 3.12.

Lemma 2.8.— *There exist open subsets V, V' of Ω and morphisms*

$$h\colon V \longrightarrow \Omega, \qquad h'\colon V' \longrightarrow \Omega$$

with the following properties:

(i) *V and V' contain e, and $h(e) = h'(e) = e$;*

(ii) *the morphism induced by*
$$h' \circ h\colon h^{-1}(V') \longrightarrow \Omega$$
is the restriction of the identity morphism;

(iii) *the k-morphisms $h \otimes_{\mathbb{Z}} k$ and $h' \otimes_{\mathbb{Z}} k$ are the restrictions, to $V \otimes_{\mathbb{Z}} k$ and $V' \otimes_{\mathbb{Z}} k$, of automorphisms of the group G_k;*

(iv) *V and V' contain U, T, U^-; the morphisms h, h' send U into U^-, U^- into U, and T into T.*

Let w^0 be the element of the Weyl group of G_k that sends R^+ to R^-. Write

$$w^0 = s_{\alpha_n} \cdots s_{\alpha_1}, \qquad \alpha_i \in \Delta$$

(with no relation to the numbering in 2.1), and put

$$w_0 = w_{\alpha_n, k} \cdots w_{\alpha_1, k} \in \mathrm{Norm}_{G_k}(T_k)(k).$$

Define recursively, for $i \leq n$, an open subset V_i of Ω and a morphism $h_i\colon V_i \to \Omega$ by

$$V_0 = \Omega, \qquad h_0 = \mathrm{id},$$

and, for $i = 0, \ldots, n-1$,

$$V_{i+1} = h_i^{-1}(V_{\alpha_{i+1}}), \qquad h_{i+1} = h_{\alpha_{i+1}} \circ h_i,$$

where V_{α_j} and h_{α_j} are those of 2.7.

Take $V = V_n$ and $h = h_n$. The conditions (i), (iii), and (iv) concerning V and h hold: for (i) and (iii) this follows immediately from 2.8, and for (iv) from the fact that $h \otimes_{\mathbb{Z}} k$ is the restriction of $\mathrm{int}(w_0)$ to $V \otimes_{\mathbb{Z}} k$.

Since $(w^0)^2 = 1$, we also have

$$w^0 = s_{\alpha_1} \cdots s_{\alpha_n} = (s^3_{\alpha_1}) \cdots (s^3_{\alpha_n}).$$

Put

$$w'_0 = (w_{\alpha_1,k})^3 \cdots (w_{\alpha_n,k})^3.$$

Repeating the construction above gives an open subset V' and a morphism h' that also satisfy (i), (iii), and (iv). Moreover, $h' \otimes_{\mathbb{Z}} k$ is the restriction of $\mathrm{int}(w'_0)$ to $V' \otimes_{\mathbb{Z}} k$. For every simple root $\alpha \in \Delta$, however, $(w_{\alpha,k})^4 = e$ (Exposé XX, 3.1), hence $w'_0 w_0 = e$. It follows that $h' \circ h$ induces the identity morphism on a nonempty open subset of $\Omega \otimes_{\mathbb{Z}} k$. Since Ω is smooth and of finite presentation over $\mathbb{Z}$, $\Omega \otimes_{\mathbb{Z}} k$ is schematically dense in Ω; this proves (ii).

Proposition 2.9.— *There exist an open subset V_1 of $\Omega \times \Omega$, an open subset V_2 of Ω, and morphisms*

$$\pi\colon V_1 \longrightarrow \Omega, \qquad \sigma\colon V_2 \longrightarrow \Omega$$

having the following properties:

(i) *if $x \in \Omega(S)$, then (e, x) and (x, e) are sections of V_1, and*

$$\pi(e, x) = \pi(x, e) = x;$$

(ii) *V_2 contains e, and $\sigma(e) = e$;*

(iii) *π_k and σ_k are the restrictions of the morphisms $G_k \times_k G_k \to G_k$ and $G_k \to G_k$ defined respectively by multiplication and inversion.*

Proof. Let (v, t, u) and (v', t', u') be two sections of Ω. By 2.8(iv), $h(u)$ is a section of U^- and $h(v')$ a section of U; thus $(h(u), e, h(v'))$ may be regarded as a section of Ω. Define V_1 as the open subset of $\Omega \times \Omega$ specified by

$$\big((v, t, u), (v', t', u')\big) \in V_1(S) \quad \Longleftrightarrow \quad (h(u), e, h(v')) \in V'(S),$$

using the notation of 2.8. If the pair on the left is a section of V_1, then $h'(h(u), e, h(v'))$ is defined and is a section of Ω; write

$$h'(h(u), e, h(v')) = (v'', t'', u'').$$

Set

$$\pi\big((v, t, u), (v', t', u')\big) = \big(v \cdot tv''t^{-1},\ tt''t',\ t'^{-1}u''t' \cdot u'\big).$$

Assertion (i) follows immediately from 2.8(ii). To verify the assertion about π in (iii), observe that

$$h'(h(u), e, h(v')) = uv' = v''t''u''$$

whenever $u \in U(S)$, $v' \in U^-(S)$, and $S \to k$, by 2.8(iii) and (ii).

The morphism σ is constructed similarly. If (v, t, u) is a section of Ω, then $h(u^{-1})$ is a section of U^-, $h(v^{-1})$ a section of U, and $h(t^{-1})$ a section of T. Thus

$$(h(u^{-1}), h(t^{-1}), h(v^{-1}))$$

is a section of Ω. Define an open subset V_2 of Ω by

$$(v,t,u) \in V_2(S) \quad \Longleftrightarrow \quad (h(u^{-1}), h(t^{-1}), h(v^{-1})) \in V'(S),$$

and define

$$\sigma(v,t,u) = h'(h(u^{-1}), h(t^{-1}), h(v^{-1})).$$

The required properties of σ are verified in the same way.

Corollary 2.10.— *π is "generically associative" and σ is a "generic inverse": if $x, y, z \in \Omega(S)$, and if the expressions below are defined (as they always are over an open subset of Ω containing the unit section), then*

$$\pi(x, \pi(y,z)) = \pi(\pi(x,y), z), \qquad \pi(x, \sigma(x)) = e = \pi(\sigma(x), x).$$

Indeed, the two sides of each formula define morphisms between smooth $\mathbb{Z}$-schemes of finite presentation, and the morphisms agree on the generic fibers by 2.9(iii).

Corollary 2.11.— *Let $\alpha \in R$, and let S be a scheme. Suppose that $x, y \in \mathbb{G}_a(S)$ satisfy*

$$(p_\alpha(x), p_{-\alpha}(y)) \in V_1(S), \qquad 1 + xy \in \mathbb{G}_m(S).$$

These conditions define an open subset of $\mathbb{G}_{a,S}^2$ containing the section $(0,0)$. Then

$$\pi(p_\alpha(x), p_{-\alpha}(y)) = \left(p_{-\alpha}\left(\frac{y}{1+xy}\right), \alpha^*(1+xy), p_\alpha\left(\frac{x}{1+xy}\right)\right).$$

The proof is the same as above, by Exposé XX, 2.1.

3. Existence theorem: conclusion of the proof

For convenience, make the following definition.

Definition 3.1.— *Let S be a scheme and G an S-group scheme. The group G is called* admissible *if there is an open immersion of S-schemes*

$$i \colon \Omega_S = \Omega \times S \longrightarrow G$$

such that:

(i) *the diagram*

$$\begin{array}{ccccc} (V_1)_S & \longrightarrow & \Omega_S \times_S \Omega_S & \xrightarrow{i \times_S i} & G \times_S G \\ \downarrow{\scriptstyle \pi} & & & & \downarrow{\scriptstyle \pi_G} \\ \Omega_S & & \xrightarrow{\qquad i_S \qquad} & & G \end{array}$$

is commutative, where π_G denotes the multiplication morphism of G;

(ii) *there is a finite set of sections $a_j \in \Omega(S)$ such that the open subsets $i(a_j)\, i(\Omega_S)$ cover G.*

By "Weil's theorem" (Exposé XVIII, 3.13(iii) and (iv)), we have:

Lemma 3.2.— *If every admissible S-group is affine whenever S is étale and of finite type over $\mathbb{Z}$, then there exists an admissible affine $\mathbb{Z}$-group.*

We now have:

Lemma 3.3.— *Let S be a scheme and G an admissible S-group. Then G is smooth and of finite presentation over S, with affine, connected, semisimple fibers.*

Since Ω_S is smooth and of finite presentation over S, with connected fibers, the same is true of G by condition (ii). To prove 3.3, we may therefore suppose that S is the spectrum of a field K. Identify Ω_K with its image in G. Plainly Ω_K is the product

$$\left(\prod_{\alpha\in R^-} U_{\alpha,K}\right) T_K \left(\prod_{\alpha\in R^+} U_{\alpha,K}\right)$$

of the subgroups T_K and $U_{\alpha,K}$, $\alpha \in R$, of G. Thus the Lie algebra of G is identified with the direct sum

$$\mathrm{Lie}(T_K) \oplus \bigoplus_{\alpha\in R} \mathrm{Lie}(U_{\alpha,K}).$$

The inner automorphism defined by a section of T_K acts on $U_{\alpha,K}$, and hence on $\mathrm{Lie}(U_{\alpha,K})$, through the character

$$\alpha \in R \subset M \simeq \mathrm{Hom}_{K\text{-gr.}}(T_K, \mathbb{G}_{m,K}).$$

The preceding decomposition of $\mathrm{Lie}(G)$ is therefore exactly its decomposition under the adjoint action of T. Thus the roots of G_K with respect to T_K are the elements $\alpha \in R$.

Apply Exposé XIX, 1.13. Let T_α be the maximal torus of $\ker(\alpha) \subset T_K$, and put

$$Z_\alpha = \mathrm{Centr}_G(T_\alpha).$$

It is enough to prove that each Z_α is reductive. But

$$Z_\alpha \cap \Omega_K = \left(\prod_{\substack{\beta\in R^-\\ \beta|_{T_\alpha}=e}} U_{\beta,K}\right) T_K \left(\prod_{\substack{\beta\in R^+\\ \beta|_{T_\alpha}=e}} U_{\beta,K}\right).$$

The roots vanishing on T_α are the rational multiples of α, hence precisely α and $-\alpha$. Consequently,

$$Z_\alpha \cap \Omega_K = U_{-\alpha,K}\, T_K\, U_{\alpha,K}.$$

By Exposé XX, 3.4, to prove Z_α reductive it is enough to show that $U_{\alpha,K}$ and $U_{-\alpha,K}$ do not commute, and this follows immediately from 2.11.

It follows from 3.2 and 3.3 that the proof will be complete once the following lemma is proved.

Lemma 3.4.— *Let S be a locally noetherian scheme of dimension at most 1, and let G be a smooth S-group of finite type, with affine, connected, semisimple fibers. Then G is affine (and hence semisimple).*

Nota. In Exposé XVI it was shown that 3.4 holds without any hypothesis on S, but the proof is comparatively delicate. Since only the special case 3.4 is needed here, we give a direct proof.

Consider the Lie algebra $\mathfrak{g}$ of G, a locally free $\mathcal{O}_S$-module, and the adjoint representation

$$\mathrm{Ad}\colon G \longrightarrow \mathrm{GL}_{\mathcal{O}_S}(\mathfrak{g}).$$

To prove that G is affine over S, it is enough to prove that Ad is affine. Since G is smooth with connected fibers, it is separated over S (Exposé VI_B, 5.5), so Ad is separated. By the result proved in the Appendix (see 4.1), it suffices to show that Ad is quasi-finite. We are thus reduced to the case in which S is the spectrum of a field. In that case G is affine and therefore semisimple, and the assertion is Exposé XXII, 5.7.14.

4. Appendix

We used the following proposition in the course of the proof.

Proposition 4.1.— *Let S be a locally noetherian scheme of dimension at most 1; let G and H be two S-group schemes of finite type; and let $f\colon G \to H$ be a quasi-finite separated group homomorphism. If G is flat over S,*[7] *then f is affine.*

We shall give the proof only when G is smooth over S, which is indeed the hypothesis satisfied in the application above.

4.2.

By EGA II, 1.6.4, we may suppose that S is reduced. By the usual techniques of passage to the limit,[8] we may suppose S local. If $\dim(S) = 0$, the assertion is trivial.[9] Suppose therefore that $\dim(S) = 1$. By faithfully flat descent, we may suppose that S is complete with algebraically closed residue field. After replacing S by its normalization $\widetilde{S}$, if necessary, we may suppose S normal (EGA II, 6.7.1, and EGA 0_IV, 23.1.5).[10] We are thus reduced to the case in which S is the spectrum of a complete discrete valuation ring A with algebraically closed residue field.

4.3.

Let η (respectively s) be the generic (respectively closed) point of S. Consider the image $f_\eta(G_\eta)$ of G_η in H_η. It is a closed subgroup scheme of H_η. Let H' be the schematic closure of $f_\eta(G_\eta)$ in H. Since $H' \to H$ is affine (it is a closed immersion), we may replace H by H', and thus suppose that H is flat over S and that f_η is surjective. Since f_η is finite and G, H are flat over S, we have

$$\dim(G_s) = \dim(G_\eta) = \dim(H_\eta) = \dim(H_s).$$

4.4.

Let $H_s^0, \ldots, H_s^n$ be the irreducible components of H_s, where H_s^0 denotes the identity component, and let $z_0, \ldots, z_n$ be their generic points. Since each local ring $\mathcal{O}_{H,z_i}$ has dimension

[7] Editors' note: We have added the flatness hypothesis, which had been omitted.

[8] Editors' note: See EGA IV_3, 8.10.5(viii).

[9] Editors' note: Indeed, if $S = \mathrm{Spec}(k)$, with k a field, then f is the composite of the projection $p\colon G \to G/\ker(f)$ and a closed immersion i. Since $\ker(f)$ is finite over k, p is finite (Exposé VI_B, 9.2).

[10] Editors' note: Indeed, the irreducible components $S_1, \ldots, S_r$ of S are complete integral noetherian local schemes. By a theorem of Nagata (EGA 0_IV, 23.1.5), the normalization $\widetilde{S}_i$ is finite over S_i, and hence $\widetilde{S}$ is finite over S. A theorem of Chevalley (EGA II, 6.7.1) then shows that if $f \times_S \widetilde{S}$ is affine, so is f.

at most 1, the morphism

$$G \times_H \mathcal{O}_{H,z_i} \longrightarrow \mathcal{O}_{H,z_i}$$

is affine, being quasi-finite and separated (see Exposé XVI, Lemma 4.2). Thus G is affine over H in a neighborhood of z_i. Let V be the largest open subset of H over which $G|_V$ is affine. Then V contains every z_i,[11] and therefore contains at least one closed point $y_i \in H_s^i$. Moreover, $\kappa(y_i) = \kappa(s)$, since $\kappa(s)$ is algebraically closed.

On the other hand, V is plainly stable under translation by any element $g \in G(S)$. We have $\dim(G_s) = \dim(H_s)$, and f_s is finite, so

$$f(s)\colon G_s^0(s) \longrightarrow H_s^0(s)$$

is surjective. Since A is complete and G is smooth over S, the canonical map $G^0(S) \to G_s^0(s)$ is surjective. Since $H_s^0(s)$ acts transitively on each $H_s^i(s)$, it follows that $V \supset H_s(s)$, and therefore, since $\kappa(s)$ is algebraically closed, $V \supset H_s$.[12]

Clearly $V \supset H_\eta$, since f_η is finite. Consequently, $V = H$. □

[11] Editors' note: The following sentence has been added.

[12] Editors' note: When G is not assumed smooth over S, one may argue as follows. Let h_0 be a rational point of H_s^0, and let g_0 be a rational point of G_s^0 such that $f(g_0) = h_0$. By Exposé $\mathrm{VI_B}$, 5.6.1, there is a commutative diagram

$$\begin{array}{ccc} S'' & \xrightarrow{g} & G \\ {\scriptstyle\pi}\downarrow & \overset{\phi}{\searrow} & \downarrow \\ S' & \xrightarrow{w} & S \end{array}$$

in which w is étale and surjective, π is finite and surjective, and $\phi^{-1}(s)$ consists of a single point s'' such that $g(s'') = g_0$. Then $G_{S''} \to H_{S''}$ is affine above a neighborhood of $h_0 y_i$, and the same is true of $G_{S'} \to H_{S'}$ (EGA II, 6.7.1), and hence of $G \to H$ by faithfully flat descent (EGA $\mathrm{IV_2}$, 2.7.1(xiii)). Thus $h_0 y_i \in V$, from which it follows that V contains $H_s(s)$, and therefore H_s.

Exposé XXVI
Parabolic Subgroups of Reductive Groups

M. Demazure

This Exposé studies the parabolic subgroups of an S-reductive group G. Its essential result is the conjugacy theorem (5.4). Its essential tool is the notion of the transversal position of two parabolic subgroups, a notion studied systematically in §4. Another fact plays an important role: the decomposition of the unipotent radical $\mathrm{rad}^u(P)$ of a parabolic subgroup P into successive extensions of vector groups (2.1).[1]

Various schemes associated with G are studied in §3; §6 deals with the split subtori[2] of G and their relations with parabolic subgroups.

Finally, in §7, we explain briefly how, over a semi-local base, one formulates the "relative theory" of reductive groups as presented over fields in the article of A. Borel and J. Tits, *Groupes réductifs*, Publications Mathématiques de l'IHÉS, no. 27. In that article, cited as [BT65] below, the reader will also find, for a base field, other results not touched upon here. [3]

1. Recollections. Levi subgroups

Definition 1.1.— *Let S be a scheme, G an S-reductive group, and P a sub-S-group-scheme of G. One says that P is a* parabolic subgroup *of G if:*

(i) *P is smooth over S;*

(ii) *for every $s \in S$, the quotient $\bar{s}$-scheme $G_{\bar{s}}/P_{\bar{s}}$ is proper (that is, by the Bible, §6.4, Theorem 4 = [Ch05], §6.5, Theorem 5, $P_{\bar{s}}$ contains a Borel subgroup of $G_{\bar{s}}$).*

Proposition 1.2 (Exp. XXII, 5.8.5).— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G. Then P is closed in G, has connected fibers, and*

$$P = \underline{\mathrm{Norm}}_G(P).$$

Moreover, the quotient sheaf G/P is representable by an S-scheme that is smooth and projective over S.

[1] *Editor's note.* Since the Levi subgroups of P form a torsor under $\mathrm{rad}^u(P)$ (1.9), this entails, when S is semi-local, that P has a Levi subgroup and hence a maximal torus (2.4).

[2] *Editor's note.* The terminology "trivial torus" has been replaced by "split torus".

[3] *Editor's note.* Version of 13 October 2024.

Proposition 1.3 (Exp. XXII, 5.3.9 and 5.3.11).— *Let S be a scheme, G an S-reductive group, and P, P' two parabolic subgroups of G. The following conditions are equivalent:*

(i) *P and P' are conjugate in G, locally for the étale* (respectively, fpqc) *topology.*

(ii) *For every $s \in S$, $P_{\bar{s}}$ and $P'_{\bar{s}}$ are conjugate by an element of $G(\bar{s})$.*

(iii) *The strict transporter $\underline{\mathrm{Transt}}_G(P, P')$ of P into P', defined for every $S' \to S$ by*

$$\underline{\mathrm{Transt}}_G(P, P')(S') = \{g \in G(S') \mid \mathrm{int}(g)P_{S'} = P'_{S'}\},$$

is a closed subscheme of G, smooth and of finite presentation over S, and is a principal homogeneous bundle on the right under P and on the left under P'.

Proposition 1.4.— *Let S be a nonempty scheme, let (G, T, M, R) be a split S-reductive group, and let R' be a subset of R. The following conditions on R' are equivalent:*

(i)
$$\mathfrak{g}_{R'} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R'} \mathfrak{g}^\alpha$$
is the Lie algebra of a parabolic subgroup of G containing T (necessarily unique, Exp. XXII, 5.3.5).

(ii) *R' is of type* (R) (Exp. XXII, 5.4.2) *and contains a system of positive roots.*

(iii) *R' is a closed subset of R and satisfies: if $\alpha \in R - R'$, then $-\alpha \in R'$; equivalently, $R = R' \cup (-R')$.*

(iv) *There exist a system Δ of simple roots and a subset $A \subset \Delta$ such that R' is the union of the positive roots and the negative roots that are linear combinations of elements of A.*

(v) *R' contains a system of simple roots of R; moreover, if $\Delta \subset R'$ is a system of simple roots of R and*
$$A = (-R') \cap \Delta,$$
then R' is the union of the positive roots and the negative roots that are linear combinations of elements of A.

One has (i)⇔(ii) by Exp. XXII, 5.4.5(ii) and 5.5.1, and (iii)⇒(ii) by Exp. XXI, 3.3.6 and Exp. XXII, 5.4.7. Clearly (v)⇒(iv)⇒(iii), while (iii)⇒(v) follows from Exp. XXI, 3.3.6 and 3.3.10.

It remains to prove that (i) implies that R' is closed in R. This last assertion may be checked on any geometric fiber, so we may suppose that S is the spectrum of an algebraically closed field.

Let P be the parabolic subgroup of G containing T whose Lie algebra is $\mathfrak{g}_{R'}$. Since the Borel subgroups of P are the Borel subgroups of G contained in P, the Bible, §12.3, Theorem 1, and Exp. XXII, 5.4.5(i), show that, if U denotes the unipotent radical of P, then $T \cdot U$ is the subgroup of G containing T whose Lie algebra is

$$\mathfrak{g}_{R''} = \mathfrak{t} \oplus \bigoplus_{\alpha \in R''} \mathfrak{g}^\alpha,$$

where R'' is the intersection of the systems of positive roots of R contained in R'. In particular, R'' is closed and $R'' \cap (-R'') = \varnothing$.

On the other hand, $H = P/U$ is reductive, the canonical image $\bar{T}$ of T is a maximal torus of H (and $T \to \bar{T}$ is an isomorphism), and there is an isomorphism of $\bar{T}$-modules, or equivalently of M-graded vector spaces,

$$\mathrm{Lie}(H) \simeq \mathfrak{t} \oplus \bigoplus_{\alpha \in R_s} \mathfrak{g}^\alpha,$$

where R_s is the complement of R'' in R'. Thus R_s identifies naturally with the roots of H relative to $\bar{T}$, and in particular $R_s = -R_s$. Consequently,

$$R'' = \{\alpha \in R' \mid -\alpha \notin R'\}, \qquad R_s = \{\alpha \in R' \mid -\alpha \in R'\}.$$

We now prove that R' is closed. Let $\alpha, \beta \in R'$ with $\alpha + \beta \in R$. If $\alpha, \beta \in R''$, then $\alpha + \beta \in R''$ because R'' is closed. If $\alpha \in R_s$, $\beta \in R''$, and $\alpha + \beta \notin R'$, then $\alpha + \beta \in -R''$, whence

$$-\alpha = -(\alpha + \beta) + \beta \in R'',$$

because R'' is closed. This gives $-\alpha \in R'' \cap R_s$, a contradiction. It remains to consider $\alpha, \beta \in R_s$. If $\alpha + \beta \notin R'$, then $\alpha + \beta \in -R''$. Since $\alpha + \beta \neq 0$, some system of positive roots of the root system R_s contains both α and β, and hence some Borel subgroup of $H = P/U$ contains the canonical images of U_α and U_β. Its inverse image in P is a Borel subgroup containing U_α, U_β, U, and therefore $U_{-(\alpha+\beta)}$, which is impossible.

Corollary 1.5.— *A parabolic subgroup of a reductive group is of type* (RC) (Exp. XXII, 5.11.1).

Proposition 1.6 (Exp. XXII, 5.11.4).— *Let S be a scheme, G an S-reductive group, and P a subgroup of G of type* (RC).[4]

(i) *P has a largest invariant sub-group-scheme that is smooth and of finite presentation over S, with connected unipotent geometric fibers. It is a characteristic subgroup of P, called the* unipotent radical *of P and denoted* $\mathrm{rad}^u(P)$. *The quotient sheaf* $P/\mathrm{rad}^u(P)$ *is representable by an S-reductive group.*

(ii) *If T is a maximal torus of P, then P has a reductive subgroup L containing T such that:*

  (a) *every reductive subgroup of P containing T is contained in L;*

  (b) *P is the semidirect product $L \cdot \mathrm{rad}^u(P)$, that is, the canonical morphism $L \to P/\mathrm{rad}^u(P)$ is an isomorphism.*

  Moreover, L is the unique subgroup (respectively, reductive subgroup) *of P containing T and satisfying (b)* (respectively, (a)). *Finally,*

$$\underline{\mathrm{Norm}}_P(L) = L, \qquad \underline{\mathrm{Norm}}_P(T) = \underline{\mathrm{Norm}}_L(T).$$

[4] *Editor's note.* "Parabolic subgroup" has been replaced by "subgroup of type (RC)", as in Exp. XXII, 5.11.4, because the statement will later be applied (4.5.1, 6.17) to $P \cap P'$ when P, P' are parabolic and $P \cap P'$ is of type (RC).

1.7. A subgroup L of P satisfying condition 1.6(ii)(b) is called a *Levi subgroup* of P. It is a maximal reductive subgroup of P. Indeed, it is reductive because it is isomorphic to $P/\operatorname{rad}^u(P)$. If L' is a reductive subgroup of P containing L, then, locally for the fpqc topology, L has a maximal torus T, and 1.6(ii) gives $L' = L$.

If L and L' are two Levi subgroups of P, they are conjugate in P, locally for the fpqc topology. Indeed, locally one may choose maximal tori $T \subset L$ and $T' \subset L'$; after a further fpqc localization they are conjugate in P, so one may assume $T = T'$, and then 1.6(ii) gives $L = L'$. Since $P = L \cdot \operatorname{rad}^u(P)$ and $\underline{\operatorname{Norm}}_P(L) = L$, one obtains:

Corollary 1.8.— *Let P be a subgroup of type* (RC) *of the S-reductive group G. If L, L' are two Levi subgroups of P, there is a unique $u \in \operatorname{rad}^u(P)(S)$ such that* $\operatorname{int}(u)L = L'$.

Let $\underline{\operatorname{Lev}}(P)$ denote the functor of Levi subgroups of P: for $S' \to S$, $\underline{\operatorname{Lev}}(P)(S')$ is the set of Levi subgroups of $P_{S'}$. Corollary 1.8 gives:

Corollary 1.9.— *Let P be a subgroup of type* (RC) *of the S-reductive group G. Then $\underline{\operatorname{Lev}}(P)$ is a principal homogeneous bundle under the S-group $\operatorname{rad}^u(P)$; in particular, it is representable by an S-scheme that is smooth and affine over S, with integral geometric fibers.*

Likewise, 1.6 immediately yields:

Corollary 1.10.— *Let P be a subgroup of type* (RC) *of the S-reductive group G. The functor $\underline{\operatorname{Tor}}(P)$ of maximal tori of P is representable by a smooth affine S-scheme. The relation $L \supset T$ defines a morphism*

$$\underline{\operatorname{Tor}}(P) \longrightarrow \underline{\operatorname{Lev}}(P),$$

whose fiber above $L \in \underline{\operatorname{Lev}}(P)(S)$ identifies with $\underline{\operatorname{Tor}}(L)$ (Exp. XXII, 5.8.3).

The first assertion of 1.10 follows from the other two and Exp. XXII, 5.8.3.

Definition 1.11.— *Let S be a nonempty scheme, G an S-reductive group, P a parabolic subgroup of G, and*

$$\mathcal{E} = (T, M, R, \Delta, (X_\alpha)_{\alpha\in\Delta})$$

a pinning of G. One says that $\mathcal{E}$ is adapted *to P, or is a* pinning of the pair (G, P), *if $P \supset T$ and the Lie algebra of P is of the form*

$$\mathfrak{t} \oplus \bigoplus_{\alpha\in R'} \mathfrak{g}^\alpha,$$

where $R' \subset R$ contains R^+.

In particular, if $T \subset B$ is the Killing pair defined by the pinning, then $T \subset B \subset P$. Under these conditions set $\Delta(P) = \Delta \cap (-R')$. Exp. XXII, 5.4.3 gives

$$\alpha \in \Delta(P) \iff \alpha \in \Delta \text{ and } U_{-\alpha} \subset P \iff \alpha \in \Delta \text{ and } U_{-\alpha} \cap P \neq e.$$

Proposition 1.4(v) and Exp. XXII, 5.11.3 and 5.10.6 now immediately give:

Proposition 1.12.— *Let S be a scheme, G an S-reductive group, P a parabolic subgroup of G, and $(T, M, R, \Delta, (X_\alpha)_{\alpha\in\Delta})$ a pinning of G adapted to P. Let $\Delta(P) \subset \Delta$ be as above.*

(i) *The unipotent radical of P is*

$$\operatorname{rad}^u(P) = U_{R''} = \prod_{\alpha\in R''} U_\alpha,$$

where R'' is the set of positive roots whose expansion in Δ contains at least one element of $\Delta - \Delta(P)$[5] *with a nonzero coefficient.*

(ii) *The unique Levi subgroup L of P containing T is*

$$Z_{\Delta(P)} = \underline{\mathrm{Centr}}_G(T_{\Delta(P)}),$$

where $T_{\Delta(P)}$ is the maximal torus of $\bigcap_{\alpha\in\Delta(P)} \ker(\alpha)$. Moreover, $T_{\Delta(P)} = \mathrm{rad}(L)$.

Corollary 1.13.— *Every Levi subgroup L of a parabolic subgroup P of a reductive group G is a* critical subgroup *of G; that is* (Exp. XXII, 5.10.4)*,*

$$L = \underline{\mathrm{Centr}}_G(\mathrm{rad}(L)).$$

This follows immediately from 1.12 and the following lemma, which is contained in 1.4 and Exp. XXII, 5.4.1:

Lemma 1.14.— *Locally for the étale topology, every pair (G, P), where P is a parabolic subgroup of the reductive group G, admits a pinning in the sense of 1.11.*

We also record:

Proposition 1.15.— *Let S be a scheme, G an S-reductive group, P a parabolic subgroup of G, and $\mathcal{E}, \mathcal{E}'$ two pinnings of G adapted to P. The unique inner automorphism of G over S that transforms $\mathcal{E}$ into $\mathcal{E}'$* (Exp. XXIV, 1.5) *comes from P, via*

$$P \longrightarrow P/\underline{\mathrm{Centr}}(P) = P/\underline{\mathrm{Centr}}(G) \longrightarrow G/\underline{\mathrm{Centr}}(G).$$

Indeed, it suffices to argue as in Exp. XXIV, 1.5, using:

Lemma 1.16 (Exp. XXII, 5.3.14 and 5.2.6).— *The maximal tori* (respectively, Borel subgroups, respectively, Killing pairs) *of a parabolic subgroup P of an S-reductive group G are conjugate in P, locally for the étale topology.*

Proposition 1.17.— *Let S be a scheme, G an S-reductive group, P, P' two parabolic subgroups of G, and B a Borel subgroup contained in both P and P'. If P and P' are conjugate in G, locally for the étale topology, then $P = P'$.*

Indeed, we may assume that $g \in G(S)$ satisfies $\mathrm{int}(g)P = P'$. The groups B and $\mathrm{int}(g)^{-1}B$ are then two Borel subgroups of P. After extending S, Lemma 1.16 lets us choose $p \in P(S)$ with $\mathrm{int}(p)\,\mathrm{int}(g^{-1})B = B$. Hence

$$pg^{-1} \in \underline{\mathrm{Norm}}_G(B)(S) = B(S),$$

so $g \in B(S) \cdot p \subset P(S)$, and therefore $P' = \mathrm{int}(g)P = P$.

Remark 1.18.— *If P, P' are two parabolic subgroups of G containing a common Borel subgroup, then $P \cap P'$ is again a parabolic subgroup of G. Indeed, it is smooth along the unit section* (Exp. XXII, 5.4.5) *and contains a Borel subgroup.*

Proposition 1.19.— *Let S be a scheme, G an S-reductive group, and G' its derived group* (Exp. XXII, 6.2.1)*.*

[5] *Editor's note.* $\Delta(P)$ has been corrected to $\Delta - \Delta(P)$.

(i) *The assignments*

$$P \longmapsto P' = P \cap G', \qquad P' \longmapsto P' \cdot \mathrm{rad}(G) = \underline{\mathrm{Norm}}_G(P')$$

are mutually inverse bijections between the parabolic subgroups of G and those of G'. Moreover, $\mathrm{rad}^u(P) = \mathrm{rad}^u(P')$.

(ii) *Let P be a parabolic subgroup of G and $P' = P \cap G'$. The assignments*

$$L \longmapsto L' = L \cap G' = L \cap P', \qquad L' \longmapsto L' \cdot \mathrm{rad}(G) = \underline{\mathrm{Centr}}_G(\mathrm{rad}(L'))$$

are mutually inverse bijections between the Levi subgroups of P and those of P'. Moreover,

$$\mathrm{rad}(L') = (\mathrm{rad}(L) \cap G')^0.$$

The proof, for example by reduction to the split case, is straightforward and is left to the reader, together with the immediate proof of:

Proposition 1.20.— *Let S be a scheme, G an S-reductive group, P a parabolic subgroup of G, and L a Levi subgroup of P. The assignments*

$$Q \longmapsto Q \cap L = Q', \qquad Q' \longmapsto Q' \cdot \mathrm{rad}^u(P)$$

are mutually inverse bijections between the parabolic subgroups of G contained in P and the parabolic subgroups of L. Moreover, the Levi subgroups of Q' are precisely the Levi subgroups of Q contained in L.

Proposition 1.6 may be completed as follows.

Proposition 1.21.— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G.*

(i) *P has a largest invariant subgroup that is smooth and of finite presentation over S, with connected solvable geometric fibers. It is a characteristic subgroup of P, called the* radical *of P and denoted* $\mathrm{rad}(P)$. *The quotient sheaf $P/\mathrm{rad}(P)$ is representable by an S-semisimple group.*

(ii) *If L is a Levi subgroup of P, then* $\mathrm{rad}(P)$ *is the semidirect product of* $\mathrm{rad}^u(P)$ *and* $\mathrm{rad}(L)$*; one has*

$$\mathrm{rad}(L) = L \cap \mathrm{rad}(P), \qquad L = \underline{\mathrm{Centr}}_G(L \cap \mathrm{rad}(P)), \qquad P/\mathrm{rad}(P) \simeq L/\mathrm{rad}(L).$$

Indeed, assertion (i) being local, one may suppose that P has a Levi subgroup L. It is then immediate that

$$R = \mathrm{rad}^u(P) \cdot \mathrm{rad}(L)$$

has the properties asserted in (i). For (ii), it only remains to prove that $\mathrm{rad}(L) = L \cap \mathrm{rad}(P)$; this follows at once because $L \cap \mathrm{rad}(P)$ is smooth with connected fibers, L being the centralizer of a torus.[6]

[6] *Editor's note.* See Exposé XIX, 1.4.

2. Structure of the unipotent radical of a parabolic subgroup

Proposition 2.1.— *Let S be a scheme, G an S-reductive group, P a parabolic subgroup of G, and $\mathrm{rad}^u(P)$ its unipotent radical. There is a sequence of sub-group-schemes of $\mathrm{rad}^u(P)$*

$$\mathrm{rad}^u(P) = U_0 \supset U_1 \supset U_2 \supset \cdots \supset U_n \supset \cdots$$

having the following properties:

(i) *Every U_i is smooth, with connected fibers, characteristic and closed in P. The commutator of a section of U_i and a section of U_j is a section of U_{i+j+1}, over a varying $S' \to S$.*

(ii) *For every $i \geq 0$, there is a locally free $\mathcal{O}_S$-module $\mathcal{E}_i$ and an isomorphism of sheaves of S-groups*

$$U_i/U_{i+1} \xrightarrow{\sim} W(\mathcal{E}_i).$$

Moreover, the automorphisms of P, over a varying $S' \to S$, act linearly on $W(\mathcal{E}_i)$.

(iii) *For every $s \in S$, one has $U_{n,s} = e$ whenever*

$$n > \dim\big(\mathrm{rad}^u(P)_s\big).$$

2.1.1. Suppose first that the pair (G, P) admits a pinning. Let $(T, M, R, \Delta, \ldots)$ be a pinning of G adapted to P, and let $\Delta(P) \subset \Delta$ be determined by P. Write $\alpha_1, \ldots, \alpha_p$ for the elements of $\Delta(P)$, and $\beta_1, \ldots, \beta_q$ for the elements of $\Delta - \Delta(P)$. Every root $\gamma \in R$ has a unique expression

$$\gamma = a_1\alpha_1 + \cdots + a_p\alpha_p + b_1\beta_1 + \cdots + b_q\beta_q.$$

Set

$$a(\gamma) = b_1 + \cdots + b_q. \tag{7}$$

[7] The definitions immediately give (cf. 1.12):

$$\begin{aligned} U_\gamma \subset P &\iff a(\gamma) \geq 0, \\ U_\gamma \subset \mathrm{rad}^u(P) &\iff a(\gamma) > 0, \\ a(n\gamma + m\gamma') &= n\,a(\gamma) + m\,a(\gamma') \qquad (n, m \in \mathbb{Z}). \end{aligned}$$

For $i \geq 0$, let R_i be the set of roots $\gamma \in R$ such that $a(\gamma) > i$. Each R_i is a closed set of roots satisfying $R_i \cap (-R_i) = \varnothing$. Consider (Exp. XXII, 5.6.5) the S-group

$$U_i = U_{R_i} = \prod_{\gamma \in R_i} U_\gamma.$$

It is a closed sub-group-scheme of G, smooth over S, with connected fibers.

Let $\alpha, \beta \in R$. Consider the commutation relation of Exp. XXII, 5.5.2:

$$p_\alpha(x)p_\beta(y)p_\alpha(-x) = p_\beta(y) \prod_{n,m \in \mathbb{N}^*} p_{n\alpha+m\beta}(C_{n,m,\alpha,\beta}x^n y^m),$$

[7] *Editor's note.* The original $a_1 + \cdots + a_p$ has been corrected to $b_1 + \cdots + b_q$.

where every

$$p_\gamma : \mathbb{G}_{a,S} \xrightarrow{\sim} U_\gamma$$

is an isomorphism of vector groups. If $a(\alpha) > i$ and $a(\beta) > j$, then, for $n, m > 0$,

$$\begin{aligned} a(n\alpha + m\beta) &= n\, a(\alpha) + m\, a(\beta) \\ &\geq n(i+1) + m(j+1) > i + j + 1. \end{aligned}$$

Hence the commutator of a section of U_α and a section of U_β belongs to U_{i+j+1}; therefore

$$(U_i, U_j) \subset U_{i+j+1}.$$

In particular U_i/U_{i+1} is commutative, and identifies naturally with

$$U_i/U_{i+1} \simeq \prod_{a(\gamma)=i+1} U_\gamma \simeq W(\mathcal{E}_i),$$

where $\mathcal{E}_i$ is the direct sum of the $\mathfrak{g}^\gamma$ for which $a(\gamma) = i + 1$.

Return to the commutation formula and suppose $a(\alpha) \geq 0$, $a(\beta) > i$. If $n, m \in \mathbb{N}^*$, then either

$$a(n\alpha + m\beta) > i + 1,$$

or $a(n\alpha + m\beta) = i + 1$, in which case necessarily $m = 1$. This first proves that $\mathrm{int}(p_\alpha(x))$ preserves U_i, and hence also U_{i+1}. It then shows that, modulo U_{i+1}, the expression for $\mathrm{int}(p_\alpha(x))p_\beta(y)$ contains only terms

$$p_{n\alpha+\beta}(C_{n,1,\alpha,\beta} x^n y),$$

which are linear in y. Thus the inner automorphisms defined by sections of U_α act linearly on $U_i/U_{i+1} \simeq W(\mathcal{E}_i)$. The same is clear for inner automorphisms defined by sections of T. Since P is generated by T and by the U_α with $a(\alpha) \geq 0$, it follows that:

(i) every U_i is invariant in P;

(ii) the inner automorphisms defined by sections of P act linearly on $U_i/U_{i+1} \simeq W(\mathcal{E}_i)$.

2.1.2. Let $(T', M', R', \Delta', \ldots)$ now be another pinning of G adapted to P. By 1.15 there is an inner automorphism of G, coming from P, that carries the first pinning to the second. After extending S, it may be written $\mathrm{int}(p)$ for some $p \in P(S)$. Repeating the construction with the second pinning produces groups U'_i and vector-group isomorphisms

$$U'_i/U'_{i+1} \simeq W(\mathcal{E}'_i)$$

obtained from U_i and $U_i/U_{i+1} \simeq W(\mathcal{E}_i)$ by transport of structure under $\mathrm{int}(p)$. The preceding invariance and linearity statements therefore give $U'_i = U_i$, and the two vector-space structures on

$$U_i/U_{i+1} = U'_i/U'_{i+1}$$

coincide.

Thus the U_i and the vector structures on their successive quotients are independent of the chosen pinning and, in particular, invariant under every automorphism of P. This proves the proposition when (G, P) admits a pinning. Assertion (iii) is immediate: by Exp. XXI, 3.1.2, the set $\{a(\gamma) \mid \gamma \in R\}$ is an interval in $\mathbb{Z}$, so $\dim U_{i,s} = \dim U_{i+1,s}$ cannot occur unless $U_{i,s} = e$.

2.1.3. In general there is an fpqc covering family $\{S_j \to S\}$ such that every pair (G_{S_j}, P_{S_j}) admits a pinning (1.14). What precedes gives descent data on the $\mathrm{rad}^u(P_{S_j})_i$, compatible with the vector structures on the quotients. The result follows by descent for closed subschemes and for locally free modules.[8]

Corollary 2.2.— *Let S be affine, G an S-reductive group, and P a parabolic subgroup of G. Then*

$$H^1(S, \mathrm{rad}^u(P)) = 0;$$

that is, every principal homogeneous bundle under $\mathrm{rad}^u(P)$ *is trivial.*

Indeed, S is the disjoint union of subschemes on each of which $\mathrm{rad}^u(P)$ has constant relative dimension. By 2.1(iii) one may thus assume that $U_n = e$ for some n. Since

$$H^1(S, U_i/U_{i+1}) = H^1(S, W(\mathcal{E}_i)) = 0$$

by TDTE I, B, 1.1 (or SGA 1, Exposé XI, 5.1), the conclusion follows.

Corollary 2.3.— *Under the preceding hypotheses, P has a Levi subgroup L. If L is any Levi subgroup of P, the canonical map*

$$H^1(S, L) \longrightarrow H^1(S, P)$$

is bijective (see the introduction to Exp. XXIV for the definition of $H^1(S, -)$).

The first assertion follows from 2.2 and 1.9. The map $H^1(S, L) \to H^1(S, P)$ is surjective because $P = L \cdot \mathrm{rad}^u(P)$. For injectivity it is enough to show that

$$H^1(S, \mathrm{rad}^u(P)_Q) = 0$$

for every principal homogeneous L-bundle Q, where the subscript denotes twisting by Q. One may either repeat the proof of 2.2, using the L-invariance of the vector structures on U_i/U_{i+1}, or observe that $\mathrm{rad}^u(P)_Q$ is the unipotent radical of the parabolic subgroup P_Q of G_Q and apply 2.2 to P_Q.

Corollary 2.4.— *Let S be a semi-local scheme, G an S-reductive group, and P a parabolic subgroup of G. There is a maximal torus T of G contained in P.*

Indeed, by 2.3 the group P has a Levi subgroup L, and it suffices to know that L has a maximal torus, which follows from Exp. XIV, 3.20.

Corollary 2.5.— *Let S be affine, G an S-reductive group, and P a parabolic subgroup of G. There is a locally free $\mathcal{O}_S$-module $\mathcal{E}$ such that* $\mathrm{rad}^u(P)$*, as an S-scheme, is isomorphic to $W(\mathcal{E})$.*

We prove by induction on i that there is an isomorphism of S-schemes

$$\mathrm{rad}^u(P)/U_i \simeq W(\mathcal{E}_0 \oplus \mathcal{E}_1 \oplus \cdots \oplus \mathcal{E}_{i-1}).$$

This is clear for $i = 0$. If $i > 0$, then $\mathrm{rad}^u(P)/U_i$ is a principal homogeneous bundle over $\mathrm{rad}^u(P)/U_{i-1}$ under

$$(U_{i-1}/U_i)_{\mathrm{rad}^u(P)/U_{i-1}} \simeq W\Big(\mathcal{E}_{i-1} \otimes \mathcal{O}_{\mathrm{rad}^u(P)/U_{i-1}}\Big).$$

[8] *Editor's note.* See SGA 1, Exposé VIII, 1.3, 1.9, and 1.10.

The base is affine, for example by induction, so the bundle is trivial (TDTE I or SGA 1, Exposé XI, *loc. cit.*). Hence

$$\mathrm{rad}^u(P)/U_i \simeq \big(\mathrm{rad}^u(P)/U_{i-1}\big) \times_S (U_{i-1}/U_i),$$

which completes the induction.

Corollary 2.6.— *Let S be semi-local, let $\{s_i\}$ be its closed points, let G be an S-reductive group, and let P be a parabolic subgroup of G. The canonical map*

$$\mathrm{rad}^u(P)(S) \longrightarrow \prod_i \mathrm{rad}^u(P)(\mathrm{Spec}\,\kappa(s_i))$$

is surjective.

Indeed, write $S = \mathrm{Spec}\,A$ and $\kappa(s_i) = A/\mathfrak{p}_i$. If $\mathcal{E}$ corresponds to the projective, hence flat, A-module E, it remains to prove that

$$E \longrightarrow \prod_i E \otimes_A A/\mathfrak{p}_i$$

is surjective. It suffices to do so for $E = A$, when it is well known (Bourbaki, *Algèbre commutative*, Chapter II, §1, no. 2, Proposition 5).

Corollary 2.7.— *Let k be an infinite field, G a k-reductive group, and P a parabolic subgroup of G. Then* $\mathrm{rad}^u(P)(k)$ *is dense in* $\mathrm{rad}^u(P)$.

Corollary 2.8.— *Let S be semi-local, let $\{s_i\}$ be its closed points, let G be an S-reductive group, let P be a parabolic subgroup of G, and, for every i, let L_i be a Levi subgroup of P_{s_i}. There is a Levi subgroup L of P whose fiber at every s_i is L_i.*

Indeed, let L_0 be a Levi subgroup of P (2.3). For every i, choose

$$u_i \in \mathrm{rad}^u(P)(\mathrm{Spec}\,\kappa(s_i)) \quad \text{with} \quad \mathrm{int}(u_i)L_{0,s_i} = L_i$$

by 1.8. If $u \in \mathrm{rad}^u(P)(S)$ induces the u_i, as 2.6 permits, then $L = \mathrm{int}(u)L_0$ has the required fibers.

Corollary 2.9.— *In the setting of 2.1, let H also be a sub-group-scheme of G, smooth and of finite presentation over S, with connected fibers, such that $P \cap H$ contains, locally for the fpqc topology, a maximal torus of G. For every $i \geq 0$ there is a locally direct-factor submodule $\mathcal{F}_i \subset \mathcal{E}_i$ for which the isomorphism*

$$U_i/U_{i+1} \xrightarrow{\sim} W(\mathcal{E}_i)$$

induces an isomorphism

$$(U_i \cap H)/(U_{i+1} \cap H) \xrightarrow{\sim} W(\mathcal{F}_i).$$

Indeed, H is a subgroup of G of type (R) (Exp. XXII, 5.2.1). The assertion is fpqc-local, so we may suppose that G is split relative to a maximal torus of $P \cap H$, and even reduce to 2.1.1 with H defined by a subset $R' \subset R$. In the notation used there, Exp. XXII, 5.6.7(ii) gives

$$U_i \cap H = \prod_{\alpha \in R_i \cap R'} U_\alpha.$$

Thus $(U_i \cap H)/(U_{i+1} \cap H)$ identifies with

$$\prod_{\substack{\alpha \in R' \\ a(\alpha)=i+1}} U_\alpha,$$

which proves the assertion.

Corollary 2.10.— *In the setting of 2.9, the conclusions of 2.2, 2.5, 2.6, and 2.7 remain valid with* $\mathrm{rad}^u(P)$ *replaced by* $\mathrm{rad}^u(P) \cap H$.

Corollary 2.11.— *Let*[9] G *be an* S*-reductive group,* P *a parabolic subgroup, and* H *a subgroup of* P *of type* (RC) *such that*

$$\mathrm{rad}^u(H) = \mathrm{rad}^u(P) \cap H.$$

Then statements 2.2 through 2.8 remain valid with P *replaced by* H.

3. Scheme of parabolic subgroups of a reductive group

3.1. Let E be a finite twisted constant S-scheme (Exp. X, 5.1). Consider the S-functor $\mathrm{Of}(E)$, where $\mathrm{Of}(E)(S')$ is the set of open-and-closed subschemes of $E_{S'}$, or equivalently the set of open-and-closed subsets of $E_{S'}$. Then $\mathrm{Of}(E)$ is representable by a finite twisted constant S-scheme. Indeed, if $E = A_S$, for a finite set A, then

$$\mathrm{Of}(E) \simeq \mathcal{P}(A)_S,$$

where $\mathcal{P}(A)$ denotes the power set of A; the general case follows by descent of open-and-closed subschemes. Plainly,

$$\mathrm{Of}(E_{S'}) = \mathrm{Of}(E)_{S'}, \qquad \mathrm{Of}(E \times_S E') = \mathrm{Of}(E) \times_S \mathrm{Of}(E').$$

3.2. Let S be a scheme and G an S-reductive group. Define the functor $\underline{\mathrm{Par}}(G)$ of parabolic subgroups of G by

$$\underline{\mathrm{Par}}(G)(S') = \{\text{parabolic subgroups of } G_{S'}\}.$$

In particular $G \in \underline{\mathrm{Par}}(G)(S)$, and $\underline{\mathrm{Bor}}(G) \subset \underline{\mathrm{Par}}(G)$. We shall define a morphism

$$t : \underline{\mathrm{Par}}(G) \longrightarrow \mathrm{Of}(\underline{\mathrm{Dyn}}(G))$$

with the following properties:

(i) t is functorial in G, with respect to isomorphisms, and commutes with base change.

(ii) If $(T, M, R, \Delta, \ldots)$ is a pinning of G adapted to a parabolic subgroup P, then the canonical isomorphism

$$\underline{\mathrm{Dyn}}(G) \simeq \Delta_S \qquad \text{(Exp. XXIV, 3.4(iii))}$$

carries $t(P)$ onto $\Delta(P)_S$, in the notation of 1.11 and 1.12.

[9] *Editor's note.* Corollary 2.11 has been added; it is used in 4.5.1 and 6.17.

First suppose that P is a parabolic subgroup of G and that $(T, M, R, \Delta, \ldots)$ is a pinning of G adapted to P. Define $t(P)$ by (ii). The resulting subscheme of $\underline{\mathrm{Dyn}}(G)$ is independent of the pinning. Indeed, if $(T', M', R', \Delta', \ldots)$ is another pinning adapted to P, then the unique inner automorphism of G carrying the first pinning to the second comes from P, by 1.15. The canonical isomorphism $\Delta \xrightarrow{\sim} \Delta'$ therefore carries $\Delta(P)$ onto $\Delta'(P)$.

Without assuming that (G, P) admits a pinning, 1.14 and the definition of $\underline{\mathrm{Dyn}}(G)$ (Exp. XXIV, 3.3) allow one to descend a unique open-and-closed subscheme $t(P)$ such that

$$t(P)_{S'} = t(P_{S'})$$

whenever $(G, P)_{S'}$ admits a pinning.

Theorem 3.3.— *Let S be a scheme, G an S-reductive group, and*

$$t : \underline{\mathrm{Par}}(G) \longrightarrow \mathrm{Of}(\underline{\mathrm{Dyn}}(G))$$

the morphism just defined.

(i) *Two parabolic subgroups P, P' of G are conjugate locally for the fpqc topology* (cf. 1.3) *if and only if $t(P) = t(P')$.*

(ii) $\underline{\mathrm{Par}}(G)$ *is representable, and t is smooth and projective, with integral geometric fibers.*

By 3.2(i), together with the fact that inner automorphisms of G act trivially on $\underline{\mathrm{Dyn}}(G)$ (Exp. XXIV, 3.4(iv)), conjugate parabolics have the same type. Conversely, suppose $t(P) = t(P')$. Locally one may first assume that both (G, P) and (G, P') admit pinnings (1.14). By the conjugacy of pinnings in G (Exp. XXIV, 1.5), one may then choose a single pinning (T, M, R, Δ) adapted to both P and P'. Equality of types gives $\Delta(P) = \Delta(P')$, hence $P = P'$ by 1.4(v). This proves (i).

For (ii), use the notation of Exp. XXII, 5.11.5.[10] There is a canonical morphism $\underline{\mathrm{Par}}(G) \to \mathscr{H}_c$, which fits into the cartesian square

$$\begin{array}{ccc} \underline{\mathrm{Par}}(G) & \xrightarrow{\ t\ } & \mathrm{Of}(\underline{\mathrm{Dyn}}(G)) \\ \downarrow & & \downarrow \\ \mathscr{H}_c & \xrightarrow{\ c\ell\ } & \mathcal{C}\ell_c. \end{array}$$

The vertical arrows are monomorphisms. By *loc. cit.*, $\mathscr{H}_c$ is representable and $c\ell$ is smooth, quasi-projective, and of finite presentation, with integral geometric fibers; hence the same is true of t.

It remains to prove that t is proper. This is fpqc-local, so one may reduce to a pinned group $G = (G, T, M, R, \Delta, \ldots)$. Then $\underline{\mathrm{Dyn}}(G) \simeq \Delta_S$, and it is enough to show that

$$t^{-1}((\Delta_1)_S)$$

is proper over S for every $\Delta_1 \subset \Delta$. Let P_1 be the parabolic containing T with $\Delta(P_1) = \Delta_1$. Part (i) shows that $g \mapsto \mathrm{int}(g)P_1$ induces an isomorphism

$$G/\underline{\mathrm{Norm}}_G(P_1) \xrightarrow{\sim} t^{-1}((\Delta_1)_S).$$

[10] *Editor's note.* Recall that $\mathscr{H}_c = \mathscr{H}_c(G)$ denotes the functor of subgroups of G of type (RC), that $\mathcal{C}\ell_c = \mathcal{C}\ell_c(G)$ denotes the functor of their "conjugacy classes", and that $c\ell : \mathscr{H}_c \to \mathcal{C}\ell_c$ is the canonical projection.

By 1.2, $G/\underline{\mathrm{Norm}}_G(P_1) = G/P_1$, which is projective over S.

Definition 3.4.— $\mathrm{Of}(\underline{\mathrm{Dyn}}(G))$ *is called the* scheme of types of parabolics *of* G, *and* $t(P)$ *is called the* type *of* P.

Corollary 3.5.— *The* S*-functor* $\underline{\mathrm{Par}}(G)$ *is representable by an* S*-scheme that is smooth and projective over* S. *The factorization*

$$\underline{\mathrm{Par}}(G) \longrightarrow \mathrm{Of}(\underline{\mathrm{Dyn}}(G)) \longrightarrow S$$

is the Stein factorization (EGA III, 4.3.3) *of the structural morphism* $\underline{\mathrm{Par}}(G) \to S$.

Corollary 3.6.— *For every* $t \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S)$, *the* S*-scheme*

$$\underline{\mathrm{Par}}_t(G) = t^{-1}(t)$$

of parabolic subgroups of type t *is smooth and projective over* S *and homogeneous under* G. *If* P *is a parabolic subgroup of* G, *there is a canonical isomorphism*

$$G/P \xrightarrow{\sim} \underline{\mathrm{Par}}_{t(P)}(G).$$

Moreover,

$$\underline{\mathrm{Par}}_{\varnothing}(G) = \underline{\mathrm{Bor}}(G), \qquad \underline{\mathrm{Par}}_{\underline{\mathrm{Dyn}}(G)}(G) \xrightarrow{\sim} S.$$

Remark 3.7.— *The* S*-scheme* $\mathrm{Of}(\underline{\mathrm{Dyn}}(G))$ *has a natural order structure, the domination relation being set-theoretic inclusion of subschemes. It is a lattice; in particular, the infimum of two open-and-closed subschemes of* $\underline{\mathrm{Dyn}}(G)_{S'}$ *is their intersection.*

If B *is a Borel subgroup of* G, *let* X *be the functor of parabolic subgroups containing* B. *The morphism*

$$X \longrightarrow \mathrm{Of}(\underline{\mathrm{Dyn}}(G))$$

induced by t *is an isomorphism of ordered schemes. This follows from* $P \subset Q \Rightarrow t(P) \subset t(Q)$ *and the next lemma.*

Lemma 3.8.— *Let* S *be a scheme,* G *an* S*-reductive group,* P *a parabolic subgroup of* G, *and*

$$t' \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S) \quad \textit{with} \quad t(P) \subset t'.$$

There is a unique parabolic subgroup P' *of* G *containing* P *and satisfying* $t(P') = t'$.

After extending the base, one may suppose that P contains a Borel subgroup B of G. Uniqueness then follows from 1.17. For existence one may work in the split case, where the assertion is immediate from §1.

Remarks 3.8.1.—

(i) *The analogue of 3.8 obtained by reversing the inclusions is false. It would imply, for example, that every group of type* A_1 *has a Borel subgroup, which is not so* (Exp. XX, §5).

(ii) *The preceding discussion shows that* $t(P) \subset t(Q)$ *means that locally for the fpqc, or étale, topology,* P *is conjugate to a subgroup of* Q. *It is enough to check this on geometric fibers. Section 5 will show that the étale topology may be replaced by the Zariski topology.*

3.9. The preceding discussion can be repeated for critical subgroups. Recall (Exp. XXII, 5.10.4 and 5.10.5) that a reductive subgroup H of a reductive group G is *critical* if

$$H = \underline{\mathrm{Centr}}_G(\mathrm{rad}(H)),$$

that a subtorus $Q \subset G$ is a *C-critical torus* if

$$Q = \mathrm{rad}(\underline{\mathrm{Centr}}_G(Q)),$$

and that critical subgroups and C-critical tori are in bijection via

$$H \longmapsto \mathrm{rad}(H), \qquad Q \longmapsto \underline{\mathrm{Centr}}_G(Q).$$

11

If (G, T, M, R) is split, the subgroup of G containing T and corresponding to $R' \subset R$ (Exp. XXII, 5.4.2) is critical if and only if R' is *vectorial*, meaning that it is the intersection of R with a vector subspace of $M \otimes \mathbb{Q}$ (Exp. XXII, 5.10.6).

For arbitrary G, Exp. XXII, 5.11.5 defines a finite étale S-scheme $\mathcal{C}\ell_{\mathrm{crit}}$; in the split case it is the constant scheme associated with the vectorial subsets of R, modulo the action of the Weyl group. If $\underline{\mathrm{Crit}}(G)$ denotes the functor of critical subgroups, there is a canonical morphism

$$c\ell : \underline{\mathrm{Crit}}(G) \longrightarrow \mathcal{C}\ell_{\mathrm{crit}}$$

in the cartesian square

$$\begin{array}{ccc} \underline{\mathrm{Crit}}(G) & \xrightarrow{c\ell} & \mathcal{C}\ell_{\mathrm{crit}} \\ \downarrow & & \downarrow \\ \mathscr{H}_c & \xrightarrow{c\ell} & \mathcal{C}\ell_c. \end{array}$$

12

Proposition 3.10.— *Let S be a scheme, G an S-reductive group, $\underline{\mathrm{Crit}}(G)$ the functor of its critical subgroups, and let $\mathcal{C}\ell_{\mathrm{crit}}$ and*

$$c\ell : \underline{\mathrm{Crit}}(G) \longrightarrow \mathcal{C}\ell_{\mathrm{crit}}$$

be as above.

(i) *Critical subgroups H, H' of G are conjugate, locally for the fpqc topology, if and only if $c\ell(H) = c\ell(H')$.*

(ii) *$\underline{\mathrm{Crit}}(G)$ is representable, and $c\ell$ is smooth and affine, with integral geometric fibers.*

The proof is the same as for 3.3 except for affineness of $c\ell$. It is enough to prove that $\underline{\mathrm{Crit}}(G)$ is affine over S. The functor $\underline{\mathrm{Crit}}(G)$ identifies naturally with the functor of critical tori of G, giving a canonical monomorphism

$$\underline{\mathrm{Crit}}(G) \longrightarrow \mathcal{M},$$

where $\mathcal{M}$ is the scheme of subgroups of multiplicative type of G (Exp. XI, 4.1). By Exp. XII, 5.3, it is enough to show that this is an open-and-closed immersion. After the base change $\mathcal{M} \to S$, this reduces to the following: if Q is a subgroup of multiplicative type in G, the $S' \to S$ for which $Q_{S'}$ is a critical torus of $G_{S'}$ are precisely those factoring through an open-and-closed subscheme of S. The condition is the conjunction of:

[11] *Editor's note.* "Critical torus" has here been replaced by "C-critical torus". Below, "critical torus" is again used for "C-critical torus".

[12] *Editor's note.* See 3.3, editor's note, for the notation $\mathscr{H}_c, \mathcal{C}\ell_c$.

(1) Q is a torus;

(2) once Q is a torus, the torus $\mathrm{rad}(\underline{\mathrm{Centr}}_G(Q))$ has the same relative dimension as Q.

Both conditions are of the required kind.

Corollary 3.11.— *The S-functor $\underline{\mathrm{Crit}}(G)$ is representable by an S-scheme that is smooth and affine over S.*

Corollary 3.12.— *Let H be a critical subgroup of the S-reductive group G. Then $G/\underline{\mathrm{Norm}}_G(H)$ and G/H are representable by S-schemes that are affine and smooth over S.*

The first assertion follows from 3.11, and the second from the first and Exp. XXII, 5.10.2.

Corollary 3.13.— *Let Q be a subtorus of the S-reductive group G. Then $G/\underline{\mathrm{Centr}}_G(Q)$ is representable by an S-scheme that is smooth and affine over S. The same holds for $G/\underline{\mathrm{Norm}}_G(Q)$ when Q is a critical subtorus of G.*

Indeed, $H = \underline{\mathrm{Centr}}_G(Q)$ is critical (Exp. XXII, 5.10.5), and when Q is critical one has $\underline{\mathrm{Norm}}_G(H) = \underline{\mathrm{Norm}}_G(Q)$ (*loc. cit.*, 5.10.8).

3.14. The conjugacy of Levi subgroups of parabolic subgroups of G gives a unique morphism

$$u : \mathrm{Of}(\underline{\mathrm{Dyn}}(G)) \longrightarrow \mathcal{C}\ell_{\mathrm{crit}}$$

such that, for every parabolic subgroup P and every Levi subgroup $L \subset P$,

$$c\ell(L) = u(t(P)),$$

compatibly with every base change.

3.15. Let S be a scheme and G an S-reductive group. Consider the S-functors[13]

$$\begin{aligned}
PL(S') &= \{(P, L) \mid P \supset L,\ P \text{ parabolic in } G_{S'},\ L \text{ a Levi subgroup of } P\},\\
PT(S') &= \{(P, T) \mid P \supset T,\ P \text{ parabolic in } G_{S'},\ T \text{ a maximal torus of } P\},\\
CT(S') &= \{(C, T) \mid C \supset T,\ C \text{ critical in } G_{S'},\ T \text{ a maximal torus of } C\},\\
PLT(S') &= \{(P, L, T) \mid P \supset L \supset T,\ (P, T) \in PT(S'),\ L \text{ a Levi subgroup of } P\}.
\end{aligned}$$

There are evident morphisms between these functors and $\underline{\mathrm{Par}}(G), \underline{\mathrm{Crit}}(G)$, and $\underline{\mathrm{Tor}}(G)$. They form the following commutative truncated cube.

Theorem 3.16 (cf. Figure 3.15.1).—

(i) *Every morphism in the diagram is smooth, surjective, and of finite presentation.*

(ii) *Every morphism except t is affine; t is projective.*

(iii) *Every morphism is either finite étale or has integral geometric fibers: f, g, h, k, p, q, u are finite étale; $a, b, c, d, r, c\ell$ have integral geometric fibers; and e is an isomorphism.*

(iv) *The square (a, b, f, g) is cartesian.*

[13] *Editor's note.* The original LT has been changed to CT.

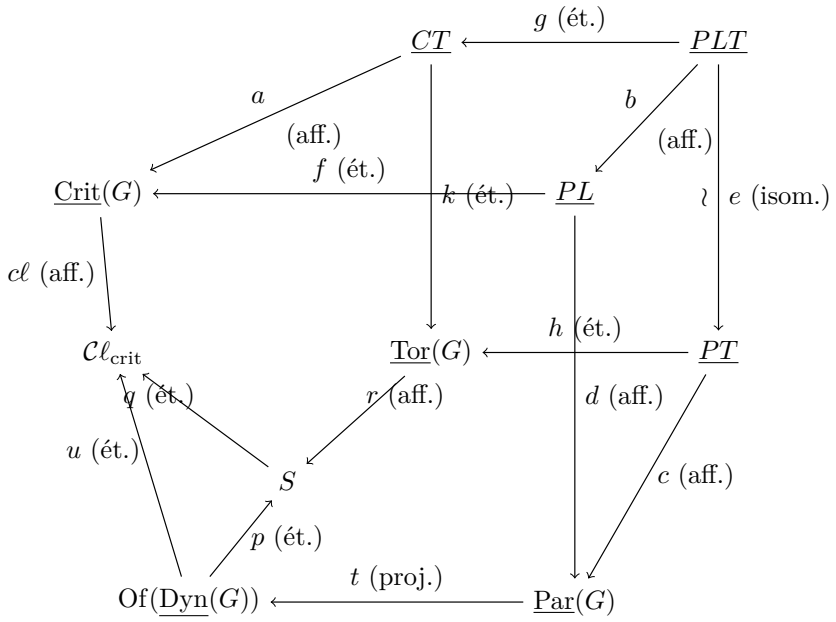

Figure 3.15.1

Proof. It is clear from 1.6(ii) that e is an isomorphism, and (iv) is immediate. The morphism a is smooth and affine with integral geometric fibers. Indeed, after the base change $\underline{\mathrm{Crit}}(G) \to S$, this reduces to the same statement for

$$\underline{\mathrm{Tor}}(L_0) \longrightarrow S,$$

where L_0 is the universal critical subgroup; L_0 is reductive by definition, so Exp. XXII, 5.8.3 applies. By (iv), b has the same properties.

The morphism d is likewise smooth and affine with integral geometric fibers, by 1.9; the same is therefore true of

$$c = dbe^{-1}.$$

The morphism r has these properties by Exp. XXII, 5.8.3, and $c\ell$ by 3.10.

We already know that p and q are finite étale and surjective (3.1 and 3.9). If f and k are finite étale and surjective, then so is g, by (iv), and so is $h = kge^{-1}$. Since the assertions about t were proved in 3.3(ii), it remains only to prove the claim for f and k. We do so for k, the proof for f being the same.

If T is a maximal torus of G, let $\mathcal{C}$ be the functor of critical subgroups containing T. We must show that $\mathcal{C}$ is represented by a finite étale S-scheme with nonempty fibers. We may suppose that G is split relative to T. If E is the set of vectorial subsets of the root system R, then $\mathcal{C}$ is represented by E_S, by 3.9. □

Corollary 3.17.— *All the functors in the preceding diagram are representable by S-schemes that are smooth over S, and all are affine over S except* $\underline{\mathrm{Par}}(G)$.

Remark 3.18.—

(i) *The fact that $f : PL \to \underline{\mathrm{Crit}}(G)$ is étale and surjective says that a subgroup of G is critical if and only if, locally for the étale topology, it is a Levi subgroup of a parabolic subgroup.*

In general the map $PL(S) \to \underline{\mathrm{Crit}}(G)(S)$ need not be surjective: a critical subgroup C may fail to arise over S from a parabolic subgroup. For example, a maximal torus

need not be contained in a Borel subgroup, as for a nonsplit form of SL_2 (Exp. XX, §5).

(ii) *Likewise,*

$$u : \mathrm{Of}(\underline{\mathrm{Dyn}}(G)) \longrightarrow \mathcal{C}\ell_{\mathrm{crit}}$$

need not be an isomorphism. Two parabolic subgroups of different types may have Levi subgroups of the same type. In a group of type A_2*, for instance, the two types of parabolics whose Levi subgroups have semisimple rank* 1 *correspond to the two vertices of the diagram, whereas there is only one type of critical subgroup of rank* 1.

The analogous example for type A_3 *shows that, even over an algebraically closed field, nonisomorphic parabolic subgroups may have Levi subgroups of the same type.*[14]

We end this section with an application to principal bundles.

Lemma 3.20.— *Let*[15] S *be a scheme,* G *an* S*-reductive group,* F *a principal homogeneous bundle under* G*, and* G_F *the corresponding twisted form. Identify* $\underline{\mathrm{Dyn}}(G)$ *with* $\underline{\mathrm{Dyn}}(G_F)$ (Exp. XXIV, 3.5)*. For every parabolic subgroup* P *of* G*, there is a canonical isomorphism*

$$F/P \xrightarrow{\sim} \underline{\mathrm{Par}}_{t(P)}(G_F).$$

In particular, the structural group of F *reduces to* P *if and only if* G_F *has a parabolic subgroup of type* $t(P)$*.*

The proof is exactly the same as that of Exp. XXIV, 4.2.1.

3.21. If S is a scheme, G an S-reductive group, and

$$t \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S),$$

write $H^1_t(S,G)$ for the subset of $H^1(S,G)$ consisting of the classes of principal G-bundles F for which the associated group G_F has a parabolic subgroup of type t. If G itself has a parabolic subgroup P of type t, then $H^1_t(S,G)$ is precisely the image of $H^1(S,P)$ in $H^1(S,G)$, and hence does not depend on the chosen P.

[14] *Editor's note.* Concretely, in GL_4, the parabolics

$$P = \left\{ \begin{pmatrix} * & * & * & * \\ 0 & * & * & * \\ 0 & 0 & * & * \\ 0 & 0 & 0 & * \end{pmatrix} \right\}, \qquad P' = \left\{ \begin{pmatrix} * & * & * & * \\ 0 & * & * & * \\ 0 & * & * & * \\ 0 & 0 & 0 & * \end{pmatrix} \right\}$$

are not isomorphic (their unipotent radicals are not isomorphic), while their Levi subgroups

$$L = \left\{ \begin{pmatrix} * & * & 0 & 0 \\ * & * & 0 & 0 \\ 0 & 0 & * & 0 \\ 0 & 0 & 0 & * \end{pmatrix} \right\}, \quad L' = \left\{ \begin{pmatrix} * & 0 & 0 & 0 \\ 0 & * & * & 0 \\ 0 & * & * & 0 \\ 0 & 0 & 0 & * \end{pmatrix} \right\}$$

are conjugate by $\left(\begin{smallmatrix} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{smallmatrix}\right)$.

[15] *Editor's note.* The numbering of the original is retained: there is no §3.19.

4. Relative position of two parabolic subgroups

4.1. A preliminary result

Lemma 4.1.1.— *Let k be a field, G a reductive k-group, and P, P' two parabolic subgroups of G.*

(i) *The intersection $P \cap P'$ is smooth, has the same reductive rank as G, and contains a maximal torus T of G.*

(ii) *The set R' of roots of $P \cap P'$ relative to T is a closed subset of the set R of roots of G relative to T.*

16

Proof. Suppose first that k is algebraically closed. Let B (respectively B') be a Borel subgroup of P (respectively P'). There is an element $g \in G(k)$ such that $\mathrm{int}(g)B = B'$. On the other hand, if T_0 is a maximal torus of B and $N = \underline{\mathrm{Norm}}_G(T_0)$, Bruhat's theorem (*Bible*, §13.4, Corollary 1 to Theorem 3) gives

$$G(k) = B(k)N(k)B(k).$$

Thus there are $b, b_1 \in B(k)$ and $n \in N(k)$ such that $g = bnb_1$, and hence $\mathrm{int}(b)\,\mathrm{int}(n)B = B'$. Consequently

$$P \cap P' \supset B \cap B' = \mathrm{int}(b)\big(B \cap \mathrm{int}(n)B\big) \supset \mathrm{int}(b)T_0.$$

Now let k be arbitrary. The preceding result shows that $P_{\bar{k}} \cap P'_{\bar{k}}$ contains a maximal torus of $G_{\bar{k}}$. By Exp. XXII, 5.4.5, $(P \cap P')_{\bar{k}}$ is smooth along the identity section; since the base is a field, it is therefore smooth (Exp. $\mathrm{VI_A}$, 1.3.1), and so $P \cap P'$ is smooth. By Exp. $\mathrm{VI_A}$, 2.3.1, the identity component $(P \cap P')^0$ is an open subgroup of $P \cap P'$, smooth over k. Applying Exp. XIV, 1.1 to it proves (i).

Finally, the set R_P (respectively $R_{P'}$) of roots of P (respectively P') relative to T is closed, and

$$R' = R_P \cap R_{P'}.$$

This proves (ii). □

Remark 4.1.2.— *One can prove* ([BT65], 4.5) *that $P \cap P'$ is connected; this fact will be used in 4.5.1.*

17

Remark 4.1.3.— *The preceding lemma is false over an arbitrary scheme. For example, let G be a reductive group over an algebraically closed field k, and let B be a Borel subgroup of G. Take $S = G$ as base and consider the Borel subgroups B_1, B_2 of G_G, where*

$$B_1 = B_G, \qquad B_2 = \mathrm{int}(g_0)B_1,$$

and g_0 is the canonical (diagonal) section of G_G. For every $g \in G(k)$, the fiber of $B_1 \cap B_2$ at g is $B \cap \mathrm{int}(g)B$. If $B \neq G$, the dimension of this fiber varies with g, so $B_1 \cap B_2$ cannot be smooth over G.

[16] *Editor's note.* Part (ii), which will be useful in 4.5.1, was added by the editors.

[17] *Editor's note.* In view of the details added in 4.5.1, the original wording "we shall not use this fact" was changed.

4.2. Transversal position

Theorem 4.2.1.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G. The following conditions on the pair (P, Q) are equivalent:*

(i) $\mathrm{Lie}(P/S) + \mathrm{Lie}(Q/S) = \mathrm{Lie}(G/S)$.

(ii) *The canonical morphism $P \times_S Q \to G$ is smooth.*

(ii′) *The canonical morphism $P \to G/Q$ is smooth.*

(iii) *The canonical morphism $P \times_S Q \to G$ is open.*

(iii′) *The canonical morphism $P \to G/Q$ is open.*

(iv) *The canonical morphism $P \times_S Q \to G$ is fiberwise dominant.*

(iv′) *The canonical morphism $P \to G/Q$ is fiberwise dominant.*

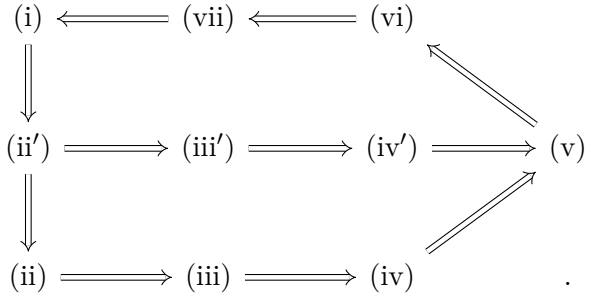
(v) *For every $s \in S$, the group $P_s \cap Q_s$ has minimum dimension, that is,*

$$\dim(P_s \cap Q_s) = \dim P_s + \dim Q_s - \dim G_s.$$

(vi) *There is an étale covering family $\{S_i \to S\}$ and, for every i, a Borel subgroup B_i of P_{S_i} and a Borel subgroup B_i' of Q_{S_i}, such that $B_i \cap B_i'$ is a maximal torus of G_{S_i}.*

(vii) *There is an étale covering family $\{S_i \to S\}$ and, for every i, a splitting $(T_i, \dots, R_i)$ of G_{S_i} and a system R_i^+ of positive roots of R_i, such that P_{S_i} (respectively Q_{S_i}) is the subgroup of type* (R) *of G_{S_i} containing T_i and defined by a subset $R_i^{(1)}$ (respectively $R_i^{(2)}$) of R_i containing R_i^+ (respectively $-R_i^+$); see Exp. XXII, 5.4.2 and 5.2.1.*

Proof. We prove the theorem according to the following logical diagram:



The implications (ii) ⇒ (iii) and (ii′) ⇒ (iii′) are immediate. If (iii) holds, the set-theoretic image of $P \times_S Q \to G$ is an open subset of G containing the identity section. Since the fibers of G are connected, this image is dense in every fiber; thus (iv) holds. The implication (iii′) ⇒ (iv′) is identical.

Condition (ii′) implies (ii), by the cartesian diagram

$$\begin{array}{ccc} P \times_S Q & \longrightarrow & G \\ {\scriptstyle \mathrm{pr}_1}\downarrow & & \downarrow \\ P & \longrightarrow & G/Q. \end{array}$$

On the other hand, (iv) or (iv′) implies (v) by dimension theory (EGA IV_2, 5.6.6). Indeed, one may assume $S = \mathrm{Spec}(k)$, with k algebraically closed; every nonempty fiber of the morphism in (iv) at a point of $G(k)$, or of the morphism in (iv′) at a point of $(G/Q)(k)$, is isomorphic to $P \cap Q$.

The implication (vi) ⇒ (vii) follows from Exp. XXII, 5.5.1 (iv) and 5.9.2. Condition (vii) implies (i), because the latter may be checked fpqc-locally. Under (vii) we may therefore suppose that G is split, $P \supset B_{R^+}$, and $Q \supset B_{-R^+}$; then already

$$\mathrm{Lie}(B_{R^+}) + \mathrm{Lie}(B_{-R^+}) = \mathrm{Lie}(G).$$

Let us prove that (i) implies (ii′). Let $u : P \to G/Q$ be the canonical morphism. Smoothness can be checked on geometric fibers, since both P and G/Q are smooth over S; hence we may suppose that S is the spectrum of an algebraically closed field. The morphism u is compatible with the evident action of P: $u(pp') = p\,u(p')$. A translation argument (compare the proof of Exp. $\mathrm{VI_B}$, 1.3) therefore reduces smoothness to the point $e \in P(k)$. By SGA 1, II, 4.7, it is enough that the tangent map at e be surjective. This map is naturally identified with

$$\mathrm{Lie}(P) \longrightarrow \mathrm{Lie}(G)/\mathrm{Lie}(Q),$$

which is surjective under (i).

It remains to prove (v) ⇒ (vi). Suppose first that S is the spectrum of an algebraically closed field. By 4.1.1 there is a maximal torus T contained in P and Q. Let R, R_1, and R_2 be the respective sets of roots of G, P, and Q relative to T. By Exp. XXII, 5.4.4 and 5.4.5,

$$\dim G = \dim T + \mathrm{Card}(R), \qquad \dim P = \dim T + \mathrm{Card}(R_1),$$
$$\dim Q = \dim T + \mathrm{Card}(R_2), \quad \dim(P \cap Q) = \dim T + \mathrm{Card}(R_1 \cap R_2).$$

Condition (v) is therefore equivalent to

$$\mathrm{Card}(R_1 \cap R_2) = \mathrm{Card}(R_1) + \mathrm{Card}(R_2) - \mathrm{Card}(R),$$

that is, to $R_1 \cup R_2 = R$. By Exp. XXII, 5.9.2 and 5.4.5, it is enough to prove that $R_1 \cap (-R_2)$ contains a system of positive roots of R. We are thus reduced to the following lemma.

Lemma 4.2.2.— *Let R be a "root system"—for example, the set of roots of a root datum in the sense of Exposé XXI. Let R_1, R_2 be two closed subsets of R, each containing a system of positive roots. If $R_1 \cup R_2 = R$, then $R_1 \cap (-R_2)$ contains a system of positive roots.*

Indeed, $R_3 = R_1 \cap (-R_2)$ is closed, so by Exp. XXI, 3.3.6 it is enough to show that $R_3 \cup (-R_3) = R$. Now

$$R_1 \cup (-R_1) = R = R_2 \cup (-R_2),$$

and the conclusion follows from the following elementary fact. If A, A', B, B' are four subsets of a set E, and

$$A \cup A' = B \cup B' = A \cup B = A' \cup B' = E,$$

then

$$(A \cap B') \cup (A' \cap B) = E.$$

This proves (v) ⇒ (vi) over the spectrum of an algebraically closed field. Return now to the general case and suppose (v) holds. Let $s \in S$. By the preceding argument, there

is a Borel subgroup $\bar{B}$ of $P_{\bar{s}}$ and a Borel subgroup $\bar{B}'$ of $Q_{\bar{s}}$ such that $\bar{B} \cap \bar{B}'$ is a maximal torus of $G_{\bar{s}}$.

The S-scheme

$$\underline{\mathrm{Bor}}(P) \simeq \underline{\mathrm{Bor}}(P/\operatorname{rad}^u(P))$$

of Borel subgroups of P is smooth. Applying "Hensel's lemma" (Exp. XI, 1.10) and working étale-locally around s, we may suppose that there is a Borel subgroup B of P specializing to $\bar{B}$. Similarly, there is a Borel subgroup B' of Q specializing to $\bar{B}'$. Since $\bar{B} \cap \bar{B}'$ is a maximal torus of $G_{\bar{s}}$, some open neighborhood U of s has the property that $B_U \cap B'_U$ is a maximal torus of G_U (Exp. XXII, 5.9.4). This proves (vi). □

Definition 4.2.3.— *A pair (P, Q) satisfying the equivalent conditions* (i)–(vii) *of Theorem 4.2.1 is said to be in* transversal position. *One also says that P is in transversal position relative to Q, or, by an abuse of language, that P and Q are in (mutual) transversal position.*

In view of (vi), this definition agrees, for Borel subgroups, with that of Exp. XXII, 5.9.1.

Corollary 4.2.4.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G.*

(i) *The pair (P, Q) is in transversal position if and only if, for every $s \in S$, the pair $(P_{\bar{s}}, Q_{\bar{s}})$ is in transversal position. If $S' \to S$ is surjective and $(P_{S'}, Q_{S'})$ is in transversal position, then so is (P, Q).*

(ii) *There is an open subscheme $U \subset S$ with the following property: a morphism $S' \to S$ factors through U if and only if $(P_{S'}, Q_{S'})$ is in transversal position.*

(iii) *Consider the subfunctors*

$$\underline{\mathrm{Gen}}(G) \subset \underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G), \qquad \underline{\mathrm{Gen}}(/Q) \subset \underline{\mathrm{Par}}(G), \qquad \underline{\mathrm{Gen}}(P/Q) \subset G,$$

defined as follows. For $S' \to S$, the set $\underline{\mathrm{Gen}}(G)(S')$ consists of pairs of parabolic subgroups of $G_{S'}$ in transversal position; $\underline{\mathrm{Gen}}(/Q)(S')$ consists of parabolic subgroups of $G_{S'}$ in transversal position relative to $Q_{S'}$; and $\underline{\mathrm{Gen}}(P/Q)(S')$ consists of the $g \in G(S')$ such that $\mathrm{int}(g)P_{S'}$ is in transversal position relative to $Q_{S'}$.

Each of these functors is represented by an open subscheme, universally schematically dense over S, of the corresponding S-scheme

$$\underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G), \qquad \underline{\mathrm{Par}}(G), \qquad G,$$

respectively.

[18]

Assertion (i) follows immediately from condition 4.2.1(i). For (ii), take

$$U = S - \mathrm{Supp}(\mathrm{Coker}\, u),$$

where

$$u : \mathrm{Lie}(P) \oplus \mathrm{Lie}(Q) \longrightarrow \mathrm{Lie}(G)$$

[18] *Editor's note.* The original expression "relatively dense" was replaced by "universally schematically dense over S"; compare EGA IV$_3$, Definition 11.10.8.

is the canonical morphism.[19]

There are cartesian diagrams

$$\begin{array}{ccc} G & \xrightarrow{f} & \underline{\mathrm{Par}}(G) \\ \uparrow & & \uparrow \\ \underline{\mathrm{Gen}}(P/Q) & \longrightarrow & \underline{\mathrm{Gen}}(/Q) \end{array} \qquad \begin{array}{ccc} \underline{\mathrm{Par}}(G) & \xrightarrow{f'} & \underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G) \\ \uparrow & & \uparrow \\ \underline{\mathrm{Gen}}(/Q) & \longrightarrow & \underline{\mathrm{Gen}}(G), \end{array}$$

where $f(g) = \mathrm{int}(g)P$ and $f'(R) = (R, Q)$. It therefore suffices to prove (iii) for $\underline{\mathrm{Gen}}(G)$.

Let P_0 be the canonical parabolic subgroup of $G_{\underline{\mathrm{Par}}(G)}$, and set

$$X = \underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G), \qquad P = \mathrm{pr}_1^*(P_0), \qquad Q = \mathrm{pr}_2^*(P_0).$$

Applying (ii) to the parabolic subgroups P, Q of G_X constructs an open subscheme $U \subset X$, which is immediately identified with $\underline{\mathrm{Gen}}(G)$. The density assertion may be checked on geometric fibers,[20] so assume $S = \mathrm{Spec}(k)$, where k is algebraically closed. Since $\underline{\mathrm{Par}}(G)$ is smooth, it is enough to show that $\underline{\mathrm{Gen}}(G)$ meets every irreducible component of $\underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G)$. By 3.3, this amounts to the following: given $t, t' \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S)$, find a pair (P, P') in transversal position such that $t(P) = t$ and $t(P') = t'$.

Choose Borel subgroups B, B' of G such that $B \cap B'$ is a maximal torus (split G and apply Exp. XXII, 5.9.2). By 3.8 there are parabolic subgroups $P \supset B$ and $P' \supset B'$ with $t(P) = t$ and $t(P') = t'$. They have the required types and are in transversal position by 4.2.1(vi). □

Corollary 4.2.5.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G, with (P, Q) in transversal position.*

(i) *Let P', Q' be parabolic subgroups of G of the same types as P, Q, respectively. The pair (P', Q') is in transversal position if and only if, étale-locally, it is conjugate to (P, Q).* (In §5 we shall see that the étale topology can be replaced by the Zariski topology.)

(ii) *The canonical morphism $P \times_S Q \to G$ induces a smooth surjective morphism*

$$P \times_S Q \longrightarrow \underline{\mathrm{Gen}}(Q/P)$$

and an isomorphism

$$(P \times_S Q)/(P \cap Q) \xrightarrow{\sim} \underline{\mathrm{Gen}}(Q/P),$$

where $R = P \cap Q$ acts on $P \times_S Q$ by

$$(p, q)r = (pr, r^{-1}q).$$

(iii) *The canonical morphism*

$$P \longrightarrow \underline{\mathrm{Par}}_{t(Q)}(G), \qquad p \longmapsto \mathrm{int}(p)Q,$$

induces a smooth surjective morphism

$$P \longrightarrow \underline{\mathrm{Gen}}(/P) \cap \underline{\mathrm{Par}}_{t(Q)}(G)$$

and an isomorphism

$$P/(P \cap Q) \xrightarrow{\sim} \underline{\mathrm{Gen}}(/P) \cap \underline{\mathrm{Par}}_{t(Q)}(G).$$

[19] *Editor's note.* The second summand, printed as $\mathrm{Lie}(G)$, has been corrected to $\mathrm{Lie}(Q)$; this is the map used in Theorem 4.2.1(i).

[20] *Editor's note.* Compare EGA IV_3, 11.10.10.

(iv) *The canonical morphism*

$$G \longrightarrow \underline{\mathrm{Par}}_{t(P)}(G) \times_S \underline{\mathrm{Par}}_{t(Q)}(G), \qquad g \longmapsto (\mathrm{int}(g)P, \mathrm{int}(g)Q),$$

induces a smooth surjective morphism

$$G \longrightarrow \underline{\mathrm{Gen}}(G) \cap (\underline{\mathrm{Par}}_{t(P)}(G) \times_S \underline{\mathrm{Par}}_{t(Q)}(G))$$

and an isomorphism

$$G/(P \cap Q) \xrightarrow{\sim} \underline{\mathrm{Gen}}(G) \cap (\underline{\mathrm{Par}}_{t(P)}(G) \times_S \underline{\mathrm{Par}}_{t(Q)}(G)).$$

Proof. Let us prove (i). The stated condition is plainly sufficient. Conversely, suppose (P', Q') is in transversal position. Since P and P' are conjugate étale-locally, we may assume $P = P'$. It is then enough to show that two parabolic subgroups Q, Q', of the same type and both in transversal position relative to P, are étale-locally conjugate by a section of P.

By 4.2.1(vi), after another étale localization there are Borel subgroups $B, B' \subset P$, $B_1 \subset Q$, and $B'_1 \subset Q'$ such that

$$B \cap B_1 = T, \qquad B' \cap B'_1 = T'$$

are maximal tori of G. The Killing pairs (B, T) and (B', T') of P are étale-locally conjugate in P (1.16). We may therefore assume $B = B'$ and $T = T'$. Then $B_1 = B'_1$ by Exp. XXII, 5.9.2, and hence $Q = Q'$ by 3.8.

Parts (ii), (iii), and (iv) are proved in parallel. We prove (ii). Let $g \in \underline{\mathrm{Gen}}(Q/P)(S)$; thus $g \in G(S)$ and $\mathrm{int}(g)Q$ is in transversal position relative to P. The preceding argument shows that Q and $\mathrm{int}(g)Q$ are, étale-locally, conjugate by a section of P. Working locally for this topology, choose $p \in P(S)$ such that $\mathrm{int}(g)Q = \mathrm{int}(p)Q$. Then

$$p^{-1}g \in \underline{\mathrm{Norm}}_G(Q)(S) = Q(S),$$

so $g = pq$ for some $q \in Q(S)$. Thus the morphism in (ii) is an étale covering. Comparing with 4.2.1(ii), it is smooth and surjective.

Finally, the equivalence relation on $P \times_S Q$ defined by $P \times_S Q \to G$ is exactly the relation associated with the action of $R = P \cap Q$,

$$(p, q)r = (pr, r^{-1}q).$$

This proves the quotient assertion, since a smooth surjective morphism is, in particular, an effective epimorphism. □

Remark 4.2.6.— *If P, Q are in transversal position, the open subset $\underline{\mathrm{Gen}}(Q/P)$ of G will often be denoted $P \cdot Q$; this notation is justified by 4.2.5*(ii).

Proposition 4.2.7.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G, with (P, Q) in transversal position.*

(i) *The group $P \cap Q$ is smooth over S (and in fact has connected fibers by 4.1.2). Its identity component $(P \cap Q)^0$* (Exp. $\mathrm{VI_B}$, 3.10) *is a subgroup of type* (RC) *of G* (Exp. XXII, 5.11.1)*, and its unipotent radical* (loc. cit., 5.11.4) *decomposes as the direct product*

$$\mathrm{rad}^u((P \cap Q)^0) = (\mathrm{rad}^u(P) \cap Q) \times_S (P \cap \mathrm{rad}^u(Q)).$$

(ii) *If S is affine, then*

$$H^1(S, \mathrm{rad}^u((P \cap Q)^0)) = 0.$$

If S is semilocal, $P \cap Q$ contains a maximal torus of G.

Proof. The group $P \cap Q$ is smooth by 4.2.1(ii) and the cartesian diagram

$$\begin{array}{ccc} P \times_S Q & \longrightarrow & G \\ \uparrow & & \uparrow \\ P \cap Q & \longrightarrow & S \end{array}.$$

The remaining assertions about $(P \cap Q)^0$ may be checked étale-locally. By 4.2.1(vii), choose a splitting (G, T, M, R) of G such that P, Q contain T and are defined by subsets R_1, R_2 of R, where R_1 contains a system R^+ of positive roots and R_2 contains the opposite system R^-. Let Δ be the set of simple roots of R^+, and put

$$A_1 = \Delta \cap (-R_1), \qquad A_2 = \Delta \cap R_2, \qquad A = A_1 \cap A_2.$$

By 1.4(v) and 1.12,

$$R_1 = R^+ \cup (R^- \cap (-\mathbb{N}A_1)), \qquad R_2 = (R^+ \cap \mathbb{N}A_2) \cup R^-,$$
$$\mathrm{rad}^u(P) = \prod_{\substack{\alpha \in R_1 \\ \alpha \notin -R_1}} U_\alpha, \qquad \mathrm{rad}^u(Q) = \prod_{\substack{\alpha \in R_2 \\ \alpha \notin -R_2}} U_\alpha.$$

Exp. XXII, 5.6.7 therefore gives

$$\mathrm{rad}^u(P) \cap Q = \prod_{\substack{\alpha \in R_1 \cap R_2 \\ \alpha \notin -R_1}} U_\alpha = \prod_{\alpha \in K_2} U_\alpha,$$
$$\mathrm{rad}^u(Q) \cap P = \prod_{\substack{\alpha \in R_1 \cap R_2 \\ \alpha \notin -R_2}} U_\alpha = \prod_{\alpha \in K_1} U_\alpha,$$

where K_2 consists of the positive roots that are linear combinations of elements of A_2, but not of elements of A, and K_1 consists of the negative roots that are linear combinations of elements of A_1, but not of elements of A. If $\alpha \in K_2$ and $\beta \in K_1$, then $\alpha + \beta$ is neither a root nor zero. Hence the two groups displayed above commute.

By Exp. XXII, 5.4.5, the group

$$H = (P \cap Q)^0$$

is defined by the set of roots

$$R_1 \cap R_2 = (R^+ \cap \mathbb{N}A_2) \cup (R^- \cap (-\mathbb{N}A_1)).$$

This set is closed, so H is of type (RC) by definition (Exp. XXII, 5.11.1). By loc. cit., 5.11.3 and 5.11.4,

$$\mathrm{rad}^u(H) = \prod_{\alpha \in K} U_\alpha,$$

where K consists of the $\alpha \in R_1 \cap R_2$ such that $\alpha \notin -(R_1 \cap R_2)$. The symmetric part of $R_1 \cap R_2$ is $R \cap \mathbb{Z}A$, and therefore $K = K_1 \cup K_2$. This proves (i).

The first assertion of (ii) follows from (i) and 2.10. For the second, the reductive group

$$(P \cap Q)^0 / \operatorname{rad}^u((P \cap Q)^0)$$

has a maximal torus $\bar{T}$ when the base is semilocal. The inverse image N of $\bar{T}$ in $(P \cap Q)^0$ is a subgroup of type (R) of G, with solvable fibers, and

$$N^u = \operatorname{rad}^u((P \cap Q)^0)$$

(Exp. XXII, 5.6.9). The scheme of maximal tori of N is a principal homogeneous bundle under N^u (loc. cit., 5.6.13), and therefore has a section because $H^1(S, N^u) = 0$. □

4.3. Opposite parabolic subgroups

4.3.1. Let G be an S-reductive group. Exp. XXIV, 3.16.6 defines a canonical "outer automorphism" s_G of G, of order at most 2.[21] It induces a canonical automorphism, again of order at most 2, of $\underline{\mathrm{Dyn}}(G)$, and hence of $\mathrm{Of}(\underline{\mathrm{Dyn}}(G))$. We denote all of these automorphisms by s_G, or simply by s. Two types of parabolic subgroups

$$t, t' \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S)$$

are said to be *opposite* if $t = s_G(t')$.

Theorem 4.3.2.— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G.*

(a) *If L is a Levi subgroup of P, there is a unique parabolic subgroup P' of G such that $P \cap P' = L$.*

(b) *For every parabolic subgroup Q of G, the following conditions are equivalent:*

(i) *For every $s \in S$, the identity component $\big((P \cap Q)_{\bar{s}}\big)^0$, which is smooth by 4.1.1, is reductive.*

(ii) *The group $P \cap Q$ is a Levi subgroup of both P and Q.*

(iii) *The groups P, Q have opposite types and the pair (P, Q) is in transversal position.*

(iv) *The groups P, Q have opposite types and* $\operatorname{rad}^u(P) \cap Q = e$.

(v)
$$\operatorname{rad}^u(P) \cap Q = \operatorname{rad}^u(Q) \cap P = e.$$

(vi) *The canonical morphism* $\operatorname{rad}^u(P) \times_S Q \to G$ *is an open immersion.*

(vi′) *The canonical morphism* $\operatorname{rad}^u(P) \to G/Q$ *is an open immersion.*

(vii) *There is an étale covering family $\{S_i \to S\}$ and, for every i, a splitting (T_i, M_i, R_i) of G_{S_i} and a subset $R_i^{(1)} \subset R_i$, such that P_{S_i} is the subgroup of type* (R) *containing T_i and defined by $R_i^{(1)}$, while Q_{S_i} is the subgroup defined by*

$$R_i^{(2)} = -R_i^{(1)}.$$

[21] *Editor's note.* "Of order 2" was replaced by "of order at most 2", since s_G may be trivial, for example when G has type $A_1, B_n, C_n, \ldots$.

Proof. We first prove part (b). Conditions (iii) and (vii) are equivalent by 4.2.1(vii) and the definition of s_G in the split case (Exp. XXIV, 3.16.2(iv)). Plainly (ii) implies (i), and (vi′) implies (vi) by base change along $G \to G/Q$.

Suppose now that (vii) holds. Since every assertion to be proved is étale-local, assume that $G = (G, T, M, R)$ is split, that P is defined by $R' \subset R$, and that Q is defined by $-R'$. Let L be the subgroup of type (R) containing T and defined by $R' \cap (-R')$. By Exp. XXII, 5.11.3, L is a Levi subgroup of both P and Q. Moreover,

$$P = L \cdot \mathrm{rad}^u(P), \qquad Q = L \cdot \mathrm{rad}^u(Q),$$

and Exp. XXII, 5.6.7 gives

$$\mathrm{rad}^u(P) \cap Q = Q \cap \mathrm{rad}^u(P) = e.$$

Thus $P \cap Q = L$, proving (ii) and (v).

Since P, Q are in transversal position, the canonical morphism $P \to G/Q$ induces an open immersion

$$P/(P \cap Q) \longrightarrow G/Q$$

by 4.2.1. The canonical morphism

$$\mathrm{rad}^u(P) \longrightarrow P/(P \cap Q) = P/L$$

is an isomorphism, so (vi′) follows. Hence all the conditions follow from (vii).

It remains to show that each of (i), (iv), (v), and (vi) implies (vii). Since the equivalence of (ii) and (iii) is already known, this may be checked on geometric fibers. We may suppose that S is the spectrum of an algebraically closed field. By 4.1.1, a maximal torus T of G is contained in $P \cap Q$. Let R, R_1, R_2 be the sets of roots of G, P, Q, respectively, relative to T. Write

$$R_1^a = \{\alpha \in R_1 \mid -\alpha \notin R_1\},$$

and define R_2^a similarly. We must prove $R_1 = -R_2$.

- Condition (i) says that $R_1 \cap R_2$ is symmetric. If $\alpha \in R_1$ and $\alpha \notin R_2$, then $\alpha \in -R_2$; if $\alpha \in R_2$, then
$$\alpha \in R_1 \cap R_2 = -(R_1 \cap R_2) \subset -R_2.$$
Thus $R_1 \subset -R_2$, and symmetry gives $R_1 = -R_2$.

- Condition (iv) gives $\mathrm{Card}(R_1) = \mathrm{Card}(R_2)$ and $R_1^a \cap R_2 = \varnothing$. The latter condition is equivalent to $R_2 \subset -R_1$, and equality of cardinalities then gives $R_2 = -R_1$.

- Condition (v) gives
$$R_1^a \cap R_2 = R_2^a \cap R_1 = \varnothing.$$
Hence $R_2 \subset -R_1$ and $R_1 \subset -R_2$, so again $R_2 = -R_1$.

- Condition (vi) gives
$$\mathrm{Lie}(\mathrm{rad}^u(P)) \oplus \mathrm{Lie}(Q) = \mathrm{Lie}(G).$$
Thus R is the disjoint union of R_2 and R_1^a, which implies $R_2 = -R_1$.

This proves part (b). For part (a), the implication (vii) ⇒ (ii) already gives the desired parabolic subgroup P' étale-locally. It remains only to prove uniqueness, and this too is étale-local. We may suppose that G is split relative to a maximal torus T of L, with P and P' defined by subsets R_1 and R'_1 of R. By hypothesis $R_1 \cap R'_1$ is symmetric. The preceding argument gives $R'_1 = -R_1$; hence P' is determined by P and L. □

Definition 4.3.3.— *Two parabolic subgroups of G satisfying the equivalent conditions* (i)–(vii) *of Theorem 4.3.2 are said to be* opposite. *If P is a parabolic subgroup of G and L is a Levi subgroup of P, the* parabolic subgroup opposite to P relative to L *is the unique parabolic subgroup Q of G such that $P \cap Q = L$.*

If T is a maximal torus of P, the parabolic subgroup opposite to P relative to T *is the unique Q such that $P \cap Q$ is the unique Levi subgroup of P containing T* (1.6)*; equivalently, it is the unique Q such that $P \cap Q$ contains T and P, Q are opposite.*

By 4.3.2(iii), Corollaries 4.2.4 and 4.2.5 immediately yield parallel results. We record one sample.

Corollary 4.3.4.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G.*

(i) *The groups P, Q are opposite if and only if $P_{\bar{s}}, Q_{\bar{s}}$ are opposite for every $s \in S$. If $S' \to S$ is surjective and $P_{S'}, Q_{S'}$ are opposite, then P, Q are opposite.*

(ii) *Let $\underline{\mathrm{Opp}}(G)(S')$ be the set of pairs of opposite parabolic subgroups of $G_{S'}$, for $S' \to S$. This functor is represented by an open subscheme of $\underline{\mathrm{Par}}(G)^2$. Let $\underline{\mathrm{Opp}}(/P)(S')$ be the set of parabolic subgroups of $G_{S'}$ opposite to $P_{S'}$. This functor is represented by an open subscheme, universally schematically dense over S, of*

$$\underline{\mathrm{Par}}_{s(t(P))}(G).$$

(iii) *Suppose P, Q are opposite, and let P', Q' be parabolic subgroups of G, with P' of the same type as P. The groups P', Q' are opposite if and only if, étale-locally, the pair (P', Q') is conjugate to (P, Q).* (In §5 the étale topology will be replaced by the Zariski topology.)

[22]

Corollary 4.3.5.— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G.*

(i) *The morphism*

$$\underline{\mathrm{Opp}}(/P) \longrightarrow \underline{\mathrm{Lev}}(P), \qquad Q \longmapsto P \cap Q,$$

is an isomorphism. The scheme $\underline{\mathrm{Opp}}(/P)$ is a principal homogeneous bundle under $\mathrm{rad}^u(P)$, acting by inner automorphisms. If S is affine, G has a parabolic subgroup opposite to P.

(ii) *Suppose S is semilocal, with closed points $\{s_i\}$. For each i, let Q_i be a parabolic subgroup of G_{s_i} opposite to P_{s_i}. There is a parabolic subgroup Q of G, opposite to P, such that $Q_{s_i} = Q_i$ for every i.*

[22] *Editor's note.* Here again, "relatively dense" was replaced by "universally schematically dense over S"; compare EGA IV$_3$, Definition 11.10.8.

(iii) *The morphism*

$$\underline{\mathrm{Opp}}(G) \longrightarrow \mathrm{PL}, \qquad (P,Q) \longmapsto (P, P \cap Q),$$

is an isomorphism.

These assertions follow from Theorem 4.3.2(a) and from 1.9, 2.3, and 2.8.

Remark 4.3.6.— *Let P, Q be opposite parabolic subgroups of G, and let $P \cdot Q$ be the open subscheme of G, introduced in 4.2.6, which is the sheaf-theoretic image of $P \times_S Q$. The product morphism $G \times_S G \to G$ induces isomorphisms*

$$\mathrm{rad}^u(P) \times_S Q \xrightarrow{\sim} P \cdot Q \xleftarrow{\sim} P \times_S \mathrm{rad}^u(Q).$$

Indeed, this follows from 4.3.2 (or 4.2.5(ii)) and from the fact that $P \cap Q$ is a Levi subgroup of both P and Q:

$$P = \mathrm{rad}^u(P) \cdot (P \cap Q), \qquad Q = \mathrm{rad}^u(Q) \cdot (P \cap Q).$$

Likewise, there is a commutative diagram

$$\begin{array}{ccc} \mathrm{rad}^u(P) & \hookrightarrow & G/Q \\ \downarrow \sim & & \downarrow \sim \\ \underline{\mathrm{Opp}}(/P) & \hookrightarrow & \underline{\mathrm{Par}}_{t(Q)}(G), \end{array}$$

in which the vertical arrows are induced by $g \mapsto \mathrm{int}(g)Q$.

4.4. Osculating position

Proposition 4.4.1.— *Let S be a scheme, G an S-reductive group, and P, Q two parabolic subgroups of G. The following conditions are equivalent:*

(i) *$P \cap Q$ is a parabolic subgroup of G.*

(ii) *Étale-locally, $P \cap Q$ contains a Borel subgroup of G.*

(iii) *Étale-locally, $P \cap Q$ contains a maximal torus of G; moreover, for every $S' \to S$ and every maximal torus T of $G_{S'}$ contained in both $P_{S'}$ and $Q_{S'}$, the parabolic subgroup opposite to $P_{S'}$ relative to T is in transverse position relative to $Q_{S'}$.*

(iv) *There is an étale covering family $\{S_i \to S\}$ and, for each i, a maximal torus T_i of G_{S_i}, contained in both P_{S_i} and Q_{S_i}, such that the parabolic subgroup opposite to P_{S_i} relative to T_i is in transverse position relative to Q_{S_i}.*

(v) *There is an étale covering family $\{S_i \to S\}$ and, for each i, a splitting (T_i, M_i, R_i) of G_{S_i} such that P_{S_i}, respectively Q_{S_i}, is the subgroup of type* (R) *of G_{S_i} containing T_i and defined by a set of roots $R_i^{(1)}$, respectively $R_i^{(2)}$, with $R_i^{(1)} \cap R_i^{(2)}$ containing a system of positive roots of R_i.*

Moreover, when these conditions hold,

$$t(P \cap Q) = t(P) \cap t(Q)$$

in the notation of 3.2.

The implications (v)⇒(ii) and (iii)⇒(iv) are immediate. Moreover, (ii)⇒(i) follows from 1.18. To prove (iv)⇒(v), one may suppose that G is split and that P, respectively Q, is defined by a set of roots R_1, respectively R_2. The parabolic subgroup opposite to P is then defined by $-R_1$, and the assertion reduces to Lemma 4.2.2. The implication (i)⇒(iii) is proved in the same way after splitting. Finally, the last assertion may be proved étale-locally: one may suppose that $P \cap Q$ contains a Borel subgroup B of G, and the assertion then reduces to 3.7.

Definition 4.4.2.— *Two parabolic subgroups of G satisfying the equivalent conditions* (i)–(v) *of 4.4.1 are said to be in* osculating position.

Corollary 4.4.3.— *Let P, Q be parabolic subgroups in osculating position, and let P', Q' be parabolic subgroups of G of the same types as P, Q, respectively. The subgroups P', Q' are in osculating position if and only if, étale-locally, the pair (P', Q') is conjugate to the pair (P, Q).*

It is enough to show that, if both P and P' are in osculating position relative to Q, then they are conjugate, étale-locally, by a section of Q. Now $P \cap Q$ and $P' \cap Q$ are parabolic subgroups of the same type contained in Q. By part (ii) of the lemma below, they are therefore conjugate étale-locally by a section of Q. We may consequently suppose $P \cap Q = P' \cap Q$; part (i) of that lemma then gives $P = P'$.

Lemma 4.4.4.— *Let P, P', Q be three parabolic subgroups of the S-reductive group G.*

(i) *The equality $P = P'$ holds if and only if P and P' are in osculating position and have the same type.*

(ii) *Suppose $P \subset Q$ and $P' \subset Q$. If $g \in G(S)$ is such that* $\mathrm{int}(g)P$ *and P' are in osculating position, then $g \in Q(S)$.*

Part (i) follows immediately from the last assertion of 4.4.1. To prove (ii), observe that Q and $\mathrm{int}(g)Q$ both contain $P' \cap \mathrm{int}(g)P$, and hence are in osculating position. They coincide by (i), so that

$$g \in \underline{\mathrm{Norm}}_G(Q)(S) = Q(S).$$

Assertions (iii) and (iv) of Proposition 4.4.1 give at once:

Corollary 4.4.5.— *Let P, P', Q be three parabolic subgroups of the S-reductive group G, containing the same maximal torus T of G. Suppose that P and P' are opposite relative to T. Then Q is in osculating position relative to P if and only if it is in transverse position relative to P'. Under these conditions, $P \cap Q$ is also in transverse position relative to P'.*

Corollary 4.4.6.— *Let P, Q be two parabolic subgroups of G containing the same maximal torus T. The subgroups P, Q are in transverse position if and only if there are parabolic subgroups $P' \subset P$ and $Q' \subset Q$ of G, opposite relative to T. One may even choose*

$$t(P') = t(P) \cap s(t(Q)).$$

[23]

The condition is plainly sufficient, by 4.2.1(i) and 4.3.2(iii). Conversely, let P^-, respectively Q^-, be the parabolic subgroup opposite to P, respectively Q, relative to T. By 4.4.5, $P^- \cap Q$ is in transverse position relative to both P and Q^-, and therefore also relative to $P \cap Q^-$, by another application of 4.4.5. Moreover,

$$\begin{aligned} t(P^- \cap Q) &= t(P^-) \cap t(Q) \\ &= s(t(P)) \cap s(t(Q^-)) \\ &= s\big(t(P) \cap t(Q^-)\big) \\ &= s\big(t(P \cap Q^-)\big). \end{aligned}$$

It follows that

$$P^- \cap Q = P', \qquad P \cap Q^- = Q'$$

are opposite, by 4.3.2(iii). Since $P' \cap Q' \supset T$, they are indeed opposite relative to T.

4.5. Standard position

In this subsection we briefly indicate how some of the preceding results generalize.

Proposition 4.5.1.— *Let P_1, P_2 be two parabolic subgroups of the S-reductive group G. The following conditions are equivalent:*

(i) *$P_1 \cap P_2$ is smooth.*

(ii) *$P_1 \cap P_2$ is a subgroup of type* (R)*, or of type* (RC)*, of G.*

(iii) *Fpqc-locally, $P_1 \cap P_2$ contains a maximal torus of G.*

(iv) *Zariski-locally, $P_1 \cap P_2$ contains a maximal torus of G.*

When S is semilocal, these conditions are also equivalent to:

(v) *$P_1 \cap P_2$ contains a maximal torus of G.*

Proof. Clearly, (iv) implies (iii), and (v) implies (iv) when S is semilocal; condition (ii) implies (i) by Exp. XXII, Definition 5.2.1. We shall prove

$$\text{(i)} \Rightarrow \text{(ii)} \Rightarrow \text{(iii)},$$

and then show that (iii) implies (i) and (iv), as well as (v) when S is semilocal. Put $K = P_1 \cap P_2$. By 4.1.1 and [BT65], 4.5, every geometric fiber $K_{\bar{s}}$ contains a maximal torus $T_{\bar{s}}$ of $G_{\bar{s}}$, is connected, and has, relative to $T_{\bar{s}}$, a closed subset of the roots of $G_{\bar{s}}$. Consequently, if K is smooth over S, then it is a subgroup of type (RC), hence a fortiori of type (R); see Exp. XXII, 5.2.1 and 5.11.1. Thus (i) and (ii) are equivalent.

If K is of type (R), it contains a maximal torus of G étale-locally, by Exp. XXII, 2.2 and Exp. XIX, 6.1. Hence (ii) implies (iii).

Assume (iii), and let us prove that K is smooth. By fpqc descent we may suppose that

$$G = (G, T, M, R)$$

[23] *Editor's note.* The involution s was defined in 4.3.1.

is split, where T is a maximal torus contained in $P_1 \cap P_2$, and that there are closed subsets R_1, R_2 of R such that

$$P_1 = H_{R_1}, \qquad P_2 = H_{R_2}.$$

Since K has connected fibers, Exp. XXII, 5.4.5 gives

$$K = H_{R_1 \cap R_2};$$

therefore K is smooth over S and of type (RC).

Let R_1^s be the symmetric part of R_1, and put $R_1^a = R_1 - R_1^s$; then

$$\mathrm{rad}^u(P_1) = H_{R_1^a}.$$

As observed in the proof of [BT65], 4.4,

$$R' = (R_1^s \cap R_2) \cup R_1^a$$

is a closed subset of R such that $R' \cup (-R') = R$. Hence, by Exp. XXI, 3.3.6, R' contains a system of positive roots of R. Moreover, the symmetric part of R' is $R_1^s \cap R_2^s$, which is contained in $R_1 \cap R_2$.

It follows that

$$P' = K \cdot \mathrm{rad}^u(P_1)$$

is a parabolic subgroup of G, and that K is a subgroup of type (RC) of P' satisfying

$$\mathrm{rad}^u(K) = K \cap \mathrm{rad}^u(P').$$

By 2.11, K therefore has a Levi subgroup L. Exp. XIV, 3.20 and 3.21 then show that K satisfies (iv), and also (v) when S is semilocal. This proves Proposition 4.5.1. □

[24]

Definition 4.5.1.1.— *When the preceding conditions hold, P_1 and P_2 are said to be in* mutual standard position*. This is the case, for example, when they are in transverse position, when they are in osculating position, or when the base is the spectrum of a field. The notion is stable under base extension and is fpqc-local.*

[25]

4.5.2. Let (P, Q) and (P', Q') be two pairs of parabolic subgroups of G in standard position. Define the subfunctor H of G by letting $H(S')$ be the set of $g \in G(S')$ such that

$$\mathrm{int}(g)P = P', \qquad \mathrm{int}(g)Q = Q'.$$

It is a closed subscheme of G, smooth over S and formally a principal homogeneous space under $P \cap Q$. It follows that the following conditions are equivalent:

(i) (P, Q) and (P', Q') are conjugate fpqc-locally;

(ii) (P, Q) and (P', Q') are conjugate étale-locally;

(iii) (P, Q) and (P', Q') are conjugate on every geometric fiber.

The pairs (P, Q) and (P', Q') are then said to have the same *type of mutual position*. This notion is stable under base change and is fpqc-local.

[24] *Editor's note.* The proof of the equivalence, together with condition (v), which was used implicitly in 6.17 of the original edition, was added in the Polo–Gille edition. The original 4.5.1 was consequently divided into Proposition 4.5.1 and Definition 4.5.1.1.

[25] *Editor's note.* See the preceding editorial note. For an example of parabolic subgroups that are not in standard position, see 7.11 below.

4.5.3. Let $\underline{\mathrm{Stand}}(G)$ be the subfunctor of $\underline{\mathrm{Par}}(G)\times_S\underline{\mathrm{Par}}(G)$ formed by the pairs in mutual standard position. The functor $\underline{\mathrm{Stand}}(G)$ is representable. There is a finite étale S-scheme $\underline{\mathrm{TypeStand}}$, the *scheme of types of mutual standard position*, and a smooth morphism of finite presentation with irreducible geometric fibers, hence in particular faithfully flat,

$$t_2 : \underline{\mathrm{Stand}}(G) \longrightarrow \underline{\mathrm{TypeStand}}.$$

This morphism is a quotient of $\underline{\mathrm{Stand}}(G)$ by the action of G: two sections of $\underline{\mathrm{Stand}}(G)$, over any $S' \to S$, have the same type of mutual position if and only if they have the same image under t_2. There is a commutative diagram

$$\begin{array}{ccc} \underline{\mathrm{Stand}}(G) & \xrightarrow{\quad t_2 \quad} & \underline{\mathrm{TypeStand}} \\ \downarrow & & \downarrow q \\ \underline{\mathrm{Par}}(G) \times_S \underline{\mathrm{Par}}(G) & \xrightarrow{t\times t} & \mathrm{Of}(\underline{\mathrm{Dyn}}(G)) \times_S \mathrm{Of}(\underline{\mathrm{Dyn}}(G)). \end{array}$$

The morphism q may be described by descent as follows. Let (P, Q) be a pair of parabolic subgroups of G in mutual standard position, and let T be a maximal torus of $P \cap Q$. The morphism

$$\underline{\mathrm{Norm}}_G(T) \longrightarrow \underline{\mathrm{Stand}}(G), \qquad n \longmapsto (P, \mathrm{int}(n)Q),$$

defined set-theoretically as displayed, induces an isomorphism

$$W_P(T)\backslash W_G(T)/W_Q(T) \xrightarrow{\sim} q^{-1}\big(t(P), t(Q)\big).$$

The left-hand side denotes the sheaf of double cosets. These assertions are immediate; note in particular that

$$t_2^{-1}\big(t_2(P, Q)\big) \simeq G/(P \cap Q).$$

4.5.4. Fix a parabolic subgroup P of G, and let $\underline{\mathrm{Par}}(G; P)$ be the functor of parabolic subgroups of G in standard position relative to P. For every

$$t \in \mathrm{Of}(\underline{\mathrm{Dyn}}(G))(S),$$

put

$$\underline{\mathrm{Par}}_t(G; P) = \underline{\mathrm{Par}}(G; P) \cap \underline{\mathrm{Par}}_t(G).$$

Both functors are obtained from $\underline{\mathrm{Stand}}(G)$ by fiber products, and are therefore represented by S-schemes, smooth and of finite presentation over S, with nonempty fibers. There is a canonical morphism induced by t_2,

$$t_P : \underline{\mathrm{Par}}_t(G; P) \longrightarrow q^{-1}\big(t(P), t\big), \qquad t_P(Q) = t_2(P, Q),$$

which is smooth and of finite presentation, with irreducible geometric fibers. The canonical morphism

$$\underline{\mathrm{Par}}_t(G; P) \longrightarrow \underline{\mathrm{Par}}_t(G)$$

is a surjective monomorphism, and may therefore be viewed as a *cell decomposition* of $\underline{\mathrm{Par}}_t(G)$, indexed by the set of connected components of $q^{-1}(t(P), t)$.

4.5.5. Suppose that the type t is of the form $t(Q)$, where Q is a parabolic subgroup of G in standard position relative to P, and suppose that $P \cap Q$ contains a maximal torus T. Then

$$\underline{\mathrm{Par}}_t(G) \simeq G/Q, \qquad q^{-1}(t(P), t) \simeq W_P(T)\backslash W_G(T)/W_Q(T),$$

and there is a diagram

$$\begin{array}{ccc} \underline{\mathrm{Par}}_{t(Q)}(G;P) & \xrightarrow{\quad f \quad} & W_P(T)\backslash W_G(T)/W_Q(T) \\ \Big\downarrow{\scriptstyle i} & & \\ \underline{\mathrm{Par}}_{t(Q)}(G) & \xrightarrow{\quad\sim\quad} & G/Q. \end{array}$$

Here i is a surjective monomorphism, and f is smooth and of finite presentation, with irreducible geometric fibers. Moreover, if Q_1, Q_2 are two sections of $\underline{\mathrm{Par}}_{t(Q)}(G;P)$, over some $S' \to S$, that is, two parabolic subgroups of $G_{S'}$ which are fpqc-locally conjugate to Q and are in standard position relative to $P_{S'}$, then Q_1, Q_2 are fpqc-locally conjugate by a section of P if and only if

$$f(Q_1) = f(Q_2).$$

If S is the spectrum of an algebraically closed field k, this gives

$$P(k)\backslash G(k)/Q(k) \simeq W_P(T)(k)\backslash W_G(T)(k)/W_Q(T)(k).$$

More generally, suppose that the scheme $W_P(T)\backslash W_G(T)/W_Q(T)$ is constant, of the form E_S, as happens for example when G is split relative to T and S is connected. The subschemes $f^{-1}(e)$, for $e \in E$, then decompose $\underline{\mathrm{Par}}_{t(Q)}(G;P)$ into open and closed subschemes. They are homogeneous spaces under P, smooth and of finite presentation over S, with irreducible geometric fibers.

4.5.6. Return to the general situation of 4.5.4. The scheme $q^{-1}(t(P), t)$ always has two distinguished sections, corresponding respectively to the types "transverse position" and "osculating position". The inverse image of the first section is a relatively dense open subscheme of $\underline{\mathrm{Par}}_t(G;P)$, as seen above; it is the cell of greatest relative dimension in the decomposition.

The inverse image of the second section is presumably a closed subscheme of $\underline{\mathrm{Par}}_t(G;P)$; it is the cell of least relative dimension in the decomposition. [26]

5. Conjugacy theorem

Theorem 5.1.— *Let S be a semilocal scheme, G an S-reductive group, and P, P' two opposite parabolic subgroups of G* (4.3.3)*. Then*

$$\mathrm{rad}^u(P)(S) \cdot P' \cdot P = G.$$

In other words, as u runs through $\mathrm{rad}^u(P)(S)$*, the open subsets $uP' \cdot P$ of G* (4.3.6) *cover all of G.*

The proof is divided into several steps.

[26] *Editor's note.* In this paragraph the Polo–Gille edition corrects $t^{-1}(t(P), t)$ to $q^{-1}(t(P), t)$, and twice corrects $\underline{\mathrm{Par}}_t(G)$ to $\underline{\mathrm{Par}}_t(G;P)$.

5.1.1. It is enough to prove the theorem when S is the spectrum of a field k; this follows at once from 2.6.

5.1.2. Put $L = P \cap P'$. Suppose that L has a Borel subgroup B_L, and let T be a maximal torus of B_L, as in Exp. XXII, 5.9.7. One checks immediately that

$$B = B_L \cdot \mathrm{rad}^u(P)$$

is a Borel subgroup of P. Let B' be the Borel subgroup of G opposite to B relative to T, so that $B \cap B' = T$. After splitting G relative to T, one immediately sees that $B' \subset P'$. We claim that

$$B^u(S) \cdot B' \cdot B \subset \mathrm{rad}^u(P)(S) \cdot P' \cdot P. \tag{x}$$

Indeed,

$$B^u(S) \subset P(S) = \mathrm{rad}^u(P)(S) \cdot L(S) \subset \mathrm{rad}^u(P)(S) \cdot P'(S),$$

so it is enough to observe that $B' \cdot B \subset P' \cdot P$. Thus (x) reduces Theorem 5.1 to the pair (B, B').

5.1.3. The theorem holds when k is algebraically closed: the hypothesis of 5.1.2 is then satisfied, and Exp. XXII, 5.7.10 applies.

5.1.4. The theorem also holds when k is infinite. Indeed, by 2.7,

$$\mathrm{rad}^u(P)(k) \text{ is dense in } \mathrm{rad}^u(P)(\bar{k}),$$

and the theorem holds over $\bar{k}$.

5.1.5. We are therefore reduced to the case of a finite field k. The scheme $\underline{\mathrm{Bor}}(L)$ is a smooth homogeneous space under L; Lang's theorem (Amer. J. Math. **78** (1956)) therefore shows that L has a Borel subgroup B_L. [27] By 5.1.2, we may consequently suppose that $P = B$ and $P' = B'$ are Borel subgroups. We write $T = B \cap B'$.

5.1.6. Let K be an algebraic closure of k. Choose a pinning of (G_K, B_K, T_K), and let R^+, respectively Δ, be the set of positive, respectively simple, roots. By Exp. XXII, 5.7.2, it is enough to prove, for every $\alpha \in \Delta$, that

$$u_\alpha B'^u(K) \subset B^u(k) B'^u(K) B(K). \tag{1}$$

Let α_i be the distinct conjugates of α over k. They belong to Δ, since B is defined over k. Let R' be the set of roots which are linear combinations of the α_i, and put $R'_- = R_- \cap R'$. Since R' is defined over k, there is a subtorus Q of T such that Q_K is the maximal torus of the common kernel of the α_i.

Put

$$Z = \underline{\mathrm{Centr}}_G(Q), \qquad B_Z = B \cap Z, \qquad B'_Z = B' \cap Z$$

(Exp. XXII, 5.10.2). It is enough to verify the desired assertion in Z, namely

$$u_\alpha B'^u_Z(K) \subset B^u_Z(k) B'^u_Z(K) B_Z(K). \tag{2}$$

[27] *Editor's note.* See also [DG70], §III.5, 7.4.

Indeed,

$$(B'^u_Z)_K = \prod_{\beta \in R'_-} U_\beta.$$

Let $R'' = R - R'$, and set

$$V = \prod_{\beta \in R'' \cap R_-} U_\beta.$$

Then

$$(B'^u)_K = (B'^u_Z)_K \cdot V,$$

and $(B_Z)_K$ normalizes V, by Exp. XXII, 5.6.7. From (2) we therefore obtain successively

$$\begin{aligned} u_\alpha B'^u(K) &= u_\alpha B'^u_Z(K) V(K) \\ &\subset B^u_Z(k) B'^u_Z(K) B_Z(K) V(K) \\ &\subset B^u_Z(k) B'^u_Z(K) V(K) B_Z(K), \end{aligned}$$

which immediately gives (1). We are thus reduced to the case $G = Z$, that is, to the case in which $\mathrm{Gal}(K/k)$ acts transitively on the simple roots.

5.1.7. The assertion to be proved says equivalently that G/B is the union of the translates, under $B^u(k)$, of the open image of B'^u. This assertion is unchanged when G is replaced by its adjoint group, or indeed by any group having the same adjoint group. We may therefore suppose that G is adjoint.

5.1.8. Consider the Dynkin diagram of G_K. The Galois group acts transitively on it. But this Galois group has only cyclic quotients, whereas the Dynkin diagram has no cycles. The diagram is consequently of type nA_1, with $n \geq 0$, or mA_2, with $m \geq 0$. Using the canonical decomposition of Exp. XXIV, 5.9, we may write

$$G = \prod_{D/K} G_0,$$

where D is a finite K-scheme and G_0 is either a torus or is of type A_1 or A_2.

By Exp. XXIV, 5.12, the group B comes from a Borel subgroup B_0 of G_0, and T comes from a maximal torus T_0 of G_0; the group B' comes from the Borel subgroup B'_0 of G_0 opposite to B_0 relative to T_0. We have

$$B'^u(k) = B^u_0(D), \qquad B'^u \cdot T \cdot B^u = \prod_{D/k} B'^u_0 \cdot T_0 \cdot B^u_0.$$

It is therefore enough to prove the assertion for the triple (G_0, B_0, T_0).

5.1.9. We may consequently suppose that G has type $\varnothing$, A_1, or A_2. Since G has a Borel subgroup B, it is quasi-split relative to B, by Exp. XXIV, 3.9.1, and hence split if it has type $\varnothing$ or A_1. The theorem is already known in the split case, by Exp. XXII, 5.7.10, so only type A_2 remains.

By Exp. XXIV, 3.11, there is a morphism $E \to \mathrm{Spec}(k)$, a principal Galois bundle under the group $\mathbb{Z}/2\mathbb{Z}$ of automorphisms of the Dynkin diagram of type A_2, such that

$$G = \text{Q-}\acute{\mathrm{E}}\mathrm{p}_{E/\,\mathrm{Spec}(k)}(A_2).$$

If E has a section, G is split and the theorem follows. Otherwise $E = \mathrm{Spec}(k')$, where k'/k is a quadratic extension. Finally, as observed in 5.1.7, we may suppose that G is simply connected, that is, that G is a form of $\mathrm{SL}_{3,k}$.

5.1.10. We are now in the following situation: k is a finite field and k'/k is a quadratic extension. Pin $\mathrm{SL}_{3,k'}$, the group of 3×3 matrices of determinant 1, as follows. Its maximal torus is the group of diagonal matrices, its Borel subgroup is the group of upper triangular matrices, and its root vectors are

$$u_\alpha = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \qquad u_\beta = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{pmatrix}.$$

The big cell Ω is given by

$$\begin{pmatrix} a & b & c \\ d & e & f \\ g & h & i \end{pmatrix} \in \Omega(S) \quad \Longleftrightarrow \quad a \text{ and } ae - bd \text{ are invertible,}$$

and

$$B^u(k) = \left\{ \begin{pmatrix} 1 & \bar{x} & z \\ 0 & 1 & x \\ 0 & 0 & 1 \end{pmatrix} \;\middle|\; x, z \in k',\ z + \bar{z} = x\bar{x} \right\}.$$

We must prove inclusion (1) of 5.1.6. Thus, for every $a, b, c \in K$, we must find $x, z \in k'$ such that $z + \bar{z} = x\bar{x}$ and

$$\begin{pmatrix} 1 & \bar{x} & z \\ 0 & 1 & x \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ a & 1 & 0 \\ b & c & 1 \end{pmatrix} \in \Omega(K). \tag{3}$$

If $a \neq -1$, take $x = z = 0$. If $a = -1$, the required conditions are

$$\begin{cases} z + \bar{z} = x\bar{x}, \\ bz - \bar{x} \neq 0, \\ (b + c)\bar{z} + bx - 1 \neq 0. \end{cases} \tag{4}$$

Let $q \geq 2$ be the number of elements of k. For every $m \in k$, the equation $z + \bar{z} = m$, with $z \in k'$, has q solutions.

If $b = 0$, take $x = 1$. It remains to solve

$$z + \bar{z} = 1, \qquad c\bar{z} \neq 1,$$

which is always possible by the preceding observation.

If $b \neq 0$, take $x = 0$. It remains to solve

$$z + \bar{z} = 0, \qquad z \neq 0, \qquad (b + c)z \neq 1.$$

This is always possible when $q \geq 3$. When $k = \mathbb{F}_2$, it is possible if $b + c \neq 1$, by taking $z = 1$.

It remains to consider $k = \mathbb{F}_2$, $b + c = 1$, and $b \neq 0$. The system becomes

$$z + \bar{z} = x\bar{x}, \qquad bz \neq \bar{x}, \qquad \bar{z} + bx \neq 1.$$

If $b = 1$, or respectively $b \notin k'$, take $x = 1$; the last two conditions become

$$z \neq b^{-1}, \qquad z \neq 1 - b,$$

and follow from any solution of $z + \bar{z} = 1$. Finally, if $b \in k' - k$, take $x = b$ and $z = \bar{b}$. This completes the proof. □

Corollary 5.2.— *Let S be a semilocal scheme, G an S-reductive group, and P, P' two opposite parabolic subgroups of G. The canonical map*

$$\mathrm{rad}^u(P)(S) \cdot \mathrm{rad}^u(P')(S) \longrightarrow (G/P)(S)$$

is surjective. In particular,

$$(G/P)(S) = G(S)/P(S).$$

Every parabolic subgroup Q of G having the same type as P is of the form

$$Q = \mathrm{int}(uu')P$$

with $u \in \mathrm{rad}^u(P)(S)$ and $u' \in \mathrm{rad}^u(P')(S)$.

The second assertion is plainly equivalent to the first, so let us prove the latter. Let s_i be the closed points of S, let V be the open subscheme of G/P which is the image of P' (and is isomorphic to $\mathrm{rad}^u(P')$, by 4.3.6), and take $x \in (G/P)(S)$. By 5.1, for every i there is

$$u_i \in \mathrm{rad}^u(P)\big(\kappa(s_i)\big)$$

such that $u_i x_{s_i}$ is a section of V_{s_i}. Choose $u \in \mathrm{rad}^u(P)(S)$ lifting all the u_i, as permitted by 2.6. Then ux is a section of V, since this may be checked on the closed fibers. Finally,

$$\mathrm{rad}^u(P')(S) \xrightarrow{\sim} V(S)$$

is bijective, and the result follows.

Corollary 5.3.— *Let S be a semilocal scheme, G an S-reductive group, and P, P', Q three parabolic subgroups of G. There is a $g \in G(S)$ such that* $\mathrm{int}(g)Q$ *is in transverse position relative to both P and P'.*

In the notation of 4.2.4(ii), we must show that the universally schematically dense open subscheme

$$\underline{\mathrm{Gen}}(Q/P) \cap \underline{\mathrm{Gen}}(Q/P')$$

of G has a section over S. [28] Choose a parabolic subgroup Q_1 opposite to Q, by 4.3.5(i), and put

$$U = \mathrm{rad}^u(Q), \qquad U' = \mathrm{rad}^u(Q_1).$$

We shall find the desired g in $U(S)U'(S)$. In this form, 4.2.4(i) and 2.6 show that it suffices to work on the fibers over the closed points of S; we may therefore suppose $S = \mathrm{Spec}(k)$.

If k is algebraically closed, there is a $g \in G(k)$ with the required property. By 5.2 it may be written

$$g = uu'q, \qquad u \in U(k), \quad u' \in U'(k), \quad q \in Q(k),$$

and $\mathrm{int}(uu')Q = \mathrm{int}(g)Q$.

Suppose k is infinite. Let V be the open subset of $U \times_k U'$ defined by the cartesian diagram

$$\begin{array}{ccc} U \times_k U' & \longrightarrow & G \\ \uparrow & & \uparrow \\ V & \longrightarrow & \underline{\mathrm{Gen}}(Q/P) \cap \underline{\mathrm{Gen}}(Q/P'). \end{array}$$

[28] *Editor's note.* The Polo–Gille edition replaces "relatively dense" by "universally schematically dense over S"; compare EGA IV$_3$, Definition 11.10.8.

Since $V(\bar{k}) \neq \varnothing$, as just shown, V is dense in $U \times_k U'$; it therefore has a k-point by 2.7.

Suppose finally that k is finite. Lang's theorem, as used in 5.1.5, shows that P, respectively P', has a Borel subgroup B, respectively B', since

$$\underline{\mathrm{Bor}}(P) \simeq \underline{\mathrm{Bor}}(P/\operatorname{rad}^u(P)), \qquad \underline{\mathrm{Bor}}(P') \simeq \underline{\mathrm{Bor}}(P'/\operatorname{rad}^u(P'))$$

are smooth. Let B_1 be a Borel subgroup opposite to B. By 5.2 there are

$$a \in B^u(k), \qquad a_1 \in B_1^u(k)$$

such that $\operatorname{int}(aa_1)B = B'$. Then

$$B_0 = \operatorname{int}(aa_1)B_1 = \operatorname{int}(a)B_1$$

is opposite to both B' and B. Let Q_0 be the unique parabolic subgroup of G containing B_0 and having the same type as Q, as in 3.8. It is in transverse position relative to P and P', by 4.2.1(vi). On the other hand, 5.2 gives

$$Q_0 = \operatorname{int}(uu')Q, \qquad u \in U(k), \quad u' \in U'(k),$$

which proves the assertion.

Corollary 5.4.— *Let S be a semilocal scheme, G an S-reductive group, and P, Q two parabolic subgroups of G. There is a $g \in G(S)$ such that* $\operatorname{int}(g)P$ *is in osculating position relative to Q; equivalently,* $\operatorname{int}(g)P \cap Q$ *is a parabolic subgroup of G.*

Choose a parabolic subgroup P' opposite to P, by 4.3.5(i). By 5.3, there is a parabolic subgroup P_1' of the same type as P', in transverse position relative to both P and Q. Let T be a maximal torus of $P_1' \cap Q$, as in 4.2.7(ii), and let P_1 be the parabolic subgroup opposite to P_1' relative to T. Then P_1 and Q are in osculating position, by 4.4.5. Since P and P_1 are both opposite to P_1', there is a

$$g \in \operatorname{rad}^u(P_1')(S)$$

such that $\operatorname{int}(g)P = P_1$, by 4.3.5(i). □

For the same reason there is a $u \in \operatorname{rad}^u(P)(S)$ such that $\operatorname{int}(u)P' = P_1'$. Hence $g = \operatorname{int}(u)u'$ for some $u' \in \operatorname{rad}^u(P')(S)$, and

$$P_1 = \operatorname{int}(uu'u^{-1})P = \operatorname{int}(uu')P.$$

This also gives another proof of 5.2.

Corollaries 5.3 and 5.4 are the essential results of this section. We first record some consequences of 5.4.

Corollary 5.5.— *Let S be a semilocal scheme and G an S-reductive group.*

(i) *If P, Q are parabolic subgroups of G and $t(P) \subset t(Q)$, then there is a $g \in G(S)$ such that* $\operatorname{int}(g)P \subset Q$.

(ii) *Let*

$$P_1 \supset P_2 \supset \cdots \supset P_n, \qquad P_1' \supset P_2' \supset \cdots \supset P_n'$$

be two chains of parabolic subgroups of G, with $t(P_i) = t(P_i')$ for every i. There is a $g \in G(S)$ such that $\operatorname{int}(g)P_i = P_i'$ *for every i.*

(iii) *Let P, Q, P', Q' be four parabolic subgroups of G, with $t(P) = t(P')$ and $t(Q) = t(Q')$. If the pairs (P, P') and (Q, Q') are both in transverse position, respectively both in osculating position, then there is a $g \in G(S)$ such that*

$$\mathrm{int}(g)P = P', \qquad \mathrm{int}(g)Q = Q'.$$

(iv) *Let P, P' be parabolic subgroups of the same type, and let L, respectively L', be a Levi subgroup of P, respectively P'. There is a $g \in G(S)$ such that*

$$\mathrm{int}(g)P = P', \qquad \mathrm{int}(g)L = L'.$$

Proof. Assertion (i) follows immediately from 5.4. Assertion (ii) is proved by induction on n, the case $n = 0$ being trivial. We may suppose that $P_i = P'_i$ for $i = 1, \ldots, n-1$. By 5.2 there is a $g \in G(S)$ such that $\mathrm{int}(g)P_n = P'_n$. But P_n and $\mathrm{int}(g)P_n$ are both contained in $P_{n-1} = P'_{n-1}$, and hence

$$g \in P_{n-1}(S)$$

by 4.4.4(ii). It follows that $\mathrm{int}(g)P_i = P'_i$ for every i.

Assertion (iv) follows at once from 5.2 and 1.8. Let us prove (iii) first in the transverse case. When the types of P and Q are opposite, the assertion follows from (iv) and 4.3.3(iii). In general, by 4.2.7(iii) and 4.4.6 one can find parabolic subgroups

$$P_1 \subset P, \quad P'_1 \subset P', \quad Q_1 \subset Q, \quad Q'_1 \subset Q'$$

such that P_1, P'_1 are opposite, Q_1, Q'_1 are opposite, and $t(P_1) = t(P'_1)$. There is consequently a $g \in G(S)$ such that

$$\mathrm{int}(g)P_1 = P'_1, \qquad \mathrm{int}(g)Q_1 = Q'_1.$$

After conjugating, we may suppose $P_1 = P'_1$ and $Q_1 = Q'_1$. Then P, P' are in osculating position and have the same type, so $P = P'$ by 4.4.4(i). Likewise $Q = Q'$.

It remains to prove (iii) in the osculating case. By 5.2 we may suppose $P = P'$. Again by 5.2 there is a $g \in G(S)$ such that $\mathrm{int}(g)Q = Q'$. But then $g \in P(S)$, by 4.4.4(ii), and therefore

$$\mathrm{int}(g)P = P = P'.$$

□

Definition 5.6.— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G. The subgroup P is said to be* minimal *if every parabolic subgroup Q of G contained in P is equal to P.*

Notice that this notion is not, in general, stable under passage to the fibers.

Corollary 5.7.— *Let S be a semilocal scheme and G an S-reductive group.*

(i) *Let*

$$t, t' \in \mathrm{Of}\big(\mathrm{Dyn}(G)\big)(S).$$

If G has a parabolic subgroup of type t and one of type t', then it has a parabolic subgroup of type $t \cap t'$. In particular, the set of $t(P)$, as P ranges over the parabolic subgroups of G, has a least element $t_{\min}$.

(ii) *Every parabolic subgroup of G contains a minimal parabolic subgroup. A parabolic subgroup of G is minimal if and only if it has type $t_{\min}$. Any two minimal parabolic subgroups of G are conjugate by an element of $G(S)$.*

This follows immediately from 5.4 and 5.5(i).

Remark 5.8.— *A parabolic subgroup opposite to a minimal parabolic subgroup is also minimal. Consequently,*

$$s(t_{\min}) = t_{\min}.$$

Corollary 5.9.— *Let S be a scheme, G an S-reductive group, and P a parabolic subgroup of G. The canonical morphism*

$$G \longrightarrow G/P = X$$

makes G a Zariski-locally trivial P_X-bundle over X. If L is a Levi subgroup of P, the canonical morphism (cf. 3.12)

$$G \longrightarrow G/L = Y$$

makes G a Zariski-locally trivial L_Y-bundle over Y.

It is enough to prove the following lifting assertion. Given a morphism $S' \to S$, with S' local, every morphism $S' \to X$ (respectively $S' \to Y$) lifts to a morphism $S' \to G$. In other words, we may assume that S is local, and must show that

$$G(S) \longrightarrow X(S), \qquad \text{respectively} \qquad G(S) \longrightarrow Y(S),$$

is surjective.

The first assertion was proved in 5.2. For the second, let $y \in Y(S)$. Its canonical image in $X(S)$ is the image of some $g \in G(S)$. The image y' of g in $Y(S)$ therefore has the same image in $X(S)$ as y. There is consequently a unique

$$u \in \mathrm{rad}^u(P)(S)$$

such that $y'u = y$, and the image of gu in $Y(S)$ is indeed y.

Corollary 5.10.— *Let S be a semilocal scheme and G an S-reductive group.*

(i) *Let P be a parabolic subgroup of G, and L a Levi subgroup of P. The canonical maps* (cf. 3.21) *induce bijections*

$$H^1(S, L) \xrightarrow{\sim} H^1(S, P) \xrightarrow{\sim} H^1_{t(P)}(S, G).$$

(ii) *If*

$$t, t' \in \mathrm{Of}(\mathrm{Dyn}(G))(S),$$

then (cf. 3.21)

$$H^1_t(S, G) \cap H^1_{t'}(S, G) = H^1_{t \cap t'}(S, G).$$

(iii) *If P and Q are two parabolic subgroups of G in osculating position, the following canonical diagram is cartesian and all its arrows are injective:*

$$\begin{array}{ccc} H^1(S, P) & \longrightarrow & H^1(S, G) \\ \uparrow & & \uparrow \\ H^1(S, P \cap Q) & \longrightarrow & H^1(S, Q). \end{array}$$

Let us prove (i). The map

$$H^1(S, L) \longrightarrow H^1(S, P)$$

is bijective by 2.3, while

$$H^1(S, P) \longrightarrow H^1_{t(P)}(S, G)$$

is surjective by 3.21. We must prove that it is injective, or equivalently that the canonical map

$$H^1(S, P) \longrightarrow H^1(S, G)$$

is injective. Let Q be a principal homogeneous bundle under P, let Q_1 be the associated principal homogeneous bundle under G, and let P' and G' be the corresponding twisted forms of P and G. Clearly G' is an S-reductive group and P' is a parabolic subgroup of G'.

The elements of $H^1(S, P)$ having the same image in $H^1(S, G)$ as the class of Q are naturally identified with the kernel of

$$H^1(S, P') \longrightarrow H^1(S, G').$$

By the exact sequence in cohomology, this kernel is in turn identified with the set of $G'(S)$-orbits in $(G'/P')(S)$.[29] But $G'(S)$ acts transitively on $(G'/P')(S)$, by 5.2.

For (ii), let Q be a principal homogeneous bundle under G, and let G_Q be the corresponding twisted form of G. By definition (3.21), we must prove that G_Q has a parabolic subgroup of type $t \cap t'$ if and only if it has parabolic subgroups of types t and t'. This is precisely the combination of 3.8 and 5.7(i). Finally, (iii) follows immediately from (i) and (ii).

We now state a consequence of 5.3.

Corollary 5.11.— *Let S be a semilocal scheme, G an S-reductive group, and P a parabolic subgroup of G. If $P \neq G$, there exist at least three distinct parabolic subgroups of G having the same type as P. In other words,*

$$P \neq G \qquad \Longrightarrow \qquad (G(S) : P(S)) \geq 3.$$

Indeed, let P' be a parabolic subgroup opposite to P, as in 4.3.5(i). Since $P \neq G$, one has $\mathrm{rad}^u(P') \neq e$, for example by 4.3.2. By 2.1, $\mathrm{rad}^u(P')(S) \neq e$; choose

$$u \in \mathrm{rad}^u(P')(S), \qquad u \neq e.$$

Then $\mathrm{int}(u)P \neq P$. By 5.3 there is a parabolic subgroup P_1 of the same type as P, opposite to both P and $\mathrm{int}(u)P$. Thus P_1, P, and $\mathrm{int}(u)P$ are three distinct parabolic subgroups of G, all of the same type. □

6. Parabolic subgroups and split tori

Proposition 6.1.— *Let S be a scheme, G an S-reductive group, $\mathfrak{g} = \mathrm{Lie}(G/S)$, and Q a split subtorus of G. Write $Q = D_S(M)$, and let*

$$\mathfrak{g} = \bigoplus_{\alpha \in M} \mathfrak{g}^\alpha$$

be the decomposition of $\mathfrak{g}$ under the action of Q. Let $M_1 \subset M$ satisfy

$$0 \in M_1, \qquad \alpha, \beta \in M_1 \Longrightarrow \alpha + \beta \in M_1.$$

[29] For these arguments in nonabelian cohomology, see Giraud's thesis, [Gi71], § III.3.

(i) *There is a unique smooth subgroup H_{M_1} of G, with connected fibers, which contains $\underline{\mathrm{Centr}}_G(Q)$ and whose Lie algebra is*

$$\bigoplus_{\alpha\in M_1} \mathfrak{g}^\alpha.$$

(ii) *The following implications hold:*

$$\begin{aligned} M_1 = \{0\} &\Longrightarrow H_{M_1} = \underline{\mathrm{Centr}}_G(Q), \\ M_1 = -M_1 &\Longrightarrow H_{M_1} \text{ is reductive}, \\ M_1 \cup (-M_1) = M &\Longrightarrow \begin{array}{c} H_{M_1} \text{ and } H_{-M_1} \text{ are opposite parabolic} \\ \text{subgroups of } G, \text{ with common Levi subgroup } H_{M_1\cap(-M_1)}. \end{array} \end{aligned}$$

Assertions (i) and (ii) are local for the fpqc topology. We may therefore suppose that Q is contained in a maximal torus T of G, and may moreover split G relative to T. Assertion (i) then follows immediately from Exposé XXII, 5.3.5, 5.4.5, and 5.4.7. The assertions in (ii) follow from Exposé XXII, 5.3.5, 5.10.1, and 5.11.3, together with 1.4 and 4.3.2 of the present Exposé.

Corollary 6.2.— *Let S be a scheme, G an S-reductive group, and Q a split subtorus of G. There is a parabolic subgroup of G having $\underline{\mathrm{Centr}}_G(Q)$ as a Levi subgroup.*

Indeed, write $Q = D_S(M)$, choose a total order on the group M, and let M_1 be the set of its positive elements. The subgroup H_{M_1} has the required property.

Corollary 6.3.— *If the S-reductive group G has a noncentral split subtorus, then it has a proper parabolic subgroup* (that is, one different from G).

Combining 6.2 with 5.9 and 5.10 gives the following result.

Corollary 6.4.— *Let S be a scheme, G an S-reductive group, and Q a split subtorus of G. The canonical morphism*

$$G \longrightarrow G/\underline{\mathrm{Centr}}_G(Q)$$

is a locally trivial fibration.

If S is semilocal, the map

$$G(S) \longrightarrow (G/\underline{\mathrm{Centr}}_G(Q))(S)$$

is surjective, and the map

$$H^1(S, \underline{\mathrm{Centr}}_G(Q)) \longrightarrow H^1(S, G)$$

is injective.

6.5.

Suppose that S is connected. If T is an S-torus and T', T'' are two split subtori of T, their product

$$T' \cdot T''$$

is again a split subtorus of T.[30] Indeed, it is identified with the quotient of $T' \times_S T''$ by $T' \cap T''$, and this quotient is split by Exposé IX, 2.11. It follows that T has a largest split subtorus, which we denote by T_{spl}.

[30] *Editor's note.* The Polo–Gille edition adopts multiplicative notation here, replacing the source's "sum $T' + T''$" by "product $T' \cdot T''$".

Lemma 6.6.— *Let S be a connected scheme, T an isotrivial S-torus, and T_{spl} its largest split subtorus. The following conditions are equivalent:*

(i) *There is a homomorphism*
$$T \longrightarrow \mathbf{G}_{m,S}$$
different from the trivial homomorphism.

(ii) $T_{\mathrm{spl}} \neq e$.

Since T is isotrivial, there are a finite group Γ, a connected principal Galois covering $S' \to S$ with group Γ, and an isomorphism
$$T_{S'} \simeq D_{S'}(M).$$
The group M is then a Γ-module, and there is a natural isomorphism
$$\mathrm{Hom}_S(T, \mathbf{G}_{m,S}) = H^0(\Gamma, M).$$

Let V be the vector subspace of $M \otimes \mathbf{Q}$ generated by the elements
$$\gamma(m) - m, \qquad \gamma \in \Gamma, \quad m \in M.$$
One checks immediately that
$$(T_{\mathrm{spl}})_{S'} \simeq D_{S'}\big(M/(M \cap V)\big).$$
Thus (i) is equivalent to
$$H^0(\Gamma, M) \neq 0,$$
or equivalently to
$$H^0(\Gamma, M \otimes \mathbf{Q}) \neq 0,$$
whereas (ii) is equivalent to $M \neq M \cap V$, or to $M \otimes \mathbf{Q} \neq V$. But
$$M \otimes \mathbf{Q} = H^0(\Gamma, M \otimes \mathbf{Q}) \oplus V.$$
This follows at once by considering the projector from $M \otimes \mathbf{Q}$ onto its invariants which sends x to the average of its transforms under Γ.

Lemma 6.7.— *Let S be a scheme, G an S-reductive group, $P \neq G$ a parabolic subgroup of G, L a Levi subgroup of P, and $Q = \mathrm{rad}(L)$. There is a homomorphism*
$$Q \longrightarrow \mathbf{G}_{m,S}$$
different from the trivial homomorphism.

Let $U = \mathrm{rad}^u(P)$. It is invariant under $\mathrm{int}(P)$, hence under $\mathrm{int}(Q)$. Consider the invertible $\mathcal{O}_S$-module
$$\det\big(\mathrm{Lie}(U)\big),$$
the highest exterior power of the locally free $\mathcal{O}_S$-module $\mathrm{Lie}(U)$. The adjoint representation defines a homomorphism
$$f : Q \longrightarrow \mathrm{Aut}\big(\det\big(\mathrm{Lie}(U)\big)\big) = \mathbf{G}_{m,S}.$$

Since $P \neq G$, one has $U \neq e$. Choose $s \in S$ such that $U_s \neq e$. After splitting G_s relative to a maximal torus containing Q_s, it is immediate that $f_s \neq e$.

Proposition 6.8.— *Let S be a connected semilocal scheme, G an S-reductive group, P a parabolic subgroup of G, L a Levi subgroup of P, and $Q = \mathrm{rad}(L)$. Let Q_{spl} be the largest split subtorus of Q, equivalently the largest central split subtorus of L. Then*

$$L = \underline{\mathrm{Centr}}_G(Q_{\mathrm{spl}}).$$

Put $L' = \underline{\mathrm{Centr}}_G(Q_{\mathrm{spl}})$. This is a reductive subgroup of G containing L, and

$$P' = P \cap L'$$

is a parabolic subgroup of L' with Levi subgroup L, by 1.20. If $L' \neq L$, then $L' \not\subset P$, since L is a maximal reductive subgroup of P by 1.7. Hence $P' \neq L'$.

Let G_1 be the derived group of G, and put $P_1 = P' \cap G_1$. By 1.19, P_1 is a parabolic subgroup of the semisimple group G_1, the group $L_1 = L \cap G_1$ is a Levi subgroup of P_1, and

$$Q_1 = \mathrm{rad}(L_1) = \big(\mathrm{rad}(L) \cap G_1\big)^0 = \big(Q \cap G_1\big)^0.$$

The group L_1 has a maximal torus T_1, by Exposé XIV, 3.20, and T_1 is isotrivial, by Exposé XXIV, 4.1.5. Therefore its subtorus Q_1 is also isotrivial, by Exposé IX, 2.11. Since $P_1 \neq G_1$, Lemmas 6.7 and 6.6 give

$$(Q_1)_{\mathrm{spl}} \neq e.$$

It follows that

$$\big(Q_{\mathrm{spl}} \cap G_1\big)^0 \neq e,$$

and hence that $Q_{\mathrm{spl}} \not\subset \mathrm{rad}(L')$, because $\mathrm{rad}(L') \cap G_1$ is finite. This contradicts the definition of L'. □

Corollary 6.9.— *Let S be a connected semilocal scheme, G an S-reductive group, and Q a critical subtorus of G, that is, a subtorus such that*

$$\mathrm{rad}\big(\underline{\mathrm{Centr}}_G(Q)\big) = Q.$$

The group $\underline{\mathrm{Centr}}_G(Q)$ is a Levi subgroup of a parabolic subgroup of G if and only if

$$\underline{\mathrm{Centr}}_G(Q) = \underline{\mathrm{Centr}}_G(Q_{\mathrm{spl}}),$$

or equivalently,

$$\mathrm{Lie}(G)^Q = \mathrm{Lie}(G)^{Q_{\mathrm{spl}}}.$$

This follows from 6.2 and 6.8.

Corollary 6.10.— *Let S be a connected semilocal scheme, G an S-reductive group, and L a subgroup of G. The following conditions are equivalent:*

(i) *There is a parabolic subgroup of G having L as a Levi subgroup.*

(ii) *There is a split subtorus of G whose centralizer is L.*

(iii) *There is a homomorphism*

$$\mathbf{G}_{m,S} \longrightarrow G$$

whose centralizer is L.

The implication (i)⇒(ii) follows from 6.8, and (iii)⇒(i) from 6.1. It remains to prove (ii)⇒(iii). Suppose therefore that

$$L = \underline{\mathrm{Centr}}_G(Q), \qquad Q = D_S(M).$$

Write $\mathfrak{g} = \mathrm{Lie}(G/S)$ and

$$\mathfrak{g} = \bigoplus_{\alpha \in M} \mathfrak{g}^\alpha,$$

and let R be the set of $\alpha \in M \setminus \{0\}$ for which $\mathfrak{g}^\alpha \neq 0$.

Since R is finite and does not contain 0, there is a homomorphism

$$u : M \longrightarrow \mathbf{Z}$$

such that $u(\alpha) \neq 0$ for every $\alpha \in R$. By duality, u yields a homomorphism $\mathbf{G}_{m,S} \to Q$, and hence a homomorphism

$$f : \mathbf{G}_{m,S} \longrightarrow G.$$

One has

$$\underline{\mathrm{Centr}}_G(f) \supset \underline{\mathrm{Centr}}_G(Q).$$

These are two smooth subgroups of G, with connected fibers, and their Lie algebras coincide, since both are equal to $\mathfrak{g}^0$. They are therefore equal, by the usual argument.

Corollary 6.11.— *Let S be a connected semilocal scheme and G an S-reductive group. The maps*

$$L \longmapsto \mathrm{rad}(L)_{\mathrm{spl}}, \qquad Q \longmapsto \underline{\mathrm{Centr}}_G(Q)$$

are mutually inverse, order-reversing bijections between:

- *the set of subgroups L of G which are Levi subgroups of parabolic subgroups of G; and*
- *the set of split subtori Q of G such that*

$$\mathrm{rad}\big(\underline{\mathrm{Centr}}_G(Q)\big)_{\mathrm{spl}} = Q.$$

Corollary 6.12.— *Let S be a connected semilocal scheme and G an S-reductive group. Consider the following assertions:*

(i) *G has a parabolic subgroup different from G.*

(ii) *G has a noncentral split subtorus.*

(ii bis) *G has a noncentral split subtorus of relative dimension 1.*

(iii) *There is a group homomorphism*

$$\mathbf{G}_{a,S} \longrightarrow G$$

which is a closed immersion.

Then

$$\text{(i)} \iff \text{(ii)} \iff \text{(ii bis)} \implies \text{(iii)}.$$

The only new assertion is (i)⇒(iii). Let $P \neq G$ be a parabolic subgroup of G. Then $U = \mathrm{rad}^u(P) \neq e$. Consider the last nontrivial subgroup U_n in the composition series of U, as in 2.1. There is an isomorphism

$$U_n \simeq W(E_n),$$

where E_n is a locally free $\mathcal{O}_S$-module, and hence is free because S is semilocal and connected. Since $E_n \neq 0$, there is a monomorphism

$$\mathcal{O}_S \longrightarrow E_n$$

whose image is locally a direct summand. It induces a closed immersion

$$\mathbf{G}_{a,S} = W(\mathcal{O}_S) \hookrightarrow W(E_n) \simeq U_n,$$

which proves (iii).

Remark 6.12.1.— *When S is the spectrum of a field of characteristic* 0*, the Jacobson–Morozov theorem gives* (iii)⇒(ii bis)*. The four preceding conditions are then equivalent* ("Godement's criterion"; cf. [BT65], 8.5).[31]

Definition 6.13.— *Let S be a connected semilocal scheme and G an S-reductive group. The group G is said to be* anisotropic *if it contains no nontrivial split subtorus.*

Corollary 6.14.— *Let S be a connected semilocal scheme. An S-reductive group G is anisotropic if and only if it has no parabolic subgroup $P \neq G$ and its radical is anisotropic.*

Combining 6.6 with Exposé XXIV, 4.1.5, and Exposé XXII, 6.2 gives:

Corollary 6.15.— *Let S be a connected semilocal scheme and G an isotrivial S-reductive group* (for example, G semisimple, or S normal; cf. Exposé X, 5.16)*. The group G is anisotropic if and only if it has no parabolic subgroup $P \neq G$ and*

$$\mathrm{Hom}_{S\text{-gr}}(G, \mathbf{G}_{m,S}) = e.$$

Proposition 6.16.— *Let S be a connected semilocal scheme and G an S-reductive group. The maximal split subtori of G are precisely the largest central split subtori of the Levi subgroups of the minimal parabolic subgroups of G. Any two such tori are conjugate by an element of $G(S)$.*

Let Q be a maximal split subtorus of G. By 6.2,

$$L = \underline{\mathrm{Centr}}_G(Q)$$

is a Levi subgroup of a parabolic subgroup P of G. Since

$$Q \subset \mathrm{rad}\big(\underline{\mathrm{Centr}}_G(Q)\big)_{\mathrm{spl}},$$

the maximality of Q gives

$$Q = \mathrm{rad}\big(\underline{\mathrm{Centr}}_G(Q)\big)_{\mathrm{spl}}.$$

[31] More generally, this remains true when S is the spectrum of a perfect field (Tits); see [BT71], Corollary 3.7.

By 6.11, L is minimal among the Levi subgroups of parabolic subgroups of G. Hence P is a minimal parabolic subgroup of G, by 1.20. It follows from 5.7 and 5.5(iv) that any two such subtori Q are conjugate by an element of $G(S)$. The conjugacy of the tori Q and of the pairs (P, L) also proves the first assertion.

Corollary 6.17.— *Let S be a connected semilocal scheme, and let P, P' be two minimal parabolic subgroups in standard position* (4.5.1.1). *Then $P \cap P'$ contains a common Levi subgroup of P and P'.*

Indeed, $P \cap P'$ contains a maximal torus T of G, by 4.5.1(v). Let L be the unique Levi subgroup of P which contains T. By 1.21,

$$\mathrm{rad}(P) \cap T = \mathrm{rad}(P) \cap L = \mathrm{rad}(L).$$

Thus $\mathrm{rad}(P) \cap T$ contains $\mathrm{rad}(L)_{\mathrm{spl}}$, which is a maximal split subtorus of G, and is therefore necessarily equal to T_{spl}. Hence

$$L = \underline{\mathrm{Centr}}_G(T_{\mathrm{spl}}),$$

and, by symmetry, L is also a Levi subgroup of P'.

Remark 6.18.— *It follows from 1.21 that a parabolic subgroup P of G is minimal if and only if* $\mathrm{rad}(P)$ *contains a maximal split subtorus of G. In that case, if T is a maximal torus of P, the torus T_{spl} is a maximal split subtorus both of G and of* $\mathrm{rad}(P)$, *and* $\underline{\mathrm{Centr}}_G(T_{\mathrm{spl}})$ *is a Levi subgroup of P. Moreover, every Levi subgroup of P is obtained in this way.*

7. Relative root datum

Throughout this section, S denotes a nonempty connected semilocal scheme, G an S-reductive group, Q a maximal split subtorus of G, and L the centralizer of Q in G:

$$L = \underline{\mathrm{Centr}}_G(Q).$$

7.1.

Since Q is the largest central split subtorus of L, every element of $G(S)$ which normalizes L also normalizes Q. Thus (cf. 7.1.1)

$$\underline{\mathrm{Norm}}_G(L)(S) = \underline{\mathrm{Norm}}_G(Q)(S).$$

On the other hand, 6.4 shows that

$$G(S) \longrightarrow (G/L)(S)$$

is surjective. Consequently there is a canonical identification

$$W_G(Q)(S) = (\underline{\mathrm{Norm}}_G(Q)/\underline{\mathrm{Centr}}_G(Q))(S) \simeq \underline{\mathrm{Norm}}_G(L)(S)/L(S).$$

Let

$$M = \mathrm{Hom}_{S\text{-gr}}(Q, \mathbf{G}_{m,S}),$$

so that $Q \simeq D_S(M)$ canonically. Denote by W the group of automorphisms of M defined by $W_G(Q)(S)$. Thus

$$W \simeq W_G(Q)(S) \simeq \underline{\mathrm{Norm}}_G(L)(S)/L(S).$$

7.1.1.

In general one does not have $\underline{\mathrm{Norm}}_G(L) = \underline{\mathrm{Norm}}_G(Q)$. For example, let S be the spectrum of a field k having a quadratic extension k', and take for G the unitary group

$$^2A_{2,k'/k}$$

(cf. Exposé XXIV, 3.11.2). The minimal parabolic subgroups of G are its Borel subgroups, and their Levi subgroups are maximal tori; hence

$$(\underline{\mathrm{Norm}}_G(L)/L)(k) = \mathfrak{S}_3.$$

Since G is not split, its maximal split tori have dimension at most 1, and are therefore isomorphic to $\mathbf{G}_{m,k}$. The group $\underline{\mathrm{Norm}}_G(Q)/L$ acts faithfully on Q, and

$$(\underline{\mathrm{Norm}}_G(Q)/L)(k) = \mathbf{Z}/2\mathbf{Z}.$$

[32]

7.2.

Let P be a parabolic subgroup of G with Levi subgroup L; such a subgroup exists by 6.2. It is necessarily minimal, by 6.18. Using the conjugacy of the minimal parabolic subgroups of G (5.7), the conjugacy of the Levi subgroups of a parabolic subgroup (1.8), and the equalities

$$P = \underline{\mathrm{Norm}}_G(P), \qquad \underline{\mathrm{Norm}}_G(L) \cap P = L$$

from 1.6, we obtain the following conclusion: the set of (minimal) parabolic subgroups of G having Levi subgroup L is a principal homogeneous space under W.

7.3.

The Lie algebra of G decomposes under the action of Q as

$$\mathrm{Lie}(G) = \mathrm{Lie}(L) \oplus \bigoplus_{\alpha \in R} \mathrm{Lie}(G)^\alpha,$$

where R is the set of nonzero characters α of Q such that $\mathrm{Lie}(G)^\alpha \neq 0$. These are the roots of G relative to Q.

Let

$$M^* = \mathrm{Hom}_{S\text{-gr}}(\mathbf{G}_{m,S}, Q).$$

It is in duality with M, and W acts on it naturally by transport of structure.

Theorem 7.4.— *With the notation of 7.3, there is a unique map*

$$R \longrightarrow M^*, \qquad \alpha \longmapsto \alpha^*,$$

which makes (M, M^*) *into a root datum* (Exposé XXI, 1.1) *with Weyl group* W.

Moreover, parabolic subgroups P *of* G *having Levi subgroup* L *correspond bijectively to systems of positive roots* R^+ *in* R *by the relation*

$$\mathrm{Lie}(P) = \mathrm{Lie}(L) \oplus \bigoplus_{\alpha \in R^+} \mathrm{Lie}(G)^\alpha.$$

[32] *Editor's note.* The French edition prints $\underline{\mathrm{Norm}}_G(Q)/Q$ in this final equality, although the immediately preceding action and the definition of the relative Weyl group use $\underline{\mathrm{Norm}}_G(Q)/L$.

7.4.1.

Suppose first that the existence of the desired map $\alpha \mapsto \alpha^*$ has been proved. By Exposé XXI, 3.4.10, s_α is the unique element of W such that

$$s_\alpha(m) - m$$

is a rational multiple of α for every $m \in M$. Consequently s_α is determined by α. Since

$$\alpha^*(m)\alpha = m - s_\alpha(m),$$

[33] the coroot α^* is also determined by α, proving the uniqueness of the map.

7.4.2.

Let $\alpha \in R$. Denote by L_α, H_α, and $H_{-\alpha}$, respectively, the unique smooth subgroups of G with connected fibers which contain L and satisfy (cf. 6.1(i))

$$\begin{aligned}
\mathrm{Lie}(L_\alpha) &= \mathrm{Lie}(L) \oplus \bigoplus_{\gamma \in \mathbf{Z}\alpha \cap R} \mathrm{Lie}(G)^\gamma, \\
\mathrm{Lie}(H_\alpha) &= \mathrm{Lie}(L) \oplus \bigoplus_{\gamma \in \mathbf{N}\alpha \cap R} \mathrm{Lie}(G)^\gamma, \\
\mathrm{Lie}(H_{-\alpha}) &= \mathrm{Lie}(L) \oplus \bigoplus_{\gamma \in -\mathbf{N}\alpha \cap R} \mathrm{Lie}(G)^\gamma.
\end{aligned}$$

The group L_α is a reductive subgroup of G, and $H_\alpha, H_{-\alpha}$ are opposite parabolic subgroups of L_α, with common Levi subgroup L, by 6.1(ii).

By 7.2 there is therefore an element

$$s_\alpha \in \underline{\mathrm{Norm}}_{L_\alpha}(Q)(S)/L(S) \subset W$$

such that $s_\alpha(H_\alpha) = H_{-\alpha}$. One has

$$s_\alpha(\alpha) = -\alpha,$$

because α, respectively $-\alpha$, is the common divisor of the elements of R occurring in H_α, respectively $H_{-\alpha}$. Moreover $s_\alpha^2 = \mathrm{id}$, because $s_\alpha^2(H_\alpha)$ and H_α are both opposite to $H_{-\alpha}$ relative to L. We have thus constructed an element $s_\alpha \in W$ with the properties

(x) $$s_\alpha(\alpha) = -\alpha, \qquad s_\alpha^2 = \mathrm{id},$$

and

(xx) s_α can be represented by an element of $L_\alpha(S)$.

The construction is canonical in α; in particular,

(xxx) $$w s_\alpha w^{-1} = s_{w(\alpha)} \qquad \text{for every } w \in W.$$

[33] *Editor's note.* Here and again in 7.4.4, the Polo–Gille edition restores the factor α omitted after $\alpha^*(m)$ in the original text.

7.4.3.

We now prove

(xxxx) $$s_\alpha(m) - m \in \mathbf{Z}\alpha \qquad \text{for every } m \in M.$$

Since S is connected, this assertion is local for the fpqc topology. We may therefore suppose that

$$L_\alpha = G_1$$

is split relative to a maximal torus T_1 of L. Let (G_1, T_1, M_1, R_1) be such a splitting. The monomorphism $Q \to T_1$ identifies M with a quotient of M_1; denote the canonical map by

$$p : M_1 \longrightarrow M.$$

The image of R_1 under p, possibly including zero, consists of the roots of G_1 relative to Q, hence of the elements of R which are integral multiples of α. Thus

$$p(R_1) \subset \mathbf{Z}\alpha.$$

By (xx), an element of $\underline{\mathrm{Norm}}_{G_1}(L)(S)$ induces s_α on Q. Exposé XXII, 5.10.10, then gives a section

$$w \in (W_1)_S(S)$$

which induces s_α on Q, where W_1 is the Weyl group of the root datum $(M_1, R_1, \ldots)$. After restricting S if necessary, we may suppose that $w \in W_1$ and that

$$p\big(w(m_1)\big) = s_\alpha\big(p(m_1)\big) \qquad (m_1 \in M_1).$$

By definition, w is a product of reflections associated with elements of R_1. Hence $w(m_1) - m_1$ is an integral linear combination of elements of R_1. It follows that

$$s_\alpha\big(p(m_1)\big) - p(m_1)$$

is an integral linear combination of elements of $p(R_1) \subset \mathbf{Z}\alpha$, and is therefore an integral multiple of α, as required.

7.4.4.

We may now define $\alpha^* \in M^*$ by

$$\alpha^*(m)\alpha = m - s_\alpha(m).$$

By (x),

$$\langle \alpha^*, \alpha \rangle = 2.$$

Moreover, (xxx) implies that for every $(\alpha, \alpha') \in R \times R$,

$$s_\alpha(\alpha') \in R, \qquad s_\alpha(\alpha'^*) = s_\alpha(\alpha')^*.$$

By Exposé XXI, 1.1, the map $\alpha \mapsto \alpha^*$ therefore defines a root datum on (M, M^*).

7.4.5.

Let W' be the Weyl group of this root datum, that is, the group of transformations of M generated by the s_α. Then $W' \subset W$.

Choose a total order on the free abelian group M, and put

$$R^+ = \{\alpha \in R \mid \alpha \geq 0\}.$$

This is a system of positive roots in R. Let $w \in W$, and represent it by an element

$$n \in \underline{\mathrm{Norm}}_G(L)(S) = \underline{\mathrm{Norm}}_G(Q)(S).$$

Put $P = H_{R^+}$, in the notation of 6.1. Then P is a parabolic subgroup of G with Levi subgroup L, and

$$\mathrm{int}(n)P = H_{w(R^+)}.$$

It follows from 7.3 that $w(R^+) = R^+$ implies $w = e$. The group W' acts transitively on the systems of positive roots in R, by Exposé XXI, 3.3.7, while the stabilizer of R^+ in W is trivial. Therefore $W = W'$.

It follows as well that $W = W'$ acts simply transitively both on the systems of positive roots in R and on the parabolic subgroups of G having Levi subgroup L. This proves the last assertion of 7.4. □

7.5.

Let P, P_1 be two minimal parabolic subgroups of G, with Levi subgroups L, L_1, and let Q, Q_1 be the largest central split subtori of L, L_1, respectively. Then the pairs (P, Q) and (P_1, Q_1) are conjugate: there is a $g \in G(S)$ such that

$$\mathrm{int}(g)P = P_1, \qquad \mathrm{int}(g)Q = Q_1.$$

Indeed, P and P_1 are conjugate by 5.7, so we may suppose $P = P_1$. Then L and L_1 are conjugate by an element of $P(S)$, by 1.8. Moreover, if g, g' are two elements of $G(S)$ which conjugate (P, Q) to (P_1, Q_1), then $g'^{-1}g$ normalizes P and Q, hence also P and L. But

$$\underline{\mathrm{Norm}}_G(P) \cap \underline{\mathrm{Norm}}_G(L) = P \cap \underline{\mathrm{Norm}}_G(L) = L = \underline{\mathrm{Centr}}_G(Q).$$

Consequently the isomorphism

$$Q \xrightarrow{\sim} Q_1$$

induced by $\mathrm{int}(g)$ is independent of g.

Let $\mathcal{R}, \mathcal{R}_1$ be the root data defined by 7.4 in

$$\mathrm{Hom}_{S\text{-gr}}(Q, \mathbf{G}_{m,S}) \quad \text{and} \quad \mathrm{Hom}_{S\text{-gr}}(Q_1, \mathbf{G}_{m,S}),$$

and let R^+, R_1^+ be the systems of positive roots corresponding to P, P_1. The canonical isomorphism $Q \simeq Q_1$ just constructed carries $(\mathcal{R}, R^+)$ to $(\mathcal{R}_1, R_1^+)$. We may therefore define the *based relative root datum* of G over S, by identifying the various pairs $(\mathcal{R}, R^+)$ through the transitive system of isomorphisms above.[34]

From now on, denote this based root datum by

$$\mathcal{R}(G/S) = (\underline{M}, \underline{M}^*, \underline{R}, \underline{R}^*, \underline{R}^+).$$

[34] A based root datum is a root datum together with the choice of a system of positive roots, equivalently of simple roots; cf. Exposé XXIII, 1.5.

For every pair $P \supset Q$ as above there is therefore a canonical isomorphism

$$\underline{M} \xrightarrow{\sim} \mathrm{Hom}_{S\text{-gr}}(Q, \mathbf{G}_{m,S})$$

which carries $\underline{R}$, respectively $\underline{R}^+$, to the roots of G, respectively of P, relative to Q, and carries $W(\mathcal{R})$ to $W_G(Q)(S)$.

7.6.

Let again Q be a maximal split torus of G, let P be a minimal parabolic subgroup of G with Levi subgroup $\underline{\mathrm{Centr}}_G(Q)$, let

$$(M, M^*, R, R^*, R^+)$$

be the corresponding based root datum of 7.4, and let Δ be the set of simple roots in R^+. For every $A \subset \Delta$, let

$$R_A = R^+ \cup (\mathbf{Z}A \cap R^-).$$

Thus R_A consists of the positive roots together with the negative roots which are integral linear combinations of elements of A. It is a closed set of roots, by Exposé XXI, 3.1.4, and every closed set containing R^+ is uniquely of this form, by Exposé XXI, 3.3.10.

By 6.1 there is a unique smooth subgroup P_A of G, with connected fibers, which contains $\underline{\mathrm{Centr}}_G(Q)$ and satisfies

$$\mathrm{Lie}(P_A) = \mathrm{Lie}(G)^0 \oplus \bigoplus_{\alpha \in R_A} \mathrm{Lie}(G)^\alpha.$$

The following result now follows immediately from 6.1, the conjugacy of minimal parabolic subgroups, and the fact that the set of roots of a parabolic subgroup of G containing Q is closed (which follows from 1.4 after splitting).

Proposition 7.7.—

(i) *The map*

$$A \longmapsto P_A$$

is an inclusion-preserving bijection from the set of subsets of Δ onto the set of parabolic subgroups of G containing P.

(ii) *Every parabolic subgroup of G is conjugate by an element of $G(S)$ to a unique P_A.*

7.8.

Let $P \supset Q$ be as above. Consider the relative root datum of G over S defined in 7.5 and the canonical isomorphism

$$f : (M, M^*, R, R^*, R^+) \xrightarrow{\sim} (\underline{M}, \underline{M}^*, \underline{R}, \underline{R}^*, \underline{R}^+).$$

The set Δ of simple roots in R^+ is carried to the set $\underline{\Delta}$ of simple roots in $\underline{R}^+$. Thus every subset $A \subset \Delta$ is carried to a subset

$$f(A) \subset \underline{\Delta}.$$

Definition 7.9.0.— *Let H be any parabolic subgroup of G. By 7.7*(ii)*, it is conjugate to a unique P_A. Put*

$$t_r(H) = f(A) \subset \underline{\Delta}.$$

The conjugacy theorems show immediately that $t_r(H)$ is independent of the choice of the pair $P \supset Q$. It is called the relative type *of H.*

Proposition 7.9.—

(i) *The map $H \mapsto t_r(H)$ induces a bijection from the set of $G(S)$-conjugacy classes of parabolic subgroups of G onto the set of subsets of $\underline{\Delta}$.*

(ii) *Let H be a parabolic subgroup of G, P a minimal parabolic subgroup contained in H, Q the largest central split torus of a Levi subgroup of P, Δ the set of simple roots of P relative to Q, and*

$$f : \Delta \xrightarrow{\sim} \underline{\Delta}$$

the canonical isomorphism. For every $\alpha \in \Delta$,

$$f(\alpha) \in t_r(H) \quad \Longleftrightarrow \quad \mathrm{Lie}(H)^{-\alpha} \neq 0,$$

and

$$H = P_A, \qquad A = f^{-1}(t_r(H)).$$

(iii) *If H, H' are two parabolic subgroups of G containing P, then* (see 3.8.1(ii) and 5.5(i) for other equivalent conditions)

$$t_r(H) \subset t_r(H') \quad \Longleftrightarrow \quad t(H) \subset t(H').$$

7.10.

The relative positions of two minimal parabolic subgroups can be described as follows. We use the notation $t_2(P, P_1)$ of 4.5.2.

(1) Let P, P_1, P', P_1' be four minimal parabolic subgroups of G. Then

$$t_2(P, P_1) = t_2(P', P_1'),$$

that is, the pairs (P, P_1) and (P', P_1') are fpqc-locally conjugate, if and only if there is a $g \in G(S)$ such that

$$\mathrm{int}(g)P = P', \qquad \mathrm{int}(g)P_1 = P_1'.$$

(2) Fix a minimal parabolic subgroup P of G with Levi subgroup L, and let T be a maximal torus of L. Consider the scheme

$$\underline{\mathrm{Par}}_{t_{\min}}(G; P)$$

of minimal parabolic subgroups of G in standard position relative to P. There is a morphism (cf. 4.5.5)

$$f : \underline{\mathrm{Par}}_{t_{\min}}(G; P) \longrightarrow W_P(T) \backslash W_G(T) / W_P(T)$$

whose fibers are the orbits of P in $\underline{\mathrm{Par}}_{t_{\min}}(G;P)$. By (1), f therefore induces a monomorphism

$$P(S)\backslash\underline{\mathrm{Par}}_{t_{\min}}(G;P)(S) \hookrightarrow (W_P(T)\backslash W_G(T)/W_P(T))(S).$$

Its image is identified with W. This is the Bruhat theorem: each orbit of $P(S)$ in $\underline{\mathrm{Par}}_{t_{\min}}(G;P)(S)$ contains exactly one parabolic subgroup of G with Levi subgroup L, that is, one of the form

$$\mathrm{int}(n)P, \qquad n \in \underline{\mathrm{Norm}}_G(L)(S).$$

(3) Equivalently, let $E(S)$ be the set of elements $g \in G(S)$ such that $\mathrm{int}(g)P$ and P are in mutual standard position. Then $E(S)$ is partitioned into double cosets modulo $P(S)$, indexed by W:

$$E(S) = P(S)\, W\, P(S).$$

Putting $U = \mathrm{rad}^u(P)$, one may also write

$$E(S) = U(S) \cdot \underline{\mathrm{Norm}}_G(L)(S) \cdot U(S).$$

This exhibits a partition of $E(S)$ into double cosets modulo $U(S)$, indexed by $\underline{\mathrm{Norm}}_G(L)(S)$.

(4) If S is the spectrum of a field, then $E(S) = G(S)$, and one recovers [BT65], 5.15.

Counterexamples 7.11.— *Let*

$$S = \mathrm{Spec}(\mathbf{Z}/4\mathbf{Z}), \qquad G = \mathrm{SL}_{2,S}\,.$$

Let B be the usual Borel subgroup consisting of the matrices

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \qquad \textit{with } c = 0,$$

and put

$$g = \begin{pmatrix} -1 & 1 \\ 2 & 1 \end{pmatrix} \in G(S), \qquad B' = \mathrm{int}(g)B.$$

Then

$$B(S) = B'(S),$$

whereas $B \cap B'$ contains no maximal torus. [35]

This shows both that two distinct minimal parabolic subgroups may have the same group of sections and that, in general, one cannot decide from the groups $P(S)$ and $P'(S)$ alone whether two minimal parabolic subgroups P, P' are in standard position. In particular, the subset $E(S)$ of $G(S)$ does not appear to be definable solely from the configuration

$$\{G(S), P(S), \underline{\mathrm{Norm}}_G(L)(S)\}.$$

In the example above, this subset is defined by $c \neq 2$. [36]

[35] Indeed, B' is the subgroup of G defined by $c = 2(a+b)$. Thus $B \cap B'$ is not flat over S, and hence contains no maximal torus, by 4.5.1.

[36] More generally, for every S-scheme S', the set $E(S')$ is defined by the condition that c is either zero or invertible.

7.12.

We now study how $\mathcal{R}(G/S)$ varies with S. Let S' be an S-scheme which is likewise nonempty, connected, and semilocal. If Q is a maximal split torus of G, then $Q_{S'}$ is a split torus of $G_{S'}$. Choose a maximal split torus Q' of $G_{S'}$ containing $Q_{S'}$, and put

$$M = \mathrm{Hom}_{S\text{-gr}}(Q, \mathbf{G}_{m,S}) \simeq \mathrm{Hom}_{S'\text{-gr}}(Q_{S'}, \mathbf{G}_{m,S'}),$$
$$M' = \mathrm{Hom}_{S'\text{-gr}}(Q', \mathbf{G}_{m,S'}).$$

The monomorphism $Q_{S'} \to Q'$ induces an epimorphism

$$u : M' \longrightarrow M.$$

Write

$$L = \underline{\mathrm{Centr}}_G(Q), \qquad L' = \underline{\mathrm{Centr}}_{G_{S'}}(Q').$$

Then $L' \subset L_{S'}$.

If H is a subgroup of G containing L, then $H_{S'}$ contains L', and

$$\mathrm{Lie}(H) = \mathrm{Lie}(L) \oplus \bigoplus_{\alpha \in R_H} \mathrm{Lie}(H)^{\alpha},$$
$$\mathrm{Lie}(H_{S'}) = \mathrm{Lie}(L') \oplus \bigoplus_{\alpha' \in R'_{H_{S'}}} \mathrm{Lie}(H_{S'})^{\alpha'}.$$

Here R_H, respectively $R'_{H_{S'}}$, denotes the set of roots of H, respectively $H_{S'}$, relative to Q, respectively Q'. It follows immediately that

$$R_H \subset u(R'_{H_{S'}}) \subset R_H \cup \{0\}.$$

Taking $H = G$, we first obtain

$$R \subset u(R') \subset R \cup \{0\}.$$

Next take for H a minimal parabolic subgroup P with Levi subgroup L. Then $R'_{H_{S'}}$ contains a system of positive roots in R'. By 7.4, there is therefore a minimal parabolic subgroup P' of $G_{S'}$, with Levi subgroup L', contained in $P_{S'}$. We have constructed the diagram of inclusions

$$\begin{array}{ccccc} Q_{S'} & \subset & L_{S'} & \subset & P_{S'} \\ \cap & & \cup & & \cup \\ Q' & \subset & L' & \subset & P'. \end{array}$$

If R^+, respectively Δ, is the system of positive, respectively simple, roots in R defined by P, and if R'^+, Δ' are defined similarly, then

$$R^+ \subset u(R'^+) \subset R^+ \cup \{0\}, \qquad \Delta \subset u(\Delta') \subset \Delta \cup \{0\}.$$

Now let

$$w \in W \simeq \underline{\mathrm{Norm}}_G(Q)(S)/\underline{\mathrm{Centr}}_G(Q)(S),$$

and choose a representative $n \in \underline{\mathrm{Norm}}_G(Q)(S)$. Since $\mathrm{int}(n)Q = Q$, one has $\mathrm{int}(n)L = L$, and hence $\mathrm{int}(n)L_{S'} = L_{S'}$. The tori Q' and $\mathrm{int}(n)Q'$ are therefore two maximal split tori of $L_{S'}$, so they are conjugate by an element $x \in L(S')$. We may choose x so that

$$\mathrm{int}(nx)Q' = Q'.$$

Thus $n' = nx$ belongs to $\underline{\mathrm{Norm}}_{G_{S'}}(Q')(S')$. Let w' be the image of n' in

$$W' \simeq \underline{\mathrm{Norm}}_{G_{S'}}(Q')(S')/\underline{\mathrm{Centr}}_{G_{S'}}(Q')(S').$$

The action of w' on M' is compatible with $u : M' \to M$, and the induced action on M is the action of w.

Using the definition of relative root data together with the conjugacy theorems gives the following result.

Theorem 7.13.— *Let S, S' be nonempty connected semilocal schemes, let $S' \to S$ be a morphism of schemes, let G be an S-reductive group, and write*

$$\mathcal{R}(G/S) = (\underline{M}, \underline{M}^*, \underline{R}, \underline{R}^*, \underline{R}^+),$$
$$\mathcal{R}(G_{S'}/S') = (\underline{M}', \underline{M}'^*, \underline{R}', \underline{R}'^*, \underline{R}'^+)$$

for the based relative root data. There is a canonical homomorphism

$$u : \underline{M}' \longrightarrow \underline{M}$$

with the following properties:

(i) *The homomorphism u is surjective.*

(ii) *For every $w \in W$, there is an element $w' \in W'$ compatible with u and inducing w on $\underline{M}$.*

(iii) *For every subset $X \subset \underline{M}$, put*

$$X^\wedge = X \cap (\underline{M} \setminus \{0\}).$$

Then

$$u(\underline{R}'^+)^\wedge = \underline{R}^+, \qquad u(\underline{\Delta}')^\wedge = \underline{\Delta}.$$

(iv) *For every parabolic subgroup H, consider*

$$t_r(H) \subset \underline{\Delta}, \qquad t_r(H_{S'}) \subset \underline{\Delta}'.$$

Then

$$\begin{aligned} t_r(H_{S'}) &= u^{-1}\big(t_r(H) \cup \{0\}\big) \cap \underline{\Delta}' \\ &= \left\{\alpha' \in \underline{\Delta}' \;\middle|\; u(\alpha') \in t_r(H) \text{ or } u(\alpha') = 0\right\}. \end{aligned}$$

Remark 7.14.— *If G is splittable over S, its maximal split tori are maximal tori, and the relative notions introduced here coincide with the previously defined absolute notions. The preceding theorem therefore describes the relative root datum $\mathcal{R}(G/S)$ and the relative type t_r in terms of the absolute root datum and absolute type of $G_{S'}$, where S' is chosen so that $G_{S'}$ is splittable* (cf. Exposé XXIV, 4.4.1). *See* [BT65], *6.12 and following, for this description.*

7.15.

Let S be a Henselian local scheme, s_0 its closed point, and S_0 the spectrum of the residue field at s_0, identified with a closed subscheme of S. For every object X over S, write X_0 for its base change to S_0. Let G be an S-reductive group.

For every parabolic subgroup $\overline{P}$ of G, the group $\overline{P}_0$ is a parabolic subgroup of G_0. Conversely, for every parabolic subgroup P of G_0, there is a parabolic subgroup $\overline{P}$ of G such that

$$\overline{P}_0 = P.$$

This follows from Hensel's lemma and from the fact that $\underline{\mathrm{Par}}(G)$ is a smooth S-scheme. In particular, by 5.7, $\overline{P}$ is minimal if and only if $\overline{P}_0$ is minimal.

Once such a subgroup $\overline{P}$ has been chosen, the same argument shows that every maximal split subtorus of $\overline{P}_0$ is of the form T_0, where T is a maximal split subtorus of $\overline{P}$. It follows readily that the relative root data of G over S and of G_0 over S_0 are canonically isomorphic. Thus the theory of parabolic subgroups of G reduces to the corresponding theory for G_0.

Conversely, every S_0-reductive group is of the form G_0, by Exposé XXIV, Proposition 1.21. This makes it possible to reduce the study of the parabolic subgroups of an S_0-reductive group to the corresponding study over S.

EXPOSÉ I

Presheaves

A. Grothendieck and J.-L. Verdier

In numbers 0 through 5 of this exposé, we present the elementary, and most often well-known, properties of categories of presheaves[i]. These properties are used constantly throughout the rest of the seminar, and knowledge of them is essential for understanding the subsequent exposés. The proofs are immediate; most often, they are omitted. In numbers 6 through 9, we take up a few themes used on various occasions later. The reader in a hurry may omit them on a first reading. Number 10 fixes the terminology used. Appendix 11 is due to N. Bourbaki. 1

0. Universes

A *universe* is a nonempty set[1] $\mathcal{U}$ having the following properties:

($\mathcal{U}$ 1) If $x \in \mathcal{U}$ and $y \in x$, then $y \in \mathcal{U}$.
($\mathcal{U}$ 2) If $x, y \in \mathcal{U}$, then $\{x, y\} \in \mathcal{U}$.
($\mathcal{U}$ 3) If $x \in \mathcal{U}$, then $\mathcal{P}(x) \in \mathcal{U}$.
($\mathcal{U}$ 4) If $(x_i, i \in I)$ is a family of elements of $\mathcal{U}$ and $I \in \mathcal{U}$, then $\cup_{i\in I} x_i \in \mathcal{U}$.

From the preceding axioms one readily deduces the following properties: 2

- If $x \in \mathcal{U}$, the set $\{x\}$ belongs to $\mathcal{U}$.
- If x is a subset of $y \in \mathcal{U}$, then $x \in \mathcal{U}$.
- If $x, y \in \mathcal{U}$, the ordered pair $(x, y) = \{\{x, y\}, x\}$ (Kuratowski's definition) is an element of $\mathcal{U}$.
- If $x, y \in \mathcal{U}$, the union $x \cup y$ and the product $x \times y$ are elements of $\mathcal{U}$.
- If $(x_i, i \in I \in \mathcal{U})$ is a family of elements of $\mathcal{U}$, the product $\prod_{i\in I} x_i$ is an element of $\mathcal{U}$.
- If $x \in \mathcal{U}$, then $\mathrm{card}(x) < \mathrm{card}(\mathcal{U})$ (strictly). In particular, the relation $\mathcal{U} \in \mathcal{U}$ does not hold.

We can therefore carry out all the usual operations of set theory starting from the elements of a universe without thereby causing the final result to cease to be an element of the universe.

The first advantage of the notion of a universe is that it provides a definition of the usual categories: the category of sets belonging to the universe $\mathcal{U}$ ($\mathcal{U}$-Ens), the category of topological spaces belonging to the universe $\mathcal{U}$, the category of commutative groups belonging to the universe $\mathcal{U}$ ($\mathcal{U}$-Ab), the category of categories belonging to the universe $\mathcal{U}$....

However, the only known universe is the set of symbols of the form $\{\{\emptyset\}, \{\{\emptyset\}, \emptyset\}\}$ etc.. (all the elements of this universe are finite sets, and this universe is countable). In particular, no universe is known that contains an element of infinite cardinality. We are

[i] The reader may also consult SGA 3 I § § 1 to 3.

[1] N.D.E.: This definition contradicts Bourbaki's appendix *below*. However, the usefulness of empty universes seems debatable...

therefore led to add to the axioms of set theory the axiom: ($\mathcal{U}\,A$) *For every set x there exists a universe $\mathcal{U}$ such that $x \in \mathcal{U}$.*

3 Since the intersection of a family of universes is a universe, it follows immediately that every set is an element of a smallest universe. One can show that axiom ($\mathcal{U}\,A$) is independent of the axioms of set theory.

We shall also add the axiom:

($\mathcal{U}\,B$) *Let $R\{x\}$ be a relation and let $\mathcal{U}$ be a universe. If there exists an element $y \in \mathcal{U}$ such that $R\{y\}$, then $\tau_x R\{x\} \in \mathcal{U}$.*

The consistency of axioms ($\mathcal{U}\,A$) and ($\mathcal{U}\,B$) relative to the other axioms of set theory has not been proved and, it seems, cannot be proved.

Let $\mathcal{U}$ be a universe and let $c(\mathcal{U})$ be the supremum of the cardinalities of the elements of $\mathcal{U}$ ($c(\mathcal{U}) \leq \mathrm{card}(\mathcal{U})$). The cardinal $c(\mathcal{U})$ has the following properties:

($F\,I$) If $a < c(\mathcal{U})$, then $2^a < c(\mathcal{U})$.

($F\,I\,I$) If $(a_i, i \in I)$ is a family of cardinals strictly less than $c(\mathcal{U})$ and if $\mathrm{card}(I)$ is strictly less than $c(\mathcal{U})$, then $\Sigma_{i\in I} a_i < c(\mathcal{U})$.

The cardinals that have properties ($F\,I$) and ($F\,I\,I$) are called *strongly inaccessible cardinals.*

The cardinal 0 and the countably infinite cardinal are strongly inaccessible.

Axiom ($\mathcal{U}\,A$) implies:

($\mathcal{U}\,A'$) *Every cardinal is strictly less than a strongly inaccessible cardinal.*

Conversely, one can show (11) that the consistency of ($U\,A'$) implies the consistency of ($U\,A$), and that the consistency of these axioms entails that of axiom ($\mathcal{U}\,B$).

4 Call an *Artinian set* any set E for which there is no infinite family $(x_n, n \in N)$ such that $x_\circ \in E$, $x_{n+1} \in x_n$. One can then show [*loc. cit.*] that there is a one-to-one correspondence between the strongly inaccessible cardinals and the Artinian universes, defined as follows: to every strongly inaccessible cardinal c we associate the unique Artinian universe U_c such that

$$\mathrm{card}(\mathcal{U}_c) = c.$$

Let $c < c'$ be two strongly inaccessible cardinals. We have:

$$\mathcal{U}_c \in \mathcal{U}'_{c'}.$$

In particular, the Artinian universes of cardinality less than a given cardinal form a well-ordered set (with respect to the membership relation). Axiom ($\mathcal{U}\,A'$) is equivalent to the axiom:

($\mathcal{U}\,A''$). *Every Artinian set is an element of an Artinian universe.*

Observe that all the usual sets ($\mathbf{Z}, \mathbf{Q}, \ldots$) are Artinian sets.

1. $\mathcal{U}$-categories. Presheaves of sets

1.0. *Throughout the remainder of the seminar and unless expressly stated otherwise, the universes under consideration will contain an element of infinite cardinality.* Let $\mathcal{U}$ be a universe. A set is said to be *$\mathcal{U}$-small* (or, when no confusion can result, *small*) if it is *isomorphic* to an element of $\mathcal{U}$. We shall also use the terminology: small group, small ring, small category[2] ...We shall often assume, without explicit mention, that the
5 schemes, topological spaces, indexing sets...with which we work are $\in \mathcal{U}$, or at least have cardinality $\in \mathcal{U}$; nevertheless, many of the categories with which we shall work will not be $\in \mathcal{U}$.

[2] N.D.E.: A category C is regarded as a set of arrows (equipped with the subset of objects, regarded as the set of identity arrows, and with the "source, target" maps). Thus, the expressions "C is an element of $\mathcal{U}$" or "C is $\mathcal{U}$-small" make sense.

DEFINITION 1.1. *Let $\mathcal{U}$ be a universe and C a category. We say that C is a $\mathcal{U}$-category if, for every pair (x, y) of objects of C, the set $\mathrm{Hom}_C(x, y)$ is $\mathcal{U}$-small.*

1.1.1. Let C and D be two categories and let $\mathrm{Fonct}(C, D)$ be the category of functors from C to D. The following assertions are immediate:

a) If C and D are elements of a universe $\mathcal{U}$ (resp. are $\mathcal{U}$-small), the category $\mathrm{Fonct}(C, D)$ is an element of $\mathcal{U}$ (resp. is $\mathcal{U}$-small).
b) If C is $\mathcal{U}$-small and D is a $\mathcal{U}$-category, $\mathrm{Fonct}(C, D)$ is a $\mathcal{U}$-category.

REMARK 1.1.2. Let D be a category having the following properties:

(C1) The set $\mathrm{ob}(D)$ is contained in the universe $\mathcal{U}$.
(C2) For every pair (x, y) of objects of D, the set $\mathrm{Hom}_D(x, y)$ is an element of $\mathcal{U}$.

(The usual categories constructed from a universe $\mathcal{U}$ have these two properties: $\mathcal{U}$-Ens, $\mathcal{U}$-Ab,...). Let C be a category belonging to $\mathcal{U}$. Then the category $\mathrm{Fonct}(C, D)$ does not in general have properties (C1) and (C2). For example, the category $\mathrm{Fonct}(C, \mathcal{U}\text{-Ens})$ has neither property (C1) nor property (C2). This justifies the adopted definition of $\mathcal{U}$-category, in preference to the more restrictive notion given by conditions (C1) and (C2) above.

DEFINITION 1.2. *Let C be a category. The category of presheaves of sets on C relative to the universe $\mathcal{U}$ (or, when no confusion can result, the category of presheaves on C) is the category of contravariant functors on C with values in the category of $\mathcal{U}$-sets.* 6

We denote by $\widehat{C}_{\mathcal{U}}$ (or more simply, when no confusion can result, by $\widehat{C}$) the category of presheaves of sets on C relative to the universe $\mathcal{U}$. The objects of $\widehat{C}_{\mathcal{U}}$ are called $\mathcal{U}$-presheaves (or simply presheaves) on C. When C is $\mathcal{U}$-small, the category $\widehat{C}_{\mathcal{U}}$ is a $\mathcal{U}$-category. When C is a $\mathcal{U}$-category, $\widehat{C}_{\mathcal{U}}$ is not necessarily a $\mathcal{U}$-category.

CONSTRUCTION-DEFINITION 1.3. Let x be an object of a $\mathcal{U}$-category C. The *$\mathcal{U}$-functor represented by x* is the functor $h_{\mathcal{U}}(x) : C^\circ \to \mathcal{U}\text{-Ens}$ whose construction is as follows [2]. Let y be an object of C.

a) If $\mathrm{Hom}_C(y, x)$ is an element of $\mathcal{U}$, then:

$$h_{\mathcal{U}}(x)(y) = \mathrm{Hom}_C(y, x)$$

b) Suppose that $\mathrm{Hom}_C(y, x)$ is not an element of $\mathcal{U}$ and let $R(Z, x, y)$ be the relation: "The set Z is the codomain of an isomorphism $\mathrm{Hom}_C(y, x) \xrightarrow{\sim} Z$". We then set:

$$h_{\mathcal{U}}(x)(y) = \tau_Z R(Z).$$

(By axiom ($\mathcal{U}B$), $h_{\mathcal{U}}(x)(y)$ is an element of $\mathcal{U}$). Let $R'(u, x, y)$ be the relation: « u is a bijection

$$u : \mathrm{Hom}_C(y, x) \xrightarrow{\sim} h_{\mathcal{U}}(x)(y) ».$$

We then set: 7

$$\varphi(y, x) = \tau_u R'(u).$$

It should be noted that, in cases (a) and (b), we have *a* canonical isomorphism:

$$\varphi(y, x) : \mathrm{Hom}_C(y, x) \xrightarrow{\sim} h_{\mathcal{U}}(x)(y).$$

[2] C° will always denote the category opposite to C.

(In case a) $\varphi(y,x)$ is the identity). Now let $u : y \to y'$ be an arrow of C. By composition of morphisms, the morphism u defines a map:

$$\mathrm{Hom}_C(u,x) : \mathrm{Hom}_C(y',x) \longrightarrow \mathrm{Hom}_C(y,x).$$

We then set

$$h_{\mathscr{U}}(x)(u) = \varphi(y,x)\,\mathrm{Hom}_C(x,u)\varphi(y,x)^{-1}.$$

It is immediate that $h_{\mathscr{U}}(x)$, so defined, is a functor $\widehat{C} \to \mathscr{U}$-Ens.

1.3.1. Similarly, using the isomorphisms φ, for every morphism $y : x \to x'$ we define a morphism of functors:

$$h_{\mathscr{U}}(y) : h_{\mathscr{U}}(x) \longrightarrow h_{\mathscr{U}}(x')$$

and it is immediate that this defines a functor

$$h_{\mathscr{U}} : C \longrightarrow \widehat{C}_{\mathscr{U}}.$$

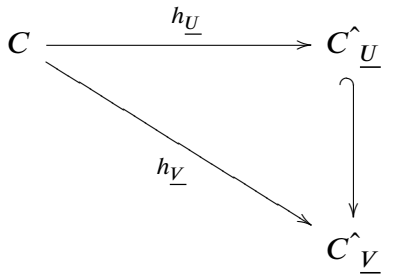
1.3.2. Now let $\mathscr{V}$ be a universe such that $\mathscr{U} \subset \mathscr{V}$. There is then a canonical fully faithful functor:

$$\mathscr{U}\text{-Ens} \hookrightarrow \mathscr{V}\text{-Ens}$$

whence a fully faithful functor:

$$\widehat{C}_{\mathscr{U}} \hookrightarrow \widehat{C}_{\mathscr{V}}$$

8 and the diagram:



commutes up to canonical isomorphism. When C is an element of $\mathscr{U}$, this canonical isomorphism is the identity.

1.3.3. *In practice, the universe $\mathscr{U}$ is fixed once and for all and is not mentioned.* We then use the notations $\widehat{C}$ (for the category of $\mathscr{U}$-presheaves of sets) and

$$h : C \longrightarrow \widehat{C}.$$

For every object x of C, the presheaf $h(x)$ is called the *presheaf represented by x*, and we shall always identify the value at $y \in \mathrm{ob}(C)$ of the presheaf $h(x)$ with $\mathrm{Hom}_C(y,x)$.

Proposition 1.4. *Let C be a $\mathscr{U}$-category, F a presheaf on C, and X an object of C. There is an isomorphism functorial in X and in F:*

$$i : \mathrm{Hom}_{\widehat{C}}(h(X),F) \xleftarrow{\sim} F(X),$$

where the map i, when F is of the form $h(Y)$, is none other than the map:

$$h : \mathrm{Hom}(h(X),h(Y)) \longleftarrow \mathrm{Hom}(X,Y).$$

In particular, the functor h is fully faithful.

1.4.1. This proposition justifies the customary abuse of language identifying an ob-
9 ject of C with the corresponding contravariant functor. A presheaf isomorphic to an object in the image of h (or, using the abuse of language noted above, isomorphic to an object of C) is called a *representable presheaf.*

1.4.2. Let $\mathscr{V}$ be a universe containing the universe $\mathscr{U}$. The category of $\mathscr{U}$-presheaves is a *full* subcategory of the category of $\mathscr{V}$-presheaves, and consequently a $\mathscr{U}$-presheaf is representable if and only if its image in the category of $\mathscr{V}$-presheaves is a representable $\mathscr{V}$-presheaf.

2. Projective and inductive limits

Let C be a $\mathscr{U}$-category and I a small category. Denote by $\mathrm{Fonct}(I, C)$ the category of functors from I to C. The category $\mathrm{Fonct}(I, C)$ is a $\mathscr{U}$-category. To every object X of C, associate the subcategory $\mathscr{X}$ of C whose only object is X and whose only arrow is the identity of X. Let $i_X : \mathscr{X} \to C$ denote the inclusion functor. There is a unique functor $e_X : I \to \mathscr{X}$, and we denote by $k_X : I \to C$ the functor $i_X \circ e_X$. (We say that k_X is the constant functor with value X.) The correspondence $X \mapsto k_X$ is clearly functorial in X, which allows us to define, for every functor $G : I \to C$, the presheaf $X \mapsto \mathrm{Hom}_{\mathrm{Fonct}(I,C)}(k_X, G)$.

Definition 2.1. *The projective limit of G, denoted by $\varprojlim_I G$, is the presheaf:*

$$X \longmapsto \mathrm{Hom}_{\mathrm{Fonct}(I,C)}(k_X, G).$$

When the presheaf $\varprojlim_I G$ is representable, we also denote by $\varprojlim_I G$ an object of C rep- 10
resenting it. Thus the object $\varprojlim_I G$ is defined only up to isomorphism. When no confusion can result, we use the abbreviated notation $\varprojlim G$.

As G varies, $\varprojlim G$ is a functor from the category $\mathrm{Fonct}(I, C)$ to $\widehat{C}$.

2.1.1. By symmetry (reversing the direction of the arrows in C), one similarly defines the inductive limit of a functor: it is a covariant functor on C with values in the category of $\mathscr{U}$-sets. We shall use the notations $\varinjlim_I G$ or $\varinjlim G$.

Observe that products, fiber products, and kernels are projective limits. Similarly, sums, amalgamated sums, and cokernels are inductive limits.

Definition 2.2. *Let I and C be two categories and $G : I \to C$ a functor. The projective limit of G is said to be representable if there exists a universe $\mathscr{U}$ such that:*

1) *The category I is $\mathscr{U}$-small.*
2) *The category C is a $\mathscr{U}$-category.*
3) *The presheaf $\varprojlim G$, with values in the category of $\mathscr{U}$-sets, is representable.*

It follows from n° 1 that the object $\varprojlim G$ representing the presheaf $\varprojlim G$ is independent, up to isomorphism, of the universe $\mathscr{U}$. Note also that there exists a smallest universe $\mathscr{U}'$ having properties (1) and (2), and that the presheaf $\varprojlim G$ necessarily takes values in the category of $\mathscr{U}'$-sets.

2.2.1. Let I and C be two categories. We say that *the I-projective limits in C are* 11
representable if, for every functor $G : I \to C$, the projective limit of G is representable. Finally, let C be a category and $\mathscr{U}$ a universe. We say that the *$\mathscr{U}$-projective limits in C are representable* if, for every category I that is $\mathscr{U}$-small and every functor $G : I \to C$, the projective limit of G is representable.

Proposition 2.3. *Let C be a category and $\mathscr{U}$ a universe. The following assertions are equivalent:*

i) *The $\mathcal{U}$-projective limits in C are representable.*
ii) *Products indexed by a small set are representable, and kernels of pairs of arrows are representable.*
iii) *Products indexed by a small set are representable, and fiber products are representable.*

PROOF. It suffices to observe that there is an isomorphism, functorial in G,

$$\varprojlim G = \mathrm{Ker}\Big(\prod_{i\in \mathrm{ob}(I)} G(i) \rightrightarrows \prod_{u\in \mathrm{F\ell(I)}} G(\mathrm{but}(u))\Big),$$

where the pair of arrows is defined by the morphisms

$$\prod_{i\in \mathrm{Ob}(I)} G(i) \xrightarrow{\mathrm{pr}_{\mathrm{but}(u)}} G(\mathrm{but}(u))$$

$$\prod_{i\in \mathrm{Ob}(I)} G(i) \xrightarrow{\mathrm{pr}_{\mathrm{source}(u)}} G(\mathrm{source}\ (u)) \xrightarrow{G(u)} G(\mathrm{but}(u)).$$

Moreover, it is clear that $\mathrm{Ker}(X \overset{u}{\underset{v}{\rightrightarrows}} Y) = X \prod_{X\times Y} X$, where the two morphisms from X to $X \times Y$ are $\mathrm{id}_X \times u$ and $\mathrm{id}_X \times v$.

2.3.1. There are of course analogous definitions and assertions for inductive limits,
12 which we shall not spell out. The same applies to finite projective and inductive limits (i.e. those relative to a finite category I).

COROLLARY 2.3.2. *Denote by $\mathcal{U}$-*Ens *the category of $\mathcal{U}$-sets and by $\mathcal{U}$-*Ab *the category of abelian group objects in $\mathcal{U}$-*Ens*. The $\mathcal{U}$-projective and inductive limits in $\mathcal{U}$-*Ens *and in $\mathcal{U}$-*Ab *are representable.*

PROPOSITION 2.3.3. *Let I be a small category, $F : I \to \mathcal{U}$-*Ens *a functor, and $G \in \mathrm{ob}\ I$ a small set of objects of I such that, for every object X of I, there exists an object $Y \in G$ and a morphism $Y \to X$ (resp. $X \to Y$). Then $\varprojlim_I F$ (resp. $\varinjlim_I F$) is representable, and $\mathrm{card}(\varprojlim_I F) \leq \Pi_{Y\in G} \mathrm{card}(F(Y))$ (resp. $\mathrm{card}(\varinjlim_I F) \leq \Sigma_{Y\in G} \mathrm{card}(F(Y))$).*

PROOF. One immediately verifies that $\varprojlim_I F'$ (resp. $\varinjlim_I F'$) is isomorphic to a subobject (resp. a quotient) of $\Pi_{Y\in G} F(Y)$ (resp. $\amalg_{Y\in G} F(Y)$); hence the proposition.

DEFINITION 2.4.1. *Let C be a category in which finite projective (resp. inductive) limits are representable, and let $u : C \to C'$ be a functor. We say that u is left exact (resp. right exact) if it "commutes" with finite projective (resp. inductive) limits. A functor that is both left and right exact is called an exact functor.*

2.4.2. It follows from 2.3 that, for a functor to be exact on the left, it is necessary and sufficient that it take the terminal object (= empty product) to the terminal object, the product of two objects to the product of their images, and the kernel of a pair of arrows to the kernel of the image pair; equivalently, that it take the terminal object to the terminal object and fiber products to fiber products (we assume that in C finite $\varprojlim$ are representable).

13 2.5.0. Let I, J, and C be three categories, and let $G : I \times J \to C$ be a functor (i.e. a functor from I with values in the category of functors from J to C). Suppose that the projective limits of the functors

$$G_i : J \longrightarrow C \qquad i \in \mathrm{ob}(I)$$
$$j \longmapsto G(i \times j)$$

are representable, and that the functor

$$i \longmapsto \varprojlim G_i$$

admits a representable projective limit. It is then clear that the functor G admits a representable projective limit and that there is a canonical isomorphism

$$\varprojlim_{I \times J} G \xrightarrow{\sim} \varprojlim_I \varprojlim_J G_i,$$

and consequently a canonical isomorphism

$$\varprojlim_I \varprojlim_J G_i \xrightarrow{\sim} \varprojlim_J \varprojlim_I G_j.$$

Hereafter we shall say more briefly that projective limits commute with projective limits. Similarly, inductive limits commute with inductive limits. But in general it is not true that inductive limits commute with projective limits.

Definition 2.5. *Let C be a category with representable fiber products, I a category, $G : I \to C$ a functor, $g : G \to X$ a morphism from G to an object of C (i.e. a morphism from G to the constant functor associated with X), and $m : Y \to X$ a morphism in C. Let* 14
$G \times_X Y : I \to C$ *be the functor*

$$i \longmapsto G(i) \times_X Y.$$

We say that the inductive limit of G is universal if, for every object X, every morphism $g : G \to X$, and every morphism $m : Y \to X$,

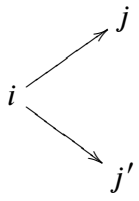
a) *the inductive limit of the functor $G \times_X Y$ is representable,*
b) *the canonical morphism $\varinjlim(G \times_X Y) \to (\varinjlim G) \times_X Y$ is an isomorphism.*

Proposition 2.6. *Let $\mathcal{U}$ be a universe. The inductive limits in $\mathcal{U}$-*Ens *that are representable (in particular, the $\mathcal{U}$-inductive limits (2.2.1) in $\mathcal{U}$-*Ens*) are universal.*

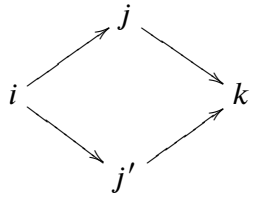
We shall also use another commutation result for projective and inductive limits, which we now present.

Definition 2.7. *A category I is pseudo-filtered if it has the following properties:*

PS 1) *Every diagram of the form*



can be embedded in a commutative diagram



PS 2) *Every diagram of the form*

$$i \underset{v}{\overset{u}{\rightrightarrows}} j$$

15 *can be embedded in a diagram*

$$i \underset{v}{\overset{u}{\rightrightarrows}} j \xrightarrow{w} k$$

such that

$$w \circ u = w \circ v.$$

A category I is said to be filtered if it is pseudo-filtered, nonempty, and connected, i.e. if any two objects of I can be joined by a sequence of arrows (with no condition imposed on the directions of the arrows); in the presence of PS 2*, this also means that $I \neq \emptyset$ and that, for any two objects a, b of I, there is always an object c of I and arrows $a \to c$ and $b \to c$. We also say that a category I is cofiltered if I° is filtered.*

Example 2.7.1. *If, in I, amalgamated sums (resp. sums of two objects) and cokernels of pairs of parallel arrows are representable, then I is pseudo-filtered (resp. filtered).*

Proposition 2.8. *Let $\mathscr{U}$ be a universe. Filtered $\mathscr{U}$-inductive limits in $\mathscr{U}$-*Ens *commute with finite projective limits.*

We are immediately reduced to proving that filtered $\mathscr{U}$-inductive limits commute with fiber products. The proof is left to the reader. One may use the description of the limit given by the following

Lemma 2.8.1. *Let I be a small filtered category and $i \mapsto X_i$ a functor from I to $\mathscr{U}$-*Ens*. On the disjoint union $\coprod_{i \in \mathrm{ob}\, I} X_i$, let R be the relation:*

(R) *Two elements $x_i \in X_i$ and $x_j \in X_j$ are related if there exists an object $k \in \mathrm{ob}\, I$ and two morphisms $u : i \to k$ and $v : j \to k$ such that the images in X_k of x_i and x_j under the transition maps u and v, respectively, are equal.*

16 *Then:*

1) *R is an equivalence relation.*
2) *The quotient $\coprod_{i \in \mathrm{ob}\, I} X_i / R$ is canonically isomorphic to $\varinjlim_I X_i$.*
3) *Two elements $x_i \in X_i$ and $x_j \in X_j$ are respectively equivalent under R to two elements of the same X_k.*
4) *For every $i \in \mathrm{ob}\, I$, two elements α and β of X_i are equivalent under R if and only if there is a morphism $u : i \to j$ such that $u(\alpha) = u(\beta)$.*

Assertion 1) follows from (PS 1) (2.7). To prove 2), one checks that $\coprod_{i \in \mathrm{ob}\, I} X_i / R$ has the universal property of the inductive limit (only (PS 1) is used). Assertion 3) follows from the fact that I is connected. Assertion 4) follows from (PS 2).

COROLLARY 2.9. *Let γ be a kind of algebraic structure "defined by finite projective limits." (The reader is asked to give a mathematical meaning to the preceding phrase. We merely note that the structures of groups, abelian groups, rings, modules, etc. are structures of this kind.) Denote by $\mathscr{U}$-γ the category of γ-objects in $\mathscr{U}$-*Ens. *The functor that associates with each object of $\mathscr{U}$-γ its underlying set commutes with filtered $\mathscr{U}$-inductive limits. Consequently, filtered $\mathscr{U}$-inductive limits in $\mathscr{U}$-γ commute with finite projective limits.*

COROLLARY 2.10. *Pseudo-filtered $\mathscr{U}$-inductive limits in $\mathscr{U}$-*Ab *commute with finite projective limits.*

(One reduces to filtered limits by decomposing the indexing category into connected components.)

We now record a result that we shall use constantly: let C and C' be two $\mathscr{U}$-categories, and let u and v be two functors $C \underset{u}{\overset{v}{\leftrightarrows}} C'$, with u *left adjoint* to v. Recall that this means that there is an isomorphism between the bifunctors with values in $\mathscr{U}$-Ens: 17

$$\mathrm{Hom}_{C'}(u(X), X') \xrightarrow{\sim} \mathrm{Hom}_{C}(X, v(X')).$$

PROPOSITION 2.11. *The functor u commutes with representable inductive limits; the functor v commutes with representable projective limits.*

This assertion means that, for every category I and every functor $G : I \to C'$ such that the projective limit of G is representable, the functor $v \circ G$ has a representable projective limit and there is a canonical isomorphism

$$v(\varprojlim G) \longrightarrow \varprojlim(v \circ G).$$

The reader may spell out the assertion concerning the functor u.

Finally, we record a computation of projective limits in the case where the indexing category has products.

PROPOSITION 2.12. *Let I and C be two categories, and $\mathscr{V}$ a universe. Assume that the $\mathscr{V}$-projective limits in C are representable and that there is in I a family of objects $(i_\alpha)_{\alpha \in A}$, where A is an element of $\mathscr{V}$, such that:*

1) *the products $i_\alpha \times i_\beta$ are representable for every pair $(\alpha, \beta) \in A \times A$,*
2) *every object of I admits a morphism to at least one of the i_α.*

Then, for every contravariant functor F from I to C,

$$F : I^\circ \longrightarrow C,$$

the projective limit of F exists, and there is an isomorphism functorial in F:

$$\varprojlim F \xrightarrow{\sim} \mathrm{Ker}\left(\prod_{\alpha \in A} F(i_\alpha) \rightrightarrows \prod_{(\alpha,\beta) \in A \times A} F(i_\alpha \times i_\beta)\right),$$

where the two arrows are defined by the projections of the products $i_\alpha \times i_\beta$ onto their factors. 18

3. Exactness properties of the category of presheaves

Let C be a $\mathscr{U}$-category and let $\widehat{C}$ be the category of presheaves on C. All the exactness properties of $\widehat{C}$ follow from the following proposition:

PROPOSITION 3.1. *The $\mathcal{U}$-projective and inductive limits in $\widehat{C}$ are representable. For every object X of C, the functor on $\widehat{C}$*

$$F \longmapsto F(X) \qquad F \in \widehat{C}$$

commutes with inductive and projective limits.

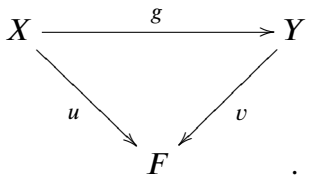
In other words, "inductive and projective limits in $\widehat{C}$ are computed argument by argument." We mention a few corollaries.

COROLLARY 3.2. *Let γ be an algebraic structure defined by finite projective limits. The category of contravariant functors with values in $\mathcal{U}$-γ is equivalent to the category of γ-objects of $\widehat{C}$.*

COROLLARY 3.3. *A morphism of $\widehat{C}$ that is both a monomorphism and an epimorphism is an isomorphism. A morphism of $\widehat{C}$ factors uniquely as an epimorphism followed by a monomorphism. The representable inductive limits in $\widehat{C}$ are universal. The filtered $\mathcal{U}$-inductive limits in $\widehat{C}$ commute with finite projective limits. The canonical functor $C \to \widehat{C}$ commutes with representable projective limits.*

19 More generally, one may say that the category $\widehat{C}$ inherits all the properties of the category of $\mathcal{U}$-sets that involve inductive and projective limits.

3.4.0. Let F be an object of $\widehat{C}$. We denote by C/F the following category. The objects of C/F are pairs consisting of an object X of C and a morphism u from X to F. Let (X,u) and (Y,v) be two objects. A morphism from (X,u) to (Y,v) is a morphism g from X to Y such that the following diagram is commutative:



PROPOSITION 3.4. *With the notation of (3.4.0), the source functor $C/F \to \widehat{C}$ admits a representable inductive limit in $\widehat{C}$. The canonical morphism*

$$\varinjlim_{C/F} \text{source}\,(.) \longrightarrow F$$

is an isomorphism.

COROLLARY 3.5. *Let F and H be two objects of $\widehat{C}$. There is a canonical isomorphism*

$$\mathrm{Hom}(F,H) \xrightarrow{\sim} \varprojlim_{(X,u)\in \mathrm{ob}(C/F)} H(X).$$

PROOF. The corollary follows immediately from 3.4 and 1.2.

20 PROPOSITION 3.6. *Let C be a $\mathcal{U}$-category, let $\mathcal{V}$ be a universe containing $\mathcal{U}$, and let $i : \widehat{C}_{\mathcal{U}} \to \widehat{C}_{\mathcal{V}}$ be the natural inclusion functor of the corresponding categories of presheaves (1.3). The functor i commutes with inductive and projective limits. Moreover, for every object F of $\widehat{C}_{\mathcal{U}}$, every subobject of $i(F)$ is isomorphic to the image under i of a unique subobject of F (thus giving a bijection from the set of subobjects of F to the set of subobjects of $i(F)$).*

4. Sieves

DEFINITION 4.1. *Let C be a category. A* sieve *in the category C is a full subcategory D of C with the following property: every object of C from which there exists a morphism to an object of D belongs to D. If X is an object of C, the sieves of X are (by an abuse of language) the sieves in the category C/X.*

Let $\mathscr{U}$ be a universe such that C is a $\mathscr{U}$-category. Let $\widehat{C}$ be the corresponding category of presheaves. To every sieve of X one associates a subobject of X in $\widehat{C}$ as follows: to every object Y of C, one assigns the set of morphisms $f : Y \to X$ such that the object (Y, f) belongs to the sieve.

PROPOSITION 4.2. *The map defined above establishes a bijection between the set of sieves of X and the set of subobjects of X in $\widehat{C}$.*

PROOF. We shall only describe what is the inverse map. To every subfunctor R of X we associate the category C/R of objects of C over R (3.4). One immediately checks that C/R is a sieve of X.

REMARK 4.2.1. One sees likewise that the sieves of C are in canonical bijective correspondence with the set of subfunctors of the "terminal functor" on C (the "terminal" object of $\widehat{C}$). 21

4.3. Let C be a $\mathscr{U}$-category. By an abuse of language, we shall also call the subobjects of X in the category $\widehat{C}$ the sieves of X. This abuse of language allows us, for every presheaf F and every sieve R of X, to define $\mathrm{Hom}_{\widehat{C}}(R, F)$ as the set of morphisms from the functor R to F. There is moreover a canonical isomorphism, functorial in F (3.5):

$$\mathrm{Hom}_{\widehat{C}}(R, F) \xrightarrow{\sim} \varprojlim_{C/R} F(.),$$

which also gives a direct definition[3]. Likewise, Proposition 4.2 allows us to transfer the usual operations on functors to sieves. We mention the following:

4.3.1. *Base change.* Let R be a sieve of X and let $f : Y \to X$ be a morphism of objects of C. The fiber product $R \times_X Y$ is a sieve of Y, called the *sieve deduced from R by base change.* The corresponding subcategory of C/Y is the inverse image of the subcategory of C/X defined by R under the canonical functor $C/Y \to C/X$ defined by f.

4.3.2. *Order relation, intersection, union.* The inclusion relation on the subfunctors of X is an order relation. The union and intersection of a family of sieves indexed by an arbitrary set may be defined as the least upper bound and the greatest lower bound of the family of corresponding subpresheaves.

4.3.3. *Image, generated sieve.* Let $(F_\alpha)_{\alpha \in A}$ be a family of presheaves and, for every $\alpha \in A$, let $f_\alpha : F_\alpha \to X$ be a morphism, where X is an object of C. The *image* of this family of morphisms is the union of the images of the f_α. The image of this family is therefore a sieve of X. In particular, if all the F_α are objects of C, the image sieve will be called the sieve generated by the morphisms f_α. The category C/R is the full subcategory of C/X formed by the objects $X' \to X$ over X for which there exists an X-morphism from X' to one of the F_α. 22

[3]N.D.E.: More simply, C/R is identified with R, so that one has the formula $\mathrm{Hom}_{\widehat{C}}(R, F) \xrightarrow{\sim} \varprojlim_R F$, where, by an abuse of notation, F denotes the composite of F and the tautological "source" functor $R \to C/X \to C$.

The reader may, as an exercise, translate the relations and operations defined here on subfunctors into the language of the categories C/R. One will then observe that these relations and operations do not depend on the universe $\mathscr{U}$ for which C is a $\mathscr{U}$-category, and that they are therefore defined for every category, without having to specify the universe to which the morphism sets belong; this could moreover have been foreseen *a priori* from 3.6.

5. Functoriality of categories of presheaves

5.0. Let C, C', and D be three categories, and let $u : C \to C'$ be a functor. We denote by u^* the functor

$$u^* : \begin{cases} \mathbf{Hom}(C'^\circ, D) & \longrightarrow & \mathbf{Hom}(C^\circ, D) \\ G & \longmapsto & G \circ u \end{cases}$$

obtained by composition with the functor u. The functor u^* commutes with inductive and projective limits.

23 PROPOSITION 5.1. *Suppose that C is small and that the $\mathscr{U}$-inductive (resp. projective) limits in D are representable. The functor u^* has a left adjoint $u_!$ (resp. a right adjoint u_*). Thus there is an isomorphism*

$$\mathrm{Hom}_{\mathbf{Hom}(C^\circ,D)}(F, u^*G) \xrightarrow{\sim} \mathrm{Hom}_{\mathbf{Hom}(C'^\circ,D)}(u_!F, G)$$
$$(\textit{resp.}\ \mathrm{Hom}_{\mathbf{Hom}(C^\circ,D)}(u^*G, F) \simeq \mathrm{Hom}_{\mathbf{Hom}(C'^\circ,D)}(G, u_*F)).$$

PROOF. We shall give only the proof of the existence of the left adjoint functor. The resp. part of the proposition will then follow formally from the isomorphisms

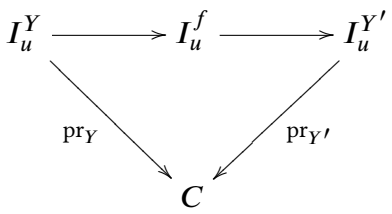
$$\mathbf{Hom}(C^\circ, D) \xrightarrow{\sim} \mathbf{Hom}(C, D^\circ)^\circ \xrightarrow{\sim} \mathbf{Hom}((C^\circ)^\circ, D^\circ)^\circ.$$

Let Y be an object of C'. Denote by I_u^Y the following category. The objects of I_u^Y are pairs (X, m), where X is an object of C and m is a morphism $Y \to u(X)$. Let (X, m) and (X', m') be two objects of I_u^Y. A morphism from (X, m) to (X', m') is a morphism $\xi : X \to X'$ such that $m' = u(\xi)m$. Composition of morphisms is defined in the evident way.

Let $f : Y \to Y'$ be a morphism of C'. By composition, the morphism f defines a functor $I_u^f : I_u^Y \to I_u^{Y'}$.

There is moreover a functor $\mathrm{pr}_Y : I_u^Y \to C$ that assigns the object X to the object (X, m). Notice that the diagram

(∗)



is then commutative.

24 Now let F be a presheaf on C, and set

(5.1.1) $$u_!F(Y) = \varinjlim_{I_u^Y} F \circ \mathrm{pr}_Y(.).$$

The commutativity of diagram (*) and the functoriality of the inductive limit make $u_!F$ a presheaf on C'. Let us show that the functor $u_!$ is a left adjoint of the functor u^*. For this, we show that for every presheaf G on C', there is a functorial isomorphism

$$\mathrm{Hom}(u_!F, G) \xrightarrow{\sim} \mathrm{Hom}(F, u^*G).$$

Let $\xi \in \mathrm{Hom}(u_!F, G)$. Thus, for every object X of C, there is a morphism

$$\xi_X : u_!(u(X)) \longrightarrow G(u(X)).$$

But $(u(X), \mathrm{id}_{u(X)})$ is an object of $I_u^{u(X)}$, and by the definition of the inductive limit there is a canonical morphism

$$F(X) \longrightarrow u_!F(u(X)).$$

For every object X of C, we therefore obtain a morphism

$$\eta_X : F(X) \longrightarrow G(u(X))$$

which is visibly functorial in X. Hence a morphism

$$\eta : F \longrightarrow u^*G.$$

Conversely, let $\eta \in \mathrm{Hom}(F, u^*G)$. For every object Y of C, this gives a morphism of functors

$$\eta_Y : F \circ \mathrm{pr}_Y \longrightarrow (u^*G)\,\mathrm{pr}_Y\,,$$

and hence, by composition with the evident morphism from the functor $(u^*G)\,\mathrm{pr}_Y$ to the constant functor $G(Y)$, a morphism

$$\xi_Y : u_!F(Y) \longrightarrow G(Y)$$

which is functorial in Y. Hence a morphism

$$\xi : u_!F \longrightarrow G.$$

The reader will check that the two maps thus defined are inverse to one another, thereby completing the proof. 25

Proposition 5.2. *Suppose that in D the $\mathscr{U}$-inductive limits are representable, finite projective limits are representable, and filtered $\mathscr{U}$-inductive limits commute with finite projective limits. Suppose also that finite projective limits are representable in C and that the functor u is left exact* (2.3.2). *Then finite projective limits are representable in* $\mathbf{Hom}(C^\circ, D)$ *and in* $\mathbf{Hom}(C'^\circ, D)$, *and the functor $u_!$ is left exact.*

Proof. The first assertion is trivial. Let us prove the second. By the proof of 5.1, for every presheaf F on C and every object Y of C', one has

$$u_!F(Y) \xrightarrow{\sim} \varinjlim_{I_u^Y} F \circ \mathrm{pr}_Y\,.$$

It therefore suffices to show that the category $(I_u^Y)^\circ$ satisfies axioms (PS 1) and (PS 2) (2.7), and that this category is connected. The verification is left to the reader.

5.3. Specializing these results to the case where D is the category of $\mathscr{U}$-sets, one obtains a sequence of three functors:

$$u_!, u^*, u_*,$$

which is a "sequence of adjoint functors" in the sense that for any two consecutive functors in the sequence, the one on the right is right adjoint to the other. Their essential 26
properties are summarized in the following proposition:

PROPOSITION 5.4. *Let C be a small category, C' a $\mathscr{U}$-category, and $u : C \to C'$ a functor.*

1) *The functor $u^* : \widehat{C'} \to \widehat{C}$ commutes with inductive and projective limits.*
2) *The functor $u_* : \widehat{C} \to \widehat{C'}$ commutes with projective limits. For every presheaf F on C and every object Y of C', one has:*

$$u_*F(Y) \xrightarrow{\sim} \mathrm{Hom}_{\widehat{C}}(u^*(Y), F).$$

3) *The functor $u_! : \widehat{C} \to \widehat{C'}$ commutes with inductive limits. The functor $u_!$ is defined only up to isomorphism, but it can always be chosen so that the diagram*

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle h}\downarrow & & \downarrow{\scriptstyle h'} \\ \widehat{C} & \xrightarrow{u_!} & \widehat{C'} \end{array}$$

(h and h' are the canonical inclusion functors) is commutative.
For every presheaf F on C, one has:

$$u_!F \xrightarrow{\sim} \varinjlim_{C/F} h' \circ u.$$

4) *If finite projective limits are representable in C and if u is left exact (2.3.2), the functor $u_!$ is left exact.*

PROOF. Assertion (1) is trivial. Assertion (2) follows from the fact that u_* is a right adjoint functor, by (2.11) and (1.4). The same is true of assertion (3), but one also applies (3.4). Finally, assertion (4) is simply (5.2), which can be applied thanks to (2.7).

27 PROPOSITION 5.5. *Let C and C' be two small categories and let $C \underset{u}{\overset{v}{\leftrightarrows}} C'$ be a pair of functors, where v is left adjoint to u. There are then isomorphisms, compatible with the adjunction isomorphisms:*

$$v^* \xrightarrow{\sim} u_!$$

$$v_* \xrightarrow{\sim} u^* \quad .$$

PROOF. It suffices to exhibit an isomorphism $v^* \xrightarrow{\sim} u_!$; the other isomorphism follows from it by adjunction. Let F be a presheaf on C and let Y be an object of C'. Then:

$$v^*F(Y) \xrightarrow{\sim} \mathrm{Hom}(v(Y), F).$$

Next, using (3.4):

$$\mathrm{Hom}(v(Y), F) \xrightarrow{\sim} \varinjlim_{C/F} \mathrm{Hom}(v(Y), .).$$

But v is left adjoint to u, and hence:

$$\varinjlim_{C/F} \mathrm{Hom}(v(Y), .) \xrightarrow{\sim} \varinjlim_{C/F} \mathrm{Hom}(Y, u(.)).$$

Now using (5.4.3)), one obtains:

$$\varinjlim_{C/F} \mathrm{Hom}(Y, u(.)) \xrightarrow{\sim} \mathrm{Hom}(Y, u_! F) \xrightarrow{\sim} u_! F(Y).$$

Thus, for every object Y of C', we have determined an isomorphism $v^* F(Y) \xrightarrow{\sim} u_! F(Y)$ that is clearly functorial in Y and in F, C.Q.F.D.

Corollary 5.5.1. *Let $u : C \to C'$ be a functor that admits a left adjoint. The functor $u_! : \widehat{C} \to \widehat{C'}$ commutes with projective limits (recall that it commutes with inductive limits by (1.4.3)).*

Remark 5.5.2. One thus obtains a "sequence of *four* adjoint functors" (cf. 5.3): 28

$$v_!, v^* = u_!, v_* = u^*, u_*,$$

of which the first three (resp. the last three) therefore commute with $\varinjlim$ (resp. $\varprojlim$).

Proposition 5.6. *The hypotheses are those of 5.4. The following conditions are equivalent:*

i) *The functor u is fully faithful.*
ii) *The functor $u_!$ is fully faithful.*
iii) *The adjunction morphism $\mathrm{id}_{\widehat{C}} \to u^* u_!$ is an isomorphism.*
iv) *The functor u_* is fully faithful.*
v) *The adjunction morphism $u^* u_* \to \mathrm{id}_{\widehat{C}}$ is an isomorphism.*

Proof. It is clear that ii) $\Leftrightarrow$ iii) and iv) $\Leftrightarrow$ v) (general properties of adjoint functors), and that ii) $\Rightarrow$ i) (5.4.3)). Let us show that i) $\Rightarrow$ iii). The functors $\mathrm{id}_{\widehat{C}}$, u^*, and $u_!$ commute with inductive limits. By (3.4), it therefore suffices to prove that $H \to u^* u_! H$ is an isomorphism when H is representable, which is evident. Let us show that iii) is equivalent to v). For every object H (resp. K) of $\widehat{C}$, denote by $\Phi(H) : H \to u^* u_! H$ (resp. by $\Psi(K) : u^* u_* \to K$) the adjunction morphism. We then have a commutative diagram:

$$\begin{array}{ccc}
\mathrm{Hom}_{\widehat{C}}(H, u^* u_* K) & \xrightarrow{\mathrm{Hom}(H, \Psi(K))} & \mathrm{Hom}_{\widehat{C}}(H, K) \\
\wr \downarrow & \nearrow_{\mathrm{Hom}(\Phi(H), K)} & \\
\mathrm{Hom}_{\widehat{C}}(u_! H, u_* K) & & \\
\wr \downarrow & & \\
\mathrm{Hom}_{\widehat{C}}(u^* u_! H, K) & &
\end{array} .$$

It follows that $\Phi(H)$ is an isomorphism for every H if and only if $\Psi(\mathscr{K})$ is an isomorphism for every K, C.Q.F.D. 29

Remark 5.7. a) The equivalences ii) $\Leftrightarrow$ iii) $\Leftrightarrow$ iv) $\Leftrightarrow$ v) are general results on adjoint functors.

b) The explicit form of $u_!$ resp. u_* given in the proof of 1.4 immediately shows that, under the general hypotheses of 1.1, if u is fully faithful, then the adjunction morphism $\mathrm{id} \to u^* u_!$ (resp. $u^* u_* \to \mathrm{id}$) is an isomorphism, i.e. that $u_!$ (resp. u_*) is fully faithful.

5.8.0. Let γ be a type of algebraic structure defined by finite projective limits, let $\mathscr{U}$-γ-Ens be the category of γ-objects of $\mathscr{U}$-Ens, and let esj: $\mathscr{U}$-γ-Ens $\to$ $\mathscr{U}$-Ens be the underlying-set functor (for simplicity, we suppose that the type of structure under consideration has only one underlying set). Let C be a category. Composition with esj gives a functor denoted by

$$\hat{\text{esj}} : \mathbf{Hom}(C^\circ, \mathscr{U}\text{-}\gamma\text{-Ens}) \longrightarrow \widehat{C}.$$

Since projective limits in $\widehat{C}$ are computed argument by argument, the functor $\hat{\text{esj}}$ factors as an equivalence

$$\mathbf{Hom}(C^\circ, \mathscr{U}\text{-}\gamma\text{-Ens}) \xrightarrow{\approx} \widehat{C}_\gamma, \tag{5.8.1}$$

where $\widehat{C}_\gamma$ is the category of γ-objects of $\widehat{C}$, followed by a functor, still denoted by

$$\hat{\text{esj}} : \widehat{C}_\gamma \longrightarrow \widehat{C},$$

and called the "*underlying presheaf of sets*" functor.

30 5.8.2. Suppose that the functor esj : $\mathscr{U}$-γ-Ens $\to$ $\mathscr{U}$-Ens has a left adjoint Lib : $\mathscr{U}$-Ens $\to$ $\mathscr{U}$-γ-Ens [3] (in fact, one can show that this condition is always satisfied). Composition with Lib gives a functor

$$\hat{\text{Lib}} : \widehat{C} \longrightarrow \mathbf{Hom}(C^\circ, \mathscr{U}\text{-}\gamma\text{-Ens})$$

and, after composition with the equivalence (5.8.1), a functor still denoted by

$$\hat{\text{Lib}} : \widehat{C} \longrightarrow \widehat{C}_\gamma$$

and called the "freely generated presheaf of γ-objects" functor. The functor $\hat{\text{Lib}}$ is left adjoint to the functor $\hat{\text{esj}}$.

Proposition 5.8.3. *Let γ be a type of algebraic structure defined by finite projective limits such that, in the category of γ-objects of $\mathscr{U}$-*Ens*, the $\mathscr{U}$-inductive limits are representable [3]; let C be a category belonging to $\mathscr{U}$, let C' be a $\mathscr{U}$-category, and let $u : C \to C'$ be a functor. Denote by $\widehat{C}_\gamma$ (resp. $\widehat{C'}_\gamma$) the category of γ-objects of $\widehat{C}$ (resp. $\widehat{C'}$), and by $u^{*\gamma}$ the functor on γ-objects induced by the functor u^*. It follows from 5.1 and the equivalence 5.8.1 that the functor $u^{*\gamma}$ has a left (resp. right) adjoint. This functor is denoted by $u_{!_\gamma}$ (resp. u_{*_γ}).*

(1) *The functor $u^{*\gamma}$ commutes with inductive and projective limits. The diagram*

(∗)
$$\begin{array}{ccc} \widehat{C'}_\gamma & \xrightarrow{u^{*\gamma}} & \widehat{C}_\gamma \\ {\scriptstyle \hat{\text{esj}}'}\downarrow & & \downarrow{\scriptstyle \hat{\text{esj}}} \\ \widehat{C'} & \xrightarrow{u_*} & \widehat{C} \end{array}$$

31 *is commutative ($\hat{\text{esj}}'$ and $\hat{\text{esj}}$ denote the "underlying-set" functors).*

[3] The functor Lib is the "free generated γ-object" functor. Examples: free group, free abelian group, free A-module, etc.

[3] One can show that this condition is always satisfied.

(2) *The functor u_{*_γ} commutes with projective limits. The diagram*

(**)
$$\begin{array}{ccc} \widehat{C}_\gamma & \xrightarrow{u_{*_\gamma}} & \widehat{C'}_\gamma \\ {\scriptstyle \mathrm{esj}\,\hat{}}\downarrow & & \downarrow{\scriptstyle \mathrm{esj}'\,\hat{}} \\ \widehat{C} & \xrightarrow{u_*} & \widehat{C'} \end{array}$$

commutes up to isomorphism.

(3) *The functor $u_{!_\gamma}$ commutes with inductive limits. Suppose that* $\mathrm{esj}\hat{}$ *(resp.* $\mathrm{esj}'\hat{}$*) has a left adjoint* $\mathrm{Lib}\hat{}$ *(resp.* $\mathrm{Lib}'\hat{}$*) (5.8.2). The diagram*

(***)
$$\begin{array}{ccc} \widehat{C} & \xrightarrow{u_!} & \widehat{C'} \\ {\scriptstyle \mathrm{Lib}\,\hat{}}\downarrow & & \downarrow{\scriptstyle \mathrm{Lib}'\,\hat{}} \\ \widehat{C}_\gamma & \xrightarrow{u_{!\gamma}} & \widehat{C'}_\gamma \end{array}$$

commutes up to isomorphism.

Suppose that $u_!$ commutes with finite projective limits (5.4) and (5.6). Then the diagram

(****)
$$\begin{array}{ccc} \widehat{C}_\gamma & \xrightarrow{u_{!\gamma}} & \widehat{C'}_\gamma \\ {\scriptstyle \mathrm{esj}\,\hat{}}\downarrow & & \downarrow{\scriptstyle \mathrm{esj}'\,\hat{}} \\ \widehat{C} & \xrightarrow{u_!} & \widehat{C'} \end{array}$$

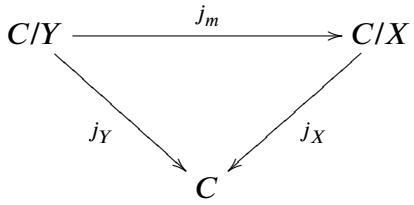
commutes up to isomorphism, and $u_{!\gamma}$ commutes with finite projective limits.

Proof. Assertion (1) is evident. So is assertion (2), since u_* is a right adjoint and therefore (2.11) commutes with projective limits and, in particular, with finite projective limits; this gives the commutativity of diagram (**). The commutativity of diagram (***) follows from the uniqueness, up to isomorphism, of the left adjoint functor, and 32
finally the commutativity of diagram (****) follows immediately from the fact that $u_!$ commutes with finite projective limits.

Notation 5.9. By an abuse of notation, the functors $u^{*\gamma}$ and $u_{*\gamma}$ will often be denoted by u^* and u_*. In view of the commutativity of diagrams (*) and (**), this cannot cause confusion. On the other hand, when $u_!$ does not commute with finite projective limits, diagram (****) does not commute up to isomorphism, and the notations $u_!$ and $u_{!\gamma}$ must be used to avoid confusion.

5.10. Let C be a small category. For every object X of $\widehat{C}$, let C/X denote the category of arrows with target X and source an object of C. The source functor defines a functor $j_X : C/X \to C$. Let $m : Y \to X$ be a morphism of $\widehat{C}$. Composition of

morphisms defines a functor $j_m : C/Y \to C/X$. The diagram



is commutative. It follows from 5.1 that, for every object F of $(C/X)\hat{}$ and every object Y of C, one has

$$j_{X!}F(Y) = \coprod_{u \in \mathrm{Hom}_{\widehat{C}}(Y,X)} F(u). \tag{5.10.1}$$

Formula (5.10.1) defines $j_{X!}$ when C is a $\mathscr{U}$-category, and one checks that the functor
33 $j_{X!}$ thus defined is always right adjoint to the functor $j_X^* : \widehat{C} \to (C/X)\hat{}$ (5.0).

Proposition 5.11. *Let C be a $\mathscr{U}$-category and let X be a presheaf on C.*

1) *The functor*

$$j_{X!} : (C/X)\hat{} \longrightarrow \widehat{C}$$

factors through the category $\widehat{C}/X$:

$$(C/X)\hat{} \xrightarrow{e_X} \widehat{C}/X \longrightarrow \widehat{C}.$$

The functor e_X is an equivalence of categories.

2) *The functor $e_X \circ j_X^* : \widehat{C} \to \widehat{C}/X$ is canonically isomorphic to the functor $H \mapsto (H \times X \xrightarrow{\mathrm{pr}_2} X)$.*

Proof. 1) Let f be the terminal object of $(C/X)\hat{}$. There is a canonical isomorphism $f \xrightarrow{\sim} \varinjlim_{Y \in \mathrm{ob}\, C/X} Y$, and hence $j_{X!}(f) = \varinjlim_{Y \in \mathrm{ob}\, C/X} j_X(Y)$ (5.4). But $j_{X!}(f) \simeq X$, which gives the factorization. To show that e_X is an equivalence, it is enough to exhibit a quasi-inverse functor. To every object $H \to X$ of $\widehat{C}/X$, associate the presheaf on C/X

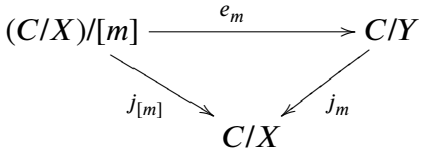
$$(Y \to X) \longmapsto \mathrm{Hom}_{\widehat{C}/X}((Y \to X), (H \to X)).$$

2) The functor $e_X \circ j_X^*$ is right adjoint to the forgetful functor, and therefore the functor $e_X \circ j^*$ is canonically isomorphic to the functor $H \mapsto (H \times H \xrightarrow{\mathrm{pr}_2} X)$.

5.12. Let $m : Y \to X$ be a morphism of $\widehat{C}$. By (5.11), the morphism m is canonically isomorphic to the image under e_X of an object of $(C/X)\hat{}$, which we denote by $[m]$. By restriction to the subcategories, the functor e_X defines an equivalence

$$(C/X)/[m] \xrightarrow{e_m} C/Y.$$

34 The diagram



commutes up to canonical isomorphism.

5.13. We record a result that will be useful in Exp. VI. Let $u : C \to C'$ be a functor between small categories. For every object H of $\widehat{C}$, denote by $u/H : C/H \to C'/u_!H$ the functor that assigns to every morphism $m : X \to H$ the morphism $u_!X \xrightarrow{u_!m} u_!H$ (we know (5.4) that we may always put $u_!X = uX$). The following diagram is commutative:

$$\begin{array}{ccc} C/H & \xrightarrow{u/H} & C'/u_!H \\ {\scriptstyle J_H}\downarrow & & \downarrow{\scriptstyle j_{u_!H}} \\ C & \xrightarrow{u} & C' \end{array} \quad . \tag{5.13.1}$$

We therefore have a diagram commutative up to isomorphism: and since $(u/H)_!$ takes the terminal object of $(C/H)\hat{}$ to the terminal object of $(C'/u_!H)\hat{}$, the diagram

$$\begin{array}{ccc} (C/H)\hat{} & \xrightarrow{(u/H)_!} & (C'/u_!H)\hat{} \\ {\scriptstyle e_H}\downarrow & & \downarrow{\scriptstyle e_{u_!H}} \\ C\hat{}/H & \xrightarrow{u_!/H} & C'\hat{}/u_!H \end{array} \tag{5.13.3}$$

commutes up to isomorphism (6.1). 35

Proposition 5.14. *Let $u : C \to C'$ be a functor between small categories. Suppose that u has the following property:*

(PPF) *For every object X of C, the functor $u/X : C/X \to C'/uX$ is fully faithful.*

Then:

1) *Let f be the terminal object of $\widehat{C}$. The functor u factors as*

$$C = C/f \xrightarrow{u/f} C'/u_!f \xrightarrow{j_{u_!f}} C'.$$

The functor u/f is fully faithful.

2) *The functor $u_! : \widehat{C} \to \widehat{C'}$ factors as*

$$\widehat{C} = (C/f)\hat{} \xrightarrow{(u/f)_!} (C'/u_!f)\hat{} \xrightarrow{e_{u_!f}} \widehat{C'}/u_!f \longrightarrow \widehat{C'},$$

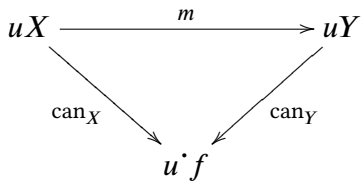
where the functor $(u/f)_!$ is fully faithful, the functor $e_{u_!f}$ is an equivalence, and the functor $\widehat{C'}/u_!f \to \widehat{C'}$ is the forgetful functor.

3) *In particular, the functor $u_!$ is faithful, and therefore the unit morphism $\mathrm{id} \xrightarrow{\Phi} u^*u_!$ is a monomorphism. Moreover, for every morphism $\alpha : H \to K$ of $\widehat{C}$, the diagram*

$$\begin{array}{ccc} H & \xrightarrow{\Phi(H)} & u^*u_!H \\ {\scriptstyle \alpha}\downarrow & & \downarrow{\scriptstyle u.u^\bullet(\alpha)} \\ K & \xrightarrow{\Phi(K)} & u^*u_!K \end{array}$$

is cartesian.

PROOF. 1) The factorization comes from diagram (5.13.1). The functor u is faithful. Hence u/f is faithful. Let us show that it is fully faithful. Let X and Y be two objects of C, let $\mathrm{can}_X : uX \to u_!f$ (resp. $\mathrm{can}_Y : uY \to u_!f$) be the canonical morphisms, and let 36



be a morphism of $C'/u_!f$. We have $u_!f = \varinjlim_{Z\in \mathrm{ob}\, C} uZ$, and therefore (3.1)

$$\mathrm{Hom}_{\widehat{C'}}(uX, u_!f) = \varinjlim_{Z\in \mathrm{ob}\, C} \mathrm{Hom}_{C'}(uX, uZ).$$

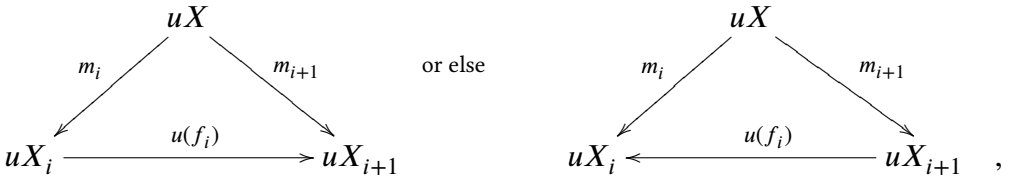
By the definition of the inductive limit, to say that $\mathrm{can}_Y\, m = \mathrm{can}_X$ is equivalent to saying that there exist

a) a finite sequence of objects X_i of C, $i \in [0, n]$, with $X_0 = X$ and $X_n = Y$,

b) for every i, a morphism $m_i : uX \to uX_i$ ($m_0 = \mathrm{id}_X, m_n = m$),

c) for every pair $(i, i+1)$, a morphism $f_i : X_i \to X_{i+1}$ or else $f_i : X_{i+1} \to X_i$,

such that the diagrams



are commutative.

It then follows immediately, by induction on i and using property (PPF), that m_i is of the form $u(p_i)$. In particular $m = u(p)$, and hence u/f is fully faithful.

37 2) The factorization is immediate. The functor $(u/f)_!$ is fully faithful by 5.6. The other assertions follow from 5.11.

3) The functor $u_!$ is the composite of the faithful forgetful functor and fully faithful functors. It is therefore faithful. It follows from the general properties of adjoint functors that the unit morphism $\mathrm{id} \to u^*u_!$ is a monomorphism. By 2), the functor $u_!$ appears as the composite of a fully faithful functor $v : \widehat{C} \to \widehat{C'}/u_!f$ and the forgetful functor. The functor u^*, right adjoint to $u_!$, is therefore the composite of the "product with $u_!f$" functor, right adjoint to the forgetful functor, and a functor w right adjoint to v. Moreover, since v is fully faithful, the unit morphism $\mathrm{id} \to wv$ is an isomorphism. The last assertion follows readily.

6. Faithful functors and conservative functors

38

DEFINITION 6.1. *Let E be a category and let $(\varphi_i : E \to F_i)_{i\in I}$ be a family of functors*

$$\varphi_i : E \longrightarrow F_i.$$

The family of functors (φ_i) is said to be faithful if, for every pair of objects X, Y of E and every pair of arrows u, $v : X \rightrightarrows Y$, the relation $\varphi_i(u) = \varphi_i(v)$ for every $i \in I$ implies $u = v$ (in other words, if the map $\mathrm{Hom}(X, Y) \to \Pi_i \mathrm{Hom}(\varphi_i(X), \varphi_i(Y))$ defined by (φ_i) is injective). The family of functors (φ_i) is said to be conservative if every arrow u of E for which $\varphi_i(u)$ is an isomorphism for every $i \in I$ is an isomorphism. We say that

(φ_i) is conservative for monomorphisms (resp. for epimorphisms, resp. ...) if the preceding condition holds whenever u is a monomorphism (resp. an epimorphism, resp. ...).

6.1.1. If we introduce the unique functor

$$\varphi : E \longrightarrow F = \prod_{i \in I} F_i$$

defined by the family of functors (φ_i), it is clear that this family is faithful (resp. conservative, resp. conservative for monomorphisms, resp. ...) if and only if the functor φ is faithful (resp. conservative, resp. ...) (by which we mean that the family consisting only of φ is faithful, resp. conservative, resp. ...). Thus, without major inconvenience, we could restrict ourselves below to a family consisting of a single functor. Nevertheless, for ease of future reference, we shall state the following results for families.

The notions of 6.1 are especially useful when the φ_i satisfy suitable exactness properties, and in that case they tend to coincide: 39

PROPOSITION 6.2. *The notation is that of 5.1.*

(i) *If the kernels of double arrows, or the cokernels of double arrows, are representable in E, and if the φ_i commute with them, then one has the implication*

$$(\varphi_i) \text{ conservative} \implies (\varphi_i) \text{ faithful.}$$

(ii) *Suppose that fiber products (resp. amalgamated sums) are representable in E, and that the φ_i commute with them. Suppose that (φ_i) is faithful or conservative; then for every arrow u of E, u is a monomorphism (resp. an epimorphism) if and only if the same holds for $\varphi_i(u)$ for every $i \in I$.*

(iii) *Suppose that fiber products and amalgamated sums are representable in E and that the φ_i commute with them, and that every arrow in E which is a bimorphism (i.e. both a monomorphism and an epimorphism) is an isomorphism. Then one has the implication*

$$(\varphi_i) \text{ faithful} \implies (\varphi_i) \text{ conservative.}$$

(iv) *Suppose that fiber products (resp. amalgamated sums) are representable in E, and that the φ_i commute with them. Then, if (φ_i) is conservative for monomorphisms (resp. for epimorphisms), it is in fact conservative.*

(v) *Let D be a type of diagram, let $F : d \mapsto F(d)$ be a diagram of type D in E, let X be an object of E, and let $u = (u_d)_{d \in D}$ be a family of arrows*

$$X \longrightarrow F(d) \quad (\text{resp. } F(d) \longrightarrow X).$$

Suppose that (φ_i) is conservative, that projective (resp. inductive) limits of type D are representable in E, and that the φ_i commute with them. Then u makes X a projective (resp. inductive) limit of F in E if and only if, for every $i \in I$, $\varphi_i(u)$ makes $\varphi_i(X)$ a projective (resp. inductive) limit of $\varphi_i(D)$ in E_i. 40

Proof.

(i) For the non-resp. statement, given a double arrow $u, v : X \rightrightarrows Y$, it suffices to express the equality $u = v$ by the condition that the inclusion $\mathrm{Ker}(u, v) \to X$ is an isomorphism. Here and below, we omit repetition of the dual argument for the dual statement.

(ii) If (φ_i) is faithful, the condition that $u : X \to Y$ be a monomorphism is expressed by the equality $\mathrm{pr}_1 = \mathrm{pr}_2$ for the fiber product $X \times_Y X$. If (φ_i) is conservative, it is expressed by the condition that the diagonal morphism $\delta : X \to X \times_Y X$ be an isomorphism.

(iv) Since in the latter argument the morphism δ is a monomorphism, we see that it would in fact have been enough to suppose that (φ_i) is conservative for monomorphisms. But this then implies that (φ_i) is conservative without qualification. Indeed, if $u \in F\ell\, E$ is such that the $\varphi_i(u)$ are isomorphisms, the preceding argument shows that these are monomorphisms, and hence they are isomorphisms by the hypothesis on (φ_i).

(iii) This is a trivial consequence of (ii).

(v) This is a trivial consequence of the definitions.

We record the following consequence of (i), (ii), and (iv):

41 COROLLARY 6.3. *Suppose that fiber products and amalgamated sums are representable in E and that the φ_i commute with them, and that kernels of double arrows or cokernels of double arrows are representable and that the φ_i commute with them. (It suffices, for example, that finite projective limits and finite inductive limits be representable in E, and that the φ_i be exact functors.) Then the following conditions are equivalent:*

a) *(φ_i) is faithful.*
b) *(φ_i) is conservative.*
c) *(φ_i) is conservative for monomorphisms.*
c′) *(φ_i) is conservative for epimorphisms.*

We also record, for reference:

PROPOSITION 6.4. *Let $\varphi : E \to F$ be a functor with a right adjoint ψ (thus $\mathrm{Hom}(\varphi(X), Y) \simeq \mathrm{Hom}(X, \psi(Y))$). The functor φ (resp. ψ) is faithful if and only if, for every element X of E (resp. every element Y of F), the unit morphism $X \to \psi\varphi(X)$ is a monomorphism. The functor φ (resp. ψ) is fully faithful if and only if the preceding unit morphism is an isomorphism.*

Indeed, if X', X are two objects of E, the map

$$(*) \qquad \mathrm{Hom}(X', X) \longrightarrow \mathrm{Hom}(\varphi(X'), \varphi(X))$$

is identified with the map obtained from

$$(**) \qquad X \longrightarrow \psi\varphi(X)$$

42 by applying the functor $\mathrm{Hom}(X', -)$. Thus, for $(*)$ to be a monomorphism (resp. an isomorphism) for every X', with X fixed, it is necessary and sufficient that the unit morphism $(**)$ be a monomorphism (resp. an isomorphism).

PROPOSITION 6.5. *Let $p : E' \to E$ be a functor. The following conditions are equivalent:*

(i) *p is faithful, conservative, and fibered* (SGA 1 VI 6.1).

(ii) *p is a fibered functor whose fibers are discrete categories.*

(iii) *For every $X' \in \mathrm{ob}\, E'$, the functor $E'_{/X'} \to E_{/p(X)}$ induced by p is an equivalence of categories that is surjective on objects.*

(iv) *(When E is a $\mathcal{U}$-category.) There exists an element $F \in \mathrm{ob}\, \widehat{C}$ and an equivalence of categories over E* (SGA 1 VI 4.3) *$E' \xrightarrow{\approx} E_{/F}$ (where $E_{/F}$ is the full subcategory of $\widehat{E}_{/F}$ formed by the arrows $X \to F$ whose source belongs to E).*

6.5.1. Recall that a category C is said to be *discrete* if it is a *groupoid* (i.e. every arrow in it is invertible) and if it is *rigid* (i.e. the automorphism group of every object is reduced to the trivial group); equivalently, the category is equivalent to the category C' defined by a set I (with $\mathrm{ob}C' = I$, and with the identity arrows as its only arrows). When C is already assumed to be a groupoid, saying that C is discrete amounts to saying that for two objects X, Y of C, there exists at most one arrow from X to Y, i.e. that C is isomorphic to the category defined by a preordered set.

The equivalence of conditions (i) and (ii) of 6.5 is an immediate consequence of the 43
preceding observations and of the following

LEMMA 6.5.2. *Let $p : E' \to E$ be a fibered functor. Then:*

(i) *For p to be conservative, it is necessary and sufficient that its fiber categories be groupoids.*
(ii) *For p to be faithful, it is necessary and sufficient that its fiber categories be ordered categories.*

Proof of 6.5.2.

(i) Suppose p is conservative. For every arrow u in a fiber E'_X, $p(u) = \mathrm{id}_X$ is an isomorphism, so u is an isomorphism in E', hence also in E'_X (since an inverse of u in E' will clearly be an inverse in E'_X). Thus E'_X is a groupoid. Conversely, suppose that the E'_X are groupoids, and let u' be an arrow of E' such that $p(u')$ is an isomorphism; let us prove that u is an isomorphism. To this end, note that, since p is fibered, we can factor $u' : X' \to Y'$ as a composite $X' \to u^*(Y') \to Y'$, where the first arrow is an X-morphism (N.B. $X = p(X')$, $u = p(u')$), and the second is a cartesian morphism over u. The first arrow is an isomorphism since E'_X is a groupoid, and the second is as well, since a *cartesian* morphism of a fibered category is clearly an isomorphism whenever its projection is an isomorphism.
(ii) Suppose p is faithful, and let X', Y' be two objects of a fiber category E_X. Then two arrows from X' to Y' lie over the same arrow id_X of E, and hence are identical, so E_X is ordered. Conversely, suppose that the fiber categories are 44
ordered, and let us prove that p is faithful. Thus let $u', v' : X' \rightrightarrows Y'$ be arrows of E' lying over the same arrow $u : X \to Y$ of E. They then factor as $X' \rightrightarrows u^*(Y) \to Y'$, where the two arrows $X' \rightrightarrows u^*(Y')$ are arrows of E'_X with the same source and target; they are therefore equal, and hence $u' = v'$, C.Q.F.D.

Let us return to the proof of 6.5. We have proved (i) $\Leftrightarrow$ (ii). On the other hand, (ii) $\Leftrightarrow$ (iv) is fairly clear: indeed, on the one hand, the category $E_{/F}$ is fibered over E, with fiber categories the discrete categories defined by the sets $F(X)$, as follows immediately from the definitions; on the other hand, if p is as in (ii), then by the sorites of SGA 1 VI 8 the fibered category E' over E is E-equivalent to the split category over E defined by the functor $E \to (\mathrm{Cat})$ determined by the functor $F : E \to (\mathrm{Ens})$, which assigns to every $X \in \mathrm{ob}\, E$ the set of isomorphism classes of objects of E'_X. Now this split category is E-isomorphic to the category $E_{/F}$. Since (iv) $\Rightarrow$ (iii) is clear, it remains to prove (iii) $\Rightarrow$ (i). Now it is clear that for p to be faithful (resp. conservative), it is necessary and sufficient that the induced functors $E'_{/X'} \to E_{/p(X)}$ be so; *a fortiori*, it suffices that these be fully faithful; therefore it remains only to prove that (iii) implies that p is fibered. But one again sees that a functor p is fibered if and only if the induced functors $E'_{/X'} \to E_{/p(X')}$ are fibered. This is in particular the case if they are equivalences of categories that are surjective on objects.

7. Generating and cogenerating subcategories

45

DEFINITION 7.1. *Let E be a category and C a full subcategory of E. We say that C is a subcategory of E* generating by strict epimorphisms (resp. by epimorphisms) *if, for every object X of E, the family of arrows of E with target X and source $X' \in \mathrm{ob}\, C$ is epimorphic (resp. strictly epimorphic) (1.3). We say that C is a subcategory of E* generating (resp. generating for monomorphisms, resp. generating for strict monomorphisms) *if, for every arrow $u : Y \to X$ (resp. every monomorphism of E, resp. every strict monomorphism of E (10.5)) such that, for every $X' \in \mathrm{ob}\, C$, the corresponding map $\mathrm{Hom}(X', Y) \to \mathrm{Hom}(X', X)$ is bijective, u is an isomorphism. Finally, we say that a family (X_i) of objects of E is generating by strict epimorphisms (resp. ...) if the full subcategory C of E generated by this family is generating by strict epimorphisms (resp. ...).*

7.1.1. Observe that, in terms of the family $(h_{X'})_{X' \in \mathrm{ob}\, C}$ of functors

$$h_{X'} : E \longrightarrow (\mathrm{Ens}) \ (X' \in \mathrm{ob}\, C)$$

represented by the $X' \in \mathrm{ob}\, C$, the condition that C be generating (resp. generating for monomorphisms, resp. generating for strict monomorphisms) can be expressed by saying that the family $(h_{X'})$ is *conservative* (resp. conservative for monomorphisms, resp. conservative for strict monomorphisms) (6.1). It also follows immediately from the
46 definitions that C is generating by epimorphisms if and only if the family $(h_{X'})_{X' \in \mathrm{ob}\, C}$ is *faithful* (6.1). We shall also give below (7.2 (i)) an analogous interpretation of the condition that C be generating by strict epimorphisms.

7.1.2. As with the notions introduced in 6.1, the notions of 7.1 are especially useful when E has suitable exactness properties, in which case the various notions introduced have a marked tendency to be all equivalent (7.3). Thus the question of which of these notions in 7.1 should be regarded as the most important scarcely arises; in the most important cases, these notions coincide, and the term "generating subcategory" may therefore be interpreted indifferently as referring to any one of the properties considered in 7.1 (for example the first, which is the strongest of all, as we shall see (7.2 (ii))).

7.1.3. Suppose that E is a $\mathscr{U}$-category, and consider the canonical functor

$$\varphi : E \longrightarrow \widehat{C} = \mathbf{Hom}(C, \mathscr{U}\text{-Ens}) \tag{7.1.3.1}$$

which is the composite of the functors $E \to \widehat{E} \to \widehat{C}$, where the first functor is the canonical functor (1.3.3), and the second is the restriction functor to C. Observe that it is plainly equivalent to say that the preceding functor φ is conservative (resp. faithful), or to say that the family of functors $h_{X'} : X \to \mathrm{Hom}(X', X) = \varphi(X)(X')$, for variable $X' \in \mathrm{ob}\, C$, is a conservative (resp. faithful) family, that is, also (7.1.2), that C is gener-
47 ating (resp. generating by epimorphisms). Similarly, φ is conservative for monomorphisms (resp. for strict monomorphisms) if and only if the family of the $h_{X'}(X' \in \mathrm{ob}\, C)$ is conservative for monomorphisms (resp. for strict monomorphisms), i.e. if and only if the subcategory C of E is generating for monomorphisms (resp. for strict monomorphisms).

PROPOSITION 7.2. *Let E be a $\mathscr{U}$-category and C a full subcategory.*

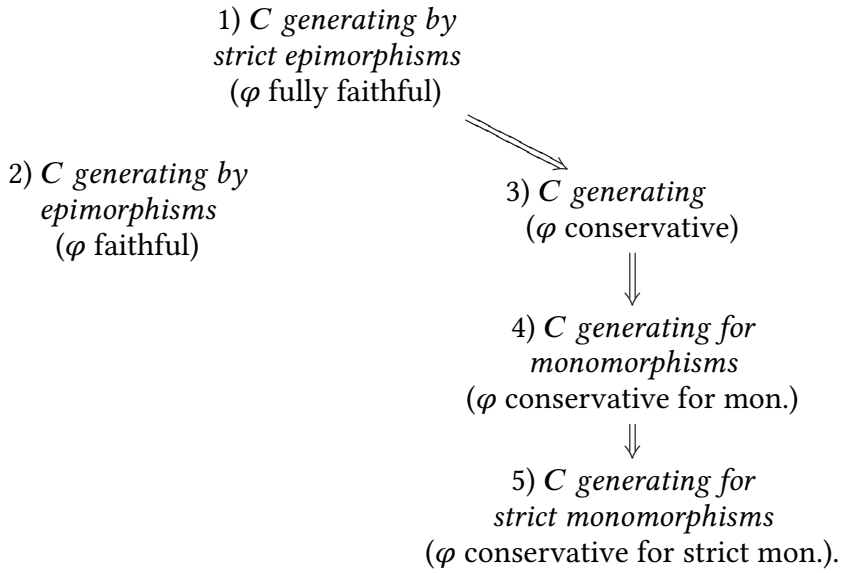
(i) *The following conditions are equivalent:*
   a) *C is a subcategory generating by strict epimorphisms.*
   b) *For every $X \in \mathrm{ob}\, E$, let $C_{/X}$ denote the full subcategory of $E_{/X}$ consisting of arrows $X' \to X$ with source $X' \in \mathrm{ob}\, C$. The natural arrow from the inclusion functor $j : C_{/X} \to E$ to the constant functor on $C_{/X}$ with value X makes X*

an inductive limit of j:

$$X \xleftarrow{\sim} \varinjlim_{C_{/X}} X'.$$

c) *The canonical functor φ of (7.1.3.1) is fully faithful.*

(ii) *Among the notions of 7.1 there are the following implications :*



(iii) *There are the following conditional implications:* 48

a) *If in E epimorphic families of arrows are strictly epimorphic, then* 2) ⇒ 1). *If in E monomorphisms are strict, then* 5) ⇒ 4).

b) *If in E the kernels of pairs of arrows (resp. fiber products) are representable, then* 3) ⇒ 2) *(resp.* 4) ⇒ 3)*).*

c) *If in E every family of morphisms $X_i \to X$ with common target X factors as a strictly epimorphic (resp. epimorphic) family $X_i \to Y$ followed by a monomorphism (resp. by a strict monomorphism) $Y \to X$, then* 4) ⇒ 1) *(resp.* 5) ⇒ 2)*).*

Let us immediately record the following.

Corollary 7.3. *All the notions considered in 6.1 (and repeated in the implication diagram in* (ii) *above) are equivalent in each of the following two cases:*

(i) *In E, the kernels of pairs of arrows and the fiber products are representable, the monomorphisms are strict, and the epimorphic families of arrows are strictly epimorphic.*

(ii) *In E, every family $(X_i \to X)_{i\in I}$ of arrows with common target X factors as an epimorphic family $(X_i \to Y)$ followed by a monomorphism $Y \to X$, every monomorphism of E is strict, and every epimorphic family of arrows of E is strict.*

Indeed, in case (i) we have 4) ⇒ 3) and 3) ⇒ 2) by b), and 5) ⇒ 4) and 2) ⇒ 1) by a). 49
In case (ii), by c), we have the implications 4) ⇒ 1) and 5) ⇒ 2). We therefore conclude by the implication diagram 6.2 (ii).

Proof of 7.2.

(i) The implication b) ⇒ a) follows at once from the definitions. Let us prove a) ⇒ b). Thus, under hypothesis a), we must prove that, for all X, $Y \in \mathrm{ob}\, E$, every

system of arrows

$$u_{X'} : X' \longrightarrow Y$$

indexed by the $X' \in \mathrm{ob}\, C_{/X}$, such that $u_{X'} f = u_{X''}$ for every arrow $f : X'' \to X'$ in $C_{/X}$, factors through an arrow (necessarily unique by hypothesis a)) $X \to Y$. By hypothesis a), it suffices to check that, for every object Z of $E_{/X}$ and every pair of morphisms $v' : Z \to X'$, $v'' : Z \to X''$ in $E_{/X}$, with X' and X'' in $C_{/X}$, we have $u_{X'} v' = u_{X''} v''$. But, by hypothesis a), the family of arrows $w : X''' \to Z$, with $X''' \in \mathrm{ob}\, C$, is epimorphic, and it therefore suffices to check that, for every such w, we have $(u_{X'} v')w = (u_{X''} v'')w$, which can also be written $u_{X'}(v'w) = u_{X''}(v''w)$ and follows at once from the hypothesis made on the family of the u.

Let us now prove the equivalence of conditions b) and c. For this, observe that, for every $X \in \mathrm{ob}\, E$, the object $\varphi(X)$ of $\widehat{C}$ is the inductive limit in $\widehat{C}$ of the canonical functor $\widehat{C}_{/\varphi(X)} \to \widehat{C}$ (3.4); but $\widehat{C}_{/\varphi(X)}$ is canonically isomorphic to $C_{/X}$, so that in $\widehat{C}$ we have

$$\varphi(X) = \varinjlim_{C_{/X}} X',$$

50 where the object X' of C is identified with the functor $\in \widehat{C}$ that it represents. Consequently, for a second object Y of E, we have a canonical isomorphism

$$\begin{aligned} \mathrm{Hom}(\varphi(X), \varphi(Y)) \simeq \varprojlim_{C_{/X}} \mathrm{Hom}(X', \varphi(Y)) &\simeq \varprojlim_{C_{/X}} \varphi(Y)(X') \text{(1.4)} \\ (*) \qquad &\simeq \varprojlim_{C_{/C}} \mathrm{Hom}(X', Y). \end{aligned}$$

This being so, the map

$$\mathrm{Hom}(X, Y) \longrightarrow \mathrm{Hom}(\varphi(X), \varphi(Y))$$

defined by φ is none other, via the isomorphism between the extreme terms of (∗), than the map

$$\mathrm{Hom}(X, Y) \longrightarrow \varprojlim_{C_{/X}} \mathrm{Hom}(X', Y)$$

deduced from the inductive system of arrows $X' \to X$ indexed by $C_{/X}$ considered in 7.2 (i) b). Thus the first map is bijective for every Y (with X fixed) if and only if X is an inductive limit of the inclusion functor $j : C_{/X} \to E$, which proves the equivalence of b) and c).

(ii) The implications 1) ⇒ 2) and 3) ⇒ 4) ⇒ 5) are trivial by virtue of the definitions. The implication 1) ⇒ 3) is obtained by interpreting property 1) as the full faithfulness of φ by (i), and by observing that a fully faithful functor is conservative. But we have already observed (7.1.1) that 3) means that φ is conservative.

51 (iii) Assertion a) is a tautology. Assertion b) follows from 6.2 (i) (resp. 6.2 (iv)) applied to the functor φ, taking into account that the latter is left exact. Finally, let us prove c). For $X \in \mathrm{ob}\, E$, consider the family of all the morphisms $X_i \to X$, with $X_i \in \mathrm{ob}\, C$; by hypothesis on E it factors as a family $X_i \to Y$ that is effective epimorphic (resp. epimorphic), followed by a monomorphism (resp. by a strict monomorphism) $Y \to X$. Then hypothesis 4) (resp. 5)) implies that $Y \to X$ is an isomorphism, so the family considered is strictly epimorphic (resp. epimorphic), C.Q.F.D.

PROPOSITION 7.4. *Let E be a category, C a full subcategory of E, and X an object of E. Suppose that C is generating in E (resp. C is generating for monomorphisms, and that the fiber product of two subobjects of X over X is representable in E). Then a strict subobject (10.11) (resp. a subobject) X' of X is determined when, for every $T \in \mathrm{ob}\, C$, one knows the subset of $\mathrm{Hom}(T, X)$ which is the image of $\mathrm{Hom}(T, X')$. Consequently, the cardinality of the set of strict subobjects (resp. of the set of subobjects) of X is bounded above by $\prod_{T \in \mathrm{ob}\, C} 2^{\mathrm{card}\, \mathrm{Hom}(T,X)}$, and if $X \in \mathrm{ob}\, C$, it is bounded above by $2^{\mathrm{card}\, F\ell\, C}$.*

Let us first prove the parenthetical assertion. Let X' and X'' be two subobjects of X such that, for every $T \in \mathrm{ob}\, C$, the images of $\mathrm{Hom}(T, X')$ and $\mathrm{Hom}(T, X'')$ in $\mathrm{Hom}(T, X)$ are equal. They are therefore also equal to the image of $\mathrm{Hom}(T, X''')$, where X''' is the fiber product of X' and X'' over X. Since C is generating for monomorphisms, it follows that the monomorphisms $X''' \to X'$ and $X''' \to X''$ are isomorphisms, so X' and X'' 52
are equal, each being equal to the subobject X''' of X.

Let us prove the nonparenthetical assertion. By definition of the notion of strict subobject, it suffices to check that knowledge of the subset $\mathrm{Hom}(T, X')$ of $\mathrm{Hom}(T, X)$ for every $T \in \mathrm{ob}\, C$ implies knowledge of those pairs of arrows $X \overset{u,v}{\rightrightarrows} T$ such that $ui = vi$, where $i : X' \to X$ is the canonical injection. But since C is generating, the relation $ui = vi$ is equivalent to the relation $(ui)f = (vi)f$ for every $f \in \mathrm{Hom}(T, X')$, i.e. to $ug = vg$ for every $g \in \mathrm{Hom}(T, X)$ coming from $\mathrm{Hom}(T, X')$ (i.e. of the form if, with $f \in \mathrm{Hom}(T, X')$), which proves our assertion.

COROLLARY 7.5. *Let E be a category, C a full generating subcategory, and X an object of C. Then a strict quotient (10.8) X' of X is determined when, for every $T \in \mathrm{ob}\, C$, one knows the subset of $\mathrm{Hom}(T, X)^2$ consisting of pairs (u, v) such that $qu = qv$, where $q : X \to X'$ is the canonical morphism. Thus the cardinality of the set of strict quotients of X is bounded above by $\prod_{T \in \mathrm{ob}\, C} 2^{\mathrm{card}\, \mathrm{Hom}(T,X)^2}$.*

Indeed, by definition, a strict quotient X' of X is determined when one knows, for every object Y of E, the subset of $\mathrm{Hom}(Y, X) \times \mathrm{Hom}(Y, X)$ consisting of pairs (u, v) such that $qu = qv$, where $q : X \to X'$ is the canonical morphism. But the relation $qu = qv$ is equivalent to the relation $(qu)f = (qv)f$ for every morphism $f : T \to Y$ with source T in C, since C is generating. This relation may also be written $q(uf) = q(vf)$, which proves the first assertion of 7.5. The second follows at once.

7.5.1. We can generalize 7.5 by introducing, for a family of objects $(X_i)_{i \in I}$ of E, 53
the notion of a *strict quotient in E of the family*, by which we mean a strictly epimorphic family $(p_i : X_i \to X')_{i \in I}$ of morphisms of E, — with the understanding, as for ordinary quotients, that we identify two such families $(p_i : X_i \to X')$ and $(q_i : X_i \to X'')$ if one can find an isomorphism $v : X' \to X''$ (necessarily unique) such that $f p_i = q_i$ for every $i \in I$. With this terminology, the proof of 7.5 applies *ne varietur* to give the

VARIANT 7.5.2. Let E, C be as in 7.5, and let $(X_i)_{i \in I}$ be a family of objects of E. Then a strict quotient X' of $(X_i)_{i \in I}$ in E (7.5.1) is determined by the following data: for every $T \in \mathrm{ob}\, C$, and every pair $(i, j) \in I \times I$, the subset of $\mathrm{Hom}(T, X_i) \times \mathrm{Hom}(T, X_j)$ consisting of the pairs (u, v) such that $p_i u = p_j v$, where for every $i \in I$, $p_i : X_i \to X'$ denotes the canonical morphism. Consequently, the cardinality of the set of strict quotients of $(X_i)_{i \in I}$ in E is bounded above by $\prod_{T \in \mathrm{ob}\, C} \prod_{i,j \in I} 2^{\mathrm{card}\, \mathrm{Hom}(T,X_i) \times \mathrm{card}\, \mathrm{Hom}(T,X_j)}$.

7.5.3. It is immediately clear that the analogous conclusion holds if one assumes only that C is generating for strict monomorphisms, provided that the products $X_i \times X_j$ are representable and that one restricts to the *effective* quotients of the family $(X_i)_{i \in I}$,

i.e. to the strict quotients X' such that the fiber products $X_i \times_{X'} X_j$ are representable in E (which is no restriction if E is stable under fiber products).

54 PROPOSITION 7.6. *Let E be a category, C a full subcategory of E generating by epimorphisms (7.1), $\Pi_\circ$ = an infinite cardinal $\geq \operatorname{card} F\ell C$, $\Pi \geq \Pi_\circ$ a cardinal, and $(u_i : X_i \to X)_{i\in I}$ a universally epimorphic family (10.3) in E consisting of pullbackable morphisms (10.7) with sources $X_i \in \operatorname{ob} C$, and such that $\operatorname{card} I \leq \Pi$. Then $\operatorname{card} F\ell C_{/X} \leq \Pi^{\Pi_\circ}$.*

Let $T \in \operatorname{ob} C$; it will suffice to prove that

$$\operatorname{card} \operatorname{Hom}(T, X) \leq \Pi^{\Pi_\circ}, \tag{7.6.1}$$

for one then obtains successively

$$\operatorname{card} \operatorname{ob} C_{/X} \leq (\Pi^{\Pi_\circ}) \times \operatorname{card} \operatorname{ob} C_{/X} \leq (\Pi^{\Pi_\circ}) \times \Pi_\circ = \Pi^{\Pi_\circ},$$

and finally $\operatorname{card} F\ell C_{/X} \leq ((\Pi^{\Pi_\circ})^2) \times \Pi_\circ = \Pi^{\Pi_\circ}$, since for two objects S, T of $C_{/X}$, one has $\operatorname{card} \operatorname{Hom}_{C_{/X}}(S, T) \leq \operatorname{car} \operatorname{Hom}_C(S, T) \leq \Pi_\circ$. To prove 7.5.3, first note the

LEMMA 7.6.2. *Let J be a set such that $\operatorname{card} J = \Pi_\circ$. For every object T of C, and every morphism $f : T \to X$, there exists an epimorphic family $(v_j : S_j \to T)_{j\in J}$, with sources $S_j \in \operatorname{ob} C$, and, for every $j \in J$, an $i(j) \in I$ and a $g_j : S_j \to X_{i(j)}$ such that $u_{i(j)} g_j = f v_j$.*

Indeed, the family of $X_i \times_X T \to$ is epimorphic by hypothesis; on the other hand, since C is generating by strict epimorphisms, for every i the family of arrows $S \to X_i \times_X T$ with source $S \in \operatorname{ob} C$ is epimorphic, and hence, by transitivity, the family of arrows $v : S \to T$ with source in $\operatorname{ob} C$ which factor through one of the $X_i \times_X T$ is epimorphic. These are precisely the arrows $v : S \to T$ with source in C for which there
55 exist an $i \in I$ and a $g : S \to X_i$ such that $u_i g = f v$. Since the set of these arrows $v : S \to T$ is contained in $F\ell\, C$, and therefore has cardinality $\leq \Pi_\circ$, it can be indexed by the index set J, whence the lemma.

Now note that a morphism $f : T \to X$ is determined once the $f v_j$ are known, and these are determined once the g_j are known. Thus $\operatorname{card} \operatorname{Hom}(T, X)$ is bounded above by the cardinality of the set of families $(i(j), S_j, v_j, g_j)_{j\in J}$; since the cardinality of the set of maps $j \to I$ is $\leq \Pi^{\Pi_\circ}$, and since, for a fixed such map $j \mapsto i(j)$, the cardinality of the set of corresponding families S_j, f_j, v_j is bounded above by that of the set of maps from J to $F\ell C \times F\ell C$, which is $\leq \Pi_\circ^{\Pi_\circ}$ because $\operatorname{card}(F\ell C \times F\ell C) = \Pi_\circ^2 = \Pi_\circ$, we find that the left-hand side of (7.6.1) is bounded above by $\Pi^{\Pi_\circ} \times \Pi_\circ^{\Pi_\circ} = \Pi^{\Pi_\circ}$, which completes the proof of 7.6.

PROPOSITION 7.7. *Let E be a category in which fiber products are representable, $(X_\alpha)_{\alpha\in A}$ a generating family of objects of E, and $(\varphi_i)_{i\in I}$ a family of functors $\varphi_i : E \to E_i$ commuting with fiber products. The family (φ_i) is conservative (5.1) if and only if, for every $\alpha \in A$ and every subobject X' of X_α distinct from X_α, there exists an $i \in I$ such that $\varphi_i(X') \to \varphi_i(X_\alpha)$ is not an isomorphism. In this case, if E is a $\mathcal{U}$-category and if A is $\mathcal{U}$-small, there exists a $\mathcal{U}$-small subset J of I such that $(\varphi_j)_{j\in J}$ is already a conservative family of functors.*

The necessity of the stated conservativity condition being obvious, let us prove its sufficiency. By 6.1 (iv), it suffices to prove that (φ_i) is conservative for monomorphisms.
56 Let $u : Y' \to Y$ be a monomorphism in E which is not an isomorphism; we must prove that there exists $i \in I$ such that $\varphi_i(u)$ is not an isomorphism. By the hypothesis on (X_α), there exist an α and a morphism $X_\alpha \to Y$ which does not factor through Y', in

other words, such that the inverse image X' of Y' is a subobject of X_α distinct from X_α. By hypothesis, there exists an $i \in I$ such that $\varphi_i(X') \to \varphi(X)$ is not an isomorphism. Since $\varphi_i(X') \simeq \varphi(X_\alpha) \times_{\varphi_{i(Y)}} \varphi_i(Y')$, it indeed follows that $\varphi_i(Y') \to \varphi_i(Y)$ is not an isomorphism.

The second assertion of 7.7 follows immediately from the first, in view of 7.4.

Corollary 7.7.1. *Let E be a $\mathscr{U}$-category in which fiber products are representable, and which admits a $\mathscr{U}$-small generating family of objects. Then every generating family $(Y_i)_{i\in I}$ of E contains a $\mathscr{U}$-small generating subfamily $(Y_j)_{j\in J}$ (card $J \in \mathscr{U}$).*

Indeed, it suffices to apply 7.7 to a $\mathscr{U}$-small generating family $(X_\alpha)_{\alpha\in A}$ of E and to the family of functors φ_i ($i \in I$) represented by the Y_i.

Proposition 7.8. *Let E be a category, C a full subcategory generating by strict epimorphisms, D a category, and $\mathbf{Hom}'(E, D)$ the full subcategory of $\mathbf{Hom}(E, D)$ consisting of the functors which commute with inductive limits of type $C_{/X}$, where X is an arbitrary object of E. Then the functor $F \to F|C$ induces a fully faithful functor*

$$\mathbf{Hom}'(E, D) \longrightarrow \mathbf{Hom}(C, D).$$

Consequently, if $\mathbf{Hom}(C, D)$ is a $\mathscr{U}$-category (1.1.), for example (1.1.1. b)) if C is $\mathscr{U}$-small 57
and D is a $\mathscr{U}$-category, then $\mathbf{Hom}'(E, D)$ is also a $\mathscr{U}$-category.

Let $F, G : E \to D$ be two functors in the first member, and let $u : F \to G$ be a natural transformation. If $X = \varinjlim X_i$ in E and if F and G commute with the inductive limit under consideration, then $u(X) : F(X) \to G(X)$ is identified with the inductive limit of the morphisms $u(X_i) : F(X_i) \to G(X_i)$, and is therefore determined once the $u(X_i)$ are known. This shows that the functor considered in 7.8 is faithful, in view of the implication a) $\Rightarrow$ b) in 7.2 (i). Conversely, let $v : F|C \to G|C$ be a natural transformation; let us prove that it comes from a natural transformation $u : F \to G$. For every $X \in \mathrm{ob}\, E$, define

$$u(X) : F(X) = \varinjlim_{C_{/X}} F(X_i) \longrightarrow G(X) = \varinjlim_{C_{/X}} G(X_i)$$

as the inductive limit of the $v(X_i)$. It is immediate that one thus obtains maps functorial in X, hence a natural transformation $u : F \to G$, and finally that the morphism induced by u from $F|C$ to $G|C$ is v, which completes the proof.

7.9. **Cogenerating families and subcategories.** Let E be a category and C a full subcategory of E. We say that C is cogenerating by strict monomorphisms (resp. cogenerating by monomorphisms, resp. cogenerating, resp. cogenerating for epimorphisms, resp. cogenerating for strict epimorphisms) if the full subcategory C° of E° is generating by strict epimorphisms (resp. etc.). The terminology for families is analogous. All the results of this section concerning the notion of a generating subcategory and its variants (7.1) therefore yield corresponding results for the dual notions, which we leave to the reader to formulate for their personal satisfaction. 58

Proposition 7.10. *Let E be a category, C a full generating subcategory (7.1), and D a full subcategory of E. The subcategory D is cogenerating (7.9) if and only if, for every pair of parallel arrows $T \overset{u,v}{\rightrightarrows} X$ in E with source $T \in \mathrm{ob}\, C$ and $u \neq v$, there exists an arrow $w : X \to I$ with target $I \in \mathrm{ob}\, D$ such that $wu \neq wv$.*

By definition, to say that D is cogenerating means that for every pair of parallel arrows $Y \overset{u,v}{\rightrightarrows} X$ in E such that $u \neq v$, there exists an arrow $w : X \to I$, with $I \in \mathrm{ob}\, D$, such that $wu \neq wv$. Thus 7.10 simply means that it suffices to test this property when $Y \in \mathrm{ob}\, C$. Now, since C is generating, the hypothesis $u \neq v$ implies that there exists $f : T \to Y$ such that $uf \neq vf$, whence, by hypothesis, there exists a $w : X \to I$ with target $I \in \mathrm{ob}\, D$ such that $w(uf) \neq w(vf)$, and hence $wu = wv$, C.Q.F.D.

Corollary 7.11. *With the notation of 7.10, suppose that the objects I of D are injective objects of E, i.e. such that for every monomorphism $X \to Y$ in E, the corresponding map $\mathrm{Hom}(Y, I) \to \mathrm{Hom}(X, I)$ is surjective. Suppose moreover that every pair of parallel arrows $T \overset{u,v}{\rightrightarrows} X$ in E factors as an epimorphic (resp. effective epimorphic) pair of parallel arrows $Y \overset{u',v'}{\rightrightarrows} X$ followed by a monomorphism $i : X' \to X$. Then, in the criterion of 7.10 for D to be cogenerating, one may restrict to the pairs (u, v) which are epimorphic (resp. effective epimorphic).*

59 We conclude:

Corollary 7.12. *Let E be a $\mathcal{U}$-category admitting a small generating subcategory C, and such that every object of E is the source of a monomorphism into an injective object of E. Suppose moreover that, for every $T \in \mathrm{ob}\, C$, the coproduct $T \amalg T$ in E is representable, and that every morphism with source $T \amalg T$ factors as an effective epimorphism followed by a monomorphism. Then E admits a small full cogenerating subcategory D. More precisely, one may take D such that* $\mathrm{card}\,\mathrm{ob}\, D \leq \prod_{T,T' \in \mathrm{ob}\, C} 2^{\mathrm{card}(\mathrm{Hom}(T', T \amalg T))^2}$.

Indeed, by 7.11, it suffices, for every $T \in \mathrm{ob}\, C$ and every effective quotient X of $T \amalg T$, to choose an embedding of X into an injective object I of E, and to take for D the full subcategory of E spanned by these I. The conclusion then follows from 7.5.

Examples 7.13. To construct small cogenerating subcategories in terms of small generating subcategories, we are thus led to seek conditions under which a $\mathcal{U}$-category E has "enough injectives", i.e. every object embeds into an injective object (by a monomorphism). It is well known [Tohoku] that this condition holds in a abelian $\mathcal{U}$-category with exact (small) filtered inductive limits (axiom AB 5 of *loc. cit.*) which admits a small generating family. Moreover, the construction of *loc. cit.* is not essentially tied to abelian categories, and also works in the category of sheaves of $\mathcal{U}$-sets on a topological space $X \in \mathcal{U}$. We shall not state here the exactness properties which make the construction
60 in question work, and shall merely point out that, in the special case of the category of sheaves of sets on X, one immediately reduces to the case of *loc. cit.* as follows. Note that if $\mathcal{O}_X$ is a ring on X, then every injective object I of the category of $\mathcal{O}_X$-modules is also injective as an object of the category of sheaves of sets. Indeed, if F is a sheaf of sets, and $\mathcal{O}_X[F]$ the "free $\mathcal{O}_X$-module generated by F", there is by definition a homomorphism of sheaves of sets

$$(*) \qquad F \longrightarrow \mathcal{O}_X[F]$$

giving rise to an isomorphism, functorial in F,

$$\mathrm{Hom}_{\mathcal{O}_X}(\mathcal{O}_X[F], I) \xrightarrow{\sim} \mathrm{Hom}(F, I).$$

Since the functor $F \mapsto \mathcal{O}_X[F]$ manifestly takes monomorphisms to monomorphisms, it follows immediately that if I is an injective $\mathcal{O}_X$-module, it is also an injective sheaf of sets. It follows that if the morphism $(*)$ is a monomorphism (as is the case if one

takes for $\mathcal{O}_X$ a constant ring with value a ring $A \neq 0$), then an embedding of $\mathcal{O}_X[F^*]$ into an injective $\mathcal{O}_X$-module I gives an embedding of F into the injective sheaf of sets underlying I.

The same argument applies, without change, to the category of sheaves of $\mathcal{U}$-sets on a $\mathcal{U}$-site, which will be introduced in the following exposé.

The chief interest of the existence of a small cogenerating subcategory lies in the representability criterion 8.12.7 below.

8. Ind-objects and pro-objects

61

8.1. Cofinal functors and cofinal subcategories.

Definition 8.1.1. *Let*

$$\varphi : I \longrightarrow I' \tag{8.1.1.1}$$

be a functor. The functor φ is said to be cofinal if, for every category C and every functor $u : I' \to C$, regarding $\varinjlim u$ and $\varinjlim u \circ \varphi$ as objects of $\mathbf{Hom}(G(\mathcal{V}\text{-Ens}))^\circ$ (2.1, 2.3.1) (where $\mathcal{V}$ is a universe such that $I, I' \in \mathcal{V}$ and C is a $\mathcal{V}$-category), the canonical morphism

$$\varinjlim u \circ \varphi \longrightarrow \varinjlim u \tag{8.1.1.2}$$

is an isomorphism. When φ is the inclusion functor of a subcategory of I', the subcategory I is said to be cofinal if φ is cofinal.

8.1.2. Notice that for given φ and u, the bijectivity of (8.1.1.2) does not depend on the choice of the universe $\mathcal{V}$.

Returning to the definition of the terms occurring in (8.1.1.2) (2.1, 2.3.1), we see that to say that φ is cofinal also means that, for every universe $\mathcal{V}$ such that I and I' are $\mathcal{V}$-small, and every functor

$$v : I'^\circ \longrightarrow (\mathcal{V}\text{-Ens}),$$

the canonical homomorphism

$$\varprojlim v \longrightarrow \varprojlim v \circ \varphi \tag{8.1.2.1}$$

is an isomorphism, i.e. a bijection. To see that this condition is indeed necessary, observe, on putting $v = v^\circ$, that it also says that the condition of Definition 8.1.1 is satisfied when $C = (\mathcal{V}\text{-Ens})^\circ$ (which implies that the inductive limits considered in (8.1.1.2) are 62
representable in C).

. It follows immediately from the definition that *the composite of two cofinal functors is cofinal.*

Proposition 8.1.3. *Let $\varphi : I \to I'$ be a functor.*

a) *For φ to be cofinal, it is necessary that φ satisfy the condition:*
   F 1) *For every object i' of I', there exists an object i of I such that $\varphi(i)$ is an upper bound of i' (i.e. such that $\mathrm{Hom}(i', \varphi(i)) \neq \phi$).*

b) *Suppose that I is filtered. For φ to be cofinal, it is necessary and sufficient that φ satisfy condition* (F 1) *and the following condition:*
   F 2) *For every object i of I and every double arrow $i' \overset{f',g'}{\rightrightarrows} \varphi(i)$ in I' with target $\varphi(i)$, there exists an arrow $h : i \to j$ in I such that $\varphi(h)f' = \varphi(h)g'$.*
   Moreover, if φ is cofinal, I' is filtered.

c) *Suppose that I' is filtered and φ is fully faithful. For φ to be cofinal, it is necessary and sufficient that it satisfy condition* F 1) *of* a). *This implies that I is filtered.*

Proof. For necessity in a) and b), use Definition 8.1.1 only in the case where u is the canonical inclusion functor (1.3.3)

$$u : I' \hookrightarrow \widehat{I'}$$

(having chosen a universe $\mathscr{U}$ such that I and I' are $\mathscr{U}$-small). We may then interpret
63 (8.1.1.2) as an arrow of $\widehat{I'}$ (3.1) whose target is the *terminal* functor on I' (3.4). It is immediately clear that condition F 1) says that this arrow is an epimorphism of $\widehat{I'}$, i.e. that it is surjective at each argument (taking into account that inductive limits in $\widehat{I'}$ are computed "argument by argument"). This proves a). Now suppose that I is filtered and φ is cofinal. Then I' is filtered: indeed, the condition that two objects of I' be bounded above by a third follows at once from the same condition on I and from F 1), and it remains only to prove condition PS 2) of 2.7, i.e. that for every double arrow

$$f', g' : i' \rightrightarrows j'$$

in I', there exists an arrow $h' : j' \to k'$ of I' such that $h'f' = h'g'$. By F 1), we may suppose that k' is of the form $\varphi(i)$. But since φ is cofinal, for every object i' of I' the set $\varinjlim_i \mathrm{Hom}(i', \varphi(i))$ consists of a single element. The standard description of *filtered* inductive limits in (Ens) (2.8.1) therefore implies that there exists an arrow $h : i \to j$ in I such that $\varphi(h)f' = \varphi(h)g'$. This completes the proof that I' is filtered and at the same time proves condition F 2).

To prove that the conditions in b) are sufficient for φ to be cofinal, use the form 8.1.2 of the definition. One sees at once that condition F 1) implies that (8.1.2.1) is a monomorphism, i.e. is injective at each argument, while condition F 2) (together with F 1)) ensures that it is bijective (taking into account the argument-by-argument computation of projective limits in $\widehat{I'^{\circ}}$). This proves b).

64 Finally, if I' is filtered and φ is fully faithful, it is immediate that condition F 1) implies that I is filtered and implies condition F 2). Thus c) follows from a) and b).

8.1.4. When I' is a filtered category and I is a full subcategory of I', we see from 8.1.3 c) that the condition that I be cofinal in I' depends only on the subset $\mathrm{Ob}\, I$ of the preordered set $OB\, I'$ (for the preorder relation "$x \leq y$" $\Leftrightarrow$ "$\mathrm{Hom}(x, y) \neq \emptyset$"). If J' is a preordered set and J a subset of J', we shall sometimes say that J is a *cofinal subset of* J' when every element of J' is bounded above by an element of J. When J' is filtered, this therefore means that the inclusion functor $\mathscr{J} \hookrightarrow \mathscr{J}'$ for the associated categories is cofinal.

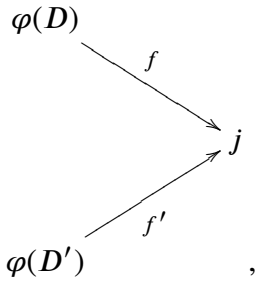
8.1.5. In what follows, we shall use the notion of cofinal functor only when the categories I and I' are filtered. Classically, one even restricted oneself to categories associated with preordered sets (i.e. categories in which there is at most one arrow with given source and target). It turns out, however, that this restriction is inconvenient in applications, since the "natural" filtered categories arising in many applications are *not* ordered categories. The following result, due to P. Deligne, shows nevertheless that there is no essential difference between the two points of view:

65 Proposition 8.1.6. *Let I be a small filtered category. Then there exist a small ordered set E and a cofinal functor $\varphi : \mathscr{E} \to I$, where $\mathscr{E}$ denotes the category associated with E.*

First suppose that the preordered set $\mathrm{Ob}\, I$ has no greatest element. A subdiagram of I is a pair $D = (\mathscr{O}, F)$ consisting of a subset F of $F\ell(I)$ and a subset $\mathscr{O}$ of $\mathrm{Ob}\, I$, such that for every $f \in F$, the source and target of f belong to $\mathscr{O}$. An element e of $\mathscr{O}$ is called a *terminal object* of the subdiagram D if, for every $x \in D'$, the set $\mathrm{Hom}(x, e) \cap F$ of arrows of D with source x and target y has exactly one element f_x, if $f_x = f_y \circ g$ for every arrow

$g : x \to y$ of D, and if $f_e = \mathrm{id}_e$. Let E be the set of *finite* subdiagrams D of I having a *unique* terminal element $\varphi(D)$, and order E by inclusion. If D, D' are two elements of E and $D \subset D'$, there is a unique arrow $\varphi(D', D)$ of D' with source $\varphi(D)$ and target $\varphi(D')$. If $D \subset D' \subset D''$ are inclusions in E, one clearly has $\varphi(D'', D) = \varphi(D'', D')\varphi(D', D)$; one also has $\varphi(D, D) = \mathrm{id}_{\varphi(D)}$. Thus we obtain a functor $\varphi : \mathscr{E} \to I$, and it remains to prove that E is filtered and φ is cofinal. In view of 8.1.3 b), three verifications are required:

1) Condition F 1) of 8.1.3: for every $i \in I$, take for D the subdiagram of I consisting only of the object i and its identity arrow; then $i \leq \varphi(D) = i$. This condition F 1) also shows that $E \neq \emptyset$.
2) Condition F 2): For every $i \in \mathrm{Ob}\, I$, every $D \in E$, and every double arrow $i \rightrightarrows \varphi(D)$, find a diagram $D' \in E$ containing D such that $\varphi(D', D) : \varphi(D) \to \varphi(D')$ *equalizes* the double arrow. Since I is filtered, there is an object j of I and an arrow $f : \varphi(D) \to j$ that equalizes the double arrow. Since I has no greatest element, we may suppose that j is a *strict* upper bound of $\varphi(D)$, which implies that it is distinct from every other object of D. Let D' be the subdiagram of I whose set of objects is $\mathcal{O} \cup \{j\}$ and whose set of arrows consists of the arrows of D, together with the composites $x \xrightarrow{f_x} \varphi(D) \xrightarrow{f} j$, where x is an object of D and f_x is the unique arrow of D with source x and target $\varphi(D)$, and id_j. It is then clear that D' is a finite subdiagram of I, that it has j as its unique terminal object, hence that $D' \in E$, and that D' satisfies the required condition. 66
3° Two subdiagrams D, $D' \subset E$ are contained in the same $D'' \in E$. Indeed, one may find a strict upper bound j of $\varphi(D)$ and $\varphi(D')$,



,

and take for D'' the subdiagram whose set of objects is the union of the sets of objects of D and D' with $\{j\}$, and whose set of arrows is the union of the sets of arrows of D and D', the set of composites $f \circ f_x$ (x an object of D) and $f' \circ f'_{x'}$ (x' an object of D'), and $\{\mathrm{id}_j\}$. This indeed gives a finite subdiagram of E. Let us show that, after replacing j, f, f' by j', gf, gf' for a suitable $g : j \to j'$, we may arrange that j is a terminal object of D'. Equivalently, for every x that is an object of both D and D', one must have $f f_x = f' f'_{x'}$. This amounts to a *finite* set of double arrows to be equalized by a $g : j \to j'$, which is possible since I is filtered. 67

This completes the proof in the case considered. The general case is reduced to it by introducing the filtered category $\mathbf{N}$ associated with the ordered set $\mathbf{N}$ of natural integers, and observing that the category $\mathbf{N} \times I$ is filtered, has no greatest element, and that the projection $\mathbf{N} \times I \to I$ is a cofinal functor.

Corollary 8.1.7. *Let I be a $\mathscr{U}$-category. There exist a small filtered ordered set E and a cofinal functor $\mathscr{E} \to I$ if and only if I is filtered and* Ob I *has a small cofinal subset I' (8.1.4).*

Necessity follows from 8.1.3 a), and sufficiency follows from 8.1.6 applied to the full subcategory of I defined by I'.

DEFINITION 8.1.8. *Let I be a filtered category. We say that I is essentially small if I is a $\mathscr{U}$-category and satisfies the equivalent conditions of 8.1.7.*

8.2. Ind-objects and ind-representable functors.

8.2.1. In what follows, we fix a $\mathscr{U}$-category C, which we always regard as embedded in the category $\widehat{C}$ of $\mathscr{U}$-presheaves by means of the canonical functor (1.3.1)

$$h : C \hookrightarrow \widehat{C}. \tag{8.2.1.1}$$

An *ind-object of* C (or an *inductive system* of C) is any functor

$$\varphi : I \longrightarrow C, \tag{8.2.1.2}$$

68 where I is a *filtered* category (2.7), called the *index category* of the ind-object. (Apart from this, I is arbitrary; in particular, we do not require I to be a $\mathscr{U}$-category.) It will often be convenient to denote an ind-object φ by the indexed notation $(X_i)_{i\in \mathrm{ob}\, I}$, or even (by another abuse of notation) $(X_i)_{i\in I}$, or $(X_i)_i$, or (X_i), where $X_i = \varphi(i)$ for $i \in \mathrm{ob}\, I$. This notation is no more and no less abusive than the notation classically used for inductive systems indexed by filtered ordered sets (where the transition morphisms are likewise not mentioned). The X_i are called the *component objects* of the ind-object $\mathscr{X}$. Note that, in the general case considered here, the "*transition morphisms*" $\varphi(f)$ of the inductive system are indexed by the set $F\ell I$ of arrows of I, which in general is not identified with a subset of $\mathrm{Ob}\, I \times \mathrm{Ob}\, I$; in other words, for given i and j, with j an upper bound of i, there may exist more than one transition morphism from X_i to X_j.

8.2.2. The most useful ind-objects $\mathscr{X} = (X_i)_{i\in I}$ of C are those for which the index category I is essentially small (8.1.8); such an ind-object is called *essentially small*. If $(X_i)_{i\in I}$ is such an object, then, using the fact that small inductive limits are representable in $\widehat{C}$ (3.1), we may consider

$$L(\mathscr{X}) \overset{\text{def}}{=} \varinjlim h \cdot \mathscr{X} = \varinjlim_i X_i \in \mathrm{ob}\, \widehat{C}, \tag{8.2.2.1}$$

where the last limit is taken *in* $\widehat{C}$. Thus $L(\mathscr{X})$ is the presheaf

$$L(\mathscr{X}) : Y \longmapsto \varinjlim_i \mathrm{Hom}(Y, X_i) \tag{8.2.2.2}$$

69 on C. This presheaf is called the *presheaf ind-represented by the ind-object $\mathscr{X} = (X_i)_{i\in I}$ of C*. A presheaf F on C is called an *ind-representable presheaf* if it is isomorphic to a presheaf $L(\mathscr{X})$ ind-represented by an essentially small ind-object. It follows moreover from 8.1.6 that, in this definition, we may suppose that I is a small category, and even that I is associated with an ordered set $\in \mathscr{U}$.

8.2.3. Consider an ind-object $\mathscr{X} = (X_i)_{i\in I}$ given by a functor $\varphi : I \to C$, and let

$$u : I' \longrightarrow I$$

be a functor, where I' is a second filtered category. Then the functor $\varphi \circ u$ is an ind-object $\mathscr{X}'$ of C with index category I'; in indexed notation it is $(X_{u(i')})_{i'\in I'}$. It is called the ind-object of C *deduced from* $(X_i)_{i\in I}$ *by a change of index categories* using the functor u. If I and I' (i.e. $\mathscr{X}$ and $\mathscr{X}'$) are essentially small, one obtains a canonical morphism

$$L(\mathscr{X}') = \varinjlim_{i'} X_{u(i')} \longrightarrow L(\mathscr{X}) = \varinjlim_i X_i \tag{8.2.3.1}$$

between the presheaves ind-represented by $\mathscr{X}'$ and $\mathscr{X}$, respectively. When u is a cofinal functor (8.1.1), $\mathscr{X}$ is essentially small if and only if $\mathscr{X}'$ is (8.1.7), and the preceding homomorphism (8.2.3.1) is an isomorphism

$$L(\mathscr{X}') \simeq L(\mathscr{X}). \tag{8.2.3.2}$$

8.2.4. Let 70

$$\mathscr{X} = (X_i)_{i\in I}, \mathscr{Y} = (Y_j)_{j\in I} \tag{8.2.4.1}$$

be two essentially small ind-objects of C, indexed by the (filtered and essentially small) categories I and J. A *morphism* from the ind-object $\mathscr{X}$ to the ind-object $\mathscr{Y}$ is any morphism

$$L(\mathscr{X}) \longrightarrow L(\mathscr{Y}) \tag{8.2.4.2}$$

between the presheaves that they ind-represent. We put

$$\mathrm{Hom}_{\mathrm{ind-ob}}(\mathscr{X}, \mathscr{Y}) = \mathrm{Hom}_{\widehat{C}}(L(\mathscr{X}), L(\mathscr{Y})). \tag{8.2.4.3}$$

(The subscript ind-ob on Hom is omitted when there is no risk of confusion.) Composition of morphisms of ind-objects of $\mathscr{C}$ is defined as composition of the morphisms of the presheaves that they ind-represent. If $\mathscr{V} \supset \mathscr{U}$ is a universe containing $\mathscr{U}$, and if we restrict to the essentially small ind-objects that belong to $\mathscr{V}$, these form the set of objects of a category whose set of arrows consists of triples $(\mathscr{X}, \mathscr{Y}, u)$, where $\mathscr{X}$ and $\mathscr{Y}$ are essentially small ind-objects $\in \mathscr{V}$ and $u : \mathscr{X} \to \mathscr{Y}$ is a morphism of ind-objects, i.e. a morphism $L(\mathscr{X}) \to L(\mathscr{Y})$. The category thus obtained is denoted by

$$\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U}). \tag{8.2.4.4}$$

When $\mathscr{V} = \mathscr{U}$, it is denoted simply by

$$\mathrm{Ind}_{\mathscr{U}}(C) \text{ or } \mathrm{Ind}(C), \tag{8.2.4.5}$$

and is called the *category of ind-objects of* C relative to $\mathscr{U}$, with the mention of $\mathscr{U}$ omitted when no confusion is likely.

Clearly, if $\mathscr{V} \subset \mathscr{V}'$ are two universes containing $\mathscr{U}$, then $\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U})$ is a full subcategory of $\mathrm{Ind}_{\mathscr{V}'}(, \mathscr{U})$; it follows from 8.2.3 that the inclusion functor is an *equivalence of categories*: 71

$$\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U}) \xrightarrow{\approx} \mathrm{Ind}_{\mathscr{V}'}(C, \mathscr{U}). \tag{8.2.4.6}$$

This shows in particular that *every essentially small ind-object of* C *defines an element of* $\mathrm{Ind}(C)$*, up to unique isomorphism.* This observation justifies the fairly common abuse of language of identifying every essentially small ind-object of C with an object of $\mathrm{Ind}(C)$.

It follows at once from the definitions that, for every universe $\mathscr{V}$, there is a canonical functor

$$L : \mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U}) \longrightarrow \widehat{C} \tag{8.2.4.7}$$

which is fully faithful. By (8.2.4.6), these functors are clearly determined up to unique isomorphism once one of them is known, and in particular once the canonical functor

$$L : \mathrm{Ind}(C) \longrightarrow \widehat{C}. \tag{8.2.4.8}$$

is known. Since this functor is fully faithful, it is often used to identify an object of the first member with the functor that it ind-represents, or even to identify $\mathrm{Ind}(C)$ with its essential image in $\widehat{C}$, consisting of the ind-representable presheaves. Note, however, that this identification has distinctly more disadvantages than the analogous identification

of C with a full subcategory of $\widehat{C}$ by the functor h (8.2.1.1), since, unlike the latter, the functor (8.2.4.8) is not in general injective on objects.

72 8.2.5. Let us express Definition (8.2.4.3) explicitly in terms of the indexed expressions (8.2.4.1) of the ind-objects under consideration. Taking Definition (8.2.2.1) into account, one obtains

$$\mathrm{Hom}(\mathscr{X},\mathscr{Y}) \simeq \varprojlim_i \mathrm{Hom}(X_i,\mathscr{Y}) \overset{\mathrm{dfn}}{=} \varprojlim_i \mathrm{Hom}(X_i, L(\mathscr{Y})) = \varprojlim_i \varinjlim_j \mathrm{Hom}_C(X_i,Y_j),$$

where the last equality follows from (8.2.2.2) applied to $\mathscr{Y}$. Thus one obtains a canonical bijection

$$\mathrm{Hom}((X_i)_{i\in I},(Y_j)_{j\in J}) \simeq \varprojlim_{i\in I} \varinjlim_{j\in J} \mathrm{Hom}_C(X_i,Y_j). \tag{8.2.5.1}$$

We leave to the reader the task of expressing composition of morphisms of ind-objects explicitly in terms of this formula. Notice that it follows at once from this formula that the set $\mathrm{Hom}(\mathscr{X},\mathscr{Y})$ of homomorphisms of ind-objects is *$\mathscr{U}$-small*, i.e. that the categories (8.2.4.4) are $\mathscr{U}$-categories. Equivalently (by (8.2.4.6)), the *category* $\mathrm{Ind}(C)$ *is a $\mathscr{U}$-category*, i.e. the second member of (8.2.5.1) is small when $I, J \in \mathscr{U}$. This follows at once from the fact that C is a $\mathscr{U}$-category, so the sets $\mathrm{Hom}_C(X_i,Y_j)$ are small.

8.2.6. Let I be an essentially small filtered category. It follows from (8.2.5.1), or from the functoriality of the inductive limit of a functor $I \to \widehat{C}$ with respect to that functor, that there is a canonical functor

$$\mathbf{Hom}(I,C) \longrightarrow \mathrm{Ind}(C). \tag{8.2.6.1}$$

Note that this functor is in general *not* fully faithful, nor even faithful.

73 Remark 8.2.7. The definitions of 8.2.4 make clear the notion of *isomorphism* of two (essentially small) ind-objects, which also means the isomorphism of the presheaves that they ind-represent. Note that this is a very weak notion of isomorphism when compared with the notion of isomorphism in categories of the form $\mathbf{Hom}(I,C)$. Thus, many fairly natural conditions that may be imposed on an ind-object (such as having its components in a given strictly full subcategory, or being strict (8.12 below)) *are not* invariant under isomorphism. Hence, if one wishes to work with notions invariant under isomorphism of ind-objects, the notions in question must be "saturated" by passing to the strictly full subcategory of $\mathrm{Ind}(C)$ generated by the subcategory of $\mathrm{Ind}(C)$ formed by the objects satisfying the condition under consideration. See, for example, the notion of essentially constant ind-object introduced below (8.4).

Exercise 8.2.8. Let $\mathscr{U} \subset \mathscr{V}$ be two universes and let C be a $\mathscr{U}$-category belonging to $\mathscr{V}$. Denote by $\mathrm{SysInd}(C)$ the following category:

a) The objects of $\mathrm{SysInd}(C)$ are the functors $\varphi : I \to C$ where I is an essentially $\mathscr{U}$-small filtered category belonging to $\mathscr{V}$.
b) Let (I,φ) and (J,ψ) be two objects of $\mathrm{SysInd}(C)$. A morphism in $\mathrm{SysInd}(C)$ from (I,φ) to (J,ψ) is a pair (m,u), where $m : I \to J$ is a functor and $u : \varphi \to \psi \circ m$ is a morphism of functors. Composition of morphisms in $\mathrm{SysInd}(C)$ is defined in the evident way.

74 Let S be the set of morphisms $(m,u) : (I,\varphi) \to (J,\Psi)$ of $\mathrm{SysInd}(C)$ such that m is cofinal and u is an isomorphism. Let (I,φ) be an object of $\mathrm{SysInd}(C)$. The category $F\ell(I)$ of arrows of I maps to I by two natural functors: source and target. These two functors are moreover linked by the canonical morphism of functors v : source $\to$ target. Hence

there are two morphisms in SysInd(C) from $(F\ell(I), \varphi \circ \text{source})$ to (I, φ): $p_1(I,\varphi) =$ (source, id) and $p_2(I,\varphi) =$ (target, $\varphi^* v : \varphi\circ\text{source} \to \varphi\circ$ target). Let p : SysInd(C) $\to$ Ind(C) be the evident functor. Let B be a category. Show that the functor $F \mapsto F \circ p$

$$\mathbf{Hom}(\mathrm{Ind}(C), B) \longrightarrow \mathbf{Hom}(\mathrm{SysInd}(C), B)$$

is fully faithful, and that a functor G : SysInd(C) $\to B$ belongs to its essential image if and only if it has the following two properties:

1) For every $s \in S$, $F(s)$ is an isomorphism of B.
2) For every object (I, φ) of SysInd(C), $F(p_1(I,\varphi)) = F(p_2(I,\varphi))$.

8.3. Characterization of ind-representable functors.

Proposition 8.3.1. *Let F be an ind-representable presheaf on C. Then F is left exact, i.e. (2.3.2) for every finite category J and every functor $\varphi : J \to C$ such that $\varinjlim \varphi$ is representable (i.e. $\varprojlim \varphi^\circ$ is representable), the canonical map*

$$F(\varinjlim \varphi) \longrightarrow \varprojlim F \circ \varphi$$

is bijective.

Indeed, since representable presheaves are clearly left exact, it follows at once from 2.8 that the same is true of every filtered inductive limit of such functors, C.Q.F.D. 75

8.3.2. Given a presheaf F on C, we shall often have occasion to work with the category

$$C_{/F} \hookrightarrow \widehat{C}_{/F}, \tag{8.3.2.1}$$

which denotes the full subcategory of the latter category formed by arrows $X \to F$ *whose source lies in* C. It follows from 1.4 that the objects of this category may be identified with pairs (X, u), where X is an object of C and $u \in F(X)$. A morphism from (X,u) to (X',u') is then interpreted as an arrow $f : X \to X'$ in C such that $F(f)(u') = u$. The functor from $\widehat{C}_{/F}$ to $\widehat{C}$ that "forgets the target" induces a functor (called *canonical*).

$$C_{/F} \longrightarrow C, \tag{8.3.2.2}$$

already considered in 3.4, where it is proved that the inductive limit of this functor exists in $\widehat{C}$ (without any smallness condition on $C_{/F}$!) and is canonically isomorphic to F.

. Note that if finite inductive limits are representable in C, and if F is left exact (i.e. takes them to finite projective limits in (Ens)), then the same is true in $C_{/F}$, and a fortiori (2.7.1) $C_{/F}$ is filtered. If, more generally, sums of two objects and cokernels of pairs of parallel arrows are representable in C, and if F takes them to products resp. kernels, then $C_{/F}$ is closed under the same types of finite inductive limits, hence it is filtered if and only if it is nonempty, i.e. if and only if the functor F is not the constant functor with value $\varnothing$. 76

Theorem 8.3.3. *Let C be a $\mathscr{U}$-category, and let $F \in \mathrm{ob}\,\widehat{C}$, $F : C^\circ \to (\mathscr{U}\text{-Ens})$ be a $\mathscr{U}$-presheaf on C. The following conditions are equivalent:*

(i) *F is ind-representable (8.2.2).*
(ii) *The category $C_{/F}$ (8.3.2) is filtered and essentially small.*
(iii) *(if finite inductive limits are representable in C.) The functor F is left exact, and* ob $C_{/F}$ *has a small cofinal subset (8.1.4).*

(iii bis) *(If sums of two objects and cokernels of pairs of parallel arrows are representable in C.) The functor F takes sums of two objects of C to products, and cokernels of pairs of parallel arrows of C to kernels; the category $C_{/F}$ is nonempty, i.e. the functor F is not the constant functor with value $\emptyset$; finally, there exists a small family of objects of $C_{/F}$ such that every object X of $C_{/F}$ is dominated by an object X_i, i.e. admits an F-morphism $X_i \to X$.*

(iv) *(if the category C is equivalent to a small category.) The category $C_{/F}$ is filtered.*

(v) *(If the category C is equivalent to a small category, and if filtered inductive limits are representable in it.) The functor F is left exact.*

77 *Proof.* (i) $\Rightarrow$ (ii). Suppose that F is ind-represented by $(X_i)_{i\in I}$, with I small. Let us prove that $C_{/F}$ is filtered. Let X, X' be two objects of $C_{/F}$, i.e. objects of C equipped with morphisms $X \to F$, $X' \to F$; let us prove that they have a common upper bound in $C_{/F}$. The morphisms $X \to F$, $X' \to F$ come from morphisms $X \to X_i$, $X' \to X'_i$, and, after replacing i, i' by a common upper bound in $\mathrm{Ob}\, I$, we may assume that $i = i'$, and take as a common upper bound of X, X' the object X_i equipped with the canonical morphism $X_i \to F$. Now let $X \overset{f,g}{\rightrightarrows} X' \xrightarrow{h} F$ be a pair of parallel arrows in $C_{/F}$; let us prove that it is equalized by an arrow $X' \to X''$ in $C_{/F}$. Now $h : X' \to F$ is given by a morphism $h_i : X' \to X_i$, and the condition $hf = hg$ means that there exists $\alpha : i \to j$ in I such that $\varphi(\alpha)(h_i f) = \varphi(\alpha)(h_i g)$, i.e. after replacing h_i by $\varphi(\alpha)h_i$, this morphism equalizes f and g. This proves that $C_{/F}$ is filtered. It is then immediate that it is essentially small, since the objects $(X_i \to F)_{\in \mathrm{Ob}\, I}$ form a small family in $\mathrm{Ob}\, C_{/F}$ that is cofinal.

(ii) $\Rightarrow$ (i). Put $I = C_{/F}$, and consider the canonical functor (8.3.2.1)

$$\varphi : I = C_{/F} \longrightarrow F.$$

We know that the presheaf ind-represented by this ind-object of C is F (3.4), so F is ind-representable by definition (8.2.2).

(ii) $\Leftrightarrow$ (iii). Indeed, (ii) $\Rightarrow$ (iii) because an ind-representable functor is left exact (8.3.1),
78 and (iii) $\Rightarrow$ (ii) because we noted (8.3.1) that if F is left exact, then $C_{/F}$ is filtered, and we apply Definition 8.1.8 to conclude that this category is essentially small.

(ii) $\Leftrightarrow$ (iii bis) is proved in the same way as (ii) $\Leftrightarrow$ (iii).

The equivalences (ii) $\Leftrightarrow$ (iv) and (iii) $\Leftrightarrow$ (v) are immediate, since if C is equivalent to a small category, then $C_{/F}$ is clearly likewise equivalent to a small category and *a fortiori* it is automatically essentially small as soon as it is filtered. This completes the proof of 8.3.3.

Remark 8.3.4. Let $F : C' \to C''$ be a functor between $\mathscr{U}$-categories. It appears that the notion of left exactness (2.3.2) is of little practical interest unless finite projective limits are representable in C'. In the case where $C'' = (\mathscr{U}\text{-Ens})$, and where C' is $\mathscr{U}$-small, writing C' in the form C° (thus $C = C'^\circ$), one should regard the "right notion" that replaces, in the general case, that of left exactness as the ind-representability of F (regarded as a presheaf on C°; i.e. the pro-representability of F, regarded as a functor on C', cf. 8.10). This notion does indeed coincide with that of left exactness when finite projective limits are representable in C' *i.e.* finite inductive limits in C are representable (8.3.3). When C' is no longer assumed $\mathscr{U}$-small, or at least equivalent to a $\mathscr{U}$-small category, the two notions for a functor F, left exactness and pro-representability, no longer necessarily coincide, even if finite projective limits in C' are representable (cf. 8.12.9). In
79 fact, it seems that in this case, left exact functors that are not ind-representable should

be regarded as pathological, while the "good" objects remain the ind-representable functors; compare 8.13.3. For the case of functors $F : C' \to C''$, with C' and C'' once again arbitrary $\mathscr{U}$-categories, we shall develop below (8.11.5), more generally, a notion that "improves" upon left exactness (namely, that of a functor admitting a pro-adjoint).

8.4. Constant and essentially constant ind-objects. Choose a terminal category e, i.e. one such that $\mathrm{Ob}\, e$ and $F\ell\, e$ each consist of a single element (for example, one may take for e the full subcategory of (Ens) on the empty set, if a canonical choice is desired). This is obviously a small filtered category. If X is an object of C, we associate with it the constant ind-object indexed by e, with value X, denoted by $c(X)$. It is clear that, as X varies, this gives a fully faithful functor

$$c : C \longrightarrow \mathrm{Ind}(C), \tag{8.4.1}$$

which is moreover injective on objects, and by which we shall identify C with a full subcategory of $\mathrm{Ind}(C)$. Note that the composite functor

$$C \xrightarrow{c} \mathrm{Ind}(C) \xrightarrow{L} \widehat{C} \tag{8.4.2}$$

is the canonical functor h (8.2.1.1).

8.4.3. More generally, let I be a filtered category. The constant functor on I whose value is an object X of C is also called *the constant ind-object with value X indexed by I*. It is clear that, if I is essentially small, this ind-object ind-represents the functor $h(X)$ represented by X, hence this ind-object is isomorphic to $c(X)$. 80

8.4.4. An ind-object $\mathscr{X}$ of C is said to be *essentially constant* if it is isomorphic (in a category $\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{V}')$, for suitable $\mathscr{V}$, $\mathscr{V}'$) to an ind-object of the form $c(X)$, $X \in \mathrm{ob}\, C$. The object X, which is then determined up to canonical isomorphism, is called the *value* of the essentially constant ind-object under consideration. Thus, by definition, the functor c of (8.4.1) induces an equivalence of C with the full subcategory of $\mathrm{Ind}(C)$ consisting of the ind-objects that are essentially constant, this subcategory being the essential image of the functor c.

Clearly a constant ind-object is essentially constant, whereas the converse holds only in the trivial case in which C is empty or a one-point category.

8.5. Filtered inductive limits in $\mathrm{Ind}(C)$.

Proposition 8.5.1. *Let C be a $\mathscr{U}$-category. In* $\mathrm{Ind}(C)$*, small filtered inductive limits are representable, and the canonical functor* (8.2.4.8)

$$L : \mathrm{Ind}(C) \longrightarrow \widehat{C}$$

commutes with them.

Since L is fully faithful, the assertions of the proposition are equivalent to the following: 81

Corollary 8.5.2. *Every small filtered inductive limit (in $\widehat{C}$) of ind-representable presheaves is ind-representable.*

This follows easily from criterion 8.3.3 (ii). The details of the verification are left to the reader.

8.5.3. The "tautological" case of filtered inductive limits in $\mathrm{Ind}(C)$ is that in which one starts with an essentially small ind-object $\mathscr{X} = (X_i)_{i\in I}$ of C. Then, in $\widehat{C}$ and hence also in $\mathrm{Ind}(C)$ (or in $\widehat{C}$), one has:

$$\mathscr{X} = \varinjlim_I X_i. \tag{8.5.3.1}$$

When writing this formula, care must be taken that it is not an inductive limit in C, and that even when the latter exists, it is not isomorphic in $\mathrm{Ind}(C)$ to $\mathscr{X}$: indeed, the canonical functor (8.4.1) $c : C \to \mathrm{Ind}(C)$ *does not in general commute with filtered inductive limits.* (Cf. 8.5.5 below.)

To avoid this possible confusion in writing (8.5.3.1), "some authors" (= P. Deligne) prefer to write it as

$$\mathscr{X} = \text{«}\varinjlim\text{»}\, X_i, \tag{8.5.3.2}$$

the quotation marks indicating that the inductive limit is taken in a category of ind-objects $\mathrm{Ind}(C)$. By extension, one should then denote by «lim» every inductive-limit operation in $\mathrm{Ind}(C)$ (without the components of the inductive system under consideration in $\mathrm{Ind}(C)$ necessarily lying in the image, or the essential image, of $c : C \to \mathrm{Ind}(C)$).

82 8.5.4. To compute the inductive or projective limit of a functor

$$\varphi : J \longrightarrow \mathrm{Ind}(C), \tag{8.5.4.1}$$

where J is now an arbitrary category, it is often convenient to make φ explicit by means of a functor

$$\Phi : J \times I \longrightarrow C, \tag{8.5.4.2}$$

where I is an essentially small filtered category, or preferably a small one. Such a Φ indeed defines a functor

$$J \longmapsto (i \longmapsto \Phi(j,i)) : J \longmapsto \mathbf{Hom}(I, C),$$

whence, by composing with the canonical arrow (8.2.6.1) $\mathbf{Hom}(I, C) \to \mathrm{Ind}(C)$, a functor

$$J \longmapsto (i \longmapsto \Phi(j,i)) : J \longrightarrow \mathrm{Ind}(C). \tag{8.5.4.3}$$

We shall say that Φ is an *indexed expression of φ, indexed by the (filtered) category I*, if the corresponding functor (8.5.4.3) is isomorphic to φ. We shall study below (8.8) general conditions for the existence of an indexed expression for a given functor φ, and here we shall restrict ourselves to starting from a functor φ given in indexed form (8.5.4.3), in the case where J is a small filtered category, in order to indicate in this case how to compute $\text{«}\varinjlim\text{»}\,\varphi = \text{«}\varinjlim_j\text{»}\,\varphi(j)$. Formula (8.5.3.2), together with the associativity formula for inductive limits (2.5.0), then immediately gives the "*tautological computation*" of $\text{«}\varinjlim\text{»}\,\varphi$:

$$\text{«}\varinjlim_J\text{»}\,\varphi = \text{«}\varinjlim_{J\times I}\text{»}\,\Phi, \tag{8.5.4.4}$$

83 i.e.

$$\text{«}\varinjlim_j\text{»}\,(i \longmapsto \Phi(j,i)) = \text{«}\varinjlim_{j,i}\text{»}\,\Phi(j,i), \tag{8.5.4.5}$$

Thus, the sought-for inductive system is none other than Φ itself (the indexing category being $J \times I$, which is indeed filtered since J and I are).

Exercise 8.5.5. Let C be a $\mathscr{U}$-category

a) Prove that the following conditions are equivalent:

(i) In C, small inductive limits are representable, and the functor $c : C \to \mathrm{Ind}(C)$ commutes with them.
(iii) The functor c is an equivalence of categories.
(ii) In C, small inductive limits are representable, and for every $X \in \mathrm{Ob}\, C$, the functor $Y \mapsto \mathrm{Hom}(X, Y)$ commutes with these limits.
(iv) Small filtered inductive limits are representable in C, and the functor $\lim c : \mathrm{Ind}\, C \to C$ (cf. 8.7.1.5) is fully faithful (or equivalently, an equivalence).

b) If C is a finite category, prove that the preceding conditions are equivalent to the following: for every projector in C (10.6), its image is representable in C.

8.6. Extension of a functor to ind-objects.

8.6.1. Let

$$f : C \longrightarrow C' \tag{8.6.1.1}$$

be a functor between $\mathscr{U}$-categories. For every ind-object

$$\varphi : I \longrightarrow C$$

of C (I a filtered category), the composite functor $f \circ \varphi$ is an ind-object of C', also denoted by $\mathrm{Ind}(f)(\varphi)$. In indexed notation, if φ is written as $\mathscr{X} = (X_i)_{i\in I}$, one obtains 84

$$\mathrm{Ind}(f)(X_i)_{i\in I} = (f(X_i))_{i\in I}. \tag{8.6.1.2}$$

Let $\mathscr{Y} = (Y_j)_{j\in J}$ be a second inductive system of C. One then obtains an evident map, also denoted by $u \to \mathrm{Ind}(f)(u)$:

$$\mathrm{Hom}(\mathscr{X}, \mathscr{Y}) = \varprojlim_i \varinjlim_j \mathrm{Hom}(X_i, Y_j) \to \tag{8.6.1.3}$$

$$\mathrm{Hom}(\mathrm{Ind}(f)(\mathscr{X}), \mathrm{Ind}(f)(\mathscr{Y})) \simeq \varprojlim_i \varinjlim_j \mathrm{Hom}(f(X_i), f(Y_j)).$$

Referring to the unwritten formula for composition of morphisms of ind-objects (8.2.5), one immediately sees that these maps are compatible with composition of morphisms of ind-objects. Thus, for every universe $\mathscr{V}$, we have obtained a functor

$$\mathrm{Ind}(f) : \mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U}) \longrightarrow \mathrm{Ind}_{\mathscr{V}}(C', \mathscr{U}) \tag{8.6.1.4}$$

(notation of (8.2.4.5)), and in particular a functor

$$\mathrm{Ind}(f) : \mathrm{Ind}(C) \longrightarrow \mathrm{Ind}(C'). \tag{8.6.1.5}$$

If there is a second functor

$$g : C' \longrightarrow C'',$$

then one clearly has an identity of functors between Ind-categories (or $\mathrm{Ind}_{\mathscr{V}}$-categories, as desired):

$$\mathrm{Ind}(gf) = \mathrm{Ind}(g) \circ \mathrm{Ind}(f), \tag{8.6.1.6}$$

and, when $C' = C$, the perennial formula 85

$$\mathrm{Ind}(\mathrm{id}_C) = \mathrm{id}_{\mathrm{Ind}(C)}. \tag{8.6.1.7}$$

One may therefore say, heuristically, that the category $\mathrm{Ind}(C)$ *depends functorially on* C (covariantly) [3]. We leave to the reader the task of making explicit even a 2-*functorial* dependence by defining, for every pair of $\mathscr{U}$-categories C, C', a canonical functor

$$\mathbf{Ind}(f) : \mathbf{Hom}(C, C') \longrightarrow \mathbf{Hom}(\mathrm{Ind}(C), \mathrm{Ind}(C')), \tag{8.6.1.8}$$

[3] For a contravariant dependence, under certain conditions, cf. 8.11.

and specifying the functorial nature of the identical isomorphisms (8.6.1.6) and (8.6.1.7).

8.6.2. Return to the functor (8.6.1.1), and consider the corresponding functor (5.1)

$$f_! : \widehat{C} \longrightarrow \widehat{C'}, \tag{8.6.2.1}$$

and the diagram of functors

$$\begin{array}{ccc} \mathrm{Ind}(C) & \xrightarrow{\mathrm{ind}(f)} & \mathrm{Ind}(C') \\ {\scriptstyle L_C}\downarrow & & \downarrow{\scriptstyle L_{C'}} \\ \widehat{C} & \xrightarrow{f_!} & \widehat{C'} \end{array} \tag{8.6.2.2}$$

where the vertical arrows denote the canonical functors L of (8.2.4.8). Since the functor $f_!$ "extends f" and commutes with inductive limits (5.4.3), and the functors L_C and $L_{C'}$ commute with small filtered inductive limits (8.5.1), it follows from (8.5.3.2) that, for every ind-object $(X_i)_{i\in I}$ of C, there is a canonical isomorphism in $\widehat{C'}$

$$f_!(L_C((X_i)_{i\in I})) \simeq \varinjlim_i f_! L_C(X_i) \simeq \varinjlim_i L_{C'} f(X_i) = L_{C'}(f(X_i)_{i\in I})$$

86 i.e. a canonical isomorphism

$$f_! L_C(\mathscr{X}) \simeq L_{C'}(\mathrm{Ind}(f)(\mathscr{X})).$$

We leave to the reader the verification that the latter is functorial, i.e. that it corresponds to a canonical isomorphism

$$f_! L_C \simeq L_{C'} \circ \mathrm{Ind}(f). \tag{8.6.2.3}$$

In other words, the *square (8.6.2.2) commutes up to canonical isomorphism.* Taking into account the fact that $f_!$ commutes with small inductive limits, and using 8.5.1, we conclude:

Proposition 8.6.3. *Let $f : C \to C'$ be a functor between $\mathscr{U}$-categories. Then the functor*

$$\mathrm{Ind}(f) : \mathrm{Ind}(C) \longrightarrow \mathrm{Ind}(C')$$

commutes with filtered inductive limits. Moreover, it makes the following diagram commutative:

$$\begin{array}{ccc} C & \xrightarrow{f} & C' \\ {\scriptstyle c_C}\downarrow & & \downarrow{\scriptstyle c_{C'}} \\ \mathrm{Ind}(C) & \xrightarrow{\mathrm{Ind}(f)} & \mathrm{Ind}(C') \end{array} ,$$

where the vertical arrows c_C, $c_{C'}$ are the canonical functors (8.4.1).

The last assertion is trivial from the definitions and has been included for ease of reference. Notice moreover that the properties stated in 8.6.3 *characterize the functor* 87 $\mathrm{Ind}(f)$ up to unique isomorphism, as the functor induced by $f_!$ (8.6.2.1), as follows from the proof of (8.6.2.3) just given.

Proposition 8.6.4. *The notation is that of 8.6.3.*

a) *The functor* $\mathrm{Ind}(f)$ *is faithful (resp. fully faithful) if and only if f is.*

b) *The functor* $\mathrm{Ind}(f)$ *is an equivalence of categories if and only if* f *is fully faithful and every object of* C' *is isomorphic to a direct factor (10.6) of an object in the image of* f.

Proof.

a) Necessity clearly follows from the fact that f is induced by $\mathrm{Ind}(f)$. For sufficiency, it is enough to use the form (8.6.1.3) of $\mathrm{Ind}(f)$ on the sets $\mathrm{Hom}(\mathscr{X}, \mathscr{Y})$, recalling that filtered inductive limits of sets and arbitrary projective limits take monomorphisms to monomorphisms and isomorphisms to isomorphisms.

b) We may already suppose that f, hence $\mathrm{Ind}(f)$, is fully faithful. Since every object of $\mathrm{Ind}(C')$ is a small filtered inductive limit of objects of C', the full faithfulness of $\mathrm{Ind}(f)$ implies that, for this functor to be essentially surjective, it is equivalent that every object X' of C' belong to the essential image. But if there is an isomorphism

$$X' \xrightarrow{\sim} \text{«}\varinjlim\text{»}\, f(X_i),$$

this isomorphism factors through one of the $f(X_i)$, showing that X' is a direct factor of $f(X_i)$ and proving necessity in b). For sufficiency, using the full faithfulness of $\mathrm{Ind}(f)$, the assertion follows immediately.

Corollary 8.6.5. *In* $\mathrm{Ind}(E)$ *the images of projectors (10.6) are representable, and the functor* $\mathrm{Ind}(f) : \mathrm{Ind}(C) \to \mathrm{Ind}(C')$ *commutes with the formation of these images.* 88

Indeed, this follows from the fact that small filtered inductive limits are representable in $\mathrm{Ind}(C)$ (8.5.1) and that $\mathrm{Ind}(f)$ commutes with them (8.6.3), taking into account that the image of a projector $p : X \to X$ may be interpreted as the inductive limit of a filtered inductive system indexed by $\mathbf{N}$

$$X \xrightarrow{P} X \xrightarrow{P} X \longrightarrow \dots$$

or, equivalently, as the inductive limit of the evident functor on the filtered category P having one object and one nonidentity arrow Π such that $\Pi^2 = \Pi$.

8.7. *The functor* $\varinjlim_C : \mathrm{Ind}(C) \to C$. *Universal characterizations of the category* $\mathrm{Ind}(C)$.

8.7.1. Let us return to a $\mathscr{U}$-category C and the canonical functor

$$c : C \longrightarrow \mathrm{Ind}(C). \tag{8.7.1.1}$$

Let $\mathscr{X} = (X_i)_{i\in I}$ be an object of $\mathrm{Ind}(C)$. It follows immediately from the definition of representable inductive limits (2.1, 2.1.1) that $\varinjlim_i X_i$ *is representable in* C *if and only if the left adjoint of* c *is defined at* $\mathscr{X}$, and that in this case $\varinjlim_i X_i$ (computed in C) is precisely the value at $\mathscr{X}$ of that left adjoint:

$$\mathrm{Hom}_C(\varinjlim_i X_i, Y) \simeq \mathrm{Hom}_{\mathrm{Ind}(C)}((X_i)_{i\in I}, c(Y)). \tag{8.7.1.2}$$

If we denote by 89

$$\mathrm{Ind}(C)' \subset \mathrm{Ind}(C) \tag{8.7.1.3}$$

the full subcategory of $\mathrm{Ind}(C)$ formed by the ind-objects of C that admit an inductive limit *in* C, the preceding observation shows that this subcategory is *strictly full*, and that there is a canonical functor

$$\varinjlim_C : \mathrm{Ind}(C)' \longrightarrow C, \tag{8.7.1.4}$$

whose value at each object $(X_i)_{i\in I}$ of $\mathrm{Ind}(C)'$ is its inductive limit in C. In the special case where small filtered inductive limits are representable in C, one therefore obtains a natural functor

$$\varinjlim_C : \mathrm{Ind}(C) \longrightarrow C. \tag{8.7.1.5}$$

. Of course, the preceding functors may also be defined on categories of the form $\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U})'$ and $\mathrm{Ind}_{\mathscr{V}}(C, \mathscr{U})$, but in view of (8.2.4.6) they are already determined (up to unique isomorphism) by the preceding functors corresponding to the case $\mathscr{V} = \mathscr{U}$.

. The preceding construction of $\varinjlim_C$ as a left adjoint functor immediately implies that this functor *commutes with arbitrary inductive limits*, and in particular with small filtered inductive limits (the latter being representable in $\mathrm{Ind}(C)$ (8.5.1)). Notice also that $\mathrm{Ind}(C)'$ always contains the essential image of c (formed by the essentially constant ind-objects), and that there is a canonical isomorphism, functorial in $X \in \mathrm{ob}\,\mathrm{Ind}(C)'$:

$$\varinjlim_C c(X) \simeq X, \tag{8.7.1.8}$$

90 i.e. , in the favorable case where C is stable under small inductive limits, there is a canonical isomorphism

$$\varinjlim_C \circ\, c \simeq \mathrm{id}_C\,. \tag{8.7.1.9}$$

8.7.2. Now consider a functor

$$f : C \longrightarrow E, \tag{8.7.2.1}$$

where E is a $\mathscr{U}$-category in which small inductive limits are representable, so that there is a functor

$$\varinjlim_E : \mathrm{Ind}(E) \longrightarrow E.$$

Since we have also defined (8.6)

$$\mathrm{Ind}(f) : \mathrm{Ind}(C) \longrightarrow \mathrm{Ind}(E),$$

we may consider the composite

$$\overline{f} = \varinjlim_E \circ\, \mathrm{Ind}(f) : \mathrm{Ind}(C) \longrightarrow E, \tag{8.7.2.2}$$

sometimes called the *canonical extension of f to ind-objects* (but not to be confused with $\mathrm{Ind}(f)$!). As a composite of two functors that commute with small filtered inductive limits (8.6.3, 8.7.1.7), this functor itself commutes with small filtered inductive limits. Moreover, the isomorphism (8.7.1.9) applied to E, together with (8.6.2.3), shows that $\overline{f}$ *extends* f up to isomorphism, i.e. there is a canonical isomorphism

$$\overline{f} \circ c_C \simeq f\,. \tag{8.7.2.3}$$

91 It is moreover fairly clear, in view of the fact that every object of $\mathrm{Ind}(C)$ is a small filtered inductive limit of objects of C, that the two preceding properties still *characterize* $\overline{f}$ up to unique isomorphism. This can be sharpened to obtain at the same time a universal characterization, up to equivalence, of $\mathrm{Ind}(C)$ among the $\mathscr{U}$-categories E in which small filtered inductive limits are representable. If E and F are two such $\mathscr{U}$-categories, denote by

$$\mathbf{Hom}(E, F)' \subset \mathbf{Hom}(E, F) \tag{8.7.2.4}$$

the full subcategory of $\mathbf{Hom}(E, F)$ formed by the functors that commute with small filtered inductive limits. Then:

PROPOSITION 8.7.3. *Let C be a $\mathscr{U}$-category, and use the notation (8.7.2.4) above. Then the canonical functor*

$$c_C : C \longrightarrow \mathrm{Ind}(C)$$

is 2-universal among the functors with source C and target a $\mathscr{U}$-category having representable small filtered inductive limits. In other words, $\mathrm{Ind}(C)$ *is such a category (8.2.5, 8.5.1), and if E is such a category, the functor*

$$g \longmapsto g \circ c_C : \mathbf{Hom}(\mathrm{Ind}(C), E)' \longrightarrow \mathbf{Hom}(C, E) \tag{8.7.3.1}$$

is an equivalence of categories.

To prove the latter point, it is enough to verify that the map $f \mapsto \overline{f}$ defined by (8.7.2.2) can be refined to a *functor*

$$f \longmapsto \overline{f} = \varinjlim_E \cdot \mathrm{Ind}(f) : \mathbf{Hom}(C, E) \longrightarrow \mathbf{Hom}(\mathrm{Ind}(C), E)', \tag{8.7.3.2}$$

and that the latter is a quasi-inverse of (8.7.3.1). The details of the essentially trivial verification are left to the reader. Alternatively, one may invoke 7.8 to conclude first that (8.7.3.1) is fully faithful, and then (8.7.2.3) to conclude that it is essentially surjective. 92

8.7.4. Return to a functor between $\mathscr{U}$-categories

$$f : C \longrightarrow E, \tag{8.7.4.1}$$

where E is a $\mathscr{U}$-category in which small filtered inductive limits are representable, giving a functor

$$\overline{f} : (X_i)_{i\in I} \longmapsto \varinjlim_i f(X_i) : \mathrm{Ind}(C) \longrightarrow E. \tag{8.7.4.2}$$

We propose to study conditions on f ensuring that $\overline{f}$ is fully faithful, resp. an equivalence of categories. Since f is isomorphic to the composite $\overline{f} \circ c_C$, and $c_C : C \to \mathrm{Ind}(C)$ is fully faithful, we see that for $\overline{f}$ to be fully faithful, it is *necessary* that f be so. Replacing C by its essential image in E, we therefore lose essentially no generality by supposing that f is the inclusion functor of a subcategory C of E, as we shall do below to simplify the notation.

PROPOSITION 8.7.5. *The notation is that of 8.7.4.*

a) *The functor $\overline{f}$ is fully faithful if and only if:*
   (i) *Every object X of C satisfies the following condition:*
   (PF) *For every small filtered inductive system $(Y_i)_{i\in I}$ in C whose inductive limit $\varinjlim_i Y_i$ exists in E, the canonical map* 93

$$\varinjlim_i \mathrm{Hom}(X, Y_i) \longrightarrow \mathrm{Hom}(X, \varinjlim_i Y_i) \tag{8.7.5.1}$$

   is bijective.

b) *The functor $\overline{f}$ is an equivalence of categories if and only if C satisfies condition* (i) *and the following two conditions:*
   (ii) *C is a generating subcategory of E by strict epimorphisms (7.1).*
   (iii) *For every object X of E, the full subcategory $C_{/X}$ of $E_{/X}$ formed by the objects X' over X whose source is in* $\mathrm{Ob}\, C$ *is filtered and essentially small.*

Condition (iii) *is satisfied in particular if C is equivalent to a small category, the finite inductive limits in C are representable, and the inclusion functor $f : C \to E$ commutes with them (i.e. for every finite category J and every functor $\varphi : J \to C$, the inductive limit of $f\varphi$ is representable and is isomorphic in E to an object of C).*

Proof.

a) With the notation of condition (i), let $\mathscr{Y}$ denote the ind-object (Y_i) and let $\mathscr{X}$ denote the constant ind-object defined by X. Then (8.7.5.1) is precisely the canonical map

$$\mathrm{Hom}(\mathscr{X}, \mathscr{Y}) \longrightarrow \mathrm{Hom}(\overline{f}(\mathscr{X}), \overline{f}(\mathscr{Y})),$$

so if $\overline{f}$ is fully faithful, this map is indeed bijective. Conversely, if $\mathscr{X} = (X_j)_{j\in J}$ and $\mathscr{Y} = (Y_i)_{i\in I}$ are arbitrary ind-objects of E, then the map $u : \mathrm{Hom}(\mathscr{X}, \mathscr{Y}) \to$
94 $\mathrm{Hom}(\overline{f}(\mathscr{X}), \overline{f}(\mathscr{Y}))$ is the projective limit over j of the maps $u_j : \mathrm{Hom}(\mathscr{X}_j, \mathscr{Y}) \to \mathrm{Hom}(\overline{f}(\mathscr{X}_j), \mathscr{Y})$, where $\mathscr{X}_j$ is the constant ind-object with value X_j. Thus u is bijective if the u_j are, and (i) therefore implies that $\overline{f}$ is fully faithful.

b) Suppose that (i), (ii), and (iii) hold, and let us prove that $\overline{f}$ is an equivalence. It remains to prove that it is essentially surjective, hence that every $X \in \mathrm{ob}\, E$ belongs to the essential image. But hypothesis (ii) means that $\varinjlim_{C_{/X}} Z \to X$ is an isomorphism, while (iii) says that the category $C_{/X}$ is filtered and essentially small. Thus X is the image of the ind-object of E defined by the natural functor $C_{/X} \to E$. Conversely, suppose that $\overline{f}$ is an equivalence. In view of a), it remains to verify (ii) and (iii). We may suppose that $E = \mathrm{Ind}(C)$, with C identified with the subcategory $c(C)$ of E. But we know (8.3.3 (ii)) that for every $X \in \mathrm{Ind}(C)$, identified if desired with the functor F on C° that it ind-represents, $C_{/X} = C_{/F}$ is an essentially small filtered category (which proves (iii)), and that the inductive limit in $\widehat{C}$ of the functor $C_{/F} \to \widehat{C}$ is F. It is therefore also so in the full subcategory E of $\widehat{C}$, since $F = X$ belongs to E, which proves (ii). It remains to prove the last assertion of b). But the hypothesis on C clearly implies that finite inductive limits are representable in the category $C_{/X}$; *a fortiori*, the category $C_{/X}$ is filtered.

95 Remark 8.7.5.2. The preceding argument shows more generally that, when condition (i) is satisfied, the essential image of the fully faithful functor $\overline{f}$ (8.7.4.2) consists of the $X \in \mathrm{ob}\, E$ such that the category $C_{/X}$ is filtered and essentially small (a condition automatically satisfied if C satisfies the conditions stated at the end of b)), *and* such that the inductive limit of the canonical functor $C_{/X} \to E$ is X.

Corollary 8.7.6. *Let E_{PF} be the full subcategory of E formed by the objects satisfying condition (PF) of 8.7.5 a). Then, for every functor $J \to E_{PF}$, where J is a finite category, that admits an inductive limit X in E, one has $X \in \mathrm{ob}\, E_{PF}$. The canonical functor $(X_i)_{i\in I} \to \varinjlim_i {}_E X_i$ deduced from the inclusion $g : E_{PF} \hookrightarrow E$*

$$\overline{g} : \mathrm{Ind}(E_{PF}) \longrightarrow E \tag{8.7.6.1}$$

is fully faithful. If finite inductive limits are representable in E and E_{PF} is equivalent to a small category, then the essential image of the functor $\overline{f}$ consists of the objects X of E such that the canonical morphism $\varinjlim_{(E_{PF})_{/X}} Y \to X$ is an isomorphism. If, moreover, the subcategory E_{PF} of E is generating by strict epimorphisms (7.1), then the functor (8.7.6.1) is an equivalence of categories.

All the assertions are evident, in the order in which they are stated, in view of 8.7.5, using 2.8 for the first assertion.

96 COROLLARY 8.7.7. *Suppose that finite inductive limits are representable in E. Let C be a full subcategory of E, equivalent to a small category, and consider the functor $(X_i)_{i\in I} \to \varinjlim_{i,E} X_i$:*

$$\overline{f} : \mathrm{Ind}(C) \to E. \tag{8.7.7.1}$$

Let E_{PF} be as in 8.7.6. The following conditions are equivalent:

(i) *The functor $\overline{f} : \mathrm{Ind}(C) \to E$ is an equivalence.*

(ii) *The category C is generating in E by strict epimorphisms, is contained in E_{PF}, and every object of E_{PF} is isomorphic in E (or in E_{PF}, which is equivalent (8.7.6)) to a direct factor of an object of C.*

When the subcategory C of E is stable under direct factors (10.6), the preceding conditions are also equivalent to the following:

(ii bis) *$C = E_{PF}$, and C is generating in E by strict epimorphisms.*

(iii) *The subcategory C of E is generating by strict epimorphisms, is contained in E_{PF}, and finite inductive limits are representable in it.*

When, moreover, finite inductive limits are representable in E, these conditions are also equivalent to

(iii bis) *The subcategory C of E is generating by strict epimorphisms, is contained in E_{PF}, and is stable in E under finite inductive limits (or, equivalently, under finite sums and cokernels of double arrows).*

We already know (8.7.5) that condition (i) implies $C \subset E_{PF}$ and that C is generating 97
by strict epimorphisms. Let us also prove that every object X of E_{PF} is then isomorphic to a direct factor of an object of C. Indeed, we know that X is a filtered inductive limit $\varinjlim_i X_i$ in E of objects of C, and by the definition of E_{PF}, for a suitable i the canonical homomorphism $X_i \to X$ has a left inverse, so X is indeed a direct factor of the object X_i of C. This proves (i) $\Rightarrow$ (ii) (without any hypothesis on C or E, moreover). Let us prove (ii) $\Rightarrow$ (i). Since C is equivalent to a small category and every object of E_{PF} is a direct factor of an object of C, we see that E_{PF} is also equivalent to a small category. Thus, by 8.7.6, the functor (8.7.6.1) is an equivalence of categories, and we conclude by 8.6.4 b) applied to the inclusion $E \hookrightarrow E_{PF}$.

When every direct factor in E of an object of C belongs to C, it is clear that (ii) $\Leftrightarrow$ (ii bis). On the other hand, (ii bis) implies (iii) resp. (iii bis) by 8.7.6. Finally, (iii) (and *a fortiori* (iii bis)) implies (i) by 8.7.5. This completes the proof.

EXERCISE 8.7.8. (*Karoubi envelopes*). Let C be a $\mathscr{U}$-category, let $E = \mathrm{Ind}(C)$, and let $E_{PF} \supset C$ be the full subcategory of E defined in 8.7.6.

a) Prove that images of projectors are representable in E_{PF} and that every object of E_{PF} is a direct factor of an object of C.

b) Call a category F *Karoubian* if images of projectors are representable in it. Let

$$\varphi : C \longrightarrow K$$

be a fully faithful functor such that K is Karoubian and every object of K is a 98
direct factor of an object in the image of C. Prove that φ is 2-*universal* among functors from C with values in Karoubian categories, more precisely: for every Karoubian category F, the functor

$$g \longmapsto g \circ \varphi : \mathbf{Hom}(K, F) \longrightarrow \mathbf{Hom}(K, F)$$

is an equivalence of categories. (Use the fact that every functor commutes with images of projectors.) The category K equipped with φ, determined up to equivalence (itself determined up to unique isomorphism) by the preceding properties, is called the *Karoubi envelope* $\widetilde{C}$ of C. (Compare also IV 7.5.)

c) Deduce from a) and b) that $\mathrm{Ind}(C)_{PF}$, equipped with the functor $C \to \mathrm{Ind}(C)_{PF}$ induced by $c : C \to \mathrm{Ind}(C)$, is a Karoubi envelope of C.

d) Show that every functor $f : C \to C'$ extends in an essentially unique way to a functor $\widetilde{f} : \widetilde{C} \to \widetilde{C'}$ of Karoubi envelopes, and that if these Karoubi envelopes are taken as in c), $\widetilde{f}$ is the functor induced by $\mathrm{Ind}(f) : \mathrm{Ind}(C) \to \mathrm{Ind}(C')$. Show that the conditions of 8.5.4 b) are also equivalent to the following: $\widetilde{f}$ is an equivalence of categories.

Exercise 8.7.9. Let E be a $\mathscr{U}$-category.

a) Show that the following conditions are equivalent:

(i) E is equivalent to a category of the form $\mathrm{Ind}(C)$, where C is a $\mathscr{U}$-category.

99 (i bis) As in (i), with C moreover Karoubian (8.7.8 b)).

(ii) The subcategory E_{PF} of E (8.7.6) is generating by strict epimorphisms, and for every object X of E, $(E_{PF})_{/X}$ is an essentially small filtered category.

Show that if C is a *Karoubian* $\mathscr{U}$-category such that E is equivalent to $\mathrm{Ind}(C)$, then C is equivalent to E_{PF} (by an equivalence determined up to unique isomorphism). Establish a 2-equivalence between the 2-category formed by the categories E satisfying the preceding conditions and the functors between them that *commute with small filtered inductive limits*, and the 2-category formed by *Karoubian* $\mathscr{U}$-categories and arbitrary functors between them.

b) Show that the following conditions are equivalent:

(i) E is equivalent to a category of the form $\mathrm{Ind}(C)$, where C is a $\mathscr{U}$-category in which finite inductive limits are representable.

(i bis) As in (i), but with C moreover Karoubian.

(ii) Finite inductive limits in E are representable, the subcategory E_{PF} of E is generating by strict epimorphisms, and for every object X of E, there exists a small subset I of $\mathrm{Ob}\, E_{PF/X}$ such that every object of $E_{PF/X}$ is bounded above by an object of I. (Use 8.9.5 b).)

100

8.8. Indexed representation of a functor $J \to \mathrm{Ind}(C)$.

8.8.1. Let

$$\varphi : J \longrightarrow \mathrm{Ind}(C) \text{ i.e. } \varphi \in \mathrm{Ob}\, \mathbf{Hom}(J, \mathrm{Ind}(C))$$

be a functor, where C is a $\mathscr{U}$-category. Recall (8.5.4) that an *indexed representation of* φ is, by definition, an ind-object of $\mathbf{Hom}(J, C)$

$$\psi : I \longrightarrow \mathbf{Hom}(J, C),$$

with I an essentially small filtered category, together with a specified isomorphism from its inductive limit in $\mathbf{Hom}(J, \mathrm{Ind}(C))$ to φ. Thus φ admits an indexed representation if and only if it is isomorphic to an essentially small filtered inductive limit in $\mathbf{Hom}(J, \mathrm{Ind}(C))$ of objects of the full subcategory $\mathbf{Hom}(J, C)$. We shall say that the category J is *admissible for* C if every functor $\varphi : J \to \mathrm{Ind}(C)$ admits an indexed representation.

Since in $\mathrm{Ind}(C)$ small filtered inductive limits are representable (8.5.1), the same is true in $\mathbf{Hom}(J, \mathrm{Ind}(C))$, and they are computed "argument by argument". Consequently, the inclusion functor

$$\mathbf{Hom}(J, C) \hookrightarrow \mathbf{Hom}(J, \mathrm{Ind}(C)) \tag{8.8.1.1}$$

extends canonically to a functor

$$\mathrm{Ind}(\mathbf{Hom}(J,C)) \longrightarrow \mathbf{Hom}(J,\mathrm{Ind}(C)) \tag{8.8.1.2}$$

(8.7.2). The objects of the essential image of this functor are then precisely the φ that admit an indexed representation; thus, to say that J is admissible for C also means that the functor (8.8.1.2) is essentially surjective. In this connection, we note:

PROPOSITION 8.8.2. *If the category J is equivalent to a finite category, the canonical functor (8.8.1.2) is fully faithful; thus J is admissible for C if and only if this functor is an equivalence of categories.* 101

By 8.7.5 a), it suffices to prove that for every small filtered inductive system $(\varphi_i)_{i\in I}$ in $\mathbf{Hom}(J,C)$ and every object φ of $\mathbf{Hom}(C,J)$, the canonical map

$$\varinjlim_i \mathrm{Hom}(\varphi,\varphi_i) \longrightarrow \mathrm{Hom}(\varphi,\varinjlim_i \varphi_i) \tag{8.8.2.1}$$

is bijective, where $\varinjlim_i \varphi_i$ denotes the inductive limit taken in $\mathrm{Hom}(J,\mathrm{Ind}(C))$. Now, if φ, ψ are two functors $J \to C$, there is an exact diagram of sets, functorial in φ and ψ:

$$\mathrm{Hom}(\varphi,\psi) \longrightarrow \prod_{X\in \mathrm{Ob}\, J} \mathrm{Hom}(\varphi(X),\psi(X)) \rightrightarrows \prod_{\substack{f\in Fl J\\ f:X\to Y}} \mathrm{Hom}(\varphi(X),\psi(Y)).$$

Since filtered inductive limits commute with kernels of double arrows and with finite products, the bijectivity of (8.8.2.1) follows when J is finite. The case in which J is equivalent to a finite category reduces immediately to the preceding case.

PROPOSITION 8.8.3. *Let $\varphi : J \to \mathrm{Ind}(C)$ be a functor, with J equivalent to a small category. For φ to admit an indexed representation, the following two conditions are sufficient, and they are also necessary when J is equivalent to a finite category:*

a) *The category $\mathbf{Hom}(J,C)_{/\varphi}$ (formed by the arrows in $\mathbf{Hom}(J,\mathrm{Ind}(C))$ with target φ and source in $\mathrm{Hom}(J,C)$) is filtered.*

b) *For every object j of J, the functor* 102

$$\psi \longmapsto \psi(j) : \mathbf{Hom}(J,C)_{/\varphi} \longrightarrow C_{/\varphi(j)} \tag{8.8.3.1}$$

is cofinal, i.e. satisfies conditions F 1), F 2) *of* 8.1.3.

Proof. Suppose a) and b) hold; let us prove that φ admits an indexed representation. We may clearly suppose that J is small. Let

$$I = \mathbf{Hom}(J,C)_{/\varphi}, \tag{8.8.3.2}$$

which is a filtered category by hypothesis, and first suppose that I is essentially small, so that the "inclusion" of I in $\mathbf{Hom}(J,C)$ defines an ind-object of $\mathbf{Hom}(J,C)$, $i \mapsto \psi_i$. Moreover, there is a canonical homomorphism

$$\varinjlim_i \psi_i \longrightarrow \varphi, \tag{8.8.3.3}$$

given argument by argument by the homomorphism

$$\varinjlim_I \psi_i(j) \longrightarrow \varphi(j) = \varinjlim_{C_{/\varphi(j)}} X$$

induced by the functor (8.8.3.1). Since the latter is cofinal, we conclude that (8.8.3.3) is an isomorphism, which proves the assertion. In the case where we do not suppose I essentially small, it is enough to construct an essentially small full subcategory I'

such that (8.8.3.3) remains an isomorphism when $\varinjlim_{I'}$ is used in place of $\varinjlim_{I}$. For this purpose, it is enough that the composite functors

$$I' \longrightarrow I \longrightarrow C_{/\varphi(j)}$$

103 induced by the functors (8.8.3.1) all be cofinal. We then conclude by the following lemma, whose proof is immediate from criterion (8.1.3 b)) and is left to the reader:

LEMMA 8.8.3.4. *Let I be a filtered $\mathscr{U}$-category, and let*

$$f_j : I \longrightarrow I_j \quad (j \in J)$$

be a small family of cofinal functors from I to essentially small filtered categories. Then there exists a full subcategory I' of I which is filtered and essentially small, and such that the functors induced by the f_j are cofinal.

Finally, let us prove necessity in 8.8.3 when J is assumed equivalent to a finite category. An indexed representation of φ by means of an essentially small filtered indexing category I defines a functor ψ

(8.8.3.5)
$$\begin{array}{ccc} I & \xrightarrow{\psi} & \mathbf{Hom}(J, C)_{/\varphi} \\ & \searrow^{\psi_j} & \downarrow \\ & & C_{/\varphi(j)} \end{array} ,$$

and it is enough to prove that ψ and each of the functors ψ_j induced by it are cofinal: by 8.1.3 b), it will then indeed follow that $\mathbf{Hom}(J, C)_{/\varphi}$ is filtered, and by definition 8.1.1 that the vertical arrow in (8.8.3.5) is also cofinal. By 8.8.2, we may identify φ with an object of $\mathrm{Ind}(E)$, where $E = \mathbf{Hom}(J, C)$, and the fact that the functor

$$\psi : I \longrightarrow E_{/\varphi},$$

104 arising from the ind-object φ of E indexed by I is cofinal is a general fact, which follows immediately from criteria (F 1) and (F 2) of 8.1.3. The same argument (with E, φ replaced by C, $\varphi(j)$) shows that ψ_j is cofinal, which completes the proof.

REMARK 8.8.4.
a) In the case where J is equivalent to a finite category, if φ admits an indexed representation, we have seen that (8.8.3.5) is a cofinal functor, which implies that the category $\mathbf{Hom}(J, C)_{/\varphi}$ is itself essentially small.
b) Suppose that in C finite inductive limits are representable. Then the same is true in $E = \mathbf{Hom}(J, C)$, and these limits are computed argument by argument and are also inductive limits in $\mathbf{Hom}(J, \widehat{C})$ and *a fortiori* in $\mathbf{Hom}(J, \mathrm{Ind}(C))$. It follows immediately that condition a) of 8.8.3 is then automatically satisfied, and it remains only to consider condition b). I do not know whether it is automatically satisfied when J is in addition assumed small.

We now come to the main result of this section:

PROPOSITION 8.8.5. *Let J be a category equivalent to a finite category, and suppose in addition that J is rigid, i.e. that for every $j \in \mathrm{Ob}\, J$, every endomorphism of j is the identity. Then J is admissible for C (for any $\mathscr{U}$-category C), i.e. every functor $J \to \mathrm{Ind}(C)$ admits an indexed representation.*

105 Upon replacing J by an equivalent category if necessary, we may suppose that J is *skeletal*, i.e. that two isomorphic objects of J are equal. Then J is in fact finite. We proceed by induction on card Ob J; the case where this number is ≤ 0 is trivial, so we shall suppose it is ≥ 1. Let $j_\circ$ be a *maximal* object of J, i.e. such that for every arrow $j_\circ \to j$, there exists an arrow $j \to j_\circ$; in view of the fact that J is rigid, this implies that $j_\circ \to j$ is an isomorphism, and since J is skeletal, it implies that $j_\circ = j$. Let J' therefore be the full subcategory obtained from J by removing the object $j_\circ$, and let J'' be the full subcategory consisting of the object $j_\circ$. The proposition then follows from the

LEMMA 8.8.5.1. *Let J be a finite category, and let J' and J'' be two full subcategories such that* Ob J = Ob J' ∪ Ob J'', *and such that for every $j' \in$ Ob J' and $J'' \in$ Ob J'', one has* $\mathrm{Hom}(j'', j') = \emptyset$. *If J' and J'' are admissible for C, then so is J.*

It is enough to prove criteria a) and b) of 8.8.3, which amounts to carrying out six elementary verifications, namely the last two filteredness conditions for $\mathbf{Hom}(J, C)_{/\varphi}$, and conditions F 1) and F 2) for the functors (8.8.3.1), successively in the cases $j \in$ Ob J' and $j \in$ Ob J''; the latter conditions moreover imply that $\mathbf{Hom}(J, C)_{/\varphi}$ is nonempty. The rather tedious verification presents no difficulty and is left to the reader. (The editor sought in vain for an elegant proof that would circumvent these unpleasant verifications.)

EXERCISE 8.8.6. a) Let J, J' be two categories admissible for C, one of them 106
being finite. Prove that $J \times J'$ is admissible for C. (Use 8.8.2.)

b) Prove that a small discrete category is admissible for every category C.

c) Let J be a category satisfying the following conditions: (i) J is rigid, (ii) Ob J is countable, (iii) For any two objects j, j' of J, $\mathrm{Hom}(j, j')$ is finite, (iv) For every object j of J, the set of objects of J that are bounded above by j, i.e. that are sources of an arrow with target j, is finite. Show that J is admissible for every $\mathscr{U}$-category C. (First show that J can be written as a filtered union of finite full subcategories J_n, such that every object of J bounded above by an object of J_n belongs to J_n. Then verify criteria a), b) of 8.8.3.)

EXERCISE 8.8.7. In our notation we identify an ordered set with the category it defines.

a) Let C be an ordered set. Let $\tilde{C}$ be the set of subsets A of C that are filtered and such that $x \in A$ and $y \leq x$ imply $y \in A$. Let $L_\circ : C \to \tilde{C}$ be the map that associates to every $x \in C$ the set $L_\circ(x)$ consisting of those $y \in A$ such that $y \leq x$. Show that L is injective and that the order on C is induced by that on $\tilde{C}$. For every $A \in \tilde{C}$, consider the inclusion $f(A) : A \to C$, which is an ind-object of C; for every ind-object $\varphi : I \to C$ of C, let $g(\varphi) \in \tilde{C}$ be the subset of C consisting of the elements of C bounded above by an element of the form $\varphi(i)$. Show that one thus obtains two mutually quasi-inverse equivalences 107

$$\mathrm{Ind}(C) \underset{\approx}{\overset{f,g}{\leftrightarrows}} \tilde{C},$$

transforming the functor $L_\circ$ into the canonical functor $L : C \to \mathrm{Ind}(C)$.

b) Suppose that for every $x \in C$, the set of elements bounding x from above (resp. from below) is finite. Show that every ind-object (resp. pro-object) of C is essentially constant, and indeed that for every such $\varphi : I \to C$ (resp. $\varphi : I^\circ \to C$) there exists an $i_\circ \in$ Ob I such that the functor induced on $I_{/i_\circ}$ is constant (i.e. takes every arrow to an isomorphism).

c) Let $C \subset \mathbf{N}^\circ \times \mathbf{N}$ be formed by the pairs of natural numbers (j, i) such that $i \geq j$. Show that $\tilde{\mathbf{N}}$ is isomorphic to the ordered set obtained from $\mathbf{N}$ (identified with an ordered subset of $\tilde{\mathbf{N}}$ as in a)) by adjoining a greatest element ∞. Show that $\tilde{C}$ is isomorphic to $\mathbf{N}^\circ \times \tilde{\mathbf{N}}$. Consider the functor

$$\varphi : \mathbf{N}^\circ \longrightarrow \tilde{C} \quad , \quad \varphi(j) = (j, \infty).$$

Show that:

1) the projective limit of φ is not representable in $\tilde{C}$, although filtered projective limits in C are representable (and are essentially constant, by b)).
2) For every functor $\psi : \mathbf{N}^\circ \to C$, one has $\mathrm{Hom}(\psi, \varphi) = \varnothing$, and *a fortiori* the functor φ admits no indexed representation.

108 Exercise 8.8.8. Let $X = \mathbf{N} \amalg \mathbf{N}$ be the disjoint union of two copies of $\mathbf{N}$, let s be the symmetry of X, and for every $i \in \mathbf{N}$, let X_i be the subset $\Delta_{i+1} \amalg \Delta_i$ of $\mathbf{N}$ (where Δ_i denotes the subset of $\mathbf{N}$ formed by the j such that $j \leq i$). Let C be the subcategory of the category of subsets of X whose objects are the X_i and whose arrows are the maps between the X_i induced by the identity of X or by its symmetry s, and let $\tilde{C}$ be the category defined analogously, but with the additional object X.

a) Show that $\mathrm{Ind}(C)$ is equivalent to $\tilde{C}$, with the canonical functor $C \to \mathrm{Ind}(C)$ corresponding to the inclusion $C \to \tilde{C}$. Show that there exists no pair (Y, f) consisting of an object Y of C and an endomorphism f of Y, together with a morphism of objects with endomorphism in $\mathrm{Ind}(C)$ from (Y, f) to (X, s).
b) Deduce that if J is the category having a single object and, in addition to the identity arrow, a single arrow of order 2, then the functor $J \to \mathrm{Ind}(C)$ defined by (X, s) admits no indexed representation.

8.9. Exactness properties of $\mathrm{Ind}(C)$.

Proposition 8.9.1. *Let C be a $\mathscr{U}$-category.*

a) *The canonical functors L (8.2.4.8) and c (8.4.1)*

$$C \xrightarrow{c} \mathrm{Ind}(C) \xrightarrow{L} \widehat{C}$$

commute with projective limits.
b) *Suppose that finite inductive limits are representable in C and that C is equivalent to a small category. Then small projective limits are representable in* $\mathrm{Ind}(C)$.
109 c) *If small projective limits (resp. finite projective limits) are representable in C, then the same is true in* $\mathrm{Ind}(C)$. *Let J be a category that is finite and rigid, or discrete; if projective limits of type J are representable in C, projective limits of the same type are representable in* $\mathrm{Ind}(C)$.
d) *Small filtered inductive limits in* $\mathrm{Ind}(C)$ *(which are representable by virtue of 8.5.1) are left exact, i.e. commute with finite projective limits.*

Proof.

a) The fact that L commutes with projective limits follows from the fact that it is fully faithful and from the computation of projective limits in $\widehat{C}$ "argument by argument," which implies that, to verify that a projective system of morphisms $F \to F_i$ $(i \in I)$ in $\widehat{C}$ exhibits F as a projective limit of the F_i, it suffices to verify that the analogous assertion holds for the projective systems of maps of sets $\mathrm{Hom}(X, F) \to \mathrm{Hom}(X, F_i)$, for every $X \in \mathrm{Ob}\, C$. But $C \subset \mathrm{Ind}(C)$.

The fact that c commutes with projective limits follows formally from the fact that L does so, as does the composite $L \circ c : C \to \widehat{C}$.

b) In view of a), the assertion amounts to saying that every projective limit of ind-representable presheaves is ind-representable, which follows at once from the criterion 8.3.3 (v), since a projective limit of left exact functors is left exact (which follows from the fact that "projective limits commute with projective limits" (2.5.0)).

c) This follows formally from the analogous property of $\widehat{C}$ (3.3), and from the fact that L is conservative (being fully faithful) and commutes with limits of the type under consideration (a) and 8.5.1). 110

d) It is well known (cf. 2.3) that the representability of finite projective limits is equivalent to that of projective limits of the types

empty , … ,

(corresponding to certain finite ordered sets), and the representability of small projective limits amounts to that of products and finite projective limits. Thus the second assertion made in (c) implies the first.

Suppose first that I is finite. Using the result 8.8.5 on the representability of functors $\varphi : J \to \mathrm{Ind}(C)$ in indexed form (8.5.4)

$$\phi : J \times I \longrightarrow C, \tag{8.9.1.1}$$

the existence of $\varinjlim \varphi$ is therefore a special case of the following more precise and more general result:

Corollary 8.9.2. *Consider a functor $\varphi : J \to \mathrm{Ind}(C)$ given in indexed form Φ (8.9.1.1), where J is a finite category. If for every $i \in \mathrm{Ob}\, I$, the partial functor $j \to \Phi(j,i)$ has a projective (resp. inductive) limit representable in C, then φ has a projective (resp. inductive) limit representable in* $\mathrm{Ind}(C)$*, and there is a canonical isomorphism*

$$\varinjlim \varphi \simeq \text{«}\varinjlim_i\text{»} \varprojlim_j \Phi(j,i) \tag{8.9.2.1}$$

(resp. 111

$$\varinjlim \varphi \simeq \text{«}\varinjlim_i\text{»} \varprojlim_j \Phi(j,i)), \tag{8.9.2.2}$$

where $\varinjlim_j$ (resp. . $\varprojlim_j$) is computed in C.

For the first formula, one simply uses the fact that in $\mathrm{Ind}(C)$ filtered inductive limits commute with $\varprojlim_j$, and that c commutes with $\varprojlim_J$ (8.9.1 d) and a)):

$$\varinjlim \varphi = \varprojlim_j \text{«}\varinjlim_i\text{»}\, \Phi(j,i) \overset{\sim}{\leftarrow} \text{«}\varinjlim_i\text{»} \varprojlim_j{}^{\mathrm{Ind}(C)} \Phi(j,i) \simeq \text{«}\varinjlim_i\text{»} \varprojlim_j{}^{C}\, \Phi(j,i).$$

The second is proved in the same way, using the commutation of inductive limits of type I with inductive limits of type J (2.5.0) and the fact that c commutes with inductive limits of type J, proved in 8.9.4 a) below.

The case where J is discrete. This case is contained in the following more precise assertion:

Corollary 8.9.3. *Let the I_α be essentially small filtered categories indexed by a small set A, and for every $\alpha \in A$, let $X(\alpha) = (X(\alpha)_{i_\alpha})_{i_\alpha \in I_\alpha}$ be an ind-object of C indexed by I_α. Let I be the product category of the I_α, and suppose that for every $\imath = (i_\alpha)_{\alpha\in A} \in I$, the product $\prod_{\alpha\in A} X(\alpha)_{i_\alpha}$ is representable in C. Then the product $\prod_{\alpha\in A} X(\alpha)$ is representable in* Ind(C)*, and it is canonically isomorphic to the ind-object indexed by I given by the formula*

$$\prod_{\alpha\in A} \text{« }\varinjlim_{i_\alpha\in I_\alpha}\text{ »}\ X(\alpha)_{i_\alpha} \simeq \text{« }\varinjlim_{\imath=(i_\alpha)_{\alpha\in A}\in I}\text{ »} \left(\prod_{\alpha\in A} A(\alpha)_{i_\alpha}\right), \tag{8.9.3.1}$$

112 *where the product on the right-hand side is the product computed in C. (Note that I is filtered and essentially small, since the I_α are.)*

Indeed, it is well known (and immediate by reduction to the case in which one works in the category of sets) that the formula in question holds when the limits are computed in $\widehat{C}$. The conclusion then follows from the fact that L commutes with the limits in question (8.9.1 a) and 8.5.1).

Remarks 8.9.4. The proof given for 8.9.2 and 8.9.3 shows, more generally, that if for every $i \in \mathrm{Ob}\, I$, $\varinjlim_j \Phi(j,i)$ (resp. $\varprojlim_j \Phi(j,i)$) *computed in* Ind(C) is representable, then the same is true of $\varprojlim_i \varphi$ (resp. of $\varinjlim_j \varphi$). This, together with the argument of c), shows that for a given category J arising from a finite or discrete ordered set (or more generally, one that is C-admissible (8.3.1)), projective limits (resp. inductive limits) of type J are representable in Ind(C) if (and only if) for every functor $\varphi : J \to C$, the projective (resp. inductive) limit of φ *computed in* Ind(C) is representable. In the nonparenthetical case, this also means, by virtue of (a), that every projective limit of type J of representable presheaves on C is ind-representable.

Proposition 8.9.5. *Let C be a $\mathscr{U}$-category.*

a) *The canonical functor*
$$c : C \longrightarrow \mathrm{Ind}(C)$$
is right exact (hence exact, in view of 8.9.1 a)*).*

b) *If finite inductive limits (resp. finite sums) are representable in C, then small inductive limits (resp. small sums) are representable in* Ind(C)*. Let J be a preordered* 113 *set that is finite or discrete; if inductive limits of type J are representable in C, the same is true in* Ind(C)*.*

Proof.

a) Suppose that in C one has $X \simeq \varinjlim_J X_j$, where J is a finite category and X and the X_j belong to C. Then, for every ind-object $\mathscr{Y} = (Y_i)_{i\in I}$ of C, one has:
$$\mathrm{Hom}(X,\mathscr{Y}) \simeq \varinjlim_i \mathrm{Hom}(X,Y_i) \simeq \varinjlim_i \varprojlim_j \mathrm{Hom}(X_j,Y_i)$$
$$\overset{2.8}{\simeq} \varprojlim_j \varinjlim_i \mathrm{Hom}(X_j,Y_i) \simeq \varprojlim_j \mathrm{Hom}(X_j,\mathscr{Y}),$$
and the desired conclusion follows by comparing the outer terms.

b) We already noted in 8.8.4 that the assertions made follow from a) and 8.9.2, at least for finite inductive limits. To prove the stated conclusions in the infinite cases, we are reduced to the case of sums, which can be interpreted as a filtered inductive limit of finite sums, and we therefore conclude by 8.5.1.

Remark 8.9.6. We have already observed that the functor c does not in general commute with filtered inductive limits, and hence does not commute with infinite sums either, in contrast to what happens for $L : \mathrm{Ind}(C) \to \widehat{C}$. On the other hand, apart from its commutation with *filtered* inductive limits (8.5.1), L has practically no commutation properties with any other type of inductive limit (initial object, sum of two objects, cokernels of double arrows). Thus, if C admits an initial object $\varnothing_C$, which is therefore an initial object of $\mathrm{Ind}(C)$ by a), $\varnothing_C$ is never an initial object of $\widehat{C}$ (i.e. identical to the constant presheaf with value $\varnothing$), since $\mathrm{Hom}(\varnothing_C, \varnothing_C) \neq \varnothing$!

Proposition 8.9.7. *Let* 114

$$f : C \longrightarrow C'$$

be a functor between $\mathscr{U}$-categories, and let J be a finite rigid category (8.8.5). If inductive (resp. projective) limits of type J are representable in C and f commutes with them, then $\mathrm{Ind}(f) : \mathrm{Ind}(C) \to \mathrm{Ind}(C')$ *also commutes with limits of this type.*

This follows at once from 8.8.5 and from the calculation 8.9.2 of finite limits in a category of ind-objects, for a functor represented in indexed form.

Corollary 8.9.8. *If finite inductive (resp. projective) limits are representable in C, and if f is right exact (resp. left exact), then the same is true of* $\mathrm{Ind}(f)$*; in the unparenthesized case,* $\mathrm{Ind}(f)$ *even commutes with all small inductive limits.*

The first assertion follows from 8.9.7. The second follows from the first, taking into account that $\mathrm{Ind}(f)$ commutes with filtered inductive limits (8.6.3).

Exercise 8.9.9. Let C be a $\mathscr{U}$-category.

a) Suppose that finite sums are representable in C. Show that if *finite* sums in C are disjoint (resp. universal) (cf. II 4.5), then in $\mathrm{Ind}(C)$ *small* sums are disjoint (resp. universal).

b) Suppose that every morphism in C factors as an epimorphism followed by a monomorphism (resp. as an effective epimorphism followed by a monomorphism, resp. as an epimorphism followed by an effective monomorphism, resp. as an effective epimorphism followed by an effective monomorphism). Show that $\mathrm{Ind}(C)$ satisfies the same property. In the last case, it follows that every epimorphism of $\mathrm{Ind}(C)$ is effective, every monomorphism of $\mathrm{Ind}(C)$ is effective, and every bimorphism of $\mathrm{Ind}(C)$ is an isomorphism; show that in this case every epimorphism (resp. monomorphism) of $\mathrm{Ind}(C)$ can be represented by an inductive system of epimorphisms (resp. monomorphisms) of C. If, in addition, every epimorphism (resp. every monomorphism) in C is assumed to be *universal*, the same property holds in $\mathrm{Ind}(C)$. 115

c) Suppose that C is additive (resp. abelian); then so is $\mathrm{Ind}(C)$.

d) Let $X = \text{« } \varinjlim_I \text{ » } X_i$ be an ind-object of C, and let $R \rightrightarrows X$ be an equivalence relation on X. For every $i \in \mathrm{Ob}\, I$, let $R_i \rightrightarrows X_i$ be the equivalence relation on X_i (regarded as an object of $\mathrm{Ind}(C)$) induced by R via $X_i \to X$. (We assume that the fiber product $R_i = R \times_{X \times X} X_i \times X_i$ in $(\mathrm{Ind}(C))$ is representable by an object of $\mathrm{Ind}(C)$, as is the case if finite projective limits are representable in C.) Show that, for R to be effective, it suffices that the R_i be effective.

e) Let X be an object of C, and let R be an equivalence relation on $c(X)$, i.e. on X regarded as an object of $\mathrm{Ind}(C)$. Suppose that fiber products are representable in C. For R to be effective, it is necessary that R be of the form $\text{« } \varinjlim_i \text{ » } R_i$, where

the R_i are equivalence relations on X (regarded as an object of C), and this
116 condition is sufficient if equivalence relations in C are assumed to be effective.

f) Suppose that every morphism in C factors as an effective epimorphism followed by an effective monomorphism, and that finite projective limits are representable. Let X be an object of C, and let R be a subobject of $X \times X$, regarded as an object of $\mathrm{Ind}(C)$. Write R in the form « $\varinjlim$ » Z_i, where $(Z_i)_{i\in I}$ is a filtered increasing family of subobjects of $X \times X$ *in* C (this is possible by b)). Show that, for R to be an equivalence relation on X, it is necessary and sufficient that, for every $i \in \mathrm{Ob}\, I$, there exists an index $j \in \mathrm{Ob}\, I$ whose corresponding subobject contains $s(Z_i)$ and $Z_i \circ Z_i$, where s is the symmetry of $X \times X$.

g) Suppose that in C finite projective limits and finite sums are representable, that every equivalence relation there is effective, and that every morphism there factors as an effective epimorphism followed by an effective monomorphism. Show that equivalence relations in $\mathrm{Ind}(C)$ are universal if and only if C satisfies the following condition:

ST) For every object X of C and every subobject Z of $X \times X$ in C, if the sequence of subobjects Z_n ($n \geq 0$) of $X \times X$ in C is defined recursively by $Z_0 = Z$, $Z_n = \mathrm{Sup}(Z_n, s(Z_n), Z_n \circ Z_n)$ (where Sup is taken in the set of subobjects of $X \times X$, which exists by the hypotheses made on C), then the sequence $(Z_n)_{n\geq 0}$ is *stationary.*

k) Show that equivalence relations in Ind((Ens)) are not necessarily effective.

* NB. For criteria ensuring that $\mathrm{Ind}(C)$ is a topos, cf. VI 8.9.9.$_*$

117 Exercise 8.9.10. Let C be a $\mathscr{U}$-category. Put $\mathrm{Pro}(C) = (\mathrm{Ind}(C^\circ))^\circ$ (cf. 8.11).

a) Suppose that finite sums (resp. small sums) are representable in C. Show that if they are disjoint (cf. II 4.5), then $\mathrm{Pro}(C)$ satisfies the same condition.

b) Let J be a small set such that sums indexed by J are representable in C, and hence also in $\mathrm{Pro}(C)$. Let $(X(\alpha))_{\alpha\in J}$ be a family of objects of $\mathrm{Pro}(C)$, with $X(\alpha) = $ « $\varprojlim_{I_\alpha}$ » X_{i_α}. Show that, for the sum of the $X(\alpha)$ in $\mathrm{Ind}(C)$ to be universal, it suffices that the same hold for each of the families $\varprojlim_J X_{i_\alpha}$, where $(i_\alpha)_{\alpha\in I} \in \prod_{\alpha\in J} I_\alpha$. Deduce that, if in C sums of type J are universal, then for the same to hold in $\mathrm{Pro}(C)$ it is necessary and sufficient that, for every family $(X(\alpha))_{\alpha\in J}$ as above, with $I_\alpha = I$ for every $\alpha \in J$, the canonical homomorphism in $\mathrm{Pro}(C)$

$$« \varprojlim_I » \amalg_\alpha X(\alpha)_i \longleftarrow « \varprojlim_{I^J} » \amalg_{\alpha\in J} X(\alpha)_{i_\alpha}$$

be an isomorphism. Deduce that in Pro((Ens)), sums of type J are universal if and only if J is finite.

Exercise 8.9.11. Let C be a $\mathscr{U}$-category.

a) Let $(X_i \to X)_{i\in I}$ be a family of morphisms in C. Show that, for it to be epimorphic in $\mathrm{Ind}(C)$, it suffices that there exists a *finite* subfamily that is epimorphic in C. Prove that this condition is also necessary when it is assumed that in C every finite family of morphisms with target X_i factors as an epimorphic family,
118 followed by an effective monomorphism (10.5). (For this last assertion, let P be the set of finite subsets of I, ordered by inclusion, and let $X' = (X'_J)_{J\in P}$ be the ind-object formed by the images of the finite subfamilies of the given family;

finally, let $X'' = X \amalg_{X'} X = \text{« lim »}\, X \amalg_{X'_J} X$. Show that the two canonical morphisms $X \rightrightarrows X''$ are distinct, but coincide on the X'_J.)

b) Suppose that every finite family of morphisms with the same target in C factors as an epimorphic family followed by an effective monomorphism. Prove that $\mathrm{Ind}(C)$ admits a small subcategory generating by epimorphisms (7.1) if and only if C admits a small subcategory C' such that every object of C is the target of a *finite* epimorphic family with source in C'. If C is assumed to admit a small generating subcategory (7.1), then $\mathrm{Ind}(C)$ admits a small subcategory generating by epimorphisms if and only if C is equivalent to a small category. (For this last statement, use 7.5.2).

c) $\mathrm{Ind}((\mathrm{Ens}))$ does not admit a small generating subcategory.

Exercise 8.9.12. Let C be a $\mathscr{U}$-category, and consider $\mathrm{Pro}(C) = \mathrm{Ind}(C^\circ)^\circ$.

a) Show that if $\mathrm{Pro}(C)$ admits a small subcategory P' generating by epimorphisms (7.1), then there exists a small subcategory C' of C that is generating by epimorphisms in $\mathrm{Pro}(C)$. (Take the category of components of the objects of P'.)

b) Show that the category $\mathrm{Pro}((\mathrm{Ens}))$ has no small subcategory generating by epimorphisms. (If C' is as in a), choose a set X whose cardinality strictly exceeds the cardinalities of the objects of C', and consider the pro-set $\mathscr{X}$ formed by the complements in X of subsets of cardinality $< \mathrm{card}(X)$. Show that, for every nonempty set Y of cardinality $< \mathrm{card}(X)$, one has $\mathrm{Hom}(Y, \mathscr{X}) = \emptyset$, but that $\mathscr{X}$ is not isomorphic to the constant pro-set $\emptyset$.) 119

8.10. Dual notions: pro-objects, pro-representable functors. Let C be a $\mathscr{U}$-category. A *pro-object* of C is a functor

$$\varphi : I^\circ \longrightarrow C, \tag{8.10.1}$$

where I is an essentially small filtered category (called the index category), and, as usual, I° denotes the opposite category. Let $\mathscr{V}$ be a universe such that $\mathscr{V} \supset \mathscr{U}$. One should note that the pro-objects of C indexed by $I \in \mathscr{V}$ are in one-to-one correspondence with the ind-objects of C° indexed by $I \in \mathscr{V}$: to every such ind-object $\psi : I \to C^\circ$ one associates the pro-object $\varphi = \psi^\circ : I^\circ \to C$. Following this correspondence, one defines "by transport of structure and reversal of arrows" the notion of a morphism between pro-objects of C from the analogous notion (8.2.4.2), (8.2.5.1) for ind-objects, and consequently defines the category of pro-objects of C indexed by $I \in \mathscr{V}$, together with a canonical isomorphism

$$\mathrm{Pro}_{\mathscr{V}}(C, \mathscr{U}) \simeq \mathrm{Ind}_{\mathscr{V}}(C^\circ, \mathscr{U})^\circ; \tag{8.10.2}$$

for $\mathscr{V} = \mathscr{U}$ one simply speaks of the *category of pro-objects of* C, denoted $\mathrm{Pro}_{\mathscr{U}}(C)$ or simply $\mathrm{Pro}(C)$, which is thus defined by 120

$$\mathrm{Pro}(C) = \mathrm{Pro}_{\mathscr{U}}(C, \mathscr{U}) \simeq \mathrm{Ind}(C^\circ)^\circ. \tag{8.10.3}$$

If two pro-objects are given in *indexed form*

$$\mathscr{X} = (X_i)_{i \in I} \quad , \quad \mathscr{Y} = (Y_j)_{j \in J}, \tag{8.10.4}$$

formula (8.2.5.1) takes here the form

$$\mathrm{Hom}(\mathscr{X}, \mathscr{Y}) \simeq \varprojlim_j \varinjlim_i \mathrm{Hom}(X_i, Y_j). \tag{8.10.5}$$

The functor (8.4.1), applied to C°, gives, upon passing to opposite categories, a canonical functor (denoted by the same letter c when there is no risk of confusion) that identifies C with a full subcategory of $\mathrm{Pro}(C)$:

$$c : C \longrightarrow \mathrm{Pro}(C); \tag{8.10.6}$$

it is in order to have such a functor, rather than $C \to \mathrm{Pro}(C)^\circ$, that we "reversed the arrows" in the definition of morphisms of pro-objects starting from the analogous definition for ind-objects. Pro-objects in the essential image of (8.10.6) are again called *essentially constant pro-objects.*

Put

$$\check{C} = (C^\circ)\hat{} = \mathbf{Hom}(C, (\mathrm{Ens})), \tag{8.10.7}$$

then the functor (8.2.4.7) may be regarded as a canonical fully faithful functor

$$L : \mathrm{Pro}_{\mathscr{V}}(C, \mathscr{U}) \longrightarrow \check{C}^\circ, \tag{8.10.8}$$

121 and in particular one obtains

$$L : \mathrm{Pro}(C) \hookrightarrow \check{C}^\circ. \tag{8.10.9}$$

We leave it to the reader to translate, as the need arises, the results of the preceding sections and of those that follow from the language of ind-objects into that of pro-objects. Depending on the mathematical context, one language or the other is more useful, not to mention the cases in which both notions arise simultaneously, for example when one must consider complex categories such as $\mathrm{Pro}(\mathrm{Ind}(C))$ or $\mathrm{Ind}(\mathrm{Pro}(C))$. We confine ourselves to giving a few additional indications, in order to fix the terminology and notation and to make the "yoga" precise.

8.10.10. A *covariant functor* $F : C \to (\mathrm{Ens})$ is called a *pro-representable functor* if it belongs to the essential image of (8.10.9) (or of 8.10.8, which amounts to the same thing); the full subcategory of $\check{C}$ formed by these functors is therefore equivalent to $\mathrm{Pro}(C)^\circ$. In general one will prefer to work in the opposite category, the essential image *as a subcategory of* (8.10.9), which is therefore equivalent to $\mathrm{Pro}(C)$ itself. In accordance with this usage, it is often preferable to regard covariant functors

$$F : C \longrightarrow (\mathrm{Ens})$$

as objects of $\mathbf{Hom}(C, (\mathrm{Ens}))^\circ = \check{C}^\circ$, and consequently to write the category of morphisms

$$X \longrightarrow F \text{ in } \check{C}^\circ,$$

122 i.e. of pairs (X, u) consisting of an object X of C and an element $u \in F(X)$, as

$$_F\backslash C\ . \tag{8.10.11}$$

With this convention, one thus obtains a *covariant* functor (source functor)

$$_F\backslash C \to C, \tag{8.10.12}$$

and 3.4 is rewritten in the form

$$F \xrightarrow{\sim} \text{“}\varinjlim_{(_F\backslash C)^\circ}\text{”}\, X \tag{8.10.13}$$

8.10.14. Criterion 8.3.3, applied to C°, becomes a pro-representability criterion for F: it is necessary and sufficient that $(_F\backslash C)^\circ$ be filtered and essentially small, the latter condition being superfluous if C is equivalent to a small category; if, moreover, finite projective limits are representable in C, this is equivalent to saying that F commutes with them, i.e. is *left exact.*

8.10.15. In $\mathrm{Pro}(C)$ small filtered projective limits are representable and the functor (8.10.9) commutes with them; in other words, this functor carries projective limits in $\mathrm{Pro}(C)$ to *inductive* limits in $\check{C} = \mathbf{Hom}(C, (\mathrm{Ens}))$, just like its composite $C \to \check{C}^\circ$ with (8.10.6), which shares with it the unfortunate property of being contravariant when regarded as taking values in $\check{C}$. One should note that pro-representable functors from C to (Ens) are the functors that are small filtered *inductive* limits of representable functors (and not projective limits, as the terminology might perhaps suggest). 123

8.11. Ind-adjoints and pro-adjoints.

8.11.1. Let

$$f : C \longrightarrow C' \tag{8.11.1.1}$$

be a functor between $\mathscr{U}$-categories, whence a functor $F \mapsto F \circ f$

$$f^* : \widehat{C}' \longrightarrow \widehat{C}. \tag{8.11.1.2}$$

We say that f *admits an ind-adjoint* if the preceding functor carries ind-representable functors to ind-representable functors. Since f^* commutes with inductive limits, and since the full subcategory of $\widehat{C}'$ formed by the ind-representable functors is stable under small filtered inductive limits, it is equivalent to say that f admits an ind-adjoint, or that f^* carries objects of C' (identified with a full subcategory of $\widehat{C}'$) to ind-representable functors on C, i.e.

$$X \longmapsto \mathrm{Hom}(f(X), Y') \text{ is ind-representable for every } Y' \in \mathrm{Ob}\, C'. \tag{8.11.1.3}$$

Another way to express the condition that f admit an ind-adjoint is to say that there exists a functor

$$g : \mathrm{Ind}(C') \longrightarrow \mathrm{Ind}(C) \tag{8.11.1.4}$$

essentially induced by f^*, i.e. such that there is an isomorphism of bifunctors

$$\mathrm{Hom}_{\mathrm{Ind}(C)}(X, g(\mathscr{Y}')) \simeq \mathrm{Hom}_{\mathrm{Ind}(C')}(f(X), \mathscr{Y}'), \tag{8.11.1.5}$$

where $X \in \mathrm{Ob}\, C$ and $\mathscr{Y}' \in \mathrm{Ob}\, \mathrm{Ind}(C')$. In fact, it even suffices to have a functor 124

$$g_\circ : C' \longrightarrow \mathrm{Ind}(C) \tag{8.11.1.6}$$

and an isomorphism of bifunctors

$$\mathrm{Hom}_{\mathrm{Ind}(C)}(X, g_\circ(Y')) \simeq \mathrm{Hom}_{C'}(f(X), Y') \tag{8.11.1.7}$$

in $X \in \mathrm{Ob}\, C$, $Y' \in \mathrm{Ob}\, C'$. The functor g (respectively $g_\circ$) is evidently determined up to unique isomorphism by f, and conversely f can be reconstructed up to canonical isomorphism from the knowledge of this g (respectively $g_\circ$). It is clear from (8.11.1.5) that the functor g commutes with inductive limits and that it "extends" the functor $g_\circ$; this therefore determines it up to unique isomorphism in terms of $g_\circ$ (8.7.2). The functor g, and sometimes also the functor $g_\circ$ that it extends, is called the *ind-adjoint functor of* f (there is no need here to specify: on the right, since the other one, if it exists, will be called the pro-adjoint; cf. 8.11.5 below).

Of course, when f admits a right adjoint

$$f^{\mathrm{ad}} : C' \longrightarrow C,$$

it admits an ind-adjoint g, and the latter is canonically isomorphic to the canonical extension of f^{ad} to ind-objects:

$$g \simeq \mathrm{Ind}(f^{\mathrm{ad}}). \tag{8.11.1.8}$$

The notion of an ind-adjoint is thus a natural generalization of the notion of a right adjoint.

125 Now consider the canonical extension

$$\mathrm{Ind}(f) : \mathrm{Ind}(C) \longrightarrow \mathrm{Ind}(C'). \tag{8.11.1.9}$$

We then have:

Proposition 8.11.2. *For the functor $f : C \to C'$ to admit an ind-adjoint, it is necessary and sufficient that the functor* $\mathrm{Ind}(f)$ (8.11.1.9) *admit a right adjoint. The latter is canonically isomorphic to the ind-adjoint* (8.11.1.4).

Sufficiency and the last assertion are immediate from the ind-adjunction formula (8.11.1.5). For necessity, note that by passing to the projective limit of this formula over the X_i, one obtains an adjunction isomorphism for the ind-objects $\mathscr{X} = (X_i)_{i\in I}$ and $\mathscr{Y}'$:

$$\mathrm{Hom}_{\mathrm{Ind}(C)}(\mathscr{X}, g(\mathscr{Y}')) \simeq \mathrm{Hom}_{\mathrm{Ind}(C')}(\mathrm{Ind}(f)(\mathscr{X}), \mathscr{Y}'), \tag{8.11.2.1}$$

C.Q.F.D.

Corollary 8.11.3. *If f admits an ind-adjoint, then* $\mathrm{Ind}(f)$ *commutes with inductive limits, and the ind-adjoint g commutes with projective limits.*

Proposition 8.11.4. *For the functor $f : C \to C'$ to admit an ind-adjoint, it is necessary that f be right exact, and this condition is sufficient when C is equivalent to a small category.*

This follows from criterion (8.11.1.3), and from 8.3.1 and 8.3.3 (iv).

For another criterion in terms of the notion of an accessible functor, cf. 8.13.3.

126 8.11.5. Now consider the functor $F \mapsto F \circ f$

$$f^{\circ *} : \check{C}' \longrightarrow \check{C} \tag{8.11.5.1}$$

induced by f. We say that f *admits a pro-adjoint* if the preceding functor carries pro-representable functors to pro-representable functors, i.e. if there exists a functor (called the *pro-adjoint functor of* f)

$$g : \mathrm{Pro}(C') \longrightarrow \mathrm{Pro}(C), \tag{8.11.5.2}$$

and an isomorphism of bifunctors

$$\mathrm{Hom}_{\mathrm{Pro}(C)}(g(\mathscr{Y}'), \mathscr{X}) \simeq \mathrm{Hom}_{\mathrm{Pro}(C')}(\mathscr{Y}', f(\mathscr{X})). \tag{8.11.5.3}$$

Of course, to say that f admits a pro-adjoint means that f° admits an ind-adjoint, so that the notions and results for ind-adjoints translate immediately into terms of pro-adjoints. We merely point out that f admits a pro-adjoint if and only if $\mathrm{Pro}(f) : \mathrm{Pro}(C) \to \mathrm{Pro}(C')$ admits a *left* adjoint, and that in this case the preceding functor g is such a left adjoint of $\mathrm{Pro}(f)$; and that for this it is necessary that f be *left* exact, this condition also being sufficient when C is equivalent to a small category. In this case, f is therefore exact if and only if it admits both an ind-adjoint and a pro-adjoint.

Example 8.11.6. Consider the case of a functor

$$f : C \longrightarrow (\mathrm{Ens}).$$

If this functor admits a pro-adjoint, it is pro-representable, and the converse is true if and only if the full subcategory of $\check{C}$ formed by the pro-representable functors is stable
127 under small products; this is the case in particular if C is equivalent to a small category (8.10.14) or if small products are representable in C (8.9.5 b), applied to C°). Up to minor

qualifications, one may thus say that for a functor $f : C \to C'$, the existence of a pro-adjoint is the *natural generalization of the notion of pro-representability of* f, which is defined when $C' = (\mathrm{Ens})$.

8.12. Strict ind-objects and pro-objects. Application to a representability criterion.

8.12.1. Let

$$\mathscr{X} = (X_i)_{i\in I}$$

be an ind-object of the $\mathscr{U}$-category C, and let F be the presheaf that it ind-represents. It is then immediately clear that it is equivalent to say that the canonical morphisms

$$X_i \longrightarrow F = \text{“}\varinjlim_i\text{”}\, X_i$$

are monomorphisms in $\mathrm{Ind}(C)$ (or, equivalently, in $\widehat{C}$, i.e. monomorphisms of functors “argument by argument”), or to say that for every arrow $i \to j$ of I, the corresponding transition arrow

$$X_i \longrightarrow X_j$$

is a monomorphism. When these conditions are satisfied, and if moreover I is an ordered category, we say that $\mathscr{X}$ is a *strict ind-object*. One should note that this condition 128
is not invariant under isomorphism of ind-objects; an ind-object will be called *essentially strict* if it is isomorphic to a strict ind-object. A presheaf will be called *strictly ind-representable* if it is ind-representable by a strict ind-object; thus $F = \text{“}\varinjlim_i\text{”}\, X_i$ is strictly ind-representable if and only if $\mathscr{X} = (X_i)_{i\in I}$ is essentially strict.

. Let F be a presheaf on C, and consider the full subcategory of $C_{/F}$ formed by the arrows $X \to F$ with source in C that are monomorphisms. We shall call it the *category of representable subfunctors of* F; it is the category associated with the ordered set of representable subfunctors of F, ordered by the order induced from that of the set of subobjects of F. The following then follows immediately from the definitions:

Proposition 8.12.2. *For the presheaf F on C to be strictly ind-representable, it is necessary and sufficient that the (ordered) category I of representable subfunctors of F be filtered and essentially small, and that one have*

$$\varinjlim_I X_i \xrightarrow{\sim} F. \tag{8.12.2.1}$$

When, for every object X of C, the set of subobjects of X in C is small (for example, if C admits a small generating subcategory (7.4)), this implies that the category of representable subfunctors is itself small.

. If F is strictly ind-representable, there is thus a preferred way of ind-representing 129
it by an ind-object, and the latter is even a strict ind-object: one takes the representation (8.12.2.1). A strict ind-object $\mathscr{Y}$ is called *saturated* if it is isomorphic to an ind-object of the form (X_i) occurring in (8.12.2.1), for a suitable F; thus, up to unique isomorphism, there exists a single saturated strict ind-object isomorphic to the given strict ind-object, namely the one considered in 8.12.2, taking $F = \varinjlim \mathscr{Y}$ (the limit in $\widehat{C}$).

. Suppose that it is already known that one can find a small cofinal subset in the set $\mathrm{Ob}\, C_{/F}$, as is the case in particular if F is ind-representable; it then follows that the same condition is satisfied in the full subcategory I considered in 8.12.2, so in criterion 8.12.2 one may omit the condition that I be essentially small.

8.12.3. Let F be a presheaf on C, and consider an object

$$u : X \longrightarrow F$$

of $C_{/F}$. We say that u (or the pair (X, u)) is *minimal* if, for every factorization of u as

$$X \xrightarrow{p} X' \xrightarrow{u'} F, \tag{8.12.3.1}$$

with p a strict epimorphism (10.2), p is an isomorphism. Regarding u as an element of
130 $F(X)$ (1.4), to say that u is minimal thus means that every strict epimorphism $p : X \to X'$ such that $u \in \mathrm{Im}(F(p) : F(X') \to F(X))$ is an isomorphism. This notion is clarified by part a) of the following lemma:

LEMMA 8.12.4. *Let F be a presheaf on C.*

a) *Suppose that F carries cokernels to kernels, and consider a morphism*

$$u : X \longrightarrow F,$$

with $X \in \mathrm{Ob}\, C$. For u to be a monomorphism, it is sufficient, when cokernels of pairs of arrows are representable in C, that u be minimal; this condition is also necessary if fiber products are representable in C.

b) *Suppose that finite $\varinjlim$ are representable in C. For the subcategory of representable subfunctors of F (8.12.1.1) to be filtered (not necessarily small) and to have F as its inductive limit, it is sufficient that F be left exact and that every morphism $u : X \to F$, with $X \in \mathrm{Ob}\, C$, factor as*

$$X \to X' \xrightarrow{u'} F,$$

with u' minimal; this condition is also necessary if fiber products are representable in C.

c) *Suppose that C admits a small generating subcategory (7.1), and that I, the category of representable subfunctors of F, is filtered; then I is small.*

131 *Proof.*

a) Suppose u is minimal; let us prove that u is a monomorphism, i.e. that for every pair of arrows $v, v' : Y \rightrightarrows X$ such that $uv = uv'$, one has $v = v'$. Indeed, if $X' = \mathrm{Coker}(v, v')$, then u factors as $X \xrightarrow{p} X' \xrightarrow{u'} F$ (since F carries cokernels to kernels), and since p is a strict epimorphism by construction, it follows that p is an isomorphism, i.e. $v = v'$. Suppose that u is a monomorphism; let us prove that it is minimal. Consider a factorization (8.12.3.1); since p is a strict epimorphism, it is the cokernel of the canonical pair of arrows $v, v' : X \times_{X'} X \rightrightarrows X$, and since $(u'p)v = (u'p)v'$ and $u'p = u$ is a monomorphism, one has $v = v'$, hence p is an isomorphism.

b) Sufficiency: Since F is left exact, $C_{/F}$ is filtered. Since we know that $F = \varinjlim_{C_{/F}} X$, by 8.1.3 c) it remains to prove that the full subcategory I of $C_{/F}$ consisting of the subobjects of F is cofinal in $C_{/F}$; by the "sufficient" part of a), this is precisely what is ensured by the hypothesis that every object of $C_{/F}$ is dominated by a "minimal" object. Necessity: Since every filtered inductive limit of right exact functors is again right exact, the first condition is trivially necessary. The second then follows from the "necessary" part of a).

c) A representable subfunctor $X \hookrightarrow F$ of F is known once one knows the full subcategory $C'_{/X}$ of $C'_{/F}$, where C' is a fixed small generating subcategory of C. (Use the hypothesis that I is filtered.) Since $C'_{/F}$ is small, the set of its full subcategories is small, whence the conclusion.

PROPOSITION 8.12.5. *Let C be a $\mathscr{U}$-category in which finite inductive limits are representable, and which admits a small generating subcategory (7.1). Let F be a presheaf on C. For F to be strictly ind-representable, it is sufficient that it satisfy the following two conditions, and these conditions are also necessary if fiber products are representable in C:* 132

a) *F is left exact.*
b) *Every pair (X,u), with $X \in \mathrm{Ob}\, C$ and $u \in F(X)$, is dominated in $C_{/F}$ by a minimal pair (8.12.3), i.e. there exists a minimal pair (X',u') ($X' \in \mathrm{Ob}\, C, u' \in F(X')$) and a morphism $f : X \to X'$ such that $u = F(f)(u')$.*

Sufficiency follows from 8.12.2 and 8.12.4 b), c), and necessity from 8.3.1 and 8.12.4 a).

REMARK 8.12.6. When F carries amalgamated sums in C to fiber products, it is immediately clear that for a given pair (X,u) as in b), the set of strict quotients X' of X such that $u \in \mathrm{Im}(F(X') \to F(X))$ is filtered decreasingly; this implies that if the set of strict quotients of X is Artinian, then condition b) of 8.12.5 is automatically satisfied. Thus, if the preceding condition on X is satisfied for every object X of C (one then also says, sometimes, that the objects of C° are *Artinian*), it follows from 8.12.5 that F is strictly ind-representable if and only if F is left exact; in this case, F is therefore strictly ind-representable as soon as it is ind-representable (8.3.1).

COROLLARY 8.12.7. *Let C be a $\mathscr{U}$-category in which small projective limits are representable, and which admits a small cogenerating subcategory (7.9, 7.13). Then a functor $F : C \to (\mathrm{Ens})$ is representable if and only if F commutes with small projective limits.* 133

Necessity is clear. For sufficiency, apply 8.12.5 to the opposite category C°. To prove first that F is (strictly) pro-representable, it remains to show that every pair (X,u), $X \in \mathrm{Ob}\, C$ and $u \in F(X)$, is dominated by a "minimal" pair. Now the family $(X_i)_{i\in I}$ of *strict* subobjects of X such that $u \in \mathrm{Im}(F(X_i) \to F(X))$ is small (7.5 in dual form). Since F is left exact, this family is cofiltered (8.12.6), and since F commutes with small projective limits, one sees that $X' = \varprojlim_i X_i$ is a least object of this family. (Use the fact that, being left exact, F carries monomorphisms to monomorphisms.) If $u' \in F(X')$ is the unique element whose image in $F(X)$ is u, one then sees that (X',u') is a minimal pair dominating (X,u). This proves that F is pro-representable, and the conclusion then follows from the

LEMMA 8.12.8.1. *Let $F : C \to (\mathrm{Ens})$ be a functor, where C is a $\mathscr{U}$-category in which small projective limits are representable. For F to be representable, it is necessary and sufficient that it be pro-representable and commute with small projective limits.*

Necessity is clear; let us prove sufficiency. To say that F is representable evidently means that ${}_F\backslash C$ admits an initial object (in fact, the initial objects of ${}_F\backslash C$ are precisely the isomorphisms $F \to X$, i.e. the representation data for F). Now, since F is pro-representable, $({}_F\backslash C)^\circ$ is filtered and equivalent to a small category, so $X = \varprojlim_{({}_F\backslash C)^\circ} X$ is representable in C, and since F commutes with the limit under consideration, it follows that X is an initial object of ${}_F\backslash C$, C.Q.F.D. 134

Corollary 8.12.8. *Under the hypotheses on C of 8.12.7, let $f : C \to C'$ be a functor from C to a $\mathscr{U}$-category C'. For f to admit a left adjoint, it is necessary and sufficient that f commute with small projective limits.*

Indeed, this reduces immediately to 8.12.7, by applying that statement to composite functors of the form $X \mapsto \mathrm{Hom}(Y', f(X))$.

Examples 8.12.9. As was pointed out in 7.13, the hypotheses on C in 8.12.7 and 8.12.8 are satisfied if C is the category of $\mathscr{U}$-sheaves of sets on a topological space $X \in \mathscr{U}$ (or, more generally, on a $\mathscr{U}$-site (II (3.0.2)). We give an instructive example[3] showing that the hypothesis of the existence of a small cogenerating subcategory D of C is not superfluous in 8.12.7. Take for C the category of groups that are elements of $\mathscr{U}$. Let J be the set of isomorphism classes of simple groups in C; for every $j \in J$ choose a simple group G_j in the class j, and let I be the filtered ordered set of $\mathscr{U}$-small subsets of J, and, for $i \in I$,
135 let $X_i = \amalg_{j\in i} G_j$. The X_i then form a projective system $(X_i)_{i\in I}$ in C, whose transition morphisms are epimorphisms, and the corresponding functor

$$(*) \qquad F(X) = \varinjlim_i \mathrm{Hom}(X_i, X)$$

takes its values in ($\mathscr{U}$-Ens) (although the index set I clearly does not have cardinality in $\mathscr{U}$); more precisely, let us show that for every small full subcategory $C_\circ$ of C, there exists an $i_\circ \in I$ such that the restriction of F to $C_\circ$ is represented by $X_{i_\circ}$, which will prove both that F takes values in $\mathscr{U}$-Ens and that it commutes with small projective limits. To prove our assertion, it suffices to note that for every $X \in \mathrm{Ob}\, C_\circ$, the cardinality of the set $J(X)$ of $j \in J$ for which there exists a nontrivial homomorphism from G_j to X is necessarily small, since such a morphism is necessarily a monomorphism (G_j being simple); consequently, if $i_\circ$ is the subset of J given by the union of the $J(X)$ for $X \in \mathrm{ob}\, C_\circ$, then $i_\circ$ is small, i.e. $i_\circ \in I$, and it has the required property. On the other hand, it is clear that F is not representable, since $\mathrm{card}\, I \notin \mathscr{U}$. From this and 8.12.7 one therefore concludes that *the category C of groups in $\mathscr{U}$ admits no small full cogenerating subcategory.* Since, on the other hand, the object $\mathbf{Z}$ of C is a generator, it then follows from the proof of 7.12 that there exists a two-generator group G that cannot be embedded in an injective object of the category C of groups in $\mathscr{U}$. It moreover seems plausible that C has no injective objects other than the trivial groups.
136

8.13. Pro-representable functors and accessible functors.

8.13.1. In this section, we use some notions and results from the following section, in particular 9.11 and 9.13, to obtain a pro-representability criterion that we shall use (incidentally) in IV 9.16. In what follows, C denotes a $\mathscr{U}$-category satisfying condition L of 9.1 b), this condition being satisfied, for example, if small filtered inductive limits are representable in C.

Proposition 8.13.2. *Let C be as above, and let*

$$f : C \longrightarrow (\mathrm{Ens})$$

be a functor.

a) *Suppose that every object of C is accessible (9.3). If f is pro-representable, then f is accessible (9.2) and left exact.*

b) *Suppose that finite projective limits are representable in C, and that C admits a cardinal filtration (9.12). If f is accessible and left exact, then f is pro-representable.*

[3] (due to H. BASS).

Proof.

a) The hypothesis on C means that the covariant representable functors from C to (Ens) are accessible. The same is therefore true of every small inductive limit of such functors (9.6 (i)), and hence also of every pro-representable functor.

b) By 8.3.3 (iii), it remains to prove that $\mathrm{Ob}({}_F\backslash C)^\circ$ contains a small cofinal subcategory. By hypothesis, there exists a cardinal Π such that f is Π-accessible. Let (X, u), $u \in F(X)$, be an object of ${}_F\backslash C$. With the notation of 9.12 c), we then have 137
$X = \varinjlim_i X_i$, with I filtered and large relative to Π and the X_i in $C' = \mathrm{Filt}^\Pi(C)$, whence $F(X) \xleftarrow{\sim} \varinjlim_i F(X_i)$. This shows that the small subcategory $({}_F\backslash C')^\circ$ is cofinal in $({}_F\backslash C)^\circ$, and completes the proof.

Corollary 8.13.3. *Let C be a $\mathscr{U}$-category satisfying the following conditions:*

a) *Finite projective limits are representable in C.*
b) *Small filtered inductive limits are representable in C.*
c) *The functor* Ker *on the category of double arrows of C is accessible (for example, it commutes with small filtered* $\varinjlim$*).*
d) *Every strict epimorphism of C is a universal strict epimorphism* (10.2).
e) *There exists a small subcategory of C generating by strict epimorphisms* (7.1).

Under these conditions, a functor $f : C \to$ (Ens) is pro-representable if and only if it is left exact and accessible (9.2).

Indeed, the conditions of 8.13.2 a) and b) on C are satisfied, by 9.11 and 9.13 respectively.

Corollary 8.13.4. *Let $f : C \to C'$ be a functor between $\mathscr{U}$-categories satisfying conditions* a) *through* e) *of 8.13.3. For f to admit a pro-adjoint, it is necessary and sufficient that f be left exact and accessible.*

Since the representable functors $h_{Y'} : X' \to \mathrm{Hom}(Y', X') : C' \to$ (Ens) are 138
left exact and accessible (9.11), if f has the same properties, so do its composites with the preceding functors; these are therefore pro-representable by 8.13.3, i.e. f admits a pro-adjoint. Conversely, suppose that f admits a pro-adjoint, and let C'_1 be a small generating subcategory of C, and Π a cardinal such that the $Y' \in \mathrm{Ob}\, C'$ are Π-accessible; to prove that f is Π-accessible, it therefore suffices to prove the same of its composites with the $h_{Y'}$, $Y' \in \mathrm{Ob}\, C'$; by hypothesis, these composites are pro-representable, hence accessible (8.13.3), and hence Π-accessible provided Π is taken sufficiently large, C.Q.F.D.

9. Accessible functors, cardinal filtrations, and the construction of small generating subcategories

The present section, which is more technical in nature than the other sections of this exposé, will be used in this seminar only in IV 9 and VI 4, which are not used elsewhere in the Seminar. The reader should therefore omit the present section, at least on a first reading!

9.0. All categories considered in this section are assumed to be $\mathscr{U}$-categories. Except for the small index categories $I, J \ldots$ that we shall have occasion to use, the developments that follow will apply primarily to "large" categories $E, F \ldots$ that are stable under small filtered inductive limits. Most often, however, it will suffice that a slightly weaker condition be satisfied (condition L in 9.1 below). All cardinals considered in the 139

present section are assumed to belong to $\mathscr{U}$.

Following a suggestion of P. DELIGNE, we shall study, for a functor $f : E \to F$ between large categories, a condition that f commute with certain types of filtered inductive limits. This condition is remarkably stable, and is satisfied by the most important functors occurring in nature. The applications we have in mind for our seminar are 9.13.3, 9.13.4 (used in VI 4), and especially 9.25, which gives, in a nontrivial case, the existence of a small generating family in a category of sections of a fibered category; this result will be used in IV 9.16.

DEFINITION 9.1. a) *Let I be a preordered set and π a cardinal. We say that I is large relative to π if I is filtered and every subset of I of cardinality $\leq \pi$ has an upper bound in I.*

b) *Let E be a category. If π is a cardinal, we say that E satisfies condition L_π if, for every small ordered set I large relative to π, E is stable under inductive limits of type I. We say that E satisfies condition L if there exists a cardinal $\pi \in \mathscr{U}$ such that E satisfies condition L_π.*

9.1.1. When, in 9.1 a), one has $\pi \geq 2$, the second stated condition already implies that I is filtered, and if π is finite, for I to be large relative to π simply means that I is filtered. In what follows we shall be concerned almost exclusively with the case in which π is infinite. Note that if π, π' are two cardinals such that $\pi' \geq \pi$, then I being large relative to π' evidently implies that it is large relative to π.

140 9.1.2. As announced in 9.0, conditions L_π and L should be regarded as technical variants of the stronger condition of stability under small filtered inductive limits. It is clear that if π, π' are cardinals such that $\pi' \geq \pi$, then condition L_π implies condition $L_{\pi'}$.

DEFINITION 9.2. *Let $f : E \to F$ be a functor. If Π is a cardinal, we say that f is Π-preaccessible (respectively Π-accessible) if E satisfies L_Π (9.1) and if, for every ordered set $I \in \mathscr{U}$ large relative to Π, and every inductive system $(X_i)_{i\in I}$ in E of type I, the canonical morphism*

$$\varinjlim f(X_i) \longrightarrow f(\varinjlim X_i)$$

is a monomorphism (respectively an isomorphism). We say that f is preaccessible (respectively accessible) (relative to the universe $\mathscr{U}$) if there exists a cardinal $\Pi \in \mathscr{U}$ such that f is Π-preaccessible (respectively Π-accessible).

The category of Π-accessible (respectively accessible) functors from E to F will be denoted $\mathbf{Hom}(E, F)_\Pi$, respectively $\mathbf{Hom}(E, F)_{\mathrm{acc}}$.

9.2.1. Evidently, a functor commuting with small filtered $\varinjlim$ (for example, a functor admitting a right adjoint) is Π-accessible for every cardinal $\Pi \geq 2$.

DEFINITION 9.3. *Let E be a category, X an object of E,*

$$h^\circ_X : E \longrightarrow (\mathscr{U}\text{-Ens})$$

the covariant functor it represents, and $\Pi \in \mathscr{U}$ a cardinal. We say that X is a Π-
141 *preaccessible (respectively Π-accessible) object of E if the functor h°_X is Π-preaccessible (respectively Π-accessible); we say that X is* preaccessible (respectively accessible) *if there exists a cardinal $\Pi \in \mathscr{U}$ such that X is a Π-preaccessible (respectively Π-accessible) object of E.*

9.3.1. We denote by E_Π the full subcategory of E formed by the Π-accessible objects of E.

When Definition 9.3 is applied to a category of the form $\mathbf{Hom}(C, F)$, the terminology just introduced presents *a priori* an ambiguity with the analogous terminology introduced in 9.2, when the objects of $\mathbf{Hom}(C, F)$ are interpreted as functors; there does not, however, seem to be any serious risk of confusion.

DEFINITION 9.4. *Let E be a category and let $\pi \in \mathscr{U}$ be a cardinal. We say that E is a π-preaccessible (respectively π-accessible) category if there exists in E a small full subcategory C that is generating (7.1) and whose objects are π-preaccessible (respectively π-accessible) (9.3). We say that E is a preaccessible (respectively accessible) category if there exists a cardinal $\pi \in \mathscr{U}$ such that E is π-preaccessible (respectively π-accessible).*

For important examples, cf. 9.11.3 below.

PROPOSITION 9.5. *Let $f : E \to F$ be a functor between categories such that F is accessible and every object of E is accessible. Then, if f admits a left adjoint, f is accessible.*

Indeed, by hypothesis, F admits a small conservative family of representable functors $F \to (\mathscr{U}\text{-Ens})$ that are accessible, so we are immediately reduced to showing that the composite of f with each of the preceding functors is accessible. But since f admits a left adjoint, these composites are functors $E \to (\mathscr{U}\text{-Ens})$ that are *representable*, and hence accessible by hypothesis on E. 142

PROPOSITION 9.6. *Let E and F be two categories, let $\pi \in \mathscr{U}$ be a cardinal, and consider the full subcategory $\mathbf{Hom}(E, F)_\Pi$ of $\mathbf{Hom}(E, F)$ formed by the Π-accessible functors (9.2) from E to F.*

(i) *This subcategory is stable under every type of $\varinjlim$ that is representable in F.*

(ii) *Suppose that F is π-accessible (9.4), and let J be a category such that $\operatorname{card} F\ell\, J \leq \pi$ and that the $\varinjlim$ of type J are representable in F, so the $\varinjlim$ of type J are representable in $\mathbf{Hom}(E, F)$. Then the subcategory $\mathbf{Hom}(E, F)_\Pi$ is stable under the $\varinjlim$ of type J.*

COROLLARY 9.7. *Let E and F be two categories, with F accessible (9.4). Then the full subcategory $\mathbf{Hom}(E, F)_{\mathrm{acc}}$ of $\mathbf{Hom}(E, F)$ formed by the accessible functors is stable under every type of inductive or projective limit, indexed by a small category J, that is representable in F (and hence in $\mathbf{Hom}(E, F)$).*

Proof of 9.6. Assertion (i) follows trivially from the commutation of the functor $\varinjlim$ with arbitrary inductive limits. For (ii), let $(f_j)_{j\in J}$ be a projective system of Π-accessible functors $E \to F$, and let $f = \varprojlim f_j$ be its projective limit, computed "argument by argument." We prove that f is Π-accessible, i.e. that for every ordered set $I \in \mathscr{U}$ large relative to Π, and every inductive system $(X_i)_{i\in I}$ in E, the canonical morphism 143

$$\varinjlim_i((\varprojlim_j f_j)(X_i)) \longrightarrow (\varprojlim_j f_j)(\varinjlim_i X_i)$$

is an isomorphism. Now the "argument-by-argument" computation of the functor $\varprojlim_j f_j$ allows us to identify the preceding canonical morphism with the canonical morphism

$$\varinjlim_i \varprojlim_j f_j(X_i) \longrightarrow \varprojlim_j \varinjlim_i f_j(X_i)$$

associated with the bifunctor

$$(i, j) \longmapsto f_j(X_i) : I \times J \longrightarrow F.$$

Thus 9.6 is a consequence of the following more general assertion:

COROLLARY 9.8. *Let F be a Π-accessible category, I an ordered set large relative to Π, J a small category such that* card $F\ell \leq \Pi$ *and such that projective limits of type J are representable in F, and $h : I \times J \to F$ a functor; then the canonical morphism*

$$\varinjlim_i \varprojlim_j h(i,j) \longrightarrow \varprojlim_j \varinjlim_i h(i,j) \tag{9.8.1}$$

is an isomorphism. In other words, the functor

$$\varinjlim_i : \mathbf{Hom}(I,F) \longrightarrow F \tag{9.8.2}$$

144 *commutes with projective limits of type J (for every small category J such that* card $F\ell(J) \leq \Pi$ *and such that projective limits of type J are representable in F). Equivalently, for every J as above, the functor*

$$\varinjlim_j : \mathbf{Hom}(J,F) \longrightarrow F \tag{9.8.3}$$

is Π-accessible.

By hypothesis, F admits a conservative family of covariant representable Π-accessible functors $g : F \to (\mathscr{U}\text{-Ens})$, so it is immediately clear that it suffices to prove 9.8 in the case $F = \mathscr{U}$-Ens. We shall then prove the assertion in the form that (9.8.2) commutes with projective limits of type J, where card $F\ell\, J \leq \Pi$. Since I is filtered, we know that (9.8.2) commutes with finite projective limits (2.8). By a standard argument (cf. 2.3), it therefore remains to prove that it commutes with products indexed by a set J such that card $J \leq \Pi$. This reduces us to proving the bijectivity of (9.8.1) when J is discrete. Let us prove injectivity: consider two elements a, b of the first member; they therefore come from $\prod_j h(i_\circ, j)$ for a suitable $i_\circ \in I$, say $\prod_j a(i_\circ, j)$ and $\prod_j b(i_\circ, j)$; suppose that the elements $\prod_j h(\infty, j)$ of the second member that they define are equal, i.e. that for every j, there exists $i(j) \geq i_\circ$ such that $a(i_\circ, j)$ and $b(i_\circ, j)$ have the same image in $h(i,j)$. Since I is large relative to card J, it follows that there exists a common upper bound $i_1 \in I$ of all the $i(j)$, which implies that the two elements under consideration of $\prod_j h(i_\circ, j)$ have the same image in $\prod_j h(i_1, j)$ and therefore define the same element of the first member
145 of (9.8.1), establishing injectivity. For surjectivity, let $\prod_j a(\infty, j)$ be an element of the second member; thus, for every $j \in J$, $a(\infty, j)$ comes from an element of $h(i(j), j)$ for a suitable $i(j) \in I$. As before, one can find a common upper bound $i \in I$ of the $i(j)$, so $\prod_j a(\infty, j)$ comes from an element $\prod_j a(i, j)$ of $\prod_j h(i, j)$, and hence lies in the image of (9.8.1). This completes the proof.

COROLLARY 9.9. *Let F be a Π-accessible (respectively accessible) category. Then, for every category J such that* card $F\ell\, J \leq \Pi$ *(respectively every small category J), and for every functor $(X_j)_{j\in J} : J \to F$ whose projective limit in F is representable, if the X_j are Π-accessible (respectively accessible), then so is $\varprojlim X_j$.*

Indeed, the functor $F \to (\mathscr{U}\text{-Ens})$ represented by $\varprojlim X_j$ is the projective limit of the functors represented by the X_j, and one applies 9.6 (ii) to the projective system formed by these functors.

REMARK 9.10. In the statements 9.6, 9.7, 9.8, and 9.9, one may everywhere replace the words "Π-accessible", "accessible" by "Π-preaccessible", "preaccessible". Indeed, the proof given also proves this variant of the preceding statements.

PROPOSITION 9.11. *Let E be a category satisfying condition L (9.1), and let C be a small full generating subcategory (7.1). Suppose that the following condition is satisfied:*

a) *E is stable under kernels of pairs of arrows, and the functor* Ker *on the category of pairs of arrows in E is accessible (for example, it commutes with small filtered inductive limits).* 146

Then every object of E is preaccessible (9.3), a fortiori E is preaccessible. Suppose that C is even generating by strict epimorphisms (7.1), and suppose that E satisfies the following conditions:

b) *E is stable under fiber products.*

c) *Every small strictly epimorphic family in E is universally strictly epimorphic (10.3), or small direct sums are representable in E and every strict epimorphism of E is a universal strict epimorphism.*

Then every object of E is accessible, a fortiori E is accessible.

The fact that, under (a), every object of E is preaccessible follows from the fact that for every object X of E, the set of strict subobjects of X is small (7.4), and from the

LEMMA 9.11.1. *Under the conditions of (9.11a), let $X \in \mathrm{ob}\, E$ and let Π be a cardinal such that E satisfies L_Π (9.1), the functor* Ker *in (9.11a) is Π-accessible, and the set of strict subobjects of X has cardinality bounded by Π. Then X is Π-preaccessible.*

Indeed, let I be an ordered set large relative to Π, let $(Y_i)_{i\in I}$ be an inductive system in E with inductive limit Y, and let $(u_i, v_i : X \rightrightarrows Y_i)$ be a pair of arrows such that the composite pair $X \overset{u,v}{\rightrightarrows} Y$ satisfies $u = v$; let us prove that there exists $j \geq i$ in I such that $u_j = v_j$. To this end, consider the inductive system of pairs of arrows $(u_j, v_j : X \rightrightarrows Y_j)_{j\geq i}$, whose inductive limit is (u, v). By hypothesis one has $X = \mathrm{Ker}(u, v) = \varinjlim_j \mathrm{Ker}(u_j, v_j) = \varinjlim_j X_j$, where $X_j = \mathrm{Ker}(u_j, v_j)$. Now the X_j are strict subobjects of X, so there exists a subset I' of I, formed by indices $j \geq i$, such that $\mathrm{card}\, I' \leq \Pi$ and every X_j is equal to one of the $X_{i'}$ $(i' \in I')$. Since I is large relative to Π, there exists an upper bound j of I' in I. Then X_j contains all the $X_{j'}$ for $j' \geq i$, so $X_j \to X$ is an epimorphism (since the family of the $X_{j'} \to X$ is epimorphic), and hence an isomorphism because it is a strict monomorphism. Thus $u_j = v_j$, which proves 9.11.1. 147

The second assertion of 9.11 follows from the first and from the

LEMMA 9.11.2. *Under the conditions of (9.11a), b), c), let X be an object of E, and let Π be an infinite cardinal such that E satisfies L_Π (9.1), that* card ob $C_{/X} \leq \Pi$, *that for two objects $X' \to X$ and $X'' \to X$ of $C_{/X}$, $X' \times_X X''$ is Π-preaccessible, and finally that X is Π-preaccessible. Then X is Π-accessible.*

With the notation of the proof of 9.11.1, it suffices to prove that every morphism $u : X \to Y$ comes from a morphism $u_i : X \to Y_i$. Consider the family of morphisms $Y_i \to Y$, which is strictly epimorphic; by b) and c), the family of morphisms $Y_i \times_Y X \to X$ is also strictly epimorphic; on the other hand, for every i, since C is generating by strict epimorphisms, the family of arrows

$$T \longrightarrow Y_i \times_Y X$$

with source in C is strictly epimorphic. In the second alternative considered in c), one can find such a strictly epimorphic arrow whose source is a (small) sum of objects of C. By the transitivity of the notion of a universally strictly epimorphic family (II 2.5), it then follows that the family of arrows $T_\alpha \overset{f_\alpha}{\longrightarrow} X$ with source in C that factor through one of 148

the $Y_i \times_Y X$ is strictly epimorphic. Let J be the index set of this family; its cardinality is bounded by $\operatorname{card} \operatorname{ob} C_{/X} \leq \Pi$. For every $\alpha \in J$, choose an $i = i(\alpha) \in I$ and an X-morphism $T_\alpha \to Y_i \times_Y X$, or, equivalently, a $v_\alpha : T_\alpha \to Y_i$ such that $p_i v_\alpha = u f_\alpha$, where $p_i : Y_i \to Y$ is the canonical morphism. Since I is large relative to Π, one can choose $i(\alpha)$ independently of α, say equal to i. For every pair of indices $\alpha, \beta \in J$, consider the composites

$$\operatorname{pr}_1 v_\alpha, \operatorname{pr}_2 v_\beta : T_\alpha \times_X T_\beta \rightrightarrows Y_i.$$

Their composites with $Y_i \to Y$ are equal, so, since $T_\alpha \times_X T_\beta$ is Π-preaccessible by hypothesis, there exists an index $i' = i(\alpha, \beta) \geq i$ such that the composites of the arrows under consideration with $Y_i \to Y_{i'}$ are equal. Since the set of pairs α, β has cardinality $\leq \Pi^2 = \Pi$ (Π being infinite), it follows once again that i' can be chosen independently of α, β. We may evidently suppose that $i' = i$. But then, since the family $(f_\alpha : T_\alpha \to X)$ is strictly epimorphic, one can find a morphism $u_i : X \to Y_i$ such that $u_i f_\alpha = v_\alpha$. One then has $p_i u_i = u$, since for every α one has $(p_i u_i) f_\alpha = p_i(u_i f_\alpha) = p_i v_\alpha = u f_\alpha$, and the family of the f_α is epimorphic. This completes the proof of 9.11.2.

149 Remark 9.11.3. As a special case of 9.11, one sees that every object in the category E is accessible in each of the following two cases: 1) E is a $\mathscr{U}$-abelian category with exact filtered inductive limits and admitting a small generating subcategory (here it is the *second* alternative of c) that applies). 2) E is the category of sheaves of sets on a topological space $X \in \mathscr{U}$. More generally, it suffices that E be the category of sheaves of sets on a $\mathscr{U}$-site (II 2.1), or that E be a $\mathscr{U}$-topos (IV 1.1).

Definition 9.12. *Let E be a category. A cardinal filtration of E is an increasing filtration $(\operatorname{Filt}^\Pi(E))_{\Pi \geq \Pi_\circ}$ of E by strictly full subcategories $\operatorname{Filt}^\Pi(E)$, indexed by the cardinals $\Pi \in \mathscr{U}$ such that $\Pi \geq \Pi_\circ$ (where $\Pi_\circ$ is a fixed infinite cardinal, depending on the cardinal filtration under consideration), and satisfying the following conditions:*

a) *For every $\Pi \geq \Pi_\circ$, $\operatorname{Filt}^\Pi(E)$ is equivalent to a small category.*

b) *E satisfies $L_{\Pi_\circ}$ (9.3), and for every $\Pi \geq \Pi_\circ$, $\operatorname{Filt}^\Pi(E)$ is stable in E under filtered inductive limits indexed by ordered sets I large relative to $\Pi_\circ$ such that $\operatorname{card} I \leq \Pi$.*

c) *For every $\Pi \geq \Pi_\circ$, and every $X \in \operatorname{ob} E$, one can find an isomorphism*

$$X \simeq \varinjlim_I X_i,$$

150 *where $(X_i)_{i \in I}$ is an inductive system in E indexed by an ordered set I large relative to Π (9.1), and where the X_i belong to $\operatorname{Filt}^\Pi(E)$. Moreover, if $X \in \operatorname{ob} \operatorname{Filt}^\Pi(E)$, $\Pi' \geq \Pi$, one may choose I such that $\operatorname{card} I \leq \Pi'^{\Pi}$.*

9.12.1. Note that it follows from b) and c) that every $X \in \operatorname{ob} E$ belongs to some $\operatorname{Filt}^\Pi(E)$, for Π sufficiently large.

Example 9.12.2. Take $E = (\mathscr{U}\text{-Ens})$, $\Phi_\circ = \aleph_\circ$, $\operatorname{Filt}^\Pi(E)$ = the full subcategory of E consisting of the sets such that $\operatorname{card} X \leq \Pi$. More generally:

Proposition 9.13. *Let E be a $\mathscr{U}$-category. Suppose that E is stable under small filtered $\varinjlim$, under sums of two objects, and under cokernels of pairs of arrows, that E is stable under fiber products, and that the epimorphisms in E are universal strict epimorphisms. Let C be a small full subcategory of E that is generating by strict epimorphisms. Let $\Pi_\circ$ be an infinite cardinal $\geq \operatorname{card} Fl\, C$. For every cardinal $\Pi \geq \Pi_\circ$, let $\operatorname{Filt}^\Pi(E)$ be the strictly full subcategory of E consisting of the objects X of E for which there exists a strictly epimorphic*

family $(X_i \to X)_{i\in I}$ *with target* X, *such that* $\operatorname{card} I \leq \Pi$ *and* $X_i \in \operatorname{ob} C$ *for every* $i \in I$. *Then* $(\operatorname{Filt}^{\Pi}(E))_{\Pi\geq\Pi_\circ}$ *is a cardinal filtration of* E. *Moreover, for every* $X \in \operatorname{ob}\operatorname{Filt}^{\Pi}(E)$, *the cardinality of the set of arrows of* $C_{/X}$ *(and a fortiori, of the set of objects of* $C_{/X}$*) is bounded by* $\Pi^{\Pi_\circ}$.

This last assertion is precisely 7.6.

To show that this is a cardinal filtration, one must prove conditions a), b), and c) of 9.12. Condition a) follows at once from 7.5.2. For b), suppose that $X = \varinjlim_I X_i$, with $\operatorname{card} I \leq \Pi$ and the $X_i \in \operatorname{ob}\operatorname{Filt}^{\Pi}(E)$. Thus the family of canonical morphisms $X_i \to X$ 151
is strictly epimorphic, and by the hypothesis on the X_i, for every $i \in I$ there exists a strictly epimorphic family $(X_{ij} \to X_i)_{j\in J_i}$, with $\operatorname{card} J_i \leq \Pi$. Taking the sums $\amalg_i X_i$ and $\amalg_{i,j} X_{ij}$, one sees by the transitivity of universal strict epimorphisms (II 2.5) that the family of composites $X_{ij} \to X_i \to X$ (indexed by the disjoint union of the J_i, for $i \in I$) is strictly epimorphic. But $\operatorname{card} J \leq \Pi^2 = \Pi$, whence the conclusion. (NB. we have used only the fact that $\varinjlim_I X_i$ exists, and not the fact that I is large relative to $\Pi_\circ$, or even that it is filtered.) Finally, let us prove c). Note that for every $X \in \operatorname{ob} E$, the family of arrows $X_i \to X$ with source in $\operatorname{ob} C$ is strictly epimorphic, since C is generating by strict epimorphisms, and is plainly small, so there exists a cardinal $\Pi \geq \Pi_\circ$ such that $X \in \operatorname{ob}\operatorname{Filt}^{\Pi}(E)$. It remains to prove that if $\Pi' \geq \Pi \geq \Pi_\circ$ are cardinals, and if $X \in \operatorname{ob}\operatorname{Filt}^{\Pi'}(E)$, then there is an isomorphism

$$X \simeq \varinjlim_I X_i,$$

with I large relative to Π, $\operatorname{card} I \leq \Pi'^{\Pi}$, and the X_i in $\operatorname{ob}\operatorname{Filt}^{\Pi}(E)$. Now, since C is generating by strict epimorphisms, one has

$$(*) \qquad X \simeq \varinjlim_{C_{/X}} T.$$

Let us also note that by successively adjoining to C sums and cokernels of pairs of arrows in C, and doing the same for the category thus obtained, and so on, one reduces to the case where C is stable under sums of two objects in E and under cokernels of pairs of arrows in E, without losing the hypothesis $\Pi_\circ \geq \operatorname{card} F\ell\, C$. We may suppose moreover that, if E contains a chosen initial object $\varnothing_E$, then $\varnothing_E \in \operatorname{ob} C$. This implies that the 152
category $C_{/X}$ is stable under sums of two objects and cokernels of pairs of arrows. It is then filtered, since it is nonempty: if it were empty, the relation $(*)$ would show that X is an initial object, and hence $C_{/X}$ would contain the arrow $\varnothing_E \to X$, a contradiction. Let I be the set, ordered by inclusion, of full subcategories i of $C_{/X}$ that are filtered and such that $\operatorname{card}\operatorname{ob} i \leq \Pi$. For every $i \in I$, let $X_i \in \operatorname{ob} E$ be the inductive limit of the composite functor $i \to C_{/X} \to E$, which exists by hypothesis. Then plainly

$$\varinjlim_I X_i \simeq \varinjlim_{C/X} T \simeq X.$$

On the other hand, we have already noted that $\operatorname{card}\operatorname{ob} C_{/X} \leq \Pi'^{\Pi_\circ}$. It follows that I is large relative to Π, and that $\operatorname{card} I \leq (\Pi'^{\Pi_\circ})^{\Pi} = \Pi'^{\Pi\Pi_\circ} = \Pi'^{\Pi}$ by the following lemma, whose proof is left to the reader (where we take $I = C_{/X}$, $c = \Pi'^{\Pi_\circ}$):

Lemma 9.13.1. *Let* J *be a filtered category, and let* c *and* Π *be two cardinals such that* $c \geq \operatorname{Sup}(\operatorname{card} F\ell\, J, \Pi)$, *and suppose that* $\operatorname{card}\operatorname{Hom}(j, J') \leq \Pi_\circ$ *for every pair of objects* j, j' *of* J. *Let* I *be the set of full filtered subcategories* i *of* J *such that* $\operatorname{card}\operatorname{ob} i \leq \Pi$. *Then, ordered by inclusion,* I *is large relative to* Π, *and one has* $\operatorname{card} I \leq c^{\Pi}$.

This completes the proof of 9.13.

153 Remark 9.13.2. A slight additional effort should make it possible to replace in 9.13 the hypothesis that E is stable under small filtered inductive limits by the hypothesis that E satisfies L (9.1), provided E is stable under small sums, or that in E every epimorphic *family* is universally epimorphic. In the proof of c), one must then choose $\Pi_\circ$ such that E satisfies $L_{\Pi_\circ}$, and restrict oneself to those full subcategories i of $C_{/X}$ that are not only filtered, but such that the preordered set $\mathrm{ob}\, i$ is large relative to $\Pi_\circ$. Using Section 8 and the hypothesis that E satisfies $L_{\Pi_\circ}$, one then finds that the X_i exist, and one should be able to conclude by a suitable variant of 9.13.1, which the editor has not verified.

Proposition 9.14. *Let $f : E \to F$ be an accessible functor (9.2) between two categories equipped with cardinal filtrations $(\mathrm{Filt}^{\Pi}(E))_{\Pi \geq \Pi_\circ}$ and $(\mathrm{Filt}^{\Pi}(F))_{\Pi \geq \Pi'_\circ}$. Then there exists a cardinal $\Pi_1 \geq \mathrm{Sup}(\Pi_\circ, \Pi'_\circ)$ such that for every cardinal $\Pi \geq \Pi_1$, one has*

$$f(\mathrm{Filt}^{\Pi}(E)) \subset \mathrm{Filt}^{\Pi^{\Pi_1}}(F). \tag{9.14.1}$$

In particular, if $\Pi = 2^c$ with $c \geq \Pi_1$, whence $\Pi^{\Pi_1} = 2^{c\Pi_1} = 2^c = \Pi$, one has

$$f(\mathrm{Filt}^{\Pi}(E)) \subset \mathrm{Filt}^{\Pi}(F). \tag{9.14.2}$$

We immediately point out the

154 Corollary 9.15. *Let E be a category equipped with two cardinal filtrations $(\mathrm{Filt}^{\Pi}(E))_{\Pi \geq \Pi_\circ}$ and $(\mathrm{Filt}'^{\Pi}(E))_{\Pi \geq \Pi'_\circ}$. Then there exists a cardinal $\Pi_1 \geq \mathrm{Sup}(\Pi_\circ, \Pi'_\circ)$ such that, for every cardinal $c \geq \Pi_1$, putting $\Pi = 2^c$, one has $\mathrm{Filt}^{\Pi}(E) = \mathrm{Filt}'^{\Pi}(E)$.*

Proof of 9.14. Let c be a cardinal such that $c \geq \mathrm{Sup}(\Pi_\circ, \Pi'_\circ)$ and such that f is c-accessible. Let, moreover, $\Pi_1 \geq c$ be such that

$$f(\mathrm{Filt}^{c}(E)) \subset \mathrm{Filt}^{\Pi_1}(F). \tag{$*$}$$

Such a Π_1 exists because $\mathrm{Filt}^{c}(E)$ is equivalent to a small category (9.12 a)), and hence so is $f(\mathrm{Filt}^{c}(E))$, so that one can apply 9.12.1 to the objects of the latter to find a $\mathrm{Filt}^{\Pi}(F)$ containing them all (taking into account that the $\mathrm{Filt}^{\Pi}(F)$ are full subcategories). Let then $\Pi \geq \Pi_1$ and $X \in \mathrm{ob}\,\mathrm{Filt}^{\Pi}(E)$; let us prove that $f(X) \in \mathrm{Filt}^{\Pi^{\Pi_1}}(F)$. Indeed, write

$$X = \varinjlim_{I} X_i,$$

where the $X_i \in \mathrm{ob}\,\mathrm{Filt}^{c}(E)$, I is large relative to c, and $\mathrm{card}\, I \leq \Pi^{c} \leq \Pi^{\Pi_1}$ (9.12c)). Since f is c-accessible and I is large relative to c, one has

$$f(X) \simeq \varinjlim_{I} f(X_i),$$

and since $\mathrm{card}\, I \leq \Pi^{\Pi_1}$ and $f(X_i) \in \mathrm{ob}\,\mathrm{Filt}^{\Pi_1}(F) \subset \mathrm{ob}\,\mathrm{Filt}^{\Pi^{\Pi_1}}(F)$ by $(*)$, one has $f(X) \in \mathrm{Filt}^{\Pi^{\Pi_1}}(F)$ by 9.12 b), C.Q.F.D.

9.15.1. The notion of cardinal filtration 9.12 is of interest mainly when the objects of E are accessible. We point out that it follows from 9.11 that this condition is satisfied
155 when, in addition to the hypotheses of 9.13, one supposes that the functor Ker on the category of pairs of arrows in E is accessible. We also point out:

Proposition 9.16. *Let E be a category equipped with a cardinal filtration $(\mathrm{Filt}^{\Pi}(E))_{\Pi \geq \Pi_\circ}$. Suppose that the objects of $\mathrm{Filt}^{\Pi_\circ}(E)$ are accessible objects of E; then there exists a cardinal*

$\Pi_1 \geq \Pi_\circ$ in $\mathscr{U}$ such that the objects of $\mathrm{Filt}^{\Pi_\circ}(E)$ *are Π_1-accessible; if Π_1 is chosen in this way, then for every cardinal $\Pi \geq \Pi_1$, we have (with the notation of 9.3.1):*

$$E_\Pi \subset \mathrm{Filt}^{\Pi}(E) \subset E_{(\Pi^{\Pi_\circ})}. \tag{9.16.1}$$

The existence of Π_1 follows immediately from the fact that $\mathrm{Filt}^{\Pi_\circ}(E)$ is equivalent to a small category (9.12a)). Now let $\Pi \geq \Pi_1$. If X belongs to $\mathrm{Filt}^{\Pi}(E)$, write $X \simeq \varinjlim_I X_i$ with $\mathrm{card}\, I \leq \Pi^{\Pi_\circ}$, $X_i \in \mathrm{ob}\,\mathrm{Filt}^{\Pi_\circ}(E)$ for every i (9.12c)). It then follows from 9.9 that X is $\Pi^{\Pi_\circ}$-accessible, whence the second inclusion (9.16.1). Suppose that X is Π-accessible, and write $X \simeq \varinjlim_I X_i$, with I large relative to Π and the $X_i \in \mathrm{ob}\,\mathrm{Filt}^{\Pi}(E)$ (9.12c)). By the hypothesis on X, the given isomorphism $X \xrightarrow{\sim} \varinjlim_I X_i$ factors through one of the X_i, so X is isomorphic to a direct factor of that X_i. We conclude that $X \in \mathrm{ob}\,\mathrm{Filt}^{\Pi}(E)$, and hence obtain the first inclusion (9.16.1), by the following lemma.

Lemma 9.16.2. *Every object of E that is a direct factor of an object of* $\mathrm{Filt}^{\Pi}(E)$ *belongs to* $\mathrm{Filt}^{\Pi}(E)$.

Indeed, if X is the image of a projector p on an object Y of E (i.e. an endomorphism p such that $p^2 = p$), and if I is an ordered filtered set, X is the inductive limit of the 156
filtered inductive system $(Y_i)_{i\in I}$ defined by $Y_i = Y$ for every $i \in I$, $p : Y_i \to Y_j$ if $i < j$. Taking I large relative to $\Pi_\circ$ and $\mathrm{card}\, I \leq \Pi$, we thus see that if $Y \in \mathrm{Filt}^{\Pi}(E)$, then the same holds for X, by 9.12 b).

Corollary 9.17. *Under the conditions of 9.16, for every cardinal $c \geq \Pi_1$, setting $\Pi = 2^c$,* $\mathrm{Filt}^{\Pi}(E)$ *coincides with the strictly full subcategory E_Π of E consisting of the Π-accessible objects.*

Corollary 9.18. *Let E be a category satisfying condition L_Π (9.1), where Π is a cardinal, and let C be a full subcategory of E. Denote by* $\mathrm{Ind}(C)_\Pi$ *the full subcategory of the category* $\mathrm{Ind}(C)$ *of ind-objects of C (8.2) consisting of ind-objects of the form $(X_i)_{i\in I}$, where I is an ordered set large relative to Π. Consider the canonical functor*

$$(X_i)_{i\in I} \longmapsto \varinjlim_I X_i : \mathrm{Ind}(C)_\Pi \longrightarrow E. \tag{9.18.1}$$

a) *This functor is fully faithful if and only if every object X of C is a Π-accessible object (9.3) of E.*
b) *Assume the conditions of 9.17, in particular $\Pi = 2^c$, and take $C = \mathrm{Filt}^{\Pi}(E)$. Then the functor (9.18.1) is an equivalence of categories.*

Assertion a) is an immediate generalization of 8.7.5 a), and is proved in the same way. Part b) then follows from 9.17 and condition 9.12 c) on cardinal filtrations, which implies that the functor under consideration is essentially surjective.

Corollary 9.19. *Under the conditions of 9.17, let $C = \mathrm{Filt}^{\Pi}(E)$, let F be a $\mathscr{U}$-category,* 157
and consider the functor

$$\mathbf{Hom}(E, F)_\Pi \longrightarrow \mathbf{Hom}(C, F) \tag{9.19.1}$$

induced by the "restriction to C" functor $f \mapsto f|C$, where the source of (9.19.1) is the category of Π-accessible functors from E to F (9.2). The preceding functor is fully faithful. If F satisfies condition L_Π (9.1), then the functor (9.19.1) is an equivalence of categories.

The first assertion is proved as in 7.8, using 9.18 b). The second is obtained by constructing a quasi-inverse functor to (9.19.1), associating to every functor $f : C \to F$ the functor $(X_i)_{i\in I} \to \varinjlim_i f(X_i)$ from $\mathrm{Ind}(E_\Pi)$ to F, and using 9.18 b) to deduce from it a functor $\overline{f} : E \to F$. It remains only to show that thelatter is Π-accessible. But this is proved in the same way as the analogous assertion 8.7.3.

Corollary 9.20. *Let E be a category admitting a cardinal filtration and such that every object of E is accessible (cf. 9.16), and let F be a category. Then:*

a) *The category $\mathbf{Hom}(E,F)_{acc}$ of accessible functors from E to F (9.2) is a $\mathscr{U}$-category. (*NB *we recall (9.0) that the given categories E, F are assumed to be $\mathscr{U}$-categories.)*

b) *Suppose that F is stable under small filtered inductive limits. For every full subcategory C of E equivalent to a small category, with inclusion functor $i : C \to E$, consider the corresponding functor*

$$i_! : \mathbf{Hom}(C,F) \longrightarrow \mathbf{Hom}(E,F)$$

158 *(5.1). A functor $f : E \to F$ is accessible if and only if there exists a small subcategory C of E such that f belongs to the essential image of the preceding functor $i_!$.*

Proof.

a) It suffices to prove that for every cardinal Π such that E satisfies L_Π, the full subcategory $\mathbf{Hom}(E,F)_\Pi$ of $\mathbf{Hom}(E,F)_{acc}$ is a $\mathscr{U}$-category. It is clearly enough to verify this for cardinals of the form 2^c, with c sufficiently large. But then this follows from 9.19, since ($C = \mathrm{Filt}^\Pi(E)$ being essentially small) $\mathbf{Hom}(C,F)$ is obviously a $\mathscr{U}$-category.

b) By transitivity of the formation of the functors $i_!$, one may restrict in the statement to subcategories C of the form $\mathrm{Filt}^\Pi(E)$, where Π is as in 9.17. One then sees readily that the composite functor $\mathbf{Hom}(\mathrm{Filt}^\Pi(E),F) \to \mathbf{Hom}(E,F)_\Pi \to \mathbf{Hom}(E,F)$, where the first arrow is quasi-inverse to (9.19.1), and the second is the inclusion, is none other than the functor $i_!$, up to isomorphism. Thus assertion b) follows from 9.19.

*Exercise 9.20.1. (The present exercise uses the notions of site and topos, developed in Exposés II and IV.) Let E be a $\mathscr{U}$-topos, let $\mathscr{V}$ be a universe such that $\mathscr{U} \in \mathscr{V}$, let C be a small full generating subcategory of the $\mathscr{U}$-topos E, and let $\Pi_\circ \in \mathscr{U}$ be an infinite cardinal such that $\Pi_\circ \in \mathrm{card}\, F\ell\, C$. For every cardinal $\Pi \geq \Pi_\circ$, $\Pi \in \mathscr{U}$, let $\mathrm{Filt}^\Pi(E)$ be the strictly full subcategory of E consisting of the objects X such that there exists
159 a strictly epimorphic family $(X_i \to X)_{i\in I}$ with target X, such that $\mathrm{card}\, I \leq \Pi$ and $X_i \in \mathrm{Ob}\, C$ for every $i \in I$.

a) Show that $(\mathrm{Filt}^\Pi(E))_{\Pi\geq\Pi_\circ}$ is a cardinal filtration of the $\mathscr{U}$-category E, and that one can choose $\Pi_\circ$ such that for every $\Pi \geq \Pi_\circ$, one has the inclusions

$$E_\Pi \subset \mathrm{Filt}^\Pi(E) \subset E_{\Pi^{\Pi_\circ}},$$

where, for every cardinal c, E_c denotes the strictly full subcategory of E consisting of the c-accessible objects.

b) Choosing a cardinal $\Pi \geq \Pi_\circ$ such that $\Pi = \Pi^{\Pi_\circ}$ (for example, Π of the form 2^c, with $c > \Pi_\circ$), and putting $C = \mathrm{Filt}^\Pi(E)$, show that there is an equivalence of categories

$$\mathrm{Ind}(C)_\Pi \xrightarrow{\sim} E,$$

(notation $\mathrm{Ind}(C)_\Pi$ of 9.18).

c) Retain the notation of b), and let $\mathscr{V}$ be a universe such that $\mathscr{U} \subset \mathscr{V}$, let $E^{\sim}_{V}$ be the $\mathscr{V}$-topos of $\mathscr{V}$-sheaves on the site E (endowed with its canonical topology). Denote by $\mathrm{Ind}(C, \mathscr{V})_\Pi$ the category of $\mathscr{V}$-Ind-objects of C indexed bypreordered index sets *large relative to* Π. Show that there is an equivalence of categories

$$\mathrm{Ind}(C, \mathscr{V})_\Pi \xrightarrow{\approx} \tilde{E}_{\mathscr{V}}.$$

d) Let $c \in \mathscr{V}$ be a cardinal, and let $\mathrm{Ind}(E, \mathscr{V})'_c$ be the full subcategory of $\mathrm{Ind}(E, \mathscr{V})$ consisting of the $\mathscr{V}$-ind-objects of E indexed by a preordered set that is large relative to every cardinal $< c$. Taking $c = \mathrm{card}\,\mathscr{U}$, show that there is an equivalence of categories 160

$$\mathrm{Ind}(E, \mathscr{V})'_c \xrightarrow{\approx} \tilde{E}_{\mathscr{V}}. \quad *$$

9.21. The present section 9.21 develops technical preliminaries for the proof of Theorem 9.22 below, which is the main result of the present section 9. Let

$$p : E \to B \tag{9.21.1}$$

be a fibered functor, where B is a small category, and where the inverse-image functors

$$f^* : E_\beta \longrightarrow E_\alpha$$

associated with the arrows $f : \alpha \to \beta$ of B are accessible (9.2). In particular, the fiber categories E_α ($\alpha \in \mathrm{ob}\, B$) satisfy condition L (9.1), and therefore, since B is small, there exists a cardinal $\Pi'_\circ \in \mathscr{U}$ such that all the categories E_α satisfy condition $L_{\Pi'_\circ}$. Let $\Pi_\circ \in \mathscr{U}$ be an infinite cardinal $> \Pi'_\circ$, so that one has

$$\Pi_\circ > \Pi'_\circ, E_\alpha \text{ satisfies } L_{\Pi'_\circ} \text{ for every } \alpha \in \mathrm{ob}\, B. \tag{9.21.2}$$

Moreover, the hypotheses made immediately imply the existence of a cardinal $c \in \mathscr{U}$ satisfying the following conditions:

$$\begin{cases} \text{a)} & c \text{ is infinite,} \\ \text{b)} & c \geq \mathrm{card}\, F\ell\, B, \\ \text{c)} & \text{for every arrow } f : \alpha \to \beta \text{ in } B, \\ & \text{the functor } f^* : E_\beta \to E_\alpha \text{ is } c\text{-} \\ & \text{accessible.} \end{cases} \tag{9.21.3}$$

Suppose moreover that, for every $\alpha \in \mathrm{ob}\, B$, one can find a full subcategory C_α of E_α satisfying the following conditions: 161

$$\begin{cases} \text{a)} & \text{For every } X \in \mathrm{ob}\, C_\alpha, \ X \text{ is } c\text{-} \\ & \text{accessible in } E_\alpha \text{ (9.3).} \\ \text{b)} & \text{For every } X \in \mathrm{ob}\, E_\alpha, \text{ one can find} \\ & \text{an isomorphism } X \simeq \varinjlim_I X_i \text{ in} \\ & E_\alpha, \text{ where the } X_i \text{ belong to } C_\alpha \text{ and} \\ & I \text{ is an ordered set large relative to} \\ & c. \end{cases} \tag{9.21.4}$$

Let Π be a cardinal such that

$$\Pi \geq \Pi_\circ \quad , \quad \text{hence } \Pi > \Pi'_\circ, \tag{9.21.5}$$

and, for every $\alpha \in \mathrm{ob}\, B$, let

$$C_\alpha^\Pi \subset E_\alpha \tag{9.21.6}$$

be formed by the objects that can be represented in the form $\varinjlim_I X_i$, where I is an ordered set large relative to $\Pi'_\circ$, such that card $I \leq \Pi$, and where the X_i belong to C_α. It is then clear, by 7.5.2, that C_α^Π is essentially small, i.e. is equivalent to a small category.

Let

$$F = \mathbf{Hom}_B(B, E) \tag{9.21.7}$$

be the category of sections of E over B, and let

$$F^\Pi \subset F \tag{9.21.8}$$

be the strictly full subcategory of F formed by the sections $X : \alpha \mapsto X(\alpha)$ such that for every $\alpha \in \mathrm{ob}\, B$ one has

$$X(\alpha) \in C_\alpha^\Pi .$$

162 Since the C_α^Π are essentially small, it is clear that the same is true of the category F^Π. We shall show that this category is generating, and more precisely:

LEMMA 9.21.9. *Under the preceding conditions and with the preceding notation, the following statements hold:*

(i) *Every object of F is accessible (9.3). If d is a cardinal $\geq \Pi'_\circ$, and if $\alpha \mapsto X(\alpha)$ is an element of F such that, for every α, $X(\alpha)$ is d-accessible in E_α, then X is d-accessible in F.*

(ii) *Suppose that $\Pi \leq c$, or that $\Pi'_\circ$ is finite (i.e. the E_α are stable under small filtered $\varinjlim$). Then every object X of F is isomorphic to an object of the form $\varinjlim_I X_i$, where the X_i belong to F^Π and I is large relative to Π.*

To prove (i), note that by (9.21.4) and 9.9, every object of E_α is accessible. On the other hand, F satisfies condition $L_{\Pi'_\circ}$ by the

LEMMA 9.21.10. *Let $p : E \to B$ be a fibered functor, let $F = \mathbf{Hom}_B(B, E)$, let I be a category, and let $i \mapsto X_i$ be a functor from I to F. For $\varinjlim_I X_i$ to be representable in F, it suffices that, for every $\alpha \in \mathrm{ob}\, B$, $\varinjlim_I X_i(\alpha)$ be representable in the fiber category E_α; when this is so, $\varinjlim_I X_i$ is "computed argument by argument". In particular, if the fiber categories satisfy condition $L_{\Pi'_\circ}$ (where $\Pi'_\circ$ is a given cardinal), then so does F.*

163 We leave the details of the (easy) proof of 9.21.10 to the reader, merely noting that it is convenient to use the following result, whose proof is immediate:

COROLLARY 9.21.10.1. *With the hypotheses and notation of 9.21.10 for $p : E \to B$ and for I, for every $\alpha \in \mathrm{ob}\, B$, the inclusion functor $E_\alpha \to E$ commutes with inductive limits of type I.*

Returning now to the general conditions of 9.21.9, let X be an object of F. Since, for every $\alpha \in \mathrm{ob}\, B$, $X(\alpha)$ is accessible in E_α, there exists a cardinal $d \in \mathscr{U}$ such that, for every α, $X(\alpha)$ is d-accessible in E_α. We may choose $d \geq \Pi'_\circ$, so that F satisfies L_d by 9.21.10. Using 9.21.10 once more to compute the inductive limits $\varinjlim_I Y_i$ in F, with I large relative to d, one immediately sees that X is d-accessible. This proves (i).

We shall now prove 9.21.9 (ii) in several steps ((9.21.11) to (9.21.16)).

Let then

$$X : \alpha \longmapsto X(\alpha)$$

be an object of F. By (9.21.4 b)), for every $\alpha \in \mathrm{ob}\, B$ one can find an ordered set I_α large relative to c, and an isomorphism $X(\alpha) = \varinjlim_{i \in I_\alpha} X(\alpha)_i$, where $i \mapsto X(\alpha)_i$ is an inductive system of type I_α in E_α, with the $X(\alpha)_i$ in C_α. Consider the product ordered

set $I = \Pi_\alpha I_\alpha$; it is clear that it is large relative to c, and that the preceding inductive systems give rise to inductive systems in the E_α, 164

$$i \longmapsto X(\alpha)_i \in \mathrm{ob}\, C_\alpha, i \in \mathrm{ob}\, I, \tag{9.21.11}$$

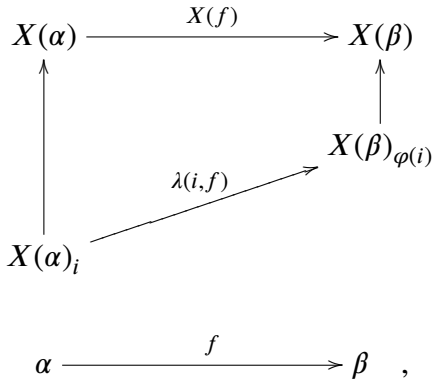
indexed by the same ordered set I, and to isomorphisms

$$X(\alpha) \xrightarrow{\sim} \varinjlim_I X(\alpha)_i \text{ in } E_\alpha, \tag{9.21.12}$$

for every $\alpha \in \mathrm{ob}\, B$. In what follows we suppose that data (9.21.11) and (9.21.12) have been fixed.

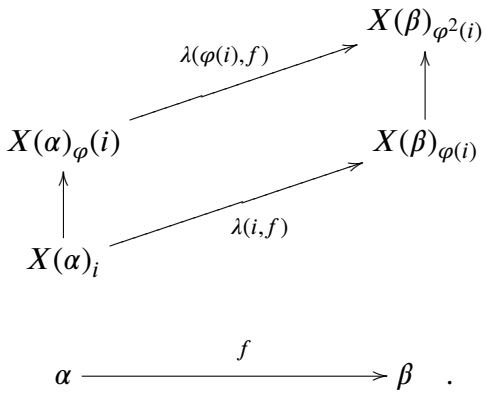
LEMMA 9.21.13. *Under the preceding conditions, one can find a map $\varphi : I \to I$ such that $\varphi(i) \geq i$ for every $i \in I$, and a map $(i, f) \mapsto \lambda(i, f)$ from $I \times \mathrm{Fl}\, B$ to $\mathrm{Fl}\, E$, satisfying the following conditions:*

a) *For $i \in I$ and $(f : \alpha \to \beta) \in F\ell B$, $\lambda(i, f)$ is an f-morphism from $X(\alpha)_i$ to $X(\beta)_{\varphi(i)}$, making the diagram*



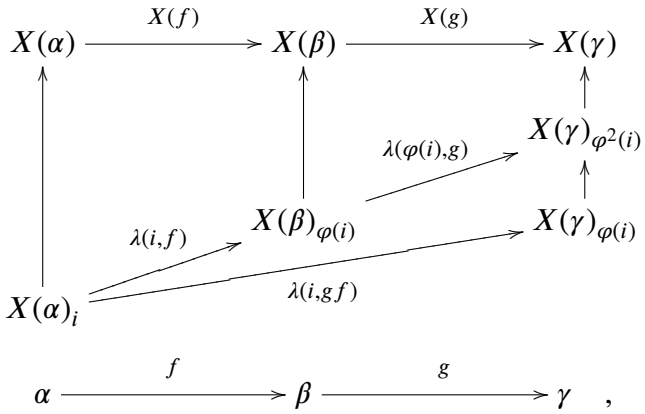
commutative, where the vertical arrows are the canonical morphisms deduced from (9.21.12).

b) *For every $i \in I$, and every $(f : \alpha \to \beta) \in \mathrm{Fl}\, B$, the diagram* 165



is commutative.

c) *For every pair of consecutive arrows* $\alpha \xrightarrow{f} \beta \xrightarrow{g} \gamma$ *of* $\boldsymbol{B}$*, the following diagram is commutative:*



where the vertical arrows are those deduced from (9.21.12).

166 One should moreover note that the commutativity of the two upper trapezoids in c) is already contained in a), so c) in fact asserts the commutativity of the lower triangle of the diagram under consideration.

Let us prove 9.21.13. Let $i \in I$, and let $f : \alpha \to \beta$ be an arrow in $\boldsymbol{B}$. Consider the composite $X(\alpha)_i \to X(\alpha) \xrightarrow{X(f)} X(\beta) \simeq \varinjlim_j X(\beta)_j$; it defines a morphism in $\boldsymbol{E}$:

$$X(\alpha)_i \to f^*(X(\beta)) \simeq f^*(\varinjlim_j X(\beta)_j) \simeq \varinjlim_j f^*(X(\beta)_j),$$

where the last equality follows from the fact that f^* is c-accessible (9.21.3 c)and that I is large relative to c. By (9.21.4 a)), since $X(\alpha)_i \in \mathrm{ob}\, C_\alpha$, the morphism under consideration factors through some $f^*(X(\beta)_j)$, where j *a priori* depends on i and on $f \in \mathrm{Fl}\,(\boldsymbol{B})$. But by (9.21.3 b)), and since I is large relative to c, one may choose j independently of f, say $j = \varphi(i)$. Since I is filtered, one may suppose $\varphi(i) \geq i$. One thus obtains, for $i \in I$ and $f \in \mathrm{Fl}\, \boldsymbol{B}$, a morphism

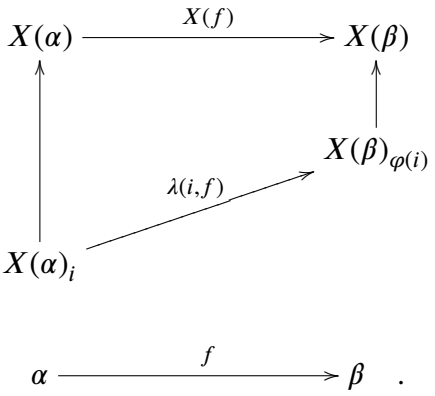
$$X(\alpha)_i \longrightarrow f^*(X(\beta)_{\varphi(i)}),$$

or, equivalently, an f-morphism

$$\lambda(i, f) : X(\alpha)_i \longrightarrow X(\beta)_{\varphi(i)},$$

which by construction makes the diagram

$D(f)$



167 commutative. Now , for given i, f, g, consider the lower triangle of the diagram in 9.21.13

c); it is not clear that it is commutative, but the two composites $X(\alpha)_i \rightrightarrows X(\gamma)_{\varphi^2(i)}$ become equal after composition with $X(\gamma)_{\varphi^2(i)} \to X(\gamma)$, as follows from the commutativity of the two upper trapezoids and of the outer trapezoid, which are respectively the diagrams $D(f)$, $D(g)$, and $D(gf)$. Thus, since $X(\alpha)_i$ is c-accessible (9.21.4 a)) and $X(\gamma) \simeq \varinjlim_{j\in I} X(\gamma)_j$, with I large relative to c, it follows that one can find an element $j \geq \varphi^2(i)$ of I such that the two arrows under consideration become equal after composition with $X(\gamma)_{\varphi^2(i)} \to X(\gamma)_j$. A priori, j depends on i, f, g. But, for fixed i, the set of possible pairs f, g has cardinality $\leq c^2 = c$, by (9.21.3 a) and b)), and hence, since I is large relative to c, one may choose j independently of f and g, say $j = \varphi'(i) \geq \varphi^2(i) \geq \varphi(i)$. For every $i \in I$ and $f : \alpha \to \beta$, let then

$$\lambda'(i, f) : X(\alpha)_i \longrightarrow X(\beta)_{\varphi'(i)}$$

be the composite f-morphism $X(\alpha)_i \to X(\beta)_{\varphi(i)} \to X(\beta)_{\varphi'(i)}$, where the second arrow is the transition morphism. It is then immediate from the construction that (φ', λ') satisfies conditions 9.21.13 a) and c) for (φ, λ). Proceeding in the same way for condition b), one sees that φ' may be chosen so that this condition is also satisfied for (φ', λ'). This completes the proof of (9.21.13).

9.21.14. Now let 168

$$J \subset I$$

be a subset of I satisfying the following conditions:

a) J is filtered,
b) for every $j \in J$, one has $\varphi(j) \in J$,
c) For every $\alpha \in \mathrm{ob}\, B$, $X_J(\alpha) = \varinjlim_{i\in J} X(\alpha)_i$ is representable in E_α.

Conditions a) and c) are satisfied in particular if J is large relative to $\Pi'_\circ$ (9.21.2). It then follows from 9.21.10.1 that, for every $\alpha \in \mathrm{ob}\, B$, $X_J(\alpha)$ is the inductive limit $\varinjlim_{i\in J} X(\alpha)_i$ in E. Now, for an arrow $f : \alpha \to \beta$ of B, the arrows $\lambda(i, f)$, with i varying in J, define, by (9.21.13 b)), a morphism of ind-objects from $(X(\alpha)_i)_{i\in J}$ to $(X(\beta)_i)_{i\in J}$, whence a morphism

$$X_J(f) : X_J(\alpha) \to X_J(\beta)$$

on the inductive limits, which is manifestly an f-morphism. Using (9.21.13 (c)), one obtains the transitivity relations

$$X_J(gf) = X_J(g)X_J(f),$$

so that a section $X_J \in \mathrm{ob}\, F$ of E over B has been defined. Finally, (9.21.13 a)) shows us that the canonical morphisms

$$X_J(\alpha) \longrightarrow X(\alpha) \quad , \quad \alpha \in \mathrm{ob}\, B,$$

are functorial in α, so there is a canonical morphism

$$u_J : X_J \longrightarrow X.$$

On the other hand, if 169

$$J' \supset J$$

is another subset of I satisfying conditions a), b), c) above, one obtains a canonical morphism

$$u_{J',J} : X_J \longrightarrow X_{J'},$$

so that the X_J form an inductive system in F, parametrized by the set (ordered by inclusion) of subsets J of I satisfying the conditions under consideration. Finally, the

morphisms u_J above define a morphism from this inductive system to (the constant inductive system defined by) X.

9.21.15. Now let K be a set of subsets J of I satisfying conditions a), b), c) considered in 9.21.14, and suppose that K is filtered and has union I. It is then clear that one has

$$\varinjlim_{J\in K} X_J \xrightarrow{\sim} X,$$

using 9.21.10.1, which reduces us to checking that there is an isomorphism argument by argument.

Take, for example, for K the set of all subsets J of I that are large relative to $\Pi'_\circ$, stable under φ, and such that $\operatorname{card} J \leq \Pi$. Then, by the definition (9.21.6) of C_α^Π, for every $\alpha \in \operatorname{ob} B$ one has $X_J(\alpha) \in \operatorname{ob} C_\alpha^\Pi$, hence $X_J \in \operatorname{ob} F^\Pi$. Consequently, 9.21.9 (ii) will be proved if we establish that K is large relative to Π (and hence filtered) and has union I. For this, it will evidently suffice to prove that every subset S of I such that
170 $\operatorname{card} S \leq \Pi$ is contained in a $J \in K$. This will indeed follow from the preliminary hypothesis stated in 9.21.9 (ii), and from the

LEMMA 9.21.16. *Let I be an ordered set, let Π be an infinite cardinal, and let $\varphi : I \to I$ be a map from I to itself.*

a) *Suppose I is filtered. Then, for every subset S of I such that $\operatorname{card} S \leq \Pi$, there exists a filtered subset $J \supset S$ of I such that $\varphi(J) \subset J$ and $\operatorname{card}(J) \leq \Pi$.*

b) *Let $\Pi'_\circ$ be a cardinal $< \Pi$, and suppose that I is large relative to Π. Then, for every subset S of I such that $\operatorname{card} S \leq \Pi$, there exists a subset $J \supset S$ of I large relative to $\Pi'_\circ$, such that $\varphi(J) \subset J$ and $\operatorname{card} J \leq \Pi$.*

Let us prove b), for example (the proof of a) being similar and simpler). Let P be the set of subsets of I of cardinality $\leq \Pi$, and let $T \mapsto i_T : P \to I$ be a map such that, for $T \in P$, i_T is an upper bound of T in I; the existence of this map merely expresses the hypothesis that I is large relative to Π. Let A be a well-ordered set such that $\operatorname{card} A = \Pi$, and such that, for every $a \in A$, the set of $a' \leq a$ has cardinality $< \Pi$. It follows in particular, since $\Pi'_\circ < \Pi$, that A *is large relative to* $\Pi'_\circ$. Define, by transfinite recursion, maps

$$S \longmapsto S_a : P \longrightarrow P \quad (a \in A),$$

by the following formulas:

$S_\circ = S$, $S_{a+1} = S_a \cup \varphi(S_a) \cup \{i_{S_a}\}$, $S_a = \bigcup_{a'<a} S_{a'}$ if a is a limit ordinal.

171 Then put, for $S \in P$,

$$J(S) = \bigcup_{a\in A} S_a.$$

It is then clear that $J(S) \supset S$, that $J(S)$ is stable under φ, that $\operatorname{card} J(S) \leq \Pi$ (since $\operatorname{card} A = \Pi$), and finally that $J(S)$ is large relative to $\Pi'_\circ$ (using the fact that A is large relative to $\Pi'_\circ$).

This proves 9.21.16 and completes the proof of 9.21.9.

We also point out a variant of 9.21.9:

LEMMA 9.21.17. *The notation is that of 9.21.9. Let F' denote the full subcategory* $\mathbf{Homcart}_B(B, E)$ *of $F = \mathbf{Hom}_B(B, E)$ formed by the cartesian sections of E over B. Then:*

(i) *Every object of F' is accessible. More precisely, let $\alpha \mapsto X(\alpha)$ be an element of F', and let d be a cardinal such that $d \geq \Pi'_\circ$, $d \geq c$, and such that, for every $\alpha \in \operatorname{ob} B$, $X(\alpha)$ is a d-accessible object of E_α. Then X is a d-accessible object of F'.*

(ii) *Suppose $\Pi \leq c$ and that the functors $f^* : E_\beta \to E_\alpha$ are $\Pi'_\circ$-accessible, or that the categories E_α are stable under small filtered inductive limits and the functors $f^* : E_\beta \to E_\alpha$ commute with these inductive limits. Then every object X of F' is isomorphic to an object of the form $\varinjlim_I X_i$, where, for every $i \in I$, X_i is an object of the full subcategory $F'^{\Pi} = F' \cap F^{\Pi}$ of F', and where I is large relative to Π.*

The proof being entirely analogous to that of 9.21.9, we shall merely indicate the 172
points at which the latter must be modified. First note:

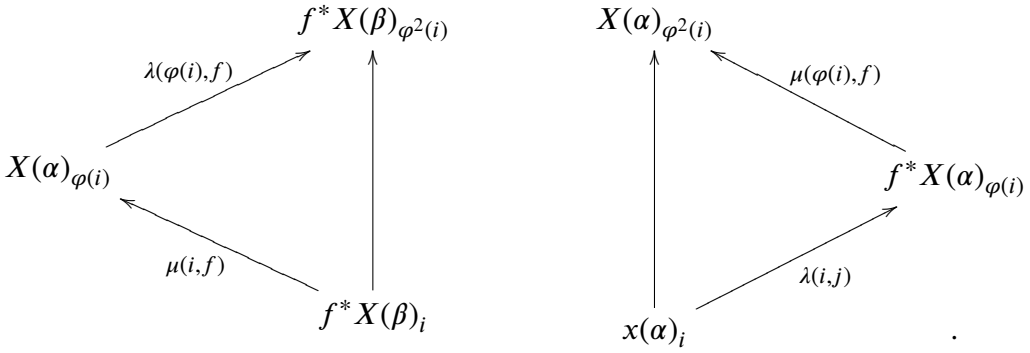
LEMMA 9.21.18. *The statement of 9.21.10 remains valid when $F = \mathbf{Hom}_B(B, E)$ is replaced there by $F' = \mathbf{Homcart}_B(B, E)$, provided that the inverse image functors $f^* : E_\beta \to E_\alpha$ commute with inductive limits of type I.*

Thus, under the conditions of 9.21.17, if d is a cardinal such that $d \geq c$ and $d \geq \Pi'_\circ$, it follows from the above and from hypothesis (9.21.3 c)) that, for every ordered set I large relative to d, inductive limits of type I are representable in F' and are computed argument by argument, whence the conclusion 9.21.17 (i) follows by an immediate argument.

To prove (ii), one must supplement 9.21.13:

LEMMA 9.21.19. *Under the conditions of 9.21.13, suppose that $X \in \mathrm{ob}\, F'$ i.e. that X is a cartesian section of E over B. Then the conclusion can be strengthened by asserting that there exists a function μ which assigns to every $i \in I$ and every arrow $f : \alpha \to \beta$ of B a morphism $\mu(i, f) : f^*X(\beta)_i \to X(\alpha)_{\varphi(i)}$ in E_α, such that:*

d) *For every $i \in I$ and every arrow $f : \alpha \to \beta$ of B, the following two diagrams are commutative:*



To prove this, one proceeds as in 9.21.13, by considering the composite morphism 173
$f^*(X(\beta)_i) \to f^*(X(\beta)) \xrightarrow{X(f)^{-1}} X(\alpha)$, where (as already in the formulation of condition d)) we identify notationally an f-morphism $R \to S$ of E with the corresponding morphism $R \to f^*(S)$ of E_α. Since $X(\alpha) = \varinjlim_j X(\alpha)_j$, and I is large relative to c, one can factor the preceding morphism through one of the $X(\alpha)_j$, where j *a priori* depends on i *and* on f, but can be chosen independently of f, say $\psi(i)$. After enlarging the function φ of 9.21.13, one may suppose that $\psi = \varphi$. Proceeding as for conditions b) and c) of 9.21.13, one sees that, after further enlarging the map φ, one may suppose that the two diagrams of 9.21.19 d) are commutative.

9.21.20. With the map φ chosen as in 9.21.19, let us repeat the argument of 9.21.14, except that we must assume that J satisfies, in addition to the stated conditions a), b), c), the following condition:

d) For every arrow $f : \alpha \to \beta$ in B, the functor $f^* : E_\beta \to E_\alpha$ commutes with inductive limits of type J.

174 We claim that, under this additional condition, the section X_J of E over B is cartesian, i.e. for every arrow $f : \alpha \to \beta$ of B, the morphism

$$(*) \qquad X_J(\alpha) \longrightarrow f^* X_J(\beta)$$

is an isomorphism. Indeed, by condition d) above, the target of the morphism under consideration is identified with $\varinjlim_{i\in J} f^*(X(\beta)_i)$, and the morphism is obtained by taking $\varinjlim_J$ of the morphism of ind-objects in E_α

$$(X(\alpha)_i)_{i\in J} \longrightarrow (f^*)(X(\beta)_i)_{i\in J},$$

induced by the morphisms $\lambda(i, f) : X(\alpha)_i \to f^*(X(\beta)_{\varphi(i)})$ for $i \in J$. Now the conditions set out in 9.21.19 ensure that the preceding homomorphism of ind-objects is in fact an isomorphism, an inverse being obtained from the homomorphism induced by the system of $\mu(i, f)$, for $i \in J$. This proves our assertion that $(*)$ is an isomorphism, and hence that $X \in \mathrm{ob}\, F'$.

9.21.21. We shall now assume that the functors $f^* : E_\beta \to E_\alpha$ are $\Pi'_\circ$-*accessible*. Then the conditions on J considered in 9.21.20 are satisfied if J is large relative to $\Pi'_\circ$, stable under φ, and such that $\mathrm{card}\, J \leq \Pi$, and we complete the proof of 9.21.17 just as in 9.21.15.

175 Theorem 9.22. *Let $p : E \to B$ be a fibered functor, where B is a category essentially equivalent to a small category, and where for every arrow $f : \alpha \to \beta$ in B the inverse image functor $f^* : E_\beta \to E_\alpha$ is accessible (9.2). Suppose moreover that for every $\alpha \in \mathrm{ob}\, E$, the fiber category E_α admits a cardinal filtration (9.12) and that every object of E_α is accessible (9.3). Then each of the categories $F = \mathbf{Hom}_B(B, E)$ and $F' = \mathbf{Homcart}_B(B, E)$ has a small full subcategory generating by strict epimorphisms (7.1), and every object of either category is accessible.*

It is immediate that the statement is not essentially changed when B is replaced by a full subcategory $B_\circ$ such that the inclusion functor $B_\circ \to B$ is an equivalence, and E by $E_\circ = E \times_B B_\circ$. This allows us to assume that B is a small category.

For every $\alpha \in \mathrm{ob}\, B$, let $(\mathrm{Filt}^\Pi(E))_{\Pi\geq\Pi_\alpha}$ be a cardinal filtration of E_α. Let $c_\circ \in \mathscr{U}$ be a cardinal satisfying the following conditions:

$$(9.22.1) \qquad \begin{cases} c_\circ \geq \operatorname{Sup}_{\alpha\in ob B} \Pi_\alpha \quad , \quad c_\circ \geq \mathrm{card}\, \mathrm{Fl}\, B; \\ \text{for every arrow } f : \alpha \to \beta \text{ of } B,\ f^* : E_\beta \to E_\alpha \text{ is } c_\circ\text{-accessible}; \\ \text{for every } \alpha \in \mathrm{ob}\, B, \text{ the objects of } \mathrm{Filt}^{\Pi_\alpha}(E_\alpha) \text{ are } c_\circ\text{-accessible}. \end{cases}$$

Set

$$c = 2^{c_\circ},$$

so that $c > c_\circ$, and, for every $\alpha \in \mathrm{ob}\, B$, let

$$C_\alpha = \mathrm{Filt}^c(E_\alpha).$$

176 We claim that the preliminary conditions of 9.21.9 and 9.21.17 are satisfied on taking $\Pi = \Pi_\circ = c$. This is clear for (9.21.2) and (9.21.3). For (9.21.4 a)), this follows from 9.17, and (9.21.4 b)) follows from condition 9.12 c) for a cardinal filtration. Let us also note that condition 9.12 b) on cardinal filtrations implies that for every $\alpha \in \mathrm{ob}\, B$, we have $C_\alpha^\Pi = C_\alpha = \mathrm{Filt}^C(E_\alpha)$, where C_α^Π is defined in (9.21.6). Consequently, 9.22 follows from 9.21.9 and 9.21.17, and more precisely, we have proved the

COROLLARY 9.23. *Under the conditions of 9.22, if $c_\circ \in \mathcal{U}$ is a cardinal satisfying conditions (9.22.1), and if $c = 2^{c_\circ}$, then the subcategory F^c of F (respectively F'^c of F') formed by the X such that $X(\alpha) \in \operatorname{ob} \operatorname{Filt}^c(E_\alpha)$ for every $\alpha \in \operatorname{ob} B$ is essentially small and generating by strict epimorphisms; more precisely, every object X of F (respectively F') is isomorphic to an object of the form $\varinjlim_I X_i$, where the X_i belong to F^c (respectively F'^c), and where I is an ordered set large relative to c.*

Under slightly stronger hypotheses in 9.22, one can moreover make 9.22 and 9.23 considerably more precise:

COROLLARY 9.24. *Under the conditions of 9.22, suppose that each of the categories E_α ($\alpha \in \operatorname{ob} B$) is stable under small filtered inductive limits, and that, for every $\Pi \geq \Pi_\alpha$, $\operatorname{Filt}^\Pi(E_\alpha)$ is stable under filtered inductive limits indexed by filtered ordered sets I such that $\operatorname{card} I \leq \Pi$ (which slightly strengthens condition 9.12 b) for cardinal filtrations). In* 177
the case where F' is being considered, suppose moreover that, for every arrow $f : \alpha \to \beta$ of B, the functor $f^* : E_\beta \to E_\alpha$ commutes with small filtered inductive limits. Finally, let $c_\circ \in \mathcal{U}$ be a cardinal satisfying conditions (9.22.1), and, for every cardinal $\Pi \geq c = 2^{c_\circ}$, consider the strictly full subcategory F^Π (respectively F'^Π) of F (respectively F') formed by the X such that $X(\alpha) \in \operatorname{Filt}^\Pi(E_\alpha)$ for every $\alpha \in \operatorname{ob} B$. Then the subcategories under consideration define a cardinal filtration (9.12) of F (respectively F').

Conditions a), b), c) of 9.12 must be checked. Conditions a) and b) follow from the analogous conditions for the given cardinal filtrations of the E_α, and from 9.21.10 (respectively 9.21.18, taking account of the second of conditions (9.22.1)). It remains to prove c), whose first part follows immediately from 9.21.9 (respectively 9.21.17), by taking $\Pi'_\circ = 0$ and $\Pi_\circ = c$. It remains to prove that if $\Pi' \geq \Pi \geq c$ are two cardinals, then for every X in $F^{\Pi'}$ (respectively $F'^{\Pi'}$) one has $X \simeq \varinjlim_{i \in K} X_i$, with the X_i in F^Π (respectively F'^Π), K large relative to Π, and $\operatorname{card} K \leq \Pi'^\Pi$. For this, return to the proofs of 9.21.9 (ii) and 9.21.17 (ii). By condition 9.12 c) on the cardinal filtration of E_α, one may suppose that each I_α has cardinality $\leq \Pi'$, and therefore one will have

$$\operatorname{card} I \leq (\Pi'^\Pi)^{\operatorname{card} \operatorname{ob} B} \leq (\Pi'^\Pi)^c = \Pi'^{\Pi c} = \Pi'^\Pi.$$

The index set K used in 9.21.15 (respectively 9.21.21) is the set of subsets J of I that are filtered (i.e. large relative to $\Pi'_\circ = 0$), stable under φ, and such that $\operatorname{card} J \leq \Pi$. It is then immediate that

$$\operatorname{card} K \leq (\operatorname{card} I)^\Pi \leq (\Pi'^\Pi)^\Pi = \Pi'^{\Pi^2} = \Pi'^\Pi,$$

which completes the proof of 9.24. 178

To conclude, it is appropriate to give a statement freed from the somewhat technical hypotheses of 9.22, replacing them by the conjunction, for the E_α, of the hypotheses that occur in 9.11 (which ensure the accessibility of the objects of the E_α) and in 9.13 (which ensure the existence of a cardinal filtration in E_α):

COROLLARY 9.25. *Let $p : E \to B$ be a fibered functor, where B is a category equivalent to a small category, and where, for every arrow $f : \alpha \to \beta$ of B, the functor $f^* : E_\beta \to E_\alpha$ is accessible (9.2). Suppose moreover that, for every $\alpha \in \operatorname{ob} B$, the fiber category E_α satisfies the following conditions:*

a) *E_α admits a small full subcategory generating by strict epimorphisms (7.1).*

b) *E_α is stable under fiber products, kernels of pairs of arrows, sums of two objects, and cokernels of pairs of arrows, and finally under small filtered inductive limits* [3].
c) *The functor* $\mathrm{Ker}(u, v)$ *on the category of pairs of arrows of E_α is accessible (for example, it commutes with small filtered inductive limits).*
d) *Every strict epimorphism of E_α (10.2) is a universal strict epimorphism.*

Under these conditions, each of the categories $F = \mathbf{Hom}_B(B, E)$ and $F' = \mathbf{Homcart}_B(B, E)$ admits a small subcategory generating by strict epimorphisms, and all its objects are accessible (9.3).

179 Moreover, 9.24 gives us:

Corollary 9.26. *Under the conditions of 9.25, and in the case where one considers $F' = \mathbf{Homcart}_B(B, E)$, suppose that the functors $f^* : E_\beta \to E_\alpha$ commute with small filtered inductive limits. Then F (respectively F') admits a cardinal filtration, which can be made explicit by the procedure of 9.24.*

10. Glossary

For the reader's convenience, we collect here the definitions of some terms used in the preceding sections. We denote a category by C.

10.1. Cartesian, cocartesian. A diagram in C

$$\begin{array}{ccc} A & \longrightarrow & B \\ \downarrow & & \downarrow \\ C & \longrightarrow & D \end{array}$$

is called *cartesian* if it is commutative and the canonical morphism from A to the fiber product $C \times_D B$ is an isomorphism. It is called *cocartesian* if the corresponding diagram in the category opposite to C is cartesian.

180 **10.2. Epimorphism, strict epimorphism.** etc. Cf. 10.3.

10.3. Epimorphic family, strictly epimorphic family. etc.: A family

$$f_i : A_i \longrightarrow B, i \in I,$$

of arrows with the same target in C is called an *epimorphic family* if, for every object C of C, the map induced by the f_i,

$$\mathrm{Hom}_C(B, C) \longrightarrow \prod_i \mathrm{Hom}_C(A_i, C), \tag{10.3.1}$$

is injective.

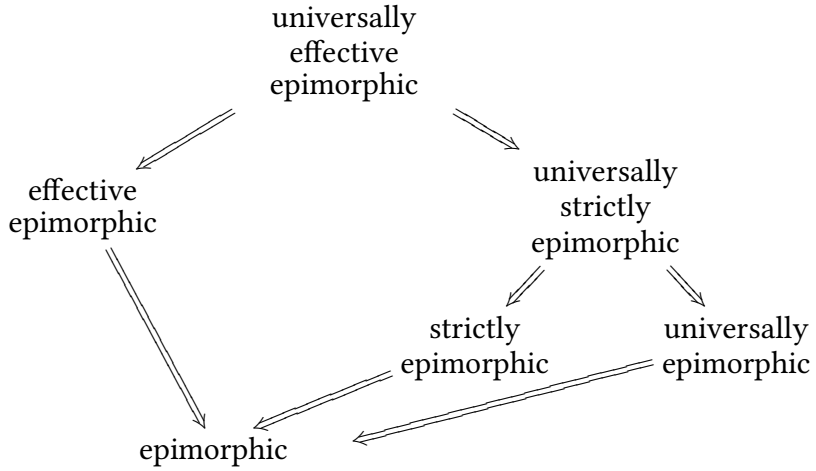
The family under consideration is called *strictly epimorphic* if the image of the map (10.3.1) consists of the families (g_i) such that, for every object R of C, every pair of indices $i, j \in I$, and every pair of arrows $u : R \to A_i$, $v : R \to A_j$ with $f_i u = f_j v$, one also has $g_i u = g_j v$. When the fiber products $A_i \times_B A_j$ are representable for $i, j \in I$, this is equivalent to saying that the image of (10.3.1) consists of the (g_i) such that, for every pair of indices $i, j \in I$, one has $g_i \,\mathrm{pr}_1 = g_j \,\mathrm{pr}_2$, where $\mathrm{pr}_1, \mathrm{pr}_2$ are the two projections of $A_i \times_B A_j$. The family $(f_i)_{i \in I}$ is called an *effective epimorphic family* if the preceding

[3] This last condition is probably unnecessary; cf. 9.13.2.

condition is satisfied, i.e. if it is strictly epimorphic and the fiber products $A_i \times_B A_j$ are representable.

The family $(f_i)_{i\in I}$ is called a *universally epimorphic* (respectively *universally effective epimorphic*) family if the morphisms f_i are pullbackable (10.3), and if, for every arrow $B' \to B$, the family of arrows $f'_i : A'_i = A_i \times_B B' \to B'$, $i \in I$, deduced from the family $(f_i)_{i\in I}$ by the base change $B' \to B$, is epimorphic (respectively effective epimorphic).

The notion of a *universally strictly epimorphic family* will be defined in (II 2.5, 2.6). 181
Note that when the morphisms f_i are pullbackable (for example, if fiber products are representable in C), this notion coincides with that of a universally effective epimorphic family (use II 2.4). In the general case, the six variants of the notion of epimorphicity under consideration are related by the logical implications:



A morphism $f : A \to B$ of C is called an *epimorphism (respectively a strict epimorphism, respectively an effective epimorphism, respectively a universal epimorphism, respectively a universal effective epimorphism, respectively a universal strict epimorphism)* if the family of morphisms consisting of the single element f is epimorphic (respectively ...).

10.4. Monomorphic family, strictly monomorphic family. etc. A family of arrows $f_i : A_i \to B$ of C is called *monomorphic (respectively strictly monomorphic,...)* if, regarded as a family of arrows of the opposite category C°, it is epimorphic (respectively strictly epimorphic,...). An arrow $f : A \to B$ of C is called a *monomorphism (respectively a strict monomorphism,...)* if the family consisting only of f is monomorphic (respectively strictly monomorphic,...), i.e. if f, regarded as an arrow of the opposite 182
category C°, is an epimorphism (respectively a strict epimorphism,...).

10.5. Monomorphism, strict monomorphism. etc.Cf. 10.4.

10.6. Projector, image of a projector, direct factor of an object. Let $f : X \to X$ be an endomorphism of an object of C. The endomorphism f is called a *projector* if $f^2 = f$. The pair (f, id_X) then has a representable cokernel X' if and only if it has a representable kernel X''; when this is the case, there exists a unique isomorphism $u : X' \to X''$ in C such that $iup = f$, where $p : X \to X'$ and $i : X'' \to X$ are the canonical morphisms.[4] One then generally identifies X' with X'' and calls it the *image of the projector* f; the projector f is said to *admit an image* if $\mathrm{Ker}(f, \mathrm{id}_X)$ is representable, i.e. if $\mathrm{Coker}(f, \mathrm{id}_X)$

[4]N.D.E.: Representability of the kernel, or of the cokernel, is also equivalent to the existence of morphisms i, p, and an isomorphism u such that $iup = f$ and $pi = u^{-1}$. In particular, this property is preserved by every functor.

is representable. A subobject (respectively a quotient) Y of X is called a *direct factor* of X if there exists a projector f on X that factors through Y and has Y as its image as a subobject (respectively as a quotient) of X. Sometimes, by abuse of language, an object of C is called a *direct factor of* X if it is isomorphic to the image of a projector on X.

10.7. Pullbackable. An arrow $f : A \to B$ of C is called *pullbackable* if, for every arrow $B' \to B$ of C, the fiber product $A \times_B B'$ is representable in C.

183 **10.8. Quotient, strict quotient.** etc.

Let A be an object of C. Two epimorphisms $f : A \to B$ and $f' : A \to B'$ with source A are called *equivalent* if there exists an isomorphism $u : B \xrightarrow{\sim} B'$ such that $uf = f'$. This defines an equivalence relation on the set of epimorphisms with source A, whose classes are called the *quotients, or quotient objects,* of A. For each quotient of A, one generally chooses an element of this class, say $f : A \to B$, and one often speaks (by abuse of language) of the quotient B of A (or of the quotient $f : A \to B$ of A). The quotient B is called a *strict quotient* (respectively an *effective quotient, respectively a universal quotient,...*) if the morphism $f : A \to B$ is a strict epimorphism (respectively an effective epimorphism, respectively a universal epimorphism,...) (10.3).

10.9. Equivalence relations. Let F and G be two presheaves of sets on C. A diagram $p_1, p_2 : F \rightrightarrows G$ is called an *equivalence relation on* G if, for every object A of C, the map

$$(p_1(A), p_2(A)) : F(A) \longrightarrow G(A) \times G(A)$$

induces a bijection from $F(A)$ onto the graph of an equivalence relation on the set $G(A)$.

A diagram $p_1, p_2 : B \rightrightarrows C$ in C is called an equivalence relation on C if the corresponding diagram of presheaves is an equivalence relation. When finite products and fiber products are representable in C, a functor $\Phi : C \to C'$ commuting with finite products and fiber products carries equivalence relations on C to equivalence relations on $\Phi(C)$.

184 Let $\pi : C \to D$ be a morphism of C such that the fiber product $C \times_D C$ is representable. Then the diagram $\mathrm{pr}_1, \mathrm{pr}_2 : C \times_D C \rightrightarrows C$ is an equivalence relation on C.

10.10. Effective equivalence relation, universally effective equivalence relation. An equivalence relation $p_1, p_2 : R \rightrightarrows A$ on an object A of C is called an *effective equivalence relation* if there exists a morphism $\pi : A \to B$ such that the square

$$\begin{array}{ccc} R & \xrightarrow{p_2} & A \\ {\scriptstyle p_1}\downarrow & & \downarrow{\scriptstyle \pi} \\ A & \longrightarrow & B \end{array}$$

is cartesian and cocartesian. (The morphism π is the cokernel of the pair (p_1, p_2) and is therefore determined up to unique isomorphism.) The morphism π is then an effective epimorphism; if it is a universal effective epimorphism (10.3), the *equivalence relation* is said to be *universally effective.*

10.11. Subobject, strict subobject. etc. These are the notions dual to those of quotient and strict quotient etc. (10.8).

II. Appendix: Universes (by N. Bourbaki(*))

185

1. Definition and first properties of universes

Definition 1. *A set U is called a universe if it satisfies the following conditions:*

(U.I) *if $x \in U$ and $y \in x$, then $y \in U$;*
(U.II) *if $x, y \in U$, then $\{x, y\} \in U$;*
(U.III) *if $x \in U$, then $\mathscr{P}(x) \in U$;*
(U.IV) *if $(x_\alpha)_{\alpha \in I}$ is a family of elements of U, and if $I \in U$, then the union $\bigcup_{\alpha \in I} x_\alpha$ belongs to U;*
(U.?) *if $x, y \in U$, then the ordered pair $(x, y) \in U$.*

N.B. Since it has, I believe, been decided that in future editions the ordered pair will be defined à la Kuratowski by $(x, y) = \{\{x, y\}, \{x\}\}$, condition (U.?) is unnecessary, since it follows from (U.II).

Examples. 1) The *empty* set is a universe, denoted by $U_\circ$.

2) Consider the nonempty finite words formed with the four symbols $''\{'', ''\}'', ''$ and $''\varnothing''$ (cf. Alg. I). Define, by induction on the length n of such a word, the notion of a *meaningful* word:

186

(a) For $n = 1$, only the word $\varnothing$ is meaningful;
(b) for a word A of length n to be meaningful, it is necessary and sufficient that there exist p distinct meaningful words $A_1, \dots, A_p$ ($p \geq 1$) of lengths $< n$ such that

$$A = \{A_1, A_2, \dots, A_p\}.$$

For example, $\varnothing$, $\{\varnothing\}$, $\{\{\varnothing\}, \{\{\varnothing\}\}, \{\varnothing, \{\varnothing\}\}\}$ are meaningful words. It is clear, by induction on the length, that every meaningful word denotes a term of Set Theory; for example, if $A = \{A_1, A_2, \dots, A_p\}$, A denotes the set whose elements are $A_1, A_2, \dots,$ and A_p; these terms are plainly *finite sets.* Let U_1 be the set of sets thus obtained. It is readily checked that U_1 satisfies conditions (U.I), (U.II), (U.III), and (U.IV) of Definition 1 (but not that idiotic condition (U.?), which is no problem if one is willing to decanulate the ordered pair). Thus U_1 is a *universe.* Note that the elements of U_1 are finite, and that U_1 is countable.

In the statements that follow, *U denotes a universe.*

Proposition 1. *If $X \in U$ and if $y \subset x$, then $y \in U$.*

Indeed, $\mathscr{P}(x) \in U$ by (U.III), whence $y \in \mathscr{P}(x)$ and $y \in U$ by (U.I).

Corollary. *If $x \in U$, every quotient set y of x is an element of U.*

Indeed, y is a subset of $\mathscr{P}(x)$. Hence $y \in U$ by (U.III) and Proposition 1.

187 Proposition 2. *If $x \in U$, then $\{x\} \in U$.*

This follows from (U.II), applied with $y = x$.

Proposition 3. *Every ordered pair, ordered triple, and ordered quadruple of elements of U is an element of U.*

This is true for ordered pairs by the N.B. or (U.?). The case of ordered triples follows, since $(x, y, z) = ((x, y), z)$, and then that of ordered quadruples, since $(x, y, z, t) = ((x, y, z), t)$.

[4] We reproduce here, with his permission, secret papers of N. Bourbaki. The references in this text are to his learned work.

PROPOSITION 4. *If $X, Y \in U$, then $X \times Y \in U$.*

Indeed, for $x \in X$, $\{x\} \times Y$ is the union of the family $\{(x, y)\}_{y \in Y}$; since $\{(x, y)\} \in U$ by (U.I), (U.II), and Proposition 3, we have $\{x\} \times Y \in U$ by (U.IV). Finally, $X \times Y$ is the union of the family $(\{x\} \times Y)_{x \in X}$; it is therefore an element of U, again by (U.IV).

COROLLARY 1. *If $X, Y, Z, \ldots$ are elements of U, all the sets of the scale constructed on $X, Y, Z, \ldots$ are elements of U* (cf. Chapter IV, §).

This indeed follows by successive applications of Proposition 4 and of (U.III).

COROLLARY 2. *If $(x_\alpha)_{\alpha \in I}$ is a family of elements of U and if $I \in U$, the sum set $\Sigma_{\alpha \in I} x_\alpha$ is an element of U.*

Indeed, this sum set is a subset of the product $(\bigcup_{\alpha \in I} x_\alpha) \times I$ (Chapter II), a product both of whose factors are elements of U (by (U.IV) and the hypothesis). We then apply Propositions 4 and 1.

PROPOSITION 5. *If X and Y are elements of U, every correspondence between X and Y (in particular, every map from X to Y) is an element of U.* 188

Indeed, such a correspondence C is an ordered triple (X, Y, Γ), where Γ is a subset of $X \times Y$ (the graph of C) (Chapter II, §). We have $\Gamma \in U$ by Propositions 4 and 1. Hence $C \in U$ by Proposition 3.

PROPOSITION 6. *If $X, Y \in U$, every set Z of correspondences between X and Y (in particular, of maps from X to Y) is an element of U.*

Indeed, Z is a subset of $\{X\} \times \{Y\} \times \mathscr{P}(X \times Y)$. Now this product is an element of U by Proposition 2 and the corollary to Proposition 4. Therefore $Z \in U$ by Proposition 1.

COROLLARY. *If $(x_\alpha)_{\alpha \in I}$ is a family of elements of U, and if $I \in U$, then $\Pi_{\alpha \in I} x_\alpha \in U$.*

Indeed, this product is a set of maps from I to $\bigcup_{\alpha \in I} x_\alpha$, and this union is an element of U by (U.IV).

PROPOSITION 7. *If X is a subset of U whose cardinality is at most that of an element of U, then X is an element of U.*

Let I be an element of U such that $\mathrm{card}(X) \leq \mathrm{card}(I)$. There is a surjection $i \mapsto x_i$ from a subset I' of I onto X. Then X is the union of the family $(\{x_i\})_{i \in I'}$; now this union is an element of U by Proposition 1, Proposition 2, and (U.IV).

COROLLARY. *If U is nonempty, every finite subset of U is an element of U, and U has elements of arbitrarily large finite cardinality.* 189

On the other hand, if $U = \varnothing$, then $\varnothing$ is a finite subset of $\varnothing$ but not an element of $\varnothing$.

Indeed, if U is nonempty, Proposition 2 shows that a one-element set x_0 belongs to U. By induction on n, put $x_{n+1} = \mathscr{P}(x_n)$. We have $x_n \in U$ by (U.III), and $\mathrm{card}(x_{n+1}) = 2^{\mathrm{card}(x_n)}$, so that U has elements of arbitrarily large finite cardinality.

REMARK. It follows from Proposition 2 and the corollary to Proposition 7 that every nonempty universe U contains the universe U_1 of Example 2; indeed, $\varnothing \in U$ by Proposition 1. Thus U_1 is the intersection of all nonempty universes. More generally:

PROPOSITION 8. *If $(U_\lambda)_{\lambda \in L}$ is a nonempty family of universes, then $U = \bigcap_{\lambda \in L} U_\lambda$ is a universe.*

This follows at once from Definition 1.

2. Universes and species of structures

Let $\mathscr{E}$ be a species of structure; suppose, to fix ideas and simplify the exposition, that every structure of species $\mathscr{E}$ is defined on an underlying set. Let (X, S) be a structure of species $\mathscr{E}$ (where X is the underlying set and S the structure), and let U be a *universe*. If $X \in U$, then all the constituent objects of the structure S on X are elements of U (by Cor. 1 of Prop. 4, n° 1, and by (U.I)), so the structure (X, S) is an element of U.

190 Suppose now that $\mathscr{E}$ is a species of structure with *morphisms*. If X and X' are elements of U endowed with structures of species $\mathscr{E}$, then the set of morphisms from X to X' is again an element of U (n° 1, Prop. 6).

Now consider the *category* $(U\text{-}\mathscr{E})$ defined in § 1, n° 2, Ex. c). Since the objects and arrows of $(U\text{-}\mathscr{E})$ are elements of U, $(U\text{-}\mathscr{E})$ is a *pair of subsets* of U, endowed with a quadruple of maps; in general, it is not an element of U. The notation $X \in (U\text{-}\mathscr{E})$ will mean that X is an element of U endowed with a structure of species $\mathscr{E}$.

The category $(U\text{-}\mathscr{E})$ is *stable* under many operations:

a) If $X \in (U\text{-}\mathscr{E})$, and if X' is a subset of X that admits an *induced structure*, then $X' \in (U\text{-}\mathscr{E})$. This follows from Prop. 1, n° 1.

b) If $X \in (U\text{-}\mathscr{E})$, and if X'' is a quotient set of X that admits a *quotient structure*, then $X'' \in (U\text{-}\mathscr{E})$ (Cor. of Prop. 1, n° 1).

c) If $X, Y \in (U\text{-}\mathscr{E})$, and if $X \times Y$ admits a *product structure*, then $X \times Y \in (U\text{-}\mathscr{E})$ (Prop. 4, n° 1). More generally, if $(X_i)_{i\in I}$ is a family of elements of $(U\text{-}\mathscr{E})$, *if* $I \in U$, and if $\Pi_{i\in I} X_i$ admits a *product structure*, then $\Pi_{i\in I} X_i \in (U\text{-}\mathscr{E})$ (Cor. of Prop. 6). The analogous assertions hold for *sum structures* (Cor. 2 of Prop. 4).

d) Let I be a preordered set, and let $(X_i, f_{ij})_{i,j\in I}$ be a *projective system* (resp. *inductive system*) of sets endowed with structures of species $\mathscr{E}$ and morphisms; let L be the limit of this system, in the sense of Chap. III. If $X_i \in U$ for every i, if $I \in U$, and if L admits a projective-limit structure (resp. an inductive-limit
191 structure), then $L \in (U\text{-}\mathscr{E})$: indeed, L is a subset of $\Pi_{i\in I} X_i$ (resp. a quotient set of $\Sigma_{i\in I} X_i$), and is therefore an element of U by n° 1.

Here are a few more particular examples:

* 1) Let $X, Y \in (U\text{-}\mathrm{Top})$ be two *locally compact* spaces. Then the set $\mathscr{C}(X, Y)$ of continuous maps from X to Y, endowed with the topology of compact convergence (General Topology X), is an element of $(U\text{-}\mathrm{Top})$. Indeed, $\mathscr{C}(X, Y) \in U$ by Prop. 6 of n° 1.*

* 2) Let $X, Y \in (U\text{-}\mathrm{Ab})$. Then the group $\mathrm{Hom}_{\mathbf{Z}}(X, Y)$ is an element of $(U\text{-}\mathrm{Ab})$ by Prop. 6 of n° 1. If, in addition, $\mathbf{Z} \in U$, the tensor product $X \otimes_{\mathbf{Z}} Y$ is an element of $(U\text{-}\mathrm{Ab})$; indeed, this tensor product is a quotient of $\mathbf{Z}^{X\times Y}$, which is a subset of $\mathbf{Z}^{X\times Y}$, which in turn is an element of U by Props. 4 and 6 of n° 1.*

* 3) Let $X \in (U\text{-}\mathrm{Unif})$ be a uniform space. Then its *completion* $\widehat{X}$ is an element of $(U\text{-}\mathrm{Unif})$. Indeed, $\widehat{X}$ is a set of equivalence classes of Cauchy filters on X; now a filter on X is an element of $\mathscr{P}(\mathscr{P}(X))$, so an equivalence class of filters is an element of $\mathscr{P}(\mathscr{P}(\mathscr{P}(X)))$, whence $\widehat{X}$ is an element of $\mathscr{P}(\mathscr{P}(\mathscr{P}(\mathscr{P}(X))))$, and hence an element of U by (U.III) and (U.I).*

N.B. Moral: Bourbaki will have to take care to "canonicalize" its constructions properly. For example, in constructions in which an element ∞ is adjoined (Alexandroff
192 compactification, projective field), it will be advantageous to take $\infty = \varnothing$ (since $\varnothing$ is an element of every nonempty universe) and to form the disjoint union of $\{\varnothing\}$ and the

given set. Of course, one should also "canonicalize" the two-element set used to construct disjoint unions; thus $\{\emptyset, \{\emptyset\}\}$ seems to me a good candidate, since it belongs to every nonempty universe.

3. Universes and categories

Let U be a universe and C a category. We write $C \in U$ if $\mathrm{Ob}(C) \in U$ and $\mathrm{Fl}(C) \in U$. This notation is justified by the fact that C is the sextuple consisting of $\mathrm{Ob}(C)$, $\mathrm{Fl}(C)$, and the four structure maps; thus, if $\mathrm{Ob}(C) \in U$ and $\mathrm{Fl}(C) \in U$, these four maps are elements of U (n° 1, Corollary 1 of Proposition 4), and hence so is the sextuple C (n° 1, Proposition 3, *cum grano salis*). This is moreover a special case of n° 2, if one considers the species of structure "cat" of a category. With the notation of n° 2, the relation $C \in U$ is also written $C \in (U\text{-cat})$.

One should note that a category such as $(U\text{-Ens})$, $(U\text{-Ord})$, $(U\text{-Top})$, or $(U\text{-Gr})$ is *not*, in general, an element of U.

Let C, D be two categories and U a universe such that $C, D \in U$. If C' is a *subcategory* of C, then $C' \in U$; the *product category* $C \times D$, the sum category of C and D, and the opposite categories C° and D° are also elements of U (cf. n° 2). The *functor category* $E = \mathbf{Hom}(C, D)$ is likewise an element of U: indeed, $\mathrm{Ob}(E)$ is a set of pairs of maps $\mathrm{Ob}(C) \to \mathrm{Ob}(D)$, $F\ell(C) \to F\ell(D)$, and hence $\mathrm{Ob}(E) \in U$ by n° 1; as for $F\ell(E)$, it is a set of natural transformations, that is, of maps $\mathrm{Ob}(C) \to F\ell(D)$, whence $F\ell(E) \in U$ by Proposition 6 of n° 1. 193

PROPOSITION 9. *Let $\mathscr{E}$ be a species of structure with morphisms, and let U, U' be two universes such that $U' \subset U$. Then $(U'\text{-}\mathscr{E})$ is a full subcategory of $(U\text{-}\mathscr{E})$.*

Indeed, if x and y are objects of $(U'\text{-}\mathscr{E})$, they are by definition objects of $(U\text{-}\mathscr{E})$. As for $\mathrm{Hom}(x, y)$, it is the same set in both categories (cf. § 1, n° 2, Example c)).

N.B. One should note that the hypothesis that U and U' are universes is unnecessary, so that Proposition 9 would be more appropriately placed in § 1, n° 4. But the Tribe asked that it be put here.

Remark. It may happen that the axioms of the species of structure $\mathscr{E}$ imply that the *cardinals* of sets endowed with structures of species $\mathscr{E}$ are *bounded* by a fixed cardinal, say c (* for example, the species of structure of finite group, finitely generated group, finitely generated module over a fixed ring A, or finitely generated algebra over A *). Suppose then that there exists an element z of U' such that $c \leq \mathrm{card}(z)$. Then, for every set x endowed with a structure of species $\mathscr{E}$, there exists an element x' of U' equipotent to x, for example a subset of z; endow x' with the structure deduced from that of x by transport of structure; this gives an element of $(U'\text{-}\mathscr{E})$. It follows that *the inclusion functor from $(U'\text{-}\mathscr{E})$ to $(U\text{-}\mathscr{E})$ is then essentially surjective* (§ 4, n° 2, Definition 2) *and is therefore an equivalence of categories* (§ 4, n° 3, Theorem 1).

4. The universe axiom

194

The very pleasant stability results of n° 2 are of interest only if they can be applied to something other than the two small universes U_0 and U_1 described in n° 1. We shall therefore add the following axiom to the axioms of Set Theory:

(A.6) *For every set x, there exists a universe U such that $x \in U$.*

This axiom implies that, if $(x_\alpha)_{\alpha \in I}$ is a *family* of sets, there exists a universe U such that $x_\alpha \in U$ for every $\alpha \in I$: indeed, it suffices to apply (A.6) to $x = \bigcup_{\alpha \in I} x_\alpha$ and then apply Proposition 1 of n° 1.

In particular, given a *category* C, there exists a universe U such that $C \in U$ in the sense of n° 3: apply the preceding result to the family $(\mathrm{Ob}(C), F\ell(C))$. This applies to categories of the form $(V\text{-}\mathscr{E})$, where $\mathscr{E}$ is a species of structure with morphisms and V is a set, for example a universe; in general one has $V \neq U$.

For example, if V is a universe, then $\mathrm{Ob}(V\text{-}\mathrm{Ens}) = V$ and $F\ell(V\text{-}\mathrm{Ens}) \subset V$ (n° 1, Proposition 5). The universes U such that $(V\text{-}\mathrm{Ens}) \in U$ are therefore those such that $V \in U$. But the relation $V \in V$ is impossible for a universe: indeed, for every subset A of V, one would have $A \in V$ (n° 1, Proposition 1), whence $\mathrm{card}(\mathscr{P}(V)) \leq \mathrm{card}(V)$, which is impossible.

5. Universes and strongly inaccessible cardinals

195

Let U be a universe. By condition (U.I) of Definition 1, every element x of U is a subset of U; hence $\mathrm{card}(x) \leq \mathrm{card}(U)$. Since the cardinals of the subsets of U form a well-ordered set, the cardinal

$$\mathfrak{c}(U) = \sup_{x \in U} \mathrm{card}(x) \tag{1}$$

exists. Note that, for every cardinal $\mathfrak{c} < \mathfrak{c}(U)$, there exists an element x of U such that $\mathrm{card}(x) = \mathfrak{c}$; indeed, by definition there exists $y \in U$ such that $\mathfrak{c} \leq \mathrm{card}(y) \leq \mathfrak{c}(U)$, and one takes for x a suitable subset of y. Conversely, if $x \in U$, then $\mathrm{card}(x) < \mathfrak{c}(U)$; indeed, $\mathscr{P}(x) \in U$ by (U.III), whence $2^{\mathrm{card}(x)} \leq \mathfrak{c}(U)$. Thus the cardinal $\mathfrak{c}(U)$ has the following properties:

1) If $\mathfrak{c}$ is a cardinal $< \mathfrak{c}(U)$, then $2^{\mathfrak{c}} < \mathfrak{c}(U)$; indeed, if x is an element of U of cardinality $\mathfrak{c}$, then $\mathscr{P}(x) \in U$ by (U.III), whence $2^{\mathfrak{c}} < \mathfrak{c}(U)$.
2) If $(\mathfrak{c}_\lambda)_{\lambda \in I}$ is a family of cardinals such that $\mathfrak{c}_\lambda < \mathfrak{c}(U)$ for every $\lambda \in I$ and $\mathrm{card}(I) < \mathfrak{c}(U)$, then the sum cardinal $\Sigma_{\lambda \in I} \mathfrak{c}_\lambda$ is $< \mathfrak{c}(U)$. Indeed, let $x_\lambda \in U$ be such that $\mathrm{card}(x_\lambda) = \mathfrak{c}_\lambda$; after replacing I by an equipotent index set if necessary, one may suppose that $I \in U$; then the sum set of the x_λ is an element of U (Corollary 2 of Proposition 4 of n° 1), which proves our assertion.

We make the following definition:

196

DEFINITION 2. *A cardinal $\mathfrak{d}$ is called strongly inaccessible if:*

(FI.1) *If $\mathfrak{c}$ is a cardinal such that $\mathfrak{c} < \mathfrak{d}$, then $2^{\mathfrak{c}} < \mathfrak{d}$.*
(FI.2) *If $(\mathfrak{c}_\lambda)_{\lambda \in I}$ is a family of cardinals such that $\mathfrak{c}_\lambda < \mathfrak{d}$ for every $\lambda \in I$, and if $\mathrm{card}(I) < \mathfrak{d}$, then $\Sigma_{\lambda \in I} \mathfrak{c}_\lambda < \mathfrak{d}$.*

Examples. The cardinal 0 and the countably infinite cardinal are strongly inaccessible. No nonzero finite cardinal is strongly inaccessible. Thus we have just proved that the universe axiom (A.6) implies the statement:

(A′.6) *Every cardinal is strictly bounded above by a strongly inaccessible cardinal.*

Conversely:

THEOREM 1. *Statement (A′.6) implies the universe axiom (A.6).*

Indeed, let A be a set. We must construct a universe U of which A is an element. Define recursively a sequence $(A_n)_{n \geq 0}$ of sets by:

(2) $A_0 = A$, A_{n+1} = the union of the elements of A_n = the set of elements of the elements of A_n.

Put $B = \bigcup_{n=0}^{\infty} A_n$. By (A′.6), let $\mathfrak{c}$ be a strongly inaccessible cardinal such that $\mathrm{card}(B) < \mathfrak{c}$.

There exists a *well-ordered* set I such that $\mathrm{card}(I) = \mathfrak{c}$. After replacing I by its smallest segment of cardinality $\mathfrak{c}$ if necessary, we may suppose that *every segment of I distinct from I has cardinality $< \mathfrak{c}$*. We denote by $\mathscr{E}$ the *least element of I*. It follows 197
from the hypothesis on segments that I has no greatest element (otherwise we would remove it), and hence that every element of I has a successor; for $\alpha \in I$, we denote the *successor* of α by $s(\alpha)$.

Now define, by *transfinite recursion*, a family $(B_\alpha)_{\alpha\in I}$ of sets by:

$$\text{(3)}\qquad \begin{cases} B_{\mathscr{E}} = B \\ B_{s(\alpha)} = B_\alpha \cup \mathscr{P}(B_\alpha) \\ B_\alpha = \bigcup_{\beta<\alpha} B_\beta \text{ if } \alpha \text{ has no predecessor.} \end{cases}$$

Put $U = \bigcup_{\alpha\in I} B_\alpha$. We shall show that U is the desired universe.

First, $A \in U$, since $A = A_0$ is a subset of $B = B_{\mathscr{E}}$, and therefore an element of $\mathscr{P}(B_{\mathscr{E}}) \subset B_{s(\mathscr{E})}$.

Next note that, for every $\alpha \in I$, one has:

$$\text{(4)}\qquad \mathrm{card}(B_\alpha) < \mathfrak{c}.$$

Indeed, proceed by transfinite recursion on α. This is true for $\alpha = \mathscr{E}$ by hypothesis. From (4) one obtains $\mathrm{card}(B_{s(\alpha)}) \leq \mathrm{card}(B_\alpha) + 2^{\mathrm{card}(B_\alpha)} < \mathfrak{c} + \mathfrak{c}$ (by (FI.1)) $= \mathfrak{c}$ (since $\mathfrak{c}$ is infinite). Finally, if α has no predecessor, the set I' of $\beta < \alpha$ has cardinality $< \mathfrak{c}$ by construction; hence (if $\mathrm{card}(B_\beta) < \mathfrak{c}$ for every $\beta < \alpha$), $\mathrm{card}(B_\alpha) = \mathrm{card}(\bigcup_{\beta\in I'} B_\beta) \leq \Sigma_{\beta\in I'} \mathrm{card}(B_\beta) < \mathfrak{c}$ (by (FI.2)). This proves (4).

Let us now show that 198

$$\text{(5)}\qquad \mathrm{card}(x) < \mathfrak{c} \text{ for every } x \in U.$$

Indeed, it suffices to show that, for every $\alpha \in I$, one has "$\mathrm{card}(x) < \mathfrak{c}$ for every $x \in B_\alpha$". Proceed again by transfinite recursion on α. This is true for $\alpha = \mathscr{E}$, since, if $x \in B_{\mathscr{E}} = B$, there exists $n \geq 0$ such that $x \in A_n$; hence $x \subset A_{n+1}$ by (2), $x \subset B$, and $\mathrm{card}(x) \leq \mathrm{card}(B) < \mathfrak{c}$. The case where α has no predecessor is evident. Finally, if $x \in B_\alpha$ and $\alpha = s(\beta)$, either $x \in B_\beta$, in which case the assertion "$\mathrm{card}(x) < \mathfrak{c}$" is true by recursion, or $x \in \mathscr{P}(B_\beta)$, whence $x \subset B_\beta$ and the assertion "$\mathrm{card}(x) < \mathfrak{c}$" is true by (4).

We are now in a position to prove that U is indeed a *universe*:

(U.I) Let $x \in U$ and $y \in x$. We must show that $y \in U$. In other words, we must show that, for every $\alpha \in I$, one has:

$$\text{“}x \in B_\alpha \text{ and } y \in x \Longrightarrow y \in B_\alpha\text{”}.$$

Proceed again by transfinite recursion on α. This is true for $\alpha = \mathscr{E}$, since $x \in B_{\mathscr{E}} = B$ implies $x \in A_n$ for some n; hence, if $y \in x$, then $y \in A_{n+1}$, whence $y \in B = B_{\mathscr{E}}$. Passage to an element α with no predecessor is evident. Finally, pass from α to $s(\alpha)$: if $x \in B_{s(\alpha)}$ and $y \in x$, either $x \in B_\alpha$, whence $y \in B_\alpha \subset B_{s(\alpha)}$ by recursion, or $x \in \mathscr{P}(B_\alpha)$, whence again $y \in B_\alpha \subset B_{s(\alpha)}$.

(U.II) Let $x, y \in U$. Since the family $(B_\alpha)_{\alpha\in I}$ is increasing by (3), there exists $\alpha \in I$ such that $x, y \in B_\alpha$. Then $\{x, y\} \in \mathscr{P}(B_\alpha) \subset B_{s(\alpha)} \subset U$.

(U.III) Let $x \in U$. Then there exists $\alpha \in I$ such that $x \in B_\alpha$. It therefore suffices to 199
show that, for every $\alpha \in I$, one has:

$$\text{“}x \in B_\alpha \Longrightarrow \mathscr{P}(x) \in B_{s(s(\alpha))}\text{”}.$$

Proceed again by transfinite recursion on α. If $\alpha = \mathscr{E}$, then $x \in A_n$ for some n, whence $y \subset A_{n+1} \subset B = B_{\mathscr{E}}$ for every subset y of x; thus $y \in \mathscr{P}(B_{\mathscr{E}}) \subset B_{s(\mathscr{E})}$ for every $y \in \mathscr{P}(x)$, whence $\mathscr{P}(x) \subset B_{s(\mathscr{E})}$ and $\mathscr{P}(x) \in \mathscr{P}(B_{s(\mathscr{E})}) \subset B_{s(s(\mathscr{E}))}$, so our assertion is true for $\alpha = \mathscr{E}$. Passage to an element α with no predecessor is immediate, since $\beta < \alpha$ then implies $s(s(\beta)) < \alpha$. Finally, pass from α to $s(\alpha)$; let $x \in B_{s(\alpha)}$; if $x \in B_\alpha$, then $\mathscr{P}(x) \in B_{s(s(\alpha))} \subset B_{s(s(s(\alpha)))}$ by recursion; if $x \in \mathscr{P}(B_\alpha)$, then $x \subset B_\alpha$, whence $\mathscr{P}(x) \subset \mathscr{P}(B_\alpha)$ and $\mathscr{P}(x) \in \mathscr{P}(\mathscr{P}(B_\alpha)) \in B_{s(s(s(\alpha)))}$.

(U.IV) Let $(x_\lambda)_{\lambda \in K}$ be a family of elements of U such that $K \in U$. We must show that the union $x = \bigcup_{\lambda \in K} x_\lambda$ is an element of U. For every $\lambda \in K$, choose an $\alpha(\lambda) \in I$ such that $x_\lambda \in B_{\alpha(\lambda)}$. Let us show that the set $\alpha(K)$ of the $\alpha(\lambda)$ is *bounded above* in I: indeed, if it were not, one would have

$$I = \bigcup_{\lambda \in K} [\mathscr{E}, \alpha(\lambda)],$$

which would contradict (FI.2), since $\mathrm{card}(K) < \mathscr{c}$ and $\mathrm{card}([\mathscr{E}, \alpha(\lambda)]) < \mathscr{c}$ for every $\lambda \in K$. Let then β be an upper bound of $\alpha(K)$; one has $x_\lambda \in B_\beta$ for every $\lambda \in K$, since the family $(B_\alpha)_{\alpha \in I}$ is increasing. Every element of x_λ then belongs to B_β by what was proved in (U.I), whence $x = \bigcup_{\lambda \in K} x_\lambda \subset B_\beta$. By (3), it follows that $x \in B_{s(\beta)}$, whence $x \in U$. C.Q.F.D.

200 DEFINITION 3. *Let x, y be two sets and let n be an integer ≥ 0. We say that y is a component of order n of x if there exists a sequence $(x_j)_{j=0,\dots,n}$ such that $x_0 = x$, $x_n = y$, and $x_{j+1} \in x_j$ for $j = 0, \dots, n-1$.*

Thus x is the only component of order 0 of x. The components of order 1 (resp. 2) of x are the elements of x (resp. the elements of the elements of x). We say that y is a *component* of x if there exists $n \geq 0$ such that y is a component of order n of x. The relation "y is a component of x" is a *preorder relation*. By the selection–union scheme (Chapter II, ...), the relation "y is a component of x" is collectivizing with respect to y, so that the components of x form a *set*.

DEFINITION 4. *Let $\mathscr{c}$ be a cardinal. A set x is said to be of type $\mathscr{c}$ (resp. of strict type $\mathscr{c}$, of finite type) if all the components of x have cardinalities $\leq \mathscr{c}$ (resp. $< \mathscr{c}$, finite cardinalities).*

EXAMPLES. The elements of the universe U_1 (n° 1, Example 2) are all of finite type. If $\mathscr{c}$ is a cardinal and x is of type $\mathscr{c}$ (resp. of strict type $\mathscr{c}$, of finite type), then every component of x and every subset of x is of type $\mathscr{c}$ (resp. of strict type $\mathscr{c}$, of finite type); likewise $\mathscr{P}(x)$ is of type $2^{\mathscr{c}}$ (resp. of strict type $2^{\mathscr{c}}$, of finite type). If x is of type $\mathscr{c}$ and if $\mathscr{c} \leq \mathscr{c}'$, then x is of type $\mathscr{c}'$.

201 LEMMA. *Let $\mathscr{c}$ be an uncountable strongly inaccessible cardinal, and let X be a set of strict type $\mathscr{c}$. Then there exists a cardinal $\mathscr{d} < \mathscr{c}$ such that X is of type $\mathscr{d}$.*

Indeed, for every integer n, let $\mathscr{d}_n$ denote the cardinality of the set X_n of components of order n of X. We have $\mathscr{d}_0 = 1$, $\mathscr{d}_1 = \mathrm{card}(X) < \mathscr{c}$, and, since $X_n = \bigcup_{y \in X_{n-1}} y$, induction on n using (FI.2) gives $\mathscr{d}_n < \mathscr{c}$ for every n. The $\mathscr{d}_n$ are therefore bounded above by the cardinal $\mathscr{d} = \Sigma_{j \geq 0} \mathscr{d}_j$, which is $< \mathscr{c}$ by (FI.2) and the hypothesis that $\mathscr{c}$ is uncountable. If Y is a component of order n of X, then $\mathrm{card}(Y) \leq \mathrm{card}(X_{n+1}) \leq \mathscr{d}$. C.Q.F.D.

PROPOSITION 10. *Let U be a universe and let $\mathscr{c}$ be a strongly inaccessible cardinal. Then the set U' of those $x \in U$ that are of strict type $\mathscr{c}$ is a universe.*

Indeed, if $x, y \in U'$ and if $z \in x$, then plainly $z \in U'$ and $\{x, y\} \in U'$. If $x \in U'$, then $\mathrm{card}(x) < \mathfrak{c}$, whence $\mathrm{card}(\mathscr{P}(x)) < \mathfrak{c}$ by (FI.1); since a component of $\mathscr{P}(x)$ is either $\mathscr{P}(x)$ itself, a subset of x, or a component of x, we have $\mathscr{P}(x) \in U'$. Finally, if $(x_\alpha)_{\alpha\in I}$ is a family of elements of U' such that $I \in U'$, then $\mathrm{card}(\bigcup_\alpha x_\alpha) < \mathfrak{c}$ by (FI.2); since every component of order > 0 of $\bigcup_\alpha x_\alpha$ is a component of some x_α, we indeed have $\bigcup_\alpha x_\alpha \in U'$. C.Q.F.D.

Remark on the cardinal $\mathfrak{c}(U)$. Let U be a universe and let $\mathfrak{c}(U)$ be the cardinal defined by (1), i.e.

$$\mathfrak{c}(U) = \sup_{x\in U} \mathrm{card}(x).$$

We plainly have $\mathfrak{c}(U) \leq \mathrm{card}(U)$, since, as we recall, $x \in U$ implies $x \subset U$. But 202
the equality $\mathfrak{c}(U) = \mathrm{card}(U)$ does not always hold. For example, let $(x_\alpha)_{\alpha\in I}$ be an *uncountable* family of symbols subject to the axioms:

$$\text{«}x_\alpha = \{x_\alpha\} \text{ for every } \alpha \in I\text{»} \quad , \quad \text{«}x_\alpha \neq x_\beta \text{ if } \alpha \neq \beta\text{»}$$

(in other words, x_α is a one-element set, namely itself). As in Example 2 of n° 1, form the "significant words" constructed from the symbols $\emptyset$, x_α, $\{$, $\}$ and so forth. Each denotes a *finite* set. Let U be the set of these words. One readily verifies that the conditions of Definition 1 are satisfied, so that U is a *universe*. Since the significant words are finite sequences of elements of a set of cardinality $\mathrm{card}(I) + 4 = \mathrm{card}(I)$, we have $\mathrm{card}(U) = \mathrm{card}(I)$ (Chapter III; in fact, $\mathrm{card}(U) \geq \mathrm{card}(I)$ suffices, and this is obvious). On the other hand, $\mathfrak{c}(U)$ is the countably infinite cardinal, and hence $\mathfrak{c}(U) < \mathrm{card}(U)$.

The strict inequality $\mathfrak{c}(U) < \mathrm{card}(U)$ is due to our having introduced sets x_α such that $x_\alpha \in x_\alpha$. If one rules out horrors of this kind, one obtains $\mathrm{card}(U) = \mathfrak{c}(U)$ for every universe U, as well as other very pretty results "which cannot possibly be useful." This is what we shall do in the next section.

6. Artinian sets and universes

DEFINITION 5. *A set x is said to be Artinian if there is no infinite sequence $(x_n)_{n\geq 0}$ such that $x_0 = x$ and $x_{n+1} \in x_n$ for every $n \geq 0$.*

Examples. The sets $\emptyset$, $\{\emptyset\}$, $\{\emptyset, \{\emptyset\}\}$, and, more generally, the elements of the universe U_1 of n° 1 are Artinian.

In pictorial terms, if x is Artinian, and if one takes an element x_1 of x, then an 203
element x_2 of x_1, etc., the process must stop, and one arrives at a component x_n of x that is *empty*. In other words, Artinian sets are "built from $\emptyset$"; this will be made more precise later (cf. (*) in the proof of Theorem 2).

Artinian sets plainly have the following properties:

(AR.I) If x is Artinian, every subset of x and every component of x is Artinian. For x to be Artinian, it is necessary and sufficient that every element of x be Artinian.
(AR.II) If x and y are Artinian, then $\{x, y\}$ is Artinian.
(AR.III) If x is Artinian, $\mathscr{P}(x)$ is Artinian.
(AR.IV) Every union of Artinian sets is an Artinian set.

These properties immediately yield the following result:

PROPOSITION 11. *If U is a universe, the set of Artinian elements of U is a universe, necessarily Artinian.*

COROLLARY. *If x is an Artinian set, there exists an Artinian universe U such that $x \in U$.*

Indeed, by axiom (A.6), x is an element of a universe V; take for U the set of Artinian elements of V.

The following proposition is even less useful than the rest of n° 6:

204 PROPOSITION 12. *Let A be an Artinian set. Then:*

a) *For every $x \in A$, one has $x \notin x$;*
b) *If $x, y \in A$, one cannot have both $x \in y$ and $y \in x$;*
c) *For every $x \in A$, the relation "y is a component of z" on the components y, z of x is an order relation;*
d) *For every nonempty element x of A, there exists $y \in x$ such that $x \cap y = \emptyset$.*

Indeed, the negation of a) (resp. of b)) entails the existence of an infinite sequence $(x_n)_{n\geq 0}$ contradicting Definition 5, namely $(x, x, x, \dots)$ (resp. $(x, y, x, y, x, y, \dots)$). The negation of c) means that there exist $x \in A$, distinct components y, z of x, and membership chains:

$$y \in y_1 \in \cdots \in y_q \in z \quad , \quad z \in z_1 \in \cdots \in z_r \in y;$$

whence, as in b), an infinite sequence $(x_n)_{n\geq 0}$ contradicting Definition 5. Finally, if d) is false, there exists a nonempty element x of A such that $x \cap y \neq \emptyset$ for every $y \in x$; set $x_\circ = x$, and take for x_1 an element of x; since $x \cap x_1 \neq \emptyset$, take for x_2 an element of $x \cap x_1$, and so on; more formally, define by induction an infinite sequence $(x_n)_{n\geq 1}$ of elements of x by means of $x_1 \in x$, $x_{n+1} \in x_n \cap x$ for $n \geq 1$; then the sequence $(x_n)_{n\geq 0}$ contradicts Definition 5.

REMARK. Let B be a set. Then B is Artinian if and only if every set A whose elements are sets of components of B satisfies condition d) of Proposition 12. Indeed, necessity
205 follows from (AR.I) and Proposition 12. Conversely, if B is not Artinian, there exists an infinite sequence $(x_n)_{n\geq 0}$ with $x_\circ = B$ and $x_{n+1} \in x_n$ for every $n \geq 0$; then take for A the set whose sole element is the set X of the x_n; thus A contains a nonempty element X such that, for every element y of X, one has $y \cap X \neq \emptyset$ (indeed, y is of the form x_n, and one has $x_{n+1} \in y \cap X$).

THEOREM 2. *Let $\mathfrak{c}$ be an infinite cardinal. Then:*

a) *The relation "x is an Artinian set of type $\mathfrak{c}$ (resp. of strict type $\mathfrak{c}$)" is collectivizing with respect to x; the set $A_\mathfrak{c}$ of Artinian sets of type $\mathfrak{c}$ has cardinality $2^\mathfrak{c}$.*
b) *If $\mathfrak{c}$ is strongly inaccessible, the set $U_\mathfrak{c}$ of Artinian sets of strict type $\mathfrak{c}$ is a universe of cardinality $\mathfrak{c}$; the cardinal $\mathfrak{c}(U_\mathfrak{c}) = \sup_{x\in U_\mathfrak{c}} \mathrm{card}(x)$ is $\mathfrak{c}$.*
c) *If a universe U contains an element of cardinality $\mathfrak{c}$, every Artinian set of type $\mathfrak{c}$ belongs to U (in other words, $A_\mathfrak{c} \subset U$).*
c′) *If a universe U is nonempty, every Artinian set of finite type is an element of U.*

Before proving Theorem 2, let us deduce from it a few illuminating corollaries:

COROLLARY 1. *If a universe U is Artinian, then* $\mathrm{card}(U)$ *is strongly inaccessible, and U is the set of Artinian sets of strict type* $\mathrm{card}(U)$.

206 Indeed, set $\mathfrak{c}(U) = \sup_{x\in U} \mathrm{card}(x)$. This is a strongly inaccessible cardinal (beginning of n° 5). First suppose that it is uncountable; then, for every infinite cardinal $\mathfrak{c} < \mathfrak{c}(U)$, every Artinian set of type $\mathfrak{c}$ is an element of U by c); hence every Artinian set of strict type $\mathfrak{c}(U)$ is an element of U by the lemma of n° 5. This last assertion remains valid if $\mathfrak{c}(U)$ is countable, by c′). Conversely, by (U.I), every set in U is of strict type $\mathfrak{c}(U)$. Thus U is the universe $U_{\mathfrak{c}(U)}$ of b), whence $\mathfrak{c}(U) = \mathrm{card}(U)$ by b).

It follows from Corollary 1 that an Artinian universe is uniquely *determined* by its cardinality (which is moreover strongly inaccessible). Thus there is a "one-to-one correspondence" between Artinian universes and strongly inaccessible cardinals. In particular:

COROLLARY 2. *The inclusion relation $U \subset U'$ on Artinian universes is a well-ordering relation.*

Indeed, the relation $\mathfrak{c} \leq \mathfrak{c}'$ on cardinals is a well-ordering relation (Chapter III), and, with the notation of b) of Theorem 2, the relations $\mathfrak{c} \leq \mathfrak{c}'$ and $U_{\mathfrak{c}} \subset U_{\mathfrak{c}'}$ are equivalent.

Observe that b) of Theorem 2 gives a second proof of Theorem 1 (n° 5).

We now turn to the proof of Theorem 2. Given a set A, we shall call a *chain* of A any finite sequence $(x_j)_{j=0,\ldots,n}$ such that $x_0 = A$ and $x_{j+1} \in x_j$ for $j = 0, \ldots, n-1$. The chains of A form a *set*, by the selection–union scheme; denote it by $G(A)$. Given a 207
chain $X = (x_j)_{j=0,\ldots,n}$, the chains of the form $(x_i)_{i=0,\ldots,q}$ with $q \leq n$ will be called less than X; this endows $G(A)$ with the structure of an *ordered set*. For A to be Artinian, it is necessary and sufficient that $G(A)$ be a "*Noetherian*" ordered set (i.e. one satisfying the equivalent conditions of Chapter III, § 6, n° 5).

We shall prove that:

(*) *If A is Artinian, it is uniquely determined by the isomorphism class of the ordered set $G(A)$.*

Indeed, given an ordered set G and an element $g \in G$, let $S(g)$ denote the set of all $g' \in G$ such that $g < g'$ and such that $g \leq h \leq g'$ implies $h = g$ or $h = g'$ (in other words, the set of "immediate successors" of g). Consider the map θ that assigns to every chain $X = (x_0, \ldots, x_n)$ in $G(A)$ the set x_n; then, for every $X \in G(A)$, we have:

$$\theta(X) = \{\theta(X') | X' \in S(X)\}.$$

Since A is the image under θ of the least element $X_0 = (A)$ of $G(A)$, it will suffice to show that θ is uniquely determined by the isomorphism class of the ordered set $G(A)$. This follows from the following lemma:

LEMMA 1. *Let G be a Noetherian ordered set and let φ be a function with domain G* 208
such that, for every $g \in G$, one has:

$$\varphi(g) = \{\varphi(g') | g' \in S(g)\}. \tag{1}$$

Then φ is uniquely determined. Moreover, if U is a universe containing an element equipotent to G, then φ takes its values in U.

The hypothesis implies that $\varphi(g) = \varnothing$ if g is a maximal element of G.

Indeed, let φ and φ' be two functions satisfying (1). If $\varphi \neq \varphi'$, the set of all $g \in G$ such that $\varphi(g) \neq \varphi'(g)$ is nonempty and hence, since G is Noetherian, has a *maximal* element h. We then have $\varphi(g) = \varphi'(g)$ for every $g > h$, in particular for every immediate successor $g \in S(h)$; hence $\varphi(h) = \varphi'(h)$ by (1), which is a contradiction. Thus indeed $\varphi = \varphi'$. Now let U be a universe containing an element x equipotent to G; let us show that φ takes its values in U. Otherwise, let h be a maximal element among those $g \in G$ such that $\varphi(g) \notin U$. Then $\varphi(g') \in U$ for every $g' \in S(h)$, so that

$$\varphi(h) = \{\varphi(g') | g' \in S(h)\}$$

is a subset of U. Since its cardinality does not exceed $\mathrm{card}(G)$, and hence does not exceed the cardinality of an element of U, we have $\varphi(h) \in U$ (n° 1, Proposition 7). This contradiction shows that φ takes its values in U.

With this established, let us prove a) of Theorem 2. We may confine ourselves to the 209

assertion without the resp. clause, since the other follows at once. Let $\mathfrak{c}$ be an *infinite* cardinal. If A is a set of type $\mathfrak{c}$, then:

$$\text{card}(G(A)) \leq \mathfrak{c} \ . \tag{2}$$

Indeed, if A_n denotes the set of components of order n of A, then $\text{card}(A_1) \leq \mathfrak{c}$ and $\text{card}(A_{n+1}) \leq \mathfrak{c} \cdot \text{card}(A_n)$, whence $\text{card}(A_n) \leq \mathfrak{c}^n$ by induction. But $\mathfrak{c}^n = \mathfrak{c}$, since $\mathfrak{c}$ is infinite (Chapter III); hence $\text{card}(\bigcup_{n=0}^{\infty} A_n) \leq \text{card}(\mathbf{N}) \cdot \mathfrak{c} = \mathfrak{c}$ (Chapter III). Now $G(A)$ is a set of *finite* sequences of elements of $\bigcup_n A_n$, so inequality (2) indeed holds (Chapter III). Now, if E is a set of cardinality $\mathfrak{c}$, specifying an order structure on a subset E' of E is equivalent to specifying the subset of $E \times E$ consisting of the (x, y) such that $x \in E'$, $y \in E'$, and $x \leq y$. Consequently, by (2), the isomorphism classes of the ordered sets $G(A)$ (where A is of type $\mathfrak{c}$) form a set $\mathfrak{F}_{\mathfrak{c}}$, and $\text{card}(\mathfrak{F}_{\mathfrak{c}}) \leq \text{card}(\mathscr{P}(E \times E)) = 2^{\mathfrak{c}}$. Let $\mathfrak{F}'_{\mathfrak{c}}$ be the subset of $\mathfrak{F}_{\mathfrak{c}}$ consisting of the classes of Noetherian ordered sets having a least element. If, to every $G \in \mathfrak{F}'_{\mathfrak{c}}$, one assigns the value of the function φ of Lemma 1 at the least element of G, one obtains a map θ on $\mathfrak{F}'_{\mathfrak{c}}$ whose image contains *all* Artinian sets of type $\mathfrak{c}$. The latter therefore do indeed form a set $A_{\mathfrak{c}}$, and we have $\text{card}(A_{\mathfrak{c}}) \leq \text{card}(\mathfrak{F}'_{\mathfrak{c}}) \leq \text{card}(\mathfrak{F}_{\mathfrak{c}}) \leq 2^{\mathfrak{c}}$.

210 It remains to show that $\text{card}(A_{\mathfrak{c}}) = 2^{\mathfrak{c}}$. For this it suffices to show that there exists an Artinian set B of type $\mathfrak{c}$ and cardinality $\mathfrak{c}$, since the subsets of B will then be elements of $A_{\mathfrak{c}}$. This existence follows from the following lemma:

LEMMA 2. *For every cardinal $\mathfrak{c}$, there exists an Artinian set B of type $\mathfrak{c}$ and cardinality $\mathfrak{c}$.*

Proceed by transfinite induction on $\mathfrak{c}$. For $\mathfrak{c} = 0$ there is no choice, and one takes $B = \emptyset$. If $\mathfrak{c}$ has a predecessor $\mathfrak{c}'$, let B' be an Artinian set of type $\mathfrak{c}'$ and cardinality $\mathfrak{c}'$; one then has $\mathfrak{c} \leq 2^{\mathfrak{c}'}$, so there exists a subset B of $\mathscr{P}(B')$ of cardinality $\mathfrak{c}$; the elements of B are subsets of B' and therefore have cardinalities $\leq \mathfrak{c}' \leq \mathfrak{c}$; the higher-order components of B are components of B', and hence also have cardinalities $\leq \mathfrak{c}' \leq \mathfrak{c}$. Finally, if $\mathfrak{c}$ has no predecessor, choose, for every cardinal $\mathfrak{c}_\lambda < \mathfrak{c}$, an Artinian set B_λ of type $\mathfrak{c}_\lambda$ and cardinality $\mathfrak{c}_\lambda$; then $B = \bigcup_\lambda B_\lambda$ has the required property. This proves Lemma 2 and completes the proof of part a).

We turn to b). Let $\mathfrak{c}$ be a strongly inaccessible cardinal. By a), we already know that the Artinian sets of strict type $\mathfrak{c}$ form a set $U_{\mathfrak{c}}$. The fact that $U_{\mathfrak{c}}$ is a universe follows immediately from properties (AR.I) to (AR.IV) of Artinian sets (beginning of n°),

211 and from cardinal estimates analogous to those of Proposition 10 of n° 5. The relation $\sup_{x \in U_{\mathfrak{c}}} \text{card}(x) = \mathfrak{c}$ followsfrom Lemma 2, applied to cardinals $< \mathfrak{c}$. Finally, to show that $\text{card}(U_{\mathfrak{c}}) = \mathfrak{c}$, first suppose that $\mathfrak{c}$ is *uncountable*; bythe lemma of n° 5, $U_{\mathfrak{c}}$ is the union $\bigcup_{\mathfrak{d} < \mathfrak{c}} A_{\mathfrak{d}}$, where $A_{\mathfrak{d}}$ denotes the set of Artinian sets of type $\mathfrak{d}$; now $\text{card}(A_{\mathfrak{d}}) = 2^{\mathfrak{d}} < \mathfrak{c}$ (by a)); on the other hand, the set of cardinals $\mathfrak{d} < \mathfrak{c}$ has cardinality $\leq \mathfrak{c}$ (Chapter III); whence $\text{card}(U_{\mathfrak{c}}) \leq \mathfrak{c} \cdot \mathfrak{c} = \mathfrak{c}$, and also $\text{card}(U_{\mathfrak{c}}) \geq \mathfrak{c}$, since $\text{card}(U_{\mathfrak{c}}) \geq \text{card}(A_{\mathfrak{d}}) = 2^{\mathfrak{d}}$ for every $\mathfrak{d} < \mathfrak{c}$.

The case $\mathfrak{c} = 0$ being trivial, there remains the case where $\mathfrak{c}$ is the *countably infinite cardinal.* In this case $U_{\mathfrak{c}}$ is the set of Artinian sets of finite type (i.e. finite together with all their components), and one uses a pleasant result of a combinatorial nature.

LEMMA 3. (D. K"onig?). *Consider two infinite sequences $(E_n)_{n \geq 1}$, $(f_n)_{n \geq 1}$ of finite sets E_n and maps $f_n : E_{n+1} \to E_n$. If there exists no infinite sequence $(x_n)_{n \geq 1}$ such that $x_n \in E_n$ and $f_n(x_{n+1}) = x_n$ for every n, then E_n is empty for all sufficiently large n.*

In other words, if all sequences (x_n) such that $f_n(x_{n+1}) = x_n$ are *finite*, their lengths are *bounded*. This can be expressed in terms of projective limits: a projective limit of nonempty finite sets is nonempty (cf. General Topology, Chapter I, 2nd ed., § 9, n° 6, Proposition 8, 2°)).

Indeed, argue by contradiction. If there exist nonempty E_n for arbitrarily large n, 212
no E_n is empty (since $E_n = \varnothing$ implies $E_{n+1} = \varnothing$ in view of the existence of $f_n : E_{n+1} \to E_n$). Call a finite sequence $(x_j)_{1\leq j\leq n}$ *coherent* if $f_j(x_{j+1}) = x_j$ for $j = 1, \dots, n-1$. We prove by induction on n the existence of a coherent sequence $(a_1, \dots, a_n)$ $(a_i \in E_i)$ that, for every $q \geq n$, can be extended to a coherent sequence $(a_1, \dots, a_n, x_{n+1}, \dots, x_q)$ of length q. This is evident for $n = 0$, since no E_q is empty. Pass from n to $n+1$. If, for every $x \in f_n^{-1}(\{a_n\}) \subset E_{n+1}$, all coherent sequences extending $(a_1, \dots, a_n, x)$ had lengths bounded by an integer $q(x)$, then all coherent sequences extending $(a_1, \dots, a_n)$ would have bounded lengths (by $\sup_x q(x)$), since E_{n+1} is finite; hence there exists $a_{n+1} \in f_n^{-1}(\{a_n\})$ such that the coherent sequence $(a_1, \dots, a_n, a_{n+1})$ admits extensions of arbitrary length. We then obtain an infinite sequence $(a_n)_{n\geq 1}$ contradicting the hypothesis.

It follows from Lemma 3 that if A is an Artinian set of finite type, then the ordered set $G(A)$ of its chains is *finite*: indeed, take for E_n the set of chains $(x_n \in x_{n-1} \in \cdots \in x_1 \in A)$ with $n+1$ terms (which is finite because the components of A of order $\leq n+1$ are finite in number and are all finite), and for f_n the map $(x_{n+1} \in x_n \in x_{n-1} \in \dots) \mapsto (x_n \in x_{n-1} \in \dots)$. Now the set of isomorphism classes of finite ordered sets is *countable*: 213
indeed, giving an order structure on a finite subset of $\mathbf{N}$ is equivalent to giving its graph, which is a finite subset of $\mathbf{N}\times\mathbf{N}$; on the other hand, the set of finite subsets of a countable set is countable (Chapter III). It follows from (*) and Lemma 1 that the set $\mathfrak{a}$ of Artinian sets of finite type is countable. It is infinite by Lemma 2 (or, more simply, by using the sequence $(z_n)_{n\geq 0}$ defined by $z_0 = \varnothing$, $z_{n+1} = \{z_n\}$). This completes the proof of b).

Remark. We have just proved that if A is an Artinian set of finite type, it has only finitely many components. There therefore exists an integer n such that A is of type n.

We turn to the proof of c). Let $\mathfrak{c}$ be an infinite cardinal, let U be a universe admitting an element of cardinality $\mathfrak{c}$, and let A be an Artinian set of type $\mathfrak{c}$. Then the ordered set $G(A)$ has cardinality $\leq \mathfrak{c}$ (formula (2) above). The second assertion of Lemma 1, applied to $G(A)$, shows that the map $(x_0, \dots, x_n) \rightsquigarrow x_n$ from $G(A)$ takes its values in U. In other words, all the components of A are elements of U. This proves c). The proof of c′) is analogous: if A is an Artinian set of finite type, we have just seen that $G(A)$ is finite; since U is nonempty, it contains an element equipotent to $G(A)$ by the corollary to Proposition 7 (n° 1). C.Q.F.D.

7. Vague metamathematical remarks

214

a) The axiom "*every set is Artinian*" is *harmless*. Indeed, if one has a model M of Set Theory, the set M' of the Artinian elements of M is also a model (cf. Proposition 11).

b) The universe axiom (A.6) (and the equivalent axiom (A′.6) on strongly inaccessible cardinals) is *independent* of the rest of Set Theory. Indeed, let $\mathfrak{c}$ be the first uncountable strongly inaccessible cardinal. The universe $U_{\mathfrak{c}}$ of Artinian sets of strict type $\mathfrak{c}$ (Theorem 2, b)) is a model of Set Theory without (A.6): the elements of $U_{\mathfrak{c}}$ are called "sets," the "membership relation" is the restriction to $U_{\mathfrak{c}}$ of the usual one, etc. The "universes" of the model are therefore the ordinary universes that are elements of $U_{\mathfrak{c}}$. But we have seen that the only universes

which are elements of U_c are the two pequeños $U_0 = \varnothing$ and U_1. Thus U_1 is a "set" which is not an element of any "universe." We therefore have a model of Set Theory in which (A.6) is false.

c) Bourbaki was too cautious in merely "presuming" that the *axiom of infinity* (A.5) is *independent* of the preceding axioms and schemes. It is indeed independent, since the countable universe U_1 of Artinian sets of finite type is a model in which (A.5) is false and the preceding axioms and schemes are true.

d) It would be very interesting to prove that the universe axiom (A.6) is harmless. That looks difficult—and in fact it is unprovable, says Paul Cohen.

215 The adjective "vague" in the title means that, when constructing models, we did not take the trouble to fiddle with the symbol τ so that it could not take us outside the model. The trick, if one is considering a model M, is to replace the ordinary $\tau_x(\mathscr{R}(x))$ by:

$$\tau_x(\mathscr{R}(x) \text{ and } x \in M).$$

One still has to check that this really turns the ordinary quantifiers into the quantifiers formerly called "typical":

$$(\forall x \in M) \quad , \quad (\exists x \in M).$$

Exercises. 1) Let n be an integer ≥ 1. Show that the set of Artinian sets of type n is infinite (the sets $z_0 = \varnothing$, $z_1 = \{\varnothing\}$, $z_{q+1} = \{z_q\}$ are of type 1).

2) Define the *height* of a set A to be the supremum (finite or infinite) of the integers n for which there exists a sequence $x_n \in x_{n-1} \in \cdots \in x_0 = A$. Show that the sets of height $\leq n$ are finite and form a finite set, whose cardinality p_n can be calculated from $p_0 = 1$, $p_{n+1} = 2^{p_n}$ (proceed by induction on n, noting that the elements of a set A of height $\leq n$ are sets of height $\leq n-1$).

3) Let G be a Noetherian ordered set having a least element g_0, and suppose that, for every $h \in G$, the set of $g \in G$ such that $g \leq h$ is finite and totally ordered.

216 a) Show that every element $h \neq g_0$ of G has a unique predecessor.

b) Let φ be the map on G defined in Lemma 1 (i.e. $\varphi(g)$ is the set of all $\varphi(g')$ as g' ranges over the successors of g). Put $A = \varphi(g_0)$. Show that A is an Artinian set. For $g \in G$, let $g_0 < g_1 < \cdots < g_n = g$ be the sequence of elements $\leq g$; put $f(g) = (\varphi(g_0), \varphi(g_1), \ldots, \varphi(g_n))$; show that f is an increasing surjection from G onto the ordered set $G(A)$ of the text. Show that, if f is *injective*, it is an *isomorphism* from G onto $G(A)$.

c) For $g \in G$, let M_g be the set of upper bounds of g. Suppose that, for every pair of distinct elements g, g' having the same predecessor p, the ordered sets M_g and $M_{g'}$ are not isomorphic. Show that the map f of b) is then an *isomorphism* from G onto $G(A)$. [If $f(g) = f(g')$ with $g \neq g'$, and if $g_0 < g_1 < \cdots < g_n = g$ and $g'_0 < g'_1 < \cdots < g'_{n'} = g'$ are the sequences of elements $\leq g$ and $\leq g'$, respectively, show that $n = n'$, and that one may assume that g and g' have the same predecessor p; then consider the set of $p \in G$ for which there exist two distinct successors g, g' of p such that $f(g) = f(g')$, a maximal element q of this set, and two distinct successors h, h' of q such that $f(h) = f(h')$; note that the restrictions of f to M_h and $M_{h'}$ are injective and hence (by b)) are isomorphisms from M_h onto $G(\varphi(h))$ and from $M_{h'}$ onto $G(\varphi(h'))$; deduce from the hypothesis that M_h and $M_{h'}$ are not isomorphic that $\varphi(h) \neq \varphi(h')$, which contradicts $f(h) = f(h')$].

217 N.B. Exercise 3) gives very precise information on how Artinian sets are "made."

We already knew that such a set A is determined by the isomorphism class of the ordered set $G(A)$ (Lemma 1). We now know how to *characterize* the ordered sets G isomorphic to some $G(A)$:

- α) G is Noetherian and has a least element;
- β) For every $g \in G$, the set of $h \in G$ such that $h \leq g$ is totally ordered and finite (whence the existence and uniqueness of the predecessor of every nonleast g);
- γ) If g, g' are distinct elements having the same predecessor, the set M_g of upper bounds of g and the set $M_{g'}$ of upper bounds of g' are not isomorphic.

4) Let $(A_n)_{n\geq 0}$ be the sequence of finite *ordinals* defined by $A_0 = \varnothing$, $A_{n+1} = A_n \cup \{A_n\}$. Show that the ordered set $G(A_n)$ has 2^n elements, and that the number of its elements of height q (in the sense of Exercise 2) is $\binom{n}{q}$.

EXPOSÉ II

Topologies and sheaves

J.-L. Verdier

After defining topologies and pretopologies (Section 1) and sheaves of sets (Section 2), in Section 3 we turn to the central theorem of this exposé (3.4): the existence of the sheaf associated with a presheaf. In order to cover all the cases encountered in practice, the existence of this functor is proved for presheaves on a $\mathscr{U}$-site (3.0.2). The consequences of this theorem for the behavior of inductive and projective limits in categories of sheaves are drawn in Sections 4 and 5. In Section 6 we define and study sheaves with values in arbitrary categories, immediately focusing attention on sheaves of rings, groups, modules, etc. 218

1. Topologies, covering families, pretopologies

DEFINITION 1.1. *A topology on a category C consists, for every object X of C, of a set $J(X)$ of sieves on X, subject to the following axioms:*

T 1) (Stability under base change). *For every object X of C, every sieve $R \in J(X)$, and every morphism $f : Y \to X$ ($Y \in \mathrm{ob}(C)$), the sieve $R \times_X Y$ on Y belongs to $J(Y)$.*

T 2) (Local character). *If R and R' are two sieves on X, if $R \in J(X)$, and if, for every $Y \in \mathrm{ob}(C)$ and every morphism $Y \to R$, the sieve $R' \times_X Y$ belongs to $J(Y)$, then R' belongs to $J(X)$.* 219

T 3) *For every object X of C, X belongs to $J(X)$.*

1.1.1. The sieves belonging to $J(X)$ will be called the *sieves covering* X, or the *refinements of* X. It follows immediately from axioms (T1), (T2), and (T3) that the set of sieves covering X is stable under finite intersections, and that every sieve containing a covering sieve is itself a covering sieve. Thus the set $J(X)$, ordered by inclusion, is cofiltered (I 8).

1.1.2. Let C be a category, and let T and T' be two topologies on C. The topology T is said to be *finer than the topology* T' if, for every object X of C, every refinement of X for the topology T' is a refinement of X for the topology T. This defines an order structure on the set of topologies.

1.1.3. Let $(T_i)_{i\in I}$ be a family of topologies on C. For every object X of C, the set of sieves on X that are covering for all the topologies T_i satisfies axioms (T 1), (T 2), and (T 3), and hence defines a topology: the *intersection topology* of the T_i, i.e. the infimum of the T_i. It is the finest topology that is coarser than all the topologies T_i. Consequently, the family $(T_i)_{i\in I}$ also admits a *supremum*: the intersection topology of the topologies finer than each of the T_i.

1.1.4. In particular, taking $J(X)$ to be the set of all sieves on X gives a topology finer than every topology on C; we call it the *discrete topology*. 220

There is a topology coarser than every topology on C: the topology for which $J(X) = \{X\}$ for every X of C. This topology is called the *coarse* or *chaotic* topology.

1.1.5. A category C equipped with a topology is called a *site*. The category C is called the *category underlying the site*.

DEFINITION 1.2. *Let C be a site and X an object of C. A family of morphisms $(f_\alpha : X_\alpha \to X)$, $\alpha \in A$, is called a covering family if the sieve generated by the family f_α (I 4.3.3) is a sieve covering X.*

1.1.6. Let C be a category. Suppose that, for each object X of C, we are given a set of families of morphisms with target X. There is then a coarsest topology T for which the given families are covering, namely the intersection (1.1.3) of all the topologies in question. This topology is called the *topology generated by the given sets of families of morphisms*. In general, it is difficult to describe all the covering sieves of this topology. The situation is more favorable, however, in the following case:

DEFINITION 1.3. *Let C be a category. A pretopology on C consists, for each object X of C, of a set* $\mathrm{Cov}(X)$ *of families of morphisms with target X, subject to the following axioms:*

221 PT 0) *For every object X of C, the morphisms in the families belonging to* $\mathrm{Cov}(X)$ *are pullbackable. (Recall that a morphism $Y \to X$ is called pullbackable if, for every morphism $Z \to X$, the fiber product $Z \times_X Y$ is representable.)*

PT 1) *For every object X of C, every family $(X_\alpha \to X)_{\alpha\in A}$ belonging to* $\mathrm{Cov}(X)$*, and every morphism $Y \to X$ ($Y \in \mathrm{ob}(C)$), the family $(X_\alpha \times_X Y \to Y)_{\alpha\in A}$ belongs to* $\mathrm{Cov}(Y)$*. (Stability under base change.)*

PT 2) *If $(X_\alpha \to X)_{\alpha\in A}$ belongs to* $\mathrm{Cov}(X)$ *and if, for every $\alpha \in A$, $(X_{\beta_\alpha} \to X_\alpha)_{\beta_\alpha\in B_\alpha}$ belongs to* $\mathrm{Cov}(X_\alpha)$*, then the family $(X_\gamma \to X)_{\gamma\in\coprod_{\alpha\in A} B_\alpha}$ (where, for every $\gamma = (\alpha, \beta_\alpha)$, $\alpha \in A$, $\beta_\alpha \in B_\alpha$, the morphism $X_\gamma \to X$ is the composite morphism $X_\gamma = X_{\beta_\alpha} \to X_\alpha \to X$) belongs to* $\mathrm{Cov}(X)$*. (Stability under composition.)*

PT 3) *The family $X \xrightarrow{\mathrm{id}_X} X$ belongs to* $\mathrm{Cov}(X)$.

1.3.1. The definition in 1.1.6 allows us to consider, for a given *pretopology* on C, the *topology* on C generated by that pretopology. Note that if C is a category in which fiber products are representable, then every topology T on C can be defined by a pretopology, namely the one for which $\mathrm{Cov}(X)$ consists of *all* the families covering X for the topology T.

PROPOSITION 1.4. *Let C be a category, E a pretopology on C, T the topology defined by the pretopology E (1.1.6), and X an object of C. Denote by $J_E(X)$ the set of sieves on X generated by families of the pretopology, and by $J_T(X)$ the set of refinements of X for*
222 *the topology T. Then $J_E(X)$ is cofinal in $J_T(X)$. In other words, a sieve R on X belongs to $J_T(X)$ if and only if there exists a sieve $R' \in J_E(X)$ such that $R' \subset R$.*

PROOF. For every object X of C, let $J'(X)$ be the set of sieves on X that contain a sieve belonging to $J_E(X)$. Clearly, $J'(X) \subset J_T(X)$. To prove that $J'(X) = J_T(X)$, it is enough to show that the data $J'(X)$ define a topology on C. Now the $J'(X)$ clearly satisfy axioms (T 1) and (T 3). It therefore remains to verify (T 2). For this, it is enough to prove that if R' is a subsieve of $R \in J_E(X)$ such that, for every $Y \to R$, the sieve $R' \times_X Y$ on Y belongs to $J'(Y)$, then the sieve R' belongs to $J'(X)$. Now the sieve R is generated by a family $(X_\alpha \to X)$ belonging to $\mathrm{Cov}(X)$, and for every α the sieve $R' \times_X X_\alpha$ contains a sieve generated by a family $(X_{\beta_\alpha} \to X_\alpha)$ belonging to $\mathrm{Cov}(X_\alpha)$. It follows that the sieve R' contains a sieve generated by the family $(X_{\beta_\alpha} \to X)$. Thus, by axiom (PT 2), R' contains a sieve belonging to $J_E(X)$ and consequently belongs to $J'(X)$, C.Q.F.D.

2. Sheaves of sets

DEFINITION 2.1. *Let C be a site whose underlying category is a $\mathcal{U}$-category. A presheaf F with values in $\mathcal{U}$ – Ens is said to be separated (resp. to be a sheaf) if, for every sieve R covering an object X of C, the map*

$$\mathrm{Hom}_{\hat{C}}(X, F) \longrightarrow \mathrm{Hom}_{\hat{C}}(R, F)$$

is injective (resp. bijective). The full subcategory of $\hat{C}$ whose objects are the sheaves is 223
called the category of sheaves of sets on C, and is most often denoted by $\widehat{C}$ [4]. When no ambiguity can result, we shall simply say the category of sheaves on C; on the other hand, we shall sometimes be more precise and say the category of sheaves with values in $\mathcal{U}$ – Ens, or the category of $\mathcal{U}$-sheaves.

PROPOSITION 2.2. *Let C be a $\mathcal{U}$-category, and let $\mathcal{F} = (F_i)_{i\in I}$ be a family of $\mathcal{U}$-presheaves on C. For each object X of C, denote by $J_{\mathcal{F}}(X)$ the set of sieves $R \to X$ such that, for every morphism $Y \to X$ in C with target X, the sieve $R \times_X Y$ has the following property: the map*

$$\mathrm{Hom}_{\hat{C}}(Y, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R \times_X Y, F_i)$$

is bijective (resp. injective) for every $i \in I$. Then the sets $J_{\mathcal{F}}(X)$ define a topology on C, which is the finest topology for which each F_i is a sheaf (resp. separated presheaf).

PROOF. The $J_{\mathcal{F}}(X)$ clearly satisfy axioms (T 1) and (T 3). It remains to show that they satisfy (T 2). For this it suffices to show the following:

1) If $R' \hookrightarrow R \hookrightarrow X$ are two sieves on X such that $R \in J_{\mathcal{F}}(X)$ and such that, for every $Y \to R$ (where Y is an object of C), the sieve $R' \times_X Y$ belongs to $J_{\mathcal{F}}(Y)$, then the sieve R' belongs to $J_{\mathcal{F}}(X)$.
2) If $R' \hookrightarrow R \hookrightarrow X$ are two sieves on X such that $R' \in J_{\mathcal{F}}(X)$, then the sieve R belongs to $J_{\mathcal{F}}(X)$.

Note that, in case 2), for every $Y \to R$ (where Y is an object of C), the sieve $R' \times_X Y$ belongs to $J_{\mathcal{F}}(Y)$. Now, in cases 1) and 2), R is the inductive limit of the objects Y of C over R (I 3.4). The inductive limits in $\hat{C}$ are universal (I 3.3). Consequently, in cases 1) 224
and 2), R' is the inductive limit of the $R' \times_X Y$. Now, in cases 1) and 2), $R' \times_X Y$ belongs to $J_{\mathcal{F}}(Y)$. Passing to the inductive limit over the objects Y of C over R, we deduce that the map

$$\mathrm{Hom}_{\hat{C}}(R, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R', F_i)$$

is a bijection (resp. an injection) for every $i \in I$. It follows that the maps

$$\mathrm{Hom}_{\hat{C}}(X, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R', F_i) \quad , \quad \mathrm{Hom}_{\hat{C}}(X, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R, F_i)$$

are, in cases 1) and 2), bijections (resp. injections). Moreover, hypotheses 1) and 2) are plainly stable under arbitrary base change $Y \to X$ (Y an object of C). It then follows that, for every object Y of C over X and every $i \in I$, the maps

$$\mathrm{Hom}_{\hat{C}}(Y, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R \times_X Y, F_i)$$
$$\mathrm{Hom}_{\hat{C}}(Y, F_i) \longrightarrow \mathrm{Hom}_{\hat{C}}(R' \times_X Y, F_i)$$

are in both cases bijections (resp. injections); this shows that R' and R belong to $J_{\mathcal{F}}(X)$, C.Q.F.D.

[4] or $\tilde{C}$, depending on the mood of the typewriter.

COROLLARY 2.3. *Let C be a $\mathscr{U}$-category, and for every X of C let $K(X)$ be a set of sieves on X. Suppose that the $K(X)$ satisfy axiom* (T 1) *of* (1.1). *A presheaf F is a sheaf (resp. a separated presheaf) for the topology generated (1.1.6) by the $K(X)$ if and only if, for every object X of C and every sieve $R \in K(X)$, the map*

$$\mathrm{Hom}_{C^\wedge}(X, F) \longrightarrow \mathrm{Hom}_{C^\wedge}(R, F)$$

is a bijection (resp. an injection).

225 COROLLARY 2.4. *In particular, let C be a $\mathscr{U}$-category equipped with a pretopology. A presheaf F is a sheaf (resp. a separated presheaf) if and only if, for every object X of C and every covering family $(X_\alpha \to X)$ belonging to* $\mathrm{Cov}(X)$, *the diagram of sets*

$$F(X) \to \prod_{\alpha \in A} F(X_\alpha) \rightrightarrows \prod_{(\alpha,\beta)\in A\times A} F(X_\alpha \times_X X_\beta)$$

is exact (resp. the map

$$F(X) \longrightarrow \prod_{\alpha \in A} F(X_\alpha)$$

is injective).

PROOF. Apply 2.3, then (I 3.5) and (I 2.12).
Corollary 2.4 recovers the definition given in [1].

DEFINITION 2.5. *Let C be a $\mathscr{U}$-category. The canonical topology of C is the finest topology for which the representable functors are sheaves (2.2). A sieve covering X for the canonical topology will be called a universally strictly epimorphic sieve. A covering family for the canonical topology will be called a universally strictly epimorphic family. If, in addition, the morphisms of the covering family are pullbackable, the family will be called universally effective epimorphic* [2].

REMARK 2.5.1. For almost all the sites that have been used up to now, the topology is *coarser* than the canonical topology; in other words, the representable functors on C
226 are sheaves, i.e. the covering families of C are universally strictly epimorphic. The only exception to this rule is the site $\widehat{C}$ studied in n° 5 (whose topology is *finer,* and most often strictly finer, than the canonical topology).

PROPOSITION 2.6. *A sieve $R \hookrightarrow X$ is universally strictly epimorphic if and only if, for every object $Y \to X$ of C over X, and for every object Z of C, the map*

$$\mathrm{Hom}_C(Y, Z) \longrightarrow \varprojlim_{C/(Y\times_X R)} \mathrm{Hom}_C(., Z)$$

is a bijection.

PROOF. Immediate upon applying 2.2 and then (I 5.3).

REMARKS 2.7.
1) Proposition 2.6 gives a characterization of the universally strictly epimorphic sieves of a category C that is independent of the universe in which the presheaves take their values, provided only that the morphism sets $\mathrm{Hom}(X, Y)$ of C belong to that universe. It thus makes it possible to define the canonical topology for any category C, without having to specify the universes.
2) Let C be a site whose underlying category is a $\mathscr{U}$-category, let F be a $\mathscr{U}$-presheaf, and let $\mathscr{V}$ be a universe containing $\mathscr{U}$. The category underlying C is a $\mathscr{V}$-category, and F may be regarded as a $\mathscr{V}$-presheaf. The $\mathscr{U}$-presheaf F is a sheaf (resp. a separated presheaf) if and only if the $\mathscr{V}$-presheaf F is a sheaf

(resp. a separated presheaf). In other words, the condition for a presheaf F to be a sheaf (resp. a separated presheaf) does not depend (in the sense just specified) on the universe in which the presheaf F takes its values. In particular, let C be a site and let F be a $\mathscr{U}$-presheaf; we say that F is a sheaf (resp. a separated presheaf) if there exists a universe $\mathscr{V}$ containing $\mathscr{U}$ such that the category C is a $\mathscr{V}$-category and such that F is a $\mathscr{V}$-sheaf (resp. a separated $\mathscr{V}$-presheaf). This property does not depend on the universe $\mathscr{V}$. 227

3. The sheaf associated with a presheaf

DEFINITION 3.0.1. *Let C be a site. A topologically generating family (or, when no confusion can result, a generating family) of C is a set G of objects of C such that every object of C is the target of a covering family of morphisms of C (1.2) whose sources are elements of G.*

DEFINITION 3.0.2. *Let $\mathscr{U}$ be a universe. A $\mathscr{U}$-site is a site C whose underlying category is a $\mathscr{U}$-category* (I 1.1)*, and which possesses a small topologically generating family. Let C be a $\mathscr{U}$-category; a $\mathscr{U}$-topology on C is a topology on C making C a $\mathscr{U}$-site. A site C is called $\mathscr{U}$-small, or, by abuse of language, small, if its underlying category is small* (I 1.0).

3.0.3. It follows immediately from the definitions that every topology finer than a $\mathscr{U}$-topology is a $\mathscr{U}$-topology, and that a small site is a $\mathscr{U}$-site.

PROPOSITION 3.0.4. *Let C be a $\mathscr{U}$-site and G a small topologically generating family of C. For every $X \in \operatorname{ob} C$, denote by $J_G(X)$ the set of sieves covering X generated by a family of morphisms* 228

$$(Y_\alpha \xrightarrow{u_\alpha} X), \alpha \in A, \text{ where } Y_\alpha \in G.$$

1) *The set $J_G(X)$ is small.*
2) *The set $J_G(X)$ is cofinal in the set $J(X)$ of all sieves covering X, ordered by inclusion.*
3) *For every $R \in J_G(X)$, there exists a small epimorphic family* (I 10.2) *$(u_\alpha : Y \to R)$, $\alpha \in A$, with $Y \in G$.*

PROOF. 1) Put $A(X) = \coprod_{Y \in G} \hom(Y, X)$. The set $A(X)$ is small (I 0) and $\operatorname{card}(J_G(X)) \leq 2^{\operatorname{card}(A(X))}$. Consequently $J_G(X)$ is small.

2) Let $R \in J(X)$. Put $A(R) = \coprod_{Y \in G} \operatorname{Hom}(Y, R)$, and let R' be the sieve of X generated by the family $(Y \xrightarrow{u} R \hookrightarrow X)$, $u \in A(R)$. One has $R' \subset R$, and it suffices to show that R' is covering. By axiom (T 2) of 1.1, it suffices to show that for every morphism $Z \to R$, $Z \in \operatorname{ob} C$, the sieve $R' \times_X Z$ of Z is covering. Now the sieve $R' \times_X Z$ contains the sieve generated by the family of all morphisms $Y \to Z$ with $Y \in G$, which is covering by hypothesis. Therefore the sieve $R' \times_X Z$ of Z is covering (axiom T2 of 1.1).

3) Let $R \in J_G(X)$. The family $(Y \xrightarrow{u} R)$, $u \in A(R) = \coprod_{Y \in G} \operatorname{Hom}(Y, R)$, is epimorphic by hypothesis. Now, for every $Y \in \operatorname{ob} C$, $\operatorname{Hom}(Y, R)$ is contained in $\operatorname{Hom}(Y, X)$, which is small. Consequently $A(R)$ is small.

3.0.5. Let C be a $\mathscr{U}$-site, $\mathscr{V}$ a universe such that $C \in \mathscr{V}$ and $\mathscr{U} \subset \mathscr{V}$, and G a $\mathscr{U}$-small topologically generating family of C. The category $\hat{C}$ of presheaves of $\mathscr{U}$-sets on C is a $\mathscr{V}$-category (I 1.1.1). Let X be an object of C. The set $J(X)$ of sieves covering X is $\mathscr{V}$-small and, ordered by inclusion, is cofiltered (1.1.1). For every $\mathscr{U}$-presheaf F, the inductive limit $\varinjlim_{J(X)} \operatorname{Hom}_{\hat{C}}(R, F)$ is therefore representable by an element of $\mathscr{V}$ (I 229

2.4.1). Moreover, it follows from (3.0.4 3)) that, for every $R \in J_G(X)$, $\mathrm{Hom}_{C^\wedge}(R, F)$ is $\mathscr{U}$-small, and since $J_G(X)$ is a $\mathscr{U}$-small set cofinal in $J(X)$ (*loc. cit.*), it follows from (I 2.4.2) that $\varinjlim_{J(X)} \mathrm{Hom}_{C^\wedge}(R, F)$ is $\mathscr{U}$-small. Choose, for every F and every X, an element of $\mathscr{U}$ representing this inductive limit, and put

$$LF(X) = \varinjlim_{J(X)} \mathrm{Hom}_{C^\wedge}(., F).$$

Let $g : Y \to X$ be a morphism of C. The base-change functor $g^* : J(X) \to J(Y)$ defines a map

$$LF(g) : LF(X) \longrightarrow LF(Y),$$

which makes $X \mapsto LF(X)$ a presheaf on C.

Since the morphism $\mathrm{id}_X : X \to X$ is an element of $J(X)$, for every object X of C one has a map

$$\ell(F)(X) : F(X) \longrightarrow LF(X),$$

which visibly defines a morphism of functors

$$\ell(F) : F \longrightarrow LF.$$

It is moreover clear that $F \mapsto LF$ is a functor in F and that the morphisms $\ell(F)$ define a morphism

$$\ell : \mathrm{Id} \longrightarrow L.$$

Finally, let $R \hookrightarrow X$ be a covering sieve of X. The definition of $LF(X)$ and (I 1.4) provide a map

$$Z_R : \mathrm{Hom}_{C^\wedge}(R, F) \longrightarrow \mathrm{Hom}_{C^\wedge}(X, LF),$$

230 and, for every morphism $Y \xrightarrow{g} X$ of C, the definition of the functor LF shows that the following diagram is commutative:

(∗)
$$\begin{array}{ccc} Z_R : & \mathrm{Hom}_{C^\wedge}(R, F) & \longrightarrow \mathrm{Hom}_{C^\wedge}(X, LF) \\ & \downarrow & \downarrow \\ Z_{R\times_X Y} : & \mathrm{Hom}_{C^\wedge}(R \times_X Y, F) & \longrightarrow \mathrm{Hom}_{C^\wedge}(Y, LF) \end{array}$$

(the vertical arrows are the evident arrows).
Let us now copy [2].

Lemma 3.1. 1) *For every covering sieve $i_R : R \hookrightarrow X$ and every $u : R \to F$, the diagram*

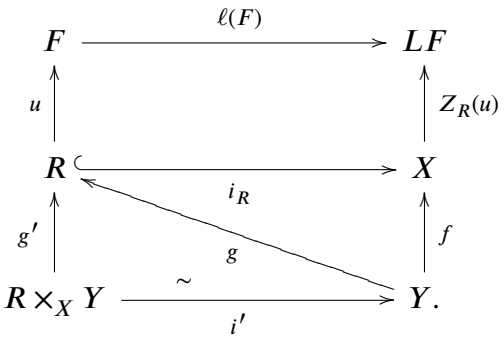
(∗∗)
$$\begin{array}{ccc} F & \xrightarrow{\ell(F)} & LF \\ {\scriptstyle u}\uparrow & & \uparrow{\scriptstyle Z_R(u)} \\ R & \xrightarrow[i_R]{} & X \end{array}$$

is commutative.

2) *For every morphism $v : X \to LF$, there exists a covering sieve R of X and a morphism $u : R \to F$ such that $Z_R(u) = v$.*
3) *Let Y be an object of C, and let $u, v : Y \rightrightarrows F$ be two morphisms such that $\ell(F) \circ u = \ell(F) \circ v$. Then the kernel of the pair (u, v) is a covering sieve of Y.*

4) *Let R, R' be two covering sieves of X, and let $u : R \to F$, $u' : R' \to F$ be two morphisms. For $Z_R(u) = Z_{R'}(u')$, it is necessary and sufficient that u and u' coincide on a covering sieve $R'' \hookrightarrow R \times_X R'$.*

PROOF. The only nontrivial assertion is assertion 1). We must show that $Z_R(u) \circ i_R = \ell(F) \circ u$. For this it suffices to show (I 3.4) that the composites of these morphisms with every morphism $Y \xrightarrow{g} R$ (Y an object of C) are equal. Consider $f = i_R \circ g$ and the fiber product $R \times_X Y$: 231



In the diagram above, i' is a monomorphism admitting a section. Consequently (1.3 3) i' is an isomorphism. By the definition of the morphism $\ell(F)$, the morphism $Z_{R\times_X Y}(u \circ g')$ is equal to $\ell(F) \circ u \circ g$. On the other hand, the commutativity of diagram (*) gives the equality $Z_{R\times_X Y}(u \circ g') = Z_R(u) \circ f$, and hence one indeed has $\ell(F) \circ u \circ g = Z_R(u) \circ i_R \circ g$.

PROPOSITION 3.2. 1) *The functor L is left exact* (I 2.3.2).

2) *For every presheaf F, LF is a separated presheaf.*

3) *The presheaf F is separated if and only if the morphism $\ell(F) : F \to LF$ is a monomorphism. The presheaf LF is then a sheaf.*

4) *The following properties are equivalent:*
   (i) *$\ell(F) : F \to LF$ is an isomorphism.*
   (ii) *F is a sheaf.*

PROOF. 1) It suffices to show (I 3.1) that, for every object X of C, the functor $F \mapsto LF(X)$ commutes with finite projective limits. By the definition of a projective limit, the functor

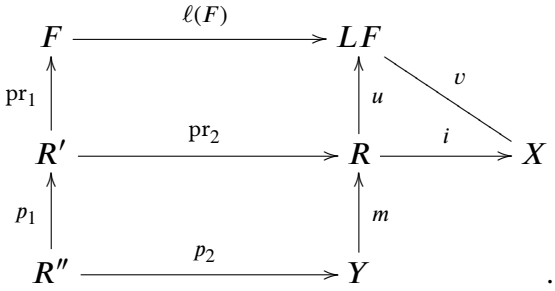
$$F \longmapsto \mathrm{Hom}_{\hat{C}}(R, F) \quad R \hookrightarrow X \in \mathrm{ob}(J(X))$$

commutes with projective limits, and the inductive limit $\varinjlim_{J(X)}$ commutes with finite projective limits because $J(X)$ is a cofiltered set (I 2.7). 232

2) Let X be an object of C, and let $f, g : X \rightrightarrows LF$ be two morphisms that coincide on a covering sieve $R \hookrightarrow X$ of X. By 3.1 2), there exists a covering sieve $R' \hookrightarrow X$, which may always be supposed contained in R, and two morphisms $u, v : R' \rightrightarrows F$ such that $Z_{R'}(u) = f$ and $Z_{R'}(v) = g$. By 3.1 1), one then has $\ell(F) \circ u = \ell(F) \circ v$. Consequently (3.1 4)) u and v coincide on a covering sieve $R'' \hookrightarrow R'$. Let w be the restriction of u to R''. One has $Z_{R''}(w) = Z_{R'}(u) = Z_{R'}(v)$, and consequently $f = g$. Thus the presheaf LF is separated.

3) If F is separated, the morphism $\ell(F)$ is a monomorphism because a filtered inductive limit of monomorphisms is a monomorphism. If $\ell(F)$ is a monomorphism, the presheaf F is a subpresheaf of a separated presheaf, and therefore is separated. Let us show that LF is then a sheaf. Let $i : R \hookrightarrow X$ be a sieve

covering an object X of C, and let $u : R \to LF$ be a morphism. It suffices to show that u factors through X. Put $R' = F \times_{LF} R$ and $v = Z_{R'}(\mathrm{pr}_1)$:



233 To show that $u = v \circ i$, it suffices to show (I 3.4) that for every morphism $m : Y \to R$ (Y an object of C), $v \circ i \circ m = u \circ m$. Put $R'' = Y \times_R R'$, and let p_1, p_2 be the projections. The projection $R'' \overset{p_2}{\hookrightarrow} Y$ is a monomorphism and makes R'' a covering sieve of Y (3.1 2)). One has $v \circ i \circ \mathrm{pr}_2 = \ell(F) \circ \mathrm{pr}_1$ (3.1 1)), and hence $v \circ i \circ \mathrm{pr}_2 = u \circ m \circ p_2$. It follows that $v \circ i \circ \mathrm{pr}_2 \circ p_1 = u \circ \mathrm{pr}_2 \circ p_1$, i.e. $v \circ i \circ m \circ p_2 = u \circ m \circ p_2$. Since the presheaf LF is separated, one has $v \circ i \circ m = u \circ m$, C.Q.F.D.

4) Clear.

Remark 3.3. Let $J'(X)$ be a cofinal subset of $J(X)$. One has

$$LF(X) = \varinjlim_{J'(X)} \mathrm{Hom}_{\hat{C}}(., F).$$

In particular, if the topology of C is defined by a pretopology $X \mapsto \mathrm{Cov}(X)$ (1.1.3), the functor L can be described using the covering families of $\mathrm{Cov}(X)$ (I 2.12 and I 3.5). Writing the formulas explicitly, one recovers the construction of [

Theorem 3.4. *Let C be a $\mathcal{U}$-site. The inclusion functor $i : \tilde{C} \hookrightarrow \hat{C}$ from sheaves into presheaves admits a left adjoint $\underline{a}$, which is left exact (I 2.3.2):*

$$\tilde{C} \underset{i}{\overset{\underline{a}}{\rightleftarrows}} \hat{C} \quad .$$

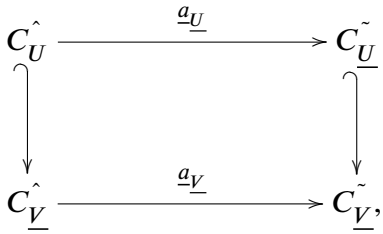
The functor $i \circ \underline{a}$ is canonically isomorphic to the functor $L \circ L$ (cf. 3.0.5). For every presheaf F, the adjunction morphism $F \to i \circ \underline{a}(F)$ is deduced, via the preceding isomorphism, from the morphism $\ell(LF)\ell(F) : F \to L \circ L(F)$.

234 Definition 3.5. *The sheaf $\underline{a}F$ is called the sheaf associated with the presheaf F.*

Theorem 3.4 follows immediately from Proposition 3.2.

Proposition 3.6. *Let C be a $\mathcal{U}$-site and let $\mathcal{V} \supset \mathcal{U}$ be a universe. Denote by $\hat{C}_{\mathcal{U}}$ and $\tilde{C}_{\mathcal{U}}$ (respectively $\hat{C}_{\mathcal{V}}$ and $\tilde{C}_{\mathcal{V}}$) the categories of $\mathcal{U}$-presheaves and $\mathcal{U}$-sheaves (respectively $\mathcal{V}$-presheaves and $\mathcal{V}$-sheaves), and $\underline{a}_{\mathcal{U}} : \hat{C}_{\mathcal{U}} \to \tilde{C}_{\mathcal{U}}$ (respectively $\underline{a}_{\mathcal{V}} : \hat{C}_{\mathcal{V}} \to \tilde{C}_{\mathcal{V}}$) the*

corresponding "associated sheaf" functors. The diagram



where the vertical functors are the canonical inclusions, is commutative up to canonical isomorphism.

PROOF. This follows from the construction of the functors $\underline{a}_U$ and $\underline{a}_V$ (3.4 and 3.0.5).

4. Exactness properties of the category of sheaves

The exactness properties of the category of sheaves follow from the exactness properties of the category of presheaves via Theorem 3.4. This section makes this philosophy explicit through some of the most useful standard statements.

THEOREM 4.1. *Let C be a $\mathscr{U}$-site, let $\widetilde{C}$ be the category of sheaves, let $\underline{a} : \hat{C} \to \widetilde{C}$ be the associated-sheaf functor, and let $i : \widetilde{C} \to \hat{C}$ be the inclusion functor.*

1) *The functor $\underline{a}$ commutes with inductive limits and is exact.*
2) *The $\mathscr{U}$-inductive limits in $\widetilde{C}$ are representable. For every small category I and* 235
   every functor $E : I \to \widetilde{C}$, the canonical morphism
$$\varinjlim_I E \longrightarrow \underline{a}(\varinjlim_I i \circ E)$$
   is an isomorphism.
3) *The $\mathscr{U}$-projective limits in $\widetilde{C}$ are representable. For every object X of C, the functor on $\widetilde{C}$: $F \mapsto F(X)$ commutes with projective limits, i.e. the inclusion functor $i : \widetilde{C} \to \hat{C}$ commutes with projective limits.*

PROOF. These properties follow essentially from Theorem 3.4 and from (I 2.11).

Thus, in the category of sheaves, products indexed by an element of $\mathscr{U}$, fiber products, sums indexed by an element of $\mathscr{U}$, amalgamated sums, kernels, cokernels, images, and coimages are representable.

COROLLARY 4.1.1. *Let C be a $\mathscr{U}$-site and let F be a sheaf of sets on C. The canonical homomorphism*
$$\varinjlim_{C/F} \underline{a}X \longrightarrow F$$
is an isomorphism.

PROOF. This follows from (I 3.4) and the fact that $\underline{a}$ commutes with inductive limits.

PROPOSITION 4.2. *Every morphism of $\widetilde{C}$ that is both an epimorphism and a monomorphism is an isomorphism.*

PROOF. Let $u : G \to H$ be a morphism of $\widetilde{C}$ that is both an epimorphism and a monomorphism. First observe that the morphism u is a monomorphism of presheaves 236
(4.1 1)). Construct the amalgamated sum $H \amalg_G H = K$ and the two canonical morphisms

$i_1, i_2 : H \rightrightarrows K$ in the category of presheaves. Since u is a monomorphism of presheaves, one immediately verifies that the following diagram is cartesian and cocartesian (I 10.1):

$$\begin{array}{ccc} G & \xrightarrow{u} & H \\ {\scriptstyle u}\downarrow & & \downarrow{\scriptstyle i_2} \\ H & \xrightarrow{i_1} & K. \end{array}$$

Applying the "associated sheaf" functor, one therefore obtains a cartesian and cocartesian diagram in the category of sheaves (4.1 1)):

$$(*) \qquad \begin{array}{ccc} G & \xrightarrow{u} & H \\ {\scriptstyle u}\downarrow & & \downarrow{\scriptstyle \underline{a}i_2} \\ H & \xrightarrow{\underline{a}i_1} & \underline{a}K. \end{array}$$

Since u is an epimorphism of sheaves, the morphism $\underline{a}i_1$ is an isomorphism, and since diagram (*) is cartesian, the morphism u is an isomorphism.

PROPOSITION 4.3. 1) *The inductive limits in $\tilde{C}$ that are representable are universal* (I 2.5).
2) *Every epimorphic family* (I 10.2) *of morphisms is universally effective epimorphic (2.6).*
3) *Every equivalence relation is universally effective* (I 10.6).
4) *Filtered $\mathscr{U}$-inductive limits commute with finite projective limits* (I 2.6).

237 PROOF. Assertions 1) through 4) hold in the category of sets, hence in the category of presheaves (I 3.1). Assertions 1) and 4) then follow immediately from the corresponding assertions for presheaves and from 4.1. Let us prove 3). Let $p_1, p_2 : R \rightrightarrows X$ be an equivalence relation in $\tilde{C}$. The diagram $R \overset{p_1}{\underset{p_2}{\rightrightarrows}} X$ is then an equivalence relation of presheaves (4.1.1). There is therefore a morphism of presheaves $u : X \to Y$ such that the diagram

$$\begin{array}{ccc} R & \xrightarrow{p_2} & X \\ {\scriptstyle p_1}\downarrow & & \downarrow{\scriptstyle u} \\ X & \xrightarrow{u} & Y \end{array}$$

is cartesian and cocartesian in the category of presheaves. Applying the "associated sheaf" functor, one obtains a cartesian and cocartesian diagram in the category of sheaves (4.1 1)). It follows that $R \overset{p_1}{\underset{p_2}{\rightrightarrows}} X$ is an effective equivalence relation. Since every equivalence relation is effective by what precedes, every equivalence relation is universally effective. Let us prove 2). Let $(u_i : X_i \to X)$, $i \in I$, be an epimorphic family in $\tilde{C}$. By (II 2.6) and (I 2.12), it suffices to prove the following assertions:

a) For every morphism of sheaves $v : Y \to X$, the family of morphisms $\mathrm{pr}_{2,i} : X_i \times_X Y \to Y$, $i \in I$, is an epimorphic family in $\tilde{C}$.

b) For every sheaf Z, the following diagram of sets is exact:

$$\mathrm{Hom}(X,Z) \to \prod_{i\in I} \mathrm{Hom}(X_i,Z) \rightrightarrows \prod_{(i,k)\in I\times I} \mathrm{Hom}(X_i \times_X X_k, Z)$$

Let X' be the union of the images of the morphisms u_i, formed in the category of presheaves, and let $j : X' \hookrightarrow X$ be the canonical injection. For every $i \in I$, the morphism $u_i : X_i \to X$ factors as a morphism $u'_i : X_i \to X'$ followed by j, and the family $u'_i : X_i \to X'$, $i \in I$, is an epimorphic family in $\hat{C}$. Since j is a monomorphism, the morphism $\underline{a}j : \underline{a}X' \to X$ is a monomorphism of sheaves (4.1). Since, for every $i \in I$, one has $u_i = \underline{a}j\underline{a}u'_i$, $\underline{a}j$ is an epimorphism of sheaves. It follows that $\underline{a}j$ is an isomorphism (4.2). Let $v : Y \to X$ be a morphism of sheaves. Base change then yields a morphism $j_v : X' \times_X Y \to Y$ and morphisms $u'_{i,v} : X_i \times_X Y \to X' \times_X Y$. Since $\underline{a}$ commutes with fiber products, $\underline{a}j_v$ is an isomorphism. Since epimorphic families in $\hat{C}$ remain epimorphic under base change, the family $u'_{i,v}$, $i \in I$, is epimorphic in $\hat{C}$. Since $\underline{a}$ commutes with inductive limits, the family $\underline{a}u'_{i,v} : X_i \times_X Y \to \underline{a}(X' \times_X Y)$, $i \in I$, is epimorphic in $\tilde{C}$, proving a). Let us prove b). Let Z be a sheaf. Since $\underline{a}j$ is an isomorphism, the map

$$\mathrm{Hom}(X,Z) \longrightarrow \mathrm{Hom}(X',Z)$$

is a bijection. Since the u'_i, $i \in I$, form an epimorphic family in $\hat{C}$, the following diagram of sets is exact:

$$\mathrm{Hom}(X',Z) \to \prod_{i\in I} \mathrm{Hom}(X_i,Z) \rightrightarrows \prod_{(i,k)\in I\times I} \mathrm{Hom}(X_i \times_{X'} X_k, Z)$$

Finally, since X' is a subpresheaf of X, the presheaf $X_i \times_{X'} X_k$, $(i,k) \in I \times I$, is canonically isomorphic to $X_i \times_X X_k$, proving b).

Remarks 4.3.1. 1) Proposition 4.3 2) formally gives us a second proof of 4.2: it is clear that, in any category, a morphism that is both a universal effective epimorphism and a monomorphism is in fact an isomorphism.

2) It follows from the preceding propositions that every morphism in the category of sheaves factors uniquely as an effective epimorphism followed by an effective monomorphism. This property naturally generalizes, to nonadditive categories, axiom (AB2) for abelian categories (coim $\simeq$ im) [Tohoku].

4.4.0. Let C be a $\mathscr{U}$-site. Composing the functor $h : C \to \hat{C}$ (I 1.3.1) with the associated sheaf functor yields a functor

$$\epsilon_C : C \longrightarrow \tilde{C},$$

called the *canonical functor* from C to $\tilde{C}$, which will be used constantly in what follows. The functor ϵ_C commutes with finite projective limits. When the topology on C is coarser than the canonical topology, ϵ_C is fully faithful and commutes with projective limits; moreover, it is then defined even when C is not assumed to possess a small topologically generating family. We shall not study in detail the behavior of ϵ_C with respect to inductive limits (cf. [SGA 3 IV]). We shall, however, need the results below.

Theorem 4.4. *Let C be a $\mathscr{U}$-site and let $(u_i : X_i \to X)$, $i \in I$, be a family of morphisms of C with target X. The following conditions are equivalent* [4]*:*

i) *The family $(\epsilon_C u_i : \epsilon_C X_i \to \epsilon_C X)$, $i \in I$, is an epimorphic family in $\tilde{C}$* (I 10.2).

[4] When the site C does not necessarily possess a small topologically generating family and when the topology on C is coarser than the canonical topology, one has ii) $\Rightarrow$ i) (cf. the proof of 4.4).

ii) *The family* $(u_i : X_i \to X)$, $i \in I$, *is a covering family of* C *(1.2).*

PROOF. ii) $\Rightarrow$ i). Let $R \hookrightarrow X$ be the sieve generated by the u_i, $i \in I$ (I 4.3.3), and let $u_i' : X_i \to R$ be the morphisms induced by the u_i. The morphisms u_i', $i \in I$, form an epimorphic family in $\hat{C}$, and R is a covering sieve of X. Consequently, for every sheaf F, the map

$$\mathrm{Hom}(X, F) \longrightarrow \mathrm{Hom}(R, F)$$

is bijective, and the map

$$\mathrm{Hom}(R, F) \longrightarrow \prod_i \mathrm{Hom}(X_i, F)$$

is injective. Thus the map

$$\mathrm{Hom}(X, F) \longrightarrow \prod_i \mathrm{Hom}(X_i, F)$$

is injective, and consequently the map

$$\mathrm{Hom}(\underline{a}X, F) \longrightarrow \prod_i \mathrm{Hom}(\underline{a}X_i, F)$$

is injective, which proves i).
i) $\Rightarrow$ ii). With the notation introduced above, let $J_R : R \hookrightarrow X$ be the canonical inclusion into X of the sieve generated by the u_i, $i \in I$. It follows from i) that the morphism of sheaves $\underline{a}J_R : \underline{a}R \to \underline{a}X$ is both an epimorphism and a monomorphism in the category of sheaves. It is therefore an isomorphism of sheaves (4.2). With the notation of n° 3, we have a commutative diagram:

$$\begin{array}{ccccc} X & \xrightarrow{\ell(X)} & LX & \xrightarrow{\ell(LX)} & \underline{a}X \\ \uparrow{\scriptstyle J_R} & & \uparrow{\scriptstyle LJ_R} & & \uparrow{\scriptstyle \wr}{\scriptstyle \underline{a}J_R} \\ R & \xrightarrow{\ell(R)} & LR & \xrightarrow{\ell(LR)} & \underline{a}R. \end{array}$$

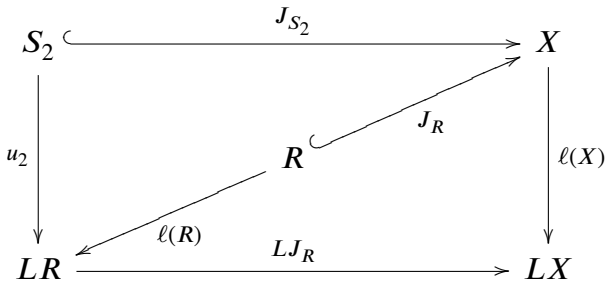
241 First of all, by 3.1 2), there exist a covering sieve $J_{S_1} : S_1 \to X$ and a morphism $u_1 : S_1 \to LR$ such that

$$\ell(LX) \circ \ell(X) \circ J_{S_1} = \underline{a}J_R \circ \ell(LR) \circ u_1 = \ell(LX) \circ LJ_R \circ u_1. \tag{4.6.1}$$

Put $m = \ell(X) \circ J_{S_1}$ and $n = LJ_R \circ u_1$. The morphisms m and n are morphisms from S_1 to LX. Let $S_2 \hookrightarrow S_1$ be the kernel of the pair of arrows (m, n). For every object Y of C and every morphism $\alpha : Y \to S_1$, one has, by 4.6.1, $\ell(LX) \circ m \circ \alpha = \ell(LX) \circ n \circ \alpha$. It then follows from (3.1 3)) that the kernel $S_2 \times_{S_1} Y$ of the pair of arrows $(m \circ \alpha, n \circ \alpha)$ is a covering sieve of Y. Consequently, by axiom (T 2) for topologies, $J_{S_2} : S_2 \hookrightarrow X$ is a covering sieve of X. Thus there is a morphism $u_2 : S_2 \to LR$ and a commutative

diagram:

(4.6.2)

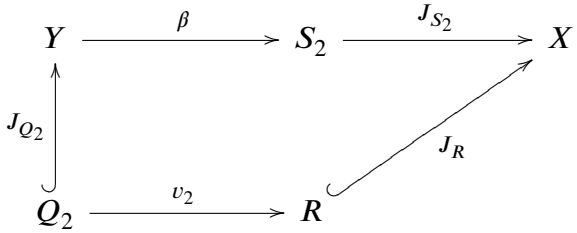


.

Let Y be an object of C and let $\beta : Y \to S_2$ be a morphism. By 3.1 2) and 1), there exist a covering sieve $J_{Q_1} : Q_1 \hookrightarrow Y$ and a morphism $v_1 : Q_1 \to R$ such that $u_2 \circ \beta \circ J_{Q_1} = \ell(R) \circ v_1$. Put $f = J_{S_2} \circ \beta \circ J_{Q_1}$ and $g = J_R \circ v_1$. Let Q_2 be the kernel of the pair $(f, g) : Q_1 \rightrightarrows X$, and let $J_{Q_2} : Q_2 \hookrightarrow Y$ be the canonical inclusion. For every object Z of C and every morphism $\gamma : Z \to Q_1$, the commutativity of (4.6.2) gives:

$$\ell(X) \circ f \circ \gamma = \ell(X) \circ J_{S_2} \circ \beta \circ J_{Q_1} \circ \gamma = LJ_R \circ u_2 \circ \beta \circ J_{Q_1} \circ \gamma =$$
$$= LJ_R \circ \ell(R) \circ v_1 \circ \gamma = \ell(X) \circ J_R \circ v_1 \circ \gamma = \ell(X) \circ g \circ \gamma.$$

It then follows from 3.1 3) that the kernel $Q_2 \times_{Q_1} Z$ of the pair $(f \circ \gamma, g \circ \gamma)$ is a covering sieve of Z. By axiom (T 2) for topologies, $J_{Q_2} : Q_2 \hookrightarrow Y$ is a covering sieve of Y. Thus, for every morphism $\beta : Y \to S_2$, there exist a covering sieve $J_{Q_2} : Q_2 \hookrightarrow Y$ and a morphism $v_2 : Q_2 \to R$ such that the following diagram is commutative: 242



Denote by $S_2 \cap R$ the fiber product of S_2 and R over X. The sieve (of Y) $(S_2 \cap R) \times_{S_2} Y$ contains the sieve Q_2, and hence $(S_2 \cap R) \times_{S_2} Y$ is a covering sieve of Y. It then follows from axiom (T 2) for topologies that $S_2 \cap R$ is a covering sieve of X, and consequently the sieve R, which contains $S_2 \cap R$, is a covering sieve of X, C.Q.F.D.

Corollary 4.4.4. *Let T be the topology of the $\mathcal{U}$-site C, and let T' (resp. T'') be the finest topology on C among those for which the objects of $\widetilde{C}$ are sheaves* (resp. separated presheaves) *(2.2). Then $T = T' = T''$.*

Indeed, one trivially has $T \leq T' \leq T''$, and 4.4 and 2.2 imply that $T'' \leq T$, C.Q.F.D.

Definition 4.5. *An initial object of a category A is an object ϕ_A that represents the empty inductive limit, i.e. such that, for every $X \in$ ob A, there exists a unique arrow $\phi_A \to X$. An object ϕ_A is called* strict initial *if it is initial and every morphism with target ϕ_A is an isomorphism. Let (S_i), $i \in I$, be a family of objects of a category A. Suppose that the sum $S = \coprod_{i \in I} S_i$ is representable. The sum S is called disjoint if the structure morphisms $S_i \to S$ are pullbackable, if they are monomorphisms, and if, for every pair i, j with $i \neq j$, the fiber product $S_i \times_S S_j$ is an initial object of A. The sum S is called disjoint and universal if it is disjoint and remains a disjoint sum after every base change $T \to S$; it follows that, for every pair i, j with $i \neq j$, the objects $S_i \times_S S_j$ are strict initial objects of A.* 243

EXAMPLE 4.5.1. In the category of sets, sums are disjoint and universal. The same is therefore true in every category of presheaves of sets (I 3.1), and hence in every category of sheaves of sets on a $\mathscr{U}$-site (4.1); in particular, the initial object of $\tilde{C}$ is strict.

PROPOSITION 4.6. *Let C be a $\mathscr{U}$-category and let $(s_i : X_i \to X)$, $i \in I$, be a family of morphisms of C. For every $\mathscr{U}$-topology $\mathscr{T}$ on C (3.0.2), denote by $\tilde{C}_{\mathscr{T}}$ the corresponding category of sheaves and by $\epsilon_{\mathscr{T}} : C \to \tilde{C}_{\mathscr{T}}$ the corresponding functor.*

1) *Let $\mathscr{T}$ be a $\mathscr{U}$-topology such that*

$$\coprod_{i\in I} \epsilon_{\mathscr{T}}(X_i) \xrightarrow{(\epsilon_{\mathscr{T}}(s_i))} \epsilon_{\mathscr{T}}(X)$$

is an isomorphism. Then, for every topology $\mathscr{T}'$ finer than $\mathscr{T}$, the morphism

$$\coprod_{i\in I} \epsilon_{\mathscr{T}'}(X_i) \xrightarrow{(\epsilon_{\mathscr{T}'}(s_i))} \epsilon_{\mathscr{T}'}(X)$$

is an isomorphism.

2) *Let $\mathscr{T}$ be a $\mathscr{U}$-topology on C. The following properties* (i) *and* (ii) *are equivalent:*

i) a) *The family $(s_i : X_i \to X)$, $i \in I$, is covering for $\mathscr{T}$.*

b) *For every $i \in I$, the diagonal morphism of presheaves $\Delta_i : X_i \hookrightarrow X_i \times_X X_i$ is sent by the associated sheaf functor (for $\mathscr{T}$) to an isomorphism (as* 244 *is the case if the s_i are monomorphisms).*

c) *For every pair (i, j) of elements of I with $i \neq j$, the presheaf $X_i \times_X X_j$ is sent by the associated sheaf functor (for $\mathscr{T}$) to the initial object of $\tilde{C}_{\mathscr{T}}$.*

ii) *$\epsilon_{\mathscr{T}}(X)$ is the sum of the $\epsilon_{\mathscr{T}}(X_i)$.*

PROOF. 1) A sheaf for $\mathscr{T}'$ is a sheaf for $\mathscr{T}$. Consequently, for every sheaf F for $\mathscr{T}'$, the morphism

$$\mathrm{Hom}_{\hat{C}}(X, F) \longrightarrow \prod_{i\in I} \mathrm{Hom}_{\hat{C}}(X_i, F)$$

is an isomorphism, which proves the assertion.

2) By definition, property ii) holds if and only if the morphism of presheaves

$$\Phi = (h(s_i), i \in I) : \coprod_i h(X_i) \longrightarrow h(X)$$

is sent by the associated sheaf functor to an isomorphism, i.e. (4.2) if and only if $\underline{a}(\Phi)$ is both an epimorphism and a monomorphism of sheaves. By (4.4), the morphism $\underline{a}(\Phi)$ is an epimorphism if and only if property a) holds. The diagonal morphism

$$\Delta : \coprod_i h(X_i) \longrightarrow (\coprod_i h(X_i)) \times_{h(X)} (\coprod_i h(X_i))$$

is the direct sum of a family $\Delta_{i,j}$, $(i, j) \in I \times I$, of morphisms defined as follows:

β) When $i = j$, $\Delta_{i,i}$ is the diagonal morphism $h(X_i) \to h(X_i) \times_{h(X)} h(X_i)$.

γ) When $i \neq j$, $\Delta_{i,j}$ is the morphism $\phi_{\hat{C}} \to h(X_i) \times_{h(X)} h(X_j)$ ($\phi_{\hat{C}}$ denotes the initial object of $\hat{C}$).

245 The morphism $\underline{a}(\Phi)$ is a monomorphism if and only if $\underline{a}(\Delta)$ is an isomorphism, and by (4.1) $\underline{a}(\Delta)$ is an isomorphism if and only if the $\underline{a}(\Delta_{i,j})$ are isomorphisms, i.e. if and only if properties b) and c) hold.

COROLLARY 4.6.1. *Let C be a $\mathcal{U}$-category and X an object of C.*

1) *Let $\mathcal{T}$ be a $\mathcal{U}$-topology on C. The object X of C is sent by the associated sheaf functor (for the topology $\mathcal{T}$) to the initial object of $\tilde{C}_{\mathcal{T}}$ if and only if the empty sieve covers X.*
2) *When X is a strict initial object of C, the sheaf associated with X, for every $\mathcal{U}$-topology finer than the canonical topology, is an initial object.*

PROOF. 1) Take the indexing set I in 4.6 2) to be the empty set.
2) By 1) and 4.6 1), it is enough to show that the empty sieve covers X for the canonical topology; i.e. by (2.6), it is enough to show that, for every object $Y \to X$ over X, Y is an initial object of C, which follows from the definition (4.5).

COROLLARY 4.6.2. *Let C be a $\mathcal{U}$-site and let $(s_i : X_i \to X)$, $i \in I$, be a family of pullbackable morphisms of C with the same target and having the following properties:*

α) The family of the s_i, $i \in I$, is covering.
β) For every $i \in I$, $s_i : X_i \to X$ is a monomorphism.
γ) For every pair (i, j) of elements of I with $i \neq j$, $X_i \times_X X_j$ is covered by the empty sieve, i.e. for every sheaf F on C, $F(X_i \times_X X_j)$ is a singleton set.

Then $\epsilon_C(X)$ is the sum of the $\epsilon_C(X_i)$, $i \in I$.

PROOF. This follows immediately from 4.6 2) and 4.6.1 1). 246

COROLLARY 4.6.3. *Let C be a $\mathcal{U}$-category and let $(s_i : X_i \to X)$, $i \in I$, be a family of pullbackable morphisms with the same target. Suppose that the canonical topology of C is a $\mathcal{U}$-topology. The following conditions are equivalent:*

i) *There exists a $\mathcal{U}$-topology $\mathcal{T}$ on C, coarser than the canonical topology, such that $\epsilon_{\mathcal{T}}(X)$ is the sum of the $\epsilon_{\mathcal{T}}(X_i)$, $i \in I$.*
ii) *The object X is the disjoint and universal sum (4.5) (in C) of the X_i.*

PROOF. ii) $\Rightarrow$ i). Since X is the universal sum of the X_i, $i \in I$, the family of the s_i, $i \in I$, is covering for the canonical topology of C (2.6). Condition α) of 4.6.2 is therefore satisfied when C is endowed with the canonical topology. Condition β) is evidently satisfied, and property γ) follows from 4.6 1) 2), whence i).
i) $\Rightarrow$ ii). Let $\mathcal{T}$ be a topology on C coarser than the canonical topology such that $\epsilon_{\mathcal{T}}(X)$ is the sum of the $\epsilon_{\mathcal{T}}(X_i)$. For every sheaf F for $\mathcal{T}$, the canonical map $\mathrm{Hom}(X, F) \to \prod_i \mathrm{Hom}(X_i, F)$ is a bijection. Moreover, every representable presheaf is a sheaf. It follows immediately that X is the sum in C of the X_i, $i \in I$. Applying this to the case where the set I is empty, one sees that if an object of C is carried to the initial object of $\tilde{C}$, that object is an initial object of C. The functor $\epsilon_{\mathcal{T}} : C \to \tilde{C}$ is fully faithful and commutes with finite projective limits. Consequently, condition b) of 4.6.2 implies that the s_i, $i \in I$, are monomorphisms of C, and condition c) implies, by what precedes, that the $X_i \times_X X_j$, $i \neq j$, are initial objects of C. Consequently X is the disjoint sum of the X_i. Since $\epsilon_{\mathcal{T}}$ commutes with fiber products, this last property is stable under every base 247
change $Y \to X$, and therefore X is the disjoint and universal sum of the X_i, $i \in I$.

COROLLARY 4.6.4. *Let C be a $\mathcal{U}$-category and X an object of C. Suppose that the canonical topology on C is a $\mathcal{U}$-topology. The following properties are equivalent:*

i) *There exists on C a topology coarser than the canonical topology such that $\epsilon_{\mathcal{T}}(X)$ is an initial object of $\tilde{C}_{\mathcal{T}}$.*
ii) *X is a strict initial object of C.*

PROOF. Take the empty set for the set I in 4.6.3.

PROPOSITION 4.7. *Let C be a $\mathscr{U}$-category, let $\tilde{C}$ be the category of sheaves on C for the canonical topology, let $\epsilon_C : C \to \tilde{C}$ be the canonical functor (4.4.0), and let $R \rightrightarrows X$ be an equivalence relation in C admitting a cokernel Y in C. Let $\Pi : X \to Y$ be the canonical morphism and suppose it is pullbackable. Consider the following properties:*

i) *$\epsilon_C(Y)$ is the quotient of the equivalence relation $\epsilon_C(R) \rightrightarrows \epsilon_C(X)$.*
ii) *The equivalence relation $R \rightrightarrows X$ is universally effective* (cf. n° 7).

One has ii) ⇒ i). *When C possesses a $\mathscr{U}$-topology coarser than the canonical topology, one has* i) ⇒ ii).

PROOF. ii) ⇒ i). The canonical morphism $R \to X \times_Y X$ is an isomorphism. Let $S \to Y$ be the sieve generated by $\pi : X \to Y$. For every presheaf F, there is an exact diagram (I 2.12):

$$\mathrm{Hom}(S, F) \to \mathrm{Hom}(X, F) \rightrightarrows \mathrm{Hom}(R, F).$$

248 It therefore suffices to show that, for every sheaf F for the canonical topology, the map

$$\mathrm{Hom}(X, F) \longrightarrow \mathrm{Hom}(S, F)$$

is a bijection, i.e. it suffices to show that S is covering for the canonical topology, or equivalently that the sieve generated by $\pi : X \to Y$ is covering, which follows from Definition 2.5.
i) ⇒ ii). The functor $\epsilon_C : C \to \tilde{C}$ commutes with finite projective limits and is fully faithful. The canonical morphism $\epsilon_C(R) \to J_C(X) \times_{J_C(Y)} J_C(X)$ is an isomorphism (4.3). Consequently the canonical morphism $R \to X \times_Y X$ is an isomorphism. The morphism $\epsilon_C(X) \to \epsilon_C(Y)$ is an epimorphism, which implies (4.4) that $\pi : X \to Y$ is a covering morphism of C for the canonical topology, C.Q.F.D.

PROPOSITION 4.8. *Let C be a $\mathscr{U}$-site. The category of sheaves on C has the following properties:*

a) *Finite projective limits are representable.*
b) *Direct sums indexed by an element of $\mathscr{U}$ are representable. They are disjoint and universal (4.5).*
c) *Equivalence relations are universally effective.*

This was proved in 4.1, 2) and 3), 4.3, 3), and 4.5.1.

These properties have been singled out because they will later allow us to characterize the $\mathscr{U}$-categories equivalent to categories of sheaves on categories belonging to $\mathscr{U}$ (IV 1.2).

REMARK. Recall that property a) is equivalent to the property:
There exists a terminal object, and fiber products are representable (I 2.3.1).

249 **4.9.** Let C be a site whose underlying category is a $\mathscr{U}$-category. Then the category $\widetilde{C}$ of $\mathscr{U}$-sheaves on C satisfies the conditions considered in I 7.3 ((i) or (ii), as desired), and therefore, by *loc. cit.*, the various variants of the notion of a *generating family* in $\widetilde{C}$ considered in I 7.1 coincide. This being understood:

PROPOSITION 4.10. *With the preceding notation, consider the canonical functor $\epsilon : C \to \widetilde{C}$ (4.4.0), and let $G \subset \mathrm{ob}\, C$ be a topologically generating family in C (3.0.1). Then the family $(\epsilon(X))_{X \in G}$ of objects of $\widetilde{C}$ is a generating family. In particular, the family $(\epsilon(X))_{X \in \mathrm{ob}\, C}$ of objects of $\widetilde{C}$ is generating.*

We must prove that every morphism $u : F \to F'$ in $\widetilde{C}$ such that

$$\mathrm{Hom}(\epsilon(X), F) \longrightarrow \mathrm{Hom}(\epsilon(X), F') \tag{4.10.1}$$

is a bijection for every $X \in G$, is an isomorphism. The preceding map identifies with the map

$$u(X) : F(X) \longrightarrow F'(X), \tag{4.10.2}$$

and we must show that if the latter is bijective for every $X \in G$, then it is so for every $X \in \mathrm{ob}\, C$. Let $(X_i \to X)_{i\in I}$ be a covering family of X by objects of G, and, for every pair of indices (i, j) in I, consider the set of all morphisms $X_{ijk} \to X_i \times_X X_j$ in $\hat{C}$, with $X_{ijk} \in G$ (k varying in an index set $I_{i,j}$). One then obtains a morphism of exact diagrams of sets

$$\begin{array}{ccccc} F(X) & \longrightarrow & \prod_i F(X_i) & \rightrightarrows & \prod_{ijk} F(X_{ijk}) \\ \downarrow & & \downarrow\wr & & \downarrow\wr \\ F'(X) & \longrightarrow & \prod_i F'(X_i) & \rightrightarrows & \prod_{ijk} F'(X_{ijk}) \end{array} ,$$

where , by hypothesis, the last two vertical arrows are bijections. The same is therefore true of the first vertical arrow, C.Q.F.D. 250

Corollary 4.11. *Suppose that C is a $\mathcal{U}$-site (3.0.2). Then the category $\widetilde{C}$ is a $\mathcal{U}$-category and admits a $\mathcal{U}$-small generating family.*

Indeed, by hypothesis one may take for G in 4.10 a small generating family, which proves the existence of a small generating family. On the other hand, if $F, F' \in \mathrm{ob}\, \widetilde{C}$, a morphism from F to F' is known once one knows the morphism (4.10.1), i.e. (4.10.2), for every $X \in \mathrm{ob}\, G$ (I 7.1.1), whence the map

$$\mathrm{Hom}(F, F') \longrightarrow \prod_{X\in G} \mathrm{Hom}(F(X), F'(X))$$

is injective. Since the second member is $\mathcal{U}$-small, so is the first, which proves that $\widetilde{C}$ is a $\mathcal{U}$-category.

Corollary 4.12. *Let C be a $\mathcal{U}$-site. Then, for every object X of $\widetilde{C}$, the set of subobjects of X and the set of quotient objects of X are $\mathcal{U}$-small.*

This follows from I 7.4, respectively I 7.5, which apply by 4.11.

5. Extension of a topology from C to $\hat{C}$

Proposition 5.1. *Let C be a $\mathcal{U}$-site and let $f : H \to K$ be a morphism of $\hat{C}$. The following conditions are equivalent:*

i) *For every $X \to K$, with $X \in \mathrm{ob}\, C$, the image of the corresponding morphism $H \times_K X \to X$ is a covering sieve of X.*

ii) *The morphism $\underline{a}(f) : \underline{a}H \to \underline{a}K$ between the associated sheaves is an epimorphism in $\tilde{C}$.* 251

ii bis) *For every sheaf F on C, the map $\mathrm{Hom}(K, F) \to \mathrm{Hom}(H, F)$ induced by f is injective.*

Proof. It is clear that ii) is equivalent to ii bis).

Let us prove that (ii) ⇒ (i). By 4.4, (i) means that $u : \underline{a}(H \times_K X) \to \underline{a}(X)$ is an epimorphism. Now, since $\underline{a}(H \times_K X) \simeq \underline{a}(H) \times_{\underline{a}(K)} \underline{a}(X)$, because $\underline{a}$ commutes with finite $\varprojlim$ (4.1), the morphism in question is obtained from $\underline{a}(f) : \underline{a}(H) \to \underline{a}(K)$ by base change. Since the epimorphisms of $\widetilde{C}$ are universal, this proves (ii) ⇒ (i). Conversely, since the family of all $X_i \to K$, with $X_i \in \mathrm{ob}\, C$, is epimorphic, the same is true of the family of $\underline{a}(X_i) \to \underline{a}(K)$ in $\widetilde{C}$ (4.1). Hence, to verify that $\underline{a}(f) : \underline{a}(H) \to \underline{a}(K)$ is epimorphic, it suffices to do so after every base change of the preceding kind $\underline{a}(X_i) \to \underline{a}(K)$, which proves i) ⇒ ii), C.Q.F.D.

Definition 5.2. 1) *A morphism $f : H \to K$ satisfying the three equivalent conditions of 5.1 is called a* covering morphism. *A family of morphisms $f_i : H_i \to K$, $i \in I$, with the same target is called* covering *if the corresponding morphism $f : \coprod_i H_i \to K$ is covering.*

2) *A morphism $f : H \to K$ is called* bicovering *if it is covering and if the diagonal morphism $H \to H \times_K H$ is covering. A family $f_i : H_i \to K$, $i \in I$, with the same target is called bicovering if the corresponding morphism $f : \coprod_i H_i \to K$ is bicovering.*

By condition i) of 5.1, to say that a family $(f_i : H_i \to K)$, $i \in I$, is covering means that, for every morphism $X \to K$, with $X \in \mathrm{ob}\, C$, the image of the family $H_i \times_K X \to X$,
252 $i \in I$, is a covering sieve of X; or equivalently, by ii), that the family of morphisms $\underline{a}(f_i) : \underline{a}H_i \to \underline{a}K$ in $\tilde{C}$ is epimorphic (taking into account that the functor $\underline{a}$ commutes with direct sums (4.1)).[4]

Proposition 5.3. *Let C be a $\mathscr{U}$-site and let $f : H \to K$ be a morphism of $\hat{C}$. The following conditions are equivalent:*

i) *The morphism f is bicovering (5.2).*

i bis) *The morphism f is covering and, for every object X of C and every pair of morphisms $u, v : X \rightrightarrows H$ such that $fu = fv$, the kernel of (u, v) is a covering sieve of X.*

ii) *The morphism $\underline{a}(f) : \underline{a}H \to \underline{a}K$ is an isomorphism in $\tilde{C}$.*

ii bis) *For every sheaf F on C, the map $\mathrm{Hom}(K, F) \to \mathrm{Hom}(H, F)$ is a bijection.*

Proof. The equivalence i) ⇔ i bis) follows from condition i) of 5.1, applied to the diagonal morphism $H \to H \times_K H$; the equivalence ii) ⇔ ii bis) is trivial.
i) ⇒ ii). The morphism $\underline{a}(f) : \underline{a}H \to \underline{a}K$ is an epimorphism (5.1). Since the functor $\underline{a}$ commutes with the formation of fiber products (4.1), the diagonal morphism $\underline{a}H \to \underline{a}H \times_{\underline{a}K} \underline{a}H$ is an epimorphism (5.1). Since a diagonal morphism is always a monomorphism, it is an isomorphism (4.2). It follows that the morphism $\underline{a}(f)$ is a monomorphism. It is therefore an isomorphism (4.2).
ii) ⇒ i). Since the functor $\underline{a}$ commutes with the formation of fiber products, the morphism f and the diagonal morphism $H \to H \times_K H$ are carried by $\underline{a}$ to isomorphisms. In particular, they are carried by $\underline{a}$ to epimorphisms. They are therefore covering, C.Q.F.D.

253 5.3.1. It follows from 5.3, and from the fact that $\underline{a}$ commutes with direct sums, that a family $(f_i : H_i \to K)$, $i \in I$, of morphisms of $\hat{C}$ is bicovering if and only if the f_i induce an isomorphism from the direct sum $\coprod_i \underline{a}H_i$ onto $\underline{a}K$ on the associated sheaves,

[4] Note that the property of a morphism or a family of morphisms of $\hat{C}$ being covering (resp. bicovering) is stable under base change.

or equivalently if and only if, for every sheaf F, the map

$$\mathrm{Hom}(K, F) \longrightarrow \prod_i \mathrm{Hom}(H_i, F)$$

is bijective.

PROPOSITION 5.4. *Let C be a $\mathscr{U}$-site. There exists a (necessarily unique) topology on $\hat{C}$ such that a family $H_i \to K$ of arrows of $\hat{C}$ with the same target is covering for this topology if and only if it is covering in the sense of 5.2. It is also the coarsest topology on $\hat{C}$ among the topologies T having the following properties:*

a) *T is finer than the canonical topology of $\hat{C}$ (i.e. every epimorphic family in $\hat{C}$ is covering for T).*
b) *Every covering family in C is covering in $\hat{C}$.*

PROOF. We shall confine ourselves to giving indications. We leave it to the reader to show that the families which are covering in the sense of 5.2 are the covering families of a topology T_C on $\hat{C}$ (one uses 4.1). The covering families of the canonical topology on $\hat{C}$ are the epimorphic families in $\hat{C}$ (2.6 and I 3.1). Since $\underline{a}$ commutes with inductive limits (4.1), the topology T_C is finer than the canonical topology of $\hat{C}$. Moreover, the covering families of C are covering families for T_C (5.1). Thus, if T' denotes the coarsest topology on $\hat{C}$ having properties a) and b), T_C is finer than T'. Let $(f_i : H_i \to K)$, $i \in I$, be a covering family for T_C. We show that $(f_i, i \in I)$ is a covering family for T'. 254
Let $s_i : H_i \to H = \coprod_i H_i$ be the canonical monomorphisms, and let $f = (f_i, i \in I) : H = \coprod_i H_i \to K$ be the morphism defined by the f_i. The family of the s_i is covering for T'. Thus, by axiom (T 2) for topologies, to show that $(f_i, i \in I)$ is a covering family for T', it suffices to show that the morphism $f : H \to K$ is covering for T'. There exists an epimorphic family in $\hat{C}$, $u_\lambda : X_\lambda \to K$, $\lambda \in \Lambda$, with $X_\lambda \in \mathrm{ob}\, C$ (I 3.4). Therefore, again by axiom (T 2) for topologies, to show that $f : H \to K$ is covering for T', it suffices to show that, for every $\lambda \in \Lambda$, the morphism $\mathrm{pr}_2 : H \times_K X_\lambda \to X_\lambda$ is covering for T'. Let $v_j : Y_j \to H \times_K X_\lambda$, $j \in J$, with $Y_j \in \mathrm{ob}\, C$, be an epimorphic family in $\hat{C}$. The family $(\mathrm{pr}_2 \circ v_j, j \in J)$ is covering for T_C. It is therefore a covering family in C (5.1), and hence a covering family for T'. Consequently, the sieve generated by $\mathrm{pr}_2 : H \times_K X_\lambda \to X_\lambda$ contains a covering sieve for T'. It is therefore covering for T', and hence $\mathrm{pr}_2 : H \times_K X_\lambda \to X_\lambda$ is covering, C.Q.F.D.

REMARK 5.4.1. The proof of 5.4 in fact shows that every topology T' on $\hat{C}$ which is finer than the canonical topology of $\hat{C}$ is the coarsest of the topologies T on $\hat{C}$ having the following properties:

a) T is finer than the canonical topology of $\hat{C}$.
b) Every family covering for T' of the form $u_i : X_i \to X$, $i \in I$, where X and the X_i are objects of C, is covering for T.

In particular, every topology T' on $\hat{C}$ which is finer than the canonical topology is uniquely determined by the families $u_i : X_i \to X$, $i \in I$, with X_i and X objects of C, which are covering for T'.

REMARK 5.4.2. It is easy to show that, for every topology T' on $\hat{C}$ which is finer 255
than the canonical topology, the set of families of morphisms $(X_i \to X)$, $i \in I$, with the same target in C, which are covering for T' is the set of covering families of a topology on C. Thus 5.4 and 5.4.1 establish a one-to-one correspondence between the topologies on C and the topologies on $\hat{C}$ finer than the canonical topology.

5.5.0. Let C be a small category. Denote by Caf the set of strictly full subcategories (every object isomorphic to an object of the subcategory is an object of the subcategory) of $\hat{C}$ whose inclusion functor admits a left adjoint which commutes with finite projective limits. Also denote by $\mathscr{T}$ the set of topologies on C. Theorem 3.4 defines a map

$$\Phi : \mathscr{T} \longrightarrow \text{Caf}\, quoi.$$

We shall define a map in the opposite direction. For this purpose, to every element $e = i' : C' \underset{\longrightarrow}{\overset{a'}{\leftarrow}} \hat{C}$ of Caf, with $\underline{a}'$ left adjoint to i', we must associate a topology T_e on C. For every object X of C, define $J_e(X)$ to be the set of subobjects of X whose inclusion morphism is carried by $\underline{a}'$ to an isomorphism. Using the hypotheses made on $\underline{a}'$, one verifies immediately that this defines a topology T_e on C. We have therefore defined a map

$$\Psi : \text{Caf} \longrightarrow \mathscr{T}\, quoi.$$

We then have the following result (due to J. GIRAUD):

256 THEOREM 5.5. *The map Φ is a bijection, and Ψ is its inverse.*

PROOF. The map $\Psi \circ \Phi$ is the identity. Indeed, this follows immediately from 5.1. The map $\Phi \circ \Psi$ is the identity. Indeed, let $i' : C' \underset{\longrightarrow}{\overset{\underline{a}'}{\leftarrow}} \hat{C}$ be an element of Caf, let T_e be the topology corresponding to it under Ψ, and let C_e be the category of sheaves for T_e. Using the definition of the topology T_e and the definition of bicovering morphisms (5.2), one proves that the following assertions are equivalent:

i) The morphism u of $\hat{C}$ is bicovering for the topology T_e.
ii) The morphism u of $\hat{C}$ is carried by $\underline{a}'$ to an isomorphism.

It is clear that C' is a full subcategory of C_e. It therefore suffices to show that every sheaf F for the topology T_e is an object of C'. But, by the equivalence above, the morphism $F \to i' \circ a'(F)$ is bicovering, and since its source and target are sheaves, it follows from 5.3 (ii) that $F \to i' \circ a'(F)$ is an isomorphism, C.Q.F.D.

6. Sheaves with values in a category

6.0. Let C and D be two categories. A contravariant functor from C to D, $F : C^\circ \to D$, is called a *presheaf on C with values in D*.

DEFINITION 6.1. *Let C be a site and D a category. A presheaf $F : C^\circ \to D$ is called a* sheaf on C with values in D *(or, more briefly, a sheaf with values in D) if, for every object S of D, the presheaf of sets*

$$X \longmapsto \text{Hom}_D(S, F(X)) \quad , \quad X \in \text{ob}(C)$$

is a sheaf. The full subcategory of $\mathbf{Hom}(C^\circ, D)$ *formed by the sheaves on C with values in D will be denoted by* $\mathbf{Hom}^\sim(C^\circ, D)$.

257 REMARKS 6.2. 1) The condition of 6.1 means that for every object X of C, every covering sieve R of X, and every object S of D, one has an isomorphism (I 3.5 and 2.1):

$$\text{Hom}_D(S, F(X)) \xrightarrow{\sim} \varprojlim_{C/R} F(.).$$

Thus, when D is the category of $\mathscr{U}$-sets, one recovers the definition of sheaves of sets (*loc. cit.*).

2) Let D' be a $\mathcal{U}$-category and let $G : D \to D'$ be a functor commuting with projective limits. By composition, the functor G carries sheaves with values in D to sheaves with values in D'.

6.3.0. Let γ be a type of algebraic structure defined by finite projective limits (I 2.9), and let $\mathcal{U} - \gamma$ be the category of γ-sets belonging to $\mathcal{U}$. Denote by $\mathrm{esj} : \mathcal{U} - \gamma \to \mathcal{U} - \mathrm{Ens}$ the "underlying set" functor. The functor esj commutes with projective limits and therefore, by the preceding remark, defines by composition the functors

$$\hat{\mathrm{esj}} : \mathbf{Hom}(C^\circ, \mathcal{U} - \gamma) \longrightarrow \hat{C}$$
$$\tilde{\mathrm{esj}} : \mathbf{Hom}^\sim(C^\circ, \mathcal{U} - \gamma) \longrightarrow \tilde{C}.$$

The functor $\tilde{\mathrm{esj}}$ is called the "underlying sheaf of sets" functor. In fact, it factors canonically through the category $\gamma - \widetilde{C}$ of γ-objects of $\tilde{C}$. Denoting again by $\widetilde{\mathrm{esj}}$ the resulting functor

$$\mathbf{Hom}^\sim(C^\circ, \mathcal{U} - \gamma) \longrightarrow \gamma - \widetilde{C},$$

we may state:

Proposition 6.3.1. *The functor* esj$\tilde{}$ *establishes an equivalence among the category of sheaves on C with values in $\mathcal{U} - \gamma$, the category of γ-objects in the category of sheaves of sets, and the category of γ-objects in the category of presheaves of sets whose underlying presheaf is a sheaf.*

Proof. The proof essentially uses (I 3.2) and the fact that a finite projective limit of 258
sheaves in the category of presheaves is a sheaf (4.1).

6.3.2. The preceding proposition justifies the abuse of language whereby a sheaf with values in $\mathcal{U} - \gamma$ is identified with the corresponding γ-object of $\tilde{C}$. We shall henceforth make this abuse of language systematically.

We shall use the classical terminology: *sheaves of groups, sheaves of commutative groups* (which we shall most often call *abelian sheaves*), *sheaves of rings, sheaves of A-modules* etc.

6.3.3. We denote by

$$\tilde{C}_\gamma (resp.\ \hat{C}_\gamma)$$

the category of γ-objects of $\tilde{C}$ (resp. of $\hat{C}$). When γ is the type of structure "A-module", we also write $\tilde{C}_A$, or simply $\widetilde{C}_{\mathrm{ab}}$ when $A = \mathbf{Z}$.

Suppose that C is a $\mathcal{U}$-site. The "associated sheaf" functor is left exact (4.1), and therefore:

Proposition 6.4. *The inclusion functor $i_\gamma : \tilde{C}_\gamma \to \hat{C}_\gamma$ admits a left adjoint a_γ which is left exact; that is, one has an isomorphism*

$$\mathrm{Hom}_{\tilde{C}_\gamma}(a_\gamma, \ ) \xrightarrow{\sim} \mathrm{Hom}_{\hat{C}_\gamma}(\ , i_\gamma).$$

Let X be an object of $\hat{C}_\gamma$. The underlying sheaf of sets of $a_\gamma(X)$ is canonically isomorphic to the sheaf of sets associated with the underlying presheaf of sets of X. The morphism of underlying presheaves of sets of the adjunction morphism $\mathrm{id} \to i_\gamma a_\gamma$ *is identified with the adjunction morphism applied to the underlying presheaf of sets.*

Proposition 6.5. *Suppose that the functor* esj $: \gamma - \mathcal{U} \to \mathcal{U} - \mathrm{Ens}$ *admits a left* 259

adjoint [4]*:*

$$\mathrm{Hom}_{\mathscr{U}-\mathrm{Ens}}(.,\mathrm{esj}(.)) \xrightarrow{\sim} \mathrm{Hom}_{\gamma-\mathscr{U}}(\mathrm{Lib}(.),.).$$

The functor $\mathrm{esj}^{\sim} : C_{\gamma}^{\sim} \to C^{\sim}$ *(resp.* $\mathrm{esj}^{\wedge} : C_{\gamma}^{\wedge} \to C^{\wedge}$*) admits a left adjoint* $\mathrm{Lib}^{\sim}$ *(resp.* $\mathrm{Lib}^{\wedge}$*), and one has a canonical isomorphism*

$$\mathrm{Lib}^{\sim} = a_{\gamma}\,\mathrm{Lib}^{\wedge}\,i.$$

Proof. The proof is formal and is left to the reader.

Corollary 6.6. *Let* (X_i)*,* $i \in I$*, be a generating family of* $C^{\sim}$ *(4.9). Then the family* $\mathrm{Lib}^{\sim}(X_i)$ *is a generating family of* $C_{\gamma}^{\sim}$*.*

Proof. The proof is formal once one observes that the functor $\mathrm{esj}^{\sim}$ commutes with projective limits and is conservative ($\mathrm{esj}^{\sim}(u)$ is an isomorphism $\Leftrightarrow$ u is an isomorphism).

Proposition 6.7. *Let* A *be a* $\mathscr{U}$*-sheaf of rings, or a small ring, and let* $C_A^{\sim}$ *(resp.* $C_A^{\wedge}$*) be the category of sheaves (resp. of presheaves) of unital* A*-modules* (6.3.3) *on a* $\mathscr{U}$*-site* C*. Then* $C_A^{\sim}$ *is an abelian* $\mathscr{U}$*-category satisfying the axioms* (AB 5) *("existence of left exact filtered inductive limits") and* (AB 3)* *("existence of infinite products") of* [Tohoku]*. It has a family of generators indexed by an element of* $\mathscr{U}$*.*

Proof. It is clear that the category $C_A^{\wedge}$ is an abelian category satisfying the axioms
260 (AB 3), (AB 4), and (AB 5) (I 2.8 and I 3.3). It then follows from 6.4 that the category $C_A^{\sim}$ is an additive category in which kernels and cokernels are representable. More precisely, let i_A and a_A be the inclusion and associated-sheaf functors, respectively, and let $u : X \to Y$ be a morphism of $C_A^{\sim}$. The functor a_A is left exact and commutes with inductive limits. The functor i_A commutes with projective limits. Consequently the functor $i_A a_A : C_A^{\wedge} \to C_A^{\wedge}$ is an additive left exact functor. One deduces canonical isomorphisms

$$(*) \qquad i_A(\mathrm{Ker}(u)) \xrightarrow{\sim} \mathrm{Ker}(i_A(u)),$$

$$(**) \qquad \mathrm{coker}(u) \xrightarrow{\sim} a_A\,\mathrm{coker}(i_A(u)).$$

Consequently there is a canonical isomorphism

$$(***) \qquad \mathrm{coim}(u) \xrightarrow{\sim} a_A\,\mathrm{coim}(i_A(u)).$$

Let us show that the canonical morphism $\mathrm{coim}(u) \to \mathrm{im}(u)$ is an isomorphism. For this, by (*), it suffices to show that the sequence

$$0 \longrightarrow i_A(\mathrm{coim}(u)) \longrightarrow i_A(Y) \longrightarrow i_A(\mathrm{coker}(u))$$

is exact. Using the isomorphisms (**) and (***), and observing that $a_A i_A(Y)$ is isomorphic to Y, one sees that this sequence is isomorphic to the sequence

$$0 \longrightarrow i_A a_A(\mathrm{coim}(i_A(u))) \longrightarrow i_A a_A i_A(Y) \longrightarrow i_A a_A(\mathrm{coker}(i_A(u))),$$

which is precisely the image under the functor $i_A a_A$ of the sequence

$$0 \longrightarrow \mathrm{coim}(i_A(u)) \longrightarrow i_A(Y) \longrightarrow \mathrm{coker}(i_A(u)).$$

This sequence is exact, and the functor $i_A a_A$ is left exact. Thus the category $C_A^{\sim}$ is an
261 abelian category. The functor $a_A : C_A^{\wedge} \to C_A^{\sim}$ is left exact and commutes with arbitrary

[4] One proves that such an adjoint always exists [C.F.]: free group, free abelian group, free A-module etc.

inductive limits. Consequently it is additive, exact, and commutes with inductive limits. Since the category $\hat{C}_A$ satisfies axiom (AB 5), the same is true of the category $\tilde{C}_A$. Finally, it is clear that in the category $\tilde{C}_A$, products indexed by an element of $\mathscr{U}$ are representable, and hence axiom (AB 3)* is satisfied. This completes the proof of the first assertion.

For every ring A which is an element of $\mathscr{U}$, the functor

$$\text{esj} : \mathscr{U} - A - \text{module} \longrightarrow \mathscr{U} - \text{Ens}$$

admits a left adjoint $X \longmapsto X_A$ (the free A-module generated by X). It therefore suffices to apply 4.10 and 6.6 to complete the proof.

NOTATION 6.8. Let H be a sheaf of sets. The sheaf of A-modules associated with the presheaf (cf. notation 6.5)

$$X \longmapsto \text{Lib}_A\, H(X) \qquad X \in \text{ob}\, C$$

is denoted by A_H. When $H = \underline{a}(X)$ (the sheaf associated with the presheaf represented by X), one sometimes simply writes A_X (by abuse of notation). The proof of 6.7 shows that the family of sheaves of A-modules A_X, $(X \in \text{ob}(C))$, is a generating family, indexed by an element of $\mathscr{U}$, of the category of sheaves of A-modules.

REMARK 6.9. According to [TÔHOKU], 6.7 shows that the category $\tilde{C}_A$, when A is an element of $\mathscr{U}$, has enough injectives. It is also known that infinite products are not necessarily exact in $\tilde{C}_A$, and therefore that, in general, the category $\tilde{C}_A$ does not have enough projectives [ROOS].

EXPOSÉ III

Functoriality of categories of sheaves

J.-L. Verdier

In I 5, we studied the behavior of categories of presheaves with respect to functors between the categories of arguments. In this exposé, we extend this study to the case of sites and categories of sheaves (n° 1 and 2). After introducing the induced topology (n° 3), we turn in n° 4 to the comparison lemma, which will play an important role in Exp. IV. In number 5, for the patient reader, we study certain commutative diagrams related to localized categories (of the form C/X). In Theorem I 5.1, we impose smallness hypotheses on the categories under consideration. In general, these hypotheses are not satisfied by the sites encountered in practice ($\mathscr{U}$-sites). This necessitates a few contortions (4.2, 4.3, 4.4). 263

1. Continuous functors

DEFINITION 1.1. *Let C and C' be two $\mathscr{U}$-sites and let $u : C \to C'$ be a functor between their underlying categories. We say that u is continuous if, for every sheaf of sets F on C', the presheaf $X \mapsto F \circ u(X)$ on C is a sheaf.*

This notion of continuity depends a priori on the universe $\mathscr{U}$ with respect to which the two sites are $\mathscr{U}$-sites. Proposition 1.5 shows that it is independent of it.

1.11. Denote by $i : C^\sim \to \hat{C}$ (resp. by $i' : C'^\sim \to \hat{C'}$) the canonical inclusion functor from sheaves into presheaves. By Definition 1.1, the functor u is continuous if and only if there exists a functor $u_s : C'^\sim \to C^\sim$ such that $iu_s = u^* i'$ (where $u^* F = F \circ u$ (I 5.0)). 264

PROPOSITION 1.2. *Let C be a small site, C' a $\mathscr{U}$-site, and $u : C \to C'$ a functor between their underlying categories. The following properties are equivalent:*

i) *The functor u is continuous.*
ii) *For every object X of C and every sieve $R \hookrightarrow X$ covering X, the morphism $u_! R \hookrightarrow u(X)$ is bicovering in $\hat{C'}$* (II 5.2 and I 5.1). [4]
iii) *For every bicovering family $H_i \to K$, $i \in I$, in $\hat{C}$, the family of morphisms $u_! H_i \to u_! K$, $i \in I$, is bicovering in $\hat{C'}$.*
iv) *There exists a functor $u^s : C^\sim \to C'^\sim$, commuting with inductive limits and "extending u", i.e. such that the diagram of canonical functors*

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle \epsilon_C}\downarrow & & \downarrow{\scriptstyle \epsilon_{C'}} \\ C^\sim & \xrightarrow{u^s} & C'^\sim, \end{array}$$

commutes up to isomorphism.

[4] "Covering" in place of "bicovering" did not necessarily suffice; cf. Example 1.9.3 below.

Moreover, when C is no longer necessarily a small site but is a $\mathscr{U}$-site, one still has i) $\Leftrightarrow$ iv), *and the functor u^s of* iv) *is necessarily a left adjoint of the functor $u_s : \widetilde{C'} \to \widetilde{C}$, and is consequently determined up to a unique isomorphism.*

265 PROOF. The proof of i) $\Leftrightarrow$ iv) when C is a $\mathscr{U}$-site will be given in 4.2. Assume that C is small. It is clear that iii) $\Rightarrow$ ii).

i) $\Rightarrow$ iii): Let $H_i \to K$, $i \in I$, be a bicovering family in $\hat{C}$. For every sheaf F on C', the presheaf u^*F (I 5.0) is a sheaf on C. Hence (II 5.3) the canonical map

$$\mathrm{Hom}(K, u^*F) \longrightarrow \prod_i \mathrm{Hom}(H_i, u^*F),$$

is bijective. By adjunction (I 5.1), it follows that the canonical map

$$\mathrm{Hom}(u_!K, F) \longrightarrow \prod_i \mathrm{Hom}(u_!H_i, F)$$

is bijective. Consequently (II 5.3) the family $u_!H_i \to u_!K$, $i \in I$, is bicovering.

ii) $\Rightarrow$ i): Let X be an object of C, let $R \hookrightarrow X$ be a covering sieve, and let F be a sheaf on C'. By (II 5.3), the map

$$\mathrm{Hom}(u_!X, F) \longrightarrow \mathrm{Hom}(u_!R, F)$$

is bijective. By adjunction (I 5.1), it follows that the map

$$\mathrm{Hom}(X, u^*F) \longrightarrow \mathrm{Hom}(R, u^*F)$$

is bijective. Consequently u^*F is a sheaf.

i) $\Rightarrow$ iv): We use the customary notation $\underline{a}$ and i (resp. $\underline{a}'$ and i') for the "associated sheaf" and "inclusion into presheaves" functors. For every sheaf G on C, set $u^sG = \underline{a}'u_!iG$. For every sheaf F on C', we have the following sequence of natural isomorphisms:

$$\begin{aligned}\mathrm{Hom}(G, u_sF) &\simeq \mathrm{Hom}(iG, iu_sF) \simeq \mathrm{Hom}(iG, u^*i'F)\\ &\simeq \mathrm{Hom}(u_!iG, i'F) \simeq \mathrm{Hom}(\underline{a}'u_!iG, F).\end{aligned}$$

266 (The first isomorphism follows from the full faithfulness of i; the second follows from the definition of u_s; the third and fourth are obtained by adjunction.) Consequently u^s is left adjoint to u_s. In particular, u^s commutes with inductive limits. For every presheaf K on C and every sheaf F on C', we have the following sequence of natural isomorphisms: $\mathrm{Hom}(u^s\underline{a}K, F) \simeq \mathrm{Hom}(\underline{a}K, u_sF) \simeq \mathrm{Hom}(K, iu_sF) \simeq \mathrm{Hom}(K, u^*i'F) \simeq \mathrm{Hom}(u_!K, i'F) \simeq \mathrm{Hom}(\underline{a}'u_!K, F)$ (the third isomorphism follows from the definition of u_s; the others are obtained by adjunction); whence a functorial isomorphism $u^s\underline{a}K \simeq \underline{a}'u_!K$. In particular, using this isomorphism when K is representable, and taking I 5.4 3) into account, we obtain a diagram commutative up to isomorphism:

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle \epsilon_C}\downarrow & & \downarrow{\scriptstyle \epsilon_{C'}} \\ \widetilde{C} & \xrightarrow{u^S} & \widetilde{C'} \end{array}$$

iv) ⇒ ii): Let $h : C \to \hat{C}$ (resp. $h' : C' \to \hat{C'}$) be the functor that assigns to an object the presheaf it represents. Consider the diagram:

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle h}\downarrow & & \downarrow{\scriptstyle h'} \\ \hat{C} & \xrightarrow{u_!} & \hat{C'} \\ {\scriptstyle \underline{a}}\downarrow & & \downarrow{\scriptstyle \underline{a}'} \\ \tilde{C} & \xrightarrow{u^S} & \tilde{C'}. \end{array}$$

The upper square is commutative (1.4 3)), and we have $\underline{a}h = \epsilon_C$, $\underline{a}'h' = \epsilon_{C'}$. 267
For every object K of $\hat{C}$, we have a canonical isomorphism (I 3.4):

$$\varinjlim_{(h(X)\to K)\in \mathrm{ob}(C/K)} h(X) \xrightarrow{\sim} K.$$

Since the functors $u_!$, u^s, $\underline{a}$, and $\underline{a}'$ commute with inductive limits, we obtain isomorphisms:

$$\varinjlim_{(h(X)\to K)\in \mathrm{ob}(C/K)} u^s\underline{a}h(X) \xrightarrow{\sim} u^s\underline{a}K,$$

$$\varinjlim_{(h(X)\to K)\in \mathrm{ob}(C/K)} \underline{a}'u_!h(X) \xrightarrow{\sim} \underline{a}'u_!K.$$

We have $u_!h = h'u$ and, by hypothesis, an isomorphism $\underline{a}'h'u \simeq u^s\underline{a}h$, whence an isomorphism

$$u^s\underline{a}K \simeq \underline{a}'u_!K,$$

which is immediately seen to be functorial in K. The diagram

$$\begin{array}{ccc} \hat{C} & \xrightarrow{u_!} & \hat{C'} \\ {\scriptstyle \underline{a}}\downarrow & & \downarrow{\scriptstyle \underline{a}'} \\ \tilde{C} & \xrightarrow{u^S} & C', \end{array}$$

is therefore commutative up to isomorphism. Since $\underline{a}i$ is isomorphic to the identity functor, we have an isomorphism $u^s \simeq \underline{a}'u_!i$, whence the uniqueness of u^s. Let $v : H \to K$ be a bicovering morphism in $\hat{C}$. Then $\underline{a}(v)$ is an isomorphism (II 5.3), and consequently $\underline{a}'u_!(v)$ (isomorphic to $u^s\underline{a}(v)$) is an isomorphism. Thus $u_!(v)$ is carried by $\underline{a}'$ to an isomorphism, and consequently $u_!(v)$ is bicovering (II 5.3), whence ii).

The additional assertion, in the case where C is small, was proved in the course of 268
the proof, C.Q.F.D.

1.2.1. The functor $u^s : \tilde{C} \to \tilde{C'}$ of 2.2 iv) may often be interpreted as an "inverse image" functor for a "morphism of topoi" $\tilde{C'} \to \tilde{C}$, cf. IV 4.9. Its properties are summarized in the following proposition:

Proposition 1.3. *Let $u : C \to C'$ be a continuous functor from a small site C to a U-site C'.*

1) *The functor u^s is left adjoint to the functor u_s.*

2) *There is a canonical isomorphism* $u^s \simeq \underline{a}' u_! i$.
3) *There is a canonical isomorphism* $u^s \underline{a} \simeq \underline{a}' u_!$.
4) *The functor* u^s *commutes with inductive limits.*
5) *When the functor* $u_!$ *is left exact (cf. I 5.4 4)), the functor* u^s *is also left exact. More generally, the functor* u^s *commutes with those types of finite projective limits with which the functor* $u_!$ *commutes.*

Proof. Assertions 1), 2), 3), and 4) were proved in the course of the proof of 1.2. Assertion 5) follows from the isomorphism in 2), since i commutes with projective limits and $\underline{a}'$ commutes with finite projective limits (II 4.1).

Remark 1.4. Combining I 5.4 3) and 1.3 3), we obtain a diagram:

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle h}\downarrow & & \downarrow{\scriptstyle h'} \\ C\hat{} & \xrightarrow{u_!} & C'\hat{} \\ {\scriptstyle \underline{a}}\downarrow & & \downarrow{\scriptstyle \underline{a}'} \\ C\tilde{} & \longrightarrow & C'\tilde{}, \end{array}$$

269 where the upper square commutes and the lower square commutes up to isomorphism. But the functors $\underline{a}$, $\underline{a}'$, $u_!$, and u^s are defined only up to isomorphism. The reader may verify that the functors $\underline{a}$, $\underline{a}'$, and u^s can be chosen so that:

1) The composite functors $\underline{a}h$ and $\underline{a}'h'$ are injective on the sets of objects;
2) the diagram

$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle \underline{a}h}\downarrow & & \downarrow{\scriptstyle \underline{a}'h'} \\ C\tilde{} & \xrightarrow{u^s} & C'\tilde{} \end{array}$$

commutes.

More precisely, the functors $\underline{a}$ and $\underline{a}'$ can be chosen so as to satisfy condition 1). Once the functors $\underline{a}$ and $\underline{a}'$ have been chosen, the functor u^s can be chosen so as to satisfy condition 2).

Proposition 1.5. *Let* $\mathscr{U} \subset \mathscr{V}$ *be two universes, let* C *and* C' *be two* $\mathscr{U}$*-sites, and let* $u : C \to C'$ *be a functor between the underlying categories. Then* u *is continuous relative to* $\mathscr{U}$ *if and only if it is continuous relative to* $\mathscr{V}$*. Moreover, when* u *is continuous, denote by* $u^s_{\mathscr{U}}$ *(resp.* $u^s_{\mathscr{V}}$*) the functor between the categories of* $\mathscr{U}$*-sheaves (resp.* $\mathscr{V}$*-sheaves) introduced in 1.2* iv)*. Then the diagram*

(1.5.1)
$$\begin{array}{ccc} \widetilde{C}_{\mathscr{U}} & \xrightarrow{u^s_{\underline{U}}} & \widetilde{C'}_{\underline{U}} \\ \downarrow & & \downarrow \\ C\tilde{}_{\underline{V}} & \xrightarrow{u^s_{\underline{V}}} & C'\tilde{}_{\underline{V}}, \end{array}$$

270 *where the vertical functors are the canonical inclusion functors, commutes up to canonical isomorphism.*

PROOF. We give the proof only in the case where C is $\mathscr{U}$-small. The general case will be proved in 4.3. It is clear that if the functor u^* carries every $\mathscr{V}$-sheaf on C' to a $\mathscr{V}$-sheaf on C, then it carries every $\mathscr{U}$-sheaf on C' to a $\mathscr{U}$-sheaf on C. Suppose that u^* carries every $\mathscr{U}$-sheaf on C' to a $\mathscr{U}$-sheaf on C. Denote by $\hat{C}_{\mathscr{U}} \hookrightarrow \hat{C}_{\mathscr{V}}$ (resp. $\hat{C'}_{\mathscr{U}} \hookrightarrow \hat{C'}_{\mathscr{V}}$) the categories of $\mathscr{U}$-presheaves and $\mathscr{V}$-presheaves, and by $u_{\mathscr{U}!}$ and $u_{\mathscr{V}!}$ the "inverse image" functors for $\mathscr{U}$-presheaves and $\mathscr{V}$-presheaves, respectively. We have a commutative diagram (cf. the explicit construction of $u_!$ in I 5.1):

(∗)
$$\begin{array}{ccc} \hat{C}_{\underline{U}} & \xrightarrow{u_{\underline{U}!}} & \hat{C'}_{\underline{V}} \\ \downarrow & & \downarrow \\ \hat{C}_{\underline{V}} & \xrightarrow{u_{\underline{V}!}} & \hat{C'}_{\underline{V}}. \end{array}$$

The inclusion functors from $\mathscr{U}$-presheaves into $\mathscr{V}$-presheaves are fully faithful and commute with projective limits. It follows from (II 5.1 i)) that a bicovering morphism of $\mathscr{U}$-presheaves is a bicovering morphism of $\mathscr{V}$-presheaves. Now let $R \hookrightarrow X$ be a sieve covering an object X of C. By 1.2 ii), the morphism $u_{\mathscr{U}!}R \to u_{\mathscr{U}!}X$ is bicovering. Using the commutativity of (∗) and what precedes, we deduce that the morphism $u_{\mathscr{V}!}R \to u_{\mathscr{V}!}X$ is bicovering. Consequently (1.2), the functor u^* carries $\mathscr{V}$-sheaves on C' to $\mathscr{V}$-sheaves on C. The commutativity of (1.5.1) then follows from the commutativity of (∗), from II 3.6, and from 1.3 2).

PROPOSITION 1.6. *Let C and C' be two $\mathscr{U}$-sites, and let $u : C \to C'$ be a functor* 271 *between the underlying categories. Consider the following conditions:*

i) *u is continuous* (cf. . 1.1 and 1.2).

ii) *For every covering family $(X_i \to X)$, $i \in I$, in C, the family $(uX_i \to uX)$, $i \in I$, in C' is covering.*

We have the implication i) ⇒ ii).

Suppose that the topology of C can be defined by a pretopology T (II 1.3) *and that the functor u commutes with fiber products.*[4] *Then conditions* i) *and* ii) *are equivalent and are also equivalent to the following condition:*

iii) *The functor u carries the covering families of T to covering families in C'.*

In particular, suppose that fiber products in C are representable and that the functor u commutes with fiber products. Then conditions i) *and* ii) *are equivalent.*

PROOF. Let us prove that i) ⇒ ii). Let $X_i \to X$, $i \in I$, be a covering family in C. For every sheaf F on C', u^*F is a sheaf. Consequently, the map

$$\mathrm{Hom}(X, u^*F) \longrightarrow \prod_i \mathrm{Hom}(X_i, u^*F)$$

is injective (II 5.1). Hence there is an injective map

$$\mathrm{Hom}(u_!X, F) \longrightarrow \prod_i \mathrm{Hom}(u_!X_i, F).$$

Therefore the family $u_!X_i \to u_!X$, $i \in I$, is covering in C' (II 5.1).

Every covering family of the pretopology T is a covering family in C, whence ii) ⇒ iii). Let us prove that iii) ⇒ i). Let X be an object of C and let $X_i \to X$, $i \in I$, be a 272

[4] In fact, it suffices that u commute with the fiber products occurring in base changes of morphisms belonging to covering families for T.

covering family in $\mathrm{Cov}(X)$ (II 1.3). The morphisms $X_i \to X$ are pullbackable, and the functor u commutes with fiber products. Consequently, the fiber products $u(X_i) \times_{u(X)} u(X_j)$ are representable and canonically isomorphic to $u(X_i \times_X X_j)$. Let F be a sheaf on C'. Then the diagram of sets

$$F(u(X)) \to \prod_i F(u(X_i)) \rightrightarrows \prod_{i,j} F(u(X_i \times_X X_j))$$

is exact (II 2.1, I 3.5, and I 2.12). Consequently, the diagram of sets

$$u^* F(X) \to \prod_i u^* F(X_i) \rightrightarrows \prod_{i,j} u^* F(X_i \times_X X_j)$$

is exact. Therefore $u^* F$ is a sheaf (II 2.4), whence i). The final assertion of 1.6 follows from what precedes and from the fact that, when fiber products are representable in C, all covering families in C[4] define a pretopology on C whose associated topology is the topology of C.

PROPOSITION 1.7. *Let C be a small site, C' a $\mathscr{U}$-site, and $u : C \to C'$ a continuous functor. Let γ be an algebraic structure defined by finite projective limits, such that in the category of γ-objects of $\mathscr{U}$ − Ens the $\mathscr{U}$-indexed inductive limits are representable* [4]. *We use the notation of Proposition* II 6.4. *The functor u_s commutes with projective limits and consequently defines a functor $u_s^\gamma : C\tilde{}_\gamma \to C'\tilde{}_\gamma$. The functor u_s^γ has a left adjoint u_γ^s with the following properties:*

273

1) *There is a canonical isomorphism $u_\gamma^s \xrightarrow{\sim} \underline{a}'_\gamma u_{\gamma!} i_\gamma$, and u_γ^s commutes with every finite projective limit with which $u_{\gamma!}$ commutes.*
2) *There is a canonical isomorphism $u_\gamma^s \underline{a}_\gamma \xrightarrow{\sim} \underline{a}'_\gamma u'_{\gamma!}$.*
3) *The functor u_γ^s commutes with inductive limits.*
4) *If u^s is left exact, the diagram* (in the notation of II 6.3.0)

$$\begin{array}{ccc} C\tilde{}_\gamma & \xrightarrow{u_Y^s} & C'\tilde{}_\gamma \\ \downarrow{\scriptstyle \mathrm{esj}\tilde{}} & & \downarrow{\scriptstyle \mathrm{esj}'\tilde{}} \\ C\tilde{} & \xrightarrow{u^s} & C'\tilde{} \end{array}$$

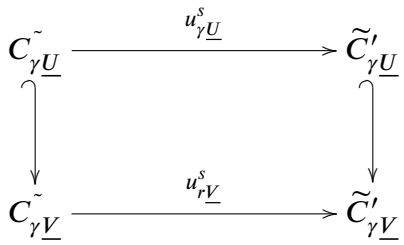
   is commutative up to isomorphism, and the functor u_γ^s is exact.
5) *Suppose that the functor* esj$\tilde{}$ *(resp.* esj$\tilde{}$*) has a left adjoint* Lib$\tilde{}$ *(resp.* Lib$'\tilde{}$*)* (II 6.5). *There is a canonical isomorphism $u_\gamma^s \mathrm{Lib}\tilde{} \xrightarrow{\sim} \mathrm{Lib}'\tilde{} u^s$.*

Moreover, when C is not necessarily a small site but is a $\mathscr{U}$-site, the functor u_s^γ has a left adjoint u_γ^s. Finally, if V is a universe containing $\mathscr{U}$ and if $u_{\gamma\mathscr{U}}^s$ (resp. $u_{\gamma\mathscr{V}}^s$) denotes the left adjoint of u_s relative to the universe $\mathscr{U}$ (resp. $\mathscr{V}$), the following diagram, analogous to diagram (1.5.1):

[4] indexed by sets belonging to a suitable universe.

[4] In fact, one can show that this condition is always satisfied.

(1.7.1)



is commutative up to canonical isomorphism.

Proof. The proof, in the case where C is a small site, is left to the reader. It will be completed in 4.3 in the case where C is a $\mathscr{U}$-site.

Notation 1.8. Henceforth we shall use the notation u_s for the functor u^{γ}_s. This notation is unlikely to cause confusion, because the functor u_s (defined on sheaves of sets) commutes with finite projective limits. 274

Likewise, when u^s is left exact, we shall use the notation u^s for the functor u^s_{γ}. This abuse of notation is justified by 1.7 4).

Example 1.9.1. Let X be a small topological space. Denote by $\mathrm{Ouv}(X)$ the category of open subsets of X (the objects of $\mathrm{Ouv}(X)$ are the open subsets of X, and the morphisms of $\mathrm{Ouv}(X)$ are inclusions), equipped with the canonical topology. A family $(U_i \subset U)$, $i \in I$, is covering if and only if the open subsets U_i cover U (II 2.6). The sheaves of sets on $\mathrm{Ouv}(X)$ are therefore the sheaves of sets in the sense of [TF]. Let $f : X \to Y$ be a continuous map. It induces a functor $f^{-1} : \mathrm{Ouv}(Y) \to \mathrm{Ouv}(X)$: for every open subset U of Y, $f^{-1}(U)$ is the inverse image of U under the map f. The functor f^{-1} is continuous (1.6). The functor $f^{-1}_s : \mathrm{Ouv}(X)^{\sim} \to \mathrm{Ouv}(Y)^{\sim}$ is the direct-image functor for sheaves, in the sense of [TF]. The functor $(f^{-1})^s : \mathrm{Ouv}(Y)^{\sim} \to \mathrm{Ouv}(X)^{\sim}$ is the inverse-image functor for sheaves in the sense of [TF]. The functor $(f^{-1})^s$ commutes with finite projective limits, by 1.3 5).

Example 1.9.2. Let X be a topological space and let $Y \hookrightarrow X$ be an open subset of X. Every open subset of Y is an open subset of X, and thus we obtain a functor $\Phi : \mathrm{Ouv}(Y) \to \mathrm{Ouv}(X)$. The functor Φ is continuous (1.6). The functor $\Phi_s : \mathrm{Ouv}(X)^{\sim} \to \mathrm{Ouv}(Y)^{\sim}$ is the "restriction to Y" functor. The functor $\Phi^s_{\mathrm{ab}} : \mathrm{Ouv}(Y)^{\sim}_{\mathrm{ab}} \to \mathrm{Ouv}(X)^{\sim}_{\mathrm{ab}}$ (II 6.3.3, I 1.7) is the "extension by zero outside Y" functor introduced in [TF]. The functor $\Phi^s : \mathrm{Ouv}(Y)^{\sim} \to \mathrm{Ouv}(X)^{\sim}$ (1.3) is analogous to the "extension by zero" functor: for every sheaf H on Y and every point $y \in Y$, the stalk of $\Phi^s H$ at y is canonically isomorphic to the stalk of H at y; for every point $x \in X$, $x \notin Y$, the stalk of $\Phi^s H$ at x is empty. The functor Φ^s is called the "extension by the empty set outside Y" functor. The functor Φ^s commutes with fiber products and with finite products over a nonempty index set, but it does not carry the terminal object of $\mathrm{Ouv}(Y)^{\sim}$ to the terminal object of $\mathrm{Ouv}(X)^{\sim}$. 275

Example 1.9.3. Let C and C' be two small sites, and let $u : C \to C'$ be a functor between the underlying categories that carries every covering family of C to a covering family of C'. The functor u is not continuous in general (cf. nevertheless 1.6). Here is a counterexample. Let S be a set of infinite cardinality in the universe $\mathscr{U}$, and let C be the full subcategory of the category of sets whose objects are the finite, nonempty subsets of S. Equip C with the canonical topology. Observe that the covering families of C are the surjective families of maps and that covering families are nonempty. Observe also that, up to isomorphism, there are only two constant sheaves on C: the sheaf with value the

empty set and the sheaf with value a one-element set. Set $C = C'$ and let $u : C \to C'$ be a constant functor. The functor u carries the covering families of C to covering families of C'. The functor u is not continuous. Indeed, since the representable presheaves of
276 C' are sheaves, for every object X of C' there exists a sheaf F on C' such that the cardinality of $F(X)$ is ≥ 2, and consequently the presheaf u^*F is not a sheaf.

2. Cocontinuous functors

DEFINITION 2.1. *Let C and C' be two $\mathscr{U}$-sites, and let $u : C \to C'$ be a functor between the underlying categories. We say that u is cocontinuous if it has the following property:*

(COC) For every object Y of C and every covering sieve $R \hookrightarrow u(Y)$, the sieve on Y generated by the arrows $Z \to Y$ such that $u(Z) \to u(Y)$ factors through R covers Y.

PROPOSITION 2.2. *Let C be a small site, let C' be a $\mathscr{U}$-site, and let $u : C \to C'$ be a functor between the underlying categories. Denote by $\hat{u}_* : \hat{C} \to \hat{C'}$ the functor right adjoint to the functor $F \mapsto F \circ u = \hat{u}^* F$ (I 5.1). The functor u is cocontinuous if and only if, for every sheaf G on C, $\hat{u}_* G$ is a sheaf on C'.*

PROOF. *The condition is sufficient.* Suppose that for every sheaf G on C, the presheaf $\hat{u}_* G$ is a sheaf. Let Y be an object of C, and let $R \hookrightarrow u(Y)$ be a covering sieve. There is an isomorphism $\mathrm{Hom}(u(Y), u_* G) \xrightarrow{\sim} \mathrm{Hom}(R, u_* G)$, hence, by adjunction (I 5.1), an isomorphism $\mathrm{Hom}(\hat{u}^* \circ u(Y), G) \xrightarrow{\sim} \mathrm{Hom}(\hat{u}^* R, G)$. It follows (II 5.3) that the morphism $\hat{u}^* R \to \hat{u}^* u(Y)$ is bicovering. But the functor $\hat{u}^*$ commutes with projective limits, and therefore the morphism $\hat{u}^* R \to \hat{u}^* u(Y)$ is a monomorphism. It is thus a covering monomorphism. On the other hand, there is a canonical morphism $Y \xrightarrow{p} \hat{u}^* u(Y)$ deduced
277 from the adjunction morphism $\mathrm{id}_C \to \hat{u}^* u_!$ (I 5.4 3)). We then make the base change $Y \xrightarrow{p} \hat{u}^* u(Y)$. This gives a covering sieve on Y:

$$\hat{u}^* R \times_{\hat{u}^* u(Y)} Y \longrightarrow Y,$$

and, on determining the arrows $Z \to Y$ that factor through this sieve, one obtains the sieve described by property (COC).

The condition is necessary. Let S be an object of C' and let $R \hookrightarrow S$ be a covering sieve on S. We must prove that, for every sheaf G on C, there is an isomorphism

$$\mathrm{Hom}(S, u_* G) \xrightarrow{\sim} \mathrm{Hom}(R, u_* G).$$

Using Proposition II 5.3 and the adjunction isomorphisms, we see that it suffices to prove that the monomorphism $\hat{u}^* R \to \hat{u}^* S$ is covering. For this, it suffices to prove (II 5.1) that for every base change $Y \to \hat{u}^* S$, the sieve $\hat{u}^* R \times_{\hat{u}^* S} Y$ is covering, where Y is an object of C. But, by the properties of adjoint functors and I 5.4 3), the morphism $Y \to \hat{u}^* S$ factors through $Y \xrightarrow{p} \hat{u}^* u(Y) \to \hat{u}^* S$, and consequently the sieve $\hat{u}^* R \times_{\hat{u}^* S} Y \hookrightarrow Y$ is obtained, by the base change $Y \xrightarrow{p} \hat{u}^* u(Y)$, from the monomorphism $\hat{u}^* R \times_{\hat{u}^* S} \hat{u}^* u(Y) \xrightarrow{q} \hat{u}^* u(Y)$. Now the functor $\hat{u}^*$ commutes with projective limits, and consequently the monomorphism q is the image under $\hat{u}^*$ of the sieve $R \times_S u(Y) \hookrightarrow u(Y)$, which is covering. Hypothesis (COC) then allows us to conclude that the sieve $\hat{u}^* R \times_{\hat{u}^* S} Y \hookrightarrow Y$ is covering, C.Q.F.D.

PROPOSITION 2.3. *Let C and C' be two $\mathscr{U}$-sites, and let $u : C \to C'$ be a cocontinuous functor. Denote by $u^* : \hat{C'} \to \hat{C}$ the functor $u^* = \underline{a} \hat{u}^* i'$, where $\underline{a}$ denotes the "associated*
278 *sheaf" functor for $\hat{C}$, $\hat{u}^*$ the functor $F \mapsto F \circ u$, and i' the inclusion functor $\widetilde{C'} \to \hat{C'}$.*

1) *The functor u^* commutes with inductive limits and is exact.*
2) *There is a canonical isomorphism $u^*\underline{a}' \simeq \underline{a}\hat{u}^*$, where $\underline{a}'$ denotes the "associated sheaf" functor for $C'^{\wedge}$.*
3) *The functor u^* has a right adjoint $u_* : \widetilde{C} \to \widetilde{C}'$. When C is small, the diagram*

(2.3.1)
$$\begin{array}{ccc} C^{\sim} & \xrightarrow{u_*} & \widetilde{C}' \\ \downarrow{\scriptstyle i} & & \downarrow{\scriptstyle i'} \\ C^{\wedge} & \xrightarrow{\hat{u}_*} & C'^{\wedge}, \end{array}$$

in which the lower functor is right adjoint to the functor $\hat{u}^*$ (I 5.1), commutes up to canonical isomorphism.

4) *Let $\mathscr{V} \supset \mathscr{U}$ be a universe. Denote by $u_{*\mathscr{U}} : C^{\sim}_{\mathscr{U}} \to \widetilde{C}'_{\mathscr{U}}$ (resp. $u_{*\mathscr{V}} : C^{\sim}_{\mathscr{V}} \to \widetilde{C}'_{\mathscr{V}}$) the right adjoint relative to the universe $\mathscr{U}$ (resp. $\mathscr{V}$) whose existence is asserted in 3). The diagram*

(2.3.2)
$$\begin{array}{ccc} C^{\sim}{}_{\underline{U}} & \xrightarrow{u_{*\underline{U}}} & \widetilde{C}'_{\underline{U}} \\ \downarrow & & \downarrow \\ C^{\sim}{}_{\underline{V}} & \xrightarrow{u_{*\underline{V}}} & \widetilde{C}'_{\underline{V}} \end{array}$$

commutes up to isomorphism.

Proof. Assertions 1) and 2) follow immediately from II 3.4. Assertion 3), when C is small, follows from 2.2. When C is a $\mathscr{U}$-site, it will be proved in 4.4. Assertion 4), when C is small, follows from the analogous commutativity assertion when the topologies on C and C' are chaotic and from I 3.5. When the topologies on C and C' are chaotic, the commutativity of (2.3.2) follows immediately from the explicit description of u_* (I 5.1). 279

2.4. We shall not develop here the considerations concerning γ-objects of categories of sheaves. It will suffice to note that the functors u^* and u_* introduced in this section always commute with finite projective limits (unlike what happened in the preceding section for the functor u^s). Consequently, they extend naturally to functors defined on γ-objects; these functors are adjoint to one another and commute with the "underlying sheaf of sets" functors. We shall make the notational abuses mentioned in 1.8, using u^* and u_* also for the extensions to γ-objects.

Proposition 2.5. *Let C and C' be two $\mathscr{U}$-sites, and let $C \underset{u}{\overset{v}{\rightleftarrows}} C'$ be a pair of functors, where v is left adjoint to u. The following properties are equivalent:*

i) *The functor u is continuous.*
ii) *The functor v is cocontinuous.*

Moreover, under these equivalent conditions, there are canonical isomorphisms $v_* \simeq u_s$ and $v^* \simeq u^s$. In particular, the functor u^s commutes with finite projective limits.

Proof. The property of a functor being continuous or cocontinuous does not depend on the universe $\mathscr{U}$ for which C and C' are $\mathscr{U}$-sites (this is immediate for a cocontinuous

functor, and follows from 1.5 for a continuous functor). We may therefore, after enlarging the universe, suppose that C and C' are small. The proposition then follows from 2.2 and I 5.6.

280 PROPOSITION 2.6. *Let $u : C \to C'$ be a continuous and cocontinuous functor between two $\mathscr{U}$-sites. Then the functor $u^* : C'^{\sim} \to C^{\sim}$ (2.3) commutes with $\mathscr{U}$-inductive and projective limits. Denote by $u_! : C^{\sim} \to C'^{\sim}$ and $u_* : C^{\sim} \to C'^{\sim}$ the functors left and right adjoint to u^*, respectively. The functor $u_!$ is fully faithful if and only if the functor u_* is fully faithful. When u is fully faithful, $u_!$ is fully faithful, and the converse holds when the topologies of C and C' are coarser than the canonical topology.*

The functor u^* has a right adjoint u_* (2.3) and a left adjoint $u_!$ (1.2). The functor u^* therefore commutes with inductive and projective limits (I 2.11). The fact that $u_!$ is fully faithful if and only if u_* is fully faithful is a general property of adjoint functors (I 5.7 1). When u is fully faithful, the functor $\hat{u}_* : \hat{C}_{\mathscr{V}} \to \hat{C'}_{\mathscr{V}}$ on $\mathscr{V}$-presheaves, for a sufficiently large universe $\mathscr{V}$, is fully faithful (I 5.7). Consequently, by the commutativity of (2.3.1) and (2.3.2), the functor $u_* : C^{\sim} \to \widetilde{C'}$ is fully faithful, and hence so is $u_!$ by what precedes. The converse follows from the existence of the commutative diagram in 1.2 iv), taking into account the fact that the functors ϵ_C and $\epsilon_{C'}$ are fully faithful when the topologies are coarser than the canonical topology, C.Q.F.D.

EXAMPLE 2.7. With the notation of 1.9.2, the functor

$$\boldsymbol{\Phi} : \mathrm{Ouv}(Y) \longrightarrow \mathrm{Ouv}(X)$$

is continuous (1.9.2) and cocontinuous (2.2). Moreover, let $i : Y \to X$ be the canonical
281 inclusion and let $i^{-1} : \mathrm{Ouv}(X) \to \mathrm{Ouv}(Y)$ be the functor that it defines (1.9.1). The functor i^{-1} is right adjoint to the functor $\boldsymbol{\Phi}$. There is therefore a sequence of three adjoint functors:

$$\begin{array}{ccc} \boldsymbol{\Phi}^s & , & \boldsymbol{\Phi}_s \\ & & \| \\ & & \boldsymbol{\Phi}^* \quad , \quad \boldsymbol{\Phi}_*, \end{array}$$

and canonical isomorphisms $\boldsymbol{\Phi}^* \simeq (i^{-1})^s$ and $\boldsymbol{\Phi}_* \simeq i_s^{-1}$.

3. Induced topology

3.1. Let C' be a site, C a category, and $u : C \to C'$ a functor. For every universe $\mathscr{U}$ such that C' is a $\mathscr{U}$-site and C is a $\mathscr{U}$-small category, denote by $\mathscr{T}_{\mathscr{U}}$ the finest among the topologies T on C that make u continuous (1.1). (Such a topology exists by II 2.2.) The topology $\mathscr{T}_{\mathscr{U}}$ does not depend on the universe $\mathscr{U}$. Indeed, if $\mathscr{V} \supset \mathscr{U}$ is a universe, then $\mathscr{T}_{\mathscr{U}} = \mathscr{T}_{\mathscr{V}}$ (1.1 and 1.5). The topology $\mathscr{T}_{\mathscr{U}}$ is called *the topology induced on C by the topology of C' by means of the functor u* [4].

PROPOSITION 3.2. *Let C be a small category, C' a $\mathscr{U}$-site, $u : C \to C'$ a functor, and $\mathscr{T}$ the topology on C induced by u. Let X be an object of C, and let $R \to X$ be a sieve on X. The following properties are equivalent:*

i) *The sieve $R \hookrightarrow X$ is covering for $\mathscr{T}$.*
ii) *For every base change $Y \to X$, where Y is an object of C, the morphism $u_!(R \times_X Y) \to u(Y)$ is bicovering in $\hat{C'}$* (II 5.2).

[4] When no confusion can result, this topology is called the *topology induced on C by the topology of C'*.

PROOF. i) ⇒ ii): This follows from axiom (T 1) for topologies and from 1.2.
ii) ⇒ i): For every sheaf F on C', the map

$$\mathrm{Hom}(Y, u^*F) \longrightarrow \mathrm{Hom}(R \times_X Y, u^*F)$$

is isomorphic, by adjunction (I 5.1), to the map 282

$$\mathrm{Hom}(u(Y), F) \longrightarrow \mathrm{Hom}(u_!(R \times_X Y), F),$$

which is bijective (II 5.3). Consequently (II 2.2), the sieve $R \hookrightarrow X$ is covering for $\mathscr{T}$.

COROLLARY 3.3. *Let C' be a site, C a category, $u : C \to C'$ a functor, and $\mathscr{T}$ the topology on C induced by the topology of C'. Let $(X_i \to X)$, $i \in I$, be a family of pullbackable morphisms in C, and suppose that u commutes with fiber products* [4]. *The following properties are equivalent:*

i) *The family $X_i \to X$, $i \in I$, is covering for $\mathscr{T}$.*
ii) *The family $(u(X_i) \to u(X))$, $i \in I$, is covering.*

PROOF. i) ⇒ ii): This follows from 1.6.
ii) ⇒ i): Let $\mathscr{U}$ be a universe such that C is $\mathscr{U}$-small and C' is a $\mathscr{U}$-site. Let $R \hookrightarrow X$ be the sieve generated by the $X_i \to X$. The presheaf R is the coequalizer of the pair of arrows (I 2.12 and I 3.5)

$$\coprod_{i,j} X_i \times_X X_j \rightrightarrows \coprod_i X_i$$

(the coproduct is taken here in $C^\wedge$). Since the functor $u_!$ commutes with inductive limits (I 5.4), the presheaf $u_!R$ is the coequalizer of the pair of arrows

$$\coprod_{i,j} u(X_i \times_X X_j) \rightrightarrows \coprod_i u(X_i).$$

Since the functor u commutes with fiber products, the presheaf $u_!R$ is the coequalizer of the pair of arrows

$$\coprod_{i,j} u(X_i) \times_{u(X)} u(X_j) \rightrightarrows \coprod_i u(X_i),$$

and consequently $u_!R \to u(X)$ is the sieve on $u(X)$ generated by the $u(X_i) \to$ 283
$u(X)$, $i \in I$. Using once again the fact that u commutes with fiber products, one shows that for every base change $Y \to X$, where Y is an object of C, $u_!(R \times_X Y) \to u(Y)$ is the sieve on $u(Y)$ generated by the $u(X_i) \times_{u(X)} u(Y) \to u(Y)$, $i \in I$. Since the family $u(X_i) \to u(X)$, $i \in I$, is covering, the family $u(X_i) \times_{u(X)} u(Y) \to u(Y)$, $i \in I$, is covering. Thus $u_!(R \times_X Y) \to u(Y)$ is a covering sieve, and consequently (3.2) $R \to X$ is covering for $\mathscr{T}$, C.Q.F.D.

COROLLARY 3.4. *Let C' be a $\mathscr{U}$-site, let C be a full subcategory of C', and let $u : C \to C'$ be the inclusion functor. Suppose that fiber products are representable in C and that u commutes with fiber products. The following conditions are equivalent:*

i) a) *For every object X of C, every covering family $(Y_j \to X)$, $j \in J$, in C' is refined by a covering family $X_i \to X$, $i \in I$, where the X_i are objects of C.*
   b) *There exists a small set G of objects of C such that every object of C is the target of a covering family in C' of morphisms whose sources belong to G.*

[4] In fact, it suffices that u commute with fiber products of the form $X_i \times_X X'$.

ii) *The topology induced by the topology of C' is a $\mathcal{U}$-topology* (I 3.0.2), *and the functor u is continuous and cocontinuous for this topology.*

PROOF. This follows immediately from 3.3 and 2.1.

284 PROPOSITION 3.5. *Let C be a $\mathcal{U}$-site and let $\epsilon_C : C \to C^\sim$ be the canonical functor* (II 4.4.0). *Equip $C^\sim$ with the canonical topology. Then the topology of the site C is the topology induced by the topology of $C^\sim$.*

PROOF. The covering families of $C^\sim$ for the canonical topology are the universally effective epimorphic families (II 2.5), that is (II 4.3), the epimorphic families. Let T be the topology of the site C, and let $\mathcal{T}_\mathcal{U}$ be the finest among the topologies T' on C such that, for every sheaf F on $C^\sim$, $F \circ \epsilon_C$ is a sheaf for T'. It suffices to show that $T = \mathcal{T}_\mathcal{U}$, for then $\mathcal{T}_\mathcal{U}$ is a $\mathcal{U}$-topology and consequently $\mathcal{T}_\mathcal{U}$ is the induced topology.

A) *The topology T is finer than $\mathcal{T}_\mathcal{U}$*: Let $(X_i \to X)$, $i \in I$, be a covering family for $\mathcal{T}_\mathcal{U}$. Then, for every sheaf F on $C^\sim$, the map $F(\epsilon_C(X)) \to \prod_i F(\epsilon_C(X_i))$ is injective, and consequently (II 5.2) $(\epsilon_C X_i \to \epsilon_C X)$, $i \in I$, is covering for the canonical topology of $C^\sim$, hence (II 5.2) $(X_i \to X)$, $i \in I$, is covering for T.

B) *The topology T is coarser than $\mathcal{T}_\mathcal{U}$*: It suffices to show that $\epsilon_C : C \to C^\sim$ is continuous (1.1). Now we shall prove in IV n° 1 that every sheaf on $C^\sim$ is representable, and consequently, for every sheaf F on $C^\sim$, $F \circ \epsilon_C$ is a sheaf on C. (We shall not use 3.5 before IV 1.)

We record two results that will be used in VI 7.

PROPOSITION 3.6. *Let $(C_i)_{i\in I}$ be a family of sites, let C be a category, and, for every $i \in I$, let $u_i : C_i \to C$ be a functor. Let $\mathcal{U}$ be a universe such that the categories C_i and C are $\mathcal{U}$-small. There exists a topology $\mathcal{T}_\mathcal{U}$ on C that is the coarsest among the topologies for which the u_i are continuous. The topology $\mathcal{T}_\mathcal{U}$ does not depend on the universe $\mathcal{U}$ relative to which the categories under consideration are small.*

The last assertion of 3.6 follows from 1.5.

Let T be a topology on C. The functors u_i are continuous if and only if, for every
285 $i \in I$ and every covering sieve $R \hookrightarrow X$ on an object X of C_i, the morphism

$$u_{i!}(R) \longrightarrow u_i(X)$$

in $\widehat{C}$ is bicovering (1.2 (ii)). Thus 3.6 is a consequence of the following lemma.

LEMMA 3.6.1. *Let C be a small category and let $(u_i : F_i \to G_i)_{i\in I}$ be a family of arrows in $\widehat{C}$. There exists on C a topology that is coarsest among those making the morphisms u_i covering (resp. bicovering)* (II 5.2).

To say that $u : F \to G$ is covering for a given topology T means that, for every arrow $X \to G$, with $X \in \mathrm{Ob}\, C$, the corresponding arrow $F \times_G X \to X$ is covering; equivalently, the family of arrows $X' \to X$ in C that factor through the preceding arrow is covering. The existence of a coarsest topology among those for which the $u_i : F_i \to G_i$ are covering thus follows from I 1.1.6, proving the assertion of 3.6.1 without the parenthetical alternative. The parenthetical assertion follows by recalling that a morphism $u : F \to G$ is bicovering if and only if the morphisms $u : F \to G$ and $\mathrm{diag}_u : F \to F \times_G F$ are covering.

PROPOSITION 3.7. *Let $(C_i)_{i\in I}$ be a family of sites, let C be a category, for every $i \in I$ let $u_i : C_i \to C$ be a functor, and let $\mathcal{U}$ be a universe such that the categories C_i and C are $\mathcal{U}$-small. There exists a topology $\mathfrak{T}_\mathcal{U}$ that is the finest for which the u_i are cocontinuous.*

The topology $\mathfrak{T}_{\mathscr{U}}$ does not depend on the universe $\mathscr{U}$ relative to which the categories under consideration are small.

Let $\mathscr{U}$ be a universe relative to which the categories under consideration are small. The functors u_i are cocontinuous for a topology $\mathfrak{T}$ on C if and only if, for every $i \in I$ and every sheaf F on C_i, the presheaf $\hat{u}_{i*}F$ is a sheaf for $\mathfrak{T}$ (2.2). It follows that the topology $\mathfrak{T}_{\mathscr{U}}$ is the finest topology for which the presheaves $\hat{u}_{i*}F$, $i \in I$, $F \in C_i^{\sim}$, are sheaves (II 2.2). The last assertion follows from 2.2.

4. Comparison lemma

286

THEOREM 4.1. (comparison lemma). *Let C be a small category, let C' be a site whose underlying category is a $\mathscr{U}$-category, and let $u : C \to C'$ be a fully faithful functor. Endow C with the topology induced by u (3.1). Consider the following properties:*

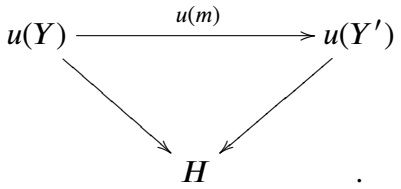
i) *Every object of C' can be covered by objects coming from C.*
ii) *The functor $F \mapsto F \circ u$ induces an equivalence from the category of sheaves on C' to the category of sheaves on C.*

We always have i) ⇒ ii). *When C' is a $\mathscr{U}$-site and the topology of C' is coarser than the canonical topology, we have* ii) ⇒ i).

4.1.1. Let us first prove i) ⇒ ii). The proof proceeds in two steps.

First step. For every presheaf H on C', the adjunction morphism $\varphi : u_!u^*H \to H$ (I 5.1) is bicovering (II 5.3), and the functor $u_s : \widetilde{C'} \to \widetilde{C}$ (1.1.1) is fully faithful.

Let C/H be the small category whose objects are the objects Y of C equipped with a morphism $u(Y) \to H$, and whose morphisms are the commutative diagrams



We have $u^*H = \varinjlim_{Y \in \mathrm{ob}\, C/H} Y$ (I 3.4), and hence (I 5.4) $u_!u^*H = \varinjlim_{Y \in \mathrm{ob}\, C/H} u(Y)$. The adjunction morphism is the evident morphism arising from the description of $u_!u^*H$ as an inductive limit. The morphism φ has the following property: (∗) For every object Y 287
of C, every morphism $m : u(Y) \to H$ factors uniquely as the canonical morphism $\alpha(m) : u(Y) \to u_!u^*H$ followed by φ. It follows immediately from i) that φ is covering (II 5.1); let us show that it is bicovering. Let $p, q : Z \rightrightarrows u_!u^*H$ be two morphisms from an object Z of C' such that $\varphi p = \varphi q$. For every object Y of C and every morphism $n : u(Y) \to Z$, we have $\varphi pn = \varphi qn$. Property (∗) then implies that $pn = qn$, and since the $u(Y)$ cover Z, the kernel of (p, q) is a covering sieve of Z. Thus φ is bicovering (II 5.3). For every sheaf H on C', u^*H is a sheaf on C, denoted by u_sH (1.1.1). Moreover, $u^su_sH = \underline{a}'u_!u_sH$ (1.3), and the adjunction morphism $u^su_sH \to H$ is obtained by applying the "associated sheaf" functor to $\varphi : u_!u^*H \to H$. Consequently (II 5.3), the adjunction morphism $u^su_sH \to H$ is an isomorphism. Hence $u_s : \widetilde{C'} \to \widetilde{C}$ is fully faithful.

Second step. The functor u is cocontinuous and the functor $u^s : C^{\sim} \to C'^{\sim}$ (1.2) is fully faithful. Consequently $u_s : C'^{\sim} \to C^{\sim}$ is an equivalence. Let Y be an object of C and let $i : R \hookrightarrow u(Y)$ be a covering sieve. Since the functor u^* commutes with projective limits (I 5.5), the morphism $u^*(i) : u^*(R) \hookrightarrow u^*u(Y)$ is a monomorphism. Since u is fully faithful, we have $u^*u(Y) \simeq Y$, and thus obtain a sieve of Y, $u^*(i) : u^*(R) \to Y$. To show that u is cocontinuous, it suffices to show that $u^*(i) : u^*(R) \hookrightarrow Y$ is a covering sieve for the

induced topology on C (2.1). For this, it suffices to show (3.2) that for every base change $m : X \to Y$, the morphism $u_!(u^*(R)\times_Y X) \to u(X)$ is bicovering. But since u^* commutes
288 with projective limits, we have $u^*(R) \times_Y X = u^*(R \times_{u(Y)} u(X))$, and $R \times_{u(Y)} u(X)$ is a covering sieve of $u(X)$. It therefore suffices to show that for every object Y of C and every covering sieve $i : R \hookrightarrow u(Y)$, the morphism in $\hat{C'}$, $u_!u^*(R) \xrightarrow{u_!u^*(i)} u(Y)$, is bicovering. Now this morphism factors as the adjunction morphism $u_!u^*(R) \to R$, which is bicovering (first step), followed by the covering monomorphism $R \hookrightarrow u(Y)$. It is therefore bicovering (II 5.3). This shows that u is cocontinuous. Since u is continuous and fully faithful, it follows from 2.6 (used in the case where C is small) that u^s (denoted by $u_!$ in 2.6) is fully faithful. Since u^s and u_s are adjoint to one another and are fully faithful, they are quasi-inverse functors, and hence u_s is an equivalence.

4.1.2. Let us now prove ii) ⇒ i). The objects Y of C form a generating family of $C^\sim$ (II 4.10), and consequently, for every object X of C', there exists an epimorphic family (in $C^\sim$) $v_i : Y_i \to u_sX$, $i \in I$. We have $u_su(Y_i) = Y_i$, and, since u_s is an equivalence of categories, $v_i = u_s(w_i)$, where the $w_i : u(Y_i) \to X$ form an epimorphic family in $C'^\sim$. It then follows from II 5.1 that the family $w_i : u(Y_i) \to X$, $i \in I$, is covering.

4.2. Completion of the proof of 1.2. Let G be a full subcategory of C whose objects form a small topologically generating family of C (II 3.0.1). Endow G with the topology induced by the inclusion functor $i : G \to C$ (3.1). The functor $(u \circ i)_s = i_s \circ u_s$ (1.1.1) has
289 a left adjoint by the first part of the proof of 1.2. Since i_s is an equivalence of categories (4.1), the functor u_s has a left adjoint u^s, and there is a functorial isomorphism $u^s \simeq (u \circ i)^s \circ i_s$. Let us show that the diagram

(4.2.1)
$$\begin{array}{ccc} C & \xrightarrow{u} & C' \\ {\scriptstyle \epsilon_C}\downarrow & & \downarrow{\scriptstyle \epsilon_{C'}} \\ C^\sim & \xrightarrow{u^s} & \widetilde{C'} \end{array}$$

commutes up to isomorphism. For every sheaf H on C', we have $\mathrm{Hom}_{\widetilde{C'}}(\epsilon_{C'}uX, H) \simeq u_sH(X)$ for every $X \in \mathrm{ob}\, C$. Moreover, $\mathrm{Hom}_{\widetilde{C'}}(u^s\epsilon_C X, H) \simeq \mathrm{Hom}_{\widetilde{C}}(\epsilon_C X, u_sH)$ by adjunction, and then $\mathrm{Hom}_{\widetilde{C}}(\epsilon_C X, u_sH) \simeq u_sH(X)$ by the definition of ϵ_C. Hence there is an isomorphism $\epsilon_{C'}uX \simeq u^s\epsilon_C X$ for every $X \in \mathrm{ob}\, C$. This proves i) ⇒ iv). Let us prove iv) ⇒ i). We have a commutative diagram

(4.2.2)
$$\begin{array}{ccccc} G & \xrightarrow{i} & C & \xrightarrow{u} & C' \\ {\scriptstyle \epsilon_G}\downarrow & & \downarrow{\scriptstyle \epsilon_C} & & \downarrow{\scriptstyle \epsilon_{C'}} \\ \widetilde{G} & \xrightarrow{i^s} & \widetilde{C} & \xrightarrow{u^s} & \widetilde{C'}, \end{array}$$

and consequently, by the first part of the proof, the functor $u \circ i : G \to C'$ is continuous. It follows at once from 4.1 and 1.1 that u is continuous, whence iv) ⇒ i). This also gives the uniqueness of u^s, since the first part of the proof gives uniqueness when C is small.

290

4.3. Completion of the proofs of 1.5 and 1.7. Let $u : C \to C'$ be a functor between two $\mathscr{U}$-sites, and let G be a full subcategory of C whose set of objects is a small topologically generating family of C (II 3.0.1). Endow G with the topology induced by the

inclusion functor $i : G \to C$. It follows immediately from 4.1 and 1.1 that u is continuous if and only if $u \circ i$ is continuous. This observation and the first part of the proof of 1.5 give the general case. The same observation also reduces the proof of 1.7 to the case where the category C is small.

4.4. Completion of the proof of 2.3. Let $u : C \to C'$ be a functor between two $\mathscr{U}$-sites, and let G be a full subcategory of C whose set of objects is a small topologically generating family of C (II 3.0.1), endowed with the topology induced by the inclusion functor $i : G \to C$. It follows from the proof of 4.1 (4.1.1, second step) that i is cocontinuous. Consequently, when u is cocontinuous, the functor $u \circ i : G \to C'$ is cocontinuous. Moreover, $i^* : \widetilde{C} \to \widetilde{G}$ is an equivalence of categories (4.1). Therefore the functor $u^* : \widetilde{C'} \to \widetilde{C}$ has a right adjoint. This proves 3). To prove 4), it suffices to observe that $(u \circ i)_* \simeq u_* \circ i_*$ and that i_* is an equivalence (4.1). The commutativity of (2.3.2) then follows from the commutativity of these diagrams when C is small.

5. Localization

291

5.1. Now let C be a $\mathscr{U}$-site and X an object of $\hat{C}$. Unless expressly stated otherwise, the category C/X will be endowed with the topology $\mathscr{T}$ induced by the functor $j_X : C/X \to C$ (3.1). The notation C/X will denote the category C/X endowed with the topology $\mathscr{T}$. Proposition I 5.11 shows that the functor $j_{X!}$ commutes with fiber products and consequently sends every monomorphism to a monomorphism. In particular, for every object $(Y \to X)$ of C/X, the functor $j_{X!}$ establishes a one-to-one correspondence between the sieves, in the category C/X, on the object $(Y \to X)$ and the sieves, in C, on the object Y.

PROPOSITION 5.2. *Let C be a $\mathscr{U}$-site, X an object of $\hat{C}$, and $j_X : C/X \to C$ the corresponding continuous functor.*

1) *A sieve R on an object $(Z \to X)$ is covering in C/X if and only if the sieve $j_{X!}(R) \hookrightarrow Z$ is covering in C.*
2) *The functor $j_X : C/X \to C$ is cocontinuous and continuous.*
3) *Let $m : Y \to X$ be a morphism of $\hat{C}$. We then have the commutative diagram*

$$\begin{array}{ccc} C/Y & \xrightarrow{j_m} & C/X \\ & {\scriptstyle j_Y} \searrow \quad \swarrow {\scriptstyle j_X} & \\ & C & \end{array} .$$

The topology induced by the functor j_Y on C/Y is equal to the topology induced by j_m on C/Y.

4) *The topology induced by $j_X : C/X \to C$ is a $\mathscr{U}$-topology (II 3.0.2).*

PROOF. 1) If the sieve R on $(Z \to X)$ is covering, the sieve $j_{X!}(R) \hookrightarrow Z$ is covering (1.6). 292

Conversely, if the sieve $j_{X!}(R) \to Z$ is covering in C, one sees that the same is true for every sieve obtained by a base change in C/X. The sieve R is therefore covering (3.2).

2) This follows immediately from 1) by applying 2.1.
3) This follows immediately from the description of covering sieves given in 1).

4) Let $(G_i)_{i\in I}$ be a small topologically generating family of C. One verifies immediately that the small family $(u : G_i \to X)$, $u \in \coprod_{i\in I} \mathrm{Hom}_{C^\sim}(G_i, X)$, is topologically generating in C/X.

Terminology and notation 5.3. By the preceding proposition, the functor j_X is both continuous and cocontinuous. It therefore defines a sequence of three adjoint functors (4.3.2) between the categories of sheaves of sets (1.3 and 2.3):

$$j_X^s : (C/X)^\sim \longrightarrow C^\sim$$
$$j_X^* = j_{X,s} : C^\sim \longrightarrow (C/X)^\sim$$
$$j_{X*} : (C/X)^\sim \longrightarrow C^\sim.$$

In the particular situation of Proposition 5.2, we shall use the following terminology and notation:

1) The functor j_{X*} will be called the *direct image functor.*
2) The functor $j_{X,s} = j_X^*$ will be denoted by j_X^* and will be called the *restriction functor to* C/X.
293 3) The functor j_X^s on sheaves of sets will be called the "extension by the empty set to C" functor and will be denoted by $j_{X!}$ (cf. 2.9.2).

Thus we have a sequence of three adjoint functors between $(C/X)^\sim$ and $C^\sim$:

$$j_{X!},\ j_X^*,\ j_{X*}.$$

Proposition 5.4. *The functor $j_{X!} : (C/X)^\sim \to C^\sim$ factors through the category $C^\sim/\underline{a}X$ ($\underline{a}$ is the associated sheaf functor):*

$(C/X)^\sim \xrightarrow{e_X^\sim} C^\sim/\underline{a}X \to C^\sim$. *The functor*

$$e_X^\sim : (C/X)^\sim \longrightarrow \widetilde{C}/\underline{a}X$$

is an equivalence of categories. The restriction functor to C/X, followed by the equivalence $e_X^\sim$, is isomorphic to the "base change by $\underline{a}X \to \epsilon$" functor ($\epsilon$ being the terminal object of $C^\sim$): $F \mapsto (F \times \underline{a}X \xrightarrow{\mathrm{pr}_2} \underline{a}X)$.

Proof. The image under $j_{X!}$ of the terminal object of $(C/X)^\sim$ is the object $\underline{a}X$, which gives the factorization. To show that the functor $e_X^\sim$ is an equivalence, we shall confine ourselves to a few indications. By I 5.11, a presheaf on C/X is defined by a presheaf F on C equipped with a morphism $F \to X$. One then proves that the following two properties are equivalent:

i) The presheaf on C/X defined by $F \to X$ is a sheaf.
ii) The following diagram is cartesian (where i and $\underline{a}$ denote the inclusion in the category of presheaves and the associated sheaf functor, respectively):

$$\begin{array}{ccc} F & \longrightarrow & i\underline{a}F \\ \downarrow & & \downarrow \\ X & \longrightarrow & i\underline{a}X \end{array} .$$

294 It follows immediately that $e_X^\sim$ is an equivalence. The last assertion is trivial.

PROPOSITION 5.5. 1) *Let C be a $\mathscr{U}$-site and X an object of $\hat{C}$. The diagram below of categories and functors commutes up to canonical isomorphisms:*

$$\begin{array}{ccccccccc}
C/X & \xrightarrow{h_X} & (C/X)\hat{} & \xrightarrow{\underline{a}_X} & (C/X)\tilde{} & \xrightarrow{\quad i_X \quad} & (C/X)\hat{} \\
\downarrow & & \downarrow{\scriptstyle e\hat{}_X} & & \downarrow{\scriptstyle e\tilde{}_X} & & \downarrow{\scriptstyle e\hat{}/X} \\
C/X & \xrightarrow{h/X} & C\hat{}/X & \xrightarrow{\underline{a}/X} & C\tilde{}/\underline{a}X & \xrightarrow{i/\underline{a}X} & C\hat{}/i\underline{a}X & \xrightarrow{\pi} & C\hat{}/X.
\end{array}$$

The notations $\underline{a}_X$ and i_X denote the "associated sheaf" and inclusion into presheaves functors for the site C/X. The notation $\underline{a}/X$ denotes the natural extension of the functor $\underline{a}$ (the associated sheaf functor for the site C) to the category of arrows with target X; similarly for the notation $i/\underline{a}X$. Finally, the notation π denotes the base-change functor along the canonical arrow $X \to i\underline{a}X$.

2) *Let, in addition, $m : Y \to X$ be a morphism of $\hat{C}$. The following diagram commutes up to canonical isomorphism:*

$$\begin{array}{ccccc}
C\tilde{}/\underline{a}X/\underline{a}Y & \xleftarrow{\quad f \quad} & (C/X)\tilde{}/\underline{a}_X Y & & \\
\| & & & \overset{g}{\nwarrow} & \\
 & & & & (C/X/Y)\tilde{} \\
 & & & \overset{e\tilde{}_m}{\swarrow} & \\
C\tilde{}/\underline{a}Y & \xleftarrow{e\tilde{}_Y} & (C/Y)\tilde{} & &
\end{array} .$$

The arrow f is the natural extension of the equivalence $e\tilde{}/X$ to the category of arrows with target $\underline{a}_X Y$, and is consequently an equivalence of categories. The arrow g is precisely the equivalence of 5.4 applied to the situation $(C/X)/[m]$. 295

3) *Denote by $j_{\underline{a}X!} : C\tilde{}/\underline{a}X \to C\tilde{}$ the "forget $\underline{a}X$" functor, and by $j^*_{\underline{a}X} : C\tilde{} \to C\tilde{}/\underline{a}X$ the "product with $\underline{a}X$" functor. The following diagrams commute up to canonical isomorphism:*

$$\begin{array}{ccc}
(C/X)\tilde{} & \xrightarrow{j_{X!}} & C\tilde{} \\
\downarrow & & \| \\
C\tilde{}/\underline{a}X & \xrightarrow{j_{\underline{a}X!}} & C\tilde{}
\end{array} \quad , \quad
\begin{array}{ccc}
C\tilde{} & \xrightarrow{j^*_X} & (C/X)\tilde{} \\
\| & & \downarrow{\scriptstyle e\tilde{}/X} \\
C\tilde{} & \xrightarrow{j^*_{\underline{a}X}} & C\tilde{}/\underline{a}X.
\end{array}$$

PROOF. The proof of these assertions follows immediately from the definition of the equivalences $e\tilde{}_X$ (5.4) and $e\hat{}_X$ (I 5.11).

EXPOSÉ IV

Topoi

A. Grothendieck and J.-L. Verdier

0. Introduction

299

0.1. We saw in II various exactness properties of categories of the form $\widetilde{\mathscr{C}}$ = the category of sheaves of sets on $\mathscr{C}$, where $\mathscr{C}$ is a small site. These properties can be expressed by saying that in many respects such categories (which we shall call *topoi*) inherit the familiar properties of the category (Ens) of (small) sets. On the other hand, experience has shown that various situations in Mathematics should be regarded *above all as a technical means of constructing the corresponding categories of sheaves* (of sets), i.e. *the corresponding "topoi."* It appears that all the genuinely important notions attached to a site (for example its cohomological invariants, studied in V; various other "topological" invariants, such as its homotopy invariants recently studied by M. Artin and B. Mazur [1]; and the notions studied in J. Giraud's book on noncommutative cohomology) are in fact expressed directly in terms of the associated topos. From this point of view, two sites should be regarded as essentially equivalent when their associated topoi are equivalent categories. The datum of a site (at least in the case, especially important in practice, where its topology is coarser than its canonical topology) should be regarded as amounting to the datum of a topos $\mathscr{E}$ (namely the associated topos formed by the sheaves of sets on the site) together with a generating family of objects of $\mathscr{E}$ (cf. II 4.9, and 1.2.1 below). This viewpoint is analogous to associating a group with a system of generators and a system of relations among those generators, and attaching interest rather to the structure of that group than to the system of generators and relations used to generate it (which are regarded as auxiliary data of the situation). Moreover, the "comparison lemma" III 4.1 provides numerous examples of pairs of sites $\mathscr{C}$, $\mathscr{C}'$ that are not isomorphic, and are not even equivalent as categories, but give rise to equivalent topoi; thus $\mathscr{C}$ and $\mathscr{C}'$ should be regarded as essentially equivalent.

300

0.2. In the present exposé we give a characterization of topoi by simple exactness properties (due to J. Giraud); we study the natural notion of a morphism of topoi, inspired by the notion of a continuous map from one topological space to another; and we develop in the setting of topoi certain constructions familiar from ordinary sheaf theory (sheaves **Hom**, tensor-product sheaves, supports). Finally, following M. Artin, we show how a topos can be reconstructed from an "open" part, its complementary "closed" part, and a certain left exact functor connecting them, which may in fact be chosen almost arbitrarily.

0.3. This gives a procedure for gluing topoi which, when applied to topoi arising from ordinary topological spaces, will in general produce a topos no longer of the same type. This is a first indication of the remarkable stability of the notion of a topos under various natural constructions, a stability lacking for the notion of a topological space (from which the notion of a topos is inspired). As a second remarkable example, let

301

us also mention the relative classifying topos of a group in a topos (cf. [1] or 5.9 below), inspired by the classical notion of the classifying space of a topological group, and the notion of a "moduli topos" associated with various "moduli problems" in Algebraic Geometry or Analytic Geometry [10] [13].

Other topoi, such as the *étale topos* of a scheme (systematically studied in the present Seminar beginning with Exp. VII) or the *crystalline topos* of a relative scheme [6], arise naturally when one wishes to develop usable cohomology theories for abstract algebraic varieties (and, more generally, schemes), replacing the classical Betti cohomology of algebraic varieties over the field of complex numbers.

0.4. Thus one may say that the notion of a topos, a natural outgrowth of the *sheaf-theoretic viewpoint* in Topology, in turn constitutes a substantial enlargement of the notion of a topological space[4], embracing a large number of situations which formerly were not regarded as belonging to topological intuition. The characteristic feature of such situations is the availability of a notion of "localization," a notion formalized precisely by that of a site and, ultimately, by that of a topos (through the topos associated with the site). As the term "topos" itself is intended precisely to suggest, it seems reasonable and legitimate to the authors of the present Seminar to regard the subject of Topology as the study of *topoi* (and not merely of topological spaces).

0.5. It seemed useful to include in this general exposé on topoi a fairly large number
302 of examples, many of which are only remotely related to the original aim of this seminar (namely, the study of étale cohomology). The reader in a hurry, interested exclusively in étale cohomology, may of course omit these examples without inconvenience, as well as most of the present exposé, consulting it only when the need arises.

1. Definition and characterization of topoi

DEFINITION 1.1. *A category E is called a $\mathcal{U}$-topos, or simply a topos when no confusion is likely, if there exists a site $C \in \mathcal{U}$ such that E is equivalent to the category $\tilde{C}$ of $\mathcal{U}$-sheaves of sets on C.*

1.1.1. Let E be a $\mathcal{U}$-topos. We always regard E as endowed with its canonical topology (II 2.5), which therefore makes it a *site*, and even, by 1.1.2 d) below, a $\mathcal{U}$-site (II 3.0.2). Unless expressly stated otherwise, we shall consider no topology on E other than the one just specified.

1.1.2. We saw in II 4.8, II 4.11 that a $\mathcal{U}$-topos E is a $\mathcal{U}$-category (I 1.1) satisfying the following conditions:

a) Finite projective limits are representable in E.
b) Direct sums indexed by an element of $\mathcal{U}$ are representable in E. They are disjoint and universal (II 4.5).
c) Equivalence relations in E are universally effective (I 10.10).
d) E admits a generating family (II 4.9) indexed by an element of $\mathcal{U}$.

303 In fact, we shall see that these intrinsic properties *characterize* $\mathcal{U}$-topoi:

THEOREM 1.2. (J. Giraud). *Let E be a $\mathcal{U}$-category. The following properties are equivalent:*

i) *E is a $\mathcal{U}$-topos* (1.1).
ii) *E satisfies conditions* a), b), c), *and* d) of 1.1.2.

[4] Cf. [9], or 4.1 and 4.2 below, for the precise relations between the notion of a topos and that of a topological space.

iii) *The $\mathscr{U}$-sheaves on E for the canonical topology are representable, and E has a small generating family (condition* 1.1.2 d)*).*

iv) *There exist a category $C \in \mathscr{U}$ and a fully faithful functor $i : E \to \hat{C}$ (where $\hat{C}$ denotes the category of $\mathscr{U}$-presheaves on C) having a left adjoint a which is left exact.*

i′) *There exists a site $C \in \mathscr{U}$ such that projective limits are representable in C and the topology of C is coarser than its canonical topology* (II 2.5)*, and such that E is equivalent to the category $\tilde{C}$ of $\mathscr{U}$-sheaves of sets on C.*

Moreover:

COROLLARY 1.2.1. *Let E be a $\mathscr{U}$-topos, and let C be a full subcategory of E, endowed with the topology induced* (III 3.1) *by that of E (1.1.1). Consider the functor*

$$E \longrightarrow \tilde{C}$$

which associates to every $X \in \mathrm{ob}\, E$ the restriction to C of the functor represented by X. This functor is an equivalence of categories if and only if ob C *is a generating family of E.*

The equivalence i) ⇔ iv) follows immediately from II 5.5, and we have already re- 304
called above that i) ⇒ ii). Since i′) ⇒ i) trivially, it remains to prove ii) ⇒ iii) and iii) ⇒ i′), which will be done in 1.2.4 and 1.2.3 below. The corollary is then obtained by observing that the functor in question factors as $E \to \tilde{E} \to \tilde{C}$; since $E \to \tilde{E}$ is an equivalence by virtue of (iii), the question reduces to determining when $\tilde{E} \to \tilde{C}$ is an equivalence. The conclusion then follows from the "comparison lemma" III 4.1; cf. the proof in 1.2.3 below.

1.2.3. *Proof of* iii) ⇒ i′). Let $\mathfrak{X} = (X_i)_{i \in I}$, $I \in \mathscr{U}$, be a small generating family of E. Since E is a $\mathscr{U}$-category, the set of isomorphism classes of finite diagrams in E whose objects are members X_i is $\mathscr{U}$-small. Consequently, the smallest set $\mathfrak{X}'$ of objects of E containing the finite projective limits of objects of $\mathfrak{X}$ is a countable union of small sets and is therefore small [4]. Setting $\mathfrak{X}^{(n+1)} = (\mathfrak{X}^{(n)})'$, and $\mathfrak{X} = \bigcup_n \mathfrak{X}^{(n)}$, we see that, after enlarging the generating family, we may suppose that $\mathfrak{X}$ is stable under finite projective limits. Let $\mathscr{V}$ be a universe containing $\mathscr{U}$ such that E is $\mathscr{V}$-small. For every object H of E, denote by $I(H)$ the set $\coprod_{i \in I} \mathrm{Hom}(X_i, H)$. Let H be an object of E and let $H' \hookrightarrow H$ be the subsheaf of H, for the canonical topology, which is the "union" of the images of the morphisms $u : X_i \to H$, $(u, i) \in I(H)$ (II 4.1). Since H' is a subsheaf of a $\mathscr{U}$-sheaf, H' is a $\mathscr{U}$-sheaf. It is therefore representable. Since the family $\mathfrak{X}$ is generating and, for every $i \in I$, the map $\mathrm{Hom}(X_i, H') \to \mathrm{Hom}(X_i, H)$ is bijective, the morphism $H' \hookrightarrow H$ is an isomorphism (II 4.9). Consequently (II 5.2), the family $(u : X_i \to H), (u, i) \in I(H)$, is covering for the canonical topology of E. Thus every object of E can be covered, 305
for the canonical topology of E, by objects of $\mathfrak{X}$. Let C be the full subcategory of E defined by the objects of $\mathfrak{X}$, and let $u : C \hookrightarrow E$ be the inclusion functor. The topology $\mathscr{C}$ induced on C by the canonical topology of E is coarser than the canonical topology of C, and when $\mathscr{U}$ contains an element of infinite cardinality, finite projective limits are representable in C. It follows from III 4.1 that the functor $F \mapsto F \circ u$ is an equivalence from E to the category of $\mathscr{U}$-sheaves on C for the topology $\mathscr{C}$, C.Q.F.D.

1.2.4. *Proof of* ii) ⇒ iii). The proof consists of four steps.

Let $\mathscr{V}$ be a universe containing $\mathscr{U}$, such that E is an element of $\mathscr{V}$. Let $\widetilde{E}$ be the category of $\mathscr{V}$-sheaves on E for the canonical topology, and let $J_E : E \to \widetilde{E}$ be the canonical functor.

[4] Here we reason with classes of objects of E up to isomorphism.

. Let $(g_i : G_i \to H)$, $i \in I \in \mathscr{U}$, be an epimorphic family in $\widetilde{E}$. If the G_i and the fiber products $G_i \times_H G_j$ are representable, then the sheaf H is representable.

Indeed, the direct sum $\coprod_{i\in I} G_i$ is represented in $\widetilde{E}$ (II 4.1) by a representable sheaf G (property b) and II 4.6). The same holds for the direct sum $K = \coprod_{(i,j)\in I\times I} G_i \times_H G_j$. Moreover, the diagram $K \rightrightarrows G \to H$ is exact and K is the fiber square of G over H. (This latter property holds in the category of presheaves, and hence in the category of sheaves (II 4.1).) It follows from c) and II 4.7 that the sheaf H is representable.

. Let X_α, $\alpha \in A \in \mathscr{U}$, be a generating family of E. For every sheaf H, denote by $I(H)$
306 the set $\coprod_{\alpha\in A} \mathrm{Hom}_E(X_\alpha, H)$. The family $(u : X_\alpha \to H, (u,\alpha) \in I(H))$ is epimorphic in $\widetilde{E}$. When H is a $\mathscr{U}$-sheaf, $I(H)$ is an element of $\mathscr{U}$.

Indeed, since every sheaf H is the target of an epimorphic family of morphisms whose sources are representable sheaves (I 3.4 and II 4.1), it is enough to prove the first assertion when the sheaf H is representable. Let G then be the image of the family $(u : X_\alpha \to H, (u,\alpha) \in I(H))$. The morphism $G \to H$ is a monomorphism. We are therefore in the situation of the first step, since $X_\alpha \times_G X_\beta$ is isomorphic to $X_\alpha \times_H X_\beta$, which is representable, and moreover $I(H)$ is an element of $\mathscr{U}$. It follows that G is representable. But since X_α is a generating family, $G \to H$ is an isomorphism. The last assertion is immediate from the definition of $\mathscr{U}$-sheaves.

. Every subsheaf of a representable sheaf is representable.

Indeed, let $G \to H$ be a subsheaf of a representable sheaf. Then G is a $\mathscr{U}$-sheaf. The family $(u : X_\alpha \to G, (u,\alpha) \in I(G))$ is therefore epimorphic in $\widetilde{E}$ and indexed by an element of $\mathscr{U}$. Moreover, the fiber products $X_\alpha \times_G X_\beta$ are isomorphic to the fiber products $X_\alpha \times_H X_\beta$, which are representable. Thus we are in the situation of the first step and G is representable.

. Every $\mathscr{U}$-sheaf is representable.

Indeed, by the first and second steps, it is enough to show that the fiber products $X_\alpha \times_H X_\beta$ are representable. But these fiber products are subobjects of the products $X_\alpha \times X_\beta$. The conclusion therefore follows from the third step. This completes the proof of Theorem 1.2.

307 Remark 1.3. Of course, for a given $\mathscr{U}$-topos E, there is in general no preferred way of representing it, up to equivalence, in the form $\tilde{C}$, with C a *small* site; or, what amounts essentially to the same thing by virtue of 1.2.1 when one restricts to C whose topology is coarser than the canonical topology, there is no preferred *small* generating family in E. When one ceases to impose on C the condition that C be small, there is, on the other hand (by virtue of 1.2 iii)), an entirely canonical choice of a $\mathscr{U}$-site C such that E is equivalent to $\tilde{C}$, namely E itself! This is one of the technical reasons why in practice it is inconvenient to work only with small sites: in fact, the most important sites of all, namely $\mathscr{U}$-topoi, are not small! Moreover, the sites generating topoi that arise in many questions in algebraic geometry (and even in topology, cf. 2.5) are not small either; examples include the étale site of a scheme (VII.1).

Proposition 1.4. *Let E be a $\mathscr{U}$-topos, let E' be a category (not necessarily a $\mathscr{U}$-category), and let F be a presheaf on E with values in E'. In order that F be a sheaf with values in E'* (II 6.1)*, it is necessary and sufficient that F take $\mathscr{U}$-inductive limits in E to projective limits in E'.*

Let $\mathscr{V}$ be a universe containing $\mathscr{U}$ and such that E' is a $\mathscr{V}$-category. By composing F with the functors $\mathrm{Hom}(X', -) : E' \to \mathscr{V}$-Ens defined by the objects X' of E', we are

reduced to the case where $E' = \mathscr{V}\text{-Ens}$, with $\mathscr{V}$ a universe. Suppose that F takes $\mathscr{U}$-inductive limits to projective limits. It then follows at once from the definitions that F is a sheaf, since a covering family $X_i \to X$ in $\mathscr{E}$, by the definition of the canonical topology 308
of $\mathscr{E}$, allows one to regard X as an inductive limit of the diagram $\left(X_i \times_X X_j \overset{\nearrow X_i}{\searrow X_j}\right)$.
Suppose that F is a sheaf, and let us prove that it takes $\mathscr{U}$-inductive limits to projective limits. If $\mathscr{V} \subset \mathscr{U}$, we may suppose that $\mathscr{V} = \mathscr{U}$, and it suffices to apply criterion 1.2 iii). To treat the general case, a little more work is needed. Let C be a full subcategory of E generated by a generating family indexed by an element of $\mathscr{U}$, and let $u : C \to E$ be the inclusion functor. Endow C with the topology induced by the canonical topology of E (III 3.5). Denote by $\tilde{C}_{\mathscr{U}}$ and $\tilde{C}_{\mathscr{V}}$ the categories of sheaves on C, by $\tilde{E}_{\mathscr{V}}$ the category of V-sheaves on E for the canonical topology, by $J_E : E \to E_{\mathscr{V}}$ the canonical functor, and by $i_{\mathscr{U},\mathscr{V}} : \tilde{C}_{\mathscr{U}} \to \tilde{C}_{\mathscr{V}}$ the inclusion functor. The diagram

(∗)
$$\begin{array}{ccc} \tilde{C}_{\underline{U}} & \xrightarrow{i_{\underline{U},\underline{V}}} & \tilde{C}_{\underline{V}} \\ \uparrow & & \uparrow \\ E & \xrightarrow{J_E} & \tilde{E}_{\underline{V}} \end{array},$$

where the vertical arrows are induced by the functor $F \mapsto F \circ u$, is commutative. It follows from the explicit construction of the associated sheaf functor (II 3) and from II 4.1 that the functor $i_{\mathscr{U},\mathscr{V}}$ commutes with $\mathscr{U}$-inductive limits. Moreover, it follows from III 5.1 and 1.5 that the vertical arrows in (∗) are equivalences of categories. Consequently, $J_E : E \to \tilde{E}_{\mathscr{V}}$ commutes with $\mathscr{U}$-inductive limits. For every object X of E, we have

$$F(X) \simeq \mathrm{Hom}_{\tilde{E}_{\mathscr{V}}}(J_E(X), F).$$

Thus F takes $\mathscr{U}$-inductive limits in E to projective limits. 309

Corollary 1.5. *Let E be a $\mathscr{U}$-topos, let E' be a $\mathscr{U}$-category, and let $f : E \to E'$ be a functor. In order that f admit a right adjoint, it is necessary and sufficient that f commute with $\mathscr{U}$-inductive limits.*

This is an immediate consequence of 1.4 in the case $E' = \mathscr{U}\text{-Ens}$.

Corollary 1.6. *Let E and E' be two $\mathscr{U}$-topoi, and let $f : E \to E'$ be a functor. The following conditions are equivalent:*

i) *f commutes with $\mathscr{U}$-inductive limits.*
ii) *f admits a right adjoint.*
iii) *f is continuous* (III 1.1).

The equivalence i) ⇔ ii) was proved in 1.5. To prove i) ⇔ iii), apply the definition of continuous functors, choosing a universe $\mathscr{V}$ such that $\mathscr{U} \in \mathscr{V}$ (so E and E' are $\mathscr{V}$-small sites). We must express that for every $\mathscr{V}$-sheaf F on E', the composite $F \circ f$ is a sheaf on E, that is (1.4), that it takes $\mathscr{U}$-inductive limits to projective limits. For this it is sufficient that i) hold, since by 1.4 F itself takes $\mathscr{U}$-inductive limits to projective limits; it is also necessary, as one sees by taking F to be a representable functor.

Corollary 1.7. *With the notation of 1.6, in order that f be the inverse-image functor u^* for a morphism of topoi* (3.1) *$u : E' \to E$, it is necessary and sufficient that f be left exact and take epimorphic families to epimorphic families.*

310 The necessity is trivial by definition (NB every right exact functor takes epimorphisms to epimorphisms). The sufficiency follows from III 1.6, which implies that f is continuous under the stated conditions, and hence commutes with $\mathscr{U}$-inductive limits by 1.6.

Remark 1.8. With the notation of 1.5, one can show that f admits a left adjoint if and only if it commutes with $\mathscr{U}$-projective limits. In other words, a *covariant* functor $E \to (\mathscr{U}\text{-Ens})$ is representable if and only if it commutes with $\mathscr{U}$-projective limits [4]. We indicate only the principle of the proof, which proceeds in three steps:

a) Standard arguments [5, n° 195, § 3] show that if F commutes with $\varprojlim$, it is prorepresentable by a strict projective system $(T_i)_{i\in I}$, where I is a filtered ordered set, *not necessarily small.* We may suppose that if $i > j$, then $T_i \to T_j$ is not an isomorphism, and under this hypothesis F is representable if and only if I is small (which in fact implies that the projective system is essentially constant).

b) To prove that I is small, knowing that for every object X of E the set $F(X) = \varinjlim_i \mathrm{Hom}(T_i, X)$ is small, it suffices to have a *small cogenerating family* $(X_j)_{j\in J}$ (i.e. one that is generating for the opposite category E°). Now one shows that every $\mathscr{U}$-topos E has a small cogenerating family.

c) To prove this last point, one observes by standard arguments [Toh] that every object X of E admits a monomorphism into an "injective" object; and then that
311 for every generating family (L_α) of E, if each L_α is embedded in this way into an injective object I_α, the family (I_α) is cogenerating.

2. Examples of topoi

2.0. We have brought together in this section a fairly large number of typical examples of topoi, which the reader will already have had occasion to encounter elsewhere, and which are intended to facilitate his access to the "yoga" of topoi. For other examples (drawn from algebraic geometry) of topologies on sites, giving rise to as many topoi, he may consult SGA 3 IV 6, and (for the étale topos) Exposé VII of the present seminar. Since later on we shall hardly refer to the present section except for questions of notation or terminology, we leave it to the reader, as an exercise, to verify the statements with which we have supplemented these examples for his general instruction. All the examples of the present section will be made more precise in 4, where their functorial dependence on the data will be examined, and in the following sections by way of illustration of the general notions concerning topoi.

2.1. Topos associated with a topological space. Let X be a small topological space, and let $\mathrm{Ouv}(X)$ be the category of open subsets of X, endowed with the canonical topology (III 1.9.1). We shall denote by $\mathrm{Top}(X)$ the topos of $\mathscr{U}$-sheaves on $\mathrm{Ouv}(X)$. This topos is equivalent to the category of étale topological spaces over X, by associating with every such space X' over X the sheaf $U \mapsto \Gamma(X'/U) = \mathrm{Hom}_X(U, X')$ on $\mathrm{Ouv}(X)$ [TF][5]
312 By an abuse of language, we shall sometimes be unable to refrain from denoting by the same letter X the topos $\mathrm{Top}(X)$ defined by the topological space X.

It is of course the preceding example that served chiefly as a guide and as an intuitive basis for the development of the theory of topoi. One should note, however, that the topoi obtained from topological spaces are of a very special nature, owing in particular

[4] A more general statement is found in I 8.12.8, I 8.12.9; the outline of the proof following a) through c) corresponds to the proof given in *loc. cit.*

[5] N.D.E.: Here [TF] denotes reference [8].

to the fact that they have been described by sites $C = \mathrm{Ouv}(X)$ in which *all morphisms are monomorphisms* (and hence whose underlying category reduces to a preordered set). It follows in particular that the sheaves represented by the objects of C are subsheaves of the terminal sheaf, and consequently that *the subsheaves of the terminal sheaf form a generating family of the topos under consideration.* This property is not shared by most topoi that arise naturally in algebraic geometry or in algebra, cf. the examples below. It is, up to minor qualifications, characteristic of topoi of the form $\mathrm{Top}(X)$ (cf. 7.1.9 below).

It is easily verified that the map $\mathrm{Ouv}(X) \to \mathrm{Top}(X)$, which associates with every open subset of X the sheaf it represents, is a *bijection* from $\mathrm{Ouv}(X)$ onto the set of subobjects of the terminal object of $\mathrm{Top}(X)$; this bijection is even an isomorphism for the natural order structures, i.e. it induces an isomorphism of the corresponding categories. This suggests that it should be possible to reconstruct the topological space X, up to homeomorphism, from $\mathrm{Top}(X)$ known up to equivalence. We shall see below (4.2) that this is indeed the case, subject to a slight restriction on X.

313

2.2. **Point topos or terminal topos, and empty topos or initial topos.** When X is a topological space consisting of a single point, the functor

$$F \longrightarrow F(X) : \mathrm{Top}(X) \longrightarrow \mathscr{U}\text{-Ens}$$

is an equivalence of categories. This shows in particular that the *category* $\mathscr{U}$-Ens is a *$\mathscr{U}$-topos.* We saw by examples in Exp. II that this $\mathscr{U}$-topos is typical from the point of view of exactness properties, in that the verification of many properties (especially exactness properties) of general topoi reduces to this particular topos. The interpretation given here in terms of the one-point topological space justifies the abuse of language by which a topos equivalent to the category $\mathscr{U}$-Ens is called a *point topos* (although, as a category, it is not at all equivalent to the one-point category!). This is the terminology that corresponds to the correct geometric intuition of the role played by these topoi. By another abuse of language, a point topos is sometimes called a *terminal topos*, cf. 4.3; we shall say "*the* terminal topos" for the topos ($\mathscr{U}$-Ens).

When X is the empty topological space, so that $\mathrm{Ouv}(X)$ is the one-point category, a presheaf F on $\mathrm{Ouv}(X)$ is a sheaf if and only if its value at the unique object ϕ of $\mathrm{Ouv}(X)$ is a singleton set. It follows that $\mathrm{Top}(\varnothing)$ is isomorphic to the category of singleton $\mathscr{U}$-sets, a category equivalent to the one-point category. From this one concludes in particular that the one-point category (as well as any $\mathscr{U}$-category equivalent to it) is a $\mathscr{U}$-topos. By an abuse of language, it is sometimes called the *empty topos* or the *initial topos* (cf. 4.4); 314
one should take care that it is not equivalent to the empty category.

2.3. **Topos associated with a space with operators.** Let X be a topological space and G a discrete group acting on X by homeomorphisms. In [Toh][6] 5.1 the category of *G-sheaves on X*, or, as we shall also say, sheaves on (X, G), was defined; these are sheaves (of sets) on X *equipped* with actions of G compatible with those of G on X. One sees at once, using Giraud's criterion 1.2 iii), that this category is a topos (NB $\mathscr{U}$ is understood throughout), which we shall simply denote by $\mathrm{Top}(X, G)$. When G is the trivial group, we recover the example of 2.1; when X is the one-point space, we obtain the topos of sets on which G acts on the left (or *G-sets*), also called the *classifying topos of the discrete group G*, and denoted by B_G. It is easily verified that the only subobjects of the terminal object e of the topos B_G are e and the empty sheaf ϕ; in particular, if G is not the trivial group, the subobjects of the terminal object of the classifying topos B_G

[6] N.D.E.: Here [Toh] denotes reference [4].

do not form a generating family of B_G. Thus B_G is then not equivalent to a topos of the type Top(X) considered in 2.1.

The notion of a G-sheaf was introduced in *loc. cit.* in order to develop the cohomological theory of abelian G-sheaves. Interpreting the latter as the abelian sheaves of the topos (X, G), that theory becomes part of the theory of Exp. V, developed in the setting of general topoi.

315 More generally, one may seek to associate an appropriate topos with a topological space X equipped with a topological group G (not necessarily discrete) of automorphisms, which would give rise to an adequate cohomological theory. The same may be done in the context of differentiable manifolds, real or complex analytic manifolds, or schemes. This is indeed possible, cf. 2.5 below.

2.4. Classifying topos of a group object. Let E be a topos, and let G be a group object of E. Let (E, G) be the category of objects of E on which G acts. It follows at once from Giraud's criterion that this is a topos. It is called the *classifying topos* of the group object G, and is denoted by B_G. When E is the point topos (2.2), i.e. when G is an ordinary group, we recover the classifying topos of 2.3.

The terminology adopted here is justified by the fact that the topos B_G plays a universal role in the classification of "torsors" (or homogeneous principal bundles) under G, or more generally under $G_{E'} = f^*(G)$, where E' is a topos "over E", i.e. endowed with a morphism $f : E' \to E$ (cf. 3.1 below). This role, made explicit in [3 Chap V] or in 5.9 below, shows that B_G plays, in the context of topoi, the same role as the classical classifying spaces of topological groups in the homotopy theory of topological spaces. The latter may be regarded (cf. 2.5) as a weakened version of the former, obtained by retaining from the classifying topos only the "homotopy type" of that topos, in a suitable sense which need not be specified here.

2.5. "Big site" and "big topos" of a topological space. Classifying topos of a topo-
316 **logical group.** [6]

Let U – Esp, or simply (Esp), be the category of topological spaces $\in \mathcal{U}$. It is known that finite projective limits are representable in (Esp). Consider on (Esp) the pretopology (II 1.3) for which Cov(X) is the set of surjective families of open embeddings $u_i : X_i \to X$. We regard (Esp) as a site by means of the topology generated by the preceding pretopology. For every object X of (Esp), regard the category

$$(\mathrm{Esp})_{/X}$$

of objects of (Esp) over X, i.e. topological spaces over X, as a site, using the topology induced by that of (Esp) via the forgetful functor $(\mathrm{Esp})_{/X} \to (\mathrm{Esp})$ (III 5.2 4)). This site is called the *big site* associated with X. One should note that it is not $\in \mathcal{U}$; nor is it a $\mathcal{U}$-site in the sense of II 3.0.2, so precautions are necessary when applying the usual results to it. To remedy this inconvenience, one may choose a universe $\mathcal{V}$ such that $\mathcal{U} \in \mathcal{V}$, so that $(\mathrm{Esp})_{/X}$ becomes a $\mathcal{V}$-site, and work with the associated $\mathcal{V}$-topos $(\mathrm{Esp})_{/X}$, which may be denoted by TOP(X) and will be called the *big topos of* X. If one is reluctant to enlarge $\mathcal{U}$, one may choose a cardinal c bounding the cardinalities of X and of all the topological spaces one intends to use in the arguments (most often, Sup(card X, card $\mathbb{R}$) will suffice!), and replace $(\mathrm{Esp})_{/X}$ by the subcategory $(\mathrm{Esp})'_{/X}$ consisting of those X' over X such that card $X' \leq c$, endowed with the induced topology; one then denotes by
317 TOP(X) the topos of sheaves on this site. To fix ideas, suppose that the first definition

[6] The introduction of these sites and topoi is due to M. Giraud, who also brought out their advantages over the traditional "small" site.

has been adopted.

The advantage of the big topos of X over the small one is that the site defining it contains $(\mathrm{Esp})_{/X}$ as a full subcategory; since the topology of this site is manifestly coarser than the canonical topology, the canonical functor from $(\mathrm{Esp})_{/X}$ to $\mathrm{TOP}(X)$, associating with every space X' over X the sheaf it represents, is seen to be *fully faithful.* Consequently, *a space X' over X is determined up to X-isomorphism by the sheaf* ($\in \mathrm{Top}(X)$) *it defines*; thus the notion of a sheaf on (the big site of) X may be regarded as a *generalization* of the notion of a topological space over X, by means of which all constructions of sheaf theory acquire a meaning for topological spaces over X.

Thus, when G is a group object of the category $(\mathrm{Esp})_{/X}$ of topological spaces over X, one may associate with it the classifying topos B_G (2.4), hence classifying cohomology groups, classifying homotopy groups, etc. (defined as the corresponding invariants of the $\mathscr{V}$-topos B_G). In particular, when X is a one-point space, G is identified with an ordinary topological group. Subject to the usual local conditions ensuring that the singular cohomology of the Cartesian products G^n agrees with cohomology in the sense of sheaves (for constant coefficients, say), for example if G is locally contractible, one may verify that the cohomology of the classifying topos of G is canonically isomorphic to that of the classifying space of G in the sense of topologists.

The introduction of classifying topoi (via "big sites") has over classifying spaces 318
the advantage of providing a richer theory, since in particular they provide useful cohomological invariants for coefficients more general than constant or locally constant coefficients. Moreover, the definition considered here adapts in an evident way to the other customary contexts: differentiable manifolds, real or complex analytic manifolds or spaces, and schemes. This point of view makes it possible in particular to connect the study of characteristic classes from the traditional and the "arithmetic" points of view, by regarding the "classical groups" as arising from schemes defined over the ring of integers; cf. [7] for indications in this direction. Likewise, the general results of J. Giraud [3] on the classification of extensions of group objects, developed in the very general and flexible setting of topoi, may, by means of "big topoi", be specialized to results on the classification of extensions of topological groups, or of real or complex Lie groups, which seem to have been scarcely known to topologists except in the case of extensions with abelian kernel [11].

2.6. Topoi of the form $\widehat{C}$. Let C be a small category. Then the category $\widehat{C}$ of U-presheaves on C is plainly a $\mathscr{U}$-topos, since it is of the form $\tilde{C}$, where C is endowed with the chaotic topology. We shall give below some details on the relations between C and $\widehat{C}$. Let us note here only that a topos E equivalent to a topos of the form $\widehat{C}$ is of a rather special nature, because *it has a small generating family (X_i) consisting of connected projective objects*, i.e. objects X such that the functor $Y \mapsto \mathrm{Hom}(X, Y)$ takes 319
epimorphisms to epimorphisms and coproducts to coproducts: indeed, it suffices to take in $\widehat{C}$ the generating family consisting of the functors represented by the $X \in \mathrm{ob}\, C$. Moreover, note that if in a topos E one has a covering family $X_i \to X$, where the X_i are projective and connected, then every other covering family of X is refined by the former (I 4.3.2, I 4.3.3). Consequently, in a topos E of the form $\widehat{C}$ every object X admits a covering family refining all the others. A topos of the form $\mathrm{Top}(X)$ (2.1), where X is a topological space whose points are closed, has the preceding property only if X is discrete.

When the category C has a single object, C is identified with a monoid G. A presheaf on C is then identified with a set on which G acts *on the right* (since it is a functor

$G^\circ \to$ (Ens)), and $\widehat{C}$ is the topos of sets with a monoid of right operators, which may also be denoted by B_{G° in view of 2.3: it is the *topos of sets with monoid of operators* G° *(the monoid opposite to* G*).* When G is a group, using the isomorphism $g \mapsto g^{-1}$ from G onto G°, one recovers the classifying topos B_G of 2.3.

2.7. Classifying topos of a pro-group.

2.7.1. Let $\mathscr{G} = (G_i)_{i\in I}$ be a projective system of groups, with G_i, $I \in \mathscr{U}$. Assume that the projective system is *strict*, i.e. that the transition morphisms $G_j \to G_i$ are surjective. If E is a set, by a (left, say) *action of* $\mathscr{G}$ *on* E we mean the following structure: a) a family $(E_i)_{i\in I}$ of subsets of E, whose union is E; b) for every $i \in I$, an action of
320 the group G_i on the set E_i; these data are furthermore required to satisfy the following condition: for $j \geq i$, E_i is the subset of E_j consisting of the elements fixed under the kernel of $G_j \to G_i$. We also say that $\mathscr{G}$ *acts on* E (on the left) if a (left) action of $\mathscr{G}$ on E has been given. The sets $\in \mathscr{U}$ endowed with an action of $\mathscr{G}$ form a category in the evident way. By Giraud's criterion, one sees at once that this category is a $\mathscr{U}$-topos. It is denoted by $B_{\mathscr{G}}$ and called the *classifying topos of* $\mathscr{G}$. When I has an initial object $i_\circ$, on putting $G = G_{i_\circ}$ one recovers the classifying topos of 2.3.

2.7.2. Another important example is that in which the groups G_i are finite, so that

$$G = \varprojlim G_i$$

is a compact totally disconnected topological group, or *profinite group.* An action of $\mathscr{G}$ on E then amounts to a continuous action of G on E, or, equivalently, to one for which the stabilizer of every point of E is an open subgroup of G. The classifying topos $B_{\mathscr{G}}$ will also be denoted by B_G, where, of course, G is to be regarded as endowed with its profinite topology.

2.7.3. Using the remarks of 2.6, it is easy to verify that the topos $B_{\mathscr{G}}$ defined by a strict projective system $\mathscr{G} = (G_i)_{i\in I}$ of groups is equivalent to a topos of the form $\widehat{C}$ only if this projective system is essentially constant; in the case of a profinite group, this means that the group is in fact finite.

2.7.4. The following geometric interpretation of the classifying topos B_G of a discrete group G is useful for giving a correct geometric intuition for these topoi. (Cf. also, in the same vein, 4.5, 5.8, 5.9, and 7.2 below.) Let X be a connected, locally connected,
321 and locally simply connected topological space, let x be a point of X, and let G be its fundamental group at x. (NB It is known that, up to isomorphism, every discrete group G may be obtained in this way.) Then the Galois theory of coverings of X gives an equivalence between the category B_G of G-sets and the category of *étale coverings* of X, i.e. spaces X' over X that are locally X-isomorphic to X-spaces of the form $X \times I$, where I is a discrete space. (Compare SGA 1 V 4,5.) The latter can moreover be interpreted as the category of locally constant sheaves on X, i.e. the category of locally constant objects (IX 2.0) of the topos Top(X).

When G is a profinite group, there is an analogous geometric interpretation of B_G as the category of X-schemes that are coproducts of finite étale coverings of a connected scheme X, equipped with a geometric point x and an isomorphism $G \simeq \pi_1(X, x)$. It is again known that every profinite group may be obtained as the fundamental group of a suitable connected scheme (the spectrum of a field, if desired). Finally, pro-groups (not necessarily profinite or essentially constant) also occur in the classification of coverings of connected and locally connected spaces that are not locally simply connected, or in the classification of étale coverings, not necessarily finite or ind-finite, of connected nonnormal schemes. For the latter case, cf. SGA 3 X 6.

EXERCISE 2.7.5. For a topos E, define the notions of connectedness, local connectedness [6], simple connectedness, and local simple connectedness. Define the notion of a constant and locally constant object of E (cf. IX 2.0). Let $f : E' \to E$ be a morphism of 322
topoi (3.1), with E' simply connected (for example, E' the point topos (2.2)), and E connected and locally connected. Define a strict pro-group $\pi_1(E, f) = (G_i)_{i\in I} = \mathscr{G}$ (called the *fundamental pro-group of E at f*) and an equivalence of categories between $B_{\mathscr{G}}$ and the category of locally constant objects of E.[6] Show that, when E is locally simply connected, $\pi_1(E, f)$ is essentially constant and hence is identified with an ordinary discrete group $\pi_1(E, f)$, called the *fundamental group of E at f*. Show that every strict pro-group $\mathscr{G}$ is isomorphic (as a pro-group) to the fundamental pro-group of a suitable connected and locally connected topos at a suitable f, with E' the point topos (take $E = B_{\mathscr{G}}$, and $f : E' \to E$ defined by the forgetful functor $f^* : E \to E' = (\mathrm{Ens})$). When $\mathscr{G}$ is essentially constant, i.e. isomorphic (as a pro-group) to an ordinary discrete group, prove that one may take E above to be locally simply connected (again take $E = B_G$).

2.8. Example of a false topos. Let $\mathscr{G} = (G_i)_{i\in I}$ be a strict pro-group, where I is a filtered ordered set and where $i > j$ implies that $G_i \to G_j$ is not an isomorphism. Suppose that $\mathrm{card}(I) \notin \mathscr{U}$. Consider the category of sets $E \in \mathscr{U}$ on which $\mathscr{G}$ acts on the left (2.7.1). It is a $\mathscr{U}$-category, and one sees as in 2.7.1 that this category satisfies conditions a), b), and c) of 1.1.2. Nevertheless, it is not a $\mathscr{U}$-topos, since it has no generating family that is $\mathscr{U}$-small. Similarly, it is not a $\mathscr{V}$-topos for any universe $\mathscr{V}$.

3. Morphisms of topoi

323

DEFINITION 3.1. *Let E and E' be two $\mathscr{U}$-topoi. A morphism[7] from E to E', or sometimes (by abuse of language) a continuous map from E to E', is a triple $u = (u_*, u^*, \varphi)$, consisting of functors*

$$u_* : E \longrightarrow E' \quad , \quad u^* : E' \longrightarrow E$$

and an "adjunction" isomorphism φ of bifunctors in $X' \in \mathrm{Ob}\, E'$, $Y \in \mathrm{Ob}\, E$:

$$\varphi : \mathrm{Hom}_E(u^*(X'), Y) \xrightarrow{\sim} \mathrm{Hom}_{E'}(X', u_*(Y)),$$

where the functor u^* is moreover required to be left exact, i.e. to commute with finite projective limits. The functor u_* is called the direct-image functor for the morphism of topoi u, the functor u^* is called the inverse-image functor for the morphism of topoi u, and the isomorphism φ is called the adjunction isomorphism for u.

3.1.1. Unless expressly stated otherwise, for a morphism of topoi $u : E \to E'$, we shall henceforth denote the corresponding direct- and inverse-image functors by u_* and u^* [7]. Note that, since u_* is right adjoint to u^* and u^* is left adjoint to u_* by the adjunction isomorphism φ, each of the two functors u_*, u^* determines the other up to unique isomorphism, by the well-known general facts about adjoint functors [14]. In practice, depending on the circumstances, it may be more convenient to define a morphism of topoi $u : E \to E'$ either by specifying $u^* : E' \to E$, or by specifying $u_* : E \to E'$; in the first case, one need only verify that the given functor u^* has a 324
right adjoint and is left exact. In the second case, one must verify that the given functor u_* has a left adjoint which is left exact. In either case, from the partial data, by *choosing*

[6] cf. 8.7 l).

[6] One may take inspiration from SGA 3 X 6.

[7] N.D.E.: Some authors speak of a *geometric morphism*.

[7] It is sometimes appropriate also to write u^{-1} instead of u^*, cf. 13.2.3.

an adjoint functor and an adjunction isomorphism, one obtains a morphism of topoi $u : E \to E'$, and the latter will be "unique up to unique isomorphism" in terms of the datum u^* resp. u_*, in a sufficiently clear sense which will moreover be made completely explicit below (3.2.1).

3.1.2. If $u : E \to E'$ is a morphism of topoi, it follows from the properties of adjoint functors (I 2.11) that the direct-image functor $u_* : E \to E'$ commutes with projective limits, and the functor $u^* : E' \to E$ commutes with inductive limits [7]. Since the latter is assumed in addition to be left exact, i.e. to commute with finite projective limits, we see in particular that u^* *is exact.* We may therefore say that *it is the inverse-image functor* u^*, in the pair (u_*, u^*), *which has the most remarkable exactness properties.* These properties ensure that, for every type of algebraic structure Σ whose data can be described in terms of arrows between the underlying sets and sets deduced from them by repeated application of operations of finite projective limits and arbitrary inductive limits, and for every "object of $\mathscr{E}'$ endowed with a structure of type Σ" (a notion which makes sense by virtue of the internal exactness properties of the topos $\mathscr{E}'$ (II 4.1)), its image under u^* is endowed with the same structures. Rather than undertake the unrewarding task
325 of giving a precise meaning to this statement and formally justifying it, we advise the reader to spell it out and convince himself of its validity for types of structure such as groups, rings, modules over a ring, comodules over a coring, bialgebras over a ring, and torsors under a group. (In these examples, the first three types of structure are defined exclusively in terms of finite projective limits, while the other notions implicitly involve constructions which also use inductive limits.) Furthermore, the functor u^* "*commutes*" with all the usual functorial operations performed in terms of such structures, more precisely with all operations which can be expressed in terms of $\varinjlim$ and finite $\varprojlim$: constructions of free objects (free groups or modules, for example) generated by an object, tensor products (cf. § 12 below), etc.

As for the direct-image functor $u_* : E \to E'$, since it commutes with projective limits, it consequently "preserves" every algebraic structure on an object (or a family of objects) of E which can be defined exclusively in terms of projective limits (such as the structures of group, ring, or module over a ring among the preceding examples). On the other hand, the functor u_* is not in general right exact, i.e. it does not in general commute with finite inductive limits, and it does not even in general take epimorphisms to epimorphisms (it is, moreover, this failure of exactness of u_* which is the source of its cohomological properties; these will be studied, from the viewpoint of commutative homological algebra, in the following exposé). Consequently it does not, in general,
326 extend to a functor on objects of the type comodule, bialgebra, or torsor under a group, and does not in general commute with operations such as "free module generated by", tensor product of modules, etc.

3.1.3. In practice, when one is given a functor $f : E \to F$ from one $\mathscr{U}$-topos to another, one should make all of its exactness properties explicit, including the possible existence of left or right adjoint functors (cf. the footnote on page 162), in order to understand the "geometric nature" of f, an understanding which will generally be an indispensable guide to a correct geometric intuition of the situation. Thus, if it turns out that f commutes with arbitrary inductive limits and finite projective limits, one should write f in the form

$$f = u^*,$$

[7] Moreover (1.5 and 1.8), for a given functor $u_* : E \to E'$ resp. $u^* : E' \to E$, this functor has a left adjoint (resp. a right adjoint) if and only if it commutes with $\mathscr{U}$-projective limits (resp. $\mathscr{U}$-inductive limits).

where

$$u : F \longrightarrow E$$

is a morphism of topoi, i.e. interpret f as an "inverse-image" functor for a "continuous map" of topoi. When f commutes with arbitrary projective limits, so that it has a left adjoint, and if the latter (which a priori commutes with arbitrary inductive limits) *also* commutes with finite projective limits, one should write f in the form

$$f = v_*,$$

where

$$v : E \longrightarrow F$$

is a morphism of topoi. In certain cases it may happen that f satisfies both of the properties under consideration (cf. 4.10 for an example). In that case one should introduce simultaneously the morphisms of topoi 327

$$u : F \longrightarrow E \quad , \quad v : E \longrightarrow F,$$

which give rise to a sequence of three adjoint functors (I 5.3):

$$v^* \quad , \quad v_* = u^* = f \quad , \quad u_*.$$

One must then distinguish carefully between the morphisms of topoi u and v, lest one lose the geometric intuition of the situation.

In this connection, note that when between two topoi E, F one has a sequence of three adjoint functors

$$e, f, g \ (e, g : F \rightrightarrows E, f : E \to F),$$

then f commutes with arbitrary inductive and projective limits, and therefore can always be written in the form u^*, where $u : F \to E$ is a morphism of topoi. Thus g can be written $g = u_*$. On the other hand, of course, e can be written in the form v^* (and then f in the form v_*) only if it also commutes with finite projective limits. This will evidently be the case if e is itself the right adjoint of a fourth functor d. Without a condition of this kind, one will often write

$$e = u_!$$

for the left adjoint of an inverse-image functor $f = u^*$ when such a left adjoint exists, this notation being suggested by the example of an open immersion $u : X \to Y$ of topological spaces. Similarly, if e is of the form v^*, i.e. if f is of the form v_*, one sometimes writes $g = v^!$ for the right adjoint of a direct-image functor v_*, when this adjoint exists [7].

3.2. Let E, E' be two $\mathscr{U}$-topoi, and let 328

$$u = (u_*, u^*, \varphi) \quad , \quad v = (v_*, v^*, \Psi) : E \rightrightarrows E'$$

be two morphisms of topoi from E to E'. A *morphism from u to v* is any morphism from u_* to v_* (in the sense of the category $\mathbf{Hom}(E, E')$ of functors from E to E'). Morphisms of morphisms of topoi compose in the evident way, thereby defining a category, which is in fact a *$\mathscr{U}$-category* (I 7.8), denoted

$$\mathbf{Homtop}(E, E'),$$

and called the *category of morphisms* (or *continuous maps*) *from E to E'*. One then has an evident functor

$$u \longmapsto u_* : \mathbf{Homtop}(E, E') \longrightarrow \mathbf{Hom}(E, E'),$$

[7] Cf. below 14.4, in the case of abelian sheaves.

which is fully faithful by the definition of arrows in the first member (but is not injective on objects).

3.2.1. Care must be taken that, if u and v are given as above, the theory of adjoint functors supplies a canonical bijection

$$\mathrm{Hom}(u_*, v_*) \xrightarrow{\sim} \mathrm{Hom}(v^*, u^*);$$

in particular, one obtains a *contravariant functor* on $\mathbf{Homtop}(E, E')$:

$$u \longmapsto u^* \,:\, \mathbf{Homtop}(E, E')^\circ \longrightarrow \mathbf{Hom}(E, E').$$

In accordance with geometric intuition, according to which the direct-image functor u_* "goes in the same direction" as the continuous map which gives rise to it, one should therefore define the direction of arrows for morphisms between morphisms of topoi *in terms of the direct-image functors*, and not in terms of the inverse-image functors (although the latter, as we have seen, possess the exactness properties characteristic of the notion of morphism of topoi).

329 3.2.2. Having defined the category $\mathbf{Homtop}(E, E')$ of morphisms from the topos E to the topos E', the notion of an *isomorphism* between two morphisms u, v from E to E' is also defined. In practice there is no need to distinguish essentially between two isomorphic morphisms of topoi, at least when one has a *canonical* isomorphism between the two (just as there is often no need to distinguish between two objects of a category when a canonical isomorphism between them is given). Let us point out in this connection that, most often, when one deals with diagrams of morphisms of topoi and questions of commutativity of such diagrams (a notion which makes sense by (3.3)), one means only commutativity up to ("canonical") isomorphism; by abuse of language, one then treats these diagrams as actually commutative diagrams.

One might try to justify this abuse of language by introducing the set $\mathrm{Homtop}(E, E')/\mathrm{Isom}$ of morphisms from E to E' up to isomorphism, and calling such an isomorphism class a morphism, instead of following Definition 3.2. But this runs into the very serious difficulties which arise whenever one tries to identify two isomorphic objects of a category without having a canonical isomorphism between them. Experience shows that such a viewpoint is impracticable, and that one must retain the "fine" notion 3.1 of a morphism between morphisms of topoi, even if one is sometimes obliged to struggle with compatibilities between canonical isomorphisms [7].

330 3.3.1. Let E, E', E'' be three $\mathscr{U}$-topoi, and consider morphisms of topoi

$$u \,:\, E \longrightarrow E' \quad , \quad v \,:\, E' \longrightarrow E''.$$

The theory of adjoint functors then gives us an adjunction isomorphism between the composite functors v_*u_* and u^*v^*, in terms of the adjunction isomorphisms for the pairs (u_*, u^*) and (v_*, v^*). On the other hand, the functor u^*v^* is left exact, as the composite of two left exact functors. Consequently one obtains a morphism from E to E'', called the *composite of the morphisms u and v*, and denoted vu:

$$vu \,:\, E \longrightarrow E''.$$

One verifies at once that composition of morphisms is associative, and that for every $\mathscr{U}$-topos E there is a morphism from E to itself which is a two-sided identity for composition: it is the morphism $(\mathrm{id}_E, \mathrm{id}_E, \varphi)$, where φ is the evident adjunction isomorphism

[7] For examples of such struggles (apparently successful), we refer the reader to Mme M. Hakim's book on relative schemes [9].

of id_E with itself. Let $\mathscr{V}$ be a universe such that $\mathscr{U} \in \mathscr{V}$. One defines a category

$$(\mathscr{V}\text{-}\mathscr{U}\text{-}\mathrm{Top}),$$

whose objects are the $\mathscr{U}$-topoi which belong to $\mathscr{V}$, whose arrows are morphisms between such $\mathscr{U}$-topoi, and whose composition of arrows is the one just described.

3.3.2. In fact, the composition map

$$\mathrm{Homtop}(E, E') \times \mathrm{Homtop}(E', E'') \longrightarrow \mathrm{Homtop}(E, E'')$$

is the map induced on objects by a "functor of composition of morphisms":

$$\mathbf{Homtop}(E, E') \times \mathbf{Homtop}(E', E'') \longrightarrow \mathbf{Homtop}(E, E''),$$

whose effect on arrows is the usual "convolution product" operation for morphisms between functors (here, direct-image functors). These composition functors satisfy a (strict) associativity property, for four topoi E, E', E'', E''', which refines the associativity of composition of morphisms of topoi. One may also say, in language which is beginning to become familiar [2], [9], that the $\mathscr{U}$-topoi are the objects (or 0-arrows) of a 2-*category*, whose 1-arrows are the morphisms of topoi and whose 2-arrows are morphisms of morphisms of topoi. 331

It is the fact that the $\mathscr{U}$-topoi (elements of a universe $\mathscr{V}$) form a 2-category, rather than merely an ordinary category like ordinary topological spaces, which from the technical viewpoint constitutes the most important difference between the theory of topoi and that of topological spaces. This fact is the source of certain technical complications already alluded to, but also of facts essentially new in comparison with traditional topology.

3.4. The fact that the $\mathscr{U}$-topoi (elements of a universe $\mathscr{V}$) form a 2-category (3.3.2) makes it possible in particular to define the notion of *equivalence of two $\mathscr{U}$-topoi E, E'*: one says that E and E' are *equivalent* if there exist morphisms of topoi $u : E \to E'$ and $v : E' \to E$ such that the composites uv and vu are isomorphic respectively to the identity morphisms of E and E'; the morphisms u and v are then said to be *quasi-inverse equivalences of one another.* 332

One sees at once that for the morphism of topoi $u : E \to E'$ to be an equivalence, it is necessary and sufficient that u_* be an equivalence, or, what amounts to the same thing, that u^* be an equivalence. (Use the fact that a functor $f : E \to E'$ between two topoi which is an equivalence is both of the form u_* and of the form v^*, with u and v morphisms of topoi); and for E and E' to be equivalent in the sense of the preceding paragraph, it is necessary and sufficient that they be equivalent as categories (i.e. as objects of the 2-category $(\mathscr{V}\text{-}\mathrm{cat})$). As it should, this shows that the notions of equivalence introduced do not depend on the choice of the universe $\mathscr{V}$ in 3.3.1.

3.4.1. In practice, there is most often no reason to distinguish essentially between equivalent $\mathscr{U}$-topoi, just as there is often no reason to distinguish essentially between two equivalent categories—provided, however, that one has an explicit equivalence from one to the other, or at least an equivalence defined up to unique isomorphism. Here it is the notion of equivalence of topoi which replaces the traditional notion of homeomorphism between two topological spaces. See the example in 4.2 below for the precise relations between these two notions.

4. Examples of morphisms of topoi

Here we return to the examples of 2, using the notion of a morphism of topoi. The comments of 2.0 apply equally to the present section. The universe $\mathscr{U}$ will generally be understood.

333

4.1. The topos $\mathrm{Top}(X)$ for a varying topological space X.

4.1.1. Let

$$f : X \longrightarrow Y$$

be a continuous map of topological spaces. We shall associate with it canonically a morphism of topoi

$$\mathrm{Top}(f) \text{ or } f : \mathrm{Top}(X) \to \mathrm{Top}(Y),$$

with the notation of 2.1. When $\mathrm{Top}(X)$ is defined as $\mathrm{Ouv}(X)^{\sim}$, the most convenient description of $\mathrm{Top}(f)$ is by means of the direct-image functor on sheaves

$$f_* : \mathrm{Top}(X) \longrightarrow \mathrm{Top}(Y),$$

defined by the formula

$$f_*(F) = F \circ f^{-1},$$

where

$$f^{-1} : \mathrm{Ouv}(Y) \longrightarrow \mathrm{Ouv}(X)$$

is the evident functor $U \to f^{-1}(U)$. We have already noted that this functor is continuous and left exact, and therefore indeed defines the functor f_* above, which admits a left adjoint f^* that is left exact (III 1.9.1). Of course, strictly speaking, the morphism of topoi $\mathrm{Top}(f)$ depends on the choice of the left adjoint f^* of f_* and hence is defined only up to canonical isomorphism. In what follows we shall refrain from explicitly pointing out phenomena of this kind.

When one adopts the "étale spaces" point of view in defining $\mathrm{Top}(X)$, it is the inverse-image functor

$$f^* : \mathrm{Top}(Y) \longrightarrow \mathrm{Top}(X)$$

334 that is the most convenient for defining the morphism of topoi $\mathrm{Top}(f)$, by simply setting

$$f^*(Y') = X \times_Y Y'$$

for every étale space Y' over Y; it is clear that the fiber product is indeed an étale space over X, and that the functor f^* so obtained is left exact and commutes with arbitrary $\varinjlim$, and therefore defines a morphism of topoi $\mathrm{Top}(f)$. For the compatibility of the two definitions obtained, we refer to [TF].

For two composable continuous maps

$$X \xrightarrow{f} Y \xrightarrow{g} Z,$$

there is a canonical isomorphism $\mathrm{Top}(gf) \simeq \mathrm{Top}(g)\,\mathrm{Top}(f)$ of morphisms of topoi. These *transitivity isomorphisms*, for three composable continuous maps f, g, h, satisfy a compatibility relation which we shall refrain from writing here, and which is precisely the one considered in SGA 1 VI 7.4 B) (for $\epsilon = (\mathrm{Esp})^\circ$). This may be expressed by saying that, as X varies in the category (Esp),

$$X \longmapsto \mathrm{Top}(X)$$

is a "pseudofunctor"

$$(\mathscr{U}\text{-esp}) \longrightarrow (\mathscr{V}\text{-}\mathscr{U}\text{-}\mathsf{T}), \tag{4.1.1.1}$$

or, in the terminology of 2-categories, that one has a *non-strict* functor of 2-categories [9]. In practice, we shall most often permit ourselves the abuse of language consisting in identifying $\mathrm{Top}(gf)$ and $\mathrm{Top}(g)\,\mathrm{Top}(f)$, that is, reasoning as if (4.1.1.1) were an actual functor between ordinary categories. We shall permit ourselves analogous abuses of language in the other examples treated below. 335

4.1.2. The preceding considerations extend immediately to topoi associated with topological spaces equipped with operator groups (2.3). If $f = (f^{\mathrm{es}}, f^{\mathrm{gr}})$,

$$f : (X, G) \longrightarrow (Y, H)$$

is a morphism of spaces with operators (where

$$f^{\mathrm{es}} : X \longrightarrow Y \quad , \quad f^{\mathrm{gr}} : G \longrightarrow H$$

are respectively continuous maps and group homomorphisms, compatible in the evident sense), one associates with it a morphism of topoi

$$\mathrm{Top}(f) \text{ or } f : \mathrm{Top}(X, G) \longrightarrow \mathrm{Top}(Y, H),$$

whose definition is left to the reader. When the groups G and H are trivial, one recovers the definition of 4.1.1; when, on the other hand, the spaces X and Y are each reduced to a point, the inverse-image functor f^* is the "restriction of the operator group" functor

$$f^* : B_H \longrightarrow B_G,$$

which associates with every H-set the G-set that it defines by means of $f : G \to H$. We shall encounter this example again in other forms in 4.5 and 4.6.1.

4.1.3. Given a continuous map $f : X \to Y$ of topological spaces, one also associates with it a morphism between the corresponding "large topoi" (2.5)

$$\mathrm{TOP}(f) \text{ or } f : \mathrm{TOP}(X) \longrightarrow \mathrm{TOP}(Y),$$

most conveniently defined by the inverse-image functor 336

$$f^* : \mathrm{TOP}(Y) \longrightarrow \mathrm{TOP}(X),$$

which is simply the *restriction functor*. This morphism $\mathrm{TOP}(f)$ is a special case of the morphism called an "inclusion" for an induced topos, which will be studied in 5. Thus, subject to the same qualifications as in 4.1.1, the topos $\mathrm{TOP}(X)$ may be regarded as a functor of X, as X varies in (Esp).

4.2. Fidelity properties of $X \mapsto \mathrm{Top}(X)$. We propose to specify to what extent a topological space X can be reconstructed in terms of the topos $\mathrm{Top}(X)$. For this purpose it is appropriate, for two spaces X and Y, to describe the category of morphisms from $\mathrm{Top}(X)$ to $\mathrm{Top}(Y)$ (3.2), so as to determine the fidelity properties of the "functor" $X \mapsto \mathrm{Top}(X)$. We shall merely state the results obtained, referring the reader to [9] for details. The reader who wishes to carry out the verification himself may consult Exercise 7.8.

4.2.1. Recall that a topological space X is called *sober* if every irreducible closed subset of X has exactly one generic point. Almost all spaces used in practice are sober; this is true in particular of a Hausdorff space, more generally of a space all of whose points are closed, or of the underlying space of a scheme. With a topological space X one associates (*loc. cit.* or EGA 0_I, new edition) a sober topological space X_{sob} and a continuous map 337

(4.2.1.1) $$\varphi : X \longrightarrow X_{\mathrm{sob}}$$

which is *universal* for continuous maps from X to sober spaces; in other words, one constructs a left adjoint $X \mapsto X_{\mathrm{sob}}$ to the inclusion functor (Espsob) $\to$ (Esp) from the

category of sober spaces to that of "arbitrary" topological spaces (the quotation marks serving as a reminder that a universe is involved!). The explicit construction takes as the points of X_{sob} the irreducible closed subsets of X, and as its open subsets the sets of the form U', where U is an open subset of X and $U' \subset X_{\text{sob}}$ denotes the set of irreducible closed subsets of X that meet U. The map (4.2.1.1) is obtained by associating with each $x \in X$ the closure of $\{x\}$. The space X is sober if and only if the preceding map is bijective, and hence a homeomorphism.

One checks that the functor

$$\varphi^{-1} : \text{Ouv}(X_{\text{sob}}) \longrightarrow \text{Ouv}(X)$$

induced by φ is an isomorphism, which implies that the morphism of topoi

$$\text{Top}(\varphi) : \text{Top}(X) \longrightarrow \text{Top}(X_{\text{sob}})$$

defined by φ is also an isomorphism. This explains a priori why X_{sob} must necessarily enter into the question of reconstructing X from $\text{Top}(X)$: since the latter depends only on X_{sob} up to isomorphism, the question can have an affirmative answer only if X is
338 sober. We shall specify below (7.1) how X_{sob} can in fact be reconstructed in terms of $\text{Top}(X)$, by interpreting its points as "points" of the topos $\text{Top}(X)$ (or, equivalently, as fiber functors).

4.2.2. On every topological space one should introduce the order relation $\leq$ for which

$$x \leq y \Longleftrightarrow \overline{\{x\}} \subset \overline{\{y\}} \text{ i.e. } x \in \overline{\{y\}}$$

(one also expresses this by saying that x is a *specialization* of y, or that y is a *generization* of x). For a space of the form X_{sob}, this is simply the inclusion relation among the irreducible closed subsets of X.

With this understood, on the set of maps from a space X to another space Y one should introduce the order relation called "specialization", deduced from that of Y, namely

$$f \leq g \Longleftrightarrow f(x) \leq g(x) \text{ for every } x \in X.$$

With these conventions, one has the following result:

4.2.3. *Let X, Y be two topological spaces, with Y sober, and let f and g be two continuous maps from X to Y. Then there is at most one morphism from* $\text{Top}(f)$ *to* $\text{Top}(g)$*, and such a morphism exists if and only if g is a specialization of f. Finally, every morphism of topoi* $\text{Top}(X) \to \text{Top}(Y)$ *is isomorphic to a morphism of the form* $\text{Top}(f)$*, where $f : X \to Y$ is a continuous map (uniquely determined by the first assertion).*

339 If , for an ordered set I, one defines the associated category $\text{cat}(I)$ by declaring that, for $i \geq j$, there is exactly one arrow from i to j, the preceding result may be summarized by saying that there is a canonical equivalence of categories

$$\text{cat}(\text{Hom}_{(\text{esp})}(X, Y)) \xrightarrow{\approx} \textbf{Homtop}(\text{Top}(X), \text{Top}(Y))$$

(where the second member is defined in 3.2).

The following is a formal consequence of these results:

Corollary 4.2.4. a) *Let $f : X \to Y$ be a continuous map. Then* $\text{Top}(f) : \text{Top}(X) \to \text{Top}(Y)$ *is an equivalence of topoi if and only if $f_{\text{sob}} : X_{\text{sob}} \to Y_{\text{sob}}$ is a homeomorphism (and hence, when X and Y are sober, if and only if f is a homeomorphism).*

b) *Let X and Y be topological spaces. The topoi* $\text{Top}(X)$ *and* $\text{Top}(Y)$ *are equivalent if and only if X_{sob} and Y_{sob} are homeomorphic (and hence, if X and Y are sober, if and only if X and Y are homeomorphic).*

4.3. Morphisms into the terminal topos: constant objects of a topos, section functors. Let P (the initial letter of "point") denote the standard terminal topos, i.e. $P = (\mathrm{Ens})$ (2.2). Let E be any topos. We shall see that *up to unique isomorphism, there exists a unique morphism of topoi*

$$f : E \to P$$

or, more precisely, that *the category* $\mathbf{Homtop}(E, P)$ *is equivalent to the one-point category*: between any two objects of this category there is therefore a unique arrow, and it is an isomorphism. (This justifies to some extent the name "terminal topos".) For this, recall (3.2.1) that $\mathbf{Homtop}(E, P)$ is equivalent to the full subcategory of $\mathbf{Hom}(P, E)^\circ$ formed by the functors 340

$$f^* : P = (\mathrm{Ens}) \longrightarrow E$$

that commute with $\varinjlim$ and are left exact. Let e be a singleton set. Every set X can then be written canonically as the "coproduct of X copies of e", from which it follows that the category of functors $g : (\mathrm{Ens}) \to E$ that commute with $\varinjlim$ is equivalent to the category E, by associating with each g the object $g(e)$ of E. In terms of $T = g(e)$, the functor g is reconstructed, up to unique isomorphism, by $g(I) = T \times I$, where one sets $T \times I = \coprod_{i \in I} T_i$, with $T_i = T$ for every $i \in I$. The fact that the functor of I so defined by T does indeed commute with $\varinjlim$ follows from the fact that it is manifestly left adjoint to the functor $X \mapsto \mathrm{Hom}(T, X)$ from E to (Ens). This said, for g to be left exact, it is plainly necessary that $g(e) = T$ be a terminal object of E (since e is a terminal object of (Ens)), and it follows easily from the fact that in E "coproducts are universal" (1.1.2 b)) that this condition is also sufficient. Thus the category of inverse-image functors f^* is equivalent to the category of terminal objects of E, which is itself plainly equivalent to the terminal category.

It follows from the foregoing that the choice of a morphism (4.3.1) is essentially equivalent to the choice of a terminal object of E, say e_E. In terms of this object, one then has canonical isomorphisms of functors

$$f^*(I) \simeq e_E \times I = \text{ coproduct of } I \text{ copies of } e_E \quad \text{for } I \in \mathrm{ob}(\mathrm{Ens}), \tag{4.3.2}$$

and 341

$$f_*(X) = \mathrm{Hom}(e_E, X) \qquad \text{for } X \in \mathrm{Ob}\, E. \tag{4.3.3}$$

4.3.4. The preceding two functors will play an important role below. For a set I, the object $f^*(I) = e_E \times I$ of (4.3.2) is called the *constant object with value* I in E (or, when E is presented as a category $\tilde{C}$ in terms of a site C, the *constant sheaf with value* I *on* C). It will also often be denoted by I_E, or by I_C when E is defined by the site C. The fact that $I \mapsto I_E$ is the inverse-image functor of a morphism of topoi specifies its exactness properties, which imply in particular that this functor respects all the usual kinds of algebraic structure, transforming a group into a group object of E, and so on (3.1.2). If, for example, one has a group G of E, one says that it is a *constant group* (or, where appropriate, a *constant sheaf of groups*) if it is isomorphic to a group of the form $G_{\circ E}$, where $G_\circ$ is an ordinary group. The same terminology is used for every other kind of "algebraic" structure, in the sense specified (more or less) in 3.1.2.

4.3.5. Notice that the functor $I \mapsto I_E$ is not necessarily fully faithful (or even faithful: take E to be the "empty topos" (2.2)); thus a constant object of E does not in general determine, up to unique isomorphism, the set I from which it arises. We say that E is 0-*acyclic*, or *connected and nonempty*, if the functor $I \mapsto I_E$ is fully faithful. By the general

properties of adjoint functors, this amounts to saying that the adjunction morphism

$$I \longrightarrow f_*(f^*(I)) = f_*(I_E) = \mathrm{Hom}(e_E, I_E)$$

342 is an isomorphism (so that the functor (4.3.3) recovers the "value" of a constant object of E). It is easily checked that this holds if and only if e_E is not the initial object ϕ_E of E, i.e. if E is not an "empty topos" (which expresses the *faithfulness* of the functor $I \mapsto I_E$[7]), *and* if e_E is a *connected* object of E, i.e. is not the sum of two objects of E which are not "empty" (i.e. which are not initial objects of E).

4.3.6. The functor (4.3.3) is also often called the *sections functor* and is denoted by Γ_E, $\Gamma(E, -)$, or simply Γ:

$$\mathrm{Hom}(e_E, X) = \Gamma_E(X) = \Gamma(E, X) = \Gamma(X). \tag{4.3.6.1}$$

It commutes with arbitrary projective limits, but is not in general right exact; its derived functors (on abelian group objects) will be studied in the next exposé.

4.4. Morphisms from the "empty topos". Let ϕ_{top} be an empty topos, corresponding to a category of sheaves Φ equivalent to the terminal category (2.2). Let E be a topos. The category of functors from E to Φ is clearly equivalent to the one-point category, and every such functor commutes with inductive and projective limits (without any merit in this), and hence may be regarded as an inverse-image functor for a morphism of topoi $\phi_{\mathrm{top}} \to E$. It follows that the *category* $\mathbf{Homtop}(\phi_{top}, E)$ *is equivalent to the one-point cat-*
343 *egory*, and in particular that *there exists, up to unique isomorphism, exactly one morphism of topoi*

$$\phi_{\mathrm{top}} \longrightarrow E. \tag{4.4.1}$$

This justifies to some extent the terminology "initial topos" introduced in 2.2.

One may also determine the morphisms of topoi

$$E \longrightarrow \phi_{\mathrm{top}}\ ; \tag{4.4.2}$$

one checks at once that such a morphism exists if and only if the initial object of E is also a terminal object, i.e. if and only if E itself is an "empty topos," and that in this case the category $\mathbf{Homtop}(E, \phi_{\mathrm{top}})$ is again equivalent to the one-point category. The unique morphism (4.4.2) (up to isomorphism) is then an equivalence of topoi.

4.5. The classifying topos B_G for a varying group G.

4.5.1. Let E be a topos, and let

$$f : G \longrightarrow H$$

be a morphism of group objects in E. It induces a "restriction of the group of operators" functor

$$f^* : B_H \longrightarrow B_G,$$

where the notation is that of 2.4. It is immediate that this functor commutes with inductive and projective limits; a fortiori, it may be interpreted as an inverse-image functor associated with a morphism of topoi

$$B_f \text{ or } f : B_G \longrightarrow B_H.$$

344 The corresponding direct-image functor

$$f_* : B_G \longrightarrow B_H$$

[7] or equivalently the fact that this functor is conservative (I 6.3).

is readily made explicit by the formula

$$f_*(X) = \mathbf{Hom}_G(H_s, X),$$

where X is an object of E with a left action of G, where H_s is H regarded as endowed with the left actions by G induced by f, and where $\mathbf{Hom}_G$ denotes the evident subobject of the object **Hom** defined below (10.2); the left action of H on $\mathbf{Hom}_G(H_s, X)$ is induced by the right actions of H on H_s by *right* translations.

Since the inverse-image functor f^* commutes with arbitrary $\varprojlim$ (and not only with finite $\varprojlim$), it is itself the right adjoint of a functor

$$f_! : B_G \longrightarrow B_H,$$

so that there is a sequence of three adjoint functors as in 3.1.3:

$$f_!, f^*, f_*.$$

The functor $f_!$ is readily made explicit by the formula

$$f_!(X) = H \times^G X,$$

where the right-hand side denotes the "contracted product" induced by the actions of G on X (on the left) and on H (on the right, via right translations and f), defined as the quotient of $H \times X$ by the action of G given by

$$g \circ (h, x) = (hg^{-1}, gx).$$

The functor $f_!$, being a left adjoint, clearly commutes with inductive limits, but is not in general left exact (i.e. it cannot in turn be regarded as an inverse-image functor 345
for a morphism of topoi $B_H \to B_G$). In fact, one checks easily that it can be left exact only if $f : G \to H$ is an isomorphism. Likewise, the functor f_*, which commutes with projective limits, is not in general right exact and, a fortiori, does not in general admit a right adjoint. At least when E is the punctual topos, i.e. when G and H are ordinary groups, f_* is right exact only if f is an isomorphism.

Given a second morphism of groups $g : H \to K$, one obtains, as in 4.1.1, transitivity up to canonical isomorphism, so that, subject to the usual reservation, the classifying topos B_G may be regarded as depending *functorially* on the group G. We leave it to the reader to generalize this functorial behavior to the case where both G *and* the topos E vary.

4.5.2. *The topos $B_{\mathscr{G}}$ for a varying pro-group $\mathscr{G}$.* We leave it to the reader to make precise the covariant character of the topos $B_{\mathscr{G}}$ (2.7) with respect to $\mathscr{G}$, by following the account given in 4.5.1. One should note, however, that in the case of a morphism $f : \mathscr{G} \to \mathscr{H}$ of pro-groups which are not essentially constant, the corresponding morphism of topoi $B_{\mathscr{G}} \to B_{\mathscr{H}}$ does not in general permit the definition of a functor $f_!$ (whose right adjoint would be the functor f^* restricting the pro-group of operators). Suppose, to simplify the statement, that $\mathscr{G}$ and $\mathscr{H}$ are defined by *profinite* groups G and H. It is then easily seen that $f_!$ exists if and only if the image of the morphism in question $f : G \to H$ has finite index in H, and in that case $f_!$ is given by the same formula as 346
in 4.5.

4.6. The topos $\widehat{C}$ for a varying category C.

4.6.1. Let

$$f : C \longrightarrow C'$$

be a functor from a category $C \in \mathscr{U}$ to another category C', and hence let

$$f^* : \widehat{C}' \longrightarrow \widehat{C} \quad , \quad f^*(F) = F \circ f .$$

It is immediate that this functor commutes with projective and inductive limits; a fortiori, it may be regarded as the inverse-image functor for a morphism of topoi

$$\widehat{f} \text{ or } f : \widehat{C} \to \widehat{C}'.$$

The corresponding direct-image functor

$$f_* : \widehat{C} \longrightarrow \widehat{C}'$$

is none other than the functor likewise denoted f_* in I 5.1. Moreover (as was to be expected from the fact that f^* also commutes with arbitrary $\varprojlim$), f^* also admits a left adjoint

$$f_! : \widehat{C} \longrightarrow \widehat{C}',$$

(which was likewise denoted $f_!$ in I 5.1). Thus one obtains a sequence of three adjoint functors

$$f_!, f^*, f_*,$$

the first of which is moreover an extension of $f : C \to C'$ to the categories of presheaves (for the usual embeddings of C and C' in the categories $\widehat{C}$ and $\widehat{C}'$). One should note that $f_!$ is not in general left exact, nor is f_* in general right exact; this removes any ambiguity
347 about the direction of variance of the topos $\widehat{C}$ associated with the varying category C: this topos is a *covariant* functor of C, subject to the usual reservation arising from the transitivity isomorphisms (cf. 4.1.1). When the sets of objects of C and C' each consist of a single element, so that C and C' identify with monoids G and G', the corresponding topoi are the classifying topoi B_{G° and $B_{G'^\circ}$, and one recovers their variance with respect to the varying G, already encountered from other viewpoints in 4.1.2 and 4.5 (where the restriction to groups rather than monoids was inessential).

4.6.2. The 2-functorial dependence of the topos $\widehat{C}$ on C can be made more precise by introducing, for two categories $C, C' \in \mathscr{U}$, a canonical functor

$$\mathbf{Hom}(C, C') \longrightarrow \mathbf{Homtop}(\widehat{C}, \widehat{C}'). \tag{4.6.2.1}$$

It remains to define this functor on arrows. For this, note that $f \mapsto f^*$ identifies (up to equivalence of categories) the right-hand side with a full subcategory of $\mathbf{Hom}(\widehat{C}', \widehat{C})^\circ$ (3.2.1). If $f, g : C \to C'$ are two functors, every morphism of functors $u : f \to g$ defines, for $F \in \mathrm{ob}\,\widehat{C}'$, a morphism of functors $F \circ g \to F \circ f$ (since F is a *contra*variant functor), hence a morphism $g^* \to f^*$ and therefore a morphism $\widehat{f} \to \hat{g}$, as asserted.

When C is the one-point category, $\widehat{C}$ is the punctual topos (2.2), denoted P, and (4.6.2.1) is interpreted as a natural functor

$$C' \longrightarrow \mathbf{Homtop}(P, \widehat{C}') \overset{\text{dfn}}{=} \mathbf{Points}(\widehat{C}') \tag{4.6.2.2}$$

348 from C' to the "*category of points*" of $\widehat{C}'$, which will be studied in 6. This functor is not necessarily an equivalence of categories (7.3.3); a fortiori, (4.6.2.1) is not necessarily an equivalence of categories.

On the other hand, the functor (4.6.2.1) is always *fully faithful.* To see this, note that if $f, g : E \to E'$ are two morphisms of topoi for which $f_!$ and $g_!$ are defined (3.1.3), then the theory of adjoint functors gives canonical isomorphisms

$$\mathrm{Hom}(f_!, g_!) \simeq \mathrm{Hom}(g^*, f^*) \simeq \mathrm{Hom}(f_*, g_*) \overset{\text{dfn}}{=} \mathrm{Hom}(f, g).$$

Applying this to functors of the form $\widehat{f}$ and $\hat{g}$ associated with $f, g : C \to C'$, one obtains the asserted result, taking into account that the natural extension map $\mathrm{Hom}(f, g) \to \mathrm{Hom}(f_!, g_!)$ is bijective (I 7.8).

4.6.3. One may ask when the functor (4.6.2.1) is an equivalence of categories, i.e. when it is essentially surjective. This is a special case of the problem of determining all morphisms of topoi $\widehat{C} \to \widehat{C}'$. More generally, if C is a category in $\mathscr{U}$ and E is a topos, one may seek to determine the morphisms of topoi

$$f : \widehat{C} \longrightarrow E.$$

The category of these morphisms is equivalent to the opposite of the category of functors $f^* : E \to \widehat{C}$ commuting with arbitrary inductive limits and finite projective limits. A functor $E \to \widehat{C}$ may be interpreted as a functor $E \times C^\circ \to (\mathscr{U}\text{-Ens}) = (\mathrm{Ens})$, or equivalently as a functor $F : C^\circ \to \mathbf{Hom}(E, (\mathrm{Ens}))$. The exactness property in question is then expressed by requiring that, for every object X of C, the functor $F(X) : E \to (\mathrm{Ens})$ commute with arbitrary inductive limits and finite projective limits (or, as we shall say in 6, that $F(X)$ is a "*fiber functor*" on E). This amounts to saying that $F(X)$ is the 349
inverse-image functor for a morphism of topoi $P \to E$, and one therefore obtains finally a canonical equivalence of categories

$$\mathbf{Homtop}(\widehat{C}, E) \xrightarrow{\approx} \mathbf{Hom}(C, \mathbf{Points}(E)), \tag{4.6.3.1}$$

where, for brevity, we write

$$\mathbf{Points}(E) = \mathbf{Homtop}(P, E)$$

for the category of points of the topos E.

When E is of the form $\widehat{C}'$, it follows immediately from the definitions that the composite of (4.6.2.1) and the preceding equivalence (4.6.3.1) is the functor

$$\mathbf{Hom}(C, C') \longrightarrow \mathbf{Hom}(C, \mathbf{Points}(\widehat{C}')) \tag{4.6.3.2}$$

defined by $F \mapsto i \circ F$, where $i : C' \to \mathbf{Points}(\widehat{C}')$ is the canonical embedding (4.6.2.2). It follows at once that *for* (4.6.2.1) *to be an equivalence, it is necessary and sufficient that* C *be empty or that* (4.6.2.2) *be essentially surjective* (and hence an equivalence of categories). This last condition on C' is satisfied in certain interesting cases, notably when C' is the one-object category defined by a group G (7.2.5).

Remark 4.6.4. [8] The association of a topos $\widehat{C}$ with an arbitrary category C suggests that a category C has invariants of a topological nature (cohomology groups, homotopy groups, etc.), just as a topos does. The cohomology groups of $\widehat{C}$ with coefficients in an abelian group object F (in the general sense studied in V) are precisely the values of the derived functors $\varprojlim^{(n)}$ of the functor $\varprojlim$, already familiar to topologists. J. L. 350
Verdier and (independently) D. G. Quillen verified that, when one restricts to constant, or more generally locally constant, coefficients, these cohomology groups identify with the cohomology groups of the semi-simplicial set $\mathrm{Nerf}(C)$ canonically associated with C

[8] N.D.E.: For a recent perspective on the notion of the homotopy type of a topos, see [15] § 7.1.6.

[5, n° 212, prop. 4.1], and moreover that, up to isomorphism in the "homotopy category" of [2], every semi-simplicial set can be obtained from a category C. With a suitable notion of homotopy type for topoi, which we do not specify here, one may say that the semi-simplicial homotopy types of topologists are precisely the homotopy types of topoi of the special form $\widehat{C}$, and more generally of topoi E in which every object admits a covering that refines every other one (2.6) [8]. In the absence of this condition on E, its homotopy type can at best be expressed by a suitable *projective system* of semi-simplicial sets [1].

4.7. The topos $C^\sim$ for a variable site C (cocontinuous functors). Let

$$f : C \longrightarrow C'$$

be a cocontinuous functor (III 2.1) between sites in $\mathscr{U}$, i.e. a functor such that the functor $\widehat{f}_*$ from $\widehat{C}$ to $\widehat{C}'$ (4.6.1) maps $C^\sim$ into $C'^\sim$, that is, induces a functor

$$\widetilde{f}_* : \widetilde{C} \longrightarrow C'^\sim \tag{4.7.1}$$

making the following diagram of functors commutative:

$$\begin{array}{ccc} C^\sim & \xrightarrow{\widetilde{f}_*} & C'^\sim \\ {\scriptstyle i_*}\downarrow & & \downarrow{\scriptstyle i'_*} \\ \widehat{C} & \xrightarrow{\widehat{f}_*} & \widehat{C}' \end{array} , \tag{4.7.2}$$

351 where i_* and i'_* are the inclusion functors. We saw (III 2.3) that the functor $\widetilde{f}_*$ then has a left adjoint $\widetilde{f}^*$, and that the latter is left exact. In other words, $\widetilde{f}_*$ is the direct-image functor associated with a morphism of topoi

$$\widetilde{f} \text{ or } f : C^\sim \longrightarrow C'^\sim,$$

the corresponding inverse-image functor being, of course, $\widetilde{f}^*$. Taking left adjoints of the functors involved, the commutative diagram (4.7.2) also gives a diagram commutative up to isomorphism:

$$\begin{array}{ccc} C^\sim & \xleftarrow{\widetilde{f}^*} & C'^\sim \\ {\scriptstyle \underline{a}}\uparrow & & \uparrow{\scriptstyle \underline{a}'} \\ \widehat{C} & \xleftarrow{\widehat{f}^*} & \widehat{C}' \end{array} , \tag{4.7.3}$$

where $\underline{a}$ and $\underline{a}'$ are the "associated sheaf" functors. This diagram immediately recovers the formula (III 2.3)

$$\widetilde{f}^* = \underline{a}\widehat{f}^* i'.$$

The transitivity property for the morphisms of topoi $\widehat{f} : \widehat{C} \to \widehat{C}'$ implies the same property for the morphisms of topoi $\widetilde{f} : C^\sim \to C'^\sim$ associated with cocontinuous functors. Thus one may say that *the topos $C^\sim$ varies functorially with C* in a *covariant* manner, when cocontinuous functors are taken as the "morphisms" of sites.

352 In all the cases encountered thus far, the cocontinuous functor f used is also con-

[8] and, more generally still, of topoi that are "locally ∞-connected" in an evident sense which we leave it to the reader to make precise.

tinuous, that is (III 1.1), it "extends" to a functor

$$\widetilde{f}_! : \widetilde{C} \longrightarrow \widetilde{C'}$$

commuting with inductive limits, which is left adjoint to $\widetilde{f}^*$, so that there is a sequence of three adjoint functors

$$\widetilde{f}_!, \widetilde{f}^*, \widetilde{f}_*.$$

One should note that the functor $\widetilde{f}_!$ is not in general left exact, nor is $\widetilde{f}_*$ right exact. This removes any ambiguity concerning the direction of the variance of the topos $\widetilde{C}$, when C varies through functors assumed only to be cocontinuous, or even continuous and cocontinuous.

Remark 4.7.4. Given a morphism of topoi

$$F : E \longrightarrow E',$$

for there to exist a functor $F_!$ left adjoint to F^*, it is necessary and sufficient that one be able to "realize" (up to equivalence) E and E' in the form $\widetilde{C}$ and $\widetilde{C'}$, for two sites $C, C' \in \mathscr{U}$, and that one be able to find a *continuous and cocontinuous* functor $f : C \to C'$ such that F identifies with $\widetilde{f}$. This is clearly sufficient; for necessity, it is enough to take for C and C' small full generating subcategories of E and E', respectively, such that

$$F_!(\mathrm{ob}\, C) \subset \mathrm{ob}\, C',$$

endowed with the topologies induced by those of E and E', and to take for f the functor induced by $F_!$ (cf. 1.2.1). Recall (1.8) that the existence of $F_!$ also means that F^* commutes with projective limits, or, equivalently here since this functor is left exact, that it 353
commutes with products.

4.7.5. If one asks which morphisms of topoi $F : E \to E'$ can be realized by a cocontinuous (not necessarily continuous) functor of sites, one likewise finds the following answer: the set of objects X of E such that the functor $X' \mapsto \mathrm{Hom}(X, F^*(X'))$ from E' to (Ens) commutes with projective limits (or, equivalently, with products) must be a *generating family of* E.[9]

4.8. The morphism of topoi $\widetilde{C} \to \widehat{C}$ for a site C. Let C be a small site, with which the two topoi $\widetilde{C}$ and $\widehat{C}$ are therefore associated (the latter does not depend on the topology placed on C). In II 3.4 we defined the "associated sheaf" functor

$$\underline{a} : \widehat{C} \longrightarrow \widetilde{C},$$

and proved that it is left exact and commutes with inductive limits. It is therefore the inverse-image functor associated with a morphism of topoi

$$p : \widetilde{C} \longrightarrow \widehat{C},\ p^* = \underline{a},$$

the corresponding direct-image functor being the canonical inclusion

$$i = p_* : \widetilde{C} \longrightarrow \widehat{C}.$$

[9] N.D.E.: This statement does not appear to be correct: the condition expressed is equivalent to the assertion that F^* commutes with arbitrary products, or equivalently that F^* has a left adjoint $F_!$. For every site C, the identity functor $F = id : C \longrightarrow C$ is cocontinuous when the term on the right is endowed with the trivial topology. The functor $F^* : \widehat{C} \longrightarrow \widetilde{C}$ is then the associated sheaf functor, and does not in general commute with arbitrary products.

It is well known that the latter functor is not in general right exact (its derived functors on abelian objects give rise to the cohomology presheaves $\mathscr{X}^n(F)$ of V 2), and that $\underline{a}$ does not in general commute with arbitrary $\varprojlim$. This removes any ambiguity concerning the direction of the "natural" morphism of topoi between $\widehat{C}$ and $C\tilde{}$.

Given a cocontinuous functor

$$f : C \longrightarrow C'$$

354 of sites, one obtains a diagram of morphisms of topoi

$$\begin{array}{ccc} C\tilde{} & \xrightarrow{\tilde{f}} & C'\tilde{} \\ {\scriptstyle p_*}\downarrow & & \downarrow{\scriptstyle p'_*} \\ \widehat{C} & \xrightarrow{\hat{f}} & \widehat{C}' \end{array}$$

which is commutative up to canonical isomorphism: this is precisely what the commutativity of the diagram of functors (4.7.2) expresses. Thus one may say that the morphism of topoi $p : C\tilde{} \to \widehat{C}$ is functorial in C, when C is varied through *cocontinuous* functors between sites.

4.9. Effect of a continuous functor of sites. Morphisms of sites.

4.9.1. Let

$$f : C \longrightarrow C'$$

be a continuous functor from C to C', i.e. such that the functor $\widehat{f}^* : \widehat{C}' \to \widehat{C}$ maps $C'\tilde{}$ into $C\tilde{}$, and hence induces a functor

$$f_s : C'\tilde{} \longrightarrow C\tilde{}.$$

We saw (III 1.2) that the latter admits a left adjoint

$$f^s : C\tilde{} \longrightarrow C'\tilde{},$$

which moreover "extends" f in the evident sense. One should note that in general f^s is not left exact (even if f is also cocontinuous), nor does f_s commute with inductive limits, so that the datum of f does not, without further hypotheses, describe a morphism of topoi in either direction between $C\tilde{}$ and $C'\tilde{}$. The case where f is cocontinu-
355 ous, i.e. where f_s commutes with inductive limits and may therefore be regarded as an inverse-image functor for a morphism of topoi $\tilde{f} : C\tilde{} \to C'\tilde{}$, was examined in 4.7. We shall examine the case where the functor f^s is left exact, and may therefore be regarded as an inverse-image functor for a morphism of topoi in the *opposite direction*:

$$\text{(4.9.1.1)} \qquad \mathrm{Top}(f) = g : C'\tilde{} \longrightarrow C\tilde{}.$$

Notice that *we have deliberately not denoted this morphism by the letter* $\tilde{f}$ *or* f*, so as to avoid confusion with the situation of 4.7, in accordance with the general recommendations of 3.1.3.* A continuous functor $f : C \to C'$ is sometimes called a *morphism of sites from* C' *to* C (note: *not from* C *to* C') if the functor f^s is left exact; in other words, if there exists a morphism of topoi (4.9.1.1) such that the corresponding inverse-image functor

$$g^* : C\tilde{} \longrightarrow C'\tilde{}$$

extends the functor f, i.e. makes the following diagram of functors commute up to isomorphism:

$$\begin{array}{ccc} C & \xrightarrow{f} & C' \\ {\scriptstyle\epsilon}\downarrow & & \downarrow{\scriptstyle\epsilon'} \\ \tilde{C} & \xrightarrow{g^*} & \tilde{C'} \end{array} ,$$

where ϵ and ϵ' are the canonical functors of II 4.4.0.

4.9.2. In practice, one recognizes that a continuous functor $f : C \to C'$ is a morphism of sites from C' to C from the fact that finite projective limits are representable in C and that f commutes with them (III 1.3 5)). Subject to the indicated condition 356
on C (which is almost always satisfied in practice), and assuming in addition that the topology of C' is coarser than the canonical topology (also almost always satisfied), the preceding sufficient condition (f left exact) for f to be a morphism of sites from C' to C is also necessary.

4.9.3. In the spirit of the preceding discussion, if C and C' are two $\mathscr{U}$-sites, the category of morphisms of sites $\mathbf{Morsite}(C', C)$ from C to C' should be defined as the full subcategory of the *opposite category* $\mathbf{Hom}(C, C')^\circ$ of the category of functors from C to C', formed by those functors which are morphisms of sites (from C' to C). In this way one obtains a canonical functor (defined up to unique isomorphism)

$$\mathbf{Morsite}(C', C) \longrightarrow \mathbf{Homtop}(\tilde{C'}, \tilde{C}).$$

Proposition 4.9.4. *Let E be a $\mathscr{U}$-topos and C a $\mathscr{U}$-site. The functor $f \mapsto f^*|C = f^* \circ \epsilon_C$, associating with every morphism of topoi $f : E \to \tilde{C}$ the "restriction" to C of the associated inverse-image functor $f^* : \tilde{C} \to E$, induces an equivalence of categories*

$$\mathbf{Homtop}(E, \tilde{C}) \xrightarrow{\approx} \mathbf{Morsite}(E, C)(\hookrightarrow \mathbf{Hom}(C, E)^\circ).$$

When finite $\varprojlim$ are representable in C, the corresponding fully faithful functor

$$\mathbf{Homtop}(E, \tilde{C}) \longrightarrow \mathbf{Hom}(C, E)^\circ$$

has as its essential image the functors $g : C \to E$ which are left exact and continuous, or equivalently those which are left exact and carry covering families to covering families. 357

The last assertion follows from the first by 4.9.2. On the other hand, it follows from III 1.2 iv) and IV 1.2 iii) that the functor $G \to G \circ \epsilon$ induces an equivalence between the category of *continuous* functors from $\tilde{C}$ to E and the category of *continuous* functors from C to E, a quasi-inverse being given by $g \to g^s$ in the notation of *loc. cit.* On the other hand, by definition, g is a morphism of sites if and only if g^s is the inverse-image functor associated with a morphism of topoi $E \to \tilde{C}$, whence the conclusion by 3.2.1; the "or equivalently" follows from III 1.6.

The main point to retain from 4.9.4 is that (when finite $\varprojlim$ are representable in C) "it amounts to the same thing" to give a morphism of topoi $f : E \to \tilde{C}$ or to give a functor $g : C \to E$ which is left exact and carries covering families to covering families.

4.9.5. Using the developments of 4.9.1 and 4.9.3, one sees as usual that, for a varying $\mathscr{U}$-site C, via the notions of a morphism of sites and a morphism between morphisms of sites just made explicit, the topos $\tilde{C}$ depends functorially (or more exactly, 2-functorially) on the site C. Note that, with the terminology just introduced, $\tilde{C}$ depends *covariantly* on the site C.

4.9.6. It is immediate that (unlike what happens for the notion of a cocontinuous functor, cf. 4.7 4) *every* morphism of topoi $F : E \to E'$ can be realized by means of a morphism of sites $f : C \to C'$ (i.e. a continuous functor $f : C' \to C$ such that
358 ...): it suffices to choose small full generating subcategories C and C' of E and E', respectively, endowed with the topologies induced by those of E and E', such that

$$F^*(\mathrm{ob}\, C') \subset \mathrm{ob}\, C,$$

and to take for f the functor induced by F^*. This explains why most morphisms of topoi encountered in practice are indeed described by morphisms of sites (rather than by cocontinuous functors as in 4.7).

4.10. Relations between the small and large topoi associated with a topological space X. We retain the notation of 2.5. In particular, $\mathscr{V}$ is a universe such that $\mathscr{U} \in \mathscr{V}$. We depart from the convention of 2.1 by using $\mathrm{Top}(X)$ to denote the topos of $\mathscr{V}$-sheaves (rather than $\mathscr{U}$-sheaves) on X. Thus, we shall work with $\mathscr{V}$-topoi and not $\mathscr{U}$-topoi. (NB it would be possible to retain $\mathscr{U}$-topoi by adopting the appropriate convention for the definition of $\mathrm{TOP}(X)$, so that the latter is a $\mathscr{U}$-topos, cf. 2.5). With this understood, we shall define TWO morphisms of topoi

$$\text{(4.10.1)} \qquad \begin{cases} f : \mathrm{Top}(X) \longrightarrow \mathrm{TOP}(X) \\ g : \mathrm{TOP}(X) \longrightarrow \mathrm{Top}(X) \end{cases}, \quad gf \simeq \mathrm{id}_{\mathrm{Top}(X)},$$

giving rise to a sequence of three adjoint functors

$$\text{(4.10.1.1)} \qquad g^* = f_! \quad , \quad g_* = f^* \quad , \quad g^! = f_*,$$

359 with the notation of 3.1.3. We shall successively define the first two functors in this sequence, the third then being defined as the right adjoint of the second.

4.10.2. The functor

$$g_* = f^* : \mathrm{TOP}(X) \longrightarrow \mathrm{Top}(X)$$

is defined simply as the *restriction functor* from $(\mathrm{Esp})_{/X}$ to the site $\mathrm{Ouv}(X)$ of open subsets of X; it does indeed take sheaves to sheaves, as follows immediately from the definition. Using underlined letters for sheaves on the large site of X, for such a sheaf $\underline{F}$ we denote by $\underline{F}_X$ its restriction to the site $\mathrm{Ouv}(X)$, thereby obtaining a functor

$$\text{(4.10.2.1)} \qquad \mathrm{Restr} : \underline{F} \longmapsto \underline{F}_X : \mathrm{TOP}(X) \longrightarrow \mathrm{Top}(X).$$

It is clear that this functor commutes with $\mathscr{V}$-projective limits, since these are computed pointwise (one could also invoke the existence of the left adjoint constructed in 4.10.4 below). I claim that it also commutes with $\mathscr{V}$-inductive limits. To see this, we shall give a very convenient interpretation of "large" sheaves on X, i.e. of objects of $\mathrm{TOP}(X)$, in terms of ordinary sheaves (NB these are $\mathscr{V}$-sheaves) on topological spaces X' over X.

4.10.3. For a large sheaf $\underline{F}$ on X, and for every space X' over X (understood that $X' \in \mathscr{U}$), one defines in the obvious way, as in 4.10.2, the "small" sheaf $\underline{F}_{X'}$, the restriction of $\underline{F}$ to X'. If

$$u : X'' \longrightarrow X'$$

360 is a morphism in $(\mathrm{Esp})_{/X}$, one then defines in the obvious way a morphism $u_*(\underline{F}_{X''}) \to \underline{F}_{X'}$, or, what amounts to the same thing, a "*transition morphism*"

$$\text{(4.10.3.1)} \qquad \varphi_u : u^*(\underline{F}_{X'}) \longrightarrow \underline{F}_{X''}.$$

As u varies, these morphisms satisfy an evident transitivity condition for a composite

$$X''' \overset{u}{\to} X'' \overset{v}{\to} X'$$

of morphisms in $(\mathrm{Esp})_{/X}$, whose explicit formulation is left to the reader. In this way one obtains a natural functor from the category $\mathrm{TOP}(X)$ of large sheaves on X to the category of systems

$$(\underline{F}_{X'}) \quad (X' \in \mathrm{ob}(\mathrm{Esp})_{/X}), (\varphi_u) \quad (u \in Fl(\mathrm{Esp})_{/X}),$$

satisfying the transitivity condition just described and, in addition, such that for every morphism $u : X'' \to X'$ which is an *open immersion* (or, more generally, a local homeomorphism), the transition morphism φ_u is an isomorphism. Since the functors $u^* : \mathrm{Top}(X') \to \mathrm{Top}(X'')$ used to describe the φ_u commute with $\mathscr{V}$-inductive limits, it follows at once that, in the preceding description of the objects of $\mathrm{TOP}(X)$ in terms of "small" sheaves $F_{X'}$, $\mathscr{V}$-inductive limits are computed pointwise, i.e. the functors of the form $\underline{F} \to \underline{F}_{X'}$ commute with $\mathscr{V}$-inductive limits.

In particular, this holds for the functor $\underline{F} \mapsto \underline{F}_X$ considered in 4.10.2. It therefore does have a right adjoint (1.5). It remains to construct a left adjoint (whose existence also follows a priori from 1.8) and to verify that the latter is left exact. This will complete 361
the definition of the morphisms of topoi announced in (4.10.1) in terms of the functors (4.10.1.1).

4.10.4. The functor

$$g^* = f_! : \mathrm{Top}(X) \longrightarrow \mathrm{TOP}(X)$$

is obtained by associating with every small sheaf F on X the system of its inverse images $(F_{X'})$, $X' \in \mathrm{ob}(\mathrm{Esp})_{/X}$, under the structural morphisms $X' \to X$, the transition morphism φ_u for $u : X'' \to X'$ being the transitivity isomorphism for inverse images of sheaves (4.1.1). One sees at once that this gives a functor

$$\mathrm{Prol} : \mathrm{Top}(X) \longrightarrow \mathrm{TOP}(X),$$

which is *fully faithful*, and whose essential image consists of the large sheaves $\mathscr{F}$ on X for which all the transition morphisms φ_u of (4.10.3.1) are isomorphisms. We leave to the reader the task of defining an adjunction isomorphism between this canonical prolongation functor and the restriction functor of 4.10.2, proving that the latter is right adjoint to the former. This is immediate from the description in 4.10.3 of the category $\mathrm{TOP}(X)$.

Remarks 4.10.5. a) The construction in 4.10.4 also shows that $g^* = f_!$ is fully faithful (or, what amounts to the same thing, that $g_* = f^*$ is a localization functor, or again that $g^! = f_*$ is fully faithful). The large sheaves on X belonging to the essential image of the functor $g^* = f_! = \mathrm{Prol}$ deserve the name of large *étale sheaves* on X, since they form a category equivalent to the category of ordinary sheaves on X, or again to that of étale spaces over X. It is moreover 362
easy to see that if X' is a topological space over X, then the large sheaf on X represented by it is étale in the preceding sense if and only if X' is an étale space over X.

b) The full faithfulness of f_* may also be expressed by saying that the adjunction morphism $f^* f_* \to \mathrm{id}_{\mathrm{Top}(X)}$ is an isomorphism, i.e. that $g_* f_* \simeq \mathrm{id}$, i.e. that $g f \simeq \mathrm{id}$. Thus g makes $\mathrm{TOP}(X)$ into a *topos over* $\mathrm{Top}(X)$, admitting a "section" f over $\mathrm{Top}(X)$.

c) The fact that the functor $g^* = f_!$ is fully faithful, exact, and commutes with $\mathscr{V}$-inductive limits partially justifies the very convenient point of view (due to J. Giraud) according to which, in practically all questions in the theory of sheaves on X, it is harmless to replace the usual sheaves, or "small" sheaves, by the associated "large" sheaves. This applies in particular to cohomological questions, since g_* is exact, the functors $R^i g_*$ (V 5) vanish for $i > 0$, and hence (V 5.4) for every *large* sheaf $\mathscr{F}$ on X there are canonical isomorphisms

$$H^i(\mathrm{TOP}(X), \mathscr{F}) \simeq H^i(\mathrm{Top}(X), \mathscr{F}_X) = H^i(X, F).$$

Applying this to a sheaf of the form $\mathrm{Prol}(F)$, where F is a small sheaf on X, we obtain (since $\mathrm{Prol}(F)_X \simeq F$ canonically) a canonical isomorphism

$$H^i(X, F) = H^i(\mathrm{TOP}(X), \mathrm{Prol}(F)).$$

Thus, *the cohomological invariants of X, computed by means of the small or the large topos of X, are essentially identical.* The same result is moreover valid in noncommutative cohomology.

363 Exercise 4.10.6. Let S be a $\mathscr{U}$-site whose topology is coarser than the canonical topology, and let $\underline{M}$ be a subset of $Fl\ S$ satisfying the following conditions:

a) The morphisms of $\mathscr{M}$ are pullbackable (I 10.7), and $\underline{M}$ is stable under base change.
b) $\underline{M}$ contains the identity arrows and is stable under composition.
c) An arrow $u : X \to Y$ such that there exists a covering family $Y_i \to Y$, with the arrows $X \times_Y Y_i \to Y_i$ in $\underline{M}$, itself belongs to $\underline{M}$.
d) For every $X \in \mathrm{ob}\, S$, every covering family of X is refined by a covering family $(f_i : X_i \to X)$, with $f_i \in \underline{M}$.

For every $X \in \mathrm{ob}\, S$, consider the site $S(X)$ (the "small site of X"), whose underlying category is the full subcategory of $S_{/X}$ consisting of the objects whose structural morphism belongs to $\underline{M}$, endowed with the topology induced (III 3.1) by that of S.

1°) For every arrow $u : X \to Y$ of S, show that base change by u from $S(Y)$ to $S(X)$ is a continuous functor, hence gives a functor commuting with inductive limits (III 1.2 iv))

$$S(u)^x : S(Y)^\sim \longrightarrow S(X)^\sim.$$

2°) Define an equivalence between the topos $S^\sim$ and the category of systems

$$(F_X) \quad (X \in \mathrm{ob}\, S) \quad , \quad (\varphi_u) \quad (u \in Fl S)$$

364 consisting of objects $F_X \in \mathrm{ob}\, S(X)^\sim$ and, for every arrow $u : X \to Y$ in S, of a morphism $\varphi_u : S(u)^x(F_Y) \to F_X$, these systems being subject to a transitivity condition for a composite $v \circ u$ of arrows of S, and to the condition that $u \in \underline{M}$ imply that φ_u is an isomorphism.

3°) Define "restriction" and "prolongation" functors

$$\mathrm{Res}_X : (S_{/X})^\sim \longrightarrow S(X)^\sim, \mathrm{Prol}_X : S(X)^\sim \longrightarrow (S_{/X})^\sim$$

Show that Res_X commutes with small inductive and projective limits and that Prol_X is *fully faithful*, its essential image consisting of the sheaves F such that φ_u is an isomorphism for every arrow u of $S_{/X}$.

4°) Define an adjunction morphism making Res_X the right adjoint of Prol_X. Deduce that there exists a morphism of topoi

$$f : S(X)^\sim \to (S_{/X})^\sim$$

making $S(X)^\sim$ a subtopos of $(S_{/X})^\sim$ and such that

$$f_! = \mathrm{Prol}_X$$
$$f^x = \mathrm{Res}_X .$$

Show that Prol_X takes abelian sheaves to abelian sheaves.

5°) Show that if $S(X)$ admits fiber products, then Prol_X is exact. Deduce that there then exists a morphism of topoi $g : (S_{/X})^\sim \to S(X)^\sim$ which is a left retraction of f, i.e. such that

$$g^x = \mathrm{Prol}_X$$
$$g_x = \mathrm{Res}_X .$$

(For an example in which $S(X)$ does not admit fiber products, take for S the category of schemes endowed with the étale topology, for M the smooth morphisms, and for X a Noetherian scheme of dimension > 0.) 365

6°) Show that for every abelian sheaf F of $(S_{/X})^\sim$ there is an isomorphism

$$H^q(X, F) \simeq H^q(X, \mathrm{Res}_X F) \qquad \forall q.$$

Show, using hypercoverings for example, that for every abelian sheaf G of $S(X)^\sim$ there is an isomorphism

$$H^q(X, G) \simeq H^q(X, \mathrm{Prol}_X G) \qquad \forall q.$$

7°) Buy a chocolate medal for the editor.

5. Induced topos

5.1. Let E be a topos and X an object of E. Then the category $E_{/X}$ of objects of E over X is a topos, as follows, for example, immediately from Giraud's criterion 1.2 ii). Alternatively, by 1.2.1, one may realize E as a category of sheaves $C^\sim$, where C is a generating subcategory of E that may be chosen so that $X \in \mathrm{ob}\, C$; one then knows 366
that $E_{/X} = C^\sim_{/X}$ is equivalent to $(C_{/X})^\sim$ (III 5.4), and hence is a topos.

The topos $E_{/X}$ is called the *topos induced* on the object X of E.

5.2. We shall define a canonical morphism of topoi

$$j_X : E_{/X} \longrightarrow E, \tag{5.2.1}$$

which is called the *inclusion morphism* of the induced topos $E_{/X}$ into the ambient topos E, or, better (cf. 5.7), the *localization morphism of E at X*. This morphism corresponds to a sequence of three adjoint functors (cf. 3.1.3)

$$j_{X!} \quad , \quad j_X^* \quad , \quad j_{X*}, \tag{5.2.2}$$

which may be described explicitly as follows:

a) The functor

$$j_{X!} : E_{/X} \longrightarrow E$$

is the functor that *forgets the structural arrow* from $E_{/X}$ to E.

b) The functor

$$j_X^* : E \longrightarrow E_{/X}$$

is defined by

$$j_X^*(Z) = (X \times Z, \mathrm{pr}_1),$$

where $\mathrm{pr}_1 : X \times Z \to X$ is the first projection. It may also be interpreted as the *base-change functor* relative to the morphism

$$X \longrightarrow e_E,$$

where e_E is the terminal object of E. By the definition of the base-change functor, it is immediate that j_X^* is indeed right adjoint to $j_{X!}$. In particular, it commutes with projective limits. It also commutes with inductive limits, by virtue of the special exactness properties of topoi (II 4).

367

c) It follows from this last fact (1.6) that j_X^* has a right adjoint

$$j_{X*} : E_{/X} \longrightarrow E.$$

For an object X' over X, the object $j_{X*}(X')$ is also sometimes denoted by one of the symbols $\prod_{X/e_E}(X'/X)$, $\mathbf{Hom}_{X/e_E}(X, X')$, or $\mathrm{Res}_{X/e_E}(X'/X)$ ("Weil restriction"), one or another of which is doubtless already familiar to the learned reader of our modest work.

5.3. One should note that the functor $j_{X!}$ commutes with fiber products and takes monomorphisms to monomorphisms, but it is not in general left exact for all that. It is left exact only if X is a terminal object of E (since $X = j_{X!}(X, \mathrm{id}_X)$ and (X, id_X) is a terminal object of $E_{/X}$), that is, if and only if j_X is in fact an equivalence of topoi (and hence all the functors in (5.2.2) are equivalences). [9]

Likewise, the functor j_{X*} is not in general right exact and does not necessarily take epimorphisms to epimorphisms.

It follows from these observations that the direction of the morphism of topoi relating $E_{/X}$ to E, for an object X of the topos E, is determined without any possible ambiguity.

5.4. The functor j_X^* is often called the *localization functor* or the *restriction functor*. The latter terminology is justified by identifying the objects of E resp. of $E_{/X}$ with the sheaves on E resp. on $E_{/X}$ (1.2 iii)), and observing that, under this identification, the adjunction formula between $j_{X!}$ (the forgetful functor) and j_X^* may be interpreted as saying that $j_X^*(F)$ *is the restriction to* $E_{/X}$ *of the sheaf* F *on* E (where "restriction" is understood in the generalized sense: composition with the "inclusion" functor $j_{X!} : E_{/X} \to E$). In accordance with notation familiar from other contexts, we shall also often write, interchangeably:

368

$$j_X^*(F) = F|X = F_X = \text{ restriction of } F \text{ to } X. \tag{5.4.1}$$

Likewise, when E is of the form $C^\sim$, where C is a (small) site, and X is of the form $\epsilon(S)$ with $S \in \mathrm{ob}\, C$, so that one has the equivalence of categories recalled in 5.1

$$E_{/X} = C^\sim_{/\epsilon(S)} \xrightarrow{\approx} (C_{/S})^\sim$$

(where $C_{/S}$ is endowed with the topology induced by that of C), the functor j_X^* is identified simply with the functor that "restricts" a variable sheaf F on C to the category $C_{/S}$.

These considerations also make it possible to foresee the important role that induced topoi and the localization morphisms (5.2.1) will play in all questions in which one is led to argue by "localization on E" (cf. 8), that is, in practically all questions involving sites or topoi.

[9] For a commutation property of $j_{X!}$ under change of topos, cf. XVII 5.1.2.

5.5. Let

$$f : X \longrightarrow Y$$

be an arrow of E, which thus allows us to regard X (or, more correctly, (X, f)) as an object of $E_{/Y}$. It is clear that there is a canonical isomorphism

$$(E_{/Y})_{/X} \xrightarrow{\sim} E_{/X} \tag{5.5.1}$$

(*transitivity of induced topoi*). Applying the construction of 5.1 to $E_{/Y}$ in place of E, one therefore obtains a canonical morphism of topoi

$$\mathrm{loc}(f) \text{ or } f : E_{/X} \longrightarrow E_{/Y}, \tag{5.5.2}$$

also called the *localization morphism (associated with f).* When Y is the terminal object of E, one essentially recovers (5.2.1). The localization morphism for f is associated with a sequence of three adjoint functors 369

$$f_! \quad , \quad f^* \quad , \quad f_*, \tag{5.5.3}$$

which may be interpreted respectively as a forgetful functor, a restriction functor, and a functor denoted, according to preference (with X' as argument), by $\prod_{X/Y}(X'/X)$, $\mathbf{Hom}_{X/Y}(X, X')$, or $\mathrm{Res}_{X/Y}(X'/X)$.

5.6. The transitivity of the forgetful functors implies that, for two composable morphisms

$$X \xrightarrow{f} Y \xrightarrow{g} Z$$

of E, there is a canonical isomorphism of morphisms of topoi

$$\mathrm{loc}(gf) \simeq \mathrm{loc}(g)\,\mathrm{loc}(f) : E_{/X} \longrightarrow E_{/Y} \longrightarrow E_{/Z}.$$

Moreover, for three composable morphisms, the preceding transitivity isomorphisms satisfy the usual compatibility relation. Thus, subject to the customary abuse of language, this allows one to regard

$$X \longmapsto E_{/X}$$

as a covariant functor from E to the category ($\mathscr{V}$-$\mathscr{U}$-top) (3.3.1). More precisely, one obtains a 2-functor (not strict in general) from E to the 2-category ($\mathscr{V}$-$\mathscr{U}$-top).

Before continuing with the general theory of induced topoi (5.10), let us give a few instructive examples.

5.7. Let X be a topological space, and hence let $\mathrm{Top}(X)$ be a topos (2.1). Let X' be an object of $\mathrm{Top}(X)$, which it will be convenient to interpret as an étale space over X, $p : X' \to X$. The category $\mathrm{Top}(X)_{/X'}$ is then identified with the category of étale spaces X'' over X, equipped with an X-morphism $X'' \to X'$. It is known that such a morphism makes X'' an étale space over X', and in this way one obtains a canonical equivalence of topoi 370

$$\mathrm{Top}(X)_{/X'} \xrightarrow{\approx} \mathrm{Top}(X').$$

The localization morphism is therefore identified with a morphism of topoi $\mathrm{Top}(X') \to \mathrm{Top}(X)$, and one sees immediately that the latter is none other than the morphism

$$\mathrm{Top}(p) : \mathrm{Top}(X') \longrightarrow \mathrm{Top}(X)$$

associated with the structural continuous map $p : X' \to X$. Intuitively, the localization morphism is thus simply the translation, into the language of topoi, of the étale map $p : X' \to X$. This both explains the appropriateness of the term "localization morphism" and counsels caution in using the term "inclusion morphism", which seems

chiefly appropriate when p is an open immersion. It will consequently be prudent in 5.1 to reserve the term "inclusion morphism" for the case where the morphism $X \to e_E$ is a monomorphism, i.e. where X is identified with a subobject of the terminal object of E.

5.8. Let E be a topos, G a group in E, and H a subgroup of G, and let

$$X = G/H$$

be the quotient homogeneous space, regarded as an object of E with a left action by G,
371 i.e. as an object of the classifying topos B_G (2.4). We shall determine the induced topos

$$(B_G)_{/X} \quad (X = G/H),$$

by defining an equivalence of topoi

$$c : B_H \xrightarrow{\approx} (B_G)_{/X}, \tag{5.8.1}$$

such that the following diagram commutes up to canonical isomorphism:

$$B_H \underset{B_i}{\overset{c}{\underset{\longrightarrow}{\hookrightarrow}}} (B_G)_{/X} \xrightarrow{j_X} B_G \tag{5.8.2}$$

where j_X is the localization morphism in B_G, and where

$$B_i : B_H \longrightarrow B_G$$

is the morphism deduced from the inclusion $i : H \to G$ (4.5).

To define (5.8.1), we shall simply give the descriptions of the inverse-image functor c^* and the direct-image functor c_*, leaving it to the reader to verify that these are indeed quasi-inverse equivalences and give rise to the commutative diagram (5.8.2) of morphisms of topoi. Let e be the subobject of E underlying X, the image of the section of X (over a chosen terminal object e_E of E) deduced from the unit section of G. If X' is an object of B_G over X, then $c^*(X')$ denotes the inverse image of e in X',

$$c^*(X') = X' \times_X e,$$

which is stable under the left action of H on X', obtained by restricting the given action of G on X'. This indeed defines a functor

$$c^* : (B_G)_{/X} \longrightarrow B_H.$$

372 On the other hand, if X' is an object of B_H, then the morphism from X' to the terminal object e_H of B_H (i.e. the terminal object e_E of E with the trivial action of H) gives, upon application of the functor $i_!$ (4.5), a morphism in B_G

$$i_!(X') \longrightarrow i_!(e_H) \simeq X,$$

which allows $i_!(X')$ to be regarded as an object of $(B_G)_{/X}$, and hence gives the desired functor

$$c_* : X' \longmapsto (i_!(X') \longrightarrow X) : B_H \longrightarrow B_G.$$

5.8.3. Thus, by (5.8.2), one sees that if G is a group in a topos and H a subgroup, *the functor "restriction of the operators from G to H" may be interpreted as a localization functor.* In particular, taking H to be the unit subgroup, one sees that the functor that *forgets the actions of G* may be interpreted as a localization functor. More generally, it follows that if (X, G) is an object of E with an action of G (i.e. an object of the classifying topos B_G), then the functor that "forgets the actions of G",

$$E' = (B_G)_{/(X,G)} \longrightarrow E_{/X}$$

may be interpreted as a localization functor with respect to a suitable object $E_{G,(X,G)}$ of E' covering the terminal object. It suffices to take $E_{G,(X,G)} = E_G \times (X, G)$, giving the cartesian diagram (where $E_G = G_S = G$ with the action of G by left translation)

(5.8.3.1)
$$\begin{array}{ccc} E_G & \longleftarrow & E_{G,(X,G)} = Z \\ \downarrow & & \downarrow \\ e_G & \longleftarrow & (X, G) \end{array} ,$$

and to observe that, by transitivity of induced topoi, the induced topos $E' = ((B_G)_{X/G)/Z}$ is equivalent to the topos $((B_G)_{/E_G})_{/Z}$; since $(B_G)_{/E_G}$ is equivalent to E by the functor c^* of (5.8.1) (with $H = e$), it suffices to verify that this equivalence takes Z to the object X of E (which is immediate) in order to deduce the desired equivalence of categories 373

$$E'_{/Z} \xrightarrow{\approx} E_{/X}.$$

We leave it to the reader to verify that the composite of this equivalence with the localization functor

$$E' = (B_G)_{/(X,G)} \longrightarrow E'_{/Z}$$

is the functor that "forgets the actions of G". Thus one sees that, upon passing to induced topoi, the cartesian diagram above gives a diagram of morphisms of topoi, commutative up to canonical isomorphism (5.6):

(5.8.3.2)
$$\begin{array}{ccccc} (B_G)_{/E_G} \approx E & \xleftarrow{\ i\ } & (B_G)_{/Z} \approx E'_{/Z} & \approx & E_{/X} \\ {\scriptstyle j}\downarrow & & \downarrow{\scriptstyle j'} & & \\ B_G & \xleftarrow{\ f\ } & (B_G)_{/(X,G)} = E' & & \end{array} ,$$

where the inverse-image functors associated with the vertical arrows j, j' are the functors that "forget the actions of G", and where the inverse-image functor i^* is identified with the localization functor $E \to E_{/X}$. This diagram is, moreover, "2-cartesian" in the sense of 5.11 below. 374

5.8.4. We leave it to the reader to extend the preceding considerations to the case of a pro-group $\mathscr{G} = (G_i)$, in the particular case where H is defined as the "kernel" of $\mathscr{G} \to G_{i_0}$. (In the case of profinite groups, this means restricting attention to *open* subgroups H of G, i.e. subgroups that are closed and of *finite index*.)

Exercise 5.9. Let E be a topos, G a group of E, B_G the classifying topos of G (2.4), and

$$\pi : B_G \longrightarrow E$$

the morphism of topoi deduced from the homomorphism from G to the unit group e of E (taking into account that $B_e \approx E$).

a) Let

$$E_G = G_s$$
